Editor
Josef S Smolen (Austria)

Associate Editors
Francis Berenbaum (France)
Dimitrios Boumpas (Greece)
Gerd Burmester (Germany)
Mary Crow (USA)
Kimme Hyrich (UK)
Rik Lories (Belgium)
Iain McInnes (UK)
Thomas Pap (Germany)
David Pisetsky (USA)
Désirée van der Heijde (The Netherlands)
Kazuhiko Yamamoto (Japan)

Methodological and Statistical Advisors
Guro Giskeødegård (Norway)
Stian Lydersen (Norway)

Social Media Advisors
Alessia Alunno (Italy)
Javier Rodriguez Carrio (Spain)
Peter Korsten (Germany)
Caroline Ospelt (Switzerland)
Christophe Richez (France)
Paul Studenic (Austria)

Guidelines for Authors and Reviewers

Full instructions are available online at http://ard.bmj.com/pages/authors. Articles must be submitted electronically at http://mc.manuscriptcentral.com/ard. Authors retain copyright but are required to grant ARD an exclusive licence to publish. (http://ard.bmj.com/pages/authors/).

Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome

Subscription Information

ARD is published monthly; subscribers receive all supplements
ISSN 0003-4967 (print); 1468-2060 (online)

Institutional Rates 2022

Print
£1,166

Online
Site licences are priced on FTE basis and allow access by the whole institution. Details available online at http://journals.bmj.com/content/subscribers or contact the Subscription Manager in the UK (see above right)

Personal Rates 2022

Print (includes online access at no additional cost)
£449

Online only
£251

EULAR congress delegates
Delegates receive a Continuous Professional Development package that includes a 12 month complimentary subscription to *ARD* in print and/or online

Personal print or online only and institutional print subscriptions may be purchased online at http://journals.bmj.com/content/subscribers (payment by Visa/Mastercard only)

Residents of some EC countries must pay VAT; for details, call us or visit http://journals.bmj.com/content/subscribers

For more information on subscription rates or to subscribe online please visit ard/bmj.com/pages/contact-us/

Scientific Abstracts

Welcome Address
EULAR 2022 Abstracts Reviewers

Oral Presentations

OP0001	Addressing the effect of Placebo, Nocebo and Contextual factors in RMDs	1
OP0002	Bench to Bedside: The complement system in rheumatic diseases	1
OP0003	Breaking the barriers: gut, lung and skin in arthritis pathogenesis	2
OP0004	Does AI really help me diagnosing RMDs?	3
OP0006	Is gender sufficiently studied in RMDs?	4
OP0008–OP0015	Plenary Abstract Session	5
OP0016–OP0023	AxSpA drug treatment: new and old drugs	9
OP0024–OP0031	Clinical aspects in Psoriatic Arthritis	17
OP0032–OP0039	From risk assesment to societal outcomes	23
OP0042–OP0049	Infection-related and other orphan rheumatic disorders	29
OP0050–OP0057	Managing chronic pain in RMDs	33
OP0058–OP0065	Modern biological treatment in RA	38
OP0066–OP0073	Adaptive immunity (T cells and B cells) in rheumatic diseases / Innate immunity in rheumatic diseases	46
OP0074–OP0081	Rheumatoid arthritis - aetiology, pathogenesis and animal models	50
OP0082–OP0089	Rheumatoid arthritis - prognosis and prediction	55
OP0090–OP0097	The Yin and Yang of scleroderma and vasculitis	60
OP0098	Microbiome and SpA	65
OP0099	The role of the synovial microenvironment during onset and progression of arthritis	65
OP0100–OP0107	Exploring the origin of inflammation in spondyloarthritis	66
OP0108–OP0115	From gene to function: genetic basis of rheumatic diseases	70
OP0124–OP0131	Pregnancy outcomes in rheumatic diseases	80
OP0132–OP0139	RA: Clinical aspects and comorbidities - I	85
OP0140–OP0147	Remission, flares and predictive factors in SLE, Sjogren and anti-phospholipid syndrome	90
OP0148–OP0155	Spondyloarthritis in practice: imaging, outcome assessment and comorbidities	95
OP0156–OP0163	The treatment and outcome of scleroderma	101
OP0164–OP0171	Translational and Clinical Research in Crystal Arthritis	108
OP0172–OP0179	Vaccination against SARS-CoV-2	113
OP0180–OP0187	Vessels glowing in the dark	120
OP0188	Active Ageing: new perspectives for RMD patients?	125
OP0190	Modern technology for precision medicine	126
OP0191	Rheumatology in Europe	127
OP0192	Vaccination in rheumatic diseases with lessons from COVID	127
OP0193	sJIA vs AOSD: Two names one disease? What have we learnt so far	128
OP0194	Autoinflammation over the course of a lifetime	128
OP0195–OP0196	Challenges of fibromyalgia	129
OP0197	Long-COVID	130
OP0199	Strengths and weaknesses of experimental models: Moving from animals to human clinical trials	131
OP0215–OP0222	Improving outcomes for children with JIA	141
OP0223–OP0230	New developments in OA	146
OP0231–OP0238	Novel etiopathogenic aspects in SLE and Sjögren's sydrome	152
OP0239–OP0246	Osteoporosis	157
OP0247–OP0254	Outcome of COVID-19 in Rheumatic Diseases	161
OP0255–OP0262	Emerging treatment strategies in PsA	167
OP0263–OP0270	RA treatment: modern strategies and new molecules	174
OP0271–OP0278	RA: Clinical aspects and comorbidities - II	181
OP0279–OP0286	Recent novelties in SLE/Sjogren and APS?	185
OP0287–OP0294	The early bird gets the worm	190
OP0297	Sjogren syndrome: from biopsy to lymphoma	197
OP0300	Crystal arthritis	199

OP0302	Rheumatology across boundaries	200
OP0305	How to review a manuscript	202
OP0306–OP0307	Interstitial lung disease in RMDs	203
OP0309	New lessons for rheumatology in genomics medicine	204

Late breaking abstracts

LB0001		206
LB0002		207
LB0003		208
LB0004		209
LB0005		210
LB0006		210

Poster Tours

POS0001–POS0011	Challenges in measuring and predicting RMDs	212
POS0012–POS0017	Challenging cases to make you think	220
POS0018–POS0028	Chronic pain - Mechanisms, epidemiology, and treatment	224
POS0029–POS0039	Genomics, functional genomics and genetic basis of inflammatory arthritis	230
POS0050–POS0060	Immunity in Rheumatic Diseases	240
POS0061–POS0071	Lung involvement in Rheumatic Diseases	247
POS0072–POS0082	New therapeutic avenues in psoriatic arthritis	253
POS0092–POS0102	Pathogenesis of SLE, Sjögren's and antiphospholipid sydrome	267
POS0103–POS0113	Rheumatoid arthritis – prognosis, predictors and outcome	274
POS0114–POS0123	Systemic lupus erythematosus, Sjogren's syndrome and anti-phospholipid syndrome	282
POS0124–POS0134	Through the looking glass	287
POS0135–POS0145	Biomarkers in pathogenesis, monitoring and treatment of rheumatic diseases	294
POS0146–POS0154	Clinical aspect of spondyloarthritis	300
POS0155–POS0163	Health services research: scoping the landscape	305
POS0164–POS0173	Improving our care and understanding of paediatric RMDs	311
POS0174–POS0182	New insights into the associations of outcomes and biomarkers in OA	317
POS0183–POS0193	New options in SLE-Sjogren and APS	323
POS0194–POS0204	Outcome of COVID-19 in patients with rheumatic diseases	330
POS0205–POS0214	RA comorbidities	338
POS0215–POS0224	Recent advances in orphan rheumatic diseases	343
POS0225–POS0233	Remodelling in OA	349
POS0234–POS0243	Rheumatoid arthritis: JAKi and beyond	353
POS0244–POS0253	Small vessels on fire	361
POS0254–POS0264	Vaccination against SARS-CoV-2	367
POS0265–POS0275	Achy-Breaky vessels	374
POS0276–POS0285	Advances in Crystal Arthritis	381
POS0286–POS0295	All you want to know about bDMARDs in RA.	387
POS0296–POS0306	AxSpA: About treatments and outcomes	394
POS0307–POS0316	Clinical aspects in Psoriatic Arthritis	403
POS0317–POS0325	Mortality, Co-morbidity and disease burden	409
POS0326–POS0333	New data on pathophysiology of spondyloarthritis including psoriatic arthritis	414
POS0334–POS0343	New insights into the management of JIA	419
POS0344–POS0351	Novel molecular regulators of bone turnover	426
POS0362–POS0372	Systemic Lupus Erythematosus: monitoring and management	434
POS0373–POS0381	Telemedicine what does it tell us	440
POS0382–POS0392	What's new in scleroderma and myositis?	445

POSTERS only

POS0393–POS0396	Genomics, genetic basis of disease and functional genomics	453
POS0397–POS0403	Adaptive immunity (T cells and B cells) in rheumatic diseases	455
POS0404–POS0406	Innate immunity in rheumatic diseases	458
POS0407	Osteo arthritis, aetiology, pathology and animal models	459
POS0408–POS0448	Rheumatoid arthritis - aetiology, pathogenesis and animal models	460
POS0449–POS0450	Spondyloarthritis - aetiology, pathogenesis and animal models	479
POS0451–POS0466	SLE, Sjögren's and APS - aetiology, pathogenesis and animal models	480
POS0467–POS0490	Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models	488
POS0491–POS0494	Vasculitis - aetiology, pathogenesis and animal models	500
POS0495–POS0497	Basic and translational science in paediatric rheumatology	502

POS0498	Basic and translational pain science	503
POS0499–POS0578	Rheumatoid arthritis - prognosis, predictors and outcome	504
POS0579–POS0635	Rheumatoid arthritis - comorbidity and clinical aspects	556
POS0636–POS0662	Rheumatoid arthritis - biological DMARDs	587
POS0663–POS0704	Rheumatoid arthritis - non biologic treatment and small molecules	604
POS0705–POS0721	SLE, Sjögren's and APS – treatment	633
POS0722–POS0790	SLE, Sjögren's and APS - clinical aspects (other than treatment)	644
POS0791–POS0821	Vasculitis – large vessel vasculitis	683
POS0822–POS0838	Vasculitis – small vessel vasculitis	702
POS0839–POS0929	Scleroderma, myositis and related syndromes	711
POS0930–POS0954	Spondyloarthritis – treatment	765
POS0955–POS1012	Spondyloarthritis - clinical aspects (other than treatment)	783
POS1013–POS1062	Psoriatic arthritis – treatment	815
POS1063–POS1104	Psoriatic arthritis - clinical aspects (other than treatment)	854
POS1105–POS1138	Osteoarthritis	881
POS1139–POS1153	Osteoporosis	898
POS1154–POS1177	Crystal diseases, metabolic bone diseases other than osteoporosis	905
POS1178–POS1189	Infection-related rheumatic diseases	917
POS1190–POS1286	COVID-19	923
POS1287–POS1288	Pain in rheumatic diseases, including fibromyalgia	981

Addressing the effect of Placebo, Nocebo and Contextual factors in RMDs

OP0001

"I WILL NEVER FORGET THE SHAME I FELT": A SURVEY TO PEOPLE WITH A RHEUMATIC DISEASE ABOUT INVALIDATION FROM HEALTH PROFESSIONALS AND OTHER PEOPLE

A. Marques[1,2,3], A. Silva[2,3], J. Vicente[4,5], E. Mateus[4], R. J. O. Ferreira[1,2]. *[1]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; *[2]Nursing School of Coimbra, Health Sciences Research Unit: Nursing (UICISA: E), Coimbra, Portugal*; *[3]Nursing School of Coimbra, Professor, Coimbra, Portugal*; *[4]Portuguese League against Rheumatic Diseases (LPCDR), Executive Board, Lisbon, Portugal*; *[5]Portuguese Association of Fibromialgia (APJOF), Executive Board, Lisbon, Portugal*

Background: The term invalidation refers to the patients' perception that their medical condition is not recognised, either in denying, lecturing, not supporting or not acknowledging the condition. This may be the felt from health professionals themselves but also from family, friends, at work and in other social areas, imposing great suffering.[1] The European Alliance of Associations for Rheumatology (EULAR) has made efforts to raise awareness for the burden imposed by rheumatic and musculoskeletal conditions (RMDs) and promote the best quality of care, including recognition and psychosocial support. However, it is unclear how frequent and severe the problem remains nowadays.
Objectives: The aims of this national survey were: (i) to identify the levels of invalidation and lack of understanding felt by adults with RMDs from health professionals and other people, (ii) to investigate the relationship between invalidation, sociodemographic characteristics and disease; and (iii) to understand its impact on people's life and health outcomes.
Methods: An online survey was developed by the national health professionals in rheumatology and patients' organisations and opened between May and December of 2021. The questionnaire included demographic and disease information, the Illness Invalidation Inventory (3*I),[1] with additional questions in a Likert format and open questions for a detailed understanding of the phenomenon. The 3*I is composed of 8 items, measured from 1 (=never) to 5 (=very often), forming two factors: Discounting (mean of 5 items; lower scores indicating more discounting) and Lack of understanding (mean of 3 items; Higher scores representing higher lack of understanding).
Quantitative data were analysed using descriptive statistics. Associations were tested with a t-student and ANOVA one-way test (Bonferroni correction). Open responses were categorised using the content analysis technique, and themes were defined *a posteriori*.
Results: From the > 1500 responses obtained, 1410 responses were filled out completely (mean age of 46 years [SD=11], 95% females, 60% with FM, among which 59% were diagnosed in the last 5 years).
Invalidation was reported by 86% of the participants and 70% rated ≤5 on a scale from 0 (nothing) to 10 (totally) on feeling understood by other people. Invalidation was mostly felt from family (56%), health professionals (48%), friends (39%) and social environment (38%). The impact of this invalidation is mainly on the psychological well-being (58%), also reducing seeking health care (41%) and therapeutic adherence (17%), affecting work (41%), and to a less extent, (family) relations (31%).
Figure 1 shows the frequency of responses and means scores on the 3*I items and factors for participants with and without FM. The burden is greater for people with FM, which was statistically significant. People with higher education felt more discounting and more lack of understanding. No differences (p>0.05) were observed for gender or civil status.
Elucidative expressions of invalidation were shared, mostly by people with FM, encompassing their ability to work and need for social support, faking pain and treatment efficacy, and even intimacy aspects. These emotionally uncomfortable situations can be linked to lesser engagement with healthcare and disease management, and therefore, with worse health outcomes.
Conclusion: Invalidation remains a source of suffering, affecting well-being and health outcomes. Specific awareness and educational campaigns are needed to target this problem on different play-actors.

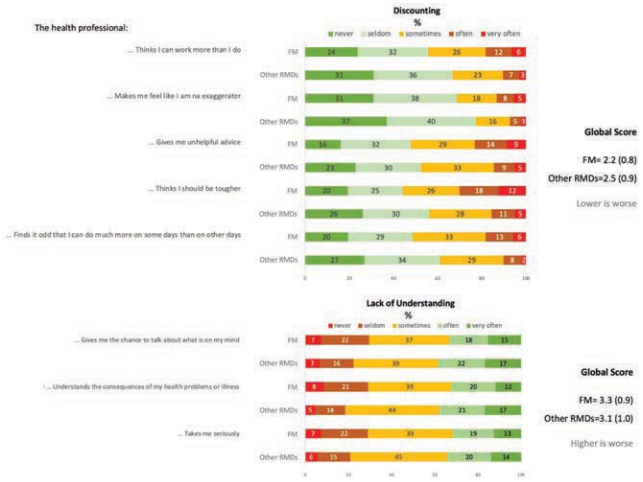

Figure 1. Percentages of responses per type of disease for the eight items of the Illness Invalidation Inventory.

Pini & CTO, Pediatric Rheumatology, Milano, Italy*

Background: The complement system is a key-player in the pathogenesis of systemic lupus erythematosus (SLE); its decreases correlate with disease activity and precedes flare. Since synthesis of complement proteins increase during gestational course, it is debated whether complement levels exert a prognostic role in pregnant women with SLE.
Objectives: We performed a network meta-analysis to assess the prognostic role of complement in pregnant SLE women, to evaluate the possible role of complement fluctuations during pregnancies.
Methods: Data from available prospective studies (Jan 2002-Dec 2020) investigating pregnancies in at least 50 SLE patients, excluding miscarriages before 12 weeks, were pooled together. After a systematic literature search, corresponding authors of 19 retrieved studies meeting inclusion criteria were invited to contribute with additional data, including complement levels [6 months before pregnancy, at conception, 1st trimester (T1), 2nd trimester (T2), 3rd trimester (T3) and 3 months after delivery].
Results: A total of 532 SLE women from four eligible studies were included in the analysis [1-4]. Lupus Nephritis (LN) was diagnosed in 237 patients (44.5%) and Antiphospholipid Syndrome in 68 (12.8%). A total of 170 patients (32%) experienced a flare during pregnancy, defined as need of new Immunosuppressants or increase of prednisone > 9 mg/day.
Patients with LN had significantly lower mean levels of complement (C3 at conception; C3 at T1; C3 after 3 months of delivery; C4 at all timepoints except for C4 at T3). SLE patients who experienced flares during pregnancy had significantly lower mean levels of complement (all timepoints for both C3 and C4). Table 1 shows the mean C3 and C4 levels in different timepoints according to diagnosis and flare during pregnancy. The lowest levels of complement were observed in patients with a concomitant diagnosis of LN and presence of flare, particularly during the T1 (Figure 1). Nevertheless, both in LN and flare groups the lowest levels of C3 and C4 were documented at T1.

Table 1. Complement levels at the different timepoints according to diagnosis or presence of flare (bold results are statistically significant)

	Patients with LN (237)	Patients without LN (295)	Patients with Flare (170)	Patients without Flare (362)	Patients with LN and Flare (73)	Patients with LN and without Flare (164)

C4 3rd trimester (mean ±SD)	17.8±4.4	17.5±5.1	**15.7±5.8**	**18.6±4**	**15.8±4.8**	**18.8±3.9**
C4 3 months after delivery (mean ±SD)	**16.2±4.3**	**19.8±6.9**	**14.9±3.9**	**20±6.4**	**13.3±3.1**	**17.6±4**

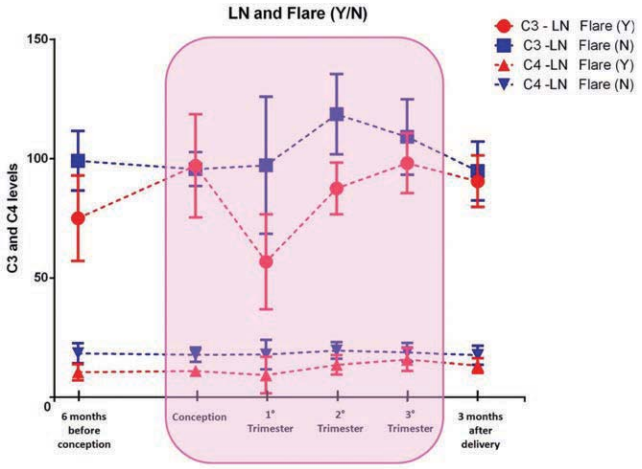

Figure 1. Complement Levels during time in patients with Lupus Nephritis and presence, or absence, of flare.

Conclusion: In this prospective large cohort of SLE patients low C3/C4 levels, particularly in T1, were associated with a higher frequency of flare. Lowering levels of complement, especially in T1, even within normal range might alert the treating clinicians in predicting disease course and consequently avoid flares, especially in LN.

OP0003

DOES IMMUNOSUPPRESSIVE THERAPY IMPROVE GASTROINTESTINAL SYMPTOMS IN PATIENTS WITH SYSTEMIC SCLEROSIS?

L. Stamm[1], A. Garaiman[1], N. Zampatti[1], M. O. Becker[1], C. Bruni[1,2], R. Dobrota[1], M. Elhai[1], S. Ismail[3], S. Jordan[1], A. Tatu[4], O. Distler[1], C. Mihai[1]. *[1]University Hospital Zürich, University of Zurich, Rheumatology, Zürich, Switzerland*; *[2]Azienda Ospedaliero Universitaria Careggi, University of Florence, Experimental Medicine, Division of Rheumatology, Florence, Italy*; *[3]National Research Center, Internal Medicine, Cairo, Egypt*; *[4]University Hospital Zürich, University of Zurich, Gastroenterology, Zürich, Switzerland*

Background: The gastrointestinal (GI) tract is frequently affected in systemic sclerosis (SSc), leading to considerable morbidity and even mortality. While important progress has been made in the last years regarding treatment of SSc, there is no disease-modifying treatment available for SSc-related GI involvement.

Objectives: We aimed to identify, in an observational cohort study of real-life patients with SSc, an association between immunosuppressive therapy and the severity of GI symptoms, measured by the University of California at Los Angeles / Scleroderma Clinical Trial Consortium Gastro-Intestinal Tract instrument 2.0 (UCLA GIT 2.0).

Methods: We selected patients from our EUSTAR centre who met the 2013 ACR/EULAR classification criteria for SSc and had at least two visits with completed UCLA GIT 2.0 questionnaires, with an interval of 12±3 months between visits. We defined the first visit with a completed UCLA GIT 2.0 questionnaire as baseline visit. Immunosuppressive therapy was defined as exposure for at least 6 months between the two visits to at least one of the following drugs, regardless of indication: mycophenolate mofetil (MMF), cyclophosphamide, methotrexate, azathioprine, leflunomide, glucocorticoids (>10mg/d prednisone-equivalent), rituximab, tocilizumab, and abatacept. The study outcome was the UCLA GIT 2.0 score at the follow-up visit. We performed multivariable linear regression with this outcome as dependent variable and immunosuppressive therapy during follow-up, immunosuppressive therapy before baseline, baseline UCLA GIT 2.0 score and several baseline parameters selected by clinical judgment as potentially influencing GI symptoms, as independent variables. Multiple imputation was implemented to handle missing values.

Results: We included 209 patients. Baseline characteristics were: 82.3% female, median (IQR) age 59.0 (48.6, 68.2) years, median disease duration 6.0 (2.7, 12.5) years, 40 (19.1%) diffuse cutaneous SSc, median baseline UCLA GIT 2.0 score 0.19 (0.06, 0.43). Of these, 71 patients were exposed to immunosuppressive therapy during the observation period: 27/71 methotrexate, 1/71 cyclophosphamide, 17/71 MMF, 3/71 leflunomide, 3/71 azathioprine, 6/71 glucocorticoids >10mg/d, 16/34 rituximab, 18/34 tocilizumab. Patients on immunosuppressive therapy during the observation period had, compared to patients without such treatment, overall more severe SSc, higher prevalence of treatment with proton pump inhibitors, similar UCLA GIT 2.0 scores at baseline and at follow up and tendentially less severe GI symptoms at baseline and follow-up by medical history. In multivariable linear regression, immunosuppressive therapy, lower body mass index, longer disease duration and lower baseline UCLA GIT 2.0 score were significantly associated with lower (better) UCLA GIT 2.0 scores at follow-up (Table 1).

Table 1.

Predictors of UCLA GIT 2.0 score at follow-up	*Estimates*	*95% CI*	*p*
Age	0.002	-0.001 – 0.006	0.136
Sex [male]	-0.056	-0.172 – 0.061	0.347
Disease duration	-0.005	-0.009 – -0.000	**0.030**
Body mass index	0.014	0.002 – 0.025	**0.017**
UCLA GIT 2.0 total score baseline	0.690	0.571 – 0.809	**<0.001**
Immunosuppressive therapy during observation period	**-0.119**	**-0.228 – -0.010**	**0.032**
Immunosuppressive therapy before baseline	0.080	-0.032 – 0.192	0.160
Modified Rodnan Skin Score	-0.001	-0.008 – 0.007	0.860
Forced vital capacity	-0.001	-0.004 – 0.001	0.302
Erythrocyte sedimentation rate	0.003	-0.001 – 0.006	0.116
Proton pump inhibitors	-0.034	-0.120 – 0.052	0.435
(Intercept)	-0.120	-0.531 – 0.291	0.566

Baseline factors associated with the total UCLA GIT 2.0 score at the end of the observation period. Multiple linear regression model with imputation for missing variables. N=209 patients

Conclusion: Immunosuppressive treatment was associated with lower UCLA GIT 2.0 scores, which suggests potential effects of immunosuppressants on GI manifestations in patients with SSc. These results need verification in additional studies and randomised controlled clinical trials.

Does AI really help me diagnosing RMDs?

OP0004 AUTOMATED RECOGNITION AND MONITORING OF DORSAL SKIN FOLDS BY A CONVOLUTIONAL NEURAL NETWORK AS A POTENTIAL DIGITAL BIOMARKER FOR JOINT SWELLING IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Hügle[1], L. Caratsch[1], M. Matteo Caorsi[2], J. Maglione[3], D. Dan[1], A. Dumusc[4], M. Blanchard[1], G. Kalweit[5], M. Kalweit[5]. *[1]Lausanne University Hospital, CHUV, Department of Rheumatology, Lausanne, Switzerland*; *[2]L2F, Informatics, Lausanne, Switzerland*; *[3]École Polytechnique Fédérale de Lausanne (EPFL), Informatics, Lausanne, Switzerland*; *[4]Lausanne University Hospital, CHUV, Division of Rheumatology, Lausanne, Switzerland*; *[5]University of Freiburg, Department of Computer Science, Freiburg, Germany*

Background: To monitor rheumatic diseases, digital biomarkers such as wearables are of increasing interest, but they lack disease specificity.
Objectives: In this study, we apply convolution neural networks (CNN) to real world hand photographs in order to automatically detect, extract and analyse dorsal finger folds lines as a correlate of proximal interphalangeal (PIP) joint swelling in patients with rheumatoid arthritis (RA).
Methods: Hand photographs from 190 RA patients were taken by a smartphone camera in a standardized manner. PIP joints were categorised as either swollen or not swollen based on clinical judgement and ultrasound. Images were automatically preprocessed by cropping PIP joints and extracting dorsal finger folds. Subsequently, metrical analysis of dorsal finger folds was performed and a CNN was trained to classify the dorsal finger lines into swollen versus non-swollen joints. Representative horizontal finger folds were also quantified in a subset of patients before and after resolution of PIP swelling and in patients with disease flares, respectively.
Results: In swollen joints, the number of automatically extracted double-contoured, deep skinfold imprints was significantly reduced compared to non-swollen joints (1.3, SD 0.8 vs. 3.3, SD 0.49). The joint diameter / deep skinfold ratio was significantly higher in swollen (4.1, SD 1.4) versus non-swollen joints (2.1 SD 0.6). The CNN model successfully differentiated swollen from non-swollen joints based on finger fold patterns with a validation accuracy of 0.84. A heatmap of the original images obtained by an extraction algorithm confirmed finger folds as the region of interest for correct classification. After significant response to DMARD +/- corticosteroid therapy, longitudinal metrical analysis of eight representative deep finger folds showed a decrease of the mean diameter/ finger fold length (finger fold index, FFI) from 3.03 (SD 0.68) to 2.08 (SD 0.57). Conversely, the FFI increased in patients with a flare of joint swelling.
Conclusion: Automated preprocessing and the application of CNN algorithms in combination with longitudinal metrical analysis of dorsal finger fold patterns extracted from real world hand photos might serve as a digital biomarker in RA.

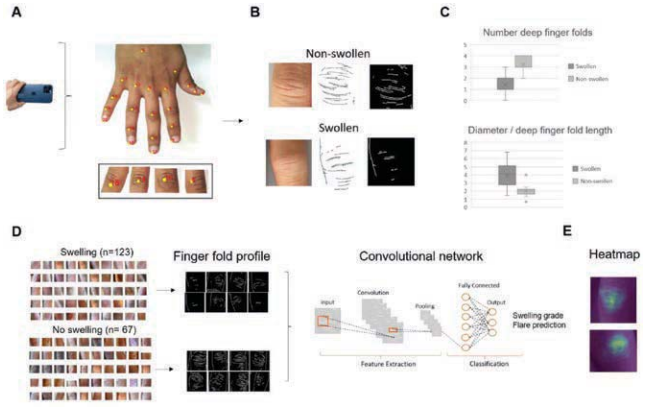

Figure 1. Automated finger fold recognition to monitor rheumatoid arthritis (RA). Hand photographs are taken by a smartphone (A). Hands, and subsequently proximal interphalangeal (PIP) joints, are automatically recognized and extracted. Finger fold lines are isolated from the images, measured and related to the joint diameter (B,C). A convolutional deep neural network was used to train a model for classification of extracted finger fold patterns into swollen vs. non swollen joints (D). On cropped PIP joint images, the heatmap of the same classification task confirms finger folds as the region of interest (E).

How to maintain your quality of life after an RMD diagnosis

OP0005-PARE DEVELOPMENT OF CONVERSATION AIDS: HOW TO GET THE MOST OUT OF YOUR RMD APPOINTMENT AND ADVANCE YOUR QUALITY OF LIFE

P. Borsje, Msc[1], P. Pennings, Msc[2], B. Maat[3], I. Hest[3], F. Van Eekelen[3], H. Van de Weijer[3], I. Schoonen-Nuijten[4], G. Willemsen- de Mey Msc[5]. *[1]National Association ReumaZorg Nederland, Patientexpert and Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands*; *[2]National Association ReumaZorg Nederland, Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands*; *[3]National Association ReumaZorg Nederland, Patientpartner at the department of Patient participation and Communication, Nijmegen, Netherlands*; *[4]Bravis Medical Centre, Rheumatology Nurse at the Department of Rheumatology, Roosendaal, Netherlands*; *[5]National Association ReumaZorg Nederland, President of the Board, Nijmegen, Netherlands*

Background: Having a Rheumatic and Musculoskeletal Disease (RMD) has a big impact on your daily life, work, relationships and quality of life. It can cause various complaints, problems and questions. Research shows that people with an RMD are often insufficiently aware that they can talk about these challenges with their RMD professional. They also don't realize that these challenges matter when making a fitting choice for treatment. It also appears that RMD professionals do not sufficiently take into account the priorities of their patient, when a treatment choice has to be made. This is unfortunate because research shows that people who decide together with their RMD professional make better informed treatment choices. They are also more likely to adhere to their treatment or medication use. A conversation aid can help people to become aware of the most important challenges or problems in their daily lives with an RMD. These uncovered challenges and problems can set the agenda for a good conversation in the RMD consultation room. Together with the RMD professional the conversation can focus on ways to deal with or treat these challenges or problems.
Objectives: To develop a conversation aid for people with an RMD that allows them to become aware of the most important challenges in their life with an RMD and that guides them in how to discuss these aspects with an RMD professional.
Methods: In the first step a review was made of all important aspects of a patient's life with an RMD. The outcome measures of ICHOM for inflammatory arthritis1 and hip- and knee osteoarthritis2 formed the starting point for this review. This was complemented with additional outcomes as measured in Dutch RMD apps and patient dashboards of Dutch hospitals. In the second step, the list of outcomes was assessed by means of a survey among Dutch patients with an RMD. The third step was to discuss the complete list with important outcomes with the Dutch rheumatology department of the Bravis Medical Centre. A first draft version of the conversation aids was made. This draft version was evaluated by patientpartners of the National Association ReumaZorg Nederland (RZN) and the Bravis Medical Centre.
Results: A total of 4 conversation aids (https://reumazorgnederland.nl/samen-beslissen-gesprekskaarten/) were made. Each aid addressing a main category of challenges with an RMD. Each main category was divided into 5 sub-categories. The 4 conversation aids are:

- **Disease**: Concerning the sub-categories: Disease activity, pain, fatigue, medication & side effects and knowledge about the disease.
- **Daily activity**: Concerning the sub-categories: Work/school, personal care, household & family, mobility, and spare time.

- **Lifestyle:** Concerning the sub-categories: Activity, food, stress & relaxing, smoking, and weight.
- **Relationships and well-being**: Concerning the sub-categories: Social contacts, intimate relationships & pregnancy & wish for children, incomprehension, loneliness, and gloom.

To advance Shared Decision Making (SDM), a separate conversation aid was made with tips and tricks for having a good conversation with your RMD professional:

- **A good conversation**: tips and tricks for preparing a conversation with your RMD professional. As well as tips and tricks that can be used during and after your conversation.

In Figure 1 the conversation aid with main category **lifestyle** is presented.

Figure 1. *Example of the conversation aid with main category Lifestyle.*

Conclusion: A consultation aid can advance a good conversation and therefore SDM, between people with an RMD and their RMD professional. A patient organisation can play an important role in developing a consultation aid.

Is gender sufficiently studied in RMDs?

OP0006

CLEANING ACTIVITIES, DUSTY CLOTHES LAUNDRY AND TALCUM HANDLING ARE UNDERESTIMATED MAJOR SOURCES OF EXPOSURE TO CRYSTALLINE SILICA IN WOMEN WITH RHEUMATOID ARTHRITIS

J. Sigaux[1,2], C. Cavalin[3,4], A. Lescoat[5], P.Y. Brillet[6], L. Sese[7], H. Nunes[8], M. C. Boissier[1,2], L. Semerano[1,2]. *[1]Avicenne Hospital, Rheumatology, Bobigny, France*; *[2]Université Sorbonne Paris Nord, UMR 1125 Inserm, Bobigny, France*; *[3]Université Paris Dauphine, IRISSO, UMR CNRS-INRAE 7170-1427, Paris, France*; *[4]Science Po, Laboratoire interdisciplinaire d'évaluation des politiques publiques (LIEPP), Paris, France*; *[5]CHU Rennes, Rheumatology, Rennes, France*; *[6]Avicenne Hospital, Radiology, Bobigny, France*; *[7]Avicenne hospital, Physiology, Bobigny, France*; *[8]Avicenne Hospital, Respiratory, Bobigny, France*

Background: Inhalation of crystalline silica ($cSiO_2$) is associated with rheumatoid arthritis (RA). Research on $cSiO_2$ has historically focused on professional exposures and on male workers. However, $cSiO_2$ is ubiquitously present in the environment, substantial exposure can take place in both men and women, in other professional activities and even beyond occupational context.
Objectives: To identify the main sources of exposure to crystalline silica in a series of RA patients not selected based on their professional activity, and to assess the association between silica exposure and disease features.
Methods: The Dust Exposure Life-Course Questionnaire (DELCQ) is a novel tool that longitudinally quantifies both occupational and non-occupational lifetime exposure to crystalline silica. The DELCQ was previously validated in a representative sample of the general French population that serves as control source for studies in specific diseases. The DELCQ was administered to 97 consecutive patients with RA, exposure scores were compared between cases and age-, sex- and smoking status-matched controls (1:4). The main sources of silica exposure were identified in cases and controls and source-specific exposure levels compared. The association between DELCQ scores and disease variables in cases was tested at uni- and multivariable analysis.
Results: In women with RA, the main sources of crystalline silica exposure were: cleaning activities, dusty clothes laundry and talcum powder handling, with higher exposure levels from these sources vs. the general population ($p<0.005$). In the whole series of RA patients, high silica exposure was independently associated with interstitial lung disease (OR 6.5 (95% CI: 1.3 to 32.6)) and mediastinal lymphadenopathy (OR 6.3 (95% CI: 1.4 to 27.7).
Conclusion: Cleaning activities, dusty clothes laundry and talcum handling are underestimated sources of crystalline silica exposure that are overrepresented in women with RA compared to the general population and may contribute to the pathogenesis of the disease.

Table 1. Association between occupational silica exposure (by quartile) and HRCT lung abnormalities

HRCT abnormality	OES (Quartiles)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Mediastinal lymphadenopathy	Q1-Q3	(ref)	(ref)
	Q4	4.1 (1.2 to 13.9)	**6.3 (1.4 to 27.7)**
Interstitial lung disease	Q1-Q3	(ref)	(ref)
	Q4	6.3 (1.5 to 26.6)	**6.5 (1.3 to 32.6)**
Emphysema	Q1-Q3	(ref)	(ref)
	Q4	6.4 (1.6 to 24.7)	2.9 (0.6 to 13.7)

Abbreviations: OES occupational exposure score. Adjusted OR: adjusted on smoking, sex, disease duration, ACPA and RF status.

"Not another pill!" Integrative pain management approaches

OP0007-HPR

AN EPIDEMIOLOGICAL STUDY OF FOOT AND ANKLE PAIN AND HEALTH-RELATED JOB LOSS IN ADULTS OVER 50: CROSS-SECTIONAL FINDINGS FROM THE HEAF COHORT

D. Jobanputra[1], L. Cherry[2], K. Walker-Bone[3], C. Price[1], S. D'angelo[3], G. Ntani[3], on behalf of Health & Employment After Fifty. *[1]University of Southampton School of Medicine, Faculty of medicine, Southampton, United Kingdom*; *[2]University of Southampton, School of Health sciences, Southampton, United Kingdom*; *[3]University of Southampton, MRC Versus Arthritis Centre for Musculoskeletal Health and Work, Southampton, United Kingdom*

Background: Foot and ankle pain (FAP), particularly that of musculoskeletal origin, is increasingly prevalent in our aging populations[1]. Moreover, governments need people to work to older ages to reduce the costs of pensions and welfare benefits. It is not currently known however whether people with FAP are able to keep working or to what extent it pushes people out of work. We investigated this question in older working adults.
Objectives: To determine whether FAP is associated with HRJL amongst older working adults.
Methods: Health And Employment After Fifty[2] is a longitudinal population-based cohort incepted 2013 to investigate health and retirement. At follow-up two years later, people were asked to complete a full-body mannequin which included the ankles/feet. Mannequins were coded: foot/ankle pain (FAP) with pain at other sites; pain elsewhere but not FAP; and no pain. Two years later, participants were asked whether they had left paid work entirely or partly because of health (Health-related job loss (HRJL). A Cox proportional hazards model was used to explore associations between health-related job loss, FAP, and other potential risk factors (such as age, mental health, BMI, and finances). A sensitivity analysis was carried out to determine which occupational activities were significantly associated with health-related job loss due to FAP.
Results: At 2 years, 4050 participants completed a pain mannequin, amongst whom 3762 were in paid work. Over 2 further years of follow-up, there were 235 incident HRJLs. Amongst those with HRJL, 73 had no pain, 54 had pain involving FAP, 108 had pain not involving FAP. After adjusting for age and sex, people with FAP had 83% increased risk of HRJL compared to people with no pain (HR=1.83, 95% CI 1.29-2.61), whilst those with pain NOT involving FAP had 34% increased

risk (HR1.34, 95% CI 1.00 – 1.80). FAP remained a significant predictor of HRJL within a fully adjusted model (HR=1.65, 95% CI 1.15-2.36). Sensitivity analyses confirmed that doing jobs which involved climbing more than 30 flights of stairs was associated with increased risk of HRJL amongst people with FAP (HR=1.96, 95% CI 1.00-3.80).

Conclusion: FAP is a risk factor for HRJL amongst older working adults, particularly if their job involves stair climbing. Potentially, modification of duties to reduce stair climbing could mitigate job loss amongst people with FAP.

Plenary Abstract Session

OP0008 A NOVEL SITE-SPECIFIC PEGYLATED IL-2 WITH POTENT AND TREG-SELECTIVE ACTIVITY IN VIVO

M. Ikeda[1], S. Yamaguchi[2], M. Murakami[2], S. Takaoka[3], Y. Sakaguchi[2], S. Yasui[2], K. Iijima[2], K. Nanya[2], H. Onodera[2], T. Amano[2]. *[1]Kyowa Kirin Co., Ltd., R&D division, Sunto-gun, Shizuoka, Japan*; *[1]Kyowa Kirin Co.,Ltd., R&D division, Sunto-gun, Shizuoka, Japan*; *[3]Kyowa Kirin Co.,Ltd., R&D division, Machida-shi, Tokyo, Japan*

Background: Decreased regulatory T cells (Tregs) and Treg dysfunction are hallmarks of a various autoimmune and inflammatory diseases. While low-dose IL-2 therapy induces Treg expansion *in vivo* and has clinical benefits in some diseases (e.g., SLE and chronic graft-versus-host disease [GvHD]), there are many concerns about adverse events due to low Treg-selectivity. Furthermore, frequent dosing is needed due to the short half-life.

Objectives: We discovered a novel site-specific PEGylated IL-2 variant, KKC80, with high Treg selectivity and a long half-life *in vivo*, which overcomes the issues of low-dose IL-2 therapy.

Methods: Based on the co-crystal structure of wild-type IL-2 and its heterotrimeric receptor (PBD ID: 2ERJ), amino acid residues that were to be PEGylation sites were substituted with oAzZLys, an azide-containing lysine derivative. The PEG molecule was site-specifically attached to oAzZLys-incorporated IL-2 by copper-free click chemistry. The binding property to the IL-2 receptors were measured by surface plasmon resonance (SPR). *In vitro*, Treg selectivity was evaluated by the IL-2-dependent proliferation activity of Tregs and NK cells from human peripheral blood mononuclear cells (PBMCs). *In vivo* pharmacological activity after the single subcutaneous administration in cynomolgus monkeys was measured by changes in Treg count and Treg activation status in peripheral blood by flow cytometry. Pharmacokinetic parameters were calculated according to serum PEGylated IL-2 concentration. Efficacy in mouse xenogeneic GvHD model using human PBMC-transplanted NOG mice and in monkey DTH model were evaluated.

Results: A novel PEGylated IL-2, KKC80 (human IL-2 desA1/C125S /I129oAzZLys_W-shaped 80 kDa PEG) was discovered by optimizing the PEGylation site and PEG structure based on Treg selectivity and PK. SPR analysis showed that the binding affinity of KKC80 to CD25 was moderately decreased from wild-type IL-2, while binding affinity of KKC80 to IL-2Rβγ was remarkably decreased due to a significant change of the association rate constant. *In vitro*, wild-type IL-2 activated both Tregs and NK cells in the same concentration range, whereas KKC80 selectively activated Tregs. The Treg selectivity of KKC80 was comparable to another IL-2 mutein, Fc.IL-2 V91K. KKC80, but not Fc.IL-2 V91K, retained its biological activity, even in the presence of a large amount of recombinant soluble CD25, which mimicked the endogenous decoy receptor for IL-2. In monkeys, KKC80 selectively increased peripheral blood Tregs in a dose-dependent manner; the average maximum rate of increase of Treg count in animals treated with 0.01, 0.03, 0.1, 0.3 and 1 mg/kg was 1.5, 3.5, 28, 50 and 154-fold, respectively. In contrast to Tregs, the rates of increase of conventional CD4+ T, CD8+ T and NK cells were low. The Treg increase peaked on day 8 or 11 and lasted for over day 29. KKC80 showed a more sustained upregulation of functional Treg markers (e.g., Foxp3 and CD25) in comparison to Fc.IL-2 V91K. The half-life of KKC80 was calculated as 83.5 to 150 h. At high doses, inflammation-related adverse effects, including increased CRP (≥0.3 mg/kg) and deterioration of general conditions (1 mg/kg) were observed. In the mouse xenogenic GvHD model, KKC80 ameliorated GvHD symptoms and suppressed multiple tissue inflammation markers. Decreased soluble CD25 and IFN-γ were also confirmed, suggesting Treg-mediated anti-inflammatory effect by KKC80 administration were exerted *in vivo.* In the monkey DTH model, KKC80 suppressed skin inflammation and antibody production.

Conclusion: Among next-generation IL-2 variants, KKC80 showed a best-in-class biological profile for Treg activation. A drastic and sustained increase of Tregs with high Treg-selectivity and anti-inflammatory effects were observed *in vivo*. These data suggest that in comparison to current IL-2 therapy, KKC80 provides superior therapeutic index and efficacy in patients with autoimmune and inflammatory diseases.

OP0009 MACHINE LEARNING IDENTIFIES A COMMON SIGNATURE FOR ANTI-SSA/RO60 ANTIBODY EXPRESSION ACROSS AUTOIMMUNE DISEASES

N. Foulquier[1], C. Le Dantec[1], E. Bettacchioli[2], C. Jamin[1], M. Alarcon-Riquelme[3], J. O. Pers[4]. *[1]Université de Brest, Laboratoire Lbai - Umr 1227, Brest, France*; *[1]Université de Brest, Laboratoire Lbai - Umr 1227, Brest, France*; *[3]GENYO, Department of Medical Genomics, Granada, Spain*; *[1]Université de Brest, Laboratoire Lbai - Umr 1227, Brest, France*

Background: Anti-SSA/Ro autoantibodies are among the most frequently detected extractable nuclear antigen autoantibodies and have mainly been associated with primary Sjögren's syndrome (pSS), systemic lupus erythematosus (SLE) and undifferentiated connective tissue disease (UCTD).

Objectives: Is there a common signature to all patients expressing anti-Ro60 autoantibodies regardless of their disease phenotype?

Methods: Using high-throughput multi-omics data collected within the cross-sectional cohort from the PRECISESADS IMI project [1] (genetic, epigenomic, transcriptomic, combined with flow cytometric data, multiplexed cytokines, classical serology and clinical data), we assessed by machine learning the integrated molecular profiling of 520 anti-Ro60-positive (anti-Ro60$^+$) compared to 511 anti-Ro60-negative (anti-Ro60$^-$) patients with pSS, SLE and UCTD, and 279 healthy controls (HCs).

Results: The selected features for RNA-Seq, DNA methylation and GWAS data allowed a clear separation between anti-Ro60$^+$ and anti-Ro60$^-$ patients. These results demonstrate that the different features selected by machine learning from the anti-Ro60$^+$ patients constitute specific signatures when compared to anti-Ro60$^-$ patients and HCs. Remarkably, the gene transcript *z*-score of three genes (*ATP10A*, *MX1* and *PARP14*), presenting an overexpression associated with a hypomethylation and genetic variation, and independently identified by the Boruta algorithm, was clearly higher in anti-Ro60$^+$ patients compared to anti-Ro60$^-$ patients in all the diseases (Figure 1). Finally, we demonstrate that these signatures, enriched in interferon stimulated genes, were also found in anti-Ro60$^+$ patients with rheumatoid arthritis and systemic sclerosis.

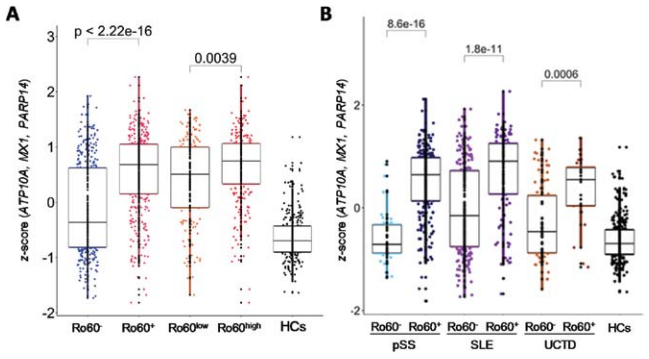

Figure 1. Three genes common to RNA-Seq, DNA methylation and GWAS analysis characterize anti-Ro60$^+$ patients. (A) *ATP10/MX1/PARP14 z*-score analyses were performed for 731 patients and 254 HCs according to anti-Ro60 expression. **(B)** *ATP10/MX1/PARP14 z*-score analyses were performed for 286 pSS, 351 SLE and 94 UCTD patients and 254 HCs. Two-tailed pairwise Wilcoxon-rank sum test results are shown. Plots show median, with error bars indicating ± interquartile range. (pSS: primary Sjögren's syndrome, SLE: systemic lupus erythematosus, UCTD: undifferentiated connective tissue disease, HCs: healthy controls).

Conclusion: Anti-Ro60$^+$ patients present a specific inflammatory signature regardless of their disease suggesting that a dual approach targeting both Ro-associated RNAs and anti-Ro60 autoantibodies should be considered.

OP0010 A MORE MATURE PLASMA CELL AND PLASMABLAST COMPARTMENT IS ASSOCIATED WITH DISEASE MANIFESTATION IN PRIMARY SJÖGREN'S SYNDROME

T. D. Steinmetz[1], G. M. Verstappen[1], H. Bootsma[1], F. G. M. Kroese[1]. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Sjögren's syndrome (pSS) is an autoimmune disorder often associated with fatigue, dry eyes and dry mouth symptoms and characterized by chronic inflammation of moisture-producing glands like salivary and lacrimal glands (1). Auto-antibodies, B cell infiltration of affected glands and lymphoma development are signs for B cell hyperactivity in pSS (1-3). The B cell effector branch, namely antibody-secreting cells (ASC) like plasmablasts and plasma cells, can sustain autoimmune pathogenicity over long time periods by secretion of auto-antibodies (4,5).

Objectives: Since B cell hyperactivity is an important pathogenic feature in pSS, antibody-secreting cells as B effector cells are studied to characterize their abundance, maturation stage and inflammatory properties and relate them to pSS manifestations.

Methods: Peripheral blood mononuclear cells (PBMC) from pSS patients and healthy individuals were subjected to spectral flow cytometry phenotyping. CD27+CD38++ ASCs were analyzed with a comprehensive tSNE approach as well as based on expression of ASC markers. This includes markers described for maturity like CD19, CD138, CD28, Blimp1 and HLA-DR and markers relevant for ASC survival like Mcl1 and BCMA. The pro-inflammatory status of the cells was assessed by CXCR3 and CXCR4 expression and their immune regulatory properties with markers like IL-10 and Lag-3. ASC properties like maturity state were correlated to characteristic pSS disease-associated features.

Results: Patients with pSS had higher frequencies and absolute numbers of ASCs then healthy controls. ASCs displayed a higher degree of maturation in pSS. ASC frequencies and their maturity state, for example reflected by CD19 down-regulation or increased CD28 expression (6), correlated with several pSS disease characteristics like ANA titers, focus scores and ocular scores indicating glandular impairment. Additionally, more mature ASCs that express low amounts of CD19 had increased Mcl1 levels indicating prolong survival of these cells. The maturation state of ASCs was associated with CXCR3+ ASC frequencies in pSS patients. Expression levels of anti-inflammatory IL-10 and pathogenic CXCR3 by ASCs in pSS patients was negatively correlated. tSNE related clusters enriched for ASCs from pSS patients were more mature but also had higher expression levels of CXCR3.

Conclusion: Circulating ASCs in pSS are more abundant and have a more mature phenotype compared to healthy individuals. Their frequencies and degree of maturation could be linked to pSS disease features. Prolonged survival and pro-inflammatory status might further increase the impact of circulating ASCs on disease manifestations. Together these findings underpin the role of B cell hyperactivity in pSS, that culminates in an altered ASC compartment.

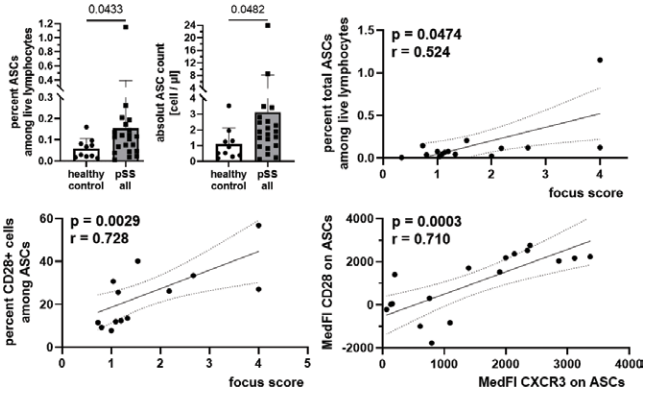

Figure 1. (A) Frequencies and absolute numbers of antibody-secreting cells (ASC) are increased in pSS patients and (B) correlate with salivary gland focus scores. (C) More mature CD28+ ASCs are associated with focus scores and (D) higher pro-inflammatory levels of CXCR3.

OP0011 HIGHLY DIFFERENTIATED CD4 AND CD8 T EFFECTOR MEMORY CELLS RE-EXPRESSING CD45RA (TEMRA) ARE ASSOCIATED WITH ACTIVE DISEASE REFRACTORY TO ANTI-TNF THERAPY IN RHEUMATOID ARTHRITIS

S. A. Yeoh[1], J. Kimpton[1], M. Shipa[1], E. Hawkins[1], A. Akbar[2], M. Ehrenstein[1]. [1]*University College London, Rheumatology, London, United Kingdom*; [2]*University College London, Experimental and Translational Medicine, Division of Medicine, London, United Kingdom*

Background: Highly differentiated T cells have been reported to be enriched in rheumatoid arthritis (RA) compared to healthy individuals[1]. The role of terminally differentiated T effector memory re-expressing CD45RA (Temra) in RA pathogenesis and disease activity is still unclear, including whether they can be used as a marker of sustained disease activity in RA patients receiving anti-TNF therapy.

Objectives: To investigate whether the frequency of peripheral blood Temra can be used as a biomarker to identify disease refractory to anti-TNF therapy in RA, if they correlate with inflammation in anti-TNF treated patients, and whether they associate with a flare following tapering anti-TNF.

Methods: RA patients on anti-TNF therapy were recruited from rheumatology clinic (cross-sectional cohort). Clinical data and whole blood were collected.

Patients were stratified based on disease activity. Remission was defined as no recorded DAS28-CRP≥2.4, no swollen joints, no C-reactive protein (CRP) of >5mg/L, and on a stable DMARD dose and no reported disease flare/loss of remission in the 6 months prior. Non-remission was defined as any other disease activity which does not fulfil the remission definition. Patients on abatacept, or methotrexate monotherapy and healthy volunteers were recruited as comparison groups. A separate cohort of anti-TNF patients (longitudinal cohort) who have been in remission on a stable dose of anti-TNF for ≥6 months and no use of corticosteroids in the last 6 months, was also recruited. Whole blood was obtained prior to dose tapering (dose halving) and at the point of a flare. Whole blood was processed by gradient centrifugation to obtain peripheral blood mononuclear cells (PBMC). PBMC were stained with fluorochrome-conjugated antibodies for multi-parameter flow cytometry. Analysis was performed on live lymphocytes using FlowJo software version 10.8. Two-tailed Mann-Whitney U test or unpaired t-test were used to obtain unadjusted values, analysis of variance (ANOVA) of log-transformed data was used to obtain age-adjusted values, Spearman's rank correlation was used to compare correlation between Temra and CRP.

Results: RA patients (36 anti-TNF, 12 abatacept, 16 methotrexate monotherapy) and 14 healthy individuals were recruited. There was a higher proportion of CD4 (age-adjusted p = 0.004) and CD8 Temra (age-adjusted p = 0.0007) in RA patients on anti-TNF with persistent disease activity compared to those who had achieved remission. These differences were confirmed when analysing absolute numbers of CD4 and CD8 Temra. Unexpectedly, the difference in Temra frequency between remission and non-remission RA was not observed in patients treated with methotrexate or abatacept. The median CD4 and CD8 Temra frequencies in RA patients in remission with all treatments studied were similar to healthy individuals.

Temra were not observed to increase with age in the anti-TNF, abatacept, or methotrexate cohorts in contrast to previous reports in healthy individuals[2]. The frequency of CD4 and CD8 Temra correlated with CRP only in patients on anti-TNF (CD4 Temra Spearman r = 0.5185, p = 0.001, and CD8 Temra Spearman r = 0.5040, p = 0.005).

There was an increase in CD4 (p = 0.003) but not CD8 Temra at 3 months in patients who flared on tapering anti-TNF compared to those who remained in remission (Figure 1).

Conclusion: Increased CD4 and CD8 Temra frequency were associated with persistent disease activity in anti-TNF treated patients but not with other DMARD therapies (abatacept and methotrexate). CD4 Temra increased in those who flared on tapering anti-TNF. These results suggest that Temra may play a role in driving persistent disease activity refractory to anti-TNF therapy rather than merely a marker of inflammation.

Isaacs[1]. *[1]Newcastle University, Institute of Translational and Clinical Research, NEWCASTLE UPON TYNE, United Kingdom*; *[2]Institut Pasteur, Translational Immunology Lab, Paris, France*; *[3]Queen Mary University of London, Centre for Translational Bioinformatics, The William Harvey Research Institute, Barts and The London School of Medicine and Dentistry, London, United Kingdom*; *[4]Newcastle University, Bioinformatics Support Unit, NEWCASTLE UPON TYNE, United Kingdom*; *[5]University College London, Department of Statistical Science, London, United Kingdom*; *[6]Kings College London, Centre for Rheumatic Diseases, London, United Kingdom*; *[7]Newcastle University, Newcastle University Biosciences Institute, NEWCASTLE UPON TYNE, United Kingdom*; *[8]RA-MAP, Consortium, Various, United Kingdom*

Background: An interferon gene signature (IGS) is present in approximately 50% of early, treatment naive rheumatoid arthritis (eRA) patients. We previously demonstrated it negatively impacts on initial disease outcomes.

Objectives: To 1) reproduce previous findings demonstrating the harmful effects of the IGS on early RA clinical outcomes, 2) identify which IFN class is responsible for the IGS and 3) seek evidence that IFN-α exposure contributes to harmful epigenetic footprint at disease onset.

Methods: In a large multicentre inception cohort (n=190) of eRA patients (RA-MAP TACERA) whole blood transcriptome, IGS (*MxA, IFI44L, OAS1, ISG15, IFI6)* and circulating interferons (IFN)-α, -β, -γ and -λ was examined at baseline and 6 months in conjunction with disease activity and clinical characteristics. A separate eRA cohort of paired methylome and transcriptome from CD4 T and CD19 B cells (n=41 for each) was used to explore any epigenetic influence of the IGS.

Results: The baseline IGS reproducibly and significantly negatively impacts on 6-month clinical outcomes. In the high IGS cohort there was increased DAS-28 (p=0.025) and reduced probability of achieving a good EULAR response (p=0.034) at 6-months. In addition, the IGS in eRA is shown for the first time to predominantly reflect raised circulating IFN-α protein, not other classes of IFN and examination of whole blood upstream nucleic acid sensors expression suggest a RNA trigger. Both the IGS and IFN-α significantly fell in parallel at 6 months (p<0.0001), whereas other classes of IFN remained statistically static. There was a significant association with IFN-α and RF titre but not ACPA. Comparison of CD4 T and CD19 B cells between IGS high and low eRA patients demonstrated differentially methylated CPG sites and altered transcript expression of disease relevant genes e.g. *PARP9, STAT1, EPTSI1* which was similarly, and persistently, altered 6 months in the separate TACERA cohort. Differentially methylated CPGs implicated altered transcription factor binding in B cells (GATA3, ETSI, NFATC2, EZH2) and T cells (p300, HIF1α) which cumulatively suggested IFN-α induced epigenetic changes promoting increased, and sustained, lymphocyte activation, proliferation and loss of anergy in the IGS high cohort.

Conclusion: We validate that the IGS is a robust prognostic biomarker in eRA predicting poor therapeutic response. Its persistent harmful effects may be driven via epigenetic modifications. These data have relevance for other IFN-α states, such as COVID-19, but also provide a rationale for the initial therapeutic targeting of IFN-α signalling, such as with JAKi, at disease onset in stratified eRA subsets.

Background: Synovial tissue macrophages significantly contribute to Rheumatoid Arthritis, yet the precise nature/function of macrophage subsets within the inflamed joint remains unexplored.
Objectives: To fully explore the spectrum of distinct macrophage activation states residing within the synovium of RA, at risk and healthy individuals.
Methods: Single-cell synovial tissue suspensions from RA (n=44), IAR (n=5), HC (n=11), PsA (n=11) and OA (n=4) were obtained, and synovial macrophage subsets examined by advanced multiparameter flow cytometric analysis, bulk RNA-sequencing, metabolic and functional assays.
Results: Multidimensional analysis identifies enrichment of CD206+CD163+ synovial-tissue macrophages co-expressing CD40 in the RA joint compared to healthy synovial-tissue, with frequency of CD206+CD163+CD40+ macrophages associated with increased disease activity and treatment response. In contrast, CX3CR1-expressing macrophages which form a protective barrier in healthy synovium are significantly depleted in RA. Importantly this signature of enriched CD40 expression coupled with depleted CX3CR1 expression is an early phenomenon, occurring prior to clinical manifestation of disease in individuals 'at-risk' of RA (IAR). RNAseq and metabolic profiling of sorted RA synovial-macrophages identified that this population is transcriptionally distinct, displaying unique inflammatory, phagocytic and tissue-resident gene signatures, paralleled by a bioenergetically stable profile as indicated by NAD(P)H emission. Functionally CD206+CD163+ RA macrophages are potent producers of pro-inflammatory mediators (reversed by CD40-signalling inhibition) and induce an invasive phenotype in healthy synovial-fibroblasts. These findings identify a distinct pathogenic population of synovial-tissue macrophage involved in shaping the immune response in RA. Crucially, this signature is present pre-disease representing a unique opportunity for early diagnosis and therapeutic intervention.
Conclusion: We have identified a novel population of tissue-resident macrophages in the RA synovium which are transcriptionally/metabolically distinct and capable of contributing to disease pathology. Uncovering the molecular patterns and cues that transform this immunoregulatory macrophage population into a dysfunctional inflammatory activation state may provide opportunities to reinstate joint homeostasis in RA patients.

OP0014 CTLA4-IG INDUCES TOLEROGENIC PROPERTIES OF DENDRITIC CELLS BY ALTERING CELLULAR METABOLISM

P. Goutakoli[1], G. Papadaki[1], S. Papanikolaou[1,2], G. Vatsellas[3], G. Bertsias[1,4], P. Verginis[5], P. Sidiropoulos[1,4]. *[1]Laboratory of Rheumatology, Autoimmunity and Inflammation, Medical School, University of Crete, Heraklion, Greece*; *[2]Institute for Bioinnovation-IBI, Biomedical Sciences Research Center "Alexander Fleming", Athens, Greece*; *[3]Greek Genome Center, BRFAA, Athens, Greece*; *[4]Clinic of Rheumatology, Clinical Immunology, University Hospital of Heraklion, Heraklion, Greece*; *[5]Division of Basic Sciences, Medical School, University of Crete, Heraklion, Greece*

Background: Dendritic cells (DCs) are well-recognized for their dual role either for T cell activation (1) or for inducing T cells tolerance (2). Their ability to modulate T-cell responses has made them an interesting tool for the immunotherapy of autoimmune diseases (3). Cytotoxic T lymphocyte antigen 4 (CTLA4) is a negative co-stimulatory molecule, which binds to CD80/CD86 on DCs. CTLA4 induces its immunoregulatory function through trans-endocytosis resulting in impaired co-stimulation (4), or through the induction of indoleamine-pyrrole 2,3-dioxygenase (IDO) enzyme (5). Moreover, it has been demonstrated that CTLA4 impairs the autophagic machinery of DCs and therefore suppresses DC inflammatory function (6). Nevertheless, the molecular mechanisms underlying the CTLA4-mediated immunomodulatory phenotype, require a more comprehensive understanding.
Objectives: In this study we focused on tolerogenic DCs (tolDCs) and we applied CTLA4-Ig as a tool to induce them. We aim to assess the immunoregulatory potential of CTLA4-mediated tolDCs and to investigate thoroughly the intracellular pathways that are involved in the induction of tolerance.
Methods: Healthy human monocytes were isolated from peripheral blood and differentiated into monocyte-derived dendritic cells (DCs). After 6 days, immature DCs activated with LPS were treated with CTLA4-Ig or IgG control for 18 hours. The anti-inflammatory function of DCs was validated using RT-PCR and flow cytometry and DCs proceeded to RNA sequencing. The metabolic pathways were studied using a Seahorse bioanalyzer.
Results: CTLA4-Ig-treated DCs showed significantly decreased HLA-DR, CD80/CD86 expression as compared to IgG-treated cells (n=4, p=0,0294, n=5 p=0,0079). Moreover, IL6 and TNFα mRNA expression, hallmarks of inflammatory cytokines secreted by DCs, was reduced upon CTLA4-Ig (n=5, p=0,0079). To elucidate the pathways involved in DC reprogramming upon CTLA4-Ig treatment, we performed RNA sequencing and we concluded with 1270 differentially expressed genes (p-value <0.05 counts>10). Interestingly, transcriptomic analysis revealed that the majority of genes (n=900) participated in metabolic processes, specifically in OXPHOS pathway and mitochondrial function. To further support the above metabolic changes, we performed Seahorse assays and confirmed that tolDCs had lower basal OXPHOS and decreased ATP production compared with mature DCs. Furthermore, expression of phosphorylated mammalian target of rapamycin (mTOR) and AKT1, central regulators of metabolism, was increased in CTLA4-mediated tolDCs (n=3, p= 0,0308 and p=0,0347).
Conclusion: Herein we confirmed that CTLA4 restricts the pro-inflammatory properties of activated DCs. RNA-seq analysis revealed that this anti-inflammatory deviation of DCs is characterized by the modification of the expression of genes implicated in cellular metabolism. Metabolic experiments confirmed that CTLA4-mediated tolDCs have reduced OXPHOS and ATP production, whereas, mTOR signaling is upregulated. In future experiments, we will investigate the mechanism that CTLA4 may promote metabolic changes thus contributes to the immunoregulatory phenotype of DCs and could represent a therapeutic target.

OP0015 PROINFLAMMATORY MONOCYTES AND MACROPHAGES IN SYNOVIAL FLUID AND BURSAL TISSUE OF PATIENTS WITH POLYMYALGIA RHEUMATICA: POTENT PRODUCERS OF IL-6 AND GM-CSF

W. F. Jiemy[1], R. Reitsema[1], A. Zhang[1], M. Sandovici[1], A. Boots[1], P. Heeringa[2], E. Brouwer[1], K. Van der Geest[1]. *[1]University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]University Medical Center Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands*

Background: Polymyalgia rheumatica (PMR) is a common, rheumatic inflammatory disease. Inflammation of bursae and tendon sheaths is a characteristic finding

in patients with PMR. Glucocorticoid treatment remains the mainstay treatment for PMR. A study published in 1996 reported that macrophages dominate the inflammatory infiltrates in the glenohumeral synovium of PMR patients[1], suggesting the importance of these cells in the immunopathology of PMR. However, the functional and phenotypical heterogeneity of the tissue-infiltrating macrophages in PMR remains obscure. Although treatment with anti-IL-6 receptor (tocilizumab) has shown promising results[2], it is unclear whether macrophages contribute to IL-6 production in PMR. Additionally, anti-GM-CSF receptor therapy (mavrilimumab), recently shown to be efficacious in the closely related disease giant cell arteritis[3], may also be useful for the treatment of PMR. Knowledge on the functional heterogeneity of monocytes/macrophages in PMR may aid in identifying novel therapeutic targets for this condition.

Objectives: To determine the phenotype of monocyte/macrophages in peripheral blood, bursal/tenosynovial fluid and bursal tissue of patients with PMR.

Methods: Paired peripheral blood (PB), bursal/tenosynovial fluid (SF) and bursal tissue biopsy samples from 11 PMR patients were included in our study. Bursal and tenosynovial samples were obtained from the shoulder. Distribution of the monocyte subsets (classical, intermediate and non-classical monocytes) was determined based on the level of CD14 and CD16 expression by flow cytometry. To study monocyte activation status, markers of 'M1' like (CD80 and CD64) and 'M2' like (CD206 and FRβ) macrophage polarization were included in the flow cytometry analysis. Immunohistochemistry of bursal tissue biopsies was focused on macrophage markers (CD68, CD86, CD64, CD206 and FRβ) andproinflammatory cytokines (IL-6 and GM-CSF), which were scored semi-quantitatively. Double immunofluorescence stainings were performed to determine the expression of IL-6 and GM-CSF by tissue-infiltrating macrophages in bursal tissue.

Results: Monocytes were detected in the SF of PMR patients. The proportion of classical monocytes was significantly lowered (p=0.001) in SF versus PB, while the proportion of intermediate monocytes was significantly elevated (p=0.001). The expression of CD206 was significantly elevated (p=0.001) but not FRβ in SF monocytes, suggesting GM-CSF skewed phenotype. In bursal tissue, macrophages displayed mixed 'M1'/'M2' traits with high expression of all macrophage polarization markers. Proinflammatory cytokines IL-6 and GM-CSF were highly expressed throughout the bursal tissue biopsies. Double immunofluorescence staining confirmed the expression of IL-6 and GM-CSF by the infiltrating macrophages.

Conclusion: SF monocytes and bursal tissue macrophages show a pro-inflammatory phenotype in PMR. Moreover, tissue-infiltrating macrophages show a prominent IL-6 and GM-CSF response in PMR. Our data add to the rationale of targeting IL-6 and GM-CSF as treatment options in PMR.

AxSpA drug treatment: new and old drugs

OP0016

EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH ACTIVE NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED PHASE 3 TRIAL

A. Deodhar[1], F. Van den Bosch[2], D. Poddubnyy[3], W. P. Maksymowych[4], D. Van der Heijde[5], T. H. Kim[6], M. Kishimoto[7], Y. Duan[8], Y. Li[8], A. Pangan[8], P. Wung[8], I. H. Song[8]. [1]*Oregon Health & Science University, Division of Arthritis & Rheumatic Diseases, Portland, OR, United States of America*; [2]*Ghent University, VIB Center for Inflammation Research, Internal Medicine and Pediatrics, Ghent, Belgium*; [3]*Charité Universitätsmedizin, Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [4]*University of Alberta, Medicine, Edmonton, Alberta, Canada*; [5]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [6]*Hanyang University Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; [7]*Kyorin University School of Medicine, Nephrology and Rheumatology, Tokyo, Japan*; [8]*AbbVie Inc., Immunology, North Chicago, IL, United States of America*

Background: Janus kinase (JAK) inhibitors have been recognized as a potential therapeutic option in ankylosing spondylitis (AS), also known as radiographic axial spondyloarthritis (r-axSpA).[1] Upadacitinib (UPA), a JAK inhibitor, has demonstrated efficacy and safety in the treatment of AS[2]; however, no JAK inhibitor studies have been conducted in non-radiographic axSpA (nr-axSpA) to date.

Objectives: To assess the efficacy and safety of UPA in patients (pts) with active nr-axSpA.

Methods: SELECT-AXIS 2 (NCT04169373) was conducted under a master protocol comprising two independent studies, one in an AS population with an inadequate response to biologic disease-modifying antirheumatic drugs and one in an nr-axSpA population. The nr-axSpA study is a randomized, double-blind, placebo(PBO)-controlled, phase 3 trial that enrolled adults ≥18 years with a clinical diagnosis of nr-axSpA (who also fulfilled 2009 ASAS classification criteria for axSpA but did not meet the radiologic criterion of modified New York criteria), who had objective signs of active inflammation consistent with axSpA on MRI of the sacroiliac (SI) joints and/or high sensitivity C-reactive protein (hs-CRP) >upper limit of normal (2.87 mg/L) at screening, and who had BASDAI and pt's assessment of total back pain scores ≥4 based on a 0 to 10 numeric rating scale at study entry. Pts were randomized 1:1 to receive oral UPA 15 mg once daily (QD) or PBO during a 52-week (wk) double-blind treatment period. The primary endpoint was ASAS40 response at wk 14. Multiplicity-controlled secondary endpoints assessed at wk 14 included BASDAI50, ASDAS ID (<1.3), ASDAS LDA (<2.1), ASDAS PR, and ASAS20, and the change from baseline (Δ) in ASDAS (CRP), SPARCC MRI SI joint inflammation score, total and nocturnal back pain, BASFI, ASQoL, ASAS HI, BASMI, and MASES. Treatment-emergent adverse events (TEAEs) are reported through wk 14 for pts who received ≥1 dose of study drug.

Results: Of 314 pts randomized at baseline, 313 received study drug (UPA 15 mg, n=156; PBO, n=157) and 295 (94%) received study drug through wk 14. Baseline demographic and disease characteristics were balanced across treatment groups and consistent with an active nr-axSpA population (58% female; mean age 42.1 years; mean BASDAI 6.9; mean hs-CRP 12.1 mg/L).

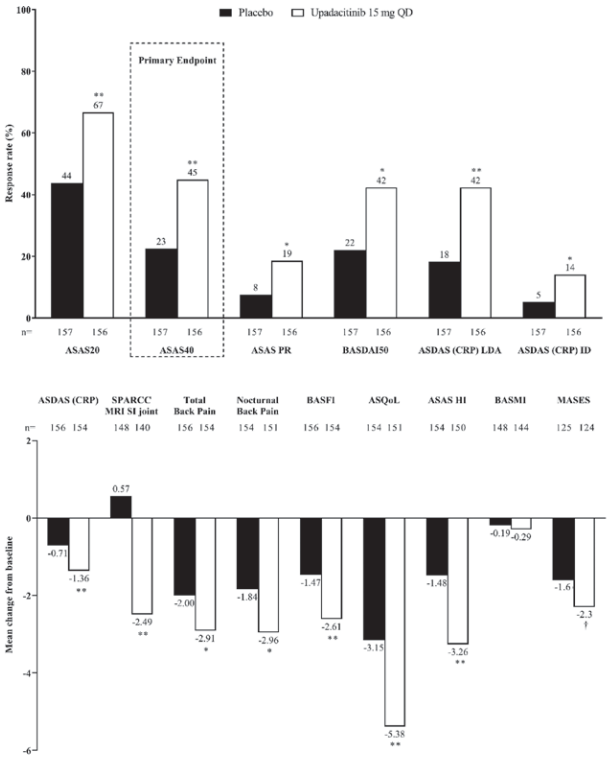

Figure. Analysis of Primary and Multiplicity-Controlled Secondary Endpoints at Wk 14

ASAS20=Assessment of SpondyloArthritis international Society 20 response; ASAS40=Assessment of SpondyloArthritis international Society 40 response; ASAS HI=Assessment of SpondyloArthritis international Society Health Index; ASAS PR=Assessment of SpondyloArthritis international Society partial remission; ASDAS (CRP)=Ankylosing Spondylitis Disease Activity Score C-reactive protein; ASDAS (CRP) ID=Ankylosing Spondylitis Disease Activity Score C-reactive protein inactive disease; ASDAS (CRP) LDA=Ankylosing Spondylitis Disease Activity Score C-reactive protein low disease activity; ASQoL=Ankylosing Spondylitis Quality of Life; BASDAI50=at least 50% improvement from baseline in Bath Ankylosing Spondylitis Disease Activity Index. BASFI=Bath Ankylosing Spondylitis Functional Index; BASMI=Bath Ankylosing Spondylitis Metrology Index; CMH=Cochran-Mantel-Haenszel; MASES=Maastricht Ankylosing Spondylitis Enthesitis Score; MMRM=mixed-effect model for repeated measurements; NRI-MI=non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19; QD=once daily; SPARCC=Spondyloarthritis Research Consortium of Canada.
†Nominal P<0.05
**P<0.01; ***P<0.0001; Significant in multiplicity-adjusted analysis.
ASDAS LDA was defined as ASDAS (CRP) <2.1 and ASDAS ID as ASDAS (CRP) <1.3.
MASES was assessed in pts with baseline enthesitis.
Binary endpoints were analyzed using the CMH test, and NRI-MI was used to handle missing data. Continuous endpoints were analyzed using MMRM. N was the number of unique subjects contributing to MMRM model estimates.

A significantly higher ASAS40 response rate at wk 14 was achieved with UPA vs PBO (45% vs 23%; *P*<0.0001; Figure 1). Statistical significance was also achieved in the first 12 of the 14 multiplicity-controlled secondary endpoints (ie, all endpoints except BASMI and MASES) at wk 14 for UPA compared with PBO (*P*<0.01; Figure 1). The proportion of pts who experienced a TEAE was similar between treatment groups (UPA, 48%; PBO, 46%). Serious TEAEs and TEAEs leading to discontinuation were reported in 4 (2.6%) pts treated with UPA and 2 (1.3%) pts treated with PBO, respectively. Few pts had serious infection or herpes zoster (each 2 [1.3%] pts on UPA; each 1 [0.6%] pt on PBO, respectively). Uveitis was reported in 1 (0.6%) pt on UPA who had a history of uveitis and none on PBO. No malignancy other than non-melanoma skin cancer, major adverse cardiovascular events, venous thromboembolic events, inflammatory bowel disease (IBD), or death were reported in the study; 1 event of basal cell carcinoma occurred with PBO.

Conclusion: UPA 15 mg QD demonstrated significantly greater improvements in disease activity, pain, function, quality of life, and MRI-detected SI joint inflammation than PBO after 14 wks of treatment in pts with active nr-axSpA. The safety profile of UPA was consistent with what has been observed with other inflammatory musculoskeletal diseases,[3–5] and no new risks were identified. These results support the potential use of UPA in pts with active nr-axSpA.

OP0017

RECAPTURE RATES WITH IXEKIZUMAB AFTER WITHDRAWAL OF THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS AT WEEK 104 FROM A RANDOMIZED PLACEBO-CONTROLLED WITHDRAWAL STUDY

R. B. M. Landewé[1], D. Poddubnyy[2], P. Rahman[3], R. Bolce[4], S. Liu Leage[4], J. Lisse[4], A. Leung[5], S. Y. Park[4], L. S. Gensler[6]. [1]*Amsterdam Rheumatology and Immunology Center, Department of Clinical Immunology and Rheumatology, Amsterdam, Netherlands*; [2]*Charité - Universitätsmedizin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [3]*Memorial University of Newfoundland, Department of Rheumatology, St. John's, Canada*; [4]*Eli Lilly and Company, Medical Affairs, Indianapolis, United States of America*; [5]*Syneos Health, Medical, Morrisville, United States of America*; [6]*University of California San Francisco, Department of Medicine, San Francisco, United States of America*

Background: COAST-Y is the first study to evaluate the effect of continuing vs withdrawing an IL-17A antagonist, Ixekizumab (IXE) on the maintenance of disease control in patients (pts) with ankylosing spondylitis and non-radiographic axial spondyloarthritis through 104 Weeks (wks).

Objectives: Here, we describe the final results of pts re-randomized to either placebo (PBO; IXE Withdrawal) or IXE, who experienced flare, and recaptured response before or after open label retreatment during COAST-Y.

Methods: COAST-Y (NCT03129100) is a Phase 3, long-term extension study that included a double-blind, PBO-controlled, randomized withdrawal-retreatment period (RWP). Eligible pts who completed an originating study (COAST-V, -W, or -X) entered a 24-Week (Wk) lead-in period and received 80 mg IXE every 2 (Q2W) or 4 wks (Q4W) (the treatment regimen at the end of the originating study); pts receiving PBO at the end of COAST-X were assigned to IXE Q4W in COAST-Y. Pts who achieved remission (Ankylosing Spondylitis Disease Activity Score (ASDAS) <1.3 (inactive disease; ID) at least once at Wk 16 or 20, and <2.1 (low disease activity; LDA) at both visits) were randomized 2:1 at Wk 24 to continue IXE (as per lead-in period) or withdrawn to PBO. Pts who subsequently experienced flare (ASDAS ≥2.1 at 2 consecutive visits or ASDAS >3.5 at any visit) were switched to open label IXE Q2W or Q4W at the next visit (same as lead-in period). Time to first flare was analyzed using the Kaplan-Meier method with treatment comparison performed using log-rank test. The observed proportion of pts who recaptured ASDAS LDA and ID were summarized for pts who experienced flare and were retreated with open label IXE.

Results: A total of 155 pts met the criteria for remission and entered the RWP (PBO [IXE withdrawal], N=53; IXE Q4W, N=48; IXE Q2W, N=54) and 138 completed Wk 104. At Wk 104, significantly more pts in the combined IXE group (75.5%, p<0.001, IXE Q4W: 75.0%, p<0.001; IXE Q2W: 75.9%, p<0.001) remained flare free through Wk 104 vs PBO (Figure 1). Notably, 35.8% of pts on PBO (IXE Withdrawal) never experienced flare. Of the PBO pts who experienced flare and were retreated during Wk 24-104 (N=28), 4 recaptured LDA before switching to open label IXE retreatment, while 23 recaptured LDA and 19 met ID after switching (Table 1). Of the continuously treated IXE pts (N=13), 7 recaptured LDA before switching to open label IXE retreatment, while 5 recaptured LDA and 4 met ID after.

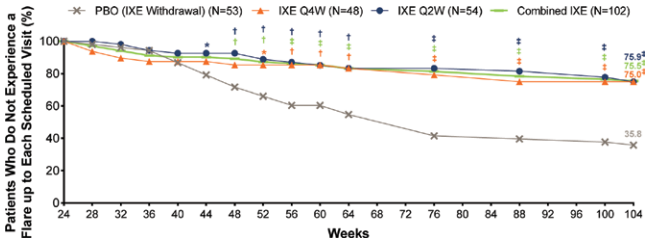

Figure 1. The proportion (%) of patients who remained flare free through 104 weeks. ‡p<0.001, †p<0.01, *p<0.05 vs PBO (IXE Withdrawal).

Table 1. Recapture of first treatment response before or after switching to open label IXE through 104 weeks among placebo (ixekizumab withdrawal)-treated patients who experienced a flare and retreated

Total patients who flared and were switched to open-label ixekizumab retreatment	Placebo (ixekizumab withdrawal) (N=28)	
ASDAS disease activity status	LDA	ID
Recaptured response before open label ixekizumab retreatment	4	1
Recaptured response with open label ixekizumab retreatment (≤16 weeks)	23	14
Recaptured response with open label ixekizumab retreatment (>16 weeks)	0	5
Total patients who recaptured response at week 104	27/28 (96%)	20/28 (71%)

Data are presented as n, (%) for the total row and n only for all other rows. In each column, the denominator is 28. ASDAS, Ankylosing Spondylitis Disease Activity Score; ID, inactive disease; LDA, low disease activity including ID; N, number of patients in the analysis population.

Conclusion: Pts continuously treated with IXE were less likely to experience flare vs pts on PBO (IXE withdrawal). The vast majority of pts withdrawn from IXE to PBO recaptured at least LDA and over half met ID with IXE retreatment. This may provide support for pts who require interruption in therapy.

OP0018

COMPARISON OF THE EFFECT OF TREATMENT WITH NSAIDS ADDED TO ANTI-TNF THERAPY VERSUS ANTI-TNF THERAPY ALONE ON PROGRESSION OF STRUCTURAL DAMAGE IN THE SPINE OVER TWO YEARS IN PATIENTS WITH ANKYLOSING SPONDYLITIS (CONSUL) – AN OPEN-LABEL, RANDOMIZED CONTROLLED, MULTICENTER TRIAL

F. Proft[1], B. Muche[1], V. Rios Rodriguez[1], M. Torgutalp[1], M. Protopopov[1], J. Listing[2], M. Verba[1], U. Kiltz[3], J. Brandt-Juergens[4], M. Sieburg[5], S. H. Jacki[6], J. Sieper[1], D. Poddubnyy[1,2]. *[1]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany*; *[2]German Rheumatism Research Centre, Epidemiology unit, Berlin, Germany*; *[3]Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*; *[4]Rheumatologische Schwerpunktpraxis, Rheumatologische Schwerpunktpraxis, Berlin, Germany*; *[5]Rheumatologische Facharztpraxis, Rheumatologische Facharztpraxis, Magdeburg, Germany*; *[6]Rheumatologische Schwerpunktpraxis, Rheumatologische Schwerpunktpraxis, Tübingen, Germany*

Background: There is some evidence that NSAIDs, in particular celecoxib (CEL), might possess not only symptomatic efficacy but also disease-modifying properties in radiographic axial spondyloarthritis (r-axSpA) formerly known as ankylosing spondylitis, retarding progression of structural damage in the spine if taken continuously. For biological disease-modifying antirheumatic drugs (bDMARDs), retardation of structural damage progression has also been demonstrated, but at least 4 years of treatment seem to be necessary (at least for tumour necrosis factor inhibitors – TNFi) to see such an effect. Therefore, a combination of an NSAID with a TNFi might bring additional benefits in terms of retardation of structural damage progression especially in high-risk patients.

Objectives: The aim of this RCT was to evaluate the impact of treatment with the COX-II-selective NSAID (CEL) when added to a TNFi (golimumab - GOL) compared with TNFi (GOL) alone on progression of structural damage in the spine over 2 years in patients with r-axSpA.

Methods: Eligible patients had r-axSpA and high disease activity (BASDAI ≥4), NSAID failure and risk factors for radiographic spinal progression: C-reactive protein >5 mg/l and/or ≥1 syndesmophyte(s). The trial consisted of two phases: a 12-week run-in phase, in which all included patients received treatment with GOL 50 mg every 4 weeks sc, followed by a 96-week controlled treatment period, in which patients who achieved a BASDAI improvement of ≥2 points were randomly assigned to GOL + CEL 200 mg bid or GOL alone arms. The primary endpoint was radiographic spinal progression as assessed by the change in the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) after 108 weeks in the intent-to-treat population, read by 3 independent readers blinded for the treatment arm and the time-point.

Results: Of the 157 screened patients, 81.5% (n=128) were enrolled into the run-in phase. 109 patients fulfilled the BASDAI response criterion at w12 and were randomized 1:1 (54 vs. 55) to GOL+CEL or GOL alone; 97 (45 vs. 52) patients completed the study at w108. Clinical characteristics of the randomized patients are shown in Tab. 1. The mSASSS change after w108 was 1.1 (95%CI 0.2; 2.0) vs. 1.7 (95%CI 0.8; 2.6) in the GOL+CEL vs. GOL alone groups, respectively, p=0.79. Figure 1 shows the cumulative probability of the mSASSS change in both treatment arms. New syndesmophytes in the opinion of three readers occurred in 11% vs. 25% of the patients in the GOL+CEL vs. GOL alone groups, respectively, p=0.12. During the study, a total of 14 serious adverse events (SAE) were reported (7 in the GOL+CEL group, 5 in the GOL alone group and 2 during the run-in phase).

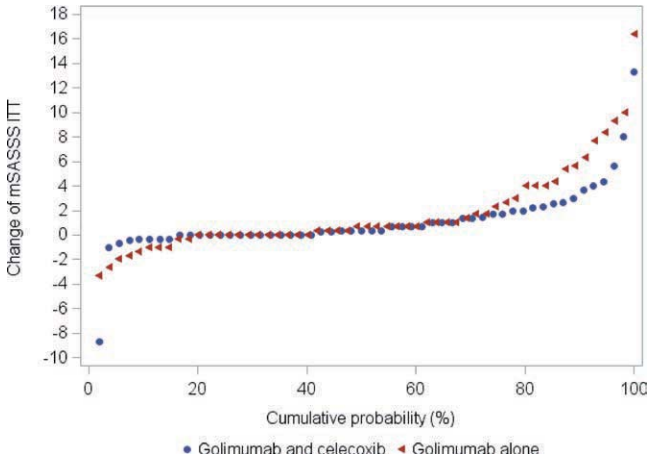

Figure 1. Cumulative probability plot of mSASSS progression over 108 weeks of treatment.

Conclusion: In this study, a combined therapy with GOL+CEL did not show significant superiority over GOL monotherapy in retarding radiographic spinal progression over two years in r-axSpA patients.

However, the observed numerical reduction in radiographic spinal progression associated with the combined treatment might be, however, clinically relevant for patients at high risk for progression.

Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. In a phase 2b study, BKZ showed rapid and sustained efficacy and was well tolerated up to 156 weeks (wks) in patients (pts) with active ankylosing spondylitis (AS).[1,2]

Objectives: To assess efficacy and safety of BKZ vs placebo (PBO) in pts with active AS up to Wk 24 in the ongoing pivotal phase 3 study, BE MOBILE 2.

Methods: BE MOBILE 2 (NCT03928743) comprises a 16-wk double-blind, PBO-controlled period and 36-wk maintenance period. Pts were aged ≥18 yrs, met modified New York criteria and had active AS (BASDAI ≥4, spinal pain ≥4) at BL. Pts were randomised 2:1, BKZ 160 mg Q4W:PBO. From Wk 16, all pts received BKZ 160 mg Q4W. Primary and secondary efficacy endpoints were assessed at Wk 16.

Results: Of 332 randomised pts (BKZ: 221; PBO: 111), 322 (97.0%) completed Wk 16 and 313 (94.3%) Wk 24. BL characteristics were comparable between groups: mean age 40.4 yrs, symptom duration 13.5 yrs; 72.3% pts male, 85.5% HLA-B27+, 16.3% TNFi-experienced. At Wk 16, the primary (ASAS40: 44.8% BKZ vs 22.5% PBO; p<0.001) and all ranked secondary endpoints were met (Table 1). Responses with BKZ were rapid, including in PBO pts who switched to BKZ at Wk 16, and increased to Wk 24 (Figure 1; Table 1). Substantial reductions of hs-CRP by Wk 2 and MRI SIJ and spine inflammation by Wk 16 were achieved with BKZ vs PBO (Table 1). At Wk 24, ≥50% pts had achieved ASDAS <2.1 (Figure 1).

Over 16 wks, 120/221 (54.3%) BKZ pts had ≥1 TEAE vs 48/111 (43.2%) PBO; three most frequent on BKZ were nasopharyngitis (BKZ: 7.7%; PBO: 3.6%), headache (4.1%; 4.5%) and oral candidiasis (4.1%; 0%). No systemic candidiasis was observed. Up to 16 wks, incidence of SAEs was low (1.8%; 0.9%); no MACE or deaths were reported; 2 (0.9%) IBD cases occurred in pts on BKZ.

Conclusion: Dual inhibition of IL-17A and IL-17F with BKZ in pts with active AS resulted in rapid, clinically relevant improvements in efficacy outcomes vs PBO. No new safety signals were observed.[1,2]

Background: Evidence reveals sex differences in physiology, disease presentation and response to treatment in axial spondyloarthritis (axSpA). Pooled data from four randomized controlled trials demonstrated reduced treatment efficacy of a tumor necrosis factor inhibitor (TNFi) in females compared to males with ankylosing spondylitis[1]. However, real-life evidence confirming these data in large cohorts is scarce. We sought to validate prior studies using data from a large multinational cohort based on real-life clinical practice.

Objectives: To investigate sex differences in treatment response and drug retention rates in clinical practice among patients with axSpA, treated with their first TNFi.

Methods: Data from biologic-naïve axSpA patients initiating a TNFi in the EuroSpA registries were pooled. In the primary analysis, propensity-score weighting was applied to assess the causal effect of sex on clinically important improvement (CII) according to ASDAS-CRP at 6 months. A generalized linear regression model was used to estimate the causal risk difference (RD) and relative risk (RR) of sex on CII. Possible covariates influencing the outcome were determined a priori and selected based on availability in the database (<20% missing). The final covariates included in the model were country, age and TNFi start year. In the secondary analysis, drug retention was assessed over 24 months of follow-up by Kaplan-Meier curves and log-rank test.

Results: In total, 6,451 axSpA patients with available data on ASDAS-CRP at baseline and 6 months were assessed for treatment response. Baseline characteristics are shown in the Table 1. In the adjusted analysis, the probability for females to have CII was 15% (RR, 0.85; 95% confidence interval [CI], 0.82 to

0.89) lower compared to males and the difference in probability for having CII was 9.4 percentage points (RD, 0.094; 95% CI, 0.069 to 0.12). The survival analysis included 28,608 axSpA patients with available data on retention rates. The TNFi 6/12/24-month retention rates were significantly lower in females (81%/69%/58%) compared to males (89%/81%/72%), see Figure 1.

Table 1.

	Female	Male
	Mean (SD), Median [IQR] or percentages	Mean (SD), Median [IQR] or percentages
Age (years)	42.0 (12.1)	41.4 (12.3)
Fulfilment of mNYC	66%	80%
Disease duration (years)	2.0 [1.0, 7.0]	3.0 [1.0, 9.0]
TNFi start year		
Start 1999-2009	7.2%	9.8%
Start 2010-2013	26%	27%
Start 2014-2016	37%	36%
Start 2017-2020	30%	27%

mNYC, modified New York criteria; TNFi, tumor necrosis factor inhibitor; BASDAI, Bath Ankylosing Spondylitis Disease Activity Indexf; BASFI, Bath Ankylosing Spondylitis Functional Index; ASDAS, Ankylosing Spondylitis Disease Activity Score; CRP, C-reactive protein; SJC, swollen joint count; TJC, tender joint count; VAS, visual analogue scale.

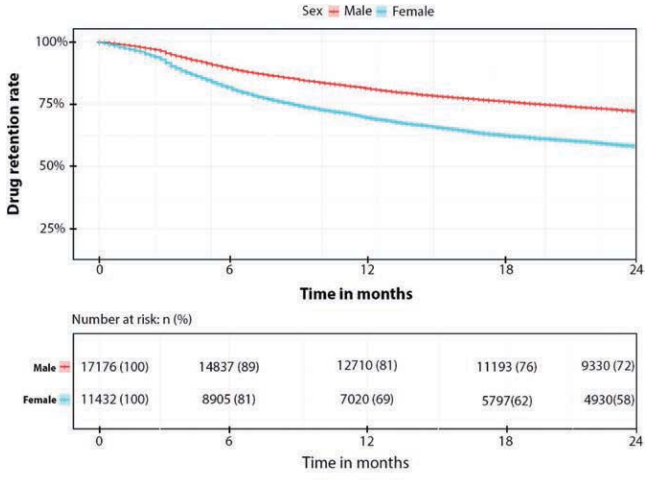

Figure. Sex differences in 24-month retention rates in first-line tumor necrosis factor inhibitors in patients with axial spondyloarthritis in EuroSpA (Kaplan-Meier, log-rank test; p<0.001).

Conclusion: Treatment efficacy and retention rates are lower among female patients with axSpA initiating their first TNFi. Females presented with lower C-reactive protein levels and higher scores on patient reported outcomes at baseline, reflecting differences in disease expression. Recognizing these sex differences is of relevance for customized patient care and may improve patient education.

TREATMENT WITH NON-STEROIDAL ANTI-INFLAMMATORY DRUGS IS ASSOCIATED WITH RETARDATION OF RADIOGRAPHIC SPINAL PROGRESSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: 10-YEAR RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT

M. Torgutalp[1], V. Rios Rodriguez[1], A. Dilbaryan[2], F. Proft[1], M. Protopopov[1], M. Verba[1], J. Rademacher[1], H. Haibel[1], J. Sieper[1], M. Rudwaleit[3], D. Poddubnyy[1]. *[1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Gastroenterology, Infectious Diseases, and Rheumatology (including Nutrition Medicine), Berlin, Germany*; *[2]Moscow City Clinical Hospital, Department of Internal Medicine, Moscow, Russian Federation*; *[3]University of Bielefeld, Department of Internal Medicine and Rheumatology, Bielefeld, Germany*

Background: There are conflicting data regarding effect of nonsteroidal anti-inflammatory drugs (NSAID) on radiographic spinal progression in axial spondyloarthritis (axSpA). The analysis of the first 2-year of the GErman SPondyloarthritis Inception Cohort (GESPIC) showed that higher NSAID intake may retard new bone formation in r-axSpA. It remained, however, unclear, whether cyclooxygenase-2 selective inhibitors (COX2i) might have a stronger effect than non-selective (NS) ones and if the effect could be observed also in nr-axSpA.

Objectives: To investigate the effect of NSAIDs (COX2i and NS) intake on radiographic spinal progression in patients with r-axSpA and nr-axSpA.

Methods: Based on availability of at least two sets of spinal radiographs during 10-year follow-up, 243 patients with early axSpA (130 and 113 nr- and r-axSpA, respectively) from GESPIC were included in this analysis. The patients contributed a total of 540 2-year radiographic intervals. Radiographs were scored by 3 trained and calibrated readers according to modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Final mSASSS was calculated as a mean of 3 readers, and progression was defined as absolute mSASSS change score over 2 years. NSAID type, daily dose, and frequency of intake were recorded at visits. The ASAS index of NSAID intake (0-100) counting both dose and duration of intake was calculated for intervals. The association between NSAID intake

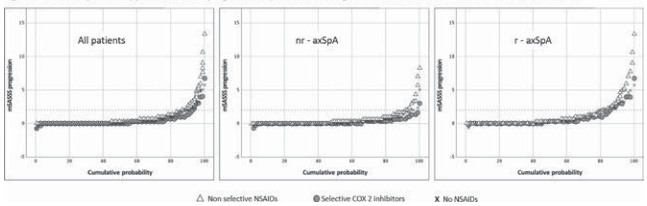
(NSAID type and NSAID score) and radiographic spinal progression over 2 years was analysed using longitudinal generalized estimated equations (GEE).
Results: At baseline, 161 (66.3%) patients were treated with NSAIDs. While 289 (53.5%) and 128 (23.7%) 2-year radiographic intervals were covered by NS and COX-2i respectively, 123 (22.8%) intervals were not covered by NSAID. The significant association between higher NSAID intake and retardation of radiographic spinal progression was found in adjusted multivariable longitudinal GEE analysis. This effect was mostly attributable to patients with r-axSpA (Table 1). mSASSS progression was numerically lower in patients taking COX2i (irrespectively of dose) as compared to patients treated with NS-NSAIDs; in stratified analysis, however, there was no clear dose-dependency (as reflected by NSAID index) in both groups (Figure 1, Table 1).

Table 1. The association between radiographic spinal progression (mSASSS change score) and NSAID intake in patients with axSpA in multivariable longitudinal GEE

	All axSpA β (95% CI)* (n=461)	nr-axSpA β (95% CI)* (n=244)	r-axSpA β (95% CI)* (n=217)
NSAID intake score, per 10 points	**-0.04 (-0.09, 0.00)**	-0.02 (-0.06, 0.02)	**-0.07 (-0.13, 0.00)**
NSAID type§			
NS inhibitors vs No NSAID	0.30(-0.07, 0.66)	0.25(-0.07, 0.57)	0.26(-0.40, 0.92)
COX2i vs No NSAID	0.17(-0.19, 0.54)	0.15(-0.15, 0.46)	0.18(-0.49, 0.85)
COX2i vs NS inhibitors	-0.12(-0.37, 0.12)	-0.10(-0.28, 0.09)	-0.08(-0.57, 0.40)
Analysis stratified according to NSAID type			
Non-selective NSAID intake score, per 10 points	-0.06(-0.12, 0.00)	-0.04(-0.09, 0.01)	-0.07(-0.17, 0.03)
COX2 selective NSAID intake score, per 10 points	-0.06(-0.13, 0.02)	-0.03(-0.07, 0.02)	-0.09(-0.18, 0.01)

axSpA: axial spondyloarthritis; COX2i, cyclooxygenase-2 selective inhibitors; n, number of current 2-year radiographic intervals in multivariable analyses; NS, non-selective COXi; NSAID, non-steroidal anti-inflammatory drugs. *All multivariable models were adjusted for sex, symptom duration at the beginning of the interval, time-averaged ASDAS the interval, classification as radiographic axSpA, smoking in the interval, mSASSS at the beginning of theinterval, and TNFi use in the interval. §NSAID intake score was added in this model.

Figure. Cumulative probability plots of mSASSS progression in patients receiving no NSAIDs, non-selective NSAIDs and selective COX2i.



Conclusion: Higher NSAID intake is associated with lower radiographic spinal progression, particularly in r-axSpA patients. COX2i might possess a stronger inhibitory effect on radiographic progression as compared to NS-NSAIDs.

Kristensen[10,11]. *[1]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark*; *[2]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*; *[3]The Parker Institue, Bispebjerg and Frederiksberg Hospital, Section for Biostatistics and Evidence-Based Research, Copenhagen, Denmark*; *[4]Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark*; *[5]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; *[6]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*; *[7]Randers Regional Hospital, Department of Rheumatology, Randers, Denmark*; *[8]Odense University Hospital, Department of Rheumatology, Odense, Denmark*; *[9]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; *[10]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark*; *[11]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*

Background: Traditionally, biologics are maintained lifelong at standard dose in patients with inflammatory arthritis (IA) when sustained low disease activity (LDA) is reached. However, evidence of possible tapering is emerging but data on the optimal approach is lacking.
Objectives: The primary outcomes at 18 months follow-up are:

- *Superiority:* The proportion of patients reduced to ≤50% of their baseline biologic dose.
- *Equivalence:* Disease activity (rheumatoid arthritis [RA] and psoriatic arthritis [PsA]: Disease Activity Score28-C-Reactive Protein [DAS28-CRP] and axial spondyloarthritis [axSpA]: Ankylosing Spondylitis Disease Activity Score [ASDAS]).

Methods: The BIODOPT trial was a randomised, open-label, equivalence trial (EudraCT 2017-001970-41). Eligible patients were adults with RA, PsA, or axSpA in LDA on stable biologic doses during ≥12 months. The randomisation ratio was 2:1 (tapering:continuation) stratified by diagnosis, centre, and repeated biologic failures. In the tapering group, the biologic dosing interval was prolonged by 25% every four months until flare or discontinuation. The continuation group was kept on their baseline biologic dosing interval; however, a small increase was allowed (as usual practise) if requested by the patient. The sample size calculation was based on a pre-defined equivalence margin of ±0.5 disease activity points (<half of the minimal important difference in DAS28-CRP [>1.2] or ASDAS [>1.1]) yielding a power of 87% for 180 enrolled patients. All analyses were based on the intention-to-treat population. Continuous outcomes were analysed with repeated-measures linear mixed-effects models with group, diagnosis, centre, repeated biologic failures, time point, and the interaction between group and time as fixed factors and the baseline value of the relevant variable as a covariate. Categorical outcomes were analysed using logistic regression with missing data imputed as trial failures.
Results: Between May, 2018, and March, 2020, 142 patients were enrolled of which 95 were randomised to tapering and 47 to continuation; inclusion was closed in April 2020 due to national implications of the coronavirus pandemic.
At 18 months, significantly more patients in the tapering group (35 patients [(37%]) achieved a significant reduction in their biologic dose (≥50%) compared to the continuation group (one patient [2%]), absolute risk difference (RD) 35%, 95%CI: 24% to 45%, p<0.0001, Table 1. Furthermore, disease activity at 18 months was within the equivalence margins of ±0.5, mean difference between groups 0.08, 95%CI: -0.12 to 0.29; Table 1 and Figure 1. Flares were more frequent in the tapering group (39 [41%] vs 10 [21%], RD 0.20, 95%CI: 0.04 to 0.35, p=0.011) but managed with rescue therapy (e.g. biologic dose escalation or glucocorticoids) as only one patient (1%) in the tapering group and three patients (6%) in the continuation group lost therapeutic response and were switched to another biological agent.

Table 1. Comparison at 18 months in the ITT population

Outcome	Tapering group N = 95	Continuation group N = 47	Group difference (95%CI)	p-value
Primary outcome:				
Biologics reduced to ≤50%, n (%)	35 (37%)	1 (2%)	0.35 (0.24 to 0.45)	<0.001
Disease activity, LSMeans (SE)	1.84 (0.15)	1.75 (0.16)	0.08 (-0.12 to 0.29)	0.428
Key secondary outcomes:				
Remission[1], n (%)	63 (66%)	33 (70%)	-0.04 (-0.20 to 0.12)	0.637
Low disease activity[2], n (%)	79 (83%)	41 (87%)	-0.04 (-0.16 to 0.08)	0.511
Flares[3], n (%)	39 (41%)	10 (21%)	0.20 (0.04 to 0.35)	0.011

N: number, CI: confidence interval, LSMeans: Least squares means, SE: Standard error. [1]: RA or PsA: DAS28-CRP <2.6. AxSpA: ASDAS <1.3. [2]: RA or PsA: DAS28-CRP <3.2. AxSpA: ASDAS <2.1. [3]: RA or PsA: ΔDAS28-CRP >1.2 or ΔDAS28-CRP >0.6 AND current DAS28-CRP ≥3.2. AxSpA: inflammatory back pain AND ΔASDAS ≥0.9 and/or ≥1 swollen joint.

Conclusion: Across IA conditions, a significant reduction of biologic dose is possible with disease activity-guided tapering while maintaining a similar disease activity state compared to continuation of biologic as usual care.

Background: Ankylosing spondylitis (AS) is a chronic, systemic inflammatory condition characterized by inflammatory back pain and is associated with extra-musculoskeletal manifestations and systemic comorbidities. Secukinumab (SEC) doses of 150 mg and 300 mg are approved to treat AS, although no dose escalation studies are available in patients who have inadequate response to SEC 150 mg.

Objectives: The ASLeap study (NCT03350815) estimated the difference in clinical response to SEC 300 mg vs 150 mg at Week (Wk) 52 in patients with AS who failed to achieve Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease status on SEC 150 mg at Wk 16.

Methods: In this randomized, double-blind, parallel-group, multicenter, phase 4 study, 322 patients with AS were assigned to receive open-label SEC 150 mg administered per the label for 16 Wks (period 1). At Wk 16, patients who did not achieve inactive disease (ASDAS < 1.3) at Wks 12 and 16 were randomized 1:1 in a double-blind manner to SEC 150 mg or escalated to SEC 300 mg q4w to Wk 52 (period 2). The primary efficacy variable was achievement of ASDAS < 1.3 and the primary analysis time point was Wk 52. Secondary efficacy variables were achievement of ASDAS clinically important improvement ≥ 1.1, 50% improvement in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50), Assessment of SpondyloArthritis international Society responses (ASAS20, ASAS40, and ASAS partial remission), and change from baseline in BASDAI, ASAS Health Index (ASAS-HI), and the Functional Assessment of Chronic Illness Therapy – Fatigue Scale (FACIT-F). Safety was evaluated by incidence of treatment-emergent adverse events (TEAEs) through Wk 52. No statistical hypothesis tests for superiority or equivalence were planned in the protocol and none were performed.

Results: Of 279 patients receiving SEC 150 mg who completed the 16-wk open-label period 1, 22 (7.9%) achieved ASDAS < 1.3 at Wks 12 or 16 and continued receiving SEC 150 mg; 207 patients did not attain ASDAS < 1.3 at Wk 12 and Wk 16 and initiated period 2. Demographics and baseline disease characteristics were balanced between patients randomized to SEC 150 mg and SEC 300 mg, including the proportion of patients who were TNFi naive (SEC 150 mg: 73 [72.3%]; SEC 300 mg: 73 [69.5%]) (Table 1). Approximately 60% of patients in either SEC group were HLA-B27 positive. After having an inadequate response to SEC 150 mg through Wk 16, patients receiving either dose of SEC experienced similar improvements at Wk 52 in disease activity as measured by achievement of ASDAS < 1.3, ASDAS clinically important improvement ≥ 1.1, BASDAI50, ASAS20, ASAS40, and ASAS partial remission; and mean changes in BASDAI, quality of life as measured by ASAS HI, and fatigue as measured by FACIT-F (Figure 1). The incidence of TEAEs through Wk 52 was similar between patients receiving SEC 300 mg (63.4%) and 150 mg (68.6%).

Table 1. Demographics and Baseline Disease Characteristics of Patients in Period 2 (safety set)

Characteristic	Secukinumab 150 mg → 300 mg N = 101	Secukinumab 150 mg → 150 mg N = 105
Age, mean (SD), years	48.5 (14.1)	47.0 (13.7)
Female, n (%)	43 (42.6)	52 (49.5)
BMI, mean (SD), kg/m^2	32.0 (8.0)	32.1 (7.7)
HLA-B27 positive, n (%)	60 (59.4)	65 (61.9)
Time since axial symptom onset, mean (SD), years	13.9 (11.7)	14.0 (12.5)
Time since diagnosis of AS, mean (SD), years	4.7 (8.6)	5.1 (9.7)
TNFi naive, n (%)	73 (72.3)	73 (69.5)
History of extra-axial involvement, n (%)		
Peripheral arthritis	34 (33.7)	30 (28.6)
Enthesitis	29 (28.7)	31 (29.5)

Clinical aspects in Psoriatic Arthritis

OP0024

DIFFERENTIATION BETWEEN IL-6 AND IL-17 PATHWAY INHIBITION IN RELATIONSHIP WITH CLINICAL OUTCOMES IN NON-BIOLOGICAL DMARD-IR AND BIOLOGICAL DMARD-IR PSORIATIC ARTHRITIS PATIENTS TREATED WITH UPADACITINIB IN SELECT-PSA 1 AND SELECT-PSA 2 STUDIES

F. Cai[1], T. Sornasse[1], M. Ruzek[2], Y. Fang[3], K. Kato[4], P. Wung[4], I. McInnes[5].
[1]AbbVie, Precision Medicine - Immunology, South San Francisco, United States of America; *[2]AbbVie, Discovery - Immunology, Worcester, United States of America*; *[3]AbbVie, DMPK-BA, South San Francisco, United States of America*; *[4]AbbVie, Immunology, North Chicago, United States of America*; *[5]University of Glasgow, Institute of Infection, Immunity, and Inflammation, Glasgow, United Kingdom*

Background: The differential contribution of IL-6 and IL-17 pathways to the pathogenesis of psoriatic arthritis (PsA) is not fully understood. Upadacitinib (UPA), an oral JAK inhibitor, was more effective than placebo (PBO) in improving key clinical manifestations of PsA in two global phase 3 trials, SELECT-PsA 1 (non-biological DMARD-IR, nbDMARD-IR) and SELECT-PsA 2 (biological DMARD-IR, bDMARD-IR).[1,2] Targeted proteomic analysis suggested that UPA modulates multiple biological pathways in innate and adaptive immune systems via direct and indirect inhibition of key regulators, including IL-6 and IL-17 pathways, with a possible shift from Th1 predominance in nbDMARD-IR PsA to a more Th17 bias in bDMARD-IR PsA.[3]

Objectives: We assessed the relationship between IL-6 and IL-17 pathway modulation and different clinical outcomes after UPA treatment in nbDMARD-IR and bDMARD-IR PsA patients.

Methods: A subset of patients was randomly selected from SELECT-PsA 1 (n=74 of UPA 15 mg QD, n=74 of PBO) and PsA 2 studies (n=90 of UPA 15 mg QD, n=81 of PBO). Serum levels of IL-6, IL-17A, IL-17F, and beta-defensin 2 (BD2) proteins were measured at baseline, week 2, and week 12 by validated immunoassays. The quantitative cytokine measurements were transformed as log10, and PASI score was transformed as $\log_{10}$ (x+1) prior to analysis. A Repeated Measure Mixed Linear Model was used to compare UPA versus PBO treatment effects in overall selected patients and between responders and non-responders defined by PASDAS score ≤ 3.6 (Minimal Disease Activity, MDA)[4] and PASI75 at week 12, respectively. The relationships between cytokines and clinical outcomes (PASI and DAS28-CRP) were assessed by Pearson's correlation at baseline and after treatment.

Results: In nbDMARD-IR PsA patients, baseline IL-17A, IL-17F, and BD2 levels correlated with each other and with PASI, while IL-6 appeared independent from the IL-17 pathway and correlated with DAS28-CRP. At week 12, UPA treatment significantly decreased IL-6 and BD2. The decrease of IL-6 was more pronounced in PASDAS MDA responders and correlated with DAS28-CRP improvement, but the decrease of BD2 was significant in PASI75 responders and correlated with PASI improvement. In contrast, IL-17A and IL-17F were not significantly changed after UPA treatment, neither correlated with clinical outcomes at week 12.

In bDMARD-IR PsA patients, baseline IL-17A level was significantly elevated compared to nbDMARD-IR patients but weakly correlated with other cytokines and show no correlation with PASI. At week 12, the reduction of IL-6 after UPA treatment was not different between responders and non-responders (PASDAS MDA or PASI75) and did not correlate with DAS28-CRP improvement, while the reduction of BD2 remained significant in PASI75 responders and correlated with PASI improvement. Further, UPA treatment significantly reduced IL-17A in PASDAS MDA responders and IL-17F in PASI75 responders compared to non-responders, respectively. The reduction of IL-17F correlated with PASI improvement at week 12.

Conclusion: IL-6 and IL-17 pathway inhibition after UPA treatment showed different profiles in relationship with clinical outcomes in nbDMARD-IR versus bDMARD-IR PsA patients. IL-6 decrease was more pronounced in nbDMARD-IR PsA patients and associated with joint manifestation improvement, while IL-17A and IL-17F decreases were only observed in bDMARD-IR PsA patients and associated with psoriasis improvement. BD2, a biomarker of Th17-associated skin pathology, significantly decreased after UPA treatment in both nbDMARD-IR and bDMARD-IR PsA studies, which likely contributed to UPA effects on psoriasis improvement in a broad range of PsA patients.

FACTORS ASSOCIATED WITH FATIGUE AND ITS IMPROVEMENT – A PRINCIPAL COMPONENT ANALYSIS OF PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS FROM GUSELKUMAB PHASE 3 TRIALS

P. Rahman[1], P. J. Mease[2], A. Deodhar[3], A. Kavanaugh[4], S. D. Chakravarty[5,6], A. Kollmeier[7], Y. Liu[8], M. Shawi[9], C. Han[8]. [1]*Memorial University of Newfoundland, Craig L Dobbin Genetics Research Centre, St John's, Canada*; [2]*Swedish Medical Center Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America*; [3]*Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America*; [4]*University of California San Diego, Center for Innovative Therapy, San Diego, United States of America*; [5]*Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America*; [6]*Drexel University College of Medicine, Division of Rheumatology, Philadelphia, United States of America*; [7]*Janssen Research & Development, LLC, Immunology, San Diego, United States of America*; [8]*Janssen Research & Development, LLC, Immunology, Spring House, United States of America*; [9]*Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America*

Background: Fatigue, one of the top 3 patient (pt)-reported symptoms of psoriatic arthritis (PsA) and a recent PsA outcome domain,[1] causes impaired health-related quality-of-life, diminished productivity, and disability.[1-3] Although the origins of fatigue are multifactorial, inflammation is hypothesized to play an important role.[4] In pts with active PsA, treatment with guselkumab (GUS) led to clinically meaningful and sustained improvements in fatigue through 1 year in DISCOVER-1 (D1) and DISCOVER-2 (D2).[5]

Objectives: To identify 1) factors associated with fatigue and 2) factors associated with change in fatigue among pts with PsA treated with GUS.

Methods: In the Phase 3 D1 (N=381, biologic-naïve and tumor necrosis factor inhibitor-experienced) and D2 (N=739, biologic-naïve) studies, pts with active PsA despite standard therapies and/or biologic disease-modifying antirheumatic drugs were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO) with crossover to GUS 100 mg Q4W at W24. The pt-reported Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue) scale measured fatigue (scored 0-52). In these post-hoc analyses of D1 and D2 pts, a principal component analysis (PCA) was performed using W0 data to identify the underlying baseline factors associated with fatigue. Additionally, linear regression analyses were performed to identify covariates associated with change in fatigue from W0 to W24.

Results: In 1120 pts (mean age 47 yrs, mean disease duration 5.9 yrs, 48% female), mean FACIT-Fatigue scores at baseline ranged from 29.1 to 31.4 (vs 43.6 for the general US population).[5] PCA showed that 62% of the variability in fatigue could be explained by 3 components (Figure 1). The first component, explaining 34% of variability in fatigue, largely comprised systemic disease activity and function measures such as pain, pt global assessment of disease activity (PtGDA), physician's global assessment of disease activity, and Health Assessment Questionnaire-Disability Index (HAQ-DI). The second component, explaining 16% of variability, comprised joint manifestations including swollen joint count (SJC) and tender joint count (TJC). Skin involvement as assessed by Psoriasis Area and Severity Index (PASI) and systemic inflammation (C-reactive protein [CRP]) could explain 12% of the variability in fatigue (Figure 1 and Table 1). In a multivariate linear regression analysis, after adjusting for effects from other variables, improvement in CRP, physical function (HAQ-DI), PtGDA, and PASI score were significantly associated with fatigue improvement in GUS-treated pts at W24 (all p<0.001).

Table 1. PCA of Pts With Active PsA in D1+D2 (N=1120; Pooled W0 data): Factor Loading Estimates by Covariates

	Component1 Systemic Disease Activity and Function	Component 2 Joint Manifestations	Component 3 Skin Involvement and Inflammation
PsA disease duration, yr	0.10	0.14	0.25
PASI total score (0-72)	0.22	0.23	**0.74**
CRP, mg/dL	0.36	-0.13	**0.55**
HAQ-DI score (0-3)	**0.73**	-0.09	-0.19
Pain (0-10 VAS)	**0.83**	-0.35	-0.13
PtGDA (0-10 VAS)	**0.82**	-0.36	-0.16
Physician global assessment of disease activity (0-10 VAS)	**0.65**	-0.18	0.23
SJC (0-66)	0.50	**0.74**	-0.12
TJC (0-68)	0.54	**0.70**	-0.18

VAS=Visual Analog Scale.

Conclusion: Among pts with PsA, measures of systemic disease activity and function, followed by joint manifestations, and skin involvement/inflammation accounted for 62% of the variability in fatigue. The large residual effect (38%) that was unexplained by the current model suggests the need for further research to identify additional factors (eg, distinct molecular pathways) contributing to the fatigue reported by PsA pts.

OP0026

CLINICAL AND IMAGING-BASED CHARACTERIZATION OF A PROSPECTIVE COHORT OF PATIENTS WITH AXIAL PSORIATIC ARTHRITIS (AXIAL PSA). GESPIC-AXIAL PSA: RESULTS OF AN INTERIM ANALYSIS

H. Käding[1], S. Lüders[1], M. Protopopov[1], J. Rademacher[1], V. Rios Rodriguez[1], L. Spiller[1], M. Torgutalp[1], D. Poddubnyy[1,2], F. Proft[1]. *[1]Charité - Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany*; *[2]German Rheumatism Research Centre, Epidemiology unit, Berlin, Germany*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease, which is subsumed together with axial spondyloarthritis (axial SpA) under the umbrella term spondyloarthritis, whose clinical presentations are very heterogeneous. Axial involvement (axial PsA) has been described to be present in 34% of PsA patients [1] and has been systematically investigated only retrospectively or in cross-sectional studies [2]. Although axial PsA seems to have similar characteristics to axial SpA, it is not clear whether axial PsA and axial SpA, are a spectrum of the same disease with different expression patterns or different diseases with great similarities.

Objectives: To prospectively investigate the clinical and imaging morphology patterns in a well-defined cohort of patients with axial PsA from the German SPondyloarthritis Inception Cohort (GESPIC).

Methods: Prospective, longitudinal, observational study of patients with an imaging confirmed diagnosis of axial PsA. In addition to clinical and laboratory characterization, conventional radiographs and magnetic resonance imaging (MRI) - scans of the entire spine and sacroiliac joints (SIJs) are performed at the baseline visit and patients are followed up every 6 months according to a predefined protocol. After 2 years, additional imaging (X-ray and MRI) is performed for follow-up. In this interim analysis baseline data are presented.

Results: Between August 2019 and December 2021, 85 axial PsA patients were included. The mean age was 45.2 ± 12.9 years with a proportion of 55.3% female patients. Peripheral involvement was present in 43 (50.6%) patients, HLA-B27 was positive in 39 (45.9%), and C-reactive protein was elevated (>5mg/l) in 27 (31.8%) patients. Inflammatory back pain (IBP) in the discretion of the treating rheumatologist was present in 64 (75.3%) patients (Table 1). The modified New York criteria were fulfilled in 44.9% (n=35). MRI of the SIJ showed active inflammatory changes in 44 (55%) and structural changes in 59 (73.8%) patients. MRI of the spine showed active inflammation in 60% (n=48). Exclusively active and/or structural changes of the spine without changes in the SIJ were seen in 18.8% (n=15) (Figure 1).

Table 1. Characteristics of patients with axial PsA

Parameters	Axial PsA (n=85)
Age in years (mean ± SD)	45.2 ± 12.9
Female sex, n (%)	47 (55.3%)
Inflammatory back pain (IBP) present, n (%)	64 (75.3%)
Peripheral Involvement, n (%)	43 (50.6%)
Nail Involvement, n (%)	39 (45.9%)
PASI-Score (mean ± SD)	3.3 ± 5.1
BASDAI (mean ± SD), 0-10	4.9 ± 2.0
BASFI (mean ± SD), 0-10	3.8 ± 2.5
ASDAS-CRP (mean ± SD)	2.8 ± 1.0
DAPSA (mean ± SD)	14.5 ± 9.2
HLA-B 27 positive, n (%)	39 (45.9%)
CRP >5mg/l, n (%)	27 (31.8%)

ASDAS-CRP =Ankylosing Spondylitis Disease Activity Score - CRP, BASDAI = Bath Ankylosing Spondylitis Disease Activity Index, BASFI =Bath Ankylosing Spondylitis Functional Index, CRP = C-reactive protein, DAPSA = Disease Activity in PSoriatic Arthritis-Score, PASI = Psoriasis Area Severity Index, PsA = Psoriatic arthritis*, SD = standard deviation.*

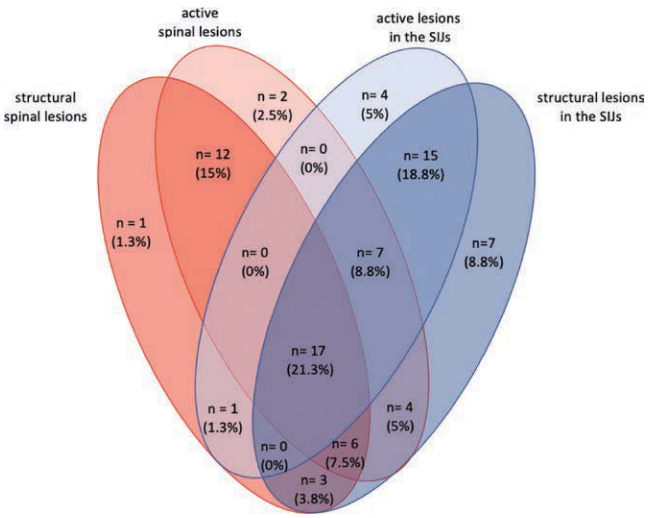

Figure 1. MRI-imaging patterns of axial PsA patients (n=80*)**.** MRI= magnetic resonance imaging, SIJs= sacroiliac joints. *Full imaging data available for 80 patients only due to variable reasons.

Conclusion: In the here presented interims analysis of the baseline data of our prospective cohort study of patients with an imaging-based diagnosis of axial PsA, it is shown that these patients are less frequently HLA-B27 positive and more frequently female when compared to previously described cohorts of "classical" axial SpA patients. Noteworthy, nearly 20% of the patients showed an isolated spinal involvement without active or structural changes in the SIJs.

ASSOCIATION BETWEEN BASELINE CARDIOVASCULAR RISK AND INCIDENCE RATES OF MAJOR ADVERSE CARDIOVASCULAR EVENTS AND MALIGNANCIES IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS RECEIVING TOFACITINIB

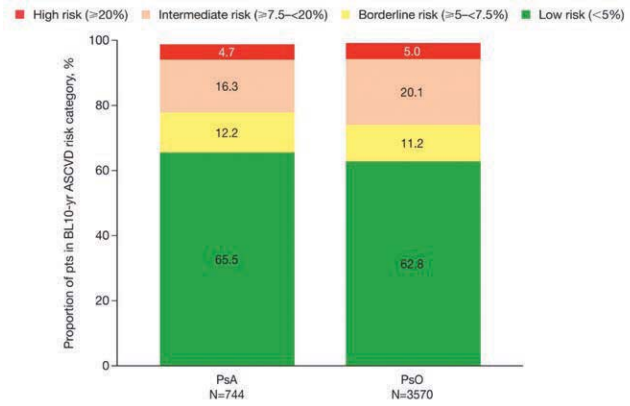
Background: Common comorbidities of psoriatic arthritis (PsA) and psoriasis (PsO) are cardiovascular (CV) disease and metabolic syndrome (MetS).[1,2] Risk of CV disease may be associated with increased risk of future malignancies.[3] Tofacitinib is a JAK inhibitor for treatment of PsA and has been investigated for treatment of PsO.
Objectives: To examine baseline (BL) CV risk and its association with incidence rates (IRs) of major adverse CV events (MACE) and malignancies in tofacitinib-treated patients (pts) with PsA and PsO.
Methods: Analysis included data from 3 (Phase [P]3/long-term extension [LTE]) trials of pts with PsA and 7 (P2/3/LTE) trials of pts with PsO receiving ≥1 dose of tofacitinib (5 or 10 mg twice daily). IRs (pts with events/100 pt-yrs) for MACE and malignancies (excluding non-melanoma skin cancer) were stratified by: history of coronary artery disease (HxCAD [≥1 of myocardial infarction, coronary heart disease, coronary artery procedure or stable angina pectoris]); BL 10-yr atherosclerotic CV disease (ASCVD) risk (ASCVD-pooled cohort equations calculator [only in pts without HxCAD]); and BL MetS (≥3 of hypertension, raised triglycerides, reduced high-density lipoprotein cholesterol, high waist circumference or high fasting glucose levels).
Results: Of 783 and 3663 pts with PsA and PsO, total tofacitinib exposure was 2038 and 8950 pt-yrs, and median duration of exposure was 3.0 and 2.4 yrs, respectively. In pts with PsA and PsO, 5.0% and 2.5% had HxCAD, respectively; in those without HxCAD, >20% had intermediate/high BL 10-yr ASCVD risk (Figure 1). At BL, 40.9% and 32.7% of pts with PsA and PsO had MetS, respectively. IRs of MACE were greatest in pts with PsA and PsO who had HxCAD/high BL 10-yr ASCVD risk (Table 1). In the PsA cohort, 5/6 pts with MACE had BL MetS. IRs of malignancies in pts with PsA were greatest in those with intermediate/high BL 10-yr ASCVD risk; 8/9 pts with malignancies in these risk categories had BL MetS (Table 1). In the PsO cohort, IR of malignancies was notably greater in those with high vs low/intermediate BL 10-yr ASCVD risk (Table 1).

Fig. BL 10-yr ASCVD risk in pts without HxCAD with PsA and PsO receiving tofacitinib



Data unavailable for 1.3% of pts with PsA and 1.0% of pts with PsO
PsA trials: NCT01877668; NCT01882439; NCT01976364. PsO trials: NCT01276639; NCT01309737; NCT01241591; NCT01186744; NCT00678210; NCT01710046; NCT01163253
N, total pts

Conclusion: In tofacitinib-treated pts with PsA and PsO, raised CV risk and MetS at BL were potentially associated with higher IRs of MACE and malignancies. Our findings support assessing CV risk in pts with PsA and PsO and enhanced monitoring for malignancies in those with raised CV risk.

OP0028

EARLY ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS IS ASSOCIATED WITH LONG-TERM IMPROVEMENTS IN QUALITY OF LIFE

S. Snoeck Henkemans[1], P. De Jong[1], J. Luime[1], M. R. Kok[2], I. Tchetverikov[3], A. Van der Helm-van Mil[1,4], M. Vis[1], on behalf of CICERO. *[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands*; *[2]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[3]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; *[4]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Minimal disease activity (MDA) is a treatment target in psoriatic arthritis (PsA) that takes both clinical manifestations (joints, skin and enthesis) and the patient perspective into account (1). In a previous study we have shown that achieving MDA in the first year is associated with better quality of life (QoL) regardless whether this was achieved early or late in the first year (2). However, the impact of achieving MDA within the first year on the long-term is lacking.
Objectives: To compare quality of life at 1, 2 and 3 years between PsA patients who achieve MDA in the first year and those who do not.
Methods: Newly diagnosed, DMARD naïve PsA patients with oligo- or polyarthritis and at least 3 years of follow-up, participating in the Dutch southwest Early PsA cohoRt (DEPAR) were included. In short the DEPAR is an observational cohort of newly diagnosed PsA (3). Study visits took place at 3, 6, 9, 12, 18, 24 and 36 months after diagnosis. Patients were categorized in three groups by achievement of MDA in the first year:

- Sustained MDA, includes patients who were in MDA at both their 9- and 12-month visit;
- Non-sustained MDA, includes patients who achieved MDA in the first year but did not sustain it at both 9- and 12-months;
- No MDA, includes patients who did not achieve MDA in the first year.

To measure QoL at 1, 2 and 3 years the Short form-36 (SF-36) questionnaire was used. Descriptive statistics were used to compare QoL.
Results: We included 243 patients (51% male) of whom 113 (47%) were classified as sustained MDA, 64 (26%) as non-sustained MDA and 66 (27%) as no MDA. At baseline, patients had a mean age of 52.7 years and median symptom duration of 9.3 months. Patients in the no MDA group seemed to be older, were more often female and had a longer symptom duration (Table 1). QoL of sustained MDA patients was comparable to the general Dutch population (4) after 1, 2 and 3 years of follow-up. However, patients who did not achieve MDA in the first year had a lower QoL compared to the sustained MDA group and these differences persist in the years thereafter (Figure 1). The physical as well as the mental QoL domains were worse in the no MDA group compared to the other groups.

Table 1. Baseline characteristics of patients categorized by MDA group

	Sustained MDA (n=113)	Non-sustained MDA (n=64)	No MDA (n=66)
Demographics			
Age (years)	51.8 ± 13	51.8 ± 14	55.3 ± 13
Sex (male)	69 (61)	33 (52)	21 (32)
Symptom duration (months)	8.5 (4-24)	8.1 (3-28)	12.9 (5-51)
Disease activity			
Swollen joint count (66)	3 (2-5)	4 (1-6)	4 (2-8)
Tender joint count (68)	3 (1-6)	4 (2-8)	8 (4-13)
Psoriasis	95 (84)	58 (91)	56 (85)
BSA in case of psoriasis (%)	3 (2-4)	3.3 (1-6.5)	3 (1.5-6)
Enthesitis	29 (26)	28 (44)	38 (58)
LEI in case of enthesitis	1 (1-2)	2 (1-2)	2 (1-4)
HAQ	0.38 (0.13-0.75)	0.75 (0.5-1)	1 (0.75-1.38)
VAS global	31 (15-56)	46 (23-65)	59 (50-77)
VAS pain	28 (12-52)	50 (26-66)	69 (53-80)

Results are shown as mean ± standard deviation, n (%) or median (interquartile range). BSA: Body Surface Area; LEI: Leeds Enthesitis Index; HAQ: Health Assessment Questionnaire; VAS: visual analogue scale.

Over the years, treatment was intensified in all groups, with biologicals use after three years at 18%, 25% and 31% in the sustained MDA, non-sustained MDA and no MDA group, respectively.

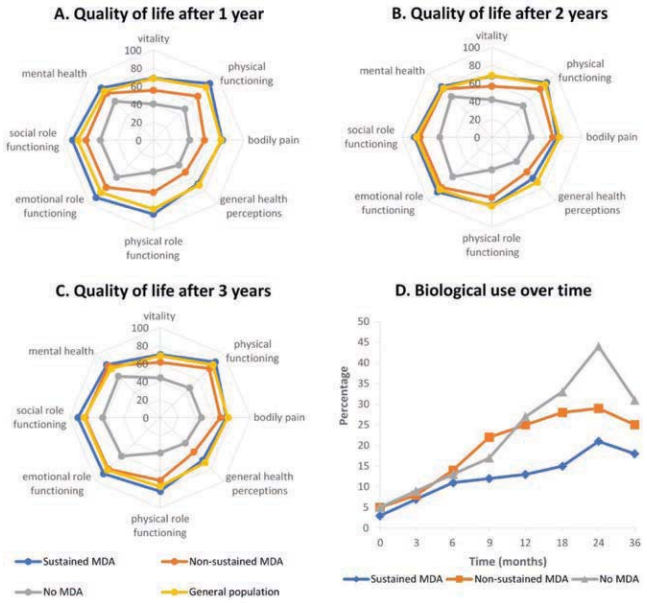

Figure 1. (A) 1 year, (B) 2 year and (C) 3 year quality of life scores, measured with the SF-36 domains, for MDA groups and compared with the general Dutch population norms (4), (D) percentage of patients who use biologicals over time per MDA group.

Conclusion: Failure to achieve MDA in the first year after PsA diagnosis is associated with worse quality of life outcomes that persist over the years despite more intensified treatment.

OP0029

PROSPECTIVE, DOUBLE-BLIND STUDY ON THE VALUE OF HANDHELD MUSCULOSKELETAL ULTRASOUND PERFORMED BY DERMATOLOGISTS FOR DETECTION OF PSORIATIC ARTHRITIS - THE PSOSONE STUDY

J. Grobelski[1], P. Brossart[1], D. Wilsmann-Theis[2], C. Behning[3], P. Karakostas[1], V. Schäfer[1]. *[1]UKB University of Bonn, Clinic of Internal Medicine III, Oncology, Haematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Germany, Bonn, Germany*; *[2]UKB University of Bonn, Clinic for Dermatology and Allergology, University Hospital Bonn, Germany., Bonn, Germany*; *[3]UKB University of Bonn, Institute for Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Bonn, Germany., Bonn, Germany*

Background: The early diagnosis of psoriatic arthritis (PsA) requires a close interdisciplinary cooperation between rheumatology and dermatology. Recent publications underlined the key role of dermatologists in this process (1). Despite available screening tools like questionnaires, there is a need to increase

sensitivity and specificity of diagnostic screening tools for PsA. Musculoskeletal ultrasonography (MSUS) has been shown to be a reliable tool for diagnosing PsA, even in preclinical situations. However, the use of MSUS screening by dermatologists in the early detection of PsA has not been studied so far.

Objectives: The purpose of this study was to assess the accuracy of early PsA identification by dermatologists who have been previously trained in MSUS utilizing an innovative handheld-ultrasound device (Butterfly IQ).

Methods: Twelve dermatologists have been trained in MSUS (2) previously by a newly designed curriculum. Six working at the clinic for Dermatology and Allergology of the University Hospital Bonn, while the remaining six serve in private practices. The MSUS training curriculum focused mainly on detecting joint effusion and synovial hyperperfusion in all joints. After successful training, these colleagues were provided with handheld-ultrasound devices in order to screen 140 psoriasis patients presenting with arthralgia. Dermatologists were asked to determine whether or not the patient had PsA based on the medical history, clinical examination, and GEPARD questionnaire. Subsequently a MSUS exam of up to three painful joints was conducted by the dermatologists using the provided handheld-ultrasound devices. The post MSUS decision was also recorded. All prescreened patients were then referred to blinded board-certified rheumatologists with MSUS certification (EFSUMB level II and III), which repeated medical history, clinical examination and MSUS. We investigated the impact of MSUS on the sensitivity and specificity of early PsA diagnosis by comparing dermatologists' pre- and post-ultrasound PsA suspicion with the final diagnosis determined by the rheumatologist.

Results: In total, 140 patients were enrolled. PsA was detected in 24 cases. The sensitivity of dermatologists' pre-MSUS PsA suspicion was 81.0 %, while the specificity was 54.5 %. After conducting MSUS the sensitivity and specificity changed to 61.9% and 90.9%, respectively. The MSUS findings lead the dermatologists to change their presumed PsA diagnosis in 46 cases, with PsA being ruled out in 45 of them.

Conclusion: We were able to demonstrate that targeted MSUS performed by dermatologists increases specificity while decreasing sensitivity, perhaps leading to fewer referrals to rheumatologists and an earlier diagnosis of PsA.

Figure 1: Accuracy of the pre- and post-ultrasound PsA suspicion by dermatologists compared to the final diagnosis determined by the rheumatologists

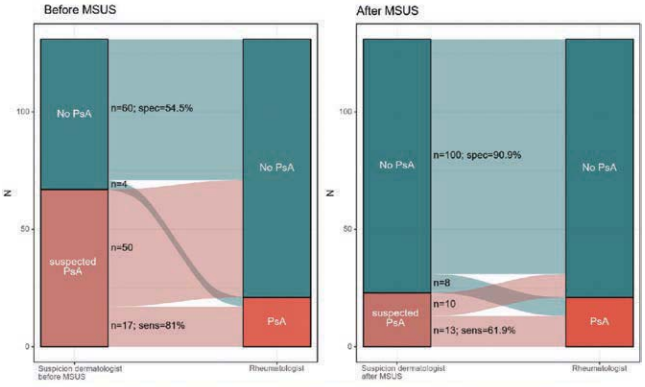

Figure 1: the change of PsA suspicion between pre-and post-ultrasound PsA screening performed by the dermatologists alongside the resulting sensitivity and specificity is shown compared to the final diagnosis set by board-certified rheumatologists. Due to inconsistent dermatological screening results in nine cases, only 131 out of 140 patients have been included in the final statistical analysis.

OP0030 ASSOCIATION OF TRADITIONAL AND DISEASE-RELATED RISK FACTORS WITH CARDIOVASCULAR EVENTS IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS

K. Colaco[1,2,3], V. Piguet[1,4], V. Chandran[3,4], P. Harvey[4,5], D. D. Gladman[3,4], L. Eder[1,4]. *[1]Women's College Hospital, Women's College Research Institute, Toronto, Canada*; *[2]University of Toronto, Institute of Medical Science, Toronto, Canada*; *[3]University Health Network, Schroeder Arthritis Institute, Toronto, Canada*; *[4]University of Toronto, Medicine, Toronto, Canada*; *[5]Women's College Hospital, Cardiology, Toronto, Canada*

Background: Patients with psoriatic arthritis and psoriasis, collectively termed psoriatic disease (PsD), have an increased risk for cardiovascular (CV) disease.

Objectives: We aimed to identify traditional CV risk factors and PsD-related risk factors associated with CV events.

Methods: Patients from a longitudinal PsD cohort without a prior history of CV events were included. Detailed information on demographics, comorbidities including traditional cardiovascular risk factors, medications and disease activity is collected according to a standard protocol. The study outcome included any of the following CV events occurring within the first 10 years of patients' initial clinic visit: angina, myocardial infarction, congestive heart failure, transient ischemic attack, cerebrovascular accident, revascularization procedures and CV death. A total of 10 traditional CV risk factors and 15 PsD-related risk factors were assessed. The association of each risk factor with incident CVEs were analyzed separately using Cox proportional hazards regression models with time-dependent covariates, adjusted for age and sex.

Results: A total of 1,376 patients with PsD, followed between 1978 and 2020, were analyzed (mean age 48.3 ± 12.9 years, 46.8% female). During the follow-up period, 102 (7.4%) patients developed incident CV events. In Cox regression models adjusted for age and sex, age (Hazard Ratio (HR) 1.08, 95% Confidence Interval (CI) 1.06, 1.10), diabetes (HR 1.88, 95% CI 1.17, 3.02), systolic blood pressure (HR 1.02, 95% CI 1.01, 1.03), body mass index (BMI) (HR 1.04, 95% CI 1.01, 1.08), triglycerides (HR 1.24, 95% CI 1.07, 1.43), treatment for hypertension (HR 1.70, 95% CI 1.13, 2.56), and use of lipid-lowering medications (HR 1.70, 95% CI 1.13, 2.56) were among the traditional CV risk factors associated with increased CV risk. Among the PsD-related risk factors, psoriasis area and severity index (PASI) (HR 1.05, 95% CI 1.02, 1.08), erythrocyte sedimentation rate (ESR) (HR 1.02, 95% CI 1.01, 1.02), number of tender joints (HR 1.03, 95% CI 1.01, 1.05), number of swollen joints (HR 1.06, 95% CI 1.01, 1.12), health assessment questionnaire (HAQ) score (HR 1.63, 95% CI 1.23, 2.17), and daily use of non-steroidal anti-inflammatory drugs (NSAIDs) (HR 1.72, 95% CI 1.16, 2.55) were associated with increased CV risk. Use of biologic medications (HR 0.63, 95% CI 0.40, 1.00) was not found to be significantly protective against CV events.

Conclusion: In patients with PsD, we identified six PsD-related risk factors that were significantly associated with incident CV events. These risk factors may be useful for the development of a PsD-specific CV risk prediction score that uses routine clinical assessments in combination with PsD-related biomarkers.

OP0031

SEROLOGICAL COLLAGEN BIOMARKERS CAN DIFFERENTIATE PATIENTS WITH PSORIASIS FROM PSORIATIC ARTHRITIS

S. S. Groen[1,2], S. Holm Nielsen[3,4], A. C. Bay-Jensen[2], M. Rasti[5], D. Ganatra[5], K. Oikonomopoulou[5], V. Chandran[5,6]. [1]*University of Copenhagen, Biomedical Sciences, Copenhagen, Denmark*; [2]*Nordic Bioscience, ImmunoScience, Herlev, Denmark*; [2]*Nordic Bioscience, ImmunoScience, Herlev, Denmark*; [4]*Technical University of Denmark, Biotechnology and Biomedicine, Kgs. Lyngby, Denmark*; [5]*Krembil Research Institute, Schroeder Arthritis Institute, Toronto, Canada*; [6]*Institute of Medical Science, Department of Medicine, Division of Rheumatology; Department of Laboratory Medicine and Pathobiology, Toronto, Canada*

Background: Psoriasis is a common chronic immune-mediated skin disease. About 25% of psoriasis patients have psoriatic arthritis (PsA) which is a chronic inflammatory disease affecting the joints, enthesis, and axial skeleton. Delayed diagnosis of PsA is associated with joint damage and disability. Therefore, optimized screening methods including identifying predictors of arthritis in patients with psoriasis have become a medical priority. Collagens are major proteins in all tissues, including skin, bone, cartilage, and connective tissues, which are affected by inflammatory processes present in both psoriasis and PsA. Throughout degradation and remodelling of the extracellular matrix (ECM), proteases cleave collagens leading to protein breakdown products which are released into the circulation. These collagen fragments can be quantified in serum as biomarkers of tissue remodelling and may be helpful in screening patients with psoriasis that have or will develop PsA.

Objectives: Our aim is to identify serum biomarkers that can differentiate patients with psoriasis without PsA (PsC) from PsA

Methods: Patients with PsC (n=87, mean ±SD age 42.01 ±12.20, 44% female; underwent a full rheumatologic assessment to exclude PsA) and patients with PsA (n=99, mean ±SD age 45.94 ±12.47, 49% female) were recruited at the Toronto Western Hospital, Canada, after appropriate ethics approval. ECM remodelling was estimated using as indices serological anabolic biomarkers quantifying formation of type III, IV, and VI collagen (PRO-C3, PRO-C4, and PRO-C6 respectively), and catabolic biomarkers measuring degradation of type I, III, IV and VI collagen (C1M, C3M, C4M, C6M respectively). Data are presented as mean ± standard deviation (SD). Statistically significant difference between the two groups was calculated by Mann-Whitney U test and a p-value below 0.05 was considered significant. Area under the receiver operating characteristic (ROC) curve (AUC) analysis was performed to describe the discrimination accuracy of each biomarker between the two patient groups.

Results: Patients with PsA presented higher levels of C1M, C3M, C6M, and PRO-C6 compared to PsC (p<0.0460-p<0.0009, Figure 1 A, B, D, G), while biomarkers levels of C4M, PRO-C3, and PRO-C4 were not significantly different between PsC and PsA patients (Figure 1 C, E, F). Moreover, C1M and C6M were able to separate between PsC and PsA patients with an AUROC=0.6277 (p=0.0027) and AUROC=0.6446 (p=0.0010), respectively, indicating that these biomarkers may be markers of joint involvement (Figure 1 H, I).

Conclusion: This work provides evidence that serum degradation biomarkers of type I and VI collagen were able to differentiate patients with PsA from PsC and may be potential biomarkers of inflammatory systemic musculoskeletal involvement. These findings suggest that serological biomarkers may be used to identify the 25% of psoriasis patients that have PsA.

From risk assesment to societal outcomes

OP0032

AN ECONOMIC WINDOW OF OPPORTUNITY FOR PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: 5-YEAR COST-EFFECTIVENESS ANALYSIS OF THE CARERA TRIAL

S. Pazmino[1], V. Stouten[1], D. De Cock[1], M. Doumen[1], D. Bertrand[1], J. Joly[2], R. Westhovens[1,2], P. Verschueren[1,2], on behalf of CareRA study group. [1]*Katholieke Universiteit Leuven, Development and Regeneration, Leuven, Belgium*; [2]*UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium*

Background: The CareRA trial showed that remission induction with methotrexate (MTX) and glucocorticoid (GC) bridging in a treat-to-target setting is cost-effective up to 2 years in early Rheumatoid Arthritis (eRA) patients.

Objectives: To evaluate the long-term cost-effectiveness of treat-to-target treatments among recently diagnosed (<1 year), DMARD naïve patients with eRA using MTX and a step-down GC scheme (COBRA-Slim) compared to (a) the same combination with either sulphasalazine (COBRA-Classic) or leflunomide (COBRA-Avant-Garde) in high-risk patients and (b) MTX without GCs (Tight-Step-Up: TSU) in low-risk patients up to 5 years.

Methods: We used data from the 2-year RCT CareRA trial and its 3-year observational follow-up, CareRA plus. Patients completing the 2-year visit of CareRA were eligible for participation in CareRA plus, in which patients were evaluated every 6 months till year 5. Healthcare costs considered in this piggyback economic analysis were rheumatology visits, RA-related medication (synthetic and biological DMARDs, GCs, and all recorded analgesics including paracetamol, non-steroidals, tramadol and opioids), hospital admissions, laboratory tests and radiographs occurring during the 5-year trial. All pricing is based on December 2021 rates. Total costs per resource were calculated by multiplying the number of resources by the cost unit price extracted from Belgian national websites. Total costs per patient were obtained by summing costs of all resources. Effectiveness was measured with DAS28-CRP and compared between the originally allocated treatment arms. An incremental cost-effectiveness ratio (ICER) was calculated by dividing the cost difference by the DAS28-CRP<2.6 remission difference per pair of treatment schemes. Multiple imputation was used to handle missing data and non-parametric bootstrapping with 25000 iterations of random sampling with replacement to calculate confidence intervals (95% CIs).

Results: Of 322 eligible patients, 252 were included in CareRA plus, of which 203 completed the trial. Rates of disease control (DAS28-CRP<2.6) at year 5 in high-risk patients were 68%, 72% and 64% in the Classic, Slim and Avant-Garde group respectively (p=0.63) and related total costs were €11 358.39 (CI 7 776.84-14 939.93), €8 463.12 (CI 6 789.44-10 136.80), €11 752.47 (CI 7 705.11-15 799.82) respectively. In the low-risk population, 80% of patients in Slim and the TSU arm reached remission (DAS28-CRP<2.6) at year 5. While the costs were €6 332.55 (CI 3 607.63-9 057.48) for Slim, and €10 398.19 (CI 4165.95-16630.43) for TSU. In the high-risk group, Classic (ICER -€723.82) and Avant-Garde (ICER -€411.17) were more expensive and less effective compared to Slim. In the low-risk group, Slim was less expensive (Δ -€4 065.64) and equally effective as TSU. Figure 1 depicts how the different medication costs evolved during the 5-year follow-up. 22% of all patients were ever on bDMARDs. More specifically in 23% (16/69) of Classic, 21% (16/75) of Slim high-risk, 25% (15/59) of Avant-Garde, 17% (4/23) of Slim low-risk, and in 15% (4/26) of TSU patients. On average a first bDMARD was started later in the Slim arms, more specifically at week 69 for Classic, week 106 for Slim high-risk, week 97 for Avant-Garde, week 102 for Slim low-risk and week 76 for TSU.

Conclusion: The combination of MTX with a GC bridging scheme (COBRA Slim) was more cost-effective (less expensive with comparable disease control) than more intensive step-down combination strategies or a conventional step-up approach 5 years after initial treatment. Over 5 years, around one-fifth of all patients, were in need of starting biological treatment and the transition to a bDMARD was later in COBRA Slim. These results point out the possibility of an early "economic" window of opportunity for diminishing costs long-term while still maintaining optimal disease control.

OP0033

EFFECTIVENESS OF NON-PHARMACOLOGICAL INTERVENTIONS TO PROMOTE WORK PARTICIPATION IN PEOPLE WITH RMDS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Butink[1,2], C. Webers[3], S. Verstappen[4], R. Christensen[5], L. Falzon[6], H. Bijlsma[7], G. R. Burmester[8], A. Boonen[3]. [1]*Maastricht University Medical Centre +, Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands*; [2]*Care and Public Health Research Institute (CAPHRI), Department of Social Medicine, Maastricht, Netherlands*; [1]*Maastricht University Medical Centre +, Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands*; [4]*University of Manchester, School of Social Sciences, Manchester, United Kingdom*; [5]*University of Southern Denmark, Section for Biostatistics and Evidence-Based Research, the Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen & Research Unit of Rheumatology, Department of Clinical Research, Denmark, Denmark*; [6]*University of Sheffield, Health Economics and Decision Science, School of Health and Related Research, Sheffield, United Kingdom*; [7]*University Medical Center Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands*; [8]*Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Work participation among people with rheumatic and musculoskeletal diseases (RMDs) remains reduced when compared to the general population. A EULAR taskforce was established to agree on Points to Consider (PtC) to support people with RMD in healthy and sustainable work participation. Non-pharmacological interventions (NPI) could have an important role in improving work participation in RMDs. However, a comprehensive evidence synthesis of the effectiveness of NPIs in people with RMDs is lacking.
Objectives: To summarise the literature on effectiveness of NPIs on work participation in people with RMDs.
Methods: A search in four databases (MEDLINE, EMBASE, CENTRAL and CINAHL) was performed. Randomised Controlled Trials (RCTs) and Longitudinal Observational Studies (LOS) assessing non-pharmacological/non-surgical interventions until August 2020 were screened. Studies including people with any RMD (except low back pain or work-related RMDs) and assessing a work participation outcome domain (sick leave, work status, presenteeism) were considered eligible. For qualitative evidence synthesis, RCTs and LOS were considered. For quantitative evidence synthesis, only RCTs were considered. For each randomized comparison, standardised mean differences (SMDs) were calculated for the three outcome domains and used as effect size in the meta-analyses; i.e. a negative SMD favouring the NPI over control. Next, Mixed Effects Meta-Regression Analyses were performed, with random effects for randomised comparisons, and a fixed effect factor for the stratified subgroups of clinical interest. Subgroups within diseases (musculoskeletal pain disorders vs. other types of RMDs), risk status for sick leave at baseline (on sick leave or at risk for sick leave; not at risk for sick leave; a combination; or not specified) and single vs. multiple component NPIs were pre-defined. Risk of Bias (RoB) of RCTs was assessed using the Cochrain tool.

Results: Out of 8,864 records, 64 studies (71 treatment comparisons) were included. Studies usually included a mixed population of several RMDs (42%). Most NPIs were conducted in a clinical setting (n=44, 62%) and NPIs usually had multiple components (n=57, 80%), such as vocational support combined with physical training (n=18, 25%). Sick leave was the most frequently reported outcome domain (n=56, 88%). In the qualitative syntheses, 30%/50%/29% of interventions were considered plausible in improving sick leave, work status and presenteeism, respectively.
In the quantitative synthesis, NPIs (37 RCTs, 42 comparisons with mostly moderate to high RoB) showed small to moderate effect sizes, favouring NPIs over comparators for sick leave (SMD=-0.23, 95%CI -0.33 to -0.13), work status (SMD=-0.38, 95%CI -0.63 to -0.12) and presenteeism (SMD=-0.25, 95%CI -0.39 to -0.12). The forest plot for sick leave is shown (Figure 1).
Subgroup analyses for sick leave revealed that, compared to control, NPIs were not effective in musculoskeletal pain disorders, in contrast to the other types of RMDs. For both other subgroup analyses (baseline risk for sick leave; single vs. multicomponent NPI), NPIs improved sick leave similarly in subgroups compared to the control. Subgroup analyses for work status and presenteeism had generally similar effects in subgroups, but the interpretation requires caution in view of the small number of comparisons. Of note, clinical and methodological heterogeneity between studies was substantial, with some concerns about methodological quality related blinding and completeness of follow up.

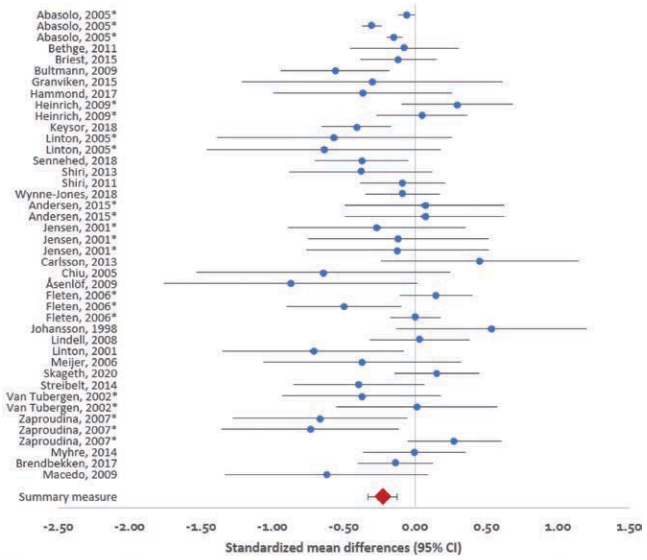

Figure. Forest plot of 42 treatment comparisons (sick leave) [<0.00 favours non-pharmacological intervention; >0.00 favours control]. An asterisk (*) indicated if a study has multiple treatment comparisons, which was taken into account in the analysis, and were therefore included multiple times in the forest plot.

Conclusion: Overall, NPIs seem to have significant, but on the average population level only small to moderate effects on sick leave, work status and presenteeism in RMDs. However, effects on sick leave varied substantially between subgroups. This synthesis suggests that tailoring NPIs to individuals' needs and context could be clinically valuable.

OP0034

IXEKIZUMAB IMPROVES SIGNS, SYMPTOMS, AND QUALITY OF LIFE IN PATIENTS WITH AXIAL SPA IRRESPECTIVE OF DISEASE DURATION: RESULTS FROM THE COAST-V, COAST-W AND COAST-X TRIALS

V. Navarro-Compán[1], J. D. Reveille[2], P. Rahman[3], J. Maldonado-Cocco[4], M. Magrey[5], R. Bolce[6], D. Sandoval[6], S.Y. Park[6], A. Kronbergs[6], M. Rudwaleit[7]. [1]*Hospital Universitario La Paz, Servicio de Reumatología, Madrid, Spain*; [2]*McGovern Medical School at UTHealth, Department of Internal Medicine-Division of Rheumatology, Houston, United States of America*; [3]*Memorial University of Newfoundland, Faculty of Medicine, St. John's, Canada*; [4]*University of Buenos Aires Faculty of Medicine, School of Medicine, ABG, Argentina*; [5]*Case Western Reserve University, School of Medicine/University Hospital, Cleveland, United States of America*; [6]*Eli Lilly and Company Corporate Center, Corporate Center, Indianapolis, United States of America*; [7]*Klinikum Bielefeld Rosenhöhe, Department of Internal Medicine and Rheumatology, Bielefeld, Germany*

Background: Ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A,[1] has demonstrated superior efficacy to placebo (PBO) in the treatment of patients (pts) with radiographic axial spondyloarthritis

(r-axSpA) (COAST-V [NCT02696785]; -W [NCT02696798]), and non-radiographic axial spondyloarthritis (nr-axSpA) (COAST-X [NCT02757352]).
Objectives: Assess treatment response to IXE categorised by disease duration since symptom onset (<5 years (yrs), ≥5yrs) in pts with r-axSpA and nr-axSpA up to 52 Weeks (Wks).
Methods: Pts fulfilled ASAS classification criteria for r-axSpA or nr-axSpA and were randomised to receive 80mg subcutaneous IXE every 2Wks or 4Wks, or PBO (16Wks COAST-V/W; 52Wks COAST-X). Data were summarized by disease duration and treatment in eligible intent-to-treat (ITT) pts. Wk16 treatment comparisons were conducted using Cochran-Haenszel-Mantel test and ANCOVA. Missing data were handled using non-responder imputation and modified baseline observation carried forward, for categorical and continuous endpoints, respectively.
Results: Table 1 presents pt demographics and baseline characteristics. Data is from pooled IXE pts. In pts with r-axSpA and <5yrs symptom duration, ASAS40 response was achieved by 51.5% at Wk16 and 60.6% at Wk52, compared to 36.9% at Wk16, significantly different to PBO (p<0.001), and 40.5% at Wk52, in pts with ≥5yrs symptom duration. In pts with nr-axSpA and <5yrs symptom duration, ASAS40 response was achieved by 42.5% at Wk16, significantly different to PBO (p=0.012), and 54.8% at Wk52, compared to 36.0% at Wk16 and 41.4% at Wk52 in pts with ≥5yrs symptom duration (Figure 1). In pts with r-axSpA and <5yrs symptom duration, ASDAS LDA <2.1 response was achieved by 39.4% at Wk16 and 48.5% at Wk52, compared to 27.5% at Wk16, significantly different to PBO (p<0.001), and 35.6% at Wk52 in pts with ≥5yrs symptom duration. In pts with nr-axSpA and <5yrs symptom duration, ASDAS LDA <2.1 response was achieved by 32.9% at Wk16, significantly different to PBO (p=0.003), and 49.3% at Wk52, compared to 23.9% at Wk16 and 36.9% at Wk52 in pts with ≥5yrs symptom duration. At Wk16, in pts with r-axSpA pts and <5yrs symptom duration, the Change from Baseline (CFB) in SF-36 Physical Component Summary (PCS) Score (LSM±SE) was 7.91 (±1.52), compared to 6.81 (±0.40) in pts with ≥5yrs symptom duration. In pts with nr-axSpA and <5yrs symptom duration, this score was 8.95 (±0.95) compared to 7.07 (±0.73) in pts with ≥5yrs symptom duration; both were significantly different to PBO (r-axSpA: p<0.001; nr-axSpA: p=0.037).

Table 1. Patient demographics and Baseline Characteristics

	Pts with r-axSpA		Pts with nr-axSpA	
	<5yrs (Ns=33)	≥5yrs (Ns=306)	<5yrs (Ns=73)	≥5yrs (Ns=111)
Age (years)	33.1 (8.15)	45.1 (12.12)	31.9 (10.07)	46.4 (11.86)
Male, n (%)	26 (78.8)	245 (80.1)	40 (54.8)	53 (47.7)
Female, n (%)	7 (21.2)	61 (19.9)	33 (45.2)	58 (52.3)
Age at axSpA onset (years)	30.4 (8.29)	27.0 (9.06)	29.9 (10.22)	29.5 (8.76)
ASDAS score, mean (SD)	3.87 (0.79)	4.03 (0.82)	3.79 (0.80)	3.85 (0.78)
BASDAI score, mean (SD)	7.16 (1.64)	7.25 (1.35)	7.00 (1.33)	7.30 (1.26)
SF-36 PCS, mean (SD)	34.02 (7.73)	32.86 (7.63)	32.84 (7.86)	32.57 (6.97)

Abbreviations: IXE=ixekizumab, n=number of pts in specified category, Ns=number of pts in each subgroup, SD=standard deviation.

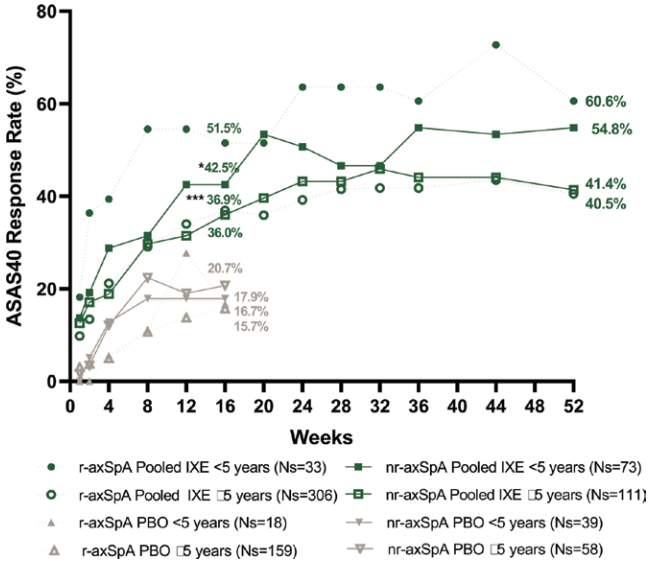

Figure 1. ASAS40 Response Rates for patients with r-axSpA (COAST-V/W) and nr-axSpA (COAST-X) Symptom Duration <5 and ≥5 years up to Week 52, ITT, NRI: Significantly greater response of IXE versus PBO at Week 16 denotated by * (p≤0.05), *** (p≤0.001). Abbreviations: PBO, placebo; IXE, Ixekizumab; NRI, nonresponder imputation; ITT, Intent-to-Treat (population), ASAS, Assessment of Spondyloarthritis International Society.

Conclusion: Efficacy response to the therapy with IXE was observed in both subgroups based on disease duration (<5 and ≥5yrs) with more robust responses in the <5 years subgroup.

OP0035 WHAT EXPLAINS THE WORLDWIDE GRADIENT OF AGE AT ONSET OF RHEUMATOID ARTHRITIS ALONG LATITUDE? A MULTILEVEL ANALYSIS IN THE METEOR REGISTRY

S. A. Bergstra[1], A. Sepriano[1,2], A. Chopra[3], L. L. Winchow[4], D. Vega-Morales[5], K. Solomon-Escoto[6], X. Matthijssen[1], R. B. M. Landewé[7,8]on behalf of METEOR. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Universidade Nova de Lisboa, NOVA Medical School, Lisbon, Portugal*; [3]*Centre for Rheumatic Diseases, Pune, India*; [4]*University of the Witwatersrand, Chris Hani Baragwanath Academic Hospital, Johannesburg, South Africa*; [5]*Universidad Autonoma de Nuevo Leon, Monterrey, Mexico*; [6]*University of Massachusetts Chan School of Medicine, UMass Memorial Health Rheumatology Center, Worcester, United States of America*; [7]*AMC, Amsterdam Rheumatology Center, Amsterdam, Netherlands*; [8]*Zuyderland MC, Rheumatology, Heerlen, Netherlands*

Background: It has been suggested that rheumatoid arthritis (RA) starts at a younger age in cities with a lower latitude (closer to both sides of the equator). This consistent finding still remains to be explained. It has been hypothesized that latitude is a proxy for presence of genetic (eg. ACPA) and environmental risk factors (eg. smoking) for RA onset.
Objectives: To study how age at RA onset varies with latitude worldwide and to what extent patient and country level factors explain this variability.
Methods: RA patients from the worldwide METEOR registry were included. Age at diagnosis as a proxy for age at RA onset, measured at the patient level, was the main outcome. The explanatory variable was the absolute value of latitude, measured as the latitude of the hospital (hospital level). Patient factors considered potentially relevant were gender, RF and ACPA positivity, smoking status, symptom duration (months), year of first visit and BMI (all patient level). Country level factors were socioeconomic indicators (physician density, health expenditure, life expectancy, GDP per capita and gross enrolment in secondary school), derived from country statistics. We hypothesized that both patient and country level factors explain (ie. mediate) a relationship between latitude and age at diagnosis (Figure 1).
We applied Bayesian multilevel linear structural equations models, which not only quantify effects at multiple levels but also disentangle at which level the effects take place. For example, they can differentiate whether hospital or country latitude affects age at diagnosis.

We examined: 1. the total effect of latitude on age at diagnosis at hospital and country level (Main model); 2. the amount of the total effect that is mediated by patient factors at the patient and hospital level (Model A); and 3. the amount of the total effect that is mediated by country factors at the country level (Model B). In each model we disentangle the effect in different measurement levels. For example, a patient level variable can vary at the patient, hospital and country level.

Results: We included 39 782 patients nested in 94 hospitals nested in 17 countries. The mean age at diagnosis per country ranged from 39 to 55 years. The study spanned a range of latitude between 9.9 and 55.8 degrees (ie. from Nigeria to the United Kingdom). In the main model, we confirmed the association between latitude and age at diagnosis and found that it only occurred at the country level (not at the hospital level). Per degree increase in country latitude, the average age at diagnosis per country increased by 0.23 years (95% credibility interval 0.07; 0.40). At the hospital level however, this effect was negligible: β= 0.040 (-0.16; 0.31). Associations between latitude and several patient factors were found at the country level, but these patient factors only associated with age at diagnosis at the patient level, not at the country (or hospital) level (Model A). This means patient-factors did not explain the association between latitude and age at diagnosis at the country level (main effect changed from 0.23 before to 0.37 after inclusion of patient factors). In model B latitude associated with most country factors (except GDP per capita). Even though none of these variables separately were significantly associated with age at diagnosis, inclusion of the set of country level factors reduced the country level effect of latitude on age at diagnosis from 0.23 to almost zero: β=-0.033 (-0.51; 0.37). Sensitivity analyses with age at symptom onset as outcome provided similar results.

Conclusion: Patients living close at the equator indeed get RA far earlier than those living closer to the poles. We here suggest that, rather than due to variation in patients' characteristics, this latitude gradient is a country level phenomenon explained by indicators of countries' socioeconomic status, and not by patient specific genetic or environmental factors. This big data analysis in a worldwide prevalence cohort provides a direct link between countries' levels of welfare and the onset of RA.

OP0036 CLINICALLY SUSPECT ARTHRALGIA PATIENTS WITH A LOW LEVEL OF EDUCATIONAL ATTAINMENT HAVE AN INCREASED RISK TO DEVELOP INFLAMMATORY ARTHRITIS

S. Khidir[1], E. Van Mulligen[1,2], A. Van der Helm-van Mil[1,2]. [1]*Leiden University Medical Centre, Leiden, Rheumatology, Leiden, Netherlands*; [2]*Erasmus Medical Centre, Rheumatology, Rotterdam, Netherlands*

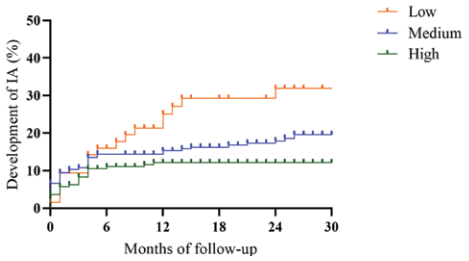
Background: Cross-sectional studies on educational levels have shown that inflammatory arthritis (IA) and rheumatoid arthritis (RA) are more prevalent among people with a lower educational attainment. Studies on educational attainment in individuals at risk for RA could shed light on the influence of socioeconomic factors on RA development, which is divided in an asymptomatic and symptomatic pre-RA stage. To our knowledge, longitudinal studies on educational attainment and IA-development in symptomatic individuals at risk of RA are lacking.

Objectives: To determine the association between educational attainment and progression from clinically suspect arthralgia to IA and to perform mediation analysis to elucidate pathways.

Methods: 600 consecutive patients presenting with clinically suspect arthralgia were followed for the development of IA, identified at joint examination by rheumatologists during median follow-up of 25 months. Educational attainment was defined as low (lower general secondary education), medium, or high (college or university education). Contrast enhanced 1.5T MRI of hand and foot were made at baseline and were evaluated for synovitis/tenosynovitis/osteitis, according to the method of rheumatoid arthritis MRI scoring system (RAMRIS) and Havaardsholm. Association between educational attainment and IA-development was studied with cox-regression analysis. To evaluate if subclinical joint inflammation is intermediary in the path of educational attainment and IA-development, a three-step mediation analysis was performed, before and after correction for age.

Results: Patients with a low level of educational attainment were older, had a higher BMI, and smoked more often compared to patients with a high educational level. Low educational attainment was associated with increased IA-development (HR=2.5, 95%CI=1.4-4.7. p=0.003; see Figure 1), also after correction for age, BMI and smoking-status (HR=2.1, 95%CI=1.03-4.4, p=0.041). Moreover, patients with a lower educational level had higher levels of subclinical inflammation at presentation, which associated with a higher risk of progression to IA. Mediation analyses revealed that the association between low educational attainment and IA-development reduced when adding the level of subclinical inflammation (HR=1.8, 95%CI=0.9-3.5, p=0.073), suggesting that the association between educational attainment and IA-development is partly mediated by higher levels of subclinical inflammation. Mediation analysis with age correction provided similar results.

Figure. Progression from clinically suspect arthralgia to inflammatory arthritis (IA), according to educational attainment



Conclusion: This is the first evidence that lower educational attainment of patients with arthralgia is associated with a higher risk of developing arthritis. This is partly caused by more severe subclinical joint inflammation. Further research into the role of socioeconomic factors on the development of RA is warranted.

Disclosure of Interests: None declared.

OP0037 USE OF PRIMARY HEALTHCARE AND RADIOLOGICAL IMAGING PRECEDING A DIAGNOSIS OF RHEUMATOID ARTHRITIS: A DANISH NATIONWIDE COHORT STUDY

A. De Thurah[1,2], H. Jensen[3,4], T. Maribo[3,5], M. Bach Jensen[6], A. Sandbæk[3,7], E. M. Hauge[1,2], L. A Rasmussen[3,4]. [1]*Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark*; [2]*Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*; [3]*Aarhus University, Department of Public Health, Aarhus, Denmark*; [4]*Aarhus University, Research Unit for General Practice, Aarhus, Denmark*; [5]*DEFACTUM, Central Denmark Region, Aarhus, Denmark*; [6]*Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*; [7]*Steno Diabetes Center, Aarhus, Aarhus, Denmark*

Background: Focus on early diagnosis and treatment initiation is key in rheumatoid arthritis (RA) to prevent permanent joint damage and systemic manifestations. Increased use of healthcare services before an RA diagnosis can be seen as a proxy for symptom presentation and the actions taken by healthcare professionals, and thus indicate an opportunity for earlier diagnosis. However, little is known about where and when people use healthcare services before an RA diagnosis.

Objectives: To explore the pattern in use of healthcare services during the 12 months preceding a diagnosis of RA in Denmark.

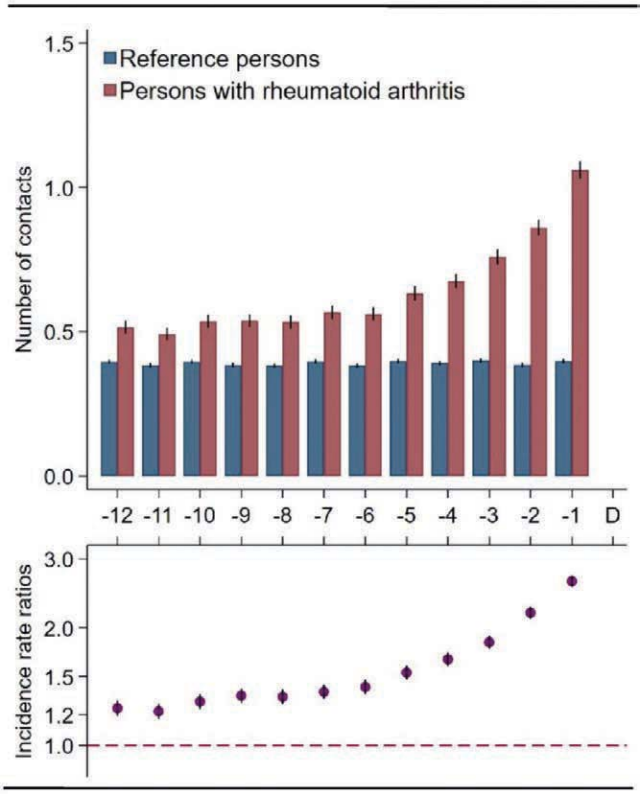
Methods: We conducted a population-based cohort study using data from Danish national registries. For every patient diagnosed with RA in 2014-2018 we matched ten reference persons from the Danish general population without RA, listed in the same general practice and with same age and sex. Healthcare use was defined as: daytime face to face contacts to general practice, contacts to private practicing physiotherapists. We estimated the monthly healthcare use for patients with RA and reference persons in the 12 months preceding the diagnosis, and we compared their healthcare use by incidence rate ratios (IRR) for each month, adjusted for socio-demographic characteristics and comorbidity.

Results: 7,427 patients with RA and 74,270 reference persons were included in the study. The median age was 62 years (interquartile interval (IQI): 51-71), and 65% were women. Patients with RA had an average of 0.5 contacts per month in general practice from 12 months until six months prior to the diagnosis (Figure 1); this number increased from six months before the diagnosis to an average of one contact in the last month before the diagnosis. Reference persons had an average of 0.4 contacts per months throughout the entire study period. Compared to their references, patients with RA had statistically significantly more contacts during all 12 months before the diagnosis date; IRR increased from 1.25 (95% CI: 1.19-1.30) to 2.63 (2.55-2.71) during the study period. Patients with RA also had statstistically significantly more contacts to physiotherapists compared to their references throughout the entire study period, and increasing contact rates from eight months before the diagnosis. This was primarily driven by more contacts in women with RA compared to their references.

Conclusion: Patients with RA had more contacts to general practice and physiotherapists in all 12 months preceding the RA diagnosis compared to references and these contact rates increased further the last six to eight months in patients with RA. This indicates symptom presentation for several months before the RA

is diagnosed, and it indicates that a window of opportunity exists to expedite referral to specialist care and the diagnosis of RA.

Figure 1: Contacts with a general practitioner in the 12 months preceding the date of a rheumatoid arthritis diagnosis and a corresponding index date assigned to references persons without rheumatoid arthritis.



Upper part: unadjusted rates. Lower part: incidence rate rations adjusted for age, civil status, ethnicity, educational level, household income and comorbidity.

OP0038

VITAMIN D AND MARINE N-3 FATTY ACID SUPPLEMENTATION FOR PREVENTION OF AUTOIMMUNE DISEASE IN THE VITAL RANDOMIZED CONTROLLED TRIAL: OUTCOMES OVER 7 YEARS

K. Costenbader[1], N. Cook[2], I. M. Lee[2], J. Hahn[1], J. Walter[2], V. Bubes[2], G. Kotler[2], N. Yang[1], S. Friedman[3], E. Alexander[4], J. Manson[2]. [1]*Brigham and Women's Hospital/Harvard Medical School, Rheumatology, Inflammation and Immunity, Boston, United States of America*; [2]*Brigham and Women's Hospital/Harvard Medical School, Preventive Medicine, Boston, United States of America*; [3]*Brigham and Women's Hospital/Harvard Medical School, Gastroenterology, Boston, United States of America*; [4]*Brigham and Women's Hospital/Harvard Medical School, Endocrinology, Boston, United States of America*

Background: Strong biologic rationale supports both vitamin D and marine omega-3 (n-3) fatty acids for prevention of autoimmune disease (AD). Within the randomized, double-blind, placebo-controlled **VIT**amin D and Omeg**A**-3 Tria**L** (**VITAL**), we tested the effects of these supplements on AD incidence. We previously reported results after 5.3 years of randomized follow-up showing overall protective effects for vitamin D on AD incidence (HR 0.78, 95% CI 0.61-0.99) and suggestive results for n-3 fatty acids (HR 0.85, 95%CI 0.67-1.08)[1].
Objectives: We aimed to test effects of these supplements with two more years of post-intervention follow-up in VITAL.
Methods: VITAL enrolled and randomized men and women (age ≥50 and ≥55 years, respectively) in a 2-by-2 factorial design to vitamin D_3 (2000 IU/d) and/or n-3 fatty acids (1000 mg/d) or placebo and followed for median 5.3 years. Here, we followed participants for another 2 years of observation to assess for sustained effects. Incident AD diagnoses were reported by participants annually and confirmed by medical record review by expert physicians using existing classification criteria. The primary endpoint was total incident AD, including rheumatoid arthritis (RA), polymyalgia rheumatica (PMR), autoimmune thyroid disease (AITD), psoriasis, and all others. Pre-specified secondary endpoints included individual common AD; and probable AD. Cox models calcuated hazard ratios (HR) for incident ADs.
Results: Of 25,871 participants randomized, 71% self-reported non-Hispanic Whites, 20% Black, 9% other racial/ethnic groups, 51% women, mean age was 67.1 years. During 7.5 years median follow-up, confirmed AD was diagnosed in 156 participants in vitamin D arm vs 198 in vitamin D placebo arm, HR 0.79 (0.64-0.97). Incident AD was confirmed in 167 participants in n-3 fatty acid arm and 187 in n-3 fatty acid placebo arm, HR 0.89 (0.72-1.10). For vitamin D, HRs trended toward reduction for RA 0.67 (0.37- 1.21), PMR 0.69 (0.46-1.03) and psoriasis 0.57 (0.33-0.99). For n-3 fatty acids, HRs trended toward reduction for RA 0.55 (0.30-1.10) and AITD 0.61 (0.33-1.12). Vitamin D's effect on AD incidence was stronger in those with body mass index (BMI) < 25 (HR 0.65, 0.44-0.96) than ≥ 25 kg/m^2 (p interaction 0.01).
Conclusion: Supplementation for 5.3 years with 2000 IU/day vitamin D (compared to placebo), followed by 2 years of observational follow-up, significantly reduced overall incident AD by 21% in older adults. HRs for RA, PMR and psoriasis trended toward reduction with vitamin D, with stronger effect in those with normal BMI. Supplementation with 1000 mg/day n-3 fatty acids did not significantly reduce total AD.

OP0039

RISK OF ARRHYTHMIA AMONG NEW USERS OF HYDROXYCHLOROQUINE: A LONGITUDINAL POPULATION-BASED COHORT STUDY ON NEWLY DIAGNOSED RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. R. Hoque[1,2], N. Lu[2], N. Daftarian[2], J. Esdaile[2,3], H. Xie[1,2], J. A. Aviña-Zubieta[2,3]. [1]*Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada*; [2]*Arthritis Research Canada, Arthritis Research Canada, Vancouver, Canada*; [3]*University of British Columbia, Division of Rheumatology, Department of Medicine, Vancouver, Canada*

Background: Previous findings on hydroxychloroquine (HCQ) use and the risk of arrhythmia are contradictory and low-level evidence-based results. Additional research is required to evaluate the safety profile of HCQ to arrhythmia in managing rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).
Objectives: To assess the association between HCQ initiation and risk of incident arrhythmia among newly diagnosed RA and SLE patients.
Methods: All patients with incident RA or SLE and no arrhythmic events or anti-arrhythmic medications and no HCQ use prior to disease index date in British Columbia, Canada, between January 1997 and March 2015 were identified using administrative databases. HCQ initiator and HCQ non-initiator groups were identified and matched 1:1 by propensity scores using baseline confounders on demographics including presence of RA or SLE disease and duration of disease prior to the index date of HCQ initiators or non-initiators, comorbidities, other medications, and healthcare utilization. Matching was done within the same calendar year to account for a potential secular trend in HCQ use and risk of arrhythmia. Outcomes were any new arrhythmias, atrial fibrillation, abnormal electrocardiogram including prolonged QT syndrome and conduction disorder, and other unspecified arrhythmias during follow-up. We used Cox proportional hazard models with death as a competing event to assess the association of HCQ initiation and the outcomes.
Results: We identified 11,518 HCQ initiators (10,655 RA and 863 SLE patients, mean ± SD age 55.9 ± 15.1 years, 76.1% female) and 11,518 HCQ non-initiators (10,639 RA and 879 SLE patients, mean ± SD age 56.0 ± 16.2 years, 76.4% female) after 1:1 propensity score matching. Over the mean follow-up of eight years, there were 1,610 and 1,646 incident arrhythmias in the HCQ initiator and non-initiator groups, respectively. The crude incidence rates of arrhythmia were 17.5, and 18.1 per 1,000 person-years, respectively. Cumulative risk of incident arrhythmia remained similar for both groups. (Figure 1). Adjusted hazard ratio (aHR) of incident arrhythmia from the Cox proportional hazard model for HCQ initiators was 0.99 (95% CI: 0.92-1.06) compared to non-initiators (Table 1). The corresponding aHRs for HCQ initiators in subtypes of arrhythmia – atrial fibrillation, abnormal electrocardiogram, and other unspecified arrhythmias were 0.95 (95% CI: 0.84-1.06), 1.04 (95% CI: 0.87-1.26), and 0.96 (95% CI: 0.86-1.08), respectively.

