Background: Takayasu arteritis (TAK) is a rare large-vessel vasculitis characterized by vascular granulomatous inflammation. TA is more prevalent in young women aged less than 40 years old. It mainly involves aorta and its major branches. Those involved arteries can progress into stenosis and occlusion, which can lead to further ischaemia of the corresponding tissue and life-threatening events. Thus, effective treatment is in need to improve patients' prognosis. To date, glucocorticoids (GCs) and immunosuppressants remain as the first-line therapy for TAK patients. According to 2021 American College of Rheumatology/Vasculitis Foundation guideline, GCs and immunosuppressants such as methotrexate and azathioprine were recommended as initial therapy [1]. LEF functions as an inhibitor of pyrimidine synthesis. It has been widely used in a variety of autoimmune disease. In TAK treatment, by comparing LEF with methotrexate or cyclophosphamide, LEF showed its superiorities in remission induction, relapse prevention and good tolerance. Tofacitinib (TOF) is a JAK1/JAK3 signaling pathway inhibitor. In TAK, increasing evidence has suggested that JAK/STAT signaling pathway played an essential role in the pathogenesis of TAK [2]. More importantly, according to our recent study, TOF is superior to MTX for complete remission (CR) induction, relapse prevention and GC tapering. However, its efficacy needs further confirmation.

Objectives: Thus, this study aimed to compare the effectiveness and safety of TOF with another effective agent, LEF in patients with TAK.
Methods: A total of 67 active patients with TAK were recruited from an ongoing observational TAK cohort. Thirty-five patients were treated with GCs and LEF, and 32 patients were treated with GCs and TOF. The study period was 12 months. The primary endpoint was effectiveness rate (ER) at 6 months. The other aspects were also evaluated at 6 or 12 months, including remission rate and relapse rate, inflammatory parameters reduction, vascular imaging changes, GCs tapering, and side effects. The treatment effect was also evaluated separately among naive or refractory patients between two groups.
Results: After 6 months' treatment, no difference was observed in ER between two groups (LEF group: 31/35 (88.57%) vs. TOF group: 28/32 (87.50%), p=1.00). During 12 months' treatment, the relapse rate was also comparable between two groups (LEF group: 6 (17.14%) vs. TOF group 7 (21.88%), p=0.76,). ESR and CRP were decreased significantly at 6 (ESR: LEF group: p<0.0001; TOF group: p=0.15; CRP: LEF group: p=0.06; TOF group: p=0.007) and 12 months (ESR: LEF group: p<0.0001; TOF group: p=0.06; CRP: LEF group: p=0.006; TOF group: p=0.14) in both groups compared with their corresponding baseline levels. The proportion of patients with imaging improvement after 12 months' treatment were low in both groups (LEF group: 1 (2.86%) vs. TOF group: 3 (9.38%) p=0.17). After treatment, the doses of GCs were significantly reduced in both groups from the third month onwards compared with their corresponding baseline dose (p<0.05). Among patients with initial GCs dose ≥ 30mg/day, patients in TOF group gained a much lower daily GCs dose than that of LEF group at 9 months and 12 months (p<0.05). Furthermore, the frequency of side effects was higher in LEF group than that of TOF group (12/35, 34.29%, vs 3/32, 9.38%; p=0.02).
Conclusion: LEF and TOF have comparable treatment effects for patients with TAK. However, TOF is superior to LEF in GCs tapering and safety profile.

POS0798 NUMANO TYPE IIB, INFLAMMATORY PROGRESSION OF DISEASE AND DILATION OF ASCENDING AORTA AND AORTIC ROOT ARE IMPORTANT RISK FACTORS CAUSING AORTIC VALVE INVOLVEMENT IN TA PATIENTS.

X. Shi[1]. [1]*Beijng Anzhen Hospital, Rheumatology, Beijing, China*

Background: Takayasu arteritis (TA) can involve cardiac valves. In Chinese patients with TA, valvular abnormalities were found in 48.9% (201/411) patients[1,2]. Another research showed that cardiac valvular involvements were found in 34.9% (373/1069) TA patients in China[3], and in a recent study, they also found that 64.08% (66/103) of TA patients had valvular damage[4]. In addition, the most common valve involved in TA is the aortic valve, and the most common valvular lesion caused by TA is valvular insufficiency. The incidence of aortic regurgitation in patients with TA has been reported as 33.2% (455/1372) in Japan[5], 21.7% (13/60) in Italy[6], 18.1% (29/160) in Korea[7], and 20.4% (84/411)[1] to 39.8% (41/103)[4] in China. AR can further induce congestive heart failure or arrhythmia, both of which are considered one of the main causes of death in TA patients[8].
Objectives: Aortic valve involvement is not uncommon in patients with Takayasu arteritis (TA). The aim of our study was to evaluate the clinical characteristics of aortic valve involvement in TA patients, and to explore the risk factors of aortic valve involvement in TA.
Methods: In this retrospective study, 174 patients with TA were divided into groups with or without aortic valve involvement. We compared the clinical manifestations, laboratory parameters, and imaging results between the two groups. The logistic regression analysis was used to identify the risk factors of aortic valve involvement in TA patients.
Results: In our study, a total of 94 TA patients (54.02%) had aortic valvular lesion. The proportion of elevated ESR and elevated high-sensitivity CRP, and ITAS-A score in the aortic valve involvement group were significantly higher than in the non-aortic valve involvement group. 2 patients were found to have the infiltration of Inflammatory cells in surgical specimens of the aortic valve. The Numano type IIb and elevated hs-CRP level were found to be statistically related to aortic valvular lesion in TA patients (6.853 [1.685-27.875], p=0.007; 4.896 [1.646-14.561], p=0.004). Dilation of the ascending aorta and aortic root were significantly associated with aortic valvular involvement in TA patients (4.509 [1.517-13.403], p=0.007; 9.340 [2.188-39.875], p=0.003).
Conclusion: The Numano type IIb, elevated hs-CRP level, dilation of the ascending aorta and aortic root are risk factors for aortic valve involvement in TA patients.

POS0799 BIOMARKER CHANGES IN TAKAYASU ARTERITIS AFTER TOFACITINIB TREATMENT AND THE MOLECULAR SIGNATURE ASSOCIATED WITH DISEASE CHARACTERISTICS

X. Dai[1], L. Wang[1], S. Wu[1], J. Wang[1], Y. Sun[1], Z. Ji[1], L. MA[1], X. Dai[1], H. Chen[1], L. MA[1], X. Kong[1], L. Jiang[1]. [1]*Zhongshan Hospital, Fudan University, Department of Rheumatology, Shanghai, China*

Background: Takayasu's arteritis (TAK) is a chronic, non-specific, granulomatous macrovasculitis and its pathogenesis is still unclear. The increasing evidence indicated that multiple pathological process involved in the development of TAK. According to previous reports, multiple biomarkers representative different pathological process (1-3), However, which biomarker can closely reflect disease activity or vascular changes and whether these abnormal processes can be prevented by current therapies remained unknown.
Objectives: To analyze changes of serum cytokine, chemokine, and growth factor profiles in patients with Takayasu arteritis (TAK) after tofacitinib treatment and explore potential molecular signatures related with various disease characteristics
Methods: Seventeen patients from a TAK cohort treated with tofacitinib and 12 healthy controls were recruited in this study. Potential biomarkers with TAK including cytokines, MMPs, chemokines and growth factors were detected in these patients (0, 6, 12 months) and healthy controls. Molecular changes, disease activity, disease remission, and vascular imaging changes were analyzed in these patients after treatment. Furthermore, molecule signatures associated with these clinical features/outcomes were explored via radar plot and correlation analysis.
Results: At baseline, all the patients were in active status. Meanwhile, patients' cytokines (PTX3, IL-6, IFN-γ), chemokines (IL-16, CCL22, CCL2), growth factor (VEGF) and MMP9 were significantly higher than those of healthy controls (all p<0.05), while FGF-2 was significantly lower in patients with TAK (p=0.02). After treatment, 94.12% of patients achieved complete remission at 6 and 12 months; patients' ESR and CRP levels were significantly reduced at 6 months (p=0.02, p=0.046 respectively); vascular improvement were observed in 6 (35.29%) patients at 12 months. With regards to these molecules, IL-10 was increased at 6 months compared with its baseline level (p=0.007). No changes were observed in other cytokines, chemokines, or growth factors. Besides, the radar plot demonstrated that PTX3 was closely correlated with disease activity. In addition, patients with vascular imaging improvement had relatively higher baseline levels of TNFα, ESR, and CRP (p=0.04, p=0.056, p=0.07, respectively), lower CCL22, FGF, and PDGF-AB levels (p=0.056, p=0.06 and p=0.08 respectively) compared with patients without it.
Conclusion: Multiple molecules representative different pathological mechanism participated in the pathogenesis of TAK. PTX3 was a prominent marker for disease activity, and CCL22 may have a predictive value for vascular imaging changes.

Background: The most frequent form of vasculitis in elderly people is giant cell arteritis (GCA) with an annual incidence rate less than 10 per 100,000 persons over the age of 50. Like most vasculitides, GCA is characterized by chronicity and relapses, leading to significant overall morbidity and higher mortality in a subset of patients with aortic involvement and dissection. Most studies carried out so far have been retrospective, used monocentric study designs and small patient cohorts. Therefore, the Joint Vasculitis Registry in German-speaking countries (GeVas) has been established to record patients, who have been recently diagnosed with vasculitis or who have changed their treatment due to a relapse (inception cohort). The GeVas-Registry allows a long-term follow-up of a substantial cohort of vasculitis patients in a prospective and multicenter manner.
Objectives: To describe the subgroup of GCA and its characteristics within the GeVas registry.
Methods: GeVas is a prospective, web-based, multicenter, clinician-driven registry for the documentation of organ manifestations, damage, long-term outcomes, and therapy regimens in various types of vasculitis. Recruitment started in June 2019. By January 2022, 17 centers in Germany were initiated and have begun enrolling patients. Meanwhile, more than 350 patients have been documented in the registry. Sites in Austria and the German-speaking cantons of Switzerland will be integrated soon (1).
Results: By mid-October 2021, the participating centers recruited 131 GCA patients into the registry. 21.7% of patients (n=28) were enrolled in the registry due to relapse, and 78.3% (n=101) due to a first-time diagnosis. In accordance with long-standing epidemiology data, the majority of patients (67,2%), were female (n=88), and 32.8% (n=43) were male. Mean age was 74 years (max. 92y, min. 52y). The most frequently recorded organ manifestations in GCA patients addressed cranial and ophthalmic symptoms, and the cardiovascular system. However, vascular lung/chest involvement was also observed in 3% of cases (n=4). Out of the 131 patients, 97.7% (n=128) received immunosuppressive therapy, three refused to take any medication. An equal number of patients were treated with glucocorticoid (GC) therapy. While about two equal parts were treated by stable long term oral GC therapy (47,7%, n=62) or by i.v. pulse therapy followed by tapering (49,2%, n=64), only about 2.3% (n=3) were treated by oral GC therapy with intermittent i.v. pulses. 48.5% (n=63) of patients received tocilizumab as additional immunosuppressive therapy, 19.2% (n=25) methotrexate, and 18.5% (n=24) cyclophosphamide i.v. pulses.
Conclusion: In June 2019, we successfully established the prospective multicenter vasculitis registry GeVAS. It describes the first systematically recorded prospective GCA cohort in German-speaking countries. Its characteristics correspond to those that can be expected from the literature, with some unexpected finding e.g. the high proportion of patients treated with cyclosphosphamid, probably reflecting a sicker patient population with e.g. aortic or central nervous involvement. After 2.5 years of follow-up documentation, the first long-term results will be systematically evaluated and interpreted. The newly acquired data on disease manifestation, diagnostics and therapy regimens will provide important insights into the treatment of GCA patients in Germany and may generate further research goals.

Marqués de Valdecilla, Internal Medicine, Santander, Spain

Background: Visual involvement is the most feared complication of Giant Cell Arteritis (GCA) **(1-5)**. Permanent visual loss (PVL) may be preceded by transient visual loss. Once blindness is established, the prognosis is poor. Most of the series of predictive factors of visual involvement in GCA are old and with a small number of patients.

Objectives: To assess the predictive factors of visual involvement and PVL in GCA.

Methods: Multicenter observational study of 471 patients with GCA. The diagnosis of GCA was performed between 2016 and 2021 according to: **a)** ACR criteria, and/or **b)** temporal artery biopsy, and/or **c)** imaging techniques.

From the 471 patients, we selected patients who developed **a)** visual involvement at any time during GCA and **b)** PVL. PVL was defined as partial or complete visual loss of >24 hours. Predictive factors were identified by multivariate analysis.

Results: Visual involvement was observed in 122 cases and PVL in 60 (Table 1). The ischemic and systemic manifestations set of variables associated with visual involvement were headache, and jaw claudication, whereas large-vessel involvement was a protective variable (Figure 1). The area under the curve (AUC) for the model was 0.72 (95%CI 0.67-0.77; p<0.0001).

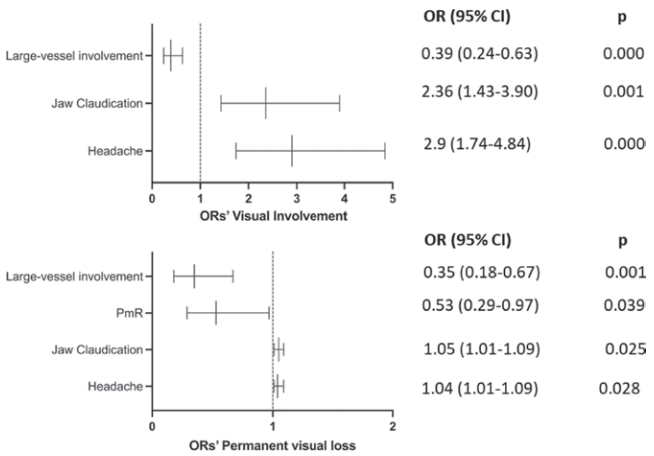

Figure 1. Forest plot of multivariate analysis.

In the same line, the set of variables associated with PVL were headache, and jaw claudication. By contrast, polymyalgia rheumatica (PmR), and large-vessel involvement were protective factors (Figure 1). The AUC for this model was 0.77 (95%CI 0.71-0.83; p<0.0001).

Conclusion: Headache, and jaw claudication seem to be associated with visual involvement in GCA, while large vessel involvement seems to be a protective factor. PmR also appears to be a protective factor for the development of PVL.

Marqués de Valdecilla, Internal Medicine, Santander, Spain

Background: Large vessel involvement in Giant Cell Arteritis (GCA), especially the aorta and/or its main branches, is frequent. Tocilizumab (TCZ) has shown efficacy and safety in GCA and other large-vessel vasculitis **(1-4)**.
Objectives: To assess the efficacy and safety of TCZ in GCA patients with involvement of the aorta and/or its main branches.
Methods: Multicenter observational study of 196 patients with GCA and involvement of the aorta and/or its major branches treated with TCZ. GCA was diagnosed by: **a)** ACR criteria, and/or **b)** temporal artery biopsy, and/or **c)** imaging techniques. The presence of aortitis was performed by imaging techniques, mainly PET, and A-MRI.
Maintained remission was considered according to EULAR definitions **(5)**.
Results: The main features of the 196 patients are showed in Table 1. Polymyalgia rheumatica, constitutional syndrome and headache were the most frequent clinical manifestations at TCZ onset. At 6 months after starting TCZ, 20% of the patients reached a sustained remission, that was progressively increasing. (Figure 1**).** A corticosteroid-sparing effect was observed from month 1 of TCZ onset (Figure 1). Relevant adverse events were observed in 12 per 100 patients-year, documenting serious infections in 4.8 per 100 patients-year (Table 1).

Table 1. Main features of 196 GCA patients with involvement of the aorta and/or its main branches treated with TCZ.

	GCA (n=196)
Features at TCZ onset	
Age(years), mean±SD	71.3±9.5
Sex, female/male (% female)	148/48 (75)
Time from GCA diagnosis to TCZ onset (months), median [IQR]	7 [2-18.25]
Systemic manifestations, n (%)	
Fever, n (%)	24 (12)
Constitutional syndrome, n (%)	87 (44)
PmR, n (%)	131 (67)
Ischaemic manifestations, n (%)	
Visual involvement, n (%)	16 (8)
Headache, n (%)	74 (38)
Jaw claudication, n (%)	27 (14)
Laboratory data	
ESR, mm 1st hour, median [IQR]	32 [14-54]
CRP, mg/dL, median [IQR]	1.5 [0.6-3.2]
Prednisone dose, mg/day, median [IQR]	15 [10-30]
Safety after TCZ onset	
Relevant adverse events, per 100 patients-year	12
Serious infections, per 100 patients-year	4.8

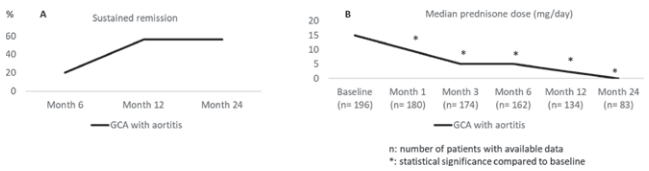

Figure 1. A) Sustained remission, and **B)** median prednisone dose required in GCA patients with aortitis treated with tocilizumab

Conclusion: TCZ seems to be effective and relatively safe in GCA patients with involvement of the aorta and/or its main branches.

POS0803 INCREASED RISK OF MALIGNANCY IN PATIENTS WITH TAKAYASU'S ARTERITIS: A POPULATION-BASED COHORT STUDY IN KOREA

S. Lee[1], S. Kang[1], Y. Eun[1], H. Kim[1], J. Lee[1], E. M. Koh[1], H. S. Cha[1]. *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Recent studies have identified neoplasms as the second most common cause of death in patients with Takayasu's arteritis (TAK) [1,2]. Various autoimmune diseases are related to the increased rates of malignancies. Despite conflicting data, most studies concluded that there is no increase in the risk of malignancies in giant cell arteritis [3]. In the case of TAK, there have been few reports of malignancies [4]. However, only one study compared the risk of malignancies in TAK to that of the general population [5]. Because the previous study only included 180 patients with TAK from single center, no definite conclusion could be drawn. Here, we evaluated the relative risk of malignancies in patients with TAK and compared them with the general population using the medical insurance data of South Korea.
Objectives: This study aimed to evaluate the relative risk of malignancy in patients with TAK compared to that in the general population.
Methods: This retrospective nationwide cohort study used data from the Korean Health Insurance Review and Assessment Service database. All newly diagnosed patients with Takayasu's arteritis were identified between January 2009 and December 2019. They were observed until the diagnosis of malignancy, death, or end of the observational period, December 2020. The occurrence of malignancy was regarded as the first claim under ICD-10 codes, including C00–97, D46, and D47.1, according to the incidence of malignancy classification published by the National Cancer Registry (NCR). The incidence of malignancy in the general population was retrieved from the 2014 NCR, which collects the annual incidence of malignancies in the entire population of South Korea. The standardized incidence ratios (SIRs) of the overall and site-specific malignancies were estimated and compared with the incidence of cancer in the general population.
Results: We identified 1,449 newly diagnosed patients with Takayasu's arteritis during the observational period (9,196 person-years). A total of 74, 66, and 8 patients had overall, solid, and hematologic malignancies, respectively. The risks of overall (SIR, 1.62; 95% confidence interval [CI], 1.27–2.03), solid (SIR, 2.04; 95% CI, 1.56–2.61), and hematologic (SIR, 4.05; 95% CI, 3.72–7.98) malignancies were increased compared to those in the general population. In solid malignancies, breast (SIR, 2.07; 95% CI, 1.16–3.42), ovarian (SIR, 4.45; 95% CI, 1.21–11.39), and major salivary gland (SIR, 19.04; 95% CI, 2.31–68.76) cancers had an increased risk. In hematologic malignancies, the risk of myelodysplasia increased (SIR, 18.02; 95% CI, 3.72–52.66). Immunosuppressive agent use was not associated with malignancy. There was no specific period when cancer more frequently occurred.
Conclusion: An increased risk of malignancy was observed in patients with Takayasu's arteritis compared to that in the general population in this large-scale nationwide population study of Korean health insurance data.

Background: Tocilizumab (TCZ) has shown to be effective for large vessel vasculitis including giant cell arteritis (GCA) and Takayasu arteritis (TAK) **(1-5)**. However, LVV-GCA and TAK show different demographic and clinical features that may influence on TCZ therapeutic response.
Objectives: To compare the effectiveness of TCZ in patients with LVV-GCA and patients with TAK.

Methods: Observational multicenter study of patients with LVV-GCA and TAK who received TCZ. Outcome variables were: **a)** proportion of patients who achieved complete clinical improvement along with normalization of laboratory markers (CRP ≤0.5mg/dL and/or ESR ≤ 20 mm/1st hour) at 12 months **b)** complete improvement in imaging techniques. A comparative study between patients with LVV-GCA and TAK was performed.
Results: We evaluated 70 LVV-GCA and 57 TAK patients who received TCZ. Main clinical and demographic characteristic are described in Table 1. Patients with TAK were younger, had longer disease duration, had received more commonly previous biologic therapy and were receiving higher doses of prednisone at baseline. TCZ intravenous administration was more common in TAK patients (80.7% vs 48.6%; p<0.01). Follow-up time after TCZ onset was similar in both groups. At 12 months, about 75% of patients achieved complete clinical improvement and ESR/CRP normalization in both groups. A follow-up imaging technique was performed in 37 LVV-GCA patients after a mean time of 12.9±6.0 months and 38 TAK patients after 9.5±5.0 months. Complete improvement in imaging techniques was only observed in 18.9% and 21.1% of patients with LVV-GCA and TAK, respectively (Figure 1).

Table 1.

	LVV-GCA (n=70)	TAK (n=57)	p
General features			
Age (years), mean ± SD	67.2 ± 10.5	40.5 ± 16.3	**< 0.01**
Sex (female), n (%)	51 (72.9)	49 (86)	0.07
Disease evolution before TCZ onset (months), median [IQR]	5 [2-15]	12 [3-37]	**<0.01**
Baseline laboratory parameters			
ESR (mm/1st hour), median [IQR]	32 [12.5-54.7]	31 [10-52]	0.82
CRP (mg/dL), median [IQR]	1.4 [0.5-2.4]	1.4 [0.5-3.5]	0.41
Baseline prednisone dose (mg/day), median [IQR]	15 [10-20]	30 [15-50]	**< 0.01**
Previous therapy			
Conventional DMARDs, n(%)	45 (64.3)	44(77.2)	0.51
Biologic therapy, n (%)	0(0)	12 (21.1)	**<0.01**
TCZ therapy			
Intravenous, n (%)	34 (48.6)	46 (80.7)	**< 0.01**
Combined with MTX, n(%)	24 (34.3)	24 (42.1)	0.37
Follow-up time after TCZ onset, median [IQR]	20 [10-36]	18 [7-41]	0.73
Complete clinical improvement and ESR/CRP normalization at 12 months, n/N (%)	35/47 (74.4)	30/39 (76.9)	0.79
Complete improvement in imaging techniques, n/N(%)	7/37 (18.9)	8/38 (21.1)	0.85

CRP: C-reactive protein; DMARDs: Disease-modifying anti-rheumatic drugs ESR: erythrocyte sedimentation rate; GCA: giant cell arteritis; IQR: interquartile range; LVV: large vessel; MTX: methotrexate; n: Number of patients; N: total number of patients: TCZ: tocilizumab; TAK:takayasu

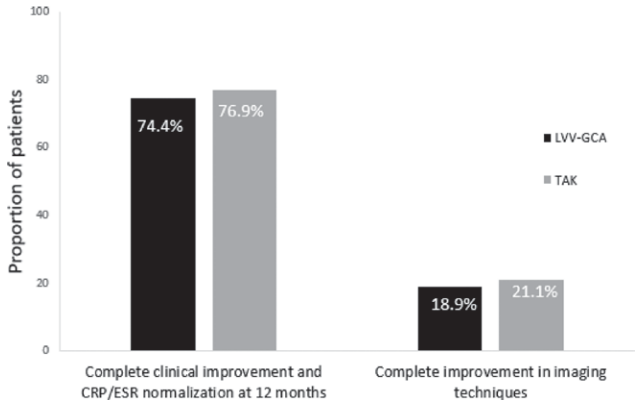

Figure 1.

Conclusion: The effectiveness of TCZ was similar in patients with LVV-GCA and TAK, despite a more refractory disease in TAK patients. A discordance between clinical and imaging activity improvement was observed in both LVV-GCA and TAK, as reported in previous studies **(3)**.

GLUCOCORTICOID-RELATED ADVERSE EVENTS IN GIANT CELL ARTERITIS: APPLICATION OF THE GLUCOCORTICOID TOXICITY INDEX IN A MONOCENTRIC COHORT OF 140 PATIENTS

F. Regola[1,2], J. Mora[1], G. Bosio[3], L. Andreoli[1,2], F. Franceschini[1,2], P. Toniati[2].
[1]University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy; [2]ASST-Spedali Civili of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; [3]ASST-Spedali Civili of Brescia, Nuclar Medicine Unit, Brescia, Italy

Background: Oral glucocorticoids (GC) are the mainstay of treatment for giant cell arteritis (GCA) but chronic exposure to GC is associated with serious comorbidities.
Objectives: The objective of this study was to determine the GC exposure and risk of GC-related adverse events (AEs) in GCA, validating the Glucocorticoid Toxicity Index (GTI) (1,2) in a cohort of real-world patients.
Methods: 140 consecutive patients with GCA were enrolled in this retrospective monocentric study. All patients were older than 50 years of age, met the 1990 ACR criteria for GCA and/or had the evidence of a large vessel vasculitis at FDG-PET/CT scan. Patients' clinical data were collected from clinical charts, calculating GC cumulative dose and GTI at baseline and in the following 5 years.
Results: 140 patients were enrolled in the study: median (IQR) age at diagnosis 74 (67-79), Female: 97 (69%), Male: 43 (31%). According to vascular involvement patients were classified in cranial-GCA (C-GCA, n:91), large vessel-GCA (LV-GCA, n:21) and cranial and large vessel-GCA (LV-C-GCA, n:28). Furthermore, 50 (36%) patients were treated with only GC, 44 (31%) with GC+methotrexate (MTX), 46 (33%) with GC+tocilizumab (in 20 cases TCZ was started in the first 3 months after diagnosis: early-TCZ, in 26 cases after 3 months for relapses or AEs: late-TCZ).
During the follow up, 57 (41%) patients presented at least one relapse. In the GC group 22 relapses in 18 patients were reported, in MTX group 33 relapses in 25 patients (with 15 relapses before and 18 after MTX start), in early-TCZ group no relapses were reported, in late-TCZ group 21 relapses in 14 patients (with 17 relapses before and 4 after TCZ start) were reported.
Median cumulative GC doses after 1 and 5 years were respectively 7.9 (6.3-9.8) gr and 16.5 (13.8-18.9) gr in GC group, 8.7 (5.9-10.0) gr and 16.5 (13.2-20.7) gr in MTX group, 7.1 (5.5-8.0) gr and 13.3 (12.8-13.7) gr in early-TCZ and 7.7 (6.2-11.1) gr and 19.7 (12.2-23.8) gr in late-TCZ. Eighty-eight percent of patients developed at least one GC-AE, with infections and hypertension being the most common reported AEs (42% e 44%, respectively). Median GTI-CWS (Cumulative Worsening Score) after 1 year was 65 (20-137) in GC, 63 (10-95) in MTX, 51 (33-116) in TCZ-early, 44 (0-91) in TCZ-late. Median GTI-CWS after 5 years was 219 (118-240) in GC, 137 (65-206) in MTX, 147 (146-147) in TCZ-early, 200 (121-231) in TCZ-late. A correlation between GTI-CWS and the GC cumulative dose was found (after 5 years r: 0.295, p: 0.026).
Conclusion: Chronic GC treatment is associated with a high risk of developing comorbidities. GTI score demonstrated to be an effective tool to assess GC-related AEs and proved to correlate with GC cumulative dose. TCZ confirmed its efficacy in reducing relapse rate, both in early and late-TCZ groups (3). TCZ showed for the first time in a real-life cohort a GC sparing effect, with a 19% reduction in GC cumulative dose and a 33% reduction in GTI-CWS in 5 years (comparing GC group *vs* early-TCZ group).

Background: Tocilizumab (TCZ) has shown to be useful in the treatment of large-vessel vasculitis, including giant cell arteritis (GCA) **(1-4)**. There is general agreement on the initial and the standard maintenance dose of TCZ. However, information on duration and optimization of TCZ in GCA is really scarce.
Objectives: Our aim was to assess the effectiveness and safety of TCZ therapy optimization in an unselected wide series of GCA in real-world clinical practice.
Methods: Multicenter study on 471 patients with GCA who received TCZ therapy. Once complete remission was reached (n=231) TCZ was optimized in 125 patients. We compared patients in whom TCZ was optimized (TCZ_{OPT} group) or not ($TCZ_{NON-OPT}$ group). Complete remission was defined as normalization of clinical and analytical (CRP and ESR) data. Optimization was done by decreasing the dose and/or prolonging the TCZ dosing interval progressively. We performed a comparison in effectiveness and safety parameters between optimized and non-optimized patients.
Results: We evaluated 231 GCA patients treated with TCZ with complete remission. No demographic or laboratory data differences was observed at TCZ onset between both groups (Table 1). The mean prednisone dose was higher in the $TCZ_{NON-OPT}$ group at TCZ onset. The first TCZ optimization was performed after a median [25-75th] follow-up of 12 [6-17] months.

Table 1. Main general features at TCZ onset of 231 GCA patients with prolonged remission.

	OPTIMIZED-TCZ GROUP (n=125)	NON-OPTIMIZED TCZ GROUP (n=106)	p
GENERAL FEATURES			
Age, years, mean± SD	72.7±8.6	74±8.7	0.197
Sex, female/male n (% female)	91/34 (72.8)	74/32 (69.8)	0.616
Time from GCA diagnosis to TCZ onset (months), median [IQR]	8 [2-21.5]	5 [2-21]	0.384
SYSTEMIC MANIFESTATIONS			
Fever, n (%)	14 (11.2)	15 (14.2)	0.500
Constitutional syndrome, n (%)	54 (43.2)	39 (36.8)	0.322
PMR, n (%)	75 (60)	69 (65.1)	0.426
ISCHEMIC MANIFESTATIONS			
Visual involvement, n (%)	14 (11.2)	16 (15.1)	0.380
Headache, n (%)	66 (52.8)	62 (58.5)	0.386
Jaw claudication, n (%)	24 (19.2)	25 (23.6)	0.417
AORTITIS (large-vessel involvement), n (%)	65 (52)	42 (39.6)	0.060
ANALYTICAL FINDINGS			
ESR, mm/1st hour, mean (SD)	39.1±29.3	37.5±33.5	0.334
CRP, mg/dL mean (SD)	2.6± 3.4	2.7± 4	0.305
Hemoglobin, g/dL, mean (SD)	13.5±9.6	12.9±1.5	0.153
GLUCOCORTICOIDS			
Prednisone dose, mg/d mean (SD)	20.3±16.4	27±17.8	**0.001**

Abbreviations: CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; GCA: giant cell arteritis; IQR: interquartile range; IV: intravenous; PMR: polymyalgia rheumatica; SC: subcutaneous; SD: standard deviation; TCZ: tocilizumab.

The median prednisone dose at first TCZ optimization was 2.5 [0-5] mg/day. At the end of follow-up prolonged remission was observed in 78.2% of TCZ_{OPT} group compared with 66.7% in the $TCZ_{NON-OPT}$ group (p= 0.001) (Figure 1). Seven (5.6%) of the 125 optimized cases relapsed. Serious adverse events were similar in both groups, while serious infections were more frequent in the $TCZ_{NON-OPT}$ group (p=0.009).
Conclusion: Once complete remission is reached in GCA patients under TCZ treatment, optimization of biologic may be performed. Based on our experience it could be performed by reducing the dose or by prolonging dosing interval of TCZ. It seems to be an effective and safe practice.

POS0807 EVALUATION OF DISEASE MANIFESTATIONS AND ADVERSE PREGNANCY OUTCOMES IN PREGNANCIES OF PATIENTS WITH BEHÇET'S SYNDROME

K. Koken[1], D. Sahin Eroglu[2], A. Ates[2], G. Kınıklı[2], T. M. Turgay[2]. *[1]Ankara University School of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Ankara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Behçet's Syndrome (BS) is a chronic, multisystemic inflammatory vasculitis with unknown etiology, generally diagnosed at reproductive age. Data related to disease manifestations and pregnancy outcomes are limited.
Objectives: To investigate disease manifestations during pregnancy and adverse pregnancy outcomes (APOs) in female patients with BS.
Methods: In this single centre study, 110 voluntary women who had long-term follow-ups in Ankara University Multidiciplinary Behçet outpatient clinic and their 323 pregnancies were evaluated. Patients were interviewed about their previous pregnancies. As 238 of 323 (73.6%) pregnancies were before BS diagnosis and additional 13 pregnancies were terminated due to family planning, we evaluated disease manifestations and APOs of 72 pregnancies. APOs were defined as spontaneus abortion, intrauterine exitus, stillbirth, premature rupture of membranes (PROM), intrauterine growth restriction/small for gestational age (IUGR/SGA), gestational diabetes mellitus (GDM), macrosomia, preeclampsia and eclampsia, arteriovenous thrombosis, congenital malformations and Rh incompatibility.
Results: A total of 30 APOs in 72 (41.7%) pregnancies was stated by participants (Table 1). There were not any statistical differences between groups in terms of gestational age and BS disease duration (p= 0.85 and p= 0.21). In 24 (33.3%) pregnancies, BS manifestations were exacerbated, genital ulcer being the most common (20.8%) followed by oral ulcers (15.3%), skin manifestations (8.3%), and both articular and skin manifestations (8.3%). Ocular flares did not occur during pregnancies whereas *de novo* venous thromboses and parenchymal neurological involvement were detected in 2 (2.8%) and 1 (1.4%).

Table 1. The characteristics of pregnancies with and without APOs

		Pregnancy without APOs (n=42, 58.3%)	Pregnancy with APOs (n= 30, 41.7%)	P value
Maternal characteristics	Gestational age, years mean (SD)	24.4 (5.6)	24.5 (5.9)	0.85
	Disease duration, years mean (SD)	6.5 (10.4)	7.9 (10.3)	0.21
APOs and other complications	Spontaneous abortion, n(%)		4 (13.3%)	
	Stilbirth, n(%)		1 (3.3%)	
	IUGR-SGA, n(%)		8 (26.7%)	
	Preeclampsia, n(%)		3 (10.0%)	
	PROM, n(%)		5 (16.7%)	
	Termination due to teratogens, n(%)		4 (13.3%)	
	Trombosis, n(%)		2 (6.7%)	
	GDM, n(%)		3 (10.0%)	
	Macrosomia, n(%)		4 (13.3%)	
	Rh incompatibility, n(%)		3 (10.0%)	
Drug use in pregnancy	Colchicine, n(%)	11 (26.1%)	8 (26.6%)	0.96
	Azathioprine n(%)		2 (6.7%)	
	Corticosteroids, n(%)		1 (3.3%)	
Neonatal outcomes	Median birth week, median (Q1-Q3)*	39.0 (38.0-40.0)	38.0 (33.5-39.0)	0.001
	Median birth weight, grams, median (Q1-Q3)**	3445.0 (3123.8-3600.0)	2850.0 (2500.0-3700.0)	0.038

SD=Standart Deviation*Calculations were done in 42 pregnancies of the group without APOs and in 26 pregnancies of the group with APOs**Calculations were done in 40 pregnancies of the group without APOs and in 21 pregnancies of the group with APOs

The effects of medications during pregnancies were also examined. There were 19 pregnancies, in which colchicine was continued. When the pregnancies were compared between continued and cessation groups, median birth weights at continued and cessation groups were 3450 (Q1-Q3: 3125-3450) grams and 3300 (Q1-Q3: 2900-3820) grams (p=0.42), respectively. There was not any statistical difference between median birth weeks of continued and cessation groups 38.0 (Q1-Q3: 38.0-39.0) weeks at continued group and 39.0 (Q1-Q3: 38.0-40.0) weeks at cessation group (p=0.18)).There were not any significant differences between two groups in terms of exacerbated manifestations of BS and APOs (p values were 0.90 and 0.96, respectively). Azathioprine was used in 2 (2.7%) pregnancies, which resulted in termination and spontaneous abortion.
Conclusion: In this study, we found that APOs occurred in almost half of BS patients and colchicine use seemed to be safe throughout pregnancy. Some BS manifestations exacerbated and even occurred *de novo* during pregnancies. Prospective studies are needed to reveal the effects of BS and drugs on pregnancy.

POS0808 CHARACTERISTICS AND PROGNOSIS OF BINOCULAR DIPLOPIA IN PATIENTS WITH GIANT CELL ARTERITIS

T. Chazal[1], T. Sene[1], G. Clavel Refregiers[1], T. Leturcq[1], C. Bouche[1], A. Lecler[2], C. Vignal-Clermont[3]. *[1]Foundation Adolphe de Rothschild Hospital, Internal Medicine, Paris, France; [2]Foundation Adolphe de Rothschild Hospital, Neuroradiology Department, Paris, France; [3]Foundation Adolphe de Rothschild Hospital, Ophthalmology Department, Paris, France*

Background: Giant cell arteritis (GCA) is a large vessel vasculitis associated with a risk of permanent ophthalmologic complications. Diplopia is an uncommon feature at GCA diagnosis and data about diplopia in GCA are scarce, especially regarding its prognosis.
Objectives: This study was designed to better characterize diplopia in newly diagnosed GCA patients.
Methods: All consecutive patients diagnosed with GCA between January 2015 and April 2021 in a French tertiary ophthalmologic center were retrospectively reviewed. GCA diagnosis relied on 1990 ACR criteria and either a positive temporal artery biopsy or high-definition MRI.
Results: Among 111 patients diagnosed with GCA in our tertiary eye-care center, 80 patients (72%) had visual signs, including 30 patients (27%) with binocular diplopia. Characteristics of patients with diplopia were similar to other GCA patients. Twenty-eight patients (93%) had cephalic symptoms (Headaches n = 25, scalp tenderness n = 14, jaw claudication n = 17) and 7 patients (23%) had associated polymyalgia rheumatica. All patients with diplopia had an elevated C-reactive protein compared with 91% of patients without diplopia (p = 0.06). Large vessel involvement was found in 4 patients (16%) with diplopia. Diplopia was attributed to cranial nerve palsy in 21/24 (88%) patients, especially third (50%) and sixth cranial nerve (48%) palsies. Median duration of diplopia before GCA diagnosis was 10 days (Inter-quartile

range [IQR]: 4-19). Eleven patients (37%) were diagnosed with ocular ischemic lesions, including 5 patients (17%) with bilateral visual impairment, resulting in a severe loss of vision in 9 patients and a resolution of binocular diplopia in all these patients due to unilateral or bilateral vision loss. Acute ischemic optic neuropathy (AION) was diagnosed in 11 eyes, central retinal artery occlusion (CRAO) in 4 eyes and paracentral acute middle maculopathy in 2 eyes. Diplopia resolved spontaneously in 6 patients (20%). In the remaining 13 patients, diplopia resolved after the initiation of corticosteroids in 12 patients (92%) with a median delay of 10 days (IQR: 5-24). IV corticosteroids seemed to be associated with a quicker improvement than oral corticosteroids (6 days [IQR 4-28] vs 11 days [IQR 6-13], p = 0.81) but with a similar resolution rate of diplopia at one month (66% vs 78 %, p = 1). Two patients had visual impairment after the initiation of corticosteroids and two patients had diplopia relapse during the course of GCA.

Conclusion: Diplopia is a rare but not exceptional feature at GCA diagnosis and should raise clinician suspicion for GCA when associated with cephalic symptoms and elevated inflammatory biomarkers. We confirmed in this study that patients with diplopia were also at risk of ischemic ocular lesions, particularly AION and CRAO, with a subsequent risk of severe loss of vision. In patients without visual impairment, the prognosis of diplopia is good after initiation of treatment with a complete resolution in most patients at one month but with a potential risk of diplopia recurrence in case of GCA relapse.

POS0809 CHARACTERIZATION OF RELAPSES IN PATIENTS WITH GIANT CELL ARTERITIS (GCA) PATIENTS- DATA FROM THE REAL-LIFE TREATMENT AND SAFETY (REATS)-GCA COHORT

V. Schönau[1], G. Corte2, S. Ott[1], K. Tascilar[1], F. Hartmann[1], B. Manger[1], B. Hellmich[3], A. Pfeil[4], P. Oelzner[4], W. A. Schmidt[5], A. Krause[5], M. Schmalzing[6], M. Fröhlich[6], M. Gernert[6], N. Venhoff[7], J. Henes[8], J. Rech[1], G. Schett[1].
[1]University Hospital Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [1]University Hospital Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [3]Mediusklinik Kirchheim, Rheumatologie, Kirchheim, Germany; [4]University Hospital Jena, Rheumatology, Jena, Germany; [5]Immanuel Albertinen Diakonie, Rheumatology, Berlin, Germany; [6]University Hospital Wuerzburg, Rheumatology, Wuerzburg, Germany; [7]University Hospital Freiburg, Rheumatology, Freiburg, Germany; [8]University Hospital Tuebingen, Rheumatology, Tuebingen, Germany

Background: Giant cell arteritis (GCA) has the tendency to relapse once treatment is tapered or stopped. Such relapses represent a potential threat to GCA patients as they can lead to severe symptoms and organ damage.

Objectives: To assess the frequency and type of relapses in patients with GCA

Methods: The Real-Life Treatment and Safety (REATS)-GCA cohort has been established by extracting the data on clinical presentation, inflammatory markers, imaging, comorbidities, treatments and serious adverse events of GCA patients from 6 specialized centres in Germany. We undertook descriptive and survival analyses (Kaplan-Meier), and compared baseline characteristics of participants with vs. without relapse. Ethical approval for the cohort was obtained.

Results: We included 395 patients with a mean age of 71 years, including 264 (66.8 %) females and 129 (32.7%) males. Diagnosis of GCA was supported by temporal artery ultrasound in 37%, ^{18}F-FDG-PET/CT in 29%, temporal artery biopsy in 14% of patients and by MRI or clinically in the remaining patients. 31% of patients presented with an isolated cranial manifestation and 18% with isolated extracranial manifestations. Most common presenting symptoms were headache (57%), fatigue (55%), weight loss (42%) and polymyalgia (38%) (Table 1). The most common comorbidities at the time of study inclusion were arterial hypertension (68%), followed by osteoporosis (26%). Within a median total follow-up duration of 22.2 (11.7-40.6) months, 97 of the 395 patients relapsed including 15 patients who relapsed more than once. The median (IQR) time to first relapse was 12.5 (7.1-21.8) months. Median relapse-free survival was 7.8 years with a relapse risk of 12% (CI, 9 to 15%) at 1 year and 38% (CI, 30 to 45%) at 5 years (Figure 1). Most common symptoms at relapse were headache (35%), polymyalgia (23%), fatigue (19%) and night sweats (12%) (Table 1). Three patients relapsed with sudden loss of vision. Among the 114 relapses observed, 94 (83%) occurred under prednisolone treatment with a median dose of 7.0 mg/day (IQR 4.0-12.5). 26 (23%) occurred under methotrexate and 14 (12%) under tocilizumab treatment. Comparing the baseline characteristics that were documented in this study, we did not find a statistically significant difference in relapsing versus non-relapsing GCA patients.

Table 1.

Symptom at disease onset	N=395 (%)	Symptom at relapse	N=97 (%)
Headache	216 (54.7)	Headache	35 (30.7)
Fatigue	208 (52.7)	Polymyalgia (PMR)	23 (20.2)
Weight loss	159 (40.3)	Fatigue	19 (16.7)
Polymyalgia (PMR)	144 (36.5)	Vision impairment	13 (11.4)
Night sweats	140 (35.4)	Night sweats	12 (10.5)
Headache in the temple area	125 (31.6)	Headache in the temple area	12 (10.5)
Jaw pain	121 (30.6)	Jaw pain	11 (9.6)
Vision impairment	118 (29.9)	Morning stiffness	7 (6.1)
Morning stiffness	89 (22.5)	Weight loss	7 (6.1)
Fever	80 (20.3)	Claudication upper limb	6 (5.3)
Swelling temporal arteries	77 (19.5)	Arthralgia	6 (5.3)
Vision loss	57 (14.4)	Claudication lower limb	5 (4.4)
Scalp tenderness	38 (9.6)	Vision loss	3 (2.6)
Claudication upper limb	38 (9.6)	Arthritis	3 (2.6)
Claudication lower limb	34 (8.6)	Scalp tenderness	2 (1.8)
Arthralgia	28 (7.1)	Fever	2 (1.8)
Arthritis	3 (0.8)	Swelling temporal arteries	2 (1.8)

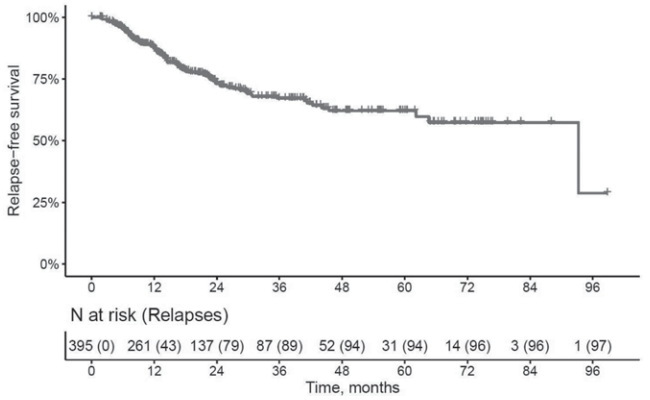

Figure 1.

Conclusion: About one fourth of GCA patients relapsed and the overwhelming majority of relapses occurred before patients were able to stop glucocorticoids. The leading symptoms at relapse are headache and fatigue, while loss of vision is rare (0.76%). Baseline characteristics seem to be poorly informative about the risk of relapse, therefore regular monitoring of GCA patients is necessary.

POS0810 FREQUENCY OF VISUAL MANIFESTATIONS IN GIANT CELL ARTERITIS IN NORFOLK

S. Mansfield-Smith[1], M. Al-Hashimi[1], C. Jones[1], C. Mukhtyar[2]on behalf of Mukhtyar Vasculitis Group. *[1]Norfolk & Norwich University Hospital, Ophthalmology, Norwich, United Kingdom; [2]Norfolk & Norwich University Hospital, Rheumatology, Norwich, United Kingdom*

Background: The ophthalmic features of giant cell arteritis (GCA) involve a spectrum of severity from transient symptoms to bilateral visual loss from anterior ischaemic optic neuropathy or less commonly central retinal or cilioretinal artery occlusion. Reported ocular involvement varies between 10-70%.[1,2]. At the Norfolk and Norwich University Hospital an interdisciplinary fast track service is provided for potential GCA patients. This report aims provides a complete picture of the frequency and nature of ocular involvement in GCA.

Objectives: 350 records of consecutive patients diagnosed objectively with GCA based on biopsy or imaging were reviewed. In our centre, the hospital pathway mandates all suspected GCA cases to have a formal ophthalmology assessment

including visual acuity, pupil exam and full-dilated fundus assessment. Systemic and Ophthalmic symptoms and signs were recorded.

Methods: From January 2012 to September 2021, 350 individuals were diagnosed with GCA by biopsy, ultrasonography or positron emission tomography. The mean age was 74 ± 7.7 years. 235 (67%) of patients were females. 101 (29%) presenting with GCA had visual symptoms and/or signs. 42 of them had mono-ocular and 5 had binocular loss of vision. A summary of the key visual symptoms and signs are shown in Table 1. Only 6 patients with visual symptoms did not have any symptoms commonly associated with GCA.

Table 1. Visual Symptoms and Signs (N=350 patients)

Visual Symptoms	101
Blurred Vision	36
Loss of vision	47
Double Vision	27
Ocular Signs	
Right CRAO[1]	1
Left CRAO[1]	10
Right AION[2]	19
Left AION[2]	23
Right extraocular muscle weakness	6
Left extraocular muscle weakness	4

[1] Central retinal artery occlusion [2] Anterior ischaemic optic neuropathy

Results: From January 2012 to September 2021, 350 individuals were diagnosed with GCA by biopsy, ultrasonography or positron emission tomography. The mean age was 74 ± 7.7 years. 235 (67%) of patients were females. 101 (29%) presenting with GCA had visual symptoms and/or signs. 42 of them had mono-ocular and 5 had binocular loss of vision. A summary of the key visual symptoms and signs are shown in Table 1. Only 6 patients with visual symptoms did not have any extra-ocular symptoms commonly associated with GCA.

Conclusion: We report the frequency of visual involvement in one of the largest cohorts of individuals with GCA. 29% have ocular symptoms. Partial or total field loss occurred in 13% of cases. 2% of patients presented with visual manifestations as the only feature of GCA. Rarely, permanent visual loss may occur without any other manifestation of GCA.

POS0811 CHARACTERISTICS OF INTESTINAL MICROBIOTA AND ITS RELATIONSHIP WITH LYMPHOCYTE SUBSETS AND CYTOKINES IN PATIENTS WITH VASCULITIS

J. Wang[1,2,3], S. X. Zhang[1,2,3], S. Song[1,2,3], J. Qiao[1,2,3], R. Zhao[1,2,3], T. Cheng[1,2,3], J. Liu[1,2,3], C. Wang[1,2,3], X. LI[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China*

Background: Vasculitis include a group of autoimmune inflammatory diseases with clinical heterogeneous characterized by inflammation of vascular wall, inflammation of perivascular tissues, and cell-like necrosis[1]. Disorder of gut microbiota, which plays a crucial role in regulating immune cells such as Th1, Th17 and Treg, is associated with other autoimmune diseases[2], and may also be involved in the pathogenesis of vasculitis.

Objectives: To investigate the changes of intestinal microbiota and its correlation with peripheral lymphocyte subsets and inflammatory factors levels in patients with vasculitis.

Methods: Combined with clinical manifestations and laboratory examination, 33 patients with vasculitis who met the 2012 revised International Chapel Hill Consensus Conference Nomenclature of Vasculitides[3] and 33 of age- and gender- matched healthy controls (HCs) were selected from the Second Hospital of Shanxi Medical University. The demographic characteristics, general laboratory indicators such as erythrocyte sedimentation rate (ESR), C-reaction protein (CRP), levels of peripheral lymphocyte subpopulations and serum cytokines detected by modified flow cytometry. Fecal microbiota detected by 16S rRNA gene sequencing and compiled and processed using Qiime2 and OTU-profiling tables were collected and analyzed in this study.

Results: Compared with HCs, the richness and diversity of intestinal flora in patients with vasculitis tended to decrease with a statistically significant difference in β diversity (P = 0.025, Figure 1 A and B). More specifically, vasculitis patients had a lower frequency of Firmicutes while higher Proteobacteria and Bacteroidota at the phylum level (P < 0.001, Figure 1C). In vasculitis patients, the relative abundances of 23 bacteria differed from HCs at the genus level was all decreased, including Gemella, Anaeroglobus, Campylobacter, Fournierella, et al (P < 0.001, Figure 1D and E). More importantly, the relative abundance of Muribaculaceae were positively correlated with the absolute count of Th2 and the proportions of Th1 and $CD4^+$T cells and negatively correlated with CRP and ESR, while relative abundance of [Eubacterium]_ventriosum were positively associated with the absolute number of Treg cells and negatively correlated with the percentages of Th2 and $CD8^+$T cells (Figure 1F).

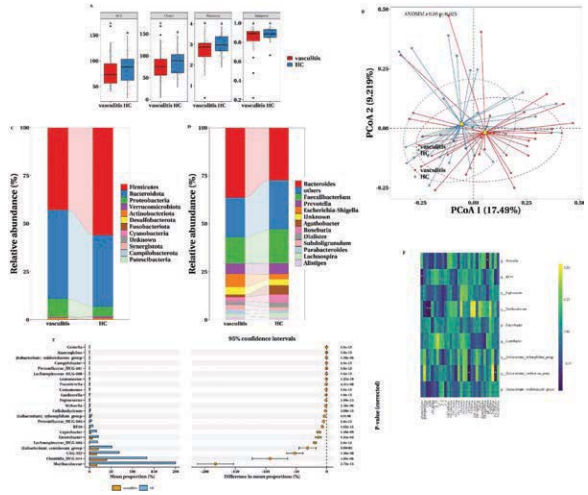

Figure 1. Differences in α diversity (A), β diversity (B), phylum (C), genus (D), and microbial composition (E) between vasculitis patients and HC and correlation analysis between differential microflora and clinical data in patients with vasculitis (F).

Conclusion: Disturbance of intestinal flora, mainly manifested by decreased diversity and richness, may be involved in the occurrence and development of vasculitis by inducing disroders in lymphocyte subsets and cytokines. Consequently, further studies on the immune mechanisms and influencing factors of intestinal flora may provide new ideas for the diagnosis and treatment of the disease for vasculitis patients.

POS0812 CAROTID INTIMA-MEDIA THICKNESS/DIAMETER RATIO AND PEAK SYSTOLIC VELOCITY AS RISK FACTORS FOR NEUROLOGICAL SEVERE ISCHEMIC EVENTS IN TAKAYASU'S ARTERITIS

L. Wang[1], Y. Sun[1], X. Dai[1], X. Kong[1], L. MA[1], X. Dai[1], L. MA[1], L. Jiang[1,2]. *[1]Zhongshan Hospital Fudan University, Department of Rheumatology, Shanghai, China; [2]Zhongshan Hospital Fudan University, Evidence-based Medicine Center, Shanghai, China*

Background: Takayasu's arteritis (TAK) is an idiopathic systemic vasculitis characterized by the involvement of the aorta and its major branches [1]. The supra-aortic arteries are often involved in TAK, with the reported prevalence ranging from 40% to 84% [2-3]. Importantly, patients with supra-aortic involvement carry a higher risk of neurological severe ischemic events (SIE) [4-5]. The common carotid artery (CCA) is the most affected artery and is more closely associated with neurologic symptoms than other supra-aortic arteries [6]. Ultrasonography (US) has been regarded as the most popular, user-friendly, and repeatable tool for the diagnosis and follow-up of CCA injuries.

Objectives: Our aim was to characterize TAK with supra-aortic involvement and determine the associations between clinical features, carotid US parameters, and neurological SIE.

Methods: Patients with supra-aortic involvement including brachiocephalic trunk, bilateral common carotid artery and internal carotid artery, and bilateral subclavian

and vertebral artery and baseline carotid US examination were enrolled. Bilateral carotid diameter, intima-media thickness (IMT), and peak systolic velocity (PSV) were measured by US. Then, IMT/diameter ratio (IDR) was calculated. Risk factors associated with neurological SIE were analyzed by multivariate logistic regression.
Results: Totally, 295 patients were included, of whom 93 (31.5%) experienced neurological SIE, with common carotid artery involved (81.7%). Involved supra-aortic artery distribution (p=0.04) and number (p<0.01) differed between neurologic and non-neurologic SIE subjects, showing higher prevalence of common carotid and vertebral artery involvement in cases with neurological SIE and 57.1% neurological SIE patients having more than four involved arteries. The left carotid IMT (p=0.03) and IDR (p<0.01) differed between patients with and without neurological SIE. The left carotid IDR (cut-off value ≥0.55, odds ratio [OR] 4.46; 95% confidence interval [CI] 2.05-9.71; p<0.01) and PSV (≤76 cm/s, OR 3.38; 95% CI 1.62-7.04; p<0.01) and involved supra-aortic artery number (≥4, OR 3.16; 95% CI 1.54-6.47; p<0.01) were independently associated with neurological SIE.
Conclusion: The left carotid IDR, PSV and involved supra-aortic artery number would perform as valuable markers for recognizing neurological SIE in TAK patients with supra-aortic lesions.

POS0813 GLUCOCORTICOIDS, CONVENTIONAL DMARDS AND TOCILIZUMAB DIFFERENTLY AFFECT 18F-FDG PET METABOLIC ACTIVITY IN GIANT CELL ARTERITIS PATIENTS.

L. Iorio[1], D. Campaniello[1], P. Zucchetta[2], D. Cecchin[2], A. Doria[1], F. Schiavon[1], R. Padoan[1]. *[1]University of Padua, Division of Rheumatology, Department of Medicine DIMED, Padova, Italy; [2]University of Padua, Nuclear Medicine Unit, Department of Medicine DIMED, Padova, Italy*

Background: Imaging role in large vessel vasculitis (LVV) patients is tremendously increased in recent years. However, the role of ^{18}F-FDG PET in evaluating treatment response is still an unmet need.
Objectives: The aim of the present study is to evaluate the effect of different treatment regimens, namely glucocorticoids (GC), conventional disease modifying anti-rheumatic drugs (cDMARDs) and tocilizumab (TCZ), on clinical and metabolic activity of giant cell arteritis (GCA) with extra-cranial involvement.
Methods: Consecutive LVV inpatients and outpatients, classified as GCA, were prospectively enrolled. We included all patients who underwent to at least 2 consecutive ^{18}F-FDG PET-CT or MR scan between October 2010 and October 2021. Demographic and clinical data as well as disease activity were assessed before every PET scan. Remission was defined absence of signs and symptoms attributable to GCA and normalization of ESR (<30 mm/Hr) and CRP (<1 mg/dL) [1]. GCA patients were compared according to current treatment regimen: GC monotherapy versus cDMARDs (methotrexate, azathiopirine) and versus TCZ (administered both subcutaneous and intravenous). For each PET scan the vessel's metabolic activity was evaluated using the Meller's grading [2] and the PETVAS score [3].
Results: The study included 47 patients (age 66 [60-70], 72.3% female) exposed to a total of 77 treatment regimens (n=37 GC monotherapy, n=26 cDMARDs, n=14 TCZ). A total of 181 PET scan were conducted (min 2 – max 6). Overall clinical remission rate during the follow-up was 75.7% in GC-treated patients, 69.2% in cDMARDs-treated and 85.7% in TCZ-treated (p=0.513).
Persistence was comparable among the different treatment regimens (GC 19±10 months vs cDMARDs 22±16 months vs TCZ 23±11 months, p=0.445).
All the treatment led to significant reduction of acute phase reactants (GC-treated: ESR 50vs20 mmh, p<0.001, ΔESR= -43.3%, CRP 13.6vs5.3 mg/L, p=0.001, ΔCRP= -87.7%; cDMARDs-treated: ESR 36vs27 mmh, p=0.134, ΔESR= -152%, CRP 13.6vs5.3 mg/L, p=0.038, ΔCRP= -66.3% and TCZ-treated: ESR 27vs3 mmh, p=0.017, ΔESR= -86.7%, CRP 11.4vs2.7 mg/L, p=0.023, ΔCRP= -80.2%).
Significant improvement in PETVAS was observed only in TCZ-treated patients (12vs4, p=0.002, ΔPETVAS -66.7%), while the other treatment approaches resulted not significant (GC treated 12vs5, p=0.052, ΔPETVAS= -50%; cDMARDs 11vs4, p=0.124, ΔPETVAS -52.4%).
Daily prednisone dose at last examination was 4.5 [0-5] mg/d in the cDMARDs group vs 1.25 [0-5] mg/d in the TCZ group (p=0.057). Interestingly, at last PET examination low-grade inflammation (Meller 1-2) was observed in 56.8% of GC-treated patients, 57.7% of cDMARDs-treated patients and 64.3% of TCZ-treated patients (p=0.884).
Conclusion: ^{18}F-FDG PET may be useful in assessing disease activity and monitoring response to therapy. Tocilizumab treatment significantly reduce vessel's metabolic activity over time, when compared to conventional treatment. A persistent low-grade uptake during remission is common features in LVV patients, irrespectively of treatment regimens.

POS0814 OUTCOME OF VASCULAR INVOLVEMENT OF BEHÇET'S SYNDROME TREATED WITH INFLIXIMAB: A RETROSPECTIVE COHORT STUDY

G. Hatemi[1,2], B. Tukek[3], S. N. Esatoglu[1,2], Y. Ozguler[1,2], S. S. Taflan[3], M. Melikoglu[1,2], S. Ugurlu[1,2], I. Fresko[1,2], Z. Kutlubay[2,4], S. Yurdakul[1,2], H. Yazici[1,2], V. Hamuryudan[1,2]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul, Turkey; [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey; [4]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Istanbul, Turkey*

Background: Vascular involvement is the most common cause of mortality and an important cause of disability in patients with Behçet's syndrome (BS). Cyclophosphamide has been the treatment choice for severe vascular involvement, but high frequency of adverse events such as infertility and infections cause concern. TNF inhibitors can be an alternative for BS patients with vascular involvement.
Objectives: To survey the efficacy and safety of infliximab (IFX) in BS patients with arterial and venous vascular involvement.
Methods: We reviewed the charts of BS patients who used IFX for vascular involvement. We extracted data on demographic and clinical features, type of vascular involvement, laboratory tests, imaging modalities, concomitant immunosuppressives, duration of IFX use, and outcome. The primary endpoint was remission, defined as the presence of all of the following 3 parameters: 1) lack of new clinical symptoms/findings associated with the vascular lesion 2)

normalization of CRP level defined as <10 mg/dl) 3) lack of worsening of the primary vascular lesion or a new lesion vascular at another site on imaging. Remission was assessed at month 6 and month 12. Secondary endpoints were relapse, overall disease activity assessed with BDCAF at baseline and at the final visit, development of new organ involvement other than vascular involvement during IFX treatment, severe adverse events leading to discontinuation of IFX therapy, hospitalization or death, and death.

Results: Among the 371 patients who used IFX between 2004 and June 2021, 127 patients (102 men, 25 women, mean age 40 ± 8.7 years) had used it for vascular involvement. The types of vascular involvement that required IFX were venous thrombosis in 61 patients (48%), pulmonary artery involvement in 37 (29%), non-pulmonary artery involvement in 16 (13%), and venous ulcer in 13 (10%). Remission rate was 72% (92/127) at month 6 and 61% (71/117) at month 12. 17/99 (17%) patients experienced 22 relapses during a mean follow-up of 28.4±21 months of IFX therapy. Among the 22 relapses, 12 were the progression of the pre-existing vascular lesion and 10 were new vascular lesions. Overall disease activity improved with a decrease in mean BDCAF score from 1.76 ± 1.27 to 0.6 ± 0.8 at the final visit (p<0.001). Remission and relapse rates according to type of vascular involvement and causes of IFX discontinuation are presented in the Table 1. Adverse events leading to IFX discontinuation were infusion reactions in 5, tuberculosis, disseminated zona, lung adenocarcinoma, fibromyxoid sarcoma, heart failure, SLE, palmoplantar pustulosis, auricular chondritis, and aortic stent graft infection in 1 patient each.

Table 1. The frequency of concomitant immunosuppressive use, duration of infliximab use and outcomes of BS patients with vascular involvement treated with IFX

	Venous thrombosis (n=61)	Pulmonary artery involvement (n=37)	Non-pulmonary arterial involvement (n=16)	Venous ulcers (n=13)	Overall (n=127)
Number of patients who used concomitant immunosuppressives	48 (79)	24 (65)	14 (87)	7 (54)	93 (73)
Duration of IFX use (mean ± SD months)	24 ± 19.7	25 ± 19.3	35 ± 29.6	26 ± 24	25 ± 21
Remission rate at month 6	50 (82)	31 (84)	10 (63)	1 (8)	92 (72)
Remission rate at month 12[a]	40 (70)	21 (64)	8 (53)	2 (17)	71 (60)
Relapse rate	4 (7)	4 (11)	9 (60)	0	17 (13)
Number of patients who discontinued IFX	31 (51)	23 (62)	5 (31)	9 (69)	68 (54)
Due to remission	15	6	0	1	22
Due to inefficacy	3	1	3	4	11
Due to relapse	1	0	1	0	2
Due to adverse event	7	4	1	1	13
Due to noncompliance	3	4	0	3	10
Due to new organ development	1	0	0	0	1
Due to other reasons[b]	1	8	0	0	9
Death	2	2	0	0	4

[a] Since 10 patients did not reach the 12th month yet, the percentages were calculated on 117 patients. [b] Other reasons were preparation for surgical operation (n=2), not wanting to come to the infusion frequently during the pandemic (n=2), pregnancy (n=1), willing to get pregnant (n=1), lack of health insurance (n=1), due to prison sentence (n=1), and death (n=1).

Conclusion: Infliximab may be beneficial in BS patients with vascular involvement, even in those who are refractory to immunosuppressives and corticosteroids.

POS0815 DIFFERENCES IN GIANT CELL ARTERITIS MANIFESTATIONS ACCORDING TO THE ULTRASOUND PATTERN OF DISEASE INVOLVEMENT

J. Martinho[1,2], M. J. Sousa Bandeira[1,2], S. C. Barreira[1,2], E. Dourado[1,2], A. R. Cruz-Machado[1,2], V. Teixeira[1,3], C. Macieira[1], N. Khmelinskii[1,2], J. E. Fonseca[1,2], C. Ponte[1,2]. [1]*Centro Hospitalar Universitário Lisboa Norte, Rheumatology Department, Lisbon, Portugal;* [2]*Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Unidade de Investigação em Reumatologia, Lisbon, Portugal;* [3]*Hospital de Faro - Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal*

Background: Giant cell arteritis (GCA) is the most common form of primary systemic vasculitis in patients aged >50 years. It predominantly affects the cranial arteries; however, extra-cranial disease involving the aorta and its major branches, known as large-vessel GCA (LV-GCA), can be present in 20-80% of cases, depending on the imaging modality used for screening the disease.

Objectives: We aim to compare the clinical features and outcomes of GCA patients with exclusive cranial, exclusive LV and combined cranial and LV involvement.

Methods: Single centre retrospective study, using data from patients diagnosed with GCA registered at the Rheumatic Diseases Portuguese Registry (Reuma.pt). All patients underwent ultrasound of both temporal (TA) and axillary (AX) arteries ± facial (FA), occipital (OC), subclavian (SC) or common carotid (CC) arteries at the time of diagnosis. Only patients with the presence of "halo sign" in at least one of these arterial segments were included. Three groups of patients were established according to their ultrasound results: i) exclusive cranial-GCA in cases of TA, FA, or OC involvement; ii) exclusive LV-GCA in cases of AX, SC, or CC involvement; and iii) cranial- and LV-GCA in cases of both cranial and LV involvement. Univariate analysis was performed using T-test, Chi-square and ANOVA, as appropriate. Multivariate analysis was performed using logistic regression modelling.

Results: We included 81 patients with GCA, 55 (67.9%) females, with a mean ± SD age of 75.8 ± 8.6 years. Halo sign was found in the TAs of 66/81 (81.5%) patients, AXs of 38/81 (46.9%) patients, FAs of 37/71 (52.1%) patients, OCs of 15/58 (25.9%) patients, SCs of 27/46 (58.7%) patients and CCs of 12/57 (21.1%) patients. A total of 37 (45.7%) cases had exclusive cranial-GCA, 14 (17.3%) had exclusive LV-GCA and 30 (37.0%) had cranial- and LV-GCA. Regarding clinical manifestations, temporal headache was more frequently found in cases of exclusive cranial-GCA than in the other groups (67.6% vs 7.1% vs 56.7%, p=0.001). By contrast, patients with exclusive LV-GCA were less likely to experience temporal and frontal headache (67.6% vs 7.1% vs 56.7%, p=0.001; 48.6% vs 0% vs 40.0%, p=0.007; respectively), jaw claudication (67.6% vs 14.3% vs 60.0%, p=0.004), scalp tenderness (32.4% vs 0% vs 23.3% p=0.037) or a cranial ischemic event (54.1% vs 21.4% vs 66.7%, p=0.020). Concerning physical examination, exclusive LV-GCA was associated with abnormalities of the upper limb arteries (0% vs 15.4% vs 3.3%, p=0.042) and lack of TA changes (37.8% vs 0% vs 30.0%, p= 0.023). No significant differences were found between groups regarding demographics, comorbidities and occurrence of relapses or mortality in the first two years of disease (p>0.05). Multivariate analysis, adjusted for jaw claudication, scalp tenderness, frontal and temporal headache, cranial ischemic events, abnormalities of the TA and upper limb arteries on examination, was performed to assess the association between these variables and the three GCA groups. The occurrence of a cranial ischemic event was independently associated with a lower probability of exclusive LV-GCA [OR: 0.069 95%CI: 0.009-0.526, p=0.010]. No other independent predictors were found.

Conclusion: GCA can encompass various patterns of vascular disease on ultrasound. LV involvement was frequently found in these patients, including in cases without evidence of cranial disease, highlighting the need to incorporate LV assessment in the diagnosis of GCA. Patients with exclusive LV-GCA had fewer cranial manifestations and more abnormalities on upper limb arteries on examination than the other groups. The occurrence of a cranial ischemic event was an independent negative predictor for exclusive LV-GCA. No differences were found between groups regarding the clinical outcomes at two years. Further studies with longer time of follow-up are needed.

University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Istanbul, Turkey; [6]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Istanbul, Turkey

Background: Infliximab (IFX) is an effective therapeutic option in the management of severe and refractory manifestations of Behçet's syndrome (BS).
Objectives: We aimed to evaluate long term drug survival of IFX in a large cohort of BS patients.
Methods: We reviewed the charts of BS patients who received IFX between 2004 and June 2021 and noted demographic features, reasons for IFX use, IFX duration, and reasons for discontinuation.
Results: 371 patients (290 men, mean age at IFX initiation: 35.5 ± 10 years) received IFX for uveitis (n=164), vascular involvement (n=114), central nervous system (CNS) involvement (n=55), arthritis (n=19), gastrointestinal (GI) involvement (n=15), mucocutaneous involvement (n=10), venous ulcers (n=13), and secondary amyloidosis (n=1). Twenty patients had more than one type of involvement requiring IFX. During a median follow-up of 30 months (IQR: 13-52), 175 (47%) patients were still receiving IFX for a median period of 40 months (IQR: 22-66) while 196 (53%) patients had discontinued IFX after a median follow-up of 19 months (IQR: 8-34). IFX retention rate was 50% for mucocutaneous involvement, 43% for uveitis, 49% for vascular involvement, 58% for CNS involvement, 37% for arthritis, 53% for GI involvement, and 31% for venous ulcer (Table 1). Reasons for discontinuation were adverse events in 56 (15%), remission in 54 (15%) patients, inefficacy in 45 (12%) (secondary inefficacy in 26 (7%), primary inefficacy in 19 (5%)), and lack of patient compliance in 18 (5%). Other reasons were preparation for surgical operation (n=4), pregnancy (n=4), lack of health insurance (n=4), preferring subcutaneous administration during the pandemic (n=3), due to prison sentence (n=3), willing to get pregnant (n=1), rejecting the treatment (n=1), and death (n=3). Adverse events (n=56) leading to the cessation of IFX were infusion reactions (n=22), infections (n=7), tuberculosis (n=6), malignancy (n=6), palmoplantar psoriasis (n=5), hepatotoxicity (n=4), lichen planus (n=1), drug induced lupus (n=1), auricular chondritis (n=1), macrophage activation syndrome (n=1), splenic infarction (n=1) and a decrease in left ventricular ejection fraction (n=1). At the end of the follow-up, 2 patients had died due to lung adenocarcinoma, 1 patient had died due to pneumosepsis, 1 due to severe parenchymal neurologic involvement and 1 with pulmonary artery involvement due to massive hemorrhage during IFX treatment. Additionally, 7 patients had died 9, 10 months, 3, 3, 4, 7 and 9 years after IFX discontinuation. The causes of death were severe nervous system involvement in 2 patients, right heart failure due to pulmonary hypertension, laryngeal adenocarcinoma, lung adenocarcinoma, sepsis and gastrointestinal bleeding in 1 patient each.
Conclusion: IFX seems to be effective for the treatment of organ and life-threatening manifestations in the majority of the patients. However, drug retention rate was not optimal, mainly due to adverse events, inefficacy and patient non-compliance.

Background: Tocilizumab (TCZ) is the only biologic drug approved in giant cell arteritis (GCA), based in two clinical trials (CT) **(1,2)**. CT included selected patients who may differ from those of clinical practice (CP). A high proportion of GCA patients treated with TCZ in CT had a newly diagnosed GCA, whereas in CP, most of them are refractory/recurrent GCA **(3,4)**. Although in CT the efficacy of TCZ seems to be similar in patients with newly diagnosed GCA and in patients with refractory/recurrent GCA, in CP it is not documented.
Objectives: To compare in CP, the effectiveness and safety of TCZ in newly diagnosed vs refractory/recurrent GCA.

Methods: Multicentre observational study on 471 GCA patients treated with TCZ. GCA was diagnosed by: **a)** ACR criteria, and/or **b)** temporal artery biopsy, and/or **c)** imaging techniques. A comparative study between patients with newly diagnosed GCA (<6 weeks) and those with refractory/recurrent GCA (>6 weeks) (according to GiACTA study definitions) **(2).** Sustained remission was based on EULAR definitions **(5)**.
Results: The 471 GCA patients were divided into 2 subgroups: **a)** newly diagnosed GCA (n=91) and **b)** refractory/recurrent GCA (n=380) (Table 1).

Table 1. Main features of patients with newly diagnosed GCA and refractory/recurrent GCA treated with tocilizumab.

	Newly diagnosed GCA (n=91)	Refractory/recurrent GCA (n=380)	p
Baseline characteristics at TCZ onset			
Age(years), mean±SD	74.3±8.5	73.3±9.1	0.35
Sex, female/male (% female)	60/31 (66)	282/98 (74)	0.11
Time from GCA diagnosis to TCZ onset (months), median [IQR]	1 [0.5-1]	10 [4-24]	**0.0001**
ESR, mm 1st hour, median [IQR]	46 [17.5-80.5]	27 [10-50]	0.02
CRP, mg/dL, median [IQR]	2.1 [0.7-8.5]	1.3 [0.4-2.8]	0.13
Haemoglobin, g/dL, mean±SD	12.3±1.5	12.7±1.5	**0.03**
Prednisone dose, mg/day, median [IQR]	40 [21.2-50]	15 [10-30]	**<0.001**
Effectiveness and Safety after TCZ onset			
Follow-up, (months), median [IQR]	15 [6-27.5]	22 [11-37]	**0.004**
Relevant adverse events, n (%)	23 (25)	102 (27)	0.54
Relevant adverse events per 100 patients-year	20	15	NS
Serious infections, n (%)	13 (14)	53 (14)	0.49
Serious infections per 100 patients-year	11.2	8	NS
MACES, n (%)	0 (0)	1 (0.3)	-
MACES per 100 patients-year	0	0.2	-
Malignancies n (%)	2 (2)	3 (0.8)	0.99
Malignancies per 100 patients-year	1.6	0.5	NS

Abbreviations: CRP: C-reactive protein;ESR: erythrocyte sedimentation rate;GCA: giant cell arteritis; IQR: interquartile range; IV: intravenous; MACEs: major adverse cardiovascular events; NS: non significant; SC: subcutaneous; SD: standard deviation

No significant differences were observed between both groups in sustained remission, although a greater tendency towards sustained remission is observed in newly diagnosed than in refractory/recurrent GCA patients (Figure 1**).** The decrease in glucocorticoids dose was faster in the first three months in the newly diagnosed GCA group, but thereafter, was similar in both groups, as well as the appearance of relevant adverse events and serious infections.

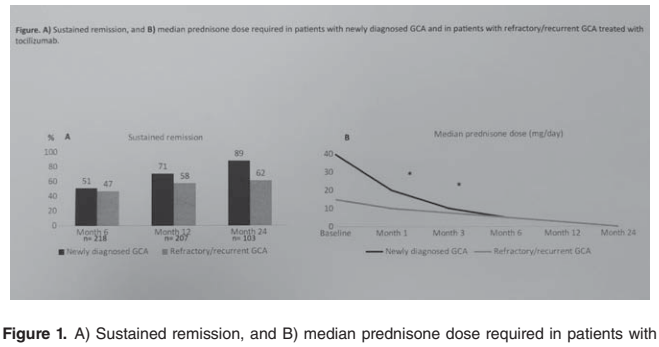

Figure 1. A) Sustained remission, and B) median prednisone dose required in patients with newly diagnosed GCA and in patients with refractory/recurrent GCA treated with tocilizumab.

Conclusion: The effectiveness and safety of TCZ seems to be similar in patients with newly diagnosed GCA and in patients with refractory/recurrent GCA.

Jackson10, K. Van der Geest[11], B. Dasgupta[1,10]. *[1]Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom; [2]University of Essex Colchester Campus, School of Sport, Rehabilitation and Exercise Science, Colchester, United Kingdom; [3]University Hospital Limerick, Rheumatology, Limerick, Ireland; [4]San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases,, Milano, Italy; [5]Azienda USL - IRCCS - di Reggio Emilia, Rheumatology, Reggio Emilia, Italy; [6]University of Modena and Reggio Emilia, Rheumatology, Modena, Italy; [7]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; [8]University of Siena, Medicine, Surgery and Neurosciences, Siena, Italy; [9]University Hospital Dorset, NHS Foundation Trust, Rheumatology, Dorset, United Kingdom; [2]University of Essex Colchester Campus, School of Sport, Rehabilitation and Exercise Science, Colchester, United Kingdom; [11]University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Ultrasound (US) is recommended as the first line imaging test in patients with suspected Giant Cell Arteritis (GCA). Traditionally, the US halo sign has been used for diagnosis. We have recently described a composite Halo Score that allows to quantify vascular inflammation on US. Prospective studies on response and disease monitoring are lacking.
Objectives: To prospectively assess the role of US in diagnosing and monitoring GCA patients. We report early baseline and 12-month data on our current recruitment in a study that has suffered disruption from the pandemic.
Methods: HAS GCA (IRAS#264294) is an ongoing, prospective, multicentre study recruiting from referrals of suspected GCA to fast-track clinics. Based on the Southend GCA clinical pre-test probability score (SPTPS)1, patients were stratified in to low, intermediate and high risk categories2. Temporal and axillary US Halo Scores were calculated from the halo thickness and extent in bilateral temporal arteries, parietal and frontal branches (TAHS) and axillary arteries (AAHS). These scores were summed (TAHS x1 plus; AAHS x3) to generate a Total Halo Score (THS)3.
Mann Whitney U test was used to compare baseline features between GCA and controls. Wilcoxon signed rank test was used to evaluate disease features at baseline and at 12 months in GCA patients. Sensitivity (Sn), Specificity (Sp) and ROC curve were calculated, where applicable. P value <0.05 is statistically significant
Results: 202 patients (71 GCA, 131 controls) have been recruited thus far: 23 completed 12-month follow up assessment; 6 were lost to follow up (4 died, 2 withdrew consent due to pandemic). Demographics, clinical features, and US results are shown (Table 1).

Table 1. Baseline features of GCA patients and controls

	GCA (n=71)	Controls (n=131)	P-value
Age, median (IQR)	75 (70-81)	68 (62-76)	0.001
Female, n (%)	38 (54)	89 (68)	0.05
SPTPS category, n (%)			
Low risk	0 (0)	59 (45)	<0.001
Intermediate risk	16 (23)	49 (37)	0.04
High risk	55 (77)	23 (18)	<0.001
Halo score (HS), median (range)			
Temporal artery HS	12 (0-22)	2 (0-17)	<0.0001
Axillary artery HS	12 (0-21)	6 (0-18)	<0.0001
Total HS	21 (2-40)	8 (0-29)	<0.0001
Clinical features, n (%)			
Temporal headache	53 (75)	93 (71)	0.62
Scalp tenderness	36 (51)	40 (31)	0.006
Jaw claudication	38 (54)	9 (7)	<0.001
PMR symptoms	29 (41)	35 (27)	0.06
Constitutional symptoms	42 (59)	29 (22)	<0.001
Visual disturbance	40 (56)	58 (44)	0.11
Vision loss	21 (30)	9 (7)	<0.001

AA, axillary artery; GCA, Giant cell arteritis; TA, Temporal artery

Among GCA patients, 50 had cranial, 5 large-vessel and 16 mixed phenotypes. Diseases were diagnosed by US and additional tests such as PET CT.

Jaw claudication (54%) and constitutional symptoms (59%) were the dominant features in GCA patients. Median age was 75 years in GCA (54% females) and 68 years in controls (68% females). GCA and controls were stratified by SPTPS to Low risk (0% vs 45%; Sn-undefined, Sp-98), Intermediate risk (23% vs 37%; Sn-81, Sp-98) and High risk (77% vs 18%; Sn-98, Sp-91). Optimal SPTPS cut-off point was ≥12 (Sn-89, Sp-76).

Median THS was 21 in GCA and 8 in controls. Optimal cut-off Halo Score in diagnosis was TAHS ≥5 (Sn-89, Sp-86), AAHS ≥11 (Sn-55, Sp-75), THS ≥15 (Sn-79%, Sp-86%). Baseline Halo Score and CRP levels showed positive correlation (spearman rank correlation). Among the 23 patients who completed 12-months follow up, median TAHS, AAHS and THS reduced from 12 to 2, 12 to 6 and 21 to 10, respectively (Figure 1).

Conclusion: Along with SPTPS, Halo Score successfully discriminates GCA from non GCA mimics and. HS is effective in showing 12-month response. This score may be a useful marker to monitor GCA disease activity

POS0819 RACIAL DIFFERENCES IN CARDIOVASCULAR AND INFECTIOUS MORBIDITY AMONG PATIENTS WITH GIANT CELL ARTERITIS

A. B. Arevalo[1], H. Zala[2], P. Shah[3], M. Majmundar[3], A. Ramirez Gomez[1].
[1]University of Chicago, Rheumatology, Chicago, United States of America; [2]Icahn School of Medicine at Mount Sinai, Clinical Research, New York, United States of America; [3]New York Medical College, Medicine, New York, United States of America

Background: Giant cell arteritis (GCA) is the most common primary vasculitis in adults. It presents with signs of vascular insufficiency of the extracranial arteries of the head, but may also affect the aorta and its primary and secondary branches. GCA is more prevalent in Caucasians of Scandinavian and Northern European descent, and is considered to be less common in African, Asian, Arab and Latin American populations.[1,2] However, this may reflect a lack of formal epidemiological data in these populations rather than a true lower incidence. This is evidenced by extensive studies in white populations and a significant paucity of data in other ethnic groups. The most frequent causes of death in GCA are cardiovascular disease (CVD) (39%) followed by cerebrovascular disease (CVA) (14%), infection (13%), and malignancy (12%).[3] Overall, the mortality rate is increased in the first two years and is associated with the disease severity, extent, ischemic, and treatment complications, particularly from glucocorticoids.[4,5]

Objectives: The aim of this study was to compare the rate of cardiovascular and infectious complications in GCA patients among different ethnicities.

Methods: In this retrospective cohort study, we identified patients with biopsy proven GCA based on ICD-10 codes, using the Nationwide Inpatient Sample database (NIS) from 2016 to 2019. We included acute coronary syndrome (ACS), CVA, thoracic ascending aneurysm rupture (TAA), and infection (composite of UTI, sepsis and pneumonia) as our outcomes of interest and compared them between Caucasian, African American (AA), and Hispanic ethnicities. We implemented logistic regression analysis in the univariable and multivariable models. In the multivariable model, we adjusted all outcomes for potential confounders, including age, sex, obesity, hyperlipidemia, congestive heart failure, peripheral vascular diseases, diabetes, hypertension, renal failure, history of smoking or alcohol abuse, history of other drug abuse, prior history of MI, primary coronary intervention, or coronary artery bypass grafting, coagulopathy, liver disease, chronic pulmonary disease, ischemic cardiomyopathy, Elixhauser comorbidity index, type of insurance, bed size of hospital, history of defibrillator or pacemaker, and long-term use of steroids. The analysis was done using the STATA software, version 17.0 (MP2).

Results: We identified 7,750 patients with GCA, of whom 5,710 (74%) were Caucasian, 1,335 (17%) were AA, and 705 (9%) were Hispanic. Our results showed that Hispanics had both a higher prevalence (16.30% vs 9.80% vs 7.50%, p-value = 0.017) and risk for infections (OR: 2.74; 95%-CI 1.4-5.5; p-value = 0.004) when compared to the other racial groups. There was no difference in the risk of ACS among Caucasians (OR: 2.72; 95%-CI 0.6-12.4; p-value = 0.2) and Hispanics (OR: 2.72; 95%-CI 0.4-17.4; p-value = 0.004) when compared to AA population. Similarly, risk of CVA was not different between racial groups (Caucasians: OR: 1.04; 95%-CI 0.6-1.7; p-value = 0.87; Hispanics: OR: 0.8; 95%-CI 0.4-1.7; p-value = 0.567). The prevalence for TAA was only reported in the Caucasian group (0.50%).

Conclusion: ACS and CVA are known complications of GCA. There does not appear to be a difference in the risks of these common cardiovascular complications among racial groups. However, there was a significantly higher rate of infections in the Hispanic population. This may be explained by biologic differences in susceptibility and racial disparities in insurance coverage and access to care.

POS0820 PREDICTIVE VALUE OF OBJECTIVE EXAMINATION OF TA ON POSITIVITY OF TAB IN GIANT CELL ARTERITIS

G. Germano[1], P. Macchioni[1], G. Klinowski[1], A. Cavazza[1], L. Boiardi[1], C. Salvarani[1,2]. [1]*ASMN-IRRCS Reggio Emilia, Rheumatology, Reggio Emliia, Italy;* [2]*Università Modena e Reggio, Rheumatology, Modena, Italy*

Background: Previous studies have reported the utility of temporal artery examination for the diagnosis of GCA but no data are available on the correlation between clinical examination and the subsequent temporal artery biopsy (TAB) results of the biopsied vessel.
Objectives: Evaluate the predictive value of temporal artery (TA) examination in patients with suspected GCA on the results of TAB of the same vessel.
Methods: 97 pts consecutively seen at our center because of suspected cranial arteritis between 01.01.2015 to 31.12.2021 were enrolled in the study. All patients had complete clinical examination, laboratory investigations (included ESR and CRP determination), clinical examination of the temporal arteries and their frontal and parietal branches for tenderness (P), reduced or absent pulse (R) and thickening (T). All patients underwent arterial ultrasound (US) followed by a TAB of the most US involved frontal branches. The presence of inflammatory infiltrate of the vessel wall or the inflammation of the periadventitial blood vessel were considered positive for the presence of arteritis. The clinical features of the biopsied vessel were compared with the histological results by chi square test and the correspondent OR with 95%CI. Sensitivity, specificity, negative and positive PV, negative and positive LR were calculated for every singular objective abnormalities.
Results: 97 pts entered the study (F 56 (58%), mean age 73 ± 8, biopsy positive 56 (57%). At clinical examination of the biopsied vessel P was reported in 26 cases (27%) of TAB + and 10 (24.4%) in TAB- group (p=0.646, OR 1.24), R in 15 (15.5%) vs 2 (4.9%) (p=0.021, OR 5.69) and T in 16 (28.6%) vs 2 (4.9%) (p=0.003, OR 7.80), anyone (T or P or R) 30 (54.5% vs 11 (26.8%) (p=0.007, OR 3.27), presence of T or R 23 (41.8%) vs 4 (9.8%) (p=0.001, OR 6.65). Sensitivity, specificity, PPV, NPV, PLR, and NLR of any singular objective data and of US examination are reported in Table 1

Table 1. SENS, SPEC, PPV, NPV. PLR, NLR, PRETEST probability, POST TEST probability of clinical objective examination and US results FOR TAB POSITIVITY

POS0821 CORONARY ARTERIAL INVOLVEMENT CAN BE OBSERVED IN A SIGNIFICANT SUBSET OF TAKAYASU'S ARTERITIS PATIENTS BY CORONARY CT-ANGIOGRAPHY

K. Abacar[1], A. Cincin[2], F. Baltacioglu[3], Z. Dogan[2], G. Sevik[1], H. Direskeneli[1], F. Alibaz-Oner[1]. [1]*Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey;* [2]*Marmara University School of Medicine, Department of Cardiology, Istanbul, Turkey;* [3]*Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey*

Background: Besides the aorta and its main branches, coronary arterial involvement is also seen at a substantial rate in patients with Takayasu's arteritis (TAK). Computerized tomography (CT)-angiography, as a non-invasive assessment tool, has started to be used instead of conventional angiography in the evaluation of coronary arteries. However limited data is available for its role in TAK patients.
Objectives: In this study, we aimed to assess the coronary arterial involvement by coronary CT-angiography in TAK patients with or without symptoms and to compare clinical characteristics of patients with or without coronary arterial involvement.
Methods: Patients with TAK (n=49, F/M: 40/9, mean age: 42.61±9.95 years) followed in Marmara University Vasculitis Clinic and underwent coronary CT-angiography with or without cardiac symptoms were evaluated retrospectively. Data of four patients who were not suitable for coronary CT-angiography but underwent conventional angiography were also included. CT angiography findings in the coronary arteries were defined as osteal stenosis, stenosis, calcific plaque and aneurysm and patients were categorized into two groups as those with or without coronary artery pathology. Demographic data, cardiac symptoms, clinical findings, BMIs, angiographic Hata and Goel classifications, treatments received for TAK, acute phase reactants and lipid levels were compared.
Results: Coronary artery pathology was detected in 14 patients (28.7%). Only 9 patients had a history of angina and 6 had cardiac symptoms in this group. Calcific plaque was present in 11 (22.5%), coronary artery stenosis in eight (16.3%) and aneurysm, osteal stenosis and occlusion in one patient each (2.0%). RCA was involved in 20.4%, LAD in 28.6%, LMCA in 22.4%, CX in 26.6% and more than one coronary arterial involvement in 26.5% of patients. In patients with coronary artery involvement, age (p=0.02), age at TAK diagnosis (p=0.004) and number of anti-hypertensive drugs (p=0.011) were significantly higher than those without coronary artery involvement. History of angina (p=0.004) and statin use (p=0.001) were also significantly higher in patients with coronary artery abnormalities, whereas HDL levels were significantly lower (p=0.037). No significant differences were observed between the groups when gender, smoking history, diabetes, BMI, ITAS2010 scores, biological therapy use, angiographic classifications, aortic involvement, presence of cardiac symptoms, CRP, ESR, total cholesterol and LDL levels were compared (Table 1).

Table 1. Comparison of patient groups with and without coronary artery involvement (BMI: Body Mass Index, SD: Standard Deviation, ITAS: Indian Takayasu Activity Score, LDL: Low Density Lipoprotein, HDL: High Density Lipoprotein)

	Presence of Coronary Arterial Involvement (n=14)	**Absence of Coronary Arterial Involvement (n=35)**	**p value**
Age	49.29 (8.23)	39.94 (9.39)	***p=0.02***
Gender (F/M)	10/4	30/5	p=0.254
Disease duration, years	7.43 (6.42)	8.46 (6.25)	p=0.608
Age at TAK diagnosis	41.21 (12.58)	31.37 (9.18)	***p=0.004***
Diabetes mellitus	3/14	1/35	p=0.065
Family history	4/14	7/35	p=0.706
Smoking history	8/14	25/35	p=0.122
BMI (kg/m^2)	25.08 (2.53)	25.17 (4.68)	p=0.930
Biological therapy	4/14	15/34	p=0.317
CRP (mg/L) mean (SD)	4.45 (3.4)	8.68 (24.08)	p=0.642
ITAS2010 mean (SD)	0.57 (0.94)	0.51 (1.15)	p=0.869
LDL (mg/dL) mean (SD)	102 (41.96)	112.44 (35.79)	p=0.398
HDL (mg/dL) mean (SD)	46.23 (12.78)	55.12 (12.62)	***p=0.037***
Cardiac Symptom	6/14	2/35	p=0.159
Aorta involvement	8/14	18/35	p=0.717
Statin use	10/14	6/34	***p=0.001***
Number of antihypertensives	1.79 (0.89)	0.85 (1.18)	***p=0.011***
Acetylsalicylic acid use	10/14	24/34	p=1
Angina history	9/14	6/35	***p=0.004***

Conclusion: Coronary artery involvement which is an important cause of morbidity and mortality can be detected non-invasively by coronary CT-angiography in up to 1/3 of patients with Takayasu's arteritis, also in patients without angina and cardiac symptoms. Traditional cardiac risk factors are present more commonly in this group.

Background: Hypertrophic pachymeningitis (HP), characterized by an inflammatory disorder indicating intracranial or spinal thickening of dura mater, is found to develop as a neurological involvement in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Meanwhile, the previous studies focusing on HP in AAV have been reported as a single-institution study, and the analyses were performed in a small number of patients because HP is a rare neurological disorder. Therefore, neither etiological nor clinical characteristics of HP in AAV have been adequately elucidated.

Objectives: This study clarified the characteristics of HP in AAV by analyzing the information of multicenter study in Japan (Japan collaborative registry of ANCA-associated vasculitis: J-CANVAS).

Methods: We analyzed the clinical information from 541 Asian patients with AAV enrolled in J-CANVAS. Of them, newly diagnosed and relapsed AAV were included in 448 and 93, respectively. The epidemiological and clinical findings were compared between patients with and without HP. Clinical manifestations related to AAV were evaluated based on the Birmingham Vasculitis Activity Score version 3. To elucidate independent factors in HP development, logistic regression analyses were additionally performed.

Results: Of the total 541 patients (mean age: 71±14 years, M:F = 1:1.2), HP was demonstrated in 28 (5.17%), including 17 (3.79%) in newly diagnosed AAV and 11 (11.8%) in relapsed AAV. The classification of granulomatosis with polyangiitis (GPA) was significantly higher in patients with HP than those without HP (50% vs. 21%, p = 0.0007). In newly diagnosed AAV, patients with HP significantly had higher GPA classification and higher positivity for PR3-ANCA than those without HP (53% vs. 17%, p = 0.001; 29% vs. 9%, p = 0.015, respectively). Conversely, positivity for MPO-ANCA was significantly higher in patients with HP than those without HP in relapsed AAV (91% vs. 55%, p = 0.025), despite not significantly different in the classification of AAV. Headache and cranial neuropathies were significant neurological symptoms in patients with HP compared to those without HP (82% vs. 6.6%, p < 0.0001; 32% vs. 2.9%, p < 0.0001, respectively). Besides, ear, nose and throat (ENT) and mucous membranes/eyes were significantly higher involvements in patients with HP than in those without HP (54% vs. 26%, p = 0.003; 29% vs. 9%, p = 0.003, respectively). Moreover, higher complications of "conjunctive hearing loss" and "sudden visual loss", which are included in the categories of ENT and mucous membranes/eyes involvement, respectively, were significantly indicated in patients with HP than those without HP (39% vs. 7.2%, p < 0.0001; 21% vs. 1.2%, p < 0.0001, respectively). Multivariable logistic regression analysis identified that ENT (odds ratio [OR] 1.28, 95% confident interval [CI] 1.09 to 1.49, p = 0.002) and mucous membranes/eyes involvement (OR 1.37, CI 1.14 to 1.65, p = 0.0006), as well as conjunctive hearing loss (OR 4.52, CI 1.56 to 13.05, p = 0.005) and sudden visual loss (OR 1.84, CI 1.12 to 3.00, p = 0.015), were independent related factors in patients with HP.

Conclusion: GPA could be significantly classified in patients with HP. Notably, patients with HP significantly showed higher positivity for PR3-ANCA than those without HP in newly diagnosed AAV. Furthermore, sudden visual loss and conjunctive hearing loss might be implicated in HP development.

POS0823 KL-6 IN ANCA-ASSOCIATED VASCULITIS PATIENTS WITH AND WITHOUT ILD: A MACHINE LEARNING APPROACH

E. Conticini[1], M. D'alessandro[2], L. Bergantini[2], D. Castillo[3], P. Falsetti[1], P. Cameli[2], E. Bargagli[2], L. Cantarini[1], B. Frediani[1]on behalf of Siena Vasculitis Study Group. *[1]University of Siena, Rheumatology Unit, Siena, Italy; [2]University of Siena, Respiratory Diseases and Lung Transplantation Unit, Siena, Italy; [3]Hospital de la Santa Creu i Sant Pau, Respiratory Unit, Barcelona, Spain*

Background: ANCA-associated vasculitis (AAV) are small vessel vasculitis which may variously affect upper and lower respiratory tract. Patients with microscopic polyangiitis (MPA) and, less commonly, granulomatosis with polyangiitis (GPA), especially those who are ANCA-MPO-positive, may suffer from interstitial lung disease (ILD), which is associated with high morbidity and mortality as it is often underdiagnosed and responds poorly to conventional treatments

Objectives: In this study, we aimed to assess whether Krebs von den Lungen-6 (KL-6), a marker of fibrotic ILD, may be useful for distinguishing AAV patients with ILD from those without ILD, and whether its changes over time are correlated with disease activity.

Methods: We enrolled all consecutive patients evaluated in the period December 2020 - November 2021. Inclusion criteria were a diagnosis of GPA or MPA, active disease, and eligibility for Rituximab treatment according to EULAR recommendations. All patients underwent concomitant rheumatological and pneumological evaluation, lung function tests, routine blood tests, autoimmunity evaluation and KL-6 assay. Current and previous treatments, Birmingham vasculitis score (BVAS) and vasculitis damage index were also recorded.

Results: A total of 13 patients (Table 1) were enrolled. One was excluded due to a concomitant diagnosis of lung cancer. Higher serum KL-6 were in AAV-ILD compared with those without ILD (972.8±398.5 vs 305.4±93.9, p=0.0040). Area under the Receiver Operating Characteristics curve showed 100% of the diagnostic performance of KL-6 for identifying the ILD involvement (accuracy 91.7%) and the best cutoff value of 368 U/mL (Sensitivity 100% and specificity 87.5%). The decision-tree model showed a 33% improvement in class purity using a cut-off value of 513 U/mL to distinguish AAV patients with and without ILD (Figure 1). Stratifying AAV patients as MPA and GPA with and without ILD considering T0 and T1 KL-6, the model obtained an improvement of 40% for classifying GPA non-ILD with a T0 serum KL-6 cut-off value of 513 U/mL and a T1 KL-6 cut-off of 301 U/mL. A direct correlation was found between serum T0 KL-6 and T0 BVAS (r=0.578, p=0.044).

Table 1. Patients' features

Sex/age	Diagnosis	Length of disease * (months)	Organs involved	Type of lung involvement	T0 KL6 levels	T0 BVAS	T0 VDI	T1 KL6 levels	T1 BVAS	T1 VDI
F/83	MPA	28	Lung, kidney, PNS	ILD, alveolar hemorrhage	625	8	7	325	0	7
M/48	GPA	1	Lung, kidney, nose, eye	Nodules	352	18	0	279	2	0
F/55	GPA	252	Lung, skin	Nodules	401	15	3	602	3	3
F/38	MPA	1	Skin	-	347	6	0	-	-	-
F/74	MPA	180	Kidney, PNS	-	368	11	5	414	0	5

M/71	GPA	24	Lung, eye, joints	Nodules, ILD	1528	9	3	-	-	-
F/64	MPA	24	Lung	ILD	756	4	-	1003	0	-
F/59	GPA	72	Lung	Nodules	338	4	-	-	0	-

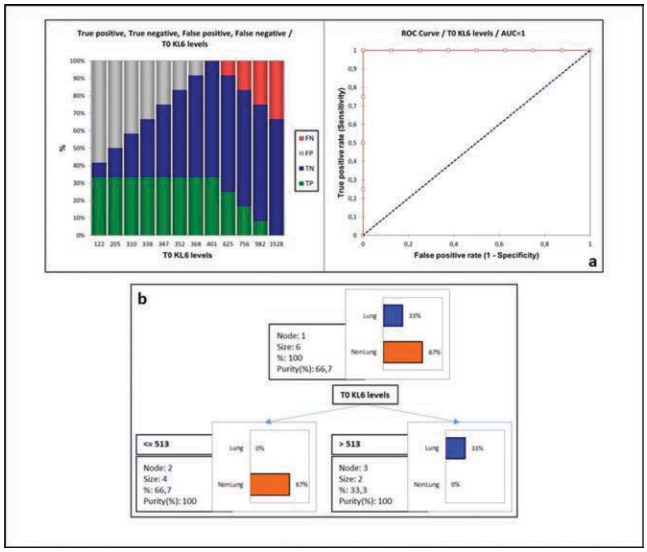

Figure 1. ROC curve and decision tree model

Conclusion: Our multicentre study demonstrated KL-6 as a reliable, non-invasive and easy-to-perform marker of ILD in AAV patients and its helpfulness for disease activity assessment. Changes in serum concentrations of KL-6 over time could be useful for monitoring AAV patients. Further study of KL-6 as a marker of response to therapy during long-term follow-up would also be worthwhile.

POS0824 SAFETY AND EFFICACY OF THE INTENSIFIED B CELL DEPLETION INDUCTION THERAPY FOR PATIENTS WITH ANCA-ASSOCIATED VASCULITIS AND SEVERE RENAL INJURY: A CONTROLLED STUDY

D. Roccatello[1], S. Sciascia[1], S. Murgia[1], G. Quattrocchio[1], M. Ferro[1], E. De Simone[1], C. Naretto[1], A. Barreca[2], D. Rossi[1], R. Fenoglio[1]. *[1]University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases (ERK-net, ERN-Reconnect and RITA-ERN Member) with Nephrology and Dialysis Unit and Center of Immuno-Rheumatology and Rare Diseases (CMID), San Giovanni Bosco Hub Hospital, and Department of Clinical and Biological Sciences of the University of Turin, Torino, Italy; [2]Città Della Salute e Della Scienza, Pathology Division, Torino, Italy*

Background: Rituximab (RTX), an anti-CD20 monoclonal antibody, has shown to be an effective induction treatment for small-vessel vasculitides associated with antineutrophil cytoplasm antibodies (AAV) in both newly diagnosed and relapsing patients. However, the role of RTX in the management of the most severe cases of AAV remains to be fully elucidated.
Objectives: to assess both safety and efficacy of an intensified B-cell depletion therapy (IBCDT) protocol, including RTX, cyclophosphamide (CYC), and methylprednisolone pulses without additional maintenance immunosuppressive therapy compared to conventional therapy regimen based on oral CYC and steroids and prolonged maintenance therapy with azathioprine (AZA) in patients with AAV and severe renal injury.
Methods: A cohort of 15 AAV patients with the most severe features of AVV renal involvement (as <15 ml/min GFR and histological findings of paucimmune necrotizing glomerulonephritis with more than 50% crescents of non-sclerotic glomeruli at the renal biopsy) was treated IBCDT and compared to compared toa control group of 10 patients with AAV treated with a conventional therapy regimen based on oral CYC and steroids and prolonged maintenance therapy with azathioprine (AZA). Independently on the pharmacologic regimen, plasma exchange (7 procedures with 1-1.5 plasma volume replacement) was performed in the presence of 1. alveolar haemorrhage, and 2. more than 50% florid crescents in the nonsclerotic glomeruli, or 3. dialysis dependence.
Results: Complete clinical remission (BVAS 0) was observed at 6 months in 14 of 15 patients (93%). All cases treated with IBCDT who achieved a complete clinical remission experienced a depletion of peripheral blood B cells at the end of therapy. Of the 10 dialysis dependent patients at onset, 6 subjects (60%) experienced a functional recovery allowing the suspension of dialysis treatment. When compared to the control group, no statistically significant difference was observed in patients treated with IBCDT in terms of overall survival, 6-month therapeutic response rate, and 6-, and 12-month functional renal recovery. The cumulative total dose of CYC in the case group was on average 1 g/patient while in the control group on average 8.5 g / patient (p = 0.00008). Plasmapheresis sessions were performed at part of the induction therapy among 13 patients (87%) in the case group and 8 (80%) in the control group.
Conclusion: The results of this study showed that IBCDT appeared to be safe and has the same efficacy profile when compared to conventional therapy with CYC plus AZA in the management of the most severe patients with AAV. Additionally, this avoids the need of prolonged maintenance therapy for long, and limits the exposure to CYC with consequent reduced toxicity and drug-related side effect rates.

POS0825 CLINICAL CHARACTERISTICS AND TREATMENT MANAGEMENT OF NON-INFECTIOUS SCLERITIS WITH CORTICOSTEROID-SPARING THERAPY. A RETROSPECTIVE STUDY FROM A TERTIARY EYE CARE CENTER.

J. Toutain[1], M. A. Gargouri[1], T. Chazal[2], S. Fares[1], I. Cochereau[1], E. Gabison[1], C. Titah[1], G. Clavel Refregiers[2]. *[1]Foundation Adolphe de Rothschild Hospital, Ophthalmology Department, Paris, France; [2]Foundation Adolphe de Rothschild Hospital, Internal Medicine, Paris, France*

Background: Non-infectious scleritis refers to a rare and sight-threatening scleral inflammation. An association with an underlying systemic disease is noted in 30% to 40% of cases. Their management may require the use of nonsteroidal anti-inflammatory drugs, oral corticosteroids, and sometimes steroid-sparing immunosuppressive agents. Because of the low incidence and prevalence of scleritis, treatment guidelines are currently not available.
Objectives: We analyzed in a retrospective observational study patients with scleritis referred to the Foundation Rothschild Hospital (Paris) from March 2011 to June 2021.
Methods: Characteristics, visual outcomes, ocular complications, associations with systemic diseases and efficacy of treatment were assessed in patients with non-infectious scleritis who needed steroid-sparing immunosuppressive agents.
Results: Among 731 patients diagnosed with scleritis, 54 patients (71 eyes, 7%) were treated by steroid-sparing immunosuppressive agents. Mean follow up was 111.9 ± 84.5 weeks. Mean age was 48.4 years ± 18.3, and 31 patients (57%) were female. Scleritis was anterior in 51 eyes (72 %), including 25 (35%) with diffuse scleritis, 24 (34%) with nodular scleritis and 2 (3%) with necrotizing scleritis. Scleritis was posterior in 20 eyes (28%). Bilateral involvement was noted in 17 patients (32 %). Ocular complications were observed in 52 eyes (73 %): scleral thinning in 25 eyes (35%), anterior uveitis in 24 eyes (34 %), loss of vision in 20 eyes (28%), posterior segment ocular complications in 18 eyes (25%), ocular hypertension in 17 eyes (24%) and corneal involvement in 16 eyes (23%). An underlying systemic disease was identified in 28 patients (52 %), and scleritis was the first manifestation of the systemic disease in 17 out of 28 patients. Rheumatoid arthritis was the most frequently identified disease (n=12), followed by granulomatosis with polyangiitis (n=8) and relapsing polychondritis (n=4). All patients received at least

one immunosuppressive agent. Corticosteroid sparing with a daily dose ≤ 5 mg of prednisone was achieved in 85% of patients. Conventional immunosuppressive agents were used as the first steroid-sparing agent in 38 patients (70%) (methotrexate n=33, azathioprine n=4, mycofenolate mofetil (MMF) n=1) and as second steroid-sparing agent in 1 patient (MMF). This treatment led to control scleral inflammation in 23 (59%) patients after a mean delay of 10.0 ± 6.0 weeks. Biologic therapy was used in 33 (61%) patients (TNF alpha inhibitor n=17, IL6-R inhibitor n=7, anti-CD20 n=9), and as the first steroid-sparing agent in 16 (30%) (TNF alpha inhibitor n=4, IL6-R inhibitor n=4, anti-CD20 n=8). This treatment led to control scleral inflammation after a mean delay of 4,9 ± 3,7 weeks in 29 patients (87.9%).

Conclusion: Scleritis is a severe ocular inflammatory disease that requires repeated and thorough ophthalmologic and general examinations given the high frequency of complications and the possibility of an underlying systemic disease. This study reports real-life experience in management of non-infectious scleritis. Biological therapies seemed to be associated with a better outcome and a quicker reponse than conventional immunosuppressive agents. Further studies are warranted to develop specific guidelines

POS0826 CIRCULAR RNA EXPRESSION PROFILES AND IDENTIFICATION OF HSA_CIRC_0028381 AS A POTENTIAL BIOMARKER OF ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Y. Liu[1], L. Jiang[1], X. Zhang[1]. *[1]Zhongshan Hospital, Fudan University, Rheumatology, Shanghai, China*

Background: Growing evidence indicated that dysregulated circRNAs play a vital role in autoimmune diseases. However, their role in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) has never been illustrated.

Objectives: This study aims to determine the expression profiles of circRNA in plasma of AAV patients and explore the potential of circRNA as biomarker of AAV.

Methods: RNA-sequencing (RNA-seq) was performed to identify the circRNAs and mRNAs expression profiles in plasma from 5 AAV patients and 5 healthy controls (HCs). Hsa_circ_0028381, one of the four candidate circRNAs were validated by quantitative reverse-transcription (qRT)-PCR in a validation cohort of 51 AAV patients and 30 HCs and was confirmed to be significantly upregulated. And it was further verified in other connective tissue diseases (CTDs) by qRT-PCR. The receiver operating characteristic (ROC) curve analysis was performed to assess the diagnostic value.

Results: RNA expression profiles revealed that 143 circRNAs and 304 mRNAs were aberrantly expressed, among which, 62 circRNAs were upregulated and 81 circRNAs were downregulated in AAV patients compared to HCs. The result of qRT-PCR verification suggested that hsa_circ_0028381 was significantly increased in plasma from AAV patients compared to that in HCs and CTDs. The receiver operating characteristic (ROC) curves analysis showed has_circ_0028381 had a good diagnostic value to distinguish AAV patients from controls (HCs and other CTDs) with area under the curve (AUC) of 0.81. In addition, has_circ_0028381 was associated with renal involvement. Most importantly, increased baseline level of has_circ_0028381 had a predictive value for renal progression to end-stage renal disease (ESRD).

Conclusion: RNA-seq revealed that circRNAs were aberrantly expressed in plasma of AAV patients. Has_circ_0028381 might function as a potential biomarker for AAV diagnosis and renal prognosis.

POS0827 VASCULITIDES AS MEDICATION-INDUCED ADVERSE EVENTS BASED ON A NATIONAL DATABASE REPORTING SYSTEM

A. Rodriguez-Pla[1]. *[1]Mayo Clinic, Rheumatology, Scottsdale, United States of America*

Background: Vasculitides have been reported as adverse events (AEs) related to a wide variety of medications.

Objectives: For the present study, we aimed to analyze the vasculitides reported to a national AEs spontaneous reporting system from October 2012 through September 2021.

Methods: All spontaneous reports of vasculitis related to any medications from October 1st, 2012, to September 30th, 2021, were retrieved from the Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) database. We performed a descriptive analysis of demographics, medications, and type of vasculitis based on 25 Medical Dictionary for Regulatory Activities (MedDRA) preferred term (PT) codes. Medications identified as the primary suspect in individual case safety reports (ICSRs) were retrieved by their product active ingredient. RStudio v1.4.1717 was used for general data analysis and the R package openEBGM v0.8.3 was used for the calculation of the Empirical Bayes Geometric Mean (EBGM) as the disproportionality score with its 90% two-sided credibility interval, frequently used in safety signal detection models. Drug-event combinations with an EBGM 5% lower limit credibility interval ≥ 2 were considered significant. An EBGM score of 2 indicates that the drug had at least 2 times as many reports for the AE as expected.

Results: During the study period, we retrieved 10,404 ICSRs reporting 10,931 AEs of vasculitis associated with a medicinal product as the primary suspect for that AE. The patient's mean age was 56.5 years, and 61% of them were female. Of the 25 PTs selected, the generic term "Vasculitis" was the most frequently reported AE (29.1%), followed by "Hypersensitivity vasculitis" (14.9%), "Polymyalgia rheumatica" (7.7%), "Anti-neutrophil cytoplasmic antibody-positive vasculitis" (ANCA-associated vasculitis) (6.2%), and "Cutaneous vasculitis" (5.4%). Of the total ICSRs with vasculitis AEs, 90% were expedited because they reported serious, unexpected AEs. Eighty drug-event combinations were disproportionately reported. Of those, the strongest association was observed for alemtuzumab and Goodpasture's syndrome (anti-glomerular basement membrane disease), followed by minocycline and polyarteritis nodosa, palivizumab and Kawasaki's disease (KD), then ribavirin and cryoglobulinemia, ezetimibe and microscopic polyangiitis, and so on. Some medications were associated with more than one AE, such as infliximab with Takayasu's arteritis (TAK), Behcet's syndrome (BS) and Henoch-Schönlein purpura (IgA vasculitis); adalimumab with BS and TAK; hydralazine with ANCA-associated vasculitis and renal vasculitis; and rituximab with granulomatosis with polyangiitis (GPA) and cryoglobulinemia.

Conclusion: Many different vasculitides were reported as AEs in the national database. Some of the medications were associated with the diseases they treat, which raises concern for possible confounding by indication. In other cases, the events were already known as adverse reactions, as for example alemtuzumab and Goodpasture's syndrome or montelukast and eosinophilic granulomatosis with polyangiitis. In other cases, no label or publication references were found, as for palivizumab and KD. These latter cases may raise a concern for potential safety signals that should be investigated. The improved understanding of the mechanism of action of drugs associated with some of these AEs may help to elucidate the pathogenesis of vasculitides.

Background: Ocular and Neurobehçet's Disease (NBD) are the most severe manifestations of Behcet's disease **(1-4)**. NBD can be classified as **a)** primary neural parenchymal lesions, also known as parenchymal NBD (p-NBD) or **b)** secondary to vascular involvement or non-parenchymal NBD (np-NBD) **(4)**. Response to biologic therapy (BT) in these two refractory subtypes of NBD is unknown.
Objectives: To assess efficacy and safety of BT in refractory subtypes of NBD.
Methods: Open-label multicenter study of refractory NBD from 21 different referral National Hospitals. NBD diagnosis was based on the International Consensus Recommendation criteria **(4)**. Efficacy was determined by complete or partial response and no-response. Complete, partial or no response was defined according to the resolution of the neurological syndrome (signs and/or symptoms) after the BT onset.
Results: We studied 41 patients (21 women/20 men; mean age: 40.6±10.8 years). NBD was classified as p-NBD (n= 33, 80.5%) and np-NBD (n=17, 41.5%). There were no significant differences in baseline general features and in neurological clinical response in both subgroups (Table 1 and Figure 1). The first BT used in p-NBD were Infliximab (IFX) (n=15), Adalimumab (ADA) (n=11), Golimumab (GLM) (n=3), Tocilizumab (TCZ) (n=2) and Etanercept (ETN) (n=2) and in np-NBD were IFX (n=9), ADA (n=6), TCZ (n=1) and ETN (n=1).

Table 1. Main features of p-NBD and np-NBD

	Total	p-NBD	np-NBD	*P* p-NBD vs np-NBD
Age at biological therapy initiation, years (mean±SD)	44±13.9	41.4±9.6	39.4±10.6	0.412
Gender, n (m/f) (%)	21/20 (48.8/52.2)	18/15 (54.5/45.5)	5/12 (29.4/70.6)	0.091
HLAB51 +/ patients tested, n (%)	15/31 (57.7)	14/25 (58.3)	4/10 (40)	0.391
Oral aphthae, n (%)	40 (97.6)	32 (97)	15 (88.2)	0.323
Cutaneous involvement, n (%)	28 (63.4)	23 (69.7)	10 (58.8)	0.603
Ocular involvement, n (%)	21 (48.8)	15 (45.5)	9 (52.9)	0.616
Vascular involvement, n (%)	9 (22)	10 (30.3)	7 (41.2)	0.442
Articular involvement, n (%)	9 (22)	7 (21.2)	3 (17.6)	0.765
Previous conventional Immunosuppressive drugs to BT				
Azathioprine	24 (58.5)	20 (60.6)	10 (58.8)	-
Methotrexate	16 (39.0)	12 (36.4)	3 (17.6)	-
Cyclophosphamide	13 (31.7)	13 (39.4)	5 (29.4)	-
Cyclosporine A	9 (22.0)	8 (24.2)	3 (17.6)	-
Mycophenolate Mofetil	2 (4.9)	2 (6.1)	0	-

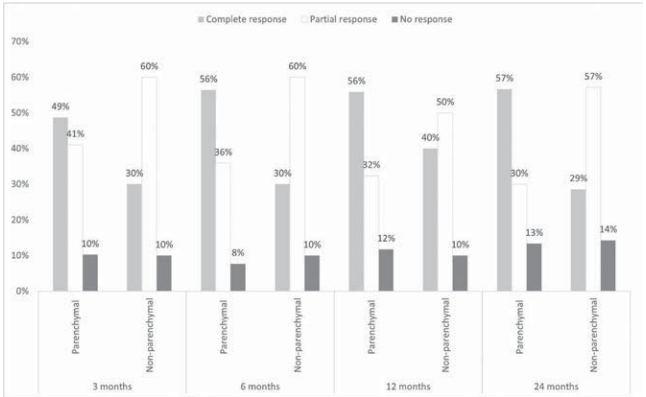

Figure 1. Response to biological therapy according to NBD subtypes.

After an overall mean follow-up of 57.5±50.9 months BT was switched in 22 patients due to inefficacy (n=16) or Adverse Effects (AE) (n=6) and in 4 cases was definitively discontinued because of complete prolonged remission (n=3) or AE (n=1). AE were observed in 7 (17.1%) patients. Severe AE were observed in 2 cases, one due to demyelinating disease and the other due to pulmonary tuberculosis, both in patients undergoing IFX therapy. The other 6 AE were infusion reaction to IFX (n=1), IFX-induced psoriasis (n=1), IFX-induced acneiform eruption (n=1), infusion reaction to TCZ (n=1), intolerance to IFX and recurrent mild infections (n=1) and erosive lichen planus and bullous impetigo (n=1).
Conclusion: In our series, BT seems equally effective and safe in both refractory p-NBD and np-NBD.

POS0829

SPECTRUM OF ANCA-SPECIFICITIES IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS IN A RETROSPECTIVE MULTICENTER STUDY

S. Arnold[1], J. Mahrhold[2], A. Kerstein-Staehle[1], E. Csernok[2], B. Hellmich[2], N. Venhoff[3], J. Thiel[3,4], K. Affeldt[5], A. Jahnke[5], G. Riemekasten[1], P. Lamprecht[1].
[1]University of Lübeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany; [2]Vasculitis Centre South, Medius KLINIK Kirchheim, Department of Internal Medicine, Rheumatology and Immunology, Kirchheim unter Teck, Germany; [3]Medical Center, University of Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; [4]Medical University Graz, Division of Rheumatology and Clinical Immunology, Department of Internal Medicine, Graz, Austria; [5]Institute of Experimental Immunology, Affiliated to Euroimmun AG, Lübeck, Germany

Background: Anti-neutrophil cytoplasmic autoantibodies specific for myeloperoxidase (MPO-ANCA) are found in 10-70% of the patients with eosinophilic granulomatosis with polyangiitis (EGPA) depending on disease activity, methodological aspects and cohort examined [1-3]. Recently, a higher prevalence of anti-pentraxin 3 (PTX3)-ANCA has been reported in EGPA compared to granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) [4].
Objectives: To investigate the spectrum of ANCA specificities in a multicenter cohort of patients with EGPA and identify novel ANCA antigens.
Methods: We conducted a retrospective analysis of 73 patients with EGPA treated between 2015 and 2020 in 3 tertiary referral centers. In addition to in-house ANCA testing with indirect immunofluorescence (IFT) on fixed human granulocytes and antigen-specific enzyme-linked immunosorbent assays (ELISA), ANCA specificities were determined using a cell-based assay (CBA; Euroimmun, Lübeck, Germany). Diagnosis was based on Chapel Hill consensus conference definitions, ACR- and MIRRA-criteria for EGPA. Patient characteristics and clinical manifestations were evaluated and compared based on ANCA status. Fisher`s exact test was employed for comparison of patient groups.
Results: ANCA findings are summarized in Table 1. MPO- and proteinase 3 (PR3)-ANCA positive patients (13.7%) had a higher prevalence of peripheral neuropathy (70% *vs.* 44.4%, p = 0.0003) and glomerulonephritis (20% *vs.* 14.3%, not significant). MPO- and PR3-ANCA-negative patients (86.3%) had a higher prevalence of heart (10% *vs.* 46%, p <0.0001), central nervous system (CNS) (0% *vs.* 14.3%, p <0.0001) and gastrointestinal (10% *vs.* 22.2%, p = 0.0327) involvement. PTX3-ANCA were associated with a higher prevalence of ear-nose-throat (ENT) (100% *vs.* 85.3%, p <0.0001), lung (100% *vs.* 89.7%, p = 0.0015), gastrointestinal involvement (60% *vs.* 17.6%, p <0.0001) and peripheral neuropathy (100% *vs.* 48.5%, p <0.0001). Kidney (0% *vs.* 16.2%, p <0.0001) and CNS involvement (0% *vs.* 13.2%, p = 0.0002) occurred less frequently in PTX3-ANCA positive patients. The 2 olfactomedin 4 (OLM4)-ANCA positive patients presented with ENT, lung and kidney involvement, and polyneuropathy, respectively.

Table 1. ANCA in EGPA cohort (n = 73). BPI = bactericidal permeability-increasing protein.

IFT / ELISA	No. of patients (%)
P-ANCA	11 (15.1)
C-ANCA	5 (6.8)
MPO-ANCA	8 (10.9)
PR3-ANCA	2 (2.7)
BPI-ANCA	1 (1.4)
PTX3-ANCA	5 (6.8)
OLM4-ANCA	2 (2.7)

Conclusion: We report on the detection of PTX3-, BPI- and OLM4-ANCA in addition to MPO- and PR3-ANCA in EGPA. OLM4-ANCA has been reported in 2 patients with non-vasculitic inflammatory symptoms previously [5]. Herein, detection of OLM4-ANCA in EGPA is reported for the first time. Our study shows that the presence of ANCA with various specificities other than MPO and PR3 contribute to a higher prevalence of ANCA in EGPA. Moreover, clinical manifestations differ between ANCA-negative EGPA and ANCA-positive EGPA, and between patients with different ANCA-specificities.

POS0830 SYSTEMATIC LITERATURE REVIEW INFORMING THE 2022 UPDATE OF THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF ANCA-ASSOCIATED VASCULITIS: FOCUS ON TREATMENT STRATEGIES

J. Schirmer[1], B. Sanchez-Alamo[2], S. Monti[3], B. Hellmich[4], D. Jayne[5]. *[1]University Medical Center Schleswig-Holstein, Clinic for Internal Medicine I, Section for Rheumatology, Kiel, Germany; [2]Lund University, Skåne University Hospital, Nephrology, Lund, Sweden; [3]University of Pavia, Fondazione IRCCS Policlinico S. Matteo, Rheumatology, Pavia, Italy; [4]University of Tübingen, Medius Kliniken, Internal Medicine, Rheumatology and Immunology, Kirchheim-Teck, Germany; [5]University of Cambridge, Addenbrooke's Hospital, Department of Medicine, Cambridge, United Kingdom*

Background: The 2008 and 2016 European Alliance of Associations for Rheumatology (EULAR) recommendations for the management of ANCA-associated vasculitis (AAV)[1,2] have supported clinicians with comprehensive recommendations for the treatment of patients with AAV in daily practice. During the past 5 years, the publication of several high-impact randomized-controlled studies have further improved the standard of care of AAV.

Objectives: The aim of this systematic review was to collect evidence supporting the 2022 update the AAV management recommendations.

Methods: The recommendations were developed based on an evidence-based approach as outlined in the 2014 EULAR standardized operating procedures (SOP)[3]. Areas of interest were adopted from the 2016 recommendations and updated by identifying additional topics through a Delphi process. Key questions were framed in the PICO (Population, Intervention, Comparator, Outcome) format and a search strategy consisting of keywords identifying treatment-related topics of interest was created based on the PICO questions. Aspects of drug treatment and other therapeutic interventions in AAV were included in the search, with a focus on remission induction, maintenance treatment and steroid sparing protocols. Outcomes such as survival, remission/relapses, infectious complications and malignancies were also covered. PubMed (Medline), Embase and the Cochrane Library databases were searched for articles providing data on the search questions. Abstracts of the annual meetings of EULAR, ACR, ERA-EDTA, ASN and the Vasculitis and ANCA Workshops were also screened, but restricted to randomized controlled clinical trials (RCTs). After deduplication publications were sorted by title and abstract first. There was full text review for articles eligible after title/abstract screening. The data were extracted from included articles and grouped according to the PICO questions. Data extraction results were collected in evidence tables.

The Cochrane revised tool for assessing risk of bias for RCTs (RoB2), ROBINS-1 for observational studies and AMSTAR II for meta-analyses were used for bias assessment. Evidence was categorized based on the GRADE system as per EULAR SOP[3].

Results: Based on the results of the Delphi, 11 topics related to therapeutic interventions were identified that were transformed into PICO questions (Table 1). Other items that received lower scores were added in the format of subquestions. Based on these research questions, search strings for the SLR were created.

Table 1. Key topics of interest for treatment strategies identified in the Delphi exercise grouped according to the PICO format

Patients	Intervention & Comparators	Outcome
Diagnosis	Cyclophosphamide	Disease-related outcomes
Granulomatosis with Polyangiitis	Rituximab	Treatment-related adverse events
Microscopic Polyangiitis	Mycophenolate	
Eosinophilic Granulomatosis with Polyangiitis	Methotrexate	
Disease severity	Azathioprine	
New-onset disease	Glucocorticoids	
Relapsing disease	Avacopan	
Organ- or life-threatening disease	Mepolizumab	
Not organ- or life-threatening disease	Plasma exchange	

The SLR was still ongoing at the time this abstract has been written and results of the SLR will be presented at the meeting.

Conclusion: This SLR identified recent developments affecting key areas of AAV treatment, that provide systematic evidence to inform the 2022 update of the EULAR recommendations for the management of AAV, which will also be presented at this meeting.

POS0831 IGA VASCULITIS IN ADULTS, PEDIATRICS AND NON-VASCULITIC IGA NEPHROPATHY

S. Levanon[1], V. Gotlieb[2], Y. Kraus[3], I. Novofastovski[1], S. Brikman[1], A. Fawaz[1], M. Aghbariyya[1], Y. Butbul[4], A. Balbir-Gurman[5], R. Mader[1], A. Bieber[1]. *[1]Emek Medical Center, Rheumatology, Afula, Israel; [2]Emek Medical Center, Pediatric Rheumatology Service, Afula, Israel; [3]Emek Medical Center, Pathology, Afula, Israel; [4]The Ruth Rappaport Children's Hospital, Pediatric Rheumatology Service, Haifa, Israel; [5]Rambam Health Care Campus, Rheumatology, Haifa, Israel*

Background: IgA vasculitis (IgAV) has been extensively studied in children, while its natural history remains poorly studied in adults. Sparse data comparing childhood and adult-onset disease has shown significant differences in their clinical presentation, especially in the severity of renal involvement, which accounts for the major long-term morbidity. IgAV shares similar renal histologic features with IgA nephropathy (IgAN), while clinically IgAN is a chronic kidney disease which may lead to end stage renal disease and dialysis. The extent of kidney injury among adults with IgAV is still a matter of uncertainty.

Objectives: We aimed to evaluate clinical manifestations, laboratory data, treatment patterns and long-term outcomes of pediatric and adult-onset IgAV in comparison to IgAN.

Methods: This retrospective collaborative study examined medical records of adults and children with IgAV and IgAN adult patients admitted to rheumatology clinic and in hospital pediatric departments in a 13-year period (2007-2019). Diagnosis of adults with IgAV relied on the Ankara criteria and was confirmed by a consistent skin biopsy with positive IgA staining by immunofluorescence. Children with IgAV were included in our study on a clinical basis. All IgAN patients had a kidney biopsy proven disease. We analyzed and compared frequencies of clinical manifestations, laboratory findings, treatment regimens and long-term outcomes at one year follow-up. Finally, we assessed long term outcomes, such as time to dialysis and all-cause mortality, till the end of the follow-up time.

Results: A total of 60 adult IgAV, 60 pediatric IgAV and 45 IgAN patients were included in our study. There were significantly more males in the IgAN group compared to the adult and pediatric IgAV groups (77.8%, 41.7% and 55% respectively, p=0.01). Adult IgAV patients were significantly older than IgAN patients (53.1±17.4 years vs. 45.1±15.7 years, p=0.02) and had significantly higher rates of diabetes (43.3% vs. 24.4%, p=0.05) and ischemic heart disease (18.3% vs. 4.4%, p=0.03). The pediatric IgAV group had a statistically higher rate of previous infection compared to the adult IgAV group (44.8% vs. 20%, p=0.02). At one year follow-up, IgAN patients had higher levels of serum creatinine compared to the adult IgAV group (2.002 vs. 1.100, p<0.01). Data observed until the end of the follow-up time showed no difference in time to dialysis (IgAV adults: 9.8-12.4 years, IgAN: 5.0-6.6 years, p>.41). Nevertheless, IgAV adult patients had significantly shorter survival time (5.5 years, 95% CI: 4.8-6.2 years) than IgAN patients (7.0 years, 95% CI: 6.6-7.5 years, p<.01).

Conclusion: This retrospective study demonstrates that IgAV in adults presents substantial clinical manifestations, including high risk of progression to persistent renal impairment and possesses higher mortality rate in comparison with pediatric-onset disease and IgAN.

POS0832 MORTALITY TRENDS IN ANCA-ASSOCIATED VASCULITIDES (AAVS): DATA FROM A CONTEMPORARY, MULTICENTER ANCA REGISTRY

C. Koutsianas[1], A. Panagiotopoulos[1], K. Thomas[2], A. Chalkia[3], A. Lazarini[4], N. Kapsala[2], S. Flouda[2], E. Argyriou[5], K. Boki[5], D. Petras[3], D. Boumpas[2], D. Vassilopoulos[1]. *[1]2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, School of Medicine, Hippokration General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; [2]4th Department of Medicine, National and Kapodistrian University of Athens, School of Medicine, Attikon General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; [3]Hippocration General Hospital, Nephrology Department, Athens, Greece; [4]Asclepeion General Hospital, Rheumatology Department, Athens, Greece; [5]Sismanogleio General Hospital, Rheumatology Department, Athens, Greece*

Background: AAVs are a group of rheumatic diseases with excess morbidity and mortality (~3-fold higher compared to the general population). Long-term studies looking at mortality trends in contemporary patient cohorts are limited.

Objectives: To investigate the overall long-term survival and all-cause mortality in a contemporary AAV patient cohort.

Methods: Multicenter cohort study of patients registered and prospectively followed in the Greek ANCA Registry.

Results: Data for 165 patients (989.38 patient-years of follow up) with a diagnosis of AAV (GPA n=95, 58%, MPA n=54, 33%, EGPA n=16, 9%) were analyzed (January 1, 1998 - January 10, 2022). 53% of patients were female, with a mean age of 65 (±16.4) years; the majority (97%) had generalized disease and were ANCA positive (76%). The mean follow-up since diagnosis was 5.9 (±5.1) years. At the end of follow-up, the overall mortality rate was 20% (33/165), whereas the cumulative mortality rates at 5 and 10 years were 24% and 26% respectively. Overall cumulative survival at 5 years was worse in patients with MPA (57%) compared to GPA (81%) and EGPA (92%), (p<0.001). There was no difference in long-term survival among those treated with different induction regimens including cyclophosphamide (CYC, n of deaths=24/83, 28.9%), rituximab (RTX, n=4/40, 10%) or the CYC+RTX combination (n=3/16, 18.7%). Furthermore, there was no difference in survival between relapsing (≥1 relapses) and non-relapsing (n=76) patients (Figure 1). Cumulative survival was worse in patients who initially presented with lung (66% *vs.* 90% at 5 years, p=0.007), kidney (56% *vs.* 96% at 5 years, p<0.001) and simultaneous lung and kidney (39% *vs.* 93% at 5 years, p<0.001) involvement. Among the 33 registered deaths, the most frequent causes were infections (52%), followed by cardiovascular events (24%), disease flares (14%) and malignancies (10%).

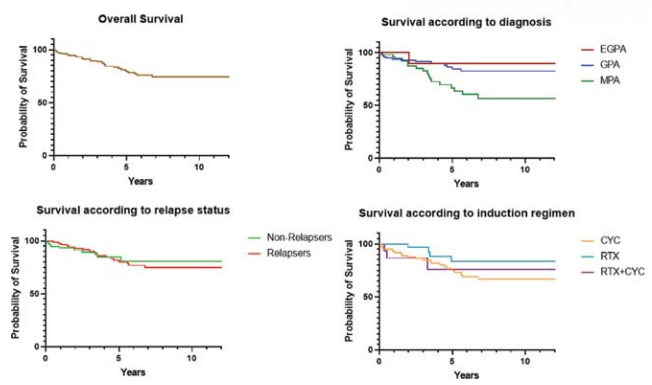

Figure 1.

Conclusion: In a contemporary multi-center AAV cohort, the cumulative mortality rates at 5 and 10 years were 24% and 26% respectively. Overall survival was worse in patients with MPA as well as those with combined lung and kidney involvement at baseline while there were no survival differences according to the initial induction regimen. Infection was the most common cause of death. These findings emphasize the unmet needs for better, less toxic therapies.

POS0833 DIFFERENCES BETWEEN AVACOPAN AND PREDNISONE FOR THE TREATMENT OF ANCA-ASSOCIATED VASCULITIS AT DIFFERENT THRESHOLDS OF GLUCOCORTICOID TOXICITY

N. Patel[1], Y. Zhang2, D. Jayne[3], P. A. Merkel[4], H. Yue[5], P. Bekker[6], J. H. Stone2. *[1]Massachusetts General Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America; [1]Massachusetts General Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America; [3]University of Cambridge, Department of Medicine, Cambridge, United Kingdom; [4]University of Pennsylvania, Division of Rheumatology, Philadelphia, United States of America; [5]Chemocentryx, Clinical Development, San Carlos, United States of America; [6]Chemocentryx, Department of Medical and Clinical Affairs, San Carlos, United States of America*

Background: Treatment with glucocorticoids (GCs) for ANCA-associated vasculitis (AAV) is associated with substantial toxicity. The Glucocorticoid Toxicity Index (GTI) was developed to measure change in GC toxicity over time.[1] Data from the composite GTI domains provide both an Aggregate Improvement Score (AIS) and a Cumulative Worsening Score (CWS) of GC toxicity, permitting the

instrument to compare both improvement and worsening of GC toxicity across treatment groups. The GTI was a pre-specified secondary outcome in ADVOCATE, a randomized, double-blind, placebo-controlled trial in patients with AAV that aimed to replace a GC taper with avacopan, a complement C5a receptor inhibitor. Patients were randomized to either avacopan or a prednisone taper on a background of either cyclophosphamide or rituximab.[2] In ADVOCATE, the median GC exposure was 400 mg vs. 2939 mg in the avacopan and prednisone groups, respectively, which is an 86% median reduction in GC exposure from all sources. Remission rates were comparable in the two groups at 26 weeks (72.3% vs. 70.1%, respectively), and avacopan was superior at 52 weeks (sustained remission in 65.7% vs. 54.9%).[2]

Objectives: To compare GC toxicity between the treatment groups at three different thresholds of GC toxicity, beginning with the minimum detectable difference (MDD) of the GTI.

Methods: The MDD for the GTI (10 points) was calculated in the initial validation phase of the instrument. Thus, any GTI score > 10 points may be considered to represent a true change in GC toxicity. We compared the two groups at GTI thresholds of 10, 20, and 30 points for both the CWS and AIS. The CWS comprises a total of all GC-related toxicities that have occurred in the GTI between baseline and 26 weeks (time of primary outcome). The AIS, in contrast, allows toxicities to be added if they are new or subtracted if they improve. Higher CWS and AIS values indicate greater severity of GC toxicity. The two scores together capture the nuances of longitudinal GC toxicity across multiple domains. We compared the percentages of those in the two treatment groups who exceeded GTI threshold values of 10, 20, and 30 points in the CWS or AIS.

Results: The percentages of patients exceeding the specified AIS thresholds differentiated the avacopan group from the prednisone group (48.2% vs. 60.4%, respectively, at the 10-point threshold, p=0.02; 29.5% vs. 45.1% at the 20-point threshold, p=0.003; and 18.1% vs. 33.5% at the 30-point threshold, p=0.001) (Table 1). The CWS differentiated avacopan from prednisone at the 20- and 30-point thresholds (57.8% vs 73.2%, respectively, at 20 points, p=0.002; 41.0% vs 55.5% at 30 points, p=0.007).

Table 1. Percentages of Patients in ADVOCATE Exceeding Selected GTI Thresholds at Week 26

GTI threshold/study group	n (%) exceeding CWS threshold	p-value	n (%) exceeding AIS threshold	p-value
GTI worsening > 10 points				
Avacopan (N = 164)	138 (83.1%)	0.147	80 (48.2%)	0.022
Prednisone (N = 166)	144 (87.8%)		99 (60.4%)	
GTI worsening > 20 points				
Avacopan (N = 164)	96 (57.8%)	0.002	49 (29.5%)	0.003
Prednisone (N = 166)	120 (73.2%)		74 (45.1%)	
GTI worsening > 30 points				
Avacopan (N = 164)	68 (41.0%)	0.007	30 (18.1%)	0.001
Prednisone (N = 166)	91 (55.5%)		55 (33.5%)	

AIS, Aggregate Improvement Score; CWS, Cumulative Worsening Score; GTI, Glucocorticoid Toxicity Index

Conclusion: Among patients with AAV, treatment with avacopan was associated with lower GC toxicity across multiple GTI thresholds compared to treatment with prednisone, consistent with the substantial reduction in total GC exposure associated with avacopan. The GTI scores differentiated the two treatment groups effectively through a composite of GC toxicity domains.

POS0834 COMPARISON OF NOVEL INFLAMMATORY MARKERS IN IDIOPATHIC AND SECONDARY LEUKOCYTOCLASTIC VASCULITIS

O. Dhrif[1], M. S. Hamdi[1], I. Kechaou[1], I. Boukhris[1], E. Cherif[1], S. Azzabi[1], L. Ben Hassine[1]. [1]*Charles Nicolle's Hospital, Internal Medicine, Tunis, Tunisia*

Background: Positive diagnosis of Leukocytoclastic vasculitis (LV) is easy to establish via cutaneous biopsy, while etiologic diagnosis can be quiet challenging which leads to a still concerning high rate of idiopathic LV (ILV). Novel inflammatory Ratios such as platelet to lymphocyte ratio (PLR), neutrophil to lymphocyte ratio (NLR), C-reactive protein (CRP) to albumin ratio (CAR) and Fibrinogen to albumin ratio (FAR) have been recently described in multiple inflammatory pathologies, but their description and role in distinguishing idiopathic and secondary LV (SLV) is yet to be explored.

Objectives: We conducted a study aiming to compare new inflammatory markers and their potential role in distinguishing both LV subtypes.

Methods: Cross sectional study in which LV diagnosis was retained on cutaneous biopsy examination from January 2001 to November 2020. Patient's clinical assessment and laboratory data measured for each patient included age and sex, aspect and extent of the LV cutaneous lesions, neutrophil (N) count, lymphocyte (L) count, platelet (PLT) count, CRP, albumin (ALB), gammaglobulin (GG). PLR, NLR, CAR and FAR were calculated according to the results of individual items. We have also defined the number of positive aetiological examination (NPE) as the sum in a unique patient of the positive para clinical examinations involved in the etiological assessment of LV. Categorical variables were compared with the $\chi 2$ -test. Comparisons of the differences of continuous variables were performed by the Mann–Whitney U test or Student's t-test. Pearson correlation ratio was used for linear correlation analysis.

Results: A total of 77 patients were included in this study with 52 patients in the SLV group and 25 patients in the ILV group, demographic and clinical characteristics of both groups were distributed respectively as followed: mean age at diagnosis was 44+/-18 vs 49+/-21, gender ratio was at 29/23 vs 11/14, petechial aspect (89% vs 92%), ecchymotic aspect (64% vs 52%), necrotic aspect (46% vs 28%), extent to the trunk (31% vs 46%) and extend to upper limbs (50% vs 55%), none of these differences were statistically significant (p>0.05). Aetiologies of SLV were distributed as followed: IGA vasculitis 16 cases, Sjogren's syndrome 6 cases, Systemic lupus erythematous and cryoglobulinemia 5 cases each, Viral hepatitis and infectious endocarditis 3 cases each, rheumatoid arthritis, granulomotosis with polyangeitis, post streptococcal and chlamydia infection 2 cases each, Castleman's disease, tuberculosis, lymphoma, primary APS, periarteritis nodosa and parvovirus B19 infection 1 case each. Comparison of PLR, NLR, CAR and FAR showed statistically significant difference in means between SLV and ILV groups with 199 (177-309) vs 127 (79-193) (p=0.01) for PLR, 3.6 (1.9-5.1) vs 2.3 (1.7-3.4) (p=0.048) for NLR, 1.9mg.g-1 (0.4-3.6) vs 0.6mg.g-1 (0.2-1.9) (p=0.043) for CAR, 156mg.g-1 (91-192) vs 108mg.g-1 (82-148) (p=0.034) for FAR. PLR, CAR and FAR were significantly positively correlated to NPE (r=0.463, P<0.001; r=0.434, P<0.001 and r=0.411, P<0.001 respectively), there was no significant correlation between NLR and NPE (r=0.165, P=0.151).

Conclusion: In conclusion, this is the first study to explore the role of PLR, NLR, CAR and FAR in LV, it demonstrates that elevation of these ratios is a good predictor of SLV and that PLR, CAR and FAR were correlated with NPE in LV, which leads us to suggest to exhaustively explore patients with elevated ratios in order to make sure not to miss any underlying aetiology and provide more specific management for LV patients.

POS0835 RELAPSE RATES IN NEWLY DIAGNOSED AND ESTABLISHED PATIENTS WITH ANTI-NEUTROPHIL CYTOPLASMIC AUTOANTIBODY (ANCA)-ASSOCIATED VASCULITIS

K. Fitch[1], C. Bazell[1], S. Metz[1], I. Von Hennigs[2]. [1]*Milliman, Inc., Healthcare, New York, United States of America;* [2]*ChemoCentryx, Medical Affairs, San Carlos, United States of America*

Background: Anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis is a life- or organ-threatening condition in which patients experience severe inflammation of small- to medium-sized blood vessels. Clinical relapses are common in ANCA-associated vasculitis and previously reported rates vary between 21-89% at 5 years depending on the regimens used for induction and maintenance (1). Relapses require repeated treatment with immunosuppressive therapy and increase the risks of adverse events.

Objectives: Identify the incidence of relapse in newly diagnosed and established granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) patients in commercially insured and Medicare fee-for-service (FFS) populations.

Methods: Using the 2016-2019 Milliman proprietary commercial claims data and Medicare 100% FFS Innovator Research data, newly diagnosed and established GPA and MPA patients were identified in index years 2017 and 2018. Newly diagnosed

patients were identified as those with at least two qualifying claims on different dates of service, coded with a GPA or MPA ICD-10-CM code, and no claim coded with GPA or MPA in the 12 months prior to their first claim. Established patients required 12-months continuous enrollment in the year of their established status and 12-months continuous enrollment in the year prior to their established status. Relapses for incident patients were identified during the 7 to 12 months after the index date for newly diagnosed patients to avoid mischaracterizing claims around the time of the initial diagnosis as relapses and over a 12-month period for the established patients. Relapse was defined based on specific inpatient and outpatient claims with a GPA or MPA diagnosis code or claims coded with one major or at least three minor vasculitis signs or symptoms followed by a claim within 30 days for plasmapheresis or cyclophosphamide or glucocorticoids (> 20 mg prednisolone equivalent) or 2+ rituximab claims within 30 days of each other. Relapse had to occur 30 days after the previous event and 6 months after index date for incident patients.

Results: 542 (GPA) and 83 (MPA) commercially insured newly diagnosed patients with 12 months eligibility following their index date and 1,748 (GPA) and 184 (MPA) commercially insured established patients were identified. 15.5% (GPA) and 15.7% (MPA) newly diagnosed patients relapsed during months 7-12 after diagnosis and 27.9% (GPA) and 29.3% (MPA) established patients relapsed over a 12-month period. 2,397 (GPA) and 655 (MPA) Medicare FFS newly diagnosed patients with 12 months of eligibility following their index date and 5,955 (GPA) and 833 (MPA) Medicare FFS established patients were identified. 19.3% (GPA) and 27.2% (MPA) newly diagnosed patients relapsed during months 7-12 after diagnosis and 33.5% (GPA) and 40.2% (MPA) established patients relapsed over a 12-month period.

Conclusion: Using administrative healthcare claims, we observed relapse rates after GPA and MPA diagnosis ranging between 15.5-27.2% in months 7-12 after diagnosis for newly diagnosed patients and between 27.9-40.2% over a 12-month period for established patients. There is an unmet need for new therapies that sustain remission and decrease relapse rates in patients with ANCA-associated vasculitis. This is an important clinical strategy to reduce the risks of adverse events from long-term immunosuppression therapy and decrease end-organ damage.

POS0836 EFFICACY OF MEPOLIZUMAB IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS AND A VASCULITIC PHENOTYPE

B. Terrier[1], D. Jayne[2], B. Hellmich[3], J. H. Bentley[4], J. Steinfeld[5], S. W. Yancey[6], N. Kwon[7], P. Akuthota[8], P. Khoury[9], L. Baylis[10], M. Wechsler[11]. *[1]Hôpital Cochin, Service de Médecine Interne, Paris, France; [2]University of Cambridge, Department of Medicine, Cambridge, United Kingdom; [3]Universität Tübingen, Medius Kliniken, Klinik für Innere Medizin, Rheumatologie & Immunologie, Kirchheim-Teck, Germany; [4]GSK, Clinical Statistics, Brentford, United Kingdom; [5]GSK, Clinical Sciences, Respiratory, Philadelphia, PA, United States of America; [6]GSK, Respiratory Therapeutic Area, NC, United States of America; [7]GSK, Clinical Sciences, Respiratory, Brentford, United Kingdom; [8]University of California, Department of Medicine, Division of Pulmonary, Critical Care, and Sleep Medicine, San Diego, CA, United States of America; [9]National Institutes of Health, National Institute of Allergy and Infectious Diseases, Human Eosinophil Section, Laboratory of Parasitic Diseases, Bethesda, MD, United States of America; [10]GSK, Global Medical Affairs, Durham, NC, United States of America; [11]National Jewish Health, Department of Medicine, Denver, CO, United States of America*

Background: Patients with eosinophilic granulomatosis with polyangiitis (EGPA) can present with vasculitic or eosinophilic phenotypes.[1] The Phase III MIRRA study demonstrated that patients with EGPA spent more time in remission and had reduced oral corticosteroid (OCS) use with mepolizumab versus placebo.[2]

Objectives: To evaluate the efficacy of mepolizumab in patients with a vasculitic EGPA phenotype enrolled in the MIRRA study.

Methods: MIRRA was a Phase III, multicentre, double-blind, parallel-group trial in adult patients with relapsing/refractory EGPA and ≥4 weeks stable OCS treatment. Patients were randomised to receive standard of care plus mepolizumab (300 mg subcutaneously every 4 weeks) or placebo for 52 weeks. Primary endpoints were: accrued weeks of remission (defined as Birmingham Vasculitis Activity Score [BVAS] of 0 and OCS dose ≤4 mg/day prednisolone or equivalent) over the 52-week study period categorised in weeks (0, >0 to <12, 12 to <24, 24 to <36 and ≥36 weeks), and the proportion of patients in remission at both Weeks 36 and 48. This post hoc analysis used data from the MIRRA study to evaluate these endpoints according to patients' antineutrophil cytoplasmic antibody (ANCA) history (current or previous positive test for myeloperoxidase[MPO]/proteinase 3[PR3]-ANCA at study baseline versus no history of a positive MPO/PR3-ANCA test at baseline), baseline BVAS (=0 vs >0) and Vasculitis Damage Index (VDI) score (<5 vs ≥5). Types of disease relapse (vasculitis [BVAS >0], asthma [active asthma symptoms and/or signs with a worsening in Asthma Control Questionnaire-6 score] and sinonasal [active nasal and/or sinus disease with a worsening in ≥1 sinonasal symptom questions]) reported during the treatment period were also described. EGPA disease characteristics focusing on vasculitic components were assessed in patients who did and did not achieve remission at any point during the study.

Results: Of the 136 patients in the study, 26 (19%) had a history of a positive ANCA test at study baseline and 110 (81%) did not. In addition, 51 (38%) had a BVAS =0 at baseline while 85 (63%) had a BVAS >0; 74 (54%) had a VDI <5 at baseline and 62 (46%) had a VDI ≥5. Accrued remission duration was greater with mepolizumab versus placebo, irrespective of ANCA positive status, baseline BVAS or baseline VDI score (Figure 1). Across all the subgroups, a larger proportion of patients achieved remission at both Weeks 36 and 48 with mepolizumab versus placebo (Figure 1). Among patients receiving mepolizumab, the numbers (proportion) of patients achieving remission at both Weeks 36 and 48 were: 7 (54%) for patients with a history of an ANCA-positive test and 15 (27%) for patients without a history of an ANCA-positive test; 14 (45%) in the BVAS =0 and 8 (22%) in the BVAS >0 groups; 11 (29%) in the VDI score <5 and 11 (37%) in the VDI score ≥5 groups. Mepolizumab reduced all types of disease relapse assessed during the treatment period, including vasculitis, asthma and sinonasal relapses, compared with placebo. Vasculitic characteristics including neuropathy, glomerulonephritis, alveolar haemorrhage, palpable purpura and ANCA positivity were generally similar among patients who did and did not achieve remission during the study.

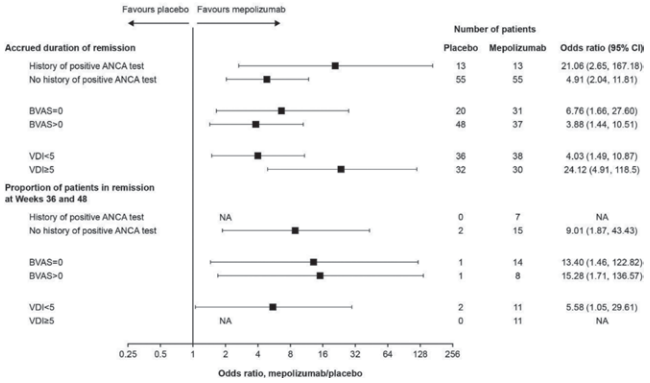

Figure 1. Mepolizumab efficacy by patient baseline characteristicsANCA, antineutrophil cytoplasmic antibody; BVAS, Birmingham Vasculitis Activity Score; CI, confidence interval; NA, data not available – estimate could not be calculated owing to a lack of patients in the placebo group achieving remission at Weeks 36 and 48; VDI, Vasculitis Damage Index.

Conclusion: Mepolizumab is associated with clinical benefits in patients with EGPA, including those with and without a vasculitic phenotype.

POS0837

EFFICACY OF ULTRA-LOW DOSE RITUXIMAB FOR REMISSION MAINTENANCE THERAPY IN ANCA-ASSOCIATED VASCULITIS

D. Campaniello[1], E. Treppo[2], B. D'onofrio[3], G. Franchi[3], A. Berti[4], L. Iorio[1], R. Bortolotti[4], C. Montecucco[3], S. Monti[3], L. Quartuccio[2], A. Doria[1], F. Schiavon[1], R. Padoan[1]. *[1]University of Padova, Division of Rheumatology, Department of Medicine DIMED, Padova, Italy; [2]University of Udine, Italy, Department of Medicine, Rheumatology Clinic, Udine, Italy; [3]IRCCS Policlinico S Matteo Fondazione, University of Pavia, Italy, Department of Rheumatology, Pavia, Italy; [4]Santa Chiara Hospital, Trento, Italy, Rheumatology Unit, Trento, Italy*

Background: Rituximab (RTX) achieved high remission-induction and sustained maintenance rates for patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) [1], [2]. However, RTX is an expensive medication, which may potentially lead to serious side effects. Defining the best dose regimen for maintenance in AAV is still an unmet need.
Objectives: The aim of the present study is to compare the effects of ultra-low dose RTX (500 mg or 1000 mg once per year) to standard low dose RTX (500 or 1000 mg twice per year) as remission-maintenance therapy in AAV patients.
Methods: We included consecutive AAV patients (classified as GPA and MPA [3]) referring to four different Rheumatology centers in Italy. We assessed all AAV patients who successfully achieved disease remission (BVASv3=0) with conventional RTX or cyclophosphamide regimens and have been subsequently treated with RTX for maintenance of remission. All included patients received at least three maintenance infusions with either 1000 mg or 500 mg, twice per year (standard low dose) or once per year (ultra-low dose). After a period of 18 months, we assessed the remission rate, damage (VDI), glucocorticoids intake, ANCA status, B-cells depletion and serum IgG levels.
Results: From January 2011 to December 2021, 83 AAV patients (mean age 51±16, 49.4% female, 95.2% ANCA positive, 65.8% anti PR3, 34.2% anti MPO), 61 classified as GPA and 22 MPA, achieved complete disease remission with conventional RTX induction regimen. After 7 [6-9] months, 29.9% patients started maintenance treatment with ultra-low dose RTX (once per year), while 70.1% patients with standard low dose (twice per year), for 18 months. No significant differences at baseline were noted between patients receiving ultra-low dose when compared to those treated with conventional low-dose.
At the end of observation period, a disease flare was observed in 22.7% of the low-dose group, and 21.2% in those treated with the standard dose (p=0.881). Relapse-free survival was comparable between the two group (log-rank p=0.818, Figure 1).

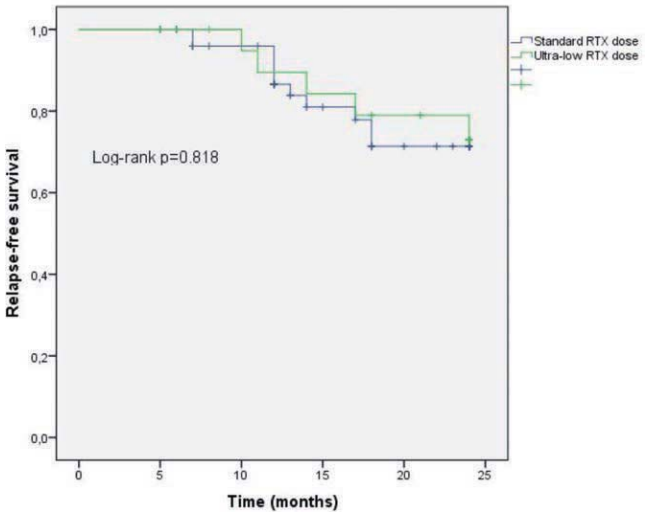

Figure 1.

When comparing AAV patients treated with ultra-low dose regimen to those treated with low-dose, no differences were noted in negative ANCA rate (72.2% vs 67.1%, p=0.262), ANCA titer (0 [0-7.8] vs 0 [0-50] UI/mL, p=0.232), B-cells depletion rate (70.6% vs 75%, p=0.725), mean serum IgG (811 [146-922] vs 680 [429-861] mg/dL, p=0.367), mean daily glucocorticoid dosage (2.5 [0-5] vs 3.75 [0-5] mg/d, p=0.647), VDI (4 [1-5] vs 2 [1-4], p=0.098), hypogammaglobulinaemia rate (31.8% vs 36.5%, p=0.697) and deaths (4.5% vs 5.8%, p=0.831).
Although not significant, patients treated with ultra-low dose had lower severe infection rate (10.5% vs 26.8%, p=0.154). Notably, in the all cohort 5 deaths were related to COVID19 pneumonia.
Conclusion: Reduced exposure to RTX was not associated with an impaired efficacy of maintenance therapy in patients with AAV. Remission maintenance with ultra-low dose RTX is a safe and more cost-effective option.

POS0838

INCIDENCE OF CANCER IS SIGNIFICANTLY INCREASED IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS PATIENTS: RESULTS FROM A MULTICENTRE STUDY.

R. Padoan[1], M. Zorzi[2], J. Battagello[2], V. Zagonel[3], G. Emmi[4], C. Baldini[5], S. Monti[6], L. Quartuccio[7], A. Doria[1], F. Schiavon[1]. *[1]University of Padova, Division of Rheumatology, Department of Medicine DIMED, Padova, Italy; [2]Veneto Tumor Registry, Azienda Zero, Padova, Italy; [3]Veneto Institute of Oncology - IRCCS, Department of Oncology, Padova, Italy; [4]University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy; [5]University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy; [6]University of Pavia, IRCCS Policlinico S Matteo Foundation, Department of Rheumatology, Pavia, Italy; [7]University of Udine, Rheumatology Clinic Department of Medicine (DAME), ASUFC, Udine, Italy*

Background: No large assessment of the general cancer occurrence in eosinophilic granulomatosis with polyangiitis (EGPA) has been reported.
Objectives: The aim is to investigate the incidence of malignancies in EGPA patients and to examine the effect of immunosuppressive therapy on malignancy risk in these patients.
Methods: The occurrence of cancers was assessed in a cohort of 303 incident EGPA patients (54.8% female, 44% MPO-ANCA positive, 53 [41-61] years old at diagnosis), diagnosed between 1987 and 2019. Demographic, clinical and laboratory data, and the use of immunosuppressive drugs were assessed. Through linkage with Regional Italian Cancer Registries, information about any malignancy occurring before and after EGPA diagnosis was collected. For each patient, the person-years (PY) of follow-up was calculated till the first event: cancer occurrence, last follow-up or death. The PY was stratified by sex, age (in 5-year groups) and calendar-decades (2000-2009 and 2010-2019). Standardized incidence ratios (SIR) between observed and expected numbers (retrieved from the AIRTUM-AIOM database) of cancers were calculated with exact Poisson regression analysis and used as a measure of risk difference.
Results: Thirty patients developed a total of 42 malignancies during a median follow-up of 4.4 [2.1-8.5] years. After excluding patients with a diagnosis of cancer before EGPA onset, 20 first malignancies were observed in 1276 PY observation period. The SIR (95% Poisson CI) malignancy risk was 1.99 (1.22-3.08; p=0.007) for all cancers at all sites, and 1.86 (0.98-2.75; p= 0.025) for all cancers excluding non-melanoma skin cancers. Incidence rates were significantly higher in ANCA positive patients (SIR 2.43 [1.30-4.16]; p=0.007) when compared to ANCA negative, and in those treated with cyclophosphamide (SIR 2.42 [1.11-4.60]; p=0.030) when compared to other immunosuppressive agents. Median latency from EGPA onset and first cancer diagnosis was 5 (2-11) years, with 63.3% of patients developing cancer within 1 and 5 years. Malignancy-free survival at 2, 5, and 10 years of follow-up was 96%, 91%, and 70%, respectively. Of these malignancies, 30% were skin cancers, 25% prostate cancers and 20% breast cancers. Comparing patients who developed malignancies with those who did not, any significant difference was noted regarding sex, ANCA status, age at diagnosis, clinical manifestations, BVAS, FFS, environmental exposure, smoking habit and cancer familiarity. Type of treatment and cumulative doses of cyclophosphamide were not associated with higher incidence of cancers.
Conclusion: EGPA patients have a two-fold risk of overall malignancy than the general population. This cancer excess might be driven by a combination of already known treatment-associated factors and other unknown disease-associated factors, which should be further investigated

POS0839

RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL TO EVALUATE EFFICACY AND SAFETY OF SC ABATACEPT IN ADULTS WITH ACTIVE IDIOPATHIC INFLAMMATORY MYOPATHY

R. Aggarwal[1], I. E. Lundberg[2], Y. W. Song[3], A. Shaibani[4], V. P. Werth[5], M. A. Maldonado[6]. *[1]University of Pittsburgh, Division of Rheumatology and Clinical Immunology, Department of Medicine, Pittsburgh, United States of America; [2]Karolinska Institutet, Division of Rheumatology, Department of Medicine, Stockholm, Sweden; [3]Seoul National University, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [4]Baylor College of Medicine, Medicine-General Medicine, Houston, United States of America; [5]Pennsylvania Medical School, Department of Dermatology, Philadelphia, United States of America; [6]Bristol Myers Squibb, Immunology and Fibrosis Research and Development, Princeton, United States of America*

Background: Limited therapies are available for patients with idiopathic inflammatory myopathy (IIM), a heterogenous group of chronic, systemic, autoimmune inflammatory diseases characterized by progressive muscle weakness and/or distinct skin rashes.[1] Abatacept, a selective co-stimulation modulator, may be a useful treatment option.[2]

Objectives: To evaluate efficacy, safety, and tolerability of abatacept + standard of care (SOC) in patients with IIM compared with SOC alone (placebo).

Methods: A 24-week, randomized, double-blind, placebo-controlled phase 3 trial of SC abatacept (125 mg weekly) + SOC (corticosteroids and immunosuppressants alone or combined; NCT02971683) in patients with active, treatment-refractory IIM (Manual Muscle Testing-8 [MMT-8] ≤ 135) was performed. Primary endpoint was proportion of patients meeting International Myositis Assessment and Clinical Studies definition of improvement (IMACS DOI) at week 24. Change from baseline in myositis Functional Index-2 (FI-2), HAQ-DI, Myositis Disease Activity Assessment Tool (MDAAT), and Myositis Response Criteria (MRC) were secondary endpoints with safety. Post hoc analyses by disease subtype were performed.

Results: Overall, 148 patients were randomized (75 abatacept; 73 placebo); IIM subtypes were dermatomyositis (DM; 53.3% vs 57.5%), polymyositis (PM; 25.3% vs 34.2%), and autoimmune necrotizing myopathy (ANM; 21.3% vs 8.2%). Mean baseline MMT-8 and HAQ-DI scores were 112.7 and 1.5, respectively. Approximately 90% of patients completed week 24. Week 24 IMACS DOI rates were abatacept 56.0% vs placebo 42.5% (adjusted odds ratio, 1.8 [95% CI, 0.9–3.5]; $P = 0.083$). Pre-specified IMACS DOI analysis showed no differences for patients with DM but notable benefit for those with non-DM subtypes, PM and ANM (Table 1). Secondary endpoints showed similar differences (Table 1). MRC at day 169 by category is shown in Figure 1. Proportion of AEs (69.3% and 75.3%) and serious AEs (5.3% and 5.5%) were similar in the abatacept and placebo arms.

Table 1. Primary and secondary (mean change from baseline at week 24) endpoints

Outcome	IIM	Abatacept	Placebo	Nominal *P* value (abatacept vs placebo) or adjusted mean difference from placebo (95% CI)
IMACS DOI,[a] n/N (%)	All	42/75 (56.0)	31/73 (42.5)	$P = 0.083$
	DM	22/40 (55.0)	21/42 (50.0)	$P = 0.679$
	Non-DM	20/35 (57.1)	10/31 (32.3)	$P = 0.040$
FI-2	All	4.1 (1.3)	1.2 (1.4)	2.9 (0 to 5.8)
	DM	2.3 (1.6)	0.3 (1.4)	1.9 (–2.3 to 6.2)
	Non-DM	3.2 (1.4)	–0.6 (1.5)	3.7 (–0.3 to 7.8)
HAQ-DI	All	–0.31 (0.07)	0.20 (0.07)	–0.12 (–0.28 to 0.04)
	DM	–0.31 (0.08)	–0.19 (0.07)	–0.11 (–0.32 to 0.10)
	Non-DM	–0.25 (0.09)	–0.07 (0.09)	–0.18 (–0.44 to 0.07)
MDAAT, Extramuscular Global Activity, (95% CI)[b]	All	–1.56 (–1.96 to –1.16)	–1.40 (–1.81 to –0.99)	–0.16 (–0.63 to 0.30)
	DM	–1.90 (–2.43 to –1.37)	–1.85 (–2.35 to 1.36)	–0.05 (–0.77 to 0.68)
	Non-DM	–1.09 (–1.46 to –0.72)	–0.85 (–1.27 to –0.43)	–0.24 (–0.80 to 0.32)
MMT-8	All	12.9 (1.9)	11.0 (2.0)	1.8 (–2.7 to 6.4)
	DM	14.4 (2.2)	14.0 (2.2)	0.4 (–5.7 to 6.4)
	Non-DM	12.1 (2.5)	7.8 (2.7)	4.3 (–3.0 to 11.7)
Physician Global Assessment[b]	All	–2.89 (0.30)	–2.69 (0.30)	–0.20 (–0.92 to 0.52)
	DM	–2.78 (0.29)	–2.43 (0.28)	–0.35 (–1.15 to 0.46)
	Non-DM	–2.35 (0.43)	–2.21 (0.48)	–0.14 (–1.43 to 1.15)
Patient Global Assessment[b]	All	–1.4 (0.31)	–0.98 (0.32)	–0.38 (–1.11 to 0.35)
	DM	–1.4 (0.33)	–1.4 (0.31)	–0.00 (–0.91 to 0.90)
	Non-DM	–1.2 (0.41)	–0.3 (0.44)	–0.93 (–2.14 to 0.29)

Data are adjusted mean change from baseline score (SE) unless stated. [a]Defined as improvement of ≥ 20% in 3 IMACS core measures, worsening by ≥ 25% in ≤ 2 IMACS core measure scores, and a reduction of < 25% in MMT-8; [b]100 mm visual analog scale.

Conclusion: In this double-blind trial of SC abatacept vs placebo, abatacept failed to meet primary or secondary endpoints. Post hoc analyses suggest a treatment benefit in patients with PM and ANM (not DM) when treated with abatacept. Abatacept use was well tolerated.

MELANOMA DIFFERENTIATION-ASSOCIATED GENE 5 ANTIBODY (ANTI-MDA5) DERMATOMYOSITIS: CLINICAL FEATURES AND OUTCOME IN A RACIALLY DIVERSE PATIENT COHORT

S. K. Koyoda[1], D. Wahezi[2], A. Kumthekar[1], X. Xie[3], S. Mahmood[1], C. Tagoe[1], B. Ayesha[1]. *[1]Montefiore Medical Center/Albert Einstein College of Medicine, Rheumatology, Bronx, NY, United States of America; [2]Children's Hospital at Montefiore, Department of Pediatric Rheumatology, Bronx, NY, United States of America; [3]Albert Einstein College of Medicine, Department of Epidemiology and Population Health, Bronx, NY, United States of America*

Background: Melanoma differentiation associated gene 5 antibody (anti-MDA5) dermatomyositis, is an idiopathic inflammatory musculoskeletal disorder with specific phenotypic manifestations of rapidly progressing interstitial lung disease (RP-ILD) and ulcerative skin lesions, with or without muscle involvement. [1] There is currently a lack of consensus and guidelines on early diagnosis and timely escalation of therapy to avoid untoward outcomes.
Objectives: To identify distinguishing clinical and laboratory features to assess disease progression amongst individuals with anti- MDA5 dermatomyositis based on the serologic, histopathologic, and radiographic status. We identified and compared the disease phenotype in a racially diverse juvenile and adult population with anti-MDA5 dermatomyositis.
Methods: After Institutional review board approval, we queried the electronic health record at the Montefiore Medical Center, NY, and identified a total of 194 dermatomyositis patients. We included 21 dermatomyositis patients with MDA5 antibody. We performed a retrospective chart review to extract clinical data and analyzed data using Fischer's exact test.
Results: Of the 21 dermatomyositis patients with anti-MDA5, 12 adult patients represented 8% of all adult dermatomyositis cases (12/148) and 9 patients represented 19 % of the pediatric dermatomyositis cases (9/46). There was a 2:1 female to male predominance in both groups. In adults, the mean age of disease onset was 45.2 years (SD 14.4 years). Nine ILD cases were noted, of which 2 were RP-ILD. The presence of the Ro52 antibody was associated with rapid disease progression. In children, the mean age of onset was 6.6 years (SD 4.9 years). All children had muscle weakness, with only 5 having ILD. Myositis was noted to be more prevalent in the pediatric population, compared to adults (9/9 Vs 4/12 cases; P=0.005). In this patient cohort, ILD was statistically significant between the African American population (9/10 cases) and non-African American population (5/11 cases), p=0.03, of these 3 African American cases had RP-ILD with mortality. The combined mortality rate of 14.2% was superior to 40-60% reported in the literature. [2]
Conclusion: Anti MDA5 dermatomyositis is relatively rare and difficult to diagnose. In this study, the general disease characteristics of our cohort were similar in both adult and pediatric patients except for myositis, which was more common in the pediatric population. The incidence of ILD by contrast was higher in the adults, especially in the African American population who had worse outcomes. The rapid escalation of therapy and use of rituximab may have improved our outcomes over historic controls. Controlled studies are needed to evaluate patients with anti-MDA5 dermatomyositis for appropriate treatment interventions and to avoid untoward outcomes.

POS0841

HIGH-INTENSITY INDUCTION THERAPY COMBINING TOFACITINIB, RITUXIMAB, AND PLASMAPHERESIS IN RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE ASSOCIATED WITH ANTI-MDA5 ANTIBODY POSITIVE DERMATOMYOSITIS

T. Shirai[1], H. Sato[1], H. Fujii[1], T. Ishii[1]. [1]*Tohoku University Hospital, Rheumatology, Sendai, Japan*

Background: Rapidly progressive interstitial lung disease (RP-ILD) associated with anti-melanoma differentiation-associated protein 5 (MDA5) autoantibody (Ab) -positive dermatomyositis (DM) is one of the most life-threatening autoimmune conditions. The clinical course is very rapid, leading to death within three months after the onset of symptoms. Although triple therapy which consists of corticosteroids, cyclophosphamide, and tacrolimus has been considered as standard therapy and additional treatments including plasma exchange (PE) and rituximab (RTX) have been reported, the survival rate of patients with poor prognostic factors is still poor even if all of these treatments were applied. Recently, there exist increasing evidences regarding the efficacy of tofacitinib (TOF) in refractory DM. We have treated anti-MDA5Ab-positive RP-ILD with multiple poor prognostic factors with high-intensity induction therapy which combined triple therapy, PE, RTX, and TOF.
Objectives: This study aimed to investigate the therapeutic efficacy of high-intensity induction therapy for patients with anti-MDA5Ab-positive RP-ILD with multiple poor prognostic factors.
Methods: 31 patients who were diagnosed with anti-MDA5Ab-positive DM during 2014 to 2021 in our institution were included in this study. The clinical characteristics for poor prognosis were retrospectively analyzed, and the outcomes of high-intensity induction therapy were analyzed for the survival and adverse events.
Results: 17 cases were treated before the introduction of TOF. Although triple therapy with RTX, PE, or intravenous immunoglobulin (IVIG) were used, eight out of 10 RP-ILD cases with a ferritin level >400 ng/mL (range, 402.5-5,831; mean, 2,342 ± 2,069) died in median 2.5 months. Poor prognosis was predicted by followings; elevated levels of serum ferritin, lactate dehydrogenase, transaminases, creatinine phosphokinase, and C-reactive protein; decrease in platelets, serum albumin, and oxygen saturation; use of oxygen; higher age; shorter disease duration to admission. The addition of RTX and PE was not enough to control RP-ILD in anti-MDA5Ab positive DM, and prevention of the initial exacerbation of ILD following induction therapy was considered to be important. Based on these observations, high-intensity induction therapy was consisted as follows; triple therapy with decreasing the dose of methylprednisolone by half from 1g to 1 mg/kg, liposteroid to suppress macrophage activity, TOF, PE, and RTX. High-intensity induction therapy was applied in eight patients (ferritin levels; range, 412.2-7,095 ng/mL; mean, 3,558±3,152 ng/mL) with multiple poor prognostic factors described above. Although deaths at two months and eight months due to ILD were observed, significant improvement of survival was documented (Figure 1). Two patients in whom RTX was not initially administered, exacerbation of ILD was observed one month later, which prompted the use of RTX. Several adverse events were observed in high-intensity induction therapy. The most common events were reactivation of cytomegalovirus, meanwhile herpes zoster was not documented. Sustained leukocytopenia and thrombocytopenia were observed in three patients, and two patients developed thrombotic microangiopathy which led to the discontinuation of tacrolimus. Fungal infections in lung were also documented. These adverse events were controllable.

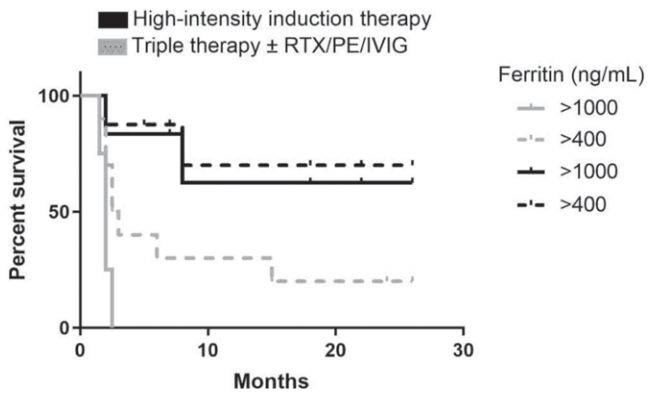

Figure 1.

Conclusion: Significant improvement of survival was observed in patients treated with high-intensity induction therapy. Meanwhile, stratification of patients for poor prognosis would be important.

POS0842 NON-INVASIVE COHERENT RAMAN IMAGING OF INVOLVED FOREARM SKIN REVEALS ALIGNED COLLAGEN IN DERMIS OF SYSTEMIC SCLEROSIS PATIENTS

P. S. Wong[1], B. Ahmed Abdi[1], J. Mansfield[2], H. Lopez[3], J. Moger[2], I. F. Uchegbu[4], R. Stratton[1]. *[1]Royal Free Hospital, Centre Of Connective Tissue Disease and Rheumatology, University College Of London, London, United Kingdom; [2]University of Exeter, School of Physics and Astronomy, Exeter, United Kingdom; [3]MURIGENICS, INC, Research and Development, California, United States of America; [4]UCL School of Pharmacy, Pharmaceutical Nanoscience, London, United Kingdom*

Background: Systemic sclerosis (SSc) is an immune-mediated connective tissue disease with clinical hallmark of inflammation, vasculopathy and fibrosis resulting in abnormal collagen and intercellular matrix formation in the dermis and internal organ. Skin severity correlates with systemic complications and mortality in SSc. Many skin assessment tools studied do not fulfilled all standards set by OMERACT which include criterion validity, construct validity, discrimination, responsiveness, reliability and feasibility. Modified Rodnan skin score (mRSS) is commonly used as outcome measure in clinical trials of SSc. It is however, limited by inter-rater variability. Studies also showed that skin biopsy samples from body part of SSc patients with clinically normal mRSS had demonstrable pathological deposition of collagen. While repeat skin biopsy to track longitudinally, may be unacceptable to patients. Hence, ongoing research for non-invasive tools are encouraged.
Objectives: We follow through our previous work studying commercially available non-invasive imaging tools in SSc skin assessment by using Coherent-Raman scattering microscopy (CRS).
Methods: Skin biopsies of 4mm were obtained from SSc (n=3) and HC (n=1). Skin samples were collected at anterior surface of forearm from newly diagnosed diffuse SSc which were treatment naïve. Samples were frozen at -80c prior to analysis under CRS at skin depth of 150-200um. The laser setting was 3% pump (802nm) and 6% stokes (1045nm) to avoid tissue burn. 3 contrast methods used are Coherent anti-Stokes Raman scattering (CARS) for imaging of lipids, Second Harmonic Generation (SHG) for collagen and Two-Photon Fluorescence (TPF) for elastin fibers. We analysed collagen and elastin fibers in the skin samples which is disease relevant end products of fibroblast activation in SSc. Descriptive study of the skin CRS characteristics is reported.
Results: The SHG analysis revealed denser collagen fibers in dermal layer of diseased skin. It also appears that the collagen deposition occurs in more superficial layers of the skin. Peak of collagen curve were at depth of 110-130um HC vs 75-90um in SSc. Collagen fibres were more aligned in the SSc (Figure 1).

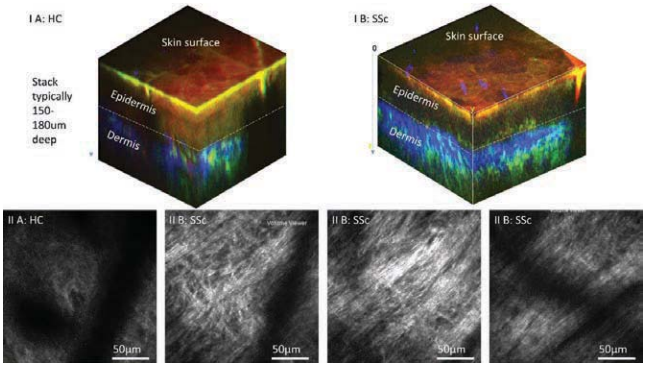

Figure 1. Microscopy analysis of SSc (B) vs HC (A) skin. I: 3D image of biopsy samples with three contrasts. Red is CARS for lipid, blue is SHG for collagen and green is TPF for elastin fibers. II. SHG. Imaging revealed denser and more aligned collagen fibers in SSc.

Furthermore, TPF revealed larger number of disordered elastin fibres in the dermal layer of SSc than HC.
Conclusion: Nailfold capillaroscopy is used to define and stage micro-vasculopathy in SSc. Inflammatory pro-fibrotic processes on the other hand cause abnormal collagen and intercellular matrix formation in the dermis and internal organ. With the demand of better tools in diagnosis of early SSc and therapeutic research, our work with CRS prove better in objective evaluation of skin changes at the molecular level. Here, we demonstrate that the SHG is altered in the early diffuse SSc skin with increased and aligned collagen in the SSc dermis compatible with mRSS score. Others have observed this alignment of the collagen, and we have published that SSc fibroblasts migrate/invade along aligned collagen and modify the underlying extracellular matrix, adding collagens I and III, cross-linking enzymes and other factors including TSP-1.
Our future work include:
1.Generating a computer module in defining pathological collagen level
2.Analysis of metabolites and pathological pathways in SSc
3.In-vivo trials with novel therapeutic peptides.
4.Lastly, manufacturing of non-invasive handheld device that is capable of diagnosis subclinical SSc and for outcome measure in clinical-therapeutic research

POS0843 PREDICTORS OF INTERSTITIAL LUNG INVOLVEMENT AND TIMING OF ONSET IN SYSTEMIC SCLEROSIS: OUR EXPERIENCE AT A THIRD-LEVEL HOSPITAL

C. Sieiro Santos[1], C. Moriano[1], X. E. Larco Rojas[1], C. Álvarez Castro[1], A. López Robles[1], E. Diez Alvarez[1]. *[1]Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Interstitial lung disease (SSc-ILD) and pulmonary hypertension are the leading causes of death in patients with systemic sclerosis (SSc). Identifying SSc-ILD development and initiating treatment is essential to optimize therapeutic benefit.
Objectives: We aimed to identify predictors of SSc-ILD and compared early (<5 years from diagnosis) versus late (>5 years from diagnosis) onset.
Methods: We conducted a retrospective cohort study by including patients diagnosed with SSc from 1980 to 2020 followed in our unit and compared the clinical profile of patients with SSc-ILD to control SSc-non-ILD patients. Demographic features, clinical and immunological characteristics, baseline pulmonary function and capillaroscopy data were retrieved. Logistic regression modelling was run to identify factors associated with SSc-ILD development. Factors associated with ILD were then determined as factors associated with early or late onset using multivariate analysis. Bonferroni correction was used to limit Type I errors.
Results: We have included 103 patients from our patient registry from 1980 to 2021 (42% with SSc-ILD). Logistic regression identified risk factors associated with increased or decreased odds ratio for developing ILD is summarized in Table 1. Smoking history, male sex, the presence of myositis, anti-Scl70 and anti-Ro52 positivity, baseline pulmonary function including FVC and DLCO, mMRC (Modified Medical Research Council) dyspnea scale>2, mMSS (Modified Rodnan Skin Score), and late pattern in capillaroscopy were identified as SSc-ILD predictors. Older age at SSc diagnosis, the presence of telangiectasias and smoking status were correlated with of SSc-ILD onset before 5 years, while male gender, the presence of myositis and antiphospholid antibodies were correlated with late-onset SSc-ILD.

Table 1. Significant logistic regressions for predictors for SSc-ILD

Predictor	OR (95% CI)	P value
Male	2.8 (1.16-6.8)	0.02
Smoking history	2.15 (1.33-3.46)	0.001
Diffuse cutaneous involvement	10.4 (2.2-48.3)	0.003
Raynaud duration	0.89 (0.79-1.0)	0.04
Myositis	3.45 (1.09-10.9)	0.03
Anti-Scl70	5.45 (2.02-14.7)	0.001
Anti-Ro52	3.37 (1.49-9.45)	0.002
FVC	0.97 (0.91-0.98)	0.03
DLCO	0.96 (0.93-0.98)	0.003
mMSS	3.73 (1.64-8.5)	0.01
mMRC>2	2.01 (1.52-4.2)	0.04
Late capilaroscopy pattern	2.3 (1.02-5.27)	0.04
Early onset SSc-ILD	**β value**	**P value**
Older age at onset	0.47	0.0017
Telangiectasias	0.29	0.04
Smoking stauts	0.37	0.02
Late onset SSc-ILD	**β value**	**P value**
Male gender	0.57	0.001
Myositis	0.34	0.02
Antiphospholipid antibodies	0.31	0.04

Conclusion: We identified 10 factors significantly associated with risk of developing SSc-ILD: smoking, male sex, diffuse cutaneous involvement, the presence of myositis, shorter Raynaud duration to SSc diagnosis, anti-Scl70 and anti-Ro52 positivity and baseline pulmonary function (lower baseline DLCO and FVC increasing risk) and late capillaroscopy pattern and identified predictors for early and late-onset SSc-ILD.

POS0844 LONG-TERM AND SHORT-TERM RISK OF MALIGNANCY IN IDIOPATHIC INFLAMMATORY MYOPATHY

S. Izuka[1], T. Komai[1], H. Shoda[1], K. Fujio[1]. [1]*The University of Tokyo, Department of Allergy and Rheumatology, Bunkyo City, Japan*

Background: Idiopathic inflammatory myopathy (IIM) is associated with a high prevalence of malignancy, in which anti-transcriptional intermediary factor 1-γ(TIF1-γ) antibody is at a high risk of malignancy compared to the other myositis-specific antibodies, including anti-aminoacyl-tRNA synthetase (ARS), melanoma differentiation-associated gene 5 (MDA5), and Mi-2 antibody [1]. Although some subgroups of IIM have a high risk of malignancy up to 10 years after diagnosis [2], long-term relationships between malignancy and each antibody are not elucidated so far.

Objectives: To clarify the risk of malignancy in IIM in each antibody type with standard incidence ratios (SIR) of malignancy and the long-term occurrence of malignancy.

Methods: From our IIM cohort at the University of Tokyo hospital, we enrolled patients who fulfilled with Bohan and Peter criteria for dermatomyositis/polymyositis or 2017 European League Against Rheumatism/American College of Rheumatology classification criteria for IIMs and with positivity for anti-ARS, MDA5, Mi-2, or TIF1-γ antibody. We retrospectively collected the data and calculated SIRs by using the database of Cancer Statistics, Cancer Information Service, National Cancer Center, Japan. Fisher exact test and Wilcoxon test were used to compare the clinical features in each group. Cumulative incidence of cancer occurrence was estimated by Kaplan-Meier methods, and Log-rank test was used to compare the cancer-free survival.

