Background: Ankylosing spondylitis (AS) is a heritable inflammatory disease eventually leading to spinal fusion [1]. Severity of structural damage is highly variable, some patients develop almost no change in spinal structure for long disease duration, whereas others have total ankylosis even in the early stage of disease.
Objectives: To identify clinical and genetic factors associated with severe radiographic damage in patients with AS.
Methods: We newly generated genome-wide variant data (833K, KoreanChip) of 444 AS patients. The severity of radiographic damage was assessed using the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). To identify clinical and genetic factors associated with severe radiographic damage, multiple linear regression analyses were performed. Human AS osteoprogenitor cells were used for functional validation. Pathway analysis was also conducted.
Results: A total 444 AS patients (male 90.3%) were enrolled. The median mSASSS at baseline was 7.7 (5.5-16.8). The patients were observed for 9.6 (7.9-11.3) years. Within this period, the median mSASSS score increased to 14.0 (7.0-36.8). The most influential clinical factor of final mSASSS was baseline mSASSS ($\beta = 0.818$, $p < 0.001$). Peripheral joint involvement was associated with decreased possibility of severe radiographic damage ($\beta = -0.221$, $p < 0.001$). Eye involvement, longer follow up duration, and increased age at enrollment were associated with increased final mSASSS ($\beta = 0.165$, $p < 0.001$; $\beta = 0.039$, $p < 0.001$; $\beta = 0.010$, $p = 0.002$, respectively). Ryanodine receptor 3 (RYR3) gene was associated with severe radiographic damage ($\beta = 1.105$, $p = 1.97x10\text{-}06$). Treatment with Rhodamine B, a ligand of RYR3, induced extracellular matrix mineralization of AS osteoprogenitors in vitro. For the pathway analysis, PI3K-Akt signaling pathway and focal adhesion pathway were associated with severe radiographic damage in AS.
Conclusion: This study identified clinical and genetic factors that contributed to better understanding of the pathogenesis and biology associated with radiographic damage in AS.

Genomics, functional genomics and genetic basis of inflammatory arthritis

POS0031 FUNCTIONAL GENOMICS INVESTIGATION OF THE ANKYLOSING SPONDYLITIS ASSOCIATED LOCUS RUNX3

C. Cohen[1], D. Simone[2], C. Selmi[3], P. Bowness[1], P. B. Wordsworth[1], M. Vecellio[4]. *[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom; [3]Humanitas Research Hospital, Clinical Immunology and Rheumatology, Rozzano, Italy; [1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Ankylosing Spondylitis (AS), is a highly heritable disease with >100 genomic loci incriminated. Among these, RUNX3, a transcription factor (TF) involved in diverse immunological processes, is robustly (10^{-15}) associated. [1] We have extensively investigated the single nucleotide polymorphism (SNP) *rs4648889* located in a 2kb regulatory locus upstream of the *RUNX3* promoter. We have demonstrated that the association between AS and this SNP can be explained by allele-specific effects on TF recruitment (including IRF4, IRF5 and the NuRD complex) that alter gene expression, specifically in CD8+ T-cells, and having a crucial role in CD8+ T-cells function. [2, 3]
Further, we have recently shown a clear chromatin looping event between the region encompassing SNP *rs4648889* and the RUNX3 promoter confirming the functional role of this genetic variant. [4]
Objectives: The purpose of this work is: (1) to better characterise the chromatin looping landscape of the whole AS-associated *RUNX3* genomic locus and (2) to determine the single-cell expression of the *RUNX3*-related genes identified previously [2, 3] in CD8+ T-cells lymphocytes.
Methods: (1) Chromosome conformation capture (3C) technique followed by qPCR was performed to define the chromatin looping events at the *RUNX3* genomic locus in relevant cell lines, including Jurkat T-cells and U937 monocytes-like cells. (2) 10X Chromium single-cell (sc) sequencing was performed to define *RUNX3* and *RUNX3*-related genes expression profile in CD8+ T cells obtained from AS cases.
Results: (1) In addition to the recent results published, [4] 3C-qPCR experiments revealed a high interaction frequency between the distal promoter of RUNX3 and an intronic region (called Int2), overlapping open chromatin and TF binding sites. This was highly reproducible in both cell lines analysed. (2) Four different clusters were identified in CD8+ T-cells obtained from AS peripheral blood via 10x sc-seq based on the expression of *RUNX3*. Five other genes (*TBX21*, *EOMES*, *CHD4*, *IRF5* and *IKZF3*) previously identified [2] were considered: cluster 1 showed a strong co-expression for RUNX3, IKZF3, CHD4 and EOMES. Further analysis is required to better characterize this subpopulation.
Conclusion: The AS-associated *RUNX3* genomic locus has a plausible functional role in AS, probably by regulating gene transcription and DNA looping. These observations are critically important in defining dysregulated pathways and potential therapeutic drug targets.

POS0032 FUNCTIONAL ROLE OF SURVIVIN IN ORGANIZATION OF BIVALENT CHROMATIN REGIONS AND CONSEQUENCE FOR ARTHRITIS-RELEVANT GENE EXPRESSION

V. Chandrasekaran[1], M. I. Bokarewa[1], N. Oparina[1], K. M. Andersson[1], G. Katona[2], M. Erlandsson[1], M. Jensen[2], A. Damdimopoulos[3]. *[1]Institute of Medicine, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; [2]University of Gothenburg, Department of Chemistry and Molecular Biology, Gothenburg, Sweden; [3]Bioinformatics and Expression Analysis Core Facility, Department of Bioscience and Nutrition, Karolinska Institute, Huddinge, Sweden*

Background: Bivalent chromatin (BvCR) is characterized by the presence of simultaneous active and repressive modifications on histone H3 proteins. Influencing expression of the genes, BvCR determine cell fate and direct differentiation and lineage commitment in primary T cells and contribute to autoimmunity. Survivin is highly expressed during cell division and in effector Th1 cells contributing to aggravation of autoimmune inflammation. Survivin can physically bind to DNA, specifically to Threonine-3 of histone H3 (1). Thus, functional, and mechanistic data point to a potential chromatin regulatory role for survivin, potentially acting in combination with histone epigenetic modifications (EMs).
Objectives: The goal of our study is to establish the colocalization of survivin with BvCRs and to deduce functional effects of this collaboration on chromatin organization and gene expression.
Methods: Chromatin from CD4+ T cells of 14 female subjects was immunoprecipitated with survivin antibodies and histone H3K27ac, H3K27me3, H3K4me3 antibodies, and coupled with DNA sequencing (ChIPseq, Hiseq2000, Illumina). BvCR were identified as exact overlaps of the three histone EM peaks and the overlapping regions were searched for co-localization with survivin using the 'ChIPPeakAnno' Bioconductor package. Tag counts K27me3>K27ac were defined as inactive/poised BvCR, while tag count K27me3<K27ac were identified asactive BvCR. Motif search was done through the MEME tool, and high/moderate complexity motifs with E-value >10e-5 were selected and scanned through the HOCOMOCO database to identify consensus transcription factor (TF) motifs. TFs co-localized with the BvCD were identified through ReMap database. To identify survivin sensitive genes, $CD4^+$ T cells were treated with survivin inhibitor YM155 and a list of reproducible DEG (log2FC>[0.4], >1 experiment) was mapped and analysed for clustering with BvCR.
Results: Co-localization of survivin ChIP peaks with individual H3-peaks was significantly less frequent compared to overlap with all three (a3)-H3 BvCR (7.1 vs 29.8%, p=8.9e-13). Overlap of a3-H3 peaks not containing survivin was less frequent (34%) compared to those which contained survivin (66%). Notably, survivin peak size was 5.5-fold higher when colocalized with a3-H3 peaks, compared to no, or any single H3 (p<2.2e-16). In contrast, no size difference for any of the H3 EM peaks was found.
Further analysis of two non-redundant groups of BvCR that contain (survivin-a3H3, n=4085), and not containing survivin (a3H3noSurv, n = 2131) demonstrated that survivin was mostly associated with inactive BvCR (OR1.29, p=6.6e-6), while no such specificity was found for BvCR with no survivin. Additionally, survivin containing BvCR contained abundant binding sites matching known consensus TF motifs. No sequence-specific motifs were identified in BvCR with no survivin. Comparison of results obtained through HOCOMOCO and ReMap databases resulted in a list of 68 unique TFs. Many of those are key regulators of adaptive immune responses, cellular metabolism, and pluripotency. Differentially expressed genes mapped to BvCR demonstrated enrichment for cellular hormone metabolic processes, regeneration and DNA biosynthesis.
Conclusion: This study provides experimental evidence that survivin defines binding specificity in bivalent chromatin regions being associated with regulation of cellular metabolism and renewal of $CD4^+$ T cells that are functionally important to resist autoimmunity.

POS0033 GENETIC INVESTIGATION OF TUMOUR NECROSIS FACTOR INHIBITOR IMMUNOGENICITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. F. Yap[1], N. Nair[1], K. Hyrich[2], A. G. Wilson[3], J. Isaacs[4], A. Morgan[5], A. Barton[1], D. Plant[1]. *[1]The University of Manchester, Centre for Genetics and Genomics, Manchester, United Kingdom; [2]The University of Manchester, Centre for Epidemiology, Manchester, United Kingdom; [3]University College Dublin, School of Medicine & Medical Science, Conway Institute, Dublin, Ireland; [4]Newcastle University, Translational and Clinical Research Institute, Newcastle University and Musculoskeletal Directorate, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom; [5]University of Leeds, School of Medicine, Leeds, United Kingdom*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that primarily affects the synovial joints. Tumour Necrosis Factor inhibitor (TNFi) therapy has transformed the clinical management of RA. However, monoclonal antibody derived TNFi is associated with development of immunogenicity and subsequent loss of therapeutic effects. Previous studies have observed associations between certain HLA alleles and TNFi immunogenicity. For example

HLA-DQA1 and *HLA-DRB1* have been associated with immunogenicity in inflammatory bowel disease [1,2] and RA [3,4], respectively.

Objectives: The aims of this study were to identify associations between HLA alleles and immunogenicity to TNFi in an observational cohort of RA patients and to replicate findings from previous studies.

Methods: Anti-drug antibody titres were measured using radioimmunoassay in serum samples from RA patients participating in Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS). An anti-drug antibody titre of ≥12 AU/mL following six months on treatment was used to define positive immunogenicity. Genotype data were generated using Illumina HumanCoreExome Arrays. Standard quality control (QC) was applied prior to HLA imputation using SNP2HLA software before low minor allele frequency markers were removed. Logistic regression was used to study the association between HLA alleles and immunogenicity, whilst the omnibus test was applied to amino acid positions; sex and concurrent conventional synthetic DMARD use were included as a covariate in all the models.

Results: In total, 445 RA patients were analysed, 377 patients (70 immunogenicity events) were underdoing adalimumab therapy and 68 certolizumab (30 immunogenicity events) therapy. Following QC, 162 HLA alleles and 361 amino acids positions were available for analysis. The strongest HLA allele association was observed for *HLA-DQA1**03 when all patients were analysed (OR = 0.61; 95% CI = 0.43 – 0.86; p-value = 5e-3). The amino acids positions 187 (p-value = 5e-3) and 26 (p-value = 5e-3) within the *HLA-DQA1* gene were significantly associated with immunogenicity events. When both drugs were analysed separately, they produced similar effect size for HLA-DQA1*03 association; patients treated with adalimumab (OR = 0.59; 95% CI = 0.38 – 0.88; p-value = 1e-2) and certolizumab (OR = 0.52; 95% CI = 0.24 – 1.1; p-value = 1e-1). Another strong association was found in HLA-DRB1*04 (OR = 0.62; 95% CI = 0.44 – 0.88; p-value = =7e-3) and the amino acid position of 180 (p-value = 7e-3) and 33 (p-value = 7e-3) of HLA-DRB1 gene. Additionally, the similar protective effect between the two presented alleles suggested possibility of linkage disequilibrium, upon investigation the r^2 between the 2 alleles is 0.69.

Conclusion: The current study increases the evidence for association between immunogenicity development with HLA-DQA1 and HLA-DRB1 alleles in patients receiving monoclonal antibody derived TNFi therapy. Further well powered studies are now required to determine the utility of HLA markers as a potential tool to aid the clinical management of RA.

POS0034 GENETIC FACTORS OF PREDISPOSITION TO JUVENILE IDIOPATHIC ARTHRITIS AND OTHER ARTICULAR PATHOLOGY IN BELARUSIAN POPULATION

H. Yatskiu[1], A. Tchitchko[2], A. Sukalo[2], R. Goncharova[1]. *[1]Institute of Genetics and Cytology of NAS of Belarus, Laboratory of Molecular Basis of Genomic Stability, Minsk, Belarus; [2]Belarusian State Medical University, 1st Department of Childhood Diseases, Minsk, Belarus*

Background: Juvenile idiopathic arthritis (JIA) is a multifactorial autoimmune disease and. JIA exhibits clinical heterogeneity and is divided into seven phenotypic subtypes. The outcome of JIA is often difficult to predict, and differential diagnosis is significantly complicated by the variety of causes of joint pain and the similarity of the clinical picture of articular syndrome, especially in the early stages of disease development.

Objectives: to detect genetic markers, associated with the risk of developing JIA, its distinct subtypes and another joint pathology in children.

Methods: 951 individuals were divided into three cohorts: 281 children with JIA (mean age 9.14±4.84), 214 children with articular syndrome in case of another joint pathology (post-infectious, post-traumatic and reactive arthritis, osteochondropathy and arthralgia; mean age 9.50±4.75) and 456 healthy controls (mean age 14.36±2.54). The JIA patients were divided into subgroups according to IIAR classification criteria. 9 SNPs of 8 genes (*IL6* (rs1800795), *IL6R* (rs2228145 and rs4845618), *STAT4* (rs7574865), *TRAF1/C5* (rs3761847), *RUNX1* (rs9979383), *PTPN2* (rs2542151), *PTPN22* (rs2476601), *FOXP3* (rs2232365)) were genotyped using Real-time PCR or PCR-RFLP.

Results: The allele frequencies of the polymorphic loci of the *FOXP3* (rs2232365), *RUNX1* (rs9979383), *PTPN2* (rs2542151), *PTPN22* (rs2476601) genes in all three groups were comparable, indicating no association with the risk of development of joint pathology in children. It was shown that CC genotype at the rs1800795 locus of the *IL6* gene is associated with JIA (OR 1.49 [1.05–2.13], p=0.026), while the GC genotype revealed protective effect (OR 0.69 [0.51–0.93], p=0.014). In addition, a weak association of GG homozygotes at the *TRAF1/C5* locus (rs3761847) with the risk of developing JIA was found (OR 1.47 [1.00-2.16], p = 0.05). Homozygous GG genotype at the rs3761847 *TRAF1/C5* and CC at the rs1800795 *IL6* loci, as well as the corresponding G and C alleles, were associated with early JIA onset (under the age of 6 years).

At the same time, CC homozygotes (OR 2.45 [1.50–3.97], p=0.0003) and C allele (OR 1.33 [1.05–1.69], p=0, 02) at the rs2228145 locus, as well as TT homozygotes (OR 1.54 [1.06–2.23], p = 0.026) at the rs4845618 locus of the *IL6R* gene were associated with joint pathology except JIA. Moreover, minor alleles, as well as the corresponding homozygous genotypes of polymorphic *IL6R* loci were significantly more common among children with other articular pathology when compared with the JIA cohort.

The association revealed for the CC genotype at the rs1800795 locus of the *IL6* gene in the general JIA group preserved in the group of oligoarticular JIA (OR 1.59 [1.04–2.41], p=0.033) while GG genotype at rs3761847 locus of the *TRAF1/C5* gene was associated with systemic JIA (OR 2.82 [1.29 – 6.15]; p = 0.013), and rheumatoid factor-negative polyarthritis was characterized by higher frequency of GT/TT genotypes at the *STAT4* rs7574865 locus (OR 1.85 [1.06–3.24], p = 0.03).

Conclusion: Thus, the *IL6* gene polymorphism increases the sensitivity of the Belarusian population to JIA, while the *IL6R* gene polymorphism affects the development of other joint pathology.

It was found that JIA subtypes significantly differ from each other by the molecular profiles of non-HLA genes. This suggests that JIA is represented by a spectrum of genetically distinct subtypes that differ in clinical course and response to therapy.

POS0035 GENE REGULATION IN T-CELLS FROM PSA PATIENTS DIFFERS BETWEEN PERIPHERAL BLOOD AND THE INFLAMED JOINTS: IMPLICATIONS FOR THE INTERPRETATION OF GWAS SIGNALS

C. Shi[1], D. Zhao[1], J. Ding[1], C. Ferrazzano[1], C. Wynn[1], A. Frantzesko[1], J. Bowes[1], P. Ho[2], A. Barton[1,3,4], M. Rattray[3,5], G. Orozco[1,3,4]. *[1]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; [2]The Kellgren Centre of Rheumatology, Manchester Royal Infirmatory, Manchester, United Kingdom; [3]Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; [4]The University of Manchester, Lydia Becker Institute of Immunology and Inflammation, Manchester, United Kingdom; [5]The University of Manchester, Division of Informatics, Imaging and Data Sciences, Manchester, United Kingdom*

Background: Genome-wide association studies (GWAS) have identified variants that are associated with complex diseases such as Psoriatic Arthritis (PsA). The majority of these variants do not affect the coding sequence of proteins but rather regulatory elements which are highly cell type and state specific, and can affect distally located genes via chromatin interaction mechanisms.

We and others have previously analysed GWAS loci for multiple conditions (including PsA and Rheumatoid Arthrtitis) in cell lines using functional genomics techniques, providing putative mechanisms to many loci with previously unknown function [1].

However, multiple studies have identified large differences in gene regulatory mechanisms between cell lines and primary cells, which could significantly alter the proposed mechanisms. Differences between between samples from healthy volunteers and patients, in particular from the affected tissue, have although not been exhaustively investigated.

Objectives: To assess the impact of using primary cells derived from PsA patients compared to healthy volunteers in functional genomics studies.

Methods: CD4+ and CD8+ T cells were isolated from peripherial blood from 10 healthy controls and 48 PsA patients and from 6 PsA synovial fluid samples. We performed RNA-seq and ATAC-seq on these two cell types to analyse the global patterns of gene expression and chromatin activity.
Results: We find subtle differences between PsA patients and healthy controls in cells isolated from blood. RNA-seq analysis identified only a handful of differentially expressed genes whilst ATAC-seq analysis identified only 28 differential loci. On the other hand, T cells isolated from synovial fluid showed significant differences compared to T cells isolated from patient's blood. Interestingly, we find that CD4+ T cells show substantially more differentially expressed genes compared to CD8+ T cells (1168 vs 346 Log2FoldChange > 1, FDR < 0.01). Genes overexpressed in synovial CD4+ T cells are more strongly enriched for immune pathways such as cytokine signaling and T cell proliferation compared to synovial CD8+ T cells
We also find that synovial CD4+ T cells highly overexpress MHC class II genes (Figure 1).

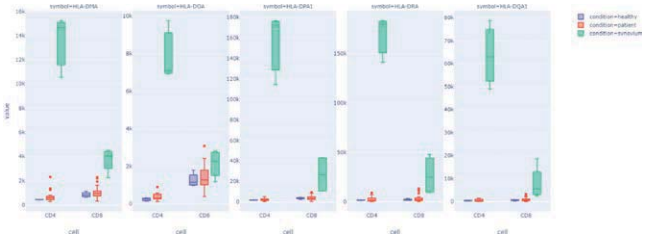

Figure 1. Normalized counts of the alpha chains of MHC class 2 genes in CD4+ and CD8+ T cells purified from blood from healthy subjects and patients and synovial fluid.

Conclusion: This preliminary analysis suggests that T cells isolated from peripherial blood do not seem to differ significantly between PsA patients and healthy controls. In contrast, cells isolated from synovial fluid are highly specialized and activated. Moreover, these cells do not resemble canonically activated T cells which means that this state can not be easily emulated in vitro.
This study indicates the importance of not only studying GWAS loci in relevant primary cells from patients, but also that attention needs to be given to cells isolated from the affected site.