Table 1. Incident arrhythmias of any type among RA and SLE patients initiating HCQ prescription compared with HCQ non-initiators

	HCQ initiator	HCQ non-initiator
Participants (number)	11,518	11,518
Mean follow-up (years)	8.00	7.89
Events (number)	1,610	1,646
Crude incidence rate per 1000 person-years	17.48	18.12
Unadjusted HR (95% CI)	0.98 (0.91-1.05)	1.00 (reference)
Adjusted# HR (95% CI)	0.99 (0.92-1.06)	1.00 (reference)

Abbreviations: **HCQ**, hydroxychloroquine; **HR**, hazard ratio.#The multivariable Cox proportional hazard model was adjusted for baseline confounders on demographics, comorbidities, medications, and healthcare utilization.

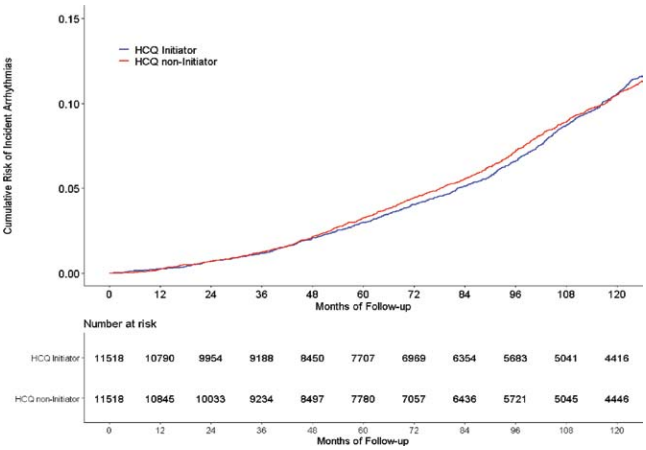

Figure 1. Cumulative risk of incident arrhythmias for HCQ initiators and non-initiators over the follow-up time.

Conclusion: There is no increased risk of any type of arrhythmia among new users of HCQ in RA and SLE patients. We believe the results of this large cohort study will add to the confidence with which HCQ can be used in RA and SLE management.

THE WEBINAR SERIES FOR THE PATIENTS "PREGNANCY AFTER DIAGNOSING ANKYLOSIS SPONDYLITIS"

O. Krichevskaya[1], T. Dubinina[1], N. Klimenchenko[2], N. Shatalova[3]. [1]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation*; [2]*National medical research center for obstetrics, gynecology and perinatology named after academician V.I.Kulakov, Obstetric department of pathology of pregnancy, Moscow, Russian Federation*; [3]*Russian ankylosing spondylitis association, Directorate, Moscow, Russian Federation*

Background: Having been diagnosed with ankylosis spondylitis (AS), 68,2% of females in Russia reconsider their plans for pregnancy, with 13% giving up motherhood altogether out of fear for their own and their child's potential health problems. However, most females allow pregnancy while experiencing emotional discomfort and anxiety[1].
Objectives: To shed more light on the mutual influence of AS and pregnancy, AS pregnancy outcomes, clinical course of AS as well as medication options during AS and lactation.
Methods: From 03/2021 to 12/2021 an on-line series of eight webinars was conducted together with the patients' Russian ankylosing spondylitis association. Each webinar included lectures of one or two rheumatologists and an obstetrician; furthermore, the series included the presentations of a physical therapy instructor (with the demonstration of exercises) and of a breast-feeding specialist. After the lecture each speaker answered the audience's questions. Topics of rheumatologists' lectures were "AS and pregnancy: problem introduction", "What do we know about AS genetics", "Features of pregnancy planning" (included therapy issues for men with AS who are planning to father a child), "Rheumatologist prenatal and postnatal care" (included the analysis of AS clinical manifestations such as potential changes in back pain type);"-Contemporary approaches to AS pregnancy treatment". A brochure for the patients with the main provisions of the lectures had been developed in support of the series.

Results: Webinars scored 703±192 views (by 29.01.2022). According to the questionnaire survey of the audience, 43,8% first knew that it was necessary to plan AS pregnancy minimum 3-6 months before conception; 25% – that conception is optimal during remission or low AS activity; 31,3% – that medical therapy can be continued during pregnancy; 18,8% – that it is necessary to inform the obstetrician about AS diagnosis and therapy received. 80% of the participants are fully satisfied with the information provided by the web series; 13,3% – reported not to had received enough information.
Conclusion: The interest in webinars shows that the choice of the form and the information provided was successful. The content of the series can be used to develop FAQ-section on the patient's website "Ankylosing Spondylitis Association». In 2022, lectures will continue taking into account patients' feedback.

OP0041-PARE SJÖGREN EUROPE: REVIEW OF ITS FIRST THREE YEARS OF ACTIVITY

A. Grosjean[1], L. Stone[1], C. Bouillot[1], A. Vieira[1], K. Antonopoulou[1], J. Koelewijn-Tukker[1], M. Oosterbaan[1]. [1]*Sjögren Europe, Federation of European Sjögren's patient associations, Bienne, Switzerland*

Background: Sjögren Europe was founded on 23 February 2019 by several European patient organisations representing Sjögren's patient to help to address the lack of visibility, attention, and solutions for Sjögren's.
Objectives: To show the first achievements and contributions of the federation.
Methods: Sjögren Europe's purpose is to promote the advancement of knowledge, research, information, treatment, and care, to foster patient involvement and participation in research and any other relevant area, to increase awareness, identify the different unmet needs and articulate patient voices throughout Europe.
Results: Finding one's bearings and the right rhythm during the first years of an organisation's life is a challenge in itself. The Covid-19 pandemic has made this process even more difficult. Our first goal was to organise a first face-to-face European patient conference. This meeting had to be postponed. However, we were able to adapt and develop a range of activities.
We organised a series of informative webinars on different topics by leading European experts for patients and others interested in the subject. We have organised various awareness campaigns such as a campaign for Sjögren Awareness Month in 2021 for which we have created 2 awareness videos and published several testimonials. We also created a 3-axis campaign about fatigue for World Sjögren's Day 2021 which won the Best Practice Award at the 2021 PARE Conference, and during which we shared the patients' perspective on fatigue in publications in 13 languages on social media. We published a booklet about fatigue developed by a specialist and produced 3 informative leaflets for patients. We also subtitled 2 videos made by one of our members in 10 European languages to disseminate quality information that many patients miss. We have been involved in various research projects, working groups and patient panels and have been able to bring the patient perspective to various stakeholders on many occasions.
Conclusion: Despite the limited contacts, we were able to create strong links and rich discussions that stimulated our creativity. Sjögren Europe has become a privileged partner, recognised, and appreciated by the various stakeholders. Patients with Sjögren's are better represented at the supranational level. It is our members, the national patient organisations, who by their trust give us our legitimacy. In return, Sjögren Europe has been able to inject a new energy and dynamism that can be felt at the different national levels and that opens up many perspectives and opportunities. We have been able to strengthen our presence and visibility with patients on social networks, where our audience is constantly growing, as well as in the rheumatology field with researchers, clinicians, industry, and associations such as EULAR. The resumption of face-to-face contacts is eagerly awaited to consolidate the links already created and to feed the richness, relevance, originality and diversity of our discussions and activities.
Disclosure of Interests: None declared.

Background: Familial Mediterranean Fever (FMF) is a chronic disease characterized by recurrent attacks of fever as well as serositis and bears the risk of serious complications (e. g. amyloidosis). Treatment of FMF according to EULAR aims to control acute attacks and subclinical inflammation as well as to improve patient´s quality of life[1]. Clinical data indicate that the inhibition of interleukin-1β with canakinumab (CAN) is effective in controlling and preventing flares in FMF patients[2].
Objectives: The present study explores the long-term efficacy and safety of canakinumab in routine clinical practice conditions in pediatric (age ≥2 years) and adult FMF patients.
Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up period. Patients with clinically confirmed FMF diagnosis who routinely receive canakinumab are enrolled in order to evaluate effectiveness and safety of canakinumab. Disease activity and remission by physicians´ assessment, disease activity, fatigue and impact on social life by patients' assessment, inflammatory markers and AIDAI (Auto-Inflammatory Diseases Activity Index) score were recorded at baseline and assessed at 6-monthly intervals within the 3-year observation period of the study.
Results: This interim analysis of FMF patients (N=74) enrolled by December 2021 includes baseline as well as 6- to 24-month data. Mean age in this cohort was 25 years (2–61 years) and the proportion of female patients was 51 % (N=38). At baseline, median duration of prior CAN treatment was 1.0 years (0–6 years).
At month 24, physician ratings report around 63% of patients in disease remission and patient-reported disease activity (mean PPA) decreased from moderate (3.0) to low (2.6) during the observation period. Other disease activity parameters also decreased (Table 1). A total of 18 serious adverse events were reported, of which 2 (1 case of tonsillectomy and 1 case of tachycardia) were classified as drug - related.

Table 1. Baseline characteristics and 4th interim analysis data of patients with FMF

	Baseline	12 months	24 months
Number of patients, N	74	46	24
Number (%) of patients with days absent from work/school during last 6 months	6 (8)	11 (24)	9 (38)
Number (%) of patients in disease remission (physician assessment)	22 (45)	23 (72)	12 (63)
Patient's assessment of current disease activity; 0–10, median (min; max)	2.0 (0; 10)	2.0 (0; 7)	2.0 (0; 10)
Patient's assessment of current fatigue; 0–10, median (min; max)	5.0 (0; 10)	2.0 (0; 10)	4.0 (0; 10)
Number (%) of patients without impairment of social life by the disease	27 (50)	28 (80)	8 (67)
CRP (mg/dl) I SAA (mg/dl) I ESR (mm/h); median	0.2 I 0.7 I 8.0	0.2 I 0.5 I 4.0	0.2 I 0.7 I 6.0
Number (%) of patients with disease-related symptoms	prior to inclusion into the study I at baseline	12 months	24 months
Fever	68 (93) I 14 (29)	8 (25)	3 (16)
Abdominal pain	67 (92) I 20 (41)	10 (31)	4 (21)
Thoracic pain	45 (62) I 5 (10)	3 (9)	1 (5)
Headache	34 (47) I 11 (22)	7 (22)	5 (26)
Myalgia	23 (32) I 6 (12)	4 (13)	2 (11)
Arthralgia/arthritis	39 (54) I 16 (33)	9 (28)	5 (26)
Dermal symptoms (urticarial, maculopapulose)	15 (21) I 5 (10)	3 (9)	0 (0)
SAE	**Number of events**	**Incidence rate# per 100 patient years**	
All types of SAE	18	14.03	
SADR	2	1.56	

Incidence rate = number of events * 36,525 / sum of observation days (=46,848).CRP, c-reactive protein; ESR, erythrocyte sedimentation rate; n. a., not annotated; SAA, serum amyloid A; SADR, serious adverse drug reaction; SAE, serious adverse events.

Conclusion: Interim data of FMF patients from the RELIANCE study, the longest running real-life canakinumab registry confirm efficacy and safety of long-term canakinumab treatment.

Background: Uncontrolled inflammation in patients with familial Mediterranean fever (FMF) can lead to severe organ failure due to amyloidosis. Colchicine is still the standard treatment and the only therapy that has been proven to reduce the risk for amyloidosis. Besides colchicine the Interleukin (IL)1-antagonists Anakinra and Canakinumab are approved, but new treatment options are still needed. The IL-6 antagonist Tocilizumab (TCZ) effectively reduces inflammation and is approved in several other rheumatic indication. Here we present data from our phase II study TCZ for the treatment of FMF – TOFFIFE.

Objectives: To explore the efficacy and safety of tocilizumab in FMF.

Methods: The TOFFIFE study was a placebo-controlled, double-blinded, randomized trial to investigate the efficacy and safety of TCZ in patients with colchicine resistant (cr)FMF. The physician's global assessment of disease activity (PGA) based on a 5 point-scale for 6 symptoms (range 0-24) was used as a clinical score and had to be >2 at screening. Patients were randomized 1:1 to either receive monthly TCZ intravenously with 8 mg/kg bodyweight or placebo over a period of 24 weeks. Patients with inadequate response after week 12 had the opportunity to receive open label TCZ at week 16. The primary endpoint was the number of patients achieving an adequate response to treatment at week 16, defined as a PGA ≤ 2 + normalized ESR or CRP (the item that led to inclusion had to be normalized) + normalized SAA. Secondary endpoints included normalization of SAA during treatment and safety of TCZ in FMF patients.

Results: 25 patients were randomized with a median age of 31 years (range 18 - 53y), of which 14 (56%) were female. At week 16, which was the timepoint for the primary end point, 2 (15.4%) patients in the TCZ arm reached the primary end point with a PGA ≤ 2 and normalization of SAA and CRP and/or ESR but none of the patients in the placebo arm. Therefore, the superiority of TCZ compared to placebo could be shown concerning the pre-specified significance level of α=0.2 (p=0.089). SAA levels normalized with TCZ but not with PBO. This difference between TCZ und PBO was highly significant; SAA p < 0.015. At week 28 with 17 remaining patients and after having had the opportunity for a rescue treatment at week 16, the responder rates (PGA ≤ 2 + normalization of SAA, ESR and/or CRP) were 25% (n=1) in those patients who changed from placebo to TCZ (n=4) and 20% (n=2) in those patients who continued with TCZ (n=10). Of note, all 3 patients remaining on PBO were non-responders (p= 0.642). In 75% of patients (n=3) CRP and in 50% SAA (n=2) normalized after changing to TCZ. No new safety aspects occurred.

Conclusion: In this first randomized, placebo-controlled study in patients with active crFMF TCZ significantly reduced and normalized SAA levels. The trial met the primary endpoint to demonstrate the superiority of TCZ over PBO although only a small numerical difference was found. Nevertheless, the proportion of patients with a successful TCZ-therapy was lower than expected due to very strict response criteria; patients had to achieve a complete remission with a PGA ≤2 (on a 0-24 scale) and normalization of the inflammatory parameters (CRP/ESR and SAA). This required no or only mildest symptoms during the last 4 weeks. A larger multicenter study is therefore justifiable and needs to clarify the benefit of TCZ treatment in FMF.

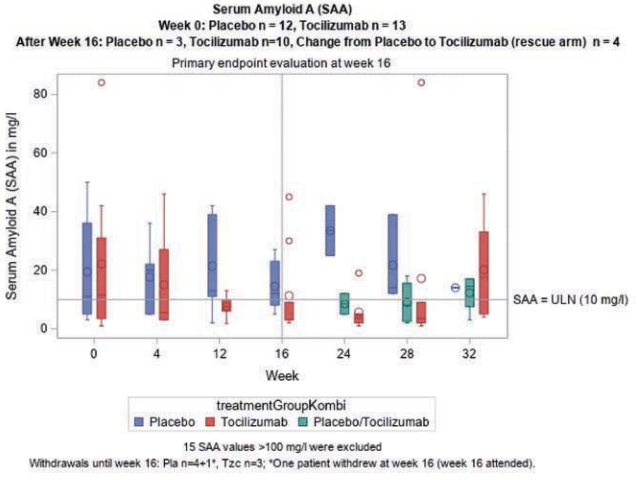

Figure 1. Secondary endpoint: Serum Amyloid A over time, showing a clear reduction in the TCZ but not in the PBO arm and rerise of SAA after discontinuation after week 28. Normal SAA value = < 10mg/l. Outliers > 100mg/l were excluded in this graph.

Background: Adult-onset Still's disease (AOSD) is a rare multigenic autoinflammatory disease of unknown aetiology burdened by life-threatening, such as macrophage activation syndrome (MAS) [1]. Considering the poor outcome of MAS patients, previous works tried to assess predictive factors of its occurrence during AOSD [2-4]. However, an integrated evaluation of clinical features with biomolecules, more reflecting the pathogenic mechanisms of the disease and its complications, is still missing.
Objectives: To multidimensionally characterise MAS complicating AOSD considering cytokine profile, inflammatory markers, and multi-visceral involvement of the disease. To perform a high-dimensional phenotypic analysis of circulating immune cells in AOSD patients with and without MAS. To assess interferon (IFN)-related pathways in AOSD synovial tissues by a bulky RNA sequencing.
Methods: The present evaluation was designed to multidimensionally compare AOSD patients with or without MAS, considering cytokine profile, inflammatory markers, and multi-visceral involvement of the disease. Clinical and biologic data were collected and compared in AOSD patients with and without MAS. Sera biomolecules were analysed by Luminex multiplexing technology. Mass cytometry (CyTOF) was used to characterise circulating immune cells. A bulky RNA sequencing was performed in AOSD synovial tissues.
Results: In this study, 40 consecutive AOSD patients (47.7±15.0 years, 50.0% male gender) were assessed at the time of diagnosis before the administration of any immunosuppressive therapy. Out of those, 14 (35%) patients were complicated by MAS. Paralleling with increases of systemic score and ferritin, MAS patients were characterised by an increased concentration of IL-1α, IL-1β, IL-1Ra, IL-2Ra, IL-6, IL-10, IL-17A, IFN-γ, G-CSF, MCP-1, MIP-1α, SCF. Among these biomolecules, IL-1Ra, IFN-γ, MCP-1, and SCF were correlated with MAS. Combining the discriminatory ability of these data in identifying MAS, the best model was composed by systemic score, ferritin, IFN-γ, and IL-10. This model was characterised by AUC=0.99 (Standard error: 0.008; 95%CI: 0.976–1.000), sensitivity=100%, specificity=95.45%. By CyTOF analysis, AOSD patients, who were complicated or not with MAS were characterised by a significant increase of circulating "classical monocytes" (CD14+CD38+). MAS patients were characterised by a significant reduction of NK cells (CD45RA+CD56dim) than AOSD patients. Finally, the transcriptomic profile, by RNA-sequencing analysis, showed that 3477 among type I, II, and III IFN-related genes (IRGs) were significantly different in AOSD synovial tissues.
Conclusion: A multidimensional characterisation of AOSD patients was provided suggesting that IFN-γ, IL-10, ferritin, and systemic score discriminated MAS, thus identifying the occurrence of the cytokine storm syndrome. The inflammatory *milieu* of AOSD and MAS may be associated with a signature of circulating immune cells. Finally, our results about IRGs reinforced the role of IFN-γ in these patients.

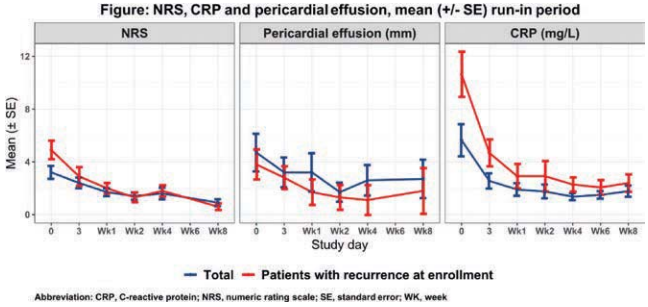
Background: Idiopathic recurrent pericarditis (IRP) is a rare autoinflammatory disease [1,2] that has similar pathogenesis with adult-onset Still's disease and monogenic autoinflammatory diseases [3,4]. IL-1α and IL-1β are the pivotal cytokines in the pathophysiology of acute pericarditis and its recurrence [5]. This report presents the interim analysis of clinical trial with goflkicept (original, fusion protein, heterodimer, binding IL-1α and IL-1β) in patients with IRP. Trial registration: ClinicalTrials.gov, NCT04692766.
Objectives: To evaluate the efficacy and safety of goflikicept treatment in patients with IRP.
Methods: Subjects with recurrence (n=9) or in inter-recurrence period (n=13) were enrolled in the run-in period of 12 weeks for treatment with NSAIDs and/or colchicine or 24 weeks for treatment with corticosteroids (CS).
Dose finding approach was applied, where subjects from the first cohort (n=10) received subcutaneous goflikicept 80 mg every 2 weeks, subjects from the second cohort (n=12) - 240 mg load within the first week, 80 mg within the second week, thereafter 80 mg every 2 weeks on top of background NSAIDs, colchicine and/or CS. Treatment response is considered as an achievement or maintenance of the following criteria: chest pain NRS≤3, CRP≤5 mg/L, absent or mild (<10 mm) pericardial effusion on Day 14. In responders NSAIDs/colchicine were stopped immediately, CS therapy was reduced and terminated within 12 weeks and for the next 12 weeks patients were on goflikicept monotherapy. At the end of the run-in responders proceeded into the double-blind, placebo-controlled randomized-withdrawal (RW) period, where received goflikicept 80 mg every 2 weeks or placebo. Primary endpoint was the time to the first pericarditis recurrence. In case of recurrence, the patients were unblinded, patients from placebo group retreated with goflikicept. According to interim analysis plan efficacy/safety analysis included only unblinded data during the RW period.
Results: Treatment response was achieved in 8 of 9 patients, enrolled with recurrence and all patients enrolled without recurrence remained in remission at Day 4. There were no new recurrence events on goflikicept therapy, despite NSAIDs/colchicine/CS discontinuation during the run-in period. In the run-in period mean NRS, CRP and pericardial effusion decreased from baseline (Figure 1). Decrease of concentrations of IL-1RA, IL-6, calprotectin was reported during the run-in period, which confirms anti-inflammatory effect of goflikicept. A total of 20 patients were randomized. Recurrent pericarditis occurred in 8 of 10 patients in placebo group, there were no recurrence events in goflikicept group to the moment of this interim analysis. After retreatment with goflikicept and recurrence resolution there were no new recurrence events. Adverse events (AEs) occurred in 15 of 22 patients (68,2%) during the run in period. During the run- in period, 6 of 22 patients (27%) experienced infections, 4 (18,2%) cholesterol elevation, 3 (13,6%) lymphopenia, 2 (9,1%) lipase elevation, 2 (9,1%) injection site reactions. AEs occurred in 4 of 8 patients (50%) during placebo treatment in the RW period. AEs occurred in 6 of 8 patients (75%) after retreatment with goflikicept. There were no deaths, no new safety signals. Overall safety profile was similar to those described for other IL-1 blockers.

Figure: NRS, CRP and pericardial effusion, mean (+/- SE) run-in period



Abbreviation: CRP, C-reactive protein; NRS, numeric rating scale; SE, standard error; WK, week

Conclusion: The first data show ability to achieve and maintain IRP remission on goflikicept monotherapy with favorable risk-benefit ratio. Final data will be provided.

OP0046 EVALUATION OF THE EFFICACY OF TOPICALLY APPLIED TACROLIMUS IN THE TREATMENT OF ORAL ULCERS IN BEHCET'S DISEASE: A DOUBLE BLIND PLACEBO CONTROLLED STUDY

M. Hassanien[1], A. Moshrif[2], M. Galal[3], F. Abuzaid[3], D. Fathalla[4], E. Talaat[1]. *[1]Assiut University, Rheumatology, Assiut, Egypt*; *[2]Al-Azhar University, Rheumatology, Assiut, Egypt*; *[3]Al-Azhar University, Oral Medicine, Periodontology, Assiut, Egypt*; *[4]Assiut University, Pharmaceutics, Assiut, Egypt*

Background: Treatment of Behcet disease (BD) associating oral ulcers is still challenging despite the advances in the systemic treatment modalities.
Objectives: We aimed to evaluate the clinical efficacy of topical Tacrolimus for treatment of BD.
Methods: In this double blind placebo controlled trial, forty BD patients with persistent active oral ulceration were equally randomized into group I (20 patients received oral colchicine plus topically applied tacrolimus) and group II (20 patients received oral colchicine plus placebo oral gel). All participants were evaluated based on Behcet's Disease Current Activity Form (BDCAF), Ulcer Severity Score (USS) and visual analog scale (VAS) before treatment, and at four-time points post-treatment (15 days, 1st, 2nd, and 3rd months).
Results: VAS was significantly lower in group I after 2 weeks (p= 0.037) and 3 months (0.025) than in group II. USS was significantly lower in group I after 3 months of follow up regarding the number of ulcers (p=0.014), ulcer size (p=0.022), and duration (p=0.009). BDCAF showed significant improvement in 3 months follow up within each group (p<0.001 for both groups), while there was insignificant difference between both groups(p=0.347).
Conclusion: Topical Tacrolimus has been proven to be a safe and effective adjunctive therapy in the management of oral ulcerations in BD.

OP0047 IMPAIRED JAK-STAT PATHWAY IN PATIENTS WITH PYODERMA GANGRENOSUM

T. Demirci Yildirim[1], A. Kahraman Akkalp[2], A. Köken Avşar[1], F. Onen[1], S. Akar[3], I. Sari[1]. *[1]Dokuz Eylul University, Faculty of Medicine, Rheumatology, Izmir, Turkey*; *[2]Izmir Katip Celebi University, Pathology, Izmir, Turkey*; *[3]Izmir Katip Celebi University, Rheumatology, Izmir, Turkey*

Background: Pyoderma gangrenosum (PG) is an inflammatory disease with an unknown etiology. Currently there is an unmet need in the of PG. In recent years, JAK/STAT pathway have been shown to have an important role in the etiology of inflammatory conditions particularly in the field of dermato-rheumatology. However, current data on JAK/STAT pathway in PG is significantly limited.
Objectives: Herein we aimed to investigate the JAK/STAT signaling pathway in the skin biopsies of PG patients and compared with psoriasis (PSO) and healthy subjects (HS).

Table 1. Summary of the findings

			Healthy Subjects (n=26)	Pyoderma Gangrenosum (n=31)	Psoriasis (n=35)
	Age, mean ± SD		**60,3 ± 18,3**	**58,1 ± 16,1**	**46,5 ± 18,4**
	Women/men (%)		**14/12**	**18/13**	**15/20**
Dermal staining	**JAK1**	Positive, n (%)	0	7 (22.6)*	3 (8.5)
	JAK3	Positive, n (%)	0	27 (87)*	31 (88.5)**
	TYK2	Positive, n (%)	0	31 (100)*	34 (97.2)**
	STAT1	Positive, n (%)	0	20 (64.5)*	27 (77.1)**
	STAT3	Positive, n (%)	0	29 (93.6)*	1 (2.8)
	STAT4	Positive, n (%)	0	7 (22.6)*	11 (31.4)**
	STAT5	Positive, n (%)	0	9 (29.3)	27 (77.1)**
	STAT6	Positive, n (%)	0	3 (9.7)	33 (94.3)**
cytoplasmic parts of epidermis	**JAK1**	Negative, n (%)	0	1	0
		Mildly positive, n (%)	0	0	0
		Moderately positive, n (%)	23 (88.4)	6 (19.4)	24 (68.5)
		Strongly positive, n (%)	3 (11.5)	24 (77.4)*	11 (31.5)**
	TYK2	Negative, n (%)	0 (0)	1 (3.2)	2 (5.7)
		Mildly positive, n (%)	0 (0)	4 (12.9)	1 (2.8)
		Moderately positive, n (%)	18 (69.2)	18 (58.1)	11 (31.4)
		Strongly positive, n (%)	8 (30.8)	8 (25.8)	21 (60)**
	STAT3	Negative, n (%)	0	1 (3.2)	0
		Mildly positive, n (%)	0	1 (3.2)	0
		Moderately positive, n (%)	12 (46.1)	1 (3.2)	1 (2.8)
		Strongly positive, n (%)	14 (53.9)	28 (90.4)*	34 (97.2)**
	STAT4	Negative, n (%)	0	1 (3.2)	0
		Mildly positive, n (%)	0	1 (3.2)	0
		Moderately positive, n (%)	12 (46.1)	3 (9.7)	6 (17.1)
		Strongly positive, n (%)	14 (53.9)	26 (83.9) *	29 (82.9) **
	STAT6	Negative, n (%)	18 (69,2%)	15 (48,4%)	1 (2,8%)
		Mildly positive, n (%)	8 (30,8%)	16 (51,6%)	0
		Moderately positive, n (%)	0	0	20 (57,2%)
		Strongly positive, n (%)	0	0	14 (40%)**
nuclear part of epidermis	**TYK2**	Negative, n (%)	22 (84,6%)	1 (3,2%)	2 (5,7%)
		Mildly positive, n (%)	4 (15,4%)	10 (32.2%)	6 (17,1%)
		Strongly positive, n (%)	0	20 (64,6%)*	27 (77,2%)**
	STAT3	Negative, n (%)	0	1 (3,2%)	0
		Mildly positive, n (%)	16 (61,5%)	2 (6,5%)	5 (14,3%)
		Strongly positive, n (%)	10 (38,5%)	28 (90,4%)*	30 (85,7%)**

Data were shown mean±SD and n (%), *= significant expression HS vs PG, **= significant expression HS vs PSO.

Methods: 31 patients with PG, 35 patients with PSO and 26 HS were included. Immunohistochemical methods were used to evaluate the expression of JAK1, JAK2, JAK3, Tyrosine Kinase 2 (TYK2), STAT1, STAT3, STAT4, STAT5, and STAT6. In the dermis the staining intensity was recorded as 'positive' or 'negative. The epidermal part is divided into cytoplasmatic and nuclear parts and staining intensity recorded by semi-quantitively as follows: negative, mildly positive, moderately positive and strongly positive.
Results: In total, there were 92 biopsies. Dermal staining was significant for all the JAK/STAT proteins for patients with PG and PSO when compared to HS. On the other hand, there were no differences in the staining patterns of PG and PSO. For the investigation of cytoplasmic parts of epidermis JAK1, STAT3, and STAT4 were highly expressed in the PG and PSO, STAT6, and TYK2 were only significantly overexpressed in psoriasis. JAK3 was overexpressed in healthy skin, PG and psoriasis. The assessment of the nuclear part of epidermis TYK2 and STAT3 were highly expressed in the PG and PSO. JAK1 was overexpressed in PG versus PSO in cytoplasmic parts of the epidermis ($p<0.001$). TYK2 and STAT6 were highly expressed in the PSO versus PG in cytoplasmic parts of the epidermis ($p = 0.024$, $p<0.001$). In the investigation of nuclear parts of epidermis STAT1, STAT6 were highly expressed in the PSO versus PG. The summary of the findings is given in Table 1.
Conclusion: In this study, the JAK/STAT inflammatory pathway is significantly activated in PG patients which is adding up new information to the current literature. Considering the unmet need in PG targeting of this pathway could be beneficial for the treatment of refractory PG.
Disclosure of Interests: None declared.

OP0048

FIRST INTERIM ANALYSIS OF THE INTERNATIONAL X-LINKED HYPOPHOSPHATAEMIA (XLH) REGISTRY: ADULT POPULATION BASELINE CHARACTERISTICS

K. Briot[1], J. Liu[2], A. Williams[3], S. Wood[4]. *[1]Hôpital Cochin, Service de Rhumatologie, Centre de Référence des Maladies Rares du Métabolisme du Calcium et du Phosphate Filière OSCAR, AP-HP, Paris, France*; *[2]Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom*; *[3]Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom*; *[2]Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom*

Background: X-Linked Hypophosphataemia (XLH) is a rare, progressive, lifelong, hereditary phosphate wasting disorder characterised by a pathological increase in fibroblast growth factor 23 concentration/activity.[1] Despite XLH being increasingly recognised as a chronic progressive disease, there are few data documenting its natural history or the impact of treatment and other medical interventions on patient outcomes.[2] The multicentre, international, XLH patient registry was established to address this lack of information in XLH to help inform future clinical practice.
Objectives: To report data from the first interim analysis of the International XLH Registry (NCT03193476), focusing on baseline characteristics of adults (aged ≥18 years [y]).
Methods: The International XLH Registry was initiated August 2017 to collect information on the natural history of XLH and will run for 10 years, aiming to recruit 1,200 people with XLH. Subjects diagnosed with XLH were enrolled from 81 sites in 16 countries (Last Patient In: 30/11/2020; Database Lock: 29/03/2021). Parameters collected at baseline included demographics, medical/treatment history, and clinical presentation.
Results: In total, 217 adults were eligible for inclusion in this analysis (18–<30y, n=56; 30–<50y, n=96; ≥50y, n=65); and 150 (69.1%) were female. Mean (SD) age was 41.9y (15.5y); median 41.1y. Mean height was 155.8 cm (n=79); mean weight, 70.0 kg (n=96); mean BMI 26.5 kg/m^2 (n=48). Most subjects resided in the UK (50.7%, n=110) and in France (18.9%, n=41). Treatment data were available for 118 subjects: conventional therapy (phosphate salts and active vitamin D), 83.9% (99/118); burosumab, 11.0% (13/118); no treatment recorded 5.1% (6/118). Of 163 subjects with available data, a genetic test result was recorded for 68 (41.7%), of whom 62 (91.2%) had a confirmed *PHEX* mutation. Data on XLH family history were available for 187 subjects; 56/140 (40.0%) reported their biological mother was affected; and 22/141 (15.6%) reported their biological father was affected. The mean time to diagnosis from first symptoms was longer in older vs younger adults: 18–<30y, 25 months (mo) (n=21); 30–<50y, 21mo (n=21); ≥50y, 112mo (n=13).
Retrospective XLH clinical data were available at study entry for 110 adult subjects. Among these subjects, joint conditions were reported by 36.4% (40/110), with osteoarthritis of the knees (60%), hips (42.5%), and shoulders (22.5%) the most frequently affected. Skeletal abnormalities were noted for 71.8% (79/110) of subjects; most common conditions were *genu varum* 53.2% (42/79), *genu valgum* 26.6% (21/79), and enthesopathy 21.5% (17/79). Historical fracture data ("yes/no") were available for 111 subjects; 41 were reported to have had a fracture. Femur fracture was reported for 22 subjects, and hip fractures for 5 subjects. Details of historical orthopaedic surgery were reported for 99 adults; osteotomy was reported for 89 subjects, and hip replacements reported in 14 subjects.
Conclusion: The demographics and baseline characteristics of subjects in the International XLH Registry are as expected for adults with XLH. The shorter time to diagnosis in younger vs older adults may indicate improved recognition and diagnosis of XLH in recent years. The analysis of this young population treated with conventional therapy highlights the frequency of musculoskeletal involvement (osteoarthritis, enthesopathies, etc). The information collected within this rare-disease registry during these 10 years provides an exciting opportunity to integrate large-scale real-world evidence into clinical practice, with the aim of improving the care and quality of life of people living with this debilitating disease.

OP0049

FURTHER CHARACTERIZATION OF CLINICAL AND LABORATORY FEATURES OCCURRING IN VEXAS SYNDROME IN A LARGE-SCALE ANALYSIS OF MULTICENTER CASE-SERIES OF 116 FRENCH PATIENTS

S. Georgin-Lavialle[1], B. Terrier[2], K. Olivier[3], A. Mekinian[4], on behalf of fench vexas group. *[1]tenon, internal medicine, Paris, France*; *[2]cochin, internal medicine, Paris, France*; *[2]cochin, internal medicine, Paris, France*; *[4]saint antoine, internal medicine, Paris, France*

Background: A new autoinflammatory syndrome related to somatic mutations of *UBA1* was recently described and called VEXAS syndrome.
Objectives: To describe clinical characteristics, laboratory findings and outcomes of VEXAS syndrome.
Methods: Case-series. Patients referred to a French multicenter registry between November 2020 and May 2021.
116 patients with VEXAS syndrome. Frequency and median of parameters and vital status, from diagnosis to the end of the follow-up.
Results: Main clinical features were skin lesions (83.5%), non-infectious fever (63.6%), weight loss (62%), lung involvement (49.6%), ocular symptoms (38.8%), relapsing chondritis (36.4%), venous thrombosis (34.7%), lymph nodes (33.9%), and arthralgia (27.3%). Hematological disease was present in 58 cases (50%), considered as myelodysplastic syndrome (MDS, n= 58) and monoclonal gammapathy of unknown significance (n=12).*UBA1* mutations included p.M41T (44.8%), p.M41V (30.2%), p.M41L (18.1%), and splice mutations (6.9%). After a median follow-up of 3.0 years, 18 patients died (15.5%), from infectious origin (n=9) and MDS progression (n=3). Unsupervised analysis identified 3 clusters: cluster 1 (47%) with mild-to-moderate disease; cluster 2 (16%) with underlying MDS and higher mortality rates; cluster 3 (37%) with constitutional manifestations, higher C-reactive protein levels and less frequent chondritis. Five-year probability of survival was 84.2% in cluster 1, 50.5 % in cluster 2, and 89.6% in cluster 3. *UBA1* p.Met41Leu mutation was associated with a better prognosis.
Conclusion: VEXAS syndrome displays a large spectrum of organ manifestations and shows different clinical and prognostic profiles. It also raises a potential impact of the identified *UBA1* mutation.
Disclosure of Interests: None declared.

Managing chronic pain in RMDs

OP0050

INTRAARTICULAR MORPHINE IN CHRONIC KNEE-ARTHRITIS – RESULTS OF A RANDOMIZED PLACEBO-CONTROLLED TRIAL

H. Haibel[1], J. Sieper[1], D. Poddubnyy[1,2], V. Rios Rodriguez[1], F. Proft[1], J. Rademacher[1,3], S. Igel[1], P. Martus[4], C. Stein[5]. *[1]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany*; *[2]German Rheumatism Research Centre, Epidemiology, Berlin, Germany*; *[3]Berlin Institute of Health, Clinician Scientist Program, Berlin, Germany*; *[4]Tübingen, Clinical Epidemiology and Statistics, Tübingen, Germany*; *[5]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Anesthesiology and Intenisve Care, Berlin, Germany*

Background: Patients with chronic inflammatory arthritis (e.g. rheumatoid arthritis; RA) or inflammatory exacerbations of chronic degenerative joint diseases (e.g. osteoarthritis; OA) suffer from recurrent pain, restricted function

and reduction of daily activities. The current standard of intraarticular (i.a.) therapy is the injection of steroids, which can increase risk of infection, cartilage degenerations, and other well-known systemic side effects. A novel approach without such complications could be the activation of peripheral opioid receptors, e.g. by i.a. application of small, systemically inactive doses of morphine.

Objectives: The aim of this randomized placebo-and active drug controlled double blind trial was to investigate reduction of pain in chronic knee arthritis patients following i.a. injections of morphine, a standard steroid (triamcinolone), or placebo. The primary hypothesis was that i.a. morphine results in significantly lower pain scores than placebo. The primary outcome parameter was reduction of the Visual Analogue Scale (VAS) pain at day 7.

Methods: Adult patients with chronic knee arthritis because of osteoarthritis (OA) or inflammatory arthritis (IA, rheumatoid arthritis, psoriatic arthritis, spondyloarthritis, oligoarthritis or monarthritis) and a high level of pain (VAS pain ≥ 4 out of 10) at baseline received a single dose of either morphine 3 mg i.a., or triamcinolone 40 mg i.a., or placebo (NaCl 0.9%) i.a., Patients were monitored closely throughout the entire study period with a total of 4 visits over weeks and documented pain in the morning and evening in a patient´s diary. Safety data was collected during the whole study period. P-values were calculated using two-sided T-tests.

Results: 114 patients were screened, 93 were treated and 89 (96%) completed day 7. Of these n= 61 (66%) were diagnosed with OA and n= 32 (34%) with IA 48 (52%) patients were female, mean age was 58.5 (SD 14 years) and mean disease duration 6.7 years (median 2 years, range <1 year – 42 yearss, IQR <1 – 10 years). The mean VAS pain improvement at day 7 for morphine, triamcinolone and placebo was -22.8, -37.7, and -19.8 respectively. The differences were not significant (p=0.69) for placebo vs. morphine, but significant for placebo vs. triamcinolone and for triamcinolone vs. morphine (p=0.013 and p=0.006). Mean improvements of the everyday pain documentation are shown in Figure 1. During the study period, there were no serious adverse events and 45 adverse events, most of them were mild.

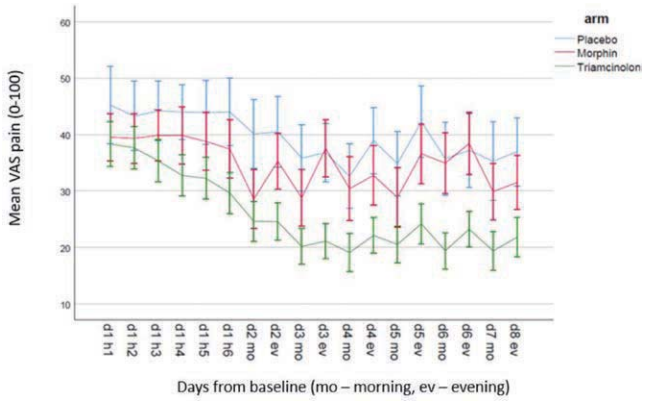

Figure 1. Mean VAS pain over one week in patients with chronic knee arthritis treated with morphine, triamcinolone or placebo as a single intraarticular injection.

Conclusion: In this randomized, placebo and active controlled double blind trial a single dose of 3 mg i.a. administered morphine did not lead to significant improvements in comparison to placebo and was inferior to triamcinolone at day 7. The same was true during the first 7 days as shown in the pain documentation in patient diaries. These data does not support the use of i.a. morphine for pain reduction in patients with chronic arthritis.

OP0051

TRENDS FOR OPIOID PRESCRIPTIONS AMONG PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES BETWEEN 2006-2020

J. Y. T. Huang[1], D. Jenkins[2,3], B. Birlie Yimer[1], J. Benitez-Aurioles[2], N. Peek[2], M. Lunt[1], W. Dixon[1], M. Jani[1]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Manchester, United Kingdom*; [2]*University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom*; [3]*University of Manchester, NIHR Greater Manchester Patient Safety Translational Research Centre, Manchester, United Kingdom*

Background: Opioid prescribing has contributed to a North American epidemic with increasing trends in several European countries[1]. Rheumatic and musculoskeletal diseases (RMDs) are one of the most common indications for prescribed opioids despite there being little evidence on opioid prescribing and the benefit of long-term use in RMDs.

Objectives: To investigate national UK opioid prescribing trends by studying the patterns of opioid prescribing in new users with the following six RMDs: rheumatoid arthritis (RA), psoriatic arthritis (PsA), axial spondyloarthritis (AxSpA), systemic lupus erythematosus (SLE), osteoarthritis (OA) and fibromyalgia.

Methods: Patients aged 18 years and older with a diagnosis of RA, PsA, AxSpA, SLE and OA with a new episode of opioid use without cancer in the Clinical Practice Research Datalink (CPRD) were included between 01/01/2006 and 31/12/2020. CPRD is a database of anonymised UK primary care electronic health records representative of the national population. New opioid users were defined as individuals with RMDs who had a new episode of opioid use in a 2-year time window up to 6 months before or after an RMD diagnosis. Rates of new opioid users were calculated by dividing the number of new opioid users with an RMD per year by the number of eligible patients registered in CPRD per year. Age- and gender-standardised rates for new opioid users were obtained using direct standardisation for each RMD. Rates of opioid prescriptions among new users for each RMD were calculated by dividing the number of opioid prescriptions among new users with an RMD in the year they had new opioid episodes by patient-years of the new users with an RMD. Trends for the rates in the study period were tested using negative binomial regression. Significant change points were identified by looking at the points where the derivative (i.e. rate of change) of the trends for the rates crossed zero. Recurrent opioid users were defined as patients who had at least 3 opioid prescriptions issued within 3 months after a new opioid episode.

Results: This study included 21,505 RA patients, 8,392 PsA patients, 4,491 AxSpA patients, 4,508 SLE patients, 944,078 OA patients, and 33,829 fibromyalgia patients, who had new opioid episodes between 2006-2020. Whilst the overall trend for RA (2.7* vs 3.9*), PsA (1.0* vs 1.8*) and fibromyalgia (3.7* vs 8.3*) has significantly increased over 15 years, from 2018 onwards, trends of new opioid users appeared to stabilise/decrease (Figure 1). The year 2018 was found to be a significant decreasing change point in the trends of new opioid users for RA, AxSpA, and SLE, whilst this was 2013 in OA and 2019 for fibromyalgia. Opioid prescription rates among new opioid users increased in SLE (4.3# vs 5.4#), OA (4.6# vs 4.9#) and fibromyalgia (5.6# vs 6.5#) but decreased in RA (5.7# vs 5.3#) from 2006 to 2020, despite fluctuations in the rates observed in this period. The highest proportions of recurrent opioid users among the 6 RMDs were patients with RA (32.6%) and fibromyalgia (31.9%).

* The number of new opioid users per 10000 persons

The number of opioid prescriptions in new users per patient years

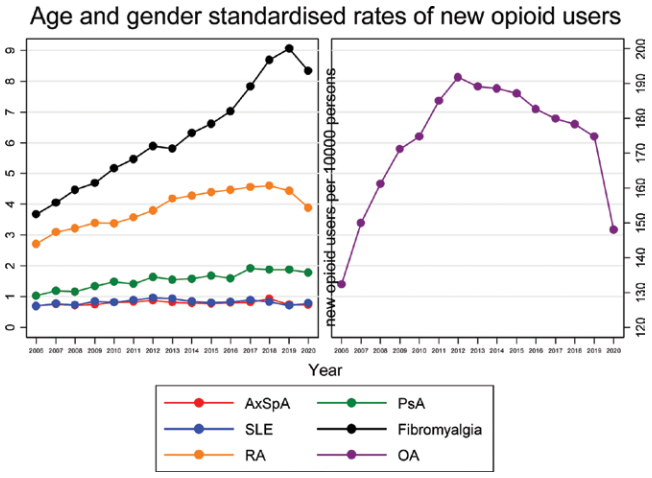

Figure 1. Trends of new opioid users by RMD, 2006-2020.

Conclusion: RA, PsA and fibromyalgia had an overall increase in new opioid users since 2006. The slight decrease in the trends of new opioid users among most of the RMDs after 2018 may reflect an increasing awareness of the opioid epidemic. The high proportions of recurrent opioid users in RA and fibromyalgia patients highlight the importance of exploring the safety of long-term opioid use and effective pain interventions for patients with RMDs.

OP0052

THE EFFECT OF TOFACITINIB ON RESIDUAL PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS WITH COMPLETE CONTROL OF INFLAMMATION

M. Dougados[1,2], P. C. Taylor[3], C. Bingham[4], L. Fallon[5], Y. Brault[6], S. Roychoudhury[7], L. Wang[8], M. Kessouri[6]. [1]*Université de Paris; Hôpital Cochin; Assistance Publique-Hôpitaux de Paris, Department of Rheumatology, Paris, France*; [2]*INSERM (U1153): PRES Sorbonne Paris-Cité, Clinical Epidemiology and Biostatistics, Paris, France*; [3]*University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [4]*Johns Hopkins University, Division of Rheumatology, Baltimore, MD, United States of America*; [5]*Pfizer Inc, Inflammation and Immunology, Montreal, QC, Canada*; [6]*Pfizer Inc, Inflammation and Immunology, Paris, France*; [7]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; [8]*Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*

Background: Residual pain often remains in patients (pts) with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) who achieve low disease activity or remission.[1,2] Tofacitinib is an oral JAK inhibitor for the treatment of RA and PsA. A descriptive analysis showed that tofacitinib may have a beneficial effect on residual pain in pts with PsA with abrogated inflammation.[3]

Objectives: To assess efficacy of tofacitinib, adalimumab (ADA) and placebo (PBO) on residual pain in pts with RA and PsA with abrogated inflammation, using a network meta-analysis (NMA).

Methods: Data were pooled from 9 randomised clinical trials of pts with RA (NCT00960440/NCT00847613/NCT00814307/NCT00856544/NCT00853385/NCT01039688/NCT02187055) or PsA (NCT01877668/NCT01882439). This analysis included pts who received ≥1 dose of tofacitinib 5 mg twice daily (BID), ADA 40 mg once every 2 weeks or PBO with background therapy, and had abrogated inflammation (swollen joint count [SJC] = 0 and C-reactive protein [CRP] <6 mg/L) at Month (M)3. ADA was included in NCT00853385/NCT02187055/NCT01877668; NCT02187055 performed tofacitinib/ADA non-inferiority/superiority comparisons. Primary outcome was pt assessment of Pain (visual analogue scale [VAS] 0 [no pain] – 100 mm [most severe pain]) at M3; scores were summarised descriptively; treatment comparisons were assessed by Bayesian NMA on individual pt-level data, accounting for within-trial imbalances and treatment effect modifiers.

Results: Abrogated inflammation at M3 was achieved in 14.1% (328/2330), 14.9% (87/585) and 3.0% (20/673) of RA and 22.7% (54/238), 29.2% (31/106) and 12.7% (30/236) of PsA pts receiving tofacitinib, ADA and PBO, respectively. RA and PsA pts receiving tofacitinib/ADA had higher CRP vs pts receiving PBO. RA pts receiving tofacitinib/ADA had lower SJC and longer disease duration vs pts receiving PBO. PsA pts receiving tofacitinib had a longer disease duration and higher Pain VAS vs pts receiving ADA/PBO. In both groups, a lower % of female pts received tofacitinib/ADA vs PBO (Table 1). Observed median (Q1; Q3) values for Pain VAS at M3 were 17.0 (6.0; 31.0), 19.0 (7.0; 31.0) and 33.5 (7.0; 48.0) in RA and 24.0 (8.0; 44.0), 21.0 (9.0; 49.0) and 27.0 (8.0; 52.0) in PsA pts treated with tofacitinib, ADA or PBO, respectively. Differences between active treatments and PBO were less prominent in PsA vs RA pts, per posterior probability values (Fig).

Conclusion: In this NMA, pts with RA and PsA achieving abrogated inflammation with tofacitinib or ADA at M3 had greater residual pain reduction vs those receiving PBO. This may imply that tofacitinib/ADA have analgesic benefits beyond those related to inflammation reduction.

OP0053

LUMBAR MECHANICALS TRACTIONS IN RADICULAR PAIN OF DISCUS ORIGIN: A PROSPECTIVE CONTROLLED RANDOMIZED TRIAL OF SUPERIORITY ON 428 PATIENTS IN REIMS HOSPITAL UNIVERSITY RHEUMATOLOGY SERVICE

E. Bernhard[1], A. Hittinger[1], I. Charlot-Lambrecht[1], M. Geoffroy[1], L. Pauvele[1], B. Loïs[1], C. Clément[1], H. Delaplace[1], J. H. Salmon[1]. [1]*CHU of Reims - Maison Blanche Hospital, Rheumatology, Reims, France*

Background: Medical cares guidelines for lumbosciatics pains are well codified in several country: NSAIDs, analgesics and physical therapy associated, at physician's discretion, to lumbar epidural infiltrations.
Lumbar mechanical tractions have not a clear identified place in the lumbosciatic pain treatment. It is empirically realized in France's several medical centers.
However, no current literature studies have shown a significant efficacy of lumbar mechanicals tractions in this indication. Most of the time, studies presented a lack of power or methodological bias. (1,2)
Objectives: The aim of this study is to demonstrate the superiority of lumbar traction associated with standard treatment (epidural injections, analgesics, NSAID) compared to medical treatment alone in lombosciatics pains of discal origin.
Methods: We performed a monocentric interventional prospective superiority study from 2013 to 2021, randomized controlled in the rheumatology unit of Reims University Hospital. Patients included had to present a lumboradicular pain, with a concordant discal hernia on MRI or scanner, and to be naive of any lumbar surgery. We recorded demographical and clinical data at baseline and during the follow up. After their consent, patients were randomized between the traction group and the medical group. The medical group received the standard treatment (NSAIDs, analgesics) associated with at least 2 epidural infiltrations. The traction group received the standard treatment, infiltrations and at least 3 lumbar tractions. Treatment was considered as effective if there was a pain diminution at least 25 % between baseline and at 1 month. Patients were assessed on their pain at baseline, at 1 month and at 3 months of their treatment. Pain was assessed using a visual analog scale on lumbar and radicular localisation.
Superiority analysis has been performed by using the Chi-2 test.
Results: Four Hundred twenty-eight patients were included: 207 patients in the lumbar traction group, 210 patients in the medical treatment alone group and 11 patients with missing data. The male/female sex ratio was 1.39:1. The patients suffered from 49.52% (205 patients) right and 50.48% (209 patients) left lumboradiculalgia, mostly L5 (41% or 172 patients) and S1 (50% or 207 patients).
The pains evaluation at one month was recorded for 377 patients: 190 in traction group (50.3%) and 187 in medical group (49.7%). Two hundred twelve/377 (56.2%) patients had a pain reduction of at least 25 % at one month: 117/377 patients in tractions group (31%) and 95/377 in medical group (25%).
Twenty/377 patients (5%) were operated on before the one-month recall. Therefore, patients treated with lumbar traction had a significant reduction in pain (p=0.036) compared to patients with medical treatment alone.
Conclusion: This study is one of the first randomized controlled studies highlighting the superiority of lumbar traction in combination with standard treatment compared to medical treatment alone.

REDUCING THE BURDEN OF LOW BACK PAIN: RESULTS FROM A NEW MICROSIMULATION MODEL

J. Kopec[1], E. C. Sayre[2], J. Cibere[3], L. Li[4], H. Wong[5], A. Okhmatovskaia[6], J. Esdaile[7]. [1]*Arthritis Research Canada, School of Population and Public Health, University of British Columbia, Vancouver, Canada*; [2]*Arthritis Research Canada, Vancouver Coastal Health Research Institute, Vancouver, Canada*; [3]*Arthritis Research Canada, Department of Medicine, University of British Columbia, Vancouver, Canada*; [4]*Arthritis Research Canada, Department of Physical Therapy, University of British Columbia, Vancouver, Canada*; [5]*University of British Columbia, School of Population and Public Health, Vancouver, Canada*; [6]*McGill University, McGill Clinical and Health Informatics, Montréal, Canada*; [3]*Arthritis Research Canada, Department of Medicine, University of British Columbia, Vancouver, Canada*

Background: Low back pain (LBP) has been the leading cause of disability worldwide for the past 30 years. In 2019, LBP was responsible for 64 million years lived with disability (YLDs) [1].
Objectives: The purpose of the present study was to project and compare the impact of three strategies for reducing the population health burden of LBP: weight loss, ergonomic interventions, and an exercise program.
Methods: We have developed a microsimulation model of LBP in Canada using a novel simulation platform, SimYouLate. The initial population was derived from Cycle 1 (2001) of the Canadian Community Health Survey (CCHS). We modeled an open population 20 years of age and older. Key variables included age, sex, education, body mass index (BMI), type of work, having a back problem, pain level in persons with back problems, and exercise. The effects of interventions on the risk of LBP were obtained from the CCHS for the effect of BMI, the Global Burden of Disease Study for occupational risks, and a published meta-analysis for the effect of exercise. All interventions lasted from 2021 to 2040. Strength of the interventions varied over a wide range. YLDs were defined as LBP prevalence multiplied by disability weight. The population health impact of the interventions was calculated as a difference in YLDs between the base-case scenario and each intervention scenario and expressed as YLDs averted per intervention unit and as % of total LBP-related YLDs.
Results: In the base-case scenario, LBP in 2020 was responsible for 424,900 YLDs in Canada and the amount increased to 460,312 YLDs in 2040. The effects of the interventions on YLDs were as follows: 27,993 (95% CI 23,373, 32,614) YLDs averted over 20 years per 0.1 unit change in log-transformed BMI (10.5% change in BMI) among overweight and obese individuals, 19,416 (16,275, 22,557) YLDs averted per 1% reduction in the proportion of workers exposed to occupational risks, and 26,058 (22,455, 29,661) YLDs averted per 1% increase in the proportion of eligible patients with back problems participating in the exercise program. Table 1 shows the intervention impact as % of total LBP-related YLDs and Figure 1 shows YLD-equivalence between the interventions. A one unit reduction in BMI per year among the overweight and obese individuals would be approximately equivalent in terms of disability reduction to an effective ergonomic intervention in 35% of at-risk workers and an exercise intervention in 27% of eligible patients with back problems over the same period (Figure 1).

Table 1. YLDs averted between 2021 and 2040 as % of total LBP-related YLDs, according to intervention type and level, in persons aged 20+ in Canada

Intervention	Effect (%)	95% LCL	95% UCL
Reduction in BMI per year			
0.1	1.4	-1.4	4.1
0.3	4.8	2.2	7.3
0.5	6.3	3.9	8.8
1.0	8.5	6.0	11.0
3.0	11.9	9.4	14.4
5.0	13.5	10.9	16.0
Reduction in occupational exposure			
20%	5.2	1.9	8.5
40%	9.5	6.4	12.7
60%	13.8	10.6	16.9
80%	18.1	14.8	21.4
100%	22.4	18.8	25.9
Increase in exercise participation			
20%	6.6	2.8	10.4
40%	12.4	8.7	16.0
60%	18.1	14.5	21.7
80%	23.9	20.1	27.6
100%	29.6	25.5	33.7

LCL: lower confidence limit. UCL: upper confidence limit.

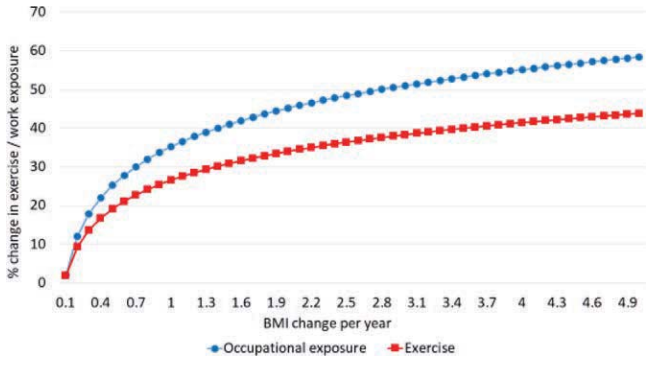

Figure 1. Equivalence between BMI, ergonomic and exercise interventions in terms of their impact on YLDs. Each point represents a specific number of YLDs averted. Values on the y-axis show reduction in % of workers at risk and increase in % exercising that are required to achieve the same reduction in YLDs as the corresponding reduction in BMI shown on the x-axis.

Conclusion: This is the first population-based microsimulation study to compare currently available preventive strategies in LBP in terms of YLDs averted and to provide measures of equivalence between these strategies.

OP0055 THE COMPARISON OF EFFECTS OF TWO DIFFERENT EXERCISE PROGRAM ON FUNCTIONAL CAPASITY AND QUALITY OF LIFE IN PREGNANT WOMEN WITH LOW BACK PAIN

E. Üzelpasaci[1], T. Akbayrak[1]. [1]*Hacettepe University, Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: Low back pain is the most common musculoskeletal problem which negatively affects functional capasity and quality of life during pregnancy (1). So, from the beginning of pregnancy, pregnant women should be supported by appropriate exercise approaches recomended as first-line therapy to reduce the complaints about low back pain (2, 3). Although there are different opinions about the type, intensity and frequency of exercise in order to improve function in pregnant women with low back pain, there are no comparative studies on the diversity and length of the exercise program.

Objectives: The aim of this study was to compare the effects of supervised, long and multivarity an exercise program (LEP) and a short exercise program (SEP), planned based on core stabilization and in line with the needs of pregnant women, on functional capasity and quality of life.

Methods: A total of 27 pregnant women complained about low back pain, without obstetric and medical complications were included in this study. Detailed sociodemographic and obstetric characteristics were recorded. Back pain intensity, functional capacity and the quality of life were determined by the Vidual Analogue Scale (VAS), 6-minute walk test and Short Form-36 Quality of Life Questionnaire. All outcome measures were evaluated at baseline, at 24 and 32 weeks of pregnancy. Starting from the 16th week of pregnancy to the 32nd week, for 16 weeks, 2 days a week, under the supervision of a physiotherapist, a stabilization-based exercise program consisting of posture training, upper extremity, lower extremity, abdominal and pelvic floor strengthening and breathing exercises was applied to the pregnant women by progressing modified. During the warm-up, loading and cool-down, while LEP consists of a total 20 different exercises; SEP consists of 9 different exercises. Both groups were advised to walk as an aerobic modarate exercise for 30 minutes, 3 days a week. The Independent Groups t-test was used to compare variables between groups at baseline 16th, 24th and 32nd week of pregnancy. Statistical significance was set at $p<0.05$.

Results: 14 pregnant women (mean age: 30.50 ± 4.11 years, mean body mass index $(BMI)_{16th,\ 24th,\ 32nd\ week\ of\ pregnancy}$: 23.42±3.81, 25.02±3.71, 26.25±3.73 kg/m^2) in LEP, 13 pregnant women (mean age: 30.75±5.05 years, $BMI_{16th,\ 24th,\ 32nd\ week\ of\ pregnancy}$: 24.73±3.84, 26.28±3.85, 27.91±3.60 kg/m^2) in SEP completed this study. Baseline parameters were similar between the two groups ($p>0.05$). There was no superiority between groups in terms of back pain intensity at the 24th and 32nd week of pregnancy ($p>0.05$). While at the 24th week of pregnancy, 6-minute walking test distance, emotional role limitation and pain sub-dimension scores of health-related quality of life were found to be higher in LEP ($p<0.05$), at the 32nd week of pregnancy, only 6 minutes walking test distance were found to be higher in LEP ($p<0.05$).

Conclusion: LEP is more effective in terms of increasing functional capacity, emotinal role limitation and pain-related quality of life in the short term and is more effective in terms of increasing functional capacity in the long term than SEP during pregnancy. In this respect; our study will guide clinicians to create indiviually exercise programs for the neeeds of pregnancy.

OP0056 "BECAUSE THAT'S THEIR JOB, ISN'T IT?": EXPLORING CHILDREN AND YOUNG PEOPLES' EXPERIENCES OF AND PERSPECTIVES ABOUT PAIN COMMUNICATION IN PAEDIATRIC RHEUMATOLOGY IN THE UK

R. Lee[1,2], D. Mountain[1,2], J. McDonagh[1,2,3], M. Connelly[4], S. Peters[5], L. Cordingley[1,2]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*Manchester University Hospital NHS Trust, National Institute for Health Research Biomedical Research Centre, Manchester, United Kingdom*; [3]*Manchester University Hospitals Trust, Royal Manchester Children's Hospital, Manchester, United Kingdom*; [4]*Children's Mercy Kansas City, Division of Developmental and Behavioral Health, Kansas City, United States of America*; [5]*University of Manchester, Manchester Centre for Health Psychology, Manchester, United Kingdom*

Background: Pain communication should be an integral part of every clinical consultation, particularly in paediatric rheumatology where children/young people often present complex long-term conditions in which chronic pain is a feature. Researchers investigating pain communication in paediatric healthcare encounters have been focused on healthcare professionals, yielding inconsistent findings about the occurrence and nature of pain discussions with children/young people. There has been limited research examining children/young peoples' own experiences and perspectives on this in the literature to date.

Objectives: The objective of this study was to investigate children/young peoples' experiences and perceptions of communicating about pain with paediatric rheumatology healthcare professionals in the UK.

Methods: Twenty-six children/young people were recruited from three UK paediatric rheumatology centres. Data were collected using semi-structured telephone interviews between April-October, 2021. A framework analysis approach was used to explore similarities and divergences in participants' narrative accounts.

Results: The mean age of children/young people was 14.0 years (SD=3.6 years, Range= 6-18 years, 58% female). Diagnoses included; Juvenile Idiopathic Arthritis, Chronic Regional Pain Syndrome, diffuse idiopathic chronic pain, localised idiopathic pain, hypermobility (including Ehlers Danlos Syndrome) and Raynaud's disease.

Findings are organised into four themes.

1) Nature and focus of appointments. Children/young people talked about pain with several professionals from the team. Participants reported that pain conversations predominantly occurred during physical examinations.
2) Co-ordination of pain communication. Children/young people identified how professionals mostly started pain conversations. They explained how they were often asked to verbally rate pain rather than use a written assessment tool. For some, questions about pain were directed to parents. Participants reported that this was problematic as parents "can't feel" pain.
3) Reflections on pain communication. There were expectations that pain should always be asked about as it was considered a main reason for a consultation. Participants discussed how these conversations gave them an opportunity to "get it off their chest" and made them feel "reassured" that professionals "care." Being asked about pain reminded them that they were different to peers and they were concerned it could highlight "something else is wrong." Children/young people talked about how it became easier to talk about pain with familiar professionals.
4) Moving forward after pain communication. Children/young people discussed how professionals could give mixed messages about how to manage pain at home following consultations, offering advice which was difficult to put into practice (e.g. "doing too much" vs "not doing enough"). Children/young people expressed their need to discuss the emotional as well as the physical effects of their pain.

Conclusion: These study findings highlight a range of effective and ineffective pain communication approaches from the experiences and perspectives of children/young people. These will be used to create recommendations for improving the communication of chronic pain in paediatric rheumatology in the future, in a way that is acceptable and valuable to children/young people.

Acknowledgements: The authors would like to thank the children/young people for kindly taking the time to share their experiences and perceptions about their interactions with healthcare professionals in paediatric rheumatology. The views expressed herein are those of the authors and not necessarily those of the National Health Service, the National Institute for Health Research, or the UK Department of Health. OP0057

RESPONSE TO INJECTION CAN PREDICT OUTCOMES OF FEMOROACETABULAR IMPINGEMENT

E. Campos Martins[1], D. Almeida Gomes[2], H. De Brito Fontana[2], D. Araujo Fernandes[1], F. De Souza Neves[3]. [1]*Federal University of Santa Catarina, Department of Surgery, Florianópolis, Brazil*; [2]*Federal University of Santa Catarina, Department of Morphological Sciences, Florianópolis, Brazil*; [3]*Federal University of Santa Catarina, Internal Medicine Department, Florianópolis, Brazil*

Background: Femoroacetabular impingement syndrome (FAIS) is a highly prevalent painful disorder that is considered a risk factor for hip osteoarthritis. In order to relieve pain and improve cartilage preservation, surgery is often performed. However, many operated patients do not show satisfactory outcomes. Reliable diagnostic tests that can inform prognosis of surgery in patients with FAIS are needed for optimized indications and contraindications to surgery.
Objectives: This systematic review aimed to answer the following question: "Can the response to intra-articular anesthetic injections be used to predict surgical outcomes in patients with FAIS?".
Methods: This study was conducted following the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) statement. Embase, CINAHL, LILACS, PubMed, SCOPUS, SPORTDiscuss, The Cochrane Library, and Web of Science databases were screened. All studies that assessed the capability of the response to intra-articular anesthetic injections in predicting surgical outcomes for patients with FAIS were considered eligible. Study selection and data collection were performed by three independent reviewers. Risk of bias of the included studies was assessed through the QUIPS tool.
Results: Seventeen articles were selected for full-text reading, of which 6 were considered eligible and included for analysis [1-6]. A summary of the studies' descriptive characteristics can be found in the Table 1. A high risk of bias due to study attrition and the presence of confounding factors was observed for all included studies. Five out of six studies [1-4,6] presented "high risk" of bias associated to the prognostic factor measurement. A high overall risk of bias was evidenced by QUIPS for all studies (Figure 1). From 6 included studies, 5 indicated that the response to intra-articular injections can be useful in the prediction of surgical outcomes [2-6].
Conclusion: Although there seems to be some evidence supporting the use of intra-articular anesthetic injections to predict surgical outcomes in patients with FAIS, it is not conclusive. Future studies taking into account the various possible sources of bias in prognostic studies are needed. Standardizing and optimizing injection protocols as well as post-injection pain assessment and outcomes measurements are also essential to fill this gap.

Background: The optimal first-line treatment of patients with early rheumatoid arthritis (eRA) is not established.

Objectives: To compare clinical and radiographic outcomes of active conventional therapy (ACT) with each of three biological therapies with different modes of action.

Methods: In this investigator-initiated, randomized, open-label, blinded-assessor study (NCT01491815), patients with treatment-naïve eRA with DAS28>3.2 and RF+/ACPA+/CRP>10mg/L, were randomized 1:1:1:1 to methotrexate combined with: 1) oral prednisolone (tapered quickly; discontinued at w36); or: sulphasalazine, hydroxychloroquine and mandatory intra-articular (IA) glucocorticoid injections in swollen joints (ACT); 2) certolizumab-pegol (CZP); 3) abatacept (ABA) or 4) tocilizumab (TCZ). IA glucocorticoid was allowed in all arms except w20-24 and w44-48. Co-primary outcomes at w48 were CDAI remission (CDAI≤2.8) and change in total van der Heijde-modified Sharp Score from baseline ($\Delta vdHSS_{w0\text{-}w48}$). A combination of Bonferroni and Dunnet's procedure adjusted for multiple testing. The primary endpoints were estimated using logistic regression and analysis of covariance, adjusted for sex, anti-CCP status and country.

Results: 812 patients were randomized. Adjusted CDAI remission rates at w48 were: 59.3% (ABA), 52.3% (CZP), 51.9% (TCZ) and 39.2% (ACT). Compared to ACT, CDAI remission rates were superior for ABA (adjusted difference +20.1%; adjusted p<0.001) and CZP (+13.1%; p=0.021), but not TCZ (+12.7%; p=0.030) (Table 1). Key secondary clinical outcomes were consistently better in biological groups compared to ACT. Adjusted mean $\Delta vdHSS_{w0\text{-}w48}$ was low (Table 1), with no significant differences between drugs.

Table 1.

Baseline characteristics	ACT (n=200)	CZP+MTX (n=203)	ABA+MTX (n=204)	TCZ+MTX (n=188) §

vdHSS progression ≤0.5, w0-w48	Ref	-3.3% (-11.1 to 4.6)	3.5% (-4.7 to 11.8)	-2.2% (-10.3 to 5.9)

Values are mean (SD), if not otherwise indicated. §Finnish patients randomised to TCZ+MTX, but not receiving it due to unavailability, are not included. [1]Values are estimated adjusted marginal means and estimated marginal differences against ACT with 95% CI. ITT: intention to treat population. *Superiority compared with ACT was demonstrated.

No new safety signals were reported. Total numbers of serious adverse events (% patients with ≥1 event) were for ABA 21 (8.3%), CZP 28 (12.4%), TCZ 20 (9.2%) and ACT 23 (10.7%).

Conclusion: Compared with active conventional therapy (csDMARD + glucocorticoids), superiority regarding CDAI remission rates was demonstrated for abatacept and certolizumab-pegol, and not for tocilizumab. Radiographic progression was low and similar between treatments.

Background: Patients with rheumatoid arthritis (RA) are at an increased risk of venous thromboembolism. Thus far, there have not been any comparative studies investigating the effects of initial antirheumatic treatments in (very) early RA patients.
Objectives: To assess the effects of different initial treatments on hemostatic parameters in patients with early RA.
Methods: NORD-STAR is an international, multicentre, open-label, assessor-blinded, phase 4 study where patients with newly diagnosed RA started methotrexate (MTX) and were randomised 1:1:1:1 to a) conventional treatment (either prednisolone tapered to 5mg/day, or sulfasalazine combined with hydroxychloroquine and intra-articular corticosteroids), b) certolizumab pegol, c) abatacept, d) tocilizumab[1]. This study is a spin-off from the main NORD-STAR study extensively investigating hemostatic system in 24 per protocol consecutive Dutch participants at baseline, 12 weeks and 24 weeks after the start of the treatment. Statistical analysis was done using paired samples t-test in SPSS version 28.
Results: The mean age of investigated patients was 51.8 (± 12.7) years and 58.3% were female. At baseline patients had an average DAS28 score of 4.6 (± 0.9) and had elevated levels of investigated coagulation biomarkers: Factor 1+2, fibrinogen, D-dimer and parameters of the two global hemostatic assays, i.e. endogenous thrombin potential (ETP) and overall hemostasis potential (OHP). These biomarkers decreased significantly at 12 and 24 weeks in patients in all groups (Table 1). Overall fibrinolytic potential (OFP) was decreased and clot lysis time (CLT) was prolonged at baseline, demonstrating impaired fibrinolytic activity in early RA. The reduction of coagulation parameters was significantly higher in biological treatment arms in comparison to the standard MTX treatment arm. In addition, tocilizumab was more effective compared to certolizumab and abatacept, (Figure 1), which was expected considering the direct inhibitory effect of this drug on the IL-6 synthesis and consequently the coagulation activation as well. After 24 weeks of treatment with methotrexate and tocilizumab, the average fibrinogen of patients was reduced by 63% vs 31% and 36% in the certolizumab and abatacept groups, respectively. The changes in DAS-28 and the changes in fibrinogen had a correlation of 0.385 which did not reach statistical significance.

Table 1. ***Measurements are marked with * if p<0.05, ** if p<0.01 and *** if p<0.001***

	Baseline	W12	W24

ttPeak (min)	7.40 (2.2)	6.61 (1.5)*	6.13 (1.4)**

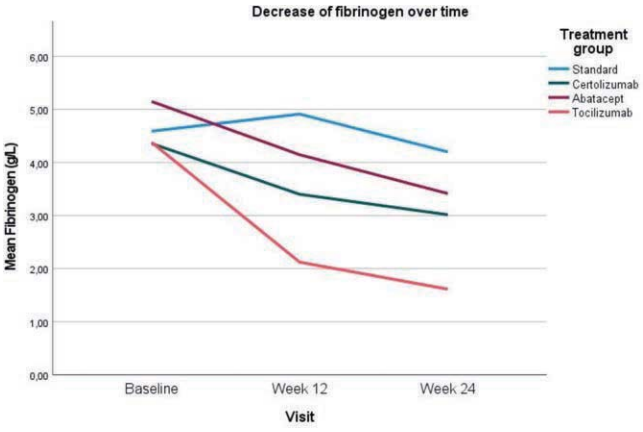

Figure 1.

Conclusion: Our results indicate an enhanced coagulation and fibrinolytic impairment in newly diagnosed RA patients. Effective antirheumatic treatments reduce this hemostatic imbalance, with significantly more pronounced effects of biologic drugs compared to conventional (MTX+glucocorticoids) treatment.

Askling[1]. *[1]Karolinska Institute, Clinical Epidemiology, Stockholm, Sweden*; *[2]Copenhagen University Hospital - Rigshospitalet,The Danish Multiple Sclerosis Registry, Department of Neurology, Glostrup, Denmark*; *[3]Diakonhjemmet Hospita, Division of Rheumatology and Research, Oslo, Norway*; *[4]Helsinki University Hospital and Helsinki University, ROB-FIN, Department of Medicine and Rheumatology, Helsinki, Finland*; *[5]Ministry of Social Affairs and Health, ROB-FIN, Pharmaceuticals Pricing Board, Helsinki, Finland*; *[6]University of Iceland, Centre for Rheumatology Research, Landspitali University Hospital, and Faculty of Medicine, Reykjavik, Iceland*; *[7]Aalborg University, Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark*; *[8]DANBIO Registry, DANBIO Registry, Copenhague, Denmark*

Background: Though rare, studies have reported increased risk of neurological events including demyelinating disease of CNS (DML), multiple sclerosis (MS), and inflammatory neuropathy (INP) in patients with inflammatory joint disease treated with tumor necrosis factor inhibitors (TNFi).[1,2] More in-depth investigations are required to elucidate the association between TNFi and neurological events in these patients, especially whether rates differ across type of TNFi mode of action.

Objectives: To estimate the incidence of neurological events in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA, including axial spondyloarthritis and psoriatic arthritis) starting treatment with TNFi across five Nordic countries. To compare the incidence of neurological events in etanercept (ETN)-treated patients to patients treated with other TNFi (oTNFi).

Methods: We defined treatment cohorts of patients initiating TNFi between 2001 through 2018 from clinical rheumatology registers in Denmark (DK), Finland (FI), Iceland (IS), Norway (NO), and Sweden (SE). One patient could contribute to more than one treatment episode. Demographic data (sex, age), co-medication (methotrexate) and clinical variables (CRP, disease duration (<1 year, 1 to 5 years, >5 years) were extracted and used as covariates. We estimated crude incidence rates (IR) for neurological events and subtypes (ICD-10 codes: MS: G35, DML: G35, G36.0, G36.8-9, G37.1, G37.3, G37.5, G37.8-9, H46, H48.1, G04.8-9, INP: G61.0, G61.8-9), all countries pooled. We compared risk of neurological events between patients treated with ETN and oTNFi using Cox regression with time since treatment start, adjusted for the above covariates, robust standard errors, and stratified by country.

Results: We included 52,682 treatment starts, in 33,885 RA patients (DK 8,259, FI 3,765, IS 723, NO 1353, SE 19,785; 75% women, mean age 56 years) and 46,549 treatment starts in 28,772 SpA patients (DK 7,000, FI 2,885, IS 962, NO 2,684, SE 15,241; 47% women, mean age 45 years).

Numbers of DML, MS, INP and all neurological events, person-years (pyrs), and IRs in RA and SpA patients, for the two treatment groups are displayed in Figure 1. IRs for these neurological events showed some variation by diagnosis (RA vs. SpA), with rates of DML (and MS) in SpA patients around two (and three, respectively) times higher than the corresponding rates in RA ($p<0.01$), but similar rates for INP in RA and SpA patients. Comparing oTNFi to ETN, all Cox regression hazard ratios (HR) were statistically non-significant and close to one, whatever the outcome and the group of patients (Figure 1), with the adjusted HR (95%CI) for developing any neurological event in oTNFi compared to ETN being 1.08 (0.91-1.28) in RA patients and 0.96 (0.78-1.19) in SpA patients.

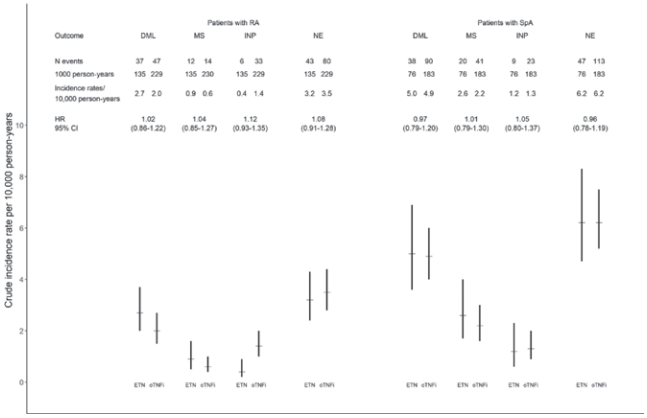

Figure 1. Number of events, pyrs and IRs of DML, MS, INP and all neurological events (NE) in RA and SpA patients, treated with ETN or oTNFi. HRs (95%CI) comparing oTNFi to ETN.

Conclusion: The incidences of DML and MS were lower in RA compared to SpA patients, while rates of INP were similar in both patients' groups. There was no evidence of differences in these rates between ETN and oTNFi. The findings are of importance from a safety perspective for patients starting TNFi.

OP0061

TIGHT CONTROL IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TARGETED THERAPIES ACROSS THE COVID-19 PANDEMIC ERA

A. F. Luppino[1,2], G. Cincinelli[1,2], F. Ingegnoli[1,2], A. Orenti[2], E. G. Favalli[1,2], P. Boracchi[3], R. Caporali[1,2]. [1]*ASST Gaetano Pini-CTO, Dept. of Rheumatology, Milano, Italy*; [2]*Università degli Studi di Milano, Dept. of Clinical Sciences & Community Health, Milano, Italy*; [3]*Università degli Studi di Milano, Dept of Biomedical and Clinical Sciences "L. Sacco", Milano, Italy*

Background: The ongoing coronavirus disease 2019 (COVID-19) pandemic and subsequent waves still represent a healthcare issue. Their impact on the treat-to-target (T2T) strategy in rheumatoid arthritis (RA) patients has been seldom investigated. Difficult access to rheumatology outpatient clinic, laboratory and imaging investigations as well as nationwide containment measures could potentially affect disease activity and tight-control strategy. Recently, we reported how a telephone-based tight control strategy ensured satisfactory management of RA treated with targeted therapies during the first wave of the pandemic [1]. However, the performance of our different patterns of healthcare delivery across different pandemic waves has not been studied yet.

Objectives: To analyze the impact of different patterns of healthcare delivery on remission of RA patients treated with targeted therapies during the first wave (2020) and second/third waves (2021) of pandemic compared to the pre-pandemic period (2019).

Methods: In this observational real-life study, data of our cohort of RA patients treated with biologic or targeted synthetic drugs were extracted from a longitudinal registry. Clinical Disease Activity Index (CDAI) was analyzed in the same period from 22nd of February to 18th of May for three consecutive years: before the pandemic (2019), during the first wave (2020), and during the second/third waves (2021). During the first wave, patients could choose whether to receive home drug delivery or to maintain their face-to-face visits, in the other periods only in-person visits were delivered. A generalized linear model with the binomial error was fitted to evaluate the difference in the proportion of patients in CDAI remission. Quantile regression was used to compare the median of CDAI in difficult-to-treat (D2T) patients [2]. In both models, the correlation of different measurements on the same patient was considered.

Results: In the pre-pandemic period (2019), 407 RA patients were included in this study. During the first wave (2020) we analyzed 450 patients, of whom 359 patients chose in-person visits, while 91 patients home drug delivery and virtual visit. Finally, 540 patients were included in 2021 (second/third wave). The percentages of patients in CDAI remission were similar in the three periods (prevalence ratio 1.07, p-value 0.423 between 2020 and 2019, and 1.01, p-value 0.934 between 2021 and 2019). The CDAI remission rate was 40.55% (N=163), 43.18% (N=155) and 40.82% (N=220) in 2019, 2020 and 2021, respectively. The disease activity profile during the three periods is reported in detail in the Table 1 below. Among our cohort of D2T patients, the median value of CDAI before (2019), during the first wave (2020), and during the second/third wave (2021) changed significantly (p= 0.053 between 2020 and 2019 and p=0.006 between 2021 and 2019).

Table 1.

RA patients	CDAI	2019		2020		2021	
		No. missing	N (%)	No. missing	N (%)	No. missing	N (%)
	Remission	0	163 (40.55%)	89	155 (43.18%)	6	220 (40.82%)
	Low	0	151 (37.56%)	89	140 (39.00%)	6	227 (42.12%)
	Moderate/ high	0	88 (21.89%)	89	64 (17.83%)	6	92 (17.07%)

Conclusion: Although the pandemic has imposed changes in our healthcare delivery, these different strategies seem to be effective in ensuring satisfactory management of RA treated with targeted therapies. The approaches modulated in the context of the different periods have been a feasible compensation for ensuring disease control even in D2T patients.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that causes not only joint pain but also bone destruction resulting in impairment of quality of life. Tumor necrosis factor inhibitors have improved prognosis of patients with rheumatoid arthritis dramatically, especially in combination with methotrexate, however, the optimal dose of the concomitant methotrexate is unclear.

Objectives: To evaluate the efficacy and safety of adalimumab in combination with reduced dose of methotrexate in patients with early RA with inadequate response to methotrexate.

Methods: The MIRACLE study was a multinational, randomized, open-label study in patients with RA with inadequate response to methotrexate conducted in Asia. It compared low dose and high dose methotrexate upon starting adalimumab. Methotrexate-naive patients with RA with a disease duration of less than two years started methotrexate at 6 to 8 mg/week and increased it to the maximum tolerable dose by week 12. Patients who have not achieved remission according to simplified disease activity index (SDAI) despite methotrexate ≥ 10 mg/week at week 24 were randomised to the maximum tolerable dose of

methotrexate group (10 to 25 mg/week) or the reduced dose group (6 to 8 mg/week) and started to receive subcutaneous adalimumab 40 mg every other week. The primary endpoint was non-inferiority in the achievement of SDAI remission at week 48 in the reduced dose group compared with the maximum tolerable dose group with a non-inferiority margin of -15% based on two-sided 90% confidence interval. (NCT03505008)

Results: A total of 300 patients were enrolled in the study. Among them, 291 started methotrexate and were included in the analysis. The mean age was 57.7±15.2 years, female was 74.6%, and the mean disease duration from the diagnosis of RA was 21.1±56.2 days. Anti-CCP antibody was positive in 211 (73.0%) and the mean SDAI at study enrollment was 26.5±12.4. At week 24, with the mean dose of methotrexate of 12.6±2.9 mg/week, 108 patients (37.1%) achieved remission according to SDAI and continued MTX monotherapy. 134 patients (46.0%) were randomised and started adalimumab with 68 patients in the maximum tolerable dose group and 66 patients in the reduced dose group. At week 48, the remission achievement rates were 38.4 % and 44.8 %, respectively, with the adjusted risk difference of the reduced dose group to the maximum tolerable dose group of 6.4% (-7.0% to 19.8%, 90% CI), which met the criterion for noninferiority. No significant difference was found in health assessment questionnaire disability index ≤0.5 (59.1% vs 62.0%, respectively, p=0.72) and in radiological remission rates (Δmodified total Sharp score ≤0.5, 66.3% vs 62.0 %, respectively, p=0.59). Adverse drug reactions tended to be more frequent in the maximum tolerable dose group than in the reduced dose group (22.1% vs 9.1%, respectively, p=0.06).

Conclusion: The MIRACLE randomised study demonstrated that, in patients with inadequate response to methotrexate, the efficacy of adalimumab with reduced dose of concomitant methotrexate was not inferior to that with maximum tolerable dose of methotrexate with better safety profile.

OP0063 OLOKIZUMAB IMPROVES PATIENT REPORTED OUTCOMES IN MODERATE TO SEVERELY ACTIVE RHEUMATOID ARTHRITIS PATIENTS INADEQUATELY CONTROLLED BY METHOTREXATE (MTX-IR): RESULTS FROM THE PHASE 3 RANDOMIZED CONTROLLED TRIAL, CREDO 2

V. Strand[1], E. Choy[2], E. Nasonov[3], T. Lisitsyna[4], A. Lila[3], S. Kuzkina[5], M. Samsonov[5], E. Feist[6]. [1]*Stanford University, Division of Immunology/Rheumatology, Palo Alto CA, United States of America*; [2]*Cardiff University, CREATe Centre, Section of Rheumatology, Cardiff, UK, United Kingdom*; [3]*V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*; [4]*V.A. Nasonova Research Institute of Rheumatology, Thromboinflammation, Moscow, Russian Federation*; [5]*R-Pharm, Medical, Moscow, Russian Federation*; [6]*Helios Fachklinik Vogelsang-Gommern; Helios Clinic, Rheumatology, Vogelsang-Gommern, Germany*

Background: Olokizumab (OKZ) is an interleukin-6-inhibitor for treatment of Rheumatoid Arthritis (RA). In these analyses, we present patient reported outcomes (PROs) reported by MTX-IR patients with moderate to severely active RA treated with OKZ vs adalimumab (ADA) or placebo in a phase 3 randomized controlled trial (RCT) (ClinicalTrials.gov number, NCT02760407).

Objectives: To assess the effect of OKZ treatment compared with placebo and ADA in patient global assessment of disease activity (PtGA), pain, physical function (HAQ-DI), fatigue (FACIT-F) and health related quality of life (SF-36 physical (PCS) and mental (MCS) component summary and domain scores) and work participation (WPS-RA) at week 12.

Methods: 1648 patients receiving MTX were randomized to receive SQ injections: 1) OKZ 64 mg every 2 weeks (q2w, n=464), 2) OKZ 64 mg q4w (n=479), 3) ADA 40 mg q2w (n=462) and 4) placebo q2w (n=243). At week 14, non-responders: subjects without ≥ 20% improvements in both swollen and tender joint counts, added rescue medication (sulfasalazine and/or hydroxychloroquine) to study treatment. Between groups differences in least-squares mean (LSM) changes from baseline were analyzed.

Results: At week 12, treatment with both OKZ doses and ADA resulted in statistically greater LSM changes from baseline than placebo across all PROs, including 7 of 8 domains of SF-36 with exception of role emotional (Table 1 and Figure 1). Reported work and household work impairments, days productivities were reduced by half and missed household work days because of arthritis were all improved (p<0.01) with OKZ and ADA treatment. PROs further improved to week 24 in the active treatment arms. Post hoc analyses demonstrated that a higher proportion of patients receiving both doses of OKZ as well as ADA reported improvements ≥ minimum clinically important differences vs placebo (p<0.01) across all PROs, indicating clinically meaningful benefits on an individual patient basis. Estimates of numbers needed to treat indicated that between 5 and 10 patients would need to be treated to achieve these benefits. More patients in both OKZ groups reported scores ≥ normative values in PtGA, HAQ-DI and SF-36 PCS scores; with ADA in PtGA and HAQ-DI.

OP0064

FREQUENCY AND PREDICTORS OF MULTIPLE TREATMENT SWITCHING IN RHEUMATOID ARTHRITIS

E. Birgersson Wettersand[1], D. Di Giuseppe[2], J. Askling[2], K. Chatzidionysiou[1].
[1]Karolinska Institute, Rheumatology Unit, Karolinska University Hospital, Department of Medicine Solna, Stockholm, Sweden; [2]Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden

Background: Despite the significant improvements in the field of rheumatoid arthritis (RA) treatment, a significant and troubling minority of patients remain refractory to multiple disease modifying antirheumatic drugs (DMARDs). The consequence of this ''difficult-to-treat" state is irreversible damage, risk of co-morbid conditions, and substantial loss of quality of life. Early, precise, and actionable identification of this challenging group of RA patients is crucial for optimal prevention and management.

Objectives: To assess the frequency and to identify predictors of switching between multiple biological and targeted synthetic DMARDs (b/tsDMARDs) in RA patients in a large national register.

Methods: Observational cohort study including RA patients starting a first-ever b/tsDMARD 2009-2018, based on data from the Swedish Quality Rheumatology register. Comorbidities were identified through linkage to the national Patient Register. Baseline (time of RA diagnosis) characteristics of the population were described. Three groups were investigated: A) Patients starting ≥3 treatment courses; B) Patients starting ≥4 treatment courses; and C) Patients starting ≥5 treatment courses. Predictors of multi-switching were explored using univariate and multivariable logistic regression analyses.

Results: 23,908 RA patients were identified. Proportions of patients starting ≥3, ≥4 or ≥5 b/tsDMARDs treatment courses were 7%, 3.2% and 1.6%, during a mean (95% CI) of 3.6 (3.5-3.7), 4.3 (4.2-2.5) and 4.9 (4.7-5.2) years from RA diagnosis, respectively. In Table 1 baseline characteristics for each multi-switching group are summarized. For definition A, the following baseline univariate predictors were identified: female sex (OR=1.57, 95% CI=1.39-1.76), younger age (OR=0.96, 95% CI=0.95-0.96), positive RF (OR=1.36, 95% CI=1.22-1.53) and ACPA (OR=1.40,

Table 1. Baseline (time of RA diagnosis) characteristics

		Multi-switching definition		
	All patients	A: ≥3 b/tsDMARDs	B: ≥4 b/tsDMARDs	C: ≥5 b/tsDMARDs
N, %	23 908 (100)	1677 (7)	755 (3.2)	385 (1.6)
Age (years), mean (SD)	59.5 (15.2)	50.3 (14.5)	50.0 (14.6)	47.6 (14.7)

Patient global, VAS 0-100 (mean, SD)	48.8 (26.8)	58.4 (25.3)	59.8 (24.5)	60.8 (24.0)
Patient pain, VAS 0-100 (mean, SD)	50.2 (26.8)	59.2 (25.4)	59.8 (25.2)	59.9 (25.2)
Fatigue, VAS 0-100 (mean, SD)	48.5 (28.8)	61.2 (26.5)	63.1 (25.9)	64.6 (23.6)
HAQ (mean, SD)	0.97 (0.66)	1.1 3(0.64)	1.15 (0.64)	1.13 (0.63)
Swollen joint count (median, IQR)	5 (2-9)	6 (3-10)	6 (3-10)	6 (3-10)
Tender joint count (median, IQR)	5 (2-9)	6 (3-12)	6 (3-12)	7 (3-11.25)
Concomitant csDMARD, %	52.5%	50.4%	51.7%	51.4%
Reumatoid factor positive, %	63.1%	69.6%	69.8%	67.8%
ACPA positive, %	67.0%	73.4%	74.3%	72.7%
DAS28-ESR (mean, SD)	4.62 (1.51)	5.00 (1.41)	5.10 (1.37)	5.12 (1.33)
VAS general health physician (mean, SD)	42.28 (23.02)	45.30 (22.19)	45.68 (20.69)	51.40 (25.83)

95% CI=1.24-1.58), higher DAS28 (OR=1.21, 95% CI=1.15-1.26), HAQ (OR=1.46, 95%=1.33-1.61), pain (OR=1.014, 95% CI=1.012-1.017) and fatigue (OR=1.017, 95% CI=1.014-1.021). In the multivariable logistic regression model, female sex, younger age, higher HAQ, pain and fatigue at baseline were independent predictors of multiple treatment switching. Similar results were found for all three multi-switch definitions. Several comorbidities (i.e. heart failure, ischemic heart disease, malignancy, renal failure) were associated with a lower risk for multiple treatment switching, suggestive of medical contraindications for b/tsDMARDs.

Conclusion: In this large national observational cohort, multiple treatment switching, indicative of difficult to treat RA, was observed in a significant proportion of patients, ranging between around 2 to 7% during the first 5 years from time of diagnosis. Risk factors include female gender, younger age, higher HAQ, pain and fatigue at the time of RA diagnosis, suggesting increased attention to this challenging group of patients.

Background: In routine care, biosimilar-to-biosimilar infliximab switching may occur to save costs (=non-medical switching). Previous studies have investigated the efficacy and safety of switches from originator infliximab to a corresponding biosimilar in patients with inflammatory rheumatic diseases (1). However, the outcomes after switching from one infliximab biosimilar to a second infliximab biosimilar remain scarcely investigated. Denmark has recently conducted a nationwide mandatory infliximab biosimilar-to-biosimilar switch.

Objectives: To investigate the effectiveness of infliximab biosimilar-to-biosimilar switch (CTP-13 to GP1111) among patients with RA, PsA and AxSpA, including patients who had previously switched from originator (originator-experienced) to CT-P13 as well as patients who were originator-naïve.

Methods: Observational cohort study based on DANBIO registry (for clinical data upon switch =baseline) linked with national patient registries (to identify prior comorbidities). Patients with RA, PsA or AxSpA who performed a biosimilar-to-biosimilar switch from CT-P13 to GP1111 between April 1st 2019 and February 1st 2020 were included. Patient were divided into two groups: originator-naïve and originator-experienced. Main outcomes in the two groups were one-year GP1111 treatment retention (Kaplan Meier "drug survival curves") and changes in disease activity 4 months before versus 4 months after switch in individual patients. Also, factors associated with GP1111 treatment retention for both groups combined were explored with Cox proportional hazard regression analyses, stratified by diagnosis (univariate-, age-and gender adjusted and fully adjusted). Analyses were adjusted for relevant clinical factors (for details: see Table 1)

Results: In total, 1,605 patients underwent an infliximab biosimilar-to-biosimilar switch and were included; 1,171 were originator-naïve and 434 were originator-experienced, 685 RA/314 PsA/606 AxSpA, median disease duration was 9 years, 42% were in DAS28/ASDAS remission at the time of switch.

At one year, 83% (95% CI 81-85) of the originator-naive and 92% (95% CI 90-95) of the originator-experienced switchers maintained GP1111 treatment (Figure 1). Changes in disease activity 4 months pre- and post-switch were close to zero for all disease activity measures (e.g. DAS28, ASDAS, VAS pain, not shown).

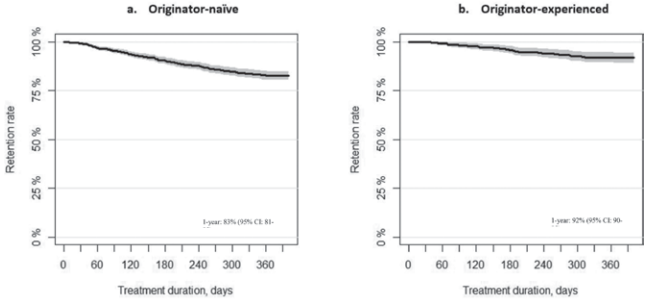

Figure 1. Kaplan-Meier plots of crude GP1111 treatment retention rates after an infliximab biosimilar-to-biosimilar switch among patients with inflammatory arthritis

The risk of GP1111 withdrawal was lower in originator-experienced compared to originator-naïve patients in patients with RA and PsA: HR 0.4 (95% CI 0.2-0.9, p-value 0.01) and HR 0.1 (0.1-0.6, p=0.01), but not significantly for AxSpA 0.56 (0.27-1.13, p=0.1). Across all indications, lower disease activity at baseline (DAS28/ASDAS remission) was associated with higher retention (Table 1).

Conclusion: Biosimilar-to-biosimilar infliximab switch was effective and well-tolerated in >1,500 real-world patients. Retention was higher in originator-experienced switchers and patients, who were in remission at the time of the switch, suggesting retention to be more affected by patient-related than drug-related factors.

Background: Tropheryma whipplei (Tw) infection is a rare condition, characterized by inflammatory joint symptoms in more than 75% of the cases, which can lead the physician to diagnose chronic inflammatory rheumatic diseases (IRD) and to initiate DMARDs. DMARDs are often ineffective and may reveal digestive signs, systemic manifestations or involvement of other organs. We hypothesized that treatment of Tw infection has a favorable impact on rheumatologic and extra-rheumatologic manifestations attributed to IRD.
Objectives: To validate this hypothesis, we initiated a registry with the objectives to describe the characteristics of IRD and their treatments, the diagnostic and therapeutic modalities of Tw infections and the impact of the treatment of Tw infection on the evolution of IRD and associated DMARDs.
Methods: We initiated a French National register including adult patients with pre-existing IRD, treated with DMARDs, later diagnosed with Tw infection. Cases were identified through a call for observation via the "Club Rhumatismes et inflammations" website. We collected clinical and biological data about the characteristics of IRD and their treatments, the diagnostic and therapeutic modalities of Tw infections, and the impact of the treatment of Tw infection on the evolution of IRD and associated DMARDs.
Results: Seventy-three IRD patients were included. Mean age at diagnosis was 49 years (SD +/- 10.9), with 78% of men, median IRD duration was 79 months (IQR 36; 140), including rheumatoid arthritis (31 cases), spondyloarthritis (14 cases), psoriatic arthritis (6 cases) and other IRDs (22 cases). All IRD patients were treated with DMARDs, with no therapeutic response in 51% of the cases, worsening of rheumatologic symptoms in 34% of the cases, and occurrence of extra-articular manifestations in 27% of the cases. Screening for Tw infection mainly involved saliva and stool PCR, while diagnostic modalities involved organ specific PCR and biopsies, in particular duodenal biopsies (PCR positive in 87% of cases and histology in only 38% of cases). At the time of Tw infection diagnosis, mean age was 58 years (SD +/- 10.1), all patients had joint involvement, 33% axial involvement, 11% entheseal involvement, 84% extra-articular manifestations, 93% elevated CRP, 86% hypoalbuminemia and 67% anemia. Tw infection treatment modalities (median follow-up of 22 months) mainly involved a combination of doxycycline (95%) and hydroxychloroquine (96%), with complete recovery in 79% of the cases and Tw-related deaths in 2 cases. At the same time, Tw infection treatment was associated with IRD remission in 93% of cases, with a median time to remission of 2 months (IQR 1; 4.25), leading to DMARD withdrawal in 94% of cases and corticosteroid therapy withdrawal in 65% of cases.
Conclusion: A Tw infection should be considered in IRD patients with peripheral joint involvement and inadequate response to DMARDs, particularly in the presence of extra-articular manifestations, elevated CRP and hypoalbuminemia. In such patients, positive results of screening and diagnostic tests for Tw infection may lead to the initiation of Tw infection treatment which is associated with complete recovery of Tw infection and rapid remission of the IRD, allowing DMARD and corticosteroid therapy withdrawal in most the cases.

OP0067

MORE THAN SIX-FOLD INCREASED MORTALITY RISK IN PATIENTS WITH INCIDENT RHEUMATOID ARTHRITIS AND DEPRESSION IN A LARGE COHORT WITH 10-YEAR FOLLOW-UP

J. K. Pedersen[1,2], N. Risbo[3], A. Pedersen[3], L. Wang[3], C. Havregaard Sørensen[4], K. Andersen[4], T. Ellingsen[5]. *[1]Odense University Hospital, Svendborg Hospital, Department of Medicine, Svendborg, Denmark*; *[2]University of Southern Denmark, Department of Clinical Research, Odense, Denmark*; *[3]Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark*; *[4]Mental Health Services in the Region of Southern Denmark, Department of Psychiatry Odense, Odense, Denmark*; *[5]Odense University Hospital, Department of Rheumatology, Odense, Denmark*00

Background: The occurrence of depression is increased in patients with rheumatoid arthritis (RA) compared with the background population. (1) Recently, we described that in RA the most frequent indication for filling antidepressant prescriptions is depression and the frequency of filling coincides with the occurrence of depression reported in the scientific literature. (2) In patients with stroke, depression defined as filling of antidepressants or a diagnosis with depression is associated with increased mortality risk and the risk is similar for both definitions of depression. (3)
Objectives: We used the first filling of antidepressants as proxy for depression with the objective to describe the mortality risk associated with depression in patients with incident RA.
Methods: We included patients diagnosed with incident RA (index date) from the nationwide DANBIO register (4) from January 1, 2008 to September 30, 2018. Participants were identified by unique personal registration numbers. Included patients were without a recorded filling of methotrexate (Anatomic Therapeutic Chemical code L01BA01) and antidepressants (N06A) in the Danish National Prescription Register or recorded hospital contacts with RA and depression (International Classification of Diseases (version 10) codes M05, M06, F32) in the Danish National Patient Register, three years prior to the index date. From the index date, we defined depression as first filling of antidepressants and collected death dates from the Danish Civil Registration System. The participants were followed until December 31, 2018 and all-cause mortality estimated in two dynamic risk periods: the period from the index date until first filling of antidepressants (if it occurred) and the period after filling of antidepressants. We calculated hazard rate ratios (HRR) by modelling filling of antidepressants as time-varying exposure for total follow-up and adjusted for potential confounders defined *a priori*: age, sex, comorbidity, cohabitation, employment status, highest attained education, and income. Cumulative mortality was described by Kaplan-Meier curves. Results were reported with 95% confidence intervals (CI).
Results: Among 11,071 RA patients followed for 56,993 person-years, 1,095 (10%) filled prescriptions for antidepressants. The median age at diagnosis was 61 years, 66% were female, and 64% diagnosed with seropositive RA. Adjusted HRR was highest in the age group <55 years but also increased between 55-70 years, >70 years, among females and males, and in patients diagnosed with seropositive and seronegative RA (Table 1). The cumulative mortality is seen in Figure 1.

Table 1.

Strata		HRR (95% CI)	
		Crude	Adjusted
Age, years	<55	8.40 (4.20-16.80)	6.66 (2.80-15.85)
	55-70	3.27 (2.35-4.54)	3.30 (2.27-4.80)
	>70	2.97 (2.36-3.75)	2.94 (2.26-3.83)
Sex	Female	3.72 (2.95-4.70)	2.91 (2.22-3.81)
	Male	3.10 (2.32-4.15)	3.70 (2.66-5.14)
RA diagnosis	Seropostive (M05)	3.73 (2.99-4.65)	3.45 (2.66-4.47)
	Seronegative (M06)	2.85 (2.07-3.91)	3.08 (2.17-4.37)

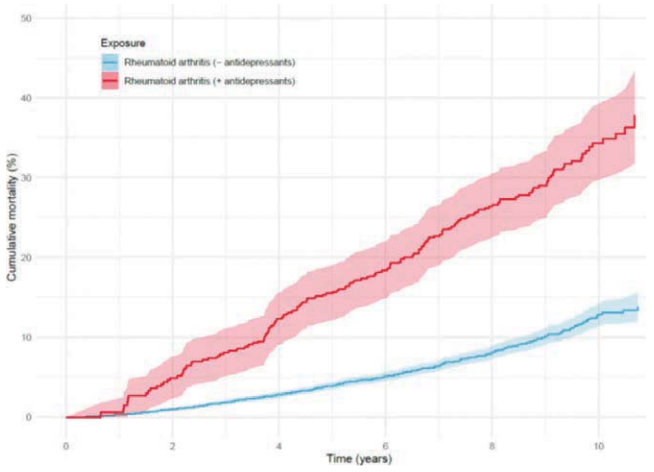

Figure 1.

Conclusion: Depression, defined as first filling of antidepressants, was associated with more than six-fold increased mortality risk in patients with incident RA.

OP0068

DISTINCT STROMAL AND IMMUNE CELL INTERACTIONS SHAPE THE PATHOGENESIS OF RHEUMATOID AND PSORIATIC ARTHRITIS

A. Floudas[1], C. Smith[2], O. Tynan[1], N. Neto[3], V. Krishna[4], S. Wade[1], M. Hanlon[1], C. Cunningham[1], V. Marzaioli[1], M. Canavan[1], J. Fletcher[2], S. Cole[4], L.Y. Hao[4], S. Nagpal[4], M. Monaghan[3], D. Veale[5], U. Fearon[1]. Background: Rheumatoid (RA) and psoriatic arthritis (PsA) are common autoimmune and autoinflammatory diseases of unknown aetiology characterised by complex synovial pathology with a detrimental effect on the patient's quality of life. Significant differences in pathophysiology may explain distinct clinical manifestations and account for differential responses to specific therapeutics. Recent implementation of single cell transcriptomic analysis of sorted synovial cells has revealed the diverse cellular landscape of the RA synovial stromal and immune cell compartments, however, a complete analysis of immune and stromal cells in tandem, for RA and PsA patient synovial tissue has not been performed.

Objectives: To combine novel scRNA transcriptomic approaches and *ex vivo* assays in order to: identify differences in the cellular landscape of RA and PsA synovial tissue inflammation and immune – stromal cell interactions that drive pathology in RA and PsA.

Methods: Single cell transcriptomic profiling of 178,000 synovial tissue cells from 5 PsA and 4 RA patients, importantly, without prior sorting of immune and stromal cells. This approach enabled the generation of a unique cell atlas of intact synovial tissue identifying immune and stromal cell interactions. State of the art data integration and annotation techniques identified and characterised 18 stromal and 14 immune cell clusters. Bioinformatic examination of cell-cell communication via construction of receptor-ligand interaction networks with further *in vitro* validation of stromal and immune cell crosstalk through flow cytometric analysis, multiplex ELISA and mitochondrial and single cell metabolic profiling by multiphoton and florescent lifetime imaging microscopy, seahorse.

Results: Following quality control and data integration the PsA and RA cellular landscape was generated and nine mega clusters indicative of fibroblasts, endothelial cells, pericytes, macrophages, dendritic cells (DC), B cells, plasma cells, T cells and NKT consisting of several sub clusters were identified. Distinct points of transcriptomic deviation and convergence between RA and PsA were identified for each of the major cell types of the joint. Specifically, cell cycle and trajectory analysis revealed that only a fraction of synovial T cells are actively proliferating. Additionally, the differential usage of immunoglobulin light chains by memory and plasma cells indicates that plasma cells are potentially not derived from the local memory B cell pool of the synovial tissue. Importantly, we report distinct fibroblast and endothelial cell transcriptomes indicating differentially abundant subpopulations in RA and PsA characterised by distinct transcription factor usage and signalling pathway enrichment. Specifically transcriptomic imputation analysis revealed abundance of invasive FAPα^{+}THY1^{+} regulated by transcription factor TEAD1 in RA compared to PsA synovial tissue. In order to identify potential cell-cell communication driving inflammation in RA and PsA, novel receptor–ligand interaction networks were generated and downstream of the receptor, target characterisation was performed. Herein we identify RA-specific synovial T cell-derived TGF-β and macrophage IL-1β synergy in driving the transcriptional profile of FAPα^{+}THY1^{+} invasive synovial-fibroblasts, expanded in RA compared to PsA synovial tissue biopsies (Figure 1). Ex vivo treatment of RA patient synovial fibroblasts identified TGF-b and IL-1b synergy are a major driver of IL-6 production, fibroblast activation and adhesion molecule expression. Interestingly, the aforementioned proinflammatory changes of RA patient synovial fibroblasts were coupled with significant alterations in mitochondrial eccentricity and size and a marked metabolic adaptation towards a strongly glycolytic profile (Figure 1).

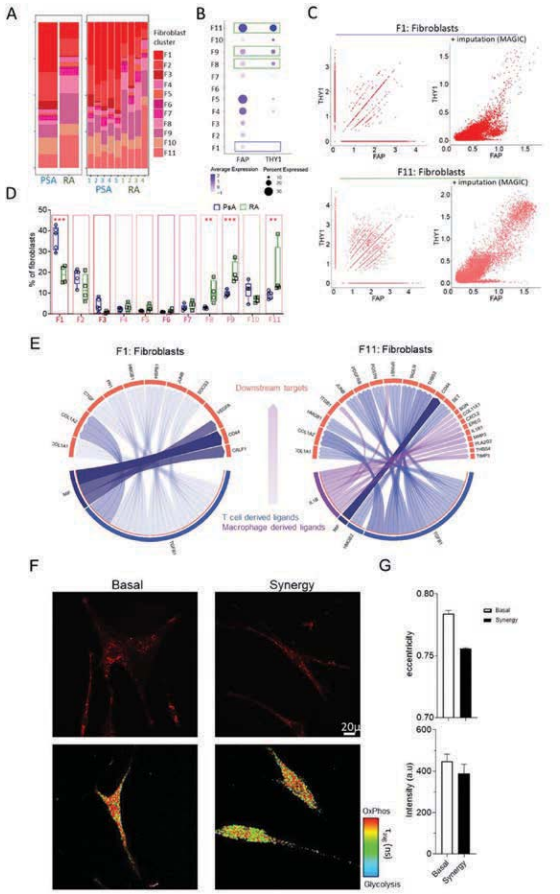

Figure: Immune-stromal cell crosstalk as a driver of synovial inflammation.
A. Abundance of fibroblast clusters in RA and PsA patient synovial biopsies. B. Expression and percentage of positive cells per fibroblast cluster for FAP and THY1. C. Scatterplots for showing the relation between THY1 and FAP expressing cells before and after data imputation for RA and PsA fibroblast cluster 1 and fibroblast cluster 11. Fibroblast clusters with significantly different abundances between RA and PsA are indicated by green (higher in RA) and blue (higher in PsA) boxes. D. Frequency of fibroblast clusters in PsA and RA patient synovial biopsies (n=4-5), data are presented as Box and whiskers plots (min to max), symbols represent individual samples. E. Circo plot depicting the top ligand and downstream target interaction for enriched in PsA synovial fibroblast cluster F1 and enriched in RA, invasive synovial fibroblast cluster F11. F. Representative images of RA patient synovial fibroblasts mitochondrial and metabolic analysis. G. Synovial fibroblast eccentricity and staining intensity under basal conditions or following treatment with TGF-b and IL-1B.

Figure 1.

Conclusion: Disrupting specific immune and stromal cell interactions offers novel opportunities for targeted therapeutic intervention in RA and PsA.

OP0069 INCLUSION OF PATIENT RESEARCH PARTNERS IN REMEDY – A RESEARCH CENTER FOR TREATMENT OF RHEUMATIC AND MUSCULOSKELETAL DISEASES

M. Skaar[1], A. T. Tveter[1], H. A. Zangi[1], S. Lillegraven[1], E. Haavardsholm[1], I. Løchting[2], A. Fryxelius[2], I. Kjeken[1]. [1]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; [2]*The Norwegian Rheumatism Association,The Norwegian Rheumatism Association, Oslo, Norway*

Background: Active collaboration between patients and researchers in development and implementation of scientific projects is important to ensure a good match between patient's preferences and the scientific focus in research, contribute to more patient-oriented health research agendas, enhance patient friendly design of research projects, and creating support for implementation (1). Such involvement is strongly advocated by EULAR and is often a prerequisite to receive funding for clinical research projects. At Diakonhjemmet Hospital in Norway, the division of rheumatology and research has for many years worked to involve patient research partners (PRPs) in research. A patient advisory board was established in 2007, led by a person (20% position) who herself has a rheumatic disease. In eight years from 2022, the division will receive funding from the Norwegian Research Council to establish and host a clinical research center for treatment of Rheumatic and Musculoskeletal diseases – the REMEDY center.
Objectives: To describe how involvement of PRPs are organised within the REMEDY center.
Methods: An organisation map was developed as part of the application for funding. The leader of the patient advisory board, together with three senior researchers, were involved in several rounds of discussions on how PRP involvement should be organised in the center, and also in meetings with the larger research group.
Results: The organisation of REMEDY is shown in Figure 1.

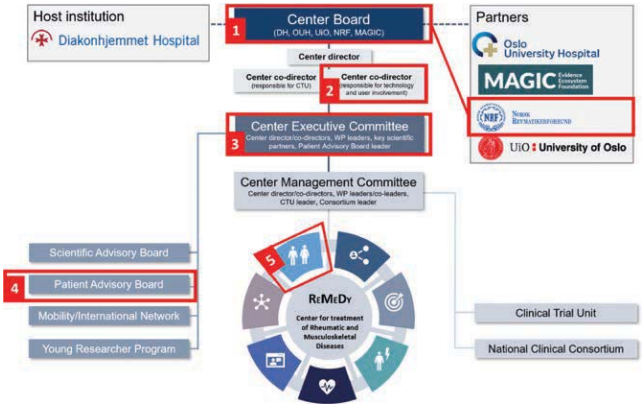

Figure 1. Organisation of REMEDY.

1.All partners, including **The Norwegian Rheumatism Association,** (the largest patient organisastion in the field), are represented at the Center Board. This ensures patient involvement at the strategic level, including setting research agendas and priorities.
2.The center is led by a centre director and two **co-directors**, of which one has a specific responsibility of PRP-involvement
3.The Centre Executive Committee (CEC) consist of the Center Director and co-directors, the WP leaders, **the leader of the patient advisory board**, the key senior scientific staff members of the partner institutions involved in the center and senior staff members deemed appropriate by the Centre Director.
4.**The patient advisory board**, consisting of 10-15 PRPs, is central within the center. Members of the board will be involved in all research projects, collaborating with researchers to improve design, methodology, research outcomes and implementation. The board provides a platform for the members for education, development, and exchange of knowledge and experience.
5.There are seven work packages (WPs) in REMEDY, each approaching the knowledge needs within rheumatic and musculoskeletal diseases (RMDs) treatment from different angles, and with international collaborators. WP7 (Empowering the individual) will provide **a platform for the Patient advisory board**, facilitating input from PRPs to all WPs. The chair of the EULAR study group for collaborative research is an international collaborator in WP7.
The leader of the Patient Advisory board has a 50% position. Additionally, there is funding for board activities, and for PRP involvement in initial project phases, whereas PRP activities are included in applications for external funding.
Conclusion: The REMEDY center is organised to ensure involvement of PRPs at all organisational levels, from individual research trials to the strategic and operational management of the center.

OP0070 INTERVENTION WITH METHOTREXATE IN ARTHRALGIA AT RISK FOR RHEUMATOID ARTHRITIS TO REDUCE THE DEVELOPMENT OF PERSISTENT ARTHRITIS AND ITS DISEASE BURDEN (TREAT EARLIER): A DOUBLE-BLIND, RANDOMISED, PLACEBO-CONTROLLED TRIAL

D. Krijbolder[1], M. Verstappen[1], B. van Dijk[1], Y. Dakkak[1], L. Burgers[1], A. Boer[1], Y. Jung Park[1], M. De Witt[2], K. Visser[3], M. R. Kok[4], E. Molenaar[5], P. de Jong[6], S. Böhringer[7], T. Huizinga[1], C. Allaart[1], E. Niemantsverdriet[1], A. van der Helm-van Mil[1,6]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Reinier de Graaf Gasthuis, Rheumatology, Delft, Netherlands*; [3]*Haga Hospital (Leyweg), Rheumatology, Den Haag, Netherlands*; [4]*Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; [5]*Groene Hart Hospital, Rheumatology, Gouda, Netherlands*; [6]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [7]*Leiden University Medical Center (LUMC), Biomedical Data Sciences, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) is the most common autoimmune disease, and requires long-term treatment to suppress inflammation. Currently, methotrexate is initiated as first-line treatment when arthritis becomes clinically apparent with joint swelling. However, disease processes begin long before and become clinically recognizable when patients develop symptoms. We hypothesized that the 'at risk phase' of symptoms and subclinical joint-inflammation is a therapeutic window to permanently modify the disease course.
Objectives: We studied if intervention in the pre-arthritis phase of arthralgia and subclinical joint inflammation prevents the development of clinical arthritis or reduces the burden of disease.
Methods: In this randomised, double-blind, 2-year proof-of-concept trial, adults with arthralgia clinically suspected of progressing to RA and MRI-detected subclinical joint-inflammation, recruited from all rheumatology outpatient-clinics in the south-west-Netherlands, were randomly assigned (1:1) to a single intramuscular glucocorticoid injection (120 mg) and a one-year course of oral methotrexate (up to 25 mg/week), or placebo injection and placebo tablets. Subsequently, participants were followed for another year without study medication. The primary endpoint was the development of clinically detectable arthritis (fulfilling the 2010 RA-criteria or involving ≥2 joints) that persisted for at least 2 weeks. Patient reported physical functioning, along with symptoms and workability, were key secondary endpoints and measured 4-monthly. Additionally, the course of MRI-detected inflammation was studied (the sum of tenosynovitis, synovitis, osteitis, scored with the RA-MRI Scoring (RAMRIS) method). All participants entered the intention-to-treat analysis. We performed two prespecified subgroup analyses. Firstly, analyses were restricted in participants with high risk of clinical arthritis development (PPV ≥70%). Secondly, analyses were stratified for ACPA-status. The trial is registered with the Netherlands Trials Registry (NTR4853 trial NL4599).
Results: From April 16th, 2015 to September 11th, 2019, we randomly assigned 236 participants to treatment (n=119) or placebo (n=117). After 24 months, arthritis free survival was similar in both groups (80% versus 82%, HR 0.81 (95%CI 0.45, 1.48)). Physical functioning improved more in the treatment-group during the first months and remained better (mean between-group difference over two-years HAQ -0·1(-0·2,-0·03;p=0·004). Similarly, pain (-9 on scale 0-100: (95%CI -12,-4; p<0·001), morning stiffness (-12 (95%CI -16,-8;p<0·001), presenteeism (-8% (95%CI -13%,-3%;p=0·001) showed sustained improvement compared to placebo. MRI-detected joint-inflammation was also persistently improved (mean difference over 2 years -1·4 points (95%CI -2·0,-0.9;p<0·001). High-risk participants in the treatment group showed a delay in clinical arthritis development: they developed the endpoint less often during treatment, but frequencies became similar at 24 months (67% in both groups). A similar delaying effect was observed in ACPA-positive participants, where 48% and 52% had developed persistent clinical arthritis at 24 months. The number of serious adverse events was equal between the groups; adverse events were as expected from methotrexate.

Conclusion: Methotrexate, the cornerstone treatment of RA, initiated at the pre-arthritis stage of joint symptoms and subclinical inflammation, did not prevent the development of clinical arthritis, but modified the disease course as measured by sustained improvement in MRI-detected inflammation, related symptoms and impairments. These findings of sustained disease modification may open up a new treatment landscape in a pre-arthritis phase of RA, where limitations can be just as severe as at the onset of clinical arthritis.

OP0071

ASSOCIATION BETWEEN LONG-TERM EXPOSURE TO AIR POLLUTION AND IMMUNE-MEDIATED DISEASES: A POPULATION-BASED COHORT STUDY

G. Adami[1], M. Pontalti[1], C. Benini[1], A. Fassio[1], E. Bertoldo[1], D. Gatti[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: Environmental air pollution has been associated with disruption of the immune system at a molecular level.
Objectives: The primary aim of the present study is to describe the association between long-term exposure to air pollution and risk of developing immune-mediated conditions.
Methods: We conducted a retrospective observational study on a nation-wide dataset of women and men. Diagnoses of various immune-mediated diseases were retrieved. Data on the monitoring of PM10 and PM2.5 concentrations were retrieved from the Italian institute of environment protection and research (ISPRA). The long-term average PMs concentrations were the exposure of interest. Every study subject was linked to a PMs exposure value, which resulted from the average concentration of urban, rural and near-traffic stations of the subject residency from January 2013 to November 2020. Patients were linked to the nearest air quality station through ZIP code centroids. Generalized linear models were employed to determine the relationship between autoimmune diseases prevalence and PM. The fully adjusted model included age, body mass index (BMI), menopause, glucocorticoid treatment, treatment with adjuvant hormone therapy for breast or prostate cancer, specialty of the physician that entered the data and macro-area of residency (stratified as a categorical variable: northern Italy, central Italy and southern Italy.
Results: 81,363 subjects were included in the study. We found a positive association between PM10 and the risk of autoimmune diseases (ρ +0.007, p 0.014). Every 10 µg/m3 increase in PM10 concentration was associated with an incremental 7% risk of having autoimmune disease. Exposure to PM10 above 30 µg/m3 and PM2.5 above 20 µg/m3 was associated with a 12% and 13% higher risk of autoimmune disease pooled together, respectively (aOR 1.12, 95% CI 1.05-1.20 and aOR 1.13, 95% CI 1.06-1.20). Exposure to PM10 was associated with an increased risk of rheumatoid arthritis (aOR 1.408, 95% CI 1.271-1.560) but no other autoimmune diseases, whereas exposure to high levels of PM2.5 were associated with an increased risk of rheumatoid arthritis (aOR 1.559, 95% CI 1.401-1.734), CTDs (aOR 1.147, 95% CI 1.024-1.286) and IBDs (1.206, 95% CI 1.028-1.415) but no other autoimmune diseases.
Conclusion: Long-term exposure to air pollution was associated with higher risk of developing autoimmune diseases, in particular rheumatoid arthritis, CTDs and IBD. Chronic exposure to levels above the threshold for human protection was associated with a 10% higher risk of developing immune-mediated diseases.

OP0072 **SMILE-RA - SELF-MANAGEMENT INDIVIDUALISED LEARNING ENVIRONMENT IN RHEUMATOID ARTHRITIS**

A. Bosworth[1]. [1]*National Rheumatoid Arthritis Society, Patient Services, Maidenhead, United Kingdom*

Background: An important but insufficient aspect of care in people with inflammatory arthritis (IA) is empowering them to acquire good understanding of their disease and build ability to deal effectively with the practical, physical and psychological impacts of it. This extends beyond drug therapy and emphasises the ability to self-manage, **with the right support**, as an **essential** component of care. Good self-efficacy and coping skills reduce health and financial burden to the individual as well as the health service, benefitting society overall. Provision of excellent supported self-management education is at the heart of what NRAS does and it was due to the difficulty of getting Commissioners to fund our face-to-face group self-management that led to our building an e-learning programme to expand on and replace our 6-week programme.
Objectives: To co-create an intuitive, easy to use, modular e-learning programme, free for all and which health professionals (HCPs) could refer their patients to. This makes supported self-management and evidence-based education accessible to all, wherever they live. SMILE enables HCPs to meet both NICE guideline and quality standards in RA against which rheumatology units in England and Wales are currently audited, as well as EULAR Recommendations for self-management strategies in inflammatory arthritis.
Methods: In 2019 with initial funding in place, we worked with our provider to help us realise our goal of developing a state-of-the art e-learning experience in a modular format for people with RA. The programme had to be 1) simple to use; 2) interactive; 3) innovative and engaging; 4) able to measure impact through achievement of learning objectives and use of a validated patient reported outcome measure. The programme also had to be integrable with our Salesforce database enabling us to collect data and target resources to individuals, driven by identified need.
Results: Delayed by COVID, we launched with 4 modules on 17/09/2021. The 4 modules comprise: Foundation Module covering the importance of self-management which has the RA Impact of Disease PROM embedded; Newly Diagnosed; Meet the Team and Managing Pain and Flares. A fifth module on Medicines in RA will be launched 1st quarter 2022 and 4 further modules will be uploaded in 2022. To date (26/01/22), 760 people have registered, of which 313 have completed a baseline RAID and this reveals that <50% are achieving minimal acceptable state of 3 or less. Over 78% of registrants are not NRAS members, and 634 modules have been completed. Early indications are that almost all are achieving learning objectives. More data will be available by June 2022.
Conclusion: Early indications demonstrate that people are successfully engaging with the programme and we have marketing activity lined up to raise further awareness of the value of SMILE with both potential users and rheumatology teams in 2022. Massive workforce issues together with significant backlogs of existing patients caused by the pandemic, have restricted the ability of Teams to provide education and self-management support for their patients. SMILE offers high quality, evidence-based learning opportunities for their patients and has been co-created with health professionals and people with RA at every step. With remote consultations here to stay, the importance of patients having access to evidence based online learning which they can tailor to their specific needs and improve their self-efficacy is even more critical.
Acknowledgements: I would like to acknowledge the support of our E-Learning Advisory Board and all health professionals and people with RA who have provided input to SMILE.
Disclosure of Interests: Ailsa Bosworth Grant/research support from: NRAS has received educational grants from a number of pharmaceutical companies. I have never received any personal payment from Industry.
DOI: 10.1136/annrheumdis-2022-eular.1565

OP0073 **NEW PERSPECTIVES IN AXIAL SPONDYLOARTHRITIS - FIRST RESULTS OF GENDER-SPECIFIC ASSESSMENT OF MRI IMAGING CRITERIA**

S. T. Ulas[1], F. Proft[2], T. Diekhoff[1], V. Rios Rodriguez[2], J. Rademacher[2], M. Protopopov[2], S. Ohrndorf[3], D. Poddubnyy[2], K. Ziegeler[1]. [1]*Charité - Universitätsmedizin Berlin, Department of Radiology (CCM), Berlin, Germany*; [2]*Charité - Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Charité – Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin, Germany*; [3]*Charité - Universitätsmedizin Berlin, Department of Rheumatology, Charité – Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany*

Background: Gender-specific differences in patients with axial spondyloarthritis (axSpA) are often seen in the clinical presentation and may differ in MRI findings[1]. Male axSpA patients tend to show structural changes earlier, whereas in female axSpA patients the peripheral joints are more often affected[2]. This can lead to a delay in axSpA diagnosis in women. For this reason, gender-specific data collection and establishment of gender-specific imaging criteria are of particular importance.
Objectives: To evaluate the diagnostic performance of different combinations of imaging markers to derive data-driven imaging criteria for MRI in axSpA, separately for men and women.
Methods: A total of 1194 patients were included in the study. Considering the exclusion criteria (available MRI image data sets, confirmed diagnoses), 684 patients (379 axSpA and 305 control group) were included for further statistical analysis. Two trained readers scored the MRI images separately for the presence of ankylosis, as well as erosion, sclerosis, fat metaplasia, and bone marrow edema differentiated for 3 regions (ventral/mid/dorsal) for sacral-sided and iliac-sided sacroiliac joint. Chi^2 test was applied to compare lesion frequencies per group. Contingency table analysis was performed to assess diagnostic performances. The diagnostic performances were compared using the diagnostic odd ratio (DOR).
Results: Overall, 136 female and 243 male axSpA patients were included. Higher prevalence for ankylosis (24.3 vs. 7.4%) and fat metaplasia (58.8 vs. 42.6%) was shown in male axSpA patients; in contrast, sclerosis was more common in female axSpA patients (75.0 vs. 57.6%). No sex differences in frequency were shown for bone marrow edema and erosion. In male axSpA patients, the most significant difference in individual parameters was shown for ankylosis (DOR 40.1) compared with females (DOR 4.7). The detection of erosion and fat metaplasia as markers was also better in male axSpA patients (DOR 17.6 vs. 11.1 and 18.6 vs. 6.3). Sclerosis and bone marrow edema were better suited in female axSpA patients (DOR 3.0 vs. 2.5 and 5.0 vs. 3.7). Overall, diagnostic accuracy was improved when only lesions in the middle and dorsal articular compartments were considered.
Conclusion: The diagnostic performance of established image markers on MRI is significantly lower in female axSpA patients. This is especially true for ankylosis, which provides the risk for false-positive findings in women. Based on these findings, future revisions of imaging criteria may include gender-specific recommendations to improve diagnostic accuracy for male and female axSpA patients.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

OP0074 **DISTINCT CIRCULATING LYMPHOCYTE SUBSETS DISTINGUISH FLARE FROM DRUG-FREE REMISSION IN RHEUMATOID ARTHRITIS**

K. F. Baker[1,2], F. Rayner[1], H. Lemos[1], D. McDonald[3], G. Hulme[3], R. Hussain[4], J. Coxhead[4], A. Pratt[1,2], A. E. Anderson[1], A. Filby[3], J. Isaacs[1,2]. [1]*Newcastle University,Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom*; [2]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Musculoskeletal Unit, Freeman Hospital, Newcastle upon Tyne, United Kingdom*; [3]*Newcastle University, Flow Cytometry Core Facility, Newcastle upon Tyne, United Kingdom*; [4]*Newcastle University, Genomics Core Facility, Newcastle upon Tyne, United Kingdom*

Background: Rheumatoid arthritis (RA) is characterised by relapsing joint and systemic inflammation, yet the immunopathological basis of these disease flares and their clinical prediction remain uncertain.
Objectives: Using mass cytometry and single cell RNA sequencing, we aimed to identify circulating lymphocyte subsets associated with RA flare, and identify potential cellular biomarkers to predict flare versus drug-free remission (DFR).
Methods: We analysed peripheral blood mononuclear cells (PBMCs) from patients recruited to the BioRRA study (Figure 1), a prospective clinical trial of conventional synthetic disease-modifying anti-rheumatic drug (csDMARD) cessation.[1] Patients with RA in clinical (DAS28-CRP < 2.4) and ultrasound (absence of power Doppler signal in 7 joints) remission stopped csDMARDs, with flare defined as DAS28-CRP ≥ 2.4 during 6 month follow-up. A 44-marker mass cytometry panel was used to profile PBMCs from 36 patients (20 flare, 16 DFR) at two time points each (baseline, and flare onset / month 6 DFR). In a subset of patients (n = 12: 8 flare, 4 DFR), fluorescence-activated cell sorting of T and B cells was followed by single cell sequencing (n = 81,923 cells) incorporating 320 immune genes, 34 oligo-tagged surface protein antibodies, and TCR/BCR CDR3 sequence. Clones were defined as ≥2 cells with identical CDR3 nucleotide sequence, and clonal expansion as a significant increase in proportion from baseline to final study visit. Statistical significance was assessed after Benjamini-Hochberg multiple test correction (adj p < 0.05).

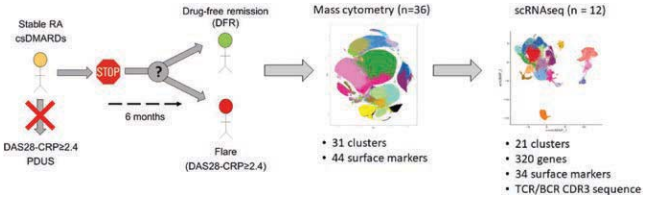

Figure 1.

Results: Mass cytometry revealed 31 distinct cell clusters: notably, greater proportions of memory (CD45RO+/PD1hi) CD4+ and CD8+ T cells, and memory (CD27+/CD21-) B cells, were observed at onset of flare versus baseline (Table 1).

Table 1.

Mass cytometry (n = 20 flare + 16 DFR)			
Contrast	Cluster	Median %	Adj. p (GLMM)
Flare onset vs baseline: Flare patients	CD4+/CD45RO+/PD1+ memory T cells	2.14 vs 0.24	<0.001
	CD8+/CD45RO+/PD1+ memory T cells	6.64 vs 0.07	<0.001
	CD19+/CD27+/CD21- memory B cells	2.39 vs 0.03	<0.001
Single cell RNAseq (n = 8 flare + 4 DFR)			
Contrast	Cluster	Median %	Adj. p (Wilcoxon)
Flare onset vs baseline: Flare patients	IgA+ plasma cells	0.37 vs 0.21	0.020
Flare vs DFR patients: Baseline	CD4+/CD25+/Foxp3+ Treg cells	0.55 vs 1.27	0.022

To better characterise these flare-associated subsets, single cell sequencing of CD45RO+/PD1hi CD4+ and CD8+ T cells, and CD19+ B cells, was performed and identified 21 distinct clusters. CDR3 sequencing revealed significant clonal expansion (Fisher exact, adj. p < 0.05) at flare onset within five unique CD8+ clones (4 patients), one CD4+ clone (1 patent), and no B clones. Overall, there was a significantly greater proportion of IgA+ plasma cells at flare onset versus baseline. In contrast, a significantly lower proportion of CD25+/FoxP3+ regulatory T cells were present at csDMARD cessation (baseline) in subsequent flare versus DFR patients (Table 1), suggesting biomarker potential.
To further assess the predictive performance of CD4+ Tregs as a biomarker for flare versus DFR, we analysed PBMCs from an independent cohort of 50 patients (25 flare, 25 DFR) stopping csDMARDs in the ongoing BIO-FLARE study.[2] By flow cytometry, we confirmed a lower proportion of CD4+/CD25hi Tregs at baseline in flare vs DFR (median 4.74 versus 6.37%, Wilcoxon p = 0.037; AUC: 0.67). In this cohort, stopping csDMARDs only in patients with elevated (> 6.11% total CD4) baseline Tregs would have prevented drug cessation in 18/25 (72%) of flare patients; 9/25 (36%) of DFR patients would have continued csDMARDs unnecessarily.
Conclusion: We present a detailed longitudinal characterisation of circulating lymphocyte surface phenotype, gene expression, and clonal expansion in RA flare vs DFR. Furthermore our data, across two independent cohorts, suggests a role for CD4+ Tregs in promoting drug-free remission meriting further investigation, with potential for future clinical biomarker development.

OP0075 FIBROBLAST/MACROPHAGE CROSSTALK VIA LACTATE: NEW THERAPEUTIC TARGET IN RHEUMATOID ARTHRITIS

V. Pucino[1], M. Nefla[1], V. Gauthier[1], S. A. Clayton[1], A. Filer[1], A. R. Clark[1], K. Raza[1], C. D. Buckley[1,2]. [1]*University of Birmingham, Inflammation and Ageing, Birmingham, United Kingdom*; [2]*University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom*

Background: The synovial membrane is the principal site of inflammation in rheumatoid arthritis (RA) and distinct subsets of fibroblasts and macrophages, with different effector functions, have been described within it[1,2,3]. Inflammation renders the RA synovial microenvironment hypoxic and acidic, with increased levels of lactate, the end product of glycolysis. Lactate acts as an immunomodulatory molecule within the synovium[4], interacting with lactate transporters present on fibroblasts and macrophages to regulate their function, movement and metabolism.
Objectives: To test whether dysfunctional crosstalk between fibroblasts and macrophages, driven by lactate, promotes the persistence of synovial inflammation.
Methods: Synovial tissues (n = 8) from patients fulfilling the 2010 ACR/EULAR RA criteria were obtained by ultrasound-guided synovial biopsy. Osteoarthritis (OA) synovial tissues of subjects undergoing joint replacement were used as control group. Monocarboxylate transporter 1 (MCT)1 and MCT4 expression on fibroblasts and macrophages was assessed via confocal microscopy. We used RA synovial fibroblasts and monocyte-derived macrophages to test the effect of lactate in vitro. Migration was assessed in trans-well plates or via scratch test assays. Seahorse was used to evaluate metabolic pathways. IL6 production was measured by ELISA. Bioinformatic data were confirmed on publicly available scRNAseq datasets.
Results: We showed that: i) The expression of MCT1 and MCT4 which regulate lactate import and export respectively, is up-regulated upon inflammation. ii) Fibroblasts preferentially express MCT1, while MCT4 is more highly expressed by macrophages. iii) Lactate, at the concentration found in RA synovial fluid (10 mM), has divergent effects on the effector functions of these two cell types. In fibroblasts, lactate promotes IL6 production and cell motility; these effects are reduced by pre-treatment with a pan-lactate transporter inhibitor. In contrast macrophages respond to lactate by reducing migration, IL6 secretion and glycolysis.
Conclusion: The contrasting effects of lactate on macrophage and fibroblast migration, IL6 production and metabolism suggest that lactate represents a key

metabolite ensuring linked choreography between fibroblast and macrophage movement in the synovium which may become uncoupled in disease. We propose that dysfunctional crosstalk between these two cell types due to high lactate levels, promotes inflammation and the establishment of persistent disease in RA. Targeting lactate/MCTs pathway may provide a novel therapeutic strategy, to restore cellular crosstalk and to reduce inflammation in RA patients.

OP0076 L-ARGININE REPROGRAMS OSTEOCLAST PURINE METABOLISM AMELIORATING BONE LOSS IN RHEUMATOID ARTHRITIS

S. Cao[1,2], R. Song[1,2], X. Meng[1], K. Kachler[1], M. Fuchs[3], X. Meng[2], Y. Li[2], V. Taudte[4], M. Kunz[3], U. Schloetzer-Schrehardt[5], U. Schleicher[6], X. Chen[2], G. Schett[1], A. Bozec[1]. *[1]Universitätsklinikum Erlangen, Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Department of Internal Medicine 3–Rheumatology and Immunology, Erlangen, Germany*; *[2]Renji Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Department of Rheumatology, Shanghai, China*; *[3]Friedrich-Alexander University of Erlangen-Nürnberg, Chair of Medical Informatics, Erlangen, Germany*; *[4]Friedrich-Alexander University of Erlangen-Nürnberg, Institute of Experimental and Clinical Pharmacology and Toxicology, Erlangen, Germany*; *[5]Universitätsklinikum Erlangen, Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Department of Ophthalmology, Erlangen, Germany*; *[6]Universitätsklinikum Erlangen, Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Mikrobiologisches Institut – Klinische Mikrobiologie, Immunologie und Hygiene, Erlangen, Germany*

Background: Bone erosion is a clinical feature of rheumatoid arthritis related to disease severity and poor functional prognosis. Excessive osteoclast differentiation and insufficient osteoblast function are the main reasons for the erosive process in RA. Our previous investigation indicated that L-arginine supplementation not only diminished arthritic inflammation in the serum-induced arthritis (K/BxN) model but also decreased inflammatory joints osteoclast numbers (1).
Objectives: In the present study, we aim to investigate the metabolic action of L-arginine supplementation in RA, especially on periarticular bone erosion and systemic bone loss. We plan to depict the metabolic features of TNFα induced inflammatory osteoclasts after *in vitro* L-arginine supplementation.
Methods: Three murine arthritis models (serum-induced arthritis (K/BxN) model, collagen-induced arthritis model, and hTNFtg mice model) were analysed in this study. L-arginine was supplemented within the drinking water after the onset of arthritis. Bone parameters for axial skeleton (spine) and peripheral skeleton (tibia) from the respective group were quantified by µCT. HE and TRAP staining were performed to address further the erosion area and osteoclast numbers in periarticular sites. *In vitro* osteoclast differentiation was conducted with or without L-arginine treatment, in the presence or not of TNFα activation. Seahorse and SCENITH analyses were adopted to delineate the metabolic features. JC-1 staining and transmission electron microscopy (TEM) were used to depict the mitochondria metabolism. RNA-seq and mass spectrometry (MS) were performed to investigate the underlying molecular mechanism.
Results: Inflammation was diminished in all three arthritis models after L-arginine supplementation with a significant reduction in arthritic score. Moreover, an amelioration of periarticular bone erosion, systemic bone loss, and decreased osteoclast numbers in periarticular sites were observed in arthritic mice after L-arginine treatment. L-arginine also inhibited osteoclastogenesis *in vitro*, particularly under TNFα activation. Seahorse and SCENITH analyses indicated TNFα promoted glycolysis while blocking mitochondria-driven oxidative phosphorylations (OXPHOS) in pre-osteoclasts. Meanwhile, JC-1 staining and TEM images also showed that TNFα decreased mitochondria membrane potential and prompted damage of mitochondria. Surprisingly, L-arginine rescued the TNFα inhibition of OXPHOS while promoting ATP production. RNA-seq and MS data confirmed the boost of OXPHOS after L-arginine treatment under TNFα activation. To interfere with OXPHOS, L-arginine inhibited cJun thus altered arginase-1 and arginase-2 expression. Moreover, the increased ATP in L-arginine treated cells facilitated purine metabolism, especially the production of inosine and hypoxanthine, contributing to the inhibition of osteoclastogenesis. Increasing Adenosine deaminase (ADA) is essential for the production of inosine and hypoxanthine due to the decreased inhibitory regulation of the transcription factor c-Jun.
Conclusion: These data strongly demonstrated that L-arginine ameliorates bone erosion in RA through metabolic reprogramming and perturbation of purine metabolism in osteoclasts. L-arginine might therefore benefit RA therapy by reducing joint inflammation and also ameliorating bone destruction.

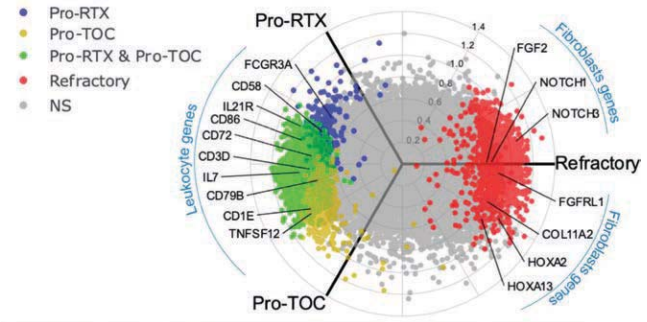
OP0077 SYNOVIAL RNA-SEQ ANALYSIS OF THE R4RA TRIAL IDENTIFIES SIGNATURES OF TREATMENT RESISTANCE AND REFRACTORY STATE IN RHEUMATOID ARTHRITIS

A. Surace[1,2], E. Sciacca[1,2], K. Goldmann[1,2], F. Rivellese[1,2], C. Cubuk[1,2], G. Giorli[1,2], L. Fossati-Jimack[1], M. Ahmed[1], E. Prediletto[1], M. Bombardieri[1], M. Lewis[1], C. Pitzalis[1], on behalf of R4RA investigators. *[1]Queen Mary University of London, Centre for Experimental Medicine and Rheumatology, London, United Kingdom*; *[2]Queen Mary University of London, Centre for Translational Bioinformatics, London, United Kingdom*

Background: Although up to 5-20% of rheumatoid arthritis (RA) patients do not respond to all current medications including biologic therapies, relatively little is known about the underlying pathogenic mechanisms driving non-response. In the first biopsy-driven randomized clinical trial in RA (R4RA)[1], patients, in whom synthetic-DMARDs and at least one anti-TNF drug were not effective, were randomised 1:1 to rituximab (RTX) or tocilizumab (TOC) with a balanced stratification based on their synovial B-cell rich/poor signature, and response was assessed at 16 weeks. Non-responders were subsequently allowed to switch to the alternative drug with 48-week follow-up.
Objectives: Investigate mechanisms of response and non-response to RTX and TOC through deep molecular (RNA-Sequencing) profiling of synovial tissue.
Methods: RNA-Seq from baseline synovial tissue biopsies of patients who received RTX (n=88) or TOC (n=94) at any point in the trial was analysed for differentially expressed genes and associated modules between responders and non-responders. Response was defined as 50% improvement in clinical disease activity index (CDAI) score. Patients who had received both drugs during the trial were subdivided into RTX only responders (pro-RTX, n=9), TOC only responders (pro-TOC, n=12) and refractory patients (no response to both RTX & TOC, n=32) and analysed for differential gene expression and performed gene module analysis.
Results: 6625 genes were significantly differentially expressed between RTX responders compared to non-responders, with a predominance of antigen presentation as well as T- and B-cell genes being associated with response, while non-response was linked to fibroblast associated genes. Comparison between TOC responders and non-responders identified fewer (85) differentially expressed genes, however lymphocyte and immunoglobulin genes were also high in the synovial tissue of TOC responders similar to RTX responders, while non-responder genes and modules also included a fibroblast signature. The cross-over study design enabled comparison of rituximab-specific responders (pro-RTX), tocilizumab-specific responders (pro-TOC) and refractory patients (non-responders to both RTX & TOC, n=32) in a 3-way analysis (see Figure 1). This identified 1980 genes upregulated both in pro-RTX and pro-TOC patients, 175 genes exclusive to the pro-RTX group and 306 to the pro-TOC group, while 1277 genes were exclusive to the refractory group. While leukocyte modules and genes dominated RTX & TOC response, the refractory state was strongly associated with fibroblast genes and modules. We confirmed the observed expansion of fibroblasts from the RNA-Seq data by immunohistochemistry showing the presence of DKK3+ sublining fibroblasts in refractory rather than responder patients.



Polar plot of 3-way differential gene expression analysis on baseline synovial biopsies.
Polar plot showing analysis of RNA-Seq TPM counts tested for differential expression by DESeq2, comparing patients who failed tocilizumab and responded to rituximab (pro-RTX, blue if False Discovery Rate <0.05), who failed rituximab but responded to tocilizumab (pro-TOC, yellow if FDR<0.05), or who failed both drugs (refractory, red if FDR<0.05).
Genes in green show significant genes overlapping in pro-RTX and pro-TOC patients and genes in grey are statistically non-significant.

Conclusion: We provide novel insights into the cellular and molecular pathways underpinning multi-biologic resistance that define a refractory RA phenotype, characterised by a stromal/fibroblast signature.

OP0078 ALTERED IMMUNOLOGICAL CIRCADIAN RHYTHMS AND THE EFFECT OF TREATMENT WITH GLUCOCORTICOIDS ON CIRCADIAN RHYTHMS OF IMMUNE CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS: BRING BACK THE RHYTHM

S. Wilantri[1,2], C. Strehl[1,2], D. Abdirama[1,2], T. Gaber[1,2], R. Biesen[1], F. Buttgereit[1,2], on behalf of AG Buttgereit. *[1]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [2]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Glucocorticoid and Bioenergetic, Berlin, Germany*

Background: In rheumatoid arthritis (RA), pain, joint swelling, and stiffness follow a clear circadian pattern. Most of these symptoms are most pronounced in the early morning and primarily attributed to elevated levels of the key proinflammatory cytokines IL-6 and TNFα, which usually peak before clinical symptoms worsen (1). Synthetic glucocorticoids (GCs) are among the most prescribed drugs in the management of patients with RA. GCs have effects on almost every immune cell. GCs suppress expression of various cytokines, including IL-1β, TNFα, IL-6, and GM-CSF. Moreover, circadian rhythms of immune cells are known to be influenced by GCs. For example, GCs govern in part the rhythm of circulating CD4+ and CD8+ T cells.
Objectives: To identify circadian patterns for optimization of diagnosis and treatment strategies, we conducted a clinical study comparing healthy donors (HD) and patients with RA in terms of circadian rhythms. We examined the effect of treatment with GCs on circadian immune rhythms in patients with RA.
Methods: We recruited 12 HD and 13 patients with active RA (DAS28≥4.0) who either were (n=8) or, for comparison, were not (n=5) under current treatment with GCs. Their biological clock was synchronized for a week before the study day by a scheduled sleep and mealtime regimen. On the study day, participants were provided with regular meals, allowed to eat snacks ad libitum and carry passive activities. We collected blood samples every two hours over a period of 24 hours. The absolute number of circulating immune cells, clock gene expression, and serum cytokine levels were measured with TruCount, qPCR, and multiplex suspension assay, respectively.
Results: Peripheral regulatory T cells are circadian in HD and RA, but the number was notably reduced in RA (Table 1). $CD8^+$ T cells, $CD14^+$ monocytes, and $CD19^+$ B cells lost their circadian rhythms in RA, but these rhythms were restored with GC treatment. Circulating NK and NK T cells, which are not diurnal in HD, exhibited circadian fluctuations in RA. GC treatment suppressed diurnal pathological circulation rhythms of NK and NK T cells by reducing the amplitude by half. In monocytes, *BMAL1*, *PER1*, *PER2*, and *REVERBA* are only circadian in HD. GC restored the rhythms of *PER2* and *REVERBA*. *CRY1* expression showed diurnal variation in RA, but not in HD. IL-6 exhibited a circadian pattern in both groups, and GC treatment showed no significant effects on IL-6. Serum IL-4, IL-5, and MIP3α showed circadian variation in HD only. The following cytokines were notably elevated in RA-patients: IFNγ, MIP1α, MIP1β, IL-1β, IL-2, IL-17A, and IL-21. GC reduced the expression of IL-10 significantly in RA.

Table 1. ***Circadian rhythms in the cellular, gene, and protein levels in HD, RA, and RA with ongoing GC treatment***

Comparison	Circadian / GC impact	Circulating immune cells	Clock genes in monocytes	Serum cytokines
HD *vs.* RA	Non-circadian in HD and RA	-	*CLOCK, CRY2, DBP, RORA*	Fractaline, IFNγ, CXCL11, GM-CSF, MIP1α, MIP1β, IL-1β, IL-2, IL-4, IL-7, IL-8, IL-10, IL-12, IL-13, IL-17A, IL-21, IL-23
	Circadian in HD and RA	$CD3^+$, $CD4^+$, regulatory T cells	*PER3*	IL-6
	Circadian in HD	$CD8^+$ T cells, $CD14^+$ monocytes, $CD19^+$ B cells	*BMAL1,PER1, PER2, REVERBA*	IL-4, IL-5, MIP3α
	Circadian in RA	NK cells, NK T cells	*CRY1*	-
RA *vs.* GCs-treated RA	Restorative effect by GC	$CD8^+$ T cells, $CD19^+$ B cells	*PER2, REVERBA*	-
	Enhancing effect by GC	regulatory T cells	*PER3, CRY1*	-
	Dampening effect by GC	NK T cells, NK cells	-	-

Conclusion: In patients with RA, we found a certain loss of circadian rhythms and the establishment of "inflammatory" rhythms. GC treatment in patients with RA resulted in three different types of effects on circadian rhythms at immune cell level: restoration, amplification, and attenuation. In conclusion, these findings provide new insights into the pathophysiology of circadian rhythms in RA that could be used to optimize diagnosis and treatment.

OP0079 SYNOVIAL FIBROBLASTS – T CELL INTERACTIONS ARE MAJOR DRIVERS OF INFLAMMATION: A CLOSER LOOK INTO THE JOINT

M. Kugler[1], M. Dellinger[1], F. Kartnig[1], A. Tosevska[1], L. Müller[1], T. Preglej[1], L. Heinz[1], H. Kiener[1], G. Steiner[1], D. Aletaha[1], T. M. Karonitsch[1], M. Bonelli[1]. *[1]Medical University of Vienna, Dept. of Rheumatology, Vienna, Austria*

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory disease, which is characterized by synovial inflammation resulting in bone and cartilage destruction. Crosstalk between activated fibroblast-like synoviocytes (FLS) and immune cells, such as $CD4^+$ T cells, within the synovium might amplify synovial inflammation and joint destruction.
Objectives: To define the interaction profile of activated FLS and $CD4^+$ T cells within an inflammatory setting and to elucidate its consequence on synovial inflammation.
Methods: To screen for factors that activate FLS in RA, isolated FLS were treated with different inflammatory cytokines and transcriptomic changes were measured with RNA-seq. Fluorescence activated cell sorting (FACS) purified naïve $CD4^+$ T-cells from the same patients were co-cultured with the cytokine pre-treated FLS. Automated fluorescence microscopy and downstream bioinformatic image analysis allowed visualization and quantification of cell-cell interactions. After co-culture T-cells were isolated and T-cell activation, proliferation and differentiation was determined by flow cytometry.
Results: To model the *in vivo* situation, FLS were pre-stimulated with different pro- and anti-inflammatory cytokines. RNA-seq revealed cytokine specific activation patterns of FLS. Correspondingly, we observed distinct $CD4^+$ T cells – FLS interaction profiles depending on the cytokine used for FLS activation. In line with distinct interaction profiles, specific patterns in $CD4^+$ T cells activation, proliferation and differentiation of naïve T cells into $CD62L^{high}$ $CD45RO^{high}$ memory T cells could be detected. Signatures of cytokine-stimulated FLS could be identified in transcriptomic data from synovial tissue samples.
Conclusion: Within this study, we describe how cytokine induced $CD4^+$ T cells – FLS interactions impact on T-cell proliferation, activation and differentiation.

OP0080 STAT3 DEGRADERS INHIBIT TH17 DEVELOPMENT AND CYTOKINE PRODUCTION RESULTING IN PROFOUND INHIBITION OF COLLAGEN-INDUCED AUTOIMMUNE MURINE ARTHRITIS

C. Hubeau[1], J. Sullivan[1], C. Brown[2], M. Mayo[2], V. Dixit[3], B. Enerson[4], H. Rong[3], B. Yang[5], C. De Savi[6], J. Gollob[7], N. Mainolfi[6], A. Slavin[1]. *[1]Kymera Therapeutics, Inflammation & Immunology, Watertown, United States of America; [2]Kymera Therapeutics, Pharmacology, Watertown, United States of America; [3]Kymera Therapeutics, Drug Metabolism & Pharmacokinetics, Watertown, United States of America; [4]Kymera Therapeutics, Drug Safety, Watertown, United States of America; [5]Kymera Therapeutics, Medicinal Chemistry, Watertown, United States of America; [6]Kymera Therapeutics, Drug Discovery, Watertown, United States of America; [7]Kymera Therapeutics, Clinical Development, Watertown, United States of America*

Background: Signal transducer and activator of transcription 3 (STAT3) is a transcription factor that belongs to a class of targets devoid of catalytic function, thus deemed "undruggable" by standard modalities such as small molecule inhibitors or biologics. STAT3 can be activated by various receptor- and non-receptor tyrosine kinases, playing a critical role in activation pathways triggered by cytokines, hormones, and growth factors, making it an attractive target for the treatment of inflammatory diseases.
Objectives: Kymera has developed heterobifunctional molecules that selectively target STAT3 for degradation and elimination by the ubiquitin-proteasome pathway. We sought to evaluate the pharmacologic potential of these STAT3 degraders through in vitro and in vivo studies relevant to human autoimmune disease, including murine collagen-induced arthritis.
Methods: We evaluated the impact of STAT3 degraders on the activation of human monocytes, dermal fibroblasts, CD4+ T cells, and PBMC by LPS, IL-6/IL-6R, IL-21, IL-23, as well as anti-CD3/CD28 plus a cocktail of cytokines and antibodies. STAT3 degradation and pSTAT3 inhibition were determined in comparison to a JAK1/2 small molecule inhibitor. Inhibition of cytokines, chemokines, and collagen release, as well as Th17 (CD4+CD25-RORγt+CXCR6+) and Treg (CD4+CD25+CD127lowFOXP3+) expansion were used as in vitro efficacy assays. Finally, STAT3 degraders were tested in vivo, in a mechanistic (IL-6 challenge) as well as a disease model (murine CIA) relevant to rheumatology indications.
Results: STAT3 degraders showed broad and potent activity *in-vitro* against TLR receptor and cytokine-induced activation of immune and stromal cells, including soluble mediator release such as MCP-1/CCL2 and Collagen1a1. STAT3 degradation in CD4+ T cells robustly inhibited the development of Th17 cells, abrogating IL-17, IL-22, IL-8/CXCL8, and TNFα production, and increased Treg numbers in a manner superior to JAK1/2 inhibition. In mice injected with IL-6, plasma levels of serum amyloid A were dose-dependently suppressed by STAT3 degradation. In the murine collagen-induced arthritis model, STAT3 degradation resulted in robust, dose-dependent delay of disease onset and decreased disease incidence, clinical scores, local cytokine expression (paws) and histopathological scores, including the complete alleviation of periosteal bone growth.
Conclusion: These data demonstrate the broad activity of STAT3 degradation in alleviating autoimmune inflammation in models relevant to human disease. Targeted protein degradation of STAT3 thus represents a novel therapeutic approach to treating autoimmune/autoinflammatory diseases such as rheumatoid arthritis.

OP0081 IL-13 REDUCES BONE EROSION IN RHEUMATOID ARTHRITIS BY UP-REGULATING OPG IN SYNOVIAL FIBROBLASTS

Z. Chen[1], X. Tang[1], H. Zhang[1], L. Sun[1]. *[1]Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Department of Rheumatology and Immunology, Nanjing, China*

Background: Bone erosion in rheumatoid arthritis (RA) is partly caused by excessive activation of osteoclasts[1]. Osteoclasts can be derived from RA synovium and their differentiation can be inhibited by OPG, a decoy receptor of the osteoclastogenesis promoting cytokine RANKL[2,3]. Fibroblast-like synoviocytes (FLSs) are a main type of stromal cells in the synovium that can secret OPG[4]. The OPG secretion by FLSs can be modulated by various cytokines[5]. Interleukin (IL)-13 is a cytokine rich in early RA synovial fluid and it decreases as RA progresses[6]. IL-13 was reported to alleviate bone erosion in RA mouse models[7]. However, how IL-13 reduces bone destruction remains unclear.
Objectives: To investigate if IL-13 can inhibit osteoclast differentiation by up-regulating OPG in FLSs of RA patients (RA-FLSs), thus reduces bone erosion in RA.
Methods: FLSs were isolated from the synovium tissue of RA patients with informed consent who underwent joint replacement surgery (Ethics No. 2021-544-01). OPG and RANKL expression by RA-FLSs were evaluated by qRT-PCR. OPG secretion was determined by ELISA. Western blot was performed to analyze OPG expression and the activation of STAT6 pathway. IL-13 and OPG siRNA pre-treated RA-FLSs conditioned medium were used in osteoclast induction to test if IL-13 can inhibit osteoclastogenesis by up-regulating OPG in RA-FLSs. Micro-CT scanning and immunofluorescence were done to determine if IL-13 can induce OPG expression and alleviate bone erosion in vivo.
Results: IL-13 can significantly upregulate OPG expression and secretion by RA-FLSs. Meanwhile, RANKL/OPG ratio was downregulated (Figure 1A). STAT6 phosphorylation and OPG upregulation of RA-FLSs by IL-13 can be significantly inhibited by a STAT6 inhibitor (inh.) (Figure 1B). IL-13 receptor α1 (IL-13Rα1) and IL-13 receptor α2 (IL-13Rα2) knockdown can inhibit OPG upregulation by IL-13 in RA-FLSs, indicating that IL-13 can induce OPG secretion in RA-FLSs through IL-13Rα1 and IL-13Rα2 via STAT6 pathway (Figure 1C). 20% conditioned medium of RA-FLSs pretreated by IL-13 can significantly inhibited osteoclast differentiation in vitro. OPG knockdown in RA-FLSs significantly reversed the inhibition, indicating that IL-13 inhibits osteoclastogenesis by upregulating OPG in RA-FLSs (Figure 1D). In collagen-induced arthritis mice, IL-13 injection can reduce bone destruction in the ankle joint. Meanwhile, OPG expression in vemintin positive FLSs was increased (Figure 1E and F).

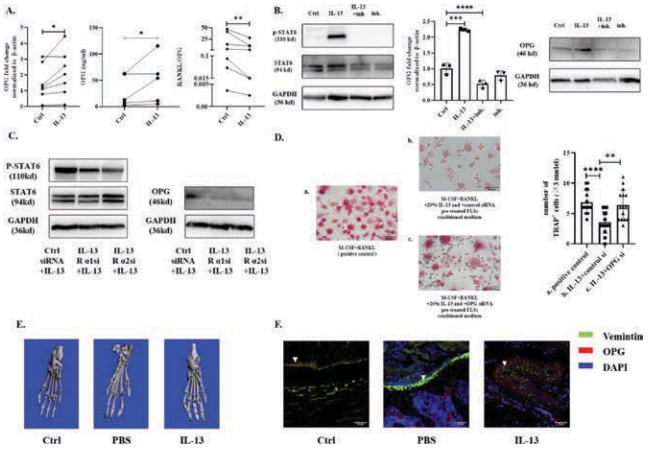

Figure 1.

Conclusion: IL-13 can inhibit osteoclastogenesis by up-regulating OPG in RA-FLSs through IL-13 receptors via STAT6 pathway, thus ameliorate bone erosion in RA.

Rheumatoid arthritis - prognosis and prediction

OP0082 DISCORDANCE BETWEEN DAS28ESR AND PRESENCE OF ULTRASOUND POWER DOPPLER DURING EARLY TREATMENT IS ASSOCIATED WITH DISTINCT CLINICAL AND IMAGING PHENOTYPES AT PRESENTATION

R. Shukla[1,2], R. Wakefield[3,4], P. Emery[3,4], D. Plant[1,2], M. H. Buch[1,2,3]. *[1]University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*; *[2]Manchester University NHS Foundation Trust, NIHR Biomedical Research Centre, Manchester, United Kingdom*; *[3]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[4]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Discordance between DAS28ESR and musculoskeletal ultrasound (MSUS) detected power Doppler synovitis (PDUS) is well-recognised and may lead to under/overtreatment. We hypothesize that clinical and imaging features at diagnosis associate with early discordance of DAS28-PDUS and change in DAS28-PDUS status following DMARD treatment.
Objectives: To identify pre-treatment clinical factors associated with discordance and change in DAS28-PDUS status during early treatment in an early RA trial cohort.
Methods: The 'VEDERA' trial[1] randomised 120 treatment-naïve, new-onset RA patients to either first-line etanercept + methotrexate (ETN+MTX) or methotrexate treat-to-target (MTX-TT) regime with escalation to ETN+MTX if not in DAS28ESR remission at week 24. Clinical and MSUS assessments were completed at baseline, weeks 12, 24 and 48. DAS28ESR ≤ 2.6 and DAS28ESR > 2.6 categorised remission and active disease respectively. PDUS presence was defined as total PDUS score ≥ 1. Active concordance (AC) was defined as active disease with PDUS while active discordance (AD) was defined as active disease without PDUS. Remission concordance (RC) was defined as DAS28ESR remission without PDUS while remission discordance (RD) was defined as DAS28ESR remission with PDUS. Bayesian multinomial logistic regression (posterior estimate and 95% credible intervals reported) was used to address the study objectives with AC as the comparator group.
Results: At baseline all patients had active disease (moderate or high DAS-28ESR) in line with trial eligibility - 68% (81/120) were AC and 32% (39/120) were AD. Compared to AD patients, AC patients were older (median age 53 vs 44), had higher DAS28ESR (5.90 vs 5.16) and CRP (11.6mg/L vs 3.6mg/L), as well as a higher presence of greyscale (GS - 100% vs 67%), power Doppler tenosynovitis (PDTS - 78% vs 49%) and erosions (20% vs 0) ($p < 0.01$). Figure 1 illustrates the pre-treatment proportions and change in group proportions at each timepoint, revealing an early shift of AC to AD (36% by week 12) or RC (22% by week 12) but persistence of those in AD from baseline at subsequent timepoints (64% at week 12). Baseline characteristics associated with each group compared to the comparator AC group (at weeks 12, 24 and 48) are reported in Table 1. For AD versus AC these were lower CRP at week 12 and female sex at week 24. For RC versus AC these were lower CRP and allocation to ETN+MTX at week 12, allocation to ETN+MTX and presence of PDTS at week 24 and younger age at week 48. For RD versus AC these were presence of PDTS at week 24 and male sex at week 48.

Table 1. Baseline characteristics associated with longitudinal discordance vs concordance. AC is the comparator group. Results in posterior estimate with 95% credible intervals

	Week 12	Week 24	Week 48
AD vs AC			
Female	0.53 (-0.44 to 1.48)	**1.52 (0.51 to 2.59)**	0.17(-0.91 to 1.25)
CRP	**-0.05 (-0.1 to -0.01)**	-0.01 (-0.04 to 0.05)	0.01(-0.02 to 0.02)
RC vs AC			
Age at diagnosis	-0.04(-0.09 to 0.01)	-0.02(-0.06 to 0.03)	**-0.08(-0.13 to -0.03)**
CRP	**-0.05 (-0.10 to -0.01)**	0.001(-0.04 to 0.03)	0.01(-0.02 to 0.04)
ETN+MTX	**1.57, (0.57 to 2.64)**	**1.26, (0.29 to 2.33)**	0.91(-0.02 to 1.85)
PDTS	0.58 (-0.5 to 1.68)	**1.23(0.2 to 2.29)**	0.8 (-0.2 to 1.83)
RD vs AC			
Female	0.23 (-1.26 to 1.72)	0.9 (-0.41 to 2.26)	**-1.59(-2.9 to -0.35)**
PDTS	1.00 (-0.55 to 2.69)	**1.79 (0.44 to 3.33)**	0.95(-0.29 to 2.27)

Conclusion: DAS28ESR and PDUS discordance and concordance have distinct clinical and imaging phenotypes at presentation. Baseline active concordance and discordance respond differently to treatment –a sizeable proportion of former transition into active discordance early on and the latter persist in the face of effective treatment. Understanding the basis for these phenotypes is essential to facilitate optimal aggressive treatment and/or alternative management strategies.

OP0083 HAND AND FOOT MRI IN CONTEMPORARY UNDIFFERENTIATED ARTHRITIS: IN WHICH PATIENTS IS MRI VALUABLE TO DETECT RHEUMATOID ARTHRITIS EARLY? – A LARGE PROSPECTIVE STUDY

N. den Hollander[1], M. Verstappen[1], N. Sidhu[1], E. van Mulligen[2], M. Reijnierse[3], A. van der Helm-van Mil[1,2]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands*; *[3]Leiden University Medical Center, Radiology, Leiden, Netherlands*

Background: Identifying patients that will develop rheumatoid arthritis(RA) among those presenting with undifferentiated-arthritis(UA) remains a clinical dilemma. Although magnetic-resonance-imaging(MRI) is helpful according to EULAR-recommendations, this has only been determined in UA-patients not fulfilling 1987-RA-criteria, whilst part of these patients are currently considered as RA because they fulfill the 2010-criteria.
Objectives: We studied the predictive value of MRI for progression to RA in the current UA-population: i.e. not fulfilling RA-classification-criteria (neither 1987- or 2010-criteria), and not having an alternate diagnosis. Additionally, the value of MRI was studied in patients with a clinical diagnosis of UA, regardless of the classification-criteria.
Methods: Two UA-populations were studied: criteria-based-UA as described above(n=405) and expert-opinion-based-UA(n=564), i.e. UA indicated by treating rheumatologists. These patients were retrieved from a large cohort of consecutively included early arthritis patients that underwent contrast-enhanced MRI-scans of hand and foot at baseline. MRIs were scored for osteitis, synovitis and tenosynovitis. Patients were followed for RA-development during 1-year. Test-characteristics of MRI were determined separately for subgroups based on joint-involvement and autoantibody-status.
Results: Among criteria-based-UA-patients(n=405), 21% developed RA. MRI-detected synovitis and MRI-detected tenosynovitis were predictive. MRI-detected tenosynovitis was independently associated with RA-progression(OR 2.79; 95%CI 1.40-5.58), especially within ACPA-negative UA-patients(OR 2.91; 1.42-5.96). Prior risks of RA-development for UA-patients with mono-/oligo-/polyarthritis were 3%, 19%, 46%, respectively. MRI-results changed this risk most within the oligoarthritis-subgroup: PPV was 27% and NPV 93%. Similar results were found in expert-opinion-based-UA(n=564).
Conclusion: This large cohort-study showed that MRI is most valuable in ACPA-negative UA-patients with oligoarthritis; a negative MRI could aid in preventing overtreatment.

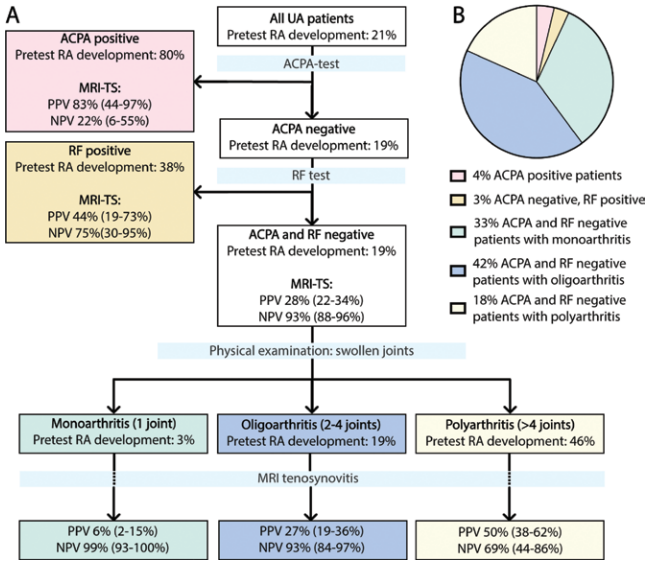

Figure 1. Flowchart for criteria-based UA-patients showing pre-test and post-test predictive-value for RA-development (A) and percentages of patients within these subgroups (B). 1A) Flowchart with NPV and PPV for MRI-detected tenosynovitis within the specified groups. Pretest-probability of developing RA is shown as a percentage of patients fulfilling 1987 and/or 2010 RA-criteria. 1B) A total of 404 patients were studied, 15 patients were ACPA-positive(4%), 13 patients were ACPA-negative and RF-positive(3%), 376 patients were ACPA- and RF-negative(93%), from which 133 patients had monoarthritis (1 swollen joint, 33%), 169 patients had oligoarthritis (2-4 swollen joints, 42%) and 74 patients had polyarthritis (more than 4 joints, 18%). 1 patient is missing in this analysis due to missing outcome for MRI-detected tenosynovitis, this patient belonged in the oligoarthritis group. *UA, Undifferentiated arthritis; RA, Rheumatoid Arthritis; ACPA, Anti-Citrullinated Peptide Antibodies (considered positive if ≥10U/mL); RF, Rheumatoid Factor (considered positive if ≥5.0IU/mL); MRI-TS, MRI detected tenosynovitis; NPV, negative predictive value; PPV, positive predictive value; Swollen joints, based on a 68-swollen joint count.*

Background: Sustained remission is the treatment goal for Rheumatoid Arthritis (RA) and once achieved patients are eligible to treatment tapering or discontinuation. However, this exposes patients to the occurrence of unpredictable disease flare, and to date there are no definitive predictive biomarkers of flare for RA in remission that could be used in clinical practice.

Objectives: To assess the impact of clinical classification of remission on synovial tissue (ST) features of RA in sustained remission and to identify predictive biomarkers of disease flare.

Methods: 200 RA in sustained clinical (102 RA with DAS<1.6 and 98 RA fulfilling Boolean remission criteria for at least 9 months, respectively) and ultrasound (US) remission (PD negative) under Methotrexate with or without biological-Disease Modifying Anti-Rheumatic Drugs (bDMARDs) were enrolled and underwent to US guided ST biopsy. 373 naive RA were included as comparison. For each patient, synovitis degree was determined using a H&E-based semiquantitative score[1]. Some ST samples of remission RA were used for synovial tissue macrophage (STMs)(CD206/MerTK) FACS phenotyping and digital spatial profiling (GeoMx DSP, Nanostring) to quantitate transcript abundance of $CD68^{pos}$ cells in 138 spatially distinct ST regions of interest (ROI). After study entry, RA were randomly assigned to tapering/discontinuation (TAP/DISC) (tapering c- or b-DMARD treatment for 6 months and discontinuing c- or bDMARD afterwards) or maintaining the same therapeutic scheme (CONT). Each RA was followed every 3 months to assess flare rate after treatment modifications for 24 months.

Results: Regardless of either DAS- or Boolean-defined, remission patients had significantly lower KSS than naive RA (p<0.0001 for both). However, ST of RA in Boolean remission had lower KSS (p<0.0001) and was enriched in $CD206^{pos}MerTK^{pos}$ STMs (p=0.0012) as compared to DAS-defined remission RA. 73(36.5%) RA experienced a disease flare regardless of the treatment change during 24 months follow-up. Stratifying RA in remission based on remission definition and treatment group, DAS-defined remission RA who had a disease flare within at least 6 months follow-up had, at study entry, significantly higher KSS (p<0.0001) than RA who maintained a sustained remission, regardless of the treatment change (CONT:p=0.0027 and TAP/DISC:p=0.0011). Logistic regression analysis revealed that baseline KSS≥3 [AUC:0.748(95%CI:0.649-0.846)p<0.0001] was an independent predictive factor of disease flare [OR:6.9(95%CI:2.82-16.81)] within 24 months follow-up in DAS-defined remission RA. Conversely, RA in Boolean remission did not differ for KSS at study entry in both the CONT (p>0.05) and the TAP/DISC (p>0.05) group in relation to disease flare. However, considering STMs phenotype, RA in Boolean remission in the TAP/DISC group who had low levels of $CD206^{pos}MerTK^{pos}$ (<38.1%), experienced more likely a disease flare compared to RA in the CONT subgroup with $CD206^{pos}MerTK^{pos}$≥38.1% (p=0.0014). Logistic regression analysis confirmed that, before treatment change, STMs phenotype ($CD206^{pos}MerTK^{pos}$ <38.1%) in RA in remission is an independent predictor of disease flare [OR:6.25(95%CI:1.33-29.43)] within 24 months. Finally, DSP analysis using CD68 morphology marker, revealed that lining and sublining layer $CD68^{pos}$ spatial transcriptomics distinguished, at baseline, remission RA who flared after treatment modification from those who did not.

Conclusion: Disease flare is a common event in RA in sustained remission after treatment modification. KSS and STMs phenotype identified by flow cytometry or by tissue spatial transcriptomic can identify RA in remission at higher risk of flare after treatment modification. Thus, spatial transcriptomic with defined panel of markers on histological biopsy tissues could be a way forward in predicting disease flare.

OP0085 CELL LINEAGE-SPECIFIC TRANSCRIPT DECONVOLUTION OF SYNOVIAL BIOPSIES FROM THE R4RA TRIAL IDENTIFIES CELL POPULATIONS ASSOCIATED WITH RESPONSE TO RITUXIMAB AND TOCILIZUMAB

F. Rivellese[1], C. Cubuk[1], A. Surace[1], K. Goldmann[1], E. Sciacca[1], G. Giorli[1], A. Nerviani[1], L. Fossati-Jimack[1], G. Thorborn[1], M. Bombardieri[1], M. Barnes[1], M. Lewis[1], C. Pitzalis[1], on behalf of R4RA Investigators. *[1]Queen Mary University of London, Centre for Experimental Medicine and Rheumatology, London, United Kingdom*

Background: The R4RA trial, the first biopsy-based randomised trial in TNF-i inadequate responder patients with Rheumatoid Arthritis, showed that molecular stratification of RA synovial tissue was associated with clinical response, demonstrating that, in patients with low/absent B-cell lineage signature in synovial-tissue, tocilizumab is superior to rituximab[1].

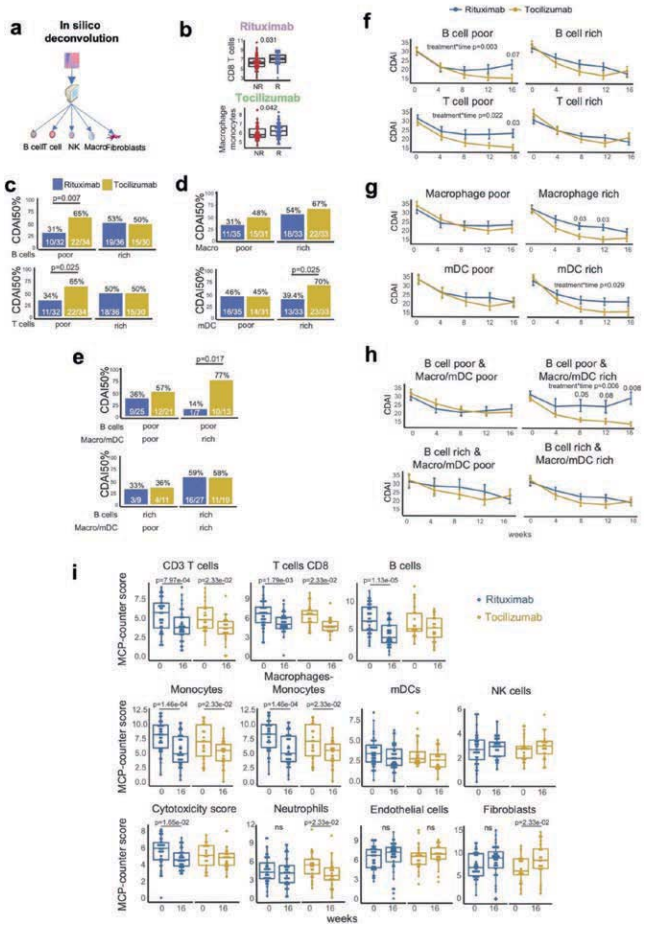
Objectives: Here, we aimed to perform cell-transcript deconvolution of pre-and post-treatment synovial biopsies from the R4RA trial.

Methods: A total of 164 patients underwent pre-treatment synovial biopsy (US-guided or arthroscopic) prior to randomization 1:1 to rituximab (83) or tocilizumab (81). 65 patients had a repeat biopsy at 16 weeks when clinical response was assessed using Clinical Disease Activity Index (CDAI) 50% improvement. RNA extracted from a minimum of 6 synovial samples/patient underwent RNA-sequencing and the abundance of tissue-infiltrating immune and stromal cell populations was estimated using the Microenvironment Cell Populations-counter (MCP-counter) method (Figure 1a).

Results: At baseline, while synovial semiquantitative immunohistochemistry scores did not differ between CDAI50% responders and non-responders,

both for rituximab and tocilizumab, MCP-counter analysis showed significantly higher CD8 T-cells in responders to rituximab and higher macrophage-monocytes and myeloid dendritic cells (mDC) in responders to tocilizumab (Figure 1b). Moreover, when patients were classified according to MCP-counter scores, B-cell poor patients (MCP-counter B cell score <median value) showed significantly higher response rates to tocilizumab, while no difference was found in B-cell rich patients (Figure 1c). In contrast, macrophage and myeloid dendritic cell (mDC) rich individuals showed higher responses to tocilizumab (Figure 1d). Combined scores for lymphoid and myeloid cells demonstrated that patients poor in B-cells but rich in macrophages/mDC had a significantly higher response to tocilizumab (77% responders to tocilizumab vs 14% responders to rituximab, p=0.017, OR 16.48, 95%CI 1.29-1000.5) (Figure 1e). By analysing disease activity over time from baseline to week 16, we found a statistically significant interaction effect between treatments and time in B-cell poor (p=0.003), T-cell poor (p=0.022), mDC rich (p=0.029) and B-cell poor/Macrophages-mDC rich patients (p=0.006) (Figure 1f-g-h). Finally, by applying MCP-counter on matched pre-and post-treatment biopsies, rituximab-treated patients showed a significant reduction of B-cells, T-cells and monocyte/macrophages, while tocilizumab-treated patients showed a significant reduction of monocyte/macrophages, T-cells, but also neutrophils, myeloid dendritic cells and, interestingly, an increase in fibroblast signature (Figure 1i).

Figure 1



Conclusion: In silico deconvolution of the synovial tissue identify pre-treatment lymphoid cell lineages associated with response to rituximab and myeloid cells for tocilizumab. The longitudinal analysis of matched pre- and post-treatment synovial biopsies indicated that both medications have an effect on synovial immune cells, but tocilizumab can also affect stromal cells.