Results: The study included 111 patients, including 16 patients being diagnosed with a malignancy within a three-year before and after the occurrence of IIM. Patients with malignancy were significantly older age at the onset of IIM (median age (interquartile range) 67.5 (62.3-70.8) vs. 52.0 (41.5-61.5). p<0.001) and more frequently with anti-TIF1-γ antibody (25.0% vs. 4.2%, p=0.015). After adjustment for age, the proportion of anti-TIF1-γ antibody remains significantly higher in the malignancy group (p=0.01). SIRs (95% confidence interval) in each type of antibody were anti-ARS of 2.21 (1.03-4.55), anti-MDA5 of 1.89 (0.49-6.02), anti-Mi-2 of 2.75 (0.14-17.84), and anti-TIF1-γ of 14.73 (4.72-40.50) (Table 1). Types of malignancy included four gastric cancers, two bladder cancers, breast cancers, cervical cancers, ovarian cancers, and lung cancer, one pancreatic cancer, rectal cancer, and renal cancer. Kaplan-Meier estimated cancer-free survival was significantly lower in patients with anti-TIF1-γ antibody than patients with anti-ARS antibody (p<0.01) (Figure 1). The frequencies of malignancy of IIM patients with anti-ARS, MDA5, Mi-2, or TIF1-γ antibody through the follow-up period were 15.6%, 20.0%, 11.1%, 50.0%, respectively.

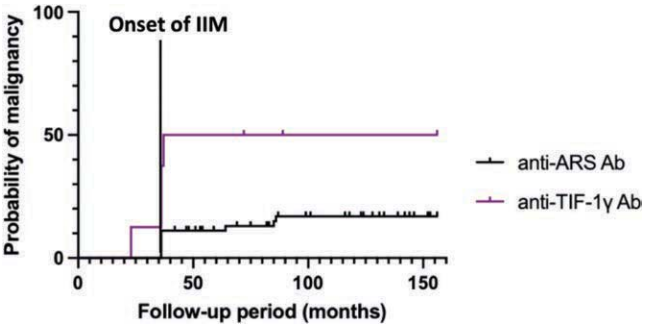

Figure 1. Comparison of malignancy rate of idiopathic inflammatory myopathy with anti-ARS, and TIF1-γ antibodies in 10 years.

Table 1. Standard incident ratio (SIR) of malignancy in idiopathic inflammatory myopathy according to myositis-specific antibodies.

	Total (Person-years)	Observed	Expected	SIR (95% CI)
Anti-ARS antibody	510	8	3.62	2.21 (1.03-4.55)
Anti-MDA5 antibody	210	3	1.59	1.89 (0.49-6.02)
Anti-Mi-2 antibody	56	1	0.36	2.75 (0.14-17.84)
Anti-TIF1-γ antibody	39	4	0.27	14.73 (4.72-40.50)
Total	815	16	5.84	2.74 (1.62-4.56)

Conclusion: IIM patients with anti-TIF1-γ antibody and with anti-ARS antibody had a higher prevalence of malignancy than the general population. In addition, anti-TIF1-γ antibody are more associated with malignancy rather than anti-ARS antibody in 10 years as well. Malignancy associated with anti-TIF1-γ positive IIM occurred exclusively within the one year before and after the IIM diagnosis, and cancer should be particularly investigated at the IIM diagnosis.

POS0845 ASSESSING FRAILTY IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY COMPARING FRAIL AND EDMONTON FRAILTY SCALES WITH PHYSICAL FRAILTY PHENOTYPE

V. Hax[1], A. A. Gasparin[1], N. Pamplona Bueno de Andrade[1], R. Cavalheiro Do Espírito Santo[1], E. Pena[1], L. Santos[1], L. Denardi Dória[1], R. Xavier[1], R. Mendonça Da Silva Chakr[1]. [1]*Hospital de Clínicas de Porto Alegre, Division of Rheumatology, PORTO ALEGRE, Brazil*

Background: Systemic sclerosis (SSc) is a chronic disease characterized by autoimmunity, vasculopathy and fibrosis. During the disease course, patients with SSc are prone to accumulate multiple organ damage, increasing their vulnerability to adverse outcomes in comparison with individuals of the same age: a phenomenon called frailty. One of the most used definitions of frailty is the physical frailty phenotype (PFP) by Fried, *et al*. The PFP consists of 5 components: unintentional weight loss, exhaustion, muscle weakness, slow walking speed, and low physical activity. There is scarce data about frailty in patients with SSc.

Objectives: To study the prevalence and clinical aspects of PFP in a sample of patients with SSc. Also, we aim to investigate the diagnostic accuracy of the Fatigue, Resistance, Ambulation, Illness and Loss of weight (FRAIL) scale and the Edmonton frailty scale (EFS) using the PFP as the reference standard.

Methods: Cross-sectional study, including patients with SSc according to the 2013 ACR-EULAR classification criteria or the criteria suggested by Le Roy and Medsger for early disease. PFP assessment was according to the original definition, except for physical activity domain, assessed with the International Physical Activity Questionnaire (IPAQ). Patients were classified according to Fried's criteria in robust (0), pre-frail (1-2), and frail (≥3). FRAIL scale and EFS were also applied to the same individuals. The FRAIL score ranges from 0 to 5 and patients were classified as robust (0), pre-frail (1-2), or frail (≥3). The EFS score ranges from 0–17 and categorizes patients as not frail (0–4), vulnerable (5–6), mild frailty (7–8), moderate frailty (9–10), and severe frailty (≥11). For the diagnostic assessment of FRAIL scale and EFS, we estimated the area under the receiver operating characteristic curve (AUC), considering PFP as the reference standard and dichotomizing the results in frail vs. non-frail.

Results: Between March and December 2019, 82 SSc patients were consecutively included. The mean age and disease duration were 60.4 (±10.6) and 13.4 (±8.2) years, respectively; 91.5% were women, and 19.5% with diffuse cutaneous SSc. The PFP distribution was: 8 (9.8%) robust, 47 (57.3%) pre-frail and 27 (32.9%) frail patients. The PFP domains´ frequencies were: low physical activity in 57 (69.5%), muscle weakness in 41 (50%), exhaustion in 34 (41.5%), unintentional weight loss in 15 (18.3%) and slow walking speed in 8 (9.8%) patients.

Using the FRAIL scale, 44 (53.7%) patients were considered pre-frail and 25 (30.5%) frail. According to the EFS, 26 patients (31.7%) were classified as vulnerable and 12 (14.6%) as frail: mild in 6 (7.3%), moderate in 4 (4.9%) and severe in 2 (2.4%). The AUC against PFP was: 0.871 (95% CI 0.789-0.954, p<0.001) for FRAIL scale and 0.870 (95% CI 0.791-0.948, p<0.001) for EFS (Figure 1).

Conclusion: Frailty is prevalent in patients with long-standing SSc, and most of them are considered pre-frail or vulnerable. Low physical activity, muscle weakness and exhaustion are among the most frequent clinical aspects of the frailty phenotype. Both FRAIL scale and EFS showed overlapping diagnostic accuracy against PFP as the reference standard, and FRAIL scale seems to be more feasible than EFS.

POS0846

MORTALITY OUTCOME OF ACUTE MYOCARDIAL INFRACTION IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES, A QUALITATIVE APPROACH ANALYSIS OF THE NATIONAL INPATIENT SAMPLE FROM 2016-2019

Z. Y. LI[1], S. Huang[2], T. Joshua[3], D. Dalal[4], A. Reginato[4]. *[1]Roger Williams Medical Center, Rheumatology, PROVIDENCE, United States of America; [2]UCSF Fresno, Medicine, FRESNO, United States of America; [3]Lifespan, Medicine, Providence, United States of America; [4]Brown Medicine, Rheumatology, Providence, United States of America*

Background: The pathophysiology of cardiovascular damage in myositis is a multi-factorial process. Myositis can cause inflammation of the myocardium with accelerated coronary atherosclerosis,the risk of cardiovascular disease in hospitalized patients with idiopathic dermatomyositis was 15% from 2016-17.[1]

Objectives: To investigate the quality of care of acute myocardial infarctions (AMI) events in myositis compared to non-myositis patients across the United States categorized by the types of hospitals, probability of myocardial events, and mortality outcome from the NIS from 2016-19.

Methods: We used SAS statistical software to perform analyses on the NIS database (2016-19) in the US. Adults with AMI and myositis at the time of discharge were identified by International Statistical Classification of Disease 10 (ICD-10) codes. Latent class analysis was used to empirically identify hospital groups across different regions in the U.S where myositis patients received their cardiac care. Once hospital groups were determined, patients were compared with and without myositis in each hospital group. Probabilities of AMI event and mortality among myositis patients were compared using logistic regression analysis.

Results: The NIS sample included 38,363 myositis patients and 24,179,176 non-myositis patients. Three hospital groups were identified, the first two represented inner-city hospitals, with the second group of hospitals tending to be larger and serving lower income patients (Table 1). The third hospital group represented rural hospitals, though they also tended to perform fewer cardiac procedures. Importantly, this third group was about half as likely to identify myositis patients and more likely to identify the unrelated confounder conditions. (myositis=0.10%, confounder=41.0%) This provides evidence that rural hospitals may lack the training and resources to properly care for myositis patients, as hypothesized. Overall, the odd ratio (OR) for myositis patients to have AMI event was 0.83 ($p < 0.0001$); among those who had AMI events, OR for mortality was 0.60 ($p < 0.0001$). Patients who received care at more rural hospitals (group 3) were at heightened mortality risk (OR=1.12, $p < 0.0001$). Opposite to the patient experiences in urban hospitals, the unique risk of mortality to myositis patients in rural hospitals was heightened (OR = 1.88, $p < 0.0001$).

Conclusion: Myositis was not associated with higher AMI events and mortality outcomes in this nationwide hospitalization cohort. Hospitals in rural locations had fewer diagnosed cases of myositis, catheter procedure and transfer out rate may have contributed to higher AMI mortality outcome in group 3. Further studies should examine if catheter procedure mortality outcome of AMI event in myositis differ in the three hospital groups.

^ Based on ICD 10 codes under M33, M60 and G72 groups± Based on ICD 10 codes under I21group* Confounder diagnoses: hypertension, hyperlipidemia, diabetes mellitus, tobacco/alcohol/substance abuses, obesity, rheumatoid arthritis, systemic lupus erythematosus and gout.

antibodies (MAA) can be detected in approximately 60% of patients with IIM. Besides, antibody titers have been suggested to be related with diagnostic accuracy, although it has not been widely studied. MSA are considered to be exclusive of patients with IIM, whilst MAA can occur in IIM and other systemic autoimmune diseases, nevertheless, most of the studies are focused exclusively on IIM patients.

Objectives: The aim of this study is to assess the relationship between MSA/MAA and diagnosis (including IIM and other AID), and to explore the impact of antibody titers in diagnostic accuracy.

Methods: We retrospectively reviewed all the serum samples obtained from patients tested for MSA/MAA between 01/01/2018 and 31/12/2020 in the Immunology department of Ramón y Cajal University Hospital (Spain). These antibodies were tested by line blot immunoassay (LIA) (EUROLINE Autoimmune Inflammatory Myopathies 16 Ag, Euroimmun, Lübeck, Germany). Positivity was stablished according to absorbance titer and adjusted by positive control of each test (arbitrary units, AU). True positive (TP) MSA and MAA were defined as those patients with IIM or AID with phenotypes expected of that MSA/MAA, according to the available information. The patients that did not have a phenotype compatible with that antibody were regarded as false positive (FP). Statistical analysis was carried out using IBM SPSS statistics version 22.

Results: We analyzed 130 positive samples which corresponded to 130 patients, 85 were women and mean age was 55.08 years. 44 patients (33.8%) were classified as IIM, 43 (33.1%) as AID, and 43 (33.1%) as non-IIM/AID. Among these 130 patients, 164 MSA/MAA were detected. 83 (50.6%) positive MSA/MAA were regarded as TP, and 81 (49.4%) as FP (positive predictive value [PPV] 50.6%). Antibodies regarded as TP had a higher antibody titer compared to FP (49,19 AU vs 26,96 AU, p<0.001). This difference was statistically significant for MSA and MAA when analysed separately (Figure 1). FP antibodies were associated with negative ANA and low titer ANA (p<0.001). Multiple positive antibodies (antibodies included in samples that were positive for > 1 MSA/MAA) were more frequently FP in comparison with isolated positive MSA/MAA (p<0.001).

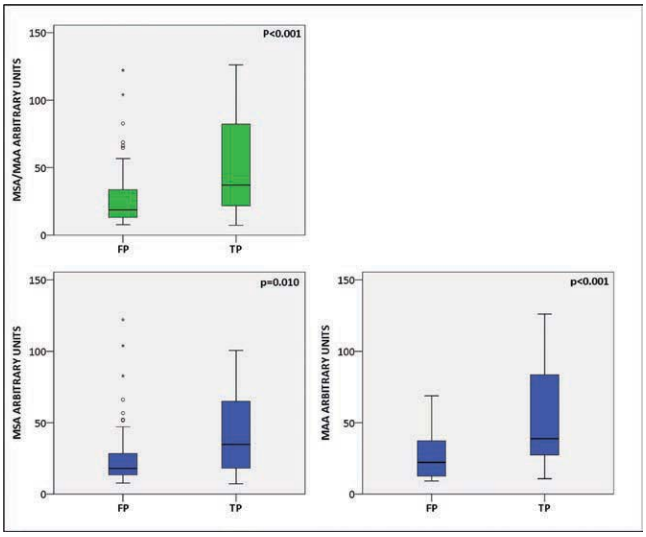

Figure 1. Autoantibody titers comparison between false positives and true positives. MSA=myositis specific antibody, MAA=myositis associated antibody, FP=false positive, TP=true positive

Conclusion: In this study we confirm that FP results using LIA are relatively frequent, and are associated with lower titer MSA/MAA, negative ANA, lower titer ANA, and with multiple positive MSA/MAA within one sample.

POS0848 HEALTHCARE RESOURCE UTILIZATION AND COST BURDEN OF DERMATOMYOSITIS

A. Bensimon[1], K. Chen[2], A. Noman[1], R. Taiji[1], E. Yim[1], V. Sikirica[3], R. Aggarwal[4]. *[1]Analysis Group, Inc., Health Economics and Outcomes Research, Boston, MA and New York, NY, United States of America; [2]Pfizer Inc., Patient & Health Impact, Cambridge, MA, United States of America; [3]Pfizer Inc., Patient & Health Impact, Collegeville, PA, United States of America; [4]Department of Medicine, University of Pittsburgh, Division of Rheumatology and Clinical Immunology, Pittsburgh, PA, United States of America*

Background: Dermatomyositis (DM) is a rare chronic systemic autoimmune disease characterized by muscle weakness and skin rashes. DM is also frequently associated with other clinical manifestations including interstitial lung disease, calcinosis, dysphagia, cardiac involvement, and malignancy. With few approved treatment options, DM has high morbidity and mortality. Limited information is available on the economic impact imposed by DM on the healthcare system.

Objectives: To estimate the economic burden associated with DM in a prevalence cohort, including healthcare resource utilization and costs from both the health insurance plan and patient perspectives.

Methods: A retrospective cohort study was conducted using a large, integrated administrative database of employer-sponsored commercial and public health plans in the United States (PharMetrics Plus, Jan 2014 - June 2020). Patients (age ≥18 years) were selected if they were diagnosed with dermatomyositis (≥1 inpatient claim or ≥2 outpatient claims ≥30 days apart with International Classification of Diseases, 10th Revision, Clinical Modification: M33.0x, M33.1x, or M33.9x) and continuously enrolled in the health plan during the 6 months before (baseline) and 1 year after (follow-up) a randomly selected DM diagnosis date (index date). Patients were matched 1:3 to a control group without DM or related myositis conditions based on birth year, gender, census region, insurance plan type, and index year. Healthcare resource use (HCRU) and costs over the 1-year follow-up period were compared between patients with DM versus matched controls to assess the incremental economic burden of DM. Statistical comparisons were conducted using generalized estimating equation models with binomial, negative binomial, or Tweedie distributions for binary, count, and cost outcomes, respectively. The models used robustly clustered standard errors to account for correlation between the matched samples.

Results: Patients with DM (N=3,207) and matched controls (N=9,621) were 49.4 years old on average and 76.8% were female. HCRU was significantly higher among patients with DM than controls in terms of outpatient, inpatient, emergency room, and other medical visits (all p<0.001; Table 1). Medical service and pharmacy costs to the plan were also significantly higher for patients with DM (p<0.001 vs. controls for all cost categories; Figure 1). Total annual costs to the healthcare plan were 5.4-fold higher among patients with DM (mean ± standard deviation: $39,508 ± 83,093) relative to controls without DM ($7,349 ± 32,816) (Δ=$32,159; p<0.001). Outpatient visit costs ($28,131) comprised 71.2% of the total for patients with DM; costs of outpatient-administered DM-related treatments ($15,855) accounted for the majority of outpatient visit costs. Patients with DM incurred 2-fold higher out-of-pocket costs (coinsurance, copayments, or deductibles) than controls ($4,803 ± 13,181 vs. $2,456 ± 10,708; Δ=$2,346; p<0.001).

Table 1. Annual resource use in patients with DM vs. controls

	Patients with DM N = 3,207	Controls N = 9,621	IRR or OR	95% confidence interval	P-value
Inpatient admissions, mean ± SD	0.2 ± 0.7	0.1 ± 0.4	3.1	(2.6 - 3.7)	< 0.001
Any inpatient admission, %	12.1%	4.9%	2.7	(2.3 - 3.1)	< 0.001
Outpatient visits, mean ± SD	27.7 ± 31.7	10.8 ± 18.9	2.6	(2.4 - 2.7)	< 0.001
Emergency room visits, mean ± SD	0.7 ± 1.6	0.4 ± 1.2	1.8	(1.6 - 2.0)	< 0.001
Any emergency room visit, %	30.4%	20.7%	1.7	(1.5 - 1.8)	< 0.001
Other visits, mean ± SD	0.3 ± 0.8	0.2 ± 0.7	1.8	(1.6 - 2.1)	< 0.001
Any other visit, %	20.0%	11.2%	2.0	(1.8 - 2.2)	< 0.001

IRR: incidence rate ratio; OP, outpatient; OR: odds ratio, SD: standard deviation.*Notes:* IRRs are reported for count outcomes; ORs are reported for binary outcomes. Other visits include durable medical equipment and dental or vision care.

Conclusion: DM is associated with substantial HCRU and costs per patient, with average incremental costs of $32,159 to the health plan and $2,346 to the patient

annually as compared to controls. This study is among the first to document the clinical burden leading to high economic impacts of DM.

POS0849 DEVELOPMENT AND VALIDATION OF A MACHINE LEARNING FOR MORTALITY IN THAI SYSTEMIC SCLEROSIS

C. Foocharoen[1], B. Thinkhamrop[2], W. Thinkhamrop[3], N. Chaichaya[3], A. Mahakkanukrauh[1], S. Suwannaroj[1]. *[1]Khon Kaen University, Department of Medicine, Khon Kaen, Thailand; [2]Khon Kaen University, Department of Epidemiology and Biostatistics, Khon Kaen, Thailand; [3]Khon Kaen University, Data Management and Statistical Analysis Center, Khon Kaen, Thailand*

Background: Clinical predictors of mortality in systemic sclerosis (SSc) are diversely reported due to different healthcare conditions and populations. A universal and simplified predictive model for SSc mortality is needed so that practitioners can be used for managing their patients appropriately.
Objectives: We aimed to develop and validate a simple predictive model for predicting mortality among patients with SSc.
Methods: Prognostic research with a historical cohort study design was conducted between January 1, 2013, and December 31, 2019, **in** adult SSc patients and attending the Scleroderma Clinic at a university hospital in Thailand. The data were extracted from the Scleroderma Registry Database. A deep learning algorithm with Adam optimizer and different machine learning algorithms (including Decision tree, AdaBoost, Random Forest, Gradient Boosting, and XGBoost) was used to classify SSc mortality. In addition, the model's performance was evaluated using the area under the receiver operating characteristic curve (auROC) and its 95% confidence interval (CI) and values in the confusion matrix.
Results: The analysis and predictive model development included 658 SSc patients, 416 (63.2%) females, 452 (69.1%) had dcSSc, and 218 died. The final model included the modified Rodnan skin score (mRSS) and the WHO functional class (WHO-FC) ≥II (model 1). The final model provided the highest predictive performance, followed by model 2 (mRSS and WHO-FC ≥III). After internal validation, the accuracy and auROC were good, and the specificity was high in models 1 and 2 (81.1%, 0.84, and 95.5% in model 1 vs. 82.7%, 0.82, and 87.1% in model 2).
Conclusion: This simplified machine learning model for predicting mortality among patients with SSc could guide early referrals to specialists and help rheumatologists with close monitoring and management planning. External validation across multi-SSc clinics should be considered for further study.

POS0850 A PHASE II RANDOMISED CONTROLLED TRIAL OF ORAL PREDNISOLONE IN EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (PREDSS)

D. Griffiths-Jones[1], Y. Sylvestre Garcia[2], D. Ryder[3], J. Pauling[4], F. Hall[5], P. Lanyon[6], J. Mason[7], C. P. Denton[8], A. Herrick[1]. *[1]University of Manchester, Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; [2]University of Manchester, Centre for Biostatistics, Manchester, United Kingdom; [3]University of Manchester, Clinical Trials Unit, Manchester, United Kingdom; [4]Royal United Hospitals Bath NHS Foundation Trust, Department of Rheumatology, Bath, United Kingdom; [5]Cambridge University Hospitals NHS Foundation Trust, Rheumatology, Cambridge, United Kingdom; [6]Nottingham University Hospitals NHS Trust, Department of Rheumatology,, Nottingham, United Kingdom; [7]Imperial College, Vascular Sciences, National Heart & Lung Institute, London, United Kingdom; [8]University College London, Centre for Rheumatology, Division of Medicine, London, United Kingdom*

Background: A highly controversial question is whether or not corticosteroids should be prescribed for patients with early diffuse cutaneous systemic sclerosis (dcSSc). Although the painful and disabling features of early dcSSc (including tight itchy skin, contractures, fatigue) have an inflammatory basis and are likely to respond to corticosteroids, corticosteroids are a risk factor for potentially life-threatening scleroderma renal crisis.
Objectives: Our aim was to examine safety and efficacy of moderate dose prednisolone in patients with early dcSSc. Specific objectives were to evaluate whether moderate dose prednisolone reduced pain and disability, and improved

Table 1. Generalizability of selected model(s) presented as accuracy, area under ROC, positive predictive value, positive likelihood ratio, specificity, and sensitivity

Selected Model	Accuracy	AUC (95%)	PPV (95%)	+LR (95%CI)	Specificity (95%)	Sensitivity (95%)
Model 1 mRSS and WHO FC ≥ II	81.1	83.6 (77.5 – 89.6)	84.6 (69.5 - 94.1)	11.3 (5.0-25.7)	95.5 (90.4 - 98.3)	51.6 (38.7 - 64.2)
Model 2 mRSS and WHO FC ≥ III	82.7	82.4 (75.8 - 88.9)	73.4 (60.9 - 83.7)	5.7 (3.6-9.1	87.1 (87.2 - 92.3)	73.4 (60.9 - 83.7)

95%CI 95% confidence interval, AUC Area Under the receiver operating characteristics (ROC), mRSS modified Rodnan skin score

skin score, and whether prednisolone was safe with particular reference to renal function

Methods: PRedSS set out as a Phase II, multicentre, double-blind randomised controlled trial, converted to open-label because of the Covid-19 pandemic. Patients were randomised to receive either moderate dose prednisolone (approximately 0.3 mg/kg) or matching placebo (or no treatment during open-label) for 6 months. The co-primary endpoints were the Health Assessment Questionnaire Disability Index (HAQ-DI) and modified Rodnan skin core (mRSS) at 3 months. Over 20 secondary endpoints included patient reported outcome measures reflecting pain, itch, anxiety and depression, fatigue and helplessness. 72 participants randomised 1:1 were planned and anticipated to yield 60 evaluable, giving over 80% power for each co-primary outcome in ANCOVA analyses [assumptions; HAQ-DI ($\alpha = 0.025$, $\delta = -0.6$, $\sigma = 0.9$, $\rho = 0.6$), mRSS ($\alpha = 0.025$, $\delta = -5.5$, $\sigma = 8.2$, $\rho = 0.6$)]. Mixed Models for Repeated Measures (week 6, month 3, month 6) were fitted with covariates trial arm, baseline score, anti-Scl-70 and their interactions with time point. An unstructured covariance matrix was assumed with the primary focus being the trial arm effect at 3 months.

Results: The study terminated early due to the Covid-19 pandemic and consequently did not meet the recruitment target of 72 patients. Thirty-five patients (Table 1) were randomised (17 to prednisolone and 18 to placebo/control, 25 during the double-blind phase), of whom 34 completed the 3 month assessment. The adjusted mean difference between treatment groups at 3 months in HAQ-DI score was -0.10 (97.5% CI -0.29 to 0.10), p=0.25, and in mRSS -3.90 (97.5% CI -8.83 to 1.03), p=0.070, both favouring prednisolone but not significantly. Patients in the prednisolone group experienced less pain, helplessness and anxiety than control patients at 3 months: mean difference in pain scores -0.49, 95%CI (-0.93 to -0.06), p=0.027, in Hospital Anxiety and Depression (HADS) anxiety scores -2.05, 95%CI (-3.73 to -0.37), p=0.018, and in helplessness scores -1.54, 95%CI (-3.01 to -0.07), p=0.040. There were no renal crises.

Table 1. Baseline characteristics of patients by treatment allocation

Characteristic	Prednisolone (n=17)	Control (n=18)
Age (years)	52.7 (14.0)	55.3 (12.7)
Female n (%)	10 (59)	9 (50)
Duration of skin thickening (years)	1.6 (0.8)	1.7 (0.8)
Anti-topoisomerase-1 n (%)	5 (29)	6 (33)
Anti-RNA polymerase III n (%)	6 (35)	8 (44)
HAQ-DI	1.6 (0.8)	1.7 (0.7)
mRSS	18.8 (7.9)	23.5 (8.6)

Values are mean (standard deviation) unless stated otherwise

Conclusion: PRedSS exemplified the challenges of running a clinical trial of an investigational medicinal product potentially associated with increased infection risk during the Covid-19 pandemic. Because PRedSS was terminated prior to target recruitment, it was underpowered, and any conclusions have to be extremely cautious. Although PRedSS suggested some benefit from moderate dose prednisolone, the small sample indicates the need for a further randomised trial.

POS0851 FREQUENCY OF METABOLIC SYNDROME AND ITS RELATIONSHIP WITH DISEASE CHARACTERISTICS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Ü. Özmen[1], E. Er Gülbezer[2,3], B. Barutçuoğlu[4], F. Yargucu[3]. [1]*Ege Üniversitesi Hastanesi, Internal Medicine, İzmir, Turkey;* [2]*Koç University Hospital, Rheumatology, İstanbul, Turkey;* [3]*Ege Üniversitesi Hastanesi, Rheumatology, İzmir, Turkey;* [4]*Ege Üniversitesi Hastanesi, Department of Medical Biochemistry, İzmir, Turkey*

Background: Although the frequency of metabolic syndrome (MetS) has been found to increase in many rheumatological diseases such as rheumatoid arthritis, systemic lupus erythematosus, few studies have been conducted on the frequency of MetS in systemic sclerosis (SSc), and the results are inconsistent.

Objectives: In our study, we aimed to investigate the frequency of MetS in patients with SSc and its relationship with disease characteristics including organ involvement.

Methods: In a cross-sectional, single-center study, 76 patients who applied to our outpatient clinic between July and September 2021 were included in the study. MetS diagnoses were determined according to anthropometric measurements, lipid parameters, blood pressures, and NCEP ATP 3 criteria, and its relationship with SSc end-organ involvement and disease characteristics was examined.

Results: MetS was detected in 37 (48.7%) of 76 patients. Systolic and diastolic blood pressure, waist circumference, height, body mass index, LDL, triglyceride, and fasting blood glucose mean were found to be statistically significantly higher in patients with MetS ($p<0.05$). In addition, HDL was found to be significantly lower in patients with MetS diagnosis than in patients without MetS ($p<0.05$). While no significant relationship was found between MetS and SSc end-organ involvement, SSc disease activities (RAI, SCTC-DI), disease duration, a significant statistical relationship was found between MetS and modified Rodnan skin score (mRSS). It was found that patients with MetS had lower mRSS (p:0.019). According to ROC analysis, the mRSS cut-off point that predicting the presence of MetS was mRSS ≤11 (specificity: 84%, sensitivity: 45.95%, AUC: 0.656, p: 0.014). No statistically significant correlation was found in the comparison with MetS risk factors for mRSS ≤11.

Conclusion: In our study, the frequency of MetS in patients with SSc was found to be lower than in the same age group in Turkey MetS prevalence studies. The frequency of Mets in our study is thought to be due to age and gender dominance rather than SSc itself. Although mRSS was found to be significantly lower in patients with MetS, its sensitivity to predict MetS was found to be low. MetS is less common in patients with high mRSS; It is thought that cachexia due to inflammation, loss of appetite, and malnutrition due to GI involvement may have been effective.

POS0852 SYMPTOMS OF GASTROESOPHAGEAL REFLUX ARE A BETTER PREDICTOR OF SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE PROGRESSION THAN QUANTITATIVE RADIOGRAPHIC ASSESSMENT OF ESOPHAGEAL PARAMETERS

E. Volkmann[1], D. Tashkin[1], M. Leng[1], G. Kim[2], J. Goldin[2], M. Roth[1]. [1]*University of California, Los Angeles, Medicine, Los Angeles, United States of America;* [2]*University of California, Los Angeles, Radiology, Los Angeles, United States of America*

Background: Esophageal dysfunction affects the majority of patients with systemic sclerosis (SSc). Gastroesophageal reflux (GERD)-associated microaspiration may serve as an inciting and/or exacerbating factor in the pathogenesis of interstitial lung disease (ILD) in SSc. Few studies have investigated the relationship between objective measures of esophageal involvement in SSc and the progression of SSc-ILD.

Objectives: (1) To investigate whether patient-reported symptoms of GERD predict SSc-ILD severity and progression; (2) To explore whether quantitative radiographic measurements of esophageal parameters predict SSc-ILD severity and progression.

Methods: Participants of Scleroderma Lung Study (SLS) II (24 months of mycophenolate versus 12 months cyclophosphamide followed by 12 months of placebo in patients with active SSc-ILD) were included.[1] The UCLA SCTC GIT 2.0 was used to assess the severity of reflux at baseline. Quantitative image analysis was used to calculate the diameter and area of the esophagus in the area of maximum dilation. Univariate and multivariable linear regression analyses were used to evaluate the relationship between baseline reflux scores/esophageal parameters and the severity and progression of SSc-ILD based on the

quantitative radiographic extent of ILD (QILD) and fibrosis (QLF) in the lobe of maximum involvement (LM). All multivariable models controlled for treatment arm and baseline ILD severity, as well as proton pump inhibitor (PPI) use.

Results: Among the 141 of 142 SLS II participants with patient-reported reflux scores at baseline, the mean score was 0.57, indicating moderate reflux. The mean maximal esophageal diameter and area at baseline were 22 mm and 242 mm^2, respectively. There were no significant correlations between reflux scores, esophageal diameter, esophageal area and QILD-LM and QLF-LM at baseline. However, in the 96 participants with HRCT scans available at 24 months, increased reflux scores were significantly associated with worsening of QLF-LM and QILD-LM (Figure 1). Even after controlling for disease severity at baseline, treatment arm and PPI use, reflux scores remained significantly associated with change in QLF-LM (P-value 0.05) and QILD-LM (P-value 0.003). Neither the maximum esophageal area, nor the maximum esophageal diameter was associated with the change in QILD-LM or QLF-LM in univariate or multivariate analyses.

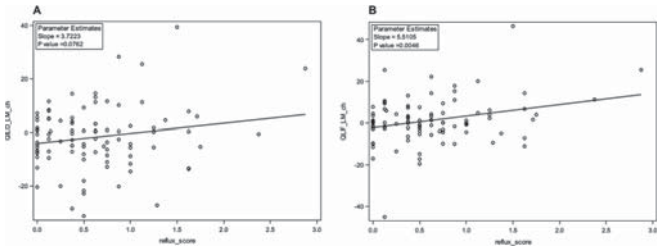

Figure 1. Increased reflux scores at baseline are associated with increased progression (worsening) of QILD (A) and QLF (B) in the lobe of maximum involvement in patients with SSc-ILD.

Conclusion: Increased self-reported reflux was independently associated with worsening radiographic fibrosis and ILD in patients receiving treatment for SSc-ILD. The maximum esophageal diameter and esophageal area did not correlate with reflux scores and did not predict severity or progression of SSc-ILD. These findings illustrate the importance of eliciting a careful patient history of reflux symptoms in patients with ILD and further highlight the need for improved objective measures of esophageal dysfunction in SSc.

KG,Translational Medicine and Clinical Pharmacology, Biberach an der Riss, Germany; [6]Boehringer Ingelheim Pharma GmbH & Co. KG, Biostatistics + Data Sciences Corp., Biberach an der Riss, Germany; [7]Boehringer Ingelheim (Schweiz) GmbH, Medicine, Basel, Switzerland; [8]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland

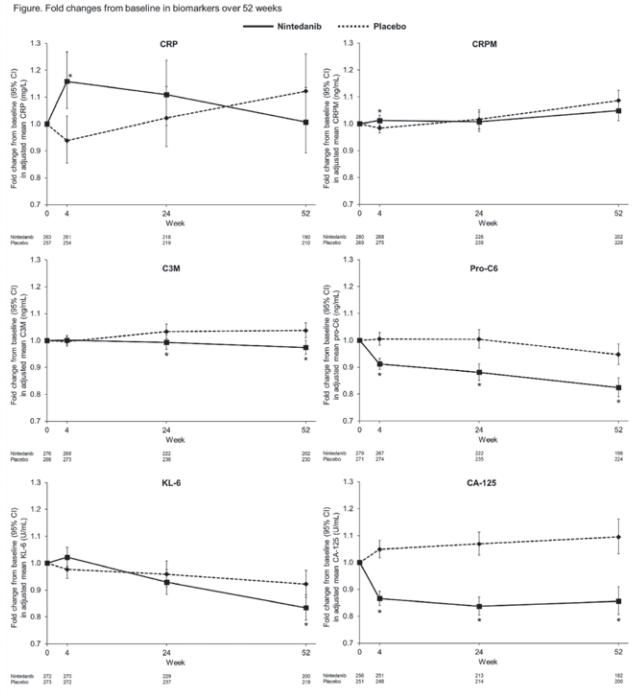
Background: In the SENSCIS trial in subjects with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) over 52 weeks by 44% compared with placebo.

Objectives: To investigate the effects of nintedanib on circulating biomarkers of extracellular matrix (ECM) turnover, epithelial injury and inflammation in the SENSCIS trial.

Methods: Subjects had SSc with first non-Raynaud symptom in the prior ≤7 years, extent of fibrotic ILD on high-resolution computed tomography (HRCT) ≥10% and FVC ≥40% predicted. Patients were randomised to receive nintedanib or placebo stratified by anti-topoisomerase I antibody (ATA). Blood samples were taken at baseline and at weeks 4, 24 and 52. Fold changes in adjusted mean levels of circulating biomarkers were analyzed using a linear mixed model for repeated measures. Data were log_{10} transformed before analysis and estimates of change from baseline were back-transformed.

Results: A total of 576 subjects received trial drug (288 nintedanib, 288 placebo). A transient increase in fold change from baseline in C-reactive protein (CRP) (a marker of inflammation) was observed in subjects who received nintedanib versus placebo at week 4. After an initial increase at week 4 in the fold change from baseline in CRP degraded by MMP-1/8 (CRPM) (a marker of ECM turnover), a trend to decreasing levels was observed in subjects who received nintedanib compared with placebo at week 52. Decreases in the fold change from baseline in collagen 3 degraded by MMP-9 (C3M) and N-terminal propeptide of type VI collagen (pro-C6) (markers of ECM turnover) were observed in subjects who received nintedanib compared with placebo from week 24 and week 4, respectively. A decrease in fold change from baseline in Krebs von den Lungen-6 (KL-6) (a marker of epithelial injury) was observed in subjects who received nintedanib versus placebo at week 52. A decrease in fold change from baseline in cancer antigen 125 (CA-125) (a marker of epithelial injury) was observed in subjects who received nintedanib versus placebo from week 4 (Figure 1).

Conclusion: Data from the SENSCIS trial suggest that nintedanib reduced circulating levels of markers of ECM turnover and epithelial injury in subjects with SSc-ILD.



*p<0.05 for difference versus placebo in fold change from baseline.
For CRP, KL-6 and CA-125: Based on linear mixed model for repeated measures for absolute change from baseline in log-transformed biomarker values, with fixed categorical effects of treatment at each visit, sex, ATA status, SSc subtype (limited cutaneous SSc, diffuse cutaneous SSc), mycophenolate use at baseline, methotrexate use at baseline, and fixed continuous effects of the baseline value of the protein biomarker at each visit, BMI and age.
For Pro-C6, C3M, CRPM: Based on linear mixed model for repeated measures for log-transformed biomarker values (including baseline timepoint), with fixed categorical effects of treatment at each visit, sex, ATA, SSc subtype (limited cutaneous SSc, diffuse cutaneous SSc), mycophenolate use at baseline, methotrexate use at baseline, and batch, and the fixed continuous effects of BMI and age.

POS0854 BASELINE CHARACTERISTICS OF PATIENTS WITH IMPROVEMENT OR PROGRESSION OF SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD) DURING THE SENSCIS TRIAL

A. M. Hoffmann-Vold[1], E. Hachulla[2], A. Herrick[3], T. Moua[4], G. Riemekasten[5], M. Vonk[6], A. James[7], M. Alves[8], O. Distler[9]on behalf of The SENSCIS trial investigators. *[1]Oslo University Hospital, Department of Rheumatology, Oslo, Norway; [2]Université de Lille, Department of Internal Medicine and Clinical Immunology, Lille, France; [3]The University of Manchester, Northern Care Alliance NHS Foundation Trust, Centre for Musculoskeletal Research, Manchester, United Kingdom; [4]Mayo Clinic Rochester, Division of Pulmonary and Critical Care Medicine, Rochester, MN, United States of America; [5]University Hospital Charité, Rheumatology and Clinical Immunology, Berlin, Germany; [6]Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands; [7]Elderbrook Solutions GmbH, Statistics, Bietigheim-Bissingen, Germany; [8]Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim am Rhein, Germany; [9]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*

Background: The course of SSc-ILD is variable, and may include periods of stability or even improvement in forced vital capacity (FVC) as well as periods of decline.
Objectives: To investigate the baseline characteristics of patients with SSc-ILD in the placebo group of the SENSCIS trial whose ILD improved or progressed over 52 weeks.
Methods: The SENSCIS trial enrolled patients with SSc with first non-Raynaud symptom in the prior ≤7 years, extent of fibrotic ILD on high-resolution computed tomography (HRCT) ≥10% and FVC ≥40% predicted. Patients who had been taking a stable dose of mycophenolate for ≥6 months were allowed to participate. We investigated the baseline characteristics of patients in the placebo group whose ILD showed improvement (absolute increase in FVC ≥5% predicted), stability (absolute decline or increase in FVC <5% predicted), progression (absolute decline in FVC ≥5% predicted), or significant progression (absolute decline in FVC ≥10% predicted) over 52 weeks. P-values based on ANOVA or Chi-squared tests were used to compare the baseline characteristics of the patients who showed improvement, stability and progression.
Results: Of 288 patients, 21 (7.3%) showed improvement, 166 (57.6%) stability, and 101 (35.1%) ILD progression, of whom 37 (12.8% of all patients) had significant ILD progression over 52 weeks. Most baseline characteristics were similar across the groups based on progression, but there were differences in DL_{CO} % predicted (p=0.02) and in the proportion of patients taking mycophenolate (p=0.09) among patients who showed improvement, stability and progression (Table 1).
Conclusion: These findings suggest that in the SENSCIS trial, patients who had higher DL_{CO} % predicted or who were taking mycophenolate at baseline were less likely to show progression of SSc-ILD over 52 weeks.

Background: Evaluation of physical function is fundamental in the management of idiopathic inflammatory myopathies (IIMs). Patient-Reported Outcome Measurement Information System (PROMIS) is a National Institute of Health initiative established in 2004 to develop patient-reported outcome measures (PROMs) with improved validity and efficacy. PROMIS Physical Function (PF) short forms have been validated for use in IIMs [1].

Objectives: To investigate the physical function status of IIM patients compared to those with non-IIM autoimmune diseases (AIDs) and healthy controls (HCs) utilizing PROMIS PF data obtained in the coronavirus disease-2019 (COVID-19) Vaccination in Autoimmune Diseases (COVAD) study, a large-scale, international self-reported e-survey assessing the safety of COVID-19 vaccines in AID patients [2].

Methods: The survey data regarding demographics, IIM and AID diagnosis, disease activity, and PROMIS PF short form-10a scores were extracted from the COVAD study database. The disease activity (active vs inactive) of each patient was assessed in 3 different ways: (1) physician's assessment (active if there was an increased immunosuppression), (2) patient's assessment (active vs inactive as per patient), and (3) current steroid use. These 3 definitions of disease activity were applied independently to each patient. PROMIS PF-10a scores were compared between each disease category (IIMs vs non-IIM AIDs vs HCs), stratified by disease activity based on the 3 definitions stated above, employing negative binominal regression model. Multivariable regression analysis adjusted for age, gender, and ethnicity was performed clustering countries, and the predicted PROMIS PF-10a score was calculated based on the regression result. Factors affecting PROMIS PF-10a scores other than disease activity were identified by another multivariable regression analysis in the patients with inactive disease (IIMs or non-IIM AIDs).

Results: 1057 IIM patients, 3635 non-IIM AID patients, and 3981 HCs responded to the COVAD survey until August 2021. The median age of the respondents was 43 [IQR 30-56] years old, and 74.8% were female. Among IIM patients, dermatomyositis was the most prevalent diagnosis (34.8%), followed by inclusion body myositis (IBM) (23.6%), polymyositis (PM) (16.2%), anti-synthetase syndrome (11.8%), overlap myositis (7.9%), and immune-mediated necrotizing myopathy (IMNM) (4.6%). The predicted mean of PROMIS PF-10a scores was significantly lower in IIMs compared to non-IIM AIDs or HCs (36.3 [95% (CI) 35.5-37.1] vs 41.3 [95% CI 40.2-42.5] vs 46.2 [95% CI 45.8-46.6], $P < 0.001$), irrespective of disease activity or the definitions of disease activity used (physician's assessment, patient's assessment, or steroid use) (Figure 1). The largest difference between active IIMs and non-IIM AIDs was observed when the disease activity was defined by patient's assessment (35.0 [95% CI 34.1-35.9] vs 40.1 [95% CI 38.7-41.5]). Considering the subgroups of IIMs, the scores were significantly lower in IBM in comparison with non-IBM IIMs ($P < 0.001$). The independent factors associated with low PROMIS PF-10a scores in the patients with inactive disease were older age, female gender, and the disease category being IBM, PM, or IMNM.

Conclusion: Physical function is significantly impaired in IIMs compared to non-IIM AIDs or HCs, even in patients with inactive disease. The elderly, women, and IBM groups are the worst affected, suggesting that developing targeted strategies to minimize functional disability in certain groups may improve patient reported physical function and disease outcomes.

POS0856 DEFINING THE CLINICAL UTILITY OF PET OR PET/CT IN IDIOPATHIC INFLAMMATORY MYOPATHIES: A SYSTEMATIC LITERATURE REVIEW

G. Bentick[1], J. Fairley[1], I. Wicks[1], S. Nadesapillai[2], J. Day[1]. [1]*The Royal Melbourne Hospital, Rheumatology, Parkville, Australia;* [2]*The Royal Melbourne Hospital, Nuclear Medicine, Parkville, Australia*

Background: Positron emission tomography (PET), now often combined with computed tomography (CT), is a well-established tool for evaluating malignancy and inflammatory disease. The idiopathic inflammatory myopathies (IIM) are chronic, multi-system diseases characterised by skeletal muscle inflammation, the potential for extramuscular manifestations such as interstitial lung disease (ILD) and an increased risk of malignancy. PET or PET/CT thus has appeal as an imaging modality that may permit simultaneous assessment of multiple features of IIM, however its role in evaluation of these diseases remains poorly defined.
Objectives: This systematic review seeks to evaluate and describe the utility of PET or PET/CT in IIM, specifically for the detection of inflammatory muscle pathology, associated malignancy and extramuscular manifestations (e.g. ILD).
Methods: We performed a search of Medline and EMBASE from 1990-2021 using keywords related to IIM and PET. We included English language studies of adults with IIM who had PET or PET/CT as part of their diagnostic workup.
Results: Our search identified 910 potentially relevant abstracts, 18 of which were included. The majority of studies used fluorodeoxyglucose (FDG) PET or PET/CT scans, while the remainder used other radiotracers including [18F] florbetapir and [^{11}C] Pittsburgh compound B ([^{11}C] PIB). 1. Malignancy – PET vs. conventional screening Six studies investigated the ability of 18F-FDG PET or 18F-FDG PET/CT to detect malignancy in people with IIM. When reported, the sensitivity and specificity of PET or PET/CT for diagnosing malignancy compared with standard detection methods was 66.7-94% and 88.9-97.8%, respectively. 2.ILD Using high-resolution CT (HRCT) as the gold standard for detection of ILD, three studies reported the ability of PET or PET/CT to detect ILD. The sensitivity of 18F-FDG PET alone for ILD was 39%, while the sensitivity of 18F-FDG PET/CT for ILD was 93-100%. FDG lung uptake was significantly increased in people with rapidly progressive-ILD (RP-ILD) in comparison to those with non-RP-ILD in two studies. 3.Muscle disease activity Ten studies evaluated either 18F-FDG PET or 18F-FDG PET/CT for its ability to detect muscle inflammation in IIM. In the nine studies where controls were used, PET or PET/CT appeared to accurately detect the presence of muscle inflammation, although correlations with clinical measures of myositis disease activity such as strength and serum creatine kinase were mixed. 4.A word on amyloid Skeletal muscle amyloid deposition was evaluated using [11C]PIB-PET in two studies and [18F] florbetapir PET/CT in one study. In all three studies, PET or PET/CT was able to differentiate sporadic inclusion body myositis (IBM) from non-IBM myositis.
Conclusion: PET or PET/CT performs relatively well as a malignancy screening tool for people with IIM in comparison to standard screening methods. While false positives for malignancy on PET can lead to unnecessary invasive investigations, this also occurs with conventional screening. PET/CT also appears to be a beneficial tool for detecting ILD in those with IIM and may predict its severity. While PET/CT may detect skeletal muscle inflammation in IIM, its utility beyond the standard and readily available diagnostic tests for measuring muscle disease activity remains unclear. Early evidence indicates PET-amyloid may be able to subtype IBM from non-IBM myopathic disease, although more data are needed. More research is needed to evaluate whether PET could be used as a tool for detecting cardiac involvement in IIM, or if extending the PET scan field of view might increase the cancer detection yield and permit a more accurate assessment of extramuscular manifestations in IIM. PET/CT holds promise as a single tool that can simultaneously evaluate multiple aspects of IIM early in the diagnostic process. These include screening for associated malignancy in high-risk patients, stratifying higher risk ILD, and providing information on muscle inflammation.

POS0857 PHARMACOKINETICS, SAFETY, AND EFFICACY OF SUBCUTANEOUS BRODALUMAB FOR SYSTEMIC SCLEROSIS WITH MODERATE-TO-SEVERE SKIN THICKENING: A SINGLE-ARM, OPEN-LABEL, MULTI-DOSE, PHASE 1 TRIAL

T. Fukasawa[1], A. Yoshizaki[1], H. Kagebayashi[2], S. Sato[1]. [1]*The University of Tokyo, Graduate School of Medicine, Department of Dermatology, Tokyo, Japan;* [2]*Kyowa Kirin Co., Ltd., Clinical Development, Tokyo, Japan*

Background: Systemic sclerosis (SSc) is a rare autoimmune disease that causes fibrosis of the skin and internal organs. The mechanism of SSc pathogenesis and progression is not clear yet and SSc is therefore a disease with high unmet medical need. Though recent evidence reveals that interleukin-17 (IL-17) may play an essential role in the pathogenesis of multiple autoimmune inflammatory diseases, the role of IL-17 in SSc has not been established.
Objectives: This trial assessed the pharmacokinetics (PK), safety, and efficacy of multiple subcutaneous doses of brodalumab, a fully human anti–IL-17RA monoclonal antibody that inhibits the activity of IL-17A, IL-17C, IL-17F, IL-17A/F, and IL-17E (also called IL 25), in Japanese SSc patients with moderate-to-severe skin thickening.
Methods: In this trial, eligible patients (the modified Rodnan skin score (mRSS):10-29, present with the first symptoms of SSc other than Raynaud's phenomenon within 60 months at enrolment) were enrolled and received subcutaneous brodalumab 210 mg every 2 weeks (Q2W) during the 52-week period. Primary endpoints were PK and safety. Secondary endpoints included change from baseline in mRSS and Composite Response Index in SSc (CRISS) score. Exploratory endpoints included lymphocyte subset testing.
Results: Eligible 8 patients were enrolled. Mean (SD) age was 53.6 (10.6) years. All patients had diffuse cutaneous SSc, total mRSS was 23.1 (5.1) and disease duration was 2.2 (1.9) years. Mean (SD) serum brodalumab trough concentration increased to 21.8 (16.7) μg/mL at week 2 and remained almost constant at week 52. Drug-related treatment-emergent adverse events were observed in three patients: oral candidiasis (n=3), vulvovaginal candidiasis (n=1), and arthralgia (n=1). A rapid decrease in mRSS was observed as early as week 4 (-1.3 vs baseline, $p<0.005$), which continued until week 52 (-10.125 vs baseline, $p<0.0001$). Brodalumab reduced dermal thickness of the lesional skin consistent with the decrease in mRSS. All patients achieved a CRISS score ≥0.6 at week 24, which continued until week 52. Brodalumab induced Th17/Treg balance to Treg dominance over 52 weeks (vs baseline, $p<0.05$). The rapid decrease in the number of immunoglobulin G class-switched memory B cells and plasmablasts (vs baseline, $p<0.01$) was accompanied by an increase in the number of transitional B cells (vs baseline, $p<0.05$) by week 52.
Conclusion: Brodalumab demonstrated a rapid and sustained decrease in mRSS over 52 weeks in Japanese SSc patients with moderate-to-severe skin thickening, which could be attributed to its direct effects on fibroblasts and indirect effects via impacts on B and T cell subsets.

POS0858 NAILFOLD VIDEOCAPILLAROSCOPY FINDINGS AND ASSOCIATIONS WITH ORGAN INVOLVEMENT IN MIXED CONNECTIVE TISSUE DISEASE

G. Boleto[1], C. Kasser[1], Y. Allanore[1], J. Avouac[1]. *[1]Université de Paris, Hôpital Cochin, Rheumatology, Paris, France*

Background: Mixed connective tissue disease (MCTD) is a rare autoimmune condition characterized by Raynaud's phenomenon, positivity of antibodies targeting the U1 small nuclear ribonucleoprotein particle (U1 snRNP), various clinical features and potential risk of severe cardio-pulmonary involvement (interstitial lung disease, ILD, and pulmonary hypertension, PH) (1), (2). Nailfold videocapillaroscopy (NVC) is a simple, non-invasive and inexpensive imaging technique that allows a detailed assessment of skin microcirculation. NVC abnormalities have been barely described in MCTD and associations between NVC features and MCTD disease characteristics have only been partially investigated.

Objectives: To describe the NVC patterns observed in MCTD and assess their potential association with disease characteristics.

Methods: Cross-sectional study based on the retrospective analysis of patients hospitalized in the department of Rheumatology, Cochin Hospital, Paris France. To be included, patients were required to fulfil at least one classification criteria used in MCTD (3). The following data were collected: demographics, clinical features, para-clinical and laboratory data, treatment, and NVC findings.

Results: 51 patients met the inclusion criteria. Mean age was 51±12 years, 44 (86%) were women, mean disease duration was 13.8±11.1 years and 16 patients (31%) had ILD. Three different NVC patterns have been identified in our cohort (Figure 1): A) normal findings in 6 patients (11,7 %); B) non-specific organic microangiopathy in 16 patients (31,4%) and C) scleroderma pattern in 18 patients (35.3%), defined by the presence of at least 3 of the 4 following features: at least 1 giant capillary, decreased capillary density (<7/mm), avascular areas and disorganization of capillary bed architecture (4). Scleroderma pattern was associated with clinical features of systemic sclerosis: skin sclerosis (9/18 vs. 5/33; p=0.008) and digital ulcers (6/18 vs. 2/31; p=0.017). Conversely, no association was observed between the normal or the non-specific NVC pattern and disease specific characteristics.

Interestingly, we observed, a significant reduction in the number of capillaries in patients with ILD (4.80±1.87 vs. 6.03±1.47; p=0.039), and patients with severe reduction of capillary density (≤4/mm) were more likely to have ILD (5/7 vs. 5/33; p=0.002). Neoangiogenesis was also more frequent in patients with ILD (6/13 vs. 4/27; p=0.034). Multivariate logistic regression analysis showed that the association between severe reduction of capillary density and ILD was observed independently of the presence of a scleroderma NVC pattern and skin fibrosis.

Figure 1.

Conclusion: We identified three main NVC patterns in MCTD patients. The scleroderma NVC pattern was associated with clinical scleroderma characteristics whereas non-specific microangiopathy and normal NVC were not associated with a specific phenotype. Moreover, severe capillary loss was independently associated with the presence of ILD. These data suggest that NVC may be helpful for disease risk stratification in MCTD, and that NVC findings, and particularly severe capillary loss, may be a warning for the presence of ILD.

POS0859 C-REACTIVE PROTEIN AND INTERLEUKIN-6: POTENTIAL BIOMARKERS OF DISEASE ACTIVITY AND TREATMENT RESPONSE IN SYSTEMIC SCLEROSIS-INTERSTITIAL LUNG DISEASE

E. Volkmann[1], D. Tashkin[1], H. Wilhalme[1], M. Lyons[2], G. Kim[3], J. Goldin[3], M. Roth[1], S. Assassi[2]. *[1]UCLA, Medicine, Los Angeles, United States of America; [2]UT Houston McGovern Medical School, Medicine, Houston, United States of America; [3]UCLA, Radiology, Los Angeles, United States of America*

Background: Clinically feasible and valid biomarkers of systemic sclerosis-interstitial lung disease (SSc-ILD) are needed. While promising candidate biomarkers are under investigation (e.g., KL-6, CCL-8), clinical assays for these proteins are not currently available. C-reactive protein (CRP) measurements are feasible, cost-effective, and have been shown to predict mortality in SSc.[1] Measuring interleukin (IL)-6, a proinflammatory cytokine implicated in SSc-ILD pathogenesis, is also feasible in most clinical settings.

Objectives: (1) To investigate whether CRP and IL-6 levels change in response to treatment with immunosuppression in SSc-ILD; (2) To explore whether the change in CRP and IL-6 predict the future course of forced vital capacity (FVC).

Methods: CRP and IL-6 levels were measured in serum at baseline and after 12 months in participants of Scleroderma Lung Study (SLS) II (patients with active SSc-ILD receiving 24 months of mycophenolate or 12 months cyclophosphamide followed by 12 months of placebo[2]). Measured values were log-transformed to remove skewness. The FVC%-predicted was measured every 3 months over the course of 24 months. Spearman's correlations evaluated the relationship between baseline CRP or IL-6 measurements and other patient parameters. Paired t-tests were used to compare the change in individual CRP and IL-6 measurements from baseline to 12 months. Linear mixed effects models were used to examine the relationship between the change in CRP and IL-6 (baseline to 12 months) and the subsequent course of the FVC (12 to 24 months). All analysis were performed for the entire cohort and separately by treatment arm.

Results: Of the 142 participants of SLS II, 101 had CRP and IL-6 measurements at baseline and 12 months. Baseline CRP and IL-6 levels correlated significantly with higher modified Rodnan skin score (CRP: r=0.3, P=0.005; IL-6: r=0.2, P=0.01) and shorter disease duration (CRP: r=-0.3, P=0.005; IL-6: r=-0.2, P=0.01) and were higher in patients with diffuse SSc (CRP: P=0.007; IL-6: P=0.01). Relationships to baseline FVC and DLCO were not observed. CRP decreased significantly from baseline to 12 months in the whole group (P=0.01), but the decrease was slightly greater in patients randomized to mycophenolate versus cyclophosphamide (-0.47 vs. -0.33 ug/mL). IL-6 also decreased from baseline to 12 months in the whole group with a trend towards significance (P=0.10) (Figure 1). The mean decrease in IL-6 was again slightly greater in patients randomized to mycophenolate versus cyclophosphamide (-0.31 vs. -0.10 pg/mL). After controlling for baseline FVC and treatment arm in the mixed effects model, there was a relationship between the decrease in CRP from baseline to 12 months and an improved course of FVC 12 to 24 months (Estimate -0.64), but this did not reach significance (P=0.14). However, after controlling for baseline FVC and treatment arm, a greater decrease in IL-6 from baseline to 12

months was significantly associated with a greater improvement in FVC from 12 to 24 months (Estimate -1.28; P=0.01).

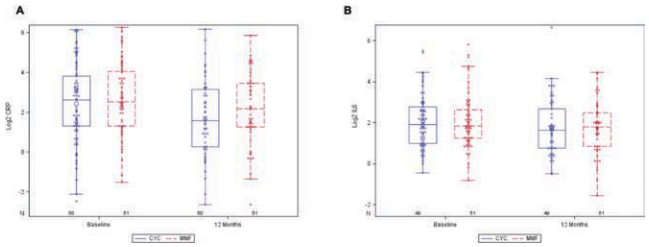

Figure 1. Change in CRP (A) and IL-6 (B) from baseline to 12 months by treatment arm in SLS II. CYC=cyclophosphamide (Blue), MMF=mycophenolate (red)

Conclusion: Patients with active SSc-ILD receiving one year of immunosuppressive therapy in the SLS II study experienced reductions in their CRP and IL-6 levels over this interval. The magnitude of the decrease in CRP and IL-6 over the first year also correlated with the course of FVC over the ensuing 12 months. These findings suggest a dynamic relationship between CRP and IL-6 measurements and the course of SSc-ILD in patients on immunosuppressive therapy. Further investigation of these findings is warranted.

POS0860 ULTRA-HIGH FREQUENCY ULTRASOUND FOR DIGITAL ARTERIES: COMPLETING THE CHARACTERIZATION OF VASCULOPATHY IN SYSTEMIC SCLEROSIS

M. DI Battista[1,2], S. Vitali[3], S. Barsotti[1], R. Morganti[4], V. Dini[5], M. Romanelli[5], A. Della Rossa[1], M. Mosca[1]. *[1]University of Pisa, Rheumatology Unit, Pisa, Italy; [2]University of Siena, Department of Medical Biotechnologies, Siena, Italy; [3]University of Pisa, Radiology Unit, Pisa, Italy; [4]University of Pisa, Section of Statistics, Pisa, Italy; [5]University of Pisa, Dermatology Unit, Pisa, Italy*

Background: Despite microangiopathy is the hallmark of systemic sclerosis (SSc), macrovascular involvement is arousing interest. In particular, proper palmar digital arteries (PPDA) play an important role in Raynaud's phenomenon and can contribute to the exacerbation of vascular damage. However, PPDA full characterization is still an unmet need.

Objectives: To assess the state of PPDA in a cohort of patients with SSc using ultra-high frequency ultrasound (UHFUS), comparing the results with those obtained in healthy controls (HC) and looking for any association with SSc-specific characteristics. Correlations between UHFUS features of PPDA and microvascular bed were also investigated.

Methods: Consecutive SSc patients without active digital ulcers and HC were enrolled. Epidemiological and SSc-specific data were collected. Each subject underwent UHFUS (70 MHz) evaluation of PPDA (2 per finger, from II to V finger bilaterally), searching for occluded or not viewable vessels and measuring the thickness of the three arterial layers, as well as the systo-diastolic excursion range. Finally, microvascular bed was investigated by capillaroscopy and laser speckle contrast analysis (LASCA).

Results: Forty-six SSc patients (87% female, mean age 55.5 years, mean disease duration 8.2 years) and 15 HC matched for age and sex were enrolled. UHFUS in SSc revealed 123 (16.7%) PPDA occluded or not viewable, whereas in HC they were all patent. Considering the finger with at least one of the two PPDA occluded or not viewable as ultrasonographically pathological, 30 (65.2%) patients presented at least one pathological finger (Figure 1). All three arterial layers were significantly thicker in SSc than in HC ($p<0.001$ for all), as well as systo-diastolic excursion range was significantly reduced in SSc ($p<0.001$). On 63 fingers previously affected by digital ulcers, 73% were ultrasonographically pathological. A direct correlation emerged between disease duration and the thickness of all three arterial layers (intima $p<0.001$; $\rho=0.527$; intima-media $p<0.001$; $\rho=0.502$; intima-media-adventitia $p=0.001$; $\rho=0.491$). No significant correlations emerged between capillaroscopy or LASCA findings and UHFUS features.

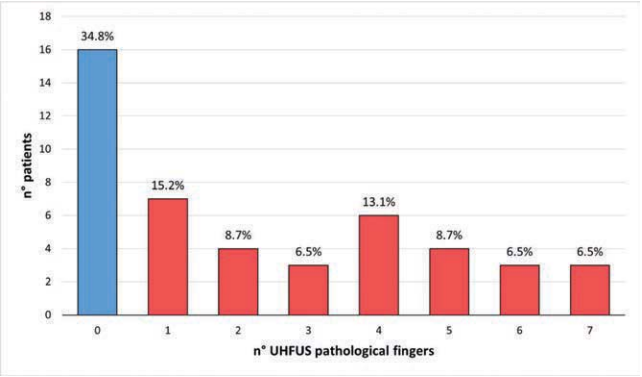

Figure 1. Representation of the number of ultrasonographically pathological fingers per patient.

Conclusion: SSc presents a vasculopathic involvement of PPDA well characterized by UHFUS, a useful diagnostic tool able to show also subclinical vascular impairment. The lack of correlations between UHFUS and capillaroscopy or LASCA reflects the existence of vasculopathic processes that are not exactly the same. Thus, UHFUS evaluation of PPDA emerges as complementary to microcirculation assessment, in order to obtain a more accurate and complete characterization of the vasculopathy in SSc.

POS0861 ANTI-KU ANTIBODY SYNDROME: IS IT A DISTINCT CLINICAL ENTITY? A CLUSTER ANALYSIS OF 75 PATIENTS.

M. Sousa[1], P. Martins[2], B. Santos[3], E. Costa[4], F. Cunha Santos[5], R. Freitas[6], M. Faria[7], F. R. Martins[8], M. Rodrigues[9], T. Santiago[1,10], J. A. P. Da Silva[1,10], L. Inês[1,11]. *[1]Coimbra, Rheumatology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Hospital de Santa Maria, Serviço de Reumatologia e Doenças Ósseas Metabólicas, Lisboa, Portugal; [3]Centro Hospitalar do Baixo Vouga, Serviço de Reumatologia, Aveiro, Portugal; [4]Hospital de Braga, Serviço de Reumatologia, Braga, Portugal; [5]Unidade de Saúde da Guarda, Serviço de Reumatologia, Guarda, Portugal; [6]Hospital Garcia de Orta, Serviço de Reumatologia, Lisboa, Portugal; [7]Hospital Central do Funchal, Serviço de Reumatologia, Funchal, Portugal; [8]Centro Hospitalar do Algarve, Serviço de Reumatologia, Faro, Portugal; [9]Hospitais da Universidade de Coimbra, Serviço de Patologia Clínica, Coimbra, Portugal; [10]University of Coimbra, Faculty of Medicine, Coimbra, Portugal; [11]University of Beira Interior, School of Health Sciences, Covilhã, Portugal*

Background: Anti-Ku antibodies are rare among patients with Connective Tissue Diseases (CTD) (1). Their potential role as a disease biomarker is not well established.

Objectives: To identify subgroups of anti-Ku positive patients according to their spectrum of anti-nuclear antibody (ANA) specificities and analyze their clinical and analytical features.

Methods: Multicenter, cross-sectional study of anti-Ku positive patients, irrespective of their diagnosis, followed at eight Rheumatology outpatient clinics. Patients were spontaneously identified according to the local work-out for suspected autoimmune diseases. Anti-Ku and other ANA specificities were determined at each hospital's Immunology lab according to the local methodology and strategy to decide on which auto-antibodies to check when faced with a positive ANA immunofluorescence. Clinical, analytical and treatment cumulative features were identified following a dedicated structured questionnaire. Hierarchical cluster analysis (method: between-groups linkage, squared Euclidian distance) for ANA specificity variables was performed to identify subgroups.

Results: Seventy-five anti-Ku positive patients were included (female: 73.3%, mean age at diagnosis: 50.5±17.9 years, mean disease duration: 4.7±5.4 years). Their clinical diagnosis were undifferentiated connective tissue disease (UCTD) (21.3%), systemic lupus erythematosus (17.3%), Sjögren's syndrome (16.0%), inflammatory myositis (14.7%), systemic sclerosis (10.7%), overlap CTD syndrome (8.0%), other connective tissue diseases (17.3%), healthy anti-Ku carrier (17.3%). Six autoantibody clusters were identified and included most patients (Figure 1): Cluster 1 - anti-Ku without any other ANA specificities (36.0%); cluster 2 - Anti-nor90 and anti-fibrillarin (8.0%); cluster 3 - anti-Jo1, PL-7, PL-12, and PM-Scl100 (9.3%); cluster 4 - anti-Scl70 (4.0%); cluster 5 - anti-Sm, anti-ribosome, and anti-dsDNA (13.3%); cluster 6 - anti-centromere, Th/To, PM-Scl75 (8.0%). The remaining patients were outliers (21.3%) not fitting in any cluster.

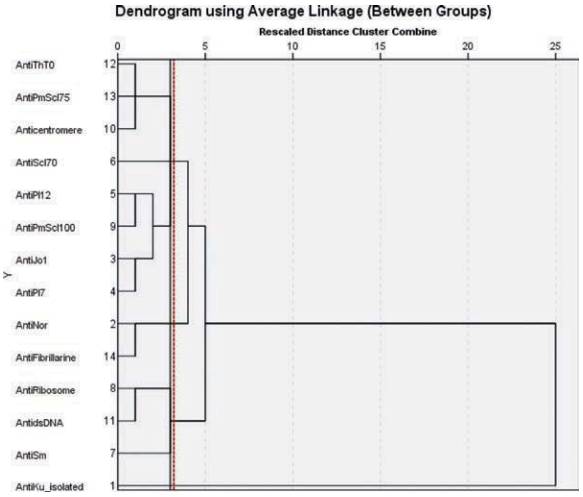

Figure 1. Hierarchical cluster analysis of ANA specificities in anti-Ku+ patients

Detailed clinical analysis of patients in cluster 1, the most numerous, presenting anti-Ku antibodies without any other ANA specificities, the most frequent clinical manifestations were: Raynaud's phenomenon (40.7%), arthritis (25.9%), sicca syndrome (25.9%), myositis (14.8%), and interstitial lung disease (ILD) (14.8%); 25.9% were healthy anti-Ku carriers. Patients from cluster 1 were most frequently treated with low dose glucocorticoids (51.9%), hydroxychloroquine (37.0%), or methotrexate (18.5%). Among the whole study population (n=75), major organ involvement was present in 18.7%, with ILD in 10.7% and renal involvement in 8.0%. None of the patients in cluster 1 presented nephritis.

Conclusion: Anti-Ku positive patients without any other ANA specificities is the largest subset and may represent a distinct entity among the differentiated CTD (2). Patients with this anti-Ku syndrome may develop ILD. In addition, anti-Ku antibodies can be found in patients with a diversity of other ANA specificities and heterogeneous CTD diagnosis.

Background: The idiopathic inflammatory myopathies (IIMs) are a heterogeneous group of diseases that can affect the muscles, skin, lungs, heart, and joints. Increase knowledge about histopathological findings, clinical manifestations and auto-antibodies have allowed further novel classification of IIMs. Today, the main IMs subgroups are: dermatomyositis (DM), inclusion body myositis (IBM), immune-mediated necrotizing myopathies (IMNM), overlap myositis (OM) and immune-checkpoint inhibitor-related myositis (ICIrm). Axial muscle involvement results either in a "Dropped Head Syndrome (DHS)," with a marked weakness of the neck extensors, or in a camptocormia (CC), with a weakness of the thoracolumbar paraspinal muscles. This atypical presentation is poorly described in the course of IMs while it may results in a major disability, and may lead to myositis diagnosis delay.

Objectives: This study aimed to describe IMs revealed by DHS and/or CC. Secondary outcomes were to define subgroups of patients according to clinical, biological and histopathological characteristics. Then, the effects of treatments used were analyzed.

Methods: A historical cohort was designed using the register MYOLYON which includes all IMs followed at the University Hospital of Lyon (France) between 2000 and 2021. All patients with IM revealed by DHS and/or CC and having an histologically proven IMs were included, after exclusion of alternative (e.g., myasthenia gravis, motoneuron disease). Clinical, biological, immunological, histopathological data as well as outcome and care were collected through a standardized form. Agreement for the study was obtained from the French Ministry of the Research and the study was approved by the Local Research Ethics Committee.

Results: Twenty-two patients were fully characterized: DM (n=4), IBM (n=7), OM (n=8), ICIrm (n=2) and one myositis with anti-Hu antibodies. Two groups of patients were identified according to the age at first symptoms and to the type of muscle axial involvement (e.g, DHS and/or CC). Before the age of 70 (n=13/22), the two most common diagnoses (n=11/13) were DM (n=4/4) and OM (n=7/8). Axial muscle involvement was diffuse (DHS and CC) in 10/13 patients. After 70 years old (n=9/22), there were a majority of IBM (n=6/9) and all cases of ICIrm (n=2). Axial involvement was restricted to one group of muscles (DHS or CC) in 5/9 patients. Finally, 77% (17/22) of patients had refractory disease and required a second line treatment (e.g, immunoglobulins). All of these results are summarized in the Figure 1.

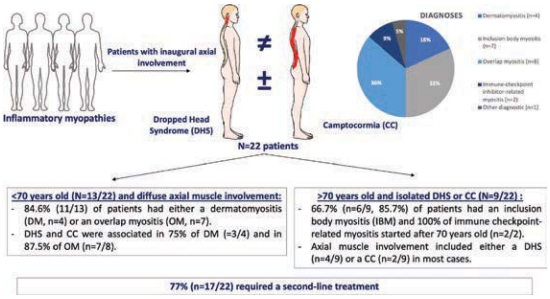

Figure 1.

Conclusion: While IM diagnosis is challenging in the presence of inaugural axial involvement, these results highlight the subset of IM to be considered according to the age at first symptoms and the type of axial involvement (e.g., DHS and/or CC).

Background: Anti-NOR90 antibodies are directed against a 90-kD nucleolar protein located in the nucleolus organizing regions (NORs), mainly described in systemic sclerosis (SSc) [1, 2, 3] but reported also in other rheumatologic and oncologic diseases [4, 5, 6]. The clinical correlates of anti-NOR90 antibodies are still to be defined because the cohorts described thus far include a low number of patients.
Objectives: To describe the characteristics of a large cohort of anti-NOR90 antibodies positive patients and compare them with a matched cohort of SSc patients negative for anti-NOR90 antibodies.
Methods: A retrospective analysis was performed on patients positive for anti-NOR90 antibodies referring to participating centres. The concomitant positivity for anti-RNA polymerase III, Th/To, PM-Scl, Ku, and PDGFR antibodies was an exclusion criterion. In all cases the diagnoses, the different organ involvement and related clinical, instrumental and laboratory characteristics were evaluated. The EUROLINE SystemicSclerosisProfile kit from Euroimmun (Lübeck, Germany) was used to detect anti-NOR90 antibodies.
Results: We included 101 patients positive for anti-NOR90 (M/F=13/88, mean age 52.5 years). They were mainly classified as SSc (n=38), undifferentiated connective tissue disease (UCTD) (n=21), interstitial pneumonia with autoimmune features (IPAF) (n=11) (graph 1). The most frequent clinical manifestations were arthralgias (n=72), Raynaud's phenomenon (RP) (n=58), sicca syndrome (n=49), ILD (n=40), puffy fingers (n=32), arthritis (n=30), and limited skin sclerosis (n=24). Anti-NOR90 antibodies were associated with anti-Ro52 antibodies in the 16% of cases, with anticentromere antibodies in the 7% of cases, and with anti-Scl70 in the 5% of cases. After excluding these patients, and considering the isolated anti-NOR90 positivity, 12 patients had SSc, 35 UCTD, and 11 IPAF. The most frequent clinical manifestations were arthralgias (n=40), RP (n=37), and sicca syndrome (n=21). Compared to 242 matched SSc without anti-NOR90 antibodies, patients with anti-NOR90 had more frequently joint manifestations and sicca syndrome and less frequently all vasculopathic manifestations (RP, telangiectasias, pitting scars, acral ulcers), dysphagia and fibromyalgia.
Conclusion: Our study shows that anti-NOR90 antibodies are more commonly observed in females, and clinically associated with the occurrence of arthritis/arthralgias, sicca syndrome and RP. In more than the 50% of cases they may be found with other autoantibodies, such as the anti-Ro52, the anticentromere, and the anti-Scl70 antibodies. Anti-NOR90 seems to play an accompanying role in the context of CTDs, without strong influence on the clinical phenotype expression of the underlying CTD.

POS0864 ASSESSMENT OF SYSTEMIC SCLEROSIS RELATED MYOCARDIAL FIBROSIS BY 68GA-FAPI-04 PET/CT

C. Treutlein[1], C. Schmidkonz[2], K. Tascilar[3], S. Chenguiti Fakhouri[3], C. Dees[3], A. H. Györfi[3], A. E. Matei[3], T. Baeuerle[1], T. Kuwert[2], M. Uder[1], G. Schett[3], J. H. W. Distler[3], C. Bergmann[3]. *[1]University Hospital Erlangen, Radiology, 91054, Germany; [2]University Hospital Erlangen, Nuclear Medicine, 91054, Germany; [3]University Hospital Erlangen, Internal Medicine III-Rheumatology, 91054, Germany*

Background: Myocardial fibrosis is a poor prognostic factor and a relevant cause of SSc-related mortality. Current non-invasive screening methods for myocardial fibrosis (MF) include echocardiography, electrocardiography and serum Nt-pro-BNP, which are not specific for MF and not sensitive for early changes. Cardiac MRI predominately visualizes extracellular space changes as consequence of long-standing fibroblast activation. Direct visualization of the remodeling fibrotic remodeling process has not been feasible so far.
Objectives: Here, we use a tracer labeled probe directed against Fibroblast-Activation-Protein (FAP) to visualize activated fibroblasts in the myocardium of SSc patients and healthy individuals to test the hypothesis that FAPI-based PET imaging might enable the assessment of disease activity in SSc-related MF.
Methods: In this exploratory trial, 7 patients with SSc-related myocardial fibrosis (MF) confirmed by cardic MRI and 8 SSc patients without myocardial involvement were enrolled. All participants underwent ^{68}Ga-FAPI-04 PET/CT imaging and cardiac MRI as well as echocardiography, electrocardiogram, and serum NT-pro-BNP. Patients were followed for at least 6 months including a follow-up cardiac MRI. Regional mapping of ^{68}Ga-FAPI-04-uptake, late gadolinium enhancement (LGE) and T1-relaxation times were performed according to the American Heart Association 17 regions model. Myocardial tissue was analysed by immunofluorescence- (aSMA and FAP) and Sirius-Red staining.
Results: Myocardial FAPI-04-accumulation was significantly increased in SSc patients with myocardial fibrosis as defined by LGE in MRI compared to SSc patients without LGE. Consistent with the previously reported widespread remodeling in SSc-associated myocardial disease, the distribution of FAPI uptake was observed across multiple areas and did not correspond to the supply areas of the coronary arteries. Histological analyses of myocardial tissue biopsied from a LGE and ^{68}Ga-FAPI-04-positive region revealed the accumulation of FAP+; SMA+ myofibroblasts in regions of pronounced collagen deposition. Slightly increased ^{68}Ga-FAPI-04 -uptake values were observed in SSc patients without LGE, but with cardiovascular risk factors. Comparing ^{68}Ga-FAPI-04-uptake with cardiac MRI based mapping techniques, we observed a partial overlap for certain regions and differences in others. These observations suggest, that ^{68}Ga-FAPI-PET/CT and cMRI could visualize different aspects of the disease process. To confirm that ^{68}Ga-FAPI-04-uptake assesses current molecular fibroblast activity rather than accumulating disease damage, we analyzed associations of ^{68}Ga-FAPI-04-uptake with changes of clinical parameters of SSc-MF on follow-up: Here we observed different dynamics of change of ^{68}Ga-FAPI-04-uptake and cardiac MRI-based, e.g. in response to start of immunosuppressive therapy.
Conclusion: Our study presents first in human evidence on a limited number of patients that FAPI-04-uptake correlates with fibrotic activity in SSc-associated myocardial fibrosis and that ^{68}Ga-FAPI-04-PET/CT may thus improve risk stratification in this population.

POS0865 THE EFFECT OF SILVER FIBER GLOVES ON RAYNAUD'S PHENOMENON IN PATIENTS WITH SYSTEMIC SCLEROSIS: A DOUBLE-BLIND RANDOMIZED CROSS-OVER TRIAL.

S. Liem[1], E. Hoekstra[2], F. Bonte-Mineur[3], C. Magro Checa[4], A. Schouffoer[5], C. Allaart[1], T. Huizinga[2], S. A. Bergstra[2], J. De Vries-Bouwstra[2]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [3]Maasstad Ziekenhuis, Rheumatology and Clinical Immunology, Rotterdam, Netherlands; [4]Zuyderland MC, Rheumatology, Heerlen, Netherlands; [5]Haga Teaching Hospital, Rheumatology, The Hague, Netherlands*

Background: Over 90% of patients with systemic sclerosis (SSc) experience Raynaud's phenomenon (RP), which strongly influences quality of life. Therapeutic options of RP include drug treatment and general lifestyle measures such as smoking cessation and avoiding cold by wearing warm clothes and gloves including electrically heated gloves or silver fiber gloves. Clinical observations suggest an additional benefit of silver fiber gloves compared to normal gloves. Silver is thought to help by reflecting heat back into the hands allowing less heat to escape and has an antimicrobial effect. Despite its generalized use among SSc patients, no objective evidence regarding its superiority for RP over normal gloves exists.
Objectives: To evaluate the added value of 8% silver fiber gloves compared to normal gloves in the treatment of patients with RP secondary to SSc.
Methods: This was a multicenter double-blind randomized cross-over trial in which 85 SSc patients were randomized in two sequences: 8% silver fiber gloves in period 1 and normal gloves in period 2 or vice versa; each period lasted six weeks. To

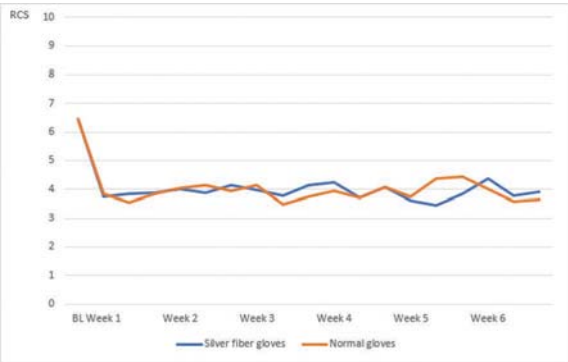
reduce bias of interindividual differences and external factors (e.g. temperature), a cross-over design was performed in the Netherlands during the winter months. The primary outcome was the triweekly Raynaud Condition Score (RCS), a scale from 1 (no symptoms) to 10 (extreme symptoms). A linear mixed model was used with RCS as dependent and type of gloves as independent variable, adjusted for baseline RCS. Secondary outcome measures included number of RP attacks, RP attack duration, Health Assessment Questionnaire (HAQ-DI) and vascular complications. Secondary outcomes were also analyzed with linear mixed models. All analyses were performed and interpreted before unblinding.

Results: The 85 included SSc patients had a mean age of 60 (SD:12), 80% were female, 60% had limited cutaneous SSc and 67% used vasoactive medication. Ten patients prematurely ended the study due to various reasons, most notable: allergic reaction to gloves (n=2). At baseline, mean RCS was 6.43 (SD 1.6), with silver fiber gloves the mean RCS decreased to 3.91 (SD 2.3) and with normal gloves to 3.90 (SD 2.3) (Figure 1). No statistically significant difference in RCS during follow-up was observed between the silver fiber gloves and normal gloves (β 0.067, 95% CI -0.006 to 0.19), meaning that on the 1-10 scale, silver fibre gloves gave only a 0.067 higher RCS compared to normal gloves (Table 1). For all other secondary outcome measures, we did not find a statistically significant difference between silver fiber gloves and normal gloves, except for the HAQ (β 0.036, 95% CI 0.026 to 0.046; Table 1), which is not clinically relevant. One vascular complication occurred in the silver fiber gloves, compared to three vascular in the normal gloves, which was not statistically significant different (OR:3.2, 95% CI 0.32 to 31.1).

Table 1. Primary and secondary efficacy outcomes

	β	95% confidence interval
Primary outcome		
Raynaud Condition Score	0.067	-0.0059; 0.194
Secondary outcomes		
Raynaud attacks frequency	-0.480	-1.215; 0.255
Raynaud attacks duration	39.80	-36.051; 115.654
VAS warmth hands	-0.086	-0.212; 0.041
Impact Raynaud	0.088	-0.035; 0.211
HAQ_DI	0.036	0.026; 0.046

VAS: visual analogue scale; HAQ: Health Assessment QuestionnaireThe reference category was Normal gloves.Linear mixed models were performed with the primary and secondary outcomes as dependent variables, the type of gloves as independent variable, adjusted for baseline Raynaud Condition Score.



RCS: Raynaud Condition Score; BL: Baseline.

Figure 1. Raynaud Condition Score during the study period

Conclusion: This trial shows that wearing any type of glove decreases the RP burden in SSc patients, but no additional benefit from gloves containing 8% silver fibers compared to normal gloves could be demonstrated. Potentially, less vascular complications may arise in SSc patients wearing silver fiber gloves. Further confirmation of this potential benefit is necessary.

Acknowledgements: The authors would like to thank all participants of this study and Skafit for providing the gloves.

POS0866 THE PARAMETERS RELATED TO DECLINE OF LUNG FUNCTION ON RITUXIMAB THERAPY IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS

L. P. Ananyeva[1], L. Garzanova[1], S. Glukhova[1], O. Desinova[1], O. Koneva[1], M. Starovoytova[1], R. Shayakhmetova[1], O. Ovsyannikova[1]on behalf of Laboratory of systemic sclerosis. *[1]V.A.Nasonova Institute of Rheumatology, Department of Systemic Diseases, Moskva, Russian Federation*

Background: Rituximab (RTX) is considered as one of the effective options for the treatment of interstitial lung disease associated with systemic sclerosis (ILD-SSc) [1]. Factors that affect the effect of RTX therapy are not well investigated.
Objectives: To evaluate associations of clinical parameters of the disease with response to RTX therapy in patients with ILD-SSc.
Methods: This prospective study included 102 patients with ILD- SSc, 86 (84%) of them were women. The mean age was 47.6±12.9 years, mean disease duration 6.2±5.5 years. The mean follow-up period was 12.9±2.1 months. The diffuse cutaneous subset of the disease had 55 pts (54%). 69 (68%) pts were positive for antitopoisomerase-1 antibody (anti-Topo-1). All pts received prednisolone at a dose of 11.3±4.5 mg/day. 49 (68%) subjects were exposed to immunosupressants (IS) at baseline. Subjects were categorized as having improvement if baseline forced vital capacity (FVC % predicted) increased by > 5% [2]. Stabilization was defined as a change in FVC of < 5 % and a decrease of > 5% in FVC as worsened ILD-SSc. Out of the 102 patients who started treatment with RTM, 46 pts (45%, group I) fulfilled the improvement criteria during follow-up. A total of 34 patients (33%) stabilized and 21 (20%,, group 2) worsened during follow-up. We compared patients of groups 1 and 2 and performed the statistical analysis, including the linear regression analysis.
Results: For the age, baseline diffusing capacity for carbon monoxide (DLCO % of predicted), anti-Topo-1 level, activity index (EScSG-AI) and mean dose of prednisolone there were no differences (all p > 0.05) between the two groups. There was a significant differences between the different response groups in a higher percentage of men (13% in group 1 vs 27% in group 2), patients with a limited form of the disease (40 vs 55%), an initially lower Rodnan skin score (median 10 (4;16) and 6 (4;9) and with ΔmRss of 0 (-1; 2) and 2 (0; 8), p=0,02), lower frequency of anti-Topo-1 (50 vs. 74%) and a higher frequency of prescribing IS before inclusion in the study (68 vs. 38%). Worsened pts initially had a higher FVC (88.8±18.1 vs 74.1±19.8, p=0.01) and DLCO (53.6±19.3 vs. 46.8±17.2, p>0.05), but received the lowest cumulative mean dose of RTX (1.2±0.5 vs 1.9±0.6, p=0.001). The linear regression analysis revealed a number of parameters associated with worsening of FVC (with a sensitivity of 75% and a specificity of 91%). These parameters included a limited subset of the disease (odds ratio (OR) 6.374, 0.83-48.8, p=0.068), increased activity index (OR 2.04, 0.19-4.18, p=0.046) and the presence of arthritis (OR 1.39, 0.08-23.19, p=0.82) at the end of the study. The risk of worsening of FVC was associated with an initially elevated level of creatine phosphokinase (OR 1.02, 0.1-0.84, p=0.054) and a decrease of glomerular filtration rate according to EPI (OR = 1.075,1.0-1.14, p=0.022). In patients initially receiving IS, the OR was 9.85, 1.154-84.066, p=0.033). The highest OR =19.6 (2.4; 156, p=0.005)] was associated with the cumulative mean dose of RTX.
Conclusion: In this study 45% of the pts improved, one third stabilized, and one fifth worsened over a one-year period. On multivariate analysis, limited scleroderma subsets (dcSSc vs lcSSc), increased activity index, the presence of arthritis at the end of the study, cumulative mean dose of RTX (<2 g per year) were found to be independently associated with the decline of FVC. Identification of this parameters could improve monitoring of rituximab effects

POS0867 COMORBIDITY AND COMPLICATIONS PRIOR TO SYSTEMIC SCLEROSIS DIAGNOSIS: A RETROSPECTIVE COHORT ANALYSIS

D. Khanna[1], D. Furst[2], J. W. Li[3], S. Shah[4], T. Lesperance[5], F. Ali[6], B. Lamoreaux[7], S. Taylor[8]. *[1]University of Michigan Medical Center, Rheumatology, Department of Internal Medicine, Ann Arbor, United States of America; [2]University of California in Los Angeles, Professor Emeritus, Medicine, Los Angeles, United States of America; [3]Trinity Life Sciences, Research, Deerfield, United States of America; [4]Trinity Life Sciences, Research, Waltham, United States of America; [5]Horizon Therapeutics plc, Pharmacoepidemiology & Risk Management, Deerfield, United States of America; [6]Horizon Therapeutics plc, Clinical Development, Deerfield, United States of America; [7]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [8]Horizon Therapeutics plc, Health Economics & Outcomes Research, Deerfield, United States of America*

Background: Systemic sclerosis (SSc) is a rare autoimmune disease characterized by progressive microvascular damage, collagen deposition and subsequent

fibrosis of the skin and internal organs which contributes to substantial morbidity and premature death.[1-2]

Objectives: The objective was to evaluate the disease burden of SSc patients prior to their SSc diagnosis.

Methods: Patients with SSc were identified in a claims dataset (IBM MarketScan Commercial Database, 2015-2019) using ICD 10 diagnosis codes for SSc. Eligible subjects were required to have > 1 inpatient or >2 outpatient/office claims with a scleroderma diagnosis code on separate days and > 24 months of continuous health plan enrollment without a SSc diagnosis before the first SSc claim ('index date') and > 12 months of enrollment after the index date. Overall comorbid disease burden was assessed via the Charlson Comorbidity Index (CCI) 13-24 and 12 months before and 12 months after index date. The prevalence of SSc-related complications for atherosclerosis, pulmonary arterial hypertension (PAH), pulmonary fibrosis (PF), Raynaud's Phenomenon (RP), and gastrointestinal (GI) complications (e.g., GERD, dysphagia, etc.) were identified using ICD codes and reported as percentages for the aforementioned time intervals relative to patients' index dates.

Results: 902 eligible SSc patients were identified for analysis. The mean age at index SSc diagnosis was 54.3 years and 84.7% of patients were female. Mean CCI scores 13-24 months before, 12 months before, and 12 months after index SSc diagnosis were 0.84, 1.13 and 1.30, respectively. From the time points 13-24 months before, 12 months before, and 12 months after index SSc diagnosis, increasing rates were also observed of atherosclerosis, PAH, PF, RP, and GI complications (Table 1).

Table 1. Charlson Comorbidity Index (CCI) and systemic sclerosis-related complications by time-interval

Clinical characteristic	13-24 months before Index	12 months before Index	12 months after Index
Mean CCI (std dev)	0.84 (1.58)	1.13 (1.71)	1.30 (1.75)
Systemic sclerosis-related complications			
Atherosclerosis	7%	9%	14%
Pulmonary arterial hypertension (PAH)	1%	4%	12%
Pulmonary fibrosis (PF)	5%	8%	16%
Raynaud's Phenomenon (RP)	13%	29%	43%
GI complications	23%	32%	46%

Conclusion: Results from this analysis suggests that SSc-related sequalae are present at least two years prior to SSc diagnosis and rates of these complications increased markedly over time. Patients' overall comorbid disease burden also worsened substantially over this period, likely because of these complications. The internal organ involvement is likely under reported due to requirements to link each diagnosis with an ICD-10 code. These data indicate the significant burden of SSc, prior to and after diagnosis, highlighting the need for awareness, prompt diagnosis, and effective therapies for SSc and its related complications.

POS0868

THE DEVELOPMENT OF THE LINEAR CRISS; A CLINICAL AND PATIENT MEANINGFUL ANCHOR TO THE ACR-CRISS IN SCLERODERMA.

L. A. Bissell[1,2], D. Furst[3], S. Johnson[4,5], P. Hansen[6], E. Recalde[7], D. Khanna[8], F. Del Galdo[1,2]on behalf of Linear Criss. *[1]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; [2]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [3]University of California, Department of Rheumatology, Los Angeles, United States of America; [4]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; [5]University Health Network & Sinai Health Systems, Toronto Scleroderma Program, Toronto, Canada; [6]University of Otago, Department of Economics, Otago, New Zealand; [7]World Scleroderma Foundation,., Basel, Switzerland; [8]University of Michigan, Division of Rheumatology/ Department of Internal Medicine, Ann Arbor, United States of America*

Background: The ACR Composite Response Index in Systemic Sclerosis (ACR-CRISS) is one of the first composite outcome measures in diffuse cutaneous Systemic sclerosis (dcSSc).[1] It relies on validated clinical domains selected through a data-driven methodology; however, it only provides a probability of response and is unable to differentiate between patients who do not improve and who worsen respectively.

Objectives: To improve the clinical interpretation of the ACR-CRISS by creating a continuous ranked score of clinically and patient meaningful changes of its individual measures.

Methods: Following OmerACT guidelines for outcome measurement development, relevant stakeholders were identified from 5 continents, including 100 physicians with proven experience in managing patients with dcSSc and 100 patients with dcSSc who have participated in at least one clinical trial. An adaptive conjoint analysis survey based on the PAPRIKA method[2] and implemented using 1000minds software was administered. Patients and doctors were asked to choose which of two hypothetical patients had a better or worse outcome according to Minimally Clinical Important Differences (MCID) in two domains at a time from FVC, HAQ-DI and mRSS and the presence of organ failure. These pairwise choices were analysed to rank and weight the MCIDs against each other. With patient and public involvement, utilising a 'think aloud' approach, a video tutorial was produced explaining the objectives and process of the adaptive survey to the participants.

Results: Eighty rheumatologists and 80 patients with dcSSc completed the survey, which ran from June 2020 to January 2021. From the survey, relative weights for the 4 domains, reflecting their relative importance with respect to improving and worsening outcomes, were determined. A continuous composite ranked score reflecting the relative weighting of the individual outcome measures (Ranked Composite Important Difference, RCID) was developed accordingly (Table 1). The score ranges from -1 (worst possible outcome) to 1 (best possible outcome), in patients who experience no organ failure and do not meet any MCID in any of the 3 domains scoring 0.

Table 1. The relative median weights of each of the core set measures within the better and worse outcome models, expressed as a score from -1 to 1

	Worsening weights			Improvement weights		
	Doctors	Patients	Combined	Doctors	Patients	Combined
Organ failure	-0.355	-0.333	**-0.326**	N/A	N/A	N/A
FVC	-0.324	-0.306	**-0.316**	0.463	0.452	**0.451**
mRSS	-0.205	-0.229	**-0.217**	0.320	0.320	**0.324**
HAQ-DI	-0.114	-0.115	**-0.141**	0.200	0.227	**0.224**

Conclusion: This collaborative process using a novel, robust methodology and involving both rheumatologists and patients has created a clinically and patient meaningful composite score that can be used as an anchor to the ACR-CRISS, or other clinical outcomes. Performance against the ACR-CRISS and revised CRISS in randomised controlled trials and in observational cohorts will determine the clinical value of the RCID.

POS0869

CYTOKINES IN SYSTEMIC SCLEROSIS RELATED INTERSTITIAL LUNG DISEASE AND IDIOPATHIC PULMONARY FIBROSIS

B. Zheng[1,2], K. Keen[2], M. Fritzler[3], C. Ryerson[2], P. Wilcox[2], B. Whalen[4], B. Sahin[4], H. Hou[5], P. Latham[6], M. F. Zhang[5], I. Yao[4], J. Dunne[2]. *[1]McGill University Health Center, Medicine, Montreal, Canada; [2]University of British Columbia, Department of Medicine, Vancouver, Canada; [3]University of Calgary, Department of Medicine, Calgary, Canada; [4]St. Paul's Hospital, Centre for Heart Lung Innovation, Vancouver, Canada; [5]University of Calgary, Mitogen Dx, Calgary, Canada; [6]Eve Technologies, Laboratory Medicine, Calgary, Canada*

Background: Immune pathways have been implicated in both systemic sclerosis (SSc)-related interstitial lung disease (ILD) and idiopathic pulmonary fibrosis (IPF). Determination of blood cytokine differences in these two disorders need to be elucidated to better understand potential biological processes and common pathogenic pathways.

Objectives: This study compared 87 circulating cytokine levels amongst healthy controls and both SSc-ILD and IPF. There was also exploration of the association between cytokine levels and disease progression based on the annualized rate of decline of forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO).

Methods: Levels of 87 plasma cytokines were measured using commercial panels for consecutive SSc-ILD, IPF, and healthy individuals recruited at a Canadian tertiary-care center. Pulmonary function tests were performed as clinically indicated every 3-12 months. Cytokine levels are compared using the Wilcoxon rank sum test for two samples pairwise. The association between differentially expressed cytokines with both percent predicted annualized FVC and DLCO change was assessed within each disease group using multiple linear models adjusted for age, sex, baseline FVC, and immunosuppressive or anti-fibrotic treatment at sampling. Correction for multiplicity of testing was by Holm's method.

Results: There were 19 healthy controls, 40 SSc-ILD, and 17 IPF participants with clinical features shown in Table 1. Eotaxin-1 and interleukin 6 (IL-6) were significantly elevated in both SSc-ILD and IPF compared to healthy controls (Figure 1). SSc-ILD had significantly lower soluble epidermal growth factor receptor (sEGFR) and higher levels of both soluble tumor necrosis factor receptor type II (sTNFRII) and soluble vascular endothelial growth factor receptor-1 (sVEGFR1) compared to healthy controls. IPF cases were distinguished from healthy controls by significantly higher monocyte chemoattractant protein-1 (MCP-1) and monokine induced by gamma interferon (MIG, also known as CXCL9) levels. No significant association was found for any of the cytokines with ILD progression based on annualized rates of either FVC or DLCO change.

Table 1. Baseline patient characteristics stratified by disease groups

	Healthy control (n = 19)	SSc-ILD (n = 40)	IPF (n = 17)
Age, year	51 ± 19	56 ± 12	73 ± 7
Male, count (%)	6 (32)	12 (30)	12 (71)
Disease duration, year	NA	6.41 (7.81)	1.76 (2.14)
Ever smoker, count (%)	2 (11)	19 (48)	14 (82)
• 4 (82)oker	0.4 [0, 1]	11 [4, 29]	19 [11, 35]
Treatment presence, count (%)	NA	16 (40)	7 (41)
Baseline FVC %	NA	80 ± 22	85 ± 21
Baseline DLCO %	NA	51 ± 17	49 ± 11
Annualized FVC % change	NA	-1.7 ± 8.2	-6.2 ± 13.6
Annualized DLCO % change	NA	-0.5 ± 6.2	-7.8 ± 18.6

The number (%), mean ± standard deviation, and median [interquartile range] are shown. Disease duration is defined as time of ILD first seen on HRCT in IPF and time from first non-Raynaud's phenomenon in SSc-ILD. Treatment includes presence of ILD therapies: nintedanib, pirfenidone, mycophenolate mofetil, azathioprine, rituximab. FVC = forced vital capacity, DLCO = diffusing capacity for carbon monoxide

Conclusion: Differences in seven circulating cytokines between healthy controls with both SSc-ILD and IPF show evidence of systemic cytokine activation. All seven cytokines have a role in immune cell extravasation and pro-fibrotic signaling, which provides further evidence of immune pathways involved in pulmonary fibrosis. Further studies will be pursued of longitudinal change of these biomarkers for halting or slowing disease progression and improving response to treatment.

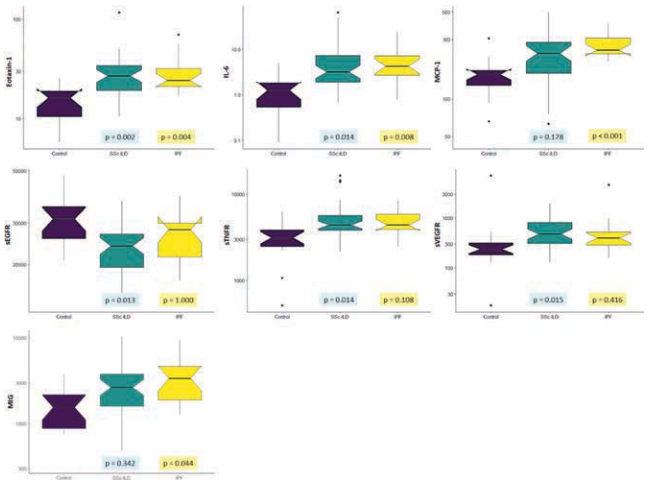

Figure 1. Notched box plots of cytokine differences between disease groups. All cytokine levels are shown on a log scale. Overlap of notches indicates lack of a statistically significant difference in medians in a pairwise comparison. P-values are for SSc-ILD or IPF compared to healthy controls using Wilcoxon rank sum two-sample test corrected for multiple testing using Holms method.

POS0870

PATIENTS WITH SYSTEMIC SCLEROSIS HAVE IMPAIRED FORCED VITAL CAPACITY, EVEN IN THE ABSENCE OF INTERSTITIAL LUNG DISEASE

H. Fretheim[1], I. Barua[1], Ø. Midtvedt[1], T. Garen[1], P. P. Diep[2], M. Durheim[3], C. Brunborg[4], A. M. Hoffmann-Vold[1]on behalf of Nor- FIORD. *[1]Oslo University Hospital, Department of Rheumatology, Oslo, Norway; [2]Oslo University Hospital, Department of Respiratory Medicine, Oslo, Norway; [2]Oslo University Hospital, Department of Respiratory Medicine, Oslo, Norway; [4]Oslo University Hospital, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway*

Background: Spirometry, in particular forced vital capacity (FVC), is a widely implemented tool in the initial diagnostic workup and monitoring of systemic sclerosis-related interstitial lung disease (SSc-ILD). In addition to ILD, several other extra-pulmonary complications can affect pulmonary function. There is currently limited data on lung function in SSc patients with and without ILD compared to a healthy reference population.

Objectives: To compare forced vital capacity (FVC) of a well-defined SSc patient cohort with and without ILD to multi-ethnic reference values provided by the European Respiratory Society (ERS) global lung function initiative (1).

Methods: SSc patients from the Oslo University hospital SSc cohort with at least one PFT were included. We registered each patient's first available FVC value and a follow-up FVC at 12 +/- 3 months if available. We registered clinical characteristics including sex, age, height, the extent of skin changes, and presence of ILD assessed on HRCT. Predicted FVC values from the reference population were calculated using the GLI 2012 equation (1), including age, height and ethnicity. Descriptive statistics were applied.

Results: In total, 404 SSc patients were included; of these 58 (14%) patients were anti-Scl 70-antibody positive, 61 (15%) were male, 155 (38%) had ILD and 93 (23%) had diffuse cutaneous SSc (dcSSc). At baseline, mean age was 55.8 (SD 14.0) years, and mean time from first non-Raynaud symptom was 35 (53.2) months. A follow-up spirometry at 12 +/-3 months was available in 164 (41%) patients. Mean FVC was 0.48 L lower at baseline compared to the reference population. At 12 +/-3 months the SSc cohorts mean FVC was 0.39 L lower compared to the reference group (Table 1). The low FVC values at baseline were most pronounced in patients with ILD (0.87L), in male patients (0.86L) and in anti—Scl 70 positive patients (0.67L). But SSc patients with no ILD showed also impaired FVC compared to the reference population (0.24L), even more pronounced when they had dcSSc (0.34L) (Table 1).

Conclusion: Mean FVC at baseline was significantly lower in SSc patients compared to the reference population. As expected, SSc patients with ILD had impaired FVC, but also patients without ILD and in patients with limited skin

Table 1.

	The Oslo SSc cohort	Matched controls	Difference in L (95% CI)	P-value
Baseline				
FVC (n=404), L (SD)	3.14 (0.86)	3.62 (1.13)	-0.48 (-0.59, -0.37)	<0.001

POS0871 DIAGNOSTIC ACCURACY OF POWER DOPPLER ULTRASONOGRAPHY FOR THE DIAGNOSIS OF IDIOPATHIC INFLAMMATORY MYOPATHIES.

E. Conticini[1], P. Falsetti[1], M. D'alessandro[2], S. Grazzini[1], C. Baldi[1], M. Bardelli[1], S. Gentileschi[1], F. Bellisai[1], G. Biasi[1], R. D'alessandro[1], E. Garcia Gonzales[1], N. Volpi[3], M. A. Mazzei[4], E. Bargagli[2], L. Cantarini[1], B. Frediani[1]. *[1]University of Siena, Rheumatology Unit, Siena, Italy; [2]University of Siena, Respiratory Diseases and Lung Transplantation Unit, Siena, Italy; [3]University of Siena, Neurology Unit, Siena, Italy; [4]University of Siena, Diagnostic Imaging Unit, Siena, Italy*

Background: No clear-cut guidelines exist about the use of imaging procedures for the diagnosis of idiopathic inflammatory myopathies (IIM). Similarly, conflicting, and scanty data exist about Power Doppler Ultrasonography (PDUS) in this subset of patients. In this regard, we recently proposed (1) a 0-3 grey scale (GS) and Power Doppler (PD) score in a cohort of patients affected by IIM, evidencing a positive, statistically significant, correlation for PD and oedema and disease activity.

Objectives: The aim of this study was to assess the diagnostic accuracy of our score in IIM patients compared to a control group.

Methods: We prospectively collected, since July 2020 to December 2021, all patients evaluated in Vasculitis and Myositis clinic, Rheumatology Unit, University of Siena, with a recent diagnosis of IIM, as well as patients with a previous, definite diagnosis of IIM and evaluated during follow-up or referred from other centres for a second opinion. As control group, we collected all patients affected by amyopathic dermatomyositis (DM) or who underwent myositis immunoblot or muscle biopsy for proximal limbs weakness but eventually received a diagnosis other than IIM. All patients underwent US examination of both thighs in axial and longitudinal scans.

Results: Forty-five IIM patients (11 anti-synthetase syndrome, 20 DM, 12 PM, 2 scleromyositis) and twenty-six controls were included. During the observational period, 7, 8, 1 and 1 patients underwent PDUS twice, three, four and five times, respectively

Assessing area under the receiver operating characteristic (AUROC) curve analysis, IIM patients and control group were distinguished according to PD sum, Oedema sum, atrophy sum and CRP values (Figure 1a). The best cut-off value for PD sum values was 0.5 (70.2% SE and 83.3% SP), for Oedema sum 1.5 (74.5% SE and 79.2% SP), atrophy sum 0.5 (63.4% SE and 65.4% SP) and CRP was 0.22 mg/dL (61.5% SE and 75% SP).

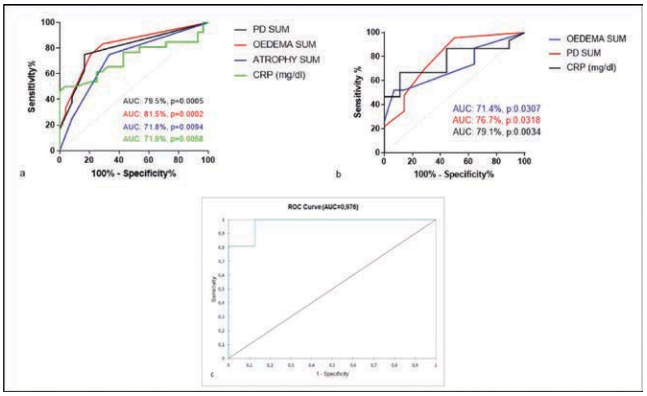

Figure 1.

Stratifying IIM population into two groups according to disease activity (PhGA≥2), AUROC curve analysis allow to distinguish these groups according to PD and oedema sum and CRP values (Figure 1b) and the best cut-off values was 1.5 (69.6% SE and 76.9% SP), 2.5 (52.2% SE and 92.3% SP) and 0.55 mg/dL (66.7% SE and 88.9% SP), respectively.

Testing the IIM group versus control as dependent variable by logistic regression, with PD sum, oedema sum, atrophy sum, CRP, CPK and myoglobin as independent variables, the AUROC was 0.976. From the probability associated with the Chi-square tests, the Type II analysis showed the variable that most influences the IIM diagnosis was PD sum and oedema sum (p=0.017 and p=0.013, respectively) (Figure 1c).

Conclusion: GS and PDUS have proven an overall good diagnostic accuracy in distinguishing between IIM and myositis mimicker. In particular, even low values of PD (sum 1.5) display a good sensitivity and specificity and, together with oedema, elevated CRP values and myositis-specific and associated antibodies, may be considered a reliable tool for a definite diagnosis of IIM.

POS0872 SERUM LEVEL OF SOLUBLE INTERLEUKIN-2 RECEPTOR IS LINKED TO BETA2-MICROGLOBULINE, NT-PRO BNP AND HIGH-SENSITIVITY TROPONIN T AND MAY HELP TO IDENTIFY PATIENTS WITH EARLY CLINICAL PROGRESS IN SSC.

L. Schumacher[1,2], S. Klapa[1], A. Müller[1], G. Riemekasten[1]. *[1]Universitätsklinikum Schleswig-Holstein, Campus Lübeck, Rheumatology & Clinical Immunology, Lübeck, Germany; [2]University of Lübeck, Medical Faculty, Lübeck, Germany*

Background: Systemic sclerosis (SSc) is characterized by chronic inflammation that leads to damage of the vascular endothelium and excessive collagen deposition in several target organs (1). The interaction of interleukin 2 (IL-2) with the corresponding receptor (IL-2R) is involved in the regulation of autoimmune processes (2). The shedding product of the IL-2R alpha chain, soluble IL-2 receptor (sIL-2R, CD25), is able to either reduce or enhance immune responses (2). Previously, elevated serum levels of sIL-2R were found in the bronchoalveolar lavage of SSc patients with interstitial lung disease (SSc-ILD) as well as serologically in patients with early SSc, and thus suggested to be a biomarker for clinical development of SSc (3,4).
Objectives: To examine concentrations of sIL-2 in patients with SSc and analyse their association with clinical and serological parameters.
Methods: To determine if serological levels of sIL-2R serve as predictor of clinical complications in SSc, sera were analysed [limited cutaneous SSc (lcSSc) n=160; diffuse cutaneous SSc (dSSc), n=137] using a sandwich ELISA. Clinical data (pulmonary fibrosis, PAH, mRSS, therapy) and serological markers (hs-CRP, NT-pro BNP, neutrophil counts, creatinine, hs-troponin T, creatinine kinase, beta2-microglobuline) were assessed at the time of serum sampling and up to 48 months after baseline. Clinical progress was defined by the need to change therapies.
Results: Patients with dSSc presented elevated levels of sIL-2R compared to SSc (dSSc: 673±428 U/ml vs. 646±473 U/ml, p=0.0001). In SSc general, sIL-2R levels correlated with beta2-microglobuline (r=0.6161, p<0.0001, ROC-AUC:0.8428), hs-CRP (r=0.4091, p<0.0001, ROC-AUC:0.7110), NT-proBNP (r=0.2610, p<0.0001, ROC-AUC:0.6793), neutrophil count (r=0.2749, p<0.0001) and hs-troponin T (r=0.4548, p<0.0001, ROC-AUC:0.8729). Further, sIL-2R levels discriminated normal from pathological levels of hs-troponin T (sensitivity 80.0%, specificity 80.1%). Using Log-rank test and Mantel-Cox proportional hazard models, we found that sIL-2R levels above 745.5 U/ml predicted early clinical progress in SSc (HR: 3.45, p=0.0070, Figure 1) within 12 months.

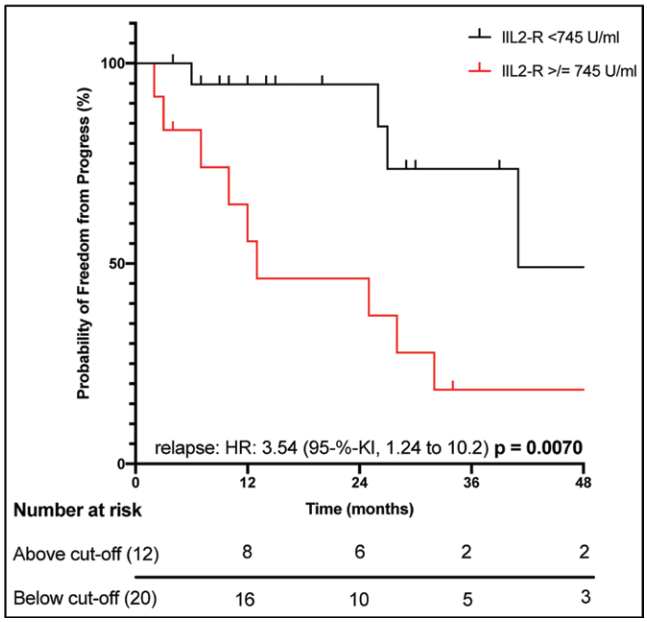

Figure 1. Kaplan-Meier survival analysis for the complete group of patients with SSc. Soluble Il-2R levels above 745U/ml were associated with early progress in SSc.

Conclusion: In SSc, serum levels of sIL-2R could be of diagnostic value by identifying clinical progress. Its role in pathophysiology, especially with regard to disease manifestations such as cardiac involvement needs to be investigated in more detail.

Background: Systemic sclerosis (SSc) is a heterogeneous autoimmune disease, with a high disease-related mortality and morbidity. A subset of patients show elevated CRP levels (20-35%), which has been reported as inflammatory SSc. Preliminary data suggest that this subset is characterized by a severe phenotype.
Objectives: To analyse the phenotype and the survival of inflammatory compared with non-inflammatory SSc patient subsets.
Methods: Data from 8571 SSc patients with available CRP measurement from the EUSTAR cohort were analysed. Exclusion criteria included acute infection, missing follow-up and tocilizumab treatment. Patients with a CRP ≥5mg/l at ≥80% of visits were stratified as persistent inflammatory and as non-inflammatory if CRP was ≥5 mg/l at <20% of visits (as described previously (1)). As a sensitivity analysis, patients were defined as inflammatory and non-inflammatory based on a single CRP measurement at baseline only (CRP ≥5 or <5mg/l, respectively). We compared baseline characteristics using Chi-square and non-parametric Kruskal–Wallis tests as appropriate. Kaplan Meier curves with log-rank tests were used to estimate time from baseline to death or censoring, and Cox regression to compare mortality risks adjusted for time from diagnosis to baseline.
Results: Out of 2883 patients with more than two visits, 404 (14%) showed persistent inflammation and 1032 (36%) a non-inflammatory phenotype. Out of 5619 patients with more than one visit, 1830 (33%) were stratified as inflammatory as defined by as single CRP measurement at baseline and 3789 (67%) as non-inflammatory. With both definitions, the inflammatory subset revealed a more severe phenotype than non-inflammatory patients, including more frequent diffuse-cutaneous disease, anti-Scl-70 autoantibodies, pulmonary fibrosis, pulmonary hypertension, higher modified Rodnan skin score, and lower forced vital capacity and diffusing capacity for carbon monoxide. Patients with persistent inflammation had a strongly increased risk of all-cause mortality (HR 7.1 [95%CI 3.7 to 13.5], p<0.001) compared to non-inflammatory patients, whereas this association was weaker when based on a single CRP measurement (HR 2.6 [95%CI 2.1 to 3.2], p<0.001).
Conclusion: The severe phenotype and decreased survival of the inflammatory SSc subset, which was most prominent in patients with persistently elevated CRP levels, suggest a distinct disease subset. Therefore both, the need for more regular monitoring of inflammatory parameters and implications for immune-modulating treatment, needs to be carefully analysed.

Background: The use of glucocorticoids (GC) in systemic sclerosis (SSc) is controversial (1). Despite the lack of solid evidence about their efficacy in SSc, GC are prescribed to control musculoskeletal symptoms, or in combination with immunosuppressive drugs (1). The extent of GC use over the disease course has been poorly investigated in SSc. As long-term GC exposure is detrimental even at low doses, estimating the use of GC and identifying patients at high risk for long-term utilization is crucial to plan better management of SSc patients.
Objectives: To estimate the prevalence of GC use in a large sample of SSc patients, identify patient characteristics associated with time spent on GC, and describe the variations in GC utilization over time and across main recruiting countries.
Methods: We included SSc patients with at least one visit in the EUSTAR database from January 2013 (defined as baseline visit) to November 2019. We analyzed the prevalence and the main features of patients using GC at baseline, and the exposure to GC over time. Multivariable linear regression analysis identified patient characteristics associated with the proportion of follow-up time spent on GC. Time trends and variations in GC utilization across main recruiting countries were explored. Missing data were imputed using multiple imputation with chained equations.
Results: The 9819 patients included were mostly females (85%), with limited cutaneous (lc) SSc (73%), and median age of 58 years. At baseline, 2769 (34%) patients (48% diffuse cutaneous (dc) SSc vs. 29% lcSSc) were on GC, at a median dose 7.5 mg/day [IQR 5-9 mg]. Only 2% of patients (n = 162) received >15 mg/day prednisone equivalent. GC were mostly used in combination with an immunosuppressive drug, mainly methotrexate (29%), cyclophosphamide (21%), and mycophenolate mofetil (21%). Compared to patients not receiving GC at baseline, GC users were more frequently males (18% vs. 14%), anti-Scl70 positive (42% vs. 27%), had more synovitis (21% vs. 8%), pericardial effusion (9% vs. 5%), C-reactive protein elevation (33% vs. 19%), increased CK (12% vs. 8%), and significantly lower respiratory volumes. In the subgroup of patients with an early disease duration (< 3 years from first non-Raynaud's onset) (n = 1896), the prevalence of GC users was similar to that observed in the entire sample, but more dcSSc patients were receiving GC in combination with immunosuppressors. On average, GC users spent 25% of their follow-up time (median 33.2 months) on GC, with no significant difference between lcSSc and dcSSc patients. Notably, 971 (33%) and 647 (22%) patients followed-up for >1 year received GC for >6 or >12 months, respectively. In multivariable analysis, patient characteristics poorly explained the variability of GC exposure (adjusted-R^2 = 0.062, P < 0.001). The yearly proportion of glucocorticoids users (2013 - 2018) gradually decreased over time (36% in 2013 vs. 23% in 2018). The rate of GC users and the median proportion of follow-up time spent on GC was highly heterogeneous within and across countries.
Conclusion: GC are widely and long-term used in SSc, mainly to patients with dcSSc, with significant between- and within-country(ies) differences. A gradual decrease in their utilization over time is observed.

POS0875 LATENT TRAJECTORY MODELING OF PULMONARY ARTERY PRESSURE IN SYSTEMIC SCLEROSIS: A RETROSPECTIVE COHORT STUDY

T. Kida[1,2], K. Matsuzaki[3], I. Yokota[4], N. Kawase[5], K. Masatoshi[5], H. Inoue[6], K. Yuji[6], S. Kaneshita[2,7], T. Inoue[2,7], M. Wada[2], M. Kohno[2], Y. Kawahito[2],

T. Iwami[1]. *[1]Kyoto University School of Public Health, Department of Preventive Services, Kyoto, Japan; [2]Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Inflammation and Immunology, Kyoto, Japan; [3]Kyoto University, Agency for Health, Safety and Environment, Kyoto, Japan; [4]Graduate School of Medicine, Hokkaido University, Department of Biostatistics, Sapporo, Japan; [5]Japanese Red Cross Society Kyoto Daiichi Hospital, Center for Rheumatic Disease, Kyoto, Japan; [6]Japanese Red Cross Society Kyoto Daini Hospital, Department of Rheumatology, Kyoto, Japan; [7]Fukuchiyama Municipal Hospital, Department of Rheumatology, Fukuchiyama, Japan*

Background: Systemic sclerosis (SSc) is an autoimmune disease that is characterized by systemic vasculopathy and fibrosis. Pulmonary hypertension (PH), defined as elevated pulmonary arterial pressure (PAP), is one of the leading causes of death of SSc[1]. In recent years, various therapies have been developed to target each of the pathogenesis of SSc – autoimmunity, vasculopathy, and fibrosis. Accordingly, treatment strategies based on risk stratification for PH progression are aspired; however, prediction of changes in PAP in diverse patients with SSc has not been established[2].

Objectives: To visualize the patterns of PAP elevation in SSc and to identify the clinical characteristics of each trajectory, by applying latent trajectory modeling for PAP measured repeatedly by echocardiography.

Methods: This was a multicenter, retrospective cohort study conducted at four referral hospitals in Kyoto, Japan. Patients with SSc who visited the study site between April 2008 and March 2021 and had at least three echocardiographic measurements of systolic pulmonary arterial pressure (sPAP) were included in this study. Follow-up concluded in March 2021. A group-based trajectory model[3] was applied to the change in sPAP over time, and individual patients were classified into distinct subgroups that followed similar trajectories. The number and shape of the trajectories were estimated based on adequacy, goodness of fit, parsimony, and interpretability of the model. Clinical plausibility was assessed by comparing PH-free survival, i.e., time to either PH or death, for each trajectory. Multinomial logistic regression analysis was performed for baseline clinical characteristics associated with trajectory assignment.

Results: A total of 236 patients with a total of 1097 sPAP measurements were included. We identified five trajectories following the quadratic function as "rapid progression (n=9, 3.8%)", "early elevation (n=30, 12.7%)", "mid elevation (n=54, 22.9%)", "late elevation (n=24, 10.2%)", and "low stable (n=119, 50.4%)". Each trajectory, in this order, showed earlier elevation of sPAP and shorter PH-free survival (Figure 1). In the multinomial logistic regression (with the "low stable" as reference), cardiac involvement was associated with the "rapid progression" (adjusted odds ratio [OR] 28.9, 95% confidence interval [CI] 3.21–259.5), diffuse cutaneous SSc was associated with the "early elevation" (OR 4.08, 95% CI 1.27–13.1), anti-centromere antibody positive was associated with the "mid elevation" (OR 4.50, 95% CI 1.11–18.2), and older age of onset was associated with the above three trajectories.

Conclusion: The pattern of changes in pulmonary artery pressure over time in SSc can be classified into five distinct trajectories. Each trajectory differed in baseline clinical characteristics and outcomes.

Background: Hand involvement is a major cause of disability in systemic sclerosis (SSc) patients. Loss of hand function is the result of a complex and overlapping series of manifestations including Raynaud's, cutaneous ulcerations as well as skin fibrosis, joint inflammation, and contractures. The natural history of hand involvement in SSc and potential biomarkers to predict its outcome are still poorly defined. Type 1 Interferon (IFN) activation has been extensively correlated with skin fibrosis, joint disease activity, vascular manifestations, and poor prognosis in SSc patients.

Objectives: To characterize hand disability burden in SSc and explore its relationship with IFN activation in a national, multicenter, longitudinal, observational cohort of patients with SSc.

Methods: The Cochin Hand Function Scale (CHFS) was assessed in consecutively enrolled SSc patients at baseline and after 12 months. CHFS values above the patient acceptable symptom state (PASS)(CHFS>25)[1] were considered as clinically meaningful hand impairment (CMHI). Minimal clinically important difference (MCID) in CHFS for improvement (reduction of 13.1%) and worsening (increase >24.6%) were assessed in longitudinal analysis. Serum IFN score was evaluated as previously described[2].

Results: A total of 397 SSc patients from 10 centers (female 85.3%, aged 54.9±11.5 years, white Caucasian 88.2%) were available for longitudinal (12m) analysis. The median disease duration was 9 (IQR 3-16) years, 37.1% of patients had a diffuse cutaneous variant, while anticentromere (ACA) and anti-Scl70 antibody positivity was reported in 41.2% and 33.5% of cases, respectively. Hand digital ulcers, forearm-hand-finger skin score ≥6, and tenosynovitis/arthritis were clinically reported in 24.0%, 15.3%, and 17.9% of patients, respectively. 37.3% of patients reported a CHFS > PASS at baseline. CMHI was associated with male gender (p<.001), diffuse cutaneous variant (p<.001), anti Scl70 positivity (p<.001), ACA negativity (p=.002), and digital ulcers (p=.001). Patients with CMHI had greater serum IFN score than patients with CHFS < PASS (p=.002). In multivariate logistic regression analysis, high serum IFN score remained associated with CHFS>PASS when adjusted for male gender, ACA positivity, anti-Scl70 positive, diffuse subset, and current digital ulcers (OR 2.67, p=.005). Over the 12-month follow-up, vasoactive and immunosuppressive treatment were escalated or introduced in 7.2 and 7.8% of patients, respectively. Median CHFS worsened over time (from 18 (IQR 5-37) to 21 (IQR 6-37), p=.002)) with 32.5% of patients having a clinically meaningful worsening and 32.0% improving their hand function. Functional hand worsening was associated with lower baseline CHFS (p=.001) and ACA negativity (p=.002), while improving with female gender (p=.047), limited cutaneous subset (p=.029), higher baseline CHFS (p=.001), and active baseline tenosynovitis (p=.014).

Conclusion: One third of the patients within our cohort complain of a significant hand impairment. This is associated with higher IFN activation and worsens at group level in patients despite standard of care treatment.

POS0877 INTERSTITIAL LUNG DISEASE IN ANTI-U1RNP SYSTEMIC SCLEROSIS PATIENTS: A EUROPEAN SCLERODERMA TRIALS AND RESEARCH (EUSTAR) ANALYSIS

G. Boleto[1], C. Campochiaro[2], A. M. Hoffmann-Vold[3], A. Gabrielli[4], O. Distler[5], J. Avouac[1,6], Y. Allanore[1,6]on behalf of European Scleroderma Trials and Research (EUSTAR). *[1]Université de Paris, Hôpital Cochin, Rheumatology, Paris, France; [2]Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UNIRAR), Milan, Italy; [3]Oslo University Hospital, Rheumatology, Oslo, Norway; [4]Università Politecnica delle Marche, Dipartimento di Scienze Cliniche e Molecolari, Ancona, Italy; [5]University Hospital Zurich, University of Zurich, Rheumatology, Zurich, Switzerland; [6]Institut Cochin, CNRS UMR8104, INSERM U1016, Paris, France*

Background: Interstitial lung disease (ILD) has become the leading cause of mortality in systemic sclerosis (SSc) patients (1). The presence of anti-U1RNP antibodies is primarily associated with mixed connective tissue disease (MCTD), however these autoantibodies may be found in up to 10% of SSc patients (2). A recent large multicenter study showed that the presence of anti-U1RNP antibodies was independently associated with more severe disease in SSc patients. However, so far, little is known about the influence of anti-U1RNP antibodies specifically on lung outcomes in SSc-ILD patients.
Objectives: To describe the clinical features, outcomes and prognosis of anti-U1RNP SSc-ILD patients.
Methods: SSc patients with available data on their autoantibody profile were identified from the EUSTAR database. Those with ILD identified by high-resolution chest tomography (HRCT) were included for analysis. Baseline demographic and disease features were compared between anti-U1RNP positive and anti-U1RNP negative patients. For the longitudinal part in patients with repeated lung function tests, the mean annual decline in %predicted forced vital capacity (%pFVC) was compared between the two groups. Predictors associated with death of any cause or severe ILD progression, defined as a drop >10% in %pFVC/year, were evaluated in SSc-ILD patients with or without U1RNP. Mild progression was defined as a loss of 5-10% in %pFVC/year. Demographic and clinical parameters were compared between patients positive and negative for anti-U1RNP antibodies in univariate analysis. Associations between anti-U1RNP status and lung involvement were tested in multivariate logistic regression models.
Results: A total of 5676 SSc-ILD patients were included for the analysis, among which 320 (5.6%) were positive for anti-U1RNP antibodies. Mean age was 56.4±13.5 years and 4645 (81.8%) were women. Anti-U1RNP+ SSc-ILD patients had more frequently limited cutaneous SSc (52.5% vs 39.8%, p<0.001), higher frequency of joint synovitis (20.0% vs 12.9%, p<0.001) and myositis (22.2% vs 18.2%, p<0.03) and lower incidence of scleroderma renal crisis (0.3% vs 2.0%, p=0.02). Anti-U1RNP+ patients had a baseline lower mean %pFVC (81.1% vs 85.3%, p=0.002) and lower mean %predicted diffusing capacity for carbon monoxide (%pDLCO) (58.9% vs 60.2%, p=0.004) than anti-U1RNP- SSc-ILD patients. No significant differences were found at baseline HRCT, including lung involvement >20% (4.4 vs 4.2%%, p=0.39), or the presence of ground glass opacities (38.1% vs 33.6%, p=0.14).A total of 2697 (50.3%) patients with SSc-ILD had at least one FVC measurement available during a mean follow-up of 20.8±20.5 months. Mean expected decline in %FVC per year was not different between U1RNP positive and negative patients (-0.21% vs -0.68%, p=0.70). Mortality or severe ILD progression was not statistically different between the two groups (35 (21.6%) vs 677 deaths (26.7%), p=0.43, and 23 (14.0%) vs 283 severe progressors (11.0%), p=0.25, respectively). Mild ILD progression was also not statistically different between the two groups (11.0% vs 10.0%, p=0.20). The proportion of patients with FVC<80% at last follow-up was similar between U1RNP positive and negative patients (50.6% vs 44.3%, p=0.13).
Conclusion: Our results from the EUSTAR database show that SSc patients positive for anti-U1RNP antibodies have more impaired baseline lung function but similar rate of progression during follow-up. This suggests that early stages might be important in RNP+ SSc-ILD patients who may require specific management and follow-up.

POS0878 ASSOCIATION OF A LOWER BODY-MASS INDEX WITH THE PRESENCE OF ILD IN SSC PATIENTS – A DERIVATION PREDICTION STUDY USING DECISION TREE-BASED ALGORITHMS

A. Garaiman[1], C. Mihai[1], R. Dobrota[1], C. Bruni[1,2], M. Elhai[1], S. Jordan[1], L. Stamm[1], A. M. Hoffmann-Vold[3], O. Distler[1], M. O. Becker[1]. *[1]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland; [2]University of Florence, Scleroderma Unit, AOUC,, Department of Experimental and Clinical Medicine, Division of Rheumatology,, Florence, Italy; [3]Oslo University Hospital, Department of Rheumatology, Oslo, Norway*

Background: Upper-gastrointestinal involvement (GI) is associated with more severe interstitial lung disease in patients with systemic sclerosis (SSc-ILD). However, there are many unexplored GI risk factors for the presence of SSc-ILD which could be potentially revealed by machine learning algorithms.
Objectives: The aim of our study was to identify GI related risk factors for the presence of SSc-ILD using machine learning algorithms based on decision trees (DT).
Methods: Data of the last follow-up visit from consecutive patients fulfilling the 2013 ACR/EULAR SSc classification criteria recorded in our local EUSTAR registry were used for this study. The study outcome was the *presence of SSc-ILD* on high-resolution computed tomography. Two sets of predictors were identified based on their potential association with GI. The first set contains the following variables available in the EUSTAR registry: *esophageal symptoms (dysphagia and reflux)*, *stomach symptoms (early satiety, vomiting)*, *intestinal symptoms (diarrhea, bloating and constipation)*, *malabsorption syndrome*, *body-mass-index (BMI)* and *proton pump inhibitor therapy, calcium channel blocker therapy and immunosuppressive therapy*. In the second set, we replaced the first three EUSTAR variables of the first set with the scales of the UCLA Gastrointestinal Tract Questionnaire 2.0 (UCLA-GIT). Of these two sets, the most important variable was selected using three different DT-based algorithms: *(1) recursive partitioning and regression trees (RPART)* –which uses trees to build decision rules, *(2) random forest (RF)* - an ensemble of DT built in parallel, and *(3) gradient boosting machines (GBM)* - an ensemble of DT built sequentially. The selected variables were eventually integrated with established predictors for presence of SSc-ILD (*diffuse cutaneous subset*, *anti-Scl-70 positivity*, *male gender*, *forced vital capacity [FVC]* and *diffusion capacity of the lung for carbon monoxide-single breath [DLCO-SB]*) into final prediction models for SSc-ILD presence using RPART, RF and GBM respectively. Their performance was evaluated by C-statistics. The importance of the newly detected predictor was assessed by variable importance plots (VIPs).
Results: We included in our study 334 patients. The median age was 61 [IQR: 50-69] years, 59 (17.7%) were males and 266 (79.6%) had limited cutaneous SSc. Median BMI was 23 [IQR: 21-26] kg/m2, 133 (39.8%) of the patients had SSc-ILD, median FVC% 93 [IQR: 81-105], DLCO 72.5 [56-84] and. Of the

UCLA-GIT scales the highest score was for the distension/bloating with a value of 0.50 [IQR: 0-1.24]. Regarding medications, 167 (50%) patients were exposed to PPI, 39 (11.7%) to CCB and 105 (31.4%) to immunosuppressive therapy.
The BMI was deemed by all three algorithms as the most important predictor of SSc-ILD among both sets of GI related variables (Figure 1A-F). The final model, which included established risk factors for presence of ILD and the BMI, supported the importance of BMI in predicting the SSc-ILD. The VIPs obtained by GBM also ranked the BMI as the most important predictor.

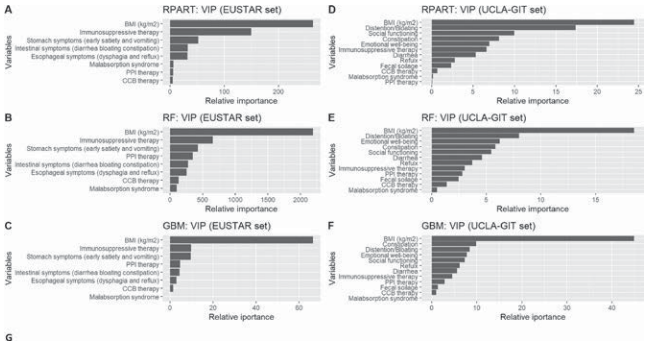

Figure 1. Tree-based algorithms revealing the importance of BMI for prediction of SSc-ILD. Panels A, B and C are variable importance plots (VIPs), which reveals the most important GI-predictor for occurrence of SSc-ILD in the EUSTAR set– the predictor with the highest relative importance is the most important predictor. Panels D, E and F are VIPs reveals the most important GI-predictor for occurrence of SSc-ILD in the UCLA-GIT set.

A lower BMI was associated with presence of SSc-ILD (C-statistics for the RPART, RF and GBM models were 0.79, 0.70 and 0.76, respectively, corresponding to a fair accuracy). As expected, also a lower FVC, and DLCO-SB, and a positivity for Scl-70 ab were associated with presence of ILD.
Conclusion: Lower BMI is a novel promising predictor for the presence of ILD, which should be confirmed in additional analyses.

POS0879 LUNG ULTRASOUND FOR INTERSTITIAL LUNG DISEASE DETECTION IN A COHORT OF SYSTEMIC SCLEROSIS PATIENTS: ROLE OF B-LINE AND PLEURAL LINE MODIFICATIONS

D. M. Reza Beigi[1], G. Pellegrino[1], M. Loconte[1], G. Paone[2], F. R. DI Ciommo[1], M. Cadar[1], I. Bisconti[1], K. Stefanantoni[1], F. Conti[1], V. Riccieri[1]. *[1]Sapienza University of Rome, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy; [2]Sapienza University of Rome, Department of Cardiovascular and Respiratory Sciences, Rome, Italy*

Background: Lung ultrasound (LUS) is a technique that showed a high diagnostic accuracy for interstitial lung disease (ILD) detection in systemic sclerosis (SSc) patients and currently in progress of standardization. Traditionally, B-lines represented the finding of ILD, with the ≥10 total cut-off reported by Tardella et al. resulting to be closely related to moderate ILD detected on high resolution chest computed tomography (HRCT). Recently, Fairchild et al. proposed novel LUS criteria for the evaluation of pleural line, disclosing high accuracy and reproducibility.
Objectives: To compare B lines cut-off with novel pleural line criteria and the respectively associated variables.
Methods: We enrolled 55 consecutive patients affected by SSc according to ACR/EULAR 2013 criteria who underwent respiratory functional tests (RFTs) during 2021, excluding smokers and those with arterial pulmonary hypertension. Twenty-four of them carried out a HRCT during a ± 6-months' time. In the same day of RFTs, two certified blinded operators performed LUS for each patient applying the 14-areas technique proposed by Gutierrez et al., looking for the presence of total ≥10 cumulative B lines and the fulfilling of Fairchild's criteria for pleural line. A 3-13 MHz operating linear probe was used. Clinical-demographic data and ongoing therapies were collected.
Results: Among 55 total SSc patients, the agreement between the two operators for Fairchild's criteria was almost perfect (Cohen's kappa (k) =0.81) and substantial for ≥10 cumulative B-lines count (k=0.74). Fairchild's criteria showed a higher diagnostic accuracy compared with ILD detected on HRCT, with an overall specificity (SP) and a positive predicted value (PPV) of 100% (Table 1). A negative correlation emerged between total lung capacity values (TLC%) and both B lines cut-off [first operator (IO): p 0.04, r -0.27; second operator (IIO): p 0.042, r-0.28] and pleural line criteria (IO: p 0.009, r -0.35; IIO: p 0.08, r – 0.36), but only the latter negatively correlated also with forced vital capacity values (FVC%) (IO: p 0.04, r – 0.27; IIO p 0.03, r -0.28). The ≥10 total B lines amount correlated positively with concurrent mycophenolate therapy (IO: p 0.09, r 0.28; IIO: p 0.005, r 0.37) and negatively with anti-centromere antibodies (IO: p 0.002, r -0.3; IIO p 0.009, r -0.34). The presence of digital ulcers showed a positive correlation with pleural line criteria (IO: p 0.03, r 0.29; IIO: p 0.005, r 0.37), with a significant association on multivariate analysis (IO: p 0.03, IIO: p 0.01).

Table 1. Overall sensitivity, specificity, positive predictive value, negative predictive value of LUS compared to ILD detected on HRCT. C.I. 95% confidence interval.

	SE (C.I.)	SP (C.I.)	PPV (C.I.)	NPV (C.I.)
Fairchild's criteria fulfilling	0.91 (0.76 - 0,97)	1 (0.78 – 1.000)	1 (0.88 -1.00)	0.82 (0,59 – 0.94)
≥10 cumulative B-lines count	0.73 (0.56 – 0.85)	0.8 (0.55 – 0.93)	0.89 (0.72 – 0.96)	0.57 (0.36 – 0.75)

Conclusion: We confirmed the feasibility and reliability of Fairchild's recently proposed pleural line LUS criteria, that showed a higher diagnostic accuracy versus ≥10 cumulative B-lines count for ILD detected on HRCT, presenting SP and PPV values of 100% in SSc. Furthermore, these LUS features seem to differently associate with other aspects of the disease such as autoantibody specificity and vascular lesions, thus deserving future deeper evaluations. For the first time, we found that Fairchild's criteria were associated with a clinical variable such as digital ulcers. Our results highlight the relevance of pleural line evaluation for ILD detection in SSc on LUS and its possible role towards a standardization of this diagnostic technique.

Distler[1], M. Elhai[1]. *[1]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland; [2]Oslo University Hospital-Rikshospitalet, Department of Rheumatology,, Oslo, Norway; [3]Hospital of Southern Norway, Department of Rheumatology, Kristiansand, Norway*

Background: Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). European consensus guidelines consider that some patients with mild disease might not need pharmacological treatment (1). Up to now, the disease characteristics and the disease course of non-treated SSc-ILD patients remain unknown.
Objectives: To describe disease characteristics and the disease course of non-treated SSc patients with ILD.
Methods: We included patients from our local EUSTAR center registered since 2008, who had a diagnosis of ILD on high-resolution computed

tomography (HRCT) and available data on pulmonary function tests and treatment. Longitudinal study included patients with at least one follow-up visit. Patients were classified as treated if they received a potential ILD modifying drug (immunosuppressive therapy or nintedanib). Treated and untreated patients were compared at baseline. Progression in the untreated group was defined as (i) forced vital capacity (FVC) decline from baseline of ≥10% or (ii) an FVC decline of 5-9% in association with a decline in diffusing capacity for carbon monoxide (DLCO) of ≥15%, or (iii) start of a ILD modifying treatment during follow-up. In the untreated group, patients who progressed at any time were compared with patients with stable disease during follow-up. Multivariable logistic regression was performed to identify (i) factors associated with non-prescription of a treatment in ILD patients at baseline and (ii) factors associated with progression in the untreated patients. Covariates were selected according to clinical experience and literature evidence.

Results: Among 496 patients included in our cohort, 209 (42%) patients had ILD on baseline HRCT: 48/209 (23%) were males, median disease duration 8 [IQR: 4-12] years, 67/209 (32%) of diffuse cutaneous subset and 86/209 (41%) had anti-Scl70 antibodies. Among them, 142/209 (68%) did not receive any potentially ILD modifying treatments at baseline. Untreated patients were older (59 vs. 54 years), had a longer disease duration, were less frequently smokers, had more frequently anticentromere antibodies and lower levels of CRP. They had more frequently a limited extent (<20%) of lung fibrosis on HRCT, higher FVC (97.02 (±19.76) % vs. 78.29 (±19.23) %) and DLCO (72.10 (±18.97) % vs. 57.57 (±20.81) %), better performances in the 6 minute walking test and were less frequently treated with low dose of glucocorticoids. In multivariable logistic regression, older age (OR: 1.04 [1.01-1.08], p=0.021), a less extensive disease on HRCT (OR: 0.29 [0.09-0.90], p=0.037) and less frequent prescription of glucocorticoids (OR: 0.036 [0.12-0.92], p=0.037) were independently associated with absence of ILD modifying treatment prescription in our cohort. From the 142 untreated patients, 96 were followed-up for 64 [39-96] months. Of these, 56 (58%) patients showed progression of ILD, of whom 43 progressed by lung function parameters. Of these 56 patients, 31 (56%) progressed in the first 18 months. Diffuse cutaneous subtype (OR: 5.26 [1.26-27.62], p=0.031), shorter disease duration (OR: 0.95 [0.90-0.99], p=0.035) and oesophageal symptoms (reflux, dysphagia) (OR: 3.51 [1.12-12.18], p=0.036) at baseline were independent predictors of progression during follow-up in untreated patients.

Conclusion: A considerable number of SSc patients with ILD are not treated in clinical practice, in particular patients with limited cutaneous SSc, older age and an overall less extensive ILD. However, during a follow-up of 5 years, contrary to the common belief, about 60% of the untreated patients showed ILD-progression. The diffuse cutaneous subtype, shorter disease duration and oesophageal symptoms at baseline characterized these patients. With the development of effective and safe therapies for SSc-ILD, our results support a change in practice for selecting patients for treatment.

POS0881

EFFICACY AND SAFETY OF SUBCUTANEOUS BRODALUMAB, A FULLY HUMAN ANTI–IL-17RA MONOCLONAL ANTIBODY, FOR SYSTEMIC SCLEROSIS WITH MODERATE-TO-SEVERE SKIN THICKENING: A MULTICENTER, RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE-BLIND PHASE 3 STUDY

T. Fukasawa[1], A. Yoshizaki[1], H. Kagebayashi[2], S. Sato[1]. [1]*The University of Tokyo, Graduate School of Medicine, Department of Dermatology, Tokyo, Japan;* [2]*Kyowa Kirin Co., Ltd., Clinical Development, Tokyo, Japan*

Background: Systemic sclerosis (SSc) is a rare chronic connective tissue disease of unknown cause characterized by autoimmunity, vasculopathy, and fibrosis of the skin and various internal organs. It is considered to constitute an area of high unmet medical needed due to limited treatment options and no sufficiently effective treatments. Our previous study (the single-arm, open-label, phase 1 study) indicated that brodalumab, a fully human anti-IL-17RA monoclonal antibody, had a potential to improve skin sclerosis in SSc patients, which could be attributed to its direct effects on fibroblasts and indirect effects via impacts on both B cell and T cell subsets (NCT04368403).

Objectives: To evaluate the efficacy and safety of brodalumab for SSc patients with moderate-to-severe skin thickening in a phase 3, multicenter, randomized, placebo-controlled, double-blind study.

Methods: Eligible patients (modified Rodnan skin score (mRSS):10-29, present with the first symptoms of SSc other than Raynaud's phenomenon within 60 months at enrolment) were randomized (1:1) to receive subcutaneous brodalumab 210 mg every 2 weeks (Q2W) or placebo during the 52-week placebo-controlled period. Primary endpoint was change from baseline of mRSS at week 24. Patients with an increase in mRSS of ≥5 points and ≥20% from baseline at or after week 24 were permitted to receive open-label treatment with brodalumab.

Results: A total of 100 patients was randomized to the brodalumab group (n=50) or the placebo group (n=50). Forty-six and 45 patients had diffuse cutaneous SSc in the brodalumab and placebo groups, respectively. In both groups, 47 patients completed the 24-week follow-up. Forty-four and 43 patients in the brodalumab and placebo groups completed the 52-week follow-up, respectively. At or after week 24, 38 patients (placebo, n=37; brodalumab, n=1) were switched to the active drug. Brodalumab achieved the primary endpoint (treatment difference of least square mean: –21.2 [95% CI -23.9, 18.5]; P<0.0001), and demonstrated a rapid, sustained reduction in mRSS over 52 weeks. Brodalumab also elevated the composite response index in SSc (CRISS) score, suppressed new development of digital ulcers, deterioration of respiratory function, and progression of lung lesions. Moreover, treatment of brodalumab improved the frequency scale for the symptoms of gastroesophageal reflux disease (FSSG) score, global assessment by physician (CGA) and patient (PGA), the Japanese version of the health assessment questionnaire-disability index (J-HAQ-DI) score, and the functional assessment of chronic illness therapy-fatigue (FACIT-Fatigue) score. The safety profile did not differ from that previously observed in other diseases such as psoriasis and ankylosing spondylitis and non-radiographic axial spondyloarthritis.

Conclusion: Brodalumab demonstrated a rapid, sustained, and significant decrease in skin sclerosis. Moreover, the outcome of brodalumab treatment suggested its therapeutic effects on lung/respiratory functions, digital ulcers, the symptoms of gastroesophageal reflux disease, and QOL without any noteworthy safety concerns.

HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY FOR THE ASSESSMENT OF CALCINOSIS, ACROOSTEOLYSIS, AND PERIPHERAL BONE MINERAL DENSITY IN PATIENTS WITH SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL PILOT STUDY

F. C. Enevoldsen[1,2], J. Therkildsen[1,2], R. Klose-Jensen[1,2], K. T. Aaen[1,2], A. L. Riis[1,2], K. Soendergaard[1,2], E. M. Hauge[1,2]. *[1]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [2]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*

Background: Systemic Sclerosis (SSc) is a rare disorder associated with hand radiological damage, typically acro-osteolysis (AO) and calcinosis, and increased risk of osteoporosis [1, 2]. Recently, high resolution peripheral quantitative computed tomography (HR-pQCT) has contributed to advances in noninvasive imaging in patients with osteoporosis, inflammatory arthritis, and osteoarthritis. Due to its three-dimensional, high resolution (82 μm^3) imaging of calcified structures, HR-pQCT might be beneficial in detecting and describing early AO changes, calcifications or bone mineral density (BMD) loss and in studying potential treatment effects on progression/resolution of pathological manifestations.
Objectives: To study the association between different types of hand radiological damage assessed by HR-pQCT, and to evaluate volumetric BMD and microarchitecture at distal radius among SSc patients with and without AO.
Methods: This single-centre, cross-sectional study included patients with SSc according to ACR/EULAR 2013 recruited from the outpatient clinic at the Department of Rheumatology, Aarhus University Hospital, between 1st of October and 21st of December 2021. All patients underwent HR-pQCT (Xtreme CT, Scanco Medical AG) scan of the dominant hand's distal radius and both hand's distal phalanges (DP) on the 2nd to 4th finger. A semiquantitative scale of 0-3 was composed to quantify the degree of soft tissue calcifications identified in the 2nd to 4th finger (Figure 1). Lengths of the DPs and soft tissue extending distally from the most distal part of DPs (ST) were measured in a three-dimensional multiplanar reconstruction. Volumetric BMD and bone microarchitecture were analyzed using HR-pQCT scanner specific software at the distal radius.
Results: We included 40 patients with SSc of whom 13 had AO according to hand radiographs. The two groups had a similar distribution regarding age, sex, and BMI. Patients with AO had longer disease duration compared to patients without AO (med. 17 yrs. (IQR 7-20 yrs.) vs 3 yrs. (IQR 2-7 yrs.) (P<0.001)). One patient was excluded from the BMD analysis, and 21 (9%) DP and 20 (8%) soft tissue measurements were excluded due to motion-induced image degradation. A higher prevalence of calcinosis was observed in patients with AO (n=11/13) compared to patients without AO (n=11/27) (P<0.05). Patients with AO had more or larger calcifications according to our grading system (med. 2 (IQR 1-3) vs 0 (IQR 0-1)) (P<0.001). Grade 3 changes were observed in patients with AO (n=6/13, 46%) but not in patients without AO. Furthermore, the patients with AO had shorter DPs on the 2nd finger on both hands (right P<0.001; left P<0.01) and less ST on the right 2nd, 3rd, and 4th (P<0.01; P<0.001; P<0.01) as well as the left 3rd (P<0.05). We observed no differences between bone volume ratio (med. 0.101 (IQR 0.068-0.143) vs 0.126 (IQR 0.104-0.141) (P=0.38)), cortical BMD (med. 828 (IQR 774-853) vs 842 (IQR 762-882) (P=0.60)), or trabecular BMD (med. 121 (IQR 82-172) vs 151.6 (IQR 125-170) (P=0.36)). Yet, the patients with AO had a lower number of trabeculae (P<0.05) and a lower homogeneity of spacing between trabeculae (P<0.05) at distal radius.
Conclusion: Patients with AO had larger and a higher number of calcifications and had significantly shortened DPs and ST on several fingers assessed by HR-pQCT. A potential superiority compared with hand radiographs is yet to be established. Still, the modality could eventually prove useful in detecting and monitoring small hand lesions and facilitate earlier diagnosis and proper treatment among patients with SSc.

BIOPHYSICAL PROPERTIES OF MONOCYTES INDICATE DISEASE ACTIVITY, SEVERITY OF FIBROTIC OR MICROVASCULAR MANIFESTATIONS AND THE RISK FOR PROGRESSION IN SYSTEMIC SCLEROSIS

A. E. Matei[1,2], K. Markéta[3,4], L. Xu[1,2], A. H. Györfi[1,2], E. Boxberger[1,2], D. Soteriou[3], M. Papava[1,2], J. Prater[1,2], X. Hong[1,2], M. Kräter[3,4], G. Schett[1,2], J. Guck[3,4], J. H. W. Distler[1,2]. *[1]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitaetsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitaetsklinikum Erlangen, Deutsches Zentrum Immuntherapie (DZI), Erlangen, Germany; [3]Max Planck Institute for the Science of Light & Max-Planck-Center für Physics and Medicine, Biological Optomechanics, Erlangen, Germany; [4]Technische Universität Dresden, Biotechnology Center, Center for Molecular and Cellular Bioengineering, Dresden, Germany*

Background: Dysregulated immune responses are major pathogenic players in systemic sclerosis (SSc). The biophysical properties (such as cell deformation, Young's modulus (a measure of cell stiffness) and area) of circulating immune cells reflect their states and functions, as well as their pathological activation (1-3). Thus, biophysical phenotyping can provide access to a novel, mostly unexplored layer of information that is currently not accessible with standard techniques of cellular and molecular biology. Real-time fluorescence and deformability cytometry (RT-FDC) is a novel technique that enables biophysical phenotyping of individual immune cells at a high throughput, which allows its use in a clinical setting (3-5).
Objectives: Here, we hypothesized that biophysical properties of circulating immune cells in SSc and rheumatoid arthritis (RA) might specifically reflect their distinct pathophysiological activation in the respective disease, and might indicate clinical outcomes such as disease activity or severity. We thus performed

RT-FDC-based biophysical phenotyping of circulating immune cells in SSc, RA and healthy controls.

Methods: 63 SSc patients, 59 RA patients fulfilling the respective ACR/EULAR classification criteria and 18 age- and sex-matched healthy controls were included in the study between 05.2019 and 09.2021. Peripheral blood mononuclear cells (PBMC) were isolated and immunolabelled. PBMC subpopulations were identified in RT-FDC by standard gating strategies based on their marker expression and their deformation, Young's modulus and area were determined.

Results: We identified SSc-specific changes (changes in SSc, but not in RA compared to healthy controls) in the biophysical properties of NK, NKT-like cells and monocyte subpopulations in SSc. Monocytes subpopulations had a higher deformation and cross-sectional area and/or more compact intra-donor distributions of these parameters in patients with active disease and with extensive skin or lung fibrosis in comparison with patients with stable disease and limited skin or lung fibrosis, respectively. All monocytes subsets were stiffer in patients with progression of skin of lung fibrosis at the time of measurement in comparison with a previous visit. The deformation and area of intermediate monocytes could also identify patients at risk for future progression of lung fibrosis. Changes in biophysical properties of monocytes can indicate, beyond fibrotic burden, clinical manifestations of microvascular damage such as active digital ulcers and pulmonary arterial hypertension.

Conclusion: We demonstrated that changes in the biophysical properties of monocytes subsets are associated with multiple clinical outcomes in SSc such as disease activity, severity of fibrotic or microvascular manifestations and risk of progression and might thus directly reflect SSc-specific pathologic immune cell activation. Our results thus provide first evidence that RT-FDC-based biophysical phenotyping of circulating immune cells may be a useful tool for clinical evaluation of SSc patients.

POS0884 DESCRIPTIVE EPIDEMIOLOGY OF SEVERE CARDIAC INVOLVEMENT IN SYSTEMIC SCLEROSIS: A BICENTRIC RETROSPECTIVE STUDY ON 459 PATIENTS

E. Bories[1], S. DE Almeida Chaves[1], T. Porel[1], L. Alric[1], L. Astudillo[1], F. Gaches[2], M. Michaud[3], F. Catros[2], G. Prevot[4], L. Sailler[1], D. Adoue[1], O. Lairez[5], G. Pugnet[1]. *[1]Toulouse University Hospital Center, Department of Internal Medicine, Toulouse, France; [2]Joseph Ducuing Hospital, Department of Internal Medicine, Toulouse, France; [3]Ambroise Paré Clinic, Department of Internal Medicine, Toulouse, France; [4]Toulouse University Hospital Center, Department of Pneumology, Toulouse, France; [5]Toulouse University Hospital Center, Department of Cardiology, Toulouse, France*

Background: The prevalence of cardiac involvement in systemic sclerosis (SSc) varies in the literature between 3% and 44% and represents a leading cause of mortality in this disease. The incidence of severe cardiac involvement and the factors associated with the occurrence of severe cardiac involvement are not known in the literature.

Objectives: The objective of this study was to evaluate the incidence, prognosis and factors associated with the occurrence of severe cardiac involvement during SSc course.

Methods: We conducted a retrospective, bi-centric study from January 1, 1966 to December 31, 2018. The patients included had a diagnosis of SS according to the ACR/EULAR 2013 criteria. The primary endpoint was the occurrence of severe cardiac involvement. Cardiac involvement was defined by the presence of at least one of the following elements: death of cardiovascular origin, left ventricular ejection fraction less than or equal to 50%, abnormality of at least 3 measurement parameters of diastolic function, global longitudinal strain less than or equal to 18 in absolute value, ventricular tachycardia, ventricular extrasystoles requiring intervention or elevated troponin. Patients with associated myositis and whose only criterion for cardiac involvement was elevated troponin were not included in the group with cardiac involvement. Severe cardiac involvement was defined by the occurrence of hospitalization for cardiovascular reasons or by death of cardiovascular origin. Univariable and multivariable Cox proportional hazards models were used to determine variables associated with severe cardiac involvement occurrence. Survival analysis was performed using the Kaplan-Meier method with comparisons performed using the log rank test.

Results: Four hundred and fifty-nine patients with SSc were included and were followed for a median of 7.1 years [3.1; 13.3]. The median age of our population was 54 years old. There were 81% of women, 77% of patients had limited cutaneous SSc, 15% diffuse cutaneous SSc and 8% SSc sine scleroderma. Of the 459 patients, 105 (23%) had cardiac involvement and 56 (12%) severe cardiac involvement. The incidence of severe cardiac involvement was 2.42 per 100 patient years. Ninety-six hospitalizations were recorded, including 40 (42%) for acute heart failure, 19 (20%) for arrhythmia, 5 (5%) for acute pericarditis, 6 (6%) for acute myocarditis and 14 (15 %) for coronary artery disease (acute coronary syndrome, myocardial infarction or coronary revascularization). The independent factors associated with severe cardiac involvement in SSc were age over 54 years at SSc-diagnosis (OR = 3.21 95% CI [1.73; 5.95], p < 0.001), the presence of myositis (OR = 5.01 95% CI [1.89; 13.28], p = 0.001), pericardial involvement (OR = 3.79 95% CI [2.05; 7.03]; p < 0.001) or scleroderma renal crisis (OR = 4.72 95% CI [2.05; 10.92], p < 0.001). The survival rate of patients with severe cardiac involvement was 70% at 5 years and 53% at 10 years. Patients with severe cardiac involvement had a mortality risk three times greater than patients without severe cardiac involvement, HR = 3.1 (95% CI [1.7; 5.7], p<0.0001) (Figure 1). Pericardial involvement was an independent risk factor for mortality, HR = 2.0 (95% CI [1.02; 4.0], p=0.04).

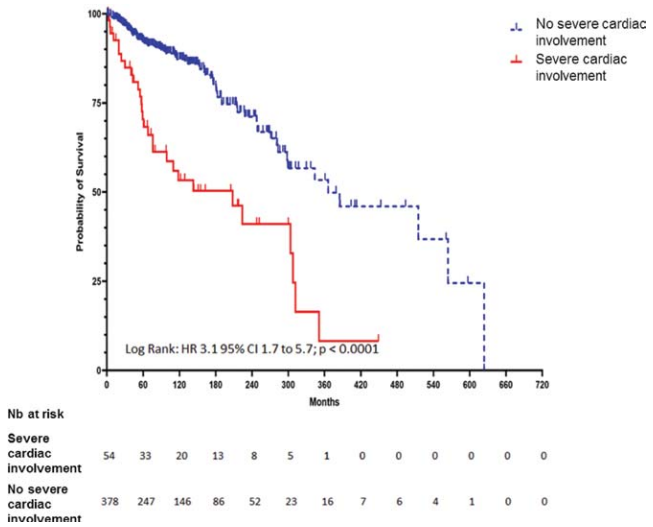

Figure 1. Survival of patients with severe cardiac involvement of systemic scleroderma. HR: Hazard ratio; 95% CI: 95% Confidence interval; Nb at risk: Number at risk

Conclusion: We need to focus our clinical attention on diagnosing and manage cardiac involvement in SSc, as severe cardiac involvement is not uncommon and is responsible for a poor prognosis.

POS0885 HYPOCHROMIC ERYTHROCYTES AS PROGNOSTIC INDICATOR OF SURVIVAL AMONG PATIENTS WITH SYSTEMIC SCLEROSIS SCREENED FOR PULMONARY HYPERTENSION

P. Xanthouli[1,2], O. Gordjani[1], C. Eichstaedt[1,3], N. Benjamin[1], B. Egenlauf[1], S. Harutyunova[1], A. Marra[1,4], V. Theobald[1], N. Milde[1], C. Nagel[1], N. Blank[2],

H. M. Lorenz[2], E. Grünig[1]. [1]*Thoraxklinik-Heidelberg gGmbH, Pulmonary Hypertension, Heidelberg, Germany;* [2]*University Hospital Heidelberg, Division of Rheumatology, Department of Internal Medicine V: Hematology, Oncology and Rheumatology, Heidelberg, Germany;* [3]*Institute of Human Genetics, Laboratory for Molecular Genetic Diagnostics, Heidelberg, Germany;* [4]*University of Naples Federico II, Translational Medical Sciences, Napoli, Italy*

Background: Iron deficiency is frequent among patients with systemic sclerosis (SSc), particularly among those with pulmonary hypertension (PH). First data indicate prognostic importance of hypochromic erythrocytes (HRC) >2% among patients with PH[1]. Hence, the aim of this study was to investigate the predictive value of HRC in SSc patients screened for PH.

Objectives: The objective of this study was to investigate the predictive value of HRC in SSc patients screened for PH.

Methods: In this retrospective, single-center cohort study SSc patients screened for PH were included. Clinical characteristics, laboratory and pulmonary functional parameters associated with the prognosis of SSc were analysed using uni- and multivariable analysis.

Results: A total of 280 SSc patients were screened, 171 were included in the analysis having complete data of iron metabolism (79% female, 61.0±12.9 years of age, 73.2% limited cutaneous SSc, 56 manifest PH and 112 pulmonary fibrosis). The patients were followed for 2.4±1.8 (median 2.4) years. HRC >2% at baseline was significantly associated with worse survival in the uni- (p=0.018) and multivariable analysis (p<0.0001). Overall 34.5% of the patients suffered from iron deficiency and 22% received iron substitution during follow-up. HRC >2% was identified as independent predictor of mortality, for patients with and without pulmonary manifestations of SSc.

Conclusion: This study detected for the first time that HRC >2% is an independent prognostic predictor and can possibly be used as a biomarker among SSc-patients. Further studies are needed to confirm these results.

Background: Interstitial lung disease (ILD) is a common condition in patients with connective tissue disease (CTD). It is associated with increased morbidity and mortality. Rituximab (RTX) has been approved for treatment of RA and some recent retrospective studies suggest that it could be an alternative treatment for patients with CTD-ILD, even in cases that prove refractory to conventional immunosuppressants.

Objectives: To analyze the efficacy and safety of RTX in connective tissue disease associated with interstitial lung disease (CTD-ILD).

Methods: We performed a multicenter, prospective, observational study of patients with CTD-ILD receiving RTX between 2015 and 2020. Patients who had worsening of respiratory symptoms or decline in the pulmonary function tests (PFT) compared to the time of ILD diagnosis were treated with rituximab. The patients were assessed using high-resolution computed tomography and PFT baseline, at 12 months, and at the end of follow-up. The main outcome measure at the end of follow-up was forced vital capacity (FVC)>10% or diffusing capacity of the lungs for carbon monoxide (DLCO)>15% and radiological progression or death. We recorded clinical characteristics, time to initiation of RTX, concomitant treatment, infections, and hospitalization. A Cox regression analysis was performed to identify factors associated with worsening of ILD.

Results: We included 37 patients with CTD-ILD treated with RTX for a median (IQR) of 38.2 (17.7-69.0) months (Table 1). At the end of the follow-up, disease had improved or stabilized in 23 patients (62.1%) and worsened in 7 (18.9%); 7 patients (18.9%) died. Mean PFT values decreased significantly at the start of RTX compared to the date of ILD diagnosis in FVC (72.2[21.3]vs 73.5 [16.9] mg/l;p=0.040) and DLCO-SB (55.9 [15.7] vs 58.3 [16.1] mg/l; p=0.041). No

Table 1. Baseline demographic and clinical characteristics of 37 patients with CTD-ILD receiving rituximab.

Variable	Total n=37	RA n=19	SS n=14	IM n=4	p Value
Female sex, n (%)	27 (73.0)	13 (68.4)	11 (78.6)	3 (75.0)	0.806
Age in years, mean (SD)	62.8 (9.9)	67.7 (9.7)	57.9 (7.9)	56.6 (5.5)	0.001
Smoking					0.147
Never smoked, n (%)	20 (54.1)	9 (47.4)	7 (50.0)	4 (100.0)	
Smoked at some time, n (%)	17 (45.9)	10 (52.6)	7 (50.0)	0 (0.0)	
Duration of CTD, months, median (IQR)	107.8 (49.5-188.8)	151.0 (8.,0-240.5)	89.6 (51.3-184.4)	35.1 (25.1-49.0)	0.017
Duration of ILD, months, median (IQR)	65.4 (31.1-110.3)	82.2 (37.4-120.1)	64.5 (35.5-107.1)	25.9 (25.0-36.0)	0.136
Time to initiation of RTX, median (IRQ)	12.0 (6.5-48.2)	25.1 (7.0-57.6)	11.4 (3.9-43.6)	7.4 (7.0-10.4)	0.455
Duration of treatment with RTX, median (IQR)	38.2 (23.4-69.9)	45.3 (22.2-79.9)	52.5 (24.7-63.3)	22.8 (17.7-36.2)	0.291
Combined with csDMARDs, n (%)	15 (40.5)	9 (47.4)	5 (35.7)	1 (25.0)	0.637
Methotrexate, n (%)	5 (13.5)	2 (10.5)	3 (21.4)	0 (0.0)	0.468
Leflunomide, n (%)	2 (5.4)	2 (10.5)	0 (0.0)	0 (0.0)	0.367
Sulfasalazine, n (%)	1 (2.7)	1 (5.3)	0 (0.0)	0 (0.0)	0.615
Hydroxychloroquine, n (%)	7 (18.9)	4 (21.1)	2 (14.3)	1 (25.0)	0.840
Combination with immunosuppressants, n (%)	20 (54.1)	7 (36.8)	9 (64.3)	4 (100.0)	0.044
Mycophenolate, n (%)	19 (51.4)	6 (31.6)	9 (64.3)	4 (100.0)	0.021
Azathioprine, n (%)	1 (2.7)	1 (5.3)	0 (0.0)	0 (0.0)	0.615
Corticosteroids, n (%)	25 (67.6)	14 (73.7)	7 (50.0)	4 (100.0)	0.121
Doses of corticosteroids, median (IQR)	5.0 (0.0-10.0)	5.0 (0.0-10.0)	2.5 (0.0-7.5)	10.0 (8.1-10.5)	0.519

significant decline was observed in median FVC (72.2 vs 70.8; p=0.530) or DLCO (55.9 vs 52.2; p=0.100). The multivariate analysis showed the independent predictors for worsening of CTD-ILD to be baseline DLCO (OR [95% CI], 0.904 [0.8-0.9]; p=0.015), time to initiation of RTX (1.01 [1.001-1.02]; p=0.029), and mycophenolate (0.202 [0.04-0.8]; p=0.034). The infection incidence rate was 0.21 patient-years.

Conclusion: Lung function improved or stabilized in more than half of patients with CTD-ILD treated with RTX. No significant increase in infection rates was observed. Early treatment and combination with mycophenolate could reduce the risk of progression of ILD.

POS0887 CHORIORETINAL MICROVASCULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS

P. G. Cerasuolo[1], G. Gambini[2], E. De Lorenzis[1,3], S. Fiore[1], L. Verardi[1], G. Natalello[1], G. Alonzi[1], S. Rizzo[2], M. A. D'agostino[1], S. L. Bosello[1]. *[1]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy; [2]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Ophthalmology Unit, Roma, Italy; [3]University of Verona-Verona, Italy., Ph.D. programme in Biomolecular Medicine-Cycle XXXV,, Verona, Italy*

Background: The optical coherence tomography angiography (OCTA) is a new non-invasive imaging technique that can detect flow and provide information about the vessel density (VD) at different layers in the eye. The ocular microvascular network has been only occasionally addressed as disease target in scleroderma (SSc) considering the relatively low prevalence of ocular symptoms in these patients.

Objectives: The study aims to evaluate retinal and choriocapillaris microvasculature in a group of SSc patients compared to matched controls (HC)and according to disease characteristics, capillaroscopy findings and pulmonary function tests.

Methods: VD was assessed through OCTA at the retinal superficial (SCP) and deep (DCP) capillary plexus, at the foveal avascular zone perimeter (FAZP) and at the choriocapillaris (CC) of 30 SSc patients compared to 30 sex- and age-matched subjects without any retinal disease.

Results: The SSc patients (age 57.3±10.0, female 86.7%) had diffuse cutaneous skin disease in 30.0% of the cases, an average disease duration of 10.4±7.2 yy, and anti-centromere and anti-Scl70 antibody positivity in 40.0%and in 30.0% of the cases, respectively. Compared to the HC, SSc showed an impaired VD at SCP (47.7±3.6 vs59.1±3.5%, p=0.009), DCP (50.0±6.7 vs 54.3±6.4%, p=0.015), FAZP (48.7±4.55 vs 51.0±3.55%, p=0.034) and CC(67.1±2.2 vs 68.6±1.7, p=.005). Moreover, in the SSc group, the presence of digital ulcers (46.7%),telangiectasias (43.3%) and interstitial lung disease (46.7%) was related to reduced VD at FAZP (46.8±4.1 vs50.3±4.3%, p=0.033), CC (66.1±1.4 vs 67.9±2.4%, p=0.004), and DCP (47.2±8.8 vs 51.9±4.3, p=0.004),respectively. Lastly, the average capillary density on capillaroscopy showed a positive correlation with VD at FAZP (r=0.474, p=0.008), DCP (r=0.414, p=0.023), and foveal CC (r=0.482, p=0.007) and there was also a correlation between CC and both DLco (r=0.467, p=0.009) and FVC/DLco (r=-0.436, p=0.004).

Conclusion: The SSc patients in our cohort showed lower ocular vessel density at different levels compared to HC. Furthermore, impaired VD at different levels of the eye correlates with the organ involvement and the degree of digital and pulmonary microvascular impairment. According to those data, the OCTA could be proposed as a biomarker tool to investigate the microvascular abnormalities in SSc.

Background: Digital ulcers(DUs) in systemic sclerosis(SSc) represent a major clinical challenge. There are no recommendations for the local management of SSc-DUs. Systemic therapy is considered the standard of care. However, there is a strong rationale for local approaches to DU by avoiding side effects from systemic therapies. The World Scleroderma Foundation DU Working Group intends to develop evidence-based recommendations for DU management including local, non-surgical treatment(ln-sT).

Objectives: To summarise the literature on the safety and efficacy of ln-sT for SSc-DUs.

Methods: A systematic literature review(SLR) of papers describing the use of ln-sT for DU in SSc was performed up to May 2021 according to the PICO framework. References were independently screened by two reviewers who independently assessed the full text of eligible articles and extracted data.

Results: Among 790 retrieved references, 12 were included. Median(range) number of patients per study was 9(7–84), mean age ranging from 37 to 62.5 years. In 5(41%) studies a control group was included. Background systemic therapies are summarized in Table 1. The most studied treatment was botulin toxin A(BTA). It was used as hand injection in 3 studies (median dose ranging from 90 to 150 U) and as 50 U single finger injection in 1 study. Healing rate after a median time of 8-49 weeks ranged from 71% to 100%. In 2 studies a reduction in VAS pain was observed from 20% to 100%. Transient muscle weakness was the most common side effect in 10% of patients. Amniotic(Am) and hydrocolloid membranes(HyM) were used in 1 study each. They were associated with a good healing rate, statistically significant for the HyM. Tadalafil 2% cream was studied in 1 study and was associated with a reduction in the median DU number from 1.6 to 1 per patient after a median time of 4 weeks and a reduction by 1.4 point in the 10-mm VAS scale. Vitamin E gel was shown to be associated with a statistically significant reduction in the healing time compared to SoC alone in 1 RCT(13.2 ± 2.7 versus 20.9 ± 3.6 weeks, P=<0.001). Low-level light therapy, hydrodissection and corticosteroid injection and extracorporeal shock wave(ESW) were evaluated in 1 study each. They were all associated with positive outcomes which was statistically significant only for the ESW. The only negative trial examined dimethyl sulfoxide and was associated with local toxicity.

Conclusion: Our SLR supports interest to develop ln-sTs for SSc-DUs. The number of studies is limited and mainly case reports and small single studies are present. Treatments were well tolerated and there was evidence of efficacy for BTA, vitamin E, ESW and HyM in refractory DUs. The evidence is not robust and confounding factors (vasodilators background therapies) could impact on the findings. Future research is indicated to conduct larger, well-designed studies.

CASE SERIES OF PATIENTS WITH EOSINOPHILIC FASCIITIS SECONDARY TO IMMUNE CHECKPOINT INHIBITORS THERAPY

W. K. Huang[1], Y. F. Mo[2], F. Y. Tang[3], Z. M. Ouyang[1], J. D. MA[1], D. H. Zheng[1], Y. Q. Mo[1], L. Dai[1]. *[1]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Rheumatology, Guangzhou, China; [2]Liwan Central Hospital of Guangzhou, Rheumatology, Guangzhou, China; [3]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Respiratory, Guangzhou, China*

Background: Eosinophilic fasciitis (EF), a fibrotic disease that causes inflammatory infiltration in the subcutaneous fascia is clinically characterized by edema and subsequent induration and tightening of the skin and subcutaneous tissue. EF is a rare immune-related adverse event of immune checkpoint inhibitors (ICI).
Objectives: This article aims to investigate the clinical features of ICI-related EF and to improve the understanding of the disease among rheumatologists.
Methods: Searching relevant articles in the electronic databases Medline, PubMed, Science Citation Index, China Biomedical Literature Database (CBM), China Journal Full Text Database (CNKI), and WANFANG Data with the key words of "eosinophilic fasciitis" or "Shulman syndrome" and "checkpoint inhibitor", "CTLA-4", "PD-1" or "PD-L1". Only articles or case reports with detailed medical records of ICI-related EF patients were included. ICI-related EF patients in our department were also included.
Results: A 58-year-old male patient with angioimmunoblastic T cell lymphoma presented with skin edema, subsequent induration, tightening of the skin, and subcutaneous tissue (Figure 1 A&B). The eosinophils elevated in peripheral blood after 6-month treatment of PD-1 inhibitor (Camrelizumab). The patient was diagnosed as ICI-related EF and then was referred to our rheumatology department. Other seventeen EF patients from the above databases were also included for analysis. Among these 18 patients, 50% (9/18) were male and the mean age was 57±14 years. The most commonly used ICI was PD-1 inhibitor such as nivolumab and pembrolizumab, accounting for 72% (13/18), next was PD-L1 inhibitor (17%, 3/18), and 3 patients used PD-L1 inhibitor combined with CTLA-4 inhibitor. Of all cases, 50% (9/18) was metastatic melanoma and 17% (3/18) was lung cancer. After ICI treatment, the median onset time of EF was 12 months. The most common involved organ was skin and 94% (17/18) of patients presenting with symmetrical skin edema and sclerosis. For other skin manifestations, 44% (8/18) of patients had typical "groove sign", and one case showed unilateral skin involvement of skin tension and erythema from pubis to left anterior iliac crest. When the affected limb raised, there is a visible sulcus due to the decrease of venous dilation pressure, namely "sulcus sign". The second common involved organ was the joints which were presented with limited function in 56% (10/18) of patients. Additionally, 39% (7/18) showed muscle involvement such as myalgia and myasthenia. Increased eosinophils in peripheral blood was observed in 72% (13/18) of patients. Twelve patients (63%) received MRI examinations which showed the signal in the subcutaneous and deep fascia increased in both fat-suppressed T2 images(Figure 1 C&E) and post-enhancement T1 images(Figure 1 D&F). Fifteen patients underwent full-thickness skin biopsy at the lesion site, the pathological changes in all patients supported the diagnosis of EF. The ICI was discontinued in 94% of patients. Meanwhile, 83% received glucocorticoids and 56% of patients were treated with methotrexate. After these treatment, the clinical symptoms of EF improved in 89% of patients (n=16), while eosinophils returned to normal after a median treatment time of 2.5 months. EF progressed even through the combined treatment of prednisone, MTX, and abatacept in one patient. Another one case died after 6 months due to metastasis of bladder cancer (stageIV).
Conclusion: Although EF is a rare adverse effect of ICI treatment, individuals receiving these drugs should be monitored closely for symptoms of EF. Discontinuation of ICI and administration of immunosuppressants may prevent the progression of EF.

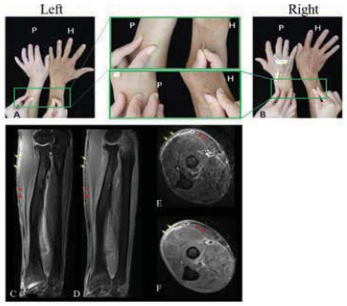

Figure1 Skin signs and MRI images of a 58-year-old male patient with eosinophilic fasciitis secondary to immune checkpoint inhibitors therapy. A&B: Skin signs of the representative patient (P) and a 58-year-old male healthy volunteer (H). The skin of the patient's left (A) and right forearm (B) was tight and difficult to lift. The fat-suppressed T2 images (C&E) and the fat-suppressed post-enhancement T1 images (D&F) showed the signal in the subcutaneous and deep muscle fascia of the right forearm increased and was enhanced obviously after enhancement (red arrows). There was a little long T2 signal of effusion shadow between myofascial and subcutaneous fatty layer (yellow arrows).

Background: Nintedanib (NTD) has been approved for Systemic Sclerosis (SSc)-Interstitial Lung Disease (ILD) following the positive results of the SENSCIS trial.
Objectives: to describe the efficacy and safety of NTD in SSc-ILD in a real-life setting.

Methods: The clinical data of SSc-ILD patients treated with NTD from 10 Italian SSc centres were retrospectively evaluated at baseline, 6 and 12 months: SSc clinical features, NTD tolerability, pulmonary function tests (PFTs) and modified Rodnan skin score (mRSS) were recorded.
Results: 69 SSc-ILD patients (22 males [32%], mean age 60±12 years, disease onset 50±13 years, 4 [6%] anti-centromere, 53 [77%] anti-topoisomerase I, 3 [4%] anti-RNA-polimerase III) were identified. The vast majority (84%) was previously treated with immunosuppressants: 27 (39%) cyclophosphamide, 45 (65%) mycophenolate mofetil, 6 (9%) methotrexate, 9 (13%) azathioprine, 6 (9%) tocilizumab and 22 (32%) rituximab. In 11 (16%) patients, NTD was the first treatment for SSc-ILD. At baseline, 57 patients (83%) were on corticosteroids (mean daily prednisone dose 6±5 mg), 58 (84%) on immunosuppressants, 47 (68%) on mycophenolate mofetil, 14 (20%) on rituximab, 3 (4%) on tocilizumab, 2 on methotrexate (3%) and 1 (1%) on azathioprine. At baseline HRCT showed UIP pattern in 27 (39%) and NSIP pattern in 42 (61%) patients. The modifications of PFTs and mRSS over time are shown in Table 1. Since NTD introduction, gastro-intestinal (GI) side effects were recorded in 34 (49%) patients, with diarrhoea being the most common complaint (35%), followed by nausea/vomiting (23%) and weight loss (16%). In 21 (30%) patients, after a mean time of 2.6±3.4 months, NTD was maintained after dose adjustment. In 5 (7%) patients NTD was stopped after a median time of 5 (1-6) months due to subocclusion and persistent diarrhoea in 3 patients, untreatable nausea and vomiting in one patient and liver toxicity in 1 patient. During the follow-up after a median time of 10 (6 – 33) months, 4 patients died.

Table 1. Pulmonary function tests and mRSS at baseline, 6 and 12 months in SSc-ILD on NTD.

	Baseline	6 months	P value	Baseline	12 months	P value
FVC (% predicted)	64 ± 18	65 ± 18 (33 pts)	0.638	70 ± 19	69 ± 18 (20 pts)	0.586
TLC (% predicted)	64 ± 15	61 ± 14 (27 pts)	0.154	64 ± 14	65 ± 18 (16 pts)	0.944
DLCO (% predicted)	40 ± 17	41 ± 18 (29 pts)	0.660	40 ± 18	38 ± 18 (20 pts)	0.304
mRSS	9 ± 6	8 ± 6 (26 pts)	0.002	7 ± 4	8 ± 6 (15 pts)	0.334

pts= patients

Conclusion: Our preliminary data confirm that in a real-life clinical scenario NTD, in combination with immunosuppressants, may stabilize PFT. However, despite the fact that GI side effects are frequent, they may be controlled with NTD dose adjustment thus retaining the drug in SSc-ILD patients. The NTD efficacy on skin involvement needs to be thoroughly evaluated on a larger SSc population.

Background: The idiopathic inflammatory myopathies (IMM) module of the Rheumatic Diseases Portuguese Register (Reuma.pt/Myositis) is a tool used to systematically evaluate IIM patients.
Objectives: To clinically characterise the Reuma.pt/Myositis cohort.
Methods: Multicentre open cohort study, including IIM patients registered in Reuma.pt up to January 2022. Data collected included demographic, clinical, and treatment data and patient-reported outcomes. Data were presented as frequencies and median (interquartile range) for categorical and continuous variables, respectively.
Results: 280 patients were included, 71.4% female, 89.4% Caucasian, with a median age at diagnosis and disease duration of 48.9 (33.6-59.3) and 5.3 (3.0-9.8) years, respectively. Patients were classified as having definite (N=57/118, 48.3%; N=35/224, 15.6%), likely (N=23/118, 19.5%; N=50/224, 22.3%), or possible (N=2/118, 1.7%; N=46/224, 20.5%) IIM by 2017 EULAR/ACR and Bohan-Peter criteria, respectively. Disease subtypes included dermatomyositis (DM, N=122/280, 43.6%), polymyositis (N=59/280, 21.1%), myositis in overlap syndromes (N=41/280, 14.6%), clinically amyopathic DM (N=17/280, 6.1%), nonspecific myositis (N=13/280, 4.6%), mixed connective tissue disease (N=12/280, 4.3%), immune-mediated necrotizing myositis (N=9/280, 3.2%), and inclusion bodies myopathy (N=7/280, 2.5%). Over the course of the disease, the most common symptoms were proximal muscle weakness (N=180/215, 83.7%), arthralgia (N=127/249, 52.9%), erythema (N=63/166, 38.0%), fatigue (N=47/127, 37.0%), Raynaud's phenomenon (N=76/234, 32.5%), and dysphagia (N=33/121, 27.3%), and the most common clinical signs were Gottron's sign (N=75/184, 40.8%), heliotrope rash (N=101/252, 40.1%), Gottron's papules (N=93/237, 39.2%), and arthritis (N=38/98, 38.8%). Organ involvement included lung (N=78/230, 33.9%), oesophageal (N=40/221, 18.1%), and heart (N=11/229, 4.8%) involvements. Most patients expressed myositis-specific (MSA, N=158/242, 65.3%) and/or myositis-associated (MAA, 112/242, 46.3%) antibodies. The most frequent antibodies were anti-SSA/SSB (N=70/231, 30.3%), anti-Jo1 (N=56/236, 23.7%), and anti-Mi2 (N=31/212, 14.6%). Most patients had a myopathic pattern on electromyogram (N=101/138, 73.2%), muscle oedema in magnetic resonance (N=33/62, 53.2%), and high CK (N=154/200, 55.0%) and aldolase levels (N=74/135, 54.8%) at diagnosis, with median highest CK levels of 1308 (518-3172) and aldolase of 42 (12-121) mg/dL. Neoplasia was found in 11/127 patients (8.7%), most commonly breast (N=3/11, 27.3%), non-melanoma skin (N=2/11, 18.2%), and colorectal (N=2/11, 18.2%) cancer (Table 1). Most patients with cancer-associated myositis had DM (N=8/11, 72.7%) and expressed MSA (N=6/11) and/or MAA (N=3/11). The most used drugs over the course of disease were glucocorticoids (N=201/280, 71.8%), methotrexate (N=117/280, 41.8%), hydroxychloroquine (N=87/280, 31.1%), azathioprine (N=85/280, 30.4%), mycophenolate mofetil (N=56/280, 20.0%), intravenous immunoglobulin (N=55/280, 19.6%), and rituximab (N=45/280, 16.1%). At the last follow-up, there was a median MMT8 of 150 (142-150), modified DAS skin of 0 (0-1), global VAS of 10 (0-50) mm, and HAQ of 0.125 (0.000-1.125).

Table 1. Autoantibodies in cancer-associated myositis

Cancer	IIM	Autoantibodies
Breast	DM (3)	Mi2, SRP (+ SSA/SSB), Pm/Scl
Skin (non-melanoma)	Clinically amyopathic DM, PM	Jo1, SAE1 (+SSA/SSB)
Colorectal	DM (2)	Mi2 (2)
Kidney	DM	-
Lung	DM	-
Lymphoma	Inclusion bodies myopathy	-
Unknown	DM	-

Conclusion: Reuma.pt/Myositis adequately captures the main features of inflammatory myopathies' patients, depicting in this first report a heterogeneous population, with frequent muscle, joint, skin and lung involvements. Of interest, most patients reached low disease activity at the last follow-up appointment.