POS0036 CORRELATION BETWEEN SYSTEMIC AND LOCAL EXPRESSION LEVELS OF MIR-146A, MIR-155 AND MIR-223 AND THE ONGOING TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS

R. Shumnalieva[1], D. Kachakova[2], R. Kaneva[2], Z. Kolarov[1], S. Monov[1]. *[1]Medical University-Sofia, Clinic of Rheumatology, Department of Rheumatology, Sofia, Bulgaria; [2]Medical University - Sofia, Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria*

Background: MicroRNAs (miRNAs) comprise a class of small, non-coding RNAs that serve as important negative regulators of gene expression at posttranscriptional level. Studies have shown remarkable changes in miRNA expression in autoimmune diseases, such as rheumatoid arthritis (RA) which makes them a potential systemic as well as local biomarkers for disease activity (1-3). On the other hand, regulation of miRNA on transcriptional and posttranscriptional level, as well as the effects of endogenous and exogenous factors on miRNA expression is under investigation. Of importance is the possible effect of the ongoing treatment on miRNA expression in the clinical practice.
Objectives: To analyze the expression levels of miR-146a, miR-155 and miR-223 in peripheral blood (PB) and synovial fluid (SF) from RA patients in regard to the ongoing treatment regimen.
Methods: A total number of 63 RA patients according to the 1987 ACR criteria were included in the study. Expression levels of miR-146a, miR-155 and miR-223 in 63 PB samples and matched 48 SF samples were determined by qPCR (SybrGreen technology) and compared to healthy controls (HCs). Relative changes of gene expression levels of the studied miRNAs were calculated by $2^{-\Delta\Delta Ct}$ method. 45 of the studied patients were on systemic treatment, which included non-steroidal antiinflammatory drugs (NSAIDs), glucocorticosteroids (GCS), conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and original biological DMARDs. There were no patients treated with conventional target DMARDs or biosimilar DMARDs. SPSS was used for statistical analysis.
Results: RA PB showed statistically significant overexpression of miR-223 (58.73%) when compared to HCs and only miR-223 expression levels could be used to differentiate RA patients from HCs (p=0.008). RA SF showed overexpression of miR-146a (in 70.83%, p=0.007), miR-155 (in 79.17%, $p=1.63x10^{-4}$) and of miR-223 (in 79.17%, $p=1.64x10^{-3}$) when compared to HCs and the studied miRNAs could be used to differentiate RA patients from HCs ($p=4.8x10^{-4}$, $p=8.0x10^{-5}$ and $p=2.8x10^{-4}$, respectively). When we analyzed the correlation between the expression of miRNAs and the ongoing treatment we found a statistically significant correlation between the PB expression levels of miR-223 and the use of NSAIDs and GCS (p=0.015 and p=0.04, respectively) and the SF expression levels of miR-146a and miR-155 and the use of NSAIDs (p=0.011 and $7.98x10^{-4}$, respectively) and GCS (p=0.039 and p=0.009, respectively). The use of csDMARDs and bDMARDs didn't show correlation with the PB nor the SF expression of the studied miRNAs.
Conclusion: The correlation between the systemic miR-223 and the local miR-146a and miR-155 expression with the NSAIDs and GCS treatment could be due to the effect of these treatment compounds on the cells lines from which the studied miRNAs origin. In our study there was no correlation between miRNA expression and the use of biological and conventional DMARDs. Further analysis with larger sets including pre- and posttreatment samples is needed to confirm if altered miRNA expression could be influenced by the treatment regimen as well as if miRNAs could serve as biomarkers for treatment response in the clinical practice.

POS0037 MULTIVARIABLE MENDELIAN RANDOMIZATION STUDY ON BMI-ADJUSTED LINK BETWEEN ADIPONECTIN AND RISK OF DEVELOPING RHEUMATOID ARTHRITIS

G. K. Vasileiadis[1,2], T. Fatima[1,2], C. Maglio[1,2,3]. *[1]Wallenberg Centre for Molecular and Translational Medicine, University of Gothenburg, Gothenburg, Sweden; [2]University of Gothenburg, Institute of Medicine, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; [3]Region Västra Götaland, Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden*

Background: Compelling evidence suggests that adiponectin is involved in the pathogenesis of rheumatoid arthritis (RA). Nevertheless, a recent Mendelian randomization (MR) study in Europeans has shown that adiponectin does not have a causal role in the development of RA[1].
Objectives: As body-mass index (BMI) is a known risk factor for RA[2] and subjects with high BMI have lower circulating levels of adiponectin, we specifically aimed to perform a multivariable MR in both European and East Asian populations to determine if adiponectin has a causal effect on RA development independently of BMI.
Methods: We performed a range of two-sample, univariable, MR analyses to assess the causal effect of adiponectin on RA in European and East Asian individuals. Two different sets (12 in Europeans and 5 in East Asians) of adiponectin-related genetic variants were used as instruments for genetically determined adiponectin levels, to calculate its causal effect on RA risk. Multivariable MR was performed to calculate the effect of adiponectin on RA risk after adjustment for BMI.
Results: Univariable MR did not provide evidence of a causal relationship between circulating adiponectin levels and RA risk in both European (OR 1.06; 95% CI 0.87-1.31; p=0.59) and East Asian (OR 1.04; 95% CI 0.91 – 1.19; p=0.54) individuals (Figure 1). Similarly, there was no evidence of a causal effect of

adiponectin on RA in both European (OR 0.97; 95% CI 0.78 – 1.22; p=0.81) and East Asian (OR 0.97; 95% CI 0.72 – 1.31; p=0.85) populations after adding BMI as a confounder in the multivariable MR model (Figure 1).

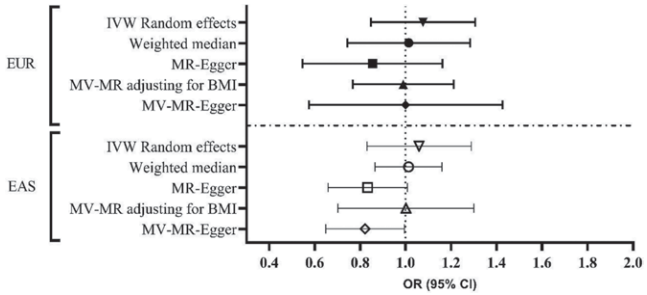

Figure 1. Forest plot of the causal effects of adiponectin-associated genetic variants on rheumatoid arthritis after adjustment for body mass index in a multivariable mendelian randomization (MR) analysis. Shown are European (EUR) and East Asian (EAS) populations. An Odds Ratio (OR) is a measure of association between an exposure and an outcome, in which the OR represents the likelihood that an outcome will occur given a particular exposure, compared to the likelihood of the outcome occurring in the absence of that exposure. Statistical analyses were performed with the use of inverse-variance weighted (IVW) estimate, MR-Egger regression weighted median analysis.

Conclusion: This MR study does not support a causal effect of genetically determined adiponectin levels on the risk of developing RA in both European and East Asian populations. By using multivariable MR to account for possible shared genetic predictors between circulating adiponectin levels and BMI we have shown that circulating adiponectin is not causally linked to RA risk after adjustment for BMI.

POS0038 GENOMICS OF JAK-STAT SIGNALING IN VENOUS THROMBOEMBOLISM

S. Haysen[1], A. L. L. Nielsen[1], P. Qvist[1], T. W. Kragstrup[1]. [1]*Aarhus University, Department of Biomedicine, Aarhus, Denmark*

Background: Janus kinase inhibitors (JAKi) have been associated with an increased risk of venous thromboembolism (VTE) [1]. VTE comprises deep vein thrombosis and pulmonary embolism and is associated with complications such as recurrent VTE, post thrombotic syndrome, pulmonary hypertension, and death. These concerns limit the use of JAKi-based therapy. To improve risk stratification and drug development, it is crucial to understand the possible implication of dysregulated JAK-signal transducers and activators of transcription (STAT) signaling in the pathogenesis of VTE.

Objectives: The objective of this study is to clarify the putative genomic vulnerability to dysregulated JAK-STAT signaling in VTE.

Methods: We are systematically mine and analyze large-scale genomic datasets generated from studies comparing VTE patients with healthy controls. Using VTE genome-wide associated (GWA) summary statistics we evaluate the representation of genes encoding the JAK-STAT pathway (KEGG hsa04630) in associated loci and assess their association to VTE. Further, we examine the genetic VTE risk burden in the chromatin interactome of STAT family transcription factors (TFs). We extract available STAT family (STAT1-3) TF binding site (TFBS) consensus DNA motifs (JASPAR database) and assess the association of genes containing STAT family TFBS within their promotor sequence (TSS -2000bp) to VTE. Through mining of deposited OMICs data from VTE patients, we examine molecular characteristics related to JAK-STAT signaling, including potential enrichment of STAT family TFBSs among query promoter sequences of differently expressed genes (DEGs).

Results: We do not observe a significant overrepresentation of JAK-STAT genes (n_{total}=162) among genes annotated to VTE significant GWA loci (n_{total}=147, p=0.48). Similarly, the JAK-STAT gene set show no cumulative association to VTE (p=0.98). Applying the same gene set association approach to the STAT target gene sets (n_{total}=4570) does not reveal significant association between VTE and STAT1 ($n_{overlap}$=10, p=0.47), STAT1:STAT2 heterodimer ($n_{overlap}$=18, p=0.17) and STAT3 ($n_{overlap}$=6, p=0.20) target gene sets. At the functional molecular level, we do not see any significant overlap between molecules acting in the JAK-STAT pathway and DEGs (n_{total}=507, p=0.06) or differentially abundant proteins (DAPs; n_{total}=35, p=0.57). However, we observe a significant overlap between downregulated DEGs (n_{total}=362) and the STAT1:STAT2 heterodimer target gene set (n_{total}= 2155, $n_{overlap}$=48, p<0.0001) including downregulation of *IL-27RA* and *CCND3* (Figure 1). Supporting the biological relevance of this finding, we find a weak but statistically significant enrichment of STAT1 TFBS motifs in the promotor sequence of downregulated DEGs compared to non-DEGs (p=0.02).

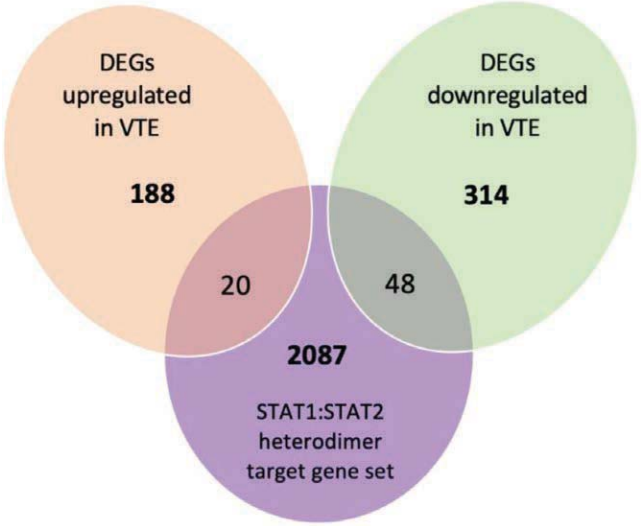

Figure 1. Overlap between STAT1:STAT2 heterodimer gene set and differently expressed genes (DEGs) in venous thromboembolism (VTE)

Conclusion: Here, we provide a coherent approach to assess the genomic basis for the reported association between JAKi treatment and VTE. Our preliminary data suggest that genes under transcriptional control of STAT family TFs may be dysregulated in VTE patients. It is conceivable, that the genomic actions of JAKi is overlapping with the molecular risk profile of VTE. *CCND3* is especially interesting because VTE occurs in up to 10% of patients treated with cyclin-dependent kinase inhibitors such as Palbociclib [2]. Obviously, genomic data mining alone cannot guide medical decision making concerning the use of JAKi. However, our results provide a basis for further investigation of adverse events seen with JAKi.

POS0039 MONOCYTE TRANSCRIPTOMICS AND TARGETED PROTEOMICS DEFINE HETEROGENEOUS SUBGROUPS IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND SUBCLINICAL ATHEROSCLEROSIS

L. Woodridge[1,2,3], E. Chocano[1,2], P. Ashford[3], G. Robinson[2], K. Waddington[1,2], A. Rahman[2], C. Orengo[3], E. Jury[2], I. Pineda Torra[1]. [1]*Centre for Cardiometabolic and Vascular Science, Division of Medicine, UCL, London, United Kingdom;* [2]*Centre for Rheumatology, Division of Medicine, UCL, London, United Kingdom;* [3]*Institute of Structural and Molecular Biology, Biosciences, UCL, London, United Kingdom*

Background: Systemic lupus erythematosus (SLE), a chronic, inflammatory autoimmune disease, predominantly affects women with a 9:1 female:male incidence. Cardiovascular disease (CVD) is a leading cause of mortality in SLE via accelerated atherosclerosis: the build-up of cells and lipids in the vascular wall and the main pathology underlying CVD.
Objectives: To define molecular profiles of SLE with subclinical atherosclerosis using multi-omics data analysis and clinical data in a well-characterised cohort of CVD-free SLE women.
Methods: Multi-omics analyses were conducted to explore the molecular signatures of SLE patients with (SLE-P) and without (SLE-NP) subclinical atherosclerosis defined by non-invasive ultrasound scanning of the carotid and femoral arteries. SLE blood CD14+ monocyte transcriptomes were investigated by bulk RNA-sequencing (SLE-P N=13, SLE-NP N=8), and targeted serum cardiometabolic and cardiovascular proteomics (OLINK) were used to explore matched protein expression (SLE-P N=17, SLE-NP N=20) (no difference in disease activity between groups). Bioinformatics approaches, including pathway and disease module enrichment analyses and extended protein-protein interaction networks, further defined molecular profiles of SLE patients with atherosclerosis from patients that remained plaque free. Gene signature-derived interferon (IFN) scores were applied to investigate heterogeneous subgroups within the cohort as a measure of inflammation.
Results: Distinct monocyte gene and protein expression profiles were identified in SLE and enriched in biological pathways relating to extracellular mechanisms, including purinergic and cytokine signalling. Lipid regulatory mechanisms were enriched in SLE-P, whereas SLE-NP patient's transcriptome and proteome profiles were defined by pathways relating to inflammation. Specifically, the type-I IFN pathway was exclusively reduced in SLE-P compared to SLE-NP. IFN scores derived from published IFN-responsive gene expression signatures stratified patients into significantly distinct subgroups (high versus low IFN-response, p=0.0001) with 66% (N=14) of patients showing high IFN expression across multiple signatures not associated with age, ethnicity, or disease activity. However, IFN scores did not predict the presence of sub-clinical atherosclerosis and further heterogeneity was revealed with 46% of SLE-P patients showing a low IFN response (N=6). Further, a measure of plaque lipid content (echogenicity) was inversely correlated with IFN score (grey scale median, p=0.03, r=-0.8) which may reflect distinct plaque phenotypes between these subgroups relating to clinical presentation and risk of cardiovascular events.
Conclusion: Lipid dysregulation is a key mechanism that drives atherosclerosis pathology and genes and proteins relating to lipid metabolism distinguished SLE patients with and without subclinical atherosclerosis. Differences in levels of interferons and other inflammatory molecules may contribute to unique patterns of gene expression between SLE patients. A distinct subset of SLE-P patients showed low interferon expression, which may be suggestive of a dampened immune response in early subclinical CVD. Further elucidating the complexity of lipid dysregulation, inflammation and immune function in atherosclerosis in SLE will help improve patient stratification towards investigating the efficacy of anti-atherosclerotic therapies.

Background: Glucocorticoids (GCs) are a key treatment for inflammatory rheumatic diseases, but they cause a wide range of adverse side-effects which are of concern both to patients and clinicians.
Objectives: The objective of this study was to explore the impact of GC therapy on health-related quality of life (HRQoL) during treatment for rheumatic diseases, as a basis for development of a Patient-Reported Outcome Measure (PROM) to be used in clinical trials and practice.
Methods: Patients from the UK, USA and Australia who were treated with GCs in the last two years for a rheumatic condition were invited to take part in semi-structured qualitative interviews. Purposive sampling was used to include participants with a range of demographic and disease features. A steering committee of patient research partners, clinicians and methodologists devised an initial conceptual framework, which informed interview prompts and cues. Interviews were carried out by experienced qualitative researchers who encouraged participants to tell their stories and talk about the effects, both adverse and beneficial, of their experiences and perceptions of treatment with GCs, to identify salient physical and psychological symptoms and aspects of HRQoL. The interview data were organised using NVivo, and inductive analysis identified initial themes and domains. Candidate questionnaire items were developed and refined using cognitive interviewing, linguistic assessment, and input from patient research partners.
Results: Sixty semi-structured qualitative interviews were conducted (UK n=34, USA n=10, Australia n=16). Mean participant age was 58 years; 39 (66.1%) were female. Purposive sampling of participants provided a broad range of demographic features, GC dosages and inflammatory rheumatic conditions, with 27% having connective tissue disease, 25% inflammatory arthritis, 30% systemic vasculitis and 16% other rheumatic conditions.
Initial domains were developed to identify key themes relating to treatment using GCs and their impact on HRQoL; see Figure 1.

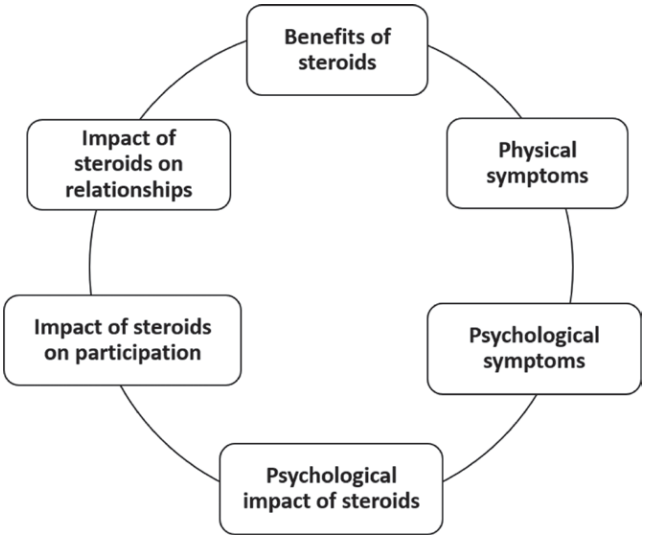

Figure 1. Steroid PRO Initial Themes

A long-list of 134 initial candidate questionnaire items was developed from the individual themes. These items were reviewed by a qualitative working group of patient research partners, researchers and clinicians to reduce duplication and ambiguity of items. The resulting 62 items were tested and refined by piloting with patient research partners, iterative rounds of cognitive interviews with patients with a range of rheumatic conditions from the UK, USA and Australia, and a linguistic translatability assessment, to define a draft questionnaire of 40 items.
Conclusion: This international qualitative study underpins the development of candidate items for a treatment-specific PROM for patients with rheumatic diseases. The draft questionnaire is currently being tested in an online large-scale survey to determine the final scale structure and measurement properties using Rasch analysis, factor analysis, test-retest, comparison with EQ5D, and known groups analysis.

POS0041-HPR OUTCOME MEASURES IN RHEUMATOLOGY APPLIED IN SELF-MANAGEMENT INTERVENTIONS TARGETING PEOPLE WITH INFLAMMATORY ARTHRITIS - A SYSTEMATIC REVIEW OF OUTCOME DOMAINS AND MEASUREMENT INSTRUMENTS

C. Hansen[1], B. A. Esbensen[2,3], A. De Thurah[4,5], R. Christensen[6,7], M. De Wit[8], P. F. Cromhout[2]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; [2]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Glostrup, Denmark; [3]University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; [4]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [5]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [6]Bispebjerg and Frederiksberg Hospital, Section for Biostatistics and Evidence-Based Research, the Parker Institute, Copenhagen, Denmark; [7]Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, University of Southern Denmark, Odense C, Denmark; [8]Outcome Measures in Rheumatology "OMERACT", Patient Research Partner, Amsterdam, Netherlands*

Background: Self-management refers to the patient's ability to manage a large range of consequences such as symptoms, medication, emotions, and preferable life-style changes coherent with living with a chronic disease. Evaluating the effect of interventions targeting to improve people with inflammatory arthritis (IA) self-management is a challenge because self-management interventions are complex and consensus on important outcomes is lacking. Solutions to these issues could be to consensus on a Core Outcome Set (COS) describing what outcomes are relevant and should be applied in future studies hereby lessening the heterogeneity between future studies. The purpose of this study was therefore to take the first actions in identifying possible candidate outcomes for such a COS.

Objectives: The aim was to identify, and map applied outcome domains and outcome measurement instruments from previous trials measuring the effect of self-management interventions targeting people with IA.