OP0086 ANTIBODIES AGAINST ADVANCED GLYCATION END-PRODUCTS (ANTI-AGE) DISTINGUISH PATIENTS WITH A MORE INFLAMMATORY PROFILE AND WORSE OUTCOME IN SERONEGATIVE RHEUMATOID ARTHRITIS

T. J. van Wesemael[1], M. D. van den Beukel[2], A. T. W. Hoogslag[1], T. Huizinga[1], R. Toes[1], L. A. Trouw[2], D. van der Woude[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center (LUMC), IMMUNOHEMATOLOGY AND BLOOD TRANSFUSION, Leiden, Netherlands*

Background: In rheumatoid arthritis (RA) around two-thirds of patients are autoantibody-positive for rheumatoid factor, anti-citrullinated protein antibodies (ACPA) and/or anti-carbamylated protein antibodies (anti-CarP). The remaining seronegative subgroup of RA is clinically heterogeneous and thus far, biomarkers predicting the disease course in these patients are lacking. Therefore, we set out to investigate the value of a new/different autoantibody in rheumatoid arthritis directed against advanced glycation end-product (AGE) modified proteins (anti-AGE). AGEs are a marker of oxidative stress, and anti-AGE have been described in multiple diseases including diabetes, and hypertension.
Objectives: To investigate the prevalence of anti-AGE in RA and non-RA arthritis patients, as well as their association with clinical parameters and disease outcome in RA.
Methods: In 648 RA patients and 538 non-RA arthritis patients from the Leiden Early Arthritis Clinic anti-AGE IgG antibody levels were measured using an in-house fetal calf serum (FCS) ELISA based assay using native FCS as control. The cutoff for positivity was set as the mean optical density plus two times the standard deviation of 80 healthy controls. Radiological progression was measured with the with Sharp van der Heijde score (SHS) on yearly basis and the association with anti-AGE was assessed with a multivariate normal regression model.
Results: Anti-AGE was found in 299 (46%) of RA patients versus 163 (30%) of non-RA arthritis patients. Interestingly, 67 (34%) of completely seronegative (RF-, ACPA- and anti-CarP-negative) RA patients were positive for anti-AGE. Within RA, anti-AGE-positive patients had significantly higher ESR (median anti-AGE-positive: 38, anti-AGE-negative: 32, p<0.001) and CRP (median anti-AGE-positive: 19, anti-AGE-negative: 17, p<0.001), indicating an more inflammatory profile in these patients. Radiographic progression, was significantly higher in anti-AGE+ patients (Figure 1A, B=1.05, p<0.001). Since ACPA and anti-CarP (in ACPA-patients) are associated with radiological progression, the analysis was first stratified for ACPA-status. In the anti-AGE+ACPA- patients a significant association with SHS was found (Figure 1B: B=1.04, P<0.001), indicating that anti-AGE is associated with radiological progression in ACPA-negative patients. Next, the ACPA-negative stratum was also stratified for anti-CarP. Interestingly, SHS was significantly higher in all anti-AGE+ groups compared to the autoantibody-negative group.
Conclusion: Almost half of the RA patients are anti-AGE positive including a substantial part of otherwise completely seronegative RA patients. Anti-AGE antibodies are associated with inflammatory parameters and radiologic progression in seronegative RA patients. Therefore, although these autoantibodies are not specific for RA, anti-AGE could potentially identify patients with a more inflammatory phenotype and more severe disease outcome in "classic" autoantibody-negative RA patients.

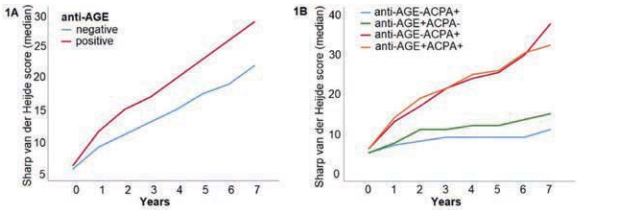

Figure 1. Erosion scores according to the presence of autoantibodies. Figure 1A: Median erosions scores assessed by Sharp van der Heijde method (SHS) during the disease course stratified for anti-advanced glycation end-products antibodies (anti-AGE). A significant difference was found between anti-AGE-negative patients and anti-AGE-positive patients (B=1.05, p<0.001). Figure 1B: Median erosions scores assessed by SHS during the disease course stratified for anti-AGE and anti-citrullinated protein antibodies (ACPA). SHS was significantly higher in all autoantibody-positive groups compared to the anti-AGE-ACPA- group.

OP0087 INTEGRATED SYSTEMS ANALYSIS OF THE GUT MICROBIOTA PHENOTYPES IN THE RHEUMATOID ARTHRITIS

J. Qiao[1,2,3], S. X. Zhang[1,2,3], M. J. Chang[2,3,4], S. Song[1,2,3], R. Zhao[1,2,3], T. Cheng[1,2,3], Y. Zhang[1,2,3], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical*

University, Department of Rheumatology, Taiyuan, China; [2]*Shanxi Medical University, Key laboratory of Cellular Physiology, Ministry of Education, Taiyuan, China*; [3]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; [4]*Shanxi Medical University, School of Management, Taiyuan, China*

Background: Patients with rheumatoid arthritis (RA) displays extreme dysbiosis in microbiota. However, such dysbiosis is difficult to characterize owing to the high dimensional complexity of the gut microbiota[1,2].
Objectives: The aim of this study was to discover the enterotype characters of intestinal flora in RA.
Methods: Fecal samples from 145 RA patients were collected for bacterial 16S rRNA genes sequencing. Mathematical modeling using Dirichlet multinomial mixtures (DMM) was applied to describe the variability in the microbiome data and cluster samples into enterotypes. The alpha-diversity, beta-diversity and the microbial composition analysis of the gut microbiome were used to define the difference of gut microbiota profiles between different enterotypes. The nonredundant taxonomic biomarkers for each enterotype were selected by using LEfSe. Inflammatory biomarkers (ESR, CRP), auto-antibodies(ACPA, MCV), peripheral lymphocytes subsets and cytokines were analyzed in our cohort using the Kruskal-Wallis test.
Results: Laplace approximation of DMM indicated two significantly distinct bacterial microbiota structures (RAE1 and RA E2) existed in the dataset (Figure 1a). Principal co-ordinates analyses confirmed that these two microbiota states explained a reasonable proportion of observed variance in microbiota composition(ANOSIM R2 = 0.267, p = 0.001; Figure 1b), with distinct bacterial genus distribution of in each enterotype (Figure 1c). RA E1 were primarily dominated by Prevotella while RA E2 by Bacteroides. Interestingly, Chao1, ACE, Shannon and Simpson revealed a higher alpha diversity in Prevotella-enriched enterotype (p< 0.001, Figure 1d). Fourteen selected taxonomic biomarkers at different phylogenetic levels showed great discriminant ability, with Log10 LDA score > 4.0 (Figure 1e-g). Further, inflammatory biomarkers (ESR, CRP) and auto-antibodies(ACPA, MCV) as well as the number of T, B and CD4+T, Th1, Th2, Th17, and Treg were consistent in RA E1 and RA E2 (p > 0.05, Figure 2h). But CD8+T were significantly higher in RA E2 than in RA E2 (p < 0.05).

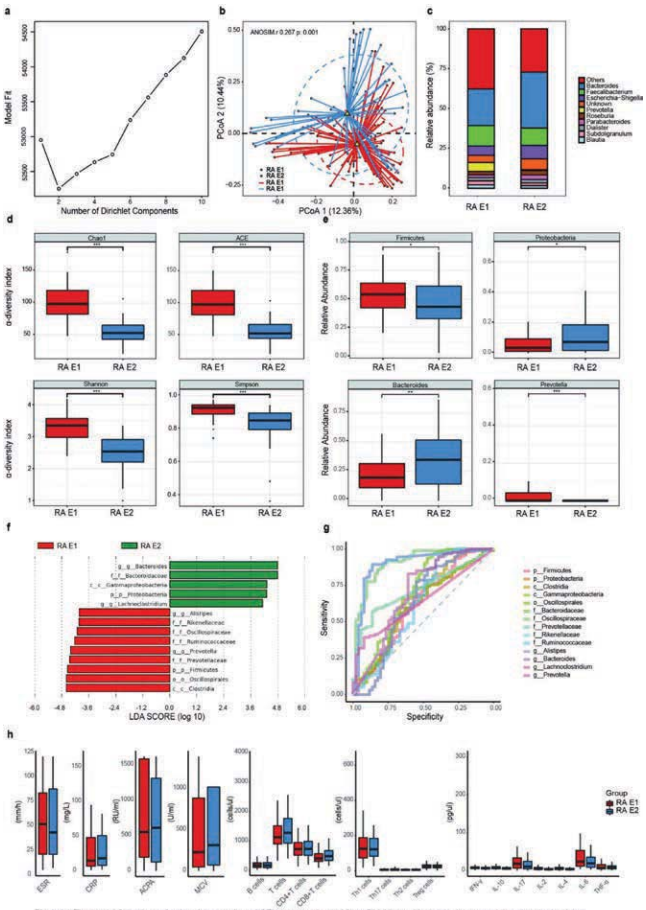

Fig 1. (a) The model fit is shown for the given number of OTU types estimated from Dirichlet multinomial mixture models using the Laplace approximation. **(b)** Principal component analysis (PCoA) plot generated from the Bray-Curtis distances. **(c)** Microbiota composition based on relative abundance at the genus levels. **(d)** Alpha-diversity assessed by richness (Chao1, ACE) and diversity (Shannon, Simpson). Median estimates compared across cohorts. **(e)** Relative abundance of Bacteroides, Prevotella for individuals within each of the two enterotypes. **(f)** Bacterial taxa differences between RA patients and HCs using LEfSe analysis. **(g)** ROC was performed for all samples using the 14 individual taxonomic biomarkers. **(h)** Alterations in inflammatory biomarkers (ESR, CRP), auto-antibodies (ACPA, MCV), peripheral lymphocytes subsets and cytokines of RA patients and HCs. Bars in a-d represent median values with interquartile ranges. Statistics were calculated using the Kruskal-Wallis test. *P < 0.05; **P < 0.01; ***P < 0.001.

Conclusion: Despite RA gut microbiota being of different dysbiosis, two patterns of dysbiosis, designated as RA-enterotypes, were predominant among the RA patient cohort. RA E2 exhibited a loss of Prevotella but a growth of Bacteroides, while RA E1 presented the opposite results.

OP0088 STRATIFIED MEDICINE: GENETIC PREDICTORS OF RADIOGRAPHIC OUTCOME IN RHEUMATOID ARTHRITIS

S. Sharma[1], N. Nair[1], J. Bowes[1], A. MacGregor[2,3], S. Verstappen[1,4], A. Barton[1,4], S. Viatte[1,5]. [1]*The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Centre for Musculoskeletal Research, Manchester, United Kingdom*; [2]*Norfolk & Norwich University Hospital, Rheumatology, Norwich, United Kingdom*; [3]*University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; [4]*Central Manchester NHS Foundation Trust, Manchester Academic Health Sciences Centre, NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester, United Kingdom*; [5]*The University of Manchester, Lydia Becker Institute of Immunology and Inflammation, Faculty of Biology, Medicine and Health, Manchester, United Kingdom*

Background: Rheumatoid arthritis (RA) displays great heterogeneity between patients for susceptibility to developing erosions. Genetic variations within the HLA-DRB1 gene (the shared epitope (SE) and polymorphisms coding for Valine at position 11) have been consistently associated with both susceptibility and radiographic outcome in RA.(1) However, associations of non-HLA markers are much less conclusive. Most studies looking outside the HLA have been candidate gene studies and very few have been replicated in independent cohorts.
Objectives:
1. Identify all single nucleotide polymorphisms (SNPs) outside the HLA that have ever been associated with radiographic outcome in RA
2. To perform a replication study to determine which of these are associated with radiographic outcome in the Norfolk Arthritis Register (NOAR), the worldwide largest prospective cohort with genetic and radiographic outcome data.

Methods: A systematic literature search was conducted as shown in the Figure 1.

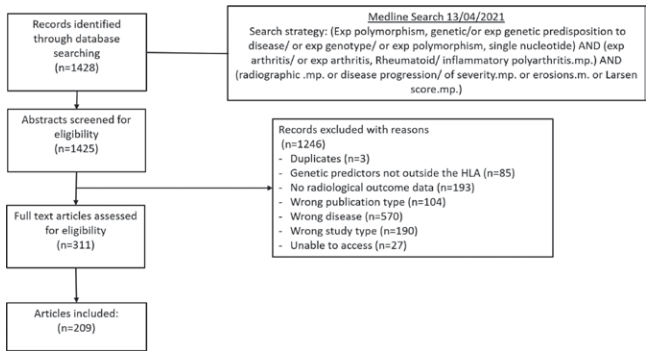

Figure 1. Flow chart for systematic review.

The Norfolk Arthritis register (NOAR) is a large primary care-based inception cohort of patients diagnosed with inflammatory polyarthritis. Patients were recruited at baseline from 1989 and followed up prospectively for up to 20 years with serial X-rays. Genome-wide genotyping was performed on the Illumina Human/Infinium Core Exome array and imputed with Minimac4 to the Haplotype Reference Consortium panel. Quality control resulted in 7.5 million SNPs available in each patient. SNPs identified from the literature were extracted and tested for an association with the presence of erosions (as a longitudinal binary

variable) using a generalized estimating equation (GEE) model in STATA/IC 14.0.in NOAR.

Results: A total of 2119 participants (2440 radiographs) were identified with both genetic and radiographic data available. 66.2% of these patients were female and 33.3% were anti-CCP positive. Median age of onset was 54.5 and 74.9% satisfied the American College of Rheumatology (ACR) 1987 criteria for rheumatoid arthritis.

A total of 113 different non-HLA SNPs associated with radiographic outcome in RA were identified from the literature. Of these, 102 were successfully identified within NOAR and 91 were deemed to be independent SNPs based on R^2 of 0.6. 14 SNPs were found to be significantly associated with the presence of erosions within NOAR (Table 1).

Table 1. SNPs found to be associated with radiographic severity within NOAR. *Significant results only; Dominant models used (Odds ratios displayed in relation to minor alleles)

Gene	Chromosome	SNP (single nucleotide polymorphism	Odds ratio (95% CI)	P value
IL2RB	2	rs743777	1.23 (1.01, 1.05)	0.0398
IL15	4	rs6821171	0.82 (0.67, 1.00)	0.0451
IL4	5	rs2243250	1.36 (1.08, 1.70)	0.0094
FOX03	6	rs12212067	0.75 (0.58, 0.97)	0.0278
OPG	8	rs2073618	0.79 (0.64, 0.98)	0.0295
TRAF1	9	rs10760130	1.33 (1.06, 1.65)	0.0118
TRAF1	9	rs10818488	1.32 (1.06, 1.64)	0.0141
TRAF1	9	rs2900180	1.32 (1.07, 1.61)	0.0079
IL4r	16	rs1805010	1.25 (1.01, 1.56)	0.0393
IL4r	16	rs1805011	1.31 (1.03, 1.66)	0.0260
LGALS9	17	rs3763959	1.28 (1.03, 1.59)	0.0260
SOST	17	rs4792909	1.34 (1.09, 1.65)	0.0052
LILRA3	19	rs103294	0.80 (0.65, 0.98)	0.0334
MMP9	20	rs11908352	0.70 (0.57, 0.85)	0.0005

Conclusion: 113 non-HLA SNPs have been previously reported to be associated with radiographic outcome in RA. Of these, only ~15% also showed an association in NOAR, the largest cohort with genetic and radiographic outcome data worldwide. Interestingly, rs2243250, a SNP located on chromosome 5 (IL4), previously found to be associated in a small Egyptian cohort, has been replicated in NOAR.(2) Current work consists of assessing the added clinical value of a genetic risk score based on HLA and non-HLA markers in predicting radiographic outcome when combined with clinical/serological/demographic markers.

Background: Rheumatoid arthritis (RA) is characterized by chronic inflammatory synovitis and progressive disability. Nowadays the natural history and the prognosis of the disease has deeply changed thanks to the availability of conventional and targeted disease modifying anti-rheumatic drugs (DMARDs). Nevertheless, clinical response to treatment is highly variable and a considerable proportion of patients do not - or only partially - respond to the treatment. The stratification of patients through the identification of biological predictors of good clinical response to treatment could allow the selection of the best therapeutic strategy for each patient. Recently, precision medicine in rheumatology could rely on the development of new transcriptomics techniques, such as RNA sequencing (RNAseq), that permit to explore complex cellular and molecular networks associated with pathophysiological aspects.

Objectives: To characterize the transcriptomic profiles (RNAseq) of whole-blood samples of moderate to severe RA patients to predict the clinical response to tofacitinib.

Methods: We selected patients with active RA, candidate to receive tofacitinib after failure of a previous therapy with conventional or biologic DMARDs. RNAseq profiling on whole-blood samples (PAX gene tubes) was performed at baseline and after 24 weeks of treatment with tofacitinib. Treatment response was evaluated at week 24 by CDAI EULAR response criteria as drug responder (major or moderate response) or non-responder (minor or no response). Differential expression of gene ontology (GO) biological processes (BP) pathways was analyzed to identify the response-associated pathways. Machine learning models were built by different data mining algorithm to predict response to tofacitinib.

Results: The study population included 33 patients, of whom 7 discontinued prematurely the treatment (5 because of adverse events and 2 because of inefficacy) and 2 were lost to follow-up. At week 24, 10 patients (38.5%) had major, 4 (15.4%) moderate, 6 (23.1%) minor, and 6 (23.1%) no clinical response to tofacitinib. No significant difference was observed between responders and non-responders in terms of baseline characteristics (age, sex, rheumatoid factor and anti–cyclic citrullinated peptide [ACPA] positivity, DMARDs and prednisone exposure, Table 1). Overall, 307 out of 2137 coding transcripts and 85 GO BP pathways were differentially expressed after treatment in responders vs non-responders (Figure 1). In detail, an up-regulation of JAK-dependent pathways, including cation transport, metabolism of membrane lipids, calcium-mediated signaling, and osteoblast proliferation was observed in responders. Conversely, in non-responders, processes related to B cell activation, proliferation, and signaling along with mRNA epigenetic modifications were increased. After extensive internal validation (50 runs of 80:20 hold-out sampling) with univariate selection of GO terms, the accuracy of Support vector Machine (SVM) learning models to predict the correct clinical response was equal to 88.3% (AUROC = 0.940).

Table 1. Demographic and baseline clinical characteristics of the study population*

	Non responders(n = 12)	Responders(n = 14)
Female, n (%)	11 (91.7%)	11 (78.6%)
Age, years (±SD)	52.6±11.2	54.3±10.5
Rheumatoid factor, n (%)	7 (58.3%)	7 (50%)
ACPA, n (%)	9 (75%)	8 (57.1%)
Concomitant csDMARDs, n (%)	5 (41.7%)	8 (57.1%)
bsDMARDs naïve, n (%)	12 (100%)	11 (78.6%)
Prednisone ≥ 5mg/day, n (%)	4 (33.3%)	6 (42.8%)

* There were no significant differences, determined by Fisher's exact test for categorical variables

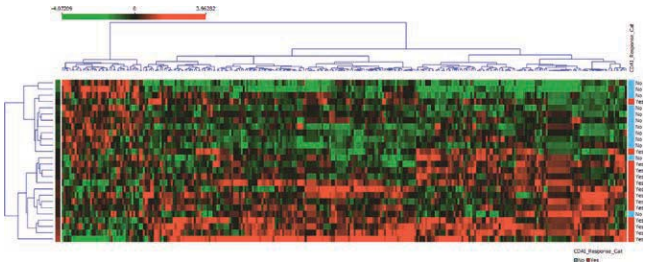

Figure 1. Heatmap representation of selected GO BP pathways in responders/non-responders.

Conclusion: Machine learning models based on transcriptomic functional pathways can accurately predict response to tofacitinib. Our study could contribute to improve the treatment customization and the optimization of RA treatment strategy toward a personalized approach. Furthermore, these findings may help to understand the mechanisms underlying the clinical response to JAK inhibitors.

The Yin and Yang of scleroderma and vasculitis

OP0090 **PRECLINICAL STUDIES OF A NOVEL CATHEPSIN C INHIBITOR IN MPO-ANCA-ASSOCIATED VASCULITIS MODEL**

A. Ishizu[1], M. Taniguchi[2], S. Arai[2], Y. Nishibata[2], S. Masuda[2], U. Tomaru[3], T. Shimizu[4], W. Sinko[4], T. Nagakura[4], Y. Terada[4]. *[1]Hokkaido University, Faculty of Health Sciences, Department of Medical Laboratory Science, Sapporo, Japan*; *[1]Hokkaido University, Faculty of Health Sciences, Department of Medical Laboratory Science, Sapporo, Japan*; *[3]Hokkaido University, Faculty of Medicine and Graduate School of Medicine, Department of Pathology, Sapporo, Japan*; *[4]Modulus Discovery, Inc., Research & Development, Tokyo, Japan*

Background: MPO-ANCA-associated vasculitis (MPO-AAV) is a systemic small vessel vasculitis with the production of MPO-ANCA in the serum. This disease develops necrotizing and crescent glomerulonephritis (NCGN) and peritubular capillaritis-mediated interstitial damages in the kidneys, and pulmonary hemorrhage due to capillaritis in the lungs. Recent studies have revealed that neutrophil extracellular traps (NETs) induced by MPO-ANCA are critically involved in its pathogenesis,[1] and neutrophil elastase (NE) plays an essential role in the formation of NETs.[2] Cathepsin C (CatC) functions as a key enzyme in the activation process of several neutrophil serine proteases (NSPs) such as NE, proteinase 3 and cathepthin G by converting the inactive forms of the NSPs to the active forms by digesting dipeptides at the N-terminus of the enzymes.[3]

Objectives: Although glucocorticoids and immunosuppressive drugs used as the standard of cares can lead remission in MPO-AAV patients, there are remaining unmet medical needs such as severe side effects, resistance to the treatment and relapse. Therefore, development of new therapeutic strategies is awaited. The aim of this study is to demonstrate the efficacy of MOD06051, a novel CatC inhibitor, against MPO-AAV, using an MPO-AAV rat model established previously.[4]

Methods: In vitro studies: Cathpsins and NE inhibitory activity was measured using recombinant enzymes and fluorescent substrates. Cellular NE activity in the granulocytes differentiated from the primary human bone marrow-derived hematopietic stem cells under the presence or absence of MOD06051 was determined using fluorescent substrates.

In vivo studies: 4-week-old Wistar Kyoto (WKY) rats were immunized with human MPO according to Little's protocol.[4] The rats were divided into three groups (n=8 in each group), and vehicle (0.5% methylcellulose) or MOD06051 (0.3 or 3 mg/kg bid) was orally administered every day for 42 days. All rats were euthanized at the end of the study for serological and histological evaluations.

Results: In vitro studies: MOD06051 inhibited the enzymatic activity of human recombinant CatC with an IC50 value of 1.5 nM, and no other cathepsins nor NE inhibition was observed at 10 μM. The NE activity in primary human granulocytes was suppressed by MOD06051 with an IC50 value of 18 nM.

In vivo studies: MPO-ANCA was induced in all groups at the same level. The percentage of affected glomeruli including those with NCGN, NET-forming neutrophils in the peripheral blood and glomeruli, and glomerular neutrophil counts were significantly suppressed by MOD06051 treatment in a dose-dependent manner. Furthermore, hematuria score, urinary NGAL (Neutrophil Gelatinase-Associated Lipocalin), tubular erythrocyte cast counts, and pulmonary hemorrhage foci were significantly decreased in the 3 mg/kg of MOD06051 treated group with the similar trends in 0.3 mg/kg group.

Conclusion: MOD06051 showed sepcific inhibition of CatC activity. This compound suppressed the serine proteases activation in primary human neutrophils and NET formation in the MPO-AAV model rats, resulting in amelioration of MPO-ANCA-induced tissue destruction, including NCGN and tubular interstitial damages in the kidneys, and disorder of alveolar septal capillaries in the lungs. MOD06051 appears to be a promising agent for treatment of MPO-AAV patients.

EXPANSION OF MYELOPEROXIDASE (MPO)-SPECIFIC IGM B CELLS IN ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA)-ASSOCIATED VASCULITIS

C. Wortel[1], R. van de Wetering[1], H. van Dooren[1], E. M. Stork[1], A. M. Bakker[1], A. S. Brehler[1], T. Kissel[1], S. Reijm[1], G. Stoeken-Rijsbergen[1], K. van Schie[1], A. Rutgers[2], L. A. Trouw[3], T. Huizinga[1], Y. K. O. Teng[4], C. van Kooten[4], P. Heeringa[2], R. Toes[1], H. U. Scherer[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [3]Leiden University Medical Center, Immunology, Leiden, Netherlands*; *[4]Leiden University Medical Center, Nephrology, Leiden, Netherlands*

Background: ANCA-associated vasculitides (AAV) are characterized by recurrent, chronic small vessel inflammation and deleterious organ damage. The main targets of ANCA are myeloperoxidase (MPO) and proteinase 3 (PR3). ANCA, B cells and the complement system are crucial to AAV pathogenesis, as evidenced by the clinical benefit of B cell depletion with rituximab and, more recently, the C5a receptor antagonist avacopan. While ANCA in serum have been studied extensively, phenotypic and functional characteristics of the underlying B cell responses remain largely unknown.

Objectives: To develop a flow cytometry-based technique for identifying MPO-specific B cells in the circulation of MPO-positive AAV patients in order to characterize this B cell response and its potential contribution to disease pathogenesis.

Methods: Human neutrophil-derived MPO was conjugated to two different fluorochromes and used to identify MPO-specific B cells by flow cytometry. An antigen-specific staining protocol was developed and validated using MPO- and PR3-specific hybridoma cells. MPO-specific B cells were phenotypically characterized and isolated from the peripheral blood of AAV patients by fluorescence activated cell sorting (FACS) and cultured as single cells. MPO-specificity was confirmed by ELISA on culture supernatants. B cell receptor (BCR) sequences were obtained from MPO-positive clones by full length ARTISAN-PCR and Sanger sequencing. MPO-specific IgG and IgM monoclonal antibodies (mAb) were produced to validate specificity and to examine their ability to activate complement. Finally, MPO-positive AAV patient plasma and plasma depleted of IgG or IgM was tested in in vitro complement assays.

Results: The newly developed, differential antigen labelling approach successfully identified MPO-specific but not PR3-specific hybridoma cells. Subsequently, we detected MPO-specific B cells in the circulation of MPO-positive AAV patients at a frequency of up to 1:1000 B cells. FACS sorting and single cell culture yielded an enrichment of MPO-specificity of ~80%. Notably, the majority of isolated, MPO-specific B cells (60-95%) displayed an IgM memory phenotype, which corresponded to the presence of anti-MPO IgM in plasma. The remainder of the MPO-specific cells were mainly IgG memory B cells and few naive cells. BCR sequencing revealed a polyclonal IgM response with diverse V-gene usage, consisting of both germline and highly mutated clones. Generation of mAb (n=5) confirmed MPO specificity by inhibition ELISA for both germline and somatically mutated clones. Interestingly, anti-MPO IgM mAb showed a high capacity for complement factor deposition upon MPO binding. MPO-specific complement assays with IgG- and IgM-depleted patient plasma showed that anti-MPO IgM activated complement much more efficiently than anti-MPO IgG.

Conclusion: We demonstrate the direct ex-vivo identification, isolation and characterization of MPO-specific B cells in human AAV. Intriguingly, we observed a remarkable expansion of MPO-specific, IgM-expressing memory B cells in patients. This so far unrecognized, active IgM-compartment may be clinically relevant, as both mAb and plasma-derived polyclonal MPO-specific IgM strongly activated complement, a pathway thought to play a central role in AAV. Next to these novel insights into autoreactive B cell biology in AAV, our findings now provide new opportunities for studying auto-reactive B cell responses in different clinical phases of AAV, amongst which active disease, remission and (imminent) flares.

OP0092

DECIPHERING THE SYNOVIAL TISSUE AND FIBROBLAST SUBSETS IN SYSTEMIC SCLEROSIS

M. Houtman[1], R. Micheroli[1], K. Bürki[1], C. Pauli[2], S. G. Edalat[1], M. Frank Bertoncelj[1], O. Distler[1], C. Ospelt[1], M. Elhai[1]. *[1]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*; *[2]University Hospital Zurich, University of Zurich, Department of Pathology, Zurich, Switzerland*

Background: Articular involvement is underestimated in systemic sclerosis (SSc), but represents a major cause of disability and is a marker of disease severity. There is no approved effective therapy for arthritis in SSc and immunosuppressive treatments are given to SSc patients by analogy with rheumatoid arthritis (RA), but with limited effect. The last few years have revolutionized the understanding of the pathogenesis of RA by deciphering the heterogeneity of synovium at both the cellular and molecular levels. Nevertheless, the pathogenesis of joint involvement in SSc remains largely unknown.

Objectives: To characterize the synovium in SSc at tissue and cellular levels and to compare it with RA synovium.

Methods: Nine consecutive patients fulfilling SSc classification criteria and having joint synovitis were included. Patients with overlap with other autoimmune rheumatic diseases were excluded. Synovial tissues (8 wrists, 1 knee) were obtained by ultrasound-guided biopsy and were compared to those obtained from five RF and CCP positive RA patients (3 wrists, 3 knees). Tolerance of the procedure was assessed after 3-5 days. Histological analysis of the synovium determined the Krenn synovitis score (0-9) and stratified the synovial tissue according to previously published histological features1. One biopsy, without synovial tissue, was not processed further. ScRNA-seq libraries were prepared with 10X Genomics technology and sequenced on NovaSeq 6000. Integrated bioinformatics analysis used Cell Ranger and Seurat software. Overexpressed genes were selected using log2 ratio (>0.25) and false discovery rate adjusted p value (< 0.05). For pathway enrichment analysis, Enrichr software was used.

Results: Of the nine SSc-patients, 6 were women, median age was 65 [IQR: 58-67] years, median disease duration was 2 [0.5-5] years and 2 had diffuse cutaneous subtype. The antibody status was as follows: anti-Scl70 (2), anti-centromere (2), anti-RNA polymerase III (3), anti-Ku (1) and isolated ANA (1). In the RA cohort, 4/5 were women, median age was 56 [54-59] years and median disease duration 6.5 [5-7.5] years. Synovial biopsy was well-tolerated by all the patients. Krenn synovitis score was lower in SSc as compared to RA across the three components of the synovitis score (lining layer, stroma and inflammatory infiltrate). In SSc, 7/8 (87.5%) biopsies were characterized by a pauci-immune pathotype, whereas in RA 3/6 (50%) were pauci-immune. Due to the low inflammatory pauci-immune pathotype in all but one SSc patients, we focused the scRNA sequencing analysis on synovial fibroblasts (SF) (number of SF studied: 4876 in SSc and 5885 in RA). We identified four clusters of SF with respective marker genes: SF1 (CXCL12, APOE, RARRES2, CCL2), SF2 (PRG4, MMP1, MMP3, CD55), SF3 (POSTN, ASPN, COMP, COL1A1) and SF4 (FN1, TIMP1, SERPIN2, PRELP). Comparison between SSc and RA SF subtypes showed differences in the proportion of the clusters between both diseases with higher enrichment of SF2 corresponding to the lining SF in SSc. 741 genes were differentially expressed between SSc and RA SF with 414 genes overexpressed in SSc SF. Pathway enrichment analysis of these 414 genes identified TGF-β (p.adj: 3.708e-18) and interferon (p.adj: 1.071e-8) signaling pathways. TGF-β signaling was enriched across all the clusters of SF, whereas interferon signaling mostly in sublining SF. The most overexpressed genes in SSc included PLCG2 (encoding the signaling enzyme PLCγ2, which plays a regulatory role in various immune pathways), PCOLCE2 (encoding a procollagen C-endopeptidase enhancer) and the transcription factor AHR (negative regulator of TGF-β).

Conclusion: Synovitis in SSc differs from RA synovitis both at histological and molecular levels. By highlighting the low inflammatory nature of the synovium and the enrichment in TGF-β and interferon signaling pathways in SSc SF, our study questions the use of the same immunosuppressive therapies in RA and SSc. These results are the basis for the development of specific targeted therapies for arthritis in SSc.

OP0093

INCREASED RISK OF SEVERE INFECTIONS AND MORTALITY IN PATIENTS WITH NEWLY DIAGNOSED ANTINEUTROPHIL CYTOPLASMIC ANTIBODY ASSOCIATED VASCULITIS: A POPULATION-BASED STUDY

K. Zhao[1], H. Xie[1], N. Dehghan[2], J. Esdaile[3], J. A. Aviña-Zubieta[3]. *[1]Arthritis Research Canada, Biostatistics, Vancouver, Canada; [2]Mary Pack Arthritis Program - Vancouver Arthritis Clinic, Clinic, Vancouver, Canada; [3]Arthritis Research Canada, Clinic, Vancouver, Canada*

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAVs) are a group of multisystem inflammatory diseases of the small blood vessels, characterized by leukocytoclastic inflammation of small blood vessels and triggered by production of ANCA autoantibodies [1]. Due to the multiorgan involvement and relapsing nature, AAV is among the systemic autoimmune rheumatic diseases with the highest morbidity and mortality [1, 2].
Objectives: To evaluate the risk of severe infection and infection-related mortality among patients with newly diagnosed AAV.
Methods: We conducted an age- and gender- matched cohort study of all patients with incident AAV between January 1, 1997 and March 31, 2015 using administrative health data from British Columbia, Canada. Primary outcome was the first severe infection after AAV onset necessitating hospitalization or occurring during hospitalization. Secondary outcomes were total number of severe infections and infection-related mortality.
Results: We identified 549 AAV patients and matched them with 5,490 non-AAV individuals from the general population, yielding 184 and 509 first severe infections during 2,539 and 33,342 person-years follow-up, respectively. The crude incidence rate ratios for first severe infection and infection-related mortality were 5.03 (95% CI, 4.25-5.96) and 3.72 (95% CI, 2.44-5.67), respectively. The corresponding adjusted hazard ratios were 3.77 (95% CI 2.94-4.85) and 3.84 (95% CI, 2.13-6.91). AAV patients had an increased risk of a greater total number of severe infections with crude rate ratio of 4.99 (95% CI, 4.42-5.62) and adjusted rate ratio of 3.20 (95% CI, 2.73-3.74).
Conclusion: AAV is independently associated with increased risks of first severe infection (3.8-fold), a greater total number of severe infections (3.2-fold) and infection-related mortality (3.8-fold).

IDENTIFICATION OF NEW AUTOANTIGENS IN PATIENTS WITH SYSTEMIC SCLEROSIS THROUGH IMMUNOPRECIPITATION COMBINED WITH LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY

J. B. Vulsteke[1,2], D. Blockmans[3,4], P. De Haes[5,6], S. Vanderschueren[3,4], P. Verschueren[1,2], K. G. Claeys[7,8], W. Wuyts[9,10], J. L. Lenaerts[2], E. De Langhe[1,2], X. Bossuyt[11,12]. *[1]KU Leuven, Development and Regeneration, Skeletal Biology and Engineering Research Center, Leuven, Belgium*; *[2]University Hospitals Leuven, Rheumatology, Leuven, Belgium*; *[3]KU Leuven, Microbiology, Immunology and Transplantation; Laboratory for Clinical Infectious and Inflammatory Disorders, Leuven, Belgium; [4]University Hospitals Leuven, General Internal Medicine, Leuven, Belgium*; *[5]KU Leuven, Microbiology, Immunology and Transplantation, Leuven, Belgium*; *[6]University Hospitals Leuven, Dermatology, Leuven, Belgium; [7]KU Leuven, Neurosciences, Laboratory for Muscle Diseases and Neuropathies, Leuven, Belgium*; *[8]University Hospitals Leuven, Neurology, Leuven, Belgium*; *[9]KU Leuven, Chronic Diseases and Metabolism, Laboratory of Respiratory Diseases and Thoracic Surgery, Leuven, Belgium*; *[10]University Hospitals Leuven, Respiratory Diseases, Leuven, Belgium; [11]KU Leuven, Microbiology, Immunology and Transplantation*; *Clinical and Diagnostic Immunology, Leuven, Belgium; [12]University Hospitals Leuven, Laboratory Medicine, Leuven, Belgium*

Background: In up to 20% of patients with systemic sclerosis (SSc) none of the established SSc-specific autoantibodies are present [1]. Notwithstanding, in many of these patients high-titer autoantibodies can be detected on the HEp-2 indirect immunofluorescence assay (HEp-2 IIFA) which suggests the presence of an autoantibody to an intracellular protein expressed by the HEp-2 cell line. Immunoprecipitation of unlabeled cell extract followed by gel-free liquid chromatography tandem mass-spectrometry analysis has the potential to identify new autoantigens in an unbiased manner.
Objectives: To identify new autoantigens through immunoprecipitation combined with liquid chromatography-tandem mass spectrometry (IP + LC-MS/MS) in HEp-2 IIFA-positive patients with SSc in whom none of the established SSc-specific autoantibody specificities are present.
Methods: Forty-nine patients from the University Hospitals Leuven that fulfilled the EULAR-ACR 2013 classification criteria for systemic sclerosis or LeRoy and Medsger's criteria for early systemic sclerosis and who were negative on the EliA CTD Screen (Thermo Fisher Scientific, United States), which includes centromere protein B, topoisomerase I, RNA polymerase III, fibrillarin, PM-Scl and U1 ribonucleoprotein, were identified. Immunoprecipitation was performed by incubation of sera of these patients (1/30 in 300 µl Tris-buffered saline) with Pierce A/G magnetic beads, subsequent cross-linking with bissulfosuccinimidyl suberate (BS3) followed by incubation with nuclear extract of HeLa cells (100-150 µg) overnight at 4°C. The eluted protein was analyzed through liquid chromatography with tandem mass spectrometry. Mass spectrometry data were matched against the Uniprot Homo Sapiens database with the Mascot search engine. Candidate autoantigens were confirmed through immunoprecipitation followed by western blot of the eluate with target-specific polyclonal rabbit antibodies or western blot of recombinant protein incubated with sera of the index patients.
Results: We identified multiple new autoantigens, including the THO complex subunit 1 (THOC1) and other subunits of the THO complex in 3 patients, nuclear valosin-containing protein like-2 (NVL) in 2 patients, nucleolar and coiled-body phosphoprotein 1 (NOLC1) and multiple interacting proteins in 1 patient, probable 28S rRNA (cytosine(4447)-C(5))-methyltransferase (NOP2) in 1 patient, telomeric repeat-binding factor 2 (TERF2) and TERF2-interacting protein (TERF2IP) in 1 patient and regulator of chromosome condensation 1 (RCC1) in 1 patient. The new targets were confirmed through immunoprecipitation-western blot or western blot of recombinant protein incubated with sera (Figure 1). Furthermore, in 10 patients known SSc-associated autoantigens were strongly immunoprecipitated including multiple Th/To subunits in 5 patients, RuvBL1/2 in 2 patients, multiple PM-Scl subunits in 2 patients (who both were negative on the EliA CTD Screen), and fibrillarin in 1 patient (who was also negative on the EliA CTD .).

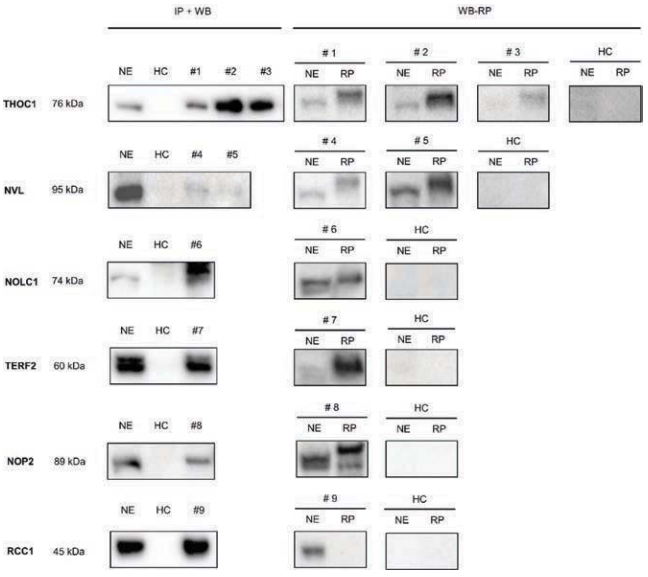

Figure 1.

Immunoprecipitation-western blot with target-specific rabbit polyclonal antibody (1/500-2000 dilution), numbers corresponding to order of description of patients, HC healthy control. NE nuclear extract. RP recombinant protein WB-RP western blot of recombinant protein incubated with patient's sera.

Conclusion: Multiple new autoantigens were identified and confirmed in patients with SSc without previously identified autoantibody specificity. Further evaluation of reactivity against the newly identified autoantigens in patients with SSc with known autoantibody specificities and other cohorts is required. IP + LC-MS/MS can identify new and established autoantigens in patients with SSc.

Background: Activated fibroblasts are the main drivers of skin fibrosis in SSc. We have recently identified dimethyl alpha-ketoglutarate (dm-aKG) as a potential repressor of myofibroblast differentiation and profibrotic activity in cultured skin fibroblasts.

Objectives: To further analyse the clinical translation of our findings by investigating the antifibrotic capacity of dm-aKG on explanted skin biopsies from SSc patients.

Methods: We cultured forearm punch skin biopsies from SSc patients (n=10) for 24h *ex vivo* in the presence/absence of 6 mM dm-aKG. Thereafter, skin biopsies (n=4) were dissociated into single cells using a combined mechanical-enzymatic dissociation protocol, followed by single cell (sc)RNA-seq library preparation (10x Genomics) and sequencing (Illumina, NovaSeq6000, 50,000 reads/cell). We mapped the scRNA-seq reads to the reference genome GRCh38.p13 and analysed the data with R/Bioconductor tools. We deconvoluted cell types in bulk skin transcriptomes from SSc cohorts (GSE: 45485, 59785, 9285, 32413) using human skin scRNA-seq data[1]. The secretion of IL-6, procollagen-1, PRO-C1 (N-terminal type I collagen pro-peptide), C1M (MMP-degradation fragment of type I collagen), and fibronectin (FBN-C) from cultured skin (n=10) was measured in supernatants by ELISA. We analysed gene and protein expression in TGFβ-activated healthy and SSc dermal fibroblasts (DF, n=10) treated or not with dm-aKG using qPCR, Western blot and ELISA. Contractile properties of DF were assessed by gel contraction assay. Traction forces generated by DF were determined by reference-free traction force microscopy.

Results: Dissociated cultured SSc skin exhibited comparable cell yield and viability in the presence (20,203; 89%) and absence (25,280; 93%) of dm-aKG, respectively. scRNA-seq skin analysis included 20,869 high quality single cell profiles segregating into 10 distinct skin cell populations (Figure 1A). This analysis demonstrated decreased proportion of fibroblasts and increased proportion of keratinocytes in dm-aKG treated skin (p<0.05; Figure 1B). Among skin cell types, skin fibroblasts exhibited the largest amount of differentially expressed genes upon dm-aKG treatment (44%, n=779, x-fold>0.5, FDR<0.05), suggesting that these cells are key targets of dm-aKG therapy in SSc skin. We identified inflammatory/cytokine signalling (hub genes *IL6, STAT1*) and extracellular matrix (ECM) organization (hub genes *MMP1, ITGB3*) as top downregulated biological processes in fibroblasts in dm-aKG treated SSc skin (Figure 1C), coinciding with a decreased abundance of proinflammatory skin fibroblast subpopulation. Specifically, these cells were identified as the main source of *IL6* (Figure 1D) and were enriched in SSc skin as revealed by deconvolution analysis of skin transcriptomes. Furthermore, dm-aKG reduced the secretion of IL-6, procollagen-1 and C1M, but not pro-C1 and FBN-C, from cultured skin explants. In cultured DF, dm-aKG blocked the inflammatory (IL-6, pSTAT3), profibrotic (aSMA, Fibronectin, Procollagen-1, Pro-C1) and contractile activities, and significantly diminished traction forces exerted by DF on the matrix substrate.

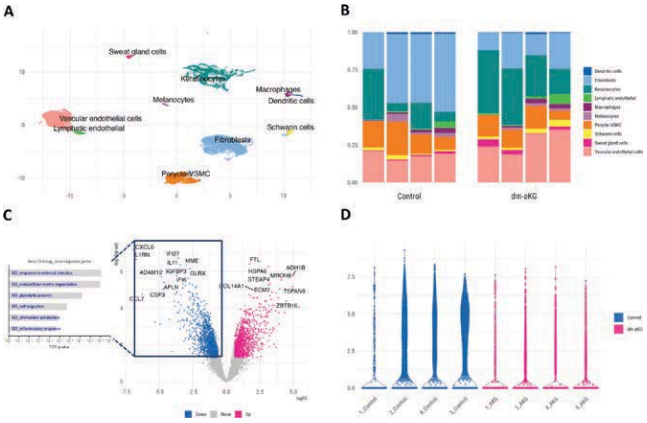

Figure 1. scRNA-seq – comparison of untreated and dm-aKG treated paired skin biopsies. (A) UMAP plot with annotated skin cells, (B) differential abundance of main skin cell types, (C) volcano plot of DE genes with top downregulated gene ontology (GO) pathways in dm-aKG treated skin fibroblasts, (D) *IL6* expression in untreated (blue) and treated (pink) skin fibroblasts.

Conclusion: Dm-aKG broadly interferes with inflammatory and ECM organizational activities of skin fibroblasts in culture and in explanted skin from SSc patients. These results confirm that dm-aKG might represent a potential new therapeutic approach for efficient targeting of skin inflammation and fibrosis in SSc.

de Lille, CHU Lille, Institut d'Immunologie, F-59000 Lille, France, Lille, France; [5]Université de lille, Institut Universitaire de France (IUF), Lille, France

Background: Autoantibodies (Aab) are frequent in systemic sclerosis (SSc) [1]. Recently, it has been showed that immunoglobulins G (IgG) from SSc promoted proinflammatory and profibrotic phenotype in monocyte secretome [2]. Fibroblasts (FB) are key effectors cells in SSc and data on FB proteins secretion in the presence of IgG from SSc patients are lacking. While recognized as potent biomarkers, the pathogenic role of Aab is much more debated.
Objectives: To explore the FB secretome in the presence of purified IgG from SSc patients
Methods: Normal dermal FB were cultured in the presence of purified IgG from patients with diffuse cutaneous SSc (dcSSc), limited cutaneous SSc (lcSSc) or healthy controls (HC). After 72 h of culture, the cell supernatants were collected, centrifuged and passed through a filter to remove the cells. After proteins digestion, secretome was explored using mass spectrometry coupled with liquid chromatography (LC-MS/MS). Analysis of variance (ANOVA) and hierarchical clustering were used to identify proteins responses patterns.
Results: Proteomic identified and quantified 1268 proteins, among them 377 were significant after ANOVA. SSc and HC secretome appeared distinct. Hierarchical clustering on significant proteins after ANOVA showed 3 distinct groups of patients secretome: a first group including mostly dcSSc anti-topoisomerase-I (ATA) positive (dcSSc ATA+) patients, a second group including mostly dcSSc ATA negative (dcSSc ATA-) patients, a third group more heterogeneous including the majority of HC, lcSSc anti-centromere positive (lcSSc ACA+) patients and dcSSc ATA- patients (Figure 1.**A**). The comparison of FB secretome in the presence of purified IgG from dcSSc ATA+ vs IgG HC revealed 203 differentially expressed proteins (DEP) (Figure 1.**B**). The enriched Gene Ontology (GO) terms upregulated in IgG dcSSc ATA+ were involved in endocytic vesicle lumen, vesicle lumen, extracellular matrix or glycosaminoglycan binding. The comparisons of IgG dcSSc ATA- vs IgG HC and IgG lcSSc ACA+ vs IgG HC revealed 85 and 15 DEP, respectively. Follistatin, amyloid beta A4 protein, myosin-9 and calreticulin were commonly overexpressed in the 3 subtypes of SSc. 40 proteins were exclusively overexpressed in the condition dcSSc ATA+. Among them, collagen alpha-1(VII) chain, galectin-3-binding protein, desintegrin and metalloproteinase domain-containing 10, low affinity immunoglobulin gamma Fc region receptor III-A, CD59 glycoprotein, growth arrest-arrest specific protein and clusterin were overexpressed in the condition dcSSc ATA+ (Figure 1.**C**).

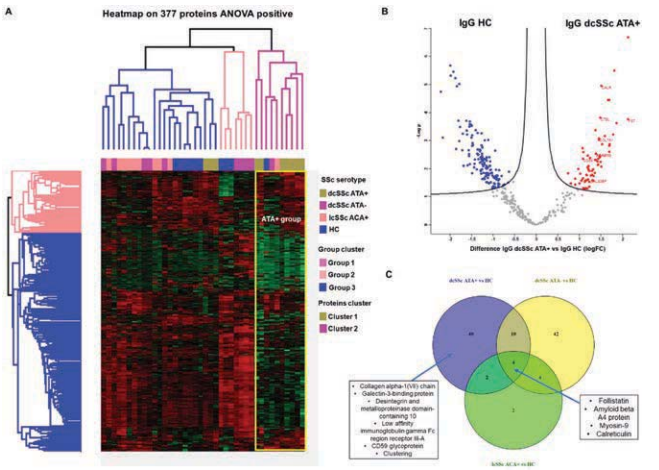

Figure 1. Heatmap representing the 377 differentially expressed proteins after ANOVA in all samples. Cluster analysis identified 3 group of patients and 2 different clusters of protein expression (A). Volcanoplot represented the comparison IgG dcSSc ATA+ vs IgG HC (B). Venn diagram representing the proteins in common and exclusive of the following comparison: IgG dcSSc ATA+ vs HC, IgG dcSSc ATA- vs IgG HC and IgG dcSSc ATA- vs IgG HC (C). *IgG HC: purified IgG from healthy controls; IgG dcSSc ATA+: purified IgG from diffuse systemic sclerosis anti-topoisomerase-I positive patients; IgG dcSSc ATA-: purified IgG from diffuse systemic sclerosis anti-topoisomerase-I negative patients; IgG lcSSc ACA+: purified IgG from limited systemic sclerosis anti-centromere positive patients. ANOVA: analysis of variance.*

Conclusion: Using sensitive proteomic approach, we identified that purified IgG from SSc patients modified FB secretome in a serotype dependent manner. The data support the pathogenic role of Aab in SSc.

OP0097 PROOF-OF-CONCEPT OF FIBROBLAST-TARGETED PHOTODYNAMIC THERAPY IN HUMAN 3D SCLERODERMA SKIN MODEL AND BLEOMYCIN-INDUCED SKIN FIBROSIS IN MICE

D. Dorst[1], A. van Caam[1], E. Vitters[1], B. Walgreen[1], M. Helsen[2], C. Klein[3], S. Gudi[4], T. Wubs[5], J. Kumari[5], P. Błyszczuk[6], M. Vonk[2], P. van der Kraan[4], M. Koenders[4]. *[1]Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands; [2]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; [3]Roche Innovation Center Zurich, Roche Pharma Research and Early Development, Schlieren, Switzerland; [4]Radboud University Medical Center, Experimental rheumatology, Nijmegen, Netherlands; [5]Radboud University, Institute for Molecules and Materials, Nijmegen, Netherlands; [6]University of Zurich, Rheumatology, Zürich, Switzerland*

Background: Systemic sclerosis (SSc) is a rare, severe auto-immune disease characterized by inflammation, vasculopathy and fibrosis. Activated (myo)fibroblasts are crucial drivers of fibrosis. By exploiting their expression of fibroblast activation protein (FAP) to perform targeted photodynamic therapy (tPDT), we can locoregionally deplete these pathogenic cells.
Objectives: We explored the use of FAP-tPDT to selectively target primary skin fibroblasts from SSc patients, both in 2D and 3D cultures, as well as in biopsies from fibrotic skin lesions in the murine bleomycin-induced skin fibrosis model.
Methods: The FAP targeting monoclonal antibody (clone 28H1) was conjugated with the photosensitizer IRDye700DX. Primary skin fibroblasts were obtained from lesional skin biopsies of SSc patients via spontaneous out-growth and subsequently cultured on plastic or collagen type I. For 2D FAP-tPDT, cells were incubated in buffer with or without the antibody-photosensitizer (Ab-PS) construct, washed after 4 h and exposed to λ = 689 nm light (50 J/cm^2 at 280 mW/cm^2). Cell viability was measured using CellTiter Glo. For 3D FAP-tPDT, cells were seeded in collagen plugs and underwent the same treatment procedure. Contraction of the plugs was followed over time to determine myofibroblast activity. Skin fibrosis was induced in mice by 3x/week injections of 1.5 IU bleomycin intradermally on the back of the mouse. After 5 weeks the mice were sacrificed and biopsies were taken from affected and not affected skin. These were incubated with or without the FAP targeting Ab-PS construct or a control Ab-PS. After washing, the biopsies were exposed to light, incubated for 1h and subsequently formalin fixed and paraffin embedded. Sections were immuno stained for the presence of cleaved caspase-3.
Results: FAP-tPDT resulted in antibody-dose dependent cytotoxicity in primary skin fibroblasts upon light exposure. Cells not exposed to light or incubated with a control Ab-PS construct did not show this response. FAP-tPDT fully prevented contraction of collagen plugs seeded with primary SSc fibroblasts. Even incubation with a very low dose of antibody (0.4 nM) inhibited contraction in 2 out of 3 donors. In fibrotic skin biopsies from mice with bleomycin-induced skin fibrosis, an upregulation of apoptosis, as evidenced by increased caspase-3 staining (Figure 1), was observed in response to FAP-tPDT. The same treatment on biopsies of control skin did not increase caspase-3 staining, nor did incubation with a control Ab-PS construct or light alone.

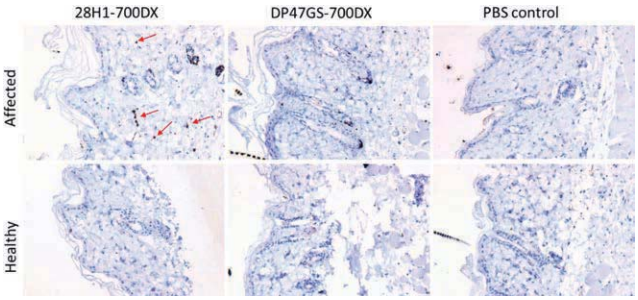

Figure 1. *Cleaved caspase-3 staining of biopsies from the skin of mice with bleomycin-induced dermal fibrosis upon treatment with FAP-tPDT. The red arrows indicate the presence of positive fibroblasts.*

Conclusion: Here we have shown, for the first time, the potential of FAP-tPDT for the selective targeting of pathogenic fibroblasts and treatment of fibrosis in SSc skin both in relevant patient-derived culture models as well as an *in vivo* model of fibrosis.

Microbiome and SpA

OP0098

PREDICTING TREATMENT OUTCOME IN PATIENTS WITH SPONDYLOARTHRITIS USING MICROBIOTA ANALYSIS

L. Amend[1], T. Strowig[1], T. R. Lesker[1], T. Witte[2]. [1]*Helmholtz Centre for Infection Research, Microbial Immune Regulation, Braunschweig, Germany;* [2]*Hannover Medical School, Department of Rheumatology and Immunology, Hannover, Germany*

Background: Autoimmune-related rheumatic diseases such as rheumatoid arthritis (RA) and spondyloarthritis (SpA) are caused by an interplay of various factors including genetics, environmental factors and lifestyle. Among them, the intestinal microbiome has been suggested to influence disease initiation and progression. While the pathogenic connection between the microbiome and autoimmunity remains ambiguous, there is evidence that, for instance, microbiota-derived antigens cross-react with autoantibodies triggering an immune response and disease development[1]. However, other hypothesis such as the leaky gut model have been explored[2]. In addition to this potential involvement in disease initiation, microbial signatures have been identified to predict treatment outcome, i.e., as shown for the first-line medication Methotrexate (MTX) in RA patients[3].
Objectives: Our study aimed to longitudinally compare gut microbiota composition between treatment-naïve patients with different forms of rheumatic disorders from disease onset to remission/relapse to identify i) disease-specific signatures and ii) their impact on therapeutic responses.
Methods: Patients with new onset of rheumatic disorders as well as their household members were recruited in the Rheuma-VOR cohort. The patients presented without treatment with steroids or DMARDs. The diagnosis was made by experienced rheumatologists. Native and stabilized fecal samples were collected, and 16S rRNA amplicon sequencing was performed to determine microbiota composition. Patients with non-inflammatory rheumatic disorders served as controls, whereas treatment was initiated in patients with inflammatory rheumatic diseases. Clinical data of patients was recorded including monitoring of medication and treatment response.
Results: A total of 422 fecal samples were analyzed from patients diagnosed with different forms of immune-mediated rheumatic diseases, non-inflammatory rheumatic diseases as well as from household controls (Table 1). Using 16S rRNA amplicon sequencing, we did not detect any clustering of patient groups during disease onset based on the microbiota composition (Figure 1A). However, PsA patients responding to MTX (MTX-R) (=patients in DAPSA remission 3-6 months after MTX initiation or patients showing partial response) and patients not in remission (MTX-NR) differed in microbial diversity (Figure 1B) and specific bacteria were enriched in MTX responders.

Table 1. ***Overview of RheumaVOR samples analyzed in this study***

Diagnosis	total number of samples	MTX treatment	MTX response: remission	MTX response: no remission	MTX response: response data not available yet
Household controls	188				
Non-inflammatory rheumatic diseases (NRD)	110				
Rheumatoid arthritis (RA)	33	28	11	6	11
Psoriatic arthritis (PsA)	47	34	13	12	9
Axial spondyloarthritis (axSpA)	35				
Reactive arthritis (ReA)	9				
In total	422				

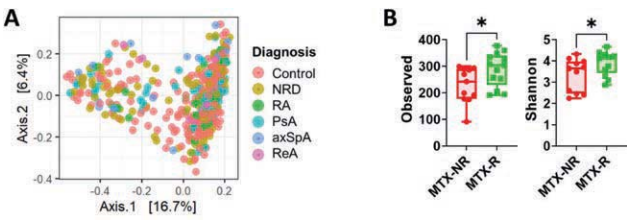

Figure 1. Microbiome analysis of RheumaVOR fecal samples. A: Analysis of beta diversity (PCoA) using Bray-Curtis distances. B: Alpha diversity of PsA patients receiving MTX as first-line medication. P values represent an unpaired nonparametric Mann–Whitney test, *p < 0.05.

Conclusion: While our study did not reveal global differences in the bacterial composition of the gut microbiota between patients diagnosed with RA and SpA as well as control groups, we identified changes in microbial diversity and the abundance of specific bacteria between MTX responders and non-responders in PsA patients. Further investigations are needed to clarify the complex interactions between the microbiome, disease onset in rheumatic disorders and DMARD treatment response to ameliorate disease progression and improve therapeutic outcome.

The role of the synovial microenvironment during onset and progression of arthritis

OP0099

INCREASED FREQUENCY OF CD4+ AND CD8+ FOLLICULAR HELPER T CELLS IN HUMAN LYMPH NODE BIOPSIES DURING THE EARLIEST STAGES OF RHEUMATOID ARTHRITIS

Background: Follicular T helper (Tfh) cells provide key help for B cell differentiation into plasma and memory B cells and are essential in germinal center formation and (auto) antibody generation (1).
Objectives: To gain more insights into the role of Tfh cells in RA development, we assessed whether Tfh cells have an altered frequency, phenotype and cytokine profile in peripheral blood, lymphoid and synovial tissues during the earliest stages of RA development.
Methods: Using flow cytometry, we analyzed the phenotpe, frequencies and cytokine profile of Tfh cells and B cells in peripheral blood and lymph node biopsies of healthy controls (HCs), autoantibody positive individuals at risk for developing RA (RA-risk individuals), and early RA patients. Using immunofluorescene we confirmed the presence of Tfh in B cell follicles of lymph nodes and synovial tissue biopsies of RA patients.
Results: In blood, the frequency of Tfh cells did not differ between study groups. In lymphoid and synovial tissue, Tfh cells were localized in B-cell areas, and their frequencies correlated strongly with the frequency of $CD19^+$ B cells. Compared to lymphoid tissue of healthy controls, that of RA patients and RA-risk individuals, showed more $CD19^+$ B cells and more $CD4^+CXCR5^+$ and $CD8^+CXCR5^+$ follicular T cells. Of note, compared to healthy controls, specifically lymph node Tfh cells of RA-risk and early RA patients produced less IL-21 upon ex-vivo stimulation.
Conclusion: Tfh cells are localised in B-cell rich areas in lymphoid and synovial tissues of early RA patients. The analysis of lymph node tissue in early RA patients showed increased frequencies of Tfh cells, where they clearly associate with B cells. Interestingly, IL-21 production is already aberrant in the very early at risk phase of the disease. Our data suggest that Tfh cells may present a novel rationale for therapeutic targeting during the preclinical stage of RA to prevent further disease progression.

Exploring the origin of inflammation in spondyloarthritis

OP0100 IL-17A BLOCKADE MODULATES DISEASE SPECIFIC IMMUNE AND STROMAL PATHWAYS IN PERIPHERAL SPONDYLOARTHRITIS SYNOVITIS

R. Fiechter[1], L. van Mens[1], I. Hammoura[1], H. de Jong[1], D. Pots[1], I. Fluri[1], S. Tas[1], D. Baeten[1], M. G. H. van de Sande[1], N. Yeremenko[1]. [1]*Amsterdam UMC, location AMC, Rheumatology and Clinical Immunology / Experimental Immunology, Amsterdam, Netherlands*

Background: The cellular and molecular mechanisms driving inflammation and structural remodelling in spondyloarthritis (SpA) remain largely unknown, though the IL-23/IL-17 pathway can contribute to synovial inflammation and radiographic progression.
Objectives: To investigate the molecular pathways affected by IL-17A blockade (IL-17Ai) with secukinumab in SpA synovitis, and assess if this response is tissue- and/or treatment-specific.
Methods: Synovial biopsies were obtained from peripheral SpA patients by needle arthroscopy before and after 12 weeks of IL-17Ai with secukinumab (n=12), and analyzed by RNA-sequencing and qPCR. We performed pathway enrichment analysis of the differentially expressed genes (DEGs) to identify pathways modulated after treatment. We compared the synovial tissue response in patients with psoriatic arthritis (PsA) in our cohort (n=7) with open source gene expression data of skin biopsies of psoriasis patients receiving secukinumab (n=22)[1] and of synovial biopsies of PsA patients receiving IL-12p40/IL-23p40 blockade (n=7)[2].
Results: IL-17Ai significantly modulated the expression of 1255 genes (549 up- and 706 down-regulated, FDR 0.1) in the synovium at week 12 compared to baseline (Figure 1). Genes downregulated upon IL-17Ai were significantly enriched in GO terms and KEGG pathways related to immune and inflammatory responses, including neutrophil and monocyte chemotaxis, TNF-mediated, NF-κB-, Wnt-, and JAK-STAT signalling pathways, and, importantly, bone-remodelling responses, such as osteoblast and osteoclast differentiation. Upregulated genes are enriched in JNK-, MAPK-, Wnt-, and PI3K-Akt signalling and negative regulation of osteoblast differentiation. We validated differential expression of selected genes from several pathways by qPCR, including: *IL1B*, p=0.027; *CXCL6*, p=0.020; *ADAMTS4*, p=0.002; *MMP3*, p=0.020; and *CHRDL2*, p= 0.039.

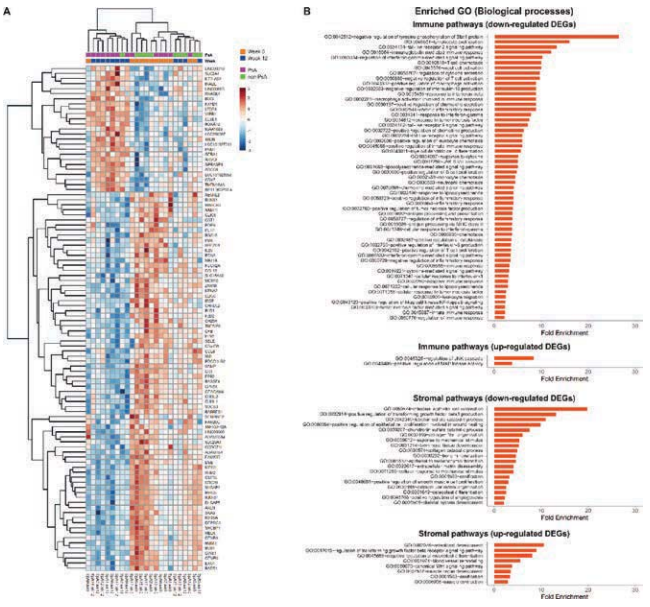

Figure 1. Heatmap of differentially expressed genes (DEGs) and pathway enrichment analyses of changes in peripheral SpA synovium 12 weeks after anti-IL-17A treatment (IL-17Ai). A. Hierarchical cluster analysis of the top 100 most significant DEGs (FDR < 0.1) modulated by IL-17Ai separates pre- and post-treated groups. Normalized and scaled log2 gene expression levels are shown. B. Pathway enrichment analysis through DAVID. Enriched (p < 0.05) gene ontology terms from IL-17Ai-induced up- and down-regulated DEGs in peripheral SpA synovium are shown.

To assess if this response is tissue- and/or treatment-specific, we compared changes in gene expression by IL-17Ai in PsA synovium versus psoriatic skin, and in the PsA synovium after IL-17Ai versus IL-12p40/IL-23p40 blockade. While many inflammation-related GO terms and KEGG pathways were over-represented in both tissues and treatments, NF-κB-, JAK-STAT-, and PI3K-Akt-signaling were enriched in DEGs in both skin and synovium after IL-17Ai, whereas JNK cascade, IL-17 signalling pathway and Th17 cell differentiation were over-represented in DEGs after IL-17Ai in the synovium specifically. Remarkably, IL-17Ai, but not IL-12p40/IL-23p40 blockade, modulated multiple bone-remodelling related pathways. Also, IL-17Ai modulated ossification and collagen catabolic process terms in PsA synovium and psoriatic skin in the opposite direction: these terms were over-represented in downregulated genes in synovium, but in upregulated genes in skin. Accordingly, genes upregulated after IL-17Ai were enriched in negative regulation of osteoblast differentiation in the synovium, but in positive regulation of osteoblast differentiation in the skin.
Conclusion: These first *in vivo* human data provide molecular confirmation of previously reported animal data[3] that demonstrated down-modulation of disease-relevant immune and stromal pathways in the synovium in response to IL-17Ai.

OP0101 MECHANICAL LOADING-INDUCED BHLHE40 PROMOTES INFLAMMATORY ARTHRITIS

E. Gracey[1,2], I. Cambre[1], E. Gilis[1], F. Stappers[1], G. Planckaert[1,3], A. Bozec[4], D. Elewaut[1,2,5]. [1]*Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium*; [2]*Vlaams Instituut voor Biotechnologie, Center for Inflammation Research (IRC), Gent, Belgium*; [3]*Ghent University Hospital, Orthopedics, Gent, Belgium*; [4]*University Hospital Erlangen, Department of Medicine, Erlangen, Germany*; [5]*Ghent University Hospital, Rheumatology, Gent, Belgium*

Background: Force induced microdamage to joint tissue is hypothesized to trigger inflammatory events in the joint leading to arthritis. Patients with inflammatory arthritis, such as rheumatoid arthritis (RA) and spondyloarthritis (SpA), are found to have inflammation in “mechanical hotspots” and mechanical loading in mouse models of these diseases is pro-arthritogenic[1,2]. To date, the molecular mechanism involved in converting force to a biological signal that promotes arthritis is not known.
Objectives: This study aims to identify stretch induced genes in synovial fibroblasts, and the effect of these “mechano-sensitive” genes on arthritis.
Methods: Human synovial fibroblasts were stretched in vitro for 4hrs using the FlexCell system and analysed by microarray. Top stretch induced genes were measured in RA, SpA and healthy synovial tissue by qPCR. Patient synovium was further analysed by immunohistochemistry. Bhlhe40 deficient mice were subjected to collagen induced arthritis (CIA) and KBxN serum transfer arthritis (STA). FACS was performed on ankle synovium. uCT was performed on whole ankles, with morphological changes scored by blinded readers, and calcaneus erosions by customs scripts in FIJI.
Results: 600 genes were found to be differentially expressed in stretched synovial fibroblasts (fold change > +/-1.5, adjusted p<0.05). 25% of these genes were found to be transcription factors, which included BHLHE40. BHLHE40 mRNA was elevated in the synovial tissue of RA/SpA vs healthy subjects (1.56 fold change), and BHLHE40 protein was widely detectable in synovial fibroblasts and macrophages (Figure 1). Bhlhe40 deficient mice were completely protected against CIA (incidence: 0% vs 40%, n=30 per group), but Bhlhe40 did not block the generation of anti-collagen antibodies. Bhlhe40 deficient mice were partially protected against STA (peak clinical score at day 7; 5.2 vs 6.8, n=15 per group), with reduced synovial macrophage (CD11b+Ly6G-F4/80+) and neutrophil (CD11b+Ly6G+) frequency observed in the arthritic Bhlhe40 deficient mice compared to wildtype controls. Bhlhe40 had no impact on bone erosions with STA.

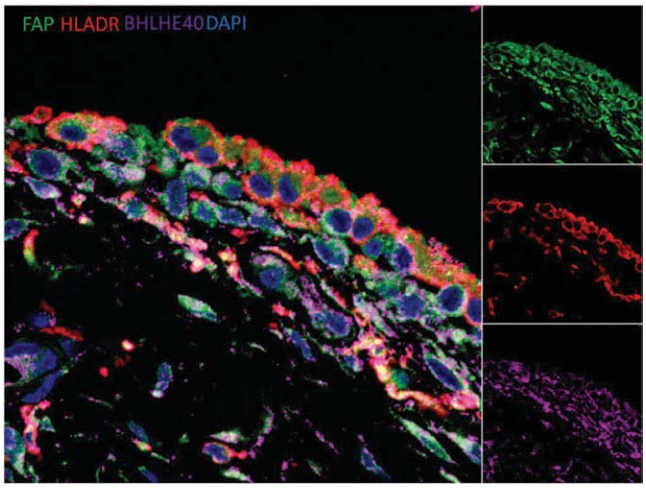

Figure 1. BHLHE40 is widely expressed in human synovium. Synovium obtained from total knee replacement. FFPE samples were stained for synovial macrophages (HLADR+) and fibroblasts (FAP+). Images acquired with the Zeiss LSM 780.

Conclusion: BHLHE40 was identified as a force-induced gene in synovial fibroblasts and was found to be upregulated in patients with inflammatory arthritis. Importantly, Bhlhe40 strongly promotes joint inflammation in murine models of arthritis and uncouples systemic autoimmunity from joint tissue inflammation. Thus, we have identified BHLHE40 as a novel regulator of mechanical loading-associated inflammation.

OP0102

THE SYNOVIUM IN CHRONIC INFLAMMATORY JOINT DISEASES: COMPARISON OF CLINICAL, HISTOLOGICAL AND SCRNA-SEQ DATA BETWEEN RA, PSA, SPA AND UA

R. Micheroli[1], M. Houtman[1], C. Pauli[2], S. G. Edalat[1], M. Frank Bertoncelj[1], O. Distler[1], A. Ciurea[1], C. Ospelt[1]. [1]*University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*; [2]*University Hospital Zurich, University of Zurich, Department of Pathology, Zurich, Switzerland*

Background: The synovium is the primary location of inflammation in various rheumatic diseases. However, specific differences of joint inflammation have not been explored on a single-cell level so far.

Objectives: To characterize the synovium of rheumatoid arthritis (RA), psoriatic arthritis (PsA), spondyloarthritis (SpA) and undifferentiated arthritis (UA) based on clinical and histological characteristics and single-cell RNA sequencing (scRNA-seq).

Methods: We performed ultrasound (US) guided synovial biopsy in patients fulfilling classification criteria: 10 RA, 4 PsA, 4 SpA and 3 UA. 3 osteoarthritis (OA) samples were obtained from surgery. Clinical data were collected at time of biopsy. Histological analysis of the synovium included Krenn score [1], synovial pathotype [2], vascularization [3] and presence of lymphoid follicles. OA histology was not available. We prepared scRNA-seq libraries with 10X Genomics and sequenced on NovaSeq 6000. ScRNA-seq data was analysed with Cell Ranger, Seurat and Harmony R packages. We selected overexpressed genes using log2 ratio (>0.25) and FDR adjusted p value < 0.05.

Results: Patients showed typical disease characteristics. In RA, 6/10 were seropositive, 8/10 were female and median age was 59 years (IQR 12). Patients with PsA, SpA and UA were seronegative. 2/4 SpA and 1/4 PsA patients were HLA-B27 positive. Median age was 53 years in PsA (IQR 14.2), 52.5 in SpA (IQR 14.8) and 53 in UA (IQR 3.5). In PsA 3/4, SpA 2/4 and UA 1/3 patients were male. RA joints had significantly higher B-Mode US scores compared to PsA and SpA joints (mean B-Mode Score: RA 2.7; PsA 2; SpA 2). Correspondingly, RA patients reported a significantly higher amount of swelling in the biopsied joint compared to PsA and SpA (mean "Swelling-Score": RA 6.85; PsA 4.25; SpA 4).

Histology showed no clear differences in the cell composition; most joints showed a lympho-myeloid pathotype. Mean Krenn Score was highest in RA (4.78) and lowest in SpA (3.33). PD-Mode US score showed a significant positive association with histological vascularization. Lymphoid follicles were significantly more seen in RA compared to all other diseases.

Integration of scRNA-seq data revealed 16 cell clusters with respective marker gene: PRG4 synovial fibroblasts (SF), THY1 SF, ACTA2 smooth muscle cells, VWF endothelial cells, TPSB2 mastcells, IGHG plasma cells, CD79 B-cells, CD69 T-Cells, CCL5 natural killer cells, DMTN Treg-cells, CXC2 neutrophil granulocytes, TREM2 macrophages, CD48 macrophages, CLEC10A macrophages, CD4 dendritic cells, MKI67 proliferating cells. OA had the lowest and RA the highest number of inflammatory cells within the synovium. SpA synovium had the highest number of neutrophils. Re-Clustering of only SF revealed 4 subtypes: PRG4 SF (3578 cells), CXCL12 SF (4539 cells), POSTN SF (2387 cells) and MFAP5 SF (1734 cells). Top 5 marker genes are shown in the Table 1. Most differentially expressed genes in OA were found in PRG4 SF; the previously described OA specific gene CSN1S1 [3] was not only underexpressed in RA but also in other inflammatory joint diseases (Figure 1). PGF, a gene associated with pathological angiogenesis, was one of the top discriminator genes, highly expressed in PsA SF (mostly PRG4 SF). RA SF (mostly CXCL12 SF) showed a high expression of CHI3L1, which is a RA specific autoantigen. High expression of hemoglobin genes was found in SpA PRG4 SF; an unexplored but previously described finding [5, 6].

Table 1. Top 5 synovial fibroblast (SF) marker genes.

Cluster	Gene
PRG4 SF	PRG4
	CSN1S1
	MMP3
	CRTAC1
	HTRA1
CXCL12 SF	APOE
	CXCL12
	CCL2
	PTGDS
	CD74
POSTN SF	COMP
	COL1A1
	POSTN
	CILP
	PTN
MFAP5 SF	MFAP5
	SFRP2
	APOD
	CXCL14
	CFD

Conclusion: We were able to compare the synovium of the most common chronic inflammatory joint diseases on various levels for the first time. The findings set the path for future diagnostic, prognostic, and therapeutic approaches in inflammatory joint diseases.

GENE EXPRESSION PROFILES RETRIEVED FROM SINGLE CELL RNA SEQUENCING REVEAL PHENOTYPIC TRAITS IN PATIENTS WITH PSORIATIC ARTHRITIS INITIATING TUMOUR NECROSIS FACTOR ALPHA INHIBITOR AND INTERLEUKIN-17 INHIBITOR

M. Skougaard[1,2,3], C. Drachmann[4], Z. R. Stisen[1], S. B. Ditlev[3], L. E. Jessen[4], L. E. Kristensen[1]. [1]*Bispebjerg and Frederiksberg Hospital, The Parker Institute, Copenhagen, Denmark*; [2]*Aarhus University Hospital, Department of Clinical Immunology, Aarhus, Denmark*; [3]*Bispebjerg and Frederiksberg Hospital, Copenhagen Center for Translational Research, Copenhagen, Denmark*; [4]*Technical University of Denmark, Department of Health Technology, Section of Bioinformatics, Kgs. Lyngby, Denmark*

Background: Patients with Psoriatic Arthritis (PsA) suffer from heterogenous debilitating symptoms caused by immune-mediated inflammation. However, great diversity in clinical response to available medical therapies targeting the immune response in PsA complicates treatment decision-making.
Objectives: The primary objective of the study was to evaluate gene expression profiles at baseline in responders versus non-responders of Tumour Necrosis Factors alpha inhibitor (TNFi) and Interleukin-17 inhibitor (IL-17i), respectively, to examine the foundation for future improved PsA patient stratification.
Methods: Single cell RNA sequencing (scRNAseq) was included to evaluate the transcriptome in responders versus non-responders of Tumour Necrosis Factor alpha inhibitor (TNFi) and Interleukin-17 inhibitor (IL-17i). Peripheral blood mononuclear cells (PBMCs) was isolated for scRNAseq and Disease Activity Score in PsA (DAPSA) retrieved in 40 PsA patients; 20 initiating TNFi and 20 initiating IL-17i. Responders and non-responders were stratified based on 50% improvement after 4-months (DAPSA50). The BD Rhapsody Whole Transcriptome Approach [1] was applied to prepare cDNA libraries sequenced to a depth of approximately 50.000 reads pr. cells on the Illumina NovaSeq 6000. The Seurat pipeline [2] was implemented for the analysis of gene expression on single cell level.
Results: A total of 273.515 cells were retrieved after initial quality control. Comparing patient demographics and characteristics at baseline revealed no difference between groups (Table 1). Dimensionality reduction with principal component analysis and additional clustering analysis indicated different phenotypic traits of responders and non-responders to TNFi and IL-17i (Figure 1). The results were limited by the DAPSA50 stratification only requiring 50% improvement at 4-month. Nevertheless, it is believed that scRNAseq can be included to improve PsA patient stratification.

Table 1. Patient characteristics

	All (n=40)	TNFi responders (n=12)	TNFi non-responders (n=8)	IL-17i responders (n=8)	IL-17i non-responders (n=12)	p-value
Sex, female	23 (57.5)	7 (58.3)	4 (50.0)	4 (50.0)	8 (66.7)	0.853
Age	51.9 ±12.1	48.4 ±10.9	54.7 ±11.6	49.6 (17.5)	52.7 ±9.9	0.766
Disease duration	8.1 ±7.4	6.7 ±6.8	10.1 ±10.1	10.4 ±7.9	13.7 ±6.4	0.903
DAPSA	36.5 ±18.5	34.4 ±23.2	34.1 ±13.8	50.5 ±17.3	38.5 ±17.9	0.176

Patient characteristics were presented as number with corresponding percentage or mean with corresponding standard deviations. P-value < 0.05 was considered statically significant. TNFi; Tumour Necrosis Factor alpha inhibitor, IL-17i; Interleukin-17 inhibitor, DAPSA; Disease Activity in Psoriatic Arthritis.

Conclusion: High-dimensional data, retrieved from scRNAseq combined with bioinformatical data modelling and clinical knowledge, is important and should possibly be implemented to explore PsA disease heterogeneity and for better stratification of PsA patients prior to initiating available medical therapies.

EXPANDED CD8+ T CELL CLONES FROM HLA-B*27-POSITIVE PATIENTS WITH SPONDYLOARTHRITIS SHOW SIGNS OF ANTIGEN-EXPERIENCE

J. Rademacher[1,2], K. Deschler[3], S. Lacher[3], A. Huth[3], M. Utzt[3], S. Krebs[4], H. Blum[4], E. Beltrán[3], D. Poddubnyy[1,5], K. Dornmair[3]. [1]*Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Germany Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany*; [2]*Berlin Institute of Health (BIH), BIH Biomedical Innovation Academy, BIH Charité (Junior) (Digital) Clinician Scientist Program, Berlin, Germany*; [3]*Ludwig-Maximilians-Universität München, Institute of Clinical Neuroimmunology, Biomedical Center and Hospital of the LMU Munich, München, Germany*; [4]*Gene Center of the LMU Munich, Germany, Laboratory for Functional Genome Analysis (LAFUGA), Berlin, Germany*; [5]*German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*

Background: The pathogenesis of Spondyloarthritis (SpA) remains unknown but its strong association with some alleles of HLA-B*27 is peculiar. The arthritogenic antigen hypothesis assumes the existence of specific peptides presented by risk-conferring HLA-B*27 alleles to antigen-specific CD8+ T cells, which then initiate or sustain autoimmune reactions. Several studies analyzing T cell receptor (TCR) repertoire found preferred Variable TCR chains and motifs in the hypervariable complementary determining region (CDR) 3, but analyzed only TCR β-chains in bulk analyses[1,2].
Objectives: To analyze full sequence information of TCR including matching α- and β-chains from single CD8+ T cells and characterize the transcriptomes of expanded and non-expanded clonotypes in synovial fluid (SF) of SpA patients.
Methods: We included 17 patients with active gonarthritis: 10 patients with HLA-B27 positive (B27pos) SpA, 4 with HLA-B27 negative (B27neg) SpA and 3 rheumatoid arthritis (RA) patients. Antigen-experienced CD8+ T cells were sorted out of SF by flow cytometry. Single cell sequencing was performed for all patients to

analyze matching TCR α- and β-chains. For 7 patients (3 B27pos SpA, 2 B27neg SpA, 2 RA), additionally whole transcriptome analyses were performed.
Results: We found strong biases when analyzing α and β chains of TCR Variable regions and CDR1 and CDR2 sequences (Figure 1 a,b): AV21, AV12-2, and AV17 were highly enriched in B27pos SpA as compared to B27neg subjects. Amongst the highest expressed clones, we could confirm enrichment for previously described TRBV genes as BV19, BV5-1 and BV6-2. We examined TCR α/β combinations and focused on those detected in at least three different B27pos SpA but not in any of the B27neg patients (Figure 1 c-f). The combinations TRBV19/TRAV21 and TRBV6-2/TRAV21 were most likely specific for B27pos SpA and might reflect interaction of these TCR chains with HLA-B*27.

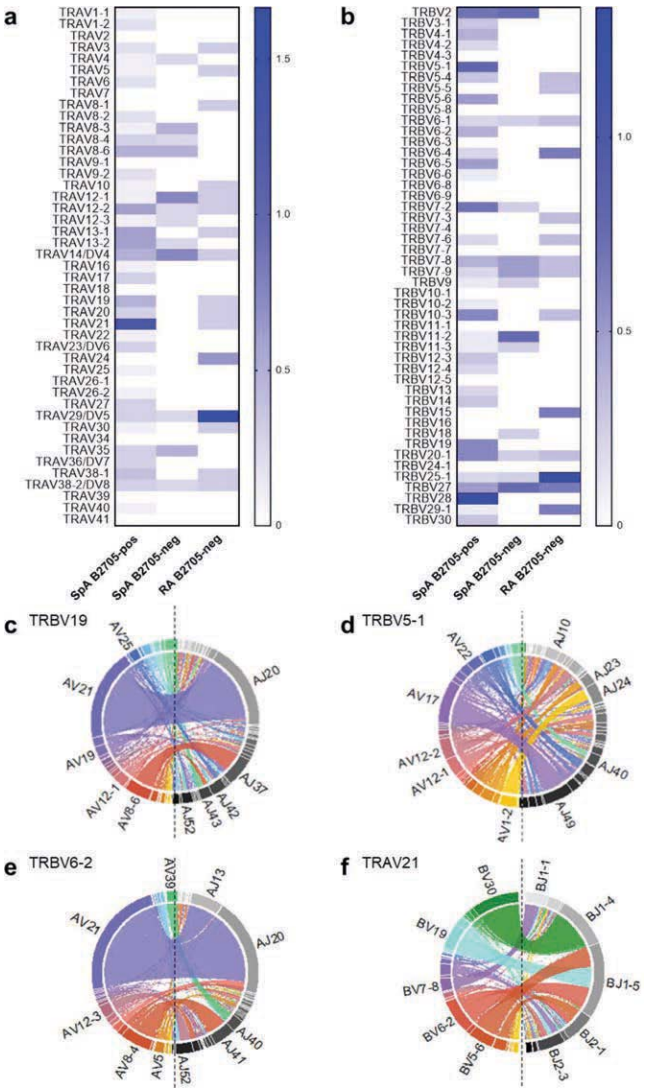

Figure 1. Distinct TCRαβ V chain usage in expanded clones from HLA-B27 positive SpA patients. A,B Mean number of all productive TRAV (A) and TRBV (B) genes used in expanded, antigen-experienced CD8 T cell clones (>1% of all cells) from SF of 10 B27pos SpA, 4 B27neg SpA and 3 B27neg RA patients. **C-F** TRAV chains paired with TRBV19 (C), TRBV5-1 (D), TRBV6-2 (E), or TRBV chains paired with TRAV21 (F) with corresponding TRAJ spanning partners in expanded cells (frequency ≥2) from all 10 B27pos SpA. Number of chains are 1250 (C), 886 (D), 1220 (E), and 4006 (F).

Sequences of CDR3 loops, which predominantly interact with HLA-bound antigenic peptides, revealed striking common structural motifs in α- and β-chains. Focusing on the most prominent TRAV21 chains pairing with TRBV19, 5-1 and 6-2 chains, revealed identical sequences in different patients and striking common structural motifs in α- and β-CDR3 sequences in other patients. Such marked similarities in the antigen-recognition loops of the β-chains associated with TRAV21 suggest common or highly similar antigens.
Gene expression levels provided evidence that expanded cell populations had tissue resident memory (TRM) phenotypes (elevated expression of activation, migration and tissue retention markers, downregulated genes characteristic for T cell egress), while this phenotype was not very pronounced in non-expanded cells. Furthermore, markers for T cell exhaustion and apoptosis were elevated in expanded cells of B27pos SpA patients.
Conclusion: Analysis of single antigen experienced CD8+ T cells from SF of B27pos SpA patients revealed significant clonal expansions and common motifs in the CDR loops. Two of the four CDR1 and CDR2 loops were highly homologous suggesting that these loops interact with α-helices of HLA-B*27. Common motifs in CDR3 loops of expanded clonotypes suggest recognition of a limited set of antigenic peptides presented by HLA-B*27. Many of the expanded clonotypes showed a TRM phenotype, were exhausted and on the way to become apoptotic, which suggests that these clones had sustained contact to specific antigens.

MIRNOME PROFILE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

A. Pekacova[1,2], J. Baloun[1], K. Bubova[1,2], M. Gregová[1,2], S. Forejtova[1,2], J. Horinkova[1,2], M. Husakova[1,2], M. Tomčík[1,2], J. Gatterova[1,2], J. Vencovský[1,2], K. Pavelka[1,2], L. Šenolt[1,2]. [1]*Institute of Rheumatology, Department of Experimental Rheumatology, Praha, Czech Republic*; [2]*First Faculty of Medicine Charles University, Department of Rheumatology, Prague, Czech Republic*

Background: microRNAs (miRNAs) are small non-coding RNAs regulating up to 60 % of human mRNAs, including genes related to axial spondyloarthritis (axSpA) (1).
Objectives: This study aims to profile miRNome and to identify candidate miRNAs determining disease severity in patietns with non-radiographic (nr) and radiographic (r) axSpA.
Methods: The miRNome profiling experiment included peripheral blood mononuclear cells (PBMCs) of 96 subjects (38 patients with nr-axSpA, 38 patients with r-axSpA and 20 healthy controls). Firstly, massive parallel sequencing on NextSeq 500 (MPS, Illumina) was performed for miRNA screening. Selected candidate miRNAs were further validated using the qRT-PCR system (SmartChip) on the validation cohort of 141 subjects (47 patients with nr-axSpA, 44 patients with r-axSpA and 50 healthy controls). We employed the DESeq2 algorithm and generalized linear modelling with a negative binomial assumption (GLM-NB) to evaluate the association of candidate miRNAs to axSpA subtype and clinical disease activity (ASDAS and CRP).
Results: MPS revealed 432 unique miRNAs in all samples. We identified 13 differently expressed miRNAs in axSpA patients compared to healthy controls, and 14 differently expressed miRNAs in axSpA patients with high to very high ASDAS compared to patients with inactive disease. Data from validation cohort revealed that the expression level of miR-4286 was higher in patients with very high disease activity compared to patients with inactive disease. Simultaneously, miR-4286 positively correlated with ASDAS. miR-4286 has been recently associated with osteogenesis and angiogenesis (2). None of the validated miRNAs was associated with the levels of CRP.
Conclusion: In this study, we identified that miR-4286 is related to disease activity and could play a role in the pathogenesis of axSpA.

OP0106 **SOLUBLE PD-1 PROMOTES LOCAL IL-17A PRODUCTION IN THE INFLAMED MICROENVIRONMENT IN SPA**

E. Rasmussen[1], R. Østgård[2], M. Hvid[1], U. Syrbe[3], D. Poddubnyy[3], B. Deleuran[1,4], S. R. Greisen[1,4]. [1]*Aarhus University, Department of Biomedicine, Aarhus, Denmark*; [2]*Silkeborg Regional Hospital, Department of Rheumatology, Silkeborg, Denmark*; [3]*Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Rheumathology, Berlin, Germany*; [4]*Skejby Sygehus, Department of Rheumathology, Aarhus, Denmark*

Background: Programmed death 1 (PD-1) is an immune checkpoint receptor expressed by activated T-cells. Activation of the PD-1 pathway reduces T cell activation and inflammation. Targeting PD-1 in cancer can result in autoimmune disease, which highlights the importance of this pathway in balancing inflammation. Both PD-1 and its ligands are present in soluble (s) forms, and we have previously showed that sPD-1 is associated to bone erosions in rheumatoid arthritis. Spondyloarthritis (SpA) is characterized by both bone erosions and bone formation. Current evidence suggests an important interaction between the PD-1 pathway and the proinflammatory cytokine IL-17A. IL-17A is central in promoting inflammation in SpA and direct osteoclast activation leading to bone erosion. We have previously demonstrated that the PD-1 ligand, PD-L2, reduces osteoclast formation under inflammatory conditions.
Objectives: We aimed at investigating the interplay between the PD-1 pathway and IL-17A in relation to inflammation and bone homeostasis in patients with SpA.
Methods: From early SpA patients, plasma was collected at baseline and after 1 year of treatment with Adalimumab. From chronic SpA patients, plasma, synovial fluid (SF), peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were collected. Plasma and PBMCs were also collected from healthy controls (HC) for comparison. Disease activity was measured by ASDAS and progression by inflammation and new bone formation in the total spine.
Facet joint biopsies were collected from SpA patients during surgery for correction of rigid hyperkyphosis. Levels of sPD-1 and sPD-L2 were measured in plasma and SF. Surface expression of PD-1 and CCR6 was evaluated on PBMCs and SFMCs. Levels of IL-17A were measured in the supernatant from stimulated PBMC cultures with recombinant human (rh)PD-1. Facet joint biopsies were stained for the presence of PD-1, PD-L1, PD-L2 and CCR6.
Results: Plasma levels of sPD-1 and sPD-L2 were equally increased in both early and chronic SpA compared to HC. Plasma levels of sPD-1 and sPD-L2 did not change following one year of treatment. In chronic SpA patients, sPD-1 levels were higher in SF than in plasma. Levels of sPD-1 and sPD-L2 in plasma and SF did not correlate with any disease activity scores or progression. Expression of PD-1 on the cell surface of PBMCs from SpA patient was comparable to healthy controls. On SFMCs, PD-1 expression was increased, supporting continuous T-cell activation in the local microenvironment. After stimulation with anti CD3/CD28, SpA PBMCs produced more IL-17A when cultured with rhPD-1 compared to healthy control PBMCs.
PD-1 and CCR6 were highly present in facet joint biopsies, but PD-L2 and PD-L1 could not be detected. This supports the PD-1 pathway to play a role at the actual site of pathology.
Conclusion: Plasma levels of the PD-1 family is unaffected by addition of anti-TNFα antibody treatment in SpA. The early SpA cohort had a low degree of progression in structural changes in the observation period, which could explain the lack correlation with sPD-1 and sPD-L2 and disease progression. Soluble PD-1 is high in the inflamed microenvironment, where it may result in increased IL-17A production. Collectively, these data suggest that the PD-1 pathway could play a role in the pathogenesis of SpA, acting in the inflamed microenvironment.

OP0107 **SERUM GRANULOCYTE-MONOCYTE COLONY STIMULATING FACTOR (GM-CSF) IS INCREASED IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS (AS) AND PERSISTS DESPITE ANTI-TNF TREATMENT**

C. Papagoras[1], S. Tsiami[2], A. Chrysanthopoulou[1], I. Mitroulis[1], X. Baraliakos[2]. [1]*First Department of Internal Medicine and Laboratory of Molecular Hematology, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Greece*; [2]*Rheumazentrum Ruhrgebiet, Herne, Ruhr-University Bochum, Herne, Germany*

Background: There is increasing evidence of the pathogenetic role of monocytes and neutrophils in AS, while the neutrophil-to-lymphocyte ratio correlates with disease activity (1). Granulocyte-Monocyte Colony Stimulating Factor (GM-CSF) is a growth factor for both myeloid lineages and a potent pro-inflammatory cytokine activating myeloid cells, including pro-inflammatory M1 macrophage polarization, production of TNF and other cytokines, and promoting osteoclastogenesis (2). It signals through the JAK-STAT pathway.
Objectives: To measure serum GM-CSF together with markers of bone metabolism in patients with AS before and after anti-TNF treatment.
Methods: The study included patients with the clinical diagnosis of AS (also fulfilling the 1984 modified NY criteria) with increased disease activity despite treatment with NSAIDs, all being eligible for treatment with a biologic DMARD. Decision for treatment with a TNF-inhibitor was made by the treating rheumatologist. Healthy donors were sampled as controls. Serum was collected before (baseline, BL) and after 4-6 months (follow-up, FU) of anti-TNF treatment and the following molecules were measured using ELISA: GM-CSF, Sclerostin (SOST) and Dickkopf-1 (Dkk-1).
Results: Twelve patients with AS (7 males, 5 females, median age 37 years, range 22-52) with a median disease duration of 1 year (range 0.5-25) and 16 age- and sex-matched controls were included. At BL, patients had mean BASDAI 6.3±2 and ASDAS 3.2±0.7. At FU the mean BASDAI decreased to 4.1±1.7 and ASDAS decreased to 2.2±0.6. At BL, AS patients had significantly higher mean serum levels of GM-CSF (150 vs 62pg/ml, p=0.049), significantly lower Dkk-1 (1228 vs 3052pg/ml, p=0.001), but similar levels of SOST (369 vs 544pg/ml, p=0.144) compared to controls. Anti-TNF treatment did not significantly affect GM-CSF, Dkk-1 or SOST levels (p>0.05 for all comparisons at FU vs baseline). Spearman correlation analysis showed that GM-CSF correlated positively with ASDAS at baseline (r=0.61, p=0.039), negatively with age (r=-0.68, p=0.018), but not with disease duration (r=-0.27, p=0.400). No correlations were identified between bone markers (Dkk-1, SOST) and GM-CSF or disease activity indices.
Conclusion: GM-CSF is increased in patients with active AS, particularly in younger ages, and strongly correlates with disease activity, but not with disease duration. In contrast, TNF inhibition does not affect GM-SCF levels, despite improving disease activity. GM-CSF may represent an important pathway in AS that could be responsible for residual inflammation during TNF blockade, but also explain the efficacy pathway of treatment with JAK inhibitors.

From gene to function: genetic basis of rheumatic diseases

OP0108 **NEW INSIGHTS IN THE GENOMIC "GRAMMAR" OF RHEUMATOID ARTHRITIS**

L. Papageorgiou[1], M. Zervou[2], G. Zisios[1], D. Vlachakis[1], G. Bertsias[2], G. Goulielmos[2], E. Eliopoulos[1]. [1]*Agricultural University of Athens, Department of Biotechnology, Athens, Greece*; [2]*University of Crete, School of Medicine, Heraklion, Greece*

Background: Rheumatoid arthritis (RA) is a complex disease, caused by a combination of genetic, epigenetic and environmental factors common to other related autoimmune diseases including Multiple Sclerosis (MS) and Systemic Lupus Erythematosus (SLE) [1]. Using state of the art Bioinformatics tools we are able to formulate an ensemble of associated components (genomic grammar) for each disease and distinguish important differences and common aspects in a specific group of disease such as ensembles of autoimmune diseases [2].
Objectives: To create, collect and evaluate the most credible and unique gene variants, epigenetic variants and single nucleotide polymorphisms (SNPs) causing the basis of an immune disease (the genomic grammar of the disease), which could potentially assist in the process of the RA disease prevention, diagnosis and treatment [3].
Methods: RA related publications from the PubMed have been analyzed using data mining and semantic techniques towards extracting the candidate causative SNPs. The extracted knowledge has been filtered, evaluated, annotated, and classified in a structured database which also includes GWAS information regarding SNPs. Additional clinical, genomic, structural, functional and biological information was also extracted from biological databases including dbSNP, LitVar, ClinVar and OMIM and cross-correlated with other available autoimmune disease related SNP databases, including the Demetra application, Epione application and Panacea application databases [3, 4].

Results: A holistic genetic map of the studied autoimmune diseases with more than 2000 related SNPs has been estimated and specific sub-clusters with crucial nodes have been identified across the RA, SLE and MS diseases. Based on these results, the three studied autoimmune diseases share a 10% common SNPs genetic background (Figure 1 and Table 1) [5]. The optimal genomic grammar of the RA contains 1682 SNPs, with 73% responding to non-coding regions and 27% responding to coding regions of more than 1.300 genes, pseudogenes, primers and promoters. RA also shares 464 common SNPs with SLE and 113 with MS.

OP0109

EXPRESSION QUANTITATIVE TRAIT LOCI IN EARLY TREATMENT-NAÏVE RHEUMATOID ARTHRITIS

K. Goldmann[1,2], E. Vigorito[3], C. Wallace[3], M. Barnes[2], A. Barton[4], C. Pitzalis[1], M. Lewis[1,2]. [1]*William Harvey Research Institute, Centre for Experimental Medicine and Rheumatology, London, United Kingdom*; [2]*William Harvey Research Institute, Centre for Translational Bioinformatics, London, United Kingdom*; [3]*University of Cambridge, MRC Biostatistics Unit, Cambridge, United Kingdom*; [4]*Manchester Academic Health Sciences Centre, Centre of Genetics & Genomics Versus Arthritis, Manchester, United Kingdom*

Background: To date more than 100 genetic loci have been associated with rheumatoid arthritis (RA), particularly in the human leukocyte antigen (HLA) region. Our understanding of the functional consequences of genetic variation in RA causality, however, is limited and it has been shown that a substantial portion of complex disease risk alleles modify gene expression in a cell-specific manner [1]. The Pathobiology of Early Arthritis Cohort (PEAC) is a longitudinal study looking at treatment-naïve RA patients with genotyped data as well as both synovial and blood RNA-sequenced biopsies prior to treatment with disease modifying anti-rheumatic drugs (DMARDs).

Objectives: To explore expression quantitative trait loci (eQTL) in synovium and blood within PEAC and characterise the effects of genetic variation on gene expression measured by RNA-sequencing. A further goal was to investigate the role of these variants in RA disease severity and response variables.

Methods: Genotypes were generated by Illumina Human CoreExome-24 version 1-0 array in 118 RA patients. Single nucleotide polymorphisms (SNPs) in the HLA region were imputed using HLA-TAPAS. A candidate gene study was performed on variants within the HLA region using Plink v2.0. Synovial (n=85) and blood (n=51) RNA-sequenced samples then underwent *cis*-eQTL analysis (loci within $\pm 5x10^5$Mb of the variant) based on linear regression models with the matrixeQTL R package using PEER [2] and PCA eigenvectors as covariates. Differences in eQTL between tissues were determined using a linear interaction term.

Results: The candidate gene study determined several amino acids around *HLA-DRB1* acting as markers for seropositivity, which replicated findings by Raychaudhuri et. al. [3]. Using eQTL analysis, around 33,000 synovial SNPs were found with genome-wide significance ($p \leq 5x10^{-8}$) and around 29,000 in blood. This corresponded to 279 unique significant genes in synovium and 417 in blood (Figure 1). There were 100 genes common to both synovium and blood, including *PSORS1C3, HLA-DRB9* and *ERAP2,* which have known associations with autoimmune diseases and inflammatory arthritis. Notably, 92 genes showed significantly different patterns of QTL expression between synovial tissue and blood ($p \leq 5x10^{-8}$). eQTL data also confirmed the triad of genetic variants significantly driving tissue gene expression of *HLA-DPB2*, while both *HLA-DPB2* SNPs and *HLA-DPB2* RNA-sequencing synovial expression correlated highly with erythrocyte sedimentation rate (ESR).

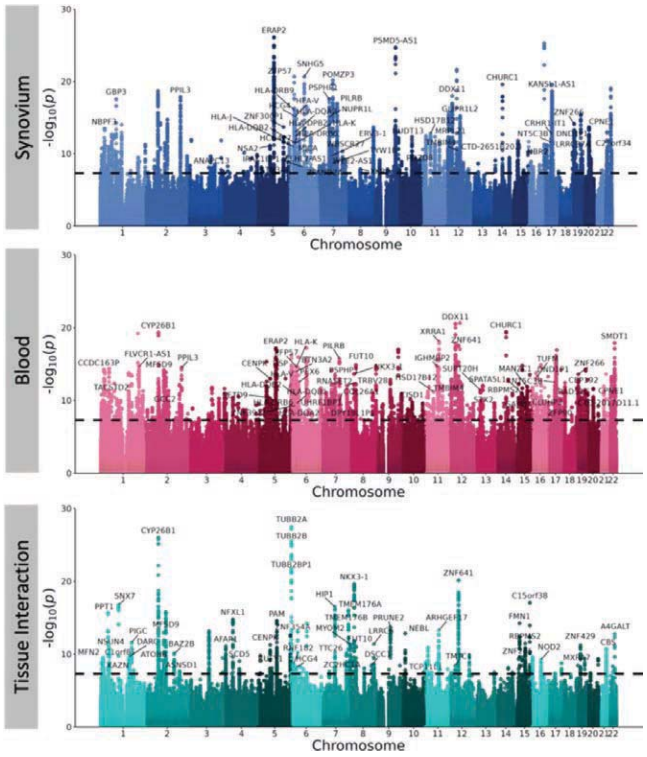

Figure 1. Manhattan plots for *cis*-expression quantitative trait loci (eQTL) analysis performed on 85 synovial samples (top) and 51 blood samples (middle). Tissue interaction eQTL (bottom) show significant differences between tissues ($p \leq 5x10^{-8}$).

Conclusion: The high significance of genes in the HLA region in both tissues is in-keeping with the strong association between HLA and susceptibility to RA, as well as other autoimmune diseases. Most notably variants linked to *HLA-DPB2* synovial expression were found to be a marker for disease severity through ESR association. Additionally, the significant differences between eQTL in blood and synovium highlight the need to explore functional consequences of genetic associations in the diseased tissue directly.

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with unknown etiology involving multiple immune cells and has diverse clinical phenotypes. This heterogeneous nature has hampered a better understanding of SLE pathogenesis and the development of effective therapeutic agents. While recent single-cell RNA sequencing studies of SLE identified several important cell subpopulations, they were limited by sparse expression information at single-cell level and small sample sizes.

Objectives: This study aimed to elucidate the dysregulated gene expression pattern linked to multiple clinical statuses of SLE with a fine cellular resolution and higher sensitivity. We also attempted to resolve a complex interaction between risk variants and the transcriptome dysregulation seen in SLE patients.

Methods: We conducted a large-scale bulk transcriptome study of 6,386 RNA-sequencing data including 27 purified immune cell types in peripheral blood from 136 SLE and 89 healthy donors in the Immune Cell Gene Expression Atlas from the University of Tokyo (ImmuNexUT) cohort[1]. At enrollment, SLE patients had diverse clinical manifestations (disease activity, organ involvement and treatment profiles) and 22 patients were re-evaluated after belimumab treatment.

Results: We first profiled two distinct cell-type-specific transcriptomic signatures: disease-state and disease-activity signatures, reflecting disease establishment and exacerbation, respectively.

After confirming the high replicability of both signatures in independent cohorts, we identified candidates of biological processes unique to each signature: e.g., upregulated *E2F* transcriptional activity in Th1, CD8+ memory T-lineage and NK cells, and dynamic increase of *IL21* and *CXCL13* in Th1 cells in an active phase of SLE. Pathway analysis highlighted the importance of immunometabolic process for SLE (e.g., oxidative phosphorylation) in cell-type-specific resolution.

Moreover, we demonstrated cell-type-specific contributions to diverse organ involvement, e.g., Th1 for mucocutaneous, monocyte-lineage cells for musculoskeletal, neutrophil-lineage cells for renal activity, respectively.

We also observed the strong associations of disease-activity signatures with treatment effect: (i) belimumab suppressed activity signatures from B-lineage cells, especially in good responders and (ii) mycophenolate mofetil substantially suppressed activity signatures from plasmablast, Th1, and central memory CD8 cells.

However, through stratified LD score regression using large-scale SLE-GWASs, we revealed that disease-activity signatures were less enriched around SLE risk variants than disease-state signatures. Consistent with this result, the directions of SLE risk alleles' expression quantitative trait locus (eQTL) effects were significantly concordant with the directions of disease-state signatures, but not with those of activity signatures. These findings suggested that the current genetic case-control studies may not well capture clinically vital biology linked to drug target discovery for SLE. Meanwhile, we also detected some examples of activity signatures that might contribute to the disease risk by modulating risk allele's eQTL effects.

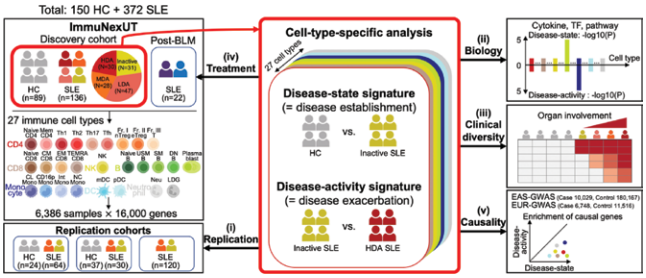

Figure 1.

Conclusion: We identified comprehensive gene signatures reflecting the establishment and exacerbation of SLE, which provide essential foundations for future genomic, genetic, and clinical studies.

Background: Sjogren's disease (SjD) is an autoimmune disease characterized by reduced function of exocrine glands (i.e., salivary and lacrimal glands). Epithelial cell damage resulting from lymphocytic infiltration has been implicated in SjD etiology [1]. How genetic and epigenetic changes influence epithelial-immune cell interactions in SjD pathogenesis remain understudied.

Objectives: Evaluate the role of SjD risk loci in salivary gland tissue to gain insights into the potential genes involved in salivary gland dysfunction.

Methods: SNPs from 16 regions with SNP-SjD associations (P<5x10-8) in our GWAS study (3232 SjD cases) and meta-analysis of ImmunoChip data (619 SjD cases) [2] were interrogated for eQTLs using Genotype-Tissue Expression (GTEx) minor salivary gland data. Subsequent analysis identified genes that were both eQTLs in the minor salivary gland and significantly expressed in RNA-seq and ATAC-seq data from the submaxillary salivary gland epithelial cell line, A253. Pathway enrichment analysis was performed using gProfiler on the genes where coalescence of eQTL, RNA-seq, and ATAC-seq data was observed. To further validate the results, we performed transcriptome-wide association study (TWAS) analysis using GWAS summary statistics and minor salivary gland eQTL GTEx data.

Results: In total, 5884 genome-wide significant SNPs from 16 SjD risk loci were identified as potential minor salivary gland eQTLs using two discovery thresholds: p(FDR)<0.05 provided by eQTL study (3566 SNPs) and p(FDR)>0.05 and p<0.05 in eQTL study (2318 SNPs). Further analysis revealed 10 SjD risk loci with SNPs that were minor salivary gland eQTLs for a total of 155 unique genes that had a coalescence of RNA- and ATAC-seq data in A253 cells. Many SNPs altered the expression of the nearest gene to the risk allele (i.e., index gene), such as *IRF5* and *TNPO3* on chromosome 7 at 128Mb; however, this locus had 12 additional genes that were eQTLs in minor salivary gland. In contrast, other loci had no reported eQTLs for the index gene, but several reported eQTLs for other genes, such *TYK2* on chromosome 19 at 10Mb that showed no change in *TYK2* expression but eQTLs for 8 distant genes, including *ICAM1*. Pathway enrichment analysis revealed an enrichment in Butyrophilin (BTN) family interactions (R-HSA-8851) (PAdj=1.564x10-5), including the *BTN2A1*, *BTN2A2*, *BTN3A1*, *BTN3A2* and *BTN3A3* gene cluster in the MHC region. In further support, TWAS of the minor salivary gland and the SjD GWAS summary statistics (after Bonferroni correction) showed association between SjD and *BTN3A2* (p=1.24x10-42), as well as many other loci in the MHC region. In addition, several long non-coding (lnc) RNAs on chromosome 17 were significant, peaking at *RP11-259G18.1* (p=4.43x10-10).

Conclusion: This study shows that SjD-associated risk alleles influence disease by altering gene expression in immune cells and minor salivary glands. Further, our analysis suggests that altered gene expression in the minor salivary gland expands beyond effects on the index gene to several genes on each locus. Interestingly, we observed minor salivary gland eQTLs for several BTN family genes, which act as cell-surface binding partners to regulate cell-cell interactions, including interactions between epithelial cells and activated T cells [3]. Future work will assess chromatin-chromatin-interactions within the 10 SjD risk loci in salivary gland cells and tissues to map local chromatin regulatory networks that regulate gene expression. Additional transcriptional studies of SjD minor salivary gland tissues will provide further insights into how altered gene expression in the salivary gland influences SjD pathology.

Background: Genome-wide association studies (GWASs) have identified 29 disease-associated single nucleotide polymorphisms (SNPs) for systemic sclerosis (SSc) in non-human leukocyte antigen (HLA) regions (1-7). While these GWASs have clarified genetic architectures of SSc, study subjects were mainly Caucasians limiting application of the findings to Asians.

Objectives: The study was conducted to identify novel causal variants for SSc specific to Japanese subjects as well as those shared with European population. We also aimed to clarify mechanistic effects of the variants on pathogenesis of SSc.

Methods: A total of 114,108 subjects comprising 1,499 cases and 112,609 controls were enrolled in the two-staged study leading to the ever-largest Asian GWAS for SSc. After applying a strict quality control both for genotype and samples, imputation was conducted using the reference panel of the phase 3v5 1,000 genome project data combined with a high-depth whole-genome sequence data of 3,256 Japanese subjects. We conducted logistic regression analyses and also combined the Japanese GWAS results with those of Europeans (6) by an inverse-variance fixed-effect model. Polygenicity and enrichment of functional annotations were evaluated by linkage disequilibrium score regression (LDSC), Haploreg and IMPACT programs. We also constructed polygenic risk score (PRS) to predict SSc development.

Results: We identified three (*FCRLA-FCGR*, *TNFAIP3*, *PLD4*) and four (*EOMES*, *ESR1*, *SLC12A5*, *TPI1P2*) novel loci in Japanese GWAS and a trans-population meta-analysis, respectively. One of Japanese novel risk SNPs, rs6697139, located within *FCGR* gene clusters had a strong effect size (OR 2.05, $P=4.9\times10^{-11}$). We also found the complete LD variant, rs10917688, was positioned in cis-regulatory element and binding motif for an immunomodulatory transcription factor IRF8 in B cells, another genome-wide significant locus in our trans-ethnic meta-analysis and the previous European GWAS. Notably, the association of risk allele of rs10917688 was significant only in the presence of the risk allele of the *IRF8*. Intriguingly, rs10917688 was annotated as one enhancer-related histone marks, H3K4me1, in B cells, implying that *FCGR* gene(s) in B cells may play an important role in the pathogenesis of SSc. Furhtermore, significant heritability enrichment of active histone marks and a transcription factor C-Myc were found in B cells both in European and Japanese populations by LDSC and IMPACT, highlighting a possibility of a shared disease mechanism where abnormal B-cell activation may be one of the key drivers for the disease development. Finally, PRS using effects sizes of European GWAS moderately fit in the development of Japanese SSc (AUC 0.593), paving a path to personalized medicine for SSc.

Conclusion: Our study identified seven novel susceptibility loci in SSc. Downstream analyses highlighted a novel disease mechanism of SSc where an interactive role of *FCGR* gene(s) and IRF8 may accelerate the disease development and B cells may play a key role on the pathogenesis of SSc.

FUNCTIONAL GENOMICS IN PRIMARY T CELLS AND MONOCYTES IDENTIFIES MECHANISMS BY WHICH GENETIC SUSCEPTIBILITY LOCI INFLUENCE SYSTEMIC SCLEROSIS RISK

D. Gonzalez Serna[1], C. Shi[2], M. Kerick[1], J. Hankinson[3], J. Ding[2], A. McGovern[2], M. Tutino[3], N. Ortego[4], J. L. Callejas-Rubio[4], J. Martin Ibanez[1], G. Orozco[2,5]. Background: Systemic sclerosis (SSc) is a complex autoimmune disease with a strong genetic component. However, the underlying mechanism by which genetics increase disease risk is still unknown. The most recent GWAS studies have identified 27 independent signals associated to SSc [1]. However, the majority of these signals affect regulatory elements that can regulate genes often located hundreds of kilobases away.

The challenge in the post-GWAS era is to use functional genomics to translate genetic findings into patients' benefit, particularly in disease-relevant cell types.

Objectives: In this study we use chromatin conformation and gene expression analysis in patient derived primary cells and healthy individuals to assess potential mechanisms by which GWAS variants increase disease risk. We identify the potentially affected genes in a cell type specific manner and potential drug targets already in use or with potential for re-purposing.

Methods: Promoter capture Hi-C (pCHi-C) and RNA sequencing experiments were performed in a total of 15 CD4+ T cells and CD14+ monocytes samples each isolated from peripheral blood from SSc patients and healthy controls. We linked SSc-associated variants with their target genes and performed differential expression and differential interaction analyses between both cell types. Potential drug targets were identified using a protein-protein interaction model and queried against the OpenTargets database.

Results: We linked SSc-associated loci to 39 new potential target genes, confirming 7 previously assigned genes. We highlight novel causal genes, such as *CXCR5* as the most probable candidate gene for the *DDX6* locus (Figure 1). We confirm some previously linked SSc genes such as *IRF8*, *STAT4*, or *CD247* which interestingly showed cell type specific interactions. We also identified 15 potential drug targets already in use in other similar immune-mediated diseases that could be repurposed for SSc treatment. Furthermore, we observed that interactions are directly related with the expression of important genes implicated in cell type specific pathways.

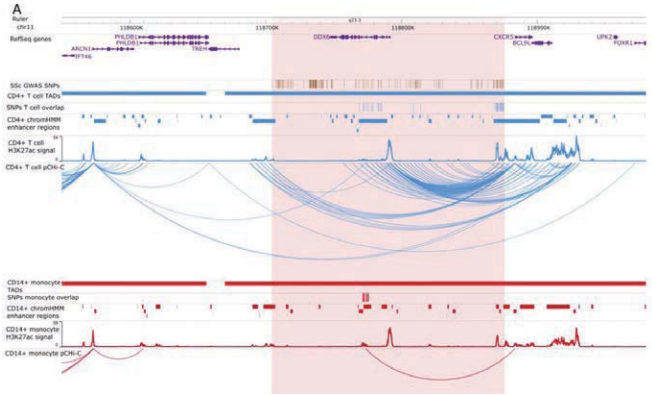

Figure 1. Promoter Capture Hi-C interactions linking the *DDX6* GWAS loci with the promoter of *CXCR5* in CD4+ T cells and CD14+ monocytes. CD4+ T cells show significantly stronger interactions as well as *CXCR5* gene expression.

Conclusion: Our study reveals potential causal genes for SSc-associated loci, some of them acting in a cell type specific manner, suggesting novel drug targets and biological mechanisms that may mediate SSc pathogenesis.

OP0114 IDENTIFICATION AND FUNCTIONAL PREDICTION OF LONG NONCODING RNA RELATED TO CONNECTIVE TISSUE DISEASE-ASSOCIATED INTERSTITIAL LUNG DISEASES

F. Dai[1], Q. B. Zhang[2], Y. X. He[1], Y. P. Tang[1], T. Y. Lei[1], Y. Jiang[1], Y. F. Qing[1].
[1]Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Nanchong, China; *[2]Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Geriatrics, the Affiliated Hospital of North Sichuan Medical College, Nanchong, China*

Background: Recently, the role of long noncoding RNA (lncRNA) in rheumatic immune diseases has attracted widespread attention[1]. However, knowledge of lncRNA in connective tissue disease-associated interstitial lung disease (CTD-ILD) is limited.

Objectives: To explore the expression profile of lncRNA in peripheral blood mononuclear cells (PBMCs) of CTD-ILD patients and the possible mechanisms of significantly differentially expressed lncRNA involved in CTD-ILD, especially systemic sclerosis (SSc)-ILD and rheumatoid arthritis (RA)-ILD.

Methods: LncRNA microarray analysis was used to identify the pattern of lncRNA dysregulation between CTD-ILD and connective tissue disease without associated interstitial lung disease (CTD-NILD). Differential genes were identified by bioinformatic analysis. Relative expression levels of five differentially expressed lncRNAs in 120 SSc and RA patients with or without ILD were detected by quantitative reverse-transcription PCR (qRT-PCR).

Results: The differential gene expression analysis revealed 46 lncRNAs were upregulated while 194 lncRNAs were downregulated in the CTD-ILD group compared to the CTD-NILD group (Figure 1). Gene Ontology and Kyoto Encyclopedia of Genes and Genomes pathway analyses identified several significant biological processes and signaling pathways, including NF-kappa B signaling pathway, IL-17 signaling pathway, Toll-like receptor signaling pathway, B cell receptor signaling pathway. QRT-PCR confirmed that the selected target genes were differentially expressed in different groups. In particular, the ENST00000604692 expression level was significantly higher in the ILD than the NILD group ($p<0.05$, Figure 1); T311354 and arginase-1were significantly higher in SSc than RA group; Furthermore, the area under receiver operating characteristic curve for ENST00000604692 in predicting ILD from NILD was 0.797 (Figure 1).

Conclusion: This research has demonstrated, for the first time, the specific profile of lncRNA in PBMCs of CTD-ILD patients and the potential signal pathways related to the pathogenesis of CTD-ILD. ENST00000604692 can effectively distinguish ILD group from NILD group,which may be a diagnostic indicator of CTD-ILD, especially SSc-ILD and RA-ILD.

Background: The development of a tool capable of identifying patients suffering the rapid progressive knee Osteoarthritis (RPOA) was established as a goal to implement prevention strategies and to include them in clinical trials. Previous studies showed that mitochondrial DNA (mtDNA) variation plays a role on the incidence and progression of OA, but their influence on the development of RPOA is unknown.

Objectives: To find new mtDNA variants related to RPOA in order to develop a predictive model based on genetic and clinical variables.

To find out the functional significance of these variants using transmitochondrial cybrids.

Methods: We used data from three independent prospective cohorts of patients: the Osteoarthritis Initiative (OAI) (N=1102) and the pooling of two European cohorts as replication cohort (N=706): the Cohort Hip and Cohort Knee (CHECK) and the Prospective Cohort of Osteoarthritis from A Coruña (PROCOAC). We classified the patients based on the following criteria:

- Rapid progressors (N Discovery=268, N Replication=107), subjects with baseline KL grade 0-1 and increase up to KL≥3 during 48-month follow-up; or baseline KL grade 2 and increase up to KL grade 4 during the follow-up.
- Non-rapid progressors (N Discovery=827, N Replication=592), subjects with the same baseline characteristics as rapid progressors, but with a slower or no evolution over time.

mtDNA variants were screened in the OAI by in-depth sequencing. Resulting variant was analyzed in the replication cohort by mini-sequencing techniques. Appropriate statistical approaches adjusting for confounding variables followed by a meta-analysis were applied.

We developed a functional study using two types of transmitochondrial cybrids carrying the most common haplogroup H: one harboring the mtDNA variant m.16519C and the other the wild type m.16519T. Cybrids were used to assess mitochondrial biosynthesis and mitochondrial fission/fusion by gene expression analyses, as well as cell viability to oxidative stress and mitochondrial reactive oxygen species (ROS) production.

Results: The in-depth sequencing of mtDNA showed the D-loop variant mt16519C significantly overrepresented in rapid-progressors (OR=1,558;95%CI=1,148-2,113;nominal p-value=0,004; Benjamini-Hochberg corrected p-value=0,044). The analysis of this variant in the replication cohort showed a similar significant trend (OR=1,647;95%CI=1,013-2,678; p=0,043).

The logistic regression model revealed that, regardless of the different clinical variables, the variant m.16519C was significantly associated with RPOA in the OAI cohort (OR=1,559;95%CI=1,125-2,161; p=0,008) (Table 1). The development of this model in the replication cohort showed a similar trend that borderlined the statistical significance (OR=1,506;95%CI=0,848-2,675;p=0,162) (Table 1). The subsequent meta-analysis for both ORs showed the variant m.16519C significantly associated with RPOA (OR=1,58;95% CI=1,22-2,05;p=0,0027) (Figure 1).

Table 1. Binary regression model including clinical variables and m.16519C in both cohorts.

Variable	A. Discovery				B. Replication			
	Sig.	O.R.	95% CI O.R.		Sig.	O.R.	95% CI O.R.	
			min	MAX			min	MAX
Age	<0,001*	1,054	1,036	1,072	0,138	0,972	0,937	1,009
BMI	<0,001*	1,073	1,037	1,110	0,727	1,010	0,957	1,066
Sex (Female)	0,142	1,258	0,926	1,710	0,190	1,582	0,796	3,144
Contralateral OA (Yes)	<0,001*	2,475	1,830	3,348	0,048*	2,056	1,005	4,208
WOMAC	<0,001*	1,122	1,065	1,183	0,060	1,062	0,997	1,130
mt.16519C	0,008*	1,559	1,125	2,161	0,162	1,506	0,848	2,675

BMI: Body Mass Index; WOMAC: Western Ontario and McMaster Universities Osteoarthritis Index; OR: Odds Ratio; CI: confidence interval; *: statistical significance declared at P < 0.05

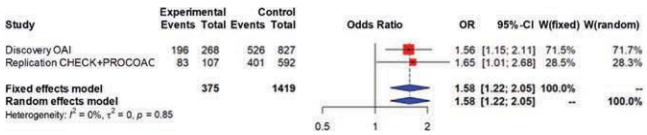

Figure 1. Forest plot of the meta-analysis of the ORs of the two predictive models

Cybrids harboring the mtDNA variant m.16519C showed lower levels of *PGC-1α* (p=0,0024) and *FIS1* (p=0,0519) than cybrids with the wild type. In addition, cybrids harboring the variant m.16519C showed lower average cell survival under oxidative stress conditions (23,42±8,88 vs 115,7±64,1;p=0,0043), as well as higher mitochondrial ROS production (4,21±1,29 vs 2,21±1,34;p=0,014).

Conclusion: D-loop variant m.16519C increases the risk of developing a rapid progression of knee OA. Among the effects caused by this variant both mitochondrial biogenesis and fission/fusion processes, as well as cell survival under oxidative stress conditions and mitochondrial ROS production seem to be affected

OP0116-HPR

PATIENTS' EXPERIENCES OF GROUP-BASED COGNITIVE BEHAVIOURAL THERAPY FOR INSOMNIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: A QUALITATIVE STUDY

K. M. Latocha[1], K. Løppenthin[2,3], P. Jennum[3,4], M. Østergaard[3,5], R. Christensen[6,7], B. A. Esbensen[3,5]. *[1]Copenhagen University Hospital - Rigshospitalet, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; *[2]Copenhagen University Hospital - Rigshospitalet, Centre for Cancer and Organ diseases, Department of Oncology, Copenhagen, Denmark*; *[3]University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark*; *[4]Copenhagen University Hospital - Rigshospitalet, Danish Center for Sleep Medicine, Department of Clinical Neurophysiology, Glostrup, Denmark*; *[5]Copenhagen University Hospital - Rigshospitalet, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; *[6]Copenhagen University Hospital - Bispebjerg and Frederiksberg, Section for Biostatistics and Evidence-Based Research, the Parker Institute, Copenhagen, Denmark*; *[7]University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense, Denmark*

Background: Despite disease-modifying anti-rheumatic drugs, residual arthritis-related symptoms and burdens are still common in patients with rheumatoid arthritis (RA)[1]. In addition, insomnia – characterised by reduced sleep quantity and quality – is highly prevalent, occurring in up to 70% of patients with RA[2]. Insomnia is associated with increased pain, fatigue, and depressive symptoms. Cognitive behavioural therapy for insomnia (CBT-I) is recommended first-line treatment for chronic insomnia[3] but has not been evaluated in patients with RA until now.

Objectives: The objective of this study was to explore patients' experiences of CBT-I and how the components of CBT-I are incorporated in their sleep management.

Methods: Participants were patients with RA who had received CBT-I as experimental treatment for insomnia in a randomised controlled trial (RCT)[4]. Data were collected during an individual face-to-face interview using a semi-structured interview guide. The analysis was based on reflexive thematic method by Braun and Clarke[5].

Results: Eleven participants (10 women and one man) from the intervention group of the RCT were interviewed. Prior to inclusion in the RCT, they had insomnia complaints for 8 years (median; interquartile range: 3;20 years).

Five themes emerged: 1) *When knowledge contributes to an altered perception of sleep* referring to the reduced misperception and increased motivation that followed sleep education, 2) *Overcoming habits and perceptions to accelerate sleep onset* referring to barriers related to sleep behaviour and mindset and how stimulus control was enabling them to find meaningful behaviour and rhythm, 3) *The sleep window of challenges in learning how to sleep right* referring to that payoff from sleep restriction did not come easily or by magic, and commitment led to progress and gave them confidence to continue, 4) *Relaxation becomes a behavioural habit and goes beyond sleep* referring to a means to achieve a relaxed body and mind and how they thereby coped better with RA-related symptoms, and 5) *Break the cycle and regain control* referring to how awareness of a vicious cycle was central to their perception of sleep and how trust in one's own accomplishment was crucial to reducing worrying (See Figure 1).

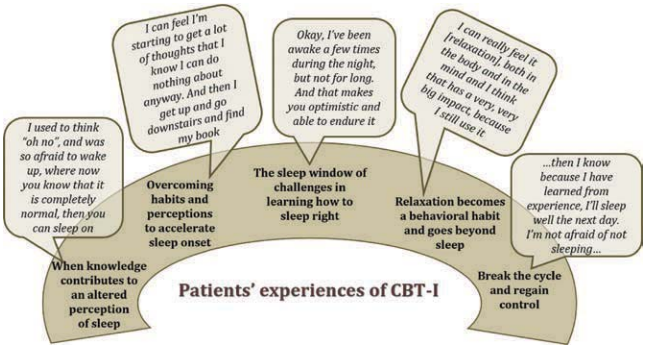

Figure 1. The five themes with quotes from participants

Overall, the participants experienced CBT-I as challenging and demanding but at the same time meaningful. The participants considered persistency, stringency, and inflexibility necessary to succeed. After the intervention, the participants had continued using those components that enabled them individually to further improve their sleep.

Conclusion: The process towards eliminating insomnia was a bodily experience and involved a changed mindset that altered behaviour and cognitions.

OP0117-HPR FROM CURE TO COPING: EXPLORING TASK-SHIFTING BETWEEN NORWEGIAN RHEUMATOLOGISTS AND OCCUPATIONAL THERAPISTS IN THE CARE OF HAND OSTEOARTHRITIS

S. Zink[1], I. Kjeken[1], M. Feiring[1,2]. *[1]Diakonhjemmet Hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway*; *[2]Oslo Metropolitan University, Department of Physiotherapy, Oslo, Norway*

Background: Task-shifting between physicians and other health professionals is increasingly used as a strategy to optimise health care services. However, there is a lack of evidence regarding task-shifting within the field of rheumatology, specifically hand osteoarthritis (HOA). HOA is a highly prevalent rheumatic joint disease, and the number of people living with debilitating HOA will continue to rise in the coming decades [1, 2]. HOA is diagnosed based on clinical examination and the first choice of treatment is non-pharmacological. Despite this, patients with HOA are increasingly referred to rheumatologists (RTs) in specialist care, contributing to long wait times and bottle-necks within the health care service. A possible solution to this challenge is task-shifting to occupational therapists (OTs).

Objectives: To explore the process of task-shifting in the care of patients with HOA between RTs and OTs in a Norwegian health care context.

Methods: This is a multi-centre qualitative study. Individual semi-structured interviews were conducted in-person or digitally with RTs and OTs between December 2020-June 2021.They were audio-recorded and transcribed verbatim. Reflexive Thematic Analysis was employed to analyse the data, and carried out in NVivo.

Results: In total, 17 participants were interviewed; 9 RTs and 8 OTs. Majority of respondents were female (n= 14), had an average of 20,5 years of experience and were 48,5 years old. Interviews lasted on average 90 minutes, (range: 45-120 minutes). The analysis resulted in 5 main themes

(1) Attitudes towards task-shifting of HOA care: Both RTs and OTs were overwhelmingly positive about task-shifting and reported OTs to be better suited caring for patients with HOA than RTs. There was agreement amongst RTs that generally, they had little to offer HOA patients besides information.

(*2) Desirability of caring for HOA*: RTs felt no occupational "ownership" of the HOA diagnosis due to the lack of curative medical treatment, and would prefer HOA patients to be seen by an OT. OTs on the other hand perceived themselves as a profession with tools, skills and competencies that would benefit patients with HOA.*3) Practical and theoretical knowledge:* OTs and RTs viewed different kinds of knowledge as central for task-shifting. Respondents emphasised that OTs must have good anatomical knowledge of the hand and confidence in identifying differential diagnoses that could potentially be more serious. Lack of knowledge lead to insecurity and hampered successful implementation of task-shifting. (*4) Communication between RTs and OTs:* RTs perceived OTs to be passive in communicating their willingness and competence in caring for this patient group. They expressed a wish for more "self-promotion" from OTs. OTs and RTs viewed communication between them as essential for task shifting. Good communication, understanding and inquisitive conversations acted as facilitators.

(5) *The importance of informal interpersonal relationships in the workplace:* Informal interpersonal relationships facilitated trust and subsequent task-shifting between RTs and OTs. Personal relations directly affected engagement in the task-shifting process.

Conclusion: The findings show a unanimous wish for HOA care to be shifted from RTs to OTs. Attitudes towards HOA as a diagnosis, interpersonal relationships between RTs and OTs, and knowledge are key facilitators and barriers affecting this process. The findings contribute to the growing body of knowledge on strategies used to optimise health care services and can be used in the design and implementation of new care pathways for patients with HOA.

OP0118-HPR GAMING FOR ADHERENCE TO MEDICATION USING E-HEALTH IN RHEUMATOID ARTHRITIS (GAMER) STUDY – A RANDOMISED CLINICAL TRIAL

B. Pouls[1,2], C. Bekker[2], J. E. Vriezekolk[1], S. van Dulmen[2,3], B. van den Bemt[1,2]. *[1]Sint Maartenskliniek, Department of Rheumatology Research, Nijmegen, Netherlands*; *[2]RadboudUMC, Radboud Institute for Health Sciences, Nijmegen, Netherlands*; *[3]Netherlands Institute for Health Services Research, Healthcare Communication, Utrecht, Netherlands*

Background: Effectiveness of pharmacological therapy in rheumatoid arthritis (RA) is limited by inadequate medication adherence. Medication adherence can be influenced by implicit attitudes of personal medication needs and concerns about adverse consequences. We targeted these implicit attitudes using a serious puzzle game.

Objectives: To assess the effectiveness of a serious game compared to usual care to improve adherence to disease modifying anti-rheumatic drugs (DMARDs) in patients with rheumatoid arthritis (RA).

Methods: A multicentre randomised clinical trial was performed with a 3 month follow-up period.[1] Inclusion criteria were adulthood, RA diagnosis, use of DMARDs and possession of a smartphone/tablet. All participants received usual care. In addition, intervention participants were invited to play the serious puzzle game at will. The game was designed to influence players' attitudes toward medication.[2] Collected data consisted of serious game play data, Compliance Questionnaire in Rheumatology (CQR), Beliefs about Medication Questionnaire (BMQ), Health Assessment Questionnaire (HAQ) and Rheumatoid Arthritis Disease Activity Index (RADAI).

Primary outcome was DMARD implementation adherence at three months assessed as the difference in proportion of non-adherent patients (<80% taking adherence) between intervention and control group using the discriminant function of the CQR using the Chi-squared test.

Two sample t-tests and Wilcoxon rank-sum test were performed to test for differences on secondary outcomes between study groups where appropriate.

Results: 229 participants were randomised and 186 participants completed the study. Of the 85 intervention participants, 70 (82%) played the serious game for at least one hour. The serious game was played a median of 36 sessions with an average playtime of 25 minutes leading to a median overall playtime of 9.7 hours. A total of 59 (69%) intervention participants showed at least 40 days of gaming activity. Control group adherence (54%) and intervention group adherence (63%) based on the dichotomised CQR-score did not differ at three months (p = 0.26) (see Table 1). Neither was there a significant difference in CQR continuous score (p = 0.20), beliefs about medication differential score (p = 0.43) or clinical outcomes (HAQ: p = 0.97; RADAI: p = 0.90) (see Table 1).

Table 1. Study outcomes at end-point (3 months)

	Control group (n=101)	*Intervention group (n=85)*	*p-value*
Primary outcome			
Adherent	55 (54)	52 (63)	0.26
*no. (%)**			
Secondary medication outcomes			
CQR continuous	75 ± 12	73 ± 11	0.20
mean ± SD			
BMQ-Specific NCD score	4.8 ± 4.2	5.3 ± 4.7	0.43
mean ± SD			
Secondary clinical outcomes			
RADAI score	2.5 [1.2 – 4.0]	2.5 [1.5 – 4.2]	0.90
median [IQR]			
HAQ score	0.8 [0.3 – 1.4]	0.6 [0.3 – 1.4]	0.97
median [IQR]			

Abbreviations: no. – number; SD – standard deviation; CQR – Compliance Questionnaire on Rheumatology; BMQ – Beliefs about Medication questionnaire; IQR – interquartile range* *Percentage of the total number of participants excluding missing data.*

Conclusion: This multicentre randomised clinical trial showed that a serious puzzle game aimed at reinforcing a positive attitude towards DMARDs was frequently played during three months. Playing the game did not improve medication adherence nor influenced beliefs about medication or clinical outcomes in RA patients.

OP0119-HPR WHO ACCEPTS OR DECLINES AN INVITATION TO CARDIOVASCULAR SCREENING – A REGISTER STUDY ON PATIENTS WITH RHEUMATOID ARTHRITIS

J. K. Karstensen[1,2,3], A. Bremander[1,2,4,5], J. Reffstrup Christensen[6,7,8], J. Primdahl[1,2,9]. *[1]Department of Regional Health Research, University of Southern Denmark, Odense, Denmark*; *[2]Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; *[3]The DANBIO Registry, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*; *[4]Spenshult Research and Development Centre,, Halmstad, Sweden*; *[5]Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden*; *[6]Research Unit of General Practice, Department of Public Health, University of Southern Denmark, Odense, Denmark*; *[7]User Perspectives and Community-based Interventions, Department of Public Health, University of Southern Denmark, Odense, Denmark*; *[8]Research Unit of General Practice,, Aarhus, Denmark; [9]Sygehus Sønderjylland, University Hospital of Southern Denmark, Aabenraa, Denmark*

Background: At the Danish Hospital for Rheumatic Diseases, patients with rheumatoid arthritis (RA) have been invited to systematic cardiovascular (CV) risk assessments since 2011, in accordance with the EULAR recommendations.(1). Patients who are assessed to have high or very high risk for CV death according to the modified Systematic Coronary Risk Evaluation (mSCORE) (SCORE multiplied by 1.5) (1, 2) or have known CV disease or diabetes mellitus, are invited to a follow-up screening consultation after one year. Information about who accepts vs. declines the CV screening invitation can help optimize the screening and tailor it to individual needs.

Objectives: I) to explore participation in the systematic CV risk assessment for patients with RA; II) explore differences between patients with high risk who accepted vs. declined a follow-up screening and III) explore differences in additional CV risk factors not included in the mSCORE between patients with low vs. high risk.

Methods: Data from all outpatients with RA connected to the Danish Hospital for Rheumatic Diseases in the period 2011-2021 were retrieved from the national rheumatology quality database, DANBIO. Differences between patients with a mSCORE (≥5%) who accepted vs. declined a follow-up consultation in terms of triglycerides, long-term blood sugar, lifestyle factors (alcohol consumption, physical activity level and waist circumference) and measures of disease impact (pain, fatigue, patient global assessment, HAQ and EQ-5D-5L) were analysed using Wilcoxon rank sum test and Fisher's exact test for groups. Crude and multiple regression analyses using the same explanatory variables, were performed to explore differences between patients with a low to moderate (<5%) vs. high to very high (≥5%) risk.

Results: Data were retrieved from 2.222 patients, of which 1.608 (72%) had been invited to screening consultations. 614 (28%) had not been invited and of these 139 (23%) were 75 years or older. 354 (22%) declined and 1.254 (78%) patients accepted the invitation. The patients who declined the invitation were older (mean 78.37 (SD 14.82) vs. mean 63.40 (SD 10.88) and had longer disease duration (mean 15.4 (SD 12.05) vs. mean 10.11 (SD 10.64)) compared to patients who had participated in a CV screening consultation. After excluding patients above 70 years of age, 888 patients remained, including patients with known CV disease or diabetes mellitus. Of these, 162 (18%) had a high or very high risk for CV death within ten years and 93 (57%) of these accepted a follow-up screening consultation. There were no significant differences between patients with a mSCORE ≥ 5% who accepted vs. declined a follow-up consultation in any of the studied variables. In the crude analyses, a significant difference was only found between patients with low to moderate vs. high or very high risk in triglycerides OR 1.70 (95% CI 1.20-2.28) and high waist circumference for women, OR 11.90 (95% CI 4.64-30.52). However, no significant differences were found between the two groups in the multivariate analysis.

Conclusion: Eight out of ten patients with RA accepted the first invitation to a CV screening consultation, and 2/3 of the patients with high or very risk for CV death adhered to a follow-up invitation. This study could not identify differences between patients with high risk SCORE who accepted vs. declined a follow-up CV screening. There is a need to explore barriers and facilitators for patients' adherence to CV screening.

OP0120-HPR IMPACT OF DIFFERENT TYPES OF PHYSICAL ACTIVITY PROGRAMS ON ANKYLOSING SPONDYLITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

J. Sigaux[1,2], R. Boudjani[1], S. Challal[1], L. Semerano[1,2]. *[1]Avicenne Hospital, Rheumatology, Bobigny, France*; *[2]Sorbonne Paris Nord University, INSERM UMR 1125, Bobigny, France*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease characterized by inflammation and ankylosis of the spine. Spinal ankylosis is responsible for significant morbidity and disability. Despite public health campaigns supporting the benefits of physical activity (PA) the average level of PA in patients with AS is low.

Objectives: This systematic review and meta-analysis of controlled studies aimed to assess the efficacy of different types of physical activity (PA) programs on ankylosing spondylitis (AS) activity, function and mobility.

Methods: We searched PubMed/Medline, Cochrane Library and Embase databases for reports of controlled trials of patients with AS with at least one activity or function outcome published up to August 2020. The studies were classified by intervention into categories defined by the 4 dimensions of PA established by the World Health Organization: aerobic, muscle strength, flexibility and neuromotor performance. We performed both overall (including any kind of PA) and subgroup analysis by type of PA program.

Results: Forty-three studies were included in qualitative synthesis and 27 in meta-analysis. The overall analysis showed a moderate effect of PA on BASDAI (-0.57, 95% CI -0.92,-0.21, p=0.002), BASFI (-0.63, 95% CI -0.85,-0.42, p<0.0001) and BASMI (-0.58, 95% CI -1.02,-0.14, p=0.01). The effect of "flexibility+muscle strength exercises" PA was large for BASMI (-1.03, 95% CI -1.64,-0.42, p=0.0009), moderate for BASDAI (-0.56, 95% CI -1.07,-0.05, p=0.03) and BASFI (-0.63, 95% CI -0.88,-0.39, p<0.005). Home-based unsupervised "flexibility+muscle strength exercises" programs improved the BASFI but not BASDAI. The effect of "flexibility+muscle strength+aerobic exercises" PA was large for BASFI (-1.26, 95% CI -1.70,-0.81, p<0.005), moderate for BASDAI (-0.77, 95% CI -1.40,-0.14, p=0.02).

Conclusion: PA has a moderate effect on AS activity and function. Programs including flexibility and muscle strength exercises may have a large effect, especially for spinal mobility. Programs including aerobic exercise showed significant efficacy for function.

HPR: From prevention to management

OP0121-HPR THE SELF- AND SHARED-MANAGEMENT OF JIA: A NEW FRAMEWORK FOR RESEARCH, POLICY, AND PRACTICE

S. Stones[1,2], V. Swallow[1,3], L. Milnes[1]. [1]*University of Leeds, School of Healthcare, Leeds, United Kingdom*; [2]*Envision Pharma Group, Engage Scientific Solutions, Wilmslow, United Kingdom*; [3]*Sheffield Hallam University, Department of Nursing & Midwifery, Sheffield, United Kingdom*

Background: Juvenile idiopathic arthritis (JIA) is a complex long-term condition requiring lifelong management [1]. Children and young people (CYP) should be empowered to self-manage their health and wellbeing (H&W) from diagnosis [2], while families should be supported in their shared-management role [3]. Self- and shared-management (SSM) interventions can be used to develop SSM capacity [4]; however, few studies have explored SSM in this population.
Objectives: To develop a framework to promote JIA SSM, applicable to CYP, families, and professionals involved in their healthcare, wellbeing, and education.
Methods: Using a realist approach [5] and underpinned by the individual and family self-management theory [6], evidence syntheses and a qualitative study were undertaken to identify, test, and refine a series of theories promoting JIA SSM. The theories developed and tested were referred to as 'question theories', akin to programme or intervention theories, written at a middle level of abstraction to map theory for future research. Twenty stakeholders were interviewed using a teacher-learner cycle approach. Data were analysed using hybrid deductive-inductive thematic analysis and were integrated into a framework promoting JIA SSM at a higher level of abstraction.
Results: Six refined question theories outlining the mechanisms by which the SSM of JIA is likely to transpire, and the different contexts under which interventions achieve their desired outcomes, were developed, and assimilated into a new, JIA-SSM framework. Within the framework, four levels of context related to SSM were identified. These were at an individual and interpersonal level of CYP, families and professionals, and at institutional and infrastructural levels across health and social care, education, and voluntary sectors. Individual healthcare plans can also act as shared-management tools to facilitate communication between CYP, families, and professionals across healthcare, wellbeing, and education.
Conclusion: The JIA-SSM framework encourages a shift towards a multi- intervention, multi-disciplinary, multi-agency approach which works with CYP and families in equipping them with the knowledge, skills, and behaviours to competently manage their H&W. Further research is recommended to apply and validate this framework in practice, to aid future design, delivery, evaluation, and implementation of SSM interventions in JIA.

OP0122-HPR DEVELOPMENT OF A SMARTPHONE APPLICATION FOR TREATMENT OF HAND OSTEOARTHRITIS – HAPPY HANDS

A. T. Tveter[1], T. Blanck[1], S. Nyheim[2], M. Maarnes[1], B. Christensen[1], S. J. Pedersen[3], C. Varsi[4], I. Kjeken[1]. [1]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; [2]*The Norwegian Rheumatism Association, The Norwegian Rheumatism Association, Oslo, Norway*; [3]*University of Oslo, Faculty of Medicine, Oslo, Norway*; [4]*University of South-Eastern Norway, Faculty of Health and Social Sciences, Drammen, Norway*

Background: International recommendations state that all patients with hand osteoarthritis (HOA) should receive education and training in ergonomic principles, use of assistive devices and hand exercises as first-line treatment (1). However, research shows that the quality-of-care service in general is sub-optimal for this patient group, with few patients receiving recommended first-line treatment before being referred to specialist healthcare (2).
Objectives: To make recommended treatment available for patients with HOA by developing a user-friendly self-management application (H*APP*Y Hands).
Methods: The development process was conducted four phases: 1) information needs analysis and patient interviews; 2) app illustrations and prototype development; 3) heuristic evaluation; and 4) pilot-testing.
Two patient research partners were involved in developing the content of the app. Researchers, in collaboration with experienced clinicians, the patient research partners and professional film photographers and animators, developed short informational videos and animations. Illustrations and a prototype of the app was developed in five two-week iterations by the University Center for Information Technology at the University of Oslo (Figure 1). Digital meetings were conducted at the end of each two-week iteration, where illustrations and prototype were discussed with developers, researchers, and patient research partners, informing the next iteration. The H*APP*Y Hands app will be pilot tested in 70 participants with HOA, simultaneously assessing the feasibility and usability of the app.

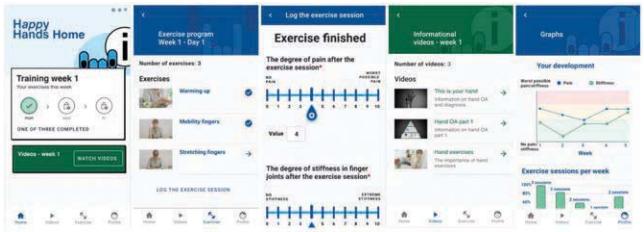

Figure 1. Illustrations of the Happy Hands smartphone application

Results: The prioritized content themes presented by the patient research partners were 1) information about hand OA; 2) goal setting, motivation, and self-efficacy; 3) assistive devices; 4) hand exercises; 5) orthoses; and 6) communication. The app was developed based on a combination of behavioural change techniques informed by Social cognitive theory and the EULAR recommendations on management of HOA. The 12-week intervention consists of 25 short informational videos addressing the prioritized themes. Additionally, the intervention includes a hand exercise program consisting of 8 videos providing instructions on warm up, exercises to improve mobility, strength and coordination, and a stretching exercise. The informational videos and exercise program are delivered in a progressive order over the 12 weeks. When downloading the app, participants are asked to specify when they plan to use the app (three days a week with time points). Thereafter, the patients get a notification on their smartphone with that week's informational videos and hand exercises at the specified days. After each exercise session the patients are asked to rate their pain and stiffness. Their answers are used to generate graphs that visualise their development over the 12-week intervention period. Each month, patients also answer questions about hand function, which they can use to self-monitor their development. Encouragement and motivational messages are provided each week to enhance continued adherence to the intervention. To date, 60 patients have been included in pilot testing of the app.
Conclusion: In this study we successfully implemented a user-centred and iterative approach to develop a e-self-management intervention for treatment of patients with hand OA. The 12-week follow-up in the pilot study will be finished medio May 2022.

OP0123-HPR INVESTIGATION OF THE EFFECTS OF UPPER EXTREMITY HOME EXERCISES ON GRIP STRENGTH, RANGE OF MOTION, ACTIVITY PERFORMANCE AND FUNCTIONALITY IN INDIVIDUALS WITH SCLERODERMA

E. İ. Şahin[1], S. Y. Cetin[1], A. Ayan[2]. [1]*Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey*; [2]*Antalya Health Sciences University, Rheumatology, Antalya, Turkey*

Background: Scleroderma is an autoimmune disease that affects the skin and internal organs such as joints, muscles, and heart and lungs. Hand involvement in individuals with scleroderma leads to functional disability. Loss of grasping ability and impaired hand mobility may be one of the important factors affecting the daily living activities of patients with scleroderma. Although hand rehabilitation is not supported by strong levels of evidence, it has been the subject of studies, and a number of interventions have been described in patients with scleroderma, but no established guidelines for rehabilitation have been established. Passive and active stretching has been shown to help the patient maintain joint range of motion and lengthen tendons and muscles, especially when fibrotic retraction is present. Literature has been shown that self-administered home programs to be benefical. In addition, evidence-based rehabilitation interventions for the upper extremity in scleroderma are limited.
Objectives: The aim of the study is to examine the effects of upper extremity exercises on joint range of motion, grip strength, activity performance and functionality in patients with scleroderma.
Methods: 46 SSc patients (42 female, 4 male) with an average age of 55.52±11.54 were included in the study. Patients were randomized into intervention (group 1) and control (group 2) groups. Group 1 received upper extremity home exercise for 5 days a week for 8 weeks. Group 2 received principles of joint protection education program. Goniometric measurement was used to evaluate the upper extremity range of motion. Dinamometer and pinchmeter was used to evaluate the hand grip and pinch strength. Canadian Occupational Performance Measure (COPM) was used to evaluate the activity performance and satisfaction. Disabilities of the Arm, Shoulder and Hand Questionnaire (DASH), Duruöz Hand Index (DHI), and Score for Assessment and Quantification of Chronic Rheumatic Affections of the Hands (SACRAH) was used to evaluate the upper extremity and hand functionality. All evaluations were performed at baseline and at the end of the 8th week.
Results: When the groups were compared before training, there was no significant difference ($p > 0.05$). In post-training comparisons, there was a significant difference in shoulder, elbow, forearm, wrist and fingers range of motion (p: 0.00-0.04); hand grip and pinch strength (p: 0.00-0.02); COPM performance-satisfaction (p: 0.00); SACRAH total and subparameters (p: 0.00), DASH and DHI (p: 0.00) in Group 1. There was a significant difference in shoulder, elbow and fingers range of motion (p: 0.00-0.04); pinch strength (p: 0.00); SACRAH total and subparameters (p: 0.00); DASH and DHI (p: 0.00) in Group 2. Comparing the groups for post-training, Group 1 was found to be superior in terms of shoulder flexion and rotations, elbow extention and deviations, fingers flexion, extention and abduction (p: 0.00-0.04); pinch strength (p: 0.00-0.04); SACRAH total and subparameters (p: 0.00-0.04).
Conclusion: As a result of our study, upper extremity home exercise program has a positive effect on ROM, hand grip and pinch strength, activity performance and functionality. In rehabilitation programs, upper extremity exercises -not only hand exercises- may be effective to increase ROM, grip strength, activity performance and functionality.

OP0124

FETAL AND MATERNAL MORBIDITY IN PREGNANT SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS: A 10-YEAR U.S. NATIONAL STUDY

B. Mehta[1,2], K. K. J. Glaser[1], D. Jannat-Khah[1,2], Y. Luo[3], L. Sammaritano[1], J. E. Salmon[1], S. Goodman[1,2], F. Wang[2]. *[1]Hospital for Special Surgery, Medicine, New York, United States of America*; *[2]Weill Cornell Medicine, Medicine, New York, United States of America*; *[3]National Institutes of Health, Medicine, Bethesda, United States of America*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disorder that affects women in their childbearing years. Previously, we demonstrated that fetal and maternal mortality has declined in SLE patients over the years, however little is known about morbidity (1).
Objectives: To determine the proportion of fetal and maternal *morbidity* in SLE deliveries compared to non-SLE deliveries in a US nationwide study over a decade.
Methods: We used retrospective data from the National Inpatient Sample database to identify all delivery related hospital admissions of patients with and without SLE from 2008 to 2017 using ICD-9 (710.0) and 10 (M32*) codes. Fetal morbidity indicators included preterm delivery and intrauterine growth restriction. 21 indicators of severe maternal morbidity were identified using the standard CDC definition: these are unexpected outcomes of labor and delivery that result in significant short- or long- term consequences to a woman's health (2). Descriptive statistics and their 95% confidence intervals were calculated using sample weights from the dataset.
Results: Among the 40 million delivery-related admissions, 51,161 patients (10,297 unweighted) were reported to have SLE. SLE patients were more likely to be older and have more comorbidities compared to non-SLE patients (Table 1). Patients with SLE had a higher risk of fetal morbidity, including intrauterine growth restriction (8.0% vs 2.7%) and preterm delivery (14.5% vs 7.3%) than patients without SLE. Amongst the CDC maternal morbidity indicators - SLE patients faced a greater risk of blood transfusion, puerperal cerebrovascular disorders, acute renal failure, eclampsia or DIC, cardiovascular and peripheral vascular disorders, and general medical issues than those without SLE (Figure 1).

Table 1. Characteristics for deliveries of patients with and without Systemic Lupus Erythematosus

	SLE deliveries		Non-SLE deliveries	
	Percent (%)	**(95 %CI)**	**Percent (%)**	**(95 %CI)**

*Population weighted values are listed.

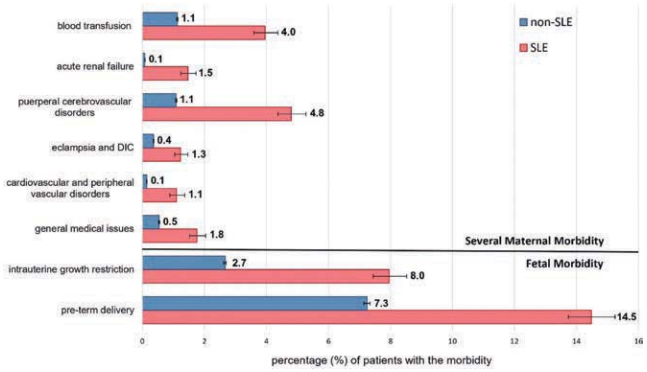

Figure 1. Fetal and severe maternal morbidity outcomes in Systemic Lupus Erythematosus (SLE) and non-SLE patients. Cardiovascular and peripheral vascular disorders include acute myocardial infarction, aneurysm, amniotic fluid embolism, cardiac arrest/ventricular fibrillation, heart failure, pulmonary edema/acute heart failure, sickle cell disease with crisis, air and thrombotic embolism, and conversion of cardiac rhythm. General medical issues include hysterectomy, shock, sepsis, adult respiratory distress syndrome, and severe anesthesia complications, temporary tracheostomy, and ventilation.

Conclusion: Our study demonstrates that fetal morbidity and severe maternal morbidity occur at a higher rate in patients with SLE compared to those without, even in this most recent decade. This work can help inform physicians to counsel and manage patients with SLE during pregnancy and its planning.

Background: Pregnancy is a topic of fundamental importance for women living with autoimmune rheumatic diseases (ARD). Efforts at national and international levels have been put in the collection and harmonization of data in order to implement an evidence-based management of pregnant patients.

Objectives: The P-RHEUM.it study was designed as a nationwide, web-based longitudinal observational cohort study to collect data about pregnancy in ARD in 26 centers in Italy. The study started in May 2018 and has been supported by the Italian Society for Rheumatology.

Methods: Pregnant patients with a definite rheumatic disease according international criteria were enrolled up to gestational week (GW) 20. The course of maternal disease activity, the use of medications, fetal and maternal complications, and the quality of life (EuroQoL questionnaire) were collected for each trimester, as well as pregnancy outcome, mode of delivery, neonatal complications, and maternal and children's follow-up to 6 months after delivery, including the screening for post-partum depression by means of EPDS (Edinburgh Postnatal Depression Scale).

Results: As of December 2021, 758 pregnancies had been enrolled, 205 (27%) ongoing and 553 (73%) with outcome. Pregnancy loss occurred in 54 (9.8%) cases (40 spontaneous miscarriages; 6 voluntary terminations). Live births were 495 (89.5%), perinatal death occurred in 4 (0.7%) cases. Table 1 reports on the group of 495 live births, along with subgroups of Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE), the two most represented diseases. Regarding treatments, 166 (30%) pregnancies were exposed to corticosteroids, 239 (43%) to hydroxychloroquine, 59 (10.7%) to csDMARDs, 84 (15.2%) to TNF inhibitors, 1 (0.2%) to non-TNFi bDMARDs, 299 (54%) to low dose acetylsalicylic acid, and 126 (22.8%) to heparin.

Table 1.

PREGNANCIES WITH LIVE BIRTHS, EXCLUDING PERINATAL DEATHS	Total pregnancies (n=495)	RA pregnancies (n=69)	SLE pregnancies (n=93)
Age at conception (years)	34 (31 - 37)	34.5 (32 - 38)	34 (31 - 36)
Disease duration (years)	6.1 (2.2 - 11.1)	7.1 (4.3 - 11.6)	9.3 (5.9 - 15.9)
Caucasian	431 (87.8%)	53 (79.1%)	75 (80.6%)
Never smokers	358 (73.8%)	53 (80.3%)	66 (71.7%)
Body Mass Index >30	45 (9.5%)	7 (10.3%)	5 (5.6%)
Arterial Hypertension	6 (1.2%)	0 (0%)	2 (2.2%)
Time to pregnancy (months)	3 (1 - 6)	3 (1 - 6)	3 (0 - 10)
Physician-reported flares in the 12 months prior to conception	107 (23%)	22 (34.4%)	13 (14.8%)
Physician global assessment at enrolment (VAS 0-100)	5 (0 - 17)	5 (0 - 20)	4 (0 - 10)
Patient global health at enrolment (VAS 0-100)	18 (7 - 30)	10 (5 - 29)	10 (5 - 25)
EuroQoL at enrolment (-1.6 – 1)	1 (0.8 - 1)	1 (0.8 - 1)	1 (0.8 - 1)
Flares during pregnancy	35 (7.1%)	6 (8.7%)	7 (7.5%)
Hypertensive disturbances*	8 (1.7%)	1 (1.6%)	6 (6.6%)
Delivery at term (≥37 GW)	410 (85.1%)	53 (77.9%)	74 (80.4%)
Spontaneous vaginal delivery	173 (35.9%)	23 (33.8%)	23 (25.3%)
Congenital malformations	11 (2.4%)	2 (3.1%)	1 (1.1%)
Small for gestational age (SGA) neonate	24 (4.9%)	1 (1.4%)	9 (9.9%)
Breastfeeding in the first 4 weeks after delivery	341 (79.7%)	45 (77.6%)	59 (76.6%)
EPDS score at risk for post-partum depression	22 (14.1%)	0 (0%)	3 (10.3%)

Continuous variables are expressed as median (interquartile range); *gestational hypertension/preeclampsia/HELLP syndrome/eclampsia.

Conclusion: Multiple factors may have contributed to the high rate of live births, including good disease control before and during pregnancy thanks to the use of anti-rheumatic drugs and low frequency of general risk factors. SLE pregnancy was affected by a higher frequency of complications (hypertensive disturbances, SGA babies) as compared to RA pregnancy. Nearly 80% of patients breastfed in the first month after delivery. For the first time, data about the screening questionnaire for post-partum depression were collected, showing at least 1 out 10 patients can be at risk.

OP0126 ARE WOMEN WITH SPONDYLOARTHRITIS AT INCREASED RISK OF ADVERSE MATERNAL AND INFANT OUTCOMES? – A SWEDISH COHORT STUDY

M. Morin[1], T. Frisell[1], O. Stephansson[1,2], K. Hellgren[1]. *[1]Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine, Solna, Stockholm, Sweden*; *[2]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden*

Background: An increased risk of adverse pregnancy and neonatal outcomes has been reported for pregnancies in women with several rheumatic diseases including rheumatoid arthritis and psoriatic arthritis. In spondyloarthritis (SpA), findings have not been uniform, with some studies reporting increased risks of Cesarean delivery, preterm birth, infants born small-for-gestational-age (SGA), and gestational diabetes- and hypertension, while others have failed to identify any significant differences between women with SpA and general population control women. Most studies reporting no differences have either been small or lacked an appropriate comparison group [1].

Objectives: To assess the risk of adverse maternal and infant pregnancy outcomes in women with SpA compared to the general population.

Methods: In this nationwide register-based study, we included singleton births between April 2007 and December 2019 in women diagnosed with ankylosing spondylitis (AS; ICD-10 codes M45 or M08.1) or undifferentiated SpA (uSpA; ICD-10 codes M46.8 or M46.9). This was performed through linkage between the National Patient Register and the Medical Birth Register. Each birth was matched on birth year, maternal age, and parity to ten comparator births in women free from chronic inflammatory arthritis at time of birth. Relative risks (RR) of adverse outcomes were estimated by Poisson regression, adjusting for

maternal country of birth, BMI, smoking in early pregnancy, educational level, and disposable income in the year before pregnancy.

Results: Women with SpA (n=1394) were found to be at increased risk of several adverse outcomes compared to general population comparators (n=13932), as displayed in the Figure 1. Women with SpA had an increased risk of gestational diabetes (adjusted RR 1.88 [95% CI 1.10; 2.56]), elective and emergency Cesarean delivery (adjusted RR 1.54 [95% CI 1.32; 1.79] and 1.23 [95% CI 1.02; 1.48], respectively), and moderately preterm birth (adjusted RR 1.52 [95% CI 1.18; 1.97]). An association was seen with both spontaneous and medically indicated preterm birth, but the increase was only significant for spontaneous preterm birth. The risk estimate for preeclampsia was also increased, but failed to reach significance (adjusted RR 1.32 [95% CI 0.96; 1.81]). Infants to mothers with SpA were not more likely to be born SGA, but there was a slightly increased risk estimate of infection during their first year of life (adjusted RR 1.23 [95% CI 0.98; 1.53]).

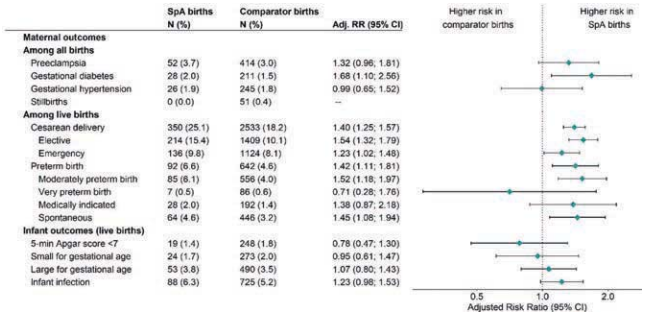

Figure 1. Number of events of adverse pregnancy outcomes among a nationwide cohort of births (n=1394) in Swedish women with SpA and comparator births (n=13932, matched 1:10 on birth year, maternal age, and parity). Relative risks from Poisson regression, adjusted for maternal country of birth, BMI, smoking in early pregnancy, educational level, and disposable income in the year before pregnancy.

Conclusion: While most pregnancies in women with SpA are uneventful, there is an increased risk for a number of adverse pregnancy outcomes. The increased risks for both emergency Cesarean delivery and spontaneous preterm birth suggest that these differences are not only driven by a different management of SpA pregnancies.

Background: Rheumatoid arthritis (RA) is one of the most common chronic inflammatory diseases and regularly affects women of childbearing age[1]. However, there is limited knowledge about the impact of the disease and its treatment on pregnancy.

Objectives: The aim of the study was to determine the factors associated with adverse pregnancy outcome in women with RA.

Methods: All RA patients (diagnosis according to the Rheumatologist) included in the national multicenter GR2 cohort from 2015 to June 2021 were included in the analysis. Patients could be included either with a pregnancy wish (i.e., preconceptional period) or because of a clinical pregnancy (<12 weeks of gestation). The main endpoint was favorable pregnancy outcome, a composite outcome defined as a live birth at term ≥ 37 gestation weeks of a healthy newborn with a weight greater than the 10th percentile. Disease activity was defined by a DAS28-CRP score > 3.2 at least once during pregnancy. We performed a multilevel logistic regression model, in which we considered patient and center random effects (patient random effect for some women included in the cohort two times). We used a multiple imputation procedure to address missing data among the explanatory variables. Results are presented as an odds ratio (OR) with confidence interval (CI).

Results: Among the 167 pregnancies in women with RA included in the GR2 cohort, 92 were retained for analysis of obstetrical outcome. Of these, 43 (46.2%), 8 (7.9%), 40 (43.5%) were exposed to corticosteroid, NSAID and biologics at least once during pregnancy, respectively. A moderate or severe disease activity at least once during pregnancy was found in 20 (21.8%) pregnancies. A live birth was found in 83 (90.2%) women, including 69 (83.1%) full-term births. Early miscarriages were observed in 9 (0.1%) women. A caesarean section was performed in 22 (23.9%) cases.

A favorable pregnancy outcome was found in 52 (56.5%) of the women. Unfavorable pregnancy outcome was mainly due to prematurity and small for gestational age, observed in 14 (16.9%) and 17 (20.5%), respectively. The multivariate model adjusted for age, BMI, nulliparity, active disease during pregnancy, smoking, and exposure to biologics and corticosteroids during pregnancy found an association between an unfavorable pregnancy outcome and nulliparity (OR 6.2 95% CI [2.1-17.8] p = 0.002), age (OR (per year) 1.1 95% CI [1.0-1.3] p = 0.02) and exposition to corticosteroids during pregnancy (OR 3.2 95% CI [1.1-9.6] p = 0.04).

Conclusion: This study provides original results on pregnancy in women with RA. It found a favorable pregnancy outcome in 56.5% of women. Unfavorable pregnancy outcome was associated with age, nulliparity and corticosteroids use during pregnancy, which argues for their careful use during pregnancy.

OP0128

ADHERENCE TO MEDICATIONS DURING PREGNANCY IN SYSTEMIC AUTOIMMUNE DISEASE

D. Zucchi[1], F. Racca[1], C. Tani[1], E. Elefante[1], C. Stagnaro[1], L. Carli[1], V. Signorini[1], F. Ferro[1], F. Trentin[1], S. Gori[1], M. Mosca[1]. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: Low medication adherence is a well known issue in the management of patients with systemic autoimmune diseases (SAD), little however is known on adherence to medication during pregnancy, especially in these patients with high risk pregnancies.

Objectives: This study is aimed at evaluating the level of adherence to medication in pregnant patients with SAD in comparison with non-pregnant patients with SAD, and at identifying determinants of low adherence.

Methods: Pregnant and non-pregnant patients with an established diagnosis of SAD were consecutively enrolled. Pregnant patients were included in a tight monitoring protocol for high risk pregnancies, and treatments were checked every month. The following data were collected at enrolment: epidemiological and demographic characteristics, disease duration and type of medications. Each patient completed the following anonymous questionnaires: the 8-item Morisky Medication Adherence Scale (MMAS-8) and Hospital Anxiety and Depression Scale (HADS) to assess the presence of anxiety and depression. With regard to MMAS-8, we assessed adherence to hydroxychloroquine (HCQ) and to other disease modifying antirheumatic drugs (DMARDs) separately. We considered a score ≥ 6 as indicator of good adherence. Vitamins and dietary supplements were not considered.
Results: A total of 80 pregnant women and 72 non-pregnant women were enrolled. Clinical data and results of the questionnaires are summarized in Table 1.

Table 1. Characteristics of the cohort

	Pregnant patients N=80	Non-pregnant patients N=72	P value
Age at study entry (years, mean ±SD)	35.8±4.3	40.1±12.2	**0.001**
Disease duration (years, mean ±SD)	8.5±6.6	8.6±9.1	n.s
Number of tablets/day (mean ±SD)	4.3±1.6	4.1±1.8	n.s
Number of assumption/day (mean ±SD)	1.4±0.6	1.6±0.8	n.s
Score MMAS for HCQ (mean ±SD)	6.99±0.2	6.38±0.2	**0.039**
Score MMAS for other DMARDs (mean ±SD)	6.99±0.3	6.39±0.2	**0.018**
Patients with good adherence to HCQ (%)	38/50 (76.0%)	34/59 (57.6%)	**0.044**
Patients with good adherence to medications (%)	53/71 (74.6%)	37/60 (61.7%)	n.s
Patients with low adherence to HCQ (%)	12/50 (24%)	25/59 (42.4%)	**0.044**
Patients with low adherence to medications (%)	18/71 (25.4%)	23/60 (38.3%)	n.s
Anxiety (%)	20 (25%)	30 (41.7%)	**0.029**
Depression (%)	11 (13.7%)	19 (26.4%)	0.051

MMAS-8 score was significantly higher in pregnant women both for HCQ (p=0.039) and other DMARDs (p=0.018), as well as the rate of patients with good medication adherence for HCQ (76.0% vs 57.6%, p=0.044). The rate of patients with good medication adherence for other DMARDs was higher in pregnant patients (74.6% vs 61.7%) but this different was not statistically different.
Demographic and clinical characteristics and the number of therapies received didn't seem to influence treatment adherence. Fifty patients (32.8%) suffered from anxiety, and this disorder was a significant determinant of low medication adherence in all groups. Conversely, depression didn't seem to have an impact on adherence on neither group.
Conclusion: Overall, pregnant patients with SAD had a good adherence to prescribed medication; nevertheless, 25% of patients didn't take therapies adequately despite being closely monitored in a dedicated clinic for high risk pregnancies and an adequate pregnancy counselling; anxiety seems to be one determinant of low medications adherence both in pregnant and non-pregnant women.

OP0129 REPORTED CONGENITAL MALFORMATIONS AFTER EXPOSURE TO NON-TNF-A INHIBITORS: A RETROSPECTIVE COMPARATIVE STUDY IN EUDRAVIGILANCE DATABASE

N. Ghalandari[1], H. J. M. J. Crijns[2], J. Bergman[3], R. Dolhain[1], E. van Puijenbroek[4], J. Hazes[1]. [1]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [2]*CBG-MEB, Pharmacovigilance, Utrecht, Netherlands*; [3]*University of Groningen, Faculty of Medical Sciences, Groningen, Netherlands*; [4]*Lareb, Pharmacovigilance,'s Hertochenbosch, Netherlands*

Background: Tumor necrosis factor-α inhibitors (TNFis) such as certolizumab pegol (CZP), are a subgroup of biologics, which have shown no increase in risk of congenital malformations (CMs) after use during pregnancy. (1) However, for the subgroup of non-TNFis, very scarce data is available.
Objectives: To evaluate the number and nature of reported CMs after intrauterine exposure to non-TNFis compared to CZP, in Eudravigilance database.
Methods: A retrospective comparative study in EudraVigilance database was conducted. Reports of all pregnancies exposed to non-TNFis and CZP, were extracted. Multiple versions of a unique case, pregnancies with unknown outcome, paternal exposures, CMs due to known genetic abnormalities, and cases exposed only via breast milk were excluded. Odd ratios for CMs were calculated for each non-TNFi, with CZP as reference group. Due to limitations of pharmacovigilance databases, such as possibility of under-reporting normal outcomes and information bias (2), in consultation with a clinical geneticist, CM patterns were compared between non-TNFi and CZP groups.
Results: In total 851 non-TNFi and 1179 CZP exposed pregnancy reports were included. Numerical differences for CMs after exposure to non-TNFis were not statistically significant except for belimumab and vedolizumab (Table 1).

Table 1. Reported number, crude and adjusted ORs [95%CIs] for major and minor CMs and TOPFAs after intrauterine exposure to non-TNFis compared to CZP

Medication	Reported CMs and TOPFAs, n/N (%)	Crude ORs [95%CIs],	Adjusted ORs (for maternal age) [95%CIs],	Stratified ORs (teratogen unexposed cases only) [95%CIs] *
Certolizumab pegol	**95/1179 (8.05)**	**Reference**	**Reference**	**Reference**
Abatacept	2/64 (3.12)	0.36 [0.08, 1.52]	0.35 [0.08, 1.47]	0.69 [0.16, 2,96]
Anakinra	3/20 (15.00)	2.01 [0.57, 6.99]	2.81 [0.77, 10.20]	3.39 [0.91, 12.63]
Belimumab	17/93 (18.27)	2.55 [1.44, 4.49]	2.63 [1.40, 4.93]	2.65 [1.35, 5.20]
Ixekizumab	1/29 (3.44)	0.40 (0.05, 3.02]	0.39 [0.05, 2.96]	0.42 [0.05, 3.16]
Rituximab	8/57 (14.03)	1.86 [0.85, 4.04]	2.47 [1.05, 5.80]	2.55 [0.94, 6.95]
Secukinumab	4/128 (3.12)	0.36 [0.13, 1.01]	0.34 [0.10, 1.11]	0.37 [0.11, 1.19]
Tocilizumab	10/124 (8.06)	1.00 [0.50, 1.97]	0.79 [0.37, 1.68]	0.62 [0.22, 1.76]
Ustekinumab	19/215 (8.83)	1.10 [0.66, 1.85]	0.92 [0.51, 1.66]	1.01 [0.56, 1.82]
Vedolizumab	23/113 (20.35)	2.91 [1.76, 4.82]	2.66 [1.53, 4.61]	2.27 [1.24, 4.15]

OR: odds ratio; CI: confidence interval; CM: congenital malformation; TOPFA: termination of pregnancy due to foetal anomaly anomaly. *After adjusting for maternal age, stratified ORs are presented for patients who had no reported teratogen exposure during pregnancy.

Pattern of CMs were reviewed by a clinical geneticist. Except for vedolizumab, no specific CM patterns were observed. For vedolizumab four cases of corpus callosum agenesis (CCA) were reported (versus null in CZP and other investigated non-TNFis). Three of the CCA cases were associated with other neurological CMs such as a neural tube defect, microcephaly and polymicrogyria. This indicates that the reported CCAs may have been related to undiagnosed genetic alterations or were associated with underlying maternal disease, although a definite relationship cannot be ruled out.
Conclusion: Except for vedolizumab, no special safety signal was identified regarding occurrence of CMs after exposure to non-TNFis. Based on available information, no firm conclusions can be made regarding observed CCA cases in vedolizumab group.

OP0130 SERIOUS INFECTIONS IN OFFSPRING EXPOSED TO TUMOUR NECROSIS FACTOR INHIBITORS DURING PREGNANCY: COMPARISON OF AGENTS WITH LOW AND HIGH PLACENTAL TRANSFER

L. K. Flatman[1,2], M. Abrahamowicz[1,2], Y. St-Pierre[2], I. Malhamé[2,3,4], O. Basso[1,5], S. Bernatsky[1,2,3,6], E. Vinet[1,2,3,6]. [1]*McGill University, Epidemiology, Biostatistics and Occupational Health, Montreal, Canada*; [2]*Research Institute of the McGill University Health Centre (RI-MUHC), Centre for Outcomes Research and Evaluation, Montreal, Canada*; [3]*McGill University, Department of Medicine, Faculty of Medicine, Montreal, Canada*; [4]*McGill University Health Centre, Division of General Internal Medicine, Montreal, Canada*; [5]*McGill University, Department of Obstetrics and Gynecology, Faculty of Medicine, Montreal, Canada*; [6]*McGill University Health Centre, Division of Rheumatology, Division of Clinical Epidemiology, Department of Medicine, Montreal, Canada*

Background: During pregnancy, maternal circulating antibodies cross the placenta. Offspring exposed in utero to tumour necrosis factor inhibitors (TNFi) may experience immunosuppression and subsequent infections in their first year of life due to TNFi entering the fetal bloodstream. TNFi subtypes have differential trans-placental passage capabilities. Most (i.e. adalimumab, infliximab, golimumab) are monoclonal antibodies, with adalimumab and infliximab having the highest transfer, reaching

higher fetal than maternal levels. Certolizumab (a pegylated Fab fragment) and etanercept (a fusion protein) display the lowest passage. Thus, depending on the TNFi subtype, the risk of immunosuppression may differ, and some offspring may be exposed to supra-therapeutic doses of TNFi. Therefore, the risk of serious infections in offspring by TNFi subtype needs to be clarified.
Objectives: We evaluated the risk of serious infections leading to hospitalization in offspring born to mothers with chronic inflammatory diseases who used TNFi during pregnancy depending on whether they had low or high placental transfer.
Methods: In this population cohort study, we identified offspring born in 2011-2019 to women with a prior diagnosis of rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, psoriasis, and/or inflammatory bowel diseases in the IBM MarketScan commercial database using commercial claims only. Women were included if they had been continuously enrolled within MarketScan with medical and pharmacy coverage for ≥12 months prior to delivery and had a child linked to them. TNFi exposure was defined as ≥1 filled prescription and/or infusion procedure code during pregnancy. Exposure was further categorized into high (i.e. infliximab, adalimumab, golimumab) and low (i.e. certolizumab, etanercept) placental transfer ability. Serious infections were ascertained based on ≥1 hospitalization with infection as the primary diagnosis in the offspring's first year of life. We performed multivariable time-to-event analysis using a Cox proportional hazards model, adjusting for maternal age at delivery, chronic inflammatory disease diagnosis, maternal co-morbidities (pre-gestational diabetes, asthma), pregnancy complications (gestational diabetes, preterm birth), and other drug use (corticosteroids and non-biologic DMARDs).
Results: We identified 26,088 offspring, among whom 2,902 (11.1%) were exposed to TNFi during pregnancy. The majority of offspring (1,506; 51.9%) were born to mothers with inflammatory bowel diseases. Out of the 2,902 offspring with TNFi exposure, 797 (27.5%) and 2,105 (72.5%) were low and high placental transfer drugs, respectively. The frequency of serious infections was 1.3% and 1.8% in those offspring exposed to TNFi with low and high placental transfer, respectively. The incidence rate (IR) of serious infections in offspring exposed to TNFi with high vs. low placental transfer was, respectively, 2.27 (95% confidence interval, CI 1.61, 3.12) cases per 100 person-years at risk vs. IR 1.59 cases per 100 person-years at risk (95% CI 0.76, 2.92). In multivariable analyses, the adjusted hazard ratio for serious infections with the use of TNFi with high versus low placental transfer was 1.20 (95% CI 0.54, 2.64).
Conclusion: Although children exposed to high transfer TNFi may have a higher risk of serious infection, we saw no clear excess risk of serious infections in children exposed in utero to TNFi with high versus low placental transfer due to the wide confidence interval.

OP0131

WHAT IS THE EFFECT OF METHOTREXATE ON SEMEN PARAMETERS OF MEN DIAGNOSED WITH IMMUNE-MEDIATED DISEASES? RESULTS OF A PROSPECTIVE COHORT STUDY (IFAME-MTX).