IDENTIFICATION OF DEFINED MICROANGIOPATHIC CHANGES IN NAILFOLD CAPILLAROSCOPY IMAGES OF PATIENTS WITH SYSTEMIC SCLEROSIS USING A VISION TRANSFORMER MODEL – A MONOCENTRIC IMPLEMENTATION AND VALIDATION COHORT STUDY

A. Garaiman[1], F. Nooralahzadeh[2], C. Mihai[1], N. Gkikopoulos[1], N. P. Gonzalez[2], M. O. Becker[1], O. Distler[1], M. Krauthammer[3], B. Maurer[4]. *[1]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland; [2]University of Zurich, Biomedical Informatics, Zurich, Switzerland; [3]University of Zurich, Department of Quantitative Biomedicine, Zurich, Switzerland; [4]University Hospital Bern, University of Bern, Department of Rheumatology and Immunology, Bern, Switzerland*

Background: An accurate assessment of nailfold capillaroscopy (NFC) images has great importance in the diagnosis and prognosis of systemic sclerosis (SSc). To overcome some of the inherent problems with NFC image analysis (operator/observer bias, time requirements), there is an interest to automate and standardize NFC image assessment using computer vision algorithms, such as the Vision Transformer (ViT), which are based on recent advances in deep learning.
Objectives: Our aims were (1) to implement and assess the performance and the reliability of ViT in detecting changes on NFC images, and (2) to compare the performance of ViT to that of practicing rheumatologists.
Methods: For this study, we used NFC images of patients with SSc enrolled in our European Scleroderma Trials and Research group (EUSTAR) and Very Early Diagnosis of Systemic Sclerosis (VEDOSS) local registries. Concretely, we included routine NFC images (all NFC images available – digit II to V of both hands-, irrespective of any image artefacts) of patients aged ≥ 18 years with visits between 2012 and 2021, who fulfilled either the 2013 American College of Rheumatology / European League Against Rheumatism classification criteria for SSc (established disease) or the preliminary criteria for VEDOSS (mild/early disease). ViT was trained to identify the following NFC signs of microangiopathy: enlarged capillaries (apex diameter of the capillary > 20 µm, and < 50µm), giant capillaries (> 50 µm), loss of capillaries (< 7 capillaries/mm), and microhaemorrhages. Absence of any of these signs was considered as being a "normal NFC", while presence of any of these signs was seen as an abnormal NFC image. Its performance was evaluated in a cross-fold (k = 5) validation setting, and the gold standard was the treating physician. Area under the ROC curve (AUC) was used as indicator of the performance. Considered cut-offs for AUC were 90-100% - excellent, 80-89.9% - good, 70-79.9% - fair, 60-69.9% - poor, 50-59.9% - fail. From the first cross-fold, a randomly sampled reliability set was created which was used to compare the NFC assessment performance of four rheumatologists (three invited and trained annotators and the treating physician) with that of of ViT.

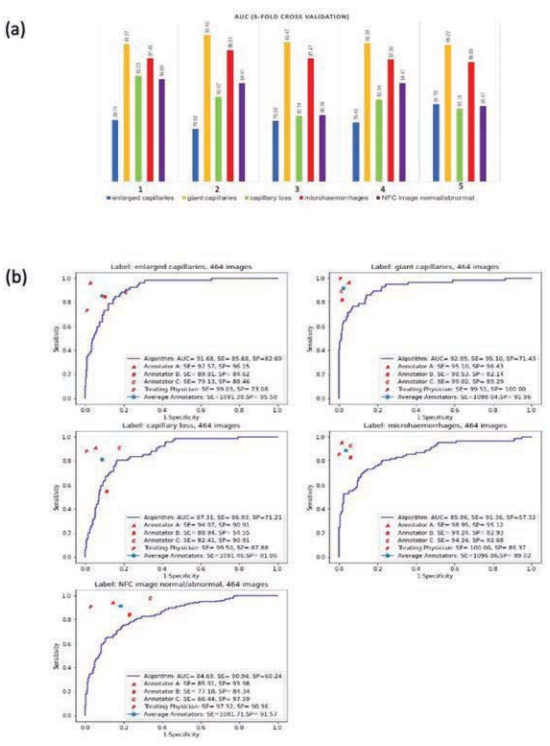

Figure 1. Performance of the ViT: (a) AUCs values for ViT in diagnosing the respective feature on NFC image. (b) Sensitivity / specificity trade-off across the images in the reliability set. The blue lines show the ROC curves corresponding to the ViT predictions, with ViT's AUC, "optimal" sensitivity and specificity shown in the box. Also shown are the point performances of each of the four annotators, with performances below the blue line indicating lower performance than ViT.

Results: We analysed 17,126 NFC images of 234 EUSTAR patients (14.6% males, 67.8% limited cutaneous SSc, median age 57 years, median disease duration 9 years) and 55 VEDOSS patients (92.7% females, median age 44 years, median time elapsed since first Raynaud's phenomenon 5 years). ViT had fair to excellent performance in identifying the different NFC changes across all five folds (of 3443 NFC images each), with an area under the ROC curve ranging from 78.59% to 90.4% (Figure 1a).
In the reliability set (see Figure 1b), we observed highest performance for diagnosing giant capillaries (AUC =92.89%) followed by identification of enlarged capillaries (AUC = 91.7%). Good AUCs were seen in depicting capillary loss (AUC = 87.3%), microhemorrhages (AUC = 85.9%) and the abnormal/normal NFC classification (AUC = 84.7%). The rheumatologists had generally higher performance in assessing NFC images. However, ViT outperformed two rheumatologists with different experience in classifying capillary loss and enlarged capillaries, respectively.
Conclusion: ViT is a modern, well performing and readily available AI model to assess signs of microangiopathy on NFC images acquired during routine practice.

FACTORS TO CONSIDER FOR MEASURING THE EFFECT OF LUNG FUNCTION ON PATIENT REPORTED OUTCOMES IN SYSTEMIC SCLEROSIS PATIENTS: ANALYSIS OF THE EUSTAR DATABASE.

M. G. Lazzaroni[1], M. Wilson[2], E. Hensor[2], J. H. W. Distler[3], G. Cuomo[4], E. Siegert[5], U. Müller-Ladner[6], Y. Allanore[7], M. J. Salvador[8], B. Anic[9], U. Walker[10], L. Czirják[11], C. Ribi[12], C. M. Tanaseanu[13], A. Gabrielli[14], A. M. Hoffmann-Vold[15], O. Distler[16], F. Del Galdo[2]. *[1]ASST Spedali Civili of Brescia, University of Brescia, -, Brescia, Italy; [2]University of Leeds, -, Leeds, United Kingdom; [3]Friedrich-Alexander-Erlangen-Nürnberg University, -, Erlangen, Germany; [4]Università della Campania, -, Napoli, Italy; [5]Charité University Hospital, -, Berlin, Germany; [6]Justus-Liebig University, Campus Kerckhoff, -, Bad Nauheim, Germany; [7]University Hospital Cochin, -, Paris, France; [8]Coimbra University Hospital, Coimbra, -, Coimbra, Portugal; [9]University Hospital Zagreb-, -, Zagreb, Croatia; [10]Unispital Basel-, -, Basel, Switzerland; [11]University of Pècs, -, Pécs, Hungary; [12]Lausanne University Hospital, -, Lausanne, Switzerland; [13]Clinical Emergency Hospital St.Pantelimon, -, Bucharest, Romania; [14]Università Politecnica delle Marche, -, Ancona, Italy; [15]Oslo University Hospital, -, Oslo, Norway; [16]University Hospital Zurich, -, Zurich, Switzerland*

Background: Patient Reported Outcomes (PROs) are central to measure how patients feel and function especially when determining the effect of disease modifying agents. In patients with Systemic Sclerosis associated Interstitial Lung Disease (SSc-ILD), dyspnea is the main driver of HAQ decline but the effect of reduced lung function on both generic and specific measures of functional impairment is not well defined, and there are many potential confounding biases that could distort the apparent extent and direction of this relationship. Moreover, collider biases potentially induced by selection into the cohort and in clinical trials can also play a role.
Objectives: To define within the EUSTAR database, the correlation of Forced Vital Capacity (FVC) and functional impairment PROs and identify potential confounders to be considered in casual inference studies.
Methods: A cross-sectional analysis included for each patient with SSc-ILD (by X-ray and/or HRCT) in the EUSTAR registry the last visit with at least one PRO (Health Assessment Questionnaire Disability Index [HAQ-DI], Cochin hand function scale [CHFS] and/or dyspnoea visual analogue scale [VAS]) and % predicted FVC (%pFVC), if available. Patients with LVEF≤50% or pulmonary arterial hypertension at RHC were excluded. SSc-ILD with restricted lung volume was defined as %pFVC≤70 [1]. Spearman's correlation analysis was performed. Results of this analysis and literature review were integrated to design a directed acyclic graph (DAG) and identify the appropriate confounder adjustment set for the total causal effect of FVC on functional impairment PROs.
Results: Among 17.338 SSc patients in the EUSTAR registry (extracted in November 2019), 727 SSc-ILD patients fulfilled the inclusion criteria (median %pFVC 90 (IQR 74-104), median %pDLCO 60 (IQR 47-52)). Patients with %pFVC<70 (n=149), as compared to those with %pFVC≥70 (n=578) had worse HAQ-DI, CHFS and VAS-dyspnoea scores (Table 1). In unadjusted analysis, %pFVC showed a weak correlation with HAQ-DI (r=-0.21) and CHFS (r=-0.17), but a stronger correlation with VAS dyspnoea (r=-0.33).

Table 1. Results are reported as number/number available (%) for dichotomic variables, or as median (IQR) (n available) for continuous variables.

	%pFVC≥70 (n=578)	%pFVC<70 (n=149)
Age at disease onset (years)	60.6 (52.3-69.3) (546)	52.5 (45.6-63-7) (137)
Disease duration (months)	134.4 (77.5-212.2) (546)	110.3 (66.3-199.7) (137)
Male sex	84/578 (14.5)	32/149 (21.5)
Anti-Scl70+	231/468 (40.7)	81/122 (66.4)
Smoker ever	52/389 (13.4)	17/107 (15.9)
Caucasian ethnicity	545/569 (95.8)	131/145 (90.3)
dcSSc	167/559 (29.9)	74/147 (50.3)
Oesophageal symptoms	319/571 (55.9)	93/147 (63.3)
Muscle weakness	78/565 (13.8)	37/149 (24.8)
CRP elevation	141/540 (26.1)	53/134 (39.6)
Elevated sPAP (ECHO)	45/456 (9.9)	21/121 (17.2)
Pericardial effusion	2/448 (0.4)	4/110 (3.6)
Diastolic function abnormality	151/431 (35.0)	31/102 (30.4)
Conduction blocks	78/480 (16.3)	35/120 (29.2)
%pDLCO	62 (52-74) (527)	42 (35-53) (118)
CHFS	7 (1-23) (493)	16 (2-34.8) (114)
HAQ-DI	0.63 (0.13-1.13) (578)	1.25 (0.38-2) (139)
VAS dyspnoea (0-100)	15 (10-45) (391)	40 (20-70) (109)
NYHA stage 3/4	47/561 (8.4)	37/143 (25.9)

Subsequently, we created a DAG showing the proposed causal pathway considered relevant to the relationship between FVC and HAQ (Figure 1).

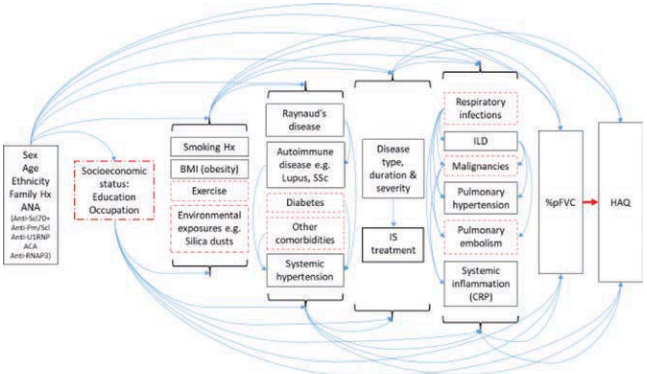

Figure 1. Directed Acyclic Graph (DAG) of factors to consider for direct casual inference of FVC on HAQ.
Variables in red dotted lines are those not systematically recorded in the EUSTAR registry.

Conclusion: Lung function as measured by FVC appears to correlate with worse patient-reported function in our unadjusted analysis of the large multicentre EUSTAR dataset. However, to estimate the total causal effect we must consider a multitude of potentially confounding factors, which need to be integrated and analysed in a causal inference framework. The proposed DAG will inform the development of simulations of the potential impact of bias (confounding, collider and omitted variable) on effect estimates we could obtain from EUSTAR cohort.

POS0894 COMPARISON OF PULMONARY AND SMALL AIRWAYS FUNCTION BETWEEN IDIOPATHIC INFLAMMATORY MYOPATHIES PATIENTS WITH AND WITHOUT INTERSTITIAL LUNG DISEASE

P. Panagopoulos[1], V. E. Georgakopoulou[2], V. Pezoulas[3], A. Goules[1], D. I. Fotiadis[3], T. Vassilakopoulos[2], A. Tzioufas[1]. *[1]School of Medicine, National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece; [2]School of Medicine, National and Kapodistrian University of Athens, Department of Physiology, Athens, Greece; [3]University of Ioannina, Unit of Medical Technology and Intelligent Information Systems, Ioannina, Greece*

Background: Pulmonary manifestations of idiopathic inflammatory myopathies (IIM) include interstitial lung disease (ILD) and respiratory muscle weakness, but function of small airways has not been studied in these patients (1). Spirometry, impulse oscillometry and measurement of respiratory resistance by the interrupter technique (Rocc) are tools to evaluate function of small airways. In addition, body plethysmography is the gold standard for measuring lung volumes, whereas nitrogen washout seems impaired, "underestimating" lung volumes in patients with small airways obstruction due to gas trapping (2). Thus, discrepancies between lung volumes measured by those two techniques may be an indication of early small airways dysfunction.

Table 1. Comparison of pulmonary and small airways function variables between IIM patients with and without ILD.

Pulmonary function variables	IIM-ILD patients (n=13)	IIM patients without ILD (n=13)	p value

R(20)%	99.4	123.4	0.09

Objectives: To compare pulmonary and small airways function between IIM patients with and without ILD.

Methods: This prospective observational study included 13 IIM patients with ILD (8 patients with dermatomyositis and 5 with polymyositis) and 13 IIM patients without ILD (9 patients with dermatomyositis and 4 with polymyositis) who were diagnosed and followed up in the outpatient rheumatology clinic of the Department of Pathophysiology between June and December 2021. All IIM patients fulfilled the 2017 EULAR/ACR classification criteria (3). The presence of ILD was determined by high resolution computed tomography of the lungs that was performed as baseline standard of care at the time of diagnosis and was evaluated by a special radiologist blindly, according to Fleischner Society definitions for ILD (4). Clinical, laboratory and immunological data were recorded at the time of diagnosis and pulmonary function was assessed by spirometry, body plethysmography, single and multiple breath nitrogen washout, impulse oscillometry and measurement of Rocc, diffusing capacity for carbon monoxide (DLco) and maximal inspiratory and expiratory pressures. Statistical analysis for categorical data was performed by Fisher exact test or $\chi 2$ square test accordingly and numerical data with Man-Whitney test or t test.

Results: IIM-ILD patients presented more frequently with dyspnea (53.8% vs 0%, p<0.01), fever (61.5% vs 7.7%, p<0.05) and arthralgias (76.9% vs 23%, p<0.05), compared to IIM patients without ILD. Inflammatory markers, serum muscle enzymes, myositis specific autoantibodies and classic spirometric parameters did not differ between the two groups. IIM-ILD patients had markedly lower predicted DLco compared to those without (mean: 56.3% vs 78.2%, p<0.01). Predicted total lung capacity and residual volume (TLC_{N2WO}%, RV_{N2WO}%) measured by nitrogen washout and the TLC nitrogen washout: TLC body plethysmography ratio (TLC_{N2WO}/TLC_{pleth}) were significantly lower in IIM-ILD patients compared to those without ILD (mean: 111.1% vs 153.4%, p<0.05, median: 171% vs 210%, p<0.05 and median: 1.28 vs 1.45, p<0.05, respectively). Similarly, ΔN2(%) was found significantly higher among non-ILD than ILD-IIM patients [5.4 vs 2.8%, p=0.013]. Predicted normal value of Rocc tended to be higher in IIM-ILD patients, although not statistically significantly.

Conclusion: Abnormal single breath nitrogen washout and discrepancies between lung volumes measured by body plethysmography and nitrogen washout in IIM-ILD patients, indicate an early small airways dysfunction in these patients.

Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; [9]University of L'Aquila, Internal Medicine and Nephrology Unit, L'Aquila, Italy

Background: Among gastrointestinal (GI) manifestations in Systemic Sclerosis (SSc) one of the predominant and challenging problems is gastroesophageal reflux disease (GERD), which occurs in ~75% of patients. Although proton pump inhibitors are useful, they are ineffective in 40% of cases with chronic use at high doses, against the background of long-term risks (e.g., cardiovascular disease and infections) which have been identified in the general population. Surgery might be an option following failure of medical therapy but currently, there is no consensus regarding the optimal surgical procedure for refractory GERD in SSc.
Objectives: To evaluate, among the surgical approaches to GERD, the feasibility of fundoplication (FP) with regards to its safety, efficacy, indications, and timing.
Methods: Four research questions based on the PICO framework were developed to guide the systematic literature review that was conducted up to 22 December 2021. The search and performed across different databases including PubMed, MEDLINE (OVID), EMBASE, Cochrane Library, Web of Science, Google Scholar, Emcare and Academic Search Premier. References were independently screened by two reviewers (PMC and AA) who also independently assessed the full text of eligible articles, and extracted data. Due to heterogeneity of retrieved studies, narrative summaries are used to present the data.

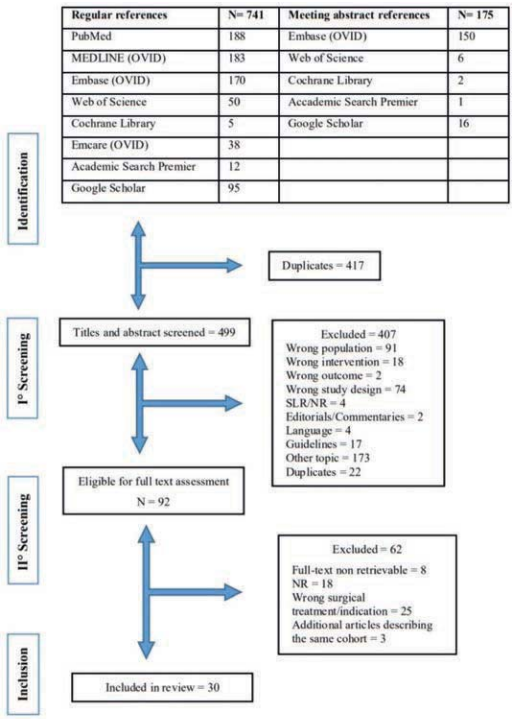

Figure 1. Flow chart of the search

Results: The search yielded 916 papers of which 30 were eligible for full text review. In these studies, out of 2919 clinically heterogeneous patients, 348 SSc patients were identified (mostly female, mean age 52.7 years). Out of these 348, only 257 underwent anti-reflux surgical procedure and were included in the analysis. Most of the studies were conducted in surgical settings and relevant rheumatological data were largely missing. Refractory GERD symptoms, were the commonest indication for surgery, with post-operative dysphagia being the most frequent complication. In 18 studies, FP was effective, whereas 4 studies had equivocal findings and in 5 a lack of efficacy was reported. The Collis-Nissen FP was the most popular procedure overall as well as in earlier studies, followed by Nissen FP, and Dor FP in relatively more recent studies, reflecting the change in surgical strategy over time. The data extracted shows also an acceptable rate of mortality and morbidity related to surgery, and heterogeneous outcome measures were used hampering any comparison of the studies (Table 1). Due to the heterogeneity of the data, it was not possible to separate the mortality and morbidity rate of SSc patients from the rest of the population.
Conclusion: Our SLR has highlighted that the surgical management of GERD in SSc patients is still highly challenging since the available evidence is scarce and of poor quality. Among the surgical approaches to the problem of GERD, overall FP seems a safe and effective procedure in SSc. Transient post-operative dysphagia was noted in many studies, particularly related with the posterior FP. In the future, it will be necessary to develop minimal requirement to conduct surgical studies in SSc as well as to design studies aimed at defining the clinical criteria for referral to surgery. Indeed, the right timing for surgery and the best surgical procedure in SSc still remains an unmet need.

POS0896 CRYOFIBRINOGEN-ASSOCIATED SYSTEMIC SCLEROSIS: POSSIBLE CORRELATIONS WITH SCLERODERMA DIGITAL ULCERS AND PULMONARY ARTERIAL HYPERTENSION

G. Amati[1], A. Spinella[1], G. Sandri[1], P. Natali[2], D. Debbia[2], M. T. Mascia[1], C. Salvarani[1,3], D. Giuggioli[1,4]. *[1]Via del Pozzo, 71, Scleroderma Unit, Rheumatology Unit, University Hospital of Modena and Reggio Emilia, Modena, Italy; [2]Via Giardini, 1355, Department of Laboratory Medicine and Anatomical Pathology, AOU of Modena, Modena, Italy; [3]Via del Pozzo, 71, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy; [4]Via del Pozzo, 71, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy*

Background: Cryofibrinogenemia (CF) is a rare disorder characterized by the presence of an abnormal protein in the plasma that precipitates when cooled and redissolves at room temperature (1). CF is rarely symptomatic, therefore it is often underestimated. Nevertheless, the cryoprecipitation of native fibrinogen could induce thrombotic occlusion of small and medium sized vessels; as a consequence, this condition could become potentially lethal without the proper treatments. CF is classified into an essential and secondary form. The association of CF with Systemic Sclerosis (SSc) is described in literature (2-4); however, the role of this phenomenon it is not completely clarified, especially because some clinical aspects could be similar in both conditions.
Objectives: The aim of our study was to analyze the clinical, laboratory, instrumental and therapeutic features of SSc patients with cryofibrinogenemia, with particular attention to the possible prevention strategy and appropriate therapy of SSc digital ulcers.
Methods: 101 SSc patients (M:F 1:13) referring to the SSc Unit-Rheumatology Unit of our University Hospital have been tested both for cryofibrinogen and cryoglobulins from February 2020 to January 2022. Clinical, laboratory, instrumental features and ongoing therapies were collected.
Results: Patients with diffuse cutaneous form, limited cutaneous form, and sine-scleroderma subsets were 20 (19,8%), 79 (78,2%), and 2 (2,0%), respectively. The overall positivity for CF was 69,3%, of which 90,7% as isolated CF and 9,3% in addition to cryoglobulins. No correlation between CF positivity and positivity for rheumatoid factor, Scl-70, CENP B, anti-fibrillarin, anti-U1RNP, anti-Th/To, anti-Ku, anti-MDA5, anti-mitochondrial, anti-SSA, anti-SSB, anti-citrullinated peptide, anti-phospholipids, anti-CORE, and anti-HCV antibodies was observed. An inverse correlation trend between CF positivity and anti-RNAP3 antibodies positivity (OR=0.0577, 95% CI 0.0029-1.1537, p=0.0620) was noted. No significant correlation between CF positivity and interstitial lung disease, pulmonary arterial hypertension (PAH), history of digital ulcers, and amputation was recorded; however, considering cryocrit sample ≥1%, a correlation between the presence of an estimated pulmonary arterial systolic pressure (ePASP) higher than 30 mmHg and the positivity of CF was obtained (OR = 2.71, 95% CI 1.01-7.28, p=0.0482). The same association was achieved if we considered patients without endothelin receptor antagonist therapy (n=47) and CF positivity (OR=6.19, 95% CI 1.19-32.2, p=0.0304).

Furthermore, no correlation between CF positivity and the presence of digital ulcers at the moment of the blood sampling was verified; however, if we stratified patients according to their ongoing treatments (absence of an endothelin receptor antagonists therapy plus PDE5 inhibitors), a significant correlation between digital ulcers and CF positivity emerged (OR=8.14, 95% CI 1.03-64,5, p=0.0470, n=91).

Conclusion: Our preliminary results on this issue are extremely interesting as they can open new perspectives on the identification of cryofibrinogen as possible prognostic marker that could be involved in the pathogenesis of scleroderma digital ulcers and PAH. Moreover, therapies which are currently used for the treatment of PAH and the management of digital ulcers, could determine circulating cryofibrinogen disappearance, with possible challenging future impact on SSc therapeutic approaches.

POS0897 A SYSTEMATIC REVIEW AND META-ANALYSIS OF DIAGNOSTIC ACCURACY OF WHOLE-BODY 18F-FDG PET AND 18F-FDG PET/CT IN DETECTING OCCULT MALIGNANCY IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHY

A. Ali[1], R. Alkilany[2], J. Asif[3], B. Basida[4], Z. Al-Sagri[5], N. Mahabadi[5], H. Sarakbi[1]. *[1]Wayne State University/Detroit Medical Center, Internal Medicine/Rheumatology Division, Detroit, United States of America; [2]CaseWestern Reserve University at MetroHealth Medical Center, Internal Medicine/Rheumatology Division, Cleveland, United States of America; [3]Beaumont Hospital, Dearborn, Internal Medicine, Dearborn, United States of America; [4]Wayne State University /Detroit Medical Center Sinai Grace Hospital, Internal Medicine, Detroit, Michigan, United States of America; [5]Wayne State University/Detroit Medical Center, Internal Medicine, Detroit, Michigan, United States of America*

Background: Idiopathic inflammatory myopathies (IIMs) are chronic, systemic autoimmune diseases that can cause muscle inflammation, weakness, and skin manifestations. Several studies have confirmed the association between IIMs and malignancy in adult population with varied frequency (4-42%), highest in patients with dermatomyositis. Detecting occult malignancy is a diagnostic challenge involving cost- and time-consuming methods. The (18)F] fluorodeoxyglucose positron emission tomography ([(18)F] FDG-PET) role in this context has been studied in multiple studies.

Objectives: The purpose of this study is to assess the diagnostic performance of whole-body ^{18}F-FDG PET or ^{18}F-FDG PET/CT for detection of occult malignancy in patients with IIMs.

Methods: A systematic search was performed in PubMed (Medline), Embase, and Scopus, Cochrane and clinicaltrial.gov to identify relevant published studies reporting the performance of ^{18}F-FDG PET or ^{18}F-FDG PET/CT in detecting occult malignancy in IIMs. Histopathologic confirmation and/or clinical follow-up was considered as the gold standard for diagnosis. Studies were eligible if all patients were 18 years or older, does not have history or current diagnosis of cancer and classified as IIMs according to Bohan and Peter classification criteria or have confirmed tissue diagnosis. The screening, full text review, quality assessment with QUADAS-2 tool and data extraction were performed by two investigators. Pooled estimates, with 95% confidence intervals (CIs), of sensitivity, specificity, and diagnostic odds ratio were calculated. A summary receiver-operating-characteristic curve (SROC) was constructed, and the area under the curve (AUC) was determined along with the Q* index.

Results: Out of 499 studies collected, six studies including a total of 293 patients with IIMs and who underwent ^{18}F-FDG PET or ^{18}F-FDG PET/CT examinations met our inclusion criteria. In two studies (87 participants), there was no clear data about the age and gender of the participants. The other four studies (total of 206 patients) 131/206 were females and 75/206 were males. Information about the type of IIMs was available in 5/6 studies with total of 283 participants; Dermatomyositis (194/283), Overlap polymyositis (41/283), Immune mediated necrotizing myositis (14/283), Polymyositis (11/283), non-specific (4/283), and orbital myositis (1/283). A total of 47 cancers were detected with lung (9/47), Breast (8/47) and nasopharyngeal (6/47) cancers were the most reported malignancies. Interestingly, all the breast cancers were reported as false negative. The pooled sensitivity, specificity, and diagnostic odds ratio of ^{18}F-FDG PET or ^{18}F-FDG PET/CT for the detection of underlying malignancy were 0.81 (95% CI, 0.67–0.91), 0.89 (95% CI, 0.84–0.92), and 38.19 (95% CI, 7.6-190.60), respectively. The heterogeneity of the studies was moderate with Chi-square, and I^2 index of 15.6 (P <0.05) and 68% respectively. The AUC and the Q* index was 0.95(SE, 0.033) and 0.89, indicating excellent diagnostic accuracy (Figure 1).

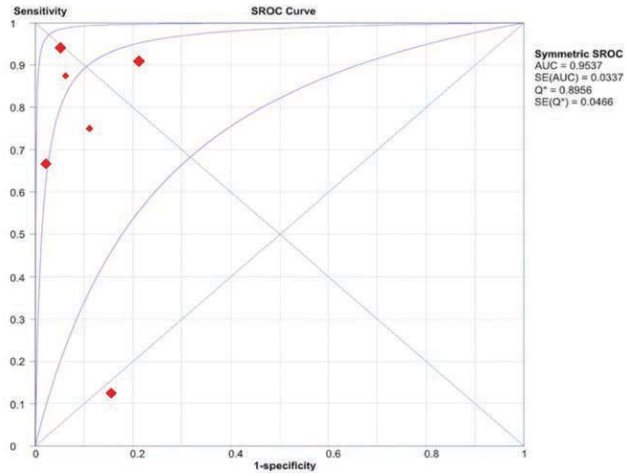

Figure 1. Summary Receiver Operating Characterestic curve of PET scan in detecting occult malignancy in IIMs

Conclusion: This meta-analysis demonstrates that whole-body ^{18}F-FDG PET or ^{18}F-FDG PET/CT has high diagnostic accuracy and moderate to high sensitivity and specificity for detection of underlying malignancy in patients diagnosed with IIMs.

SVF =stromal vascular fraction P = prospective. R = retrospective. RCT= double blind randomized-controlled trial. ETA = endothelin antagonist. CCB= calcium channel blockers. APA= anti-platelet agents. PG= prostaglandins. ARB= angiotensin receptor antagonist. ACEi= ACE inhibitors. PDE-5i= PDE-5 inhibitors. IS= immunosuppression. M=median. SoC= standard of care. HR= healing rate

Background: Management of digital ulcers (DUs) in systemic sclerosis (SSc) is a major clinical challenge. To date, systemic therapy is generally considered as the 'standard of care' for significant SSc-DUs. However, there is a strong rationale to develop local approaches to DUs, to avoid side effects from systemic therapies. World Scleroderma Foundation DU Working Group intends to develop practical, evidence-based recommendations for DU management including local, Surgical Treatment (L-ST).

Objectives: To summarize the literature on the safety and efficacy of L-ST for SSc-DUs.

Methods: A systematic literature review (SLR) was conducted up to May 2021. According to the PICO framework, eligibility criteria were defined and original research articles about surgical treatment of SSc DUs in adult patients were included. References were independently screened by 2 reviewers who assessed the full text of eligible articles and extracted data.

Results: Thirteen eligible articles out of 790 total publications were identified (Table 1). Due to the paucity of randomized controlled trials of surgical treatments for SSc-DU, we included retrospective studies and case series with at least 4 patients. Autologous fat (adipose tissue AT) grafting was the surgical modality mostly identified (7 studies of which 1 RCT and 6 prospective open label single arm). The healing rate (HR) with autologous fat grafting (4 studies) ranged from 66-100 %. In the RCT, two age and sex matched groups were included, adipose tissue (AT) group (n=25 pts) and sham procedure (SP) group (n=13), DU healing was reported in 23/25 in AT group versus 1/13 in the SP group in 8 wks, ($p<0.0001$), 12 pts in the SP group, received rescue AT injection, all of them healed after 8 wks. Three studies reported autologous adipose-derived stromal vascular fraction(SVF) grafting and the HR ranged from 32-60%, followed up to 12 months. Transient edema and paresthesia were reported in 2 studies, and amputation in 2 ulcers in 1 study, and no complications were reported in other studies. Surgical sympathectomy was reported in 3 studies, with a median healing rate of 81%. Bone marrow derived cell transplantation in a single study showed 87% healing rate over (4-24 wks). Two surgical studies (of direct microsurgical revascularization N=4, and microsurgical arteriolysis, N=6), showed 100% healing of ulcers, no complications reported.

Conclusion: Our SLR has identified several surgical modalities for SSc-DUs. L-STseemed generally effective and safe for DU healing, thus Significant methodological issues emerged including small numbers of pts, lack of comparator, failure to report confounders such as background therapies and variable follow up. Future research is warranted to rigorously investigate surgical interventions for Dus.

Background: Idiopathic inflammatory myopathies (IIM) are a rare, multisystem, heterogeneous diseases, and contribute to high psychological burden. The patients' perception of physical health, deteriorating independence and social and environmental relationships may not always be a direct function of disease activity. To face with these aspects, several worldwide specialized organization have recommended the use of patient reported outcome measures (PROMs) both in clinical trials and observational studies to highlight patient's perception of the disease (1). Unfortunately, data on fatigue scores in IIM is limited.

Objectives: We compared fatigue VAS scores in patients with IIM, autoimmune diseases (AIDs) and healthy controls (HCs) and triangulated them with PROMIS physical function in a large international cohort made up of answers from the e-survey regarding the COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.

Methods: Data of 16327 respondents was extracted from the COVAD database on August 31th 2021. VAS fatigue scores were compared between AID, HC and IIM using univariate followed by multivariate analysis after adjusting for baseline differences. We further performed a propensity score matched analysis on 1827 subjects after adjusting for age, gender and ethnicity. The Kruskal-Wallis test was used for continuous variables and chi-square test for categorical variables, and Bonferroni's correction was applied for the post hoc analyses considering IIMs as a reference group.

Results: We analyzed answers from 6988 patients, with a mean age of 43.8 years (SD 16.2). The overall percentage of female was 72% and the population ethnicity was mainly composed of White (55.1%), followed by Asian (24.6%), and Hispanic (13.8%). The overall fatigue VAS was 3.6 mm (SD 2.7). IIMs VAS was 4.8 mm (SD 2.6), AIDs 4.5 mm (SD 2.6), and HC 2.8 mm (SD 2.6) (P <0,001). VAS fatigue scores of IIMs were comparable with AIDs (P 0.084), albeit significantly higher than the HCs (P <0,001). Notably, fatigue VAS was lower in IIMs than AIDs in two distinct subsets: inactive disease as defined by the patient's perception and the "excellent" general health condition group, where IIMs had worse scores (P <0,05). Interestingly, fatigue VAS was comparable in active disease defined by physician assessment, patient perception, based on general functional status, or when defined by steroid dose being prescribed. Notably, after propensity matched analysis of patients adjusting for gender, age and ethnicity (1.827 answers, i.e. 609 subjects per group, P =1) the differences disappeared and IIMs and AIDs had comparable fatigue levels across all levels of disease activity, although the fatigue discrepancies with HCs were substantially confirmed. After application of a multivariate linear regression analysis we found that lower fatigue VAS scores were related to HC (P <0,001), male gender (P <0,001), Asian and Hispanic ethnicities (P <0,001 and 0,003).

Conclusion: Our study confirms that there is a higher prevalence of fatigue in all the AIDs patients, with comparable VAS scores between IIMs and other AIDs. We can also read our data commenting that females and/or Caucasians patients suffer a higher impact of this manifestation of chronic autoimmune diseases upon their lives. This is why these subjects, to our judgement, should be carefully evaluated during outpatients visits and to whom we should spend some extra time to discuss health related issues and how to improve them.

Background: Digital ulcers (DU) are common in systemic sclerosis (SSc) and associated with reduced survival, high morbidity and poor quality of life. Recommendations have previously been proposed for DU management yet there remains significant unmet patient need. Therefore the World Scleroderma Foundation DU Working Group intends to develop practical evidence based recommendations for DU management.

Objectives: To summarise data on efficacy and safety of systemic treatments for SSc DU.

Methods: A systematic literature review to May 2021 was performed. PubMed, MEDLINE, Embase, Web of Science, Cochrane Library, Emcare (OVID) and Academic Search Premier databases were searched for original studies on adult patients with SSc DU treated with systemic pharmacological treatment. Based on the PICO framework, eligibility criteria were defined and references were independently screened by two reviewers. Reviewers independently assessed the full text of eligible articles. Owing to interstudy heterogeneity narrative summaries were used to present data.

Results: The search strategy identified 1271 references of which 45 eligible articles were included. Seventeen studies were randomised placebo controlled trials (RCT) pertaining to PDE5 antagonists (PDE5i) (n=3), endothelin receptor antagonists (ERA) (n=3), prostanoids (n=7), antiplatelet agents (n=1) and other (n=3) (Table 1). No head to head RCT was retrieved. All other studies were observational studies (OBS). Studies were highly heterogeneous with application of differing definition of DU, variable study eligibility criteria, clinical endpoints and follow up periods. This limited the calculation of effect size and comparison across studies.

Table 1. Characteristics of placebo controlled randomised controlled trials

Author Year	Intervention	n	Follow up	Outcome	Favours intervention
Hachulla 2016	Sildenafil	83	12 weeks	Time to DU healing	-
Andrigueti 2017	Sildenafil	41	12 weeks	DU healing	+
Shenoy 2010	Tadalafil	24	6 weeks	New DU	+
Khanna 2016	Macitentan	554	16 weeks	New DU	-
Matucci-Cerinic 2011	Bosentan	188	32 weeks	New DU Time to healing of DU	+-
Korn 2004	Bosentan	122	12 weeks	New DU	+
Kawald 2008	IV iloprost	50	12 months	DU healing	-
Wigley 1992	IV iloprost	35	10 weeks	DU healing	+
Wigley 1994	IV iloprost	73	9 weeks	50% reduction in DU-score	-
Seibold 2017	Treprostinil	148	20 weeks	Net DU burden	-
Vayssairat 1999	Beraprost	107	25 weeks	% patients with new DU	-
Denton 2017	Selexipag	74	12 weeks	Number of new DU DU healing	-
Lau 1993	Cicaprost	33	4 weeks	Number of DU	-
Abou-Raya 2008	Atorvastatin	84	4 months	Number of DU	+
Au 2010	Cyclophosphamide	158	12 months	Number of patients with DU	-
Beckett 1984	Dipyridamole / aspirin	41	2 years	Change in general SSc	-
Nagaraja 2019	Riociguat	17	32 weeks	Net DU burden	-

+ significantly superior to comparator- non significantly different from comparatorDU: digital ulcers IV: intravenous SSc: systemic sclerosis

Several RCT found improved DU healing with treatment: two with PDE5i, one with iloprost and one showed improved DU healing and prevention with atorvastatin. Two RCT demonstrated effective prevention of new DU with bosentan. OBS studies with a total of 621 patients showed variable improvements in the healing of DU with CCB, PDE5i, ERA, statins, N-acetylcysteine, prostanoids and ketanserin and prevention of new DU with ERA. Regarding safety, all treatments were generally tolerated with few serious adverse events. Treatment was ceased in 6.25-17.5% of patients in RCT due to treatment related side effects.

Conclusion: Despite several studies assessing the efficacy and safety of systemic pharmacological treatment of SSc DU, it is not possible to draw solid conclusions due to study heterogeneity. Small RCT have shown treatment benefit with PDE5i, iloprost and atorvastatin. Large studies demonstrated effective prevention of new DU with bosentan. Our results highlight the urgent need for improved clinical trial design to generate more robust evidence and novel therapies to guide the management SSc DU.

Department, Ponta Delgada, Portugal; [17]Unidade Local de Saúde de Castelo Branco, Rheumatology Department, Castelo Branco, Portugal

Background: Mixed connective tissue disease (MCTD) is a rare systemic rheumatic disease characterized by the expression of autoantibodies targeting the U1-ribonucleoprotein and overlapping clinical features of systemic sclerosis, systemic lupus erythematosus, and inflammatory myopathies. Interstitial lung disease (ILD) is present in 47% to 78% of patients and has been associated with higher mortality rates. Associations of ILD with Raynaud's phenomenon, dysphagia, anti-Ro52 antibodies, and a scleroderma pattern on nailfold capillaroscopy have been reported in MCTD patients.
Objectives: This study aims to identify clinical and serological associations and independent predictors of ILD for patients with MCTD.
Methods: Multicenter retrospective study using data collected from clinical records. Adult patients who underwent lung computed tomography (CT) and met at least one of four MCTD diagnostic criteria (Sharp, Alarcón-Segovia, Kasukawa, or Kahn criteria) were included. Univariate analysis was performed using Chi-Square, Fischer's Exact, and Mann-Whitney tests, as appropriate. Multivariate analysis was performed using binary logistic regression modelling. The linearity of the continuous variables concerning the logit of the dependent variable was assessed via the Box-Tidwell procedure. Cases with missing information and outliers were excluded from the multivariate analysis to fulfil all assumptions necessary to assure the validity of the regression.
Results: Fifty-seven patients, of whom 37 were Caucasian (64.9%) and 48 were females (84.2%), with a mean age of 39.4±14.0 years, were included. Twenty-seven patients had ILD (47.4%), of whom 22 had nonspecific interstitial pneumonia (81.5%), 4 had usual interstitial pneumonia (14.8%), and 1 had lymphoid interstitial pneumonia (3.7%) pattern on CT. Among patients with ILD, 13 were asymptomatic (48.1%), while 14 had respiratory symptoms (51.9%), including dyspnea (N=13, 48.1%), cough (N=7, 25.9%), and pleuritic chest pain (N=1, 3.7%). Pulmonary function tests were performed in 22 patients (81.5%), 20 of whom had a restrictive pattern (90.9%).
In the univariate analysis, lymphadenopathy at disease onset (22.2% vs 3.3%, p=0.045) and esophageal involvement at any time point (40.7% vs 16.7%, p=0.043), were associated with ILD.
The binary logistic regression model predicting ILD included 56 patients, and the model explained 36.5% (Nagelkerke R2) of the variance in ILD and correctly classified 75% of all cases. Older age at diagnosis (OR 1.10/year, 95%CI: 1.00-1.12, p=0.046) and lymphadenopathy at disease onset (OR 19.65, 95%CI: 1.91-201.75, p=0.012) were identified as predictors of ILD in MCTD patients, irrespective of sex and esophageal involvement.
Conclusion: Older age at diagnosis and lymphadenopathy at disease onset were independent predictors of ILD in MCTD. Therefore, these factors should be considered when evaluating MCTD patients, especially at the time of diagnosis. To the best of our knowledge, this is the largest study ever describing predictors of ILD for MCTD patients.

POS0902 RISK FACTORS FOR LUNG FUNCTION DECLINE IN SYSTEMIC SCLEROSIS INTERSTITIAL LUNG DISEASE IN A LARGE SINGLE-CENTER COHORT

A. Ramahi[1], A. Lescoat[2], D. Roofeh[1], S. Jaafar[1], V. Nagaraja[1], S. Huang[1], D. O'dwyer[3], K. Flaherty[3], E. Kazerooni[4], D. Khanna[1]. *[1]University of Michigan, Division of Rheumatology and Scleroderma Program - Department of Internal Medicine, Ann Arbor, Michigan, United States of America; [2]University of Rennes, CHU Rennes, Inserm, EHESP, Irset -Institut de Recherche en Sante, Environnement et Travail-UMR1085, Internal Medicine & Clinical Immunology, Rennes, France; [3]University of Michigan, Division of Pulmonary and Critical Care - Department of Internal Medicine, Ann Arbor, Michigan, United States of America; [4]University of Michigan, Division of Cardiothoracic Radiology - Department of Radiology, Ann Arbor, Michigan, United States of America*

Background: Systemic sclerosis associated interstitial lung disease (SSc-ILD) is the leading cause of scleroderma-related mortality.
Objectives: This work identifies factors associated with SSc-ILD decline on pulmonary function testing (PFT).
Methods: This single center cohort identified 312 patients with ILD as determined by high resolution chest. 184 patients (59% of 312) completed baseline and serial PFTs (with at least two follow-up PFTs) and were included in this analysis. Mixed linear models were fit to assess the decline in the percent predicted forced vital capacity (ppFVC) over time. Demographics, disease factors, autoantibodies, and ILD features were included in the univariate mixed linear model; those achieving a p-value <0.20 were included in the multivariable mixed linear model. Patients were followed longitudinally, with survival as an endpoint identified using the National Death Registry Index, reviewing death certificates, and hospital records.
Results: The 184 patients were an average of 53.2 [12.1] years old; the median [IQR] disease duration from the first non-Raynaud's phenomenon symptom was 1.8 [0.7, 4.8] years. SSc subtype was diffuse in 55.4% (n=102), limited in 32.6% (n=60), overlap syndrome in 8.2% (n=15), and SSc sine scleroderma in 3.87% (n=7). Serologies were positive for anti-topoisomerase I (ATA), anti-centromere and anti-RNA polymerase III in 31.4% (n=53/169), 10.4% (16/154) and 22.9% (25/109) respectively. Mean ppFVC was 70.8 (18.9) and ppDLco 57.2 (20.8). Whole lung involvement (WLI%) of ≥20% on visual read was found in 49.3% of subjects (74/150 (49.3%)) where quantification was available. Over a median of 4.9 (2.4, 6.8) years, 21 patients (11.4%) died. The ppFVC declined a mean of 0.28/year in the overall group. There were differences in terms of ppFVC decline/year between patients who died in the first 2 years (n=10, -8.28%), 2-8 years (n=5, -3.89%), after 8 years (n=6, -1.00%), or who were still alive (n=163, -0.13%). The primary cause of death was ILD (6/21, 28.6%); those who died in the first 2 years most often died from progressive ILD (4/6, 67%). Factors significantly associated with decline in ppFVC on univariate analyses, included longer disease duration (ref. < median, P=0.0048), ATA positivity (ref. negative, P=0.0081), and WLI ≥20% (ref. 0-20%, P=0.0484). In multivariate analysis the only statistically significant variable associated with decline in ppFVC/ year was ATA positivity.
Conclusion: In a large single center cohort of SSc-ILD, ATA positivity is a risk factor for developing progressive SSc-ILD, consistent with other SSc-ILD cohorts. Stratifying patients by survival demonstrates that lung function declines dramatically in those who died within 2 years, whose main cause of death was progressive ILD. These data support the growing need to identify risk factors for disease severity and risk for progression, and to target intervention in patients most likely to develop progressive SSc-ILD[1,2].

POS0903 ASSOCIATION STUDY BETWEEN ANTI-TIF 1Γ ANTIBODY AND DEVELOPMENT OF NEOPLASIA IN THREE TERTIARY HOSPITALS.

M. Pavía Pascual[1], I. Jarque[2], J. L. Morell Hita[3], J. Loarce-Martos[3], L. F. Montaño Tapia[4], O. Rusinovich[1], N. De la Torre Rubio[1], P. Navarro Palomo[1], M. Machattou[1], C. Barbadillo Mateos[1], H. Godoy[1], J. Sanz[1], M. Fernandez Castro[1], L. F. De Villa[1], C. Merino Argumánez[1], B. Garcia-Magallon[1], J. L. Andréu Sánchez[1], J. Campos Esteban[1]. *[1]Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain; [2]Puerta de Hierro Majadahonda University Hospital, Inmunology, Majadahonda, Spain; [3]Hospital Ramón y Cajal, Rheumatology, Madrid, Spain; [4]Prince of Asturias University Hospital, Rheumatology, Meco, Spain*

Background: Anti-transcriptional intermediary factor 1γ (anti-TIF 1γ) antibody is robustly linked with cancer-associated dermatomyositis (DM) in adults, but its specificity varies widely between series. TIF 1γ can act either as a tumor promoter or suppressor and may behave as an autoantigen.
Objectives: Investigate the association between anti-TIF 1γ antibody positivity and development of neoplasia.
Methods: A retrospective chart review was conducted among patients with positive anti-TIF 1γ antibodies detected by immunoblot from March 2019 to December 2021 in three tertiary hospitals. Demographic variables, creatine kinase (CK) values, other autoantibodies, associated autoimmune diseases (AIDs) and existence or not of a cancer diagnosis were analyzed. To rule out malignancy, patients had to present a PET-CT scan without pathological findings or a chest CT scan, a gynecological study and a digestive study without alterations. A descriptive statistical analysis was performed.

Results: 29 patients with anti-TIF 1γ antibodies were analyzed, 82.7% women, with a mean age of 61 years (31-96 years).
The reason for requesting this antibody was: clinical features suggestive of DM in 10 patients (34.5%), muscle weakness in 9 (31%), interstitial lung disease (ILD) in 5 (17.2%), persistent CK elevation in 3 (10.3%), constitutional syndrome in 1 (3.5%) and antiphospholipid syndrome in 1 patient (3.5%). The mean time from symptoms onset to the detection of anti-TIF 1γ was 14 months (0-60 months).
10 patients (34.5%) had a diagnosis of DM; 4 patients (13.8%) systemic lupus erythematosus (SLE); one (3.5%) had a SLE/DM overlap syndrome; one patient (3.5%) subacute cutaneous lupus; one (3.5%) was diagnosed with diffuse systemic sclerosis; one patient (3.5%) limited systemic sclerosis; one patient (3.5%) antiphospholipid syndrome; one patient (3.5%) HLA-B27+ spondyloarthritis and 9 patients (31%) had no associated AIS. 5 patients (17.2%) showed ILD with different patterns: UIP (n=2), NSIP (n=2) and COP (n=1). Only 9 patients (31%) had elevated CK levels at the time of antibody determination. 10 patients (34.5%) were diagnosed with cancer: lung adenocarcinoma (n=2), small cell lung carcinoma (n=2), breast carcinoma (n=2), hepatocarcinoma (n=1), cervical cancer (n=1), ovarian carcinoma (n=1) and gallbladder adenocarcinoma (n=1). Of those, 7 patients (70%) had elevated CK levels and 6 (60%) had a diagnosis of DM. None of the patients diagnosed with cancer had ILD. In 4 patients (40%), the diagnosis of cancer was simultaneous with the diagnosis of anti-TIF 1γ antibodies; in 4 (40%), the diagnosis of the tumor preceded the finding of the antibodies; in the other 2 (20%), the finding of the antibodies preceded that of the tumor. 30-month survival after cancer diagnosis was 10%.
In 17 patients (58.6%) no malignancy has been found so far in the annual cancer screening. In two patients (6.9%) no cancer screening was performed.
Conclusion: In our study, 60% of patients with DM and anti-TIF 1γ presented neoplasia, a prevalence similar to that established in other series (60-80%). Furthermore, 21% of patients with antibodies and without DM were diagnosed with cancer, suggesting that anti-TIF 1γ antibodies could also be associated with neoplasia in patients without DM. Patients with ILD did not present cancer, supporting the observation of previous studies in which the presence of ILD is a marker of low risk for neoplasia in patients with DM. HyperCKemia might predict the association with neoplasia in patients with anti-TIF 1γ antibodies.

POS0904 CHANGES OF PULMONARY ARTERY SYSTOLIC PRESSURE IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS ON RITUXIMAB TREATMENT

L. Garzanova[1], L. P. Ananyeva[1], O. Koneva[1], O. Ovsyannikova[1], O. Desinova[1], M. Starovoytova[1], R. Shayakhmetova[1]. *[1]V A Nasonova Research Institute of Rheumatology, Laboratory of Systemic Sclerosis, Moscow, Russian Federation*

Background: Nowadays, there is already published a lot of data on the treatment of systemic sclerosis (SSc) with rituximab (RTX). Recent studies reported about improvement of skin fibrosis and interstitial lung disease associated with SSc (ILD-SSc) on RTX treatment. However, there is not enough data on changes of pulmonary artery systolic pressure (PASP) in SSc patients (pts) on RTX therapy.
Objectives: To evaluate changes of PASP in ILD-SSc pts on RTX therapy.
Methods: 30 pts with initially elevated PASP (detected as ≥35mmHg by echocardiography) were retrospectively selected from a group of 103 SSc pts who received RTX as a therapy for ILD. The mean follow-up period was 25.3±2.4 months. The mean age was 52.6 years (30-65), female-26 pts (87%), the diffuse cutaneous subset of the disease had 13 pts (43%). The mean disease duration was 7.2±6.3 years. The cumulative mean dose of RTX was 2.3±1.1 grams. All pts received prednisolone at a dose of 11.3±3.7mg/day, immunosuppressants received 47% of them. All pts were positive for ANA. An assessment of basic parameters was obtained at baseline (Point 0), after 13.6±2.7 months (Point 1) and at the end of follow-up (25.3±2.4 months - Point 2). The results at baseline and at the end of the follow-up are presented in the form of mean values.
Results: There was already an improvement of all main parameters at the point 1 and further - by the end of follow-up (Table 1). There was a significant decrease in PASP, which was accompanied by the improvement of lung function - increase in forced vital capacity % predicted (FVC), stabilization of diffusion capacity for carbon monoxide % predicted (DLCO). A moderate negative statistically significant correlation was found between the PASP and FVC (r=-0,522; p=0,003). There was a significant increase in 6-minute walk distance (6-mwd), ejection fraction of left ventricular (ER), activity index (EScSG-AI) and a decrease of Rodnan skin score.

Table 1. Changes of the main parameters on RTX treatment.

Parameters	Point 0 (baseline)	Point 1 (13.6±2.7 month)	Point 2 (25.6±2.4 month)	P Point 0-1	P Point 0-2
FVC, %, M±σ	75.6±20.1	82.5±19.2	88.2±22.5	0.01	0.002
PASP, mmHg, M±σ	48.2±13.8	44.4±12.3	39.5±11.8	0.008	0.004
DLCO, %, M±σ	42.7±16.2	42.6±15.2	44.9±15.6	NS	NS
ER, %, M±σ	61.6±5.5	63.5±6.2	65.8±5.7	0.02	0.01
Rodnan skin score, M±σ	11.1±12.4	7.2±8.1	6.1±7.6	0.003	0.0001
6-mwd, m, M±σ	419.6±103	453.8±85	458.8±78.4	0.02	0.02
Activity index (EScSG-AI), M±σ	3.3±1.5	1.5±1.3	1.4±1.1	0.001	0.001
Cumulative mean dose of RTX, g, M±σ	-	1.65±0.69	2.3±1.1	-	-

Conclusion: In our study, the PASP significantly decreased already in a year after initiation of RTX therapy and further there was an improvement of this parameter at the end of the observation. Decrease of PASP correlated with an increase of FVC and was accompanied by an increase of 6-minute walk distance, ejection fraction of left ventricular, improvement of Rodnan skin score and disease activity index. RTX could be considered as a potentially effective in combined treatment of ILD-SSc, complicated with pulmonary hypertension.

POS0905 CHARACTERISATION OF SWEDISH MYOSITIS PATIENTS WITH ANTI-MDA5 AUTOANTIBODIES AND CORRELATION OF CLINICAL FEATURES WITH AUTOANTIBODY LEVELS

D. Demirdal[1], E. Van Gompel[1,2,3], E. Wigren[1,2,4], M. Dastmalchi[1,2], B. Horuluoglu[1,2], A. S. Galindo-Feria[1,2], S. Gräslund[1,2,4], K. Chemin[1,2], I. E. Lundberg[1,2], A. Notarnicola[1,2]. *[1]Karolinska University Hospital, Rheumatology, Stockholm, Sweden; [2]Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden; [3]KU Leuven, Laboratory of Tissue Homeostasis and Disease, Skeletal Biology and Engineering Research Center, Leuven, Belgium; [4]Structural Genomics Consortium, Center for Molecular Medicine, Stockholm, Sweden*

Background: The association between anti-melanoma differentiation association protein 5 autoantibodies (aMDA5) and rapidly progressive interstitial lung disease (RP-ILD) in clinically amyopathic dermatomyositis is well established in Asian population cohorts. In western cohorts, ILD has been strongly associated with aMDA5 but data regarding RP-ILD have been more conflicting. It is also suggested that western cohorts have more pronounced myopathic features than Asian.
Objectives: To characterise the disease manifestations of a Swedish aMDA5 positive idiopathic inflammatory myositis (IIM) cohort and to explore antigen reactivity of the MDA5 protein.
Methods: First available serum samples collected from 28 consecutive patients with IIM and positive aMDA5 ever tested by ELISA, Line Blot (LB) or Immunoprecipitation, attending Karolinska University Hospital between 1999 and 2021, were included. Clinical data including presence of anti-SSA autoantibodies by ELISA or LB was retrieved retrospectively. An in-house ELISA was used to screen serum samples for reactivity against a recombinant MDA5 protein (rMDA5, aa A110-D1025, UniProt ID Q9BYX4) and seven MDA5-derived constructs containing different domains. Correlations between aMDA5 reactivity levels and clinical data were explored.
Results: Nine patients showed no reactivity to any of the rMDA5 constructs by ELISA and were excluded from further analysis.
Reactivity against rMDA5 was confirmed by ELISA in 19 patients (median 184.7 µg/mL (interquartile range (IQR) 277.07). The cohort included 13 male and 6 female patients, 94% Caucasian, with mean age at diagnosis of 41.05 years (standard deviation (SD) 10.5). Median disease duration at time of sampling was 0 months (IQR 1). All patients except one had signs of muscle involvement (muscle weakness, elevated muscle enzymes, muscle oedema or muscle biopsy consistent with myositis). At diagnosis 63.2% of patients reported muscle weakness (21.1 % had a manual muscle test 8 score <75). Dermatological findings were observed in 17/19 (89.7 %). During disease course nine patients (47.4%) had confirmed arthritis. ILD was diagnosed in 16/19 patients (84.2%), four of these (25%) developed a RP-ILD. One patient passed away due to RP-ILD and one required a lung transplant. Patients with ILD had a statistically significant higher mean age at diagnosis than those without (42.8.5 (SD 10.3) vs 31.3 (SD

4.7) years, p=0.02). Patients developing RP-ILD were not significantly older than patients with chronic ILD. Respiratory symptoms were reported by 75% of patients with ILD at time of diagnosis. The mean total lung capacity (TLC) of the ILD cohort was 68% (SD 17), mean diffusion capacity of carbon monoxide (DLCO) was 59% (SD 15) and mean forced vital capacity (FVC) was 62% (SD 19). There was a higher proportion of patients with CRP ≥ 3 times the reference range at diagnosis amongst patients with FVC <70 % than patients with FVC >70 % (88.9 % vs 16.7 %, p= 0.01).

Ten patients (52.6%) had anti-SSA autoantibodies, all had ILD. Anti-SSA positive patients had a statistically significant lower TLC than those without (62% vs 79% respectively, p=0.04) and a lower FVC (57% vs 76% respectively, p=0.05).

We found a weak non-statistically significant negative correlation between titres of aMDA5 and TLC, DLCO and FVC (Pearson coefficients -0.187, -0.289, -0.130 respectively). Frequency of ILD was higher in patients with aMDA5 titres >100 µg/mL than those with titers <100, but not statistically significant (81.3% vs 18.8%, respectively).

Conclusion: In this Caucasian cohort of aMDA5 positive IIM patients, ILD was present in over 80% of patients, of these, one quarter had RP-ILD. Older patients were more likely to present with ILD. Anti-SSA positivity and higher CRP levels were associated with worse lung function. We found a weak negative correlation between aMDA5 titres and lung function tests, as well as a trend of higher frequency of ILD in patients with higher aMDA5 titres. Muscle and skin involvement were found in a high proportion of patients.

POS0906 PREVALENCE OF SPECIFIC AND ASSOCIATED MYOSITIS ANTIBODIES IN A COHORT OF PNEUMOLOGICAL PATIENTS: FROM THE DIAGNOSIS OF INTERSTITIAL LUNG DISEASE TO A POSSIBLE DIAGNOSIS OF CONNECTIVE TISSUE DISEASE

F. Angeli[1], E. Pedretti[1], M. Fredi[1], I. Cavazzana[1], D. Modina[2], P. Ceruti[2], L. Andreoli[1], E. Garrafa[3], F. Franceschini[1]. *[1]ASST Spedali Civili of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy; [2]ASST Spedali Civili of Brescia, Pneumology and Respiratory Physiopathology Unit, Brescia, Italy; [3]ASST Spedali Civili of Brescia, Diagnostic Laboratory, Department of Molecular and Translational Medicine, Univesity of Brescia, Brescia, Italy*

Background: Interstitial lung disease (ILD) could be the first and only manifestation of idiopathic inflammatory myopathies (IIMs). Myositis-associated (MAA) or myositis-specific autoantibodies (MSA) are found in 60%-65% of cases [1, 2], but only anti-Jo1 have been included in EULAR 2017 criteria [3].

Objectives: Aim of this work is to evaluate the presence of MSA/MAA in patients with ILD on serum analyzed by line blot (LB) immunoassay, the associated clinical diagnoses and the consistency of these diagnoses with antibody specificity.

Methods: Between march 2017 and march 2021, 267 sera were analyzed for MSA/MAA, 84 (31.4%) of which requested after a pneumological evaluation. The search was performed by LB (EUROLINE, Autoimmune Inflammatory Myopathies 16 Ag Profile). Medical records were analyzed for patients with at least one MSA/MAA and diagnosis divided in: connective tissue disease (CTD), interstitial pneumonia with autoimmune features (IPAF) or only pneumological diagnosis.

Results: A positivity for at least one MSA/MAA was found in 37/84 (44%) patients that had the following pneumological diagnosis: 13 non-specific interstitial pneumonia (NSIP, 35.1%), 10 organizing pneumonia (OP, 27%), 10 usual interstitial pneumonia (UIP, 27%), 1 acute interstitial pneumonia (AIP, 2.7%), 1 lymphoid interstitial pneumonia (LIP, 2.7%), 1 iatrogenic ILD for amiodarone (2.7%) and 1 idiopathic pulmonary artery hypertension (IPAH, 2.7%). Distribution of antibodies is reported in Table 1. The most frequent autoantibody was anti-Ro52 (13 sera, 35.2%), while anti-Mi2 was the most frequent MSA (10 sera, 32.4%) followed by anti-Jo1 and anti-SRP with 5 (13.5%) positive sera each. In Figure 1 the heatmap represents the frequency of MSA/MAA and their mutual associations. Multiple autoantibodies were found in 17 (46%) sera. More than one MSA was found in 8 (21.6%) sera of patients with the following diagnosis: 4 only pneumological diseases, 3 ASS and 1 IPAF.

Table 1. Distribution of MSA/MAA and associated autoimmune diseases

Autoantibodies distribution N (%)	Sera with a single MSA/MAA (N/positive; %)	CTD* (N/positive; %)	IPAF (N/positive; %)
MSA			
Jo-1 = 5 (13.5)	2/5 (40)	3/5 (60)	0
PL7 = 4 (10.8)	0	2/4 (50)	1/4 (25)
PL12 = 6 (16.2)	3/6 (50)	3/6 (50)	0
OJ = 3 (8.1)	2/3 (66.6)	1/3 (33.3)	2/3 (66.6)
EJ = 1 (2.7)	1/1 (100)	1/1 (100)	0
Mi-2 = 10 (32.4)	3/10 (30)	2/10 (20)	0
NXP2 = 1 (2.7)	0	0	1/1 (100)
SRP = 5 (13.5)	2/5 (40)	2/5 (40)	0
TIF1gamma = 2 (5.4)	0	1/2 (50)	0
MAA			
Ro-52 = 13 (35.2)	3/13 (23)	9/13 (69.2)	1/13 (7.6)
PM/Scl = 6 (18.9)	4/6 (66.6)	0	1/6 (16.6)

For some patients there are multiple positive antibodies.*The following diagnosis were included: antisynthetase syndrome, dermatomyositis, polymyositis and systemic sclerosis.

During the diagnostic work-up, at least one MSA/MAA were detected in 13 patients diagnosed with a CTD (35%), 5 with a IPAF (13%), 19 (51%) only a pneumological diagnosis. Of these 19 patients, 11 (57.9%) had a single autoantibody positivity (8 for a MSA, 3 for a MAA) while 8 (42.1%) had multiple positivity (4 with a MSA plus MAA and 4 with multiple MSA positivity).

The most frequently diagnosed CTD was ASS with 9 patients (24.3%), followed by 2 polymyositis (5.4%), 1 dermatomyositis (2.7%) and 1 systemic sclerosis (2.7%). Pulmonary involvement in patients with CTD was represented by 9 cases of NSIP (69,3%) and 4 UIP (30,7%).

Conclusion: During the last 4 years about 1/3 of research for MSA/MAA requests to our laboratory had a pneumological indication and MSA/MAA were found in 44% of these patients. In patients with pulmonary involvement and MSA/MAA positivity 35% developed a CTD. Interstitial lung disease could be the first manifestation of a systemic autoimmune disease: research for MSA/MAA and a collaboration between rheumatologist and pneumologist allows a correct diagnostic work-up and therapeutic approach.

Background: There are different measures and tools validated to evaluate disease activity and damage in idiopathic inflammatory myopathies (IIM). Disease activity and damage in patients with early diagnosis is not still well defined.
Objectives: To analyze disease activity outcomes and their association with damage in IIM differentiating between incident and prevalent cases.
Methods: Multicenter cross-sectional study of a cohort of patients included in the Spanish Registry of patients with IIM (Myo-Spain)(1). Patients were classified as incident cohort (time between diagnosis and study initiation ≤ 12 months) or prevalent cohort (> 12 months). Activity and damage data were collected at the initial visit. Differences between both groups were tested by Chi-square, Student's t and Mann-Whitney tests. Spearman's correlation coefficients (Rho) were used to analyze correlations between disease activity and damage measures (weak ≥ 0.2 - <0.3; moderate ≥ 0.3 <0.7; strong ≥ 0.7).
Results: We included 139 (67.63% women) and 417 patients (74.34% women) with a mean age at diagnosis of 54 and 48 years in the incident and prevalent cohort, respectively. Patients in the incident cohort had significantly higher disease activity measures: myositis disease activity assessment visual analogue scale (MYOACT) total, extramuscular activity of MYOACT, physician global activity (PhGA), patient global activity (PGA), manual muscle testing (MMT)8, CK, and HAQ ($p < 0.001$).The organ systems with the bigger differences between the incident and the prevalent cohort were skin and constitutional ($p<0.001$). No significant differences were found respect to physician global damage (PhGD), patient global damage (PGD) and myositis damage index (MDI), between both cohorts ($p > 0.2$). Correlations between disease activity and damage measures are showed in the Table 1. The main differences found between both cohorts were the correlations of PhGA, CK, PGD and MDI with other measures of disease activity.
Conclusion: Incident cases had higher disease activity. In those in whom damage was detected, no differences were found in damage measures with prevalent cases. The correlation between the different measures of activity and damage was slightly better in prevalent patients.

POS0908 AUDIOLOGICAL DISTURBANCES IN PATIENTS WITH SYSTEMIC SCLEROSIS: ASSOCIATION WITH CLINICAL MANIFESTATIONS AND NAILFOLD CAPILLARY MICROSCOPIC ABNORMALITIES

C. Mazeda[1], S. P. Silva[1], J. Romão[2], D. Matias[2], R. Aguiar[1], L. Azevedo[2], A. Barcelos[1]. *[1]Centro Hospitalar Baixo Vouga, Rheumatology, Centro Académico Clínico Egas Moniz, Aveiro, Portugal; [2]Centro Hospitalar Baixo Vouga, Otolaryngology, Aveiro, Portugal*

Background: Systemic Sclerosis (SSc) is a rare connective tissue disease with several systemic and organ specific manifestations, characterized by immune dysfunction, vascular abnormalities, and fibrosis. The microvascular damage is a prominent feature of SSc, being easily assessed by nailfold video-capillaroscopy (NVC). These vascular changes may result in the involvement of the inner ear as the cochlea is highly sensitive to these changes. Blood changes and hypoxia seem to culminate with necrosis of the cochlear tissue, which is clinically expressed as hypoacusis and tinnitus. Hearing loss and auditory symptoms have been reported in 20 to 40% of SSc patients. The prominence of other symptoms may be a reason for audiovestibular symptoms being neglected in these patients, but this can negatively affect patient's quality of life (QoL) and social interaction.
Objectives: The aim of this study is to assess the prevalence of audiological disturbances in patients with SSc and to evaluate its relationship with the duration, characteristics, and severity of the disease.
Methods: Cross-sectional study included 24 patients with SSc, who fulfilled ACR/EULAR criteria followed at outpatient rheumatology clinic between 2012 and 2020 and 20 healthy controls. Socio-demographic, clinical data and pattern of NVC were collected. Both groups underwent a complete ear-nose-throat physical examination, pure-tone audiometry, speech audiometry and impedance. QoL was assessed by the European Quality of Life–5 Dimensions (EQ-5D) questionnaire. Descriptive analysis was performed, p-value <0.05 was statistically significant.
Results: Clinical characteristics and audiometric findings of all patients are listed in Table 1. 13% of patients with SSc reported hearing loss and 38% reported tinnitus and vertigo. Similar values were reported in control group with exception to vertigo symptoms (20%). 37.5% patients presented abnormal hearing loss in the pure-tone audiometry compared with 5% of the controls (p=0.02). Sensorineural hearing loss and abnormal speech reception threshold were more common in SSc patients compared to controls (p=0.03; p=0.04). Auditory recruitment was found in 1 SSc patient. There was no correlation between objective hearing loss and type of scleroderma, duration of disease, type of antibodies, skin score, NVC

Myositis disease activity assessment visual analogue scale (MYOACT), physician global activity (PhGA), patient globalactivity (PGA), manual muscle testing (MMT)8, health assessment questionnaire (HAQ), physician global damage(PhGD), patient global damage (PGD), myositis damage index (MDI).

patterns and organ involvement but there were statistically significant differences with history of digital ulcers. We also found middle ear dysfunction: absence of stapedius reflex (20.8%) and abnormal tympanometry (45.8%) in patients with SSc versus control group (p=0.001). The mean value of EQ-VAS was lower in SSc group (63.8±13.1) compared to controls (71.1±11.0) (p=0.04), but without significant differences with the changes in the pure-tone or speech audiometry.

Table 1. Clinical characteristics and audiometric findings of all patients

	SSc n=24	Controls n=20	*p*
Age, years (mean±SD)	58.4±11.4	55.3±10.3	0.63
Sex (M/F), n	5/19	6/14	0.49
Duration disease (mean±SD)	50.3±41.2	-	
Diffuse cutaneous, n (%)	7 (29.2)	-	
Anti-Scl70 antibody, n (%)	6 (25.0)	-	
Anticentromere antibody, n (%)	14 (58.3)	-	
Anti-RNA polymerase III antibody, n (%)	3 (12.5)	-	
Pulmonary involvement, n (%)	7 (29.2)	-	
Gastrointestinal involvement, n (%)	8 (33.3)	-	
Articular involvement, n (%)	2 (8.3)	-	
Nailfold video-capillaroscopy pattern		-	-
Nonspecific	1 (4.2)		
Early	11 (45.8)		
Active	8 (33.3)		
Late	4 (16.7)		
Subjective hearing loss, n (%)	3 (12.5)	3 (15)	0.58
Tinnitus, n (%)	9 (37.5)	4 (20)	0.41
Objective hearing loss, n (%)	9 (37.5)	1 (5)	**0.02**
Sensorineural hearing loss (%)	7 (29.2)	1 (5)	**0.03**
EQ-VAS (mean±SD)	63.8±13.1	71.1±11.0	**0.04**

Conclusion: Our study found higher prevalence of inner and middle ear pathologies in SSc patients. It is also important to emphasize the relationship found with history of digital ulcer. In these patients, this type of involvement should be considered both during diagnostic and therapeutic procedures. Further investigation is needed for a better understanding of ear damage in these patients.

POS0909 THE ROLE OF IMACS CORE SET MEASURES TO ROUTINELY EVALUATE THE QUALITY OF LIFE OF IDIOPATHIC INFLAMMATORY MYOPATHIES PATIENTS IN CLINICAL PRACTICE

C. Cardelli[1,2], R. Marinai[1], S. Barsotti[2,3], A. Tripoli[2], M. Diomedi[1,2], E. Laurino[1,2], L. Carli[2], M. Mosca[1,2]. *[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy; [3]Ospedale di Livorno, Medicina Interna, Livorno, Italy*

Background: Idiopathic Inflammatory Myopathies (IIMs) are rare, multisystemic and complex diseases, often impacting on patients' quality of life (QoL). Patient Reported Outcomes (PROs) assess the overall health status of patients, particularly for emotional and functional domains. In clinical practice the administration of PROs might have some limitations, because they tend to be time-consuming and sometimes difficult to be filled in by patients. The International Myositis Assessment & Clinical Studies Group Disease Activity Core Set Measures (IMACS-CSM) are a tool created to specifically assess disease activity and QoL in IIMs.
Objectives: To evaluate the ability of IMACS-CSM in assessing IIMs patients' QoL in comparison with both generic and IIMs specific PROs.
Methods: Consecutive adult patients with an established diagnosis of IIM (2017 EULAR/ACR criteria) followed at our Myositis Clinic were enrolled and evaluated during scheduled follow-up visits. Demographic and clinical data (age, sex, disease subset and duration, organ involvement) were collected. IMACS-CSM [Physician Global Activity (PhGA), Patient Global Activity (PGA), 8-items Manual Muscle Testing (MMT8), Health Assessment Questionnaire (HAQ), CPK values, Myositis Disease Activity Assessment Tool (MDAAT)] were used to evaluate both disease activity and QoL. Patients' perspective was evaluated also by administration of PROs not included in the IMACS-CSM: Short-Form 36 Items Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-F), Myositis Activity Profile (MAP), MD Anderson Dysphagia Inventory (MDADI). Results were expressed as mean±SD for continuous variables and as percentage for categorical variables. Intergroup comparisons were assessed by using Chi-square, t-test and ANOVA. Pearson coefficient was used to analyse the correlations between IMACS-CSM variables and the other PROs. P values <0.05 were considered significant.
Results: Sixty patients (65% female, mean age 59.9±13.5 years, mean disease duration 7.7±6.1 years), 37 (61.7%) with polymyositis, 20 (33.3%) with dermatomyositis and 3 (5%) with inclusion body myositis, were enrolled. Among IMACS-CSM, the mean HAQ and PGA scores were significantly worse in case of muscle (p=0.017) and oesophageal involvement (p=0.017), respectively; as expected, MMT8 score was associated with muscle involvement (p=0.017); MDAAT score was instead associated with oesophageal dysfunction (p<0.001). No associations were found between IMACS-CSM and others clinical and demographic parameters. FACIT-F correlated positively with MMT8 (r 0.432, p=0.001) and negatively with PhGA, PGA, HAQ and MDAAT (all r <-0.404 and p≤0.002 except for PhGA with r=-0.338 and p=0.016). SF-36 domains correlated positively with MMT8 (all r >0.259, p≤0.05) and negatively with PGA (all r <-0.393, p≤0.001), HAQ (all r <-0.422, p≤0.001) and MDAAT (all r <-0.276, p≤0.05). Opposite correlations were found for MAP domains: MMT8 all r <-0.297, p≤0.05; PGA all r >0.326, p≤0.05; HAQ all r >0.483, p≤0.001; MDAAT all r >0.268, p≤0.05. Similarly, MDADI scores correlated negatively with MMT8 (r <-0.363, p=0.005) and positively with PGA, HAQ and MDAAT (all r >0.318, p≤0.015). Notably, no correlations emerged between these PROs and CPK values.
Conclusion: Even if IMACS-CSM offer a partial evaluation of patients' perspective, our data show how not only HAQ and PGA, but also PhGA, MMT8 and MDAAT (expressing rheumatologist's point of view) seem to adequately reflect overall health status of IIMs patients, thus giving to clinicians a reliable assessment of their QoL. Therefore, the core set should be routinely used in clinical practice during every outpatient visit, while more accurate and complex PROs might be administered at larger time intervals or during disease flares, to optimize IMACS-CSM's analysis.

POS0910 PSYCHIATRIC COMORBIDITIES ASSESSMENT: AN UNMET NEED IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES?

C. Cardelli[1,2], M. Diomedi[1,2], S. Barsotti[2,3], M. DI Battista[1,2], A. Tripoli[2], L. Carli[2], M. Mosca[1,2]. *[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy; [3]Ospedale di Livorno, Medicina Interna, Pisa, Italy*

Background: Idiopathic Inflammatory Myopathies (IIMs) are rare and complex chronic diseases, with a strong impact on patients' Quality of Life (QoL) in terms of both physical and emotional functioning. Despite its key role in daily life, patients' emotional status could be difficult to be investigated by physicians. As known, patients with chronic conditions are at higher risk of anxiety and depression, but data about their prevalence in IIMs are still limited. The Hospital Anxiety and Depression *Scale* (*HADS*) is a validated questionnaire to evaluate the presence and severity of both anxiety (HADS-A) and depression (HADS-D) in patients.
Objectives: To determine the prevalence of anxiety and depression in a monocentric cohort of IIMs patients and to evaluate possible correlations with clinical features, disease activity and parameters of QoL.
Methods: Consecutive adult patients with a diagnosis of IIM (2017 EULAR/ACR criteria) were recruited during a scheduled follow-up visit. Demographic and clinical features were recorded (sex, age, disease subset and duration, organ involvement, comorbidities). IIM disease activity was evaluated following International Myositis Assessment & Clinical Studies Group Disease Activity Core Set Measures. To detect anxiety and depression status, HADS was administered to patients, who were also asked to fill in Short-Form 36 Items Health Survey (SF-36). For both HADS-A and -D subscales, patients were classified as at risk for scores ≥8 (borderline for scores 8-10, high risk if ≥11). Results were reported as mean±SD for continuous variables and as percentage for categorical variables. Intergroup comparisons were assessed by using Chi-square, t-test and ANOVA. Pearson coefficient was used to analyse the correlations between variables. P values <0.05 were considered significant.
Results: Fifty-three patients (72% female; mean age 64.8±12.0 years; mean disease duration 7.4±6.2 years) were enrolled. Twenty (37.7%) showed increased anxiety scores (mean 11.35, min. 8 – max. 17): 10 (50%) borderline and 10 (50%) high risk. Twenty (37.7%) had an increased depression score (mean 11.75, min. 8 – max. 19): 6 (30%) borderline and 14 (70%) high risk. If abnormal scores of both HADS-A and -D were found in 15 patients (28.3%), 17 patients (32.1%) were at high risk of at least one of the conditions. Sex, age, disease subset and duration did not seem to influence patients' emotional status. Apart from an association between Raynaud's Phenomenon occurrence and higher HADS-A scores (p=0.045), no significant correlations with organ involvements emerged. A strong association was found between fibromyalgia and higher HADS-A and -D scores (p=0.006 both). Patients with elevated anxiety levels presented significantly higher scores of Patient Global Assessment (PGA, p=0.002) and Health Assessment Questionnaire (HAQ, p=0.007) and significantly lower scores of Manual Muscle Testing (MMT8, p=0.004). HADS-D scores were similarly associated with PGA (p=0.001), HAQ (p<0.0001) and MMT8 (p=0.001). The presence of anxiety and depression was associated with lower scores in all SF-36 domains (all p≤0.016 for HADS-A and all p≤0.006 for HADS-D). Moreover, a correlation was found among SF-36 scores and PGA (all r <-0.516, p<0.01), HAQ (all r <-0.541, p<0.01) and MMT8 values (all r >0.299, p<0.05).
Conclusion: These results show nearly 40% of our cohort was at risk of anxiety or depression; almost 30% were at risk of developing both conditions together and quite one third was at high risk to develop at least one of them. As expected, these conditions were favoured from a concomitant fibromyalgia. Moreover, a compromised QoL and a functional limitation, as evaluated by PGA, HAQ and MMT8, in agreement with SF-36

domains, were significant risk factors for their occurrence. Therefore, our data, although preliminary, underline the need of a more comprehensive evaluation of IIMs patients, who should be screened for psychiatric comorbidities and, in case of high risk, referred to a specialist evaluation, in the perspective of improving their quality of care.

POS0911 DIAGNOSTIC VALUE AND CLINICAL RELEVANCE OF MUSCLE BIOPSY IN PATIENTS WITH SUSPECTED MYOSITIS

K. Kastrati[1], N. Nakhost Lotfi[1], M. Tawfik[2], E. Gelpi[3], R. Hoeftberger[3], H. Kiener[1], D. Aletaha[1], M. Bonelli[1], H. Radner[1]. [1]*Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine 3, Vienna, Austria;* [2]*Suez Canal University, Department of Rheumatology and Rehabilitation, Ismailia, Egypt;* [3]*Medical University of Vienna, Division of Neuropathology and Neurochemistry, Vienna, Austria*

Background: Diagnosis of idiopathic inflammatory myopathies (IIM) represents a clinical challenge and muscle biopsy itself is regarded as the cornerstone for confirming diagnosis of IIM. However, the significance of muscle biopsy as diagnostical tool remains inconclusive

Objectives: To determine the diagnostic accuracy and clinical relevance of muscle biopsy in patients with suspected myositis.

Methods: In this retrospective cohort study, histopathological findings of muscle biopsy specimens of adult (≥ 18 years of age) patients with clinically suspected or differential diagnosis of myositis referred from all over Austria to the Medical University of Vienna through the period of 01.01.2007-31.10.2021 were analyzed. Following information were extracted from handwritten assignment sheets: referral department, suspected diagnosis (inflammatory and/or non-inflammatory myopathy), sampling location, demographic, clinical, laboratory and serologic data, and imaging results. Histological findings were grouped in: 1) inflammatory, 2) non-inflammatory (neurogenic, metabolic etc.), 3) inflammatory and non-inflammatory mixed, and 4) normal. Clinical information on start of immunosuppressive treatment after muscle biopsy could be partly retrieved form electronical medical records (EMR). Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) of histological results were calculated using clinical diagnosis (defined as initiation of immunosuppressive therapy) as gold standard.

Results: 778 muscle biopsy specimens of 762 patients with suspected myositis (49.6% female, mean age of 56 years) were analyzed. Cohort descriptives are displayed in Table 1. Overall, 373/778 (47.9%) muscle biopsies revealed inflammatory features only or had mixed results with non-inflammatory characteristics. Out of 541 samples with suspected diagnosis of myositis, diagnosis was confirmed histologically in 300 (55.5%) cases; 46 (8.5%) specimens additionally showed co-features of non-inflammatory myopathy, whereas 221 (40.3%) were non-inflammatory at all and 15 (2.8%) were normal. Proportion of myositis was more pronounced, when CK was elevated at time of biopsy (Figure 1).

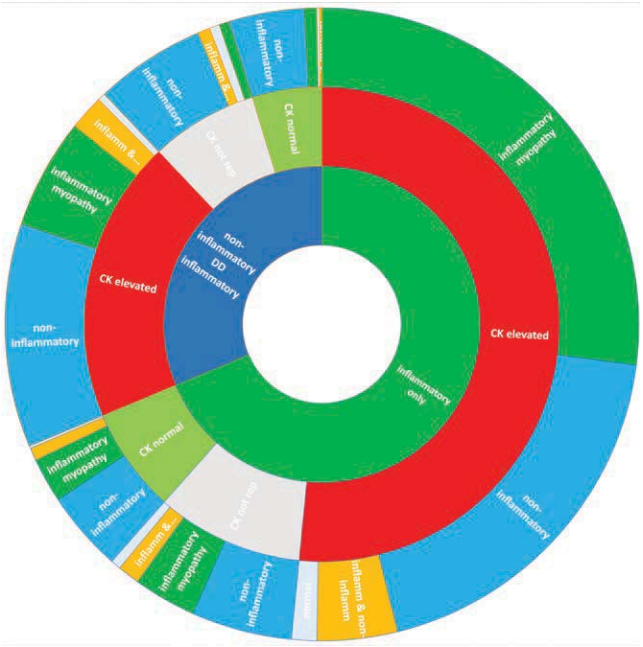

Figure 1. From suspicion to histological verification depending on CK-levels

Out of 237 samples with differential diagnosis of non-inflammatory myopathy in addition to myositis, 53 (22.4%) were histology. confirmed as inflammatory only and 20 (8.4%) showed mixed features. 153 (64.6%) biopsies were non-inflammatory only and 8 (3.4%) normal. Samples with no pathological features were observed in 24/778 (2.3%) of the cases, with 0.8% sampling error (no muscle tissue). Of 421/778 (54.1%) patients, clinical data could be extracted from EMR of which 209/421 (49.6%) had histological features of inflammation. In 287/421 (68%) cases, information regarding initiation of immunosuppressive treatment were available on EMR. 224/287 (78%) patients received immunosuppression (steroids and/or disease-modifying anti-rheumatic drug [DMARD]), thus fulfilled clinical diagnosis of myositis. In 155/224 (69.2%) cases, muscle biopsy confirmed histology. features of inflammation. Tests on diagnostic accuracy of muscle biopsy using initiation of any immunosuppressive treatment as gold standard were performed. The sensitivity of the test (biopsy) for diagnosing IIM was 71.4% with a specificity of 79.6%. PPV was high (92.8%), whereas NPV low (43.1%).

Conclusion: Less than 50% of biopsy samples with suspected diagnosis of myositis histologically revealed an inflammatory myopathy. The percentage increased when CK levels were elevated. Sensitivity and specificity of muscle biopsy was moderate, when using start of immunosuppressive therapy as gold standard for IIM diagnosis.

POS0912 THE EFFECT OF A 24-WEEK TRAINING ON METABOLIC PARAMETERS OF SKELETAL MUSCLE CELLS DERIVED FROM PATIENTS WITH ESTABLISHED IDIOPATHIC INFLAMMATORY MYOPATHIES.

M. Vokurková[1], L. Vernerová[1], S. Oreska[1,2], M. Špiritović[1,3], M. Klein[1,2], Z. Verner[4], M. Nemec[5], J. Ukropec[5], B. Ukropcová[5,6], M. Tomčík[1,2], J. Vencovský[1,2]. [1]*Institute of Rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic;* [2]*First Faculty of Medicine, Charles University in Prague, Department of Rheumatology, Prague, Czech Republic;* [3]*Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic;* [4]*Faculty of Science, BIOCEV, Charles University, Department of Parasitology, Prague, Czech Republic;* [5]*Institute of Experimental Endocrinology, Slovak Academy of Sciences, Biomedical Research Center, Bratislava, Slovakia (Slovak Republic);* [6]*Faculty of Medicine, Comenius University, Bratislava, Institute of Pathophysiology, Bratislava, Slovakia (Slovak Republic)*

Background: Persistent muscle weakness after reduction of inflammation and resistance to immunosuppressive therapy in some patients with idiopathic inflammatory myopathies (IIM) suggest that not only immune but also non-immune

mechanisms, such as mitochondrial abnormalities and metabolic disturbance, contribute to the pathogenesis of myositis. Exercise improves muscle function in IIM patients.

Objectives: To evaluate the effect of activities-of-daily-living, resistance and stability training on metabolic parameters of primary tissue culture myotubes established from muscle biopsies obtained from patients with established IIM.

Methods: Seven patients with established IIM underwent a 24-week supervised training focused on activities of daily living, muscle-strengthening and stability. Muscle biopsy was performed before and after the 24-week program in patients, and in healthy controls (n=9). Isolated skeletal muscle cells were grown and differentiated into myotubes for 6 days. After differentiation, the myotubes were cultured for another 24 hours in fresh medium, and then the conditioned media were collected, and the cells were harvested in TRIzol. A relative number of mitochondria was quantified by the ratio between mitochondrial gene (NADH dehydrogenase subunit 1) and reference nuclear gene (lipoprotein lipase) and determined by qPCR. Glucose, pyruvate, lactate, citrate, and fumarate were assessed in a conditioned medium using the comprehensive two-dimensional gas chromatography coupled to time of flight mass spectrometer.

Results: Patients significantly improved their muscle strength and endurance during the 24-week training [1]. There was no difference in the relative number of mitochondria in muscle tissue and myotubes between IIM patients and controls. A significant increase in the number of muscle tissue mitochondria was found in IIM patients after 24 weeks of training ($p = 0.004$), on average twofold. A similar effect was observed in cultured myotubes, with at least 4 of 7 IIM patients showing a twofold increase in mitochondria number. Compared with myotubes from HC, myotubes derived from IIM patients consumed non-significantly more glucose and pyruvate from the culture medium; however, their glucose and pyruvate utilization were significantly reduced as a result of the 24-week training ($p = 0.016$ and $p = 0.030$, respectively). Skeletal muscle cells from IIM patients before training intervention did not differ from HC cells in the amount of released lactate; however, the lactate concentration in the conditioned medium from myotubes obtained from patients after the 24-week training was significantly lower ($p = 0.016$). When measuring citrate cycle products released into the culture medium, no difference in citrate and fumarate secretion was observed between myotubes of myositis patients and myotubes of healthy controls. In contrast, their release was significantly ($p < 0.05$) lower in myotubes from IIM patients after 24 weeks of training compared to muscle cells isolated prior to intervention.

Conclusion: In conclusion, 24 weeks of rehabilitation training in patients with IIM significantly increases the number of mitochondria in muscle tissue. Lower release of lactate and citrate cycle intermediates (citrate and fumarate) by myotubes obtained from patients after training intervention indicates an increase in mitochondrial functional capacity and confirms a positive response to exercise in muscles previously affected by the inflammatory process in IIM.

POS0913 INCREASED HEALTH CARE UTILIZATION IN SYSTEMIC SCLEROSIS PATIENTS WHO HAVE DIGITAL ULCERS

T. Nevskaya[1], L. Martin Calderon[2], M. Baron[3], J. Pope[1]on behalf of Canadian Scleroderma Research Group. *[1]Western University, Rheumatology, London, Canada; [2]Western University, Medicine, London, Canada; [3]McGill University, Rheumatology, Montreal, Canada*

Background: Systemic sclerosis is a multi-system autoimmune disease characterized by fibrosis of the skin and internal organs, and vasculopathy which manifests as pulmonary arterial hypertension and digital ulcers. Digital ulcers are debilitating and painful lesions most commonly present in the digit tips or extensor surfaces of the hands leading to significant morbidity and decreased quality of life. SSc patients with digital ulcers may require increased support and therefore may have greater healthcare resource utilization compared to those patients without digital ulcers.

Objectives: We assessed the impact of DUs on resource utilization including hospitalizations, outpatient visits and procedures within a large SSc Canadian registry.

Methods: A cohort of patients with SSc and digitals ulcers was derived from the Canadian Scleroderma Research Group registry and matched to controls individually based on sex, age (±3 years), SSc subtype, and disease duration (±2 years). Eligible patients met the 2013 ACR/EULAR criteria (confirmed by an experienced rheumatologist), were 18 years of age, had completed the Resource Utilization Questionnaire (RUQ), and had active digital ulcers at two consecutive annual visits (baseline study visit and at 1st year). The Medgser Disease Severity Scale was used to assess ulcer disease severity. Unadjusted and adjusted regression analyses compared the association between DUs and resource utilization.

Results: RUQs in 104 SSc patients with active DUs at two consecutive annual visits were compared with 104 patients without DUs matched 1:1 for age, sex, disease subtype and duration. Over one year, DUs were associated with a higher number of tests ($p<0.05$) and visits to health professionals, especially to a rheumatologist ($p<0.0001$) and internist ($p=0.003$), a greater need for an accompanying person ($p<0.05$) and aids purchased/received ($p<0.05$). Having DUs was associated with more severe disease, even after excluding the peripheral vascular domain from a total DSS (9.7±4.5 vs 5.6±2.7, $p<0.0001$). After adjustment for disease severity in other organs, the presence of DUs remained a significant predictor of more frequent physician visits and more tests (all<0.05) by linear regression analysis.

Conclusion: SSc patients with DUs utilized significantly more healthcare resources per annum even after adjustment for disease severity in other organ systems.

Background: Skin fibrosis is a cardinal feature of systemic sclerosis (SSc) and associated with significant disability. The early trajectory of skin fibrosis provides

insights into the course of the disease including mortality; however, little is known about late skin fibrosis in SSc.

Objectives: The aims of our study were to ascertain the prevalence and characteristics of late skin fibrosis in SSc.

Methods: We developed and tested three conceptual scenarios of late (>5 years after 1st non-RP sign or symptom) skin fibrosis (Figure 1):

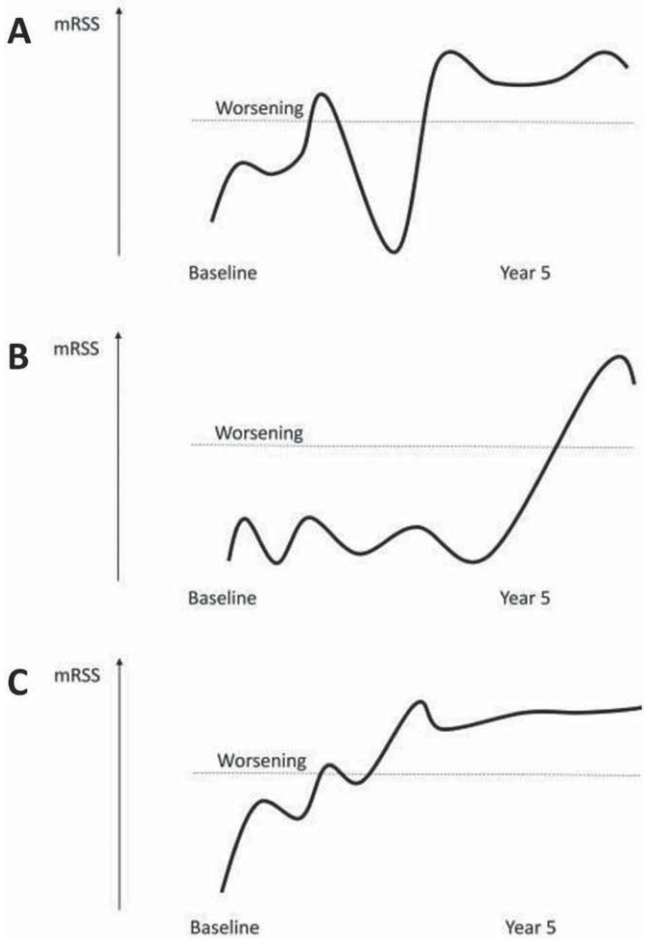

Figure 1. Conceptual models/scenarios of late skin fibrosis in SSc. A: worsening and then improvement (>3 mRSS) during the first 5 years, and then worsened again after 5 years. B: worsening for the first time after 5 years. C: worsening in the first 5 years and stayed high after 5 years (i.e., failure to improve).

A. Worsening and then improvement (>3 mRSS) during the first 5 years, and then worsened again after 5 years.
B. Worsening for the first time after 5 years.
C. Worsening in the first 5 years and stayed high after 5 years (i.e., failure to improve).
We defined skin worsening as modified Rodnan skin score (mRSS) ≥ 5 units or ≥ 25%. Using strict inclusion criteria including complete mRSS, we identified 1,043 (out of 19,115) patients within the EUSTAR database for our analysis. We further restricted analysis within 887 (out of 1,043) patients who had limited (lcSSc) or diffuse cutaneous SSc (dcSSc) at baseline.

Results: One-fifth of patients among the whole cohort (n=208/1043, 19.9%) including in patients with lcSSc or dcSSc at baseline (n=193/887, 21.8%) developed late skin fibrosis. This was largely due to new skin worsening or failure to improve. Patients with lower baseline mRSS and lcSSc were more likely to develop late skin fibrosis. Anti-Scl-70 antibodies (Table 1) were associated with progression from baseline lcSSc to dcSSc, and anticentromere antibodies were protective.

Conclusion: Late skin fibrosis affects approximately 20% of SSc patients >5 years after onset of disease. We have identified different patterns relevant to clinical practice and trial design. Late skin fibrosis is usually due to new worsening or failure of skin to improve. Progression from baseline limited to diffuse cutaneous SSc was associated with anti-Scl-70 antibodies, and anticentromere antibodies were protective. Late skin fibrosis is a neglected manifestation of SSc and warrants further investigation including to determine clinical outcomes and optimal therapeutic strategy.

MYOSITIS-SPECIFIC AND ASSOCIETED ANTIBODIES, ESPECIALLY ANTI-ARS ANTIBODIES AND ANTI-RO52 ANTIBODY MAY PREDICT THE CHARACTERISTICS AND FIBROSING PROGRESS OF INTERSTITIAL LUNG DISEASE WITH DERMATOMYOSITIS / POLYMYOSITIS

S. Nakashima[1], H. Nakaishi[2], H. Shimada[1], R. Wakiya[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], T. Kameda[1], H. Dobashi[1]. *[1]Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan; [2]Kagawa University Hospital, Department of Clinical Laboratory, Kagawa, Japan*

Background: Myositis-associated antibodies (MAA) and myositis-specific antibodies (MSA) have been associated with clinical manifestations of dermatomyositis and polyneuropathy, including interstitial lung disease (ILD), myopathy, malignancy, arthritis, and skin rashes. Among them, anti-ARS and anti-MDA5 antibodies are strongly associated with complications of ILD that are associated with life expectancy. It has been reported that anti-Ro52 antibody affects severity of myositis and ILD. (1) Based on these findings, it is possible that autoantibodies possessing features of ILD associated with dermatomyositis and polymyositis may be predictive.

Table 1. Impact of autoantibody status on progression from baseline limited to diffuse cutaneous SSc (dcSSc).

Objectives: The purpose of this study is to clarify the relationship between MSA/MAA and clinical features of ILD complicated by dermatomyositis and polymyositis.
Methods: We retrospectively analyzed IIMs patients diagnosed according to Peter & Bohan's diagnostic criteria in our hospital from 2011 to 2018. The presence of 14 MSA / MAA (Jo1, PL12, PL7, EJ, OJ, KS, Mi2, MDA5, TIF1γ, SRP, PM-Scl70, 100, Ku, Ro52) was measured using ELISA (MESACUP, MBL, Japan) and line blot (EUROLINE myositis profile3, EUROimmun, Germany). Clinical characteristics, including HRCT imaging findings, were extracted from medical records. HRCT imaging findings were analyzed by multiple radiologists. The association between the extracted clinical features and the MSA / MAA held was analyzed.
Results: Seventy-eight cases of IIM were included in the analysis. The frequency of ILD complications was 53/78 (68%), and 60% of ILD complications were ARS antibody positive. The complication rate of ILD in MDA5- and ARS-positive cases was 100% (3/3 cases) and 94% (32/34 cases), respectively. These MDA5- and ARS-positive patients with ILD had rapidly progressive ILD. One of the three MDA5 antibody-positive RPILD cases died, but none of the four ARS antibody-positive RPILD cases died. However, in patients with multiple MSA or MAA including ARS, three case had rapidly progressive ILD, and none died. n the analysis of the presence of Ro52 antibody, it was detected in 46% (36 cases) of all cases, but in 74% of anti-ARS antibody positive cases.
In the analysis of ILD patterns by radiologists using HRCT, fibrosing NSIP (fNSIP), fibrosing OP (fOP), and UIP were the most frequent in that order. analysis of the association between ILD patterns and MSA / MAA showed that there was no MSA / MAA associated with each ILD pattern. No MSA/MAA was found to be associated with each ILD pattern. ARS antibody-associated ILD, the most common type of ILD, had a worse prognosis than other MSA / MAA positive ILD. Death due to ILD was observed in 5 patients (PL7: 3cases, PL12: 1case, PM-Scl75: 1case). Oxygen was required for ILD progression in 3 Jo1-positive patients, 1 PL7-positive patients, and 1 PL12-positive patient, respectively. The frequency of UIP, which is considered to have a poor prognosis in other rheumatic diseases, was higher in patients with anti-ARS and anti-Ro52 antibodies.
Conclusion: The prognosis of anti-ARS antibody-positive ILD associated with dermatomyositis and polymyositis was associated with fibrosis by analysis of HRCT patterns, and the prognosis was confirmed to be poor.In addition, the UIP pattern, which is strongly associated with fibrosis, was found to be associated with anti-Ro52 antibody. In the treatment of ILD, which is strongly associated with the prognosis of dermatomyositis and polymyositis, it may be necessary to consider antifibrotic treatment for patients with anti-ARS antibody and anti-Ro52 antibody positivity.

POS0916 A 10-YEAR JOURNEY OF CARING FOR PATIENTS WITH SYSTEMIC SCLEROSIS: FOLLOW-UP DATA ON DISEASE DURATION OF THE LEIDEN CCISS COHORT.

S. Liem[1], S. Ahmed[1], J. Ciaffi[2], L. Beaart- van de Voorde[1], A. Schouffoer[3], J. Geelhoed[4], N. Ajmone-Marsan[5], T. Huizinga[1], J. De Vries-Bouwstra[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands; [2]IRCCS Rizzoli Orthopedic Institute, Medicine and Rheumatology Unit, Bologna, Italy; [3]Haga Teaching Hospital, Rheumatology, Den Haag, Netherlands; [4]Leiden University Medical Center, Pulmonology, Leiden, Netherlands; [5]Leiden University Medical Center, Cardiology, Leiden, Netherlands*

Background: Combined Care in Systemic Sclerosis (CCISS) is a prospective cohort of patients referred to Leiden University Medical Center for Raynaud's Phenomenon (RP), a suspicion of systemic sclerosis (SSc) or a connective tissue disease. This cohort is characterized by its standardized and extensive annual follow-up. Since initiation of the cohort in 2009, diagnostic criteria for SSc have been updated leading to a higher sensitivity for early SSc (ACR 2013 criteria). A recent Dutch study showed that there is a gap to time of diagnosis between men and women, despite of overall increase of SSc awareness (PMID: 31539063).
Objectives: To determine whether 1. time between first disease symptoms and diagnosis has changed over time, and 2. disease characteristics of SSc at first presentation in an expert clinic have changed over time for the total cohort, and between male and female patients.
Methods: Patients included in the CCISS cohort undergo annual evaluation and clinical, laboratory, and imaging variables are systematically recorded. For this study, patients fulfilling the ACR/EULAR 2013 SSc criteria were included, and categorized into three groups based on the cohort entrance year: 1) 2010 – 2013, 2) 2014 – 2017, and 3) 2018 – 2021. SSc patients with a baseline visit in 2009 (n=65) were excluded as these patients were often not newly referred. Disease duration was defined by months since first RP, since first non-RP symptom and months between first date of diagnosis by a physician and first non-RP symptom. Disease characteristics included presence of interstitial lung disease (ILD), pulmonary arterial hypertension, digital ulcers (DU), diffuse cutaneous SSc, anti-topoisomerase and anticentromere antibodies. At baseline, disease duration and disease characteristics were compared between the three groups using appropriate tests. In addition, disease duration was compared between males and females in the three groups.
Results: In total, 643 SSc patients were included of whom 229 (36%) had their baseline visit from 2010 until 2013, 207 (32%) from 2014 until 2017, and 207 (32%) from 2018 until 2021. The proportion of female patients was significantly higher in the 2010 – 2013 group compared to the 2014 – 2017 and 2018 – 2021 group (Table 1). Over time, disease duration defined by RP duration and non-RP duration decreased as well as time between diagnosis and first non-RP symptom (Table 1). The proportion of patients presenting with ILD and DU was highest in the first group (Table 1).

Table 1.

	2010 - 2013 N=229	2014- 2017 N=207	2018 – 2021 N=207	P-value
BASELINE				
Age, mean (SD)	53 (15)	57 (14)	55 (14)	0.003
Female, %	86	76	75	0.010
RP duration, months (IQR)	122 (46 – 240)	93 (20 – 202)	67 (20 – 210)	0.003
Non RP duration, months (IQR)	43 (16 – 227)	20 (5 – 112)	17 (6 – 54)	<0.001
Diagnosis duration, months (IQR)	116 (80 - 177)	65 (45 – 105)	25 (5 – 45)	<0.001
ΔRP and Non-RP, months (IQR)	24 (0 – 99)	18 (0 – 118)	22 (0 – 120)	0.337
Anti-centromere antibodies, %	38	43	49	0.092
Anti-topoisomerase antibodies, %	24	24	18	0.259
Diffuse cutaneous SSc, %	19	23	16	0.073
Interstitial lung disease, %	43	31	31	<0.001
Pulmonary arterial hypertension, %	3	2	4	0.746
Digital ulcers, %	20	13	11	0.041

In both male and female SSc patients, disease duration and time between diagnosis and first non-RP decreased over time with a longer time in females for all durations which was significantly different for time between first RP and non-RP in 2014-2017 and 2018-2021 (Figure 1). For the 2018 – 2021 group, duration since diagnosis for female was 26 (4 - 46) and male 17 months (7 – 39; p=0.355), and time between RP and non-RP for female 24 (0 - 168) and male 12 months (0 – 48; p=0.029).

Figure 1.

Conclusion: Over time, we observe a decrease in disease duration and in SSc patients presenting with ILD or DU at cohort entrance. Our results indicate increased awareness of early SSc and identification of SSc patients before severe complications have occurred. At the same time our results show the urge for specific attention to improve timely diagnosis in female SSc patients.

POS0917 TRANSTHORACIC LUNG SONOGRAPHY (LUS) – USEFUL SURVEILLANCE TOOL IN SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE?

M. D'orazio[1], A. Lackner[1], S. Zenz[1], A. Haidmayer[2], J. Gretler[1], S. Kielhauser[1], J. Thiel[1], H. P. Brezinsek[1], F. Fürst-Moazedi[1]. *[1]Medical University of Graz, Rheumatology and Immunology, Graz, Austria; [2]Hospital Southern Styria, Internal Medicine, Bad Radkersburg, Austria*

Background: The Interstitial lung disease (ILD) represent a major cause of mortality in Systemic sclerosis (SSc). Validated methods for screening and therapy monitoring of SSc-ILD are needed. In the recent literatur, the transthoracic lung sonography (LUS) emerges as a reliable tool for the early detection of lung alterations. It was recently reported that SSc-ILD-patients have thicker artefacts reflecting the pleuraline compared with SSc-patients without ILD, but it still remains unknown if the thickness of the pleuraline changes with a proper therapy response.

Objectives: The aim of the study was to compare the thickness of the pleuraline of SSc-ILD-patients without biological Disease Modifying Anti-Rheumatic Drugs (bDMARDS) with those successfully treated with bDMARDs in order to establish if LUS can be a reliable surveillance tool in SSc-ILD. Additionally, since our Grazer-Schema (Mycofenolat mofetil (MMF)+ rituximab (RTX) 500 mg i.v. in week 0 and 2 every 3 months) is succesfully used in our clinic since more than 10 years in patients nonresponding to methotrexate (MTX) or cyclophosphamide, we report 10 years follow-up data of 5 Patients before and after receiving that schema.
Methods: 29 prospectively enrolled SSc-patients were assessed according to the European League Against Rheumatism Scleroderma Trial and Research standards. Written informed consent was obtained from all patients and the study was approved by the Ethics Committee of Graz. Validated clinical scores, such as the scleroderma disease activity (SScAS) and the scleroderma disease severity scale (SScSS) were assessed. The thickness of the pleuraline was detected with LUS. The presence of ILD was assessed by high-resolution computed tomography. Twenty-five SSc-patients enrolled between 2008 and 2009, who underwent LUS with the same technical instruments and some of the same operators, were taken as a control group since they were untreated yet or were not assuming bDMARDs(1).
Results: Of the 29 SSc-patients (27 females/2 males) enrolled between 2019 and 2020, seventeen patients had radiographic signs of ILD (SSc-ILD+/2019-20, n=17). Until the LUS was performed, all SSc-ILD+/2019-20 showed a good clinical response to the therapy with RTX in combination with MMF. Of the 25 SSc-patients enrolled in our previous study, (n=25; 23 females/ 2 males), twelve of these patients had radiographic signs of ILD (SScILD+/2009-10, n=12); 7 were under MTX or Cyclosporin and 5 were untreated. Additionally, data collected from 5 SSc-ILD+/2009-2010 at baseline were analysed in a 10- years- follow up. As expected, SSc-ILD+ patients had a thicker pleuraline than SSc-ILD- patients. The pleura was significantly thinner in patients under MMF und RTX compared to the pleuraline of patients without bDMARDs (1,8 mm ± 0,7 Vs 0,95 ± 0,31; p < 0,00). Interestingly those patients reported less frequently dry cough or dyspnoea, showing that the lower pleura thickness could be associated with a better clinical outcome. In a 10 Year follow-up after continued treatment with MMF and RTX, a significant reduction of the thickness of the pleura could be found (Mean 0,68 ± 0,2 VS 1,5 ± 0,4; p < 0,00). Interestingly, such significant improvement could be found in all of these 5 patients receiving our Grazer Schema. Remarkably, the pleuraline-thickness was comparable to the thickness of the pleura of SSc-ILD-patients. This finding shows that the increase in thickness of the pleuraline can be totally reversible under treatment.
Conclusion: Due to the encouraging validity, reliability and simplicity of LUS, it has been increasingly considered as an excellent screening tool for SSc-ILD. Its sensitivity to reveal parenchyma and pleura changes over time in treated patients, make it also a helpful and safe methodology to follow up SSc-ILD patients.

POS0918 TARGET-CONTROLLED INFUSION (TCI) WITH PROPOFOL AND REMIFENTANIL FOR PROCEDURAL SEDATION AND ANALGESIA (PSA) IN PATIENTS WITH SYSTEMIC SCLEROSIS (SSC) UNDERGOING AUTOLOGOUS FAT GRAFTING PROCEDURES

R. Feminò[1], A. Spinella[2], A. Carratta[1], M. De Pinto[2], M. Starnoni[3], E. Bertellini[1], G. De Santis[3,4], C. Salvarani[2,5], D. Giuggioli[2,4]. *[1]University of Modena and Reggio Emilia, Department of Anesthesia and Intensive Care, Modena, Italy; [2]University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy; [3]University of Modena and Reggio Emilia, Division of Plastic Surgery, Modena, Italy; [4]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy; [5]University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy*

Background: Systemic sclerosis-SSc is an autoimmune disease characterized by vascular alterations and fibrosis. Difficult airway management, peripheral venous access and systemic comorbidities are often concomitant. Therefore, performing general anesthesia or moderate to deep sedation in these patients can be challenging. A high psychiatric burden is also common. These conditions, in association with a history of chronic pain, make even the local anesthesia procedure less effective than usual. Oral/digital autologous fat grafting approaches may improve aesthetic/functional aspects in SSc but the surgical procedure itself is painful and requires proper sedation. Target-Controlled Infusion with propofol (hypnotic) and remifentanil (opioid) is a well consolidated anesthesia technique and could be the best Procedure Sedation and Analgesia strategy to tolerate these interventions.
Objectives: Developing a new Procedural Sedation and Analgesia-PSA protocol to obtain moderate to deep sedation in Day Surgery environment to allow complete analgesia, amnesia and safe discharge in SSc patients undergoing autologous fat grafting procedures.
Methods: Eighteen-18 SSc patients referring to the Scleroderma Unit of our University Hospital were recruited for oral/digital autologous fat grafting procedures between July and December 2021. A proper anaesthesiology schedule was assessed by an expert anesthesiologist of the team. After informed consent acquisition, patients were monitored with ECG/SpO2/Non Invasive Blood Pressure-NIBP. A peripheral intra-venous line with an ultrasound probe was placed if needed and TCI was started. Patients were maintained in spontaneous breathing and supplementary oxygen (4lt/min) with a rhinopharyngeal cannula. The use of TCI pumps for the delivery of propofol and remifentanil allowed trained anesthesiologists to control and adjust the level of sedation and analgesia. The synergy between both propofol and remifentanil is well known, main risk for such technique is to oversedate patients resulting in respiratory depression and hypotension. Bispectral Index-BIS was used to monitor sedation level starting from 60-80, then tailoring the infusion according to surgical needs. TCI was stopped at the end of surgery. Vital parameters were registered every 5 minutes and potential complications were monitored (hypotension=PAS<30% of basal line, hypoxia=SpO2<92%). Paracetamol 1g/ketorolac 15mg were administered for postoperative analgesia. A simplified satisfaction questionnaire based on LPPSq was also administered before discharge.
Results: All subjects have successfully undergone surgery and no hospitalization after the procedures was needed. A peripheral blood desaturation (SpO2<90%) was registered as main complication in 4 subjects, promptly relieved through nasal cannula replacement. One patient registered transient hypotension (decrease in systolic blood pressure>30% below baseline) without vasoactive drugs need. Mean time to recovery of consciousness was 6.3 minutes (range 3-11). Two patients experienced transient pain and nausea, 1 itchiness, and 1 subjective difficulties in breathing/talking some minutes after the surgery with spontaneous resolution. All patients gave their consent to perform the same approach in the future.
Conclusion: TCI of propofol and remifentanil might be successfully used to ensure procedural sedation and analgesia in SSc surgical settings in presence of a skilled anesthesiologist. Further data are required to assess the incidence of possible major complications and patients' satisfaction.

Giuggioli[1,3]. *[1]University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy; [2]University of Modena and Reggio Emilia, Department of Oncology and Hematology, Modena, Italy; [3]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy; [4]AUSL-IRCCS of Reggio Emilia, Rheumatology Unit, Reggio Emilia, Italy; [5]University of Modena and Reggio Emilia, Pathology Unit, Modena, Italy; [6]University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy; [7]AUSL-IRCCS of Reggio Emilia, Department of Oncology, Reggio Emilia, Italy; [8]AUSL-IRCCS of Reggio Emilia, Pathology Unit, Reggio Emilia, Italy; [9]University of Modena and Reggio Emilia, Division of Plastic Surgery, Modena, Italy*

Background: Systemic Sclerosis (SSc) is a life-threatening connective tissue disease characterized by endothelial dysfunction, autoimmune abnormalities and aberrant fibrosis. Several reports showed an increased risk of cancer in SSc compared to general population, including breast cancer (BC). The relationship between BC and SSc has long been discussed with contradictory results. In our recent Sclero-Breast study we analyzed clinical-pathological features of BC in SSc; we finally observed the development of BC with early stages and good prognosis among these patients.
Objectives: The aim of this project was to explore the immunohistochemical (IHC) expression of potential biomarkers involved in the molecular pathways at the basis of SSc and BC etiophatogenesis as update analysis from the Sclero-Breast study.
Methods: Our observational multicenter retrospective study, performed at Modena University Hospital and Reggio Emilia Hospital in northern Italy, enrolled 33 SSc women with a personal history of BC between January 2017 and December 2019. Clinical and pathological characteristics of BC and SSc were collected. For 22 patients, BC tissues were available and IHC analysis was performed using specific antibodies to evaluate biomarkers and pathways potentially involved. The antibodies used included: PI3K/mTOR/TGFβ/PDGFRα/PDGFRβ/VEGF/EGFR/IL-6/CTLA-4/PDL1. We also reported TILs percentage (stromal tumor-infiltrating

lymphocytes) of each sample. The following scores were assigned for general IHC analysis: (-) negative, (1+) positive tumor cells <20%, (2+) positive tumor cells 20-50%, (3+) positive tumor cells >50%. For PDL1 we considered a positivity in case of PD-L1 expression ≥1% in infiltrating inflammatory cells. For TILs quantification we applied the score: 0 (negative), ≤ 50% (low-median expression), >50% (high expression).

Results: The first IHC analysis was performed on the samples of invasive BC patients (20 pts) and showed a prevalence of high PI3K expression (score of 3+ in 55% of cases) with mTOR overexpression in 45%. A PDL1 positivity was detected in 30%, with high TILs expression in 30%. Biopsies from the 2 pts with ductal carcinoma in situ were characterized by a negativity of almost all parameters, except for a medium-high TILs expression reported (40%/90% respectively). See Figure 1. IHC analysis was also performed according to BC subtypes. The group of HR+/HER2 negative showed high PI3K expression (score 3+) in most of cases (59%) with mTOR overexpression in 50%. CTLA-4 and PDL1 were positive in 25%, with high TILs expression in 25%. HER2 positive patients showed a high PI3K positivity in 50% of cases with mTOR positivity (score 3+) in 25% and high TGFβ expression (score 3+) in 25%. PDL1 was positive in 50% with high TILs expression in 25%. In Triple Negative group, PI3K overexpression was found in 75% of pts with half of cases represented by mTOR score 3+. PDL1 was positive in 50% with high TILs representation (80% of total cell count) in 50% of pts.

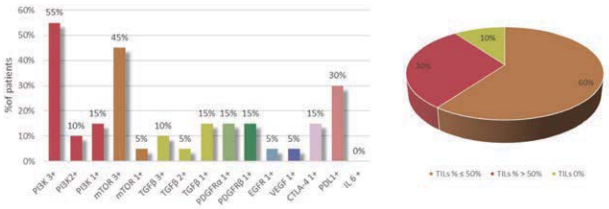

Figure 1. IHC analysis and TILs% expression in histological samples of SSc patients with invasive BC.

Conclusion: According to our results, SSc patients with BC showed high positivity for PDL1 and high TILs representations in all subtypes. Furthermore, the high expression of PI3K, did not always correlate with mTOR overexpression. Further investigations on larger numbers are needed; however, these aspects seem to confirm that SSc subjects might develop BC at good prognosis, suggesting again a de-escalation strategy of cancer therapies. Finally, the possibility to personalize oncological targeted treatments in this subset of fragile patients could be promising.

POS0920 THE EFFECT OF COVID-19 PANDEMIC ON IDIOPATHIC INFLAMMATORY MYOSITIS PATIENTS – A SINGLE CENTRE'S EXPERIENCES

T. G. Béldi[1], A. Vincze[1], B. Miltényi-Szabó[1], Z. Varga[1], M. Nagy-Vincze[1], Z. Griger[1]. *[1]University of Debrecen, Faculty of Medicine, Department of Internal Medicine, Division of Clinical Immunology, Debrecen, Hungary*

Background: Pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-Cov2/COVID19) determines the life of clinicians and patients since 2 years. Limited information is available on the nature, prognosis, and complications of SARS-Cov2 virus infection in patients with idiopathic inflammatory myopathies (IIM). There are also few data on triggered humoral response, side effects and disease course after COVID19 infection or vaccination in IIM.

Objectives: The primary goals of the current research were to assess frequency and outcome of COVID-19 disease and to determine the vaccination rate and effect in our IIM cohort. Secondary objectives were to search for risk factors of infection, predictive factors of hospitalization and to assess incidence of vaccination adverse events, complications and post vaccination breakthrough infections.

Methods: We retrospectively identified the confirmed COVID19 positive patients and assessed the symptoms, disease course and outcome on 01/06/2021 then patients were prospectively followed. Incidence and complications of vaccination were determined by questionnaires. Anti-SARS-CoV-2 S enzyme electrochemiluminescent immunoassay has been used to assess seroconversion, which measures total antibody (IgM and IgG) to the SARS-CoV2 S protein and SARS-CoV2 N protein. Disease activity was determined by physician global activity.

Results: A total of 176 patients were screened and 101 participated in the study. By 01/06/2021, the COVID infection rate was 34,7% (mean age: 49.54 years, 72.72% women), which was significantly higher than the national prevalence at that time (8.2%). A third of these infections occurred asymptomatically or mild but 20% of the infected patients were hospitalized, one patient died. Longer disease duration (8.67 vs. 17.87 years; p=0.003) and higher incidence of anti-Jo-1 antibody (57% vs. 10% p=0.018) were significantly associated with hospitalization. All of COVID infected patients became seropositive regardless of immunosuppressive therapy or symptoms severity. 53,4 % of the patients received anti-COVID19 vaccine, 75,9 % choose the mRNA type. The titer of antibodies against the spike protein induced by vaccines showed high variance, but 72,3% of patients became seropositive after vaccination. Higher antibody titer against spike protein was detected after Pfizer-BioNTech vaccination compared to others (177,1 U / ml vs. 81.1 U / ml; p <001). Patients receiving steroid therapy had decreased post-vaccination antibody response compared to those without steroid treatment (94,03 U/ml vs. 165.6 U/ml; p = 0.008). With the follow-up of vaccinated patients, we did not found short term vaccine related major adverse events, but long term data revealed 7,4 % post vaccination disease relapse. Breakthrough infection was detected in 9.25 % of the vaccinated patients, one cancer associated patient without post vaccination seroconversion died due to COVID pneumonia. All the fatal COVID infections occurred in patients with seronegativity to anti- SARS-CoV2 S protein.

Conclusion: Based on our results, myositis may be associated with an increased risk of infection with SARS-CoV-2. Independent risk factor for hospitalization is anti-Jo1 positivity and longer disease duration. Anti-SARS-CoV2 vaccines are safe, tolerable and strongly recommended for IIM population, but further investigation is required to assess clinical significance of post-vaccination disease flare.

POS0921 DIGITAL GANGRENE IN SYSTEMIC SCLEROSIS: AUTOLOGOUS FAT GRAFTING AND BONE SHAVING TO AVOID AMPUTATION

M. Starnoni[1], A. Spinella[2], R. Feminò[3], M. De Pinto[2], M. Dominici[4], G. De Santis[1,4], C. Salvarani[2,5], D. Giuggioli[2,4]. *[1]University of Modena and Reggio Emilia, Division of Plastic Surgery, Modena, Italy; [2]University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy; [3]University of Modena and Reggio Emilia, Department of Anesthesia and Intensive Care, Modena, Italy; [4]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy; [5]University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy*

Background: Systemic Sclerosis (SSc) is a connective tissue disease characterized by microvascular dysfunction, abnormal fibroblast activation and antibodies production, with cutaneous and visceral involvement. Hand-related manifestations include sclerosis, loss of elasticity, sclerodactyly, painful digital ulcers, atrophy, and gangrene. Autologous fat grafting is based on the implantation of adipose-derived stem cell (ADSCs) which have demonstrated to have pro-angiogenic, anti-inflammatory, regenerative, and immunosuppressive properties. This technique, combined with bone shaving, is believed to be effective in avoiding finger amputation in SSc-patients affected by digital gangrene.

Objectives: Evaluate our experience with the use of autologous fat grafting and bone shaving for the treatment of digital necrosis in patients affected by SSc.

Methods: According to our schedule, we treated 7 female SSc patients with digital gangrene and exposed bone at the fingertips, enrolled in our University Hospital from March 2018 to January 2020. Digital gangrene was treated by a combination of bone shaving and autologous fat grafting in order to avoid amputation. During the bone shaving, necrotic tissue was removed until bone bleeding was obtained. This procedure could be repeated by trained rheumatologists every 2 weeks in our Clinic. The aim of this repeated debridement was to promote the progression of the granulation tissue inside the dead tissue of the finger. Autologous fat grafting consists of a surgical procedure of ADSCs implantation at the base of the finger. It is performed in order to empower the neurovascular bundle and improve tissue healing. This treatment could be performed every 3 months by trained plastic surgeons. The combination of these two techniques allows the maximum finger length preservation.

Results: Complete healing of all fingers was achieved in 6-12 months by performing bone shaving every 2 weeks and 2 treatments of autologous fat grafting. Results have proved to be long-lasting. At 1-year follow-up, patients did not present any recurrence. Every procedure was performed under local anaesthesia and appropriate analgesic therapy. A high degree of compliance and satisfaction of all patients was noted.

Conclusion: Finger amputation in Systemic Sclerosis should be avoided. This traumatic surgical procedure is responsible for microvascular damages worsening SSc-related vasculopathy. Stump ulcers often occurs and wound healing usually takes place by secondary intention. In our experience, the combination of bone shaving and autologous fat grafting has proven to be effective and safe in preserving the maximum amount of viable tissue and obtaining a long-lasting result in treated SSc patients.

RECOMBINANT HUMAN HYALURONIDASE-FACILITATED SUBCUTANEOUS IMMUNOGLOBULIN FOR IDIOPATHIC INFLAMMATORY MYOSITIS: A MULTICENTER OBSERVATIONAL STUDY

A. Palermo[1], A. Bettiol[1], M. L. Urban[1], A. Barilaro[2], M. G. Danieli[3], M. Capassoni[4], S. Guiducci[4], C. Campochiaro[5], L. Dagna[5], V. Canti[6], P. Rovere-Querini[6], C. Cardelli[7], M. Mosca[7], G. Emmi[1]. *[1]University of Firenze, Department of Experimental and Clinical Medicine, Firenze, Italy; [2]Careggi University Hospital, Neurology Unit 2, Firenze, Italy; [3]Polytechnic University of Marche, Clinica Medica, Department of Clinical and Molecular Sciences, Torrette di Ancona, Italy; [4]University of Firenze, Rheumatology Unit, Department of Clinical and Experimental Medicine, Firenze, Italy; [5]IRCCS Ospedale San Raffaele and Vita-Salute San Raffaele University, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; [6]IRCCS San Raffaele Institute and Vita-Salute San Raffaele University, Division of Immunology, Transplantation & Infectious Diseases, Milan, Italy; [7]University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: The spectrum of idiopathic inflammatory myositis (IIM) includes a heterogeneous group of diseases characterized by chronic inflammation of skeletal muscle, often associated with skin, joints, lungs, esophageal, gastrointestinal and cardiac involvement. Conventional treatment for IIM is based on glucocorticoids and immunosuppressants. Moreover, intravenous immunoglobulin (IVIg) has emerged as a promising steroid- and DMARD-sparing treatment for myositis [1]. However, the long-term use of IVIg is complicated by the fact that the intravenous route requires in-hospital drug administration, which not only influences patients' quality of life, but is also associated with an increased risk of systemic adverse effects, difficulties in venous access over time, and high costs [2]. On these bases, administration of subcutaneous Ig (SCIg) by a programmable pump has been considered as a possible alternative to IVIg. Recombinant human hyaluronidase-facilitated (hf)-SCIg is currently approved for the use in patients with primary immunodeficiency disorders, while its efficacy and safety in myositis disorders is limited [3].
Objectives: This multicenter retrospective observational study is sought to evaluate the effectiveness and safety of recombinant human hf-SCIg in patients with IIM treated at different referral centers.
Methods: A multicenter, retrospective, cohort study was conducted on adult patients diagnosed with IIM according to the EULAR/ACR classification criteria [4] treated with recombinant human hf-SCIg according to routine clinical practice. The effectiveness of this treatment was assessed in terms of variations in the Medical Research Council (MRC) score, creatine kinase values, inflammatory parameters, and daily prednisolone dosage. Safety data were also collected.
Results: Twenty-three patients with IIM treated with hf-SCIg were included (16/23 females, 70%; median age at diagnosis of 61 years (IQR 43-65)).
In most patients (22/23, 96%), IIM had been initially treated with high-dose corticosteroids (+/- synthetic or biologic DMARDs), and 20/23 patients (87%) had received previous IVIg treatment (in 12 for remission induction and in 8 for maintenance).
Hf-SCIg were introduced after a median time of 2 years (1-4) from the diagnosis of IIM, mostly for remission maintenance (18/23). Hf-SCIg was started in combination with oral corticosteroids in 19/23 [83%, at a median dose of 5 mg/day (4-12.5)] and/or with traditional or biologic DMARDs (18/23, 78%).
At time of hf-SCIg introduction, the median MRC score was 4 (3-4) and the median creatine kinase level was of 134 U/L (44-243). After 6 months of treatment, the median MRC score was 4 (3-5); no patient discontinued hf-SCIg, and only one experience a mild adverse event.
Conclusion: Hf-SCIg seems effective to maintain remission in a high proportion of IIM patients, while showing a good safety profile in the first 6 months of treatment.

POS0923

EXTRACELLULAR VESICLES AS POTENTIAL BIOMARKERS OF EARLY DISEASE STAGE IN SYSTEMIC SCLEROSIS

J. Colic[1], I. Pruner[2], N. Damjanov[3], J. Antovic[2], M. Sefik Bukilica[4], A. Antovic[5]. *[1]Institute of Rheumatology, Department of Rheumatology Unit, Belgrade, Serbia; [2]Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [3]Institute of Rheumatology, Department of Rheumatology Unit, Former Director of the Institute, Belgrade, Serbia; [4]Institute of Rheumatology, Department of Rheumatology Unit, Head of Clinic IVb Department, Belgrade, Serbia; [5]Karolinska Institute, Department of Medicine, Rheumatology Unit, Stockholm, Sweden*

Background: Extracellular vesicles (EVs) are membrane-coated vesicles most often generated from the vasculature and circulating blood cells upon cell activation and during the early phase of apoptosis (1).
Objectives: To evaluate the concentration of different subpopulations of EVs in plasma from patients with SSc in relation to the disease duration and to the markers of endothelial injury.
Methods: Our study included 59 SSc patients (36 limited (lSSc) and 23 diffuse cutaneous subset (dSSc)) and 46 healthy age and gender matched controls subjects. Disease duration less than 3 years in patients with dSSc and less than 5 years in those with lSSc was considered as early disease stage. Clinical evaluation of patients was performed. EVs were analysed with flow cytometry after staining platelet poor plasma with fluorescent cell-specific monoclonal antibodies. The concentration of following phosphatidylserine-positive EVs (PS+ EVs) were analyzed: total EVs, endothelial EVs (EEVs; CD144+), platelet EVs (PEVs; CD42b+), monocytes EVs (LEVs; CD14+), EVs expressing ICAM1 (CD54+), VCAM1 (CD106+) and P selectin (CD62p+). Serum levels of ICAM1, VCAM1 and P selectin were determined with ELISA.
Results: Median disease duration of our cohort was 4 (0-29) years (early lSSc [20/36]: 2.5 (0-4.5) years; early dSSc [11/23]: 10 (1-30) months). All types of investigated EVs were significantly elevated in SSc patients compared to controls ($p<0.05$). Patients with early disease stage had significantly increased levels of all PS+EVs compared to HC ($p<0.05$). Moreover, the levels of EVs expressing ICAM1 and VCAM1 showed good validity in identifying patients with early disease stage (AUC 0.7, $p<0.01$). PEVs were increased in early dSSc compared to early lSSc, but the difference did not reach statistical significance ($p=0.07$). There was a correlation between serum levels and the levels of EVs expressing specific adhesion molecules (ICAM1: $r=0.7$, $p<0.01$; VCAM1: $r=0.7$, $p<0.01$; P selectin: $r=-0.7$, $p<0.01$), only within the group with early dSSc subtype of the disease. Further correlations were detected between ICAM1+EVs with either mRSS ($r=0.07$, $p< 0.01$) or EUSTAR activity index ($r=0.07$, $p= 0.02$) among patients with early dSSc.
Conclusion: Increased levels of circulating EVs of different cell origin were present in patients with early SSc. EVs expressing either ICAM1 or VCAM1 could be novel biomarkers of early disease. EVs expressing ICAM1 showed association with severity of skin involvement and disease activity in patients with early dSSc giving insight into their role in the pathogenesis of SSc.

POS0924

THE ROLE OF RAYNAUD'S PHENOMENON ON MATERNAL AND FETAL OBSTETRICAL OUTCOMES

E. Bellis[1,2], V. Codullo[2], B. L. Palermo[2], F. Bottazzi[2], A. Biglia[2], C. Bellingeri[3], F. Beneventi[3], A. Spinillo[3], C. Montecucco[2], G. Zanframundo[2], L. Cavagna[2]. *[1]Mauriziano Umberto I Hospital, Rheumatology Unit, Turin, Italy; [2]IRCCS Policlinico S. Matteo Foundation and University of Pavia, U.O.C. Reumatologia, Pavia, Italy; [3]IRCCS Policlinico S. Matteo Foundation and University of Pavia, Department of Obstetrics and Gynecology, Pavia, Italy*

Background: It is established that Raynaud's phenomenon (RP) may influence pregnancy outcomes when secondary to rheumatic conditions (1,2). Data on the impact of primary RP (pRP) on pregnancy are very limited.
Objectives: To retrospectively evaluate the impact of pRP on pregnancy outcomes.
Methods: Women with pRP were included in the study. They were compared with a group of women affected by UCTD with RP, and by UCTD without RP. These women were assessed and followed at our outpatient clinic from January 2011 to October 2020 and they did not exhibit an evolution to a UCTD or to a definite CTD during at least one-year follow-up. Antiphospholipid antibody positivity, twin pregnancies and voluntary termination of pregnancy were exclusion criteria. Women with pRP were also compared with a group of healthy pregnant women

enrolled by our gynaecologist during the first trimester of pregnancy. Maternal and foetal outcomes were retrospectively recorded. ANOVA or the Kruskal-Wallis test for continuous variables, and the Chi2 test or the Fischer exact test for categorical were performed (level of significance. P<0.050). In the post-hoc analysis we used the Mann-Whitney test (quantitative variables) or with the Chi2 test/ Fischer exact test (qualitative variables), applying the Bonferroni correction with pRP women as a reference group (level of significance: p<0.0167).

Results: The analysis included 188 women with a total of 375 pregnancies divided in 4 groups:

-Group "pRP": 46 women with RP without secondary causes, and a total of 106 pregnancies (reference group),

-Group "RP-UCTD": 48 UCTD women with RP and a total of 88 pregnancies,

-Group "UCTD": 37 UCTD women without RP and a total of 88 pregnancies,

-Group "HC": 57 healthy women with a total of 93 pregnancies.

The reference group did not differ from the others regarding age at conception. Prophylactic acetylsalicylic acid was administered during pregnancy to 9% of patients with pRP compared to 1% in HC (p=0.010). In contrast, in the RP-UCTD this percentage was significantly higher (32%, p<0,001) than in pRP.

pRP group showed an increased rate of 1st trimester miscarriages (33% vs 16%, p=0.006, OR 2.05 and 95%CI 1.05-3.98), a lower median birth weights (3038 g vs 3358 g, p=0.002), a higher rate of infants with a birth weight <10th percentile (21% vs 3%, p=<0.001, OR 8.36 and 95% CI 1.85 - 37.84) with respect to HC. There was no statistically significant difference between the reference and the UCTD groups.

No statistically significant differences were observed when considering obstetrical outcomes (eg: mode of delivery, median gestation duration, gestational diabetes mellitus, hypertensive disorder of pregnancy, premature rupture of membranes, oligo-anhydramnios).

Conclusion: Our study shows that pRP in a retrospective cohort has an impact on pregnancy outcomes, with significantly more miscarriages and lower birth weight infants compared to HC. Importantly, pregnancy outcome in pRP women did not differ with respect to UCTD with and without RP, conditions generally associated to maternal morbidity, but in the RP-UCTD group prophylactic acetylsalicylic acid was more commonly prescribed. Further prospective studies aiming at evaluating these differences and at identifying the appropriate follow-up and the possible benefit from the use of prophylactic acetylsalicylic acid during pregnancy in RP are necessary.

POS0925 HIGH LEVELS OF BOTH CCL2 AND CCL17 WERE ASSOCIATED WITH MORE SEVERE SSC-ILD

I. Barua[1], V. Palchevskiy[2], H. Fretheim[3], H. Didriksen[4], T. Garen[4], T. M. Aaløkken[5], S. S. Weigt[2], Ø. Molberg[3,4], J. Belperio[2], A. M. Hoffmann-Vold[3,4]. *[1]Oslo University Hospital, Norway,, Department of Rheumatology,, Oslo, Norway; [2]UCLA Medical Center,, Department of Pulmonary and Critical Care Medicine, Los Angeles, United States, United States of America; [3]Oslo University Hospital, Norway,, Department of Rheumatology,, Oslo, Norway; [4]University of Oslo, Norway, University of Oslo, Norway, Oslo, Norway; [5]Oslo University Hospital,, Department of Radiology,, Oslo, Norway*

Background: Systemic sclerosis (SSc) carries a high risk for progressive interstitial lung disease (ILD). Several anti-inflammatory therapies have been used to treat SSc-ILD and recently the first antifibrotic therapy has been approved. Personalized treatment strategies are largely missing to date. The two chemokines, CCL2 (MCP-1) and CCL17 (TARC), have been shown to be markers of inflammation and fibrosis, respectively.

Objectives: To examine associations between ILD severity and serum levels of CCL2 and CCL17 in two different but complementary sources of biomaterial.

Methods: Sera from the prospective Oslo University Hospital SSc cohort (n=371) and healthy blood donor controls (HC; n=100) and lung tissue at the time of lung transplantation from UCLA SSc-ILD patients (n = 12) and healthy donors (n = 12) were analyzed for CCL2 and CCL17 by multiplex assays. CCL2 and CCL17 levels were defined in serum as high or low using 95% CI in HC sera as cut-off values. Paired pulmonary function tests and HRCT images were obtained at baseline and follow-up. ILD was diagnosed on HRCT and categorized by the extent of lung fibrosis as limited (<10%) or extensive (>10%) ILD. Cellular sources of CCL-2 and CCL-17 in lung tissues were determined by immunohistochemistry. Descriptive statistics were applied.

Results: CCL2 and CCL17 were increased in SSc in sera and in lung tissue compared to HC (Figure 1). High levels of CCL17 (>700 pg/ml) and CCL2 (>1000pg/ml) in sera were identified in 43/254 (17%) and 84/471(18%) of the SSc patients (Table 1 and Figure 1). High levels of both CCL17 and CCL2 were associated with lower FVC at baseline and higher extent of lung fibrosis on HRCT (Table 1). Of those with high CCL2 and CCL17, 67% had extensive lung fibrosis. Categorization of ILD into no ILD, limited or extensive ILD showed an association between high CCL17 levels and the extent of fibrosis (Table 1). Reactive epithelium and macrophages and plasma cells expressed TARC, while more AM and infiltrating mononuclear cells expressed CCL-2.

Conclusion: High levels of both CCL17 and CCL2 were associated with more severe ILD and expressed in end-stage kung tissue and may reflect an ongoing inflammatory and fibrotic processes in SSc-ILD. This may have an implication on treatment choices for SSc-ILD.

POS0926 HOW GOOD ARE WE AT CAPTURING THE GI SYMPTOMS IN OUR PATIENTS WITH SCLERODERMA?

R. Parry[1], C. Rhys Dillon[1]. *[1]Royal Glamorgan Hospital, Rheumatology, Llantrisant, United Kingdom*

Background: Scleroderma is a rare autoimmune condition affecting around 1 in 10,000 individuals causing multisystem inflammation and fibrosis. The gastrointestinal (GI) system is the most commonly affected system, with nearly 90% of patients experiencing GI manifestations. The disease can affect any part of the GI tract with symptoms ranging in severity. Complications include oesophagitis and oesophageal strictures, vascular lesions in the stomach, reduced movement and absorption within the intestines and anorectal involvement. Recent guidance by the BSR highlight the importance of GI complications.

Objectives: To conduct a quality improvement project to improve the care provided to our scleroderma patients, focusing on GI symptom burden and identifying any unmet need when comparing local care to BSR guidelines and consensus best practice guidelines.

Methods: A proforma was developed for assessing and treating GI symptoms based on BSR and consensus best practice guidelines. This proforma was trialled on an initial cohort of 32 scleroderma patients from the Royal Glamorgan Hospital in Wales. The last clinical assessment was assessed for the following - regurgitation, nausea, vomiting, heartburn, dysphagia, abdominal pain, bloating, diarrhoea, faecal incontinence, constipation and weight loss. The symptoms were recorded as present, not present or not documented. The management of symptoms were evaluated against the guidelines. The cohort were then contacted regarding their last clinical assessment and asked if they were experiencing these symptoms at the time of their last assessment. The results from the documented assessment were compared to the additional patient information to address unmet needs.

Results: The results show that there is limited documentation of the presence of GI symptoms amongst scleroderma patients at clinic appointments. The initial assessment results were compared with the subsequent patient telephone reported symptoms in order to identify unmet need. The following refer to unidentified symptoms at assessment - regurgitation 9%, nausea 6%, vomiting 3%, heartburn 31%, dysphagia 31%, abdominal pain 9%, bloating 25%, diarrhoea 6%, faecal incontinence 9%, constipation 15% and weight loss 19%. Many patients stated they were unaware that their condition could cause GI symptoms and would not routinely mention these symptoms in a rheumatology assessment. The proforma proves to be an effective way to document and guide management of these patients. The clinical proforma that has now been created will help us improve patient care which can be reassessed in the future.

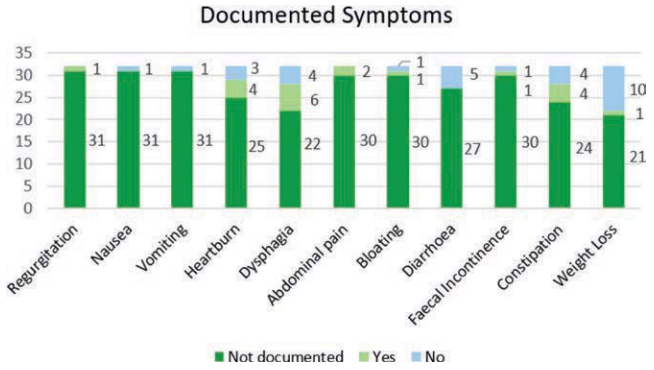

Table 1.

Symptoms	Management
Regurgitation	1 case - not investigated due to pre-existing dysmotility
Nausea	0 cases
Vomiting	0 cases
Heartburn	4 cases – 3 on PPIs, 1 gastroscopy arranged
Dysphagia	6 cases – 2 of known dysmotility, 3 not investigated
Abdominal pain	2 cases – not investigated
Bloating	1 case – not investigated
Diarrhoea	0 cases
Faecal incontinence	1 case – MRI arranged for query small bowel obstruction
Constipation	4 cases – 1 longstanding issue, 1 MRI arranged, 2 not investigated
Weight loss	1 case – not investigated

Conclusion: The piloting of our proforma of the GI assessment of patients with scleroderma has identified that the documentation of GI symptoms was poor. We don't know whether GI symptomology was discussed during assessment however it's evident that it was not often documented. Patients don't always report symptoms unless targeted questions are asked. A clinic proforma would be invaluable, leading to an increased awareness amongst both practitioners and patients of the potential clinical manifestations. Having presented this data locally we have now introduced such a proforma and will re-evaluate clinical practice in the future. Sharing this information will hopefully help improve patient care elsewhere.

POS0927 CORONARY ARTERY CALCIFCATION IN SYSTEMIC SCLEROSIS: EVALUATION OF CARDIOVASCULAR RISK AND CLINICAL OUTCOME

S. Sciacca[1], C. Rotondo[1], A. Corrado[1], D. Cici[1], F. P. Cantatore[1]. [1]*University of Foggia, Rheumatology Unit, Department of Medical and Surgical Sciences, Foggia, Italy*

Background: The primary prevention of cardiovascular disease (CVD) is a priority element of the worldwide health care agenda. An increased risk of CVD and CV mortality has been shown in lots of studies conducted on patients affected by inflammatory and autoimmune diseases. A routine evaluation of CV risk in these patients should be encouraged and in particular cases is recommended.
Objectives: The aim of this study is to evaluate the presence of subclinical atheromatosis, the CV risk and its performance in a cohort of patients affected by Systemic Sclerosis (SSc) from a single reference tertiary care hospital.
Methods: Sixty-seven patients with SSc according to the ACR/EULAR 2013 criteria were included. Traditional CV risk factors and SSc related factors were analyzed. Thoracic high resolution computed tomography (CT) was performed, using the quantification of coronary calcium for the study. Furthermore, a doppler ultrasonography of the carotids and the lower extremity arteries was conducted for the detection of subclinical atheromatosis. The CV risk has been calculated through different CV risk scales including the MESA CAC, the Italian Progetto Cuore, the Framingham score, the Score2 and the QRISK3. After conducting a 5-year follow up, CV outcome and electrocardiography abnormalities were examined.
Results: Calcium artery coronary score > 0 was reported in twenty-eight SSc patients (41,8%). Considering traditional CV risk factors, the multivariate regression analysis showed a correlation with age (OR 1.151 [95% CI 1.06–1.25], P = 0.001) and systemic arterial hypertension (OR 5 [95% CI 1.148–22.357], P = 0.032). Instead, the presence of anti-CENP-B (OR 3.47 [95% CI 1.09–11.06], P = 0.035) and late-onset disease (OR 1.062 [95% CI 1.007–1.119], P = 0.026) were identified as potential specific disease risk factors. The prevalence of ultrasonography atherosclerosis was high: peripheral artery disease (PAD) and carotid plaque were respectively 43% and 41%, and the presence of coronary calcifications was a risk factor for their detection with a OR respectively of 20.39 and 20.49 (p=0.0001). All CV risk scores considered SSc patients in a low risk, except for the QRISK3, whose values were higher in patients with coronary calcifications (18.4±12.6 vs 5.1±4.9, p=0.0001). In 5-years follow up only 1 patient died for CVD and 2 CV events occurred. Electrocardiography anomalies were found in 28.35% of patients, and in particular in 43% of patients with coronary calcifications (OR 3.321 [95% CI 1.094-10.08], P = 0.03).
Conclusion: Subclinical coronary atherosclerosis seems to be largely observed in SSc patients and may represent an additional risk factor for electrocardiography anomalies and subclinical atheromatosis in other anatomical districts, with no impact on CVD mortality. In our study coronary calcifications well correlated with CV risk score, especially the novel QRISK3 by classifying these patients between low and moderate CV risk. Other studies are needed to support the hypothesis that subclinical coronary atherosclerosis, occasionally detected in thoracic CT, may represent a clinical alert to establish timing and weight of diagnostic and specific treatment protocols for the CV prevention in SSc patients.

POS0928 THE IDENTIFICATION OF PENTRAXIN 3 AS BIOMARKER OF DISEASE ACTIVITY IN IDIOPATHIC INFLAMMATORY MYOPATHIES

M. Fornaro[1], G. Carabellese[1,2], F. Cacciapaglia[1], C. Scioscia[1], L. Coladonato[1], V. Venerito[1], R. Bizzoca[1], D. Natuzzi[1], N. Lacarpia[1], G. Lopalco[1], F. Iannone[1]. [1]*Department of Emergence and Transplantation (DETO), University of Bari,, Rheumatology Unit, Bari, Italy;* [2]*Department of Medical and Surgical Sciences, University of Foggia Medical School, Rheumatology Clinic, Foggia, Italy*

Background: Muscle involvement is only one feature of idiopathic inflammatory myopathies (IIM). Muscle enzymes do not always represent the best marker of disease activity and other inflammation markers such as ESR and CRP may be normal even with an active disease. Pentraxin-3 (PTX3) is an inflammatory marker produced in many inflammatory and non-inflammatory cells and serum level has been related to higher risk of major cardiovascular events and atherosclerosis[1]. PTX3 levels have been examined in various rheumatic and autoimmune diseases[2], but data of PTX3 levels in patients affected with IIM have not been reported.
Objectives: The aim of the current study was to identify whether serum PTX3 level could be a marker of disease activity in patients affected with IIM.
Methods: Twenty patients affected with IIM (13 Dermatomyositis and 7 Polymyositis), 10 rheumatoid arthritis patients and 10 healthy controls (HC) aged, sex and BMI matched were evaluated. PTX3 levels was assessed using a commercially available enzyme-linked immunosorbent assay (Human Pentraxin3 ELISA Kit, Abcam) kit. Three different cardiovascular risk scores were used to estimate the 10-years CV risk. Carotid intima media thickness (cIMT) was measured with a My Lab XPro80 (Esaote SpA, Genova, Italy) using a linear array ultrasound probe small parts broadband transducer (5–15 MHz) both in right and left carotid. Myositis disease activity was evaluated by using myositis disease activity assessment visual analog scales (MYOACT) [19] established by the International Myositis Assessment and Clinical Studies (IMACS) group. Manual muscle test (MMT8) was used to assess muscle impairment. Exclusion criteria were a diagnosis of diabetes or a history of previous major CV events.
Results: Demographic and disease characteristics of our cohort are showed in Table 1. IIM patients showed higher levels of PTX3 compared to HCs (518±260 pg/ml vs 275±114 pg/ml, p<0.05), while no difference was observed compared to RA patients (383±260 pg/ml). PTX3 levels do not correlate with lipid levels, QIMT and cardiovascular risk scores both in IIM, RA and HC. No correlation was found between DAS28-ESR and PTX3 levels in RA patients. Of note, a direct correlation

was found between PTX3 levels and MYOACT-GLOBAL DISEASE ACTIVITY (r=0.675, p=0.002), PTX3 levels and MYOACT- GLOBAL-EXTRA-SKELETAL MUSCLE DISEASE ACTIVITY (r=0.542, p=0.013), while an inverse correlation was found between PTX3 levels and MMT8 (r=-0.510, p=0.02).

POS0929

MICRO VASCULAR IMAGING AS A NOVEL TOOL TO QUANTIFY BLOOD FLOW IN THE FINGERTIPS IN PATIENTS WITH SYSTEMIC SCLEROSIS VS. HEALTHY CONTROLS: A SINGLE-CENTER FEASIBILITY STUDY

J. G. Rademacher[1], R. M. Buschfort[1], P. Korsten[1]. [1]*University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*

Background: Systemic sclerosis (SSc) is characterized by tissue fibrosis and vasculopathy. Raynaud's phenomenon is present in almost all patients (1). Nailfold video capillaroscopy is an established imaging tool for a morphologic assessment but is not able to quantify blood flow (2). Micro Vascular Imaging (MVI) is a novel ultrasound technique for blood flow quantification, especially of small vessels with low flow (3). The technique has not been used in SSc to quantify blood flow.

Objectives: To evaluate Micro Vascular Imaging (MVI) as a novel ultrasound tool for flow quantification of small fingertip vessels in healthy controls (HC) compared to SSc patients.

Methods: In this single-center prospective cohort study MVI scans of the second to fifth fingertip were performed in 20 healthy controls vs. SSc patients. Demographic data were analyzed using descriptive statistics. For flow velocity analysis, MVI peak systolic (PS) and end-diastolic (ED) flow values were used. Receiver operator characteristics (ROC) curves were generated to detect an optimal cut-off value for each parameter to discriminate between HCs vs. SSc patients. Sensitivity and specificity were reported with 95% CI based on Youden's J.

Results: The median age of the 20 HCs was 26 years (19-56), and 13 (65%) were female. 19 (95%) participants were right-handed. Twenty female SSc patients were included. The median age was 60 years (24-79). All SSc patients were right-handed (100%). SSc patients were older than HCs (p<0.0001) and included more female participants (p=0.0083). Some of the recruited SSc patients were past (n=4, 20%) or current (n=2, 10%) smokers, while all HCs were non-smokers (p=0.0293). No differences were found regarding dexterity (p>0.9999). 13 SSc patients had limited cutaneous SSc, five had diffuse cutaneous SSc, one patient was diagnosed with Very Early Diagnosis of Systemic Sclerosis, and one patient had no skin involvement (*sine* scleroderma). Eighteen patients (90%) reported the presence of RP. It was shown that PS flow velocity and ED flow velocity were significantly higher in HCs (Figure 1). For all fingers measured, the difference of the medians (D) for PS velocity was 4.675 cm/s (95% CI 3.3-5.25, p<0.0001), for ED velocity 1.375 cm/s (95% CI 0.85-1.65, p<0.0001). No correlation with age was found, neither in HCs (r2=0.03 for PS flow, r2=0.18 for ED flow), nor in SSc patients (r2=0.08 for PS flow, r2=0.01 for ED flow).

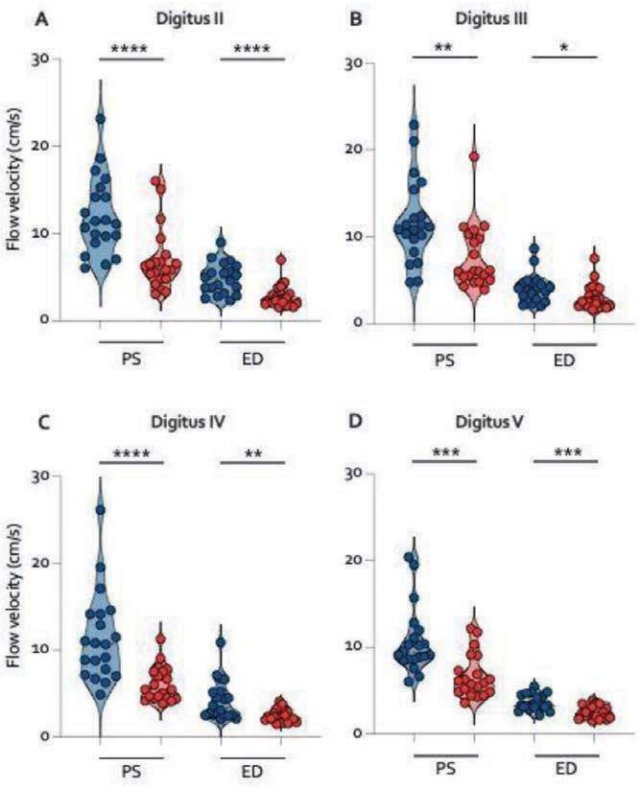

Figure 1. Comparison of peak systolic (PS) and end-diastolic (ED) blood flow of Digitus II-V in healthy controls (blue) vs. systemic sclerosis patients (red).

The highest PS velocity was measured on Digitus II with 5.225 cm/s (95% CI 2.95-7.5, p<0.0001), and 2.325 (95% CI 1.1-3.1, p<0.0001) for ED flow velocitiy, while lowest values were observed at Digitus V with PS = 3.325 cm/s (95% CI 2.2-5, p<0.001), and ED = 0.875 cm/s (95% CI 0.6-1.6, p<0.001). For PS flow velocity, an optimal cut-off point of <6.13 cm/s showed excellent sensitivity (0.90, 95% CI 0.70-0.98) and specificity (0.85, 95% CI 0.64-0.95), corresponding to a LR+ of 6.0. For ED flow velocity, the optimal cut-off point was calculated at <2.13 cm/s, sensitivity was 0.85 (95% CI 0.64-0.95), specificity was 0.80 (95% CI 0.58-0.92), corresponding to a LR+ of 4.25.

Conclusion: We present the first study of MVI as a novel imaging technique to measure blood flow velocity in patients with SSc. We report the method's feasibility and discriminative cut-off points between HCs and SSc. In an extenstion of this study, we aim to longitudinally assess the results with organ manifestations or vascular complications of SSc in a larger cohort.

Spondyloarthritis - treatment

POS0930 SAFETY AND EFFICACY OF IXEKIZUMAB TREATMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: 3-YEAR CLINICAL TRIAL RESULTS FROM THE COAST PROGRAMME

A. Deodhar[1], D. Poddubnyy[2,3], P. Rahman[4], R. Bolce[5], S. Liu Leage[5], A. Kronbergs[5], C. Johnson[5], A. Leung[6], D. Van der Heijde[7]. *[1]Oregon Health and Science University, Division of Arthritis & Rheumatic Diseases, Portland, United States of America; [2]Charite Universitätsmedizin, Department of Rheumatology, Berlin, Germany; [3]German Rheumatism Research Centre, Department of Epidemiology, Berlin, Germany; [4]Memorial University of Newfoundland, Department of Medicine, St John's, Canada; [5]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America; [6]Syneos Health, Biostatistics, Morrisville, United States of America; [7]Leiden University Medical Center, Department of Medicine, Leiden, Netherlands*

Background: Ixekizumab (IXE) has demonstrated efficacy at week (wk) 16 which was maintained through 2 years (yrs) and was associated with a consistent safety profile in patients (pts) with r- and nr-axSpA, who are bDMARD-naïve and TNFi-experienced.[1-3]

Objectives: To report safety and efficacy from the COAST programme at 3 yrs: 1 yr of the originating studies (COAST-V/W/X) and 2 yrs of COAST-Y.

Methods: COAST-Y (NCT03129100) is the phase 3, long-term extension study of the 3 originating studies COAST-V/W/X. Pts continued with the dose received at the end of the originating trial at week (wk) 52: either with 80 mg IXE every 4 wks (Q4W) or every 2 wks (Q2W). Pts assigned to adalimumab (ADA) or placebo (PBO) were re-randomised to IXE Q4W or Q2W at wk 16 in COAST-V and -W. Pts who received PBO for 52 wks in COAST-X were switched to IXE Q4W to continue in COAST-Y. Starting at wk 116 (wk 64 of COAST-Y), pts receiving IXE Q4W could have their dose escalated to Q2W. This analysis focused on pts receiving ≥1 dose of IXE Q4W, observed data while on IXE Q2W dose escalation are excluded. Continuous data are summarised as observed. Safety data while on IXE were analysed for pts who received ≥1 dose of IXE; observed data while on PBO or ADA are excluded.

Results: A total of 932 pts received ≥1 dose of IXE, 414 received ≥1 dose of IXE Q4W, and 562/932 (60%) pts completed 3 yrs of follow-up (PBO→IXE Q4W, 63/119 (53%); ADA→IXE Q4W, 29/44 (66%); and IXE Q4W→IXE Q4W, 114/251(45%)). Through 3 yrs, the most frequently reported treatment-emergent adverse events were infections [incidence rate (IR) 25.7/100 patient years (PY)] and injection site reactions [IR 7.4/100 PY]; the majority of which were mild/moderate in severity. Serious adverse events were reported at an IR of 4.8/100 PY, of which osteoarthritis was the most frequent at 0.4/100 PY. A total of 3 deaths were reported among all pts who received ≥1 dose of IXE [IR 0.1/100 PY]. For all pts, baseline disease activity (Ankylosing Spondylitis Disease Activity Score; ASDAS) was high (see Table 1). The 3 yr mean (SD) change from baseline (observed) in ASDAS among bDMARD-naïve pts with r-axSpA, TNFi-experienced pts with r-axSpA, and bDMARD-naïve pts with nr-axSpA is presented in the Table 1. A consistent disease control through 3 yrs was confirmed across additional efficacy endpoints (Table 1).

Conclusion: This analysis of a subset of pts in COAST-Y demonstrated that the safety profile is consistent with the established safety profile, with no new safety signals observed. IXE Q4W was efficacious (observed data) in all patients studied who remained on the treatment through 3 yrs.

Background: Ixekizumab (IXE), a monoclonal antibody that selectively targets interleukin IL-17A, has shown efficacy in patients with radiographic axial spondyloarthritis (r-axSpA). Spinal pain, in particular spinal pain at night (SP-N), is a major contributor to the patient burden of r-axSpA.
Objectives: To assess SP-N improvement in patients up to week (W) 52 and to determine the association of SP-N improvement in patients treated with IXE with other patient-reported outcomes (PROs) at W16 and with reaching ASDAS LDA at W52.
Methods: The Phase III COAST-V (NCT02696785) trial investigated the efficacy of IXE in 341 patients with r-axSpA and were biological disease-modifying anti-rheumatic drug (bDMARD)-naïve. Patients were randomised to IXE every 2W (IXEQ2W), IXE every 4W (IXEQ4W), adalimumab (ADA) or placebo (PBO) up to W16. Only approved dose IXEQ4W data are presented here. SP-N was measured at each visit using a numeric rating scale (NRS) (0-10). A clinically relevant improvement in SP-N was defined as >2 point improvement from baseline. Differences in baseline variables between those achieving versus not achieving >2 improvement in SP-N were tested using Fisher's exact test (binary variables) and analysis of variance (ANOVA; continuous variables). Associations of SP-N improvement with PROs (BASFI, Fatigue Severity NRS, Jenkins Sleep Evaluation Questionnaire (JSEQ), SF-36 PCS) at W16, and ASDAS LDA at W52 were tested using analysis of covariance (ANCOVA; continuous variables) and logistic regression (binary variables). Missing values were imputed using non-responder imputation, and modified baseline observation carried forward.
Results: A greater proportion of patients achieved >2 improvement in SP-N with IXE treatment compared to PBO at W16 (63.0% vs. 32.2%, p <0.001) and improvement was sustained up to W52 (Figure 1). Of the 81 patients originally randomised to IXE, those achieving >2 improvement in SP-N (63%) at W16 were younger, more frequently positive for HLA-B27 and had higher disease activity at baseline compared to those that did not achieve >2 improvement (Table 1). Achieving >2 improvement in SP-N was associated with improvement in PROs including BASFI, Fatigue Severity, JSEQ and SF-36 PCS at W16 and with achieving ASDAS<2.1 at W52 compared to those not achieving >2 improvement in SP-N (Table 1).

Table 1. Baseline demographics, clinical characteristics, and PROs of IXE treated patients achieving vs. not achieving >2 improvement in SP-N at W16.

POS0932 UPTAKE OF NEWER BIOLOGIC AND TARGETED SYNTHETIC DMARDS IN PSORIATIC ARTHRITIS, RESULTS FROM FOUR NORDIC BIOLOGIC REGISTRIES

B. Glintborg[1,2], D. DI Giuseppe[3], J. K. Wallman[4], D. Nordström[5], B. Gudbjornsson[6,7], M. L. Hetland[1,2], J. Askling[8], G. Gröndal[6,7], T. Sokka-Isler[9,10], S. Aarrestad Provan[11], U. Lindström[12]. *[1]University Hospital of Copenhagen Rigshospitalet, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; [2]University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; [3]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden; [4]Lund University, Skåne University Hospital, Lund, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; [5]Helsinki University Hospital and University of Helsinki, ROB-FIN, Helsinki, Finland; [6]Landspitali University Hospital, Centre for Rheumatology Research (ICEBIO), Reykjavik, Iceland; [7]University of Iceland, The Faculty of Medicine, Reykjavik, Iceland; [8]Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; [9]Jyväskylä Central Hospital, Rheumatology, Jyväskylä, Finland; [10]Faculty of Health Sciences, UEF, Kuopio, Finland; [11]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway; [12]Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*

Background: The treatment landscape in psoriatic arthritis (PsA) is changing, including newer biologic and targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) with different modes of action becoming available. However, the most effective treatment strategy in routine care remains to be established.
Objectives: To explore the uptake and treatment patterns of newer b/tsDMARDs, namely JAK-inhibitors (JAKi; baricitinib, tofacitinib, upadacitinib), IL-17-inhibitors (ixekizumab, secukinumab), abatacept, apremilast, and ustekinumab in PsA patients from the Nordic countries. Furthermore, to describe patient characteristics and extra-musculoskeletal manifestations at treatment start (=baseline).
Methods: Observational cohort study, using prospectively collected routine care data from 4 Nordic rheumatology registries. Treatments (newer b/tsDMARDs with tumor-necrosis-factor inhibitors (TNFi) as the reference) initiated from January 2009 until December 2020 and corresponding baseline patient characteristics were identified. Linkage to national patient registries was used to identify previous extra-musculoskeletal manifestations (0-5 years). Country-level data were pooled for analyses. Uptake of each drug was explored as the cumulative number of treatment starts (a) overall, irrespective of previous b/tsDMARD experience, and (b) in b/tsDMARD-naïve patients. Each patient could contribute >1 treatment course.
Results: Overall, 13,364 unique patients contributing 24,325 treatment courses with either a newer b/tsDMARD (4,855, 20%) or a TNFi (19,470, 80%, whereof 10,897 were started year 2015-20) were identified. For the sub-group of 11,892 first b/tsDMARD treatment courses, 1,009 (8%) were a newer b/tsDMARD (10,883 were a TNFi, whereof 5,956 were started year 2015-20). Secukinumab dominated the newer b/tsDMARD uptake (1,848 new-starts, Figure 1). Ustekinumab-uptake increased over time both overall and in b/tsDMARD-naïve patients. In b/tsDMARD-naïve patients, apremilast had the fastest uptake (490 new-starts) (Figure 1). Use of JAKi was limited, especially in b/tsDMARD-naïve patients.

Numbers are mean (SD) unless otherwise statedIBD: inflammatory bowel disease, bDMARD: biologic DMARD, ts: targeted synthetic*0-5 years previously, available all study period for Iceland, Sweden, Finland until 31Dec2018, not available for Denmark

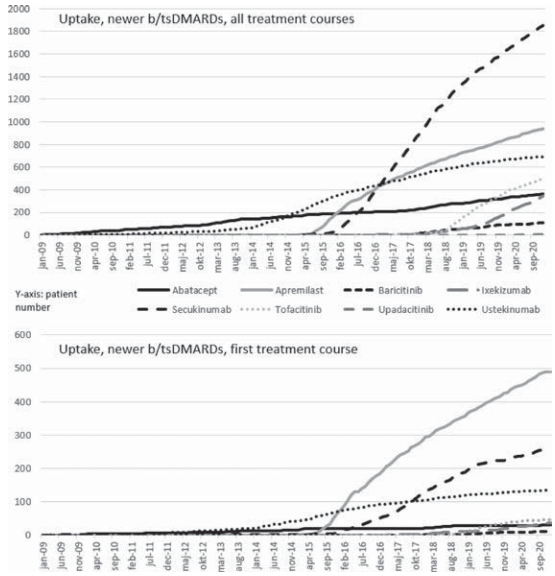

Figure 1.

Patients starting a newer b/tsDMARD tended to have longer disease duration and slightly higher disease activity at baseline (DAS28, patient-reported outcomes) than TNFi initiators (Table 1). Previous extra-musculoskeletal manifestations (uveitis, IBD) were rare, and with similar distributions across treatments (Table 1).

Conclusion: In this cross-country collaboration we were able to explore uptake of newer b/tsDMARDs. TNFi still dominates compared to newer b/tsDMARDs in routine care treatment of PsA. Newer b/tsDMARDs are mainly used in patients with several previous treatment failures, i.e. with longer disease duration and higher disease activity, indicating difficult to treat disease. Further studies are planned to explore real-world treatment patterns and outcomes.

POS0933

IMPACT OF SACROILIAC JOINT STEROID INJECTION IN AXIAL SPA PATIENTS WITH BONE MARROW EDEMA ON DIFFERENT DISEASE OUTCOME MEASURES: A RANDOMIZED CONTROLLED TRIAL

S. Mahrous[1], A. Radwan[1], A. Khalifa[1], M. Ibraheem[2], F. Ali[3], A. Elsaman[1].
[1]*Sohag University Hospital, Rheumatology and Rehabilitation, Sohag, Egypt;* [2]*Sohag University Hospital, Radiology Department, Sohag, Egypt;* [3]*Minia University, Rheumatology and Rehabilitation, Minia, Egypt*

Background: Sacroiliac joint injection in axial spondyloarthritis (SpA) patients with steroid was controversial. A well designed randomized clinical trial testing its effect on different disease outcome measures particularly bone marrow edema was missing [1].

Objectives: To test the effect of steroid injection in the sacroiliac joint of axial SpA patients on different disease outcome measures.

Methods: N = 43 were registered. They were randomly assigned into 2 groups; Group I (23 cases) received sacroiliac joint injection lidocaine hydrochloride mixed with triamcinolone, whereas Group II (22 cases) received subcutaneous saline injections. All participants fulfilled the ASAS criteria for axial SPA and they all had bone marrow edema at baseline. Outcomes measures were: Visual Analogue Scale (VAS), ASDAS, BASFI, and SPARCC scores. Participants were assessed at baseline (before and after sacroiliac joint injection) and after 3 months.

Results: There was a significant difference between both groups regarding pain, spine mobility, SPARCC and ASDAS scores in favor of group I. Spine mobility showed the earliest improvement, followed by pain whilst SPARCC and ASDAS scores showed improvement after 3 months. Higher disease activity, younger age, and shorter disease duration all were associated with better outcomes. Bilateral hip involvement was a predictor of poor response

Conclusion: Sacroiliac joint injection of lidocaine and triamcinolone in axial SpA patients is effective in controlling pain, improving function, disease activity scores, and bone marrow edema with acceptable complications and relatively sustained effect.

Background: Patients with PsA and axial involvement have higher disease activity and greater reductions in quality of life;[1] however, there are no accepted criteria for identifying axial involvement in PsA.

Objectives: The objective of this post-hoc analysis is to assess the efficacy of upadacitinib (UPA), a Janus kinase inhibitor, on axial symptoms in patients with active PsA and axial involvement defined by investigator assessment and PRO-based criteria from two phase 3 SELECT trials.[2,3]

Methods: Patients with active PsA (≥3 swollen joints and ≥3 tender joints) and prior inadequate response or intolerance to ≥1 non-biologic (SELECT-PsA 1) or ≥1 biologic (SELECT-PsA 2) DMARD were randomly assigned to once daily oral UPA 15 mg or 30 mg, placebo (PBO), or every other week subcutaneous adalimumab (ADA) 40 mg (SELECT-PsA 1 only).[2,3] At baseline, axial involvement in PsA was determined by investigator assessment based on the totality of clinical information, such as duration and character of back pain, age of onset, and previous imaging. In addition to investigator assessment, PRO-based criteria for axial involvement (BASDAI ≥4 and BASDAI Question 2 ≥4 at baseline) were applied for this analysis to identify patients with active disease. Efficacy in the sub-group of patients defined using both investigator assessment and PRO-based criteria was evaluated at week 24 for UPA 15 mg vs PBO and ADA (SELECT-PsA 1 only). Data were analyzed using mixed-effect model repeated measures (MMRM) or non-responder imputation (NRI), with nominal *P*-values shown.

Results: Based on investigator assessment alone, 31.3% (n=534/1704) of patients in SELECT-PsA 1 and 34.2% (n=219/641) in SELECT-PsA 2 were defined as having axial involvement. When both investigator assessment and PRO-based criteria were applied, 23.1% (n=393/1704) of patients in SELECT-PsA 1, or 73.6% (n=393/534) of those defined using investigator assessment alone, and 27.5% (n=176/641) in SELECT-PsA 2, or 80.4% (n=176/219) using investigator assessment alone, met the combined criteria for axial involvement. In both studies, UPA 15 mg showed significantly greater clinical responses vs PBO at week 24 across all endpoints assessed (Figure 1). In SELECT-PsA 1, UPA showed numerically greater responses than ADA at week 24 across all BASDAI and Ankylosing Spondylitis Disease Activity Score (ASDAS) endpoints. The proportion of patients achieving ASDAS clinically important improvement (CII) at week 24 was significantly greater with UPA vs ADA based on nominal *P*-value.

Conclusion: Patients with active PsA and axial involvement defined by both investigator assessment and PRO-based criteria demonstrated statistically greater clinical responses related to their axial involvement with UPA 15 mg compared to PBO, and consistently numerically higher responses compared to ADA, at week 24 in the SELECT-PsA trials. Findings from this post-hoc analysis are consistent with previous data based on investigator assessment alone.[4]

HIGHER 5-YEAR SURVIVAL OF CERTOLIZUMAB PEGOL IN YOUNG WOMEN WITH AXIAL SPONDYLOARTHRITIS. BIOBADASER DATA

M. Moreno[1], C. Sánchez-Piedra[2], V. Jovani[3], R. Cáliz Cáliz[4], Y. Perez-Vera[5], V. Emperiale[6], F. Sanchez-Alonso[2], M. Pombo[7], M. Llop Vilaltella[1], J. Calvet[1]on behalf of BIOBADASER project working group. *[1]Parc Tauli Hospital Universitari, I3PT,(UAB), Rheumatology, Sabadell, Spain; [2]Spanish Society of Rheumatology., Research Unit, Madrid, Spain; [3]Hospital General Universitario de Alicante, Rheumatology, Alicante, Spain; [4]Hospital Virgen de las Nieves, Rheumatology, Granada, Spain; [5]Hospital Universitario de Gran Canaria Dr. Negrín, Rheumatology, Gran Canaria, Spain; [6]Hospital Universitario Príncipe de Asturias, Rheumatology, Madrid, Spain; [7]Hospital Universitario de Santiago de Compostela, Rheumatology, Santiago de Compostela, Spain*

Background: Certolizumab pegol (CZP) in women of childbearing age with rheumatoid arthritis has a more favorable response, suggesting a possible distinctive effect in this group[1,2].
Objectives: To evaluate the retention rate of CZP compared to other anti-TNFs and anti-IL17A in patients affected by axSpA, grouped according to gender and age
Methods: Cross-sectional study within the BIOBADASER registry. Patients older than 17 years old, with axSpA receiving anti-TNFs or anti-IL-17A were selected. Mean and standard deviations of ASDAS-CRP and BASDAI were performed at baseline, 1st and 2nd year of treatment. Patients were classified according to treatment into groups 1) CZP, 2) anti-TNF, and 3) anti-IL17A, and according to sex and age in the following groups: 1) women between 18 and 45 years old (young), 2) women over 45 years old (old), 3) men.
Results: Groups and gender distribution, treatment prescription, ASDAS-CRP and BASDAI values according to therapeutic line and demographical characteristics are shown in Table 1. Overall, young women treated with CZP showed remission or low activity during follow-up, compared to low activity for the rest of the molecules. A greater survival of CZP compared to other treatment groups was observed in young women. This difference was observed since the first year of treatment (71,4 (64.2-77.4) all antiTNF, 84.4 (66.4-93.2) CZP, 72.2 (53.2-84.5) antiIL17) and the magnitude was maintained during the first 5 years of follow-up (Figure 1). In older women, a higher retention rate was observed for both CZP and anti-IL17A compared to anti-TNFs (71.6 (65.4-76.8) in all antiTNF, 78.1 (54.9-90.3) in CZP, 75.3 (61.3-84.9) in antiIL17). In males there were no long-term differences (79.2(76.3-81.8) all antiTNF, 73.0 (62.0-81.4) CZP, 64.6 (57.3-71.0) antiIL17)

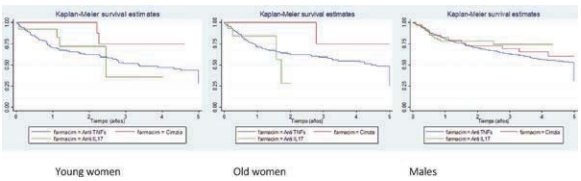

Figure 1. Five years retention rate (first line treatment)

Focussed on first line treatment, the differences were greater in young women. The second and subsequent lines showed the same trends with a lesser extend. Globally, we do not observe these differences in men.
Conclusion: These data suggest a possible specific effect of Certolizumab Pegol in women with axial spondyloarthritis, especially in young women and when used as first line treatment.

DISEASE TRAJECTORIES OF AXIAL SPONDYLOARTHRITIS PATIENTS INITIATED ON BIOLOGIC DMARDS: PRELIMINARY ANALYSIS FROM A REAL-WORLD COHORT

R. Barnett[1,2], L. Carpenter[3], C. Cavill[1], R. Sengupta[1]. *[1]Royal National Hospital For Rheumatic Diseases, Royal United Hospitals Bath NHS Foundation Trust, Rheumatology, Bath, United Kingdom; [2]University of Bath, Health, Bath, United Kingdom; [3]King's College London, Institute of Psychiatry, Psychology & Neuroscience (IOPPN), London, United Kingdom*

Background: The number of biologic/targeted synthetic (b/ts) disease-modifying anti-rheumatic drugs (DMARDs) available for the treatment of axial spondyloarthritis (axSpA) are increasing. However, 1 in 4 axSpA patients may discontinue their first bDMARD within the first 12-months (1). A greater understanding of real-world axSpA disease/treatment trajectories pre- and post-bDMARD initiation is needed to inform optimal treatment for patients.
Objectives: To explore the use of biologic therapies in patients living with axSpA, and estimate the natural progression of disease and patient reported measures pre- and post- initiation of first bDMARD.
Methods: Data was extracted from the Bath SpA Research Biobank for all bio-naïve axSpA patients initiated on bDMARDs between 7th March 2000 and 1st February 2021. Patients were grouped based on first bDMARD. Linear regression models were used to explore changes in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and Bath Ankylosing Spondylitis Functional Index (BASFI) over time; from 36-months before first bDMARD initiation, to 36-months after initiation. Changes in BASDAI/BASFI were estimated using piecewise mixed-effects linear regression. Models included fixed terms for age, sex, HLA-B27 status and disease duration. Switches to a second bDMARD and reasons for switching were captured.
Results: In total, 282 axSpA patients were included, and grouped into 3 cohorts based on first bDMARD: adalimumab (46.1%), etanercept (30.9%), other (23.1%; 6.4% certolizumab pegol, 5.0% golimumab, 5.3% infliximab, 0.7% rituximab, 5.7% secukinumab). Mean age at diagnosis was 30.7 (SD 11.3), 69.9% of patients were male, 11.0% diagnosed with non-radiographic axSpA and 85.3% HLA-B27 positive. In the 36-month period before bDMARD initiation, patients on average had a BASDAI score of 4.50 (95% CI 4.21-4.79) and BASFI of 4.02 (95% CI 3.68-4.38), with a linear and statistically significant worsening of 0.56 (95% CI 0.43-0.68) per year for the BASDAI and 0.55 (95% CI 0.41-0.69) for the BASFI (minimally clinically important difference defined as 1.1 and 0.6 for BASDAI and BASFI, respectively (2)). Following bDMARD initiation, patients indicated a statistically significant reduction in BASDAI to 3.13 (95% CI 2.82-3.45), 3.23 (95% CI 2.83-3.63) and 3.46 (95% CI 3.04-3.88) and reductions in the BASFI to 3.22 (95% CI 2.86-3.60), 3.06 (95% CI 2.61-3.53) and 3.64 (95% CI 3.16-4.12) for those treated with adalimumab, etanercept or other biologics respectively. Reduced scores were maintained over 36-months post initiation (Figure 1). Details of first and second bDMARD are outlined in Table 1. Reasons for switching were switch to biosimilar (32.4%), intolerance (25.1%), inefficacy (22.2%), malignancy (1.9%) or other (18.4%).

Table 1. ***First and second bDMARD***

	Second bDMARD		
First bDMARD	**Adalimumab**	**Etanercept**	**Other**
Adalimumab	59 (57.3%)	22 (21.4%)	22 (21.4%)
Etanercept	28 (40.6%)	37 (53.6%)	4 (5.8%)
Other	15 (48.4%)	8 (25.8%)	8 (25.8%)

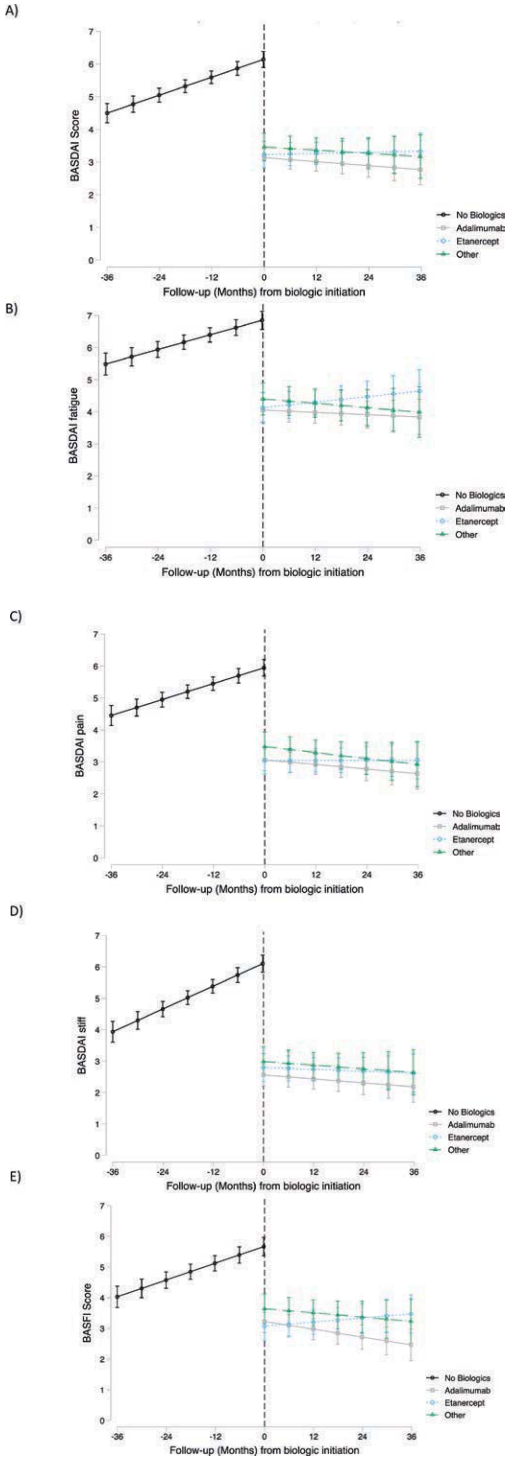

Figure 1. Predictive margins of BASDAI and BASFI 36-months pre- and post- bDMARD initiation*A-E, Predictive margins of the BASDAI score (overall – all components, A); BASDAI Q1 fatigue (B); BASDAI average of Q2-Q4 spinal pain, joint pain, enthesitis (C); BASDAI average of Q5-Q6 morning stiffness (D); and BASFI (E).*

Conclusion: In our study population, there was clinically meaningful worsening of disease activity over 36-months prior to initiation of first bDMARD, despite baseline (36-months prior to first bDMARD initiation) BASDAI exceeding the current threshold for bDMARD treatment (BASDAI≥4). A clinically meaningful and maintained improvement in disease activity was reported across all cohorts in the 36-months following first bDMARD initiation.

POS0937

MEASURE 2: SECUKINUMAB PROVIDES RAPID AND SUSTAINED RELIEF FROM KEY CLINICAL SYMPTOMS OF ACTIVE ANKYLOSING SPONDYLITIS IN TNFI-NAÏVE PATIENTS THROUGH 5 YEARS

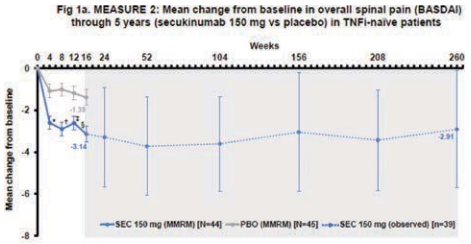
K. Pavelka[1], A. Kivitz[2], R. Calheiros[3], E. Quebe-Fehling[4], P. Pertel[5], R. Blanco[6].
[1]Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic; [2]Altoona Center for Clinical Research, Altoona Center for Clinical Research, Duncansville, PA, United States of America; [3]Novartis Pharmaceuticals Corporation, US Clinical Development and Medical Affairs, Rheumatology, East Hanover, NJ, United States of America; [4]Novartis Pharma AG, Global Medical Affairs Biostatistics in Global Drug Development, Basel, Switzerland; [5]Novartis Pharma AG, Global Medical Affairs, Rheumatology, Basel, Switzerland; [6]Hospital Universitario Marques de Valdecilla (IDIVAL), Servicio de Reumatología, Santander, Spain

Background: Ankylosing spondylitis (AS) is a chronic, inflammatory disease resulting in debilitating clinical symptoms such as pain (70–83%), stiffness (54–90%) and fatigue (53–62%).[1-3] Secukinumab (SEC 150 mg) has demonstrated long-term efficacy across multiple indications and is approved for the treatment of active AS in adults who have had an inadequate response to NSAIDs.[4,5]

Objectives: The Phase 3 MEASURE 2 trial (NCT01649375) assessed long-term efficacy, safety and tolerability of SEC in patients (pts) with active AS. This post-hoc analysis was conducted specifically to evaluate long-term efficacy of SEC 150 mg on key clinical symptoms of pain, morning stiffness, physical function and fatigue in TNFi-naïve pts over 5 years.

Methods: The MEASURE 2 study design has been reported previously.[5] This post-hoc analysis evaluated key clinical symptoms at baseline through Wk 260. Assessments included total and nocturnal back pain (visual analogue scale [0–100 mm]), overall spinal pain (neck, back, or hip) from BASDAI, and morning stiffness (average BASDAI). Physical function (SF-36 PCS, BASFI), fatigue (BASDAI, FACIT) and disease activity (ASDAS-CRP) are also reported. Data are presented as LS mean change (± SE) using mixed model repeated measures from Wks 4–16 and observed data (mean ± SD) from Wks 24–260.