Methods: We performed an informative systematic literature review following guidance from the Handbooks described by 'Outcome Measures in Rheumatology' (OMERACT) and 'Core Outcome Measures in Effectiveness Trials' (COMET) initiatives. Randomized and non-randomized trials describing their experimental intervention as "self-management" and included a population of adults (≥18 years) with at least 50% diagnoses with IA (Rheumatoid arthritis, Psoriatic arthritis, Spondylarthritis) was included. Both screening of possible trials and data extraction was performed independently by two reviewers. Extracted data included: study characteristics, outcome domains and the corresponding measurement instruments. During analysis two reviewers simultaneously grouped and categorized domains and subdomains, and two senior researchers approved the categorization.

Results: Searches was performed 2021.02.08 on online databases, trial registers, conference abstracts and references of included trials. From a total of 2,502 records, we included 38 trials published between 1988 and 2021. The interventions were heterogenic and patients primarily female, diagnosed with Rheumatoid Arthritis, and a calculated mean age of 54 years. We identified 12 different outcome domains, covering 39 subdomains, collected with 119 different measurement instruments. The most frequently applied outcome domains were self-efficacy, pain, physical functioning/disability, anxiety and depression, quality of life, fatigue, global assessment/disease activity and coping. Please see Figure 1 for all outcome domains identified. The applied measurement instruments varied within each outcome domain with up to 10 different instruments applied to measure the same domain. Instruments were predominantly patient-reported outcomes.

Conclusion: The outcome domains and measurement instruments used in self-management trials were widely diverse and differ from the current general OMERACT Core Outcome Sets (COS) for IA conditions. Further steps towards the establishment of a COS to be reported in all self-management intervention trials will enhance the relevance and the subsequent impact on the body of evidence from these trials.

POS0042-HPR HOW DOES WEEKLY SUPERVISED GROUP EXERCISE CONTRIBUTE TO FULFILLING EXERCISE RECOMMENDATIONS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS?

B. Hilberdink[1], M. Carbo[2], D. Paap[2,3], S. Arends[2,4], T. P. M. Vliet Vlieland[1], F. Van der Giesen[5], A. Spoorenberg[2,4], S. Van Weely[1]. *[1]Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; [2]University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; [3]Saxion University of Applied Sciences, Department of Physical Therapy, Enschede, Netherlands; [4]Medical Center Leeuwarden, Department of Rheumatology, Leeuwarden, Netherlands; [5]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*

Background: Supervised group exercise (SGE) has been recommended for people with axial spondyloarthritis (axSpA) since decades, but the proportion and type of axSpA patients that engage in SGE is unknown. In addition, the 2018 EULAR recommendations for physical activity advocate that people with axSpA should engage in aerobic, strength and mobility exercises according to public health physical activity guidelines. However, it is unclear if SGE contributes to fulfilment of these exercise recommendations.

Objectives: To compare characteristics, health status and fulfilment of exercise recommendations between axSpA patients with and without SGE.

Methods: Cross-sectional data from three Dutch axSpA study cohorts were analysed: two cohorts with patients recruited at rheumatology outpatient clinics (n=196 and n=153) in which participation in SGE was recorded (yes/no) and one cohort with only SGE participants (n=128). Assessments included sociodemographic and disease characteristics, health status (ASAS Health Index), spinal mobility and the 'short questionnaire to assess health enhancing physical activity'

(SQUASH). The SQUASH was used to determine fulfilment of the public health recommendations for leisure-time aerobic exercise (≥150 min/week of moderate-intensity or ≥75 min/week of vigorous-intensity exercise) and for strength and mobility exercises (≥2 sessions/week). Differences between patients with and without SGE were analysed using the Mann-Whitney U test and the Chi-Square test. Multivariate regression models were performed to correct the association between SGE and fulfilment of the exercise recommendations for age, sex, employment and health status.

Results: In the two outpatient axSpA cohorts, 17 of the 349 patients (5%) participated in SGE. The total group of SGE participants (n=145) was significantly older, had longer disease duration, was less frequently employed, used less disease related medication and had worse spinal mobility than the patients without SGE (n=332). There were no significant differences in health status. AxSpA patients with SGE performed more minutes per week of aerobic exercise (median 420; IQR 285-660) than patients without SGE (median 283; IQR 120-540), $p < 0.001$. As shown in Figure 1, SGE participants fulfilled the recommendations for moderate-intensity aerobic exercise (89% vs. 69%, $p < 0.001$) and for strength and mobility exercise (44% vs. 29%, $p < 0.01$) more often than patients without SGE. However, the recommendation for vigorous-intensity aerobic exercise was fulfilled less often by the SGE participants (5% vs. 12%, $p < 0.05$). After correcting for age, sex, employment and health status, the differences in fulfilment of the moderate-intensity aerobic and strength and mobility exercise recommendations remained significant.

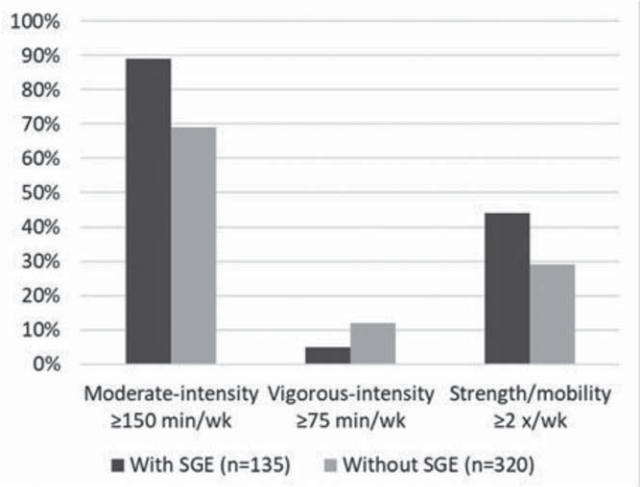

Figure 1. Differences in meeting exercise recommendations between axSpA patients with and without SGE.

Conclusion: SGE is used by just few and especially older axSpA patients and contributes to fulfilling recommendations for moderate-intensity aerobic as well as mobility and strength exercise. However, both in patients with and without SGE, only a minority fulfilled the recommendations for vigorous-intensity aerobic and strength and mobility exercises. Therefore, future promotion of physical activity should focus on implementing these types of exercise.

POS0043-HPR DO COPING STRATEGIES, ILLNESS PERCEPTIONS AND RELATIONSHIP DYNAMICS CONTRIBUTE TO SEXUAL DYSFUNCTION FOR WOMEN WITH SJÖGREN'S SYNDROME?

J. Mccready[1], V. Deary[2,3], T. Collins[1], D. Lendrem[4], K. Hackett[1,3]. *[1]Northumbria University, Department of Social Work, Education and Community Wellbeing, Newcastle Upon Tyne, United Kingdom; [2]Northumbria University, Department of Psychology, Newcastle Upon Tyne, United Kingdom; [3]Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom; [4]Newcastle University, Translational and Clinical Research Institute, Newcastle Upon Tyne, United Kingdom*

Background: Women with Sjögren's syndrome (SS) are more likely to experience vaginal dryness, dyspareunia and reduced sexual function than healthy controls[1]. There is limited data investigating relationships with psychosocial influences, such as coping mechanisms, illness perceptions, partners behaviours and relationship satisfaction.

Objectives: To investigate associations between sexual function and psychosocial parameters in women with SS.

Methods: Cisgender women aged 18+, diagnosed with SS, were invited to participate in a cross-sectional online survey. Ethical approval and informed consent were obtained. Participants completed the Female Sexual Function Index (FSFI), EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), NRS scale for vaginal dryness (0-10), Profile of Fatigue and Discomfort (ProFaD), Cognitive Emotion Regulation Questionnaire (CERQ), Brief Illness Perceptions Questionnaire (BIPQ), West-Haven Yale Multidimensional Pain Inventory (WHYMPI – Part II) and Maudsley Marital Questionnaire (MMQ – Marital subscale). Associations between the FSFI and the outcome measures were assessed using Spearman's correlations. Variables that significantly correlated with FSFI total score were entered into a backward stepwise multiple regression.

Results: The survey was completed by 98 women (M = 48.13, SD = 13.26), 70.4% were diagnosed as having primary SS (disease duration range = 3 – 348 months); 43.8% were premenopausal and 48% were postmenopausal. Vaginal dryness was reported by 92.9% of participants, and sexual dysfunction was identified in 85.2% (n = 69/81) of cases (<26.55). Participants who were not sexually active in the previous three-month period (n = 17) were excluded from analyses as inactivity may cause a low FSFI score which may be incorrectly construed as sexual dysfunction. Reduced sexual function was significantly associated with increases in age, vaginal dryness, mental fatigue (ProFaD), self-blame, rumination and catastrophising (CERQ), consequences and identity (BIPQ), negative partner responses (WHYMPI) and relationship dissatisfaction (MMQ). Reduced sexual function was also significantly associated with decreases in positive reappraisal and perspective (CERQ), personal control (BIPQ), solicitous responses and distracting responses (WHYMPI) (Table 1). No significant associations were found for disease duration, relationship duration or ESSPRI total. Results from regression analyses indicated that vaginal dryness (β = -.278, p = .004), CERQ positive reappraisal (β = .322, p = .003) and CERQ catastrophising (β = -.277, p = .009) were significantly related to sexual function and explained 42.0% of the variance in total FSFI scores (F(3,72) = 17.394, p < .001).

Table 1. Associations between sexual function and psychosocial parameters

	FSFI total			
	r_s	*p*	95% CI (LB, UB)	
Age (years)	-.270	**.015**	-.467	-.049
Disease duration (months)	-.030	.793	-.253	.196
Relationship duration (months)	-.180	.119	-.396	.054
VAS Vaginal dryness	-.350	**.001**	-.533	-.136
ESSPRI total	-.165	.141	-.376	.062
ProFaD Mental Fatigue	-.294	**.008**	-.486	-.074
CERQ Self-Blame	-.264	**.017**	-.461	-.042
CERQ Rumination	-.296	**.007**	-.488	-.077
CERQ Positive Reappraisal	.469	**.000**	.273	.628
CERQ Perspective	.341	**.002**	.126	.525
CERQ Catastrophising	-.499	**.000**	-.651	-.310
BIPQ Consequences	-.237	**.033**	-.438	-.013
BIPQ Personal Control	-.288	**.009**	-.481	-.068
BIPQ Identity	-.294	**.008**	-.487	-.075
MMQ	-.282	**.013**	-.483	-.054
WHYMPI Negative Responses	-.252	**.028**	-.457	-.021
WHYMPI Solicitous Responses	.267	**.020**	.037	.470
WHYMPI Distracting Responses	.311	**.006**	.085	.506

Note. N = 81. Associations that were not significant are not shown.

Conclusion: Women with SS using positive coping strategies have better sexual function than those with negative coping strategies. Learning positive coping strategies may be an important line of approach for managing sexual dysfunction in SS.

POS0044-HPR FEASIBILITY OF FITNESS ASSESSMENTS IN GROUP EXERCISE THERAPY FOR INDIVIDUALS WITH AXIAL SPONDYLOARTHRITIS

A. K. Rausch Osthoff[1], C. Horvath[2], K. Niedermann[1]. *[1]Institut for Physiotherapy, Health, Winterthur, Switzerland; [2]Medbase Brunngasee, Sports Medical Center, Winterthur, Switzerland*

Background: Assessments should be standard in individual as well as group physical therapy. The Ankylosing Spondylitis Association of Switzerland has translated the EULAR recommendations for physical activity (PA) in a concept for group exercise therapy, which, in addition to guidance on exercising in all four fitness dimensions (aerobic, strength, flexibility, neuromotor function), also includes PA counselling and regular fitness assessments for the planning and documentation of the individual therapy progress as well for quality monitoring of the exercise groups.
Objectives: To evaluate the feasibility of the selected assessments across all four fitness dimensions, rating the acceptance, practicability, and integration by physiotherapists (PTs) and people with axSpA.
Methods: A feasibility study was conducted in four pilot exercise therapy groups. PTs performed the assessment battery, consisting of a) the Chester Step Test (CST) for aerobic fitness; b) the modified Core Strength Test for core strength, c) the Bath Ankylosing Spondylitis Metrology Index (BASMI) for spinal mobility and d) the Single Leg Stance Test (SLST) for balance, with the participants of the exercise therapy groups. Subsequently, the PTs and the participants with axSpA rated the acceptance, practicability, and integration by means of questionnaires. Acceptance was operationalised as satisfaction and perceived applicability, practicability was operationalised as feasibility and comprehensibility, and integration was operationalised as usefulness and repeatability. An ordinal scale with four answer options (very good, good, moderate, bad) and a free text field for comments was used. The categories 'very good' and 'good' were interpreted as 'positive evaluation'. The feasibility of the assessments was defined based on three levels (I-III): with a positive evaluation of >80% (level I) a specific assessment was considered suitable, with a positive evaluation of 50-80% (level II) adjustments were necessary, with a positive evaluation of <50% (level III) a specific assessment was not considered suitable for group exercise therapy and a new choice had to be made.
Results: The BASMI was rated level I by people with axSpA and PTs, no adaptations were necessary. The CST was rated level I by people with axSpA and level II by PTs (too time consuming and failure-prone software), resulting in the adaptation that the test can now be performed without software, and a training will make the testing PTs more efficient. The modified Core Strength Test was rated level I by people with axSpA and level II by PTs (instructions unclear), leading to adaptations in the instruction manual. The SLST was rated level I by people with axSpA and level II by PTs (instruction "standing on one leg as long as possible" not useful for persons without balance deficit), leading to the adaptation that the test can be stopped after 60 seconds as the normal values are below that threshold.
Conclusion: From patient perspective, the feasibility of the tests was evaluated positive in terms of acceptance, practicability and integration (all level I). From PTs' perspective some adaptations were necessary (level II, except BASMI). After the adaptations, the assessment battery can now be used in group exercise therapy for individuals with axSpA. In this way, the individual fitness status can be evaluated, and interventions can be adapted, and thus the quality of group exercise therapy can be continuously monitored and improved if necessary.
Acknowledgements: We thank all participants and the SVMB for their support.

POS0045-HPR HEALTHCARE PROFESSIONALS' ATTITUDE TOWARDS REMOTE MONITORING

E. E. Kvernberg Thomassen[1], A. T. Tveter[1], E. Kristianslund[2], I. J. Berg[2], N. Østerås[1]. *[1]Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology (NKRR), Oslo, Norway; [2]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*

Background: The pandemic has accelerated the use of remote monitoring of patients (1), but there is still lack of knowledge in regards to barriers and facilitators for using remote monitoring among health care professionals. Patients with rheumatic diseases are monitored frequently by healthcare professionals, and follow-up strategies with less hospital visits could reduce the resource use.
Objectives: To explore healthcare professionals' attitude, facilitators and barriers on use of remote monitoring in a specialist healthcare setting.
Methods: Approximately 100 employees at a department of rheumatology at a single Norwegian hospital were invited to complete an anonymous 22-item questionnaire in December 2021. To ensure anonymity, demographic data were limited to age (under/over 45 years of age) and current position (doctor, nurse, allied healthcare/leaders/secretaries). In addition, participants completed questions on frequency of use of video consultation, phone consultation and patient-reported software. For investigating attitudes, facilitators and barriers the participants also responded to 16 statements related to perspectives on the use of remote monitoring in patients with low and stable disease activity using a 10-point numeric rating scale (NRS) from 0="Strongly disagree" to 10="Strongly agree". We developed the statements as potential facilitators or barriers for the use of video consultations and remote monitoring based on facilitators and barriers identified in previous research (2-4). The statements that had median score for agreement >=6 were categorized as either facilitator or barrier and presented with median score and interquartile range (IQR).
Results: Seventy (70 %) participants completed the questionnaire. In the study sample 44 % were under the age of 45, 35 % were doctors, 36 % nurses and 28 % were allied health professionals, secretaries, or leaders. None used video consultation on a daily basis, while 6 % used phone consultation daily. The participants had a positive attitude towards the use of remote monitoring in patients with low and stable disease activity (median: 9 (IQR: 8-10). For the remaining 7 statements the median scores were close to 5 – which indicates that they cannot be regarded as neither facilitators nor barriers. The remaining statements focused on adequate internet connection, patients underreporting, scepticism towards new software and mistrust in technical systems. The facilitators and barriers for remote monitoring with median score >=6 among health care professionals are presented with box-plots including median score and IQR in Figure 1.

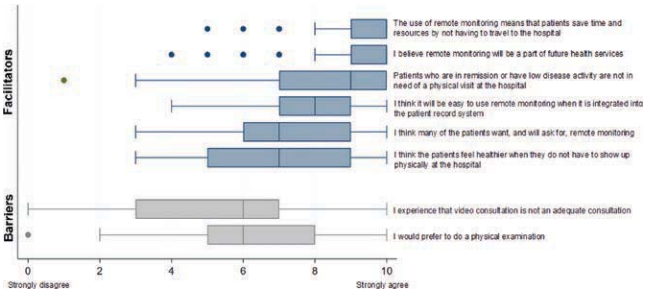

Figure 1. Facilitators and barriers presented with median score (IQR) in box-plots arrangement

Conclusion: Health care professionals showed positive attitudes towards the use of remote monitoring. Main facilitators on use of remote monitoring were: patients saving time, the belief of remote monitoring being part of future health care, remote monitoring being integrated with patient record system, patients wish to use remote monitoring and patient feeling less burdened by not visiting hospital. The main barriers were the inability to physically examine the patients and limitations related to the use of video consultation.

POS0046-HPR THE EFFECT OF MEDITATION, MINDFULNESS, AND YOGA IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Slagter[1], K. Demyttenaere[2], D. De Cock[1,3]. *[1]KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium; [2]KU Leuven, Psychiatry Research Group, Leuven, Belgium; [3]KU Leuven, Clinical and Experimental Endocrinology, Leuven, Belgium*

Background: Non-pharmacological approaches additional to the pharmacological treatment of rheumatoid arthritis (RA) may include meditation, as well as yoga and mindfulness. These mind-body therapies (MBTs) create an interaction between the mind and body to enhance overall health. MBTs are perceived as valuable in RA management, but the extent of this contribution is unclear, as well as patients subgroups who benefit most from these MBTs.
Objectives: To investigate the effects of meditation, mindfulness, and yoga in patients with RA in a systematic literature review.
Methods: A search was performed in 4 databases (PubMed, Embase, Web of Science (core collection, Chinese and Korean collection) and CINAHL). All studies were screened by two independent reviewers, via title/abstract/full text. Studies included any form of meditation, mindfulness and/or yoga as an intervention

Table 1. Overview of included studies

Author (year)	Intervention	Country	Outcome	Author (year)	Intervention	Country	Outcome
Yoga				**Mindfulness**

MBCT = Mindfulness-Based Cognitive Therapy; PMR = Progressive muscle relaxation; MBSR = Mindfulness-based stress reduction, MERT = mindfulness-based emotion regulation therapeutic program, MAAT = mindfulness-based emotion regulation therapeutic program QoL= quality of life

for patients with RA. Animal studies, case reports, non-English articles, qualitative studies, conference abstracts and articles without full text access were excluded. Each study was assessed for quality.

Results: Out of the 1,527 records, 23 studies were included after screening (Table 1). There was considerable heterogeneity, both in applied interventions and outcome measurements. All MBTs showed limited beneficial effects on psychosocial outcomes, such as vitality, functioning, and mental health, as well as on disease activity markers. Mindfulness-based interventions mainly reduced the subjective disease activity (e.g., joint tenderness/pain), rather than objective disease activity (e.g., swollen joints/CRP). RA patients with recurrent depression seemed to benefit more from these non-pharmacological therapies than patients without recurrent depression.

Conclusion: This systematic literature review found that MBTs have added value in RA management, especially for patients with depressive symptoms. These non-pharmacological approaches as an addition to treatment can be a way to diminish polypharmacy in specific RA patient populations.

POS0047-HPR GOALS AND ACTION PLANS ACROSS TIME AND PLACE IN PERSON-CENTRED REHABILITATION - A QUALITATIVE STUDY EXPLORING THE IMPORTANCE OF CONTEXT

L. Eggen[1], J. Thuesen[2,3]. *[1]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; [2]University of Southern Denmark, Danish Knowledge Centre for Rehabilitation and Palliative Care, Nyborg, Denmark; [3]University College Absalon, Center for Nutrition and Rehabilitation, Næstved, Denmark*

Background: Person-centeredness is increasingly addressed in relation to rehabilitation interventions (1). Collaborative goal setting and action plans are key elements in person-centered rehabilitation (2). There is a lack of knowledge about how person-centered goals and action plans developed during inpatient rehabilitation are experienced by the patients after discharge.