L. F. Perez-Garcia[1], E. Röder[1], R. Van Adrichem[1], L. J. Kranenburg - van Koppen[1], E. Zirkzee[2], M. Van Doorn[3,4], G. Dolhe[5], R. Dolhain[1]. [1]*Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*; [2]*Maasstad Ziekenhuis, Rheumatology, Rotterdam, Netherlands*; [3]*Erasmus University Medical Center, Dermatology, Rotterdam, Netherlands*; [4]*Centre for Human Drug Research, Leiden, Netherlands*; [5]*Erasmus University Medical Center, Urology, Rotterdam, Netherlands*

Background: Methotrexate (MTX) is one of the most frequently prescribed medications for the treatment of several immune-mediated diseases (IMD). MTX has well-established safety and efficacy profiles. Nonetheless, the available scientific evidence to support the decision whether men with an active desire to become a father should be treated with MTX is dubious (1). This knowledge gap is characterized by a lack of prospective studies evaluating the semen parameters before and after exposure to MTX (2).
Objectives: Our objective is to compare the semen parameters (sperm concentration, volume and progressive motility) between men diagnosed with IMD (pre and post exposure to MTX) and healthy controls.
Methods: This is a prospective cohort study. Men diagnosed with an IMD (RA, SpA, psoriasis) who were older than 18 years and received a medical indication to start therapy with MTX were invited to participate (naïve cases). These men were instructed to produce 2 semen samples (a pre-exposure sample before initiating MTX therapy and a post-exposure sample 12 weeks after initiating MTX therapy). Healthy men who were over 18 years old were invited to participate as healthy controls. Furthermore, to evaluate the semen parameters of men chronically exposed to MTX, men diagnosed with an IMD who had been exposed to MTX (≥15 mg/week) for at least 1 year were also invited to participate (chronic cases). These men produced one semen sample (post-exposure). All participants were proven fertile (fathered a child or their partner reported a positive pregnancy test). Continuous variables were compared using a paired t-test or a one-way analysis of variance.
Results: In total 18 naïve cases, 25 healthy controls and 5 chronic cases were included. Their demographic characteristics and the results of the conventional semen analysis are presented per group in Table 1. Compared to the semen parameters (sperm concentration, volume and progressive motility) from healthy controls, pre-exposure and post-exposure semen parameters from naïve cases were not statistically significant different (see Figure 1). The semen parameters of chronic cases were also not statistically significant different compared to pre-exposure samples from naïve cases and to healthy controls. Oligospermia (sperm concentration <15 10^6/mL) was identified in two samples from a naïve case (pre and post-exposure to MTX) and no cases of azoospermia were identified.

Table 1. Demographic, clinical characteristics and semen parameters

	MTX naïve		Controls	MTX chronic	p value
	Pre-exposure	Post-exposure			
Total, n	18		25	5	
Age, mean (95% CI)	36.52 (33.65-39.39)		34.56 (32.75-36.36)	36.80 (31.95 – 41.64)	
MTX dose mg/ week, mean (95% CI)	-	16.52 (14.54 – 18.49)	-	18.00 (14.59 – 21.40)	
Sperm concentration, mean × 10^6/ mL (95% CI)	84.27 (44.27-123.83)	64.31 (42.55 – 86.35)	92.56 (60.45 –124.66)	44.60 (25.11 – 64.08)	p=0.358* p=0.280**
Progressive motility*, % (95% CI)	63.20 (55.44-70.95)	60.11 (49.56-70.67)	56.95 (51.05-62.85)	50.40 (34.82 – 65.97)	p=0.562* p=0.456**
Semen volume, mean mL, (95% CI)	2.93 (2.09-3.76)	2.90 (2.08-3.71)	3.12 (2.51-3.73)	2.50 (1.55-3.44)	p=0.608* p=0.593**

*Comparisons between pre and post exposure samples were tested using a paired t-test,**Comparisons between pre, post exposure and healthy controls were tested using a one way analysis of variance.

Conclusion: This is the largest prospective study ever conducted to evaluate the impact of MTX on semen parameters in men diagnosed with IMDs. We demonstrated that exposure to MTX did not result in statistically significant different semen parameters. Based on semen parameters, our findings suggest that MTX therapy can be continued in men diagnosed with an IMD and a wish to become a father.

PREVALENCE AND COMORBIDITIES OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE IN SPAIN: A RETROSPECTIVE ANALYSIS OF ELECTRONIC HEALTH RECORDS USING NATURAL LANGUAGE PROCESSING

J. A. Román Ivorra[1], I. De la Morena[2], N. Costas Torrijo[2], B. Safont[3], J. Fernández-Melón[4], B. Nuñez[5], L. Silva Fernández[4], L. Cebrián Méndez[6], L. Lojo[6], B. López-Muñiz[7], E. Trallero[8], M. Lopez Lasanta[8], R. M. Veiga Cabello[9], M. D. P. Ahijado Guzman[9], D. Benavent[10], D. Vilanova[11], R. Castellanos Moreira[12], S. Lujan Valdés[12] on behalf of RA-W-ILD Study Group. *[1]Hospital Universitario La Fe, Rheumatology Unit, Valencia, Spain; [2]Hospital Clínico Universitario, Rheumatology Unit, Valencia, Spain; [3]Hospital Clínico Universitario, Pulmonary Unit, Valencia, Spain; [4]Hospital Universitari Son Espases, Rheumatology Unit, Palma de Mallorca, Spain; [5]Hospital Universitari Son Espases, Pulmonary Unit, Palma de Mallorca, Spain; [6]Hospital Universitario Infanta Leonor, Rheumatology Unit, Madrid, Spain; [7]Hospital Universitario Infanta Leonor, Pulmonary Unit, Madrid, Spain; [8]Hospital Universitario Vall D´Hebron, Rheumatology Unit, Barcelona, Spain; [9]Hospital Universitario Fuenlabrada, Rheumatology Unit, Madrid, Spain; [10]SAVANA Group, Medical, Madrid, Spain; [11]Bristol Myers Squibb, HEOR, Madrid, Spain; [12]Bristol Myers Squibb, Medical, Madrid, Spain*

Background: Interstitial lung disease (ILD) is one of the most frequent extra-articular manifestations of rheumatoid arthritis (RA) and leads to a significantly increased risk for morbidity and mortality compared with RA alone [1]. The analysis of Electronic Health Records (ERHs) using machine learning (ML) and Natural Language Processing (NLP) holds great promise to better characterize the disease in real-world settings.

Objectives: This study aims to a) estimate the prevalence of RA in Spain, b) determine the frequency of RA-ILD among RA patients, and c) describe the demographic and clinical characteristics in RA/RA-ILD patients.

Methods: Observational, retrospective, and multicenter study based on the secondary use of unstructured clinical data in EHRs from 6 Spanish hospitals between January 1, 2014 and December 31, 2019. The free-text information from patients' records was captured with SAVANA's *EHRead*, a validated NLP technology which extracts clinical information from EHRs and standardizes it into a SNOMED-CT-based clinical terminology [2]. The study population comprised all adult patients ≥18 years with RA in the selected period and sites. Descriptive statistics were presented in summary tables. Prevalence was calculated dividing the total number of patients with RA over the total number of attended patients. This analysis was performed by age and sex.

Results: Among all attended patients in the participating hospitals within the study period, 11,163 patients with RA were identified; of these, 8.6% (n = 959) had RA-associated ILD (RA-ILD). The age-adjusted prevalence of RA is shown in Figure 1. The estimated prevalence (95% CI) in the overall population was 0.49 (0.37-0.60), being 0.26 (0.19-0.32) in males and 0.71 (0.54-0.87) in females. Most patients in the RA (73.9%; n = 8,250) and RA-ILD populations (63.3%, n = 607) were female (Table 1). The median age (Q1, Q3) was 60.8 (49, 74) and 67 (56, 77) years in the RA and RA-ILD groups, respectively. Regarding disease course, the time from RA to ILD diagnosis was 27.6 (3.7, 73.2) months. Most comorbidities presented higher rates in the RA-ILD population, as shown in Table 1. Among patients with available ILD subtype information (n = 618), the most common was usual interstitial pneumonia (29.8%; n = 184).

Table 1. Demographics and comorbidities in the RA and RA-ILD patient populations

	RA* N=11,163	RA-ILD N=959
Gender, n (%)		
Female	8,250 (73.9)	607 (63.3)
Male	2,913 (26.1)	352 (36.7)
Age at first mention of disease (years)[1]		
Median (Q1, Q3)	61 (49, 74)	67 (56, 77)
Comorbidities, n (%)		
Dyslipidaemia	4369 (39.1)	316 (33)
Hypertension	3851 (34.5)	320 (33.4)
Diabetes mellitus	2970 (26.6)	248 (25.9)
Infections	2129 (19.1)	328 (34.2)
Bone fracture	1875 (16.8)	210 (21.9)
Osteoporosis	1275 (11.4)	150 (15.6)
Malignancies	1004 (9)	169 (17.6)
Kidney failure	1006 (9)	156 (16.3)
Heart failure	993 (8.9)	184 (19.2)
Depression	825 (7.4)	99 (10.3)
Psoriasis	773 (6.9)	39 (4.1)
Obesity	732 (6.6)	90 (9.4)
Asthma	740 (6.6)	82 (8.6)
Atrial Fibrillation	729 (6.5)	102 (10.6)

*RA includes patients in the RA-ILD population. [1]Patients' age when either RA or ILD was first detected in the EHRs. RA = rheumatoid arthritis; ILD = interstitial lung disease

Conclusion: This pioneering study is the first to characterize RA-ILD using NLP methodology in a multicenter setting. By analyzing readily available real-world data in patients EHRs, we were able to estimate the prevalence of RA in the Spanish population and describe the demographic and clinical characteristics of patients with RA/RA-ILD.

OP0133

THE DECREASE OF MUSCLE MASS BY THE BEHAVIORAL RESTRICTION OF COVID-19 PANDEMIC IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Tada[1], Y. Yamada[2], K. Mandai[3], Y. Matsumoto[4], N. Hidaka[1]. *[1]Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan; [2]Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan; [3]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan; [4]Osaka City University Graduate School of Human Life Science, Medical Nutrition, Osaka, Japan*

Background: We previously reported the prevalence of sarcopenia and body compositions at patients with rheumatoid arthritis (RA)[1]. The behavioral restriction of COVID-19 pandemic influenced for the lifestyle of people included patients with RA.
Objectives: The change of exercise and daily life activity of patients with RA were investigated and body composition and muscle function were compared pre- and post-behavioral restriction.
Methods: We used the date from prospective observational study (CHIKARA study: UMIN000023744). 70 from 100 patients with RA were followed-up and evaluated the change of exercise and daily life activity by visual analog scale. They were measured the muscle mass, fat mass, basal metabolic rate by body composition analyzer and grip strength as muscle function. The relationship between the change of exercise and daily life activity and body composition was investigated by univariate analysis.
Results: Mean age was 69.7 years (women n=57, men n=13). The rate of decrease of exercise by <25%, 26~50%, and 51%< were 70%, 21%, and 9%, respectively (mean:20% decrease). Whereas, the rate of decrease of daily life activities by <25%, 26~50%, and 51%< were 37%, 27%, and 36%, respectively (mean:44% decrease). Muscle mass at post-behavioral restriction decrease significantly compared that at pre-behavioral restriction activities (34.0kg vs 34.7kg, P<0.001). Fat mass at post-behavioral restriction increase significantly compared that at pre-behavioral restriction (16.2kg vs 15.5kg, P=0.014). Grip strength at post-behavioral restriction decrease significantly compared that at pre-behavioral restriction (16.2kg vs 17.2kg, P=0.026). The change of exercise was significantly positively correlated with the change of muscle mass and basal metabolic rate (R=0.273, P=0.021 and R=0.256, P=0.033, relatively) at Table 1. Whereas, the change of daily living activities was not significantly correlated with the change of muscle mass and muscle function.

Table 1. Univariate analysis of the changes in daily living activities or exercise and those in body composition or muscle function

	Change of daily living activities		Change of exercise	
	R value	P value	R value	P value
Δ Weight (kg)	-0.123	0.311	-0.131	0.279
Δ BMI (kg/m^2)	-0.108	0.397	-0.113	0.345
Δ Muscle mass (kg)	0.140	0.311	0.273	0.021
Δ Fat mass (kg)	-0.061	0.614	-0.075	0.539
Δ Fat percentage (%)	-0.003	0.982	-0.018	0.884
Δ Basal metabolic rate (kcal)	0.201	0.095	0.256	0.033
Δ Grip strength (kg)	0.117	0.336	0.037	0.762
Δ Walk speed (m/s)	0.169	0.161	0.139	0.250

Δ, change from pre- to post-behavioral restriction; BMI, body mass indexAnalyzed by Spearman's rank correlation coefficient

Conclusion: Muscle mass and grip strength decrease and fat mass increase in patients with RA by the behavioral restriction of COVID-19 pandemic. Muscle mass and basal metabolic rate decrease in patients without exercise habits. Maintenance of muscle mass might be important during the COVID-19 pandemic.

OP0134 ACTIVE RHEUMATOID ARTHRITIS AND ASSOCIATED COMORBIDITIES INCREASE RISK OF DEMENTIA: A POPULATION-BASED COHORT STUDY

C. Kodishala[1], C. A. Hulshizer[2], V. Kronzer[1], J. M. Davis III[1], V. K. Ramanan[3], M. Vassilaki[2], M. Mielke[2,3], C. S. Crowson[1,2], E. Myasoedova[1,2]. *[1]Mayo Clinic, Division of Rheumatology, Rochester, United States of America; [2]Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America; [3]Mayo Clinic, Neurology, Rochester, United States of America*

Background: Growing evidence from observational studies indicates that patients with rheumatoid arthritis (RA) have a higher risk of developing dementia. However, the incidence of dementia among RA patients has declined in recent years [1]. It is unknown if this reflects broader trends of dementia incidence over time, changes in the prevalence or treatment of associated comorbidities, advances yielding better control of inflammation in RA, or other factors (e.g., environmental risk factors). Longitudinal population-based studies assessing risk factors for dementia among RA patients are scarce [2].
Objectives: We aimed to identify risk factors for incident dementia in a large inception cohort of patients with RA.
Methods: This retrospective population-based cohort study included residents of Olmsted County, MN, who were ≥50 years when they met 1987 ACR criteria for incident RA in 1980-2014. All individuals were followed until death/migration or 12/31/2019. Patients with dementia before RA incidence were excluded (n=12). Incident dementia was defined as two relevant ICD-9/10 codes at least 30 days apart. Risk factors including socio-demographics, RA disease characteristics and medications, cardiovascular/cerebrovascular disease (CVD) risk factors and other comorbidities were abstracted from medical records. Any CVD was defined as coronary heart disease (i.e., angina pectoris, coronary artery disease, myocardial infarction, coronary revascularization procedures, cerebral stroke or heart failure (HF). Association of individual risk factors with incident dementia was examined using Cox proportional hazard models. Three models were utilized: Model 1, adjusting for age, sex, and calendar year of RA incidence; Model 2, adding smoking, obesity, hypertension, diabetes mellitus, and hyperlipidemia to the first; and Model 3, adding 'any CVD' to the second. Time-dependent covariates were used to represent factors that developed during follow-up.
Results: The study included 886 patients with RA (mean age 65 years, 65% females). During the follow-up period (median=8.5 years), 103 patients developed dementia. Mean age at the diagnosis of dementia was 82.3 (7.2) years. The cumulative incidence of dementia increased by 2-3% every 5 years after the diagnosis of RA. Older age at RA incidence (Hazard Ratio (HR) 1.14 per 1 year increase, confidence interval (CI): 1.12-1.17) was consistently associated with risk of dementia. Presence of rheumatoid nodules (HR 1.76, CI: 1.05-2.95), large joint swelling (HR 2.11, CI: 1.33-3.34), hypertension (HR 1.84, CI: 1.19-2.85), HF (HR 2.72, CI: 1.29-5.74), and depression (HR 2.23, CI: 1.36-3.67) at baseline or during the first year after RA incidence were significantly associated with risk of dementia. Large joint swelling (HR 2.03, CI: 1.14-3.60), any CVD (HR 2.25, CI: 1.38-3.66), anxiety (HR 1.86, CI: 1.16-2.97), and depression (HR 2.63, CI: 1.76-3.93) at any time during the disease increased the risk of dementia. Among CVD conditions, stroke (HR 3.16, CI: 1.84-5.43) and HF (HR 1.82, CI: 1.10-3.00) significantly increased risk of dementia. After adjusting for CVD risk factors (Model 2), or CVD risk factors plus any CVD (Model 3), all the covariates listed above were still significantly associated with the risk of dementia.
Conclusion: Apart from age, CVD (particularly hypertension), depression and anxiety, which are universally recognized risk factors for dementia, we observed that clinically active RA was associated with an elevated risk of dementia incidence among RA patients. Studies are ongoing to further evaluate the role of systemic inflammation and its interactions with other risk factors in dementia overall and by dementia subtype in patients with RA.

OP0135 RISK OF CARDIOVASCULAR EVENTS UNDER JANUS KINASE INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL DATA FROM THE GERMAN RABBIT REGISTER

Y. Meissner[1], K. Albrecht[1], J. Kekow[2], S. Zinke[3], H. P. Tony[4], M. Schaefer[1], A. Strangfeld[1]. *[1]German Reumatism Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany; [2]Helios Fachklinik Vogelsang-Gommern, Rheumatology, Vogelsang-Gommern, Germany; [3]Private Practice, Rheumatology, Berlin, Germany; [4]Uniklinikum Würzburg, Medizinische Klink 2 Rheumatologie/Klinische Immunologie, Würzburg, Germany*

Background: In 2021, the European and US-American regulatory agencies EMA and FDA issued warnings about the cardiovascular (CV) safety of the Janus kinase inhibitor (JAKi) tofacitinib and required changes in labelling. These actions were based on results of the post-authorisation safety trial Oral Surveillance[(1)].
Objectives: To analyse major cardiovascular events (MACE) under treatment with JAKi, tumor necrosis factor inhibitors (TNFi) or conventional synthetic

Table 1. Patient characteristics at the start of a JAKi, TNFi or csDMARD.

Previous smokers	551 (31.4)	692 (31.9)	230 (28.1)	300 (28.3)	338 (28.6)	114 (23.9)

Values are given as mean ± standard deviation or number (percentage). *Age ≥50 years and ≥ 1 CV risk factor (hypertension, coronary heart disease, diabetes, hyperlipoproteinaemia, current smoking)

disease-modifying anti-rheumatic drugs (csDMARDs - bionaive) in patients with rheumatoid arthritis (RA) observed in daily rheumatological care.

Methods: Data from patients enrolled in the biologics register RABBIT with treatment episodes from 01/2017 - 04/2021 were included. Incidence rates (IR) of MACE per 100 patient-years (PY) with 95% confidence intervals (CI) and adjusted risk ratios (RR) were calculated for all and for high-risk patients (age ≥ 50 years and ≥ 1 CV risk factor). Poisson regression analysis was adjusted for age, sex, smoking, disease activity, prior therapies, glucocorticoids and comorbidities.

Results: Starting from 2017, 2030 JAKi, 2338 TNFi and 871 csDMARD initiations were documented. Patients with a JAKi start were slightly older, more often women and had a longer RA disease duration (Table 1). The proportion with positive autoantibodies was higher than in the TNFi and csDMARD group, the physical function was lower, and they had received more previous biologic treatments. Characteristics of high-risk patients are also given in the Table 1.

In total, 28 incident MACE were reported. Patients under treatment with JAKi, TNFi and csDMARD showed comparable IR for MACE between 0.26 and 0.41 events per 100 PY (Figure 1). High-risk patients showed higher IRs. The median time under treatment was 10 months on JAKi and TNFi, and 12 months on csDMARDs. The majority of events were reported in the first year after treatment start. In the adjusted analyses, JAKi (RR 0.94 [95% CI 0.39; 2.28]) and csDMARDs (RR 0.85 [0.25; 2.88]) did not show a significantly increased risk for MACE compared with TNFi in unselected patients, and also not in high-risk patients (JAKi: RR 0.90 [0.37; 2.17]; csDMARDs: RR 0.61 [0.16; 2.28]).

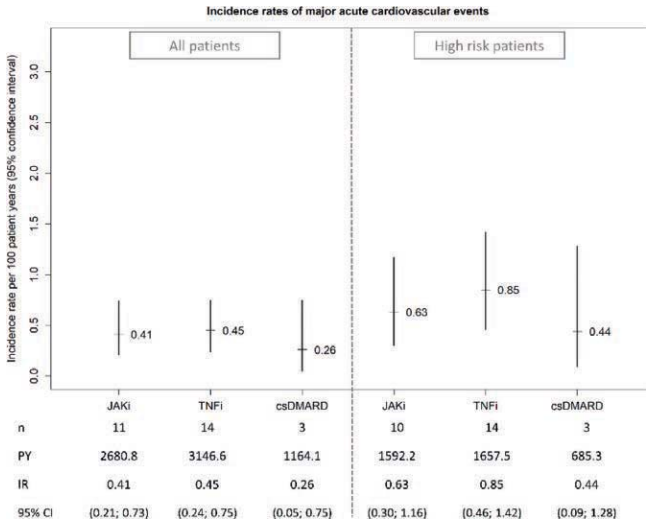

Figure 1. Incidence rates of MACE per 100 patient years by treatment group.

Conclusion: IR of MACE in patients receiving JAKi in a real-world setting was lower than the IR reported for tofacitinib in the Oral Surveillance study. We found no evidence of an increased risk of MACE with JAKi compared to TNFi, although patients in the JAKi group were older and had longer disease duration.

SERUM CHOLESTEROL LOADING CAPACITY ON MACROPHAGES AND INTERACTIONS WITH TREATMENTS ON CORONARY ATHEROSCLEROSIS BURDEN AND EVENT RISK IN RHEUMATOID ARTHRITIS

G. Karpouzas[1,2], B. Papotti[3], S. Ormseth[2], M. Palumbo[3], E. Hernandez[2], C. Marchi[3], F. Zimetti[3], M. Budoff[4,5], N. Ronda[3]. [1]*Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America*; [2]*The Lundquist Institute, Rheumatology, Torrance, United States of America*; [3]*University of Parma, Food and Drug, Parma, Italy*; [4]*Harbor-UCLA Medical Center, Cardiology, Torrance, United States of America*; [5]*The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: Cholesterol loading capacity (CLC) describes the ability of serum to deliver cholesterol to cells. It is linked to foam cell formation, a pivotal step in atherosclerotic plaque development. Rheumatoid arthritis (RA) serum promoted foam cell formation significantly more than control serum. Likewise, RA patients display greater plaque burden and higher-risk features than non-RA controls. bDMARDs and statins lower cardiovascular risk by reducing new coronary plaque formation, promoting regression, altering the composition and stabilizing prevalent atherosclerotic lesions.

Objectives: To evaluate the associations between CLC, coronary plaque burden and cardiovascular event risk in patients with RA. We further explored the conditioning effects of RA treatments on these relationships.

Methods: 140 patients underwent coronary CT angiography for atherosclerosis evaluation and were prospectively followed for cardiovascular events over 6.0±2.4 years. Coronary artery calcium score (CAC), number of segments with plaque (segment involvement score [SIS]) and plaque composition were assessed. CLC was the macrophage cholesterol content, measured by fluorometric assay, after a 24-hour incubation with whole serum. Robust linear regression examined the effects of CLC and the interaction between CLC and bDMARD use on SIS and CAC. Negative binomial regression evaluated CLC and CLC × bDMARD interaction effects on number of high-risk (low-attenuation) plaques. With data discretized into 1-month intervals, weighted pooled logistic regression models with robust variance estimation evaluated CLC and time-varying bDMARD use as predictors of event risk, and the effect of CLC × time-varying bDMARD use on risk. Stabilized inverse probability of treatment and censoring weights were estimated as a function of ASCVD risk, SIS, RA duration, and baseline and time-varying CRP and statin use.

Results: Mean (SD) CLC was 12.67 (2.83) μg/mg protein. In analyses adjusting for ASCVD score, HDL, prednisone and statin use, CLC (per 1-SD unit) was not related to SIS (β -0.05 [95%CI -1.19,0.09]), number of high-risk plaques (rate ratio [RR] 1.20 [95%CI 0.80-1.80]) or ln-transformed CAC (β 0.017 [95%CI -0.133,0.147]). However, in analyses stratified by baseline bDMARD use, CLC

(per 1-SD unit) was positively related to number of high-risk plaques (RR 2.14 [95%CI 1.04-4.40]) and ln-transformed CAC (β 0.21 [95%CI 0.01-0.41]) among bDMARD-naïve individuals (Figure 1). In addition, CLC inversely associated with SIS (per SD increment; β -0.16 [95%CI -0.32, -0.01]) only in bDMARD-treated patients. Baseline statin use did not significantly modify the effect of CLC on coronary plaque (not shown). CLC associated with cardiovascular event risk (per SD increment; adjusted odds ratio 2.02 [95%CI 1.27-3.50], p=0.011) covarying for ASCVD score and time-varying bDMARD use. The CLC × time-varying bDMARD use interaction also predicted event risk (p =0.010); current bDMARD use associated with lower event risk at higher (1 SD above the mean) CLC levels (p=0.037) but not average or lower (1 SD below the mean) CLC levels (p=0.064 and 0.756, respectively).

Conclusion: CLC associated with greater CAC score and high-risk plaque burden in bDMARD-naïve RA patients and lower total plaque burden in bDMARD-treated patients at baseline. CLC also predicted long-term cardiovascular risk and its effect was mitigated by bDMARD use.

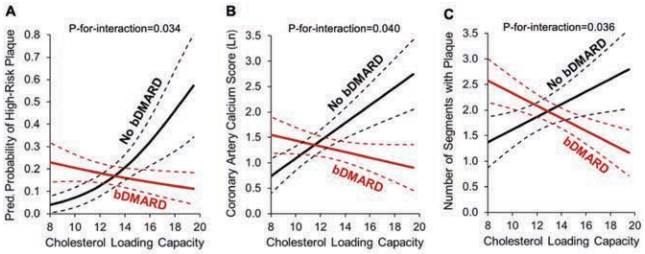

Figure 1 Impact of CLC on coronary atherosclerosis burden in RA and mitigation by bDMARDs

OP0137

ABDOMINAL OBESITY MAY CONFOUND THE ACCURACY OF CARDIOVASCULAR RISK PREDICTION IN RHEUMATOID ARTHRITIS; CAN CORONARY ATHEROSCLEROSIS IMAGING AND BIOMARKERS HELP?

G. Karpouzas[1,2], S. Ormseth[2], E. Hernandez[2], M. Budoff[3,4]. [1]*Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America*; [2]*The Lundquist Institute, Rheumatology, Torrance, United States of America*; [3]*Harbor-UCLA Medical Center, Cardiology, Torrance, United States of America*; [4]*The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: Accurate cardiovascular risk stratification is essential in rheumatoid arthritis (RA) care. RA patients who are underweight incur greater total and cardiovascular mortality compared to those who are overweight or obese.

Objectives: We explored whether abdominal obesity impaired the accuracy of risk prediction estimates in RA patients without known cardiovascular disease (CVD). We further interrogated the potential utility of coronary atherosclerosis assessment and serum levels of related cardiac damage biomarkers to optimize risk prediction in obese RA patients.

Methods: In a single center observational study, 150 participants with coronary CT angiography for atherosclerosis evaluation and prospective follow-up for cardiovascular events over 6.0±2.4 years were assessed. Framingham cardiovascular risk score was computed at baseline. Obesity was defined as waist circumference >88 cm in females and >102 cm in males. Segment involvement score (SIS) described the number of coronary segments with plaque. Serum highly-sensitive cardiac troponin I (hscTnI)-related both to coronary plaque burden and event risk in RA- was measured with Erenna immunoassay. Serum leptin, which is closely related to obesity, was measured with radioimmunoassay. CVD risk estimates were contrasted in non-obese vs. obese patients and those with low vs. high leptin correspondingly using area under the curve (AUC) comparisons. Improvements in risk estimate accuracy in obese patients were explored by sequentially adding hscTnI information and coronary plaque burden estimates to a baseline model of Framingham score and evaluating sequential change in AUC, net reclassification index (NRI) and integrated discrimination improvement (IDI).

Results: A significant interaction between Framingham cardiovascular risk score and obesity was observed (p=0.032). Lower estimates were seen in obese [AUC 0.660, 95%CI 0.487-0.832] vs. non-obese RA patients [AUC 0.952, 95%CI 0.897-1.007, p=0.002, Figure 1A]. Likewise, risk estimates were lower in patients with higher (>22.1 ng/ml) vs. lower (<22.1 ng/ml) leptin [AUC 0.618, 95%CI 0.393-0.842 vs. 0.874, 95%CI 0.772-0.976 respectively, p=0.042, Figure 1B]. In obese patients, sequential addition of the highest hscTnI tertile values and extensive atherosclerotic plaque presence (SIS>5) to a base model including Framingham risk score, significantly improved risk prediction estimates based on changes in NRI [1.093 95%CI 0.517-1.574], IDI [0.188, 95%CI 0.060-0.526], as well as AUC [0.179, 95%CI 0.058-0.378, p=0.02]. The final, combined model accurately predicted 83.9% of incident cardiovascular events (Figure 1C).

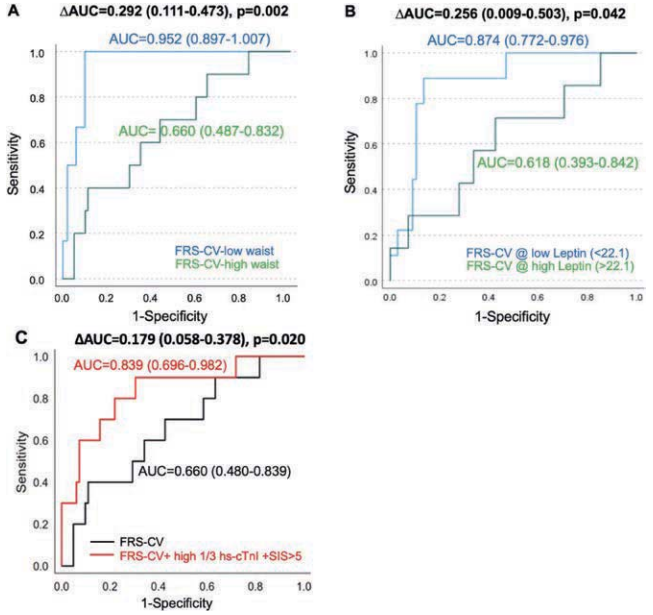

Figure 1. **A** and **B.** Obesity attenuates accuracy of clinical cardiovascular risk estimates in RA. **C.** Addition of information from hs-cTnI measurements and coronary atherosclerosis assessment significantly improve risk prediction

Conclusion: Obesity significantly reduced cardiovascular risk estimate accuracy in patients with RA. The optimization of cardiac risk stratification with the help of non-invasive assessment of coronary atherosclerosis burden and related cardiac damage biomarkers in the serum may warrant further study.

OP0138

RISK OF CANCER AFTER BIOLOGIC AND TARGETED SYNTHETIC DMARDS INITIATION IN PATIENTS WITH RHEUMATIC DISEASES AND A HISTORY OF PRIOR MALIGNANCY: DATA FROM THE BIOBADASER REGISTRY

J. Molina Collada[1,2], F. Sánchez-Alonso[3], C. Bohórquez[4], C. Diaz-Torne[5], C. Perez-Garcia[6], J. M. Blanco[7], P. Vela-Casasempere[8], I. Castrejon[1,2]. [1]*Hospital General Universitario Gregorio Marañón, Rheumatology, Madrid, Spain*; [2]*Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Rheumatology, Madrid, Spain*; [3]*Unidad de investigación, Sociedad Española de Reumatología, Rheumatology, Madrid, Spain*; [4]*Hospital Príncipe de Asturias, Rheumatology, Madrid, Spain*; [5]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; [6]*Hospital del Mar, Rheumatology, Barcelona, Spain*; [7]*Hospital de Basurto, Rheumatology, Bilbao, Spain*; [8]*Hospital General Universitario de Alicante, Rheumatology, Alicante, Spain*

Background: Patients with a history of cancer are routinely excluded from randomized controlled trials. As consequence, data on the safety of biologic disease modifying antirheumatic drugs (bDMARDS) and targeted synthetic (ts) DMARDs are limited. Although real world data from various national registries have not provided evidence of increased cancer recurrence, additional data from real-world registries may help to confirm safety of non-TNFi bDMARDs and tsDMARDs regarding cancer recurrence to guide treatment decisions.

Objectives: To compare the risk of incident malignancy with exposure to different bDMARDs and tsDMARDs in patients with rheumatic diseases and a prior malignancy.

Table 1. Baseline characteristics and rate of incident cancer.

	Anti-TNF (n = 185)	JAKi (n = 61)	Anti-CD20 (n= 61)	Anti-IL6 (n= 68)	Anti-CTLA-4 (n= 47)	Anti-IL17 (n= 39)	Total (n=352)
Female, n (%)	129 (69.7)	49 (80.3)	43 (70.5)	54 (79.4)	34 (72.3)	21 (53.9)	247 (70.2)

Metastatic cancer, n (%)	2 (1.1)	2 (3.3)	2 (3.3)	1 (1.5)	3 (6.4)	0 (0.0)	7 (2.0)
Incident cancer							
New cancer diagnosis, n (%)	18	2	2	5	5	0	32
Time of exposure, sum (years)	470,1	91,6	163	104,9	96,8	63,8	1178,6
Rate of incident cancer (per 1,000 PY)	38.3 (24.1-60.8)	21.8 (5.5-87.3)	12.3 (3.1-49.1)	47.7 (19.8-114.5)	51.7 (21.5-124.1)	0 (0-0)	27.1 (18.6-38.3)
Rate ratio of incident cancer (vs anti-TNF)	-	0.6 (0.1-2.5)	0.3 (0.1-1.4)	1.2 (0.5-3.4)	1.3 (0.5-3.6)	-	-

Methods: The study population comprised patients with a prior malignancy from the BIOBADASER 3.0 up to 2021. BIOBADASER is a large national drug safety registry of patients with rheumatic diseases starting treatment with any bDMARD or tsDMARD and followed thereafter at the time an adverse event or a change in biological therapy occurs. Incident cancer was defined as any cancer (new primaries, local recurrence or metastases) during the exposure classified according to Meddra dictionary. Incidence rate ratios of cancer per 1000 patients-year (PY) and 95% CI were estimated. Rates of incident cancer in tsDMARDs and other bDMARDs versus anti-TNF treated patients were compared.

Results: A total of 9,129 patients treated with bDMARDs and tsDMARDs are included in BIOBADASER 3.0 at the time of the study. Of them, 352 with a prior history of malignancy at time of enrollment were selected for analysis (Figure 1). Overall, there were 32 incident malignancies (17 solid cancer, 14 non-melanoma skin cancer and 1 melanoma). The overall rate of incident malignancy was 27.1 (95% CI 18.6-38.3) events/1,000 PY, ranging between none events/1000 PY in the anti-IL17 group to 51.7 events/1000 PY in the anti-CTLA-4 group (Table 1). The overall rate of incident cancer did not differ significantly in patients exposed to JAKi [0.6 (95% CI 0.1-2.5)], anti-CD20 [0.3 (95% CI 0.1-1.4)], anti-IL6 [1.2 (95% CI 0.5-3.4)] or anti-CTLA-4 [1.3 (95% CI 0.5-3.6) versus anti-TNF therapy. The rate of different types of cancer (melanoma, non-melanoma skin cancer or solid tumors) did not differ between the different treatment groups when compared to anti-TNF therapy (Table 1).

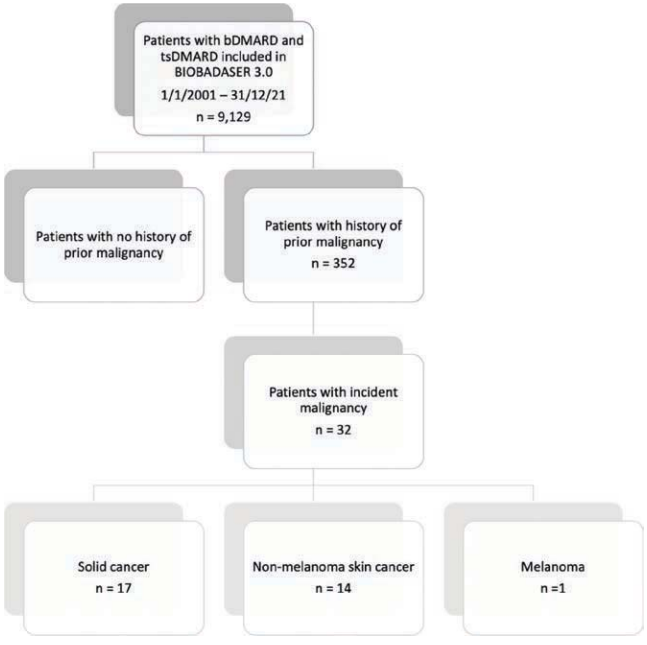

Figure 1. Flowchart of patients included.

Conclusion: The risk of incident cancer in patients with rheumatic diseases and a prior malignancy does not differ according to the type of bDMARD and tsDMARD exposure.

OP0139

IMPACT OF CHRONIC JOINT DISEASES ON THE SEXUAL SPHERE WITH REGARDS TO A HEALTHY POPULATION: A MULTICENTER STUDY.

C. Valera-Ribera[1], M. Robustillo-Villarino[2], E. Flores-Fernández[1], P. Andújar-Brazal[1], I. Vázquez-Gómez[1], A. Ybañez Garcia[1], À. Martínez-Ferrer[1], E. Valls-Pascual[1], J. J. Alegre-Sancho[1]. *[1]Doctor Peset University Hospital, Rheumatology, València, Spain*; *[2]Hospital Universitari de La Plana, Rheumatology, Villarreal, Spain*

Background: Chronic joint diseases impair the quality of life. This occurs not only by the deformity generated, but also by the pain and disability produced by them [1, 2]. There are a limited number of studies on joint diseases and sexuality [3, 4]. Besides, many lack a control group and do not explore the different areas of sexuality[1-4].

Objectives: To describe the prevalence of sexual dysfunction (SD) in patients with rheumatoid arthritis (RA) and psoriatic arthritis (PA). To compare the results obtained between the two diseases and a healthy population. To analyse the factors associated with SD in the 3 populations.

Methods: Cross-sectional observation study. Patients diagnosed of PA (CASPAR criteria) and RA (EULAR/ACR 2010 criteria), followed in outpatient Rheumatology offices of two different university hospitals of the same geographical area, were consecutively included. The following variables were collected: (age, gender, year of diagnoses, perceived health, marital status, level of education, employment situation and the annual level of income), as well as (history of depression and active treatment of mental health disease). The results were compared against healthy individuals, acting as a control group. Only adult patients, of any sexual orientation, were included. The CSFQ-14 questionnaire, which evaluates changes in sexual function due to the disease or its medication, was applied. This questionnaire studies 4 different domains in both genders (pleasure, desire, arousal, orgasm and pain during orgasm) and in addition, it evaluates orgasm completion in women and erection in men. A regression model was created to estimate the influence of the collected variables on the obtained results.

Results: 188 patients were included (52.7% women and 47.3% men); 72 of them were diagnosed of PA and 27 of RA. Moreover, 30.43% of the patients with PA, 48.15% of the patients with RA and 5.88% of the control group had scores on the CSFQ-14 test in the SD range.

SD was found related to being diagnosed of PA and RA ($p < 0.001$), age ($p < 0.001$), employment status ($p < 0.001$) and the annual level of income ($p = 0.002$). On the CSFQ-14 test, men had a mean score 7.5 points higher than women, although this score decreased to 6.15 points in men with PA. Furthermore, patients with PA and RA had a mean score 8.2 points lower than the control goup. All of the domains of the CSFQ-14 questionnaire were negatively affected by having PA or RA ($p < 0.001$). The estimated odds ratio of having SD was 8.7 times higher in patients diagnosed of PA and 10 times higher in patients diagnosed of RA.

Conclusion: Patients with RA or PA have a deteriorated sexual life when compared to a healthy population. This detriment affects all of the domains of the sexual sphere (pleasure, desire, arousal and orgasm). As shown in previous studies, age, gender, perceived health, employment situation and economic status, are related to the risk of suffering from SD. Therefore, these factors must be considered when attending this area of our patient's health. The CSFQ-14 questionnaire provides a complete approach to sexual health and can be a tool for the management of chronic joint diseases.

Remission, flares and predictive factors in SLE, Sjogren and anti-phospholipid syndrome

OP0140 IMPACT OF TIME TO REMISSION, FLARES AND TIME ON IMMUNOSUPPRESSIVES ON THE ESTIMATED GLOMERULAR FILTRATION RATE IN LUPUS NEPHRITIS

K. Tselios[1], D. D. Gladman[2,3], J. Su[2], M. B. Urowitz[2,3]. [1]*McMaster Lupus Clinic, Department of Medicine, Hamilton, Canada*; [2]*University Health Network, Schroeder Arthritis Institute, Toronto, Canada*; [3]*University of Toronto, Department of Medicine, Toronto, Canada*

Background: Time to complete remission, subsequent flares and time on immunosuppressives after complete remission are major determinants of the progression to advanced chronic kidney disease in lupus nephritis (LN). However, the impact of these factors on the rate of glomerular filtration rate (GFR) deterioration is not known.
Objectives: To determine the impact of time to remission, flares and time on immunosuppressives after remission on the estimated GFR in LN.
Methods: Patients with LN based on biopsy or abnormal proteinuria (>0.5g/day) with or without hematuria or pyuria or casts for two consecutive visits were retrieved from the Toronto Lupus Clinic long-term longitudinal database. Individuals with advanced chronic kidney disease at baseline (eGFR≤29ml/min/1.73m^2) were excluded. All patients were followed for at least 5 years. The primary outcome was any decrease of the estimated GFR on an annual basis (slope). Remission was defined as proteinuria<0.5g/24h, inactive urinary sediment and serum creatinine ≤120% of the baseline value. Flare was defined as any abnormal proteinuria (>0.5g/day) or increase in serum creatinine (SCR) from normal to abnormal or >120% of the baseline value after remission. Slopes of eGFR changes (standard error) were calculated using Ordinary Least Square method in each complete remission/flare group. Linear Mixed model was performed to account for factors associated with deterioration of eGFR.
Results: Out of 418 eligible patients, 209 (50%) achieved remission within the first year from LN diagnosis, 102 (24.4%) within the 2nd and 3rd years, 70 (16.7%) after 3 years and 37 (8.9%) never achieved remission. Regarding flares, 82 patients (19.6%) never flared, 75 (18%) had one flare and 261 (62.4%) had two or more flares. The trajectory and annual slope of eGFR according to time to remission and number of flares is shown in the Figure 1.

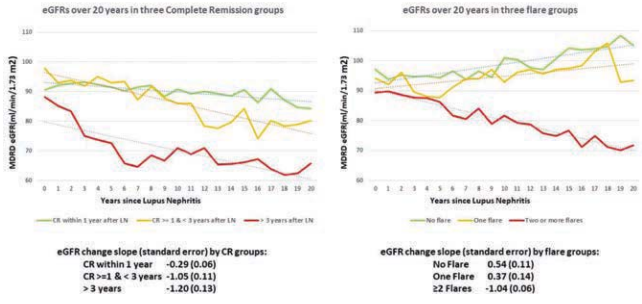

Figure 1.

Regression analysis (linear mixed model) for the outcome of eGFR was performed to adjust for other variables that impact eGFR (Table 1).

Predictors	Estimate	Standard Error	p value
Each one later decade of LN onset	4.45	0.93	<0.0001
Years on immunosuppressives since remission	0.71	0.19	<0.0001
Age at LN onset	-0.76	0.11	<0.0001
Hypertension at LN	-7.73	2.75	0.005
CR < 1 year after LN	0 (Ref.)		
CR between 1-3 years comparing to < 1 year after LN	-1.60	2.90	0.581
No CR or CR later than 3 years comparing to < 1 year after LN	-12.31	2.90	<0.0001
No Flare	0 (Ref.)		
One flare any time after LN vs. no flare	-3.48	3.79	0.358
Two or more flares any time after LN vs. no flare	-14.79	3.01	<0.0001

Conclusion: Complete remission after 3 years or no remission is associated with a significant decrease in eGFR, while remission during the 2nd and 3rd year from LN diagnosis is not associated with significant decrease of renal function over time. Patients with one flare did not have significant impact on their renal function. Patients with 2 or more flares had a significant decrease of eGFR over 20 years, even after adjustment for other covariates. Time on immunosuppressives after complete remission is protective against eGFR decline. Our findings emphasize the importance of rapid remission and flare prevention by prolonged maintenance treatment with immunosuppressives to optimize renal outcomes.

OP0141 TREAT TO TARGET IN SYSTEMIC LUPUS ERYTHEMATOSUS FROM THE PATIENTS' PERSPECTIVE – RESULTS FROM AN INTERNATIONAL PATIENT SURVEY

J. Mucke[1], D. Pencheva[2,3], A. Parra Sanchez[4], K. Kramer[5], M. Schneider[1], I. Bultink[4]. [1]*University Hospital Duesseldorf, Policlinic and Hiller Research Unit, Duesseldorf, Germany*; [2]*Medical University of Sofia, Department of Physiology and Pathophysiology, Sofia, Bulgaria*; [3]*Medical University of Sofia, University Clinical Hospital "St. Ivan Rilski", Sofia, Bulgaria*; [4]*Amsterdam Rheumatology and Immunology Center, Department of Rheumatology, Amsterdam, Netherlands*; [5]*Patient Research Partner, Amsterdam, Netherlands*

Background: Treat-to-target (T2T) is a generally accepted treatment concept in rheumatology care. It is assumed that T2T could significantly improve systemic lupus erythematosus (SLE) care and the patients' outcomes. However, T2T has not yet been studied systematically and clinical trials are currently in preparation [1]. Furthermore, the patients' opinion on T2T has barely been taken into account.
Objectives: As the success of T2T is largely determined by the involvement of patients, it was our aim to investigate the attitude towards, need, and willingness of SLE patients to participate in a T2T study and to identify possible obstacles.
Methods: A questionnaire on T2T, its acceptance, the need and willingness to participate in a T2T trial and possible obstacles for T2T was designed by the authors in cooperation with patient research partner and performed in the Netherlands (NL), Austria (AU), Germany (GE) and Bulgaria (BG). The web-based survey consisted of 13 questions with single and multiple answers and/or free text. After back-and-forth translation from German to Dutch and Bulgarian, it was distributed among members of the patient organizations of NL, GE, AU, BG via newsletter (GE, AU, BG), personal invitation (NL) and a closed Facebook group (BG). Castor Electronic Data Capture (NL) and SoSci-Survey (GE, AU, BG) were used as platforms.
Results: A total of 863 patients (n=316 NL, n=271 GE, n=232 BG, n=44 AU) with self-declared diagnosis of SLE completed the questionnaire. 93.3% were female, 52.2% were 41-60 years old. The disease duration was longer than 10 years in 54.8%, 12.4% had a disease duration of 0-2 years. Regarding the satisfaction with the current health status, 56.2% were somewhat to all the way satisfied, 29.3% were not at all or hardly satisfied. 65.5% were satisfied with their current therapeutic treatment, 14.8% where not at all or hardly satisfied.

48.4% declared being currently in remission, 13% did not know if they were in remission. As most important treatment goal, normalization of quality of life was chosen most frequently (37.4%) followed by prevention of organ damage (24.6%) and the absence of disease activity (22.6 %).
Regarding shared decision making, the majority reported to be somewhat to all the way involved in treatment decisions (62.1%) while 20,7% where hardly or not at all involved.
As most difficult decisions in T2T and shared decision making, respondents named the start of new SLE medication (37.9%) and to change medication while feeling good (39.4%). An increase in the dose of glucocorticoids to reach remission was difficult for 22.7%.
The majority of patients considered research of T2T in SLE useful (55,4% all the way, 29.8% somewhat useful) and 67% would probably or definitely participate in such scientific research. The perceived advantages and disadvantages of T2T are depicted in Figure 1.

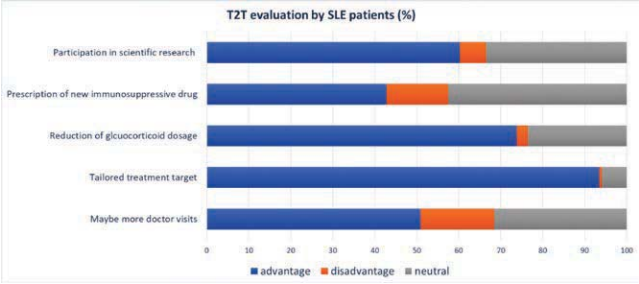

Figure 1. Consequences of T2T rated as advantage or disadvantage by SLE patients. *SLE systemic lupus erythematosus, T2T treat-to-target.*

Conclusion: Despite many SLE patients being satisfied with their treatment and health status, T2T is considered an important subject to be studied in clinical trials. Advantages did overweigh possible disadvantages of T2T with the possibility of more doctors' visits and the prescription of a new drug as biggest disadvantage. Quality of life named as most important treatment goal emphasizes its importance as outcome parameter. Most patients would be willing to participate in a trial about T2T.

Background: Lupus low disease activity state (LLDAS) attainment has been reported to be associated with reduced damage accrual, flare, and mortality, as well as improved quality of life, in cohorts of SLE patients with established disease. Whether these associations are present in recent-onset disease is less well known.
Objectives: To evaluate the associations of LLDAS attainment with outcomes in patients with recent onset SLE.
Methods: Data from a 13-country longitudinal SLE cohort (ACR/SLICC criteria) were collected prospectively between 2013 and 2020 using standard templates. Organ damage and flare were captured using SLICC Damage Index and SELENA-SLEDAI Flare Index, respectively. LLDAS was defined as Golder *et al.*, 2019 [1]. An inception cohort was defined based on duration since SLE diagnosis<1 year at enrolment. Patient characteristics between inception and non-inception cohorts were compared using Wilcoxon rank-sum (continuous variables) or Pearson's Chi-squared tests (categorical variables). Survival analyses were performed to examine the association between LLDAS attainment and damage accrual and flare.
Results: The study cohort included 4,106 patients of whom 680 (16%) were recruited within 1 year of SLE diagnosis (inception cohort). Compared to the non-inception cohort, inception cohort patients were significantly younger, had higher disease activity (SLEDAI-2K and physician global assessment), used more glucocorticoids and immunosuppressants but had less organ damage at enrolment and only 88 (13.6%) patients accrued damage during a median 2.2 years follow-up (Table 1).

Table 1.

	Non-inception cohort	Inception cohort	p-value
	n=3426	n=680	
Age at enrolment (years), *median [IQR]*	40 [31, 51]	33 [25, 44]	<0.001
Age at diagnosis (years), *median [IQR]*	28 [21, 38]	33 [25, 43]	<0.001
SLE duration at enrolment (years), *median [IQR]*	10 [5, 16]	1 [0, 1]	<0.001
Study duration (years), *median [IQR]*	2.5 [1.0, 5.4]	2.2 [0.9, 3.7]	<0.001
Females, *n (%)*	3155 (92.1%)	623 (91.6%)	0.68
Asian ethnicity, *n (%)*	3037 (89.1%)	595 (88.1%)	0.49
Prednisolone (PNL) use - ever, *n (%)*	2865 (83.6%)	620 (91.2%)	<0.001
Time adjusted mean (TAM)-PNL, *median [IQR]*	5.0 [2.2, 8.6]	6.2 [3.2, 10.3]	<0.001
Cumulative PNL (g), *median [IQR]*	3.4 [0.5, 9.7]	3.8 [1.1, 8.5]	0.26
Anti-Malarial use - ever, *n (%)*	2669 (77.9%)	569 (83.7%)	<0.001
Immunosupressant use -ever, *n (%)*	2367 (69.1%)	521 (76.6%)	<0.001
AMS (TAM-SLEDAI-2K), *median [IQR]*	2.8 [1.2, 4.6]	3.1 [1.6, 5.0]	0.002
TAM-PGA, *median [IQR]*	0.4 [0.2, 0.7]	0.4 [0.3, 0.8]	<0.001
Mild/moderate/severe flare ever, *n (%)*	1789 (52.2%)	391 (57.5%)	0.012
Organ damage accrual, *n (%)*	629 (20.8%)	88 (13.6%)	<0.001
LLDAS at baseline, *n (%)*	1730 (50.5%)	195 (28.7%)	<0.001
LLDAS-ever (at least once), *n (%)*	2637 (78.2%)	492 (73.9%)	0.014
≥50% time in LLDAS (LLDAS-5), *n (%)*	1612 (50.6%)	256 (41.1%)	<0.001

Significantly fewer inception cohort patients were in LLDAS at enrolment than the non-inception cohort (29% vs. 51%, p<0.001). However, 74% of inception and 78% of non-inception cohort patients achieved LLDAS at least once during follow-up. Limiting analysis only to patients not in LLDAS at enrolment, time to first LLDAS attainment was assessed: inception cohort patients were 60% more likely to attain their first LLDAS (HR = 1.60 (95%CI: 1.40, 1.82), p<0.001) than non-inception cohort patients. LLDAS attainment was significantly protective against flare in the inception (HR, 95% CI) and non-inception (HR, 95% CI) cohorts. Trends towards protection against damage accrual in association with LLDAS in the inception cohort were not significant.

Conclusion: LLDAS attainment is protective from flare in recent onset SLE. Significant protection from damage accrual was not observed, due to low rates of damage accrual in the first years after SLE diagnosis.

OP0143 INTERCURRENT INFECTION AS A RISK FACTOR FOR DISEASE FLARES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

F. el Hadiyen[1], M. Tsang-A-Sjoe[1], B. Lissenberg-Witte[2], A. Voskuyl[1], I. Bultink[1].
[1]*Amsterdam UMC, locatie VUmc, Rheumatology, Amsterdam, Netherlands*;
[2]*Amsterdam UMC, locatie VUmc, Epidemiology and Data Science, Amsterdam, Netherlands*

Background: Intercurrent infections are presumed potential triggers of systemic lupus erythematosus (SLE) disease flares.[1] However, most of the evidence is obtained from a limited number of observational studies, and the results of these studies are conflicting.[2,3]

Objectives: To determine whether intercurrent infections are a risk factor for disease flares in SLE.

Methods: Demographic and clinical characteristics of 203 SLE patients from the Amsterdam SLE cohort were collected at baseline, and at the start of an intercurrent infection that either was or was not followed by a flare within three months. Relevant data regarding infections and flares were collected systematically by chart review. Major and minor infections were defined as, respectively: infections for which hospital admission or intravenous antibiotic therapy was required, and infections (proven or not proven, but highly likely based on clinical symptoms and/or response to therapy) for which hospital admission was not warranted. SLE flares were defined as an increase in disease activity requiring intensification of immunosuppressive therapy. Flares were categorized as major or minor depending on fulfillment of a predefined set of criteria.[4] Incidence rates for infections, flares, and infections followed by a flare within three months were calculated using Poisson regression. Descriptive analyses were performed where appropriate. Proportional hazard models with recurrent events and time-varying covariates were used to estimate the hazard ratio of SLE flares.

Results: Table 1 shows the demographic and clinical characteristics of all 203 SLE patients. Fifty-six major infections occurred in 1060 patient years, and 670 minor infections occurred in 1048 patient years. The incidence rates of major and minor infections were 5.3 per 100 patient years (95% CI: 4.1 – 6.9) and 63.9 per 100 patient years (95% CI: 59.3 – 69.0), respectively. In total, 198 flares occurred within 1060 patient years. The incidence rate of flares is 18.7 per 100 patient years (95% CI: 16.3 – 21.5), 3.6 per 100 patient years (95% CI: 2.6 – 4.9) for major flares and 15.1 per 100 patient years (95% CI: 12.9 – 17.6) for minor flares. The incidence rates of, respectively, major and minor infections followed by a flare within three months were 0.7 per 100 patient years (95% CI: 0.3 – 1.4) and 2.3 per 100 patient years (95% CI: 1.5 – 3.4). Intercurrent infections (major and minor) were associated with the occurrence of SLE flares (major and minor; HR 1.9, 95% CI:1.3 – 2.9) (Figure 1). The hazard ratio for a major SLE flare following a major infection was 7.4 (95% CI 2.2 – 24.6). Major infections were not associated with the occurrence of minor flares.

Table 1. Baseline demographic and clinical characteristics

Variables	SLE patients (n = 203)
Sex, Female, n (%)	184 (91)
Age, years (median (IQR))	40.0 (32.0 – 47.0)
Caucasian ethnicity, n (%)	137 (68)
SLICC/ACR damage index (median (IQR))	1 (0 – 2)
SELENA-SLEDAI2k (median (IQR))	4 (2 – 6)
Disease duration, years (median (IQR))	6 (1 – 11)
History of:	
Biopsy proven lupus nephritis, n (%)	38 (19)
Renal insufficiency (eGFR < 45), n (%)	6 (3)
Diabetes mellitus, n (%)	7 (3)
Malignancy, n (%)	5 (3)
Stroke, n (%)	12 (6)
Asplenia, n (%)	5 (3)
Treatment variables:	
Glucocorticoids, n (%)	106 (52)
Antimalarials, n (%)	151 (74)
Immunosuppressants, n (%)	75 (37)
NSAIDs, n (%)	67 (33)

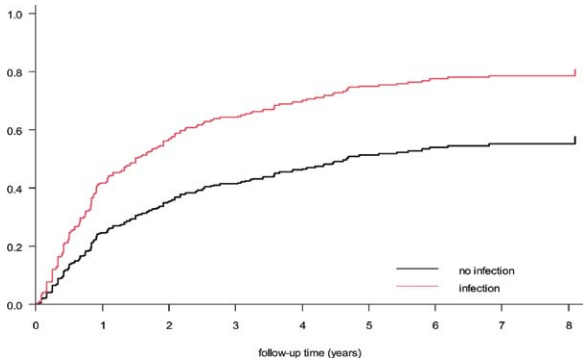

Figure 1. Estimated cumulative incidence of SLE flares (major and minor) following an intercurrent infection within three months

Conclusion: The results of the present study confirm a high frequency of infections in SLE patients and suggest that intercurrent infection is a risk factor for SLE flares. These findings underline the importance of prevention and treatment of infections in SLE patients and create awareness of infections as potential triggers of SLE flares.

OP0144 SLE-T2T – A DIGITAL TREAT-TO-TARGET CLINICAL DECISION SUPPORT SYSTEM FOR THE MANAGEMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: DEVELOPMENT AND USABILITY EVALUATION

A. Parra Sanchez[1], M. G. Grimberg[2], M. M. A. Hanssen[2], M. O. Aben[2], E. E. Jairth[2], P. S. Dhoeme[2], M. Tsang-A-Sjoe[3], A. Voskuyl[3], J. H. Leopold[4], R. van Vollenhoven[1]. [1]*Amsterdam UMC, locatie AMC, Amsterdam Rheumatology Center ARC, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; [2]*University of Amsterdam, Medical Informatics Bachelor's Program, Amsterdam, Netherlands*; [3]*Amsterdam UMC, locatie VUmc, Amsterdam Rheumatology Center ARC, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; [4]*Amsterdam UMC, locatie AMC, Dept. of Medical Informatics, Amsterdam, Netherlands*

Background: Treating-to-target (T2T), a treatment approach focussed on achieving a specific goal by stepwise changes in treatment, is a well-established strategy in various diseases and has been proposed for systemic lupus erythematosus (SLE)[1]. However, the implementation of such strategies has been shown to be difficult in practice with low clinician adherence[2]. Clinical decision support systems (CDSS) are designed to assist health care professionals in their decision-making process[3]. SLE-T2T is an online CDSS tool designed to help rheumatologists to apply a T2T strategy in the management of SLE patients.

Objectives: We aimed to design and develop a first prototype of SLE-T2T, and test its usability for the implementation of a treat-to-target strategy in the management of patients with SLE.

Methods: The creation process was composed of three phases: first, SLE-T2T was conceived as a web-based application with a specific task - to generate appropriate treatment advice based on entered patients' data. A general sketch of the program was made, and general consensus was achieved with regards to the desired functionalities. In the development phase, a beta version of SLE-T2T was conceived using a free integrated development environment, and based on Javascript, HTML and CSS. After, the system was hosted temporarily on the website of the Amsterdam Rheumatology & Immunology Center[4], to be accessible for the participants in evaluation phase. Finally, a System Usability Score survey (SUS)[5,6] was chosen as the usability test tool, given its simplicity and advantages; coupled with unstructured feedback about areas of improvement, collected from the participants using the "think aloud" method to determine whether the CDSS was user-friendly, comprehensible, easy-to-deliver, and workflow-oriented.

Results: The SLE-T2T web-based system was developed, consisting of: (1) an input scheme with the set of indexes and scores existing for the measurement of SLE disease activity (cSLEDAI-2K, SLEDAI-2K, PGA score) as well as the patients' medication; (2) a rule-based interface that collects and processes patients' data, and (3) an output dashboard with the generated set of recommendations tailored for the patients clinical state and aiming to reach a pre-stablished target of treatment (Figure 1). In the interim usability and acceptance evaluation, 7 participants completed the SUS survey. The mean usage time for SLE-T2T was 8 minutes. On a scale of 0 (worst) to 100 (best), the median SUS score of SLE-T2T was 79, categorizing the application as 'good' and indicating the need for minor improvements to the design necessary to reach a final version for later implementation in a treat-to-target pilot study.

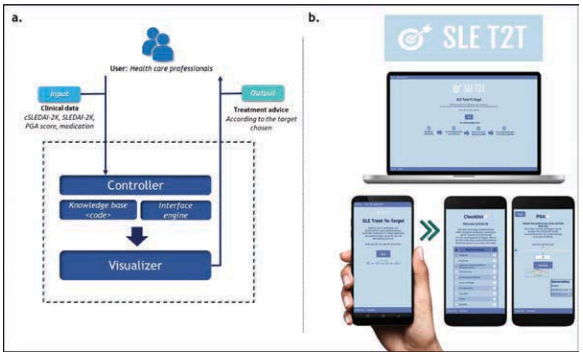

Figure 1. ***Overview of SLE-T2T CDSS tool.*** a. Architecture of the SLE-T2T app. b. Desktop and mobile example views.

Conclusion: To the best of our knowledge, SLE-T2T is the first eHealth tool to be designed for the management of SLE patients in a treat-to-target context. The SUS score and unstructured feedback showed high acceptance of this digital instrument.

OP0145 VALIDATION OF 3 PREDICTION MODELS FOR THROMBOSIS IN ANTIPHOSPHOLIPID SYNDROME PATIENTS BASED ON A PROSPECTIVE COHORT

Y. Zhao[1], C. Huang[1], W. Qi[1], J. Zhao[1], M. Li[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital, Rheumatology and Clinical Immunology, Beijing, China*

Background: Antiphospholipid syndrome (APS) is a rare and complicated acquired autoimmune thrombophilia characterized by arterial/venous thrombosis and/or recurrent pregnancy loss. Thrombosis is the first cause of death of APS patients. However, there has been no generally acknowledged model to predict thrombosis. Only adjusted global APS score (aGAPSS) was developed for prediction but based on a cross-sectional study[1]. Additionally, the predictive ability of Padua score and Caprini score has not been validated in APS patients.

Objectives: Aim to validate the ability of aGAPSS, Padua score and Caprini score to predict thrombosis in APS patients basing on a prospective cohort.

Methods: Consecutive APS patients who fulfilled the 2006 Sydney Revised Classification Criteria for APS, referred to Peking Union Medical College Hospital were included. Clinical data, aGAPSS, Padua score, and Caprini score at the time of diagnosis were collected. Patients with less than 1-year follow-up were excluded. Harrell c-index and calibration curve were used to validate the prediction models.

Results: A total of 302 patients were enrolled in this study. The mean age was 32±12 years old, and 202 (66.9%) were female (Table 1). Patients were followed up for a median of 36 months. During the follow-up period, there were 62 thrombotic events, with 40 (13.25%) venous and 22 (7.28%) arterial thrombosis. The 1-, 3-, and 5-year thrombosis risks were 8.9%, 16.9%, and 21.3% respectively (Figure 1A). The Harrell c-indexes for predicting thrombosis of aGAPSS, Padua score, and Caprini score were 0.56 (95% confidence interval [CI], 0.52-0.60), 0.58 (95% CI, 0.54-0.62), and 0.61 (95%CI, 0.57-0.65) respectively. The model predicting venous thrombosis with the best discrimination was Padua score whose Harrell c-index was 0.64 (95% CI, 0.60-0.68), and the model predicting arterial thrombosis with the best discrimination was Caprini score whose Harrell c-index was 0.62 (95%CI, 0.56-0.68). The calibration curves illustrated that the calibration for predicting thrombosis within 3 years after diagnosis of all the 3 models was poor (Figure 1B-D).

Table 1. Demographic characteristics and clinical manifestations at baseline

	N=302		N=302
Age, mean±SD	32±12	**Clinical manifestations**	
Female, n (%)	202 (66.9)	Venous thrombosis, n (%)	156 (51.7)
Disease duration (months), median (Q1, Q3)	11.50 (3.00, 44.00)	Deep venous thrombosis, n (%)	112 (37.1)
Secondary to SLE, n (%)	73 (24.2)	Pulmonary embolism, n (%)	70 (23.2)
Smoking history, n (%)	63 (20.9)	Visceral venous thrombosis, n (%)	12 (4.0)
Hypertension, n (%)	59 (19.5)	Cranial venous sinus thrombosis, n (%)	13 (4.3)
Hyperlipidemia, n (%)	151 (50.0)	Arterial thrombosis, n (%)	113 (37.4)
BMI, mean±SD	23.96±3.89	Stroke/TIA, n (%)	62 (20.5)
LA positive, n (%)	241 (79.8)	Myocardial infarction, n (%)	14 (4.6)
aCL positive, n (%)	208 (68.9)	Arterial thrombosis of lower extremities, n (%)	22 (7.3)
aβ2GPI positive, n (%)	242 (80.1)	Visceral arterial thrombosis, n (%)	18 (6.0)
Triple aPL positive, n (%)	165 (54.6)	Thrombocytopenia, n (%)	118 (39.1)
Obstetric manifestations, n (%)	**N=202**	Valvular lesions, n (%)	24 (7.9)
Pregnancy morbidity	103 (51.0)		
Early miscarriages (<10 weeks)	13 (6.4)		
Fetal death (>= 10 weeks)	68 (33.7)		
Preeclampsia, eclampsia and placental dysfunction	36 (17.8)		

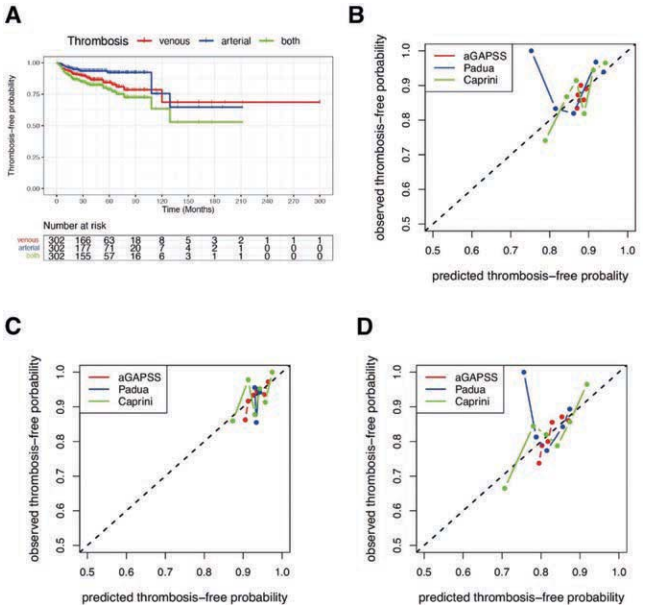

Figure 1. The Kaplan-Meier curve and the calibration curve of 3 prediction models within 3 years after diagnosis. A: The Kaplan-Meier curve of venous, arterial and both venous and arterial thrombosis. B: The calibration curves for venous thrombosis. C: The calibration curves for arterial thrombosis. D: The calibration curves for both venous and arterial thrombosis.

Conclusion: The ability of aGAPSS, Padua score and Caprini score to predict thrombosis in APS patients is relatively poor. Construction of a new prediction model specifically for APS patients is required to help with early prevention and treatment.

ISOLATED ANTI-RO52 ANTIBODIES IN SJÖGREN'S SYNDROME: A MILDER INFLAMMATORY PHENOTYPE AT HIGHER RISK FOR FIBROTIC ORGAN INVOLVEMENT

S. Fonzetti[1], F. Ferro[1], G. La Rocca[1], G. Fulvio[1], I. C. Navarro García[1], G. Governato[1], V. Donati[2], M. Mosca[1], C. Baldini[1]. *[1]University of Pisa, Rheumatology Unit, Clinical and Experimental Medicine, Pisa, Italy; [2]Unit of Pathological Anatomy 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

Background: Autoimmune response against the Ro antigen (Ro52 and/or Ro60 subunits) represents a distinctive serological hallmark in primary Sjögren Syndrome (pSS). The double positivity for anti-Ro60 and anti-Ro52 has been associated with a higher glandular inflammation and B-cell hyperactivity. By contrast, the clinical significance of isolated anti-Ro52 antibodies in pSS remains controversial.

Objectives: To investigate the association between isolated anti-Ro52 antibodies and glandular and extra-glandular pSS features in order to explore whether anti-Ro52 antibodies may help to identify a specific subset of pSS.

Methods: In this retrospective study we included unselected pSS patients prospectively followed at our Unit between 2012 to 2021. Of them, anti-Ro/SSA positive patients were identified and stratified by the presence of anti-Ro52 isolated, anti-Ro60 isolated and both anti-Ro60 and anti-Ro52. Demographics, clinical, biological and histological data were compared between the three groups. Data were presented as mean±SD, or percent frequency as appropriate. Intergroup comparisons were made using the t-test/Mann–Whitney test for continuous variables and Fisher's exact test for categorical variables.

Results: Out of a study cohort of 432 pSS patients, we included 300 anti-Ro/SSA positive patients (21 M: 279 F, mean age 57±14 yrs) followed for a mean follow-up of 6.5±6.7 years. Of them, 59/300 (19.7%) presented isolated Ro52 antibodies, 214/300 (71.3 %) both anti-Ro60 and anti-Ro52 and 27/300 (9%) had isolated Ro60 antibodies. At diagnosis, patients with anti-Ro52 alone were older than those with double positivity (57.4±13.2 vs 48.8±13.8, p=0.0001) and presented a lower focus score (FS) in their minor salivary gland biopsies (MSGBs) (p=0.9±1.0 vs 1.6±0.9, p=0.02). No differences in demographic and glandular infiltrate were detected between anti-Ro52 alone and anti-Ro60 alone patients. Similarly, the three subgroups did not differ in oral and ocular function tests as well as in the patient reported outcomes (ESSPRI, OHIP and OSDI). Salivary gland ultrasonography showed a decreasing trend of the OMERACT scoring system with the highest grade detected more commonly in anti-Ro60 and anti-Ro52 patients and the lowest grade in anti-Ro60 alone. Regarding extraglandular manifestations significant differences were observed among the three subgroups as shown in the heat map (Figure 1). Patients with anti-Ro52 alone presented the highest frequency of interstitial lung disease (ILD) and primary biliary cirrhosis (PBC) and the lowest prevalence of lymphadenopathy, anti-La/SSB and hyper-IgG (p<0.05). By contrast, patients presenting anti-Ro52 in association with anti-Ro60 had a prominent B cell hyperactivity with higher levels of serum IgG, anti-La SSB antibodies and Rheumatoid factor positivity (p<0.05). Finally, patients with isolated anti-Ro60 presented a milder disease activity and an ESSDAI (3.4±4.5 vs 6.3±4.8 vs 5.2±5.1, p=0.009) significantly lower than the other two subgroups.

Conclusion: Patients with isolated anti-Ro52 seems to represent a specific subset of pSS with milder tissue focal inflammation but at higher risk for systemic fibrotic changes, particularly in the lungs. The identification of molecular pathogenetic processes, common to both isolated anti-Ro52 pSS and other anti-Ro52 positive connective tissue diseases may offer new insights into our understanding of disease etiology, and facilitate the development of targeted therapeutic approaches.

THE SLE-DAS REMISSION AND LOW DISEASE ACTIVITY STATES DISCRIMINATE DRUG FROM PLACEBO AND BETTER HEALTH-RELATED QUALITY OF LIFE: POST-HOC ANALYSIS OF THE BLISS-52 AND BLISS-76 PHASE III TRIALS.

D. Jesus[1,2], C. Henriques[3,4], A. Matos[3,5], A. Doria[6], L. Inês[2,7]. *[1]Centro Hospitalar de Leiria, Rheumatology Department, Leiria, Portugal*; *[2]Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal*; *[3]Polytechnic Institute of Viseu, School of Technology and Management, Viseu, Portugal*; *[4]University of Coimbra, Centre for Mathematics, Coimbra, Portugal*; *[5]Research Centre in Digital Services, (CISeD), Viseu, Portugal*; *[6]University of Padova, Rheumatology Unit, Department of Medicine, Padova, Italy*; *[7]Centro Hospitalar e Universitário de Coimbra, CHUC Lupus Clinic, Rheumatology Department, Coimbra, Portugal*

Background: Accurate and practical outcome measures for clinical trials in systemic lupus erythematosus (SLE) are lacking. The SLE Disease Activity Score (SLE-DAS) is a recently validated 17-item instrument, with high accuracy and sensitivity to changes in SLE disease activity. The SLE-DAS definitions of remission and low disease activity (LDA) were newly validated in the clinical setting[1,2]. These definitions may constitute accurate and easy to apply endpoints for SLE trials.
Objectives: (1) To evaluate the ability of SLE-DAS remission and LDA definitions to discriminate drug from placebo in SLE phase 3 trials; (2) To determine if attainment of these SLE-DAS targets are associated with better health-related quality of life (HR-QoL).
Methods: Post-hoc analysis of the merged study population in the BLISS-52 and -76 trials (NCT00424476; NCT00410384) of intravenous belimumab versus placebo for moderate to severe SLE disease activity. We analyzed the British Isles Lupus Assessment Group (BILAG), Physician Global Assessment (PGA), Functional Assessment of Chronic Illness Therapy (FACIT) and 36-Item Short Form Survey (SF-36) trial data. The fulfillment of SLE-DAS remission and LDA definitions were retrospectively assessed from the individual participants' data. Proportion of patients attaining SLE-DAS Boolean remission (defined as absence of all SLE-DAS clinical items and prednisone ≤5mg/day) and LDA (defined as SLE-DAS≤2.48 and prednisone ≤7.5mg/day), at week 52, was compared between belimumab and placebo arms, using likelihood ratio chi-square test. We further compared the SF-36 physical component summary (PCS) and mental component summary (MCS) and domain scores and the FACIT score between patients attaining SLE-DAS remission *vs* non-remission and SLE-DAS LDA *vs* non-LDA, using t-test and Mann-Whitney test.
Results: A total of 1684 SLE patients were included: 562 on placebo, 559 on belimumab 1mg/Kg and 563 on belimumab 10mg/Kg. At week 52, significantly more patients attained SLE-DAS LDA on belimumab 1mg/Kg and 10mg/Kg as compared with placebo (13.0% *vs* 17.9%, OR=1.459, p=0.023, and 13.0% *vs* 21.7%, OR=1.853, p<0.001, respectively). Likewise, more patients attained SLE-DAS remission on belimumab 10mg/Kg as compared with placebo (10.1% *vs* 14.7%, OR= 1.532, p=0.019) (Table 1). Importantly, none of the patients achieving SLE-DAS remission or LDA presented a new BILAG A or more than 1 new B domain score, neither a worsening in PGA≥0.3.
At week 52, patients attaining SLE-DAS remission and SLE-DAS LDA presented higher SF-36 domain and summary scores (all p<0.001) (Figure 1). Additionally, FACIT scores were higher in patients attaining SLE-DAS remission than non-remission patients (mean±SD: 38.24±10.65 *vs* 33.45±12.13, p<0.001), and in patients attaining SLE-DAS LDA than non-LDA (mean±SD: 37.22±11.00 *vs* 33.37±12.17, p<0.001), at week 52.

Table 1. Attainment of SLE-DAS Boolean remission and LDA at week 52 in BLISS-52 and BLISS-76 trials, according to the treatment groups (n =1684).

	Placebo	Belimumab 1mg/Kg	Belimumab 10mg/Kg
SLE-DAS remission (n=211)	10.1%	12.7%, OR=1.289 (0.89-1.866), p=0.178	14.7%, OR 1.532 (1.069-2.195), p=0.019
SLE-DAS LDA (n=295)	13.0%	17.9%, OR=1.459 (1.052-2.025), p=0.023	21.7%, OR 1.853 (1.349-2.545), p<0.001

LDA: Low disease activity; SLE-DAS Boolean remission: absence of all SLE-DAS clinical items and prednisone ≤5mg/day; SLE-DAS LDA: SLE-DAS≤2.48 and prednisone ≤7.5mg/day.

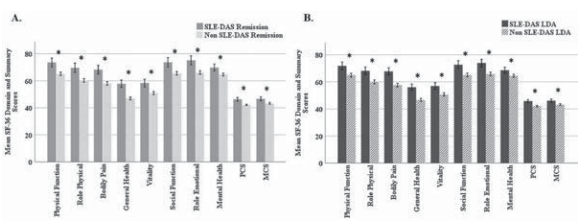

Figure 1. Mean SF-36 domain and summary scores at week 52; *p<0.001; MCS, Mental Component Summary; PCS, Physical Component Summary; SF-36, Medical Outcomes Survey Short Form.

Conclusion: The SLE-DAS remission and LDA showed discriminant validity for identifying patients receiving active drug in clinical trials. These treatment targets are associated with better HR-QoL and lower fatigue.

Spondyloarthritis in practice: imaging, outcome assessment and comorbidities

OP0148

THE ASAS CORE MEASUREMENT SET FOR AXIAL SPONDYLOARTHRITIS

V. Navarro-Compán[1], A. Boel[2], A. Boonen[3], P. J. Mease[4], M. Dougados[5], U. Kiltz[6], R. B. M. Landewé[7], D. van der Heijde[2]on behalf of The ASAS axSpA core measurement set working group. *[1]Hospital La Paz, IdiPaz, Rheumatology, Madird, Spain*; *[2]LUMC, Rheumatology, Leiden, Netherlands*; *[3]MUMC+, Rheumatology, Maastricht, Netherlands*; *[4]Swedish Medical Center/Providence St, Joseph Health and the University of Washington, Rheumatology, Seatle, United States of America*; *[5]Cochin Hospital, Rheumatology, Paris, France*; *[6]Rheumazentrum Ruhrgebiet, Ruhr-Universität, Rheumatology, Bochum, Herne, Germany*; *[7]Rheumatologist, Zuyderland MC, Rheumatology, Heerlen, Netherlands*

Background: Recently, the core domains of the 20-years old core outcome set for ankylosing spondylitis were updated.[1] The next step is to define the measurement core set, which includes at least one instrument for each domain.
Objectives: To define the instruments for the ASAS-OMERACT core outcome set for axial spondyloarthritis (axSpA).
Methods: The scientific committee invited an international working group representing all key stakeholders (patients, rheumatologists, health professionals and pharmaceutical industry). The instrument selection process is presented in Figure 1.

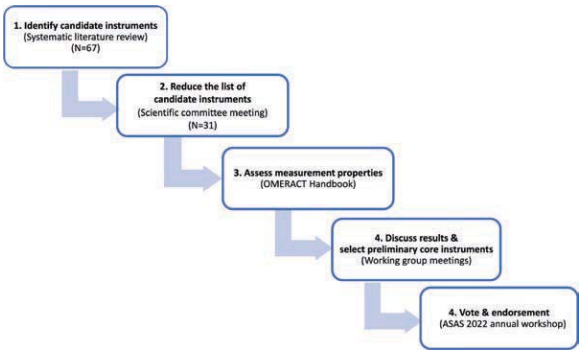

Figure 1. Development process to determine the core measurement set

Results: The updated core measurement set for axSpA is shown in Table 1. This includes seven instruments for six domains that are mandatory for all trials: ASDAS and NRS patient global assessment for disease activity, NRS total back pain for pain, composite index for morning stiffness, NRS fatigue for fatigue, BASFI for physical function, and ASAS Health Index for overall functioning and health. There are 9 additional instruments for disease modifying drugs (DMARDs): two MRI activity scores (SPARCC SIJ and SPARCC spine) for disease activity, the three extra-musculoskeletal manifestations uveitis, IBD and psoriasis assessed as recommended by ASAS[2], the three peripheral manifestations (44 swollen joint count, MASES and Dactylitis count[2]) and mSASSS for structural damage. The imaging outcomes are mandatory to be included at least in one trial for a drug that is considered to be a DMARD. The other instruments specific for DMARDs should be included in every trial. This core set is applicable to patients with radiographic and non-radiographic axSpA. Furthermore, 11 other instruments were also endorsed by ASAS and can additionally be used in axSpA trials: BASDAI, CRP, Berlin MRI-SIJ and MRI-spine activity scores for disease activity, NRS back pain at night for pain, severity (BASDAI Q5) and duration (BASDAI Q6) for morning stiffness, SF-36 for overall functioning and health, 66 swollen joint count and SPARCC enthesitis for peripheral manifestations and MRI-SIJ erosions scores (SPARCC SSS) for structural damage.

Table 1. Updated core measurement set for axial spondyloarthritis.

Instruments mandatory for all trials	
Domain	**Instrument**
Disease activity	ASDAS
	Patient global assessment of disease activity (NRS)
Pain	NRS total back pain (BASDAI Q2)
Morning stiffness	Severity and duration (BASDAI (Q5+Q6)/2))
Fatigue	NRS fatigue (BASDAI Q1)
Physical function	BASFI
Overall functioning & health	ASAS Health Index
Additional instruments mandatory for disease modifying drugs trials	
Disease activity	SPARCC MRI-SIJ*
	SPARCC MRI-spine*
Extra-musculoskeletal manifestations	uveitis (ASAS CRF)[2]
	psoriasis (ASAS CRF)[2]
	inflammatory bowel disease (ASAS CRF)[2]
Peripheral manifestations	44 Swollen joint count
	MASES
	Dactylitis count (ASAS CRF)[2]
Structural damage	mSASSS*

*Needs to be assessed at least once in a disease modifying drug programme; [2]Dougados M, et al. Ann Rheum Dis 2012;71(6):1103-04. ASDAS: Ankylosing Spondylitis Disease Activity Score; NRS: Numerical Rate Scale; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; Q: question; BASFI: Bath Ankylosing Spondylitis Functional Index; SPARCC: SpondyloArthritis Research Consortium of Canada Scoring System; MRI: Magnetic Resonance Imaging; SIJ: Sacroiliac Joint; CRF: Case Report Form; MASES: Maastricht Ankylosing Spondylitis Enthesitis Score; mSASSS: modified Stoke Ankylosing Spondylitis Spinal Score.

Conclusion: The previous core measurement set has been updated and endorsed by ASAS for the use in all axSpA trials.

RADIOGRAPHIC PROGRESSION FROM NON-RADIOGRAPHIC TO RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: RESULTS FROM A 5-YEAR MULTICOUNTRY PROSPECTIVE OBSERVATIONAL STUDY

D. Poddubnyy[1,2], J. Sieper[1], S. Akar[3], S. Muñoz-Fernández[4], H. Haibel[1], T. Diekhoff[5], M. Protopopov[1], E. Altmaier[6], F. Ganz[7], R. Inman[8]. *[1]Charité-Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; *[2]German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*; *[3]Izmir Katip Celebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*; *[4]Hospital Universitario Infanta Sofía, Universidad Europea, Servicio de Reumatología, Madrid, Spain*; *[5]Charité-Universitätsmedizin Berlin, Department of Radiology, Berlin, Germany*; *[6]Gesellschaft für Therapieforschung mbH, GKM, Munich, Germany*; *[7]AbbVie Inc., Global Medical Affairs, Baar, Switzerland*; *[8]Schroeder Arthritis Institute, University Health Network, University of Toronto, Toronto, Canada*

Background: Patients (pts) with axial spondyloarthritis (axSpA) are classified into radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-axSpA) based on the presence or absence of radiographic sacroiliitis. Approximately 20% to 80% of newly diagnosed axSpA pts have nr-axSpA and 8% to 40% progress to r-axSpA over the next 2 to 10 years.

Objectives: To evaluate progression from nr-axSpA to r-axSpA over 5 years in a prospective multicentre cohort.

Methods: PROOF was a global, real-world, prospective, observational study conducted in rheumatology clinical practices in 29 countries across 6 different geographic regions.[1] The study enrolled adults with chronic back pain for ≥3 months and onset before 45 years of age. This analysis included pts diagnosed with axSpA who also fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA. Study visits occurred at baseline (BL) and yearly thereafter. Baseline and follow-up radiographs of sacroiliac joints (SIJ) were evaluated for pts with initial nr-axSpA diagnosis independently by 2 central readers according to the modified New York criteria. In the case of disagreement on the classification (nr- or r-axSpA), images were adjudicated by a third reader. Radiographic progression from nr-axSpA to r-axSpA over 5 years was evaluated by Kaplan-Meier analysis. Cox proportional hazards regression analyses for time to radiographic progression from nr-axSpA to r-axSpA were conducted. For model 1, 'imaging arm vs clinical arm' was used as an independent variable, and for model 2, 'active inflammation on magnetic resonance imaging highly suggestive of sacroiliitis associated with SpA' was used. Further, potential predictive factors included in the models were age, gender, back pain duration, number of SpA parameters, smoking status, CRP, good response to NSAIDs, HLA-B27 status, and current use of NSAIDs and TNF inhibitors.

Results: Among 2633 enrolled pts, 2165 (82%) were diagnosed with axSpA and fulfilled the ASAS classification criteria. Among these, 1612 (74%) were classified as having r-axSpA (1050 [65%]) or nr-axSpA (562 [35%]) by central reading. The majority of nr-axSpA pts (77%) fulfilled the ASAS classification criteria due to positive findings on imaging (plus ≥1 SpA feature) and 23% were classified according to the clinical arm. A total of 246 nr-axSpA pts who had ≥1 follow-up SIJ radiograph were included in this analysis. Among these 246 pts, progression from initial nr-axSpA to r-axSpA at any of the follow-up visits was observed in 40 pts (16%) over 5 years. Mean time to radiographic progression was 2.4 years (ranging from 0.9 to 5.1 years) in descriptive analysis (Kaplan-Meier curve shown in Figure 1). In model 1 of the Cox regression analysis, male gender (hazard ratio [HR]: 3.16 [95% CI: 1.22–8.17]; P=0.0174), fulfilment of the imaging arm (HR: 6.64 [1.37–32.25]; P=0.0188), and good response to NSAIDs, (HR: 4.66 [1.23–17.71]; P=0.0237), were significantly associated with progression to r-axSpA (Figure 1). In model 2, HLA-B27 positivity showed a significant association with progression (HR: 3.99 [1.10–14.49]; P=0.0353; Figure 1).

Conclusion: In this study, 16% of nr-axSpA pts progressed to r-axSpA within 5 years. The mean time to disease progression was 2.4 years. Predictors of radiographic progression were male gender, good response to NSAIDs, and fulfilment of the imaging arm as well as HLA-B27 positivity.

Background: Clinicians face uncertainties in their daily practice when requesting imaging examinations for patients with suspected axial spondyloarthritis (axSpA) or when producing an imaging report because the requirements and desired information of radiologists and rheumatologists / orthopedics alike are sometimes not completely known or understood.
Objectives: This project aimed to develop practical consensus recommendations for the standardized communication around imaging of sacroiliac joints and spine for diagnostic purposes in patients with suspected axSpA or their management in clinical practice.
Methods: An international task force was established combining radiologists (n=7) and rheumatologists (n=13) from the Assessment of SpondyloArthritis international Society (ASAS), two members of Young ASAS and a patient representative. The task force defined the project's aims and developed a project statement. Then, considering published literature and the work of other groups, two survey rounds were designed, and all ASAS members invited to respond: first, to identify items for further consideration, second, to consider the detail of information to be communicated. Finally, ASAS members discussed the recommendations proposed by the task force during the ASAS annual workshop in January 2022 and voted regarding endorsement of the recommendations.
Results: The final set of recommendations is presented in Figure 1. Six recommendations deal with imaging requests in patients with axSpA. The first three recommendations entail clinical features, patients' symptoms and risk factors. Recommendation 4 concerns previous imaging and reports and recommendation 5 refers to contraindications to imaging or contrast media. Recommendation 6 is about the suspected diagnosis and possible clinical differential diagnoses and the reason for the examination. Eleven additional recommendations refer to the radiology report. The first point addresses clinical information included in the report. Recommendations 2 to 4 advise on information about the technical conduct of the exam, the use of contrast media and image quality. Imaging findings that should be mentioned in the report if present are listed in recommendations 5 to 7. Finally, recommendations 8 to 11 combine advice for the conclusion, and for suggesting additional imaging or referral to a rheumatology expert if a different physician requested the imaging. The recommendations were endorsed by ASAS with approval from 73% of voting members (43 agreed, 10 rejected, 6 abstained).

	Imaging request
1	The referring physician should communicate important clinical information when requesting imaging exams. This clinical information should include the patient's age, sex and HLA-B27 status.
2	Requests for imaging should include current or past history of back pain, its duration, localization, and inflammatory features, whether present or not. For follow-up exams, a change in clinical symptoms should be indicated.
3	Radiologists should be informed if the patient undertakes physically demanding activities or has history of childbirth (number of children and date of most recent childbirth).
4	Radiologists should have access to previous exam images for comparison or to the respective reports if those are not available.
5	The referral should include possible contraindications to certain types of imaging or contrast medium.
6	The referring physician should indicate the suspected clinical diagnosis and possible alternative explanations for the symptoms, whether SpA was previously diagnosed, and if the exam is requested for primary diagnosis, to assess disease activity or treatment response.

	Imaging report
	Clinical data
1	The report should start by summarising essential clinical information, including the patient's age, sex, a summary of symptoms, the suspected diagnosis, whether the exam was requested for primary diagnosis or follow-up, and what imaging was available for comparison.
	Technical data
2a	Radiography: The report should include the number of images, types of projections, and the patient's positioning.
2b	MRI: The report should include the applied field strength and sequences with slice orientation and thickness, if fat suppression was applied, and whether and what type of contrast medium was administered.
2c	CT: The report should include the patient's position, reconstructions' orientation and slice thickness, and a general indicator for the radiation dose (e.g., dose length product).
3	The anatomical coverage of the exam should be indicated.
4	The report should include a general statement about image quality and complications from imaging, particularly if the exam or its interpretation is affected.
	Report
5a	SIJ: Bone marrow oedema/osteitis, erosions and fat lesions are significant findings that the report should list semi-quantitatively with their localization specified. Their absence should be stated clearly.
5b	SIJ: The report should include if other active or structural lesions are present. Structural lesions should be reported per individual bone. The radiologists can summarize the absence of those active or structural lesions in the report.
6a	Spine: The report should semi-quantitatively list bone marrow oedema/osteitis at vertebral corners. All other active and structural lesions should be mentioned if present.
6b	Spine: The location of the findings mentioned above is essential for clinical correlation, and it should be stated at the level of the individual vertebra or discovertebral unit.
7	Findings unrelated to SpA but of potential clinical importance should be mentioned when present. These include for example gas inside the joint ("vacuum phenomenon"), osteophytes, transitional vertebrae, anatomical variations, and spinal malposition.
	Conclusion
8	The radiologist should state clearly if findings are compatible with SpA, based on the images and clinical information available. The conclusion should provide whether there is active inflammation or structural changes with the most prominent lesions, and give an indication of the confidence in interpretation of the findings.
9	Based on the exam findings, differential diagnoses and their probability should be mentioned, especially if more likely than SpA.
10	If the exam findings are inconclusive, radiologists should suggest further imaging according to their expertise.
11	If the exam is indicative of SpA and a rheumatologist did not request the imaging investigation, the report should recommend referral to a rheumatologist for further assessment.

Figure 1. ASAS recommendations for requesting and reporting imaging in patients with suspected axial Spondyloarthritis.

Conclusion: These ASAS recommendations provide guidance for requesting and reporting imaging examinations in the context of axSpA and for standardizing and enhancing communication between rheumatologists and radiologists to improve diagnosis and patient care.

PREDICTION OF RADIOGRAPHIC PROGRESSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: USING GROUP-BASED TRAJECTORY MODELING AND DECISION TREE ANALYSIS

J. Kang[1], T. H. Lee[2], B. S. Koo[3], S. Y. Park[4], S. Lee[5], T. H. Kim[6]. *[1]Inje University Busan Paik Hospital, Internal Medicine, Busan, Korea, Rep. of (South Korea)*; *[2]Keimyung University Dongsan Medical Center, Internal Medicine, Daegu, Korea, Rep. of (South Korea)*; *[3]Inje University Seoul Paik Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[4]Korea National Open University, Statistics and Data Science, Seoul, Korea, Rep. of (South Korea)*; *[5]Hanyang University Seoul Hospital, Radiology, Seoul, Korea, Rep. of (South Korea)*; *[6]Hanyang University Hospital for Rheumatic Diseases, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Ankylosing spondylitis (AS) tends to develop at a relatively young age and is characterized by long-term disease progression (1). During that time, various radiographic changes occur in the spine, which eventually lead to disability in the patient's lifetime (2). Although the duration of the disease, aging, and passage of time are predicted to be highly associated with spinal progression of AS, it is difficult to predict its progression in the spine of patients.

Objectives: We aimed to find ways to predict spinal progression over time in patients with AS and analyze its associated clinical factors.

Methods: Data from the medical records from a single center were extracted between 2001 and 2018. We analyzed the data on patients who fulfilled the modified New York Criteria for AS and had two or more sets of radiographs taken during the observation period. The modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) was estimated by two independent radiologists. Group-based trajectory modeling (GBTM) was used to classify patients into distinct subgroups of longitudinal mSASSS. And when these trajectories and statistically associated factors acted on a patient, which group the patient was most likely to belong to was predicted using a decision tree analysis.

Results: Data on 1,125 patients were analyzed, and the trajectories were evaluated by dividing them into three groups based on duration of the disease. We confirmed that sex, age at diagnosis, ocular involvement and peripheral joint involvement were associated with the classified spinal progression trajectories. AS onset in older age and ocular involvement were associated with worse radiographic progression, while female sex and peripheral joint involvement were associated with slower radiographic progression (Figure 1 and Table 1).

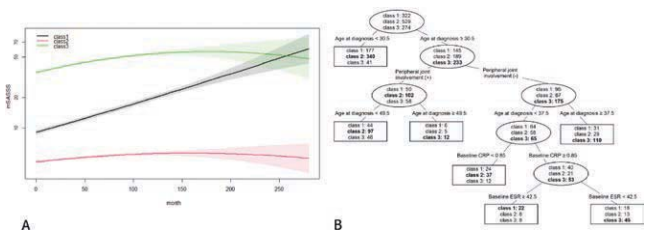

Figure 1. Longitudinal mSASSS trajectory groups for disease duration (A) and decision tree for three trajectory classes (B). (A) Time in month is shown along the x-axis, and logarithmic transformed total mSASSS is shown along the y-axis. The solid line represents the estimated mean in the same-colored area representing the 95% confidence interval. (B) In each terminal node, the class written in bold text is the class representing that node.

Conclusion: We identified three patterns of radiographic progression according to duration of the disease. The progression trend of patients with AS identified in this study is expected to be helpful in the treatment and management of patients in actual clinical settings.

Poddubnyy[3,9]. *[1]Charité – Universitätsmedizin Berlin, Department of Radiology, Berlin, Germany*; *[2]Berlin Institute of Health at Charité – Universitätsmedizin Berlin, N/A, Berlin, Germany*; *[3]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; *[4]Technical University of Munich, Department of Diagnostic and Interventional Radiology, Munich, Germany*; *[5]University of Alberta, Department of Radiology and Diagnostic Imaging, Edmonton, Canada*; *[6]Ruhr Universität Bochum, Department of Rheumatology, Bochum, Germany*; *[7]Rheumazentrum Ruhrgebiet, Department of Rheumatology, Herne, Germany*; *[8]University of Alberta, Department of Medicine, Edmonton, Canada*; *[9]German Rheumatism Research Centre, Department of Epidemiology, Berlin, Germany*

Background: Magnetic resonance tomography (MRI) plays a key role in the early diagnosis of axial spondyloarthritis (axSpA). However, the detection of changes indicative of axSpA requires specific expertise, which poses a challenge to non-specialized centers. Deep learning (an advanced machine learning method) based on training an artificial neural network may facilitate and support diagnostics in clinical practice.

Objectives: To create a reliable deep learning tool for the detection of active inflammatory and structural changes indicative of axSpA on MRI of sacroiliac joints.

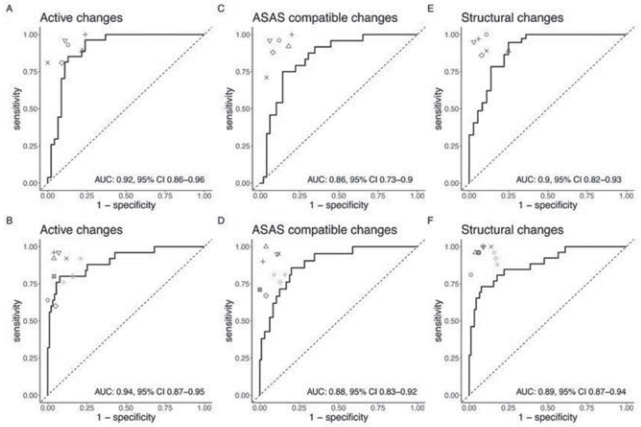
Methods: In this study, MRIs of sacroiliac joints from 477 patients from four cohorts (GESPIC-AS, GESPIC-Crohn, GESPIC-Uveitis and OptiRef comprising 266 patients with and 211 without axSpA) were used to develop a deep learning framework (randomly divided into training, n=404, and validation, n=73, datasets). MRIs from the ASAS cohort (n=116) were used for independent testing (test dataset). Each examination in the training/validation dataset was evaluated for the presence of active inflammatory and structural changes indicative of SpA by six experienced, trained and calibrated readers and by seven expert readers in the test dataset. The presence of the changes was defined as the majority vote amongst readers. Discordant cases in the training/validation dataset underwent consensus reading. In addition, the test dataset was evaluated by three radiologists not specifically trained in SpA. Diagnostic performance was evaluated using the area under the receiver operating characteristic curve (AUC), accuracy, sensitivity and specificity.

Results: The prevalence of positive imaging findings for active inflammatory/structural changes indicative of axSpA was 41%/51% in the training/validation dataset and 22%/22% in the test dataset. The model for the detection of active inflammatory changes showed an AUC of 0.91 (0.83 – 0.97) – Figure 1 – and an accuracy of 84% on the validation dataset; the corresponding sensitivity and specificity were 96% and 76%, respectively. Despite a substantially lower prevalence of active inflammatory changes in the test dataset, the model showed good generalization with an AUC of 0.91 (0.84–0.97) and an accuracy of 75%; the sensitivity and specificity were 88% and 71%, respectively. The model demonstrated

a similar performance on the validation and test datasets for the detection of active inflammatory changes fulfilling the ASAS definition. The model for the detection of structural changes indicative of axSpA showed good performance on the validation dataset with an AUC of 0.90 (0.82-0.96) for the detection of structural changes and an overall accuracy of 85%. The associated sensitivity and specificity were 95% and 75%, respectively. The model showed reasonable generalization to new data with an AUC of 0.89 (0.81–0.96) and an accuracy of 79%; the sensitivity and specificity were 85% and 78%, respectively. Overall, the model performed close to the individual human experts - Figure 1.

Conclusion: The developed framework allowed the detection of active inflammatory and structural changes indicative of axSpA on MRI. This approach may be used as an assistant tool in the diagnostic workflow.

Figure 1. ROC curves and associated AUCs for model performance compared to the individual human experts.



A, C and E represent the ROC curves for diagnostic performance on the validation dataset, while the ROC curves for the test dataset are given in B, D and F. The model performance did not exceed that of the trained experts (black symbols) but came close, especially for the detection of active inflammatory changes. The performance of three board-certified radiologists who did not undergo specific training for axSpA imaging is indicated by the orange symbols in B, D and F.

Background: Spondyloarthritis (SpA) is one of the most common chronic inflammatory diseases and regularly affects women of childbearing age[1]. However, there is limited knowledge about the impact of the disease and its treatment on fertility[2].
Objectives: The aim of the study was to determine factors associated with time-to-conception in women with SpA.
Methods: We performed an analysis of SpA patients (diagnosis according to the rheumatologist) included in the national multicenter cohort GR2 from 2015 to June 2021. Patients could be included either with a pregnancy wish (i.e., preconceptional period) or because of a clinical pregnancy (<12 weeks of gestation): for this analysis, only patients included preconceptionally were included. The main endpoint was time-to-conception, and the secondary endpoints were the number of subfertile patients (i.e., time-to-conception >12 months or non-achievement of pregnancy), as well as the number exposed to csDMARDs and biologics in the preconception period. We performed survival analyses, using a Cox model including a random effect for the center to account for heterogeneity of practices among participating centers. We used a multiple imputation to address missing data among the explanatory variables. Results are presented as a hazard ratio (HR) with confidence interval (CI) to assess associations between the factors studied and time-to-conception.
Results: Among the 207 patients with SpA included in the GR2 cohort, 88 were selected for analysis of time-to-conception (i.e., include preconceptionally). Of these, 56 (63.6%) had a clinical pregnancy during follow-up. Subfertility was observed in 40 (45.4%) women and the median time-to-conception was 16.1 months. The mean preconceptional BASDAI score was 2.9 (+/- 2.1). Patients were treated with NSAIDs, corticosteroids, csDMARDs and biotherapy in 23 (26.1%), 8 (9.1%), 12 (13.6%), and 61 (69.3%) cases, respectively. The multivariate model adjusted for age, BMI, nulligestity, BASDAI, disease duration, smoking, form of spondyloarthritis (axial, peripheral, or both), and exposure to NSAIDs, csDMARDs, and biotherapy in the preconception period found an association between longer time-to-conception and age (HR 1. 22 95% CI [1.08-1.40] p < 0.001), as well as the use of NSAIDs during preconception (HR 3.01 95% CI [2.15-3.85] p = 0.01).
Conclusion: This study provides original results on fertility in women with SpA. The factors associated with a longer time-to-conception were age and the NSAIDs use during the preconception period, which argues for their cautious use in case of pregnancy wish in patients needing continuous NSAID intake for the management of their disease.

Background: Comorbidities in ankylosing spondylitis (AS) occur more frequently than in the general population and are associated with higher morbidity and mortality. Some comorbidities may occur together, making one more likely in the presence of another, and different combinations of comorbidities may have differential considerations for AS management and outcomes.

Objectives: To examine the association of baseline comorbidities with disease activity and functional status in AS.

Methods: We used baseline data from the Prospective Study Of Ankylosing Spondylitis (PSOAS) cohort, a multicenter, prospective cohort from five centers (4 in the US, 1 in Australia). AS patients ≥ 18 years fulfilling mNY criteria for AS (2002-20) were included. Patient-reported AS comorbidities (N=28) and extra-musculoskeletal manifestations (EMMs, N=2) within 3 years of enrollment (prespecified on the baseline case-report form) and only those occurring in ≥1% were included. Undocumented comorbidities were assumed to be absent if missing in <15% of patients, and those missing in >50% of patients were excluded. Comorbidity clusters were identified using K-median clustering. The optimal number of clusters was determined using scree plot of the sum of squared errors and "elbow" on the graph line. Baseline characteristics of the clusters were compared, and associations of with disease activity and functional status measures (primary outcomes: ASDAS-CRP and BASFI) were examined using linear regression adjusted for age and sex.

Results: There were 1,270 AS patients included with a mean age of 44.6 ±14.3 years, 74.4% males, and 81.2% whites. Mean AS symptom duration was 20.6±5.6 years, 81.6% HLA-B27 positive, and CRP elevated in 27.5% of patients at baseline. Depression was the most prevalent comorbidity (31.4%) followed by hypertension (26.1%); uveitis was the most common EMM (30.4%). The five clusters identified included depression (27%), no comorbidities (22%), hypertension (21%), uveitis (20%), and asthma/low bone mass (10%) (Figure 1). The cluster with no comorbidities was significantly younger, with lower symptom duration (p<0.001). Females had higher odds of being in the depression (OR=2.00, 95% CI 1.38- 2.90) and uveitis (OR=2.09, 95% CI 1.41-3.11) clusters compared to the cluster with no comorbidities. The number of comorbidities and clusters with depression and hypertension were significantly associated with worse disease activity and functional status (Table 1).

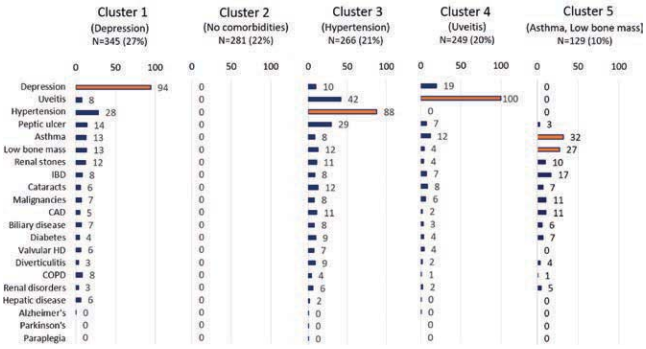

Figure 1. Comorbidity clusters in PSOAS cohort at baseline

Conclusion: Distinct comorbidity clusters were identified in AS patients in the PSOAS cohort. In addition to the number of comorbidities, the type of comorbidity seems to be important. Depression and hypertension clusters seem to be associated with worse disease activity and function.

Background: Presence of vertebral corner inflammation (VCI) increases the likelihood of a new syndesmophyte in the same vertebral corner (VC) in patients with r-axSpA. It was suggested that subsequent vertebral corner fat deposition (VCFD) partially explains this effect. However, this has not been formally tested.
Objectives: To determine how much of the effect of VCI on the development of new syndesmophytes is explained by new VCFD.
Methods: Two datasets (SIAS cohort, ASSERT clinical trial) were analyzed. Patients with r-axSpA were assessed at baseline (T0), an intermediate visit (T1) (SIAS: 1 year; ASSERT: 24 weeks) and the end of follow-up (T2) (SIAS: 2 years; ASSERT: 102 weeks). Syndesmophytes were assessed on whole spine low dose CT (SIAS) or spinal radiographs (ASSERT) at T0 and T2 and considered present if seen by 2 of 2 readers. VCI (T0) and VCFD (T0 and T1) on spinal MRI were present if seen by ≥2 of 3 readers (SIAS) or 2 of 2 readers (ASSERT). VCs with VCFD or a syndesmophyte at baseline were excluded. We used the counterfactual approach[1] to decompose the total effect of VCI at T0 (binary exposure) on the formation of a new syndesmophyte in the same VC at T2 (binary outcome) into the effect that is explained (natural indirect effect, NIE) and the effect that is not explained (natural direct effect, NDE) by new VCFD (binary mediator) at T1. Because there was no interaction between the exposure and mediator (p=0.88 for SIAS; p=0.82 for ASSERT), the average NIE (aNIE) and average NDE (aNDE) are reported. The aNIE, aNDE and total effect, expressed as absolute increase in risk, were estimated in R using the 'mediation' package, which takes into account the 2-level structure of the data (VCs nested within patients).
Results: In total, 49 patients (2,667 corners) in SIAS and 168 patients (2,918 corners) in ASSERT were included. A new syndesmophyte occurred at T2 in 124/2,667 (5%) corners in SIAS and 91/2,918 (3%) corners in ASSERT (Table 1). New VCFD at T1 was also uncommon (SIAS: 4%; ASSERT: 2%), but occurred more often in corners with (SIAS: 12%; ASSERT: 18%) than without VCI at T0 (SIAS: 3%; ASSERT: 1%). Applying the mediation formula, in SIAS, the presence of VCI at T0 increased the probability of a new syndesmophyte in the same VC at T2 by 9.3% [total effect (95% CI)=9.3% (4.5; 15.0)]. There was only a 0.2% increase in this probability that was mediated by the formation of new VCFDs at T1 [aNIE=0.2% (-0.4; 1.0)]. In contrast, 9.1% of the increase in probability remained unexplained [aNDE=9.1 (4.3; 15.0)]. This means that only 2% (0.2/9.3) of the total effect of VCI on the formation of new syndesmophytes was explained by new VCFD [% mediated=2.0% (-4.1; 13)]. In ASSERT, the total effect was somewhat lower than in SIAS [total effect=7.3% (2.0; 16.0)], and again the aNIE was small [aNIE=0.8% (-0.2; 3.0)], and the aNDE composed most of the total effect [aNDE=6.5% (1.3; 14.0)]. The proportion of the total effect explained by VCFD (0.8/7.3=10% (-3.1;44)) was larger than in SIAS but still non-significant.
Conclusion: In these two datasets we see that VCI only infrequently leads to syndesmophyte formation via visible VCFD.

The treatment and outcome of scleroderma

OP0156 **TOCILIZUMAB USE IN SYSTEMIC SCLEROSIS: SYSTEMATIC REVIEW AND META-ANALYSIS**

R. Dos-Santos[1], E. Guadalupe[2], D. Fernández Fernández[1], I. González Fernández[1], M. Sanchez-Wonenburger[1], P. Castro-Santamaria[1], A. Mata[1], J. L. Puga Guzmán[1], E. Perez-Pampín[1], A. Souto Vilas[1], A. Mera Varela[1]. [1]*Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain*; [2]*Universidade de Santiago de Compostela, Medicine Department, Santiago de Compostela, Spain*

Background: Systemic sclerosis (SSc) is a low-prevalent autoimmune disease with a heterogeneous presentation. Skin involvement is the most frequent symptom and its treatment is orphan, only attending at Raynaud's phenomenon and classic immunosuppressive therapy for fibrosis. Lung implication is still remaining as the first cause of death. Interstitial lung disease (ILD) is the most frequent presentation and treatments most used includes cyclophosphamide and mycophenolate.[1] In 2021, the Food and Drug Administration (FDA) approved the first biologic therapy for ILD-SSc, tocilizumab (TCZ), based on 2 clinical trials.[2,3]
Objectives: To assess TCZ efficacy in SSc, either in ILD or skin involvement.
Methods: A systematic literature review was made using Medline, Embase, Cochrane Library and the Web of Science databases. Search strategy focused in synonyms of SSc and TCZ, also including MeSH terms. A random-effects model meta-analysis was performed to evaluate TCZ efficacy, when comparable measures were found. Clinical trials, observational studies and case-series were eligible.
Results: Search strategy identified 1036 articles, finally 13 studies were eligible for the review. Regarding the effect of TCZ in SSc skin involvement, measured by the modified Rodnan Skin Score (mRSS), a non-significant 40% improvement in mRSS and change in mean mRSS was reported (OR 1.22 [0.74-2.01], p=0.43 and SMD -0.69 [-1,48-0.10], p=0.09, respectively). About ILD-SSc, a significant non-worsening 10% Forced Vital Capacity (FVC) was reported in patients treated with TCZ (OR 0.45 [0.23-0.86), p=0.02) (Figure 1). As well, a non-significant Diffusing capacity for carbon monoxide (DLCO) was observed in patients treated with TCZ (SMD -0.66 [-1.48- -0.17], p=0.12).

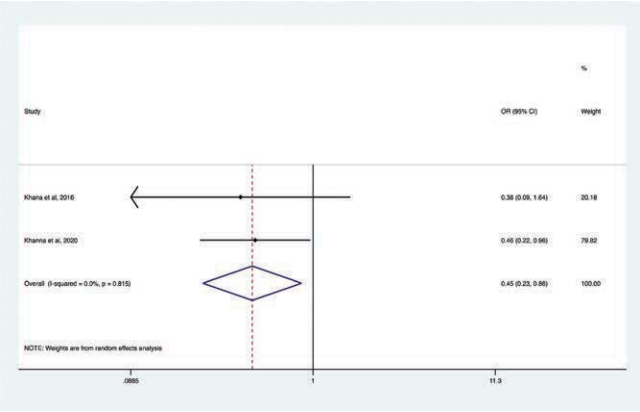

Figure 1.

Conclusion: Our study is the first review and meta-analysis of SSc patients treated with TCZ. This results show that TCZ could delay the worsening of ILD-SSc, being one therapeutic alternative to classical immunosuppressive therapy. Further studies are needed for better disease understanding and TCZ implications in other organ impairment.

Background: In the SENSCIS trial conducted in a population of subjects with SSc-ILD with a mean time since first non-Raynaud symptom of 3.5 years and 52% with diffuse cutaneous SSc (dcSSc), nintedanib reduced the rate of decline in FVC (mL/year) over 52 weeks by 44% versus placebo. Risk factors for a rapid decline in FVC in patients with SSc include early SSc, elevated inflammatory markers, significant skin involvement, and dcSSc. Patients with SSc with these risk factors for rapid progression of ILD are typically given immunosuppressants but not nintedanib.

Objectives: To analyse the rate of decline in FVC and the effect of nintedanib on FVC decline in subjects with risk factors for a rapid decline in FVC in the SENSCIS trial.

Methods: In post-hoc analyses of data from the SENSCIS trial, we analysed the rate of decline in FVC (mL/year) over 52 weeks in all subjects and in those with early SSc (<18 months since first non-Raynaud symptom), elevated inflammatory markers (C-reactive protein ≥6 mg/L and/or platelets ≥330 x 10^9/L), or significant skin fibrosis using two approaches (modified Rodnan skin score [mRSS] 15-40 or mRSS >18) at baseline. We also analysed the rate of decline in FVC over 52 weeks in subjects with one of these risk factors and dcSSc.

Results: Of 575 subjects analysed, 79 (13.7%) had <18 months since first non-Raynaud symptom, 210 (36.5%) had elevated inflammatory markers, 172 (29.9%) had mRSS 15-40 and 118 (20.5%) had mRSS >18. Of 299 subjects with dcSSc, 29 (9.7%) had <18 months since onset of first non-Raynaud symptom, 129 (43.1%) had elevated inflammatory markers, 162 (54.2%) had mRSS 15-40 and 118 (39.5%) had mRSS >18. In the placebo group, the rate of decline in FVC over 52 weeks was numerically greater in subjects with these risk factors for rapid decline in FVC compared with all subjects (Figure 1). Across the subgroups, the rate of decline in FVC was numerically lower in subjects treated with nintedanib than placebo (Figure 1).

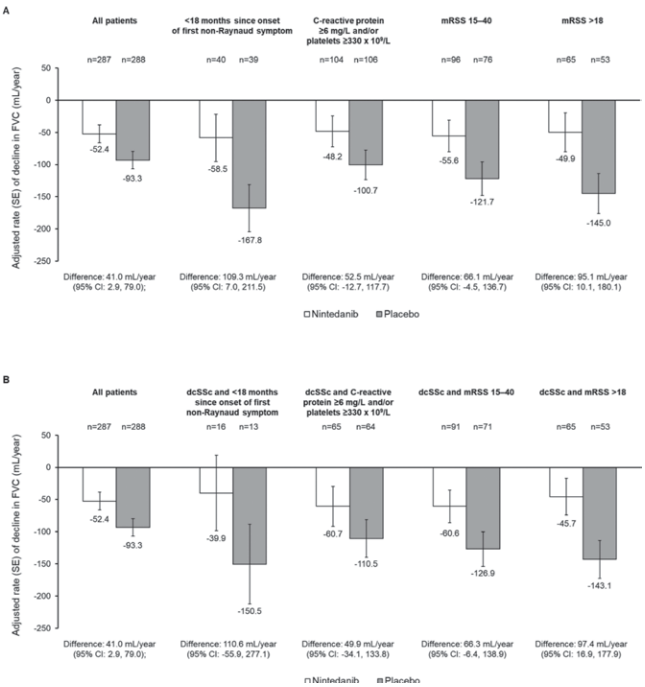

Figure 1. Rate of decline in FVC (mL/year) over 52 weeks in (A) all patients and in patients with risk factors for rapid decline in FVC at baseline and (B) all patients and in patients with dcSSc and risk factors for rapid decline in FVC at baseline in the SENSCIS trial.

Conclusion: The SENSCIS trial included a broad range of subjects with a fibrotic ILD complicating SSc, including those with risk factors for a rapid decline in FVC. In the placebo group, subjects with these risk factors had a more rapid decline in FVC over 52 weeks compared with the overall trial population. By targeting fibrosis with nintedanib, the rate of decline in FVC in patients with risk factors for FVC decline was reduced in patients treated with nintedanib compared with placebo.

Acknowledgements: The SENSCIS trial was funded by Boehringer Ingelheim. Toby M Maher and Masataka Kuwana were members of the SENSCIS trial Steering Committee.

Background: Enrichment strategies from clinical trials for progressive systemic sclerosis-associated interstitial lung disease (SSc-ILD) have been partly successful but have not been tested in a real life cohort.

Objectives: Analyse the efficacy, representativeness and feasibility of enrichment strategies in SSc-ILD patients from the EUSTAR cohort.

Methods: We applied the inclusion criteria of major recent SSc-ILD trials (focuSSced, SLS II and SENSCIS) in SSc-ILD patients and assessed progressive ILD, defined as absolute change in forced vital capacity (FVC) and as significant progression (FVC decline >10%) over time. Data were compared to all patients and patients not fulfilling any inclusion criteria.

Results: In total, 2258 SSc-ILD patients were included, with 31.2% meeting SENSCIS, 5.8% SLS II, 1.6% focuSSced criteria and 1529 (67.7%) not meeting any criteria (Table 1). In the first 12+/-3 months, a slow FVC% decline of –0.1% was seen in the total, unselected cohort and in patients fulfilling SENSCIS criteria. Patients fulfilling criteria from focuSSced showed a strong FVC decline of –3.7%. Notably, patients enriched for SLS II criteria showed FVC improvement of +2.3% (Figure 1). Similarly, compared to the total unselected cohort, the number of significant progressive events was numerically higher in patients fulfilling focuSSced criteria, the same for SENSCIS criteria and even slightly lower for patients fulfilling the SLS2 criteria.

4	40 (2.7)	0 (0)	3 (2)	4 (1)*

*P-value: 0.001–0.05; †P<0.001, between focuSSced, SENSCIS or SLS compared with not fulfilling any study criteria.

In the second 12 months period, SENSCIS enriched patients had a further absolute FVC% decline as described for the total cohort. In contrast, patients fulfilling the focuSSced and SLS II inclusion criteria showed numerical improvement of lung function in the second period (Figure 1). There were no significant associations of enrichment criteria and ILD progression in the second period.

Over the mean observation period of 2.3 years, patients not fulfilling any inclusion criteria showed the same FVC decline of –0.9 (12.1) as observed for the total cohort (–0.9% (12.6)). There were numerical differences in FVC changes in the enriched patient cohorts, varying from –2.8% FVC decline in patients fulfilling the focuSSced criteria to +3.4% FVC improvement with SLS II criteria.

Conclusion: Application of enrichment criteria from previous clinical trials showed enrichment for progression with variable success but led to selected patient populations reducing feasibility of recruitment. These findings are important for future clinical trial design and interpretation of the results of published trials.

Figure: Mean FVC% pred change from 0-12 months, 12-24 months and from first to last assessment

INCREASE RISK FOR CORONARY ARTERY DISEASE AND MYOCARDIAL INFARCTION IN SCLERODERMA-A NATIONAL INPATIENT SAMPLE ANALYSIS

K. Raj[1], V. Jyoti[1], M. Marte Furment2, B. Ann Joseph[3], K. Jyotheeswara Pillai[4]. *[1]Saint Peter University Hospital/Rutgers, Internal Medicine, New Brunswick, United States of America*; *[1]Saint Peter University Hospital/Rutgers, Internal Medicine, New Brunswick, United States of America*; *[3]Saint Peter University Hospital/Rutgers, Internal Medicine, New Brunswick, United States of America*; *[4]Saint Peter University Hospital/Rutgers, Endocrinology, New Brunswick, United States of America*

Background: Several rheumatologic diseases such as SLE and Rheumatoid arthritis are well known to increase cardiovascular risk. Scleroderma is well known to cause microvascular dysfunction, which can cause microvascular Coronary artery disease (CAD). However, Scleroderma is not classically associated with macrovascular CAD.

Objectives: We wanted to study the association of both microvascular and macrovascular CAD and Myocardial infarction (MI) in Scleroderma patients using the NIS (National inpatient sample) of the United States (US).

Methods: We included adult patients admitted to teaching hospitals with a primary or secondary diagnosis of Scleroderma from the National inpatient sample (NIS) of 2016, 2017, and 2018. The NIS is the largest publicly available all-payer inpatient care database in the United States, containing data on more than seven million hospital stays. After coding for the relevant variables based on the ICD-10 coding system, we performed univariate and multivariate logistic regression analysis to determine if Scleroderma was associated with CAD and MI. As there was no ICD-10 code for macrovascular CAD, we used Percutaneous intervention (PCI) and Coronary artery bypass grafting (CABG) to indicate the presence of macrovascular CAD. Four separate models with outcomes as CAD, MI, PCI, and CABG were created.

Results: A total of weighted 57,739 (95% CI 55,787-59,692) hospitalizations with Scleroderma were included. Only 0.1% of CAD and MI patients had a history of Scleroderma. On univariate logistic regression, Scleroderma was not associated with an increased risk of CAD (OR 0.82, 95% CI 0.79-0.86, P<0.01). After adjusting for age, sex, race, family history of CAD, dyslipidemia, diabetes, hypertension, and smoking, Scleroderma was associated with CAD (OR 1.40, 95% CI 1.34-1.47, P<0.01) (Table 1) and MI (OR 1.13, 95% CI 1.02-1.25, P=0.01) but not with PCI (OR 0.86, 95% CI 0.73-1.01, P=0.07) or CABG (OR 0.79, 95% CI 0.61-1.03, P=0.09).

Conclusion: CAD in Scleroderma is due to the combined effect of Scleroderma itself and co-existing cardiovascular risk factors. In our large epidemiological study, Scleroderma was associated with CAD and MI despite adjusting for the traditional risk factors for CAD, which is consistent with our current understanding of Scleroderma. Scleroderma is suspected of causing recurrent coronary microvascular inflammation and ischemia, which leads to ischemic necrosis and myocardial fibrosis (1). Other mechanisms include coronary Raynaud phenomenon and myocarditis. The lack of association of PCI and CABG with Scleroderma likely suggests that CAD in Scleroderma is mostly microvascular. Potential limitations of our study are its retrospective nature and the lack of catheterization data. Cardiovascular diseases account for 12% of mortality, and CAD accounts for 5% mortality in Scleroderma patients (2). Therefore, care for Scleroderma patients should involve aggressive management of Scleroderma and the risk factors for CAD.

Background: There is a gap between how IIM patients are classified in practice and current validated classification criteria[1]. Also, different associations with genetic variations in *HLA* can inform about different T-cell mechanisms involved in disease pathogenesis.

Objectives: We aimed to systematically study associations between *HLA-DRB1* alleles, clinical manifestations, and autoantibody-defined IIM subgroups.

Methods: We included 1348 IIM patients from five European countries. An unsupervised cluster analysis was performed using 14 autoantibodies: anti-Jo1, -PL7, -PL12, -EJ, -OJ, -SRP, -U1RNP, -Ro52, -Mi2, -TIF1γ, -MDA5, -PMScl, -SAE1, and -NXP2 to identify patients' subgroups. Logistic regressions were used to estimate the associations between *HLA-DRB1* alleles, clinical manifestations and the identified subgroups.

Table 1. Autoantibody-defined subgroups using an unsupervised cluster analysis.

*IIM patients negative for the tested autoantibodies.

Results: Eight subgroups were defined by the autoantibody status (Table 1). Three of the subgroups (1, 2 and 6) have overlapping autoantibodies, while four are almost monospecific (3,4,5 and 7), and one (8) has patients negative for tested autoantibodies. Figure 1 represents the significant associations between *HLA-DRB1* alleles and the eight subgroups. Heliotrope rash and Gottron's sign were significantly more frequent in subgroups 3 (OR:2.2 95%CI:[1.1-4.8], OR:2.6 95%CI:[1.3-5.9], respectively), 4 (OR:12 95%CI:[3.6-75], OR:7.8 95%CI:[2.8-33], respectively) and 7 (OR:22 95%CI:[4.5-385], OR:10 95%CI:[3.1-65], respectively), and Raynaud's phenomenon was significantly more frequent in subgroup 6 (OR:3.3 95%CI:[1.2-11]).

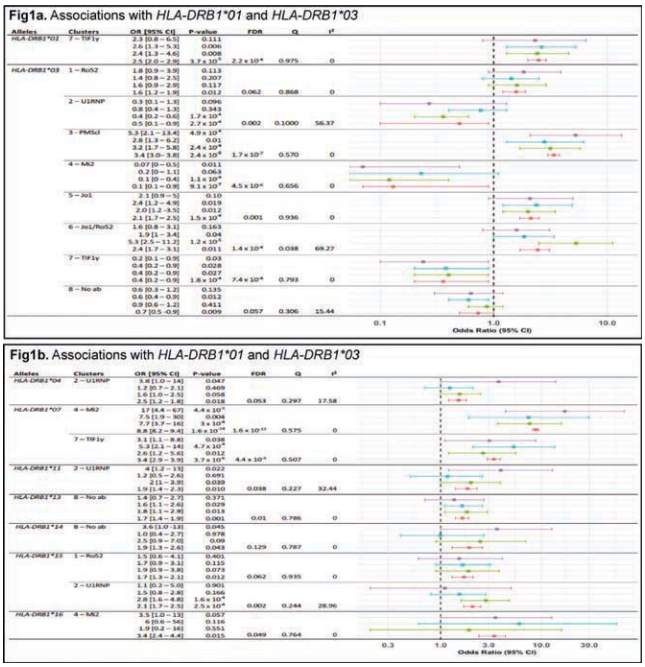

Figure 1. Forest plot of significant associations of *HLA. *DRB1* alleles with autoantibody-defined subgroups. Scandinavia includes patients from Denmark, Norway, and Sweden.

Conclusion: Our study reveals that certain subgroups of IIM patients are characterized by overlap of myositis -specific and -associated autoantibodies, which in turn are associated with different *HLA-DRB1* alleles including potential novel associations. These results point to different disease mechanisms in the subgroups, as well as suggest that IIM classification could be improved by integrating broader serological and genetic data.

Background: Idiopathic inflammatory myopathies (IIM) are a group of heterogeneous autoimmune disorders with limited standardization of treatment protocols.
Objectives: To evaluate frequency and patterns of various treatments used for IIM based on disease subtype, world region, and organ involvement.
Methods: Cross-sectional data from the international CoVAD self-report e-survey[1] was extracted on Sep 14th, 2021. Patient details included demographics, IIM subtypes (dermatomyositis (DM), polymyositis (PM), inclusion body myositis (IBM), antisynthetase syndrome (ASSD), necrotizing myositis (NM) and overlap myositis (OM)), clinical symptoms, disease duration and activity, and current treatments. Treatments were categorized in corticosteroids (CS), antimalarials, immunosuppressants (IS), intravenous immunoglobulins (IVIG), biologics, and others. Typical clinical symptoms (dyspnea, dysphagia) were used as surrogate for organ involvement. Factors associated with IS were analyzed using multivariable logistic regression, adjusting for IIM subtype, demographics, world region, disease activity, and prevalent clinical symptoms (>10%).
Results: In 1418 patients with IIM, median age was 61 years [IQR 49-70], 62.5% were females, median disease duration was 6 years [IQR 3-11], most common subset was DM (32.4%).
The most used treatments were IS (49.4%, including Methotrexate 19.6%, Mycophenolate Mofetil 18.2%, Azathioprine 8.8%, Cyclosporine 2.7%, Tacrolimus 2%, Leflunomide 1.6%, Sulfasalazine 1%, and Cyclophosphamide 0.6%), followed by CS (40.8%), antimalarials (13.8%) and IVIG (9.4%). Biologics were used in 4.3% of patients.
Treatment patterns differed significantly by IIM subtypes with a higher frequency of IS (77.7%) and CS (63.4%) use in ASSD; antimalarials (28.6%) and biologics (9.8%) use in OM and IVIG use in NM (24.6%) (Table 1). Also, treatment patterns were different in regions of the world (Figure 1), with a higher frequency of CS use in Europe (60.5%) and IS use in South America (77.2%). Antimalarials were most used in Asia (19.4%), while IVIG use was most common in Oceania (16.9%). Dyspnea was associated with higher use of IS (69.9%) and CS (65.8%) (p<0.001), whereas dysphagia was negatively associated with IS (39.7%) and CS (32.7%) likely due to a higher proportion in IBM patients reporting dysphagia.
Multivariable logistic regression analysis showed an association of IS with the IIM subtype (least used in IBM (OR 0.07 [95%CI 0.04-0.13] compared to DM), world region (most used in South America (OR 2.35 [1.12-4.91] compared to North America), active and worsening disease activity (OR 3.49 [1.76-6.91] compared to remission), and some clinical features (dyspnea, fatigue, and muscle weakness).
Conclusion: IIM treatment patterns differ significantly by disease subtypes, world regions and organ involvement, highlighting the need for unified international consensus-driven guidelines.

OP0162

EFFICACY AND SAFETY OF LENABASUM IN THE PHASE 3 DETERMINE TRIAL IN DERMATOMYOSITIS

V. Werth[1], B. White[2], N. Dgetluck[3], K. Hally[4], S. Constantine[4], R. Aggarwal[5,6], D. Fiorentino[7], I. E. Lundberg[8], C. V. Oddis[6]. [1]*University of Pennsylvania, Dermatology, Philadelphia, United States of America*; [2]*Corbus Pharmaceuticals, Chief Medical Officer, Norwood, United States of America*; [3]*Corbus Pharmaceuticals, Biostatistics, Norwood, United States of America*; [4]*Corbus Pharmaceuticals, Clinical Operations, Norwood, United States of America*; [5]*University of Pittsburgh, Department of Rhematology, Pittsburgh, United States of America*; [6]*University of Pittsburgh, Department of Rheumatology, Pittsburgh, United States of America*; [7]*Stanford University, Department of Medicine, Stanford, United States of America*; [8]*Karolinska Institutet, Division of Rheumatology, Department of Medicine, Stockholm, Sweden*

Background: Safe and effective treatments are of significant unmet need in DM. Lenabasum, a CB2 agonist that activates resolution of inflammation, improved skin disease, patient-reported outcomes, and biomarkers in a Phase 2 study of DM patients with active skin disease.
Objectives: To evaluate the efficacy and safety of lenabasum in a Phase 3 double-blind study in DM.
Methods: DM patients ≥ 18 years old with active skin with or without muscle involvement were enrolled in 55 sites in North America, Europe, and Asia-Pacific. Stable doses of background immunosuppressants were allowed. Subjects were randomized 2:1:2 to lenabasum 20 mg BID, lenabasum 5 mg BID, or placebo BID for 52 weeks, with visits ≤ 8 weeks apart. The study was stopped after all subjects completed Week 28. Some subjects had completed Week 52 by then. The primary efficacy endpoint was Total Improvement Score (TIS) at Week 28 and a secondary efficacy endpoint was TIS at Week 52, for lenabasum 20 mg BID vs placebo.
Results: 175 subjects (69 lenabasum 20 mg BID, 35 lenabasum 5 mg BID, 71 placebo BID) received study drug; 167 completed Week 28, and 103 completed Week 52. The most common reasons for study discontinuation were study stopped by Sponsor (34.3%), withdrawal of consent (4.5%), and adverse events (AEs, 3.9%), with similar rates among groups. Baseline demographics and disease measurements were similar among groups and in total subjects were (mean or %): age 52.0 years; 81.1% female, 75.4% White; MMT-8 133.3; CDASI activity score 23.4; HAQ-DI 0.84, MDGA 5.55, EMGA 5.23; and PtGA

5.12. Corticosteroids were used by 48.1% and 38.0%, immunoglobulins by 5.8% and 7.0%, and other immunosuppressives by 51.0% and 54.9%, and monoclonal antibodies by 8.7% and 7.0% of lenabasum and placebo groups at baseline, respectively. The primary efficacy endpoint was not met - mean (SD) TIS score was 28.3 (19.75) vs 27.2 (19.23) at Week 28 for lenabasum 20 mg BID vs placebo, p = 0.3311, MMRM. Week 52 values were 40.6 (16.88) vs 34.8 (19.94), p = 0.2290. When analyses were restricted to subjects with muscle weakness at baseline (MMT8 < 142), TIS scores and treatment differences were greater and reached nominal statistical significance at Week 40, p = 0.0172. Mean (SD) improvements in CDASI activity score were numerically greater but not statistically different between lenabasum 20 mg BID group vs placebo at Week 28 [-7.1 (7.76) vs -5.8 (8.88) points, p = 0.2775] and Week 52 [-10.0 (9.45) vs -6.2 (12.8) points, p = 0.0932]. When restricting analysis of participants without muscle weakness (MMT-8 = 150), improvement in CDASI activity score was greater in the lenabasum 20 mg BID group vs placebo at Week 28, p = 0.0461, and Week 52 p = 0.0059.

Treatment-emergent AEs (TEAEs) occurred in 87.0%, 85.7%, and 87.3% of lenabasum 20 mg BID, lenabasum 5 mg BID, and placebo groups, with no deaths. Related TEAEs leading to withdrawal of study product were infrequent, occurring in 1.4%, 0%, and 2.0% of subjects in the same groups. Serious TEAEs occurred in 11.6%, 8.6%, and 4.2% of subjects in the lenabasum 20 mg BID, lenabasum 5 mg BID, and placebo groups. No serious TEAE preferred term occurred in more than 1 subject in any group. TEAE occurring in ≥ 10% of lenabasum 20 mg BID subjects were (% lenabasum vs % placebo): dermatomyositis (flare) 27.5% vs 40.8%; diarrhea 14.5% vs 8.5%; dizziness 13.0% vs 4.2%; nausea 11.6% vs 4.2%; headache 10.1% vs 14.1%; and arthralgia 10.1% vs 2.8%.

Conclusion: Although, primary or secondary endpoints were not met in the study, subgroup analysis of patients with muscle weakness and without muscle weakness, showed improvement in muscle strength and rash, respectively in lenabasum 20 mg BID group vs placebo. Lenabasum was administered safely and was well-tolerated in this study.

OP0163

A MATRIX PREDICTION MODEL FOR THE SIX-MONTH MORTALITY RISK IN PATIENTS WITH ANTI-MELANOMA DIFFERENTIATION-ASSOCIATED PROTEIN-5 POSITIVE DERMATOMYOSITIS

A. J. Tang[1,2], F. Y. Tang[3], Z. M. Ouyang[1], J. Lin[1], Z. H. Yang[4], L. J. Yang[1], X. N. Wei[1], Q. H. Li[1], J. J. Liang[1], D. H. Zheng[1], L. Dai[1], Y. Q. Mo[1,2]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*; [2]*Shenshan Medical Center, Memorial Hospital of Sun Yat-Sen University, Department of Rheumatology, Shanwei, China*; [3]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Respiratory, Guangzhou, China*; [4]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Departments of Radiology, Guangzhou, China*

Background: Recently, the autoantibody recognizing melanoma differentiation-associated gene 5 (anti-MDA5) is of the greatest concern as a specific autoantibody of dermatomyositis (DM), since it delineates a unique clinical phenotype of DM with a high risk of life-threatening lung complications. Considering routine clinical characteristics at baseline are still desired candidates for

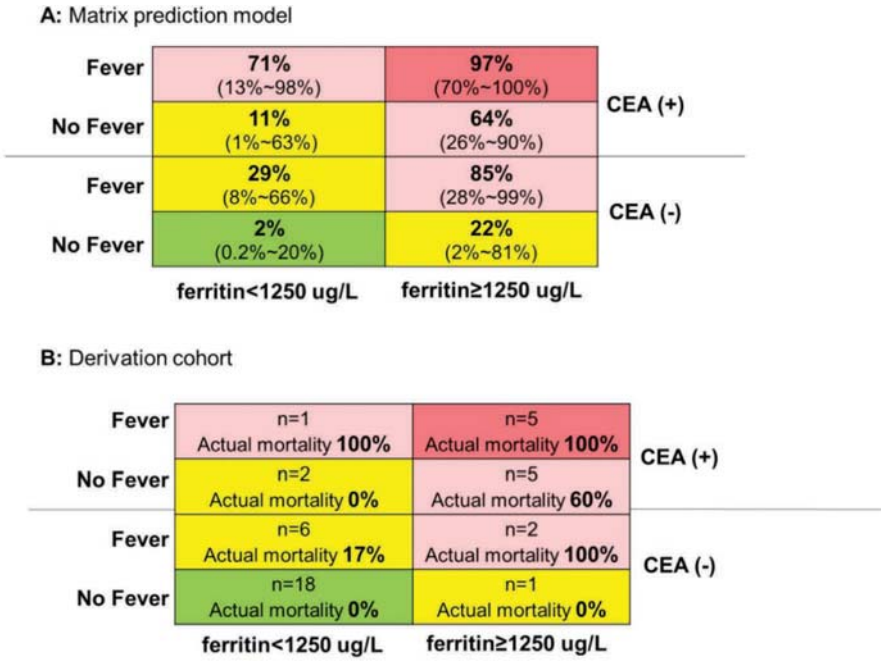

Figure 1 Matrix prediction model for 6-month all-cause mortality in anti-MDA5-positive DM patients.

A: Fever yes or no, CEA positive or negative, and ferritin<1250 ug/L or ≥1250 ug/L were combined to generate a matrix and then the relative mortality risk probability of death within six months in each grid was calculated. The 95% confidence intervals of the probabilities were shown in the parentheses. The anti-MDA5-positive IIM patients could be stratified into three subpopulations: high-risk (in red, the predicted mortality >50%; dark red indicated extremely high-risk), moderate risk (in yellow, the predicted mortality between 49%~10%), and low-risk (in green, the predicted mortality <10%). CEA, carcinoembryonic antigen. B: The actual mortality in each grid.

screening potential mortality predictors, in order to as early as possible stratify the mortality risk in anti-MDA5 positive DM patients before making therapeutic strategies.

Objectives: To investigate the baseline independent risk factors for predicting 6-month mortality of anti-MDA5-positive DM patients and develop a matrix prediction model formed by these risk factors.

Methods: This was a real-world prospective observational study. The hospitalized patients with DM were included if they fulfilled the criteria including: aged over 18 years old; diagnosed as having DM according to the criteria proposed by Bohan and Peter or the modified Sontheimer definitions; and positive anti-MDA5 which was determined by both line immunoassay testing and enzyme-linked immunosorbent testing. The primary outcome was all-cause 6-month mortality after enrolment. A matrix prediction model was built with the mortality risk probability.

Results: There were 82 DM patients enrolled (mean age of onset 50±11 years and 63% female), with 40 (49%) showing positive anti-MDA5. Gottron sign/papules (OR: 5.135, 95%CI: 1.489~17.708), arthritis (OR: 5.184, 95%CI: 1.455~18.467), interstitial lung disease (ILD, OR: 7.034, 95%CI: 1.157~42.785), and higher level of C4 (OR: 1.010, 95%CI: 1.002~1.017) were independent associators with positive anti-MDA5 in DM patients. Anti-MDA5-positive DM patients had significant higher 6-month all-cause mortality than those with anti-MDA5-negative (30% vs. 0%). Among anti-MDA5-positive DM patients, compared to the survivors, non-survivors had significantly advanced age of onset (59±6 years vs. 46±9 years), higher rates of fever (75% vs. 18%), positive carcinoma embryonic antigen (CEA, 75% vs. 14%), higher level of ferritin (median 2858 ug/L vs. 619 ug/L, all p<0.05). Multivariate COX regression showed ferritin≥1250 μg/L (HR: 10.4, 95%CI: 1.8~59.9), fever (HR: 11.2, 95%CI: 2.5~49.9), and positive CEA (HR: 5.2, 95%CI: 1.0~25.7) were independent risk factors of 6-month mortality.

According to the matrix prediction model, anti-MDA5-positive DM patients could be stratified into three subgroups based on various probabilities of predicted mortality: (i) High-risk: eight patients with two of the above three features (including fever, serum ferritin≥1250 μg/L, and positive CEA) had high predicted mortality probability with 64%~85% (three red grids in Figure 1A), and the actual mortality was 75% (n=6) with 60%, 100%, and 100% respectively in three red grids (Figure 1B). Five patients with all of three features had extremely high predicted mortality probability with 97% (95%CI: 70%~100%, the dark red grid of Figure 1A), and the actual mortality was 100% in Figure 1B; (ii) Moderate-risk: nine patients with one of the above three features had moderate predicted mortality probability with 11%~29% (three yellow grids in Figure 1A), and the actual mortality was 11% (n=1) with 0%, 0%, and 17% respectively in three yellow grids (Figure 1B); (iii) Low-risk: eighteen patients with none of the above three features had low predicted mortality probability with 2% (95%CI: 0.2%~20%, the green grid in Figure 1A), and the actual mortality was 0% in the green grid (Figure 1B).

Conclusion: Baseline characteristics of fever, positive CEA, and ferritin≥1250 μg/L are risk factors for 6-month all-cause mortality in anti-MDA5-positive DM patients. A novel matrix prediction model composed of these three clinical indicators is firstly proposed to provide a chance for exploration of individual treatment strategies in anti-MDA5-positive DM subgroups with various probabilities of mortality risk.

OP0164

A POPULATION-BASED, PROSPECTIVE METABOLOMICS STUDY IN THE UK BIOBANK IDENTIFIES GLYCOPROTEIN ACETYLS AS A NOVEL BIOMARKER OF INCIDENT GOUT

A. Joshi[1], N. McCormick[2], C. Yokose[2], N. Lu[3], H. Choi[2]. [1]*Massachusetts General Hospital, CTEU, Mongan Institute, Department of Medicine, Boston, United States of America*; [2]*Massachusetts General Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America*; [3]*Arthritis Research Canada, Arthritis Research, Vancouver, Canada*

Background: Serum urate (SU) level is the strongest known causal predictor of clinical gout, but only ~20% with prolonged hyperuricemia develop gout, motivating the need for additional biomarkers for risk prediction and stratification. The metabolome represents a compelling intermediate trait between genome and phenome to elucidate disease mechanisms. Multiple cross-sectional studies of *prevalent* gout from men in Asia have been conducted, but *no prospective data for incident gout* (prediagnostic metabolome) are available.

Objectives: Our objectives were to (1) conduct a discovery-based metabolome-wide study to *identify novel* biomarkers of incident gout; and (2) replicate novel metabolomic biomarkers of gout in independent samples.

Methods: We conducted a prospective cohort analysis of 105,703 UK Biobank (UKB) participants (46% males, mean age 57.2 years) with targeted NMR metabolomic profiling (N=168 metabolites, including routine lipids and amino acids) available from baseline samples (2006-10), and no prior diagnosis of gout or urate lowering therapy use. Incident cases of gout were documented from linked medical records until gout diagnosis, death, or end of study period (Dec 31/19). We used Cox proportional hazard models to obtain hazard ratios (HR) and 95% confidence intervals (CIs) per standard deviation (SD) increase in each of the 168 metabolites to determine associations with incident gout.

To replicate our findings, we assessed association of metabolome-wide significant metabolites in a replication set, restricted to 4,804 **non-overlapping** participants who provided blood in the repeat assessment visit (2012-13).

Results: During a median 10.4 years follow-up, we documented 1,367 cases of incident gout in the discovery set. After correction for multiple comparisons, glycoprotein acetyls (GlycA) were positively associated with risk of incident gout (multivariable HR per 1SD increase = 1.34 (1.27 to 1.41), P = 9.04×10^{-28}) after adjusting for age, sex, and lifestyle and clinical covariates (Table 1). This association persisted even after SU adjustment (HR 1.07, P = 0.0091). In the replication set, among 4,804 participants followed for a median of 6.8 years, we documented 22 cases. In this dataset, we replicated GlycA association with incident gout (multivariable HR per 1SD increase =1.56 (1.08 to 2.25), P = 0.017).

Conclusion: In this large-scale, prospective metabolomics study, we identified and independently replicated our findings that plasma levels of GlycA are associated with incident gout in UKB participants. GlycA is novel for gout, though this pro-inflammatory biomarker has predicted risk of other cardiometabolic-inflammatory phenotypes, independent of CRP.[1] These findings may provide insight into the metabolic-inflammatory pathogenesis of gout, with implications for risk prediction, even beyond SU, but call for further investigation with more extensive metabolome profiling and external replication.

OP0165

JAK3-STAT5 SIGNALING PATHWAY IS INVOLVED IN THE PATHOGENESIS OF GOUTY INFLAMMATION

F. N. Xiao[1], G. L. Jian[1], Q. B. Zhang[1], Y. Xie[1], T. Li[1], Z. M. Xu[2], Y. F. Qing[3].
[1]Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Geriatrics, the Affiliated Hospital of North Sichuan Medical College, Nanchong, China; [2]Institute of Medcine, North Sichuan Medical College, Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Nanchong, China; [3]Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Nanchong, China

Background: Studies have confirmed that JAKs-STATs signaling pathway is involved in the pathogenesis of a variety of autoinflammatory diseases, and has been transformed into the treatment of rheumatic diseases. So far, the research of JAKs-STATs in the mechanism of gout is very limited.
Objectives: To determine whether JAKs-STATs pathway is involved in the pathogenesis of gouty inflammation.
Methods: 1.The transcription and protein phosphorylation levels of 4 JAKs (JAK1, JAK2, JAK3 and Tyk2) and 7 STATs (STAT1, stat2, STAT3, STAT4, STAT5a/5b and STAT6) in PBMCs of 100 gout patients (concluding acute gout (AG) and intermittent gout (IG) patients 50 cases, respectively) and 50 healthy subjects (HC) were measured; 2.To detect the changes of JAK3-STAT5 signal pathway in synovium of rat ankle model of gouty inflammation;3.To explore the changes of JAK3-STAT5 signal pathway in synovium of gouty inflammation model after colchicine treatment.
Results: 1.The phosphorylation levels of JAK3 and STAT5 in PBMCs,the plasma IL-2 level in the AG group were all significantly higher than those in the HC group (P<0.05, respectively; Figure 1G,H), while there were no differences with respect to the other JAKs and STATs molecules between the two groups (P>0.05, respectively); 2.JAK3 and STAT5 phosphorylation levels in synovial tissue of rat ankle, cytokine IL-1β and IL-2 productions in synovial fluid of rat ankle from gout model were all significantly increased (P<0.05, respectively;Figure 1A-F);3.Phosphorylation levels of JAK3 and STAT5,IL-1β and IL-2 levels were significantly reduced after colchicine treatment (P<0.05, respectively;Figure 1A-F)

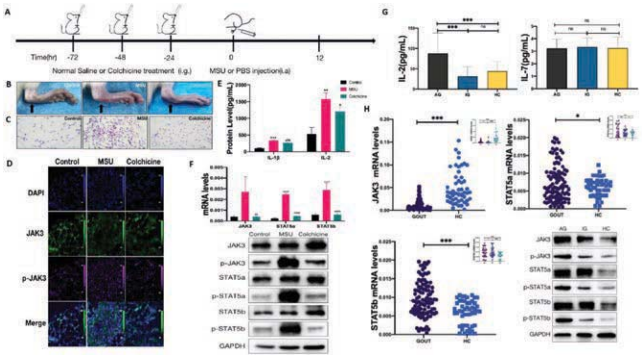

Figure 1. JAK3-STAT5 participates in the pathogenesis of gouty inflammation. In vivo experimental protocol (A-F): A. Male Wistar rats were used. The model Colchicine group was intragastrically administered with 0.104 mg/kg/d colchicine solution, and the Control group was intragastrically administered with the same amount of saline. After 3 days of continuous intragastric administration, the right ankle joint was injected with MSU (8 mg/100μl) or PBS (100 μl) to establish a gout arthritis model(MSU group) or Control group. B. Representative photographs of ankles 12 hr after MSU or PBS injection. C. Representative microscopic photos of ankle tissue sections from Control, MSU and Colchicine groups. D. Representative confocal laser scanning images showed JAK3 protein and its phosphorylated protein staining in ankle tissues in the three groups. Areas staining positive for JAK3 protein are shown in green. Regions staining positive for p-JAK3 protein are shown in red. E. IL-1β and IL-2 production in ankle flushing was detected by ELISA.*P <.05,**P<.01,***P<.001, significantly different from Control group; #P<.05,##P<.01, ###P< .001,significantly different from MSU group. F. At 12 h after MSU injection, JAK3 and STAT5 mRNA, protein in ankle tissues were determined by qRT-PCR and Western blotting, respectively. The panel displays the representative images of JAK3, STAT5, p-JAK3, p-STAT5a and GAPDH protein expression from the three groups.*P <.05,**P<.01,***P<.001, significantly different from Control group; #P<.05,##P<.01, ###P< .001, significantly different from MSU group. G.IL-2 and IL-7 levels in plasma of acute gout(AG), intermittent gout(IG) patients and healthy individuals (HC) were detected using ELISA. *P<.05, **P<.01, ***P < .001. H. JAK3 and STAT5 mRNA, protein levels in PBMCs of AG, IG, and HC groups were measured by qRT-PCR and Western blotting, respectively. *P<.05, **P<.01, ***P < .001.

Conclusion: IL-2-JAK3-STAT5 signaling pathway is involved in the regulation of gouty inflammation. Colchicine could treat gouty inflammation through inhibiting IL-2-JAK3-STAT5 pathway; JAK3 is expected to be a therapeutic target for acute gouty inflammation.

OP0166

CHRONIC KIDNEY DISEASE AND AMPLIFICATION OF SERUM URATE IMPACT ON GOUT RISK: POPULATION-BASED STUDY OF > 450,000 UK BIOBANK PARTICIPANTS

N. McCormick[1,2,3,4], L. Lu[4], C. Yokose[1,2,3], A. Joshi[2,3,5], Y. Zhang[1,2,3], H. Choi[1,2,3,4]. *[1]Massachusetts General Hospital, Rheumatology, Allergy, and Immunology, Boston, United States of America; [2]The Mongan Institute, Medicine, Boston, United States of America; [3]Harvard Medical School, Medicine, Boston, United States of America; [4]Arthritis Research Canada, -, Vancouver, Canada; [5]MGH Clinical and Translational Epidemiology Unit, Medicine, Boston, United States of America*

Background: Serum urate (SU) is a necessary causal factor for development of gout, while chronic kidney disease (CKD) is associated with increased inflammatory biomarkers, cytokines, and reduced AMPK activity levels. Furthermore, CKD has been found to be associated with an increased risk of incident gout, even beyond (i.e., independent of) SU levels. As such, the impact of SU may be enhanced by presence of CKD, but this hypothesis has not been evaluated.
Objectives: To prospectively examine whether CKD modifies the relation between SU levels and risk of incident gout.
Methods: We conducted a prospective cohort analysis of UK Biobank participants with urate and creatinine levels available from baseline blood samples (2006-2010), and no prior diagnosis of gout or urate lowering therapy use. CKD Stage ≥ 3 status (eGFR <60 mL/min) was determined from latest CKD-Epi equations (*NEJM* 2021; *JASN* 2021).[1,2] Incident cases of gout were ascertained from linked hospitalisation, primary care, and death records. Participants were

followed from baseline up to 10 years or until gout diagnosis, death, or end of study period (Dec 31/19).
We calculated 10-year cumulative incidence of gout according to baseline SU category and CKD status and evaluated their individual and joint impact on gout risk using multivariable Cox proportional hazards models.
We further assessed for additive and multiplicative interactions[3] between levels of SU and inverted eGFR, on a standardized continuous scale per SD.
Results: We included 458,244 individuals (45% male, mean age 56.5 years), of whom 6,559 had CKD at baseline, and documented 5,847 cases of incident gout over 4,442,866 person-years.
10-year cumulative incidence of gout ranged from 0.2% (baseline SU < 5 mg/dL) to 33% (baseline SU ≥ 10 mg/dL), and in each category incidence was higher for those with CKD than without (Table 1; Figure 1**-left**), Multivariable hazard ratio (HR) for the joint effect of CKD and highest SU level (≥ 10 mg/dL), compared to non-CKD and lowest SU (<5mg/dL), was 242 (95% CI: 189 to 309) (Figure 1**-right**).
There was a significant additive interaction between continuous SU and eGFR (relative excess risk due to interaction=0.16 [0.09 to 0.24], p < 0.001), with HRs of 3.7 (3.6 to 3.8) per SD increase of SU, 1.2 (1.2 to 1.3) per SD increase of inverted eGFR, and 4.1 (3.9 to 4.2) for their joint effect. Their multiplicative interaction was also significant (p < 0.001).
Conclusion: These large prospective cohort data suggest CKD presence enhances the effect of elevated SU levels on risk of incident gout. They support roles of CKD-associated factors beyond SU in developing gout, such as reduced AMPK activity levels and altered inflammatory factors in CKD, which warrant further investigation.

OP0167 ULTRASONOGRAPHY IN THE PREDICTION OF GOUT FLARES: A 12-MONTH PROSPECTIVE OBSERVATIONAL STUDY

E. Cipolletta[1], A. Abhishek[2], J. Di Battista[1], W. Grassi[1], E. Filippucci[1].
[1]Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Ancona, Italy; *[2]University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom*

Background: Gout flares are a distinctive feature of gout. Although imaging techniques, such as ultrasonography (US), can visualise monosodium urate (MSU) crystals and synovial inflammation and estimate their burden, the role of imaging in predicting gout flares has not been fully investigated.
Objectives: To evaluate whether US findings indicative of MSU deposits and subclinical inflammation predict gout flares over 12 months.
Methods: Participants with gout on urate-lowering therapy (ULT) for at least the preceding six months were enrolled consecutively in this 12-month prospective, observational, single-centre study.
A nested case-control analysis was performed. Cases were participants with at least one gout flare in the follow-up period while controls did not self-report any gout flares. Clinical assessment was scheduled at 6-month intervals. In addition, at baseline, each patient underwent an US examination using a standardised scanning protocol including the following sites: knees, ankles, 1st metatarsophalangeal joints, elbows, wrists and 2nd metacarpophalangeal joints. The US findings indicating MSU deposits [i.e., aggregates, double contour (DC) sign and tophi] and inflammation [i.e., Power Doppler (PD) signal] were identified according to the 2015 Outcome Measure in Rheumatology definitions (Figure 1).

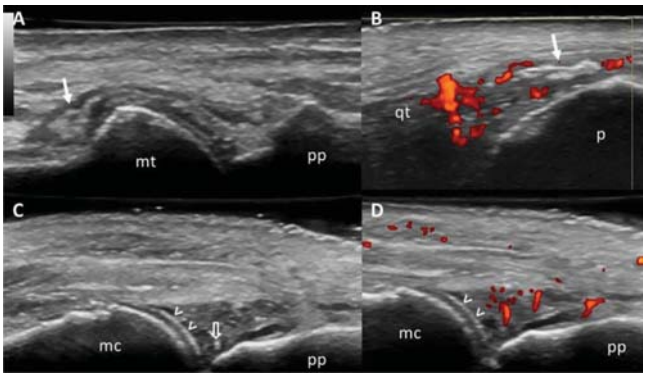

Figure 1.

Summated scores were calculated for each US finding.
During follow-up visits, patients were asked to report any gout flares using an internationally-validated definition [1].
Multivariate logistic regression analysis was used to measure the association between baseline US findings and the occurrence of gout flares over 12 months. US scores were tested separately, including the following covariates: age, gender, disease duration, presence of subcutaneous tophi, current serum urate>360 µmol/l, increasing dose of ULT during the study period and ongoing flare prophylaxis. In addition, multivariate zero-inflated Poisson regression analysis was used to investigate the association between US findings and the number of flares over 12 months.
Results: Eighty-one gout participants were enrolled, and 71 completed the study. Thirty (42.3%) of 71 participants experienced at least one flare over 12 months, with a median of 2.0 flares. There was no difference among baseline clinical and laboratory characteristics of patients with and without flares except for the presence of subcutaneous tophi (23.3% vs 4.9%; p=0.02) and higher current SU levels (360.8 vs 301.4 µmol/l mol/L, p=0.01).
Participants with flares had a greater baseline US burden of MSU deposits (2.0±1.8 vs 0.5±0.9, p=0.01 for DC sign; 2.1±2.3 vs 0.8±1.0, p=0.01 for tophi; 2.6±2.0 vs 1.6±1.6, p=0.03 for aggregates) and of subclinical inflammation (3.73±3.53 vs 0.82±1.44, p<0.01).
The baseline extent of MSU deposits and subclinical inflammation estimated by US was significantly associated with gout flares over 12 months in multivariate logistic regression analyses. DC sign score (aOR: 2.20, 95%CI: 1.22-4.34; p=0.01), tophi score (aOR: 2.16, 95%CI: 1.12-4.18; p=0.02) and PD score (aOR: 1.63, 95%CI: 1.12-2.40; p=0.01) predicted gout flares, whereas aggregates score (aOR: 1.40, 95%CI: 0.94-2.10; p=0.10) did not reach the statistical significance. Similar results were obtained in multivariate Poisson regression models (aIRR for DC score: 1.39, 95%CI: 1.18-1.64, p<0.01, aIRR for tophi score: 1.30, 95%CI: 1.17-1.45, p<0.01, aIRR for PD score: 1.29, 95%CI: 1.19-1.40, p<0.01, aIRR for aggregates score: 1.13, 95%CI: 1.00-1.29, p=0.05).
Conclusion: Baseline US findings indicating MSU deposits and subclinical inflammation are independent predictors of gout flares over 12 months.

Background: Ultrasound (US) has proven to be an excellent imaging technique for detecting calcium pyrophosphate (CPP) deposition disease (CPPD); it is also widely available and inexpensive and can be performed during the clinic visit making it the preferred imaging modality for many rheumatologists. However, no validated grading systems have yet been developed allowing for a quantification of the extent of crystal deposition in CPPD.
Objectives: The aim of this study was to develop a scoring system for the quantification of CPP deposition at a patient level according to the OMERACT framework.
Methods: As part of the OMERACT methodology, we performed a systematic literature review (SLR) and meta-analysis aimed to estimate the prevalence of CPP deposition in peripheral joints by imaging, in order to identify relevant joints for CPPD monitoring. A preliminary survey was also circulated among the members of the OMERACT US – CPPD working group to collect their own suggestions according to their personal experience. Subsequently, a Delphi survey was prepared and circulated between members of the group, including statements that reflected both the results of the SLR and of the preliminary survey. In total, 32 statements were generated regarding the type of scoring for single structures, the sites to be included, the final scoring at patient level, and the scanning technique. Participants were asked to reply on a 5-point Likert scale (1, strongly disagree to 5, strongly agree) and agreement was achieved when 4 and 5 grades reached 75% or more of concordance. In case of disagreement, new statements were proposed according to the members' suggestions and circulated for voting in a subsequent round. After agreement of a scoring system, the validation process began. Two rounds of a web-based exercise on static images were conducted on 120 images representing equally all sites under investigation and all degrees of crystal deposition, to assess the intra- and inter-reader reliability of the new scoring system. Representative images of the scoring system were visible throughout the entire exercise in order to facilitate the scoring of the lesions.
Results: Three Delphi rounds were needed to reach agreement on all items. 32/41 members of the OMERACT US-CPPD working group replied in the first round, 26/32 in the second, and 25/26 in the third round. Twenty statements were approved in the first round, 3 in the second, and 3 in the third round. Only the knees (menisci and hyaline cartilage) and the triangular fibrocartilage of the wrist were included in the final score, using a four-grade system (0-3). It was decided that each anatomical structure should be scored separately and then also summed in order to define the joint score. The sum of the assessed joints was the total score at patient level. The final scoring system with the definitions and the relative technical notes is represented in Figure 1. 33/41 members participated to the reliability exercise. The inter-reader reliability of the scoring was substantial (kappa of 0.72), and the intra-reader reliability was almost perfect (kappa of 0.82).
Conclusion: This is the first study for developing a scoring system for the extent of CPP crystal deposition in patients with CPPD. The scoring system demonstrated to be reliable in static images. The next step of the validation process is to assess the reliability of the scoring system in a patient-based exercise. This study represents a fundamental step in the OMERACT process of validating US as an outcome measure instrument, and above proposed scoring system will hopefully provide a useful tool for clinical practice and research.

OP0169 **INPATIENT DISCONTINUATION OF ALLOPURINOL – A QUALITATIVE IMPROVEMENT (QI) INITIATIVE**

S. Farshad[1], A. Ramahi[1], A. Murphy[1], Y. Aleatany[1], P. Khanna[1]. [1]*University of Michigan, Rheumatology, Ann Arbor, United States of America*

Background: Gout is a chronic inflammatory arthritis induced by hyperuricemia and manifested by recurrent acute flares of debilitating joint pain, when left untreated. Allopurinol is often used as long-term urate lowering therapy. Discontinuation of allopurinol leads to worsening flares, disability, poor quality of life, and frequent use of acute care facilities. Recent data revealed that 56% of hospitalized patients had allopurinol discontinued during an episode of acute gout flare, suggesting an unmet need for ongoing provider education (1). Gout flares are 14 times more likely to develop in patients who have allopurinol discontinued upon admission to the hospital (2).
Objectives: We performed a qualitative analysis of the current rate of discontinuation of allopurinol during hospitalizations at an academic hospital in order to develop a continuous improvement model.
Methods: We leveraged our electronic health records (EHR) to obtain data on gout patients admitted to the university hospital from 2019-2020, with IRB approval. Patients on allopurinol as an active home medication that was discontinued during hospitalization and/or after hospital discharge were included to calculate the rate of discontinuation. Lean thinking methodology with A3 process mapping for root cause analysis (RCA) was utilized. We first identified stakeholders involved in medication reconciliation – nurses and various providers, including trainees, and invited them to participate in an anonymous survey to understand the rationale behind allopurinol discontinuation during hospitalization. Next, we created countermeasures and actionable recommendations that could be implemented at an institutional level.
Results: A total of 2138 patients who were hospitalized had allopurinol listed as an active home medication. Of these, 364 (17%) did not receive allopurinol during hospitalization. Based on the survey data, providers chose to discontinue allopurinol due to the following factors – acute gout flare, renal impairment, gastrointestinal issues, cytopenia, drug interactions, NPO status, and always discontinued the medication. The RCA revealed layers of reasoning at various levels of the medication reconciliation process which impacted the decision-making algorithm. This in turn led to discontinuation during the admission and subsequent omission of allopurinol on the discharge medication list. Several actionable and high-impact recommendations emerged as countermeasures, including – a) pharmacy involvement at admission medication reconciliation, b) creation of a clinical practice guideline, and c) automated routing by EHR to standardized guidelines when allopurinol was discontinued on admission (Figure 1).

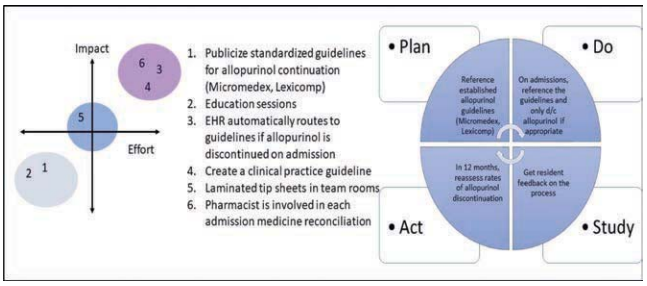

Figure 1. Countermeasures and Implementation Plan

Conclusion: There is evidence of inappropriate discontinuation of allopurinol that leads to gout flares in the outpatient setting and unnecessary resource utilization. We developed an implementation plan to mitigate this systematically at an institutional level. Testing these recommendations next to devise a standardized protocol as a continuous improvement strategy may help improve gout care and patient outcomes.

OP0170

PHASE 2A, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF THE EFFICACY AND SAFETY OF A TRANSDERMAL ALKALINIZING AND PAIN-RELIEVING TREATMENT FOR REDUCING PAIN ASSOCIATED WITH AN ACUTE GOUT FLARE

P. Khanna[1], R. Beal[2]. [1]*University of Michigan, Rheumatology Clinic | Taubman Center, Ann Arbor, United States of America*; [2]*Dyve Biosciences, Management, Camarillo, United States of America*

Background: Monosodium urate (MSU) deposition is pathognomonic for gouty arthropathy. MSU crystal formation and dissolution is affected by pH and theoretically, alkalinizing agents (eg, sodium bicarbonate, $NaHCO_3$) that raise the joint microenvironment pH, could facilitate MSU crystal dissolution[1] and decrease the pain of an acute gout flare. However, oral $NaHCO_3$ use is fraught with intolerable gastrointestinal side effects.

Objectives: To determine if $NaHCO_3$ in a patented transdermal formulation could effectively and safely reduce the pain of an acute gout flare.

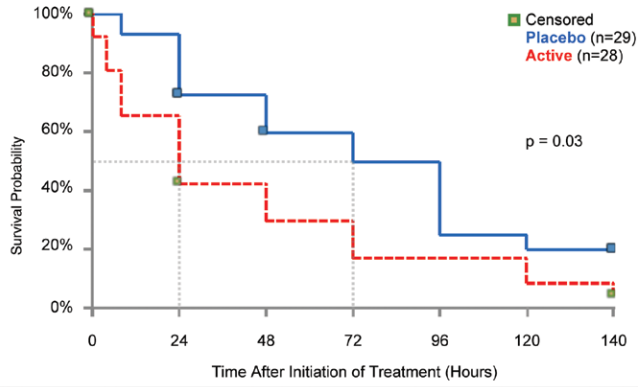
Methods: A Phase 2a prospective, double-blind, randomized, placebo-controlled study enrolled 418 subjects across 20 US sites. Patients with a diagnosis of gout using ACR/EULAR criteria (Score ≥ 8), ages 18-75, history of ≥ 2 gout flares in 12 months prior to randomization and on stable doses of urate lowering therapy were included. Exclusion criteria were BMI > 40kg/m^2, > 12 gout flares in the year prior to randomization, history of rheumatoid arthritis, psoriatic arthritis, evidence of septic arthritis, acute polyarticular gout (≥ 4 joints), and arthritis of any other cause. Patients were randomized to receive placebo lotion or transdermal $NaHCO_3$. Upon flare they initiated colchicine (1.2 mg followed by 0.6 mg 1 hour later) and applied study product to the limb of the affected joint. Outcome measures included pain-numeric rating scale (NRS, 0-10), time to resolution of pain (50% reduction), rescue medication use, joint tenderness, and physical function (PROMIS PF-20). Data were collected in patient diaries for the pain and PROMIS measures at several time points from baseline through Day 7, as were adverse events. Statistical analyses utilized ANCOVA (baseline pain as a covariate), Kaplan-Meier curves for homogeneity, and two-proportion z-test, all with α=0.05.

Results: 98 patients had a gout flare during the 14-month study period. Those in the active arm (ITT, N=48) had an overall responder rate of 94.5% vs. 79.3% (p=0.01) in the placebo arm (ITT, N=50) over the 7-day follow up. Rescue medication use was lower in the active arm vs. placebo (6.3% vs. 20.0%, p=0.02); and PROMIS PF-20 showed greater improvements over 7 days (22.2 vs. 16.7 points, p=0.05). The most common adverse event was hypertension (14.2%) with no significant difference between arms. Per protocol analyses were conducted to adjust for adherence on Day 1 for time to resolution of pain (Figure 1) and additional 24hr endpoints (Table 1).

Table 1. Key 24hr Endpoints (Per Protocol, n = 57)

	Active (n = 28)	Placebo (n = 29)	P value
Median time to resolution, hrs[1]	24	72	0.03
Change in 24hr PROMIS PF-20 score[2]	16.7	9.4	0.01
Physician-assessed moderate-to-severe joint tenderness 24hr[3]	28.0%	57.1%	0.02

[1]≥ 50% reduction in pain; K-M Est.; Subjects using rescue medication, discontinuing study drug, or missing pain scores censored [2]Consists of 20, 0-5-point questions; higher scores indicate better function [3]LIKERT: 0 (no pain), 1 (pain), 2 (wincing), 3 (wincing and withdrawal)



[1] Resolution is defined as at least a 50% reduction in pain; Kaplan-Meier Estimates; Subjects who use rescue pain medication, discontinue use of study drug, or otherwise have missing pain score data were censored at the date of the latest valid NRS pain score; Log-rank test for homogeneity between treatment K-M curves.

Figure 1. Time to resolution of pain[1] (per protocol population, n = 57)

Conclusion: Transdermal $NaHCO_3$ reduced the pain intensity and duration of an acute gout flare with higher overall response rates, faster time to resolution, improvements in physical function and a reduction in rescue medication use. The lack of adverse events makes this topical a promising therapeutic choice; especially during debilitating acute gout flares in patients with concomitant comorbidities.

Background: Patients (pts) with gout refractory to oral urate-lowering therapy (ULT) have few treatment options. Pegloticase (pegylated uricase) lowers serum uric acid (sUA) in these pts,[1] but response rates are limited by anti-drug antibodies (ADAs), which decrease urate-lowering efficacy and increase infusion reaction (IR) risk.[2] Because methotrexate (MTX) is commonly used in RA

and prevents ADA development against biologics, co-administering MTX with pegloticase in uncontrolled gout pts is of interest. A small open-label study of pegloticase+oral MTX suggested an increased efficacy rate,[3] so a randomized controlled trial (RCT) was conducted to compare pegloticase with/without MTX immunomodulation.

Objectives: To determine safety/efficacy of oral MTX as co-therapy with pegloticase for sustained urate-lowering response in a randomized placebo (PBO) controlled trial.

Methods: Pegloticase+MTX and pegloticase+PBO co-therapy were compared in uncontrolled gout pts (sUA≥7 mg/dL, ULT failure/intolerance, and ≥1 of the following: ≥1 tophus, ≥2 flares in past yr, chronic gouty arthritis). Primary endpoint was the proportion of Month 6 treatment responders (sUA<6 mg/dL for ≥80% of the time during Wks 20-24). Key exclusion criteria included MTX contraindication, immunosuppressant use, G6PD deficiency, and renal impairment (eGFR<40 ml/min/1.73 m^2). Pts were randomized 2:1 to oral MTX (15 mg/wk) or PBO. Following a 4 wk MTX/PBO run-in, pegloticase was initiated (Day 1). Both pegloticase (biweekly 8 mg infusions) and MTX/PBO were administered over 52-wks (treatment period). Efficacy was examined in the intent-to-treat population (ITT, all randomized pts); safety (AEs, laboratory values) in the safety population (all pts receiving ≥1 dose blinded MTX/PBO). Treatment was discontinued if pre-infusion sUA >6 mg/dL for 2 consecutive visits Wk 2 or later.

Results: 152 pts (88.8% male) were randomized at 42 sites; 100 to pegloticase+MTX, 52 to pegloticase+PBO. 4 MTX, 3 PBO pts discontinued before first pegloticase dose; 26 MTX, 30 PBO pts who received pegloticase discontinued treatment at or before Wk 24. The primary endpoint was met with a 6-month response rate of 71.0% (71/100) vs 38.5% (20/52) in the MTX vs PBO co-therapy groups (p<0.0001; modified ITT [all pts receiving ≥1 pegloticase dose]: 74.0% [71/96] vs 40.8% [20/49], p<0.0001). In the first 24 wks of therapy, 81.3% vs 95.9% experienced ≥1 AE (Table 1), with gout flare in 66.7% (64/96) vs 69.4% (34/49) of MTX vs PBO pts. Infusion reactions (IRs) were more frequent in the PBO group (30.6%) than in the MTX group (3.1% plus anaphylaxis [NIAID/FAAN criteria] in 1 MTX pt). A single cardiovascular event of cardiac arrest occurred in 1 MTX pt >2 wks after pegloticase infusion 3 (deemed unrelated to study drug by site investigator). MTX-associated AEs[4] did not occur more frequently in the MTX group (Table 1).

Table 1. Key efficacy and safety findings through Month 6 of treatment.

	Pegloticase+MTX	Pegloticase+PBO
ITT population	N=100	N=52
Age, yrs, mean±SD	55.6±12.7	53.0±12.1
Tophi at baseline, %	74.0%	78.8%
sUA at baseline, mg/dL, mean±SD	8.7±1.6	9.1±1.7
6-mo treatment responders (primary endpoint), %	71.0%	38.5%
Safety population	N=96	N=49
≥1 Serious AE, %	8.3%	10.2%
≥1 treatment-emergent AE, %	81.3%	95.9%
Gout flare*	66.7%	69.4%
IR*, anaphylaxis*	3.1%, 1.0%	30.6%, 0%
Cardiac event*	1.0%	0%
Infection/infestation†	10.4%	16.3%
Gastrointestinal†	9.4%	16.3%
Skin†	7.3%	12.2%
Respiratory/thoracic†	5.2%	4.1%
Blood/lymphatic†	2.1%	2.0%
Renal/urinary†, hepatobiliary†	2.1%, 0%	2.0%, 2.0%

*AE of special interest, †known MTX AE

Conclusion: This RCT demonstrated significantly higher rate of sustained urate-lowering response over 6 months in pts co-treated with pegloticase+MTX vs pegloticase+PBO. No new safety concerns were seen through Month 6 and IR incidence was markedly lower in patients co-administered MTX vs PBO.

Vaccination against SARS-CoV-2

OP0172

THE IMPACT OF IMMUNOMODULATING TREATMENT ON THE IMMUNOGENICITY OF COVID-19 VACCINES IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY RHEUMATIC DISEASES COMPARED TO HEALTHY CONTROLS. A SWEDISH NATIONWIDE STUDY (COVID19-REUMA)

M. Frodlund[1], K. Chatzidionysiou[2], A. Södergren[3], E. Klingberg[4], A. Bengtsson[5], L. Klareskog[6], M. C. Kapetanovic[5]on behalf of COVID19REUMA. *[1]Linköping University, Faculty of Medicine and Health Sciences, Biomedical and Clinical Sciences, Linköping, Sweden*; *[2]Karolinska Institute, Department of Medicine, Solna, Rheumatology Unit, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden*; *[3]Umeå Universitet, Department of Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden*; *[4]Sahlgrenska Academy, Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, Gothenburg, Sweden*; *[5]Lund University, Department of Clinical Sciences, Lund, Section for Rheumatology, Lund, Sweden*; *[6]Karolinska Institute, Department of Medicine, Solna, Rheumatology Unit, Stockholm, Sweden*

Background: Initial studies on the immunogenicity of COVID-19 vaccines in patients with immune-mediated inflammatory rheumatic diseases (IRD) reported diminished antibody response in general, and particularly when treated with rituximab or abatacept (1). Additional data are needed, especially for patients with IRD and immunomodulatory treatments.

Objectives: To elucidate the antibody response after two doses of COVID-19 vaccine in patients with IRD treated with biologic or targeted synthetic disease modifying anti-rheumatic drugs (b/ts DMARDs) as monotherapy or combined with conventional synthetic DMARDS (csDMARDs).

Methods: Antibodies against two antigens representing Spike full length protein and Spike S1 and a Nucleocapsid C-terminal fragment (used to confirm previously COVID-19 infection) were measured in serum obtained before and after the second vaccination using a multiplex bead-based serology assay (2). Patients with IRD receiving immunomodulating treatment, followed at a rheumatology department and healthy individuals (controls) were recruited from five Swedish regions. Antibody positivity was classified as the signal passing an antigen specific cutoff based on the mean intensity signal of 12 selected negative pre-pandemic controls plus 6SD for Spike/S1 and 12SD for Nucleocapsid-C. Good vaccine response was defined as having antibodies over cut-off level for both spike antigens. Percentage of responders in each treatment group was compared to controls (Chi2 test). Predictors of antibody response were determined using logistic regression analysis.

Results: In total, 414 patients (320 RA/JIA/psoriatic arthritis/axial spondylarthritis, 60 systemic vasculitis and 32 other IRD) and 61 controls participated. Patients receiving rituximab (n=145; 65% female; mean age 65years), abatacept (n=21; 77% female; mean age 66 years), IL6 inhibitors (n=77; 74% female; mean age 64years), JAK-inhibitors (n=58; 75% female, mean age 53years), TNF-inhibitors (n=68; 66% female; mean age 44years;), IL17 inhibitors (n=42; 54% female; mean age 44years) and controls (n=61; 74% female, mean age 49years) were studied. Patients receiving IL6 inhibitor (81.0%), abatacept (43.8%) or rituximab (33.8%) had a significantly lower antibody response rate compared to controls (98.4%), further pronounced if combined with csDMARD (p<0.001) (Figure 1). In the adjusted logistic regression analysis, higher age, rituximab, abatacept, concomitant csDMARD but not IL6 inhibitors, concomitant prednisolone, or a vasculitis diagnosis, remained significant predictors of antibody response (Table 1). All vaccines were well tolerated. 14 (3.4%) patients reported an increased activity in their IRD following vaccination.

Conclusion: In this nationwide study including IRD patients receiving b/ts DMARDs a decreased immunogenicity of COVID-19 vaccines was observed in patients receiving rituximab, abatacept and to some extent IL-6 inhibitors. Concomitant csDMARD gave further attenuation. Patients on rituximab and abatacept should be prioritized for booster doses of COVID19 vaccine.

OP0173

INCIDENCE OF COVID-19 INFECTION AND HOSPITALISATION ACCORDING TO VACCINATION STATUS AND DMARD TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE MATCHED COHORT STUDY FROM DENMARK

R. Cordtz[1], S. Kristensen[1,2], R. Westermann[1], K. Duch[1,3], F. Pearce[4], J. Lindhardsen[5], C. Torp-Pedersen[6,7], M. P. Andersen[6], L. Dreyer[1,2,8]. *[1]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark*; *[2]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*; *[3]Aalborg University Hospital, Unit of Clinical Biostatistics, Aalborg, Denmark*; *[4]University of Nottingham, Division of Epidemiology and Public Health, Department of Rheumatology, Nottingham, United Kingdom*; *[5]Rigshospitalet, Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark*; *[6]Nordsjællands Hospital, Department of Cardiology, Hillerød, Denmark*; *[7]University of Copenhagen, Department of Public Health, Copenhagen, Denmark*; *[8]DANBIO, The DANBIO Registry, All Regions, Denmark*

Background: Patients with rheumatoid arthritis (RA) may have impaired immunogenicity to COVID-19 vaccines.

Objectives: To investigate the incidence of COVID-19 infection and hospitalisation in unvaccinated and vaccinated patients with RA compared with matched individuals; and secondarily in patients with RA according to DMARD treatment.

Methods: Danish nationwide matched cohort study from January to October 2021. Patients with RA were identified in DANBIO and matched 1:20 with individuals from the general population on age, sex, and vaccination status (month and exact type of vaccination). Primary and secondary outcomes were COVID-19 hospitalisation (Danish National Patient Register) and positive SARS-CoV2 PCR test (Danish COVID-19 Surveillance Register), respectively. Stratified by vaccination status, incidence rates (IRs) per 1000 person years (PY) and comorbidity-adjusted hazard ratios (aHRs) in cause-specific Cox models were calculated with 95% confidence intervals. Using the Aalen-Johansen estimator, the cumulative incidence of COVID-19 hospitalisations was visualised according to RA and vaccine exposure status.

Results: Regardless of vaccination status, patients with RA had increased incidence of COVID-19 hospitalisation compared to matched individuals (Table 1). However, the absolute risk was 0.20% for unvaccinated patients at 60 days and 0.08% for comparators, whereas it remained below 0.05% at 180 days of follow-up in both groups when fully vaccinated (Figure 1). Increased SARS-CoV2 infection rates were seen only among unvaccinated patients with RA (Table 1). Unadjusted analyses showed increased incidence of COVID-19 hospitalisation among rituximab-treated compared with conventional DMARD treated: unvaccinated HR 4.71 (1.98 to 11.18) and vaccinated HR 11.69 (2.07 to 66.06). However, the proportions of patients with previous cancer and treated with prednisolone were higher among the rituximab treated.