Results: Of TNFi-naïve pts randomised to SEC 150 mg, 89 were included (SEC, n=44, placebo [PBO], n=45) in this analysis. Of these pts randomised to SEC 150 mg, 84% completed 5 years of treatment. Significantly greater improvements were observed in pts treated with SEC 150 mg vs PBO at Wk 16 and were sustained through 5 years (Figure 1; Table 1).



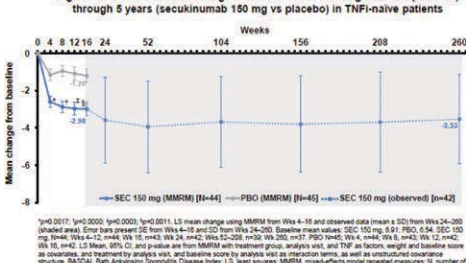


Table 1. Pain, physical function and fatigue scores

MAINTENANCE OF RESPONSE TO BIMEKIZUMAB OVER 3 YEARS OF TREATMENT IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: POST HOC ANALYSES FROM THE BE AGILE STUDY AND ITS OPEN-LABEL EXTENSION

V. Navarro-Compán[1], M. Rudwaleit[2], N. De Peyrecave[3], C. Fleurinck[3], M. Oortgiesen[4], V. Taieb[5], X. Baraliakos[6]. *[1]La Paz University Hospital, Department of Rheumatology, IdiPaz, Madrid, Spain; [2]University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany; [3]UCB Pharma, N/A, Brussels, Belgium; [4]UCB Pharma, N/A, Raleigh, United States of America; [5]UCB Pharma, N/A, Colombes, France; [6]Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Bochum, Germany*

Background: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL17A, has demonstrated significant and rapid efficacy in patients (pts) with active ankylosing spondylitis (AS) treated for up to 48 weeks (wks) in the phase 2b BE AGILE study.[1] Maintaining stringent disease control is an internationally recognised treatment target in spondyloarthritis and a relevant goal in clinical research.[2]

Objectives: To report on the maintenance of clinical response, including the achievement of sustained remission or low disease activity (LDA), to support and extend previous findings on the long-term efficacy of BKZ in pts with active AS treated for up to 3 years (yrs) in BE AGILE and its open-label extension (OLE).[3]

Methods: Study design of the 48-wk BE AGILE study (NCT02963506) and its ongoing 4-yr OLE (NCT03355573) have been reported previously.[1,3] During the OLE, pts received BKZ 160 mg every 4 wks (Q4W) regardless of prior dosing. In this post hoc study, maintenance of response analyses through 156 wks were conducted for Ankylosing Spondylitis Disease Activity Score (ASDAS) <2.1 and Assessment in SpondyloArthritis international Society 40 (ASAS40) response. ASDAS <2.1 includes both ASDAS-LDA (1.3–<2.1) and ASDAS inactive disease (ID; <1.3). Data from pts randomised at baseline to BKZ 160 mg and 320 mg Q4W were used for these analyses. ASDAS and the ASAS components were assessed at every study visit to Wk 24, then every 12 wks. All reported analyses are observed case.

Results: At baseline, 121/303 pts were randomised to BKZ 160 mg (n=60) or 320 mg (n=61). Overall, 36/121 (29.8%) had ASDAS high disease (HD) and 84/121 (69.4%) had very high disease (VHD) activity. At Wk 12, 48/119 (40.3%) had achieved ASDAS <2.1, increasing further to 66/111 (59.5%) at Wk 48 and 63/93 (67.7%) at Wk 156, of which 32 pts (32/63; 50.8%) had ID. Improvement in ASDAS was consistent across both BKZ 160 mg and 320 mg groups, with treatment response levels maintained following dose reduction to 160 mg at Wk 48 in the 320 mg group (Figure 1). Of those pts who achieved ASDAS <2.1 at Wk 12 across both groups, 33/37 (89.2%) maintained ASDAS <2.1 at Wk 156. In the most stringent maintenance of response analysis, 24/37 (64.9%) pts who achieved ASDAS <2.1 at Wk 12 maintained this state at every ASDAS assessment during Wks 12–156. Efficacy measured by ASAS40 response was also sustained over 3 years, with 56/119 (47.1%) pts having achieved ASAS40 at Wk 12, 72/111 (64.9%) at Wk 48 and 69/96 (71.9%) at Wk 156. In line with ASDAS <2.1, of those pts who achieved ASAS40 at Wk 12, 44/47 (93.6%) maintained ASAS40 at Wk 156, and 36/47 (76.6%) had maintained ASAS40 at every assessment during Wks 12–156.

Conclusion: BKZ 160 mg Q4W provided a robust maintenance of disease control over 3 yrs in pts with active AS who initially responded at Wk 12, irrespective of the initial dosing regimen (BKZ 160 mg or 320 mg Q4W).

Fleurinck[13], A. Ellis[12], T. Vaux[14], J. Smith[14], X. Baraliakos[15]. *[1]Oregon Health & Science University, Division of Arthritis & Rheumatic Diseases, Portland, United States of America; [2]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [3]University of California San Francisco, Department of Rheumatology, San Francisco, United States of America; [4]Shanghai Changzheng Hospital, Affiliated to Second Military Medical University, Department of Rheumatology and Immunology, Shanghai, China; [5]Norfolk and Norwich University Hospital NHS Trust, Rheumatology Department, Norwich, United Kingdom; [6]Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa, Japan; [7]University of Alberta, Department of Medicine, Alberta, Canada; [8]University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany; [9]Case Western Reserve University, MetroHealth Medical Center, Cleveland, United States of America; [10]Ghent University Hospital, Department of Rheumatology, Ghent, Belgium; [11]Ghent University, Center for Inflammation Research, Ghent, Belgium; [12]UCB Pharma, N/A, Raleigh, United States of America; [13]UCB Pharma, N/A, Brussels, Belgium; [14]UCB Pharma, N/A, Slough, United Kingdom; [15]Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Bochum, Germany*

Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. BKZ has shown rapid and sustained efficacy and was well tolerated up to 156 weeks (wks) in a phase 2b study in patients (pts) with active ankylosing spondylitis.[1,2]
Objectives: To assess efficacy and safety of BKZ vs placebo (PBO) in pts with active non-radiographic axial spondyloarthritis (nr-axSpA) up to Wk 24 in the ongoing pivotal phase 3 study, BE MOBILE 1.
Methods: BE MOBILE 1 (NCT03928704) comprises a 16-wk double-blind, PBO-controlled period and 36-wk maintenance period. Pts were aged ≥18 yrs, had BASDAI ≥4 and spinal pain ≥4 at BL, and sacroiliitis on MRI and/or elevated CRP at screening. Pts were randomised 1:1, BKZ 160 mg Q4W:PBO. From Wk 16, all pts received BKZ 160 mg Q4W. Primary and secondary efficacy endpoints were assessed at Wk 16.
Results: Of 254 randomised pts (BKZ: 128; PBO: 126), 244 (96.1%) completed Wk 16, 240 (94.5%) Wk 24. BL characteristics were comparable between groups: mean age 39.4 yrs, symptom duration 9.0 yrs; 54.3% pts male, 77.6% HLA-B27+, 10.6% TNFi-experienced. At Wk 16, the primary (ASAS40: 47.7% BKZ vs 21.4% PBO; p<0.001) and all ranked secondary endpoints were met (Table 1). Responses were rapid with BKZ, including in PBO pts who switched to BKZ at Wk 16, and increased to Wk 24 (Figure 1; Table 1). Substantial reductions of hs-CRP by Wk 2 and MRI SIJ inflammation by Wk 16 were achieved with BKZ vs PBO (Table 1). At Wk 24, >50% of pts initially randomised to BKZ had achieved ASDAS <2.1 (Figure 1).
Over 16 wks, 80/128 (62.5%) pts had ≥1 TEAE on BKZ vs 71/126 (56.3%) on PBO; most frequent were nasopharyngitis (BKZ: 9.4%; PBO: 4.8%), upper respiratory tract infection (BKZ: 7.0%; PBO: 7.1%) and oral candidiasis (BKZ: 3.1%; PBO: 0%). No systemic candidiasis was observed. Up to 16 wks, incidence of SAEs was low (BKZ: 0.0%; PBO: 0.8%); no MACE or deaths were reported; 0 IBD cases occurred in pts on BKZ vs 1 (0.8%) in a pt on PBO.
Conclusion: Dual inhibition of IL-17A and IL-17F with BKZ in pts with active nr-axSpA resulted in rapid, clinically relevant improvements in efficacy outcomes vs PBO. No new safety signals were observed.[1,2]

POS0940

FACTORS ASSOCIATED WITH LONG-TERM RETENTION OF TREATMENT WITH GOLIMUMAB IN A LARGE COHORT OF PATIENTS WITH RHEUMATIC DISEASES, WITH UP TO 8 YEARS OF FOLLOW-UP

M. Pombo-Suarez[1], D. Seoane-Mato[2], L. Cea-Calvo[3], F. Diaz-Gonzalez[4], F. Sánchez-Alonso[2], M. Sánchez-Jareño[3], F. J. Manero Ruiz[5], L. Ruiz[6], V. Jovani[7], I. Castrejon[8]on behalf of BIOBADASER investigators. *[1]Santiago de Compostela University Hospital, Rheumatology, Santiago de Compostela, Spain; [2]Spanish Society of Rheumatology (SER), Research Unit, Madrid, Spain; [3]MSD Spain, Medical Affairs, Madrid, Spain; [4]Canarias University Hospital, Rheumatology, Santa Cruz de Tenerife, Spain; [5]Miguel Servet University Hospital, Rheumatology, Zaragoza, Spain; [6]Príncipe de Asturias University Hospital, Rheumatology, Alcalá de Henares, Spain; [7]Alicante General University Hospital, Rheumatology, Alicante, Spain; [8]Gregorio Marañón University Hospital, Rheumatology, Madrid, Spain*

Background: The long-term retention rate of a biological drug is a surrogate marker of its effectiveness and tolerability.

Objectives: We assessed the probability of golimumab retention (persistence or drug survival) and the associated factors in a large cohort of patients with rheumatic diseases, with up to 8 years of follow-up.

Methods: This was an analysis of the BIOBADASER database (Spanish registry of biological drugs of the Spanish Society of Rheumatology and the Spanish Medicines Agency) on all adult patients who had initiated golimumab for treating rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (SpA). The probability of golimumab retention was assessed with the Kaplan-Meier method, differences between groups with the log-rank test, and factors related to retention with a Cox-regression model. Patients were right-censored if they were still treated with golimumab at the last observation for data analysis.

Results: A total of 885 patients were included, of whom 59 had received golimumab in 2 separate cycles (with a grace period of 3 months), totaling 944 cycles of treatment (286 RA, 396 axial SpA and 262 PsA). At golimumab initiation, mean (SD) age was 52 (13) years, 54% were women and median duration of disease was 7.6 (2.8-14.4) years. Golimumab was prescribed as first, second and third/subsequent biological drug in 313 (33%), 303 (32%) and 328 (35%) treatments. Concomitant medications at golimumab initiation included methotrexate (MTX) (32%), steroids (29%), leflunomide (13%) and sulphasalazine (6%). The probability of retention of golimumab since treatment initiation was 71% (95% confidence interval [CI]: 68 – 74) at year 1, 60% (95% CI: 57-63) at year 2, 54% (95% CI: 51-58) at year 3, 48% (95% CI: 44-51) at year 4, 44% (95% CI: 40-48) at year 5, 41% (95% CI: 37-45) at year 6 and 38% (95% CI: 33-42) at year 7 and at year 8. In bivariate analysis, the retention rate was higher when golimumab was used as first biological agent (p log-rank <0.001), in patients with axial SpA or PsA compared to RA (p <0.001, Figure 1) in men (p<0.001) and in those not using steroids (p<0.001). As first biological drug the probability of retention was 82% at year 1 and 50% at year 7. As second, it was 70% at year 1 and 35% at year 8, and at third/further, 62% (year 1) and 28% (year 8). Cox-regression analysis (Table 1) showed that golimumab retention was positively associated to use as first vs second or third biological, to axial SpA or PsA compared to RA and to use of methotrexate, and inversely to corticosteroid use and to disease activity over the median at golimumab initiation.

Table 1. Cox-regression analysis. Hazard Ratio for discontinuation of golimumab

	Hazard Ratio	95% Confidence interval	p
Age at golimumab initiation	1.01	1.00-1.02	0.063
Gender (women vs men)	1.23	0.98-1.55	0.079
Axial SpA vs RA	0.59	0.44-0.80	<0.001
PsA vs RA	0.67	0.51-0.89	0.005
Second vs first biological drug	1.52	1.17-1.97	0.002
Third or further vs first biological drug	1.79	1.38-2.32	<0.001
Corticosteroids	1.46	1.16-1.85	0.001
Methotrexate	0.79	0.63-0.99	0.041
Disease activity over the median*	1.29	1.05-1.59	0.015

*DAS28 > 4.3 (RA, PsA) or BASDAI > 5.6 (axial SpA) at golimumab initiation

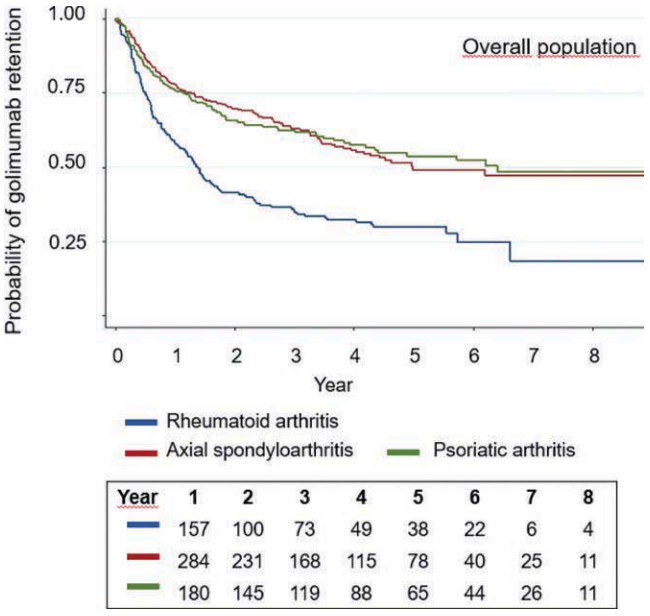

Figure 1.

Conclusion: This study provides new information on long-term golimumab effectiveness for the treatment or rheumatic diseases, with retention rates of 71% at year 1, 44% at year 5 and 38% at year 8. The probability of golimumab retention was higher as first biological drug, in patients with PsA or axial SpA and in those treated with methotrexate, and lower in those treated with steroids or with higher disease activity at golimumab initiation.

LONG-TERM CLINICAL OUTCOMES OF CERTOLIZUMAB PEGOL TREATMENT IN PATIENTS WITH ACTIVE NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS STRATIFIED BY BASELINE MRI AND C-REACTIVE PROTEIN STATUS

P. Robinson[1], W. P. Maksymowych[2], L. S. Gensler[3], M. Rudwaleit[4], B. Hoepken[5], L. Bauer[5], T. Kumke[5], M. Kim[6], A. Deodhar[7]. [1]*University of Queensland School of Clinical Medicine, University of Queensland, Brisbane, Australia;* [2]*Department of Medicine, University of Alberta, Alberta, Canada;* [3]*University of California San Francisco, N/A, San Francisco, California,, United States of America;* [4]*University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany;* [5]*UCB Pharma, N/A, Monheim am Rhein, Germany;* [6]*UCB Pharma, N/A, Smyrna, Georgia, United States of America;* [7]*Oregon Health & Science University, N/A, Portland, Oregon, United States of America*

Background: Certolizumab pegol (CZP) has demonstrated clinical efficacy in patients with active non-radiographic axial spondyloarthritis (nr-axSpA) and objective signs of inflammation during the 52-week (wk) placebo (PBO)-controlled period and 104 wk open-label (OL) safety follow-up extension (SFE) of the C-axSpAnd study.[1] There is, however, a paucity of data on the long-term efficacy of biologics in nr-axSpA according to patients' baseline MRI and C-reactive protein (CRP) status.

Objectives: This post hoc analysis from C-axSpAnd aimed to evaluate whether patients' baseline MRI and CRP status impacted long-term (3-year) clinical responses to CZP.

Methods: C-axSpAnd (NCT02552212) was a 3-year, phase 3, multicentre study. Adults (N=317) with nr-axSpA fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria and objective signs of inflammation (CRP ≥ upper limit of normal (10 mg/L) [CRP+] and/or evidence of sacroiliitis on MRI [MRI+])[2] were randomised 1:1 to PBO or CZP (400 mg at Wks 0, 2 and 4, then 200 mg every 2 wks [Q2W]) for 52 wks.[3] Those enrolled into the SFE received OL CZP (200 mg Q2W) for an additional 104 wks. Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) alongside the percentage of patients achieving ASDAS major improvement (ASDAS-MI, C-axSpAnd primary outcome) and ASAS 40% response (ASAS40) at Wks 52 and 156 were assessed according to prespecified subgroups based on MRI/CRP status (MRI+/CRP+, MRI–/CRP+, MRI+/CRP–). All data are reported as observed case.

Results: 243/317 (76.7%) patients entered the SFE, 120 from the group initially randomised to CZP (36 MRI+/CRP+, 32 MRI–/CRP+ and 52 MRI+/CRP–) and 123 from the initial PBO group (30 MRI+/CRP+, 34 MRI–/CRP+ and 59 MRI+/CRP–; 75/123 had switched to OL treatment in the 52 wk double-blind phase). 206/243 completed the SFE; 102/120 (85.0%) from the group initially randomised to CZP, 104/123 (84.6%) from the initial PBO group. Among CZP-randomised patients, mean ASDAS was similar between timepoints (MRI+/CRP+: 1.6 at Wk 52 vs 1.6 at Wk 156; MRI–/CRP+: 2.1 vs 2.2; MRI+/CRP–: 1.7 vs 1.6), the percentage achieving ASDAS-MI was lower at Wk 156 compared to Wk 52 across all subgroups (Figure 1 **A**). Patients initially randomised to PBO showed improvements in mean ASDAS over time (MRI+/CRP+: 2.1 Wk 52 vs 1.8 Wk 156; MRI–/CRP+: 2.2 vs 1.9; MRI+/CRP–: 2.0 vs 1.7) and a sustained proportion of patients achieved ASDAS-MI. Similar results were shown for BASDAI, with mean scores for CZP-randomised patients sustained from Wk 52 to Wk 156 across all subgroups (Figure 1 **B**). Mean BASDAI decreased (indicative of clinical improvements) from Wk 52 to Wk 156 in patients initially randomised to PBO, at which point the values aligned with those reported for the CZP-randomised group. In CZP-randomised patients, ASAS40 responses were sustained at Wk 156 compared to Wk 52. An increased percentage of patients achieved ASAS40 in all MRI/CRP subgroups initially randomised to PBO at Wk 156 compared to Wk 52 (Figure 1 **C**).

Conclusion: In this analysis of patients with nr-axSpA and objective signs of inflammation, long-term clinical outcomes achieved after 1 year were generally sustained at 3 years across MRI+/CRP+, MRI–/CRP+ and MRI+/CRP– subgroups; ASDAS-MI was numerically highest in the MRI+/CRP+ subgroup.

POS0942 DEVELOPMENT OF PREDICTION MODEL FOR FLARE AFTER TAPERING OF TNF INHIBITORS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

J. Yeo[1], K. Shin[2], E. Y. Lee[3], T. H. Kim[4], J. W. Park[3]. *[1]Gachon University Gil Medical Center, Division of Rheumatology, Department of Internal Medicine, Incheon, Korea, Rep. of (South Korea); [2]Seoul Metropolitan Government-Seoul National Boramae Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [3]Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [4]Hanyang University Hospital for Rheumatic Diseases, Department of rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Tumor necrosis factor inhibitors (TNFi) have become a mainstay of management for axial spondyloarthritis (axSpA). However, it remains unclear whether patients with axSpA should continue the standard-dose TNFi after achieving stable disease activity. Although complete discontinuation of TNFi is followed by early relapse in most cases, several studies documented that reduced doses of TNFi in patients with prolonged low disease activity showed similar effects on disease control and drug survival compared to standard dose of TNFi. One of the main problem in the dose-tapering strategies for TNFi is a selection of the appropriate patient. However, there has been a lack of robust evidence regarding clinical factors predicting the flare after tapering of TNFi in patients with axSpA.

Objectives: This study aims to develop and validate the prediction model to select the patients in whom tapering of TNFi does not lead to flare.

Methods: We used the data from Korean College of Rheumatology Biologics registry, which included a total of 1,730 patients receiving biologic DMARD from 2017 to 2019 in South Korea. In this study, a total of 526 patients who were initially treated with the standard-dose TNFi and tapered the dose after at least 1 year of the treatment were analyzed. Dose quotient (DQ, 0-1) was applied to quantified TNFi used during interval. The main outcome was an occurrence of flare defined as ASDAS-CRP score of ≥2.1 after 1 year of tapering TNFi. To develop the prediction model, clinical factors having relevant association ($p < 0.1$) with the outcome were first selected as candidate predictors. Logistic regression using a stepwise approach through backward elimination was used for the final model.

Results: Patients' mean (SD) age was 37.5 (11.9) years, 418 (79.5%) were men, and 474 (90.1%) were HLA-B27 positive. Mean disease duration was 5.0 (6.1) years and 433 (82.3%) were TNF naïve. The mean BASFI and ASDAS-CRP at baseline were 3.4 (2.6) and 3.7 (1.0), respectively. Approximately two-thirds of the patients (65.8%) were initiated TNFi tapering at the first 1 or 2 years from baseline. At the time of TNFi tapering, the mean DQ was 0.67 (0.15) and 381 (72.4%) were prescribed concurrently with NSAIDs, and the mean BASFI and ASDAS-CRP were 1.3 (1.8) and 1.6 (0.9), respectively. During 12 months of follow up starting from the TNFi tapering, 127 (24.1%) experienced the flare. The multivariable analysis revealed that HLA-B27 positivity (OR 0.337; 95% CI 0.161-0.705; p=0.004), inflammatory back pain (OR 2.920; 95% CI 1.283-6.648; p=0.011), ASDAS-CRP at tapering (OR 2.798; 95% CI 2.030-3.856; p<0.001), and BASFI at tapering (OR 1.214; 95% CI 1.051-1.402; p=0.008) were significantly associated with flare. Based on the results of the logistic regression analysis, the predicted probability was calculated by the following formula: P=1/[1+ exp{-(1.088 x HLA-B27 negativity + 1.072 x inflammatory back pain + 1.567 x psoriasis + 0.623 x family history of axSpA + 1.092 x diabetes mellitus + 0.435 x DQ at TNFi tapering + 1.029 x ASDAS-CRP at TNFi tapering + 0.194 x BASFI at TNFi tapering)}]. The best cut-off value of the model to define the flare was 0.2416 (95% CI 0.176, 0.301) with sensitivity 74.0% and with specificity 81.0%. AUC was 0.828 (95% CI 0.786-0.869) indicating a good predication (Figure 1). The internal validation with bootstrapping showed minimal overfitting (estimated AUC 0.794) and good calibration between observed and predicted values (calibration slope 1.110, 95% CI 0.903, 1.317; intercept 0.026, 95% CI -0.091, 0.039).

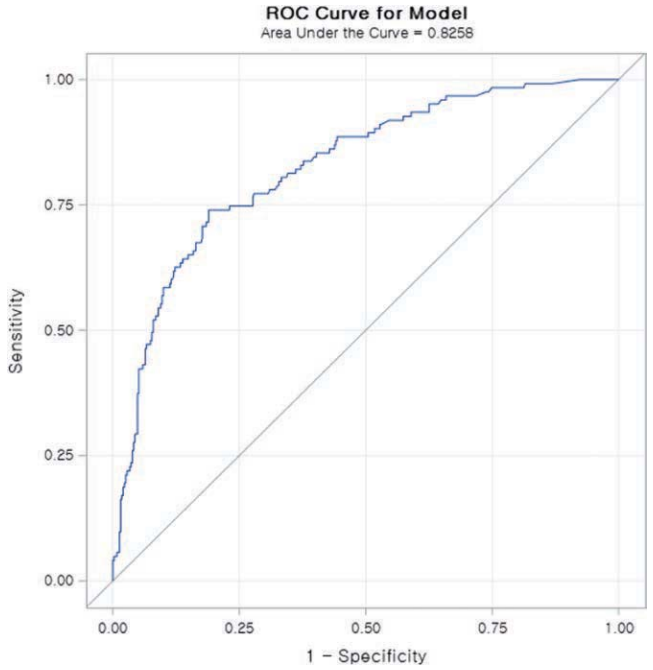

Figure 1. Apparent performance of developed model for prediction of flare after 12 months of tumor necrosis factor inhibitors tapering.

Conclusion: We developed the prediction model for the flare after 12 months of TNFi tapering in patients with axSpA. It might be applicable in real world setting, although external validation will be required in the future investigation.

POS0943 EFFECT OF NERIDRONATE ON AXIAL SPONDYLOARTHRITIS WHEN BDMARDS ARE NOT AN OPTION: RESULTS FROM A RESTROSPECTIVE STUDY

C. Crotti[1], R. Dl Taranto[1,2], E. G. Favalli[1,2], R. Caporali[1,2]. *[1]ASST Gaetano Pini-CTO, Department of Rheumatology, Milano, Italy; [2]University of Milan, Department of Clinical Sciences & Community Health, Milano, Italy*

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended as first-line treatment of axial Spondyloarthritis (axSpA) and biological disease-modifying antirheumatic drugs (bDMARDs) are effective in the management of patients refractory to NSAIDs. However, in some cases the introduction of bDMARDs is limited by absolute contraindications or patient opposition. Beyond the well-known anti-osteoclastic properties, bisphosphonates (BPs) can exert their benefits through other mechanisms, including reduction of proinflammatory cytokines (such as IL6 and TNFα), and modulation of macrophage and osteoblast activity.

Objectives: To examine the potential therapeutic properties of a BP, IV neridronate (IVNer), in patients with axSpA refractory to NSAIDs and not eligible for a second-line therapy with bDMARDs.

Methods: We retrospectively collected data of patients affected by axSpA according to ASAS classification criteria, treated with IVNer, referred to a tertiary Rheumatology Centre between Sept 2015 and Dec 2021. Patients with active disease, as defined by a BASDAI score ≥4, with active sacroileitis (SI) on MRI (according to ASAS MRI definition of active SI), who had failed/were intolerant to NSAIDs and not eligible for bDMARDs, were recruited. IVNer (100 mg) was given intravenously on Days 1, 4, 7, and 10, over 3 h in 500 ml of 0.9% saline. Response to IVNer was evaluated after 60 days from the last infusion as the mean change from baseline of BASDAI and visual analogue scale (VAS) pain score, and the improvement of MRI imaging.

Results: We included 30 patients (77% females, mean age±SD 39.0±16.8 yrs, and mean disease duration of 24±14.4 months (range 1.0-298). Fourteen had ankylosing spondylitis (AS), six had undifferentiated SpA, two had enteropathic arthritis, one had non-radiographic axSpA, and seven had axial psoriatic arthritis. 50% had axial involvement, 30% axial and peripheral arthritis, and 20% had axial and enthesis involvement. Eleven were HLA-B27 positive. On MRI evaluation, 43% had

monolateral SI, 57% bilateral SI and 7% had erosions. Among the reasons of ineligibility to bDMARDs, 6 patients have concurrent solid tumor, 11 had comorbidities contraindicating bDMARDs, and 12 preferred not to undergo to bDMARDs. Mean BASDAI significantly decrease after IVNer (5.86±1.98 vs 3.52±2.39, p=0.0002, Figure 1a), as well as VAS pain score (6.14±1.92 vs 3.18±2.62, p<0.05, Figure 1b). MRI showed a complete resolution of SI in 47%, partial resolution in 33%, and persistent active SI in 40% of patients, without correlation with the previous presence of erosions.

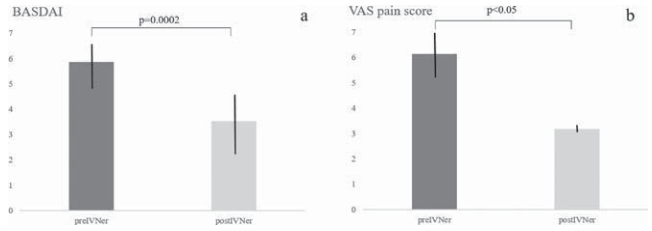

Figure 1.

Conclusion: IVNer was effective in reducing disease activity measured by BASDAI and VAS pain score in patients with axSpA refractory to NSAIDs and not eligible for bDMARDs. When recommended second-line treatments are contraindicated or according to patients' preference, IVNer can be considered as a potential alternative therapeutic option. Further evaluations in controlled trials are needed to confirm these results.

POS0944 PREDICTORS OF SUSTAINED REMISSION IN PEOPLE WITH AXIAL SPONDYLOARTHRITIS TREATED WITH BIOLOGIC DRUGS

B. Farisogullari[1,2], G. K. Yardımcı[1], E. Bilgin[1], E. C. Bolek[1], E. Duran[1], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1], P. M. Machado[2]. *[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; [2]University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, LONDON, United Kingdom*

Background: The ultimate goal of treatment in axial spondyloarthritis (axSpA) is sustained remission. Data on predictors of sustained remission are scarce in axSpA.

Objectives: To determine predictors of sustained remission in people with axSpA after treatment with their first biological disease-modifying anti-rheumatic drug (bDMARD).

Methods: Hacettepe University Rheumatology Biologic Registry (HUR-BIO) is a prospective, single center registry of rheumatic disease patients treated with bDMARDs. Patients with axSpA were selected and sustained remission defined as attainment of Assessment of SpondyloArthritis International Society partial remission (ASAS-PR) and/or Ankylosing Spondylitis (AS) Disease Activity Score C-reactive protein Inactive Disease (ASDAS-ID) for two or more consecutive visits spanning ≥6 months during follow-up. Patients achieving and not achieving sustained remission were compared using the independent t-test. Multivariable logistic regression analysis was performed to determine independent factors predictive of sustained remission. Variables with a p-value<0.1 were re-tested in multivariable models. Forward selection was performed until the best-fit model was obtained, taking possible confounders into account. Two separate multivariable models were built, one with and one without the covariate "achievement of remission at 3-6 months", to assess consistency of findings and to account for missing information regarding remission status between 3 and 6 months.

Results: Data on 990 patients with sustained remission data were available. Of these, 299 (30%) were in sustained remission, while 691 (70%) were not. Patients in sustained remission were younger, had earlier disease onset, were more frequently male, had lower BMI and were more frequently HLA-B27 positive, compared to patients not in sustained remission. Furthermore, at the start of bDMARD treatment, Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI), and patient global assessment (PGA, 0-10 scale) were lower, while acute phase reactants (ESR and CRP) were higher, in the sustained remission group. In multivariable analysis, male gender (OR 2.2, 95% CI 1.21-3.95), concomitant conventional synthetic DMARD (csDMARD) use (OR 3.63, 95% CI 1.29-10.19), PGA (OR 0.96, 95% CI 0.95-0.98), and early achievement (between 3-6 months) of remission (OR 13.1, 95% CI 7.13-24.02) were independently associated with sustained remission (Table 1, model 1). In the model without the variable early achievement of remission (Table 1, model 2), similar and a few additional associations were described: age at diagnosis (OR 0.97, 95% CI 0.96-0.99), male gender (OR 2.31, 95% CI 1.60-3.35), concomitant csDMARD use (OR 1.88 95% CI 1.23-2.86), PGA (OR 0.98, 95% CI 0.97-0.99), BASDAI (OR 0.87, 95% CI 0.78-0.96), and baseline symptom duration (OR 0.97, 95% CI 0.94-0.99).

Table 1. Multivariable analysis (best-fit model) of predictors of sustained remission

	Model 1		Model 2	
	Multivariable Analysis (n= 541)		Multivariable Analysis (n=739)	
Covariates	**OR (95% CI)**	**p-value**	**OR (95% CI)**	**p-value**
Age at diagnosis	NS	NS	0.97 (0.96-0.99)	0.006
Male sex	2.84 (1.71-4.70)	<0.001	2.31 (1.60-3.35)	<0.001
Concomitant csDMARD use (at baseline or follow-up)	2.94 (1.57-5.51)	0.001	1.88 (1.23-2.86)	0.003
Baseline PGA	0.97 (0.96-0.98)	<0.001	0.98 (0.97-0.99)	0.002
Baseline BASDAI	NS	NS	0.87 (0.78-0.96)	0.009
Baseline symptom duration	NS	NS	0.97 (0.94-0.99)	0.021
Achievement of remission at 3-6 months after baseline	11.70 (7.11-19.23)	<0.001	NA	NA

NA: not applicable; NS: not selected (not contributing to the model). Baseline refers to start of bDMARD treatment.

Conclusion: This study demonstrates that patients in sustained remission after starting bDMARD treatment have distinctive characteristics compared to patients not in sustained remission. These data can be used to aid clinical and personalized management of axSpA, and to facilitate better communicate between health care professionals and patients regarding the course and prognosis of their condition.

POS0945 IMPROVEMENT OF ENDOTHELIAL DYSFUNCTION AND INFLAMMATION IN ANKYLOSING SPONDYLITIS: IMPROVE-AS STUDY

A. Syngle[1,2], N. Garg[3,4], P. Krishan[4], D. Syngle[5,6,7]on behalf of Medical Innovators. *[1]Cardio-Rheuma & Healing Touch City Clinic, Rheumatology, Chandigarh, India; [2]Fortis Multispecialty Hospital, Rheumatology, Mohali, India; [3]Chitkara College of Pharmacy, Chitkara University, Rajpura, India; [4]Punjabi University, Department of Pharmaceutical Sciences & Drug Research, Patiala, India; [5]Government Multi Specialty Hospital, MBBS Intern, Chandigarh, India; [6]Shri Guru Ran Rai Institute of Medical & Health Sciences, Under Grad, Dehra Doon, India; [7]Healing Touch Foundation, Innovation, Chandigarh, India*

Background: Cardiovascular (CV) disease is the leading cause of death in Ankylosing Spondylitis (AS)[1]. The chronic inflammatory-driven endothelial dysfunction and accelerated atherosclerosis contribute to the enhanced CV risk in AS. However, the therapeutic options to treat the enhanced CV risk are limited.

Objectives: To investigate the impact of Olmesartan and Rosuvastatin on endothelial dysfunction and inflammation in AS.

Methods: 60 consequtive AS patients were randomized to receive 24-weeks of treatment with Olmesartan (OLME) (10 mg/day, n=20), Rosuvastatin (Rvs) (10 mg/day, n=20), or placebo (PL) (n=20) as an adjunct to existing stable csDMARDs. Endothelial function was assesed by brachial artery flow-mediated dilatation (FMD) using AngioDefender. EPCs ($CD34^+/CD133^+$) were estimated by flow cytometry. Serum nitrite, TBARS, ICAM-1, VCAM-1 and lipids levels estimated at baseline and after treatment. Inflammatory measures included: ASDAS, BASDAI, BASFI, ESR and CRP, pro-inflammatory cytokines. Quality of life and CV 10-year risk (SCORE high risk charts) were estimated using standard tools.

Results: Baseline levels of FMD and EPC population were impaired indicating endothelial dysfunction. Basal concentrations of inflammatory markers, pro-inflammatory cytokines and markers of endothelial dysfunction were elevated among three

groups. After 24-weeks of treatment, FMD improved significantly in the rosuvastatin and olmesartan group as compared to placebo from their baseline levels: {OLME vs. PL (p≤0.01), Rvs vs. PL (p<0.01), Rvs vs. OLME (p=0.10) (Figure 1A). EPCs and nitrite (Figure 1B) levels improved significantly in both rosuvastatin and olmesartan groups. A significant reduction found in ICAM-1 after rosuvastatin treatment (p<0.01) where as olmesartan significantly decreased VCAM-1 (p=0.04) levels. Both rosuvastatin and olmesartan resulted in significant reductions of ASDAS, BASDAI, BASFI, ESR, CRP, IL-6 (Figure 1C) and TNF-α (Figure 1D) as compared to placebo. A significant reduction found in TBARS concentration after olmesartan treatment (p<0.01) as compared with rosuvastatin and placebo. There was a significant reduction in SCORE, HAQ-DI & SF-36 (PH) after treatment with rosuvastatin and olmesartan.

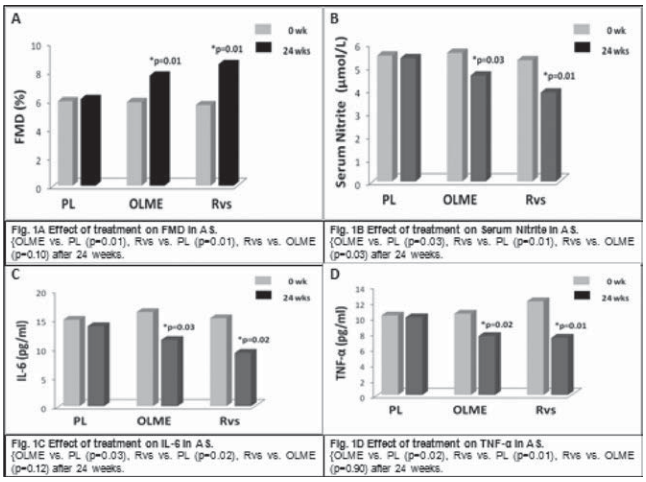

Fig. 1A Effect of treatment on FMD in AS. {OLME vs. PL (p=0.01), Rvs vs. PL (p=0.01), Rvs vs. OLME (p=0.10) after 24 weeks.

Fig. 1B Effect of treatment on Serum Nitrite in AS. {OLME vs. PL (p=0.03), Rvs vs. PL (p=0.01), Rvs vs. OLME (p=0.03) after 24 weeks.

Fig. 1C Effect of treatment on IL-6 in AS. {OLME vs. PL (p=0.03), Rvs vs. PL (p=0.02), Rvs vs. OLME (p=0.12) after 24 weeks.

Fig. 1D Effect of treatment on TNF-α in AS. {OLME vs. PL (p=0.02), Rvs vs. PL (p=0.01), Rvs vs. OLME (p=0.90) after 24 weeks.

Conclusion: Olmesartan and rosuvastatin improve endothelial dysfunction and vascular inflammation and QoL in AS patients. Olmesartan and Rosuvastatin lower the proinflammatory cytokines, especially TNF-α, that upregulate eNOS and downregulates the production of adhesion molecules, CRP and nitric oxide which, in turn, improves endothelial dysfunction. Both drugs also decrease nitrite concentration and improve the EPC population in AS patients. The augmentation of EPCs by olmesartan and rosuvastatin represents a fascinating new approach for the management of AS. However, Rosuvastatin in addition also favorably impacted ICAM-1 and lipid abnormalities. In contrast, olmesartan has beneficial effect on blood pressure. Thus, both rosuvastatin and olmesartan have anti-inflammatory, immunomodulatory, vasculoprotective and cardioprotective effects in AS mediated through anti-proinflammatory cytokine action. These findings suggests that both drugs could mediate modest but clinically apparent anti-inflammatory effects with modification of CV risk in the context of high-grade autoimmune inflammation of AS and may provide a novel strategy to prevent cardiovascular events in these patients.

POS0946 THE COURSE OF BONE MINERAL DENSITY DURING 8 YEARS OF TREATMENT WITH TNF-α INHIBITORS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Siderius[1,2], A. Spoorenberg[1,2], F. Wink[1,2], S. Arends[1,2]. *[1]University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: Bone loss reflected by lower bone mineral density (BMD) compared to age and gender matched healthy controls is a common feature of ankylosing spondylitis (AS) and can already be observed at early stages of the disease[1]. AS patients starting TNF-α inhibitors (TNFi) show overall a rapid increase in BMD[2]. However, the course of BMD during long-term TNFi in these patients is not known.

Objectives: To assess the course of BMD of the lumbar spine (LS) and hip in AS patients treated with TNFi during 8 years.

Methods: Patients from the GLAS cohort who received TNFi for at least 8 years were included. Patients were excluded when they used bisphosphonates. BMD of the LS (AP projection L1-L4) and hip (total proximal femur) was measured at baseline, 1 year, 2 years and then bi-annually using DEXA. Low BMD was defined as LS and/or hip BMD Z-score ≤1. Generalized estimating equations were used to analyze BMD Z-scores over time within subjects.

Results: 131 AS patients were included; 73% were male, mean ± SD age was 41.3 ± 10.8 years, median (IQR) symptom duration was 14 (7-24) years, 83% were HLA-B27+, mean ASDAScrp was 3.8 ± 0.8, median CRP level was 13 (6-22) mg/L, and median vitamin 25(OH)D3 was 61 (46-80) nmol/L at baseline. Disease activity showed rapid and sustained during TNFi treatment, with mean ASDAScrp of 2.1 ± 0.9 and median CRP of 2 (2-5) at 8 years. Serum levels of vitamin D remained stable, with median vitamin 25(OH)D3 of 60 (47-81) at 8 years. At baseline, mean LS and hip BMD Z-scores were -0.37 ± 1.08 and -0.05 ± 1.04, respectively. Low BMD at the LS and hip (Z-score ≤1) was present in 34% and 19% of patients, respectively. Overall, both LS and hip BMD Z-scores improved significantly during TNFi at all follow-up visits compared to baseline. Significant improvement of BMD Z-scores compared to the previous time point was found up to and including 4 years for LS and up to and including 2 years for hip. Thereafter, deflection of improvement was observed. Median percentage of improvement in absolute BMD after 8 years of TNFi compared to baseline was 7.1% (IQR 0.8-13.5) for LS and 1.6% (IQR -3.5-5.5) for hip (Figure 1). At 8 years, low BMD at the LS and hip (Z-score ≤1) was present in 23% and 19% of patients, respectively.

Conclusion: In AS patients treated long-term with TNFi, both hip and LS BMD significantly increased especially during the first 2-4 year of treatment and stabilized thereafter. This effect was most pronounced in the LS and small in the hip.

POS0947 LONG-TERM GOLIMUMAB PERSISTENCE: 5-YEAR TREATMENT RETENTION DATA POOLED FROM FIVE PHASE III CLINICAL TRIALS IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, AND ANKYLOSING SPONDYLITIS

C. Weinstein[1], M. Govoni[2], J. Lin[1], A. Meehan[1], Z. Qureshi[1]. *[1]Merck & Co., Inc., MRL, Kenilworth, United States of America; [2]MSD Italy, Medical Affairs, Rome, Italy*

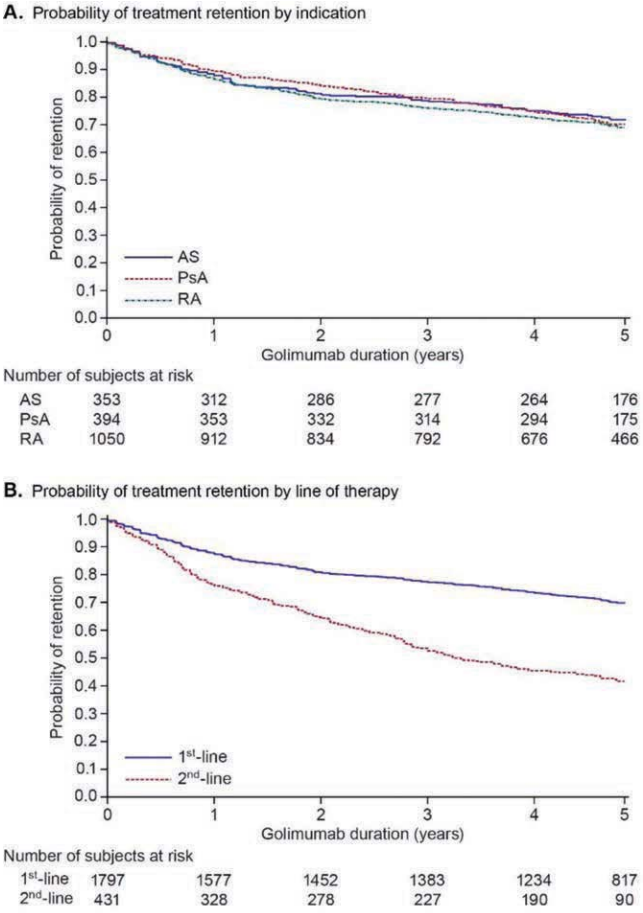
Background: Tumor necrosis factor-alpha inhibitors (TNFi), such as golimumab (GLM), are widely prescribed for treatment of chronic immune-mediated rheumatic diseases, such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Long-term persistence of GLM response in these diseases has previously been described from individual randomized controlled trials.[1-5] While treatment retention is considered an important factor for disease progression, health care utilization, and overall quality of life, and has previously been described, the probability of retention on GLM treatment in these trials has not been evaluated.

Objectives: To evaluate probability of GLM treatment retention over a 5-year period in adult patients with immune-mediated rheumatic diseases, by indication and line of therapy, using pooled data from five Phase III randomized controlled clinical trials.

Methods: Using data prospectively collected from five Phase III studies, this post-hoc analysis evaluated subcutaneous (SC) GLM (50 mg or 100 mg every 4 weeks) for up to 5 years in participants with RA (GO-BEFORE,[1,6] GO-AFTER[2,7] and GO-FORWARD[3,8]), PsA (GO-REVEAL[4,9]), and AS (GO-RAISE[5,10]). Four of the five studies (GO-BEFORE, GO-FORWARD, GO-REVEAL and GO-RAISE) were pooled to examine 1st-line GLM therapy, while the remaining

study (GO-AFTER) was used to examine 2nd-line (i.e., ≥ 1 line) GLM therapy in participants who had previously received and discontinued at least one other TNFi (etanercept, adalimumab, or infliximab) for any reason. Log-rank tests were performed to estimate retention rates by indication and line of therapy. Similarly, Kaplan-Meier analysis was used to estimate the probability of GLM retention over time.

Results: Among the 2228 participants enrolled in the 5 trials, 1797 participants had received GLM as1st-line treatment (RA = 1050; PsA = 394; AS = 353) and 431 participants had received GLM as 2nd-line treatment. Compared to the pooled 1st-line GLM analysis cohort, more participants receiving 2nd-line GLM were female (78.7% vs 62.2%), were > 50 years (61.5% vs 41.2%), and had a longer disease duration (median of 9.2 years vs 3.7 years). In the pooled 1st-line studies, GLM treatment retention remained high over five years, with an overall probability of retention of 87.8% (95% confidence interval [CI], 86.2–89.2) at Year 1 (Week 52), 80.9% (79.0–82.6) at Year 2 (Week 104), 77.3% (75.3–79.2) at Year 3 (Week 156), 73.5% (71.4–75.5) at Year 4 (Week 208) and 69.8% (67.6–71.9) at Year 5 (Week 252). GLM retention rates were similar across the four 1st-line GLM studies with no notable differences observed by indication over time (Figure 1, panel A). Treatment retention was better in participants using GLM as a 1st-line therapy compared to 2nd-line therapy (Figure 1, panel B), with a probability of retention at 5 years (Week 252) with 2nd-line therapy of 41.6% (95% CI: 36.8-46.3).



2nd-line refers to any participant receiving GLM after ≥1 line of another TNFi therapy. In the 2nd-line study, 115 (25%) participants had received two and 43 (9%) had received three TNFi therapies before enrollment.

Figure 1.

Conclusion: In this post-hoc analysis of prospectively collected clinical trial data, the probability of 1st-line GLM treatment retention at 5-years was consistently high across all rheumatic indications (RA, PsA and AS). Probability of long-term GLM treatment retention with 2nd-line therapy, while lower than 1st-line therapy, also remained favorable. Collectively, these data support the value of GLM as a 1st- or 2nd-line therapy in these chronic immune-mediated rheumatic diseases.

POS0948

SIX YEARS TREATMENT WITH TNF-α INHIBITORS DOES NOT LEAD TO LONG-TERM CONTINUOUS HYPERMINERALIZATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Siderius[1], A. Spoorenberg[1], E. Van der Veer[2], F. G. M. Kroese[1], S. Arends[1].
[1]University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands

Background: In a previous study, we showed that the bone turnover balance favored bone formation, especially mineralization, during the first years of treatment with TNF-α inhibitors (TNFi)[1] in patients with ankylosing spondylitis (AS).

Objectives: To explore if this effect continues during more long-term TNFi treatment. Therefore our goal was to investigate the prolonged course of serum levels of bone turnover markers (BTM) during 6 years of TNFi treatment in patients with AS.

Methods: Included were consecutive AS outpatients from the UMCG GLAS cohort who were treated with TNFi for at least 6 years. Patients were excluded when they used bisphosphonates. Data for a specific visit was coded as missing when patients either had experienced a fracture or received systemic corticosteroids within 1 year from that particular visit regarding the possible effect on BTM. Standardized follow-up visits were performed at baseline (before start of TNFi), 3 and 6 months, 1, 2, 4 and 6 years. Serum markers of collagen resorption sCTX, bone regulation OC, collagen formation PINP, and bone mineralization BALP were measured. Z-scores were calculated to correct for the normal influence of age and gender using a healthy reference population. Generalized estimating equations were performed to analyze BTM Z-scores over time within patients.

Results: 53 AS patients were eligible for analyses: 66% were male, mean (SD) age was 38.5 ± 11.3 years, median (IQR) symptom duration was 16 (9-25) years, 87% were HLA-B27+, mean ASDAS was 3.8 ± 1.0, and median CRP 14 (7-27) mg/L. Etanercept, infliximab or adalimumab was prescribed as first TNFi in 60%, 2% and 38% of patients, respectively. 26% (n=14) of patients switched to a second TNF-α inhibitor during follow-up. Disease activity showed rapid and sustained improvement after start of TNFi (Figure 1). At group level, collagen resorption marker sCTX Z-score did not significantly change during treatment. Bone regulation marker OC Z-score was only significantly increased at 3 months compared to baseline. Collagen formation marker PINP Z-score showed significantly increased levels at 3 and 6 months and 2 years. Bone mineralization marker BALP Z-score was significantly increased at all time points up to and including 2 years and decreased thereafter. Only a few patients still had higher BTM values above the normal range (+2 SD) (Figure 2). The net effect of collagen metabolism corrected for the normal influence of age and gender (PINP Z-score – sCTX Z-score) confirmed that the initial balance was in favor of collagen formation; this increase was only significant at 6 months compared to baseline.

Conclusion: In AS patients receiving long-term TNFi, the bone turnover balance favored bone formation during the first 2 years of treatment. Thereafter, at group level, serum levels of BTM returned to levels not significantly different from baseline. Therefore, 6 years of treatment with TNF-α inhibitors did not seem to lead to long-term continuous hypermineralization in patients with AS.

POS0949

NO CHANGE IN SERUM LEVELS OF BONE TURNOVER MARKERS CORRECTED FOR AGE AND GENDER DURING THE FIRST YEAR OF SECUKINUMAB TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Siderius[1], S. Arends[1], F. Wink[2], A. Spoorenberg[1]. [1]*University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands;* [2]*Medical Centre Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: In patients with ankylosing spondylitis (AS), TNF-α inhibitors influence the course of serum bone turnover markers (BTM), favoring an increase in mineralization during the first years[1]. Little is known about the effect of IL-17 inhibitors on these serum BTM levels.

Objectives: To evaluate serum markers of bone resorption, formation, and mineralization during 1 year of secukinumab treatment in AS patients in daily clinical practice.

Methods: Included were consecutive outpatients from the GLAS cohort with a clinical diagnosis of AS who started treatment with secukinumab between April 2016 and June 2020, and had available serum samples at ≥1 visit. Standardized follow-up visits were performed at baseline (before start of secukinumab) and after 3 or 6 months and 1 year of treatment. BTM were measured in serum: osteocalcin (OC; regulation marker), serum type 1 collagen C-telopeptide (sCTX; collagen resorption marker), procollagen type 1 N-terminal peptide (PINP; collagen formation marker) and bone-specific alkaline phosphatase (BALP; bone mineralization marker). BTM Z-scores were calculated using a healthy reference population to correct for the normal influence of age and gender. Patients using bisphosphonates were excluded from analyses. Data was coded missing if patients experienced a fracture or received systemic corticosteroids within 1 year of a study visit. Generalized estimating equations were used to analyze BTM Z-scores over time within patients.

Results: In total, data of 26 AS patients were eligible for analyses; 50% were male, mean age was 46.0±14.6 years, 81% were HLA-B27 positive, mean ASDAS at baseline was 3.7±1.0, and 50% was TNFi naïve. Before secukinumab treatment, median PINP and BALP Z-scores were +0.6 and +0.7 SD, respectively, compared to age and gender matched healthy controls, however, the large majority remained within the normal range of ±2 SD. Overall, BTM Z-scores of OC, sCTX, PINP and BALP did not change significantly compared to baseline during the 1st year of secukinumab treatment (Figure 1).

Conclusion: In daily clinical practice, serum BTM levels including mineralization corrected for the normal influence of age and gender did not change during the 1st year of secukinumab treatment in patients with AS. Our data confirm recent findings of stable BTM levels at group level during 2 years of secukinumab treatment in posthoc analysis of MEASURE 1[2].

POS0950 LONG-TERM FOLLOW-UP OF STARTING AND SWITCHING FROM ORIGINAL ADALIMUMAB TO ADALIMUMAB BIOSIMILAR: REAL-WORLD DATA IN AXIAL SPONDYLOARTHRITIS

A. S. Pinto[1], K. Flora[2], D. Matharu[3], A. Isaacs[3], P. Machado[3,4]. [1]*Unidade Local de Saúde da Guarda, Rheumatology, Guarda, Portugal;* [2]*Northwick Park Hospital, London North West University Healthcare NHS Trust,, Pharmacy, London, United Kingdom;* [3]*Northwick Park Hospital, London North West University Healthcare NHS Trust, Rheumatology, London, United Kingdom;* [4]*Institute of Neurology, University College London, Centre for Rheumatology, Division of Medicine & Department of Neuromuscular Diseases, London, United Kingdom*

Background: Biological drugs have revolutionized the treatment of rheumatic diseases, and the recent expiry of the patents for many biological agents has led to the marketing of highly similar, low-cost versions known as biosimilars. However, questions regarding its efficacy compared to bio-originator drugs, in a real-life setting, have been raised. National Institute for Health and Care Excellence (NICE) guidelines state that the response to biologic disease-modifying anti-rheumatic drugs (bDMARDs) should be assessed 12 weeks after the beginning of the drug. Treatment should only be continued if there is clear evidence of response, defined as a reduction in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score to 50% of the pre-treatment value or by 2 or more units and a reduction in the 10-cm spinal pain visual analogue scale (VAS) by 2 cm or more.
Objectives: To compare the response to adalimumab (ADA) originator and biosimilar in bDMARD-naïve patients with axial spondyloarthritis (axSpA) and in patients who switched from originator to biosimilar drug, accordingly to NICE guidelines; to compare the effectiveness and safety of the originator and biosimilar drugs in patients with axSpA, measured by persistence rates (PR) over three years.
Methods: A retrospective observational single-centre UK study was performed in bDMARD-naïve patients with a clinical diagnosis of axSpA who initiated treatment with ADA (original or biosimilar) and in patients who switched from originator to biosimilar drug. Descriptive statistics were used. Disease activity at baseline and follow-up data at 3 and 6 months of treatment was compared using the chi-square test. The Kaplan-Meier method was used to calculate persistence rates in biologic treatment over time. Reasons for discontinuing therapy were summarized using descriptive statistics and stratified by treatment.
Results: A total of 153 patients were included: 83 patients started on original ADA, 31 started on biosimilar ADA and 40 switched from original to biosimilar drug. The population's baseline characteristics are similar in the three groups. However, some differences were found, namely disease duration was longer in the group that did switch and the disease activity is similar in patients who started original and biosimilar ADA and was lower in the group of patients who switched from original to the biosimilar. The 3-year PR was not significantly different between originator and biosimilar ADA in bDMARD naïve patients and in the group of patients that switched from original drug to biosimilar drug (p=0.080), as shown in Figure 1. In the original ADA group, 3-years PR was 67.5% with a median time-on-drug (TOD) of 29.5 months; for biosimilar drug, 3-years PR was 64.5%, with a median TOD of 24.2 months. In patients who switched from original to biosimilar drug, 3-years PR was 77.5% with a median TOD of 30.3 months. Response to treatment according to NICE guidelines was similar between original and biosimilar drugs (p>0.05). Overall, 47 (30.7%) patients stopped adalimumab (27 patients on original drug and 20 on biosimilar drug). Discontinuations due to adverse events and inefficacy were the most frequent, and there were no significant differences between original and biosimilar drugs. Other reasons for discontinuation were less frequent, such as patient choice, loss of follow-up and death, and again without differences between original and biosimilar drugs.

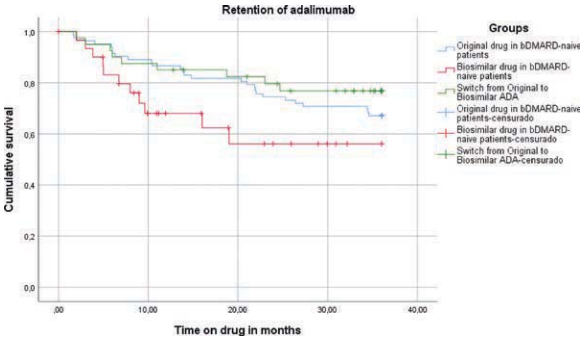

Figure 1. Drug survival in the three adalimumab groups (original adalimumab – blue line, biosimilar adalimumab – red line, and switch from original to biosimilar adalimumab – green line)

Conclusion: Adalimumab original and biosimilar used as a first-line biological treatment showed similar effectiveness and safety in our long-term cohort of patients with axSpA. Switch from original to biosimilar drug showed to have a good persistence on drug after three years of follow-up (77.5%).

POS0951 SERUM PROTEIN RESPONSE TO A SINGLE HIGH-INTENSITY INTERVAL TRAINING BOUT – COMPARISON BETWEEN INDIVIDUALS WITH SPONDYLOARTHRITIS AND HEALTHY CONTROLS

Å. Andersson[1], E. Haglund[1,2,3], E. Berthold[4], E. Mogard[5], A. Torell[6], M. C. Olsson[1]. [1]*Halmstad University, Dept. of Environmental and Biosciences, Halmstad, Sweden;* [2]*FoU Spenshult Spenshult Research and Development Centre, Spenshult Research and Development Centre, Halmstad, Sweden;* [3]*Lund University, Dept. of Clinical Sciences, Section of Rheumatology, Lund, Sweden;* [4]*Halmstad University, Halmstad University, Halmstad, Sweden;* [5]*Rheumatology, Dept. of Clinical Sciences Lund, Lund university, Lund, Sweden;* [6]*Ängelholm Hospital, Dept. of Rehabilitation, Ängelholm, Sweden*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease affecting mainly the axial skeleton. To decrease the risk of cardiovascular comorbidity, aerobic training is recommended as a part of disease management in patients with axSpA. High-intensity interval training (HIIT) interventions are, in addition to other recommended treatments, believed to positively affect the disease activity (1). However, the knowledge about the acute effects of HIIT on the inflammatory process at the molecular level is less studied. Understanding the acute HIIT effects on cytokines and additional serum proteins in axSpA is important for further long-term HIIT interventions and recording of the effect of HIIT on the axSpA disease profile.
Objectives: To study the acute effects on serum proteins, such as cytokines, myokines, and inflammatory- and bone-related proteins, in response to a single bout of HIIT, and to compare the levels between baseline and post-HIIT in patients with axSpA and healthy controls (HC).
Methods: The pilot study included twenty-one participants (10 female, 11 male), mean (SD) age 40 (7) years, ten with axSpA, and eleven age and sex matched HC, who performed a single HIIT on a cycle ergometer consisting of 4x4 minutes interval (90% heart rate, HR-max) with three minutes active rest in between (70% of HR-max). Disease activity (BASDAI, 0-10) in patients with axSpA was 1.6 (0.8). Health status EuroQol (EQ5D, 0-1) were 0.87 (0.11) for axSpA, and 0.93 (0.10) for HC. The groups were well matched with no difference in baseline data for weight, BMI, EQ5D, blood pressure or aerobic capacity.
Blood samples were taken before (baseline) and one hour after the single HIIT. The following serum proteins were analyzed on a Luminex MAGPIX

System (Luminex corporation, Austin, TX USA): Interleukin (IL)-6, IL-17, IL-18, TNFαAGPIX System (Luminex corporatiosteoprotegerin, osteocalcin, osteopontin, and FGF-23. A three-way analysis of variance (ANOVA) was used to detect differences between groups, between sexes, and before and after a HIIT bout in a 2(group)*2(sex)*2(time) design. For main effects or interactions significant at p≤0.05, simple effect t-tests were used to determine the specific effects.

Results: A group main effect (p=0.048) showed that the serum level of IL-6 was increased one hour after the HIIT session primarily in the HC, 0.4 pg/ml (SD±0.4) at baseline vs. post-HIIT 1.8 (2.0). The concentration of the cytokines/chemokine IL-17, IL-18, TNFα group main effect (p=0.048) showed that the serum level of IL-6 was increased one hour after the HIIT session primarily in30) in VEGF-A showed that the axSpA group had significantly lower VEGF-A at baseline, 159 pg/ml (138) vs 326 (184) in the control group (which might be due to anti-inflammatory medication). A sex main effect (p=0.029) was observed from baseline to post-HIIT for the bone hormone osteocalcin, with a more pronounced decrease of serum osteocalcin in women with axSpA, 14.0 ng/ml (8.3) vs. post HIIT 13.2 (6.9). Moreover, the level of the multifunctional protein osteopontin was significantly lower (sex main effect, p=0.021) in women, 10.7 ng/ml (7.0) vs. men 20.4 (10.1), post-HIIT.

Conclusion: This pilot study shows that one bout of HIIT influences the expression of proteins involved in inflammation and metabolism, and that sex is an important factor in the response to HIIT. The results should be followed up in longer intervention studies including higher numbers of participants.

POS0952 THE IMPACT OF DIET ON DISEASE ACTIVITY IN SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

A. Ortolan[1], M. Felicetti[1], M. Lorenzin[1], G. Cozzi[1], G. Striani[1], A. Doria[1], R. Ramonda[1]. [1]*University of Padova, Rheumatology Unit, Department of Medicine DIMED, Padova, Italy*

Background: Diet is thought to have a role in inflammatory diseases development and course. However, at present, no recommendations can be given to spondyloarthritis (SpA) patients regarding a specific type of diet/dietary supplement, as evidence on the topic is sparse.

Objectives: To review the evidence about the effect of diet/dietary supplements on SpA disease activity

Methods: A systematic literature review (SLR) was conducted in MEDLINE and SCOPUS according to the "PEO" format (Population: SpA, axial or peripheral, including Psoriatic Arthritis-PsA; Exposure: any kind of diet/dietary supplement; Outcome: any available disease activity measurement). Inclusion criteria were: adult patients, Randomized Controlled Trials (RCTs) and longitudinal studies (so that a pre-and post-intervention assessment were available), papers in English. Risk of bias (RoB) was independently judged by 2 authors (AO, MF) and conducted with different tools according to the study design: Newcastle Ottawa Scale (NOS) for observational studies, the ROBINS-1 tool for non-randomized studies, and the Cochrane risk of Bias tool 2.0 for RCTs.

Results: Literature search yielded 286 publications. After exclusion of 59 duplicates, 171 titles/abstract, and 44 full-texts, we included 8 interventional and 3 observational studies (Table 1). Among the former, 2 RCTs, one at unclear and one at low RoB, failed to show benefit of probiotics in SpA. One RCT at unclear RoB showed that weight loss, but not hypocaloric diet, was associated to MDA achievement in PsA. The other RCT, as well as the 4 quasi-interventional studies, were at high/serious RoB respectively. Among the observational studies, one study on Mediterranean diet demonstrated an association of diet adherence and a>=20% decrease of ASDAS in axSpA. Two other studies were judged of poor quality.

Conclusion: weight loss seems to be able to impact disease activity in SpA, while probiotics were not effective in the available RCTs so far. Adherence to Mediterranean diet might play a role in reducing disease activity. Evidence for effectiveness of dietary behaviors in SpA is quite heterogeneous and high quality studies are warranted to better understand the role of diet in SpA.

PsA: Psoriatic arthritis, AS ankylosing spondylitis, SpA spondyloarthritis, ax: axial; RA Rheumatoid Arthritis, PU polyunsaturated; RCT Randomized Controlled Trial; exp=experimemntal; MDA Minimal Disease Activity; CONSORT CONsolidated Standards of Reporting Trials; BASFI Bath Ankylosing Spondylitis Functional Index; (+) or (-) indicate whether the primary outcome of the study was met or not

Background: Other studies have shown the ability of a wearable activity tracker (TAP) to improve physical activity (PA) in different rheumatic diseases. Given the importance of PA in spondyloarthritis, our hypothesis is that the use of a TAP could improve physical activity and thus disease activity.
Objectives: The purpose of this study is to evaluate the impact of a TAP used to encourage PA on disease activity in patients with spondyloarthritis.
Methods: In this randomized controlled trial consisting of three 12-week stages (Figure 1). Patients with spondyloarthritis were randomized to a group with TAP (GT), or a group without TAP (GST). For the first stage, both groups received physical activity counseling. In the second 12-week stage, no patients received TAP. In the third 12-week stage, all patients received supervised PA combined with TAP for GT only. Disease activity, performance (assessed by the TM6 6-minute walk test), and quality of life (assessed by the Short Form 36 Health Survey Questionnaire [SF-36]) were assessed at 12, 24, and 36 weeks. The primary endpoint was the progression of relapses between baseline and 12 weeks.

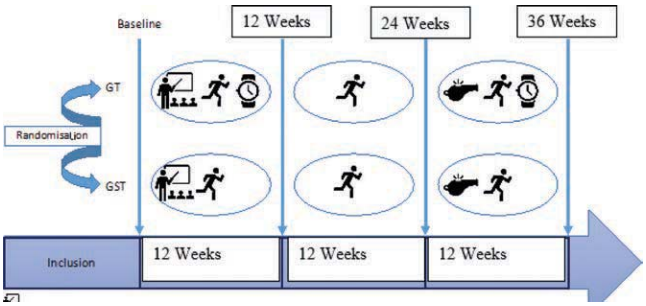

Figure 1.

Results: A total of 108 patients were included in the study. At 12 weeks, both groups showed a non-significant improvement in the number of relapses: mean change (Δ), -0.32 [95% CI-0.68;60.09] in GT and Δ, -0.38 [95% CI-0.68;60.09] in GST. But, differences in outcome between groups were not significant (p=0.87). The TM6 was improved in the GT and GST groups at 12, 24, and 36 weeks ($p < 0.01$, and $p < 0.001$, respectively). We observed improvement in different dimensions of the SF36, mainly in physical function, emotional role, general health, and physical pain at 12 weeks ($p < 0.01$). Multivariate analysis showed improvement over time in performance ($p < 0.01$) and moderate flare-ups ($p < 0.01$) without the influence of a PAR ($p = 0.29$, and $p = 0.66$, respectively).
Conclusion: To our knowledge, our study is the first to explore the impact of TAP use on disease activity in spondyloarthritis. We observed an improvement in disease activity, physical performance and quality of life without significant difference between the two groups. The lack of difference could be explained by the encouragement of physical activity to both groups. But also by the fact that our patients presented a significant number of severe relapses. Indeed, authors have shown the limits of the use of TAP in severe diseases, particularly in pulmonary pathologies [1]. Our study did not show any effect of the use of a connected object on disease activity. However, this study confirmed the benefits of physical activity on disease activity, quality of life and physical performance in patients with spondyloarthritis.

POS0954

WHAT DOES IT MEAN – A GOOD RESPONSE TO NSAIDS? A SYSTEMATIC COMPARISON OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND CONTROLS WITH CHRONIC BACK PAIN

X. Baraliakos[1], I. Redeker[1], E. Bergmann[1], S. Tsiami[1], J. Braun[1].
[1]*Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany*

Background: A fast response to non-steroidal anti-inflammatory drugs (NSAIDs) is an important finding in the evaluation of clinical findings within the items comprising the ASAS classification criteria but also for the treatment decision for escalation to a bDMARD in patients with axial spondyloarthritis (axSpA). However, the differentiation of NSAID responses between patients with axSpA and degenerative or unspecific back pain is still unclear.
Objectives: To study the differences in the velocity and magnitude of NSAID response velocity in patients with established bDMARD naïve axSpA vs. patients with other, non-inflammatory reasons of back pain.
Methods: Patients with axSpA without degenerative reasons for back pain or patients with degenerative or unspecific back pain presenting due to high levels of back pain (NRS≥4/10) were consecutively recruited. Assessments included clinical examination, laboratory tests and MRI of the lumbar spine.
Previous NSAID intake was allowed only if it was taken in low doses without showing a clinical response, otherwise patients were NSAID naïve. Upon study inclusion, patients were treated with the maximum possible dose of an NSAID that they have reported to tolerate in lower doses in the past, independent of whether this was a Cox-2 inhibitor or a non-coxib. Assessment of response was performed using a standardized questionnaire after 2, 6, 12, 24, 36, 48 hours and after 1, 2 and 4 weeks. Any NSAID response was defined as improvement of pain >2/10 points and a good response to NSAIDs as an improvement >50% from the initial status.
Results: A total of 68 patients with axSpA, 107 patients with degenerative back pain and 58 patients with unspecific back pain were included.
The mean age was 42.7±10.7, 51.2±11.3, and 45.8±10.0 years, the main symptom duration 15.1±11.1, 16.1±12.6, and 11.9 ±10.1 years and the proportion of males was 57.4%, 19.6%, and 19.0% respectively. Inflammatory back pain was reported by 42 (75%), 48 (57.8%), and 29 (60.4%) patients, respectively and the mean pain score was 6.2±2.3,6.7±1.8, and 6.2±1.8, respectively.
In axSpA, the mean BASDAI and BASFI scores were 5.5±1.8 and 4.5±2.5, respectively. There was no difference in the cumulative response to NSAIDs between all three diagnoses, with an overall proportion of 27%-30% of patients showing improvement. However, better but not faster responses were found for the subgroups of patients with nr-axSpA (Figure 1) and for the male patients in the entire axSpA group, while axSpA patients with systemic inflammatory activity defined by increased CRP showed lower rates of response as compared to non-inflammatory reasons of back pain diagnoses. All other subanalyses did not reveal any differences between axSpA patients and other non-inflammatory reasons of back pain.

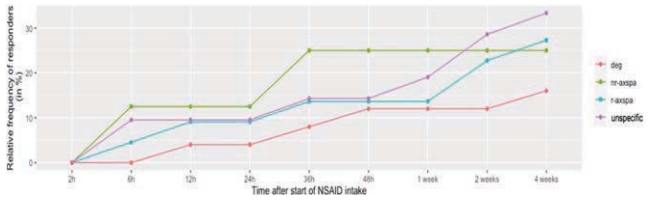

Figure 1.

Conclusion: In this prospective evaluation, the generally proposed better response of axSpA patients to treatment with high doses of NSAIDs as compared with non-inflammatory back pain was not confirmed, although the overall rate of responders was similar to previously reported rates. On the other hand, better responses were found in patients treated in the early (nr-axSpA) stage and in male patients. axSpA patients with increased CRP values showed lower rates of response.

Spondyloarthritis - clinical aspects (other than treatment)

POS0955

PATIENTS' PERSPECTIVES ON DISEASE- AND TREATMENT-RELATED ISSUES ARE ESSENTIAL FOR TREATMENT SUCCESS IN PATIENTS WITH SPONDYLOARTHRITIS AND ASSOCIATED DISEASES: A QUALITATIVE CLINICAL CONCEPT MAPPING STUDY

Z. R. Stisen[1], M. Skougaard[1,2], R. L. Hansen[1], K. R. Christensen[3], L. E. Kristensen[1], T. S. Jørgensen[1]. [1]*The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark;* [2]*Department of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark;* [3]*Department of Gastroenterology, Herlev and Gentofte Hospital, Copenhagen, Denmark*

Background: Each patient's way of living with and relating to their chronic disease is unique. However, patients with chronic diseases may have some mutual concerns and challenges. They must not only handle the disease itself, but also the consequences that the disease has for their everyday and emotional lives[1]. Exploring the patient's perspectives for significant factors of relevance for patients living with a chronic disease is important in order to discover unmet needs and challenges for complying with a comprehensive lifelong treatment strategy and ensuring high-quality lives. Increasing awareness about the possible discrepancy between doctor experienced quality in care and patient experienced quality in care is of high relevance when aiming to ensure optimal disease management.
Objectives: The objective of this study was to explore disease- and treatment-related issues and concerns experienced by adult patients with spondyloarhtritis (SpA) and associated diseases; psoriatic arthritis (PsA), psoriasis (PsO), axial spondyloarthritis (axSpA), and inflammatory bowel disease (IBD; Crohn's disease (CD) and ulcerative colitis (UC)), and whether these factors were generic or disease dependent.
Methods: Concept Mapping were used to identify and organize disease- and treatment-related issues and concerns[2]. Concept Mapping is a formal group process with a structured approach to identify ideas on a topic of interest and organize them into cogent domains. Participants were asked to respond to an initial task: 'Thinking as broadly as you can, please list your thoughts (issues and concerns) related to your disease", PsA, PsO, axSpA, CD or UC, respectively. Data were obtained through a nominal group technique and then organized using participants' themes, multidimensional scaling, cluster analysis, participant validation, and thematic analyses to generate a conceptual model of disease- and treatment related issues and concerns experienced by patients with PsA, PsO, axSpA, CD, and UC.
Results: Seven AxSpA patients, 8 PsA patients, 9 PsO patients, 13 CD patients, and 13 UC patients contributed to generating the conceptual models. Seven AxSpA clusters, 7 PsA clusters, 7 PsO clusters, 10 CD clusters, and 11 UC clusters with each cluster having sub-clusters, emerged from the workshops producing 137 AxSpA statements, 160 PsA statements, 187 PsO statements, 335 CD statements, and 408 UC statements. Some clusters were generic: 'Concerns about the disease and the future', 'Consequences of the disease', 'Acceptance of the disease', 'Medication and treatment', and 'At the doctor' (Figure 1). Specific clusters were: for AxSpA: 'Use of public services, for PsA: 'Difficult to have an invisible disease', for PsO: 'Ashamed (about appearance)', for CD: 'Speculations and thoughts; life now and in the future - can I expect more surgeries in the future?', and for UC: 'The influence and importance of the diet' and (Figure 1).

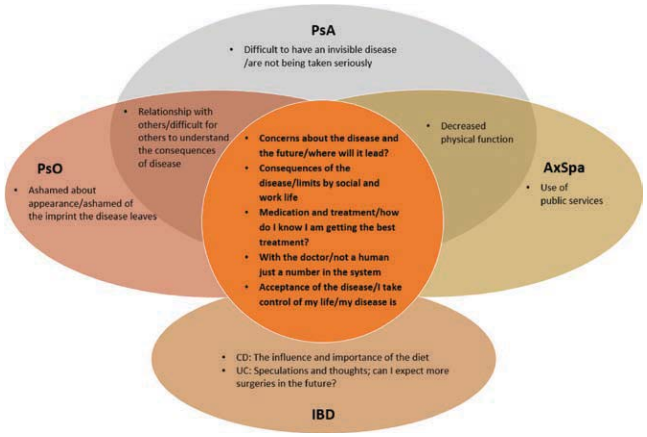

Figure 1.

Conclusion: Patients with SpA and associated diseases largely agree on which concepts describe their disease- and treatment-related issues and concerns with a few of them being disease-dependent.
Living a good life with a chronic disease is much more than having clinical control of the disease. This study gives insight to patients' perspectives on themes that are essential when living with a chronic disease. Considering the patients' perspectives, it is necessary to promote patient empowerment and adherence to treatment, and thereby optimize disease management and quality of life.

POS0956

HIGH INFLAMMATORY BURDEN PREDICTS CARDIOVASCULAR EVENTS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A LONG-TERM FOLLOW-UP STUDY

J. L. H. Shi[1], S. H. M. Lam[1], H. So[1], E. LI[1], T. K. LI[1], C. C. Szeto[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China*

Background: Axial spondyloarthritis (axSpA) patients had a higher risk of cardiovascular disease (CVD) than the general population (1). It is also suggested that inflammation, rather than a particular disease, drives the increased risk of CVD (2). But the relationship between inflammation in axSpA and CVD is unknown.
Objectives: To examine whether inflammatory burden over time can predict cardiovascular events (CVE) independent of baseline CV risk factors in axial spondyloarthritis (axSpA) patients.
Methods: A cohort analysis was performed in patients who had been recruited since January 2001. The primary outcome was a first CVE occurring between January 2001 and December 2020. Three CVD risk scores were computed at baseline. The performance of the original and modified (x 1.5 multiplication factor) CV risk algorithms were assessed. Time-varying Cox proportional hazard models and Kaplan-Meier survival analysis were used to assess whether inflammatory burden (Bath ankylosing spondylitis disease activity index [BASDAI] and inflammatory markers), non-steroidal anti-inflammatory drugs (NSAIDs) and disease modifying anti-rheumatic drugs (DMARDs) can predict the development of first CVE.
Results: 463 patients [35(26-45) years, male: 360(77.8%)] were recruited. After a median follow up of 12 (7-19) years, 61 patients (13.2%) experienced a first CVE. Traditional/modified CV risk scores underestimated CV risk. Erythrocyte sedimentation rate (ESR)≥20 mm/hr was associated with a significantly higher risk of CVE during follow-up [HR: 2.07, 95%CI (1.10, 3.98), p=0.008]. Active disease as indicated by a rising BASDAI also showed positive trend towards a higher risk of developing CVE over time. After adjusting for CV risk scores in the multivariable models, high ESR level (ESR≥20 mm/hr) over time remained significantly associated with a higher risk of developing CV events (Table 1a and 1b). A significant difference in the CV event-free survival between patients with ESR≥20 mm/hr and ESR<20 mm/hr was demonstrated in Figure 1.

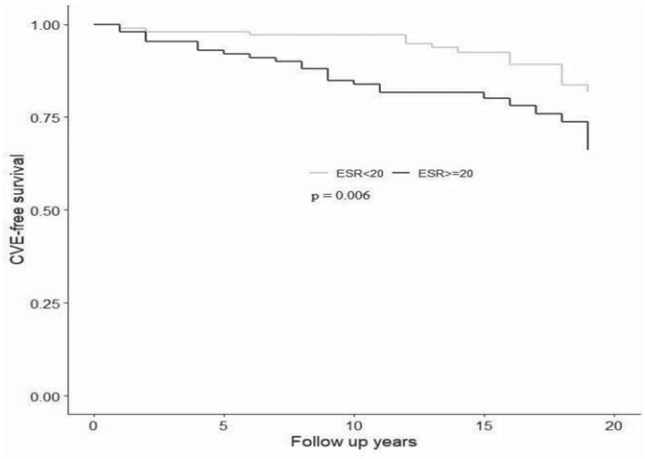

Figure 1. Kaplan-Meier survival analysis between time-varying ESR level and CVE. P=0.006 for difference in CVE-free survival rate between patients with ESR≥20mm/hr and ESR<20mm/hr during their follow-up intervals. ESR: Erythrocyte Sedimentation Rate.

POS0957 EXTERNAL VALIDATION OF THE ALTERNATIVE ANKYLOSING SPONDYLITIS DISEASE ACTIVITY SCORE IN THREE PHASE-3 RCTS

A. Ortolan[1,2], S. Ramiro[1,3], D. Van der Heijde[1]. *[1]Leiden University Medical Center, Leiden,The Netherlands, Department of Rheumatology, Leiden, Netherlands; [2]University of Padova, Rheumatology Unit, Department of Medicine DIMED, Padova, Italy; [3]Zuyderland Medical Centre Heerlen, Department of Rheumatology,, Herleen, Netherlands*

Background: In axial spondyloarthritis (axSpA), an alternative ASDAS (altASDAS) was developed to be used when Patient Global Assessment (PGA) is unavailable. AltASDAS replaces PGA with BASDAI total score and has so far only been internally validated [1].

Objectives: To test the psychometric properties of altASDAS in an external cohort, according to the OMERACT filter 2.0 (truth, discrimination; feasibility was evaluated in our previous work).

Methods: Cohorts from the COAST trial programme of ixekizumab (COAST-V,-W,-X;primary endpoint: 16-week), enrolling radiographic/non-radiographic axSpA (r-/nr-axSpA) patients, were pooled. AltASDAS was calculated for all evaluations. ***Truth*** was assessed by: 1) agreement with original-ASDAS, as a continuous score and as a categorical variable (disease activity-DA-states), with intraclass correlation coefficients (ICC) and weighted Kappa respectively; 2) Bland & Altman plots with mean difference (MD) and 95% limits of agreement (LoA) 3) comparison of Pearson correlations of altASDAS and original-ASDAS with other constructs. ***Discrimination*** was tested by 1) the ability of altASDAS to distinguish high/low DA states according to an external anchor (nocturnal pain>6 indicating high DA) 2) agreement (kappa) with original-ASDAS in major/clinically important-improvement (MI/CII) achievement at 16-weeks 3) comparison of number of patients reaching MI/CII in the treatment versus placebo arm at 16-weeks, according to original and altASDAS (higher Chi-square=better discrimination).

Results: 958 patients were included, 70% males, mean age 42.7 years, 68% r-axSpA. ***Truth:*** 1) agreement with original-ASDAS: ICC=0.97 (95%CI:0.93-0.99), kappa=0.84 (0.83-0.85) 2) MD with original-ASDAS: 0.14; 95% LoA -0.56 to 0.28 3) correlation coefficients of altASDAS with related constructs were within a pre-specified 0.3-wide band around those between original-ASDAS and the same construct (Table 1 *a*). ***Discrimination*** altASDAS discriminated between DA states (Table 1 *b*) and in sensitivity to change (Kappa with original-ASDAS for MI=0.87 95%CI:0.83-0.91; for CII=0.93; 95%CI:0.90-0.95) and Table 1 *e c*

Table 1. Psychometric properties of alternative Ankylosing Spondylitis Disease Activity Score (altASDAS)

a) Truth: correlations with constructs related to disease activity

Data expressed as correlation coefficient r

	Function (BASFI)	Quality of Life (MCS)	Quality of life (PCS)	Overall functioning and health (ASAS HI)
Original-ASDAS	0.58	-0.11	-0.48	0.35
altASDAS	0.57	-0.11	-0.47	0.35
b) Discrimination: disease activity states				
Anchor to define disease activity: Nocturnal pain (NRS 0-10)	**NRS >6 Mean ASDAS (SD)**	**NRS ≤ 6 Mean ASDAS (SD)**		**SMD**
Original-ASDAS	3.99 (0.76)	2.61 (0.86)		-1.68
altASDAS	3.87 (0.83)	2.46 (0.96)		-1.57
c) Discrimination: sensitivity to change				
	Treatment N (%)	**Placebo N (%)**		**Chi-square**
N° of patients	628	272		-
Original-ASDAS MI	151 (24)	12 (4)		49.3
altASDAS-MI	167 (26)	13 (5)		56.4
Original-ASDAS CII	342 (54)	62 (23)		76.9
altASDAS-CII	350 (56)	64 (23)		79.2

BASFI: Bath Ankylosing Spondylitis Functional Index, MCS and PCS: mental and physical component summary of Short-Form 36; ASAS HI: ASAS Health Index; NRS: Numerical rating scale; SD: standard deviation; SMD: standardised mean differences; MI and CII: Major and Clinically Important Improvement

Conclusion: AltASDAS was shown to be truthful and discriminative in an external cohort and as such has been fully validated and can be used in cases when PGA is unavailable.

PROGRESSIVE IMPROVEMENT IN TIME TO DIAGNOSIS IN AXIAL SPONDYLOARTHRITIS THROUGH AN INTEGRATED REFERRAL AND EDUCATION SYSTEM

A. Chan[1], K. Rigler[1], N. Ahmad2, T. Lafont2. *[1]Royal Berkshire Hospital, Department of Rheumatology, Reading, United Kingdom; [1]Royal Berkshire Hospital, Department of Rheumatology, Reading, United Kingdom*

Background: Despite the advances in the treatment and management of axial spondyloarthritis (axSpA), there remains a significant delay in the diagnosis of the condition. The diagnostic delay is 8-10 years in Europe and 8.5 years on average in the United Kingdom. This is contributed by the lack of awareness of axSpA, limited access to diagnostic tests and unstructured referral pathways. The delayed diagnosis leads to higher morbidity from the condition.

Objectives: To assess the delay in the diagnosis of axSpA over time in a real world axSpA cohort diagnosed over a 7 year period from 2015 and to evaluate factors associated with this delay. During this time, we evaluated the effectiveness of the interventions to reduce the delay to diagnosis.

Methods: A cohort of axSpA patients newly diagnosed between 2015 to 2021, were studied. This was a cross-sectional study on patients with axSpA who visited a specialist rheumatology clinic at a single centre. The demographic, clinical and diagnostic variables were recorded. Diagnostic delay was defined as the time interval between the year of first symptom and year of diagnosis. The mean and median diagnostic delay were calculated. An integrated educational and referral system were implemented from 2015[1]. This included education to the main referrers in to the system including general practitioners (GPs) and community musculoskeletal (MSK) triage physiotherapists. The electronic referral systems were updated annually according to best practice guidelines[2]. An impact analysis was performed evaluating diagnostic delay for axSpA during this period.

Results: Of the 110 axSpA patients studied, 60 (54.4%) were male and 50 (45.5%) female. The mean (range) age was 37 (18-52) years. All patients met the ASAS classification criteria for axSpA. Radiographic axSpA (Ankylosing spondylitis) fulfilling New York criteria, was diagnosed in (62%) of the patients. There were more patients with radiographic axSpA in the earlier years of diagnosis (100% in 2015) and more of non-radiographic axSpA in the later years (83% in 2021). HLA-B*27 positivity was found in 79 (71.8%) of patients. The majority of referrals were from general practitioners 63 (57.2%), physiotherapists 19 (17.3%), orthopaedics 18 (16.4%) and other specialties 10 (9.1%). There was no significant difference in the mean (years) delay to diagnosis from the source of the clinic referral. The mean and median delay to diagnosis by year of diagnosis were 9.9, 9.5 (±3.1) years in 2015, 7.1, 7(±1) in 2016, 5.3,5 (±2.7) in 2017, 4.9, 4 (±3) in 2018, 4.4, 2.5 (±4.8) in 2019, 3.6, 2 (±3.2) in 2020, 2.2, 1 (±2.6) in 2021. The majority of the patients were diagnosed between 31-40 years (41%), 22% between 18-30 years, 31% between 41-50 years and 4% after the age of 50 years. Higher age at diagnosis was associated with a longer diagnostic delay. Diagnosis of disease at 18-30 years of age was associated with shorter mean delay to diagnosis (2.9 years), age 31-40 (4.6), age 41-50 (5.9), and age > 51 (6.5).

Conclusion: Delay in axSpA diagnosis has significantly improved in this real-world cohort during the last seven years. The mean diagnostic delay was 2 years indicating diagnostic delay may be for most patients shorter than previously reported. The factors associated with a faster diagnosis were a) more recent year of first rheumatology consult b) earlier age at presentation. Increased educational and awareness campaigns in primary care and musculoskeletal triage has led to the early recognition of axSpA. Early referral to a rheumatology service using electronic referral symptom can improve the diagnostic delay of axSpA. With continuous improvement cycles, our aim is to get reduce delays to diagnosis to under 1 year with line with the Gold Standard to Diagnosis in axSpA.

RISK FACTORS FOR NON-VERTEBRAL FRACTURES IN ANKYLOSING SPONDYLITIS

K. Bengtsson[1,2], J. Askling[3], M. Lorentzon[4,5,6], B. Rosengren[7], A. Deminger[1,2], E. Klingberg[1,2], L. T. H. Jacobsson[1], H. Forsblad-D'elia[1,2]. *[1]Institute of Medicine at Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Göteborg, Sweden; [2]Region Västra Götaland, Department of Rheumatology, Sahlgrenska University Hospital, Göteborg, Sweden; [3]Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; [4]Institute of Medicine at Sahlgrenska Academy, University of Gothenburg, Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Göteborg, Sweden; [5]Region Västra Götaland, Department of Geriatric Medicine, Sahlgrenska University Hospital, Mölndal, Sweden; [6]Australian Catholic University, Mary MacKillop Institute for Health Research, Melbourne, Australia; [7]Lund University and Skane University Hospital, Clinical and Molecular Osteoporosis Research Unit, Departments of Orthopedics and Clinical Sciences, Malmö, Sweden*

Background: Osteoporosis is common in patients with ankylosing spondylitis (AS) and a risk factor for fragility fractures. Additional established risk factors for fractures in the general population include higher age, female sex, previous fracture, fall tendency, glucocorticoid treatment, insulin dependent diabetes, smoking and high alcohol consumption.

Objectives: To estimate the influence of established risk factors for fragility fractures on the development of non-vertebral fractures in AS and population controls.

Methods: Through linkage of national population and health care registers 2001-2016, patients with AS (n=11611, 65.5% men, mean age 48 years) and age-, sex- and geography-matched population controls (n=58050) were identified and from 1 January 2007 (or 3 months after the first registered AS diagnosis if this occurred later) followed prospectively until the time of a non-vertebral fracture, death, emigration or end of study (30 December 2016). Occurrence of established risk factors for a fracture and AS related characteristics at start of follow-up were identified in the National Patient and Prescribed Drug Registers using ICD-10 and ATC codes. Smoking status and anthropometric measurements are not available in these registers. Chi-square, Fischer's exact test and T tests were used to compare between subjects with and without a non-vertebral fracture during follow-up, separately for AS and controls. Multivariable Poisson regression

Table 1.

	AS			Controls		
	No fracture (n=10637)	Fracture (n=974)	P-value	No fracture (n=53944)	Fracture (n=4106)	P-value
Male sex	7002 (65.8)	603 (61.9)	0.014	35448 (65.7)	2572 (62.6)	<0.001
Mean age (SD)	47.6 (14.7)	53.8 (14.8)	<0.001	47.8 (14.7)	53.0 (15.0)	<0.001

Use of TNF inhibitor[¤]	1539 (14.5)	109 (11.2)	0.005	43 (0.1)	4 (0.1)	0.573

The data is presented as number (%) if not stated otherwise. *Diagnosed osteoporosis and/or use of osteoporosis medication. [#]Prednisolone equivalent cumulative dose of ≥450 mg within the last year before start of follow-up. [¤]Use within the last year before start of follow-up.

was used to estimate the influence of each established risk factor in AS and controls. Risk factors for which there were ≤20 observed events in the AS cohort were not included. Results are presented as incidence rate ratios (IRR) with 95% confidence intervals.

Results: In total 974 (8.4%) patients with AS and 4106 (7.1%) of their controls were registered with a non-vertebral fracture during the study period. The characteristics of the patients and controls at start of follow-up are presented in Table 1 stratified by fracture status during follow-up. Figure 1 displays the results from the Poisson regression.

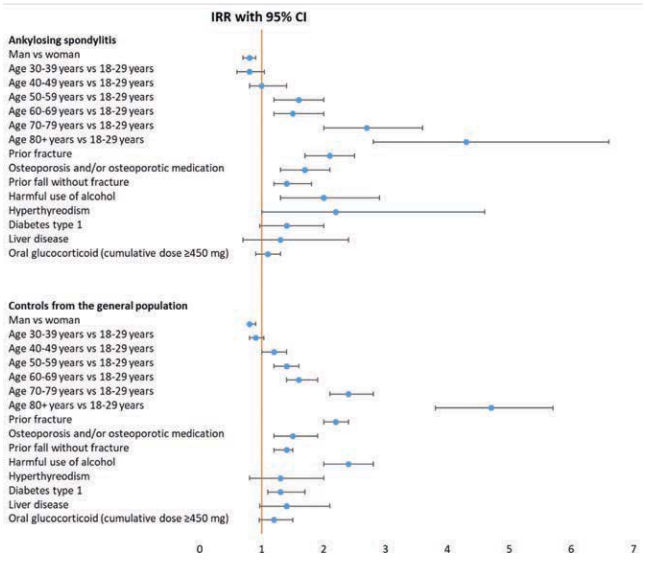

Figure 1. Multivariable Poisson regression analyses for a non-vertebral fracture during follow-up, with results presented for each included baseline variable as IRR with 95% CI, separately for AS and controls.

Conclusion: The influence of established risk factors for fragility fractures in AS is similar to that in the general population; in both populations with advanced age, prior fracture and harmful use of alcohol being the strongest risk factors.

POS0960 INCIDENCE AND RISK OF OVERALL INFECTIONS IN PATIENTS WITH ANKYLOSING SPONDYLITIS RECEIVING BIOLOGIC THERAPIES: A REAL-WORLD PROSPECTIVE OBSERVATIONAL STUDY USING KOBIO REGISTRY

K. M. Ko[1], S. J. Moon[2]. [1]*International St. Mary's Hospital, Catholic Kwandong University, College of Medicine, Rheumatology, Incheon, Korea, Rep. of (South Korea);* [2]*Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Rheumatology, Uijeonbu, Korea, Rep. of (South Korea)*

Background: Infection is a perpetual concern in patients treated with biological therapy. However, long-term real-world data on infectious profile of AS patients are lacking.

Objectives: The aim of this study was to characterize infection events in a longitudinal cohort of patients with ankylosing spondylitis (AS) and to identify the risk factors associated with the development of infections receiving biologics therapies in a real-world setting.

Methods: This was a prospective observational cohort study including AS patients in the KOBIO registry starting a biologics from December 2012 to April 2020. Infections were evaluated by types or organ during the follow-up period. Infection rates (IR) per 1,000 person-years were calculated with 95% CI based on Poisson distribution method. Cox proportional hazard regression models with adjustment of confounding factors was used to estimate hazard ratios (HRs) with 95% CIs for occurrence of infection. Confounders included demographics, comorbidities and disease severity index.

Results: A total of 1610 AS patients were included in the analysis. Most (76.8%) were men and the median age was 37 years with 5.73 median AS duration. 129 infection events occurred during 5020.5 person-years of follow-up. The most frequent infections were upper and lower respiratory tract (39.8%), followed by herpes zoster (23.7%), skin and soft tissue (except herpes infection), gastrointestinal tract, and genitourinary tract. The overall incidence of any infection was 25.7/1000 patient-years (PY) of follow-up (95% confidence interval [CI] 21.5 - 30.5): 29.5/1000 PY (95% CI 20.6 – 41.1) among those treated with infliximab and biosimilar; 26.8/1000 PY (95% CI 20.1 – 34.9) among those treated with adalimumab; 21.5/1000 PY (95% CI 14.1 -31.6) among those treated with golimumab; 17.8/1000 PY (95% CI 9.5 -30.5) among those treated with etanercept and biosimilar.; 81.1/1000 PY (95% CI 2.1 – 451.9) among those treated with secukinumab. Significant univariate risk factors for infection were age, ischemic heart disease, complicated diabetes, solid tumor, abnormal chest x-ray, anemia, and biologics user. In multivariate Cox regression model, ischemic heart disease, very high disease activity (ASDAS-ESR>3.5), complicated diabetes, abnormal chest x-ray and current biologics users remained significant.

Conclusion: In the KOBIO-AS registry, the total incidence rate of infections was 26 events/1000 PY of follow-up, with respiratory infection being the most common, followed by herpes zoster infection. In this large cohort of AS patients, ischemic heart disease, very high disease activity (ASDAS-ESR>3.5), complicated diabetes, abnormal chest x-ray and current biologics user were risk factors for any infection in this large cohort of patients with AS, whereas male gender was protective factor for developing infection.

POS0961 CLINICAL PROFILE AND TREATMENT UTILIZATION IN HLA-B27 POSITIVE VERSUS HLA-B27 NEGATIVE PATIENTS: RESULTS FROM ASAS-PERSPA STUDY

M. Magrey[1], C. López-Medina[2], M. A. Khan[3]. [1]*Case Western Reserve University School of Medicine/ University Hospitals, Medicine, Cleveland, United States of America;* [2]*Cochin Hospital, Rheumatology, Paris, France;* [3]*Professor Emeritus, Case Western Reserve University School of Medicine, Medicine, Cleveland, United States of America*

Background: HLA-B27 is a genetic marker strongly associated with axial spondyloarthritis (axSpA). However, the strength of this association varies worldwide. Although some regional studies have assessed the effect on HLA-B27 status on clinical features of axSpA, no worldwide study has been performed.

Objectives: To characterize differences in the clinical features, extra-articular manifestations, and treatment utilizations in a global axSpA cohort based on their HLA-B27 status.

Methods: We performed a post-hoc analysis of the ASAS-PerSpA study (Peripheral involvement in Spondyloarthritis) dataset that includes patients with axial (axSpA) and peripheral SpA(pSpA), psoriatic arthritis (PsA), juvenile SpA, SpA associated with inflammatory bowel disease (IBD) and reactive arthritis based on their rheumatologist's diagnosis. We identified patients that had been diagnosed with axSpA meeting the 2009 ASAS classification criteria and been typed for HLA-B27. The patient characteristics were compared between the HLA-B27(+) and HLA-B27(–) subgroups using Student's t-test and the Mann-Whitney U test. Multivariable logistic regression with backward stepwise selection was conducted to identify predictors of HLA-B27 positivity. Variables with p-value <0.15 on univariate analysis were included in the multivariable model. All tests were two-tailed with p-value <0.05 considered significant.

Results: A total of 4465 patients with axSpA from 24 countries were identified. We observed that 2910 patients fulfilled the 2009 ASAS classification criteria. Of these patients, 2269 were tested for HLA-B27 (HLA-B27+: 1753 and HLA-B27-: 516). Significant differences were observed between these two groups in age of symptom onset and manifestations of the disease as shown in Table 1. The HLA-B27(-) patients had a significantly later age of symptom onset and disease diagnosis, more often had concomitant IBD, psoriasis, peripheral arthritis, enthesitis and were more often treated with csDMARDS. On multivariable logistic regression factors significantly associated with HLA-B27 positivity included male sex (OR: 1.99), family history of axSpA (OR: 2.26), and occurrence of anterior uveitis (OR: 2.72).

Conclusion: In a large heterogeneous cohort of AxSpA patients from 24 countries, we found that male sex, family history, and occurrence of anterior uveitis are significant predictors of HLA-B27 positivity. In contrast, the HLA-B27(-) have a significantly later age of onset and longer delay in diagnosis, more often have concomitant IBD, psoriasis, peripheral arthritis and enthesitis, and also more often receive treatment with csDMARDs.

CAN RADIOMICS REPLACE SPARCC SCORING SYSTEM IN EVALUATING BONE MARROW OEDEMA OF THE SACROILIAC JOINTS IN AXIAL SPONDYLOARTHRITIS?

M. Zheng[1], S. Miao[1], D. Chen[2], F. Yao[1], Q. Xiao[1], G. Zhu[1], C. Pan[3], T. Lei[3], C. Ye[3], Y. Yang[4], L. Ye[2]. *[1]The First Affiliated Hospital of Wenzhou Medical University, Department of Radiology, Wenzhou, Zhejiang, China; [2]The First Affiliated Hospital of Wenzhou Medical University, Department of Rheumatology, Wenzhou, Zhejiang, China; [3]Wenzhou Medical University,The First School of Medicine, Wenzhou, Zhejiang, China; [4]The First Affiliated Hospital of Wenzhou Medical University, Department of Nuclear Medicine, Wenzhou, Zhejiang, China*

Background: Bone marrow oedema (BMO) of the sacroiliac joints (SIJs) is evaluated to diagnose, classify and monitor disease activity in patients with axial spondyloarthritis (axSpA). Available quantitative methodologies rely on human visual assessment, and errors can't be completely avoided. Radiomics can extract and select discriminative and quantified features from regions of interest (ROIs), making a more accurate and objective description of BMO.
Objectives: To develop a more objective and efficient method based on radiomics to evaluate BMO of the SIJs by magnetic resonance imaging (MRI) in patients with axSpA in comparison with Spondyloarthritis Research Consortium of Canada (SPARCC) scoring system.
Methods: From September 2013 to July 2021, 523 patients with axSpA underwent 3.0T SIJ-MRI were included, who were randomly classified as training cohort(n=367) and validation cohort(n=156). The optimal radiomics features, selected from the 3.0T SIJ-MRI in the training cohort, were included to build the radiomics model. Four clinical risk predictors were adopted to build the clinical model. The performance of the clinical and radiomics models was evaluated by ROC analysis and decision curve analysis (DCA). Rad-scores were calculated by the radiomics model and SPARCC scores were performed to quantify the BMO of SIJs. We also assessed the correlation between Rad-score and SPARCC score.
Results: The radiomics model, built by 15 optimal features, showed favorable discrimination about SPARCC score <2 or ≥2 both in the training (AUC, 0.91; 95% CI: 0.88-0.94) and the validation cohort (AUC, 0.89; 95% CI, 0.84-0.94). DCA confirmed that the radiomics model was clinically useful. Furthermore, Rad-score has significant correlation with SPARCC score for scoring the status of BMO (r_s=0.78, P< 0.001), and moderation correlation for scoring the change (r=0.40, P=0.005).
Conclusion: The radiomics can accurately assess the BMO of the SIJs in axSpA, providing an alternative to SPARCC scoring system. There was a positive correlation between Rad-score and SPARCC score.

HOW IS EARLY SPONDYLOARTHRITIS DEFINED IN THE LITERATURE? RESULTS FROM A SYSTEMATIC REVIEW

D. Benavent[1], D. Capelusnik[2], D. Van der Heijde[3], R. B. M. Landewé[4,5], D. Poddubnyy[6], A. Van Tubergen[7], L. Falzon[8], S. Ramiro[3,5], V. Navarro-Compán[1]. *[1]Hospital Universitario La Paz, IdiPaz, Department of Rheumatology, Madrid, Spain; [2]Instituto de Rehabilitación Psicofísica (IREP), Department of Rheumatology, Buenos Aires, Argentina; [3]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [4]Amsterdam University Medical Center, Department of Clinical Immunology and Rheumatology, Amsterdam, Netherlands; [5]Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands; [6]Charité Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany; [7]Maastricht University Medical Center and School for Public Health and Primary Care (CAPHRI), Maastricht University, Department of Medicine, Division of Rheumatology, Maastricht, Netherlands; [8]University of Sheffield, School of Health and Related Research, Sheffield, United Kingdom*

Background: The term "early spondyloarthritis (SpA)" has been frequently used to refer to the first phase of the disease, however, no standardized definition on "early" has been established. The ASAS-SPEAR (SPondyloarthritis EARly definition) project aims at developing a consensual definition on what is meant by "early SpA". In order to inform the ASAS-SPEAR working group, it is highly relevant to assess the current meaning of "early SpA" in the literature.
Objectives: To identify all possible definitions of "early SpA" employed in the literature, including "early axial SpA (axSpA)" and "early peripheral SpA (pSpA)".
Methods: A systematic literature review was conducted in Medline, EMBASE and the Cochrane Library (through April 28th, 2021). The eligibility criteria were studies with any design, in adults that included any mention of "early SpA" or its subtypes in the title or abstract. Two reviewers independently identified eligible studies and extracted data, including the literal definition of early SpA used in each of them. The proportion of studies reporting a definition was calculated, and the different definitions were assessed, including the core of the definition: whether they were based on symptom duration, disease duration, radiographic damage, a combination of them or any other aspects, and their boundaries.
Results: Out of 9,651 titles identified, 355 publications reporting data from 186 studies were included (291 full papers, 64 conference abstracts). Among them, 217 (61%) were cohort studies, 72 (20%) were reviews and 46 (13%) were

clinical trials. Over time, an increasing number of publications on early SpA were identified: <2005 (n=34), 2005-2010 (n=48), 2011-2015 (n=109) and 2016-2020 (n=164). Overall, 63 studies (34%) included the term "early axSpA", 60 (32%) "early ankylosing spondylitis (AS)", 58 (31%) "early SpA", 4 (2%) "early non-radiographic axSpA (nr-axSpA)" and 1 (1%) "early pSpA". In total, 116 (62%) studies reported a specific definition: 40 (34%) based it on symptom duration, 35 (30%) on radiographic damage, 32 (28%) on disease duration, 6 (5%) on both symptom/disease duration and radiographic damage, and 3 (3%) on other aspects. Symptom duration was defined as the time since the onset of low back pain in 21/40 (53%) studies, whereas in 14/40 (35%) the symptom of onset was not specified. Thirty-five of 116 studies (30%) included a definition referred to "early SpA", 38 (33%) to "early axSpA", 38 (33%) to "early AS", 4 (3%) to "early nr-axSpA", and 1 (1%) to "early pSpA". Figure 1 shows the 18 distinct definitions that were identified (after combining some similar categories). The three most used definitions per subtype of disease are shown in Table 1. Regarding the studies that referred to "early axSpA", the most used definition was symptom/disease duration <5 years, whereas for "early AS" was symptom/disease duration <10 years. After 2010, the definition of "early axSpA" based on the absence of radiographic sacroiliitis was less used compared to before 2010 (5/30, 17% vs 3/8, 38%).

Table 1. Top 3 candidate definitions for "early SpA" and subtypes

	Core of the definition	Number of studies, n (%)
SpA (n= 35)	nr-axSpA	10 (29%)
	< 2 years duration	10 (29%)
	< 1 year duration	6 (17%)
AxSpA (n=38)	< 5 years duration	12 (34%)
	< 3 years duration	9 (24%)
	nr-axSpA duration	8 (21%)
AS/r-axSpA (n=38)	<10 years duration	9 (24%)
	nr-axSpA	7 (18%)
	< 2 years duration	6 (16%)
nr-axSpA (n=4)	nr-axSpA	2 (50%)
	< 1 year & nr-axSpA	1 (25%)
	< 5 years & nr-axSpA	1 (25%)
pSpA (n=1)	< 12 weeks duration	1 (100%)

"Duration" refers to symptom duration or disease duration.

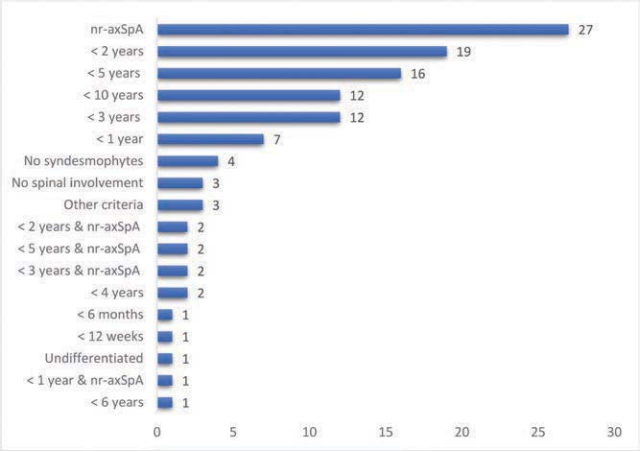

Figure 1. Number of studies stratified by the core of the definition.

Conclusion: Over time, the term "early SpA" and its subtypes are increasingly used. Despite addressing early SpA, more than one third of the studies did not include a clear definition of the term. The studies reporting a definition of early SpA showed a large heterogeneity, with two out of three of them based on the duration of symptoms or disease. These results emphasize the need for a standardised definition of early SpA.

POS0964

IS LOW VERTEBRAL BONE DENSITY ASSOCIATED WITH SUBSEQUENT BONE FORMATION AT THE SAME VERTEBRA IN AXIAL SPONDYLOARTHRITIS? – A MULTILEVEL ANALYSIS FROM THE SIAS COHORT

M. L. Marques[1,2], N. Pereira Da Silva[3], D. Van der Heijde[1], R. Stal[1], X. Baraliakos[4], J. Braun[4], M. Reijnierse[5], C. Bastiaenen[6], F. A. Van Gaalen[1], S. Ramiro[1,7]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; [3]Centro Hospitalar e Universitário de Coimbra, Radiology, Coimbra, Portugal; [4]Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet, Bochum, Germany; [5]Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands; [6]Maastricht University, Epidemiology, Maastricht, Netherlands; [7]Zuyderland MC, Rheumatology, Heerlen, Netherlands*

Background: In radiographic axial spondyloarthritis (r-axSpA) it has been hypothesized that inflammation-driven bone loss triggers bone repair at anatomically distinct sites of the same vertebra: bone loss occurring in the trabecular bone and ectopic bone formation in the periosteum[1].

Objectives: To investigate whether inflammation is associated with lower bone density (surrogate of bone loss) and subsequently, if lower bone density is associated with 2-year bone formation in r-axSpA at the same vertebra.

Methods: Data from the Sensitive Imaging in Ankylosing Spondylitis (SIAS), a multicentre 2-year cohort, was used. Baseline vertebral bone density was assessed by Hounsfield Units (HU) on low dose Computed Tomography (ldCT) by two independent readers (Figure 1). Baseline magnetic resonance imaging (MRI) bone marrow edema (BME) status scores, and 2-year ldCT syndesmophyte formation or growth change scores were assessed by three and two readers respectively. Inter-reader reliability was assessed for each imaging scoring by vertebra. Average of readers´ continuous scores (bone density HU) or readers´ agreement in binary scores (MRI-BME and bone formation) were used at the same vertebra (1-present in ≥1 quadrant/0-absent in all quadrants). The hypothesised associations were tested in multilevel generalised estimating equations models adjusted for confounders, the unit of analysis being the vertebra.

Results: We analysed 1,100 vertebrae in 50 patients with r-axSpA. Intraclass correlation coefficients for HU measurements varied from 0.89 to 0.97, Fleiss Kappa values for MRI-BME were between 0.41-0.78 and Cohen´s kappa for syndesmophyte formation/growth change scores varied from 0.36 to 0.74. Bone density HU decreased from cranial to caudal vertebrae. Baseline MRI-BME was present in 300/985 (30%) and syndesmophytes in 588/910 (65%) vertebrae, both most prevalent at the thoracolumbar region. Syndesmophyte formation or growth was observed in 18% of at-risk vertebrae (124/691). A significant association was found between inflammation (MRI-BME) and lower bone density (regression coefficient=-51; 95% CI:-63;-39) (Table 1***A***). Bone density was not associated with 2-year syndesmophyte formation or growth (adjOR 1.00; 95% CI:0.99;1.00) (Table 1***B***).

Table 1. Relationships between (A) baseline MRI detected spinal inflammation (MRI-BME) and bone density, and (B) baseline bone density and ldCT bone formation after two years, at the same vertebra.

A.	**Independent variables**	**Bone density (Hounsfield Units)**	
		Univariable analysis Reg coeff. (95% CI) N = 910 to 985	Multivariable analysis Adj Reg coeff. (95% CI) N = 985
	MRI-BME (presence)	**-51 (-63 to -39)**	**-51 (-63 to -39)**
	Age (years)	-1 (-2 to 1)	-1 (-2 to 1)
	Gender (male)	21 (-20 to 63)	16 (-24 to 57)
	TNFi treatment (yes)	26 (-7 to 59)	27 (-6 to 61)
	Baseline syndesmophytes (presence)*	**-42 (-54 to -30)**	-
B.	**Independent variables**	**Syndesmophyte formation or growth§**	
		Univariable analysis OR (95% CI) N = 672 to 691	Multivariable analysis AdjOR (95% CI) N = 672
	Bone density (HU)	1.00 (0.99 to 1.00)	1.00 (0.99 to 1.00)
	Age (years)	1.02 (0.99 to 1.06)	1.02 (0.98 to 1.05)
	Gender (male)	0.44 (0.13 to 1.52)	0.56 (0.15 to 2.06)
	Smoking (current)	0.89 (0.40 to 1.97)	1.02 (0.42 to 2.44)
	Treatment with TNFi (yes)	1.34 (0.56 to 3.21)	1.30 (0.43 to 3.90)
	MRI-BME (presence)	**2.03 (1.23 to 3.71)**	**1.73 (1.06 to 3.34)**
	Baseline syndesmophytes (presence)*	**2.84 (1.83 to 4.41)**	-

*Multicollinearity with MRI-BME. § Absolute agreement of readers. **adjOR -** adjusted odds ratio; **CI-**confidence interval; **BME -** bone marrow edema; **HU -** Hounsfield units; **ldCT -** low dose computed tomography; **MRI -** magnetic resonance imaging; **TNFi –** Tumour necrosis factor inhibitors. Statistical significance highlighted in bold.

Conclusion: While in r-axSpA vertebral inflammation associates with low vertebral bone density, lower vertebral bone density itself does not increase the risk for ectopic bone formation at the same vertebra.

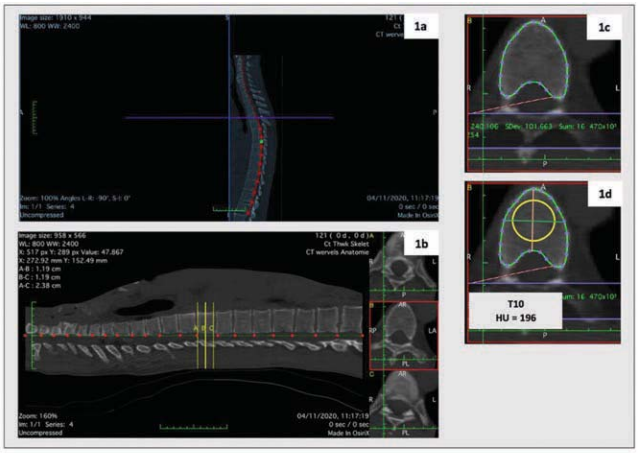

Figure 1. **Methodology of Hounsfield Units (HU) measurement.** Using a three-dimensional curved-multiplanar reconstruction the curve of the spine was identified from the spinal canal (**1a**). On the obtained sagittal image, the vertebrae could be identified. At each vertebra, two lines of reference were positioned at the superior (yellow line A) and inferior (yellow line C) limits of the vertebra. Equidistant to A and C, the yellow line B was positioned at the center of the vertebral body (**1b**). In the reconstructed cross-sectional slice, the vertebral body was delimited (**1c**). A centered region of interest (ROI) was manually selected, having a diameter equal to 75% of the average of anteroposterior and transverse diameters, and the density of the vertebra was calculated as the average image density within the sample region, reported in HU. (**1d**).

MAGNETIC RESONANCE ENTEROGRAPHY AS A SCREENING TOOL FOR AXIAL SPONDYLOARTHRITIS IN CROHN'S DISEASE: A PROSPECTIVE SINGLE-CENTER CROSS-SECTIONAL OBSERVATIONAL STUDY USING MRE SCREENING FOLLOWED BY CLINICAL ASSESSMENT (PROSPA-CD)

J. Evans[1,2], T. Raine[3], S. Mcdonald[4], K. Poole[1,5], R. Samworth[6], P. Riede[4], E. Rees[7], S. D'amore[1], M. Parkes[3,8], D. Jadon[1,5]. *[1]Addenbrooke's Hospital, Rheumatology, Cambridge, United Kingdom; [2]University of Cambridge School of Clinical Medicine., School of Clinical Medicine, Cambridge, United Kingdom; [3]Addenbrooke's Hospital, Gastroenterology, Cambridge, United Kingdom; [4]Addenbrooke's Hospital, Radiology, Cambridge, United Kingdom; [5]University of Cambridge School of Clinical Medicine., Clinical Medicine, Cambridge, United Kingdom; [6]University of Cambridge, Department of Pure Maths and Mathematical Statistics, Cambridge, United Kingdom; [7]West Suffolk Hospital, Radiology, Bury St Edmunds, United Kingdom; [8]University of Cambridge School of Clinical Medicine., Gastroenterology, Cambridge, United Kingdom*

Background: Patients with inflammatory bowel disease (IBD) have an excess burden of axial spondyloarthritis (axSpA) (1), but currently there are no reliable screening tools available. Magnetic resonance enterography (MRE) is an oral contrast MRI of the small bowel used to aid the diagnosis of Crohn's disease (CD) (2). MRE also captures the sacroiliac joints (SIJs) but the radiological assessment of this is often overlooked. MRE scans therefore contain potentially valuable unreported data, which could be used to screen for axSpA in CD patients.

Objectives: To determine: (i) the validity, sensitivity, specificity and area under the receiver operating characteristic (ROC) curve (AUC) of MRE as a screening tool for axSpA in CD, using dedicated axial MRI scans with clinical assessment as the gold standard; (ii) the proportion of patients with evidence of axSpA on MRE who fulfill the 2009 Assessment of Spondyloarthritis International Society (ASAS) criteria for axSpA; (iii) whether the presence of extra-intestinal manifestations (EIMs) or CD location can predict the occurrence of axSpA in CD.

Methods: ProSpA-CD was a pair of linked prospective observational studies conducted at a large secondary care university hospital in the UK. In ProSpA-CD-Screen, patients who had undergone MRE between 2015-2019 were assessed for eligibility. The consenting participants' MRE images were evaluated by a rheumatologist and a radiologist, using a scoring system for evidence of axSpA. Participants with evidence of axSpA and a control group of participants without evidence of axSpA were invited to participate in ProSpA-CD-Assess, in which the performance of MRE as a screening test was assessed against a gold standard of clinical assessment, serological testing and dedicated MRI of the spine and pelvis of each participant. ROC curve and logistic regression analyses were performed.

Results: A total of 1344 MRE scans were performed between 2015-2019, of which 501 eligible patients were identified. For ProSpA-CD-Screen, 259 participants were recruited. MRE SIJ abnormalities were identified in 94/259 participants and from these, 90 cases were recruited to ProSpA-CD-Assess. For the control group, 71/165 participants with normal SIJs were recruited to ProSpA-CD-Assess (total cases + controls = 161). A clinical diagnosis of axSpA was made in 41/161 (25.47%) participants, of which 25/161 (15.53%) fulfilled ASAS criteria. We constructed a ROC curve to assess test performance using different thresholds on the MRE scoring system. The optimum threshold corresponded to a sensitivity of 0.60 (95%CI 0.39, 0.79) and specificity of 0.85 (95%CI 0.78, 0.91) for MRE as a screening tool for axSpA (ASAS criteria) with an AUC value of 0.78 (95%CI 0.65, 0.86, p<0.05). We did not find a significant association between axSpA and CD location. Multivariable logistic regression demonstrated significant associations between axSpA (ASAS criteria) and inflammatory back pain (OR 11.03; 95%CI 2.53, 48.10; p<0.05), *HLA B27* (OR 9.94; 95%CI 1.84, 53.87; p<0.05), history of dactylitis (OR 51.01; 95%CI 1.07, 2423.90; p<0.05) and plantar fasciitis (OR 9.08; 95%CI 1.30, 63.55; p<0.05).

Conclusion: We have shown that MRE as a screening tool for axSpA in a cohort of CD patients has good specificity, but poor sensitivity, suggesting that its use as a screening tool is limited. There was no significant association between axSpA and CD location or CD EIMs.

POS0966 DEVELOPMENT AND VALIDATION OF AN ANKYLOSING SPONDYLITIS RISK PREDICTION MODEL USING LONGITUDINAL REAL-WORLD DATA FROM A LARGE INTEGRATED HEALTHCARE DELIVERY SYSTEM

A. Kawatkar[1], E. Yi[2], E. Estrada[1], J. Pio[1], C. Portugal[1], D. Yi[1], T. Habeshian[1], D. Wei[3], S. Lee[4]. *[1]Kaiser Permanente Southern California, Kaiser Permanente Research & Evaluation, Pasadena, United States of America; [2]Novartis Pharmaceuticals Corporation, Global Medical Affairs, East Hanover, United States of America; [3]Novartis Pharmaceuticals Corporation, US HEOR, East Hanover, United States of America; [4]Southern California Permanente Medical Group, Department of Rheumatology, Fontana, United States of America*

Background: Early detection and diagnosis of Ankylosing spondylitis (AS) is challenging due to heterogeneity in disease presentation, lack of specific biomarkers and high prevalence of mechanical back-pain that is difficult to distinguish from inflammatory back-pain. However, if diagnosed and treated early, the risk of AS complications and disease progression can be slowed.
Objectives: To develop and validate a risk prediction model for early identification of patients at high risk of AS, using a large longitudinal real-world clinical data in the US.
Methods: This retrospective study included all members aged ≥ 21 years with back pain symptoms who were enrolled in the Kaiser Permanente Southern California health plan between 01/2009-12/2013. Patients who presented with back pain symptoms at a physician visit were followed until 12/2020 to see if they subsequently developed AS. The cohort was randomly divided into a training (60%) and a validation (40%) sample. A proportional odds model was specified to create a risk score for AS in the training sample. Best fit model was determined based on Area Under the Curve (AUC) and Akaike Information Criterion (AIC). The cut off threshold of "high-risk" was based on Youden's (1950) index.[1] We assessed the model performance for internal validity using split-samples. The model was further validated using manual chart review of 900 patient records. These 900 records were selected such that 70% (N=630) met the high-risk cut-off and the remainder had scores below the cut-off. We also derived the probability of AS in each chart reviewed case using the method proposed by Feldtkeller et al. (2013) and Rudwaleit et al. (2006).[2,3]
Results: The cohort comprised 527,509 members with mean age 54 years and majority female (58%). Sixty-six percent were White race and 33% were Hispanic ethnicity. The crude incidence of AS was 1% and increased steadily during the follow-up period (Figure 1). The final risk prediction model included 15 risk factors and had an AUC of 0.72 (Table 1). Using Youden's index, a cut-off value of 11 or higher was identified as the threshold to define high-risk. No evidence of overfitting to our training sample was observed based on the split-sample analysis. The model validation based on manual chart review of 900 records showed sufficient ability to discriminate between those at high-risk vs those not identified to be high-risk. When a concrete rule out or rule in determination could be made using Feldtkeller et al. approach, our model correctly classified 75% of such records.

Table 1. Final Model Coefficients and Derived Risk Score

	Model Coefficient	Pr(>|z|)	Risk Score
Age above 45 years	0.146	0.011	1.46
Male Sex	-0.292	<0.001	-2.92
White Race	0.259	<0.001	2.59
Non-Hispanic Ethnicity	0.177	<0.001	1.77
Corticosteroid Use (Yes/No)	0.235	<0.001	2.35
*NSAID User (Yes/No)	0.202	<0.001	2.02
Opioid Analgesic User (Yes/No)	0.416	<0.001	4.16
Had Enthesitis (Yes/No)	0.298	<0.001	2.98
Had Disorders of the Back (Yes/No)	0.973	<0.001	9.73
Had Fatigue and/or Malaise (Yes/No)	0.155	0.056	1.55
Had Psoriasis (Yes/No)	0.288	0.008	2.88
Had Spondylosis (Yes/No)	0.838	<0.001	8.38
Had Synovitis (Yes/No)	0.143	0.066	1.43
Had Uveitis (Yes/No)	0.621	0.007	6.21
Depression Diagnosis (Yes/No)	0.099	0.017	0.99

*** NSAID: Non-steroidal anti-inflammatory drugs**

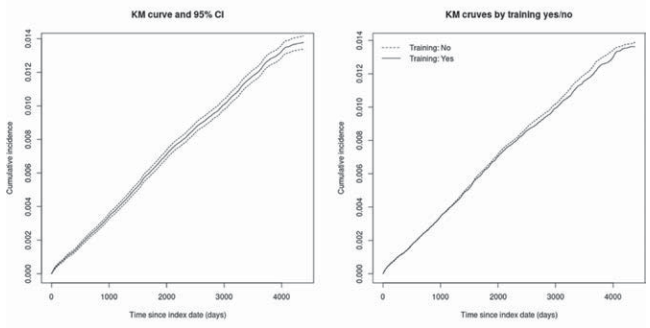

Figure 1. Cumulative Incidence Over Time (in Days)

Conclusion: To aid early detection, we have developed and validated an AS risk prediction model with an easy to implement scoring system using demographics, medication use and diagnosis data that is routinely collected in clinical practice.

POS0967 THE IMPACT OF PSORIASIS ON THE CLINICAL CHARACTERISTICS, DISEASE BURDEN AND TREATMENT PATTERNS OF PERIPHERAL SPONDYLOARTHRITIS: AN ANCILLARY ANALYSIS OF THE ASAS-PERSPA STUDY

T. Izci Duran[1,2], M. Torgutalp[1], V. Rios Rodriguez[1], F. Proft[1], C. López-Medina[3,4], M. Dougados[3,5], D. Poddubnyy[1,6]. *[1]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany; [2]Ondokuz Mayıs University Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Samsun, Turkey; [3]Université de Paris, Hôpital Cochin, Assistance Publique, Hôpitaux de Paris, Department of Rheumatology, Paris, France; [4]Reina Sofía Hospital, IMIBIC, University of Cordoba, Department of Rheumatology, Cordoba, Spain; [5]PRES Sorbonne Paris-Cité, INSERM (U1153): Clinical Epidemiology and Biostatistics, Paris, France; [6]German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*

Background: Psoriasis (PsO) is one of the common extramusculoskeletal manifestations of spondyloarthritis (SpA). There is a natural overlap between peripheral SpA (pSpA) and psoriatic arthritis. However, there are several unmet needs in patients with pSpA who cannot be classified otherwise (i.e., patients without PsO and without axial involvement) due to a lack of formally approved treatment options and lack of evidence of efficacy of different drug classes in this specific population.
Objectives: To evaluate the clinical characteristics, disease burden, and treatment patterns of pSpA patients with and without PsO using data from the cross-sectional ASAS-perSpA study.
Methods: We analysed 433 patients who had a diagnosis of pSpA according to the rheumatologist's diagnosis from the ASAS-perSpA cohort. A personal history of PsO was defined as the presence of signs of PsO on physical examination, psoriatic nail dystrophy, including onycholysis, pitting, and hyperkeratosis, or a personal history of PsO diagnosed by a dermatologist. Clinical characteristics, patient-reported outcomes and treatment patterns were compared between subgroups with and without PsO.
Results: A total of 83 patients (19.2%) had a personal history of PsO. Patients with PsO were older (48.4 vs. 43.2 years), had a longer diagnostic delay (7.4 vs. 3.5 years), a higher frequency of dactylitis (36.1 vs. 20.0%), and enthesitis (65.1 vs. 55.4%) than patients without PsO (Table 1). A longer diagnostic delay (odds ratio – OR=1.06 [95% CI 1.01-1.11]), lower HLA-B27 positivity (OR=0.31 [95% CI 0.15-0.65]), and higher frequency of enthesitis (OR=2.39 [95% CI 1.16-4.93])

were associated with the presence of PsO in the multivariable logistic regression analysis (Figure 1). Higher patient global assessment scores and lower use of bDMARD treatments were observed in patients without PsO as compared to patients with PsO.

Table 1. Demographics and clinical characteristics of patients with pSpA according to the presence or absence of personal history of PsO

	Total N=433	Patients without personal history of PsO N=350	Patients with personal history of PsO N=83	p-value

POS0968 CESAREAN SECTION IN WOMEN WITH SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS

C. Skorpen[1,2], S. Lydersen[3], K. Å. Salvesen[4], M. Wallenius[1]. *[1]NTNU, Department of Neuromedicine and Movement Science (INB), Trondheim, Norway; [2]Alesund Hospital, Rheumatology, Ålesund, Norway; [3]NTNU, Regional Centre for Child and Youth Mental Health and Child Welfare, Trondheim, Norway; [4]NTNU, Department of Clinical and Molecular Medicine, Trondheim, Norway*

Background: There is sparse documentation on pregnancy outcomes in women with spondyloarthritis (SpA) and psoriatic arthritis (PsA). Data on disease activity is often lacking, preventing the direct investigation of the effect of inflammation on pregnancy outcomes. A cesarean section (CS) implies a higher risk for the mother than vaginal delivery. It delays mobilization after birth necessary to counteract inflammatory pain and stiffness as well as the (re)start of disease modifying medication.
Objectives: To explore the possible association of disease activity (inflammation) and occurrence of cesarean section in women with SpA and PsA.
Methods: Data from the Medical Birth Registry of Norway (MBRN) were linked with data from RevNatus, a nationwide observational register recruiting women with inflammatory rheumatic diseases. Singleton births in women with SpA and PsA included in RevNatus 2010 to 2019 were cases. All other singleton births registered in MBRN during this time served as population controls.
Results: CS occurred more frequently in both SpA (21.9%) and PsA (29.4%) compared to population controls (15.6%), with even higher frequencies in active SpA (23.5%) and active PsA (30.1%). Women with SpA had higher risk for elective CS (risk difference 4.1%, 95% CI 1.4% to 7.9%, p=0.002), while women with PsA had higher risk for emergency CS (risk difference 9.8%, 95% CI 3.8% to 17.6%, p<0.001) as compared to population controls.
Conclusion: Women with SpA and PsA had increased odds for elective and emergency CS, respectively. Further analysis will explore the role of active inflammation.

POS0969 GENETIC AND MOLECULAR DISTINCTIONS BETWEEN AXIAL PSORIATIC ARTHRITIS AND ANKYLOSING SPONDYLITIS

A. Kavanaugh[1], X. Baraliakos[2], S. Gao[3], W. Chen4, K. Sweet[3], S. D. Chakravarty[5,6], Q. Song[3], M. Shawi[7], F. Behrens[8], P. Rahman[9]. *[1]University of California San Diego, Division of Rheumatology, Allergy, and Immunology, San Diego, CA, United States of America; [2]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Internal Medicine and Rheumatology, Herne, Germany; [3]Janssen Research & Development, LLC, Department of Translational Science, Spring House, PA, United States of America; [3]Janssen Research & Development, LLC, Department of Translational Science, Spring House, PA, United States of America; [5]Janssen Scientific Affairs, LLC, Department of Rheumatology, Horsham, PA, United States of America; [6]Drexel University College of Medicine, Department of Rheumatology, Philadelphia, PA, United States of America; [7]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, PA, United States of America; [8]Goethe University, Rheumatology and Fraunhofer ITMP - Translational Medicine*

and Pharmacology, Rheumatology, Frankfurt, Germany; [9]Memorial University of Newfoundland, Faculty of Medicine, St. John's, NL, Canada

Background: Psoriatic arthritis (PsA) and ankylosing spondylitis (AS) represent the prototypical spondyloarthritides. PsA patients may also suffer from axial disease (axPsA). Despite overlapping symptoms, axPsA and AS may be distinct disorders with differing clinical manifestations, genetic associations, and radiographic findings.[1] These disorders also respond differently to immunomodulatory therapies such as anti-interleukin (IL)-23 inhibitors. While guselkumab, a human monoclonal antibody targeting the IL-23p19 subunit, improved symptoms of axPsA,[2] risankizumab, a humanized monoclonal antibody targeting the IL-23p19 subunit, did not show improvement in the primary endpoint of proportion of AS patients achieving an Assessment of SpondyloArthritis International Society 40% (ASAS40) response at week (W) 12.[3]

Objectives: To understand molecular distinctions between axPsA and AS to differentiate these diseases and guide treatment choice.

Methods: Whole blood and serum samples were collected from consenting patients in the NCT03162796/NCT0315828 studies of guselkumab in PsA and the NCT02437162/NCT02438787 studies of ustekinumab in AS. axPsA patients were investigator-verified as having magnetic resonance imaging- or pelvic x-ray-confirmed sacroiliitis at screening (locally read). Human leukocyte antigen (HLA) genotypes were determined by RNA sequencing, limited to Caucasian patients to reduce genetic variability,[4] and select serum cytokine levels were analyzed alongside samples from healthy individuals. Differential prevalence of HLA alleles in axPsA versus AS was determined using a Fisher's Exact test. Statistical significance of differential baseline serum cytokine expression among axPsA versus non-axPsA versus AS patients, and of guselkumab effect on serum cytokine reduction versus placebo among axPsA and non-axPsA patients, were determined with a generalized linear model performed on log2-transformed data. Biomarker data from guselkumab every-4-weeks and every-8-weeks treatment arms were pooled.

Results: Among the 186/234 Caucasian axPsA/AS patients with available data, 34%/15% were female, 70%/14% used methotrexate at baseline, mean serum C-reactive protein (CRP) levels were 2.8/2.4 mg/dL and mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores were 6.4/7.5, respectively. Aside from race, baseline demographics and disease characteristics were representative of the overall population. The prevalence of class I HLA allele -B27, -C01, and -C02 carriers was significantly lower in axPsA than AS patients (30.7% versus 92.3%, p<0.001; 5.9% versus 31.6%, p<0.001; and 28.0% versus 62.0%, p<0.001, respectively), while the prevalence of HLA-C06 was significantly higher in axPsA than AS populations (36.0% versus 8.6%, p<0.001). Baseline serum levels of IL-17A and IL-17F were significantly higher in axPsA (N=71) than in AS (N=58) patients (p<0.01 and p<0.001, respectively). Comparable IL-17A/F expression was seen for axPsA and non-axPsA (N=229) patients (both p=not significant). Significant and comparable reductions from baseline in serum IL-17A/F in axPsA and non-axPsA patients were seen with guselkumab treatment (axPsA N=41, non-axPsA N=160) versus placebo (axPsA N=30, non-axPsA N=69) at W4/24 (all p<0.05).

Conclusion: Adults with axPsA and AS exhibit different genetic risk factors and serum IL-17 levels, supporting the concept of distinct disorders. Guselkumab demonstrated significant pharmacodynamic effects in axPsA patients that aligned with such effects in non-axPsA patients, consistent with observed clinical improvement.[2]

SAME OR DIFFERENT? ANALYSIS OF SIMILARITIES AND DIFFERENCES OF CROHN'S DISEASE AND ULCERATIVE COLITIS IN SPONDYLOARTHRITIS: AN ANCILLARY ANALYSIS FROM THE WORLDWIDE ASAS-PERSPA STUDY.

V. Rios Rodriguez[1], T. Izci Duran[2], M. Torgutalp[1], C. López-Medina[3,4], M. Dougados[3,5], M. Kishimoto[6], K. Ono[6], S. Lüders[1], M. Protopopov[1], H. Haibel[1], J. Rademacher[1], D. Poddubnyy[1,7], F. Proft[1]. *[1]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany; [2]Ondokuz Mayıs University, Department of Internal Medicine, Division of Rheumatology, Samsun, Turkey; [3]Cochin Hospital, Department of Rheumatology, Paris, France; [4]Hospital Universitario Reina Sofía, Department of Rheumatology, Córdoba, Spain; [5]Inserm, Clinical Epidemiology and Biostatistics, Paris, France; [6]Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan; [7]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology Unit, Berlin, Germany*

Background: Crohn's disease (CD) and ulcerative colitis (UC) are grouped as inflammatory bowel disease (IBD), and both are frequently found as extra-musculoskeletal manifestations in spondyloarthritis (SpA). Several studies have described the connection between SpA and IBD in both directions. Still until today, no studies have investigated possible differences in the musculoskeletal manifestations between the two main entities of inflammatory bowel disease: CD and UC.

Objectives: To evaluate the clinical characteristics associated with the presence of CD or UC in patients with spondyloarthritis from the international cross-sectional ASAS-perSpA study.

Methods: We analyzed 3152 patients from the ASAS per-SpA cohort who had a diagnosis of axial SpA or peripheral SpA according to the treating rheumatologist. Patients with IBD - confirmed by endoscopy - were identified and stratified by CD or UC. Patients in which their IBD disease was not specified, were excluded. Demographics, clinical characteristics, treatments and patient-reported outcomes were compared between both subgroups.

Results: Among the 146 patients diagnosed with IBD from the 3152 patients included in the analysis, 87 (59.6%) presented with CD (75 patients with axial SpA and 12 with peripheral SpA) and 39 (26.7%) with UC (34 patients with axial SpA and 5 with peripheral SpA) - Figure 1. A total of 20 (13.7%) patients with IBD were excluded, due to an inconclusive diagnosis of IBD. Patients with CD and UC had similar age (44.9 vs 44.0 years old) and sex distribution, although a slightly higher frequency of males was observed in CD than UC (63.2% vs 51.3%). The diagnostic delay for SpA was 7.0 years for CD and 8.1 years for UC. We did not find differences between both groups related to any musculoskeletal manifestations such as chronic back pain, uveitis, arthritis, enthesitis or dactylitis (Table 1). The only parameter showing a significant difference between CD and UC was the Bath Ankylosing Spondylitis Functional Index (BASFI) with a mean score of 3.3 vs 2.2 respectively (p=0.02) (Table 1). CD patients showed a higher tendency to be HLA-B27 positive (51.9% in CD vs. 39.4% in UC), but this did not reach statistical significance. No differences were observed regarding treatment patterns between both groups.

Table 1. Demographics and clinical characteristics related to spondyloarthritis of patients with concomitant Crohn's disease or ulcerative colitis (n=146).

	Crohn's Disease N=87	Ulcerative Colitis N=39	P
Age, mean (SD)	44.9 (13.5)	44.0 (13.0)	0.68

POS0971

THE RELATIONSHIP OF AXIAL [18F]FLUORIDE UPTAKE ON PET-CT TO ANATOMICAL CHANGES ON MRI AND X-RAY IN CLINICALLY ACTIVE ANKYLOSING SPONDYLITIS PATIENTS

J. De Jongh[1], N. Pouw-Verweij[1], G. C. J. Zwezerijnen[2], J. C. Van Denderen[3], I. Van der Horst-Bruinsma[4], J. Bot[2], B. J. H. Boden[5], R. Hemke[6], F. F. Smithuis[6], A. Voskuyl[1], M. Boers[7], M. Yaqub[2], C. J. Van der Laken[1]. *[1]Amsterdam UMC, location VUmc, Rheumatology & Clinical Immunology, Amsterdam, Netherlands; [2]Amsterdam UMC, location VUmc, Radiology & Nuclear Medicine, Amsterdam, Netherlands; [3]Reade, Rheumatology, Amsterdam, Netherlands; [4]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; [5]OLVG, Radiology & Nuclear Medicine, Amsterdam, Netherlands; [6]Amsterdam UMC, location AMC, Radiology & Nuclear Medicine, Amsterdam, Netherlands; [7]Amsterdam UMC, Vrije Universiteit, Epidemiology & Data Science, Amsterdam, Netherlands*

Background: Bone formation is a histopathologic feature of ankylosing spondylitis (AS), causing structural changes through the formation of syndesmophytes and spinal ankyloses (1, 2) Recent studies with [^{18}F]Fluoride Positron emission tomography (PET) demonstrated that disease activity of AS is best reflected by bone formation rather than inflammation and is sensitive to change during therapy (2, 3). [^{18}F]Fluoride PET(/CT) identifies more lesions in active AS than bone marrow edema on MRI, so may provide complementary information about the disease activity (3). A direct comparison between [^{18}F]Fluoride PET(/CT) and MRI and X-rays will allow better understanding of PET-CT positive lesions and will support further positioning of the technique for diagnostics and monitoring of AS.
Objectives: To relate uptake of [^{18}F]Fluoride on PET-CT to abnormalities on MRI and conventional radiography in patients with clinically active AS.
Methods: Ten patients (female 6/10, age 38±11 years) with AS based on modified New York criteria, a BASDAI of ≥ 4 and naïve to biologicals were included. All patients received a [^{18}F]Fluoride PET(/CT) scan, MRI scan and x-rays of the spine and SI-joints. Experienced readers blinded to clinical data and findings on other modalities scored the respective scans. PET scans were dichotomously scored for PET-positivity. MRI scans were scored in the spine for fatty lesions, erosions, ankylosis and bone marrow edema (BME) and erosions, ankylosis and BME in the SI-joints. X-rays were scored for erosions, syndesmophytes and ankylosis. Lesions on all modalities were compared with Cohen's kappa, linear regression, and univariate and multivariate analysis with a generalized mixed model.
Results: In total, 69 lesions with enhanced [^{18}F]Fluoride uptake compared to local background, 257 MRI lesions and 88 x-ray lesions were observed in the spine (Table 1). Most lesions were found in the thoracic spine. PET lesions were frequently located outside the field of view (FOV) of the MRI and X-ray in respectively costovertebral and facet joints (31/69; 45%). Univariate analysis PET positivity had the strongest association with the presence of MRI BME and x-ray bridges (OR 6.6, 95% C.I. 2.0 – 21.1, p = 0.002 and OR 34, 95% C.I. 6.0 – 183, p <0.001 respectively). Multivariate analysis confirmed these findings (OR 39, 95% C.I. 7 – 223, p < 0.01 and OR 6.4, 95% 1.7 – 23.5, p < 0.01 respectively) (Figure 1). However, of all PET-positive lesions only 7/24; 29% within the FOV of the MRI showed BME and 13/23; 56% of the PET lesions within the FOV of the X-ray showed bridges on X-ray. In the SI-joints, a total of 15 lesions (15/20; 75%) with PET enhancement were found. Erosions, ankylosis and BME lesions on MRI were observed in respectively 13/15; 87%, 4/15; 27% and 13/15; 87% of the lesions with PET enhancement.

Table 1. ***Distribution of lesions throughout the spine on different modalities.***

Number of lesions	Cervical spine	Thoracic spine	Lumbar spine	Total
PET	4	42	23	69
PET, within FOV MRI	1	11	12	24
PET, within FOV x-ray	1	10	12	23
MRI – fatty lesions	15	30	15	60
MRI – erosions	0	0	1	1
MRI – ankylosis	2	121	27	150
MRI – BME	1	35	10	46
X-ray erosions	14	25	0	39
x-ray syndesmophytes	1	0	1	2
X-ray bridges	4	31	12	47

FOV: field of view

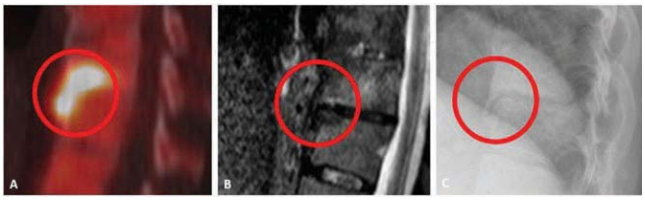

Figure 1. Example of Fluoride uptake on PET (A), corresponding BME on MRI (B) and bridges on X-ray (C).

Conclusion: Lesions with [^{18}F]Fluoride on PET showed significant correlation to MRI BME and x-ray bridge lesions. It showed partial agreement with BME of MRI and bridges on X-ray. This suggests that [^{18}F]Fluoride PET visualizes different mechanisms central to AS disease activity compared to MRI and X-ray, thereby providing novel and additional information.

MOST DISEASE OUTCOME MEASURES BUT NOT ASDAS ARE INFLUENCED BY GENDER IN PATIENTS WITH AXIAL SPA: RESULTS FROM ASAS-PERSPA

D. Benavent[1], D. Capelusnik[2], S. Ramiro[3,4], A. Moltó[5,6], C. López-Medina[6,7], M. Dougados[5,6], V. Navarro-Compán[1]. *[1]Hospital Universitario La Paz, IdiPaz, Department of Rheumatology, Madrid, Spain; [2]Instituto de Rehabilitación Psicofísica (IREP), Department of Rheumatology, Buenos Aires, Argentina;*

[3]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [4]Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands; [5]Hospital Cochin, Department of Rheumatology, Paris, France; [6]INSERM U1153, ECAMO team, Paris, France; [7]Reina Sofia University Hospital, Department of Rheumatology, Córdoba, Spain

Background: There is growing evidence revealing that females report worse patient-reported outcomes compared to males in axial spondyloarthritis (axSpA). However, in which precise outcomes there is a meaningful difference across gender and whether this also occurs in patients with peripheral spondyloarthritis (pSpA) and psoriatic arthritis (PsA) is not fully understood.
Objectives: To investigate the influence of gender on disease outcomes in patients with SpA, including axSpA, pSpA and PsA, in a worldwide setting.
Methods: Data from 4185 patients with axSpA, pSpA or PsA from the ASAS-PerSpA study were analysed. The ASAS-PerSpA is a cross-sectional study that recruited consecutive patients with SpA (according to their rheumatologist) from 24 countries. Associations between gender and disease activity [Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Score (BASDAI), C-reactive protein (CRP)], function [Bath Ankylosing Spondylitis Functional Index (BASFI)], and overall health [ASAS-Health Index (ASAS HI), European Quality of Life Five Dimension (EQ-5D)] were investigated. Multilevel (country) univariable and multivariable linear mixed models were used. Interactions between gender and disease phenotype (SpA, pSpA and PsA) were analysed, and if relevant, models were stratified by disease subtype. Models were adjusted for relevant confounders (Table 1).

Table 1. Multivariable multilevel model by disease phenotype

		Disease phenotype		
Outcome	Determinant of interest	**AxSpA**	**pSpA**	**PsA**
ASDAS $^{+}$	Gender (female vs male)	0.02 (-0.07, 0.11)	**0.36 (0.15, 0.58)**	**0.25 (0.12, 0.38)**
BASDAI *		**0.39 (0.20, 0.58)**	**1.22 (0.77, 1.69)**	**0.88 (0.59, 1.16)**
BASFI $^{-}$		0.01 (-0.14, 0.17)	0.30 (-0.12, 0.71)	**0.46 (0.20, 0.72)**
CRP^		-1.36 (-3.17, 0.44)		
ASAS-HI$^{\#}$		**0.90 (0.70, 1.10)**

All models are adjusted by age, gender and education. $^{+}$Also adjusted for marital status, BMI, smoking, axial involvement, peripheral arthritis, enthesitis, fibromyalgia, NSAIDs, steroids, csDMARDs, bDMARDs* Also adjusted for marital status, BMI, smoking, axial involvement, peripheral arthritis, enthesitis, psoriasis, fibromyalgia, NSAIDs, bDMARDs^{-} Also adjusted for marital status, BMI, ASDAS, radiographic damage, fibromyalgia, NSAIDs, bDMARDs^ Also adjusted for marital status, BMI, radiographic damage, concomitant NSAIDs, steroids, csDMARDs$^{\#}$ Also adjusted for smoking, ASDAS, BASFI, peripheral arthritis, enthesitis, fibromyalgia° Also adjusted for BMI, smoking, ASDAS, BASFI, radiographic damage, HLA-B27, enthesitis, fibromyalgiaResults are expressed in β (95% CI). Estimates with p<0.05 are highlighted in bold

Results: In total, 4185 patients were included, of which 2719, 1033 and 433 had a diagnosis of axSpA (mean age 42 years, 32% female), PsA (mean age 52 years, 52% female) and pSpA (mean age 44 years, 53% female), respectively. A significant interaction between gender and disease phenotype was found for ASDAS, BASDAI and BASFI. Multivariable models for each outcome are shown in Table 1 (stratified by disease phenotype). While being female independently contributed to higher BASDAI across the three disease phenotypes (though with varying magnitude), female gender was only associated with higher ASDAS in pSpA [β (95% CI): 0.36 (0.15, 0.58)] and PsA [0.25 (0.12, 0.38)] but not in axSpA [0.016 (-0.07, 0.11)]. Female gender was associated with higher BASFI in PsA [0.46 (0.20, 0.72)]. No associations were observed between gender and CRP levels. Female gender was associated with higher ASAS-HI [0.90 (0.70, 1.10)] and EQ5D [-0.02 (-0.03, -0.01)], without significant differences across disease phenotype.
Conclusion: Female gender was associated with less favorable outcomes across the SpA spectrum, except for CRP in which there were no differences between gender. While female gender influenced BASDAI across disease phenotypes, ASDAS was not associated with gender in axSpA. These results suggests that ASDAS should be the preferred instrument in clinical practice both for females and males with axSpA.

POS0973 INFLUENCE OF ANATOMICAL VARIATION OF THE SACROILIAC JOINTS ON INFLAMMATORY LESIONS ON MAGNETIC RESONANCE IMAGING

K. Ziegeler[1], S. T. Ulas[1], D. Poddubnyy[2], F. Proft[2], V. Rios Rodriguez[2], J. Rademacher[2,3], K. G. Hermann[1], T. Diekhoff[1]. [1]Charité Universitätsmedizin Berlin, Department of Radiology, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, (2)Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany; [3]Charité Universitätsmedizin Berlin, Berlin Institute of Health, Berlin, Germany

Background: Anatomical variation of the sacroiliac (SI) joints is more common among patients with LBP than healthy controls; increased biomechanical strain to the joint may play a role in axial spondyloarthritis (axSpA).
Objectives: To assess the association of lesions joint shape variation on inflammatory lesions on SI joint magnetic resonance imaging (MRI) in patients with axSpA.
Methods: In this post-hoc analysis a total of 684 patients from four different prospective cohorts were evaluated (379 axSpA). Two readers independently scored all patients for joint form, erosion, sclerosis, fat metaplasia and bone marrow edema (BME). Logistic regression analyses were used to assess the association of lesions on imaging joint form; this analysis was performed separately for axSpA patients and controls.
Results: Typical joints were observed in 56.5% of axSpA patients (200/354) and 55.7% of control patients (169/303); in axSpA patients exhibited a significantly higher proportion of intra-articular variants (18.4% vs. 11.6%; p<0.001) and crescent joint shapes (11.0% vs. 5.3.%; p<0.001) than controls. AxSpA patients with intraarticular joint form variants had increased odds for erosions (OR 2.09; 95%CI 1.18-3.69) and BME (OR 1.79; 95%CI 1.13-2.82); this association was not seen in controls. Accessory joints increased the odds for sclerosis in axSpA patients (OR 2.54;95%CI 1.10-5.84) and for BME (2.05; 95%CI 1.03-4.07) and sclerosis (OR 17.91; 95%CI 6.92-46.37) in controls.
Conclusion: Joint form variations are associated with inflammatory lesions on SI joint MRI of axSpA patients but not controls; this indicates a role for atypical joint forms in sacroiliitis.

POS0974 LOW DOSE COMPUTED TOMOGRAPHY HOUNSFIELD UNITS: A RELIABLE METHODOLOGY FOR ASSESSING CHANGES IN VERTEBRAL BONE DENSITY IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

M. L. Marques[1,2], N. Pereira Da Silva[3], D. Van der Heijde[1], M. Reijnierse[4], J. Braun[5], X. Baraliakos[5], F. A. Van Gaalen[1], S. Ramiro[1,6]. [1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; [3]Centro Hospitalar e Universitário de Coimbra, Radiology, Coimbra, Portugal; [4]Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands; [5]Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet Herne, Bochum, Germany; [6]Zuyderland MC, Rheumatology, Heerlen, Netherlands

Background: Assessing local vertebral bone loss in radiographic axial spondyloarthritis (r-axSpA) poses challenges, namely because Dual-energy X-ray absorptiometry (DXA) only allows assessment of lumbar vertebrae. The measurement of Computed Tomography (CT) vertebral Hounsfield Units (HU) has been shown to correlate with vertebral bone density as measured by DXA in trauma patients. We have recently reported the excellent reliability of low dose CT (ldCT) HU measurements from C3 to L5 in patients with r-axSpA[1]; however, HU change scores have never been studied.
Objectives: To describe ldCT HU change scores and their inter-reader reliability per vertebra in patients with r-axSpA over 2 years.
Methods: We used spine ldCT scans of r-axSpA patients included in the multicenter 2-year Sensitive Imaging in Ankylosing Spondylitis (SIAS) study. A standardized protocol and automatic exposure control calibration in ldCT imaging acquisition were used. Baseline and 2-year ldCT scans were independently assessed by two trained readers. The HU measurements were performed as described in Figure 1. Mean (standard deviation, SD) for the change-from-baseline

Table 1. Change scores for both readers, mean differences and intraclass correlation coefficients (ICC) from C3 to L5

§ C3-C7: n=44; T1-L5: n=49 **#** % of vertebrae in which both readers agreed on a change score > smallest detectable change.

scores were provided by reader, together with the respective mean differences (SD). Inter-reader reliability for the change scores was assessed using intraclass correlation coefficients (ICC) absolute agreement, applying two-way random effect models. Agreement was assessed using the smallest detectable change ($SDC = 1.96 \times SD_{difference} / (\sqrt{2} * \sqrt{k})$; $SD_{difference}$ is the SD of the differences in change scores between the two readers, and k=2 readers) and Bland-Altman plots. The percentage of vertebrae in which readers agreed on the direction of the change (positive vs negative) and on change scores > |SDC|were also computed.

Results: Whole spine ldCT scans from 49 r-axSpA patients (mean age of 49 (SD 10) years; 88% male and 84% HLA-B27 positive) were included. In total, 1,053 vertebrae were assessed by both readers. The HU mean change values varied from -23 to 28 and -23 to 29 for reader 1 and 2, respectively – Table 1. More vertebrae showed a positive change in the cervical spine compared with the thoracic and lumbar spine. Inter-reader reliability was excellent (ICC: 0.91 to 0.99). SDC varied from 4 to 7, mean and median of 5. Bland-Altman plots showed homoscedasticity throughout the whole spine, with negligible systematic error between the readers. The two readers agreed on the direction of the change score in 88-96% of vertebrae, and agreement on change scores > |SDC| was obtained in 64-96% of the vertebrae.

Conclusion: LdCT measurement of HU is a reliable method to assess changes in bone density at each vertebra from C3 to L5. This methodology can aid the study of bone loss in r-axSpA, a disease affecting the whole spine.

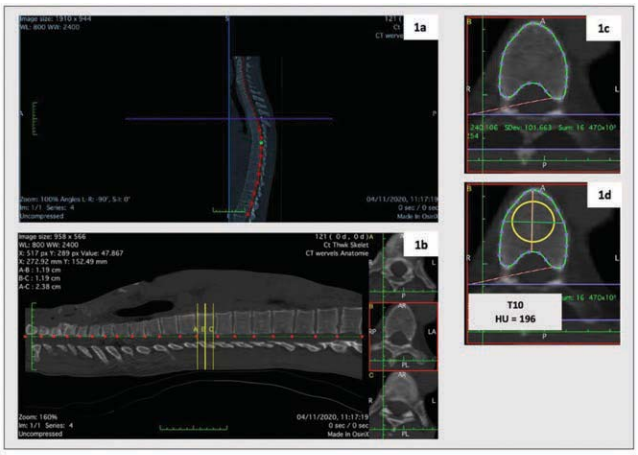

Figure 1. **Methodology of Hounsfield Units (HU) measurement.** Using a three-dimensional curved-multiplanar reconstruction the curve of the spine was identified from the spinal canal (**1a**). On the obtained sagittal image, the vertebrae could be identified. At each vertebra, two lines of reference were positioned at the superior (yellow line A) and inferior (yellow line C) limits of the vertebra. Equidistant to A and C, the yellow line B was positioned at the center of the vertebral body (**1b**). In the reconstructed cross-sectional slice, the vertebral body was delimited (**1c**). A centered region of interest (ROI) was manually selected, having a diameter equal to 75% of the average of anteroposterior and transverse diameters, and the density of the vertebra was calculated as the average image density within the sample region, reported in HU. (**1d**).

POS0975 COMPARISON OF CLINICAL AND DEMOGRAPHIC FINDINGS OF PATIENTS DIAGNOSED AS WITH FULL SPINAL FUSION AND WITHOUT ANY SPINE DAMAGE

C. Yörük[1], S. Gulle[2], İ. Sari[2], F. Onen[2], A. Balcı[3]. *[1]Dokuz Eylül Üniversitesi Hastanesi, Internal Medicine, Izmir, Turkey; [2]Dokuz Eylül Üniversitesi Hastanesi, Rheumatology, Izmir, Turkey; [3]Dokuz Eylül Üniversitesi Hastanesi, Radiology, Izmir, Turkey*

Background: Erosions and sclerosis are early manifestations of radiographic progression, which can form syndesmophytes that bridge between the vertebrae and eventually lead to spinal fusion or the characteristic bamboo spine appearance in some patients.Bridging syndesmophytes in the spinal column plays a key role in the progression of AS.[1] The development of ankylosis in the axial skeleton is considered to be the most important long-term outcome parameter for axial pondyloarthritis (axSpA).[2]

Objectives: In this study, we aimed to evaluate patients with ankylosing spondylitis (AS) diagnosed with grade 4 sacroiliitis followed in our rheumatology clinic, without spinal column involvement and with complete spinal ankylosis (bamboo vertebra), together with their clinical, demographic and laboratory findings.

Methods: A total of 202 patients with unilateral/bilateral grade 4 sacroiliitis, who were registered in the Dokuz Eylul University Hospital data system, diagnosed with AS according to the modified New York criteria, were included in the study. Cervical, dorsal and lumbar radiographs of all patients were evaluated for structural damage, in addition to lateral and anteroposterior aspects, as well as posterior and facet joint involvement. In the study, all radiographs were evaluated twice at separate times.

Results: It was found that 19 (9.5%) patients had no involvement of the spinal column and 19 (9.5%) had spinal fusion appearance. It was determined that patients with spinal fusion were older (p<0.001) and the frequency of male gender was higher (p=0.042) than patients without any spinal involvement.(Table 1) In multivariate analysis; ≥45 years old [OR: 10.5, CI: 95%, 2.8-39.2; (p<0.001)] and male patients [OR: 10.5, CI: 95%, 1.14-96.56; (p=0.042)] was found to have an increased risk for the development of spinal fusion. TNFi retention rates (78.9% vs. 52.6%), TNF switch rates (53.3% vs. 45.5%) and TNF type distributions were similar in both groups (p>0.05). There was no significant difference between the patients with complete spinal fusion and no spinal involvement in terms of right and left hip BASRI scores (p>0.05).

Conclusion: In our study, we reached four important clinical results: (1) Spinal fusion was observed in 9.5% of the patients with bilateral Grade 4 sacroiliitis diagnosed with AS, 9.5% had no spinal involvement and 81% had varying degrees of spinal injury. (2) Anti-TNF treatment responses were similar in patients with spinal fusion and no spinal involvement. (3) Except for being >45 years old and having a male gender, no other factor was found to predict the development of spinal fusion. (4) There was no difference in the degree of hip involvement between patients with complete spinal fusion and no spinal involvement.

POS0976

IMPACT OF PATIENT AND DISEASE CHARACTERISTICS ON GLOBAL FUNCTIONING AND HEALTH IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A BAYESIAN NETWORK ANALYSIS OF DATA FROM AN EARLY AXSPA COHORT

I. Redeker[1], R. B. M. Landewé[2], D. Van der Heijde[3], S. Ramiro[2,3], A. Boonen[4], M. Dougados[5], J. Braun[1], U. Kiltz[1]. *[1]Rheumazentrum Ruhrgebiet and Ruhr-Universität Bochum, Rheumatology, Herne, Germany; [2]Zuyderland MC, Rheumatology, Heerlen, Netherlands; [3]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [4]Academic Hospital Maastricht, Rheumatology, Maastricht, Netherlands; [5]Cochin Hospital, Rheumatology, Paris, France*

Background: Current knowledge on the health status of patients (pts.) with axial spondyloarthritis (axSpA) mainly focusses on physical function and disease activity. Using a generic measure for physical- or mental health (SF36), a hierarchical relationship between disease activity, spinal damage, spinal mobility, physical function and overall health has been demonstrated in pts. with radiographic axSpA (r-axSpA) [1]. Disease-specific global functioning and health can be assessed in pts. with axSpA using the ASAS Health Index (ASAS HI), which encompasses physical function, as well as aspects of emotional and social functioning and aspects of activity and participation.

Objectives: To build a structural model that visualizes interrelationships of different patient- and disease characteristics with global functioning and health in pts. with early axSpA.

Methods: Data of pts. with axSpA from the DESIR cohort was analyzed, which included information on socio-demographics (age, BMI), disease activity (ASDAS), physical function (BASFI), spinal mobility (BASMI), structural damage (mSASSS), disease-specific global functioning (ASAS HI), and comorbidity count. Information on patient- and disease characteristics was retrieved from the visit performed 72 months after inclusion, which was the first time point of ASAS HI collection. A Bayesian network (BN) was used to obtain insight of the underlying structural model. BNs are probabilistic graphical models consisting of "nodes" (representing specific variables) joined by "edges" (lines representing directions of effects). They are capable of capturing complex relationships between variables and allow the incorporation of existing (prior) knowledge from previous studies.

Results: The DESIR cohort contained data from 582 pts. at month 72, of whom 398 had data for ASAS HI. Descriptive information of these pts. is shown in Table 1. The mean ASAS HI was 5.7 (range: 0 - 16). Applying existing cut-offs for ASAS HI, 51% had 'good' global functioning (ASAS HI ≥5), 40% had 'moderate' global functioning (5< ASAS HI <12) and 9% had 'bad' global functioning (ASAS HI ≥12). The structural model that was constructed from combining data and prior expert knowledge is visualized in Figure 1. It suggests that ASDAS and BASFI have a direct impact on ASAS HI and that ASDAS has an indirect impact via BASFI. The model also suggests that ASDAS has an impact on the number of co-morbidities via BMI and that BASFI determines BASMI, which is in turn also influenced by age and mSASSS. In addition, it suggests a direct effect of age, BMI and ASAS HI on the comorbidity count. The model denies a relationship between BASMI or mSASSS and ASAS HI.

Table 1. Patient and disease characteristics at month 72

	N = 398
Gender (male), N (%)	181 (45%)
Age (years)	40.7 (8.7)
Symptom duration (years)	7.5 (0.9)
BMI (kg/m^2)	25.0 (4.6)
ASDAS	2.0 (1.0)
BASFI (0–10)	2.3 (2.1)
BASMI (0–10)	2.5 (1.0)
mSASSS (0-72)	1.0 (3.6)
ASAS HI (0-17)	5.7 (3.9)
good global functioning: ASAS HI ≤5, N (%)	201 (51%)
moderate global functioning: 5< ASAS HI <12, N (%)	160 (40%)
bad global functioning: ASAS HI ≥12, N (%)	37 (9%)
Comorbidity count	1.4 (0.7)

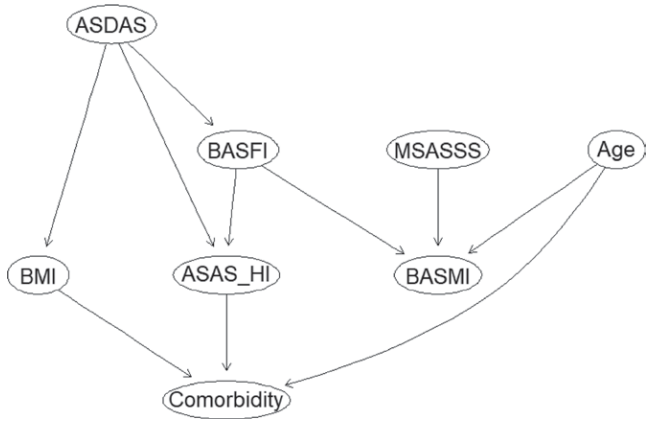

Figure 1. Structural model on interrelationships of different patient- and disease characteristics with global functioning and health (ASAS HI) in patients with early axSpA

Conclusion: The BN-analysis approach, that combines prior knowledge and measured data, serves to better understand the construct of global functioning and health in pts. with early axSpA. Our model shows that global functioning (ASAS-HI) is determined both by patient-reported physical function (BASFI) and by disease activity (ASDAS), which confirms the hierarchical model once proposed by Machado et al. The observed directional relationship between ASAS HI and comorbidity count is counterintuitive and requires further investigation.

POS0977 ASSOCIATION OF DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER AND AXIAL SPONDYLOARTHRITIS WITH THE M694V MUTATION

M. Kiracı[1], E. Bilgin[2], E. Duran[2], B. Farisogullari[2], E. C. Bolek[2], G. K. Yardımcı[2], Z. Özsoy[2], G. Ayan[2], G. Sandal Uzun[2], T. H. Akbaba[3], B. B. Peynircioglu[3], O. Karadag[2], A. Akdoğan[2], Ş. A. Bilgen[2], S. Kiraz[2], A. İ. Ertenli[2], U. Kalyoncu[2], L. Kılıç[2].
[1]Mamak State Hospital, Internal Medicine, Ankara, Turkey; [2]Hacettepe University, Rheumatology, Ankara, Turkey; [3]Hacettepe University, Medical Biology, Ankara, Turkey

Background: The incidence of co-occurrence of FMF and axial spondyloarthritis (axSpA) in adults is reported to be 0.5-7.5%. M694V mutation is the most frequent variant in patients with FMF+AxSpA (1).
Objectives: To evaluate the association of demographic and clinical characteristics of patients with FMF+axSpA with the M694V mutation.
Methods: A total of 9630 FMF patients were identified according to the ICD-10 code (E85.0) in the electronic database of Hacettepe University Hospital. 7525 patients aged <18 years old and no hospital admissions after 2014 were excluded. 2105 adult FMF patients screened for accompanying axSpA according to ICD-10 code (M45) and 241 patients detected as FMF+axSpA. FMF diagnosis was confirmed with Tel-Hashomer criteria. The diagnosis of axSpA was confirmed by the presence of sacroiliitis on sacroiliac radiography according to the Modified New York (mNY) criteria or the presence of active sacroiliitis on sacroiliac magnetic resonance imaging according to the ASAS criteria. According to these criterias, the diagnosis of FMF+AxSpA association was confirmed in 136 patients. MEFV gene result was present in 113 (83%) of 136 patients and were included in the study. Patients were divided into two groups as M694V (+) and M694V (-) according to the M694V mutation, and the demographic and clinical characteristics of the patients were compared. p<0.05 was considered statistically significant.
Results: Of 113 patients with known MEFV gene result, 91 (80.5%) were M694V (+), 22 (19.5%) were M694V (-), 45 (39.8%) were homozygous for M694V. In the M694V (+) group, symptom onset and diagnosis of both FMF and axSpA were at an earlier age compared to M694V (-) patients (p<0.05). The frequency of radiographically proven moderate to severe hip involvement (24.2% vs. 9.1%) and total hip replacement (11% vs. 4.5%) was higher in M694V (+) patients. However, these differences were not statistically significant (p=0.12; p=0.36). In the homozygous M694V (+) group, symptom onset and diagnosis of both FMF and axSpA were significiantly at an earlier age than in the group homozygous M694V (-) (p<0.001). Although erysipelas-like skin rash was more common in homozygous M694V (+) group (28.9% vs. 11.8% p=0.02), other symptoms and findings were similar in both groups (Table 1).
Conclusion: FMF and SpA symptoms appear at an earlier age in M694V positive patients. The M694V mutation is associated with severe disease and early disease onset.

POS0978 LUMBAR FACET JOINTS ARTHRITIS RELATES TO ITS ADJACENT MRI INFLAMMATORY LESIONS IN AXIAL SPONDYLOARTHRITIS

Z. Huang[1,2], L. Huang[1,2], X. Guo[1], Q. Huang[1], M. Liu[1,2], F. Feng[1], T. LI[1,2,3].
[1]Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; [2]Southern Medical University, The Second School of Clinical Medicine, Guangzhou, China; [3]Zhaoqing Central People's Hospital, Department of Rheumatology and Immunology, Zhaoqing, China

Background: Facet joints are frequently impaired in patients with axial spondyloarthritis (axSpA), which raises high disease activity and poor physical function. However, insufficient attention is paid to the relationship between the feature of disease and facet joint arthritis (FJA) in magnetic resonance imaging (MRI) examination, because of lacking an ideal assessment tool. The Canada-Denmark (CANDEN) MRI scoring system is adopted in our study because it is a comprehensive method to assess the alteration of spine [1].
Objectives: We aimed to find relevant factors for lumbar FJA in axSpA patients.
Methods: This was a cross-sectional study that analyzed the lumbar MRI of axSpA patients using the CANDEN system. Demographic and clinical information was recorded. Univariate and multivariate linear mixed model (LMM) was used to screen related factors for lumbar FJA in MRI examinations.
Results: (1) Totally 108 axSpA patients were investigated in our study, while ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA) accounted for half respectively. Sixty-five (60.19%) participants were male and their median age was 35 years. (2) Twenty (37.10%) and 1 (1.80%) AS and nr-axSpA suffered lumbar FJA (P<0.05). (3) Univariate LMM found gender, vertebral body corner inflammation subscore (VBCIS), spondylodiscitis subscore (SDS), posterolateral elements inflammation subscore (PLEIS), fat posterior elements subscore (FPES), fat vertebral body subscore (FVBS), and AS disease activity score with C-reactive protein (ASDAS) related to lumbar FJA in AS patients. Besides, gender, the duration of symptom, peripheral arthritis, enthesitis, non-steroidal anti-inflammatory drugs, VCBIS, SDS, PLEIS, FPES, the ankylosis of sacroiliac joints, and bony erosion of hips were involved in the univariate LMM for nr-axSpA. (4) Multivariate LMM displayed that odd ratio (OR) and 95% confidence intervals (CI) of PLEIS, FPES, and ASDAS were 0.66 (0.40, 0.91), 0.45 (0.20, 0.71), and 0.23 (0.01, 0.44) (P<0.05). OR (95%CI) for VBCIS and PLEIS were 0.02 (0.00, 0.04) and 0.23 (0.16, 0.30) in nr-axSpA patients (P<0.05).
Conclusion: Prevalence of lumbar FJA is higher in AS patients than nr-axSpA. This lesion is mainly related to MRI changes of its neighborhood structure, especially inflammatory alterations, rather than demographic and clinical characteristics.

POS0979

IMPROVING THE VALIDITY OF DIAGNOSTIC CODES AND POINT PREVALENCE ESTIMATION OF SPONDYLOARTHRITIS IN A LARGE POPULATION-BASED DATABASE

J. Feld[1,2], W. Saliba[2,3], N. Stein[3], T. Gazitt[1], D. Zisman[1,2]. [1]*Carmel Medical Center, Rheumatology, Haifa, Israel;* [2]*Technion - Israel Institute of Technology, Medicine, Haifa, Israel;* [3]*Carmel Medical Center, Department of Community Medicine and Epidemiology, Haifa, Israel*

Background: Large population-based databases provide an opportunity to study the epidemiology of spondyloarthritis (SpA), however, strict validation procedures for case ascertainment are required (1).
Objectives: To examine the validity of the ICD-9 codes of SpA in a large population-based database and to assess whether applying a specific algorithm would improve the case ascertainment. Finally, the point prevalence of SpA in the database was estimated using the validated algorithm.
Methods: A Database of a large public health fund, which serves approximately 3.17 million enrollees older than 18 years old, was used. The database includes real-time input from pharmaceutical, medical and administrative operating systems. At first, the database was searched for all individuals who received an ICD-9 code of SpA, 720.0: 7200, 7201, 7202, 7208, 72081 and 72089. All medical records of a random sample of 169 patients were thoroughly reviewed by a rheumatologist. Based on the information available in the database, a decision was made whether SpA diagnosis was: 1) definite/probable SpA; 2) not SpA/; not enough data to verify the diagnosis of SpA. The positive predicted value (PPV) and 95% confidence interval (CI) were calculated. In order to improve the case ascertainment, a second validation process was performed using a specific algorithm. The algorithm applied was: a permanent ICD-9 code of SpA assigned by the family physician plus at least one of the following criteria: 1. At least one visit at a rheumatology clinic either in the community or at a hospital outpatient clinic; 2. A diagnosis of SpA given during a hospital admission; 3. A prescription fulfilled of an anti-Tumor Necrosis Factor agent or anti IL-17 agent. This algorithm was validated by two rheumatologists in a random sample of 182 cases. Finally, the point prevalence of SpA was estimated applying the validated algorithm.
Results: The PPV of the ICD-9 codes of SpA was 44% (95%CI 36%-52%). The specific algorithm improved the PPV to 90% (95%CI 85%-94%). The concordance between the two rheumatologists was 91.3 95%CI (85.7-94.8). On the 31/12/2021, the validated algorithm identified 2892 live SpA patients older than 18 among a population of 3,167,329 enrollees in the database, reflecting a point prevalence of 0.09%, 94 patients per 100,000. Fifty one percent of the patients were male, 49% females. The point prevalence of males was 0.096%, and females - 0.087%. On the 31/12/2021, 6% of the patients were 18-29 years old, 34% 30-44 years old and 60% older than 45.
Conclusion: A specific algorithm can accurately identify patients with SpA in this large population-based database. The estimated prevalence of SpA is 0.09%. This figure is consistent with other population-based estimates (2).

Background: Axial spondyloarthritis (axSpA) is associated with a high disease burden which may require patients to make functional adaptations in response to the disease
Objectives: The aim is to identify factors associated with implementing functional adaptations due to axSpA.
Methods: Data from 2,846 unselected patients participating in EMAS, an online survey (2017-2018) across 13 European countries, were analysed. Adaptations were assessed by: "Please indicate any steps you have taken since you have been affected by Spondylitis/ Spondyloarthritis?" with possible answers: purchasing customized or comfortable shoes, workplace or home or car adaptations. BASDAI (0-10), spinal stiffness (3-12), functional limitation (0-54), and mental health via the General Health Questionnaire GHQ-12 (0-12) were collected. Univariable and multivariable logistic regression models were used to identify variables associated with life adaptations, including sociodemographic factors, PROs, employment status, health behaviours, and comorbidities (n= 2,754).
Results: Mean age was 43.8 years, 61.5% female, 48.9% had a university degree, and 67.6% married. 76.9% (n=2,118) patients had made at least one adaptation: 72.0% (n=1,525) purchased customised or comfortable shoes, 54.9% (n=1,163) adapted their workplace, 40.7% (n=861) their home, and 29.0% (n= 614) their car. Compared to those who did not require adaptations, those who made adaptations were typically female (78.9% vs. 73.7% male, p=0.002), separated/divorced/widowed (82.0% and 80.0% vs. 71.5% singles, p=0.002), had retired early, or were on sick leave (temporary or permanent) (85.0%, 84.0%, 84.3% vs. 74.5% of employed), members of a patient organisation (81.5% vs. 74.0% of non-member, p<0.001), physically active (78.9% vs. 66.5% vs. not physically active, p<0.001), and overweight/obese (78.6% vs. 75.1% of underweight/normal weight). Those requiring functional adaptations reported greater BASDAI (5.7 vs. 4.9), functional limitations (21.4 vs. 16.5), poorer mental health (5.2 vs. 4.3), and longer diagnostic delay (7.9 vs. 6.0), all p<0.001. The variables independently associated with functional adaptations were being physically active (OR=1.98), patient organisation membership (OR=1.39), female gender (OR=1.31), being overweight or obese (OR=1.26), separated, divorced or widow status (OR= 1.20), higher BASDAI (OR= 1.14) and functional limitation (OR= 1.01; Table 1).

Table 1. Regression analysis for variables associated with the presence of at least one functional adaptations (n= 2,162)

	Univariable logistic analysis		Multivariable logistic analysis	
	OR	**95%CI**	**OR**	**95%CI**

Patient organization. Member[4]	1.55	**1.29, 1.88**	1.39	**1.12, 1.74**
Physical activity	1.88	**1.51, 2.35**	1.98	**1.52, 2.59**
Body Mass Index. Overweight/ obesity[5]	1.22	**1.02, 1.46**	1.26	**1.02, 1.55**
BASDAI (0-10)	1.21	**1.16, 1.27**	1.14	**1.07, 1.22**
GHQ-12 (0-12)	1.06	**1.03, 1.08**	1.01	0.98, 1.04
Functional Limitation (0-54)	1.02	**1.01, 1.03**	1.01	**1.00, 1.02**
Spinal Stiffness (3-12)	1.10	**1.06, 1.14**	0.99	0.94, 1.03
Diagnostic delay	1.03	**1.02, 1.04**	1.01	0.99, 1.03
Anxiety	1.26	**1.03, 1.54**	0.87	0.65, 1.18
Depression	1.56	**1.25, 1.95**	1.31	0.95, 1.79
Sleep disorders	1.54	**1.27, 1.86**	1.17	0.91, 1.51

[1]Male vs. Female; [2]Separated/divorced/widow vs. married/single; [3]Sick leave/early retirement vs. other employment status; [4]Member vs. non-member; [5]Overweight/obesity vs. underweight/normal weight

Conclusion: Three out of four axSpA patients made at least one functional adaptation due to their axSpA, which were often implemented by those with higher body weight, disease activity, engaging in physical activity, and patient organization membership. This is most likely explained by need as those with high disease burden or weight may face limitations, which can be alleviated through functional adaptations, enabling them to engage in physical activity.

POS0981

RELATIONSHIP BETWEEN CLINICAL MANIFESTATIONS OF AXIAL SPONDYLOARTHRITIS AND PROGRESSION OF COXITIS.

E. Agafonova[1], S. Erdes[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of SpondyloArthritis, Moscow, Russian Federation*

Background: Almost half of the patients with axial spondyloarthritis (axSpA) in Russia diagnosed hip joint lesions (HJ), but the causes and rates of progression

are not studied. Until now, it remains unclear whether synovitis detected on MRI and ultrasound of hip joint is a predictor of radiological progression of coxitis.
Objectives: To determine the factors influencing the progression of coxitis in axSpA.
Methods: 77 patients (mean age 28 ± 5.92 years) with a diagnosed with axSpA (ASAS criteria 2009), which were observed for at least 2 years. Among them, AS according to the modified New York criteria (1984) - 66 (86%) patients, and 11 (14%) were diagnosed with nr-axSpA. The median duration of the disease was 30 [3–60] months, BASDAI 4.5 [3.2; 5.9], BASFI 2.4 [0.9; 4.8]. All patients underwent clinical, X-ray, ultrasound and MRI examination of the hip joint during the entire observation period. For ultrasound, coxitis was considered an increase in the cervical-capsular distance (CCD) of more than 7mm. For MRI inflammatory changes were taken as osteitis of the acetabulum and / or femoral head and synovitis in STIR mode. The sum of stages of radiographic coxitis (ssrC) was used to assess HJ injury progression. During the study, a formula was developed to assess the progression rate of radiographic coxitis (R-rpC).
Results: Cluster analysis of the main parameters was performed to detect the relationship between the clinical manifestations of axSpA and radiological progression of coxitis (Figure 1). During the analysis, it was found that the most closely related group of clinical parameters, such as the presence of the HLA B 27 gene and the sex of patients, the rate of radiographic progression of coxitis and srsc (Euclidean distance < 20). The second group of related measures included the BASDAI and ASDAS-CRP disease activity indices, as well as their associated functional impairment (BASFI index) (Euclidean distance < 30). These two groups of signs are also related to each other — Euclidean distance < 30. It should be noted that laboratory indicators of inflammation (ESR and CRP), the age of patients, and especially the duration of the disease, turned out to be weakly related to each other (Euclidean distance > 100). It should also be noted that the relationship between laboratory indicators of inflammation and disease activity indices is relatively weak, as well as with structural damage in axSpA.

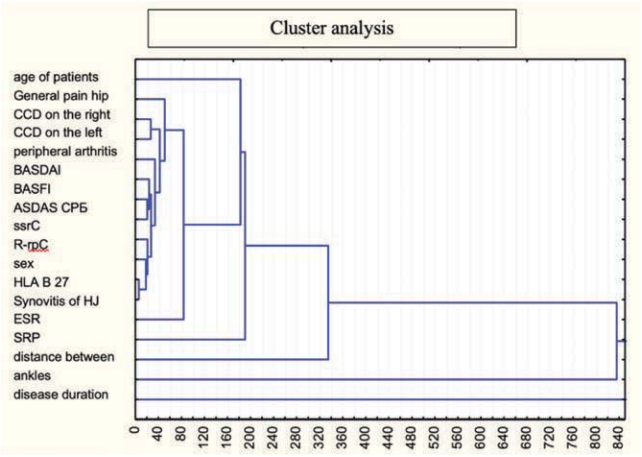

Figure 1.

Conclusion: Factors influencing the development and progression of coxitis in axSpA are a combination of such features as high clinical activity of the disease, the presence of peripheral arthritis, HLA B27 positivity and male sex.
Disclosure of Interests: None declared

POS0982 ANTIBODIES TO TWO NOVEL PEPTIDES IN NEW ONSET AXIAL SPONDYLOARTHRITIS

P. Ruytinx[1], P. Vandormael2, E. Luyten[1], A. S. De Craemer[3], F. Van den Bosch[3], D. Elewaut[3], V. Somers[1]. *[1]Biomedical Research Institute, Hasselt University, Department of Immunology and Infection, Diepenbeek, Belgium; [1]Biomedical Research Institute, Hasselt University, Department of Immunology and Infection, Diepenbeek, Belgium; [3]Ghent University Hospital, Rheumatology, Gent, Belgium*

Background: Diagnosis of axial spondyloarthritis (axSpA) is challenging since clinical manifestations often overlap with other disorders and a specific laboratory test for diagnosis is lacking. Previously, we identified antibodies to 3 Hasselt University (UH)-axSpA peptides which could provide a novel tool for diagnosis of a subset of axSpA patients. Validation of antibody reactivity in plasma samples of early axSpA patients (disease duration < 5 years) from the UH and the Leuven Spondyloarthritis (Biologics) Cohort ((Bio)SPAR) cohorts revealed antibody reactivity against at least one of these 3 peptide targets in 14.2% of early axSpA patients (22/155)[1].
Objectives: We aim to validate the diagnostic potential of the antibodies to these 3 peptides in a third independent cohort of new onset axSpA patients and controls.
Methods: Using enzyme-linked immunosorbent assays (ELISA), presence of antibodies to the 3 peptides was determined in 188 serum samples of the Belgian Inflammatory Arthritis and Spondylitis (Be-Giant) cohort, 74 controls with non-specific chronic low back pain (CLBP) and 112 age and gender-matched healthy controls from the UH cohort. Patients were classified as having axSpA according to the ASAS classification criteria and had a mean age of 32.7 years. We further investigated whether clinical and disease characteristics were correlated with antibody reactivity.
Results: The presence of antibodies against 2 of the 3 UH-axSpA peptides was confirmed in the Be-Giant cohort. Antibody reactivity against 1 of the 2 UH-axSpA peptides was found in 11.2 % of newly diagnosed axSpA patients (21/188) compared to 3.6% (4/112, *p=0.0290*) in HC and 6.8% (5/74, *p=0.3619*) in CLBP. We did not detect a significant difference in age, sex, HLA–B27 status, enthesitis, symptom duration, treatment, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), BathAnkylosing Spondylitis Functional Index (BASFI), erythrocyte sedimentation rate (ESR), or C-reactive protein (CRP) levels between axSpA patients with and those without antibody reactivity against these 2 UH-axSpA peptides.
Conclusion: The presence of antibodies to 2 UH-axSpA peptides was confirmed in an independent cohort of newly diagnosed axSpA patients and could be of added value for discriminating axSpA patients from HC in the Be-Giant cohort.