Objectives: This aim of the study was to explore how rheumatic patients experience the relevance of goals and action plans after discharge from an inpatient rehabilitation stay.

Methods: Individual narrative interviews were conducted with eight patients with a rheumatic disease three to five weeks after discharge from a two-week inpatient rehabilitation stay. A convenience sampling strategy was applied. In order to the exploratory nature of the study, we strived for variety in diagnoses, age and gender (3). One male and seven female patients participated, aged between 40 and 60 years. Six of the participants were active at the labor market and two were retired. Data collection, analysis and interpretation of data were performed within a phenomenological-hermeneutic framework inspired by Paul Ricoeur's interpretative philosophy (4).

Results: The analysis derived one core theme: 'The relevance of goals and action plans is contextual' and three subthemes: 'The hospitalization - a protected bubble', 'Being at home - a harsh reality', and 'Need for support after discharge'. The participants expressed that during the admission there was time and peace to exercise and to take a rest. They were relieved from everyday duties, and received support from the interdisciplinary team in how to exercise and during conversations where they focused on management of their symptoms and illness. Back home after discharge, the participants experienced how their everyday life differed from the hospital context. They found it challenging to work further with goals and actions plans in their everyday life. They described in particular challenges with incorporation of new habits in everyday life, challenges they were not prepared for. On challenging days with pain and fatigue, the participants missed having someone to talk to. The participants suggested involvement of their relatives to support action plans and called for follow-up support to enable them to continue working to achieve their goals and action plans after discharge. They suggested support by telephone calls from a nurse from the hospital after one, two or three months after discharge to ask how they felt. They believed that it would be motivating and could support the outcomes of the admission.

Conclusion: Goals and actions plans are relevant for rheumatic patients, but must be adapted to the patient's everyday life. There is a need to plan during the hospitalization how goal and action plans can be transferred to the rheumatic patient's everyday life after discharge from a rehabilitation stay. Likewise, there is a need for follow-up support after discharge to support the patients to pursue their goals and cope with challenges in everyday life.

POS0048-HPR HEALTHCARE PROFESSIONALS' EXPERIENCES OF LIFESTYLE MANAGEMENT IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS – A QUALITATIVE STUDY

K. Drake af Hagelsrum[1], E. Mogard[2,3], A. Bremander[2,4,5,6], E. Lindqvist[2,3], I. Larsson[1,2,4]. *[1]Halmstad University, School of Health and Welfare, Halmstad, Sweden; [2]Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; [3]Skane University Hospital, Department of Rheumatology, Lund, Sweden; [4]Spenshult, Research and Development Centre, Halmstad, Sweden; [5]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; [6]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory systemic disease that mainly affects joints and with symptoms such as stiffness, pain, and increased fatigue. RA also appears to be an independent risk factor for accelerated atherosclerosis with an increased risk of cardiovascular diseases,

why national and international guidelines recommend proper pharmacological treatment together with a healthy lifestyle (1). Supporting people with early RA to achieve and maintain a healthy lifestyle is therefore of great importance. However, few studies have explored healthcare professionals' views of working with lifestyle management. A healthy lifestyle does not only have the potential to lower cardiovascular risk but may also improve a person's quality of life.

Objectives: The aim of this study was to explore healthcare professionals´ experiences of lifestyle management in patients with early RA.

Methods: In this explorative qualitative study, individual interviews were conducted with 20 healthcare professionals who had a mean of 16 years of professional experience in the field of working with patients with RA. An interview guide with open-ended questions was used e.g.: "How do you work with lifestyle changes in patients with RA?" and "What theories do you use to support lifestyle changes?" Qualitative content analysis was used, where three categories emerged: "The importance of a well-functioning organization", "The importance of teamwork" and "The importance of person-centered care" and nine subcategories, representing the overall content of the interviews (Table 1).

Table 1. ***Overview of categories and subcategories that describes healthcare professionals´ experiences of lifestyle management in patients with early RA***

Categories	Subcategories
The importance of a well-functioning organization	Supportive leadership
	Priority of lifestyle management
	Competence development in lifestyle management
The importance of teamwork	Interdisciplinary team
	Professional expertise in lifestyle habits
	Structured approach to lifestyle management
The importance of person-centered care	Individually tailored lifestyle management
	Shared decision-making
	Patient engagement

Results: Healthcare professionals' experiences of lifestyle management in patients with early RA included the importance of a well-functioning organization with supportive leadership, priority of lifestyle management, and competence development in lifestyle management. The importance of teamwork was emphasized including interdisciplinary team, professional expertise in lifestyle habits, and structured approach to lifestyle management. The healthcare professionals also highlighted the importance of person-centered care with individually tailored lifestyle management, shared decision-making, and patient engagement.

Conclusion: Healthcare professionals' experiences of lifestyle management in patients with early RA reveal that commitment from both the management, the team, and the patient is important.

POS0049-HPR PATIENT SATISFACTION WITH THE INTERDISCIPLINARY, RHEUMATOLOGIST-MANAGED AND RHEUMATOLOGY NURSE-CONDUCTED, DIAGNOSTIC APPROACH FOR FIBROMYALGIA PATIENTS

D. Nørlov[1]. [1]*Frederiksberg Hospital, Rheumatology Outpatient Clinic, Frederiksberg, Denmark*

Background: Based on the evidence that substituting specialized nurses for rheumatologist in the diagnostic process for fibromyalgia (FM) is safe (Kroese et al., 2008) and leads to patient satisfaction and reduction of costs (Kroese et al., 2011), the Capital Region of Denmark increased its respective capacities by introducing a rheumatologist-managed and specialized nurse-conducted diagnostic approach at the Frederiksberg Hospital in January 2018.

Objectives: The objective of this quality insurance survey was to get patients' feedback on their satisfaction with the nurse-conducted diagnostic approach.

Methods: An evaluation-questionnaire was developed. Patients were asked: *Did you feel confident in the nurse-conducted diagnostic approach? How clearly did the nurse communicate? How much did you profit from the final, diagnostic consultation with the nurse? Do you feel the need for further medical examinations?* The answers were given on a 4-point Likert scale with the points: to a high degree; to some degree; to a lesser degree; not at all. All patients that had undergone the diagnostic approach were offered to evaluate it by anonymously filling in the evaluation-questionnaire on an iPad. The data analysis consisted of counting the number and calculating the percentage of respondents in each of the response-categories.

Results: 601 patients were offered to evaluate the approach during the period from 1.1.2018 to 27.2.2020. 60% (n=358) of these patients filled in the evaluation questionnaire. 88% (n=315) of the respondents were very confident in the nurse-conducted diagnostic process, as well as thought that the nurses communicated very clearly. Furthermore, 94% (n=317) of the respondents thought that they profited from the nurse-conducted diagnostic consultation focused on the explanation of FM and treatment options. Lastly, only 11 % (n=39) felt a pronounced need for further examination. Complete overview of the results is presented in the Table 1. Number and % of respondents per each question and per each response category.

Table 1. Number and % of respondents per each question and per each response category.

Questions	Total number of respondents	Number of respondents (%) per each Likert scale point			
		to a high degree	to some degree	To a lesser degree	not at all
Confidence in the nurse	358	315 (88%)	28 (8%)	11 (3%)	4 (1%)
Clarity of nurse- communication	358	315 (88%)	39 (11%)	4 (1%)	0 (0%)
Profit from the diagnostic consultation	338	189 (56%)	128 (38%)	17 (5%)	4 (1%)
Perceived need for further examinations	357	39 (11%)	82 (23%)	114 (32%)	122 (34%)

Conclusion: The patients were confident in the nurse-conducted diagnostic process and had profited from the diagnostic consultation focused on the explanation of FM and current treatment options. Thus, specially trained nurses contribute to the effectiveness of the FM diagnostic process and to patients' satisfaction. This facilitates patients' timelier access to treatment options.

Background: Vaccination is considered efficient in controlling infections incl. SARS-CoV-2. Prior studies showed that patients receiving rituximab (RTX) with low B cell counts are at increased infectious risk (1) and risk of inadequate vaccination responses (2, 3). Thus, the ability to further define and predict vaccination responses in these patients may guide their optimal protection.

Objectives: To assess predictive biomarkers of vaccination responses upon SARS-CoV-2 vaccination in RTX treated patients.

Methods: B cell characteristics before vaccination were evaluated to predict responses in 15 patients with autoimmune inflammatory rheumatic diseases receiving RTX. 11 patients with rheumatoid arthritis on other therapies (RA), 11 kidney transplant recipients (KTR) and 15 healthy volunteers (HC) served as controls. A multidimensional analysis of B cell subsets and a correlation matrix were performed to identify predictive biomarkers.
Results: Significant differences regarding absolute B cell counts and specific subset distribution pattern between the groups were validated at baseline. Here, the majority of B cells from vaccination responders of the RTX group (RTX IgG+) comprised naïve and transitional B cells, whereas vaccination non-responders (RTX IgG-) carried preferentially plasmablasts and double negative (CD27-IgD-) B cells (Figure 1). Moreover, there was a positive correlation between neutralizing antibodies and absolute B cell numbers with B cells expressing HLA-DR and CXCR5 (involved in antigen presentation and germinal center formation) as well as an inverse correlation with CD95 expression and CD21low expression (marker for activation and exhaustion) on B cells.
Conclusion: Substantial repopulation of naïve B cells upon RTX therapy appears to be essential for an adequate vaccination response requiring germinal center formation. In contrast, expression of exhaustion markers (CD21low, CXCR5-, CD95+) indicate negative predictors of vaccination responses. These results may guide optimized vaccination strategies in RTX treated patients clearly requiring antigen-inexperienced B cells for appropriate protection.

POS0051

DIFFERENTIAL PHARMACODYNAMIC ALTERATIONS AFTER TREATMENT WITH ABATACEPT OR ADALIMUMAB IN MTX-INADEQUATE RESPONDER PATIENTS WITH EARLY RA: WHOLE BLOOD RNA-SEQ ANALYSIS OF THE EARLY AMPLE STUDY

C. Wu[1], Y. Li[2], N. Ray[3], M. A. Maldonado[4], P. Schafer[5], S. L. Bridges[6], W. Rigby[7], V. Bykerk[8], J. Buckner[9], J. Liu[5]. *[1]Bristol Myers Squibb, Translational Bioinformatics, Princeton, United States of America; [2]Parexel International, N/A, Durham, United States of America; [3]Bristol Myers Squibb (at the time of analysis), Global Drug Development, Princeton, United States of America; [4]Bristol Myers Squibb, Clinical R&D, Immunoscience, Princeton, United States of America; [5]Bristol Myers Squibb, Translational Medicine, Princeton, United States of America; [6]Hospital for Special Surgery, Department of Medicine, New York, United States of America; [7]Dartmouth-Hitchcock Medical Center, Rheumatology Section, Department of Medicine, Lebanon, United States of America; [8]Hospital for Special Surgery, Division of Rheumatology, New York, United States of America; [9]Benaroya Research Institute at Virginia Mason, Center for Translational Immunology, Seattle, United States of America*

Background: Despite advances in available novel pharmacologic agents for RA,[1] the dearth of effective response predictors for specific therapies remains an unmet need. To inform clinical decision making, it is critical to define molecular signatures of these therapeutic agents by investigating their mechanisms of action (MoAs) and differential impacts on patients' immune systems. Adalimumab and abatacept are biologic DMARDs with distinct MoAs used to treat RA. A better understanding of the differential pharmacodynamic (PD) changes of these 2 agents may provide guidance for the selection of treatment options.[2] The Early AMPLE (Abatacept versus adaliMumab comParison in bioLogic-naïvE RA subjects with background MTX) study compared treatment with abatacept or adalimumab in a population of patients with early RA to explore differential PD effects; abatacept treatment resulted in numerically higher efficacy responses vs adalimumab after 24 weeks of treatment.[3]
Objectives: To investigate PD changes in response to treatment with abatacept or adalimumab, and to identify and differentiate the impact of each drug on modulation of immune cells at the molecular level.
Methods: The phase 4 Early AMPLE trial (NCT02557100) was a head-to-head comparison of treatment response to either abatacept or adalimumab in patients with early RA with an inadequate response to MTX, high anti-citrullinated protein antibody titers, and RF positivity, with or without shared epitope. Whole blood RNA sequencing (RNA-Seq) was conducted on samples collected from patients at different visits (day 1; weeks 4, 8, 16, 24, 28, 32, 40, 48). Differential gene expression analyses were performed using Limma-voom pipeline in R, adjusting for batch effect and sex. Over-representation tests were used to identify enriched Gene Ontology pathways. xCell, a gene signatures–based method learned from thousands of pure cell types, was applied for immune cell type deconvolution and enrichment analysis.
Results: PD and association analyses were performed for 14,540 protein-coding genes in 664 RNA-Seq samples (79 patients with RA at 9 visits). Baseline association analysis showed that 248 differentially expressed genes and 6 cell cycle–related pathways were significantly associated with baseline SDAI score. After treatment, gene-enrichment analysis demonstrated that twice as many genes and pathways were significantly altered in the adalimumab- vs abatacept-treated arm. Abatacept treatment decreased immune cell cycle gene expression while adalimumab treatment increased expression of these genes. The increases due to adalimumab were reversed after switching to abatacept (open-label period). Using gene signatures to identify key immune cell subsets (Figure 1), adalimumab therapy increased expression of genes defining several key immune cell types involved in RA disease development, including dendritic cells, T cells, and B cells; these effects were also reversed after switching to abatacept.
Conclusion: The differential gene expression seen after treatment with abatacept or adalimumab was noted in genes identified as correlating with RA disease activity. These findings may inform on the mechanism for the relatively greater clinical improvements seen with abatacept vs adalimumab in the Early AMPLE study. Abatacept treatment may selectively modulate genes that are relevant to disease pathology/progression, with the potential to restore the immune homeostasis dysregulated in RA. Our findings warrant further studies to investigate the potential positive correlation between RA-relevant PD effects and better therapeutic outcomes.

Background: Interstitial lung disease (ILD) is a common and life-threatening complication in patients with autoimmune diseases (AD), mainly in those with systemic sclerosis (SSc) and rheumatoid arthritis (RA). Growing evidence indicate that vascular abnormalities constitute the early phase in the pathogenesis of these inflammatory diseases [1]. We recently reported a decrease of angiogenic T cells (TAng), that promote endothelial repair and revascularization cooperating with endothelial progenitor cells (EPC) [2], in patients with AD-ILD$^+$ [3]. Nevertheless, no studies have been conducted on the role of TAng in the presence of ILD in RA, SSc or other AD.

Objectives: To determine the contribution of TAng in the pathogenic processes of vasculopathy and lung fibrosis in RA-ILD$^+$, SSc-ILD$^+$ and other AD-ILD$^+$, as well as their relationship with EPC in all the AD-ILD$^+$ patients.

Methods: Peripheral venous blood was collected from 21 RA-ILD$^+$ patients, 21 SSc-ILD$^+$ patients and 15 patients with other AD-ILD$^+$. Furthermore, we included 4 comparative groups: 25 RA-ILD$^-$ patients, 20 SSc-ILD$^-$ patients, 21 idiopathic pulmonary fibrosis (IPF) patients and 21 healthy controls (HC). TAng were considered as CD3$^+$CD184$^+$CD31$^+$ cells by flow cytometry. Additionally, EPC data were previously published by Pulito-Cueto *et al.* [4-5].

Results: Regarding the role of TAng in vasculopathy, the frequencies of these cells were significantly lower in patients with RA-ILD$^+$, SSc-ILD$^+$ and other AD-ILD$^+$, as well as with IPF in relation to HC (p=0.007, p=0.016, p=0.005 and p<0,001, respectively, Figure 1). No differences between RA-ILD$^-$ patients, SSc-ILD$^-$ patients and HC were found (Figure 1). With respect to TAng involvement in fibrosis, TAng frequencies were similar in patients with RA-ILD$^+$, SSc-ILD$^+$, other AD-ILD$^+$ and those with IPF (Figure 1). Nevertheless, patients with RA-ILD$^+$ and SSc-ILD$^+$ showed significantly lower TAng frequencies than those with RA-ILD$^-$ and SSc-ILD$^-$, respectively (p=0.006 and p=0.044, respectively, Figure 1). In this line, a higher frequency of TAng was found in SSc-ILD$^-$ and RA-ILD$^-$ patients in relation with those with IPF (p<0.001 and p=0.003, respectively, Figure 1). Moreover, TAng frequency did not show significant correlation with EPC frequency in the whole cohort of AD-ILD$^+$ patients.

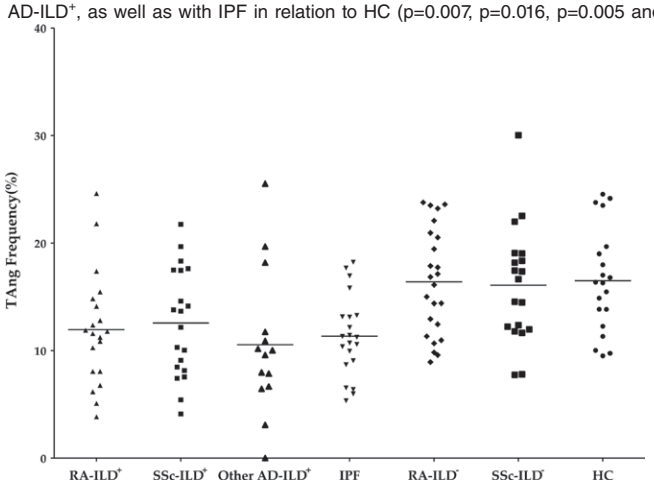

Figure 1. *Quantification of TAng population by flow cytometry in all individuals included in the study.*

Conclusion: TAng play a relevant role in the lung vasculopathy of RA-ILD$^+$, SSc-ILD$^+$ and other AD-ILD$^+$. Interestingly, circulating TAng may be considered as a useful biomarker of the presence of ILD in patients with RA and SSc.

POS0053 ABUNDANT AUTOANTIBODY ISOTYPES IN IDIOPATHIC INFLAMMATORY MYOPATHIES

C. Preger[1,2], A. Notarnicola[1], C. Hellström[3], E. Wigren[1,2], I. E. Lundberg[1], P. J. Jakobsson[1], H. Persson[3], S. Gräslund[1,2]. *[1]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden; [2]Structural Genomics Consortium, Karolinska Institutet, Stockholm, Sweden; [3]KTH, Royal Institute of Technology, Department of Protein Science, SciLifeLab, Stockholm, Sweden*

Background: Anti-synthetase syndrome (ASSD), a sub-group of idiopathic inflammatory myopathies (IIM) is characterized by the presence of autoantibodies targeting aminoacyl tRNA synthetases (aaRS) and specific clinical manifestations such as myositis and interstitial lung disease (ILD) [1]. Some of the most common anti-aaRS autoantibodies in ASSD are anti-Jo1, -PL7, -PL12 and-EJ. In addition, many anti-aaRS positive patients are also positive for anti-Ro52. Having the combination of anti-Jo1 and anti-Ro52 increases the risk of developing ILD [2]. The presence of autoantibodies is an important part of the classification of ASSD, however only autoantibodies of IgG isotype are usually analyzed in the clinical setting. In rheumatoid arthritis there is evidence that anti-citrullinated protein/peptide antibodies (ACPA) can be found as IgG, IgA and IgM, and importantly, specific isotypes might correlate with disease activity [3, 4].

Objectives: To verify if other autoantibody isotypes, besides IgG, might be present in sera of patients with IIM/ASSD and to compare with the corresponding frequencies in population controls (PC).

Methods: Stored sera collected from consecutive 366 IIM patients and 156 age/gender matched PC at Karolinska University Hospital were retrospectively selected. The serum samples were screened for the presence of autoantibodies of isotypes IgG, IgA and IgM, against a panel of 20 antigens representing Jo1 (HisRS), PL7 (ThrRS), PL12 (AlaRS), EJ (GlyRS), and Ro52 (TRIM21) using a multiplex bead array assay.