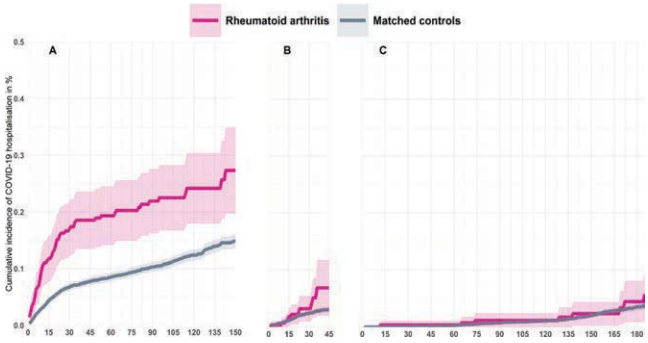

Figure 1. Cumulative incidence of COVID-19 hospitalisation (%) as a function of follow-up time (days) for (A) unvaccinated, (B) partially vaccinated and (C) fully vaccinated patients and comparators.

Conclusion: The incidence of COVID-19 hospitalisation was increased for both unvaccinated and vaccinated patients with RA compared with controls. Importantly, the parallel decreasing risk for patients with RA suggests a comparable

OP0174 T-CELL RESPONSE AFTER COVID-19 VACCINE IS NOT IMPAIRED BY EARLY RITUXIMAB TREATMENT OR BELIMUMAB IN SYSTEMIC AUTOIMMUNE DISORDERS

G. De Marchi[1], M. Fabris[2], R. Domenis[2], S. Guella[2], N. Cabas[1], F. Caponnetto[2], A. P. Beltrami[2], S. De Vita[1], F. Curcio[2], L. Quartuccio[1]. *[1]Division of Rheumatology, Department of Medicine, Udine, Italy*; *[2]Institute of Pathology, Department of Medicine, Udine, Italy*

Background: Patients with autoimmune systemic diseases have an increased risk to contract infections and develop severe complications; infections in turn can reactivated and worsen the disease itself in a vicious circle. Thus, vaccination is the main weapon to prevent infectious diseases and represents an important and safe instrument of care for rheumatic patients that needs to be further promoted. However, the immunosuppressive drugs used to treat rheumatic diseases may impair response to vaccines, in particular those targeting B or T cells directly (1).

Objectives: The aim of this study is to evaluate the B and T-cell mediated immune response to mRNA vaccination in patients with systemic autoimmune diseases, such as vasculitis or systemic connective tissue diseases, early or continuously treated with B-cell targeting therapies, rituximab (RTX) or belimumab (BEL), by comparing with controls and each other. Secondary we evaluated the in vitro effective neutralizing capacity in belimumab-exposed patients.

Methods: Twenty-eight consecutive patients under treatment with rituximab (RTX, n=11) or belimumab (BEL, n=17) and 13 age/sex matched controls (non-rheumatic healthcare personnel) were enrolled in the study. Nobody presented anti-SARS-CoV2 antibodies related to previous viral contact and all were always negative at the molecular swab monthly control. All patients and controls received mRNA vaccines and were tested three to four weeks after complete vaccination. All RTX patients started vaccination within 5 months from the last infusion, and all but one of them were B-cell depleted. Anti-SARS-CoV-2 RBD total antibodies were analysed by a diagnostic assay (Elecsys, Roche) while T-cell response was evaluated using the IGRA test (Euroimmun). A subgroup of BEL-patients was tested with pseudovirus neutralization assay.

Results: Detectable anti-SARS-CoV2 RBD antibodies were documented in 1/11 RTX patients versus 16/17 BEL patients ($p<0.0001$). The median concentration was significantly lower than that observed in controls (39.6 AU/ml vs 1133 AU/ml, $p<0.0001$). A very low titer of anti-RBD antibodies were documented only in 1 out of 11 patients in the RTX subgroup (0.93 U/ml, positive if >0,79 U/ml) and the patient was the only one who showed an initial B-cell recovery (CD19+ B-cell 5 cells/microL). Anti-RBD antibodies were documented in 16 out 17 of patients in the BEL subgroup. The median anti-RBD antibody titer in patients receiving BEL was 243 [77.55-744.0] U/ml, and it was significantly lower compared to the controls ($p=0.002$).

The IGRA test was positive in 8/11 (72.7%) RTX patients vs 16/17 (94.1%) BEL patients ($p=0.7$), with interferon release comparable to control subjects ($p=0.2$).

Six patients with BEL were also stratified according to total antibodies (IgG+IgA+IgM) against-RBD into high responders (>800 AU/mL, n=3) and low responders (≤45 AU/mL, n=3) and tested with pseudovirus neutralization assay. Two thirds of low titer group of patients neutralized the Wuhan-Hu1 strain at medium-low titer (IC50 ≈102) but were almost ineffective in inhibiting the B.1.1.7 entry into target cells (IC50 =10). Regarding high responders, while two patients were able to inhibit both the strains at medium-high titer (approximately IC50 ≈103 for Wuhan-Hu1 and B.1.1.7), one patient neutralized only the WT strain.

Conclusion: B-cell targeting therapies do not preclude SARS-CoV-2 vaccination since a cellular immunity can raise even in the absence of circulating B cells. Most importantly, the immunogenicity of COVID-19 vaccination in SLE patients treated with belimumab is supported. However, patients showing the lowest humoral response to vaccine could remain at higher risk of infections, due to low neutralizing capacity.

Rubbert-Roth[11]. *[1]SCQM Foundation, Biostatistics, Zurich, Switzerland*; *[2]Hôpitaux Universitaires de Genève (HUG), Service des Maladies Infectieuses, Genève, Switzerland*; *[3]Universitätsspital Basel, Immunology, Basel, Switzerland*; *[4]University Hospital of Zürich, Rheumatology, Zürich, Switzerland*; *[5]Hôpitaux Universitaires de Genève (HUG), Sérothèque/ Biothèque, Genève, Switzerland*; *[6]SCQM Foundation, -, Zurich, Switzerland*; *[7]RheumaCura, -, Bern, Switzerland*; *[8]Hôpitaux Universitaires de Genève (HUG), Rheumatology, Genève, Switzerland*; *[9]Inselspital, Rheumatology, Bern, Switzerland*; *[10]Hôpitaux Universitaires de Genève (HUG), Genetics and Laboratory Medicine, Genève, Switzerland*; *[11]Kantonsspital St.Gallen, Rheumatology, St. Gallen, Switzerland*

Background: Patients on immunomodulatory treatments mount an attenuated immune response following mRNA COVID-19 vaccination, yet long-term studies of vaccine-induced anti-SARS-CoV-2 antibody (Ab) kinetics are missing.

Objectives: In this prospective observational study, we mapped the humoral antibody response to mRNA COVID-19 vaccines up to 24 weeks post full vaccination in patients with inflammatory rheumatic diseases (IRDs). We aimed to assess differences due to treatment, age, past SARS-CoV-2 infection, and vaccine (BNT162b2 vs. mRNA-1273).

Methods: Adult patients from the SCQM cohort who assented to an mRNA COVID-19 vaccine were recruited between 3/21 – 9/21. Participants answered questionnaires via an app and received kits for the self-collection of capillary blood samples at baseline, 4, 12, and 24 weeks post full vaccination. Samples were tested for IgG Ab against the S1 domain of the SARS-CoV-2 spike protein (anti-S1-IgG) using the EUROIMMUN ELISA. To examine differences in Ab titres arising from the defined parameters, while accounting for inter-assay variability, mixed effects continuous outcome logistic regression models were applied at each timepoint.

Results: Samples were obtained from 570 patients: 67% female, mean age 53 y (SD 12 y) with 37% RA, 36% axSpA, 21% PsA, and 6% UA (undifferentiated arthritis), on no medication (no DMARDs & no glucocorticoids; 15%), csDMARDs (10%), TNFi (48%), IL-1/6/17/23i (14%), JAKi (6%), rituximab (RTX; 4%), or abatacept (ABA; 2%) in mono/combination therapy at the first vaccination. 10% of patients had a past SARS-CoV-2 infection, 54% received BNT162b2, 46% mRNA-1273.

For any Ab threshold, the odds of having a higher Ab titre at 4, 12, and 24 weeks post full vaccination were 3.3 – 4 times higher with mRNA-1273 compared to BNT162b2 (Table 1, Figure 1). TNFi, JAKi, RTX, and ABA as monotherapy resulted in significantly lower Ab levels compared to no medication at almost all timepoints. In combination therapy, TNFi, IL-1/6/17/23i, RTX, and csDMARDs led to consistently lower Ab titres at all timepoints compared to respective monotherapy.

Table 1. The OR of being above a given Ab threshold, regardless of the threshold. Ref. levels: mean age, no medication, no past SARS-CoV-2 inf., BNT162b2. Included in model but not shown: diagnosis, infrequently used medication (all non-signif.)

* p < 0.05; ** p < 0.01; *** p < 0.001; **** p < 0.0001; †Medication as monoth. vs no medication ‡Interaction terms showing how OR of mRNA-1273 (vs BNT162b2) increases with age §Interaction terms with medications: medication in combination th. vs medication as monoth.

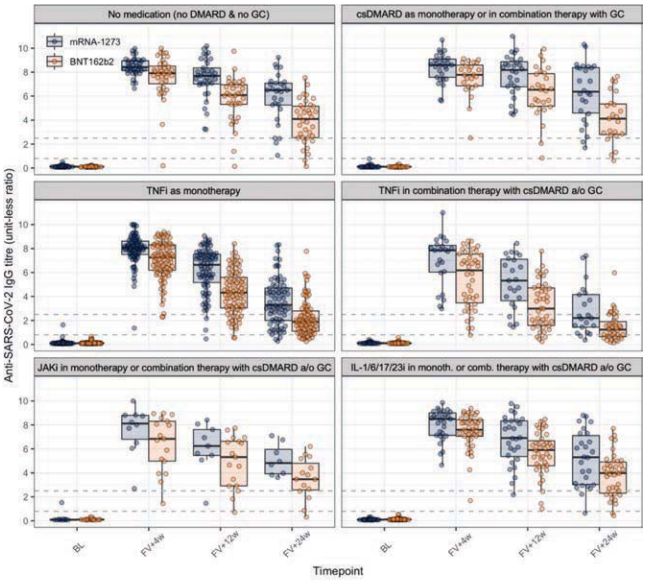

Figure 1. The variation with time of anti-S1 antibodies post mRNA COVID-19 vaccination in adult **SARS-CoV-2 naïve** IRD patients **as a function of medication** (in mono/combination therapy) **and vaccine**. Only medication groups corresponding to at least 10% of the study population are shown. Results are reported as a ratio (sample optical density/ calibrator optical density). The dashed lines indicate the thresholds below (0.8) and above (2.5) which the results are considered negative and positive for the presence of anti-SARS-CoV2 IgG, respectively; samples with results in the zone between the two thresholds were considered indeterminate and were further tested with recombinant immunofluorescence. GC = glucocorticoids; csDMARD = conventional synthetic disease-modifying antirheumatic drug; TNFi = tumour necrosis factor inhibitor; JAKi = janus kinase inhibitor; IL-1/6/17/23i = interleukin inhibitors. BL = baseline (sample taken on day before or on day of first vaccination, before vaccination), FV+4w/12w/24w = 4/12/24 weeks post full vaccination. Boxplot whiskers extend to 1.5*IQR.

Conclusion: Compared to no medication, some immunomodulatory therapies resulted in markedly lower Ab levels at all timepoints. In IRD patients, a past SARS-CoV-2 infection resulted in strikingly increased immunogenicity, as did mRNA-1273 compared to BNT162b2.

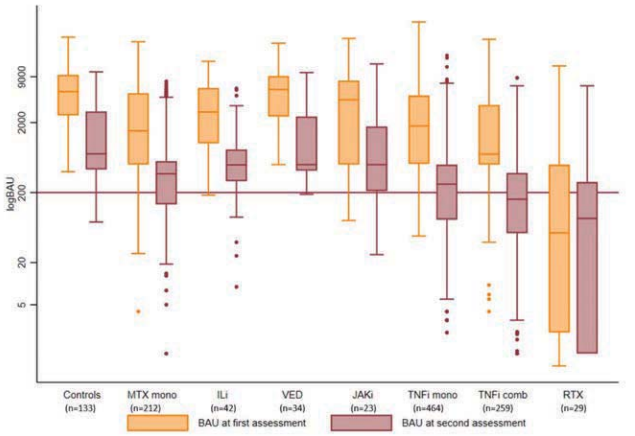
Aarrestad Provan[1]. *[1]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; *[2]Oslo University Hospital, Department of Immunology, Oslo, Norway*; *[3]Norwegian Institute of Public Health, Department of Infectious Disease Immunology, Oslo, Norway*; *[4]Oslo University Hospital, Department of Microbiology, Oslo, Norway*; *[5]Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway*; *[6]Akershus University Hospital, Department of Gastroenterology, Lørenskog, Norway*

Background: Limited data is available regarding long-term effectiveness of SARS-CoV-2 vaccines in patients with immune-mediated inflammatory diseases (IMIDs) on immunosuppressive therapy. Whether the persistence of vaccine-induced humoral immunity against SARS-CoV-2 differs between this patient population and the general public is currently unknown.

Objectives: To compare the persistence of anti-Spike antibodies following two SARS-CoV-2 vaccine doses between IMID patients using immunosuppressive medication and healthy controls and identify predictors of antibody decline.
Methods: We included patients with inflammatory joint- and bowel diseases on immunosuppressive medication and healthy controls enrolled in the prospective observational Nor-vaC study. Serum samples were collected at two time points following two dose SARS-CoV-2 vaccination (first assessment within 6–48 days and second within 49–123 days). Sera were analysed for antibodies binding the receptor-binding domain (RBD) of the SARS-CoV-2 Spike protein. Anti-RBD <200 BAU /ml were defined as low levels. The estimated percent reduction in anti-RBD standardised to 30 days was calculated and factors associated with reduction were identified in multivariable regression models.
Results: A total of 1097 patients (400 rheumatoid arthritis, 189 psoriatic arthritis, 189 spondyloarthritis, 129 ulcerative colitis, 190 Crohn´s disease) (median age 54 years [IQR 43–64]; 56% women) and 133 controls (median age 45 years [IQR 35–56]; 83% women) provided blood samples within the defined intervals (median 19 days [IQR 15–24] and 97 days [86–105] after second vaccine dose). Antibody levels were significantly lower in patients compared to controls at both assessments, with median anti-RBD 1468 BAU/ml [IQR 500–5062] in patients and 5514 BAU/ml [2528–9580] in controls (p<0.0001) and 298 BAU/ml [IQR 79–500] in patients and 715 BAU/ml [28–2870] in controls (p<0.0001), at first and second assessment respectively. Figure 1 show antibody levels at both assessments after medication group. At the second assessment, anti-RBD antibody levels decreased below 200 BAU/ml in 452 (41%) patients and in 1 (0.8%) control (p<0.0001) (Table 1). The percentage change in anti-RBD levels were -86 % in patients and -77 % in controls (p<0.0001). The majority of patients using rituximab had low antibody levels at both assessments, Figure 1. In the multivariable regression analyses, patients had a greater decline in anti-RBD levels compared to controls β -3.7 (95% CI -6.0, -1.4) (p<0.001). Use of tumor necrosis factor inhibitors in mono- or combination therapy was associated with the greatest decline compared to controls, β -6.1 (95% CI -8.1, -4.1) and β -6.4 (-8.4, -4.2) respectively (p<0.001).
Conclusion: Within four months after the second vaccine dose, anti-Spike antibody levels declined considerably in both IMID patients and controls. Patients had lower antibody levels at the first assessment and a more pronounced decline compared to controls, and were consequently more likely to have low antibody levels four months after the second vaccine dose. Our results support that IMID patients lose humoral protection and need additional vaccine doses sooner than healthy individuals.

Figure 1. Level of anti-RBD antibodies at first and second assessment after medication group



MTX mono: methotrexate monotherapy; ILi: Interleukin inhibitors including tocilizumab, ustekinumab, iksekizumab, risankizumab, secukinumab; VED: vedolizumab; JAKi: janus kinase inhibitor; TNFi mono: Tumor necrosis factor inhibitor in monotherapy; TNFi comb: Tumor necrosis factor inhibitor in combination with metabolite inhibitor(s) or vedolizumab; RTX: rituximab. All groups include patients using prednisolone in doses <10mg/day in combination with other medication.
A cut-off at 200 BAU/ml is indicated.

Background: Data on the kinetics of the immune response to SARS-CoV-2 vaccination in patients with autoimmune inflammatory rheumatic diseases (AIIRD) are limited.
Objectives: To evaluate the kinetics of the immune response induced by two and three doses of the BNT162b2 mRNA vaccine in adult patients with AIIRD and immunocompetent controls.
Methods: A prospective multicenter study investigated the antibody response to the BNT162b2 vaccine by serial measurement of serum anti-SARS-CoV-2

S1/S2 IgG titers at the following time points: 2-6 weeks (AIIRD n=720, controls n=122) and six months (AIIRD n=628, controls=116) after the second vaccine dose, and 2-6 weeks after the third vaccine dose (AIIRD n=169, controls n=45). A seropositive response was defined as a detectable anti-S1/S2 IgG titer ≥ 15 BAU/ml. T-cell immune response was evaluated in a sample of patients (n=28) and controls (n=9) by intracellular staining of S-stimulated $CD4^+$ T-cells for TNFα and IFNγ production.

Results: The two-dose vaccine regimen induced a higher humoral response in controls compared to patients, as reflected by the post-vaccination seropositivity rates of 100% vs 84.72%, p<0.0001, and 96.55% vs 74.26%, p<0.0001 at 2-to-6 weeks and at 6 months, respectively. The decline of S1/S2 IgG titers within six months was similar in controls and patients. Following the 3rd vaccine, the seropositivity rate increased to 80.47% and 100% in AIIRD and control groups, p=0.0028, with a significantly higher increase of S1/S2 IgG titers in controls compared with AIIRD patients, 284.09±76.58 vs 219.39±151.55 BAU/ml, p=0.0016. At all-time points, S1/S2 IgG titers were significantly lower in AIIRD patients compared with controls (Figure 1).

We further investigated the impact of therapies on the vaccine's immunogenicity (Figure 1). Glucocorticoids (GC) were associated with a significantly lower seropositivity rate and lower S1/S2 IgG titers compared to controls at all time points. Monotherapy with methotrexate (MTX) was associated with a comparable to controls humoral response at all time points. Anti-cytokine biologics (TNFi, IL6i, IL17i) were associated with an initial high seropositivity rate, similar to controls, followed by a steeper decline at 6 months, 79.82% vs 96.55%, p=0.0001, and restoration of seropositivity after the 3rd vaccine dose in all patients. JAKi were associated with a mildly decreased seropositivity rate after the 2nd vaccine dose and similar to controls response after the 3rd vaccine dose. Abatacept was associated with a reduced immunogenicity after the 2nd vaccine dose, but was restored to 100% seropositivity after the 3rd vaccine dose. Rituximab (RTX) significantly blunted the humoral response at all time points, with a seropositivity rate of 42% after the 2nd vaccine dose, 29% at 6 months, and with increase to 40% after the 3rd vaccine dose. A third of the RTX-treated patients who were seronegative after two vaccine doses, seroconverted after the 3rd dose. The multivariate model for predicting the seropositive response to vaccination found that higher S1/S2 IgG titers after the 2nd vaccine dose was associated with a higher seropositivity rate following the 3rd vaccine dose, OR 1.026 (1.008-1.045), p=0.0027, and that treatment with RTX was associated with a 14.3-fold risk for a negative humoral response, p≤0.0001. Cellular immune response, evaluated mainly in RTX treated patients, was preserved prior to and after the 3rd vaccine dose and was similar to controls.

Conclusion: Over a six-month period, the two dose BNTb262 vaccination was associated with a similar extent of waning of the humoral immune response in AIIRD patients and controls. The 3rd vaccine dose restored the response in all controls and in patients treated with MTX monotherapy, anti-cytokine biologics, abatacept, and JAKi. Treatment with GC and RTX was associated with an impaired humoral response at all time points.

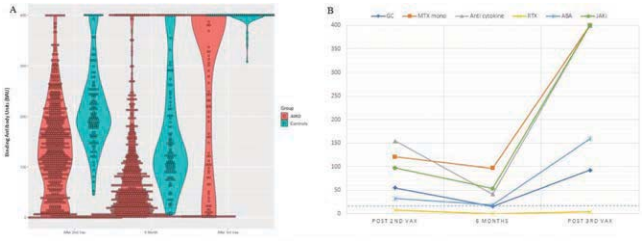

Figure. Kinetics of humoral response (S1/S2 IgG titer, BAU/mL) after two and three BNT162b2 vaccine doses. Panel A: AIIRD patients and controls. Panel B: AIIRD patients according to immunosuppressive treatment used.

BAU, binding antibody units; vax, vaccine dose; AIIRD, autoimmune inflammatory rheumatic disease; GC, glucocorticoids; MTX mono, monotherapy with methotrexate; anti cytokine includes tumor necrosis factor, interleukin 6 and interleukin 17 inhibitors, RTX, rituximab, ABA, abatacept, JAKi, janus kinase inhibitors.

Tas[5], R. van Vollenhoven[5], M. Nurmohamed[1,5], M. Boers[1,6], M. van Ham[3], T. Rispens[3], T. Kuijpers[7], F. Eftimov[4], G. J. Wolbink[1,5]on behalf of The T2B! immunity against SARS-CoV-2 study group. *[1]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology, Amsterdam, Netherlands*; *[2]Amsterdam UMC, locatie AMC, Neurology and Neurophysiology, Amsterdam, Netherlands*; *[3]Sanquin Research and Landsteiner Laboratory, Immunopathology, Amsterdam, Netherlands*; *[4]Amsterdam UMC, locatie VUmc, Neurology, Amsterdam, Netherlands*; *[5]Amsterdam Rheumatology and immunology Center, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[6]Amsterdam UMC, locatie VUmc, Epidemiology and Data Science, Amsterdam, Netherlands*; *[7]Amsterdam UMC, locatie AMC, Pediatric immunology, Amsterdam, Netherlands*

Background: Concerns have been raised regarding risks of COVID-19 breakthrough infections in vaccinated patients with immune-mediated inflammatory diseases (IMIDs) treated with immunosuppressants, but data on COVID-19 breakthrough infections in these patients are still scarce.

Objectives: The primary objective was to compare the incidence and severity of COVID-19 breakthrough infections with the SARS-CoV-2 delta variant between fully vaccinated IMID patients with immunosuppressants, and controls (IMID patients without immunosuppressants and healthy controls). The secondary objective was to explore determinants of breakthrough infections.

Methods: In this study we pooled data collected from two large ongoing prospective multi-center cohort studies (Target to-B! [T2B!] study and ARC study). Clinical data were collected between February and December 2021, using digital questionnaires, standardized electronic case record forms and medical files. Post-vaccination serum samples were analyzed for anti-RBD antibodies (T2B! study only) and anti-nucleocapsid antibodies to identify asymptomatic breakthrough infections (ARC study only). Logistic regression analyses were used to assess associations with the incidence of breakthrough infections. Multivariable models were adjusted for age, sex, cardiovascular disease, chronic pulmonary disease, obesity and vaccine type.

Results: We included 3207 IMID patients with immunosuppressants and 1810 controls (985 IMID patients without immunosuppressants and 825 healthy controls). The incidence of COVID-19 breakthrough infections was comparable between patients with immunosuppressants (5%) and controls (5%). The absence of SARS-CoV-2 IgG antibodies after COVID-19 vaccination was independently associated with an increased incidence of breakthrough infections (P 0.044). The proportion of asymptomatic COVID-19 breakthrough cases that were additionally identified serologically in the ARC cohort was comparable between IMID patients with immunosuppressants and controls; 66 (10%) of 695 patients vs. 64 (10%) of 647 controls. Hospitalization was required in 8 (5%) of 149 IMID patients with immunosuppressants and 5 (6%) of 86 controls with a COVID-19 breakthrough infection. Hospitalized cases were generally older, and had more comorbidities compared with non-hospitalized cases (Table 1). Hospitalization rates were significantly higher among IMID patients treated with anti-CD20 therapy compared to IMID patients using any other immunosuppressant (3 [23%] of 13 patients vs. 5 [4%] of 128 patients, P 0.041; Table 1).

Table 1. Determinants of the severity of COVID-19 breakthrough infections.

	Ambulatory care (n = 222)		Hospitalized (n = 13)	
Group - no. (%)				
IMID patients with immunosuppressants	141	(64)	8	(62)
IMID patients without immunosuppressants	49	(22)	3	(23)
Healthy controls	32	(14)	2	(15)
Patient characteristics				
Age, years – mean (SD)	51	(14)	60	(11)
Female sex – no. (%)	143	(64)	4	(31)
Comorbidities – no. (%)				
Cardiovascular disease	17	(8)	5	(39)
Chronic pulmonary disease	17	(8)	4	(31)
Diabetes	15	(7)	3	(23)
Obesity	34	(15)	5	(39)
Immunosuppressants– no. (%)				
Methotrexate	36	(16)	2	(15)
TNF inhibitor	48	(22)	2	(15)
Anti-CD20 therapy	13	(6)	3	(23)
Mycophenolate mofetil	3	(1)	0	(0)
S1P modulator	5	(2)	0	(0)
Other immunosuppressants	70	(32)	3	(23)

Conclusion: The incidence of COVID-19 breakthrough infections in IMID patients with immunosuppressants was comparable to controls, and infections were mostly mild. Anti-CD20 therapy might increase patients' susceptibility to severe COVID-19 breakthrough infections, but traditional risk factors also continue to have a critical contribution to the disease course of COVID-19. Therefore, we argue that most patients with IMIDs should not necessarily be seen as a risk group for severe COVID-19, and that integrating other risk factors should become standard practice when discussing treatment options, COVID-19 vaccination, and adherence to infection prevention measures with patients.

Background: SARS-CoV-2 vaccines offer the most effective way to reduce the risk of severe COVID-19. Recent data indicate sufficient immune response after vaccination in most patients with inflammatory rheumatic diseases (IRD) on immunomodulatory treatments.

Objectives: To investigate the clinical profile of SARS-CoV-2 breakthrough infections among double and triple vaccinated patients with IRD.

Methods: Data from the German COVID-19-IRD registry, collected by treating rheumatologists between February 2021 and January 2022 were analysed. Patients double or triple vaccinated against COVID-19 ≥14 days prior to proven SARS-CoV-2 infection were identified, and type of IRD, vaccine, immunomodulation, comorbidities and outcome of the infection were compared with 737 unvaccinated IRD-patients with COVID-19.

Results: In total, 271 cases of breakthrough infections were reported, 250 patients (91%) had received two doses of vaccines, 21 (9%) patients three. More than 70% of the patients received Pfizer/Biontech vaccine for the first, second and third vaccination. The median time from second/third vaccine dose to infection was 148 days (range 14-302) days. Most of the patients were diagnosed with inflammatory joint diseases (Table 1). Most of the patients were treated with methotrexate (Table 1). The use of Januskinase inhibitors(i) was more frequently reported in double vaccinated patients (10.4% vs 4.8%), whereas tumor necrosis (TNF)i were reported more often in triple vaccinated patients (33.3% vs. 22.8). Hospitalisation rate was higher in unvaccinated IRD-patients than in vaccinated ones, while fatality rate was similar in unvaccinated and double vaccinated patients. Although the rate of comorbidities and median age were higher in triple-vaccinated patients, infected patients showed a lower rate of hospitalisation, neither COVID-19 related complications, nor the need of oxygen treatment or death.

Conclusion: In this cohort of triple-vaccinated IRD patients no fatal courses and no COVID-19 related complications were reported, although median age and rate of comorbidities were higher compared to double-vaccinated and unvaccinated patients. These results support the general recommendations to reduce the risk of severe COVID-19 disease by administering three doses of vaccine, especially in patients with older age, presence of comorbidities, and on immunomodulatory treatment.

EFFECT OF AVACOPAN ON RELAPSE RATES AND RELAPSE-FREE TIME IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS, RESULTS OF THE PHASE 3 ADVOCATE STUDY

P. A. Merkel[1], H. Yue[2], E. deGoma[2], P. Bekker[2], D. Jayne[3]. [1]*University of Pennsylvania, Division of Rheumatology, Philadelphia, United States of America*; [2]*ChemoCentryx, Clinical, San Carlos, United States of America*; [3]*University of Cambridge, Department of Medicine, Cambridge, United Kingdom*

Background: For patients with ANCA-associated vasculitis, both failure to achieve remission and relapse after achieving remission are associated with worse long-term outcomes. Avacopan, an oral selective inhibitor of the C5a receptor, is approved for the treatment of ANCA-associated vasculitis. The phase 3 ADVOCATE study tested daily avacopan as a substitute for a standard oral glucocorticoid taper regimen. At week 26, the avacopan group achieved a remission rate (72.3%) comparable to the prednisone group (70.1%) and superior sustained remission at Week 52 (65.7% avacopan vs. 54.9% prednisone groups, respectively [1]). The median (mean) total glucocorticoid dose from all sources was 400 mg (1349 mg) in the avacopan group versus 2939 mg (3655 mg) in the prednisone group, representing 86% (63%) lower glucocorticoid exposure in the avacopan group. Compared with the prednisone group, the avacopan group showed a reduction in the proportion of patients who relapsed after achieving remission and, among patients who achieved remission, a longer time to relapse (1).

Objectives: To further characterize efficacy, additional post-hoc analyses compared the avacopan and prednisone groups regarding i) failure to achieve remission and ii) relapse after achieving remission.

Methods: ADVOCATE, a phase 3, randomized, double-blind, controlled trial in 330 patients, evaluated the efficacy and safety of avacopan. Patients with ANCA-associated vasculitis (new-onset or relapsing disease) were randomized to receive avacopan 30 mg twice daily, or a standard 20-week oral prednisone taper, plus matching placebos, in addition to background immunosuppressant therapy. For the purpose of these analyses, remission was defined as the first timepoint when a BVAS of 0 was achieved. Relapse was defined as worsening of disease, after having previously achieved remission, that involved one or more major or three or more minor items in the BVAS, or one or two minor items in the BVAS recorded at two consecutive study visits.

Two post-hoc sensitivity analyses of patients in the intent-to-treat population examined: i) the proportion of patients who failed to achieve remission, or achieved remission and subsequently relapsed after achieving that remission, and ii) relapse-free time. For patients who achieved remission, relapse-free time was calculated as the number of days from the initial remission achieved to relapse. For patients who failed to achieve remission, relapse-free time was imputed as one day (remission and relapse on the same day). Patients who did not relapse were censored at the time of the last BVAS assessment.

Results: Baseline characteristics and time to achieve initial remission were similar between groups, and the incidence of BVAS 0 at any point in the study occurred approximately equally in both groups (158 avacopan vs. 157 prednisone). In the first sensitivity analysis, the avacopan group showed a reduction in the proportion of patients who failed to achieve remission, or relapsed after remission, compared with the prednisone group (24 [14.5% vs 40 [24.4%], p=0.011). In the second sensitivity analysis that included all patients in the trial, the hazard ratio of relapse-free time for avacopan vs prednisone was 0.57, 95% CI (0.35, 0.96), p=0.029 (log-rank test) (Figure 1).

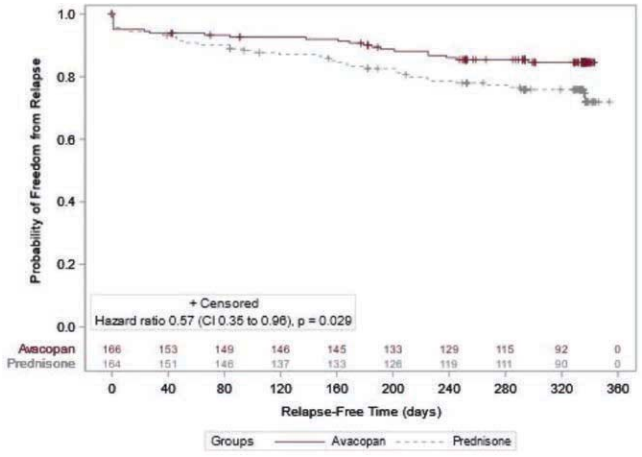

Figure 1. Relapse-free time among patients with ANCA-associated vasculitis in ADVOCATE (intention-to-treat population).

Conclusion: In the phase 3 ADVOCATE study of ANCA-associated vasculitis, more patients in the avacopan group compared to the prednisone group achieved remission, and fewer in the avacopan group relapsed after achieving remission. Patients receiving avacopan had a longer relapse-free time compared to the prednisone group. These post-hoc sensitivity analyses provide additional evidence of the efficacy of avacopan for the treatment of ANCA-associated vasculitis.

OP0181 MORTALITY IN POLYMYALGIA RHEUMATICA: A 35-YEAR PROSPECTIVE OBSERVATIONAL STUDY FROM SOUTHERN NORWAY.

S. Tengesdal[1], G. Myklebust[2]. [1]*Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway*; [2]*Hospital of Southern Norway, Research Department, Kristiansand, Norway*

Background: Polymyalgia rheumatica (PMR) is a common inflammatory rheumatic disease in the elderly characterized by proximal muscular pain and stiffness. Although PMR is associated with systemic inflammation, prolonged glucocorticoid therapy and probably cardiovascular diseases, previous studies have not shown increased mortality. However, the number of studies is limited.
Objectives: The aim of this study was to determine whether PMR is associated with increased mortality in a large PMR cohort followed prospectively for a period of 35 years.
Methods: All patients diagnosed with PMR according to the criteria of Bird between 1987 and 1997 in the county of Aust-Agder, Southern Norway, were identified. Further details about the inclusion process have been published previously [1]. Patients in the prospective part of this study were followed until death or December 31, 2021. Standard mortality ratios (SMR) were calculated using population data (age- and gender-matched) from Statistics Norway as reference. Difference in survival between men and women was estimated using the Kaplan-Meier method. The study was approved by the regional ethics committee.
Results: A total of 296 patients were included. Among these were 200 (67.6%) females, and the mean age at diagnosis was 71.9 (SD 8.4). The vast majority, 277 patients (93.6%), were deceased at the censoring date of December 31, 2021. Mean observation time for all patients was 13.8 years (95% CI 12.8-14.7). The overall SMR was 1.05 (95% CI 0.93-1.18), for females 1.14 (95% CI 0.99-1.31) and for men 0.91 (95% CI 0.73-1.11). SMRs and mean survival times are presented in Table 1. The Kaplan-Meier survival curve showed no pronounced difference in survival between men and women (Figure 1).

Table 1. Standard Mortality Ratios.

	n	Person-years	Observed	Expected	SMR	95% CI	Mean survival time	95% CI
All patients	296	4079	277	263.18	1.05	0.93-1.18	85.7	84.9-86.5
- Male	96	1326	89	98.04	0.91	0.73-1.11	85.0	83.5-86.4
- Female	200	2752	188	165.14	1.14	0.99-1.31	86.0	85.0-87.0
Age at diagnosis								
<60	31	678	21	17.16	1.24	0.78-1.84	78.6	78.0-81.3
60-69	91	1626	84	83.14	1.01	0.81-1.25	83.8	82.2-85.4
70-79	123	1394	121	118.39	1.03	0.85-1.22	86.8	85.7-87.9
≥80	51	380	51	50.64	1.00	0.76-1.31	90.7	89.5-91.8
Men								
2 years		185	9	8.29	1.09	0.53-1.99		
5 years		436	17	21.03	0.81	0.49-1.27		
10 years		788	36	43.67	0.82	0.59-1.13		
25 years		1272	83	88.57	0.94	0.75-1.16		
Women								
2 years		392	11	12.76	0.86	0.45-1.50		
5 years		934	32	35.80	0.89	0.62-1.25		
10 years		1678	68	74.03	0.92	0.72-1.16		
25 years		2687	172	156.21	1.10	0.95-1.28		

"Years": refer to calculated survival time from date of diagnosis; "Observed": number of deaths in the PMR cohort; "Expected": number of expected deaths in age-matched, sex-matched, and year-matched background Norwegian Population.

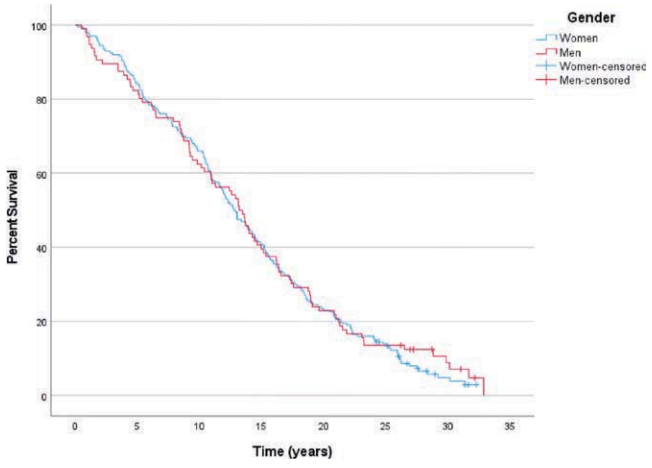

Figure 1. Kaplan-Meier survival curve.

Conclusion: To our knowledge, this is the first prospective study following a large PMR cohort from diagnosis to death. In women, overall mortality (SMR) was increased compared to the general Norwegian population. This tendency to increased mortality in women was observed during the last decades of the study period. Furthermore, increased SMR was observed in patients aged <60 at time of diagnosis and in men the first 2 years after diagnosis, although with wide confidence intervals due to the limited number of deaths in these subsets.

OP0182 SECUKINUMAB IN GIANT CELL ARTERITIS: THE RANDOMISED, PARALLEL-GROUP, DOUBLE-BLIND, PLACEBO-CONTROLLED, MULTICENTRE PHASE 2 TITAIN TRIAL

N. Venhoff[1], W. A. Schmidt[2], R. Bergner[3], J. Rech[4], L. Unger[5], H. P. Tony[6], M. Mendelson[7], C. Sieder[8], M. Maricos[8], J. Thiel[1,9]. Background: Little is known about glucocorticoid-sparing agents in giant cell arteritis (GCA) except for IL-6 inhibition. Secukinumab (SEC) has shown significant improvements in the signs and symptoms of IL-17A driven medical conditions such as plaque psoriasis, psoriatic arthritis, and axial spondyloarthritis.[1,2] It has a favourable long-term safety profile.[1,2]
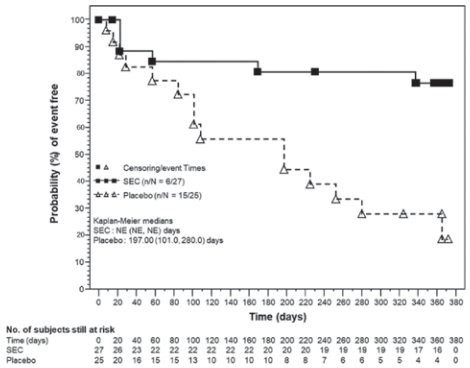
Objectives: TitAIN is the first randomised controlled trial investigating the potential efficacy, safety, and tolerability of SEC in GCA patients (pts).
Methods: This phase 2, randomised, double-blind, placebo (PBO) controlled, multicentre, proof-of-concept trial enrolled pts (aged ≥50 years) with new onset (diagnosed within 6 weeks (wks) of baseline) or relapsing (diagnosed >6 wks from baseline) GCA, naïve to biological therapy. Pts were randomised (1:1) to SEC 300 mg or PBO initially administered wkly (5 doses) and every 4 wks thereafter through Wk 48 (last dose), in combination with a 26-wk prednisolone taper regimen starting from baseline. Proportion of GCA pts in sustained remission until Wk 28 was the primary endpoint assessed by a Bayesian analysis of the posterior distribution with non-responder imputation. Other key endpoints included proportion of GCA pts in sustained remission until Wk 52 (based on study data with non-responder imputation) and time to first GCA flare after baseline.
Results: Out of 52 randomised pts (SEC, n=27; PBO, n=25), 71.2% (n=37) completed study treatment (SEC, 81.5%; PBO, 60.0%). Overall, 42 (80.8%) pts had new onset GCA and 10 (19.2%) pts had relapsing GCA at baseline. Proportion (posterior median with 95% credibility interval) of GCA pts in sustained remission until Wk 28 was higher with SEC, 70.1% (51.6%-84.9%), than with PBO, 20.3% (12.4%-30.0%); odds ratio (posterior median with 95% credibility interval), 9.31 (3.54-26.29) (Table 1). Until Wk 52, proportion (95% confidence interval) of GCA pts in sustained remission were 59.3% (38.8%-77.6%) in SEC group and 8.0% (1.0%-26.0%) in PBO group (Table 1). Median (95% confidence interval) time to first GCA flare after baseline was not reached for GCA pts treated with SEC and was 197.0 (101.0-280.0) days for PBO (Figure 1). Overall, treatment-emergent adverse events (AEs) occurred in 98.1% (SEC vs PBO, 100.0% vs 96.0%) and serious AEs in 32.7% (SEC vs PBO, 22.2% vs 44.0%) pts. Two pts in each SEC and PBO groups had AEs that led to study drug discontinuation and 1 pt in each group had AEs that led to death (not treatment-related). There were no new or unexpected safety signals identified with SEC treatment.

Table 1. Proportion of GCA patients with sustained remission (Full analysis set) until Week 28 and 52

Proportion of pts	Secukinumab (N=27)	Placebo (N=25)
Median percentage (95% credibility interval), Wk 28	70.1% (51.6%, 84.9%)	20.3% (12.4%, 30.0%)
Percentage (95% confidence interval), Wk 52	59.3% (38.8%, 77.6%)	8.0% (1.0%, 26.0%)

The full analysis set comprises all pts to whom study treatment has been assigned by randomisation and who received at least one dose of randomised study treatment (secukinumab or placebo).GCA, giant cell arteritis; N, number of pts in each treatment group in the full analysis set, pts, patients; Wk, Week



The triangles and rectangular shapes are showing the censoring/event times. The drop in the line of SEC or placebo patients is associated with an event (i.e., first post-baseline GCA flare). Patients who prematurely discontinued study treatment prior to Week 52 without having an event were censored at the time of premature discontinuation and patients who completed study treatment without having an event were censored at their last visit in the treatment phase. The full analysis set comprises all patients to whom study treatment has been assigned by randomisation and who received at least one dose of randomised study treatment (SEC or placebo). Time to first GCA flare after remission refers to time from first day of study treatment until first post-baseline GCA flare.
GCA, giant cell arteritis; n, total number of patients with a response; N, number of patients in each treatment group; NE, not evaluable; SEC, secukinumab.

Figure 1. Kaplan-Meier plot of time to first GCA flare from baseline up to Week 52 (Full analysis set)

Conclusion: SEC demonstrated a higher sustained remission rate and longer time to first GCA flare vs PBO through 52 wks in pts with GCA. This proof-of-concept phase 2 study supports further development of SEC as a potential treatment in combination with 26 wk glucocorticoid taper for pts with GCA.

OP0183 VALIDITY OF THE EULAR RECOMMENDATIONS ON THE USE OF ULTRASOUND IN THE DIAGNOSIS OF GIANT CELL ARTERITIS

E. Fernández-Fernández[1], I. Monjo[1], D. Peiteado[1], A. Balsa[1], E. de Miguel[1]. [1]*La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: The EULAR recommendations for the use of imaging in large vessel vasculitis establish that an imaging test supported by clinical pre-test probability (PTP) is sufficient for the diagnosis of giant cell arteritis (GCA)[1].

Objectives: To determine the validity of the EULAR recommendations on the use of Colour doppler ultrasound (CDUS) in GCA after calculating the PTP based on the Southend pre-test probability score (SPTPS).

Methods: We collected data of all patients referred to our fast-track clinic between 2016 and 2020. The SPTPS was calculated and classified as low (LR), intermediate (IR) and high risk (HR) according to the values obtained by its authors, <9, 9-12 and >12, respectively[2]. All patients underwent a CDUS of the temporal arteries with their common, parietal and frontal branches, and the most also axillary (86.5%), subclavian and carotid arteries. Other diagnostic tests were performed when deemed necessary by the responsible physician. TAB was performed in 34 patients (11.4%), PET-CT in 48 (16.2%) and other imaging tests such as AngioMRI or AngioCT in 8 (2.7%). The gold standard diagnosis was made according to the physician's criteria after at least nine months of follow-up.

Results: Of the 297 referred patients, 97 (32.7%) were diagnosed with GCA. The SPTPS area under the ROC curve was 0.787. The LR category included 105 patients (35.4%), of which 10 (9.5%) had GCA. The IR category included 125 patients (42.1%), 40 with GCA (32%) and 85 without (68%). The HR category included 67 patients (22.5%), 47 with GCA (70.1%). In 4 of the 97 patients with GCA, the CDUS was negative and the diagnosis was confirmed with PET-CT. On the other hand, 6 of the 200 included patients without GCA (3%) had a false positive result of CDUS.

There were 93 patients classified as LR with negative CDUS, and 1 of them has a final clinical diagnosis of GCA. Of the 46 patients classified as HR with positive CDUS, 1 was a false positive diagnosis of GCA. And, within the IR group, of the 84 patients with negative CDUS one had a final GCA diagnosis and of those with positive CDUS 2 were not GCA (Figure 1). Therefore, the combined use of SPTPS + CDUS only miscassified 5/297 cases (<2%).

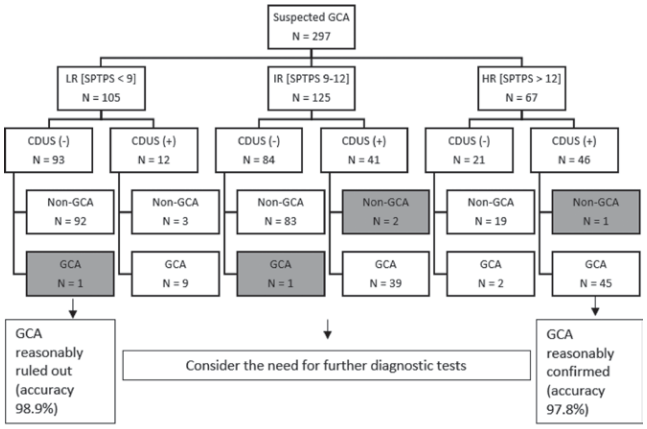

Figure 1. Flow-chart of the results of the diagnostic performance of SPTPS + CDUS.

Conclusion: Combining the results of a pre-test probability score, such as SPTPS, and the CDUS allows for an accurate diagnosis of GCA, as established by the EULAR group, with less than 2% misclassification of diagnosis. Even a negative CDUS in patients with IR shows a strong association with a negative diagnosis.

OP0184 PREVALENCE OF SUBCLINICAL GIANT CELL ARTERITIS IN PATIENTS WITH POLYMYALGIA RHEUMATICA

E. de Miguel[1], P. Macchioni[2], E. Conticini[3], C. Campochiaro[4], R. Karalilova[5], S. Monti[6], C. Ponte[7], G. Klinowski[8], I. Monjo[1], P. Falsetti[3], A. Tomelleri[4], Z. Batalov[5], A. Hocevar[8]on behalf of GCA/PMR study group. [1]*Hospital Universitario La Paz, Rheumatology, Madrid, Spain*; [2]*Department of Rheumatology, IRCCS-S.Maria Nuova, Rheumatology, Reggio Emilia, Italy*; [3]*Department of Medicine, Surgery and Neurosciences, University of Siena, Rheumatology, Siena, Italy*; [4]*Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR). San Raffaele Scientific Institute, Rheumatology, Milan, Italy*; [5]*Medical University of Plovdiv, University Hospital Kaspela, Rheumatology, Plovdiv, Bulgaria*; [6]*IRCCS Policlinico S Matteo Fondazione, University of Pavia, Rheumatology, Pavia, Italy*; [7]*Hospital de Santa Maria, Centro Hospitalar Universitario Lisboa Norte EPE, Rheumatology, Lisboa, Portugal*; [8]*Department of Rheumatology, IRCCS-S.Maria Nuova, Rheumatology, Emilia Regia, Italy*; [9]*University Medical Centre Ljubljana, Rheumatology, Ljubljana, Slovenia*

Background: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are closely related diseases. PMR occurs in approximately 50 % of patients with GCA[1]; however the prevalence of subclinical GCA in PMR has not yet been widely studied.

Objectives: The aim of our multicenter, prospective study was to determine the prevalence of subclinical GCA in newly diagnosed PMR, using vascular ultrasound (US) as a diagnostic tool.

Methods: Eight European centers participated in the study. The studied cohort represented consecutive newly diagnosed patients with PMR who fulfilled 2012 EULAR/ACR Provisional Classification Criteria for Polymyalgia Rheumatica[2] without symptoms or signs suggestive for GCA. All patients underwent ultrasound (US) of both hips and shoulders, as well as of four bilateral arterial territories (i.e. temporal, common carotid, subclavian and axillary arteries). Patients with positive halo signs were considered to have subclinical GCA [3]. An intima-media thickness ≥0.34 mm for frontal and parietal TA, 0.42mm for common TA, and ≥1 mm for common carotid, axillary and subclavian arteries for positive result. Clinical demographic and laboratory characteristics of the PMR pure group were compared with the PMR/GCA patient group.
Results: A total of 258 patients were included, 137 (53.1%) females with a mean age of 73±8.4 years. Table 1 shows the main differences in PMR patients with and without subclinical GCA. The only statistical significant difference between the two groups was the higher prevalence of morning stiffness > 40 minutes in the pure PMR group (p<0.05). A halo sign was found on at least one of the examined arteries in 56/258 patients (21.7%).
The different subtypes of vessel involvement were available in 216 cases. Data compatible with the diagnosis of GCA was found in 41 cases (19%): 10 (24.3%) had only temporal artery involvement ("cranial" GCA), 27 (65.8%) had an extra-cranial artery involvement and 4 (9.8%) a mixed form with both cranial and extra-cranial artery involvement (Figure 1).

Table 1. Clinical and demographic characteristics

	PMR study n=258	PMR without GCA n=202	PMR with GCA n=56

OP0185 TOCILIZUMAB IN COMBINATION WITH 8 WEEKS OF PREDNISONE FOR GIANT CELL ARTERITIS

S. Unizony[1], M. Matza[1], A. Jarvie[1], A. Fernandes[1], J. H. Stone[1]. [1]*Massachusetts General Hospital - Harvard Medical School,Vasculitis and Glomerulonephritis Center, Boston, United States of America*

Background: Even with the use of tocilizumab (TCZ), significant glucocorticoid exposure (usually ≥ 6 months) continues to be an important problem in giant cell arteritis (GCA).
Objectives: We aimed to evaluate the efficacy and safety of tocilizumab (TCZ) in combination with 2 months of prednisone in a group of patients with GCA.

Methods: We conducted a prospective, single arm, open-label study of TCZ in combination with 2 months of prednisone for new-onset and relapsing GCA patients with active disease (ClinicalTrials.gov Identifier NCT03726749). GCA diagnosis required confirmation by temporal artery biopsy or vascular imaging. Active disease was defined as presence of cranial or polymyalgia rheumatica symptoms necessitating treatment within 6 weeks of baseline. All patients received TCZ 162 mg subcutaneously every week for 12 months and an 8-week prednisone taper starting between 20 mg and 60 mg daily (Figure 1). The primary endpoint, sustained prednisone-free remission, was defined as absence of relapse from induction of remission up to week 52 while adhering to the prednisone taper. Relapse was defined as the recurrence of symptoms of GCA requiring treatment intensification regardless of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels. Safety was also evaluated.

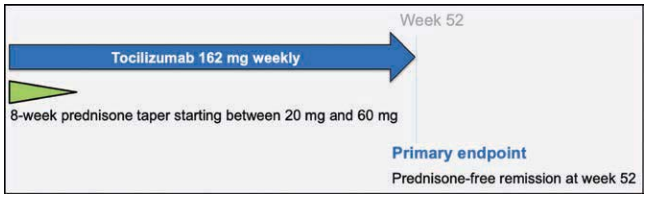

Figure 1. Clinical Trial Schema

Results: Between 11/2018 and 11/2020 we enrolled 30 patients (mean age 74 years, 60% females, 50% new-onset disease, 77% temporal artery biopsy-proven, 47% imaging-proven). The mean ESR and CRP at screening were 45 mm/hour and 48 mg/L, respectively. The initial prednisone dose was 60 mg (n = 7), 50 mg (n = 1), 40 mg (n = 7), 30 mg (n = 6) and 20 mg (n = 9). All patients entered remission within 4 weeks of baseline. The primary endpoint was achieved by 23 (77%) patients (Table 1). The mean (SD) cumulative prednisone dose in these 23 patients was 1052 (390) mg. After a mean period of 16 weeks, 7 (23%) patients relapsed (Table 1). All relapses but one occurred after the completion of the study prednisone taper. Overall, 6 of the 7 patients with relapse received a second prednisone taper over 8 weeks. Of these 6 patients, 4 achieved and maintained remission for the remainder of the trial period, and 2 withdrew from the study after having a second relapse. One patient with relapse received a second prednisone taper over 26 weeks and stayed in remission until the end of the study. The mean (SD) cumulative prednisone dose in the 7 patients with relapse was 1883 (699) mg (Table 1). Overall, 4 (13%) participants developed a serious adverse event (Table 1). No cases of ischemia-related visual symptoms including permanent vision loss occurred during the study.

Table 1. Efficacy and Safety Outcomes

	GCA patients (n = 30)
Efficacy	
Sustained, prednisone-free remission by week 52	23.0 (76.7)
Cumulative prednisone dose (mg) at week 52, mean (SD)	1051.5 (390.3)
Relapse	7.0 (23.3)
Time to relapse, weeks: mean (SD)	15.8 (14.7)
Prednisone dose (mg/day) at relapse, mean (SD)	2.1 (5.2)
Cumulative prednisone dose (mg), mean (SD)	1883.1 (699.2)
Clinical manifestations at relapse	
Cranial symptoms	4 out of 7 patients
Ischemic visual symptoms	0 out of 7 patients
PMR symptoms	4 out of 7 patients
Safety	
Serious adverse events	4.0 (13.3)
Cellulitis	1
COVID-19	1
Fragility fracture	1
Cholecystitis	1

Values represent number and (%) unless otherwise specified. SD, standard deviation; PMR, polymyalgia rheumatica

Conclusion: These results suggest that 12 months of TCZ in combination with 8 weeks of prednisone could be efficacious for inducing and maintaining disease remission in patients with GCA. Confirmation of these findings in a randomized controlled trial is required.

OP0186

SENSITIVITY TO CHANGE OF DIFFERENT ULTRASOUND SCORES IN A PROSPECTIVE FOLLOW-UP OF NEW-ONSET TREATMENT-NAÏVE GCA PATIENTS.

B. D. Nielsen[1,2,3], P. Therkildsen[2,3], K. Keller[2,3], L. C. Gormsen[3,4], I. Hansen[2,3], E. M. Hauge[2,3]. *[1]The Regional Hospital Horsens, Department of Medicine, Horsens, Denmark*; *[2]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; *[3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*; *[4]Aarhus University Hospital, Department of Nuclear Medicine and PET Centre, Aarhus, Denmark*

Background: The role of ultrasound (US) for monitoring giant cell arteritis (GCA) is not clarified. Follow-up assessment of number of halos (halo count) and different quantitative scores based on intima media complex (IMC) measurement of halos, have demonstrated potential to show sensitivity to change (STC)[12]. Including IMC of normalized arteries in such scores may reduce the risk of missing new arteritic lesions and assessment bias towards a response. We aimed to evaluate US scores based on halo features and scores based on IMT measurements of all assessed arteries.

Objectives: To compare different US score's 1) STC after institution of treatment and 2) correlation with disease activity.

Methods: In a prospective cohort of new-onset GCA patient, pre-treatment diagnostic evaluation including US and PET/CT and subsequently temporal artery biopsy (TAB) was performed per protocol. All patients were started on 60 mg of prednisolone and followed a routine tapering. Follow-up visits including clinical evaluation, blood tests, US, the physician's and patient's global NRS (0-10) were performed after 8 weeks, 24 weeks and in a subgroup (n=24) at 15 months. US of temporal, carotid and axillary arteries included assessment of halo and IMC measurement in all arteries.

For each visit, max IMC, max halo IMC, sum IMC, sum halo IMC, mean IMC and halo count were calculated for all and for temporal (TA) and large vessels (LV) separately. Accordingly, halo IMC scores only included positive arteries whereas other IMC scores included all arteries assessed.

The change from baseline was assessed by Student's *t*-test. Standard response means (SRM=meanΔ(visit-baseline)/SE_{Δ}) were computed for each timepoint as STC estimates. Correlation with disease activity markers was assessed by Spearman's correlation. A $p<0.05$ was considered statistically significant.

Results: In total 47 patients were included (60% women, mean (CI) age 67 (62-69) years, mean (CI) CRP 75 (63-89)). Baseline US was positive(+) in 94% (72% TA+, 72% LV+), PET/CT+ in 96% (77% cranial arteries, 85% large vessel vasculitis) and TAB+ in 72% of patients. All patients completed the per protocol planned follow-up visits. Two patients experienced a relapse at week 8 and 10 patients at week 24.

All US outcomes improved during follow-up and was apparent by week 8 (Table 1) and forward. However, only scores including TA consistently showed statistically significant change from baseline to follow-up. In accordance the magnitude of change as expressed by SRM was large in TA, whereas SRM in LV was small (Figure 1).

All TA based US scores showed significant moderate-strong correlation with disease activity markers (CRP, patient and physician global NRS). Some LV based US scored showed weak correlation with CRP but otherwise did not correlate with clinical disease activity.

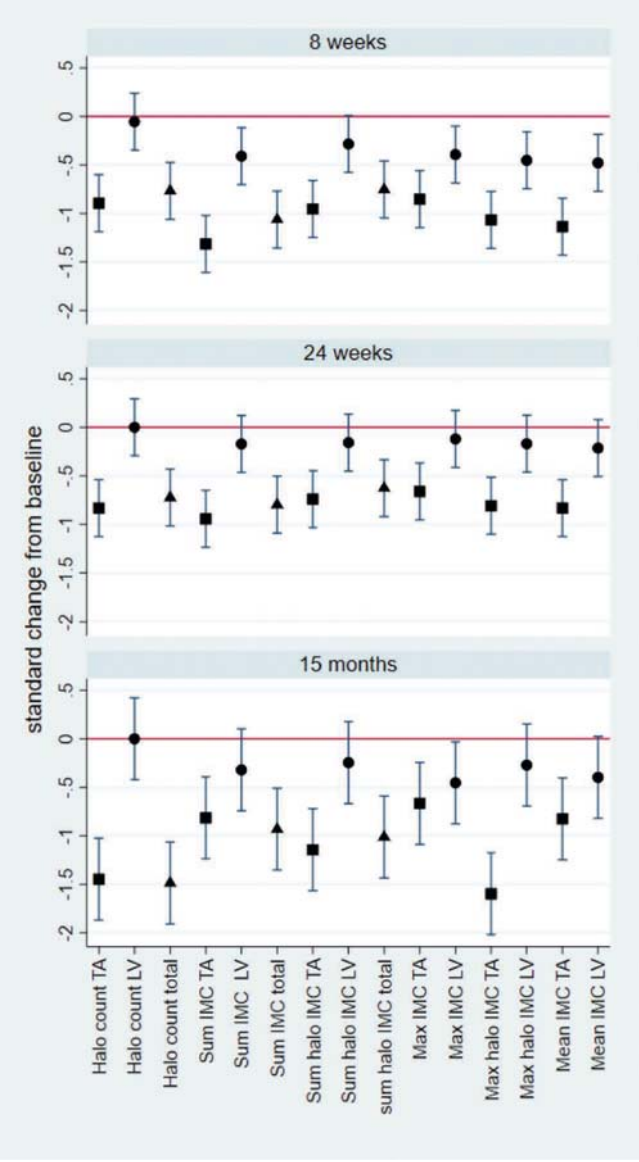

Figure 1.

Table 1.

US score changes during follow-up

		Baseline (IQR)	Δw8 (SE)	Δw24 (SE)	Δm15 (SE)
Halo count	**TA**	2 (0-4)	**-1.68 (.28)**	**-1.70 (.30)**	**-2.63 (.37)**
	LV	1 (0-2)	**-0.04 (.11)**	**0.00 (.11)**	**0.00 (.31)**
	Total	4 (2-6)	-1.72 (.33)	-1.70 (.34)	-2.63 (.36)
Sum IMC	**TA**	0.8 (0-1.8)	**-0.72 (.08)**	**-0.69 (.11)**	**-0.76 (.19)**
	LV	1.5 (0-2.8)	**-0.33 (.12)**	-0.13 (.11)	-0.33 (.21)
	Total	2.6 (1.6-4.4)	**-1.05 (.14)**	**-0.81 (.15)**	**-1.09 (.29)**
Sum halo IMC	**TA**	1.9 (1.6-2.5)	**-0.90 (.14)**	**-0.90 (.17)**	**-1.29 (.23)**
	LV	3.5 (2.8-4.0)	-0.33 (.17)	-0.15 (.14)	-0.47 (.39)
	Total	5.5 (4.6-6.3)	**-1.23 (.24)**	**-1.04 (.24)**	**-1.76 (.35)**
Max IMC	**TA**	0.5 (0.4-0.6)	**-0.17 (.03)**	**-0.14 (.03)**	**-0.17 (.05)**
	LV	1.2 (0.9-1.6)	**-0.16 (.06)**	-0.04 (.05)	**-0.20 (.09)**
Max halo IMC	**TA**	0.5 (0-0,6)	**-0.29 (.04)**	**-0.26 (.05)**	**-0.40 (.05)**
	LV	1.2 (0-1.6)	**-0.27 (.09)**	-0.09 (.08)	-0.23 (.17)
Mean IMC	**TA**	0.32 (0.27-0.43)	**-0.11 (.01)**	**-0.10 (.02)**	**-0.13 (.03)**
	LV	0.88 (0.7-1.03)	**-0.9 (0.3)**	-0.04 (.03)	**-0.10 (.05)**

Baseline medians, Δ mean difference from baseline. Bold indicates $p<0.05$.

Conclusion: STC was maintained in US scores that included all assessed arteries hereby reducing potential assessment bias. These findings confirm US as a potential tool for monitoring treatment response.

OP0187

COMPARATIVE EFFICACY OF NON-BIOLOGIC IMMUNOSUPPRESSANTS IN TAKAYASU ARTERITIS

R. Goel[1], M. Babu[2], S. Padiyar[1], G. Joseph[3], D. Danda[4]. *[1]Vellore, Clinical Immunology and Rheumatology, Christian Medical College, Vellore, India*; *[2]Christian Medical College, Biostatistics, Vellore, India*; *[3]Christian Medical College, Cardiology, Vellore, India*; *[4]Christian Medical College, Clinical Immunology and Rheumatology, Christian Medical College, Vellore, India*

Background: The choice of immunosuppressant (IS) in patients with Takayasu arteritis (TAK) is often arbitrary due to lack of comparison studies.

Objectives: In this retrospective, we aimed to compare the efficacy of 3 non biologic IS including azathioprine (AZA), mycophenolate mofetil (MMF) and methotrexate (MTX) in inducing and maintaining sustained remission in patients with TAK.

Methods: Patients with a diagnosis of TAK, attending our clinics between Jan 2000 and May 2019 were identified. Those who satisfied either ACR or Sharma's classification or EULAR PRINTO PRES criteria and/or had angiographic evidence of Takayasu arteritis with a minimum 2 follow up visits were included. Patients who received upfront biologics were excluded. The patients were matched for parameters statistically different among three groups using propensity score analysis. Clinical details at the index visit defined as the time of initiation of first IS and follow up visits were prospectively recorded and retrospectively noted from electronic medical records. The primary outcomes were attainment of complete remission and relapses. Disease activity was assessed by Indian Takayasu arteritis score (ITAS), C-reactive protein and angiograms. Relapse was defined as ITAS-A(CRP) >=2 and/or progression in angiograms and/or escalation of steroid dose and/or switching of IS due to active disease. The baseline variables of patients receiving AZA, MMF and MTX were compared using chi square test or Mann Whitney U test. The comparative efficacy of IS to induce complete remission was calculated using logistic regression and presented as odds ratio (95% CI). The cumulative risk of relapse was calculated using Cox-proportional hazards model with hazards ratio and 95% confidence interval (CI) after adjusting for duration of symptoms and juvenile onset disease. The patients were censored at the time of relapse or time of switching to another IS or last follow up whichever was the earliest. AZA was arbitrary chosen as the reference drug for all the analysis. The missing values (visits) were not included in analysis and the last observation was carried forwards. Data after switching of immunosuppressant of interest till the last follow up visit was analysed descriptively. All analysis were done for matched and unmatched patient groups. The results of matched and unmatched cohort were similar, hence the results of unmatched groups are presented here.

Results: Overall, 234 patients satisfying inclusion criteria including 53 (22.6%), 156 (66.7%) and 25 (10.7%) patients receiving AZA, MMF, Mtx respectively were studied. Complete remission (CR) was attained in 183 (78.2%) patients after initiating steroids and IS. 79.2%, 77.6% and 80% of patients receiving AZA, MMF or MTX respectively achieved CR yielding an odds ratio of 1.10 (0.52-2.37), p= 0.80 and 0.96 (0.29-3.12), p= 0.94 for MMF and MTX as compared with AZA. CR was sustained in 22 (52.4%), 80 (66.1%) and 11 (55%) of patients on AZA, MMF and MTX respectively. When compared with AZA, adjusted hazards ratio (AHR) of relapse was 1.51 (0.79-2.89), p=0.21 and 2.45 (1.00-5.99), p= 0.05 with MMF and MTX after adjusting for juvenile onset disease, type 1 and type 4 disease by angiography. The frequency of remission in patients who received MMF was significantly higher in patients who presented with type 4 disease (96%) as compared with the patients who had other types on angiography (74%), p= 0.017. Conversely, 63.6% of patients with type 1 disease responded to MMF which was significantly lower than 81.3% of patients with other angiographic types (p=0.037) while no such differential response was observed for AZA or MTX. Retrospective design and small number of patients in AZA and Mtx group were the major limitations of the study.

Conclusion: In our patients with TAK, all the three IS were comparable in inducing remission. Azathioprine was equal to MMF but superior to MTX in maintaining relapse free sustained response. The efficacy of MMF differed across various angiographic types of disease.

Active Ageing: new perspectives for RMD patients

OP0188 **CLINICAL EFFECTIVENESS OF STRATIFIED EXERCISE THERAPY COMPARED TO USUAL EXERCISE THERAPY IN PATIENTS WITH KNEE OSTEOARTHRITIS: A CLUSTER RANDOMIZED CONTROLLED TRIAL (OCTOPUS-STUDY)**

J. Knoop[1], J. Dekker[2], H. van Dongen[1], M. van der Leeden[2,3], M. de Rooij[3], W. F. Peter[3,4], W. van Berkel-de Joode[1], L. van Bodegom-Vos[5], N. Lopuhaä[6], K. Bennell[7], W. Lems[3,8], M. van der Esch[3,9], T. P. M. Vliet Vlieland[4], R. Ostelo[1,10,11]. [1]*Vrije Universiteit Amsterdam, Department of Health Sciences, Amsterdam, Netherlands*; [2]*Amsterdam UMC (VUmc), Department of Rehabilitation Medicine, Amsterdam, Netherlands*; [3]*Reade, Amsterdam Rehabilitation Research Centre, Amsterdam, Netherlands*; [4]*Leiden University Medical Center, Department of Orthopaedics, Leiden, Netherlands*; [5]*Leiden University Medical Center, Department of Biomedical Data Sciences, Leiden, Netherlands*; [6]*ReumaNederland, -, Amsterdam, Netherlands*; [7]*University of Melbourne, School of Health Sciences, Department of Physiotherapy, Melbourne, Australia*; [8]*Amsterdam UMC (VUmc), Department of Rheumatology, Amsterdam, Netherlands*; [9]*Amsterdam University of Applied Sciences, Center of Expertise Urban Vitality, Health Faculty, Amsterdam, Netherlands*; [10]*Amsterdam UMC (VUmc), Department of Epidemiology and Data Science, Amsterdam, Netherlands*; [11]*Vrije Universiteit Amsterdam, Amsterdam Movement Sciences, Amsterdam, Netherlands*

Background: There is strong, high-quality evidence for the effectiveness of exercise therapy in people with knee osteoarthritis (OA).[1] However, although effective, the average effect size is only moderate (approximately 0.5).[1] This may be attributed to the current 'one-size-fits-all' exercise approach, while a stratified approach may yield superior clinical and economic outcomes. We are the first to test a model of stratified exercise therapy in patients in knee OA. This model was based on 3 previously identified subgroups[2] that are aligned with well-accepted OA phenotypes[3], namely a 'low muscle strength subgroup' ('age-induced phenotype'), 'high muscle strength subgroup' ('post-traumatic phenotype') and 'obesity subgroup' ('metabolic phenotype'). For each subgroup, a subgroup-specific exercise therapy intervention was developed and pilot-tested[4], which was supplemented by a dietary intervention for the 'obesity subgroup'.

Objectives: The OCTOPuS-trial aimed to determine the effectiveness of stratified exercise therapy in reducing knee pain and improving physical function, compared to usual, 'non-stratified' exercise therapy, in patients with knee OA.

Methods: We conducted a pragmatic cluster randomized controlled trial in a primary care setting in 335 people with knee osteoarthritis: 153 in the experimental arm and 182 in the control arm. Physiotherapy practices were randomized into the experimental arm providing the model of stratified exercise therapy supplemented by a dietary intervention from a dietician for the 'obesity subgroup' or the control arm proving usual, 'non-stratified' exercise therapy. Primary outcomes were knee pain severity (NRS pain, 0-10) and physical function (KOOS subscale daily living, 0-100). Measurements were performed at baseline, and 3- (primary endpoint), 6-, and 12-months follow-up. Intention-to-treat, multilevel, regression analysis was performed.

Results: We found statistically non-significant differences in knee pain (mean difference (95% confidence interval): 0.19 (-0.31, 0.69)) and physical function (-0.40 (-3.91, 3.12)) at 3-months follow-up, with within-group effect sizes ranging between 0.5 and 0.7. Non-significant differences were also found for all other time points and for nearly all secondary outcome measures. Moreover, effects of experimental and control intervention were similar in each of the 3 subgroup separately.

Conclusion: This trial demonstrated no added value with respect to clinical outcomes of our model of stratified exercise therapy compared to usual exercise therapy. This could be attributed to the experimental arm therapists facing difficulty in effectively applying the model (especially in the 'obesity subgroup') and to elements of the model possibly being applied in the control arm.

From childhood to adulthood - growing up with an RMD

OP0189-PARE **NEW JIA-AT-NRAS RESOURCE MEDICINES IN JUVENILE IDIOPATHIC ARTHRITIS**

D. Wilson[1]. [1]*National Rheumatoid Arthritis Society, JIA, Maidenhead, United Kingdom*

Background: Biologics have been commissioned by the NHS for use to treat JIA since 2014. Many of the original biologics that were first developed have since lost exclusivity, allowing other manufacturers to produce highly similar versions (biosimilars). This difference between the originator and the biosimilar has caused confusion within the patient community, especially in how it has been communicated to them. Parents found the concept of biosimilars confusing and wanted more information about this, recommending that written material be provided. Previous conversations with healthcare professionals, parents and young people living with JIA had also found there was a lack of written information on all JIA medications so we looked into how this gap could be filled.

Objectives: Produce a new resource to clarify the confusion about the biosimilars and originators for the JIA patient community. Explain the different medications to treat JIA in a patient/parent friendly format so it can be easily referred

to. Easy to see the different categorisation of the medications e.g. pain management, DMARDS, biologics and targeting synthetic DMARDS and include information regarding how they are taken, how often and usage.

Methods: Knowing there was a need for this information, a focus group was convened with young people with JIA, parents of children with JIA and healthcare professionals. From this focus group and separate conversations with healthcare professionals it very quickly became apparent a resource not only covering medications for JIA but detailing the wider JIA journey was needed. This resource would need to cover each step from diagnosis to a young person taking control of their disease management. It would also cover how the complexity of the immune system means that some children/young people respond differently to medication; help them to learn about the unpredictability of the disease and to take control of managing their disease, particularly as they move onto adult rheumatology services.

NRAS worked collaboratively with health writer and healthcare professionals to make sure this new resource covered all the topics that were discussed at the focus group and detailed all the medications used to treat JIA, including information on the issue of differentiating between biologics and biosimilars.

Results: The Medicines in JIA booklet is now freely available to all parents, young people and healthcare professionals from the jia.org.uk website. The addition of visuals makes the information easier to navigate, clearer to understand and helps to illustrate the JIA journey. Along with the medicine directory which details all the medications to treat JIA.

Conclusion: The feedback NRAS has received from both healthcare professionals and parents has been very positive:

"We think that they're absolutely fantastic, they cover everything, and I'm so pleased I've got these to give to parents and children." **Paediatric Rheumatology Nurse Haywood Hospital**

"This is brilliant and much needed. Great piece of work much appreciated by all of us". **Lead Nurse Nottingham Children and Young People's Rheumatology Service**

"This has been my absolute saviour! It gives you support on administering the medicines and made me feel right at ease after reading it". **Parent of child with JIA**

Background: Rituximab is widely used to treat rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) but clinical response varies. Efficacy is determined by the efficiency of depletion, which may depend on a variety of Fc gamma receptor (FcγR)-dependent mechanisms. Previous research was limited by complexity of the *FCGR* locus, not integrating copy number variation with functional SNP, and small sample size.

Objectives: The study objectives were to assess the effect of the full range of FcγRs variants on depletion, clinical response and functional effect on NK-cell-mediated killing in two rheumatic diseases with a view to personalised B-cell depleting therapies.

Methods: A prospective longitudinal cohort study was conducted in 873 patients [RA=611; SLE=262] from four cohorts (BSRBR-RA and BILAG-BR registries, Leeds RA and Leeds SLE Biologics). For RA, the outcome measures were 3C-DAS28CRP and 2C-DAS28CRP at 6 (+/-3) months post-rituximab (adjusted for baseline DAS28). For SLE, major clinical response (MCR) was defined as improvement of active BILAG-2004 domains to grade C/better at 6 months. B-cell depletion was evaluated by highly-sensitive flow cytometry. Qualitative and quantitative polymorphisms for five major FcγRs were measured using a commercial multiplex ligation-dependent probe amplification. Median NK cell FcγRIIIa expression (CD3-CD56+CD16+) and NK-cell degranulation (CD107a) in the presence of rituximab-coated Daudi/Raji B-cell lines were assessed using flow cytometry.

Results: In RA, for *FCGR3A*, carriage of V allele (coefficient -0.25 (SE 0.11); p=0.02) and increased copies of V allele (-0.20 (0.09); p=0.02) were associated with greater 2C-DAS28 response. Irrespective of *FCGR3A* genotype, increased gene copies were associated with a better response. In SLE, 177/262 (67.6%) achieved BILAG response [MCR=34.4%; Partial=33.2%]. MCR was associated with increased copies of *FCGR3A*-158V allele, OR 1.64 (95% CI 1.12-2.41) and *FCGR2C*-ORF allele 1.93 (1.09-3.40). Of patients with B-cells data in the combined cohort, 236/413 (57%) achieved complete depletion post-rituximab. Only homozygosity for *FCGR3A*-158V and increased *FCGR3A*-158V copy number were associated with increased odds of complete depletion. Patients with complete depletion had higher NK cell FcγRIIIa expression at rituximab initiation than those with incomplete depletion (p=0.04) and this higher expression was associated with improved EULAR response in RA. Moreover, for *FCGR3A*, degranulation activity was increased in V allele carriers vs FF genotype in the combined cohort; p=0.02.

Conclusion: FcγRIIIa is the major low affinity FcγR and increased copies of the *FCGR3A*-158V allele, encoding the allotype with a higher affinity for IgG1, was associated with clinical and biological responses to rituximab in two autoimmune diseases. This was supported by functional data on NK cell-mediated cytotoxicity. In SLE, increased copies of the *FCGR2C*-ORF allele was also associated with improved response. Our findings indicate that enhancing FcγR-effector functions could improve the next generation of CD20-depleting therapies and genotyping could stratify patients for optimal treatment protocols.

Rheumatology in Europe

OP0191 **CONCEPTUALISING PATIENT AND PUBLIC INVOLVEMENT IN MUSCULOSKELETAL GUIDELINES IMPLEMENTATION: THE ALLIANCE FRAMEWORK**

O. Babatunde[1], S. Dawson[2], A. Adebajo[3], K. Dziedzic[1]. *[1]Keele University, Arthritis Research UK Primary Care Centre, Newcastle, United Kingdom*; *[2]Bristol University, Bristol Medical School, Bristol, United Kingdom*; *[3]Sheffield University, School of Health and Related Research, Sheffield, United Kingdom*

Background: Patient and Public Involvement (PPI), have supported high quality Rheumatology research which have now been successfully curated into widely endorsed evidence-based recommendations and guidelines. However, uptake and applicability of guidelines is less than optimal, significant variation exist in care, and health and socio-economic burdens attributed to rheumatic conditions continues to rise, suggesting an implementation challenge.
Objectives: We conducted a rapid review to investigate the role of PPI in guideline implementation.
Methods: A comprehensive search for relevant literature was undertaken (three databases - Medline, Embase, Cinahl, and two large repositories -WHO, G-IN). A priori eligibility criteria and systematic review-based methods were used to identify primary studies with explicit reference to PPI involvement in a rheumatic/musculoskeletal - MSK guideline implementation activity. Extracted data from included studies was interrogated for details regarding activities, contexts, outcomes, and impact of PPI in guidelines implementation and further discussed in review project meetings. Findings were brought together in a narrative synthesis. Recommendations for future research and practice, and a conceptual framework for PPI in Rheumatic and MSK guidelines implementation were co-developed with a public contributor.
Results: Ten papers were included, only 1 from the global south. A prevalence of consultative PPI activities in guidelines dissemination (e.g., language translations, patient versions) was found. Few studies explicitly report high-level PPI engagement in relation to care pathway adjustments, care commissioning, institutional operations and policy with a view to MSK guideline implementation. Training, development, and practice of PPI in MSK guideline implementations were not evidenced to have spread much beyond Europe and are also not well reported in literature nor rightly accrued as PPI activities in guideline implementation. The alliance framework (Figure 1) highlighting an iterative process of "creative thinking/co-production" and "strategic doing" helps to conceptualise PPI in MSK guideline implementation. The framework guides knowledge translation from guidelines to real world practice and aims to drive quality improvement for MSK care with patients, for patients, across and within care settings globally.

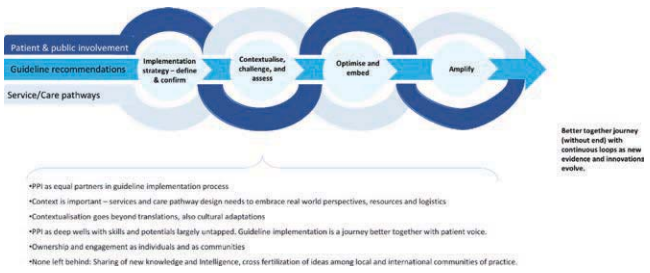

Figure 1. The Alliance framework for conceptualising Patient and Public Involvement in Rheumatic and Musculoskeletal guidelines implementation.

Conclusion: Despite success of PPI in rheumatology/MSK research, oversight or ineffective PPI in guideline implementation may hamper translation of novel advances in MSK care into real world practice and patient benefit. The Alliance framework prioritises effective PPI in MSK guideline implementation design, delivery, and evaluation, ideally applied in parallel with the development of evidence-based guidance recommendations. It highlights continuous application of innovative thinking, dynamic, and impactful collaborations for bridging the evidence-practice gap and improving quality of care for MSK patients globally through novel partnerships.

Vaccination in rheumatic diseases with lessons from COVID

OP0192 **SEROLOGICAL RESPONSE AND SAFETY OF A THREE-DOSE SARS-COV-2 VACCINATION STRATEGY IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES ON IMMUNOSUPPRESSIVE THERAPY**

I. Jyssum[1], A. T. Tveter[1], J. Sexton[1], I. E. Christensen[1], T. T. Tran[2], S. Mjaaland[3], D. J. Warren[4], T. K. Kvien[1], K. H. Bjørlykke[5], G. B. Kro[6], J. Jahnsen[5], L. A. Munthe[2], E. A. Haavardsholm[1], J. T. Vaage[2], G. Grodeland[2], F. Lund-Johansen[2], S. Aarrestad Provan[1], K. K. Jørgensen[5], G. L. Goll[1], S. W. Syversen[1]. *[1]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; *[2]Oslo University Hospital, Immunology, Oslo, Norway*; *[3]Norwegian Institute of Public Health, Infectious Diseases and Immunology, Oslo, Norway*; *[4]Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway*; *[5]Akershus University Hospital, Gastroenterology, Lørenskog, Norway*; *[6]Oslo University Hospital, Microbiology, Oslo, Norway*

Background: Patients with immune-mediated inflammatory diseases (IMIDs) on immunosuppressive therapy have an inadequate serologic response following two-dose SARS-CoV-2 vaccination, and a standard vaccination strategy of three doses for this patient group is currently under implementation in several countries. However, the serological response and safety of this strategy has not been evaluated.
Objectives: To assess serological response and safety of a three-dose vaccination strategy in IMID patients on immunosuppressive therapy as compared to standard two-dose vaccination of healthy controls.
Methods: The prospective observational Nor-vaC study (NCT04798625) enrolled adult patients on immunosuppressive therapy for inflammatory joint- and bowel diseases. Healthy controls were health care workers from participating hospitals. All participants received standard vaccines according to the national vaccination program with three doses in patients and two doses in controls. The third dose was offered to IMID patients >4 weeks after the second dose. Analyses of antibodies binding the receptor-binding domain of the SARS-CoV-2 Spike protein were performed prior to, and 2-4 weeks after the second and third vaccine doses. Levels were compared across groups by Mann-Whitney U tests and multivariate linear regression was used to identify predictors of response.
Results: Overall, 961 patients (315 rheumatoid arthritis, 156 spondyloarthritis, 171 psoriatic arthritis, 132 ulcerative colitis and182 Crohn's disease) (median age 54 years [IQR 43-64]; 56 % women) and 227 controls (median age 44 years [IQR 32-55]; 83 % women) were included in the present analyses. TNFi monotherapy was used by 399 patients, 229 used TNFi in combination with other immunomodulators, 189 methotrexate monotherapy, 39 vedolizumab, 32 JAKi and 73 patients used other drugs. Patients on rituximab were not included. Patients were vaccinated with Pfizer BNT162b2 (54% patients, 14% controls), Moderna mRNA-1273 (16% patients, 40% controls) or a combination of vaccines (30% patients, 46% controls). Patients received the third vaccine dose a median of 120 (IQR 102-143) days after the second dose. After two doses, median anti-Spike antibody levels were significantly lower in patients (861 BAU/ml (IQR 418-4275) than controls (6318 BAU/ml (IQR 2468-9857)), p<0.001 (Figure 1). Following the third dose, patients achieved antibody levels comparable to the two-dose vaccinated controls (median 5480 BAU/ml (IQR 1081-12069), p=0.28) (Figure 1). In the patients anti-Spike antibody levels increased by a median of 2685 BAU/ml (IQR 265-9129) from the second to the third dose. Main factors associated with increased antibody level after the third dose were younger age (β -87.7 (p=0.002)), and vaccine status (mRNA-1273 vaccine (β 5549 (p<0.001)) or a combination of vaccines (β 4367.3 (p<0.001)).
Adverse events were reported by 438 (48%) of patients after the third dose as compared to 471 (54%) after the second dose and 193 (78 %) of controls. Disease flares were reported by 42 (5%) and 69 (8%) patients after the second and third dose, respectively.
Conclusion: This study suggests that a third vaccine dose for immunosuppressed patients closes the gap in serological response between patients and

the healthy population. Antibody levels following the three-dose regimen in IMID patients were comparable to healthy controls vaccinated twice, and no new safety issues emerged. This finding was consistent across all diagnoses and treatment groups, supporting the implementation of a three-dose vaccine regimen as standard in the IMID population.

sJIA vs AOSD: Two names one disease? What have we learnt so far

OP0193

EFFICACY AND SAFETY OF EMAPALUMAB, AN ANTI-INTERFERON GAMMA MONOCLONAL ANTIBODY, IN PATIENTS WITH MACROPHAGE ACTIVATION SYNDROME (MAS) IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS (SJIA) WHO HAD FAILED HIGH-DOSE GLUCOCORTICOIDS

F. De Benedetti[1], A. Grom[2], P. Brogan[3], C. Bracaglia[1], M. Pardeo[1], G. Marucci[1], D. Eleftheriou[3], C. Papadopoulou[3], P. Quartier[4], J. Anton[5], R. Frederiksen[6], V. Asnaghi[6], C. de Min[6]. [1]*Ospedale Pediatrico Bambino Gesù, IRCCS, Division of Rheumatology, Rome, Italy*; [2]*Cincinnati Children's Hospital, Division of Rheumatology, Cincinnati, United States of America*; [3]*Great Ormond Street Hospital NHS Foundation Trust, UCL Institute of Child Health, London, United Kingdom*; [4]*Necker Hospital, Assistance Publique-Hôpitaux de Paris, Université de Paris, IMAGINE Institute, RAISE Reference Center, Pediatric Immuno-Hematology and Rheumatology Unit, Paris, France*; [5]*University of Barcelona, Hospital Sant Joan de Déu, Division of Pediatric Rheumatology, Barcelona, Spain*; [6]*Swedish Orphan Biovitrum AG (Sobi), Clinical Science, Basel, Switzerland*

Background: MAS is a severe, life-threatening complication of rheumatic diseases that occurs most frequently in patients with sJIA. The mainstay of treatment for MAS is high dose glucocorticoids (GCs); however, GCs do not provide adequate control in all patients. Additional treatments are used without a standardized approach; however, morbidity and mortality remain high. Data from animal models of MAS and from observational studies in patients suggest that overproduction of IFNγ is a driver of the hyperinflammation observed in MAS; neutralization of IFNγ has been shown to revert the signs and symptoms of MAS in murine models, and high IFNγ levels are strongly correlated with laboratory parameters of disease severity in patients.
Objectives: To assess the efficacy and safety of intravenous (IV) infusions of emapalumab, a fully human, anti-IFNγ monoclonal antibody, in patients with MAS in sJIA.
Methods: Open-label, single-arm, phase 2 study (NCT03311854) that included patients with MAS (2016 ACR/EULAR criteria) in sJIA who had failed high-dose IV GCs and other treatments. Emapalumab was initiated at a dose of 6 mg/kg on Day 0 and continued at 3 mg/kg every 3 days until Day 15, and then twice weekly until Day 28 to ensure rapid and complete IFNγ neutralization after initiating treatment. As per protocol, 10 infusions were planned over the 4 weeks; however, treatment could be shortened if MAS remission was achieved earlier, or extended if required to achieve remission. Complete response (CR) was defined as resolution of clinical signs and symptoms of MAS according to the investigator, and normalization of laboratory parameters relevant to MAS. All patients were followed up for 4 weeks after the last infusion of emapalumab and offered to enter a 1-year, follow-up study (NCT02069899).
Results: Fourteen patients (10 females) were enrolled (11 in Europe, 3 in the USA). Several patients had previously received cyclosporine A and/or anakinra, in addition to high-dose GCs. Six patients received emapalumab until Day 28. Seven patients discontinued emapalumab early due to MAS remission (as per investigator's assessment); one patient received treatment up to Day 38. Emapalumab treatment rapidly neutralized IFNγ, as documented by CXCL9 levels. A CR was achieved by 13/14 patients during the study. One patient stopped emapalumab after 3 doses because of achievement of MAS remission as per investigator's assessment, but lactate dehydrogenase levels remained >1.5× upper limit of normal. At Week 8, 11/14 patients had a CR; 2 achieved a CR during the study, but not at Week 8, because of a single laboratory parameter abnormality in each patient. Overall, all measured laboratory parameters related to MAS activity rapidly improved with emapalumab treatment. GCs were tapered in all patients by Week 8 (≥50% reduction, n=12; GC dose ≤1 mg/kg/day, n=8). Administration of anakinra for the treatment of underlying sJIA was maintained/introduced during the study, as required. No patients discontinued treatment for safety reasons. One treatment-related serious adverse event was reported (cytomegalovirus reactivation that resolved with antiviral treatment). All patients entered the long-term, follow-up study and were alive at last visit.
Conclusion: Emapalumab administration led to rapid IFNγ neutralization, was efficacious in controlling MAS in all patients, and was well tolerated with a favorable safety profile. These results support the pathogenic role of IFNγ in MAS in sJIA and the therapeutic value of IFNγ neutralization in MAS patients who have failed high-dose GCs.

Autoinflammation over the course of a lifetime

OP0194

COMBINATION ANAKINRA AND TOCILIZUMAB TO TREAT REFRACTORY MACROPHAGE ACTIVATION SYNDROME TRIGGERED BY ADULT-ONSET STILL'S DISEASE.

E. Alveyn[1], A. Rutherford[1]. [1]*King's College London, Centre for Rheumatic Disease, Department of Inflammation Biology, London, United Kingdom*

Background: Adult-onset Still's disease (AOSD) is associated with the development of macrophage activation syndrome (MAS) [1], sometimes termed secondary haemophagocytic lymphohistiocytosis (sHLH), a severe hyperinflammatory state with high mortality. Successful management of AOSD and MAS is contingent on early identification and treatment of the syndromes and any triggers, with aggressive immunosuppression in acutely unwell patients [2].
Objectives: To describe the case of a patient with newly diagnosed AOSD who developed severe MAS requiring ICU admission and immunosuppression with high-dose glucocorticoids, tocilizumab and anakinra.
Methods: Case report
Results: A 24-year-old woman attended hospital with a 4 month history of fever, arthralgia, rash and later dry cough. She became hypoxic and was admitted to the ICU for ventilation and vasopressor support. Imaging revealed splenomegaly, pleural effusions and lung consolidation but there was no response to antibiotics and no clear evidence of infection. Cytomegalovirus (CMV) DNA was initially absent, with IgG avidity indicating prior exposure. Bloods confirmed significant inflammation (CRP 107 mg/L, ferritin 6154 µg/L, ESR 47mm/hr) without disordered haematopoiesis. A bone marrow aspirate showed no haemophagocytosis. After extensive investigation a diagnosis of AOSD was made given the fulfilment of the Yamaguchi criteria and absence of evidence of an alternative driver of inflammation.
The patient deteriorated further, with deranged liver chemistry, rising CRP, triglycerides and ferritin (>100,000 µg /L), and trilineage cytopenia raising concern for MAS. This was managed by treating the presumed trigger (AOSD) with intravenous methylprednisolone (IVMP, 3x 500mg then 32mg daily) and anakinra (100mg twice daily). She developed a CMV viraemia that progressed despite aciclovir and later valganciclovir, which was switched to foscarnet and CMV immunoglobulin. The viraemia then stabilised and improved.
Due to persistent pyrexia, tachycardia, and elevated inflammatory markers, further IVMP (3x250mg), increased anakinra doses (100mg IV TDS) and intravenous immunoglobulin (2x60g) were given. A repeat bone marrow biopsy was consistent with MAS and testing for HLH-associated genes was negative.
The patient became increasingly hypoalbuminaemic and oedematous, developing acute kidney injury requiring continuous haemodiafiltration in the ICU. Anakinra was increased to 500mg daily in divided doses. The blood counts improved transiently, before the ferritin rose sharply again, with fevers and broad-spectrum antimicrobials continuing. Cytokine profile testing at this point revealed significant elevation in IL-1b and IL-6. Tocilizumab 8mg/kg fortnightly was added to existing therapy.
After tocilizumab initiation the inflammatory markers, blood counts and clinical state improved, though the patient remained hypertensive despite numerous antihypertensives. She left the ICU ten weeks after initial presentation. Corticosteroids and anakinra were weaned and she was discharged on tocilizumab monotherapy. Renal function did not return, and she continues outpatient haemodialysis.
Conclusion: The evidence base for effective therapies in MAS is poor. Reports exist of the use of either anakinra or tocilizumab [3] but not both agents in combination. In this case, cytokine blockade with both agents produced significant clinical improvement in a critically unwell patient.

Challenges of fibromyalgia

OP0195

PREVALENCE OF SURVEY-BASED CRITERIA FOR FIBROMYALGIA AND IMPACT ON HOSPITAL BURDEN: A 7 YEARS FOLLOW UP STUDY FROM AN OUTPATIENT CLINIC

P. Lage-Hansen[1], S. Chrysidis[2], K. Amris[3], S. Fredslund-Andersen[2], R. Christensen[4], T. Ellingsen[5]. *[1]Southern West Hospital, Rheumatology, Esbjerg, Denmark*; *[1]Southern West Hospital, Rheumatology, Esbjerg, Denmark*; *[3]The Parker Institute, Bispebjerg & Frederiksberg Hospital, Rheumatology, Copenhagem, Denmark*; *[4]The Parker Institute, Bispebjerg & Frederiksberg Hospital, Rheumatology, Copenhagen, Denmark*; *[5]Odense University Hospital, Rheumatology, Odense, Denmark*

Background: The prevalence of Fibromyalgia (FM) among newly referred patients to rheumatic outpatient clinics is unknown. It is well described that FM patients have increased use of the secondary healthcare facilities, however to what extent the presence of FM burdens the different medical specialties in the secondary health care sector is still unknown.
Objectives: To evaluate the prevalence of fulfilment of survey-based criteria for FM (1) among newly referred patients in a rheumatic outpatient clinic and to compare the use of secondary health care services between survey-based FM- and non-FM cases.
Methods: This is an observational cohort study. Newly referred patients with the suspicion of rheumatic inflammatory disease in an outpatient clinic were evaluated for fulfilment of 2011 FM survey criteria during a 6-month period in 2013. Demographic data were obtained at baseline. Seven years later, patients' medical files were evaluated, and comparisons between groups were made regarding the use of hospital healthcare facilities during the observation period. Results were adjusted for sex, age, and multiplicity.
Results: 248 patients of 300 invited (83%) completed the questionnaire; 90 patients (36%) fulfilled FM criteria at enrolment (Figure 1). FM cases were primarily women (80% vs. 54%) and received more public economical support (62% vs. 20%). At 7 years follow up, adjusted results shows that FM cases had higher number of hospital courses (13 vs. 9) and had undergone more invasive procedures (78% vs. 60%), however differences concerning number of diagnoses between groups were small. Neurologists (42% vs. 28%), gastroenterologists (30% vs. 13%), endocrinologists (40% vs. 21%), pain-specialists (13% vs 3%), psychiatrists (20% vs. 7%), and abdominal surgeons (43% vs. 30%) were consulted more often by FM cases than non-FM cases.
Conclusion: Fulfilment of FM survey criteria among newly referred patients with the suspicion of a rheumatic inflammatory disease to a rheumatic outpatient clinic is frequent. The burden to the secondary healthcare system in these patients is significant. The finding of a minimal difference between groups regarding the number of resulting diagnoses underlines that prolonged and excessive use of healthcare services with referral to multiple specialists should be avoided. Our study findings also support that FM continues to present a challenge for healthcare professionals as well as for patients. A timely and coordinated effort across medical specialties, including rheumatologists, could reduce diagnostic delay, facilitate management, and reduce healthcare utilisation in this patient population.

OP0196

HIGH SYMPTOM BURDEN AND LIMITED CHANGES IN FIBROMYALGIA PATIENTS' HEALTH STATUS TWO YEARS AFTER PARTICIPATION IN A MULTICOMPONENT REHABILITATION PROGRAMME

H. A. Zangi[1,2], T. Haugmark[1], S. A. Provan[1], K. B. Hagen[3]. *[1]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; *[2]VID Specialized University, Faculty of Health, Oslo, Norway*; *[3]Norwegian Institute of Public Health, Division for Health Services, Oslo, Norway*

Background: Patients with fibromyalgia (FM) suffer from high symptom burden and few available treatments. EULAR evidence-based recommendations for the management of FM state that optimal management should focus on prompt diagnosis, patient education and non-pharmacological treatments[1]. A recent systematic review of mindfulness- and acceptance-based interventions for patients with FM showed small to moderate beneficial health effects[2]. We tested a 10-session group-based mindfulness- and acceptance-based intervention, the Vitality Training Programme[3], followed by low threshold physical exercise counselling in primary health care, compared to treatment as usual (TAU) for patients diagnosed with FM.
Objectives: To explore possible changes in health status in a group of FM patients two years after participation in a multicomponent rehabilitation programme.
Methods: A total of 170 patients with confirmed FM diagnosis according to ACR 2011-criteria were randomised, 85 to intervention and 85 to control. Self-reported data were collected electronically at baseline, 3 and 12 months. There were no statistically significant health effects in any disease-related variables at 12 months. However, there were significant between-group differences in patients' tendency to be mindful[4]. All patients were asked to complete the same questionnaires two years after completion of the intervention group. Because the TAU-group had been offered the same programme after 12 months, only data from the intervention group was included in this study. Primary outcome was Patient Global Impression of Change (PGIC), scored as 1= much worse, through 4=no change, to 7=much better. Values 6 and 7 were considered clinically relevant improvement. Secondary outcomes were self-reported pain, fatigue, sleep quality, psychological distress, mindfulness, physical activity, motivation and barriers for physical activity, and work participation. Mean changes from baseline to two years were analysed by paired sample t-tests.
Results: Totally, 48 (56.5%) of the patients who had been randomised to the intervention group responded to the questionnaires, 94% female, median (range) age 47 (28 to 54), symptoms duration 12 (5 to 33) years. Only seven patients reported clinically relevant improvement on PGIC; 32 (67%) reported little better, worse or no change (Figure 1). There were small improvements in pain (p=0.048), fatigue (p=0.014) and self-efficacy for physical activity (p=0.012), but the changes were probably not clinically relevant. The improvement seen in patients' tendency to be mindful at 12 months was sustained (p=0.012). Only 58% were in paid work compared to 70% at baseline.

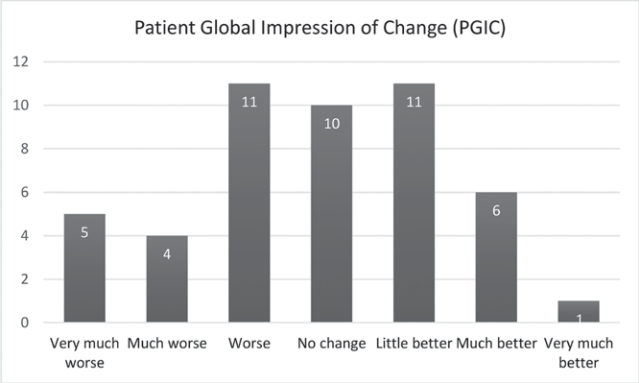

Figure 1.

Conclusion: Two years after participation in a multicomponent rehabilitation programme comprising mindfulness and acceptance training and physical activity counselling, FM patients still reported high symptom burden and no improvement in their health status. The increased tendency to be mindful was not reflected in improvements in disease-related outcomes. It was not possible to compare groups (intervention and TAU), because the TAU-group had been offered the intervention before the two-years data collection. However, there was no worsening of symptoms, which might have been the case without any intervention.

Scagnellato[1], A. Valevich[1], F. Fattorini[1], I. C. Navarro García[1], I. Palla[3], V. Lorenzoni[3], A. Gaglioti[1], C. Carmassi[2], C. Tani[1], G. Turchetti[3], L. Dell'Osso[2], M. Mosca[1]. [1]*University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*; [2]*University of Pisa, Psychiatric Clinic, Department of Clinical and Experimental Medicine, Pisa, Italy*; [3]*Institute of Management, Scuola Superiore Sant'Anna, Pisa, Italy*

Background: The COVID-19 pandemic, with its uncertainties, fears of contagion, mass lockdowns and containment measures, has dramatically impacted on people's everyday lives leading to an increased risk of mental disorders, particularly Post-Traumatic Stress Disorder (PTSD). Despite evidence in general population and healthcare workers1,2, scant data emerged on vulnerable populations, such as of patients with chronic illness, particularly rheumatic and musculoskeletal diseases (RMDs)3,4, who also underwent difficulties in the management and treatment of their disorders.
Objectives: To assess PTSD and post-traumatic stress symptoms in a sample of patients with RMDs, during the COVID-19 pandemic in Italy.
Methods: PERMAS is a monocentric prospective observational study led by the Rheumatology Unit, the Psychiatric Clinic and the Institute of Management of the School of Advanced Studies. Patients with a RMD diagnosis, were consecutively enrolled from May 2021 to January 2022. During the visit, sociodemographic characteristics and psychopathological data were collected through online survey, whereas clinical data were collected by physician. The survey included the Trauma and Loss Spectrum- Self Report (TALS-SR) and the Impact of Event Scale- Revised (IES-R), aimed to assess symptomatological PTSD and post-traumatic stress symptoms related to the impact of the COVID-19 pandemic.
Results: A total of 194 eligible patients, with a mean age of 50.3±12.17 years, was included: 142 (73.19%) were females; 112 (57.74%) patients reported connective tissue diseases (CTD), 63 (32.47%) arthritis and 19 (9.8%) vasculitis. A total of 33 (17%) subjects reported a symptomatological PTSD by means of the TALS-SR. The prevalence of Partial PTSD (defined by at least 2 out of the 4 criteria for DSM-5 diagnosis of the disorder) was 56.7%, with significant higher rates among females (90, 81.8%) with respect to males (20, 18.2%) (p=.013). Accordingly, a IES-R mean total score of 21.90 ±15.98 was found in the total sample and a gender difference emerged, with higher mean scores among females rather than males (23.42 ±16.26 vs 21.90 ±15.98, p=.031).
Conclusion: The present findings point out high prevalence rates of symptomatological PTSD among patients suffering from RMDs, highlighting the potentially traumatic burden of the COVID-19 pandemic in this particular population, especially among females, suggesting the need of further investigations to address tailored prevention and intervention strategies.

How do we overcome the research-to-practice gap? Implementation of evidence into the rheumatology practice

OP0198-HPR DEVELOPMENT OF AN INTERDISCIPLINARY NURSE-COORDINATED SELF-MANAGEMENT INTERVENTION (INSELMA) FOR PATIENTS WITH INFLAMMATORY ARTHRITIS

J. Primdahl[1,2,3], K. M. Latocha[4], A. Bremander[1,2,5], O. Hendricks[1,2], M. Østergaard[6,7], L. Andersen[8], K. V. Jensen[4], B. A. Esbensen[6,7]. [1]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; [2]*Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; [3]*Sønderborg Sygehus, University Hospital of Southern Denmark, Aabenraa, Denmark*; [4]*Patient research partner, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital - Rigshospitalet, Glostrup, Copenhagen, Denmark*; [5]*Lund University, Department of Clinical sciences, Lund, Sweden*; [6]*Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital - Rigshospitalet, Glostrup, Glostrup, Denmark*; [7]*University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; [8]*Patient research partner, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*

Background: Up to 30% of patients with inflammatory arthritis (IA) do not respond sufficiently or tolerate the pharmacological treatment. Consequently, they may experience a substantial impact of their arthritis in everyday life. Even patients in remission or low disease activity state are at risk of substantial arthritis related symptoms and burden. These patients may need coherent interdisciplinary self-management support to manage symptoms and life with the chronic condition to increase their quality of life. A previous EULAR review on the effectiveness of self-management interventions in patients with IA (1) found that well-structured self-management programmes were lacking or were poorly reported.
Objectives: This study aimed to develop a nurse-coordinated interdisciplinary self-management intervention, delivered in routine clinical care, for patients with inflammatory arthritis and with a substantial impact of their arthritis to support their self-management ability.
Methods: The study was planned across two Danish hospitals following the British Medical Research Councils (MRC) framework for developing and evaluating Complex Interventions (2). The development process consisted of four phases: 1) a comprehensive scoping review on patients support needs and elements in self-management interventions; 2) six workshops involving health professionals (rheumatologists, nurses, physiotherapists, occupational therapists, a social worker and a psychologist) and 2 patient representatives from the two hospitals and staff from primary health care, 40 people in total; the workshops focused on ideas for the content, outline of the intervention and needs for competence development of the staff; 3) self-management, self-efficacy, health literacy and principles of Acceptance and Commitment therapy (ACT) were selected as theories to tailor the intervention and 4) development of a manual through recurrent feedback from patient research partners, clinicians and the involved researchers. Two patient research partners with IA were involved in all phases of the development of the intervention.
Results: A six month nurse-coordinated interdisciplinary self-management intervention was developed (Figure 1) consisting of: 1) an initial holistic assessment is carried out by a coordinating outpatient nurse. Patients are asked to identify up to five important activities they are unable to perform or having difficulty with in accordance with the Patient Specific Functional Scale; 2) a goal-setting and action planning process involving the patient, relatives and the coordinating nurse; 3) Ongoing support to achieve the goals. The opportunities for support include individual consultations by the coordinating nurse (telephone, online or face-to-face, 2.5 hours in total), and a maximum of four consultations by a physiotherapist and or an occupational therapist. Also, support from primary care, and an online session by a social worker about social support opportunities are offered. Two team conferences led by the coordinating nurse can be held during the intervention period. A status consultation will be held after 6 months. A manual for the initial screening, inclusion, detailing the intervention, outcomes and additional materials to support the intervention was developed. Competence development of the health professionals who are to deliver the intervention was planned and completed.

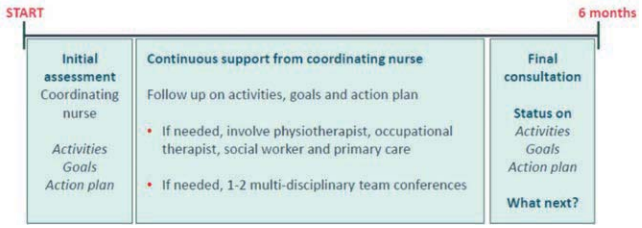

Figure 1. Illustration of the 6-month INSELMA intervention

Conclusion: A nurse-coordinated interdisciplinary self-management intervention (INSELMA) was developed and described based on MRC's framework for the development of Complex Interventions. The intervention is ready for feasibility testing before adaptation and test in a subsequent Randomized Controlled Trial.

Strengths and weaknesses of experimental models: Moving from animals to human clinical trials

OP0199 RADIOMIC SIGNATURES REFLECT TREATMENT RESPONSE TO NINTEDANIB IN PRECLINICAL LUNG FIBROSIS MODEL

D. Lauer[1,2,3], J. Schniering[4], H. Gabrys[5], M. Maciukiewicz[1,2,3], M. Brunner[1,2], O. Distler[3], T. Frauenfelder[6], S. Tanadini-Lang[5], B. Maurer[1,2]. [1]*University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland*; [2]*University of Bern, Department for Biomedical Research (DBMR), Bern, Switzerland*; [3]*University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland*; [4]*Helmholtz Zentrum München, Institute of Lung Health and Immunity (LHI), Comprehensive Pneumology Center, Munich, Germany*; [5]*University Hospital Zurich, University of Zurich, Department of Radiation Oncology, Zurich, Switzerland*; [6]*University Hospital Zurich, University of Zurich, Institute of Diagnostic and Interventional Radiology, Zurich, Switzerland*

Background: Responses to anti-fibrotic drugs in preclinical disease models are difficult to quantify by histological analysis of single tissue sections. Quantitative in-depth analysis of imaging data, termed "radiomics", may represent a more reliable and accurate measure of treatment response since the pathology of the whole organ is captured.
Objectives: To study the potential of µCT-derived radiomic features to reflect response to Nintedanib in the bleomycin (BLM)-induced murine model of fibrosing interstitial lung disease.
Methods: All C57BL/6J mice from both study groups were intratracheally instilled with 2 U/kg BLM on day 0 to induce lung fibrosis. Nintedanib was administered daily by gavage at 60 mg/kg for two weeks starting from day 7 (n=15). Controls received equivalent treatment with vehicle-only (n=19). Whole lung µCT scans (SkyScan 1176, Bruker) of each animal were acquired at baseline (day 0), pre-treatment (day 7), and post-treatment (day 21). The Ashcroft score was assessed on Sirius Red stained lung sections post-treatment. Lung volumes in µCTs were defined semi-automatically in MIM Software (6.9.2), followed by extraction of radiomic features with our in-house developed software Z-Rad (7.3.1). Each data set contained 1'386 features, describing image characteristics with histogram, texture, and wavelet functions. Data pre-processing involved removal of features sensitive to intra- and interobserver delineation variability (ICC<0.75), highly correlated features (Pearson's r>0.95), and features not

significantly changing between days 0 and 7 (p>0.05). Agglomerative clustering of radiomic temporal trajectories was performed on the Nintedanib group to identify distinct feature clusters. The identified feature sets were then used to plot average feature value trajectories for both study groups in each cluster. To identify features significantly different between a) Nintedanib vs. control, and b) pre- vs. post-treatment, Mann-Whitney U and Wilcoxon signed-rank tests were used, respectively. Samples were pooled from two independent experiments.

Results: Evaluation of tissue sections did not show a significant treatment-induced reduction of fibrosis with average Ashcroft scores of 3.7 (±1.2 s.d.) and 3.4 (±1.6 s.d.) in Nintedanib and control samples, respectively (p>0.05). Radiomics data analysis revealed two feature clusters in Nintedanib samples, composed of 52 features (cluster 1) and 96 features (cluster 2), the trajectories of which were then plotted for both study groups. In cluster 1, feature value trajectories significantly decreased in both Nintedanib and control group between pre-and post-treatment (p<0.001), whereas feature values in cluster 2 remained flat (p>0.05). Importantly, Nintedanib-treated mice displayed a much more pronounced feature value decrease post-treatment in cluster 1 compared to the control group (p<0.05). Here, feature values post-treatment resembled pre-disease baseline conditions in the Nintedanib group (p>0.05), whereas the control group remained significantly different from baseline (p<0.01). Cluster 1 was composed of 6 histogram, 11 texture, and 35 wavelet features, emphasizing the role of high-dimensional metrics for the detection of differences.

Conclusion: Histological quantification of lung fibrosis accounts only for a small fraction of the whole pathology in a spatially heterogeneous disease. We demonstrated that µCT-derived radiomic features identified significant differences on imaging level following Nintedanib treatment, which we could not reliably detect on tissue level using Ashcroft scoring. These findings hold great potential for the development of novel readouts for improved stratification of anti-fibrotic treatment effects in preclinical models.

From abstract to concrete – the variety of activities of PARE organizations

OP0200-PARE BARING IT ALL: A REPORT ON THE SEXUAL AND REPRODUCTIVE HEALTH EXPERIENCES OF WOMEN+ WITH INFLAMMATORY ARTHRITIS, RHEUMATIC AND PSORIATIC DISEASES

L. Proulx[1], S. Ketelaars[2], R. Manion[3], A. Scali[4]. [1]*Canadian Arthritis Patient Alliance, Patient Organisation, Ottawa, Canada*; [2]*Canadian Spondylitis Association, Patient Organisation,Toronto, Canada*; [3]*Canadian Association of Psoriasis Patients, Patient Organisation, Ottawa, Canada*; [4]*Canadian Psoriasis Network, Patient Organisation,Toronto, Canada*

Baring it All: a report on the sexual and reproductive health experiences of women+ with inflammatory arthritis, rheumatic and psoriatic diseases

Background: Inflammatory arthritis and psoriasis commonly affect women+ in the prime of their lives with significant impacts on sexual, reproductive and mental health. There have been some efforts to provide educational resources and other support by patient organizations globally but no broad efforts to evaluate patient needs and experiences throughout their lives and disease course.

Objectives: The Canadian Arthritis Patient Alliance, Canadian Association of Psoriasis Patients, Canadian Psoriasis Network and Canadian Spondylitis Association co-developed and launched the ***Women's Sexual and Reproductive Health Survey*** on International Women's Day 2021. Findings were analyzed in the report, ***Baring it All: A survey and recommendations on sexual and reproductive health needs of women+ with rheumatic, inflammatory and psoriatic diseases.***

Methods: Survey participants were asked about their experiences with:

- sexual health
- family planning
- parenting
- perimenopause/menopause
- pain
- mental health
- accessing care and treatments (including paying for medications)

A total of 439 people across Canada who identified as female (women+) living with inflammatory arthritis, rheumatic, and psoriatic diseases participated. Results were analyzed to provide a national picture and insights based on Canadian geography, age, and identification as a member of a racialized community and/or as LGBTQ2S+.

Results: Over 60% of survey participants indicated that they did not have enough information about sexual health and their condition(s) and identified information needs relating to managing the impact of fatigue on their sex life, advice on improving sex drive, and sexual positions comfortable for their body as priorities. Less than half of survey participants indicated receiving counseling from a doctor before pregnancy. Many participants expressed a need for information about medication safety during pregnancy and breastfeeding and managing the impact of pain.

Two in five survey participants (40%) indicated they were currently experiencing symptoms of perimenopause or menopause; however, only half of them (21%) indicated they understood how menopause affects their condition(s). Over 50% of participants indicated they understand how menopause affects bone health.

Though 91% of survey participants indicated that they can honestly discuss pain with their healthcare provider, only 58% feel like their healthcare provider relates to the pain they experience from their condition. The vast majority (87%) of survey participants worry about the impact of their condition on their mental health, yet only 16% of participants identified having a mental health professional (e.g., psychiatrist, psychologist, social worker) as part of their care team.

Conclusion: There are several unmet needs in accessing care and information throughout the lives of women+ living with inflammatory arthritis, psoriatic and rheumatic diseases. A shift in models of care to focus on patient needs could assist patients in navigating a range of difficult decisions, such as choosing safe medications for pregnancy and breastfeeding, reconciling health, work and parenting demands, understanding menopause, accessing mental health support, and managing pain. A sex and gender lens can be used in the creation of resources and policies to support people with these condition(s).

OP0201-PARE DEVELOPMENT THROUGH CO-CREATION OF A PERSONALIZED, MULTIMODAL, PHYSIOTHERAPIST-LED, WORK-ORIENTED INTERVENTION TO INCREASE WORK ABILITY IN WORKING PEOPLE WITH RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS.

N. Bakker[1], J. Knoop[2], N. Hutting[3], Y. Heerkens[3], J. Engels[3], J. B. Staal[2], M. van der Leeden[4], A. Boonen[5], J. Tiggeloven[6], N. Schuur[6], T. P. M. Vliet Vlieland[1], S. van Weely[1]. [1]*Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands*; [2]*HAN University*

of Applied Sciences, Musculoskeletal Rehabilitation Research Group, Nijmegen, Netherlands; [3]*HAN University of Applied Sciences, Research Group Occupation & Health, Nijmegen, Netherlands*; [4]*Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands*; [5]*Maastricht University Medical Center, Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands*; [6]*General Board Member Axial SpA Foundation, not applicable, not applicable, Netherlands*

Background: Although work ability is considered a key element of quality of life for working people, work is underexposed in current treatment in people with rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA). Most people with RA or axSpA attend a physiotherapist (PT). Physiotherapy can effectively improve physical fitness, which is associated with work ability. Therefore, PTs might play an important role in optimizing work ability of people with RA or axSpA.
Objectives: Developing a personalized, multimodal, PT-led, work-oriented intervention for working people with RA or axSpA who have a reduced work ability, through a co-creation process.
Methods: A systematic co-creation process with all relevant stakeholders was conducted following the Medical Research Council (MRC)-framework for complex interventions (see Figure 1). In step 1, all relevant clinical guidelines and treatment protocols were assessed. Based on the results of this assessment, a draft version of the intervention was developed, consisting of mandatory (i.e., work-oriented intake, patient education, exercise therapy, referral-roadmap of work-related professionals) and optional treatment modalities (i.e., workplace-intervention, self-management course). In step 2, focus groups with people with RA/axSpA, PTs and occupational/rheumatology experts were organized and qualitatively analysed. In the focus groups, barriers and facilitators of work-oriented treatments and necessary adaptations to the draft intervention were discussed. In step 3, a pre-test was performed to test the feasibility of the intervention in a primary physiotherapy setting, which was evaluated in the group of PTs participating in the pre-test in step 4. Finally, in step 5, a final focus group with researchers in this field was held to discuss the findings from previous steps in this co-creation process and to agree on necessary adaptations in the final intervention.

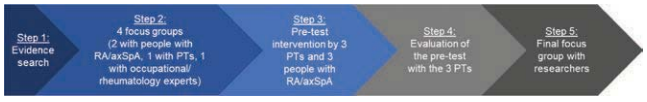

Figure 1. Process of systematic development of co-created, work-oriented physiotherapist-led intervention following the MRC-framework.

Results: After developing the draft intervention, we conducted two focus groups with people with RA/axSpA (n=16; 4 with RA, 12 with axSpA), one focus group with PTs (n=12) and one focus group with occupational/rheumatology experts (n=9; 2 rheumatologists, 2 nurse specialists, 1 physiatrists, 1 physician assistant, 1 nurse practitioner, 1 labour expert and 1 occupational therapist). People with RA or axSpA emphasized 3 aspects: i) PTs should have adequate expertise in RA/axSpA, ii) high potential for a role of 'buddy' by PTs to support them in work-related problems, and iii) most PTs currently lack adequate expertise on work-related problems. PTs and experts underlined the importance of extensive training of PTs on work-related laws and regulations and adequate (work-related) interprofessional collaboration. After revision of the draft intervention, the intervention was tested for feasibility by three PTs and three working people (2 with RA, 1 with axSpA), who indicated that the intervention was feasible and that the developed intervention facilitated PTs to support people in optimizing their work ability. However, adequate training on providing this intervention was recognized to be essential. In a final focus group with researchers (n=6), consensus was reached on minor adjustments to the intervention that were based on findings from previous steps.
Conclusion: Through a systematic co-creation process based on the MRC-framework, we have been able to develop a personalized, multimodal, PT-led, work-oriented intervention for working people with RA or axSpA and a reduced work ability. The (cost-)effectiveness of this intervention is currently being tested in a large trial (Physiotherapy WORKs study).

OP0202-PARE NRAS NEW2RA RIGHT START SERVICE FOR PEOPLE RECENTLY DIAGNOSED WITH RA

A. Bosworth[1], C. Jacklin[2]. [1]*National Rheumatoid Arthritis Society, Services, Maidenhead, United Kingdom*; [1]*National Rheumatoid Arthritis Society, Services, Maidenhead, United Kingdom*

Background: The National Rheumatoid Arthritis Society (NRAS) follows best practice, evidence-based standards in all we do. Huge strides have been made in the diagnosis and treatment of Rheumatoid Arthritis (RA), but impact on quality of life can be significant and for many, RA remains hard to come to terms with. Anxiety and depression are frequent co-morbidities seen in RA, and this can impede people's ability to acquire knowledge of their disease together with supported self-management skills and coping strategies.
Objectives: The aim of Right Start (RS) is to improve outcomes of the recently diagnosed with RA through a framework of emotional, educational and peer support, and access to high quality supported self-management resources tailored to individual need. RS also enables us to dispel myths and unhelpful health beliefs so that people get the 'right start' on their journey with RA to maximise health outcomes. A diagnosis of an incurable disease treated with life-long strong drugs is a life-changing event and without the right support it can be an isolating and emotionally very challenging experience for both the individual and their close family. We also wanted to give an understanding of the key role that supported self-management can play in improving quality of life, giving people back some control over their symptoms. Our goal was also to create a quick and easy way for HCPs to refer their patients to Right Start in a consented and GDPR compliant way.
Methods: HCPs are able to refer their patients via the 'Refer a patient' button on our website which takes them to a simple form which is filled in and submitted to NRAS with the patient's consent. NRAS receive the referral and the form is integrated with our Salesforce database, and we contact the patient. RS involves a simple, 4-step process and the individual receives: A call (up to 1 hr) with a member of our helpline; 1:1 peer support (phone/Teams/Zoom) from trained volunteers with RA and access to 24/7 online community support; a tailored package of hard copy information with e-links/video/webinars of interest sent by post; further follow up available from helpline and individual peer support. RS enables health professionals to meet their responsibilities against NICE Quality Standard 33, Statement 3, (patient education and access to self-management resources) on which they are audited through National Early Inflammatory Arthritis Audit (NEIAA). RS is included in the NICE shared learning database of best practice examples. RS also supports the EULAR Recommendations for implementation of self-management strategies in inflammatory arthritis.
Results: Since launch at BSR 2019, over 90 UK rheumatology units have referred over 435 patients to this service. Approx. 1/3rd cannot be contacted and after 3 attempts a letter and newly diagnosed pack are sent, inviting contact at future date. Anecdotally people are highly satisfied with this service and a number of units are referring multiple patients where the service is embedded in the patient pathway. To gather empirical data on the impact of the service NRAS has partnered with Manchester University to undertake an Enhanced Right Start pilot in 5 UK rheumatology units involving the use of validated patient reported outcome and experience measures from users recruited, and quantitative/qualitative data from health professionals. The pilot is due to commence recruitment in early Feb, 2022. Meantime, referrals to the standard service continue to grow.
Conclusion: Workforce shortages in all posts within the multi-disciplinary team), 2 years of pandemic resulting in HCPs under immense pressure and time poor with a large backlog of patients has meant it's extremely difficult for HCPs to meet Quality Standards and goals of audit. Feedback informs that HCPs find Right Start a beneficial service to refer their patients to and people with RA have found it more than helpful. We anticipate that the results of the Enhanced Right Start Service Pilot (see Results) will provide additional evidence to support HCP patient-referral to this service.
Acknowledgements: I would like to acknowledge the support of a number of UK consultant rheumatologists in the early stages of the development of this service, in particular Dr. James Galloway.

OP0203-PARE FATIGUE IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: A SCOPING REVIEW ON ITS DEFINITION, MEASUREMENT INSTRUMENTS, DETERMINANTS, IMPACT AND INTERVENTIONS

E. Beckers[1,2], K. Hermans[1,2], A. van Tubergen[1,2], A. Boonen[1,2]. [1]*Maastricht University Medical Center, Internal Medicine, Division of Rheumatolgy, Maastricht, Netherlands*; [2]*Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*

Background: Fatigue is one of the most important symptoms of patients with rheumatic and musculoskeletal diseases (RMDs) and numerous studies on fatigue in patients with RMDs have been published. However, no overview exists

of all topics relevant to understand and manage fatigue in patients with rheumatoid arthritis (RA), spondyloarthritis (SpA, including psoriatic arthritis (PsA)), osteoarthritis (OA) and fibromyalgia (FM).
Objectives: To scope published reviews on aspects of fatigue identified by patients in a preceding initiative as relevant for care and mapped to the following research areas: 1) definitions for fatigue, 2) measurement instruments for fatigue, 3) determinants of fatigue, 4) impact of fatigue, and 5) effect of interventions on fatigue in patients with RMDs of interest.
Methods: A methodological framework for scoping reviews was followed[1]. A systematic literature search was performed in five bibliographical databases. Data selection followed by data extraction was done by two independent researchers.

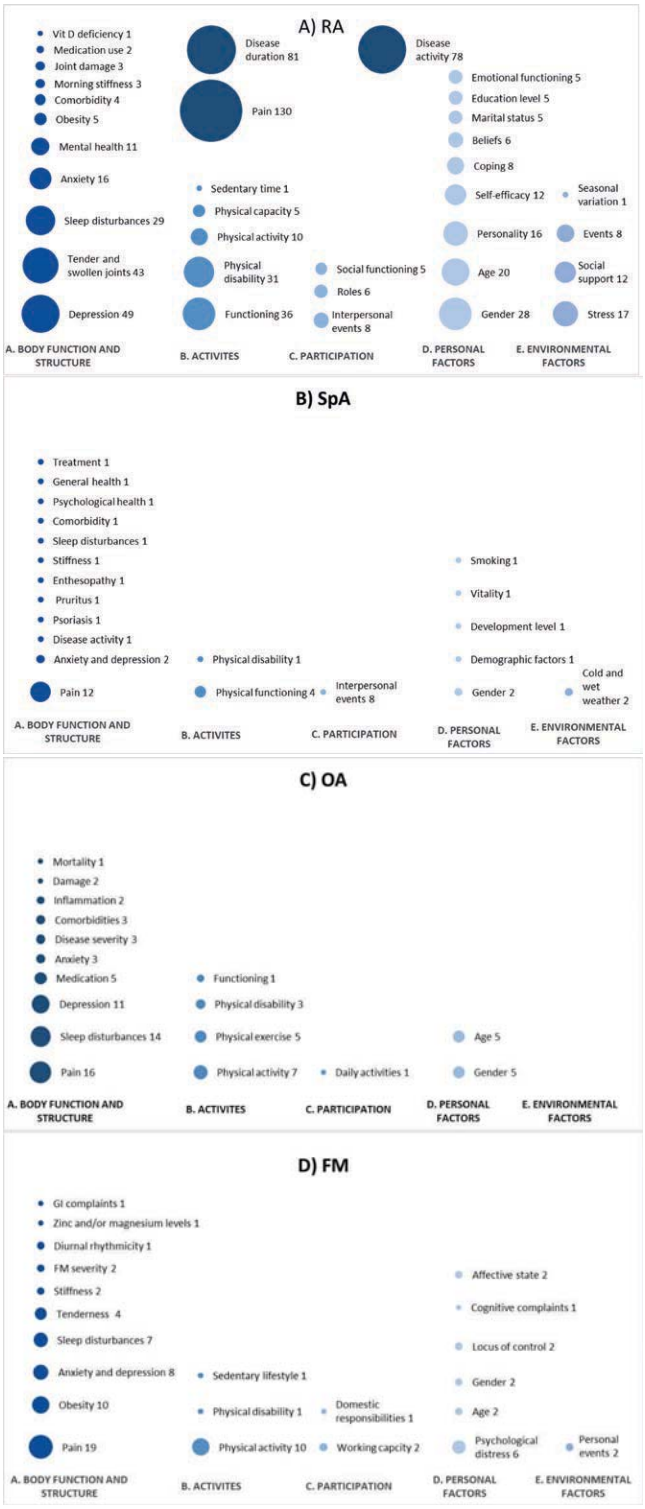

Figure 1. Determinants of fatigue and the related minimal number of underlying studies within reviews

Included reviews were categorized in Cochrane reviews (CRs), non-Cochrane systematic reviews (SRs) or narrative reviews (NRs). Data extraction was performed hierarchal based on review type (CRs followed by SRs and NRs) and year of publication. SRs and NRs were excluded if there was overlap in the underlying studies within the reviews. Data synthesis accounted for hierarchy in level of evidence by review type (CRs were considered as best evidence followed by SRs and NRs). For each research area and stratified per type of RMD, a narrative synthesis was performed. Two meetings were organized with a patient panel to discuss the results from a patient perspective.
Results: The scoping review included 144 reviews (18 CRs, 42 SRs and 84 NRs). RA was addressed most frequently (60/144 (42%)). Fatigue was a secondary outcome in the majority of these reviews.
No agreed upon definition for fatigue in any of the RMDs was found. Across reviews, there was agreement that fatigue is a complex multifactorial and highly subjective symptom, including various subtypes with specific characteristics.
Reviews discussed 23 generic and 3 disease-specific self-reported outcome instruments to measure fatigue in RA, SpA and FM, but no reviews on outcome instruments for OA were found. Four of these 23 (17.4%) instruments included validated cut-off values to diagnose or classify excessive fatigue.
Numerous factors were associated with fatigue (Figure 1), but the study design (often cross-sectional) hindered studying causality. Across RMDs, pain, physical function, and depressive symptoms were the most frequently studied disease related factors; gender and stress the most frequent contextual factors related to fatigue. The strength of association was small or moderate, but mostly not reported. Work disability was one of the most frequently studied consequences of fatigue in RMDs, followed by impact on pain, physical activity and stress. Strength of these associations was not reported.
Finally, both pharmacological and non-pharmacological interventions, including physical activity-based and psychological interventions, generally had a small positive effect on fatigue in RMDs. No reviews described the effect of pharmacological interventions on fatigue in OA.
All results were relatable for the patient panel and some missing aspects were pointed out. The patient panel advised to develop a research agenda to specifically diagnose and treat excessive fatigue in RMDs, as continuing the current path is likely to increase publications about fatigue, but unlikely to change patients' lives.
Conclusion: This scoping review emphasizes the complexity of fatigue. Only a minority of the reviews had a primary focus in fatigue, whereas to patients this prominent symptom deserves specific attention.

OP0204-PARE

MEANINGFUL PATIENT INVOLVEMENT IS CRITICAL TO SUCCESSFUL INTERNATIONAL GRANT APPLICATIONS: THE CASE OF THE HIPPOCRATES CONSORTIUM

L. Werner[1] on behalf of HIPPOCRATES consortium ["Health initiatives in Psoriasis and PsOriatic arthritis ConsorRTium European States"]. [1]*The Danish Psoriasis Association, Research, Copenhagen, Denmark*

Background: HIPPOCRATES is a large, international research project addressing the unmet needs of people with psoriatic arthritis (PsA). It aims to improve early identification of PsA in people with psoriasis, as well as therapeutic options and outcomes for people living with PsA. The project will run for five years with a budget of € 21 million provided by the Innovative Medicines Initiative (IMI) – a joint undertaking of the European Union and the European Federation of Pharmaceutical Industries and Associations (EFPIA). During the evaluation of the HIPPOCRATES grant application, the patient involvement was highly praised: "*A strength of this proposal is that patient representative organisations seem highly integrated in the proposal and will be important avenues for dissemination.*"
Objectives: To explore the components of an effective strategy for incorporating the patient perspective in an international research consortium.
Methods: The experiences of the first six months of patient involvement in HIPPOCRATES were examined. We organized a survey and an online workshop with all participating patient research partners (PRPs) to gather data on the experiences of participation in the different working groups of the project, as well as to discuss common challenges and solutions.
Results: Patient involvement was visible and reported from the very beginning of the project, including participation of PRPs in the first consortium meeting for study design. The chosen strategy is characterized by an integrated approach containing multiple layers of patient involvement [Figure 1], with the consortium following the EULAR recommendations for the inclusion of patient representatives in scientific projects.

The active participation of 13 PRPs with well-defined roles and responsibilities ensures the preservation of the patient perspective during the entire duration of the project. Together they form the HIPPOCRATES Patient Advisory Council (PAC). PRPs are represented in the project's management team, in all work packages and in the External Advisory Board. Three patient organisations support the project: GRAPPA-EU (Group for Research and Assessment of Psoriasis and Psoriatic Arthritis) and EULAR PARE (People with Arthritis/Rheumatism in Europe) as consortium partners, and EUROPSO (European Federation of Psoriasis Patients' Associations). EULAR is co-leading the work package focusing on Communication, Dissemination, Exploitation and Sustainability, and especially those activities targeting patients, PRPs (regular educational sessions), patient organisations and the general public. Finally, people with PsO will be recruited for a large European cohort study (HIPPOCRATES Prospective Observational Study, HPOS) which aims to identify clinical and molecular risk factors for developing PsA.
Results from the PRP survey were positive. Almost all PRPs have been invited to their work package meetings and included in email exchanges, and all feel well-included in their assigned groups and roles. Nevertheless, it was reported that some PRPs may be reluctant to raise their voice or to be involved in discussions at virtual meetings. This was one of the topics addressed during the online workshop, together with discussions on ethics and recruitment strategies for HPOS.

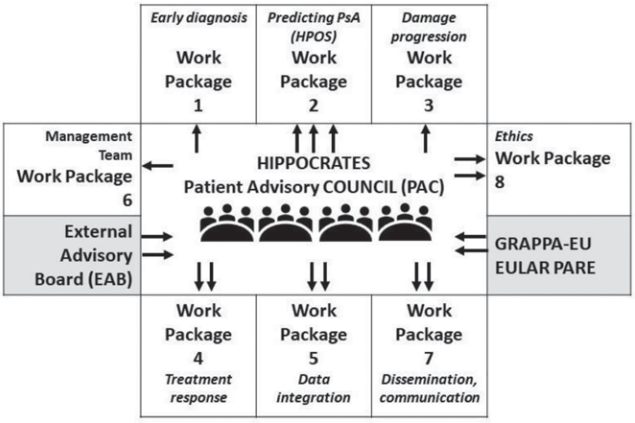

Figure 1 Multiple layers of patient involvement in HIPPOCRATES

Conclusion: It has been central to the HIPPOCRATES ethos that highly experienced PRPs were involved from its initial conception. PRPs with leading responsibilities in patient organisations or representing relevant academic backgrounds have contributed substantially to the definition of research priorities and will have active on-going engagement in the interpretation and implementation of future results. By demonstrating the pervasive benefit of the patient voice throughout the project, HIPPOCRATES will be an example for future projects in RMD and health research.

OP0205-PARE GREEK RMDS PATIENTS' NEED FOR SELF-MANAGEMENT AND THE USE OF NEW TECHNOLOGIES: THE CASE STUDY OF THE HELLENIC LEAGUE'S AGAINST RHEUMATISM SUPPORT LINE

N. Malliou[1], K. Antonopoulou[2]. [1]*Hellenic League Against Rheumatism, ELEANA/HELAR, Thessaloniki, Greece*; [2]*Hellenic League Against Rheumatism, ELEANA/HELAR, Athens, Greece*

Background: The Hellenic League Against Rheumatism (ELEANA/HELAR) offer psychosocial support to its member, patients with RMDs, their families and everyone else that's interested in RMDs. More than 5000 members from all over Greece, with local ELEANA/HELAR groups in major cities such as Athens, Patras, Karditsa, Trikala, Thessaloniki and others. The helpline has been receiving incoming calls from patients with RMDs, members of ELEANA, their relatives and others that are interested in RMDs or are requesting information.
Objectives: This case study aimed at outlining that self-management is the main reason for incoming calls to ELEANA's helpline and secondly that during the pandemic and even after lockdown measures being lifted patients still use the online support offered thus making it apparent that digitalization is not a trend anymore but a necessity.
Methods: Empirical data from the helpline were gathered through the day-to-day helpline registry. This is a detailed registry containing basic info on demographics of the callers, reasons for calling and outcome of communication. Descriptive statistics as well as qualitative data have been used such as observations of the trained staff of the helpline.
Results: From 543 incoming calls, 49,91% were about self-management and the rest 50,09% were calls requesting information. 52,40% of self-management calls were about psychological issues (anxiety, depressive symptoms) and the rest were about treatment (adherence), such as the use of medication, alternative treatments, medical issues and questions on RMDs. 40,96% of patients with RMDs called again the helpline to follow up and 61,25% used online tools to communicate with the helpline both times. Psychologists receiving calls observed that patients needed counseling regarding their self-management, especially during the pandemic and that even though lockdown is lifted they keep on requesting online communication instead of face-to-face meetings.
Conclusion: The above findings show that digitalization is not a trend rather than a necessity in the self-management of RMDs. Patients seem to find it easier receiving support online and the requests for online support for their anxiety, depressive symptoms, difficulties in managing their medication makes it clear that more emphasis needs to be put on self-management programs.

OP0206-PARE FOOD COMMUNITIES

P. Del Pin[1]. [1]*Gentofte, The Danish Rheumatism Association, Gentofte, Denmark*

Background: In recent years the focus on healthy food and lifestyle has become a more important part of everyday life for many – with or without RMD. Many NGO-initiatives engaging citizens cooking and eating together has seen the light of day; people meet to talk, laugh and have a good time while making a healthy meal.
The kitchen is an often discussed topic among the volunteers and members of The Danish Rheumatism Association. "Simple" tasks as opening a can of beans or cutting bread can be complicated for people with RMDs. The fundamentals of cooking are different for this group of people; hence the idea of communities around "arthritis friendly" food unfolded during fall 2019.
Objectives: The main objective is to create "food communities" for people with RMDs, helping them to get a better understanding of how to make "arthritis friendly food", dispel the myth that it is expensive and hard, and to give them inspiration to better working positions with assistive devices - resulting in a healthier lifestyle which is important to keep the inflammation low and the quality of life high.
Methods: To obtain these objectives, a dietitian is facilitating 6 three hour "courses" guiding the participants through healthy cooking – each course with a different theme/subject which is introduced through a short presentation. Two volunteers are responsible for booking kitchen facilities (often school kitchens which is free of charge), coordination with the dietitian and making sure everything runs smoothly and that the atmosphere is top-notch. An occupational therapist is joining the group one time to ensure optimal working positions and introducing and demonstrating assistive devices.
One of our main goals is to create sustainable and longer lasting (more than 6 facilitated courses) communities, which is why an important part of the volunteer's responsibility is to initiate a talk about the opportunity of meeting without a dietitian. The 6 facilitated courses aim to give the group the ability to find recipes (provided by DRA) and being comfortable cooking with ingredients that the average Dane might not use very often. Furthermore, our assumption is that the group creates social bonds and therefore an interest in keeping these relations.
Results: About twenty groups all around Denmark has been a part of the course so far. The feedback from the participants is extremely good – they feel they are learning in an inspiring environment while having a great time with their new acquaintances. Unfortunately, only one of the groups has become a community that exists after the facilitated courses. One of the reasons is, without a doubt, that most of the groups have been affected by different Covid-19 restrictions which has had an impact on the level of social bonding and feeling of ownership. But most participants feel that the dietitian is crucial for further engagement.
Conclusion: The concept has been very successful in terms of creating a course that imparts useful knowledge about "arthritis friendly" food and lifestyle for people with RMD's. It seems we need to make corrections to create the basis for sustainable communities; small changes that helps the group visualizing how to overcome the challenge of the absence of a dietitian, the logistics of grocery shopping for a group etc. We plan to leave out the dietitian from the fifth of the six courses to prepare the group to establish their own "food community" with lots of healthy food, learning experiences and high spirit.

HPR interventions on the spotlight

OP0207-HPR EFFECT OF FOOT ORTHOSES IN REDUCING PAIN IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A 12-MONTH RANDOMISED CLINICAL TRIAL

A. Fellas[1], J. Chaitow[2], D. Singh-Grewal[2], D. Santos[3], M. Clapham[4], A. Coda[1].
[1]University of Newcastle, College of Health, Medicine and Wellbeing, Callaghan, Australia; [2]Sydney Children's Hospital, Randwick, Paediatric Rheumatology, Randwick, Australia; [3]Queen Margaret University, Podiatry, Edinburgh, United Kingdom; [4]Hunter Medical Research Institute, Statistics, New Lambton Heights, Australia

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children and adolescents [1]. The manifestation of JIA may include joint swelling, tenderness, and painful limitation with joint movement. Only few studies have explored the effect of foot orthoses (FOs) alone in children with JIA [2,3]. These studies showed FOs can reduce pain in children with JIA, however, further research with larger sample sizes and longer follow-ups are needed [4]. Prescribing FOs on the same day of the initial assessment may promote early clinical and targeted intervention, which is the gold standard approach in paediatric rheumatology.
Objectives: This single blinded multicentre randomised clinical trial (RCT) aims to investigate the effect of customised prefabricated FOs in reducing pain amongst children and adolescents with JIA.
Methods: Overall, 66 children and adolescents with JIA presenting with foot symptoms were recruited from the Sydney Children's Hospitals Network (Westmead and Randwick) and John Hunter Children's Hospital (Newcastle). The primary outcome measure was pain with a minimal clinical significance of 8mm on the visual analogue scale (VAS). Participants were randomly allocated to receive either customised prefabricated or sham FOs. The trial intervention was a low-density Slimflex Simple device that was customised at chair-side. The control (sham) device was made of 2mm flat leather board with no corrective modifications. Standardised tests such as the Foot Posture Index, navicular drift and drop were used to identify biomechanical abnormalities. The FOs were worn for a total of 12 months, with data collected at baseline, 4 weeks, 3, 6 months and 12 months.
Results: Reduction in self-reported pain was statistically and clinically significant at 4-weeks (p=0.018, -14.92 [-27.30, -2.55]) and 3 months (p=<0.001, -28.93 [-40.90, -16.96]) post intervention in favour of the trial group. The 6- and 12-month follow-ups were not statistically or clinically significant. Parent reported pain was statistically and clinically significant at the 3-month (p=<0.001, -21.92 [-33.16, -10.67]) in the reduction of pain in favour of the trial group. However, parent reported pain was not statistically significant at the 4-week, 6- and 12- month follow-ups. These results are similar to child reported pain with a p-value of less than 0.001 and average coefficients twice that of the clinical significance cut-off for VAS pain in paediatric rheumatology. The trial intervention was safe and tolerated well by participants with high compliance and adherence rates.
Conclusion: Results of this clinical trial indicate customised preformed FOs can be effective in reducing pain and in children with JIA experiencing foot and ankle symptoms. Significant clinical effects appear to be within the first 3-months of intervention prescription and reduce beyond 6 months. Overall, this podiatric intervention was safe, inexpensive, well tolerated and it can be easily implemented as part of the multidisciplinary paediatric rheumatology care.

OP0208-HPR EFFECT OF AN 8-WEEK SPECIALIZED PHYSICAL THERAPY PROGRAM ON SEXUAL HEALTH IN FEMALE PATIENTS WITH SYSTEMIC SCLEROSIS AND IDIOPATHIC INFLAMMATORY MYOPATHIES: A PILOT STUDY

B. Heřmánková[1,2], M. Špiritović[1,2], S. Oreska[1,3], H. Štorkánová[1,3], K. Pavelka[1,3], L. Šenolt[1,3], J. Vencovský[1,3], R. Bečvář[1,3], M. Tomčík[1,3]. *[1]Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic; [2]Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic; [3]First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*

Background: Systemic rheumatic diseases like systemic sclerosis (SSc) and idiopathic inflammatory myopathies (IIM) may affect all aspects of life, including sexual health However, no non-pharmacological treatment has been proposed to date.
Objectives: This is the pilot project aiming to investigate the effect of an 8-week physical therapy program on sexual function in women with SSc and IIM.
Methods: In total, 12 women with SSc and 4 women with IIM, who fulfilled the ACR/EULAR 2013 criteria for SSc and the Bohan/Peter 1975 criteria for DM/PM, respectively, were enrolled in the study. Based on patient's possibilities and willingness to participate in the program, they were divided into an intervention group (IG) (6 SSc/2 IIM, mean age: 46.8±3.1 years) and a control group (CG) (6 SSc/2 IIM, mean age: 46.3±3.0 years). The IG underwent the 8-week tailored physiotherapy program, including the pelvic floor exercise and physiotherapy of musculoskeletal problems subjectively limiting the patient's sexual function (1 hour supervised physiotherapy twice weekly), whereas the control group received no specialized therapy. At weeks 0 and 8, all patients filled in questionnaires assessing sexual function: Female Sexual Function Index (FSFI), Brief Index of Sexual Functioning for Women (BISF-W); sexual quality of life: Sexual Quality of Life-Female (SQoL-F); functional ability: Health Assessment Questionnaire (HAQ); quality of life: Medical Outcomes Short Form-36 (SF-36) and depression: Beck's Depression Inventory-II (BDI-II). At the baseline, patients in IG were assessed by a physician (medical history, mRSS, ESSG activity score, MITAX, MYOACT) and by a physiotherapist (pelvic floor function assessment–PERFECT scheme, MMT-8, Functional Index-II). Normality of data was tested, and inter-group analysis was performed with 2-way ANOVA and intra-group analysis by Friedmann's test.
Results: Compared to observed statistically significant deterioration in CG over the period of weeks 0-8, we found statistically significant improvement in both sexual function questionnaires: FSFI (p=0.043), BISF-W (p=0.040), functional status: HAQ (p=0.018), and quality of life: SF-36 Physical Somponent score (0.050). Only numerical improvement in IG compared to numerical deterioration in CG, which has not reached statistical significance, was observed in SQoL-F, BDI-II, and SF-36 Mental Component Score.
Conclusion: Our physiotherapy program not only prevented the natural course of progressive deterioration of functional abilities, but also led to a significant improvement in sexual function and overall quality of life in women with SSc and IIM. Physical therapy might become one of the possible therapeutic treatments for sexual problems in women with SSc and IIM.

OP0209-HPR BRIDGE – A QUALITY IMPROVEMENT PROGRAM IN TEAM-BASED REHABILITATION: RESULTS FROM A MIXED METHODS STUDY

A. L. Sand-Svartrud[1], G. Berdal[1], G. J. Aanerud[2], M. Azimi[3], T. N. Dager[1], C. van den Ende[4], I. Johansen[5], H. Lindtvedt Valaas[6], H. Solveig Dagfinrud[1], I. Kjeken[1]. *[1]National Advisory Unit on Rehabilitation in Rheumatology,*

Division of Rheumatology and Research, Oslo, Norway; [2]*The Norwegian Rheumatism Association, NRF, Oslo, Norway*; [3]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; [4]*Sint Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands*; [5]*Institute of Health and Society, Department of General Practice, University of Oslo, Oslo, Norway*; [6]*Vikersund Rehabilitation Center AS, Center for Rehabilitation and Coping, Vikersund, Norway*

Background: There is a well-known variability in the quality of rehabilitation provided to patients with rheumatic and musculoskeletal diseases (RMDs). Elements to be improved are a higher standardization of the core content, optimal patient participation in goal setting and continuation of the process in tailored follow-up. More knowledge is needed on critical features for successful delivery of improvement programs in rehabilitation.
Objectives: To investigate how a team-based quality improvement program was implemented and how it influenced the quality in RMD rehabilitation.
Methods: This convergent mixed methods study is nested within a stepped-wedge, randomized controlled trial where providers at 8 rehabilitation-centers delivered traditional programs in the control phase (T1), and added the BRIDGE quality improvement program in the intervention phase (T2). The BRIDGE program addressed a dialog-based, multidisciplinary approach to support the patients' self-management, comprising motivational interviewing, goal setting, plans for rehabilitation, feedback and monitoring of progress, and tailored follow up. Providers answered 19 structure indicators from a quality indicator (QI) set for RMD rehabilitation [1] at T1 and T2, and a program-fidelity checklist with 18 items at T2 (both scored 0-100%, 100=best). Qualitative data was collected in three focus groups (FG) with the BRIDGE providers, and analyzed using reflexive thematic analysis. Integration and discussion of findings from the different data sources are ongoing, in our research group.
Results: Median summary pass rate for the structure QIs for all centers increased from 53 to 90% between T1 and T2. Program-fidelity was high, with a median summary score of 94% (range 6–100%), but lowest for program-components related to follow-up and communication with external services. Themes developed from the FG interviews reflected that variations in how the program was implemented related to features of the providers and institutions. More specific; the delivery of high-quality rehabilitation depended on the degree to which the providers trained their communication skills, used available tools to support their practice, and grounded their interventions in professional reasons. Critical organisational features at the institutions were dedicated time for team-work based on the patients' plans for self-management, and sufficient attention to needs for involvement of next of kin or external services. Additionally, better program-implementation occurred if providers experienced an institutional culture for quality improvement, such as educational initiatives from the leaders.
Preliminary integration of data is summarized in Figure 1. Congruent evidence in both quantitative and qualitative findings addressed the sustained needs for better quality in the area of follow-up across levels of care. However, the qualitative findings provided expanded insights on variability also in initial parts of the rehabilitation process. Presumably, these variations in delivery reported in interviews are important for the effectiveness of a quality improvement program, but difficult to capture in questionnaires.

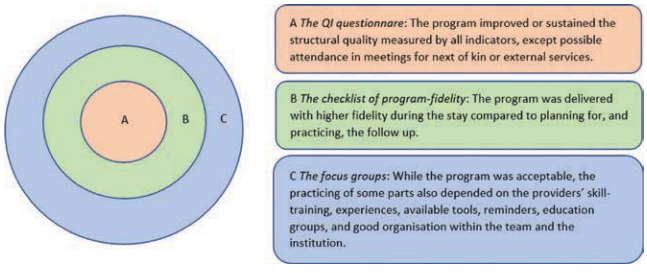

Figure 1. Complementary viewpoints on how the BRIDGE program was provided and how it influenced the quality of rehabilitation.

Conclusion: To target specific strategies for quality improvement, we suggest a combined attention not only to recommended care reflected in quality indicators and measurable aspects of fidelity, but also to contextual factors, including the providers' confidence and skills needed to provide a high-quality delivery of all components in a rehabilitation improvement program.

OP0210-HPR

THE OCCURRENCE OF OVERWHELMING FATIGUE IN INDIVIDUALS WITH KNEE OSTEOARTHRITIS: A DAILY DIARY STUDY

M. W. J. Heijman[1], C. van den Ende[1], C. Popa[2,3], J. E. Vriezekolk[1]. [1]*Sint Maartenskliniek, Research, Nijmegen, Netherlands*; [2]*Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*; [3]*Radboudumc, Rheumatology, Nijmegen, Netherlands*

Background: Cross sectional research shows that nearly half of the individuals with osteoarthritis (OA) experience fatigue and over one third experience severe fatigue (1). However, few studies have addressed the unpredictable and fluctuating course of fatigue in OA including the occurrence of overwhelming fatigue as evidenced from qualitative research (2). In-depth understanding of the course of fatigue and its determinants may inform clinical decision making and treatment.
Objectives: To explore 1) the occurrence of overwhelming fatigue and its determinants and 2) the variability of daily experienced fatigue in individuals with knee OA.
Methods: A daily diary design. 73 participants with a self-reported diagnosis of knee OA aged >40 years and in possession of a Smartphone completed a baseline questionnaire on demographics, health status (EQ5D-VAS), and self-efficacy (Arthritis Self-Efficacy Scale (ASES)). This was followed by daily assessments with regard to overwhelming fatigue, fatigue severity, pain, sleep, and perceived exertion of physical activities (PEPA) over a 7 day period. A yes/no format was used to assess overwhelming fatigue and a numeric rating scale (NRS, 0-10) was used to assess fatigue severity, pain, sleep, and PEPA. The variability of fatigue was assessed by calculating the standard deviation (SD) per participant over this 7 day period. Comparisons between participants with and without overwhelming fatigue were conducted by unpaired t-tests and Pearson's chi-square tests where appropriate.
Results: 47 participants were included in the analysis. Overwhelming fatigue occurred at least once in 26 (55%) participants with mean= 2.7 (SD= 1.4) over a 7 day period. Differences of participants with and without overwhelming fatigue are displayed in Table 1.

Table 1. Characteristics of participants (n=47) included in the analysis.

Characteristics*	All participants (n=47)	Participants with overwhelming fatigue (n=26)	Participants without overwhelming fatigue (n=21)	Difference (95% CI)	p-value
Age	63.4 (8.6)	61.7 (8.5)	65.5 (8.5)	-3.8 (-8.8; 1.2)	0.13
Female (n (%))	39 (83%)	23 (88%)	16 (76%)		0.47
BMI	27.4 (4.6)	28.0 (5.1)	26.5 (3.8)	1.5 (-1.1; 4.1)	0.25
Health status	67.5 (13.8)	66.0 (13.5)	69.5 (14.2)	-3.5 (-11.7; 4.7)	0.39
ASES pain	2.9 (1.0)	3.2 (0.8)	2.5 (1.1)	0.7 (0.1; 1.3)	0.02
ASES os	2.5 (0.8)	2.7 (0.8)	2.2 (0.7)	0.5 (0.1; 1.0)	0.02
Fatigue severity	4.9 (1.7)	5.5 (1.5)	4.1 (1.6)	1.3 (0.4; 2.3)	0.01
Pain	4.2 (1.9)	4.8 (1.6)	3.4 (2.0)	1.4 (0.3; 2.5)	0.01
Sleep	5.9 (1.6)	5.5 (1.7)	6.4 (1.4)	-0.9 (-1.8; -0.0)	0.05
PEPA	4.9 (1.2)	5.0 (1.2)	4.8 (1.3)	0.2 (-0.6; 0.9)	0.64

ASES, Arthritis Self-Efficacy Scale; ASES os, other symptoms; PEPA, perceived exertion of physical activities. For health status, ASES pain, ASES os, and sleep, higher scores reflect better outcomes; for PEPA, higher scores reflect more PEPA; for fatigue severity and pain, higher scores reflect higher levels. *mean (SD) unless otherwise statedg.

The variability of daily experienced fatigue per participant ranged from SD= 0.2 to 2.9 (Figure 1). This was not significantly different between participants with and without overwhelming fatigue.

Figure 1. ***Standard deviations of average fatigue severity over a 7 day period per participant (n=47).***

Conclusion: Our findings suggest that more than half of the participants experienced at least one episode of overwhelming fatigue and that this is related to self-efficacy, fatigue severity, pain, and sleep. Fatigue remained fairly stable over time by the majority of participants.

EXPERIENCES DURING THE COVID-19 PANDEMIC AMONG PEOPLE WITH INFLAMMATORY ARTHRITIS. "REOPENING OF SOCIETY IS HARDER THAN LOCK-DOWN" - A QUALITATIVE INTERVIEW STUDY

L. Lund[1], M. Løwe[1], O. Hendricks[2], K. Schreiber[2], B. Glintborg[3], R. Petersen[2], C. Plischke[4], W. Fick[4], J. Primdahl[2,5]. *[1]University College UC SYD, Esbjerg, Denmark, Research Center of Applied Health Science (SuPra), UC SYD, Esbjerg, Denmark, Esbjerg, Denmark*; *[2]Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark, Department of Regional Health Research, University of Southern Denmark, Odense, Denmark, Sønderborg, Denmark*; *[3]DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, University Hospital of Copenhagen Rigshospitalet, Glostrup, Denmark, Department of Clinical Medicine, Faculty of health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, Copenhagen, Denmark*; *[4]Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark, Patient Research Partner, Sønderborg, Denmark*; *[5]University Hospital of Southern Denmark, Aabenraa, Denmark, Sygehus Sønderjylland, Aabenraa, Denmark, Aabenraa, Denmark*

Background: People with inflammatory arthritis (IA) treated with conventional or biological immunosuppressive disease-modifying anti rheumatic drugs (DMARDs), were initially considered to have an increased risk of severe illness from SARS-CoV-19 (COVID-19) infection compared to the general population. Although resent studies have not confirmed this, people with IA have reported high level of anxiety and self-isolation during the pandemic (1). Only few studies have qualitatively explored how people with IA experience the impact the COVID-19 pandemic and the SARS-CoV-19 vaccinations.
Objectives: To explore how people with IA experienced restrictions during the COVID-19 pandemic and the possible impact of vaccination on their protection against COVID-19 and their everyday lives.
Methods: Semi-structured in-depth interviews were conducted via telephone or video with 19 people with IA in May – August 2021, shortly after they were enrolled in the national COVID-19 vaccination programme (all Danish citizens >18 years of age invited for SARS-CoV-19 vaccination, free of charge, with timing depending on age and comorbidities). At the same time, society gradually reopened after a complete lock-down. Qualitative content analysis, inspired by Graneheim and Lundman (2), was applied to analyse the data. Two patient research partners were involved in development of the study protocol, an interview guide and in the interpretation of findings.
Results: The participants' age ranged from 21 to 64 years, median 50 years. 7 male and 12 female, all diagnosed with IA (Psoriatic arthritis n=4, Axial Spondyloarthropathy n=4, Rheumatoid arthritis n=9, and Juvenile arthritis n=2) and 14 were treated with DMARDs. Two had not accepted vaccination.
The analysis derived five themes: 1: *"Changing and divergent information".* The participants experienced there was an overload of general information to the public, while targeted information on the specific risk for people with IA was lacking; 2: *"Individual interpretation of own risk",* reflecting that participants had to find their own level of daily-life restrictions, a task they found to be very difficult; 3: *"Impact on everyday life".* They took self-imposed precautions to protect themselves and their families from attracting COVID-19; *4*: *"Position in society and the vaccination programme",* emphasizing that participants were affected by the inconsistent announcements from authorities whether they were considered to be in particular risk or not, and some expressed concerns regarding the DMARDs influence on the effect of the vaccine and 5: *"Reopening is somehow harder than lock down".* A societal spirit of being "in this together" emerged through the lock-down and some were concerned that fewer restrictions during reopening of the society would put them in higher risk of a COVID-19 infection and force them to continue self-isolation.

Table 1. Quotation to illustrate the findings

"… you felt like one in the crowd and then everything is easier. Even though it was difficult. But then; it was difficult for all of us. It had nothing to do with my rheumatic disease… we were in this together... But it was harder when the reopening started. Because it´s like; I'm back on the platform and can't just jump on the train, can't go anywhere, that is...I'm just not quite ready to jump into society like everyone else..."

Conclusion: The COVID-19 pandemic affected the everyday lives of people with IA due to the authorities' restrictions and further self-imposed precautions throughout lock down and reopening of society. People with IA experienced a lack of consistent information and felt alone to assess their own SARS-Cov-19 infection risk.

OP0212-HPR

PATIENT ASSESSMENT CHRONIC ILLNESS CARE (PACIC) AND ITS ASSOCIATIONS WITH QUALITY OF LIFE AMONG SWISS PATIENTS WITH SYSTEMIC SCLEROSIS – A MIXED METHODS STUDY

A. Kocher[1,2], M. Simon[1,2], A. A. Dwyer[3,4], C. Blatter[1], J. Bogdanovic[1], P. Künzler-Heule[1,5], P. Villiger[6], D. Dan[7], O. Distler[8], U. Walker[9], D. Nicca[1,10]. *[1]Institute of Nursing Science (INS), University of Basel, Department Public Health (DPH), Basel, Switzerland*; *[2]Inselspital, Bern University Hospital, Department of Nursing, Bern, Switzerland*; *[3]Connell School of Nursing, Boston College, Chestnut Hill, Massachusetts, United States of America*; *[4]Munn Center for Nursing Research, Massachusetts General Hospital, Boston, Massachusetts, United States of America*; *[5]Cantonal Hospital St. Gallen, Department of Gastroenterology/Hepatology and Department of Nursing, St. Gallen, Switzerland*; *[6]Medical Center, Monbijou, Bern, Switzerland*; *[7]Lausanne University Hospital, University of Lausanne, Service of Rheumatology, Lausanne, Switzerland*; *[8]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*; *[9]University Hospital Basel, Department of Rheumatology, Basel, Switzerland*; *[10]Institute for Epidemiology, Biostatistics and Prevention, University of Zurich, Department of Global and Public Health, Zurich, Switzerland*

Background: Variable disease presentation and symptom burden in patients living with systemic sclerosis (SSc) require a chronic care approach including competent, coordinated, multidisciplinary collaboration as well as self-management support targeting individual patient needs. The Chronic Care Model (CCM) is a longstanding and widely adopted model guiding chronic illness management.[1] Little is known about how CCM elements are implemented in SSc care or how patients' care experiences relate to health-related quality of life (HRQoL).
Objectives: First, to describe current SSc care in Switzerland according to the CCM from the patient perspective and examine relationships with HRQoL. Second, to explain these results by patients' illness and care experiences.
Methods: We employed an explanatory sequential mixed methods design (Figure 1). First, we conducted a cross-sectional quantitative survey (n=101 Swiss patients) using the Patient Assessment of Chronic Illness Care (PACIC-20)[2] and Systemic Sclerosis Quality of Life (SScQoL)[3] questionnaires. Because PACIC has not been used in the context of SSc, we used the Mokken model to test the construct validity of the PACIC scale and its subscales. After excluding five problematic items, *H* coefficients were 'strong' for the subscales and the global scale (0.52) suggesting a robust unidimensional scale.

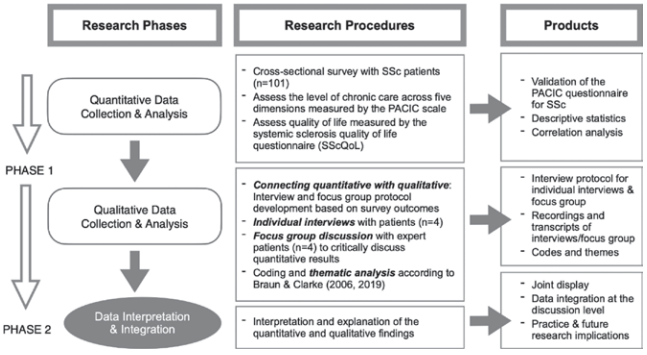

Figure 1. Schematic of the explanatory, sequential mixed methods design

Next, we used data from individual patient interviews (n=4) and one patient focus group (n=4) to further explore care experiences of people living with SSc with a focus on the PACIC dimensions.
Results: The mean overall PACIC-15 score was 3.0 / 5.0 (95% CI: 2.8–3.2, n= 100), indicating care was 'never' to 'generally not' aligned with the CCM. Lowest subscale scores related to 'goal setting/tailoring' (mean = 2.5, 95% CI: 2.2–2.7) and 'problem solving/contextual counselling' (mean = 2.9, 95% CI: 2.7–3.2) (Table 1). No significant associations were identified between the mean PACIC-15 and SScQoL scores.

Table 1. Summary of scores (n=101) for the 15-item PACIC scale (adapted version of the original 20-item scale)

	PACIC mean scores (95% CI)
PACIC 15-item mean score	3.0 (2.8–3.2)
1: Patient activation *(mean of items 1–3)*	3.4 (3.1–3.6)
2: Delivery system design/ Decision Support *(items 4–6)*	3.2 (3.0–3.4)
3: Goal setting/ Tailoring *(items 7–9)*	2.5 (2.2–2.7)
4: Problem solving/ Contextual Counselling *(items 12–15)*	2.9 (2.7–3.2)
5: Follow-up/ Coordination *(items 19–20)*	3.3 (3.0–3.5)

Note: CI=Confidence interval; PACIC=Patient Assessment of Chronic Illness Care

Interviews revealed patients frequently encounter major shortcomings in care including *experiencing organized care with limited participation, not knowing which strategies are effective or harmful and feeling left alone with disease and psychosocial consequences*. Patients often responded to challenges by *dealing with the illness in tailored measure, taking over complex coordination of care and relying on an accessible and trustworthy team.*

Conclusion: The low PACIC mean overall score is comparable to findings in patients with common chronic diseases. Key elements of the CCM have yet to be systematically implemented in Swiss SSc management. Identified gaps in care related to lack of shared decision-making, goal-setting and individual counselling –aspects that are essential for supporting patient self-management skills. Furthermore, there appears to be a lack of complex care coordination tailored to individual patient needs.

OP0213-HPR RECOMMENDATIONS FOR NURSES IN THE MANAGEMENT OF RA PATIENTS ON TREATMENT WITH JAKINIBS

J. M. Martín Martín[1], S. García-Díaz[2], A. Molina[3], C. Dominguez[4], L. Carmona[5], L. Cano Garcia[6]. [1]*Hospital Universitario Nuestra Señora de la Candelaria, Rheumatology, Santa Cruz de Tenerife, Spain*; [2]*Consorci Sanitari Integral, Rheumatology, L'Hospitalet de Llobregat, Spain*; [3]*University Hospital of Gran Canaria Dr. Negrin, Rheumatology, Las Palmas de Gran Canaria, Spain*; [4]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*; [5]*Instituto de Salud Musculoesquelética (Inmusc), -, Madrid, Spain*; [6]*Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain*

Background: The number of new treatments available in rheumatology continues to increase. Kinase inhibitors, or jakinibs, pose an added challenge due to their variety and because they are oral. The most important role of the rheumatology nurse is patient education, especially on how to take the medication. The better the nurse understands the drugs, the better their practical recommendations and decisions will be and the better they will be able to respond to the patient. Guidelines or recommendations for inflammatory diseases do not usually include key practical details for nurses. It is our understanding that these points that will subsequently determine adherence and safety should be specially addressed in a specific document for nurses.

Objectives: To establish practical, evidence-based nursing recommendations for the management of people with RA undergoing treatment with jakinibs.

Methods: To reach an evidence-based consensus we used systematic review and Delphi survey. A multidisciplinary panel of experts was formed with 6 rheumatology nurses, 2 rheumatologists, 1 psychologist, 1 dietician-nutritionist and 1 patient on treatment with jakinibs. This panel met on 2 occasions and was kept informed at all times of the progress of the project through the Miro platform. At the preparatory meeting the scope and users, structure and PICOt questions were established (these included efficacy and adverse effects, infections, cardiovascular risk, surgery, vaccination, pregnancy and breastfeeding, interactions and switches between jakinibs).

The steering group made recommendations based on the issues raised at the first meeting. Only those that achieved 65% in favour were included as items in a Delphi survey. The Delphi survey was sent to all members of the society nurses and rheumatologists (n=60). Voting ranged from 0 to 10 (strongly disagree to strongly agree). Items with more than 75% agreement in the first round did not proceed to a second round.

Results: The Table 1 shows the recommendations with their level of evidence and level of agreement after the Delphi (n=40; 67%). One item with only 50% agreement was rejected and did not proceed to a second round.

Table 1.

Recommendation	Level of evidence	Degree of agreement
Before starting treatment with a jakinib, it should be confirmed that the patient has no contraindications.	5	100%
The patient's efficacy and outcome expectations for the drug should be explored and those that need to be adjusted.	5	85%
It should be indicated that a double dose should not be taken if one is missed.	4	100%
As with other DMARDs, the patient should be instructed that close management will follow.	5	99%
The use of contraception and discontinuation of the drug is recommended in case of gestational desire or unplanned pregnancy.	3	96%
It is recommended to explain the warning signs of infection: fever, blisters, burning pain in the ribs, itching when urinating, productive cough, diarrhoea, pus-filled wounds, phlegmon.	1a	100%
It is recommended to instruct the patient on preventive measures for infectious diseases (dental and hand hygiene, HPV, social distance, etc.).	1a	89%
Vaccination against common germs in immunocompromised persons and shingles with the current vaccine is recommended.	1a	93%
CV risk factors should be monitored, and the patient trained for signs of thrombosis, HF or ischaemic heart disease.	1a	89%
Close monitoring of elderly patients (CV risk, infections) is recommended.	2	100%
Emphasis on adherence is recommended for jakinibs to be effective.	3	100%
Before surgery, discontinuation of jakinib should be scheduled depending on the type of surgery and comorbidities.	3	89%

Conclusion: These recommendations will allow a practical approach to the management of jakinibs by nurses and enjoy an adequate consensus among potential users.

Background: Health professionals in rheumatology (HPRs) should participate in post-graduate or continuous education to update and advance their knowledge and skills. This can improve patient outcomes and increase quality of care.[1] EULAR aims to become a leading provider of postgraduate education for HPRs.

Objectives: The aims of this study were to evaluate the current motivations for participating in postgraduate education of HPRs, identify barriers and facilitators for participation in postgraduate education, and evaluate participation in the current educational offerings of EULAR for HPRs across Europe.

Methods: An online survey was developed and distributed in collaboration with the EULAR Standing Committee of Education and Training (ESCET) and the Paediatric Rheumatology European Society (PReS). The questionnaire was translated by national HPR representatives in 24 languages to cover the 25 national member organisations. Barriers were assessed using 5-point Likert scales, higher scores representing higher barriers. Quantitative data were analysed using descriptive statistics. In addition, we ran the Latent Dirichlet Allocation (LDA) on the answers to the open questions. LDA is an unsupervised probabilistic topic modelling technique that extracts the meanings of a pre-defined number of topics. Design of the survey and reporting of results were done according to the Checklist for Reporting Results of Internet E-Surveys (CHERRIES).

Results: The online questionnaire was accessed 3,589 times but only 667 complete responses were recorded. HPRs from 34 European countries responded to the survey; 80% of whom were women. The highest-ranked educational need was prevention, including lifestyle interventions and professional development. Although EULAR was well known among HPRs, only 32.1% of HPRs in adult care and 18.6% of HPRs in paediatric care have ever heard of the EULAR School of Rheumatology (Table 1 A).

Table 1. A: Feedback on EULAR. Data are presented separately for HPRs in adult and paediatric care; except for the filter questions, no mandatory questions were included in the survey. To clarify the number of responses per question, the number of valid answers for each question was reported.

Variables	HPRs in adult care	HPRs in paediatric care
Have you ever heard of the EULAR School of Rheumatology?	614	43
I am not sure, n(%)	62 (10.1%)	7 (16.3%)
No, n(%)	355 (57.8%)	28 (65.1%)
Yes, n(%)	197 (32.1%)	8 (18.6%)
Are you aware of courses offered by the EULAR School of Rheumatology? (sub question)	197	8
I am not sure, n(%)	30 (15.2%)	2 (25.0%)
No, n(%)	63 (32.0%)	5 (62.5%)
Yes, n(%)	104 (52.8%)	1 (12.5%)
Have you ever attended one of the EULAR School of Rheumatology courses? (sub question)	103	1
I am not sure, n(%)	1 (1.0%)	0
No, n(%)	47 (45.6%)	0
Yes, n(%)	55 (53.4%)	1 (100%)
Have you ever participated in a EULAR annual congress meeting?	618	43
I am not sure, n(%)	11 (1.8%)	0
No, n(%)	457 (73.9%)	39 (90.7%)
Yes, n(%)	150 (24.3%)	4 (9.3%)

The main barriers to participation in EULAR's educational offerings were identified by HPRs in adult care and in paediatric care (respectively) as: the unfamiliarity with the course content (3.48 [±1.50]; 3.92 [±1.46]), the associated costs (3.44 [±1.35]; 3.69 [±1.28]) and English language (2.59 [±1.50]; 2.80 [±1.34]).

Conclusion: EULAR is well-known by HPRs in Europe, however, awareness of educational offerings is low and barriers to participation are numerous. To become the leading provider of postgraduate training by 2023, EULAR could use a "franchise" model that can be tailored to local conditions. This could be achieved by strengthening national organizations by actively involving them in the development of training programs and disseminating these programs and offerings through their networks.

Figure 1: Worldmap of the respondents in this survey. The graph below shows the distribution of the HPRs' responses according to the geographical distribution.

Improving outcomes for children with JIA

OP0215

WHAT DOES THE PATIENT WELL-BEING VAS TELL US WHEN THE PHYSICIAN GLOBAL ASSESSMENT SCORE IS ZERO? ANALYSIS OF A LARGE MULTINATIONAL DATASET

M. Burrone[1], R. Naddei[1], F. Ridella[2], C. Trincianti[2], C. Herrera Mora[3], C. Malagon[4], A. Ibañez[5], O. Arguedas[6], N. Ruperto[1], A. Ravelli[1], A. Consolaro[1]. *[1]IRCCS Istituto Giannina Gaslini, Clinic of Paediatrics and Rheumatology, Genoa, Italy*; *[2]Giannina Gaslini Institute, University of Genova, Genova, Italy*; *[3]Hospital de Niños Roberto Gilbert Elizalde, Reumatología, Guayaquil, Ecuador*; *[4]Hospital Universitario Simon Bolivar, Clínica Infantil Colsubsidio, Bogota, Colombia*; *[5]National Institute Salud del Nino, Rheumatology, Lima, Peru*; *[6]Hospital Nacional De Ninos Dr. Carlos Saenz Herrera, Immunology, San Josè, Costa Rica*

Background: Parent- and child-reported outcomes (PCROs) are measures that reflect the parent and child perception of rheumatic disease course and effectiveness of therapeutic interventions. Among PCROs for the assessment of patients with juvenile idiopathic arthritis (JIA), the most widely adopted is the parent/patient global evaluation or well-being visual analogue scale (WB-VAS). Several studies in JIA have highlighted the discrepancies in the assessment of the disease status between the physician and the parent/patient. This difference might be due to the WB-VAS measuring a broader construct than the physician global assessment (PGA).

Objectives: To evaluate, in a large multinational sample of JIA patients, the disease characteristics of subjects considered as inactive by the physician with an increased WB-VAS score.

Methods: Data from the multinational dataset of patients enrolled in the Epidemiology Treatment and Outcome of Childhood Arthritis (EPOCA) study were analyzed. We have included only subjects with a PGA score of 0. PCROs were collected through the juvenile arthritis multidimensional assessment report (JAMAR). We compared demographic features, socio-economic status, level of education, subtype of JIA diagnosis and the main PCROs (pain level, presence of morning stiffness, count of joints with swelling or pain, functional ability, disease activity level, ongoing therapy, presence of medications side effects and health related quality of life measured with the pediatric rheumatology quality of life (PRQL) scale) between subjects with WB-VAS ≤ 1 and > 1.

Results: A total of 3537 patients were sorted into two groups according to the WB_VAS score: 2862 subjects were included in a first group (WB_VAS ≤1); 675 in a second one (WB-VAS >1). Respectively, 17,6% and 18,1% of families belonged to the lower socio-economic status, 70,5% and 71% to the intermediate, 11,9% and 10,8% to the higher. The percentages of patients in the three levels of education was not different in the two groups:20,2% and 22% in the lower, 48,9% and 50,1% in the intermediate, 30,8% and 27,9% in the higher level of education. No significant difference was observed in the distribution of JIA categories in the two groups. Subjects in first group were younger at disease onset (5.6 vs 6.4 years). Comparison of main PCROs results is presented in the Table 1 below.

Table 1.

PCROs	WB_VAS ≤1	WB_VAS >1	p
VAS_Pain (mean)	0.3 (0.9)	2.4 (2.4)	<0.001
Presence of morning stiffness (%)	227 (8.0)	285 (42.4)	<0.001
Patients under treatment (%)	1919 (67.2)	540 (80.2)	<0.001
Reporting side effects (%)	421 (22.1)	236 (43.9)	<0.001
Number of adverse events to the therapy (mean)	0.2 (0.7)	0.8 (1.5)	<0.001
Juvenile Arthritis Functionality Scale (JAFS)Total Score (mean)	0.5 (1.6)	3.0 (4.4)	<0.001
JIA Quality of Life (JQL) Total Score (mean)	1.6 (2.3)	6.4 (4.4)	<0.001
VAS-Disease Activity (mean)	0.4 (1.3)	2.3 (2.4)	<0.001
Count of active joints (mean)	0.2 (0.7)	1.4 (2.2)	<0.001

Conclusion: We have analyzed the variables that might determine a difference between the physician's assessment of inactive disease and the parent's/patient's perception of well-being. In particular, socio-economic status, level of education, and gender representation seem not to impact on the general perception of well-being, while pain seems to have the greatest influence on the parent/patient quality of life assessment. Finally, children with lower WB-VAS score were younger at disease onset.

Background: The lack of pediatric classification criteria for axial disease is a major impediment to the conduct of clinical trials for juvenile spondyloarthritis (JSpA).

Objectives: We aimed to develop classification criteria for axial JSpA that will enable identification of a more homogeneous group representative of children with SpA and axial disease for entry into observational or clinical trials. These criteria are not intended to capture all possible subjects, but instead most patients with shared key features of axial disease. Treatment and diagnostic decisions should adhere to evidence-based recommendations.

Methods: 304 cases with JSpA and suspected axial disease from 6 international centers were collected on a standardized case report form; all had an MRI that was reviewed by an independent team of experts in musculoskeletal imaging. Candidate criteria were developed in an earlier phase of the project through an iterative process that included an international Delphi exercise for item generation, systematic literature review, and an item reduction exercise. Using the preliminary candidate criteria, 14 international clinical SpA experts scored and rank-ordered 20 representative SpA cases. During four, 3-hour virtual meetings, the clinical expert panel reviewed the interrater reliability of case ranking, refined the criteria definitions and domain levels, and participated in a multi-criterion decision consensus methodology exercise to generate relative weights of the criteria. The expert panel assessed whether the criteria weighting was in accordance with their consensus clinical judgment as a test of face validation of the weighting/scoring system and revisions were made as necessary. Next, 30 cases from the derivation cohort were scored and ranked using the relative weights for each category and domain. Each expert independently determined the score or "threshold" below which they were no longer confident enough that a patient had axial disease to enroll the child in a Phase 3 randomized clinical trial of a drug with unclear efficacy and safety. Results of this exercise were discussed and a provisional threshold score for classification was achieved by consensus.

Results: The preliminary axial disease criteria for JSpA included the PRINTO provisional criteria for enthesitis/spondylitis-related JIA or a rheumatologist diagnosis of SpA as obligatory entry criteria as well as additive weighted criteria for 7 domains (SIJ active inflammation on imaging, SIJ structural lesions on imaging, pain chronicity, pain pattern, pain location, morning stiffness, and genetics) (Figure 1). Interrater reliability of the pre-consensus meeting case rankings was poor

(Kendall's correlation coefficient was 0.20 for clinical data-only and 0.23 for clinical plus imaging data). The multi-criterion decision analysis was repeated for the imaging domains when the initial criteria weighting was not in accordance with the expert panel's opinion. The multi-criterion decision analysis involved a total of 58 pairwise decisions agreed by expert consensus. After criteria weights and additive scores were re-calculated, experts reached consensus for axial disease in JSpA for all cases scoring 55 and greater.

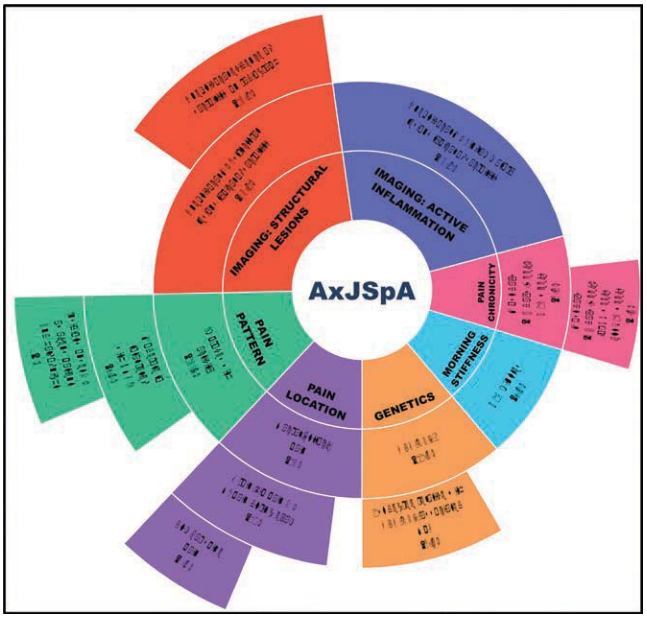

Figure 1. Axial juvenile spondyloarthritis (AxJSpA) classification criteria domains and levels. The first ring represents the domains and the items branching out are the levels moving from highest level (closest to center) to lowest level (farthest from center) in each domain. Assigned weights are shown below each item description.

Conclusion: Using an iterative process, the JSpA axial disease criteria definitions were refined, preliminary weights were generated, and a provisional threshold score for classification was determined. The most heavily weighted domains were active inflammation and structural lesions on imaging. Imaging typical of sacroiliitis was necessary, but not sufficient without any clinical criterion, to surpass the axial disease classification threshold.