POS0983 LIFESTYLE IN AXIAL SPONDYLOARTHRITIS - COMPARISONS BETWEEN PATIENTS AND CONTROLS, AXIAL SPONDYLOARTHRITIS SUBTYPES, MALE AND FEMALE PATIENTS, AND ITS ASSOCIATION WITH DISEASE AND HEALTH OUTCOMES. RESULTS FROM THE SPARTAKUS COHORT

E. Mogard[1], T. Olofsson[1], A. Bremander[2,3,4,5], J. Sagard[1], J. K. Wallman[1], E. Lindqvist[1]. *[1]Lund University, Skane University Hospital, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; [2]Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; [3]Spenshult, Research and Development Centre, Halmstad, Sweden; [4]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; [5]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*

Background: Healthy lifestyle behaviours are associated with better health outcomes and quality of life in the general population (1, 2). In patients with axial spondyloarthritis (axSpA), however, little is known regarding multiple lifestyle behaviours and their associations with disease and health outcomes.
Objectives: To study lifestyle behaviours in patients with axSpA in relation to healthy controls, between axSpA subtypes and male and female patients, respectively, and to assess how the presence of two or more unhealthy lifestyle factors associate with disease and health outcomes.
Methods: We performed a cross-sectional study of 250 well-characterized axSpA patients (167 with radiographic axSpA [r-axSpA; ASAS and/or modified New York criteria], 83 with non-radiographic axSpA [nr-axSpA; ASAS criteria]) and 48 controls (frequency-matched to the patients for age and sex), participating in the population-based SPARTAKUS study in southern Sweden. Self-reported data on smoking, alcohol use, physical activity, dietary habits, and objectively measured body mass index (BMI), respectively, for all subjects was categorized as fulfilling national recommendations or not (healthy/unhealthy), and summarized in an index (0-5, indicating the number of unhealthy lifestyle factors). The index was also dichotomized into 0-1 vs. 2-5 unhealthy lifestyle factors. Comparisons between patients and controls, axSpA subtypes (r-axSpA vs. nr-axSpA), and between male and female patients were performed by Student's t-test/Chi-square test, as appropriate. Linear regression analyses were used to explore associations between having ≥2 unhealthy lifestyle factors (yes/no) and disease and health outcomes.
Results: Characteristics and lifestyle factors for axSpA patients and controls are presented in the Table 1. Reporting ≥2 unhealthy lifestyle factors was more common in axSpA patients than controls (35% vs. 19%, p=0.029), while no difference was found between the axSpA subtypes (Figure 1 a and b). Male patients more often reported several unhealthy lifestyle factors than female patients (Figure 1 c), with more frequent unhealthy alcohol use (19% vs. 9%, p=0.023) and overweight/obesity; BMI ≥25 (63% vs. 50%, p=0.043), while smoking, physical activity, and dietary habits were similar. In addition, older patients displayed more unhealthy lifestyle factors (Figure 1 d). Having ≥2 unhealthy lifestyle factors was associated with worse disease activity (ASDAS-CRP) (β-est [95% CI]) (0.34 [0.11: 0.58]), physical function (BASFI) (0.73 [0.18; 1.28]), pain (1.03 [0.39; 1.67]), fatigue (0.95 [0.24; 1.66]), and quality of life (EQ-5D) (-0.09 [-0.15; -0.02]) in axSpA patients, adjusted for age, sex, and axSpA subtype (all p≤0.010)

Table 1. Characteristics and lifestyle factors

	r-axSpA/nr-axSpA combined n = 250	Controls n =48
Female sex	116 (46%)	24 (48%)
Age, years	51 (13)	51 (14)
Symptom duration, years	7.7 (7.6)	N/A
ASDAS-CRP	1.8 (0.9)	N/A
BASFI	2.0 (2.2)	N/A
BASMI	3.0 (1.6)	N/A

BMI, not fulfil rec.	142 (57%)	15 (31%)*

Mean (SD) or n (%). * p<0.05 by Chi^2-test or Student t-test, as appropriate. Missing data: ≤ 2%.

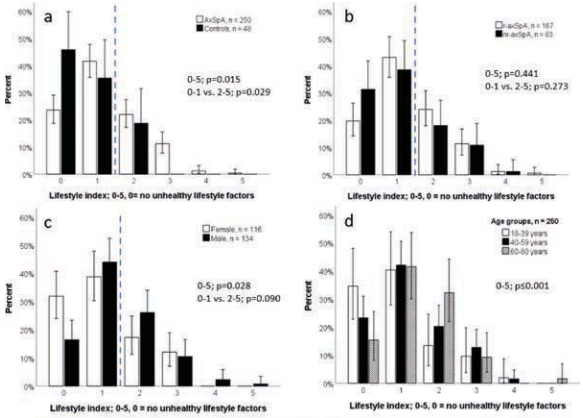

Figure. Percental distribution of lifestyle index; 0-5 and dicotomized; 0-1 vs. 2-5 for a) axSpA patients versus healthy controls, b) r-axSpA versus nr-axSpA, c) female versus male axSpA patients, d) axSpA patients in different age groups. Comparisons by Chi-square test.

Conclusion: Unhealthy lifestyle behaviours were more common in axSpA patients than controls, and in male axSpA patients compared to females. Having two or more unhealthy lifestyle factors was associated with worse disease activity, physical function, pain, fatigue, and quality of life in the axSpA patients.

POS0984

PREVALENCE OF AXSPA IN PATIENTS TREATED FOR CHRONIC BACK PAIN IN CHIROPRACTIC CLINICS: THE OREGON CHIROPRACTIC AXIAL SPONDYLOARTHRITIS STUDY (ORCAS) – AN INTERIM ANALYSIS

S. Kiwalkar[1], S. Bhalerao[2,3], K. Phung Nguyen[1], R. Quinn[1], D. Perham[3], W. Malatestinic[4], R. Bolce[4], T. Hunter[5], P. Khurana[6], A. Deodhar[1]. *[1]Oregon Health & Science University, Division of Arthritis & Rheumatic Diseases, Portland, United States of America; [2]University of Pittsburgh, Department of Physical Therapy, Pittsburgh, United States of America; [3]Private Practice, Chiropractor, Portland, United States of America; [4]Eli Lilly and Company, Medical Affairs, Indianapolis, United States of America; [5]Eli Lilly and Company, Value, Evidence, and Outcomes, Indianapolis, United States of America; [6]ICON plc, Global Health Economics, Outcomes Research and Epidemiology, Philadelphia, United States of America*

Background: Non-rheumatology settings such as chiropractor clinics, where chronic back pain (CBP; including chronic back, buttock, or hip pain) patients are first seen, lack consistency in referral of patients to rheumatologists where the underlying cause may be axial spondyloarthritis (axSpA).

Objectives: Primary objective was to estimate the prevalence of axSpA in CBP patients attending four chiropractic clinics in Portland, Oregon, referred to a rheumatology clinic using a referral strategy identifying features of spondyloarthritis (SpA).

Methods: Adults attending one of four chiropractor clinics between Nov 2020 and Nov 2021 for CBP starting before age of 45, without prior diagnosis of SpA were eligible for inclusion. Patients were referred to rheumatologist for diagnostic assessment via phone consultation, if they had inflammatory back pain (IBP) and/or ≥1 of the following features: a family history of SpA, inflammatory bowel disease (IBD), psoriasis, good response to non-steroidal anti-inflammatory drugs, history of heel pain, uveitis, or joint swelling. The subsequent rheumatology assessment included history, C-reactive protein, HLA-B27, x-ray and MRI of the sacroiliac joints. Based on the assessment, patients were categorized as radiographic axSpA, non-radiographic axSpA, peripheral SpA, or no SpA. Endpoints were summarized using descriptive statistics.

Table 1. Demographic and clinical characteristics stratified by diagnosis as confirmed by Rheumatologist

	Radiographic axSpA (N = 1)	Non-radiographic axSpA (N = 5)	Peripheral SpA Including PsA (N= 2)	No SpA (N = 55)
Age, years (Mean; SD)	73 (-)	36.8 (6.4)	46 (1.4)	45.1 (12.1)
Sex, Female – n (%)	0	4 (80.0)	2 (100)	32 (58.2)
Family history of spondyloarthritis, Yes – n (%)	0	1 (20.0)	1 (50.0)	9 (16.4)
Chronic back pain duration, years (Mean; SD)	49 (-)	12.4 (6.0)	11 (7.0)	15 (10.8)
Confirmed during rheumatology visit – n (%)				
IBP* (4 out of 5 criteria as checked by patient)	1 (100)	3 (60.0)	1 (50.0)	27 (49.1)
IBP* (4 out of 5 criteria per rheumatologist's opinion)	0	2 (40.0)	0	22 (40.0)
History of plantar fasciitis or Achilles tendinitis	0	4 (80.0)	2 (100)	14 (25.5)
History of peripheral joint swelling	0	0	1 (50.0)	8 (14.6)
Positive response to NSAIDs	1 (100)	1 (20.0)	2 (100)	21 (38.2)
Psoriasis	1 (100)	0	1 (50.0)	2 (3.6)
Inflammatory bowel disease	0	0	0	1 (1.9)
Uveitis	0	0	0	1 (1.8)
HLA-B27 positive	0	2 (40.0)	1 (50.0)	4 (7.3)
CRP, Above 10.0 mg/L	0	2 (40.0)	1 (50.0)	1 (1.8)
SI Joints X-ray positive for sacroiliitis (modified New York criteria)	1 (100)	0	0	1 (1.8)
SI Joints MRI positive for active inflammation	1 (100)	3 (60.0)	0	0

*According to the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA

Results: A total of 3,103 visits were recorded at four chiropractic offices between Nov 2020 and Nov 2021. Top ten chief complaints are presented in Figure 1. In total, 115 patients were referred by the chiropractors and 84 patients were confirmed to be eligible. Of the 74 patients who provided consent, 59 (79.7%) had IBP, and 66 (89.2%) had at least one clinical SpA feature. At interim data lock, 63 patients were fully assessed by a rheumatologist, of which 7 (11.1%) were HLA-B27 positive and 24 (38.1%) had rheumatologist-evaluated IBP. Eight (12.7%) patients had SpA, 6 (9.5%) were diagnosed as axSpA and fulfilled Assessment of Spondyloarthritis International Society (ASAS) classification criteria, 1 (1.6%) patient was diagnosed as psoriatic arthritis without imaging evidence of axial involvement and fulfilled Classification Criteria for Psoriatic Arthritis, and 1 (1.6%) had undifferentiated peripheral SpA and fulfilled ASAS Classification Criteria.

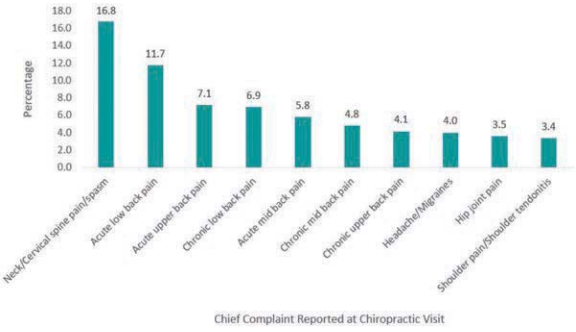

Figure 1. Chief complaints reported by patients at chiropractor visits (n=3103)

Conclusion: More than 10% of patients attending chiropractic clinics for musculoskeletal complaints had undiagnosed SpA conditions, with axSpA being the most common. Educational efforts targeted at chiropractors to suspect and refer appropriate cases to rheumatologists are needed.

MILD PSORIASIS SEEMS OFTEN UNDERDIAGNOSED IN PATIENT WITH AXIAL SPONDYLOARTHRITIS

L. Van Marle[1], A. Rondags[2], B. Horvath[2], F. Wink[3], S. Arends[1], A. Spoorenberg[1]. *[1]University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, University of Groningen, Dermatology, Groningen, Netherlands; [3]Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: Axial spondyloarthritis (axSpA) is known to be associated with several extra-skeletal manifestations, including the inflammatory skin disease psoriasis. It is important to recognize and diagnose psoriasis timely in axSpA to provide the most optimal treatment and outcome for both axSpA and psoriasis. Furthermore, in patients suspected of axSpA, it may add to making the axSpA diagnosis.

Objectives: To explore the self-reported prevalence of psoriasis in axSpA patients using a questionnaire with prototypical color pictures, and to compare this with the prevalence of a verified diagnosis. Secondly, to explore if there are differences in disease and patient characteristics between axSpA patients with and without self-reported psoriasis.

Methods: All patients from the Dutch Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort included before June 2016, were sent a questionnaire with self-screening psoriasis questions. The applied self-diagnostic psoriasis question "Do you have psoriasis?" was supported with the following brief elucidation: "Psoriasis is a skin disease in which red and scaly patches develop on the body, especially on the elbows, knees and hairy head. The nails can also be affected, and sometimes there are joint complaints." In addition, to enable patients to self-assess the presence of psoriasis more accurately, prototypical color pictures of psoriasis lesions were added. Patients could reply with "no", "yes, in the past" or "yes, currently". In patients who indicated having psoriasis symptoms, a medical record check was done to verify previously diagnosed psoriasis. The diagnosis of psoriasis was considered valid if it was described in the medical record by a dermatologist or rheumatologist.

Results: Of the 592 questionnaires sent, 471 (79.6%) were returned, of which 448 (75.7%) were eligible for analysis. Of these 448 included patients, 79% were diagnosed with AS and 21% with nr-axSpA, mean (±SD) age was 50.1±12.7 years, 64% were male, median (IQR) SpA symptom duration was 21.0 (12.0-32.0) years, 79% were HLA-B27 positive and mean $ASDAS_{CRP}$ was 2.2±1.0. History of peripheral arthritis, enthesitis and dactylitis was present in 39%, 20% and 7% of patients, respectively. The male-female ratio between the 448 included and 144 excluded patients was similar. Excluded patients were significantly younger (43.3 ± 13.6, p<0.001). Of the 448 respondents, 58 (13%) had a positive self-screening for psoriasis symptoms, currently or in the past. In 28 (48%) of these 58 patients, psoriasis diagnosis could be verified by medical records, resulting in a confirmed psoriasis prevalence rate of 6.3%. AxSpA patients reporting psoriasis symptoms without a verified diagnosis mentioned more often mild than moderate or severe psoriasis symptoms (25% vs. 3%, p=0.02) and their psoriasis lesions were less often located on the torso area (3% vs. 18%, p=0.04), intergluteal cleft (0% vs. 25%, p=0.02) and legs (7% vs. 43%, p<0.01) compared to axSpA patients with a confirmed diagnosis. Of the 31 axSpA patients who reported currently active psoriasis (irrespective of confirmed diagnosis), 23 (74%) had only mild psoriasis symptoms.

Conclusion: Especially mild psoriasis seems often underdiagnosed in patient with axSpA according to a patient questionnaire with prototypical pictures of psoriasis lesions. This questionnaire could be beneficial in tracing patients with undiagnosed psoriasis in daily clinical practice, however further validation of this questionnaire is needed in daily clinical practice.

POS0986

SELF-REPORTED PHYSICAL ACTIVITY IN PATIENTS WITH AXSPA: ADHERENCE TO PUBLIC HEALTH RECOMMENDATIONS AND ASSOCIATION WITH HEALTH STATUS IN TWO DUTCH COHORTS

M. Carbo[1], B. Hilberdink[2], D. Paap[1], F. Wink[3], T. P. M. Vliet Vlieland[2], S. Van Weely[2], A. Spoorenberg[1], S. Arends[1]. *[1]University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]Leiden University Medical Center, Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; [3]Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: In general, regular physical activity (PA) is associated with a reduced risk of cardiovascular disease and all-cause mortality. In people with axial spondyloarthritis (axSpA) specifically, regular PA has shown beneficial effects on function, spinal mobility and pain. The World Health Organization (WHO) developed public health recommendations for the frequency, intensity and duration of PA in adults required to offer significant health benefits and mitigate health risks.

Objectives: To assess the proportion of axSpA patients fulfilling the WHO PA recommendations and to investigate the association of the amount of PA with health status and quality of life (QoL).

Methods: Patients from two Dutch cohorts were included; one in the Northern (GLAS cohort, n=148) and one in the Western (LUMC cohort, n=193) part of the Netherlands. The (m)SQUASH was used to assess the type, intensity and time spent on PA during a normal week in the past month. Fulfillment of the WHO PA recommendations was defined as aerobic PA of least 150 minutes of moderate-intensity or 75 minutes of vigorous-intensity (or an equivalent combination), and muscle-strengthening activities twice a week. Univariate linear regression analysis was used to explore the association of (m)SQUASH total score with health status (ASAS-HI) and quality of life (ASQoL). Multivariate regression analysis was used to correct these associations for age, gender, BMI and ASDAS as potential confounders.

Results: In the GLAS cohort, 59% were male, mean age (± SD) was 48.5 ± 13.2 years, median (IQR) ASAS-HI was 4.4 (1.9-8.1) and median ASQoL was 4 (1-9). In the LUMC cohort, 69% were male, mean age was 55.7 ± 14.1 years, and median ASAS-HI was 5.3 (2.1-8.0). Of these GLAS and LUMC patients, 57 (40%) and 62 (35%) fulfilled the WHO PA recommendations, respectively. Total (m)SQUASH score was significantly associated with ASAS-HI (GLAS cohort: R^2 0.16, B (95%CI) -0.4 (-4.3;-1.6); LUMC cohort: R^2 0.13, B (95%CI) -0.3 (-4.3;-2.0)) and ASQoL (GLAS cohort: R^2 0.18, B (95%CI) -4.4 (-3.5;-1.4). These associations remained significant after correcting for age, gender, BMI and ASDAS (Table 1).

Conclusion: In both Dutch cohorts, only 35-40% of axSpA patients fulfilled the WHO PA recommendations, which seems less compared to the average 48% in the Dutch adult population[1]. AxSpA patient reporting a higher level of PA had better health status and QoL. Therefore, in daily clinical practice, greater awareness and focus on moderate-to-high intensity and muscle strengthening activity is desirable for axSpA patients.

POS0987

DETERMINANTS OF CLINICALLY IMPORTANT WORSENING IN EARLY AXIAL SPA: ANALYSIS OF THE DESIR COHORT OVER 5 YEARS

F. Hamitouche[1], S. Kumaradev[2,3], D. Van der Heijde[4], S. Ramiro[5], A. Sepriano[4,6], A. Moltó[1,2]. [1]*Cochin Hospital, Rheumatology Department, Paris, France;* [2]*Université de Paris, INSERM U1153, CRESS, Paris, France;* [3]*Université de Paris, Epidemiology of Ageing and Neurodegenerative Diseases, Inserm U1153, CRESS, Paris, France;* [4]*Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands;* [5]*Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands;* [6]*Universidade Nova de Lisboa, NOVA Medical School, Lisboa, Portugal*

Background: A definition for clinically important worsening (CIW) of axSpA has been proposed by ASAS: i.e. an increase of ≥0.9 points of ASDAS. However, it is unknown how this definition performs in an early axSpA cohort.
Objectives: To determine the prevalence of CIW in a population of early axSpA, as well as the association between the occurrence of CIW and the presence of concomitant signs of inflammation; finally, to determine whether MRI inflammation was predictive of a future CIW.
Methods: 708 patients with early axSpA from the French DESIR cohort were included in the analysis. Patients were followed every 6 months for the first 2 years and annually thereafter. All patients had an MRI of spine and sacroiliac joints at baseline, but only patients from the APHP centers performed those at 2 and 5 years. Prevalence of CIW was calculated during the 5 years of follow-up in the cohort. The association between CIW and concomitant objective signs of inflammation (such as swollen joint count) was assessed over time using mixed models adjusted for sociodemographic and other clinical covariates. CIW predictive factors including the predictive capacity of MRI inflammation (measured by SPARCC at SIJ and spine) and MRI structural damage (defined by presence of ≥5 structural lesions of SI joints or spine) on the occurrence of a future CIW (time-lagged models) were evaluated.
Results: Total number of CIW was 378 in 5 years with 42.8% (303/708) of patients presenting at least one CIW during the follow-up. There were no significant sociodemographic or clinical differences at inclusion between patients with at least one episode of CIW and those without CIW during follow-up.
In the association models, concomitant tender joint count (OR 1.02, CI95%[1.00; 1.03]) and ASAS-NSAID score last week (OR 1.00, CI95%[1.00; 1.01]) were significantly associated with CIW over time. Presence of MRI-SIJ inflammation (OR (per SPARCC point) 1.02, CI95%[1.01; 1.04]) and MRI-SIJ structural damage (OR 2.74, CI95%[1.27; 5.93]) were predictive of future (next visit) occurrence of CIW.
Conclusion: Patients with CIW according to the ASAS definition had significantly more objective signs of inflammation concomitantly but also over time. These data support the construct validity of this definition of CIW in an early axSpA population. MRI-SIJ inflammation and structural damage may have a predictive role in the subsequent occurrence of CIW.

POS0988

ANKYLOSING SPONDYLITIS (AS) ACTIVITY DURING THE YEAR AFTER CHILDBIRTH.

O. Krichevskaya[1], E. Ilinykh[1], T. Dubinina[1], S. Glukhova[1], A. Demina[1], I. Andrianova[1]. [1]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of Axial Spondyloarthritis, Moscow, Russian Federation*

Background: Currently, data on the course of AS during pregnancy are being accumulated. However, information about the activity of AS in the postpartum period including against the background of lactation, remains scanty and contradictory.
Objectives: To assess the dynamics of activity of AS during the year after childbirth, to identify predictors of high activity.
Methods: 44 women with confirmed AS (modified New York criteria, 1984) were followed within 1 year after childbirth. The visits were carried out in 1, 6 and 12 months after delivery. The average age of the patients was 32,5 ± 5,8 years, the duration of the disease was 149,0 ± 96,3 months. The activity according to the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) in the 1st, 2nd and 3rd trimesters of pregnancy was 2,8 ± 1,9; 2,9 ± 1,9 and 2,7 ± 1,8, respectively. The Ankylosing Spondylitis Disease Activity Score CRP (ASDAS-CRP) was 1,8 [1,6; 2,5]; 2,1 [1,5; 2,9] and 2 [1; 3,5], respectively. Delivery period was 39,0 ± 1,2 weeks. Lactation was established in 40 women and the duration was 10 [4; 12] months.
Results: Subjective deterioration of well-being was noted by 36 (81,8%) women after 8 [4; 17] weeks after delivery, while 29 (65,9%) patients associated deterioration of well-being with increased activity of AS, including recurrence of uveitis and arthritis, and 7 cases of increased severity of back pain of mechanical rhythm was revealed. 1 month after delivery, 39 patients (88,6%) reported back pain with NRS intensity of 3,0 [2,0; 6,0]; night pain – 29 women with intensity of 3,0 [2,0; 6,0]. 6 months after delivery, back pain was observed in 38 (86,4%) patients, its intensity was 4,0 [3,0; 5,0]; nocturnal pain – in 32 women with intensity of 3,0 [2,0; 5,0]. 12 months after delivery, 33 (75%) women experienced back pain with NRS intensity of 4,0 [3,0; 6,0]; Night pain – 27 women with intensity of 2,0 [1,0; 4,0]. The BASDAI at 1, 6 and 12 months after giving birth was: 2,4 [1,4; 4,2]; 2,6 [1,4; 4,4]; 2,7 [1,5; 4,1], respectively (p > 0,05). ASDAS-CRP was 2,0 [1,2; 2,7]; 1,9 [1,4; 2,5]; 1,7 [1,3; 2,3], respectively (p > 0,05). CRP level – 3,4 [2,0; 8,6], 3,5 [1,0; 7,8] and 2,6 [0,8; 8,2] mg/l, respectively (p >0,05). There were no differences between activity during 1 year after childbirth and during pregnancy. There were no differences between the values of BASDAI, ASDAS-CRP, CRP, and the severity of night pain between women with and without lactation. Predictors of high AS activity (BASDAI ≥ 4) 1 month after delivery were: BASDAI ≥ 4 in the 1st trimester (OR 8,1; 95% CI 1,8 – 37,0; p = 0,006) and 2nd trimesters of pregnancy (OR 5,1; 95% CI 1,2 – 20,6; p = 0,02); NRS back pain > 4 in the 2nd trimester (OR 4,3; 95% CI 1,1 – 17,2; p = 0,04); cancellation of bDMARD therapy in the 1st trimester of pregnancy (OR 21,0; 95% CI 1,0 – 440,9; p = 0,05). Predictors of high AS activity in 6 months after delivery were: BASDAI ≥ 4 in the 1st trimester (OR 6,5; 95% CI 1,5 – 28,7; p = 0,01), in the 2nd (OR 6,7; 95% CI 1,6 – 27,8; p = 0,009) and in the 3rd trimesters of pregnancy (OR 8,7; 95% CI 1,9 – 38,6; p = 0,005); high activity in 1 month after delivery (OR 4,0; 95% CI 1,0 – 15,9; p < 0,05). The predictor of high activity in 12 months after delivery was high activity 6 months after delivery (OR 8,3; 95% CI 1,9 – 37,2; p = 0,005).
Conclusion: There was no increase in AS activity according to BASDAI and ASDASCRP within 1 year after childbirth, while 66% of women noted a subjective deterioration of well-being associated with AS symptoms intensification. High AS activity during pregnancy was a risk factor for high activity within 6 months after delivery. Given the generally accepted opinion that AS activity at the time of conception is a predictor of activity during gestation, we can talk about the importance of pregnancy planning from the point of view of the postpartum period. Further studies on large groups of patients are required to clarify the dynamics of AS activity after childbirth.

DEVELOPMENT OF INTERNATIONAL CONSENSUS ON A STANDARDIZED IMAGE ACQUISITION PROTOCOL FOR DIAGNOSTIC EVALUATION OF THE SACROILIAC JOINTS BY MRI – AN ASAS-SPARTAN COLLABORATION.

Reijnierse[10], M. Tuite[11], W. P. Maksymowych[12]on behalf of ASAS SPARTAN MRI Working Group. [1]*University of Alberta, Radiology and Diagnositc Imaging, Edmonton, Canada;* [2]*Ruhr-University Bochum, Rheumatology, Herne, Germany;* [3]*Brooke Army Medical Center, Radiology, Fort Sam Houston, Texas, United*

States of America; [4]Hospital for Special Surgery, Radiology & Imaging, New York, New York, United States of America; [5]Charité Universitaetsmedizin Berlin, Clinic for Radiology, Berlin, Germany; [6]Sheba Medical Center, Radiology, Tel Hashomer, Israel; [7]Ghent University, Radiology, Ghent, Belgium; [8]Aarhus University Hospital, Radiology, Aarhus, Denmark; [9]McMaster University, Radiology, Hamilton, Ontario, Canada; [10]Leiden University Medical Center, Radiology, Leiden, Netherlands; [11]University of Wisconsin School of Medicine and Public Health, Radiology, Madison, Wisconsin, United States of America; [12]University of Alberta, Medicine, Edmonton, Canada

Background: In 2009, ASAS published a 'Definition of active sacroiliitis on MRI for classification of axial spondyloarthritis (axSpA)'. This definition relied on two MRI sequences to make this determination – semicoronal T1 and STIR. Since then, this approach has frequently been used for diagnosis, even though that was never the intent of the definition. In 2015, the European Society of Skeletal Radiology (ESSR) published its recommendations for an SIJ MRI image acquisition protocol (IAP) for diagnostic purposes that required 4 MRI sequences but there is still no IAP that has been widely accepted as a minimum standard worldwide. In 2020, an informal survey of 24 academic sites (12 Europe, 12 North America) confirmed that 24/24 sites performed a minimum of 3 MRI sequences for diagnosis (19 performed 4-8 sequences) because the 2-sequence protocol was considered inadequate.
Objectives: To develop the minimum requirements for a standardized IAP for MRI of the sacroiliac joints for diagnostic ascertainment of sacroiliitis.
Methods: All radiologist members of the ASAS and SPARTAN Classification in axSpA (CLASSIC) project, along with one European and one North American rheumatologist with extensive MRI experience in SpA clinical practice and research, were invited to participate in a consensus exercise. A draft IAP was circulated to all participants along with background information and justification for the draft proposal. Feedback on all issues was received by email, tabulated and recirculated. Participants were broadly in favour of the proposal and two months later a teleconference meeting took place and remaining points of contention were resolved. Examples of the proposed IAP performed on new, 10 and 22 years' old MRI scanners were made available for review in DICOM format. Next the revised draft of the IAP was presented at the ASAS annual meeting to the entire membership on 14 January 2022, and voted on.
Results: A 4-sequence IAP, 3-semicoronal and 1-semiaxial, is recommended for diagnostic ascertainment of sacroiliitis and its differential diagnoses (Table 1). It must meet the following requirements: Semicoronal sequences should be parallel to the dorsal cortex of the S2 vertebral body, and include: 1) a sequence sensitive for the detection of active inflammation being T2-weighted with suppression of fat signal; 2) a sequence sensitive for the detection of structural damage in bone and bone marrow with T1-weighting; 3) a sequence that is designed to optimally depict the bone-cartilage interface of the articular surface and be sensitive for detection of bone erosion; plus 4) a semiaxial sequence sensitive for inflammation detection. The IAP was approved at the ASAS annual meeting by a vote of the entire membership with 91% in favour.

Table 1. A standardized SIJ MRI Acquisition Protocol for diagnostic ascertainment of sacroiliitis

Orientation	Sequence	Target Lesion(s)
Semicoronal Parallel to the dorsal cortex of the S2 vertebral body	T1-weighted Spin Echo	Structural: Fat lesions, erosion, sclerosis, backfill, ankylosis.
	T2-weighted with suppressed fat signal (STIR, T2FS or equivalent)	Inflammatory: Bone marrow edema (BME)
	T1-weighted with suppressed fat signal (2D or 3D T1FS)	Structural: Erosion of the articular surface
Semiaxial Perpendicular to semicoronal	T2-weighted with suppressed fat signal (STIR, T2FS or equivalent)	Inflammatory: Bone marrow edema (BME)

Conclusion: A standardized IAP for MRI of the sacroiliac joints for diagnostic ascertainment of sacroiliitis is recommended and should be comprised of a minimum of 4 sequences, in 2-planes, that will optimally visualize inflammation, structural damage, and the bone-cartilage interface.

POS0990 DEEP LEARNING ALGORITHMS FOR MAGNETIC RESONANCE IMAGING OF INFLAMMATORY SACROILIITIS IN AXIAL SPONDYLOARTHRITIS.

H. Y. Chung[1], C. W. S. Chan[2]. *[1]Chiron Medical, Rheumatology, Hong Kong, Hong Kong (SAR); [2]The University of Hong Kong, Rheumatology and clinical immunology, Hong Kong, Hong Kong (SAR)*

Background: Magnetic resonance imaging (MRI) of the sacroiliac (SI) joints is increasingly important in the management of axial spondyloarthritis (SpA). Artificial intelligence (AI) may be the next crucial step in enabling the widespread application of MRI.
Objectives: To develop a deep learning algorithm for detection of active inflammatory sacroiliitis in short tau inversion recovery (STIR) sequence MRI.
Methods: A total of 326 participants with axial spondyloarthritis (SpA), and 63 participants with non-specific back pain (NSBP) were recruited. STIR MRI of the SI joints was performed and clinical data were collected. Region of interests (ROIs) were drawn outlining bone marrow edema, a reliable marker of active inflammation, which formed the ground truth masks from which "fake-colour" images were derived. Both the original and "fake-colour" images were randomly allocated into either the training and validation dataset or the testing dataset. Attention U-net was used for the development of deep learning algorithms. As comparison, an independent radiologist and rheumatologist blinded to the ground truth masks, were tasked with identifying bone marrow edema in the MR images.
Results: Inflammatory sacroiliitis were identified in 1398 MR images from 228 participants. No inflammation was found in 3944 MR images from 161 participants. The mean sensitivity of algorithms derived from the original dataset and "fake-colour" image dataset were 0.86±0.02, and 0.90±0.01 respectively. The mean specificity of algorithms derived from the original and "fake-colour" image dataset were 0.92±0.02, and 0.93±0.01 respectively. The mean testing dice coefficients were 0.48± 0.27 for the original dataset and 0.51±0.25 for the "fake-colour" image dataset. The area under the curve of the receiver operating characteristic (AUC-ROC) curve of the algorithms using original dataset and "fake-colour" image dataset were 0.92 and 0.96 respectively. Sensitivity and specificity of algorithms were comparable to interpretation by a radiologist, but outperformed the rheumatologist.
Conclusion: An MRI deep learning algorithm was developed for detection of inflammatory sacroiliitis in axial SpA.

POS0991 PREDICTORS OF DEVELOPMENT OF ADVANCED SPINAL ANKYLOSIS/BAMBOO SPINE IN AXIAL SPONDYLOARTHRITIS: RESULTS FROM REAL-LIFE DATA

B. Farisogullari[1], G. K. Yardımcı[1], E. Bilgin[1], E. C. Bolek[1], E. Duran[1], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], U. Kalyoncu[1], A. İ. Ertenli[1]. *[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: In axial spondyloarthritis (axSpA), intervertebral ossification bridges of consecutive vertebrae may progress to advanced spinal ankylosis and bamboo spine over the years [1].
Objectives: To identify demographic, clinical, disease activity and treatment factors associated with development of bamboo spine / advanced spinal ankylosis and bamboo spine-only in the Hacettepe University Rheumatology Biologic Registry (HUR-BIO) cohort.
Methods: HUR-BIO is a prospective, single center database of biological disease-modifying antirheumatic drug (bDMARD) treatments. 770 patients on bDMARDs treatment had both lumbar and cervical lateral radiographies at the time of the data collection, and were included in the study. Bamboo spine was defined Bath Ankylosing Spondylitis Radiologic Index (BASRI)-spine grade 4 with a complete fusion of lumbar and cervical spines. Advanced spinal ankylosis was defined as the presence of at least two intervertebral adjacent bridges and/or

Table 1. Predictors of Bamboo Spine and Advanced Spinal Ankyloses, and Bamboo Spine-only

Multivariable Model

	Bamboo Spine and Advanced Spinal Ankylosis		Bamboo Spine	
Covariates	**OR (95% CI)**	**p-value**	**OR (95% CI)**	**p-value**
Age	1.12 (1.07-1.17)	**<0.001***	1.17 (1.09-1.3)	**<0.001***
Male (vs female)	4.26 (1.75-10.41)	**0.001***	8.31 (2.09-33.1)	**0.003***
Delay Diagnosis (≥ 24 months vs <24 months)	2.7 (1.27-5.74)	**0.01***	2.39 (0.85-6.71)	0.09

fusion at the lumbar and/or cervical spine without bamboo spine. We analyzed the ensemble of variables by multivariable logistic regression to identify predictors associated with bamboo spine / advanced spinal disease, and bamboo spine-only.
Results: In the study, there were 99 patients with advanced spinal ankylosis and 78 patients with bamboo spine. Older age (OR 1.12, 95% CI 1.07-1.17), male gender (OR 4.26, 95% CI 1.75-10.41), delay diagnosis ≥ 24 months (OR 2.7, 95% CI 1.27-5.74), obesity (OR 4.03, 95% CI 1.53-10.64), hip involvement (OR 4.94, 95% CI 1.94-12.6), smoking ≥ 10 package/year (OR 2.28, 95% CI 1.003-5.2) were significantly associated factors with bamboo spine / advanced spinal ankylosis. Similarly, older age (OR 1.17, 95% CI 1.09-1.3), male gender (OR 8.31, 95% CI 2.09-33.1), obesity (OR 5.15, 95% CI 1.25-21.27), hip involvement (OR 4.74, 95% CI 1.32-16.96) and smoking ≥ 10 package/year (OR 3.19, 95% CI 1.03-9.89) were showed statistical significance with bamboo spine (**Table 1**).
Conclusion: Data on the predictors of development of advanced spinal ankylosis and bamboo spine are scarce. In this study, we showed that older age, male gender, delay in diagnosis, obesity, hip involvement and smoking are factors that predict the development of advanced spinal involvement in axSpA.

POS0992 CLINICAL AND IMAGING FEATURES IN SPONDYLOARTHRITIS PATIENTS WITH AND WITHOUT HLA-B27 AND HLA-B51: A VALIDATION COHORT

F. Carubbi[1], A. Alunno[1], J. Cipollone[1], C. Martini[1], V. Moronti[1], C. Ferri[1]. *[1]Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*

Background: Despite being commonly expressed in the general population, the human leucocyte antigen (HLA)-B27 allele strongly increases the susceptibility to develop spondyloarthritis (SpA). Likewise, the association between the HLA-B51 allele and the development of Behçet's disease is well documented. In a previous pilot study, we identified similarities and differences in patients with axial or peripheral SpA according to the presence of HLA-B51 only, HLA-B27 only or neither of the two.
Objectives: To investigate the clinical and imaging findings of SpA patients according to the absence or presence of HLA-B27 or HLA-B51 in an independent validation cohort.
Methods: We retrospectively analyzed patients with axial or peripheral SpA, according to the ASAS criteria, referring to our institution between 2020 and 2021. All patients had been tested for HLA-B alleles. Patients with HLA-B51 haplotype and fulfilling the criteria for Behçet's disease were excluded.
Results: The independent validation cohort included 185 patients and was comparable to the original cohort of 236 patients with regard to age, gender, age at diagnosis and symptom duration. In line with the findings in the original cohort we observed that aphtous lesions were more prevalent in patients with HLA-B51 (p< 0.001) while inflammatory bowel disease was more prevalent in the double negative group (p=0.0006). Unlike the original cohort, patients of the validation cohort did not show a different prevalence of inflammatory back pain (IBP) at disease onset or in the disease course based on the HLA status. A sub-analysis by gender demonstrated a comparable prevalence of IBP in males and females within the 3 groups. As novel finding, we observed that enthesitis and psoriasis were significantly more prevalent in the double negative group compared to the B27 and B51 groups (p=0.004) and their prevalence did not differ when comparing B27 and B51 groups. With regard to imaging in patients with axial manifestations, in the original cohort we observed that sacroiliitis, assessed by X-ray or magnetic resonance imaging (MRI), were more prevalent in double negative and HLA-B27 patients, compared to HLA-B51 patients and the latter showed a significant negative association with sacroiliitis on imaging (OR 0.342 CI 0.189-0.619 p<0.0005). In this validation cohort we observed that the prevalence of sacroiliitis on X-ray was similar in the 3 groups while sacroiliitis on MRI scan was significantly more prevalent in the B27 group (81%) compared to the double negative (63%) and the B51 group (51%). A negative association between sacroiliitis on MRI and HLA-B51 but not double negative status was observed in the validation cohort (OR=0.23, 95% CI=0.07-0.8, p=0.02).
Conclusion: Our findings underscore the clinical and radiological heterogeneity of patients with SpA and HLA-B51 alone or neither HLA-B27 nor HLA-B51 compared to those with HLA-B27 only and underline the need to explore further this area by means of registry data with large real-life cohorts.

POS0993 RADIOLOGICAL CERVICAL INVOLVMENT IN ANKYLOSING SPONDYLITIS

S. Carvès[1], R. Burns[2], O. Fogel[1], B. Banneville[3], R. Belkhir[4], J. Gross[5], B. Saint-Marcoux[6], L. Semerano[7], J. Sellam[8], P. Richette[9], H. Guérini[2], C. López-Medina[1], C. Miceli Richard[1]. *[1]APHP, Hopital Cochin, Rheumatology, Paris, France; [2]APHP, Hopital Cochin, Radiology, Paris, France; [3]APHP, Hopital de la Pitié Salpétrière, Rheumatology, Paris, France; [4]APHP, Hopital Bicêtre, Rheumatology, Le Kremlin-Bicêtre, France; [5]APHP, Hopital Henri Mondor, Rheumatology, Créteil, France; [6]Hopital Intercommunal Robert Ballanger, Rheumatology, Aulnay-sous-Bois, France; [7]APHP, Hopital Avicennes, Rheumatology, Bobigny, France; [8]APHP, Hopital Saint-Antoine, Rheumatology, Paris, France; [9]APHP, Hopital Laribosière, Rheumatology, Paris, France*

Background: Cervical involvement in ankylosing spondylitis (AS) is particularly disabling and has been poorly studied yet. Actual radiologic scoring design to assess disease progression does not provide a comprehensive picture of the cervical involvement in AS. [1] Association with clinical features such as psoriasis are discussed.
Objectives: We aimed to assess radiographic features of cervical involvement in AS and clinico-biological parameters associated with this specific radiographic location.
Methods: Cross-sectional study based on radiographic analysis of a subgroup of patients included in the French BambooSpine cohort, originally designed to study the genetic risk factors of AS structural severity. The analysis was based on patients included in Parisian hospitals to have access to images of the entire spine on the Picture Archiving and Communication System (PACS) shared by all University Hospitals in Paris. A double reading of the images was performed by a rheumatologist/radiologist pair until consensus was reached, to identify syndesmophytes, zygapophyseal joint (ZJ) involvement and posterior ligament structures (PLS) at each cervical level, syndesmophytes in the thoracic region, and ZJ and PLS involvement in the lumbar region.
Results: Of the 113 assessed patients, 101 were men, mean age 53 years (+/- 11 years) with 27 years (+/- 13 years) of disease duration (Table 1). Of those whose HLA B27 status was known, 85% (70/82) were carriers. Among 86 patients with radiological cervical involvement, 83% had syndesmophytes, 86% had ZJ involvement and 24% had PLS involvement. In the cervical region, 13 patients (15%) had zygapophyseal fusion without syndesmophytes. 26/113 patients were completely free of any cervical involvement while 30/113 had a maximal cervical involvement (anterior and posterior). In univariate analyses, HLA-B27 was

significantly associated with ZJ involvement at the cervical and lumbar level (p=0.016). Cervical involvement of any type was not associated with psoriasis. Low educational level (not beyond secondary school) was significantly associated with syndesmophytic involvement (p=0.035). There was a non-significant trend for an association between arthritis and ZJ involvement.

Table 1. Clinical features

Men (n,%)	101/113	89,4%
Age at diagnosis (mean, SD)	31,2	11,68
Duration of evolution (mean, SD)	27,0	13,0
Smoking ever (n,%)	65/112	58,0 %
Chronic Back Pain (for > 3 months) (n,%)	109/113	96,5%
Chest pain	45/110	40,9%
Buttock pain	78/109	71,6%
Arthritis	36/111	32,4%
Enthesitis	38/112	33,9%
Dactylitis	6/111	5,4%
HLA B27	70/82	85,4%
CRP	87/103	84,5%
X ray sacro-iliitis	112/112	100%
Personnal history		
-Uveitis	41/113	36,3%
-Inflammatory bowel disease	13/113	11,5%
-Reactive arthritis	2/112	1,8%
-Psoriasis	19/111	17,1%

Conclusion: Cervical involvement was very frequent (76% of this severe AS population) but not associated with psoriasis, as usually thought. Zygapophyseal involvement was present in 86 % of cases and exclusive in 15 % of cases. This latter radiological form of the disease, i.e. without syndesmophytes, is usually more difficult to diagnose, and should be systematically assessed among AS patients with cervical pain and/or patients with reduced cervical mobility.

POS0994 DEVELOPMENT OF AN AUTOMATED ALGORITHM BASED ON METHODS OF ARTIFICIAL INTELLIGENCE TO ASSIST IN THE PREDICTION OF CORRECT REFERRALS OF PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS BY USING PATIENT HISTORY TEXTS

H. Kratz[1,2], S. Ginzel[3], S. Ohrndorf[4], X. Baraliakos[5,6], S. Tsiami[5,6], E. Haedecke[2,3], N. Doll[2,3], J. Holz-Müller[1,2], S. Rüping[3], F. Behrens[1,2,7], M. Köhm[1,2,7]. *[1]Fraunhofer-Institute for Translational Medicine & Pharmacology ITMP, Clinical Research, Frankfurt, Germany; [2]Fraunhofer Excellence Cluster for Immune-Mediated Diseases CIMD, Clinical Research, Frankfurt, Germany; [3]Fraunhofer-Institute for Intelligent Analysis and Information Systems IAIS, Knowledge Discovery, St. Augustin, Germany; [4]Charité Universitätsmedizin, Rheumatology, Immunology, Berlin, Germany; [5]Ruhr-Universität Bochum, Rheumatology, Bochum, Germany; [6]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [7]University Hospital Frankfurt, Rheumatology, Frankfurt, Germany*

Background: Diagnosis and treatment of PsA and axSpA is often delayed due to missing clear diagnostic criteria and limitations in resources for referral to rheumatologist including high numbers of incorrect referrals. Primary care is usually provided by either general practitioner, dermatologists, or orthopedics. Clinical discriminators with a high specificity for rheumatic conditions include morning stiffness (MST; peripheral or axial, >30min). Artificial intelligence (AI) and natural language processing (NLP) methods offer algorithms for learning systems to recognize disease associated terms and classify clinical phenotypes using large data sets that may support early identification of patients with suspected diagnosis of PsA or axSpA.

Objectives: AI and NLP methods are used to identify patients with typical attributes for inflammation by using morning stiffness as one potential discriminating pattern, which can be detected automatically and might help to prioritize referral for rheumatologist appointments.

Methods: Within a multicentre observational study, patients with visits at the rheumatologist with a suspected diagnosis of PsA or axSpA from the referral primary care provider were recruited. All data on clinical examinations and findings were collected and evaluated by rheumatologists in focus on criteria for diagnosis of PsA/axSpA (gold standard for evaluation). Unstructured text from the patient history was used to extract diagnosis-relevant characteristics. The information extraction algorithms used NLP models to detect expert curated "morning stiffness" (MST) keywords and puts them into a contextualized framework that allows to capture possible negations.

Results: A total of 116 patients were recruited (73 female, 63%) with a median age of 42 (IQR: 34-54). 51 patients were referred as axSpA (44%) and 60 as PsA (52%) by primary care providers. After preselection for PsA and axSpA patients, we observed a 23% rate of referrals without rheumatic diagnosis. Only 7.1% of patients were admitted without signs of MST, 29% with axial MST, 35% with peripheral MST and 28% with both MST types. Average morning stiffness duration was recorded as 35 minutes; patients with a finally confirmed rheumatic diagnosis had a higher average MST duration reported (36 minutes) compared to patients without a confirmed diagnosis. Our AI assisted extraction of MST identified MST in 82.7% of patient history texts. In 75% NLP methods correctly identified the negation of MST symptoms (6 of 8), and 94% of MST was detected when both axial and peripheral joints were affected (30 of 32). Manual inspection of 20 patient history reports where MST was not detected by our automated algorithm revealed that 17 reports did not contain information about MST and three mention unspecific early morning discomfort, without mention of MST.

Conclusion: The high rate of correct detection of MST from patient history text using NLP methods allowed us to assess the potential for NLP models to support automated analysis of patient reports to facilitate intelligent patient referral.

Lambert[11]. *[1]CARE ARTHRITIS LTD, Rheumatology, Edmonton, Canada; [2]University of Alberta, Medicine, Edmonton, Canada; [3]Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; [4]University Hospital Zurich, Rheumatology, Zurich, Switzerland; [5]Geneva University Hospital, Rheumatology, Geneva, Switzerland; [6]First Faculty of Medicine, Charles University, Rheumatology, Prague, Czech Republic; [7]University Hospital Ghent, Rheumatology, Ghent, Belgium; [8]UMC Ljubljana, Radiology, Ljubljana, Slovenia; [9]Geneva University Hospitals, MSK Radiology Unit, Radiology Section – Diagnostic Department, Geneva, Switzerland; [10]Sheba Medical Center, Radiology, Tel Aviv, Israel; [11]University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada*

Background: The web-based Spondyloarthritis Research Consortium of Canada (SPARCC) real-time iterative calibration (RETIC) modules for scoring MRI lesions in axial spondyloarthritis (axSpA) have been created by SPARCC developers to enable remote training of readers to appropriately use the SPARCC MRI inflammation and structural damage instruments and to attain adequate scoring proficiency.

Objectives: We aimed to test the performance of these modules in enhancing scoring proficiency in comparison to SPARCC developers.

Methods: The $SPARCC_{RETIC}$ SIJ inflammation and structural damage modules are each comprised of 50 DICOM axSpA cases with baseline and follow up scans and an online scoring interface based on SIJ quadrants. Continuous visual real-time feedback regarding concordance/discordance of scoring per SIJ quadrant with expert readers is provided by a color-coding scheme. Reliability is assessed in real-time by intra-class correlation coefficient (ICC), ICC data being provided every 10 cases, which are scored until proficiency targets for ICC are attained. In the present exercise, participants (n=15) from the EuroSpA Imaging project were randomized, stratified by reader expertise in scoring with SPARCC, to one of two reader training strategies (groups A and B) that each comprised 3 stages (25 patients per stage, 2 timepoints, blinded to chronology; independent assessment of Inflammatory and structural lesions): Group A. 1. Review of original SPARCC manuscript describing scoring method. 2. Review of PowerPoint summary of SPARCC method plus completion of $SPARCC_{RETIC}$ module. 3. Re-review of PowerPoint summary. Group B. Same 3-step strategy as A except $SPARCC_{RETIC}$ module completed at stage 3. The reliability of scoring was compared to an expert radiologist (SPARCC developer).

Results: Very good scoring proficiency for status and change scores was evident for SPARCC BME even by non-experienced readers with similar levels of reliability irrespective of prior expertise. The beneficial impact of the $SPARCC_{RETIC}$ module on scoring proficiency was most consistently evident for the scoring of structural lesions and for Strategy B, where the impact was evident for all structural lesions, level of reader expertise, and status as well as change scores (Table 1). Scoring proficiency improved the most for the least experienced readers (Figure 1).

Table 1. Inter-rater reliability (Status/Change ICC) compared to radiologist SPARCC developer

Conclusion: Attaining scoring proficiency for MRI structural lesions in axSpA is difficult but can be consistently improved by using the $SPARCC_{RETIC}$ module, even for experienced readers.

EFFECTS OF DISEASE MODIFYING ANTI RHEUMATIC DRUGS ON SACROILIAC MRI SCORE IN AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS.

A. Hansmaennel[1], A. Gerazime[2], O. Fakih[3], M. Chouk[3], C. Prati[4,5], D. Wendling[1,6], F. Verhoeven[7,8]. *[1]CHU Besancon, Rheumatology, Besancon, France; [2]CHU Besancon, UMETH, Besancon, France; [3]CHRU Besancon, Rheumatology, Besancon, France; [3]CHRU Besancon, Rheumatology, Besancon, France; [5]Université de Franche Comté, EA 4267 PEPITE, Besancon, France; [6]Université de Franche Comté, EA 4266 EPILAB, Besancon, France; [7]CHU Besancon, rheumatology, Besancon, France; [5]Université de Franche Comté, EA 4267 PEPITE, Besancon, France*

Background: Sacroiliac bone marrow edema is an important factor in the diagnosis and management of axial spondyloarthritis (axSpA).

Objectives: The aim of this meta-analysis is to assess the effect of the different bDMARDs and tsDMARDs on the SPARCC score at 12-16 and 48-52 weeks.

Methods: A systematic review, performed on Pubmed, Embase and Cochrane databases, included randomized controlled studies evaluating the sacroiliac joint (SIJ) SPARCC score at 12-16 or 48-52 weeks in patients with axSpA meeting the ASAS 2009 criteria or the modified New York criteria. We included studies evaluating the effects of the different treatments on the SPARCC score of SIJ in axial spondyloarthritis in comparison to a control group.

Results: Fifteen studies were included in the meta-analysis. Nine studies evaluated the effect of TNF inhibitors (TNFi), two for ixekizumab, one for filgotinib and one for tofacitinib. At 12 and 16 weeks, SIJ SPARCC score was significantly improved by TNFi (WMD: - 3.29 [95% CI -4.25; -2, 34]), IL-17 inhibitors (WMD: -3.98 [95% CI –5.76; -2.20]) and by JAK inhibitors (JAKi) (WMD: - 3.02 [95% CI -4.54; -1.51]). There was no difference between the molecule subgroups. At 48-52 weeks, TNFα inhibitors, introduced at baseline, reduced more SIJ SPARCC, but not significantly (WMD: -2.26 [95% CI -4.94; 0.42]), than placebo groups who began a TNFi treatment with delay.

Conclusion: Our meta-analysis shows a comparable improvement of the SIJ SPARCC score regarding TNFi, JAKi and IL-17 inhibitors at three months and suggests the presence of an opportunity window.

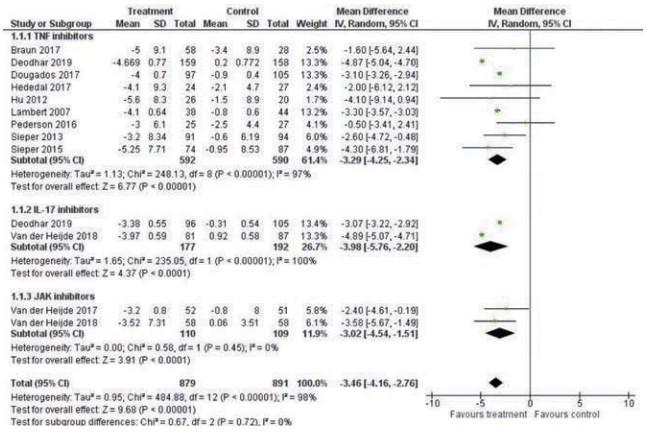

Figure 1. Forest plot of SPARCC SIJ score for all therapeutic agents versus controls at week 12-16.

CLINICAL FEATURES OF UVEITIS ASSOCIATED TO SPONDYLOARTHRITIS. SINGLE CENTER UNIVERSITY STUDY.

L. Sanchez-Bilbao[1], I. Gonzalez-Mazon[1], A. Herrero-Morant[1], A. De Vicente-Delmás[2], V. Calvo-Río[1], D. Martínez-López[1], J. Rueda-Gotor[3], M. J. García-García[4], N. Palmou-Fontana[1], M. A. González-Gay[1], R. Blanco[1]. *[1]H.U. Marqués*

de Valdecilla, Rheumatology, Santander, Spain; [2]Hospital de Algeciras, Rheumatology, Algeciras, Spain; [3]H.Sierrallana, Rheumatology, Torrelavega, Spain; [4]H.U. Marqués de Valdecilla, Gastroenterology, Santander, Spain

Background: Uveitis is a frequent extraarticular manifestation of spondyloarthritis (SpAs). It has been classically reported that whereas uveitis in axial spondyloarthritis (ax-SpA) is predominantly anterior, unilateral, acute, and non-recurrent; in psoriatic arthritis (PsA) and in inflammatory bowel disease (IBD) it has been described as posterior, bilateral, insidious, and continuous [1,2].
Objectives: In a large unselected series of SpAs, our aim was to assess the epidemiology and clinical features of SpAs-associated uveitis.
Methods: Study of consecutive patients from a single University Hospital with **a)** ax-SpA, **b)** PsA, and **c)** IBD (Crohn's disease and Ulcerative colitis). We have selected patients with uveitis that were classified according to Standarization Uveitis Nomenclature (SUN) Working Group. Main general features, and uveitis pattern, location and onset were recorded.
Results: We studied 2156 (1038 women/118 men) patients with SpAs: IBD (n= 1449; 67.2%); PsA (n= 406; 18.8%); and ax-SpA (n= 301; 14%).
Uveitis was present in 87 (4%) (102 eyes) of 2156 patients with SpAs. However, uveitis occurs with varying frequency according to the SpAs subtype:14.6% of axSpA (n=44), 4.9% of PsA (n=20), and 1.6% of IBD (n=23) (**Table 1**).
In the global SpAs, the most common pattern of uveitis was typically anterior (n=78; 89.7%), unilateral (n=72; 82.8%), acute (n=19; 82.6%), and non-recurrent (n=83; 95.4%).
The comparative study between these three groups of SpAs showed a significant greater frequency of HLA-B27 positive, anterior location and acute onset in ax-SpA-related uveitis (**Table 1**).

Table 1. Main clinical features and uveitis pattern.

	Ax-SpA (n=44)	PsA(n=20)	IBD(n=23)	p
Main general features				
Age, years, mean ±SD	45.6 ± 10.3	43.1 ± 14.5	49.1 ± 14.6	0.472
Sex, w/m, n, (% of women)	25/19 (56.8)	12/8 (60)	17/6 (73.9)	0.382
Disease Duration, years, mean±SD	18.6 ± 10.5	9.9 ± 8.2	17.4 ± 10.2	0.067
HLA-B27 positive, n (%)	37 (84.1)	9 (45)	5 (2.8)	**0.001***
Uveitis location				
Anterior, n (%)	44 (100)	16 (80)	18 (78.3)	**0.006***
Posterior, n (%)	0 (0)	0 (0)	4 (17.4)	-
Panuveitis, n (%)	0 (0)	0 (0)	1 (4.5)	-
Uveitis pattern				
Unilateral, n (%)	37 (84.1)	16 (80)	19 (82.6)	0.922
Uveitis onset				
Acute, n (%)	44 (100)	20 (100)	19 (82.6)	**0.003***

Conclusion: Although SpAs associated uveitis have different frequencies depending on the underlying disease, they share the same clinical pattern: anterior, unilateral, acute, and non-recurrent, in contrast with published data from selected series.

POS0998 DEPRESSION IN SPONDYLOARTHRITIS: THE CHOICE OF MEASUREMENT INSTRUMENT MATTERS

C. Webers[1,2], U. Kiltz[3,4], J. Braun[3,4], D. Van der Heijde[5], A. Boonen[1,2].
[1]Maastricht University Medical Centre, Rheumatology, Maastricht, Netherlands; [2]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; [3]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [4]Ruhr-Universität Bochum, Rheumatology, Bochum, Germany; [5]Leiden University Medical Centre, Rheumatology, Leiden, Netherlands

Background: The prevalence of depression is increased in spondyloarthritis (SpA). Research on this topic in SpA is challenging for several reasons, one of them being the wide variety of different instruments used to assess depressive symptoms. It is unknown whether these instruments are comparable in measuring the construct 'depression' and can be considered interchangeable. If these instruments actually differ in what they measure, this should be taken into account when designing and interpreting studies, and in clinical practice when monitoring patients with SpA.
Objectives: To compare the constructs of several instruments used to assess depressive symptoms in patients with SpA.
Methods: Data from the international ASAS Health Index Validation Study were used. Included patients had a diagnosis of SpA and fulfilled the ASAS classification criteria for axial/peripheral SpA. Data on demographics and disease characteristics were collected. The following instruments that have been used to assess depressive symptoms in SpA were available: the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D), the Short Form 36 (SF-36) and item 5 of the 5-level EuroQoL 5D (EQ-5Di5). The HADS-D ranges 0-21 (best-worst), with scores ≥8 and ≥11 indicating possible (HADS-possible) and probable depression (HADS-probable), respectively. The SF-36 was summarized using all 36 items in a Mental Component Summary (SF-36MCS, score ≤40 indicating depression), or using only 5 items in the Mental Health subscale (SF-36MH, score ≤56 indicating depression). For the EQ-5Di5, a score of at least "moderately" (level ≥3 on 1-5 scale) or "severely" depressed (level ≥4) indicated depression. Spearman correlations between instrument scores, agreement (kappa) between depressed states, and test characteristics (sensitivity [SE], specificity [SP], positive and negative predictive value [PPV, NPV]) were calculated with HADS-D as external standard, as it was specifically designed to detect depression and considered to have highest content validity.
Results: In total, 1548 patients were included, of which 1281 (83%) had axial SpA, mean age was 41.6 (SD 13.5) years, 1005 were male (65%), mean symptom duration 14.5 (11.4) years, mean ASDAS 2.6 (1.2) and BASDAI 4.1 (2.5). The prevalence of depression varied around 1 in 3 patients for the lower thresholds of depression (32% for HADS-possible, 45% for SF-36MH, 33% for SF-36MCS and 24% for EQ-5Di5-moderately) and was lower for the more stringent thresholds of HADS-probable (15%) and EQ-5Di5-severely (6%); 192 patients (24% of those who scored positive for depression on ≥1 instrument) scored positive on all instruments (Figure 1). Correlations between instruments were moderate (rho = 0.59-0.66), except between SF-36MH and MCS (rho = 0.85). Agreement between instruments was moderate for lower thresholds for depression (pairwise kappa = 0.47-0.58 for HADS-possible, SF-36MCS, SF-36MH, EQ-5Di5-moderately) and substantial for higher thresholds (pairwise kappa = 0.75 for HADS-probable/EQ-5Di5-severely). Using HADS-D as external standard, EQ-5Di5 was very specific but less sensitive, while SF-36MCS/MH were more sensitive but less specific (Table 1).

Table 1. Test characteristics of instruments

	External standard: HADS-D≥8 (possible)			
Definition of 'depression'	**SE**	**SP**	**PPV**	**NPV**
EQ-5Di5 ≥3 (moderate)	51	89	69	80
EQ-5Di5 ≥4 (severe)	17	99	85	72
SF-36MCS ≤40	68	83	66	85
SF-36MH ≤56	78	71	56	87
	External standard: HADS-D≥11 (probable)			
Definition of 'depression'	**SE**	**SP**	**PPV**	**NPV**
EQ-5Di5 ≥3 (moderate)	67	84	41	94
EQ-5Di5 ≥4 (severe)	30	98	68	89
SF-36MCS ≤40	83	75	37	96
SF-36MH ≤56	88	63	29	97

All values are percentages.

Conclusion: Instruments used to assess depression in SpA are not interchangeable. The choice of instrument should be taken into account when interpreting studies on depression in SpA. SF-36MCS and SF-36MH are sensitive and could be considered for screening while EQ-5Di5 is useful when high specificity is required. In situations where assessment of depression is the primary objective, depression-oriented instruments such as the HADS are recommended.

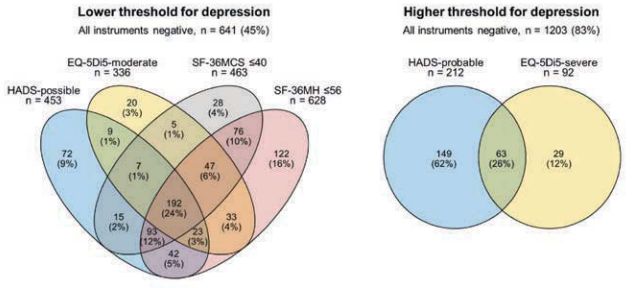

Figure. Venn diagram of instruments used to assess depression
Number of patients that scored positive for depression on the instrument(s). The percentages in the diagrams are based on the population of patients that scored positive on at least one of the assessed instruments (n=784 for lower threshold and n=241 for higher threshold for depression).

POS0999

HIGHER CARDIOVASCULAR MORBIDITY SEEN IN MEN WITH LONGER DELAY TO THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS

J. Carty[1], K. Marsh[1], P. Gallagher[2], F. B. O'shea[3,4], G. Fitzgerald[1,5]. *[1]University Hospital Galway, Rheumatology, Galway, Ireland; [2]St. Vincent's University Hospital, Rheumatology, Dublin, Ireland; [3]Trinity College Dublin, Medicine, Dublin, Ireland; [4]St James's Hospital, Rheumatology, Dublin, Ireland; [5]National University of Ireland, Galway, Medicine, Galway, Ireland*

Background: Diagnostic delay in axial spondyloarthritis (axSpA) is a well-defined feature of the disease, despite increased awareness. Morbidity and mortality are higher in axSpA than the general population[1]. Much of this excess burden is due to increased comorbidity. However, the association between delayed diagnosis and increased comorbidity in this population is unknown.

Objectives: (1)Examine the relationship between delayed diagnosis and comorbidity in a large cohort of well characterised individuals with axSpA
(2)Assess the impact of sex on the relationship between diagnostic delay and comorbidity.

Methods: The Ankylosing Spondylitis Registry of Ireland (ASRI), a descriptive epidemiological study of the Irish axSpA population, provided the cohort for this study. A standardised clinical assessment was performed on each patient. Delay to diagnosis was calculated as age at diagnosis minus age at symptom onset. Comorbidities were considered as any condition present in addition to axial SpA, excluding extra-musculoskeletal manifestations (EMM). SPSS was used for statistical analysis, with appropriate tests used for normally and non-normally distributed data.

Results: Of the 913 included patients, 659 (72%) were male and mean age was 46 years (SD 13). Detailed baseline clinical and demographic characteristics are outlined in Table 1. Median delay to diagnosis was 5 (2, 12) years. Comorbidity was present in 37% (n=341) of the cohort, with hypertension the most prevalent (see Figure 1).

Table 1. Baseline demographic and clinical characteristics

Variable	
Age, mean (SD)	45.8 (12.6)
Female, n (%)	254 (27.8)
Caucasian, n (%)	819 (96.5)
Ever Smoker, n (%)*	527 (57.7)
HLA-B27 positive, n (%)	631 (89.9)
Disease duration, median (25^{th},75^{th})	17.1 (9.5, 27.8)
Delay to diagnosis, median (25^{th}, 75^{th})	5.0 (2.0, 12.0)
AAU, n (%)	308 (34.4)
PsO, n (%)	150 (16.7)
IBD, n (%)	96 (10.7)
Biologic use, n (%)	628 (68.5)
BASMI, mean (SD)	3.6 (2.1)
BASFI, mean (SD)	3.4 (2.9)
BASDAI, mean (SD)	3.9 (2.4)
HAQ, median (25^{th}, 75^{th})	0.38 (0.0, 0.9)

The median delay to diagnosis was significantly longer in those with ≥1 comorbidity compared to those with none (7 v 5 years, p<0.01). Hypertension (6 v 5 years, p=0.1) and cerebrovascular disease (10 v 5 years, p=0.03) were associated with a significantly longer delay to diagnosis, with a similar trend seen in those with hyperlipidaemia (7 v 5 years, p=0.09) and ischaemic heart disease (10 v 5 years, p=0.07). The delay to diagnosis was also longer in those that currently (7 v 5 years, p=0.03) or ever smoked (6 v 5 years, p<0.01). The delay to diagnosis was significantly longer in those with depression (9 v 5, p<0.05). The presence of EMM did not contribute to a delay to diagnosis, and there was no association with any categories of medication.

There was no significant difference in the median delay to diagnosis between females (5 v 6 years) for males. However, there were differences in the relationship between delay to diagnosis and the pattern of comorbidities between sexes. There was a significantly (p<0.05) longer delay to diagnosis in men with cerebrovascular disease (12 v 6 years), ischaemic heart disease (10 v 6 years) and diabetes (10 v 6 years), which wasn't evident in females. Depression was associated with a longer delay to diagnosis in males (10 v 6 years, p<0.05), but not females (6 v 5 years, p=0.5).

Conclusion: Delay to diagnosis of axSpA was associated with a higher prevalence of comorbidities. This was particularly evident in men, with higher cardiovascular morbidity in those with a longer delay to diagnosis. Further research is needed to determine if shortening the delay to diagnosis would reduce the burden of cardiovascular morbidity.

Background: Spondyloarthritis (SpA) is one of the most common chronic inflammatory diseases and regularly affects women of childbearing age[1]. However, there is limited knowledge about the impact of the disease and its treatment on pregnancy.

Objectives: The aim of the study was to determine the factors associated with adverse pregnancy outcome in women with SpA.

Methods: All SpA patients (diagnosis according to the Rheumatologist) included in the national multicenter GR2 cohort from 2015 to June 2021 were included in the analysis. Patients could be included either with a pregnancy wish (i.e., preconceptional period) or because of a clinical pregnancy (<12 weeks of gestation). The main endpoint was favorable pregnancy outcome, a composite outcome defined as a live birth at term ≥ 37 gestation weeks of a healthy newborn with a weight greater than the 10th percentile. We performed a multilevel logistic regression model, in which we considered patient and center random effects (patient random effect for some women included in the cohort two times). Disease activity was defined by a BASDAI score ≥ 4 at least once during pregnancy. We used a multiple imputation to address missing data among the explanatory variables. Results are presented as an odds ratio (OR) with confidence interval (CI).

Results: Among the 207 pregnancies in women with SpA included in the GR2 cohort, 126 were retained for analysis of obstetrical outcome. Of these, 29 (23.0%), 14 (11.1%), 69 (54.8%) were exposed to corticosteroid, NSAID and biologics at least once during pregnancy, respectively. An active disease at least once during pregnancy was found in 47 (37.3%) pregnancies. A live birth was found in 116 (92.1%) women, including 110 (87.3%) full-term births. Early miscarriages and stillbirths were observed in 7 (0.06%) and 3 (0.02%) women, respectively. A caesarean section was performed in 20 (17.2%) cases.

A favorable pregnancy outcome was found in 80 (63.5%) of the women. Unfavorable pregnancy outcome was most frequently due to small for gestational age,

observed in 22 (19%) pregnancies. The multivariate model adjusted for age, BMI, nulliparity, active disease during pregnancy, smoking, and exposure to NSAIDs and corticosteroids during pregnancy found an association between unfavorable pregnancy outcome with nulliparity (OR 2.63 95% CI [1.01-6.81] p = 0.05).

Conclusion: This study provides original results on pregnancy in women with SpA. It found a favorable pregnancy outcome in 63.5% of women. Unfavorable pregnancy outcome was most frequently due to small for gestational age, which should lead to a coordinated management with obstetricians for the follow-up of pregnancy in women with SpA.

POS1001 CURRENT SMOKING IS ASSOCIATED WITH LOWER RISK OF UVEITIS AND PERIPHERAL ARTHRITIS IN MALES WITH AXIAL SPONDYLOARTHRITIS

K. Marsh[1], J. Carty[1], P. Gallagher[2], S. Maguire[3,4], F. B. O'shea[3,4], G. Fitzgerald[1,5]. *[1]University Hospital Galway, Rheumatology, Galway, Ireland; [2]St. Vincent's University Hospital, Rheumatology, Dublin, Ireland; [3]Trinity College Dublin, Medicine, Dublin, Ireland; [4]St James's Hospital, Rheumatology, Dublin, Ireland; [5]National University of Ireland, Galway, Medicine, Galway, Ireland*

Background: The associations between smoking and extra-axial manifestations of axial spondyloarthritis (axSpA) are inadequately described. Previous observational studies have demonstrated smoking as protective against some but not other manifestations. However, the impact of sex on these associations is unknown.

Objectives: Using a large descriptive epidemiological dataset, we performed a sex-stratified analysis of the association between smoking status and extra-axial manifestations in axSpA.

Methods: This study was carried out within the framework of ASRI (Ankylosing Spondylitis Registry of Ireland), a descriptive epidemiological study of the axSpA population of Ireland. A standardised clinical assessment was performed on each patient, collecting demographic and clinical data. Smoking status was characterised as current, previous or never. The number of cigarettes per day, plus number of years smoking was also collected. Data on the following extra-axial manifestations was collected: arthritis, enthesitis, dactylitis, acute anterior uveitis (AAU), psoriasis (PsO), inflammatory bowel disease (IBD). Standardised measures of disease severity were also collected. Separate logistic regression models were used to define the association between extra-axial manifestations and smoking, controlling for potential confounders. SPSS was used for statistical analysis.

Results: Smoking data was available for 913 out of the 917 axSpA individuals with data in ASRI (mean age 46 (SD 13) years, disease duration 19 (SD 12) years, 72% male, 97% Caucasian). Twenty eight percent (n=259) were current smokers, 29% (n=268) were past smokers and 42% (n=386) were never smokers. Of the current smokers, the mean number of cigarettes per day was 12 (SD 7) and number of years smoking was 22 (SD 12). Thirty one percent had peripheral arthritis, 7% had dactylitis, 18% had enthesitis, 34% had AAU, 17% had psoriasis and 11% had IBD. Current smokers had a significantly lower prevalence of arthritis and uveitis than past or non-smokers (see Table 1). A sex-stratified analysis was performed. There was no association between smoking status and any extra-axial manifestation in females. However, current smoking was associated with lower prevalence of arthritis in males compared to past or non-smokers (22% v 36% v 42%, p=0.002). A similar pattern was seen for uveitis, where male current smokers had a lower prevalence than non-smokers (24% v 38%, p=0.01). In contrast, psoriasis was more prevalent in men who were current smokers compared to non-smokers (18% v 12%, p=0.01), with no difference seen in females. There was no association with number of cigarettes smoked or number of years smoking.

Table 1. Association between smoking status and extra-axial manifestations in axSpA.

	AxSpA cohort	Current smoker	Past smoker	Non-smoker
Arthritis	30.9%	**22.4%[a]**	**35.5%[b]**	**33.3%[b]**
Dactylitis	6.7%	5.5%[a]	6.7%[a]	7.4%[a]
Enthesitis	18.1%	17.4%[a]	16.2%[a]	19.9%[a]
Uveitis	34.3%	**27.4%[a]**	**35.0%[b]**	**38.6%[b]**
Psoriasis	16.7%	18.5%[a]	19.3%[a]	13.8%[a]
Inflammatory bowel disease	10.7%	9.9%[a]	13.2%[a]	9.5%[a]

Different subscript letters denote significant (p<0.05) differences between groups. Significant values highlighted in bold.

There was no association between smoking status and disease severity by subjective or objective measures, either for the cohort as a whole or by sex.

When compared to non- or ex-smokers and controlled for potential confounders including sex, age, biologic use, the association remained only between current smokers and lower risk of uveitis (OR 0.68, 95% CI 0.49 to 0.96) and arthritis (OR 0.62, 95% CI 0.43 to 0.88), in separate logistic regression models. The association between current smoking and increased prevalence of psoriasis in males did not remain significant once controlled for confounders (OR 1.10, 96% CI 0.73 to 1.65).

Conclusion: We demonstrated that current smoking is independently associated with a lower risk of uveitis and arthritis in males with axSpA, but not females. More research is needed to further investigate this paradoxical finding.

POS1002 DIAGNOSTIC DELAY AND ITS ASSOCIATED FACTORS IN CHINESE AXIAL SPONDYLOARTHRITIS: A RETROSPECTIVE STUDY

X. Zheng[1], Z. Chen[1], X. Wu[1], X. LI[1], Y. Xie[1], J. Wu[1], M. Xiao[1], S. Cao[2], Q. Wei[1], W. Zhu[3], Y. Rao[4], Q. Chen[5], Y. Wen[5], J. Gu[1]. *[1]Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology, Guangzhou, China; [2]Seventh Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology, Shenzhen, China; [3]Gaozhou People's Hospital, Department of Rheumatology, Gaozhou, China; [4]Chashan Hospital of Dongguan, Department of Gastroenterology and Rheumatology, Dongguan, China; [5]Third Affiliated Hospital of Sun Yat-Sen University Yuedong Hospital, Department of Rheumatology, Meizhou, China*

Background: Few data on the prolonged diagnosis and its associated factors in Chinese axial spondyloarthritis (axSpA) is available.

Objectives: To delineate the landscape of diagnostic delay in Chinese axSpA, investigate its associated factors and explore its potential impact on medication modalities.

Methods: A total of 1,295 patients fulfilling the ASAS classification criteria were obtained. Demographic and clinical data were collected through predesigned questionnaires and available medical records. Logistic regression analyses in univariate and multivariable model were performed, using the median of diagnostic delay as cut-off point for group classification. Differences between early and late diagnosed group were subsequently compared by the Pearson chi-square test or Mann-Whitney U test.

Results: The median (IQR) diagnostic delay in Chinese axSpA was 3.0 (1.0~7.0) years and 24.8% of them reported a history of misdiagnosis. Older age at onset (OR=0.97, *P*<0.001) and higher education attainment (*P*=0.001) were correlated with early diagnosis of axSpA, whereas coming from less developed areas (*P*=0.002), a history of peripheral arthritis at the time of diagnosis (OR=1.58, *P*=0.002) and history of misdiagnosis (OR=1.98, *P*<0.001) increased the risk of diagnostic delay. Medication modalities were similar between two groups, but the proportion with no medication ever and percentage without regular medication in recent 3 months were higher in the late diagnosed group than early group (26.5% vs. 20.7%, *P*=0.02; 34.7% vs. 28.6%, *P*=0.02).

Conclusion: Our findings depicted a detailed spectrum of diagnostic delay in Chinese axSpA, verified five associated factors and pinpointed a remarkable treatment delay even after diagnosis, especially in late diagnosis group.

POS1003 IMPACT OF ELECTRONIC MEDICAL RECORD MANAGEMENT SYSTEM ON DISEASE ACTIVITY AND FREQUENCY OF OUTPATIENT VISITS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

H. H. Chen[1]. [1]*Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China*

Background: We developed an electronic medical record management system (EMRMS) at the Taichung Veterans General Hospital (TCVGH) to assess ASDAS by integrating patient reported outcomes (assessed by an independent nurse) and ESR/CRP for AS patients. We aimed to investigate the impact of the EMRMS on frequency and time of outpatient visits.

Objectives: To investigate the impact of the EMRMS on frequency and time of outpatient visits.

Methods: We identified 652 AS patients who were followed up for at least one year before and after the first ASDAS assessment. We compared the number of outpatient visit and average visit time within one year before and after the initial ASDAS assessment. We identified 201 AS patients who received ≥ 3 continuous ASDAS assessment with an interval of 3 months and compared the 2nd and 3rd ASDAS with the first ASDAS.

Results: The annual number of outpatient visits was increased after starting ASDAS assessment (5.8±3.5 vs. 5.4±3.4, p<0.001), in particular among those whose initial ASDAS-CRP was > 3.5 (8.7±4.0 vs. 5.7±3.4, p<0.001). The average visit time was shortened within one year after ASDAS assessment (8.7±3.8 vs. 9.2±4.4 minutes, p = 0.030), especially among patients whose ASDAS-CRP was <1.3 (8.5±3.3 vs. 9.2±4.2 minutes, p=0.022). Among patients who received at least 3 ASDAS assessments, the 3rd ASDAS-CRP was significantly lower than the 1st ASDAS-CRP (1.5±0.8 vs. 1.6±0.8, p=0.040).

Conclusion: EMRMS may increase the frequency of ambulatory visits for AS patiets with very high disease activity and decrease the visit time for AS patients with inactive disease. Continual ASDAS assessment may help control disease activity of AS patients.

POS1004 THE IMPACT OF MRI SLICE THICKNESS ON THE DETECTION OF SPINAL SYNDESMOPHYTES IN AXIAL SPONDYLOARTHRITIS

K. Klavdianou[1,2], A. D. Mewes[3], S. Tsiami[1], P. Sewerin[1], X. Baraliakos[1]. [1]*Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany;* [2]*Asklepieion' General Hospital, Department of Rheumatology, Voula, Athens, Greece;* [3]*University Dusseldorf, Medical Faculty, Department of Diagnostic and Interventional Radiology, Dusseldorf, Germany*

Background: Conventional radiographs (CR) are the gold standard for detecting syndesmophytes in axial Spondyloarthritis (axSpA), mainly because magnetic resonance imaging (MRI) is not able to detect thin bony structures due to its slicing technique.

Objectives: To assess the ability and performance of detection of syndesmophytes using different slice thicknesses on MRI and compare them with findings on CR.

Methods: MRI with T1W and STIR images with slice thicknesses of 1-6mm and CR of the lower thoracic and lumbar spine performed on the same day were prospectively performed in 43 axSpA patients. Clinical and laboratory characteristics of the patients from the same timepoint were available. Each vertebral corner (VC) (anterior superior and posterior, inferior anterior and posterior) from the thoracic (Th11) to the lumbar (L5) vertebral body were assessed for the presence/absence of syndesmophytes but also fat lesion (FL) on MRI by two experienced readers (one radiologist and one rheumatologist) independently. Disagreements were solved in consensus.

Results: A total of 1.204 VCs was assessed from all patients. The mean time needed for scoring the MRIs varied between 2:27 and 4:12min for the MRI thicknesses of 1-6mm, respectively.

Syndesmophytes were detected in 19.3% VCs on CR and in 38.3%, 37.5%, 34.8%, 33.7%, 31.4%, 28.7% VCs on MRI slice thicknesses of 1-6mm, respectively (p≤0.001 for all MRI vs. CR evaluations and within MRI slice thicknesses). The anterior superior VC of L1 was the most affected site among all vertebral corners in all MRI slice thicknesses and CRs. In thoracic spine, the anterior superior corner of T12 was the most frequently affected site in both MRI (all slice thicknesses) and CR. Although MRI could detect more syndesmophytes in both lumbar and thoracic vertebrae than CR, MRI at any slice thickness could not detect 15.4%-23.2% of syndesmophytes detected in CR (Table 1).

Table 1. Agreement and disagreement of CR and MRI for syndesmophyte detection per MRI slice thickness

		CR		Agreement CR/MRI	False positive MR based on CR as gold standard
MRI		yes	no		
1mm	yes	182	279	72,6%	23,2%
	no	51	692		
2mm	yes	184	267	73,8%	22,2%
	no	49	704		
3mm	yes	181	238	75,9%	19,8%
	no	52	733		
4mm	yes	175	231	76,0%	19,2%
	no	58	740		
5mm	yes	169	209	77,3%	17,4%
	no	64	762		
6mm	yes	160	186	78,5%	15,4%
	no	73	785		

Fat lesions were detected in 38.3%, 37.5%, 34.8%, 33.7%, 31.4%, 28.7% of VC with MRI slice thicknesses of 1-6mm, respectively. MRI slice thickness had no role in detecting fat lesions (p>0.05 within MRI slice thicknesses).

Conclusion: MRI of the lower thoracic and the lumbar spine at any slice thickness detected more syndesmophytes than CR, but the best agreement and least false-positive findings on MRI based on CR as gold standard was found in the thicker slice thicknesses. The presence of fat lesions did not influence syndesmophyte detection on MRI. These results may influence the performance of spinal MRI in identification of SpA-specific spinal lesions in daily practice.

POS1005 ACTIVE INFLAMMATORY LESIONS OF THE SPINE IN SACROILIAC JOINTS MRI (SIJS-MRI): AN OVERLOOKED FINDING BY RADIOLOGISTS.

N. Di Meglio[1], F. Gentili[2], S. Guerrini[2], G. Bagnacci[1], A. Perrella[1], E. Conticini[3], B. Frediani[3], L. Cantarini[3], L. Volterrani[1], M. A. Mazzei[1]. [1]*University of Siena, Department of Medical, Surgical and Neurosciences, Diagnostic Imaging, Siena, Italy;* [2]*Azienda Ospedaliera Universitaria Senese, Diagnostic Imaging Unit, Siena, Italy;* [3]*University of Siena, Rheumatology Unit, Siena, Italy*

Background: Establishing a diagnosis for axial spondylarthritis (axSpA) is based on the combined presence of several clinical and laboratory features in association with imaging: the presence of active inflammatory lesions (bone marrow edema, BME) in sacroiliac joints (SIJs), also associated with structural lesions, is the main element in favor of a diagnosis of axSpA and SIJ MRI is currently the main recommended technique for detecting inflammation, enabling early diagnosis in patients with normal radiographic findings. MRI of the spine is generally not recommended for axSpA diagnosis, since spine involvement is considered less sensitive and specific. Several studies explored the incremental value of spine MRI for diagnosing patients with axSpA, especially when the findings of SI are equivocal, and "predicting" clinical disease activity.

Objectives: To evaluate the effectiveness of the MRI study dedicated to SIJs to identify the inflammatory involvement of the lumbar spine in patients with active sacroiliitis and clinical diagnosis of axSpA.

Methods: MRI of 96 patients (26 M, 70 F, mean age 48 years) with SIJs-MRI positive for inflammatory involvement according to ASAS criteria, were evaluated retrospectively. The presence of signs of inflammation of posterior spinal elements and vertebral bodies included in the field of vision (FOV) was therefore researched
Results: Of 96 patients with active sacroiliitis, 88 had concomitant inflammatory lesions of the lumbar spine. Facet capsulitis (87.6 %) and posterior enthesitis (42.2 %) were the most common lesions and these lesions frequently coexisted (39.3%). Twelve patients with facet capsulitis presented also facet arthritis. Only 20 out of 96 patients (22%) had vertebral bodies inflammatory lesions: 15 corner inflammatory lesions and 5 aseptical spondylodiscitis.
Conclusion: On the basis of current working consensus MRI examination of the spine is not recommended for axSpA diagnosis, because it is considered less sensitive and specific. However the high prevalence (91.7%) of spinal inflammatory changes in patients with active sacroiliitis suggests that these features can be used as an additional element in favor of diagnosis, especially in doubtful cases. This evaluation takes little reporting time, without any increase in MRI execution time.

POS1006 DIAGNOSIS OF AXIAL SPA AND ADDITIONAL FEATURES IN HLA-B27 POSITIVE INDIVIDUALS REPORTING CHRONIC INFLAMMATORY BACK PAIN: DATA FROM A LARGE DUTCH POPULATION-BASED COHORT

S. Kieskamp[1], S. Arends[1], E. Brouwer[1], H. Bootsma[1], I. M. Nolte[2], A. Spoorenberg[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Department of Epidemiology, Groningen, Netherlands*

Background: Chronic low back pain (CLBP; back pain >3 months with age of onset <45) and inflammatory back pain (IBP) are regarded as early and key features of axSpA. HLA-B27 is the most important genetic risk factor. Despite improved diagnostics, especially the use of MRI in demonstrating active sacroiliitis, the substantial delay in axSpA diagnosis has not improved[1].
Objectives: To explore the presence of CLBP and IBP in combination with HLA-B27 and the presence of other axSpA associated features in the general population.
Methods: Participants of the Lifelines cohort, a large population-based cohort which is representative of the mostly Caucasian Northern region of the Netherlands[2], responded to a survey with questions concerning the presence of CLBP and the European Spondyloarthropathy Study Group (ESSG) criteria for IBP. HLA-B haplotypes were imputed from genome-wide SNPs genotyped with the Illumina GSA beadchip-24 v1.0, using the R-package HIBAG with published parameter estimates. Analyses were performed on participants with available HLA-B haplotype and CLBP/IBP data. Prevalence rates were calculated and logistic regression was performed to identify whether participant characteristics and other available SpA features were independently associated with the presence of the key axSpA features HLA-B27, CLBP and IBP.
Results: 20,619 participants had data available on CLBP, IBP and HLA-B haplotype. Of these participants, 1,610 (7.8%) were HLA-B27+, 3,717 (18.0%) reported CLBP, 2,670 (13.0%) fulfilled the IBP criteria, and 47 (0.23%) reported a previous SpA diagnosis, of which 37 (0.18%) reported axSpA. In total, 226 (1.1%) participants had the combination of CLBP/IBP/HLA-B27. Only 11 (4.9%) of these 226 participants reported a previous SpA diagnosis, all of which were axSpA. Participant characteristics and the presence of other available SpA related features are presented in Table 1.
In multivariable logistic regression analysis, current NSAID use and a reported history of peripheral arthritis were independently associated with the axSpA key features CLBP, IBP, and IBP+HLA-B27.
Conclusion: In this large Dutch population-based cohort only 4,9% of participants presenting the combined axSpA key features IBP and HLA-B27 reported a previous axSpA diagnosis, indicating possible axSpA underdiagnosis. Although not all SpA features were available in Lifelines, current NSAID use and a history of peripheral arthritis in combination with the axSpA key features may have additional value in identifying patients with axSpA in primary care.

POS1007

MRI CHANGE SCORE BUT NOT THE STATUS SCORE IS RELATED TO DISEASE ACTIVITY AND CLINICAL RESPONSE OVER TIME IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM ESTHER STUDY.

V. Rios Rodriguez[1], M. Torgutalp[1], H. Haibel[1], K. G. A. Hermann[2], F. Proft[1], M. Protopopov[1], J. Rademacher[1,3], J. Sieper[1], D. Poddubnyy[1,4]. [1]*Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Gastroenterology, Infectious Diseases, and Rheumatology (including Nutrition Medicine), Berlin, Germany;* [2]*Charité – Universitätsmedizin Berlin, Department of Radiology (including Pediatric Radiology), Berlin, Germany;* [3]*Berlin Institute of Health,., Berlin, Germany;* [4]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology Unit, Berlin, Germany*

Background: Magnetic resonance imaging (MRI) of the spine and sacroiliac joints (SIJ) are important tools for the diagnosis of axial SpA. However, there is very little data investigating how clinical symptoms and response to treatment relate to the degree of MRI inflammation and to its change over time.

Objectives: To evaluate the relationship between clinical response in axial SpA patients and inflammation in MRI of spine and SIJ after 6 months of treatment.

Methods: In the ESTHER study[1], a total of 76 patients with early axial SpA with a symptom duration less than 5 years, and with active inflammation on MRI in the spine and/or SIJ at baseline were randomized to be treated with etanercept (n=40) or sulfasalazine (n=36) for one year.

Clinical and laboratory outcome assessments included C-reactive protein (CRP), Bath ankylosing spondylitis disease activity index (BASDAI), Bath ankylosing spondylitis functional index (BASFI) and ankylosing spondylitis disease activity score (ASDAS). The following efficacy parameters were calculated: change in CRP, BASDAI, BASFI and ASDAS between baseline and Week 24; response of the ASAS response criteria for 20 and 40% improvement in disease activity (ASAS20 and ASAS40); and ASAS criteria for partial remission at Week 24.

MRI of spine and SIJ were performed at weeks 0, 24, and 48; and were scored by two radiologists, who were blinded for all clinical data, treatment arm and time point, according to the Berlin scoring system. The final osteitis score for the SIJ and for the spine was calculated as the mean score of both readers. Residual inflammation in MRI at Week 24 was defined as an osteitis score of ≥5 for SIJ and >0 for the spine (median values at Week 24).

To understand the relationship between MRI and clinical outcomes, two types of models were performed: 1) a model with status scores at baseline and Week 24 for MRI and clinical outcome parameters; and 2) a model with change scores between baseline and Week 24 for MRI and clinical outcome parameters.

Results: A total of 67 patients with axial SpA were included in this analysis due to availability of MRIs at baseline and Week 24. The characteristics of patients included for this analysis were similar to the whole group of the ESTHER study. SIJ and spine osteitis score on MRI at baseline (mean±SD) was 6.9±6.1 and 1.5±2.5, respectively. The status scores showed no association at baseline, neither at Week 24, with the only exception of ASAS20 at Week 24 (Figure 1). However, changes in osteitis score of SIJ and spine were associated to clinical response outcomes between baseline and Week 24 (Figure 1). Further, we compared patients with and without residual inflammation on MRI of the spine and SIJ as defined above. There were no differences between the groups regarding clinical response and disease activity at week 24.

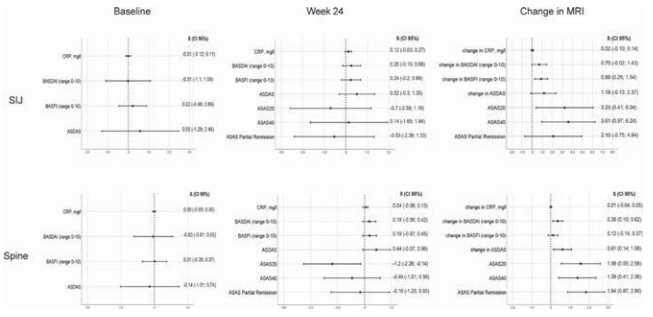

Figure 1. Association between disease activity parameters and MRI osteitis score in spine and SIJ in patients with axial spondyloarthritis over 6 months of treatment. Each line in the figure refers to an outcome (dependent variable) in the multivariable regression analysis, which were adjusted for age, sex, symptom duration and HLA-B27 positivity. MRI, magnetic resonance imaging; SIJ, sacroiliac joints.

Conclusion: Change of score for osteitis in MRI of spine and SIJ was associated to disease activity in patients with axial SpA during 6 months of treatment. Presence of residual inflammation on MRI after 6 months of treatment seems to be irrelevant regarding clinical response and clinical disease activity.

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease affecting sacroiliac joints, spine and peripheral joints. In addition to spinal and peripheral manifestations, root joints (hip or sholder) involvement may also develop. Hip involvement is reported 24-36% in patients with Ankylosing Spondylitis (AS) by clinical evaluation of the rheumatologists. However, there is limited data regarding the factors related with the presence of hip involvement and treatment preference in patients with axSpA.

Objectives: The aim of this study was to evaluate the factors/covariates associated with the hip involvement and its impact on the treatment preferences in patients with axSpA patients who initiated their first biologic therapy.

Methods: In total, 1600 axSpA patients who initiated his/her first biologic were included in the study. The data for the current study was obtained from the TReasure web-based registry. Baseline demographics and disease related characteristics were collected. Characteristics and treatment preference of patients with and without hip involvement were compared. The factors/covariates associated with the presence of hip involvement were evaluated by regression analysis.

Results: Hip involvement was reported in 375 patients (23.4%). Patients with hip involvement were more common male patients in addition they had lower education level, lower BMI and more frequent HLA-B27 positivity as well as longer disease duration. Hip involvement was more frequent in patients with r-axSpA than patients with nr-axSpA. We found lower percentages of peripheral arthritis, enthesitis and dactylitis, higher BASFI or ASDAS-CRP scores, higher serum CRP levels and ESR values in patients with hip involvement. Moreover, patients with hip involvement had less frequently SpA-related family history (Table 1). When we analyzed patients according to age at diagnosis (≥ 16 years, <16 years) we found that patients with hip involvement were more common in juvenile onset axSpA group. In multivariate analysis, we found that lower education level (OR:2.029, 95%CI:[1.461-2.817]; p<0.001), diagnosis (r-axSpA) (OR:0.532, 95%CI:[0.337-0.839]; p=0.007) longer disease duration (OR:1.002, 95%CI:[1.001-1.004]; p=0.002), lower percentages of enthesitis (OR:0.405, 95%CI:[0.283-0.579]; p<0.001), higher BASFI scores (OR:1.086, 95%CI:[1.025-1.151]; p=0.005) and serum CRP levels (OR:1.005, 95%CI:[1.001-1.010]; p=0.019) absence of SpA family history (OR:0.713, 95%CI:[0.528]; p=0.027) were associated with hip involvement.

Table 1. Characteristics of patients with axSpA

	All patients (n=1600)	Hip involvement (+) (n=375)	Hip involvement (-) (n=1225)	P*
Juvenile (<16 years) onset, n(%)	30 (1.9)	12 (3.2)	18 (1.5)	0.031
Male sex, n(%)	940 (58.8)	255 (68)	685 (55.9)	<0.001
HLA-B27 positivity, n(%)	605 (55)	178 (62.7)	427 (52.3)	0.002
BMI, kg/m^{2}mean (SD)	27.2 (5.2)	26.7 (5.0)	27.4 (5.2)	0.023
Education duration (≤12 years), n (%)	1014 (65.9)	263 (71.3)	751 (64.2)	0.013
mNY positivity, n(%)	1276 (79.8)	338 (90.1)	938 (76.6)	<0.001
Disease duration (month) median (IQR 25-75)	82 (36-151)	111 (52-200)	74.5 (32-139)	<0.001
SPA-related family history, n (%)	544 (34)	110 (29.3)	434 (35.4)	0.029
BASFI, mean (SD)	3.9 (2.5)	4.3 (2.1)	3.8 (2.7)	0.007
ASDAS-CRP, mean (SD)	3.1 (1.5)	3.7 (1.4)	2.9 (1.5)	<0.001
CRP (mg/dl), median (IQR 25-75)	8.6 (3-21)	12.0 (4.0-27.9)	7.6 (2.5-19)	<0.001

When we compared the treatment patterns of axSpA patients with and without hip involvement, we found that the percentages of NSAID as well as csDMARD use were similar in groups. However, the percentages of patients who were prescribed etanercept were higher in axSpA patients with hip involvement (p<0.001).
Conclusion: In addition to inflammation and function, hip involvement seems to be related with diagnosis (r-axSpA), education level and absence of SpA family history. Moreover, enthesitis may not accompany hip involvement.

POS1009 COMPARING OF DISEASE ACTIVITY, FUNCTION AND QUALITY OF LIFE IN PATIENTS FROM THE CLINICAL AND IMAGING ARM OF NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

S. Dimitrov[1], S. Hristova[1], S. Bogdanova-Petrova[1], T. Georgiev[1], T. Shivacheva[1]. [1]*Medical University Varna, Rheumatology, Varna, Bulgaria*

Background: The concept of axial spondyloarthritis (axSpA) and non-radiographic axSpA (nr-axSpA), a subgroup of axSpA, has recently emerged. There are several studies proving the similar levels in disease activity and quality of life in patients with or without structural damage in spondyloarthritis.
Objectives: The aim of this study is to compare disease activity, functional status and quality of life in patients from the clinical and imaging arm of nonradiographic axial spondyloarthritis in Bulgaria.
Methods: A cross-sectional survey was conducted with rheumatologists and their consulting patients in Bulgaria from February 2012 through April 2019. Patients who had a rheumatologist confirmed diagnosis of nr-axSpA were eligible to participate. An information about patient demographics and symptoms duration were collected. Acute- phase reactants, patients' reported data for disease activity (BASDAI), functional status (BASFI) and quality of life (ASQoL) were compared between the patients with or without MRI data for sacroiliitis. The level of significance was set to 0.05.
Results: A total of 98 patients from the imaging arm of nonradiographic arm and 62 patients from the clinical arm of nr-axSpA patients were included in this analysis. A higher proportion of patients from the imaging arm were male patients (51% vs 37%). The mean age was 33.8±7.71 in the imaging arm and 34.12±6.95 in the clinical arm (p>0.05), with mean symptoms duration in both groups- respectively 0.76±0.26 and 0.48±0.13 years (p>0.05). The mean value of C-reactive protein in the imaging arm was 14.81±28.59 and 7.05 ± 10.04, p=0.02 in both groups. The disease activity determined using patients reported data from BASDAI was 4.1±0.67 vs 4.01±0.78 (p>0.05) and using ASDAS-CRP 2.31±0.87 vs 2.05±0.52 (p>0.05) in the imaging and clinical arm. The evaluation of the function BASFI was 5.06±1.28vs 4.48±1.18, p>0.05 in both groups of patients with nr-ax SpA. The QoL, determined by ASQoL revealed non statistical significant values between the groups – 4.79±3.27 and 5.18±3.03, p>0.05.
Conclusion: Patients from the imaging and clinical arm of nr-axSpA share the same clinical features. The burden of the disease, as assessed by ASQoL measurement, is also similar in the investigated subgroups of Bulgarian nr-axSpA patients.

POS1010 SPINAL RADIOGRAPHIC PROGRESSION AND ITS ASSOCIATION WITH PROGRESSION TO ANKYLOSING SPONDYLITIS IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS.

S. Kieskamp[1], M. Siderius[1], R. Wilbrink[1], F. Maas[1], F. Wink[2], R. Bos[2], H. Bootsma[1], S. Arends[2], A. Spoorenberg[1]. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands;* [2]*Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: Prevention of structural damage of the axial skeleton is an important goal of treatment in axial spondyloarthritis (axSpA)[1]. Most studies concerning spinal radiographic progression focused on ankylosing spondylitis (AS). Data on spinal radiographic progression in patients with non-radiographic (nr)-axSpA is limited and data on the relation between spinal and sacroiliac radiographic progression in this population is lacking.
Objectives: To assess long-term spinal radiographic progression in patients with nr-axSpA. Secondly, to explore the association between radiographic progression to AS and spinal radiographic progression in these patients.
Methods: Patients enrolled in the ongoing Groningen Leeuwarden Axial SpA (GLAS) cohort, classified as nr-axSpA at baseline, with pelvic and spinal (lumbar and cervical) radiographs available at baseline and at least one follow-up visit at 2, 4 or 6 years were selected for analyses. Progression from nr-axSpA to AS was defined as progression to modified New York (mNY) sacroiliitis score ≥2 bilaterally or ≥3 unilaterally. Radiographs of nr-axSpA patients were randomized with radiographs of AS patients and scored in known time sequence by two trained readers blinded for patient characteristics. SK and RW scored the SI joints and in case of disagreement in axSpA classification, the score of a third independent reader (AS) was used. SK and MS scored the spinal radiographs according to the modified stoke ankylosing spondylitis spinal score (mSASSS; 0-72), and the mean of both total scores was calculated. In case of >5 points discrepancy between both readers, the mSASSS of a third independent reader (FM) together with the closest of the scores of the primary readers was used. The mSASSS change of nr-axSpA patients who did en did not progress to AS was compared with Mann-Whitney U tests.
Results: Included were 60 patients with a clinical diagnosis of nr-axSpA, confirmed by their sacroiliac radiographic score at baseline. Mean age was 37±10 years, 53% were male, median symptom duration was 9 (IQR 2-17) years, 75% were HLA-B27$^+$, and mean ASDAS was 2.6±1.1.
In total 15 patients progressed to AS. Median mSASSS at baseline was 1.5 (IQR 0.5 – 4.4). Median change in mSASSS from baseline was 0.0 (IQR 0.0 – 1.0) vs. 1.0 (IQR 0.0 – 1.5) at 2 years; 1.2 (IQR 0.3 – 3.5) vs. 2.0 (0.5 – 2.7) at 4 years; and 1.8 (1.0 – 3.8) vs. 2.5 (0.5 – 3.5) at 6 years for non-AS progressors and AS progressors, respectively (Figure 1). These mSASSS changes weres were not significantly different at any timepoint (p = 0.456, p=0.814, p=0.929 for 2-, 4-, and 6-year follow-up, respectively).

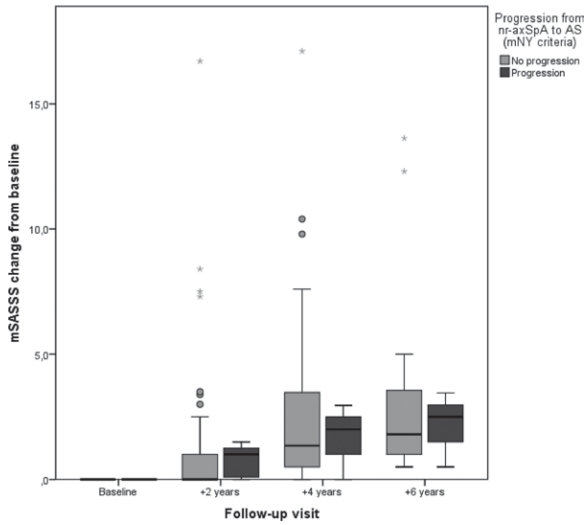

Figure 1. Comparison of mSASSS progression between patients with and without progression to AS during the first 6 years of follow-up.

Conclusion: In our observational cohort of patients with nr-axSpA with up to 6 years of follow-up, mSASSS progression was low (< 1 mSASSS unit/year) and was not different between patients who did and did not progress to AS.

POS1011 THE STUDY OF DETECTION OF FECAL CALPROTECTIN AS A MARKER OF EARLY DIAGNOSIS OF THE DEVELOPMENT OF INFLAMMATORY BOWEL DISEASES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

D. Tarasova[1,2], L. Shilova[2], A. Feoktistova[3]. [1]*Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation;* [2]*Volgograd State Medical University, Department of Hospital Therapy, Military Field Therapy, Volgograd, Russian Federation;* [3]*Volgograd State Medical University, Department of Pathological Anatomy, Volgograd, Russian Federation*

Background: Ankylosing spondylitis (AS) can be characterized not only by the detection of the musculoskeletal system, but by the probable contribution of extraskeletal manifestations (ESMs), which can aggravate the course of the disease, and may occur in the first place in terms of the activity of the process. At the same time, according to the findings, in 3.5-10% of patients with AS, a diagnosis of IBD was detected, and in 70% of patients with AS, subclinical symptoms of intestinal disorders were detected. AS and IBD have common links of pathogenesis: microbiota and intestinal wall condition. Currently, highly sensitive fecal laboratory tests are used to monitor inflammation activity in IBD prior to ileocolonoscopy. Fecal calprotectin (FCP) is a marker of neutrophilic inflammation in gastrointestinal diseases and an indicator of the intensity of the inflammatory process in the intestine. The concentration of FCP is statistically significantly higher in IBD patients with signs of clinical activity and, as a rule, does not go beyond the normal range in patients with irritable bowel syndrome. These data make it possible to consider fecal calprotectin as a promising marker of the onset and latent course of inflammatory bowel disease in patients with ankylosing spondylitis.
Objectives: To reveal the peculiarities of fecal calprotectin concentration in patients with ankylosing spondylitis in case of occurrence and recurrence of inflammatory bowel diseases as extraskeletal manifestations.
Methods: The study included 80 patients with ankylosing spondylitis: women - 28 (35%), men - 52 (65%). The average age of patients was 45.12±12.4 years, the average age of onset symptoms - 28.43±13.18 years, mean duration of AS - 18.7±11.75 years. Patients already diagnosed with AS were asked to complete a questionnaire using the Universal Questionnaire to identify signs of immunoinflammatory diseases - psoriasis, psoriatic arthritis, IBD (Crohn's disease, ulcerative colitis) to identify clinical signs of intestinal damage. With a positive answer to one main and one additional questions, the patient was asked to conduct a qualitative determination of fecal calprotectin. Before the study, patients were stopped taking non-steroidal anti-inflammatory drugs for two weeks. Patients in whom the presence of calprotectin in the feces was detected, at the next stage, a semi-quantitative determination of calprotectin in the feces was carried out by immunochromatographic method. Patients who had an increase in the concentration of fecal calprotectin above 200 μg/g were recommended to perform a diagnostic colonoscopy on an outpatient basis to clarify the diagnosis. The next step was the determination of fecal calprotectin in patients with a positive survey result. In 26 patients (32.5%) a positive result was revealed.
Results: In 71 (88.7%), according to the results of the questionnaire, subclinical signs of intestinal damage were identified. At the next stage, patients with a positive result in the determination of FCP underwent an immunochromatographic test to detect the concentration of calprotectin in the feces. Of these, 22 patients (84.6%) had a concentration of 50-200 μg/g, which indicates the need for dynamic monitoring of this group of patients. In 4 patients (15.38%), the concentration of PCP was found to be higher than 200 μg/g.
Conclusion: Among patients with ankylosing spondylitis, 88.7% have subclinical signs of intestinal damage. Of these, calprotectin is determined in feces in 32.5%, which may indicate a latent course or debut of inflammatory bowel disease. Determination of the presence of fecal calprotectin in patients with ankylosing spondylitis contributes to the early diagnosis of inflammatory bowel disease.

POS1012 PATIENT CHARACTERISTICS AND CLINICAL ASSESSMENTS ASSOCIATED WITH PROGRESSION FROM NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS TO ANKYLOSING SPONDYLITIS

S. Kieskamp[1], R. Wilbrink[1], M. Siderius[1], F. Wink[2], R. Bos[2], H. Bootsma[1], S. Arends[1], A. Spoorenberg[1]. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands;* [2]*Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: Part of the patients with non-radiographic spondyloarthritis (nr-axSpA) will progress to ankylosing spondylitis (AS). Varying factors are reported to be predictive of this progression of which the presence of elevated CRP and active sacroiliitis on MRI are most often found[1].
Objectives: To explore patient characteristics and clinical assessments associated with progression from nr-axSpA to AS up to 6 years follow-up in daily clinical practice.
Methods: Patients from the ongoing Groningen Leeuwarden axial SpA (GLAS) cohort classified as nr-axSpA enrolled into the cohort (baseline) between 2009 and 2018 were included in the analyses. Nr-axSpA was defined as sacroiliitis of ≥ 2 grade bilaterally or ≥ 3 unilaterally on the AP view of pelvic radiographs, according to the modified New-York (mNY) criteria. Baseline and available radiographs at 2 (n=85), 4 (n=53) and 6 years (n=30) of follow-up were randomized with radiographs of patients with AS and scored with known time sequence according to the mNY criteria by 2 trained readers (SK and RW). In case of disagreement in classification, the score of a third independent reader (AS) was used. Progression to AS was defined as progression in mNY sacroiliitis score to a score of ≥2 bilaterally or ≥3 unilaterally at any time during the 6-year follow-up period. Patient characteristics and clinical assessments at baseline were compared between patients who did and did not progress from nr-axSpA to AS, using chi-squared tests, Mann-whitney U tests or independent t-tests when appropriate.
Results: 85 patients were classified as nr-axSpA at baseline. Mean age was 39±11 years, 52% was male, median symptom duration was 6 (IQR 3-17) years, 75% was HLA-B27$^+$, and mean ASDAS was 2.7±1.1.
After 2, 4 and 6 years, 9/85 (10.6%), 4/47 (8.5%) and 2/24 (8.3%) of nr-axSpA patients progressed to AS. In total, 15 patients progressed to AS and 31 and 19 patients did not yet reach follow-up at 4 and 6 years, respectively.
Patients with nr-axSpA progressing to AS were significantly more often current smokers (62% vs. 21%, p=0.003) and had more often a history of uveitis (47 vs. 11%, p=0.001). Furthermore, patients with nr-axSpA progressing to AS tended to have higher CRP (and therefore ASDAS), more entheseal involvement, and worse lumbar spinal mobility then non-progressors; however, due to the relatively low number of progressors during the analyzed follow-up period, significance could not be reached (Table 1).
Conclusion: In our cohort, active smoking and a history of uveitis were independently associated with the progression of nr-axSpA to AS. Combining data of different cohorts will help to assess a more robust picture of axSpA features and patient characteristics associated with progression to AS.

Psoriatic arthritis - treatment

POS1013 HOW DOES BODY MASS INDEX AFFECT SECUKINUMAB TREATMENT OUTCOMES AND SAFETY IN PATIENTS WITH PSORIATIC ARTHRITIS? – REAL WORLD DATA FROM THE GERMAN AQUILA STUDY

U. Kiltz[1], J. Brandt-Juergens[2], P. Kästner[3], E. Riechers[4], D. Peterlik[5], C. Budden[5], H. P. Tony[6]on behalf of on behalf of the AQUILA Study Group. *[1]Rheumazentrum Ruhrgebiet, Herne and Ruhr-Universität Bochum, Herne, Germany; [2]Rheumatologie, Schwerpunktpraxis, Berlin, Germany; [3]Ambulantes Rheumazentrum, Medizinisches Versorgungszentrum, Erfurt, Germany; [4]Medizinische Hochschule, Hannover, Hannover, Germany; [5]Novartis Pharma GmbH, Immunologie, Hepatologie & Dermatologie, Nürnberg, Germany; [6]Medizinische Klinik II - Rheumatologie/Immunologie, Universitätsklinikum Würzburg, Würzburg, Germany*

Background: There is a higher prevalence of obesity in patients (pts) with psoriatic disease[1]. The German non-interventional study AQUILA provides real-world data on the influence of body mass index (BMI) of pts with psoriatic arthritis (PsA) on therapeutic effectiveness and safety under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits IL-17A.

Objectives: The aims of this interim analysis are to describe selected baseline (BL) demographics and to evaluate secukinumab treatment outcomes on disease activity and impact of disease on health and to report safety profile depending on the BMI of PsA pts.

Methods: AQUILA is an ongoing, multi-center study including up to 3000 pts with active PsA or ankylosing spondylitis. Pts were observed from BL up to week (w) 52. Real-world data were assessed prospectively and analyzed as observed. Data were collected on Psoriatic Arthritis Impact of Disease-12 items (PsAID-12 score) and Patient's Global Assessment (PGA). For calculation of proportion of pts that experienced (serious) adverse events ((S)AEs), all PsA pts were included that received at least one dose of secukinumab. This interim analysis focuses on BMI subgroups *≤25* kg/m^2 (normal weight), *>25 to ≤30* kg/m^2 (overweight) and *>30* kg/m^2 (obese) in PsA pts.

Results: At BL, BMI data were available for 1228 PsA pts: 26.5% (n=325) normal weight, 35.0% (n=430) overweight and 38.5% (n=473) obese PsA pts. Proportion of men was lower in normal weight and obese PsA pts. As BMI increased, so did age and comorbidities/extraarticular manifestations (EAMs; Table 1); e.g. percentage of PsA pts with heart-related disease increased from 5.2% in normal weight to 9.3% in obese PsA pts.

Table 1. Overview of baseline characteristics in PsA pts depending on BMI

Demographics	BMI ≤25 kg/m^2 (N=325)	BMI >25 to ≤30 kg/m^2 (N=430)	BMI >30 kg/m^2 (N=473)
Male*	105 (32.3)	219 (50.9)	188 (39.7)
Age, years**	49.5 (±12.7)	53.2 (±11.0)	54.1 (±10.6)
PsAID**	4.7 (2.4)	4.9 (2.2)	5.4 (2.0)
PGA**	4.8 (2.6)	5.4 (2.4)	5.5 (2.4)
Comorbidities/EAMs*			
Heart-related disease	17 (5.2)	29 (6.7)	44 (9.3)
Coronary heart disease	10 (3.1)	25 (5.8)	35 (7.4)
Stroke	1 (0.3)	9 (2.1)	11 (2.3)
Heart insufficiency	9 (2.8)	15 (3.5)	15 (3.2)
Uveitis	5 (1.5)	6 (1.4)	10 (2.1)
Depression	137 (53.5)	190 (55.2)	231 (58.5)

*variables are given as n (%); **variables given as mean (SD)

Mean PsAID at BL was similar for all BMI subgroups (*≤25*: 4.7; *>25-≤30*: 4.9; *>30*: 5.4; Figure 1A). Mean improvement from BL to w52 was 1.9 (40.4%) for normal weight, 1.8 (36.7%) for overweight, and 1.7 (31.5%) for obese PsA pts.

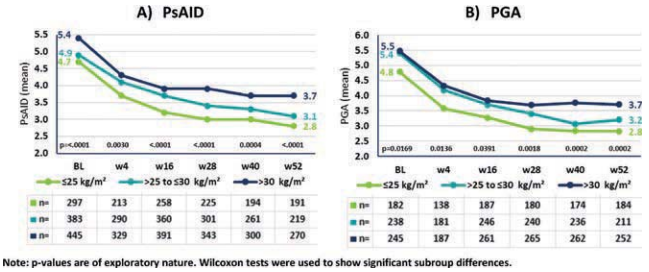

Figure 1. Impact of disease and PGA in PsA pts stratified by BMI. Note: p-values are of exploratory nature. Wilcoxon tests were used to show significant subroup differences.

Mean PGA developed in a similar way over time with lowest scores for normal weight and highest scores for obese PsA pts (Figure 1B). Mean improvement from BL to w52 was 2.0 (41.6%) for normal weight, 2.2 (40.7%) for overweight, and 1.8 (32.7%) for obese PsA pts.

The occurrence of AEs/SAEs with or without suspected relationship to secukinumab was most frequent in overweight and obese PsA pts. For example, the percentage of SAEs in normal weight PsA pts was 21.6%, in overweight 26.3% and in obese 25.9%. There were no unexpected safety signals in either subgroup. One male obese PsA patient died. Cause of death was not reported, however, treating physician did not suspect a causal relationship to secukinumab.

Conclusion: In a real-world setting, secukinumab improved impact of disease and patient´s global assessment of disease activity in all BMI subgroups of PsA pts. However, normal weight PsA pts had numerically better PsAID and PGA scores than obese PsA pts. Altogether, real-world data of this interim analysis show that secukinumab is an effective treatment with a favorable safety profile up to 52 weeks in PsA pts in all BMI subgroups.

POS1014 IMPACT OF SERUM INTERLEUKIN 22 AS A BIOMARKER FOR THE DIFFERENTIAL USE OF MOLECULAR TARGETED DRUGS FOR PSORIATIC ARTHRITIS

I. Miyagawa[1], S. Nakayamada[1], M. Ueno[1], Y. Miyazaki[1], Y. Tanaka[1]. *[1]University of Occupational and Environmental Health, Japan,The First Department of Internal Medicine, Kitakyushu, Japan*

Background: Although each bDMARD target different molecules, no optimal drug selection method has been established. Because studies directly comparing TNF-i and IL-17-i have shown that these drugs are equally effective, the establishment of an optimal selection method for these drugs can contribute to better patient outcomes. We reported the possibility of stratification of patients by peripheral blood lymphocytes phenotyping and precision medicine based on the selective use of bDMARDs in psoriatic arthritis (PsA). However, since peripheral blood lymphocytes phenotyping is complex, the development of simple methods using biomarkers to stratify patients and simple treatment strategies based on such methods is needed to promote precision medicine in a real-world clinical setting.

Objectives: We explored whether serum cytokines could be used as biomarkers for optimal use TNF-i and IL-17-i in patients with PsA.

Methods: In cohort 1 (IL-17-i [n=23] or TNF-i [n=24] for ≥1 year), we identified serum cytokines that predicted the achievement of DAPSA remission (REM), PASI 90 and Minimal Disease Activity after 1 year of TNF-i or IL-17-i therapy. Subsequently, we developed treatment strategies based on the identified cytokines. In cohort 2, treatment responses were compared between the strategic treatment group (n=17), which was treated based on the treatment strategies, and the mismatched treatment group (n=17) to verify the validity of the treatment strategies developed using serum cytokines as biomarkers.

Results: In cohort 1, serum IL-22 concentrations were statistically identified as a predictor of DAPSA remission after 1 year of IL-17-i therapy. However, no baseline serum cytokines were identified as factors contributing to achievement of DAPSA-REM in the TNF-i-treated group or achievement of PASI90 and Minimal Disease Activity in either group. Using a cut-off value of 0.61376 (sensitivity, 81.8%; specificity, 91.7%; area under the curve, 0.848) determined by a ROC analysis, we stratified 47 patients into the IL-22 high group (n=25) (0.61376<) and the IL-22 low group (n=22) (< 0.61376). Serum IL-17 concentrations were significantly higher in both the IL-22 high and IL-22 low groups than in the healthy control (HC), whereas no significant difference was observed between the IL-22 high and IL-22 low groups. The serum TNF-α concentrations did not significantly differ between the IL-22 low and HC; however, they were significantly higher in the IL-22 high group than in the HC and IL-22 low groups. Based on these results, we created treatment strategies using TNF-i and IL-17-i based on serum IL-22 concentrations, that is, initiation of IL-17-i therapy in patients with low IL-22 concentrations and TNF-i therapy in patients with high IL-22 concentrations. To

validate the efficacy of the treatment strategies, we retrospectively compared the efficacy of the bDMARDs at 1 year between the following groups in cohort 2. The strategic treatment group (n=17) included patients with low IL-22 concentrations who were treated with IL-17-i and those with high IL-22 concentrations who were treated with TNF-i. The mismatched treatment group (n=17) included patients with low IL-22 concentrations who were treated with TNF-i and those with high IL-22 concentrations who were treated with IL-17-i. No statistically significant differences were observed between the two groups in baseline characteristics at the initiation of bDMARD. After initiation of bDMARD, tender joint counts, swollen joint counts, CRP, DAPSA, and PASI were significantly improved in both groups. When the treatment responses over 1 year were compared between the two groups, the rate of achieving DAPSA-REM (58.8% vs. 25.3%, P=0.0399) and Minimal Disease Activity (82.3% vs. 41.2%, P=0.0162) at M12 was significantly higher in the strategic treatment group. There were no statistically significant differences in the rates of achieving PASI75 or PASI90 at M 6 or 12.

Conclusion: We verified that serum IL-22 can be used as a simple biomarker for the proper selection of TNF-i and IL-17-i.

Acknowledgements: The authors thank the study participants, without whom this study could not have been accomplished, and all medical staff at all participating institutions for providing the data, especially Ms. Hiroko Yoshida, Ms. Youko Saitou, Ms. Machiko Mitsuiki and Ms. Ayumi Maruyama for the excellent data management. The authors thank Ms. M. Hirahara for providing excellent technical assistance. Yu[12], E. Leibowitz[13], M. Marrache[14], L. Coates[15]. *[1]Memorial University of Newfoundland, Discipline of Medicine, Division of Rheumatology, St. John's, Canada; [2]Geneva University Hospitals, University of Geneva, Department of Dermatology, Geneva, Switzerland; [3]Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; [4]Icahn School of Medicine at Mount Sinai, Department of Dermatology, New York, United States of America; [5]University of Glasgow, Institute of Infection, Immunity and Inflammation, Immunology, Glasgow, United Kingdom; [6]Janssen Scientific Affairs, Immunology, Zug, Switzerland; [7]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology, Horsham, United States of America; [8]Janssen Research & Development, LLC, Biostatistics, Spring House, United States of America; [9]Janssen, Biostatistics, Breda, Netherlands; [10]Janssen Research & Development, LLC, Immunology, San Diego, United States of America; [11]Janssen Scientific Affairs, LLC, Immunology, Solna, Sweden; [12]Janssen Research & Development, LLC, Immunology, Spring House, United States of America; [13]Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America; [14]Janssen Inc., Medical Affairs, Toronto, Canada; [15]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Guselkumab (GUS), a selective IL-23p19 subunit inhibitor, demonstrated efficacy and a favorable safety profile in active psoriatic arthritis (PsA) in the Phase (Ph)2[1], Ph3 (DISCOVER [D]-1&2)[2,3], and Ph3b COSMOS[4] randomized controlled trials (RCTs).

Objectives: Assess GUS safety through 2 years (Y) in biologic (bio)-naïve and tumor necrosis factor inhibitor (TNFi)-experienced (exp) active PsA patients (pts) pooled across 4 RCTs (Week [W] 56: Ph2 and COSMOS; W60: D1; W112: D2).

Methods: Eligible pts in COSMOS had inadequate response to 1 or 2 prior TNFi; 9% of Ph2 pts and 30% of D1 pts had 1 or 2 prior TNFi; D2 pts were bio-naïve. Incidence rates of adverse events (AEs) are summarized among all treated pts for the placebo (PBO)-controlled (W0-24) and active treatment periods through 2Y (max duration of exposure 100W) according to actual treatment received, calculated as the number of events per 100 pt-Y of follow-up (PY), along with 95% confidence intervals (CI). Gastrointestinal (GI)-related serious AEs (SAEs) were identified using the Medical Dictionary for Regulatory Activities (MedDRA) system-organ class; major adverse cardiovascular events (MACE; predefined as MI, Stroke, or CV death) and opportunistic infections (OIs) were identified through medical review.

Results: Across the 4 RCTs, 1508 pts with active PsA received GUS 100 mg every 4 weeks (Q4W) or Q8W and were followed for a median of 1.2 Y, representing 2125 PY. In the overall population (N=1554), which includes PBO-treated pts that discontinued study agent prior to W24, 1138 pts were bio-naïve and 416 pts were TNFi-exp. Among all treated pts, the overall GUS safety profile was generally consistent with that of PBO through W24; rates remained low through 2Y of GUS (Table 1). The GUS safety profile was similar to that observed with PBO within the bio-naïve and TNFi-exp cohorts through W24. Incidence rates of AEs were generally consistent between cohorts in GUS-treated pts; whereas, TNFi-exp PBO-treated pts had more SAEs, study agent d/c due to AEs, and serious infections than bio-naïve PBO pts (Figure).

Conclusion: The favorable GUS safety profile demonstrated through W24 persisted through 2Y across bio-naïve and TNFi-exp pts.

RELATIONSHIPS BETWEEN DISEASE DURATION AND RADIOGRAPHIC PROGRESSION AMONG PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH SECUKINUMAB IN FUTURE 5

C. T. Ritchlin[1], A. M. Orbai[2], B. Parikh[3], C. Gaillez[4], X. Meng[5], P. J. Mease[6]. *[1]University of Rochester Medical Center, Division of Allergy, Immunology, and Rheumatology, Rochester, United States of America; [2]Johns Hopkins University School of Medicine, Division of Rheumatology, Psoriatic Arthritis Program, Baltimore, United States of America; [3]Novartis Pharmaceuticals Corporation, Rheumatology, East Hanover, United States of America; [4]Novartis Pharma AG, Rheumatology, Basel, Switzerland; [5]Novartis Pharmaceuticals Corporation, Biostatistics, East Hanover, United States of America; [6]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America*

Background: For patients with psoriatic arthritis (PsA), delays in diagnosis and treatment can lead to permanent radiographic damage, even early in the course of disease.[1] In the phase 3 FUTURE 5 study (NCT02404350), treatment with secukinumab (SEC) was shown to inhibit progression of structural damage through Week 104 in patients with PsA.[2] However, the effect of disease duration on inhibition of radiographic progression by SEC has not been characterized.
Objectives: This post hoc analysis explored relationships between time since diagnosis (TSD) of ≤1 year vs >1 year and radiographic progression among patients with PsA receiving SEC over 2 years in FUTURE 5.
Methods: Patient data from FUTURE 5 were stratified by TSD ≤1 year vs >1 year and analyzed by treatment arm. Through Week 24, patients received SEC 300 or 150 mg with subcutaneous loading dose (LD), SEC 150 mg without LD, or placebo (PBO) (period 1). After Week 24, patients receiving PBO were switched to SEC 300 or 150 mg (period 2), and a protocol amendment allowed those with suboptimal clinical response to SEC 150 mg to escalate to SEC 300 mg after Week 52 per investigator judgment.[2] The proportion of patients with no radiographic progression, defined as change from baseline in van der Heijde total modified Sharp score ≤0.0, was analyzed at Weeks 24, 52, and 104. Mean total Sharp score was evaluated at baseline, and mean change from baseline was determined at Weeks 24, 52, and 104.
Results: Of 996 patients with PsA included here, 217 (21.8%) had a TSD ≤1 year and 779 (78.2%) had a TSD >1 year. At baseline, patients with TSD >1 year had greater radiographic damage than patients with TSD ≤1 year as determined by mean total Sharp score (Table 1). As early as Week 24, patients receiving SEC had less radiographic progression than those receiving PBO, regardless of TSD. From Week 24 to Week 104, radiographic progression remained low among all patients receiving SEC, with a trend of least progression among patients randomized to SEC 300 mg at baseline. Regardless of treatment, patients with TSD >1 year had numerically greater radiographic progression than those patients with TSD ≤1 year. Overall, the proportion of patients receiving SEC who did not have any radiographic progression was higher than that of placebo at Week 24 irrespective of TSD, with a trend towards a higher number of non-progressors among those treated with SEC 300 mg (Figure). Patients randomized to SEC 300 mg were the least likely to experience radiographic progression through 52 weeks.
Conclusion: SEC resulted in low rates of radiographic progression through 2 years of treatment among patients in FUTURE 5, regardless of time since PsA diagnosis.

Background: Recent guidelines from the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) recommend that psoriatic arthritis (PsA) therapy achieve lowest possible disease activity across 6 key domains and related conditions.[1] In the DISCOVER-1&2 trials, guselkumab (GUS) significantly improved signs and symptoms of PsA at Week (W) 24.
Objectives: Evaluate GUS efficacy through W100 of DISCOVER-2 by GRAPPA-recommended PsA domains (peripheral arthritis, skin, dactylitis, enthesitis, axial disease [nails not evaluated]) and related conditions of inflammatory bowel disease (IBD) and uveitis.
Methods: Enrolled adults had active PsA, were naïve to biologics/JAK inhibitors, and had ≥5 swollen and ≥5 tender joints and CRP ≥0.6 mg/dL. Randomized (1:1:1) patients (pts) received GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then every 8 weeks (Q8W); or placebo (PBO) with crossover to GUS 100 mg Q4W at W24. Outcomes selected aligned with GRAPPA-recommended domains/conditions: overall disease activity (Psoriatic Arthritis Disease Activity Score [PASDAS], Minimal Disease Activity [MDA]), peripheral arthritis (changes

*Repeated Measures Generalized Linear Mixed Effects Models; excludes pts who achieved endpoint at BL. †Pts with BL IGA≥2 and BSA≥3%. ‡IGA skin response = score of 0 or 1 and ≥2grade improvement from BL. §Among pts with domain at BL.

in Disease Activity Index for Psoriatic Arthritis [DAPSA] and clinical DAPSA [cDAPSA]), skin (Psoriasis Area and Severity Index [PASI], Investigator's Global Assessment of psoriasis [IGA]), dactylitis (Dactylitis Severity Score [DSS]), enthesitis (Leeds Enthesitis Index [LEI]), axial disease (spinal pain) and IBD/uveitis (adverse events [AEs]). Among 493 GUS-randomized pts, change from baseline (BL) through W100 in continuous outcomes were analyzed by Repeated Measures Generalized Linear Mixed Effects Models adjusting for respective BL score and GUS regimen. Achievement of therapeutic endpoints was summarized by descriptive statistics using nonresponder imputation (NRI) for missing categorical data.

Results: ~90% of GUS-randomized pts completed treatment at W100. For continuous outcomes, improvements over time in key PsA domains extended through W100 of GUS (Figure 1). Therapeutic endpoint response rates also increased incrementally through W100 (Table 1). Mean improvements and response rates were consistent across key domains with no significant difference between GUS regimens. For related conditions, 1 GUS pt had IBD and 4 had uveitis at BL and none had AE of exacerbation through W100. No pt developed IBD through W100 (vs 1 PBO pt through W24); 1 GUS pt had AE of iridocyclitis through W100 (vs 1 PBO pt through W24).

Conclusion: In DISCOVER-2 bio-naïve PsA pts, both GUS regimens provided continued improvements in key GRAPPA-recommended domains of PsA through up to 2 years of treatment.

POS1018

DRUG SURVIVAL AND TREATMENT RESPONSE RATES IN PSORIATIC ARTHRITIS PATIENTS SWITCHING TO FIRST- OR SECOND-LINE IL-17 INHIBITOR TREATMENT: A DANISH POPULATION-BASED COHORT STUDY

R. L. Hansen[1], T. S. Jørgensen[1], A. Egeberg[2], N. Lippert Rosenoe[2], M. Skougaard[1,3,4], Z. R. Stisen[1], L. Dreyer[4,5], L. E. Kristensen[1]. *[1]The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen, Denmark; [2]University of Copenhagen, Department of Dermatology and Allergy, Herlev and Gentofte Hospital, Denmark; [3]Aarhus University Hospital, Department of Clinical Immunology, Aarhus, Denmark; [4]Aalborg University hospital, Department of Rheumatology, Aalborg, Denmark; [5]The Danish Rheumatologic Database (DANBIO), Rigshospitalet, Glostrup Hospital, Copenhagen, Denmark*

Background: Psoriatic arthritis (PsA) is a seronegative spondyloarthropathy associated with psoriasis [1]. It is defined as a multifaceted chronic inflammatory disease with chronic peripheral and/or axial arthritis, enthesopathy and dactylitis. PsA patients also experience fatigue, decreased physical functions and sleep disturbances, which may result in impaired social activity and decreased work productivity [2, 3]. All of these disease associated symptoms can cause substantial functional and mental impairment and thereby result in decreased quality of life [4-5]. Patient impacting factors are important when trying to further understand the disease and when choosing a treatment option to properly manage the symptoms of PsA [2].

Objectives: The objective of this study was to assess the effectiveness of switching to a first- or second-line IL-17 inhibitor treatment in patients with PsA from 2014 to 2021, using data from the Danish Rheumatology registry (DANBIO) by investigating drug survival and treatment response rates.

Methods: PsA patients recorded in DANBIO who switched to a first- or second-line IL-17 inhibitor treatment from a previous biologic disease-modifying antirheumatic drugs (bDMARD) between 2014 and 2021 were included in this study. Baseline characteristics were analyzed in subgroups: first-line IL-17 inhibitor treatment and second-line IL-17 inhibitor treatment and presented as median and interquartile ranges or number and percentage. Visual analog scale (VAS) fatigue 50% improvement and VAS pain 50% improvement, Disease Activity Scores-28 C-reactive protein (DAS-28-CRP) remission and ΔDAS28 scores at 6- and 12-months follow-up was reported. Drug survival of first- or second-line IL-17 inhibitor treatment was reported as a Kaplan Meier plot.

Results: 583 patients were identified and included in the study. Baseline characteristics (Table 1) showed that the age, percentage of females, CRP, HAQ, VAS patient pain, VAS global and DAS28CRP in both first- and second-line IL-17 inhibitor treatment was comparable. First- and second-line IL-17 inhibitor treatment had almost identical drug survival (Figure 1).

Table 1.

	First-line IL-17 inhibitor n= 434	Second-line IL-17 inhibitor n= 97
Age, years	51.0 (49.6-52.3)	51.9 (46.4-54.7)
Female, % (n)	59.0 (256)	53.6 (52)
Disease duration, years	6.8 (6.1-7.8)	8.2 (6.5-12.6)
CRP, mg/dl	4.0 (4.0-5.2)	3.0 (2.9-5.3)
HAQ	1.1 (1.1-1.3)	1.0 (0.9-1.3)
VAS pain, 100 mm	68 (65-72)	73 (66-76)
VAS global, 100 mm	75 (73-78)	80 (75-88)
DAS28-CRP	4.0 (3.8-4.1)	4.2 (3.7-4.6)
Previous bDMARD	2.0 (1.0-3.0)	4.0 (2.0-5.5)

CRP: C-reactive protein, HAQ: Health Assessment Questionnaire, VAS: Visual analog scale, DAS28: 28-joint Disease Activity Score, DMARD: disease-modifying antirheumatic drug.

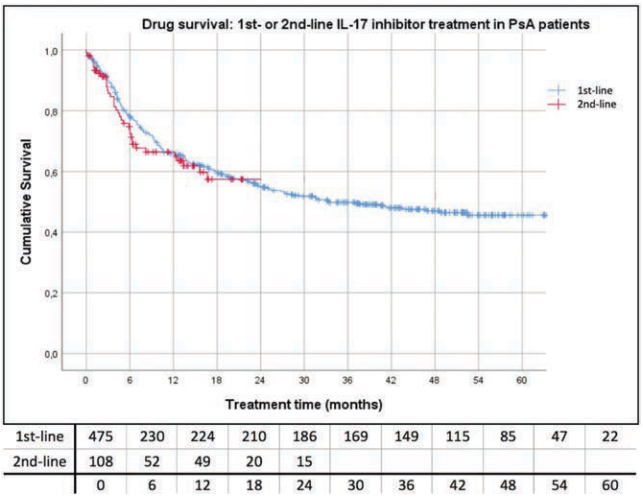

Figure 1.

Conclusion: PsA patients switching to a first- or second-line IL-17 inhibitor showed comparable baseline characteristics and an almost identical drug

survival. Thus, treatment failure of a first-line IL-17 inhibitor treatment, should not block for a second-line IL-17 inhibitor treatment.

Youssef[1,7,8]. *[1]OPAL Rheumatology Ltd, Rheumatology, Sydney, Australia; [2]Monash University, Rheumatology, Clayton, Australia; [3]WriteSource Medical Pty Ltd, Lane Cove, Sydney, Australia; [4]UNSW Sydney, Medical Sciences, Sydney, Australia; [5]Dandenong, Rheumatology, Dandenong, Australia; [6]Pfizer Australia, Clarence Street, Sydney, Australia; [7]The University of Sydney, Rheumatology, Camperdown, Australia; [8]Royal Prince Alfred Hospital, Rheumatology, Camperdown, Australia*

Background: Tofacitinib (TOF), a potent selective inhibitor of Janus kinase (JAK), is an approved treatment of psoriatic arthritis (PsA). In Australia, patients with active PsA despite six months of therapy with a pre-specified combination of csDMARDs are eligible to receive subsidised b/tsDMARDs. The clinician can prescribe the b/tsDMARD they deem to be the most clinically appropriate for the patient. Limited data exist to describe the real-world treatment patterns, characteristics and clinical outcomes of patients with PsA who receive TOF in the real-world setting.
Objectives: To describe real-world treatment patterns and treatment persistence among patients with PsA treated with TOF in the Australian post-approval setting using the OPAL dataset.
Methods: The OPAL dataset is a collection of deidentified clinical data derived from the electronic medical records of 112 rheumatologists at 43 sites around Australia. Adult patients with a diagnosis of PsA who received at least one prescription of TOF, a tumour necrosis factor inhibitor (TNFi) or an interleukin 17 inhibitor (IL-17Ai) between May 2019 and Sept 2020 were eligible, with data up to Sept 2021 included in the analysis. Results were summarised descriptively. Treatment persistence was summarised using Kaplan-Meier methods.
Results: Of 16,692 patients with PsA identified in the OPAL dataset, 1,486 (TOF n=406, IL-17Ai n=416, and TNFi n=664) were eligible for inclusion in this study. At the time of treatment initiation, the mean (SD) age of TOF, IL-17Ai and TNFi treated patients was 55.56 (12.68), 52.65 (12.72) and 50.32 (14.57) years, respectively. 19.2% of patients receiving TOF were first line compared with 41.8% of IL-17Ai and 62.8% of TNFi treated patients. The mean (SD) time from symptom onset to treatment initiation was longest for patients receiving TOF in first line (153.29 (127.50) months) compared to first line IL-17Ai (116.83 (113.97) months) and TNFi treated patients (92.37 (89.01) months). Overall, 34.2% of TOF, 32.9% of IL-17Ai and 26.4% of TNFi treated patients initiated therapy without concomitant cDMARDs being recorded.
Overall median persistence was 16.54 months (95% CI 13.84, 19.53) for TOF treated patients, 17.65 months (95% CI, 15.75, 19.56) for IL-17Ai treated patients and 17.16 months (95% CI 14.86, 20.48) for TNFi treated patients. As expected, persistence was generally longer in patients treated as first line (Figure 1) with patients receiving TOF observed to have slightly higher persistence in the first 15 months of treatment.

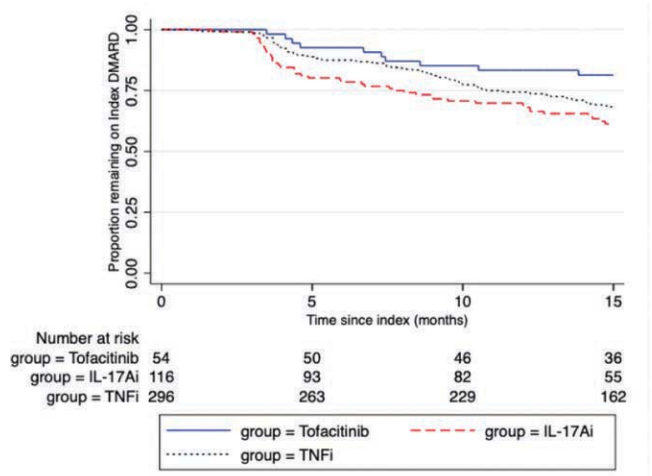

Figure 1. Treatment persistence of patients receiving TOF, IL-17Ai and TNFi as first line therapy. Plot curtailed at 15 months as relatively few patients have information past this point. Where no stop date was recorded, censoring occurs at last recorded visit

Conclusion: In this analysis of a large Australian real-world dataset, TOF was more commonly utilised as a later line therapy for patients with PsA. Patients receiving TOF were observed to have slightly higher persistence within the first 15 months of starting first line therapy in this preliminary analysis.

POS1020 BIOLOGICAL DMARD TREATMENT IN PSORIATIC ARTHRITIS IS LIKEWISE EFFECTIVE IN PATIENTS WITH HIGH AND WITH LOW JOINT COUNTS – RESULTS FROM THE SWISS CLINICAL QUALITY MANAGEMENT (SCQM) FOR RHEUMATIC DISEASES COHORT STUDY

B. Moeller[1], A. Ciurea[2], R. Micheroli3, M. J. Nissen[4], E. Papagiannoulis[5], A. Scherer[5], G. Scholz[1], N. Yawalkar[6]on behalf of Swiss Clinical Quality Management (SCQM) for rheumatic diseases. *[1]Inselspital - University Hospital Bern, Rheumatology and Immunology, Bern, Switzerland; [2]University Hospital Zurich, Rheumatology, Zürich, Switzerland; [2]University Hospital Zurich, Rheumatology, Zürich, Switzerland; [4]University Hospital Geneva, Rheumatology, Geneva, Switzerland; [5]Swiss Clinical Quality Management in Rheumatic Diseases, Statistics, Zurich, Switzerland; [6]Inselspital - University Hospital Bern, Dermatology, Bern, Switzerland*

Background: Biological and targeted synthetic (b/tsDMARDs) may be used in absent remission in psoriatic arthritis (PsA) independent of a defined number of affected joints. However, minimum three swollen and three tender joints are a common inclusion criterion in trials of b/tsDMARDs, and less is currently known about their effectiveness in PsA patients with low joint counts.
Objectives: To characterize PsA patients with low or high joint counts (LJC/HJC), analyze their drug treatment in routine care, and estimate the effectiveness of a first bDMARD in LJC and HJC patients.
Methods: We defined patients with less than three tender *or* swollen joints as LJC, and those with at least three tender *and* swollen joints as HJC patients. Patients were twice categorized according to their joint counts at registration in

the registry, and at start of a first bDMARD (Table 1). We compared HJC and LJC at registration for current and future DMARD therapies, and at start of a first bDMARD for treatment effectiveness, using drug retention in univariate and in multivariable Cox regression models.

Table 1. Selected characteristics of bDMARD naïve PsA patients with a low and with a high number of affected joints at start of their first bDMARD.

Variable	Levels	HJC	% high	LJC	% low	N all	p
bDMARD type	TNFi	176	92.6	175	88.8	351	=0.22

Enthesitis	Yes	63	61.8	55	47.0	118	=0.03
BMI	mean (SD)	27.65	(5.05)	26.58	(4.72)	333	=0.046
MASES	mean (SD)	2.86	(3.93)	1.61	(2.47)	219	=0.005
HAQ-DI	mean (SD)	0.77	(0.58)	0.60	(0.50)	292	=0.010
EQ-5d	mean (SD)	62.22	(20.63)	67.22	(16.27)	294	=0.022
Patient global	mean (SD)	5.93	(2.41)	4.83	(2.58)	288	<0.001
Tender joint count	mean (SD)	10.15	(8.93)	4.92	(8.17)	387	<0.001
Swollen joint count	mean (SD)	7.16	(4.91)	1.37	(2.15)	387	<0.001
Patient pain	mean (SD)	5.96	(2.47)	4.85	(2.51)	290	<0.001

Abbreviations: DAPSA: Disease activity of PsA. BMI: Body mass index, EQ-5d: European Quality of Life Measurement in five dimensions. HAQ-DI. Health assessment questionnaire disability index. HJC: High joint count, LJC: Low joint count, MASES: Maastricht ankylosing spondylitis enthesitis score, MDA: minimal disease activity, OMA: other mode of action than TNFi.

Results: We followed DMARD therapies for median (IQR) 3.2 (1.6, 5.0) in 675 LJC patients and for 3.4 (1.8, 5.2) years in 334 HJC patients. LJC patients at registration as well as at start of a first bDMARD were less often female, with less severe skin, enthesitis, dactylitis and nail involvement. Furthermore, LJC patients had lower disability indices and a more favorable health related quality of life. When defined at registration, LJC were as frequent as HJC patients on csDMARDs, but less often on bDMARDs. During their follow-up, a csDMARD, a first and a second bDMARD were less often and on average later commenced in LJC than in HJC patients. However, when defined at start of a first bDMARD, drug retention did not significantly differ between LJC and HJC patients (Figure 1).

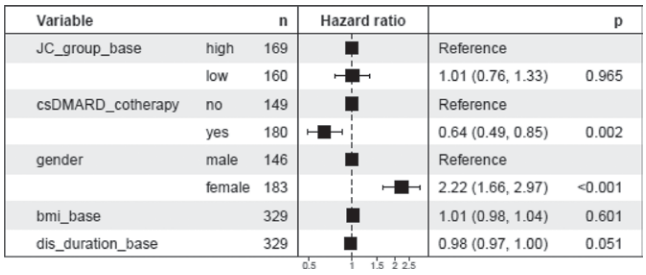

Figure 1. Multivariable adjusted Cox regression model for discontinuation of a first bDMARD. Abbreviation: JC_group_base: Low and high joint count groups at baseline.

Conclusion: The majority of Swiss PsA patients is in LJC status, which also means a better status in most PsA domains than in HJC patients. LJC status was associated with established bDMARD therapy and with slower treatment escalation. However, bDMARDs were likewise effective in bDMARD-naïve LJC and HJC patients, and should not withhold only for reasons of a low joint count.

THE EFFECT OF CANNABIDIOL ON QUANTITATIVE SENSORY TESTING PARAMETERS IN PATIENTS WITH HAND OSTEOARTHRITIS AND PSORIATIC ARTHRITIS: A RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED TRIAL

J. Vela[1], K. Kjær Petersen[2], L. Dreyer[1,3], L. Arent-Nielsen[2], S. Kristensen[1,3]. *[1]Aalborg University Hospital North, Rheumatology, Aalborg, Denmark; [2]Aalborg University, Centre for Neuroplasticity and Pain, SMI, School of Medicine, Aalborg, Denmark; [3]Aalborg University, Clinical Medicine, Aalborg, Denmark*

Background: Cannabidiol (CBD) has been proposed as an analgesic/anti-inflammatory treatment modality for joint pain. This study is based on a randomised, placebo controlled, double blind study (NORDCAN), investigating the effect of CBD in patients with painful hand osteoarthritis or psoriatic arthritis [1].

Objectives: The aim of the present study was to investigate the effect of CBD on quantitative sensory testing (QST) parameters.

Methods: The present randomised, placebo controlled, double blind study included 128 patients with hand osteoarthritis or psoriatic arthritis with chronic pain of moderate intensity. The trial compared 12 weeks of 20-30 mg CBD treatment with placebo. The QST parameters were assessed at baseline and after treatment. Pressure pain thresholds was measured at the most painful finger joint (local site) and the shin of the right leg (distal non-painful site). Temporal summation of pain and conditioned pain modulation were assessed using computer-controlled cuff algometry with the tourniquets on lower leg at the level of the upper portion of the gastrocnemius.

Results: Baseline characteristics (demographics and pain) for the CBD treated group and placebo group were comparable. No significant differences were observed in QST variables between baseline and end of treatment when comparing CBD and placebo.

Conclusion: No differences in modulation in QST parameters were demonstrated in patients in treatment with 20-30 mg CBD compared to placebo. Further studies of patients with rheumatic diseases treated with different dosage of CBD are needed to clarify the effect of CBD on pain in this patient group.

POS1022

RELATIONSHIPS BETWEEN INHIBITION OF RADIOGRAPHIC PROGRESSION AND ACHIEVEMENT OF LOW DISEASE ACTIVITY OR REMISSION AND THEIR CORE COMPONENTS IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH SECUKINUMAB IN FUTURE 5 DURING THE FIRST 24 WEEKS

P. J. Mease[1], A. M. Orbai[2], B. Parikh[3], C. Gaillez[4], X. Meng[5], C. T. Ritchlin[6].
[1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America; [2]Johns Hopkins University School of Medicine, Division of Rheumatology, Psoriatic Arthritis Program, Baltimore, United States of America; [3]Novartis Pharmaceuticals Corporation, Rheumatology, East Hanover, United States of America; [4]Novartis Pharma AG, Rheumatology, Basel, Switzerland; [5]Novartis Pharmaceuticals Corporation, Biostatistics, East Hanover, United States of America; [6]University of Rochester Medical Center, Division of Allergy, Immunology, and Rheumatology, Rochester, United States of America

Background: Patients with active psoriatic arthritis (PsA) experience inflammation that may result in structural damage and disability. In the phase 3 FUTURE 5 study, treatment with secukinumab (SEC) inhibited radiographic progression and led to sustained remission and low disease activity (LDA) through Week 104.[1,2]
Objectives: This post hoc analysis of FUTURE 5 explored relationships between radiographic progression status and achievement of LDA or remission in patients treated with SEC.
Methods: Patients were randomized 2:2:2:3 to receive SEC 300 mg with loading dose (LD), 150 mg LD, SEC 150 mg without LD, or placebo (PBO) at Baseline, Weeks 1, 2, 3, 4, and every 4 weeks thereafter until Week 24. In this post hoc analysis, patients were grouped by radiographic progression status at Week 24 (non-radiographic progressors: change from baseline in modified total Sharp score [mTSS] ≤0.0; radiographic progressors: change from baseline in mTSS >0.0). Efficacy (achievement of Minimal Disease Activity [MDA] or Very Low Disease Activity [VLDA] and their individual components, and Disease Activity Index for Psoriatic Arthritis [DAPSA] LDA or remission) was assessed at Week 24.
Results: Of 933 patients with available data, 675 (72.3%) were classified as non-radiographic progressors and 258 (27.7%) were radiographic progressors at Week 24. Non-progressors at Week 24 were more likely than progressors to achieve DAPSA LDA and remission at Week 24 across all treatment arms (Figure 1A). In addition, non-progressors were more likely to achieve MDA and VLDA at Week 24 than progressors across all treatment arms (Figure 1B). Similar trends were observed for all of the individual MDA/VLDA criteria at Week 24 among patients treated with SEC 300 mg or SEC 150 mg LD (Table 1). Notably, non-progressors were more likely to achieve improvements in physical function, pain, and patient global assessment of disease activity than progressors across all treatment arms.
Conclusion: Patients who did not have radiographic progression over 6 months of SEC treatment were more likely to achieve LDA or remission and improvement in physical function at Week 24. Additional analyses will explore relationships between radiographic progression and additional clinical and patient-reported outcomes over longer time periods.

POS1023

LONG-TERM SAFETY OF RISANKIZUMAB IN PATIENTS WITH PSORIATIC DISEASE: FINDINGS FROM INTEGRATED ANALYSES OF 17 CLINICAL TRIALS IN PSORIASIS AND 4 IN PSORIATIC ARTHRITIS

K. B. Gordon[1], A. Blauvelt[2], H. Bachelez[3], B. Kaplan[4], W. Koetse[4], L. Drogaris[4], R. Sinvhal[4], K. Papp[5]. *[1]Medical College of Wisconsin, Dermatology, Milwaukee, United States of America; [2]Oregon Medical Research Center, Dermatology, Portland, United States of America; [3]APHP Hôpital Saint-Louis, Université de Paris, Department of Dermatology, Paris, France; [4]AbbVie Inc., Immunology, North Chicago, United States of America; [5]Probity Medical Research, K Papp Clinical Research, Waterloo, Canada*

Background: Risankizumab, an interleukin-23 inhibitor, was efficacious and well tolerated in phase 2 and 3 clinical studies in patients with psoriatic disease.
Objectives: To report long-term risankizumab safety in patients with psoriatic disease.
Methods: Risankizumab safety data to March 25, 2021 were pooled from 17 phase 1–3 clinical trials in plaque psoriasis (PsO) and 4 phase 2/3 trials in psoriatic arthritis (PsA). Adverse events (AEs) of safety interest were reported for patients receiving ≥1 dose risankizumab.
Results: Among 3197 patients with PsO (9982.6 patient years' [PY] exposure; median (range) treatment duration, 3.7 years [1 day–6.9 years]) and 1542 patients with PsA (1594.9 PY; 1.0 year [84 days–2.0 years]), rates of treatment-emergent AEs (158.3 and 160.8 events (E)/100PY), serious AEs (7.6 and 8.4 E/100PY) and AEs leading to discontinuation (1.9 and 2.3 E/100PY) were similar. Nasopharyngitis (PsO 14.5 E/100PY, PsA 7.9 E/100PY) and upper respiratory infection (PsO 7.8 E/100PY, PsA 5.6 E/100PY) were the most common infections; sepsis and pneumonia for PsO (0.1 E/100PY each) and COVID-19 for PsA (0.4 E/100PY) were the most common serious infections. Rates of opportunistic fungal infections were <0.1 and 0.1 E/100PY in PsO/PsA patients. Rates of non-melanoma skin cancer (NMSC) were 0.7 and 0.4 E/100PY, and malignant tumors excluding NMSC were 0.6 and 0.3 E/100PY in PsO/PsA patients. Rates of major adverse cardiovascular events were 0.5 and 0.4 E/100PY in PsO/PsA patients.
Conclusion: Rates of AEs of safety interest remained low in this largest and longest safety reporting for risankizumab to date, supporting the safety of risankizumab for the long-term treatment of patients with psoriatic disease.

EFFICACY AND SAFETY OF RISANKIZUMAB (RZB) FOR ACTIVE PSORIATIC ARTHRITIS (PSA): 52-WEEK RESULTS FROM KEEPSAKE 1

L. E. Kristensen[1], M. Keiserman[2], K. Papp[3], L. Mccasland[4], D. White[5], W. Lu[6], A. M. Soliman[6], A. Eldred[6], L. Barcomb[6], F. Behrens[7]. *[1]Copenhagen University Hospital, Bispebjerg and Frederiksberg, The Parker Institute, Copenhagen, Denmark; [2]Pontifical Catholic University, School of Medicine, Rheumatology Section, Porto Alegre, Brazil; [3]Probity Medical Research, K Papp Clinical Research, Waterloo, Canada; [4]Loyola University Medical Center, Department of Rheumatology, Maywood, United States of America; [5]Waikato Hospital, Rheumatology Department, Hamilton, New Zealand; [6]AbbVie Inc., Immunology, North Chicago, United States of America; [7]Goethe University, CIRI/ Rheumatology, Frankfurt, Germany*

Background: RZB, a humanized immunoglobulin G1 monoclonal antibody that specifically inhibits the p19 subunit of the human cytokine IL-23, is being investigated as a treatment for PsA.
Objectives: To compare efficacy and safety of RZB vs. placebo (PBO) in patients with PsA who had an inadequate response or intolerance to conventional synthetic disease modifying antirheumatic drug (csDMARD-IR).
Methods: KEEPsAKE 1 (NCT03675308) is an ongoing, phase 3 study that includes a screening period; a 24-week double-blinded, placebo-controlled, parallel-group period (period 1); and an open-label extension period (period 2). Eligible patients aged ≥18 years with active PsA (symptom onset ≥6 months prior to screening, meeting the Classification Criteria for PsA [CASPAR], and ≥5 swollen and ≥5 tender joints) and who had an inadequate response or intolerance to ≥1 csDMARD-IR, were randomized 1:1 to receive RZB 150 mg or placebo (PBO) at weeks 0, 4, and 16. The primary endpoint was the proportion of patients achieving ≥20% improvement in American College of Rheumatology (ACR20) response at week 24. Period 2 started at week 24, and patients were switched to receive open-label RZB 150 mg every 12 weeks through week 208. Mixed-effect model repeated measures and nonresponder imputation methods were used to assess continuous and binary variables, respectively. Efficacy and safety were analyzed in all patients who received ≥1 dose of study drug through week 52. Treatment-emergent adverse events (TEAE) were summarized using exposure-adjusted event rates (EAERs, events/100 patient-years [PY]).
Results: At week 24, a greater proportion of RZB-treated (N=483) vs PBO-treated (N=481) patients achieved ACR20 (55.3% and 32.8%, respectively). At week 52, 70% of patients who were randomized to receive RZB and 63% of patients who were randomized to receive PBO and switch to RZB at week 24 achieved ACR20. In patients with ≥3% of body surface area affected at baseline, 52.7% of RZB-treated patients (N=273) and 9.9% of PBO-treated patients (N=272) achieved ≥90% improvement in Psoriasis Area and Severity Index (PASI 90) at week 24; 67.8% who were randomized to receive RZB and 59.9% who were randomized to receive PBO and switch to RZB at week 24 achieved PASI 90 at week 52. Similar results were observed for other efficacy measures. RZB was well tolerated through 52 weeks of treatment. EAERs of adverse events were stable between weeks 24 and 52. At the week 52 data cut-off (19 April 2021), the total EAER of any TEAE in patients receiving RZB was 143.1/100 PY.
Conclusion: Continuous RZB treatment provided durable efficacy and a consistent safety profile through 52 weeks of treatment in patients with active PsA who were csDMARD-IR.

POS1025 COMPARISON OF COMPOSITE INDICES FOR DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH UPADACITINIB: A POST-HOC ANALYSIS FROM SELECT-PSA 1

J. S. Smolen[1], E. Lubrano[2], M. Kishimoto[3], A. Balanescu[4], V. Strand[5], T. Gao[6], N. Vranich[6], R. Lippe[7], W. Tillett[8]. *[1]Medical University of Vienna, Medicine, Vienna, Austria; [2]Department of Medicine and Health Sciences Vincenzo Tiberio, University of Molise, Campobasso, Italy; [3]Department of Nephrology and Rheumatology, Kyorin University School of Medicine, Tokyo, Japan; [4]"Carol Davila" University of Medicine and Pharmacy, Department of Internal Medicine and Rheumatology "Sf. Maria" Hospital, Bucharest, Romania; [5]Stanford University, Department of Medicine, Palo Alto, United States of America; [6]AbbVie Inc., Immunology, North Chicago, United States of America; [7]AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany; [8]Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom*

Background: Achieving low disease activity (LDA) or remission is a main treatment target in PsA. Composite indices used to assess disease activity include Disease Activity index for PsA (DAPSA) and PsA Disease Activity Score (PASDAS), which both have cut points for the states of remission and LDA. In addition, LDA and remission can be assessed by the pure state instrument Minimal Disease Activity (MDA)/Very Low Disease Activity (VLDA).

Objectives: These analyses aim to identify overlap and differences between these composite indices in PsA patients treated with upadacitinib (UPA), a Janus kinase inhibitor, or adalimumab (ADA) in the phase 3 SELECT-PsA 1 trial.

Methods: In SELECT-PsA 1 (phase 3, randomized controlled trial, with long-term extension up to 5 years), patients with moderate to severely active PsA with prior inadequate response or intolerance to ≥1 non-biologic DMARD were randomized to oral UPA at doses of 15 mg or 30 mg (once daily), subcutaneous ADA 40 mg (every other week), or placebo.[1] LDA was assessed using MDA (threshold: 5/7 criteria), DAPSA (≤14), PASDAS (≤3.2), and Patient Global Assessment of Disease Activity (PtGA; ≤3).[2,3] These post-hoc descriptive analyses include 1-year (cut off: week 56) *as observed* data from UPA 15 mg and ADA.

Results: In total, 858 patients (UPA 15 mg: n=429; ADA: n=429) were included in these analyses. Patients receiving UPA and ADA were on average 52 years of age, 54% were female, with an average disease duration of approximately 6 years.[1] With both UPA and ADA, there was a high degree of overlap in the proportion of patients achieving LDA thresholds in MDA, DAPSA, and PASDAS (Figure 1), with reported PtGA improvements showing a similar trend. Defining LDA according to MDA or respective cut points for DAPSA, PASDAS, or PtGA, the proportion of "non-responders" (ie, patients who did not reach such states) is shown in Figure 2. Of the individual components included in these indices, fewer patients reported low levels of SF-36 Physical Component Summary (SF36-PCS), Patient Assessment of Pain Numeric Rating Scale (Pain NRS), and Health Assessment Questionnaire - Disability Index (HAQ-DI) scores, as well as Tender Joint Count 68 (TJC68), with similar responses observed across all indices.

Conclusion: In this post-hoc analysis from the SELECT-PsA 1 trial, there was a high degree of overlap between patients in LDA across the composite indices, including MDA, DAPSA, and PASDAS, irrespective of treatment with UPA 15 mg or ADA and despite variability in inclusion of certain components in some indices but not others. Across all indices, fewer patients reported low levels of SF36-PCS, Pain NRS, and HAQ-DI scores, and TJC68. These data show that improvements in (subjective) "patient-driven" components were the most challenging to achieve. These data indicate a similar pattern of residual disease activity, or influence by residual damage or external factors, regardless of composite endpoint utilized.

POS1026 PREDICTORS FOR ACHIEVEMENT OF LOW DISEASE ACTIVITY AT WEEK 56 IN PATIENTS WITH PSORIATIC ARTHRITIS WHO RECEIVED UPADACITINIB 15 MG ONCE DAILY: POOLED ANALYSIS OF TWO PHASE 3 STUDIES

D. Aletaha[1], P. J. Mease[2], R. Lippe[3], F. Behrens[4], D. Haaland[5], P. Palominos[6], A. Lertratanakul[7], M. Lane[7], K. Douglas[7], P. Nash[8], A. Kavanaugh[9]. *[1]Department of Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria; [2]Swedish Medical Center/Providence St. Joseph Health, University of Washington, Seattle, United States of America; [3]AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany;*

[4]Rheumatology and Fraunhofer Institute for Translational Medicine and Pharmacology (ITMP), Goethe-University, Frankfurt, Germany; [5]McMaster University, Medicine, Hamilton, Canada; [6]Division of Rheumatology, Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [7]AbbVie Inc., Immunology, North Chicago, United States of America; [8]University of Queensland, Rheumatology, Brisbane, Australia; [9]Division of Rheumatology, Allergy Immunology, University of California, San Diego, United States of America

Background: Upadacitinib (UPA) 15 mg once daily (QD) has demonstrated efficacy and safety in patients with psoriatic arthritis (PsA) for up to 56 weeks in the Phase 3 SELECT-PsA 1 and 2 trials.[1,2]

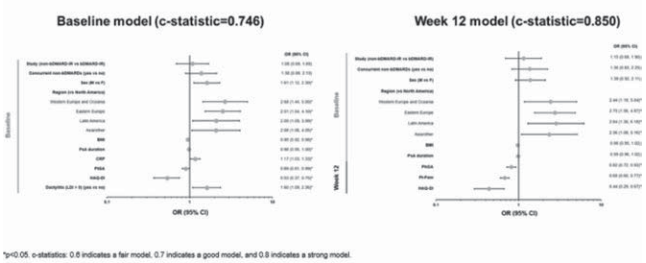
Objectives: This post hoc analysis of these studies explored the association of baseline characteristics and short-term responses with achievement of minimal disease activity (MDA) and Disease Activity Index for Psoriatic Arthritis (DAPSA) low disease activity (LDA).

Methods: Data were pooled from patients with prior inadequate response or intolerance to ≥1 non-biologic (b) DMARDs (SELECT-PsA 1) or ≥1 bDMARDs (SELECT-PsA 2) originally randomized to UPA 15 mg QD. Logistic regression models were used to assess the association between baseline characteristics and short-term (Week 12) responses with achieving MDA or DAPSA LDA at 56 weeks, sustained MDA (MDA at Weeks 36 and 56), or sustained DAPSA LDA (DAPSA LDA at Weeks 36, 44, and 56). Each predictor was evaluated separately in an initial model that included effects for study and concurrent non-bDMARD use. Odds ratios and concordance (c-)statistics were used to determine the predictive accuracy. Statistically significant predictors were then evaluated simultaneously using stepwise logistic regression with the Akaike Information Criterion for model-building.

Results: Of 640 patients included in the analysis, 40% and 47% achieved MDA and DAPSA LDA, respectively, at 56 weeks. Evaluated separately, younger age, sex (male), geographic region, lower weight, lower body mass index, the presence of dactylitis or enthesitis, and lower scores of Patient's Assessment of Pain (Pt-Pain), Patient's Global Assessment (PtGA), tender joint count in 68 joints, and Health Assessment Questionnaire-Disability Index (HAQ-DI) were significant baseline predictors for achieving MDA and DAPSA LDA at Week 56. Lower Pt-Pain (Weeks 12–24) and PtGA (Weeks 16–24) scores were strongly predictive (c-statistics >0.8) of achieving MDA at Week 56, and both measures (from Week 8) were moderately predictive (c-statistics >0.7) of achieving DAPSA LDA. Evaluated simultaneously with several baseline characteristics, lower Pt-Pain and HAQ-DI scores at Week 12 were included in models strongly predictive of achieving MDA (c-statistic=0.850; Figure 1) and DAPSA LDA (c-statistic=0.840; Figure 2) at Week 56. For each 1-point increase in Pt-Pain or HAQ-DI scores at Week 12 (after adjusting for other effects in the model), patients were less likely to achieve MDA (by 32% or 56%, respectively) or DAPSA LDA (by 23% or 31%, respectively) at Week 56. Predictors for achieving sustained MDA and sustained DAPSA LDA were generally similar to those identified for achieving MDA and DAPSA LDA, respectively.

Conclusion: In patients with PsA receiving UPA 15 mg, baseline characteristics and early responses strongly predicted achievement of MDA or DAPSA LDA at Week 56. This may guide considerations of treatment targets in clinical trials and encourage physicians to further optimize treatment of their patients in clinical practice.

Figure 1. Predictors of Achievement of MDA at Week 56 with Upadacitinib 15 mg – Evaluated Simultaneously

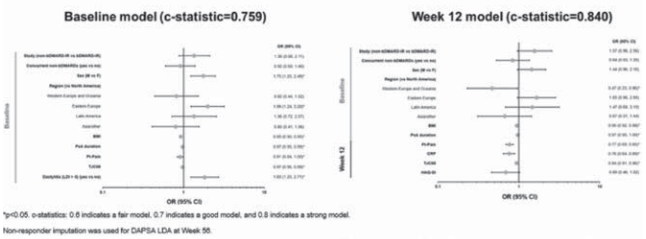


*p<0.05. c-statistics: 0.8 indicates a fair model, 0.7 indicates a good model, and 0.8 indicates a strong model.

Non-responder imputation was used for MDA at Week 56.

bDMARD, biologic disease-modifying antirheumatic drug; BMI, body mass index; CI, confidence interval; CRP, C-reactive protein; F, female; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, inadequate responder; LDI, Leeds Dactylitis Index; M, male; MDA, minimal disease activity; OR, odds ratio; PhGA, Physician's Global Assessment; PsA, psoriatic arthritis; PtGA, Patient's Global Assessment; Pt-Pain, Patient's Assessment of Pain.

Figure 2. Predictors of Achievement of DAPSA LDA at Week 56 with Upadacitinib 15 mg – Evaluated Simultaneously



*p<0.05. c-statistics: 0.8 indicates a fair model, 0.7 indicates a good model, and 0.8 indicates a strong model.

Non-responder imputation was used for DAPSA LDA at Week 56.

bDMARD, biologic disease-modifying antirheumatic drug; BMI, body mass index; CI, confidence interval; CRP, C-reactive protein; DAPSA, Disease Activity Index for Psoriatic Arthritis; F, female; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, inadequate responder; LDA, low disease activity; LDI, Leeds Dactylitis Index; M, male; OR, odds ratio; PsA, psoriatic arthritis; Pt-Pain, Patient's Assessment of Pain; TJC68, tender joint count in 68 joints.

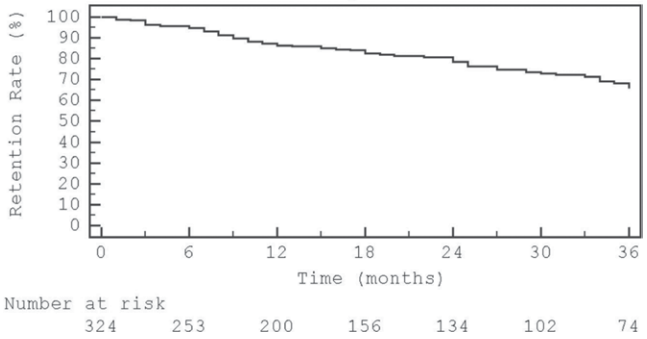
Background: Apremilast, an inhibitor of the phosphodiesterase 4, is indicated for Psoriatic Arthritis (PsA) treatment. The 3 years retention rate, an outcome indirectly related to efficacy, observed in clinical trials [1] is 55,5%. A single subsequent real world setting study [2] suggested a lower efficacy as it reported that the six months retention rate was about 57%.
Objectives: The main aim of this retrospective observational study is the assessment of apremilast 3 years retention rate in a real world PsA patients' cohort. Moreover, the secondary objective is reporting the reasons of apremilast suspension and the most relevant factor related to treatment persistence.
Methods: In thirteen Italian rheumatological referral centers, all PsA consecutive patients who received apremilast were enrolled. Anamnestic data, treatment history and PsA disease activity (DAPSA) at baseline and after 6 and 12 months were recorded. The Kaplan-Meier curve and the Cox analysis computed the apremilast retention rate and treatment persistence-related risk factors. A p-value < 0.05 was considered statistically significant.
Results: The three-hundred-twenty-four enrolled patients (median age 60 [Inter-Quartile Range IQR 52-67] yrs; female prevalence 57,0%) median observation period was 17 [IQR 7-36] months (6848 patients-months). The apremilast retention rate at 6, 12 and 36 months was, respectively, 95%, 86% and 66% (Figure 1). The main discontinuation reasons were: primary inefficacy (40% of interruptions), secondary inefficacy (18%) and gastro-intestinal intolerance (17%%). The oligo-articular onset was the only factor associated to apremilast persistence (Hazard ratio 0.57 IQR 0.34-0.96). Sex, age, and sever comorbidities (cancer, chronic infections etc) were not related to treatment discontinuation. The basal DAPSA (24.1, IQR 18.5-32.0) decreased after 6 and 12 months (respectively 14.5, IQR 10.1-22.6 and 10.5, IQR 8,0-15.2). Remission or minimal disease activity (DAPSA < 15) was achieved after 12 months in 38.0% of patients.

Figure 1



Conclusion: Almost two third of PsA patients receiving apremilast were still in treatment after 3 years. The study's data, confirmed its efficacy and safety profile. Apremilast appear a good treatment choice in patients with oligo articular PsA or burdened by severe comorbidities.

Background: Guselkumab (GUS), a selective inhibitor of IL-23, significantly improved the diverse manifestations of active psoriatic arthritis (PsA), including dactylitis and enthesitis, in DISCOVER (D)-1 & 2 trials of patients (pts) with active PsA[1,2], with maintenance of response rates through 1 year (yr).[3,4] Dactylitis and enthesitis, extra-articular manifestations of PsA, can be difficult to treat and cause significant disease burden.[5,6]
Objectives: To evaluate the ability of GUS to provide long-term resolution of dactylitis and enthesitis in pts with PsA through 2 yrs of D-2.
Methods: D-2 biologic naïve pts with active PsA were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo (PBO). At W24, PBO pts crossed over to GUS Q4W. Independent assessors evaluated dactylitis (total score: 0-60) and enthesitis (Leeds Enthesitis Index [LEI]; total score 0-6). These post hoc analyses assessed baseline (BL) frequency and severity of enthesitis in pts with dactylitis and dactylitis frequency in pts with enthesitis. Post BL, changes in dactylitis and LEI scores over time (least squares [LS] mean changes; analysis of covariance [ANCOVA]) and rates of resolution of dactylitis and enthesitis (Chi square correlation test) were determined in pts with these manifestations at BL (missing data imputed as no change/response).
Results: At BL, more D-2 pts had enthesitis (68%) than dactylitis (45%). At BL, 78% of pts with dactylitis vs 61% without (w/o) dactylitis had enthesitis and 51% of pts with enthesitis vs 32% w/o enthesitis had dactylitis. Among pts with enthesitis at BL, a higher percentage of pts with dactylitis (52%) had severe enthesitis (LEI score ≥3) vs pts w/o dactylitis (44%). Among those with the condition at BL, resolution rates of dactylitis (57%, Q4W; 64%, Q8W) and enthesitis (44%, Q4W; 54%, Q8W) at W24 increased through W52 (dactylitis: 74%, Q4W; 78%, Q8W; enthesitis: 57%, Q4W; 61%, Q8W) and were maintained at W100 (dactylitis: 72%, Q4W; 83%, Q8W; enthesitis: 62%, Q4W; 70%, Q8W). Consistent results were observed when evaluating mean changes in dactylitis and LEI scores and in pts who crossed over from PBO to GUS Q4W at W24 (Table 1). In pts with dactylitis and enthesitis at BL, GUS-treated pts showed significant correlations between resolution of enthesitis and dactylitis at W24 (p=0.004), W52 (p<0.001) and W100 (p=0.039), with nearly 90% of pts with enthesitis resolution also achieving dactylitis resolution at W52 and W100 (Figure).

Table 1. LS mean change from baseline over time in dactylitis and LEI scores in pts with manifestation at baseline

	GUS 100 mg Q4W	GUS 100 mg Q8W	PBO → GUS 100 mg Q4W
Dactylitis score (0-60)			
Pts, N	121	111	99
W24[a]	-5.9 (-6.7, -5.0)	-6.0 (-6.8, -5.1)	-4.0 (-5.0, -3.1)
W52[a]	-6.5 (-7.2, -5.8)	-7.2 (-7.9, -6.5)	-6.9 (-7.6, -6.2)
W100[a]	-6.5 (-7.1, -5.8)	-7.5 (-8.1, -6.8)	-6.9 (-7.6, -6.2)
LEI score (1-6)			
Pts, N	170	158	178
W24[a]	-1.5 (-1.8, -1.3)	-1.6 (-1.8, -1.4)	-1.0 (-1.3, -0.8)
W52[a]	-1.8 (-2.0, -1.6)	-1.9 (-2.1, -1.7)	-2.0 (-2.2, -1.8)
W100[a]	-1.9 (-2.1, -1.7)	-2.1 (-2.3, -1.8)	-2.1 (-2.3, -1.9)

[a]Results are LS mean change (95% confidence interval [CI]); LS mean change determined by ANCOVA; missing data was imputed as no change for pts who discontinued treatment and using multiple imputation for remaining missing data GUS, guselkumab; LEI, Leeds Enthesitis Index; LS, least squares; PBO, placebo; pts, patients; Q4W, every 4 weeks; Q8W, every 8 weeks; W, week

Conclusion: Pts with PsA often present with concurrent enthesitis and dactylitis, both of which can be recalcitrant to treatment. GUS resolved enthesitis and dactylitis in substantial proportions of pts through W100. GUS-treated pts who achieved enthesitis resolution were more likely to achieve dactylitis resolution and vice versa.

EFFECTS OF TREATMENT WITH RISANKIZUMAB ON MINIMAL DISEASE ACTIVITY (MDA) AND DISEASE ACTIVITY IN PSORIATIC ARTHRITIS (DAPSA): AN ANALYSIS OF THE KEEPSAKE-1 AND -2 TRIALS

J. F. Merola[1], I. Mcinnes[2], A. Kavanaugh[3], P. Nash[4], Z. Xue[5], V. Stakias[5], A. Eldred[5], S. Ciecinski[5], K. Douglas[5], L. Coates[6]. [1]*Brigham and Women's Hospital, Harvard Medical School, Boston, United States of America;* [2]*University of Glasgow, Institute of Infection Immunity and Inflammation, Glasgow, United Kingdom;* [3]*University of California San Diego, Medicine, San Diego, United States of America;* [4]*Griffith University, School of Medicine, Queensland, Australia;* [5]*AbbVie Inc., Immunology, North Chicago, United States of America;* [6]*Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*

Background: Risankizumab (RZB) is a monoclonal antibody that specifically inhibits interleukin 23.

Objectives: To evaluate the achievement of Minimal Disease Activity (MDA), its components, and achievement of Disease Activity in PsA Low Disease Activity and Remission (DAPSA LDA+REM, [DAPSA score ≤14]) in patients receiving RZB or placebo (PBO) in the KEEPsAKE 1 and 2 clinical trials.

Methods: KEEPsAKE-1 and -2, double-blind, phase 3 trials, evaluated the efficacy of RZB versus PBO for the treatment of adult patients with active psoriatic arthritis (PsA). Patients were randomized (1:1) to receive subcutaneous RZB 150mg or PBO at weeks 0, 4, and 16. The open label extension began at Week 24 with all patients receiving RZB 150mg every 12 weeks thereafter. Achievement of MDA, its components, and achievement of DAPSA LDA+REM are reported using non-responder imputation.

Results: MDA achievement at Week 52 in KEEPsAKE-1 was 37.9% for patients originally randomized to RZB and 27.4% for patients originally randomized to PBO. In KEEPsAKE-2, MDA achievement was 27.2% and 33.8% for patients originally randomized to RZB and PBO, respectively. Achievement of MDA and its components are presented in Figure 1. In KEEPsAKE-1, at Week 52 59.2% of patients originally randomized to RZB and 51.4% of patients originally randomized to PBO achieved DAPSA LDA+REM. At Week 52 in KEEPsAKE-2, DAPSA LDA+REM was achieved by 44.6% of patients originally randomized to RZB and 46.6% of patients originally randomized to PBO (Figure 1).

Conclusion: Patients treated with RZB demonstrate achievement of MDA, its components, and DAPSA LDA+REM at Weeks 24 and 52.

Figure 1

POS1030

PAIN RESPONSE IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH GUSELKUMAB IS DRIVEN PREDOMINANTLY BY INFLAMMATION-INDEPENDENT EFFECTS

P. J. Mease[1], E. Soriano[2], S. D. Chakravarty[3,4], E. Rampakakis[5], M. Shawi[6], P. Nash[7], P. Rahman[8]. *[1]Swedish Medical Center/Providence St. Joseph Health and Univ Washington, Rheumatology Research, Seattle, United States of America; [2]Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; [3]Janssen Scientific Affairs, LLC, Immunology, Rheumatology, Horsham, United States of America; [4]Drexel University College of Medicine, Division of Rheumatology, Philadelphia, United States of America; [5]McGill University, Department of Pediatrics, Montreal, Canada; [6]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; [7]Griffith University and U of Queensland, Rheumatology Research Unit, Maroochydore, Australia; [8]Memorial University of Newfoundland, Discipline of Medicine, Division of Rheumatology, Craig L Dobbin Genetics Research Centre, St. John's, Canada*

Background: Although reducing inflammation has been associated with pain improvement, the two do not always correlate. Recent studies have suggested that, in addition to its role in inflammation pathogenesis, IL-23 may be involved in pain regulation in a lymphocyte-independent manner[1]. Guselkumab (GUS), a fully human monoclonal antibody that selectively inhibits IL-23, has demonstrated safety and efficacy in treating multiple domains of active PsA in the DISCOVER-1&2 (D1&D2) trials[2,3].
Objectives: To quantify the role of reducing inflammation on the observed relationship between GUS and pain response in PsA patients (pts) using mediation modelling.
Methods: Pooled data from the D1&D2 studies were analyzed. Pts in D1 had ≥3 swollen and ≥3 tender joints (SJC/TJC) and C-reactive protein (CRP)≥0.3 mg/dL; in D2, pts had ≥5 SJC and ≥5 TJC and CRP≥0.6 mg/dL. 31% of D1 pts received 1-2 prior tumor necrosis factor inhibitors (TNFi); D2 pts were bio-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then every 8 weeks (Q8W); or placebo (PBO); PBO pts crossed over to GUS 100 mg Q4W at W24. Pts with history of fibromyalgia were excluded from the analysis. Least square mean changes in pt-reported pain (0-100 VAS) through W52 were estimated with a repeated measures linear mixed model adjusting for known pain determinants. Mediation modelling was performed separately for Q4W & Q8W, W4 & W24, and TNFi-naïve & -experienced (exp) pts. In each model, change in pt-reported pain was the dependent variable; treatment regimen was the independent variable; inflammation, measured by change in SJC or CRP, was the designated mediator; covariates were: age; sex; and baseline (BL) pain score, BMI, SF-36 MCS score, and NSAID use.
Results: Mean (SD) BL pain levels in the GUS Q4W, GUS Q8W, and PBO groups were 60.4 (19.8), 62.0 (20.2), and 61.1 (19.6), respectively. Treatment with GUS was associated with significantly greater pain improvement compared with PBO as early as W4 ($\Delta_{Q4W\text{-}PBO}$ [95%CI]: -4.9 [-7.6, -2.2]; $\Delta_{Q8W\text{-}PBO}$ [95%CI]: -5.2 [-7.9, -2.5] (Figure 1). These between-group differences were further enhanced by W24 ($\Delta_{Q4W\text{-}PBO}$ [95%CI]: -14.6 [-17.6, -11.5]; $\Delta_{Q8W\text{-}PBO}$ [95%CI]: -14.3 [-17.3, -11.2]); by W52, GUS-randomized pts exhibited an approximate 30-point (-50%) decrease in pain. Similar results were observed for TNFi-naïve and TNFi-exp pts.

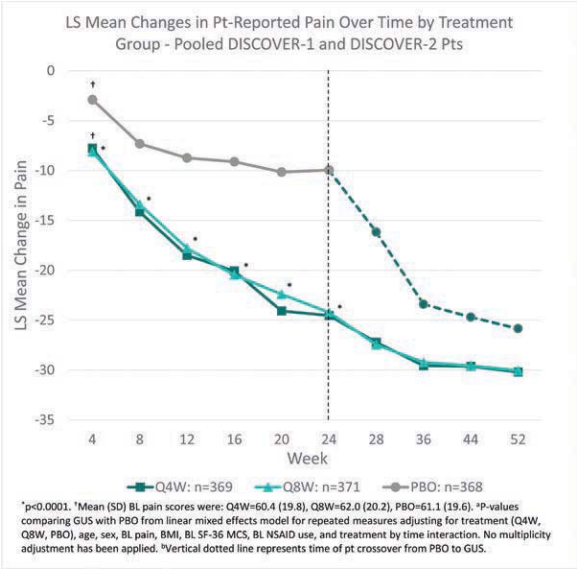

Figure 1.

Mediation analyses demonstrated that the majority of GUS effect on pain at W4 was not attributable to SJC (direct effect), specifically ≤6% was mediated by inflammation as assessed by changes in SJC (indirect effect; Table 1). Similarly, at W24, the indirect effect via SJC improvement represented ≤10% of the GUS treatment effect. No differences were observed between TNFi-naïve and -exp pts at either timepoint.
Consistent results were obtained when using CRP as the mediator variable instead of SJC, whereby ≤2-9%% of GUS effect on pan was mediated by inflammation and 91-98% was direct (Table 1).

Table 1. Direct (D) Treatment Effect vs. Indirect (IND) Effect via Inflammation Markers on Pain Improvement

Mediator	Week	Pt Group	Effect	GUS Q4W	GUS Q8W
SJC	4	All	D	96.7%*	97.0%*
			IND†	3.3%	3%
		TNFi-Naive	D	93.7%*	98.5%*
			IND†	6.3%	1.5%
		TNFi-Exp	D	100%*	100%*
			IND†	0%	0%
	24	All	D	94.8%*	92.0%*
			IND†	5.2%*	8.0%*
		TNFi-Naive	D	89.6%*	90.1%*
			IND†	10.4%*	9.9%*
		TNFi-Exp	D	99.8%*	95.7%*
			IND†	0.2%	4.3%
CRP	4	All	D	97.6%*	95.0%*
			IND‡	2.4%	5.0%
		TNFi-Naive	D	98.2%*	95.4%*
			IND‡	1.8%	4.6%
		TNFi-Exp	D	97.6%*	95.3%*
			IND‡	2.4%	4.7%
	24	All	D	97.2%*	94.2%*
			IND‡	2.8%	5.8%*
		TNFi-Naive	D	98.1%*	95.9%*
			IND‡	1.9%	4.1%
		TNFi-Exp	D	96.5%*	91.4%*
			IND‡	3.5%	8.6%

*p<0.05; †via SJC; ‡via CRP

Conclusion: GUS induced significant improvement in pt-reported pain as early as W4 of treatment, which was continuously enhanced through W52. While the known mediation effect of SJC and CRP, as markers of inflammation, on pain was confirmed, the majority of GUS's effect on pain reduction was independent of its effect on these markers, regardless of dosing regimen or prior TNFi experience.

Background: Guselkumab (GUS), an IL-23p19-subunit inhibitor, demonstrated efficacy and a favorable safety profile in patients (pts) with psoriasis (PsO) and psoriatic arthritis (PsA). In the Phase 3, double-blind, placebo (PBO)-controlled DISCOVER-2 study, GUS 100 mg every 4 or 8 weeks (Q4W or Q8W) significantly improved joint and skin symptoms; GUS-treated pts had smaller mean changes in radiographic progression vs. PBO at W24.[1] Low rates of radiographic progression were observed through 2 years among GUS-treated pts, regardless of dosing regimen.[2,3]
Objectives: Determine whether earlier clinical improvement predicts long-term radiographic progression through 2 years in DISCOVER-2.
Methods: DISCOVER-2 included biologic-naïve pts with active PsA (≥5 swollen and ≥5 tender joint counts [SJC/TJC]; CRP ≥0.6 mg/dL) randomized (1:1:1) to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W (PBO→Q4W) at W24. For pts randomized to GUS Q4W or Q8W, predictive models (mixed linear) were developed post-hoc to assess the associations of earlier (at W16) improvement in disease activity (DAPSA remission, DAPSA Improvement, DAPSA Improvement more than the median of 20.7 [>20.7]) or skin improvement (PASI90, PASI≤1) with changes in total PsAmodified van der Heijde-Sharp [vdH-S] score through W100, after adjusting for known baseline (BL) determinants of radiographic progression (vdH-S score, age, gender, and CRP).
Results: PsA duration, CRP, and SJC at BL weakly correlated with BL vdH-S score. No correlation was seen between BL PASI and BL vdH-S score (Table 1). Greater improvement in DAPSA score (β [95%CI]: -0.03 [-0.04, -0.01]) and improvement >20.7 in DAPSA from BL to W16 was associated with significantly less radiographic progression through W100 after adjusting for BL DAPSA score, vdH-S score, age, gender, and CRP level. Achievement of PASI90, PASI≤1, and DAPSA remission at W16 was associated with numerically less radiographic progression through W100 after adjusting for BL PASI, vdH-S score, age, gender, and CRP (Figure).