Results: We identified IIM patients with autoantibodies of different isotypes, and a low frequency in PC (Figure 1). For anti-Jo1 autoantibodies we could detect IIM patients with only IgG (n=13), only IgM (n=8) and only IgA (n=4), but the majority had a combination of two (n=32) or three isotypes (n=16). For the other anti-aaRS autoantibodies the distribution was more equal to each of the three isotypes with anti-PL12 and anti-PL7 being represented by a slightly higher

frequency of IgG and only a few patients had antibodies of more than one isotype targeting PL12, PL7 or EJ. The majority of anti-Ro52 positive IIM patients (n=52) only harbored IgG isotype. The combination of anti-Ro52 and anti-aaRS autoantibodies was identified in 28 patients (anti-Jo1 (n=19), -PL12 (n=2), -PL7 (n=3), and -EJ (n=4)). Most patients with such combination had anti-Ro52 IgG together with anti-aaRS IgG or IgG in combination with IgA and/or IgM. The exception was observed for three anti-Jo1 positive patients who had the combination anti-Ro52 IgG with only anti-Jo1 IgM and one anti-PL7 positive patient who had anti-Ro52 IgA together with anti-PL7 IgA and IgG.

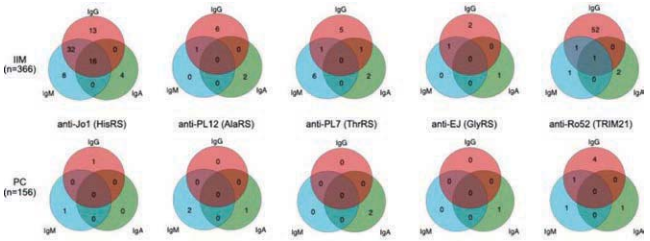

Figure 1. Venn diagrams showing reactivity in idiopathic inflammatory myopathies (IIM) (top) and population controls (PC) (bottom) for the three autoantibody isotypes IgG, IgA and IgM against five myositis antigens: Jo1 (HisRS), PL12 (AlaRS), ThrRS (PL7), EJ (GlyRS) and Ro52 (TRIM21).

Conclusion: The frequency of the different autoantibody isotypes seems to be autoantigen dependent. Our results suggest that for anti-aaRS autoantibodies it could be important to investigate additional autoantibody isotypes, as some patients only harbor autoantibodies of IgM or IgA isotypes but not IgG. The clinical relevance of the different antibody isotypes still needs to be determined.

POS0054 DYSFUNCTION OF REGULATORY B CELLS IN GIANT CELL ARTERITIS (GCA)

M. Stöcker[1,2,3], U. Kiltz[1,3], J. Braun[1,3], B. Wilde[4]. *[1]Rheumazentrum Ruhrgebiet, Rheumatology, Bochum, Germany; [2]Augusta-Krankenanstalt Bochum, Pneumology and Infectious Diseases, Bochum, Germany; [3]Ruhr-Universität Bochum, Rheumatology, Bochum, Germany; [4]University Hospital Essen, Nephrology, Essen, Germany*

Background: The pathophysiology of GCA is not clearly understood, but most research has pointed towards a major role of T cells with proinflammatory Th1 und Th17 cells as dominant drivers of disease. The role of B cells in the pathogenesis of GCA has not been much studied to date.

Objectives: To study the role of proinflammatory T cell mediators and anti-inflammatory regulatory B cells (Bregs) as their counterpart in patients with GCA compared to healthy controls (HC).

Methods: GCA Patients and HC were recruited prospectively and included after informed consent. Peripheral blood mononuclear cells were freshly isolated from whole blood and included into 3 experimental setups, using flow cytometry and fluorescent antibodies: (i) pro-inflammatory T cell mediators (IL-2, GMCSF, IL-17a, IFN-y), (ii) granzyme B production of Bregs after stimulation with different agents (anti-human IgG + IgM, IL-21, anti-CD40L) and (iii) the IL-10 production of Bregs were measured. Disease activity was defined as unequivocal evidence of cranial symptoms of GCA and/or increased concentrations of C-reactive protein and/or halo-sign, leading to a change in therapy according to the treating rheumatologist. Statistical comparisons between groups were performed by the Mann-Whitney-U-Test and Spearman's rank correlation.

Results: A total of 47 GCA patients (14 with active disease and 33 in remission) and 49 HC were included (Table 1). $CD4^+$ T cells of GCA patients with active disease produced less IFN-y than HC (p=0.016, Figure 1a). There was also a trend towards lower expression of IL-2 (p=0.18), GMCSF (p=0.1) and IL-17a (p=0.18) by $CD4^+$ T cells from GCA patients compared to HC. Bregs of GCA patients produced lower amounts of granzyme B after stimulation with anti-human IgG and IgM compared to HC, and this was similar in active patients (p=0.04, Figure 1b) and in quiescent patients (p=0.021, Figure 1b). With other stimuli, including IL-21 and anti-CD40L, there was also a trend towards a lower expression. The IL-10 production of Bregs did not show substantial differences between groups. Importantly, the dose of glucocorticoids did not influence cytokine production of T-cells or B-cells.

Table 1. Demographics

Variables	GCA Patients (n=47)	Healthy Controls (n=49)
Age, years	71 *(54-83)*	65 *(45-86)*
Sex, n (%)	31 female (65.9)	40 female (81.6)
Disease activity	14 active disease (9 first diagnosis, 5 relapse) 33 in remission	NA
Therapy	Prednisolone: n= 29 Methotrexat: n=23 Tocilizumab: n=13	none
Dosage of prednisolone	None: n=18 1-7,5 mg/d: n=15 > 7,5 mg/d: n=14	

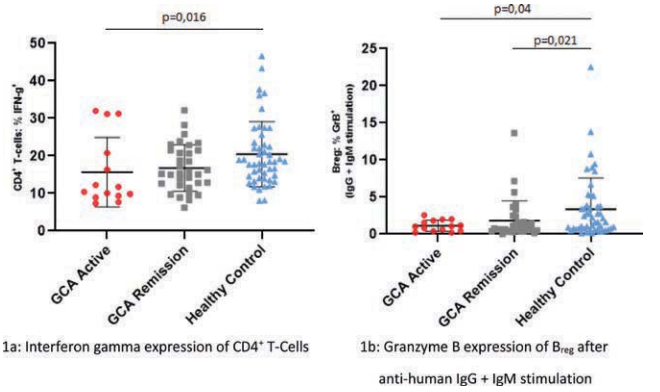

Figure 1. 1a: Interferon gamma expression of CD4+ T-Cells / 1b: Granzyme B expression of Breg after anti-human IgG + IgM stimulation

Conclusion: The *in vitro* cytokine production of proinflammatory $CD4^+$ T cells and anti-inflammatory Bregs after stimulation, especially regarding granzyme B production, showed some differences between patients and HC. A lower granzyme B production was found in patients with active disease indicating a lack of Breg–mediated suppressive capacity towards pro-inflammatory T cells. This finding may play a role in the pathogenesis of GCA.

POS0055 TNF-α REGULATION OF MIR-29B EXPRESSION IN CD14+PBMS AND ITS RELEASE OF PROINFLAMMATORY CYTOKINES IN RHEUMATOID ARTHRITIS

D. Yun[1,1], D. Liu[1], G. Cui[2]. [1]*The First Affiliated Hospital of Xi'an Medical University, Department of Rheumatology and Immunology, Xi'AN, China;* [2]*Luoyang Central Hospital Affiliated to Zhengzhou University, Department of Orthopedics, LuoYang, China*

Background: It was found that the expression of mir-29b was significantly up-regulated in PBMs, and we tried to clarify TNF- α The production of proinflammatory cytokines was increased by inducing the overexpression of mir-29b in CD14 +PBMs in patients with rheumatoid arthritis (RA), and by using TNF-α that the expression of mir-29b was significantly urapy to reverse regulate mir-29b, and carry out relevant experiments to verify our scientific research hypothesis.
Objectives: By observing patients with RA treated with TNF-α significantly urapy to reverse regulate mir-29b, and carry out relevant experimenperipheral blood mononuclear cells (CD14+PBMs) and releases pro-inflammatory cytokines.
Methods: (1) Cell experiment: PBM cells from RA patients were collected and extracted for CD14+ cell expression labeling. Different doses of TNF-α blood mononuclear c500 ng/ml) were used for intervention. Meanwhile, the expression of mir-29b was analyzed by rt-qpcr at the level of TNF-α100 ng/ml for different periods of time (0,6,12,24h). In addition, the supernatant of cell culture was collected and human cytokines IL-1α, IL-1β, TNFα, IL-6, IFN-α and IL-8 were measured using a V-plex human cytokine 30-plex kit. (2)Grouping experiment of clinical intervention: 21 patients with RA diagnosis and 15 healthy volunteers were divided into three groups. TNF-α inhibitor group: RA patients treated with TNF-α inhibitor were collected (n=15); IL-6 monoclonal antibody group: RA patients treated with tocilizumab (n=6); Control group: healthy volunteers (n=15) were used as normal controls. PBMc was extracted from TNF-α inhibitor group for 6 months, IL-6 monoclonal antibody group for 6 months, and control group, respectively, to observe the difference of Mir-29b expression in CD14+PBMs of the three groups.
Results: The expression of miR-29b was dose-dependent and time-dependent with the incubation of TNF-α, and there was a significant difference ($P < 0.05$). Compared with the control group, the overexpression of miR-29b also led to an increase in the expression levels of a wide range of chemokines and proinflammatory cytokines (including IL-1α, IL-1β, TNFα, IL-6, IFN-α and IL-8) ($P < 0.05$). The expression of miR-29b in RA patients treated with TNF-α inhibitor was significantly reduced compared with that treated with Totuzumab ($P<0.05$).
Conclusion: TNF-α inflammatory factors can induce the overexpression of miR-29b in RA patients, and then producing a large number of proinflammatory cytokines, which can aggravate the inflammation mechanism of RA. In RA patients, TNF-α inhibitors may partially reduce the inflammatory response through the TNF-α/CD14+PBMs/ Mir-29b signaling pathway. Therefore, more attention should be paid to the expression of Mir-29b in TNF-α and CD14+PBMs in clinical practice, which may accurately indicate the state of immune disease in patients, and provide a basis for more accurate judgment of prognosis and the course of immunotherapy, as well as optimization of immunotherapy programs.

POS0056 GLOBAL STEROID METABOLISM IN MACROPHAGES: SHAPING INFLAMMATORY FUNCTION AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

C. S. Martin[1], M. Singh Kalirai[1], A. Crastin[2], D. Somma[3], M. Kurowska-Stolarska[3], J. D. Turner[4], L. Schiffer[1], L. C. Gilligan[1], A. E. Taylor[1], D. Scheel-Toellner[4], K. Raza[4], A. Filer[4], S. Jones[4], W. Arlt[1], M. Hewison[1], R. S. Hardy[2]. [1]*Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, United Kingdom;* [2]*Institute of Clinical Sciences, University of Birmingham, Birmingham, United Kingdom;* [3]*Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom;* [4]*Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom*

Background: Macrophages are key drivers of joint destruction and disease pathophysiology in rheumatoid arthritis (RA), where their inflammatory function is influenced by steroid hormones such as androgens and glucocorticoids (GCs). Local bioavailability of these steroids is determined by both systemic adrenal/gonadal synthesis and local metabolism in peripheral target tissues. The inflammatory regulation and function of steroid hormone metabolism by key rate limiting enzymes in chronic inflammatory diseases such as RA remain poorly defined and could present new therapeutic targets.
Objectives: Characterise regulation of global steroid metabolism in macrophages in RA and determine its contribution to androgen and GC availability, macrophage function and disease activity.
Methods: Bulk and single cell RNA-sequencing of FACS-sorted macrophages were analysed using previously published datasets from RA patients (27 female, 8 male)(1, 2). Gene expression of rate limiting steroid metabolism enzymes were assessed in macrophages and their subsets and correlated to clinical parameters of disease activity. Primary human monocyte-derived macrophages were polarised to non-inflammatory (M-CSF 20ng/ml) and inflammatory activated (M-CSF 20ng/ml, IFNγ 20ng/ml, TNFα 10ng/ml) subsets and treated with active or inactive metabolites of GCs (cortisol/cortisone 100nmol/l) and androgens (androstenedione/testosterone/DHEA 100nmol/l; DHT 10nmol/l). Metabolism and functional effects were assessed in primary cultures and RA synovial fluids by liquid chromatography mass spectrometry, RT-qPCR and ELISA.
Results: Significant differentially expressed genes (DEGs) were identified in the GC and androgen metabolism pathways in synovial macrophages when stratified for high and low disease activity by DAS28-CRP. Expression of the GC-activating enzyme HSD11B1 and androgen activating enzyme SRD5A1 were significantly increased and positively correlated with disease severity. The androgen activating enzyme AKR1C3 was significantly suppressed and negatively correlated with disease severity. SRD5A1 and HSD11B1 expression were localised to $S100A12^{pos}$ and $SPP1^{pos}$ subsets associated with active RA, whilst AKR1C3 was primarily expressed by $MerTK^{pos}TREM2^{high}$ subsets associated with RA remission. Inflammatory activation of primary macrophages decreased AKR1C3, and increased HSD11B1 and SRD5A1 expression. This resulted in a shift in intracrine production of active GCs and androgens favouring increased levels of the active GC cortisol and the potent androgen DHT. The resulting changes in steroid ratios in inflammatory activated macrophages resulted in lower expression and release of the pro-inflammatory mediators TNFα, IL6 and IL12 indicating functional significance. In vivo, metabolic changes favouring increased GC activation and reduced androgen activation correlated with disease severity determined by DAS28-CRP.
Conclusion: We have shown for the first time a role for macrophages and their tissue subsets in the inflammatory metabolism and activation of GCs and androgens in RA, which influence macrophage function and disease activity. Targeting these key metabolic pathways represents a novel route to modifying and suppressing disease activity and joint destruction in chronic polyarthritis.

POS0057 INDUCIBLE REGULATORY SYNOVIAL MACROPHAGES: A PROOF-OF-CONCEPT STUDY FOR A CELL-BASED TARGETED THERAPY FOR RHEUMATOID ARTHRITIS

A. Small[1], K. Lowe[1], A. Ferrante[2,3], M. Smith[1], S. Proudman[4,5], H. Weedon[1], M. Wechalekar[6]. [1]*Flinders University, College of Medicine and Public Health, Bedford Park, Australia;* [2]*SA Pathology, Department of Immunopathology, North Adelaide, Australia;* [3]*University of Adelaide, School of Medicine and School of Biological Sciences, Adelaide, Australia;* [4]*Royal Adelaide Hospital, Department of Rheumatology, Adelaide, Australia;* [5]*University of Adelaide, School of Medicine, Adelaide, Australia;* [6]*Flinders Medical Centre, Department of Rheumatology, Bedford Park, Australia*

Background: Infiltration of monocyte-derived macrophages into the synovial tissue (ST) is a hallmark of rheumatoid arthritis (RA) pathology. These macrophages promote inflammation, local joint effusion, and joint damage via the release of cytokines, oxygen reactive species, and tissue damaging enzymes. However, balancing these, are the 'regulatory' macrophages with inflammation-resolving properties, characterised by expression of CD206 and MerTK, dominant within the ST of healthy individuals as well as RA patients in remission (1). Indeed, these cells are believed to actively contribute to the maintenance of remission.

Macrophages are known to exhibit remarkable phenotypic plasticity and understanding the role of this characteristic in regulating inflammation and pathology remains a major challenge, as does the characterization of factors in the microenvironment such as the synovium that control such macrophage characteristics. Importantly, whether the infiltrating, inflammatory macrophages of the RA ST similarly exhibit such phenotypic plasticity, and whether this occurs during the process of reaching remission, remains to be studied.

Objectives: We investigated the phenotypic plasticity of inflammatory synovial macrophages from patients with RA in vitro, investigating their ability to convert from an inflammatory macrophage population into 'regulatory' CD206$^+$MerTK$^+$ macrophages. These findings will provide a proof-of-concept as to the utility of these macrophage for a cell-based therapy in resolving inflammation in patients with RA, and will likely extend our understanding of the mechanisms of action of currently used therapeutics.

Methods: Synovial fluid (SF) mononuclear cells were obtained from patients with active early RA (<1 year; fulfilling 2010 ACR/EULAR classification criteria). Cryopreserved SFMCs were cultured for 48hr in the presence of 10 ng/mL interferon(IFN)γ, 50 ng/mL dexamethasone, 10 µg/mL Infliximab, or diluent. Following culture, cells were immunostained and analysed using a Beckman Coulter CytoFLEX flow cytometer and FlowJo software. SF macrophages were characterised by expression of CD14, CD45, CD68 (Figure 1A), and proportions of CD206$^+$ MerTK$^+$ macrophages measured.

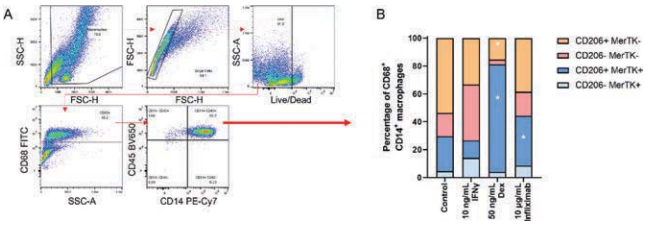

Figure 1. Synovial fluid CD68$^+$ macrophage plasticity *in vitro*. (A) Gating strategy depicting CD68$^+$ CD45$^+$CD14$^+$ SF macrophage determination. (B) Proportions of CD206 and MerTK-expressing SF macrophages after 48hr culture in the presence of 10 ng/mL IFNγ, 50 ng/mL dexamethasone or 10 µg/mL Infliximab, or absence. Data are representative of 5 individual experiments. Data were analysed by two-way ANOVA followed by Dunnett's multiple comparison test, *p<0.05.

Results: Prior to culture, the CD68$^+$ macrophage populations present in SF were found to be predominantly CD206$^-$MerTK$^-$. After 48 hours of culture, in the absence of any stimulus, there was an increase in proportions of CD206$^+$MerTK$^+$ macrophages. Treatment with either dexamethasone or anti-TNF (Infliximab) resulted in a further increase in proportions of CD206$^+$ MerTK$^+$, M2-like macrophages. In contrast, culture with IFNγ induced a reduction in this population. Importantly, we found that the generated CD206$^+$MerTK$^+$ macrophages were phenotypically stable in culture following removal of these differentiating agents.

Conclusion: Our findings demonstrate that inflammatory SF cells are indeed able to polarise to regulatory, CD206$^+$MerTK$^+$ macrophages *in vitro*. The findings provide further mechanistic insights into the basis for the therapeutic benefits of glucocorticoids and TNF inhibitors, as well as providing initial proof-of-concept in the use of regulatory macrophages as a cellular-based therapy or therapeutic target for patients with RA.

POS0058 IDENTIFICATION OF NOVEL BIOMARKERS OF DISEASE ACTIVITY IN SYSTEMIC AUTOIMMUNE DISEASES THROUGH NEXT GENERATION PROTEOMICS

C. Lopez-Pedrera[1], L. Muñoz-Barrera[1], A. Escudero Contreras[1], M. Á. Aguirre-Zamorano[1], P. Ortiz Buitrago[1], C. López-Medina[1], J. Calvo Gutierrez[1], R. Ortega Castro[1], F. U. Pilar[1], I. Sanchez-Pareja[1], M. C. Ábalos-Aguilera[1], N. Barbarroja Puerto[1], E. Collantes Estevez[1], C. Perez-Sanchez[1]. [1]*IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology, Cordoba, Spain*

Background: Systemic autoimmune diseases such as Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) are characterised by aberrant autoimmune and inflammatory processes, which are directly associated with the development and progression of these disorders. Novel biomarkers associated with the severity of these diseases are needed to better characterise and monitor their progression as well as to develop new and more effective therapeutic strategies.

Objectives: To identify common and distinctive novel biomarkers of disease activity in SLE and RA using high-throughput proteomics.

Methods: Serum samples from 170 patients, including 100 RA and 70 SLE, were profiled with the disruptive technology "proximity extension assay" from Olink, which analysed the levels of a panel of 92 inflammatory proteins. The methodology involves protein-specific antibodies linked to DNA-encoded tags which are amplified by RT-PCR.

Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Disease activity score in 28 joints (DAS28) were assessed in SLE and RA patients respectively to characterise the disease status of all patients.

Pearson´s correlation studies were performed using molecular information and clinical data to identify biomarkers of disease activity in each disease (FDR<0.05). Gene ontology enrichment analysis were performed to gain insight about the biological meaning of the biomarker signatures.