Background: Tocilizumab (TCZ) has been approved for treatment of juvenile idiopathic arthritis (JIA) for 10 years.
Objectives: Evaluation of 12-month efficacy and safety of TCZ compared to TNF inhibitors (TNFi).
Methods: BIKER WA 29358 is a 5-year multi-centre prospective, observational cohort study including polyarticular JIA patients in Germany starting treatment between 2015 and 2020 with TCZ and matched 1:1 by date of treatment start and region to patients starting an approved TNFi. Clinical disease activity (JADAS10), JADAS MDA (≦3.8)/remission (≦1.0), safety and drug adherence at 12 months were assessed and compared between cohorts.
Results: The analysis included 342 participants with 12-month treatment data (TCZ n=171; TNFi n=171). TCZ was used as 2nd line biologic in the majority of patients (84%) while TNFi were mostly 1st line biologics (86%). Patients starting TCZ had a longer disease duration. Efficacy was demonstrated by a marked decrease in JADAS10 in both cohorts (TCZ vs. TNFi at baseline: 15.0+/-6.7 vs. 14.6+/-6.3; at month 12: 3.8+/-5.1 vs. 3.4+/-4.5). Proportions of patients in TCZ/TNFi cohorts achieving JADAS remission at 12 months were 48%/41% in 1st line biologic users and 32%/33% in 2nd line biologic users. JADAS MDA was achieved in 64%/69% in 1st line and 52%/58% in 2nd line users of TCZ/TNFi.
After 12 months of treatment JADAS10 (mean +/SD) was higher in the 2nd line TNFi cohort compared to the 1st line (4.5+/-5.6 vs. 3.2+/-4.3), similar to patients receiving 2nd or 1st line TCZ (4.0+/-5.2 vs. 2.9+/-4.4). Patients receiving TCZ or TNFi as first biologic reached JADAS10 remission and MDA numerically more frequently but not statistically significant compared to 2nd line users.
Safety was assessed based on adverse event (AE) reporting. 57 (33%) patients in the TCZ cohort and 43 (25%) patients in the TNFi cohort reported AE. The AE

Concomitant						
MTX, n (%)	120 (82%)	13 (54%)	133 (78%)	17 (63%)	75 (52%)	92 (54%)
Steroid, n (%)	37 (25%)	4 (17%)	41 (24%)	8 (30%)	35 (24%)	43 (25%)
Discontinuations, n (%)	5 (3.4%)	1 (4.2%)	6 (3.5%)	4 (16%)	28 (19%)	32 (19%)
-Inefficacy	1 (0.7%)		2 (1.2%)	3 (12%)	24 (17%)	27 (16%)
-Intolerance	2 (1.4%)	1 (4.2%)	2 (1.2%)		2 (1.4%)	2 (1.2%)
-Other	2 (1.4%)		2 (1.2%)	1 (4%)	4 (2.8%)	5 (3.0%)

rate was significantly higher in the TCZ cohort (69 vs. 44.8/100 patient years, RR 1.5 [95%CI 1.1-2.0], p=0.006, Wald-test). There were 6 serious AE in the TCZ and 3 in the TNFi cohort. Injection site reactions were more common in the TNFi cohort (9 vs. 1, p=0.043). No further differences were identified to date. There was no death and no opportunistic infection.

In the TCZ cohort, 32 patients discontinued treatment, 27 due to lack of efficacy, while in the TNFi cohort only 6 patients discontinued treatment. Treatment discontinuation was more frequent among the 2nd biologic users (n=29; 17.4%) than in first line users (n= 9; 5.1%).

Conclusion: In this first interim analysis, treatment targets were reached with similar frequency after 12 months of treatment with TCZ or TNFi. TCZ was used predominantly as 2nd line biologic. Higher rates of remission /MDA were observed in 1st line compared to 2nd line biologic users. Although more AE were reported in the TCZ cohort, the occurrence of serious AE and infections was comparable in both cohorts. No new safety signals were identified. Observation is ongoing.

Background: Psychiatric comorbidities can be a significant additional burden in chronic diseases. The most common chronic inflammatory rheumatic disease in children and adolescents is juvenile idiopathic arthritis (JIA). Data on mental illness in children and adolescents with JIA are heterogeneous.

Objectives: To assess the frequency of depressive and anxious symptoms in patients with JIA compared to healthy peers.

Methods: Data were analysed from JIA patients and healthy controls of the same age included in the inception cohort of newly diagnosed children and adolescents with JIA (ICON). Depressive symptoms (using the Patient Health Questionnaire (PHQ-9, score 0-27) and anxious symptoms (Generalised Anxiety Disorder Scale (GAD-7, score 0-21) were captured 7 or 9 years after inclusion in ICON in patients aged thirteen years or older at the time of filling in these questionnaires. Symptom severity for both instruments was assessed by sum score with the following cut-off values: PHQ-9 score < 5: none, 5-9: mild, 10-14: moderate, 15-19: severe, ≥ 20: very severe. GAD-7 Score < 5: none, 5-9: mild, 10-14: moderate, ≥ 15: severe. Disease parameters such as Physician Global Assessment of Disease Activity (PhGA Disease Activity, numerical rating scale, (NRS),0-10, 0=best), joint count (n) and patient-reported outcomes on functional limitations ((C)HAQ, score 0-3, 0=best), Patient Global Assessment of Well-being (PGA Well-being), pain and fatigue (NRS, 0-10, 0=best) were also documented.

Results: The analysis included 344 patients, 157 (45.6%) < 18 years old (mean 15.5 ± 1.5 years, 64.3% female), 187 (54.4%) ≥ 18 years old (mean 21.5 ± 2.1 years, 65.2% female) and 224 control subjects, 115 (51.3%) < 18 years old (mean 15.2 ± 1.5 years, 60% female), 109 (48.7%) ≥ 18 years old (mean 21.4 ± 1.9 years, 58.7% female). Almost 40% of patients had oligoarthritis (26% persistent OA, 12.5% extended OA), 27% rheumatoid factor (RF)-negative polyarthritis, 6% psoriatic arthritis, 17% enthesitis-related arthritis; 3% each had systemic JIA and RF-positive polyarthritis. In the total cohort, 14% of patients and 7% of controls had a PHQ-9 ≥ 10 and 10% of patients and 2% of controls had a GAD-7 ≥ 10. Within the categories of JIA, the rate of a PHQ-9 ≥ 10 ranged from 9.3% (oligoarthritis extended) to 33.3% (RF-positive polyarthritis) and a GAD-7 ≥ 10 ranged from 0% (systemic arthritis) to 22.2% (psoriatic arthritis).

Patients aged ≥ 18 years had higher scores for both PHQ-9 (≥ 10: 18.7%) and GAD-7 (≥ 10: 14.4%) compared to patients < 18 years (PHQ-9 ≥ 10: 8.3%, GAD-7 ≥ 10: 5.1).

In patients < 18 years with PHQ-9 < 10 versus ≥ 10, there were no significant differences in either PhGA disease activity (0.8±1.6 / 1.0±2.0, p = 0.673) or joint count (0.5±1.3 / 0.5±1.6, p = 0.999). In contrast, there was a significant difference in PhGA disease activity (0.8±1.5 / 1.6±1.4, p = 0.005) but not in joint count (0.7±3.1 / 0.8±1.3, p = 0.850) in patients ≥ 18 years with PHQ-9 < 10 versus PHQ-9 ≥ 10.

Female patients were more often found to have higher scores for depression and anxiety than male patients (PHQ-9 ≥ 10: female 17.5%, male 7.4%, GAD-7 ≥ 10: female 13.5%, male 4.1%) and patients more often had higher scores for depression than controls (PHQ-9 ≥ 10: female patients 17.5%, female controls 8.3%, male patients 7.4%, male controls 4.4%). The difference in the proportion of female patients with GAD-7 ≥ 10 (13.5%) compared to control subjects (2.3%) was remarkable, but in male patients this proportion (4.1%) was only slightly higher than in male control subjects (2.2%).

Conclusion: Depressive and anxious symptoms are common in adolescents and young adults with JIA, especially in females. In the continuous care of these patients, standardised diagnostic tools should be implemented to detect

these comorbidities, to optimise therapy and thereby reduce the burden of disease. Further research is needed to identify possible predictors of the development of depression and anxiety in JIA patients in order to pursue preventive approaches.

OP0219 HIGH INCIDENCE OF MIS-C AND OTHER AUTOIMMUNE DISEASES AFTER SARS-COV-2 INFECTION COMPARED TO COVID-19 VACCINATION IN PEDIATRIC POPULATION FROM SOUTH CENTRAL EUROPE

M. Bizjak[1], N. Emersic[1], M. Zajc Avramovič[1], T. Vesel Tajnšek[1], G. Markelj[1], S. Della Paolera[2], E. Conversano[2], V. Berce[3], N. Toplak[1,4], A. Taddio[2,5], T. Avcin[1,4]. [1]*University Children's Hospital, University Medical Centre Ljubljana, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia*; [2]*IRCCS "Burlo Garofolo", Institute for Maternal and Child Health, Trieste, Italy*; [3]*University Medical Centre Maribor, Division of Pediatrics, Maribor, Slovenia*; [4]*University of Ljubljana, Faculty of Medicine, Pediatrics, Ljubljana, Slovenia*; [5]*University of Trieste, Faculty of Medicine and Surgery, Trieste, Italy*

Background: In contrast to adults, children are less likely to develop serious disease upon infection with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) but are at increased risk for inflammatory and autoimmune diseases linked to the virus (1). The reported incidence of multisystem inflammatory syndrome in children (MIS-C) varied from 0.2 to 11.4/100,000 persons under 21 years (2,3). It is yet unknown whether MIS-C can recur after SARS-CoV-2 reinfection or COVID-19 vaccination.
Objectives: To estimate the incidence and describe the spectrum of inflammatory and autoimmune diseases linked to SARS-CoV-2 infection and coronavirus (COVID-19) vaccination in pediatric patients from two neighbouring South Central European countries and regions, Slovenia and Friuli Venezia Giulia (FVG), Italy.
Methods: We performed a multi-centre prospective cohort study of all children and adolescents (under 18 years) newly diagnosed with MIS-C or other inflammatory/autoimmune diseases linked to SARS-CoV-2 infection, who were admitted to the pediatric tertiary care hospitals in Slovenia or FVG, Italy during the period from January 1, 2020, to December 31, 2021. These hospitals serve a combined population of 587,053 children and adolescents. Only patients who had positive anti-SARS-CoV-2 antibodies and/or positive SARS-CoV-2 PCR test within 3 months prior to disease onset were considered for estimating the disease incidence. We obtained the number of patients with serious adverse events (SAE) after COVID-19 vaccination and the number of patients with severe COVID-19 in the same population. This study was conducted as a part of the EU interregional Italy-Slovenia project CATTEDRA (Cross border cooperation for innovative diagnosis of rare diseases in paediatrics).
Results: 192 children and adolescents were diagnosed with inflammatory and autoimmune diseases linked to SARS-CoV-2 (Figure 1). Median age at diagnosis was 11.9 years (IQR 7.6 -14.7). All included patients were White. Incidence of MIS-C was one in 921 children and adolescents after SARS-CoV-2 infection and one in 5870 of all children and adolescents. Cumulative incidence of MIS-C since the start of the pandemic was 17/100,000 children and adolescents. Until December 31, 2021, 92,139 children and adolescents (15.7 %) received at least one dose of COVID-19 vaccine. Three patients presented with inflammatory/autoimmune disease after COVID-19 vaccination, including 2 patients with MIS-C and one patient with myositis. All 3 had evidence of recent SARS-CoV-2 infection in form of positive anti-N SARS-CoV-2 antibodies. In the same period, 15 children and adolescents were hospitalised with severe COVID-19. Seven patients from our cohort were vaccinated against COVID-19 median 8 months after MIS-C and further 6 patients had a SARS-CoV-2 reinfection 3-14 months after MIS-C. None of them experienced SAE or recurrence of MIS-C.

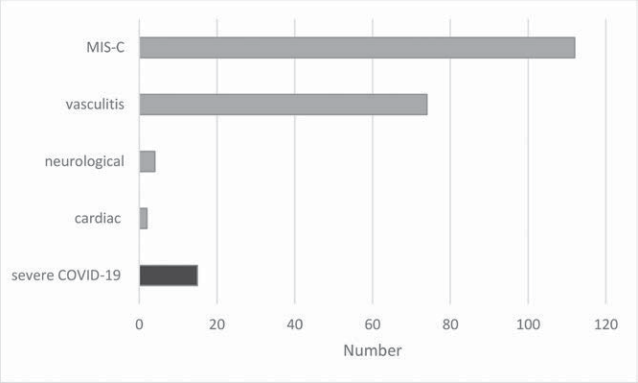

Figure 1. Inflammatory and autoimmune diseases linked to SARS-CoV-2 and severe COVID-19 in pediatric population in Slovenia and FVG, Italy

COVID-19=coronavirus disease, FVG=Friuli Venezia Giulia region in Italy, MIS-C=multisystem inflammatory syndrome in children, SARS-CoV-2=severe acute respiratory syndrome coronavirus 2
Conclusion: MIS-C was the most common manifestation and its incidence in this predominantly white population was higher than previously reported. Based on our limited experience, MIS-C does not seem to recur after SARS-CoV-2 reinfection or COVID-19 vaccination, however long-term data are lacking. Autoimmune diseases were much more common after SARS-CoV-2 infection than after COVID-19 vaccination. Hospitalisations due to MIS-C were seven times as frequent as hospitalisations due to severe COVID-19 in children.

Background: Treatment of children with juvenile idiopathic arthritis (JIA) is a major challenge in paediatric rheumatology. The presence of synovitis, which is difficult to detect in children, is associated with structural damage. Musculoskeletal ultrasonography (MSUS) can be used in JIA patients to reveal subclinical synovitis.
Objectives: Our aim was to determine if the use of MSUS is associated with therapeutic modifications in JIA. Secondary outcomes were to identify other factors associated with therapeutic modifications.
Methods: We conducted an observational study based on the JIRECHO multicentre cohort which was developed to provide a systematic MSUS follow-up for JIA patients. Follow-up occurred every six months and included clinical and US examinations. We included children who underwent MSUS of the elbows, wrists, second metacarpophalangeal joints, knees and ankles. Synovitis in US was defined by the presence of joint effusion and/or synovial hypertrophy in B-mode (≥ grade 1) associated or not with Doppler signals (≥ grade 1). US was performed by expert sonographers with good experience in the field of JIA who previously participated in the study of the reliability of

the OMERACT paediatric US synovitis definitions and scoring system in JIA (1). Clinical and biological data, disease activity score and information on therapeutics were collected.

Results: We included 112 patients with 185 visits in total. Three groups of patients were defined according to their therapeutic status: increased(22%), decreased(14%) or stable(64%) treatment. First, we compared patients with treatment escalation with the other patients. Patients with "increased treatment" had more synovitis in B-mode US than the other patients (80% vs. 65%, p=0.06). There was no difference for the presence of synovitis in Power Doppler (PD) US (30% vs 23%, p=0.4). Patient's and physician's visual analogue scale (VAS) scores were significantly higher in patients with therapeutic escalation [3.3 vs 1.7, p<0.01 and 3.6 vs 1.6, p<0.0001] as well as disease activity score and inflammatory biological markers. Then, we compared patients with therapeutic de-escalation with the other patients. There was no difference in the presence of synovitis in US when compared with patients with stable treatment (62% vs. 69%, p=0.5) but there was less synovitis in B-mode ≥ grade 2 (8% vs. 24%, p=0.05).

We performed ROC curves analysis that showed that the sensitivity and specificity of the US in B-mode was similar to the physician's VAS, disease score activity or inflammatory biological markers (Figure 1).

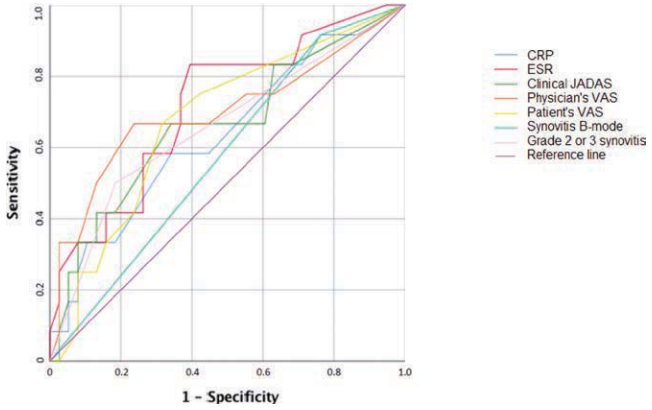

Figure 1. ROC curves for clinical and biological items and US in B-mode in patients with « therapeutic escalation »

Conclusion: In our study, MSUS of ten joints was not statistically associated with treatment escalation or de-escalation in B-mode and PD in patients with JIA.

Background: Enthesitis-related Arthritis (ERA) is a category of juvenile idiopathic arthritis (JIA) characterised by heterogeneous and insidious manifestations comprising axial and/or peripheral arthritis, and enthesitis.[1] Secukinumab (SEC) demonstrated efficacy and safety in both ERA and juvenile psoriatic arthritis (JPsA) in the JUNIPERA trial.[2]

Objectives: To evaluate the rate of flare risk reduction and efficacy of SEC on axial and peripheral manifestations in patients (pts) with active ERA.

Methods: ERA pts (2 to <18 years of age) with active disease (both ≥3 active joints and ≥1 active enthesitis site) were included. In the open-label (OL) treatment-period (TP)1, s.c. SEC (75/150 mg in pts <50/ ≥50 kg) was administered at baseline (BL), and at Week (Wk) 1–4, 8 and 12. Pts who achieved at least JIA-ACR30 response at Wk 12 were randomised into the double-blinded TP2 to continue SEC or placebo (PBO) every 4 wk until a disease flare, or up to Wk 100. The primary endpoint was time to flare in ERA and JPsA pts. The juvenile spondyloarthritis disease activity Index (JSpADA) is a disease activity assessment tool that contains 8 items to measure axial and peripheral disease activity.[3] Evaluation of axial and peripheral manifestations at the end of TP1 and TP2 in pts who experienced these symptoms at BL included modified Schober test (lumbar flexion), inflammatory back pain, FABER (Flexion, ABduction, External Rotation) test, JIA-ACR responses, Juvenile Arthritis Disease Activity Score (JADAS)-27, and resolution of enthesitis and dactylitis for peripheral disease. These outcomes were also used to assess JIA disease course at the end of TP2.

Results: A total of 52/86 (60.5%) pts with ERA were enrolled in the OL period TP1 (mean age, 13.7 years; male, 78.8%). In total, 51/52 (98.1%) pts completed TP1 and 41/44 (93.2%) completed TP2. At BL, mean JADAS-27 was 14.8, mean JSpADA index was 3.9, mean enthesitis and dactylitis counts were 2.7 and 0.4, respectively, mean number of active joints was 6.2 and of mean joints with limited range of motion 4.9. The relative risk reduction of experiencing a disease flare in TP2 was 55% (HR 0.45, 95% CI: 0.16–1.28, p=0.075) in ERA pts (Figure 1). The overall axial and peripheral disease symptoms improved over time and are presented in the Table 1. At the end of TP1, 84.6% (44/52) of pts achieved JIA-ACR 30 and 65.4% (34/52) achieved JIA-ACR 70. Clinically relevant reduction of functional ability as assessed by Childhood Health Assessment Questionnaire (CHAQ) also occurred (see Table 1).

Table 1. Resolution of axial and peripheral disease symptoms and JIA ACR responses at the end of TP1 and 2

Clinical response, mean (SD) change from BL (unless otherwise stated)	TP1-Wk 12	End of TP2*	
	SEC (N=52)	SEC (N=22)	PBO (N=22)
JSpADA index	–2.4 (1.7)	–2.7 (1.7)	–2.3 (2.1)
JSpADA Schöber, %	58.3	100.0	100.0
Inflammatory back pain, %	77.8	100.0	50.0
FABER test, %	52.6	100.0	83.3
Clinical sacroiliitis, %	53.3	100.0	50.0
Enthesitis	–2.2 (1.9)	–2.5 (2.1)	–1.3 (1.8)
Dactylitis	–0.2 (0.8)	–0.2 (1)	–0.1 (0.4)
JIA ACR30, %	84.6	90.9	68.2
JIA ACR50, %	78.8	81.8	68.2
JIA ACR70, %	65.4	68.2	54.5
JIA ACR90, %	32.7	45.5	50.0
JIA ACR100, %	26.9	36.4	45.5
Inactive disease, %	38.5	50.0	50.0
CHAQ	–0.5 (0.5)	–0.6 (0.7)	–0.4 (0.5)
CRP, median (SD) change from BL	–1.8 (38.7)	–5.8 (38.3)	0 (35.9)
JADAS-27	–9.6 (7.5)	–11.0 (8.9)	–7.6 (8.9)
Resolution of enthesitis#, %	72.3	78.6	83.3
Resolution of dactylitis#, %	50	66.7	0

*End of TP2 is based on individual pts' last visit at TP2. #At BL, in TP1, enthesitis (n= 46); dactylitis (n=5). In TP2, no. of pts who had presence at BL and showed complete resolution at the end of TP2: enthesitis, SEC 14, PBO 18; dactylitis, SEC 3, PBO, 0. CRP, C-reactive protein

Conclusion: In pts with ERA, SEC demonstrated longer time to disease flare vs PBO and exhibited rapid and sustained improvement of axial and peripheral manifestations up to Wk 104.

IDENTIFICATION OF CAUSAL GENES AND MECHANISMS BY WHICH GENETIC VARIATION MEDIATES JUVENILE IDIOPATHIC ARTHRITIS SUSCEPTIBILITY USING FUNCTIONAL GENOMICS AND CRISPR-CAS9

A. Frantzesko[1], V. Malysheva[2,3], C. Shi[1], J. Ding[1], J. Bowes[1,4], W. Thomson[1,4], S. Eyre[1,4], M. Spivakov[2,3], G. Orozco[1,4]. Background: We recently performed the largest juvenile idiopathic arthritis (JIA) genome-wide association study (GWAS) to date [1]. Disease-associated loci contain multiple single nucleotide polymorphism (SNPs), and the majority map to non-coding enhancers, making it challenging to define causal variants and genes. Functional genomics datasets in disease-relevant tissues have shown to be essential for the functional interpretation of GWAS loci. In particular, capture Hi-C (CHi-C) has been successful in detecting chromosomal interactions linking GWAS loci to their target genes. However, such datasets are lacking in JIA.
Objectives: The aim of this study is to bridge this gap and advance the knowledge of the biological mechanisms that underpin susceptibility to JIA, by integrating GWAS with public epigenomics datasets and in-house generated CHi-C from JIA patients. We focus on CD4+ T-cells, which have been shown to be one of the most relevant cell types in JIA. In addition, we use CRISPR-Cas9 to validate the regulatory effect of prioritised variants on their predicted target genes.
Methods: Credible SNP sets for the top JIA risk loci ($P < 5x10^{-6}$) were annotated using EpiMap data [2]. Low input whole genome promoter CHi-C (PCHi-C) was performed on CD4+ T-cells isolated from blood from 3 JIA oligoarthritis patients, and data was analysed using CHiCAGO [3]. GWAS and PCHi-C data were combined to prioritise causal genes using the Capture Hi-C Omnibus Gene Score (COGS) pipeline [4]. We subsequently employed CRISPR activation (CRISPRa) and CRISPR interference (CRISPRi) in Jurkats to assess whether prioritized JIA variants were capable of regulating the expression of the interacting genes.
Results: 614 credible SNPs (out of 735) were found to overlap active enhancers in CD4+ T-cells, and were prioritized for further analysis.
We identified numerous significant chromatin interactions in 19 out of 44 non-MHC JIA associated loci, linking JIA SNPs mapping to T-cell enhancers to a total of 61 target genes and revealing potential novel disease pathways. Moreover, COGS prioritised a total of 7 genes (*RGS14*, *ERAP2*, *HIPK1*, *CCR4*, *CCRL2*, *CCR2*, *CCR3*).
A JIA associated locus on chromosome 3 contains 39 SNPs. It maps to an intergenic region and the causal gene/s are unclear. Our PCHi-C data revealed that this JIA locus presents chromatin interactions with the promoters of several genes, such as *CCRL2*, *CCR2*, *CCR3* and *CCR5*, three of which were prioritised by COGS. Two variants were selected for further analysis: rs79815064, which had the highest posterior probability, and rs8005404,the only variant within a CD4+ T-cell enhancer linked to surrounding gene activity.
When both SNPs were targeted with CRISPRa and CRISPRi, we observed an increased and decreased expression, respectively, of *CCRL2*, *CCR2*, *CCR3* and *CCR5,* confirming their role in disease. These genes belong to the chemokine receptor family and are important regulators of the inflammatory response.
Conclusion: Our work shows how functional genomics can help identify biological mechanisms by which GWAS variants increase risk of JIA, which in turn will benefit patients through personalised medicine and the identification of therapeutic targets.

Background: Joint damage in the knee can be severe in both rheumatoid arthritis (RA) and osteoarthritis (OA) such that total knee replacement (TKR) is often the only management option. Pathological assessment of the extent or type of

synovial tissue inflammation from joint explants or biopsies can be useful. However, an ongoing challenge in using semi-quantitative assessments of synovitis is the disagreement between human pathologist scores of the same sample. We previously developed and validated a computer vision algorithm to automatically count each cell nucleus in an H&E-stained synovial whole slide image and yield a value of cell density, defined as mean nuclei count per mm^2 of tissue[1].

Objectives: We sought to develop methods to distinguish OA from RA based on machine learning analysis of histologic features on H&E-stained synovial tissue samples.

Methods: We measured 14 pathologist-scored histology features (137 RA and 152 OA patients) and computer vision quantified cell density (60 RA and 147 OA patients) in H&E stained synovial tissue samples from total knee replacement arthroplasty explants. A random forest model was trained using disease state (OA vs RA) as classifier and histology features and/or cell density as inputs, and feature importance scores for the model were calculated.

Results: Synovium from patients with RA exhibited increased lymphocytic inflammation, lining hyperplasia, neutrophils, detritus, plasma cells, Russell bodies, binucleate plasma cells, sub-lining giant cells, synovial lining giant cells, and fibrin (all $p<0.001$), while synovium from patients with OA had increased mast cells and fibrosis (both $p<0.001$). Fourteen pathologist-scored features allowed for discrimination between RA and OA samples, producing a macro-averaged area under the receiver operating curve (AUC) of 0.85. This discriminatory ability was comparable to that of the computer vision score of cell density alone (AUC = 0.88). Combining the pathologist scores with the cell density metric improved the discriminatory power of the model (AUC = 0.91). The three most important features in this combined model were mast cells followed by cell density and fibrosis (Figure 1). AUC values for each individual feature are provided in Table 1. The optimal cell density threshold to distinguish RA from OA synovium was 3,400 cells per mm^2, which yielded a sensitivity of 0.82 and specificity of 0.82.

Table 1. Area under receiver operating characteristic curves (AUC) of the synovial features in distinguishing RA and OA patients

Feature	AUC
Automated Cell Density	0.88
Fibrosis	0.84
Mast cells	0.80
Lining hyperplasia	0.78
Lymphocytic inflammation	0.69
Fibrin	0.68
Plasma cells	0.66
Detritus	0.64
Binucleate plasma cells	0.60
Neutrophils	0.60
Synovial giant cells	0.58
Sub-lining giant cells	0.57
Russell bodies	0.56
Germinal centers	0.51
Mucoid change	0.50

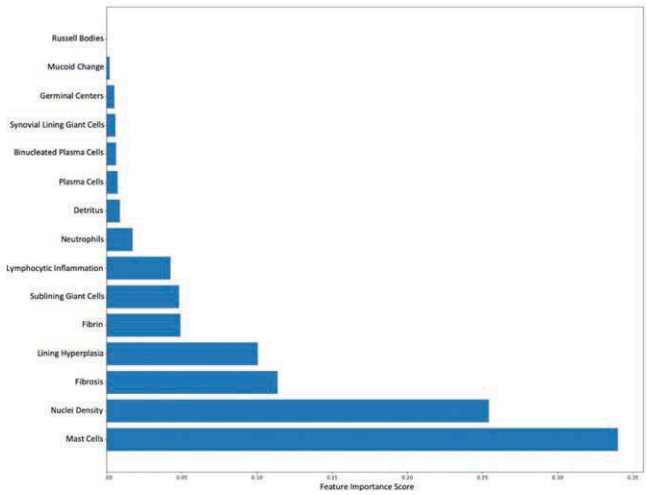

Figure 1. Importance of synovial features in distinguishing RA and OA synovium

Feature importance scores for supervised machine learning model including all 14 pathology scores and the computer vision-generated cell density.

Conclusion: H&E-stained images of RA and OA TKR explant synovium are distinct. We identified cell density, mast cells and fibrosis as the three most important features for making this distinction, with RA being characterized by increased cell density, low mast cells, and low fibrosis. Cell density greater than 3400 per mm^2 of tissue yields a sensitivity of 0.82 and a specificity of 0.82 for distinguishing RA from OA. In the future, this can have clinical and research applications as this technique removes the requirement for subjective selection of a certain field of interest, is reproducible, and is scalable as it does not require technical expertise of a pathologist.

Background: The characterization of differential molecular endotypes in osteoarthritis (OA) is essential for enabling patient stratification to enhance clinical trials, facilitate the development of targeted and individualized treatments.

Objectives: This study aimed to characterize the profile and dynamics over 24 months (24M) of proteins present in the sera from patients in the IMI-Applied Public-Private Research enabling OsteoArthritis Clinical Headway (APPROACH) cohort who exhibited structural (radiographic) and pain progression compared to participants who did not progressed during this period.

Methods: Forty-five patients enrolled in the IMI-APPROACH cohort were selected for the proteomic analysis. Among these, 15 showed the highest structural progression (group S) and 15 the highest pain progression (group P) at 24M, according to the APPROACH criteria [1], while 15 did not progressed neither in S nor in P. Baseline (BL) and 24M serum samples were depleted of the top 14 most abundant proteins and then analysed by liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) on a nanoElute-LC coupled to a high-resolution TIMS-QTOF (timsTOF Pro, Bruker Daltonics). Proteins were identified and quantified using the LFQ algorithm of MaxQuant software. Further statistical and bioinformatic analyses were performed using Perseus and OmicsAnalyst software.

Results: The proteomic analysis resulted in the identification of 558 proteins (10,466 peptides) in the serum samples. A label-free quantification algorithm was employed to quantify 468 proteins in the samples. Hierarchical clustering of the data showed the differences in protein abundance were more relevant longitudinally (BL to 24M) than in cross-sectional comparisons between the three groups under study (N, P or S). Sixty-three proteins were significantly altered (fold change >=1.5, p<0.05) when comparing BL to 24M in the N group (15 increased and 48 decreased), 53 in the P group (20 increased and 33 decreased) and 93 in the S group (19 increased and 74 decreased). Interestingly, two different endotypes were detected at baseline in the N and S groups, based on these protein modulations.

The overlapping of these proteomic profiles was analyzed between groups and is shown in the Figure 1. Proteins modulated specifically in the N group may be associated with mechanisms related with joint repair. On the other hand, six proteins (including two apolipoproteins) were increased at 24M only in the P group. Finally, 30 proteins were modulated only in the S group: five of them increased and 25 decreased. Remarkably, this latter group includes lubricin, chaperones and proteins related with proteoglycan binding, such as COMP, fibronectin or histidine-rich glycoprotein.

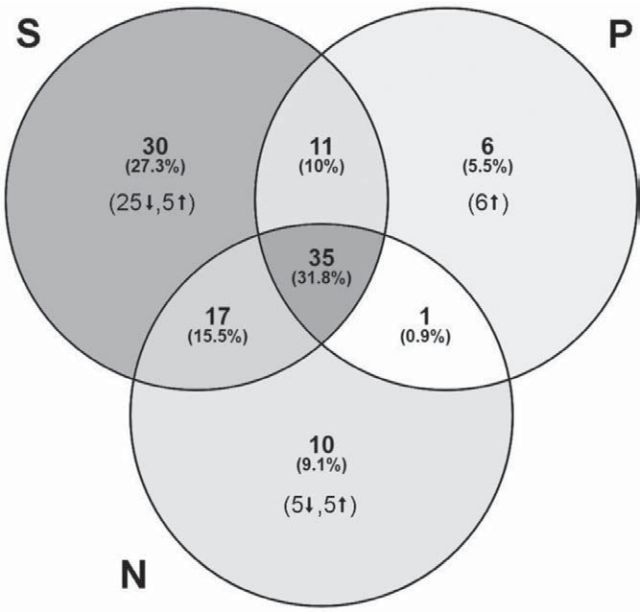

Figure 1. Circulating proteins identified as modulated after 24M follow-up in 45 patients from the APPROACH cohort that progressed in structure (S group; n=15), pain (P group; n=15) or did not progressed (N group; n=15). The numbers with arrows indicate those proteins that decrease (arrow pointing down) or increase (arrow pointing up) compared to baseline.

Conclusion: The modulation of specific protein profiles in serum were identified as associated with the progression in structure, pain or non-progression in patients from the APPROACH cohort. Proteomic changes found specifically in the S group may be interesting circulating markers of the structural affectation occurring in the joint.

OP0225

RISK OF COMORBIDITY FOLLOWING OSTEOARTHRITIS DIAGNOSIS: A COHORT STUDY IN THE NETHERLANDS FROM THE FOREUM* INITIATIVE

A. Kamps[1], J. Runhaar[1], M. de Wilde[2], M. de Ridder[2], J. van der Lei[2], S. Swain[3,4], W. Zhang[3], D. Prieto-Alhambra[4], M. Englund[5], E. de Schepper[1], S. M. A. Bierma-Zeinstra[1,6]on behalf of FOREUM Comorbiditis in Osteoarthritis.

[1]Erasmus Universty Medical Center, Department of General Practice, Rotterdam, Netherlands; *[2]Erasmus Universty Medical Center, Department of Medical Informatics, Rotterdam, Netherlands*; *[3]University of Nottingham, School of Medicine, Nottingham, United Kingdom*; *[4]University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom*; *[5]Lund University, Clinical Epidemiology Unit, Lund, Sweden*; *[6]Erasmus Universty Medical Center, Department of Orthopedics & Sports Medicine, Rotterdam, Netherlands*

Background: Osteoarthritis (OA) is a common and disabling disease that places a significant burden on both patients and health care systems. Previous studies have already shown that patients with OA have a higher risk of developing comorbidities. However, many focused on one or a few conditions only, or did not consider the chronology of the disease onset relative to OA.

Objectives: To determine the risk of physician-diagnosed comorbidity following the diagnosis of knee or hip OA, using electronic health records in the Netherlands.

Methods: A cohort study was conducted using the Integrated Primary Care Information (IPCI) database, an electronic health record database with medical records of 2.5 million patients from Dutch general practice. The study population consisted of patients aged 18 years or older, that were at risk for incident OA and comorbidity. Diagnosis of knee or hip OA (i.e. exposure) was defined as the first registration of the corresponding diagnostic code from the International Classification of Primary Care (ICPC) coding system in the medical record. Fifty-eight long-term comorbidities (i.e. outcome) were selected and defined by their corresponding ICPC codes.

Patients' follow-up started after registration in the database, and ended at the diagnosis date of the comorbidity (i.e. event), or at deregistration, death or at December 31st, 2019 (i.e. censoring), whichever came first. Exposure to knee or hip OA was a time-varying exposure: time between the start of follow-up and diagnosis of OA was defined as unexposed time, and between diagnosis of OA and the end of follow-up as exposed time. Patients' age was used as time axis to correct for age non-linearly. Sex-adjusted hazard ratios (HRs) comparing exposed and unexposed patient status were estimated with 99.9% confidence intervals (CI).

Results: The study population consisted of 1,890,712 patients. For 11 of the 58 studied comorbidities exposure to knee OA showed a statistically significant HR larger than 1, indicating an increased risk of being diagnosed with these comorbidities after a diagnosis of knee OA. For none of the comorbidities there was a statistically significant negative association (HR<1) with exposure to knee OA. For 7 comorbidities exposure to hip OA showed a statistically significant HR larger than 1. Again, for all other comorbidities the HR of hip OA was non-significant. For an overview of the statistically significant positive associations see Table 1.

Table 1. ***Comorbidities with significant HRs of exposure to knee or hip OA***

Knee OA				Hip OA			
Comorbidity	**HR**	**99.9% CI**		**Comorbidity**	**HR**	**99.9% CI**	
Anemia	1.33	1.09	1.64	**Anemia**	1.29	1.02	1.63
Back pain	1.28	1.04	1.57	**Atrial fibrillation**	1.46	1.14	1.88
Cataract	1.27	1.02	1.59	**Fibromyalgia**	6.09	1.25	29.53
Chronic kidney disease	1.30	1.06	1.59	**Peripheral vascular disease**	1.64	1.09	2.49
Coronary heart disease	1.34	1.03	1.75	**Sleeping disorder**	1.44	1.10	1.87
Gout	1.43	1.01	2.03	**Solid malignancy**	1.32	1.11	1.55
Hearing loss	1.34	1.00	1.79	**Spinal disc herniation**	2.03	1.46	2.83
Neck pain	1.58	1.16	2.16				
Obesity	2.02	1.06	3.83				
Sleeping disorder	1.33	1.04	1.69				
Thromboembolic disease	1.40	1.01	1.94				

Conclusion: This study showed that certain comorbidities were diagnosed more often in patients exposed to knee or hip OA, and none were less frequently diagnosed in patients exposed OA. This suggests that the management of OA should consider the risk of other long-term-conditions and that further research on causality between OA and comorbidity is needed.

OP0226 TRAJECTORIES OF BODY MASS INDEX FROM EARLY ADULTHOOD TO LATE MIDLIFE AND INCIDENCE OF TOTAL KNEE ARTHROPLASTY FOR OSTEOARTHRITIS: FINDINGS FROM A PROSPECTIVE COHORT STUDY

S. M. Hussain[1], I. Ackerman[1], Y. Wang[1], D. English[2], A. Wluka[1], G. Giles[3], S. Graves[4], F. Cicuttini[1]. *[1]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*; *[2]The University of Melbourne, Melbourne School of Population and Global Health, Melbourne, Australia*; *[3]Cancer Council Victoria, Cancer Epidemiology Division, Melbourne, Australia*; *[4]Australian Orthopaedic Association National Joint Replacement Registry, South Australian Health and Medical Research Institute, Adelaide, Australia*

Background: There is limited evidence regarding the association between trajectories of body mass index (BMI) across adulthood and knee osteoarthritis.

Objectives: We examined the association between body mass index (BMI) trajectories across early adulthood to midlife and risk of total knee arthroplasty (TKA) for osteoarthritis.

Methods: This study examined 24,368 participants (40-70 years at recruitment) in the Melbourne Collaborative Cohort Study who had weight collected at 1990–1994, 1995–1998, and 2003–2007 and recalled weight at age 18–21 years. BMI trajectories were derived using weight data at the four timepoints. Incidence of TKA after 2003–2007 until December 2018 was determined by linking cohort records to the National Joint Replacement Registry.

Results: Using group-based trajectory modelling, six distinct trajectories (TR) of BMI from early adulthood to late midlife were identified: lower normal to normal BMI (TR1: BMI at age 18-21 years to BMI at approximately 62 years (kg/m2), 20.0±1.9 to 22.1±1.7; 19.7%); normal BMI to borderline overweight (TR2: 21.5±2.3 to 25.8±1.7; 36.7%), normal BMI to overweight (TR3: 22.0±2.2 to 29.5±1.9; 26.8%), overweight to borderline obese (TR4: 28.5±2.7 to 30.5±2.3; 3.5%), normal BMI to class 1 obesity (TR5: 22.8±2.5 to 34.3±2.3; 10.1%), and overweight to class 2 obesity (TR6: 25.6±3.9 to 39.2±2.9; 3.2%). Over 12.4 years, 1,328 (5.4%) participants had TKA. The hazard ratios for TKA increased in all TR compared with TR1: TR2 2.03 (95% CI 1.64-2.52), TR3 4.00 (3.19-4.91), TR4 5.17 (3.77-7.10), TR5 7.00 (5.54-8.80), and TR6 8.59 (6.44-11.46). It is estimated that 28.4% TKA would be reduced if individuals followed the trajectory that was one lower, a national health system savings of $AUD 373 million. Most of this reduction would occur in TR2 (population attributable fraction 37.9% (26.7%-47.3%) and TR3 PAF 26.8% (20.0%, 31.2%) (Table 1).

Conclusion: Our study suggests that prevention of weight gain from young adulthood to midlife in order to reduce overweight and obesity could have a major impact on reducing the burden of severe knee osteoarthritis and associated healthcare costs.

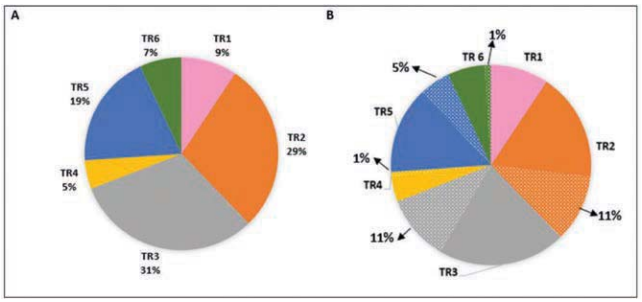

Figure 1. A. Proportion of Total Knee Arthroplasties in each trajectory category B. Speculated patters and associated percentages represents the proportion of Total Knee Arthroplasties that could be avoided in each trajectory category if the participants followed the lower trajectory category i.e. TR2 followed TR1

Total population	24368	1328	952	376 (28.4)	-

*if the trajectory is changed, ** PAFs and related 95%CIs were calculated by the Stata punafcc package using the formula $\sum pKR_i[(HR_i - 1)/HR_i]$, where pKR_i is the proportion of total knee replacements observed in the ith obesity trajectory and HR_i is the hazard ratio (HR) associated with that category. PAFs were calculated using pKR_i and HR_i estimated from the entire sample. All HR_i values were generated from Cox proportional hazards regression models adjusted for covariates (age at baseline, sex, country of birth, physical activity, smoking history, and comorbidity) and postestimation analyses.

New South Wales, St Vincent's Clinical School, Sydney, Australia; [5]*The University of Western Australia, School of Human Sciences, Crawley, WA, Australia*

Background: Overweight and obesity are associated with greater incidence and progression of the structural defects of knee osteoarthritis, but it is unknown if weight loss is of benefit.
Objectives: To describe the association between change in body mass index (BMI) and the incidence and progression of structural defects in knee osteoarthritis.
Methods: Scores from radiographic analyses of knees at baseline and at 4 to 5 years' follow up were obtained from three independent data sets (the OAI and MOST data sets from the United States from America, and the CHECK data set from the Netherlands). The exposure of interest was change in BMI from baseline to 4 to 5 years' follow up. To investigate the incidence of structural defects of knee osteoarthritis, we selected a total of 9732 knees (from 5802 participants) that had a Kellgren-Lawrence (KL) grade of knee osteoarthritis at baseline of 'none' (0) or 'doubtful' (1) (the 'incidence cohort'), and determined the odds of having a KL grade at follow-up of 'minimal' (2), 'moderate' (3), or 'severe' (4). To investigate progression, we selected a total of 6084 knees (from 3996 participants) that had a KL grade at baseline of 'minimal' (2), 'moderate' (3), or 'severe' (4) (the 'progression cohort'), and determined the odds of increasing by 1 or more KL grades by follow up. The degradation of three individual structural features of knee osteoarthritis (i.e., joint space narrowing, osteophytes on the femoral surface, and osteophytes on the tibial surface), on both the medial and lateral sides of the knee, were also investigated in both the incidence and progression cohorts. Here, degradation was defined as an increase by 1 or more Osteoarthritis Research Society International (OARSI) grades.
Results: Change in BMI was positively associated with both the incidence and progression of knee osteoarthritis, as defined by KL grade. Specifically, for each one-unit change in BMI, the adjusted odds ratio for incidence was 1.05 (95% confidence interval [CI] 1.02 to 1.09), and for progression, the same adjusted odds ratio and 95% CI was also observed. Change in BMI was also positively associated with degradation (i.e., narrowing) of joint space on the medial but not the lateral side of the knee, with an adjusted odds ratio of 1.08 (95% CI 1.04 to 1.12) in the 'incidence cohort' and 1.08 (95% CI 1.03 to 1.12) in the 'progression cohort'. Degradation of the tibial and femoral surfaces (i.e., osteophytes) was also seen on the medial but not the lateral side of the knee, but only in one of the two cohorts investigated (the 'incidence cohort'), with an adjusted odds ratio of 1.07 (95% CI 1.03 to 1.12) for osteophytes on the femoral surface, and 1.05 (95% CI 1.01 to 1.09) for osteophytes on the tibial surface.
Conclusion: Each one-unit reduction in BMI is associated with a 5 to 8% decrease in the odds of the incidence and progression of the structural defects of knee osteoarthritis, with lower odds of structural degradation specific to the medial – not lateral – side of the knee.
Acknowledgements: We acknowledge the provision of datasets and/or research tools from three studies: the Osteoarthritis Initiative (OAI) Study; the Multicenter Osteoarthritis Study (MOST); and the Cohort Hip and Cohort Knee (CHECK) Study.
OAI is a collaborative informatics system created by the National Institute of Mental Health and the National Institute of Arthritis, Musculoskeletal and Skin Diseases (NIAMS) to provide a worldwide resource to quicken the pace of biomarker identification, scientific investigation and OA drug development. The OAI data repository is housed within the National Institute of Mental Health (NIMH) Data Archive (NDA). For the MOST data set, we wish to acknowledge the contributions of the study participants, investigators and research staff involved. MOST is comprised of four (4) cooperative grants: U01 AG18820 David T. Felson (Boston University); U01 AG18832 James Torner (University of Iowa); U01 AG18947 Cora E. Lewis (University of Alabama at Birmingham); U01 AG19069 Michael C. Nevitt (University of California, San Francisco), funded by the National Institutes of Health, a branch of the Department of Health and Human Services, and conducted by MOST investigators. This manuscript was prepared using MOST data and does not claim, infer, or imply endorsement by MOST, by the MOST investigators and their respective institutions or by the University of California of the Data Recipients' use of the Data, of the entity or personnel conducting the research, or of any results of the research.

Department of General Practice, Rotterdam, Netherlands*; [3]*Erasmus MC University Medical Center Rotterdam, Department of General Practice, Rotterdam, Netherlands*; [4]*Lund University, Department of Clinical Sciences Lund, Lund, Sweden*; [5]*University of Oxford, NDORMS, Oxford, United Kingdom*; [6]*Keele University, School of Medicine, Keele, United Kingdom*; [7]*Chang Gung Memorial Hospital, Division of Rheumatology, Allergy and Immunology, Taiwan, Taiwan, Republic of China*; [8]*University of Nottingham, Department of Primary Care, Nottingham, United Kingdom*; [9]*University of Bristol, Musculoskeletal Research Unit, Bristol Medical School, Bristol, United Kingdom*

Background: People with osteoarthritis (OA) are at higher risk of developing a wide array of comorbidities. Whether the use of non-steroidal anti-inflammatory drugs (NSAIDs) contributes to the increased risk of some incident comorbidities remains unknown.
Objectives: To examine the contribution of NSAIDs in the development of a wide range of comorbidities in people with and without OA.
Methods: This observational cohort study used the UK primary care Clinical Practice Research Datalink (CPRD) GOLD containing data on 20+ million people covering 937 practices. We identified 259,000 people with incident OA and 259,000 age (±2 years), sex, and practice matched controls at 1:1 ratio. Controls were assigned the same index date (the date of first diagnosis of OA) as cases for the start of follow-up. Both cases and controls were further divided into two groups according to NSAID prescriptions at any time after the index date. This allowed us to examine both the main effect of each exposure and interaction between OA and NSAID exposure after the index date. People with an NSAID prescription before the index date were excluded from the study. NSAID exposure was defined as at least two prescriptions within 90 days. Exposure status of each participant was assessed every six months as yes/no until the end of the study/outcome of interests/death/last data available, whichever came first. Comorbidities were grouped into 9 categories as cancer, cardiovascular disease (CVD), endocrine, psychological, renal, gastrointestinal (GI), genitourinary, hepatic, and neurological conditions. Propensity scores for the prescription of NSAIDs were calculated using a logistic regression model including age, sex, body mass index (BMI), musculoskeletal and pain related conditions covariates. The propensity score adjusted time varying exposure analysis was undertaken using a multivariate COX model and hazard ratio (HR) and 95% confidence intervals were calculated. Proportional hazard assumption was tested using Schoenfeld test. Smoking, alcohol, ever prescription of proton pump inhibitors (PPIs) and other comorbidities were included in the adjusted model. The additional contribution of NSAIDs

and OA towards the incident comorbidity was estimated using addictive interaction methods. We also investigated the individual risk across non-selective, and COX-2 selective NSAIDs.

Results: The mean age was 59.4±12.8 years in people with OA and 60.2±12.8 years for controls with 57.7% being female. Nearly two thirds of people with OA were prescribed NSAIDs as defined, compared to one third in the control population. People with OA and exposed to NSAIDs had highest risk of developing psychological (1.51; 1.43,1.60), CVD (1.38; 1.33,1.43), cancer (1.34; 1.25,1.44), GI (1.25; 1.16,1.34) and renal (1.17; 1.11,1.24) comorbidities after adjusting for all the covariates and PPI drugs, compared to the non-OA and non-NSAID group. (Figure 1) Interaction between OA and NSAID was significant for cancer, GI, renal, hepatic, and neurological outcomes. Within people with OA, non-selective NSAIDs increased the risk of CVD (1.25; 1.20,1.30), cancer (1.11; 1.04,1.19), endocrine (1.15; 1.10,1.19), renal (1.19; 1.13,1.26) and psychological (1.21; 1.15,1.28) comorbidities, whereas COX-2 selective NSAIDs increased risk of incident CVD (1.34; 1.25,1.44), endocrine (1.13; 1.04,1.21), renal (1.25; 1.14,1.37), and psychological (1.21; 1.09,1.34) comorbidities.

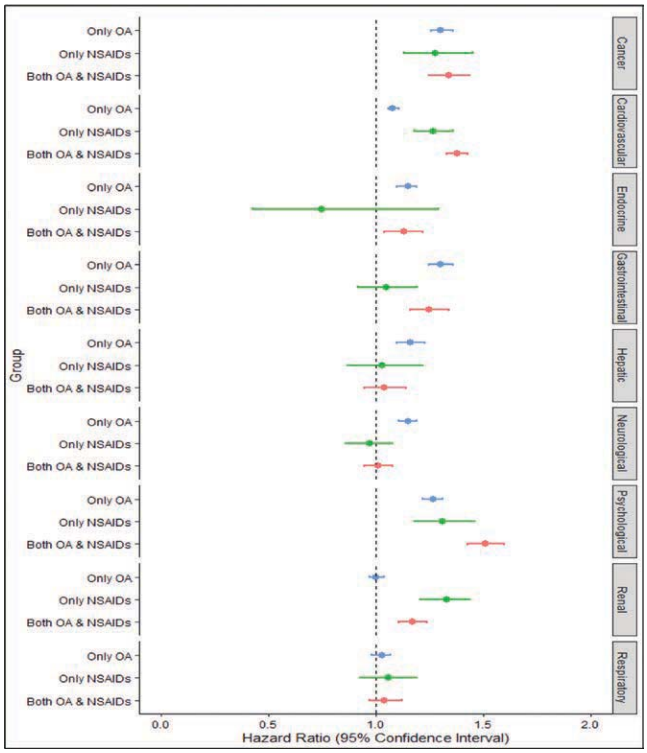

Figure 1. Hazard ratio of developing different comorbidities (reference group: no OA and no NSAIDs) OA- Osteoarthritis; NSAIDS- Non-steroidal anti-inflammatory drugs.

Conclusion: Use of NSAIDs among people with OA is associated with increased risk of a wide variety of comorbidities. Non-selective and COX-2 selective NSAIDs are both associated with increased risk of cardiovascular, renal, and psychological comorbidities.

OP0229

OSTEOARTHRITIS OF THE KNEE, INFLAMMATION, AND THE EFFECT OF ADALIMUMAB (OKINADA): A RANDOMIZED PLACEBO-CONTROLLED TRIAL

W. P. Maksymowych[1,2], L. Bessette[3], R. G. Lambert[4], A. Carapellucci[2], C. T. Appleton[5,6]. *[1]University of Alberta, Medicine, Edmonton, Canada*; *[2]CARE ARTHRITIS LTD, Rheumatology, Edmonton, Canada*; *[3]Université Laval, Medicine, Quebec City, Canada*; *[4]Uinversity of Alberta, Radiology, Edmonton, Canada*; *[5]Bone and Joint Institute, Medicine, London, Canada*; *[6]Schulich School of Medicine and Dentistry, Western University, London, Canada*

Background: Cytokines such as tumor necrosis factor (TNFα) have been shown to elicit inflammatory and catabolic events in the joints of patients with osteoarthritis. Recent RCTs demonstrated that TNFα inhibition has no effect on pain and MRI-detected synovitis or bone marrow lesions in patients with erosive hand OA[1-3]. However, the progression of bone erosions was reduced in a subgroup of patients with more clinically swollen distal interphalangeal joints in one RCT[1]. Consequently, it remains possible that TNFα inhibition may have beneficial effects in specific subgroups of patients with a high inflammatory component.

Objectives: We aimed to evaluate the efficacy and safety of a TNFα inhibitor, adalimumab (ADA), in a proof-of-concept study in patients with inflammatory OA of the knee.

Methods: OKINADA was a 52-week, randomized, double-blind, placebo-controlled, parallel-group study done at 11 sites in Canada (NCT02471118). Eligible participants were adults (aged ≥18 years) with a diagnosis of OA of the index knee and classified according to American College of Rheumatology criteria, including radiological evidence of OA (Kellgren-Lawrence grades 2 or 3) with clinical signs of knee effusion. Subjects had persistent knee pain of ≥ one month duration with a pain score of ≥ 4 (0-10 NRS) in the index knee at screening and baseline despite conventional treatment with maximum tolerated acetaminophen and/or non-steroidal anti-inflammatory drug. Patients were randomly assigned (1:1) to receive subcutaneous 40 mg ADA every 2 weeks or placebo (PBO). Primary endpoint was the Outcome Measures in Rheumatology and Osteoarthritis Research Society International set of responder criteria (OMERACT-OARSI) at week 16 defined as: (1) improvement in pain or function ≥50% and an absolute change ≥20 mm; or (2) improvement of ≥20% with an absolute change ≥10 mm in at least two of the following three categories: pain, function, and patient's global assessment. Secondary endpoints included: the Knee Injury and Osteoarthritis Outcome Score (KOOS) for the domains of pain, activities of daily living (ADL), OA symptoms, sport and recreation function (SRF), and knee-related quality of life (QoL), patient's global assessment of disease status (PGAD), investigator global assessment of disease status (IGAD), and expanded Target Joint Assessment (TJA) score.

Results: A total of 59 patients were randomized (29 to PBO, 30 to ADA). The primary endpoint was not met: OMERACT-OARSI combined (ADA: 9 [30.0%] vs PBO: 7 [24.1%], p=0.62). For KOOS pain, ≥20% improvement was noted in 11 (36.7%) ADA vs 7 (24.1%) PBO patients (p=0.30), and ≥50% improvement in 5 (16.7%) ADA vs 6 (20.7%) PBO patients (p=0.69). There were no significant treatment-group differences in baseline to 16-week change in continuous secondary endpoints (ADA vs PBO: KOOS ADL 6.5 vs 8.4 (p=0.71), KOOS QoL 10.1 vs 7.4 (p=0.66), KOOS symptoms 7.8 vs 11.5 (p=0.42), KOOS SRF 5.8 vs 7.7 (p=0.76), PGAD -1.0 vs 0.1 (p=0.10), IGAD -1.5 vs -2.1 (p=0.30), TJA -2.4 vs -2.2 (p=0.87) or in lab markers (ESR, CRP). There were 11 withdrawals (4 ADA, 7 PBO) of which 2 were for adverse events (1 ADA, 1 PBO) and 2 for increasing knee pain (1 ADA, 1 PBO). No new safety signals were identified and there were no serious adverse events.

Conclusion: Although the treatment was safe, short-term treatment with anti-TNFα therapy does not appear to provide clinically meaningful improvements in OA symptoms in patients with established radiographic knee OA. Analyses of structural endpoints will be reported when results are available.

OP0230

ANTIHISTAMINE USE AND STRUCTURAL PROGRESSION OF KNEE OA: A POST-HOC ANALYSIS OF TWO PHASE III CLINICAL TRIALS

A. R. Bihlet[1], C. P. Miller[1], I. Byrjalsen[1], J. R. Andersen[1], M. Karsdal[2], M. C. Baker[3,4], T. Rao[3]. [1]*NBCD A/S, Herlev, Herlev, Denmark*; [2]*Nordic Bioscience A/S, Herlev, Herlev, Denmark*; [3]*Mobility Bio Inc., Palo Alto, Palo Alto, CA, United States of America*; [4]*Stanford, Division of Immunology and Rheumatology, Stanford, United States of America*

Background: Prior studies indicate that mast cells are involved in chronic inflammation and that their activity in the synovium may contribute to structural progression of osteoarthritis (OA), however the exact role of mast cells in OA remains unclear. Antihistamines act by blocking histamine receptors, and further are found to have anti-inflammatory effects by stabilizing mast cell membranes. Current reports describing antihistamine use in OA patients suggest that antihistamines may reduce development of OA and lead to reduced risk of structural progression.

Objectives: We aimed to investigate whether antihistamine use during a two-year trial period was associated with differences in structural progression of OA, as compared with non-use.

Methods: This is a post-hoc analysis of two large phase III trials investigating oral salmon calcitonin in knee OA (NCT00486434 and NCT00704847). The primary outcome measure was structural progression defined as the change in minimum joint-space width measured by use of x-ray imaging from baseline to Year Two. In these trials, participants reported use of antihistamines, defined as medication coded with the ATC code R06A. In our study, we evaluated differences between groups of participants who reported use of antihistamines, versus those who did not, over the 2-year study period. Secondly, the duration of antihistamine use divided into categories of either no use, 1-49, 50-299 or >300 days of use was investigated to evaluate exposure-response relationships. The effect of use of antihistamines was evaluated using ANCOVA analysis adjusting for age, sex, BMI, and baseline JSW.

Results: Of a total study population of 2,206 participants, 1,485 completed the trial. Of these, 1,327 were non-users of antihistamines (mean age 64.4 years, 64.1% female, mean BMI 29.0 kg/m^2) and 158 reported use of antihistamines of any duration during the trial (mean age 64.5 years, 75.2% female, mean BMI 28.1 kg/m^2). Seventy-four participants reported use of antihistamines of a duration between 1-49 days, 21 participants between 50-299 days, and 63 reported use of 300 days or more. As illustrated in Figure 1A, the mean JSW change from baseline in the group of non-users was -0.32 mm (95% CI: -0.36 to -0.29), versus -0.19 mm (95%CI: -0.29 to -0.08, p=0.02 for difference) in the group of patients reporting antihistamine use of any duration. A trend towards an association between duration of antihistamine use and reductions in narrowing of JSW was observed (p for trend: 0.02), Figure 1B).

Conclusion: Use of antihistamines was associated with reduced structural progression in knee OA. Further research evaluating the role of antihistamines in OA is needed to further characterize this observation.

Background: Systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), systemic sclerosis (SSC), Sjögren's syndrome (SJS), mixed connective tissue disease (MCTD), primary antiphospholipid syndrome (PAPS) and undifferentiated connective tissue disease (UCTD) are classified as systemic autoimmune diseases (SADs). They are diagnosed based on different clinical and laboratory criteria. Due to their high internal heterogeneity and overlapping symptoms, SADs are difficult to diagnose. Therefore, molecular and cellular-based studies need to be undertaken to precisely classify the patients. Mass cytometry is a single-cell proteomics technology that measures approximately 50 markers per cell, thus it is a suitable tool to perform deep-phenotyping studies in SADs.

Objectives: Explore differences and similarities between SADs and build reclassification framework using high-dimensional cytometry data.

Methods: The whole blood samples collected from 129 individuals, including patients and controls were stained with a 39-plex antibody panel and acquired

in 9 batches on a CyTOF (HELIOS) instrument. Data were cleaned, and normalized for batch effects using semi-automated cytof analysis pipeline. Cell frequencies and median signal intensities (MSI) for each population were extracted using FlowSOM for mononuclear cells (PBMC) and Phenograph for granulocytes. Secretion of 44 cytokines and chemokines were analyzed using a multiplexed luminex assay. Diseases were compared by Kruskal-Wallis analysis and hierarchical clustering and reclassification was done using unsupervised k-means clustering. Cytokine analysis across clusters was performed using Kruskal-Wallis test.

Results: Differently expressed features were observed between patient groups, regarding frequency of classical monocytes, B and T cells subpopulations, mature and immature granulocytes and intensities of CD38, HLA-DR and CD95 across various populations. However, none of them were disease specific. K-means clustering identified four patient clusters, which were composed by a mixture of different diagnosis. Cluster C1 was characterized by increased levels of circulating cells from PBMC compartment, and lower activation of different populations of the T cell compartment. It presented lower frequency in multiple granulocyte populations and the highest expression of CD95 and CD38. This cluster was also associated with antimalarial and steroid treatment. Clusters C1 and C2 were exactly opposite to each other, cluster C3 was characterized by intermediate features between C1 and C2 and cluster C4 could be considered as undifferentiated, mixed group. Higher production of TNFα, IL-10 and IP-10 were found in patients from C1 compared to C2, suggesting more active phenotype in C1 and physiological one in C2. The cytokine levels were independent of the treatment.

Conclusion: We constructed a patient reclassification framework using cell frequencies and expression levels of functional markers. To our knowledge this is the first time when 7 different SADs were compared using mass cytometry. In agreement with other reports we did not detect any disease-specific cellular markers. Distribution of diagnosis across different clusters confirms diseases heterogeneity. Patients can be classified into phenotypically similar groups, that could potentially benefit from the same line of treatment.

OP0232

HIGH PLASMA C4D/C4 IDENTIFIES LUPUS NEPHRITIS PATIENTS WITH DISEASE MEDIATED BY ACTIVATION OF THE CLASSICAL COMPLEMENT PATHWAY

A. Mongan[1], P. Suri[2], D. R. Artis[2], E. Cahir-McFarland[2], H. A. Kroon[1], Y. Andrews-Zwilling[2], S. Rose[3], S. Keswani[3], M. Dall'Era[4], T. Yednock[2].
[1]Annexon Biosciences,Translational Medicine, San Francisco, United States of America; *[2]Annexon Biosciences, Research, San Francisco, United States of America*; *[3]Annexon Biosciences, Clinical Development, San Francisco, United States of America*; *[4]University of California, Department of Medicine, San Francisco, United States of America*

Background: Proliferative lupus nephritis (LN) involves immune complex deposition in the kidney that can severely impact normal renal clearance mechanisms. Immune complexes can activate C1q and the classical complement cascade, and along with pathogenic anti-C1q antibodies (PACAs), may amplify inflammation and disease progression. Martin et al reported that circulating C4d, a marker of complement activation downstream of the C1 complex, correlated well with C4d immunohistochemistry score in kidney tissue and could be a sensitive and specific biomarker for diagnosing active LN.[1]

Objectives: To confirm and extend observations by Martin et al, and to extend a link between C4d, C1q activation, and PACA levels to identify patients most likely to have the classical complement pathway as a driving component of disease. Such patients would be potential candidates for anti-C1q therapy, such as ANX009, to dampen disease activity and slow disease progression (NCT04535752).

Methods: Plasma samples were collected from a cohort of 40 LN patients (20 with disease flare and 20 without disease flare) from the California Lupus Epidemiology Study (CLUES), a multi-racial/ethnic cohort of individuals with physician-confirmed systemic lupus erythematosus, and 20 healthy controls (Table 1). A panel of complement factors, including 15 complement protein and relevant complexes, were measured using an enzyme-linked immunosorbent assay. Clinical disease activity was measured using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and proteinuria was evaluated by a random spot urine protein to creatinine ratio (UPCR).

Table 1. Patient Demographics

Characteristics	Healthy Control(n=20)	LN Flare(n=20)	LN Without Flare(n=20)
Median age (years)*	50 (31-60.8)	28.5 (26-34.5)	43.5 (33.5-52)
Sex, n (%)			
Female	18 (90)	17 (85)	18 (90)
Demographics, n (%)			
Caucasian	8 (40)	1 (5)	5 (25)
Hispanic	3 (15)	9 (45)	4 (20)
African American	1 (5)	3 (15)	3 (15)
Asian	8 (40)	7 (35)	8 (40)
Median UPCR (mg/mg)*	N/A	1.8 (1.3-6.5)	0.4 (0.2-0.6)
Median SLEDAI*	N/A	12 (9-16)	2 (2-4)

*Reported as median (IQR). LN, lupus nephritis; N/A, not applicable; SLEDAI, Systemic Lupus Erythematosus Disease Activity Index; UPCR, urine protein:creatinine ratio.

Results: We observed evidence of coordinated complement activation in LN patients relative to healthy controls. Specifically, levels of C4d and the C4d/C4 ratio were highly increased in LN patients with flare, while levels of C1q, C1s, and C4 were decreased, consistent with activation of the classical complement pathway (increased activation and component consumption). The C4d/C4 ratio also correlated with levels of PACA isotypes 1 and 3 that are known to activate the classical pathway. Improvements in C4 and C4d/C4 ratio were associated with improvements in proteinuria and SLEDAI following treatment for disease flare, indicating their potential value as biomarkers of treatment response.

Conclusion: A subset of LN patients exhibited high C4d/C4 ratio along with specific markers of classical pathway activation, indicating that the classical complement pathway may be a driving component of their disease. Reduction in this ratio appears to correlate with treatment response, but its levels are generally not normalized, suggesting an insufficient resolution of complement-mediated inflammation by currently available treatments. Our data support a clinical hypothesis that a subset of LN patients may benefit from a precision medicine approach targeting the classical complement pathway (Figure 1). This hypothesis will be evaluated in a forthcoming clinical trial testing the subcutaneously administered C1q inhibitor ANX009 in patients with active LN.

OP0233 CELLULAR SENESCENCE IN A MOUSE MODEL OF LUPUS NEPHRITIS

G. Tilman[1], L. Watteyne[1], D. Nolf[1], C. Bouzin[2], F. Houssiau[3], N. Limaye[1]. [1]*de Duve Institute, UCLouvain, Genetics of Autoimmune Diseases and Cancer, Brussels, Belgium*; [2]*Institut de Recherche Expérimentale et Clinique, UCLouvain, IREC Imaging Platform (2IP), Brussels, Belgium*; [3]*Institut de Recherche Expérimentale et Clinique and Cliniques Universitaires Saint-Luc, UCLouvain, Department of Rheumatology, Brussels, Belgium*

Background: A third of patients with lupus nephritis (LN) show a decline in renal function despite treatment, with 5-10% developing end-stage renal disease within ten years. Prognostic markers that would allow for timely treatment decisions are hence eagerly sought, as are novel therapeutic targets. It is clear that lupus kidney is not simply a passive target of systemic autoimmunity but also hosts pathogenic mechanisms determining renal disease severity. These likely involve both the infiltrating immune and resident renal cell compartments. Cellular senescence is the irreversible arrest of the cell cycle through the accumulation of cyclin dependent kinase (CDK) inhibitors such as $p16^{INK4a}$ (*CDKN2A)*. Senescent cells nevertheless remain metabolically active and undergo morphological and physiological changes including the acquisition of a pro-inflammatory, pro-fibrotic senescence-associated secretory phenotype (SASP). Aberrant accumulation of senescent cells has been observed in renal aging and pathology. We recently described the presence of $p16^{INK4a}$-positive cells (a senescence hallmark) in LN renal biopsies, and their association with baseline disease severity and 5 year outcome[1]. In addition, we observed a spatial co-distribution between tissue-infiltrating CD8 T cells, senescent kidney cells, suggesting a pathogenic functional interaction between them.
Objectives: We hypothesize that cellular senescence may contribute to tissue damage in a few different ways: **(a)** Presentation of senescence-associated antigens that attract and activate CD8 T cells. Alternatively, CD8 T cells may be summoned to the kidney by other means, and may contribute to senescence-induction through the secretion of certain cytokines; **(b)** Secretion of pro-fibrotic, pro-inflammatory molecules, and/or **(c)** Functional incapacitation of kidney cells, particularly renal progenitor cells, responsible for repairing and restoring kidney function upon damage. In parallel with our work on patient samples, we aim to establish a relevant pre-clinical model in which we may test for the effects of senescence and senescence-directed interventions, on kidney damage.
Methods: Here, we assess for whether the B6.*Sle1.Sle2.Sle3* spontaneous lupus-prone mouse may serve as an appropriate model in which to study the role of cellular senescence. We evaluated the presence and distribution of $p16^{Ink4a}$-positive cells by immunohistochemistry, and tested for an association with CD8 T cell infiltration and renal and systemic disease, in a cohort of 21 B6.*Sle1.Sle2.Sle3* female mice. This is now being followed-up by a systematic, longitudinal study for the time of onset of different renal and systemic disease parameters, as compared to the detection of renal cell senescence in this well-characterized model.
Results: As observed in renal biopsies from LN patients, staining for $p16^{Ink4a}$-positive cells was heterogenous between mouse kidney samples. Interestingly, $p16^{Ink4a}$ seems to be associated with CD8 T cell infiltration, renal impairment and damage, independently of age. This will now be confirmed using the "senescence-associated β-galactosidase" assay, the other classic measure of cellular senescence.
Conclusion: We report the occurrence of cellular senescence, and its correlation with CD8 T cell infiltration and disease severity, in the B6.*Sle1.Sle2.Sle3* mouse model of lupus. These mice provide a pre-clinical model in which to test for the role of cellular senescence in the pathogenesis of LN *in vivo* (by the induction vs. selective elimination of senescent cells). They also serve as an alternative source (alongside patient samples) of cells for *in vitro* functional assays to test for the effects of senescent renal cells on CD8 T cells and *vice versa*.

OP0234 RNA-SEQ IN PERIPHERAL BLOOD IMMUNE CELLS IDENTIFIES MODULAR NETWORKS PREDICTIVE AND PROTECTIVE FOR PROGRESSION FROM ANA POSITIVITY TO CLASSIFIABLE SYSTEMIC AUTOIMMUNE DISEASE.

L. M. Carter[1,2], M. Y. Md Yusof[1,2], D. Plant[3], A. Alase[1], J. Arnold[1,2], A. Psarras[1], Z. Wigston[1], E. Vital[1,2]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [2]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; [3]*University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom*

Background: Anti-nuclear antibody (ANA) positivity represents a complex 'At-Risk' state for development of connective tissue disease (CTD). While ANA may become positive years in advance of clinically manifest CTD, they are also harboured in at least low titre by up to 25% of the wider population, of whom only a small fraction ultimately develop systemic autoimmunity. Complex immune disturbances including plasmacytoid dendritic cell exhaustion and non-haematopoietic interferon (IFN) production are evident even among ANA positive individuals who do not ultimately progress to overt disease [1].
In a prospective observational cohort of ANA positive individuals At-Risk for CTD we have shown that a validated blood IFN-Score was predictive of progression to classifiable SLE [2]. However, the wider transcriptional fingerprint of the At-Risk state and other factors modifying risk of progression are not known. We hypothesise that diverse immune processes, both independent and interacting with IFN pathway activation, could modulate risk of progression.
Objectives: To investigate how peripheral blood immune cell transcriptional signatures derived by RNA Seq associate with progression or non-progression from At-Risk ANA positivity to clinically apparent CTD.
Methods: Peripheral blood mononuclear cells (PBMCs) were isolated at baseline from ANA-positive At-Risk individuals demonstrating ≤1 clinical criterion for classifiable CTD, symptom duration <12 months and naive of glucocorticoid or immunosuppressive therapy. Progression was prospectively adjudicated at 12 months and defined as accrual of clinical/ immunological criteria sufficient to meet classification for SLE (SLICC 2012) or other relevant CTDs. Bulk RNASeq was performed on PMBCs from 16 progressors and 19 non-progressors. Weighted gene co-expression network analysis (WGCNA) was performed using WGCNA package and gene ontology enrichment was evaluated using ClusterProfiler, in R Bioconductor. The top 20% genes ranked by connectivity were defined as hub genes. Major cell subsets were quantified in parallel by multiparameter flow cytometry.
Results: 29 modules were identified by WGCNA. Eigengenes for 3 modules were significantly associated with progression status. A single, 152 gene module showed strong positive correlation with progression ($R=0.55$, $p<0.001$). Hub genes were significantly enriched for type I IFN-signalling pathway and included established interferon stimulated genes such as IFI44 and IRF7.
Two further modules had a negative, i.e. protective, association with progression; a smaller 37 gene module, correlated negatively with both blood interferon score ($R=-0.46$, $p=0.005$) and with progression ($R=-0.43$, $p=0.01$). A larger 252 gene module was also negatively related to progression ($R=-0.43$, $p=0.009$) and demonstrated significant pathway enrichment for regulation of cell morphogenesis and actin cytoskeleton organisation.
Conclusion: We identify novel modular transcriptomic signatures implicated in SLE disease initiation. We show (i) IFN-pathway activation is the single strongest transcriptomic risk marker of progression from the ANA positive At Risk state and (ii) we identify 2 novel protective signatures in peripheral blood immune cells for which further network-based characterization is ongoing.

OP0235

GENOME-WIDE DNA METHYLATION ANALYSIS IN MULTIPLE IMMUNE CELL POPULATIONS REVEALS WIDESPREAD PROMOTER AND INTERGENIC B CELL HYPERMETHYLATION IN SYSTEMIC LUPUS ERYTHEMATOSUS

C. Ulff-Møller[1], J. Tost[2], S. Jacobsen[1]. [1]*Copenhagen Lupus and Vasculitis Clinic, Centre for Rheumatology and Spine Diseases, Copenhagen, Denmark*; [2]*Centre National de Génotypage, CEA-Institut de Génomique, Laboratory for Epigenetics and Environment, Evry, France*

Background: Patients with systemic lupus erythematosus (SLE) display an aberrant DNA methylation (DNAm) pattern with a predominant interferon signature. However, the DNAm patterns in purified immune cell populations are not well described.

Objectives: To examine genome-wide DNAm changes in sorted CD4$^+$ T cells, monocytes, granulocytes and B cells in SLE patients compared to healthy controls (HC).

Methods: Genome-wide analysis was performed in 20 SLE patients with active lupus nephritis (LN) and 20 age-, sex- and ethnicity-matched HCs. Peripheral blood was processed using gradient density centrifugation for the granulocyte fraction, and CD4$^+$ T-cells, monocytes and B cells were isolated from the mononuclear cell fraction using a RoboSep device (Stemcell Technologies). DNA was extracted using the DNA/RNA/miRNA Universal kit (Qiagen). Genome-wide DNAm was evaluated using Infinium MethylationEPIC BeadChips (Illumina Inc.). Top differentially methylated CpG sites (DMC) were validated using pyrosequencing, and further analysed in follow-up samples, as well as extended to another 36 SLE patients with inactive LN, 36 SLE with never-LN and 20 HCs. Patients and HCs were compared using a paired *t*-test stratified by cell type. A false discovery rate (FDR) <0.05 was considered statistically significant. Clustering of non-gene annotated CpGs was defined as distance <5000 bp with proximity to neighbouring genes <1x10^5 bp, identified through mapping of Entrez Gene Identifiers.

Results: Overall, SLE patients with active LN compared to HCs exhibited DMCs in 22, 46, 312 and 78,068 probes in CD4$^+$ T cells, monocytes, granulocytes and B cells, respectively. In CD4$^+$ T cells, monocytes and granulocytes, the majority of DMCs were hypomethylated and related to interferon-regulated genes. In B cells, the majority of DMCs were hypermethylated with 1360 genes in the promoter region restricted to differential methylation >10% and ≥2 DMCs, of which 1087 were hypermethylated. Of these, the most significantly hypermethylated CpGs in the promoter region included *CABYR, TMPRSS7, SLC6A2, KLK10/KLK11, WIZ, LPAR1, ZNF385B* and *IL1R1* (Figure 1). Top hypomethylated genes included *IFI44L* and *MX1*. Ingenuity Pathway Analysis (IPA) predicted top upstream regulators in B cells to be *IL4*, *TNF* and *IFNG*. In addition, we identified 1437 DMCs associated with ncRNA and 4626 DMCs with no genic association. The non-gene associated DMCs were related to 275 non-coding clusters. Top non-coding clusters were in proximity to *BMP7*, *ARHGEF10*, *PRDM1, RIN2* and *CCR6,* which themselves were differentially methylated. IPA predicted *IL2, CD40LG* and *NFKB1* as the most important upstream regulators for neighbouring genes of non-coding clusters.

Pyrosequencing confirmed B cell hypermethylation in *CXCR5, DDR1, MTA3, RAB30* and *TRAF5,* and in non-coding clusters located on chromosome 3 upstream of *FGF12* and chromosome 22 downstream of *XPNPEP3* and *RBX1*. Hypermethylation in *CXCR5, DDR1, MTA3, RAB30* and hypomethylation in *IFI44L, LGALS3BP* and *PARP9* was stable at follow-up as well as in patients with inactive and never-LN. Patients in the active LN group exhibited significantly more pronounced hypomethylation in *PLSCR1* in CD4$^+$ T-cells, granulocytes and B-cells compared to the other patient groups. Greater β2 microglobulin, anti-DNA antibodies and disease activity were significantly associated with greater B cell *CXCR5* hypermethylation (p<0.001), *IFI44L* hypomethylation in all but CD4$^+$ T cells*, LGALS3BP* hypomethylation in granulocytes (p<0.0001)*, PARP9* hypomethylation in all but B cells and *PLSCR1* hypomethylation in all but monocytes. Proteinuria was related to *PLSCR1* hypomethylation in all but monocytes, as well as hypermethylation at the non-coding cluster in chromosome 3 (p=0.05) and *MTA3* (p=0.03) in B cells.

Conclusion: B cell hypermethylation in SLE patients is widespread, and may indicate a novel mechanism for SLE pathogenesis. Differential methylation of several interferon-regulated genes may be associated with disease activity.

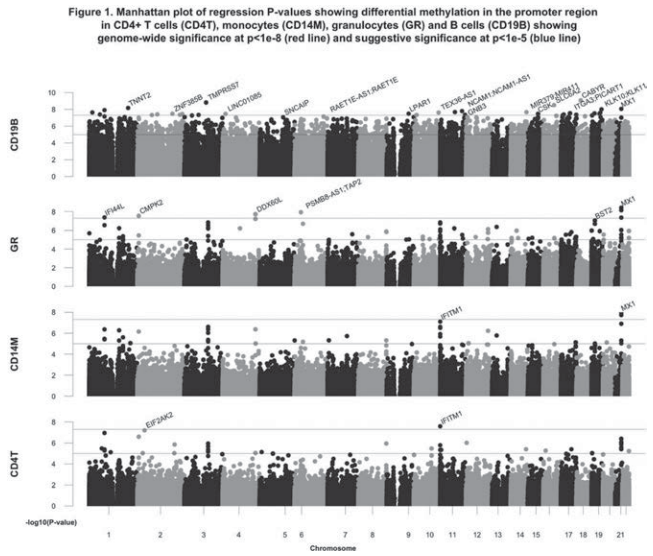

Figure 1. Manhattan plot of regression P-values showing differential methylation in the promoter region in CD4+ T cells (CD4T), monocytes (CD14M), granulocytes (GR) and B cells (CD19B) showing genome-wide significance at p<1e-8 (red line) and suggestive significance at p<1e-5 (blue line)

JAK-STAT INHIBITION RESTORES EPITHELIAL CELLS' HOMEOSTASIS IN PRIMARY SJOGREN'S SYNDROME

S. Colafrancesco[1], C. Barbati[1], R. Priori[1], F. Giardina[1], A. Gattamelata[1], R. Izzo[1], B. Cerbelli[2], C. Giordano[2], S. Scarpa[3], M. Fusconi[4], F. R. Spinelli[1], G. Cavalli[5], C. Alessandri[1], F. Conti[1]. [1]*Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*; [2]*Sapienza University of Rome, Dipartimento di Scienze Radiologiche, Oncologiche e Anatomo Patologiche, Rome, Italy*; [3]*Sapienza University of Rome, Dipartimento di Medicina Sperimentale, Rome, Italy*; [4]*Sapienza University of Rome, Dipartimento Organi di Senso, Rome, Italy*; [5]*Università Vita Salute San Raffaele, Unità di Immunologia, Reumatologia e Allergologia, Milan, Italy*

Background: Although salivary gland epithelial cells (SGECs) are key players in the pathogenesis of autoimmune epithelitis that characterizes primary Sjögren's Syndrome (pSS), the mechanisms sustaining SGECs activation in pSS remain largely undetermined. Therefore, therapeutic strategies to counteract SGECs activation in pSS are also lacking. In previous studies, we revealed that maladaptive autophagy sustains survival and pro-inflammatory activation of SGECs in pSS (1).

Objectives: To determine the therapeutic potential of JAK/STAT inhibition with baricitinib to restore homeostatic regulation of SGECs in pSS, by reducing autophagy, survival, and expression of adhesion molecules.

Methods: Primary SGECs were isolated from minor salivary glands (SG) of large cohort of patients with pSS or sicca syndrome and subjected to mechanistic and functional studies including flow-cytometry, immunoblotting, and immunofluorescence to assess autophagy (autophagic-flux, LC3IIB, p62, LC3B+/LAMP1+ staining), apoptosis (annexin V/PI, Caspase-3) and activation (ICAM, VCAM). Focus score and germinal centers were determined in homologous SG biopsies to assess correlations of findings with histological disease severity. Primary SGECs of patients with pSS were treated with Baricitinib (1 mM) for 24 prior to assessment of autophagy, apoptosis and activation.

Results: SGECs from pSS patients (n=29) exhibited increased autophagy (as determined by autophagic-flux p=0.001; LC3IIB p=0.02; p62 p=0.064; LC3IIB/LAMP1+ staining), increased expression of anti-apoptotic molecules (Bcl2 p=0.006), and reduced apoptosis (Annexin-V/PI p=0.002, Caspase-3 p=0.057) compared to sicca (n=16). Induction of autophagy in pSS SGECs correlated with histologic disease severity. Treatment of pSS SGECs with baricitinib *ex vivo* suppressed autophagy, increased apoptosis, and reduced expression of adhesion molecules.

Conclusion: SGECs in the inflammatory milieu of pSS are characterized by induction of autophagy and pro-survival mechanisms, and by expression of adhesion molecules. These changes correlate with SG infiltration with immune cells and with histologic disease severity. Among clinically available therapies, the JAK/STAT inhibitor baricitinib effectively reduced autophagy, countered the state of maladaptive activation of SGECs, and restored epithelial cell homeostasis. Transcriptomics and metabolomics studies are ongoing to dissect the specific mechanisms responsible for these beneficial effects.

OP0237 DISTINCT IMMUNE NETWORKS STRATIFY ORGAN INVOLVEMENT AND RESPONSE TO B CELL TARGETED THERAPIES IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Shipa[1], L. Santos Ribeiro[1], D. Nguyen[1], A. Embleton-Thirsk[2], M. Parvaz[1], D. Isenberg[1], C. Gordon[3], M. Ehrenstein[1]. [1]*University College London, Rheumatology, London, United Kingdom*; [2]*University College London, Comprehensive Clinical Trials Unit, London, United Kingdom*; [3]*University of Birmingham, Rheumatology Research Group- Institute of Inflammation and Ageing, Birmingham, United Kingdom*

Background: The results from the double-blind BEAT-lupus trial comparing belimumab vs placebo, both after rituximab in systemic lupus erythematosus (SLE) have recently been reported (1). We sought to identify biomarkers of response to belimumab after rituximab to aid a personalised approach to therapy for SLE.

Objectives: To identify biomarkers of clinical response to belimumab after rituximab in the BEAT-lupus trial.

Methods: We constructed a model utilising a range of clinical, routine and exploratory laboratory data, from the BEAT-lupus trial to identify variables at baseline (screening) that could predict a major clinical response (MCR, defined as reduction to BILAG C in all domains, steroid dose of ≤7.5mg/day & SLEDAI≤2, without anti-dsDNA antibody component) at 52 weeks. Relevant serum autoantibodies and cytokines were assayed by ELISA/Simoa, and interferon signatures and BAFF expression measured by RT-PCR. A linear mixed model was applied to longitudinal data collected during the trial stratified by treatment and clinical response. An independent cross-sectional lupus cohort was recruited to validate biomarker association with organ involvement.

Results: A major clinical response (MCR) was achieved in 48% (10 responders, 11 non-responders) of patients who received belimumab after rituximab compared to 35% (8 responders, 15 non-responders) in the placebo group (i.e. rituximab alone), added to tapered standard of care, at 52 weeks. Baseline serum IgA2 anti-dsDNA antibody levels emerged as the only positive predictor of attaining MCR in belimumab treated patients (AUROC 0.8, 95% confidence interval [CI] 0.7-1.0), but negatively predicted MCR in the placebo arm (AUROC 0.2, CI 0.1-0.4). At baseline, 77% and 85% of patients were positive for serum IgA2 anti-dsDNA antibodies in belimumab and placebo arms respectively, which reduced to 30% at 52 weeks in the belimumab group but remained unchanged with placebo (Fisher exact test, p=0.007). In striking contrast, the percentage of patients who remained IgG anti-dsDNA antibody positive from baseline to 52 weeks were similar between the belimumab and placebo group, despite the serum levels significantly falling in the belimumab group (1). A significant reduction in serum IgA2 anti-dsDNA antibody levels at 24 and 52 weeks from baseline was only observed in belimumab responders (Figure 1).

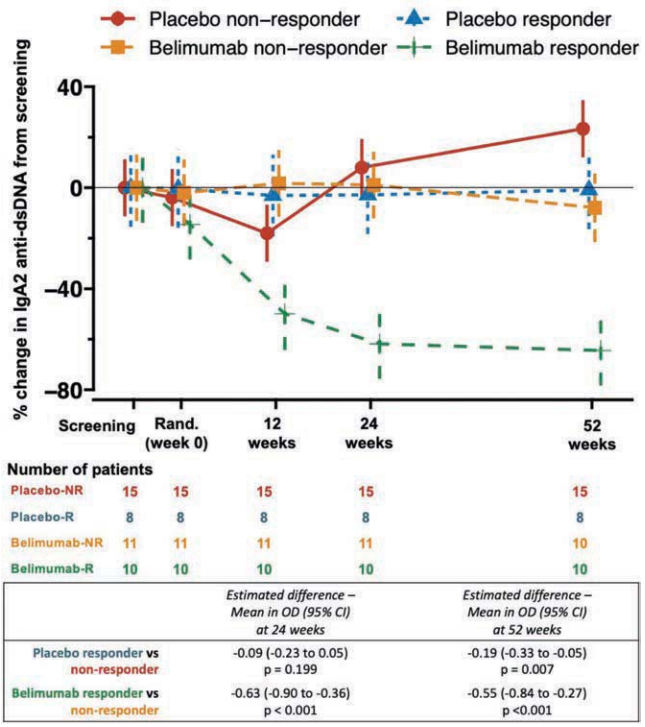

Figure 1. Percentage change in serum IgA2 anti-dsDNA antibody levels through to 52 weeks stratified by clinical response to belimumab (after rituximab) and placebo (after rituximab) at 52 weeks.

The number of circulating IgA2-secreting (but not total) plasmablasts (p=0.032) and T follicular helper cells (p=0.031) were significantly reduced at 52 weeks in the belimumab treated arm compared to placebo. Elevated serum IgA2 anti-dsDNA antibody levels were also associated with active renal disease irrespective of treatment arm (odds ratio, OR 3.2, CI 1.7-5.8, p<0.001). In contrast, serum IgA1 anti-dsDNA antibody (OR 1.3, CI 1.0-1.7, p=0.042) and interferon-alpha levels (OR 1.4, CI 1.0-2.0, p=0.041), and interferon transcriptional signature (OR 1.1, CI 1.0-1.3, p=0.027) showed a modest association with mucocutaneous disease activity; but did not predict response to B cell targeted therapy. Patients with a high baseline serum IL-6 were less likely to achieve an MCR irrespective of therapy (OR 0.4, CI 0.2-0.9, p=0.033). The associations between serum IgA2 and IgA1 anti-dsDNA antibody levels and active renal and mucocutaneous disease respectively were confirmed in an independent cross-sectional lupus cohort.

Conclusion: IgA2 anti-DNA autoantibodies is a biomarker of response to belimumab after rituximab, and of active renal disease, in systemic lupus erythematosus. Our study reveals distinct molecular networks associated with renal and mucocutaneous involvement, and response to B cell targeted therapies, which could guide precision targeting of current therapies for this heterogenous disease.

OP0238

CLINICAL ANALYSIS OF 34 CASES OF CARDIAC COMPLICATIONS REQUIRING SURGICAL INTERVENTION IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ASSESSMENT ABOUT MECHANISM OF DEVELOPMENT WITH IMMUNOLOGICAL ANALYSIS

T. Kawamoto[1], H. Amano[2], S. Matsushita[3], K. Minowa[1], M. Matsushita[1], K. Yamaji[1], A. Amano[3], N. Tamura[1]. [1]*Juntendo University School of Medicine, Internal Medicine and Rheumatology, Tokyo, Japan*; [2]*Juntendo University School of Medicine Nerima Hospital, Internal Medicine and Rheumatology, Tokyo, Japan*; [3]*Juntendo University School of Medicine, Cardiovascular Surgery, Tokyo, Japan*

Background: In cases of systematic lupus erythematosus (SLE) that lead to surgery due to the development of heart diseases such as valvular disease, ischemic heart disease and aortic aneurysm, early detection and careful monitoring are important. An absence of background diseases or immunopathological examination of the myocardial tissue in SLE cases with cardiovascular lesions demonstrates the lack of knowledge in this area. In recent years, however, there have been reports of neutrophil extracellular traps being involved in the fulminant onset of SLE.
Objectives: This study aimed to analyze clinically and immunohistopathologically the pathophysiology of heart diseases associated with SLE.
Methods: We performed left atrial appendage resection in 34 patients, including patients with cardiovascular lesions, who underwent heart surgery for SLE complications from 2012 to 2021. Tissue analysis was conducted in 9 cases. The left atrial appendage, in cases of non-collagen valvular disease, was used as the control. Tissue staining of cardiomyocytes was carried out by adding anti-neutrophil extracellular(NE) antibodies(Abs) to anti-human IgG antibody (Ab), anti-IgM Ab and anti-C3 Ab.
Results: Of the 34 SLE patients 14 had valvular disease, 8 had ischemic heart disease and 12 had aneurysms. Preoperative SLE activity was relatively stable with only 1 patient below the CH50 standard and 6 patients above the anti-DNA Ab standard. The Ab positivity rate for the patients in this study was higher than that of the 687 SLE patients who were previously tested in 2019. The presence of anti-CL Abs was 55.6%, which was higher than the 25.5% observed in previous SLE patients. In this study, anti-SS-A and anti-RNP Abs tended to be relatively numerous. An example of immunohistochemical staining of IgG in the left atrial appendage is presented (Figure 1a). IgG deposits were not observed on the left side of the myocardial fibers in the control group, whereas IgG deposits were observed on the right side in the SLE group. Deposits were also observed in tissues that were not located in the affected areas. The presence or absence of tissue deposition in the myocardial fibers and clinical findings in 2 cases of the control group and 9 cases of the SLE complication group are reported in Table 1. IgG deposits were found in the myocardial fibers of 6 of the 9 patients in the SLE complication group, and deposits were found in the left atrial appendage tissue regardless of the type of heart disease, suggesting a potential change in the heart tissue. In the SLE group, 5 cases were positive for antiphospholipid (APS) Abs, while 7 cases were positive for either anti-SS-A or anti-RNP Abs. Only 2 cases had elevated preoperative anti-DNA Ab and complement reduction. Of the SLE complication group, 2 of the 9 cases were negative for all Abs but IgG deposits were observed in a case. Of these 4 cases were selected and stained with anti-IgM, anti-C3 and anti-NE Abs. However IgM and C3 deposits were only observed in one patient who developed myocardial infarction at the age of 39 and was triple positive for APS, anti-SS-A and anti-RNP Abs (Figure 1b). There were also no NE deposits in any of the cases. Even if complement and anti-DNA Ab levels in the serum are normal, attention should be paid to heart disease complications during the long-term observation of SLE patients. In particular, attention should be paid to various autoantibody-positive cases such as APS, anti-SS-A Ab and anti-RNP Ab. The anti-NE Ab was not stained in this study because the tissue was different from the lesion site and because it occurred during the chronic course.
Conclusion: In SLE patients who developed cardiovascular lesions and required surgery, immunological abnormalities may occur in the myocardial tissue even if serum complement and anti-DNA Ab levels are stable.

Osteoporosis

OP0239

REAL-LIFE SHORT-TERM EFFECTIVENESS OF ANTI-OSTEOPOROTIC TREATMENTS: A LONGITUDINAL COHORT STUDY

G. Adami[1], I. Gavioli[1], A. Fassio[1], C. Benini[1], E. Bertoldo[1], O. Viapiana[1], D. Gatti[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: Data from randomized clinical trials showed that anti-osteoporotic treatments increase bone mineral density (BMD) and reduce the risk of fragility fractures. However, data on the real-life effectiveness of such medications is still scarce.
Objectives: The primary objective of the present study is to assess the real-life effectiveness of anti-osteoporotic treatment in a representative cohort of Italian women at high risk of fracture
Methods: We conducted a cohort study on women at high risk of fracture. We retrieved clinical and densitometric data from the DeFRA database, which derives from the DeFRA tool, a web-based fracture risk assessment tool. Multivariable Cox regression survival models were employed to analyze the effectiveness of

different anti-osteoporotic drugs on fracture. In sensitivity analyses we generated 1:1 matched cohorts of patients with prescription of bisphosphonates, denosumab, teriparatide or without any pharmacological prescription at baseline and 1:1 matched cohort based on the T-score variation over the time (increase in T-score vs decrease or stability in T-score values).

Results: Data from 50,862 women were available. Among these, 3,574 individuals had at least 2 consecutive visits. The crude fracture rate was 91.9/1,000 person-year for non-treated patients. The crude fracture rate in bisphosphonate users was 72.1/1,000 person-year, in denosumab users was 58.2/1,000 person-year and in teriparatide users was 19.3/1000 person-year. Overall, we found that bisphosphonates were associated with a 30% lower risk of fracture compared to no treatment (aHR 0.70, 95% CI 0.50-0.98), denosumab and teriparatide were associated with 60% and 90% lower risk of fracture, respectively (aHR 0.43, 95% CI 0.24-0.75 and aHR 0.09, 95% CI 0.01-0.70). Bisphosphonate use was associated with a lower risk of fracture only after one year of treatment. In Figure 1 are presented the Kaplan Meier curves free from fragility fracture after propensity score matching.

Conclusion: In conclusion, we found that all anti-osteoporotic medications effectively reduced the risk of fracture in the real-life. Bisphosphonate's effect on fracture risk was apparent only after the first year of treatment. Our findings do not support the use of bisphosphonates in patients at imminent risk of fracture.

Figure 1. Kaplan-Meier curves displaying the fracture (vertebral and non-vertebral fractures) probability for 1:1 matched groups of bisphosphonate users and individuals without treatment (log-rank p <0.0001)

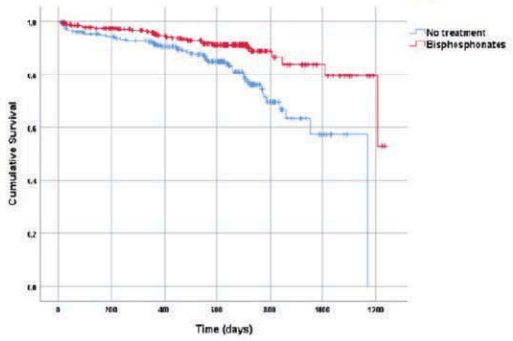

Figure 2. Kaplan-Meier curves displaying the fracture (vertebral and non-vertebral fractures) probability for 1:1 matched groups of denosumab users and individuals without treatment. (log-rank p 0.037)

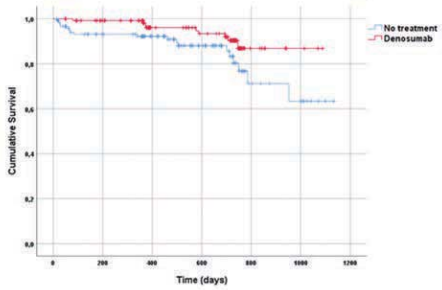

Figure 3. Kaplan-Meier curves displaying the fracture (vertebral and non-vertebral fractures) probability for 1:1 matched groups of patients with increasing BMD and stable or decreasing BMD. (log-rank p <0.0001)

ZOLEDRONATE-RELATED OSTEONECROSIS OF THE JAW IN OSTEOPOROSIS: INCIDENCE, RISK FACTORS AND COMPARISON TO ORAL BISPHOSPHONATES

C. Amigues[1], A. Fresse[2], C. Roux[1], S. Gauthier[3], M. H. Vieillard[4], M. D. Drici[5], V. Breuil[1,6]on behalf of French Network of Pharmacovigilance Centers. [1]*Hospital Pasteur, Rheumatology, Nice, France*; [2]*CHRU de Nancy - Hôpitaux de Brabois, Centre Régional de Pharmacovigilance de Nancy, Vandœuvre-lès-Nancy, France*; [3]*Chu De Lille, Centre Régional de Pharmacovigilance de Nancy, Lille, France*; [4]*Chu De Lille, Department of Rheumatology, Lille, France*; [5]*Hospital Pasteur, Pharmacology, Nice, France*; [6]*France, UMR E-4320 MATOs CEA/iBEB/SBTN, Nice, France*

Background: Mediatization of bisphosphonate(BP)-related osteonecrosis of the jaw (ONJ) has hampered the treatment of osteoporosis (OP). The risk of ONJ associated with oral BP in OP and zoledronate (ZOL) in oncology has previously been reported. However, the risk of ZOL-related ONJ in OP has only been reported in Randomized clinical trials.

Objectives: Therefore, we aimed to characterize ZOL-related ONJ in OP and compare it's incidence with oral BP in real life setting.

Methods: All reports of adverse events (AEs) of BP (ZOL, alendronate (ALN), risedronate (RIS)) were extracted from the French pharmacovigilance database (FPD) since its origin till 2020. For ZOL, cases were separated by indication, rheumatological (ZOL-R) or oncological (ZOL-K). The risk factors analyzed for ONJ were age, sex, active smoking, alcoholism, diabetes, corticotherapy, neoplasia, previous treatment by chemo or immunotherapy, recent dental care and time of exposure to BP. The association between the occurrence of ONJ and the associated BP was assessed by calculating the reporting odds ratio (ROR) in a case/non-case study. Stratification on assumed risk factors was performed to assess their impact on the risk of ONJ.

The incidence of ONJ under BP between 2011 and 2020 was estimated by relating the number of ONJ cases under BP reported to the FPD to the estimated number of patients treated with ZOL, ALN and RIS over the same period according to health insurance reimbursement data of Medic AM database. Incidence rate calculation, confidence interval calculation, and comparison of incidence rates (Fischer exact test) were performed.

Results: For ZOL 2254 AEs were reported: 568 ONJ/1103 AES with ZOL-K and 70 ONJ/1151 AEs with ZOL-R. For ZOL-R-related ONJ, 30/70 cases had recent dental care and 48.7 months of mean time of exposure to BP. Risk factors for ONJ were smoking, history of neoplasia and chemotherapy. For ALN, 1,010 AEs were reported, including 188 ONJ. 91/188 ONJ had recent dental care and 70.9 months of mean time of exposure to BP. Risk factors for ONJ were age ≥65 years, diabetes, corticotherapy, and history of neoplasia. For RIS, 771 AEs were reported including 68 cases of ONJ. 28/68 ONJ had recent dental care and 53.6 months the average time of exposure to BP. The risk factors were age ≥ 65 years, smoking, corticotherapy, history of neoplasia and chemotherapy. ROR calculation shows that corticotherapy was associated more frequently with RIS (2.10 [1.64-2.69]) and ALN (1.33 [1.04-1.70]) as compared with ZOL-R, with no other significant difference. The incidence of ONJ was significantly higher with ZOL-R than with RIS ($p<0.001$) and ALN ($p<0.001$). Indeed, between 2011 and 2020, 614 932 patients were treated with ZOL-R and 59 cases of ONJ reported yielding an incidence of 9.6/100,000 person-years; 2 233 536 patients were treated with RIS and 44 cases of ONJ reported yielding an incidence of 2.0/100 000 person-years; 2 432 373 patients were treated with ALN and 125 cases of ONJ reported yielding an incidence of 5.1/100 000 person-years.

Conclusion: Our data confirm in real-life settings and a large population, that BP-related ONJ is a rare event associated with OP. The risk of BP-related ONJ appears related to the potency of bone resorption inhibition, as RIS has the lowest and ZOL-R the highest risk. Smoking appears a consistent risk factor of ONJ, as is recent dental care. However, we must stress out the usual limitations of pharmacovigilance studies, their retrospective nature, common under-reporting of adverse-events, and the fact that the Medic AM database only refers to city reimbursements.

To our knowledge, this is the first study reporting the risk of ONJ under ZOL from the national pharmacovigilance database. Our study confirms the rarity, in OP, of BP-related ONJ. The risk of incidence of ONJ on ZOL-R is higher than on RIS and ALN, suggesting a risk associated with the inhibitory power of bone resorption.

BONE MICROARCHITECTURE ASSESSED BY HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY (HR-PQCT) PREDICTS FRACTURE RISK IN PATIENTS WITH RHEUMATIC DISEASES ON GLUCOCORTICOIDS

H. So[1], S. L. Lau[2], V. W. Hung[3], H. T. Pang[4], S. K. Y. Ying[5], K. Kwok[6], J. M. Lee[7], J. J. W. Lee[8], J. F. Griffith[9], L. Qin[10], L. S. Tam[2]. *[1]The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; *[1]The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; *[3]The Chinese University of Hong Kong, Orthopedics & Traumatology, Hong Kong, Hong Kong (SAR)*; *[4]Kwong Wah Hospital, Medicine and Geriatrics, Hong Kong, Hong Kong (SAR)*; *[5]Princess Margaret Hospital, Medicine and Geriatrics, Hong Kong, Hong Kong (SAR)*; *[6]Queen Elizabeth Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[7]Tai Po Hospital, Medicine and Geriatrics, Hong Kong, Hong Kong (SAR)*; *[8]The Chinese University of Hong Kong, Centre for Clinical Research and Biostatistics, Hong Kong, Hong Kong (SAR)*; *[9]The Chinese University of Hong Kong, Imaging & Interventional Radiology, Hong Kong, Hong Kong (SAR)*; *[3]The Chinese University of Hong Kong, Orthopedics & Traumatology, Hong Kong, Hong Kong (SAR)*

Background: Peripheral bone micro-architectural parameters assessed by high-resolution peripheral quantitative computer tomography (HR-pQCT) were able to discriminate vertebral fracture in patients with rheumatic diseases on glucocorticoid (GC) independent of areal bone mineral density aBMD. Whether these parameters could predict future fracture remained to be determined.
Objectives: The aim of this study was to compare the differences in baseline vBMD, bone microarchitecture and estimated bone strength in these patients with and without incident fragility fracture over a period of 5 years.
Methods: This was a multi-centered, retrospective, case-controlled study. Patients with rheumatic diseases on long term GC from 7 regional hospitals who had dual-energy X-ray absorptiometry (DXA) and HR-pQCT done were invited to have a 5th year follow-up assessment. X-rays were repeated. The occurrence of new fragility fracture after 5 years was documented. The baseline clinical characteristics, aBMD, FRAX and HR-pQCT parameters in patients who experienced a new fragility fracture during the 5-year follow-up period (incident fracture group) were compared with patients who did not experience a fragility fracture (control group).
Results: A total of 140 patients were recruited. The mean age of the patients, who were mostly female (80.7%), was 58.7 ± 12.5 years at baseline. SLE and RA were the commonest diagnoses. At baseline, 45.0% and 28.6% of the patients had osteopenia or osteoporosis respectively. The baseline 10-year major osteoporotic and hip fracture risks by FRAX were 13.3% and 6.0% respectively. After 5 years, 47 (33.6%) of the patients developed new fractures. The baseline clinical characteristics of incident facture group and the control group are shown in Table 1. Patients with incident fracture were older. They also had more prevalent fracture and worse mobility. The aBMD and FRAX scores were significantly higher in the incident fracture group. When comparing the HR-pQCT parameters, the incident fracture group had significantly worse vBMD, microarchitecture and bone strength particularly over the tibia at baseline. However, the changes in these parameters were not different between the 2 groups. Multivariate regression confirmed that the baseline vBMD, microarchitectural parameters and estimated bone strength over distal tibia were independent predictors of new fractures after adjusting for age, gender as well as baseline fracture, mobility and osteoporosis status.
Conclusion: A significant proportion (33.6%) of patients with rheumatic diseases on long-term GC developed new fragility fracture in 5 years, which could be predicted by the worse vBMD, microarchitecture and bone strength over tibia at baseline on HR-pQCT independent of aBMD.

OP0242

ASSOCIATION BETWEEN EXPOSURE TO FINE PARTICULATE MATTER AND OSTEOPOROSIS: A POPULATION-BASED COHORT STUDY

G. Adami[1], C. Benini[1], A. Fassio[1], E. Bertoldo[1], O. Viapiana[1], D. Gatti[1], M. Rossini[1]. *[1]University of Verona, Rheumatology Unit, Verona, Italy*

Background: Environmental air pollution has been associated with disruption of bone health at a molecular level. Particulate matter (PM) exposure can simultaneously stimulate bone resorption and halt bone formation.
Objectives: The primary aim of the present study is to describe the association between long-term exposure to PM and osteoporosis in a large cohort of women at high risk of fracture.
Methods: Clinical, demographic and densitometric data were extracted from the DeFRAcalc79 dataset, which gathers data on women at risk for osteoporosis. Data on the monitoring of PM10 and PM2.5 concentrations were retrieved from the Italian institute of environment protection and research (Istituto Superiore per la Protezione e la Ricerca Ambientale, ISPRA). Every study subject was linked to a PM exposure value, which resulted from the average concentration of urban, rural and near-traffic stations of the subject residency (ZIP code centroids 25 km) from January 2013 to December 2019. Generalized linear models with robust estimators were employed to determine the relationship between BMD and PM long-term exposure. We sequentially adjusted for confounders. Model 1 included age, body mass index (BMI), presence of prevalent fragility fractures, family history of vertebral or hip fractures, and menopause. Model 2 was further adjusted for glucocorticoid treatment and comorbidities. Model 3 (main model) added to model 2 the macro-area of residency (stratified as a categorical variable: northern Italy, central Italy and southern Italy).
Results: 59,950 women from 110 Italian provinces were included in the study. PM 2,5 exposure was negatively associated with T-score levels at the femoral neck (β -0.005, 95 CI -0.007 to -0.003) and lumbar spine (β -0.003, 95% CI -0.006 to -0.001). Chronic exposure to PM2.5 above 25 μg/m^3 was associated with a 16% higher risk of having osteoporotic T-score at any site (aOR 1.161, 95% CI 1.105 to 1.220), exposure to PM10 above 30 μg/m^3 was associated with a 15% higher risk of having osteoporotic T-score at any site (aOR 1.148, 95% CI 1.098 to 1.200).
Conclusion: Long-term exposure to air pollution was associated with higher risk of osteoporosis. Femoral neck site seemed to be more susceptible to the detrimental effect of PM exposure than lumbar spine site.

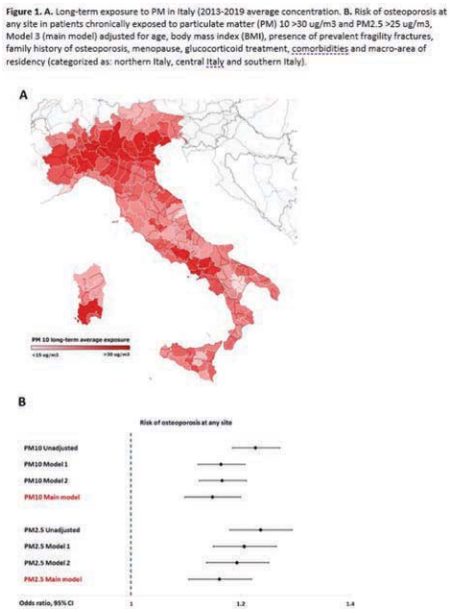

Figure 1. A. Long-term exposure to PM in Italy (2013-2019 average concentration. **B.** Risk of osteoporosis at any site in patients chronically exposed to particulate matter (PM) 10 >30 ug/m3 and PM2.5 >25 ug/m3, Model 3 (main model) adjusted for age, body mass index (BMI), presence of prevalent fragility fractures, family history of osteoporosis, menopause, glucocorticoid treatment, comorbidities and macro-area of residency (categorized as: northern Italy, central Italy and southern Italy).

OP0243 OSTEOPOROSIS CASE-FINDING IN PEOPLE UNDERGOING ROUTINE DIAGNOSTIC CT SCANS ALMOST TRIPLED THE RATE OF OSTEOPOROSIS TREATMENT AT 12 MONTHS. A RANDOMISED, MULTI-CENTRE FEASIBILITY STUDY USING WAITING ROOM FRAX, OPPORTUNISTIC CT BONE DENSITY AND VERTEBRAL FRACTURE ASSESSMENT VERSUS USUAL CARE.

K. Poole[1], D. Chappell[2], J. Brown[2], E. Clark[3], J. Fleming[4], L. Shepstone[5], T. Turmezei[6], A. Wagner[7], K. Willoughby[1], S. Kaptoge[4]. *[1]University of Cambridge School of Clinical Medicine, Medicine, Cambridge, United Kingdom*; *[2]Addenbrooke's Hospital, Rheumatology, Cambridge, United Kingdom*; *[3]University of Bristol, Clinical Science at North Bristol, Bristol, United Kingdom*; *[4]Cambridge Institute of Public Health, Public Health and Primary Care, Robinson Way, United Kingdom*; *[5]Norwich Clinical Trials Unit, Statistics, Norwich, United Kingdom*; *[6]Norfolk & Norwich University Hospital, Radiology, Norwich, United Kingdom*; *[7]Norwich Clinical Trials Unit, Health Economics, Norwich, United Kingdom*

Background: Up to 40% of all diagnostic computed tomography (CT) scans include views of the spine or hips. Among older people, osteoporosis or vertebral fractures have been found in 30% of such CT scans. Our 'PHOENIX' intervention repurposes CT scans taken for other reasons to identify fractures and measure bone density as an 'added extra'. Early detection and treatment of osteoporosis in CT-attending patients could improve health outcomes.
Objectives: To determine the feasibility and efficacy of PHOENIX versus usual care in a multi-centre, randomised, pragmatic study conducted in Eastern England involving our Cambridge Specialist Hospital 'hub' and four regional General Hospital 'spokes'.
Methods: Women ≥65 and men ≥75 years attending for routine diagnostic CT scans were invited to participate via a novel consent form incorporating FRAX Fracture Risk Assessment questions. After calculating their FRAX 10-year risk score, higher risk patients were block randomised (1:1:1) to Group 1) PHOENIX intervention, 2) Active Control, where the GP was sent the patients' FRAX answers only, or 3) Usual Care where data were only analysed after 13 months had elapsed. The CT scans of high FRAX risk patients in Group 1 were retrieved by the Cambridge team using NHS Connecting for Health (Burnbank, UK). The team performed vertebral fracture assessment and measured bone density using QCT Pro (Mindways, USA). They added patient-specific treatment and investigation management advice from 'drop down' menus before results were reviewed by a physician, authorised and sent to general practitioners (GPs). Baseline CT scans from groups 2 and 3 were assessed in the same way after 13 months to ensure no patient with osteoporosis/fractures was neglected long term. Assuming 25% attrition, the study was powered to find a superior osteoporosis treatment rate in Group 1 (estimated 20%) versus 16% (Active Control) and 5% (Usual Care). Co-primary feasibility endpoints were the ability to a) randomise 375 patients within 10 months and b) retain 75% of survivors able to complete a 1-year bone health outcome questionnaire. Secondary outcomes included osteoporosis/vertebral fracture identification rates and osteoporosis treatment rates. Stakeholder acceptability and economic aspects will be reported separately.
Results: From 1828 invites, 595 participants consented to participate of whom 213 were excluded due to 'low' FRAX score. Mortality at 12 months was 20%. Both feasibility objectives were achieved: 1) 382 people were randomised within 10 months; 2) 84.4% of survivors at 1 year (95%CI: 80.5, 88.3) were successfully followed-up. Groups were well matched at baseline. The average age of 375 patients (334 female, 41 male) was 75.2 years (74.6, 75.9). Osteoporosis of the hip/spine was present in 41% of 362 analysable CT scans. From the 264 spines that were suitable for VFA, 20% (n=53) were found to have vertebral fractures, with 8.3% having multiple vertebral fractures (n=22). Osteoporosis treatment was reported in 8.5% of Usual Care group (2.9, 14.2) and 24.2% (15.4, 33.0) of PHOENIX group participants, while in the Active Control group (FRAX only) it was 18.8% (10.9, 26.6 p=0.021). In the PHOENIX group, a recommendation to treat was sent to 50 patients' GPs at baseline. Only 18 of the 50 patients (36%) were found to be taking osteoporosis treatment 12 months after this advice was sent.
Conclusion: Osteoporosis treatment rates were almost tripled by screening patients attending for routine diagnostic CT scans with waiting room FRAX, CT-bone densitometry and vertebral fracture analysis.
Acknowledgements: This project is funded by the National Institute for Health Research (NIHR) under its Research for Patient Benefit (RfPB) Programme (Grant Reference Number PB-PG-0816-20027) and by the Cambridge NIHR Biomedical Research Centre (BRC-1215-20014). The views expressed are those of the author(s) and not necessarily those of the NIHR or the Department of Health and Social Care. Funding is in place to 31.03.2022. Three individuals, Mr Jeremy Dearling, Mrs Tessa Plume and Dr Ann Frost joined our trial group as PPI representatives; they were specifically involved in patient documentation design (particularly the PHOENIX pack, informed consent form which facilitated consent without having a researcher present) and contributed to suggestions for increasing patient recruitment and follow up.

OP0244 AROMATASE INHIBITORS AND FRACTURE PREVENTION – DO NEW GUIDELINES WORK IN REAL WORLD?

A. Mirza[1], Z. Win Naing[1], P. Khonsari[1], H. Khan[1], P. Rezai[1], A. K. Abbas[1], M. Nisar[1]. *[1]Luton & Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: 2,261,419 women were diagnosed with breast cancer worldwide in 2020. For postmenopausal women with hormone sensitive disease, aromatase inhibitors (AI) are recommended for their mortality benefit. However, AI bone loss (AIBL) is a recognised adverse event with resultant increase in fracture risk. In 2017, a consensus statement of 7 international bone and cancer societies was published proposing an algorithm based on clinical risk factors and different bone mineral density (BMD) threshold for bone active therapeutic intervention.
Objectives: To determine the real-world impact of the 2017 consensus guidelines on AIBL and whether bone sparing therapy utilising proposed risk stratification model is effective in fracture prevention.
Methods: Over a 7-year study period, 1001 women were prescribed AI at our university teaching hospital. The new guidelines were adopted in July 2017. We split the participants in two groups: 361 (36%) women had commenced their AI prior to the adoption of guidelines and 640 (64%) were in the post implementation group. First group were offered bone active treatment based on NOS 2009 guidelines whereas the second group followed the 2017 consensus guidelines. Women with osteoporosis were all offered treatment, however the difference in guideline is pertinent to osteopenia and we compared the results of that group.
Results: 1001 women were included. Mean age was 64 years (range 29-93). 929 (93%) were Caucasian, 57 (6%) were Asian and 15 (1%) were Afro-Caribbean. 723 women (72%) had invasive ductal carcinoma and 863 women (86%) were postmenopausal. At diagnosis, 428 women (43%) had node positive disease and 35 women (4%) had metastases. 91 women (9%) had sustained fractures prior to their cancer diagnosis.
276 women (28%) were offered oral bisphosphonates based on DEXA result, with 58 (6%) offered parenteral therapy.
First group: 361 women had a baseline DEXA with a mean left neck of femur (LNOF) BMD of 0.888 g/cm2 (range 0.552-1.222). 143 (40%) women had a normal DEXA, 174 (48%) had osteopenia and 44 (12%) had osteoporosis.
Of the women with osteopenia, 44 (25%) women were offered treatment and 33 women had a repeat DEXA after a mean of 4 years. In the treatment group, LNOF mean BMD remained relatively unchanged from 0.814 g/cm2 to 0.812 g/cm2 at the repeat DEXA (p= 0.94).
Of the 174 women with osteopenia, 22 (13%) women had a fracture.
Second group: 640 women had a baseline DEXA with a mean LNOF BMD of 0.888 g/cm2 (range 0.512-1.390). 216 (33%) women were normal, 322(50%) had osteopenia and 107 (17%) had osteoporosis.
Of the women with osteopenia, 127 (39%) women were offered treatment and 56 women had a repeat DEXA after a mean of 3 years. In the treatment group, LNOF mean BMD remained relatively unchanged from 0.822 g/cm2 to 0.829 g/cm2 at the repeat DEXA (p= 0.6169).
Of the 322 women with osteopenia, 8 (2.5%) women had a fracture.
Conclusion: Our study provides real world evidence of the success of 2017 consensus statement in lowering fracture risk. Though there has been data for positive impact on BMD decline with this approach, evidence for fracture prevention has been limited. This study showcases the success of lowering bone active therapy threshold employing alternative risk modelling strategy for women with breast cancer commenced on AI. A significant reduction in fractures pre (13%) and post guidelines change (2.5%) was demonstrated (absolute risk reduction of 10.5%) which has implications for healthcare systems worldwide as we have demonstrated this approach can reduce morbidity.

OP0245 **ASSOCIATION OF BARIATRIC SURGERY WITH THE RISK OF FRACTURE IN PATIENTS WITH OBESITY: A META-ANALYSIS OF REAL-WORLD EVIDENCE**

S. Hussain[1], J. Klugarova[2], M. Klugar[2]. [1]*Czech National Centre for Evidence-Based Healthcare and Knowledge Translation (Cochrane Czech Republic, Czech EBHC: JBI Centre of Excellence, Masaryk University GRADE Centre), Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic*; [2]*Czech National Centre for Evidence-Based Healthcare and Knowledge Translation (Cochrane Czech Republic, Czech EBHC: JBI Centre of Excellence, Masaryk University GRADE Centre), Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic*

Background: Evidence from published epidemiological studies found inconsistent evidence on the association of bariatric surgery with fracture risk.
Objectives: To evaluate the impact of bariatric surgery on fracture risk.
Methods: Electronic databases PubMed, and Embase were searched for studies assessing the association between bariatric surgery and fracture risk by two independent investigators. The study search period was from inception to September 2021. Study selection, data extraction, and risk of bias were assessed by investigators independently. Newcastle-Ottawa Scale (NOS) was used to assess the risk of bias. The primary outcome was to compute the pooled fracture risk in patients with obesity who underwent bariatric surgery. Secondary outcomes include fracture risk based on follow-up duration and sites of fracture (hip, upper limb). Certainty of findings was assessed using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) criteria.
Results: This meta-analysis was based on seven studies with a total of 156233 patients with a mean age of 41.65 ± 10.63 years. Included studies were of low risk of bias. A significantly increased risk of any fracture was found in the bariatric surgery group as compared to the non-surgical group with a pooled relative risk (RR) of 1.34 (95% CI: 1.05 – 1.70), p= 0.02 (Figure 1).

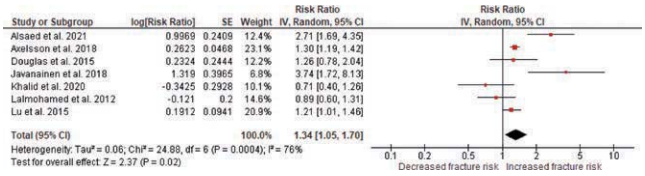

Figure 1. Forest plot showing high fracture risk in the bariatric surgery group

Subgroup analysis based on follow-up duration also revealed a significantly higher fracture risk with a RR of 1.75 (95% CI: 1.34 – 2.30), p= <0.0001 for studies with a follow-up period of >5 years. Likewise, analysis based on fracture sites revealed a significantly higher risk of hip fracture RR 1.34 (95% CI: 1.03 – 1.75), p=0.03 (Figure 2). Evidence was of low certainty as per the GRADE rating system.

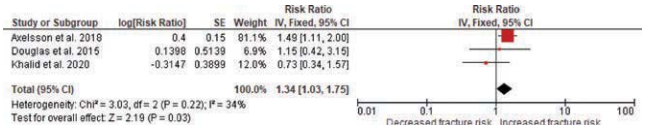

Figure 2. Forest plot showing high hip fracture risk in the bariatric surgery group

Conclusion: The current study found that bariatric surgery was associated with increased fracture risk. Clinicians should also evaluate the bone health profiling of the patients before the surgery.

OP0246 **TO SCAN OR NOT TO SCAN (BOTH HIPS) – A BRISTOL EXPERIENCE**

A. Anilkumar[1], S. Saeed[2], E. Elsayed[1], C. N. R. Jayatilleke[1], S. Webber[2], M. A. Roy[1]. [1]*University Hospitals Bristol and Weston NHS Foundation Trust, Adult Rheumatology, Bristol, United Kingdom*; [2]*University Hospitals Bristol and Weston NHS Foundation Trust, Adult Rheumatology, Weston, United Kingdom*

Background: The current International Society of Clinical Densitometry (ISCD) recommendation for bone densitometry practice is that single hip measurement is sufficient in clinical practice, as there is overall a good correlation between the two hip bone mineral densities (BMD) (1) (2). However, discordance in individual T- scores and BMD between the 2 hips due to increasing age and osteoarthritis (3)-(5) is well recognised.
Objectives: We aimed to identify whether discordant hip BMD values would lead to differences in the FRAX risk assessment score between the two hips, and thereby impact treatment decisions in clinical practice.
Methods: We looked at all DXA scans performed at our centre for 2 months between 23/7/21 and 23/9/21. Cases in which both hips were scanned and anti-resorptive treatment was advised were included in our study. The femoral neck with the lower BMD is used to calculate the FRAX score and this was referred to as the 'reported' hip. The FRAX score for 'reported' and 'unreported' hip were calculated and the T-score of the spine was also noted. Our local treatment threshold is set at 20% for a major osteoporotic fracture and 5% for hip fracture. Cases of difference in scores crossing the 20%/5% FRAX threshold were highlighted and reviewed in more detail.
Results: DXA scans were performed in 328 patients over the 2 month period, of which 201 patients had both of their hips scanned. Of these, 50 patients were advised to start anti-resorptive treatment. The majority of the treatment decisions (60%; 30/50 cases) were based on the hip/femoral neck BMD value, while 40% (20/50 cases) were based on the spine T-score.
Where the treatment decision was based on hip/femoral neck BMD, 20% (6/30 cases) were found to have a FRAX risk above the treatment threshold at one hip only, meaning that treatment may not have been offered if both hips had not been scanned. Similarly, where treatment was advised based on spinal T-scores, 20% (4/20 cases) had a FRAX risk above treatment threshold at one hip only.
Mean age across these 10 cases with a discordant FRAX risk between the two hips was 72 years (range 59 – 83); 80% (8/10) were female. Steroid use and chronic inflammatory co-morbidities were the predominant indications for these DXA Scans.
Conclusion: A significant proportion of patients in our cohort (20%; 10/50) may not have been offered treatment if only one hip was scanned. Scanning both hips does not require much additional time and can help mitigate the risk of undertreating patients. The recommendation for best practice for DXA BMD measurements should be reviewed to consider lumbar spine and dual hip BMD as standard of care.

Outcome of COVID-19 in Rheumatic Diseases

OP0247 **RISK FACTORS FOR SEVERE COVID-19 OUTCOMES: A STUDY OF IMMUNE-MEDIATED INFLAMMATORY DISEASES, THERAPIES AND COMORBIDITIES IN A LARGE US HEALTHCARE SYSTEM**

P. J. Mease[1], Q. Wei[2], M. Chiorean[3], L. Iles-Shih[3], J. Hadlock[2]. [1]*Swedish Medical Center/Providence St. Joseph Health, Rheumatology, Seattle, United States of America*; [2]*Institute for Systems Biology, Hadlock Lab, Seattle, United States of America*; [3]*Swedish Medical Center, Gastroenterology, Seattle, United States of America*

Background: The risk of acquiring COVID-19, and the severity of illness if acquired, in the context of immune-mediated inflammatory diseases (IMIDs) and their therapy, remains incompletely understood. Reported infection rates and outcomes have varied depending on the IMIDs being studied, the nature and size of the study population, and the presence or absence of appropriate control populations. Having more reliable analysis on larger populations is essential for current and future pandemics.
Objectives: Health records from one of the largest health systems in the US are analyzed to determine whether specific IMIDs, including common rheumatologic conditions and specific immunomodulatory drugs, are associated with certain COVID-19 outcomes, using multivariate models that include common chronic comorbidities.
Methods: Patients (pts) with and without IMIDs who were tested for SARS-CoV-2 antigen (n=1,101,431) were identified from the EHR from Providence St. Joseph Health, which serves much of the western US. Immunomodulatory drug therapy was defined as use within three months prior to the first test. Multivariate logistic regression (LR) was applied with machine learning metrics (feature importance, p-value) reported on an 80% training set and AUROC reported on 20% test set.
Results: Rates for positive COVID-19 tests, invasive mechanical ventilation (IMV) and mortality were not greater in the IMID than non-IMID population, whilst hospitalization was similar (Table 1). Importance and statistical significance of selected factors are shown in (Figure 1). The most important risk factors for hospitalization were age and heart failure. Heart failure was the most important risk factor for IMV, and age for increased mortality. Diabetes showed weak associations with these three outcomes. Spondyloarthritis was weakly associated with decreased hospitalization, IMV, and death. The use of conventional synthetic disease-modifying antirheumatic drugs (csDMARDS) and corticosteroids (CS) showed a weak association with hospitalization, and rituximab (RTX) showed a weak association with increased mortality. Limitations include lack of vaccination status and IMID disease severity/flare status. Testing was not universal.

Table 1. COVID-19 test results, hospitalization, invasive mechanical ventilation, and mortality

	Tested for COVID	COVID+	Hospitalized *n*, % of COVID+	IMV *n*, % of COVID+	Mortality % of COVID+
	n (%)	*n*, % of tested	*n*, % of COVID+		
All pts	1,101,431 (100%)	128,962 (11.7%)	19,704 (15.3%)	1,001 (0.8%)	2,232 (1.7%)
Pts without selected IMIDs	1,049,007 (95.3%)	123,943 (11.8%)	18,729 (15.1%)	959 (0.8%)	2,165 (1.7%)
Pts with selected rheumatologic IMIDs	28,411 (2.5%)	2,974 (10.5%)	578 (19.4%)	27 (0.9%)	51 (1.7%)
Pts with other selected IMIDs	24,013 (2.2%)	2,045 (8.5%)	397 (19.4%)	15 (0.7%)	16 (0.8%)

Selected rheumatologic IMIDs = RA, SpA, PsA, SLE, PsO, SSc; Other selected IMIDs = IBD, MS.

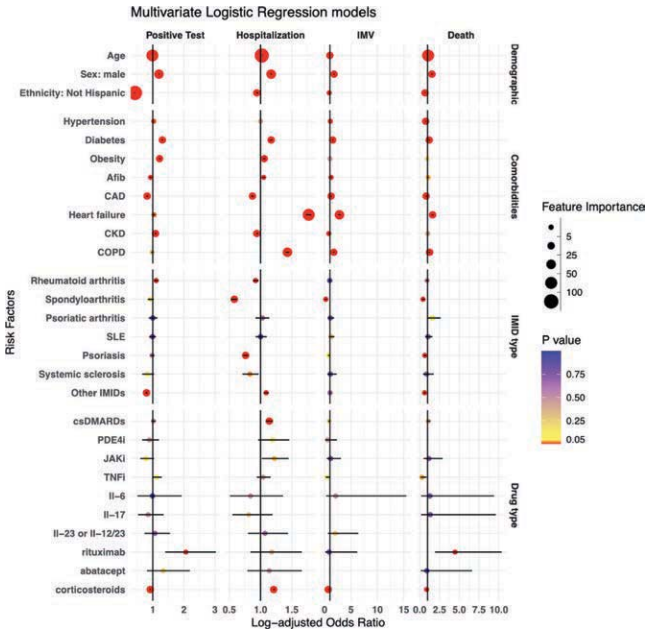

Figure 1. Odds ratio (OR) for selected risk factors for COVID-19 positive test, hospitalization, IMV, and mortality

Conclusion: This analysis of COVID+ patients (n=1,101,431) from a large US health care system analyzes outcomes of patients with *and* without IMIDs; the majority were rheumatologic IMIDs. Patients with IMIDs had a similar rate of hospitalization, IMV, and death as those without IMIDs. The strongest associations with COVID-19 severity included heart failure and age. Spondyloarthritis was weakly associated with favorable outcomes whilst other conditions, including rheumatologic, were not worse than those of non-IMID patients. csDMARDs and corticosteroids were weakly associated with hospitalization and RTX with increased mortality. Other therapies were not associated with severe adverse outcomes.

SEVERE COVID-19 OUTCOMES AMONG PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES: A POPULATION-BASED STUDY

S. Marozoff[1], Z. A. Fazal[1,2], J. Tan[1,3], N. Lu[1], A. Hoens[1,4], D. Lacaille[1,5], J. Kopec[1,6], H. Xie[1,7], J. M. Loree[8,9], J. Esdaile[1,5], J. A. Aviña-Zubieta[1,5]. [1]*Arthritis Research Canada, N/A, Vancouver, Canada*; [2]*University of British Columbia, Faculty of Land and Food Systems, Vancouver, Canada*; [3]*University of British Columbia, Faculty of Science, Vancouver, Canada*; [4]*University of British Columbia, Department of Physical Therapy, Vancouver, Canada*; [5]*University of British Columbia, Division of Rheumatology, Department of Medicine, Vancouver, Canada*; [6]*University of British Columbia, School of Population and Public Health, Vancouver, Canada*; [7]*Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada*; [8]*University of British Columbia, Division of Medical Oncology, Department of Medicine, Vancouver, Canada*; [9]*BC Cancer, N/A, Vancouver, Canada*

Background: Individuals with autoimmune rheumatic diseases (ARDs) may be at greater risk of severe COVID-19 outcomes than individuals in the general population.
Objectives: This study assesses the risk of COVID-19-related hospitalization, intensive care unit (ICU) admission, and COVID-19-specific mortality in patients with ARDs compared to matched general population comparators.
Methods: We conducted a population-based cohort study, using administrative datasets from British Columbia, Canada (February 2020-August 2021). Among all test-positive SARS-CoV-2 adults, we used ICD codes to identify all individuals with an **ARD**: rheumatoid arthritis (RA), psoriasis/psoriatic arthritis (PsO/PsA), ankylosing spondylitis (AS), and systemic autoimmune rheumatic diseases (SARDs), including systemic lupus erythematosus (SLE), Sjogren's syndrome, systemic sclerosis, myositis, and adult systemic vasculitides. Individuals with an ARD were matched 1:5 to general population test-positive SARS-CoV-2 individuals on age (± 5 years), sex, month/year of initial positive SARS-CoV-2 test, and health authority. Conditional logistic regression models adjusting for socioeconomic status, Charlson comorbidity index, hypertension, rural address, and number of previous COVID-19 PCR tests were performed to assess risk of COVID-19-related hospitalizations, ICU admissions, and COVID-19-specific mortality (mortality with primary ICD code for COVID-19).
Results: The risk of COVID-19-related hospitalization was significantly increased for patients with ARDs overall (aOR: 1.30) (Table 1). Within ARDs, the patient group at greatest risk of hospitalization was adult systemic vasculitides (aOR: 2.18). The risk of ICU admission was significantly increased for patients with ARDs overall (aOR: 1.30). Within ARDs, the patient group at greatest risk of ICU admission was those with AS (aOR: 2.03). The risk of COVID-19-specific mortality was significantly increased for patients with ARDs overall (aOR: 1.24). Within ARDs, the patient group at greatest risk of COVID-19-specific mortality was those with AS (aOR: 2.15).

Table 1. Risk of severe COVID-19 outcomes among patients with ARDs

	Hospitalizations		ICU admissions		COVID-19-specific mortality

Myositis comparators (150)	12 (8.0)	1.00	<5	1.00	7 (4.7)	1.00
Vasculitides *(82)*	25 (30.5)	**2.18 (1.17, 4.05)**	8 (9.8)	1.70 (0.70, 4.16)	<5	*
Vasculitides comparators (404)	64 (15.8)	1.00	21 (5.2)	1.00	16 (4.0)	1.00

Results for systemic sclerosis not presented; sample size too small. *Unable to be calculated (small sample size)

Conclusion: The risk of severe COVID-19 outcomes is increased in some ARDs, although magnitude differs across individual diseases. Strategies to mitigate risk, such as booster vaccination, prompt diagnosis, and early intervention with available therapies (e.g., oral antivirals) should be prioritized in these groups according to risk.

Background: Some factors associated with severe COVID-19 outcomes have been identified in patients with psoriasis (PsO) and inflammatory/autoimmune rheumatic diseases, namely older age, male sex, comorbidity burden, higher disease activity, and certain medications such as rituximab. However, information about specificities of patients with PsO, psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA), including disease modifying anti-rheumatic drugs (DMARDs) specifically licensed for these conditions, such as IL-17 inhibitors (IL-17i), IL-23/IL-12+23 inhibitors (IL-23/IL-12+23i), and apremilast, is lacking.

Objectives: To determine characteristics associated with severe COVID-19 outcomes in people with PsO, PsA and axSpA.

Methods: This study was a pooled analysis of data from two physician-reported registries: the Psoriasis Patient Registry for Outcomes, Therapy and Epidemiology of COVID-19 Infection (PsoProtect), comprising patients with PsO/PsA, and the COVID-19 Global Rheumatology Alliance (GRA) registry, comprising patients with PsA/axSpA. Data from the beginning of the pandemic up to 25 October,

2021 were included. An ordinal severity outcome was defined as: 1) not hospitalised, 2) hospitalised without death, and 3) death. A multivariable ordinal logistic regression model was constructed to assess the relationship between COVID-19 severity and demographic characteristics (age, sex, time period of infection), comorbidities (hypertension, other cardiovascular disease [CVD], chronic obstructive lung disease [COPD], asthma, other chronic lung disease, chronic kidney disease, cancer, smoking, obesity, diabetes mellitus [DM]), rheumatic/skin disease (PsO, PsA, axSpA), physician-reported disease activity, and medication exposure (methotrexate, leflunomide, sulfasalazine, TNFi, IL17i, IL-23/IL-12+23i, Janus kinase inhibitors (JAKi), apremilast, glucocorticoids [GC] and NSAIDs). Age-adjustment was performed employing four-knot restricted cubic splines. Country-adjustment was performed using random effects.

Results: A total of 5008 individuals with PsO (n=921), PsA (n=2263) and axSpA (n=1824) were included. Mean age was 50 years (SD 13.5) and 51.8% were male. Hospitalisation (without death) was observed in 14.6% of cases and 1.8% died. In the multivariable model, the following variables were associated with severe COVID-19 outcomes: older age (Figure 1), male sex (OR 1.53, 95%CI 1.29-1.82), CVD (hypertension alone: 1.26, 1.02-1.56; other CVD alone: 1.89, 1.22-2.94; vs no hypertension and no other CVD), COPD or asthma (1.75, 1.32-2.32), other lung disease (2.56, 1.66-3.97), chronic kidney disease (2.32, 1.50-3.59), obesity and DM (obesity alone: 1.36, 1.07-1.71; DM alone: 1.85, 1.39-2.47; obesity and DM: 1.89, 1.34-2.67; vs no obesity and no DM), higher disease activity and GC intake (remission/low disease activity and GC intake: 1.96, 1.36-2.82; moderate/severe disease activity and no GC intake: 1.35, 1.05-1.72; moderate/severe disease activity and GC intake 2.30, 1.41-3.74; vs remission/low disease activity and no GC intake). Conversely, the following variables were associated with less severe COVID-19 outcomes: time period after 15 June 2020 (16 June 2020-31 December 2020: 0.42, 0.34-0.51; 1 January 2021 onwards: 0.52, 0.41-0.67; vs time period until 15 June 2020), a diagnosis of PsO (without arthritis) (0.49, 0.37-0.65; vs PsA), and exposure to TNFi (0.58, 0.45-0.75; vs no DMARDs), IL17i (0.63, 0.45-0.88; vs no DMARDs), IL-23/IL-12+23i (0.68, 0.46-0.997; vs no DMARDs) and NSAIDs (0.77, 0.60-0.98; vs no NSAIDs).

Conclusion: More severe COVID-19 outcomes in PsO, PsA and axSpA are largely driven by demographic factors (age, sex), comorbidities, and active disease. None of the DMARDs typically used in PsO, PsA and axSpA, were associated with severe COVID-19 outcomes, including IL-17i, IL-23/IL-12+23i, JAKi and apremilast.

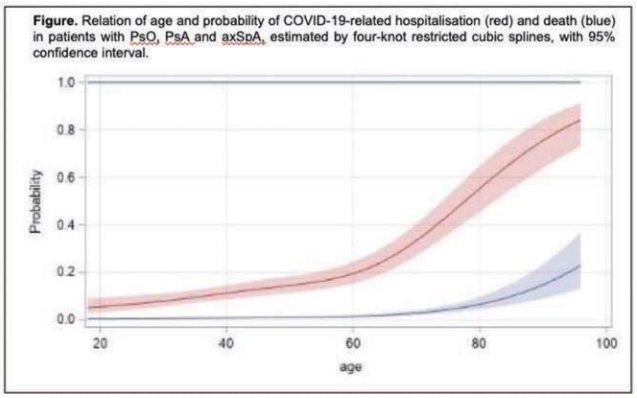

Figure. Relation of age and probability of COVID-19-related hospitalisation (red) and death (blue) in patients with PsO, PsA and axSpA, estimated by four-knot restricted cubic splines, with 95% confidence interval.

OP0250 BREAKTHROUGH INFECTIONS AND PREDICTING SEVERE COVID OUTCOMES DURING RITUXIMAB THERAPY IN AUTOIMMUNE RHEUMATIC DISEASES

M. Y. Md. Yusof[1,2], J. Arnold[1], B. Saleem[3], C. Vandevelde[3], S. Dass[1], S. Savic[1], E. Vital[1,2], P. Emery[1,2]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[3]Leeds Teaching Hospitals NHS Trust, Rheumatology, Leeds, United Kingdom*

Background: As rituximab (RTX) is a B-cell depleting agent, there are concerns regarding its safety during the COVID pandemic. Data from registries during pre-vaccination period reported increased risk of poor outcomes in RTX-treated patients vs TNFi. However, registry data could be limited by reporting bias in determining true incidence. There are also limited data on breakthrough infections following COVID vaccination.

Objectives: To assess the incidence of breakthrough infections and predictors of severe COVID outcomes in RTX-treated autoimmune rheumatic diseases (ARDs) with a view to establishing a treatment algorithm for safe RTX administration.

Methods: An observational cohort study was undertaken in the first consecutive 300 ARD patients in a single centre between index date 01/09/2019 (i.e. 6 months prior to pandemic) and 31/01/2022. Only PCR positive cases were included. COVID outcomes were categorised as Mild (i.e. not hospitalised) or Moderate/Severe (i.e. hospitalised and requiring at least oxygenation or death). Predictors of moderate/severe outcomes were analysed using Cox-regression proportional hazard.

Results: Mean (SD) at index date was 59 (14) years, 226/300 (75%) patients were female and 254 (85%) were Caucasians. The diagnoses were RA=212 (71%), SLE=33 (11%), AAV=26 (9%), Sjogren=9 (3%), IIM=8 (3%) and others=12 (4%). Therapy included concomitant DMARDs = 205 (68%) and oral prednisolone = 84 (28%). Median (range) no. of previous RTX courses was 4 (0-19). 534 RTX courses were administered. Of 294 patients with available vaccine data, 17 (6%) were unvaccinated, 4 (1%) had a single dose, 47 (16%) were double-vaccinated, 217 (74%) triple-vaccinated and 9 (3%) quadruple-vaccinated. Of those who were vaccinated, for the first dose, 11% were given within 12 weeks post-RTX, 15% within 26 weeks and 74% were >26 weeks post-RTX. The rate of overall COVID and moderate/severe infections were 11.2/100 PYs and 2.6/100 PYs respectively. Vaccinated patients had lower rate of moderate/severe infection (2.6/100 PYs) vs unvaccinated (18.6/100 PYs) [Table 1]. Over 650.7 PY follow-up, 17/300 patients (5.7%) had moderate/severe COVID including 2 deaths. Factors associated with time-to-infection in imputed multivariable analysis were number of comorbidities [HR 1.46 (95% CI 1.05-2.04)] and low IgG (<6g/L) [6.15 (1.95-19.41)]. A history of COVID vaccination reduced risk [HR 0.13 (0.03-0.51)]. Demographics including concomitant prednisolone, RTX- and vaccine-associated factors (e.g. RTX dose, time from RTX to vaccine, vaccine mode, peripheral B-cell depletion) were not predictive.

Table 1. Incidence of COVID infection

	Pre-Vaccination Programme	Post-Vaccination Programme	Overall Follow-up
Overall COVID rate	3.3/100 PY	Non-vaccinated = 37.7/100 PY Vaccinated = 18.6/100 PY	73 cases in 650.7 years] = 11.2/100 PY
Moderate/Severe COVID rate	2.1/100 PY	Non-Vaccinated = 15.1/100 PY Vaccinated = 2.6/100 PY	17 cases in 650.7 years] = 2.6/100 PY

Conclusion: The rate of moderate/severe COVID infection in this cohort is comparable to the pre-pandemic severe infection rate in rituximab trials in RA. The high vaccination uptake in our cohort was effective in preventing severe infection despite the termination of national shielding programme in March 2021 and the spread of the Delta and Omicron variants. Individualised risk–benefit assessment should be undertaken in those with comorbidities, low IgG and unvaccinated when scheduling rituximab therapy.

Sparks[5]. *[1]Mayo Clinic, Division of Rheumatology, Jacksonville, United States of America*; *[2]Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; *[3]Mayo Clinic, Department of Biostatistics, Scottsdale, United States of America*; *[4]Massachusetts*

General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; [5]*Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America*

Background: RA has been associated with poor COVID-19 outcomes, but few studies have investigated outcomes in RA features such as interstitial lung disease.
Objectives: To assess COVID-19 outcomes in patients with RA overall, and those with and without ILD, compared to general population comparators.
Methods: A multicenter, retrospective cohort study was conducted at Mayo Clinic (19 hospitals and affiliated outpatient centers in 4 states) and Mass General Brigham (14 hospitals and affiliated outpatient centers in New England). Consecutive patients with RA meeting ACR/EULAR criteria and a positive COVID-19 test from March 1, 2020 through June 6, 2021 were matched 1:5 on age, sex, race, and COVID-19 test date with general population comparators without RA. RA features assessed included: RA-ILD per Bongartz criteria [1], duration, rheumatoid factor (RF), cyclic citrullinated peptide antibody (CCP), bone erosions, and treatments. The primary outcome was a composite of hospitalization or death following COVID-19 diagnosis. We used multivariable Cox regression to investigate the association of RA, and features such as ILD, with COVID-19 outcomes compared to matched comparators.
Results: We analyzed 582 patients with RA and 2892 comparators without RA, all with COVID-19. Mean age was 62 years, 51% were female, and 79% were White. Mean RA duration was 11 years, 67% were seropositive (52% RF+ and 54% CCP+), 27% had bone erosions, 28% were on steroids, and 79% were on DMARDs. 50/582 (9%) patients with RA had ILD.
The COVID-19 hospitalization or death rate for RA patients was higher than comparators (3.0 per 1,000 days [95% CI 2.5-3.6] vs. 1.9 per 1,000 days [95% CI 1.7-2.1], respectively). Overall, RA patients had a 53% higher risk of hospitalization or death than comparators after adjustment (95% CI 1.20-1.94).
Among those with RA-ILD, the hospitalization or death rate was significantly higher than comparators (10.9 [95% CI 6.7-15.2] vs. 2.5 per 1,000 days [1.8-3.2], respectively). RA-ILD was associated with nearly 3-fold higher risk for hospitalization or death than comparators (multivariable HR 2.84 [95% CI 1.64-4.91], Table 1). There was a significant interaction between RA/comparator status and presence/absence of ILD for risk of severe COVID-19 (p<0.001, Figure 1). The elevated risk for severe COVID-19 was similar for RA subgroups defined by serostatus or bone erosions.

Table 1. Frequencies, proportions, and hazard ratios for COVID-19 outcomes, comparing all RA patients, and subgroups with or without RA-ILD, to matched comparators.

COVID-19 Outcomes	All RA Patients (n=582)	RA-ILD (n=50)	RA Patients without ILD (n=532)	Comparators (n=2,892)
Hospitalization, n (%)	121 (21)	24 (48)	97 (18)	402 (14)
Unadjusted HR (95% CI)	1.58 (1.27, 1.96)	2.65 (1.71, 4.09)	1.43 (1.12, 1.82)	Ref.
Adjusted* HR (95% CI)	1.45 (1.14, 1.83)	2.35 (1.38, 4.00)	1.31 (1.00, 1.70)	Ref.
Death, n (%)	26 (4)	9 (18)	17 (3)	63 (2)
Unadjusted HR (95% CI)	1.72 (0.98, 3.01)	5.88 (2.07, 16.71)	1.13 (0.56, 2.29)	Ref.
Adjusted* HR (95% CI)	1.24 (0.66, 2.32)	13.94 (4.30, 45.18)	0.75 (0.35, 1.63)	Ref.
Hospitalization or death, n (%)	126 (22)	25 (50)	101 (19)	419 (14)
Unadjusted HR (95% CI)	1.66 (1.33, 2.07)	3.01 (1.93, 4.70)	1.47 (1.14, 1.89)	Ref.
Adjusted* HR (95% CI)	1.53 (1.20, 1.94)	2.84 (1.64, 4.91)	1.34 (1.02, 1.77)	Ref.

*Adjusted for age, sex, race, and smoking

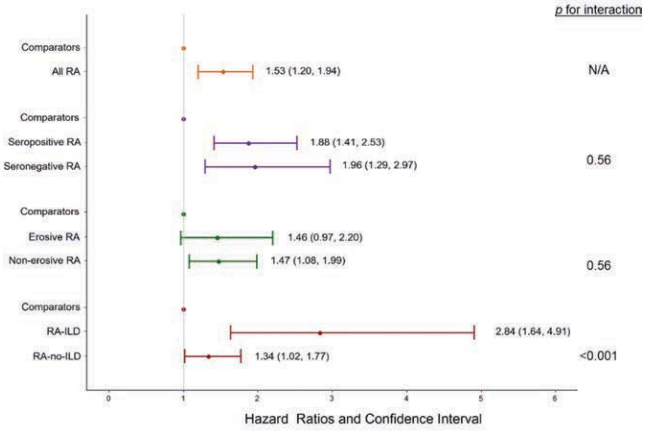

Figure 1. Multivariable hazard ratios for the composite outcome of hospitalization or death from COVID-19, comparing all RA and subgroups by serostatus, bone erosions, and ILD to matched comparators without RA.

Conclusion: We confirmed that RA was associated with severe COVID-19 outcomes compared to the general population. We found evidence that ILD may be an effect modifier for the relationship between RA and severe COVID-19 outcomes, but RA subgroups defined by serostatus and bone erosions had similarly elevated risk. These findings suggest that ILD or its treatment may be a major contributor to severe COVID-19 outcomes in RA.

Background: There is a paucity of data in the literature about the outcome of patients with idiopathic inflammatory myopathy (IIM) who have been infected with SARS-CoV-2.
Objectives: To investigate factors associated with severe COVID-19 outcomes in patients with IIM.
Methods: Data on demographics, number of comorbidities, region, COVID-19 time period, physician-reported disease activity, anti-rheumatic medication exposure at the clinical onset of COVID-19, and COVID-19 outcomes of IIM patients were obtained from the voluntary COVID-19 Global Rheumatology Alliance physician-reported registry of adults with rheumatic disease (from 17 March 2020 to 27 August 2021). An ordinal COVID-19 severity scale was used as primary outcome of interest, with each outcome category being mutually exclusive from the other:a) no hospitalization, b) hospitalization (and no death), or c) death. Odds ratios (OR) were estimated using multivariable ordinal logistic regression. In ordinal logistic regression, the effect size of a categorical predictor can be interpreted as the odds of being one level higher on the ordinal COVID-19 severity scale than the reference category.
Results: Complete hospitalization and death outcome data was available in 348 IIM cases. Mean age was 53 years, and 223 (64.1%) were female. Overall, 167/348 (48.0%) people were not hospitalized, 136/348 (39.1%) were hospitalized (and did not die), and 45/348 (12.9%) died. Older age (OR=1.59 per decade of life, 95%CI 1.32-1.93), male sex (OR=1.63, 95%CI 1.004-2.64; versus female), high disease activity (OR=4.05, 95%CI 1.29-12.76; versus remission), presence of two or more comorbidities (OR=2.39, 95%CI 1.22-4.68; versus none), prednisolone-equivalent dose >7.5 mg/day (OR=2.37, 95%CI 1.27-4.44; versus no glucocorticoid intake), and exposure to rituximab (OR=2.60, 95%CI 1.23-5.47; versus csDMARDs only) were associated with worse COVID-19 outcomes (Table 1).

Table 1. Multivariable logistic regression analysis of factors associated with the ordinal COVID-19 severity outcomes. AZA, azathioprine; CI, confidence interval; combo, combination; CSA, ciclosporin; CYC, cyclophosphamide; DMARD, disease-modifying anti-rheumatic drug; b/tsDMARD, biologic/targeted synthetic DMARD, csDMARD, conventional synthetic DMARD; HCQ, hydroxychloroquine; IVIg, intravenous immunoglobulin; LEF, leflunomide; MMF, mycophenolate mofetil; mono, monotherapy; MTX, methotrexate; OR, odds ratio; Ref, reference; RTX, rituximab; SSZ, sulfasalazine; TAC, tacrolimus.

Variable	OR (95%CI)	P-value	Variable	OR (95%CI)	P-value
Age (per decade)	**1.59 (1.32-1.93)**	**<0.001**	**Comorbidities**

Prednisolone-equivalent dose			One	1.46 (0.79-2.72)	0.228
None	Ref	NA	Two or more	**2.39 (1.22-4.68)**	**0.011**
>0 to 7.5mg/day	1.10 (0.57-2.11)	0.779	**Physician-reported disease activity**		
>7.5mg/day	**2.37 (1.27-4.44)**	**0.007**	Remission	Ref	NA
IVIg	0.41 (0.15-1.16)	0.093	Low/moderate	1.23 (0.67-2.28)	0.504
DMARDs			High	**4.05 (1.29-12.76)**	**0.018**
csDMARD only (mono or combi - HCQ, MTX, LEF, SSZ)	Ref	NA	**Region**		
No DMARD	1.84 (0.90-3.75)	0.094	Europe	Ref	NA
b/tsDMARD mono or combi (except RTX)	1.60 (0.49-5.26)	0.435	North America	0.89 (0.49-1.61)	0.694
CSA/CYC/TAC mono or combi (except RTX or b/tsDMARDs)	1.55 (0.52-4.58)	0.429	Other	**4.25 (2.21-8.16)**	**<0.001**
AZA mono	1.70 (0.69-4.19)	0.249	**Time period**		
MMF mono	1.22 (0.53-2.82)	0.634	Before 15 June 2020	Ref	NA
AZA/MMF combi (except RTX or b/tsDMARDs)	0.71 (0.25-2.00)	0.517	16 June - 30 September 2020	0.58 (0.26-1.27)	0.171
RTX mono or combi	**2.60 (1.23-5.47)**	**0.012**	After 1 October 2020	**0.58 (0.35-0.95)**	**0.032**

Conclusion: These are the first global registry data on the impact of COVID-19 on IIM patients. Older age, male gender, higher comorbidity burden, higher disease activity, higher glucocorticoid intake and rituximab exposure were associated with worse outcomes. These findings will inform risk stratification and management decisions for IIM patients.

OP0253 COVID-19 ADMISSIONS AND MORTALITY IN PATIENTS WITH EARLY INFLAMMATORY ARTHRITIS: RESULTS FROM A NATIONAL COHORT

M. Adas[1], M. Russell[1], E. Cook[1], E. Alveyn[1], S. Oyebanjo[2], P. Amlani-Hatcher[3], J. Ledingham[4], S. Norton[1,5], J. Galloway[1]. [1]*King's College London, Centre for Rheumatic Disease, London, United Kingdom*; [2]*British Society of Rheumatology, NEIAA, London, United Kingdom*; [3]*British Society for Rheumatology, NEIAA Patient Panel, London, United Kingdom*; [4]*Portsmouth Hospitals University NHS Trust, Rheumatology Department, Portsmouth, United Kingdom*; [5]*King's College London, Psychology Department, London, United Kingdom*

Background: There has been a major concern about the impact of COVID-19 in patients with inflammatory arthritis during the pandemic, with recommendations from governments for patients to shield.
Objectives: Our aim was to describe the risk factors for COVID-19 hospitalisation and mortality amongst patients recruited to the National Early Inflammatory Arthritis Audit (NEIAA) in England.

Methods: An observational cohort study design was used. The population included adults in England with new diagnoses of inflammatory arthritis between May 2018 and March 2021 who enrolled in NEIAA. The outcomes were hospitalisation due to COVID-19 (primary admission reason or nosocomial acquisition) and death due to COVID-19 (COVID-19 stated on a death certificate), identified via linkage with secondary care records. Hazard ratios were calculated using Cox proportional hazards models, with adjustment for patient factors (age, gender, smoking status, and comorbidity) and disease factors (seropositivity, 28-joint disease activity score, patient-reported disability (HAQ), and functional impact (MSK-HQ)) recorded at baseline. Individuals were considered at risk from the date of diagnosis or February 2020 (whichever was later) and censored at a COVID-19 event, death or May 2021 (whichever was sooner).

Results: 14,127 patients were included. The mean age was 57 years; 62% were female; 19% were current smokers, while 29% were ex-smokers. The frequency of comorbidities at baseline were: hypertension (19%), diabetes mellitus (9%), and lung disease (9%). Overall, 20% had two or more comorbidities. Rheumatoid factor or CCP antibodies were positive in 56%. At presentation, mean scores for DAS28 were 4.6 (+/- 1.5), 1.1 (+/- 0.7) for HAQ, and 25 (+/- 11) for MSK-HQ. Initial DMARD therapy was known for 13,682/14,127 patients: methotrexate was the most common (54%), followed by hydroxychloroquine (23%), and sulfasalazine (11%).

There were 143 COVID-19 hospital admissions and 47 deaths, corresponding to incidence rates per 100 person-years for hospitalisation: 0.94 [95% CI: 0.79-1.10] and death: 0.31 [95% CI: 0.23-0.41]. Increasing age, male gender, diabetes, hypertension, lung disease and smoking status all predicted COVID-19 hospitalisation and death. Higher baseline DAS28 predicted COVID-19 hospitalisation (HR 1.24 [95% CI: 1.10-1.39]) and mortality (HR 1.33 [95% CI: 1.09-1.63]). Higher HAQ predicted both COVID-19 hospitalisation and death. Seropositivity was not a significant predictor of any COVID-19 event, nor was MSK-HQ. In unadjusted models, corticosteroids associated with COVID-19 death (HR 2.29 [95% CI: 1.02-5.13], and sulfasalazine monotherapy associated with COVID-19 hospitalisation (HR 1.93 [95% CI: 1.04-3.56]. In adjusted models, associations for corticosteroids and sulfasalazine were no longer significant. Only age, smoking status, and comorbidities independently predicted COVID-19 events.

Conclusion: The burden of COVID-19 amongst early arthritis patients was substantial during the pandemic, with concerns about the use of csDMARDs and corticosteroids.[1,2] Patient characteristics and rheumatoid disease severity at diagnosis appear to be the more important predictors of COVID-19 events than initial treatment strategy. An important limitation is that we have not looked at treatment changes over time, and must acknowledge that many patients, especially those recruited in 2019, may have changed therapy prior to the pandemic.

Background: To our knowledge, no published work has described precisely the severity and evolution of SARS-CoV-2 infection in patients with spondyloarthritis (SpA). Data on COVID-19 from cohorts of patients with immune-mediated inflammatory diseases concern small samples of SpA.

Objectives: Our objective was to describe the severity and course of COVID-19 in a large cohort of patients with SpA, including axial SpA (axSpA) and psoriatic arthritis (PsA), and to identify factors associated with severe forms.

Methods: Patients: individuals with Spondyloarthritis (SpA) from the French RMD COVID-19 cohort (observational, national, multicenter cohort) with a diagnosis of COVID-19 (clinical, PCR, CT or serology) were included.

Data collected: demographics, type of SpA, comorbidities, treatments, severity of COVID-19. Severity of COVID-19 was graded according to care needed: mild = outpatient care; moderate = non-intensive hospital treatment; severe = intensive care unit admission or death; severe = moderate or severe.

Statistical analyses: Logistic regression models were used to identify factors associated with these severe forms. All variables with p <0.20 in the univariate analysis were proposed in the multivariate model. Treatment variables (non-steroidal anti-inflammatory drugs (NSAIDs), methotrexate (MTX), sulfasalazine (SLZ), TNF inhibitors (TNFi), IL-17 inhibitors (IL-17i) and IL-23p19/p40 inhibitors (IL-23p19/p40i)) were included in the models, even if p≥0.20.

Results: Between March 2020 and April 2021, 626 SpAs reported COVID-19 with a mild course in 508 cases (81.1%), moderate in 93 cases (14.8%), and severe in 25 cases (3.9%), including 6 deaths.

The cohort analyzed included 349 women (55.8%), mean age 49.3 ± 14.1 years, mean BMI 27.1 ± 5.4 with 403 axSpA (64.4%), 187 PsA (29.9%) and 36 other SpA, duration of disease 11.3 ± 9.8 years; 352 (56.2%) had at least one comorbidity, of which obesity (23.6%), hypertension (15.5%), and smoking (10.4%) were the most frequent. Among them, 104 were treated with NSAIDs (16.6%), 186 with conventional synthetic disease-modifying antirheumatic drugs (DMARDs) including 156 MTX, and 460 (73.5%) with biological DMARDs (379 TNFi, 57 IL-17i, 15 IL-23p19/p40i, 9 others).

The following variables were associated with severe COVID-19 outcomes: age, body mass index, chronic obstructive lung disease, cardiovascular disease, diabetes, hypertension, interstitial lung disease, renal failure, and corticosteroids intake.

The factors independently associated with severe COVID-19 outcomes were corticosteroid intake (3.15 [CI95%: 1.46-6.76], p 0.004), and age (OR=1.06 [CI95%: 1.04-1.08], p <0.001] while anti-TNF (OR=0.26 [CI95%: 0.09-0.78], p=0.01]) was protective. NSAIDs intake (OR=0.97 [CI95%: 0.48-1.98]), SLZ (OR=7.9 [CI95%: 0.60-103]), or anti-IL17 (OR=0.37 [CI95%: 0.10-1.31]) was not associated with infection severity.

Conclusion: The course of COVID-19 was mild for the majority of SpA patients (81.1%). Corticosteroid intake was associated with more severe COVID-19 outcomes, whereas TNFi were found to be protective.

Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. BKZ has shown sustained efficacy and tolerability up to 152 wks in a phase 2b study in patients (pts) with active psoriatic arthritis (PsA).[1,2]

Objectives: To assess efficacy and safety of BKZ vs placebo (PBO) in pts with active PsA and prior inadequate tumour necrosis factor inhibitor (TNFi) response in the 16-wk pivotal phase 3 study, BE COMPLETE.

Methods: BE COMPLETE (NCT03896581) comprises a 16-wk double-blind, PBO-controlled period. Pts were aged ≥18 yrs, had a diagnosis of adult-onset, active PsA with ≥3 tender joints and ≥3 swollen joints, and inadequate response or intolerance to treatment with 1 or 2 TNFi. Pts were randomised 2:1 to BKZ 160 mg Q4W or PBO. From Wk 16, pts were eligible to enter an open-label extension, receiving BKZ 160 mg Q4W. The primary endpoint was a ≥50% improvement in American College of Rheumatology response criteria (ACR50) at Wk 16. Primary and ranked secondary efficacy endpoints were assessed at Wk 16.

Results: Of 400 randomised pts (BKZ: 267; PBO: 133), 388 (97.0%) completed Wk 16 (BKZ: 263 [98.5%]; PBO: 125 [94.0%]). Baseline characteristics were comparable between groups: mean age 50.5 yrs, weight 86.0 kg, BMI 29.8 kg/m^2, time since diagnosis 9.5 yrs; 47.5% pts were male.

At Wk 16, the primary endpoint (ACR50: 43.4% BKZ vs 6.8% PBO; p<0.001; Figure 1) and all ranked secondary endpoints (HAQ-DI CfB, PASI90, SF-36 PCS CfB and MDA response) were met (all p<0.001; Table 1). The ACR50 response was rapid with separation from PBO observed from Wk 4 (nominal p<0.001). Additional outcomes, including ACR20/70, TJC and SJC CfB, and PASI75/100, demonstrated numerical improvement with BKZ compared to PBO at Wk 16 (all nominal p<0.001; Table 1).

Table 1. Disease characteristics at baseline and efficacy at Wk 16

Randomised set (N=400). *Primary endpoint; †Secondary endpoint; ‡Nominal p value. [a]In patients with ≥3% BSA with PSO at BL; [b]n=88; [c]n=176.

Over 16 wks, 107/267 (40.1%) pts on BKZ had ≥1 TEAE vs 44/132 (33.3%) pts on PBO; the three most frequent TEAEs on BKZ were nasopharyngitis (BKZ: 3.7%; PBO: 0.8%), oral candidiasis (BKZ: 2.6%; PBO: 0%) and upper respiratory tract infection (BKZ: 2.2%; PBO: 1.5%). Incidence of SAEs was low (BKZ: 1.9%; PBO: 0%); none led to discontinuation. 2 pts on BKZ discontinued due to a TEAE (BKZ: 0.7%; PBO: 0%). No systemic candidiasis, cases of IBD, MACE, uveitis, VTE or deaths were reported.

Conclusion: Dual inhibition of IL-17A and IL-17F with BKZ in pts with active PsA and prior inadequate TNFi response resulted in rapid, clinically relevant and statistically significant improvements in efficacy outcomes vs PBO. No new safety signals were observed.[1,2]

OP0256 FIBROBLAST ACTIVATION PROTEIN (FAP) PET-CT IMAGING ALLOWS TO DEPICT INFLAMMATORY JOINT REMODELING IN PATIENTS WITH PSORIATIC ARTHRITIS

Schett[2], A. Ramming[2]. *[1]Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and University Hospital Erlangen, Department of Nuclear Medicine, Erlangen, Germany*; *[2]Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and University Hospital Erlangen, Department of Internal Medicine 3, Rheumatology & Immunology, Erlangen, Germany*; *[3]Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and University Hospital Erlangen, Institute of Radiology, Erlangen, Germany*; *[4]Hospital Clinic and IDIBAPS, Arthritis Unit, Rheumatology Department, Barcelona, Germany*

Background: Psoriatic arthritis (PsA) is characterized by substantial mesenchymal tissue activation in the context of inflammation leading to structural damage. Measuring mesenchymal tissue activation in humans in vivo is challenging but may represent a possibility to detect regions at risk for structural damage. Recently, theranostic ligands have been developed that selectively bind Fibroblast Activation Protein (FAP) and allow recognition of activated mesenchymal cells in vivo. Accumulation of such FAP-based tracers can be visualized by positron-emission tomography (PET) (1).

Objectives: In this study, we analyzed whether FAP tracer-based PET-CT can detect mesenchymal tissue activation in patients with PsA and whether this signal is associated with joint damage.

Methods: 120 consecutive PsA patients fulfilling CASPAR criteria and 100 healthy controls without musculoskeletal disease received full-body PET-CT investigation using a ^{68}Ga-labelled FAP inhibitor (^{68}Ga-FAPI-04) tracer, specifically binding FAP. For all visually identified pathological tracer-positive lesions the mean and maximum standardized uptake value (SUV mean, SUV max) was assessed. Tracer uptake was quantified in peripheral and axial joints and correlated to various composite scores of PsA. Hand MRI scans were performed in parallel to assess inflammation and structural lesions. Follow-up ^{68}Ga-FAPI-04 PET-CT scans were obtained in a subset of patients treated with cytokine inhibitors (follow-up between 3-6 months) to assess joint damage over time. In addition, FAP related tissue responses in synovial biopsy samples were evaluated on a molecular level by high-resolution slide RNA-sequencing in a subset of patients.

Results: ^{68}Ga-FAPI-04 accumulated at synovial and enthesial sites in patients with PsA compared to healthy controls ($p < 0.0001$). Active pain in peripheral as well as axial joints as measured on a visual analogue scale highly correlated with an increased ^{68}Ga-FAPI-04 uptake (peripheral pain: $R = 0.718$, $p < 0.0001$; back pain: $R = 0.875$, $p < 0.0001$). Disease Activity in PSoriatic Arthritis (DAPSA) score also correlated with the SUV mean and SUV max of FAP expression ($R = 0.774$; $p = 0.0001$). Increased ^{68}Ga-FAPI-04 uptake at baseline was associated with progression of joint damage 3-6 months later as assessed by PsAMRIS score ($R = 0.778$, $p < 0.0001$). Treatment with cytokine inhibitors partially reduced FAP expression which was associated with arrest of joint damage in MRI. In contrast, persistent FAP expression was associated with a rapid progression of joint damage in MRI. Molecular analysis of synovial biopsy samples from FAP+ lesions revealed interactions between FAP+ fibroblasts and T cells, innate lymphoid cells and macrophages, which was correlated to a strong upregulation of NF-kB related pathways fostering cartilage and bone destruction.

Conclusion: Our study presents the first in-human evidence that fibroblast activation correlates with disease progression and joint damage in patients with PsA. FAP related imaging might therefore improve the risk assessment of rapidly emerging joint damage in PsA and open new options of treat-to-target strategies in PsA.

Background: Several autoimmune inflammatory diseases, including rheumatoid arthritis (RA), are associated with increased risk of malignant lymphomas. There is also a longstanding concern of lymphoma development with tumour necrosis factor inhibitor (TNFi) treatment, but most studies in RA to date do not indicate an additionally increased risk. Corresponding studies in psoriatic arthritis (PsA), both with respect to the underlying risks, and risks in relation to treatment with TNFi, are limited. Data on myeloid malignancies in PsA are scarce.

Objectives: To estimate the risk of haematological malignancy overall and by lymphoid and myeloid types in TNFi treated versus (vs.) biologics-naïve patients with PsA across the five Nordic countries. Additionally, we investigated the underlying risk of haematological malignancies in PsA as compared to the general population.

Methods: We identified patients with PsA starting a first ever TNFi from the clinical rheumatology registers (CRR) in Sweden (SE), Denmark (DK), Norway (NO), Finland (FI), and Iceland (ICE) from 2006 through 2019 (n=10 621). We identified biologics-naïve patients with PsA from a) the CRR (n=18 705, all countries) and b) the national patient registers (NPR, n=27 286, SE and DK only). To estimate the underlying risk of haematological malignancy in PsA, we randomly sampled general population comparators in SE and DK matched on year of birth, sex, and calendar year at start of follow-up, to the patients with PsA.

Through linkage to the mandatory national cancer registers in all five countries, we collected information on haematological malignancy overall, and categorised into lymphoid or myeloid types. By applying a modified Poisson regression, we estimated pooled incidence rate ratio (IRR) with 95% confidence intervals (CI) for TNFi treated vs. biologics-naïve PsA and for PsA vs. the general population, adjusted for age (18-55, 56-65, 66-70, >70 years), sex, calendar period (2006-2010, 2011-2019) and country, and using robust standard errors.

Results: We observed 40 events of haematological malignancies (during 59 827 person-years) among TNFi treated PsA, resulting in a crude incidence rate (IR) of 67 per 100 000 person-years. The corresponding IR was 91 (63 events) for biologics-naïve PsA from the CRR, and 118 (172 events) for biologics-naïve PsA from NPR. This resulted in a pooled IRR of 0.97 (0.69 to 1.37) for TNFi-treated vs. biologics-naïve PsA patients from the CRR, and 0.84 (0.64 to 1.10) vs. biologics-naïve PsA patients from the NPR. The pooled IRR of haematological malignancies in PsA overall vs. the general population was 1.35 (1.17 to 1.55). Throughout, the estimates were largely similar for lymphoid and myeloid malignancies (Figure 1). The crude IR of haematological malignancies were substantially akin across different TNFi agents.

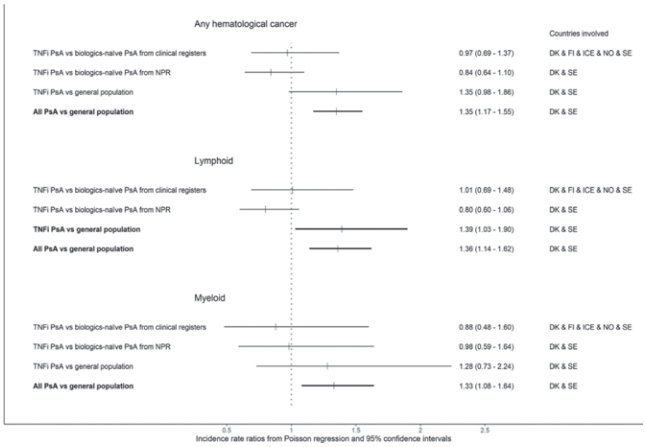

Figure 1. Pooled incidence rate ratios (IRRs) (95% CI) of haematological malignancy overall and by lymphoid and myeloid types, in first ever TNFi treated versus biologics-naïve patients with PsA, and versus general population comparators. **Legend:** Lymphoid malignancies include international classification of diseases (ICD) 10 codes C81-86, C88, C90-91. Myeloid malignancies include ICD10 codes C92-95, D45-D46, D47.1, D47.3-5. Incidence rate ratios adjusted for age (18-55, 56-65, 66-70, >70 years), sex, calendar period (2006-2010, 2011-2019) and country, and using robust standard errors.

Conclusion: In this large five-country cohort study, we did not observe any increased risk of haematological malignancies overall, nor for lymphoid and myeloid types, in patients with PsA treated with TNFi. By contrast, there were signals of a moderately increased underlying risk of haematological malignancies, both of lymphoid and myeloid types, in patients with PsA overall as compared to the general population. The findings are of importance from a patient information perspective.

Background: Psoriatic arthritis (PsA) is a chronic, immune-mediated inflammatory disease with heterogenous musculoskeletal manifestation (arthritis, spondylitis, enthesitis, dactylitis) and extra-musculoskeletal manifestation (skin and nail psoriasis). In addition, PsA is commonly associated with comorbidities such as metabolic syndrome and cardiovascular diseases where IL-17 is a key driver of this disease.

Izokibep is a unique IL-17A inhibitor with extraordinary potency and small molecular size designed to overcome the limitations of monoclonal antibodies such as poor tissue distribution.

Here, we report 16-week phase 2 results in patients with active PsA.

Objectives: To assess efficacy, safety, pharmacokinetics and immunogenicity of izokibep versus placebo.

Methods: This is a prospective, multicenter, randomized, double-blind, placebo-controlled, parallel-groups, dose-finding trial studying bi-weekly 80 mg or 40 mg izokibep administered subcutaneously versus placebo until Week 16 (Period 1) and dose-controlled treatment until Week 46 (Period 2). PsA patients had to have ≥3 swollen and ≥3 tender joints of the 66/68 joint count, and an inadequate response to previous NSAIDs, csDMARDs or TNF inhibitor therapy. The primary endpoint was to evaluate ACR50 responses of 80 mg bi-weekly versus placebo at Week 16. Key secondary endpoints were ACR20/70, MDA, DAS28, DAPSA, SPARCC, LDI, PASI as well as tolerability and safety. Efficacy outcome measures were assessed in all patients who received at least one dose of study treatment. This trial is registered with ClinicalTrials.gov, NCT04713072.

Results: 135 patients were randomized and treated between June 2020 and July 2021 in 22 European sites located in Austria, Belgium, Czech Republic, Germany, Hungary, Poland and Spain.

At baseline, patients had a mean age of 48.5 (SD 12.0) years, a mean BMI of 29.0 (SD 4.8) kg/m^2, a mean swollen joint count (SJC) of 9.9 (SD 6.6), and a mean tender joint count (TJC) of 16.7 (SD 10.4). The mean PsA disease duration was 7.1 (SD 7.8) years. 13% failed previous TNF inhibitor treatment and 80% received a concomitant csDMARD.

At Week 16, the confirmatory primary endpoint ACR50 response rate was met (p=0.0003). ACR50 response rate was 52% in the 80 mg group, 48% in the 40 mg and 13% in the placebo group. The ACR20/50/70 response rates up to Week 16 by treatment group are presented in Figure 1.

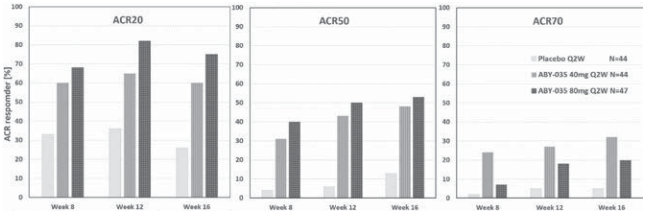

Figure 1. ACR20/50/70 response rates

SJC and TJC rapidly decreased with active treatment as indicated in Table 1.

Table 1. SJC and TJC by visit until Week 16

	Mean SJC (SD)			Mean TJC (SD)		
Study Week	Placebo Q2W N=44	40 mg Q2W N=44	80 mg Q2W N=47	Placebo Q2W N=44	40 mg Q2W N=44	80 mg Q2W N=47
BL	9.2 (6.4)	10.1 (7.0)	10.4 (6.4)	16.4 (11.3)	16.7 (10.3)	17.0 (9.7)
2	8.4 (6.1)	7.3 (6.5)	7.6 (7.6)	14.9 (10.0)	13.3 (9.5)	13.8 (10.7)
4	7.7 (7.7)	6.0 (7.0)	5.6 (6.2)	14.1 (11.8)	12.5 (11.6)	11.2 (9.2)
8	6.0 (6.2)	3.5 (4.1)	3.7 (4.7)	10.5 (7.5)	9.0 (10.5)	7.4 (7.2)
12	5.1 (5.2)	2.6 (3.4)	2.3 (3.4)	10.9 (8.7)	8.1 (8.9)	6.0 (6.7)
16	5.0 (5.7)	2.4 (3.7)	1.7 (2.7)	10.7 (9.1)	7.1 (7.7)	5.6 (6.8)

There was a dose-response relationship and a fast onset of response.

No serious or severe adverse events occurred during Period 1. The three most frequently affected System Organ Classes (SOCs) were SOC General disorders and administration site conditions comprising mainly mild injection site reactions or erythema followed by SOC Infections and infestations and SOC Metabolism and nutrition disorders. One mild, transient vulvovaginal *Candida* infection with active treatment was reported. Apart from injection site reactions there were no apparent differences in the occurrence of adverse events between active and placebo patients.

Conclusion: In this phase 2 study, izokibep showed a dose-dependent high degree of efficacy in patients with active PsA having failed previous treatment. Overall, izokibep was well tolerated.

These data strongly support further clinical development.

Background: Guselkumab (GUS), a human monoclonal antibody targeting the interleukin-23p19 subunit, demonstrated joint and skin efficacy in patients with active psoriatic arthritis (PsA) in the Phase III DISCOVER-1/-2 trials.[1,2] Minimal disease activity (MDA), a multi-domain composite outcome, is a clinically relevant measure of therapeutic response in PsA.[3] However, response dynamics and the effect of individual domains on achieving MDA are not well understood.
Objectives: Characterise response patterns in MDA domains over time and identify potential baseline (BL) response predictors using machine learning.
Methods: Data from bio-naïve patients with active PsA receiving GUS 100 mg every 4 or 8 weeks were pooled across DISCOVER-1/-2. Eligibility criteria are described elsewhere.[1,2] Unsupervised machine learning using the time-series K-means clustering algorithm was performed to identify clusters according to MDA domain responses over 52 weeks. MDA domain thresholds were tender joint count (TJC), swollen joint count (SJC), Psoriasis Area and Severity Index (PASI) and Leeds Enthesitis Index (LEI) each ≤1; patient global assessment (PtGA) visual analogue scale (VAS) ≤20; patient pain VAS ≤15 and Health Assessment Questionnaire-Disability Index (HAQ-DI) ≤0.5. BL characteristics were described for each cluster (Table 1). Missing data were not imputed.

Table 1. BL characteristics of four MDA response clusters (C1–4) in bio-naïve patients with active PsA treated with GUS 100 mg every 4 or 8 weeks

	Cluster			
	C1	C2	C3	C4
Patients, N	201	97	209	64
Age, years	46.1 ± 12.2	45.5 ± 11.5	46.1 ± 11.3	47.0 ± 11.1
Female, %	47.8	55.7	36.4	43.8
BMI, kg/m^2	29.4 ± 6.3	29.2 ± 6.5	28.9 ± 5.4	28.7 ± 5.7
CRP, mg/dl	1.8 ± 2.4	1.8 ± 1.6	1.4 ± 2.0	1.9 ± 2.1
PsA disease duration, years	5.5 ± 5.8	5.3 ± 5.7	5.2 ± 5.9	5.8 ± 5.9
SJC (0–66)	10.7 ± 5.4	10.6 ± 5.0	10.1 ± 6.2	21.1 ± 12.2
TJC (0–68)	18.1 ± 9.6	18.8 ± 8.8	16.3 ± 10.7	41.2 ± 13.3
Spondylitis, %	28.9	26.8	29.7	42.2
PASI score (0–72)	8.6 ± 8.9	7.8 ± 8.0	10.6 ± 12.0	13.1 ± 14.6
Dactylitis, %	42.8	42.3	35.4	71.9
Dactylitis score (0–60)	3.7 ± 6.9	1.6 ± 2.9	2.0 ± 4.4	11.7 ± 15.2
Dactylitis count (0–20)	2.1 ± 4.0	0.9 ± 1.7	1.3 ± 2.8	6.0 ± 6.8
Enthesitis, %	62.2	62.9	56.9	89.1
LEI (0–6)	1.5 ± 1.6	1.7 ± 1.8	1.5 ± 1.7	3.6 ± 2.0

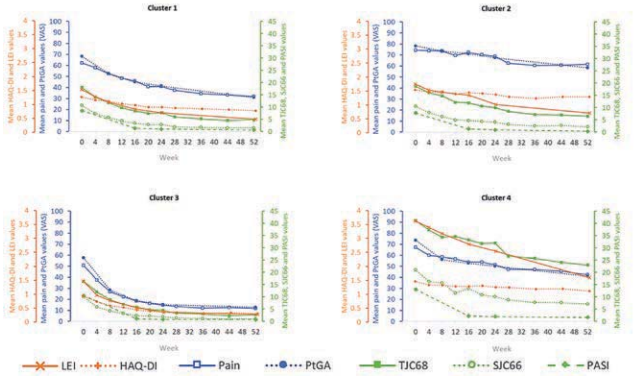
PtGA (0–100 VAS)	68.3 ± 17.8	78.2 ± 14.1	57.6 ± 21.6	73.7 ± 15.8
Pain (0–100 VAS)	62.1 ± 17.0	74.3 ± 13.7	50.8 ± 21.3	67.2 ± 15.2

Data are mean ± standard deviation or %. CRP, C-reactive protein.