Table 1. Correlation of Select BL Disease Characteristics with BL vdH-S Score Among GUS Randomized Pts

BL Determinants	Spearman's correlation coefficient	p-value
Age	0.27335	<.0001
CRP	0.28181	<.0001
PASI Score	0.03078	0.5153
PsA Duration	0.37070	<.0001
PsO Duration	0.20509	<.0001
SJC (66)	0.26321	<.0001

Conclusion: In GUS-treated biologic-naïve pts with active PsA, following adjustment for known BL determinants of radiographic progression, earlier (W16) DAPSA improvement was a significant predictor of less radiographic progression through W100; DAPSA remission and skin improvement at W16 each showed a numerical trend toward less radiographic progression through W100.

RISANKIZUMAB FOR ACTIVE PSORIATIC ARTHRITIS: INTEGRATED SUBGROUP ANALYSIS FROM 2 DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE 3 STUDIES (KEEPSAKE 1 AND KEEPSAKE 2)

J. F. Merola[1], K. Callis-Duffin[2], B. Padilla[3], Z. Xue[3], H. Photowala[3], B. Kaplan[3], I. Mcinnes[4]. *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, United States of America; [2]University of Utah, Medicine, Salt Lake City, United States of America; [3]AbbVie Inc., Immunology, North Chicago, United States of America; [4]University of Glasgow, Medicine, Glasgow, United Kingdom*

Background: Risankizumab (RZB), a monoclonal antibody that specifically inhibits interleukin 23, is being investigated as a treatment for adults with psoriatic arthritis (PsA).
Objectives: We report the proportion of patients with active PsA treated with RZB vs placebo who achieved ≥20% improvement in American College of Rheumatology criteria (ACR20) by baseline demographics and by concomitant or prior medication use subgroups.
Methods: KEEPsAKE 1 (NCT03675308) and KEEPsAKE 2 (NCT03671148) are ongoing, multicenter, randomized, double-blind, placebo-controlled, phase 3 studies. Patients with active PsA with an inadequate response or intolerance to conventional synthetic disease-modifying, anti-rheumatic drug (csDMARD; KEEPsAKE 1 and 2) and/or biologic therapy (KEEPsAKE 2) received RZB 150 mg or placebo (1:1). The primary endpoint was the proportion of patients achieving ≥20% improvement in ACR criteria (ACR20) at week 24.
Results: In KEEPsAKE 1 (RZB, n=483; placebo, n=481) and KEEPsAKE 2 (RZB, n=224; placebo, n=219), baseline demographics and characteristics were generally balanced between treatment groups. In this integrated analysis, a greater proportion of patients receiving RZB vs placebo achieved ACR20 at week 24, regardless of age (<65 years, ≥65 years, ≥65 to <75 years, ≥75 years), sex, body mass index (<25 kg/m^2, ≥25 to <30 kg/m^2, ≥30 kg/m^2), race (White, non-White), PsA duration (≤5 years, >5 to ≤10 years, >10 years), baseline hs-CRP (<3 mg/L, ≥3 mg/L), concomitant csDMARD at baseline (any csDMARD, any methotrexate, none), or prior biologics use (yes, no). The proportion of RZB-treated patients who achieved ACR20 was generally similar across most assessed demographic or prior treatment subgroups. No new safety concerns were observed with RZB.

Conclusion: RZB demonstrates efficacy vs placebo for active PsA as shown by greater proportions of patients achieving ACR20 at week 24, regardless of baseline demographics, concomitant csDMARD use at baseline, or prior biologic use.

DYNAMICS OF NAIL PSORIASIS WITH GUSELKUMAB TREATMENT AND WITHDRAWAL IN ASSOCIATION WITH SKIN RESPONSE AND PATIENT-REPORTED OUTCOMES: A POST HOC ANALYSIS OF THE VOYAGE 2 PHASE 3 TRIAL

W. Tillett[1,2], A. Egeberg[3], E. Sonkoly[4,5,6], P. Gorecki[7], A. Tjärnlund[8], J. Buyze[9], S. Wegner[10], D. Mcgonagle[11,12]. *[1]Royal National Hospital for Rheumatic Diseases,, Bath, United Kingdom; [2]University of Bath, Department of Pharmacy and Pharmacology, Bath, United Kingdom; [3]Bispebjerg Hospital, Department of Dermatology, Copenhagen, Denmark; [4]Karolinska Institutet, Dermatology and Venereology Division, Stockholm, Sweden; [5]Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden; [6]Uppsala University, Department of Medical Sciences, Uppsala, Sweden; [7]Janssen-Cilag Ltd,, High Wycombe, United Kingdom; [8]Janssen-Cilag AB,, Solna, Sweden; [9]Janssen-Cilag BV,, Breda, Netherlands; [10]Janssen-Cilag GmbH,, Neuss, Netherlands; [11]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [12]Leeds Teaching Hospitals NHS Trust, National Institute for Health Research, Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Nail psoriasis can be difficult to treat, affects ~50% of patients with psoriasis and can involve the nail matrix (pitting, leukonychia) and/or nail bed (onycholysis, splinter haemorrhages). Evidence suggests nail psoriasis may be associated with risk of developing psoriatic arthritis, in particular distal interphalangeal joint erosion.[1–3] Data to Week (Wk) 24 from VOYAGE 1 and 2, two Phase 3 clinical trials, indicate that the anti-interleukin-23 monoclonal antibody guselkumab (GUS) is more effective than placebo and as effective as adalimumab in treating nail psoriasis.[4] Furthermore, GUS is also associated with maintained Psoriasis Area and Severity Index (PASI) following treatment withdrawal in VOYAGE 2; however, nail response is not as well understood in this context.[5]
Objectives: This VOYAGE 2 *post hoc* analysis evaluated nail response and its association with skin response and patient-reported outcomes (PROs) in two groups, one experiencing GUS withdrawal and the other receiving continuous GUS.
Methods: Patients had moderate-to-severe plaque psoriasis and nail psoriasis, were initially randomised to GUS, and achieved PASI 90 at Wk 28. Patients were then re-randomised to placebo (GUS withdrawal) or GUS every 8 wks (GUS continuation). Nail Psoriasis Severity Index (NAPSI; grading the most affected nail), fingernail Physician's Global Assessment (f-PGA), PASI and Dermatology Life Quality Index (DLQI) are reported as observed at Wk 0, 16, 24 and 48.
Results: Among 209 patients, NAPSI, f-PGA, PASI and DLQI showed similar trends in both groups until Wk 24. All endpoints improved from baseline; and at Wk 24, patients in the GUS withdrawal and GUS continuation groups achieved a mean NAPSI of 1.7 and 1.8 (nail matrix 1.0 and 1.0; nail bed 0.7 and 0.8); f-PGA 0.9 and 0.9; PASI 0.6 and 0.6; and DLQI 2.2 and 2.3, respectively (Table 1). Nail changes continued to follow skin trends through Wk 48 (Figure 1); with GUS withdrawal, worsening of PASI and DLQI was proportionally greater than that of NAPSI and f-PGA; with GUS continuation, PASI and DLQI remained fairly stable, and NAPSI and f-PGA continued to improve. Nails were numerically slower to respond to GUS initiation and withdrawal than skin, with a more pronounced delay for nail matrix vs nail bed. In patients who sustained a PASI 90 response at Wk 48, despite GUS withdrawal, a high level of nail response was also maintained.

Table 1. NAPSI, f-PGA, PASI and DLQI through Wk 48 in GUS withdrawal and GUS continuation groups

	Wk 0	Wk 16	Wk 24	Wk 28	Wk 48
GUS withdrawal*	**GUS**			**R**	**Placebo**
n	97	96	96		96
NAPSI	5.0 (2.1)	2.5 (1.9)	1.7 (1.9)		1.9 (2.1)
Nail matrix	2.7 (1.3)	1.5 (1.3)	1.0 (1.2)		0.9 (1.3)
Nail bed	2.2 (1.2)	0.9 (1.0)	0.7 (1.0)		1.0 (1.1)
n	98	97	97		97
f-PGA	2.5 (0.8)	1.3 (0.9)	0.9 (0.8)		1.1 (1.0)
n	101	101	100		100
PASI	23.1 (9.0)	1.3 (2.7)	0.6 (1.4)		5.2 (6.1)
n	101	101	100		100
DLQI	14.5 (6.1)	2.8 (4.1)	2.2 (3.6)		7.0 (7.4)
GUS continuation	**GUS**			R	**GUS**
n	108	106	107		105
NAPSI	4.4 (1.8)	2.4 (2.2)	1.8 (2.0)		1.2 (1.6)
Nail matrix	2.5 (1.2)†	1.4 (1.3)	1.0 (1.2)		0.7 (1.0)
Nail bed	1.9 (1.2)	1.0 (1.1)	0.8 (1.0)		0.5 (0.8)
n	108	106	107		105
f-PGA	2.4 (0.9)	1.1 (0.9)	0.9 (0.9)		0.7 (0.8)
n	108	108	108		106
PASI	22.6 (8.8)	1.2 (2.1)	0.6 (1.1)		1.3 (3.5)
n	107	108	108		104
DLQI	14.3 (6.4)	2.9 (4.2)	2.3 (4.0)		1.8 (3.4)

Data are mean (standard deviation). *n=10 reinitiated GUS upon loss of 50% of Wk 28 PASI 90 (at n=1 Wk 36, n=2 Wk 40, n=7 Wk 44); †n=107; R, re-randomisation of PASI 90 responders.

Conclusion: GUS treatment through Wk 48 improved nail psoriasis, skin psoriasis and PROs. When GUS was withdrawn, loss of response was slower in nails vs skin. These findings support that nail outcomes follow skin outcome trends with GUS treatment and that nail outcomes should contribute to evaluation of treatment efficacy and disease progression.[2,3,6]

EVOLVING MECHANISM OF ACTION PREFERENCE FOR THE TREATMENT OF PSORIATIC ARTHRITIS IN AUSTRALIA: AN ANALYSIS OF THE OPAL DATASET

P. Youssef[1,2,3], S. Ciciriello[1,4], G. S. Ngian[1,4,5], J. Aw[1,6], B. Kane[1,7], C. Osullivan[1], T. Smith[1], C. Deakin[1], G. Littlejohn[1,5]. [1]*OPAL Rheumatology Ltd, Rheumatology, Sydney, Australia;* [2]*The University of Sydney, Rheumatology, Camperdown, Australia;* [3]*Royal Prince Alfred Hospital, Rheumatology, Camperdown, Australia;* [4]*The Royal Melbourne Hospital, Rheumatology, Parkville, Australia;* [5]*Monash University, Rheumatology, Clayton, Australia;* [6]*Peninsula Rheumatology, Rheumatology, Langwarrin, Australia;* [7]*Concord Repatriation General Hospital, Rheumatology, Sydney, Australia*

Background: There are currently ten biologic and targeted synthetic (b/ts)DMARDs acting via five different modes of action (MOA) available for the treatment of psoriatic arthritis (PsA) in Australia. b/tsDMARDs are government-subsidised, and once the patient reaches the eligibility requirements, the clinician can prescribe the agent deemed most appropriate. Available agents include TNF inhibitors (TNFi, adalimumab, etanercept, infliximab, golimumab, certolizumab pegol), IL-17A inhibitors (IL-17Ai, secukinumab, ixekizumab), and IL-12/23 inhibitor (IL-12/23i, ustekinumab). Two new MOAs were recently added to the rheumatologist's armamentarium: the first JAK inhibitor (JAKi, tofacitinib) was subsidized from May 2019 followed by upadacitinib from Oct 2021, and an IL-23 inhibitor (IL-23i, guselkumab) was subsidized from July 2021.
Objectives: The aim of this analysis was to describe the changing patterns of b/tsDMARD use for the treatment of PsA in real-world practice in Australia.
Methods: Deidentified clinical data were sourced from the OPAL dataset, which is collected in a custom-built electronic medical record during the routine consultation1. Data from patients >18 years with a physician diagnosis of PsA who were prescribed a b/tsDMARD between Jan-2007 and Sept-2021 were included in the analysis. The software program Tableau was used to display the data.
Results: At Sept 2021, 6,150 (38% of the total) patients with PsA in the OPAL dataset were prescribed b/tsDMARDs. Of these patients, 3741 (61%) were currently prescribed a TNFi, 1503 (24%) an IL-17Ai, 556 (9%) a JAKi, 222 (4%) an IL-12/23i and 134 patients (2%) an IL-23i. Over time, the 1st line TNFi initiations have decreased from 79.5% in 2018 to 65.2% in 2021. Conversely, 1st line IL-17Ai initiations have increased from 14.4% in 2018 to 22.2% in 2021. In 2021, TNFi accounted for 53.4% of 2nd line initiations and 38.2% of 3rd line initiations. IL-17Ai accounted for 30.4% of 2nd and 37.0% of 3rd line initiations and JAKi accounted for 10.5% of 2nd line and 14.2% of 3rd line initiations. In the 3 months that IL-23i has been subsidised, this MOA was the most initiated agent for patients who had been treated with more than two prior b/tsDMARDs. In 2021, 52.1% of patients switching from a 1st line TNFi switched to an alternative TNFi, 33.3% switched to an IL-17Ai and 11.3% switched to a JAKi in 2nd line. Of those switching from a 1st line IL-17Ai, 59.6% initiated a TNFi, 21.2% switched to an alternative IL-17Ai and 11.5% switched to a JAKi.
Conclusion: The patterns of b/tsDMARD utilisation for the treatment of PsA, when the choice of agent is at the discretion of the rheumatologist, remains dynamic and is evolving as new MOAs become available. TNFi remains the most prescribed b/tsDMARD for first line therapy. However an increase in first line use of alternative MOAs has been observed. TNFi cycling remains a commonly utilised real world treatment strategy but appears to be declining as new MOAs become available.

Background: In the phase 3 DISCOVER-2 (D2) study, guselkumab (GUS) 100 mg every 4/8 weeks (Q4W/Q8W) significantly improved joint and skin symptoms in patients (pts) with active psoriatic arthritis (PsA); GUS-treated pts had smaller mean changes in radiographic progression vs placebo (PBO) at W24.[1] Clinical response rates and favorable safety profile were durable through W100.[2, 3]
Objectives: To report details of radiographic assessments comprising Reading Session 3 through W100 of D2, including relationships between radiographic changes and measures of clinical outcomes.
Methods: Biologic-naïve adults with active PsA (≥5 swollen + ≥5 tender joint count; CRP ≥0.6 mg/dL) were randomized (1:1:1) to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W (PBO→Q4W) at W24, all through W100. Radiographic Reading Session 3 included assessments at W0/24/52/100 (or at discontinuation after W52) from pts ontinuing study treatment at W52; readers were blinded to treatment group and timepoint. Observed mean changes in total PsA-modified van der Heijde-Sharp (vdH-S), joint space narrowing (JSN), and erosion scores were reported. Changes in total vdH-S scores from W0-100 were determined in pts who did and did not achieve clinical response at W100, assessed by ACR20/50/70, low disease activity (LDA) based on Disease Activity in Psoriatic Arthritis score (DAPSA; ≤14) or Psoriatic Arthritis Disease Activity Score (PASDAS; ≤3.2), minimal disease activity (MDA), and normalized Health-Assessment Questionnaire-Disability Index (HAQ-DI) score (<0.5).
Results: Of 739 randomized pts, 664 had evaluable data from Reading Session 3; 629 had evaluable data from W52-100. Mean total baseline vdH-S scores were: Q4W, 28.0; Q8W, 23.9; PBO→Q4W, 25.6. Mean progression of joint damage from W0-24 was numerically lower in GUS- than PBO-treated pts for erosion, JSN, and total vdH-S scores (Table 1), consistent with the results from Reading Session 1.[1] Mean changes in radiographic scores from W52-100 indicated low rates of radiographic progression across GUS groups. Among GUS-randomized pts, mean changes in vdH-S score from W0-100 were numerically lower for pts achieving clinical response assessed using ACR20/50/70, DAPSA LDA, PASDAS LDA, MDA, and HAQ-DI vs pts not achieving response at W100 (Figure 1).
Conclusion: In biologic-naïve pts with active PsA enriched for greater risk of radiographic progression, GUS 100 mg (Q4W or Q8W) was associated with low rates of radiographic progression through 2 years. Pts achieving clinical response across several global measures of disease activity or normalized physical function at W100 had lower mean changes in total PsA-modified vdH-S scores compared with nonresponders.

Table 1. Observed erosion, joint space narrowing, and total PsA-modified vdH-S scores through W100 of DISCOVER-2

	GUS Q4W			GUS Q8W			PBO→GUS Q4W

Background: RZB, a humanized immunoglobulin G1 monoclonal antibody that specifically inhibits the p19 subunit of the human cytokine interleukin-23, is being investigated as a treatment for PsA.
Objectives: Evaluate longer-term safety and efficacy of RZB in patients with active PsA who experienced inadequate response or intolerance to 1 or 2 biologic therapies and/or to at least 1 csDMARD therapy.
Methods: KEEPsAKE 2 (NCT03671148) is an ongoing, phase 3, multicenter study that includes a screening period; a 24-week double-blinded, randomized, placebo-controlled, parallel-group period (period 1); and an open-label extension period (period 2). Eligible patients were ≥18 years of age with active PsA (symptom onset ≥6 months before screening, meeting Classification Criteria for PsA [CASPAR], and ≥5 tender and ≥5 swollen joints) and had inadequate response or intolerance to 1 or 2 biologic therapies (Bio-IR) and/or ≥1 conventional synthetic disease modifying antirheumatic drug (csDMARD-IR). Patients received RZB 150 mg or placebo (PBO) at weeks 0, 4, and 16 (1:1). The primary endpoint was the proportion of patients achieving ACR20 response at week 24. Period 2 started at week 24, and patients were switched to receive open-label RZB 150 mg every 12 weeks through week 208. Efficacy and safety were analyzed in patients who received ≥1 dose of study drug through week 52. Mixed-effect model with repeated measures and nonresponder imputation methods were used to assess continuous and binary variables, respectively. Treatment-emergent adverse events (TEAEs) were summarized using exposure-adjusted event rates (EAERs, events/100 patient-years [PY]).
Results: At week 24, 51,3% of RZB-treated (N=224) and 26.5% of PBO-treated (N=219) patients achieved ACR20. At week 52, 58.5% of patients who were randomized to RZB and 55.7% of patients who were randomized to PBO and then switched to RZB at week 24 achieved ACR20. In patients with ≥3% of body surface area affected at baseline, 55.0% of RZB-treated patients (N=123) and 10.2% of PBO-treated patients (N=119) achieved PASI 90 at week 24. At week 52, 64.2% of patients randomized to RZB and 59.7% of patients who were randomized to PBO and then switched to RZB at week 24 achieved PASI 90. For other efficacy measures, similar trends were observed. RZB was well tolerated through 52 weeks of treatment, and EAERs of adverse events were stable between weeks 24 and 52. At the week 52 data cutoff (19 April 2021), the total EAER of any TEAE in patients receiving RZB was 184.2/100 PY.
Conclusion: Continuous RZB treatment resulted in maintained efficacy responses with a consistent safety profile through 52 weeks of treatment in patients with active PsA who were Bio-IR and/or csDMARD-IR.

Background: Guselkumab (GUS), a selective IL-23p19 inhibitor, showed greater mean improvements in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores vs placebo (PBO) at Week (W) 24 in patients (pts) with active PsA and investigator-confirmed sacroiliitis in pooled post hoc analyses of data from phase 3 DISCOVER (D)-1&2 trials. Improvements in symptoms of axial involvement were maintained through 1 year.[1]

Objectives: To assess maintenance of GUS effect on symptoms of axial involvement in biologic-naïve PsA pts with investigator-confirmed sacroiliitis through 2 years of D-2.

Methods: In D-2, 739 bio-naïve pts with active PsA (≥5 swollen + ≥5 tender joints, CRP ≥0.6 mg/dL despite standard therapies) were randomized 1:1:1 to GUS 100 mg every 4W (Q4W; n=245), GUS 100 mg at W0, W4, then Q8W (n=248), or PBO (n=246) with PBO→GUS 100 mg Q4W at W24. Pts with investigator-identified axial symptoms and sacroiliitis (prior X-ray or MRI, or pelvic X-ray at screening) were evaluated. Efficacy was assessed by changes in BASDAI, modified BASDAI (mBASDAI, excluding Q3 [peripheral joint pain]), and BASDAI Q2 (Spinal Pain) scores, and proportions of pts achieving BASDAI 50, Spinal Pain score ≤2, and AS Disease Activity Score (ASDAS) responses through W100. Through W24, pts who met treatment failure criteria or had missing data were considered nonresponders. After W24, missing data were imputed as nonresponse for binary endpoints or no change from baseline for continuous endpoints (nonresponder imputation [NRI]). Axial-related outcomes were also summarized by HLA-B27 status (+/-).

Results: 246 pts had investigator-confirmed sacroiliitis. Baseline characteristics were similar across treatment groups (62% male; mean age 44.4 years; mean BASDAI scores 6.5-6.6). At W24, LS mean/mean changes in BASDAI (-2.4/-2.6) and ASDAS (-1.3/-1.5) scores were greater in GUS- vs PBO-treated pts. Improvements were maintained through W100 in GUS-treated pts: BASDAI, -3.1; Spinal Pain, -3.1; mBASDAI, -3.1; ASDAS, -1.7. Response patterns were similar for BASDAI 50 response rates in GUS-treated pts (W24 38-40%; W100 49-54%). At W24, GUS-treated pts had higher response rates for achievement of ASDAS inactive disease, major improvement, and clinically important improvement vs PBO; response rates (NRI) were maintained, or in some cases further increased, at 2 years. Results were consistent for achievement of ASDAS LDA and Spinal Pain score ≤2 (data not shown). GUS-related improvements in axial symptoms through W100 were generally consistent in HLA-B27+/- pts (data not shown).

Conclusion: In bio-naïve pts with active PsA and investigator-confirmed sacroiliitis, GUS provided durable improvements in axial symptoms through W100, with substantial proportions of pts achieving and maintaining clinically meaningful improvements.

POS1038

GUSELKUMAB EFFICACY IN PSORIATIC ARTHRITIS ASSESSED BY MULTI-DOMAIN COMPOSITE INDICES: DATA FROM THE PHASE 3B COSMOS TRIAL IN A TNFI-IR POPULATION

L. Gossec[1], E. Theander[2], M. Neuhold[3], P. Bergmans[4], M. Shawi[5], M. Perate[6], C. Contre[7], L. Coates[8]. [1]*Sorbonne Université and Pitié-Salpêtrière Hospital, Rheumatology department, Paris, France;* [2]*Janssen, Scientific Affairs, LLC, Solna, Sweden;* [3]*Janssen, Scientific Affairs, LLC, Zug, Switzerland;* [4]*Janssen, Biostatistics, Breda, Netherlands;* [5]*Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America;* [6]*Janssen, Scientific Affairs, LLC, Horsham, United States of America;* [7]*Janssen, Scientific Affairs, LLC, Issy-les-Moulineaux, France;* [8]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences (NDORMS), Oxford, United Kingdom*

Background: The Phase 3b COSMOS study (NCT03796858) demonstrated the efficacy and safety of guselkumab (GUS), an IL-23 p19 subunit inhibitor, in patients (pts) with psoriatic arthritis (PsA) who had inadequate response (IR; insufficient efficacy or intolerance) to 1–2 tumour necrosis factor inhibitors (TNFi).[1]

Objectives: Assess the efficacy of GUS 100 mg Q8W in TNFi-IR pts through 1 year by using and comparing 6 multi-domain composite indices validated in PsA.

Methods: In total, 285 pts (189 GUS, 96 placebo [PBO]) were enrolled in COSMOS; mean age was 49 years and mean disease duration was 8.4 years.[1] Pts who received PBO crossed over to GUS at either Week (W) 16 (early escape, n=45/96) or W24 (planned, n=51/96). PsA Disease Activity Score (PASDAS), GRAppa Composite scorE (GRACE), Disease Activity Index for PsA (DAPSA), modified Composite Psoriatic Disease Activity Index (mCPDAI, excludes BASDAI), PsA Response Criteria (PsARC), and Minimal Disease Activity (MDA) were analysed (thresholds as published[2,3]). As-observed data are presented at baseline (BL), W24 and W48, without imputation of missing data.

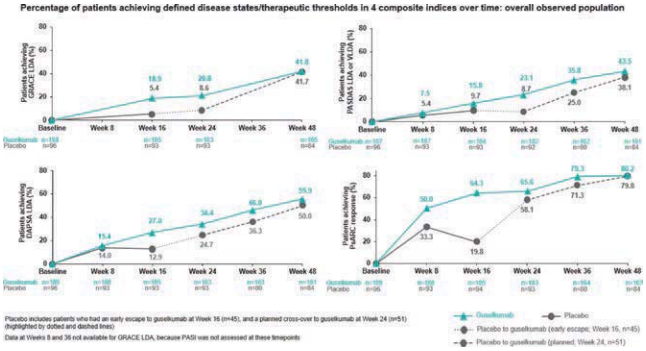

Figure 1.

Results: Overall, 167/189 (88%) GUS and 83/96 (86%) PBO→GUS pts completed the study through W44. Pts had active disease, with similar BL mean values for PASDAS, GRACE, DAPSA and mCPDAI between GUS and PBO groups (Table 1). Across these indices, GUS pts demonstrated robust improvements (45–62%) in mean scores from BL to W48 (Table 1). PBO pts who crossed over to GUS at W16 or W24 also showed rapid improvement in their index scores, with mean values and % improvement at W48 consistent with those observed in pts randomized to GUS at BL (Table 1).

Conclusion: GUS provided robust and substantial benefits to pts with active TNFi-IR PsA across multiple domains. Importantly, rates of achieving low levels of disease activity continued to increase through the duration of the study without an observable plateau at W48. Thresholds for DAPSA and PsARC response were easier to achieve than comprehensive indices with more domains that are required to improve simultaneously (eg GRACE, PASDAS, MDA). GUS performed well regardless of the focus of the composite indices (joints, skin, enthesitis, dactylitis, or patient-reported outcomes). Together, these findings support the role of GUS as an effective treatment option for the diverse domains of PsA.

Among the 4 indices with defined disease states/therapeutic thresholds for low disease activity (LDA) (Figure 1), those focusing on joints (PsARC [4 components] and DAPSA [5 components]) resulted in the highest response rates (range, 50–80%); LDA according to GRACE (8 items, including skin) and PASDAS (8 items, focus on musculoskeletal with no skin assessment) was attained less frequently (range, 38–44%). Using the PsARC, 50% of GUS pts responded as early as W8. Response rates among GUS-treated pts generally did not plateau by W48 (Figure 1). At W48, 33% and 30% of GUS and PBO→GUS pts, respectively, achieved a status of MDA.

POS1039 DEUCRAVACITINIB, AN ORAL, SELECTIVE TYROSINE KINASE 2 INHIBITOR, IN A PHASE 2 TRIAL IN PSORIATIC ARTHRITIS: ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY AND ITS COMPONENTS

A. Kavanaugh[1], L. Coates[2], J. F. Merola[3], P. J. Mease[4], M. Nowak[5], S. Banerjee[6], L. Hippeli[7], T. Lehman[8]. *[1]University of California, San Diego, Rheumatology, La Jolla, United States of America; [2]University of Oxford, Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [3]Brigham and Women's Hospital, Harvard Medical School, Dermatology, Boston, United States of America; [4]Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; [5]Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; [6]Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America; [7]Bristol Myers Squibb, Biostats, Princeton, United States of America; [8]Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America*

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase in the Janus kinase (JAK) family that mediates the signalling of multiple cytokines, including those central to the immunopathogenesis of psoriatic arthritis (PsA), such as IL-23. Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of TYK2 that acts by binding to the unique regulatory domain on the enzyme. In a Phase 2 trial in patients with active PsA, DEUC was significantly more efficacious than placebo (PBO) after 16 weeks of treatment and was well tolerated.[1]
Objectives: This analysis further evaluated the effect of DEUC in this trial on achievement of individual components of minimal disease activity (MDA).
Methods: This double-blind, multicenter Phase 2 trial (NCT03881059) enrolled patients (n=203) with a PsA diagnosis ≥6 months who fulfilled Classification Criteria for Psoriatic Arthritis at screening and had active joint disease (≥3 tender and ≥3 swollen joints), high-sensitivity C-reactive protein ≥3mg/L, and ≥1 plaque psoriasis lesion (≥2cm). Eligible patients had failed or were intolerant to ≥1 nonsteroidal anti-inflammatory, conventional synthetic DMARD, and/or 1 tumour necrosis factor inhibitor (≤30%). Patients were randomized 1:1:1 to receive PBO, DEUC 6mg once daily (QD), or 12mg QD. The percentage of patients achieving MDA (5/7: tender joint count [TJC] ≤1, swollen joint count [SJC] ≤1, tender entheseal points [TEP] ≤1, Patient Global Assessment of disease activity [PtGA] ≤20, Patient Global Assessment of pain [Pain] ≤15, Health Assessment Questionnaire-Disability Index [HAQ-DI] ≤0.5, and Psoriasis Area and Severity Index [PASI] ≤1 or body surface area [BSA] ≤3%) as well as proportions of patients achieving each of the MDA components in all patients, MDA responders, and nonresponders were assessed through Week 16.
Results: Of 203 patients randomized, 180 (89%) completed 16 weeks of treatment (PBO, 58/66 [88%]; DEUC 6mg QD, 63/70 [90%]; DEUC 12mg QD, 59/67 [88%]). Demographic and baseline disease characteristics were generally similar across groups. Although no patient had met 5 of 7 criteria required for achieving MDA at baseline, several individual components of MDA were met at baseline, most frequently TEP ≤1 (PBO, 57.6%; DEUC 6mg QD, 64.3%; DEUC 12mg QD, 65.7%). After 16 weeks of treatment, 7.6%, 22.9%, and 23.9% of patients in the PBO, DEUC 6mg QD, and DEUC 12mg QD groups, respectively, achieved MDA response. Treatment with DEUC was associated with a numerically greater mean reduction from baseline in all MDA components versus PBO over 16 weeks of treatment in all patients. At Week 16, more patients receiving DEUC versus PBO achieved the threshold for each of the MDA components (Figure 1).
Conclusion: In this study, patients treated with DEUC achieved a higher rate of MDA response compared with patients treated with PBO after 16 weeks of treatment. More patients receiving DEUC treatment achieved each of the MDA components compared with patients receiving PBO.

POS1040 SAFETY OF DEUCRAVACITINIB, AN ORAL, SELECTIVE TYROSINE KINASE 2 INHIBITOR: AS ASSESSED BY LABORATORY PARAMETERS – RESULTS FROM A PHASE 2 TRIAL IN PSORIATIC ARTHRITIS AND 2 PHASE 3 TRIALS IN PSORIASIS

R. M. Fleischmann[1], D. Thaçi[2], M. Gooderham[3], B. Strober[4], N. J. Korman[5], S. Banerjee[6], T. Lehman[7], M. Nowak[8], A. Sreih[9], A. Morita[10], P. J. Mease[11]. *[1]University of Texas Southwestern Medical Center, Rheumatology, Dallas, United States of America; [2]University of Lübeck, Dermatology, Lübeck, Germany; [3]SKiN Centre for Dermatology, Queen's University, Probity Medical Research, Dermatology, Peterborough, Canada; [4]Yale University, Dermatology, New Haven, United States of America; [5]Case Western Reserve University and University Hospitals, Dermatology, Cleveland, United States of America; [6]Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America; [7]Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America; [8]Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; [9]Bristol Myers Squibb, Veracity Clinical Research, Princeton, United States of America; [10]Nagoya City University Graduate School of Medical Sciences, Dermatology, Nagoya, Japan; [11]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America*

Background: Deucravacitinib (DEUC) is a novel, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor with a unique mechanism of action distinct from Janus kinase (JAK) 1/2/3 inhibitors. DEUC mediates signalling of key cytokines in psoriatic arthritis (PsA) and psoriasis (PsO). DEUC was well tolerated and efficacious vs placebo (PBO) in a Phase 2 trial in patients (pts) with PsA,[1] and vs PBO or apremilast in 2 Phase 3 PsO trials.[2]
Objectives: To assess the effects of DEUC on multiple laboratory parameters through the first 16 weeks of treatment (PBO-controlled) in these trials.
Methods: The Phase 2 double-blind PsA trial randomised pts (n=203) 1:1:1 to PBO, DEUC 6mg once daily (QD), or 12mg QD. The Phase 3 double-blind PsO trials, POETYK PSO-1 and POETYK PSO-2, randomised pts (n=666 and 1020, respectively) 1:2:1 to PBO, DEUC 6mg QD, or apremilast 30mg twice daily. Changes from baseline in haematologic (neutrophils, lymphocytes, platelets, haemoglobin) and chemistry (cholesterol, triglycerides, alanine aminotransferase [ALT], aspartate aminotransferase [AST], and creatine phosphokinase [CPK]) parameters were evaluated. Shifts in Common Terminology Criteria for Adverse Events (CTCAE; version 5.0) severity grade ≥3 of laboratory abnormalities were assessed.
Results: In the PsA trial, 65% of pts were on concomitant conventional synthetic DMARDs (csDMARDs) and 54.7% of pts were on methotrexate. The vast majority of pts continued to have laboratory parameters within normal range throughout the 3 trials in PsO and PsA. No clinically meaningful changes from baseline were observed in laboratory parameters in pts treated with DEUC, PBO, or apremilast. Rates of CTCAE grade 3 and 4 were rare (≤1 pt) and similar across DEUC-, PBO-, and apremilast-treated pts for the following parameters: lymphocytes, neutrophils, platelets, haemoglobin, AST, ALT, and cholesterol (Table 1). Shifts to CTCAE grades ≥3 in triglycerides and CPK were infrequent and generally comparable across treatment arms.
Conclusion: DEUC treatment did not result in clinically meaningful laboratory changes, abnormalities often seen with JAK 1/2/3 inhibition, through 16 weeks of treatment in a Phase 2 trial in PsA, despite two-thirds of pts being on concomitant csDMARDs, and in 2 large Phase 3 trials in PsO.

POS1041

LONG-TERM EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS REFRACTORY TO BIOLOGIC THERAPIES: 2-YEAR RESULTS FROM THE PHASE 3 SELECT-PSA 2 STUDY

P. J. Mease[1], A. Setty[2], K. Papp[3], F. Van den Bosch[4], S. Tsuji[5], M. Keiserman[6], X. Bu[2], L. Chen[2], R. Mccaskill[2], E. Mcdearmon-Blondell[2], P. Wung[2], W. Tillett[7].

[1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America; [2]AbbVie Inc., Immunology, North Chicago, United States of America; [3]Papp Clinical Research and Probity Medical Research, Dermatology, Waterloo, Canada; [4]Ghent University, VIB Center for Inflammation Research, Internal Medicine and Pediatrics, Ghent, Belgium; [5]National Hospital Organization, Osaka Minami Medical Center, Orthopaedics/Rheumatology, Osaka, Japan; [6]Pontifical Catholic University, School of Medicine, Rheumatology, Porto Alegre, Brazil; [7]Royal National Hospital For Rheumatic Diseases, Rheumatology, Bath, United Kingdom

Background: Upadacitinib (UPA), an oral Janus kinase (JAK) inhibitor, demonstrated efficacy and safety in patients (pts) with psoriatic arthritis (PsA) and prior inadequate response or intolerance to ≥1 biologic disease-modifying antirheumatic drug (bDMARD) at week (wk) 56 in the phase 3 SELECT-PsA 2 study.[1]

Objectives: To evaluate the efficacy and safety of UPA at wk 104 from the ongoing long-term extension of SELECT-PsA 2.

Methods: Pts were randomized to UPA 15 mg (UPA15), UPA 30 mg (UPA30), or placebo (PBO) for 24 wks; PBO pts were then switched to UPA15 or UPA30. For continuous UPA treatment groups, efficacy endpoints at wk 104 were analyzed using non-responder imputation (NRI) and as observed (AO) (binary endpoints) or mixed-effect model repeated measures (MMRM) and AO (continuous endpoints). Treatment-emergent adverse events (TEAEs) were summarized for pts who received ≥1 dose of study drug using visit-based cut-off at wk 104.

Results: A total of 641 pts received ≥1 dose of study drug. At wk 104, 38.4% of all patients had discontinued study drug, with the highest discontinuation observed

in patients randomized to PBO at baseline (all PBO: 46.7%). The most common reasons for discontinuation were lack of efficacy (UPA15: 12.3%, UPA30: 8.7%, all PBO: 21.7%) and adverse event (UPA15: 10.9%, UPA30: 13.3%, all PBO: 12.7%). The proportion of UPA pts that achieved ACR20/50/70, MDA, PASI75/90/100, and resolution of dactylitis and enthesitis were generally similar, or further improved, with 104 wks of treatment vs 56 wks[1] (Table 1). Similarly, mean change from baseline in HAQ-DI, patient's assessment of pain, BASDAI, and ASDAS was improved with UPA treatment. At 104 wks of therapy, clinical responses were largely similar with UPA15 and UPA30. Generally, safety data at wk 104 (Figure 1) were consistent with that reported at wk 56.[1] Rates of serious infection, herpes zoster, hepatic disorder, anemia, neutropenia, lymphopenia, and CPK elevation remained numerically higher with UPA30 vs UPA15, while rates of malignancies, MACE, and VTE were similar for both UPA groups. One death was reported with UPA15 (unexplained due to lack of information; however, the patient had recently been diagnosed with ovarian cancer) and 2 with UPA30 (pancytopenia and COVID-19 pneumonia).

Table 1. Efficacy Endpoints at Week 104

Endpoint	UPA15 (n=211)		UPA30 (n=218)	
Proportion of Pts (%)[a]	**NRI**	**AO**	**NRI**	**AO**
ACR20	55.5	80.3	54.6	81.8
ACR50	44.5	62.9	39.9	59.4
ACR70	23.2	32.2	21.6	31.5
Minimal Disease Activity (MDA)	29.4	41.3	33.9	49.3
PASI75[b]	47.7	69.8	52.7	81.1
PASI90[b]	37.7	55.2	44.3	67.8
PASI100[b]	23.1	35.4	35.9	55.6
Resolution of enthesitis by LEI[c]	39.8	67.8	37.5	68.4
Resolution of dactylitis by LDI[d]	54.5	97.4	52.0	96.9
Change from BL[e]	**MMRM**	**AO**	**MMRM**	**AO**
Health Assessment Questionnaire - Disability Index (HAQ-DI)	-0.36	-0.39	-0.50	-0.53
Patient's assessment of pain (numeric rating scale)	-2.7	-3.0	-2.9	-3.1
Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)[f]	-2.6	-3.0	-2.6	-2.9
Ankylosing Spondylitis Disease Activity Score (ASDAS)[f]	-1.4	-1.7	-1.3	-1.5

ACR20/50/70, ≥20%/50%/70% improvement in American College of Rheumatology criteria; AO, as observed; BL, baseline; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; MMRM, mixed effect model repeated measurement; NRI, non-responder imputation; PASI75/90/100, ≥75%/90%/100% improvement in Psoriasis Area and Severity Index; pts, patients; UPA, upadacitinib.[a]Data shown as NRI and AO for binary endpoints.[b]For pts with psoriasis affecting ≥3% of body surface area at BL. [c]For pts with LEI >0 at BL; resolution LEI=0.[d]For pts with LDI >0 at BL; resolution LDI=0. [e]Data shown as MMRM (LS mean) and AO (mean) for continuous endpoints.[f]For pts with psoriatic spondylitis at BL.

Conclusion: In PsA pts with prior inadequate response or intolerance to ≥1 bDMARD, clinical responses were maintained with UPA15 and UPA30 up to 2 years of treatment. No new safety signals were identified in this long-term extension.

IMPACT OF RISANKIZUMAB ON IMPROVING HEALTH-RELATED QUALITY OF LIFE, WORK PRODUCTIVITY, AND REDUCING FATIGUE AMONG PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: A POOLED ANALYSIS OF TWO PHASE 3 CLINICAL TRIALS

L. E. Kristensen[1], A. M. Soliman[2], K. Papp[3], L. Barcomb[2], A. Eldred[2], Z. Wang[2], D. White[4], F. Behrens[5]. [1]*The Parker Institute, Copenhagen University Hospital, Bieber and Frederiksberg, Copenhagen, Denmark;* [2]*AbbVie Inc., Immunology, North Chicago, United States of America;* [3]*K Papp Clinical Research, Probity Medical Research, Waterloo, Canada;* [4]*Rheumatology Department, Waikato Hospital, Hamilton, Waikato Clinical School, University of Auckland, Auckland, New Zealand;* [5]*Rheumatology, Fraunhofer Institute Translational Medicine and Pharmacology ITMP & Cluster of Excellence CIMD, Goethe University, Frankfurt, Germany*

Background: Risankizumab (RZB) has been approved in the UK and Europe for the treatment of adults with active PsA. Patient-reported outcomes (PROs) are important tools for understanding a therapy's efficacy from the patient's perspective.

Objectives: This study evaluated the impact of RZB versus placebo on health-related quality of life (HRQoL), fatigue, and work productivity in patients with psoriatic arthritis (PsA) and inadequate response to 1 or 2 biologics and/or ≥1 conventional synthetic DMARDs in two Phase 3 trials (KEEPsAKE 1&2).

Methods: Eligible patients with active PsA (n=1402) were randomized (1:1) to receive risankizumab 150 mg (n=706) or placebo (n=696). Patient-reported

outcomes assessed were 36-Item Short-Form Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-Fatigue), EQ-5D-5L, and Work Productivity and Activity Impairment–PsA questionnaire. Least squares (LS) mean changes from baseline at Week 24 were compared between risankizumab versus placebo by mixed-effects repeated regression modeling.

Results: At Week 24, risankizumab- versus placebo-treated patients reported greater improvements in LS mean changes with between-group differences (all nominal $P<0.001$) in SF-36 physical component score (mean difference=3.5, 95% confidence interval [CI] 2.7, 4.2) and mental component score (mean difference=1.8, 95% CI 0.9, 2.6), FACIT-Fatigue (mean difference=2.5, 95% CI 1.5, 3.4), EQ-5D-5L index score (mean=0.07, 95% CI 0.05, 0.09), and EQ-5D-5L visual analogue scale score (mean difference=5.8, 95% CI 3.6, 8.0). In addition, risankizumab- versus placebo-treated patients reported greater reductions with between-group differences (all nominal $P<0.001$) in overall work impairment (mean difference= –8.9%, 95% CI –13.1, –4.7), activity impairment (mean difference= –7.7%, 95% CI –10.3, –5.2), and presenteeism (mean difference= –9.8%, 95% CI –13.3, –6.3).

Conclusion: Compared to placebo, risankizumab resulted in greater improvements in HRQoL, fatigue, and work productivity among patients with PsA.

POS1043

STRONG CORRELATION BETWEEN SHORT- VS LONG-FORM COMPOSITE MEASURES OF PSORIATIC ARTHRITIS DISEASE ACTIVITY IN A TNFI-IR POPULATION TREATED WITH GUSELKUMAB: DATA FROM THE PHASE 3B COSMOS TRIAL

W. Tillett[1], L. Coates[2], M. Neuhold[3], E. Theander[4], P. Bergmans[5], M. Shawi[6], M. Perate[7], C. Contre[8], P. Helliwell[9]. *[1]University of Bath, Centre for Therapeutic Innovation, Bath, United Kingdom; [2]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences (NDORMS), Oxford, United Kingdom; [3]Janssen, Scientific Affairs, LLC, Zug, Switzerland; [4]Janssen, Scientific Affairs, LLC, Solna, Sweden; [5]Janssen, Biostatistics, Breda, Netherlands; [6]Janssen, Immunology Global Medical Affairs, Horsham, United States of America; [7]Janssen, Scientific Affairs, LLC, Horsham, United States of America; [8]Janssen, Scientific Affairs, LLC, Issy-les-Moulineaux, France; [9]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Accurate assessment of psoriatic arthritis (PsA) disease activity in clinical practice requires a feasible, continuous, multidimensional composite instrument to assess key domains of this heterogeneous disease. While currently available composite tools used in PsA, including the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis Composite Exercise (GRACE) and the PsA Disease Activity Score (PASDAS), are useful in clinical trials, their complexity and time required to complete limit their use in clinical practice.[1] Abbreviated instruments, known as 3 visual analogue scale (VAS) and 4VAS, have demonstrated good performance in an observational study, but further testing was recommended.[2]

Objectives: Explore the correlation between 3VAS or 4VAS and GRACE, PASDAS and measures of quality of life using data from COSMOS.

Methods: The Phase 3b COSMOS study assessed guselkumab (GUS) 100mg Q8W versus placebo (PBO) in tumour necrosis factor inhibitor (TNFi) inadequate response (IR, inadequate efficacy or intolerance) pts with active PsA.[3] Pts who received PBO crossed over to GUS at either Week (W) 16 (early escape [EE], n=45/96) or W24 (planned, n=51/96). Each domain of the 3VAS (physician global, pt global, pt skin) and 4VAS (physician global, pt pain, pt joint, pt skin) was evaluated using a 0–10 VAS (higher score=more active disease), and calculated mean scores were plotted over time in a pt-continuer population (those with W0 *and* W48 data). Pearson correlation assessed relationships between observed values over time for 3VAS/4VAS versus GRACE, PASDAS, the Health Assessment Questionnaire-Disability Index (HAQ-DI), and the 36-item Short Form Health Survey Physical Component Summary (SF-36 PCS) score.

Results: Data from 285 pts were examined (GUS, n=189; PBO, n=96). Substantial improvements (>45%) were seen in GRACE, PASDAS, 3VAS and 4VAS scores through W48 in GUS-treated pts (Table 1), with separation from PBO as early as W8 (Figure 1). Strong correlations between 3VAS/4VAS and GRACE (r=0.83–0.92)/PASDAS (r=0.72–0.85) were observed in GUS-randomized pts at each visit (Table 1). 3VAS/4VAS showed moderate correlation with HAQ-DI (r=0.45–0.63) and SF-36 PCS (r=–0.40 to –0.65). Consistent results were observed in PBO→GUS pts.

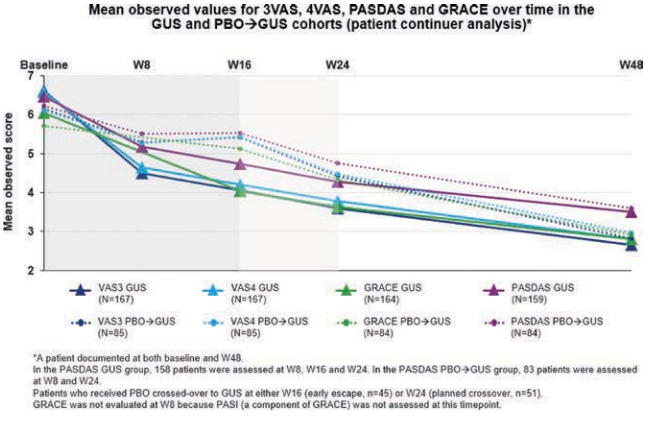

Figure 1.

Conclusion: In these TNFi-IR pts, GUS treatment led to substantial improvements in PsA disease activity through 1 year using several composite indices. All indices, including the 3VAS/4VAS, allowed early discrimination between the GUS and PBO cohorts. The strong correlation between 3VAS/4VAS and GRACE/PASDAS in this pt population is promising and highlights that abbreviated composite indices can provide an accurate assessment of disease activity that may, because of better feasibility, lead to a wider use of such instruments and thus improve pt care. As a next step, thresholds for disease states should be further evaluated.

GUSELKUMAB PROVIDES CONSISTENT AND DURABLE PAIN IMPROVEMENT IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS OF 2 PHASE 3, RANDOMIZED, CONTROLLED CLINICAL TRIALS

P. Nash[1], L. S. Tam[2], W. C. Tsai[3], Y. Y. Leung[4], D. Furtner[5], S. Sheng[6], Y. Wang[6], M. Shawi[7], A. Kollmeier[8], J. Sherlock[9,10], D. Cua[11]. *[1]Griffiths University and University of Queensland, Department of Rheumatology Research, Maroochydore, Queensland, Australia; [2]The Chinese University of Hong Kong, Department of Medicine & Therapeutics, Shatin, Hong Kong (SAR); [3]Kaohsiung Medical University, Division of Allergy, Immunology and Rheumatology, Kaohsiung City, Taiwan, Republic of China; [4]Singapore General Hospital, Duke-NUS Medical School, Department of Rheumatology & Immunology, Singapore, Singapore; [5]Janssen, a division of Johnson & Johnson Pte. Ltd., Department of Immunology, Singapore, Singapore; [6]Janssen Research and Development, LLC, Department of Biostatistics, Spring House, PA, United States of America; [7]Janssen Global Services, LLC, Department of Immunology, Rheumatology, Horsham, PA, United States of America; [8]Janssen Research and Development, LLC, Department of Immunology, San Diego, CA, United States of America; [9]Janssen Research and Development, LLC, Department of Immunology, Spring House, PA, United States of America; [10]Kennedy Institute of Rheumatology, University of Oxford, Department of Rheumatology, Oxford, United Kingdom; [11]Janssen Research and Development, LLC, Department of Immunology, Horsham, PA, United States of America*

Background: Guselkumab (GUS), an anti-IL23p19-subunit mAb, demonstrated significant efficacy vs placebo (PBO) in achieving ACR20 response at week (W) 24 in patients (pts) with active PsA in phase 3 trials, DISCOVER-1&2 (D1&2).[1,2] Pts with PsA report pain relief as a treatment priority.[3]

Objectives: To assess GUS treatment effect through 2 years on pt-reported pain across outcome measures.

Methods: Pts with active PsA in D1 (n=381; 31% received 1-2 prior TNFi) and D2 (n=739; biologic-naïve) were randomized (1:1:1) to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W at W24 (PBO→Q4W). Pts rated pain using visual analog scale (VAS; 0-10; Pt Pain) and reported Bodily Pain intensity over past 4 W via 36-Item Short-Form Health Survey question 21 (0-5). Pts with spondylitis and peripheral arthritis at baseline (BL) rated Spinal and Joint Pain (0-10). Observed mean change, % improvement from BL in tender (TJC; 0-68) and swollen joint counts (SJC; 0-66), and proportion of pts achieving ≥20/≥50% improvement in Pt Pain (nonresponder imputation [NRI]) were evaluated.

Results: In D2, mean BL for Bodily Pain (range: 4.4-4.5), Pt Pain (6.2-6.3), Spinal Pain (6.5-6.7), Joint Pain (6.3-6.8), SJC (11.7-12.9) and TJC (19.8-22.4) indicated moderate pain and disease activity at study outset. GUS-treated pts reported ~2x improvement in Pt Pain, Spinal Pain, Joint Pain, and Bodily Pain intensity at W24 vs PBO, which were maintained or increased at W52 and W100. PBO→Q4W pts had similar improvements. Pt-reported pain appeared more sensitive to treatment effect, with larger differences in % improvement vs PBO than physician-reported TJC/SJC at W24. D1 showed consistent results through 1 year. In 748 GUS-treated pts across D1&2, substantial proportions achieved meaningful improvement in Pt Pain at early time points: 32% (W4) and 48% (W8) achieved ≥20% improvement; 28% (W12) and 33% (W16) achieved ≥50% improvement. At W24, 63%/39% reported ≥20%/≥50% improvement in pain.

Conclusion: GUS provided consistent and durable improvements in pt-reported pain across several outcome measures. Pt-reported pain as an early and sensitive indicator of treatment effect in pts with active PsA and additional factors merits further evaluation.

MASS SPECTROMETRY-BASED PROTEOMICS FOR THE IDENTIFICATION OF CANDIDATE SERUM PROTEIN BIOMARKERS THAT MAY PREDICT TREATMENT RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS

J. Waddington[1], R. Zhou[1], O. Coleman[1], B. Wundervald[1,2], A. Parnell[2], P. J. Mease[3,4], V. Chandran[5], L. Fallon[6], D. Chapman[7], R. Pollock[8], S. Deng[9], O. Fitzgerald[10], S. Pennington[1,10]. *[1]Atturos,, Dublin, Ireland; [2]Maynooth University, Hamilton Institute, Kildare, Ireland; [3]Swedish Medical Center,, Seattle, WA, United States of America; [4]University of Washington,, Seattle, WA, United States of America; [5]Toronto Western Hospital, Department of Medicine, Division of Rheumatology, Toronto, ON, Canada; [6]Pfizer Inc, Inflammation and Immunology, Montreal, QC, Canada; [7]Pfizer Inc, Rare Disease, New York, NY, United States of America; [8]Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada; [9]Pfizer Inc, Translational Biomarker Statistics, Waterford, CT, United States of America; [10]University College Dublin, Conway Institute for Biomolecular Research, Dublin, Ireland*

Background: The Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) has identified a need for biomarkers to predict which patients (pts) with psoriatic arthritis (PsA) are most likely to respond to a specific therapy. Failure to identify effective treatments early on results in sub-optimal PsA disease management. Tofacitinib is an oral JAK inhibitor for the treatment of PsA. The efficacy and safety of tofacitinib 5 and 10 mg twice daily (BID) in pts with PsA have been demonstrated.[1,2]

Objectives: To identify protein biomarker candidates, which may identify responders (R) vs non-responders (NR) to treatment of PsA, using mass spectrometry-based proteomics.

Methods: Baseline (BL) serum samples from pts with PsA receiving tofacitinib 5 or 10 mg BID, adalimumab or placebo in OPAL Broaden (NCT01877668)[1] were analysed. Pts were identified as R and NR based on the Psoriatic Arthritis Disease Activity Score (PASDAS) at Month 3; pts with lowest PASDAS ≤3.2 were defined as R, those with highest PASDAS >3.2 as NR. Two proteomic strategies were employed for analysis of BL serum samples: (1) targeted mass spectrometric multiple reaction monitoring analysis of an in-house panel ('PAPRICA') comprising of 206 proteins, originally developed to distinguish between different arthropathies, and (2) unbiased discovery liquid chromatography-tandem mass spectrometry (LC-MS/MS). PAPRICA data were normalised using two methods: normalisation to stable isotopically labelled peptide spike-ins (SIL; corrects for fluctuations in sample injections/mass spectrometry loading amounts), and normalisation to an endogenous peptide panel representing total serum protein abundance (TSPA; corrects for different amounts of total serum protein across samples). Univariate analyses (Student's t-test) and multivariate machine learning Random Forest (RF) modelling[3] were performed. Univariate analysis of the PAPRICA panel of proteins was performed on R vs NR, and within each treatment arm, with no adjustment for multiplicity.

Results: 96 pts were identified as 47 R and 49 NR based on PASDAS scores. Of pts receiving tofacitinib 5 or 10 mg BID (data pooled), adalimumab or placebo, there were 26 R vs 26 NR, 13 R vs 13 NR and 8 R vs 10 NR, respectively. Results from univariate analysis identified 110 differentially expressed PAPRICA peptides between R vs NR ($p \leq 0.05$). RF multivariate analysis of all data (n=96) revealed a set of PAPRICA peptide signatures with the ability to differentiate between R and NR. Two RF models generated from the PAPRICA peptide data had training area under curves (AUCs) 0.956 [95% CI 0.93, 0.99] (TSPA) and 0.959 [95% CI 0.94, 0.98] (SIL). In total, 115 PAPRICA peptides representing 87 proteins were identified as potential biomarkers for predicting treatment response. Using unbiased discovery LC-MS/MS, univariate analysis of all data revealed one candidate peptide biomarker ($p \leq 0.05$). RF modelling revealed peptides that contributed to two prediction models with training AUCs of 0.903 [95% CI 0.86, 0.96] and 0.928 [95% CI 0.89, 0.96]. In total, from unbiased discovery LC-MS/MS, 66 peptides representing 39 proteins that may act as potential peptide biomarkers were identified in univariate and multivariate analyses.

Conclusion: Using two complementary proteomic approaches and a combination of univariate and machine learning models, a total of 181 candidate biomarker peptides corresponding to 106 proteins have been identified that may act as potential biomarkers for predicting response to treatment of PsA. Further study is required to verify and evaluate these candidate biomarkers, and we will report how these proteins map to biological processes, pathways and networks.

POS1046 DEUCRAVACITINIB LONG-TERM EFFICACY AND SAFETY IN PLAQUE PSORIASIS: 2-YEAR RESULTS FROM THE PHASE 3 POETYK PSO PROGRAM

R. B. Warren[1], H. Sofen[2], S. Imafuku[3], J. Szepietowski[4], A. Blauvelt[5], L. Spelman[6], E. Colston[7], J. Toms[8], A. Buck[9], S. Banerjee[10], A. Menter[11]. *[1]The University of Manchester, Dermatology, Manchester, United Kingdom; [2]UCLA School of Medicine, Dermatology, Los Angeles, United States of America; [3]Fukuoka University Hospital, Dermatology, Fukuoka, Japan; [4]Wroclaw Medical University, Dermatology, Wroclaw, Poland; [5]Oregon Medical Research Center, Dermatology, Portland, United States of America; [6]Veracity Clinical Research, Dermatology, Woolloongabba, Australia; [7]Bristol Myers Squibb, Dermatology, Princeton, United States of America; [8]Bristol Myers Squibb, New Indications, Clinical Development - Dermatology, Princeton, United States of America; [9]Bristol Myers Squibb, Biostats, Princeton, United States of America; [10]Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America; [11]Baylor University Medical Center, part of Baylor Scott & White Health, Dermatology, Dallas, United States of America*

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates signalling of key cytokines (eg, interleukin [IL]-23 and Type I interferons) involved in the pathogenesis of immune-mediated diseases including plaque psoriasis and psoriatic arthritis (PsA). Deucravacitinib is a novel, oral, selective TYK2 inhibitor that achieves high selectivity by uniquely binding to the regulatory domain of the enzyme, rather than to the more conserved active domain. Deucravacitinib showed superior efficacy compared with placebo at 16 weeks in a Phase 2 trial in patients with PsA.[1] The efficacy and tolerability of deucravacitinib in patients with moderate to severe psoriasis were previously demonstrated in 2 pivotal, Phase 3, double-blind trials, POETYK PSO-1 and PSO-2.[2]

Objectives: To assess the long-term efficacy and safety of deucravacitinib in patients with psoriasis in a Phase 3, open-label, long-term extension (LTE) trial.

Methods: The 52-week PSO-1 and PSO-2 trials randomised patients with moderate to severe plaque psoriasis 2:1:1 to deucravacitinib 6 mg once daily, placebo, or apremilast 30 mg twice daily. Patients could then enrol in the LTE trial and receive open-label deucravacitinib 6 mg once daily.

Results: 1221 patients enrolled in the LTE trial and received ≥1 dose of deucravacitinib. Demographic and baseline disease characteristics were balanced across treatment groups; mean age at disease onset was 28.6 years, mean disease duration was 18.9 years, and 18.0% of patients had PsA at baseline. Cumulative exposures in person-years from randomisation in PSO-1 or PSO-2 and the LTE trial were 2166.9 and 2482.0 for efficacy and safety analyses, respectively. At enrolment in the LTE trial, PASI 75 and sPGA 0/1 response rates were 65.1% and 50.9%, respectively, and were maintained for up to 2 years after initial randomisation (Week 48 of LTE; PASI 75: 75.7%; sPGA 0/1: 56.4% [as observed]). Exposure-adjusted incidence rates per 100 person-years for adverse events were similar in the controlled period (Weeks 0–52) of PSO-1 and PSO-2 and during the cumulative PSO-1, PSO-2, and LTE trial period (229.2 [controlled period] vs 154.4 [cumulative period]), serious adverse events (5.7 vs 6.1), discontinuations (4.4 vs 2.8), deaths (0.2 vs 0.4), herpes zoster (0.9 vs 0.7), malignancies (1.0 vs 0.9), major adverse cardiovascular events (0.3 vs 0.4), and venous thromboembolism (0.1 vs 0.1).

Conclusion: Deucravacitinib demonstrated persistent efficacy and consistent safety profiles in patients with psoriasis for up to 2 years after initial randomisation in the POETYK PSO-1, PSO-2, and LTE trials.

POS1047 TRAF3IP2, HCP5 AND IL10 GENES POLYMORPHISMS INFLUENCE THE RESPONSE TO TNF-I IN PATIENTS WITH PSORIATIC ARTHRITIS

M. S. Chimenti[1], A. Latini[2], P. Conigliaro[1], P. Triggianese[1], E. Greco[1], G. De Benedittis[2], L. Novelli[3], C. Ciccacci[3], A. Bergamini[1], G. Novelli[2], P. Borgiani[2]. *[1]Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy; [2]Department of Biomedicine and Prevention, Genetics Section, University of Rome Tor Vergata, Rome, Italy; [3]UniCamillus-Saint Camillus, International University of Health Sciences, Rome, Italy*

Background: Psoriatic Arthritis (PsA) is a chronic inflammatory disease, characterized by both articular and periarticular manifestations, usually associated with psoriasis. The identification of the correct therapy for patients is still a critical issue, but the use of biological drugs, such as TNFi (Tumor Necrosis Factor Inhibitors), modified the outcome of PsA patients even if there is great variability in the clinical efficacy. Since the response to drugs is a complex trait, the identification of genetic factors could help to define new genomic biomarkers for more effective and personalized therapy.

Objectives: The aim of this study was to evaluate the potential role of polymorphisms in genes already known to be involved in PsA susceptibility (ERAP1, HCP5, IL10, MIR146, PSORS1C1, STAT4, TNFAIP3 and TRAF3IP2) as predictors of efficacy of treatment, in a cohort of Italian PsA patients, treated with first-line TNF-i, in particular with Etanercept (ETN) and Adalimumab (ADA).

Methods: Polymorphisms were analyzed in a cohort of 163 patients with peripheral PsA. For each patient was estimated the Disease Activity in Psoriatic Arthritis (DAPsA) score. Genotyping was performed by allelic discrimination by TaqMan assay. The possible association between the selected SNPs and mean values of DAPsA differences, at 22 (ΔT22) and 54 (ΔT54) weeks from the beginning of the TNF-i treatment, were evaluated by T-test. A multivariate logistic regression analysis was used to evaluate the contribution of each genetic variant investigated in the TNF-i treatment response.

Results: We have observed that TRAF3IP2 SNP was associated with TNF-i treatment response in PsA patients. In particular, the patients carrying variant alleles seem to respond better to treatment, both at 22 ($P = 0.032$) and 54 weeks ($P = 0.019$). Moreover, the variant allele of TRAF3IP2 SNP resulted associated with a better response of joints involvement. Indeed, the number of tender and swollen joints decrease more in patients carrying variant allele ($P = 0.006$ and $P = 0.024$, respectively). We also observed that PsA patients carrying IL10 variant allele decrease their mean DAPsA value less than patients with wild-type genotype only at 54 weeks of treatment ($P = 0.031$). Also, HCP5 polymorphism showed a difference of mean difference of DAPsA values between genotypes for both follow up, even if these difference does not reach a statistical significance (

P = 0.068 and P = 0.086). The multivariate regression analysis was performed with a stepwise method and it confirmed the involvement of TRAF3IP2 (P = 0.016) and HCP5 (P = 0.035) polymorphisms in the TNF-i response after 22 weeks and of TRAF3IP2 (P = 0.007), IL10 (P = 0.022) and HCP5 (P = 0.036) polymorphisms after 54 weeks. The two final models explain about 6% and 11% of the variability in TNF-i treatment response at 22 and 54 weeks respectively.
Conclusion: Our results suggest that some polymorphisms in genes associated to PsA susceptibility could also play a role in TNFi treatment response and could give a contribution in the definition of a genetic profile associated with the response to anti-TNF drugs.

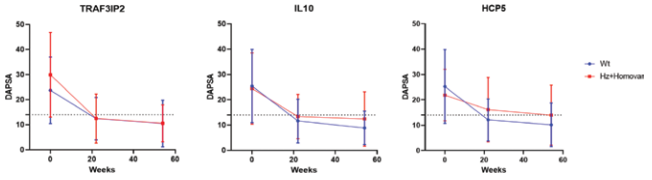

Figure 1. Mean differences of DAPsA values in the genotypic classes for TRAF3IP2, IL10 and HCP5 SNPs. DAPsA = Disease Activity Index for PsA; Wt = wild-type genotype; Hz = heterozygous genotype; Homo var = homozygous variant genotype.

SAFETY AND EFFICACY OF DEUCRAVACITINIB, AN ORAL, SELECTIVE TYROSINE KINASE 2 INHIBITOR, IN PATIENTS WITH PSORIATIC ARTHRITIS: 52-WEEK RESULTS FROM A RANDOMISED PHASE 2 TRIAL

P. J. Mease[1], A. Deodhar[2], D. Van der Heijde[3], F. Behrens[4], A. Kivitz[5], J. Neal[6], M. Nys[7], T. Lehman[8], N. Delev[9], S. Korish[10], M. Nowak[11], S. Banerjee[12]. *[1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; [2]Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America; [3]Leiden University Medical Center, Rheumatology, Leiden, Netherlands; [4]CIRI/Rheumatology and Fraunhofer Institute, Translational Medicine and Pharmacology ITMP, Goethe University, Translational Medicine and Pharmacology ITMP, Frankfurt, Germany; [5]Altoona Center for Clinical Research, Department of Rheumatology, Duncansville, United States of America; [6]Arthritis Center of Lexington, University of Kentucky School of Medicine, Rheumatology, Lexington, United States of America; [7]Bristol Myers Squibb, Biostatistics, Princeton, United States of America; [8]Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America; [9]Bristol Myers Squibb, Rheumatology Clinical Development, Princeton, United States of America; [10]Bristol Myers Squibb, Development, Immunology & Fibrosis, Princeton, United States of America; [11]Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; [12]Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America*

Background: Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of tyrosine kinase 2 (TYK2) that acts by binding to the unique TYK2 regulatory domain, thereby suppressing signalling of key cytokines (eg, IL-23) involved in skin psoriasis and psoriatic arthritis (PsA) pathogenesis. Results from the initial 16-week (wk), placebo (PBO)-controlled period (Part A) of a 52-wk, blinded Phase 2 trial in PsA showed that DEUC was significantly more efficacious than PBO.[1] The Psoriatic Arthritis Disease Activity Score (PASDAS), a validated comprehensive measure assessing a variety of PsA clinical domains, was used to assess efficacy of DEUC up to 52 wks.
Objectives: Evaluate the safety and efficacy of DEUC in Part B (Wks 16-52) in the Phase 2 PsA trial.
Methods: Patients (pts) with PsA were randomised 1:1:1 to PBO, DEUC 6 mg once daily (QD), or 12 mg QD. After Wk 16 (Part A), pts could enrol in an optional, double-blind period until Wk 52 (Part B). In Part B, pts receiving DEUC who had achieved minimal disease activity (MDA) at Wk 16 continued DEUC treatment and those who had not achieved MDA were switched to ustekinumab (UST) at the approved PsA dose. All pts treated with PBO in Part A switched to UST in Part B. Pts were assessed up to 52 wks for adverse events (AEs) and exploratory efficacy endpoints including change in PASDAS. Analyses were descriptive using data as observed.
Results: Of 203 pts randomised in Part A, 180 (89%) completed 16 wks of treatment and 173 (96%) of these pts chose to enrol in Part B. Of 118 pts initially randomised to DEUC, 25% (29/118; 6 mg QD, 22% [13/60]; 12 mg QD, 28% [16/58]) achieved MDA at Wk 16 and continued at the same dose. All other pts switched to UST in Part B: PBO, 100% (55/55; including 5 pts who had achieved MDA at Wk 16); DEUC 6 mg QD, 78% (47/60); DEUC 12 mg QD, 72% (42/58). The safety profile of DEUC in Part B (Table 1) was consistent with that in Part A, and all AEs were mild or moderate except 2 AEs in 1 pt with severe cataract/macular fibrosis. There were no opportunistic infections, herpes zoster, malignancy, thrombotic events, or treatment-related serious AEs reported in pts who remained on DEUC. Decreases in mean PASDAS score observed at Wk 16 were maintained at Wk 52 in pts who continued on DEUC (Figure 1). Improvements in other outcomes, including ACR components, PASI, and FACIT-Fatigue, were also sustained at Wk 52 in pts who continued DEUC treatment. Pts who had not achieved MDA on DEUC at Wk 16 showed a decrease in mean PASDAS score at Wk 52 after switching to UST.

Table 1. Overall summary of safety in Part B (Weeks 16 to 52)

AE, n (%)[a]	DEUC 6 mg QD n = 13	DEUC 12 mg QD n = 16	DEUC 6 mg QD →UST n = 47	DEUC 12 mg QD → UST n = 42	PBO → UST n = 55
Total AEs	11 (84.6)	8 (50.0)	26 (55.3)	26 (61.9)	30 (54.5)
Deaths	0	0	1 (2.1)[d]	1 (2.4)[d]	0
SAE	1 (7.7)[b]	0	3 (6.4)	4 (9.5)	0
Treatment-related SAE	0	0	0	0	0
Discontinued due to AE	0	1 (6.3)[c]	0	2 (4.8)[c,e]	0

Includes all treated patients in Part B. Medical Dictionary for Regulatory Activities version 23.0 was used. [a]n is the number of patients who experienced an event. [b]One patient had SAEs of psoriatic arthropathy in 1 joint and peripheral neuropathy. [c]Patient had an AE of COVID-19 infection leading to discontinuation. [d]Deaths in UST arms were due to car accident and sudden death in a 71-year-old patient with hypertension. [e]Patient had an AE of urinary tract infection leading to discontinuation. AE, adverse event; DEUC, deucravacitinib; PBO, placebo; QD, once daily; SAE, serious adverse event; UST, ustekinumab.

Conclusion: In the 16- to 52-wk blinded Part B of a Phase 2 study in pts with PsA, no new safety signals were observed with continuous DEUC treatment vs the earlier Part A period. Efficacy in PASDAS, as well as other key efficacy measures, was maintained with continued DEUC treatment through Wk 52.

POS1049 ASSESSING TREATMENT PATTERNS WITH DISEASE-MODIFYING ANTIRHEUMATIC DRUGS AND PREDNISONE FOR PSORIATIC ARTHRITIS BY RACE/ETHNICITY

F. Ahmed[1], A. Ogdie[2], R. Fitzsimmons[1], D. Shin[1], J. Takeshita[1]. *[1]University of Pennsylvania, Department of Dermatology, Philadelphia, United States of America; [2]University of Pennsylvania, Department of Rheumatology, Philadelphia, United States of America*

Background: Psoriatic arthritis (PsA) is a comorbidity commonly associated with psoriasis. Studies have demonstrated delays in the diagnosis and treatment of PsA[1] that may disproportionately affect racial/ethnic minority patients as indicated by one study that found Black Medicaid patients with PsA to be less likely to receive disease-modifying antirheumatic drugs [DMARDs] than White Medicaid patients with PsA [2]. Yet much remains unknown about potential racial/ethnic disparities in PsA management.

Objectives: The objective of our study was to evaluate treatment patterns for PsA by race/ethnicity.

Methods: We performed a cross-sectional study of adult (≥18 years old) patients with PsA who had at least one outpatient visit within the University of Pennsylvania health system between 2010 and 2019. Patients with PsA were identified by the presence of at least two International Classification of Diseases (ICD)-9 or ICD-10 codes for PsA associated with two different healthcare encounters. The primary outcomes were receipt of a prescription for: (i) an oral DMARD, (ii) a biologic DMARD, and (iii) prednisone. Oral DMARDs included apremilast, methotrexate, sulfasalazine, leflunomide, azathioprine, cyclosporine, tofacitinib, hydroxychloroquine, and upadacitnib. Biologic DMARDs included abatacept, adalimumab, brodalumab, certolizumab, etanercept, golimumab, guselkumab, infliximab, ixekixumab, secukinumab, ustekinumab, and risankizumab. The primary independent variable was race/ethnicity categorized as White (reference), Black, Asian, Hispanic, or other race. Multivariable logistic regression was used to assess the relationship between race/ethnicity and each treatment outcome.

Results: The study population included 1781 patients with PsA who were a mean age of 50.7 (SD 14.3), 54.6% female, and 72.5% commercially insured. The racial/ethnic distribution was 81.9% White, 5.6% Black, 4.0% Asian, 3.0% Hispanic, 2.5% other race, and 3.1% missing race/ethnicity. Of these patients, 64.3% were prescribed an oral DMARD, 55.6% were prescribed a biologic, and 44.1% were prescribed prednisone. There were no statistically significant differences across race/ethnicity for prescription of either oral or biologic DMARDs. However, prescription of prednisone did differ by race/ethnicity (p<.005) with Black (54.6%) and Hispanic (56.6%) patients being more likely to receive prednisone prescriptions and Asian (32.4%) patients being less likely to receive prednisone prescriptions than White (44.2%) patients. In adjusted logistic regression models controlling for sociodemographic and other factors, Hispanic patients were more likely to receive a prednisone prescription (OR 1.79, 95% CI 1.01 – 3.20, p=0.05) while Asian (OR 0.58, 95% CI 0.34 – 0.97, p=0.04) patients were less likely to receive a prednisone prescription compared to White patients.

Conclusion: We found Hispanic patients with PsA to be more likely to receive prednisone prescriptions than White patients with PsA but did not identify any racial/ethnic differences in prescription patterns for oral or biologic DMARDs for PsA. Greater use of prednisone among Hispanic patients may reflect different diseases trajectories (e.g., more disease flares or greater disease severity) or other factors that affect prescription patterns that require further study.

POS1050 UPADACITINIB VERSUS ADALIMUMAB ON ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3 (RAPID3) IN PATIENTS WITH PSORIATIC ARTHRITIS

L. Coates[1], A. Kavanaugh[2], E. Mcdearmon-Blondell[3], A. Mandelin[4], T. Gao[3], W. Tillett[5]. *[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]University of California San Diego, Division of Rheumatology, Allergy, and Immunology, San Diego, United States of America; [3]AbbVie Inc., Immunology, North Chicago, United States of America; [4]Northwestern University Feinberg School of Medicine, Medicine, Chicago, United States of America; [5]Royal National Hospital for Rheumatic Diseases, University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom*

Background: RAPID3 (Routine Assessment of Patient Index Data 3) is a disease activity index that is calculated from 3 patient-reported measures: physical function, pain, and patient global assessment. A fast and convenient tool, RAPID3 can be easily used in clinical practice and is applicable to multiple rheumatic diseases, including psoriatic arthritis (PsA), and was shown to correlate with other clinical composite measures of disease activity[1]. Here, we assessed the long-term effect of upadacitinib (UPA), an oral JAK inhibitor, and adalimumab (ADA) on RAPID3 scores in patients with PsA via a post hoc analysis from the SELECT-PsA 1 phase 3 trial[2,3].

Objectives: To evaluate the impact of treatment with UPA vs ADA on RAPID3 through 56 weeks in SELECT-PsA 1, as well as the association of RAPID3 with other disease measures used in PsA.

Methods: Data are from the double-blind SELECT-PsA 1 trial, in which patients with PsA and an inadequate response or intolerance to ≥1 non-biologic DMARD received UPA 15 mg or 30 mg once daily, ADA 40 mg every other week (wk), or placebo (PBO; switched at wk 24 to either UPA 15 mg or 30 mg). This analysis included data from the UPA 15 mg, ADA, and PBO treatment arms. RAPID3 endpoints were calculated using pain scores, patient's global assessment of disease activity, and HAQ-DI (each rescaled to 0–10 in this analysis); summed together, RAPID3 scores range from 0 (no disease activity) to 30 (severe activity). Mean change from baseline (BL) in RAPID3 as well as the proportions of patients reporting minimal clinically important differences (MCID) in RAPID3 and RAPID3 remission (≤3), low (LDA, >3 to ≤6), moderate (MDA, >6 to ≤12), and high disease activity (HDA, >12) were assessed through wk 56. Associations between RAPID3 scores and disease activity in psoriatic arthritis (DAPSA) and Minimal Disease Activity (MDA)/Very Low Disease Activity (VLDA) were determined by Mantel-Haenszel chi-square test. All data are as observed.

Results: A total of 1,274 patients (PBO: n=421; UPA 15 mg: n=425; ADA: n=428) were included from SELECT-PsA 1. RAPID3 scores at BL were comparable across all treatment arms, and most patients were in HDA. Patients receiving UPA showed a greater improvement from BL in RAPID3 vs ADA at all visits from wk 16 to wk 56 as well as better responses compared with PBO at all assessments (**Figure 1**). Similarly, a higher proportion of patients treated with UPA achieved MCID in RAPID3 scores than those on ADA from wk 24 to wk 56. By wk 56, approximately half of patients on either therapy were in RAPID3 remission or LDA, with UPA showing a slight numerical improvement relative to ADA (30/21/31/18% of patients were in remission/LDA/MDA/HDA on UPA vs 28/17/30/25% on ADA). RAPID3 disease categories were strongly associated with DAPSA and MDA/VLDA status at wk 56 across all treatment arms pooled together (**Table 1**) and for the UPA 15 mg arm alone (nominal *P* <0.0001 for all associations).

Table 1. Association of RAPID3 With DAPSA and MDA/VLDA Across All Treatment Arms at Week 56[a]

	RAPID3		
n (%)	**Moderate-High [>6]**	**Low [3 - ≤6]**	**Remission [≤3]**
DAPSA (n=879)			
Moderate-High [>14]	292 (33)	33 (4)	14 (2)
Low [4 - ≤14]	154 (18)	122 (14)	87 (10)
Remission [≤4]	6 (1)	21 (2)	150 (17)
MDA/VLDA (n=907)			
Not in MDA	410 (45)	39 (4)	5 (1)
MDA but not VLDA	63 (7)	129 (14)	80 (9)
VLDA	0	13 (1)	168 (19)

[a]DAPSA vs RAPID3 and MDA/VLDA vs RAPID3 were nominally significant at P <0.0001. Data were pooled across UPA 15 mg, ADA, and PBO to UPA 15 mg groups.

Conclusion: UPA 15 mg treatment led to greater improvements over PBO in RAPID3 scores over 56 wks in patients with PsA, and greater improvements over ADA from wk 16 to 56. The majority of patients achieved MCID in RAPID3 after 12 wks of UPA or ADA, with higher proportions achieving MCID on UPA vs ADA by wk 24. RAPID3 was strongly associated with other joint-focused (DAPSA) or multiple manifestation (MDA/VLDA) composite measures, further supporting the utility of RAPID3 in assessing disease activity in PsA.

TO WHAT EXTENT ARE BASELINE CHARACTERISTICS IN BIOLOGIC-EXPERIENCED PATIENTS WITH PSORIATIC ARTHRITIS ASSOCIATED WITH ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY AT WEEK 24 OF GUSELKUMAB TREATMENT: A POST HOC ANALYSIS OF THE PHASE IIIB COSMOS CLINICAL TRIAL

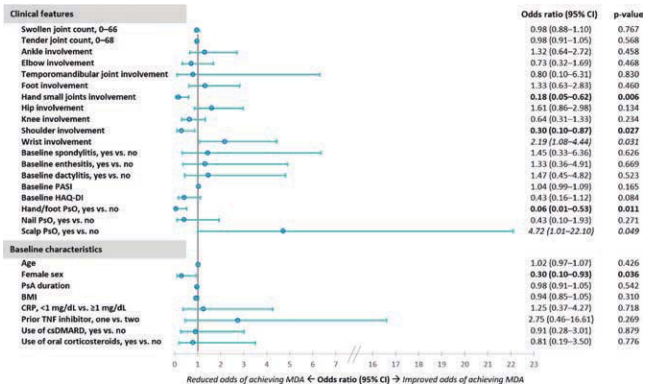
W. Tillett[1], S. Ohrndorf[2], J. Ramírez[3], M. Neuhold[4], R. Wapenaar[5], E. Theander[6], C. Contre[7], M. Sharaf[8], M. Shawi[9], M. Vis[10]. *[1]Royal National Hospital for Rheumatic Diseases, University of Bath, Bath, United Kingdom; [2], Charité – Universitätsmedizin Berlin, Berlin, Germany; [3], Hospital Universitari Clínic, Barcelona, Spain; [4], Janssen-Cilag, Zug, Switzerland; [5], Janssen-Cilag BV, Breda, Netherlands; [6], Janssen-Cilag, Solna, Sweden; [7], Janssen-Cilag, Issy-les-Moulineaux, France; [8], Janssen-Cilag, Dubai, United Arab Emirates; [9], Janssen Global Services, LLC, Horsham, PA, United States of America; [10], Erasmus MC Universitair Medisch Centrum, Rotterdam, Netherlands*

Background: Guselkumab (GUS) is a human monoclonal antibody targeting the interleukin-23p19-subunit. It has demonstrated efficacy at Week 24 in the Phase IIIb COSMOS clinical trial of patients with active psoriatic arthritis (PsA) and inadequate response or intolerance to one or two tumour necrosis factor inhibitors (TNFis).[1]

Objectives: The aim of this *post hoc* analysis was to identify predictors of minimal disease activity (MDA) with GUS at Week 24 in patients with active PsA and inadequate response or intolerance to one or two TNFis.

Methods: A multiple logistic regression analysis was performed to identify potential predictors of MDA with GUS at Week 24 in TNFi-refractory patients with PsA. Odds ratios, 95% confidence intervals and p-values were calculated. Baseline characteristics assessed as predictors included age, sex, body mass index (BMI), C-reactive protein (CRP), other medication use and disease duration. Clinical features included tender and swollen joint counts (TJC/SJC), affected joint location, dactylitis, enthesitis, spondylitis, Psoriasis Area and Severity Index (PASI) score and psoriasis (PsO) localisation (Figure 1). Missing data for MDA at Week 24 were imputed as non-response; missing baseline values were imputed for two patients.

Figure 1. Odds ratios and 95% CIs for potential predictors of minimal disease activity response to guselkumab 100 mg every 8 weeks at Week 24 in patients with PsA and an inadequate response or intolerance to one or two prior TNF inhibitors.



BMI, body mass index; CI, confidence interval; CRP, C-reactive protein; csDMARD, conventional systemic disease-modifying anti-rheumatic drug; HAQ-DI, Health Assessment Questionnaire - Disability Index; MDA, minimal disease activity; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; PsO, psoriasis; TNF, tumour necrosis factor.N=187 for all clinical features and baseline characteristics. Negative predictors are indicated by bold text and positive predictors by italicisation (p<0.05).

Results: Of the 187 patients in this study, 54.6% were women and the mean disease duration was 8.3 years. The patients had a mean TJC 0–68 of 21.0, a mean SJC 0–66 of 10.3, a mean PASI score of 11.6 and a mean BMI of 28.9. Furthermore, 67.9% had enthesitis and 35.8% had dactylitis at baseline. One prior TNFi had been received by 88.2% of patients, and two received by 11.8%. At

Week 24, 17.1% of patients (32/187) achieved MDA. Wrist involvement (p=0.031) and scalp PsO (p=0.049) were positive predictors of MDA. Women were significantly less likely to achieve MDA (p=0.036) than men; other negative predictors included involvement of shoulder or small joints of the hand, and hand/foot PsO (all p<0.05). Age, BMI, CRP, TJC/SJC, HAQ-DI, PASI, spondylitis, enthesitis, dactylitis, other medication use and number of prior TNFis were not predictive of MDA (Figure 1).

Conclusion: Baseline characteristics and clinical features may be positively (wrist involvement, scalp PsO) or negatively (female sex, involvement of shoulder or small joints of the hand, hand/foot PsO) associated with achieving MDA with GUS at Week 24 in a TNFi-refractory population. Though the low patient number limits the generalisability of this analysis, assessment of Week 48 data may further elucidate potential predictors of MDA after longer-term treatment.

POS1052

DEVELOPING EVIDENCE-BASED PATIENT FOCUSED LEARNING MATERIALS TO SUPPORT HEALTH BEHAVIOUR CHANGE FOR PEOPLE LIVING WITH PSORIATIC ARTHRITIS

L. Hailey[1], C. Bundy[2], L. Howells[3], S. Kirtley[4], S. Martin[5], D. O'sullivan[6], I. Steinkoenig[7], M. Stepney[5], L. Coates[1]. *[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]Cardiff University, Behavioural Medicine/ Health Psychology School of Healthcare Sciences, Cardiff, United Kingdom; [3]University of Nottingham, Centre of Evidence Based Dermatology, Nottingham, United Kingdom; [4]University of Oxford, Centre for Statistics in Medicine, Oxford, United Kingdom; [5]University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom; [6]Patient Research Partner,, Kildare, Ireland; [7]Patient Research Partner,, Cleveland, United States of America*

Background: Psoriatic arthritis (PsA) is a complex condition that requires high levels of self-management from those living with the condition. It is associated with many comorbidities, including depression, metabolic syndrome, and increased cardiovascular disease risk and can adversely affect quality of life. There is growing evidence that people living with psoriatic arthritis (PsA) are more likely to be overweight, consume alcohol above recommended levels, smoke, be affected by poor sleep, fatigue, anxiety, and take insufficient exercise for healthy living. These modifiable health behaviours further increase the already known risk of cardiovascular morbidity and mortality. These issues are not systematically addressed in routine clinical care due to low confidence in effective delivery and time constraints.

Objectives: To co-develop evidence-based patient-focused learning materials to support healthy lifestyle changes for people living with PsA.

Methods: The development of the materials was overseen by a steering group of people living with PsA, psychologists, rheumatologists, and researchers. The COM-B model was used in the development of the materials, and they are designed around motivational interviewing principles. Firstly, a systematic literature review was performed to establish the evidence for the current burden and potential interventions aimed at these issues in PsA. These included diet, weight, alcohol, smoking, exercise, anxiety, depression, and stress. An initial focus group of people living with PsA was used to identify priority behaviours and ideas for content. The steering group developed draft materials, and we partnered with a design agency to create engaging materials. They developed a website and downloadable postcards. A second focus made up of people living with PsA was held for people to give their views on the draft content for the materials and initial design ideas. A third focus group was held with people living with PsA and a fourth with clinicians to refine the design materials and ensure they were accessible, interesting, and helpful to initiate and maintain change. A final evaluation survey was performed to review the draft website before launching the final materials. The Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) approved the final materials.

Results: Following the steering and focus groups' input, 15 candidate topics were prioritised (Table 1). A website and downloadable postcards summarising each of the topics were developed by the design team and refined following feedback from the patient focus groups. An example of the postcard for 'keeping active' can be found in Figure 1. The resources are free to use and can be accessed at https://www.informatree.org.

Table 1.

Topics	
1	Pain
2	Fatigue
3	Healthcare appointments

13	Intimacy
14	Travel
15	Using treatments

Figure 1.

During the development of the website and downloadable postcards, particular attention was paid to making the material as accessible and as friendly as possible for patients.

Conclusion: This project created patient-focused information to support behaviour change in clinical practice. It addresses common concerns of people living with PsA about how they may optimise their health by providing practical and

brief interventions to challenge and support them to make personal changes. Future research is needed to test the impact of the resource.

Background: SERENA is an ongoing, longitudinal, observational study of more than 2900 patients (pts) with moderate to severe psoriasis, active psoriatic arthritis (PsA), and ankylosing spondylitis (AS) conducted at 438 sites across Europe with an expected duration of up to 5 years.[1,2]

Objectives: We report long-term results (at least 3 years follow up) on secukinumab (SEC) retention, effectiveness and safety in pts with active PsA or AS from the SERENA study.

Methods: This analysis includes data of 524 PsA and 473 AS pts enrolled in the study and followed up for at least 3 years. Pts (aged ≥18 years) with active PsA or AS were required to have received at least 16 weeks of SEC treatment before enrolment in the study. Retention rate was defined as the percentage of pts who have not discontinued SEC treatment. Effectiveness assessments included swollen and tender joint counts (SJC and TJC) in pts with PsA, and BASDAI score in pts with AS. Safety assessments included the number of pts with any adverse events (AEs) and serious AEs, treatment-emergent AEs, AEs of special interest and their incidence rates.

Results: The mean (SD) treatment duration prior to enrolment in the study for PsA and AS pts was 1.0 (0.5) years and 0.9 (0.5) years, while time since diagnosis was 8.7 (7.4) and 9.8 (9.5) years, respectively. Prior to SEC initiation, 67.4% of pts with PsA and 63.0% of pts with AS received a biologic therapy, with lack of efficacy reported as major reason for discontinuation (PsA: 89.5%; AS: 87.6%). SEC retention rates after at least 3 years since enrolment in the study were 67.3% for pts with PsA and 72.1% for pts with AS. Survival probabilities for individual indications are presented in Figure 1. Over 3 years of observation, SEC showed sustained effectiveness in pts with PsA [SJC, mean (SD): baseline, 3.2 (5.6); Year 3, 1.7 (2.7) and TJC: baseline, 6.4 (9.4); Year 3, 4.9 (6.4)] and AS [BASDAI, mean (SD): baseline, 3.2 (2.3); Year 3, 2.7 (2.2)]. No new or unexpected safety signals were reported; 11.0% of pts with PsA (N=574) and 12.9% of pts with AS (N=505) reported serious AEs (Table 1).

Conclusion: After more than 3 years of observation in the SERENA study, SEC showed sustained retention rates, indicating high persistence in a real-world setting. Responses across effectiveness assessments in both PsA and AS cohorts were maintained or improved during the 3 years of follow up in the study. SEC showed a favourable safety profile, consistent with previous reports.

POS1054 PAIN AND DEPRESSION ARE ASSOCIATED WITH NON-RESPONSE TO METHOTREXATE IN PATIENTS WITH PSORIATIC ARTHRITIS

F. R. Kasiem[1], L. Tucker[2], M. Vis[1], J. Luime[1], I. Tchetverikov[3], K. Wervers[1], J. Hazes[1], L. Coates[2], M. R. Kok[4]on behalf of CICERO. *[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands; [2]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, Oxford, United Kingdom; [3]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands; [4]Maasstad Hospital, Rheumatology and Clinical Immunology, Rotterdam, Netherlands*

Background: Psoriatic arthritis (PsA) is a heterogeneous, immune-mediated inflammatory arthritis. Methotrexate (MTX) is the first-line treatment in PsA patients, despite diverse clinical phenotypes and highly varied responses(1). As yet, it is not possible to predict MTX treatment response. The identification of demographic, clinical and psychosocial factors associated with MTX non-response, would facilitate a paradigm shift from a 'one-size-fits-all' approach to a more personalized medicine strategy, based on individual patient characteristics.
Objectives: The aim of this study was to identify demographic, clinical and psychosocial factors associated with MTX non-response 3 months after MTX initiation in adult patients with PsA.
Methods: Newly diagnosed, adult PsA patients were recruited to the DEPAR (Dutch southwest Early Psoriatic Arthritis cohort) study. MTX non-response was defined as patients achieving <5/7 point of the Minimal Disease Activity (MDA) criteria after 3 months of MTX therapy. A logistic regression analysis was performed to identify demographic, clinical and psychosocial factors associated with MTX non-response. Demographic characteristics included age, sex, alcohol use, smoking (pack years) and body mass index (BMI). Clinical characteristics included duration of PsA symptoms, swollen and tender joint counts (66/68), Psoriasis Area and Severity Index (PASI) scores, presence of dactylitis and enthesitis scores (Leeds Enthesitis Index/Maastricht Ankylosing Spondylitis. [LEI_MASES]). Psychosocial variables included both subscales of the Hospital and Anxiety Depression Scale (HADS).
Results: Complete data of the variables of interest were available for 174/332 (52%) patients starting MTX monotherapy within the first year of diagnosis. Mean (SD) age was 53 (14) years and 88 patients (51%) were male. A total of 39 patients (22%) achieved MDA after 3 months of MTX therapy. Correlations between the variables and regression statistics are shown in Table 1. A significant correlation was seen between MTX non-response and enthesitis (OR 0.66, CI 0.47-0.94) and depression (OR 0.41, CI 0.25-0.66). Furthermore, the interaction of BMI with tender joint count (OR 0.95, CI 0.91-1.00) was found to be significantly correlated, whereas the independent variables were not.

Table 1. Final model of the logistic regression analysis of methotrexate non-response 3 months after methotrexate initiation.

Independent variables	Odds Ratio	95% CI
Demographic variables		
BMI	1.26	0.61-2.60
BMI[3]	1.00	1.00-1.00
Clinical characteristics		
Tender joint count (68)	3.16	0.94-10.57
Enthesitis (LEI/MASES)	**0.66**	**0.47-0.94**
Psoriasis (PASI)	1.11	0.99-1.25
BMI*Tender joint count (68)	**0.95**	**0.91-1.00**
Patient reported outcomes		
Depression (HADS)[†]	**0.41**	**0.25-0.66**

FootnotesSignificant values in bold face[†] Root transformed

Conclusion: Our results indicate that enthesitis, depression and the combination of a higher BMI with a tender joint count are all associated with MTX non-response 3 months after MTX initiation. Pain may be the common denominator preventing patients from achieving MDA.

POS1055 IDENTIFICATION OF PSA PHENOTYPES WITH MACHINE LEARNING ANALYTICS USING DATA FROM A PHASE 3 CLINICAL TRIAL PROGRAMME OF GUSELKUMAB IN A BIO-NAÏVE PATIENT POPULATION

P. Richette[1], M. Vis[2], S. Ohrndorf[3], W. Tillett[4], M. Neuhold[5], M. Van Speybroeck[6], E. Theander[7], W. Noel[8], M. Shawi[9], A. Kollmeier[10], A. Zabotti[11]. *[1]Rheumatology Department Lariboisière Hospital, Paris University, Paris, France; [2], Erasmus MC Universitair Medisch Centrum, Rotterdam, Netherlands; [3], Charité – Universitätsmedizin Berlin, Berlin, Germany; [4]Royal National Hospital for Rheumatic Diseases, University of Bath, Bath, United Kingdom; [5], Janssen-Cilag, Zug, Switzerland; [6], Janssen Pharmaceutica, Beerse, Belgium; [7], Janssen-Cilag, Solna, Sweden; [8], Janssen-Cilag BV, Breda, Netherlands; [9], Janssen Global Services, LLC, Horsham, PA, United States of America; [10]Janssen-Cilag, Research & Development, LLC, San Diego, CA, United States of America; [11]Department of Medical and Biological Sciences, Rheumatology Unit, University of Udine, Udine, Italy*

Background: Psoriatic arthritis (PsA) is typically described by its individual domains or clinical components.[1,2]
Objectives: This *post hoc* analysis aimed to identify hypothesis-free phenotype clusters according to patients' clinical features and baseline (BL) characteristics with data from the Phase 3 DISCOVER-1 and -2 guselkumab (GUS) clinical trials.
Methods: Data from bio-naïve patients with PsA treated with GUS 100 mg every 4 or 8 weeks in DISCOVER-1 and -2 were retrospectively analysed. Non-negative matrix factorisation was used as an unsupervised machine learning technique to identify clusters of PsA phenotypes, with BL characteristics and clinical observations as input features, according to which clusters were described.
Results: Data from 661 patients were pooled and 8 distinct clusters of PsA phenotypes identified (Table 1). Cluster 1 was characterised by lower limb involvement and the lowest rates of severe skin involvement (Figure 1); Cluster 2 by high skin involvement, the lowest proportion of women and highest proportion of overweight patients (body mass index [BMI] 25–<30, 70%); and Cluster 3 by high burden of disease in the hand/wrist. In Cluster 4 all patients had dactylitis and ≥3% body surface area (BSA) psoriasis involvement and the second highest proportion of men. Cluster 5 had the highest BL enthesitis rate; large joint involvement was also common. Cluster 6 had a high level of small joint involvement in the hands/feet, but low mean dactylitis score; nail involvement and BL enthesitis were also common. In Cluster 7, all patients had axial involvement at BL, 49.4% had dactylitis, 69.9% had enthesitis and most had BSA ≥3% (Figure 1). Cluster 8 had limited joint involvement, extensive skin involvement and the highest proportion of obese patients (BMI >30, 67%). Minimal disease activity (MDA) response rates at Week (W)24 and W52 were

POS1056

PREDICTORS OF RISK OF ANTI-TNF TREATMENT WITHDRAWAL IN PATIENTS WITH PSORIATIC ARTHRITIS – DATA FROM MOSCOW UNIFIED ARTHRITIS REGISTRY (MUAR)

K. Lytkina[1], E. Koltsova[2], E. Shmidt[3], G. Lukina[2,4], E. Zhilyaev[5,6,7]. *[1]The Hospital for War Veterans №3, Rheumatology, Moscow, Russian Federation; [2]Moscow Clinical Scientific Center Named After A.S.Loginov, Rheumatology, Moscow, Russian Federation; [3]City Clinical Hospital 1 Named After N.I.Pirogov, Rheumatology, Moscow, Russian Federation; [4]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [5]Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation; [6]Pirogov Russian National Research Medical University, Rheumatology, Moscow, Russian Federation; [7]CJSC «European Medical Center», Rheumatology, Moscow, Russian Federation*

Background: Retention on therapy is the most important integrative indicator of the success of the drug, reflecting both the effectiveness and tolerability and general acceptability of treatment. This indicator can be evaluated with high accuracy in observational trials.

Objectives: to identify predictors of TNF inhibitors withdrawal risk in patients with PSA.

Methods: Patients with (PSA) from Moscow Unified Arthritis Registry (MUAR) treated with TNF inhibitors were analyzed. All treatment episodes interrupted due to non-medical reasons were excluded from the study. Breaks in biologic therapy up to 4 months were allowed (for infliximab a break in therapy up to 6 month was considered possible) The search for predictors of treatment withdrawal risk was carried out in two steps. At the first step possible predictors of the risk of TNF inhibitors therapy discontinuation were selected in univariate correlations. At the second step significant predictors of retention on TNF inhibitors therapy were selected by forward stepwise variable selection within multivariate Cox regression. The relationship between the line of anti-TNF treatment and the risk of therapy discontinuation was analyzed separately.

Results: We analyzed 371 treatment episodes in 239 patients with PSA enrolled in MUAR, 97 male (40.6%), 50.2±12.1 years old. The age of disease onset was 36.8 ± 12.7 years. The patients received adalimumab (ADA) (101 treatment episodes), golimumab (GOL) (n=32), infliximab (INF) (n=55), certolizumab pegol (CER) (n=31), etanercept (ETA) (n=152). There were 187 (50.4%) completed treatment episodes. The relationship between risk of TNF inhibitors discontinuation and the drug line was analyzed. We found that the withdrawal risk on the second TNF inhibitor didn't significantly differ from the withdrawal risk on the first line anti-TNF drug (p=0,201). The third and subsequent lines of TNF inhibitors where associated with the significantly higher risk of withdrawal. Direct step-by-step selection of variables made possible to identify the following significant predictors of retention on therapy – social status, the presence of HLA B-27, fever during the disease, pain in sacral zone at the onset of the disease, coccidinia during the disease, patient reports on the association of the onset of the disease with a genital infection (uretritis, adnexitis, prostatitis, endometritis) (Table 1)

Table 1. Independent predictors of anti-TNF treatment discontinuation

Predictors	Direction of association with the dicontinuitation risk	p
Social status	Working patients had a lower risk	0.038
The presence of HLA-B27	HLA-B27 positive patients had lower risk	0.005
Temperature elevation during the disease	Patients WHO reported an increase in body temperature during the disease had an increased risk	< 0.001
Sacral pain at the onset of the disease	Patients who reported sacral pain at the onset of the disease had an increased risk	0.037
Coccygeal pain during the disease	Patients who reported pain in the coccyx during the disease had an increased risk	0.026
Presence of genital infections	Patients who reported a link between the onset of the disease and a history of urethritis or endometritis had a high risk	0.011

After adjusting for the line of therapy and the identified predictors of the risk of drug withdrawal it was found that retention on all analyzed TNF inhibitors in patients with PSA didn't differ significantly (Figure 1)

Conclusion: The identified significant mutually independent predictors of the risk of discontinuation of treatment may be useful when choosing biological therapy in patients with PSA. Discontinuation therapy risk of various TNF inhibitors does not differ significant.

The risk of withdrawal therapy with the second TNF inhibitor is not significantly differ from the first one. Thus, in case of failure of the first attempt of treatment with an TNF inhibitor, a second attempt can be made The probability of success of subsequent attempts seems to be very low

POS1057

IMPACT OF RISANKIZUMAB ON ENTHESITIS AND ASSOCIATED PAIN: POOLED RESULTS FROM THE PHASE 3, RANDOMIZED, DOUBLE-BLIND KEEPSAKE 1 AND 2 TRIALS

M. Magrey[1], M. Jain[2], R. Ranza[3], J. Stigler[4], E. Mcdearmon-Blondell[4], C. Yue[4], B. Padilla[4], C. Kaufmann[4], D. Mcgonagle[5,6]. *[1]University Hospitals, Rheumatology Division, Cleveland, United States of America; [2]Great Lakes Clinical Trials, Rheumatology, Chicago, United States of America; [3]Federal University of Uberlândia, Rheumatology Unit, Hospital das Clínicas, Uberlândia, Brazil; [4]AbbVie Inc., Immunology, North Chicago, United States of America; [5]University of Washington, Division of Rheumatology, Seattle, United States of America; [6]University of Leeds, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Controlling or improving musculoskeletal disease activity of psoriatic arthritis (PsA) (eg, enthesitis and associated pain) is a treatment priority for patients, rheumatologists, and dermatologists.[1] Enthesitis is the cardinal lesion in PsA and is immunogenetically and experimentally linked to the interleukin-23 (IL-23) pathway.[2] Risankizumab (RZB), a humanized immunoglobulin G1 monoclonal antibody that specifically inhibits IL-23 by binding to its p19 subunit, was studied in a phase 3 adult PsA program (KEEPsAKE clinical trials).[3,4] Pooled analyses from the program demonstrated the efficacy of RZB to treat enthesitis and pain associated with PsA, and increase the proportion of patients whose enthesitis resolved compared with placebo (PBO) in those patients who had an inadequate response or intolerance to ≥1 conventional synthetic disease-modifying antirheumatic drugs (KEEPsAKE 1 and 2) and/or ≤ 2 biological therapies (KEEPsAKE 2).

Objectives: To investigate whether patients without enthesitis at baseline (BL) (Leeds Enthesitis Index [LEI] = 0 at BL) remained enthesitis-free through week (W) 52, patients with enthesitis at BL (LEI > 0 at BL) had resolution of enthesitis through W52, and if greater pain relief was achieved with RZB 150 mg in patients with enthesitis at BL vs PBO up to W24.

Methods: The study design and primary results of KEEPsAKE 1 (NCT03675308) and KEEPsAKE 2 (NCT03671148) have been previously reported.[3,4] Briefly, patients were randomized to receive RZB 150 mg or PBO subcutaneously at weeks 0, 4, and 16 during a 24-week, double-blind treatment period; at W28 all patients received open label RZB 150 mg. For this post hoc analysis, the RZB 150 mg and PBO groups were pooled across the 2 studies. Pain reductions (as measured by change from BL in visual analogue scale [VAS] scores) were assessed at each time point through W24 among patients with enthesitis at BL (LEI > 0 at BL) using mixed-effect model repeated measurement analysis. Additional enthesitis analyses were calculated on the data as observed.

Results: Across the pooled population, over 60% of patients in each treatment group had enthesitis at BL (RZB=444/707 [63%]; PBO=448/700 [64%]). Conversely, 37% (263/707) and 36% (252/700) had no enthesitis (LEI=0) at BL among those randomized to RZB and PBO, respectively. Among enthesitis-free patients at BL (LEI=0 at BL), 84.7% on PBO and 90% on RZB remained free of enthesitis through W24; by W52, approximately 93% of patients in both groups (RZB and PBO to RZB) remained enthesitis free. A numerically higher proportion of patients with enthesitis at BL (LEI > 0 at BL) treated with RZB (52.1%) achieved an enthesitis-free state at W24 vs PBO (41.8%); similar proportions achieved an enthesitis-free state at W36 and W52 during open label treatment (Figure 1). Among patients with enthesitis at BL, a significantly greater improvement in VAS pain scores was observed in patients treated with RZB 150 mg vs PBO, as early as W4 ($P < .01$) and increased through W24 (Figure 1; $P < .001$).

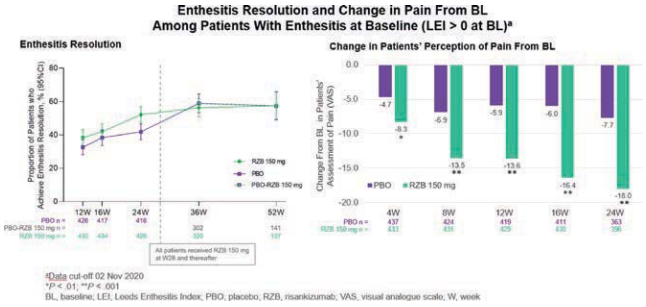

Figure 1.

Conclusion: Long-term maintenance of an enthesitis-free state (LEI = 0) was similar between the RZB 150 mg and PBO groups, with approximately 93% of patients remaining free of enthesitis at W52. For LEI > 0 patients, the RZB 150-mg group had numerically more patients whose enthesitis resolved at W24, and similar proportions were observed at W52 after the open label switch. Patients with enthesitis at BL treated with RZB 150 mg had statistically greater improvements in pain compared with patients taking PBO starting at W4 through to W24.

POS1058 BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN PSORIATIC ARTHRITIS: PREDICTORS OF TREATMENT SURVIVAL IN A REAL-LIFE SETTING

F. Ceccarelli[1], F. Natalucci[1], G. Olivieri[1], G. Galasso[1], C. Pirone[1], V. Orefice[1], C. Garufi[1], F. R. Spinelli[1], R. Scrivo[1], C. Alessandri[1], F. Conti[1]. [1]*Sapienza Università di Roma, Reumatologia, Dipartimento di Scienze Cliniche, Anestesiologiche e Cardiovascolari, Roma, Italy*

Background: Psoriatic arthritis (PsA) is a chronic, immune-mediated, inflammatory arthropathy, distinctively involving joints and enthesis. The improved understanding of PsA pathogenesis has enabled the development of biological disease-modifying anti-rheumatic drugs (bDMARDS) targeting specific cytokines and signalling pathways. The availability of these drugs deeply modified PsA history, by preventing disease progression and by improving quality of life. Nevertheless, bDMARDS are not effective in all the patients who may experience primary or secondary inefficacy or adverse events development.

Objectives: In a real-life scenario, we evaluated the bDMARDs retention rate in a large PsA cohort. In detail, we compared drug survival of the first and second biological drug and we investigated the presence of factors associated with the bDMARDs treatment withdrawal.

Methods: We longitudinally evaluated adult PsA patients (2016 CASPAR criteria) treated with at least one bDMARD during disease history. For each PsA patient, the clinical and laboratory data, including demographics, past medical history with the date of diagnosis and treatments, clinical disease phenotypes, were collected in a standardized, computerized and electronically filled form. The retention rate was estimated by using the Kaplan-Meier method. Predictors for bDMARDs withdrawal were investigated in univariate and multivariate Cox proportional hazards analysis, adjusted for relevant variables.

Results: The present analysis included 223 PsA patients [M/F 91/132; median age 57 years (IQR 17); median disease duration 120 months (IQR 132)]. Adalimumab and Etanercept were the most frequently prescribed bDMARDs (41.5% and 41.0%, respectively). The retention rate of the first prescribed bDMARD as reported in Figure 1A: in detail, we found a 12-months retention rate of 79.8%. The comparison between etanercept and adalimumab showed a similar 12-months retention rate, but significantly higher for etanercept at 24 months (82.4% versus 69.5%, p=0.0034, Figure 1B). Out of 223 enrolled PsA patients, 109 (48.9%) received only one bDMARDs, while the remaining 114 (51.1%) received at least 2 drugs. When comparing these two groups of patients, drug survival at 24 months was significantly higher in patients treated with one bDMARD in comparison with those treated with at least two drugs (67.7% versus 52.2%, p=0.03, Figure 1C). Finally, female sex and anxiety-depressive disorders were significantly associated with the treatment with at least two dDMARDs (p=0.005 and p=0.01, respectively).

Conclusion: The results of the present study demonstrated a higher retention rate in the first-line bDMARDs treatment in comparison with second-line. Female sex and anxiety-depressive disorders may negatively affect drug retention rate.

POS1059 EFFICACY OF UST IN ACTIVE PSA IS INDEPENDENT FROM CONCOMITANT MTX USE, EVEN IN PATIENTS WITH MORE SEVERE SKIN PSORIASIS: SUBGROUP ANALYSIS FROM A RANDOMIZED PLACEBO-CONTROLLED INVESTIGATOR INITIATED CLINICAL TRIAL

M. Köhm[1,2,3], T. Rossmanith[2,3], A. C. Foldenauer[2,3], H. Kellner[4], U. Kiltz[5,6], J. Rech[7], G. R. Burmester[8], D. M. Kofler[9], J. Brandt-Juergens[10], C. Jonetzko[2,3], H. Burkhardt[1,2,3], F. Behrens[1,2,3]. [1]*University Hospital Frankfurt, Rheumatology, Frankfurt, Germany;* [2]*Fraunhofer Institute for Translational Medicine & Pharmacology ITMP, Clinical Research, Frankfurt, Germany;* [3]*Fraunhofer Excellence Cluster for Immune-Mediated Diseases CIMD, Clinical Research, Frankfurt, Germany;* [4]*Praxis Prof. Dr. Kellner, Rheumatology, München, Germany;* [5]*Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany;* [6]*Ruhr-Universität Bochum, Rheumatology, Bochum, Germany;* [7]*University Hospital Erlangen, Medicine 3, Rheumatology, Erlangen, Germany;* [8]*Charité Universitätsmedizin, Rheumatology, Immunology, Berlin, Germany;* [9]*University Hospital Köln, Rheumatology, Köln, Germany;* [10]*Rheumapraxis Brandt-Jürgens, Rheumatology, Berlin, Germany*

Background: The use of bDMARDs treatments in patients with psoriatic arthritis (PsA) usually requires treatment failure or intolerance of csDMARD/MTX before initiation. The value of MTX in combination with bDMARDs is still unclear. We designed an investigator-initiated, randomized, placebo-controlled trial (IIT) in active PsA to examine if outcomes of treatment with ustekinumab (UST) in combination with MTX (either newly initiated or ongoing) were different from UST only (+Placebo; PBO). With known efficacy of MTX on skin psoriasis outcomes may differ in patients with or without significant skin involvement of their psoriatic disease.

Objectives: To compare efficacy outcomes in UST+PBO vs UST+MTX in dependency of skin involvement (Body Surface Area [BSA]) at baseline.

Methods: A total of 186 patients with active PsA (defined as TJC≥4, SJC≥4 [68/66 joint count] and DAS28≥3.2) were screened for eligibility. 173 patients were randomized to UST+MTX (new or ongoing) or UST+PBO. With this post hoc subgroup analysis outcome parameters were compared between patients with or without skin psoriasis > 3 % BSA. Demographic data and disease activity status of arthritis (joint count [TJC/SJC], DAPSA, DAS28), skin (PASI, BSA), HR-QoL (EQ5D, DLQI) and physical function (HAQ) were compared between groups.

Table 1. Outcomes at Week 24 (LOCF)

	UST+MTX		UST+PBO	
	BSA ≤3%	**BSA >3%**	**BSA ≤3%**	**BSA >3%**
	n=46	**n=40**	**n=51**	**n=23**
TJC68 change from BL	-7.83 (SD 10.3)	-9.5 (SD 10.3)	-8.9 (SD 9.5)	-7.3 (SD 7.4)
SJC66 change from BL	-6.0 (SD 5.4)	-7.1 (SD 3.5)	-6.5 (SD 6.2)	-6.4 (SD 3.8)
PASI change from BL+	-1.3 (SD 1.9)	-8.5 (SD 9.6)	-1.5 (SD 2.4)	-9.0 (SD 10.7)
DAS-28 ESR [mm/hr] change from BL	-1.6 (SD 1.1)	-1.8 (SD 1.2)	-1.7 (SD 1.4)	-1.8 (SD 1.1)
DAS-28 CRP [mg/l] change to BL	-1.5 (SD 1.2)	-1.5 (SD 1.3)	-1.6 (SD 1.2)	- 1.7 (SD 1.1)
DAPSA change from BL	-17.4 (SD 16.8)	-20.8 (SD 13.2)	-20.5 (SD 16.6)	-20.4 (SD 15.3)
HAQ change from BL	-0.1 (SD 0.4)	-0.2 (SD 0.5)	-0.3 (SD 0.3)	-0.3 (SD 0.5)
DLQI change from BL	-3.1 (SD 5.5)	-5.5 (SD 8.2)	-2.3 (SD 3.3)	-6.4 (SD 7.9)
EQ5D VAS Health State change from BL	6.7 (SD 24.7)	11.7 (SD 23.6)	8.0 (SD 24.2)	21.3 (SD 25.3)

Results: BL data were well-balanced between main treatment groups (UST+MTX, n=86; UST+PBO, n=74) including gender (42.5% vs 40.5% female) and mean values for age (49.2 vs 47.2 years), BMI (29.4 vs 28.9 kg/m2), SJC (8 vs 8), TJC (12 vs 12), DAS28-CRP (4.6 vs 4.4), DAPSA (36.7 vs 34.9) and PASI (2.8 vs 2.4. Disease activity remained well-balanced even after dividing groups according to skin involvement ((a) BSA ≤3% and (b) BSA >3%) with a trend of more severe joint involvement (SJC, TJC) in BSA >3% for UST+MTX compared to UST+PBO. At week 24, relative changes in TJC (-62% vs -62%), change in DAS28 and DAPSA were equal in all treatment groups independent from skin involvement (Table 1). Differences between the groups according to skin involvement were seen for relative changes in SJC (BSA >3%: -74.8% UST+MTX vs -84.3% UST+PBO), subject global assessment (SGA), physician global assessment (PGA), DLQI and EQ5D. Highest levels for changes were detected in the UST+PBO group with high skin involvement (BSA >3%).

Conclusion: IL12/23 inhibition with UST is an effective treatment for active PsA independent of MTX use. Data from this IIT indicate that additional MTX has no positive impact on UST efficacy for arthritis, skin, HR-QoL and physical function. This independency of UST effect from MTX can also be demonstrated in patients with active skin involvement despite known efficacy of MTX for skin psoriasis.

POS1060

CHANGES IN DISEASE ACTIVITY AND PATIENT-REPORTED OUTCOMES IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH IXEKIZUMAB IN A REAL-WORLD US COHORT

J. Birt[1], W. Tillett[2], C. Cavanaugh[3], Y. Jung[3], A. Vadhariya[1], S. Ross[4], J. Paulus[3], A. T. Sprabery[4], E. Lubrano[5]. *[1]Eli Lilly and Company, Value, Evidence, and Outcomes, Indianapolis, United States of America; [2]Royal National Hospital for Rheumatic Disease, Department of Rheumatology, Bath, United Kingdom; [3]OM1, OM1, Boston, United States of America; [4]Eli Lilly and Company, Medical Affairs, Indianapolis, United States of America; [5]Università Degli Studi del Molise, 4.Academic Rheumatology Unit, Dipartimento Di Medicina e Scienze, Campobasso, Italy*

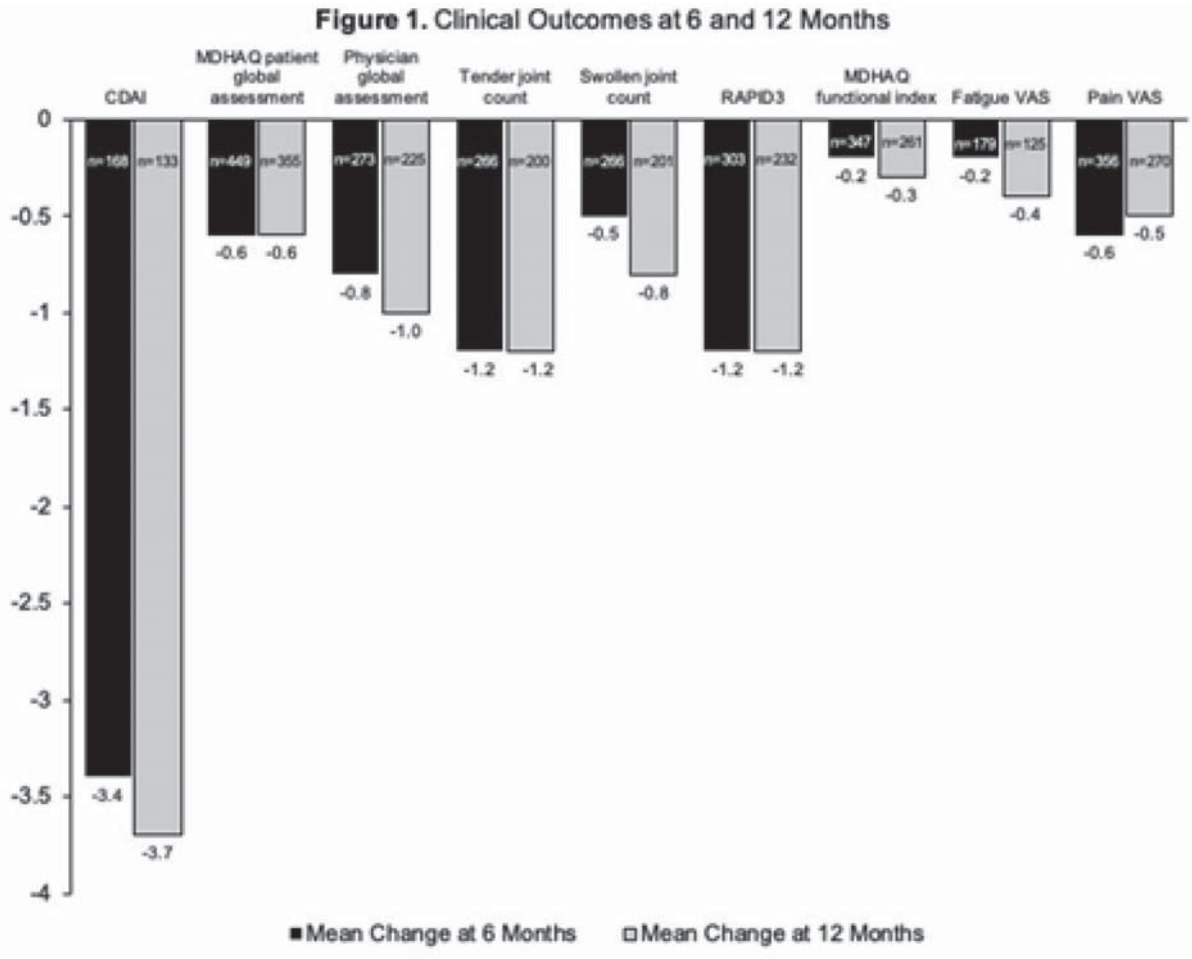
Background: Ixekizumab (IXE), an IL-17A inhibitor, has demonstrated efficacy in clinical trials[1-3] but real-world effectiveness (RWE) data are limited.[4]

Objectives: To describe changes in disease activity and patient-reported outcomes (PROs) at 6 and 12 months follow-up among psoriatic arthritis (PsA) patients initiating IXE in a routine clinical setting.

Methods: This retrospective cohort study included patients from the OM1 PsA Registry (OM1, Boston, MA), a linked electronic medical record and administrative claims dataset with over 50,000 patients. Eligible patients had ≥1 prescription for IXE (first = index), were ≥18 years old at index, had ≥1 diagnosis code for PsA in the 12 months before or on index, and had ≥12 months of baseline and ≥6 months of follow-up data as of June 2021. For patients with baseline and follow-up measures available, changes in Clinical Disease Activity Index (CDAI), PROs, and other clinical outcomes from baseline to 6 and 12 months were described. For patients on IXE monotherapy, change in CDAI score from

Table 1. Demographic and Clinical Characteristics by Therapy Status

		All Patients (N=1,812)	*Monotherapy (N=1,485)*	*Combination Therapy (N=327)*
Age (years)	Mean (s.d.)	53.7 (12.2)	53.9 (12.3)	52.9 (11.7)
	Median (Q1-Q3)	55 (46-62)	55 (46-62)	54 (45-61)
Sex	Female	1,108 (61.1%)	909 (61.2%)	199 (60.9%)
	Male	704 (38.9%)	576 (38.8%)	128 (39.1%)
Charlson Comorbidity Index	Mean (s.d.)	1.3 (1.6)	1.3 (1.6)	1.5 (1.7)
	Median (Q1-Q3)	1 (0-2)	1 (0-2)	1 (0-2)
BMI	Underweight: <18.5	10 (0.6%)	10 (0.7%)	0 (0.0%)
	Normal weight: 18.5-24.9	210 (12.2%)	172 (12.2%)	38 (12.1%)
	Overweight: 25-29.9	455 (26.5%)	379 (27.0%)	76 (24.2%)
	Obese: >= 30	1,045 (60.8%)	845 (60.1%)	200 (63.7%)
	Missing	92	79	13
Domains of PsA: Psoriasis	Yes	1,490 (82.2%)	1,222 (82.3%)	268 (82.0%)
	No	322 (17.8%)	263 (17.7%)	59 (18.0%)
Domains of PsA: Enthesitis	Yes	510 (28.1%)	409 (27.5%)	101 (30.9%)
	No	1,302 (71.9%)	1,076 (72.5%)	226 (69.1%)



baseline to 6 and 12 months was assessed using mixed effects linear models adjusted for age, sex, and baseline CDAI score.

Results: The study population included 1,812 patients with a mean age of 53.7 years (Table 1). Psoriasis was present in 82% and enthesitis in 28%. Over 60% of patients were obese, and the mean CharIson Comorbidity Index was 1.3. Most patients (84%) had prior treatment with a biologic disease-modifying antirheumatic drug (bDMARD) and 40% with a targeted synthetic DMARD (tsDMARD). The mean number of bDMARDs and tsDMARDs used during all available prior history was 2.3 and 1.1, respectively. The most common prior bDMARDs were secukinumab (n=428, 24%) and adalimumab (n=245, 14%). Of patients with a baseline CDAI score, 61% had moderate or severe disease activity. For all patients, CDAI scores improved (decreased) by an average of 3.4 and 3.7 points at 6 and 12 months, respectively, from a baseline mean of 15.4. All disease activity measures and PROs improved from baseline to 6 and 12 months (Figure 1). In patients persistent with IXE, 35.3% and 33.7% were in CDAI remission or low disease activity at 6 and 12 months after initiation, respectively. For IXE monotherapy users (82% of patients), at baseline, patients had a mean CDAI of 14.3 (n=131) and 15.1 (n=105) for the 6 and 12 month analyses, respectively. Adjusted mean changes in CDAI from baseline to 6 months (-3.6 points, $p < 0.0001$) and 12 months (-4.9 points, $p < 0.0001$) were statistically significant.

Conclusion: In this cohort of PsA patients with multiple prior b/tsDMARD failures, improvements in disease activity and PROs were observed at 6 and 12 months after initiating treatment with IXE. Improvements were observed in patients overall and in the monotherapy subgroup. More real-world research on IXE and other bDMARDs are important to understand the effect of treatment choices on clinical and PROs in both bDMARD-naive and experienced PsA patients.

POS1061

HYPOVITAMINOSIS D IN PSORIATIC ARTHRITIS PATIENTS: PREDICTIVE ROLE ON DRUG SURVIVAL OF METHOTREXATE MONOTHERAPY AND FIRST LINE OF B-DMARDS.

C. Rotondo[1], D. Cici[1], S. Stefania[1], A. Altomare[1], F. P. Cantatore[1], A. Corrado[1].
[1]*University of Foggia, Department of Medical and Surgical Sciences – Rheumatology Unit, Foggia, Italy*

Background: The immunomodulatory role of vitamin D is extensively studied enough to hypothesize a pathogenetic role in chronic arthritis and psoriasis. Few data has been published on possible interference of hypovitaminosis D on drug response in rheumatoid arthritis patients, but data in psoriatic arthritis (PsA) patients is completely lacking.

Objectives: To compare drug survival and retention rate of methotrexate (MTX) and the first line of biotechnological drugs (b-DMARDs) in PsA patients with hypovitaminosis D and those with normal level of vitamin D.
Methods: We conducted a retrospective study on 250 PsA patients (age 57,3 years ± 13,2). All patients were required to fulfill the CASPAR criteria for PsA and were tested for vitamin D levels at baseline visit. Clinical characteristics, MTX and first line of b-DMARDs treatment duration and comorbidities information were recorded for each patient. The evaluations of drug survivals were realized by Kaplan-Meier estimate, followed by log-rank (Mentel-Cox) test for the comparison between the groups of patients in study. Statistical significance was set at $p \leqslant 0.05$.
Results: Sixty-four percent of PsA patients presented hypovitaminosis D (22,2ng/ml ± 8,8). PsA patients with hypovitaminosis D and those with normal levels were comparable for age (56,8 years ± 13 vs 58,5 years ± 12), and disease activity at baseline visit (DAS 28 VES: 4 ± 0,8 vs 3,8 ± 0,8). MTX monotherapy survival was shorter in hypovitaminosis D group (90 ± 19 weeks vs 166,8 ± 28 weeks, p=0,041), with discontinuation risk hazard ratio = 1,4 (95% CI: 1,005 – 2,014; p=0,046). The drug survival of first line of b-DMARDs was significantly shorter in patients with hypovitaminosis D (246,1 ± 40 weeks vs 302,1 ± 35 weeks; p=0,048), with discontinuation risk hazard ratio = 1,5 (95% CI: 1,1-2,4; p=0,05).
Conclusion: Vitamin D seems play an important role not only in the regulation of immune system but also in the modulation on immune response induced by drugs, as MTX or b-DMARDs. The evaluation of sera levels of vitamin D at the begging of immunomodulatory therapy could have a predictive role on treatment management in PsA patients. Further studies should be useful to detect if supplementation of vitamin D could improve the performance of immunomodulatory drugs.
Disclosure of Interests: None declared

POS1062 HARNESSING THE POWER OF MACHINE LEARNING TO PREDICT REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS ON SECUKINUMAB: IMPLEMENTATION AND VALIDATION OF A CANDIDATE ALGORITHM ON 121 PATIENTS

V. Venerito[1], M. Fornaro[1], F. Cacciapaglia[1], S. Tangaro[2], G. Lopalco[1], F. Iannone[1]. *[1]University of Bari "Aldo Moro", Rheumatology Unit-Department of Emergency and Organ Transplantations, Bari, Italy; [2]National Institute of Nuclear Physics, Rheumatology Unit-Department of Emergen, Bari, Italy*

Background: Although novel therapies with biotechnological agents and small molecules may lead to the complete clearing of psoriasis in the vast majority of patients, the latter drugs only allow Psoriatic Arthritis (PsA) disease control in up to 50% of patients (1). In an increasing number of clinical scenarios, machine learning (ML) is emerging as a tool for the implementation of multi-parametric decision algorithms. ML allows to handle complex non-linear relationships between patient attributes that are hard to model with traditional statistical methods, merging them to output a forecast or a probability for a given outcome, enabling personalized medicine (2).
Objectives: We aimed to develop a ML algorithm capable of predicting the probability of remission in PsA patients on Secukinumab to support clinicians in choosing the optimal treatment strategy.
Methods: Patients with classified PsA according to CASPAR criteria undergoing Secukinumab treatment between September 2017 and September 2020 at our tertiary Centre were retrospectively observed.Either at treatment baseline and at 12-month follow up, we retrieved demographic and clinical characteristics, including Body Mass Index (BMI), disease phenotypes, Disease Activity in PsA (DAPSA), Leeds Enthesitis Index (LEI) and Ankylosing Spondylitis Disease Activity Score (ASDAS, on C-Reactive Protein). After a ML variable selection method, based on an eXtreme Gradient Boosting (XGBoost) wrapper, an attribute core set with the least number of predictors was used for implementing n.3 ML algorithms, namely Logistic Regression (LR), Decision Trees (DT) and XGBoost. Each algorithm was trained and validated with 10-fold cross-validation. The performance of each algorithm in both phases was assessed in terms of of accuracy and area under receiver operating characteristic curve (AUROC).
Results: The dataset consisted of n.121 PsA patients (62/121 female, 51.2%), with mean age (±SD) 52.9±10.1 years and mean disease duration of 5.9 ±10.4 years. Twenty-five of them (20.7%) had axial involvement whereas 88/121 (72.7%) had polyarticular involvement. Psoriasis was present in 84/121 patients (69.4%). At baseline, mean DAPSA was 14.9 ± 9.2, mean HAQ-DI 1.1 ± 0.7, mean LEI 0.6 ± 1, mean ASDAS 2.5 ± 0.8, mean PASI 2 ± 2.9, mean BMI 28.4 ± 4.9 . Secukinumab at 300 mg dose was administered to 79/121 patients (65.3%). At 12 months DAPSA remission was achieved by 24/121 patients (19.8%). Accuracy of LR, DT and XGBoost was of 0.70 ± 0.11, 0.81 ± 0.07 and 0.89 ± 0.05, respectively. Consistently AUROC (Figure 1 Panels ABC) were 0.63 ± 0.2, 0.79 ± 0.2 and 0.93 ± 0.1, respectively. A sample decision tree explaining XGBoost algorithm function has been provided (Figure 1 Panel D). LEI and DAPSA at baseline were shown as the most important attributes for such algorithm (Figure 1 Panel E).

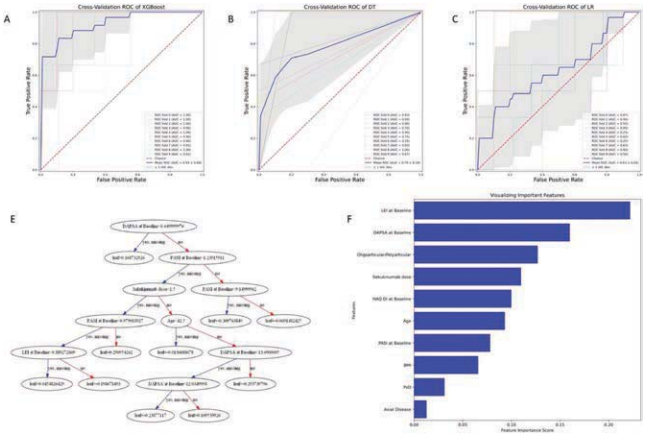

Figure 1.

Conclusion: ML can support Rheumatologists in profiling those patients more likely to respond to Secukinumab.

Psoriatic arthritis - clinical aspects (other than treatment)

POS1063 STAT PHOSPHORYLATION AS A MARKER FOR DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS: AN EXPLORATIVE ANALYSIS

B. Dreo[1], D. R. Pietsch[1], R. Husic[1], A. Lackner[1], J. Fessler[2], J. Rupp[1], A. S. Muralikrishnan[1], J. Thiel[1], M. Stradner[1], P. Bosch[1]. *[1]Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria; [2]Otto Loewi Research Center for Vascular Biology, Immunology and Inflammation, Medical University of Graz, Division of Immunology and Pathophysiology, Graz, Austria*

Background: Numerous cytokines that influence disease activity in psoriatic arthritis (PsA) are modulators of the Janus Kinases/Signal Transducers and Activators of Transcription (JAK/STAT) pathway. The JAK1/STAT1/STAT3/STAT5 network can drive the expansion of Th17 and regulatory T cells via proinflammatory cytokines in PsA joints,[1], [2] while hyperphosphorylation of STAT3 in immune cells has previously been shown to promote PsA pathogenesis through the Interleukin (IL)-23/IL-17/IL-22 axis.[3] Therefore, the phosphorylation status of STAT molecules in leucocytes of PsA patients may indicate active disease and could potentially guide treatment with JAK inhibitors.
Objectives: To analyse phosphorylated STAT (pSTAT) levels of circulating leucocyte subsets in PsA patients with active and inactive disease
Methods: Whole blood was drawn on consecutive PsA patients fulfilling the CASPAR criteria[4] to perform flow cytometry analysis using the BD FACS-Lyric platform. Disease activity was assessed using the Disease activity for psoriasis arthritis (DAPSA) score.[5] All steps from storage of drawn blood to cell fixation were performed at 4°C to prevent auto-activation of leucocytes. The geometric mean fluorescence intensities (gMFI) of pSTATs in granulocytes, monocytes, B cells and CD4+/- naïve/memory T cells were compared between patients with moderate to high (MoDA/HDA) and remission to low disease activity (REM/LDA). Correlation analysis between gMFIs and DAPSA scores were performed.
Results: Forty-two patients (female ratio: 0.48) with established PsA (median ± standard deviation, age: 56 ± 12.54 years, disease duration: 8.50 ± 7.10 years) were included in this study. Twenty-one percent of patients were in MoDA/HDA, while the remaining 79% were in REM/LDA. Patients in MoDA/HDA showed significantly higher pSTAT3 levels in CD4+ naïve (gMFI median ± standard deviation: 284.5 ± 79.9 vs 238 ± 92.9, p = 0.011), CD4- naïve (297 ± 107.5 vs 238 ± 98.4, p = 0.04), CD4+ memory (227 ± 62.9 vs 190.5 ± 72.2, p = 0.009) and CD4- memory T cells (209 ± 66.8 vs 167.0 ± 64.9, p = 0.036). On the other hand, PsA patients in remission or low disease activity displayed higher pSTAT1 levels in granulocytes (2509 ± 1887 vs 1330.5 ± 784.1, p = 0.040) and monocytes (255 ± 230 vs 144 ± 62.5, p = 0.049). Positive correlations were found between DAPSA scores and pSTAT3 in CD4+ naïve and memory T cells (Spearman's correlation coefficient rho (ρ) = 0.5, p = 0.0012 and ρ = 0.47, p = 0.0025 resp.) whereas pSTAT1 in granulocytes and monocytes were negatively correlated with the DAPSA scores (ρ = -0.45, p = 0.0074 and ρ = -0.34, p = 0.05).
Conclusion: Differential phosphorylation of STAT3 and STAT1 molecules in circulating leucocyte subsets indicates PsA disease activity. Further studies to examine the value of STAT phosphorylation patterns guiding JAK inhibitor therapy are underway.

POS1064 CLINICAL AND ECONOMIC BURDEN OF PATIENTS WITH PSORIATIC ARTHRITIS WITH AND WITHOUT AXIAL INVOLVEMENT

M. Bergman[1], J. Patel[2], C. Saffore[2], E. Mcdearmon-Blondell[2], I. Topuria[3], C. Cavanaugh[3]. *[1]Drexel University College of Medicine, Rheumatology, Philadelphia, United States of America; [2]AbbVie Inc., Immunology, North Chicago, United States of America; [3]OM1, Inc., Research, Boston, United States of America*

Background: Axial involvement affects about 12% to 50% of patients (pts) with psoriatic arthritis (PsA),[1,2] and these pts report worse pain and function than pts without axial involvement.[3] Limited evidence exists quantifying the clinical and economic impact of axial involvement and pain in pts with PsA.
Objectives: To examine the clinical and economic burden of pts with PsA with and without axial involvement and assess the relationship between pain and frequency/costs of healthcare resource utilization (HCRU).
Methods: This cross-sectional study was conducted using de-identified linked electronic medical record and administrative claims data from the OM1 PsA Registry, a subset of the OM1 Real-World Data Cloud (OM1, Inc, Boston, MA, US). Adults aged ≥18 years with PsA (ICD-10 codes: L40.5x except for L40.53) were divided into two cohorts based on the presence or absence of the diagnosis code for axial involvement (ICD-10: L40.53) during 2019. Demographic and clinical characteristics between pts with and without axial involvement were compared with t-tests or Chi-square tests. Poisson regression models were used to assess the association of pain with HCRU. Mean costs per HCRU encounter (inpatient and emergency department [ED] visits) in 2019 were obtained from Optum's de-identified Clinformatics Data Mart Database (2007-2019) and multiplied by the mean annual rate of HCRU encounters to generate per patient per year (PPPY) costs.
Results: Of 11,531 pts with PsA, 1,118 (10%) were diagnosed as having axial involvement. The two cohorts were similar in age, Charlson comorbidity score, and biologic disease-modifying antirheumatic drug (DMARD) use (Table 1). More pts with vs without axial involvement were commercially insured, had higher pain, and used opioids. Higher mean annual rates of inpatient (9 vs 5 per 100 pts) and ED (19 vs 14 per 100 pts) visits were seen in pts with vs without axial involvement, respectively, which translated to higher mean annual inpatient ($1,899 vs $1,055) and ED ($222 vs $164) visit costs PPPY (Figure 1). A 1-point higher pain score was associated with a higher likelihood of inpatient (52% vs 11%) and ED (20% vs 10%) visits (Table 1) and additional mean annual inpatient ($987 vs $116) and ED ($44 vs $16) visit costs PPPY (Figure 1) in pts with and without axial involvement, respectively.

Table 1. Demographics, treatment utilization, and healthcare resource utilization

Mean (SD), unless otherwise specified	PsA pts without axial involvement n=10,413	PsA pts with axial involvement n=1,118	p-values
Age, years	56.7 (13.0)	56.8 (14.0)	0.8948
Female, n (%)	6,401 (61%)	653 (58%)	0.0494
Insurance, n (%)			<0.0001
Commercial	3,285 (62%)	414 (73%)	
Medicaid	110 (2%)	18 (3%)	
Medicare	1,618 (30%)	103 (18%)	
Charlson comorbidity score	0.4 (1.0)	0.4 (1.0)	0.9900
Pain, VAS (0–10)	4.2 (2.6)[a]	4.5 (2.6)[b]	0.0422
bDMARD use, n (%)	6,871 (66%)	753 (67%)	0.3762
tsDMARD use, n (%)	1,117 (11%)	91 (8%)	0.0072
Opioid use, n (%)	1,722 (17%)	224 (20%)	0.0034
Inpatient visits/100 pts	5 (32)	9 (35)	0.0021
ED visits/100 pts	14 (63)	19 (72)	0.0168
Association of pain and HCRU, IRR (95% CI)[c]			
Inpatient visits	1.11 (1.08–1.15)*	1.52 (1.13–2.03)**	
ED visits	1.10 (1.07–1.13)*	1.20 (1.05–1.38)**	

bDMARD, biologic DMARD; CI, confidence interval; IRR, incidence rate ratio; MTX, methotrexate; NSAIDs, non-steroidal anti-inflammatory drugs; SD, standard deviation; tsDMARD, targeted synthetic DMARD; VAS, visual analog scale. *p<0.0001 and **p<0.01 for association between 1-point increase in pain and HCRU. [a]n=9,981 [b]n=320 [c]Based on Poisson regression model adjusted for age, sex, race, insurance type, Charlson comorbidity score, and PsA treatments (b/tsDMARDs, MTX, and NSAIDs).

Conclusion: Axial involvement in PsA was associated with an increased clinical and economic burden. Higher pain was associated with higher HCRU and costs in pts with vs without axial involvement.

POS1065

IMPACT OF HYPERURICEMIA ON CLINICAL PHENOTYPE, COMORBIDITIES, AND RESPONSE TO SECUKINUMAB IN PSORIATIC ARTHRITIS: POST HOC ANALYSIS OF FUTURE AND MAXIMISE STUDIES

R. Felten[1,2], L. Widawski[3], L. Spielmann[3], C. Gaillez[4], W. Bao[5], J. E. Gottenberg[1,2], P. M. Duret[3], L. Messer[3,6]. [1]*Strasbourg University Hospitals, Department of Rheumatology, National Reference Center for Rare East-South-West Autoimmune Systemic Diseases (RESO), Strasbourg, France;* [2]*Institute of Molecular and Cellular Biology (IBMC), Laboratory of Immunopathology and Therapeutic Chemistry, Strasbourg, France;* [3]*Colmar Civilian Hospitals, Rheumatology Department, Colmar, France;* [4]*Novartis Pharma AG, Immunology, Hepatology and Dermatology, Basel, Switzerland;* [5]*Novartis Pharmaceutical Corporation, Immunology, Hepatology and Dermatology, East-Hanover, United States of America;* [6]*Dynamiques Européennes, UMR 7367, Strasbourg, France*

Background: Hyperuricemia (HU) is a metabolic abnormality associated with psoriasis (PsO) and psoriatic arthritis (PsA)[1]. The prevalence of HU is 2–13% in general population, 19–20% in PsO patients (pts), and 27–32% in PsA pts[1,2]. Pts with PsO/PsA are at significantly increased risk of HU and development of gout[1]. The pathogenic role of chronic HU in the development and maintenance of PsA is based on epidemiological, clinical, and fundamental arguments and hence does not appear fortuitous. These processes can influence each other[3]. Moreover, PsA with HU has been shown to be more peripheral, destructive, and challenging to treat[4].
Objectives: To evaluate the impact of HU on PsA in terms of clinical presentation, severity, comorbidities, and response to secukinumab (SEC) over 1-year.
Methods: This *post hoc* analysis included pooled data from PsA pts enrolled in the FUTURE 2–5 and MAXIMISE phase 3 trials. Pts were stratified into 2 groups based on baseline (BL) serum uric acid (SUA) level (HU: ≥360 µmol/L; without HU: <360 µmol/L and no history of gout and/or uric acid lowering therapies [ULT]). Demographic and disease characteristics, PsA and therapeutic history, and comorbidities data, were collected at BL. Evaluations included ACR20/50/70 responses, Psoriasis Area and Severity Index (PASI) 90 response, resolution of enthesitis and dactylitis, Health Assessment Questionnaire Disability Index (HAQ-DI), and mean change in SUA level, up to Week 52. All analyses were performed at a descriptive level and data presented as observed.

Results: Overall, 2504 PsA pts were included in the analysis, of which 822 (32.8%) had HU (62 [2.5%] with gout; 49 [2.0%] treated with ULT). At BL, pts with HU were mostly male (76.0% vs 34.2%) and had a higher body mass index (30.9 vs 28.3 kg/m^2) with more comorbidities, such as hypertension (43.8% vs 31.3%), compared to pts without HU. A higher proportion of pts with HU had dactylitis (34.5% vs 25.9%), and PsO (48.3% vs 36.3%) with a greater mean PASI score (13.6 vs 10.2), compared to pts without HU (Table 1). The proportion of pts achieving ACR50, resolution of enthesitis/dactylitis, and mean change in HAQ-DI score were comparable up to Week 52 irrespective of BL HU status. The PASI90 response rate was higher in pts without HU with SEC 150 mg (with and without load) and similar in SEC 300 mg group irrespective of BL HU status (Figure 1).

Table 1. Demographics and baseline characteristics

Parameters, mean ± SD unless specified	With hyperuricemia (N=822)	Without hyperuricemia (N=1682)
Age (Years)	48.5 ± 12.41	48.3 ± 12.19
Gender (Male), n (%)	625 (76.0)	576 (34.2)
Weight (kg)	92.71 ± 18.62	79.59 ± 17.55
BMI (kg/m^2)	30.90 ± 5.86	28.33 ± 5.91
History of hypertension, n (%)	360 (43.8)	526 (31.3)
History of diabetes mellitus, n (%)	85 (10.3)	144 (8.6)
TJC	20.6 ± 15.52	21.3 ± 16.25
SJC	10.9 ± 9.31	10.8 ± 9.13
Enthesitis, n (%)	412 (50.1)	852 (50.7)
Dactylitis, n (%)	284 (34.5)	436 (25.9)
Evidence of current psoriasis; n (%)	397 (48.3)	611 (36.3)
Mean PASI score*	13.61 ± 11.03	10.16 ± 9.13
TNFi naïve, n (%)	477 (58.0)	938 (55.8)
MTX use at randomization, n (%)	321 (39.1)	685 (40.7)
Serum uric acid (µmol/L)	420.7 ± 57.11	274.9 ± 51.98
CRP (mg/L)	11.6 ± 18.66	10.7 ± 23.36

*not collected in MAXMISE BMI, body mass index; CRP, C-reactive protein; MTX, methotrexate; SJC, swollen joint count; TJC, tender joint count; TNFi, tumor necrosis factor inhibitor

Conclusion: In this pooled analysis of SEC PsA studies, pts with HU reported a higher prevalence of hypertension, with more clinical dactylitis, and more PsO, with higher PASI score compared to pts without HU. Efficacy across all musculoskeletal manifestations was similar with SEC 150 and 300 mg; while PASI90 response rate was slightly better in patients without HU with SEC 150 mg, and similar with SEC 300 mg irrespective of HU status, at 1-year.

DEVELOPMENT OF PHYSICAL AND MENTAL COMPONENT SUMMARY SCORES FROM PROMIS-29 INSTRUMENT IN PATIENTS WITH PSORIATIC ARTHRITIS

L. Coates[1], A. M. Orbai[2], A. Deodhar[3], A. Kollmeier[4], M. Shawi[5], Y. H. Liu[6], Y. Liu[6], C. Han[6]. [1]*University of Oxford, Nuffield Department of Orthopaedics,*

Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]Johns Hopkins University School of Medicine, Psoriatic Arthritis Program, Baltimore, United States of America; [3]Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America; [4]Janssen Research & Development, LLC, Immunology, San Diego, United States of America; [5]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; [6]Janssen Research & Development, LLC, Immunology, Spring House, United States of America

Background: Patients (pts) with psoriatic arthritis (PsA) experience pain, fatigue, anxiety, depression, sleep disturbance, and impaired physical function that can negatively affect health-related quality of life (HRQoL).[1] As the Patient-Reported Outcomes Measurement Information System-29 (PROMIS-29) Profile is a generic instrument assessing 7 health outcome domains, composite scores to summarize these domains into generalized concepts of mental and physical health using physical component summary (PCS) and mental component summary (MCS) scores[2,3] will be useful to evaluate overall HRQoL in pts with PsA.
Objectives: Calculate and validate PCS and MCS scores, using PROMIS-29 data from the DISCOVER-1 Phase 3 study, and compare the scores for guselkumab (GUS) vs placebo (PBO).
Methods: The DISCOVER-1 study evaluated 381 pts with active PsA (≥3 swollen & ≥3 tender joints; C-reactive protein ≥0.3 mg/dL; 31% with prior tumor necrosis factor inhibitor exposure) and inadequate response to standard therapies.[4] The PROMIS-29 Profile contains 4 items for each of 7 domains (physical function, anxiety, depression, fatigue, sleep disturbance, social participation, pain interference; 28 items scored on 5-point Likert scale) and 1 pain intensity item (0-10 visual analog scale). Using standardized scoring coefficients,[3] PROMIS-29 PCS/MCS at baseline and Week 24 were calculated based on the 7 domains and pain intensity item. The validity of scores was assessed by Spearman correlation between PROMIS-29 PCS/MCS and 36-item Short-Form (SF-36) PCS/MCS, Health Assessment Questionnaire-Disability Index (HAQ-DI), and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scores. To evaluate the ability of derived PROMIS-29 PCS/MCS scores to distinguish between treatments, responder analyses (employing an improvement of ≥1/2 standard deviation [SD] of baseline scores) by treatment group (GUS 100 mg Q4W, GUS 100 mg Q8W, PBO) were conducted and compared with SF-36 PCS/MCS scores.
Results: As construct validity analysis, PROMIS-29 PCS/MCS strongly/very strongly correlated with SF-36 PCS/MCS scores at baseline and Week 24 (coefficients 0.66-0.86; Table 1). PROMIS-29 and SF-36 PCS scores showed strong/very strong correlations with HAQ-DI scores, a key component of physical health (coefficients 0.66-0.83), while PROMIS-29 MCS and SF-36 MCS scores showed strong/very strong correlations with FACIT-F scores, a key component of mental health (coefficients 0.63-0.91). The proportions of pts achieving improved PROMIS-29 PCS/MCS scores (≥1/2 SD at baseline) were similar to a comparable degree of improvement in SF-36 PCS/MCS scores (≥1/2 SD at baseline). For both PROMIS-29 PCS/MCS and SF-36 PCS/MCS scores, significantly higher proportions of GUS Q4W/Q8W- vs PBO-treated pts achieved these response thresholds (all p<0.05; Figure 1) with the deltas between both GUS groups vs PBO for PROMIS-29 PCS/MCS responses numerically greater than for SF-36 PCS/MCS responses.

Table 1. Mean (SD) PCS and MCS Scores: Construct Validity

	Instruments Assessing Physical Aspects of HRQoL		Instruments Assessing Mental Aspects of HRQoL	
	SF-36 PCS	**PROMIS-29 PCS**	**SF-36 MCS**	**PROMIS-29 MCS**
Baseline, N	381	381	381	381
Mean (SD)	34.6 (8.2)	39.4 (7.2)	47.4 (10.2)	45.3 (7.7)
Median	34.4	38.2	47.8	45.1
Spearman's correlation PROMIS-29 vs SF-36	0.76		0.66	
Week 24, N	380	381	380	381
Mean (SD)	39.6 (9.3)	43.3 (8.3)	50.3 (9.7)	49.3 (8.5)
Median	39.3	42.2	52.3	50.0
Spearman's correlation PROMIS-29 vs SF-36	0.86		0.71	

Conclusion: PROMIS-29 PCS/MCS scores calculated in DISCOVER-1 showed evidence of validity as summary scores with the ability to efficiently evaluate pt-reported HRQoL outcome in PsA. PROMIS-29 PCS/MCS scores, similar to the commonly employed and validated SF-36 PCS/MCS scores, may reliably be used to assess physical and mental health in pts with PsA.

Background: Despite effective treatments, a minority of psoriatic arthritis (PsA) patients (pts) realize sustained minimal disease activity (MDA).[1] Pt-driven domains of MDA are less frequently achieved, potentially arising from comorbid conditions.[1]
Objectives: Identify domains contributing to and factors influencing MDA achievement in the 2-year Phase 3 DISCOVER-2 trial.
Methods: Randomized and treated adults (N=739) had active PsA, were biologic/JAK inhibitor-naive, and had swollen and tender joint counts (SJC/TJC) each ≥5 and C-reactive protein ≥0.6 mg/dL. Pts with medical history of fibromyalgia (FM) were not excluded. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then every 8 weeks (Q8W); or placebo (PBO); PBO pts crossed over to GUS 100 mg Q4W at W24. MDA requires fulfillment of ≥5/7 criteria: TJC ≤1, SJC ≤1, Psoriasis Area and Severity Index (PASI) score ≤1, Pt Pain score ≤15, Pt global disease activity (PtGA) score ≤20, Health Assessment Questionnaire – Disability Index (HAQ-DI) score ≤0.5, and ≤1 tender entheses. A longitudinal trajectory of achieving each MDA

criterion through W100 was derived (nonresponder imputation [NRI]). Time to achieve was estimated via Kaplan-Meier survival curve for scores deriving from native scales and those normalized to a 0-66 scale (corresponding to SJC). Multivariate regression models for time to achievement (cox proportional hazard) and achievement (logistic regression) of MDA at W100 identified predictors of response.

Results: Among 492 GUS pts, continuous improvement across all MDA domains was shown through proportions of pts achieving criteria at W24 & W100 (NRI): SJC (45% & 65%), TJC (16% & 34%), PASI (71% & 72%), Pt Pain (23% & 37%), PtGA (29% & 45%), HAQ-DI (34% & 44%), entheseal points (75% & 80%). Times to achieve minimal SJC, PASI, and enthesitis with GUS were significantly faster than for PtGA, Pt Pain, TJC, and HAQ-DI for native-scale scores; when normalized, PtGA, Pt Pain, and HAQ-DI were achieved less often (Figure 1). Higher baseline (BL) Pt Pain score and lower BL Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score (worse fatigue) were significant predictors of longer time; lower BMI was associated with shorter time to achieve Pt Pain ≤15. Results for achieving Pt Pain ≤15 at W100 were similar. Worse baseline fatigue and PtGA were significant predictors of longer time to PtGA ≤20; worse fatigue also predicted non-achievement of PtGA ≤20 at W100. For time to achieve HAQ-DI ≤0.5, significant BL negative predictors were higher age and BL HAQ-DI score, which were also significant predictors of HAQ-DI ≤0.5 non-achievement at W100. Although seen in only a small number of pts, a significant impact of FM history and suicidal ideation/behavior on Pt Pain ≤15 and HAQ-DI ≤0.5, respectively, was observed (Table 1).

Table 1. Predictors of Time to Achievement and Achievement of Recalcitrant MDA Domains at Week 100 in GUS-randomized Pts (N=492)

Time to achievement	Independent BL Variables	Pt Pain ≤15	PtGA ≤20	HAQ-DI ≤0.5

§Higher score indicates less fatigue
‖Wald CL

Conclusion: GUS provided continuous improvement in each MDA domain through W100. BL domain score, as well as age, fatigue, and BMI, were significant determinants of MDA achievement in recalcitrant pt-driven domains (Pt Pain, PtGA, HAQ-DI). The impact of FM and mental health status merits further evaluation.

POS1068 DISCOVERY OF ARTHRITIS IN PSORIATIC PATIENTS FOR EARLY RHEUMATOLOGICAL REFERRAL (DAPPER): DEVELOPMENT OF A SCREENING TOOL FOR ACTIVE PSORIATIC ARTHRITIS IN PSORIASIS PATIENTS

T. Van Hal[1], M. Mulder[1], M. Wenink[1], J. Van den Reek[2], E. M. G. J. De Jong[2]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [2]Radboud University Medical Center, Dermatology, Nijmegen, Netherlands*

Background: One in three patients with psoriasis (Pso) will develop psoriatic arthritis (PsA). Active PsA can lead to disability and joint damage. Current screening methods are targeted at finding all PsA patients in a Pso population. However, PsA patients with inactive disease are unlikely to benefit from rheumatological referral.

Objectives: To develop a screening tool for dermatologists to identify patients with a high risk for active PsA in their Pso population, who would benefit from rheumatological referral.

Methods: This observational study consisted of Pso patients, stratified 1:1:1 for current therapy (topical, conventional systemic, biologic). Patients were screened by a rheumatologist for PsA, adjacent to a regular scheduled dermatologist visit. Active PsA was defined as a diagnosis of PsA, with at least 1 inflamed joint or entheses, or evidence of active spondyloarthritis. Inactive PsA was defined as a diagnosis of PsA, with no active (spondylo)arthritis at moment of screening. Univariable logistic regression was used to determine variables indicative of the presence of active PsA versus Pso only. Parameters with a P < 0.1 were entered into a multivariable model. A P-value of < 0.05 was considered significant. Sensitivity, specificity, positive and negative likelihood of the model were calculated using a 2x2-grid.

Results: The DAPPER cohort consisted of 304 patients: 225 (74%) Pso only, 48 (16%) Pso and inactive PsA, 30 (10%) Pso and active PsA. One patient could not be classified. Mean age was 54 ± 16.1 years (Pso 53 ± 16.6; inactive PsA 55 ± 15.7; active PsA 52 ± 13.5). Thirty six percent of patients were female (Pso 30/225 – 36%; inactive PsA 19/48 – 40%, active PsA 10/30 – 33%). Univariable logistic regression showed significant differences between Pso only and Pso with active PsA for: treatment history with methotrexate (OR 3.03; 95% CI 1.12, 8.23), treatment history with biologics (OR 4.96, 95% CI 2.17, 11.37), current use of biologics (OR 3.37; 95% CI 1.55, 7.33), patient-reported history of nail Pso (OR 3.01; 95% CI 1.28, 7.04), patient-reported history of swollen joints (OR 7.95; 95% CI 3.12, 20.28), patient-reported history of swollen digits (OR 4.82, 95% CI 2.19, 10.62), previous diagnosis of arthritis by physician (OR 15.09; 95% CI 6.32, 36.03), current joint pain (OR 5.81; 95% CI 1.35, 25.098); current back pain (OR 2.74; 1.23, 6.12); prolonged morning stiffness (OR 4.43; 95% CI 1.90, 10.34), and a higher VAS joint pain (OR 1.02; 95% CI 1.00, 1.03). Two backward selection models were made: model 1 using 4 variables with the highest significance, model 2 using 4 variables with the highest effect size. Both methods resulted in 2 predictors: patient-reported history of swollen joints (OR 3.95; 95% CI 1.43, 10.95), and previous diagnosis of arthritis by physician (OR 9.53; 95% CI 3.80, 28.88). A forward selection model using all parameters with a P-value <0.1 resulted in a model with 3 variables: age at start Pso (OR 0.96; 95% CI 0.93-0.99), patient-reported history of swollen joints (OR 3.68; 95% CI 1.30, 10.12), and previous diagnosis of arthritis by physician (OR 11.22; 95% CI 4.21, 29.92). Based on these models, we developed a screening tool using two questions: 1. Did you ever have a swollen joint? 2. Did a doctor ever tell you that you had arthritis? A positive answer to either question would indicate a positive test. This screening method results in a sensitivity for active PsA of 84%, a specificity of 52%, with a positive likelihood ratio of 1.74 and a negative likelihood ratio of 0.31.

Conclusion: This dermatology-based Pso cohort showed that ten percent of Pso patients had active PsA. We showed that the best predictors for the presence of active PsA were a patient-reported history of swollen joints, and a previous diagnosis of arthritis by physician. With these predictors, we could detect 84% of patients with active PsA.

	Pso + not-active PsA	Active PsA	Total
Negative Test	141	5	146
Positive Test	131	26	157
Total	272	31	303

POS1069

COVERAGE OF THE SWEDISH RHEUMATOLOGY QUALITY REGISTER: TO WHAT DEGREE ARE B/TSDMARD TREATMENTS FOR PSORIATIC ARTHRITIS RECORDED?

D. DI Giuseppe[1], U. Lindström[2], J. K. Wallman[3], L. Ljung[1,4], J. Askling[1]. *[1]Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; [2]Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; [3]Lund University, Skåne University Hospital, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; [4]Umeå University, Department of Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden*

Background: In a national context, the Swedish Rheumatology Quality register (SRQ) is a major source of information on clinical data for patients treated with biological and targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) for rheumatic diseases. Data from SRQ are fundamental for research on drug effectiveness and safety.
Objectives: To understand to what degree patients with psoriatic arthritis (PsA) and their dispensed b/tsDMARD treatments are recorded in the SRQ.
Methods: We identified all dispensed oral or subcutaneously administered b/tsDMARDs, approved for use in PsA, from the Swedish Prescribed Drug register (PDR, with 100% coverage) in 2018-2019. We required the patients who received the dispensation to have at least one ICD code for PsA (L405, M070, M071, M072, M073) as main diagnosis from a visit to a rheumatology or internal medicine (IM) unit in the National Patient Register (NPR) before dispensation, but no main diagnosis of rheumatoid arthritis (ICD code: M05, M06 (excluding M06.1 and M06.4), M12.3). Furthermore, to limit the assessment to patients with contemporary contact with the specialized rheumatology care, we also required at least one visit with a PsA main diagnosis from rheumatology/IM during 2017-2019. We then checked if the patients and their treatments were registered in SRQ. In a sensitivity analysis, we excluded patients with a visit in dermatology within 6 weeks prior to the first prescription of each b/tsDMARD, in order to exclude patients being prescribed the drug for cutaneous psoriasis.
Results: In 2018-2019, a total of 7922 unique b/tsDMARD prescriptions had been dispensed to 6311 patients with PsA, having contemporary contact with the specialized rheumatology care. Of them, 5687 patients were registered in SRQ (90.1%), of which 94.4% with a PsA diagnosis and 95.5% with at least one registration of a b/tsDMARD. The coverage of the single drugs in SRQ, as compared to dispensations in PDR, ranged between 53.5% to 93.3% (69.3% to 95.8% considering only patients also in SRQ), with the tumor necrosis factor inhibitors (TNFi) having the best coverage (79.4-93.3%) (Table 1). In a sensitivity analysis, among the 5290 patients without a main diagnosis of psoriasis before start of treatment, 4919 (93%) were registered in SRQ, of which 94% with a PsA diagnosis and 96% with at least one registration of a b/tsDMARD.

Table 1. coverage of the single b/tsDMARD approved for use in PsA patients in the SRQ as compared to the prescribed drug register, 2018-2019

ATC	Drug*	Total patients in PDR	Patients with the same drug in SRQ	Percentage	Percentage only considering patients included in SRQ
L04AB01	Etanercept	2753	2348	85.3%	92.5%
L04AB04	Adalimumab	2436	1933	79.4%	88.8%
L04AB05	Certolizumab pegol	243	213	87.7%	89.9%
L04AB06	Golimumab	418	390	93.3%	95.8%
L04AA24	Abatacept	94	73	77.7%	83.9%
L04AA32	Apremilast	547	294	53.7%	69.3%
L04AC10	Secukinumab	833	656	78.8%	84.8%
L04AC13	Ixekizumab	118	71	60.2%	74%
L04AC05	Ustekinumab	219	138	63%	76.2%
L04AA29	Tofacitinib	261	194	74.3%	77%

* In Sweden intravenously administered drugs are not prescribed and therefore not included in the PDR. Also, some hospitals administer ustekinumab in hospital, due to its high cost. However, all b/tsDMARDs, irrespectively of administration route, can be registered in SRQ.

Conclusion: The coverage of b/tsDMARD-treated PsA patients in SRQ as compared to the PDR in Sweden is ranging between 90 and 93%, and SRQ is performing well in the registration of the single drugs, especially for TNFi. These results suggest that research studies based on data from the SRQ are representative of the Swedish b/tsDMARD-treated PsA population.

BASELINE DETERMINANTS OF PAIN RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS RECEIVING GUSELKUMAB

P. Nash[1], C. T. Ritchlin[2], P. Rahman[3], M. Shawi[4], E. Rampakakis[5,6], Y. Lee[7], A. Kollmeier[8], X. L. Xu[8], J. Sherlock[9,10], D. Cua[9], S. Khattri[11], E. Soriano[12], D. Mcgonagle[13]. *[1]Griffith University and University of Queensland, Rheumatology Research Unit, Maroochydore, Australia; [2]University of Rochester Medical Center, Department of Medicine - Allergy/Immunology and Rheumatology, Rochester, United States of America; [3]Memorial University of Newfoundland, Craig L Dobbin Genetics Research Centre, Discipline of Medicine, Division of Rheumatology, St. John's, Canada; [4]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; [5]McGill University, Department of Pediatrics, Montreal, Canada; [6]JSS Medical Research, Inc, Scientific Affairs, Montreal, Canada; [7]Janssen Asia Pacific, Immunology Medical Affairs, Seoul, Korea, Rep. of (South Korea); [8]Janssen Research & Development, LLC, Immunology, San Diego, United States of America; [9]Janssen Research & Development, LLC, Immunology, Spring House, United States of America; [10]University of Oxford, Immunology, Oxford, United Kingdom; [11]Icahn School of Medicine at Mount Sinai, Dermatology, New York, United States of America; [12]Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; [13]University of Leeds, Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Pain in patients (pts) with psoriatic arthritis (PsA) has multifaceted origins; sustained improvement is difficult to achieve.[1] Guselkumab (GUS), a fully human monoclonal antibody that selectively inhibits IL-23, is effective in treating multiple domains of PsA including joint, skin, and entheseal symptoms, and also elicits long-lasting improvements in pt-reported pain in the DISCOVER-1&2 trials of pts with active PsA.[2]
Objectives: These post hoc analyses were conducted to identify determinants of changes in pt-reported pain in PsA pts using pooled data through 1 year of DISCOVER-1&2.
Methods: Enrolled adult pts had active PsA despite standard therapies. DISCOVER-1 pts had ≥3 swollen and ≥3 tender joints and C-reactive protein (CRP) ≥0.3 mg/dL; DISCOVER-2 pts had ≥5 swollen and ≥5 tender joints and CRP ≥0.6 mg/dL. 31% of DISCOVER-1 pts received 1-2 prior tumor necrosis factor inhibitors; DISCOVER-2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (wks) (Q4W); GUS 100 mg at W0, W4, then every

8 wks (Q8W); or placebo (PBO); PBO pts crossed over to GUS 100 mg Q4W at W24. Determinants with a statistically important effect ($p<0.15$) on pain (0-100 mm Visual Analogue Scale) in univariate Repeated Measures Generalized Linear Mixed Effects Models were included in a multivariate model employing backward stepwise selection ($P_{out}=0.1$) to identify independent determinants of pain improvement over 24 wks; the model was then tested separately in pts treated with PBO (through W24) and with GUS (through W24 and through W52).
Results: GUS was associated with significantly greater improvement in pain compared to PBO as early as 2 wks post-treatment; there was a significant interaction between treatment group and time, with effect of GUS on pain continuously enhanced through W24. Higher baseline (BL) pain score, worse mental health (assessed with the Short-Form-36 Mental Component Summary [SF-36 MCS] score), and lower fatigue level and lower tender joint count [TJC] were also associated with significantly greater pain improvements at W24, while background use of NSAIDs was a negative predictor of pain improvement (Table 1). Treatment effect on pain was independent of PsA duration, gender, PsA subtype, prior TNFi exposure, BL skin disease, and BL swollen joint count (SJC). Continuous significant improvement from BL in pain with GUS extended through W52 even after adjustment for the identified determinants of pain improvement through W24 (Figure 1). At W52, predictors of change in pain remained significant with the exception of SF-36 MCS score (Table 1). Results did not exclude a small number of enrolled pts with fibromyalgia (FM: $n_{GUS}=8$; $n_{PBO}=4$). According to these exploratory findings, medical history of FM was associated with lower pain improvement through W24 ($p=0.066$); in the models run separately in pts with GUS and PBO, pts with FM treated with GUS had a mean (95% CI) pain improvement (-9.1 [-19.5, 1.2]) while pts treated with PBO had a mean worsening (0.7 [-12.5, 13.9]). Pain improvement through 52 wks was significant regardless of FM: pts with FM had a mean (95% CI) improvement of -14.7 (-25.9, -3.6) comparable to non-FM pts at W24, while pain improvement in pts with no FM was -22.2 (-24.0, -20.4).

Table 1. Significant Predictors of Change in Pain (W24 and W52)

BL Determinant	W24	W52
	Estimate (95% CL)	Estimate (95% CL)
Pain score	-0.62 (-0.69:-0.55) ‡	-0.75 (-0.83:-0.67) ‡
Fatigue	-0.38 (-0.50:-0.27) ‡	-0.37 (-0.53:-0.22) ‡
SF-36 MCS	0.20 (0.11:0.30)‡	0.11 (-0.02:0.24)
TJC	0.13 (0.06:0.19) †	0.12 (0.04:0.21) †
NSAID use (Y vs N)	2.29 (0.62:3.96) †	2.76 (0.55:4.98) *

* $p<0.05$; †$p<0.01$; ‡$p\leq0.0001$

Conclusion: Early significant effects of GUS on pain were enhanced through 1 year. Significant predictors of change in pain were consistent at W24 and W52, with the exception of mental health measures. The impact of mental status on pt-reported pain and the potential for GUS to improve pain in pts with FM warrant further consideration.

POS1071 [18F]FLUORIDE PET-CT SCANS VISUALIZE BOTH AXIAL AND PERIPHERAL BONE FORMATION IN PSORIATIC ARTHRITIS PATIENTS

J. De Jongh[1], R. Hemke[2], G. C. J. Zwezerijnen[3], M. Yaqub[3], I. Van der Horst-Bruinsma[4], M. G. H. Van de Sande[5], A. Van Kuijk[6], I. Bultink[1], L. Burgemeister[6], N. M. A. Van Dillen[6], A. Voskuyl[1], C. J. Van der Laken[1]. *[1]Amsterdam UMC, location VUmc, Rheumatology & Clinical Immunology, Amsterdam, Netherlands; [2]Amsterdam UMC, location AMC, Radiology & Nuclear Medicine, Amsterdam, Netherlands; [3]Amsterdam UMC, location VUmc, Radiology & Nuclear Medicine, Amsterdam, Netherlands; [4]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; [5]Amsterdam UMC, location AMC, Rheumatology & Clinical Immunology, Amsterdam, Netherlands; [6]Reade, Rheumatology, Amsterdam, Netherlands*

Background: Psoriatic arthritis (PsA) can present with peripheral (i.e. arthritis, enthesitis, dactylitis) and/or axial (spondyloarthritis) manifestations. Positron Emission Tomography (PET) may be a promising imaging technique for detection of whole body disease activity since it combines quantification and picomolar sensitivity for accurate depiction of pathologic processes with anatomical low dose CT imaging as a reference (3, 4). It was recently demonstrated that [^{18}F]Fluoride PET-CT scans can successfully visualize and monitor ankylosing spondylitis disease activity by imaging of bone formation in the axial skeleton (5). Since bone formation is associated with enthesitis and synovitis in PsA, [^{18}F]Fluoride may enable sensitive, whole body detection of disease activity in PsA.
Objectives: To investigate the feasibility of [^{18}F]Fluoride PET-CT to visualize disease activity of PsA by imaging of bone formation at axial and peripheral sites in PsA patients.
Methods: Sixteen patients (female 10/16, age 50.6 ±8.9 years) with PsA fulfilling CASPAR criteria and clinically active disease including ≥1 clinically active enthesitis site were included. Clinical disease activity was assessed by swollen joint count/tender joint count 44, MASES and SPARCC. Of each patient, a whole body [^{18}F]Fluoride PET-CT scan at 45 minutes post injection was performed. All scans were dichotomously scored by two board certified readers (blinded for clinical data) for PET-positive lesions in the joints, peripheral enthesis sites and spine. Low dose CT was used for anatomical reference.
Results: Out of 1088 evaluated joints, 109 joints showed PET enhancement, most frequently in the interphalangeal- and metatarsal joints of the feet (14/109, 12,9%) (Figure 1A) and the distal interphalangeal joints of the hands (14/109, 12,9%). Out of 416 evaluated entheseal sites, PET positivity was found at 44 sites, mainly located at the patella tendon insertion (11/44, 25%) (Figure 1B) and the quadriceps tendon insertion (10/44, 22.7%). Of the PET positive joints and entheses sites, respectively 81.1% and 70.5% were not associated with tender or swollen joints and clinical enthesitis, respectively. In 11 out of the 16 patients ≥1 axial PET positive lesion was observed (Figure 1C), most frequently located in the cervical spine (19/49 observed axial lesions, 38.8%). Two patients showed PET enhancement in one sacro-iliac joint (SIJ) without any inflammatory back pain (IBP). Only four out of 15 patients reported IBP and missing data for 1 patient. In two patients clinical dactylitis was observed which was also depicted on PET-CT.

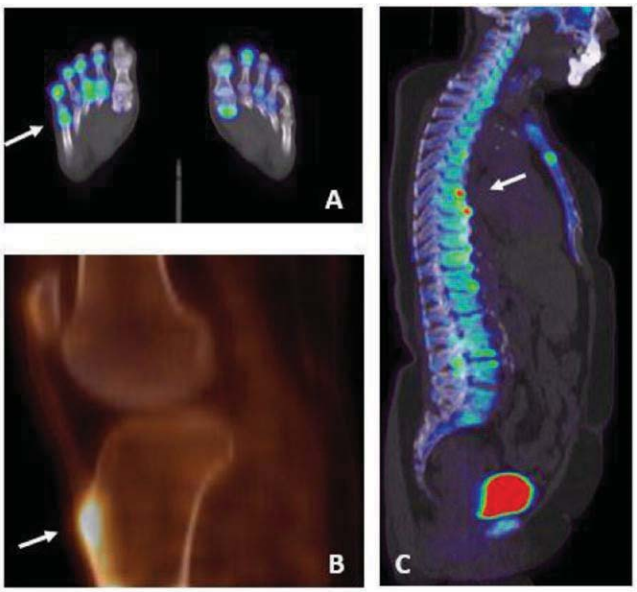

Figure 1. [^{18}F]Fluoride uptake in the metatarsal and IP-joints of the feet (A), in the patella tendon (B) and in the spine (C)

Conclusion: [^{18}F]Fluoride PET-CT scans can visualize disease activity at whole body musculoskeletal manifestations of PsA by demonstrating local bone formation in joints, entheses and the axial skeleton. By sensitive imaging of bone formation at active sites, [^{18}F]Fluoride PET-CT adds information to clinical disease activity, reflected by a high number of clinically negative, PET positive sites on top of concordant findings.

POS1072 OBESITY AND LOWER LIKELIHOOD OF ACHIEVING MINIMAL DISEASE ACTIVITY AND REMISSION IN PSORIATIC ARTHRITIS PATIENTS

E. Vallejo-Yagüe[1], T. Burkard[1], B. Moeller[2], A. M. Burden[1]. [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Institute of Pharmaceutical Sciences, Zürich, Switzerland;* [2]*Inselspital, University Hospital of Bern, Rheumatology, Immunology and Allergy, Bern, Switzerland*

Background: Among patients with psoriatic arthritis (PsA), obesity is a common comorbidity, and it is associated with difficulted disease management. This may be explained by the understanding of obesity as a low-grade inflammatory disease, which shares pathological pathway with PsA.

Objectives: We aimed to assess the impact of elevated body mass index (BMI) on the achievement of successful clinical outcomes in PsA patients within one-year after starting their first biologic or targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD).

Methods: This observational cohort study was performed using data from the Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) registry (from 1997 to July 31st 2019), and it included adult PsA patients starting their first b/tsDMARD. Patients were classified according to their BMI as normal weight (BMI <25), overweight (BMI 25.0-29.9), and obese (BMI ≥30). Overweight and obese patients were compared to the normal weight group (reference group). Logistic regression (crude and adjusted by confounders) was used to assess the impact of elevated BMI category on the achievement of clinical outcomes at ≤12-months after start of the patient's first b/tsDMARD. These clinical outcomes included Minimal Disease Activity (MDA), as well as remission defined by Disease Activity for Psoriatic Arthritis (DAPSA), clinical DAPSA, and 28-joint disease activity score (DAS28). Similarly, the likelihood of treatment persistence at one year was compared between the overweight and obese groups *vs* the normal weight group. Additionally, the overlapping or accordance across the study outcomes was investigated.

Results: The study included 306 (39.53%) normal weight, 285 (36.82%) overweight, and 183 (23.64%) obese patients. Compared to the normal weight group, obese patients had lower odds of achieving MDA at ≤12-months (Adjusted odds ratio [ORadj] 0.45, 95% confidence interval [CI] 0.24-0.82). This was consistent with the observed reduced odds of achieving DAPSA remission (ORadj 0.42, 95%CI 0.21-0.85), clinical DAPSA remission (ORadj 0.51, 95%CI 0.27-0.96), and DAS28 remission (ORadj 0.51, 95%CI 0.32-0.81) in obese *vs* normal weight patients. No differences were observed in treatment persistence across the BMI strata. And there was high overlap between achievement of MDA and clinical DAPSA remission.

Conclusion: Among PsA patients starting b/tsDMARDs, obesity was associated with ca. 50% reduced odds of achieving MDA and remission in comparison to normal weight patients, while it did not impact treatment persistence.

Acknowledgements: We thank all patients and rheumatologists contributing to the SCQM registry, as well as the entire SCQM staff. POS1073 INCREASED NUMBER OF COMORBIDITIES AND CARDIOVASCULAR RISK FACTORS IN EARLY PSORIATIC ARTHRITIS PATIENTS SUGGESTS AN INTRINSIC DISEASE IMPACT.

A. Ishchenko[1,2], S. Pazmino[1,3], K. De Vlam[1,3], R. Lories[1,3]. [1]*University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium;* [2]*Ziekenhuis Netwerk Antwerpen, Department of Rheumatology, Antwerpen, Belgium;* [3]*KU Leuven, Skeletal Biology and Engineering Research Centre, Department of Development and Regeneration, Leuven, Belgium*

Background: Metabolic and cardiovascular comorbidities in psoriatic arthritis (PsA) are seen as a consequence of long-lasting inflammation. Patients with Pso and PsA develop metabolic and cardiovascular comorbidities over the course of time[1]. PsA patients have a higher burden of comorbidities and cardiovascular risk factors (CV RF) as compared to those with other forms of arthritis[2,3]. Despite a lower grade of systemic inflammation as measured by CRP, the nature of this increased prevalence in PsA is not fully understood. We hypothesize that the risks may be intrinsic to the disease, and be already present in early stages.

Objectives: The aim of this study was to investigate the presence of comorbidities and CV RF in treatment naïve Early PsA (EPsA) as compared to sex- and age-matched healthy volunteers and to study factors contributing to the metabolic burden of the patients.

Methods: Clinical, demographic characteristics, cardiovascular risk factors and comorbidities of newly diagnosed treatment-naïve adult patients with PsA compared to sex- and age-matched controls were studied in an observational prospective longitudinal multicentre study.

Results: Sixty-seven EPsA patients were matched to 61 healthy volunteers. At diagnosis, 73% of EPsA had oligoarticular and 22% polyarticular disease. Majority had mild PASI scores (median PASI 1.2). The median duration of skin psoriasis before the onset of PsA was 11.4 years. Symptom duration at onset of PsA was 0.6 years.

Table 1.

	early PsA, baseline (n=67)	healthy controls, baseline (n=61)	p value
male sex, n (%)	47 (70.1)	35 (57.4)	0.144
age, mean (±SD)	47.9 (±14.3)	45 (±14.2)	0.25
BMI, mean (±SD)	28.2 (±4.5)	25.7 (±(5.2)	0.006*
Obesity (BMI ≥30), n patients (%)	27 (40.3)	11 (18.3)	0.011*
Abdominal obesity#	34 (50.7)	18 (29.5)	0.019*
number (%) of patients with ≥2 comorbidities	35 (52.2)	17 (27.9)	0.007*
presence of cardiovascular risk factors ≥1, n patients (%)	55 (82.1)	23 (37.7)	0.017*
number (%) of patients with ≥2 CV RF	38 (56.7)	16 (26.2)	<0.001*
cardiovascular morbidity, n patients (%)	14 (20.7%)	4 (6.6)	0.07
Charlson comorbidity index, n patients (%)	21 (31.3)	4 (6.6)	<0.001*
median (IQL)	0 (0-1)	0 (0)	0.005*§
metabolic syndrome, n patients (%)	15 (22.4)	5 (8.2)	0.03*
diabetes mellitus t2, n patients (%)	8 (11.9)	1 (1.6)	0.034*
dyslipidemia, n patients (%)	43 (64.2)	24 (39.3)	0.008*

EPsA showed a significantly higher rate of obesity (40.3% vs 18.3% in controls, p=0.011). PsA patients had significantly higher rates of dyslipidemia and metabolic syndrome than controls. Rate of insulin resistance, arterial hypertension, depression, COPD, gout were similar in EPsA and in controls. The overall number of comorbidities was comparable in EPsA and healthy controls, but strikingly 82% of EPsA patients had CV RF already present at baseline as compared to 38% of the controls (p=0.017). More than half of PsA patients had multiple (≥2) comorbidities and CV RF at baseline as compared to controls(33%) (Figure 1*)*. Overall rate of cardiovascular morbidity and Charlson comorbidity index were low, but were significantly higher in the PsA group (p=0.007 and <0.001 accordingly). Duration of skin psoriasis had no effect on comorbidities or CV RF in EPsA.

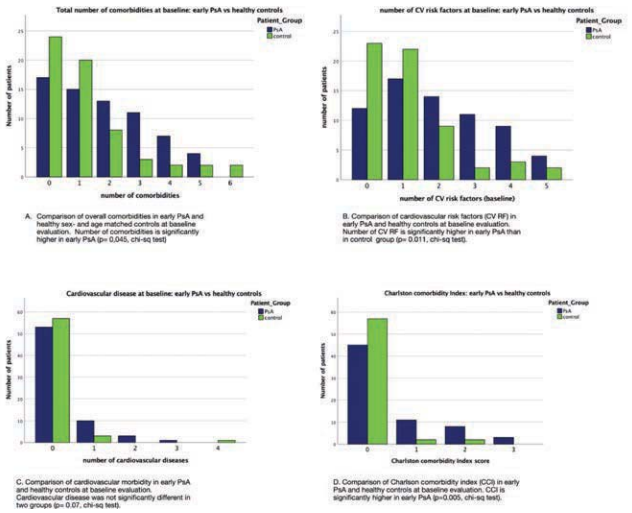

Figure 1. Comparison of comorbidities, CV RF, cardiovascular disease and Charlson comorbidity index in early PsA and healthy controls.

In multiple regression analysis diagnosis of PsA was the strongly associated with the number of comorbidities and CV RF after adjusting for age, sex and BMI.

Conclusion: Our data imply that PsA patients have higher comorbidities and cardiovascular burden at early stages of the disease. Rates of dyslipidemia, metabolic syndrome and obesity are significantly higher in the early PsA population. Presence of metabolic and lipid disturbances at early stages of the disease might suggest a bidirectional relationship and potentially playing role as initial triggers of PsA.

Rheumatology Department, Barcelona, Spain; [11]Universidad Autónoma de Madrid, Knowledge Engineering Institute, Madrid, Spain*

Background: Very few data are available on predictors of minimal disease activity (MDA) in patients with recent-onset psoriatic arthritis (PsA). Such data are crucial, since the therapeutic measures used to change the adverse course of PsA are more likely to succeed if we intervene early.

Objectives: To detect patient and disease variables associated with achieving MDA in patients with recent-onset PsA.

Methods: We performed a multicenter observational prospective study (2-year follow-up, regular annual visits), promoted by the Spanish Society of Rheumatology. Patients aged ≥18 years who fulfilled the CASPAR criteria, with less than 2 years since the onset of symptoms, were included. The intention at the baseline visit was to reflect the patient's situation before disease progress was modified by the treatments prescribed by the rheumatologist. All patients gave their informed consent. The study was approved by the Clinical Research Ethics Committee of the Principality of Asturias. MDA was defined as fulfillment of at least 5 of the following: ≤1 tender joint; ≤1 swollen joint; PASI ≤1 or BSA ≤3%; score on the visual analog scale (VAS) for pain provided by the patient ≤1.5; overall score for disease activity provided by the patient ≤2; HAQ score ≤0.5; ≤1 painful enthesis [1]. The dataset contained data for the independent variables from the baseline visit and from follow-up visit number 1. These were matched with the outcome measures from follow-up visits 1 and 2, respectively. We trained a random forest–type machine learning algorithm to analyze the association between the outcome measure and the variables selected in the bivariate analysis. In order to understand how the model uses the variables to make its predictions, we applied the SHAP technique. This approach assigns a SHAP value to each value of each variable according to the extent to which it affects the prediction of the model (the higher the absolute SHAP value, the greater the influence of this data item on prediction) and to how it affects the prediction (if the SHAP value is positive, the data item positively affects the prediction, that is, it confers a higher value on the prediction). The SHAP summary graphs order the predictors by their importance in the predictions of the model. This importance is calculated with the mean of the SHAP values assigned to each data item of a variable; mean values <0.01 indicate the low importance of the variable in the model. We used a confusion matrix to visualize the performance of the model. This matrix shows the real class of the data items, together with the predicted class, and records the number of hits and misses.