Results: SLE patients were characterised by an average SLEDAI of 5.2 (min-max, 0-29) while RA patients exhibited an average DAS28 of 4.6 (min-max, 1.5-7.8).

Correlation studies revealed 14 proteins directly associated with SLEDAI in SLE patients, including ADA, CCL25, CD40, CDCP1, CSF1, FGF21, FLT3L, IL10RB, LAP-TGFB1, MMP20, OPG, SLAMF1, TNFRSF9 and uPA. The subsequent enrichment analysis revealed that those molecules were associated with pathways such as cytokine-cytokine receptor interaction and MAPK signalling.

In RA patients 26 proteins were directly correlated with DAS28 including AXIN1, BNGF, CASP8, CCL23, CD40, CSF1, CXCL9, CXCL10, CXCL11, EN-RAGE, FGF23, GDNF, HGF, IL10RB, IL15RA, IL6, IL7, IL19, IL20, IL33, LAP-TGFB, MCP3, OPG, SLAMF1, TNFRSF9 and TWEAK which were enriched in biological pathways such as chemokine-chemokine receptor interaction and JAK-STAT signalling.

The levels of five pro-inflammatory mediators were commonly associated with the disease activity status of both diseases such as IL10RB (receptor for IL10, IFNL2 and IFNL3), CSF1 (macrophage colony-stimulating factor 1 receptor), SLAMF1 (Signaling lymphocytic activation molecule), TNFRSF9 and OPG (both, tumor receptor factor ligand superfamily members), suggesting a key common role of these molecules in the underlying molecular mechanisms associated with both diseases.

Conclusion: The analysis of the inflammatory profile of systemic autoimmune diseases with novel high-throughput proteomic technologies in non-invasive samples allow the identification of relevant biomarkers associated with the disease activity, which can improve the monitoring of the disease and the development of new targeted therapies.

Background: Axial spondyloarthritis (axSpA) is associated with a certain genetic predisposition, i.e., with the presence of human leukocyte antigen (HLA)-B27. However, the pathogenesis remains largely unexplained. Animal models of ankylosing spondylitis have shown inhibition of complement to be beneficial in terms of limiting structural damage (1). The lectin pathway of complement activation serves as a key component of the innate immune system and plays a pivotal role in both homeostasis and development. The influence of complement in axSpA is mainly unexplored. We have, however, previously reported elevated plasma levels of the lectin pathway proteins L-ficolin and H-ficolin in patients with axSpA compared with blood donors (2).

Objectives: Our aim was to investigate plasma levels of lectin pathway proteins in a clinical cohort of patients with axSpA and compare them to relevant controls that we often experience significant challenges in differentiating from axSpA.

Methods: Plasma samples were obtained from individuals in a cohort of patients suffering from low back pain (LBP) including: 1) 23 patients with axSpA, 2) 55 patients without axSpA experiencing SpA-features/symptoms, and 3) 64 patients

with nonspecific LBP without SpA-features or MRI findings suggestive of axSpA. Diagnosis of axSpA was based on multidisciplinary team conference consensus after 3.5 years of follow-up (3). Plasma levels of 10 lectin pathway proteins (MBL, CL-L1, H-ficolin, L-ficolin, M-ficolin, MASP-1, MASP-2, MASP-3, MAp44, and MAp19) were measured by immunoassays developed in-house.

Results: Patient characteristics are shown in Table 1. Plasma levels of lectin pathway proteins L-ficolin, M-ficolin and CL-L1 differed significantly in the patient groups ($p \leq 0.03$). L-ficolin and M-ficolin were elevated in axSpA-patients compared with patients with SpA-features without axSpA and nonspecific LBP patients (Figure 1). CL-L1 was elevated in axSpA-patients and patients with SpA-features without axSpA compared with nonspecific LBP patients (Figure 1). No significant differences were observed for MBL, H-ficolin, MASP-1, MASP-2, MASP-3, MAp44, and MAp19. L-ficolin levels correlated with CRP in axSpA-patients (Spearman's rho=0.58 p=0.004). M-ficolin levels correlated weakly with CRP in nonspecific LBP patients (Spearman's rho=0.36 p=0.003). Lectin pathway protein levels did not correlate with disease activity (ASDAS).

Table 1. Patient characteristics

	axSpA (n=23)	Not axSpA (n=55)	Non-specific low back pain (n=64)	*p*-value
Median age, years (range)	32 (19-40)	33 (19-41)	32 (18-39)	0.75[a]
Males, n (%)	10 (43)	37 (67)	26 (41)	0.01[b]
HLA-B27 positive, n (%)	17 (74)	11 (20)	5 (8)	0.00[b]
Inflammatory back pain, n (%)	18 (78)	28 (51)		0.03[c]
Good response to NSAID	14 (61)	17 (31)		0.01[c]
Sacroiliitis on MRI acc. ASAS, n (%)	22 (96)	45 (82)		0.11[c]
Elevated CRP, n (%)	3 (13)	7 (13)		0.97
ASDAS (range)	2.5 (1.2-3.7)	2.3 (0.8-3.8)		0.52[d]

[a] compared by Kruskal-Wallis test. [b] all three groups compared by Chi2 test. [c] compared by Chi2 test. [d] compared by Mann Whitney U test.

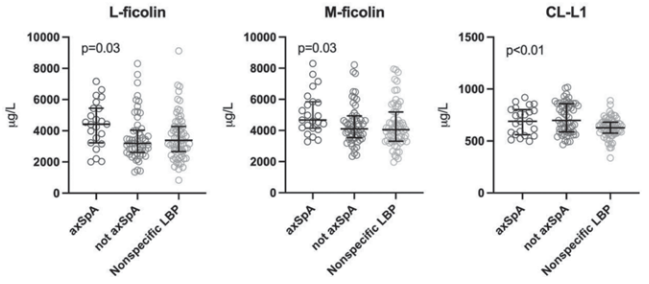

Figure 1. Plasma levels of L-ficolin, M-ficolin and CL-L1.

Conclusion: L-ficolin and M-ficolin are increased in patients with axSpA when compared with relevant control cohorts of patients with LBP or with SpA-features without axSpA. Our findings support a potential pathogenic role for complement in axSpA, however, further studies are needed to elucidate the diagnostic potential of the specific complement proteins.

POS0060

MEASUREMENTS OF COMPLEMENT ACTIVITY SPECIFICALLY THOUGH THE LECTIN -OR THE CLASSICAL PATHWAY IN PATIENTS WITH SLE

M. C. L. Larsen[1], A. Troldborg[1,2,3], E. Toonen[4], L. Hurler[5], Z. Prohászka[5,6], L. Cervenak[5], A. G. Hansen[2], S. Thiel[2]. *[1]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [2]Aarhus University, Department of Biomedicin, Aarhus C, Denmark; [3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [4]Hycult Biotech, R&D Department, PB Uden, Netherlands; [5]Semmelweis University, Department of Internal Medicine and Haematology, Budapest, Hungary; [6]Semmelweis University-Eötvös Loránd Research Network (Office for Supported Research Groups), Research Group for Immunology and Haematology, Budapest, Hungary*

Background: In systemic lupus erythematosus (SLE), the complement system (CS) is activated and thought to occur primarily through the classical pathway (CP) [1]. Traditionally, when diagnosing SLE or assessing disease activity, measurement of low C3 or C4 are used as proxies for complement activation [2]. However, measurement of C3 and C4 does not differentiate which complement pathway initiated the activation (i.e., the lectin pathway (LP), the CP, or the alternative pathway) [1, 3].

C1-esterase inhibitor (C1inh) is one of the key regulators of the CS. C1inh is the exclusive inhibitor of the active CP enzymes C1r and C1s [4], and the major inhibitor of active LP enzymes MASP-1 and MASP-2 [5]. A possible way of assessing complement activation through a specific pathway, is by measuring activated enzymes complexed with C1inh in plasma, as these complexes only exist after complement enzyme activation.

Objectives: Our aim was to investigate and unravel LP and CP complement activation in SLE, by measuring the protein complexes MASP1/C1inh (LP specific activation) and C1r/C1inh (CP specific activation). Furthermore, we aimed to investigate whether there is an association between complement activity, disease activity (SLEDAI) and disease manifestations (lupus nephritis (LN)).

Methods: A cross sectional cohort of 150 patients with SLE fulfilling the 1997 ACR classification criteria for SLE were included from the out-patient clinic at the department of Rheumatology, Aarhus University Hospital (AUH), Denmark. Disease manifestations and disease activity using SLEDAI score was assessed at inclusion. Fifty healthy individuals included at the Blood Bank, AUH, were used as controls. Both C1s/C1inh and MASP1/C1inh complexes were measured in all samples using two newly developed sandwich ELISAs (C1s/C1inh: cat# HK399; MASP1/C1inh: Cat#3001, Hycult Biotech, Uden, The Netherlands). EDTA-samples from both SLE patients and controls were measured in duplicates.

Results: When comparing SLE patients to controls, we observed a difference in complement activation through the LP, where a lower mean MASP1/C1inh plasma concentration was observed ($p<0.01$).

C1s/C1inh concentrations were significantly increased in active SLE patients (SLEDAI >6) when compared to SLE patients with low disease activity (SLEDAI <6, $p<0.01$) and correlated with SLEDAI score ($r=0.285$, $p<0.01$). C1s/C1inh concentrations were increased in SLE patients with active LN compared to non-active LN, however this not statistically significant ($p=0.09$).

No differences in MASP1/C1inh plasma concentrations were observed between active SLE patients and patients with low disease activity ($p=0.11$), nor did we observe a significant correlation with disease activity ($r=0.12$, $p=0.13$). In active LN, plasma concentrations of MASP1/C1inh were significantly elevated compared to non-active LN ($p=0.02$).

Conclusion: Our data suggest that the CP and the LP is activated in SLE. CS is generally activated in active SLE disease, whereas activation of the LP might be more specific to particular disease manifestations like LN.

Our findings warrant further research into activation of the specific complement pathways in relation to specific disease manifestations in SLE.

Lung involvement in Rheumatic Diseases

POS0061

THE RISK OF LUNG CANCER IN RHEUMATOID ARTHRITIS AND IN RELATION TO AUTOANTIBODY POSITIVITY AND SMOKING

K. Chatzidionysiou[1], D. Di Giuseppe[2], J. Söderling[2], A. Catrina[1], J. Askling[1,2]. *[1]Karolinska Institute, Rheumatology Division, Department of Medicine Solna, Stockholm, Sweden; [2]Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden*

Background: Lung cancer is a common malignancy in rheumatoid arthritis (RA)[1,2]. Since smoking is a risk factor for both (seropositive) RA and lung cancer, it remains unclear whether RA, in itself, increases lung cancer risk.
Objectives: The aim of this study was to examine whether and to what extent the increased risk of lung cancer in RA may (or may not) be attributable to smoking, and to examine this association, both in terms of absolute and relative risks, specifically in relation to RA serostatus.
Methods: We performed a population-based cohort study of RA patients and individually matched general population reference individuals identified in Swedish registers and from the EIRA early RA study, prospectively followed for lung cancer occurrence 1995 through 2018. We calculated incidence rates and performed Cox regression to estimate hazard ratios (HR) including 95% confidence intervals (CI) of lung cancer, taking smoking and sero-status into account.
Results: Overall, we included 44,101 RA patients (590 incident lung cancers, 56 per 100,000), and 216,495 matched general population individuals (1,691 incident lung cancers, 33 per 100,000), corresponding to a crude HR (95% CI) of 1.76 (1.60-1.93). In subset analyses this increased risk remained after adjustment for smoking (HR=1.77, 95% CI 1.06-2.97). Compared to general population subjects who were never smokers, RA patients who were ever smokers had almost 7 times higher risk of lung cancer.
Positive autoantibody status was associated with an at least doubled risk of lung cancer in ACPA positive patients (vs. ACPA negative patients) and double seropositive (vs. double seronegative) patients after adjusting for comorbidities and smoking (Table 1).
The average absolute five-year risk of lung cancer counting from RA diagnosis was 1.3% in ever-smoking seropositive RA. At 20 years the risk was almost 3% in RA overall, and over 4% for patients who were ever smokers and had at least one autoantibody.
Conclusion: RA seropositivity is a strong and at least seemingly independent risk factor for lung cancer in RA. The absolute risks point to the potential for regular lung cancer screening, at least in seropositive RA.

Background: Despite a high morbi-mortality rate, there are no definite strategy for subclinical interstitial lung disease (ILD) screening in patients with rheumatoid arthritis (RA).
Objectives: Our objectives were: 1. to identify risk factors for subclinical RA-ILD in a prospective discovery cohort (ESPOIR) 2.to develop a risk score for subclinical RA-ILD and 3. to validate the risk score in an independent replication cohort (TRANSLATE 2).
Methods: Patients without pulmonary symptoms from 2 prospective RA cohorts who underwent chest HRCT scans were included. All patients were genotyped for *MUC5B* rs35705950. A risk score based on independent risk factors for subclinical RA-ILD was developed using multiple logistic regression in the discovery cohort. The risk score was tested for validation in the replication cohort.
Results: Discovery and replication cohorts included 163 and 89 patients, respectively. Subclinical ILD was detected in 19.0% and 16.9% of the patients, respectively. In the discovery cohort, independent risk factors for subclinical RA-ILD were the *MUC5B* rs35705950 T risk allele (odds ratio [OR]=3.74; 95% confidence interval [CI] [1.37–10.39], male sex (OR=3.93; 95%CI [1.40–11.39]), older age at RA onset (for each year, OR=1.10; 95%CI [1.04–1.16]) and increased mean DAS28-ESR (for each unit, OR=2.03; 95%CI [1.24–3.42]). We developed a risk score for subclinical RA-ILD with AUC=0.82; 95%CI [0.70–0.94] (sensitivity (Se)=71.0%) and specificity (Sp)=79.6%). The risk score was validated in the replication cohort with AUC=0.78; 95%CI [0.65–0.92] (Se=86.7%, Sp=62.2%).
Conclusion: Our risk score could help identifying patients at high-risk for subclinical RA-ILD before the onset of pulmonary symptoms.

Table 1. Number of events, person-years of follow-up, number of events per 100,000 person-years, and relative risk of lung cancer according to autoantibody status in the EIRA sub-cohort. Five Hazard ratios are presented: a) crude; b) adjusted for age, sex, index year, county of residency (model A); c) age, sex, index year, county of residency and comorbidities (renal failure, heart failure, ischemic heart disease, COPD, respiratory infections, hospitalization) (model B) c) all the above plus smoking (model C) and d) as model C with packet-years instead of smoking ever vs. never.

	No of events (person years of follow-up; No of events/100 000 person years)		Crude Hazard ratio (95% CI)	Model A Hazard ratio* (95% CI)	Model B Hazard ratio** (95% CI)	Model C Hazard ratio** (95% CI)	Model D with smoking as pack-years instead of ever/never

Kowal-Bielecka[13], Y. Allanore[14], O. Distler[9]. *[1]Oslo University Hospital, Rheumatology, Oslo, Norway; [2]Oslo University Hospital, Biostatistics, Oslo, Norway; [3]Spedali Civili di Brescia, Reumatologia e Immunologia Clinica, Brescia, Italy; [4]Nasonova Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [5]Medical School of Pécs, Rheumatology and Immunology, Pécs, Hungary; [6]University of Firenze, Department of Experimental and Clinical Medicine, Firenze, Italy; [7]Hôpital Claude Huriez, University of Lille, Internal Medicine and Clinical Immunology, Lille, France; [8]Peking Union Medical College Hospital (West Campus), Rheumatology, Beijing, China; [9]University Hospital Zurich, University of Zurich, Rheumatology, Zurich, Switzerland; [10]University of Medical Center Schleswig-Holstein, Rheumatology and Clinical Immunology, Lubeck, Germany; [11]National & Kapodistrian University of Athens Medical School, Rheumatology, Athens, Greece; [12]Università della Campania "Luigi Vanvitelli", di Medicina di Precisione, Napoli, Italy; [13]Medical University of Bialystok, Rheumatology and Internal Medicine, Bialystok, Poland; [14]Descartes University, APHP, Cochin Hospital, Rheumatology, Paris, France*

Background: Short disease duration is a predictor for progressive systemic sclerosis-associated interstitial lung disease (SSc-ILD), but studies assessing ILD progression in later disease stages are lacking. To individually tailor management of ILD in SSc patients in clinical practice it is, however, of high importance to understand disease behaviour also in patients with late disease.

Objectives: Analyse ILD progression in SSc-ILD patients from the EUSTAR cohort segregated by subgroups of disease duration.

Methods: We segregated SSc-ILD patients into four categories of disease duration (≤3 years, >3- ≤7 years, >7- ≤15 years and >15 years after onset of Raynaud's phenomenon). We assessed progressive ILD, defined as forced vital capacity (FVC) decline >10% or FVC decline ≥10% and FVC decline 5–10% and diffusing capacity of the lungs for carbon monoxide (DLCO) decline ≥15% (composite decline) over the first and second 12+/-3 months period after first registration (baseline) into EUSTAR. Clinical characteristics, pulmonary involvement, treatment at first registration and ILD progression were evaluated by descriptive statistics.

Results: In total, 2258 SSc-ILD patients were included, with 469 (20.8%) having a disease duration ≤3 years, 550 (24.4%) between >3- ≤7 years, 752 (33.3%) between >7- ≤15 years and 488 (21.6%) of >15 years (Table 1). Baseline characteristics and treatment patterns differed between the four subgroups, with more younger male patients with diffuse cutaneous SSc, anti-topoisomerase I antibody and higher Rodnan skin score having ≤3 years disease duration. Lung function with FVC and DLCO were similar between the four groups (Table 1). Notably, in the first and second 12+/-3 months periods after first registration in the EUSTAR database, there were no significant difference in FVC decline >10% or composite FVC and DLCO decline within the four subgroups. For example, patients with disease duration >7- ≤15 years and >15 years frequently showed disease progression of FVC >10%: 41/347 (11.8%) and 32/228 (14%) compared to 38/244 (15.6%) and 33/273 (15.6%) for disease duration ≤3 years and >3- ≤7 years (P=0.529), respectively (Figure 1).

Table 1. Demographics and baseline clinical characteristics of EUSTAR patients

Disease duration	≤ years (n=460)	>3- ≤7 years (n=550)	>7- ≤15 years (n=752)	>15 years (n=488)	p-value

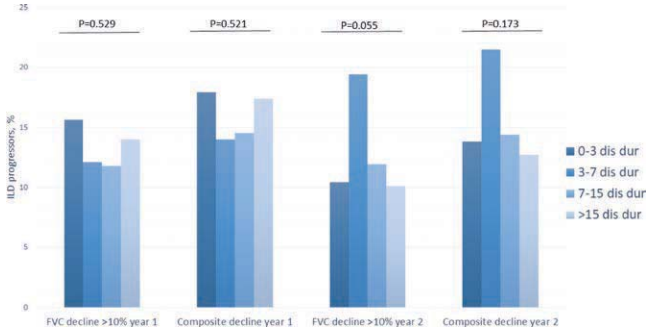

Figure 1. FVC decline >10% and composite FVC and DLCO decline in the first and second 12+/-3 months within the four subgroups segregated by disease duration

Conclusion: It was long believed that ILD burned out in late disease stages. In our analysis of ILD progression by four disease duration categories, we showed that ILD frequently progressed also in late disease stages. This has important implications for clinical practise, as SSc patients need to be regularly monitored for ILD progression independent of disease duration.