Figure 1. Response patterns of individual MDA domains from Week 0 to Week 52 in four MDA response clusters (C1–4) of bio-naïve patients with active PsA treated with GUS 100 mg every 4 or 8 weeks



Data points are mean cluster values.
GUS, guselkumab; HAQ-DI, Health Assessment Questionnaire-Disability Index; LEI, Leeds Enthesitis Index; MDA, minimal disease activity; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; PtGA, patient global assessment; SJC66, swollen joint count 0-66; TJC68, tender joint count 0-68; VAS, visual analogue scale.

Results: This analysis included 571 of 669 patients receiving GUS and identified four distinct response clusters (C1–4; Table 1). Mean age and body mass index (BMI) were similar across clusters; C3 had a lower proportion of female patients. Relative to C3, a high burden of BL disease was observed in C4 across clinical measures and patient-reported outcomes (PROs), and across PROs only in C2. Through Week 52, MDA response rates were highest in C3 and lowest in C4, yet all clusters showed continuous improvement in mean values across all MDA domains (Figure 1). In C3, all individual domain thresholds were rapidly reached. C1, 2 and 4, met PASI threshold and showed a substantial reduction in SJC while other domains varied. In C1 and 2, improvement in clinical measures paralleled that of C3; however, PROs appeared to take longer to resolve. Responses were slowest in C4, though improvements were substantial given the high BL disease burden. Improvement in pain, PtGA and HAQ-DI occurred earlier in C1 than C2.
Conclusion: Machine learning identified four clusters of GUS-treated PsA patients based on differing response patterns in individual MDA domains. Response types may differ due to BL disease burden, especially in patients with higher pain, PtGA and functional disability scores. These results offer an innovative, complementary approach to identifying treatment response patterns across diverse clusters of bio-naïve patients with PsA, which may facilitate clinical decision-making.

Background: Power Doppler ultrasound (PDUS) is a sensitive non-invasive imaging tool that allows the visualisation of articular and periarticular inflammation in patients with psoriatic arthritis (PsA).[1] ULTIMATE (NCT02662985) was the first large randomised clinical trial that showed the responsiveness of the Global OMERACT-EULAR ultrasound synovitis score (GLOESS) in PsA and confirmed the rapid and continued benefits of secukinumab through 52 weeks.[2,3]
Objectives: To report the distribution of ultrasound-detected synovitis at joint level, by degree of severity at baseline and over time, and the contribution of each core component of GLOESS, synovial hypertrophy (SH) by greyscale (GS; B-mode) and power Doppler (PD) signal, to responsiveness.[3]
Methods: This was a 52-week study with a 12-week double-blind, placebo-controlled treatment period followed by a 12-week open-label period and a 6-month open-label extension secukinumab treatment period.[3] The number of joints with synovitis measured by GLOESS[2] was assessed up to Week 52. The assessments included distribution of synovitis based on composite PDUS score across 24 pairs of joints (with worse score of the pair of the joints used) by grade of severity (0-3) and change from baseline to Week 52 in each core component of GLOESS.[3-5] Data are presented as observed.
Results: A total of 166 patients (mean age, 46.7 years; males, 45.2%) were enrolled, of which 90% (75/83) of secukinumab and 83% (69/83) of placebo-secukinumab participants completed 52 weeks. The mean (SD) number of PDUS detected synovitis at baseline was 9.2 (4.9) and 10.2 (5.2) in the secukinumab and placebo group, respectively. The most frequent locations with synovitis at baseline were: wrist, metatarsophalangeal (MTP), knees and metacarpophalangeal (MCP) joints (Table 1). An early and continued improvement in GLOESS was observed in both secukinumab and placebo-secukinumab groups after switching to active therapy, as previously reported at Week 12 and through Week 52.[2,3] Among the two core components of GLOESS, SH was mainly responsible for the change in GLOESS from baseline to Week 52, in contrast with PD signal in this dataset. The distribution of synovitis by grade of severity showed that MTP joints, wrist, knee, MCP1/2 and tibiotalar joints mostly contributed to the composite PDUS at Week 12 (Figure 1). Similar patterns were observed through 52 weeks.

Table 1. Proportion of patients with PDUS detected synovitis at baseline*

Synovitis joint, data presented as n (%)	Secukinumab (N=83)	Placebo (N=83)
Wrist	66 (80)	66 (80)
MTP2	56 (68)	65 (78)
MTP1	58 (70)	60 (72)
MTP3	52 (63)	60 (72)
MTP4	46 (55)	59 (71)
Knee	50 (60)	47 (57)
MCP1	36 (43)	52 (63)
MCP2	35 (42)	41 (49)
MTP5	30 (36)	41 (49)

*Data for top nine pairs of joints with most frequently detected power Doppler ultrasound (PDUS) synovitis are presented here. Synovitis was scored by a OMERACT-EULAR synovitis composite score >0 for each paired joint (irrespective of right or left side). The OMERACT-EULAR composite PDUS score (for individual joints) ranged from 0 to 3 and was composed of the two core components synovial hypertrophy and power Doppler. N, total number of randomised patients; n, number of evaluable patients

Conclusion: The distribution of synovitis at baseline reflected a predominance of small joints (feet and hands) and large joints (wrist and knee) and were mostly responsive to secukinumab over time in the ULTIMATE trial. Synovial hypertrophy was the most responsive core component of GLOESS driving an early and continued reduction of synovitis with secukinumab through Week 52. This finding could be useful to select a restricted number of joints in future ultrasound trials in PsA.

OP0261 TREAT-TO-TARGET DOSE REDUCTION AND WITHDRAWAL STRATEGY OF TNF INHIBITORS IN PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS: A RANDOMIZED CONTROLLED NON-INFERIORITY TRIAL

C. Michielsens[1,2], N. den Broeder[1,2], F. van den Hoogen[1], E. Mahler[1], S. Teerenstra[3], D. van der Heijde[4], L. M. Verhoef[1], A. den Broeder[1,2]. [1]*Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*; [2]*Radboud Institute for Health Sciences, Rheumatic Diseases, Nijmegen, Netherlands*; [3]*Radboud Institute for Health Sciences, Health Evidence, Section Biostatistics, Nijmegen, Netherlands*; [4]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Tumour Necrosis Factor inhibitors (TNFi) are effective in Psoriatic Arthritis (PsA) and axial SpondyloArthritis (axSpA), but are associated with a somewhat increased infection risk, patient burden, and high costs. Treat-to-target (T2T) tapering might ameliorate these drawbacks, but no high quality T2T tapering studies have been done in PsA and axSpA.
Objectives: To investigate whether a T2T strategy with tapering is non-inferior to a T2T strategy without tapering.
Methods: We performed a pragmatic open-label, monocenter, randomized, controlled non-inferiority (NI) trial on T2T tapering of TNFi. PsA and axSpA patients using a TNFi with ≥6 months stable low disease activity (LDA) were randomized to a T2T tapering or no-tapering strategy, in a ratio of 2:1 and followed-up for 12 months. LDA was defined as a Psoriatic Arthritis Disease Activity Score (PASDAS) ≤3.2 for PsA and/or Ankylosing Spondylitis Disease Activity Score (ASDAS) <2.1 and/or judgement of physician and patient. Tapering consisted of 3-monthly tapering steps (66%, 50%, 0%), with re-intensification in case of flare. Primary endpoint was the difference in proportion of patients having LDA at 12 months, compared to a prespecified NI margin of 20%. The primary Bayesian analysis was adjusted for stratification factors (diagnosis and csDMARD use). Secondary endpoints included the mean percentage Daily Defined Dose (%DDD) at month 12 and mean 3-monthly disease activity and %DDD. Other endpoints included the proportion of patients discontinuing their TNFi, the cumulative incidence of flares (change from baseline PASDAS≥0.8 or ASDAS≥0.9), the use of concomitant medication and (serious) adverse events.
Results: 122 patients were included (N=81 tapering (PsA, N=42, axSpA, N=39); N=41 no-tapering (PsA, N=22, axSpA, N=19)) (Table 1). Proportion of patients in LDA at 12 months for the tapering and no-tapering group was

69% and 73%: adjusted difference 5% (Bayesian 95% credible interval: -10% to 19%), confirming NI. The mean percentage %DDD was respectively 53% and 91% at month 12 (Figure 1). At 12 months, 58 (72%) patients of the tapering group were successfully tapered, of whom 23 (28%) discontinued their TNFi. The cumulative incidence of flares was 85% in the tapering and 78% in the no-tapering group (p=0.32). Start or escalation of concomitant medication was more frequent in the tapering group, significantly so for NSAID use: csDMARDs (only for PsA): 1 (2%) vs. 1 (5%) (p=0.64); NSAIDs: 44 (54%) vs. 10 (24%) (p=0.002); glucocorticoids: 24 (30%) vs. 7 (17%) (p=0.13). For serious adverse events, similar results were seen. The risks of grade 3/4 infections and injection site reactions were respectively 46% and 23% lower in the tapering group than the no-tapering group.

Table 1. Baseline characteristics of T2T strategy treated PsA and axSpA patients with or without tapering.

Characteristic	T2T with tapering (N=81)	T2T without tapering (N=41)
Diagnosis, n (%)		
-Psoriatic arthritis	42(52%)	22(54%)
-Axial spondyloarthritis	39(48%)	19(46%)
Female, n (%)	28(35%)	20(49%)
Age in years at inclusion, mean (SD)	50(14)	52(15)
Disease duration at inclusion, years, median (IQR)	11(5-21)	12(5-21)
CASPAR Criteria, n (%)	34(81%)	17(77%)
ASAS Criteria, n (%)	35(90%)	17(89%)
Disease activity, mean (SD)		
-PASDAS - (64/64 PsA)	1.60(1.26)	1.63(0.98)
-ASDAS - (57/58 axSpA)	1.34(0.87)	1.21(0.61)
Duration of current bDMARD use, years, median (IQR)	2(1-6)	2(2-7)
Current bDMARD use, n (%)		
-Adalimumab	62(77%)	28(68%)
-Etanercept	10(12%)	6(15%)
-Certolizumab Pegol	2(2%)	1(2%)
-Golimumab	2(2%)	1(2%)
-Infliximab	5(6%)	5(12%)

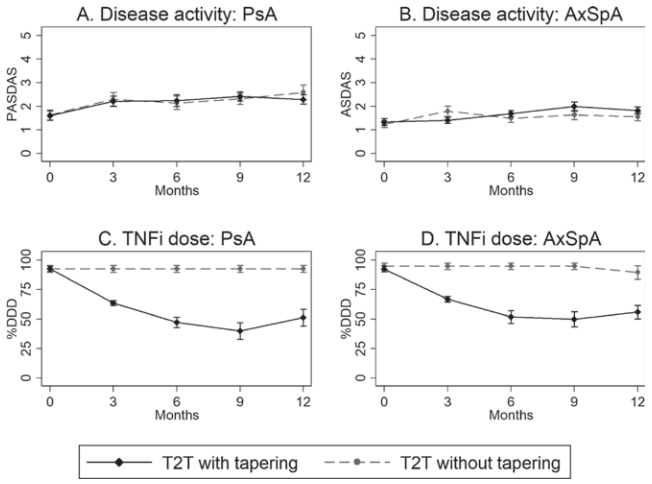

Figure 1. Mean disease activity and %DDD of T2T strategy treated PsA (A. and C.) and axSpA (B. and D.) patients with or without tapering at baseline, 3, 6, 9 and 12.

Conclusion: A T2T TNFi tapering strategy is non-inferior to a T2T strategy without tapering with regard to the proportion of patients still in LDA at 12 months and results in a substantial reduction of TNFi use, albeit with slightly more use of other medication.

OP0262

PREVALENCE AND PREDICTORS OF ACHIEVING SUSTAINED REMISSION IN PSORIATIC ARTHRITIS

O. Palsson[1,2,3], J. T. Einarsson[1,2], J. K. Wallman[1,2], T. Love[3,4], B. Gudbjornsson[3,5], M. C. Kapetanovic[1,2]. *[1]Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden*; *[2]Skåne University Hospital, Department of Rheumatology, Skåne, Sweden*; *[3]University of Iceland, Faculty of Medicine, Reykjavík, Iceland*; *[4]Landspitali University Hospital, Department of Science, Reykjavik, Iceland*; *[5]Landspitali University Hospital, Centre for Rheumatology Research, Reykjavik, Iceland*

Background: Increased availability and a wide selection of b/tsDMARDs with different mode of action has made long-term remission a realistic treatment goal in psoriatic arthritis.

Objectives: To estimate the prevalence and possible predictors of sustained remission in patients with psoriatic arthritis (PsA) treated with biologic or targeted synthetic disease-modifying anti-rheumatic drugs (bDMARD/tsDMARD) in Sweden.

Methods: All patients initiating treatment with bDMARDs or tsDMARDs for PsA in Sweden and registered in the national Swedish Rheumatology Quality Register (SRQ) were included. Data on disease and treatment characteristics from the start of the first b/tsDMARD (baseline) and all registered subsequent visits were extracted from SRQ. Sustained remission (SR) was defined as DAS28-CRP ≤ 2.6, DAPSA28 ≤ 4 or the evaluator's global assessment of disease activity (0-4 on a Likert scale) = 0, during at least two consecutive visits over at least six months. To compensate for factors that may temporarily raise disease activity measures, such as concurrent infections, one visit with higher disease activity was allowed if the treatment regimen was not altered at that point and if less than two years between adjacent visits in remission. A sensitivity analysis was performed with a more stringent SR definition, not allowing any such visits with higher disease activity. Logistic regression was used to identify possible predictors of SR.

Results: 5 459 PsA patients with 50 811 visits were included in the analysis. According to DAS28-CRP, 78% of patients achieved a state of remission at some point, and 49% achieved SR at least once. When the more stringent DAPSA28 remission criteria were applied, 27% of patients reached a state of remission at some point, and 11% ever achieved SR. Corresponding figures using the evaluator's global assessment were 64% and 34% for ever reaching remission or SR, respectively (Figure 1). The sensitivity analysis rendered similar results with a ≤3% difference from the main results for all outcomes. Higher age at start of the first b/tsDMARD therapy was associated with a lower likelihood of SR, but males were significantly more likely to achieve SR than females (OR 1,79-2,63 for reaching SR depending on the remission criteria used).

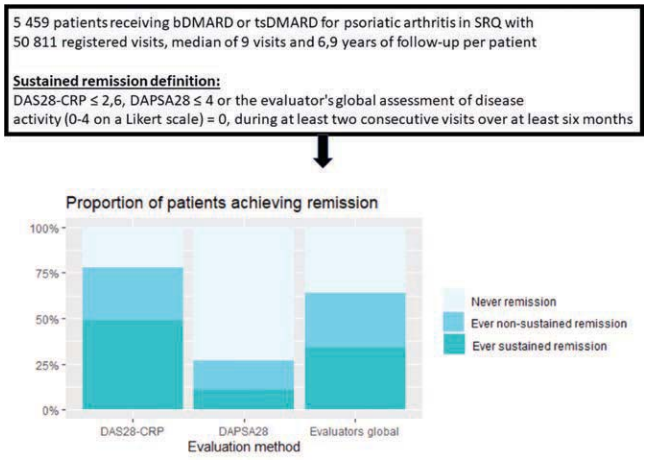

Figure 1. Proportion of patients achieving sustained and non-sustained remission at any point after SRQ registration.

Conclusion: Despite increased availability and a wider selection of b/tsDMARDs with different modes of action, a considerable proportion of PsA patients receiving such treatments never achieve a state of remission, and less than half ever achieve a more extended period of sustained remission. Males are more likely than females to enter sustained remission.

Background: Low-dose glucocorticoid (GC) therapy is widely used in RA but the true balance of benefit and harm is still unknown.
Objectives: We studied the effects of prednisolone (5 mg/day, 2 years) in RA patients aged 65+, requiring adjustment of antirheumatic therapy (DAS28≥2.60).
Methods: Pragmatic double-blind placebo-controlled randomized trial; all co-treatments and changes therein were allowed during the trial except long-term open label GC; Ca/D supplementation was advised in all patients. Minimal exclusion criteria were tailored to seniors.
Harm outcome: the number of patients with ≥1 serious adverse event (SAE), or ≥1 'other adverse event of special interest' (other AESI). Other AESI comprised any AE (except worsening of RA) causing study discontinuation, and GC-specific events (Table 1).

Table 1. Adverse events of special interest (AESI).*

	prednisolone (n=224)		placebo (n=225)	
Events by protocol-defined category	SAE	other AESI	SAE	other AESI
Infection	26	124	16	91
Urinary tract	4	49	4	29
Pneumonia	2	17	2	13
Other	20	58	10	49
Cardiovascular	8	2	6	0
Symptomatic fracture	2	11	4	6
New onset				
Hypertension	1	4	0	7
Diabetes mellitus	0	2	0	1
Cataract	0	7	2	6
Glaucoma	0	1	0	3
Other†	43	43	35	26
Total	80	194	63	140

*AESI: Comprises serious adverse events (SAE) and other AESI, defined by protocol. †'Other' other AESI: non-serious AE outside of the above predefined categories, but associated with premature discontinuation.

Benefit outcomes: improvement in disease activity (DAS28) and joint damage progression (Sharp/van der Heijde).
Longitudinal mixed models analyzed the data. Given prior knowledge we report one-sided 95% confidence limit (95%CL) and statistical tests, performed only for the main outcomes.
Results: We randomized 451 RA patients in 7 EU countries, 449 received the intervention; of these 63% prednisolone vs 61% placebo patients completed 2 years of follow up. Discontinuations were similar in both groups: for AE (14%) and active disease (4%); the remainder mostly for 'trial fatigue' and covid-related access issues (20%). Mean time on study drug was 19 (SD 8) months.
70% of patients were female, mean age was 72 (max 88) years, RA duration 11 years; 67% were RF+, 56% ACPA+, 96% had joint damage on radiographs: mean score 20, median 8. Mean DAS28 was 4.5. Most patients (79%) were on current DMARD treatment, including 14% on biologics; 47% had previously used GC, 14% changed DMARD therapy at baseline. Patients had mean 2.1 active comorbidities, and used median 7 drugs.
Benefit: Disease activity rapidly declined to stabilize after 1 year (Figure 1), and was lower on prednisolone (adjusted mean difference in DAS28 over 2 years: 0.37, 95%CL 0.23, p<0.0001). The contrast in early (3-month) response was larger in 331 patients adherent to protocol on stable treatment: mean difference in DAS28 0.62 (95%CL 0.44), more responders on prednisolone (Figure 1). Significant time-treatment interaction in secondary analyses suggested a decrease in contrast after the first year, most likely caused by significantly more changes in DMARD treatment on placebo. Joint damage progression over 2 years was significantly lower on prednisolone: mean 0.6 (SD 1.9) v 1.8 (6.4) score points on placebo, difference 1.2 (95%CL 0.2, p=0.02).
Harm: 60% prednisolone vs 49% placebo patients experienced the harm outcome: adjusted RR 1.24, 95%CL 1.04, p=0.02; number needed to harm 9.5 (Table 1). During the study 1 vs 2 patients died, and 3 vs 0 died within 5 months of discontinuation. Per 100 patient-years, AE totaled 278 in prednisolone vs 206 in placebo patients, and the difference was most marked for infections (Table 1); these were mostly mild or moderately severe. Other GC-specific AESI were rare without relevant differences.
Conclusion: Add-on low dose prednisolone has beneficial long-term effects on disease activity and damage progression in senior RA patients on standard treatment. The tradeoff is a 24% increase in patients with mostly mild to moderate AE, suggesting a favorable balance of benefit and harm.

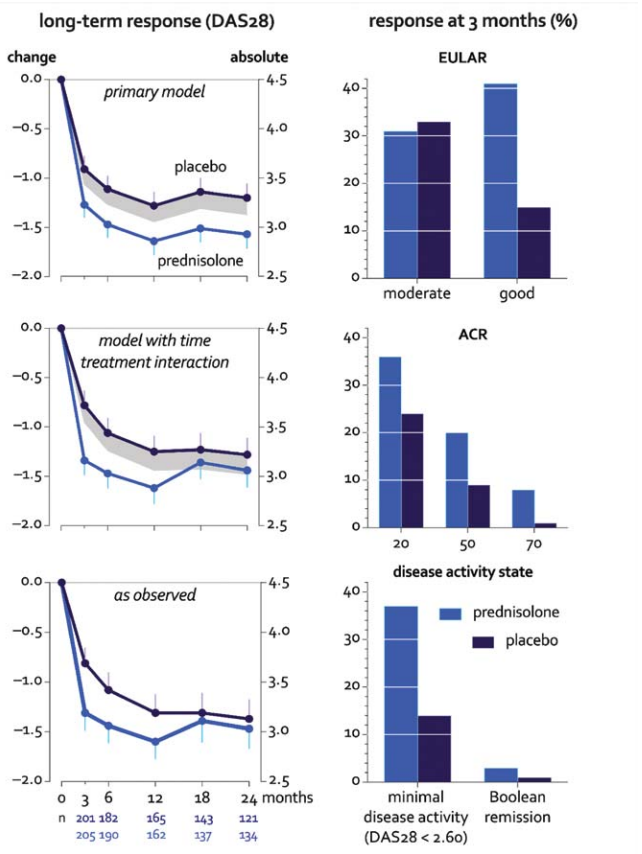

Figure. Better response in disease activity on prednisolone compared to placebo.
Left: long-term change in DAS28: primary model, model with time-treatment interactions, and as observed, with observed number of patients.
Right: response at 3 months in the stable adherent population (n=331).
Grey area: one-sided 95% confidence bound for the difference between groups at each time point.
Error bars: one half of the two-sided 95%CI for the group means.

OP0264

IMPACT OF BASELINE CARDIOVASCULAR RISK ON THE INCIDENCE OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN THE TOFACITINIB RHEUMATOID ARTHRITIS CLINICAL PROGRAMME

M. Dougados[1,2], C. Charles-Schoeman[3], Z. Szekanecz[4], J. T. Giles[5], S. R. Ytterberg[6], D. L. Bhatt[7], G. G. Koch[8], I. Vranic[9], J. Wu[10], C. Wang[10], K. Kwok[11], S. Menon[10], C. A. Connell[10], A. Yndestad[12], J. L. Rivas[13], M. H. Buch[14]. *[1]Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Université de Paris, Department of Rheumatology, Paris, France*; *[2]PRES Sorbonne Paris-Cité, INSERM (U1153): Clinical Epidemiology and Biostatistics, Paris, France*; *[3]University of California, Department of Medicine, Los Angeles, CA, United States of America*; *[4]University of Debrecen, Division of Rheumatology, Faculty of Medicine, Debrecen, Hungary*; *[5]Columbia University Vagelos College of Physicians and Surgeons, Division of Rheumatology, New York, NY, United States of America*; *[6]Mayo Clinic, Division of Rheumatology, Rochester, MN, United States of America*; *[7]Brigham and Women's Hospital and Harvard Medical School, Department of Cardiovascular Medicine, Boston, MA, United States of America*; *[8]University of North Carolina at Chapel Hill, Department of Biostatistics, Chapel Hill, NC, United States of America*; *[9]Pfizer Ltd, Inflammation and Immunology, Tadworth, Surrey, United Kingdom*; *[10]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; *[11]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; *[12]Pfizer Inc, Inflammation and Immunology, Oslo, Norway*; *[13]Pfizer SLU, Inflammation and Immunology, Madrid, Spain*; *[14]University of Manchester and NIHR Manchester Biomedical Research Centre, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, Faculty of Biology, Medicine and Health, Manchester, United Kingdom*

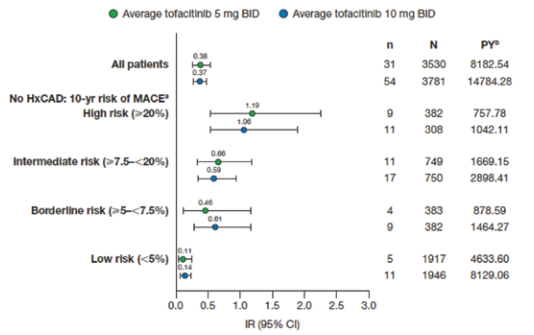
Background: Results from ORAL Surveillance, a post-authorisation safety study, indicated that patients (pts) with rheumatoid arthritis (RA) aged ≥50 yrs with ≥1 additional cardiovascular (CV) risk factor have an increased risk of major adverse CV events (MACE) with tofacitinib vs tumour necrosis factor inhibitors.[1]
Objectives: To evaluate the impact of baseline (BL) CV risk on MACE in the wider tofacitinib RA clinical programme.
Methods: Data for pts who received ≥1 tofacitinib dose in 21 Phase 1–3b/4 (excluding ORAL Surveillance) and 2 long-term extension tofacitinib RA studies were pooled and analysed post hoc as two cohorts: (1) overall cohort and (2) CV risk-enriched cohort (pts aged ≥50 yrs with ≥1 additional CV risk factor [current smoker, hypertension, HDL-cholesterol <40 mg/dL, diabetes mellitus, history of myocardial infarction (MI) or coronary heart disease (CHD)]). Data were summarised by average tofacitinib 5 or 10 mg twice daily (BID; average total daily dose of <15 or ≥15 mg, respectively). Incidence rates (IRs; pts with first events/100 pt-yrs) for adjudicated MACE were calculated. MACE IRs were stratified by pts' BL CV risk profile: pts were first categorised by history of coronary artery disease (HxCAD), then pts without a HxCAD were categorised by 10-yr risk of MACE, per the ASCVD-PCE risk calculator[2] with a 1.5 multiplier applied.[3]
Results: The overall cohort included 7964 pts (average tofacitinib 5 mg BID, n=3969; average tofacitinib 10 mg BID, n=3995); of these, 3125 (39.2%) pts were included in the CV risk-enriched cohort (average tofacitinib 5 mg BID, n=1614; average tofacitinib 10 mg BID, n=1511). In both treatment arms, as expected, higher proportions of pts in the CV risk-enriched cohort had a HxCAD or a high or intermediate 10-yr predicted risk of MACE at BL vs the overall cohort (Table 1). MACE IRs (95% CIs) were lower in the overall cohort (0.38 [0.26, 0.54] and 0.37 [0.27, 0.48] for average tofacitinib 5 and 10 mg BID, respectively) vs the CV risk-enriched cohort (0.72 [0.46, 1.09] and 0.67 [0.46, 0.93], respectively), and were similar between treatment arms. MACE IRs were lower than reported in ORAL Surveillance.[1] In the overall cohort, adjudicated MACE most commonly occurred in pts with a HxCAD (IR [95% CI] 0.98 [0.02, 5.47] and 1.05 [0.13, 3.78] for average tofacitinib 5 and 10 mg BID, respectively), or in pts with a high 10-yr risk of MACE at BL (Figure 1). A lower predicted 10-yr MACE risk was associated with lower MACE IRs (Figure 1); trends were similar for the CV risk-enriched cohort (data not shown).

Table 1. Proportions of pts with a HxCAD and pts without a HxCAD categorised by 10-yr risk of MACE, per ASCVD-PCE risk calculator[2] with a 1.5 multiplier applied[3]

	Average tofacitinib 5 mg BID		Average tofacitinib 10 mg BID	
	Overall cohort(N=3969)	CV risk-enriched cohort(N=1614)	Overall cohort(N=3995)	CV risk-enriched cohort(N=1511)
HxCAD, n (%)	61 (1.5)	61 (3.8)	65 (1.6)	60 (4.0)
No HxCAD: 10-yr risk of MACE, n (%)				
High (≥20%)	440 (11.1)	365 (22.6)	337 (8.4)	276 (18.3)
Intermediate (≥7.5–<20%)	853 (21.5)	593 (36.7)	788 (19.7)	530 (35.1)
Borderline (≥5–<7.5%)	435 (11.0)	234 (14.5)	404 (10.1)	195 (12.9)
Low (<5%)	2133 (53.7)	342 (21.2)	2058 (51.5)	307 (20.3)
Missing data	47 (1.2)	19 (1.2)	343 (8.6)	143 (9.5)

CAD is defined as any of MI or CHD. n, number of pts with specified characteristic; N, number of evaluable pts

Fig. IRs (pts with first events/100 PY; 95% CI) for adjudicated MACE, stratified by HxCAD and 10-yr risk of MACE in the overall cohort



[a]Pts without a HxCAD were categorised according to their 10-yr risk of MACE, per the ASCVD-PCE risk calculator[2] with a 1.5 multiplier applied[3]
[b]Total PY of exposure accrued during the risk period
95% CIs were constructed using Exact Poisson distribution
Includes pts from studies with CV adjudication process applied to data after 25 February 2009
Risk period was defined as the time from first study dose to last study dose +28 days, or to the death date, whichever was earlier
CAD is defined as any of MI or CHD
ASCVD-PCE, atherosclerotic CV disease-pooled cohort equations; n, number of pts with event; PY, pt-yrs

Conclusion: In the tofacitinib RA clinical programme, MACE were largely associated with BL CV risk in the overall cohort, consistent with results of ORAL Surveillance, although results should be interpreted with caution due to low pt-yrs of exposure in some pt groups. Noting this limitation, these findings emphasise the importance of assessing and addressing BL CV risk when treating pts with RA.

OP0265

COMPARISON OF THE EFFECT OF DIFFERENT JANUS KINASE INHIBITORS ON ACTIVATION, FUNCTION AND PROPERTY OF NK CELLS TO CONTROL CANCER CELL LINES PROLIFERATION: AN EX VIVO AND IN VITRO STUDY.

L. Meudec[1,2], P. Richebé[2], J. Pascaud[1], X. Mariette[1,2], G. Nocturne[1,2]. *[1]Center for Immunology of Viral Infections and Autoimmune Diseases, INSERM UMR 1184, Université Paris-Saclay, Kremlin-Bicêtre, France*; *[2]AP-HP, Hôpital Bicêtre, Le Kremlin-Bicêtre, Kremlin-Bicêtre, France*

Background: Janus kinase inhibitors (JAKi) are effective targeted synthetic DMARDs licensed in rheumatoid arthritis (RA) and in other immune-mediated diseases. Among the adverse events described, the increased risk of herpes zoster is specific of this therapeutic class but variable depending on the drugs, especially lower with filgotinib (FILGO)[1]. Recently the ORAL Surveillance study highlighted an increased risk of lymphoma and lung cancer with tofacitinib (TOFA) in RA patients older than 50 years with cardio-vascular risk factors[2]. Because of their antitumor and antiviral role, especially against herpes viruses, effect of JAKi on NK cells may play a causal role in these adverse events. Our working hypothesis is that the different JAKi could have a differential impact on the activation and function of NK cells leading to the variability of the tolerance profiles observed between the molecules.

Objectives: To evaluate the phenotypic and functional impact of JAKi on NK cells.

Methods: We first performed ex vivo phenotypic analyses of NK cells in RA patients treated with TOFA or baricitinib (BARI) in comparison with patients treated with methotrexate (MTX). To go deeper, we phenotyped sorted NK cells from healthy donors after 6 days of culture with 4 JAKi (TOFA, BARI, upadacitinib (UPA) and FILGO) or control (DMSO). We used 3 different doses carefully chosen to mimic in vivo exposure [therapeutic concentration (therap) defined as mean concentration in patients at the licensed dose, infra therapeutic (infra, mean -2DS) and supra therapeutic concentration (supra, mean +2Ds)]. Thirdly, we stimulated sorted NK cells from healthy donors exposed to TOFA or BARI at therap and supra concentrations with anti-NKp30 crosslinking to assess NK cells function: intra-cellular IFNγ/TNF production and degranulation (CD107a). Finally, we challenged sorted NK cells from healthy donors exposed in vitro to TOFA or BARI at therap and supra doses with 2 different tumor cells line to assess degranulation and cytotoxicity: a lung cancer line A549 and a lymphoma cell line SU-DHL-4.

Results: Twenty-eight RA patients were included in the ex vivo assay (12 MTX, 6 TOFA, and 10 BARI). Patients under TOFA and not under BARI had a significant reduced CD69 (an activation marker) expression on NK cells ($p<0.05$) compared to MTX. After in vitro culture of NK cells with JAKi, we confirmed the negative impact of JAKi on NK cells activation (CD69), maturation markers (CD57, Tim3) and activating receptor (NKp30), more pronounced with TOFA and UPA (Figure 1A). After crosslinking with anti-NKp30, NK cells exposed to TOFA produced significantly less IFNγ/TNF and expressed less CD107a compared to DMSO ($p<0,005$). There was a non-significant trend for a dose-effect (Figure 1B). BARI did not induce any significant effect. Lastly, when NK cells were co-cultured with the cancer cell lines, previous exposition to TOFA but not to BARI led to a significant reduction of CD107a expression on NK cells ($p<0.005$) and to reduced cytotoxicity ($p<0.05$) of NK cells versus A549 at therap dose. Studies regarding SU-DHL-4 are still in progress.

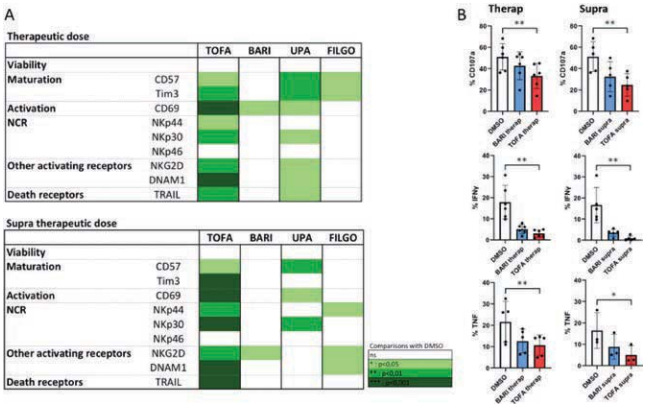

Figure 1. Impact of in vitro exposure to JAKi at therap and supra dose on NK cells regarding phenotype (A) and function after crosslinking (B)

Conclusion: JAKi have a phenotypic and functional dose-effect impact on NK cells activation, both in ex vivo and in vitro experiments. TOFA has more impact than other JAKi on NK cells phenotype and function and has the property to impair the control of proliferation of lung cancer and lymphoma cell lines by NK cells. The question remains open if this mechanism could explain the increased risk of lung cancer and lymphoma observed with TOFA in the ORAL surveillance trial.

Background: The recently presented "ORAL Surveillance Study" has suggested increased risk of serious adverse events (AEs) with tofacitinib, a JAK-inhibitor (JAKi), compared to a comparator TNF-inhibitor (TNFi). Currently, there is limited real world evidence for the tolerability and safety of JAKi (1).

Objectives: To assess the safety of JAKi compared to other biologic agents in rheumatoid arthritis (RA) patients in a real-world population, by evaluating treatment discontinuation for AEs.

Methods: Pooled patient database from 16 national RA registries from across Europe, Québec (Canada), Turkey, and Israel were used. Treatment discontinuation due to AEs by treatment groups, JAKi versus (vs) TNFi and JAKi vs bDMARDs with other modes of action (OMA), were compared as an overall measure of tolerability and safety of JAKi. Standard descriptive statistics were used for baseline characteristics. We plotted unadjusted cumulative incidence, then the cause-specific Cox model was used to account for competing risks, and to obtain association between covariates and the instantaneous hazard rate for AEs. Variables listed in Table 1 were used for adjustment in the fully-adjusted cause-specific Cox model.

Table 1. Baseline characteristics of the study population

	JAKi[1] (BARI, FILGO,TOFA,UPA)	OMA[2] (ABA, ANAK, SARI, TOCI)	TNFi[3] (ADA, CERT, ETAN, GOL, INFL)

HAQ	1.2 (0.7)	1.2 (0.7)	1.1 (0.7)
BMI	27.1 (5.9)	26.8 (5.8)	26.8 (5.8)
Patients with at least one Comorbidity (%)	51.7	53.9	49.6

csDMARDs = classical synthetic DMARDs, MTX = methotrexate, GC = glucocorticoids, CRP = C-reactive protein, CDAI = Clinical Disease Activity Index, DAS 28 = Disease Activity Score 28, HAQ = Health Assessment Questionnaire, BMI = Body Mass Index, *Treatment duration (median [IQR]) = Last visit date – start date (if treatment is ongoing), treatment stop date – treatment start date (if treatment has stopped). [1]BARI (baricitinib; 44.41 %), FILGO (filgotinib; 0.23%), TOFA (tofacitinib; 49.59%), UPA (upadacitinib; 5.78%); [2]ABA (abatacept; 39.96%), ANAK (anakinra; 2.64%), SARI (sarilumab; 3.14%), TOCI (tocilizumab; 52.55%); [3]ADA (adalimumab; 31.00%), CERT (certolizumab; 8.33%), ETAN (etanercept; 38.83%), GOLI (golimumab; 9.36%), INFL (infliximab; 12.56%)

Results: 90,478 treatment courses were included in the analysis (Table 1). We observed similar crude incidence rate of treatment discontinuation due to AEs between JAKi and TNFi, but less in JAKi vs OMA (Figure 1). The fully adjusted hazard rate of treatment stop for AEs was also similar in JAKi vs TNFi (HR = 1.02 (95% CI 0.92 – 1.13)), and in JAKi vs OMA (HR= 1.08 (95% CI 0.97 – 1.20)). The rate of treatment stop for AEs was higher in women (HR = 1.29 (95% CI 1.21 – 1.37)) and with an increasing number of previous b/tsDMARDs (HR = 1.50; 1.48; 1.68 for 1, 2, and 3 or more previous b/ts DMARDs, respectively).

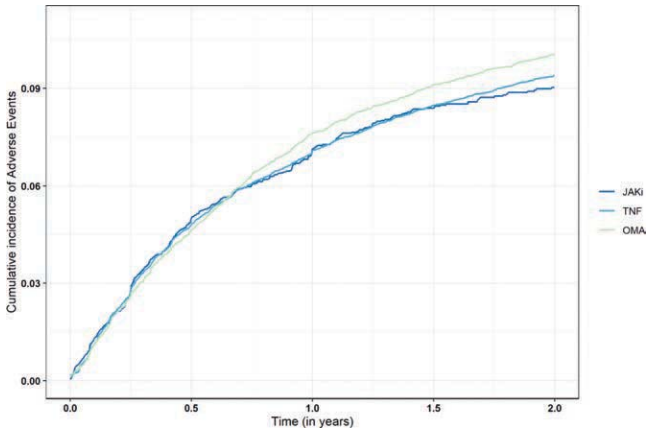

Figure 1. Comparison of cumulative incidence of treatment discontinuation for adverse events in JAKi, TNFi, and OMA group

Conclusion: After adjusting for potential confounders, the rate of treatment discontinuation for AEs was comparable between JAKi and OMA or TNFi. Treatment discontinuation for AEs comprises a wide range of AEs; future analyses will be performed to investigate specific AEs, such as cancer, serious infections or major adverse cardiovascular events.

OP0267 A GENOME-WIDE INVESTIGATION OF PERSISTENCE TO TREATMENT WITH METHOTREXATE IN SWEDISH EARLY RHEUMATOID ARTHRITIS PATIENTS

A. Öberg Sysojev[1], S. Saevarsdottir[1,2], L. M. Diaz-Gallo[3], L. Alfredsson[4], L. Klareskog[3],SRQ Biobank Group[5], T. Frisell[1], L. Padyukov[3], J. Askling[1,6], H. Westerlind[1]on behalf of Swedish Rheumatology Quality Register Biobank Group. *[1]Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden*; *[2]University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavík, Iceland*; *[3]Karolinska Institute, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; *[4]Karolinska Institute, Institute of Environmental Medicine, Stockholm, Sweden*; *[5]Karolinska Institute, Department of Medicine, Solna, Stockholm, Sweden*; *[6]Karolinska University Hospital, Department of Rheumatology,Theme Infection and Inflammation, Stockholm, Sweden*

Background: Despite being the anchor drug for treating rheumatoid arthritis (RA), methotrexate (MTX) provides a good response only in some of the treated patients [1]. If MTX treatment outcome has a substantial genetic component, genetic variants could provide useful predictors for identification of patients likely to respond and remain on treatment. So far, studies have focused mainly on primary response, and attempts to explain the inter-patient variability through genetic variants have been inconclusive or underpowered [2,3].

Objectives: We aimed to investigate whether there are genetic variants associated with persistence to treatment with MTX (at one and three years) in early RA, and to estimate any underlying heritability.

Methods: We conducted a genome-wide association study (GWAS) on persistence to treatment with MTX in DMARD-monotherapy. We included participants from the Epidemiological Investigation of RA (EIRA) study and the Swedish Rheumatology Quality Register's biobank, diagnosed with early RA and treated with MTX as their first ever DMARD. Persistence to MTX was defined as remaining on treatment at one and three years, respectively, with no additional DMARDs added during that period. Estimation of SNP-based heritability was done using restricted maximum likelihood. We performed the analyses for all RA, and two disease subsets: those positive for either ACPA or rheumatoid factor, and those negative for both.

Results: After quality control, 3403 of an initial 3609 early RA patients of European ancestry and above five million SNPs remained for the primary analysis. Among these, 65% were persistent at one year, and 44% were persistent at three years. In secondary analysis we excluded 218 patients due to missing sero-status. Of the remaining, 72% were seropositive. No SNP reached genome-wide significance, neither for persistence at one nor at three years. The SNP-based heritability was estimated to 0.35 (95%CI 0.04-0.65) for persistence at one year and 0.09 (95%CI 0.00-0.37) for persistence at three years. Analyses stratified by sero-status provided results comparable to the main analysis with similar proportions of persistent patients and no SNP reaching genome-wide significance for any of the subgroups. Point estimates of heritability for persistence in the seropositive group at one year (h^2 = 0.08, 95%CI 0.00-0.51) was lower than for seropositive persistence at three years (h^2 = 0.19, 95%CI 0.00-0.62) while point estimates for the seronegative heritability were zero for both persistence outcomes.

Conclusion: Despite being the largest GWAS on an MTX treatment outcome to date, no genome-wide significant associations were detected. The low heritability observed along with the lack of strong independent associations, may indicate that genetic influence from common genetic variants on persistence to MTX is minor, and of a polygenic nature.

OP0268 COMPARISON OF MAJOR CARDIOVASCULAR AND THROMBOEMBOLIC EVENTS IN SAFETY REPORTS BETWEEN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH JAK INHIBITORS VERSUS ANTI-TNF: RESULTS FROM VIGIBASE

F. Montastruc[1], C. Flumian[2], Y. Degboe[3], A. Constantin[3], A. Ruyssen-Witrand[4]. *[1]Toulouse University Hospital, Department of Medical and Clinical Pharmacology, Centre of PharmacoVigilance and Pharmacoepidemiology, Centre d'Investigation Clinique 1436,Team PEPSS « Pharmacologie En Population cohorteS et biobanqueS »,Toulouse, France*; *[2]Toulouse University Hospital, Department of Medical and Clinical Pharmacology, Centre of PharmacoVigilance and Pharmacoepidemiology,Toulouse, France*; *[3]Toulouse University Hospital, Rheumatology Center, Inserm UMR Infinity, Paul Sabatier University,Toulouse, France*; *[4]Toulouse University Hospital, Rheumatology Department, Centre d'Investigation Clinique 1436,Team PEPSS « Pharmacologie En Population cohorteS et biobanqueS »,Toulouse University Hospital,Toulouse, France*

Background: Recently, awareness has raised regarding JAK inhibitor safety in rheumatoid arthritis (RA), in particular with tofacitinib. Indeed, in a trial involving more than 4,000 patients (ORAL Surveillance), a numerically higher number of major cardiovascular events (MACEs) in patients treated with tofacitinib compared to anti-TNF (1), and a higher risk of venous thromboembolic events (VTE) in patients treated with tofacitinib 10mg twice a day compared to patients treated with tofacitinib 5mg twice a day or anti-TNF was observed. This increased risk of MACEs was also suspected in another study performed on American Health databases (2). Recently, the FDA extended warnings and use's recommendations to other JAK-inhibitor drugs (3).

Objectives: To corroborate these safety warnings, we compared the reporting MACEs and VTEs with JAK inhibitors versus anti-TNF alpha drugs from the World Health Organization (WHO) Global Individual Case Safety Report (ICSR) database (VigiBase).

Methods: We selected reports in Vigibase of patients aged between 18 and 75 years, between 01/01/2011 and 12/31/2020, with JAK inhibitors (tofacitinib, baricitinib, upadacitinib, filgotinib) or anti-TNF (etanercept, adalimumab, infliximab, certolizumab pegol, golimumab) with a diagnosis of RA. In these reports we selected MACEs including myocardial infarction, strokes and cardiovascular deaths and VTE including deep venous thromboses (DVT) and pulmonary embolisms (PE). Characteristics of reports including age of patients, country of declaration, drug involved, co-reported drugs, and type of event were described. The reporting risk was investigated using disproportionality analyses and expressed as Reporting Odds Ratios (ROR) with 95% Confidence Interval (95%CI). A sensibility analysis was performed stratifying by age category (≥ 65 years, ≥ 50 years), and by sex.

Results: Of the 11,455,891 reports in patients aged between 18 and 75 years in the period of interest, 39,097 of reports were for a JAK-inhibitor in RA (mean age 60.6 years, SD:16.3) and 231,860 of reports were for an anti-TNF in RA (mean age: 57.2 years, SD: 13.0). Most of the reports came from USA and Canada (respectively 77.4% and 12.5% for JAK-inhibitor and 86.4% and 2,6% for anti-TNF). Among the reports, 611 (1.6%) in JAK-inhibitor treated patients and 3240 (1.4%) in anti-TNF treated patients were MACEs

while 341 (0.9%) in JAK-inhibitors and 571 (0.2%) in anti-TNF treated patients were VTE. Disproportionality analyses identified an increased risk of reporting VTE events in JAK-inhibitors compared to anti-TNF (DVT: ROR = 3.99 [95%CI: 3.15-5.04], PE: ROR = 3.47 [2.90-4.13], Figure 1). This risk was not modified after stratification by age or sex. No increased ROR for MACE was found.

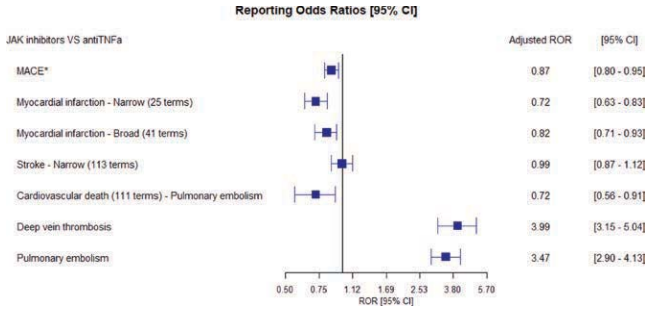

Figure 1.

Conclusion: Based on real-world data, the analysis did not identify an increase of declaration of MACEs with JAK-inhibitor compared to anti-TNF whereas we could observe more than three times declarations of VTE in Vigibase with JAK-inhibitors compared to anti-TNF.

OP0269

BIOMARKERS TO PREDICT RISK OF VENOUS THROMBOEMBOLISM IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TOFACITINIB OR TUMOUR NECROSIS FACTOR INHIBITORS

Z. Szekanecz[1], C. Charles-Schoeman[2], I. Vranic[3], B. Sahin[4], S. A. Paciga[5], Z. Wang[6], C. Hyde[6], D. Martin[7], J. I. Weitz[8]. *[1]University of Debrecen, Division of Rheumatology, Faculty of Medicine, Debrecen, Hungary*; *[2]University of California Los Angeles, Division of Rheumatology, Department of Medicine, Los Angeles, CA, United States of America*; *[3]Pfizer Ltd, Inflammation and Immunology, Tadworth, Surrey, United Kingdom*; *[4]Pfizer Inc, Inflammation and Immunology, Istanbul, Turkey*; *[5]Pfizer Inc, Early Clinical Development, Groton, CT, United States of America*; *[6]Pfizer Inc, Early Clinical Development, Cambridge, MA, United States of America*; *[7]Pfizer Inc, Inflammation and Immunology, Cambridge, MA, United States of America*; *[8]Thrombosis and Atherosclerosis Research Institute and McMaster University, Departments of Medicine and Biochemistry and Biomedical Sciences, Hamilton, ON, Canada*

Background: In the ORAL Surveillance study of patients (pts) aged ≥50 yrs with moderate to severe rheumatoid arthritis (RA) and ≥1 additional cardiovascular risk factor (NCT02092467), the incidence of pulmonary embolism was higher with tofacitinib than with tumour necrosis factor inhibitors (TNFi).1

Objectives: To explore whether biomarkers explained the associations of tofacitinib vs TNFi with venous thromboembolism (VTE) in ORAL Surveillance.

Methods: ORAL Surveillance was a prospective, open-label, event-driven, non-inferiority, post-authorisation safety study. Pts were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily or a TNFi (adalimumab 40 mg every 2 weeks or etanercept 50 mg once weekly). For this exploratory post hoc analysis, 294 soluble, proteomic, genetic and antibody biomarkers were assessed (of which 79 have a known role in inflammation, coagulation, vascular biology and/or Janus kinase signalling). Biomarkers were quantified in serum collected at baseline (BL) and Month (M)12 in VTE cases and 4:1 matched controls. D-dimer was analysed with a larger control group (all eligible pts without VTE) and final adjudicated data from BL, M12 and study end.

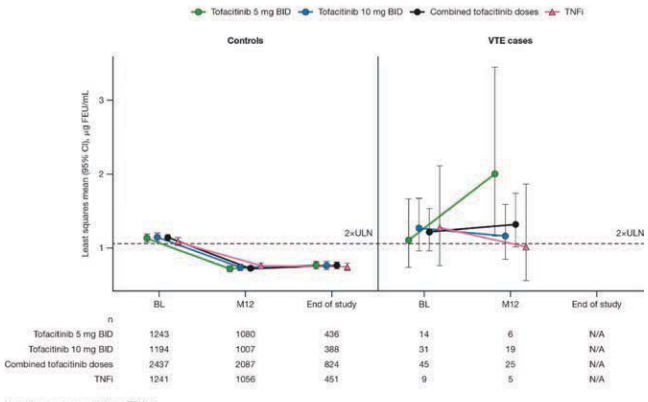
Results: Of the 4362 randomised and treated pts, D-dimer was quantified in 3732 pts (54 with VTE; 3678 without) and the remaining biomarkers were analysed in 285 pts (57 VTE cases; 228 matched controls). BL characteristics were generally similar in those with or without VTE and between treatment groups. At BL, D-dimer levels were ≥2×upper limit of normal for ~50% of controls and 67% of VTE cases. Mean D-dimer levels decreased from BL to M12 in controls across treatment groups (Figure 1). Key findings from the biomarker analyses are shown in the Table 1. No biomarker showed a clear mechanistic association with the increased risk of VTE for tofacitinib vs TNFi, or demonstrated adequate performance for prognostic use in pts with RA.

Table 1. Summary of results from biomarker analyses

Biomarker	Key results
Tier 1	
C-reactive protein	• No association with VTE in any treatment arm at BL or M12
D-dimer Thrombopoietin	• Higher M12 levels were prospectively associated with greater risk of subsequent VTE with tofacitinib 10 mg BID o For D-dimer, the same effect was observed with tofacitinib 5 mg BID • Treatment specificity of effects could not be established
Tier 2	
Factor VIII Thrombin–antithrombin complex Tissue factor pathway inhibitor Plasminogen activator inhibitor-1 Protein C Antithrombin Apolipoprotein C-III Leptin	• No clinically meaningful differences across treatment arms
Tiers 3 & 4	
Exploratory proteomic assays (276 markers from multiplex panels)	• Two biomarkers with no known relationship to VTE (angiogenin and TNFSF13B) showed significant associations with pulmonary embolism in the tofacitinib 10 mg BID arm o Treatment specificity of effects could not be established for either analyte
Genetic biomarkers	
Factor V Leiden R506Q, prothrombin G20210A and JAK2 V617F mutations	• Factor V Leiden and prothrombin risk alleles, individually or combined, were associated with increased incidence of VTE but did not explain excess events with tofacitinib • No VTE cases or matched controls had the JAK2 mutation
Antibody biomarkers	
ACA IgG and IgM, anti-β2GP1 IgG and IgM	• No statistical differences were observed between treatment arms or between VTE cases and matched controls

ACA, anticardiolipin antibody; β2GP1, beta-2-glycoprotein 1; IgG, immunoglobulin G; IgM, immunoglobulin M; JAK2, Janus kinase 2; TNFSF13B, tumour necrosis factor ligand superfamily member 13B

Fig. Least squares mean (95% CI) values of D-dimer by treatment arm in VTE cases and controls at BL, M12 and end of study



Normal assay range: <0.53 µg FEU/mL
VTE events included deep vein thrombosis and pulmonary embolism
Data collected after pts who were randomised to tofacitinib 10 mg BID had their dose reduced to 5 mg BID were included in the tofacitinib 10 mg BID group
The TNFi group received adalimumab 40 mg every 2 weeks (US, Puerto Rico and Canada) or etanercept 50 mg once weekly (rest of the world)
The end of study visit was conducted within 1 month of study completion, which was declared when the targeted number of major adverse cardiovascular events and malignancies (excluding non-melanoma skin cancer) had been met. The median duration of treatment was 44 months. To exclude the confounding effect of anticoagulant therapy, M12 samples were not analysed in pts with early VTE events (before M12) and end of study samples were not analysed in VTE cases
BID, twice daily; CI, confidence interval; FEU, fibrinogen equivalent units; N/A, not available; ULN, upper limit of normal

Conclusion: This post hoc exploratory analysis did not identify biomarkers at BL or M12 that explain the increased VTE risk for tofacitinib vs TNFi. Notably, ORAL Surveillance was neither designed nor powered to compare the risk of VTE across treatments or to identify biomarkers with a mechanistic relationship

to VTE. Individual VTE risk should be considered when making decisions about initiation or maintenance of tofacitinib treatment.

OP0270

TAPERING OF LONG-TERM, LOW-DOSE GLUCOCORTICOIDS IN SENIOR RHEUMATOID ARTHRITIS PATIENTS: FOLLOW-UP OF THE PRAGMATIC, MULTICENTRE, PLACEBO-CONTROLLED GLORIA TRIAL

A. Almayali[1], M. Boers[1,2], L. Hartman[1,2], D. Opris-Belinski[3], R. Bos[4], M. R. Kok[5], J. A. P. da Silva[6], E. N. Griep[7], R. Klaasen[8], C. Allaart[9], P. Baudoin[10], H. Raterman[11], Z. Szekanecz[12], F. Buttgereit[13], P. Masaryk[14], W. Lems[2], M. Cutolo[15], M. Ter Wee[1]. *[1]Amsterdam UMC, Vrije Universiteit, Department of Epidemiology & Data Science, Amsterdam, Netherlands*; *[2]Amsterdam UMC, Vrije Universiteit, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands*; *[3]Carol Davila University, Rheumatology, București, Romania*; *[4]Medical Centre Leeuwarden, Department of Rheumatology, Leeuwarden, Netherlands*; *[5]Maasstad Hospital, Department of Rheumatology and Clinical Immunology, Rotterdam, Netherlands*; *[6]University of Coimbra, Rheumatology, Coimbra, Portugal*; *[7]Antonius Hospital, Department of Rheumatology, Sneek, Netherlands*; *[8]Meander Medical Center, Department of Rheumatology, Amersfoort, Netherlands*; *[9]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[10]Reumazorg Flevoland, Rheumatology, Emmeloord, Netherlands*; *[11]Northwest Clinics, Department of Rheumatology, Alkmaar, Netherlands*; *[12]University of Debrecen, Department of Rheumatology, Debrecen, Hungary*; *[13]Charité-University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[14]National Institute for the Rheumatic Diseases, Rheumatology, Piešťany, Slovakia (Slovak Republic)*; *[15]University of Genoa, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Genoa, Italy*

Background: Guidelines suggest glucocorticoids (GC) should be used as bridge therapy in rheumatoid arthritis (RA), but many patients are treated chronically with low doses. The effects of withdrawal in such patients has not been studied extensively.

Objectives: To study disease activity score (DAS28), disease flares and signs of adrenal insufficiency after withdrawal of blinded trial medication (prednisolone 5 mg/day or placebo for 2 years).

Methods: The 2-year, double-blind GLORIA trial evaluated the long-term benefits and harms of low dose GC added to standard care (see main GLORIA trial abstract). Senior RA patients (≥ 65 years) were randomly assigned to prednisolone 5 mg/day or placebo.

After the final trial visit study medication was linearly tapered to zero in 3 months by adding a stop day every two weeks, and patients were reassessed. Those who successfully completed the trial and did not receive open-label GC during the 4 weeks after the final trial visit were included in this follow-up study.

The primary outcome was change in DAS28 at follow-up compared to the final trial visit. Secondary outcomes included the occurrence of disease flares (DAS28 increase > 0.6 or open-label GC between week 4 and 12 of the taper phase) and signs of adrenal insufficiency, assessed by 9 items selected from the 57-symptom list from the MDHAQ questionnaire (1) and hypotension (systolic RR < 90 or diastolic RR < 60). In a subset of patients from 3 Dutch centres, cortisol and ACTH were measured in spot serum samples during the follow-up visit.

Analysis of covariance assessed the change in DAS28. Linear regression and chi-square test were used for the remaining outcomes.

Results: 278 participants completed the GLORIA study, 21 received GC within 4 weeks after the end of the trial, 58 had missing data, leaving 199 patients eligible for this study.

34 patients received open label GC after 4 weeks and were excluded for the primary analysis. In the remaining 165 patients (80 prednisolone, 85 placebo), mean (SD) DAS28 was higher on placebo: 3.14 (1.04) vs 2.92 (1.13) prednisolone at the final trial visit. After tapering, disease activity increased significantly (p=0.02) in the prednisolone group to 3.18 (1.20) but was stable in placebo (3.14). The difference in the increase of DAS28 between the groups was 0.21 (95%CI –0.05;0.47; p=0.11).

For signs of adrenal insufficiency, 33 out of 165 had missing data, leaving 60 in the prednisolone group and 72 in placebo (Table 1). Mean (SD) number of signs for prednisolone was 1.1 (1.1) versus 0.9 (1.3) for placebo at final trial visit and 0.8 (1.2) versus 0.8 (1.0) at follow-up. Difference in the change of the number of signs was –0.1 (95%CI –0.4;0.3; p=0.66).

Table 1. Adrenal insufficiency signs and symptoms.

	prednisolone (n=60)		placebo(n=72)	
	end of trial	change after 3 months	end of trial	change after 3 months
Fatigue (unusual)	15	1	13	–1
Appetite loss	5	–1	4	4
Muscle weakness	7	–2	6	–2
Dizziness	3	2	10	1
Stomach pain	3	4	3	1
Muscle pain	19	–6	19	–1
Nausea	5	–3	2	2
Vomiting	1	0	0	1
Diarrhoea	5	–2	3	–2
Hypotension*	2	–1	4	–2
Sum**	1.1 (1.1)	–0.2 (1.3)	0.9 (1.3)	0.0 (1.3)

* Systolic RR < 90 or diastolic RR < 60. **Mean (SD)

No differences were seen in ACTH or cortisol levels: mean (SD) ACTH was 5.8 (4.1) in 23 prednisolone patients, and 5.1 (3.7) in 24 placebo patients; cortisol 296 (113) v 310 (166), cortisol/ACTH 67 (40) v 77 (54). Two prednisolone and one placebo patient had cortisol levels below 80. None developed clinical hypoadrenalism during further follow-up.

199 patients qualified for the disease flares sample, 99 prednisolone and 100 placebo; 44 patients flared on prednisolone tapering vs 31 on placebo, relative risk 1.43 (95%CI 0.99; 2.07; p=0.07).

Conclusion: Tapering prednisolone moderately increases disease activity to placebo levels (mean still at low disease activity levels) and numerically increases the risk of flare without any evidence of adrenal insufficiency. This suggests that withdrawal of low dose prednisolone is feasible after 2 years of administration.

RA: Clinical aspects and comorbidities - II

OP0271 INCREASED RISK OF DEMENTIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE POPULATION-BASED COHORT STUDY

Y. Eun[1], K. D. Han[2], S. Y. Kang[3], S. Lee[3], H. S. Cha[3], E. M. Koh[3], J. Lee[3], H. Kim[3,4]. [1]*Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Internal Medicine, Seoul, Korea, Republic of South Korea*; [2]*Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Republic of South Korea*; [3]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Republic of South Korea*; [4]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Republic of South Korea*

Background: There have been conflicting results of previous studies on the association between rheumatoid arthritis (RA) and the risk of dementia.
Objectives: In this study, we aimed to investigate the association between RA and dementia in a large nationwide population-based cohort.
Methods: Among patients diagnosed with RA between 2010 and 2017, patients who had undergone a national health examination within two years prior to RA diagnosis were included in the study (n = 138,592). Control group included age- and sex-matched non-RA controls who received a health check-up at the same time as RA patients (n = 692,960). The primary outcome of the study was incident dementia, which was defined by an ICD-10 code and the use of dementia medications. Kaplan-Meier curves and Cox proportional hazards regression analysis were used for the analysis.
Results: Mean follow-up duration of the study was 4.7 ± 2.2 years. RA patients had a 1.2 times higher risk of dementia than controls (adjusted hazard ratio [aHR] 1.19, 95% CI 1.16–1.23). In patients with RA, the aHR for Alzheimer's disease (AD) was 1.21 (95% CI 1.67-1.25) and the aHR for vascular dementia (VD) was 1.10 (95% CI 0.99-1.21). In a stratified analysis according to age, gender, lifestyle factors and comorbidities, the association between RA and dementia was consistently found.
Conclusion: In a large nationwide population-based cohort, RA was associated with an increased risk of incident dementia. Appropriate evaluation of dementia is required when cognitive impairment occurs in RA patients. Further studies are warranted to identify mechanisms of increased risk of dementia in RA patients.

OP0272 PREDNISONE USE AND THE INCIDENCE OF HYPERGLYCEMIA OR DIABETES IN PATIENTS WITH RHEUMATOID ARTHRITIS; A 10-YEAR SUB ANALYSIS OF THE BEST STUDY.

J. van der Pol[1], S. A. Bergstra[1], T. Huizinga[1], C. Allaart[1]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*

Background: Use of prednisone in rheumatoid arthritis has been questioned because it may trigger side effects such as hyperglycemia and diabetes.
Objectives: To assess whether in RA the use of prednisone is associated with the development of hyperglycemia and diabetes.
Methods: The BeSt study is a multicenter, assessor-blinded randomized controlled 10-years follow-up trial in 508 non-diabetic early RA patients. Patients were randomised to 4 dynamic DMARD treatment strategy groups: 1) sequential monotherapy, 2) step-up combination therapy, 3) initial combination therapy including prednisone (60 mg/day, tapered to 7.5 mg/day in 7 weeks) and 4) initial combination therapy with infliximab. In groups 1, 2 and 4, prednisone had a maximum dose of 7.5 mg/day by protocol. Treatment was steered at disease activity score (DAS) ≤2.4. We performed a GEE over time to assess whether current prednisone use or cumulative prednisone dose were associated with hyperglycemia (glucose levels ≥7.8) and cox regression analyses to investigate the relationship between cumulative prednisone dose, previous prednisone use and diabetes (defined as either use of anti-diabetic medication or two instances of a glucose ≥ 11.1), assessed at 3-monthly visits. All analyses were adjusted for potential confounders.
Results: In total, 33/508 patients (6.5%) developed diabetes during the trial; 12 of these (36%) had received prior treatment with prednisone (any dose). Median (IQR) duration of prednisone use in all 508 patients was 9 (15) months and cumulative doses ranged from 0 to 27942 mg. The mean cumulative dose ranged from 55.5 mg in group 1 to 6170.0 mg in group 3. Previous prednisone use nor cumulative prednisone dose was associated with hyperglycemia or diabetes, with effect sizes ranging from a hazard ratio of 0.588 (95% CI 0.285; 1.21) for the association between any prednisone dose and diabetes to an odds ratio of 1.04 (95% CI 0.978; 1.13) for the association between cumulative prednisone dose and diabetes (Table 1). To identify potential causes for these results, we investigated the relationship between DAS and the same outcomes. We found a higher DAS was significantly associated with development of diabetes, but not with hyperglycemia.

Table 1. The relationship between prednisone dose, DAS and glucose levels, hyperglycemia and diabetes

GEE	hyperglycemia*	OR	95% CI
Any prednisone dose[1]		*0.949*	*0.805; 1.12*
Cumulative dose[1]		*1.04***	*0.978; 1.13*
DAS[2]		1.24	0.842; 1.85
Cox Regression	**diabetes (any of the definitions)**	**HR**	**95% CI**
Any prednisone dose[3]		*0.588*	*0.285; 1.21*
Cumulative dose[3]		*0.996***	*0.960; 1.03*
DAS[2]		1.60	1.13; 2.26

CI: confidence interval, GEE: Generalized Estimating Equations, OR: odds ratio, HR: hazard ratio, DAS: disease activity* hyperglycemia: glucose level above 7.8 mmol/L; diabetes: random glucose level above 11.1 mmol/L at at least two time points** odds ratio per 500mg cumulative prednisone increase: [1]adjusted for DAS, age, diabetes and BMI: [2]adjusted for cumulative prednisone dose, age, gender and BM: [3]adjusted for DAS, age and BMI

Conclusion: In early RA patients, cumulative dose nor any previous prednisone use was associated with the risk of hyperglycemia or diabetes. A higher DAS was significantly associated with increased risk of developing diabetes. Potential risks of prednisone may have been mitigated by suppression of DAS.

OP0273 CHARACTERISTICS OF PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS IN FRANCE

S. Hecquet[1,2], A. Combier[3], A. Steelandt[3], M. Pons[3], D. Wendling[1], A. Moltó[3], C. Miceli Richard[3], Y. Allanore[3], J. Avouac[3]. [1]*Centre Hospitalier Régional Universitaire de Besançon, Rheumatology, Besançon, France*; [2]*University of Franche-Comté, UR 4267 PEPITE, Besançon, France*; [3]*Cochin Hospital, Rheumatology, Paris, France*

Background: Recently, EULAR has proposed a definition of difficult-to-treat rheumatoid arthritis (D2TRA). However, descriptive data on D2TRA are scarce and only one Japanese publication details the D2TRA encountered in routine practice, no similar work has been done in Europe so far.
Objectives: To describe D2TRA patients encountered in France according to two definitions and evaluate their therapeutic responses to different targeted therapies.
Methods: We reviewed all patients with RA treated in day hospital at Cochin University Hospital between 2020 and 2021. We divided our population into two groups of patients, a D2TRA group and a non-D2TRA group. This division was made on the same population according to two different definitions of D2TRA, resulting in four patient groups. The first definition is the one proposed by EULAR (EULAR D2TRA) defining D2TRAs as RAs with failure of ≥2 b/tsDMARDs (with different mechanisms of action) after failing csDMARD therapy. The second defined as D2TRA patients who have failed at least two targeted therapies, without prejudging the mechanism of action (non-EULAR D2TRA). We analyzed clinical characteristics and evaluated their response to different targeted therapies. Disease activity was assessed using the DAS for 28 joints (DAS28) at the latest visit.
Results: In total, we included 320 patients, we identified 76 EULAR D2TRA patients (mean age 59 years, 87% female) with 244 of corresponding non-DTRA patients (mean age 60 years, 85% female) and 120 non-EULAR D2TRA patients (mean age 58.7 years, 87% female) with 200 of corresponding non-DTRA (mean age 61 years, 85% female). Compared to non-D2TRA patients, there were significantly more D2TRA patients from low socioeconomic backgrounds in both D2TRA groups. In the EULAR-D2TRA group, compared to the non-D2TRA, there were significantly more patients with diabetes (14% vs 6%, p=0.024). D2TRA patients in both groups had significantly more rheumatoid factor (RF), interstitial lung disease (ILD) and a higher DAS28 than non-D2TRA patients. No difference was noted regarding ACPA and erosions. We observed a lower proportion of remission in both D2TRA groups than in non-D2TRA group (21% in EULAR-D2TRA vs 34% in non-D2TRA, p=0.034 and 23% in non-EULAR D2TRA vs 36% in non-D2TRA, p=0.024). There were significantly fewer patients on Methotrexate in the non-EULAR D2TRA group compared to the non-D2TRA group (53% vs 64%, p=0.046). In the non-EULAR D2TRA group, there were significantly more patients in remission on Rituximab than on TNF inhibitors (41% vs 5%, p=0.0032). We did not observe a significant difference in achieving remission in patients on JAK inhibitors or IL-6 inhibitors in the two groups of D2TRA.

Table 1. Clinical data of patients with D2TRA

	NON D2T RA n=200	NON-EULAR D2T RA n=120	p-value	NON D2T RA n=244	EULAR D2T RA n=76	p-value
Low socioeconomic level	69 (35)	61 (51)	**0.005**	91 (37)	39 (51)	**0.032**
TJC (0-28), mean (SD)	3.4 (4.6)	4.9 (5.8)	**0.0167**	3.5 (4.5)	5.6 (6.5)	**0.001**
SJC (0-28), mean (SD)	2.4 (3.1)	3.5 (4.3)	**0.0067**	2.6 (3.3)	3.5 (4.3)	0.0503
CRP in mg/dl, mean (SD)	6 (9.5)	7 .5 (12.1)	0.2128	6.1 (9.9)	7.9 (12.3)	0.2060
DAS28CRP, mean (SD)	3.2 (1.2)	3.6 (1.4)	**0.0044**	3.2 (1.3)	3.6 (1.4)	**0.0052**
Remission	71 (36)	28 (23)	**0.024**	83 (34)	16 (21)	**0.034**
RF positive, n (%)	156 (78)	105 (88)	**0.037**	193 (79)	68 (89)	**0.043**
Anti-CCP positive, n (%)	152 (76)	101 (84)	0.099	188 (77)	66 (87)	0.075
Erosion, n (%)	114 (57)	69 (58)	1	138 (56)	46 (60)	0.596
Interstitial Lung Disease, n (%)	16 (8)	19 (16)	**0.041**	17 (7)	18 (24)	**<0.001**
Corticosteroids, n (%)	84 (42)	64 (53)	0.064	101 (41)	46 (61)	**0.004**
Dose (mg), mean ± SD	6 (4.9)	5.5 (3.4)	0.416	6 (4.6)	5.3 (3.6)	0.374
Methotrexate, n (%)	128 (64)	63 (53)	**0.046**	149 (61)	42 (55)	0.422
Dose (mg), mean ± SD	17.3 (4.25)	17.5 (5.3)	0.786	17.2 (4.5)	18.1 (5.1)	0.291

Conclusion: The complexity of managing RA patients can be explained by socio-economic status and the presence of comorbidities such as diabetes and ILD. Our work suggests that D2TRA patients have less Methotrexate and better response to Rituximab. These data need to be confirmed in prospective studies to allow personalized management of D2TRA.

OP0274

HOSPITALISATION FOR TUBERCULOSIS AND OTHER OPPORTUNISTIC INFECTIONS IN PATIENTS WITH INFLAMMATORY JOINT DISEASES BEFORE AND AFTER THE INTRODUCTION OF BIOLOGICAL THERAPY.

J. Nossent[1,2], H. Keen[1,3], D. Preen[4], C. Inderjeeth[1,2]. [1]*The University of Western Australia, Medical School, Crawley, Australia*; [2]*Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*; [3]*Fiona Stanley Hospital, Rheumatology, Murdoch, Australia*; [4]*The University of Western Australia, UWA School of Population and Global Health, Nedlands, Australia*

Background: Over the last 20 years aggressive therapy for inflammatory joint diseases (IJD) has become standard of care following the acceptance of Methotrexate as anchor drug and extensive of use biologic therapy since 2003. Immunosuppression increases the risk for common and uncommon infections (1).
Objectives: To compare the temporal rates and associated mortality of hospitalisation with opportunistic infections (OI) (Table 1) for IJD patients in Western Australia between 1985 and 2015.
Methods: All patients hospitalized in Western Australia in the period 1980-2015 with ≥ 2 diagnostic codes for rheumatoid arthritis (RA, n=8490), psoriatic arthritis (PsA, n=601), axial spondylarthritis (AS, n=1419). Overall incidence rates (IR) with microbiologically confirmed OI (Mycobacterial, Fungal and viral infections) (Table 1) during 306.514 person years were expressed per 1000 person years and compared across IJD by incidence rate ratios (IRR) with 95% CI. IR trend rates across 5-year periods for each IJD were analyzed by least square regression (R^2). Mortality rate ratio (MRR) was number of deaths per 1000 observation years in patients with OI compared to patients in same disease category hospitalized without OI.

Table 1. Diagnostic codes applied to define conditions and opportunistic infections in hospital discharge database.

	ICD9CM	ICD10AM
RA	714.0-714.9	M05.0-M06.9
AS	720.0	M45, M08.10-M08.19
PsA	696.0	M07.0-M07.3, L40.5
Tuberculosis	010.x-018.x	A15–A19
Non-tuberculous mycobacteria	031.x	A30-A31
Cryptococcosis	117.5	B45
Aspergillosis	117.3	B44
Histoplasmosis	115	B39
All mycosis	114.0 - 118.9	B35.0 - B49.9
Pneumocystosis	136.3	B59
Cytomegaloviral disease	078.5	B25
Influenza	487.x, 488.x	J09, J10
Herpes zoster	053.x	B02
Varicella	052.x	B01

Results: The IR for all OI in RA patients (5.19, CI 4.8-5.6) was significantly higher than for PsA (IRR 0.56, CI 0.41-0.76 and AS (IRR 0.64, CI 0.53-0.79) with lower IRR observed especially for tuberculosis and H Zoster in PsA (0,49 and 0,47) and AS patients (0,43 and 0,49). H Zoster, TBC and other mycobacteria were the most frequent cause of OI with cryptococcal and pneumocystis only seen in RA. The IR for TBC decreased over time in RA (R^2 0.51, p=0.08), and AS (R^2 0.47, p=0.09) while the IR for H. zoster decreased in RA only (R^2 0.46, p=0.09) (Figure 1). In-hospital mortality rate in patients with OI was 4.9 % for RA, 2.6 % for PsA and 2.2% for AS, but MRR for RA (1.15; 0.71-1.97), PsA (1.64; 0.82-3.57) and AS patients (1.35; 0.68-2.89) was not significantly increased.

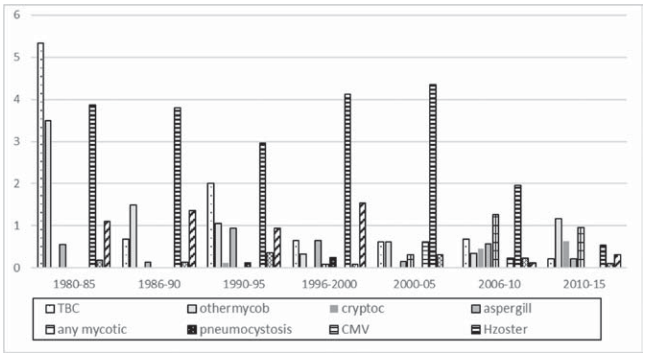

Figure 1. Incidence rate per 1000 personyears over time for hospitalisation with opportunistic infections in RA patients.

Conclusion: The IR for hospitalization with OI is twice as high for RA patients compared to AS and PsA patients. Admission rates for most OI including have decreased in RA patients over the two decades where more intensive treatment became standard of care. This suggests efficacy of preventative measures. Hospital admission with OI associated with a moderate risk of death, but did not incur a higher risk of death than admission for other medical complications in IJD patients

OP0275

DISEASE FEATURES AND SURVIVAL OUTCOMES IN A RETROSPECTIVE COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE AFTER LUNG TRANSPLANTATION

A. Razmjou[1], E. Volkmann[1], V. Ranganath[1]. [1]*UCLA Medical Center, Rheumatology, Los Angeles, United States of America*

Background: Interstitial lung disease (ILD) is a leading cause of morbidity and mortality in patients with rheumatoid arthritis (RA). While the disease course of ILD is variable, some patients with RA have a progressive fibrosing ILD phenotype refractory to treatment. Lung transplantation (LTx) represents a life-extending option for patients with end-stage lung disease; however, data on the clinical features and outcomes of these patients are limited.
Objectives: (1) To characterize the clinical features of RA-ILD patients who received LTx at a high-volume lung transplantation center; (2) To evaluate survival and predictors of mortality in this cohort.
Methods: This retrospective study included all patients with RA-ILD who received LTx between 2004 to 2020 at UCLA. Patient demographics, RA disease features, explant pathology, pulmonary function tests (PFTs), and survival

status were extracted from the electronic medical record. Descriptive statistics were used to summarize disease features. A Kaplan-Meier curve was created to evaluate survival, and a Cox proportional hazards model was created to identify predictors of survival.

Results: 42 RA-ILD patients underwent LTx. The majority of patients were male (57.1%), seropositive (91.4%), with a mean RA disease duration of 12.9 years at LTx (Table 1). Over the study period, 16 (36%) patients died. Compared with patients who had survived, deceased patients were slightly older at the time of transplantation (59.0±9.7 vs. 57.3±11.5, respectively), and were more likely to have usual interstitial pneumonia (UIP) in the lung explant (87.7% vs. 56.0%, p <0.05). The median follow up was 2.3 years (IQR 1.3, 4.7), and median survival time was 5.3 years (IQR 2.7, 7.6; Figure 1). In the univariate Cox proportional hazards analysis, there was a relationship between the presence of UIP pathology and increased mortality, although this did not reach significance (HR 7.13, p=0.06).

Table 1. Disease features of study cohort*

	All patients (N=42)
Age at LTx	58.0±10.7
Female	18 (42.9)
BMI (kg/m2)	25.7±4.2
Race- Caucasian	28 (66.7)
Ethnicity- Hispanic	11 (26.2)
Smoking, ever	17 (40.4)
Pack years	6.5±12.8
RA Disease Duration at Time of LTx (years)	12.9±11.4
ILD Before/Concurrent to RA#	12 (28.6)
Erosive	11 (40.7)
Seropositive%	32 (91.4)
Pathology- UIP	28 (68.3)
Pathology- NSIP	7 (17.0)
Pathology- Other	13 (31.7)
FVC% at Time of LTx	46.9±14.0
DLCO% at Time of LTx	34.4±17.9
Post-Transplant Rheumatology Follow-Up	20 (47.6)

*Values are N(%) or mean ±SD #ILD diagnosis was made within 12 months of RA diagnosis %RF or CCP

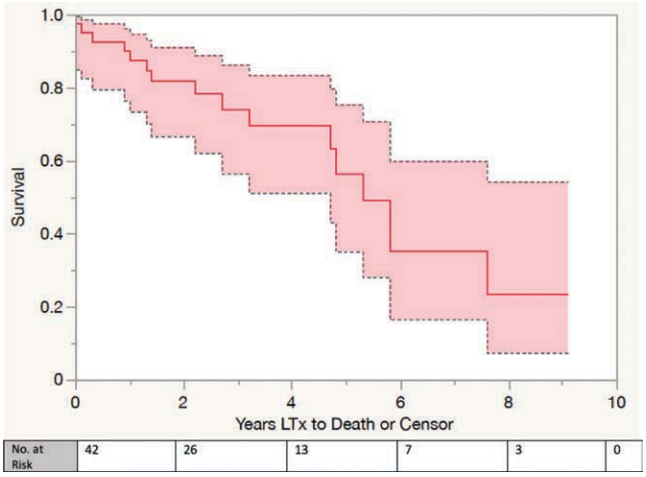

Figure 1. Kaplan-Meier survival curve for RA-LTx patients from time of LTx to death, or censor. The shaded area represents the 95% confidence interval. Median time to death was 5.3 years (IQR 2.7, 7.6).

Conclusion: This single-center study of RA-ILD patients who underwent LTx demonstrated a median survival time comparable to other LTx cohorts.[1] There appeared to be a relationship between the presence of a UIP pattern, and increased risk of mortality, though the small sample size may have precluded the ability to reach statistical significance. Future prospective studies are needed to validate these findings. Understanding the disease features of RA patients who undergo LTx may facilitate the early identification of RA patients at the greatest risk of developing progressive fibrosing phenotype.

Background: There is a growing research focus on the development of interventions to reduce risk of rheumatoid arthritis (RA) in at-risk individuals.(1) A recent survey of the general population asked to assume a 60% risk of RA established that hypothetical preventive treatments were acceptable to most participants.(2) However the preferences of individuals who actually have an elevated risk of RA, such as first-degree relatives (FDRs) of RA patients, are not well understood.

Objectives: To quantify FDRs' preferences for preventive treatments for RA.

Methods: Adult FDRs in the UK and Germany were invited to take part in a web-based survey via patients with clinician-confirmed RA either during a rheumatology clinic visit or by mail. In addition, FDRs taking part in a UK-based prospective cohort (PREVeNT-RA) were invited via email. Participants received information about RA followed by questions to check comprehension, and an introduction to the survey including warm-up questions. They were asked to imagine they were experiencing arthralgia and had positive autoantibody tests indicating a 60% chance of developing RA in the next two years. Using a discrete choice experiment, participants were offered a series of 15 choices between no treatment and two unlabeled hypothetical treatments to reduce risk of RA. Treatments were defined by six attributes with varying levels, describing benefits, risks, and frequency/route of administration (Table 1). Attribute selection and presentation was informed by qualitative research, ranking surveys, systematic literature review, and expert opinion. Survey layout was informed by patient research partners and qualitative pre-testing. A two-class latent class analysis was used to estimate preferences and calculate relative importance of treatment attributes and predicted uptake. A panel mixed logit model was used to obtain maximum acceptable risk estimates.

Table 1. Treatment attributes and levels

Attribute	Levels
Chance of developing RA reduced from 60% to	10%; 20%; 30%; 40%
How the treatment is taken	A shallow injection under the skin A drip into the vein One or two tablets
How often the medication has to be taken	Daily Weekly Monthly Every 6 months
Chance of mild side effects	2%; 5%; 10%
Chance of a serious infection due to treatment	0%; 1%; 5%
Chance of a serious side effect that is potentially irreversible	1 in 100,000 people 20 in 100,000 people 100 in 100,000 people

Results: 356 FDRs (252 female, 289 in the UK) responded. While treatment effectiveness was the most important attribute in both classes (Figure 1), the importance of other attributes differed between classes, with method and frequency of treatment administration being more important in class 2 and risk of mild side effects only impacting treatment choice in class 1. Perceived risk of developing

RA predicted class assignment; those with higher perceived risk were more likely to belong to class 1. On average, the predicted uptake of treatment profiles estimating prevention candidates: abatacept; atorvastatin; hydroxychloroquine; tolerogenic cell-based therapy; and no treatment would be 50%, 15%, 9%, 18% and 0%, respectively. Finally, the maximum acceptable risk participants were willing to accept were 81%, 25% and 3% point increases in risk of mild side effects, serious infection, and serious side effects, respectively, for medicines that would reduce their risk of developing RA in the upcoming two years from 60% to 20%.

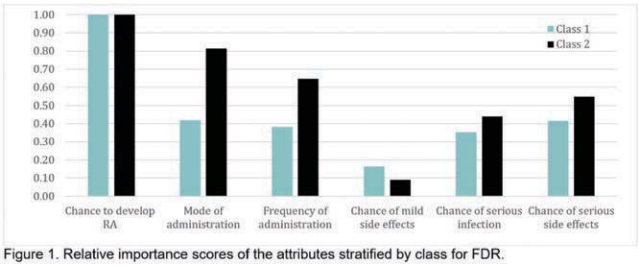

Figure 1. Relative importance scores of the attributes stratified by class for FDR.

Conclusion: Effective preventive treatments for RA were acceptable to FDRs asked to assume a 60% chance of developing RA. Mode and frequency of treatment administration had a greater impact on treatment choices for participants with a lower perceived risk of RA. These findings are informative for target product profile development, endpoint selection, benefit-risk assessment, regulatory approval, and development of informational resources for those at risk of RA.

OP0277 PERSISTENT EXCESS OF STROKE EVENTS IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY FROM HORDALAND, NORWAY FROM 1972 TO 2014

C. L. Alsing[1,2], J. Igland[3,4], G. S. Tell[3,5], H. Næss[6,7,8], T. W. Nystad[9], B. T. Svanes Fevang[2,9]on behalf of BEaBiRD - Bergen Group of Epidemiology and Biomarkers in Rheumatic Disease. [1]*Haraldsplass Deaconess Hospital, Department of Internal Medicine, Bergen, Norway*; [2]*University of Bergen, Department of Clincal Science, Bergen, Norway*; [3]*University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway*; [4]*Western Norway University of Applied Science, Department of Health and Social Science, Bergen, Norway*; [5]*Norwegian Institute of Public Health, Division of Mental and Physical Health, Bergen, Norway*; [6]*Haukeland University Hospital, Department of Neurology, Bergen, Norway*; [7]*University of Bergen, Department of Clinical Medicine (K1), Bergen, Norway*; [8]*Stavanger University Hospital, Centre for Age-Related Medicine, Stavanger, Norway*; [9]*Haukeland University Hospital/Health Bergen, Department of Rheumatology, Bergen, Norway*

Background: Patients with rheumatoid arthritis (RA) have an excess risk of cardiovascular disease (CVD), including stroke [1]. After the introduction of biological DMARDs in 1999 and the treat to target strategy, more patients reach low disease activity and remission, which is associated with lower CVD risk [2]. Few previous studies have examined stroke occurrence in RA patients before and after these improvements in RA management.

Objectives: To investigate stroke events in RA patients diagnosed before and after 1999 compared with the total population.

Methods: We included 771 RA patients diagnosed during 1972-1998 and 1050 during 1999-2013 at the main rheumatological department of Hordaland county, Norway. The total population of the same county and time period were used as a comparison cohort. Data on stroke events were obtained from regional cardiovascular registries or hospital patient administrative systems during 1972-2014. Aggregated counts of stroke events and population counts from the comparison cohort were used to estimate expected counts of stroke hospitalisation in the RA cohort per 5-year age group, sex and calendar year. We then estimated standardised event ratios (SERs) by Poisson regression as a measure of excess stroke events in RA patients compared with the total population.

Results: In total, 152 stroke events occurred in 112 RA patients diagnosed during 1972-1998 over 15137 person-years of follow-up and 86 stroke events in 70 RA patients diagnosed during 1999-2013 over 8672 person-years of follow-up. RA patients diagnosed in the later period were on average 2.1 years older (56 years) at RA diagnosis, but the proportion of women was similar in both groups. Both RA patients diagnosed before and after 1998 had an excess of stroke events compared with the total population (SER 1.20, 95% CI 1.00-1.44 and SER 1.22, 95% CI 1.05-1.42 respectively). RA patients younger than 60 years of age did not appear to have significant excess stroke events in either group.

Conclusion: These results indicate a similar excess of stroke events in RA patients diagnosed before and after 1999. This warrants continued awareness regarding stroke prevention in RA patients, even after the recent improvements in RA treatment.

OP0278 MUSCULOSKELETAL IMMUNE-RELATED ADVERSE EVENTS IN 927 PATIENTS TREATED WITH IMMUNE CHECKPOINT INHIBITORS FOR SOLID CANCER

A. Melia[1], E. Fockens[2], A. Madroszyk[3], P. Lafforgue[2], T. Pham[2]. [1]*Aix Marseille University, APHM, University Hospital of Marseille Sainte-Marguerite, Department of Rheumatology, Marseille, France*; [2]*Aix Marseille University, APHM, University Hospital of Marseille Sainte-Marguerite, Department of Rheumatology, Marseille, France*; [3]*Institut Paoli-Calmettes, Oncology Department, Marseille, France*

Background: The prevalence of the musculoskeletal immune-related adverse events (irAEs) is probably underestimated, as most studies report only severe side effects. The largest prospective study with systematic monitoring by a rheumatologist, for musculoskeletal irAEs, concerned 35 patients.
Objectives: The main objective was to describe each type of musculoskeletal irAEs: prevalence, clinical features, treatment regimen, ICI drug, time of occurrence and management of musculoskeletal irAEs. The secondary objectives were to describe IrAEs'course ant to investigated tumor response at 3 months after introduction of ICI according to IrAEs'grade, clinical features, pain patterns and the treatments used to manage musculoskeletal irAEs.
Methods: We conducted a retrospective study among patients who received ICI from 07/27/2014 to 05/08/2020 at the medical oncology department of the Institut Paoli-Calmettes, Marseille, France. All medical files were systemically reviewed by a rheumatologist who collected clinical features, time of occurrence, treatment regimen, irAEs management, course, outcomes and tumor response 3 months after introduction of ICI.
Results: In our cohort of 927 patients treated with ICI for a solid tumor, 118 patients (12.7%) presented a musculoskeletal irAE. Their median age was 66.5, 61% were male, and they mainly had a lung (57.6%) or urological cancer (27.1%). The most frequently involved ICI was an anti PD-1. Arthralgias and myalgias were the most frequent musculoskeletal irAEs (76.3%) and inflammatory rheumatic features were reported in 36 patients (30.5%) with elevated acute phase reactants and negative immunological markers. The median time of onset was 2 months (IC 95% 1.8; 2.7). Musculoskeletal irAEs were mainly mild and no deaths were related. Painkillers were the most widely used treatments (86.4%). Systemic corticosteroids were used in 38 patients (32.2%) with a mean dose of 43 ± 35 milligrams/day. Among the inflammatory rheumatic features, 20 (55.5%) were treated with systemic corticosteroids and 8 with csDMARDs (16.7%). bDMARDs were not used in our cohort. Musculoskeletal irAEs resulted in discontinuation of the responsible ICI in 23 patients (19.5%). The majority of musculoskeletal irAEs (79.7%) resolved within a median time of 3 months (IC 95% 2.2;4.0). Tumor response at 3 months did not differ according to musculo-skeletal irAE severity, type of manifestation (arthralgias/myalgias versus inflammatory rheumatic features), pain patterns (mechanical versus inflammatory) or irAE treatments.
Conclusion: Our single-center cohort is the largest to our knowledge to describe all musculoskeletal irAEs in patients treated with ICI without focusing on severe or inflammatory manifestations. These musculoskeletal irAEs are frequent, mostly mild and well tolerated, resolving and allowing possible continuation of ICI treatment. Collaboration between oncologists and rheumatologists should be further encouraged to determine whether all musculoskeletal irAEs, even non-severe and non-inflammatory ones, are associated with a good tumor response to ICI.

Recent novelties in SLE/Sjogren and APS?

OP0279 **CAR-T CELL TREATMENT OF REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS- SAFETY AND PRELIMINARY EFFICACY DATA FROM THE FIRST FOUR PATIENTS**

G. Schett[1], S. Boeltz[1], F. Müller[2], A. Kleyer[1], S. Völkl[2], M. Aigner[2], R. Gary[2], S. Kretschmann[2], D. Simon[1], S. Kharboutli[2], D. Mougiakakos[3], G. Krönke[1], M. Andreas[2]. *[1]FAU Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology/Immunology, Erlangen, Germany*; *[2]FAU Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 5, Hematology/Oncology, Erlangen, Germany*; *[3]University of Magdeburg, Department of Hematology, Oncology, and Stem Cell Transplantation, Magdeburg, Germany*

Background: While treatment of Systemic lupus erythematosus (SLE) has substantially improved, a subset of patients experiences severe progressive disease despite T- and B cell targeted therapy. Furthermore, drug-free remission and seroconversion is difficult to achieve in SLE to date
Objectives: To study the safety, tolerability, and preliminary efficacy of deep B cell depletion using autologous CD19 chimeric antigen receptor (CAR) T cells in patients with severe and treatment-refractory SLE
Methods: The CAR product was manufactured by CliniMACS Prodigy system (Miltenyi Biotec, Bergisch Gladbach, Germany). T-cells were enriched from the patients' peripheral blood apheresis product and $1x10^8$ cells were used as starting cell population. The cells were transfected with a lentiviral vector encoding an anti-CD19 CAR is composed of the FMC63 scFv, a CD8- derived hinge region, TNFRSF19-derived transmembrane domain, CD3ζ intracellular domain, and 4-1BB co-stimulatory domain (Miltenyi Biotec) and expanded for 12 days. After conditioning with cyclophosphamide/ fludarabine patients received $1x10^6$ CD19-CAR-T cells/kg body weight as a single infusion. All SLE treatments with the exception of low dose prednisolone were stopped before CAR-T cell administration. After CAR-T cell treatment, also prednisolone was stopped. Tolerability was assessed by monitoring for Cytokine-release syndrome (CRS), immune-related effector cell neurotoxicity syndrome (ICANS) and infections. Preliminary efficacy was assessed by reaching a Lupus Low Disease Activity State (LLDAS), seroconversion in dsDNA antibodies and ANA and cessation of all SLE-specific treatments
Results: As of January 22, 2022, our 4 SLE patients had been treated with CD19 CAR-T cells with a follow up of 10 months (patient 1, female aged 20, SLEDAI-2K: 16), 7 months (patient 2, male aged 22; SLEDAI-2K:8), 2 months (patient 3, female aged 22; SLEDAI 2K: 6), and 1 month (patient 4; female aged 24; SLEDAI-2K: 6), respectively. All patients had active severe SLE with failure of standard treatment including pulsed steroids, hydroxychloroquine, mycophenolate, cyclophosphamide, intravenous immunoglobulins, rituximab and belimumab before CD19 CAR-T cell administration. All patients had active kidney disease. No infections occurred. All four patients experienced fever without proof of infectious disease (CRS °I); only one patient was treated with a single dose of tocilizumab. No ICANS and no CRS of other organs occurred. In vivo, CAR-T cells rapidly expanded to a maximum of 27,6% (day 9, patient 1), 41,2% (day 9, patient 2), 11,5% (day 9, patient 3) and 59,1% (day 9, patient 4) of total circulating T cells followed by a typical decline, with circulating CAR-T cells being continuously detectable during the next months. Expansion of CAR T cells preceded the complete and sustained depletion of circulating B cells. Patient 1 experienced sustained drug-free remission (SLEDAI-2K=0) with complete loss of ANA and dsDNA antibodies despite reappearance of B cells at 6 months. Patient 2 also experienced complete loss of ANA and dsDNA antibodies with B cells not yet returned. Low-level proteinuria remained most likely due to previously accrued damage in glomerular filter function (SLEDAI-2K: 2). Patient 3 and patient 4 had a shorter observation period to date but also achieved clinical remission (both SLEDAI-2K 0). All patients met LLDAS and could successfully stop all SLE-specific medication, including glucocorticoids. No SLE flare occurred so far.
Conclusion: Taken together, these data show that CD19 CAR T-cell therapy is well tolerated and may induce rapid remission of severe refractory SLE.

Background: Lupus nephritis (LN) is a frequent complication of systemic lupus erythematosus (SLE). Severe (proliferative) forms of LN are treated with an induction immunosuppressive therapy (IST), followed by a maintenance IST, to target remission and avoid relapses. The optimal duration of maintenance IST for proliferative LN is unknown.
Objectives: The WIN-Lupus trial tested whether IST discontinuation after 2-3 years in proliferative LN was non-inferior to IST continuation for 2 more years.
Methods: WIN-Lupus is an investigator-initiated academic randomized controlled trial, conducted in 28 French centers. Patients on maintenance IST with azathioprine or mycophenolate mofetil for a minimum of 2 years and a maximum of 3 years, and who were taking Hydroxychloroquine, were randomized (1:1) between 2 groups: IST continuation and IST discontinuation. The primary endpoint was the relapse rate of proliferative LN at 24 months. Secondary endpoints were the rate of severe SLE flares, survival without renal relapse or severe flare, adverse events, kidney function, disease activity, corticosteroid exposure, patient-reported outcome and medico-economic impact.
Results: Between 2011 and 2016, 125 patients were screened and 96 were randomized in the trial: 48 in the IST continuation group, 48 in the IST discontinuation group. In the per-protocol population, a relapse of proliferative LN occurred in 5/40 (10.4%) patients with IST continuation, and in 12/44 (25%) patients with IST discontinuation (difference 14.8%, 95%CI [-1.9; 31.5]). Non-inferiority was not demonstrated for relapse rate. Time to renal relapse did not differ between groups (p=0.092). Severe SLE flares (renal or extra-renal) were less frequent in patients with IST continuation compared to IST discontinuation (5/40 vs 14/44 patients, p=0.035). IST discontinuation was associated with lower health-related costs. Adverse events did not differ between groups.
Conclusion: Non-inferiority of maintenance IST discontinuation after 2 to 3 years was not demonstrated for renal relapse. IST discontinuation was associated with a higher risk of severe SLE flare.

Background: BEL is approved for active SLE and lupus nephritis (adults only). Despite failed trials,[1] RTX remains in the SLE treatment armamentarium. Sequential BEL and RTX therapy offers a promising strategy to target B cells by distinct but complementary mechanisms.
Objectives: To assess the pharmacodynamic effects of BEL and a single RTX cycle on immunologic biomarkers in adults with SLE.
Methods: In this 104-week (wk) study (NCT03312907), all pts with active SLE received subcutaneous BEL 200 mg/wk for 52 wks. Pts were randomised to receive intravenous (IV) RTX 1000 mg at Wks 4+6 (BEL/RTX), IV PBO at Wks 4+6 (BEL/PBO), or continued treatment with standard therapy (BEL/ST). For BEL/RTX and BEL/PBO pts, a 52-wk treatment-free observational phase followed the 52-wk treatment phase; BEL/ST pts continued to receive BEL for 104 wks. Changes from baseline (BL) in anti-dsDNA and C3/C4 levels, and counts of total B cells ($CD19^+$) and B-cell subsets ($CD20^+$; naïve; memory; activated B-cells), were analysed.
Results: 292 pts received ≥1 study treatment dose (BEL/PBO n=72; BEL/RTX n=144; BEL/ST n=76). For pts assessed at Wk 52, reductions from BL in anti-dsDNA levels were seen in all 3 groups with a significant difference between BEL/RTX and BEL/PBO (p=0.0495). C3/C4 levels increased from BL to Wks 52 and 104 in all groups, with trends for greater increases with BEL/RTX versus BEL/PBO (Table 1). At Wk 52, total B cells and most B-cell subsets decreased in all 3 groups (Table 1), with significant differences between BEL/RTX and BEL/PBO ($p<0.0001$ for all). During the observation period, repopulation of total $CD19^+$ B cells (comprising mostly of naïve $CD20^+CD27^-$) towards BL levels by Wk 104 was most evident with BEL/RTX, while low circulating $CD20^+CD27^+$ memory B cell levels remained relatively unchanged (Table 1).
Conclusion: An improvement in anti-dsDNA and C3/C4 levels was generally observed across all 3 treatment groups with greater reductions in anti-dsDNA antibodies following BEL/RTX versus BEL/PBO and BEL/ST. We believe that BEL induced a pharmacodynamic window for subsequent RTX treatment for a marked reduction in circulating memory B cells and other B-cell subsets. Our findings underscore the need for better understanding of the bridge from pharmacodynamic to clinical outcomes, given that BEL/RTX did not show an improvement in disease control over BEL/PBO.[1]

OP0282

IMPACT OF ANIFROLUMAB ON NEUROPSYCHIATRIC MANIFESTATIONS OF DEPRESSION AND SUICIDALITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Manzi[1], C. Lindholm[2], I. Hupka[3], L. J. Zhang[4], M. Shroff[5], G. Abreu[2], S. Werther[2], R. Tummala[4]. *[1]Allegheny Health Network, Lupus Center of Excellence, Autoimmunity Institute, Pittsburgh, PA, United States of America*; *[2]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*; *[3]AstraZeneca, BioPharmaceuticals R&D, Warsaw, Poland*; *[4]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America*; *[5]AstraZeneca, BioPharmaceuticals R&D, Waltham, MA, United States of America*

Background: Neuropsychiatric (NP) disease is more common in patients with systemic lupus erythematosus (SLE) than in the general population.[1] Increased incidence of NP events (depression and suicidality) has been reported with biologic therapies, including SLE therapies.[2] Depression and suicidality were evaluated in patients with SLE treated with anifrolumab, a type I interferon receptor antibody, in the TULIP-1 and TULIP-2 trials.[3,4]

Objectives: To understand the impact of anifrolumab treatment on NP manifestations (depression and suicidality) in patients with SLE relative to standard therapy using pooled data from the TULIP trials.

Methods: TULIP-1/-2 were randomized, placebo-controlled, 52-week trials of intravenous anifrolumab every 4 weeks in patients with moderate to severe SLE despite standard therapy.[3,4] Patients with active severe or unstable NP SLE were excluded. Patients who received ≥1 dose of anifrolumab 300 mg or placebo were analyzed for depression and suicidality.[3,4] The Personal Health Questionnaire Depression Scale-8 (PHQ-8) and Columbia Suicide Severity Rating Scale (C-SSRS) were used to assess clinical depression and suicidal ideation and behavior, respectively. Incidence of adverse events (AEs) within the standardized Medical Dictionary for Regulatory Activities query of depression (excluding suicide and self-injury) and antidepressant use at baseline and during the study were also assessed.

Results: In the TULIP pooled analysis, 360 patients received anifrolumab and 365 received placebo. Mean PHQ-8 scores were in the mild range (≥5 to <10); 9.7 in both groups at baseline (Table 1). Excluding patients taking antidepressants, mean PHQ-8 scores were 9.5 in the anifrolumab group and 9.7 in the placebo group at baseline. No clinically meaningful worsening in mean PHQ-8 scores was observed from baseline to Week 52 in the anifrolumab (–2.0) or placebo (–1.3) groups; excluding patients taking antidepressants, mean changes in PHQ-8 were –2.0 and –1.2, respectively. Depression AEs during the study were reported in 11 anifrolumab-treated patients (3.1%) and 9 patients who received placebo (2.5%). At baseline, antidepressant use was comparable between groups (anifrolumab group, 7 patients [1.9%]; placebo group, 9 patients [2.5%]). During the study, 8 anifrolumab-treated patients (2.2%) and 12 patients who received placebo (3.3%) used antidepressants; 1 (0.3%) and 4 (1.1%) patients, respectively, initiated antidepressant therapy during the study (1 in the placebo group stopped therapy). Suicidal ideation or behavior, as assessed by C-SSRS, during the study was reported in 5 anifrolumab-treated patients (1.4%) and 11 patients who received placebo (3.0%). Excluding patients taking antidepressants, suicidal ideation or behavior during the study was reported in 4 anifrolumab-treated patients (1.1%) and 9 patients who received placebo (2.5%) (Figure 1).

Conclusion: Patients with SLE treated with anifrolumab did not experience increased depression, suicidality, or need for antidepressants when compared with standard therapy, irrespective of baseline antidepressant use.

OP0283 MYCOPHENOLATE MOFETIL VS CYCLOPHOSPHAMIDE FOR TREATMENT OF LUPUS NEPHRITIS: A SINGLE-CENTER COHORT REAL-WORLD ANALYSIS

X. Zhang[1], H. Huang[1], D. Gao[1], Y. Fan[1], Z. Zhang[1]. [1]*Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China*

Background: Mycophenolate mofetil (MMF) or low-dose intravenous cyclophosphamide (CYC) are recommended as initial (induction) treatment in many recommendations for the management of lupus nephritis (LN), and randomized controlled trials have shown their similar efficacy. However, there is little to no real-world data.
Objectives: We conducted the real-world analysis to compare the efficacy and safety of MMF and CYC for the induction treatment of LN.
Methods: Our patients came from PKUFH SLE cohort, a single-center longitudinal observational cohort set up in 2007, and only patients received initial remission induction therapy for initial or recurrence LN were analyzed. The primary outcome measure was complete renal remission (CR) as defined by (proteinuria <500 mg/24 hours and serum creatinine within 10% from baseline in 12 month. All statistical analyses were performed with SPSS 26.0 and two sides $p < 0.05$ was considered statistically significant.
Results: The 237 LN patients with a median age of 35.0 years had a mean duration of disease of 5.2 years. Of these, 97 patients received CYC, 98 patients received oral MMF, and 42 patients received other immunosuppressive agents or combination therapy. The CR rate in 6-month in MMF was significantly higher than CYC group (CR 57.6% vs 45.2%, p=0.005), and that also applied to 12 month (74.7% vs 56.3%, p=0.001). MMF group patients had lower serum creatinine (76.8±14.5 vs. 93.3±62.9, p=0.012), lower dose glucocorticoid exposure (9.7±3.3vs.11.2±5.6, p<0.05), and lower 24-hour protein level (0.4±0.7 vs. 0.7±1.0, p=0.017) than CYC group. However, MMF did not showed superior to CYC in the LN induced remission (6 month:87.5% vs 73.7%, p=0.064, 12 month:87.7% vs 90.6%, p=0.632) after propensity score matching, just as the Kaplan-Meier analysis showed (Figure 1). Chinese patients usually adopted lower dose MMF (78.8% 1.5g/d,) compared Caucasian populations, and which was also effective.

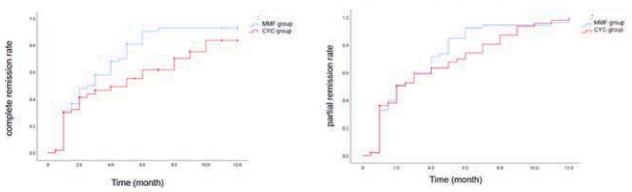

Figure 1. Kaplan-Meier analysis of complete(left) or at least partial remission rate (right)in 12 month after propensity score analysis.

97(47.5%) patients had at least one adverse event, 34% patients had experienced one or more infection. CYC group patients had higher incidence of digestive adverse reactions compared with MMF group (16.3% vs. 2.1%, p<0.001), and no evidence for a statistically significant difference in other aspects. However, patients with CYC induce-therapy are more likely to develop menstrual disturbance (11.2% vs 4.1%) and pneumonia (11.2% vs 3.1%), even failed to reach statistical significance.
No significant difference attributable to ACEIs or ARBs was found in remission rates, SLEDAI, C3 lever and prednisone dose. However, ACEIs/ARBs was benefit to decrease the urine protein (0.2±0.3 vs 0.6±1.0, p=0.031) and may increase the plasma albumin (41.8±3.8 vs 40.6±3.4, p=0.130), thus protect renal function (SCr 74.7±13.4 vs 100.4±82.0, p=0.027). There was no significant difference in remission rate and other parameters, regardless of Hydroxychloroquine (HCQ) or not.
Conclusion: This was the first real-word study to compare the effectiveness and safety of MMF in LN compared with low dose CYC. We found that MMF had similar induced remission rate, with lower gastrointestinal adverse reactions and may less influence on menstruation and less pneumonia, even at relatively low doses. ACEIs/ARBs was benefit to decrease the urine protein and protect renal function.

Gemelli, IRCCS, Rome, Italy*; [5]*Division of Rheumatology, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: Belimumab, the first biological drug approved for the treatment of patients with Systemic Lupus Erythematosus (SLE), is a fully human IgG1λ monoclonal antibody directed against BlyS (B Lymphocyte Stimulator). BLyS inhibition is associated with a reduction in circulating B subsets and short-lived plasmacells
Objectives: The aim of this study was to characterize the B cell phenotype in SLE patients at baseline and after B-cell targeted therapy with Belimumab in a cohort of active SLE patients.
Methods: Fifty-four SLE patients diagnosed according to the 2012 SLICC criteria (49 females, mean age 40.6±13.2 years, disease duration 12.3±9.0 years, SLEDAI-2K 6.6±3.1) who received belimumab were enrolled. Phenotyping of peripheral blood (PB)- derived B lymphocytes (using as phenotypic markers IgD, CD27 and CD38) was performed at six (T6) and twelve (T12) months in 38 SLE patients, together with the expression of BAFF and BAFF- R by flow cytometry.
Results: In the whole SLE cohort, a reduction over time was observed in the percentage of $CD19^{pos}$[T0:11.1±6.1% vs T6:6.4±3.4%,p<0.01;T12:4.2±3.4 %,p<0.01] and naïve B cells ($IgD^{pos}CD27^{neg}$) [T0:55.8±28.7% vs T6:34.9±22 .2%,p<0.01;T12:30.0±19.4%;p=0.04] and an increase of switched memory B cells ($IgD^{neg}CD27^{pos}$)[T0:21.0±20.2% vs T6:37.5±21.4%,p<0.01;T12:42.2±21.% 7,p=0.02] after B-cell targeted therapy with anti-BLyS. Moreover, a reduction of $IgD^{neg}CD27^{neg}$ memory B cells at T6(p=0.01) was observed. Conversely, BAFF and BAFFR expression in peripheral blood-derived $CD19^{pos}$ cells remained unchanged during therapy with anti-BLyS. Stratifying SLE patients based on severe (renal and/or neurological) and mild (articular and/or cutaneous) organ involvement, a significant reduction of $CD19^{pos}$ percentage[T0:10.7±4.6% vs 6:6.8±2.4%,p=0.03;T12:4.5±3.5%,p=0.03] and naïve B cells[T0:61.0±24.6% vs T6:38.9±17.5%,p<0.01;T12:36.9±16.0%,p=0.03] was found in SLE patients with mild organ involvement and a significant increase of switched memory B cell subsets in both subgroups [(severe T0:24.1±25.0% vs T6:44.9±27.4%,p=0.01) (mild T0:18.9±18.3 vs T6:31.2±12.7%,p<0.01)]. Evaluating the B cell subsets regarding the response to treatment (based on the reduction of the SLEDAI-2K), a significant reduction of naïve B cells was observed at T6 in both SLE group,[(responders T0:55.4±29.3 vs T6:32.3±19.9,p<0.01)(no responders T0:63.1±41.3% vs T6:41.4±33.5%,p=0.05)] and switched memory B cells[(responders T0:22.4±21.2% vs T6:39.6±19.4%,p<0.01)(no responders T0:20.6±26.1% vs T6:38.6±35.3%,p<0.05)], with a significant higher percentage at baseline of switched memory B cells in responder SLE than in no-responder SLE group (22.4±21.2% vs 20.6±26.1%,p=0.02). ROC curve analysis of $IgD^{neg}CD27^{pos}$ subset [AUC(95% CIs):0.761:(0.566-0.957)p=0.023] identified a cut-off of 9.94% associated with response at 6 months. Moreover, having a $IgD^{neg}CD27^{pos}$ rate ≥9.94% [OR:4.5(95% CIs:0.9-17.2)]; and the presence of anti-dsDNA antibodies at baseline[OR:5.2(95%CIs:1.2-22.1)], identified SLE patients who achieved early response within 6 months from belimumab therapy initiation.
Conclusion: Anti BLyS therapy significantly impacts on the composition of peripheral blood B-cell subpopulations in SLE patients in relation with the distinct organ involvement. Moreover, baseline immunological features and $IgD^{neg}CD27^{pos}$ B cell subset rate are novel putative biomarkers of response to anti-BLyS therapy in SLE patients.

OP0285

VOCLOSPORIN IS EFFECTIVE IN ACHIEVING PROTEINURIA TREATMENT TARGETS IN LUPUS NEPHRITIS DEFINED BY EULAR/ERA RECOMMENDATIONS

H. J. Anders[1], R. Federico[2], S. Randhawa[2], H. Leher[2]. [1]*Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, München, Germany*; [2]*Aurinia Pharmaceuticals Inc., Medical Affairs, Victoria, Canada*

Background: The novel calcineurin inhibitor voclosporin was approved in 2021 for the treatment of adult patients with active lupus nephritis (LN) in combination with background immunotherapy. Voclosporin has a favorable metabolic profile and a consistent dose-concentration relationship, eliminating the need for therapeutic drug monitoring.
The Phase 2 AURA-LV and Phase 3 AURORA 1 studies demonstrated that the addition of voclosporin to mycophenolate mofetil (MMF) and low-dose steroids led to significantly higher complete renal response rates in AURA-LV at 24 weeks (32.6% vs 19.3%; odds ratio [OR] 2.03; p=0.046) and in AURORA 1 at 52 weeks (40.8% vs 22.5%; OR 2.65; p<0.0001) of treatment in patients with LN.
Objectives: The European League Against Rheumatism and European Renal Association (EULAR/ERA) published updated treatment recommendations for LN with targeted reductions in proteinuria over the course of the first year of therapeutic intervention.[1] Here we report on a post-hoc analysis of pooled data from the similarly designed 48-week AURA-LV and 52-week AURORA 1 studies based on these updated response criteria.
Methods: AURA-LV and AURORA 1 enrolled patients with biopsy-proven active lupus nephritis (Class III, IV, or V ± III/IV) and proteinuria ≥1.5 mg/mg (≥2 mg/mg for Class V). Pooled data included 268 patients in the voclosporin (23.7 mg BID) group and 266 patients in the control group, with all patients receiving MMF (target dose 1 g BID) and low-dose steroids (target dose 2.5 mg/day by week 16 according to protocol-defined steroid taper). We assessed the following EULAR/ERA treatment targets: ≥25% reduction in urine protein creatinine ratio (UPCR) by 3 months, ≥50% reduction in UPCR by 6 months, UPCR ≤0.7 mg/mg by 12 months, and steroid dose ≤7.5 mg/day by 3, 6, and 12 months.
Results: Within the first 3 months of treatment, 78.4% of patients in the voclosporin group and 62.4% of patients in the control group achieved ≥25% reduction in UPCR (odds ratio [OR] 2.25; 95% confidence interval [CI] 1.52, 3.33; p<0.0001). The percentage of patients achieving a reduction of ≥50% in UPCR by 6 months was also significantly greater in the voclosporin group compared to control (66.0% vs 47.0%, respectively; OR 2.24; CI 1.57, 3.21; p<0.0001). After 12 months of treatment, 52.6% and 33.1% of patients receiving voclosporin and control, respectively, had achieved a UPCR ≤0.7 mg/mg (OR 2.52; CI 1.75, 3.63; p<0.0001). Given the protocol-defined steroid taper, at both 3 and 6 months, a similar proportion (>90%) of patients in both groups had achieved the recommended steroid dose, with 89.6% and 82.8% in the voclosporin and control groups, respectively, on the recommended dose at 12 months. The proportion of patients meeting all three UPCR targets during the one-year study period and having a steroid dose ≤7.5 mg/day at 12 months was 37.3% in the voclosporin group and 23.3% in the control group (OR 2.11; CI 1.43, 3.10; p=0.0001).
Conclusion: The addition of voclosporin to a background regimen of MMF and low-dose steroids in patients with LN significantly increased the likelihood of achieving the 3-, 6-, and 12-month UPCR targets of therapy recommended by EULAR/ERA.

Background: Today, there are still no DMARDs licensed for primary Sjögren Syndrome (pSS) patients. Among the explanations, are the limitations of current outcome measures used as primary endpoints: e.g; high placebo response rate, evaluation of either symptoms or systemic activity, and important features not being assessed. The NECESSITY consortium (https://www.necessity-h2020.eu/), including pSS experts from academia, pharmaceutical industry and patient groups formed to develop a new composite responder index, the Sjögren's Tool for Assessing Response (STAR) that solve the issues of current outcome measures in pSS and is intended for use in clinical trials as an efficacy endpoint.
Objectives: To develop a composite responder index in primary Sjögren's syndrome (pSS): the STAR.
Methods: To develop the STAR, the NECESSITY consortium used data-driven methods, based on 9 randomized controlled trials (RCTs), and consensus techniques, involving 78 experts and 20 patients. Based on reanalysis of rituximab trials (TRACTISS and TEARS) and literature review, the Delphi panel identified a core set of domains to include in the STAR, with their respective outcome measures. STAR options combining these domains were designed and proposed to the panel to select and improve them. For each STAR option, sensitivity to change was estimated by the C-index (derived from Effect size) in all 9 RCTs. Delphi rounds were run for selecting STAR among these options. The Delphi panel also voted to classify trials as positive, negative or "in between" in regards to primary but also key secondary endpoints. For the options remaining before the final vote, meta-analyses of the RCTs were performed separately for positive and "in between" trials together, and for negative trials.
Results: The Delphi panel identified 5 core domains (systemic activity, patient symptoms, lachrymal gland function, salivary gland function and biological parameters), and 227 STAR options, combining these domains, were selected to be tested for sensitivity to change. After two Delphi rounds, meta-analyses of the 20 remaining options were performed. The candidate STAR was selected by a final vote based on metrological properties and clinical relevance. In positive/in between trials, candidate STAR detected a difference between arms (OR 3.29, 95%-CI [2.07;5.22], whereas it did not in negative trials (OR 1.53, 95%-CI [0.81;2.91]).
Conclusion: The candidate STAR is a composite responder index, including in a single tool all main disease features, and is designed for use as a primary endpoint

in pSS RCTs. Its rigorous and consensual development process ensures its face and content validity. The candidate STAR showed good sensitivity and specificity to change. The candidate STAR will be prospectively validated in a dedicated three arms RCT of the NECESSITY consortium that will evaluate combination of synthetic DMARDs (hydroxychloroquine + lefunomide or hydroxychloroquine + mycophenolate vs placebo). We encourage the use of STAR in any ongoing and future trials.

Table 1. Candidate STAR

Domain	Point	Definition of response
Systemic activity	3	Decrease of clinESSDAI ≥ 3
Patient reported outcome	3	Decrease of ESSPRI ≥ 1 point or ≥ 15%
Lachrymal gland function	1	Schirmer: If abnormal score at baseline: increase ≥ 5 mm from baseline If normal score at baseline: no change to abnormal ***Or*** Ocular Staining Score: If abnormal score at baseline: decrease ≥ 2 points from baseline If normal score at baseline: no change to abnormal
Salivary gland function	1	Unstimulated Whole Salivary Flow: If score > 0 at baseline: increase ≥ 25% from baseline If score is 0 at baseline: any increase from baseline ***or*** Ultrasound: Decrease ≥ 25% in total Hocevar score from baseline
Biological	1	Serum IgG levels: decrease ≥ 10% ***or*** Rheumatoid Factor levels: decrease ≥ 25%
Candidate STAR responder		**≥ 5 points**

The early bird gets the worm

OP0287 **LONGITUDINAL ASSESSMENT OF THE ULTRASOUND GOUT LESIONS USING THE VALIDATED OMERACT SEMI-QUANTITATIVE SCORING SYSTEM**

S. N. Christiansen[1], M. Østergaard[1,2], O. Slot[1], V. Fana[1], L. Terslev[1,2].
[1]Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopedics, Glostrup, Denmark; *[2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*

Background: In gout, ultrasound (US) is a promising tool to detect changes in monosodium urate (MSU) depositions during urate-lowering therapy (ULT). The OMERACT US group has developed definitions of gout-specific US lesions[1] and a semi-quantitative scoring system for US lesions representing MSU deposition (tophus, double contour (DC) and aggregates)[2], but the responsiveness of lesions when applying this scoring system has not yet been assessed.
Objectives: The primary aim was to evaluate the responsiveness of gout-specific US lesions in patients receiving treat-to-target ULT using both a binary (present/absent) and the OMERACT-defined semi-quantitative (0-3) scoring system. The secondary aims were to determine the most responsive US measure for MSU deposition at patient level and the optimal joint/tendon set for monitoring lesions.
Methods: US (28 joints, 14 tendons) was performed in microscopically verified gout patients initiating/increasing ULT and repeated after 6 and 12 months. Static images and videos of pathologies were stored. Tophus, DC and aggregates were scored binarily and semi-quantitatively. Individual lesion-scores were calculated at patient level as were combined crystal sum scores. Standardised response means (SRM) for lesions when scored binarily and semi-quantitatively were calculated at patient and joint/tendon level.
Results: Sixty-three patients were followed for 12 months. Plasma urate levels were effectively lowered during follow-up (Table 1). US showed statistically significant decreases in tophus and DC sum scores, both when scored binarily and

Table 1. Course and SRMs of US scores during 12 months' follow-up

	Baseline		6-months' follow-up		12-months' follow-up		P-value*			SRM

US, ultrasound; SQ, semi-quantitative; SRM, standardised response mean; DC, double contour; TD-sum score, tophus+DC sum score, TDA-sum score, tophus+DC+aggregates sum score. * Wilcoxon signed rank test, statistically significant results are indicated by bold-face type.

semi-quantitatively, whereas aggregates were almost unchanged during follow-up (Table 1). SRMs for the semi-quantitative tophus and DC sum scores were markedly higher than those for the binary. The most responsive measure for urate deposition at patient level was a combined semi-quantitative tophus-DC-sum score (SRM 0.92, Table 1). A reduced joint/tendon set for monitoring included knee and 1st–2nd metatarsophalangeal joints and peroneus and distal patella tendons representing the most prevalent and responsive sites (SRM 1.13, Figure 1).

Conclusion: The OMERACT consensus-based semi-quantitative US gout scoring system showed longitudinal validity with both tophus and DC being highly responsive to treatment. A responsive US measure for urate deposition and a feasible joint/tendon set for monitoring are proposed.

Background: The ultrasonographic (US) Halo Score provide a quantitative measure of the extent of vascular inflammation in patients with giant cell arteritis (GCA). High Halo Scores correlate with systemic markers of inflammation, rate of ocular ischaemia and may help to firmly diagnose GCA with high specificity. However, an increase in the intima media thickness (IMT) in patients with elevated cardiovascular risk (CVR) may lead to false-positive US findings.

Objectives: Our aim is to evaluate the impact of CVR on the diagnostic accuracy of the US Halo Score in patients with suspected GCA.

Methods: This is a retrospective observational study of patients suspected of having GCA and referred to our US fast track clinic. All patients underwent US exam within 24 hours per protocol. The IMT was measured in gray scale mode in cranial and extra-cranial (carotid, subclavian and axillary) arteries and the Halo Score was also determined to assess the extent of vascular inflammation. GCA diagnosis was confirmed after 6-month follow-up by the referring clinician. The European Society of Cardiology (ESC) Guidelines on CV Disease Prevention in clinical practice were used to define different categories of CVR. Patients were classified as very high, high, moderate or low CVR according to the Systemic Coronary Risk Evaluation (SCORE) obtained using the ESC CVD Risk Calculator app for mobile devices. Comparison between groups was performed and the diagnostic accuracy of the Halo Score in patients according to CVR was evaluated using ROC curves.

Results: Of the 157 patients referred to our US fast track clinic (67.5% female, mean age 73.7 years), 47(29.9%) had GCA confirmed after 6-month follow-up. There were no differences in CVR between patients with and without GCA (mean SCORE 20.6[21.6] vs 18.7[21];p=0.601). Among patients without GCA, extra-cranial artery IMT was significantly higher in patients with high/very high CVR than in those with low/moderate CVR (Table 1). The Halo Score was significantly higher in patients with high/very high CVR in non-GCA patients (9.38 (5.93) vs 6.16 (5.22);p=0.007). The area under the ROC curve of the Halo Score to identify GCA was 0.835 (CI95% 0.756-0.914), slightly greater in patients with low/moderate CVR (0.965 [CI95% 0.911-1]) versus patients with high/very high CVR (0.798[CI95% 0.702-0.895]) (Figure 1). A statistically weak positive correlation was found between the Halo Score and the SCORE (r 0.245;p=0.002).

Table 1. Measurements of IMT in cranial and extracranial arteries and Halo Score values according to CVR

	Patients with GCA n=47			Patients without GCA n=110		
Artery IMT mm, mean (SD)	Patients with high/very high CVR n=37(78.7%)	Patients with low/moderate CVR n=10(21.3%)	p	Patients with high/very high CVR n=79(71.8%)	Patients with low/moderate CVR n=31(28.2%)	p
Superficial temporal artery (both)	0.66(0.25)	0.45(0.11)	0.025	0.35(0.09)	0.32(0.07)	0.354
Frontal branch (both)	0.42(0.18)	0.31(0.15)	0.056	0.26(0.05)	0.26(0.06)	0.577
Parietal branch (both)	0.43(0.17)	0.35(0.12)	0.102	0.27(0.04)	0.28(0.08)	0.173
Carotid artery (both)	0.88(0.21)	1.2(0.6)	<0.001	0.83(0.16)	0.74(0.13)	<0.001
Subclavian artery (both)	0.86(0.31)	1.2(0.5)	0.001	0.74(0.18)	0.6(0.13)	<0.001
Axillary artery (both)	0.92(0.38)	1.22(0.73)	0.021	0.72(0.16)	0.59(0.15)	<0.001
Halo Score, mean (SD)	18.5(8.8)	17.2(10.6)	0.69	9.38(5.93)	6.16(5.22)	0.007

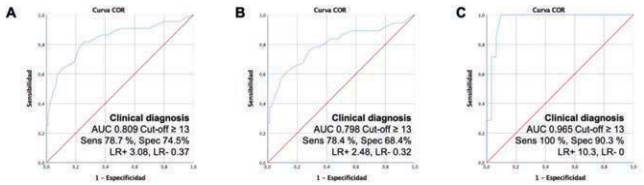

Figure 1. Diagnostic accuracy of the Halo Score for a clinical diagnosis of GCA after 6-month follow-up in (A) all GCA suspected patients, (B) patients with high/very high CVR and (C) patients with low/moderate CVR

Conclusion: High CVR may influence the diagnostic accuracy of the US Halo Score leading to false-positive findings in these patients. Higher IMT values may be found in extracranial arteries of subjects with high/very high CVR without GCA. Thus, CVR should be taken into consideration in the US vascular assessment of patients with suspected GCA. These results need to be confirmed in larger cohorts to develop a modified US Halo Score applicable to patients with high CVR.

OP0289 SHORT- AND LONG-TERM EFFICACY OF ULTRASOUND-GUIDED NEEDLE FRAGMENTATION OR LAVAGE (BARBOTAGE) IN SYMPTOMATIC SHOULDER CALCIFIC TENDONITIS REFRACTORY TO SUBACROMIAL STEROID INJECTION. PROSPECTIVE LONGITUDINAL STUDY OF 181 PATIENTS.

E. Casado[1], S. Garcia-Cirera[1], S. Retamozo[1], M. Rusiñol[1], E. Costa Moya[1], L. Lluís[1], J. Calvet[1], J. Gratacos-Masmitja[1]. *[1]University Hospital Parc Taulí, I3PT Research Institute, Rheumatology, Sabadell, Spain*

Background: Rotator cuff calcific tendinopathy is a common cause of shoulder pain and disability in young patients. Despite analgesics or steroid injection some patients still experience symptoms and may require surgery. Ultrasound-guided fragmentation or lavage are minimally invasive techniques that can be used instead of surgery to remove calcification and improve symptoms. However, evidence is poor because of most of published studies are retrospective or with few patients.

Objectives: To assess the short and long-term efficacy of ultrasound guided needle fragmentation or lavage (barbotage) in a large cohort of patients with symptomatic shoulder calcific tendonitis refractory to previous subacromial steroid injection.

Methods: Prospective study, including all consecutive patients referred to a Rheumatology out-patient clinic between Jul 2008-Dec 2020 because of symptomatic (visual analog scale or VAS≥4) calcific tendonitis of the rotator cuff refractory to at least one subacromial corticosteroid injection. After informed consent, all patients were treated with minimally invasive ultrasound-guided technique: fragmentation between Jul 2008-Dec 2013 or lavage (barbotage) between Jan 2014-Dec 2020. Corticoids were injected in the subacromial-subdeltoid bursa in all patients after procedure. Shoulder pain (VAS) and shoulder X-ray were assessed at baseline and after 4 months since the intervention. A new clinical assessment was made after 12 months or when clinical relapse occurred.

Results: One hundred and eighty-one subjects (56 men and 125 women), were included in the study. Mean age was 49.7 years (range 29 -72). Mean duration of symptoms was 33.0 months (2-150), with mean VAS 7.6±1.5. Right shoulder was the location most frequently affected (66,3%). Mean size of calcification by X-ray was 13.7 mm (5-40). 55 patients (30.4%) underwent fragmentation, 115 (63.5%) lavage and 11 (6.1%) both techniques. There were not significant differences between groups at baseline. 4 months after procedure, mean VAS pain was 4.5±3.8 and 82.9% of subjects experienced a X-ray resolution (56.8%) or size reduction (26.1%) of the calcification. A clinical relapse occurred in 73 patients (40.3%) in the first 4 months of follow up, and in 33 patients (18.2%) between months 4 and 12. Symptoms disappeared in most of patients with a new steroid injection. Only 31 patients (17.1%) required a second fragmentation or lavage, and 13 patients (7.2%) a rotator cuff surgery. Any patient suffered local or systemic complications after fragmentation or lavage. Patients treated with lavage had higher shoulder pain when clinical relapse (mean VAS 6.5 vs 4.0; p=0.01) and needed more frequently a new steroid injection (54.8% vs 34%; p=0.004) or ultrasound guided-procedure (17.5% vs 13.1%; p=0.008). There were no significant differences between both techniques in the radiographic resolution or size decrease of the calcification.

Conclusion: Ultrasound guided needle fragmentation and lavage (barbotage) are effective and safe at short and long-term to treat patients with symptomatic shoulder calcific tendonitis, avoiding surgery in more than 90% of cases. Fragmentation seems to have better clinical outcomes than lavage.

OP0290 WHICH INFLAMED TISSUES EXPLAIN A POSITIVE SQUEEZE TEST OF THE METATARSOPHALANGEAL JOINTS? A LARGE IMAGING STUDY TO INCREASE UNDERSTANDING OF A COMMONLY PERFORMED DIAGNOSTIC PROCEDURE

B. van Dijk[1], Y. Dakkak[1], D. Krijbolder[1], J. van Zeben[2], I. Tchetverikov[3], M. Reijnierse[4], A. van der Helm-van Mil[1,5]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Franciscus Gasthuis & Vlietland, Rheumatology, Rotterdam, Netherlands*; *[3]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; *[4]Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands*; *[5]Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: The squeeze test of metatarsophalangeal (MTP-)joints is frequently used, because it is easy and cheap, and is traditionally perceived as a test for synovitis. Besides classic intra-articular synovitis also tenosynovitis and intermetatarsal bursitis (IMB) represent synovial inflammation, albeit juxta-articularly located. Both are frequently present in RA and occasionally in other arthritides. However, the contribution of IMB to MTP squeeze test positivity is unknown and the contribution of tenosynovitis has only been partially studied.

Objectives: To assess whether tenosynovitis and IMB contribute to a positive MTP squeeze test.

Methods: 192 early arthritis patients and 693 CSA-patients underwent the MTP squeeze test and forefoot MRI at first presentation. MRI measurements in age-matched healthy controls were used to define positivity for synovitis, tenosynovitis and IMB. Logistic regression was used; multivariable models adjusted for sex and simultaneous presence of inflammation features.

Results: In early arthritis patients synovitis (OR 4.8 (95%CI 2.5–9.5)), tenosynovitis (2.4 (1.2–4.7)) and IMB (1.7 (1.2–2.6)) associated with positivity of the MTP squeeze test. Synovitis (3.2 (1.4–7.2)) and IMB (3.9 (1.7–8.8)) remained associated in multivariable analyses. Of patients with a positive MTP squeeze test, 79% had synovitis or IMB: 12% synovitis, 15% IMB and 52% both synovitis and IMB. In CSA-patients, subclinical synovitis (3.0 (2.0–4.7)), tenosynovitis (2.7 (1.6–4.6)) and IMB (1.7 (1.2–2.6)) associated with MTP squeeze test positivity. In multivariable analyses, synovitis remained independently associated (2.5 (1.5-4.1)) whilst tenosynovitis (1.5 (0.8-2.9)) and IMB did not (1.2 (0.8-1.8)). Of patients with a positive MTP squeeze test, 39% had synovitis or IMB: 10% synovitis, 15% IMB and 13% both synovitis and IMB.

Conclusion: Besides synovitis, also IMB contributes to pain upon compression in early arthritis, presumably due to its location between MTP joints. This is the first evidence showing that a positive MTP squeeze test positivity is not only explained by intra- but also juxta-articular inflammation.

Background: Structural damage in rheumatoid arthritis (RA) includes bone erosion, cartilage change, and joint malalignment; historically evaluated with conventional radiography. Ultrasound (US) has been shown to be a valid tool for evaluating both cartilage change and bone erosion.
Objectives: To obtain agreement on definitions and develop semiquantitative scoring systems for assessing structural damage by US and to validate these in a web-based reliability exercise.
Methods: A Delphi survey of statements was prepared by an OMERACT US Working Group task force (USWG) based on a previously published systematic literature review (1) and circulated between group members, including definitions on normal US appearance of joint components, definitions of elementary lesions and scoring systems for bone erosions and joint malalignment. Definitions and a US scoring system for scoring cartilage change were recently developed and validated by the USWG (2) After agreement was achieved (≥75% of grades 4-5 on 1-5 Likert scale) on the statements, still images of metacarpophalangeal and proximal interphalangeal joints 2-5 in healthy controls and in RA patients with varying degrees of pathology were acquired by the USWG members. A dataset of 100 anonymized images, representing various grades of the 3 components of structural damage was created and utilized in 2 rounds of a web-based exercise. Intra- and inter-reader reliability of the scoring systems was assessed by kappa statistics.
Results: 19 USWG members needed 4 Delphi rounds to reach agreement on a total of 9 statements. 4/12 statements were approved in the first, 2/6 in the second, 1/5 in the third and 2/2 in the fourth round. Final scoring systems and representative images are shown in Table 1 & Figure 1. 22 members participated in the web-based reliability exercise. The intra-reader reliability was almost perfect for bone erosion (kappa: 0.87) and cartilage change (kappa: 0.83) and substantial for malalignment (kappa of 0.72). The inter-reader reliability was almost perfect for bone erosion (kappa: 0.85), and substantial for cartilage change (kappa: 0.79) and malalignment (0.62).

Table 1. Final definitions of scoring systems of elementary lesions of structural damage in rheumatoid arthritis

		Agreement
Bone erosion	A 4-grade semiquantitative scoring system can be used to score erosions as follows: grade 0. intact cortical bone; grade 1. single small erosion (diameter: ≤2mm); grade 2. single large erosion (diameter: >2mm) or 2 small erosions; grade 3. 2 large erosions or ≥3 erosions, regardless of size. Both longitudinal and transverse scans should be considered, and the largest measure chosen for each erosion.	100%
Cartilage change	A 3-grade semiquantitative scoring system can be used to grade hyaline cartilage change as follows: grade 0. normal cartilage; grade 1. minimal change: focal thinning or incomplete loss of cartilage; grade 2. severe change: diffuse thinning or complete loss of cartilage.	80% (2)
Malalignment	A 3-grade semiquantitative scoring system can be used to grade malalignment as follows: 0. normal alignment; 1. subluxation or partial dislocation, where the two bone endings are malaligned so that one bone ending is dislocated from its normal position, but still within the articulation; 2. luxation or total dislocation, where the luxated bone ending moves beyond the articulation and the opposing bone ending. Bone position may be compared with a contralateral or similar intact joint if available.	94%

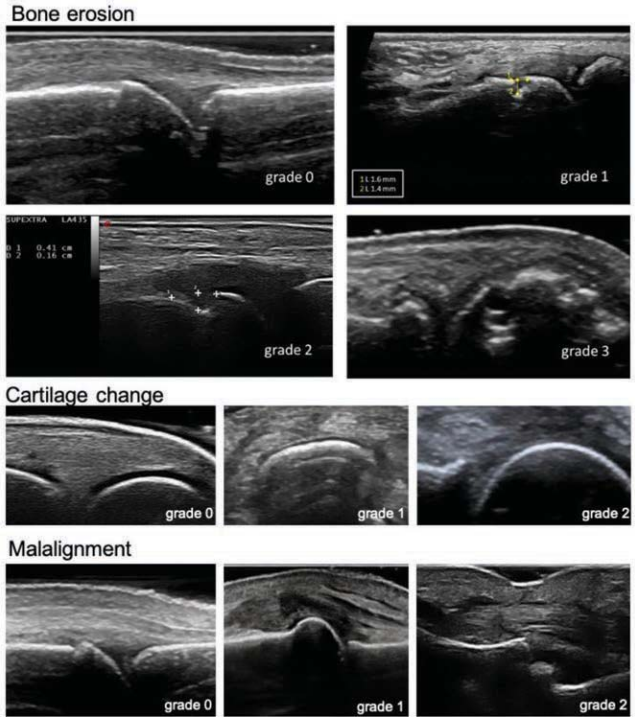

Figure 1. Representative images of the scoring systems for bone erosion (A), cartilage change (B) and malalignment (C)

Conclusion: This first attempt to create a composite US instrument based on scoring systems encompassing all aspects of structural damage, demonstrates that US is a reliable tool for evaluating and scoring bone erosion, cartilage change and malalignment in the finger joints of RA patients.

OP0292 CLASSIFICATION OF PSORIATIC ARTHRITIS, SERONEGATIVE RHEUMATOID ARTHRITIS, AND SEROPOSITIVE RHEUMATOID ARTHRITIS USING DEEP LEARNING ON MAGNETIC RESONANCE IMAGING

L. Folle[1], S. Bayat[2], A. Kleyer[2], F. Fagni[2], L. Kapsner[3], M. Schlereth[4], T. Meinderink[2], K. Breininger[4], K. Tascilar[2], G. Krönke[2], M. Uder[3], M. Sticherling[5], S. Bickelhaupt[3], G. Schett[2], A. Maier[1], F. Roemer[3], D. Simon[2].
[1]University of Erlangen-Nuremberg, Computer Science, Erlangen, Germany; *[2]University Clinic Erlangen, Rheumatology, Erlangen, Germany*; *[3]University Hospital Erlangen, Radiology, Erlangen, Germany*; *[4]University of Erlangen-Nuremberg, Artificial Intelligence in Biomedical Engineering, Erlangen, Germany*; *[5]University Clinic Erlangen, Dermatology, Erlangen, Germany*

Background: While MRI evaluation of joints has been primarily used to quantify inflammation at a cross-sectional and longitudinal level, less is known about the potential of MRI in distinguishing different patterns of inflammation in the various forms of arthritis.
Objectives: To evaluate (i) whether deep learning using neural networks can be trained to distinguish between seropositive rheumatoid arthritis (RA+), seronegative RA (RA-), and psoriatic arthritis (PsA) based on structural inflammatory patterns on hand magnetic resonance imaging and (ii) to assess if psoriasis patients with subclinical inflammation fit into such patterns.
Methods: ResNet 3D [1] neural networks were trained to distinguish (i) RA+ vs. PsA, (ii) RA- vs. PsA and (iii) RA+ vs. RA- with respect to hand MRI data. Diagnosis of patients was determined using the following guidelines: ACR/EULAR 2010 [2] for RA and CASPAR [3] for PsA. Results from T1 coronal, T2 coronal, T1 coronal and axial fat suppressed contrast-enhanced (CE) and T2 fat suppressed axial sequences were used. The performance of such trained networks was analyzed by the area-under-the-receiver-operating-characteristic curve (AUROC) with and without imputation of demographic and clinical parameters (Figure 1A). Additionally, the trained networks were applied to psoriasis patients without clinical signs of PsA.

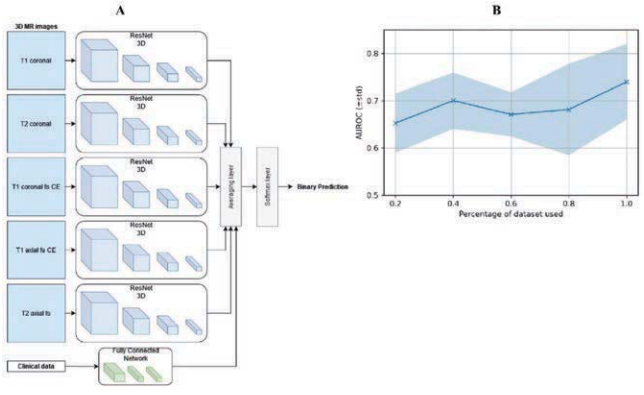

Figure 1. (A) Neural network combining MR sequences with optional additional clinical data. The prediction for a single case is formed by averaging the prediction of all sequences and the clinical data. (B) Plot of the AUROC for increasing percentages (0.6 – 60%) of training data for the differentiation between RA+ and PsA by the neural network. The light blue area around the dark blue mean indicates the uncertainty measured using a 5-fold cross-validation.

Results: MRI scans from 649 patients (135 RA-, 190 RA+, 177 PsA, 147 psoriasis) were included (Table 1). The AUROC for differentiation between disease entities was 75% (SD 3%) for RA+ vs. PsA, 74% (SD 8%) for RA- vs. PsA, and 67% (6%) for RA+ vs. RA-. All MRI sequences were relevant for classification, however, when deleting CE sequences, the loss of performance was only marginal. The addition of patient-specific data to the networks did not provide significant improvements. Increasing amounts of training data demonstrated improved performance of the networks (Figure 1B). Psoriasis patients were mostly assigned to PsA by the neural networks, suggesting that PsA-like MRI pattern may be present early in the course of psoriatic disease.

Table 1. Overview of demographic and clinical information.

		RA+	RA-	PsA	Psoriasis
Total Number (N)		649			
Number (N)		190	135	177	147
Age (years), mean±SD		56.9±12.6	60.5±10.3	56.3±12.0	49.6±13.8
Sex (female/male)		126/64	93/42	92/85	71/76
BMI (kg/m^2), mean±SD		26.6±10.5	27.6 ±9.3	29.1±11.3	26.7±6.9
Disease duration (years), mean±SD		2.6±4.9	1.3±2.3	0.8±2.3	4.2±5.1
DAS28, mean±SD		3.3±1.3	3.4±1.2	3.2±1.3	-
CRP (mg/L), mean±SD		0.9±2.5	0.7±1.2	0.5±0.8	0.5±1.3
HAQ, mean±SD		0.8±0.6	0.9±0.8	0.6±0.6	0.3±0.4
Medication	bDMARD	88.46%	83.87%	81.32%	35.01%
	csDMARD	89.52%	88.89%	80.54%	12.28%

Conclusion: Deep learning can be successfully applied to differentiate MRI inflammatory patterns related to RA+, RA-, and PsA. Early changes in psoriasis patients can be recognized by neural networks and are characterized by a pattern that allowed the networks to classify them as PsA.

Background: Treatment success of a rheumatic disease crucially depends on whether a patient is sufficiently informed about the disease[1]. Visual methods are suitable for explaining diseases[2]. Cinematic rendering (CR) is a new method that allows to segment standard medical images into images that illustrate disease pathologies in a photorealistic way. As such, CR provides new opportunities to visualize diseases and but could therefore be a valuable tool for patients with rheumatic and musculoskeletal disease (RMD).[3]

Objectives: We questioned, if it is possible to apply CR on images from structural lesions of patients with rheumatoid arthritis (RA), Psoriatic Arthritis (PsA) and axial Spondyloarthritis (axSpA) and to test whether such images are helpful to patients with RMDs to understand their disease process. application in doctor-patient communication.

Methods: We selected conventional computed tomography (CT) and high-resolution peripheral CT (HR-pQCT) from patients with rheumatoid arthritis (RA), Psoriatic Arthritis (PsA) and axial Spondyloarthritis (axSpA) that showed typical changes of the respective disease. HR-pQCT measurements were performed in RA and PsA at the Rheumatology Department. CT Measurements of the spine in an axSpA patient was provided from AH. All images were segmented to CR images using a prototype software by the manufacturer Siemens Healthineers. In a prospective study on consecutive patients with RA, PsA, axSpA these images were used to explain the depicted pathognomonic pathologies and compared to conventional imaging in a structured doctor-patient interview. In the last step, patients filled in a quantitative questionnaire (Likert Scale 1-5) about their perspectives answering following questions: Did you understand your disease in the provided Cinematic Rendering images? Did you understand your disease better through the presentation using Cinematic Rendering images than with a normal X-ray image? Do you think it would be reasonable to use this type of Cinematic Rendering to improve patients' understanding of their disease? Descriptive statistical methods were used.

Results: CR images of rheumatic diseases were successfully generated from above mentioned imaging data (CT, HR-pQCT). Bone erosions, osteophytes, enthesiophytes, osteoporosis and ankylosis of the spine could be visualized in photorealistic detail. Figure 1 shows examples of a images of a patient with RA and axSpA with typical bone changes.

65 patients (23 RA/23 PsA/19 axSpA; f 55%) were guided through CR images of their respective disease by an experienced rheumatologist, followed by completing the questionnaire mentioned above. Patients stated that CR was very helpful to understand their disease process (4.39±0.15), that understanding diseases by CR was better than the one obtained by conventional radiographs (4.43±0.20) and that they considered such technology helpful for improving disease understanding (4.35±0.09).

Conclusion: CR seems to be a promising teaching tool for RMD patients facilitating an improved understanding of their disease process and in consequence my also improve adherence of RMD patients to their anti-rheumatic treatment.

Figure 1 shows examples of Cinematic Rendering images from patients with rheumatoid arthritis (a/b) and axial Spondyloarthritis (c). Figure 1a shows erosions and deterioration of bone microarchitecture in MCP joints HR-pQCT. Figure 1b illustrates an os carpale with ankylosis and deformation of all carpal bones as well as the pronounced peripheral demineralization. Figure 1c shows an ankylosed spine of an axSpA patient. CR impressively visualizes the ubiquitous ankylosing process and formation of syndesmophytes.

Background: The combined use of B-mode ultrasound (US) and Power Doppler (PD; combination termed as PDUS) allows visualisation of morphological and pathophysiological changes of the synovium. ULTIMATE (NCT02662985) was the first large, randomised, double-blind, placebo-controlled PDUS phase IIIb study in psoriatic arthritis (PsA), to demonstrate that Global OMERACT EULAR Synovitis Score (GLOESS), a US score at patient level, was sensitive to detect the early and continuous decrease in synovitis in a multicenter setting using different US devices and examiners.[1] However, the US assessment for GLOESS was time-consuming owing to the number of joints assessed.

Objectives: To investigate the value of various reduced joint sets to predict the validated GLOESS score.

Methods: ULTIMATE was a 52-week study with a 12-week double-blind, placebo-controlled period followed by 12-week open-label (OL) treatment and 6-month OL extension period.[1] In the ULTIMATE trial, GLOESS for the 24 paired joints was calculated, with a potential score ranging between 0 to 144.[1] A Spearman's rank correlation matrix and a Cluster Image Map were constructed to identify highly correlated joint clusters based on the composite PDUS scores. Based on the different approaches (best correlation, model optimization, etc.), representative joints were then selected from each group, which yielded several corresponding combinations of joints. Linear models were developed with these reduced joint sets as predictors of GLOESS, using data from 60% of patients randomly selected from the

ULTIMATE study. The remaining 40% data were used for model validation and diagnostics.

Results: Five models were established with reduced pairs of joint sets (9–13 pairs). The joints included in each linear model are summarized in Table 1. All five models of reduced joint sets showed high correlation with GLOESS score of R^2 ~ 0.95. Figure 1 depicts all the 5 models of reduced joint sets for PDUS-detected synovitis versus the actual GLOESS in secukinumab and placebo-secukinumab groups, with modified GLOESS scores using reduced PDUS joint sets demonstrating changes very close to that of validated GLOESS.

Table 1. Joints included across five linear models, indicated by green shading

Table 1. Primary and key secondary outcomes at week 7 and week 26, and differences between treatment groups (based on the ITT population)

	CBT-I n=31	Usual care n=31	Difference between groups (95% CI)	P-value
At week 7				
Sleep efficiency (PSG, %)[1]	88.7 (1.8)	83.7 (2.0)	5.0 (-0.4 to 10.4)	0.068
At week 26				
Sleep efficiency (PSG, %)	84.8 (1.9)	86.3 (2.0)	-1.5 (-7.0 to 3.9)	0.577
Total sleep time (PSG, minutes)	376.5 (11.8)	394.6 (12.8)	-18.1 (-52.5 to 16.4)	0.302
Sleep onset latency (PSG, minutes)	14.2 (2.2)	10.0 (2.4)	4.2 (-2.2 to 10.7)	0.197
Wake after sleep onset (PSG, minutes)	52.1 (10.7)	41.5 (11.6)	10.6 (-20.7 to 41.9)	0.505
Insomnia severity (ISI 0-28)[2]	7.6 (0.7)	17.4 (0.7)	-9.8 (-11.8 to -7.9)	<0.0001
Sleep quality global (PSQI 0-21)[3]	5.9 (0.5)	11.1 (0.5)	-5.2 (-6.6 to -3.8)	<0.0001
Fatigue (BRAF-MDQ 0-70)[4]	24.0 (1.4)	36.4 (1.5)	-12.4 (-16.5 to -8.4)	<0.0001
RA impact of disease (RAID 0-10)[5]	4.2 (0.20)	5.5 (0.20)	-1.4 (-1.9 to -0.80)	<0.0001
Depressive symptoms (HADS-D 0-21)[6]	3.8 (0.5)	6.5 (0.5)	-2.7 (-4.1 to -1.3)	<0.0001

Values are reported as least squares means (standard errors) by group, while the differences between groups are reported with 95% confidence intervals.[1]Polysomnography, [2]Insomnia Severity Index, [3]Pittsburgh Sleep Quality Index, [4]Bristol Rheumatoid Arthritis Fatigue - Multidimensional Questionnaire, [5]Rheumatoid Arthritis Impact of Disease, [6]Hospital Anxiety and Depression Scale - Depression.

University Hospital, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Glostrup, Denmark; [7]*Mental Health Centre Glostrup, University of Copenhagen, Glostrup, Denmark*; [8]*University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense, Denmark*

Background: Insomnia is highly prevalent in patients with rheumatoid arthritis (RA) and may exacerbate symptoms and burdens, such as fatigue, depressive symptoms, and pain[1]. Cognitive behavioural therapy for insomnia (CBT-I) has been shown to produce positive effects on sleep in other clinical populations[2,3]. However, CBT-I has not previously been investigated in patients with RA.
Objectives: The primary objective was to compare the effect of nurse-led group-based CBT-I to usual care on sleep efficiency, measured by polysomnography (PSG) immediately after the intervention (i.e. seven weeks after baseline) in patients with RA. Secondary objectives included comparing the longer-term effect of CBT-I on sleep and RA-related outcomes at 26 weeks' follow-up.
Methods: In a randomised controlled trial, using a parallel group design, the experimental intervention was six weeks' CBT-I; the control comparator was usual care. CBT-I was delivered face-to-face by a CBT-I trained nurse. The primary analyses were based on the intention-to-treat (ITT) population; missing data were statistically handled using repeated-measures linear mixed effects models adjusted for the level at baseline.
Results: The ITT population consisted of 62 patients (89% women), with an average age of 58 years (SD 10), DAS28-CRP of 3.4 (SD 1.0), Insomnia Severity Index (ISI) score of 18.9 (SD 4.4) and median Patient Global Assessment score of 55 (IQR 28;71).
When primary outcome was measured by PSG at week seven, sleep efficiency was 88.7% in the CBT-I group, compared to 83.7% in the control group (difference: 5.0 [95% CI -0.4 to 10.4]; p=0.068) (See Table 1). Secondary outcomes measured by PSG had not improved at week 26 either. However, for all secondary sleep and RA-related patient-reported outcomes, there were statistically highly significant differences between CBT-I and usual care e.g. insomnia (ISI: -9.8 [95% CI -11.8 to -7.9]), RA impact of disease (RAID: -1.4 [95% CI-1.9 to -0.80]) and Patient Global Assessment (-13.0 [95% CI -20.9 to -5.1]) at 26 weeks' follow-up.
Conclusion: Nurse-led, group-based CBT-I for two hours per week for six weeks, did not improve objectively measured sleep efficiency or any other outcomes measured by PSG. However, CBT-I showed long-term improvement on patient-reported outcomes such as fatigue, impact of disease, depression, pain, and Patient Global Assessment – a finding that could have important clinical implications.

Complexity of care in RMD: intersection between health and social care

OP0296-HPR HEALTH AND SOCIAL CARE PROFESSIONALS' WORK TO ACHIEVE COHERENT REHABILITATION PATHWAYS FOR PEOPLE WITH INFLAMMATORY ARTHRITIS - A QUALITATIVE INTERVIEW AND OBSERVATIONAL STUDY

H. Feddersen[1,2,3], J. Soendergaard[4], B. M. Schmidt[2], L. Andersen[2], J. Primdahl[2,3,5]. [1]*University College South, Department of Health Education, Aabenraa, Denmark*; [2]*University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*; [3]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; [4]*University Hospital of Southern Denmark, Department of Public Health, Odense, Denmark*; [5]*University Hospital of Southern Denmark, Sygehus Sønderjylland, Aabenraa, Denmark*

Background: 20-40% of people with inflammatory arthritis (IA) do not tolerate or do not have sufficient effect of their medication and experience substantial impact of their disease. They need rehabilitation to develop or restore functioning and become able to live an independent and meaningful life (1). Rehabilitation and the organisation of health and social care services are characterised by a high degree of complexity and many different professionals working across different departments, primary and secondary sectors.
Objectives: To investigate how health and social care professionals across different departments, levels and sectors work to achieve coherent rehabilitation pathways for people with IA.
Methods: In total, 26 professionals across primary and secondary health and social care participated in semi-structured interviews. These professionals were all pointed out by people with IA because they had made a significant difference to achieve coherent rehabilitation pathways for them. In addition, participant observations and informal interviews with the healthcare professionals were conducted during the rehabilitation stay. Formula stories (2) and institutional ethnography (3) guided the interpretation of data. In the findings, the term people is changed to users to underline their interactions with the professionals.
Results: The analysis derived three themes:
1) Interactions with users: the professional's interactions with users were predominantly characterized by the ideal of focusing on the individual human being with respect for individual's norms, values and wishes. However, this ideal was challenged when their professional knowledge contradicted the user's norms, values and wishes.
2) Dependent interactions between professionals: expresses dependency of collaboration between professionals both internally within the same department or organization but also across organizations and sectors. Dependency on information about the user to carry out examinations, deliver care or treatment or dependency on referrals to legitimize the efforts the professionals considered necessary for the user.
3) The significance of organisation within institutional frameworks for the professionals' work: the professionals experienced that they were not always able to meet the users demand for care due to organizational requirements for efficiency, economic cost reductions and documentation. These issues led to lack of time to prepare, implement, and follow up on communication with users and other professional partners.
Conclusion: The professionals want to meet the individual with a person-centred approach but sometimes they find it difficult to combine this with their own professional knowledge and values. The professionals are dependent on collaboration with other professionals across departments and sectors. This study shows that the institutional and organizational framework can hinder rather than promote the professionals' intentions to create coherent rehabilitation.

Sjogren syndrome: from biopsy to lymphoma

OP0297 DIAGNOSTIC VALUE OF LABIAL MINOR SALIVARY GLAND BIOPSY IN THE DIAGNOSIS OF SJÖGREN'S SYNDROME: HISTOLOGIC FINDINGS OF 678 BIOPSIES AND ASSOCIATIONS WITH LABORATORY MARKERS, CLINICAL AND PATIENT ASSOCIATED PARAMETERS.

K. Triantafyllias[1], M. Bach[2], S. Boegel[2], A. Schwarting[1,2]. [1]*Rheumatology Center Rhineland-Palatinate, Rheumatology, Bad Kreuznach, Germany*; [2]*Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany*

Background: Histologic findings of salivary gland biopsy are a crucial part of the current ACR-EULAR classification criteria of Sjögren's syndrome (SS) (1). Particularly, the finding of a focal lymphocytic sialadenitis (focus

score ≥ 1/4 mm^2) corresponds to 3 scoring points out of 4 needed to reach a positive classification for SS [1]. Moreover, there is increasing evidence that salivary gland biopsy can provide prognostic information regarding systemic involvement and the development of lymphoma in the context of the disease.

Objectives: The aim of this study was to analyze the minor labial salivary gland (MLSG) biopsy findings of a large SS cohort and to examine their associations with disease specific laboratory markers, clinical and patient associated parameters.

Methods: We included all patients from two large rheumatological medical departments in Germany having undergone a diagnostic MLSG between 01/2010 and 12/2019. The data have been collected partly in a retrospective and party in a prospective manner. Next to the examination of histological results we focused on activity and chronicity parameters of the underlying disease, autoantibodies, presence of systemic and haematological involvement, as well as on current and previous comorbidities. The statistical analyses included sensitivity and specificity examinations via receiver operating characteristics (ROC), correlation analyses, Mann-Whitney-U-Tests and ANOVA.

Results: In total, 678 patients have been included (615 ♀, median age 55 years [47-63, IQR]). 306 patients (45.1%) had a positive focus score. The remaining 372 patients with a negative focus score served as a control group. There were significant correlations between the level of the focus score and nicotine use (p=0.002), hypergammaglobulinemia [1.27 (0.71-3.36, IQR) vs. 0.73 (0.0-0.76, IQR); p<0.001], ANA positivity [1.18 (0.11-3, IQR) vs. 0.64 (0-1.34, IQR); p<0.001] and rheumatoid factor positivity (p<0.001). Moreover, focus score levels correlated significantly with disease modifying antirheumatic treatment [1 (0-2.34, IQR) vs. 0.87 (0-1.8, IQR); p=0.004] and weakly significantly with erythrocyte sedimentation rate (r=0.235, p<0.001).

Within the group of patients with primary SS there were significant correlations between the level of the focus score and presence of systemic involvement [2 (1.1 - 4, IQR) vs. 1.44 (1-2.62, IQR); p=0.015], glandular involvement [4 (2.98-6.2, IQR) vs. 0.72 (1.6-3, IQR); p=0.007] and haematologic manifestations (p=0.002). SSA-antibodies showed the best diagnostic performance compared to MLSG, as examined by ROC (Table 1).

Table 1. Diagnostic value of SSA-antibodies, Sicca, Schirmer´s and Saxon´s test compared to minor labial salivary gland biopsy findings (reference focus score ≥ 1/ 4 mm^2)

	Specificity	Sensitivity	Area under the curve
SSA-Ro antibodies	88.2%	43.4%	0.658
Sicca	15%	91.9%	0.535
Schirmer´s test	27.3%	73%	0.507
Saxons´s test	57.9%	39%	0.541

Interestingly enough, among 159 patients who were admitted due to the diagnosis of primary fibromyalgia (FM), 63 (39.6%) could be diagnosed with SS on the basis of histologic findings and the ACR-EULAR classification criteria.

Conclusion: By examining one of the largest cohorts in the literature we could show that MLSG biopsy findings not only play a key role in the classification and diagnosis of SS, but could also provide important information regarding the presence of a systemic, glandular or haematological involvement. Furthermore, MLSG can help differentiate patients with FM and other chronic pain disorders from patients with subclinical SS who suffer primarily from chronic pain.

Enhancing research through patient involvement

OP0298-PARE **EXPERIENCES AND IMPACT OF PATIENT AND PUBLIC INVOLVEMENT IN SWEDISH RHEUMATOLOGY RESEARCH: A SURVEY OF RESEARCHERS AND PATIENT RESEARCH PARTNERS**

M. Persson[1], E. Lampa[2], S. Grzechnik[1], M. Nylander[1], E. Johansson[1], G. Von Perner[1], E. M. Dufva[1]. [1]*Swedish Rheumatology Association (Reumatikerförbundet), Research, Stockholm, Sweden*; [2]*Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden*

Background: Patient and public involvement (PPI) in research is based on the principle that research should be conducted "with" or "by" members of the public, rather than "to", "for", or "about" them.(1) Successful PPI is dependent on active partnerships between researchers and people living with rheumatic diseases throughout the research process. Such partnerships have been shown to improve the quality and relevance of the research. However, as funding bodies increase their demands for PPI, so too may the risk for tokenistic "involvement".

Since 2008, the Swedish Rheumatism Association (SRA) has trained people living with rheumatic diseases to become patient research partners (PRPs) and encouraged their involvement in research projects. The network has grown substantially in terms of the number of registered PRPs, the number of research projects aiming to include PRPs, as well as the number of active partnerships between researchers and PRPs. However, the quality of partnerships and the impact of PPI on Swedish rheumatology research is unknown.

Objectives: To examine the extent of PPI in Swedish rheumatology research, the nature of partnerships between researchers and PRPs, and the perceived impact of PRPs on the research processes.

Methods: The target population was researchers and PRPs linked to the SRA in 2021, the largest private funder of Swedish rheumatology research. In practice, this included researchers who had applied for research grants from the SRA, researchers that had sought PRPs through the SRA, PRPs trained and registered with the SRA, as well as external PRPs named in grant applications submitted to the SRA.

An online questionnaire was developed to examine the target population's understanding of the concept of PPI, their current involvement and experience of PPI, the nature of the partnerships between PRPs and researchers, and their future needs.(2,3) The survey was shared via email to the target population and remained open for one month.

PRPs were involved in the development and testing of the survey and will be involved in the interpretation and implementation of results.

Results: A total of 126 researchers that had submitted research grant applications to the SRA were identified. A further 5 researchers who had previously registered interest in collaborating with PRPs were identified from our records. Review of our internal register of trained PRPs identified 36 PRPs, whilst a further 9 external PRPs were identified from grant applications. However, contact details were unavailable for 7 of the external PRPs. As such, the survey was circulated to 131 researchers and 38 PRPs.

Preliminary response rates, one week into the survey period, were 31.3% for the researchers (41 responses) and 39.5% for the PRPs (15 responses).

Conclusion: As funding bodies increase their demands for PPI in grant applications, evaluations of the nature of PPI are required to ensure that funders' efforts do not mistakenly result in tokenistic efforts to include patients and the public in research. A better understanding of the nature of PPI, the impact of PPI on research, and the needs of the researchers and PRPs will allow appropriate support and training to be developed. This will allow growth not only in the number of partnerships, but also in the quality of partnerships between researchers and PRPs. This, in turn, is likely to improve the quality of rheumatology research.

Background: The Covid-19 pandemic has meant a modification of the patterns of the doctor-patient relationship, favoring online visits and reducing face-to-face visits. Likewise, the implementation of Patient-Reported Outcomes (PROs) that do not require the intervention of the doctor in our clinical practice and that given their close relationship with the clinical activity of chronic inflammatory joint diseases (CIJD) has favored an empowerment of patients and can allow the development of the online visit.
Objectives: Know the use and acceptance of patients with CIJD: rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthropathies (SpA) of a non-face-to-face online visit, through a digital environment.
Methods: Patients were included in a platform called Rheumanet for access by username and passwords (https://www.laconsultacercadeti.com/). At the time of inclusion, demographic variables were collected: date of birth, sex, level of education (primary education, secondary education, vocational training, further education and higher education), distance from the hospital to the patient's home, and clinical variables such as diagnosis: RA, PsA or SpA, as well as the duration of the disease. Prior to the appointment, patients were encouraged to complete a PRO survey to assess their clinical situation: Routine Assessment of Patient Index Data 3 (RAPID3) for RA, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for SpA and RAPID3 and / or BASDAI for the PsA. Both the RAPID3 and BASDAI were scored for the patient's knowledge and assigned to a color scale based on disease activity in green (remission or low activity), orange (moderate activity) or red (severe activity). Likewise, they were ordered to express through a free text what they would tell us as if they were in a face-to-face consultation. Complementary tests (analytical, radiological studies and others) are obtained simultaneously from the medical records and a joint assessment of the visit is carried out.
Results: Between September 1, 2020 and January 31, 2022, a total of 248 patients (113 RA, 53 SpA and 82 PsA) were included in the platform. 172 (69.3%) patients used the digital platform and made at least one non-face-to-face visit during follow-up. The number of online visits made by each patient ranged from 1 to a maximum of 13 visits. 80 patients (70.7%) suffered from RA, 40 (75.4%) from SpA and 52 (63.4%) from PsA. The number of patients who made non-face-to-face visits was 38 (72.3%) for a disease duration of <5 years and 137 (64.5%) for >5 years. When the ages of the patients were analyzed, the number of patients who made visits was 75 (73.5%) between 18 and 30 years old, 50 (67.7%) between 30 and 50 and 47 (66.4 %) from 50 years. According to the degree of activity of the disease, 75 patients were in remission or low activity at some point during the visits, 63 patients with moderate activity and 34 with severe activity. The distribution according to level of education was: 11 (6.3%) primary education, 21 (12.2%) secondary education, 37 (21.5%) vocational training, 63 (36.6%) further education and 40 (23.2%)higher education. The number of online visits was higher in patients who lived at a distance of 50 km or more from the hospital, reaching 100% of the visits in this subgroup of patients.
Conclusion: The online visit through a digital platform through PROs is well accepted by our population with CIJD, especially in the young population, with a higher cultural level and whose home is far from the hospital. The online visit was made by patients regardless of the severity of their disease activity. Speed and ease of use using PROs already known to the patient and clinician is an important consideration for rheumatologists working in healthcare systems where patient contact time is limited. It would be interesting to obtain this information in non-pandemic situations such as COVID-19, which would make it possible to assess actual acceptance and its use in this type of patient in circumstances in which fear of contagion is not a variable to consider.

Crystal arthritis

OP0300 5-YEAR TRAJECTORIES OF URATE-LOWERING THERAPY AND IMPACT OF COLCHICINE ON CARDIOVASCULAR RISK: REAL-LIFE DATA ON 70,000+ PATIENTS

A. Latourte[1], A. Bellamine[2], R. Sigogne[3], H. K. Ea[1], T. Bardin[1], M. Maravic[1,2], P. Richette[1]. [1]*Hôpital Lariboisière, APHP.Nord, Université de Paris, Rheumatology, Paris, France*; [2]*IQVIA, Real World Solutions, La Défense, France*; [3]*IQVIA, Data Science and Advanced Analytics, La Défense, France*

Background: Urate-lowering therapy (ULT; allopurinol: ALLO and febuxostat: FBX) are recommended to treat gout on the long term, but gout management is often suboptimal. Colchicine can reduce the rate of gout flares upon ULT initiation, and several randomized clinical trials suggest that this drug is also associated with a decreased risk of cardiovascular events.
Objectives: The objectives of this study were to analyze in a real-life setting 1) ULT trajectories and maintenance following initiation and 2) the long-term impact of co-prescribing colchicine on the cardiovascular (CV) risk.
Methods: The LRx database contains the dispensing data of nearly 45% of French pharmacies. Patients who initiated ULT in 2016 (no dispensing in the previous year) and who received regular dispensing (any drug/device) from the LRx pharmacy network until the end of 2020 were included. A multivariate Cox model investigated the factors associated with ULT maintenance over time. In the same cohort, the maintenance of ULT was compared with that of other treatments for chronic diseases. The therapeutic trajectory (continuation, change of dose or type of ULT, discontinuation) was also evaluated. The impact of co-prescribing colchicine on CV risk was studied in the subgroup of patients over 50 years of age without previous delivery of CV treatment (antidiabetics, antiaggregants, antihypertensives, diuretics, statins) in the year prior to ULT initiation. The incidence of CV treatments prescription (≥ 2 deliveries) was compared between patients who initiated ULT with or without colchicine) and those treated with colchicine without ULT using logistic regression.
Results: In 2016, 74,665 patients (mean age ± SD: 70 ± 13 years, 64% men) had initiated ULT, mainly in primary care by a general practitioner (GP) (77%). ALLO was initiated in 68% of patients (100mg/d: 56%, 200mg/d: 32%, 300mg/d: 8%); FBX in 32% (80mg/d: 85%). Colchicine was co-prescribed in 34% of patients. Factors associated with better ULT maintenance were male sex, age < 70, initial prescription by a GP, and co-prescription of colchicine. Conversely, initiation in a hospital setting was associated with poorer ULT maintenance (all p<0.0000001). Half of the patients had stopped ULT after 316 days. This time was shorter than that observed in the same population with anti-diabetics (894 days), ACE inhibitors/sartans (725 days), antiaggregants (718 days). A change in the dose or type of ULT was observed in only a minority of patients. The daily dose of colchicine was associated with a lower risk of initiating a CV treatment (OR per quartile: 0.93 [0.91; 0.96], regardless of co-prescribing with ULT, suggesting a CV benefit of colchicine.
Conclusion: This study illustrates that gout management with ULT remains largely suboptimal in France, especially in comparison with other chronic conditions. In addition, our results suggests that flare prophylaxis with colchicine might lower CV risk in gout patients.

Digital-Health and Tailored Interventions for Improving Patients' Adherence: Opportunities and Challenges

OP0301-HPR PATIENT ADHERENCE TO E-HEALTH INTERVENTIONS FOR REMOTE DISEASE MONITORING IN CHRONIC ARTHRITIS

C. Van Lierde[1], M. Doumen2, D. De Cock2, S. Pazmino2, D. Bertrand2, R. Westhovens2, P. Verschueren2. *[1]KU Leuven, Development and Regeneration, Leuven, Belgium*; *[1]KU Leuven, Development and Regeneration, Leuven, Belgium*

Background: Chronic inflammatory arthritides require lifelong follow-up and treatment. Electronic health (eHealth) could be used to remotely monitor disease, possibly improving patient self-management and lowering the burden of in-person consultations. For clinical use, it is important to understand adherence rates of patients with chronic arthritis to eHealth tools.
Objectives: To systematically review the literature on adherence to eHealth tools for remote monitoring of symptoms or disease activity in chronic arthritis.
Methods: We systematically searched the following databases: Embase, PubMed, Cochrane Central, CINAHL, Web of Science, Clinicaltrials.gov, and the International Clinical Trials Registry Platform (ICTRP). Eligible articles reported adherence rates to an eHealth tool in patients with rheumatoid arthritis (RA), juvenile idiopathic arthritis (JIA), spondyloarthritis (SpA), osteoarthritis (OA), or gout. Included texts were screened individually. Finally, quality assessment was done with the Newcastle-Ottawa scale (NOS) and the PEDro scale.
Results: The literature search resulted in 7027 articles. After deduplication, 4219 articles were screened for eligibility, and 47 articles were included. We found highest adherence rates in studies applying electronic diaries (81.8%), followed by text messages (79.9%), web-based platforms (74.6%), activity trackers (73%), and smartphone applications (65.5%). Highest adherence was reported in studies on patients with OA (79.7%), followed by patients with gout (73.7%), RA (71.3%), ankylosing SpA (67%), and JIA (59%). Demographic characteristics did not seem to affect patient adherence. Based on frequency of data entering, a time interval of once-daily showed highest adherence rates (72.6%), followed by entering data more than once a day (72.3%) and once a week (67.7%), or longer (59.2%). Adherence declined with longer study duration.
Conclusion: Our literature review identified declining adherence levels with longer study duration, and highest adherence rates for patients with OA, making use of electronic diaries, and requesting once-a-day completion. OA studies had an overall shorter duration than RA studies, which could be an explanation as to why OA patients showed higher adherence. Lower adherence rates were reported in studies in juvenile populations, while older age did not seem to affect reported adherence.

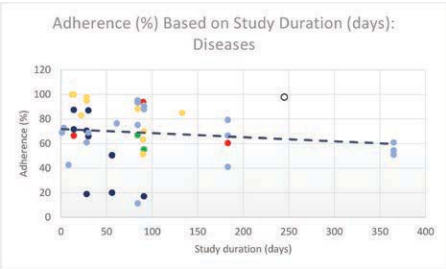

Figure 1. Linear regression model of adherence based on study duration per disease. X = study duration (days), Y = adherence (%). Y = -0.0332X + 71.84. Light blue = RA, yellow = OA, dark blue = JIA, red = Gout, green = SpA, white = >1 disease

Rheumatology across boundaries

OP0302 IS INCREASED RISK OF UROLITHIASIS IN AXIAL SPONDYLOARTHRITIS DRIVEN BY GUT INFLAMMATION? RESULTS FROM THE SPARTAKUS COHORT

J. K. Wallman[1,2], E. Mogard[1,2], J. Sagard[1,2], L. E. Kristensen[3], E. Lindqvist[1,2], T. Olofsson[1,2]. *[1]Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden*; *[2]Skane University Hospital, Department of Rheumatology, Lund, Sweden*; *[3]Parker Institute, Copenhagen University Hospital, Department of Rheumatology, Frederiksberg and Bispebjerg, Copenhagen, Denmark*

Background: A nationwide, Swedish study found a doubled urolithiasis risk in ankylosing spondylitis (AS) compared to population controls.[1] Inflammatory bowel disease (IBD) is a known risk factor for urolithiasis, e.g. via enteric hyperoxaluria causing calcium oxalate stones.[2] With microscopic gut inflammation in around 50% of axial spondyloarthritis (axSpA) patients,[3] and overt IBD in 5-10%, gut inflammation may also drive the increased urolithiasis risk in axSpA.
Objectives: To study whether axSpA patients with a history of urolithiasis have an increased prevalence of comorbid IBD or display elevated biomarkers of gut inflammation/pathology.
Methods: AxSpA patients in the population-based SPARTAKUS cohort study in southern Sweden (non-radiographic axSpA [nr-axSpA] n=86, ASAS criteria; AS n=168, modified New York criteria) self-reported their history of prior urolithiasis (no/yes). Faecal (F) calprotectin and ASCA (anti-*Saccharomyces cerevisiae* antibodies) in serum were measured by commercially available ELISAs (Calpro AS; ORGENTEC Diagnostika). For a subgroup of patients (n=164), presence of gut dysbiosis was also assessed by the GA-Map Dysbiosis Test (Genetic Analysis). Demographics, disease/treatment characteristics, comorbid IBD and the gastrointestinal biomarkers (F-calprotectin/ASCA/dysbiosis) were compared between patients with versus without prior urolithiasis. Finally, the same biomarkers were also compared between patients with versus without urolithiasis history, after exclusion of subjects with known IBD.
Results: Urolithiasis history was reported by 13% (n=33) of the axSpA patients, and comorbid IBD was significantly more common in this group (27% versus 6.8%, p<0.001; Table 1). F-calprotectin levels were also significantly higher among patients with prior urolithiasis, as was presence of gut dysbiosis (Table 1). ASCA seropositivity did not differ between the groups. Moreover, prior urolithiasis was associated with longer disease duration and AS-phenotype. After exclusion of cases with comorbid IBD, urolithiasis history was reported by 10% (24 of 230 patients). F-calprotectin elevation ≥100 mg/kg remained significantly associated with urolithiasis history also in this population, while only being numerically increased when assessed as a continuous variable (p=0.053; Figure 1). Gut dysbiosis also remained associated with prior urolithiasis in the non-IBD population (56% [9 of 16 patients with prior urolithiasis] versus 30% [40 of 132 patients without], p=0.037), whereas ASCA status did not differ between the groups (data not shown).

Table 1. Included studies. Adh = adherence SA = smartphone app, ED = electronic diary, AT = activity tracker, OP = online platform, TM= text message. JIA= Juvenile Idiopathic Arthritis, PsA = Psoriatic Arthritis, SpA = Spondyloarthritis, OA = osteoarthritis, RA = Rheumatoid arthritis

Table 1.

	Urolithiasis history	
	No, n=221	**Yes, n=33**
Male sex	115 (52%)	23 (70%)
Age, years	50 (13)	59 (12)*
Disease duration, years	25 (14)	31 (14)*
AS (versus nr-axSpA)	141 (64%)	27 (82%)*
Inflammatory bowel disease	15 (6.8%)	9 (27%)*
ASAS 3-month NSAID score	31 (40)	37 (48)
Ongoing bDMARD therapy	87 (39%)	16 (49%)
bDMARD therapy ever	113 (51%)	20 (61%)
ASDAS-CRP	1.8 (1.0)	1.9 (0.8)
BASFI	2.0 (2.1)	2.7 (2.6)
BASMI	2.9 (1.5)	4.3 (2.1)*
F-Calprotectin, mg/kg		*#
Mean (SD)	58 (97)	115 (176)
Median (IQR)	29 (49)	39 (152)
F-Calprotectin ≥100 mg/kg	28 (14%)	10 (32%)*
ASCA IgA ≥10 U/ml	12 (5.7%)	4 (13%)
ASCA IgG ≥10 U/ml	45 (21%)	10 (33%)
Gut dysbiosis†	45 (32%)	17 (71%)*

Mean (SD) or n (%) if not otherwise stated. † GA-Map Dysbiosis Test, dysbiosis index ≥3. * p<0.05 by Chi^2-test or Student t-test, as appropriate. # Log_{10}-transformed values compared. Missing ≤13%, except for gut dysbiosis available in 140/24 patients without/with urolithiasis history.

Conclusion: The current results lend support to the hypothesis that the increased urolithiasis risk in axSpA may be driven by gut inflammation/pathology. Prospective studies are, however, needed to assess the causality.

The COVID-19 pandemic – what did we learn?

OP0303-PARE

HEALTH DEMOCRACY IN THE TIME OF COVID-19: A COLLABORATIVE INITIATIVE BETWEEN PATIENT ORGANIZATIONS AND HEALTHCARE PROFESSIONALS TO SUPPORT PEOPLE LIVING WITH RHEUMATOID ARTHRITIS

S. Tropé[1], R. M. Flipo[2]. [1]*ANDAR, Direction, Paris, France*; [2]*Centre Hospitalier Universitaire de France, Department of Rheumatology, LILLE, France*

Background: Has the COVID-19 crisis overwhelmed health democracy? This question may have arisen since extraordinary measures taken in response to the pandemic were developed almost exclusively by scientific expert committees. Citizens, patients, patient organizations, healthcare professionals, and even experts from these committees have recognized a lack of health democracy in the decision-making process regarding the COVID-19 response in France. Indeed, patient voices were barely heard during the early stages of the pandemic; yet inclusive dialogue is crucial for building trust and adherence to policy. Moreover, patients also need to be assisted in handling the overabundance of COVID-19 information, particularly misleading and false information, referred to as an "infodemic" by the WHO.

Objectives: To show a practical and effective application of health democracy in rheumatology through collaboration between patient associations and rheumatologists during the COVID-19 pandemic. To collect, select, analyze, abstract, and translate COVID-19 literature to provide rheumatoid arthritis (RA) patients with useful, convenient and quality educational materials that answer patients' medical, scientific and daily life questions. This initiative is consistent with patient-centered COVID-19 response.