Results: The sample comprised 158 patients. 14.6% were lost to follow-up. 55.5% and 58.3% of the patients had MDA at the first and second follow-up visit, respectively. The importance of the variables in the model according to the mean of the SHAP values is shown in Table 1. The variables with the greatest predictive ability were global pain, impact of the disease (PsAID), patient global assessment of disease and physical function (HAQ-Disability Index). The SHAP values for each value of each variable are shown in Figure 1. The percentage of hits in the confusion matrix was 85.94%.

Table 1. Variables in the predictions of the random forest for MDA according to the SHAP method.

Variable	Importance according to SHAP[1]
Global pain	0.069
PsAID	0.064
Patient global assessment of disease	0.047
HAQ	0.044
Articular pattern at diagnosis	0.029
Physician global assessment of disease	0.023
Tender joint count	0.014
Sex	0.009
Weekly alcohol consumption	0.009

[1]Mean of the SHAP values for each value of the variable. MDA: minimal disease activity.

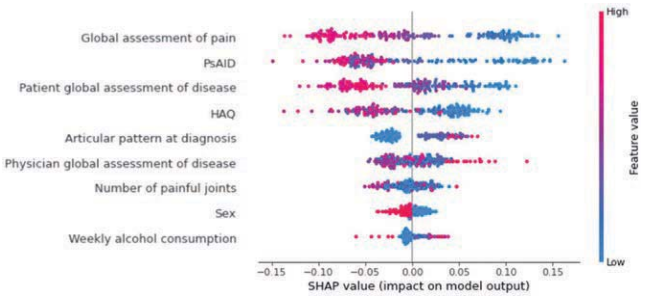

Figure 1. SHAP summary graph.

Conclusion: A key objective in the management of PsA should be control of pain, which is not always associated with inflammatory burden, and the establishment of measures to better control the various domains of PsA.

CROSS-SECTIONAL OBSERVATIONAL AND MULTICENTER STUDY FOR THE VALIDATION OF THE SPANISH VERSION OF THE PURE-4 QUESTIONNAIRE

R. Queiro Silva[1], I. Belinchón[2], A. Lopez-Ferrer[3], M. Ferran I Farrés[4], R. Rivera Díaz[5], D. Vidal Sarro[6], L. Rodriguez Freire[7], P. De la Cueva Dobao[8], J. Santos Juanes[2], V. Rocamora Duran[9], C. Sanabra[10], G. Guinea Uzábal[10], V. Martín Vázquez[10]on behalf of PURE4 Study Group. *[1]Hospital Universitario Central de Asturias, Servicio de Reumatología, Oviedo, Spain; [2]Hospital General Universitario de Alicante-ISABIAL, Servicio de Dermatología, Universidad Miguel Hernández, Alicante, Spain; [3]Hospital de la Santa Creu i Sant Pau, Servicio de Dermatología, Barcelona, Spain; [4]Hospital del Mar, Servicio de Dermatología, Barcelona, Spain; [5]Hospital 12 de Octubre, Servicio de Dermatología, Madrid, Spain; [6]Hospital de Sant Joan Despí Moisés Broggi, Servicio de Dermatología, Barcelona, Spain; [7]Hospital Universitario Virgen del Rocío, Servicio de Dermatología, Sevilla, Spain; [8]Hospital Universitario Infanta Leonor, Servicio de Dermatología, Madrid, Spain; [9]Hospital de Manacor, Servicio de Dermatología, Islas Baleares, Spain; [10]Novartis Pharmaceuticals,, Barcelona, Spain*

Background: The Psoriatic arthritis UnclutteRed screening Evaluation (PURE-4) has been culturally adapted to Spanish language recently following the standardized methodology.[1] A group of experts in psoriasis and psoriatic arthritis (PsA) has recently recommended the use of the Spanish version of PURE-4 due to the reduced number of items, its high sensitivity and specificity and the feasibility to implement in the clinical practice.

Objectives: To validate the Spanish version of the PURE-4 questionnaire.

Methods: Cross-sectional, observational and multicenter study conducted with primary data collection under conditions of routine clinical practice in Spain. The study included adult patients with diagnosis of psoriasis of any time of evolution and any type of severity, that voluntarily accepted to participate. Primary endpoint: validation of PURE-4 questionnaire in terms of sensitivity, specificity, feasibility, reliability (internal consistency) and construct validity. The study consists in two cross-sectional evaluations: assessment I (a visit performed by a dermatologist, followed by an independent visit to the rheumatologist within the following 4 weeks after to the dermatologist's visit and scheduled according to routine clinical practice) and assessment II (patients without PsA in assessment I will be evaluated by the rheumatologist one year ±2 months later and the rheumatologist will perform the PsA diagnostic confirmation according to the rheumatologist criteria and will collect clinical characteristics). Since data from assessment II are not yet available, data from assessment I are presented.

Results: 268 evaluable patients included, 57.1% male, with a mean (SD) age of 47.1 (12.6) years, a mean (SD) time from diagnosis of 18.6 (12.9) years and mostly receiving psoriasis treatment (88.8%), biological treatment being the most common (43.3%). Mean (SD) PURE-4 score for all patients was 1.4 (1.3), being 2.3 (1.1) for patients with PsA and 1.3 (1.3) for patients without PsA diagnosis (Table 1). 268 (100.0%) patients answered the full PURE-4 questionnaire. Area under the receiver-operating characteristic (ROC) curve was 0.7185 (95% CI: 0.6391, 0.7978), showing good quality of fit or quality of the questionnaire (Figure 1). Using the Youden index, which determines the optimal cut-off point for the classification of patients, it was identified that a score ≥2 indicated a diagnosis of PsA. PURE-4 questionnaire showed a sensitivity of 77.1% and a specificity of 61.1%.

Table 1. Sociodemographic and clinical baseline characteristics (assessment I)

Characteristics	With PsA diagnosis (n=35)	Without PsA diagnosis (n=226)	Not assesable (n=7)	Total (n=268)
Age, mean (SD)	50.5 (10.0)	46.5 (12.9)	49.9 (11.2)	47.1 (12.6)
Female, n (%)	14 (40.0%)	97 (42.9%)	4 (57.1%)	115 (42.9%)
Years since diagnosis, mean (SD)	19.7 (14.2)	18.3 (12.8)	22.4 (9.0)	18.6 (12.9)
Current treatment for psoriasis, n (%)	32 (91.4%)	199 (88.1%)	7 (100.0%)	238 (88.8%)
Phototherapy, n (%)	5 (15.6%)	16 (8.0%)	0 (0.0%)	21 (8.8%)
Topic treatment, n (%)	20 (62.5%)	66 (33.2%)	3 (42.9%)	89 (37.4%)
Conventional systemic no biological treatment, n (%)	7 (21.9%)	40 (20.1%)	2 (28.6%)	49 (20.6%)
Biological treatment, n (%)	8 (25.0%)	91 (45.7%)	4 (57.1%)	103 (43.3%)
Phosphodiesterase-4 inhibitors, n (%)	0 (0.0%)	8 (4.0%)	0 (0.0%)	8 (3.4%)
Others, n (%)	0 (0.0%)	3 (1.5%)	0 (0.0%)	3 (1.3%)
PASI, mean (SD)	8.7 (5.5)	7.0 (5.0)	4.2 (3.1)	7.2 (5.1)
Mild (PASI<7), n (%)	11 (31.4%)	95 (42.0%)	5 (71.4%)	111 (41.4%)
Moderate/severe (PASI≥7), n (%)	24 (68.6%)	131 (58.0%)	2 (28.6%)	157 (58.6%)

APs, psoriatic arthritis; PASI, *Psoriasis Area and Severity Index*; SD, standard deviation.

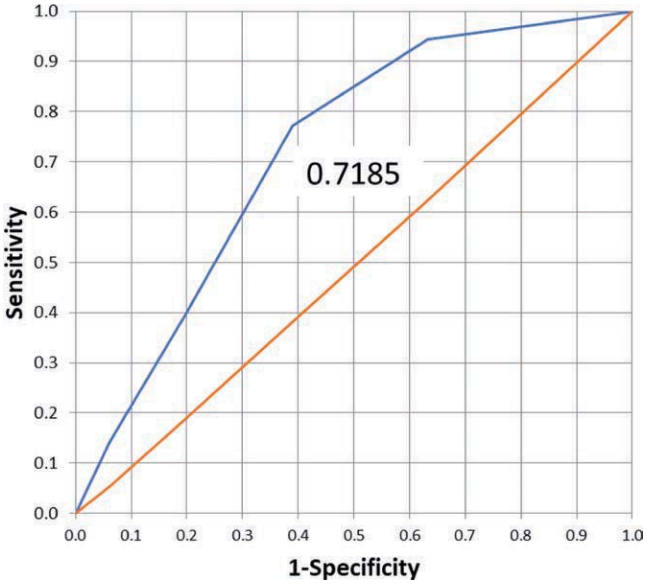

Figure 1. Area under the ROC curve (assessment I)

Conclusion: PURE-4 is a valid and compliant questionnaire with clinical practice in dermatology. It could be answered by patients in the waiting room and reviewed by dermatologists during the visit to support decision-making. PURE-4 could also help rheumatologists to early diagnose PsA patients in clinical practice.

Background: Obesity is a risk factor for psoriatic arthritis (PsA) and is associated with higher disease activity [1].
Objectives: We aimed to evaluate whether obese patients with PsA were less likely to achieve remission/low disease in a real-life multi-centre cohort.
Methods: We used data from the ReFlap study (NCT03119805)[2], which recruited consecutive adult patient with definite PsA for more than 2 years of disease duration from 14 countries. We collected demographic characteristics, self-reported weight and height, clinical data and patient reported outcomes. Remission/low disease was defined as Disease Activity in PSoriatic Arthritis (DAPSA) ≤ 4, or Minimal disease activity (MDA). Obesity was defined as body mass index (BMI) ≥ 30kg/m^2. We compared patient characteristics, disease activity parameters and impact scores between patients with obesity versus non-obese. A multivariable regression model was performed for demographic variables associated with reaching each definition of remission/low disease, adjusted on age, sex, level of education, disease duration, current use of conventional (c-) and biological (b-) disease modifying anti-rheumatic drugs (DMARDs).
Results: Among 414 patients (49.3% women, mean disease duration 11.0 ±8.2 years), 119 (28.7%) had BMI ≥ 30kg/m^2 (obese). Obese patients were more likely to be female, had higher swollen joint and enthesitis counts, higher self-reported pain, poorer physical function, more fatigue and poorer mental health (Table 1). Obese patients were half as likely to achieve MDA or DAPSA remission in multivariable analysis with odd ratios of 0.6 (95% confidence interval, CI: 0.3, 0.8, p=0.049) and 0.4 (95% CI: 0.2, 0.8, p=0.012), respectively for obese compared to non-obese patients (Figure 1).

Table 1. Patient characteristics and remission achievement between obese and non-obese patients with psoriatic arthritis

	Non-obese (n=295)	BMI ≥30 (n=119)	p
Female, %	44.3	61.5	0.002
Number of comorbidities	1.61 (0.93)	2.83 (2.01)	<0.001
Tender joints, 0-68	3.56 (7.81)	5.75 (10.0)	0.018
Swollen joints, 0-66	2.19 (7.29)	1.46 (2.39)	0.285
Leeds enthesitis index, 0-6	0.48 (1.23)	0.86 (1.70)	0.012
PGA disease activity, 0-10	3.90 (2.73)	4.76 (2.67)	0.004

Mean (SD) shown unless specified otherwise. HAQ-DI: Health Assessment Questionnaire – Disability Index; PsA: psoriatic arthritis; PGA: patient global assessment of disease activity; DAPSA: Disease Activity in PSoriatic Arthritis; PsAID: Psoriatic Arthritis Impact of Disease.

Conclusion: In this real-life data from 14 countries, obesity was frequent and PsA patients with BMI ≥ 30kg/m^2 were more likely to be female, and had higher subjectively reported disease activity and illness impact compared to those with lower BMI. Obese patients had a two-fold lower likelihood of achieving remission/low disease defined by both MDA and DAPSA compared to non-obese patients. PsA patients with comorbid obesity may have different disease profiles from non-obese patients, and require specific management.

POS1077 LARGE JOINT INVOLVEMENT AND SUBSTANTIAL DISEASE BURDEN IN PATIENTS WITH OLIGOARTICULAR AND POLYARTICULAR PSORIATIC ARTHRITIS IN THE MULTINATIONAL UPLIFT SURVEY

W. Tillett[1], A. Ogdie[2], P. Richette[3], A. B. Gottlieb[4], S. Jardon[5], S. Richter[5], A. Flower[5], J. Merola[6]. *[1]University of Bath, Department of Pharmacy*

& Pharmacology, Bath, United Kingdom; [2]University of Pennsylvania, Rheumatology, Philadelphia, United States of America; [3]Hôpital Lariboisière, Rheumatology, Paris, France; [4]Icahn School of Medicine at Mount Sinai, Dermatology, New York, United States of America; [5]Amgen Inc, Medical Affairs, Thousand Oaks, United States of America; [6]Brigham and Women's Hospital, Dermatology, Boston, United States of America

Background: Patients (pts) with oligoarticular psoriatic arthritis (PsA) report quality-of-life impairment similar to polyarticular PsA pts despite less joint involvement. In the 2020 Understanding Psoriatic Disease Leveraging Insights for Treatment (UPLIFT) survey, we evaluated other aspects of disease burden in pts with oligoarticular (≤4 joints) and polyarticular (>4 joints) PsA.

Objectives: To explore joint involvement distribution and relative disease burden in pts with self-reported healthcare provider (HCP)–diagnosed PsA who self-identified with oligoarticular vs polyarticular joint involvement.

Methods: UPLIFT was a multinational Web-based survey in adults who reported an HCP diagnosis of PsA and/or psoriasis. This analysis evaluated demographics, disease characteristics, joint distribution, and quality-of-life measures in pts with PsA with or without psoriasis with self-identified oligoarticular vs polyarticular joint involvement. Small joint classification includes foot/toes, hands/fingers, and thumbs; intermediate joints includes wrists, elbows, and ankles; and large joints includes shoulders, hips, and knees.

Results: Of the 1256 pts with PsA completing the survey, 44% had oligoarticular PsA and 56% polyarticular PsA. The polyarticular PsA group had higher mean age, fewer males, and more pts with body mass index ≥25 kg/m^2 (Table 1). Prevalence of depression, hypertension, and diabetes was generally similar between groups (Table 1). In pts with oligoarticular and polyarticular PsA, respectively, involvement of large joints was most prevalent (63%, 91%), followed by intermediate (46%, 87%) and small (20%, 76%) joints. Axial involvement was less prevalent in pts with oligoarticular (30%) vs polyarticular (67%) PsA. Common areas of joint involvement were the knees, elbows, and shoulders for oligoarticular PsA pts and the knees, hands, and elbows for polyarticular PsA pts (Figure 1). Involvement in the hands, wrists, thumbs, feet, and ankles was proportionately greater in polyarticular pts vs oligoarticular pts. Dactylitis, enthesitis, and nail disease, respectively, were each present in approximately one third of oligoarticular PsA pts and more than half of polyarticular PsA pts. Mean Patient Assessment of PsA Severity, Health Assessment Questionnaire (HAQ)-8, and Psoriatic Arthritis Impact of Disease 12-item (PSAID-12) scores indicated similar disease burden between the two groups (Table 1). In both groups, >70% reported an unacceptable PsA symptom state (PSAID >4), and >60% had Patient Health Questionnaire 2-item (PHQ-2) score ≥3, consistent with positive screening for depression (Table 1).

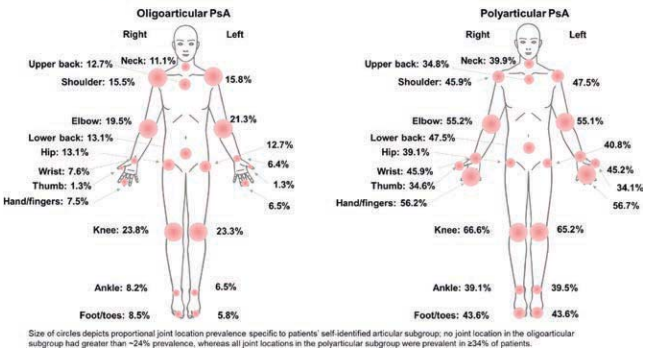
Table 1. Demographics and Patient Characteristics

	Oligoarticular PsA (n=550)	Polyarticular PsA (n=706)
Age, mean (SD), y	39.5 (15.23)	45.6 (14.89)
Male sex, n (%)	327 (60)	347 (49)
Body mass index ≥25 kg/m^2 (overweight/obese), n (%)	164 (30)	292 (41)
PsA duration, mean (SD), y	11.1 (10.44)	13.8 (11.40)
PsA treatment use, n (%)*		
Prior oral prescription	231 (44)	217 (31)
Prior injectable/intravenous	177 (34)	169 (24)
Current oral prescription	185 (35)	364 (53)
Current injectable/ intravenous	154 (29)	246 (36)
Comorbidities, n (%)		
Hypertension	230 (42)	302 (43)
Depression	214 (39)	291 (41)
Diabetes	201 (37)	236 (33)
Skin or non-skin cancer	200 (36)	168 (24)
Heart disease	149 (27)	123 (17)
Inflammatory bowel disease	156 (28)	142 (20)
Liver disease	149 (27)	98 (14)
Patient Assessment of PsA Severity, mean, (SD)	5.0 (2.92)	5.7 (2.53)
HAQ-8, mean, (SD)	0.9 (0.65)	0.8 (0.64)
PSAID-12, mean, (SD)	5.3 (2.54)	5.6 (2.42)
PSAID >4, n (%)	389 (71)	533 (76)
PHQ-2 ≥3, n (%)	383 (70)	452 (64)

*n=525 with oligoarticular PsA; n=691 with polyarticular PsA.

Conclusion: In the UPLIFT survey, almost half of pts with PsA self-identified with oligoarticular PsA. Both oligoarticular and polyarticular PsA groups experienced similar levels of disease burden, including a high prevalence of an unacceptable PsA symptom state and a PHQ-2 score ≥3, indicative of a positive screen for depression.

Figure. Distribution of Joint Involvement



Size of circles depicts proportional joint location prevalence specific to patients' self-identified articular subgroup; no joint location in the oligoarticular subgroup had greater than ~24% prevalence, whereas all joint locations in the polyarticular subgroup were prevalent in ≥34% of patients.

POS1078 COMPARISON OF PATIENTS WITH AXIAL PSA AND PATIENTS WITH AXSPA AND CONCOMITANT PSORIASIS

A. Regierer[1], A. Weiß[1], X. Baraliakos[2], F. Behrens[3], D. Poddubnyy[4], G. Schett[5], H. M. Lorenz[6], M. Worsch[7], A. Strangfeld[1]. *[1]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology, Berlin, Germany; [2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [3]Goethe University Frankfurt, Rheumatology, Frankfurt, Germany; [4]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany; [5]University Hospital Erlangen, Rheumatology, Erlangen, Germany; [6]University clinic, Heidelberg, Rheumatology, Heidelberg, Germany; [7]Rheumatologist, Muehlhausen, Rheumatology, Muehlhausen, Germany*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease affecting the peripheral and axial musculoskeletal system as well as skin and nails. Diagnostic criteria of axial PsA (axPsA) are not well defined. Treatment strategy is mostly based on evidence generated for axial spondyloarthritis (axSpA), as only rare clinical trial data for axPsA exist. However, it is still unclear whether axSpA with concomitant psoriasis (axSpA/pso) is the same as axPsA.

Objectives: To compare PsA patients with axial manifestations with axSpA patients with concomitant psoriasis.

Methods: RABBIT-SpA is a prospective longitudinal cohort study including PsA and axSpA patients enrolled at start of a new conventional treatment or b/tsDMARD treatment. Two definitions of axPsA were used:

Clinical definition: documentation of axial manifestation as diagnosed by a rheumatologist

Radiographic definition: presence of sacroiliitis according to modified NY criteria (mNYc).

axSpA patients were stratified into axPsA/pso (with psoriasis either in patient history or present) and axSpA.

Results: Psoriasis was documented in 182/1407 axSpA patients (13%). Of 1355 PsA patients, 295 (22%) fulfilled the clinical definition of axPsA. Using the radiographic definition, 127 (9%) PsA patients fulfilled mNYc, 230 (17%) did not fulfil mNYc and 998 (74%) did not undergo radiographic evaluation.
AxSpA/pso patients differed from axPsA regardless of the definition (Table 1). axPsA patients were older, less often HLA-B27 positive, and peripheral manifestations were much more often present in axPsA than in axSpA/pso. Uveitis and inflammatory bowel disease were more common in axSpA/pso.

Table 1. Baseline characteristics of axSpA/pso patients and clinical resp. radiographic defined axPsA.

	axSpA/pso	axPsA/clin	axPsA/rad
N	182	295	127
female gender, n (%)	80 (44)	178 (60.3)	80 (63)
age, mean (SD)	47 (12.8)	51.1 (11.3)	51.6 (11.4)
HLA-B27 positive, n (%)	106 (67.1)	44 (22.7)	28 (32.9)
CRP mg/l, mean (SD)	8.7 (14.6)	7.1 (11.8)	6.9 (11.5)
CRP ≥5 mg/l, n (%)	70 (42.4)	106 (40)	50 (45.9)
uveitis ever, n (%)	26 (14.3)	10 (3.4)	7 (5.5)
IBD ever, n (%)	13 (7.1)	14 (4.7)	7 (5.5)
≥3 comorbidities, n (%)	48 (26.4)	117 (39.7)	48 (37.8)
peripheral manifestations, n (%)	65 (36.3)	251 (85.1)	109 (85.8)
enthesitis, n (%)	29 (16.2)	77 (26.4)	32 (25.4)
number of sites with enthesitis, mean (SD)	0.5 (1.6)	0.9 (2.2)	0.9 (1.9)
affected joints, n (%)	53 (29.6)	234 (80.1)	102 (80.3)
number of affected joints, mean (SD)	1.4 (3.7)	6.8 (8.4)	5 (5.9)
physician global disease activity, mean (SD)	5.6 (2.1)	5.6 (1.9)	5.6 (2)
patient global disease activity, mean (SD)	5.4 (2.6)	5.9 (2.3)	5.8 (2.2)
patient pain, mean (SD)	5.5 (2.6)	5.7 (2.3)	5.7 (2.2)
sakroiliitis, n (%)	124 (84.4)	97 (56.1)	127 (100)
clinical axial definition, n (%)	n.d.	295 (100)	97 (76.4)

In contrast, disease activity measured by physician global as well as patient global, and patient pain were similar in axSpA/pso and axPsA.
Conclusion: Regardless whether clinical or radiographic definitions of axPsA were used, differences to axSpA/pso patients were identified. These data indicate a need for a specific diagnostic, and a potentially more targeted treatment approach for axPsA.

POS1079 CLINICAL CHARACTERIZATION OF PRODROMAL AND VERY EARLY PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW FOR THE DEFINITION OF CLINICAL AND IMAGING SUSPICIOUS FEATURES FOR PROGRESSION TO PSORIATIC ARTHRITIS

A. Zabotti[1], G. De Marco[2], L. Gossec[3], X. Baraliakos[4], J. Emmel[5], D. Aletaha[6], A. Iagnocco[7], J. S. Smolen[6], D. Mcgonagle[2]on behalf of EULAR Task Force for the definition of clinical and imaging features suspicious for progression to psoriatic arthritis, 2021-22D. *[1]Rheumatology, Department of Medicine, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), University of Leeds, Leeds, United Kingdom; [3]Pitié-Salpêtrière hospital, Sorbonne Université, Paris, France; [4]St. Anna Hospital Herne, Marien Hospital Herne, Universitätsklinikum der Ruhr-Universität Bochum, Bochum, Germany; [5]Medical Education, Leeds Teaching Hospitals NHS Trust, Library & Evidence Research Centre, X35 Old Site, Leeds General Infirmary LS1 3EX, Leeds, United Kingdom; [6]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [7]Academic Rheumatology Centre, Università Degli Studi Di Torino,, Torino, Italy*

Background: The transition from psoriasis (PsO) to psoriatic arthritis (PsA) is a focus of considerable scientific interest: is it possible to target pre-PsA and very early PsA, in particular for physiopathology and drug studies? Recently, a EULAR taskforce has been set up in this area (1).
Objectives: To characterize the prodromal and the very early PsA through a systematic literature review (SLR).
Methods: A SLR explored MEDLINE, EMBASE and CENTRAL, up to 22 October 2021. The objective was to identify the symptoms, objective signs, lab tests, imaging features and other characteristics of patients later diagnosed as "new onset" PsA in two key populations: 1) patients with PsO and 2) patients with early undifferentiated arthritis (UA). Studies of adult patients published in English were included, if they reported characteristics of pre-PsA or new onset PsA patients, and data were extracted by 2 readers. Meta-analysis was not done due to data heterogeneity (PsA classification criteria, outcome measures and length of observation). Results are reported semi-quantitatively.
Results: Of 31449 references, 22 studies were included of which 12 were prospective; 7 retrospective and 3 cross-sectional. Eighteen studies reported on patients with PsO (n=95828) later diagnosed as PsA (n=2136) with a mean duration of follow up of 5.2 (±3.9) years. Seven out of 18 (38.8%) studies were informative regarding the clinical features of the new onset PsA. Four studies on early UA patients (n=492) later diagnosed as PsA (n=49) were included. Progression to PsA was associated with the presence of musculoskeletal (MSK) complaints (mainly joint tenderness) and the presence of subclinical MSK inflammation detected by imaging. Peripheral oligo-arthritis was the prevalent clinical presentation of new onset PsA.
Conclusion: As expected, joint pain and imaging evidence of MSK inflammation were associated with PsA development in PsO patients. The SLR highlights the lack of robust evidence regarding data associated with the development of PsA. More prospective studies focusing on transition from PsO to PsA are needed.

Table 1.

Features		Transition from PsO to PsA (n = 18 studies)	Transition from UA to PsA (n = 4 studies)	Clinical characterization of New Onset PsA (n = 5 studies)
Patient reported symptoms	VAS pain	+++		NA

POS1080 CHARACTERIZATION OF JOINT DISTRIBUTION AND DISEASE BURDEN IN PATIENTS WITH EARLY OLIGOARTICULAR PSORIATIC ARTHRITIS: RESULTS FROM THE ONGOING FOREMOST STUDY

D. D. Gladman[1], L. Coates[2], L. Gossec[3], J. Aelion[4], J. Vasandani[5], S. Cheng[6], L. Tang[6], S. Jardon[6], S. Richter[6], P. J. Mease[7]. *[1]Toronto Western Hospital, Schroeder Arthritis Institute, Krembil Research Institute, Toronto, Canada; [2]University of Oxford, Rheumatology, Oxford, United Kingdom; [3]Sorbonne*

Université and Pitié Salpêtrière Hospital, Rheumatology, Paris, France; [4]West Tennessee Research Institute, Rheumatology, Jackson, United States of America; [5]West Texas Clinical Research, Rheumatology, Lubbock, United States of America; [6]Amgen Inc, Medical Affairs, Thousand Oaks, United States of America; [7]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Rheumatology, Seattle, United States of America

Background: Oligoarticular psoriatic arthritis (PsA) is commonly reported in early disease. Although fewer joints are involved, there may be significant impact on patients' (pts) quality of life. The ongoing FOREMOST study (NCT03747939) is investigating the efficacy of apremilast vs placebo for treatment of early oligoarticular PsA (>1 but ≤4 tender and swollen joints involved).
Objectives: To characterize disease burden in pts with early oligoarticular PsA and disease phenotype including location and size of involved joints and presence of certain baseline clinical PsA manifestations in FOREMOST pts.
Methods: Baseline swollen and tender joint distribution was analyzed. Baseline disease burden was assessed in the overall group and a subgroup with small joint involvement only (for context) using clinical disease activity measures, pt-reported outcomes, and additional PsA manifestations.
Results: At data cut-off for analysis, 220 pts of 285 planned were enrolled. In the overall group, disease duration was <1 year and joint distribution for swollen or tender joints involved predominantly small joints, with ~48% of joint involvement observed in finger proximal interphalangeal (PIP) joints and <2% in temporomandibular and clavicular joints across swollen or tender joints (Figure 1). Mean Physician's and Patient Global Assessment of Disease Activity (PhGA and PtGA, respectively) scores were 43.9 and 51.3; mean pt pain assessment score was 50.7. Mean Health Assessment Questionnaire Disability Index (HAQ-DI) functional assessment score was 1.0; 25.5% of pts had HAQ-DI ≤0.5. Pts reported an average PsA Impact of Disease (PsAID-12) domain score of 4.7. Additional manifestations of PsA at baseline included dactylitis (14.5%), enthesitis (32.7%), nail involvement (67.3%), and skin disease (47.7% with body surface area [BSA] ≥3%). Within the overall group, 59% had >1 joint size involved (small [metacarpophalangeal, metatarsophalangeal, distal interphalangeal, PIP, hand carpometacarpal and mid-tarsal]; intermediate [wrist, elbow, ankle, temporomandibular, acromioclavicular, sternoclavicular]; large [shoulder, hip, knee]). Of those with only 1 joint size involved (41% of pts), the majority had small joint involvement predominantly in PIPs (n=84 for small joints; n=1 for intermediate joints; n=5 for large joints). The overall pattern of clinical and disease presentation indicated elevated burden for pts with early oligoarticular PsA, including those pts with only small joints involved (Table 1).

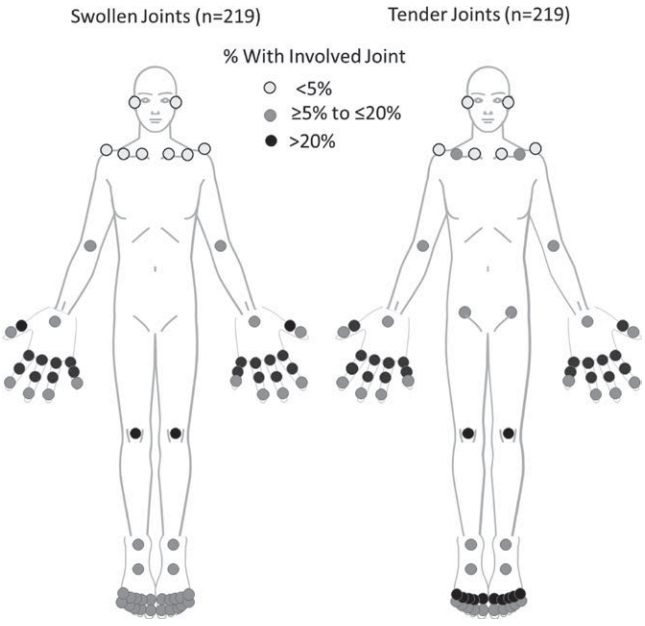

Figure 1. FOREMOST population: baseline demographics and disease burden in the overall population and pts with involvement in small joints only

Conclusion: In FOREMOST, despite few joints involved, pts with early oligoarticular PsA experienced high disease burden and impaired quality of life. Small joint involvement, although less commonly expected in oligoarticular PsA, was the most frequently observed pattern.

Table 1.

Characteristics	Overall Population (PBO + APR), N=220	Small Joints Only (PBO + APR), N=84
Age, mean, y	49.6	51.3
Men, n (%)	98 (44.5)	40 (47.6)
Europe/Russia, n (%)	47 (21.4)/66 (30.0)	22 (26.2)/11 (13.1)
Canada/United States, n (%)	8 (3.6)/99 (45.0)	1 (1.2)/50 (59.5)
Body mass index, mean, kg/m^2	30.4	29.3
Duration of disease, mean, y	0.69	0.71
Previous cDMARD use, n (%)	143 (65.0)	48 (57.0)
Tender joint count (0–68), mean	3.2	3.1
Swollen joint count (0–66), mean	2.6	2.8
PhGA (VAS 0–100)[a], mean	43.9	39.0
PtGA (VAS 0–100)[a], mean	51.3	45.6
Patient's Assessment of Pain (VAS 0–100)[a], mean	50.7	46.3
Dactylitis present, n (%)	32 (14.5)	14 (16.7)
Enthesitis present, n (%)	72 (32.7)	21 (25.0)
BSA ≥3%, n (%)	105 (47.7)	34 (40.5)
Nail involvement present, n (%)	148 (67.3)	53 (63.1)
HAQ-DI (0–3)[a], mean	1.02	0.84
HAQ-DI ≤0.5, n (%)	56 (25.5)	31 (36.9)
PsAID-12 (0–10)[a], mean	4.73	3.98

cDMARD, conventional disease-modifying antirheumatic drugs; VAS, visual analog scale.[a]Higher scores indicate greater burden/worse status. Early oligoarticular = ≤2 years in the initial protocol; ≤5 years in the current protocol for inclusion.

POS1081 SERUM MPO-DNA COMPLEX LEVEL CORRELATES WITH DISEASE ACTIVITY IN PSORIATIC ARTHRITIS

B. LI[1], G. LI[1], Z. Song[1], Y. Wang[1], Z. Zhang[1]. *[1]Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China*

Background: NETosis has been found to participate in the pathogenesis of many autoimmune diseases, however rarely reported in psoriatic arthritis (PsA).
Objectives: We aimed to explore the involvement of NETosis in the inflammation of PsA.

Methods: Serum MPO-DNA complex was detected by a modified enzyme-linked immunosorbent assay (ELISA) and compared among 74 patients with PsA, 58 patients with psoriasis (PsO) and 20 healthy controls. The association of MPO-DNA level with disease activity index at baseline and follow-up was analyzed in PsA patients. Receiver operating characteristic curve was used to evaluate the predictive value of MPO-DNA for treatment response.
Results: MPO-DNA complex level in serum was significantly increased in PsA/PsO patients compared to healthy controls (p<0.001). The level of MPO-DNA was positively associated with DAPSA score and its components (including TJC, SJC, PGA, EGA, VAS-pain and CRP, r=0.25-0.409, all p-value<0.05). Serum MPO-DNA level was downregualted at 12-week after treatment compared to baseline (p=0.022). The decrease of MPO-DNA level was more dramatic in PsA patients who achieved both ACR50 and PASI50 response than those achieving neither of them at 12 weeks (p=0.023). ROC analysis revealed that the serum MPO-DNA level predicted both ACR50 and PASI50 achievement at week 12 (p=0.04, 95% CIs 0.56-0.94). Moreover, the baseline MPO-DNA level (p=0.009, 95% CIs 0.748-1) and change of MPO-DNA at week 12 from baseline (p=0.004, 95% CIs 0.802-1) were associated with the achievement of both ACR70 and PASI75 response.
Conclusion: NETosis plays an important role in psoriatic diseases. The level of MPO-DNA complex in serum reflects disease activity. Serum MPO-DNA complex may be a useful biomarker to predict the therapeutic response in PsA.

Table 1. Treatment response and changes of serum MPO-DNA of 29 PsA patients.

Items	Baseline	12 weeks	24weeks
TJC, median (IQR)	3(7)	3(4)	2(3.5)
SJC, median (IQR)	2(5)	2(2)	1(3)

POS1082 **CHARACTERISTICS OF PSORIATIC ARTHRITIS (PSA) PATIENTS WITH ENTHESITIS. DATA FROM RUSSIAN PSA REGISTRY (RU-PSART).**

E. Loginova[1], T. Korotaeva[1], E. Gubar[1], Y. Korsakova[1], S. Glukhova[2], E. Nasonov[3], V. Sorotskaya[4], I. Patrikeeva[5], P. Shesternya[6], I. Shchendrigin[7].
[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, г.Москва, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [4]Medical Institute of the Tula State University, Rheumatology, Tula, Russian Federation; [5]Tyumen Regional Clinical Hospital №1, Rheumatology, Tyumen, Russian Federation; [6]Krasnoyarsk State Medical University V.F. Voino-Yasenetsky, Rheumatology, Krasnoyarsk, Russian Federation; [7]Center of Responsible Rheumatology "Induktsia", Rheumatology, Stavropol, Russian Federation

Background: Psoriatic arthritis (PsA) is a disease with multidomain clinical presentation such as arthritis, enthesitis, dactylitis, spondylitis and psoriasis (PsO). [1]. Enthesitis is a key clinical feature of PsA with significant impact on function, quality of life and choice of treatment [2]. There are limited real-world studies on the characteristics of patients (pts) with PsA and enthesitits.
Objectives: To compare clinical characteristics of PsA pts with and without enthesitis.
Methods: 603 pts (M/F=278/326) with PsA according to CASPAR criteria were examined. Data was collected from 6 rheumatology clinics of the Russian Federation. Pts' mean age 46.6±12.5 years (yrs.), PsA duration 9.7±7.1 yrs, PsO duration 20.45±13.0 yrs. Median (Me) DAPSA 25.5 [15.2; 41.8], body mass index (BMI) 27.5 [24.3; 31.2]. At baseline (BL) PsA activity by tender/swelling joint count (TJC)/68, (SJC)/66, enthesitis by LEI and plantar fascia, BSA (%), PASI, HAQ, DAPSA were evaluated. DAPSA>28 indicate high disease activity (HDA). The one-factor model of logistic regression was used to identify a group of features that are associated with presence of enthesitis. M±SD, Me [Q25; Q75], Min-Max, %, t-test, Pearson-χ^2, Manna-Whitney tests, ORs with 95% CI were performed. All p<0.05, were considered to indicate statistical significance.
Results: Enthesitis was found in 295 out of 603 pts (49%). Comparative analysis in both groups with and without enthesitis and one-factor model of logistic regression showed the following features at BL were associated with enthesitis: TJC>5 (p=0.001), SJC>3 (p=0.001), dactylitis (p=0.001), high disease activity by DAPSA (p=0.001), HAQ≥0.5 (p=0.001), BSA>10% (p=0.001), nail PsO (p=0.003), CRP>10 mg/l (p=0.018), BMI>30 kg/m^2 (p=0.02). Pts with enthesitis had significantly more often depression (p=0.026), metabolic syndrome (p=0.047), fatty hepatosis (p=0.017), OR analysis with CI 95% for all parameters are shown on Figure 1.

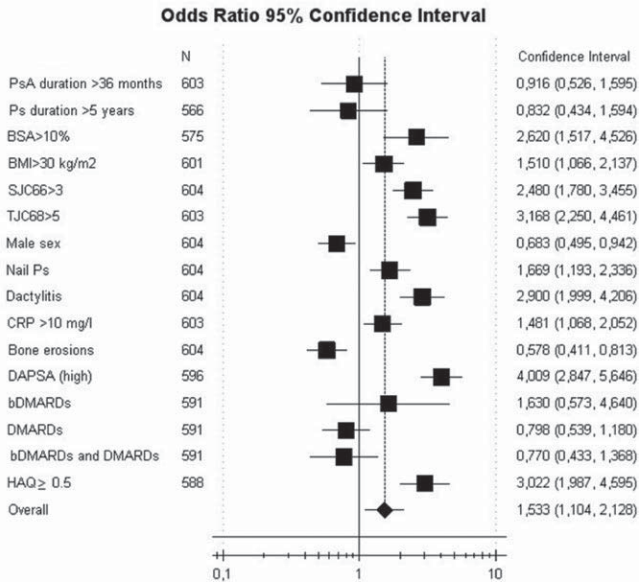

Figure 1. Factors associated with enthesitis in PsA pts.

Conclusion: In real clinical practice enthesitis was found in half of PsA pts. Enthesitis are associated with more severe peripheral arthritis, dactylitis, skin and nail PsO, higher PsA activity by DAPSA, worse quality of life and more likely to have depression, metabolic syndrome and fatty hepatosis. This should be considered for optimizing disease management strategy.

POS1083

INCREASED INTESTINAL PERMEABILITY IN PATIENTS WITH PSORIATIC ARTHRITIS CLASSIFIED AS TREATMENT FAILURES DURING THE 26-WEEK FLORA TRIAL

M. Skov Kragsnaes[1,2], J. Miguens Blanco[3], E. Chekmeneva[3], A. Salam[3], M. R. Lewis[3], J. Kjeldsen[2,4], H. C. Horn[1], H. L. Munk[1], J. K. Pedersen[5], J. Marchesi[3], T. Ellingsen[1,2]. *[1]Odense University Hospital, Department of Rheumatology, Odense, Denmark; [2]University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [3]Imperial College London Faculty of Medicine, Division of Digestive Diseases, London, United Kingdom; [4]Odense University Hospital, Department of Medical Gastroenterology, Odense, Denmark; [5]Odense University Hospital, Svendborg Hospital, Section of Rheumatology, Department of Medicine, Svendborg, Denmark*

Background: Changes in the integrity of the intestinal wall may be implicated in the gut-joint axis of inflammatory arthritis.[1] Yet, the gut barrier is only poorly evaluated in psoriatic arthritis (PsA).[2]

Objectives: In this exploratory study, we evaluated intestinal permeability before and 26 weeks after one faecal microbiota transplantation (FMT) or sham intervention in adults with PsA.

Methods: We have previously reported the clinical results of a 26-week, double-blind, parallel-group, 1:1 randomised, sham-controlled, superiority trial of gastroscopic-guided FMT as an add-on treatment to methotrexate in 31 adults with active peripheral PsA (FLORA trial, NCT03058900).[3] The primary efficacy endpoint was the proportion of participants who experienced treatment failure through 26 weeks, defined as need for more than one intra-articular glucocorticoid injection and/or anti-TNFα inhibition. We encouraged patients not to take nonsteroidal anti-inflammatory drugs during the trial. The FMT material was obtained from one of four healthy blood donors. As part of the trial, we performed a lactulose and mannitol test (L:M test) at baseline (n=31) and at the final 26-week visit (n=26) to assess the permeability of the intestinal wall (higher L:M ratios indicate higher permeability). After an overnight fasting, patients provided a urine sample before ingesting 10 g of lactulose and 5 g of D-mannitol. Samples were collected after 3 hours and stored at –80°C until analysis. No food or drinking (except for water) was allowed during the test. We measured the lactulose-to-mannitol ratio in the urine samples using a Waters Acquity UPLC system coupled to a high-resolution mass spectrometer Waters Xevo G2 QToF (Waters Corp., Milford, MA, USA). MassLynx software (Waters Corporation) was used for data acquisition and visual inspection. We used StataSE-64 to perform the Wilcoxon rank sum and the matched-pairs signed-rank test. Data is presented as median and range. The level of significance was set to 0.05.

Results: At baseline, no significant difference was observed in the L:M ratio between donors (n=4) and patients (n=31) (0.0065 [0–0.063] vs 0.014 [0–0.28]; p=0.50). The L:M ratio increased from baseline to week 26 in both the FMT (0.0020 [-0.27 – 0.32] and the sham group (0.0046 [-0.012 – 0.088]), but only in the sham group differed the baseline L:M ratio significantly from the one measured at week 26 (p=0.92 [FMT] and p=0.032 [sham]). The patients who were classified as treatment failures during the trial (n=7) had a significantly higher L:M ratio at week 26 compared to the patients who were non-failures (n=19) (0.027 [0.017 – 0.33]) vs 0.012 [0 – 0.064], p=0.01), please see Figure 1.

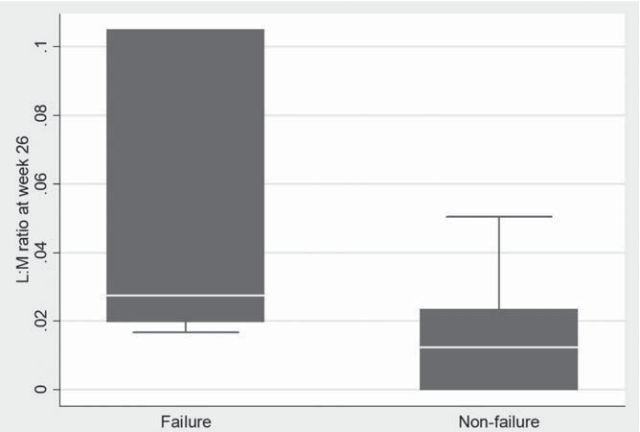

Figure 1. L:M ratios at week 26 in treatment failures (n=7) and non-failures (n=19), respectively. Higher L:M ratios indicate higher intestinal permeability.

Conclusion: In the FLORA trial, intestinal permeability evaluated by the L:M test did not differ significantly between donors and patients at baseline. Whether the higher intestinal permeability observed in patients classified as treatment failures compared to non-failures at week 26 can be attributed to differences in disease activity and/or the instigation of additional immunosuppression in the failure group during the trial needs further investigation.

POS1084

IMPACT OF PSORIASIS REMAINS IMPORTANT IN PSORIATIC ARTHRITIS PATIENTS WITH LOW MUSCULOSKELETAL DISEASE ACTIVITY

F. R. Kasiem[1], M. R. Kok[2], J. Luime[1], I. Tchetverikov[3], K. Wervers[1], J. Hazes[1], M. Vis[1]on behalf of on behalf of CICERO. *[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands; [2]Maasstad Hospital, Rheumatology and Clinical Immunology, Rotterdam, Netherlands; [3]Albert Schweitzer Hospital, Rheumatology, Rotterdam, Netherlands*

Background: Psoriatic arthritis (PsA) is a complex, chronic auto-immune disease that affects health-related Quality of Life (HRQoL). Earlier research showed that general HRQoL in PsA patients is mainly affected by musculoskeletal pain.[1] However, psoriasis has also shown to impact HRQoL.[2] Therefore, it is of value to know if HRQoL of PsA patients who reached musculoskeletal low disease activity can be further improved by additionally achieving remission of their psoriasis.

Objectives: The aim of this study was to assess HRQoL in patients with active psoriasis who reached musculoskeletal low disease activity one year after their diagnosis.

Methods: Data were collected from the Dutch south west Psoriatic Arthritis cohort. Musculoskeletal low disease activity (LDA) was defined as Disease Activity in Psoriatic Arthritis Low disease activity (DAPSA) ≤14 and active skin at baseline as Psoriasis Area and Severity Index (PASI) >0. Patients who reached DAPSA-LDA after one year were divided based on reaching psoriasis remission (PASI ≤1). General HRQoL, and dermatology-specific HRQoL were compared between both groups.

Results: We included 624 patients, of which 106 (17%) patients had no psoriasis and 518 (83%) had active psoriasis. After one year, 230 (44%) patients with active psoriasis at baseline reached DAPSA-LDA, of which 108 (47%) patients also achieved psoriasis remission. The group of patients with active psoriasis (n=122, 53%) contained significantly more men (63% vs. 48%) and scored lower on the 12-item Psoriatic Arthritis Impact of Disease questionnaire (p=0.012). This group also had significantly lower median (IQR) scores of the psychosocial subscale (1 [0-5]) and symptoms subscale (4 [2-5]) of the dermatology-specific Skindex-17 questionnaire. Clinically, this implies little impairment psychosocially and a few physical symptoms. Evaluation of the absolute scores of the Skindex-17 subscales in this group showed that 31% of patients experienced moderate to high psychosocial impairment and 28% experienced a lot of symptoms (Figure 1).

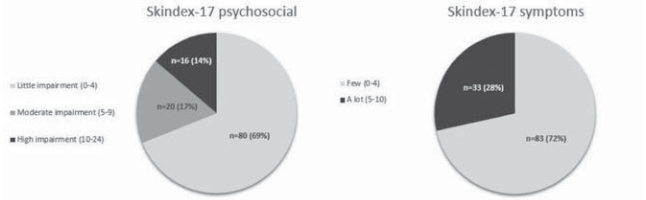

Figure 1. Clinical categories of Skindex-17 psychosocial and symptoms scores of patients with DAPSA-LDA and active psoriasis (PASI>1) one year after diagnosis (n=116)

Conclusion: In daily clinical practice approximately half of PsA patients who reached musculoskeletal low disease activity (DAPSA-LDA) one year after their diagnosis has not reached psoriasis remission. The majority of these patients has a good HRQoL. However, a proportion of them still experiences considerable skin burden. We therefore recommend rheumatologists to always assess and treat psoriasis in order to reduce skin burden, even in PsA patients who achieved musculoskeletal low disease activity.

POS1085 FREQUENCY OF DYSLIPIDEMIA AND COMPLIANCE WITH THE TREATMENT IN PSA PATIENTS USING BDMARDS

N. E. Gezerer[1], G. Ayan[2], E. Bilgin[2], G. K. Yardımcı[2], E. C. Bolek[2], B. Farisogullari[2], E. Duran[2], Z. Özsoy[2], G. Sandal Uzun[2], M. Ekici[2], E. Unaldi[2], L. Kılıç[2], A. Akdogan[2], O. Karadag[2], Ş. A. Bilgen[2], S. Kiraz[2], A. İ. Ertenli[2], U. Kalyoncu[2]. *[1]Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey*

Background: Dyslipidemia is the leading treatable-modifiable factor among comorbidities in Psoriatic arthritis (PsA) patients. International treatment recommendations have left the management of dyslipidemia to national guidelines and especially to the rheumatologists.
Objectives: In this study, we aimed to determine the frequency of dyslipidemia and the rates of initiation of treatment within the indication in PsA patients using bDMARDs.
Methods: The Hacettepe University biological database (HUR-BIO), was established in 2005 and data of 520 PsA patients included until 2021 were analyzed. In all included patients, the diagnosis of PsA was made by therheumatologist. Lipid profiles of PsA patients were evaluated at diagnosis, during the first bDMARD initiation, and at the last visit. Total cholesterol (TC), Triglyserides (TG), HDL-C and LDL-C values were grouped as optimal, borderline, high and severely high according to the Turkish Endocrine and Metabolism society criteria (1).
Results: Lipid profile values of PsA patients were known at diagnosis (n=159, 30.6%), in the initial bDMARD baseline (n=161, 30.9%), and at the last visit (n=203, 39.0%). The time to diagnosis of PsA and first bDMARD use was 2.8 years, and the time between the start of bDMARD and the last visit was 3.7 years. Accordingly, the rates of high TC, borderline TG, and high LDL increased over time. Rates at the time of PsA diagnosis, first bDMARD onset and at the last visit are as follows; high TC (14.3%, 17.1% and 28.0%), borderline TG (20.4%, 27.7% and 40.5%) and high LDL (17.0, 24.0% and 27.9%). On the other hand, low HDL-C slightly improved in men (33.3%, 29.4% and 23.1%), but did not show a significant change in women. While LDL-C level was >160 in 24.0% of patients who were started on bDMARD, anti-hyperlipidemic drug was started in only 6.2% of them. A similar situation persisted at the last visit (27.9% had LDL-C levels >160, but 10.8% received anti-hyperlipidemic therapy) (Table 1).

Table 1. Lipid levels and changes over time

Lipid levels	At the time of diagnosis n= 159	At the time of bDMARD initiation n=161	bDMARD last visit n= 203
Total Cholesterol (TC) mean (SD)	195 (42)	201 (43)	214 (47)
- TC < 200 (optimal) (%)	56.5	52.8	45.3
- TC 200-239 (borderline) (%)	27.2	30.1	25.7
-- TC > 240 (high) (%)	14.3	17.1	28.0
Triglyceride (TG) mean (SD)	115 (52)	132 (90)	158 (103)
- TG < 150 (optimal) (%)	79.6	71.7	58.0
- TG 150-499 (borderline) (%)	20.4	27.7	40.5
- TG 500-880 (high) (%)	0	0	1.0
-- TG ≥ 880 (severely high) (%)	0	0.6	0.5
HDL-C mean (SD)	51.8 (13.1)	50.6 (13.0)	53.2 (12.5)
- ≥60 (optimal) (%)	20.6	20.4	25.6
- 40-59 (borderline) in men (%)	54.6	60.8	52.3
- 50-59 (borderline) in women (%)	32.3	24.5	30.3
- Male < 40 (low) (%)	33.3	29.4	23.1
-- Women < 50 (low) (%)	32.3	39.6	33.8
LDL-C mean (SD)	126 (33)	132 (37)	139 (36)
- LDL-C < 100 (optimal) (%)	21.4	21.1	14.2
- LDL 130-159 (borderline) (%)	22.5	25.1	27.0
- LDL 160-190 (high) (%)	17.0	24.0	27.9
-- LDL > 190 (very high) (%)	4.4	6.3	8.4
Anti-hyperlipidemic drug n (%)	5 (3.1)	10 (6.2)	22 (10.8)

Conclusion: Among the modifiable risk factors for cardiovascular comorbidities in PsA patients, the leading risk factor is dyslipidemia. On the other hand, dyslipidemic drug use rates in daily practice are significantly lower. Although attention is paid to the management of comorbidities in all recommendations, there is still work to be done in real life.

POS1086 HIGH CARDIOVASCULAR RISK IN PATIENTS WITH PSORIATIC ARTHRITIS: EVALUATION OF MACROANGIOPATHY AND ITS PREDICTORS BY AORTIC PULSE WAVE VELOCITY.

K. Triantafyllias[1], S. Liverakos[1], A. Klonowski[2], A. Schwarting[1,2]. *[1]Rheumatology Center Rhineland-Palatinate, Rheumatology, Bad Kreuznach, Germany; [2]Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany*

Background: Systemic inflammatory rheumatic diseases are associated with macroangiopathy and increased cardiovascular (CV) risk [1, 2]. Psoriatic arthritis (PsA) has also been associated with an increased risk of CV events. However, data on diagnostic CV markers in PsA are scarce. Carotid-femoral pulse wave velocity (cfPWV; oscillometric diagnostic method) is considered to be the gold standard evaluation method of aortic stiffness and is used in the general population to assess CV risk (Figure 1). Moreover, EULAR and the European Society of Cardiology (ESC) recommend the use of Systematic Coronary Risk Evaluation (ESC-SCORE) in order to screen and classify patients regarding CV risk.

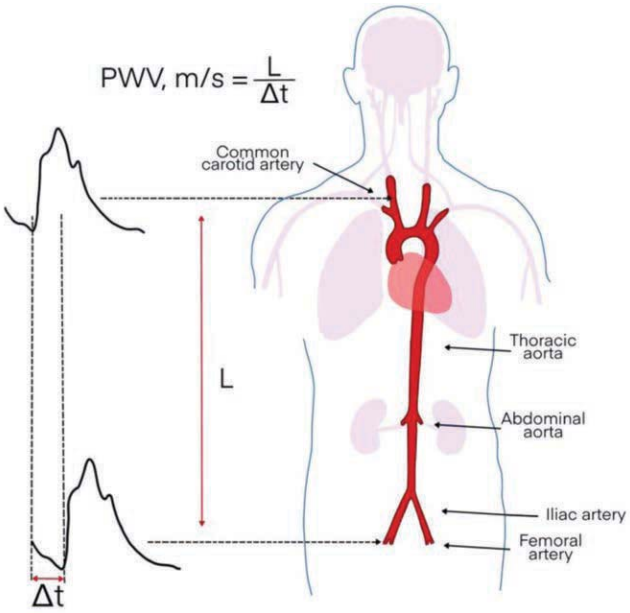

Figure 1. Measurement of aortal pulse wave velocity: pulse waves of carotid and femoral artery (Δt: time, L: distance between the two arteries, m/s: meters/second), modified after [3].

Objectives: Aim of this study was to evaluate aortic stiffness and CV risk in patients with PsA based on measurements of cfPWV and ESC-SCORE. Moreover, we sought to investigate associations of cfPWV with patient- and disease-associated characteristics, as well as with traditional CV risk factors.
Methods: cfPWV measurements were performed in patients with PsA from two large rheumatological medical departments in Germany, according to the classification criteria for psoriatic arthritis (CASPAR), and in healthy control subjects. In addition to assessing cfPWV, clinical and laboratory parameters were evaluated, traditional CV risk factors were documented, and the ESC-SCORE was determined. Differences in cfPWV measurements between the two groups and associations between cfPWV and patient- or disease-associated characteristics were

examined statistically (correlation analyses, Mann-Whitney-U-Tests, ANOVA and multivariate regression analyses).
Results: 112 patients with PsA [55.45%♀, median age: 55 years, IQR 47-63] and 88 healthy control subjects [81%♀, median age: 51 years, IQR 36.5-58] were recruited. cfPWV was significantly higher in PsA patients compared to the healthy control subjects ($p < 0.001$), even after the adjustment for the effect of confounding factors. In both the patient and the control group, cfPWV correlated with age ($r = 0.560$, $p < 0.01$ and $r = 0.638$, $p < 0.01$, respectively). In addition, cfPWV showed a moderate significant correlation with the ESC-SCORE ($r = 0.280$, $p = 0.22$) and a weak significant association with mean arterial pressure (rho =0.19, $p = 0.043$) in the patient group. No statistical associations could be found between cfPWV and lipid levels, CRP levels or DAS28 (all; $p>0.05$). Moreover, no significant differences regarding cfPWV measurements could be observed between patients with and without active disease.
Conclusion: This is one of the largest CV surrogate marker studies in patients with PsA. We were able to show that PsA patients had significantly higher aortic stiffness values, and thus, a higher CV risk compared to healthy individuals. Therefore, cfPWV could be a useful tool for the identification of PsA patients at high-risk. The fact that aortic stiffness can be predicted by mean arterial pressure and ESC-SCORE could assist forming therapeutic strategies that would promote artery de-stiffening and thus CV risk lowering.

POS1087 THE RELATIONSHIP BETWEEN CHANGES IN PSORIATIC ARTHRITIS DISEASE ACTIVITY AND COMORBIDITIES IN PATIENTS TREATED WITH BDMARDS

G. Ayan[1], N. E. Gezerer[1], E. Bilgin[1], G. K. Yardımcı[1], E. C. Bolek[1], B. Farisogullari[1], E. Duran[1], Z. Özsoy[1], G. Sandal Uzun[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdogan[2], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. *[1]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; [2]Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey*

Background: Comorbidities are common in psoriatic disease, needed to be recognized and managed to effectively when treating psoriatic arthritis (PsA) patients. However, the data on the impact of particular comorbidities on the disease activity in patients requiring bDMARDs are very small.
Objectives: Our aim was to understand the relationship between the disease activity and comorbidities in PsA patients under bDMARDs.
Methods: The Hacettepe University biological database (HUR-BIO), was established in 2005 and data of 520 PsA patients included until 2021 were analyzed. In all included patients, the diagnosis of PsA was made by the rheumatologist. DAS-28 score (at the last visit) and all comorbidities were documented after bDMARD initiation. Multivariate analysis was performed to understand comorbidities that have impact on DAS-28 remission.
Results: There were 469 patients with a known DAS-28 score median (IQR) 28 (61) months after bDMARD initiation. It was detected in 214/469 (45.6%) patients with a DAS-28 score below 2.6. Patients in remission of DAS-28 were younger, remission was less frequent in women, and comorbidities, mainly BMI, Diabetes Mellitus (DM) and hypertension, were also found less frequent (Table 1). In the multivariate analysis, no determining factor was found in male gender. On the other hand, in females, smoking, presence of comorbidity, Body mass index (BMI) at the start of bDMARDs, age at onset of bDMARDs, DM at the start of bDMARDs, HT at the start of bDMARDs, coronary artery disease, and cardiovascular risk factors were included in the analysis and revealed, bDMARD baseline BMI [OR 1.06 (95% CI 1.02-1.11), p= 0.004] and presence of bDMARD baseline DM [OR 3.08 (95% CI 1.14-8.30), p=0.026] had significant impact on DAS-28 remission.

Table 1. Relationship between remission according to DAS-28 score and comorbidities

Parameters	DAS-28 ≤ 2.6 (n=214)	DAS-28 > 2.6 (n=255)	p
Age, mean (SD), years	43.8 (11.7)	47.5 (12.5)	**0.001**
Age at PsA diagnosis, mean (SD), years	36.8 (11.5)	41.6 (11.7)	**<0.001**
Gender, female, n(%)	115 (53.7)	211 (82.7)	**<0.001**
Comorbidity count	1.54 (0.98)	1.98 (1.31)	**<0.001**
Comorbidity (yes/no)	67 (31.9)	118 (47.6)	**0.001**
Comorbidity distribution			**0.001**
-No	143 (68.1)	130 (52.4)	
-1 Comorbidity	38 (18.1)	47 (19.0)	
-≥ 2 Comorbidity	17 (8.1)	36 (14.5)	
-≥ 3 Comorbidity	12 (5.7)	35 (14.1)	
Body Mass Index (BMI)	28.1 (5.4)	30.3 (5.9)	**<0.001**
BMI > 30, n(%)	70 (32.9)	123 (48.4)	**0.001**
Diabetes Mellitus, n(%)	10 (4.7)	35 (13.7)	**0.001**
Hypertension, n(%)	29 (13.6)	71 (27.8)	**<0.001**
Total cholesterol > 240, n(%)	8 (10.5)	22 (28.6)	**0.019**
Thyroid Disease	20 (9,8)	43 (17,3)	0,02

Conclusion: Previous data showed that obesity, hypertension and at least 1 point from charlson comorbidity index are poor prognositc factors for treatment outcomes (1). Our data showed that BMI and presence of DM were determined as factors affecting bDMARD treatment response in female PsA patients.

POS1088 CHALLENGES IN THE MANAGEMENT OF PSORIATIC ARTHRITIS IN LATIN AMERICA: A SYSTEMATIC REVIEW

A. Ribeiro[1], L. Dullius[1], N. Sartori[1], A. Azeredo-Da-Silva[2], O. Monticielo[1], C. Kohem[1], L. Coates[3], P. Palominos[1]. *[1]Hospital de Clínicas de Porto Alegre, Rheumatology, Porto Alegre, Brazil; [2]Hospital de Clínicas de Porto Alegre, Internal Medicine, Porto Alegre, Brazil; [3]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Rheumatology, Oxford, United Kingdom*

Background: In 2020, the International League of Associations for Rheumatology (ILAR) recommendations for management of psoriatic arthritis (PsA) were published. This aimed to adapt GRAPPA and EULAR recommendations to resource-poor settings. At that time, the paucity or absence of clinical studies endorsing the management of PsA patients in Latin America was remarked on by the international working group. Despite several challenges faced by patients and physicians in resource-poor countries, the literature on this theme is scarce.
Objectives: To recognize the main challenges on the management of PsA in Latin America described in recent publications.
Methods: A systematic literature review of clinical trials reporting at least one challenge/difficulty on the management of PsA in Latin America was conducted following PRISMA statements. References published in English, Spanish, French and Portuguese language and published in PubMed, Embase, and LILACS between 1980 and 2020 were included. The selection of references was conducted independently by two researchers in Rayyan QCRI program. Data were independently extracted by two reviewers. The Cochrane tool was used to assess the quality of studies. All challenges were noted and categorized into domains. Data analysis was descriptive.
Results: The search strategy resulted in 1505 references. Sixteen studies (15,145 PsA patients) were included in the final analysis: most were performed in Brazil (81.2%, N=13), recruited patients on biological therapy (75.0%, N=12) and were observational studies (87.5%, N=14). Difficulties faced by PsA patients and physicians in Latin America were the high incidence of opportunistic infections (described in 43.7% of publications, N=7), non-adherence to therapy (18.7%, N=3), discordance between patients and physicians regarding remission rates (18.7%, N=3), limited access to DMARDs (12.5%, N=2), issues related to the storage of biological drugs (12.5%, N=2), high impact of PsA on work and productivity (12.5%, N=2), elevated cost of biological drugs (12.5%, N=2), low drug persistence (6.2%, N=1), limited access to medical care (6.2%, N=1) and diagnostic delay (6.2%, N=1).
Conclusion: The challenges in the management of PsA in Latin America go beyond the care of opportunistic infections: special attention should be paid to logistical questions (e.g., correct medication storage, access to drugs and

medical care) and educational problems (e.g., importance of adherence, patients understanding of disease and therapy)

POS1089 HLA-CW6 ALLELE AND BIOLOGICAL TREATMENTS ARE PROTECTIVE FACTORS AGAINST LIVER FIBROSIS IN PSORIATIC ARTHRITIS PATIENTS

C. Macía-Villa[1], J. L. Morell Hita[2], M. Revenga[2], C. Díaz-Miguel[2]. *[1]Hospital Severo Ochoa, Rheumatology, Leganés, Spain; [2]Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Non-alcoholic fatty liver disease can be expressed from an indolent steatosis, evolve to steatohepatitis and eventually evolve to liver fibrosis. This spectrum of non-alcoholic inflammatory liver disease is increased in psoriasis and psoriatic arthritis (PsA). To date, the relationship between non-alcoholic liver fibrosis and genetics in PsA has not been studied.

Objectives: The objective of our study is to evaluate the association between the HLA-Cw6 allele and the FIB-4 (fibrosis-4) index in patients with PsA.

Methods: Retrospective longitudinal study in patients older than 18 years with PsA according to CASPAR criteria with determination of the HLA-Cw6 allele. To estimate liver fibrosis, the FIB-4 index was obtained, calculating it at the onset of PsA and at the last available visit. A descriptive analysis of the variables was carried out using mean and standard deviation (SD) for those with symmetric distribution, and median and interquartile range (IR) for the asymmetric ones. Qualitative variables were described using absolute values and percentages. A bivariate analysis was carried out using parametric and non-parametric hypothesis contrast tests to determine the association between the main variable (current FIB-4) and the secondary variables. Bivariate correlations were analyzed using Pearson's coefficient. A multivariate model was developed to assess the association between HLA-Cw6 and liver fibrosis adjusted for potential confounding factors, and results were presented as Odds Ratio (OR) with 95% confidence interval (CI) and level of statistical significance p-value=0.05. The statistical program SPSS version 20 was used. The study was approved by the local committee.

Results: 209 patients with PsA were included (56.9% men, mean age 42.72±14.24 years), 84.7% with psoriasis, and median (IR) ESR (mm/h) of 16.9(9-28) and CRP (mg/l) 5.0(2.52-12.25). 74.3% of patients were HLA-Cw6 negative. 79.4% of patients were receiving treatment with MTX, and 59.8% biological therapy. Regarding comorbidities, 29.6% had hypertension, 24% dyslipidemia, 10.1% diabetes, and 4.2% acute myocardial infarction. FIB-4 could be calculated in 154 patients at the onset of PsA, with a mean of 1.53±9.05 points, being 58.9% of patients at FIB-4 F0-1 (non advanced fibrosis, <1, 30 points). At the last available visit, FIB-4 could be calculated in 180 patients, mean of 1.35±0.85 points, 86.4% of the patients at FIB-4 F0-1. Table 1 shows bivariate analysis and Table 2 the multivariate one.

Table 1. Bivariate analysis of the main variable (current FIB-4) categorized into normal (result F0-1, non advanced fibrosis, <1.30 points) and altered (result F2-3-4, intermediate zone and significant fibrosis, >1.3 points). [1]Median (IR) [2]Mean±SD. * p-value < 0.05. AMI acute myocardial infarction.

	Normal current FIB-4 (N = 106)	Altered current FIB-4 (N = 74)	p value
HLA-Cw6 (%)	18.54	6.74	0.024 *
ESR (mm/h)[1]	16 (9-32)	10 (6-19)	0.362
CRP (mg/l)[1]	5.31 (2.41-12.97)	3.30 (2.11-9.00)	0.348
PsA age onset (years)[2]	37.33±11.71	51.53±12.33	0.630
Male sex (%)	60.4	39.6	0.627
Biologic (%)	64.3	35.7	0.059
Methotrexate (%)	56.8	43.3	0.211
Leflunomide (%)	60	40	0.915
Psoriasis (%)	58.9	41.1	0.648
Hypertension (%)	42.2	57.8	0.002 *
Diabetes (%)	40	60	0.079
AMI (%)	16.7	83.3	0.023 *
Dyslipidemia (%)	45.9	54.1	0.030 *

Table 2. Multivariate analysis. * p-value < 0.05.

Variable	OR (IC 95%)	p value
HLA-Cw6	0.210 (0.062-0.707)	0.012 *
Male sex	1.553 (0.624-3.864)	0.344
Hypertension	2.973 (1.125-7.858)	0.028 *
Diabetes	1.478 (0.395-5.530)	0.561
Dyslipidemia	1.429 (0.541-3.773)	0.471
Methotrexate	1.113 (0.357-3.466)	0.854
ESR at onset (mm/h)	0.993 (0.967-1.019)	0.605
AMI	6.302 (0.495-80.246)	0.156
Biologic	0.397 (0.166-0.949)	0.038 *

Conclusion: In our study, having the HLA-Cw6 allele and receiving biological treatment behaved as a protective factor for liver fibrosis in PsA, while arterial hypertension was an independent risk factor. The presence of psoriasis was not related to hepatic fibrosis measured by FIB-4.

POS1090 THE IMPACT OF NUMBER OF COMORBIDITIES ON ACHIEVEMENT REMISSION OR LOW DISEASE ACTIVITY BY DAPSA IN PSORIATIC ARTHRITIS. DATA FROM THE RUSSIAN OBSERVATIONAL COHORT

Y. Korsakova[1], E. Gubar[1], E. Loginova[1], T. Korotaeva[2], V. Sorotskaya[3], I. Patrikeeva[4], P. Shesternya[5], I. Umnova[6], E. Nasonov[7]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation; [2]Medical Institute of the Tula State University, Medical Institute of the Tula State University, Tula, Russian Federation; [3]Medical Institute of the Tula State University, Rheumatology, Tula, Russian Federation; [4]Tyumen Regional Clinical Hospitai №1, Rheumatology, Tyumen, Russian Federation; [5]Krasnoyarsk State Medical University V.F. Voino-Yasenetsky, Rheumatology, Krasnoyarsk, Russian Federation; [6]Omsk region "Regional clinical hospital», Rheumatology, Omsk, Russian Federation; [7]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: The goal of psoriatic arthritis (PsA) treatment is achievement remission (REM) or Low Disease Activity (LDA) by DAPSA. The impact of comorbidities, especially obesity, metabolic syndrome on PsA activity and on biological treatment response are shown in some registry [1]. Obesity, hypertension and Charlson Comorbidity Index ≥1 are prognostic factors for poorer treatment outcome rates in PsA [2]. But influence of number of comorbidities on treatment response has not been fully studied in real practice

Objectives: To evaluate the impact of number of comorbidities on achievement remission by DAPSA in PsA pts

Methods: 528 pts (M/F=256 (48.5%)/272 (51.5%) with PsA according to CASPAR criteria were included in the Russian observational cohort. Mean age 48.7±12.33 years (yrs.), PsA duration 122.6±81.85 months (mo.), psoriasis (Ps) duration 239.0±155.45 mo. Pts who completed ≥2 visits were analyzed. Mean observational period 73.6±83.47 mo. All pts underwent standard clinical examination: tender joint count (TJC)/68, swollen joint count (SJC)/66, Pain (VAS), Patient global assessment of disease activity (PtGA, VAS), CRP mg/l, BSA (%), BMI, HAQ, comorbidities by ICD-10, X-ray of hands and foods. DAPSA>28 indicates as high disease activity (HDA), >14-28 - moderate activity (MoDA), >4-14 – LDA, ≤4 – REM. Analyses were performed based on number of comorbidities: 1st group (gr) - without comorbidities, 2nd gr – pts with 1 comorbidity, and 3rd gr – pts with ≥ 2 comorbidities. M±SD, %, t-test, Pearson-χ^2, ORs with 95% CI were calculated. All p<0.05 were considered to indicate statistical significance

Results: In 236 out of 528 (44.7%) pts no comorbidity found, in 145 out of 528 (27.5%) found 1 comorbidity and 147 out of 528 (27.8%) pts had ≥ 2 comorbidities. Comparative analysis in groups showed the following features: pts of 3rd gr were significantly more often females, had longer Ps and PsA duration, they were older, had worse HAQ, higher BMI, TJC (p<0.05). Joint erosions were found significantly more often in the 2nd gr compared to the 1st gr (p=0.02). No significant differences were in the frequency of axial PsA (p=0.906), Ps severity (BSA>10%) (p=0.237), the number of pts receiving bDMARDs (p=0.078). REM/LDA achievement according to DAPSA was significantly lower in the 3rd gr (15 (10,2%)/69(46.9%) comparing to the 1st gr (62 (26,3%)/94 (39.8%), and to the 2nd gr (32 (22,1%)/69 (47.6%) (p=0.007). The probability of achieving REM/LDA is 1.6 times lower in the gr of pts with ≥2 comorbidities compared to the gr of pts without comorbidities (OR 0.608, 95% CI 0.394 to 0.936) and 1.3 times lower compared to gr of pts with 1 comorbidity (OR 0.789, 95% CI 0.489 to 1.243) (Figure 1)

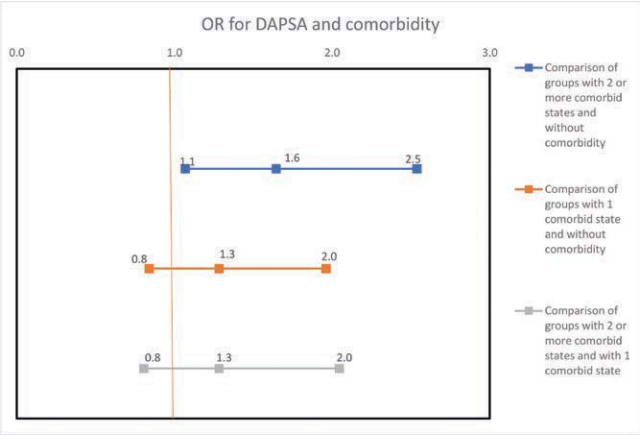

Figure 1. Chances of REM/LDA achievement in pts with ≥2 comorbidities compared to pts with 1 comorbidity and pts without comorbidities

Conclusion: In real clinical practice comorbidities were seen in more than half PsA pts. Third of PsA pts had number of comorbidities. PsA pts with number of comorbidities are associated with high disease activity, reduced quality of life and are 1,6 times more likely to have no chance to attain REM/LDA by DAPSA. It should be considered for personalized treatment

POS1091 LESS RADIOGRAPHIC SPINAL DAMAGE IN PSORIATIC ARTHRITIS PATIENTS COMPARED TO SPA PATIENTS

M. De Hooge[1,2], A. Ishchenko[3], A. S. De Craemer[1,2], S. Steinfeld[4], A. Nzeusseu Toukap[5], D. Elewaut[1,2], R. Lories[3,6], F. Van den Bosch[1,2], K. De Vlam[3,6].
[1]Ghent University Hospital, Rhematology, Gent, Belgium; [2]VIB-UGent, Center for Inflammation Research, Gent, Belgium; [3]University Hospitals Leuven, Rheumatology, Leuven, Belgium; [4]Clinique St Jean,, Brussels, Belgium; [5]St Luc University Hospitals, UCLouvain, Rheumatology, Leuven, Belgium; [6]KULeuven Skeletal Biology and Engineering Research Center, Development and Regeneration, Leuven, Belgium

Background: Psoriatic arthritis (PsA) is an inflammatory joint disease that is traditionally included in the Spondyloarthritis (SpA) spectrum. Prevalence and impact of axial involvement in PsA remain understudied but increasingly affect treatment decisions.

Objectives: A step towards fathoming this issue is to report on baseline radiographic spinal damage in PsA and SpA patients (pts) from 2 prospective multicentre cohort studies in private and academic rheumatology practices.

Methods: Data on PsA pts were from the Belgian Epidemiological Psoriatic Arthritis Study (BEPAS); prospective multicentre cohort in 17 Belgian rheumatology practices. Recruitment was Dec2012-Jul2014. Pts were included when fulfilling the Classification criteria for Psoriatic Arthritis (CASPAR). SpA pts were from a Belgian observational cohort (Be-Giant) of SpA pts fulfilling the ASAS SpA classification criteria. Radiographs of the spine were obtained at baseline and after 2 years. Two calibrated readers evaluated radiographic damage by assessing modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Readers were blinded for time sequence, clinical data and information from other obtained images (radiographs of hands, feet, sacroiliac joints). Consensus scores are described.

Results: In total 461 pts were included in BEPAS. Mean age was 52.79±12.29 years and 43.0% (n=198) were female; average disease duration was 8.5 ± 9.3 years and approximately 34% of the pts reported inflammatory axial pain. From 312 pts spinal radiographs were obtained. At baseline, the vast majority of PsA pts had an mSASSS of 0 (n=273, 87.5%), according to both readers. In 33 PsA pts (10.6%) mSASSS was 2 or more. For the SpA pts percentages were lower but the trend was similar (see Figure 1). Though lesser pts showed abnormalities, the SpA pts with spinal damage show a higher mSASSS, therefore indicating more spinal damage then the PsA pts ($p<0.05$). Both patient groups show some outliers with high mSASSS, increasing the average mSASSS especially in the SpA cohort (mean mSASSS = 9.1±14.11) compared to the median of 3 (IQR 2-6) in both cohorts Syndesmophytes are seen in 10.6% and 6.2% of the PsA and SpA pts, respectively. Similar to the mSASSS, SpA pts had more syndesmophytes (mean: 4.4±5.50) compared to PsA pts (mean 2.0±1.45); $p<0.05$. PsA pts had more often syndesmophytes located in the cervical spine (24/35, 68.6%) compared to the SpA patient group (9/21, 42.9%); $p<0.05$. Erosions and especially sclerosis and squaring are uncommon in both patient groups.

Conclusion: Spinal damage is seen in approximately 10% or less of both PsA and SpA pts in these cohorts. SpA pts show higher mSASSS values and more syndesmophytes as compared to the PsA pts. Syndesmophytes in PsA pts are more often located in the cervical spine while the location is more equally distributed in SpA pts.

Background: Obesity is over-represented in patients with psoriatic arthritis (PsA) and associated with increased disease activity. We have previously shown that weight loss treatment with Very Low Energy Diet (VLED) in patients with PsA and obesity was associated with a sustained weight reduction and significant improvement of the disease activity in joints, entheses and skin during 24 months follow-up. A side effect with a large weight loss is however a concomitant reduction of muscle mass, which can negatively affect physical fitness.
Objectives: This study aimed to evaluate the effects of weight loss treatment on physical fitness i.e., muscle strength, cardiorespiratory fitness, body composition and self-reported physical functioning, in patients with PsA and obesity compared to matched controls undergoing the same treatment.
Methods: In total, 46 patients with PsA (Caspar criteria) and obesity and 52 controls (matched for age, sex, body weight and height) were included. VLED (640 kcal/day) was provided to all participants for 12-16 weeks depending on baseline BMI (<40 or ≥40 kg/m^2), followed by reintroduction of energy restricted diet. Brief support for physical activity was given. Primary outcome was muscle strength, assessed in hand-grip with a dynamometer (Grippit) and in leg muscle by measuring the time (seconds) needed to stand up ten times from a standard chair (Timed Stand Test: TST). Secondary outcomes were cardiorespiratory fitness (O_2 l/ min), measured with the Åstrand's submaximal bicycle test, body composition analyzed with dual energy x-ray absorptiometry and physical functioning, assessed with the Short Form 36 Health Survey Physical Component Score (SF-36PCS). Outcomes were evaluated at baseline (BL), six (M6) and 12 months (M12).
Results: In total, 41 PsA patients (median age 54; 63% women) and 42 controls (median age 54; 74% women) completed the treatment. At M6 the median weight loss since baseline in patients and controls was 18.9 kg and 23.0 kg respectively (p=0.546), and at M12 16.1 kg and 16.6 kg (p=0.885). Significant changes (all p<0.001) were seen at M12 in the body composition of both patients and controls, with decreases in total fat mass (-30.1% vs. -27.4%), total lean mass (-7.0 % vs -8.3 %), lean arm mass (-13.7% vs -2.4%) and lean leg mass (-6.0% vs -8.6%). Leg muscle strength did however improve in both patients and controls at M6 (p<0.001) and remained improved at M12 (p=0.001 and p<0.001), while hand-grip strength was unchanged in both groups. Cardiorespiratory fitness increased in controls at M6 (p=0.018) and M12 (p=0.028), but not in the patients. Physical functioning improved in both groups at M6 and remained improved at M12.
Conclusion: Patients with PsA and obesity can benefit from weight loss treatment without risk of deterioration in muscle strength. However, muscle strength and cardiorespiratory fitness were below suggested normative values for the majority of the patients at all timepoints, implying that more structured exercise strategies might be warranted to counteract physical fitness deficiencies in patients with PsA undergoing weight loss treatment.

POS1093

EFFECT OF DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ON DEPRESSION IN PATIENTS WITH PSORIATIC ARTHRITIS IN A LONGITUDINAL COHORT

A. J. Mathew[1,2], M. Sutton[2], D. Pereira[2], D. D. Gladman[2], V. Chandran[3].
[1]Christian Medical College, Department of Clinical Immunology and Rheumatology, Vellore, India; [2]Centre for Prognosis Studies in the Rheumatic Diseases, Psoriatic Arthritis Program, Schroeder Arthritis Institute, Krembil Research Institute, University Health Network, Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, Canada; [3]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network, Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, Canada

Background: Depression, and its improvement with disease modifying anti-rheumatic drugs (DMARDs) is understudied in psoriatic arthritis (PsA).
Objectives: To determine the effectiveness of DMARDs on depression in PsA patients.
Methods: Patients enrolled from January 2000 to May 2020 in a large PsA cohort were included. Depression was defined as medical outcomes study short form-36 (SF-36) mental component summary score (MCS) ≤ 40 or mental health (MH) subscale score ≤ 56. Primary outcome was resolution of depression within 1 year of DMARDs, defined by two definitions: 1) MCS > 40 and/or MH subscale score of > 56; 2) Increase in MCS by 2.5 and MH subscale score by 5, the minimal clinically important difference (MCID). Baseline medications [non-steroidal anti-inflammatory drugs (NSAIDs) and/or conventional or targeted (c/t) DMARDs] were recorded for all patients and stratified into 3 mutually exclusive ordinal categories: I-No treatment/NSAIDs; II-cDMARDs±NSAIDs without tDMARDs; III-tDMARDs±cDMARDs/NSAIDs. Univariable and multivariable logistic regression models were created to determine the association between medications and resolution of depression, after controlling for age, sex, disease duration and baseline MCS/MH subscale score.
Results: Based on the MCS and MH subscale score definitions, 608 (48%) and 655 (52%) of the 1270 patients, respectively were depressed at baseline. 374 (50.8% males) and 399 (52.4% males) patients were followed up in the groups defined by MCS and MH subscales, respectively for 1 year. Patients in both groups had comparable body mass indices, baseline psoriasis area and severity index and active joint count. Mean MCS and MH subscale scores (standard deviation) were 33.2 (5.2) and 46.0 (10.2). A mean of 11.9 and 11.7 months was noted for resolution of depression in the MCS based analysis and MH subscale-based analysis groups, respectively. More patients achieved resolution of depression based on definition 2 (MCS, 64.7%; MH, 62.2%) as compared to definition 1 (MCS, 54.5%; MH, 53.9). The proportion of patients on each category of medications in both models is shown in the Figure 1. Table 1 depicts the univariate and multivariable regression results by both the definitions of primary outcome in the MH subscales model. The global p-value for medication categories showed a trend towards significance in both models using definition 2. There was a trend towards higher likelihood of response when comparing patients in treatment category III vs category I. A significant response was noted when comparing patients in category III with category II as reference (OR 1.71; 95% CI 1.05-2.76; p 0.03). No significant effect of treatment category on depression was noted using definition 1.

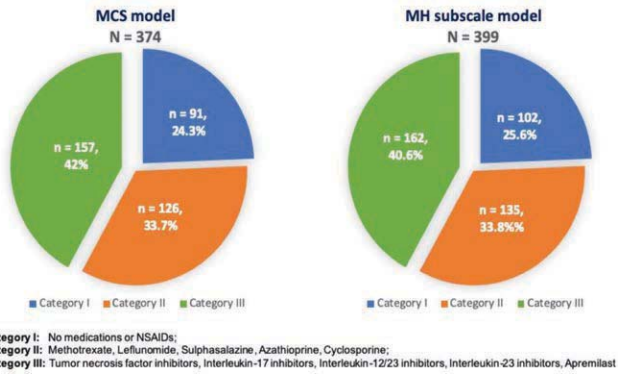

Figure 1. Patients in each drug category.

Conclusion: In an observational setting, resolution of depression occurs in majority of patients with PsA within 1 year. Patients on t-DMARDs may experience better improvement in depression compared to other treatments. Future effectiveness studies warrant better definitions of depression and treatment response.

POS1094 CORRELATION OF FLUORESCENCE-OPTICAL IMAGING AND PHYSICIAN TJC/SJC ASSESSMENT AND ULTRASOUND IN PSORIASIS PATIENTS WITHOUT ARTHRITIS BUT MUSCULOSKELETAL COMPLAINTS WITHIN THE LAST 6 MONTHS

M. Köhm[1,2,3], S. Ohrndorf[4], X. Baraliakos[5,6], K. Hallmann[2,3], S. Kempinski[5,6], A. C. Foldenauer[2,3], T. Rossmanith[2,3], U. Henkemeier[2,3], F. Behrens[1,2,3]. *[1]University Hospital Frankfurt, Rheumatology, Frankfurt, Germany; [2]Fraunhofer-Institute for Translational Medicine & Pharmacology ITMP, Clinical Research, Frankfurt, Germany; [3]Fraunhofer Excellence Cluster for Immune-Mediated Diseases CIMD, Clinical Research, Frankfurt, Germany; [4]Charité Universitätsmedizin, Rheumatology, Immunology, Berlin, Germany; [5]Ruhr-Universität Bochum, Rheumatology, Bochum, Germany; [6]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*

Background: Psoriasis (PsO) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to PsO; up to 40% of PsO patients develop PsA. The transition from PsO to PsA includes different stages with unspecific clinical symptoms such as fatigue or musculoskeletal (MSK) symptoms as well as changes in synovial vascularization combined with increased expression of proangiogenic factors [1]. Fluorescence-optical imaging (FOI, [Xiralite]) is an easy-to-use method to detect changes in microvascularisation of the hands.

Objectives: To compare findings from FOI assessment to clinical examination (SJC/TJC) and musculoskeletal ultrasound in patients (MSUS) with non-specific MSK-symptoms and changes in microvascularisation without evidence of clinical active PsA.

Methods: The German multicentre observational XCITING study recruited patients with dermatological confirmed PsO at risk for development of PsA (either nail psoriasis or MSK symptoms such as joint pain or swelling within the last 6 months). Clinical examination (CE; swollen (66) and tender (68) joint count, enthesitis, dactylitis assessment), standardized MSUS and FOI assessment were performed by a qualified rheumatologist at one time point with focus on the question of presence of PsA. Data were analyzed in focus on increased vascularization of MSK structures of both hands as marker of inflammation. The patients at-risk for PsA development but without clinically active PsA (CE negative, FOI positive) were analyzed. Results from CE of joints, MSUS and FOI were compared.

Results: 391 PsO patients were recruited for the XCITING study in total. 108 patients (27.6%) were identified as at-risk population (CE negative, FOI positive). Baseline characteristics included a mean age of 51.4 years (SD 11.3), 61.1% female, mean BMI 27.8 kg/m2 (SD 5.2), mean age of onset PsO 30.4 years (SD 17), mean duration of PsO of 16.9 years (SD 14.4), mean PASI 4.3 (SD 5.8) and mean patient's global disease activity for PsO of 24.4mm (SD 21.1). In 24.1% psoriasis plaques on the hand were documented. Pattern for frequency of scores in FOI, CE and MSUS in the dominant hand were compared (Figure 1). Frequency of swollen joints and synovitis with power Doppler activity (PD Mode) was very low in these patients whereas TJC, detection of synovitis in MSUS and FOI signals were detected in overlapping regions at the hands, showing high correlation. The highest correlation is found between TJC and FOI (Figure 1).

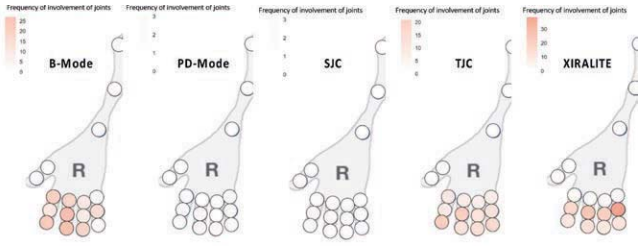

Figure 1. Overview of frequency of involvement in joints for the different assessments (MSUS, SJC/TJC and FOI)

Conclusion: FOI signals in the hands correlate to the findings of TJC (and B-Mode US) in the clinical examination indicating early stages of MSK inflammation that may result in active PsA development. FOI as standardized and easy-to-use technique might be a suitable tool for early detection of PsA in Psoriasis population. A follow up in these patients will reveal prediction values of the method.

POS1095 RELATIONSHIP BETWEEN PLASMA IL-12, IL-23 LEVELS AND ENDOTHELIAL DYSFUNCTION IN PATIENTS WITH PSORIATIC ARTHRITIS

B. Gokce Ozcan[1], T. Pirildar[2], C. Ulman[3], M. Farasat[4]. *[1]Tepecik Research and Training Hospital, Department of Internal Medicine, Izmir, Turkey; [2]Manisa Celal Bayar University, Department of Internal Medicine, Division of Rheumatology, Manisa, Turkey; [3]Manisa Celal Bayar University, Biochemistry, Manisa, Turkey; [4]Manisa Celal Bayar University, Radiology, Manisa, Turkey*

Background: Psoriatic arthritis (PsA) is a heterogeneous, chronic, inflammatory spondyloarthropathy associated with psoriasis. PsA is accompanied by many comorbidities, especially hypertension, metabolic syndrome, obesity, hyperlipidemia and cardiovascular diseases (CVD) (1). Mediators that cause chronic inflammation such as IL-23R, IL-17, IL-12B are thought to play an important role in the pathogenesis of both PsA and its comorbidities (2,3).

Objectives: The aim of our study was to compare plasma levels of IL-12 and IL-23 with endothelium-dependent (FMD) and independent dilatation (NMD) measurements in psoriatic arthritis (PsA), ankylosing spondylitis (AS) patients and healthy controls and to look for the relationship of IL-12, IL-23 with FMD, NMD, clinical findings, laboratory parameters and disease activity scores of patients.

Methods: A total of 136 subjects (49 patients with PsA, 46 patients with AS and 41 healthy controls) were included in the study. Subjects were evaluated with detailed anamnesis and physical examination. The routine biochemical parameters, CRP, ESR of all subjects and disease activity scores of all patients were noted. IL-12 and IL-23 were measured using ELISA method. Endothelial-dependent and independent dilatations were measured by Doppler USG on the brachial artery.

Results: Though IL-12 levels were higher in the PsA group when compared with the healthy group, this difference was not statistically significant. IL-23 levels were significantly higher in PsA patients when compared with the healthy control group (Table 1). IL-12 and IL-23 levels were found to be significantly higher in the AS group compared with the healthy group. A statistically significant difference in endothelial dependent measures were found between PsA patients and healthy controls. No statistically significant correlation was found between IL-12, IL-23 levels and brachial artery basal diameter, FMD, NMD values in PsA patients. Fasting blood glucose and triglyceride levels were higher in PSA patients, while CRP and ESR were higher in AS patients. HDL levels of healthy controls were higher than those of PSA and AS patients. There was no significant correlation between IL-12, IL-23 and BASDAI, BASFI, DAPSA, DAS 28, PsAQoL, HAQ, HAD-A, VAS scores in PSA group; hospital anxiety and depression scale (HAD) and BASMI were positively correlated with IL-23. In the AS group, IL-23 was correlated with VAS and BASMI and IL-12 was correlated with HAQ score.

Table 1. The average of the interleukin levels according to the diagnoses of the participants

			p
IL 12	PSA AS	**0,007**	**0,027**
	PSA Healthy Control	0,995	
	AS Healthy Control	**0,009**	
IL 23	PSA AS	0,706	**<0,001**
	PSA Healthy Control	**0,006**	
	AS Healthy Control	**0,010**	

Conclusion: In the PsA group, IL-23 levels and FMD values were higher than the healthy group in our study. The risk of metabolic syndrome and CVD increases due to high insidence of glucose dysregulation, dyslipidemia and obesity in these patients. PsA patients should be monitored for the development of these comorbidities and preventive measures should be taken. More studies are necessary to examine the relationship between IL-12, IL-23 levels and endothelial dysfunction, which is an early indicator of CVD and atherosclerosis in PsA patients.

POS1096 **CHARACTERIZATION OF A PSA COHORT IN CLINICAL ROUTINE CARE USING THE DAPSA AND ITS CORE-SET PARAMETERS.**

A. Kerschbaumer[1], J. S. Smolen[1], D. Aletaha[1]. [1]*Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria*

Background: A large number of therapeutics have become available to treat Psoriatic Arthritis (PSA). Still, the level of disease activity in contemporary PSA patients in clinical practice may span broadly across the range.

Objectives: To investigate disease activity in PsA patients at their last clinical visit in a tertiary academic European centre using treat-to-target as management principle, and with access to all contemporary treatments, by Disease Activity in PSA (DAPSA) index and its components.

Methods: Disease characteristics of 138 PSA patients at an academic referral centre was assessed at their last clinical visit, including DAPSA scores, DAPSA states, and DAPSA components (swollen joint count 66, tender joint count 68, patient global assessment, patients' assessment of pain and C-reactive protein), as well as ongoing DMARD therapy. Cumulative frequencies of DAPSA core-set parameters and Health-Assessment Questionnaire Disability Indices were calculated and tabulated. All patients provided their written informed consent to participate, and this study was approved by the local ethics committee.

Results: Of 138 PsA patients included, 68 were female (49%), the mean disease duration was 11.8 years and patients had 2.4 mean swollen joints and 6.4 tender joints. Most patients received conventional synthetic DMARDs as monotherapy (73/138 53%), but about the half of patients (53%) were not at treatment target of DAPSA low disease activity or remission (Table 1). When investigating the composition of disease activity by components, about 50% of patients had ≤1 swollen joint (0-66), ≤3 tender joints (0-68), ≤4.0cm of patient global assessment (0-10) and ≤4.0cm of pain (0-10) as well as a HAQ ≤0.5 and normal CRP values.

Table 1. Demographics and clinical characteristics of 138 patients at their last visit in a tertiary academic European centre (shown as numbers and percent or mean and standard deviation).

N	138
Female	68 (49%)
Age (years)	48.8±17.5
Disease duration (years)	11.9±10.2
Swollen Joint Count (0-66)	2.4±3.2
Tender Joint Count (0-68)	6.4±9.4
Patient Global Assessment (VAS 0-10cm)	4.0±2.9
Patients Assessment of Pain (VAS 0-10cm)	3.6±2.6
C-reactive Protein (mg/dL)	1.1±2.6
Health Assessment Questionnaire (0-3)	0.7±0.8
DAPSA	18.7±16.5
Treatment	
Any csDMARD	91 (66%)
Methotrexate	78 (57%)
Leflunomide	10 (7%)
Sulfasalazine	6 (4%)
Any bDMARD	35 (25%)
TNF inhibition	30 (22%)
IL17 inhibition	1 (1%)
IL12/23 inhibition	4 (3%)
csDMARD monotherapy	73 (53%)
bDMARD monotherapy	17 (12%)
bDMARD + csDMARD combination	18 (13%)
DAPSA disease activity state	
Remission	26 (19%)
Low Disease Activity	40 (29%)
Moderate Disease Activity	45 (33%)
High Disease Activity	27 (20%)

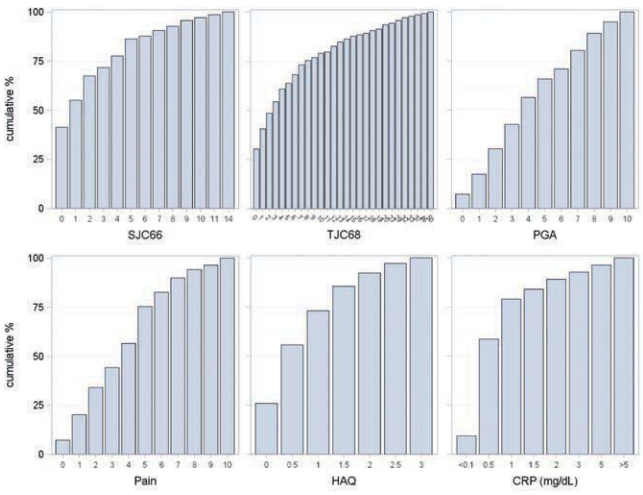

Figure 1. Cumulative probability plots of swollen and tender joint assessments, patient global assessment (PGA), patients assessment of pain, Health Assessment Questionnaire (HAQ) Disability Index and C-reactive protein (CRP).

Conclusion: This analysis of PsA patients in routine care at a European tertiary academic center showed that many patients are not on treatment target. Their presentation is oligoarticular, with moderate levels of pain and patient global assessments, but mostly normal or slightly elevated CRP levels. Despite the treat-to-target strategy and a large number of therapeutics, and overall good control of objective measures of disease activity, many patients in real life may potentially benefit from more intensive treatment escalation.

Background: Osteoarthritis (OA) is a slow progressive disease characterized by degeneration within the joint cartilage, leading to destruction and dysfunction of the involved joints. Psoriatic arthritis (PsA) is a chronic inflammatory disease manifesting itself in skin lesions and progressive inflammatory changes within the musculoskeletal system, leading to joint damage and functional limitation. Although OA and PsA are considered to be distinct diseases, they share overlapping clinical and inflammatory features that can cause diagnostic challenges. Throughout these inflammatory and degenerative processes in the joint tissues, proteases hold a major role in remodelling of the extracellular matrix (ECM) which results in protein breakdown products released into the synovial fluid (SF). These protein fragments can be quantified in SF as biomarkers of tissue remodelling and may be helpful in characterizing disease-specific or overlapping pathologies between OA and PsA.

Objectives: Our aim of this study is to measure biomarkers of inflammation and joint tissue turnover in SF to explore the distinct and overlapping pathologies between OA and PsA.

Methods: SF samples were collected from patients with OA (n=54, mean ±SD age 62.1 ±11.9, 48% female) and patients with PsA (n=59, mean ±SD age 47.8±13.3, 37% female) recruited through Toronto Western Hospital, Canada. Study was approved by the local ethics committee. Biomarkers of inflammation reflecting macrophage activity (VICM) and neutrophil activity (CPa9-HNE) were measured in the SF samples. Moreover, ECM remodelling was assessed in the SF samples by biomarkers quantifying type II collagen formation (PRO-C2), fibronectin turnover (FBN-C), and aggrecan degradation (ARGS). Data were log-transformed and presented as mean ± standard deviation (SD). An ANCOVA corrected for age was applied to test the difference between biomarker levels across the two patient groups and a p-value below 0.05 was considered significant. Area under the receiver operating characteristic (ROC) curve (AUC) analysis was performed to describe the discrimination accuracy of each biomarker between the two patient groups.

Results: PsA patients presented significantly higher levels of macrophage; VICM, activity compared to OA (p<0.001, Figure 1A). On the other hand, OA patients demonstrated increased type II collagen formation and aggrecan degradation compared to PsA (p<0.001, Figure 1C, E). Interestingly, no significant difference in biomarkers levels of neutrophil activity and fibronectin remodelling was observed between the two disease groups. Moreover, VICM, PRO-C2, and ARGS showed high distributional difference between OA and PsA patients with an AUROC=0.915 (p<0.001, Figure 1F), AUROC=0.737 (p<0.001, Figure 1G), and AUROC=0.725 (p<0.001, Figure 1H), respectively.

Conclusion: PsA patients demonstrated higher macrophage activity in the SF compared to the OA patients, while higher levels of cartilage formation and degradation were observed in OA patients compared to PsA. No differences between OA and PsA were observed in neutrophil activity and fibronectin turnover, which may mirror the clinical difficulty in telling the two arthritides apart. Identifying the unique characteristics of the pathological processes underlying the two diseases may improve diagnosis and allow for the precise management of both OA and PsA patients.

POS1098 DO THE CHANGES DETECTED BY ULTRASOUND AFFECT THE QUALITY OF LIFE OF YOUNG AND MIDDLE-AGED PATIENTS WITH PSORIATIC ARTHRITIS?

I. Fairushina[1], E. Kirillova[1], D. Abdulganieva[1]. [1]*Kazan State Medical University, Internal Diseases, Kazan, Russian Federation*

Background: The quality of life (QoL) is included in the main domain for psoriatic arthritis (PsA) course assessment.[1] In the last years, the role of imaging has grown up. The European League Against Rheumatism recognized that ultrasound (US) has higher sensitivity than clinical examination to detect inflammatory disease activity. The data showing the association between (b/w) QoL and US changes in PsA is limited.

Objectives: To study relationship b/w US articular and entheseal involvement and QoL in PsA.

Methods: 18-60-aged patients (n=92) were enrolled to study with fulfilled PsA criteria (CASPAR, 2006). Clinical and demographical data was fixed. All patients completed questionnaires (Health Assessment Questionnaire-Disability Index (HAQ-DI), FACIT-Fatigue, Dermatology Life Quality Index (DLQI), Short Form – 36 (SF-36). US was done by 2 US rheumatologists - 1288 large joints and 4968 entheses at the projection of these joints (total number - 54) were examined. The following was evaluated: synovitis count (by Grey Scale), Power Doppler(PD)+

synovitis), thickening and hypoechogenicity at enthesis, PD+ enthesitis, entheses with structural components. Entheseal findings were fixed according to consensus-based US definition and scoring for enthesitis in spondyloarthritis and PsA (OMERACT US).[2]

Results: In all 92 patients: male - 42 (45.7%), mean age was 42.9±9.6 (SD) years (y), PsA duration was 7 (2; 11.8) y, Disease Activity in PsA score was 15.2 (10.2; 21.4). Thus, the impact of psoriasis on the quality of life of patients with PsA was revealed. DLQI scores correlated with skin psoriasis activity and nail onychodystrophy, as well as clinical enthesitis (p<0,01). Minimal (67.4%) and moderate (29.3%) disability levels were found. HAQ-DI scores were associated with higher PsA activity and duration, age and clinical enthesitis (p<0,01). Physical and mental health (SF-36) correlated with Disease Activity in PsA and clinical enthesitis (p<0,05). Fatigue was found in 50% of patients and increased with PsA activity and duration, and clinical enthesitis (p<0,01). US data showed no association with QoL in PsA (p>0.05).

Conclusion: QoL scores of this study were related to clinical data, particularly to clinical enthesitis. US articular and entheseal inflammation were not correlated with QoL scores. This is probably due to the subclinical course of US changes. This allows us to conclude that QoL is associated with clinical than with US characteristics in PsA.

POS1099

QUALITY OF LIFE, WORK IMPAIRMENT, AND DAILY ACTIVITY IMPAIRMENT OF PATIENTS WITH PSORIASIS VERSUS PSORIATIC ARTHRITIS: A REAL-WORLD SURVEY IN US AND EUROPE

J. F. Merola[1], L. E. Kristensen[2], F. Yang[3], S. Peterson[3], R. Teneralli[3], N. Massey[4], S. D. Chakravarty[5,6], M. Hughes[4], M. Shawi[3], S. Weatherby[4], C. Contre[7], I. Lin[8], F. Hassan[9], M. E. Husni[10]. *[1]Brigham and Women's Hospital, Harvard Medical School, -, Boston, United States of America; [2]The Parker Institute Bispebjerg-Frederiksberg Hospital, and Copenhagen University, Department of Health Sciences, Copenhagen, Denmark; [3]Janssen Global Services, LLC, -, Horsham, United States of America; [4]Adelphi Real World, -, Bollington, United Kingdom; [5]Janssen Scientific Affairs, LLC, -, Horsham, United States of America; [6]Drexel University College of Medicine, -, Philadelphia, United States of America; [7]Janssen-Cilag France, LLC, -, Issy les Moulineaux, France; [8]Janssen Pharmaceuticals, LLC, -, Horsham, United States of America; [9]Janssen-Cilag LTD, -, High Wycombe, United Kingdom; [10]Cleveland Clinic, -, Cleveland, United States of America*

Background: Psoriasis (PsO) and psoriatic arthritis (PsA) and are chronic immune-mediated diseases characterised by joint inflammation and skin lesions which negatively impact patients' health-related quality of life (HRQoL). Several previous comparative studies have focused on PsA patients with or without skin involvement. Better understanding of the impact of both PsO and PsA on HRQoL and work / activity impairment will improve understanding of the incremental burden of PsA compared to PsO, and may lead to more personalised treatment options.

Objectives: To compare HRQoL, work impairment, and daily activity impairment of patients with a PsO diagnosis (dx) only, PsO dx with musculoskeletal (MSK) symptoms (sx), PsA dx with active skin sx, and PsA dx without active skin sx.

Methods: Data were drawn from the Adelphi PsO & PsA Disease Specific Programmes™ (DSP), real-world point-in-time surveys of rheumatologists, dermatologists and their consulting patients in the United States and Europe (France, Germany, Italy, Spain and UK); conducted in 2018/19. Patients were grouped according to their symptoms and confirmed diagnoses, comprising four groups:

1. Patients with PsO dx only,
2. Patients with PsO dx and with MSK sx,
3. Patients with PsA dx and with active skin sx,
4. Patients with PsA dx with no active skin sx,

Multivariate linear regression analyses with marginal mean predictions examined differences in patient-reported outcome measures (PROMs) between the four groups. Measures included HRQoL (EuroQol 5-Dimension 5-Level [EQ-5D Utility] and EuroQoL Visual Analogue Scale [EQ-VAS]), work impairment, and daily activity impairment (Work Productivity and Activity Impairment Questionnaire [WPAI]). Analyses controlled for demographics (age, sex, BMI), comorbidities present in >10% of patients and current treatment class (biologics, csDMARDs, steroids & other).

Results: 4491 patients were included: Group 1 (n=1833), Group 2 (n=91), Group 3 (n=2451), and Group 4 (n=116). 54% of patients were male, 89% of patients were white, with a mean age of 46.6 years. Demographics were consistent across all patient groups.

The model-predicted EQ-5D-Utility was lower in Groups 2, 3 and 4, compared with Group 1 (p=0.003, p<0.001 and p=0.004 respectively). Similarly, predicted EQ-VAS was lower in Group 3 compared with Group 1 (p=0.006), Table 1.

Table 1. Predictions of PROMs for PsO-PsA patient groups

PRO tool	Group [n]*	Predicted PRO value	Population norm (MCID)	Regression model p-value (vs. reference group)
EQ-5D Utility score (n=1839)	1 (ref) [743]	0.922	0.88 (0.07)	
	2 [32]	0.816		**0.003**
	3 [1023]	0.810		**<0.001**
	4 [41]	0.850		**0.004**
EQ-VAS (n=1882)	1 (ref) [763]	78.78	78.2 (n/a)	
	2 [36]	70.56		0.057
	3 [1040]	73.89		**0.006**
	4 [43]	75.23		0.248
WPAI % overall work impairment (n=1015)	1 (ref) [422]	15.36	n/a (15.0)	
	2 [14]	17.86		0.560
	3 [558]	22.16		**<0.001**
	4 [21]	26.09		**0.014**
WPAI % work time missed (n=1028)	1 (ref) [424]	0.91	n/a (n/a)	
	2 [14]	3.57		0.486
	3 [569]	4.46		**0.002**
	4 [21]	10.43		**0.003**
WPAI % impairment while working (n=1153)	1 (ref) [486]	14.90	n/a (20.0)	
	2 [18]	13.89		0.846
	3 [626]	19.63		**<0.001**
	4 [23]	17.39		0.435
WPAI % activity impairment (n=1818)	1 (ref) [732]	18.02	n/a (20.0)	
	2 [32]	26.25		0.122
	3 [1012]	26.14		**<0.001**
	4 [42]	25.24		**0.044**

*n values provided for reference, but margins are predictions as a result of the model and not for the specific number of patients in each subgroup.
(1) patients with PsO dx only
(2) Patients with PsO dx and MSK sx
(3) Patients with PsA dx and with active skin sx
(4) Patients with PsA dx with no active skin sx

Overall work impairment increased in Groups 3 and 4, compared with Group 1 (p<0.001 and p=0.014 respectively). Furthermore, Groups 3 and 4 missed more work compared with Group 1 (p=0.002 and p=0.003 respectively). Group 3 patients exhibited an increase in presenteeism and activity impairment compared with Group 1 (p<0.001), Table 1.

Conclusion: Patients experiencing PsA dx or MSK sx experienced an additional disease burden compared to patients with PsO sx alone, as measured by worse HRQoL and work impairment.

POS1100 PSYCHOMETRIC PROPERTIES OF PATIENT GLOBAL ASSESSMENT IN THE EVALUATION OF PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

E. Chessa[1], M. Piga[1], A. Floris[1], M. Congia[1], M. M. Angioni[1], A. Cauli[1].
[1]Rheumatology Unit - University and AOU of Cagliari, Public Health and Medical Sciences, Monserrato, Italy

Background: Recommendations emphasize the need for the physician to work in partnership with the patient and a shared decision-making process is nowadays fundamental to manage properly Psoriatic Arthritis (PsA). Patient Global Assessment (PtGA) is a score that reflects the patient's judgment about the disease activity and is getting more used in clinical routine and research.
Objectives: The objective of this systematic literature review (SLR) is to analyze the role of PtGA in PsA and to describe its psychometric properties.
Methods: This SLR was conducted by two independent reviewers in accordance with the PRISMA statement, searching for articles reporting on the use of PtGA in PsA. All articles published until February 2021 in Pubmed were screened with no limitation about years of publication, language or patients' age. Articles reporting data of PtGA of skin assessment were excluded. Psychometric properties data were analysed according to the OMERACT (Outcome Measures in Rheumatology) Filter methodology version 2.1. Measurement properties of the PtGA were analysed according to the COnsensus-based Standards for the selection of health Measurement INstruments (COSMIN) terminology.
Results: The literature search identified 45 studies, accounting for 8516 patients in 20 longitudinal cohort studies, 15 cross-sectional studies, 5 randomized controlled trials, 2 post-hoc analyses, 1 retrospective study and one review. Ten articles were excluded because PtGA was referred to the assessment of cutaneous psoriasis. Content validity was reported in 32 studies. Different definitions, acronyms, scales and questions to assess PtGA were retrieved through the literature (see Table 1).

Table 1. Different questions, definitions, acronyms, scales and scores used to assess Patient Global Assessment retrieved. STD: studies

QUESTIONS
"How would you rate the patient's joint disease activity?"
"In all the ways in which your PSORIASIS and ARTHRITIS, as a whole, affect you, how would you rate the way you felt over the past week?"
"How active was your rheumatic disease on average during the last week?"
"Considering all the ways PsA has affected you during the last week, circle the number that best describes how you have been doing"
"How do you estimate your disease activity today?"
"How active do you feel your joint disease is today?"
DEFINITIONS
Pt visual analogue scale (VAS) for pain and global assessment
Pt general disease assessment
Pt global activity
Pt global assessment
Pt global disease activity
Pt opinion on the level of disease activity
Pt global evaluations
Pt perception of disease
Pt disease severity
ACRONYMS
PtGA; PGA; PaGA
SCALES
VAS (23 std); NRS (12 std)
SCORES
0-100 (23 std); 0-10 (11 std); 0-5 (5 std)

Face validity was reported in all the articles retrieved. PtGA was always used together with other instruments, alone or as part of composite indices: supporting its face validity, in 2 studies it was considered the instrument of reference to assess the outcome. A good correlation with PhGA, DAS28, BASDAI, ASDAS and DAPSA was found (see Figure 1). One study showed that the correlation became better (ES 1.81, 95%CI 1.42 2.19) during the follow up assessment. Three studies analyzed the discordance between patient and physician global assessment and in 25.0-49.0% found a positive discordance (PtGA higher than PhGA). Criterion validity was assessed exploring the PtGA correlation with quality of life measurements, demographic characteristics, biomarkers levels, treatment changes and damage assessments in 11 studies. The intrarater reliability was calculated only in 1 study, with an optimal correlation (ICC=0.87; 95%CI 0.83–0.90). PtGA responsiveness was used to evaluate response to treatment in 14 studies.

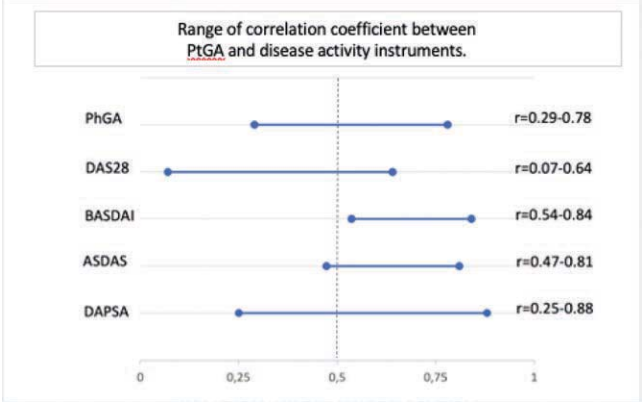

Figure 1. Forest plot showing correlation between PtGA and other instruments

Conclusion: PtGA demonstrated to be valid and feasible, but more studies are necessary to confirm its reliability and to evaluate its sensitivity to change. In addition, a clear definition of what PtGA refers to, what time and what kind of scale to adopt should be standardized.

POS1101 DAPSA CORRECTED FOR PSAID12 IMPROVES ITS CONCORDANCE WITH MINIMAL DISEASE ACTIVITY.

G. Gonzalez Arribas[1], C. L. Iñíguez[2], F. Maceiras-Pan[3], V. Quevedo Vila[4], L. Fernández-Dominguez[5], J. A. Mosquera Martínez[6], C. García-Porrúa[2], J. L. Guerra-Vazquez[7], J. A. Pinto Tasende[8]on behalf of GIGAPs. *[1]Hospital Universitario da Coruña, Rheumatology, A Coruña, Spain; [2]Hospital Lucus Augusti, Rheumatology, Lugo, Spain; [3]Hospital do Meixoeiro, Rheumatology, Vigo, Spain; [4]Hospital Comarcal de Monforte de Lemos, Rheumatology, Monforte de Lemos, Spain; [5]Complexo Hospitalario Universitario de Ourense, Rheumatology, Ourense, Spain; [6]Hospital Montecelo (Pontevedra), Rheumatology, Pontevedra, Spain; [7]Hospital Arquitecto Marcide, Rheumatology, Ferrol, Spain; [8]Hospital Universitario da Coruña, Rheumatology. INIBIC, A Coruña, Spain*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease of highly variable presentation, which determines a physical and psychological deterioration, with a negative impact on the quality of life of patients and knowing the patient's perception of their health status is very important for a good management of PsA.
Objectives: To assess an adjustment of the DAPSA according to the status of the PsAID-12 (Impact of the disease in psoriatic arthritis) and to analyze its relation in clinical practice with the minimal activity of the disease (Minimal Disease Activity or MDA) in psoriatic arthritis.
Methods: Multicenter cross-sectional study, which recruited 200 patients, who met the criteria for Classification of Psoriatic Arthritis (CASPAR), in six Spanish rheumatology centers. At the time of the visit, demographic, clinical, laboratory data, HAQ (0-3) and PsAID12 (0-10) self-questionnaires were collected. Disease activity was measured using DAPSA (with its cut-off points), MDA status was obtained, and the PsAID12 index was calculated. When a PsAID≤4 was not reached, the DAPSA was scaled to a higher interval (DAPSA corrected) obtaining a new index, DAPSA-PsAID. All analyzes were performed using SPSS23 software. Differences were considered statistically significant if $p < 0.05$.
Results: Of the total number of patients, 55% were men, with an age of 55.2 ± 11.6 years; 75% had only peripheral involvement and 25% had pure or mixed axial involvement. 43% were on biological treatment (18% join to csDMARDs). The patients who reached the MDA were 102 (51%), 62.7% in men vs 37.3% in women (p 0.025). With the PsAID-corrected DAPSA, the proportion of patients in low activity-remission who did not reach the MDA was lower than with the standard DAPSA (see Table 1), 16.3% vs 27.6% (Kappa 0.750 vs 0.688). In the binary regression analysis for MDA status, adjusted for sex, an OR (95% CI) for DAPSA and DAPSA corrected for PsAID of 8.12 (1.88-35.04) and 12.31 (3.74-40.50), respectively, was obtained.

Table 1.

	MDA N=102	No MDA N= 98	p
HAQ≤0.5, n (%)	82 (92.0)	**31 (36.5)**	<0.0001
DAPSA REM/LDA, n (%)	98 (96.1)	**27 (27.6)**	<0.0001
PsAID≤4, n (%)	92 (90.2)	**45 (45.9)**	<0.0001
DAPSA-PsAID REM/LDA, n (%)	93 (91.2)	**16 (16.3)**	<0.0001

Conclusion: A PsAID-corrected DAPSA could be a more reliable alternative to MDA than conventional DAPSA and facilitate clinician decisions in daily practice.

POS1102 THE PREVALENCE OF INFLAMMATORY BACK PAIN IN PATIENTS WITH SKIN PSORIASIS WITHOUT PSORIATIC ARTHRITIS. DATA FROM DERMATOLOGICAL REAL-WORLD SETTING.

N. Pereverzina[1], L. Kruglova[1], T. Korotaeva[2], A. Lila[3]. *[1]Central State Medical Academy of the Administrative Department of the President of Russia, Department of Dermatology and Cosmetology, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Psoriasis (PsO) is an inflammatory disease associated with psoriatic arthritis (PsA). PsA affects peripheral and axial joints[1,2]. Psoriasis can precede the onset of PsA by approximately 3 to 8 years, axial involvement often undiagnosed[3]. There are limited data about the prevalence of inflammatory back pain (IBP) in PsO patients (pts) without clinical symptoms of PsA[4].

Objectives: To study the prevalence of IBP in PsO pts without PsA symptoms

Methods: 108 PsO pts without PsA over a 10-month period (March 2021 to December 2021) were incluided. Participants filled out a questionnaire on IBP. Additionaly the prevalence of stiffness in the back and neck was estimated. IBP was defined as an affirmative answer to the question 'Did you suffer from low back pain for ≥3 months?' and IBP criteria was based on criteria ASAS (the ASsessment in Ankylosing Spondylitis) and was confirmed if at least 3 out of the following 4 criteria were present: (a) onset before age 40, (b) insidious onset, (c) improvement with exercise, (d) associated with morning stiffness

Results: It was found that more than 40% of patients complained of pain or stiffness in the back. Stiffness and pain in the neck were observed in every fourth patient on average. Of those patients who complained of pain in the back or neck, 37% noted that they had pain at rest (when they get up in the morning or lie down for a long time), and 21.3% had inflammatory pain at night (when patients are forced to woke up, they needed to do exercises) (Table 1). It was found that the risks of developing spondylitis with neck pain, neck stiffness, back pain, back stiffness were higher in 4,549 times (95% CI [1,720; 12,031]), in 19,444 times (95% CI [6,480; 58,343]) 15 times (95% CI [4.646; 48.427]) and 34.857 times (95% CI [7.583; 160.230]), respectively.

Conclusion: IBP was found in more than 40% PsO patients. Every fourth PsO patients complained of stiffness and pain in the neck. The presence of these symptoms significantly increased the risk of developing PsA with spondylitis. The presence of IBP should be taken into account for early diagnosis of PsA in the dermatological practice.

P.J. Mease[1], D. Furst[2], E. Siegel[3], V. Strand[4], M. Mcilraith[5], M. E. Husni[6], M. C. Hay[7]. *[1]2Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, Washington, United States of America; [2]University of California Medical Center, Rheumatology, Los Angeles, California, United States of America; [3]Georgetown University School of Medicine, Rheumatology, Washington DC, United States of America; [4]Stanford University, Immunology and Rheumatology, Palo Alto, California, United States of America; [5]MMc Consulting, Research, Dallas, United States of America; [6]Cleveland Clinic, Rheumatologic and Immunologic Disease, Cleveland, Ohio, United States of America; [7]Miami University, Anthropology, Oxford, Ohio, United States of America*

Background: Recent psoriatic arthritis (PsA) treatment recommendations (1) highlight the importance of shared decision making; this ideally requires the clinician understands "what matters" to each patient regarding their disease. Concurrently, patient research partners have been incorporated into projects for the OMERACT core domain set (2) and measures of physical function and (health related) quality of life (3). Currently, less is known about the similarities and differences between patient and clinician perspectives.

Objectives: To interrogate and deliniate commonalities and discrepancies in "what matters" to patients and to physicians in routine clinical care.

Methods: A comprehensive list of items describing the PsA patient experience was generated in medical anthropologist-designed (CH) peer-to-peer discussions in 4 patient focus groups across the United States (Seattle, Cleveland, Washington, DC). These items were combined with those from the GRAPPA-OMERACT PsA Outcomes patient-physician consensus project (2). A PsA physician and patient steering committee reviewed and revised the list with additional topics considered to be of importance. The final list of 51 items went through a 3 round Delphi process starting with 53 PsA patients and a 2 round Delphi with 13 PsA expert rheumatologists. In each round, participants rated each item for level of importance out of 100 total points.

Results: Top priority items for each group are depicted in Figure 1. Both patients and physicians rated 'Arthritis -Joint pain and swelling' in the top two. Five additional items were included for both groups but with different scores; all related to disease manifestations or physical consequences. Several items received disparate priority between groups. In this set, patients included two unique items: access to care and future health uncertainty. Other items affecting everyday function were noted. Physician priorities included specific disease manifestations and physical/functional outcomes, and the topic of "disease management goals", focusing on patient-physician communication regarding a treatment plan.

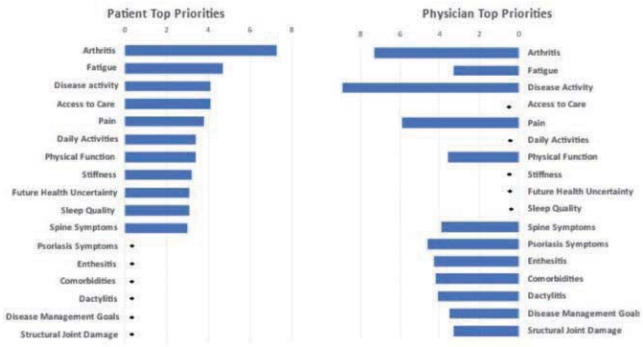

Figure 1. Top Patient and Physician Priorities *Not in set of highest ranked items for that group

Conclusion: Patients and physicians were in consensus that arthritis disease activity, pain and fatigue are key features of the patient's experience of PsA. Differences appeared in other domains; physicians ranked clinical domains such

as enthesitis, dactylitis, and skin disease more highly, patients considered items such as access to care, future health uncertainty and sleep quality to be most important. This study highlights the need for physicians to ask and address "what matters" with patients and to educate patients about potential differences in physicians' areas of concern to optimize shared decision making.

POS1104

PHYSIOLOGIC ADAPTIVE CHANGE OF THE PATELLAR AND ACHILLES TENDONS: SENSITIVITY TO CHANGE DETECTED BY COMPUTER ANALYSIS OF SEQUENTIAL STATIC IMAGES

C. Guillén-Astete[1], Á. Andreu-Suárez[1], M. Tortosa-Cabañas[1], C. Pijoan Moratalla[2], P. Barrio Rufino[3], E. Muñoz Rodriguez[3], J. Mollá Cuadrillero[3].
[1]University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain; [2]Hospital Universitario Fundación Alcorcón, Rheumatology, Alcorcón, Spain; [3]CEU San Pablo University, Faculty of Medicine, Madrid, Spain

Background: Sensitivity to change is the ability of a tool to detect changes in the measurement of a variable when this measurement is made on the same target over time. In the follow-up of patients with immune-mediated diseases, it is required that the instruments used to evaluate changes over time demonstrate enough precision. However, ultrasound studies stratify the results of the evaluations in ordinal degrees of intensity of findings dependent on the evaluator's opinion. Computer analysis of static images has recently been introduced in the study of patients with rheumatic diseases. Nonetheless, its application in musculoskeletal ultrasound is still very limited.

Objectives: -To determine if this type of image analysis is sensitive to structural adaptive change of the patellar and Achilles tendons in healthy subjects.

Methods: We recruited young volunteers with a declared sedentary habit and with a normal BMI. They carried out a supervised physical exercise routine for 6 months.

Two ultrasound measurements of the patellar and the Achilles long axis were performed. Also, two elastographies of the same tendons and two anthropometric measurements of the thigh and calf were made at the beginning and end of the training period. To demonstrate sensitivity to change, a correlation was made between the ultrasound, elastrographic and anthropometric morphological changes, and the result of the computer analysis of the image in terms of gray scale mean and mode.

Results: 19 volunteers were evaluated (mean age 24 ±2 years, 12 women).
After the exercise routine, we found statistically significant differences between calf perimeter (mean -3,70 ±1,803; p .000), Achilles elastography (-,347 ±,294; p .000), Achilles and patellar MGI (4,229 ±4,849; p .001 and 2,331 ±3,115; p,004). Regarding the non-normal distributed variables, we met statistically significant differences between patellar elastography (average range 11,45, sum of the ranks 126,00; Z -2,343; p,019), Achilles and patellar grey intensity modes (average 12,92, sum 168,00; Z -2,938; p,003 and average 11,77, sum 176,50; Z -3,28; p,001). The correlations study is shown in Table 1.

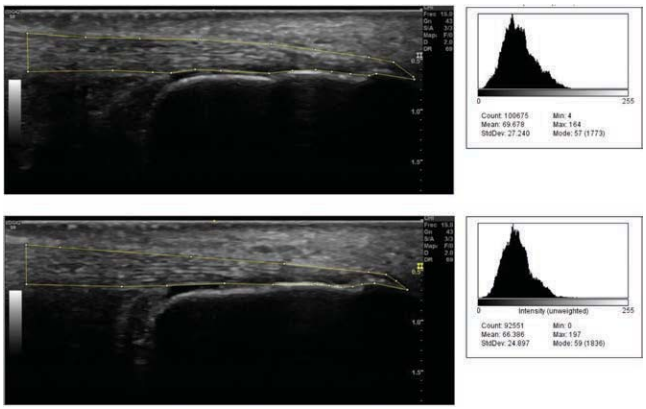

Figure 1. Before (upper) and after (lower) evaluation.

Conclusion: Computer analysis of static images of the Achilles and patellar tendons is sensitive to the change induced by exercise in young and healthy subjects. The mean gray intensity correlates better with elastography. This shows that the predominance of the fibrillar pattern induced by exercise produces a higher speed of sound conduction. The gray intensity mode correlates better with the anthropometric changes experienced by the subjects. The concentration of shades in white extremes translates into greater anthropometric changes. This demonstrates that the stiffness or elasticity of a tendon correlates with the global distribution of gray. The response to mechanical stimuli correlates with the concentration of more intense white tones that are not necessarily scattered (endophytes or pre-enthesophytes).

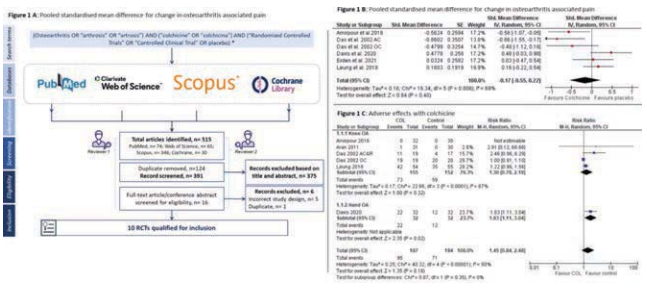
EFFICACY AND SAFETY OF COLCHICINE FOR THE TREATMENT OF OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF INTERVENTION TRIALS

A. Singh[1], P. Molina-Garcia[2,3], S. Hussain[4], A. Paul[5], S. K. Das[6], Y. Y. Leung[7], J. Samuels[8], B. Antony[9]. *[1]Menzies Institute for Medical Research, Musculoskeletal Health and Disease, Hobart, Australia; [2]Virgen de las Nieves University Hospital, Granada, Spain, Biohealth Research Institute (ibs.Granada) Physical Medicine and Rehabilitation Service, Granada, Spain; [3]University of Granada, Granada, Spain, PROFITH (PROmoting FITness and Health through physical activity) Research Group, Department of Physical Education and Sports, Faculty of Sport Sciences, Granada, Spain; [4]Masaryk University, Brno, Czech Republic, Czech National Centre for Evidence-Based Healthcare and Knowledge Translation (Cochrane Czech Republic, Czech EBHC: JBI Centre of Excellence, Masaryk University GRADE Centre), Institute of Biostatistics and Analyses, Faculty of Medicine, Brno, Czech Republic; [5]University of Tasmania, School of Pharmacy and Pharmacology, Hobart, Australia; [6]Era's University, Lucknow, India, Department of Rheumatology, Lucknow, India; [7]Singapore General Hospital, Singapore, Department of Rheumatology and Immunology, Singapore, Singapore; [8]NYU Grossman School of Medicine, New York, New York, USA, Department of Medicine, Division of Rheumatology, New York, United States of America; [9]University of Tasmania, Hobart, Tasmania, Australia, Menzies Institute for Medical Research, Hobart, Australia*

Background: Colchicine, an approved treatment for gout, has been trialled in many diseases, including osteoarthritis (OA), due to its anti-inflammatory effects. However, its efficacy and safety remain unclear in OA.
Objectives: This systematic review and meta-analysis evaluated the efficacy and safety of colchicine for the treatment of OA.[1]
Methods: PubMed, Web of Science, Scopus, and Cochrane Central were searched from inception through November 2020. Two reviewers independently screened for randomised controlled trials (RCTs) comparing colchicine with placebo or other active-comparators for the treatment of OA (knee, hand, or hip OA), extracted data, and performed Cochrane risk of bias assessments.
Results: The search retrieved 391 articles after removing duplicates, and 16 full-text articles were reviewed for eligibility (Figure 1**A**). Ten RCTs, nine in knee OA, one in hand OA, consisting of 847 patients (429 in colchicine arm, 409 in control arm) were included. RCTs were conducted between 2002 and 2021; three in India, two in Iran and Turkey, and one each in Australia, Singapore, and Iraq; follow-up period ranged 2 to 12 months. Moderate-quality evidence showed no clinically important pain reduction with colchicine compared to placebo in knee/hand OA patients (standardised mean difference [SMD], -0.17; 95% confidence interval [CI], -0.55 to 0.22) (Figure 1**B**). Moderate-quality evidence showed no improvement in dysfunction with colchicine compared to placebo in knee OA patients (SMD, -0.37; 95% CI, -0.87 to 0.13). Colchicine showed an acceptable safety profile with AEs/SAEs comparable to placebo (Figure 1**C**)



Conclusion: Current evidence does not conclusively suggest a benefit of colchicine in reducing pain and improving physical function in hand/knee OA patients. Future trials should focus on the sub-groups of OA patients with local or systemic evidence of inflammation and/or mineralisation who may benefit from colchicine.

POS1106

MEDIATORS OF THE EFFECT OF THERAPEUTIC EXERCISE ON PAIN AND FUNCTION IN PATIENTS WITH KNEE AND HIP OSTEOARTHRITIS; AN INDIVIDUAL PATIENT DATA MEDIATION STUDY FROM THE OA TRIAL BANK.

J. Runhaar[1], M. Holden[2], M. Hattle[2], J. Quicke[2], R. Riley[2], E. Healey[2], D. Van der Windt[2], K. Dziedzic[2], M. Van Middelkoop[1], S. M. A. Bierma-Zeinstra[3], N. Foster[4]on behalf of the OA Trial Bank Exercise Collaborative. *[1]Erasmus MC University Medical Center Rotterdam, General Practice, Rotterdam, Netherlands; [2]Keele University, Primary Care Centre Versus Arthritis, School of Medicine, Keele, United Kingdom; [3]Erasmus MC University Medical Center Rotterdam, General Practice and Orthopedics & Sports Medicine, Rotterdam, Netherlands; [4]The University of Queensland and Metro North Health, STARS Education and Research Alliance, Surgical Treatment and Rehabilitation Service, Brisbane, Australia*

Background: Currently, there is no cure for osteoarthritis (OA). Therapeutic exercise is recommended in all international guidelines to improve pain and function (1). However, randomised controlled trials (RCTs) investigating therapeutic exercise showed that, on average, effect sizes are small to moderate compared to non-exercise controls (2-3). Better knowledge about how therapeutic exercise works to improve pain and function could help improve the design and delivery of future therapeutic exercise interventions and potentially improve patient outcomes.
Objectives: To evaluate the mediating effects of 1) muscle strength, proprioception, and range of motion (ROM) among patients with knee OA, and 2) muscle strength among patients with hip OA, using the procedures established for Individual Participant Data (IPD) analyses by the OA Trial Bank.
Methods: Relevant IPD were sought from all published RCTs comparing therapeutic exercise to a non-exercise control group among people with knee and/or hip OA, using previously published methods (4). For each potential mediator separately, the effect of exercise on the absolute change in pain/function directly after the intervention was determined, controlling for the relative change in mediator under investigation and potential mediator-outcome confounders, using the 'counterfactual framework' (5). Next, the effect of exercise on the relative change in the mediator was determined. The percentage mediated was calculated by dividing the natural indirect effect by the total effect.
Results: We obtained IPD from 12 RCTs and 1407 participants (knee OA = 1113; hip OA n=294) that were eligible for inclusion in one or more mediation analyses. Therapeutic exercise showed a significant effect on the relative change in muscle strength in knee OA, but not for proprioception or ROM in knee OA, nor for muscle strength in hip OA. Of all mediators, only the change in muscle strength had a significant effect on the change in pain in knee OA, and on function in knee OA and in hip OA. The percentage mediated for each mediator and each outcome was small (5.3% or less, see Table 1).

Table 1. Percentage mediated for all potential mediators, by outcome and joint.

	Knee OA Pain	Knee OA Function	Hip OA Pain	Hip OA Function
Muscle strength	2.4%	2.3%	absent	absent
Proprioception	absent	0.2%	-	-
Range of motion	1.8%	5.3%	-	-

'absent': no percentage mediated calculated, since direct and indirect effect had opposite directions;'-': factors not considered a potential mediator for therapeutic exercise in hip OA.

Conclusion: In the first IPD mediation analysis to our knowledge of this scale, muscle strength, proprioception and ROM did mediate the effect of therapeutic exercise for pain and function in knee OA, but only to a very small degree. We observed no such mediating effect of muscle strength for therapeutic exercise in patients with hip OA. The challenge remains to better understand the key mechanisms of action of therapeutic exercise for knee and hip OA, so that exercise interventions can be designed and delivered to target these and therewith optimise the effects for patients.

POS1107 CHANGE IN ULTRASOUND-BASED KNEE JOINT INFLAMMATORY MARKERS AFTER WEIGHT LOSS IN PATIENTS WITH OSTEOARTHRITIS: A PROSPECTIVE COHORT STUDY.

K. Ellegaard[1], J. Guldberg-Møller[1], M. Boesen[2], L. E. Kristensen3, H. Gudbergsen[1], L. Jensen[1], A. Overgaard[1], H. Bliddal[1], M. Henriksen[1]. *[1]Bispebjerg and Frederiksberg Hospital,The Parker Institute, Frederiksberg, Denmark; [2]Bispebjerg and Frederiksberg Hospital, Department of Radiology, Copenhagen, Denmark; [1]Bispebjerg and Frederiksberg Hospital,The Parker Institute, Frederiksberg, Denmark*

Background: Pain and impaired function due to knee OA (KOA) can be reduced with weight loss in obese patients. The role of synovitis in symptom improvement after weight loss is not fully understood. MRI and ultrasound (US) can be used in assessment of inflammation in the KOA. Knee joint synovitis assessed by MRI does not seem to change with weight loss, however, the typical MRI score is semiquantitative, which might be less sensitive to change than a quantitative score. US has a higher resolution than MRI and borders between synovium and surrounding tissues might be clearer allowing for a quantitative score. Changes in US-based synovitis following a weight has not been assessed.
Objectives: To assess changes in US synovitis in the knee joint after 8 weeks low-calorie weight loss intervention in overweight persons with KOA.
Methods: prospective cohort study (NCT02931370) including overweight persons (BMI ≥ 27 kg/m^2) with KOA. Weight loss was induced by an intensive 8-week diet (1200 kcal/day), participants had symptomatic and radiographically confirmed KOA (KL grade 1-3). At week 0 and 8 all participants filled in the KOOS questionnaire assessing pain, physical function, symptoms, quality of life, and sport/recreation in relation to KOA (0= worst; 100=best). Furthermore, an US examination of the most affected knee was performed assessing the amount of synovial hypertrophy (SH) and effusion in medial and lateral recesses. The US examination was performed in a strictly standardized manner on a high-end US machine. The subsequent image evaluation was done both according to a semiquantitative score from 0 to 3 (0=no SH/effusion and 3=pronounced SH/effusion) and a quantitative scoring system using specific anatomic landmarks to measure the synovial hypertrophy/effusion in millimeter. Statistical analyses were performed on the per protocol population (participants completing diet intervention).
Results: 135 patients with KOA with a mean age of 60y (SD 9.8), a body weight of 106.0 kg (SD18.5) and mean BMI of 36.4 (SD5.4) completed the weight loss intervention. After the diet intervention mean weight change was -12.8 kg (95%CI -13.3 to -12.4) and the reductions in SH were -0.3mm (95%CI -0.5 to -0.1) (medial recess) and -0.4mm (95%CI -0.6 to -0.1) (lateral recess), and -0.03 (-0.13 to 0.07) (medial recess) and -0.07 (-0.20 to 0.05) using the semi-quantitative system. The mean change in the KOOS subscales range from 15.8 (sport/recreation) to 7.4 (QoL). See Table 1.

Table 1.

n=135	Baseline	Change	
	Mean (SD)	Mean (95%CI)	P
Age	60.0 (9.8)	-	-
Females, n (%)	87 (64.4%)	-	-
BMI	36.4 (5.4)	-4.4 (-4.5 to -4.3)	<.0001
KL-scores; 1	22 (16.3%)	-	-
KL-scores; 2	56 (41.5%)	-	-
KL-scores; 3	57 (42.2%)	-	-
KL-scores; 4	0 (0%)	-	-
Synovial Hypertrophy			
Medial, mm	3.8 (1.8)	-0.3 (-0.5 to -0.1)	0.0198
Lateral, mm	5.3 (2.3)	-0.4 (-0.6 to -0.1)	0.0210
Medial, 0-3	1.2 (0.6)	-0.03 (-0.13 to 0.07)	0.5584
Lateral, 0-3	1.8 (0.8)	-0.07 (-0.20 to 0.05)	0.2311
KOOS, 0-100			
Pain	64.1 (16.0)	12 (10.2 to 13.8)	<.0001
Function	68.4 (17.3)	14 (12.4 to 15.6)	<.0001
Symptoms	68.9 (16.4)	9 (7.2 to 10.8)	<.0001
Sports/Recreation	35.9 (24.0)	15.8 (13.2 to 18.3)	<.0001
QoL	43.8 (17.5)	7.4 (5.7 to 9.2)	<.0001

SD = Standard Deviation; CI = Confidence Interval; BMI = Body Mass Index; KOOS = Knee injury and Osteoarthritis Outcome Score; QoL = Knee-related Quality of Life

Conclusion: Quantitative measures of SH assessed by US decreased after a significant weight loss over 8-weeks; however, no linear association with weight loss magnitude was seen. A weak correlation between changes in SH in the lateral recess and change in pain was seen. This indicates changes in SH assessed by US examination is associated with a low-calorie diet but seems uncoupled with weight loss magnitude. The weight loss induced changes in synovitis and KOA symptoms seem vaguely related.

POS1108 USE OF MACHINE LEARNING IN OSTEOARTHRITIS RESEARCH: A SYSTEMATIC LITERATURE REVIEW

M. Binvignat[1,2,3], V. Pedoia[4], A. Butte[3], K. Louati[1], D. Klatzmann[2], F. Berenbaum[1], E. Mariotti-Ferrandiz[2], J. Sellam[1]. *[1]Sorbonne Universite, Rheumatology, Paris, France; [2]Sorbonne Universite, I3 lab (Immunology Immunopathology Immunotherapy), Paris, France; [3]UCSF, Bakar Computational Health Science Institute, San Francisco, United States of America; [4]UCSF, Radiology and Biomedical Imaging Department, San Francisco, United States of America*

Background: Artificial intelligence techniques, in particular machine learning (ML), are increasingly used in rheumatology and especially in osteoarthritis (OA). ML studies in OA are very heterogeneous, hence the need to have an overview of their field of application.
Objectives: The aim of this systematic literature review is to provide a comprehensive and exhaustive landscape of the use of ML in the clinical care of OA.
Methods: A systematic review of the literature was performed in July 2021 using the Medline database with key words and MeSH terms referring to ML methods in OA. Only original articles in English were considered. Articles related to replacement surgery, theorical imaging, rehabilitation, molecular biology, and spinal or temporomandibular OA were excluded. For each selected article, the

number of patients, the ML algorithms used, the type of data analyzed, the validation methods, and the data availability were collected.
Results: From 1,148 screened articles, 46 were selected and analyzed, most of which were published after 2017 (Figure 1). Twelve articles were related to diagnosis, 7 to prediction, 4 to phenotyping, 12 to severity and 11 to progression. The number of patients included ranged from 18 to 5,749. Deep learning (DL) was used in 35% of the cases. Imaging analyses represented 74% of the studies. Knee OA was studied in 85% of these articles while 15% investigated hip OA. None were on hand OA. Most of the studies were done on the same cohort with data from the Osteoarthritis Initiative (OAI) used in 46% of the articles whereas the Multi-Center Osteoarthritis Study (MOST) and the Cohort Hip and Cohort Knee Study (CHECK) cohort were respectively used in 11 % and 7 % of the articles. Data and source code were publicly available in 54% and 22% of the articles. External validation was provided in only 7 % of the articles.

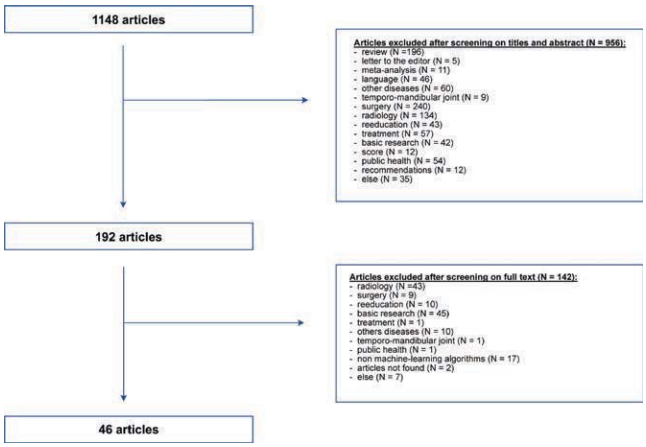

Figure 1. Article selection flow chart

Conclusion: This review provides a comprehensive update of ML in OA research. The number of ML articles in OA has increased exponentially over the last 5 years with applications across all major research themes. However, there is methodological heterogeneity, with articles based mainly on radiological data, but also on knee OA. To date, there is no ML article on digital osteoarthritis. This work also shows the need to develop clinical cohorts to bring more diversity in ML work and to allow external validation This article is the first systemic review of the literature in OA and provides an overview of ML in OA, its applications, limitations and perspectives.

POS1109 GENETIC MARKERS PREDICT THE DEVELOPMENT OF POSTOPERATIVE PAIN

V. Nesterenko[1], A. Karateev[2], M. Makarov[3], E. Bialik[3], S. Makarov[3], A. Lila[4], V. Bialik[3], S. Glukhova[3], M. Nurmukhametov[3], V. Kuznecov[3], N. Burikov[3], A. Roskidailo[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rheumoorthopaedics and Rehabilitation, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Department of Inflammatory Joint Diseases, Москва, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumoorthopaedics and Rehabilitation, Москва, Russian Federation; [4]V.A. Nasonova Research Institute of Rheumatology, Director, Москва, Russian Federation*

Background: Postoperative pain (POP) is a serious complication that affects the outcome of total arthroplasty (TA) of the knee (CJ) and hip (HJ) joints in patients with osteoarthritis (OA). The search for the genetic characteristics of POP is an urgent direction in the study of this problem.
Objectives: To determine the relationship between the polymorphisms of the KCNS1, COMT, and OPRM1 genes and the development of postoperative pain in patients with osteoarthritis of the knee joint and hip joint who underwent total arthroplasty.
Methods: The study group consisted of 95 patients with knee osteoarthritis and / or hip joint osteoarthritis (64.6% of women; mean age - 65.4 ± 9.0 years) who underwent TA CJ (47.8%) or TA HJ (52.2 %). The presence of POP was determined when it persisted or appeared after 3 and 6 months. After surgery, pain in the area of the operated joint ≥40 mm by 100 mm visual analogue scale. All patients underwent genotyping of KCNS1 (rs734784), COMT (rs6269, rs4633), and OPRM1 (rs1799971) gene polymorphisms by real-time polymerase chain reaction using original sequence-specific primers and probes labeled with various fluorescent labels. Registration and interpretation of the obtained results were carried out on a DT-96 amplifier (DNA-Technology LLC, Russia).
Results: POP was observed in 32.6% of patients who underwent TA CJ or TA HJ. The incidence of POP after TA CJ and TA HJ was 30.2% and 34.0%, respectively (p = 0.882). There were no differences in the frequencies of genotypes of the studied genes (p>0.05). The presence of the homozygous GG genotype of the KCNS1 gene polymorphism (rs734784) was associated with the presence of POP in accordance with the recessive genetic model (GG vs AA + AG; odds ratio (OR) - 3.96 [95% confidence interval (CI): 1, 51; 10.37]; p = 0.005). The presence in the genotype of the mutant allele T (TT + CT) of the COMT polymorphism (rs4633) reduced the risk of developing POP compared with the carriage of the CC genotype (OR = 0.32 [95% CI: 0.12; 0.83]; p = 0, 02) according to the dominant genetic model. There was no statistically significant correlation between the development of POP and the carriage of various genotypes and alleles of the COMT (rs6269) and OPRM1 (rs1799971) genes.
Conclusion: There is a statistically significant association between the polymorphism of the KCNS1 (rs734784) and COMT (rs4633) genes and the development of chronic POP in patients who underwent TA CJ and TA HJ. Further studies of the genetic predisposition to POP are required using more clinical material.

POS1110 WHAT FACTORS ARE ASSOCIATED WITH THE DEVELOPMENT OF PAIN AFTER TOTAL JOINT REPLACEMENT?

V. Nesterenko[1], A. Karateev[2], M. Makarov[1], E. Bialik[1], S. Makarov[1], V. Bialik[1], M. Nurmukhametov[1], A. Roskidailo[1], N. Burikov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rheumoorthopaedics and Rehabilitation, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Department of Inflammatory Joint Diseases, Moscow, Russian Federation*

Background: Chronic postoperative pain (CPP) is one of the most common complications of total hip (HJ) and knee (CJ) arthroplasty (TA). The search for the factors that determine this pathology is an urgent scientific and practical task.
Objectives: To determine the factors associated with the development of CPP in patients who underwent TA, CJ or HJ.
Methods: The study group consisted of 124 patients with osteoarthritis of the knee or hip joint, mean age 63.6 + 9.9 years, 63% of women and 37% of men, who in 2019-2020 year done out by TA KJ or HJ. The development of CPP was assessed after 3 and 6 months. telephone survey of patients. This complication was diagnosed in the presence of moderate to severe pain (≥40 mm on a visual analogue scale, VAS), persisting for at least 3 months, causing concern in patients and / or requiring regular use of analgesics. A comparison was made between the groups of patients with CPP and the absence of CPP for a number of factors determined in the preoperative period.
Results: The incidence of CPP was 27.4%. There were no differences in the incidence of CPP in patients who underwent TA CJ and TA HJ: 28.1% and 26.9%, respectively (p = 0.88). The presence of CPP was significantly associated with such preoperative indicators as a higher body mass index (BMI), a higher intensity of pain at rest, higher values of the WOMAC pain index, WOMAC and WOMAC stiffness in general, and the severity of symptoms of neuropathic pain. (PainDetect questionnaire), signs of depression and anxiety (HADS questionnaire). The risk of developing CPP was significantly higher (p <0.05) in patients

with BMI> 30 kg / m2 - odds ratio (OR) 2.755 (95% confidence interval, CI 1.053-7.206), for pain at rest ≥40 mm VAS - OR 1.349 (95% CI 0.478-3.803), Pain Detect score ≥13 - OR 3.598 (95% CI 1.048-12.36), depression score HADS ≥8 - OR 2.193 (95% CI 0.745-6.454), number of pain sources ≥ 2 - OR 6.996 (95% CI 2.358-20.756).

Conclusion: The risk of CPP after TA CJ and HJ is higher in patients with overweight, high preoperative pain, signs of neuropathic pain and depression, and in the presence of several sources of musculoskeletal pain (except for the affected joint planned for TA).

POS1111 WHAT DOES GRIP STRENGTH REFLECT IN HAND OSTEOARTHRITIS? RESULTS FROM THE DIGICOD COHORT

E. Tan[1], S. Tuffet[2], A. Rousseau[2], B. Fautrel[3], F. Rannou[4], F. Berenbaum[1], J. Sellam[1], A. Courties[1]. *[1]Saint-Antoine Hospital, Rheumatology, Paris, France; [2]Saint-Antoine Hospital, Unité de Recherche Clinique de l'Est Parisien (URCEST), Paris, France; [3]Pitié-Salpêtrière Hospital, Rheumatology, Paris, France; [4]Cochin Hospital, Physical and Rehabilitation Medecine, Paris, France*

Background: Among the general population over 60 years-old, the decrease in grip strength is a marker of morbidity and mortality: its measurement during follow-up consultations is considered as a predictive marker of good health status or the patient's overall fragility (1). However, hand osteoarthritis (HOA), which can modulate grip strength and is also associated with comorbidities is never taken into account, while it is a very common disease.

Objectives: The objectives of this study are to describe grip strength in a symptomatic HOA population, to investigate painful osteoarthritic joints associated with decreased grip strength, and to determine whether decreased grip strength is independently associated with comorbidities in this population.

Methods: DIGICOD is a hospital-based observational cohort including patients with radiographic features of HOA of at least 2 joints or radiographic thumb base OA. Inflammatory rheumatism or crystal arthropathy were excluded. The data at baseline were used for the analysis. Grip strength was the higher score of 3 repeated measures using a Jamar dynamometer. Baseline grip strength of the dominant hand was compared in the cohort between men and women (Student's T test) and was described by age (by 10-year age groups using Kruskal-Wallis test). In this cross-sectional study, factors associated with a decreased grip strength were investigated using univariate and then multivariate linear regression analysis (with adjustment on age, BMI and variables with $p \leq 0.2$ in univariate analysis) with stratification by sex. Results were presented by beta coefficients and their 95% confidence intervals. A first analysis focused on the association of grip strength with local factors: painful locations in the dominant hand by row and radiographic severity according to the total Kellgren-Lawrence (KL) score. The second analysis assessed the patient-level association between decreased grip strength and general characteristics, including cumulative comorbidities and markers of radio-clinical severity of hand OA, namely the AUSCAN pain score and total KL score. A sensitivity analysis was performed to look for association between grip strength and each comorbidity.

Results: 394 patients were analyzed, including 329 women (mean ± SD of the dominant hand's grip strength of 21.6 ± 6.9 kg) and 65 men (34.9 ± 9.8 kg) with a mean age of 66.9 ± 7.3 years. Grip strength decreased with age ($p<0.001$) and was lower for women ($p<0.0001$). Among women, locally, decreased grip strength was independently associated with painful involvement of at least 2 metacarpophalangeal joints (MCPs) (estimated coefficient [95% CI] -3.6 [-6.2; -1.0] kg versus no painful MCPs) but not with proximal and distal interphalangeal joints, and with a high KL total sum score (-0.06 [-0.10; -0.01] kg per additional point). At the patient-level, decreased grip strength was not associated with comorbidities but with radio-clinical severity ($p<0.05$), i.e. a higher KL total sum score and AUSCAN pain score. Among men, neither radiographic severity nor painful locations were independently associated with a decrease of grip strength. Conversely, decreased grip strength was associated with at least 3 comorbidities (-8.5 [-15.5; -1.43] kg versus a single comorbidity being OA), independently of radiographic severity. The study of comorbidities individually did not show any particular association with grip strength.

Conclusion: In this cohort of symptomatic HOA, the decrease of grip strength reflects the radio-clinical severity of hand OA among women, whereas among men, it is independently associated with the accumulation of comorbidities. The presence of hand OA should be considered for further studies investigation the relationship between grip strength and morbi-mortality.

POS1112 A RANDOMIZED, CROSS-OVER STUDY TO INVESTIGATE THE EFFECT OF WEIGHT-BEARING VS NON-WEIGHT-BEARING EXERCISE AND CARDIOVASCULAR STRESS ON TYPE II COLLAGEN TURNOVER IN KNEE OSTEOARTHRITIS PATIENTS – BIOMARKER DATA FROM THE EFEX-OA-02 STUDY

J. Bjerre-Bastos[1,2], C. Sejersen[3], H. B. Nielsen[4], M. Boesen[5], N. Secher[3], G. Distajo[6], V. Flood[6], Y. Henrotin[7], M. Uebelhoer[7], A. Mackey[1], P. Krustrup[8], C. C. Kitchen[3], E. Petersen[2], C. Thudium[9], J. R. Andersen[2], A. R. Bihlet[2]. *[1]University of Copenhagen, X-Lab, Department of Biomedical Sciences, Copenhagen, Denmark; [2]NBCD A/S, NBCD, Herlev, Denmark; [3]Rigshospitalet, Niels Secher Lab, Department of Anaestesiology, Copenhagen, Denmark; [4]Roskilde Hospital, Department of Anaestesiology, Roskilde, Denmark; [5]Bispebjerg and Frederiksberg Hospitals, Department of Radiology, Copenhagen, Denmark; [6]Prosoft Clinical, Prosoft Clinical, Philadelphia, United States of America; [7]Artialis Group, Artialis, Liege, Belgium; [8]University of Southern Denmark, Department of Sports Science and Clinical Biomechanics, Odense, Denmark; [9]Nordic Bioscience, Translational Research, Herlev, Denmark*

Background: Biomechanical stress is a prerequisite for OA development and studies have shown a difference in the effect of impact- and shear stress[2], although studies of the direct impact of exercise on cartilage turnover have not demonstrated clear trends[1].

Objectives: Exploring how weight-bearing (WB), non-weight-bearing (NWB) exercise and cardiovascular stress influence circulating biomarkers of cartilage extracellular matrix turnover in OA.

Methods: EFEX-OA-02 was a randomized, cross-over, clinical study investigating the direct effect of exercise on joint biomarkers in knee OA. Subjects were randomized to an order of cycling and running followed by adrenaline infusion and finally resting one week apart. Exercise and infusion sessions were multiphasic, consisting of 4x5-minute intervals. Peak cardiorespiratory stress (PCS) per interval was set to ≥80% of the heart rate reserve during exercise. Blood samples were obtained before, during, at five time points after and 24 h post exercise/infusion. For adrenaline infusion, 0.06 mg/kg of adrenaline was prepared in a 50 mL saline solution and administered intravenously. At rest, samples were collected at corresponding time points, except for the 24 h sample, which was omitted. Levels of serum C2M, T2CM (type II collagen degradation) and PRO-C2 (type II collagen formation) were measured using ELISA-assays (Nordic Bioscience). Coll2-1 and Coll2-1NO2 (type II collagen degradation) were measured using ELISA (Artialis).Changes in biomarker concentrations after activity were compared to baseline (BL) and the corresponding resting samples. We used ANCOVA and Dunnett's test with geometric means of change from BL up to 240 min as the dependent variable and subject and activity as covariates. Paired t-test was used to compare values at 24-hour to BL.

Results: Forty subjects were included. Mean age was 60.4 years (SD: 8.7), 24 (60%) were females, mean BMI was 27.0 kg/m^2 (SD: 3.5), 18 had cumulated KL grade of 2 or 3 (45%) and 22 (55%) had KL 4, 5 or 6. and mean KOOS pain at BL was 67.5 (SD: 15.2) corresponding to mild-moderate pain. All subjects

reached minimum PCS during exercise, but only an average of 70% (SD: 8.7) of that during infusion. Cycling induced a small reduction in C2M (peak: -5.3%, 95%CI: -7.8 to -2.7%). PRO-C2 increased rapidly in response to cycling (peak: 11.7%, 95%CI: 4.3 to 19.1%) and running (peak: 12.9%, 95%CI: 3.54 to 22.2%). T2CM decreased up to one hour after cycling (peak: -10.8%, 95%CI: -15.1 to -6.5%) and running (peak: -9.5%, 95%CI: -15.5 to -3.6%), similar to adrenaline, then increased. Coll2-1NO2 increased rapidly following cycling (peak: 12.5%, 95%CI: 2.8 to 22.2%) and running (peak: 9.8%, 95%CI: 0.26 to 19.6%). Trends of increase was found in Coll2-1 (21.3%, 95%CI: 2.9 to 39.6) and Coll2-1NO2 (11.6%, 95%CI: -7.9 to 31.1%) in response to running at 240 min (Figure 1 – Error bars: SE, *Change to resting, †Change from BL, */†: P < 0.05, **/††: P < 0.01 ***/†††: P<0.001).

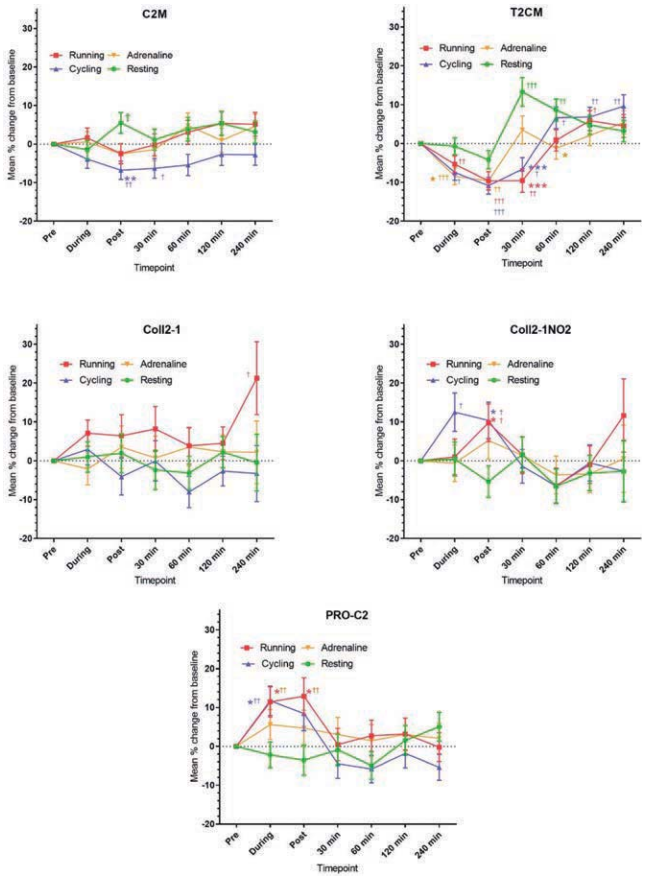

Figure 1.

At 24h PRO-C2 reduced -9.4% (95%CI: -18.2 to -0.5%) after cycling, Coll2-1NO2 reduced -8.33% (95%CI: -17.0 to 0.3%) after running and T2CM elevated by 6.0% (95%CI: -0.8 to 12.8%) after running and 7.1% (95%CI: 0.5 to 13.7%) after cycling.
Conclusion: Running, cycling and adrenaline infusion induced rapid small-to-moderate changes in circulating biomarkers reflecting type II collagen turnover. Changes after adrenaline-infusion suggests a cardiovascular contribution to exercise-induced changes. This model could potentially be used to evaluate treatment effects on collagen turnover.

POS1113

CONSTRUCT VALIDITY, RELIABILITY, RESPONSIVENESS AND INTERVAL SCALE TRANSFORMATION OF THE WESTERN ONTARIO AND MCMASTER UNIVERSITIES OSTEOARTHRITIS INDEX (WOMAC) IN PATIENTS UNDERGOING KNEE ARTHROPLASTY

Y. Y. Leung[1], J. Thumboo[2], S. J. Yeo[3], V. Wylde[4], A. Tennant[5]. [1]*Singapore General Hospital, Rheumatology & Immunology, Singapore, Singapore;* [2]*Singapore, Rheumatology & Immunology, Singapore, Singapore;* [3]*Singapore, Orthopedic Surgery, Singapore, Singapore;* [4]*University of Bristol, Musculoskeletal Research Unit, Bristol, United Kingdom;* [5]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) is commonly used in research studies of knee osteoarthritis (OA). It is commonly reported as ordinal raw scores. Previous validation studies using Rasch models requires item deletion. Conversion table to Interval scale for meaningful measurement is not available.
Objectives: We aim to evaluate the fit of WOMAC to the Rasch model in a large sample of patients with knee OA who have undergone knee arthroplasty (KA) to derive the transformation table for interval scale measurement.
Methods: We used data collected from knee OA patients undergoing KA before surgery and at 6-months after KA. We collected demographics, WOMAC, Short-form-36 (SF-36) and Oxford Knee Score (OKS) with the latter two as comparison. WOMAC was calibrated for fit to Rasch model for monotonicity, homogeneity, local item independence and absence of differential item functioning (DIF) in a randomly selected sample of 300 patients from each time point. Parameter estimates were then imported into the full data set to provide the necessary estimates of all the scales. We report responsiveness through Standard Error of Measurement (SEM); Smallest Detectable Difference (SDD), %SDD and effect sizes (ES) between pre-operative and 6-months. Transformation tables of the ordinal to interval values for WOMAC was performed.
Results: Data was analysed for 1136 patients (mean age 65.9 years, 69% female) who underwent KA. WOMAC pain, function and total scores had adequate fit to unidimensional Rasch model with good reliability (Person Separation Index: 0.76, 0.80 and 0.79). No item deletion was required. The SEM, SDD and %SDD of WOMAC total were 4.4, 6.9, 10.1, and ES was 1.97 between pre-operative and 6-months. No significant DIF was seen for age, sex, body mass index, education level or uni-compartmental versus total KA. WOMAC pain, function and total scales were transformed to interval scales.
Conclusion: The WOMAC total, pain and function scales had adequate fit to the Rasch model, providing unidimensional measure with good reliability and responsiveness. Transformation of WOMAC to interval scale measurement is feasible and applicable to wide ranges of studies.

POS1114 LABORATORY BIOMARKERS OF JOINT REMODELING AND INFLAMMATION IN PATIENTS WITH EARLY KNEE OSTEOARTHRITIS

V. Klementeva[1], T. Chernysheva[1], K. Korochina[1], I. Krivotulova[1], I. Mitrofanova[1], I. Korochina[2]. *[1]Orenburg State Medical University,The Department of Internal Diseases, Orenburg, Russian Federation; [2]Orenburg State Medical University, The Department of Polyclinic Therapy, Orenburg, Russian Federation*

Background: Record prevalence of osteoarthritis (OA) around the world is aggravated by the fact that doctor most often meets it on advanced stage, so that therapeutic interventions can no longer provide significant success [1]. It is advisable to study early joint remodeling, when gross irreversible changes have not yet occurred, and laboratory markers appear to be valuable diagnostic and prognostic tool, potentially able to identify patients-responders to particular treatment method [2].
Objectives: To verify joint tissue remodeling and synovitis in patients with early knee OA Kellgren-Lawrence (K-L) Grades 0-2 using laboratory biomarkers.
Methods: The study included 90 patients with knee OA K-L Grades 0-2 (3 groups of 30 people each) and 30 healthy volunteers; to clarify early OA, Luyten FP criteria (2018) were used [3]. Among persons with knee OA, there were 57 women (63.3%) and 33 men (36.7%), mean age 32 [27; 35] years; participants without OA were presented by 18 (60%) men and 12 (40%) women, mean age 29,5 [25; 34] years. Knee radiography, ultrasonography, laboratory biomarkers assessment including interleukin-1beta (IL-1b), N-Terminal Propeptide of Type 1 Procollagen (P1NP), Beta-Cross laps, cartilage oligomeric matrix protein (COMP) were carried out.
Results: All groups with knee OA was characterised by women predominance (Table 1). Laboratory study revealed slight increase in IL-1β and both bone markers in K-L Grade 0. Grade 1 was characterized by elevation of COMP and Beta-Cross Laps on background of IL-1β increased. In Grade 2 the highest level of COMP, slight decrease in Beta-Cross Laps and IL-1β, weak increase in P1NP were found. Correlation analysis have detected positive significant relationships between COMP and IL-1β (r=0.37), as well as Beta-Cross Laps and P1NP (r=0.43). The analysis of laboratory and instrumental relationships demonstrated significant correlation between COMP and medial condyle cartilage thickness (r=-0.18), COMP and bursa suprapatellar square (r=0.26), Beta-Cross Laps and osteophytes size (r=0.79), IL-1β and synovial membrane thickness (r=0.24).
Conclusion: Early knee OA of K-L Grade 0 is characterized by bone metabolism activation and synovial inflammation before articular cartilage involvement. On Grade 1, cartilage destruction appears and bone resorption is enhanced. Grade 2 is characterized by significant intensification of cartilage destruction, weakening of bone resorption on the background of synovial inflammation. In addition to cartilage damage, COMP is associated with joint inflammation, which requires further research to take in account it as also synovial biomarker.

POS1115 EFFICACY AND SAFETY OF THE COMBINATION OF PRP + NON-CROSSLINKED HYALURONIC ACID VERSUS HYALURONIC ACID, IN MONO-INJECTION, IN SYMPTOMATIC KNEE OSTEOARTHRITIS. RANDOMIZED CONTROLLED PHASE III TRIAL, SINGLE BLIND

T. Delgado[1], R. Ferreira Lopez[2], P. Adam[3], Y. M. Pers[2], L. Benguella[1], C. Cyteval[4], V. De Fourmestraux[5], S. Lombion[6], P. Ornetti[1]. *[1]University Hospital F.mitterand Dijon-Bourgogne, rheumatology, Dijon, France; [2]Montpellier University Hospital, Rheumatology, Montpellier, France; [3]Medipole Garonne, Imaging,Toulouse, France; [4]Montpellier University Hospital, Imaging, Montpellier, France; [5]regenLab, Research, Lausanne, Switzerland; [6]EURL SLc, Statistics, Chamesey, France*

Background: Despite the recent results of meta-analyses of randomized controlled trials (RCTs), the place of PRP and hyaluronic acid in the symptomatic treatment of knee osteoarthritis (KOA) remains uncertain in the latest international recommendations. Very few studies are available on the potential synergistic effect of their combination in mild to moderate forms of KOA(1).
Objectives: Randomized, controlled, multicenter, non-inferiority trial (*clinical trial NCT03328728*), single-blinded (investigator) to compare the efficacy and safety of the combination of PRP and non-crosslinked hyaluronic acid (PRP-HA, *Cellular Matrix A-CP-HA, Regen Lab*) as a single injection versus Hylan G-F 20 (HA), with follow-up at 1, 3 and 6 months, on an intention-to-treat (ITT) basis.
Methods: Patients aged 40-80 years with symptomatic femorotibial KOA (WOMAC A1 (pain on walking) or WOMAC Function > 50/100) and a Kellgren and Lawrence (KL) radiographic stage II or III were randomized into two groups: PRP-HA vs. HA, as a radio- or ultrasound-guided single injection at M0. Patients should not have received injectable treatments (corticosteroids, HA or PRP) for 3 months, nor per os NSAIDs for at least 1 month. A 6-month follow-up of the impact of the KOA was performed at M1, M3 and M6. The primary endpoint was the difference in the WOMAC score for pain on walking between M0 and M6 between the 2 groups. Secondary endpoints were collected and compared at M1, M3, and M6 (WOMAC Pain, Function, and Total; SF-36 score) as well as the percentage of patients responding at M6 according to the OMERACT-OARSI criteria, according to the Patient Acceptable Symptomatic State (PASS), and the Minimal Clinical Important Improvement (MCII) of the WOMAC pain. The factors of good response (PASS and MCII responders) at M6 were investigated in univariate and multivariate analysis. Tolerance was assessed by comparing adverse events over 6 months in both groups.
Results: 156 patients were included in three French teaching hospitals between 2018 and 2021 with the following characteristics: age 59.6±9.2 years, BMI 28.1±5.8 kg/m^2, 37.8% grade II KL and 62.2% grade III KL. The two groups were homogeneous at inclusion except in terms of analgesic consumption (PRP-HA vs. HA, 30% vs. 45%, p=0.042) and KL III radiographic stage (70% vs. 53%, p=0.04). The symptomatic improvement (WOMAC pain, function and WOMAC Total) was significant in both groups at M1, M3 and M6. The difference in WOMAC pain on walking at M6 was significant for the non-inferiority test (-6.34 [-12.51; -0.18], p=0.044) and for the superiority

Table 1. ***Comparative analysis of clinical and laboratory parameters in patients of different knee OA Grades and volunteers***

Parameter	Volunteer group	Knee OA groups			Significan-cy, p-value
		K-L Grade 0	K-L Grade I	K-L Grade II	
0	1	2	3	4	5
Gender	M-18 (60%) F-12 (40%)	M-13 (43,3%) F- 17 (56,7%)	M-10 (33,3%) F -20 (66,7%)	M-10 (33,3%) F -20 (66,7%)	1-3: 0,038 1-4: 0,038
Mean age, years	29,5 [25; 34]	26 [20; 32]	39 [36; 44,5]	45 [43,5; 48]	1-4: 0,049 2-4: 0,038
COMP, ng/ml	527,3 [355,1;576,5]	495,7 [421,9;737,2]	737,5 [660,2; 1033]	1683,5 [1288,4; 2260,1]	1-3: 0,044 1-4: 0,002 2-4: 0,011 3-4: 0,058
P1NP, ng/ml	58 [51,3; 64,3]	98,2 [72,4; 126,1]	101,3 [85,0; 123,4]	117,1 [105,1; 142,7]	1-2: 0,042 1-3: 0,039 1-4: 0,024
Beta-Cross Laps, ng/ml	0,545 [0,466;0,645]	0,697 [0,656; 0,861]	0,939 [0,823; 1,497]	0,793 [0,697; 1,032]	1-3: 0,032 1-4: 0,044 2-4: 0,092
IL-1β, pg/ml	3,7 [2,5; 6,0]	7,3 [5,0; 16,3]	19,1 [15,4; 29,5]	10,4 [8,6; 20,2]	1-3: 0,012 1-4: 0,028

test (-6.34 [-12.45; -0.22], p=0.042) in favor of PRP-HA. At M6, there was a non-significant difference in terms of OMERACT-OARSI responders in favor of the PRP-HA combination (58% vs. 48%, p=0.261) but significant in terms of MCII responders (78.8% vs. 61.3%, p=0.036) and PASS responders (50.6% vs. 33.3%, p=0.035).PASS response was associated in univariate analysis with pain and total WOMAC at inclusion (p<0.001) as well as with allocated treatment (p=0.03). In multivariate analysis, only allocated treatment was associated with a good response at M6 for both PASS (PRP+HA, OR=2.05 [1.02-3.92]; p=0.05) and MCII (PRP+HA, OR=2.21 [1.09-4.44]; p=0.02). There was no difference in patient satisfaction at M1, M3 and M6, nor in the occurrence of adverse events.

Conclusion: In this non-inferiority RCT in symptomatic knee osteoarthritis, the combination of PRP-non-crosslinked HA in mono-injection was at least equivalent to Hylan G-F 20 for symptomatic benefit (WOMAC) at 6 months, with a good safety profile. The proportion of patients achieving PASS and MCII of WOMAC pain was higher in the PRP-HA group.

POS1116 DIETARY INFLAMMATORY INDEX AND KNEE STRUCTURES ON MRI AND PAIN: A PROSPECTIVE COHORT STUDY

F. Pan[1], J. Tian[1], M. Cervo[2], D. Scott[3], F. Cicuttini[4], G. Jones[1]. *[1]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; [2]Monash University, School of Clinical Sciences at Monash Health, Melbourne, Australia; [3]Deakin University, School of Exer & Nutr Sciences, Melbourne, Australia; [4]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*

Background: While some individual dietary nutrients/components have been shown to be associated with knee osteoarthritis (OA) progression, the associations of the dietary inflammatory index (DII), which reflects the overall inflammatory potential of a diet, with MRI-detected structural changes and pain have not been investigated.

Objectives: This longitudinal study aimed to determine whether DII scores are associated with knee structural changes and pain over a 10.7-year follow-up in community-dwelling older adults.

Methods: This study utilised the data from a prospective population-based cohort study (mean age 63 years, 51% women) in which 1,099, 875, 768 and 563 participants completed assessments at baseline, 2.6, 5.1 and 10.7 years, respectively. T1-weighted or T2-weighted MRI of the right knee was performed to measure cartilage volume (CV) and bone marrow lesions (BMLs) at baseline and 10.7 years. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain questionnaire was used to measure knee pain at all assessments. Baseline energy-adjusted DII (E-DII) scores were calculated using a validated Food Frequency Questionnaire. X-ray was performed to assess radiographic knee osteoarthritis (ROA). Linear, log-binomial regression and linear mixed-effects modelling with adjustments for covariates were used to examine the associations of E-DII with CV loss, BML size increase and knee pain, respectively. Pain trajectories (i.e., 'Minimal Pain', 'Mild Pain', and 'Moderate Pain') were previously identified in this cohort using group-based trajectory modelling [1]. Multi-nominal logistic regression was used to examine the association between E-DII and pain trajectory groups.

Results: The mean E-DII at baseline was -0.48±1.39. In multivariable analyses, E-DII score was not associated with tibial CV loss and BML size increase [CV loss: β=0.03% per annum, 95%CI -0.01–0.06; BML size increase: relative risk (RR)=0.94, 95%CI 0.84–1.05;]. Higher E-DII was associated with greater pain score over 10.7 years (β=0.21, 95%CI 0.004-0.43) and an increased risk of belonging to 'Moderate pain' as compared to 'Minimal Pain' trajectory group [relative risk ratio (RRR): 1.19, 95%CI 1.02-1.39] after adjustment for age, body mass index, physical activity, education level, employment, emotional problems, comorbidities, and ROA.

Conclusion: Higher DII was associated with greater pain score and higher risk of more severe pain trajectory, but not structural changes, suggesting discordance between effects of diet on structural damage and pain, and that targeting pro-inflammatory diets may be beneficial to reduce pain.

POS1117 SAFETY AND EFFICACY OF ADIPOSE-DERIVED MESENCHYMAL STEM CELLS FOR OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Gadelkarim[1], A. Abd Elmegeed[2], A. Hafez[3], A. K. Awad[4], M. Ahmed Shehata[5], A. Abouelen[6], A. M. Afifi[7]. *[1]Loyola University Medical Center, Department of Surgery, Maywood, United States of America; [2]Faculty of Science, Menoufia University, N/A, Shebein el kom, Egypt; [3]Faculty of Medicine, Menoufia University, N/A, Shebein el kom, Egypt; [4]Faculty of Medicine, Ain Shams University, Cairo, Egypt, N/A, cairo, Egypt; [5]Alexandria Faculty of Medicine, N/A, Alexandria, Egypt; [6]Faculty of pharmacy, Alexandria University, Alexandria, Egypt, N/A, alexandria, Egypt; [7]Baylor College of Medicine, Department of Internal Medicine, Houston, United States of America*

Background: Osteoarthritis (OA) is a debilitating joint disorder affecting articular cartilages and subchondral bones, prompting synovial membrane irritation and inflammation (1). Nowadays, knee OA can be treated either by surgical or non-surgical approaches, while the Osteoarthritis Research Society International (OARSI) suggested pharmacological medications joined with other functional approaches such as exercise, joint inflammation instructions, and weight reduction (2), yet most of them exhibit modest safety and efficacy (3). Mesenchymal stem cells (MSCs) have been well-known in regenerative medicine for their wide differentiation capacity. Moreover, MSCs can be derived from various sources (4); however, Adipose-derived mesenchymal stem cells (ADMSCs) are easiest to assemble for clinical use with higher isolation yields (4).

Objectives: This study investigated the potential and regenerative capacity of adipose-derived mesenchymal stem cells (ADMSCs) for osteoarthritis (OA).

Methods: We created a search strategy and applied it to six databases. After screening the records for eligibility, we identified and evaluated the risk of bias in both the randomized and non-randomized research studies. Then, data were extracted and implemented into single-arm and double-arm analyses

Results: 16 studies with 469 patients were included. We found a significant improvement in the quality of life (QOL) among the three doses subgroups (high, medium, and low doses) which was estimated by the SF-36 scores after a year of follow up (low dose: Mean (M) -23.991; p = 0.000; medium dose: M -15.96; p = 0.000; high dose: M -19.306, p = 0.000). Furthermore, we noticed a significant decrease in pain as estimated by the numeric pain rating scale (NPRS) after three months of follow-up with no significant difference between the low and medium doses (low dose: M -3.119; p = 0.002; medium dose; M -2.17; p = 0.000). Our double-arm analyses illustrated significant pain reduction in the ADMSCs group over the control after 12 months as estimated by WOMAC pain subscore (Mean difference (MD) -1.85, p =0.03); moreover, The knee functions and activity levels improved significantly among the low dose group as measured by the WOMAC physical function and stiffness subscales after six months (M -23.797; p = 0.001; M -10.249; p = 0.009, respectively) and the KOOS scores after 12 months ($p \leq 0.007$ for all KOOS subscales). No significant adverse events were observed in the ADMSCs injections group (Event rate (ER) p = 0.001).

Conclusion: Although ADMSCs were associated with significant reductions in pain scores, improvements in QOL score and knee functions, and achieving disease modification in patients with OA, they did not significantly differ from the control. Therefore, implementing ADMSCs in routine clinical practice needs more studies with large sample sizes, longer follow-up periods.

POS1118

METFORMIN AS A POTENTIAL DISEASE-MODIFYING DRUG IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW OF PRE-CLINICAL AND HUMAN STUDIES

Y. Lim[1], Y. Wang[1], M. Estee[1], J. Abidi[2], M. Udaya Kumar[2], S. M. Hussain[1], A. Wluka[1], C. Little[3], F. Cicuttini[1]. [1]*Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia;* [2]*The Alfred, Alfred Hospital, Melbourne, Australia;* [3]*The University of Sydney, Raymond Purves Bone and Joint Research Laboratories, Kolling Institute, New South Wales, Australia*

Background: Osteoarthritis causes significant pain and disability with no approved disease-modifying drugs. There is evidence emerging from pre-clinical and human studies suggesting metformin may have disease-modifying properties in osteoarthritis[1-5]. Given its pleiotropic effects and safety profile, metformin has the potential to be a novel therapy for osteoarthritis.

Objectives: We systematically reviewed the evidence from both pre-clinical and human studies for the potential disease-modifying effect of metformin in osteoarthritis.

Methods: Ovid Medline, Embase and CINAHL were searched between inception and June 2021 using MeSH terms and key words to identify studies examining the association between metformin use and outcome measures related to osteoarthritis. Two reviewers performed the risk of bias assessment and 3 reviewers extracted data independently. Qualitative evidence synthesis was performed. This systematic review is registered on PROSPERO (CRD42021261052 and CRD42021261060).

Results: Fifteen (10 pre-clinical and 5 human) studies were included. Most studies (10 pre-clinical and 3 human) assessed the effect of metformin using knee osteoarthritis models. In pre-clinical studies, metformin was assessed for the effect on structural outcomes (n=10); immunomodulation (n=5); pain (n=4); and molecular pathways of its effect in osteoarthritis (n=7). For human studies, metformin was evaluated for the effect on structural progression (n=3); pain (n=1); and immunomodulation (n=1). Overall, pre-clinical studies consistently showed metformin having a chondroprotective, immunomodulatory and analgesic effect in osteoarthritis, predominantly mediated by adenosine monophosphate-activated protein kinase activation. Evidence from human studies, although limited, was consistent with findings in pre-clinical studies.

Conclusion: We found consistent evidence across pre-clinical and human studies to support a favourable effect of metformin on chondroprotection, immunomodulation and pain reduction in knee osteoarthritis. Further high-quality clinical trials are needed to confirm these findings as metformin could be a novel therapeutic drug for the treatment of osteoarthritis.

POS1119

EFFICACY OF CORTICOSTEROIDS FOR HAND OSTEOARTHRITIS - A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

M. Estee[1], F. Cicuttini[1], M. Page[1], A. Butala[1], A. Wluka[1], S. M. Hussain[1], Y. Wang[1]. [1]*Monash University, Epidemiology and Preventive Medicine, Melbourne, Australia*

Background: Hand osteoarthritis (OA) is a prevalent joint condition, causing disabling pain, reduced mobility, impaired daily functioning and quality of life [(1-2)]. Corticosteroids are anti-inflammatory medications frequently used in musculoskeletal diseases. There is some evidence that corticosteroids may have a beneficial effect in hand osteoarthritis [(3-4)].

Objectives: To examine the efficacy of corticosteroids on symptoms and structural outcomes in hand osteoarthritis.

Methods: Ovid MEDLINE, Embase and Cochrane Central Register of Controlled Trials were searched from inception to October 2021 for randomized controlled trials investigating the efficacy of corticosteroids in hand osteoarthritis. Two authors independently screened records, extracted data, and assessed risk of bias using the RoB 2 tool. Standardized mean difference (SMD) or mean difference was calculated, and random-effects meta-analyses were performed.

Results: Of 13 included trials, three examined oral and ten examined intra-articular injection of corticosteroids on clinical outcomes. In meta-analysis, oral corticosteroids reduced pain (SMD=-0.53, 95%CI -0.79 to -0.28) and improved function (SMD=-0.37, 95%CI -0.63 to -0.12) at 4-6 weeks, and intra-articular corticosteroid injection improved function (SMD=-0.48, 95%CI -0.90 to -0.06) at 4-6 weeks. Corticosteroids had no significant effects on pain and function over 3 months and 6-12 months. Two trials evaluated joint structure at 4-6 weeks: one study showed oral corticosteroids reduced synovial thickening, neither showed an effect on synovitis.

Conclusion: There was low-certainty evidence for a medium effect of oral corticosteroids on pain relief and small-to-medium effect on functional improvement at 4-6 weeks. Intra-articular corticosteroids showed low-certainty evidence for a medium effect on functional improvement at 4-6 weeks. Corticosteroids had no significant effect on any outcomes over longer term. No trials examined the effect of corticosteroids on disease progression. The role of corticosteroids in hand osteoarthritis is limited.

POS1120

ASSOCIATION OF ADIPOKINES WITH SEVERITY OF KNEE OSTEOARTHRITIS ASSESSED CLINICALLY AND ON MAGNETIC RESONANCE IMAGING

T. Chong[1], J. R. Tan[2], C. MA[1], S. B. S. Wong[3], Y. Y. Leung[1]. [1]*Singapore, Rheumatology & Immunology, Singapore, Singapore;* [2]*Singapore General Hospital, Radiology, Singapore, Singapore;* [3]*SengKang General Hospital, Radiology, Singapore, Singapore*

Background: Adipokines secreted by adipose tissue create a low grade systemic inflammatory state that could contribute to the pathogenesis of knee OA (KOA). Previous studies of association between adipokines and radiographic KOA represented late-stage disease shown as bony changes. Magnetic Resonance Imaging (MRI) has the advantage of showing early changes of KOA in all joint structures.

Objectives: We aimed to evaluate the association between the adipokines: Leptin, Adiponectin, Resistin, and hs-CRP with clinical, radiographical and MRI assessment of KOA severity.