EPIDEMIOLOGY OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC LUPUS ERYTHEMATOSUS IN FRANCE: A NATION-WIDE POPULATION-BASED STUDY OVER 10 YEARS

A. Mageau[1], R. Borie[2], B. Crestani[2], J. F. Timsit[3], T. Papo[1], K. Sacre[1].
[1]Université de Paris Bichat, Médecine Interne, Paris, France; [2]Université de Paris Bichat, Pneumologie, Paris, France; [3]Université de Paris Bichat, Réanimation Medicale, Paris, France

Background: Data regarding interstitial lung disease (ILD) in the setting of systemic lupus erythematosus (SLE) are limited
Objectives: We used a nation-wide database to determine the incidence and the prevalence of ILD in SLE patients.
Methods: Characteristics of all SLE inpatients admitted between 2011 and 2012 in France were analyzed through the French medico-administrative database. Features associated with the presence of ILD were studied. Cox proportional hazard model was used to look for the impact of ILD on survival from the first stay to 2020. The incidence rate of ILD in SLE was estimated by analysing the onset of ILD from 2013 to 2020 in SLE patients who had no evidence of ILD in 2013.
Results: Between 2011 and 2012, 10 460 SLE patients had at least one hospital stay and could be traced until 2020. Among them, 134 (1.2%) had an ILD diagnosed at baseline. The frequency of ILD in SLE was higher in patients who had an associated autoimmune disease – such as Sjögren's syndrome or systemic sclerosis (29.9% vs 5.9%; p< 0.0001). ILD was associated with an increased risk of death in SLE after adjustment on comorbidities in the multivariable analysis (HR [CI95] 1.992 [1.420-2.794]; p <0.0001). Among the 31 029 SLE patients with no evidence of ILD at baseline, ILD occurred in 795 SLE patients (2.6%) between 2013 and 2020. The incidence rate of ILD in SLE was 10.26 for 1000 patient-years [CI95: 10.24-10.28].
Conclusion: In SLE, ILD is exceedingly rare, often associated with another systemic autoimmune disorder and appears as a major risk factor for death.

INTERSTITIAL LUNG DISEASE ASSOCIATED WITH PRIMARY SJÖGREN'S SYNDROME IS FREQUENTLY PROGRESSIVE

A. M. Hoffmann-Vold[1], H. Fretheim[1], P. P. Diep[2], K. Lerang[1], H. Andersson[1], Ø. Midtvedt[1], T. Garen[1], M. Durheim[2], T. M. Aaløkken[3], Ø. Palm[1], Ø. Molberg[1].
[1]Oslo University Hospital, Rheumatology, Oslo, Norway; [2]Oslo University Hospital, Respiratory Medicine, Oslo, Norway; [3]Oslo University Hospital, Radiology, Oslo, Norway

Background: Interstitial lung disease (ILD) in primary Sjögren's syndrome (pSS) has been reported to be present in 10-15% of patients, but pSS-ILD behavior over time is not well characterized.
Objectives: Assess the pattern of ILD in pSS, its disease behavior and factors associated with disease progression in a well-characterized pSS-ILD cohort.
Methods: All pSS patients from the Oslo University Hospital (OUH) were included if ILD was diagnosed on HRCT. Clinical characteristics, lung function tests including forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO) and ILD pattern on HRCT assessed by a radiologist were evaluated. We determined ILD progression, defined as absolute FVC decline >5% or absolute DLCO decline >10% over 12 +/-6 months and increasing extent of ILD on HRCT over the observation period. Factors associated with disease progression were chosen based on expert opinion. Descriptive analyses were conducted
Results: Of 702 pSS patients followed at OUH, we identified 60 pSS patients with ILD with 33 (55%) having follow-up at 12 months (Table 1). Patients with pSS-ILD were characterized by high number of males (18%) and by frequent other extra-pulmonary organ involvement (48%) (Table 1). Mean time from pSS diagnosis to ILD diagnosis was 7.4 years. In 67% ILD was diagnosed after pSS, in 13% simultaneously, in 11% before pSS diagnosis and in 9% unknown. In total, 28 (47%) were diagnosed with lymphocytic interstitial pneumonia (LIP) and 32 (53%) with reticular pattern on HRCT. Over mean follow-up of 10.9 months (SD 4.2), 7/33 (21%) showed a FVC >5% decline, 9/32 (28%) a DLCO >10% decline and 12 (36%) had at least one of these defined lung function declines on standard of care treatment. Treatment was registered as ever used and by any indication. Over an observation period of 15.4 (SD 10.6) years, 27/47 (45%) showed any ILD progression on HRCT. HRCT pattern was not associated with risk of >10% DLCO decline or ILD progression on HCRT. >5% FVC decline occurred more frequently in patients with reticular pattern compared to LIP (6/17 (35%) vs 1/16 (6%), p=0.041). Factors significantly associated with ILD progression on lung function included higher baseline FVC (99% (SD16.4) vs 87% (SD14.9), p=0.032), higher DLCO (81% (SD13.1) vs 67% (SD17.4), p=0.020), increased CRP (2/10 (20%) vs 0/16 (0%), p=0.045) and presence of polyneuropathy (2/9 (22%) vs 1/17 (6%), p=0.045).

Table 1. Clinical characteristics, demographics and outcome of pSS with ILD

	pSS-ILD (n=60)
Age at pSS diagnosis, y (SD)	50 (21.9)
Time from pSS to ILD diagnosis, y (SD)	7.4 (8.9)
Male sex, n (%)	11 (18)
Anti-SSA AB, n/50 (%)	46 (92)
Increased CRP, n/47 (%)	7 (15)
Low complements, n/49 (%)	5 (10)
Extra-pulmonary involvement, n/46 (%)	22 (48)
Deceased, n (%)	10 (17)
Pulmonary involvement	
FVC% predicted (SD)	91 (18.7)
FVC decline>5%, n/33 (%)	7 (21)
DLCO% predicted (SD)	70 (20.7)
DLCO decline >10%, n/32 (%)	9 (32)
ILD progression on HRCT, n/47 (%)	27 (45)
Treatment during follow up	
Rituximab, n (%)	11 (18)
Any other immunosuppressive, n (%)	20 (33)
Hydroxychloroquine, n (%)	16 (27)
Nintedanib, n (%)	1 (2)
Lung transplant, n (%)	1 (2)

Conclusion: A substantial number of patients with pSS-ILD progressed during the time of observation. This highlights the importance of close monitoring and active consideration of treatment options in pSS-ILD. Recommendations for disease management including screening, diagnosis, disease monitoring and treatment for pulmonary involvement in pSS are lacking to date, but are highly needed.

Background: Mixed connective tissue disease (MCTD) is a rare autoimmune condition characterized by Raynaud's phenomenon, positivity of autoantibodies

targeting the U1 small nuclear ribonucleoprotein particle (U1RNP), and various clinical features of other connective tissue diseases (1-2). Interstitial lung disease (ILD) is an established complication of the disease that is suspected to affect morbidity and mortality (3). However, little is known about MCTD-associated ILD (MTCD-ILD) phenotype including first presentation, outcomes and predictive factors for progression.

Objectives: To compare two distinct populations of MCTD patients with and without associated ILD and to identify predictive factors for lung progression and severity.

Methods: International multicenter retrospective study (12 tertiary hospitals). To be included, patients were required to fulfill at least one MCTD international classification criteria (4). ILD was defined by the presence of typical chest high-resolution computed tomography (HRCT) abnormalities. Patients were divided into two groups: with or without ILD, at a ratio of 1:1 and matching on disease duration (+/- 2 years).

Results: 300 patients were included. Mean age at MCTD diagnosis was 39.7±15.4 years and 191 (63.7%) were women.

At baseline, we identified several variables associated with the presence of ILD: older age (42.2 vs 37.5 years, p=0.01), scleroderma-like phenotype (38.7 vs 27.3%, p=0.03), upper gastro-intestinal (GI) symptoms (54.7 vs 30.7%, p<0.001), forced vital capacity (FVC) <80% (80.4 vs 95.3%, p<0.0001), diffusing capacity for carbon monoxide (DLCO) <80% (62.4 vs 74.8%, p<0.0001), anti-topoisomerase antibodies (6 vs 0 patients, p=0.01), SSA/Ro antibodies positivity (29.3 vs 19.3%, p=0.02), cryoglobulinemia (5.3 vs 1.3%, p=0.04) and elevated C-reactive protein (CRP) >5mg/L (54.7 vs 28.7%, p<0.001). Among the previous variables older age (OR 1.03, 95% CI 1.01 to 1.05), upper GI symptoms (OR 1.92, 95% CI 1.03 to 3.58) and CRP >5mg/L (OR 8.77, 95% CI 2.94 to 26.22) remained significantly associated with the presence of ILD by multivariate analysis.

Patients with MTCD-ILD were more likely to be treated with synthetic immunosuppressant agents (68.7 vs 49.3%, p<0.001) including mycophenolate mofetil (MMF) (7.3 vs 1.3%, p=0.03).

Mean follow-up was 7.8±5.5 years. In longitudinal analyses, mortality was higher in the MTCD-ILD group (8 vs 0 deaths, p<0.001). In the MCTD-ILD group, among 60 patients with complete data on lung function tests, we observed a FVC decline >10% in 33 (55%) patients. With regards to the risk of progression, we identified that history of digital ulcers (DU) was a risk factor for FVC decline >10% (OR 6.75, 95% CI 1.7-26.4, p=0.006).

Conclusion: In this large international cohort of patients with MTCD, we identified several factors associated with ILD development. Our findings highlight a high risk of mortality in MCTD-ILD patients and that digital ulceration seems to be at risk of more progressive ILD.

[1]La Fe University and Polytechnic Hospital, Rheumatology, València, Spain; [2]Instituto de Investigación Sanitaria La Fe de Valencia, Rheumatology, València, Spain

Background: Interstitial lung disease (ILD) is a frequent complication of systemic sclerosis (SSc) and is often progressive and has a poor prognosis. A restrictive ventilatory defect could suggest ILD either alone or in combination with pulmonary arterial hypertension.

Nowadays, Early-SSc is well defined as preliminary stage of SSc. Patients who meet criteria for Early-SSc could benefit from an early diagnosis of pulmonary involvement.

Objectives: Our aim was to assess the pulmonary function in patients diagnosed of Early SSc.

Methods: Retrospective observational study of a wide and unselected series of patients diagnosed as Early-SSc from a single university hospital from 2012 to 2022. Patients were classified as Early-SSc following Le Roy criteria. Despite this, patients already did not meet 2013 ACR/EULAR classification criteria for SSc. We reviewed pulmonary function through conventional spirometry and diffusing capacity of lungs for carbon monoxide (DLCO).

Results: We included 61 patients with a mean age of 52.9±6.2 years (90.9% women; 9.1% men).

At the diagnosis of Early-SSc, no one of our patients evidenced a restrictive ventilatory pattern. DLCO was below normal limits in 21 patients (34.4%). Small airway obstruction expressed according decreased maximal (mid-) expiratory flow (MMEF) 25-75 was present in 26 patients (42.6%).

After a mean follow-up period of 42.4±3.2 months, 29 (47.5%) patients fulfilled 2013 ACR/EULAR criteria. The average time between diagnosis of Early-SSc and achieve SSc classification was 24.4±1.8 months. The remaining 32 patients continued classified as Early-SSc.

An analysis of the subgroup of patients which progressed to SSc showed that DLCO was decreased in 15 of those 29 patients (51.7%) and 18 of 29 patients (62.1%) presented decreased MMEF 25-75. Comparing with the subgroup of patients which not progressed to SSc were significant differences (Decreased DLCO: 51.7% vs 10.4%; p=0.01 and decreased MMEF 25-75: 42.8% vs 24.6%; p=0.05).

The analysis of pulmonary function of the subgroup of patients continued classified as Early-SSc after follow-up period did not show significative changes after follow-up.

Conclusion: In our study, a third of the patients classified as Early-SSc presented at diagnosis abnormal values of DLCO and/or signs of small airway obstruction without the presence of a restrictive ventilatory pattern. Moreover, this pulmonary disfunction was significantly more frequent in patients who progressed to definitive SSc. Patients which remains classified as Early-SSc did not experience significative changes.

Our results support the concept that pulmonary function was impaired in Early-SSc and that it should probably be considered for future Early-SSc classification criteria.

POS0068 CHANGES IN QUANTITATIVE INTERSTITIAL LUNG DISEASE SCORES ON HIGH-RESOLUTION CT IN IDIOPATHIC INFLAMMATORY MYOSITIS

J. Yeo[1], S. H. Yoon[2], J. Y. Kim[3], J. M. Koo[2], J. S. Lee[4], E. Y. Lee[3], L. Pourzand[5], J. Goldin[5], G. Kim[5], Y. J. Ha[6]. *[1]Gachon University Gil Medical Center, Division of Rheumatology, Department of Internal Medicine, Incheon, Korea, Republic of South Korea; [2]Seoul National University Hospital, Department of Radiology, Seoul, Korea, Republic of South Korea; [3]Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Republic of South Korea; [4]Korea Advanced Institute of Science and Technology (KAIST), Clinic Pappalardo Center, Daejeon, Korea, Republic of South Korea; [5]David Geffen School of Medicine, University of California, Los Angeles (UCLA), Department of Radiology, Los Angeles, United States of America; [6]Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, GyeongGi-Do, Korea, Republic of South Korea*

Background: The idiopathic inflammatory myopathies (IIM) are autoimmune connective tissue diseases affecting skeletal muscle, skin and other organ systems. IIM-related interstitial lung disease (IIM-ILD) is the most common extra-muscular manifestation, being the leading cause of morbidity and mortality. Several studies have suggested that ILD pattern based on chest high-resolution computed tomography (HRCT) can be related to disease course and treatment response, but the results vary considerably. Moreover, the clinical impact of the quantitative ILD (QILD) score, a validated computer-aided scoring system in assessing ILD severity from HRCT, and its longitudinal changes have not yet been evaluated in IIM-ILD.

Objectives: This study aims to investigate ILD patterns and QILD scores in patients with IIM-ILD, to identify their clinical impact, and to delineate longitudinal changes of QILD measurement.

Methods: A total of 80 patients with IIM (polymyositis 22, and dermatomyositis 58) who underwent at least 2 times of serial HRCT scans were included. Visual ILD patterns were assessed by multiple thoracic radiologists. Quantitative analysis of HRCT was presented as total extent of QILD scores (%) in whole lung and most severe zone. Individual time-estimated ΔQILD score between first 2 visits was derived using a linear approximation of yearly change, where the duration of median (IQR) was 1.0 (0.4-1.6) years in the first 2 HRCT scans.

Results: The median (IQR) age of the patients was 52.0 (43.5-58.5) years and 60 (75.0%) were women. Baseline median score of whole lung-QILD and most severe zone-QILD were 28.1% (19.1-43.8) and 68.0% (45.5-81.8), respectively, and QILD score showed significant correlations with pulmonary function tests (r=-0.349, p=0.002 for % predicted forced vital capacity; and r=-0.381, p=0.001 for % predicted diffusing capacity for carbon monoxide). The individual time-estimated yearly ΔQILD score between first 2 visits presented that approximately half of the patients showed improvement or stability in QILD scores; however, when patients were sorted by visual assessment in ILD subtype on HRCT, approximately two-thirds of the patients with usual interstitial pneumonia (UIP) pattern were aggravated in QILD scores and less than half of subjects with nonspecific interstitial pneumonia and organizing pneumonia were aggravated (Figure 1, 80% for UIP vs. 44.4% for non-UIP, p=0.013). There was no immunosuppressive drugs related to meaningful improvement in QILD scores during first 2 visits. Notably, we observed significant aggravation of QILD scores in tacrolimus users (n=7, median time-estimated whole lung-yarly ΔQILD 20.3 (2.7-38.4)) compared with tacrolimus non-users (n=73, median time estimated whole lung-yearly ΔQILD -1.2 (-8.3-6.5)). Among 80 patients, 6 (7.5%) were died due to various lung complications. Higher baseline QILD scores were noted in deaths (median whole lung-QILD 45.4 (32.9-56.5)) than in survivors (median whole lung-QILD 26.9 (19.0-42.4)), albeit not significant (p=0.084). Poor survival rate was observed in patients with high grade of ground glass opacity by visual assessment in right upper lobe (log-rank test, p=0.042). Among subgroup of patients with 3 serial HRCT scans (n=41), dynamic changes of four distinct patterns (improving, worsening, convex, and concave) were observed.

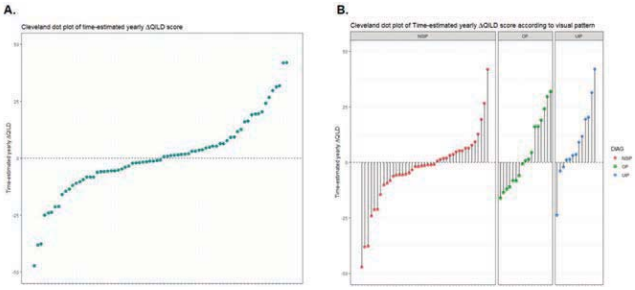

Figure 1. Cleveland dot plot of individual time-estimated yearly ΔQILD during fist 2 visits.

Conclusion: The changes in QILD score in IIM-ILD are dynamic and present different by visual assessment. QILD score has the potential for evaluation of the severity changes, prognosis and medication response in patients with IIM-ILD.

POS0069 LONGITUDINAL CHANGES ON QUANTITATIVE CHEST HIGH-RESOLUTION COMPUTED TOMOGRAPHY IN EARLY DIFFUSE SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION.

G. Pugnet[1], A. Petermann[2], S. Collot[2], P. Otal[2], P. Lansiaux[3], A. Maria[4], N. Ait Abdallah[3], G. Lorillon[5], M. Resch-Rigon[6], Z. Marjanovic[7], D. Farge[3]. *[1]CHU Toulouse, Service de Médecine Interne Immunologie Clinique, Toulouse, France; [2]CHU Toulouse, Service de Radiologie, Toulouse, France; [3]APHP, Hôpital Saint Louis, CRMR MATHEC, Paris, France; [4]CHU Montpellier, Service de Médecine Interne, Montpellier, France; [5]APHP, Hôpital Saint Louis, Service de Pneumologie, Paris, France; [6]APHP, Hôpital Saint Louis, SBIM, Paris, France; [7]APHP, Hôpital Saint Antoine, Service d'Hématologie, Paris, France*

Background: Since Burt *et al.* first demonstrated in the ASSIST trial (1) that lung disease high-resolution computed tomography (HRCT) volumetric measurement decreased in autologous hematopoietic stem cell transplantation (aHSCT) recipients and increased in controls receiving cyclophosphamide iv one year after starting treatment, limited data have been reported concerning the evolution of Systemic Sclerosis-Interstitial Lund disease (SSc-ILD) since and its relationship with the evolution of esophageal volume is unknown.

Objectives: To evaluate High-Resolution Computed Computed Tomography (HRCT) interstitial lung disease (ILD) and esophageal involvement in early diffuse systemic sclerosis (dSSc)-patients before and after autologous Hematopoietic Stem Cell Transplantation (aHSCT).

Methods: Overall chest HRCT, lung function and skin score changes were evaluated in 33 consecutive dSSc-patients before and after aHSCT during yearly routine follow-up between January 2000 and september 2016.Two independent radiologists blindly assessed the ILD extent using semi-quantitative Goh and Wells method (2), the widest esophageal diameter (WED) and the esophageal volume (EV) on HRCT. Patients were retrospectively classified as radiological responders or non-responders at 24 months after aHSCT according to the stability or a 5% or more decrease of HRCT ILD extent. Two by two time points comparisons after versus before aHSCT were performed using linear regressions. Survival rates were assessed for all patients by Kaplan-Meier method.

Results: Twenty-four months after aHSCT, HRCT median [IQR] ILD (-2 [-10.3; 0] points, p=0.0002) and ground-grass opacities (-2.1 [-8.3; 0] points, p=0.02) extent scores had improved, with 18 patients radiological responders (probability of response 0.78, 95% CI (0.58;0.90), whereas median WED (from 24.5 [18; 29] to 28 [19; 33] mm; p= 0.005) and EV (from 19 [13; 33] to 30 [13; 58] mm^3, p=0.01) increased significantly. Kaplan-Meier analyses showed a trend towards better 5 years survival rates (100% versus 60%; HR 0.23 95%CI 0.03 to 1.62, P = 0.11) among radiological responders versus non-responders at 24 months.

Conclusion: Real-world data analysis confirmed significant HRCT SSc-ILD improvement 24 months after aHSCT, although esophageal dilatation worsened requiring specific attention.