Methods: At the instigation of a patient association in October 2021, a working group was established to develop a COVID-19 patient education resource to meet the expectations and needs of RA patients. The working group consisted of health professionals and patients identified by the partner patient organization. A committee of rheumatologists checked the reliability and accuracy of the scientific and medical information. A committee of patients assessed materials' relevance, readability, and understandability. Materials were written in lay language without distorting the meaning of the scientific data. The methodology is detailed in Figure 1.

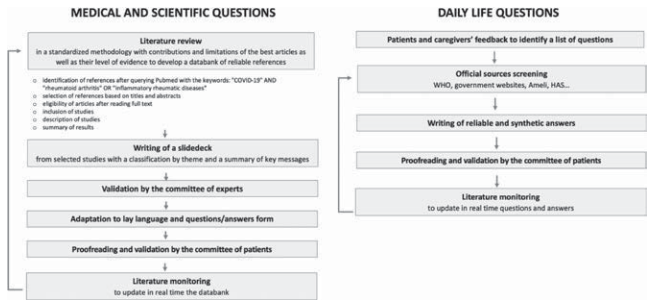

Figure 1. Process flowchart

Results: The document is available to download on www.polyarthrite-andar.com (number of unique visits on the webpage for the last version: 1176). A printed version was also provided directly to patients by rheumatologists. To provide up-to-date information, the brochure was updated 7 times between the first edition in January 2021 and the last version in August 2021. This last version included 49 questions. Each update was announced to all members of the patient organization in its monthly newsletter (number of newsletter's subscribers: 1863; number of followers: Facebook=2632; Twitter=1382; Instagram=921; LinkedIn= 590; Youtube=2907). The "Medical and scientific questions" section provided reliable and expert-reviewed information about the virus, protective measures, testing, vaccination, integrating RA specificities and its treatments for each item. The "Daily life questions" section provided practical advice during the pandemic, in particular by addressing the "TousAntiCovid" smartphone application, isolation certificates, remote working and lockdown instructions.

Conclusion: This initiative demonstrates the benefits that can be achieved by greater collaboration between patients and healthcare professionals to address population health problems. The patient could be an active contributor in improving disease management of his peers. This patient education tool is a good example of the relevance of the motto of 'nothing about us, without us'. The

COVID-19 pandemic has highlighted the importance of bringing patients' voices to affect evidence-based policies centered around the needs of patients. Health democracy needs to form the backbone of how a health system is structured.

OP0304-PARE **"THE CORONA PANDEMIC – AND HOW WE REACTED TO PATIENTS' NEEDS"**

C. Elling-Audersch[1]. [1]*German League Against Arthritis, NRW, Bonn, Germany*

Background: The pandemic had major negative effects and is a big challenge to all patient organisations in Europe. Our organisation (Deutsche Rheuma-Liga) with about 270.000 members is already equipped with various tools and skills for the support of our members. We are offering not only information, but exercise-programs, self-management courses, different events to meet and exchange. But after two years of the pandemic, the problems have piled up. Our members are missing the face-to-face contact. It was impossible, due to the limitation and restriction of contact, to conduct events, meetings, consultations, and exercise programs. Most of our offers came to a standstill.
Objectives: Due to these problems, it was not only difficult to live with a chronic rheumatic disease, but there was also no possibility to get access to helpful information and advice or to use the various services, either. Especially the fear of Covid-19, which impact it has on RMDs, questions regarding the vaccination and the medication were increasing to a substantial extent.
Methods: Three different measures were taken:
Information needs:
By improving our website, it was possible to provide digital content to our members. We offer essential and understandable information with additional links to the most current expert information on COVID-19, like the EULAR recommendations and those of our national rheumatologist society (DGRh).
Activity needs:
Different digital exercise-programs were developed by our nineteen national member organisations. We shared this services on the website of our umbrella organisation with all members, nationwide. Our campaign "Keep on moving" shall encourage our members nationwide practising their exercise and developing innovative ideas into the daily routine.
Results: *Interaction needs:*
Regarding our "Rheuma-Forum" (a digital exchange format for people with arthritis)
I want to explain in detail with dates and facts how our organisation enhances the contact to our members and other people with arthritis who were looking to our organisation for information. We replied to questions and addressed the needs on an individual basis. Since the beginning of the pandemic, we implemented four Expert-Forums per year, addressing many comparable questions regarding the issues of COVID-19 (like RMDs and the covid vaccination, possible side effects). Our experts are well-known, specialized rheumatologists and trained RMD patients. The figures speak for themselves.
2020 – 4 Expert Forums with 857 Q&A within 65.396 accesses
2021 - 4 Expert Forums with 677 Q&A within 28.180 accesses
2022 – 1 Expert Forum within 242 Q&A within 10750 accesses
Conclusion: We can be pleased that our strategy to provide information to our members and other people with arthritis via the digital way was successful. We already know that this will be an ongoing process. But we are on the right path to encourage our members in difficult pandemic times and give them important and valid information. Our example of the expert forum shall encourage patient organisations to try out new digital and interactive solutions not only in pandemic times.

Piantoni[10] on behalf of EMEUNET. [1]*Sint Maartenskliniek, Research, Ubbergen, Netherlands*; [2]*University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom*; [3]*University of Trento, Santa Chiara Regional Hospital and Department of Cellular, Computational and Integrative Biology (CIBIO), Trento, Italy*; [4]*Hacettepe University, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey*; [5]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [6]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [7]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [8]*Queen Mary University, Rheumatology, London, United Kingdom*; [9]*University Hospitals of Geneva, Rheumatology, Geneva, Switzerland*; [10]*ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: In 2012, the Emerging EULAR (European Alliance of Associations for Rheumatology) Network (EMEUNET) started a mentoring program in collaboration with the editorial board of top-leading journals in rheumatology, the Annals of the Rheumatic Diseases (ARD) and a few years later RMD Open, with the aim of improving peer reviewing skills of young researchers (mentees).[1] In this program, now in its 6th edition, senior reviewers (mentors) critically discuss manuscripts submitted to ARD or RMD Open with mentees. At the end of the program, senior reviewers certify the capability of mentees to independently conduct a good quality review. The program is organized by members of the EMEUNET Peer Mentoring Subcommittee, including facilitating communication within the groups. Several strategies, such as face-to-face meetings and periodic videoconferences, were implemented recently, following the outcome of a previous survey among mentees.[1]
Objectives: To assess the experienced benefits and challenges of the EMEUNET Peer Mentoring program of young rheumatologists and researchers and their mentors.
Methods: In November 2021, a survey was sent by email to mentors and mentees who successfully completed the first five editions of the program (launched between 2012 and 2019), asking for demographics, and potential benefits and challenges of the program. Felt change in peer-review skills before and after the program were rated on a scale from 0 (no skill) to 10 (perfect skill). Results were analysed descriptively.
Results: A response rate of 55% for mentors (11/20) and 43% for mentees (37/87) was obtained. Mentors had a mean(SD) age of 52(9.5) years, 64% were male and 7 different nationalities were included. Mentees had a mean age of 34(3.7), 43% were male and 16 nationalities were included. Mentees/mentors from all the editions were included, although recent editions were somewhat overrepresented. Almost all respondents said their overall experience with the program was positive (46/47), that the objectives of the peer-reviewing mentoring program were met (46/47) and that they would recommend the program to others (44/45).
Mentors indicated an initial average peer-review skill level of 5.2(1.8) for content and 4.2(1.9) for form, which improved by 2.7(1.3) points 3.2(1.8) points, respectively. Interestingly, improvement scores of the mentees paralleled those of mentors: content and form were initially rated at 4.9(1.7) and 5.1(1.8) and improved by 2.6(1.3) and 2.7(1.7), respectively. Nine out of ten mentors said the program had helped them improve their own skills (i.e., peer-reviewing, mentoring, and teaching). The number of peer reviews after completion of the program varied quite significantly between mentees (median 10, IQR 9.5-29). For most mentees, the number of peer-reviews stayed the same (18/32) or increased (12/32). Fifteen out of 32 respondents said they were invited as an independent reviewer for ARD and/or RMD Open after completion of the program. Potential benefits and challenges of the program are depicted in Figure 1. Added value mentioned by both mentors and mentees was the opportunity to contribute to high quality peer-review standards and improve their skills. Challenges reported by mentors were communication with mentees, stringent deadlines, and the program being time-consuming; challenges for mentees were the communication with their mentor, deadlines and insufficient clarity of the process.

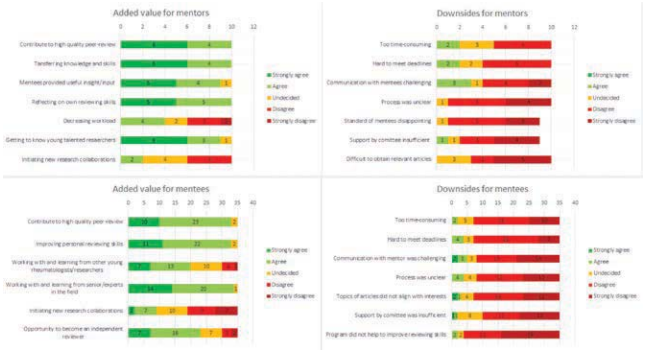

Figure 1. Rating of potential benefits and downsides of the program. X-axis: Items of the survey; Y-axis: the number of respondents (10/11 mentors and 35/37 mentees).

Conclusion: After 5 editions over 10 years, the EMEUNET Peer-Review Mentoring Program continues to be a highly valued opportunity in the field of rheumatic diseases, as both mentors and mentees experience a significant impact on their skills. Areas for improvement were identified (e.g., communication, deadlines) and will be addressed in future editions.

Interstitial lung disease in RMDs

OP0306 IMPACT OF INFLAMMATION ON INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS - AN ANALYSIS OF THE GERMAN BIOLOGICS REGISTER RABBIT

R. Ramien[1,2], T. Rudi[1], M. Schneider[3], S. Balzer[4], A. Krause[5], M. Schaefer[1], Y. Meissner[1], A. Strangfeld[1]. [1]*German Rheumatism Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany*; [2]*Schlosspark-Klinik Charlottenburg, Department of Internal Medicine II, Berlin, Germany*; [3]*Heinrich-Heine-Universität Düsseldorf, Rheumatology, Düsseldorf, Germany*; [4]*Praxis Balzer, Rheumatology, Bautzen, Germany*; [5]*Immanuel-Krankenhaus Abteilung für Innere Medizin/Schwerpunkt Rheumatologie, Rheumatology, Berlin, Germany*

Background: Ten percent of patients with prevalent rheumatoid arthritis (RA) develop an interstitial lung disease (ILD), which is associated with higher mortality *(1)*. A previous study identified high/moderate disease activity, but not CRP, as a risk factor for RA-ILD *(2)*.
Objectives: To analyse whether systemic inflammation (CRP and ESR) and/or disease activity measured with a composite score (DAS28-ESR) are associated with the occurrence of ILD in patients with RA.
Methods: Data from RA patients observed in the biologics register RABBIT until 10/2020 were included. Patients with incident ILD were selected as cases and matched 1:5 to controls using a modified risk-set sampling (controls had no ILD during the entire observation time). Matching criteria were age, sex, RA duration, date of enrolment and observation time. Odds ratios (OR) and 95% confidence intervals (CI) were computed by conditional logistic regression and adjusted for factors identified by a directed acyclic graph (DAG), namely smoking, rheumatoid factor (RF), chronic obstructive pulmonary disease, number of biologics until index date (date of ILD-diagnosis in cases, date after the respective observation time in controls) and mean glucocorticoid dosage (12 months prior index date). For the regression, CRP and ESR were log-transformed due to their skewed distribution, and missing values were addressed by multiple imputations (n=10).
Results: Out of 19,148 RA patients enrolled since 2001, 133 patients with incident ILD were identified. Half of the ILDs were diagnosed by computed tomography (n=67), 8% by x-ray (n=10) and in 42% the method was unknown (n=56). At baseline, cases and controls had a mean age of 61 years, 68% were female, and mean RA disease duration was 9 years. Differences were observed in smoking status (59% ever smokers in cases vs. 48% in controls), RF positivity (84% vs. 72%) and the sum of comorbidities (means 3.1 vs. 2.3).
During the 12 months prior to the index date, mean values of CRP and especially of ESR were significantly higher in cases compared to controls. This difference was not observed for DAS28 (Figure 1, upper figures). Furthermore, more cases than controls were in a high inflammatory status, but not in at least moderate disease activity (Figure 1, lower figures). The adjusted regression analyses confirmed these results: CRP and ESR were significantly associated with incident ILD both at the time of diagnosis and in the 12 previous months, and results were even more pronounced with elevated CRP and ESR, which was not the case for DAS28 (Table 1).

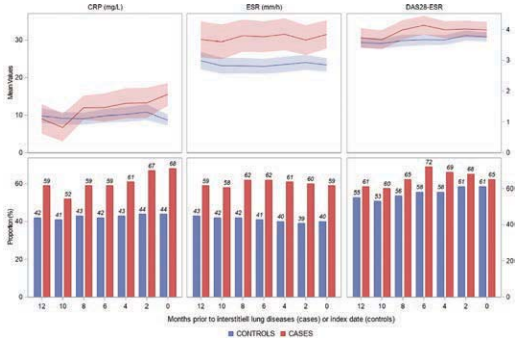

Figure 1 . Upper Figures. Unimputed and untransformed CRP, ESR and DAS28 12 months prior to the index date as means with 95% CI, computed by mixed models with matching strata as random effects. The left y-axis refers to CRP and ESR, the right to DAS28. **Lower Figures**. Percentages of patients with CRP≥5, ESR>21 and DAS28>3.2 12 months prior to the index date.

Table 1. Results of the conditional logistic regression for the risk of ILD.

	Crude OR (95% CI)	Adjusted OR (95% CI)
At index date		
Log CRP	1.55 (1.25 – 1.92)	1.55 (1.24 – 1.94)
CRP≥5 vs. CRP<5	2.43 (1.55 – 3.81)	2.41 (1.49 – 3.88)
Log ESR	1.56 (1.22 – 2.00)	1.56 (1.21 – 2.01)
ESR >21 vs. ESR ≤21	2.12 (1.40 – 3.19)	2.12 (1.37 – 3.29)
DAS28	1.17 (1.01 – 1.35)	1.16 (0.99 – 1.35)
DAS28 >3.2 vs. DAS28 ≤3.2	1.31 (0.86 – 1.99)	1.32 (0.85 – 2.06)
Within 12 months prior to index date		
Log CRP	1.41 (1.14 – 1.75)	1.38 (1.09 – 1.74)
CRP≥5 vs. CRP<5	2.60 (1.59 – 4.27)	2.60 (1.54 – 4.41)
Log ESR	1.65 (1.26 – 2.16)	1.60 (1.21 – 2.12)
ESR >21 vs. ESR ≤21	2.43 (1.53 – 3.86)	2.35 (1.45 – 3.81)
DAS28	1.16 (0.99 – 1.36)	1.13 (0.95 – 1.34)
DAS28 >3.2 vs. DAS28 ≤3.2	1.37 (0.82 – 2.30)	1.37 (0.79 – 2.35)

Conclusion: In contrast to other data, our analyses found that markers of systemic inflammation, but not the DAS28 composite score, are associated with the occurrence of incident ILD in patients with RA and can be predictors for the development of RA-ILD. Therefore, in a treat-to-target approach, rheumatologists should pay particular attention to controlling systemic inflammation.

OP0307 PULMONARY FIBROSIS IN EARLY RHEUMATOID ARTHRITIS IN RELATION TO GENETIC LOCI AND INDIVIDUAL ACPA SPECIFICITIES

M. Brink[1], L. Ljung[1], M. Hansson[2], J. Rönnelid[3], R. Holmdahl[4], K. Skriner[5], G. Serre[6], L. Klareskog[2], S. Rantapää Dahlqvist[1]. [1]*Umeå University, Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden*; [2]*Karolinska Institute, Medicine, Stockholm, Sweden*; [3]*Uppsala University, Immunology, Genetics and Pathology, Uppsala, Sweden*; [4]*Karolinska Institute, Medical Inflammation Research, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden*; [5]*Charite, Universitätsmedizin, Berlin, Germany*; [6]*Université de Toulouse, Institut Toulousain des Maladies Infectieuses et Inflammatoires, UMR 1291 Inserm, Toulouse, France*

Background: Pulmonary manifestations in rheumatoid arthritis (RA) are common comorbidities but the underlying mechanisms are largely unknown. We found in a previous study 3 SNPs associated with pulmonary fibrosis (PF); rs35705950 (MUC5B), rs111521887 (TOLLIP), and rs2609255 (*FAM13A*) besides age, rheumatoid factor positivity and methotrexate treatment.
Objectives: To evaluate for the added value of a multiplex of anti-citrullinated peptide antibodies (ACPA) for the development of pulmonary fibrosis (PF) in an inception cohort of RA patients.
Methods: A total of 1184 patients with early RA were consecutively included and followed prospectively from the date of diagnosis (index date) until death or until 31 December 2016. The diagnosis of PF was based on high resolution tomography. The presence of 21 ACPA fine specificities were analysed in plasma sampled at index date, using a custom-made microarray chip (Thermo Fisher Scientific, Uppsala, Sweden). Data on both ACPA and genetic data was available for 841 RA patients, of whom 50 developed PF. Associations were analysed using logistic regression analysis and presented as the odds ratio (OR) with the 95% confidence interval (CI). Models were adjusted for sex, age, DAS28 and presence of RF at RA diagnosis, smoking ever, and HLA-SE and in a second step for the three SNPs (.rs35705950, rs111521887 and rs2609255), respectively.

Results: In unadjusted analyses eight ACPA reactivities were found associated with PF development (p< 0.05-0.001). The number of ACPA reactivities was related to PF development, both in crude and adjusted models (p<0.05 for both). In models concomitantly adjusted for the three SNPs (rs35705950, rs111521887 and rs2609255) respectively, in addition to mentioned adjustments the number of ACPA reactivities (p<0.05 for all three nmodels), Vim60-75 (p<0.05, in all three models), Fibβ62–78 (72) (p<0.001-p<0.05) and F4-CIT-R (p<0.01-p<0.05) were all found significantly associated to PF development irrespective of the SNPs.
Conclusion: The development of PF in an inception cohort of RA patients was associated both with risk genes and, independently of the risk genes, the presence of certain ACPA, and the number of ACPA reactivities.

Keeping the "Dark clouds" away: Psychological distress and RMDs

OP0308-HPR

MORE THAN HALF OF RA PATIENTS WITH A LIFETIME HISTORY OF MOOD DISORDERS WERE ANXIOUS AND DEPRESSED DURING THE COVID-19 PANDEMIC: RESULTS FROM THE CANADIAN EARLY COHORT (CATCH) STUDY

S. J. Bartlett[1], O. Schieir[2], M. F. Valois[2], G. Boire[3], G. Hazlewood[4], C. Thorne[5], D. Tin[5], C. Hitchon[6], J. Pope[7], E. Keystone[8], L. Bessette[9], V. Bykerk[10]on behalf of the CATCH Investigators. *[1]McGill University & McGill University Health Centre, Medicine, Montreal, Canada*; *[2]McGill University, Medicine, Montreal, Canada*; *[3]University of Sherbrooke, Rheumatology, Sherbrooke, Canada*; *[4]University of Calgary, Rheumatology, Calgary, Canada*; *[5]CARE, Rheumatology, Newmarket, Canada*; *[6]University of Manitoba, Rheumatology, Winnipeg, Canada*; *[7]Western University, Rheumatology, London, Canada*; *[8]RheumKey, Rheumatology, Toronto, Canada*; *[9]Laval University, Rheumatology, Quebec City, Canada*; *[10]Hospital for Special Surgery, Rheumatology, New York, United States of America*

Background: A growing number of studies indicate the considerable mental health impacts of the prolonged COVID-19 pandemic in the general population as chronic stress is a risk factor for the development of depression and anxiety. Mood disorders are more prevalent in RA and a history of anxiety or depressive disorders increases the risk of recurrence in the future.
Objectives: To compare trends in prevalence of anxiety and depressive symptoms, prior to and during the COVID-19 pandemic in RA patients with and without a lifetime history of mood disorders.
Methods: Data were from RA patients diagnosed and treated for RA in rheumatology clinics across Canada enrolled in the Canadian Early Arthritis Cohort (CATCH) Study. We estimated monthly trends in prevalence of clinically significant levels of anxiety and depression (PROMIS Depression and Anxiety 4a score 55+) from all visits between Mar 2019 and Jan 2022 and compared monthly trends in anxiety and depression in the year prior to (Mar 2019- Feb 2020) and during the pandemic (Mar 2020 to Jan 2022) stratified by lifetime history of mood disorders.
Results: 4,148 visits were completed from Mar 2019 to Jan 2022 in 1,644 RA patients with a mean (SD) age of 60 (14) and disease duration of 6 (4) years. 73% were women, 84% white, 60% had completed some post-secondary education, and 77% were in CDAI REM/LDA at the visit closest to the start of pandemic. 253 (15%) reported a lifetime history of depression and 217 (13%) a lifetime history of anxiety; 8% reported prior treatment for either.
Patients with a history of mood disorders had higher levels of depression and anxiety prior-to and during the pandemic compared with patients without a history of mood disorders (Table 1). Proportions were highest during COVID waves in all and were substantially higher and more variable in people with a previous history of mood disorders as compared to those without a history (Figure 1). While depressive symptoms peaked early in the pandemic, anxiety increased with each wave, peaking in Wave 3 (May-Jun 2021).

Table 1. Prevalence of depression and anxiety symptoms prior to and during the COVID-19 pandemic in RA patients with and without a history of mood disorders.

Period Prevalence (monthly range)	Depression		Anxiety	
	No history	Prior History	No History	Prior History
N observations	3527	621	3610	538
Prepandemic (3/19 - 2/20)	21% (14%-30%)	51% (29%-64%)	27% (20%-35%)	58% (31%-89%)
Pandemic (3/20 - 1/22)	22% (15%-29%)	53% (33%-78%)	28% (20%-43%)	59% (33%-80%)

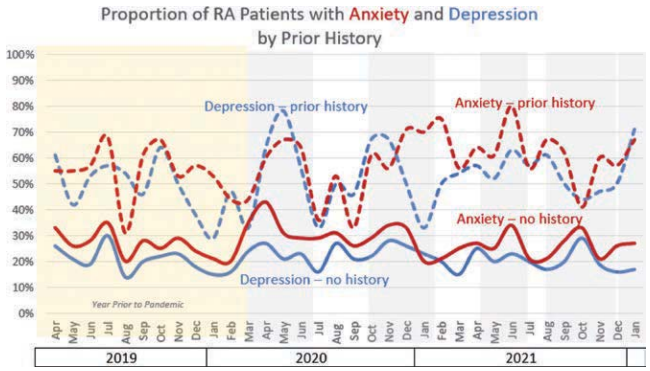

Figure 1.

During the first 22 months of the COVID-19 pandemic, the proportion of patients with depression and anxiety increased in all groups. More than half of those with a history of emotional distress had clinically significant levels of depression and anxiety; proportions were highest during COVID waves in all and were substantially higher in people with previous history as compared to those without a history (see Figure 1). Whereas depressive symptoms peaked early in the pandemic, anxiety increased with each wave, peaking in Wave 3 (May-Jun 2021).
Conclusion: Symptoms of anxiety and depression were common in Canadian adults with RA prior to and after the onset of the COVID-19 pandemic. Whereas others have found that high levels of depression and anxiety occurred early in the pandemic but declined fairly rapidly in the general population[1], emotional distress was not attenuated over time in this large cohort of RA patients. Individuals reporting lifetime history of mood disorders were more than twice as likely to report anxiety and depression, with depression peaking early in the pandemic and anxiety growing with each successive wave in the first year. The results demonstrate the importance of applying a lifetime perspective as previous episodes of anxiety and depression may be an important marker of increased vulnerability and recurrence in RA patients, particularly during the pandemic.

New lessons for rheumatology in genomics medicine

OP0309

WES ANALYSIS OF RARE FAMILIES POINTS TO A PATHOGENIC ROLE FOR THE CGAS/STING-TYPE I IFN AXIS IN SSC

P. Maus[1], V. Smith[2], T. Du Four[2], M. Vanthuyne[3,4], B. Lauwerys[5], N. Limaye[1]. *[1]de Duve Institute, UCLouvain, Genetics of Autoimmune Diseases & Cancer (GEDI), Brussels, Belgium*; *[2]Ghent University Hospital, Department of*

Rheumatology, Ghent, Belgium; [3]*Cliniques Universitaires Saint-Luc, UCLouvain, Rheumatology Department, Brussels, Belgium*; [4]*Grand Hôpital De Charleroi, Rheumatology Department, Charleroi, Belgium*; [5]*Institute of Experimental and Clinical Research, UCLouvain, Rheumatology Pole, Brussels, Belgium*

Background: Systemic sclerosis (SSc) is a rare (prevalence ±20/100,000), chronic condition characterized by vascular, immunological and connective tissue abnormalities. Genetic factors contribute to disease, as evidenced by a 15-fold increased relative risk in relatives of patients. Case-control studies have identified numerous associated loci; the identification and functional validation of risk alleles has however been elusive. No monogenic or oligogenic causes of SSc have been demonstrated, likely due to the infrequency of familial clustering (≤ 1.6% of cases) in this disease. We are fortunate to have access to DNA samples from five such families, with two affected first-degree relatives each: To our knowledge the only series of its kind.
Objectives: The goal of our research is to identify and functionally validate genes that drive SSc pathogenesis in these families, thereby shedding light on fundamental disease mechanisms. In light of the apparent lack of a multi-generational effect, we hypothesize that SSc may be transmitted as a di/oligogenic trait in these families, with two-to-a-few genes acting together to cause disease.
Methods: Whole exome sequencing (WES) was performed on all available blood-DNA (Figure 1). We filtered for variants that are (a) shared by both affected individuals within each family, (b) absent-to-rare in the general population, and (c) predicted to affect protein function by multiple *in silico* tools. Candidate gene prioritization and pathway analysis is followed by *in vitro* testing of a subset of SSc-variants, to assess for their effects on protein function. Where two strong candidate genes are identified in the same family, *in vitro* validation of both variants will be followed by the generation of single- vs. double- knock-in mice, to test for di/oligogenic effects of variant combinations on SSc-related phenotypes.

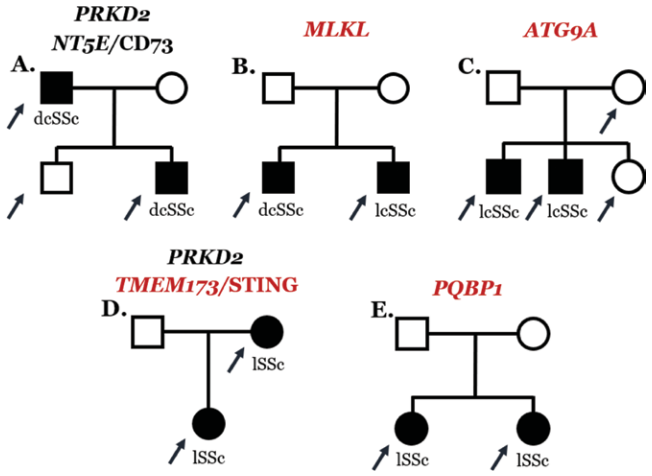

Figure 1. SSc families. Filled symbols: affected. Arrows: WES on blood-DNA. lSSc: Limited SSc; lcSSc: Limited cutaneous SSc; dcSSC: Diffuse cutaneous SSc. cGAS/STING (red) and IFN I (black) - related candidate genes.

Results: WES yielded 23-45 genes per family with variants that satisfied the above criteria. Prioritization of candidates was based on systematic annotation of all 180 genes for expression pattern, function, and potential impact of the SSc-variants. Our data suggest familial SSc is genetically heterogeneous, with little sharing of candidates between families. We therefore assessed for pathways represented in gene-lists from multiple families, and found that participants in the cGAS/STING - type I-IFN axis are identified in all (Figure 1). This would suggest a unifying disease mechanism.
cGAS/STING is a sentinel system responsible for the production of anti-viral type I interferons (IFN-α/β) and pro-inflammatory cytokines in the presence of cytoplasmic double stranded DNA (dsDNA). cGAS/STING-dependent self-dsDNA sensing has been implicated in silica-induced inflammation: a risk factor in SSc and pulmonary fibrosis. A type I IFN-response signature is identified in SSc patients and correlates with disease severity. Mutations in two of our candidates cause Mendelian diseases with phenotypic overlaps with SSc, and all but one cause disease-relevant phenotypes when perturbed in mice. Finally, preliminary *in vitro* data suggest gain-of-function effects of the variant identified in *TMEM173*/STING, and loss-of-function effects in *NT5E*/CD73 and *PRKD2* (the last with two different variants identified in two families; Figure 1). All would lead to increased IFN-I signaling.
Conclusion: We report, for the first time, WES analysis of a familial SSc series of unprecedented size for this rare disease. The identification of potential "driver" gene variants in cGAS/STING-type I IFN signaling regulators across all families points to an important pathogenic role for this pathway in SSc.

Volunteering for the RMD Community

OP0310-PARE **AN APP FOR VOLUNTEERS IN DENMARK**

J. Lange[1]. [1]*The Danish Rheumatism Association, Department of Volunteers, Gentofte, Denmark*

Background: The Danish Rheumatism Association wanted to improve its communication with and between its volunteers. We had an existing system that worked like a database of information, but our volunteers found it difficult and lacking the needed information. Furthermore, they wanted to be in closer contact with other volunteers with similar functions in the organization to be able to share ideas and learn from each other.
Objectives: We wanted to find a platform with which we could increase the connectability between our volunteers across the organization as well as making existing information more accessible for them. We also wanted an easier way of contact to our volunteers that did not require them to use their e-mails.
Methods: First we identified the tasks we wanted our "solution" to solve. Then we decided that the ideal tool for this probably would be an App that supported the connectability as well as a "database" with documents and instructions in which we could present important and useful information to our volunteers.
We searched the marked for platforms and invited three companies to make a presentation on how their product could support our ideas and wishes.
After the presentation, we settled on the solution with the best connectability functions, as we wanted to present our volunteers with a completely new experience of contact with the organization and each other.
We introduced the App on a big conference for our volunteers we have every two years. We had a big workshop planned with instruction and tests, where our volunteers could try the App and its functions. Prior to the conference, we had sent out instructions to all the participants on how to install the app, and registered them as users of the app, making sure all was in place and ready for the conference and our introduction.
Results: We found, that instructing such a large group of people all at once proved to be more demanding than we had expected. After the conference, we continued with the introduction of the app to new volunteers as well as sending information and updated instructions to existing app- users.
We have found that the introduction of this new app has been quite a success. We now have a platform for easy and fast communication to and between all our volunteers, as well as access to relevant news and important information from the organization about their roles and tasks as volunteers.
It has been quite a time-consuming task to implement the app and we have invested a great deal of working hours making sure the app would be used by our volunteers. We have found it necessary to develop a separate communication plan to ensure our volunteers accept and remember the app as an important working tool.

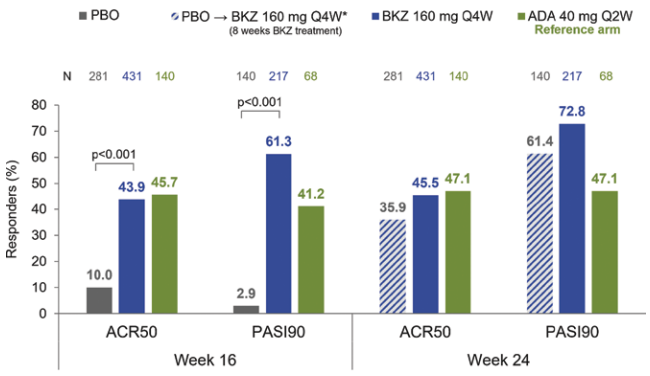
Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A.

Objectives: Assess BKZ efficacy and safety vs PBO in bDMARD-naïve pts with active PsA to Wk 24 of BE OPTIMAL.

Methods: BE OPTIMAL (NCT03895203) comprises 16 wks double-blind PBO-controlled and 36 wks treatment-blind. Pts were ≥18 yrs, bDMARD-naïve, with adult-onset, active PsA, ≥3 tender and ≥3 swollen joints. Pts randomised 3:2:1, subcutaneous BKZ 160 mg Q4W:PBO:adalimumab (ADA; reference arm) 40 mg Q2W. From Wk 16, PBO pts received BKZ 160 mg Q4W. Primary endpoint: ACR50 at Wk 16.

Results: 821/852 (96.4%) pts completed Wk 16 and 806 (94.6%) Wk 24. Mean age 48.7 yrs, BMI 29.2 kg/m^2; since diagnosis: 5.9 yrs; 46.8% male. BL characteristics comparable across arms. Primary endpoint met (Wk 16 ACR50: 43.9% BKZ vs 10.0% PBO, p<0.001; ADA: 45.7%; Figure 1). All ranked secondary endpoints met at Wk 16 (Table 1). As early as Wk 2, ACR20 was higher in BKZ vs PBO (27.1% vs 7.8%, nominal p<0.001; ADA: 33.6%). Outcomes continued to improve at Wk 24 (Table 1). To Wk 16, pts with ≥1 TEAE, BKZ: 59.9%; PBO: 49.5%; ADA: 59.3%. SAE rate low (1.6%; 1.1%; 1.4%). Most frequent (≥5%) AEs for all arms: nasopharyngitis (9.3%; 4.6%; 5.0%), URTI (4.9%; 6.4%; 2.1%), increased ALT (0.7%; 0.7%; 5.0%). Candida infections: 2.6%, 0.7%, 0%; no systemic candidiasis. 2 malignancies (BKZ: basal cell carcinoma; PBO: breast cancer stage 1); no MACE, uveitis, IBD or deaths.

Figure. ACR50 and PASI90 response at Wks 16 and 24



Randomised set. Data reported as NRI. *PBO→BKZ pts received PBO to Wk 16, switched to BKZ 160 mg Q4W through Wk 24 (8 wks BKZ).

Abbreviations: ACR20/50/70: ≥20/50/70% improvement in American College of Rheumatology criteria; ADA: adalimumab; AE: adverse event; ALT: alanine aminotransferase; bDMARD: biologic disease -modifying antirheumatic drug; BKZ: bimekizumab; BL: baseline; BMI: body mass index; BSA: body surface area; CfB: change from baseline; HAQ DI: health assessment questionnaire disability index; hs-CRP: high-sensitivity C-reactive protein; IBD: inflammatory bowel disease; IL: interleukin; LDI: Leeds Dactylitis Index; LEI: Leeds Enthesitis Index; MACE: major adverse cardiovascular events; MDA: minimal disease activity; MI: multiple imputation; NRI: non responder imputation; PASI: psoriasis area and severity index; PASI75/90/100: ≥75/90/100% improvement in PASI; PBO: placebo; PsA: psoriatic arthritis; pt: patient; Q2W: every 2 weeks; Q4W: every 4 weeks; RBMI: reference-based multiple imputation; SAE: serious adverse event; SF-36 PCS: 36-item short form survey Physical Component Summary; SJC: swollen joint count; TEAE: treatment-emergent adverse event; TJC: tender joint count; URTI: upper respiratory tract infection; vdHmTSS: van der Heijde modified Total Sharp Score; Wk: week; yr: year.

Conclusion: Dual inhibition of IL-17A and IL-17F with BKZ in bDMARD-naïve pts with active PsA resulted in rapid, clinically relevant improvements in musculoskeletal and skin outcomes vs PBO. No new safety signals observed.[1,2]

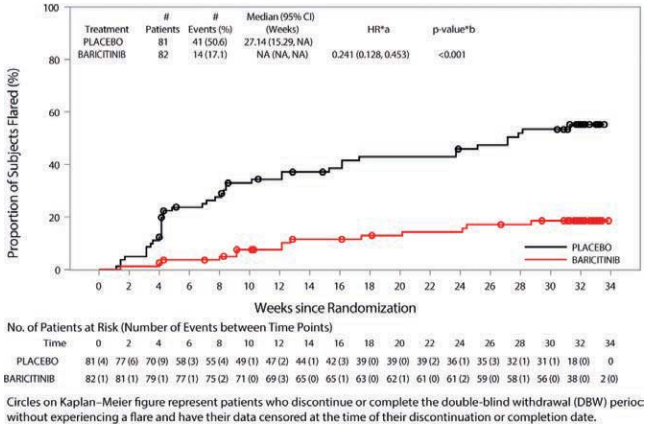
Giannina Gaslini, Senior Scientist for the Paediatric Rheumatology International Trials Organization (PRINTO), Genova, Italy*

Background: Baricitinib is a JAK1/2 selective inhibitor approved for the treatment of rheumatoid arthritis. Juvenile idiopathic arthritis (JIA) is a group of diseases characterized by immune mediated chronic arthritis which often requires treatment with conventional synthetic or biologic disease-modifying antirheumatic drugs (cs or b-DMARDs).

Objectives: To investigate baricitinib efficacy and safety in pediatric patients with JIA and an inadequate response to cs or b-DMARDs.

Methods: This Phase 3 multicenter, double-blind, withdrawal, efficacy, and safety study, enrolled patients (pts) age 2 to <18 years with extended oligo- or poly-articular JIA, ERA, or JPsA, per ILAR criteria, and an inadequate response to ≥1 cs and/or b-DMARDs (NCT03773978). There were 3 periods: a 2-week (wk) pharmacokinetic/safety assessment (PKS), a 12-wk open-label lead-in (OLLI), and an up-to 32-wk double-blind withdrawal (DBW). Dosage and safety were confirmed in the PKS and then pts, including those from the PKS, enrolled in the OLLI, receiving age-based, oral, once daily doses of baricitinib. Pts with a JIA-ACR30 response at wk12, end of OLLI, entered the DBW to be randomized 1:1 to continued baricitinib or newly started placebo (PBO) and remained until flare or up to wk32. Primary endpoint was time to flare during the DBW. Secondary endpoints included JIA-ACR30/50/70/90 response rates at wk12, and proportion of pts with a flare during the DBW. Survival curves were estimated using the Kaplan-Meier method.

Results: Of 220 pts enrolled, 29 participated in the PKS, 219 entered the OLLI, and 163 entered the DBW. The JIA-ACR30/50/70/90 response at wk12 was 76.3%/63.5%/46.1%/20.1%, respectively. During the DBW, time of flare was significantly shorter with PBO vs baricitinib (hazard ratio 0.24 [95% CI 0.13,0.45], p<0.001; Figure 1). The proportion of pts with a flare during the DBW was significantly lower for baricitinib vs PBO (14 (17.1%) vs. 41 (50.6%), p<0.001). In the PKS and OLLI periods, 126 (57.3%) pts reported ≥1 treatment emergent adverse event (TEAE), while 6 (2.7%) reported ≥1 serious adverse event (SAE); Table 1. In the DBW, 38 (46.9%) and 54 (65.9%) pts reported ≥1 TEAE for PBO and baricitinib, respectively, whereas those with ≥1 SAE were 3 (3.7%) and 4 (4.9%). The mean wks of exposure was higher in the baricitinib vs PBO group during DBW (26.34 vs 18.91) due to study design. There were no deaths, cardiovascular events or uveitis and 1 case of herpes zoster.



Circles on Kaplan–Meier figure represent patients who discontinue or complete the double-blind withdrawal (DBW) period without experiencing a flare and have their data censored at the time of their discontinuation or completion date.

Table 1. Safety data

Events, N (%)		PKS and OLLI (N=220)	Events, N (%)	DBW Placebo (N=81)	DBW Baricitinib (N=82)
Discontinuations due to AEs		2 (0.9)		2 (2.5)	1 (1.2)
TEAEs		126 (57.3)		38 (46.9)	54 (65.9)
most common TEAEs	Nasopharyngitis	19 (8.6)	URTI	1 (1.2)	9 (11.0)
	Headache	14 (6.4)	Headache	3 (3.7)	9 (11.0)
	Arthralgia	12 (5.5)	Nasopharyngitis	3 (3.7)	6 (7.3)
	URTI	11 (5.0)	Arthralgia	3 (3.7)	6 (7.3)
	Nausea	11 (5.0)	Oropharyngeal pain	1 (1.2)	5 (6.1)
SAEs		6 (2.7)		3 (3.7)	4 (4.9)
All reported SAEs	Arthralgia	1 (0.5)	COVID-19	0	1 (1.2)
	Joint Destruction	1 (0.5)	Gastroenteritis	0	1 (1.2)
	Joint Effusion	1 (0.5)	Headache	0	1 (1.2)
	JIA	1 (0.5)	Pulmonary Embolism	0	1 (1.2)
	Musculoskeletal Chest Pain	1 (0.5)	Bronchospasm	1 (1.2)	0
	Decreased Appetite	1 (0.5)	JIA	1 (1.2)	0
			Suicide Attempt	1 (1.2)	0
Potential opportunistic infections		2 (0.9)		1 (1.2)	1 (1.2)
	Herpes virus	1 (0.5)	Herpes virus	1 (1.2)	0
	Herpes zoster	1 (0.5)	Candida	0	1 (1.2)

URTI= Upper Respiratory Tract Infection

Conclusion: Baricitinib significantly reduced time to and frequency of JIA flares in pts with JIA versus PBO, and improved JIA-ACR scores in the majority of pts within 12wks. Safety findings were consistent with the known safety profile in adult rheumatoid arthritis indications. These findings support baricitinib as a treatment for signs and symptoms of JIA with an inadequate response to cs or b-DMARDs.

WITHDRAWING METHOTREXATE AFTER BOTH VERSUS ONLY SECOND DOSE OF THE CHADOX1 NCOV-19 VACCINE IN PATIENTS WITH AUTOIMMUNE INFLAMMATORY ARTHRITIS: TWO INDEPENDENT RANDOMIZED CONTROLLED TRIALS (MIVAC I AND II)

A. Sreekanth[1], T. Skaria[2], S. Joseph[2], R. Umesh[1], M. Mohanan[2], A. Paul[2], S. Ahmed[3], P. Mehta[4], S. Oomen[2], J. Benny[2], J. George[2], A. Paulose[2], K Narayanan[1 2], S. Joseph[1 2], A. Vijayan[1 2], K. Nalianda[1 2], P. Shenoy[1 2]. *[1]Sree Sudheendra Medical Mission, Kochi, Kerala, India, Rheumatology, Kochi, India*; *[2]Centre for Arthritis and Rheumatism Excellence (CARE), Kochi, Kerala, India, Rheumatology, Kochi, India*; *[3]Clinical Immunology & Rheumatology, Kalinga Institute of Medical Sciences, Bhubaneswar, Odisha, India, Rheumatology, Odisha, India*; *[4]Clinical Immunology and Rheumatology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India, Rheumatology, Lucknow, India*

Background: Pausing methotrexate (MTX) for two to four weeks, improved immunogenicity of influenza vaccination in patients with rheumatoid arthritis (RA), albeit a risk of disease flare (1). This guided the framing of guidelines on MTX withdrawal for COVID-19 vaccination (2). However, evidence for MTX withdrawal for COVID-19 vaccination is limited to observational studies only.

Objectives: To compare the efficacy and safety of holding MTX after each (MIVAC 1) and only after the second dose (MIVAC II) of the ChAdOx1 vaccine versus continuation of MTX in two randomized controlled trials (RCTs).

Methods: Two single centre, investigator-blinded, RCTs were conducted in patients with RA or Psoriatic arthritis (PsA) on stable doses of MTX without prior COVID-19 (CTRI reg. no. MIVAC I: CTRI/2021/07/03463 & MIVAC II: CTRI/2021/07/035307). In MIVAC I, unvaccinated patients were randomised (1:1) to hold or continue MTX for two weeks after each dose of the vaccine. MIVAC II included patients who had continued MTX during the first dose of ChAdOx1 and were randomised (1:1) to hold or continue MTX for 2 weeks after the second vaccine dose. The primary outcome for both the trials was the anti-Receptor Binding Domain (RBD) antibody titres measured four weeks after the second vaccine dose (per protocol analysis). Secondary outcome was the flare rate, defined as an increase in disease activity scores (DAS28/cDAPSA) or physician intent to hike DMARDs.

Results: 250 patients were randomized for MIVAC 1 and 178 for MIVAC II and after due exclusions, 158 and 157 were eligible for analysis respectively (Figure 1). In MIVAC I, median anti-RBD titres were significantly high in the MTX hold group [2484 (1050-4388) versus 1147(433-2360), p=0.001] but the flare rate was higher in the hold group [20 (25%) versus 6(8%) p=0.005] compared to continue group. In MIVAC II median anti-RBD titres were significantly high for the MTX hold group [2553 (1792-4823) versus 990 (356-2252), p=0.001] when compared to continue group but there was no difference in the flare rate between the groups [9(11.8%) and 4(7.9%), p=0.15] (Table 1). Since both were parallel studies in similar population, MTX hold arms across both the trials were compared for anti-RBD titres and flare. There was no difference in the anti-RBD titres [p=0.2] between the groups. In MIVAC I, 29(36.25%) patients had reported flare (19 in either first or second dose, 10 for both doses) when compared to MIVAC II where only 9(11.84%) patients had reported flare after the second dose (P <0.001).

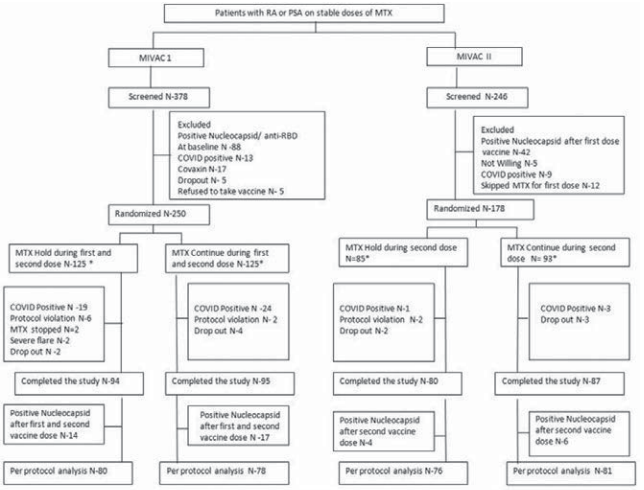

Figure 1 .Trial design *the interval between two ChadOx1 vaccines were 3 months

Conclusion: Holding MTX after both the doses or only after the second dose of ChAdOx1 yields higher anti-RBD antibody titres as compared to continuing MTX. Comparing across the trials, holding MTX only after the second dose appears to be non-inferior to holding MTX after both doses of the vaccine with a lesser risk of flare.

Background: Tyrosine kinase 2 (TYK2) mediates signaling of Type I interferons, IL-23, and IL-12, key cytokines involved in lupus pathogenesis. Deucravacitinib (DEUC) is an oral, selective, allosteric TYK2 inhibitor with a unique mechanism of action, distinct from Janus kinase (JAK) 1/2/3 inhibitors, and has shown efficacy in psoriasis and psoriatic arthritis.

Objectives: Assess efficacy and safety of DEUC in patients with active systemic lupus erythematosus (SLE).

Methods: This was a 48-week (wk), randomized, double-blind, placebo (PBO)-controlled, phase 2 trial (NCT03252587). Eligible patients met SLICC criteria, were seropositive (ANA/anti-dsDNA/anti-Sm), and had a SLEDAI-2K score ≥6 and ≥1 BILAG index A or >2 BILAG B manifestations from the musculoskeletal or mucocutaneous domain. Patients on standard background medications were randomized 1:1:1:1 to PBO or DEUC (3 mg BID, 6 mg BID, 12 mg QD). Oral corticosteroid tapering to 7.5 mg/day was required from wks 8-20; further tapering was optional from wks 32-40. The primary endpoint was the proportion of patients achieving SRI(4) at wk 32. Key secondary endpoints at wk 48 included SRI(4), BICLA, LLDAS, CLASI-50, and change from baseline in active (tender and swollen) joint count.

Results: A total of 363 patients were randomized, with baseline demographic and disease characteristics similar across treatment groups. Of randomized patients, 275 (76%) completed 48 wks of treatment. The primary endpoint at wk 32 was met, with significantly greater proportion of patients in DEUC 3 mg BID and 6 mg BID groups vs PBO achieving SRI(4) responses (PBO: 34.4%; DEUC 3 mg BID: 58.2%, *P*=0.0006; DEUC 6 mg BID: 49.5%, *P*=0.021; DEUC 12 mg QD: 44.9%, *P*=0.078). SRI(4) response was sustained across all DEUC groups up to 48 wks (Figure 1). At wk 48, the DEUC 3 mg BID group demonstrated statistical significance in BICLA, LLDAS, CLASI-50, and active joint count, and the two other DEUC groups demonstrated clinically meaningful differences vs PBO (Figure 1). Rates of adverse events (AEs), serious AEs, and AEs of interest were similar between DEUC and PBO groups (Table 1). Most common AEs (≥10%) with DEUC were upper respiratory tract infection, nasopharyngitis, headache, and urinary tract infection. No deaths, major cardiac events, thrombotic events, systemic opportunistic infections, or active tuberculosis occurred. Malignancies were rare with similar rates across all groups. No meaningful abnormalities in mean levels of hematology and chemistry laboratory parameters were observed.

Figure. Summary of key efficacy results

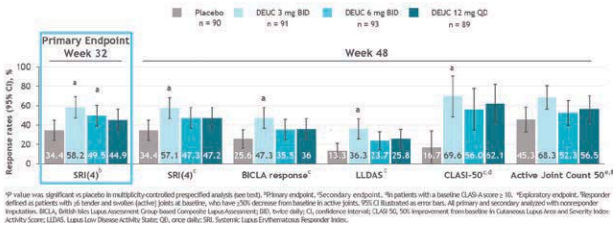

Table 1. Summary of Adverse Events Through Week 48

AE, n[a] (%)	Placebo n = 90	DEUC 3 mg BID n = 91	DEUC 6 mg BID n = 93	DEUC 12 mg QD n = 89
AE	79 (87.8)	85 (93.4)	81 (87.1)	75 (84.3)
SAE	11 (12.2)	7 (7.7)	8 (8.6)	7 (7.9)
AEs leading to treatment discontinuation	3 (3.3)	8 (8.8)	6 (6.5)	11 (12.4)
Skin-related AEs[b]	12 (13.3)	15 (16.5)	32 (34.4)	30 (33.7)
Overall infections/ infestations	48 (53.3)	60 (65.9)	60 (64.5)	45 (50.6)
Serious infections/ infestations	1 (1.1)	1 (1.1)	2 (2.2)	1 (1.1)
Infections of interest				
Tuberculosis	0	0	0	0
Herpes zoster[c]	4 (4.4)	3 (3.3)	3 (3.2)	2 (2.2)
Influenza	1 (1.1)	3 (3.3)	1 (1.1)	3 (3.4)
COVID-19	3 (3.3)	3 (3.3)	5 (5.4)	3 (3.4)
Malignancy events	1 (1.1)[d]	1 (1.1)[e]	0	1 (1.1)[f]
MACE	0	0	0	0
Thrombotic events	0	0	0	0

[a]n is the number of patients who experienced an event. [b]Includes (≤8.6% in any arm) acne, rash, dermatitis acneiform, pruritus, skin lesion, urticaria. [c]Includes herpes zoster, herpes ophthalmic, genital herpes zoster. [d]Basal cell carcinoma. [e]Breast carcinoma. [f]Vaginal squamous cell carcinoma. AE, adverse event; COVID-19, coronavirus disease 2019; DEUC, deucravacitinib; MACE, major adverse cardiac events; SAE, serious adverse event.

Conclusion: In patients with active SLE, DEUC showed statistically significant and sustained clinical efficacy in SRI(4), improvement across multiple composite and organ-specific measures up to 48 wks, and was well tolerated. DEUC shows promise as a novel therapy for SLE and warrants further investigation in phase 3 trials.

Background: Orelabrutinib is an oral, highly-selective, irreversible inhibitor of Bruton's tyrosine kinase (BTK). Orelabrutinib has been approved for the treatment of B cell malignancies in China. Two distinct lupus animal models showed significant efficacy of orelabrutinib in reducing disease activity, which supported the clinical development of orelabrutinib in Systemic Lupus Erythematosus (SLE).
Objectives: This phase Ib/IIa, randomized, double-blind, placebo-controlled, dose-finding study aimed to evaluate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), preliminary efficacy and biomarkers of orelabrutinib in patients with mild to moderate SLE who received standard of care (SoC) therapy.
Methods: Patients diagnosed with SLE by the ACR classification criteria for ≥ 6 months, who had a SLEDAI-2K score ≥5 at screening, and were autoantibody-positive, were randomized 1:1:1:1 to receive oral orelabrutinib at 50mg, 80mg, 100mg or placebo once daily for 12 weeks, respectively.
Results: This study randomized 60 patients with 55 patients who completed 12-week treatment. Age at baseline was 33.7±9.8 years and 96.7% were female. Baseline disease characteristics were generally balanced across treatment groups. Adverse events (AEs) were reported in 80%, 93.3% and 100% of orelabrutinib treated patients at doses of 50mg, 80mg and 100mg QD respectively versus 85.5% in placebo group. AEs were mostly mild or moderate. Treatment-related SAEs were reported in 3 patients treated with orelabrutinib, only 1 of which was grade 3. No deaths were reported. The plasma exposure of orelabrutinib (AUC and Cmax) was proportionally increased with doses. Nearly complete BTK occupancy was achieved at all dose levels, and the occupancy lasted for 24 hours without any decrease compared to that at 4 hour post-dosing. In all evaluable patients, the SLE Response Index (SRI)-4 response rates at week 12 were 50.0%, 61.5% and 64.3% in patients treated with orelabrutinib at 50mg (n=14), 80mg (n=13) and 100mg (n=14) respectively, compared with 35.7% in patients treated with placebo (n=14), which indicated the trend of dose-dependent improvement. Among the subgroup of patients with SLEDAI-2K≥8 at screening, SRI-4 response occurred in 70%, 70% and 66.7% of patients treated with orelabrutinib at 50mg (n=10), 80mg (n=10) and 100mg (n=9), respectively, compared with 30% who received placebo (n=10). Trends of reduced proteinuria, anti-dsDNA and IgG, total B cells and increased complements C4 were also observed following orelabrutinib treatment.
Conclusion: Orelabrutinib was generally safe and well tolerated in patients with SLE. Preliminary results also suggested encouraging efficacy which supports further development of orelabrutinib in larger and longer trials for SLE.

Table 1. Efficacy results at week 12.

	Placebo	Orelabrutinib	Orelabrutinib	Orelabrutinib
All Evaluable Patients		**50 mg**	**80 mg**	**100 mg**
N=55	14	14	13	14
SRI-4 response, n (%)	5 (35.7%)	7 (50.0%)	8 (61.5%)	9 (64.3%)
Treatment difference vs. PBO (%)		14.3%	25.8%	28.6%
SLEDAI-2K≥8, N=39	10	10	10	9
SRI-4 response, n (%)	3 (30.0%)	7 (70.0%)	7 (70.0%)	6 (66.7%)
Treatment difference vs. PBO (%)		40.0%	40.0%	36.7%

Note: All evaluable patients at week 12 efficacy data were included in the efficacy analysis.

Background: Interleukin-6 (IL-6) is elevated in patients with active polymyalgia rheumatica (PMR) and is associated with disease activity, relapse and severity. Clinical trials with IL-6 receptor (IL-6R) inhibitors in PMR showed higher remission rates and reduced glucocorticoid (GC) use vs GC alone.[1-4]
Objectives: The SAPHYR study (NCT03600818) assessed the efficacy and safety of sarilumab (SAR), a fully human anti IL-6Rα monoclonal antibody, with a 14 week (wk) GC taper in patients with steroid resistant active PMR who flared on ≥7.5 mg/day prednisone or equivalent.
Methods: Patients were randomized (1:1) to 52 wks of treatment with SAR 200 mg every 2 wks (Q2W) + 14 wk GC tapered regimen (SAR arm) OR placebo Q2W + 52 wk GC tapered regimen (comparator arm). The primary endpoint was the proportion of patients achieving sustained remission at wk 52, defined as disease remission by wk 12, absence of disease flare, CRP normalization from wks 12 to 52 and adherence to the per protocol GC taper from wks 12 to 52.
Results: The study was terminated early due to protracted recruitment timelines during the COVID-19 pandemic, resulting in 118 of the intended 280 patients recruited between Oct 2018 and Jul 2020, and 117 were treated (SAR n=59, comparator n=58). The demographics were balanced; patients were primarily female, Caucasian, and a median age of ~70 years (Table 1). Overall, 78 patients completed the treatment (SAR n=42; comparator n=36). Primary reasons for treatment discontinuation were adverse events (AEs; SAR n=7, comparator n=4) and lack of efficacy (SAR n=4, comparator n=9). Sustained remission rate was significantly higher in the SAR arm vs the comparator arm (28.3% vs 10.3%; P=0.0193). Results of a sensitivity analysis excluding CRP from the sustained remission definition was consistent with the primary analysis (31.7% vs 13.8%; P=0.0280). All sustained remission components favored SAR (Figure 1). Patients in the SAR arm were 44% less likely to have a flare after

achieving clinical remission vs the comparator arm (16.7% vs 29.3%; HR 0.56; 95% CI 0.35–0.90; P=0.0158). The comparator arm required more additional GCs vs the SAR arm, mainly due to PMR flare (median difference in actual and expected cumulative dose 199.5 mg vs 0.0 mg; P=0.0189). The cumulative GC toxicity index scores numerically favored SAR but the difference was not statistically significant. PMR activity scores improved in the SAR arm vs the comparator arm (LS mean -15.57 vs -10.27, nominal P=0.0002). Patient reported outcomes (eg, physical and mental health component scores, disability index, etc) favored SAR (Figure 1). Incidence of treatment-emergent AEs (TEAEs) was numerically higher in the SAR arm vs the comparator arm (94.9% vs 84.5%) and included neutropenia (15.3%) and arthralgia (15.3%) in the SAR arm, and insomnia (15.5%) in the comparator arm. Conversely, the frequency of serious AEs was higher in the comparator arm vs the SAR arm (20.7% vs 13.6%). No deaths were reported.

Table 1. Demographics and baseline characteristics

Parameter	SAR + 14 wk GC taper (n=60)	Placebo + 52 wk GC taper (n=58)
Age, median years (range)	69 (51–88)	70 (52–88)
Sex (female), n (%)	45 (75.0)	37 (63.8)
Race, n (%)		
Caucasian	50 (83.3)	48 (82.8)
Asian	1 (1.7)	2 (3.4)
Not reported	9 (15.0)	8 (13.8)
PMR duration (diagnosis date to baseline),* median days (range)	292 (78–3992)	310 (66–2784)
Any prior disease modifying anti rheumatic drugs, n (%)		
Methotrexate	5 (8.3)	10 (17.2)
Leflunomide	2 (3.3)	1 (1.7)
Azathioprine	0	1 (1.7)
Hydroxychloroquine	1 (1.7)	1 (1.7)
Adalimumab	1 (1.7)	0
Tocilizumab	0	1 (1.7)
CRP (mg/L), median (range)	6.8 (0.5–38.2)	5.7 (0.1–62.3)
Erythrocyte sedimentation rate (mm/h), median (range)	25.0 (2.0–115.0)	22.0 (5.0–85.0)

*SAR n = 54; comparator n= 50.

Conclusion: SAR + 14 wk GC taper demonstrated significant efficacy vs the comparator arm in steroid refractory PMR patients, including clinically meaningful improvement in quality of life. Safety was consistent with the known safety profile of SAR.

Background: In axial spondyloarthritis (axSpA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is a key patient-reported outcome. However, one or more of its components may be missing when recorded in clinical practice.
Objectives: To determine whether an individual patient's BASDAI at a given timepoint can be reliably calculated with different single imputation techniques and to explore the impact of the number of missing components and/or differences between missingness of individual components.
Methods: Real-life data from axSpA patients receiving tumour necrosis factor inhibitors (TNFi) from 13 countries in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were utilized [1]. We studied missingness in BASDAI components based on simulations in a complete dataset, where we applied and expanded the approach of Ramiro et al. [2]. After introducing one or more missing components completely at random, BASDAI was calculated from the available components and with three different single imputation techniques: possible middle value (i.e. 50) of the component and mean and median of the available components. Differences between the observed (original) and calculated scores were assessed and correct classification of patients as having BASDAI<40 mm was additionally evaluated. For the setting with one missing component, differences arising between missing one of components 1-4 versus 5-6 were explored. Finally, the performance of imputations in relation to the values of the original score was investigated.
Results: A total of 19,894 axSpA patients with at least one complete BASDAI registration at any timepoint were included. 59,126 complete BASDAI registrations were utilized for the analyses with a mean BASDAI of 38.5 (standard deviation 25.9). Calculating BASDAI from the available components and imputing with mean or median showed similar levels of agreement (Table 1). When allowing one missing component, >90% had a difference of ≤6.9 mm between the original and calculated scores and >95% were correctly classified as BASDAI<40 (Table 1). However, separate analyses of components 1-4 and 5-6 as a function of the BASDAI score suggested that imputing any one of the first four BASDAI components resulted in a level of agreement <90% for specific BASDAI values while imputing one of the stiffness components 5-6 always reached a level of agreement >90% (Figure 1, upper panels). As expected, it was observed that regardless of the BASDAI component set to missing and the imputation technique used, correct classification of patients as BASDAI<40 was less than 95% for values around the cutoff (Figure 1, lower panels).

Table 1. Level of agreement between the original and calculated BASDAI and correct classification for BASDAI<40 mm

		Level of agreement with Dif≤6.9 mm* (%)	Correct classification for BASDAI<40 mm** (%)
1 missing component	**Available**	93.9	96.9
	Value 50	73.9	96.3
	Mean	94.2	96.8
	Median	93.1	96.8
2 missing components	**Available**	83.7	94.8
	Value 50	40.7	92.8
	Mean	83.5	94.8
	Median	82.8	94.7
3 missing components	**Available**	71.9	92.6
	Value 50	28.1	87.3
	Mean	72.2	92.6
	Median	69.7	92.2

* The levels of agreement with a difference (Dif) of ≤6.9 mm between the original and calculated scores were based on the half of the smallest detectable change. Agreement of >90% was considered as acceptable. ** Correct classification of >95% was considered as acceptable.

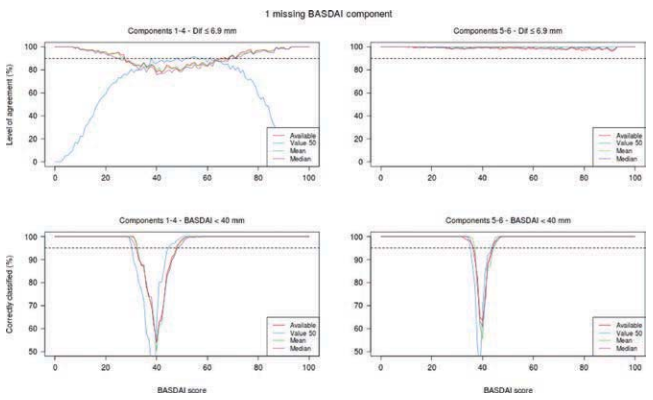

Figure 1. Level of agreement between the original and calculated BASDAI and correct classification for BASDAI<40 mm as a function of the original score

Conclusion: BASDAI calculation with available components gave similar results to single imputation of missing components with mean or median. Only when missing one of BASDAI components 5 or 6, single imputation techniques can reliably calculate individual BASDAI scores. However, missing any single component value results in misclassification of patients with original BASDAI scores close to 40.

POS0002

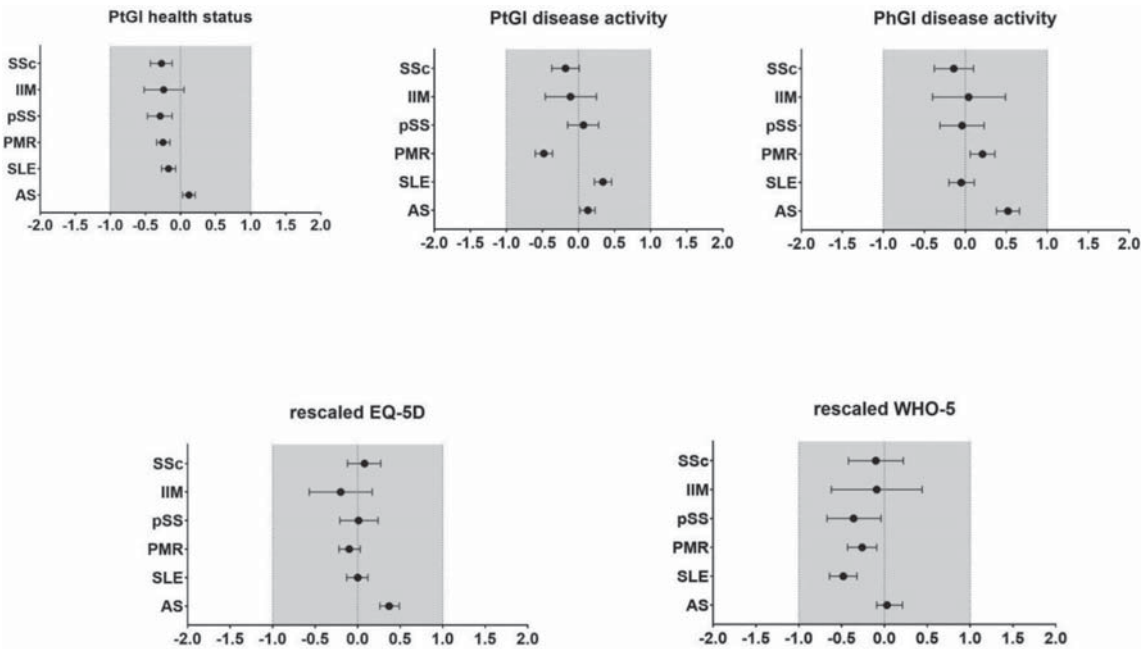
IS THE RHEUMATOID ARTHRITIS IMPACT OF DISEASE SCORE (RAID) AN INFORMATIVE INSTRUMENT FOR OTHER INFLAMMATORY RHEUMATIC DISEASES?

K. Thiele[1], K. Albrecht[1], A. Zink[1], M. Aringer[2], K. Karberg[3], S. Spaethling-Mestekemper[4], U. Von Hinueber[5], J. Callhoff[1]. *[1]German Rheumatism Research Centre Berlin (DRFZ), Epidemiology and Health Care Research, Berlin, Germany; [2]University Medical Center and Faculty of Medicine TU Dresden, Rheumatology, Medicine III, Dresden, Germany; [3]Rheumatologist, -, Berlin, Germany; [4]Rheumatologist, -, München, Germany; [5]Rheumatologist, -, Hildesheim, Germany*

Background: The rheumatoid arthritis impact of disease score (RAID) is a patient-reported outcome measure to evaluate the impact of rheumatoid arthritis (RA) on patients' quality of life (1). While an adapted instrument has been developed for psoriatic arthritis (2), there are no comparable instruments for other inflammatory rheumatic diseases. Since the RAID includes generic questions on pain, functional capacity, fatigue, physical and emotional well-being, sleep disturbances and coping, it could be an informative instrument beyond RA.

Objectives: To analyse the performance of the RAID in ankylosing spondylitis (AS), systemic lupus erythematosus (SLE), polymyalgia rheumatica (PMR), primary Sjögren's syndrome (pSS), idiopathic inflammatory myositis (IIM), and systemic sclerosis (SSc) compared to RA.

Methods: From 2015 to 2019, a total of 12,398 patients reported the RAID in the National Database of the German Collaborative Arthritis Centres. We calculated the age- and sex-adjusted partial correlation (0.3-0.5 weak, 0.5-0.7 moderate, > 0.7 strong correlation) between the RAID score and five other patient- or physician-reported outcomes, namely patient global (PtGl) health status, PtGl disease activity, physician global (PhGl) disease activity, the World Health Organisation Well-Being Index (WHO-5) and the EuroQoL-5 Dimensions (EQ-5D). Furthermore, for each of the diagnoses the mean difference between the RAID and the other outcomes was compared with the respective differences for RA. The EQ-5D and WHO-5 were rescaled to match the scale of the



Linear regression model: The dependent variable is the difference between RAID score and five respective outcomes. Independent variables were sex, age and diagnosis with RA as the referent category. An effect of a diagnosis was defined as clinically relevant if the mean change of difference was at least one unit.
Abbr.: PtGl, Patient Global; PhGl, Physician Global; EuroQoL-5 Dimensions (EQ-5D); World Health Organisation Well-Being Index (WHO-5)

RAID (range 0-10). General linear regression was used to assess the age- and sex-adjusted effect of each diagnosis on the difference between the RAID and the five other scores with RA as the referent diagnosis. We defined the effect of a diagnosis as clinically relevant if the mean change of difference was at least one unit.

Results: The mean RAID score in RA (3.6) was lower than in AS (4.0) and SSc (3.8) and higher than in SLE, PMR, pSS or IIM (Table 1). Across all diagnoses, the RAID correlated strongly with PtGl health status (0.72 to 0.83), moderately to strongly with PtGl disease activity (0.55 to 0.78) and WHO-5 (0.67 to 0.83), moderately with the EQ-5D (0.61 to 0.68), and weakly with PhGl disease activity (0.25 to 0.41). Small mean differences were found between the RAID and either PtGl disease activity (0 to -0.6), PtGl health status (-0.4 to -0.9) or WHO-5 (-0.7 to -1.3). A higher deviation was observed for EQ-5D (1.1 to 1.7) and PhGl disease activity (1.4 to 2.2). However, the discrepancies between the five outcomes and the RAID turned out to be similar across all diagnoses and, more importantly, comparable to RA. Linear regression revealed no clinically relevant effect of any of the diagnoses on the difference between RAID and the other outcomes (Figure 1).

Conclusion: The RAID score performed comparably well across all diagnoses investigated. These findings support the use of the RAID for measuring the impact of disease not only in RA, but also in AS, SLE, PMR, pSS, IIM and SSc.

POS0003 DEVELOPMENT AND VALIDATION OF A DISEASE SPECIFIC PATIENT REPORTED OUTCOME FOR GIANT CELL ARTERITIS

J. Robson[1,2], C. Almeida[1], J. Dawson[3], E. Dures[1], R. Greenwood[2], C. Guly[2], S. Mackie[4,5], A. Bromhead[2], S. Stern[2], M. Ndosi[1]. *[1]University of the West of England - UWE Bristol, Health and Social Wellbeing, Stoke Gifford, United Kingdom; [2]University Hospitals Bristol and Weston NHS Foundation Trust, Bristol Royal Infirmary, Bristol, United Kingdom; [3]University of Oxford, Old Road Campus, Department of Public Health, Oxford, United Kingdom; [4]University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [5]Leeds General Infirmary, Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Giant cell arteritis (GCA) is caused by inflammation of the blood vessels of the head and neck; patients can present with cranial, ocular or large vessel vasculitis involvement. Treatment is with glucocorticoids, steroid sparing agents and biologics to control inflammation and protect sight.

Objectives: The aim of this study was to produce a validated disease specific PROM for patients with GCA, to capture the impact of GCA and its treatment on health-related quality of life.

Methods: Patients with clinician- confirmed GCA from the UK, either diagnosed in the last three years or with a flare in the last year, were included in the survey. A longlist of 40 candidate questionnaire items, each with a 5-point Likert scale, had previously been developed, based on a qualitative study with patients from the UK and Australia [1]. In this cross-sectional survey, patients completed the 40-item draft GCA-PROM alongside EQ5D-5L, CAT-PRO5 and self-report of GCA disease activity. Rasch and factor analysis were used in an iterative manner to determine the underlying construct validity of the new PROM. Items were fitted to the Rasch model to determine its construct validity, reliability, unidimensionality and statistical sufficiency of the total score from the scale. Factor analysis was used to establishing factor structure. Item reduction decisions were be based on clinical importance, lack of fit to the Rasch model, and redundancy detected during principal component analysis. External validity was tested by comparing the scores of the newly validated GCA-PROM (i) in participants who self-identify as having 'active disease' versus patients 'in remission' (known groups validity) (ii) with scores derived from EQ5D-5L and CAT-PRO5 (convergent validity).

Results: The survey included 428 patients; 327 (76%) cranial GCA, 114 (26.6%) large vessel vasculitis and 142 (33.2%) ocular involvement. 285 (67%) of participants were female with a mean age (SD) of 74.2 (7.2). 167 (39%) temporal artery biopsies and 177 (41.4%) temporal artery ultrasounds, and 51 (11.9%) Positron Emission Tomography and Computed Tomography (PET-CT)s were reported as positive. 108 (25%) received second-line immunosuppressants, and 34 (7.9%) anti-IL6 therapy. Active disease was reported in 197 (46%). Four factors (domains) were identified after deletion of 10 redundant items: Acute symptoms (8 items), Activities of daily living (7 items), Psychological (7 items) and Participation (8 items). The four domains were analysed as 'super-items' and shown to fit the Rasch model. The overall scale had an adequate fit to the Rasch model: X^2 = 25.219, DF=24, p=0.394 including reliability PSI=0.828. The raw-to-linear transformation scale was calibrated to enable parametric analyses if desired. Each domain was shown to have known-groups validity (p<0.001 patients reporting active versus inactive disease) and correlation with EQ5D-5L and CAT-PRO5 (Rs) ranging between 0.4.42 and 0.778.

Conclusion: The GCA-PROM is a new patient reported outcome measure for patients with GCA which demonstrates good internal and external validity.

POS0004 WHAT DOES WORSENING IN DAPSA DISEASE ACTIVITY CATEGORIES MEAN FOR PATIENTS WITH PSORIATIC ARTHRITIS? AN ANALYSIS OF 222 PATIENTS

M. Sousa[1], J. S. Smolen[1], C. Gorlier[1], M. de Wit[1], L. Coates[1], U. Kalyoncu[1], A. Ruyssen-Witrand[1], K. Leung[1], R. Scrivo[1], J. d. D. Cañete[1], P. Palominos[1], S. Meisalu[1], A. Balanescu[1], U. Kiltz[1], S. Aydin[1], I. Gaydukova[1], E. Dernis[1], B. Fautrel[1], A. M. Orbai[1], E. Lubrano[1], L. Gossec[1]on behalf of the ReFlaP Study Group. *[1]Paris, ReFlap Study Group, Paris, France*

Background: In psoriatic arthritis (PsA), disease activity states have been defined using the DAPSA (Disease Activity index for Psoriatic Arthritis) score (1). The disease activity states have been validated using structural progression as the gold standard (2). However, the worsening in DAPSA states has not been compared to the patient's perspective.
Objectives: To assess the association between a worsening in disease activity (i.e., change in DAPSA disease activity category) versus the patient's judgement of disease worsening.
Methods: ReFlap (NCT03119805) was a longitudinal study in 14 countries of consecutive adult patients with definite PsA and more than 2 years of disease duration. Patients were seen twice in the context of usual care, around 4 months apart (3). Worsening in disease activity between the 2 visits was defined as a transition to a more active disease category, based on the DAPSA categories [(remission, low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA)] (1).This change was compared to (a) patient perceived-flares collected according to a patient-reported question: "At this time, are you having a flare of your psoriatic arthritis, if this means the symptoms are worse than usual?"; and (b) a worsening according to the MCID (Minimal Clinical Important Difference) question. The agreement between the definitions of worsening were calculated by frequency, Cohen's kappa and prevalence adjusted bias adjusted kappa (PABAK). There was no imputation of missing data.
Results: Overall, 222 patients were analyzed: 127 (58.8%) were male, aged 53.5±12.3 years and with 10.8±8.3 years of disease duration. Disease activity was moderate: 35.9% had no current psoriasis skin lesions, mean tender joint count (TJC, 0-68) was 3.0±7.5, mean swollen joint count (SJC, 0-66) was 1.6±6.6, and mean DAPSA was 11.5±14.0.
At 4.5±2.2 months follow-up, the proportion of DAPSA worsening was 40.1% [95% confidence interval, 33.9-46.7] (n=89). Most of the changes corresponded to patients going from remission to LDA (N=24, 27.0% of worsened patients) or from LDA to MDA (N=24, 27.0%).
Patient-reported flares were reported in 27.0% [21.6-33.2] (n=60), and MCID worsening was reported in 14.0% [33.9-46.5] (n=31).
Figure 1 shows the distribution of patients with worsening in DAPSA category, versus patient-defined worsening. Of the 89 patients who worsened according to DAPSA categories, 41 (46.1%) had self-perceived flares and 20 (22.5%) had worsening according to MCID. Among patients who worsened in DAPSA category, the mean change in DAPSA was higher in patients with self-perceived flares (increase of 22.2±15.0) than in patients without self-perceived flares (increase of 14.3±12.3). Of 133 patients with no worsening according to DAPSA, 114 (85.7%) had no self-perceived flares and 122 (91.7%) had no MCID worsening. The kappa [95% confidence interval] (PABAK) coefficients between DAPSA and either patient flare or MCID worsening were 0.34 [0.21-0.46] (0.40) and 0.16 [0.05-0.27] (0.28), respectively.

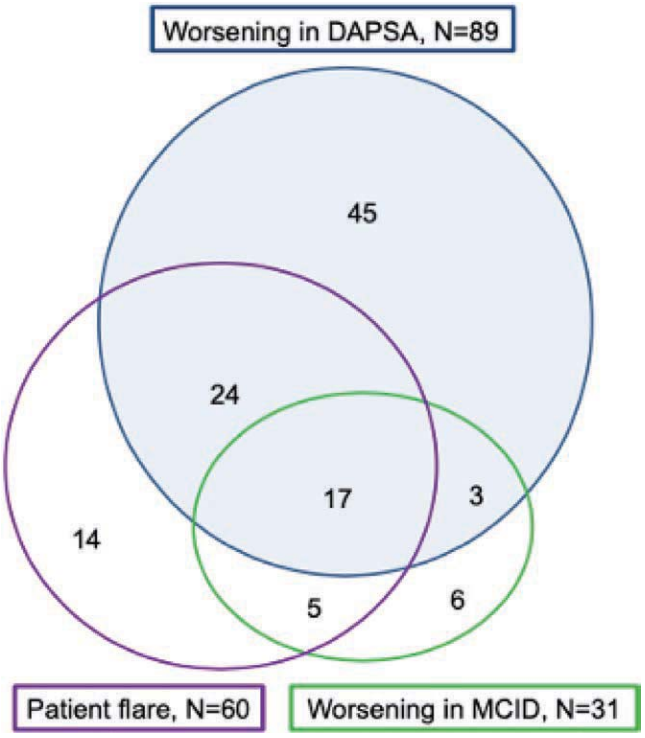

Figure 1. Venn diagram for disease worsening between 2 visits

Conclusion: After 4 months of follow-up, 40.1% patients with long-standing PsA had a change in DAPSA category corresponding to more active disease. Most of these changes reflected transitions from remission to LDA, or from LDA to MDA. Among patients changing DAPSA category, only 46.1% reported themselves in flare at the second visit and only 22.5% reported themselves as worsened by MCID, leading to only fair (for flares) to low (for MCID worsening) agreement between the assessments of worsening. It is important to assess both disease activity, and the patient's perspective of flare.

BASELINE BIOMARKERS PREDICT BETTER RESPONSES TO DEUCRAVACITINIB, AN ORAL, SELECTIVE TYROSINE KINASE 2 (TYK2) INHIBITOR, IN A PHASE 2 TRIAL IN PSORIATIC ARTHRITIS

O. Fitzgerald[1], D. D. Gladman[2], P. J. Mease[3], C. T. Ritchlin[4], J. S. Smolen[5], L. Gao[6], S. Hu[7], M. Nowak[8], S. Banerjee[9], I. Catlett[10]. *[1]Conway Institute, University College Dublin (UCD), Rheumatology, Dublin, Ireland; [2]University of Toronto, Rheumatology, Toronto, Canada; [3]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; [4]University of Rochester Medical Center, Allergy, Immunology, and Rheumatology, Rochester, United States of America; [5]Medical University of Vienna, Rheumatology, Wien, Austria; [6]Bristol Myers Squibb, Immuno-Science and Small Molecule, Princeton, United States of America; [7]Bristol Myers Squibb, Bioinformatics, Princeton, United States of America; [8]Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; [9]Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America; [10]Bristol Myers Squibb, Dermatology, Princeton, United States of America*

Background: Deucravacitinib (DEUC) is a novel, oral, selective TYK2 inhibitor with a unique allosteric mechanism of action that has demonstrated efficacy in patients with psoriasis (PsO)[1] and psoriatic arthritis (PsA).[2] TYK2 mediates signalling of select immune cytokines, eg, interleukin (IL) 23, IL-12, and Type I interferons, whereas the related Janus kinases (JAK) 1/2/3 mediate signalling of a wider array of cytokines and mediators involved in inflammatory, developmental, metabolic, and hematopoietic pathways. DEUC reduced inflammatory markers associated with skin and joint manifestations but did not result in laboratory abnormalities associated with inhibition of JAK1/2/3 in a PsA trial.[3]
Objectives: To identify baseline biomarkers that predict response to DEUC in patients with PsA.
Methods: The double-blind Phase 2 trial (NCT03881059) enrolled 203 patients with PsA randomised 1:1:1 to placebo (PBO), DEUC 6 mg once daily (QD), or 12 mg QD.[2] Molecular profiling of baseline serum samples was performed by immunoassays. Clinical response at Week 16 was measured by ≥20% improvement from baseline in American College of Rheumatology Improvement Criteria (ACR 20) and ≥75% improvement from baseline in Psoriasis Area and Severity Index (PASI 75) scores.
Results: Biomarkers of the IL-23/T helper cell type 17 pathway, including IL-17A, IL-17–induced β-defensin 2 (BD2), and IL-19, were associated with higher PASI but not Psoriatic Arthritis Disease Activity Scores overall at baseline. PASI 75 responders in DEUC-treated groups had higher baseline levels of IL-17A compared with nonresponders. In contrast, PASI 75 responders in PBO-treated patients had lower baseline expression of IL-17A, BD2, and IL-19 compared with nonresponders. In patients treated with DEUC 12 mg QD, greater reductions in BD2 were observed in the PASI 75 responder group compared with nonresponder group. When patients were dichotomised by median baseline biomarker level, higher clinical responses in both PASI 75 and ACR 20 were achieved in those with higher baseline overall biomarker levels in the DEUC-treated groups compared with the PBO group. Higher baseline expression of IL-23 biomarkers IL-17A, IL-19, and BD2 enriched ACR 20 response in patients treated with DEUC compared with PBO (OR=5.64, 6.68, and 4.99, respectively). While greater benefit was observed in high-biomarker groups, the low-biomarker populations still manifested clinical responses although not significant (Figure 1).
Conclusion: Patients who had higher expression of IL-23 pathway biomarkers were more likely to benefit from DEUC compared with placebo in skin and joint manifestations of PsA. These results reinforce the value of TYK2 inhibition in patients with IL-23–mediated diseases. The potential value of IL-23-pathway markers in predicting higher responses to DEUC should be further explored in larger trials.

POS0006 IDENTIFICATION OF FIBROTIC AND FIBROLYTIC ENDOTYPES IN RHEUMATIC DISEASE COHORTS

A. C. Bay-Jensen[1], S. Holm Nielsen[1], P. Frederiksen[1], M. Karsdal[1], W. Chen[2], S. Gao[2]. [1]*Nordic Bioscience, ImmunoScience, Herlev, Denmark;* [2]*Janssen Research & Development, Immunology, Spring House, United States of America*

Background: Ankylosing spondylitis (AS), psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE) are distinct diseases with common molecular features, such as an imbalance in fibrolysis and fibrosis of connective and calcified tissues. Type III, IV and VI collagens are abundant in connective tissue, and type I, II and X of the skeletal tissue. Blood biomarkers are available to measure fibrolysis (C1M, C2M, C3M, C4M, C6M, C10C) and fibrosis (PRO-C1, PRO-C2, PRO-C3, PRO-C4, PRO-C6) of these collagens.
Objectives: To profile AS, PsA and SLE patients (pts) using blood biomarkers of collagen formation and degradation.
Methods: Baseline serum samples from consenting pts of the AS (NCT02437162/NCT02438787), PsA (NCT0315828), and SLE (NCT02349061) studies were included in the analyses. Healthy donor samples were acquired from Discovery LS. Biomarkers were measured by immunoassays. Biomarker levels were compared by Kruskal-Wallis test. Before hierarchical clustering (Ward.D2), biomarker levels were log-transformed and standardized by median centering and scaling by median absolute deviation (MAD).
Results: When compared with healthy individuals, VICM was elevated in all indications (although markedly less so in SLE pts). The fibrosis marker PRO-C3 was elevated in all indications vs. healthy, while PRO-C4 and PRO-C6 were elevated only in AS and PsA. The fibrolysis markers C3M, C4M and C6M were elevated in all indications. The cartilage fibrosis marker PRO-C2, but not C2M, was elevated in AS and PsA, but not in SLE, ps. The bone fibrosis marker PRO-C1 was at the level of healthy for all. The fibrolysis marker C1M was elevated in all, while elevated C10C was seen only in PsA and SLE, pts (Table 1). Four clusters (C) of blood markers were extracted (Figure 1). C1 was characterized by low biomarker levels (68% of healthy, 1% of PsA, 3% of SLE pts). C2 was described by high levels of C10C and median levels of VICM (20% of healthy, 12% of AS, 19% of PsA, 42% of SLE pts). C3 was described by median biomarker levels (8% of healthy, 67% of AS, 48% of PsA, 46% of SLE pts). C4 had high biomarker levels (4% of healthy, 21% of AS, 31% of PsA, 9% of SLE pts).
Conclusion: Fibrosis and fibrolysis blood biomarkers were significantly elevated in AS, PsA and SLE pts. Subsets of pts from each indication were found in clusters with either low (C1/2), median (C3) or high (C4) levels of fibrosis/fibrolysis biomarkers. These findings may provide a first step towards precision medicine for guiding the use of anti-inflammatory vs. anti-fibrotic treatments in pts with rheumatological disorders.

Fig. Radar plot showing medians of standardized biomarker levels by cluster.

Cluster 1 (C1): Low turnover
Most marker levels below the median (0) of the population

Cluster 2 (C2): Low turnover, with COL10 high and VICM median levels
All marker levels at or below the median, but COL10Neo at +1MAD. VICM is higher than C1.

Cluster 3 (C3): Median turnover
Most marker levels at the median level

Cluster 4 (C4): High turnover
Most marker levels above the median

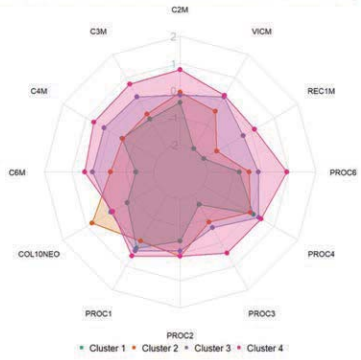

Table. Patient group description and fibrosis/fibrolysis biomarkers levels (ng/ml) in healthy and AS, PsA or SLE pts.

		Healthy	AS	PsA	SLE
	N	77	66	267	97
	Age	45 (32, 54)	41 (30, 49)	46 (37, 54)	41 (32, 49)

POS0007 HLA-DQ2 IS ASSOCIATED WITH ANTI-DRUG ANTIBODY FORMATION TO INFLIXIMAB ACROSS IMMUNE-MEDIATED INFLAMMATORY DISEASES

M. K. Brun[1,2], K. H. Bjørlykke[3], M. K. Viken[4,5], B. Stenvik[1], R. A. Klaasen[6], J. Gehin[6], D. J. Warren[6], J. Sexton[1], Ø. Sandanger[7], C. Mørk[8], T. K. Kvien[1,9], E. A. Haavardsholm[1,2], J. Jahnsen[2,3], G. L. Goll[1], B. A. Lie[2,4,5], K. K. Jørgensen[3], N. Bolstad[6], S. W. Syversen[1]. [1]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway;* [2]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway;* [3]*Akershus University Hospital, Gastroenterology, Lørenskog, Norway;* [4]*Oslo University Hospital, Medical Genetics, Oslo, Norway;* [5]*Oslo University Hospital, Immunology, Oslo, Norway;* [6]*Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway;* [7]*Oslo University Hospital, Dermatology, Oslo, Norway;* [8]*Akershus Dermatology Center, Akershus Dermatology Center, Lørenskog, Norway;* [9]*Oslo University Hospital, Institute of Clinical Medicine, Oslo, Norway*

Background: Immunogenicity is a leading cause of treatment failure to TNF inhibitors, and also affects drug safety. Variations in HLA class II genes have been suggested to predispose to anti-drug antibody formation (ADA), but characterisation of biologically relevant HLA haplotypes, based on high-resolution genotyping, is lacking.
Objectives: To assess associations between HLA loci and formation of ADA to infliximab across different immune mediated inflammatory diseases.
Methods: Patients with immune mediated inflammatory diseases on infliximab therapy (N=612; 181 spondyloarthritis, 120 rheumatoid arthritis, 72 psoriatic arthritis, 114 ulcerative colitis, 80 Crohn's disease and 45 psoriasis) participating in the Norwegian Drug Monitoring (NOR-DRUM) trials (1, 2) were included in the present analyses. Neutralising ADA were assessed with an automated fluorescence assay at each infusion. Next generation sequencing-based HLA typing was performed. Associations with ADA formation were assessed at locus, allele, haplotype and amino acid level. Peptide binding predictions for infliximab were performed.
Results: ADA were detected in 147 patients (24%). Significant associations were shown between ADA and several HLA loci, whereas conditional analyses indicated *HLA-DQB1* (p=1.4x10-6) as the primary risk locus. Highest risk of ADA formation was seen for patients carrying at least one of the HLA-DQ2 haplotypes; DQB1*02:01~DQA1*05:01 and DQB1*02:02~DQA1*02:01 (OR 3.18, 95% CI 2.15 to 4.69, p=5.9x10-9) (Figure 1). These findings were consistent across diagnoses (Table 1), and remained significant when adjusting for other possible predictors of ADA. Computational predictions indicated that both these HLA-DQ2 haplotypes could strongly bind two peptide motifs (INTVESEDI and VYACEVTHQ) in the infliximab heavy and light chain.

Table 1. HLA-DQ2 carrier frequencies according to the different disease phenotypes and for all diagnosis combined

Diagnosis	HLA-DQ2 carrier-frequency among patients with ADA formation	HLA-DQ2 carrier-frequency among patients without ADA formation	P-value
RA (N=120)	0.316	0.134	0.02
PsA (N=72)	0.55	0.231	0.01
SpA (N=181)	0.364	0.182	0.02
UC (N=114)	0.556	0.264	0.006
CD (N=80)	0.429	0.303	0.33
Ps (N=45)	0.867	0.267	0.0004
All disease phenotypes	0.469	0.217	$5.9x10^{-9}$

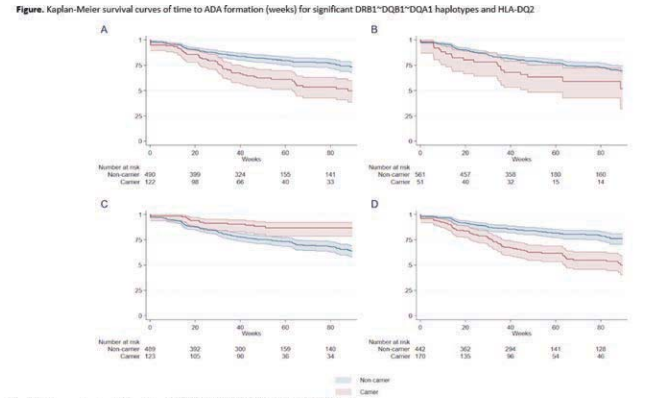

Figure. Kaplan-Meier survival curves of time to ADA formation (weeks) for significant DRB1~DQB1~DQA1 haplotypes and HLA-DQ2

(A) Patients carrying the risk haplotype DRB1*03:01~DQB1*02:01~DQA1*05:01 in red.
(B) Patients carrying the risk haplotype DRB1*07:01~DQB1*02:02~DQA1*02:01 (analysed as DRB1*07:01~DQB1*02:01~DQA1*02:01) in red.
(C) Patients carrying the protective haplotype DRB1*01:01~DQB1*05:01~DQA1*01:01 in red.
(D) Patients carrying at least one of the two HLA-DQ2 risk haplotypes in red.

Conclusion: The risk of ADA to infliximab was three-fold higher in patients carrying the HLA-DQ2 risk haplotypes across diseases. A biological role for the HLA-DQ2 molecules encoded by the two different HLA-DQ2 risk haplotypes in the formation of ADA was further supported by peptide binding predictions. These novel findings provide promise for future incorporation of HLA-DQ2 testing to facilitate personalised treatment decisions.

POS0008 THE UTILITY OF TRANS-BRONCHIAL LUNG BIOPSIES TO GUIDE THE TREATMENT IN PATIENTS WITH RHEUMATIC INFLAMMATORY DISEASES: A RETROSPECTIVE CROSS-SECTIONAL STUDY

M. Andersen[1], T. K. Lund[2], T. H. L. Jensen[3], M. Iversen[2], M. Perch[2], B. Baslund[1]. *[1]Copenhagen University Hospital Rigshospitalet, Center for Rhematology and Spine Diseases, Copenhagen, Denmark; [2]Copenhagen University Hospital, Rigshospitalet, Department of Cardiology, Section for Lung Transplantation and Respiratory Medicine, Copenhagen, Denmark; [3]Copenhagen University Hospital, Rigshospitalet, Department of Pathology, København Ø, Denmark*

Background: Rheumatic inflammatory disease associated interstitial lung disease (R-ILD) is associated with significant mortality and morbidity[1]. On a patient-to-patient level, imaging which is a cornerstone in diagnosing R-ILD may not be sufficent to determine the underlying cause of the imaging pathology or the degree of reversibilty. Furthermore the precense of co-morbidity and diffential diagnoses such as infections or malignacy needs to be taken into account when dertemining the therapeutic strategy. The role of transbronchial lung biopsies (TBB) in the diagnostic workup of R-ILD is unclear and TBB is not generally recommended[2-4].
Objectives: The study objective was to examine the utility of TBB to guide treatment in a population of patients with R-ILD reffered for bronchoscopy.
Methods: All patients from the Department of Rheumatology, Rigshospitalet, Copenhagen, Denmark referred for a TBB on the suspicion of R-ILD, from 2002 to 2016 were identified.
Patient demographics as well as smoking status, previous lung disease, pulmonary function test, CTD-diagnosis, imaging results and immunomodulatory therapy pre- and post-bronchoscopy were obtained.
Histology findings were used to dichotomize patients into a high inflammatory group or a low inflammatory group. The high inflammation group primarily consisted of non-specific interstitial pneumonia (NSIP), organizing pneumonia (OP), lymphocytic infiltrating pneumonia (LIP) and granulomatous inflammation whereas the low inflammation group primarily consisted of histological findings of usual interstitial pneumonitis (UIP) and biopsies describing fibrosis and/or sparse unspecific inflammation. Therapeutic consequence was defined as intensification of therapy. Differences in treatment intensification were calculated using a binominal logistic regression model. Differences in treatment intensification were calculated using a binominal logistic regression model adjusted for age, gender, smoking status, previous lung disease, diffusion capacity, rheumatologic diagnose, c-reactive protein level prior to TBB. Covariates with P>0.1 were excluded by a stepwise 'backwards' elimination.
Results: 96 patients had TBB performed. Biopsies from 55 patients were categorized as high-inflammatory and 41 as low-inflammatory, respectively. In the high inflammatory group thirty-eight (69%) had their therapy intensified compared to 6 (14%) in the low-inflammatory group (P <0.001). TBB inflammation type was the only covariate that was significantly associated with treatment intensification.
No procedure related complications were registered.
Conclusion: TBB findings can guide treatment strategy in R-ILD patients with suspected activity in the pulmonary disease. TBB appears safe and could be considered as part of the diagnostic workup in patients with inflammatory rheumatic diseases where clinical features, bloodsamples, imaging and/or pulmonary function test do not provide suffcient information to guide the therapeutic strategy.

POS0009 SUBJECTIVE ASSESSMENT OF PHYSICAL FUNCTION DOES NOT SUFFICIENTLY EXPLAIN VARIANCE OF MEASURED HAND FUNCTION AND GRIP STRENGTH IN ARTHRITIS PATIENTS AND NON-ARTHRITIS CONTROLS

A. M. Liphardt[1,2], K. Tascilar[1,2], B. Coppers[1,2], E. Manger[1], S. Liehr[1], L. Bieniek[1], S. Bayat[1,2], D. Simon[1,2], M. Sticherling[2,3], J. Rech[1,2], A. Hueber[4], G. Schett[1,2], A. Kleyer[1,2]. *[1]University Hospital Erlangen & Friedrich-Alexander-University Erlangen-Nürnberg, Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]University Hospital Erlangen & Friedrich-Alexander-University Erlangen-Nürnberg, German Centre for Immuntherapy, Erlangen, Germany; [3]University Hospital Erlangen & Friedrich-Alexander-University Erlangen-Nürnberg, Dermatology, Erlangen, Germany; [4]Klinikum Nürnberg, Internal Medicine 5 – Oncology and Hematology, Nuremberg, Germany*

Background: Monitoring disease activity in patients with inflammatory arthritis is essential for effective treatment. While the health assessment questionnaire (HAQ) is commonly used to assess physical function, additional functional tests, such as isometric grip strength and the Moberg Pick-Up-Test (MPUT), provide objective measures for hand function and allow assessing hand function across different diseases (1). It remains unclear to date, if measured hand function is already reflected by the HAQ, as the most widely used patient reported outcome measure of physical function in arthritis.
Objectives: To estimate the proportion of hand function and grip strength variability explained by HAQ, patient-reported hand function, and between-person variation in patients with inflammatory arthritis and non-arthritic controls.
Methods: Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis without PsA (PsO) and healthy controls (HC) were investigated. Subject characteristics (age, sex, disease) and HAQ were recorded. Hand function was assessed by vigorimetric grip strength, MPUT, and a patient-reported tool (Michigan Hand Questionnaire, MHQ). Mixed pure-random-effect linear regression models were used to estimate the proportion of variance in measured hand function or grip strength explained by subject characteristics (age, hand dominance, sex, reported hand function, disease group).
Results: 299 subjects were tested, 101 with RA (Age: 59.1±13.3 years, BMI: 27.2±5 kg/m^2, HAQ-DI score: 0.9±06), 92 with PsA (Age: 58.8±11.6 years, BMI: 29±6.1 kg/m^2, HAQ-DI score: 0.6±0.7) and 106 non-arthritic controls (51 with Pso (Age: 47.3±14.1 years, BMI: 29.8±7.3 kg/m^2, HAQ-DI score: 0.4±06) and 55 HC (Age: 54.6±16.5 years, BMI: 25.2±3.3 kg/m^2, HAQ-DI score: 0.1±0.2). Overall variation of MPUT is mostly accounted for by between-person variation (43.1%), followed by HAQ (20.3%) and MHQ (20.2%) (Figure 1A). Overall variation in grip strength is mostly accounted for by sex (59.8%), between-person variation (21.1%) and HAQ (11.3%) (Figure 1B). Overall variation in MHQ is mostly accounted for by HAQ (59.2%) and residual variation (28.3%). Study group specific result are summarized in Table 1.

Table 1. Variance proportions for each of the four study groups.

	Variance proportions (%)							
	Hand function (MPUT)				Grip strength			
Group	Control	PsA	PsO	RA	Control	PsA	PsO	RA
MHQ	3.4	39.0	0.0	0.0	0.0	2.1	0.0	0.0
ID	34.8	36.2	51.6	52.8	16.1	12.9	21.3	27.9
Age	0.0	13.8	0.0	0.7	8.4	8.4	0.0	0.0
HAQ	35.8	10.8	34.3	16.4	3.8	3.1	10.3	12.0
Dominant hand	0.6	0.2	0.0	0.0	3.5	0.6	1.3	0.2
Sex	12.1	0.0	0.0	4.3	64.2	68.9	63.7	55.0
Residual	13.3	0.0	14.1	25.8	3.9	4.0	3.4	5.0

Conclusion: While the variance variation in grip strength is mainly explained by sex and between-person variation for all subject groups, the proportions of explained variance for measured hand function is not similar between diseases. In all groups > 50% of the variation in measured hand function remains unexplained by the variables used. Especially in arthritis patients, HAQ explained less than 25% of the variance in measured hand function. Grip-strength can be considered a poor surrogate for hand function in this context due to its large gender dependence. The explainability of MHQ variation largely by HAQ indicates that it has limited potential to provide further information beyond overall functional impairment. In contrast, the large between-person variation in MPUT likely indicates unexplored movement patterns of hand motion that may be further dissected using sensor-based analyses (2) and can help identify movement components a potential for an in-depth assessment of subtle hand-function alterations in inflammatory arthritis.

POS0010 THE PSORIATIC ARTHRITIS 5-THERMOMETER SCALES (PSA-5TS): A NEW INSTRUMENT FOR ASSESSING THE STATUS OF DISEASE ACTIVITY IN PSORIATIC ARTHRITIS

F. Salaffi[1], M. Carotti[2], S. Farah[1], M. Di Carlo[1]. *[1]Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale "Carlo Urbani", Jesi, Italy; [2]Università Politecnica delle Marche, Dipartimento di Scienze Radiologiche, Ospedali Riuniti, Ancona, Italy*

Background: There are a variety of composite disease activity monitoring methods and patient-centered metrics available for psoriatic arthritis (PsA). The Psoriatic Arthritis 5-Thermometer scales (PsA-5Ts) is a new tool, proposed, with the aim of improving its diagnostic accuracy.
Objectives: The goal of this research was to evaluate data on the measurement qualities of the PsA-5Ts, a composite measure of disease activity in PsA patients, in a real-world scenario (Figure 1).

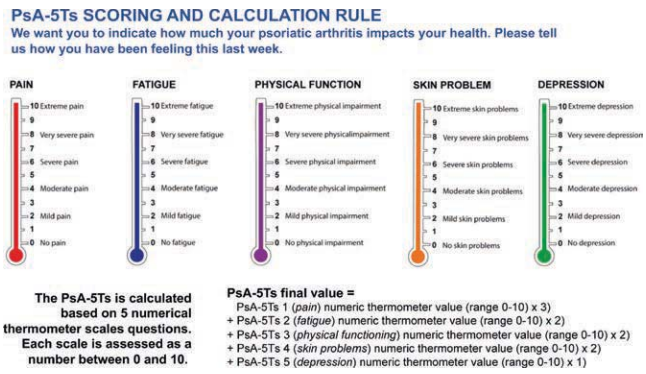

Figure 1. The Psoriatic Arthritis 5 Thermometer scales (PsA-5Ts) scoring and calculation rule

Methods: A total of 155 PsA patients were enrolled between May 2018 and December 2021. Adult-onset PsA CASPAR criteria were used to classify patients affected by PsA, while ASAS criteria were used to classify patients affected by axial-PsA (axPsA). All patients completed the PsA-5Ts, a simple instrument with five "thermometers" that incorporate pain, fatigue, physical function, skin disorders, and depression into a single assessment of disease activity. Additional continuous measures of disease activity (e.g., DAPSA, PASDAS, CPDAI) and patient-reported outcomes (PROs) measures of disease health status (e.g., PSAID and SF-36) were analyzed as comparisons. Spearman's correlations and cross-tabulations were used to examine concurrent validity. Receiver operating characteristic (ROC) curve method was used to assess discriminant validity. As an external criterion, the Minimal Disease Activity (MDA) levels were used.
Results: The 96 female and 59 male patients ranged in age from 20 to 79 years old and had been living with PsA for an average of 8.35.2 years (6 months to 22 years). The PsA-5Ts' area under the ROC curve (AUC-ROC) was 0.944. (95 percent CI 0.895 to 0.974) (Figure 2). The PsA-5Ts had same discriminant validity as the DAPSA, CPDAI, PASDAS, and PSAID, but it was better than the SF-36 (p=0.0011). PsA-5Ts subscales were highly significantly different between the MDA status (all at p<0.0001) when categorizing patients into those who rated their condition as reaching MDA (Kruskal-Wallis test). PsA-5Ts were also shown to have a remarkable (p<0.0001) correlation with known PsA activity measurement techniques.

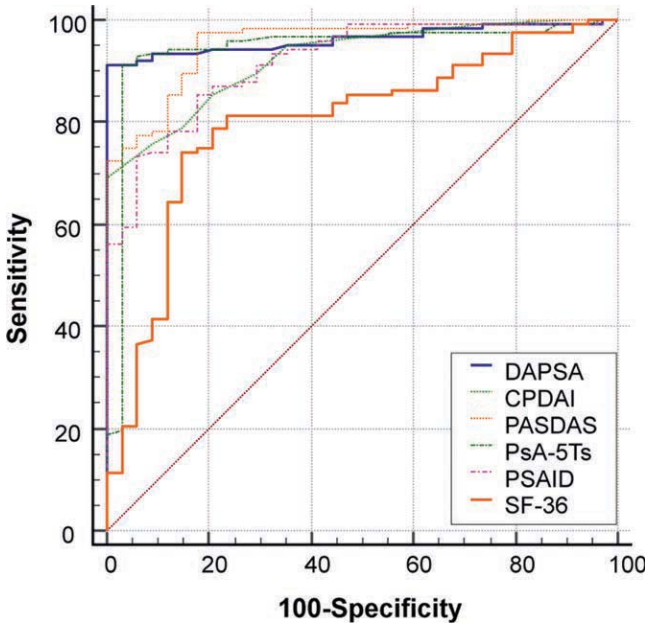

Figure 2. ROC curve analysis (AUC-ROC curves values, standard error and 95% confidence intervals) for the discriminatory power of disease activity, according to the different composite disease activity indices (DAPSA; CPDAI and PASDAS) and patient-reported outcomes (PROs) measures (PsA-5Ts, PSAID and SF-36). Receiver operating characteristic curves illustrating the relationship between sensitivity and complement of specificity (100-specificity) in PsA for activity measures using MDA as an external indicator. A line that runs diagonally across the figure from lower left to upper right will have an area of 0.5; this represents an instrument that does not discriminate.

Conclusion: For the evaluation of disease activity in PsA, PsA-5Ts is a useful alternative to continuous composite indices and other patient-centered assessments. The PsA-5Ts make data collection simpler, and they should be used in both clinical studies and everyday clinical treatment. In order to establish the tool's clinical relevance, longitudinal construct validity, which concerns the measure's capacity to identify a real change in health status as well as its accuracy in detecting changes of various magnitudes, must be addressed.

Sakellariou[12], S. Meisalu[13], J. K. Wallman[14], D. Lacaille[15]on behalf of the EULAR-PRO Working Group At-Work Productivity Loss. *[1]The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; [2]Maastricht University Medical Center, 1Department of Internal Medicine, Maastricht, Netherlands; [3]Institute of Work and Health, N/A, Toronto, Canada; [4]NRAS, N/A, Maidenhead, United Kingdom; [5]Rheumatology and Osteoporosis, N/A, Lisbon, Portugal; [6]Università degli Studi di Torino, Academic Rheumatology Centre, Turin, Italy; [7]Private Practice, N/A, Paris, France; [8]Patient Partner, N/A, Toronto, Canada; [9]University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland; [10]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [11]Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands; [12]University of Pavia, Istituti Clinici Scientifici Maugeri IRCCS, Pavia, Italy; [13]East Tallinn Central Hospital, Rheumatology, Tallinn, Estonia; [14]Lund University and Skane University Hospital, Rheumatology, Lund, Sweden; [15]University of British Columbia, Arthritis Research Centre of Canada, Vancouver, Canada*

Background: Work is an important outcome for people with inflammatory arthritis (IA including PsA, RA, AxSpA) and osteoarthritis (OA). It is known that people with IA and OA are at increased risk of sick leave and have to stop working early due to ill health. In addition to being at increased risk of becoming work disabled and increased absenteeism, high levels of presenteeism (i.e. reduced productivity/limited ability to work due to ill health whilst at work) have also been reported. Several instruments exist to measure presenteeism, including single-item global measures and multi-item instruments. In some studies using single-item global instruments may be more feasible. However, available global instruments differ in concept, recall period and reference. It is important to understand which of the measures have good psychometric properties before using them in clinical studies.
Objectives: To assess the psychometric properties of four global presenteeism instruments.
Methods: Patients with IA or OA were recruited via rheumatology outpatient clinics to a large international, longitudinal observational study including 8 European countries and Canada. Participants completed a survey at baseline, 1, 2, 3, 4 wks, 2 months and 3 months. The four global measures of presenteeism included: Work Productivity and Activity Impairment Questionnaire (WPAI), Work Productivity Scale–Rheumatoid Arthritis (WPS-RA), Work Ability Index (WAI) and the Quality*Quantity questionnaire (QQtotal/10) scale. To facilitate score interpretation the WAI and QQtotal were reversed. Pain was measured using an 11-point Likert scale. Spearman correlations were calculated between the presenteeism measures and the Workplace Activity Limitations Scale (WALS), a validated multi-item measure of presenteeism, and HAQ to evaluate construct validity (validity: r <0.50=low; r >0.50-<0.70=moderate; r >0.70=high). Test-retest reliability of the 4 presenteeism scales (baseline-1wk) was measured applying ICC in patients with stable disease (i.e. same pain score at baseline and 1wk) (reliability: ICC<0.40=poor; ICC 0.40-0.75=fair to good; ICC >0.75=excellent). Responsiveness during 3 months was measured comparing patients with improvement in pain score (>1 point improvement in pain score (~MCID pain)) with patients with no change or worsening in pain score. The two groups were compared applying Mann Whitney U test.
Results: This international study included 550 patients with a mean age of 47.8 (SD 9.9) yrs and 61.4% were female. Mean (SD) disease duration since diagnosis was 10.8 (10.4) yrs and 91.2% had IA. Mean (SD) presenteeism scores at baseline were: WPAI=2.9 (2.7); WPS-RA=3.4 (2.7); WAI=2.7 (2.4); and QQtotal=3.1 (3.2). The correlations between the global measures and with WALS and HAQ were moderate to good, except for QQtotal and HAQ which was low (Table 1). In patients with the same stable pain scores at baseline-1wk (n=141) ICC scores were good to excellent, respectively: WPAI (0.771), WPS-RA (0.752), WAI (0.663), and QQtotal (0.650). An improvement in pain during the 3 month study duration was observed in 145/381 (38%) of the patients. In these patients a significant reduction in mean (SD) change presenteeism was observed for all four presenteeism scales compared to those with no change or worsening of the pain score: WPAI (-1.0 (2.37) vs 0.68 (2.40), p<0.01); WPS-RA (-0.76 (2.57) vs 0.43 (2.10), p<0.001); WAI (-0.09 (2.34) vs 0.41 (2.46), p<0.001); QQtotal (-0.57 (3.16) vs 0.79 (3.1), p<0.01).

Table 1.

	WPAI	WPS-RA	WAI	QQtotal	WALS	HAQ
WPAI	-	0.8164	0.5992	0.5184	0.6269	0.5592
WPS-RA		-	0.5836	0.5217	0.6055	0.5669
WAI			-	0.5866	0.5231	0.5168
QQtotal				-	0.5025	0.4367

Conclusion: The psychometric properties of all 4 global presenteeism scales were moderate to good, with slightly better scores for both the WPS-RA and WPAI instruments both measuring the impact of OA and IA on productivity.

Challenging cases to make you think

POS0012 A NEW TNFRSF1A GENE MUTATION IN A TURKISH FAMILY WITH TNF RECEPTOR-ASSOCIATED PERIODIC SYNDROME (TRAPS).

T. S. Öğüt[1], B. Aslan[1], V. Yazısız[1], F. Erbasan[1], M. E. Terzioğlu[1]. [1]*Akdeniz University, Rheumatology Clinic, Antalya, Turkey*

Background: Tumor necrosis factor (TNF) receptor-1 associated periodic syndrome (TRAPS) is a rare autosomal dominant autoinflammatory syndrome caused by pathogenic variants in the tumor necrosis factor receptor 1 (TNFR1) gene (TNF receptor superfamily member 1A, TNFRSF1A). For definitive diagnosis, genetic tests are needed to show variants in the TNFR1 gene (1). Information on genotype-phenotype relationships is limited due to the rarity of the disease.
Objectives: This study presents novel R97S mutation in TNFRSF1A gene and relevant clinical findings in a patient with amyloidosis of unknown etiology and his sister.
Methods: Case; Proband 33-year-old male patient presented with swelling in the legs 9 years ago. In his history, he described muscle pain, unilateral eye redness, swelling and discharge, which occurred several times in 2-3 months and lasted for up to 2 weeks. Kidney biopsy was found to be consistent with AA amylodiosis. FMF (familial Mediterranean fever) gene mutation was detected negative. Colchicine was started at 2x0.5 mg per day.
Despite colchicine treatment in the following years, acute phase reactants remained high, proteinuria continued at nephrotic level (5060 mg in 24-hour urine), progressive deterioration of kidney functions, end-stage renal failure developed. Gene analysis was performed for other autoinflammatory diseases; R97S (Nucleotide change c.290_310dup heterozygous) mutation was detected in the TNFRSF1A gene.
Sister; 31-year-old female patient was admitted to our clinic after a heterozygous mutation in the TNFRSF1A gene was detected in her brother. In her history, she described muscle pain, edema, redness and discharge around the eyes, which occurred 1-2 times a year and lasted for about 2 weeks, especially triggered by the menstrual cycle. TNF (tumor necrosis factor) receptor-associated periodic syndrome mutation was found to be heterozygous positive R97S.
Father; The father of the first two cases started having sore throat, diarrhea, muscle pain, swelling around the eyes and fever attacks starting from the age of 29. Renal biopsy revealed apple-green birefringence with congo-red stain, which was indicative of amyloidosis. When he was 32 years old, peritoneal dialysis was started first and then continued with hemodialysis due to end-stage renal disease. Three months after the start of hemodialysis, he died due to high fever, hypotension and septicemia.
Results: In this article, a novel mutation of TRAPS which has not been reported in the literature so far, is presented in a Turkish family.
Conclusion: Our patient and her sister with the R97S mutation did not have frequent clinical findings such as febrile serositis attacks and skin rashes. In addition, the incidence of conjunctivitis and periorbital edema in TRAPS cases reported in the literature is between 10-20% (1). Three members of the family presented here had periorbital edema and two had conjunctivitis. It is possible that R97S mutations in the TNFRSF1A gene are associated with the development of periorbital lesions and secondary amyloidosis.
Our country is endemic for FMF disease, a study by Bilge et al. (2) demonstrated that mutation analysis of 9% of all subjects with FMF in our country provided negative results. In our opinion genetic analysis should be performed to detect other autoinflammatory diseases in cases that classical FMF attacks are not seen, as in this case series. These and similar cases followed as FMF are likely to be associated with other autoinflammatory diseases. Diagnosing these rare diseases will provide both appropriate and effective treatment options to patients and a better definition of the clinical feature - mutation relationship.

POS0013 SJÖGREN-LIKE SYNDROME, MULTIPLE AUTOIMMUNE DISEASES, THYMOMA AND GENETIC VARIANTS IN AIRE

J. Cramer[1], E. Husar-Memmer[2], D. Schoerghofer[3], J. Zwerina[2], G. Uyanik[3,4], R. Fritsch-Stork[2,5]. [1]*Sigmund Freud University Vienna, Faculty of Medicine, Wien, Austria;* [2]*ÖGK Hanusch-Krankenhaus - Österreichische Gesundheitskasse, Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of Oesterreichische Gesundheitskassa and Allgemeine Unfallversicherungsanstalt, First Medical Department, Wien, Austria;* [3]*ÖGK Hanusch-Krankenhaus - Österreichische Gesundheitskasse, Department of Medical Genetics, Wien, Austria;* [4]*Sigmund Freud University Vienna, Medical Faculty of Genetics, Wien, Austria;* [5]*Sigmund Freud University Vienna, Medical Faculty of Rheumatology, Wien, Austria*

Background: The autoimmune regulator gene *AIRE* is the main controlling factor for developing central immunotolerance. Variants in *AIRE* lead to autoimmunity and underly the autoimmune polyendocrine syndrome type 1 (APS-1 or APECED), defined by the clinical triad chronic mucocutaneous candiasis hypoparathyroidism and adrenal insufficiency.(1, 2) Manifold additional manifestation have been described, including Sjögren-like disease lacking the typical serology.(3) Furthermore, serological abnormalities, e.g. antibodies against IL-22, IL-17F and IFNώ are a hallmark of the disease. Due to the diversity in clinical manifestations and the genetic variants in AIRE, diagnosis is often delayed.
Objectives: Case report of a patient with 2 new variants in *AIRE* with diverse rheumatological and autoimmune disorders as well as thymoma.
Methods: Case report.
Results: The 38-year-old male patient was transferred to our clinic for immunoglobuline therapy, from his treating neurologist. His medical history included diabetes mellitus type 1, diagnosed in 1996, followed by Grave's disease in 2000, culminating in a thyroidectomy in 2017. In 2009 he underwent a thymectomy for a thymoma. He had been treated with a series of immunosuppressive therapies including prednisolone, rituximab and mycophenolate, as well as plasmapheresis and immunopheresis for his atypical, seronegative myasthenia gravis. Due to the limited effect of the previous therapeutic regimen

a trial with intravenous immunoglobulin had been initiated inducing clinical stabilization.

We diagnosed Sjogren-like syndrome based on sicca symptoms and a suspicious submandibular salivary gland in sonography, without typical serology. Family history was negative for autoimmune diseases. The clinical findings pointed towards immunodysregulation, prompting cytokine examination, lymphocyte phenotyping and genetic testing. Cytokines (IFNγ, IL-2, IL-4, IL-10, IL-17) under immunosuppression with 20 mg prednisolone and 2 g of mycophenolate were all low/below detection threshold. Flow cytometry showed no abnormalities except for a low CD20 (after Rituximab) and a slightly elevated T-reg count. Genetic testing revealed heterozygous variants in exon three (c.354C>G) and eight (c.927C>G) of *AIRE*. The patient´s mother showed the same genotype - indicating that the variants in the patient are *in cis* - but is asymptomatic. (Figure 1)

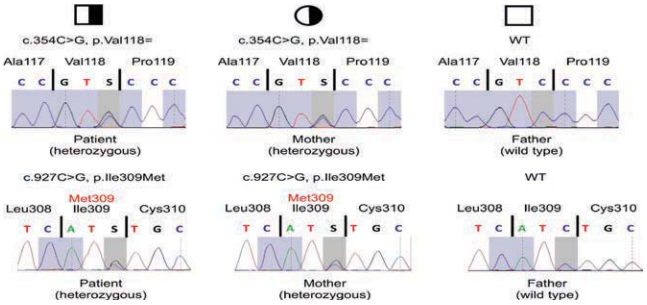

Figure 1. Electropherograms of the heterozygous patient, his heterozygous, asymptomatic mother and his asymptomatic father, who has a wildtype of AIRE.

Conclusion: To our knowledge this is the first report of a patient with thymoma and genetic variant(s) in the AIRE gene displaying several autoimmune diseases. Although clinical similarities between thymoma patients and APECED / APS1 are known (4), a genetic link between these 2 diseases has not yet been described. As rheumatic autoimmunity can be induced by either, rheumatologists should be aware of these potentially underlying causes.

An additional point of interest is the lack of autoimmunity in the mother with the same genetic variants, which suggests an additional environmental trigger (e.g. smoking, viral infection) in the patient.

POS0014

EFFICACY AND SAFETY OF JAK INHIBITORS IN REFRACTORY OR INITIAL TREATMENT OF ADULT ONSET STILL'S DISEASE

Z. Chen[1], J. Tan[1], T. Cheng[1], X. Wu[1], J. Gu[1], Z. Liao[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Rheumatology and Immunology Department, Guangzhou, China*

Background: Inappropriate activation of pro-inflammatory cytokines such as interleukin (IL)-1, IL-6 or IL-18, is a pathogenic cornerstone in adult onset Still's disease (AOSD). Beyond therapies targeting IL-1 and IL-6, Janus kinases (JAK) inhibitors have been suggested to be efficient in refractory AOSD patients [1].

Objectives: To assess the efficacy and safety of JAK inhibitors in the treatment of AOSD patient refractory to, or with initial treatment.

Methods: This retrospective study was based on our single center of the department of rheumatology and immunology. The data was collected from the patients' medical records using a standardized questionnaire and analyzed at different time points. The response to JAK inhibitors was categorized as complete remission (CR), partial remission (PR) or failure (F) [2].

Results: 7 patients were recruited (Table 1), including 4 refractory patients and 3 initial patients. Mean age at JAK inhibitor treatment start was 27.5 years for refractory patients and 35 years for initial patients; and mean disease duration was 66.5 months and 1 month respectively. All patients had fever and polyarthritis, 5 patents had rash. In addition, pulmonary hypertension, abnormal liver function tests, abdominal pain, and heart failure were also observed in our patients. Response to corticosteroids, conventional synthetic or biological Disease Modifying Anti-Rheumatic Drugs (DMARDs) had been considered inadequate in 4 refractory patients. Tofacitinib was added in the initial treatment for 3 patients for high disease activity. In total, baricitinib was used in 2 patients and tofacitinib in 5 patients. Steroids were concurrently used in 6 patients, MTX in three, SASP and NSAIDs in one. At a mean follow up of 3.8 months, complete remission was observed in one patient (with tofacitinib), partial remission was in 5 patients (4 patients with tofacitinib and one with baricitinib), and failure in one (patients with baricitinib). At the last visit, steroids could be decreased but not stopped in those 6 patients. Tolerance of JAK inhibitors was excellent, none infectious disease or other severe side effect were observed.

Conclusion: JAK inhibitors treatment may be helpful for some patients with refractory AOSD, or patients with severe disease activity at initial treatment. Different treatment responses were observed in these short series of cases, which might be due to the phenotype of patients. However, the scale of patients in our study was too low to draw a conclusion. Further study and additional information are needed to evaluate more precisely the risk-benefit ratio of this treatment, and a possible difference in efficacy among the different groups of patients or JAK inhibitors.

BULLOUS SYSTEMIC LUPUS ERYTHEMATOSUS SUCCESSFULLY TREATED WITH MYCOPHENOLATE MOFETIL COMBINED WITH GLUCOCORTICOID: A CASE REPORT

H. Du[1], J. Hu[1], J. Su[1], T. Wu[1], R. Wu[1], J. Zhu[1]. [1]*Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Department of Rheumatology and Immunology, Chengdu, China*

Background: Bullous systemic lupus erythematosus (BSLE) is a rare subtype of systemic lupus erythematosus, accounting for less than 1% of systemic lupus erythematosus (SLE) [1]. It is common in adults aged 20 to 40, with female predominace [2]. Its skin manifestations are mainly tensive blisters, especially involving oral and genital mucosa, Nissl's sign is mostly negative, blisters break and heal to form pigmentation of varying degrees, leaving no scar. At present, the main treatment is systemic application of corticosteroids combined with immunosuppressants. Here, we report a BSLE who successfully treated with mycophenolate mofetil (MMF) combined with glucocorticoid.
Objectives: To be vigilant in the early identification of BSLE, and through the treatment experience of this case, it can provide a basis for the use of Mycophanol ester as the preferred drug for the treatment of BSLE in the future.
Methods: The clinical manifestation, laboratory test, treatment, and outcome were described.
Results: A 50-year-old female patient with systemic lupus erythematosus presented with wandering joint pain for 1 year and sporadic patchy erythema on eyelid, hands, and neck for 7 months. There are blisters on part of her erythema and normal skin, about 1mm-15mm in diameter, the blister fluid is cool, fusion is broken, and Nissl's sign is negative. She suffered from anemia, albuminuria, polyserous effusion and other system damage. Skin histopathology showed mild hyperkeratosis of epidermis, formation of subepidermal blisters and accumulation of a large number of neutrophils; direct immunofluorescence showed that the positive expressions of IgA, IgG and C3 were found in the basement membrane of the skin, leading to a diagnosis of BSLE. In the initial stage, patients were treated with high-dose glucocorticoid (160 mg, qd) combined with immunosuppressants (thalidomide and hydroxychloroquine), but the number of blisters increased. After treatment with MMF (1 g, bid), the skin lesions disappeared, joint pain relieved, anemia was corrected, and polyserous effusion was absorbed. She was followed up for half a year and there was no recurrence.
Conclusion: Patients with BSLE are often accompanied by multiple system damage [2], so it is critical to correctly identify BSLE and provide appropriate treatment as soon as possible. For patients who do not respond to single glucocorticoid therapy, combined with MMF can be used as the preferred drug for the treatment of BSLE in the future.

POS0016

COMMON VARIABLE IMMUNODEFICIENCY DISEASE FROM THE PERSPECTIVE OF RHEUMATOLOGY

T. Yuce Inel[1], G. Can[1]. [1]*Dokuz Eylul University, Division of Rheumatology, Izmir, Turkey*

Background: Common variable immunodeficiency (CVID) is a primary immunodeficiency characterized by impaired B cell differentiation and immunoglobulin production. In addition to increased susceptibility to infection, patients also have an increased tendency to autoimmune disease. Since rheumatological findings usually start earlier than other autoimmunities, it is very important to increase the awareness of rheumatologists about this disease, for accurate diagnosis and to prevent delay in treatment.
Objectives: To increase the awareness of rheumatologists about the main symptoms and findings of CVID.
Methods: Adult patients referred to the rheumatology department since January 2015 were included in the study. Demographic and clinical characteristics (infections, pulmonary and extrapulmonary granulomatous involvement, autoimmune manifestations), laboratory and imaging findings and treatments of the patients were analyzed.
Results: Ten adult patients with CVID were included in the study. The gender distribution of the patients was similar and the median age was 38±10.0 years.

Table 1. Autoimmune manifestations of common variable immunodeficiency patients

	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6	Case 7	Case 8	Case 9	Case 10
Age/Sex	36/F	43/F	40/M	25/M	23/M	36/M	41/M	57/F	35/F	48/F
Symptom duration (years)	12	11	11	4	17	12	11	13	12	7

Splenomegaly	+	+	+	+	-	+	+	-	+	-
Immunosuppressive Treatment	Steroid, AZA, CSA, Adalimumab	Steroid	Steroid, SSZ	Steroid, MMF, CYC	-	Steroid, SSZ, MTX, LEF, CSA	Steroid	Steroid, MTX, AZA, CSA	Steroid, AZA	-

Abbreviations: AZA-azathioprine, CSA-cyclosporine, CYC-cyclophosphamide, F-female, GI-gastrointestinal, ILD-interstitial lung disease, LEF-leflunomide, M-male, MTX-methotrexate, SSZ-sulfasalazine*right lower lobectomy, ** right foot 5th toe enucleation, * mediastinoscopic lymph node biopsy ° interstitial granulomatous nephritis

The mean duration of diagnosis was 123.5±89.3 months. At least one autoimmune manifestation was observed in 80% of the patients. In the follow-up period, 40% of the patients developed arthritis. Involvement of lower extremity joints such as knee and ankle was more prominent. While all patients were given 0.8 g/kg/3 weeks of intravenous immunoglobulin, 80% required immunosuppressive therapy for autoimmune manifestations. The demographic and clinical characteristics of the patients are summarized in Table 1.

Conclusion: Autoimmune diseases can be seen in patients with CVID, and sometimes this may be the first presentation of CVID. Heterogeneous clinical findings of the disease may lead to delay in diagnosis. Clinicians should be more careful about the different manifestations of CVID to avoid delay in diagnosis.

POS0017 SEVERE GENERALIZED EDEMA AS INITIAL PRESENTING SYMPTOM IN POLYMYOSITIS

L. Francis[1], B. Mathew[2], R. Medina-Flores[3]. *[1]Marshfield Clinic, Rheumatology, Marshfield, United States of America; [2]Marshfield Clinic, Cardiology, Marshfield, United States of America; [3]Marshfield Clinic, Pathology, Marshfield, United States of America*

Background: 53 year old female developed pain and swelling of the metacarpophalangeal and proximal interphalangeal joints of both hands. She was diagnosed to have possible inflammatory arthropathy since her workup showed elevated inflammatory markers with CRP 2.2 and ESR 35. Rheumatoid factor and antiCCP antibody were negative. She was treated with hydroxychloroquine, methotrexate followed by leflunomide. She had non pitting edema around both ankles at initial presentation which later spread to the thighs, abdomen and chest. There was no erythema of the skin, tenderness or skin rash. BNP was normal at 58. TSH was normal. Echocardiogram was normal. Blood and urine cultures were negative. CT scan of the chest, abdomen and pelvis showed moderate subcutaneous edema. She was noted to have elevated liver enzymes with AST 438 and ALT 245. Hepatitis panel was negative. Smooth muscle antibody and antimitochondrial antibody were negative. Ultrasound abdomen showed diffusley increased echogenicity throughout the liver. Liver biopsy showed mildly active steatohepatitis centrizonal and portal/periportal fibrosis. ANA was positive 1:640 speckled pattern. ENA showed a positive antiRNP antibody. ANCA was negative. CK was elevated at 853 U/L. Myomarker panel was negative for antiJo, Anti Mi2, antiSRP, antiNXP and anti Ku antibodies. She had a workup for malignancy including CT chest, abdomen and pelvis, mammogram and colonoscopy which were negative.

Objectives: About 4 months after she presented with edema, she developed progressive proximal muscle weakness of both lower extremities which later involved both upper extremities. She also had neck muscle weakness. She also complained of difficulty swallowing. Swallow evaluation was normal. She did not have any skin rashes.

Methods: Concentric needle electromyography showed abnormal spontaneous activity; small amplitude and often polyphasic motor unit action potentials, along with increased recruitment pattern in tibialis anterior, vastus lateralis, medial gastrocnemius, tibialis posterior and short head biceps femoris muscle in the left lower extremity. The findings were suggestive of myopathy. She underwent a muscle biopsy from the left deltoid muscle which showed dense perimysial and endomysial lymphoplasmacytic inflammatory infiltrates with degenerating myofibers.

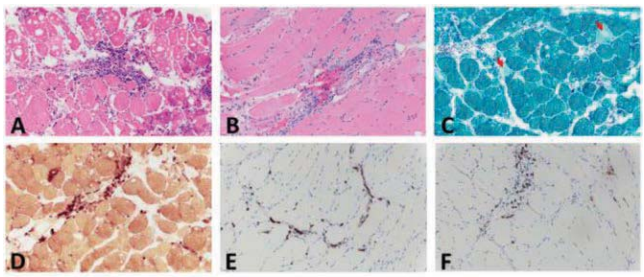

Figure. 1 Left Deltoid Muscle Biopsy. A. Dense perimysial and endomysial lympho-plasmacytic inflammatory infiltrates, with degenerating myofibers. Frozen section, H&E stain, 20x magnification. **B.** Perimysial and endomysial inflammatory infiltrates. Formalin fixed, paraffin-embedded, H&E stain, 20 x magnification. **C.** Degenerating myofibers (arrows) with pales staining on Frozen section, Gomori Trichrome, 20x magnification. **D.** Inflammatory infiltrates and degenerating myofibers are highlighted. Frozen Section, Esterase stain, 20x magnification. **E.** Endomysial mononuclear inflammatory cells are predominantly T-cells. Formalin fixed, paraffin-embedded, CD3 immunostain, 20 x magnification. **F.** The majority of T-cells have a cytotoxic (CD8+) phenotype. Formalin fixed, paraffin-embedded, CD8 immunostain, 20 x magnification.

Results: Patient has proximal muscle weakness in both upper and lower extremities along with elevated CK, EMG findings suggestive of an underlying myopathy and biopsy evidence of inflammation and a diagnosis of polymyositis was made.She was initiated on treatment with a tapering course of prednisone starting at 60 mg daily. Her edema has improved. Liver function tests and CK have improved. Muscle strength has improved in both upper extremities with some residual weakness in the proximal muscles of lower extremities.

Conclusion: Patient presented with severe generalized edema as the initial presenting symptom of polymyositis. Rheumatologists should be aware of subcutaneous edema as a presenting manifestation of inflammatory myopathy and may precede the development of muscle weakness. Previously reported cases of edematous inflammatory myopathy were mostly dermatomyositis. This case demonstrates that polymyositis could also present as subcutaneous edema.

Chronic pain - Mechanisms, epidemiology, and treatment

POS0018 REDUCTION OF DIFFUSE NOXIOUS INHIBITORY CONTROL IN ACTIVE INFLAMMATORY RHEUMATISM: A DEMONSTRATION OF CENTRAL SENSITISATION

A. P. Trouvin[1,2], A. Simunek[1], J. Coste[1,3], T. Medkour[1,2], S. Carvès[1], D. Bouhassira[2,4], S. Perrot[1,2]. [1]*Cochin University Hospital, Pain Medicine Department, Paris, France;* [2]*INSERM, U987, Boulogne Billancourt, France;* [3]*GHU Paris Centre – Cochin, Biostatistics and Epidemiology Unit, Paris, France;* [4]*Ambroise Paré University Hospital, Pain Medicine Department, Boulogne Billancourt, France*

Background: In rheumatoid arthritis (RA) and spondyloarthritis (Spa), persistent pain remains challenging. It is thought to result from central pain sensitisation, which can be measured by quantitative sensory testing (QST) and conditioned pain modulation (CPM).
Objectives: The main objective of the RAPID (Rheumatism Pain Inhibitory Descending pathways) study, was to assess descending pain modulation (through CPM paradigms) in patients with RA or Spa, comparing these patients with healthy sex- and age-matched controls. The secondary objectives were the measurement pain thresholds (heat and cold) in a non-articular, non-painful area in patients and controls as a means of detecting possible widespread hyperalgesia as another index of central sensitisation in our patients.
Methods: We included 50 RA and 50 Spa patients and 100 age- and sex-matched controls. We assessed clinical disease variables for patients, together with responses to various psychological questionnaires. All participants underwent QST with the determination of heat and cold pain thresholds (HPT-CPT) and CPM. In CPM, a conditioning stimulus was applied to a foot and the non-dominant hand in a randomised sequence. Descending pain control was assessed as the change in HPT (in °C) following a conditioning stimulus: the higher the CPM effect, the more efficient the inhibitory control.
Results: HPT and CPT were similar in patients and controls. Mean CPM effect was significantly weaker in patients than controls: 0.25°C (±2.57) and 2.79°C (±2.31) for patients and controls, respectively (p<0.0001) for conditioning on the foot; 0.57°C (±2.74) and 2.68°C (±2.12) (p<0.0001), respectively, for conditioning on the hand. The heat pain threshold was 42.35°C (± 3.68°C) for patients and 41.54°C (± 3.34°C) for healthy controls; this difference was not statistically significant. The cold pain threshold was 13.11°C (± 10.04°C) for patients and 13.28°C (± 9.34°C) for healthy controls; this difference was not significant. The weaker CPM effect in patients was associated with higher pain intensity. In all participants, a weak CPM effect was associated with high Central Sensitisation Inventory score, anxiety, depression, sleep disturbance and pain catastrophising.
Conclusion: Diffuse noxious inhibitory control is weaker in patients with active chronic inflammatory rheumatism than in healthy subjects, supporting the hypothesis of central sensitisation.

POS0019 CENTRAL SENSITIZATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: ASSOCIATION WITH DISEASE ACTIVITY

V. Bombela[1], M. Stanislavchuk[1]. [1]*National Pirogov Memorial Medical University, Vinnytsya, Ukraine, Department of Internal Medicine #1, Vinnytsya, Ukraine*

Background: Rheumatoid arthritis (RA) is the most common inflammatory arthropathy with a predominance of autoimmune mechanisms of pathogenesis and pain as the main clinical manifestation. Recent evidence has found showed that Central Sensitization (CS) may be a new mechanism for the formation of pain [1]. There is insufficient data on this phenomenon in patients with RA [2].
Objectives: To determine the prevalence of the phenomenon of CS in patients with RA and evaluate its association with disease activity.
Methods: The study involved patients with RA according to the ACR / EULAR criteria (2010). RA activity was determined by DAS-28, SDAI, CDAI, and the functional ability of patients - by HAQ. Visual analog scoring (VAS) were used to evaluate the intensity of pain. The radiological stage of RA was determined according to the Kellgren-Lawrence classification. The presence of the CS phenomenon was established using the Central Sensitization Inventory (CSI) (Mayer, T. G. et al., 2012). MS Excel and SPSS22 (© SPSS Inc.) software packages were used for statistical processing of results.
Results: 110 patients (84% of women) with RA were included. The participants' mean age was (M±SD) 53.5 ± 12.2 years, with a disease duration 8.5 ± 8.1 years. Among the examined, radiological stage I was detected in 16 (15%) patients, II - in 59 (53%), III - in 23 (21%), IV - in 12 (11%). According to the DAS28-ESR index, 56 (51%) patients had high activity (DAS 28-ESR: > 5.1) and 54 (49%) patients had moderate activity (3.2 <DAS28-ESR ≤5.1). Mean values of SDAI and CDAI also showed high disease activity: 36.5 ± 10.2 and 33.3 ± 9.8, respectively. The average value of HAQ was 1.4 ± 0.7.
CS (CSI>40) was revealed in 40 (36%) patients. Correlation analysis showed that CSI was significantly correlated with disease activity, VAS pain and HAQ: DAS28-ESR (r = 0.477; p <0.01), SDAI (r = 0.559; p <0.01), CDAI (r = 0.544; p <0.01), VAS (r = 0.575; p <0.01), HAQ (r = 0.694; p <0.01). It was found that the group of patients with CS had higher rates of disease-specific values compared to patients without CS. Significance of differences between groups was at the level of p <0.01 (Table 1).

Table 1. Characteristics of the RA patients with and without CS on the indices disease activity, VAS pain and HAQ.

	CSI<40 (n=70)	CSI>40 (n=40)	P
CDAI	29,7±7,8	38,9±9,7	<0,01
SDAI	32,9±8,6	42,3±9,6	<0,01
HAQ	1,1±0,6	1,9±0,6	<0,01
DAS28-ESR	4,9±0,9	5,7±0,8	<0,01
VAS	6,3±1,3	7,8±1,2	<0,01

Notes: SDAI – The Simple Disease Activity Index, CDAI - The Clinical Disease Activity Index, DAS-28 - The Disease Activity Score-28, HAQ-DI - Health Assessment Questionnaire,VAS - Visual Analog Scoring, p – the significance of differences between groups.

Conclusion: Central sensitization is common in RA patients. The phenomenon of central sensitization is associated with higher disease activity, loss of functional ability and severity of pain.

POS0020 PAIN PHENOTYPING IN PATIENTS WITH PSORIATIC ARTHRITIS AND HAND OSTEOARTHRITIS

J. Vela[1,2], L. Dreyer[1,2], K. Kjær Petersen[3], L. Arent-Nielsen[3], S. Kristensen[1,2]. [1]*Aalborg University Hospital, Rheumatology, Aalborg, Denmark;* [2]*Aalborg University, Clinical Institute, Aalborg, Denmark;* [3]*Aalborg University, Centre for Neuroplasticity and Pain, Aalborg, Denmark*

Background: Chronic pain is experienced by many patients with joint disease but underlying pain phenotypes including impact of concomitant fibromyalgia (cFM) have not been investigated in patients with psoriatic arthritis (PsA) and hand osteoarthritis (hand-OA).
Objectives: To investigate pain parameters (quantitative sensory testing) in patients with hand-OA and PsA using pressure pain thresholds (PPT), temporal summation of pain (TSP) and conditioned pain modulation (CPM) compared with healthy controls. Furthermore, to explore whether alternations in underlying pain mechanisms and psychological factors are associated with cFM compared to those patients without.
Methods: Patients with verified PsA or hand-OA and healthy controls underwent quantitative sensory testing using hand-held and cuff pressure algometry to measure PPT, TSP and CPM. Psychosocial factors were assessed via the Hospital Anxiety and Depression Scale, Pain Catastrophizing Scale, Pittsburgh Sleep

Quality Index, and disability was assessed via the Health Assessment Questionnaire Disability Index and pain quality via the painDETECT questionnaire. cFM was identified using the revised 2016 American College of Rheumatology criteria.
Results: A total of 75 patients with hand-OA, 58 patients with PsA and 20 controls were included. Patients with hand-OA or PsA had statistically significant lower PPTs and CPM, and greater TSP than controls and greater psychosocial impact. Limiting the analysis to patients without cFM yielded a similar result. Patients with cFM (58%) had greater scores of depression, anxiety, catastrophizing, disability and reduced sleep quality when compared to patients without cFM. Additionally, in cFM the TSP and painDETECT scores were higher compared to patients without cFM.
Conclusion: Patients with hand-OA and PsA experienced a greater degree of pain facilitation and psychosocial impact when compared with controls. Patients with cFM had greater TSP, painDETECT, disability, catastrophizing and reduced sleep quality, than patients without, indicating greater degree of sensitisation, psychosocial burden, and disability.

POS0021 CHANGES OF GUT MICROBIOTA IN CONNECTIVE TISSUE DISEASE AND ITS RELATIONSHIP WITH LYMPHOCYTE SUBSETS AND CYTOKINES

J. Q. Zhang[1,2,3], J. Luo[1,2,3], Q. Y. Su[1,2,3], J. Qiao[1,2,3], S. X. Zhang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*

Background: Connective tissue disease (CTD) is a group of autoimmune diseases characterized by the damage of connective tissue components in various parts of the body, which involved multiple organs and systems. Dysbiosis in the gut microbiome is associated with various autoimmune diseases such as CTD.
Objectives: To explore the characters of gut microbiota and their relationship with peripheral lymphocyte subsets and cytokines in patients with CTD.
Methods: Stool samples were collected from 63 CTD patients and 63 age- and sex-matched healthy controls(HCs). Microbial genomes were extracted for 16S rRNA gene sequencing. Gut microbiota characters (alpha diversity, beta diversity, and microbial composition) were analysed by R (version 4.0.1). Peripheral lymphocyte subsets were assessed by flow cytometry. Pearson correlation analysis was used to detect the correlation between the relative abundance of genus in the sample and the activity index; correlations with $p < 0.05$ were considered significant.
Results: Shannon and Simpson index revealed a decreased alpha diversity in CTD compared with that of HCs ($p < 0.05$), though not significantly difference in ACE and Chao1 parameters ($p > 0.05$, Figure 1A). Bray curtis distance-based beta-diversity analysis indicated significant differences in microbial communities between CTD and HCs ($p = 0.0014$, ANOSIM, Figure 1B). At the genus level, CTD patients had higher abundances of Terrisporobacter ($p<0.01$), Paraprevotella ($p<0.01$), CAG–352 ($p<0.01$), et al. but lower abundances of Streptococcus ($p<0.01$), Pseudomonas ($p<0.01$), Bacteroides($p<0.01$), et al (Figure 1D). IgM was positively correlated with Lactococcus ($p<0.05$), Family_XIII_AD3011_group ($p<0.05$), Streptococcus ($p<0.05$). Th17 was positively correlated with Pseudomonas ($p<0.01$). Th2 was positively correlated with Christensenellaceae_R–7_group ($p<0.001$), UCG–010 ($p<0.001$) was positively correlated. Treg and Th2 were positively correlated with Christensenellaceae_R–7_group ($p<0.01$), UCG–010 ($p<0.01$). Treg was positively correlated with Lachnoclostridium ($p<0.05$) (Figure 1E).
Conclusion: Pattients with CTD had disbiosis of gut microbiota charaterized by impared diversity and abnomal composition,which was closely correlated with peripheral lymphocyte subsets.

POS0022 CHARACTERISTICS OF PAIN IN UK PATIENTS WITH BEHÇET'S SYNDROME: A PROSPECTIVE OBSERVATIONAL COHORT STUDY

K. Plant[1], L. Chadwick[1], A. Goebel[2,3], J. Nair[1,4,5], R. Moots[1,4,5], N. Goodson[1,6]. *[1]Liverpool University Hospital NHS Foundation Trust, Rheumatology, Liverpool, United Kingdom; [2]Liverpool University, Institute of Life Course and Medicine Sciences, Pain Research Institute, Liverpool, United Kingdom; [3]The Walton Centre NHS Foundation Trust, Pain Medicine, Liverpool, United Kingdom; [4]National Behcet's Centre of Excellence, Rheumatology, Liverpool, United Kingdom; [5]Liverpool University, Institute of Life Course and Medicine*

Sciences, Liverpool, United Kingdom; [6]Liverpool John Moores University, Research Institute for Sport and Exercise Sciences, Liverpool, United Kingdom

Background: Behçet's syndrome (BS) is a rare multi-organ systemic vasculitis of unknown aetiology with hallmark manifestations of mucocutaneous ulcers and skin lesions. Morbidity is high in BS; with high prevalence of pain, fatigue and poor quality of life. Fibromyalgia syndrome (FMS), a common cause of widespread musculoskeletal (MSK) pain, is more prevalent in rheumatological conditions including BS. However, there is limited research into the aetiology and characteristics of pain in BS. To our knowledge, there are no studies describing pain in a UK BS population.
Objectives: To describe the pain characteristics and incidence of comorbid FMS in patients with BS, and investigate their relationship with disease activity.
Methods: This is a prospective observational study of patients with a diagnosis of BS attending the National Centre for BS in Liverpool between February 2017 and March 2019. Patients were defined as "Complete BS" if they satisfised the International Study Group criteria and "Incomplete BS" if they met one criterion plus genital ulcers. BS severity was assessed using the Behçet's disease current activity form (BDCAF). High and low disease activity were defined as a BDCAF score ≥ 4 or < 4 respectively. FMS prevalence was determined from consultant diagnosis. To minimise inflation of disease severity in the FMS cohort, a modified BDCAF (with arthralgia and arthritis components removed) was calculated (mBDCAF). Assessments of pain included: The Pain Visual Analogue Scale (VAS), Pain Mannequin and Short Form McGill (SF-MPQ-2) questionnaires. Generalised pain data was imputed from the pain mannequin using the American College of Rheumatology 2016 definition, pain in all quadrants (upper left, upper right, lower left and lower right) plus axial distribution. Pain and FMS prevalence were compared between high and low disease activity using Chi-Square Test of Independence. The mean mBDCAF was compared between those with and without FMS using a student's T-Test. Data analysis was conducted in Microsoft Excel and STATA.
Results: 101 patients, 75 female and 26 male, of age 10-74 years were assessed. 81.2% of patients met the ISG criteria (Complete BS); The remaining 18.8% met Incomplete BS status. 90% of patients reported moderate-severe pain with a median VAS score of 68/100 [38, 81]. 35.6% of patients had a diagnosis of FMS and 46.5% experience generalized pain. 76% of patients with high disease activity reported severe pain, a VAS greater than 70, compared to 39.1% with low disease activity *(p=.003)*. Pain was more generalised in high disease activity (72%) compared to low disease activity (37.7%) *(p=.003)*. The qualitative assessment of pain (SF-MPQ-2) stratified by disease activity, Figure 1, demonstrates that pain intensity is higher in high disease activity. Continuous descriptive terms were most commonly selected indicating a chronic nature of the pain. Concomitant FMS diagnosis was more prevalent in the high disease activity group (52%) than the low disease activity group (29%) *(p=0.04)*. The mean mBDCAF of patients with FMS was 2.09 ± 1.3 compared to 1.53 ± 1.3 in patients without FMS *(p= 0.047)*.

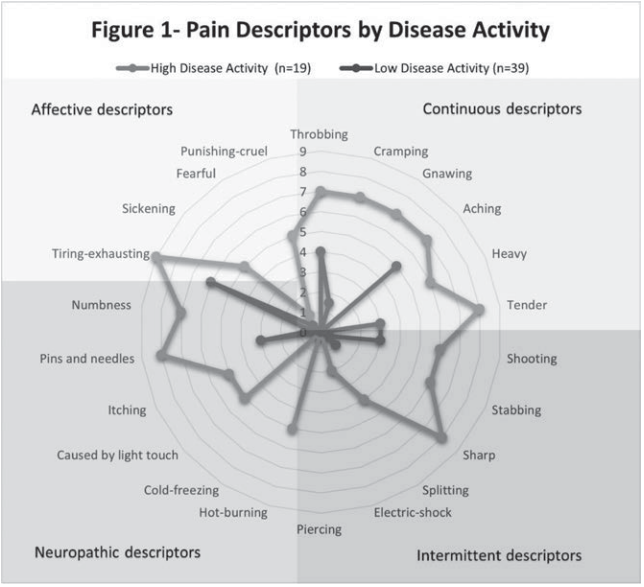

Figure 1. Pain descriptors from the SF-MPQ-2 stratified by high (BDCAF ≥4) and low disease activity (BDCAF <4). Descriptors are rated no pain to the worst pain ever (0 – 10). The median value for each descriptor is plotted. The descriptors are divided into four categories: affective, continuous, neuropathic and intermittent.

Conclusion: This the first study to describe the pain experience of a UK population of BS patients. The majority of patients experience moderate to severe chronic MSK pain. Severe generalised MSK pain is more prevalent in those with high BS disease activity. We have demonstrated a relationship between high disease activity, worse pain intensity, and comorbid FMS. Our findings pose new questions into the research of pain in BS. Further studies are required to explore the mechanism of generalised pain and its correlation with disease activity.

POS0023 PREVALENCE AND IMPACT OF FIBROMYALGIA SYNDROME IN A COHORT OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE

L. Guida[1], S. Sirotti[2,3], G. Filippou[2], A. Dell'era[1], D. Gridavilla[1], M. E. Romano[2], D. Ventura[2], G. M. C. La Paglia[2], S. Farah[4], S. Ardizzone[1], P. Sarzi-Puttini[2,3].
[1]Luigi Sacco University Hospital, Gastroenterology Department, Milan, Italy; [2]Luigi Sacco University Hospital, Rheumatology Department, Milan, Italy; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [4]Polytechnic University of Marche, Rheumatology Department, Jesi, Italy

Background: Fibromyalgia (FM) is a common chronic disorder characterized by widespread pain, fatigue, sleep disturbances and functional symptoms, reaching a prevalence of 2–3% worldwide. It can present as a comorbidity in patients with concomitant chronic disease and can have a significant impact on the quality of life. There are very few studies on the prevalence and the impact of FM in patients with inflammatory bowel disease (IBD).
Objectives: The aims of this study were to assess the prevalence of FM in a cohort of patients with IBD, and to evaluate the impact of FM on the quality of life of those patients.
Methods: Consecutive patients with IBD were enrolled from August to November 2021 in two IBD units, patients with severe disease activity according to the Crohn's disease activity index (CDAI) and to the Mayo score for UC, or with other concomitant chronic diseases were excluded. Clinical and demographic data and Patient Reported Outcomes (PROs) (Widespread Pain Index (WPI), Symptom Severity Score (SSS), IBD Questionnaire (IBD-Q), Depression anxiety stress scales-21 (DASS-21), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Impact of event scale-revised (IES-R), Pittsburgh Sleep Quality Index (PSQI)) were collected. FM was diagnosed according to 2011 ACR classification criteria by an expert rheumatologist. Mann-Whitney test, chi-square test, and Student t test were used for statistical analyses. A multivariate analysis was performed to estimate the effect of independent variables (BMI, age, CRP, CDAI, Mayo score, WPI, DASS-21, FACIT-F, PSQI) on patients' quality of life (IBD-Q). A p value < 0.05 was considered as significant.
Results: A total of 196 IBD patients were enrolled (86 female (44%) with a mean age of 50 ± 15 yo), 105 with Crohn's disease (CD) and 91 with ulcerative colitis (UC). 147 patients were in remission, 35 had low disease activity and 14 moderate disease activity. The overall prevalence of FM in the IBD cohort was 17/196 (8.7%) [95% IC 5% – 13%], 10 (11.6%) women and 7 (6.3%) men; with a prevalence of 7.6% (8/105) in CD and 9.9% (9/91) in UC.
In Table 1 are indicated the characteristics of patients with IBD + FM and IBD alone. No significant demographic and clinical differences between the two groups were detected.

Table 1.

	IBD + FM (n=17)	IBD without FM (n=179)	p
Female/Male (%)	10/7 (59%/41%)	75/102 (42%/58%)	0.19
Age, years (SD)	56.8 (± 13)	48.5 (± 17)	0.06
BMI (SD)	21 (± 8.7)	23.7 (± 4.8)	0.46
CD (%)/UC (%)	8 (47%)/9 (53%)	97 (54%)/82 (46%)	0.57
CRP, median (SD)	0.16 mg/dL (± 2.8)	0.2 mg/dL (± 1.5)	0.87
IBD remission	14 (82%)	133 (74%)	0.33
IBD low disease activity	1 (6%)	34 (19%)	
IBD moderate disease activity	2 (12%)	12 (7%)	
Ongoing conventional treatment	6 (35%)	70 (39%)	0.27
Ongoing biological treatment	11 (65%)	112 (63%)	0.42
PROs			
IBD-Q	150.3	176.9	<0.001
DASS-21 DEPRESSION	15.3	8.24	<0.001
DASS-21 ANXIETY	16.6	9.13	<0.001
DASS-21 STRESS	13.4	6.13	<0.001
FACIT-F	25.5	38.2	<0.001
IES-R	36.9	16.3	<0.001

The quality of life among IBD patients and IBD + FM patients, assessed with IBD-Q, appear significantly lower (p <0.001) in the second group. Similar results were obtained evaluating depression, anxiety, stress, chronic fatigue, and patients' discomfort (Table 1).

The multivariate analysis demonstrated that the variables influencing the quality of life (IBD-Q) were the disease activity (CDAI) (p 0.0256), the chronic fatigue (FACIT-F) (p 0.0061) and sleep disturbances (PSQI) (p 0.0440), for CD; while for UC the only variable that correlate with IBD-Q was the disease activity (Mayo score) (p 0.0129).

Conclusion: FM is a common disorder especially in patients with other concomitant chronic diseases. This study reported a prevalence of FM of 8.7% in IBD patients without any significant differences between CD and UC. Moreover, the comorbidity of FM in IBD can have a considerable impact on quality of life and on measures of disease severity, with worst values in all PROs measurements.

POS0024 PREDICTION OF SPONTANEOUS IMPROVEMENT IN PATIENT REPORTED OUTCOME SCORES IN OSTEOARTHRITIS USING MARKERS OF JOINT TISSUE TURNOVER

M. Mukundan[1], A. C. Bay-Jensen[2], J. Samuels[1], M. Karsdal[2], S. Abramson[1]. *[1]NYU Grossman School of Medicine, Division of Rheumatology., Department of Medicine, New York, United States of America; [2]Nordic Bioscience, ImmunoScience, Herlev, Denmark*

Background: Osteoarthritis (OA) is a chronic disease characterized by pain and disability. There is no modifying treatment approved for OA today. This may be attributed to the difficulty generating a robust response based on patient-reported outcomes (PROs) linked to the drug mode of action. There is a need in drug development to test and validate biomarkers that objectively relate to PROs or even predict changes in PROs. Biomarkers of cartilage and bone turnover are associated with structural and symptomatic progression.[1] In addition, recent findings suggest that a subset of OA patients have elevated serum levels of C-reactive protein metabolites (CRPM), which is predictive of radiographic progression.[2,3]

Objectives: This explorative study aimed to investigate the association between PROs and markers of joint tissue formation and degradation in patients with either high or low levels of CRPM. In particular, whether levels could predict spontaneous improvement in PROs.

Methods: 146 knee OA patients, 62% women, from the NYU cohort were included.[4] Mean (SD) age, 62.5 (10.1); BMI, 26.6 (3.6); 32% NSAID users; and 67.6% w. radiographic OA (KL≥2). PROs were recorded at baseline (BL) and 2 years (FU), and the current investigation was: WOMAC pain, stiffness, and function. The mean (SD) for WOMAC pain, stiffness, and function were 35.4 (22.9), 40.8 (25.7), and 41.7 (28.3) mm on a 100 mm scale. Twenty-one healthy individuals were included as a reference. Eight serum biomarkers of type I, II, III, and IV collagen degradation (C1M, C2M, C3M, C4M) and formation (PRO-C1, PRO-C2, PRO-C3, and PRO-C4) as well as the inflammatory biomarker CRPM, were assessed at baseline. LN-transformed data was adjusted for race, Sec, age, BMI, and NSAID use when comparing OA to controls and in the predictive model. Marked symptomatic (S) OA was defined as ≥40 mm in either of the WOMAC scores at BL and improvement as 20 mm decreased in any of the scores from BL to FU.

Results: There was no difference in mean marker levels between controls and OA patients. Only C2M correlated with the WOMAC scores at baseline in the ALL population (p <0.001). This correlation was maintained in both the high and low CRPM groups. A high correlation was observed between the PROs and PRO-C4, C1M and C3M, but only in the high CRPM group. Next, we investigated whether the markers could predict symptomatic improvement in patients with marked SOA. A combination of C4M, Age and BMI was predictive of pain improvement in the ALL population (Table 1). Interestingly the predictors were different in the low vs. high CRPM group; PRO-C2, PRO-C3, PRO-C4 and Sex predicted a 20 mm decrease in WOMAC pain in the low group, while C2M alone predicted an improvement in the high CRPM group. Moreover, C2M predicted an improvement in stiffness in the CRPM high, but not in the low CRPM group. C1M and C3M predicted a 20 mm decrease in function only in the high CRPM group.

Conclusion: Levels of the joint tissue markers weew subtle compared to controls. However, the markers, together with sex and BMI, could predict symptomatic improvement. This may provide novel insight into the link between tissue turnover and PROs.

POS0025 PREVALENCE OF ATTENTION DEFICIT HYPERACTIVITY DISORDER AMONG ADULT PATIENTS WITH FIBROMYALGIA

S. Moyano[1], W. Berrios[2], I. Gandino[1], E. Soriano[1], J. Rosa[1]. *[1]Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; [2]Hospital Italiano de Buenos Aires, Neurology, Buenos Aires, Argentina*

Background: Fibromyalgia (FM) and attention deficit hyperactivity disorder (ADHD) share some clinical features, and a reduced dopamine function has been proposed for both disorders. ADHD is a chronic condition, marked by persistent inattention, impaired concentration, hyperactivity, impulsivity, emotional lability, anxiety and disorganized behaviour. High rates of comorbidity between ADHD and FM have been reported, as well as some evidence that patients with both conditions experience heightened disease severity.

Table. Prediction of symptomatic regressive OA in patients with symptomatic knee OA. Multiple variate logistic regression including ln-transformed biomarkers and baseline clinical characteristics (age, gender, race, BMI and NSAID use). Not adjusted for multiplicity.

Regressive vs. stable OA		AlL	Low CRPM	High CRPM
		20 mm change[1]	***20 mm change[1]***	***20 mm change[1]***
WOMAC pain	n (%)[2] Predictors AUC [95%-CI] P	61 (41.0) C4M, Age, BMI 0.73 (0.60 - 0.84) 0.0042	35 (34.3) PRO-C2, PRO-C3, PRO-C4, Sex 0.73 (0.62 -0.83) 0.056	26 (50.0) C2M 0.79 (0.58 - 0.92) 0.024
WOMAC stiffness	n (%)[2] Predictors AUC [95%-CI] P	57 (47.4) C2M 0.67 [0.53 – 0.79] 0.020	33 (48.5) None	24 (45.8) C2M 0.85 (0.64 - 0.96) 0.0007
WOMAC function	n (%)[2] Predictors AUC [95%-CI] P	61 (27.8) None	35 (22.7) None	26 (34.6) C1M, C3M 0.83 (0.63 – 0.95) 0.0074

[1]Regressive disease was defined as 10 or 20 mm or more decrease in VAS pain, WOMAC pain, stiffness or function, and 30 mm or 60 mm or more decrease in WOMAC total, over two-years. [2] Rate of regression in percentage in each of the sub-populations.

Objectives: Our purpose was to determine the prevalence of ADHD symptoms in patients with FM and to assess the relationship with disease impact.
Methods: Consecutive patients, older than 18 years, with diagnosis of FM (ACR 2016 criteria) without known cognitive impairment, seen at the Rheumatology Unit between April 2018 and December 2019, were included. At inclusion visit the collected data included Revised Fibromyalgia Impact Questionnaire (FIQ-R) and Health Assessment Questionnaire, Argentine version (HAQ-A). During the Neurology visit, the following tests were performed: Montreal Cognitive Assessment (MoCA) test for evaluating the presence of cognitive impairment, Conners Continuous Performance Test II (CPT II) for the assessment of ADHD, and Wender-Utah Rating Scale (WURS) to retrospectively assess childhood ADHD symptoms. Univariate analysis was performed using t-tests for normally distributed continuous variables, and Wilcoxon rank sum test for non-normally distributed continuous variables. A chi-square or Fisher test was used when appropriate for categorical variables. Predictors that were found to be related to ADHD ($p \leq 0.20$) were then entered into a multivariable logistic regression model.
Results: 60 patients with FM and 71 matched controls without FM or known cognitive impairment were included. FM patients' characteristics are shown in Table 1. 61.7% (n=37) of the patients with FM tested positive for adult ADHD. In 48.6% (18/37) of them, the diagnosis had been missed in childhood. Participants with both FM and a positive adult ADHD screening test did not score significantly higher on the FIQ-R (52.3, SD= 16.1 vs. 47.9, SD= 12.3; p= 0.2693) and HAQ-A (0.693, SD= 0.455 vs. 0.521, SD= 0.428; p=0.1523) compared with patients without ADHD. Retrospectively assessed childhood ADHD was significantly associated with adult persistence (OR 55.1, CI=3.6 to 842.6, p=0.004).

Table 1. Clinical and demographic characteristics of patients with FM.

Characteristics	n=60
Female, n (%)	53 (88.3)
Age (years), mean (SD)	58.3 (14.2)
Time from diagnosis (years), mean (SD)	5.2 (5)
Scholarity (years), mean (SD)	12.9 (3.4)
HAQ-A, mean (SD)	0.627 (0.449)
FIQ-R, mean (SD)	50.6 (14.8)
Cognitive complaint, n (%)	34 (56.7)
Depression, n (%)	35 (58.3)
Anxiety, n (%)	27 (45)
Concomitant personality disorders	39 (65)

Patients with FM had significantly higher prevalence of cognitive impairment (43.3% vs. 16.9%; p<0.0001), childhood ADHD symptoms (31.7% vs. 14.1%; p=0.016) and adult ADHD symptoms (61.7% vs. 23.9%; p<0.0001) than the control group (Figure 1).

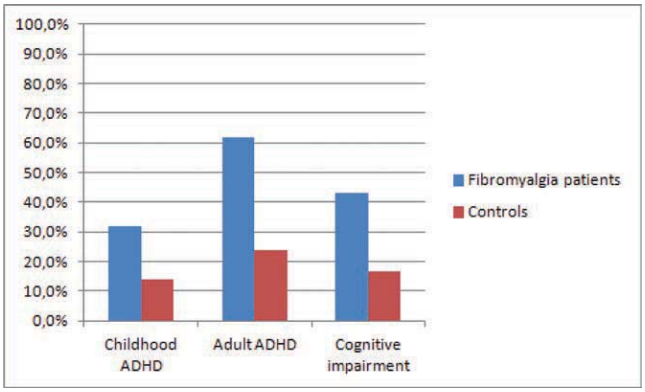

Figure 1. Percentage of FM patients with cognitive impairment, childhood and adult ADHD. Comparison with the control population.

Conclusion: The co-occurrence of adult ADHD in FM was highly prevalent. In nearly half of the patients the diagnosis had been overlooked during childhood and it was associated with adult persistence. The prevalence of cognitive impairment, and childhood and adult ADHD was higher in patients with FM compared with the control group. ADHD was not associated with the FM impact. Evaluation of ADHD symptoms in patients with FM is important for recognition and treatment of this comorbidity.

POS0026

LOSS OF PRODUCTIVITY IN MILD, MODERATE, AND SEVERE FIBROMYALGIA FEMALE WORKERS: CROSS-SECTIONAL STUDY

F. Salaffi[1], M. Di Carlo[1], S. Farah[1], C. Mariani[1], S. Fulginei[1], G. P. Martino[2], P. Sarzi-Puttini[3]. *[1]Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale "Carlo Urbani", Jesi, Italy; [2]Ospedale Murri, Internal Medicine Department, Fermo, Italy; [3]ASST Fatebenefratelli-Sacco, Rheumatology Unit, Internal Medicine Department, Milano, Italy*

Background: Patients suffering from FM are challenged by symptoms such as chronic pain, fatigue, sleep disturbance and emotional distress. These symptoms lead to a physical capacity impairment, and FM patients report consequences on their activities of daily life and difficulties in fulfilling their work roles, resulting in reduced work capacity, presenteeism (coming to work despite health or personal issues, often resulting in a loss of productivity), absenteeism, and inability to work. Changes in ability to work are crucial to comprehend since they provide a more objective sign of function than other self-reported measures.
Objectives: To assess (a) the impacts of fibromyalgia (FM) symptoms on patients' ability to work and (b) the relationship between FM severity level and lost productivity from the perspective of patients.
Methods: FM female patients were retrospectively evaluated for this cross-sectional study. FM severity was determined using the revised Fibromyalgia Impact Questionnaire (FIQR). Work Productivity and Activity Impairment-Fibromyalgia (WPAI-FM) was used to evaluate patients' employment status. Differences across FM severity states were evaluated using the one-way analysis of variance (ANOVA) and chi-square or Fisher's exact test. The Pearson's r test was performed for the correlation analysis.
Results: The study included 209 subjects, 64 (30.6%) had mild, 64 (30.6%) had moderate, and 81 (38.8%) had severe FM; 57.9% were working full-time, and 42.1% were working part-time. According to WPAI-FM the work productivity and activity impairment resulted: absenteeism 7.03%; presenteeism 44.35%; activity impairment 47.24%; overall work productivity loss 58.23%. Disease severity was associated with decreased work productivity. Presenteeism, overall work productivity loss, and activity impairment demonstrated significant correlations with FIQR and PainDETECT Questionnaire.
Conclusion: FM severity is associated to a reduced job productivity. Early identification and treatment of FM may provide a window of opportunity for job preservation.

POS0027

SPONDYLOARTHRITIS AND COMORBID FIBROMYALGIA IN PATIENTS WITH ACUTE ANTERIOR UVEITIS: CLINICAL AND ULTRASONOGRAPHIC ASSESSMENT

G. Citriniti[1], P. Macchioni[1], N. Girolimetto[1], L. Cimino[2], A. Marchesoni[1], C. Salvarani[1,3]. [1]*AUSL-IRCCS Reggio Emilia, Rheumatology Department, Reggio Emilia, Italy;* [2]*AUSL-IRCCS Reggio Emilia, Ophtalmology Department, Immunology Eye Unit, Reggio Emilia, Italy;* [3]*Rheumatology Unit, University of Modena & Reggio Emilia, Rheumatology Unit, Modena, Italy*

Background: Musculoskeletal pain is an important feature in patients (pts) with anterior acute uveitis (AAU), as a symptom of spondyloarthritis (SpA). Fibromyalgia (FM), which is more prevalent in pts with chronic inflammatory diseases, has a widely recognized effect on both differential diagnosis and evaluation of outcome measures in SpA.

Objectives: To estimate the prevalence of primary FM and concomitant FM and SpA in a cohort of pts with AAU, and to compare clinical and ultrasonographic findings in SpA pts with (SpAFM+) and without (SpAFM-) concurrent FM and SpA.

Methods: 152 consecutive pts affected by AAU from the Immunology Eye Unit (AUSL-IRCCS Reggio Emilia, Italy) were enrolled.

A complete rheumatological assessment, including 68/66 peripheral joint count, Leeds Enthesitis Index (LEI) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), and Fibromyalgia Impact Questionnaire (FIQ) was performed.

Using an Esaote MyLabClass, 18-6MHz linear multifrequency transducer, 6 entheses (lateral epicondyle, distal quadriceps insertion, proximal and distal patellar tendon insertions, calcaneal insertion of Achilles tendon and plantar fascia) were evaluated bilaterally for the presence of any elementary lesion, structural damage and active enthesitis, according to OMERACT definitions[2].

Pts were classified as having SpA and/or FM according to ASAS criteria and 2010 ACR diagnostic criteria for FM, respectively.

Results: 103 pts were diagnosed with anterior acute non granulomatous uveitis (AANGU) and 49 with anterior acute granulomatous uveitis (AAGU) (F/M 93/59, age 46.2±12.3 years, BMI 25±5.1, disease duration 43.8±85.2 months).

14 pts (9.2%) met the ACR criteria for FM, of whom 8 pts had concomitant FM and SpA. All FM pts had AANGU. FM pts showed significantly higher enthesitis count and report worse disease activity and function scores (Table 1). Fulfillment of ASAS criteria was associated with FM (p=0.004).

Table 1. Demographic and clinical data of FM patients (results for continuous variables expressed as mean ± standard deviations, for discrete variables as n° and percentage)

	FM + (14)	FM - (138)	p	OR (95%CI)
Age	48 ± 11.7	46.1 ± 12.4	0.569	
Female	10 (71.4%)	83 (60%)	0.409	
BMI	24.7 ± 5.5	25 ± 5.2	0.831	
AANGU	14 (100%)	89 (64.5%)	0.005	
SpA	8 (57%)	30 (22%)	0.004	4.8 (1.6 – 14.9)
ax-SpA	6 (43%)	18 (13%)	0.004	5 (1.6 – 16.1)
Psoriasis	2 (14.3%)	9 (6.5%)	0.268	
IBP	7 (50%)	19 (14%)	0.001	6.3 (2 – 19.9)
Buttock pain	9 (64%)	24 (17%)	<0.001	8.6 (2.63 – 27.8)
History of enthesitis	7 (50%)	20 (14.5%)	0.001	5.8 (1.9 – 18.6)
TJC	2.6 ± 3.8	0.6 ± 1.8	0.072	
LEI	1.9 ± 1.2	0.5 ± 1	<0.001	
MASES	3.8 ± 3.4	0.8 ± 2	0.07	
BASDAI	5.1 ± 1.7	1.8 ± 1.7	<0.001	
BASFI	2 ± 1.4	0.6 ± 1.2	<0.001	
FIQa	0.6 ± 0.6	0.3 ± 0.8	0.176	
FIQb	4.2 ± 2.3	1.1 ± 1.8	<0.001	
FIQc	1.9 ± 2.4	0.4 ± 1.3	0.044	
FIQd	38.9 ± 13.5	16.2 ± 13.9	<0.001	

SpAFM+ pts more frequently reported an history of enthesitis [75% vs 23.3% p=0.011 OR 9.9 (95% CI 1.6 – 60.2) and buttock pain [75% vs 33.3% p=0.034 OR 6 (95% CI 1.02 – 35.3)] when compared with SpAFM-, whereas no significant differences in LEI, MASES, joint count, and inflammatory back pain (IBP), as well as in sex, age and BMI were observed.

BASDAI, FIQb and FIQd were increased in SpAFM+ (6±1.1 vs 3.4±1.8 p<0.001, 4.3±2.1 vs 1.7±2.2 p= 0.005 and 43.6±11.4 vs 24.6±15.5 p=0.003 respectively).

Abnormal US findings were detected in 35/38 SpA pts (92.1%), without significant differences in elementary lesions and structural damage between SpAFM+ and SpAFM-. At patient-level, a significantly higher percentage of SpAFM+ pts had at least one active enthesitis, as compared with SpAFM- (25% vs 3.4%, p = 0.048).

Conclusion: Comorbid FM was frequent in SpA associated with AANGU, affecting both clinical presentation and outcome measures, whereas no FM patients were found in the AAGU group. In our cohort the role of ultrasonography in discriminate SpAFM- from SpAFM+ is not clear.

THE EFFECTS OF TELEREHABILITATION WITH REMOTELY SPINAL STABILIZATION EXERCISES ON CLINICAL VARIABLES, FUNCTIONAL ACTIVITIES, EXERCISE ADHERENCE AND MUSCLE ARCHITECTURE OF NECK MUSCLES IN INDIVIDUALS WITH CHRONIC NECK PAIN

D. Onan[1], O. Ulger[1]. [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, ANKARA, Turkey*

Background: Doing a job with functional activity may aggravate chronic neck pain(CNP). Thickness, PCSA of the neck muscles can be improved with exercise. During the Covid-19 pandemic, people has caused an increase in home workload, the frequency of performing functional activities related to performance has increased. The distance between physiotherapists and the patient should be at least 2 meters in clinics due to the risk of transmission. As a result, the importance of telerehabilitation has increased.

Objectives: Our aim is to investigate the effect of remotely spinal stabilization exercises(SSE) with telerehabilitation on clinical variables, the functional activities, exercise adherence and muscle architecture patients with CNP.

Methods: The demographic characteristics were recorded. Pain intensity with Visual Analog Scale (VAS), disability level with Neck Disability Index (NDI), neck awareness with Fremantle Neck Awareness Questionnaire (FreNAQ), the functional capacity levels with neck function capacity evaluation test, the difficulty of functional activities with VAS were assessed. Muscle thickness of M. Sternocleideomastoideus, M. Upper Trapezius, PCSA of M. Longus Colli, M. Cervical Multifidus was evaluated in the resting with 3.5-10 MHz ultrasound. The exercise adherence with Exercise Adherence Rating Scale and exercise program satisfaction with VAS were evaluated. The telerehabilitation group (TG) used exercises videos and video conferences, control group (CG) did SSE in the clinic. To study the effects of the interventions, the outcome measures were compared time-by-group interaction effects, one the within-groups factor (time) and one the between-groups factor (group) by repeated-measures two-way ANOVA. The Mann Whitney-U test was performed to compare two groups for non-parametric data.

Results: Twenty-eight patients were randomly allocated to the TG and the CG. The VAS, NDI, FreNAQ, the functional capacity levels, muscle architecture showed similar changes over time in both groups. Results showed no significant time-by-group interaction effects of VAS, NDI, FreNAQ, the functional capacity levels, the difficulty of functional activities and muscle architecture (p>0.05); a significant effect for time in the VAS, NDI, FreNAQ, the functional capacity levels, the difficulty of functional activities and muscle architecture (p<0.001). There was no difference between the groups in terms of VAS, NDI, FreNAQ, the functional capacity levels, the difficulty of functional activities and muscle architecture. Results showed no significant effect for the group in the VAS, NDI, FreNAQ, the functional capacity levels, the difficulty of functional activities and muscle architecture (p>0.05). Both groups adapted well to the exercise program and were highly satisfied with the SSE (p<0.05).

Conclusion: The VAS, NDI, difficulty of functional activities decreased; FreNAQ, functional capacity levels, architecture of neck muscles increased in both groups after 8 weeks SSE. It was determined that telerehabilitation with remotely SSE was beneficial as face-to-face SSE.

Genomics, functional genomics and genetic basis of inflammatory arthritis

POS0029 CHARACTERISING THE CLINICAL AND RADIOLOGICAL PHENOTYPE OF PSORIATIC ARTHRITIS: A CLASS I AND II HLA ALLELES STUDY

E. Espartal[1], A. Erra[1], X. Michelena[1], M. Almirall Bernabé[1], M. Lopez Lasanta[1], H. Borrell Paños[1], A. Pluma Sanjurjo[1], S. Sandoval[1], H. Avalos Bogado[1], S. Marsal[1]. [1]*Hospital Universitari Vall d'Hebron, Vall d'Hebron Hospital Campus, Rheumatology, Barcelona, Spain*

Background: Psoriatic arthritis (PsA) is a heterogeneous disease affecting multiple tissues including skin and joints. Few studies have fully explored the association between class I and II HLA alleles and different clinical and radiological manifestations.
Objectives: To examine the association between different class I and II HLA alleles and certain PsA phenotypes.
Methods: Cross-sectional study including patients with PsA over 18 years. All patients fulfilled the CASPAR classification criteria for PsA. Demographic, clinical, laboratory and radiology data were gathered including variables related to joint phenotype, type of skin involvement and response to biological disease-modifying drugs (bDMARDs) treatment. HLA class I (A, B, C) and II (DR, DQ, DP) determinations were performed with high-resolution techniques. We explored possible associations with univariate logistic regression and applied the Bonferroni method to correct for multiple comparisons. bDMARDs resistant patients were defined if failure to two or more bDMARDs.
Results: A total of 246 patients were included. Mean age of the cohort was 59.8 years and 53% were men. Average articular disease duration was 12.4 years. A total of 39.8% patients had axial involvement and 90.7% peripheral, being the polyarticular the most frequent subtype in 48% of cases. Considering the skin, mean disease duration was 22.2 years, being the plaque psoriasis the most frequent subtype in 75.2% of cases. 44.3% of the patients presented a history of dactylitis whilst 24% presented enthesitis. Uveitis was reported in 3.7% of patients and Crohn's disease in 0.4%. 30.9% of PsA patients had erosions in hand or feet x-ray. More than half (59.3%) were treated with bDMARDs with a median exposure of 2 different drugs.
Table 1 shows the HLA I and II alleles with a frequency greater than 5%.

Table 1. HLA class I and II alleles with frequencies greater than 5%

GEN	ALLELE	N	FREQUENCY (%)
HLA-A	02:01	79	23.87
	01:01	51	15.41
	29:02	29	8.76
	03:01	26	7.85
HLA-B	27:05	31	9.06
	44:03	26	7.6
	51:01	22	6.43
	08:01	21	6.14
HLA-C	07:01	39	11.78
	06:02	38	11.48
	04:01	34	10.27
	12:03	32	9.67
HLA-DR	07:01	60	18.13
	01:01	37	11.18
	03:01	28	8.46
HLA-DQ	05:01	60	19.8
	02:02	49	16.17
	03:01	39	12.87
	02:01	29	9.57

HLA-B*27:05 (OR 2.3, CI 95% 1.01-5.47) and HLA-C*02:02 (OR 2.8, CI 95%, 1.08-7.55) were associated with axial involvement. HLA-DRB*03:01 (OR 3.1, CI 95%, 1.22-8.36) and HLA-DQ*02:01 (OR 3.24, CI 95%, 1.3-8.82) were associated with the polyarticular subtype, HLA-B*08:01 (OR 5, CI 95%, 1.81-14.33), HLA-C*07:01 (OR 2.65, CI 95%, 1.19-5.76) and HLA-DQ*02:01 (OR 2.55, CI 95%, 1.03-6.11) with enthesitis; HLA-A*29:02 (OR 2.68, CI 95%, 1.12-6.75) and HLA-A*11:01 (OR 2.77, CI 95%, 1.06-7.78) with dactylitis; HLA-C*06:02 (OR 2.33, CI 95%, 1.09-5.06) with nail psoriasis; HLA-C*04:01 (OR 3.52, CI 95%, 1.18-9.64) with palmo-plantar psoriasis; HLA-C*06:02 (OR 4.5, CI 95%, 1.33-23.7) and HLA-C*12:03 (OR 3.59, CI 95%, 1.05-19.05) with plaque psoriasis and HLA-A*24:02 (OR 3.03, CI 95%, 1.17-7.92) with erosions. No association was found between alleles and bDMARD resistant PsA patients.
Conclusion: In our cohort, we have confirmed previously described associations in the literature[1] and found new significant associations with clinical and radiographic PsA manifestations including class II HLA analysis.