Methods: We performed a cross-sectional study in participants with early KOA. Demographics, clinical (WOMAC), and MRI (BLOKS scoring) KOA severity were assessed. Serum leptin, adipokines, resistin and hs-CRP were measured. Association of adipokines with clinical and MRI severity outcomes were evaluated using regression models with adjustment with age, sex, and body mass index (BMI).

Results: 139 participants with early KOA (82% women, mean ± SD age: 55.5 ± 7.8 years) were included. Participants had moderate KOA symptoms, mean WOMAC pain and function were 31.1 ± 18.4, and 32.0 ± 19.9 respectively. Mean BMI was 26.0 ± 5.9 kg/m^2. After adjustment with age, sex and BMI, Leptin (p=0.001) and hs-CRP (p=0.03) were positively associated, while adiponectin (p=0.02) and resistin (p=0.03) were negatively associated with osteophyte size

(Table 1). In addition, leptin was statistically significantly associated with cartilage loss, synovitis, and effusion, while hs-CRP was associated with meniscus extrusion. As for WOMAC assessed severity, only adiponectin was statistical significantly associated with WOMAC function.

POS1121 HAND OSTEOARTHRITIS IS ASSOCIATED WITH LIMITATIONS IN PAID AN UNPAID WORK PARTICIPATION AND RELATED SOCIETAL COSTS: THE HOSTAS COHORT

S. Terpstra[1], L. Van de Stadt[2], A. Boonen[3], F. Rosendaal[4], M. Kloppenburg[2,4].
[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands;
[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands;
[3]Maastricht University Medical Center, Rheumatology, Maastricht, Netherlands;
[4]Leiden University Medical Center, Epidemiology, Leiden, Netherlands

Background: Rheumatic musculoskeletal diseases (RMDs) can cause impairment in paid and unpaid work which can contribute to societal burden and costs. However, data on this topic concerning hand osteoarthritis (OA) is scarce, while this is crucial for assessing the societal impact of this disease.
Objectives: To investigate the association of hand OA with paid and unpaid work limitations, productivity loss and costs of productivity loss.
Methods: We used data of the Dutch Hand OSTeoArthritis in Secondary care (HOSTAS) cohort, a primary hand OA cohort from a general rheumatology outpatient clinic. The treating rheumatologist defined hand OA presence. We assessed patient and OA characteristics using validated questionnaires and tests. We investigated work impairment due to hand OA with the Health and Labour Questionnaire (HLQ) which assesses the last two weeks on hand-OA related limitations, hours of sick leave and unproductiveness during paid work, and limitations and hours of the necessity of being replaced by others for unpaid work tasks. We estimated societal costs of paid work by multiplying unproductive and sick leave hours due to hand OA by the average Dutch hourly societal costs of paid work for persons of the same age category and sex. We estimated societal costs of unpaid work by multiplying the hours of unpaid work replaced by others by the Dutch gross average hourly salary of a household help (€12.50).
Results: HLQ data was available for 382 patients (mean age 61 years, 86% women, 26% having a university degree, 41% having any comorbidity). Of these persons, 181 (47%) had paid work, 16 (4%) had full work disability due to hand OA and 117 (30%) were retired. Thirteen employed persons (7%) reported sick leave due to hand OA in the last two weeks, for whom a median of 42 working hours (interquartile range (IQR) 24 to 54) was lost. Unproductive paid work hours were present for 28 (15%) patients, with a median of 4 hours in the last two weeks (IQR 2 to 6). Hinder at work in the last two weeks was reported by 120 out of 181 working patients (66%), for whom median hinder score (score range 6-24) was 7 (IQR 6 to 8). Work production loss in the last two weeks due to hand OA (the sum of sick leave hours and unproductive hours) was present for 36 patients (19%). Patients with paid work productivity loss (n = 35, 19%) did not differ statically significantly in patient and disease characteristics from those without productivity loss (n = 146, 19%). Unpaid work replacement in the last two weeks was reported by 171 patients (45%), with a median of three hours replaced (IQR 2 to 7). Any unpaid work hinder was reported by 297 (78%). Median unpaid work hinder score (score range: 4-16) was 8 (IQR 7 to 10) . Patients with unpaid work replacement by others due to hand OA (n=171, 45%) were statically significantly more often female and had a higher BMI than with those without any replacement (n=210, 55%). We estimated total societal costs of hand OA related to paid work production loss at €61 (95% confidence interval (CI) 27 to 96) per two weeks, and societal costs for unpaid work at €33 (CI 27 to 40). Total estimated work-related societal costs per patient with hand OA were €94 (CI 59 to 130), translating to €2452 (CI 1528 to 3377) per year.
Conclusion: Hand OA is associated with impairment in paid and unpaid work, which translates into substantial societal costs. This highlights the social and economic importance of adequate hand OA treatment. It also highlights the importance of investigating work impairment experienced by hand OA patients visiting the outpatient clinic, for potentially more tailored treatment.

POS1122 ULTRASOUND GUIDED INJECTIONS OF HYADD4 FOR KNEE OSTEOARTHRITIS IMPROVES PAIN AND FUNCTIONAL OUTCOMES AT 3 AND 6 MONTHS WITHOUT CHANGES IN SYNOVIAL FLUID VOLUMES.

R. Meehan[1], M. Gill[1], E. Hoffman[1], M. Wolf[2], I. Amigues[1], L. M. Kastsianok[1], E. Regan[1], J. Crooks[3,4], G. Czuczman[5], C. Coeshott[2], V. Knight[6]. *[1]National Jewish Health, Medicine/Rheumatology, Denver, United States of America; [2]National Jewish Health, Pathology/ADx Immunology Labs, Denver, United States of America; [3]National Jewish Health, Bioinformatic, Denver, United States of America; [4]CU Anschutz School of Medicine, School of Public Health, Aurora, United States of America; [5]National Jewish Health, Radiology, Denver, United States of America; [6]Children's Hospital, Immunology, Aurora, United States of America*

Background: Prior studies have demonstrated improved accuracy and efficacy when Intra-articular (IA) therapeutics are injected using ultrasound (US) guidance. There is also growing evidence that many patients with knee osteoarthritis (OA) exhibit a pro-inflammatory catabolic synovial fluid (SF) profile. However, it is not known if temporary clinical improvement in pain and function after IA Hyaluronic acid (HA) injections is associated with changes in SF volumes.
Objectives: The purpose of this study was to determine if IA HA injections delivered using US directed needle visualization with an external pneumatic compression device would result in improved clinical outcomes for knee OA at 3 and 6 months, and if this was associated with a reduction in the amount of knee synovial fluid (SF) measured on US.
Methods: 49 eligible subjects with symptomatic Knee OA, BMI < 40 and KL radiographic rating of II or III OA were consented for this open label prospective IRB approved Investigator Initiated SF OA biomarker study (HS 3179, NCT 04093232). All standing radiographs were reviewed by a fellowship-trained MSK radiologist. 36 subjects had adequate aspirated SF volumes of > 500 mcl for biomarker analysis and therefore were eligible to receive two IA injections of HYADD4, 24 mg/3ml (Fidia Farmaceutici S.p.A. Italy) 7 days apart by a MSK US certified Rheumatologist. An external pneumatic compression device and US visualized needle insertion ensured injections were delivered into the intra-synovial space. Despite COVID-19 restrictions, 34 patients (17 women and 17 men) between 35 and 78 years of age returned for 3 month evaluations and 30 had evaluations at 6 months. The following clinical variables were measured: Western Ontario and McMaster Universities Index (WOMAC) total scores, Visual Analog Pain Scale (VAS, 0-10), PCS scores on the SF-36 health survey questionnaires (physical function/bodily pain and general health), 6-minute walking distance in meters (6 MWD), and measured SF depth before and after an external pneumatic compression device was inflated to 100 mmHg to facilitate aspiration by increasing available SF volumes under positive presure. The SF depth was measured on the recorded US image (GE logiq e) as the largest anechoic region selected for aspiration on either the lateral (n= 30) or medial (n=4) compartment. SF and simultaneous peripheral blood samples were centrifuged and cryopreserved at -80 ^{o} C within 45 minutes of aspiration for future analysis. Statistical differences between baseline values compared to those levels at 3 and 6 months were determined using a paired ANOVA test with $p < 0.05$ significance.
Results: Improvements over baseline values were observed at 3 and 6 months respectively, after IA HA injections in WOMAC (40%, 40%), VAS (45%, 51%) and PCS (15%, 18%) all $p < 0.0001$. The 6 WWD improved by 7 % at 3 months ($p < 0.007$) but was not statistically improved at 6 months. US measured SF depth at baseline was 3.2 ± 2.2 mm before inflation and 6.4 + 3.7 mm after inflation of the

pneumatic external compressioin device but statistical differences in SF depth were not observed at 3 and 6 months.

Conclusion: Despite improvements in WOMAC, VAS scores, and PCS scores on the SF 36 at 3 and 6 months after US guided knee injections with an HA product, a statistically significant reduction in the amount of US measured SF was not observed. The 6 MWD improved at 3 months but was not statistically different from the baseline distance by 6 months. IA injections using US needle visualization confirmed that the product was delivered into the synovial space with 100 % accuracy which might have resulted in improved efficacy results in this study compared to prior IA HA studies injected without US or using different HA products. In the future, we hope SF biomarkers may identify which individual OA patients will likely achieve the greatest benefit with IA HA injections and to determine if this is associated with a reduction in catabolic pro-inflammatory proteins.

POS1123 WEAK OPIOIDS AND TREATMENTS WITH ANTICHOLINERGIC PROPERTIES INCREASE BUT ANTIHYPERTENSIVE TREATMENTS DECREASE THE NUMBER OF FALLS IN PATIENTS FOLLOWED FOR KNEE AND/OR HIP OA: ANALYSES OF THE KHOALA COHORT

M. Aqlan[1], M. L. Bocca[1], G. Loggia[1,2], E. Attoh-Mensah[1], C. Chavoix[1], A. C. Rat[1,3]. *[1]Caen-Normandy University, UNICAEN, Inserm, UMR-S 1075 COMETE, PFRS, Caen, France;, Caen, France; [2]University Hospital Center Caen, Department of geriatrics, Caen, France; [3]University Hospital Center, Rheumatology Department, Caen, France*

Background: The risk of falling is increased in people with knee osteoarthritis (OA) but the risk factors may not be the same as in the general population. The level of evidence for the associations between the different risk factors and falls in OA is moderate, the number of studies for each factor being small.

Objectives: The main objective of the study was to identify factors associated with the number of falls in patients with symptomatic knee and/or hip OA during five years of follow-up, in particular the drug-related risk factors that are modifiable factors.

Methods: This study was based on data from the KHOALA (Knee and Hip OsteoArthritis long term Assessment) cohort, consisting of 878 patients aged 40 to 75 years, with symptomatic knee and/or hip OA, recruited between 2007 and 2009 in the general population. Patients were followed up annually for 10 years. This study is a longitudinal analysis using data from years 5 to 10, with falls data collected from year 5.

The primary endpoint was the number of falls reported by the patient. The potential risk factors studied were: medications grouped into ATC classes, a score of treatments with anticholinergic properties*, demographic (age, sex, education, socio-professional category), clinical (comorbidities), perceived health (WOMAC-pain, WOMAC-function, quality of life by the SF-36), and radiological (Kellgren stage) data. Statistical analyses used generalized linear mixed models.

Results: 661 patients were included in the analyses. The majority of the sample was female (69%); the mean age was 62 years at year 5, and 153 patients (23.15%) had reported one or more falls in the previous 12 months.

In multivariate analyses, and thus independent of pain and functional abilities, a significantly higher number of falls was found in women (OR [CI95%] 1.70 [1.12-2.57]), patients living alone (0.65, [0.47-0.95], P=0.02), retired people (1.92, [1.094-3.37]), patients with more comorbidities (OR 1.10, [.01-1.21]), using fewer antihypertensive drugs (OR 0.61, [.42-0.90]), more weak opioids (OR 1.44, [.05-1.96]) and more treatments with anticholinergic properties (OR 1.31, [.00-1.73])

Conclusion: Weak opioids and the score of treatments with anticholinergic properties increased, but antihypertensive treatments decreased the number of falls in patients followed for knee and/or hip OA. The risk factors found in this study are identical to those of the general population, whose pain and functional capacities are less impaired.

Doherty[2,9], A. Sarmanova[10], M. Englund[5], S. M. A. Bierma-Zeinstra[4,11], W. Zhang[2,9], D. Prieto-Alhambra[1], S. Khalid[1]on behalf of FOREUM OA Comorbidity. *[1]University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences (NDORMS), Oxford, United Kingdom; [2]University of Nottingham, Academic Rheumatology, School of Medicine, Nottingham, United Kingdom; [3]University of Oxford, Department of Primary Care Health Sciences, Oxford, United Kingdom; [4]Erasmus University Medical Center, Department of General Practice, Rotterdam, Netherlands; [5]Lund University, Clinical Epidemiology Unit, Orthopaedics, Department of Clinical Sciences Lund, Lund, Sweden; [6]Keele University, School of Medicine, Keele, United Kingdom; [7]Chang Gung Memorial Hospital, Division of Rheumatology, Allergy and Immunology, Taoyuan, Taiwan, Republic of China; [8]University of Nottingham, Division of Primary Care, School of Medicine, Nottingham, United Kingdom; [9]University of Nottingham, Pain Centre Versus Arthritis, Nottingham, United Kingdom; [10]University of Bristol, Musculoskeletal Research Unit, Bristol Medical School, Translational Health Sciences, Bristol, United Kingdom; [11]Erasmus MC University Medical Center, Department of Orthopedic Surgery & Sports Medicine, Rotterdam, Netherlands*

Background: Osteoarthritis (OA) patients are more likely to have other comorbidities (Swain, Sarmanova et al. 2020). Improving the understanding of comorbidity profiles of OA patients may lead to improvement in their clinical care.

Objectives: To identify sub-groups in patients diagnosed with hip OA using patterns of comorbidity.

Methods: Routinely-collected data of individuals ≥18 years with an incident diagnosis of hip OA (baseline/time of diagnosis), with at least 1 year of follow-up in SIDIAP (Information System for Research in Primary Care, a primary case database from Spain) were collected from January 1st 2006 to June 31st 2020. Those with soft-tissue disorders or other bone/cartilage diseases at the same joint in the year prior/after baseline were excluded. Comorbidities associated with OA in the literature and

present in ≥1% of the study population were included. Clusters of comorbidities were identified at baseline using latent class analysis (LCA), a soft clustering method that classifies individuals according to the distribution of their measured items. The number of clusters or sub-groups within the study population was decided by comparing goodness of fit parameters (CAIC, BIC, ABIC) and log-likelihood changes of models from 2 to 8 clusters. The selected model was externally evaluated by a survival analysis assessing 10 years mortality within each cluster, where the weight of the posterior probability was used as a probability of sampling weight.

Results: We identified 94,720 individuals with an incident diagnosis of hip OA, 56.3% women and 43.7% men, with a mean age (SD) of 67.2 (13.1) years. We selected the LCA model with 5 clusters that could be described as: healthier (lower prevalence of all comorbidities than average in the cohort), multimorbidity (higher prevalence of all comorbidities, multiple comorbidities), back/neck pain plus mental health (B/N-mental), cardiovascular disease (CVD), and metabolic syndrome (MetS) (Figure 1). Cox regression (HR [95CI%]) showed higher mortality risk for multimorbidity (3.76 [3.70-3.83]), CVD (1.56 [1.53-1.59]) and MetS (4.56 [4.35-4.78]), compared to healthy. No difference was observed for B/N-mental cluster.

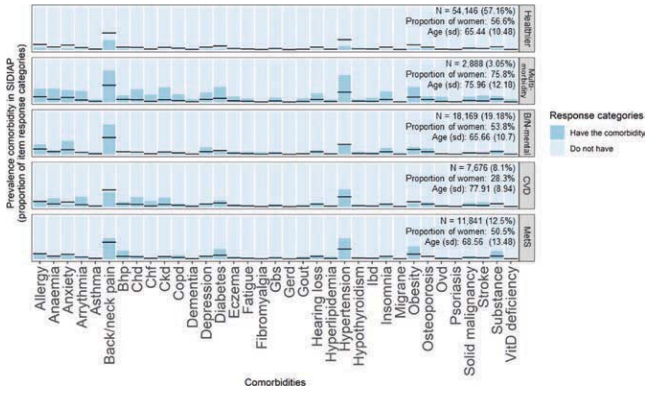

Figure 1. Distribution of comorbidities within each cluster using latent class analysis. Clusters were described as Healthier, Multimorbidity, B/N-mental, CVD and MetS. Black horizontal lines represent the prevalence of the comorbidity before the clusterization. Abbreviations: Healthier, lower prevalence of all comorbidities; Multimorbidity, higher prevalence of all comorbidities; B/N-mental, back/neck pain plus mental health disorders; CVD, cardiovascular disease; Met, metabolic syndrome; Bhp, benign prostate hypertrophy; Chd, chronic heart disease; Chf, chronic heart failure; Ckd, chronic kidney disease; Copd, chronic obstructive pulmonary disease; Gbs, gall bladder stone; Gerd, gastroesophageal reflux disease; Ibd, inflammatory bowel disease; Ovd, other vessel diseases; Substance, substance abuse.

Conclusion: Clustering of co-morbidities in hip OA patients at the time of diagnosis has the potential to detect sub-groups of hip OA patients who might require additional care.

POS1125

EFFICACY OF TUMOR NECROSIS FACTOR INHIBITORS IN HAND OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

M. Estee[1], F. Cicuttini[1], M. Page[1], A. Wluka[1], Y. Wang[1]. [1]*Monash University, Epidemiology and Preventive Medicine, Melbourne, Australia*

Background: Hand osteoarthritis (OA) is a leading cause of functional impairment associated with chronic pain and stiffness in hand joints[(1)]. It is well documented that inflammation plays an important role in the pathogenesis of hand [(2)]. Therefore, therapies targeting inflammation may offer a novel approach for the management of hand OA. Tumor necrosis factor (TNF) inhibitors are a class of anti-inflammatory drugs that have been used in musculoskeletal conditions [(3-5)].

Objectives: To examine the efficacy of tumor necrosis factor (TNF) inhibitors on symptoms and structural outcomes in hand osteoarthritis.

Methods: The study was carried out according to PRISMA protocol. Ovid Medline, Embase and Cochrane Central Registry of Controlled Trials were searched from inception to October 2021 for randomized controlled trials examining the efficacy of TNF inhibitors in hand osteoarthritis. We performed quantitative extraction of data and risk of bias assessment for the eligible studies. Where data were available, mean difference was calculated and random effect meta-analysis was performed. Quality of the evidence was assessed using GRADE criteria.

Results: Four studies were identified involving 276 participants in total. There studies had low risk of bias and one study had some concerns. Meta-analysis showed that TNF inhibitors had no effect on pain at 4-6 weeks and 24-26 weeks and no effect on grip strength at 1 year (Table 1). There was no effect of TNF inhibitors on most of the clinical and structural outcomes. There was conflicting evidence for the effect of TNF inhibitors on radiographic progression, bone marrow lesion or erosive evolution at 12 months. Quality of evidence was low for the effect of TNF inhibitor on pain and moderate for grip strength.

Conclusion: Our systematic review found no effect of TNF inhibitors on clinical outcomes and the effect of TNF inhibitors on structural outcome over longer term is inconclusive. More clinical trials are needed to clarify the role of TNF inhibitors in the management of hand OA.

POS1126

CLINICAL EFFICACY AND SAFETY OF MONOCLONAL ANTIBODY AGAINST NERVE GROWTH FACTOR AND FIBROBLAST GROWTH FACTOR-18 THERAPY OF OSTEOARTHRITIS

M. Pallav[1], L. Zaripova[2], D. Tazhibaeva[2], N. Kabdualieva[2]. [1]*Astana Medical University, Department of Pathological Physiology, Nur-Sultan, Kazakhstan;* [1]*Astana Medical University, Department of Pathological Physiology, Nur-Sultan, Kazakhstan*

Background: Osteoarthritis (OA) is the most common chronic progressive musculoskeletal system disease affecting more than 500 million people globally, which represents the formidable public health challenge. Currently osteoarthritis treatment includes acetaminophen, NSAIDs and/or opioids, intra-articular corticosteroid injections. Some guidelines also recommended chondroitin and glucosamine sulfate, suggested that they may be effective and reduce functional impairment. However, despite of the huge amount of data on the problem of OA, there is still no effective treatment that slows down the progression of the disease. Recently appeared monoclonal antibodies against nerve growth factor (NGF) as well as fibroblast growth factor (FGF)-18 may be the promising tool for clinical improvement of OA

Objectives: To evaluate the safety and efficacy of anti-NGF and FGF-18 on patients with osteoarthritis by a systematic review.

Methods: In the current study the search process was conducted in PubMed using the following strategy: "FGF-18" or "anti-NGF" and "OA", "monoclonal antibody" + "osteoarthritis". All articles published in the format of Case Reports, Clinical Study, Clinical Trial Protocol, Clinical Trial, Multicenter Study were reviewed. Clinical outcomes were assessed using clinical scores, included the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) Pain and Physical Function score, Patient's Global Assessment of OA (PGA-OA), adverse events (AEs); cartilage repair and total femorotibial joint cartilage thickness were assessed using magnetic resonance imaging.

Results: Based on our search 23 publication were included in the study after omitting repetitions. Among 23 studies, 16 used anti-NGF monoclonal antibodies (Tanezumab, Fasinumab, Fulranumab), and **7** used recombinant human FGF-18 (Sprifermin). The total of 6679 patients were analysed in these articles. In the pooled analysis NGF inhibitors demonstrated statistically significant improvements compared with placebo in WOMAC Pain and Physical Function score (all studies revealed significantly better clinical outcomes in the anti-NGF group). After treatment with FGF-18 (Sprifermin) there was also improvement in WOMAC scores though not statistically significant. However, FGF-18 therapy was associated with the reductions in loss of total and lateral femorotibial cartilage thickness. Moreover, it does not only significantly reduce cartilage loss but also increase cartilage thickness. In terms of cartilage repair, 5 of 7 studies reported improvement in total femorotibial joint cartilage thickness. The AEs of FGF-18 or anti-NGF therapies were not serious, however they may affect the compliance and satisfaction of patients and clinicians. The proportion of patients with adverse events in anti-NGF treatment group was higher than that in FGF-18. The following conditions were reported in anti-NGF: abnormal peripheral sensation such as hypoesthesia (7.43%), paraesthesia (9.15%), hyperesthesia (0.36%), peripheral neuropathy and sensory disturbance (0.35%); arthralgia (15%), back pain (15.06%), pain in extremity (10%), headache (9.11%), upper respiratory tract infection (10.65%), diarrhoea (11.95%), sinusitis or nasopharyngitis (10.13%). The difference in AEs between sprifermin and placebo groups was found insignificant, most frequently reported event was arthralgia.

Conclusion: In recent years significant progress has been achieved in search for pathogenetic therapy of OA. Based on the results of current research findings, NGF inhibitors relieved pain and enhance joint function and may be considered as the most effective for functional improvement. FGF-18 decrease the cartilage loss and may improve cartilage thickness. However, further clinical longitudinal studies characterised the risk-benefit are needed to establish their safety and efficacy.

POS1127

USE OF ARTIFICIAL INTELLIGENCE AND CLOUD-BASED INFRASTRUCTURE TO IMPROVE THE SPEED AND ACCURACY OF ELIGIBILITY READS IN OSTEOARTHRITIS TRIALS.

O. Kubassova[1], M. Boesen[2], C. Pereira Da Costa[3], J. O'lynn[1], A. Patterson[3], D. Kessler[3]. [1]*Image Analysis Group, R&D, Philadelphia, United States of America;* [2]*Copenhagen University Hospital Bispebjerg-Frederiksberg,, Department of Radiology,, Copenhagen, Denmark;* [3]*Image Analysis Group, Imaging, London, United Kingdom*

Background: The Kellgren-Lawrence grading (KLG) system is used in clinical trials of osteoarthritis (OA) to define the structural severity of the disease as part of patient eligibility assessment. However, the use of KLG system has proven to be challenging due to considerable inter-reader variability[1], [2], which may result in recruitment of sub-optimal patient cohort or delays in patient recruitment.

Objectives: The objective of this study was to determine the impact of an AI-assisted, cloud-based data management system on the rate of adjudication and the speed of OA patient recruitment.

Methods: A total of 3855 bilateral fixed-flexion posteroanterior radiographs of the tibiofemoral joints from global multi-centre trials were included in this study. Two experienced readers performed an initial KLG assessment of both knees; the adjudication was performed by a third experienced reader. A cloud-based imaging data management system was deployed, the readers could access the data simultaneously and adjudication was automatically triggered. We quantified the adjudication rate and the distribution of disagreements in KLG scores provided by the initial readers. Furthermore, the delay in delivery time of the KLG reports to the recruiting site was recorded.

Results: 48% (1836) of the initial reads required adjudication. Approximately 70% of the disagreements affected the conventional KLG 2-3 inclusion range of OA clinical trials. Use of the cloud-based data management allowed 41% of the reports to be delivered within 24 hours, if no adjudication was required vs an average of 5 days as estimated based on the readers' prior experience. Table 1 provides details on the distribution of disagreements resulting in adjudication reads. Figure 1 shows the delivery time for KLG with and without adjudication.

Table 1. Distribution of disagreements of initial reads resulting in an adjudication read being triggered.

Disagreement triggering Adjudication	Number of Cases	Percentage
KLG 0 – 1	713	27.8%
KLG 1 – 2	820	31.9%
KLG 2 – 3	482	18.7%
KLG 3 – 4	446	17.4%
Other	110	4.3%
Total	2569	100%

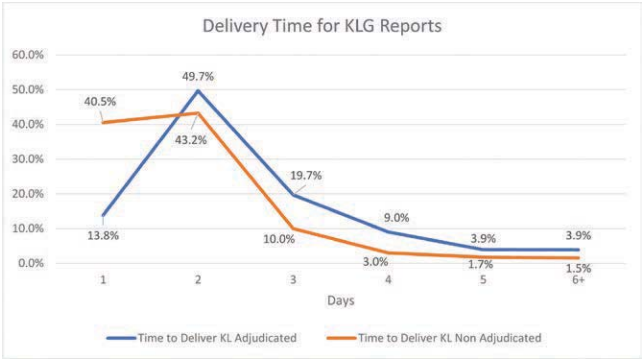

Figure 1. Time to deliver eligibility report

Nehrer *et al.* showed that assisting the readers with AI generated KLG scoring reports, the agreement rate between readers for KLG assessment increased by 21% [2]. Adding to this, 30% of the adjudications (stemming from KLG 0 –1 disagreements between readers) could be avoided when using AI generated reports.

Conclusion: We assess the rate of adjudication and speed of reporting of KLG of data from multi-centre OA clinical trials. Future work is planned to assess the effect of AI-assisted OA grading systems within our cloud-based data management system on reader agreement and recruitment speed in global clinical trials.

POS1128

SERUM MARKERS OF GUT PERMEABILITY AND ENDOTOXEMIA IN PATIENTS WITH METABOLIC SYNDROME-ASSOCIATED KNEE OSTEOARTHRITIS: AN EXPLORATORY STUDY

I. Shirinsky[1], N. Kalinovskaya[1], V. Shirinsky[1]. [1]*Federal State Budgetary Scientific Institution, Research Institute of Fundamental and Clinical Immunology, Laboratory of Clinical Immunopharmacology, Novoibirsk, Russian Federation*

Background: Metabolic syndrome (MetS)-related osteoarthritis (OA) has been proposed as a distinct phenotype of OA (1). One of the many putative pathways linking MetS with OA is increased gut permeability resulting in endotoxemia, systemic inflammation, and cartilage damage. There is a lack of studies evaluating markers of gut permeability and endotoxemia in patients with MetS-associated OA.
Objectives: In this exploratory study we aimed to: a. compare serum markers of gut permeability and endotoxemia in patients with knee OA and concomitant MetS vs patients with knee OA b. evaluate possible associations between the studied biomarkers, knee pain, function and body mass index (BMI) in patients with MetS plus OA.
Methods: In this cross-sectional study, we evaluated consecutive patients diagnosed with knee OA according to ACR criteria and willing to participate in the study. MetS was defined in accordance with NCEP ATP III criteria. Knee pain and function were assessed using the WOMAC scale. Serum concentrations of gut permeability marker zonulin, lipopolysaccharide (LPS), and soluble LPS receptor (sCD14) were measured using commercial ELISA kits.
Results: Forty patients (19 with OA plus MetS, 21 with OA), all women, mean age 65.5 years, were included in the study. The participants in the compared groups were of similar age. Patients with MetS had significantly higher BMI, increased knee pain, impaired knee function, and elevated serum C-reactive protein levels. Serum LPS, sCD14, and zonulin concentrations were significantly higher (1.5 fold, 2 fold, and 3.5 fold, respectively) in patients with OA+MetS. In the latter group, serum zonulin, sCD14, and LPS concentrations were moderately positively correlated with BMI. There were no correlations between the studied serum biomarkers and WOMAC knee pain, only zonulin was moderately positively associated with WOMAC knee function (Figure 1)

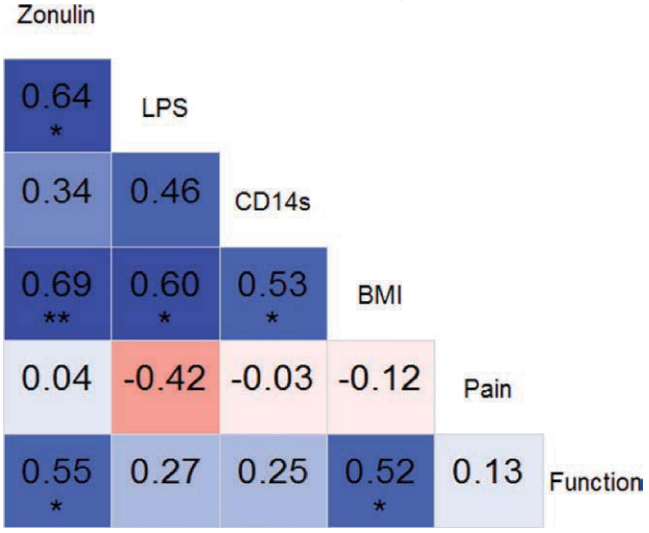

Figure 1. Spearman correlation between serum gut permeability markers, BMI, knee pain and function. * - p<0.95, ** - p<0.01

Conclusion: These findings suggest that while associated with MetS, increased gut permeability may not play a significant role in OA clinical manifestations.

POS1129

MAIN PREDICTORS OF STRUCTURAL PROGRESSION IN PATIENTS WITH METABOLIC PHENOTYPE OF OSTEOARTHRITIS

E. Taskina[1], N. Kashevarova[1], K. Telyshev[1], D. Kudinsky[1], E. Strebkova[1], E. Sharapova[1], L. Alekseeva[1,2], A. Lila[2,3]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation;* [2]*Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation;* [3]*V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Objectives: to determine the main predictors of structural progression in patients with metabolic phenotype of knee osteoarthritis (OA).
Methods: 82 female patients with metabolic phenotype of knee OA (diagnosis of OA according to the ACR criteria, radiologic stages varying I-III Kellgren & Lawrence) aged 40-75 were included in this prospective study. Mean age was 59.1 ± 8.5 years (42-74), BMI was 32.5 ± 3.48 kg/m^2, disease duration was 13 (7-19) years. Individual case report forms, which included history of the disease, physical assessment data, VAS knee pain, WOMAC, joint status, comorbidities and previous medications, were filled out for each patient. All patients performed plain knee radiography, ultrasound and MRI (WORMS).
Results: 13 patients (15.9%) showed structural progression at two years of follow-up. When comparing groups with (n=13, group 1) and without (n=69, group 2) structural progression, there were no differences in terms of age, age of disease onset and disease duration. However, in the progression group patients had higher bodyweight: 99 ± 12.9 vs 82.5 ± 8.1 kg (p = 0.0003), they also had higher VAS knee pain (69 (66-73) vs 54 (34-66) mm (p=0.0009), and WOMAC (359 (339-381) vs 255 (200-316) mm (p=0.003)). More patients from the progression group had hypertension (92.3% vs 79.7%) and type 2 diabetes (100% vs 4.3%). MRI showed significant intergroup differences in terms of both frequency and severity of cartilage damage. Cartilage defects (via WORMS) were more frequent in the medial tibial compartment of group 1: 50% vs 4.9%, RR=10.2, 95% CI 2.9-35.1, p=0.0004. Identical trend was found when evaluating bone marrow lesions (BMLs) in the medial (75% vs 27.9%, RR=2.7, 95% CI 1.6-4.5, p=0.003) and lateral (50% vs 16.4%, RR=3.05, 95% CI 1.4-6.8, p=0.02) tibial compartments. Synovitis was verified via MRI in 100% of group 1 patients vs 56.5% (RR=1.8, 95% CI 1.4-2.2, p=0.007).
Correlation analysis confirmed the relationship (p<0.05 for all) between metabolic phenotype structural progression and the following parameters: bodyweight (r=0.39), WOMAC pain (r=0.37), type 2 diabetes (r=0.27), synovium thickness via ultrasound (r=0.32), medial (r=0.44) and lateral (r=0.32) tibial compartment subchondral BMLs, medial tibial cartilage defects (r=0.42), presence of subchondral bone cysts in the medial tibial compartment (r=0.38) and femur (r=0.37); lateral tibial (r=0.28) compartment and femur (r=0.28) and also synovitis (r=0.32).
Discriminant analysis has shown that the most significant risk factors for structural progression of the metabolic phenotype of knee OA were high WOMAC pain, synovitis, type 2 diabetes and medial tibial compartment BMLs. Based on the selected factors and their coefficients, we have created a formula that allows to predict the risk of structural progression of metabolic OA.
Conclusion: this prospective trial has shown that the main predictors for metabolic knee OA phenotype progression are high WOMAC pain, type 2 diabetes, MRI-detected synovitis and BMLs in the medial tibial compartment. These risk factors may serve as a basis for further personalized therapeutic and preventive approaches.

A RANDOMISED CONTROLLED STUDY OF POLYACRYLAMIDE HYDROGEL VS. HYALURONIC ACID IN KNEE OSTEOARTHRITIS: RESULTS AT 12-MONTHS

H. Bliddal[1], J. Beier[2], A. Hartkopp[3], P. G. Conaghan[4], M. Henriksen[1]. [1]*The Parker Institute, Bispebjerg Frederiksberg Hospital, Copenhagen, Denmark;* [2]*Rheumatolog Odense, Rheumatolog Odense, Odense, Denmark;* [3]*A2 Rheumatology and Sports Medicine, A2 Rheumatology and Sports Medicine, Holte, Denmark;* [4]*Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

Background: Polyacrylamide hydrogel (iPAAG), manufactured by Contura International, is CE marked for the symptomatic treatment of patients with knee osteoarthritis (OA). iPAAG fulfils an unmet clinical need for an effective, long-acting, safe and minimally invasive treatment that may postpone and potentially prevent knee surgery for those with OA.

Objectives: To compare the effectiveness of single intra-articular injections of iPAAG and hyaluronic acid (HA) in participants with moderate to severe knee OA. To compare the effectiveness of iPAAG and HA in subgroups based on age, BMI or Kellgren-Lawrence (KL) grade at baseline by assessing changes from baseline in transformed WOMAC pain subscale scores.

Methods: This prospective, double-blind study (NCT04045431) randomized 239 participants to receive a single intra-articular injection of either 6 mL iPAAG (n=119) or 6 mL HA (n=120). The study was approved by the Capital Region's Committee on Health Research Ethics. All participants provided informed consent prior to study activities. Outcomes included changes in the WOMAC pain, stiffness and function subscales and Patient Global Assessment of disease impact (PGA) at 52 weeks. All statistical analyses were based on the ITT principle using a mixed model for repeated measurement with a restricted maximum likelihood-based approach. The estimated mean treatment difference based on this model was reported with 95 % CI and p-value.

Results: Demographic and baseline characteristics were similar between treatment groups with an average age at treatment of approximately 67 years (range 31 – 90 years) and slightly more females (53%) than males. There was a clinically relevant decrease in WOMAC pain subscale score from baseline to 52 weeks in both groups (Figure 1). There were also clinically relevant decreases in the WOMAC stiffness subscale and physical function subscale and PGA in both groups. Treatment differences in favor of iPAAG compared to HA, were measured for the 3 WOMAC subscales and PGA. However, none of these differences reached statistical significance.

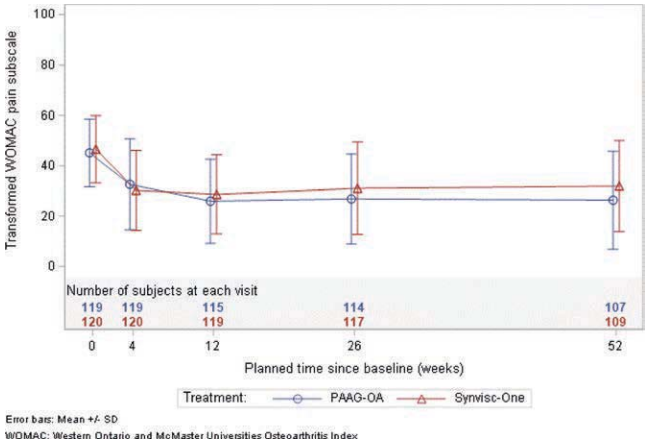

Figure 1. Mean plot of transformed WOMAC pain subscale (0-100) – ITT analysis set

The treatment difference in favor of iPAAG compared to HA for the WOMAC pain subscale score was statistically significant in the subgroup with age at baseline <70 years but did not reach statistical significance in the subgroup with age at baseline ≥70 years. The treatment difference in favor of IPAAG compared to HA for the WOMAC pain subscale score was statistically significant in the subgroup with normal BMI but did not reach statistical significance in the subgroups with overweight or obese BMI. The treatment difference in favor of IPAAG compared to HA for the WOMAC pain subscale score was statistically significant in the subgroup with KL grade 2 or 3. In the subgroup with KL grade 4, a treatment difference in favor of HA was not statistically significant.

Table 1. Change from baseline in transformed (0-100) WOMAC pain subscale at week 52

	LSMean (95% CI)	Treatment difference (95% CI)	p-value
Overall			
HA	-13.3 (-16.7; -10.0)		
iPAAG	-17.9 (-21.3; -14.6)	4.6 (-0.1; 9.4)	0.0572
Age <70 years			
HA	-14.0 (-18.3; -9.6)		0.0195
iPAAG	-21.3 (-25.5; -17.0)	7.3 (1.2; 13.4)	
Age ≥ 70 years			
HA	-12.5 (-17.6; -7.4)		0.7970
iPAAG	-13.4 (-18.7; -8.2)	1.0 (-6.3; 8.2)	
BMI normal			
HA	-13.5 (-18.1; -8.9)		0.0110
iPAAG	-17.5 (-22.2; -12.9)	10.9 (2.6; 19.1)	
BMI overweight			
HA	-14.3 (-19.5; -9.2)		0.6114
iPAAG	-16.1 (-21.0; -11.3)	1.8 (-5.3; 8.9)	
BMI obese			
HA	-14.5 (-22.7; -6.2)		0.5565
iPAAG	-17.8 (-25.6; -10.0)	3.3 (-8.0; 14.7)	
KL grade 2 or 3			
HA	-13.4 (-17.0; -9.7)		0.0332
iPAAG	-18.9 (-22.5; -15.4)	5.6 (0.5; 10.7)	
KL grade 4)			
HA	-13.1 (-21.9; -4.3)		0.6757
iPAAG	-10.3 (-20.6; 0.0)	-2.8 (-16.4; 10.8)	

Conclusion: At 52 weeks after treatment, the effectiveness of iPAAG was numerically superior to HA but not statistically significantly different.
In subgroups of participants with normal BMI, participants <70 years old or participants with KL grade 2 or 3 iPAAG performed statistically significantly better than HA at 52 weeks after treatment.

POS1131

ASSOCIATION BETWEEN ANTIBIOTIC USE AND RADIOGRAPHIC PROGRESSION OF OA: DATA FROM THE OSTEOARTHRITIS INITIATIVE

I. Shirinsky[1], V. Shirinsky[1]. [1]*Federal State Budgetary Scientific Institution, Research Institute of Fundamental and Clinical Immunology, Laboratory of Clinical Immunopharmacology, Novoibirsk, Russian Federation*

Background: Gut dysbiosis has been proposed as one risk factor for osteoarthritis (OA) (1).To date, there have been no studies assessing association between the use of antibiotics and structural progression of knee OA.

Objectives: To evaluate association between the use of antibiotics and radiographic progression of knee OA.

Methods: For the current study we used 9-year longitudinal data obtained from the Osteoarthritis Initiative (OAI) progression (n= 1390) and incidence (n = 3284) subcohorts, which are publically available at https://oai.nih.gov. For the assessment of antibiotic influence on knee OA progression we analyzed all knees having baseline JSN<3 from both subcohorts. The main outcome was knee OA progression (defined as increase in semiquantitative JSN or a new knee replacement). To acquire information about the use of antibiotics, a medication inventory method was used. We excluded participants who used antibiotics at or 30 days prior to baseline (a "new-user" design). Antibiotic users were defined as those with at least one recorded use during first four years of the study. Other participants who did not use antibiotics prior to baseline and throughout the observation period were classified as non-users. Logistic regression models were used to evaluate the relationship between the outcome and antibiotic use. Generalized estimating equations (GEE) were used to adjust for the correlation between knees.

Results: A total of 8415 of knees (7404 non-user knees and 1011 user knees) were included in the analysis. No association between the use of antibiotic and radiographic progression of knee OA was found (odds ratio 1.23, 95% confidence interval 0.59-2.56, p = 0.59). No associations were also observed in multiple stratified analyses based on different duration of antibiotic use, particular classes of antibiotics, or different baseline KL grades.

Conclusion: These findings do not support the effects of antibiotics on knee OA progression.

POS1132

PATTERNS OF JOINT SURGERY IN THE TEN YEARS PRIOR TO PRIMARY KNEE REPLACEMENT IN ENGLAND AND SWEDEN – A POPULATION-BASED CASE-CONTROL STUDY

A. Dell'isola[1], T. Appleyard[2], D. Yu[2], C. Hellberg[1], G. Thomas[2], A. Turkiewicz[1], G. Peat[2], M. Englund[1]. [1]*Lund University, Clinical Epidemiology Unit, Lund, Sweden;* [2]*University of Keele, Primary Care Centre Versus Arthritis, Keele, United Kingdom*

Background: Primary knee replacement (KR) is an effective intervention for end-stage knee osteoarthritis (OA). However, there are no definitive recommendations for the timing at which patients should receive this surgery, potentially resulting in differences in referral patterns depending on geographical area or the clinicians' preferences.
Objectives: To investigate the prevalence of meniscus, knee ligament and knee synovial surgeries as well as knee osteotomy and hip replacement (HR) across the ten years preceding a KR in cases and controls in England and Sweden.
Methods: This was a multi-national, population-based, case-control study within England and Sweden. Cases underwent primary TKR and controls, matched using risk-set sampling by age, sex and practice/region, did not. Electronic healthcare databases were used; the Clinical Practice Research Datalink (CPRD) in England, and the Health Register of Skåne (Sweden's southernmost region) in Sweden.
ICD-10 codes and KVÅ codes in Sweden and Medcodes (SNOMED CT (UK edition) and Read codes) in England were used to identify subjects aged ≥45 years who underwent primary KR between 1st January 2015 and 31st December 2019. Eligible cases had to be registered for ≥10 years prior to the primary KR (index date), and have no record of prior KR in that period. Office of Population Censuses and Surveys (OPCS) codes in England and ICD-10 codes in Sweden were used to identify selected orthopaedic surgeries. Meniscal (e.g. excision, resection, repair) and ligament surgery (e.g. ligament reconstruction, replacement, suture) were included, as well as osteotomy (e.g. angle, rotational or displacement osteotomy of the knee or lower leg). Hip replacement (HR) (any primary HR) was also included, to evaluate the rate at which patients undergoing KR also undergo further major arthroplasty in the years preceding this – The annual prevalence of having at least one recorded surgery for each type in each of the 10 years preceding KR was estimated using Poisson regression models and expressed per 1,000 people.
Results: We identified 6,337 and 47,010 subjects who underwent a knee replacement between 2015 and 2019 in southern Sweden and England, respectively (Table 1). Overall, the prevalence of all analysed surgeries was consistently lower in the controls with minimal trends detectable throughout follow-up in both England and Sweden (Figure 1).

Table 1. demographic

	Sweden		England	
	Cases (n=6,337)	Controls (n=6,337)	Cases (n=47,010)	Controls (n=47,010)
Age, mean (SD)	69.0 (8.9)	68.9 (9.1)	69.6 (9.6)	69.6 (9.6)
Female Sex, n (%)	3,585 (56.6%)	3,585 (56.6%)	26,154 (55.6%)	26,154 (55.6%)
Surgeries, n				
Hip replacement	562	324	3,933	1,889
Meniscus	384	44	8,659	833
Ligaments	16	5	90	11
Synovial	164	15	369	30
Osteotomy	98	3	107	5

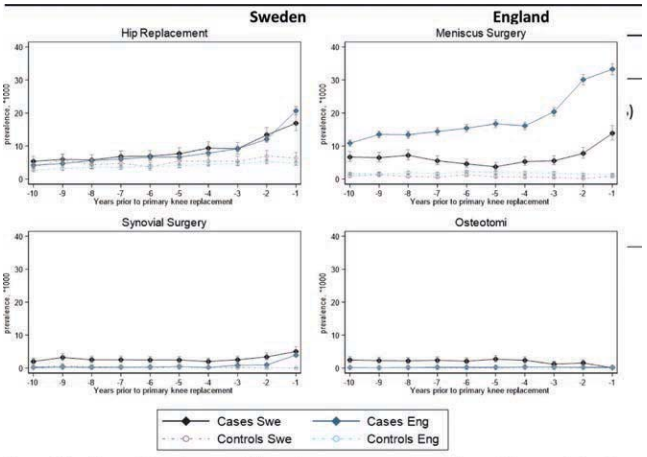

Figure 1: Prevalence of hip replacement (HR), meniscus surgery, osteotomy and synovial surgery in the 10 years leading to a joint replacement

On the other hand, an increasing trend among the cases, signifying a higher prevalence of surgeries when nearing KR, was observed for HR and meniscal surgeries in both nations. The prevalence of HR was similar in England and southern Sweden at all-time points showing an increase most noticeable in the 3 years before KR. The prevalence of meniscus surgery in England was higher than the one observed in Sweden throughout the follow-up. Prevalence in England increased most noticeably in the four years prior to KR reaching 33.2 (95%CI 31.6, 34.9) surgeries per 1,000 people in the year preceding KR. In Sweden, the prevalence of meniscus surgery remained between four and eight surgeries per 1,000 people until the last year prior to KR when the prevalence increased to 13.8 (95%CI 11.9, 16.2) surgeries per 1,000 people.
Conclusion: HR and meniscal surgeries are common procedures that a person is likely to have experienced in the ten years prior to a KR. Comparing England and southern Sweden, we noticed similar prevalence and trends for what concerns HR suggesting similar practice in the two healthcare systems. Meniscus surgeries were more frequently utilised in England. Nevertheless, in both countries, a marked increase in the prevalence of this surgery was observed in the last years prior to the KR.

POS1133

IRISIN LEVELS IN KNEE OSTEOARTHRITIS ARE RELATED TO GENDER, OBESITY AND LOCAL INFLAMMATION

C. Orellana[1], M. Rusiñol[1], E. Costa Moya[1], J. Calvet[1], S. Garcia-Cirera[1], M. Garcia Manrique de Lara[1], C. Galisteo[1], J. Gratacos-Masmitja[1]. [1]*Hospital Universitari Parc Taulí, Rheumatology, Sabadell, Spain*

Background: Irisin is a myokine synthesized mainly in skeletal muscle with exercise, although its secretion has also been observed in other tissues such as adipose and has been related to obesity and other metabolic alterations. Although obesity and other metabolic factors are risk factors for knee osteoarthritis and patients with this condition often do less exercise and have poor muscular state, irisin has been poorly studied.
Objectives: To measure irisin levels in synovial fluid and plasma and evaluate their relationship with clinical severity and inflammation parameters in patients with knee osteoarthritis.
Methods: Patients with symptomatic and radiographical osteoarthritis were studied. Demographic and anthropometric variables, Kellgren-Lawrence scale radiographic stage, the presence of synovial fluid and hypertrophy on ultrasound (at medial patellar line), clinical severity by Lequesne algofunctional index and physical exercise level were recorded. Levels of irisin, IL-6, TNF and hs-PCR were determined using ELISA.
Results: We included 168 women (age 69 ±1.5 y, symptoms duration 48 ±3 m) and 31 men (age 66.5 ±4 y, symptoms duration 36 ±12 m). Significantly higher levels of irisin in synovial fluid were observed in women who did not perform any physical exercise compared to those who did exercise sporadically or regularly (p.0.05), while in plasma a non-significant trend was observed. A weakly positive correlation between intraarticular levels (r= 0.17, p .0.05) and plasma levels (r= 0.16, p. 0.05) of irisin and Lequesne index in women was also evidenced. Regarding inflammatory parameters, in female patients the synovial levels of irisin presented a weak positive correlation with the synovial levels of IL-6 (r= 0.18, p< 0.05) but not in plasma; an association was also found in women between synovial levels of irisin and synovial fluid >8mm and severe synovial hypertrophy (p<0.05) in women, but not with plasma levels. All significant associations disappeared when adjusting by IMC except in the case of synovial hypertrophy. No statistically significant results were obtained in men.
Conclusion: Levels of irisin are related to gender and obesity in patients with knee osteoarthritis. However, the association with the intraarticular levels of IL-6 and the synovial hypertrophy could point to a possible local inflammatory effect at intraarticular level.

POS1134

THE EFFECT OF ETORICOXIB ON PAIN AND SIGNS OF CENTRAL SENSITIZATION IN PATIENTS WITH OSTEOARTHRITIS

E. Polishchuk[1], A. Karateev[1], V. Amirdzhanova[1]. [1]*V.A.Nasonova Research Institute of Rheumatology, pain management, Moscow, Russian Federation*

Background: Central sensitization (CS) plays an important role in the development of chronic pain in osteoarthritis (OA).
Objectives: to evaluate the effect of etoricoxib on pain and signs of CS in patients with OA.
Methods: 790 patients with OA (knee or hip) were included in an open observational study. Most of them (71.6%) were female, mean age 54.5 ± 13.0 years. All patients received etoricoxib 60 mg/day for 2 weeks. The dynamics of pain was assessed on a numerical rating scale (NRS 0-10), the dynamics of the sign of CS was assessed using the Central Sensitization Inventory (CSI). CSI ≥ 40 was observed in 35.3% of patients.

Results: After 2 weeks of treatment with etoricoxib, the intensity of pain at movement, at rest and at night decreased by 58.8±24.1%, 69.7±32.6% and 70.1±32.8. There was a decrease in CSI values by 33.1±14.5% (p<0.001), as well as a decrease in the number of patients with CSI ≥40: from 35.3% to 10.3% (p<0.001). There were no serious complications during the treatment. The total number of adverse events was 5.9%, mainly dyspepsia and arterial hypertension.
Conclusion: Etoricoxib improved pain in OA patients and reduces the severity of signs of CS, supporting the central mode-of-action of the drug.

POS1135 METABOLIC OSTEOARTHRITIS: THE ROLE OF THE NUMBER OF COMPONENTS OF METABOLIC SYNDROME AND EXPRESSION OF CARTILAGE TISSUE DESTRUCTION GENES.

E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], E. Sharapova[1], D. Kusevich[1], L. Alekseeva[1,2], A. Lila[2,3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; [2]Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Osteoarthritis (OA) associated with metabolic syndrome (MS) or its components is considered as the metabolic phenotype of OA. It is well known that obesity and other components of MS affect the clinical picture, course and progression of OA. The cumulative effect of metabolic disorders has an effect on the course and outcomes of OA. The study of molecular genetic relationships between the expression of cartilage tissue destruction genes and metabolic OA is one of the little-studied and relevant directions in rheumatology.
Objectives: To determine the role of MS component count and gene expression associated with cartilage tissue destruction in metabolic OA.
Methods: The study included women (n = 117) 45-75 y.o with knee OA (according by ACR criteria) I-III X-ray stage by Kellgren-Lawrence with different numbers of MS components. The duration of the study was 2 years. The clinic conducted visits 1 times a year. At each visit, anthropometric patient scores, articular status, VAS for knee pain, WOMAC and comorbidities were recorded. Patients underwent a laboratory examination (biochemical blood examination: glucose, total cholesterol, LDL, HDL, TG, isolation of blood RNA to determine the level of expression of cell proliferation genes - m-TOR and cartilage destruction - cathepsin K), instrumental examination (X-ray of knee joints) 1 once a year.
Results: All patients with knee OA included in the study (n = 117) showed an abdominal type of obesity (waist circumference > 80 cm in women), which is the main criterion for MS. With frequency analysis in 5.5% of patients, 1 component of MS was detected, in 13.5% - 2 components of MS, in 70.2% - 3 components of MS, in 10.8% - 4 components of MS. Median (Me, 25%; 75% percentile) duration of knee OA disease was greater in patients with 2 or more MS components and was 7.3 years (6.0-8.0) compared to patients with 1 MS component, in whom the duration of OA was 5.4 years (2.0-11.0), p < 0.05. Spearman correlation analysis showed significant relationships between MS component count and OA duration, age, BMI, VAS for knee pain, WOMAC (Table 1).

Table 1. Analysis of the relationship between the number of MS components and OA by Spearman.

Parameters	Number of MS components	p
Age	r=0,57	<0,05
Duration of knee OA	r=0,56	<0,05
X-ray stage by Kellgren-Lawrence of knee OA	r=0,24	<0,05
BMI	r=0,48	<0,05
VAS for knee pain	r=0,36	<0,05
WOMAC pain	r=0,47	<0,05
WOMAC stiffness	r=0,42	<0,05
WOMAC functional insufficiency	r=0,47	<0,05
Total WOMAC	r=0,46	<0,05

Patients showed high expression rates of m-TOR cell proliferation regulator (11.08 (4.27-15.5)) and cathepsin K articular cartilage destruction (9.34 (3.66-12.5)). In analysis of Spearman correlations of cell metabolism gene expression with clinical manifestations of OA and MS components, direct positive correlations with VAS for knee pain were found (p < 0.001, r = 0.95), body weight (p < 0.001, r = 0.92), the number of MS components (p < 0.001, r = 0.78) and WOMAC pain (p < 0.001, r = 0.76).
Conclusion: In our work, it has been demonstrated that 3 or more components of MS in patients with knee OA are observed at pronounced X-ray stages of OA with longer disease duration and a long history of obesity. There are positive correlations between the number of MS components and the clinical course of OA, X-ray severity of OA, hyperexpression of cell proliferation and cartilage destruction genes.

POS1136 OSTEOARTHRITIS AND METHOTREXATE: EFFICACY AND SAFETY.

L. Alekseeva[1,2], E. Strebkova[1], N. Kashevarova[1], E. Taskina[1], E. Sharapova[1], D. Kusevich[1], A. Lila[2,3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; [2]Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: One of the common phenotypes of osteoarthritis (OA) is the "inflammatory phenotype," which is characterized by persistent synovitis of knee joints, small joints of the hands, the development of the erosive hand OA (EOA), and insufficient effectiveness of standard OA therapy. In the inflammatory OA phenotype, changes observed in the synovial sheath have similar features to rheumatoid arthritis, so baseline anti-inflammatory drugs used in RA may be considered as possible treatments for OA. The literature presents few studies with mixed results on the use of methotrexate (MTX) in patients with OA.
Objectives: To examine the efficacy and safety of MTX use in patients with inflammatory knee OA and hand EOA.
Methods: The study included 40 patients (women) with OA (according by ACR criteria) and insufficient effectiveness of previous OA standard therapy: with knee OA (47.5%), hand EOA (25%) and a combination of these 2 localizations (27.5%). The clinical characteristics are shown in Table 1. For 24 weeks, patients received MTX subcutaneously with a dose escalation of 10mg to 15mg per week combined with folic acid 5mg per week and meloxicam 15mg "on demand." The efficacy of MTX therapy was assessed by WOMAC and AUSCAN, by the OMERACT-OARSI criteria. During the study, laboratory indicators were monitored (clinical, biochemical, immunological blood tests, general urine test).
Results: As a result of 24 weeks of MTX therapy, there was a statistically significant decrease in pain, stiffness and functional insufficiency in the small joints of the hand on the AUSCAN index and in the knee joints on the WOMAC index (Figure 1). In hand EOA, there was a decrease in pain by 40.21%, stiffness by 48.21%, functional insufficiency by 23.72%. In knee OA, there was a reduction in pain by 50.45%, stiffness by 49%, and functional failure by 42.7%. 85.5% of patients with knee OA and 72.5% of patients with hand EOA became responders to therapy according to the OMERACT-OARSI criteria. The best clinical effect was achieved in knee OA (89.9% of patients). As a result of MTX therapy, the need for non-steroidal anti-inflammatory drugs (NSAID) decreased: initially, 85% of patients took NSAID daily or more than 3 times a week, and after 6 months of MTX therapy, only 15% of patients took NSAID daily. In general, the tolerability of MTX was satisfactory. The study of 7 patients was stopped: 4 (10%) due to nausea, 3 (8%) due to a moderate increase

Table 1. Clinical characteristic of patients.

Parameters	Values
Age, y.o., Me [25%; 75% percentiles]	62.5 [58;69]
Age of OA onset, y.o., Me [25%; 75% percentiles]	51.0 [46;58]
Duration of disease, years, Me [25%; 75% percentiles]	9.53 [5;15]
Kellgren-Lawrence grades of knee OA	
II grade, %	73.3%
III grade, %	26.7%
BMI, kg/m^2 (M ± δ)	30.68±6.48
WOMAC pain, mm, Me [25%; 75% percentiles]	328 [236; 360]
WOMAC stiffness, mm, Me [25%; 75% percentiles]	100 [87;121]
WOMAC functional insufficiency, mm, Me [25%; 75% percentiles]	776 [610; 1019]
Total WOMAC, mm, Me [25%; 75% percentiles]	1220 [819; 1640]
AUSCAN pain, mm, Me [25%; 75% percentiles]	235 [191;313]
AUSCAN stiffness, mm, Me [25%; 75% percentiles]	56 [35;66]
AUSCAN functional insufficiency, mm, Me [25%; 75% percentiles]	430 [334;580]
Total AUSCAN, mm, Me [25%; 75% percentiles]	671 [392;912]
ESR, mm/h, Me [25%; 75% percentiles]	11 [7;13]
CRP, mg/l, Me [25%; 75% percentiles]	1.3 [0.8;2.5]

Graph 1. Dynamics of the total AUSCAN and total WOMAC as a result of MTX therapy

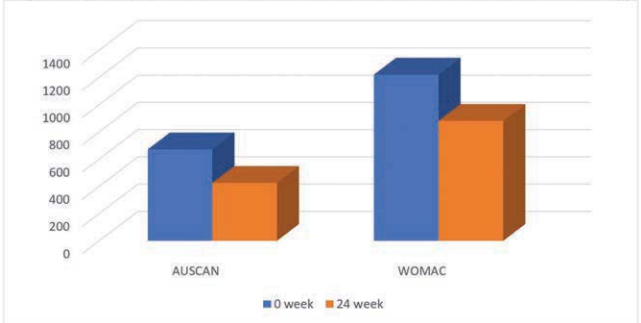

Figure 1.

in transaminases, one of these patients (3%) had one episode of neutropenia up to 1.82x10*9/l (norm 2.04 - 5.80 x10*9/l). There were no serious adverse events.
Conclusion: The results demonstrated a good symptomatic effect of MTX in patients with knee OA and hand EOA. There was a statistically significant decrease in pain, stiffness and functional insufficiency in knee joints and small joints of the hands, a decrease in the need for NSAID throughout MTX therapy. The best clinical effect was achieved in patients with knee OA. Thus, the study showed that MTX has a good clinical effect in OA and a satisfactory safety profile.

POS1137 CORRELATIONS BETWEEN CLINICAL PARAMETERS AND SERUM CYTOKINE LEVELS IN OSTEOARTHRITIS PATIENTS WITH TYPE 2 DIABETES MELLITUS

E. Trifonova[1], E. Zonova[2], O. Sazonova[2]. *[1]Novosibirsk State Medical University, Department of Pharmacology, Clinical Pharmacology and Evidence-Based Medicine, Novosibirsk, Russian Federation; [2]Novosibirsk State Medical University, Department of Therapy, Hematology and Transfusiology, Novosibirsk, Russian Federation*

Background: Type 2 diabetes mellitus (T2DM) is one of frequent factor that can influence on development and progression of osteoarthritis (OA) and has similar mechanisms of immunopathogenesis.
Objectives: To explore the symptoms and the proinflammatory serum cytokine levels in OA (hand, knee, and hip) patients with T2DM and to estimate relationships between clinical and immunological features.
Methods: Patients who participated in this study (n=137) were divided in two groups: patients with bilateral hand, knee and hip OA (n=56) and T2DM and control group (n=81) which had only hand, knee and hip OA without such comorbidity. All patients were comparable in age, sex and duration of OA. We assessed serum cytokine levels (IL-1b, IL-6, IL-10, IL-18), NO including adipokines such as adiponectin, leptin and C-reactive protein (CRP), erythrocyte sedimentation rate (ESR). Various symptoms of OA and mental health were measured using visual analog scale (VAS), Functional Index for Hand Osteoarthritis (FIHOA), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC Knee/Hip), Knee injury and Osteoarthritis Outcome Score – (KOOS), Hip injury and Osteoarthritis Outcome Score – (HOOS) and with short form 36 (SF-36), Psychological Health Questionnaire (PHQ9), Coping Pain Strategy Questionnaire (CSQ). We used U-Mann-Whitney test to detect differences between groups. Correlation was assessed using Spearman correlation coefficient (r_s).
Results: Patients with OA and T2DM are characterized by the prevalence of KOOS symptoms (median (Me) 58,3; interquartile range (IQR) 50–71,5; p<0.001), WOMAC Knee Total (Me 1327; IQR 930,8–1546; p<0.001) and low values of mental health (SF-MH) (Me 48; IQR 33–56; p<0.001). We found increase of IL 6 (p = 0.0018), IL18 (p = 0.0006), NO (p < 0.0001) levels in the blood serum of patients with OA and comorbidity. Patients with OA and T2DM had high ESR level (p < 0.0001) and leptin level (p = 0,0002) also. Correlation analysis identified the relationships between clinical parameters and such cytokines as IL-1b, IL-6, IL-10 and leptin, CRP in OA patients with T2DM. Some data are presented (Table 1).

Table. Relationships between clinical parameters and serum cytokine levels in studied groups.

Cytokines	OA patients with T2DM (n=56)							
	Pain (VAS)	General Health (VAS)	Knee Symptoms (KOOS)	Hip Pain (HOOS)	Hand OA Index (FIHOA)	Social Functioning (SF-36-SF)	General Physical Health (SF-36-PH)	Coping Pain Strategy (CSQ)
IL-1b (pg/ml)	0,07	0,01	**–0,28***	0,09	0,13	0,08	–0,16	–0,15
IL-6 (pg/ml)	**0,3***	0,21	–0,15	**0,42***	**0,31***	**–0,27***	**–0,27***	–0,03
IL-10 (pg/ml)	0,07	**0,36***	–0,11	0,07	–0,08	–0,09	–0,21	**–0,41***
NO (pg/ml)	0,05	–0,06	–0,11	0,14	0,13	0,14	–0,15	0,11

Table legend: * r- $p < 0,05$

Conclusion: Such comorbidity as OA and T2DM has clinical and laboratory features of progression of OA. Such immunological factors as serum cytokines concentrations, adipokines, CRP are linked with the severity of T2DM-associated OA. A different variation of correlations may suppose role of this proinflammatory factors in the pathogenesis of this OA phenotype. These data should be verified by larger studies.

POS1138 PERSISTENCY OF DEPRESSIVE SYMPTOMS AND PHYSICAL PERFORMANCE IN KNEE OSTEOARTHRITIS

R. Mehta[1], M. Shardell[1], A. Ryan[2], Y. Dong[3], B. Beamer[2], J. Gallo[4], E. Stuart[4], M. Schuler[5], M. Hochberg[2], A. Rathbun[1]. *[1]University of Maryland School of Medicine, Epidemiology and Public Health, Baltimore, United States of America; [2]University of Maryland School of Medicine, Medicine, Baltimore, United States of America; [3]University of Maryland School of Medicine, Psychiatry, Baltimore, United States of America; [4]Johns Hopkins Bloomberg School of Public Health, Mental Health, Baltimore, United States of America; [5]Rand Inc., Policy Research, Boston, United States of America*

Background: Knee osteoarthritis (OA) is the most prevalent arthritic disorder, characterized by joint paint, which is exacerbated by chronic depressive episodes. Depression in knee OA is also associated with declines in physical activity level and greater disability; however, the impact of persistent depressive symptoms on physical performance remains unclear.
Objectives: To determine how the persistence of depressive symptoms affects functional capacity in knee OA.
Methods: Participants (n=2,212) were from the Osteoarthritis Initiative cohort and included individuals with radiographic disease (Kellgren-Lawrence grade ≥ 2) and complete data on study measures at baseline. Depressive symptoms were assessed using the Center for Epidemiologic Studies Depression Scale (CES-D; range 0-60) at baseline and the first three follow-up visits. Physical Performance was measured using 20-meter gait speed (meters per second) during follow-up at the first four annual visits. Persistency of depressive symptoms was operationalized as a cumulative exposure using average severity over time. Gait speed was standardized so that outcome estimates could be interpreted in standard deviations. Time-invariant confounders measured at study enrollment included demographic, socioeconomic, and lifestyle factors. Time-varying confounders assessed concurrent to CES-D scores were body mass index, analgesic medications, pain, and other knee OA signs and symptoms. Marginal structural models accounting for time-dependent confounding and selective attrition were the primary method of analysis. The outcome model included all potential statistical interactions between depressive symptoms and follow-up time indicators. Post-estimation linear combinations estimated time-specific effects of time-averaged CES-D scores on standardized gait speed and differences in physical performance between participants with (i.e., CES-D=16) and without (i.e., CES-D=0) depressive symptoms satisfying screening criteria for major depression.
Results: The interaction between depressive symptoms and time was statistically significant (P=<0.001). Time-specific associations indicated that the largest negative impact of depressive symptoms on physical performance was from baseline through year one (β = -0.0077; 95% CI: -0.0125, 0.0030). However, the effect of persistent depressive symptoms decreased over time and reversed in magnitude and directionality, evidenced by the time-specific associations between time-averaged CES-D scores from baseline through year one and year two and gait speed at year two (β = -0.0033; 95% CI: -0.0084, 0.0019) and year three (β = 0.0014; 95% CI: -0.0046, 0.0074), respectively. Consequently, the strongest negative affect of depressive symptoms on gait speed (β = -0.1232; 95% CI: -0.1998, -0.0473) between participants with and without depressive symptoms satisfying screening criteria for major depression was when depressive symptoms were first measured closest to the initial gait speed assessment.
Conclusion: In the contrast to the dose-dependent relationship between chronic depressive episodes and pain in knee OA, study findings imply that the negative effect of depressive symptoms on physical performance decreases over time with increasing depression persistency. These results may reflect diminishing marginal effects, where the largest impact on physical performance in knee OA is during the first depressive episode closest to initial gait speed assessment, especially when averaged against improvement in symptoms over the same duration.

Osteoporosis

POS1139 GLUCOCORTICOIDS AND BONE DENSITY IN POLYMYALGIA RHEUMATICA, GIANT CELL ARTERITIS, AND OTHER VASCULITIDES – A CROSS-SECTIONAL ANALYSIS OF THE RH-GIOP COHORT

A. Palmowski[1], E. Wiebe[1], B. Muche[1], S. Hermann[1], C. Dejaco[2], E. Matteson[3], F. Buttgereit[1]. *[1]Charité - Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; [2]Medical University Graz and South Tyrol Health Trust, Department of Rheumatology and Immunology and Rheumatology Service, Graz and Bruneck, Italy; [3]Mayo Clinic College of Medicine and Science, Division of Rheumatology and Division of Epidemiology, Departments of Internal Medicine and Health Sciences Research, Rochester, MN, United States of America*

Background: There are only few, inconclusive investigations on bone density and the effects of glucocorticoids (GCs) in polymyalgia rheumatica (PMR) and vasculitides.
Objectives: To determine whether GCs are associated with bone density in patients with PMR and other vasculitides after adjustment for confounders.
Methods: The Rh-GIOP cohort study started in 2015 and investigates bone health in patients with rheumatic diseases. In this cross-sectional analysis of baseline visits, we included patients with PMR and vasculitides. Multiple regression was used to model the effect of current and cumulative GC intake on the minimum T-score (mTs; lumbar spine or hip) with adjustment for several confounders such as age, sex, body mass index (BMI), or inflammation (measured by c-reactive protein (CRP)). GCs were modelled both as continuous and as categorical predictors in separate models. Several sensitivity analyses were performed. Patients with early disease (<3 months) were excluded from inferential analyses as were patients with very high GC dosages (>100mg/d prednisolone equivalent). Multiple imputation by chained equations was used for missing data (about 5%).
Results: 198 patients (mean age 68 ± 11 years; 68% females) with a mean disease duration of 5.3 ± 6.3 years were included. The most common rheumatic disease was PMR (36%), followed by giant cell arteritis (26%) and granulomatosis with polyangiitis (17%). 87% were currently taking GCs, 88% received vitamin D supplements, 7% had a deficiency. Osteoporosis (OP) diagnosed by DXA (T-score ≤ -2.5) was present in 20% of patients. Mean CRP was 13.2 ± 26.1 mg/l. Scatter- and boxplots of mTs and GC intake are presented in Figure 1 **A-D**. GC dose was not associated with mTs in any model (current intake: β(continuous model) = -0.01, 97.5% CI -0.02 to 0.01; *p*(all models) ≥ 0.49; cumulative intake: β(continuous model) = 0.01, 97.5% CI -0.04 to 0.07; *p*(all models) ≥ 0.35). Inflammation (measured by CRP) was also not associated with mTs (*p*(all models) ≥ 0.56), and no significant interaction between CRP and GC intake was found (*p* for interaction(all models) ≥ 0.32). Lower body mass index (*p*(all models) ≤ 0.01), history of vertebral fractures (*p*(all models) ≤ 0.02), and proton-pump inhibitor intake (*p*(all models) ≤ 0.04) were associated with bone loss in all models. The results were similar with femoral neck and lumbar spine T-scores as dependent variables, and after excluding patients with PMR.

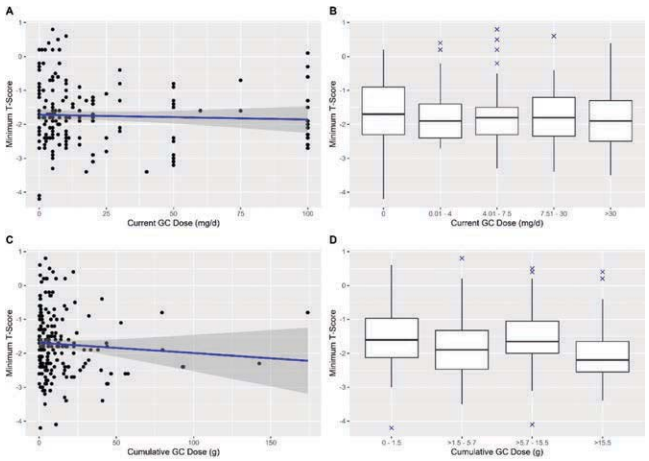

Figure 1.

Conclusion: In this cohort of PMR and vasculitides, the prevalence of OP was similar to the overall elderly German population.[1] Vitamin D supplementation was common while deficiencies were surprisingly rare – In population-based studies, about 32% of Germans are estimated to have a vitamin D deficit.[2] We found no association between current or cumulative GC intake, inflammation, and bone density. Proton-pump inhibitor intake and BMI as modifiable risk factors were associated with mTs. These findings need confirmation from longitudinal analyses of our and other cohorts.

POS1140 SHORT-TERM EXPOSURE TO FINE PARTICULATE MATTER AND RISK OF FRAGILITY HIP FRACTURES, A CASE-CROSSOVER STUDY ON 1,042 HIP FRACTURES

G. Adami[1], M. Pontalti[1], A. Fassio[1], C. Benini[1], D. Gatti[1], S. Negri[2], P. Olivi[2], M. Rossini[1]. *[1]University of Verona, Rheumatology Unit, Verona, Italy; [2]University of Verona, Orthopedic Unit, Verona, Italy*

Background: Fragility femoral fracture is a common, world-spread, medical condition, that has a relevant impact both clinically and economically. Chronic exposure to environmental air pollution has been linked with a higher risk of developing osteoporosis. However, little is known regarding the relationship between short-term exposure to air pollution and bone fractures.
Objectives: Our study aims to investigate the link between short-term exposure to fine particulate matters and fragility hip fractures
Methods: We retrieved data of patients suffering of hip fractures admitted to the Orthopedic Unit of the University of Verona Hospital from 2015 to 2020. We retrieved data on the monitoring of PM10 concentrations from the Italian institute of environment protection and research (ISPRA). We designed a case-crossover study to compare the exposure to particulate matters (PM10) in the 30-day period immediately before the fracture (hazard period) referent to a 30-day control period (from day -30 to -60 from the fracture). Exposure to PM10 was evaluated as mean value and AUC. Case-crossover is a peculiar study design applied to longitudinal datasets that controls for within-person time-invariant and between-patient confounders such as indoor air pollution, chronic comorbidities or concomitant medications and have been used extensively to study the effects of transient, short-term exposures on the risk of acute events (Figure 1**A**)
Results: 1042 patients (73.7% female n=768), with a hip fracture admitted to the hospital were included in the study. Mean age of the cohort was 82.6 years (±9.55). Average exposure to PM 10 in the control period was 33,84 ug/mm3, cumulative exposure (AUC) was 952,42 ug/mm3 compared 31,72 ug/mm3 and AUC of 920,24 ug/mm3 in the hazard period (Figure 1**B**) The difference between levels of PM10 in the two periods was statistically significant as levels of PM10 was higher in the hazard period compared to control period, with a p-value = 0,027 (α <0,05) when comparing average concentrations in the two groups and a p-value = 0,024 (α <0,05), when comparing AUCs.
Conclusion: Our study suggests that the short-term exposure to environmental air pollution might increase the risk of femoral fragility fractures. Further studies should be taken to further investigate the biological mechanisms underlining this finding.

Figure 1. A. Case-crossover study design B. Mean exposure to PM10 before a hip fracture compared to the control period (-30 to -60 days).

POS1141 FACTOR ANALYSIS OF FRAGILITY FRACTURES BY SITE IN PATIENTS REFERRED FOR DUAL-ENERGY X-RAY ABSORPTIOMETRY SCAN

Z. Sultan[1], M. Bukhari2. *[1]Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom; [1]Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom*

Background: Fragility fractures are defined as fractures which occur secondary to low energy trauma (1). Fractures lead to substantial pain, reduced quality of life and significant burden to society, with 3.5 million fragility fractures occurring in the EU in 2010 costing €37 billion (2). It is predicted that by 2025 this cost will have increased by 25% (2). Studying fractures is in the interest of our ageing society in order to aid management of patients at risk. To our knowledge, no other studies have grouped fractures based on site by factor analysis.
Objectives: 1.Determine which fractures are most common in patients who present for dual-energy X-ray absorptiometry (DEXA) scan
2.Apply a factor analysis to establish any patterns in the incidence of fractures based on site
Methods: Between 1996 and 2017, 31546 patients presented to a district general hospital in the North West of England for bone mineral density estimation by DEXA scan. Demographic details, risk factors, incidence of fractures and site of fractures were recorded at time of scan. These data were retrospectively studied to identify patients who had sustained at least one fracture. *STATA* was used to conduct a factor analysis using the principal component factors (PCF) method. Ethical approval was granted by the Northwest Regional Ethics Committee.
Results: 11839 patients were identified to have had at least one fracture (14756 total fractures). Mean age was 67.96, with 9993 females and 1846 males. Mean height was 161.21 cm, mean weight was 70.41 kg and mean BMI was 27.04 kg/m2. Mean T-scores at femoral neck, total femur and lumbar spine were -1.55, -1.38 and -1.30 respectively. The most common fracture site was at the wrist/forearm with 5421 (36.74%) cases. Further, there were 2795 tibia/fibula (18.94%), 2530 spine (17.15%), 1363 femur (9.24%), 1224 humerus (8.29%), 1063 rib (7.20%), 315 pelvis (2.13%), 43 elbow (0.29%) and 2 ankle (0.01%) fractures. 9390 patients had 1 fracture and 2449 patients had more than 1, with 9 patients sustaining 5 fractures. Factor analysis on fracture sites revealed 6 factors with an eigenvalue > 1. Fracture sites were grouped together based on those fractures which loaded most heavily on each factor. Loading was as follows: spine and ribs on Factor 1; spine, pelvis and wrist/forearm on Factor 2; humerus and femur on Factor 3; elbow and ankle on Factor 4; ribs and humerus on Factor 5; ribs and femur on Factor 6 (Table 1).

Table 1. Factor analysis on sites of fractures using the PCF method.

Variable	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5	Factor 6	Uniqueness

Elbow	0.0397	0.1300	-0.0740	0.7306	0.0305	0.0363	0.4401
Ankle	0.0547	0.1082	-0.1084	0.7189	-0.0365	0.0716	0.4503
Wrist/forearm	-0.8856	0.2389	-0.2461	-0.0479	-0.0608	0.0071	0.0920

Conclusion: In-keeping with published data, the most common site for fracture was forearm (3). Factor analysis grouped together sites of fractures into 6 factors, suggesting that these fractures are more likely to co-exist. Moving forward it would be beneficial to ascertain differences between the groups in terms of demographics, risk factors and any bone protection measures taken. This may highlight clinically relevant data in order to make evidence based decisions in the identification and management of patients at risk of fragility fractures.

POS1142 A CONCORDANCE STUDY OF CT DENSITOMETRY WITH DXA DENSITOMETRY

R. Mawella[1], R. Rajak[2]. *[1]Croydon Health Services NHS Trust, Medicine, London, United Kingdom; [2]Croydon Health Services NHS Trust, Rheumatology, London, United Kingdom*

Background: Osteoporosis is a skeletal disorder characterised by compromised bone strength resulting in an increased risk of fracture. Although DXA is the only technology that can be used for diagnostic classification of osteoporosis according to WHO, computed tomography imaging (CT) densitometry of the spine has equal or superior ability to predict vertebral fractures in postmenopausal women. Therefore the continued use of DXA as the primary modality of calculating BMD may lead to inaccurate exclusion of osteoporosis and prognostication.
Objectives: To assess the concordance of spinal CT densitometry with current standard of assessment through DXA-derived densitometry.
Methods: 50 patients who had had both a DXA scan of the lumbar spine and CT lumbar spine/thorax/abdomen performed within 18 months of each other were included. The CT images were analysed to attain a mean Hounsfield score of the lumbar vertebrae and this was compared to DXA derived T-scores. A Hounsfield score of 131 was used as the threshold for diagnosing osteoporosis akin to a DXA-derived T score of -2.5. The final data was analysed to find correlation values of Hounsfield score with T-score using Pearson correlation coefficient.
Results: The mean Hounsfield score was 108.4 (osteoporotic) compared to a mean T-score of -1.22 (osteopenic) with a statistically significant correlation coefficient of 0.447, ($p<0.01$).Using T score ≤ -2.5, 15 (30%) of the patients included on our study would have a diagnosis of osteoporosis whereas this would be 36 patients (72%) if using the threshold of Hounsfield score <131. Out of the 50 patients included, 15 had vertebral fragility fractures. The mean T-score for these patients was -1.2 (indicating osteopenia) and mean Hounsfield score was 108 (indicating osteoporosis).
Conclusion: Our study showed a moderate positive correlation between the DXA-derived T-scores and CT Hounsfield scores. This further validates previous studies that suggest CT scans can be used to identify patients with osteoporosis. 93% of patients with vertebral fragility were identified as having osteoporosis using CT densitometry whereas only 40% were identified via DXA. These findings highlight the limitations of DXA, particularly in terms of overestimation of bone mineral density related to degenerative changes. CT images of the thorax, abdomen or lumbar spine that have already been performed for other indications can be used to opportunistically screen

for osteoporosis without additional radiation exposure, waiting time or cost. This may allow for more accurate diagnosis and subsequent treatment and fracture risk reduction.

POS1143 FIVE-YEAR TREATMENT OUTCOME OF DENOSUMAB ON OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS, IN CLINICAL PRACTICE

Y. Hirano[1], Y. Ono[1]. [1]*Toyohashi Municipal Hospital, Rheumatology,Toyohashi, Japan*

Background: Osteoporosis (OP) is a frequent complication identified in patients with rheumatoid arthritis (RA). Effective treatment must be provided to treat OP in RA (RAOP). Denosumab (DMB) is a promising drug, currently being used for the treatment of RAOP. Although DMB was determined to be effective in a long-term FREEDOM extension trial [1] for treating postmenopausal OP, its efficacy in the treatment of RAOP in real-world is not be fully evaluated.

Objectives: This retrospective study assessed the five-year treatment outcome of DMB in Japanese patients with RAOP.

Methods: Data from the Toyohashi RA Database (TRAD) was used, which is a collection of single-center retrospective data. Our study included 65 female patients with RAOP for whom DMB treatment was initiated between October 2013 and May 2016. The following information was collected: 1) baseline characteristics, 2) DMB continuation rates using the Kaplan–Meier method and reasons for stopping DMB, 3) fracture occurrence during DMB treatment, and 4) time-course of bone mineral density (BMD) [lumbar spine (LS) and total hip (TH)] and bone turnover markers (BTM) [bone-specific alkaline phosphatase (BAP), type I procollagen-N-propeptide (P1NP), type I procollagen-N-propeptide (NTX), and tartrate-resistant acid phosphatase-5b (TRACP-5b)] in 38 patients who underwent DMB treatment over a period of five years.

Results: 1) The mean age and RA duration were 69.4 years (46–86) and 17.2 years (1–49), respectively. Prednisolone and biologics were administered in 21 (32.3%) and 20 (30.8%) patients, respectively. Twenty-seven patients (41.5%) had a history of fragility fractures, and 24 patients (36.9%) had a history of vertebral fractures. Pretreatment drugs for OP were as follows: bisphosphonate in 22 patients; teriparatide, 17; none, 16; activated vitamin D, 7; and selective estrogen receptor modulator, 3.

2) Continuation rates of DMB were 96.9% at one year, 95.4% at two years, 85.8% at three years, 79.4% at four years, and 71.1% at five years. DMB treatment was terminated in 24 patients due to lack of efficacy in nine patients, death in seven patients (unknown reason in four, pneumonia in two, and senile decay in one), adverse events except death in five patients (worsening of dementia in two, brain hemorrhage in one, necrosis of jaw in one, and pneumonia in one), and other reasons in three patients.

3) Nine patients (13.8%) experienced fractures during DMB treatment; vertebral and non-vertebral fractures occurred in three and four patients, respectively. Two cases of fractures remained undefined.

4) Both mean LS-BMD and TH-BMD significantly increased in 38 patients for whom DMB administration was continued for five years. Average percent changes of LS-BMD and TH-BMD were 3.9% and 3.0% at six months, 5.5% and 3.8% at one year, 7.6% and 4.1% at two years, 9.8% and 5.7% at three years, 10.8% and 6.5% at four years, and 12.9% and 6.8% at five years (Figure 1). Four BTMs, BAP, P1NP, NTX, and TRACP-5b, significantly decreased from six months to five years when compared to baseline values, with average changes at 5 years equaling –38.4%, –37.8%, –23.8%, and –24.6%, respectively.

Conclusion: DMB treatment of RAOP proved effective and reasonably safe, and it increased BMD by a percentage similar to that observed in the FREEDOM extension trial. However, DMB administration was ceased in 13.8% of cases due to fractures and lack of efficacy. Although DMB is recommended for the treatment of RAOP, future evaluations should be conducted to predict its efficacy and determine alternative treatment strategies.

POS1144 INCREASED EXPRESSION OF RECEPTOR FOR ADVANCED GLYCATION END-PRODUCTS IN SARCOPENIC PATIENT SKELETAL MUSCLE

J. S. Hwang[1], J. Kim[1], H. S. Gong[1], G. H. Baek[1]. [1]*Seoul National University College of Medicine, Department of Orthopedic Surgery, Seoul, Korea, Rep. of (South Korea)*

Background: Animal studies suggest that advanced glycation end-products (AGEs) and their interaction with receptor for AGEs (RAGE) are involved in sarcopenia, but their relationship in human skeletal muscles has yet to be elucidated.

Objectives: We aimed to determine whether RAGE expression in human skeletal muscle is associated with serum AGE levels and sarcopenia-related changes.

Methods: We reviewed 33 consecutive women (mean age, 65 years) with distal radius fracture who had consented to donate a sample of forearm flexor muscle for research purposes, which was taken during surgical fracture repair. The muscle RAGE expression was measured with immunohistochemistry staining and serum AGE levels using ELISA method. We compared RAGE expression and AGE levels in patients with and without sarcopenia. We also correlated RAGE expression with such clinical parameters as age, body mass index, bone mineral density (BMD), as well as sarcopenia-related changes, including grip strength, appendicular skeletal muscle mass, and muscle cross-sectional area (CSA) ratios.

Results: Twelve patients (36%) were diagnosed with sarcopenia according to the Asian Working Group for Sarcopenia. They had a significantly higher RAGE expression ($p = 0.044$) and AGE level ($p < 0.001$) than those without sarcopenia. The RAGE expression correlated significantly with a high serum AGE level ($r = 0.510$, $p = 0.011$) and correlated inversely with a muscle CSA ratio ($r = -0.696$, $p < 0.001$).

Conclusion: This study shows that RAGE expression increases in sarcopenic patient skeletal muscles. This expression also correlates positively with serum AGE levels and inversely with muscle CSA ratios. Further studies are necessary to determine whether targeting RAGEs can be a therapeutic option for sarcopenia.

[3] Riuzzi F, Sorci G, Sagheddu R, Chiappalupi S, Salvadori L, Donato R. RAGE in the pathophysiology of skeletal muscle. *J Cachexia Sarcopenia Muscle.* 2018; 9: 1213-34.

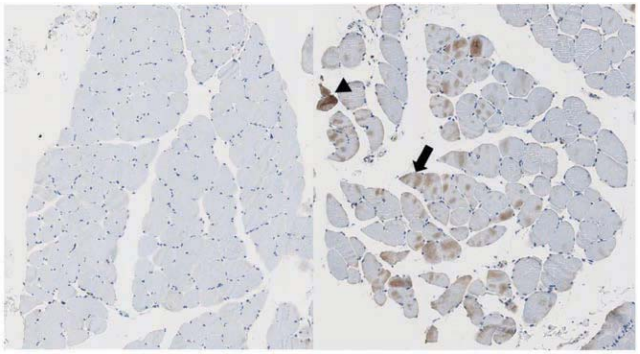

Figure 1. Skeletal muscle tissue (x 7.0) obtained from (a) a 76-year-old female with receptor for advanced glycation end-products (RAGE) expression scoring 14, and (b) a 75-year-old female with RAGE expression scoring 50. Disparity between the percentage of fibers with signal intensity of 1+ (arrow) and those with signal intensity of 2+ (arrowhead) is obvious. Difference in the diameter and homogeneity of the muscle fibers imply the role of RAGE hyper-expression in sarcopenia.

POS1145 PREDICTORS OF FRACTURE IN PATIENTS WITH NORMAL BONE DENSITY, AN OBSERVATIONAL STUDY

J. Malcolm[1], Z. Sultan[2], M. Bukhari[2]. *[1]Lancaster University, Lancaster Medical School, Lancaster, United Kingdom; [2]Royal Lancaster Infirmary, Rheumatology Department, Lancaster, United Kingdom*

Background: Although most fragility fractures occur in osteoporotic patients, fractures of the lumbar spine and the femora are also common in patients with normal bone mineral density (BMD). A number of risk factors are known to be associated with fractures in patients with reduced BMD. However, risk factors for fractures in patients with normal BMD remain relatively unexplored.
Objectives: Evaluate the risk factors associated with fractures in patients with a normal BMD (T-score ≥ -1.00) in the lumbar spine and right and left femur in an observational cohort
Methods: Data was collected from patients attending a District General Hospital in the Northwest of England for a DEXA scan between 2004 to 2019. Patients with a T-score ≥-1.00 in L1-4 and the right and left femur were included. Chi-squared test and Student's t-test were used to compare risk factors in patients with and without fractures. A series of logistic regression models that adjusted for age and sex were then fitted to determine risk factors associated with a fracture. Area under the ROC curve was calculated for each model. Ethical approval was obtained from the Northwest Regional Ethics Committee.
Results: 6,504 patients were included in analysis, 1,491 (22.9%) of whom had a fracture. Mean age (SD) at scan was 58.64 (12.98) years and 5,347 (82.2%) were female. Risk factors and their association with fracture occurrence after adjusting for age and sex are shown in Table 1. Weight, BMI, and current alcohol use were statistically significantly (p <0.05) associated with increased risk of fracture. History of Rheumatoid Arthritis, steroid use, and increased T-score in L1-4 or the right or left femur were statistically significantly (p <0.05) associated with decreased risk of fracture.

Table 1. Logistic regression with adjustment for age and sex

Characteristic	Odds ratio (95% confidence interval)	P-value	AUC
Height, cm	1.006 (0.997, 1.016)	0.176	0.5666
Weight, kg	1.010 (1.007, 1.014)	0.000	0.5804
BMI	1.027 (1.016, 1.037)	0.000	0.5773
Current smoker	1.164 (0.975, 1.389)	0.094	0.5664
Previous smoker	1.120 (0.976, 1.284)	0.106	0.5672
Current excess alcohol use	1.299 (1.033, 1.634)	0.025	0.5668
Pervious excess alcohol use	1.441 (0.943, 2.202)	0.091	0.5664
History of Rheumatoid Arthritis	0.674 (0.520, 0.874)	0.003	0.5708
Current steroid use	0.498 (0.406, 0.611)	0.000	0.5911
Previous steroid use	0.796 (0.669, 0.946)	0.010	0.5682
Mean T-score L1	0.929 (0.880, 0.980)	0.007	0.5698
Mean T-score L2	0.917 (0.874, 0.961)	0.000	0.5734
Mean T-score L3	0.906 (0.868, 0.947)	0.000	0.5758
Mean T-score L4	0.925 (0.889, 0.962)	0.000	0.5734
Mean T-score left neck of femur	0.866 (0.803, 0.933)	0.000	0.5662
Mean T-score total left femur	0.839 (0.780, 0.902)	0.000	0.5710
Mean T-score right neck of femur	0.847 (0.785, 0.914)	0.000	0.5672
Mean T-score total right femur	0.839 (0.779, 0.904)	0.000	0.5723

Conclusion: In the FRAX tool, increased weight is considered protective against fractures, and steroid use and Rheumatoid Arthritis are thought to increase fracture risk. In our cohort of patients with normal BMD, patients with increased weight had a higher risk of fracture, and patients with Rheumatoid Arthritis and steroid use had a decreased fracture risk.
While there is overlap in the risk factors associated with fractures in patients with reduced BMD and normal BMD, our study suggests that some characteristics protective of fractures in osteoporotic patients may increase the risk of fracture in patients with a normal BMD.

POS1146 ROMOSOZUMAB INCREASE BONE MINERAL DENSITY AT LUMBAR AND FEMORAL IRRESPECTIVE OF PREOSTEOPOROSIS TREATMENT, HISTORY OF FRAGILITY FRACTURE AND COMBINATION OF VITAMIN D

S. Anno[1,2,3], T. Iida[4,5], Y. Yamada[1], T. Okano[1], Y. Sugioka[6], K. Inui[7], S. Wakitani[4], H. Nakamura[1]. *[1]Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan; [2]Osaka Social Medical Center, Orthopaedic Surgery, Osaka, Japan; [3]Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; [4]Koryokai Hospital, Orthopaedic Surgery, Osaka, Japan; [5]Takahiro Clinic, Orthopaedic Surgery, Nishinomiya, Japan; [6]Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [7]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*

Background: Romosozumab, a monoclonal antibody that binds sclerostin, increases bone formation and decreases bone resorption. Romosozumab has an excellent therapeutic effect on patients with osteoporosis. However, there are few reports investigated the efficacy and the effect of various factors relative to osteoporosis in real-world.
Objectives: We evaluated bone mineral density (BMD) and bone metabolism marker (BMM) change in osteoporosis patients treated with romosozumab, and assessed the effect of various factors, such as preosteoporosis treatment, history of fragility fracture and combination of vitamin D.
Methods: This study included 141 osteoporosis patients (132 female, mean age: 78.8 ± 7.5 years, mean hight: 151.1 ± 7.5 cm, mean weight: 50.9 ± 8.9 kg) treated with romosozumab. BMD measurements using dual energy X-ray absorptiometry (DXA) and BMM measurements using N-terminal propeptide of type 1 collagen (P1NP) were evaluated at 0, 4, 6, and 12 months after treatment. DXA were performed at the lumbar spine (n=92), at proximal femoral and femoral neck (n=92), and at distal third radius (n=49). We evaluated the influence of preosteoporosis treatment, history of fragility fracture and combination of vitamin D for BMD change.
Results: BMD at lumbar spine (5.2%: p<0.01, 9.2%: p<0.01, 10.8%: p<0.01), proximal femoral (1.3%: p=0.02, 2.8%: p<0.01, 4.5%: p<0.01) and femoral neck (2.0%: p=0.03, 2.7%: p=0.06, 5.0%: p=0.01) were significantly increased at 4, 8, 12 months after treatment. BMD at distal third radius (-1.5%: p<0.01, -0.8%: p=0.17, -1.0%: p=0.13) were not increased at 4, 8, 12 months after treatment. P1NP chane were 63% (p<0.01), 6.4% (p=0.55), -2.3% (p=0.2) at 4, 8, 12 months after treatment. There were no significant differences in 1 year improvement ratio of BMD at lumbar spine, proximal femoral and femoral neck between 38 patients with pretreatment of osteoporosis and 54 patients without pretreatment of osteoporpsis (13.5 vs 9.5%: p=0.1, 4.9 vs 4.4%: p=0.7, 6.1 vs 4.6%: p=0.67), between 33 patients with a history of fragility fracture and 59 patients without a history of fragility fracture (7.3 vs 11.7%: p=0.42, 0.8 vs 5.5%: p=0.08, -0.7 vs 6.6%: p=0.14), between 50 patients with romosozumab alone and 42 patients with romosozumab plus vitamin D (11.3 vs 10.0%: p=0.93, 4.1 vs 5.3%: p=0.59, 6.8 vs 2.3%: p=0.47). There were no significant differences in 1 year improvement ratio of BMD at distal third radius between 33 patients with pretreatment of osteoporosis and 16 patients without pretreatment of osteoporpsis (-1.1 vs -0.9%: p=0.63), between 31 patients with a history of fragility fracture and 18 patients without a history of fragility fracture (-1.5 vs -0.5%: p=0.3).
Conclusion: Romosozumab improved BMD at lumbar and femoral independently regardless of preosteoporosis treatment, history of fragility fracture and combination of vitamin D.

POS1147

CHALLENGES IN CONDUCTING PRAGMATIC CARE STRATEGY STUDIES IN OSTEOPOROSIS: PATIENT PERCEPTIONS

L. Jackson[1], E. Mcneeley[1], N. C. Techarukpong[1], F. Mugeta[1], K. Aaron[1], A. Mudano[1], J. Merchant[1], K. Warren[1], J. Foster[1], K. Saag[1], M. Danila[1]. [1]*University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America*

Background: Large pragmatic osteoporosis studies to improve outcomes are needed. Direct-to-patient studies have highest generalizability but achieving sufficient sample size is difficult; recruitment challenges represent an important consideration given limited participant eligibility and interest. The Fracture Liaison Service (FLS), a team approach to post-fracture care, is a secondary fracture prevention method that has significantly improved outcomes internationally.
Objectives: Our goal was to evaluate the interest, barriers, and lessons learned in recruiting participants for a future trial assessing remote FLS approaches for post-fracture care.
Methods: We used ICD10 fracture codes to identify patients > 50 years of age with a documented hip/pelvis, spine, humerus, or wrist fracture in the previous 1 year. We excluded patients with i) prescriptions for osteoporosis medications (e.g., bisphosphonates, parathyroid hormone analogs, denosumab, romosozumab, raloxifene) in the prior 1 year; ii) an ICD10 code for end-stage renal disease, non-osteoporotic metabolic bone disease, malignant neoplasm, or motor vehicle accident. In December 2021, research assistants reviewed electronic health records (EHR) of potentially eligible patients for evidence of additional serious illness limiting life expectancy to < 1 year or non-ambulatory status prior to fracture. Research assistants called preliminary eligible patients that met inclusion and exclusion criteria and asked them to complete a survey by phone. Interest in a FLS future clinical trial was evaluated using a Likert scale (1="Definitely would not volunteer," to 5="Definitely would volunteer"). We used descriptive statistics to analyze baseline demographic, clinical characteristics, and interest. This pilot was approved by the UAB Institutional Review Board (IRB-300008310-005).
Results: We identified 1,577 patients > 50 years of age with a fracture. After applying exclusion criteria, we identified 869 preliminary eligible patients. Over 3 weeks, we screened the medical records of a random sample of half of the preliminary eligible patient cohort (n=414), of whom we contacted 271 patients determined potentially eligible, and successfully reached 141 (52% of those contacted) by phone. A total of 108 (77% of those reached) persons, mean (SD) age 69.5 (11.5) years, 40% men, 21% Black or non-white Hispanics completed the survey. Among those contacted, 68 (63%, interest rate) said they would be very or highly interested in participating in a future clinical trial evaluating FLS approaches. Among the 40 (37%) people who said they were not sure, unlikely or very unlikely to volunteer the most common reasons cited were "I don't want to participate in a study" (33%); "I don't feel well enough to participate" (10%); "I don't understand what the study is for" (3%). From this pilot, we calculated a refined eligibility/interest rate of 9.1% among those patients preliminarily identified as eligible using administrative data alone.
Conclusion: Based on our pilot, we estimate that approximately 9% of eligible patients with fractures will be interested in enrolling in a future comparative effectiveness study to prevent recurrent fragility fractures. We identified several potential modifiable barriers to clinical trial recruitment. Patient perceptions collected from this pilot will inform enrollment strategies, which can be incorporated early when planning direct-to-patient pragmatic osteoporosis studies to achieve recruitment goals.

POS1148

SONOGRAPHIC VARIATION OF SYNOVITIS IN RHEUMATOID ARTHRITIS IS SUGGESTIVE OF BONE MINERAL DENSITY CHANGE.

J. Chen[1], T. T. Cheng[1], Y. Chen[1]. [1]*Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, College of Medicine, Division of Rheumatology, Allergy, and Immunology, Department of Internal Medicine, Kaohsiung city, Taiwan, Republic of China*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder initiated from local synovium inflammation and consequently bone/cartilage destruction. Active disease status brings persistent inflammation, which stimulates the activation of osteoclasts, accelerating systemic bone loss and decreasing bone mineral density (BMD)(1). Ultrasound (US), a powerful tool for clinical practice, was reported to be beneficial for the prediction of new bone erosion and disease activity (2, 3), based on the synovitis grading recommendation by the European League against rheumatism- Outcome Measures in Rheumatology Clinical Trial (EULAR-OMERACT) Taskforce. The severity of RA synovitis is associated with local bone destruction; however, the impact on systemic bone loss is still unknown.
Objectives: This pilot study aims to investigate if the US-detected synovitis change is associated with systemic bone loss.
Methods: A registry was conducted in Chang Gung Memorial Hospital, Kaohsiung, from September 2014 till April 2021 to monitor BMD changes in patients with rheumatic diseases. In RA patients, we regularly assessed synovium change of bilateral wrist by ultrasound at enrollment and one year later, based on EULAR-OMERACT system(4), which is a semiquantitative grading tool incorporating both gray-scale synovial hypertrophy (SH) and power Doppler (PD) signal. These ultrasound scans were performed by an independent and well-trained rheumatologist, using MyLab 70 system (Esaote, Firenze, Italy) and B-mode frequency at 12–18 MHz. We performed a longitudinal scan of volar and dorsal wrists, observing GS and PD signals. All participants who underwent standard care for RA were followed at least three years to monitor BMD change, and those who underwent anti-osteoporosis therapy at index day were excluded. We defined improvement of US-detected synovitis (US+) as a change from high to low grade by EULAR-OMERACT score. Conversely, patients who failed improvement were recorded as "US- ", defined as change from low to high grade. Patients who improved one or more grades, such as from Grade 3 to 2 (or from Grade 2 to 0), were registered as US+1 (or US+2) and vice versa. If there is no change of synovitis grade, we registered as US+0.
Results: A total of 212 participants were enrolled in the current study, with a mean age of 56.0 ± 10.1 years and a mean RA disease duration of 13.6 ±9.1 years. In patients with US+, the mean change of hip BMD [defined as (final BMD-baseline BMD)/baseline BMD, in percentage] was 0.73 ±6.8%, while US- was -2.2 ±7.7% and US+0 -1.9 ±6.6% (p=0.047). in post-hoc analysis, US+ demonstrated borderline significance compared to US-(p=0.059) and US+0 (p=0.087) by Bonferroni method. Subsequent analysis (Figure 1 A) revealed that patients with US+2 presented preservation of hip bone mass (3.1 ±6.8%), followed by US+1 (0.1 ±6.8%) and then US+0. US-1 and US-2 showed rapid bone loss on the hip (-2.1 ±7.9% and -2.3 ±6.7%, respectively).

(A). Variations of ultrasound-detected synovitis grading are associated with hip BMD change.

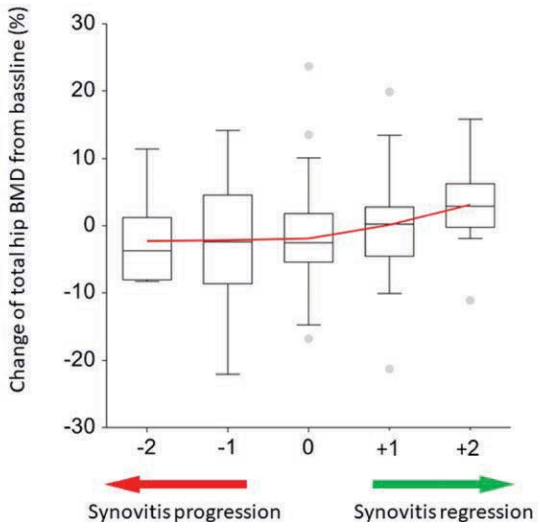

Figure 1.

Conclusion: Persistent synovitis is associated with total hip bone loss, and detection of synovitis change by ultrasound with EULAR-OMERACT scoring system is helpful to predict hip BMD change.

POS1149 BONE MANIFESTATIONS IN SYSTEMIC MASTOCYTOSIS AND RELATED RISK FACTORS

H. Avalos Bogado[1], M. Barceló-Bru[1], M. Pascual-Pastor[1], A. D. Ulloa Navas[1]. *[1]Hospital Universitari Vall d'Hebron, Rheumatology, Barcelona, Spain*

Background: Clinical characteristics in Systemic Mastocytosis (SM) range from asymptomatic (indolent) to aggressive forms. Up to 28-34% of patients with SM have symptoms related to bone involvement at diagnosis and 16% have fractures (1). Skeletal manifestations include bone pain, osteoporosis (OP), osteosclerosis, focal osteolytic and osteoblastic lesions. OP is frequently related to indolent SM but not the aggressive forms (2).
Objectives: To describe bone involvement in patients with SM and analyze related risk factors.
Methods: Retrospective cohort study comprising patients with SM that attended the Rheumatology Department from 2010 to 2021. Sociodemographic variables, SM classification, OP risk factors, bone lesions, fracture presence and analytical parameters were collected, and we analyzed whether they were associated with the presence of fractures (Table 1). Densitometry data were registered at diagnosis and up to 8 years of follow-up.

Table 1. Clinical features and differences between fractured and not fractured patients

	ALL	Fractures	No fractures	
	(N=22)	(N=3)	(N=19)	*p*
Age (y), mean (SD)	47.05(12.4)	44.3 (13.3)	47.5 (2.5)	0.69
Sex W/M, N(%)	15(68.2)/7 (31.8)	1(33.3)/2(66.7)	14 (73.7)/5(26.3)	0.23
Mastocytosis classification N(%)				0.37
Indolent	19(86.4)	2(66.7)	17 (89.5)	
Aggressive forms*	3(13.6)	1(33.7)	2(10.5)	
Menopause, N(%)	8 (36.4)	1 (100%)	7(83.6)	0.66
Low calcium intake, N(%)	16(72.7)	2 (66.7%)	14 (73.7)	0.63
Low BMI, N(%)	5 (22.7)/17(77.3)	0	5(26.3)	0.44
Smoking, N(%)	2 (9.1)	0	2 (10.5)	0.74
Alcoholism, N(%)	2(9.1)	0	2 (10.5)	0.74
Hypovitaminosis D, N(%)	5(22.7)	0	5(41.7)	-
Hyperparathyroidism, N(%)	5(22.7)	0	5(45.5)	-
Tryptase, mean (SD)	34.4(26.1)	20(-)	35.3(26.7)	0.58
BMD at diagnosis, mean (SD)				
Lumbar spine (g/cm^2)	0.976 (0.2)	0.509	1.012(0.1)	**<0.01**
Femoral neck (g/cm^2)	0.860 (0.1)	0.704	0.872(0.1)	0.17

*Aggressive forms include smoldering, hematologic malignancy, and mast cell leukemia

Results: 22 patients were included, 19 SM were indolent, 1 smoldering, 1 hematologic malignancy and 1 mast cell leukemia. Radiologically, 17 patients did not present lesions, 4 presented sclerotic lesions and 1 lytic lesions. Vertebral fractures were observed in 3 patients and 2 of them were before SM diagnosis. 10 patients received anti-osteoporotic treatment, 3 of them with teriparatide. At diagnosis, 2 patients (9.1%) had osteoporosis and 11 (50%) osteopenia. None of the analyzed risk factors were associated with OP presence. Of note, during follow-up significant changes were observed between those with indolent SM and aggressive forms at lumbar spine (LS) and femoral neck (FN) at 2 years (change in LS in indolent form -2.9% vs 29.6% in aggressive forms, p <0.001 and change at FN of 1% vs 20.5%, respectively, p=0.003). At 4 years change at LS was -4.1% vs 25.8%, p=0.034 between indolent and aggressive forms but there were no differences regarding the presence of fractures (2 fractures in indolent group and 1 in aggressive, p=0.371).
Conclusion: Bone involvement was present in more than 50% of patients at diagnosis and the presence of fractures was not uncommon (14%), especially at lumbar spine (LS). Aggressive forms were associated with an increase in aBMD. The presence of fractures was associated with lower LS aBMD at diagnosis.

POS1150 BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. Grygorieva[1], G. Dubetska[1]. *[1]D. F. Chebotarev Institute of Gerontology, NAMS of Ukraine, Clinical Physiology&Pathology of Locomotor Apparatus, Kyiv, Ukraine*

Background: Patients with systemic lupus erythematosus (SLE) have an increased risk of osteoporosis and low trauma fractures due to several important factors: the inflammatory disease itself, low vitamin D level, use of some disease-modifying anti-rheumatic drugs, glucocorticoids, etc. [1]. Bone mineral density (BMD) and trabecular bone score (TBS) measured by DXA are the important parameters of bone strength that evaluate the different aspects of bone architecture [1, 2].
Objectives: The aim of the research was to determine BMD and TBS in women with SLE.
Methods: We have examined 150 females from 20 to 75 years old (average age – 51.1±11.6 years) which were divided into 2 groups: patients with SLE (n=50) and healthy women (n=100). The females did not differ in terms of age (51.4±10.8 and 50.4±13.2 years, respectively; p=0.60), height (163.8±15.4 and 163.6±6.6 cm, p=0.86), body mass (73.6±15.9 and 68.8±14.8 kg, p=0.09), and the duration of the postmenopausal period (8.9±6.9 and 9.6±8.1 years, p=0.81), but the age of menopause was significantly lower in patients with SLE (47.9±4.7 and 42.1±15.3 years, respectively, p<0.05). The BMD was measured at the lumbar spine, femoral neck, proximal femur, and total body, by means of the "Prodigy" unit (CE Medical systems, model 8743, 2005). The TBS was evaluated using the installed TBS iNsight software for an X-ray densitometer (Med-Imaps, Pessac, France).
Results: The parameters of BMD were significantly lower in patients with SLE compared to the healthy women in all measured areas: in the total body (0.95±0.05 and 1.06±0.12 g/cm^2, respectively; p=0.03), in the lumbar spine (0.87±0.13 and 0.96±0.17 g/cm^2, p=0.02), femoral neck (0.68±0.11 and 0.75±0.14 g/cm^2, p=0.03), proximal femur (0.83±0.10 and 0.92±0.16 g/cm^2, p=0.02). In the patients with SLE TBS was significantly lower compared to the index in healthy women (1.28±0.11 and 1.33±0.12 un., p=0.02).
Conclusion: The parameters of BMD and TBS in women with SLE are significantly lower than in the healthy population. Our results emphasize the importance of combined BMD and TBS measurement in the evaluation of the different aspects of bone architecture for dynamic monitoring of bone health and risk of fracture in patients with SLE and timely start of osteoporosis treatment.

POS1151 OPPORTUNISTIC BONE MINERAL DENSITY SCREENING IN PATIENTS UNDERGOING CARDIAC CT SCANS: EFFECT OF USING IMAGES CONTAINING INTRAVENOUS CONTRAST

A. Cheneymann[1], J. Therkildsen[2,3], S. Winther[1], L. Nissen[1], J. Thygesen[4], B. Langdahl[3,5], E. M. Hauge[2,3], M. Böttcher[1]on behalf of Dan-NICAD. *[1]Gødstrup Hospital, Department of Cardiology, Herning, Denmark; [2]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [3]Aarhus University Hospital, Department of Clinical Medicine, Aarhus, Denmark; [4]Aarhus University Hospital, Department of Clinical Engineering, Aarhus, Denmark; [5]Aarhus University Hospital, Department of Endocrinology, Aarhus, Denmark*

Background: Osteoporosis is under-diagnosed worldwide causing increased risk of fractures and death (*1*). Computed tomography (CT) scans performed on other indications such as coronary artery disease harbor the potential for automatic detection of low volumetric bone mineral density (vBMD) of the vertebrae using quantitative CT (QCT); hence allowing estimation of future fracture risk (*2*). CT is often performed with intravenous (iv) contrast administration. In 2015, the International Society of Clinical Densitometry stated: "*There is insufficient evidence to judge the effect of contrast agents on a classification of low BMD*" (*3*); this position remains. Thus, it is important to assess the effect of contrast enhancement in order to broaden the potential of vBMD screening using routine CT scans.
Objectives: We aimed to compare thoracic vBMD measurements from CT scans with and without iv contrast enhancement.
Methods: This cross-sectional multicenter sub-study is based on a larger clinical trial, Dan-NICAD-1, from which we randomly selected a cohort of 136 participants. First, a non-contrast scan was performed followed by a contrast-enhanced scan during which 60-90mL of iv contrast was administered (Iomeron, 350 mgI/

mL). Mindways QCT Pro software was used to measure BMD values (mg/cm^3) and the mean estimate was calculated for each participant (*4*). American College of Radiology quantitative CT cut-off values for lumbar spine were used to categorize patients into very low (<80mg/cm^3), low (80-120mg/cm^3), or normal BMD (>120mg/cm^3).

Results: In 136 participants undergoing cardiac CT (Table 1), we found a different mean vBMD before vs. after contrast; 117.5 mg/cm^3 [95%CI: 111.6–123.4] vs. 132.1 mg/cm^3 [95%CI: 125.1–139.1], *p<.0001*. The absolute difference was 14.7mg/cm^3 [95%CI: 12.3–17.0]; the relative difference, was 12.5% [95% CI: 10.5–14.5]. In total, 8/15 (53%) participants changed from very low BMD to low BMD after contrast administration, and 21 participants (21/63, 33%) changed from low to normal BMD (Figure 1). No participants changed from very low BMD to normal BMD.

Table 1. Demographics by vBMD*

Characteristics	All (n=136)	Very low BMD (n=15)	Low BMD (n=63)	Normal BMD (n=58)
Gender M:F	89:47	8:7	49:14	32:26
Age, yrs (range)	57±9 (40-73)	64±6 (48-72)	59±8 (44-73)	54±8 (40-72)
Mean vBMD before contrast, mg/cm	92.2±16.1	68.0±10.5	98.0±10.1	151.5±21.9
Mean vBMD after contrast, mg/cm	95.2±16.0	68.6±10.5	100.8±10.3	159.6±31.6

* Classifications defined by American College of Radiology and grouped using the non-enhanced CT. Data: number of participants, (range) and mean with standard deviations. ** Self-reported

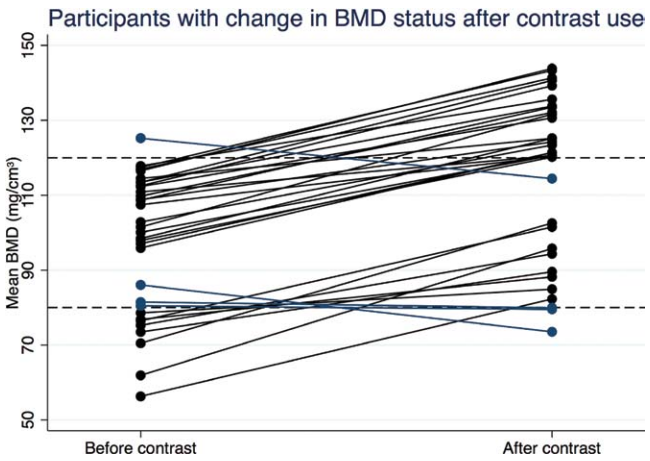

Figure 1. Participants with change in BMD category after contrast administration Figure 1. vBMD measurements before and after contrast administration. 33/136 participants changed BMD category illustrated by the dotted lines (80 mg/cm^3; 120 mg/cm^3). Black lines: increase in vBMD after contrast (n=29); blue lines: decrease in vBMD after contrast (n=4).

Conclusion: Our data suggest a significant effect of contrast on clinical vBMD measurements; thus, this should be adjusted for before using contrast-enhanced cardiac CT for opportunistic vBMD screening. This urges further studies on the effect of scan protocols on the contrast-enhanced increase in BMD.

POS1152

BONE AND MUSCLE IMPAIRMENT AND HIGHER VISCERAL ADIPOSE TISSUE MASS IN WOMEN WITH LONG-TERM POLYARTICULAR JUVENIL IDIOPATHIC ARTHRITIS

S. Ribeiro[1], L. Peixoto Sales[2], L. Silva[2], V. Caparbo[2], L. Takayama[2], R. M. Pereira[2]. *[1]University of São Paulo, Rheumatology Division, São Paulo, Brazil; [1]University of São Paulo, Rheumatology Division, São Paulo, Brazil*

Background: Some studies suggest that patients with juvenile idiopathic arthritis (JIA) may have reduced bone parameters and muscle mass. Despite those considerations, there is no validated consensus about this topic in the literature as the population and the methods for bone and muscle evaluation are often heterogeneous and not standardized.

Objectives: To assess bone parameters and body composition of women with long-term polyarticular JIA and compare them to healthy controls.

Methods: Twenty-seven women with long-term polyarticular JIA were compared with twenty-seven healthy controls, matched by sex, age, and body mass index (BMI). Dual-energy X-ray absorptiometry (DXA) was performed to evaluate the lean mass, body fat percentage (% Fat), and visceral adipose tissue mass (VATm). High resolution peripheral quantitative computed tomography (HR-pQCT) at the distal radius and tibia was performed to assess trabecular (Tb.) and cortical (Ct.) volumetric bone mineral density (v.BMD) and strength bone parameters (stiffness - S; estimated fail load - FL). Group means were compared using Student's t-test.

Results: Polyarticular JIA patients have a lower trabecular and cortical volumetric bone density, a lower bone strength, and a lower lean mass compared to healthy controls. Moreover, long-term JIA patients have a higher visceral adipose tissue mass (Table 1).

Table 1. Bone parameters using high resolution peripheral quantitative computed tomography (HR-pQCT) and body composition in long-term polyarticular patients and healthy controls.

	Polyarticular JIA n=27	Healthy controls n=27	*p-value*
Age, years	31.8 ± 7.6	33 ± 8.2	0.597
BMI, Kg/m^2	24 ± 4.8	24.6 ± 4.7	0.931
Disease duration, years	22 ± 10	-----	
Remission or low activity, n (%)	16 (59)	-----	
Use of prednisone, n (%)	5 (18)	-----	
Rheumatoid factor	9 (33)	0 (0)	
Lean mass, kg	35.7 ± 4.7	39 ± 7.2	**<0.001**
%Fat, %	39 ± 8	37 ± 7	0.364
VATm, kg	588 ± 538	212 ± 209	**0.001**
HR-pQCT at the distal radius			
Tb.v.BMD, mg HA/cm^3	125 ± 32	159 ± 38	**<0.001**
Ct.v.BMD, mg HA/cm^3	994 ± 46	1035 ± 43	**<0.001**
S, kN/mm	64 ± 11	78 ± 18	**0.001**
FL, N	3174 ± 879	3710 ± 827	**<0.001**
HR-pQCT at the distal tibia			
Tb.vBMD, mg HA/cm^3	128 ± 48	162 ± 32	**0.003**
Ct.vBMD, mg HA/cm^3	990 ± 57	993 ± 52	0.811
S, kN/mm	179 ± 39	212 ± 40	**<0.001**
FL, N	8519 ± 1773	9675 ± 2525	**0.004**

Data expressed as mean ± standard deviation or frequency (percentage). Tb.vBMD – trabecular volumetric bone mineral density, Ct.vBMD – cortical volumetric bone mineral density; S - stiffness; FL - estimated fail load

Conclusion: Pre-menopausal women with long-term polyarticular JIA have an impairment of bone mineral density at peripheral sites in addition to lower muscle mass and higher visceral adipose tissue. These findings may contribute to the increasing osteoporosis/fractures and cardiovascular risk in this population, suggesting that measures should be considered to prevent these damages.

CHARACTERISTICS OF GUT MICROBIOME AND THEIR ASSOCIATIONS WITH PERIPHERAL LYMPHOCYTE SUBPOPULATIONS AND CYTOKINES IN RHEUMATOID ARTHRITIS PATIENTS COMPLICATED WITH OSTEOPOROSIS

T. Cheng[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], M. J. Chang[4], R. Zhao[1,2,3], S. Song[1,2,3], C. Wang[1,2,3], X. LI[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; [3]Shanxi Medical University,, Academy of Microbial Ecology, Taiyuan, China; [4]Shanxi Medical University,, School of Management, Taiyuan, China*

Background: Osteoporosis(OP) is one of the major comorbidities of rheumatoid arthritis(RA) which is associated with immune disorders[1]. The gut microbiota has been highlighted to be an important environmental factor to influence immune system in maintaining bone health and regulating bone remodeling[2]. However, the alterations of intestinal flora and its relationship with immune system in RA patients with OP are unclear.
Objectives: To investigate the characteristics of gut microbiome as well as the associations between flora and peripheral lymphocyte subpopulations and cytokines in rheumatoid arthritis patients complicated with osteoporosis.
Methods: Total 28 RA patients were divided into 14 RA-non-OP and 14 gender- and age-matched RA-OP groups according to their bone mineral density (BMD) and the history of fragility fracture. Gut microbiota of participants were investigated by 16s rRNA and peripheral lymphocyte subsets and cytokines were assessed via flow cytometry. Indicators like erythrocyte sedimentation rate (ESR), C-reaction protein (CRP), anti-cyclic citrullinated peptide antibody (ACPA) and anti-mutated citrullinated vimentin (MCV) antibody were recorded meanwhile. Alpha diversity (ACE, Chao1, Simpson, Shannon) and beta diversity indices were analyzed using QIIME2. Biomarker species were recognized based on STEMP. Spearman analysis was adopted for correlation of two variables. All *P*-values reported herein were two-tailed and *P*-value<0.05 was taken as statistically significant.
Results: The alpha-diversity have no significant difference between RA-non-OP and RA-OP groups (*P* >0.05, Figure 1A). The community structure of microflora differed between two groups (*P* <0.05, Figure 1B). As for the composition of intestinal flora at genus level, Faecalibacterium, Proteus, Catenibacterium, Enterobacter and Erysipelatoclostridium in RA-OP group as well as Lachnospiraceae_ND3007_group, Parasutterella, Megasphaera, Tyzzerella, UCG-005, Clostridium_sensu_stricto_1, UCG-002, Lachnospiraceae_NK4A136_group, Christensenellaceae_R-7_group, Prevotella, Parabacteroides in RA-non-OP group were significantly increased (Figure 1C). There were positive correlations between Lachnospiraceae_NK4A136_group and the level of T, Th1 and Th17 cells, but negative relevance with ESR, CRP and IL-10 (*P* <0.05). The relative abundance of Faecalibacterium was negatively correlated with IL-2, IL-4, TNF-α and positively with MCV (*P* <0.05). Clostridium_sensu_stricto_1 and Lachnospiraceae_ND3007_group were negatively correlated with ACPA and MCV respectively as well as IL-2 (*P* <0.05, Figure 1D-E).
Conclusion: Abnormality of immune system may contribute directly or indirectly to OP in RA, which may be related to the disturbance of gut microbiota.

Crystal diseases, metabolic bone diseases other than osteoporosis

POS1154

OUTCOMES AND RESOURCE UTILIZATION AFTER TOTAL HIP ARTHROPLASTY IN PATIENTS WITH CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

M. Constantinou[1], M. Lampi[1], B. Bhattarai[2,3], K. Parperis[4,5]. *[1]University of Cyprus Medical School, Medicine, Nicosia, Cyprus; [2]Valleywise Health Medical Center, Biostatistics, Phoenix, United States of America; [3]University of Arizona College of Medicine, Epidemiology, Phoenix, United States of America; [4]University of Cyprus Medical School, Department of Internal Medicine, Division of Rheumatology, Nicosia, Cyprus; [5]University of Arizona College of Medicine, Division of Rheumatology, Phoenix, United States of America*

Background: Total hip arthroplasty (THA) is a safe and effective treatment option in patients with advanced degenerative joint disease who have failed conservative management. Calcium pyrophosphate deposition disease (CPPD) is a common crystal-induced arthritis in older adults characterized by the deposition of calcium pyrophosphate crystals in the articular and periarticular tissues[1]. CPPD might manifested with acute and chronic arthritis that can lead to joint damage and the need for joint replacement. To our knowledge, no previous studies investigated the outcomes of CPPD patients who underwent THA.
Objectives: We aim to examine the mortality, in-hospital complications, and resource utilization following THA in patients with and without CPPD.
Methods: We queried the US National Inpatient Sample (NIS) database to identify patients who underwent THA between 2006 and 2014. The ICD-9 code 81.51 was used to identify the patients who underwent THA and of those, we classified 2 groups of patients: (i) those with ICD-9 codes defining CPPD (275.49 and 712.1–712.39) and (ii) those without any CPPD code. Data collection included patient demographics and comorbidities. Outcomes post-THA were in-hospital mortality, hospital length of stay, hospital charges, and discharge disposition. Associations between CPPD and specific morbidity were evaluated with chi-square tests. T tests were used for continuous variables.
Results: Among the 4,111,808 (adjusted for sampling weight) patients who underwent THA between 2006 and 2014, 6198 (0.15%) had CPPD, with a mean age of 77 years and 65.2% were females (Table 1). CPPD patients were more likely to be older (mean age 77 vs 72.7; p<0.001) than non-CPPD patients. Comorbidities more frequently observed among CPPD patients included chronic kidney disease, osteoarthritis, rheumatoid arthritis, gout, hyperparathyroidism and hypomagnesemia. Further, Charlson Comorbidity Index scores ≥ 2 was more frequent seen in CPPD (96.1% vs 89.1%, p <0.001). The in-hospital mortality post-THA was lower in the CPPD patients (0.76% vs 1.72%, p <0.001). THA in CPPD patients was associated with a longer mean length of stay than those

without CPPD (6 vs 5.1 days; p <0.001) while mean total charges were not statistically different between the 2 groups (p=0.344). CPPD patients were more likely to be discharged to rehabilitation or other nursing facilities (p<0.001).

Table 1. Demographics, clinical characteristics, outcomes and resource utilization of patients with and without CPPD who underwent hip arthroplasty between 2006-2014.

	No CPDD, n (%) (N=4105610)	CPPD, n (%) (N=6198)	P-value*
Age in years at admission, median (mean ± SD)	75 (72.7 ± 31.5)	80 (77.0 ± 24.2)	<0.001†
Female	2507971 (61.1)	3979 (64.2)	<0.001
Chronic kidney disease	516688 (12.5)	1154 (18.6)	<0.001
Osteoarthritis	684171 (16.6)	1280(20.6)	< 0.001
Gout	139648 (3.4)	330 (5.3)	<0.001
Rheumatoid arthritis	199175 (4.8)	478(7.7)	<0.001
Hyperparathyroidism	7959 (0.1)	24(0.3)	<0.001
Hypomagnesemia	100390 (2.45)	239 (3.86)	<0.001
Charlson Comorbidity Index score ≥ 2	3659906 (89.1)	5961(96.1)	<0.001
Outcomes/Resource utilization			
Length of stay, (mean ± SD)	5.15 ± 11.72	6.04 ± 13.91	<0.001†
Total hospital charges, (mean ± SD)	$ 41284 ± 108238	($ 42757 ± 124894)	0.344†
Death during hospitalization	70706 (1.7)	47 (0.7)	<0.001†
Discharge Disposition			
Home (including home health care)	2653860 (64.7)	3558 (57.4)	<0.001
All others§	1447312 (35.3)	2635 (42.5)	<0.001

*Chi-square P except †t-test §All others include transfer to nursing or rehabilitation facility.

Conclusion: CPPD patients who underwent THA were more likely to be older, with a higher comorbidity burden, longer length of stay, and discharged to a non-home setting, than non-CPPD patients.

POS1155 THE INTERNATIONAL X-LINKED HYPOPHOSPHATAEMIA (XLH) REGISTRY: OVERVIEW OF THE DATA SET

G. Ariceta[1], J. Liu[2], A. Williams[2], S. Wood[2], D. Schnabel[3]. *[1]Hospital Vall d'Hebron, Pediatric Nephrology, Barcelona, Spain; [2]Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom; [3]Charité, University Medicine Berlin, Center for Chronically Sick Children, Pediatric Endocrinology, Berlin, Germany*

Background: X-Linked Hypophosphataemia (XLH) is a rare, progressive, lifelong, hereditary renal tubule phosphate-wasting disorder characterised by a pathological increase in fibroblast growth factor 23 concentration/activity.[1] Despite XLH being increasingly recognised as a chronic progressive disease, there are few data documenting its natural history or the impact of treatment on patient outcomes.[2] The International XLH Registry was established to address this lack of information on XLH to help inform future clinical management. The Registry will collect data to characterise the treatment, burden of disease, disease progression and long-term outcomes of XLH.

Objectives: To provide an overview and status update of the International XLH Registry as of 31 December 2021.

Methods: The International XLH Registry (NCT03193476) was initiated in August 2017, aims to recruit 1,200 children and adults with XLH, and will run for 10 years. This Registry is an international, multicentre, non-interventional data collection programme and will provide the largest single dataset representing children and adults with XLH. To be eligible for inclusion in the registry, patients must meet all the following criteria:1) Male or female subjects of all ages; 2) Diagnosis of XLH with clinical, radiological, biochemical and/or genetic findings consistent with XLH. The Registry captures any treatment details and clinical outcome variables in patients with XLH and patients are followed for as long as informed consent (and assent, where applicable) and regulatory permissions are maintained. Only data collected during standard routine examinations are recorded within the Registry, and no specific examinations/data entries are mandated. Parameters collected at baseline included demographics, medical and treatment history, and clinical presentation data. The conduct of the International XLH Registry is overseen by 17 Steering Committee physician members representing the region.

Results: As of 31 December 2021, 1,043 subjects diagnosed with XLH were enrolled from 88 hospital sites in 19 countries. The geographic distribution of subjects is as follows: Belgium n=29, Bulgaria n=7, Czech Republic n=8, Denmark n=23, France n=267, Germany n=79, Hungary n=11, Ireland n=5, Israel n=21, Italy n=88, The Netherlands n=26, Norway n=23, Portugal n=9, Slovakia n=5, Slovenia n=3, Spain n=55, Sweden n=43, Switzerland n=17, and the UK n=324. A further 30 sites are yet to enrol (including sites in Austria and Latvia). Overall, 400 adults (18–29y, n=116; 30–39y, n=81; 40–49y, n=95; 50–59y, n=58; ≥60y, n=50) and 620 paediatric subjects (<5y, n=138; 5–12y, n=321; 13–17y, n=161) have been enrolled (date of birth not reported, n=23). The majority of enrolled subjects are female (648 (62.1%), with 372 male (35.7%) and 23 for whom sex was not reported (2.2%). The quantity of data from the patients included in this Registry will enable ongoing snapshot and prospective analyses to be conducted over the coming years to answer research questions and inform clinical practice.

Conclusion: This International XLH Registry forms the largest dataset of subjects with XLH collected to date. Patients have been recruited from a wide geographical region and baseline demographics are consistent with a hereditary X-linked dominant disease. Information collected during the 10-year Registry duration will generate real-world evidence to help inform clinical practice throughout the region, with the aim of improving the care and quality of life of adults and children living with this debilitating disease.

POS1156 PHASE 1 TRIALS OF NOVEL ORAL ENZYME THERAPY (ALLN-346) FOR HYPERURICEMIA & GOUT: SAFETY, PHARMACODYNAMICS, AND LACK OF SYSTEMIC ABSORPTION OF SINGLE AND MULTIPLE ASCENDING DOSES IN HEALTHY VOLUNTEERS

D. Clark[1], D. Grujic[2], C. Tosone[3], N. Dahl[4], R. Terkeltaub[5]. *[1]Allena Pharmaceuticals, Inc., Clinical Development, Newton, United States of America; [2]Allena Pharmaceuticals, Inc., Pharmacology, Newton, United States of America; [3]Allena Pharmaceuticals, Inc., Clinical Operations, Newton, United States of America; [4]Allena Pharmaceuticals, Inc., Medical Affairs, Newton, United States of America; [5]SDVAHCS/UC San Diego, Medicine, San Diego, United States of America*

Background: Currently available therapies for gout in patients with advanced chronic kidney disease (CKD) are either dose-limited or contraindicated due to safety and tolerability concerns. In gout patients with advanced CKD, the intestinal tract becomes the major route of urate elimination, in contrast to healthy people with normal kidney function whose kidneys are the primary route of uric acid excretion.[1.] Considering some of the limitations of present urate lowering therapies (ULTs) in gout & CKD and the extra-renal pathway of urate secretion, a new oral therapy with ALLN-346 (engineered urate oxidase) is under development as a non-absorbed, urate specific enzyme, designed to enhance degradation and secretion of urate in the intestinal tract. [2]

Objectives: To assess safety and tolerability and evidence for the lack of systemic absorption at various dose levels of ALLN-346 in normal healthy volunteers (NHV) up to 7 days.

Methods: Two randomized, double-blind Phase 1 studies of ALLN-346 or placebo were conducted in adult NHV in a domicile setting; a single-ascending dose (SAD) study of 3 doses on a single day of dosing, and a multiple ascending dose (MAD) study of 2 doses during 7 days (NCT04236219 and NCT04829435, respectively). In the SAD study, subjects received 3 ascending doses of ALLN-346 (3 capsules,6 capsules, and 6 capsules administered twice, or placebo) and were randomized 3:1 (ALLN-346:placebo, n=24). In the MAD study, subjects received 3 (Cohort A) or 5 (Cohort B) of ALLN-346 capsules or placebo (2:1 randomization, n=18) administered orally 3 times daily for 7 days. To assess possible ALLN-346 absorption, a specific ELISA and uricase potency assay were used on PK serum samples collected from all subjects in both studies pre-dose and at intervals post dose.

Results: In both studies, all randomized subjects completed treatment with 100% compliance. ALLN-346 was well-tolerated, with no serious adverse

events (AE) and with no clinically significant safety signals across all cumulative doses. Clinical and laboratory parameters revealed no clinically significant safety signals among all cumulative dosing cohorts across hematology, serum biochemistry, vital signs, or ECGs. The majority of reported AEs were mild with no pattern of differences between ALLN-346 and placebo. No evidence of systemic absorption of ALLN-346 was seen, as confirmed by both ELISA and by uricase potency assay of all PK serum samples from all subjects from SAD (n=240) and MAD (n=324).

Conclusion: ALLN-346, a new oral enzyme therapy in development for the treatment of hyperuricemia and gout in advanced CKD was well tolerated. Consistent with its mechanism of action, no evidence of systemic absorption was demonstrated. Furtherstudies in hyperuricemia patients with gout and CKD are underway.

POS1157 SAFETY AND EFFICACY OF ALLN-346 ORAL ENZYME THERAPY IN PATIENTS WITH HYPERURICEMIA AND CHRONIC KIDNEY DISEASE (CKD): RESULTS OF THE PHASE 2A STUDY 201

R. Terkeltaub[1], D. Clark[2], C. Tosone[3], B. Kandinov[3], P. Zhang[3], N. Dahl[4], D. Grujic[5], D. Goldfarb[6]. *[1]SDVAHCS/UC San Diego, Medicine, San Diego, United States of America; [2]Allena Pharmaceuticals, Inc., Clinical Development, Newton, United States of America; [3]Allena Pharmaceuticals, Inc., Clinical Operations, Newton, United States of America; [4]Allena Pharmaceuticals, Inc., Medical Affairs, Newton, United States of America; [5]Allena Pharmaceuticals, Inc., Pharmacology, Newton, United States of America; [6]NYU Langone Health, Medicine, New York, United States of America*

Background: Currently available urate lowering therapies (ULTs) are limited in their use for gout patients with advanced CKD based on dosing restrictions, tolerability, safety concerns, and reduced effectiveness, compared to options for the broader gout population. In gout patients with advanced CKD, the intestinal tract becomes the major route of urate elimination, as opposed to in healthy people with normal kidney function where kidneys are the primary route of uric acid excretion.[1] Considering some of the limitations of present urate-lowering therapies (ULTs) in gout & CKD and the extra-renal pathway of urate secretion, a new oral therapy, ALLN-346 (engineered urate oxidase), is under development as a non-absorbed, urate specific enzyme, designed to enhance degradation and secretion of urate in the intestinal tract.[2]

Objectives: To assess the safety, tolerability, and initial bioactivity data of ALLN-346 in adults with hyperuricemia and CKD.

Methods: This one-week inpatient Phase 2a study (NCT04987242) was conducted at a clinical pharmacology unit. Eleven otherwise healthy adult patients with hyperuricemia (sUA ≥ 6.8 mg/dL) and normal to Stage 2 CKD (eGFR ≥60), not on concurrent ULTs, were randomized (2:1) to receive either 5 capsules of ALLN-346 or matching placebo, three times daily for 7 days. Serum urate was measured daily, and urine uric acid was assessed on days -2, -1, 1, 4, and 7. Safety was monitored throughout the study. To assess possible ALLN-346 systemic absorption, a specific ELISA was used on serum samples collected pre- and post-dose over 7 days.

Results: Of the 11 patients 7 received ALLN-346 and 4 received placebo. Most patients had Stage 2 CKD, including 5 of the 7 subjects treated with ALLN-346. A statistically significant reduction in mean sUA was recorded with ALLN-346 compared to placebo [Figure 1]. The largest mean % reduction in sUA was observed among patients with stage 2 CKD; sUA reduction was correlated with eGFR in the ALLN-346 group (r=0.95; *P*=0.003), but not the placebo group (r=-0.2; *P*=0.91). No serious adverse events were reported, and clinical and laboratory parameters revealed no significant safety signals. Lack of systemic absorption of ALLN-346 was confirmed by ELISA assays.

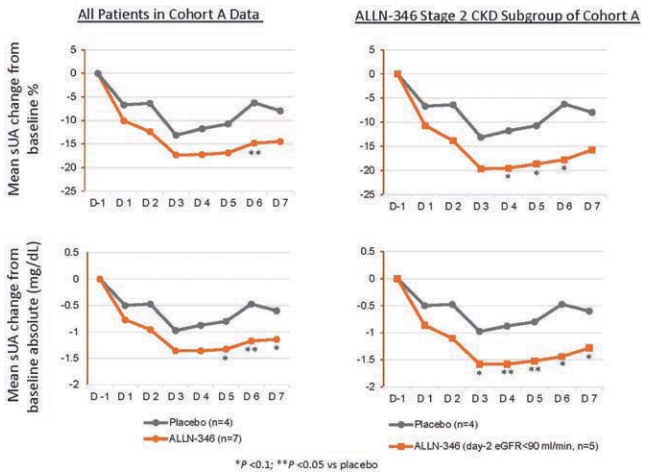

Figure 1. Absolute and Percent Change from Baseline in Serum Urate over 7 -days of Treatment

Conclusion: In this study, oral therapy with ALLN-346 for 7 days was well tolerated and resulted in a significant reduction in sUA. Consistent with the known pathophysiologic adaptation of increased intestinal elimination of uric acid in patients with impaired kidney function and the intestinal-based mechanism of action of ALLN-346, there was a strong correlation between the effect of ALLN-346 on sUA reduction and the level of kidney function. The generated data support proof of pharmacology for the intestinal mechanism of action of ALLN-346 to degrade urate either formed or secreted in the gut. Future studies in the larger gout population with CKD are underway.

POS1158 CHARACTERIZATION OF GOUT IN US PATIENTS UNDERGOING HEMODIALYSIS (HD) AND PERITONEAL DIALYSIS (PD)

A. Karaboyas[1], J. Zhao[1], B. Lamoreaux[2], B. Marder[2], B. Gorlitsky[3], V. Domingues[4], R. Pecoits-Filho[1], B. Robinson[1]. *[1]Arbor Research Collaborative for Health, Research, Ann Arbor, United States of America; [2]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [3]Carolina Nephrology, Nephrology, Greenville, United States of America; [4]Florida State University, Rheumatology, Tallahassee, United States of America*

Background: Gout is the most common inflammatory arthritis and occurs frequently in patients with renal disease often leading to a significant burden on quality of life and functional status.[1,2] Despite the established connection of renal disease with gout, little has been reported on the prevalence, patient characteristics, and associations of gout with other outcomes in the US hemodialysis (HD) and peritoneal dialysis (PD) population.

Objectives: This project used a large end-stage renal disease (ESRD) focused-database, Dialysis Outcomes and Practice Patterns Study (DOPPS), to examine gout in dialysis-dependent patients.

Methods: Gout patients were identified by active prescription (Rx) of (1) colchicine, (2) febuxostat, or (3) allopurinol; or by (4) prior diagnosis of gout from US cohorts of 70,297 HD (DOPPS, 2012-2020) patients and 5117 PD (Peritoneal DOPPS, 2014-2020) patients. Outcomes of HD and PD patients with and without a history of gout were compared with propensity score matching. Outcomes included erythropoietin resistance index (ERI = ESA dose/(hemoglobin*weight),

cardiovascular death, all-cause mortality/hospitalization, and baseline patient-reported outcomes (PROs).

Results: Gout prevalence was 13% in HD and 21% in PD and was highest among incident dialysis patients. Of the gout patients identified, the most-commonly used gout-related medications were allopurinol (9-12%), followed by colchicine (2-3%), and then febuxostat (1%, Figure 1). Both HD and PD patients with gout (vs. no gout) were older and more likely male. Gout HD and PD patients had higher BMI and higher prevalence of cardiovascular comorbidities than HD and PD patients without gout. After propensity score matching, mean ERI was 4% higher for gout vs. non-gout patients, while there was minimal evidence of association with clinical outcomes (mortality and hospitalization) or PROs.

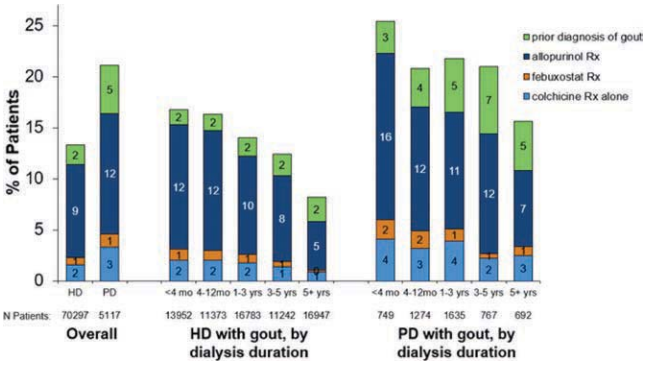

Figure 1. Gout prevalence by dialysis duration in patients undergoing HD and PD. Criteria for gout included gout diagnosis and use of a urate-lowering therapy. HD, hemodialysis; PD, peritoneal dialysis; mo, months; Rx, prescription; yrs, years. Some patients were included in multiple gout categories.

Conclusion: Gout was common in US HD and PD patients, with a large proportion of these patients treated with drugs indicated for hyperuricemia (allopurinol and febuxostat) and gout flares (colchicine). The true prevalence of gout was likely higher than observed when considering potential under-ascertainment of gout diagnosis history in nephrology/dialysis-focused clinical settings.[3] This report provides a snapshot of gout in the US dialysis population and offers opportunities to expand on research to improve awareness and care for patients with gout and ESRD.

POS1159 SUBCLINICAL ATHEROSCLEROSIS IN GOUTY ARTHRITIS PATIENTS: A CROSS SECTIONAL STUDY BY ULTRASONOGRAPHY

Y. Wang[1], Z. Zhang[1]on behalf of none. *[1]First hospital of Peking university, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Hyperuricemia is closely associated with cardiovascular disease (CVD). However, it has not been definitively established whether this association is independent of traditional cardiovascular risk factors in gout patients.

Objectives: To clarify the incidence of subclinical atherosclerosis and associated factors in gouty arthritis patients by ultrasonography.

Methods: We conducted this cross-sectional study to investigate the frequency and clinical factors correlated with carotid changes in patients with gout by ultrasonography.

Results: 200 consecutive patients with gout were recruited. Carotid ultrasound was performed in all patients in First hospital of Peking University from 2014 to 2020, finding atheroma plaques in 33.0% patients. None of these patients received urate-lowering drugs. On univariate analysis, the pattern was significantly associated with age, estimated gout duration, clinical tophi, double contour sign at the scanned joint and decreased estimated glomerular filtration rate; While arterial hypertension, hyperuricemia were not associated with carotid plaques. On multivariable analysis, the atheroma plaques were associated with estimated disease duration, clinical tophi, double contour sign and decreased estimated glomerular filtration rate. Thus, carotid plaque was frequently demonstrated in gout patients with tophaceous gout and associated with features of tubulointerstitial nephritis. This finding reveals the hypothesis of crystal-led inflammation and comorbidities relates to gout associated cardiovascular disease, predominantly seen in high uric acid burden patients, which could be an important treatment target for gout therapy.

Conclusion: Ultrasonography can detect crystal deposits in joints and connective tissues. We investigated the frequency and clinical correlates of plaques in carotid by ultrasound in consecutive gout patients.

The pattern was significantly associated with age, estimated gout duration, clinical tophi, double contour sign and decreased estimated glomerular filtration rate.

POS1160 PROTECT: PEGLOTICASE TREATMENT FOR UNCONTROLLED GOUT IN KIDNEY TRANSPLANTED PATIENTS; RESULTS FROM A PHASE 4 TRIAL

A. Abdellatif[1], L. Zhao[2], K. Cherny[2], B. Marder[3], J. Scandling[4], K. Saag[5]. *[1]Baylor College of Medicine and CLS Health, Nephrology Division, Houston, United States of America; [2]Horizon Therapeutics plc, Clinical Development, Deerfield, United States of America; [3]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [4]Stanford Medicine, Division of Nephrology, Stanford, United States of America; [5]The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America*

Background: A phase 4 trial (NCT04087720) of kidney transplant (KT) recipients on stable immunosuppressants with uncontrolled gout previously reported that pegloticase produced a sustained decrease in serum uric acid (sUA) levels and was associated with clinically meaningful improvements in pain and disability without worsening of key kidney function markers. Pegloticase treatment was well tolerated overall with no infusion reactions or anaphylaxis. Here we report additional exploratory and secondary endpoints.

Objectives: To evaluate the results of clinically important efficacy endpoints as supportive evidence for the efficacy of pegloticase in kidney transplant patients on immunosuppression.

Methods: PROTECT a multicenter, open-label, efficacy and safety study of pegloticase in included kidney transplant recipients (KT>1 year prior) with uncontrolled gout (sUA ≥7 mg/dL, oral urate lowering therapy contraindication/inefficacy, and with either visible tophi, chronic gouty arthritis, or ≥2 flares in past year), who had a functioning graft (estimated glomerular filtration rate [eGFR] ≥15 ml/min/1.73m^2), and were on a stable immunosuppressant regimen. Pegloticase (8 mg infusion) was administered biweekly for 24 weeks (12 infusions) followed by a final follow up visit 3 months post-treatment. The global health component of the Health Assessment Questionnaire (HAQ-Health), and the physician global assessment of gout (PGA) were assessed at baseline, weeks 6, 14, 20, 24, and the end of pegloticase infusions (EOI) visit (if applicable, when the final infusion occurred prior to week 22). Both were visual analog scales (VAS), where HAQ-health ranged from 0 (very well) to 100 (very poor) and PGA ranged from 0 (excellent) to 10 (very poor). Heart rate and blood pressure measurements were recorded at baseline, weeks 6, 12, 18, 24 and the EOI visit.

Results: 20 patients received at least 1 dose of pegloticase and were included in the analysis with the majority (90.0%) 40 to 81 years of age. Most were male (85.0%), 45.0% white, and 35.0% black or African American. Median body weight (88.46 kg) and body mass index (29.68 kg/m^2) were high. Median baseline eGFR and baseline Urine Albumin-Creatinine Ratio (UACR) were 41.70 mL/min/1.73m^2 and 312.00 mg/g, respectively. An improvement from baseline to weeks 14

(n=18), and 24 (n=15 [PGA], n=14 [HAQ]) in mean PGA and HAQ-Health was observed. Change from baseline (Mean [SD]) at 14 and 24 weeks for PGA was -2.3 (1.94) and -2.3 (2.19), and for HAQ-Health was -32.74 (21.26) and -21.52 (27.47) respectively. Improvement was sustained at the 3-month post-treatment follow-up visit. Mean decreases from baseline in sitting systolic blood pressure, diastolic blood pressure, and mean arterial pressure were observed at weeks 6, 12, 18 and 24. Change from baseline values at 24 weeks (n=15) for systolic, diastolic and mean arterial pressures were (Mean [SD]) -11.01 (14.04), -4.37 (9.18), and -6.58 (9.675) mmHg respectively. Heart rate showed no clinically meaningful trends from baseline at any of the post-baseline timepoints.

Conclusion: Clinically important improvements in both HAQ and PGA were demonstrated for pegloticase treated kidney transplant patients. Improvements were also observed in systolic, diastolic, and mean arterial blood pressure. These data support the benefits of pegloticase treatment for uncontrolled gout in kidney transplant recipients using immunosuppression.

POS1161 CAN DOCTORS TREAT GOUT WELL? INSIGHT ON GOUT MANAGEMENT IN REFERRAL CENTRES

C. Jauffret[1], S. Ottaviani[2], A. Latourte[3], H. K. Ea[3], S. Graf[4], F. Lioté[3], T. Bardin[3], P. Richette[3], T. Pascart[5]. *[1]Lille Catholic Hospitals (GHICL), Rheumatology, Lille, France; [2]Bichat Hospital (APHP), Rheumatology, Paris, France; [3]Lariboisière Hospital (APHP) & Université de Paris (Inserm UMR 1132 Bioscar), Rheumatology, Paris, France; [4]Lille Catholic Hospitals (GHICL), Delegation for Clinical Research and Innovation, Biostatistics department, Lille, France; [5]Lille Catholic Hospitals (GHICL) & Lille University (MABLab, ULR 4490), Rheumatology, Lille, France*

Background: Recent studies have shown a lack of implementation of gout recommendations in primary care. In this context of therapeutic inertia, the French Society of Rheumatology (SFR) published its first recommendations on gout (RECO) in 2020 [1,2], which were deliberately simple and concise.

Objectives: To determine the profile of patients referred to French gout expert centres, and to examine the results of their management.

Methods: Three hundred patients attending a first visit for gout management in three French referral centres were retrospectively included. Visits were performed at baseline (M0) and scheduled for month 6 (M6), month 12 (M12), and month 24 (M24). Data collected included: patient profile; disease activity and treatments; serum urate (SU) level; estimated glomerular filtration rate (eGFR).

Results: Patients were 81% male, mean age 62.2 ± 15.2 years, 42.7% prevalence of eGFR <60ml/min/1.73m^2, 28.1% diabetes mellitus, and 25.4% had a history of major cardiovascular event. Management followed French recommendations after the baseline visit in 94.9% of cases. Overall, 50 patients (16.7%) received off-label anakinra for flare treatment or flare prophylaxis. SU levels were below 6.0mg/dL in 59.4% of patients at M6, 67.9% at M12, and 78.6% at M24. At M24, 50% of patients were treated with allopurinol (313 ± 105 mg/d), which exceeded renal restrictions of doses in 61.5% of them, and 48.2% received febuxostat (84 ± 36mg/d). At inclusion, 94% of patients had experienced at least one flare in the previous six months, versus 23.6% at M12, and 13.1% at M24 (of which 8/12 (66.7%) had SU>6.0mg/dL).

Conclusion: Simple application of gout management guidelines is feasible in clinical practice, and is efficient with a majority of patients achieving SU targets and clinical improvement. A minority of patients in referral centres have 'difficult-to-treat' gout requiring specific management.

POS1162 PREVALENCE AND IMPACT OF DERMATOLOGIC CONDITIONS IN PATIENTS WITH GOUT

J. Shiyayo[1,2], L. Padnick-Silver[3], B. Lamoreaux[3]. *[1]Rosalind Franklin University of Medicine and Science, College of Pharmacy, North Chicago, United States of America; [2]Horizon Therapeutics plc, Post-doctoral fellowship, Deefield, United States of America; [3]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Gout is the most common inflammatory arthritis in adults and affects approximately 3-5% of the population in Europe and the United States.[1] Chronic hyperuricemia leads to monosodium urate (MSU) crystal deposition in both joints and soft tissues, including the heart, eyes, kidney, skin, and liver.[2] Systemic manifestations of gout have been well-characterized, with dermatologic involvement typically described as subcutaneous tophi, miliary gout, gouty panniculitis, and gout nodulosis.[2] Other dermatologic conditions may occur more often in gout patients and provide better understanding of a patient's overall condition.

Objectives: This claims-based study examined the prevalence of dermatological conditions in a large US population of gout patients. Patients with and without dermatologic conditions (identified by diagnosis codes) were compared to assess comorbidity burden, review healthcare utilization, and better understand the underlying consequences of dermatological manifestations of gout.

Methods: The Symphony 2012-2017 claims database was searched to identify patients with ≥1 ICD-9 or -10 gout code (ICD-9: 274.xx, ICD-10: M1*) using Bellweather software (PearlDiver Technologies™). All patients were in the database ≥1 year before and ≥2 years after first gout code (index). Patients were said to have a dermatologic condition if they had ≥1 diagnosis code for atopic dermatitis (ICD-9: 6918, ICD-10: L2*), psoriasis (ICD-9: 6961, ICD-10:L4*), osteomyelitis (ICD-9:73008, ICD-10: M86*), melanoma (ICD-9:1729, ICD-10: C43*), peripheral ulcers (ICD-9: 70710), varied cutaneous abscesses (ICD-9: 9829, ICD-10: L022*), or cellulitis (ICD-9:6826, ICD-10: L03*). Diagnosis code prevalence and healthcare utilization were examined and compared between those with/without a dermatological diagnosis code.

Results: Of the nearly 1.7 million identified gout patients, 29% had ≥1 dermatology diagnosis code. Patients with and without ≥1 dermatology code were of similar age at index (62.72 vs. 61.84 years) but those with ≥1 code were less often male (62% vs. 65%). The most common dermatological codes identified included cellulitis (10.7%), dermatitis (4.8%), psoriasis (2.2%), and osteomyelitis (2.1%, Table 1). Overall, comorbidity diagnosis codes were more prevalent in patients with ≥1 dermatology code, including hypertension, chronic kidney disease, cardiovascular disease, and type 2 diabetes (Table 1). Additionally, healthcare utilization and pain medication use were higher in gout patients with dermatological conditions despite similar ULT use.

Table 1. Incidence of select dermatologic conditions in gout vs general US populations and comorbidity prevalence among gout patients with/without ≥1 dermatological diagnosis code.

Dermatologic conditions	Gout population	General US population	p-value
Cellulitis, incidence, cases/100,000 person-yrs	1094	199[3]	<0.001
Osteomyelitis, incidence, cases/100,000 person-yrs	219	22[4]	<0.001
	Gout pts with ≥1 dermatology code (N=488,356)	**Gout pts without a dermatology code** (N=1,201,082)	
Age, years, mean ± SD	62.72 ± 12.35	61.84 ± 12.67	----
Male, n (%)	305,012 (63%)	779,103 (65%)	<0.001
Comorbidity, n (%)			
Hypertension	446,577 (91%)	1,040,381 (87%)	<0.001
Chronic kidney disease	215,670 (44%)	408,826 (34%)	<0.001
Cardiovascular disease	358,930 (73%)	749,577 (62%)	<0.001
Type 2 diabetes	254,914 (52%)	435,911 (36%)	<0.001

Conclusion: These claims-based analyses suggest the prevalence of dermatologic conditions other than those historically associated with gout. Additionally, gout patients with dermatologic conditions had higher comorbidity burden than those without. Therefore, as with other conditions, the skin may provide clues of a larger, systemic disease burden.

POS1163 PHARMACOKINETICS OF PEGLOTICASE AND METHOTREXATE POLYGLUTAMATE(S) IN PATIENTS WITH UNCONTROLLED GOUT RECEIVING PEGLOTICASE AND CO-TREATMENT WITH METHOTREXATE

Y. Xin[1], Y. Song[1], M. E. Weinblatt[2], J. Chamberlain[3], J. Zarzoso[3], K. Obermeyer[4], S. Sainati[5], C. Canavan[5], S. Ramanathan[6]. *[1]Horizon Therapeutics plc, Clinical Pharmacology, South San Francisco, United States of America; [2]Brigham and Women's Hospital, Division of Rheumatology, Immunology, and Allergy, Boston, United States of America; [3]Horizon Therapeutics plc, Translational Sciences, South San Francisco, United States of America; [4]Horizon Therapeutics plc, Biostatistics, Deerfield, United States of America; [5]Horizon Therapeutics plc, Research and Development, Deerfield, United States of America; [6]Horizon Therapeutics plc, Research and Development, South San Francisco, United States of America*

Background: In a prior open-label, single-arm trial in adults with uncontrolled gout (MIRROR open-label [OL] trial), methotrexate (MTX) co-treatment with pegloticase suggested improved efficacy of pegloticase by reducing its immunogenicity.[1,2] The current randomized, controlled trial (MIRROR RCT) confirmed that pegloticase-MTX co-therapy markedly increased pegloticase response rate (response defined as serum uric acid <6 mg/dL during ≥80% of Month 6) compared to pegloticase-placebo (PBO) co-therapy (71.0% vs. 38.5%) with a decreased infusion reaction rate and no new safety signals reported.
Objectives: To evaluate systemic exposures of pegloticase and its immunogenicity in uncontrolled gout patients receiving pegloticase with and without MTX as part of the MIRROR RCT; and to determine exposure of methotrexate polyglutamate(s) (MTX-PGs) in uncontrolled gout patients through Month 6 of treatment.
Methods: In MIRROR RCT, MTX (15 mg/wk) or matching PBO was given orally 4 weeks prior to the first pegloticase dose and continued weekly, in combination with pegloticase 8 mg given intravenously every 2 weeks, over a 52-week treatment period. Pre-infusion blood samples were collected to measure MTX polyglutamates (MTX-PGs, including MTX-PG_{1-5}) in red blood cells and pre- and post-infusion serum samples were obtained to measure trough (Cmin) and peak (Cmax) concentrations of pegloticase, respectively, at multiple visits. MTX-PG and pegloticase concentrations were summarized by visit and by treatment group. Pre-infusion serum samples for anti-polyethylene glycol (PEG) antibody (Ab) measurement were also collected at multiple pre-defined time points. Anti-PEG Ab incidence and titer were summarized by visit and by treatment group.
Results: Overall, higher Cmax and Cmin of pegloticase were observed in the pegloticase + MTX group than in the pegloticase + PBO group (Figure 1). At Week 14, median (first quartile [Q1], third quartile [Q3]) Cmin was 1.32 (0.73, 1.74) µg/mL and 0.63 (0.30, 1.28) µg/mL for the pegloticase + MTX and pegloticase + PBO groups, respectively. Median (Q1, Q3) Cmax was 3.01 (1.94, 3.94) µg/mL and 2.66 (1.45, 3.20) µg/mL for the pegloticase + MTX and pegloticase + PBO groups, respectively. Improved pegloticase response was associated with higher pegloticase concentrations. At Week 14, Cmin was below the quantitation limit (0.6 µg/mL) for 8 of 10 non-responders and 1.26 (0.72, 1.71) µg/mL for responders. MTX co-administration reduced the incidence of new anti-PEG antibody formation. The proportion of subjects with an increase from baseline in anti-PEG Ab titers or who were negative at baseline and developed an anti-PEG Ab response at ≥1 post-dose time point during pegloticase treatment was 29.5% and 51.0%, for the pegloticase + MTX and pegloticase + PBO groups, respectively. The pegloticase + MTX group had overall lower titer levels than those in the pegloticase + PBO group. Positive anti-PEG Ab status was associated with a lower pegloticase Cmin. Concentrations of MTX-PGs were maintained during the treatment course in the pegloticase + MTX group, suggesting compliance with MTX administration. There was no apparent difference in concentrations of MTX-PGs (including MTX-PG_3, the predominant form of MTX-PGs[4]) between responders and non-responders. MTX-PG concentrations were in the same range as those reported for low-dose oral MTX use in patients with rheumatoid arthritis,[3] suggesting no impact of pegloticase on MTX PK.

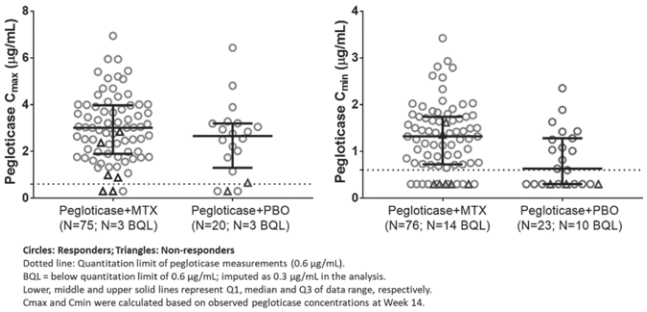

Figure. Comparison of pegloticase exposures (Cmax and Cmin) with and without MTX co-treatment

Conclusion: Pegloticase 8 mg IV every 2 weeks with MTX co-treatment (oral 15 mg weekly) reduced anti-PEG Ab incidence and resulted in higher pegloticase exposures compared to pegloticase administered with PBO, consistent with the increased clinical efficacy observed with pegloticase + MTX co-administration.

POS1164 COMPARISON OF PATIENTS WITH EARLY-ONSET GOUT AND COMMON GOUT: A CLAIMS-BASED ANALYSIS

A. Amatucci[1], L. Padnick-Silver[1], B. Lamoreaux[1], D. Bulbin[2]. *[1]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [2]Geisinger Medical Center, Rheumatology, Danville, United States of America*

Background: Data from the United States indicate that 8% of gout patients have disease onset before 40 years of age (early-onset gout [EOG]),[1,2] with similar age stratification in the United Kingdom, The Netherlands, and New Zealand.[3] At diagnosis, EOG patients have lower rates of renal and cardiometabolic comorbidities than their counterparts who developed gout at a later age.[4-6] Published reports also indicate that patients with EOG are less responsive to urate-lowering therapy[4] and more often have severe gout, with higher flare rate[4-6] and polyarticular disease occurrence.[4,5] At present, the literature is limited in comparisons between EOG and common gout (CG) patients.
Objectives: These claims-based analyses on a very large population examined and compared characteristics and comorbidity profile of patients with EOG and CG.
Methods: Patients with ≥1 ICD-9 or -10 gout code were identified in the Symphony claims database using Bellweather software (PearlDiver Technologies™). All patients were in the database ≥2 years before and ≥3 years after first gout code. Patients were said to have EOG if their first gout code occurred before 40 years of age. Patient demographics and comorbidities were compared to those with CG, defined here as first gout code at ≥50 years of age.
Results: 68,709 and 933,375 patients were classified as having EOG (mean age: 33.2±5.0 years) and CG (66.3±8.3 years), respectively. The EOG group had a higher proportion of men (72% vs. 62%). EOG and CG patients were in plan for a mean of 5.74±1.57 and 5.72±1.61 years, respectively after first gout diagnosis code. Prior to first gout code, comorbidity rates were lower in EOG than CG patients, including hypertension, cardiovascular disease, diabetes, stroke/transient ischemic attack, and renal disease. Additionally, the proportion of EOG and CG patients with hypertension, type 2 diabetes, and chronic kidney disease codes increased following the first gout code at a faster rate than in the general US population of a similar age (Figure 1).[7-9] As a result comorbidity rates were markedly higher in both EOG and CG groups in the years following gout diagnosis.
Conclusion: In agreement with prior studies,[4-6] these claims-based analyses suggest that patients with EOG have a lower comorbidity burden than patients with CG, though still higher than the general US population. Importantly, our

data suggest that, in the years following gout diagnosis, EOG patients develop comorbidities at a faster rate than their peers without gout. Further study of how gout influences comorbidity development in EOG patients is warranted to better understand and verify these claims-based findings.

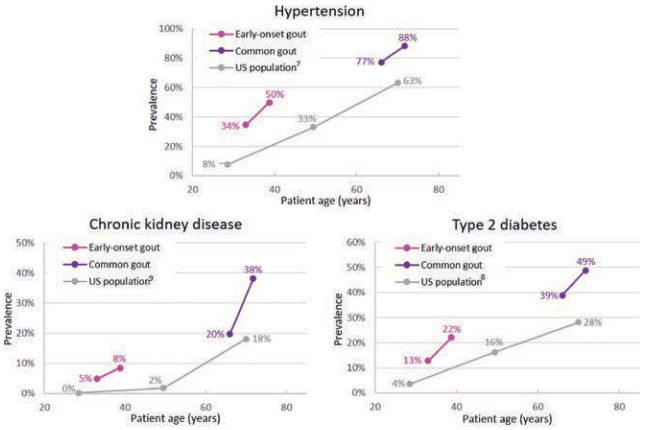

Figure. Key comorbidity prevalence and change with age in the early-onset gout (EOG), common gout (CG), and the general US populations.[7-9] First gout code occurred at mean age of 33 years in the EOG group and 66 years in the CG group. Mean time in plan following first gout code averaged 5.7 years in both groups.

POS1165 ASSOCIATION OF LDHD RARE VARIANTS WITH EARLY-ONSET GOUT IN TWO FAMILIES WITH AN ADDITIONAL ASSOCIATION OF RHBG VARIANT IN ONE.

T. Bardin[1,2], Y. M. Ducrot[3], Q. Nguyen[1], E. Letavernier[4], H. K. Ea[4,5], F. Touzain[6], D. M. Do[7], J. Corot[6], Y. Barguil[6], A. Biron[6], P. Richette[5], C. Collet[5]. *[1]Vien Gout Medical Centre, French-Vietnamese Research Centre on Gout and Chronic Diseases, Ho Chi Minh City, Vietnam; [2]Université de Paris, INSERM UMRS1132, Paris, France; [3]Lifou Island, Centre Médico-Social de Wé, Wé, New Caledonia; [4]Sorbone University, INSERM UMRS1155, Paris, France; [5]Université de Paris, INSERM UMRS1132, Hôpital Lariboisière, Paris, France; [6]Centre Hospitalier Territorial, Laboratoire de Biologie Médicale, Nouméa, New Caledonia; [7]University of Medicine and Pharmacy, Center for Molecular Biomedicine, Ho Chi Minh City, Vietnam*

Background: Elevated lactate is known to favor urine urate reabsorption by the URAT1 urate/anion exchanger. Autosomal recessive gout caused by pathogenic variant in the *LDHD* gene encoding for D-lactate deshydrogenase has been recently identified in a large consanguineous Bedouin-Israeli kindred (1).
Objectives: We report here on two families in whom early-onset gout was linked to other variants leading to deficient D-LDH enzymes.
Methods: Studies of the two families were approved by appropriate Ethics committees. Whole exome sequencing (WES) was used to identify the genetic cause of familial gout. Dosages of D-lactate were performed on immediately frozen serum and urine samples by ELISA, using a D-lactate colorimetric assay kit (Abcam ab83429).
Results: Family 1 was Melanesian, living in the Lifou island of New Caledonia. The two index patients were two sisters who developed gout at the age of 13 and 16 years respectively. When seen at the ages of 25 and 27 years, they both had severe gout with frequent polyarticular flares, and multiple tophi and destructive arthropathies in the earliest age of onset one. WES, performed on the 2 affected sisters, their non-consanguine parents, and an unaffected brother, showed that the 2 affected sisters carried homozygous rare variant in *DLDH* gene (NM_153486.3: c.206 C>T; rs1035398551). This variant was at heterozygote level in both parents and absent in the unaffected brother. It was considered as probably damaging according to in silico prediction software. No association with any other gene was found. The c.206C>T variant in *LDHD* was searched by Sanger sequencing method in 13 other extended family members. One 23 year-old brother of the two diseased sisters with atypical MTP flares, high uricemia and double contours at US examination of his MTPs, carried the c.206 C>T variant at the homozygous level. Three other heterozygous patients were found; two of whom were male with late-onset gout, the third one being a non-menopausal female with no gout. No variant carrier was found in the other 9 genotyped family members. The 3 homozygous patients for the c.206 C>T variant had very high hyperuricemia (range 738-834 was searched by Sanger sequencing method in 13 other extended family members. One 23 year-old brother of the two diseased sisters with atypical MTP flares, high uricemia and double contours at US examination of had very low or no D-lactate in plasma and urine. L-lactate blood and urine levels were normal in all subjects. Family 2 was Vietnamese, living in a remote area of central Vietnam. The two affected children suffered from an extremely severe, destructive gout, which started at the age of 21 years in a daughter and at the age of 9 in her youngest brother, who had developed for the last 3 years, dysarthria, night shakes, memory loss, urine incontinence and an inability to read and count and died at the age of 34, a few months after being seen by us. WES was performed in the two probands, their father and mother (who denied consanguinity), and an unaffected brother. An undescribed variant in *LDHD* (NM_153486.3: c.1363dupG) was identified in homozygous level in the 2 juvenile gout patients and at the heterozygous level in their 2 parents and unaffected brother. This variant led to a frameshift followed by a stop codon p.(AlaGly432fsTer58). In addition, the two juvenile gout patients were homozygous for an undescribed frameshift (NR_046115.1: c.1064dup) variant of the *RHBG* gene encoding for a Rhesus Blood Group family ammonium transporter. The two parents carried the heterozygous variant which was not identified in the non-gout brother.
Conclusion: We report on 2 families in whom autosomal recessive juvenile gout was due to rare or undescribed, damaging *LDHD* gene variants. In addition, we observed in the Vietnamese family, an additional non-described frameshift homozygous variant in *RHBG*, the pathophysiological role of which deserves to be investigated.

POS1166 GOUT AND SERIOUS KIDNEY DISEASE IN THE US: A NATIONAL PERSPECTIVE

G. Singh[1,2], M. Sehgal[2,3], B. Marder[4], B. Lamoreaux[4], A. Mithal[2]. *[1]Stanford University School of Medicine, Department of Medicine, Stanford, United States of America; [2]ICORE, Department of Epidemiology, Woodside, United States of America; [3]UCLA, Department of Computer Science, Los Angeles, United States of America; [4]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: There is a strong association between gout and kidney disease due to the kidney's key role in uric acid excretion.[1-4] Several studies have also demonstrated that serum uric acid is an independent risk factor for decline in renal function[1,2]. There are little national data available regarding the clinical burden of kidney disease in gout patients in the US.
Objectives: To estimate the percentage of US hospitalizations with a concomitant diagnosis of gout and either acute or chronic kidney disease compared with percentage of hospitalizations with kidney disease in the general population.
Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. Detailed information including clinical and nonclinical data elements on each hospital stay including International Classification of Diseases (ICD) 10 diagnosis, age, gender, length of stay, payer, charges, and comorbidities etc. is available. We examined all hospitalizations with acute renal failure (ICD10 codes N170-179), chronic kidney disease stages 3-5 (ICD10 codes N183-185), N19 (unspecified kidney failure), and end-stage renal disease (ICD10 code N186) in persons with gout (ICD 10 codes M10.* and M1A.*) and compared these with hospitalizations with kidney disease in the general US population.

Results: In 2019, there were 35.4 million all-cause hospitalizations in the US. Of these, 7.9 million had a diagnosis of serious kidney disease (22.3%). There were 915,070 hospitalizations with primary or secondary diagnosis of gout in the US (mean age 70.8 years, 68.4% men and 31.6% women). Of these 533,365 hospitalizations (mean age 72.6 years, 65.9% men) also had a concomitant diagnosis of serious kidney disease (58.3%, p<0.0001 compared to general population). Concomitant diagnosis of serious kidney disease increased with age, reaching 38.3% of all hospitalizations in 65 years and older in the general population compared to 62.5% in persons with gout (p<0.001).

Table 1. Kidney disease-related hospitalization in the US general and gout populations.

	GENERAL US HOSPITALIZATIONS		US HOSPITALIZATIONS WITH COMORBID GOUT	
Patient Age	Overall Hospitalizations N	Hospitalizations with Serious Kidney Disease n (%)	Overall Hospitalizations N	Hospitalizations with Serious Kidney Disease n (%)
18-44 years	8,356,284	622,170 (7.4%)	32,445	13,480 (41.5%)
45-64 years	8,440,831	2,160,220 (25.6%)	232,695	116,490 (50.1%)
≥65 years	13,421,154	5,257,220 (39.2%)	649,865	414,620 (83.8%)
Total in 2019	**35,419,023**	**7,907,730 (22.3%)**	**915,070**	**533,365 (58.3%)**

Note: Total numbers include patients 0-17 years old.

Conclusion: Acute and chronic kidney disease are highly prevalent comorbid conditions in overall US hospitalizations. Among patients admitted with a diagnosis of gout, the proportion of kidney dysfunction is significantly higher affecting 58% of these hospitalizations. The high prevalence of kidney dysfunction in hospitalized gout patients in the US may represent an impactful component to the duration, complexity, and costs of hospital care.

POS1167 EFFICACY AND SAFETY OF FEBUXOSTAT IN PATIENTS WITH STAGE 4-5 CHRONIC KIDNEY DISEASE NOT YET ON DIALYSIS: A META-ANALYSIS OF OBSERVATIONAL STUDIES

C. N. Son[1], H. J. Jeong[1], W. Y. Park[2], S. H. Kim[1]. *[1]Kemyung University School of Medicine, Rheumatology, Daegu, Korea, Rep. of (South Korea); [2]Kemyung University School of Medicine, Nephrology, Daegu, Korea, Rep. of (South Korea)*

Background: The efficacy and safety of febuxostat in patients with stage 4-5 chronic kidney disease (CKD) are still unclear, even though it's commonly used in clinical practice [1]. However, clinical trials are lacking to determine them due to ethical problems about enrollment of advanced CKD patients.

Objectives: We aimed to evaluate the efficacy and safety of febuxostat in patients with stage 4-5 CKD not yet on dialysis through a meta-analysis of observational studies.

Methods: We performed a systematic search in PubMed, Ovid MEDLINE, Embase, and the Cochrane Library to find articles reporting on advanced CKD patients from observational cohorts who start or take febuxostat at baseline in September 2021. Articles had to describe change from baseline in serum urate levels and renal function as assessed by estimated glomerular filtration rate (eGFR). The articles were screened by two independent reviewers (YP, HJ). Meta-analysis using a random-effects model was performed. R software was used for statistical analyses.

Results: Among 148 retrieved studies, 5 relevant observational studies were included in the meta-analysis. The febuxostat dose was administered at 10-120 mg per day, and the treatment period was 3 to 12 months. Five studies were included with a total of 327 patients to analyze urate-lowering efficacy. The urate-lowering effect after use of febuxostat medication showed statistical significance (weighted mean difference, -1.85; 95% CI, -2.04 to -1.67; I^2; 0%, Figure 1A). Three studies with 145 patients were available for assessment of eGFR. Renal function as assessed by eGFR did not decrease even after use of febuxostat (weighted mean difference, 0.11; 95% CI, -0.25 to 0.47; I^2; 45%, Figure 1B).

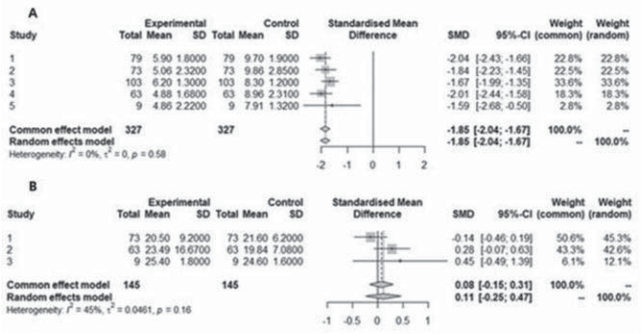

Figure 1. Meta-analyses of serum urate levels and estimated glomerular filtration rate at baseline and follow-up.

Conclusion: Our meta-analysis showed that febuxostat had good urate-lowering efficacy and renal safety in hyperuricemia patients with stage 4-5 CKD, who are not yet on dialysis. More studies with larger sample sizes and higher quality are required to clarify the efficacy and safety of febuxostat in advanced CKD.

Background: New therapies, management approaches and evidence regarding the management of gout have become available over the past years. This triggered the need for updated recommendations for the management of gout.

Objectives: to develop an up-to-date consensus evidence-based clinical practice guideline for the management of gout including recommendations for management of acute gout flares, optimum usage of urate lowering therapy for chronic gout as well as patient education and lifestyle guidance.

Methods: An extensive systematic literature review was performed, and evidence-based recommendations were extrapolated, based on 16-key questions identified according to population, intervention, comparator, and outcomes (PICO) approach. For each item, the level of evidence was determined using the Oxford Centre for Evidence-based Medicine (CEBM) system. These were evaluated by a panel of 17-experts via online surveys over a 2-round Delphi process.

Results: At the end of round 2, a total of 30-recommendation items, categorized into 10 domains to were obtained. Agreement with the recommendations (rank 7-9) ranged from 90-100%. Consensus was reached (i.e.≥75%of respondents strongly agreed or agreed) on the wording, the grade of recommendation and level of evidence of all the 30 clinical standards identified by the scientific committee. The guideline emphasized that all gouty patients should be screened for comorbidities. Based on this, an algorithm for treat to target management approach tailored to the individual patient's needs and associated comorbidities has been outlined.

Conclusion: This work provides updated evidence-based recommendations for the prevention and treatment of acute as well as chronic gouty arthritis. It provides an approach for physicians and patients making decisions on the management of gout. It will also facilitate improvement and uniformity of care.

THE INFLAMMATION INDUCED BY MONOSODIUM URATE AND CALCIUM PYROPHOSPHATE CRYSTALS DEPENDS ON OSMOLARITY AND AQUAPORIN CHANNELS.

T. W. Chirayath[1], N. Pham[1], C. Duranton[2], I. Rubera[2], A. Gauffenic[1], M. Cohen Solal[1], A. Latourte[1], T. Bardin[1], P. Richette[1], F. Lioté[1], H. K. Ea[1]. *[1]UNIVERSITY DE PARIS, INSERM UMR 1132 (BIOSCAR), HOSPITAL LARIBOISIERE, PARIS, France; [2]University of Nice-Sophia Antipolis, Laboratoire de Physiomedecine Moléculaire CNRS-UMR 7370, NICE, France*

Background: The inflammation induced by monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals is driven by interleukin (IL)-1β production. This later relies on NLRP3 inflammasome which can be activated by variation of ion concentration.
Objectives: To assess the role of osmolarity and water flux in MSU and CPP crystal-induced inflammation.
Methods: In vitro, THP1 monocytes were stimulated by pyrogen-free synthetic MSU and CPP crystals in iso-, hypo- or hyperosmotic media. Cytokine production was quantified by ELISA in cell culture supernatants. Cell size was measured using video microscopy. The role of aquaporin channels was assessed by pharmacological inhibitor (mercury chloride, HgCl2). In vivo, murine air pouch model was used. MSU and CPP crystals were injected in air pouch of mice treated or not with HgCl2 or mannitol. Osmolarity of mouse sera and patient synovial fluids (SF) were measured using freezing point osmometer. The size of cells collected from SF was assessed with imageJ software.
Results: MSU and CPP crystal-induced IL-1β production was substantially reduced by HgCl2 treatment (MSU 4900 vs 880 pg/ml; CPP 10500 vs 980, p<0.0001) or when cells were cultured in hyperosmotic medium. MSU and CPP crystals induced a transient increase in cell size which was 1.6 and 1.5 bigger after 30 and 100 min of stimulation by MSU and CPP crystals, respectively. After 150 min of stimulation, cell size decreased to their baseline size. Cell size increase was abolished by HgCl2 or hyperosmotic medium. In vivo, MSU and CPP crystal-induced inflammation (assessed by cell infiltration, IL-1β and CXCL2 production in air pouch lavage) was drastically reduced by HgCl2 or mannitol treatment. The serum osmolarity was higher in mannitol-treated mice than untreated mice (320 vs 300 mmosm/L). In patients, cells collected from SF during CPP or MSU crystal-induced flares had a bigger size than cells collected from osteoarthitic SF. The osmolarity of MSU or CPP crystal-containing SF was lower than the osmolarity of osteoarthritic SF (270 vs 310 mmosm/L). Finally, the IL-1β concentration in SF was strongly correlated with cell size and SF osmolarity.
Conclusion: These results suggest that the variation of osmolarity plays central role in MSU and CPP crystal-induced inflammation. Deciphering how crystals modulate osmolarity will identify new therapeutic targets.

ASYMPTOMATIC URATE-CRYSTALS DEPOSITS IN PATIENTS WITH STAGES 3-5 CHRONIC KIDNEY DISEASE DETECTED BY ULTRASOUND

E. Calvo-Aranda[1], L. Barrio Nogal[2], B. A. Blanco Cáceres[3], M. Novella-Navarro[4], D. Peiteado[4], J. Arroyo Palomo[3], E. De Miguel[4], A. Prada Ojeda[2], L. Sala Icardo[2], M. T. Navio Marco[1], M. Vázquez Díaz[3], C. M. Gomez-Gonzalez[1], R. Alcazar Arroyo[5], J. A. Martin Navarro[5], M. Vaga Gallardo[6], M. Fernandez Lucas[7], M. E. Diaz Dominguez[7]on behalf of GEACSER. *[1]Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain; [2]Torrejón University Hospital, Rheumatology,Torrejón de Ardoz, Spain; [3]Hospital Ramón y Cajal, Rheumatology, Madrid, Spain; [4]La Paz University Hospital, Rheumatology, Madrid, Spain; [5]Hospital Universitario Infanta Leonor, Nephrology, Madrid, Spain; [6]La Paz University Hospital, Nephrology, Madrid, Spain; [7]Hospital Universitario Ramón y Cajal, Nephrology, Madrid, Spain*

Background: One in ten patients with hyperuricemia may develop gout over time, with urate deposition sometimes asymptomatic. Recent reviews support ultrasound (US) to assess asymptomatic hyperuricemic (AH) patients to detect gout lesions, showing double contour (DC) and tophus the highest specificities and positive predictive values. Hyperuricemia and gout are common in chronic kidney disease (CKD), especially with glomerular filtration rate (GFR) <60, and are associated with worse prognosis. US gout lesions have been found more frequently in AH (up to 35%) than in normouricemic (NU) patients, but evidence is scarce in CKD.
Objectives: To assess the prevalence of urate deposit in stages 3-5 CKD detected by US, and to investigate if there are differences between AH and NU patients.
Methods: Case-control study, recruiting patients aged ≥18 years with AH and stages 3-5 CKD in 4 hospitals from January 2020 to December 2021. Controls were patients with stages 3-5 CKD and NU. Exclusion criteria: previous diagnosis of gout, tophi. Hyperuricemia was defined as serum uric acid (sUA) >6.8 mg/dl, documented at least twice during the last 12 months. A standardized US exam of the knees and bilateral first metatarsophalangeal joints was performed to assess patients for DC/tophus as defined by OMERACT. Demographic, clinical and laboratory data were recorded. A descriptive analysis was performed using SPSS. Pre-clinical gout (PCG: DC and/or tophus) was considered as outcome variable. Chi-square and Fisher's exact test were used for qualitative variables, and Mann-Whitney U test for quantitative variables; significant threshold p<0.05.
Results: Forty-four patients with stages 3-5 CKD (59.6% stage 3, 19.1% stage 4, 21.3% 5) were recruited, 35 AH and 9 NU. Hyperuricemia was associated with a higher prevalence of US findings, with significant differences between cases (AH) and controls (NU): PCG 19 vs 1 (p=0.023), DC 13 vs 1, and tophus 11 vs 0. No significant differences were found in demographic variables, comorbidities and treatments. sUA levels, were higher in patients with PCG (8.3±1.4 vs 7.6±2.2; p=0.36), and these patients also showed lower GFR (31.4±14.1 vs 33.7±16.9; p=0.62). Patients with PCG also showed a non-significant trend towards shorter duration of CKD [6.3±5.7 vs 8.3±4.9 years; p=0.1] and younger age (66.4±15.1 vs 70.0 ±11.0; p=0.30).
Conclusion: We found an outstanding prevalence of asymptomatic urate deposits in our cohort of patients with stages 3-5 CKD, that is higher in hyperuricemic than in normouricemic patients. The prevalence of DC and tophus in our cohort of AH patients with stages 3-5 CKD was higher than that reported in AH patients in studies conducted in general population (37% vs 16-31% and 31% vs 16%, respectively). Early diagnosis of pre-clinical gout by ultrasound might change therapeutic approach in CKD.