POS0070 CONTINUED TREATMENT WITH NINTEDANIB IN PATIENTS WITH LIMITED CUTANEOUS SYSTEMIC SCLEROSIS (LCSSC) AND INTERSTITIAL LUNG DISEASE (ILD)

Y. Allanore[1], D. Khanna[2], V. Smith[3], M. Aringer[4], A. M. Hoffmann-Vold[5], M. Kuwana[6], P. A. Merkel[7], A. James[8], S. Sambevski[9], M. Alves[10], C. P. Denton[11]. *[1]Descartes University, APHP, Cochin Hospital, Department of Rheumatology A, Paris, France; [2]University of Michigan, Department of Medicine, Ann Arbor, MI, United States of America; [3]Ghent University Hospital, Department of Rheumatology and Internal Medicine, Ghent, Belgium; [4]University Medical Center and Faculty of Medicine Carl Gustav Carus, TU Dresden, Division of Rheumatology, Department of Medicine III, Dresden, Germany; [5]Oslo University Hospital, Department of Rheumatology, Oslo, Norway; [6]Nippon Medical School Graduate School of Medicine, Department of Allergy and Rheumatology, Tokyo, Japan; [7]University of Pennsylvania, Division of Rheumatology, Department of Medicine, Philadelphia, United States of America; [8]Elderbrook Solutions GmbH, Statistics, Bietigheim-Bissingen, Germany; [9]Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim am Rhein, Germany; [10]Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim am Rhein, Germany; [11]Centre for Rheumatology and Connective Tissue Diseases, University College London Division of Medicine, London, United Kingdom*

Background: Few data are available on the progression and management of ILD, or the management of adverse events associated with drug treatment, in patients with lcSSc. SENSCIS-ON is an open-label extension trial that is collecting data on decline in forced vital capacity (FVC) and adverse events in patients treated with nintedanib over the long term.

Objectives: To assess decline in FVC and adverse events in patients with lcSSc and ILD treated with nintedanib in SENSCIS-ON.

Methods: Patients with SSc-ILD were eligible to enter SENSCIS-ON if they completed the randomized placebo-controlled SENSCIS trial (in which patients received trial drug until the last patient reached week 52 but for ≤100 weeks) or a drug–drug interaction (DDI) study of nintedanib and oral contraceptive (in which female patients received nintedanib for ≤28 days). Among patients with lcSSc, we analysed changes from baseline in FVC and adverse events over 52 weeks of SENSCIS-ON in patients who received nintedanib in SENSCIS and continued it in SENSCIS-ON ("continued nintedanib" group) and in patients who received placebo in SENSCIS and initiated nintedanib in SENSCIS-ON or who received nintedanib for a short time in the DDI study ("initiated nintedanib" group). Analyses were descriptive.

Results: There were 98 patients with lcSSc in the continued nintedanib group and 127 patients with lcSSc (114 from SENSCIS, 13 from the DDI study) in the initiated nintedanib group. In these groups, respectively, mean (SD) FVC values

at inclusion in SENSCIS-ON were 2449 (662) mL and 72.7(16.7) % predicted and 2508 (771) mL and 74.1 (17.4) % predicted. Mean (SE) changes in FVC from baseline to week 52 of SENSCIS-ON were –45.1 (19.1) mL in the continued nintedanib group, –41.5 (24.0) mL in the initiated nintedanib group, and –43.3 (15.3) mL in all patients with lcSSc, similar to the change in FVC in patients with lcSSc at week 52 of the SENSCIS trial (–39.1 [22.2] mL). The adverse event profile of nintedanib in SENSCIS-ON was consistent with that reported over 52 weeks of the SENSCIS trial (Table 1). Over 52 weeks, adverse events led to discontinuation of nintedanib in 3.1% of patients with lcSSc who continued nintedanib in SENSCIS-ON and 16.5% who initiated nintedanib in SENSCIS-ON.

Table 1. Adverse events (irrespective of causality) reported over 52 weeks in patients with lcSSc and ILD in SENSCIS and SENSCIS-ON.

	SENSCIS		SENSCIS-ON	
	Nintedanib (n=135)	Placebo (n=142)	Continued nintedanib (n=98)	Initiated nintedanib (n=127)
Most frequent adverse events*				
Diarrhoea	104 (77.0)	43 (30.3)	70 (71.4)	89 (70.1)
Nausea	45 (33.3)	20 (14.1)	19 (19.4)	32 (25.2)
Vomiting	33 (24.4)	16 (11.3)	15 (15.3)	31 (24.4)
Nasopharyngitis	21 (15.6)	29 (20.4)	18 (18.4)	23 (18.1)
Upper respiratory tract infection	18 (13.3)	19 (13.4)	13 (13.3)	18 (14.2)
Skin ulcer	11 (8.1)	18 (12.7)	11 (11.2)	14 (11.0)
Cough	17 (12.6)	25 (17.6)	13 (13.3)	8 (6.3)
Adverse event(s) leading to permanent treatment discontinuation	25 (18.5)	12 (8.5)	3 (3.1)	21 (16.5)
Adverse event(s) leading to dose reduction	47 (34.8)	5 (3.5)	17 (17.3)	62 (48.8)
Serious adverse event(s)	30 (22.2)	26 (18.3)	22 (22.4)	31 (24.4)

n (%) of patients with lcSSc with ≥1 such event reported over 52 weeks (or until 28 days after last drug intake if earlier in SENSCIS or until 7 days after last trial drug intake if earlier in SENSCIS-ON). *Adverse events reported in >10% of patients with lcSSc in either group in SENSCIS-ON. Adverse events were coded according to preferred terms in the Medical Dictionary for Regulatory Activities.

Conclusion: The change in FVC in patients with lcSSc and ILD who received nintedanib over 52 weeks, and the safety profile of nintedanib, in SENSCIS-ON were similar to that observed in patients with lcSSc and ILD who received nintedanib in SENSCIS. These analyses support a continued effect of nintedanib on slowing decline in FVC and the ability to manage adverse events of nintedanib in patients with lcSSc and ILD over the longer term.

POS0071

THE EFFICACY OF PIRFENIDONE COMBINED WITH IMMUNOSUPPRESSANT THERAPY IN THE CONNECTIVE TISSUE DISEASE-ASSOCIATED PULMONARY INTERSTITIAL DISEASE, A 24-WEEK PROSPECTIVE CONTROLLED COHORT STUDY

J. Wang[1,2], X. Wang[1,2], X. Qi[1,2], Y. Cui[3], T. Zhang[4], Q. Shu[1,2]. *[1]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Rheumatology, Jinan, China; [2]Qilu Hospital, Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Jinan, China; [3]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Radiology, Jinan, China; [4]School of Public Health, Cheeloo College of Medicine, Shandong University, Biostatistics, Jinan, China*

Background: Pulmonary interstitial disease(ILD)is very common in connective tissue disease (CTD). Different subtypes display significant differentiations in prognosis. Pirfenidone (PFD), the targeted anti-fibrosis and anti-inflammatory drug, started to apply in CTD-ILD, while its strategy of combination with immunotherapy, bridging time and service time are worth discussing.

Objectives: To evaluate the efficacy and safety of PFD combined with immunosuppressant (IS) in the treatment of several CTD- ILD.

Methods: 111 CTD-ILD patients were involved from Aug 2019 to Dec 2021 (ClinicalTrials.gov Identifier NCT04928586), including systemic sclerosis (SSc, n=30), inflammatory myopathy (IIM, n=51), rheumatoid arthritis (RA, n=17) and other CTDs (such as systemic lupus erythematosus, sjogren's syndrome, n=13). Patients were treated with relative stable dose of glucocorticoid (GC) and/or IS since screening.After the evaluation of HRCT, pulmonary function (FVC% and

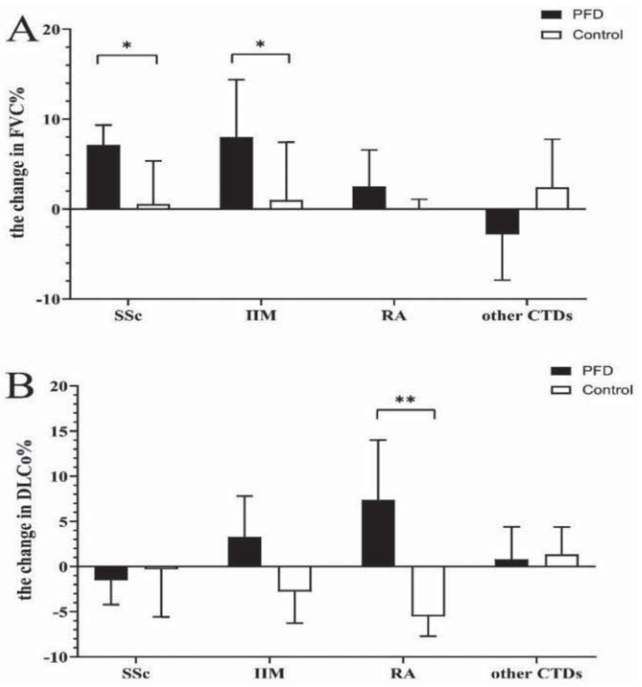

Figure 1. The changes of FVC% and DLco% in PFD treated CTD-ILD for 24 weeks. **(A)** FVC% changes in SSc, IIM, RA and other CTD-ILD from baseline.; **(B)** DLco% changes in SSc, IIM, RA and other CTD-ILD from baseline. * $p < 0.05$, compared to no PFD treatment group.

DLCo%) and basic disease activity, PFD was added or not and followed up regularly for 24 weeks. The changes of lung function and imaging were recorded in different subgroups.

Results: At baseline, The FVC% in the SSc-PFD (n=14), IIM-PFD (n=25) pts were lower than that of SSc-no-PFD (n=16), IIM-no-PFD (n=26) respectively, that was 81.06 *vs* 99.63(p=0.014), 78.23 *vs* 91.12, (p= 0.010). And IIM-PFD group present a lower baseline DLCo% than IIM-no-PFD pts (64.25 *vs* 72.82, p=0.034). DLCo% in the other CTDs was lower than SSc, IIM, RA pts (54.58 vs 65.55, 68.71, 66.89, p=0.036), while there were no significant differences in baseline FVC% among these disease.

After 24 weeks of treatment, FVC% in SSc-PFD group was improved by 7.15%, while that was -0.91% in SSc-no-PFD pts (p=0.042). The elevation in FVC% was also significant between the IIM-PFD and IIM-no-PFD control (8.00 *vs* 1.40, p=0.016). On the other hand, DLCo% of RA-PFD obviously enhanced 7.40%, compared with RA-no-PFD decrease 5.50% from baseline(p=0.002) (Figure 1).

When performing subgroup analysis with manifestations in HRCT, the change of FVC% in SSc-PFD pts with usual interstitial pueumonia tendency(SSc-PFD-UIP) was higher than SSc-PFD-non-UIP group (8.05 *vs* -3.20, p=0.014). However, the non-UIP tendency in IIM-PDF pts displayed superior therapeutic effects than IIM-PDF-UIP pts (10.50 *vs* 1.00, p=0.005). In addition, DLCo% improved significantly in RA-PDF-non-UIP subgroup, compared with RA-PDF-UIP pts (10.40 *vs* -4.45, p=0.017).

According to whether the baseline FVC% and DLCo% value was less than 70%, the improvement of FVC% was significantly higher in PFD treatment group than no-PFD pts of SSc and IIM with baseline High-FVC%(6.60 *vs* 0.10, p=0.047),(6.30 *vs* 1.10, p= 0.089).In RA-PFD pts, DLCo% showed a significant increase in baseline DLCo% less than 70% subgroup, compared to RA-no-PDF (7.40% vs -6.60%, p=0.011).The basic IS were considerable between PFD and-no-PFD pts throughout the study and no differences of GS and IS dosages at baseline and follow up among all subgroups.

Multiple linear regression analysis found that baseline FVC%<70%(HR=4.56,6.81) and prescription of PFD(HR=4.56,4.37) could positively affect the changes of FVC% and DLCo% (all p<0.05).

Conclusion: The response of pulmonary function to PFD were varied in different CTD-ILD subsets. SSc and IIM pts acquired obviously improvement on FVC%, especially with high baseline FVC group. DLco% elevated in RA-PFD, highlight those baseline Low-DLco and No-UIP pts.

Mease[14]. *[1]University of Glasgow, Immunology, Glasgow, United Kingdom; [2]Arizona Arthritis & Rheumatology Associates, Rheumatology, Phoenix, United States of America; [3]Michigan Medicine Rheumatology Clinic, University of Michigan Medical School, Rheumatology Internal Medicine, Ann Arbor, United States of America; [4]Brigham and Women's Hospital, Division of Rheumatology and Immunology, Harvard Medical School, Dermatology and Medicine, Boston, United States of America; [5]Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America; [6]Drexel University College of Medicine, Rheumatology, Philadelphia, United States of America; [7]McGill University, Pediatrics, Montreal, Canada; [8]JSS Medical Research, Inc, Scientific Affairs, Montreal, Canada; [9]University of Saskatchewan, Community Health and Epidemiology, Saskatoon, Canada; [10]Janssen Research & Development, LLC, Immunology, San Diego, United States of America; [11]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; [12]Janssen Cilag Global Medical Affairs, Immunology Global Medical Affairs, Issy-les-Moulineaux, France; [13]University of New South Wales, Medicine, Randwick, Australia; [14]Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America*

Background: Psoriatic arthritis (PsA) patients (pts) with differing baseline (BL) characteristics may vary in their response to treatment. In the phase 3 DISCOVER-1 and DISCOVER-2 studies, guselkumab (GUS) significantly improved joint symptoms, skin disease, enthesitis, dactylitis, physical function, and quality of life at Week (W) 24 in pts with PsA.[1,2] Clinical responses across these disease domains were maintained or increased with GUS at W52,[3,4] regardless of BL pt demographics, disease characteristics, or conventional synthetic disease-modifying antirheumatic drug (csDMARD) use.[5] Durable efficacy with GUS through W100 across multiple disease domains was observed.[6]

Objectives: Assess both BL predictors of, and by BL pt subgroups, GUS efficacy across PsA disease domains through W100 of DISCOVER-2.

Methods: Biologic-naïve adults with active PsA despite standard therapies were enrolled in DISCOVER-2 (swollen joint count [SJC] ≥5 & tender joint count [TJC] ≥5, C-reactive protein [CRP] ≥0.6 mg/dL). Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO).[2] GUS effects on joint, skin, enthesitis, dactylitis, spinal pain, and disease severity endpoints (change in Disease Activity in PsA [DAPSA], SJC, and TJC scores; Psoriasis [PsO] Area Severity Index [PASI] score [among pts with BL IGA ≥2 and body surface area [BSA] with PsO ≥3%]; Leeds enthesitis index [LEI] score [among pts with enthesitis at BL]; dactylitis score [among pts with dactylitis at BL]; spinal pain score; and PsA Disease Activity Score [PASDAS], respectively) at W100 were evaluated for GUS-randomized pts, both by treatment group and by pooling pts across Q4W and Q8W treatment arms. A multivariate linear model adjusting for BL pt characteristics assessed associations between BL predictors of interest and changes in DAPSA, PASI, and LEI scores from BL to W100, and to assess least squares mean (LSM) changes and 95% confidence intervals (CIs) in all continuous endpoints from BL to W100 within subgroups of pts defined by BL sex, body mass index (BMI), PsA duration, SJC, TJC, CRP level, %BSA, PASI score, and csDMARD use.

Results: 442 (90%) GUS-randomized pts completed study treatment through W100.[6] Among the BL predictors of long-term GUS efficacy assessed (see above), only PsA duration (p=0.032), SJC (p<0.001), and TJC (p<0.001) were significant predictors of long-term (BL to W100) DAPSA score change; %BSA (p=0.002), PASI score (<0.001), SJC (p=0.008), and csDMARD use (p=0.014) were significant predictors of long-term PASI score change; and none significantly predicted long-term LEI score change among pooled GUS pts (Figure 1). However, statistically significant improvements from BL to W100 in DAPSA, PASI, and LEI scores were observed across all BL strata, including those indicating more extensive or severe disease, in pooled GUS Q4W+Q8W pts (Figure 1, all p<0.001) and within each dosing group. Similar improvements were observed for other continuous endpoints assessed (change in Psoriatic Arthritis Disease Activity Score [PASDAS], SJC, TJC, spinal pain, and dactylitis score).

Conclusion: GUS significantly improved PsA signs and symptoms through W100 across all BL pt subgroups evaluated, including pts with highly active disease, and regardless of dosing regimen.

POS0073

COMPARISON OF TIME FROM METHOTREXATE INITIATION TO START OF A B/TSDMARD IN PSORIATIC ARTHRITIS VERSUS RHEUMATOID ARTHRITIS. A NATIONWIDE REGISTER-BASED STUDY.

U. Lindström[1], D. Di Giuseppe[2], S. Exarchou[3], G. M. Alenius[4], T. Olofsson[5], E. Klingberg[1], L. T. H. Jacobsson[1], J. Askling[2], J. K. Wallman[5]. *[1]Sahlgrenska Academy at University of Gothenburg, Rheumatology and Inflammation Research, Gothenburg, Sweden; [2]Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; [3]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; [4]Umeå University, Department of Public Health and Clinical Medicine/ Rheumatology, Umeå, Sweden; [5]Lund University, Skane University Hospital, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden*

Background: In Sweden, methotrexate (MTX) is recommended as first-line DMARD for both psoriatic arthritis (PsA) and rheumatoid arthritis (RA). Whereas in RA the use of MTX monotherapy is supported by efficacy data from randomized trials, in PsA no clear efficacy has been demonstrated in placebo-controlled trials. Therefore, the use of MTX in PsA is mostly based on clinical experience and results from studies not primarily designed to evaluate MTX efficacy.

Objectives: To compare time from MTX initiation until start of a biological or targeted synthetic DMARD (b/tsDMARD), as marker of insufficient MTX response, in previously DMARD-naïve, incident cases with PsA and matched, corresponding, reference subjects with RA.

Methods: Patients with PsA, having collected a prescription of MTX as their first ever DMARD any time between 2011 through 2018, and with a first ever PsA diagnosis in the Swedish National Patient Register within two years prior to this date, were included. Each individual was required to have a visit in rheumatology, but no visit in dermatology, within 6 weeks prior to MTX initiation, to ensure that PsA rather than psoriasis was the main reason for MTX treatment. For each individual with PsA, a corresponding individual with incident RA was identified, matched on sex, age, and year of MTX initiation. Only PsA cases with an identified RA comparator were included. All individuals with a diagnosis indicating axial spondyloarthritis prior to MTX start were excluded. The data were enriched through linkage to other national registers.

Follow-up was defined as the time from MTX initiation until start of any b/tsDMARD. Censoring was performed at the first of death, migration or 31 Dec 2020. Time until start of a b/tsDMARD was compared for PsA and RA through crude survival curves and conditional Cox-regression, crude and adjusted for comorbidity, level of education and patient global health.

Results: 3098 patients with PsA, and their individually matched RA comparators were included. At initiation of MTX, PsA cases had a mean 28-joint disease activity score (DAS28) of 4.0 and RA-controls of 4.6, while patient-reported global health was 51 (of 100) for both groups and number of swollen joints (28-joint count) 4.0 for PsA and 6.8 for RA, Table 1. The comorbidity burden was similar at baseline.

Table 1. Characteristics of PsA cases and matched RA controls at start of MTX.

	Psoriatic arthritis N=3098	Rheumatoid arthritis N=3098
Age, mean (sd)	55 (14)	55 (14)
Sex, male	49%	49%
Length of education, yrs		
<10	20%	24%
10-12	51%	49%
>12	28%	26%
Diabetes[1, 2]	7.4%	6.7%
Myocardial infarction[1]	1.3%	1.8%
Malignancy[1]	4.7%	5.0%
Congestive heart disease[1]	0.2%	0.2%
Chronic lung disease[1]	1.6%	2.2%
Use of anti-depressive drugs[1, 3]	15.4%	11.4%
DAS28-CRP, mean (sd)[4]	4.0 (1.1)	4.6 (1.2)
Patient global, mean (sd)[4]	51 (23)	51 (23)
CRP, median (IQR)[4]	7 (14)	10 (21)
Tender joint count (28), mean (sd)[4]	5.2 (4.9)	7.0 (5.7)
Swollen joint count (28), mean (sd)[4]	4.0 (4.1)	6.8 (5.2)

1) Diagnosis within 5 years. 2) Also identified by collecting ≥1 prescription of anti-diabetics in 1 year. 3) Identified by collecting ≥1 prescription within 1 year before methotrexate start. 4) Data on disease activity variables available for 28-36% of PsA and 56-62% of RA.

During a mean follow-up of 4.5 and 4.4 years, 34% and 33% of PsA and RA patients, respectively, started a b/tsDMARD, of whom 63% and 84% had also used ≥1 non-MTX conventional synthetic DMARD before the b/tsDMARD initiation. The crude survival curves for time from MTX initiation until start of a b/tsDMARD were identical for PsA and RA, Figure 1A. The adjusted HR for starting a b/tsDMARD in PsA compared with RA was 0.99 (95% CI 0.90-1.09). No calendar time trends were observed (Figure 1B and C).

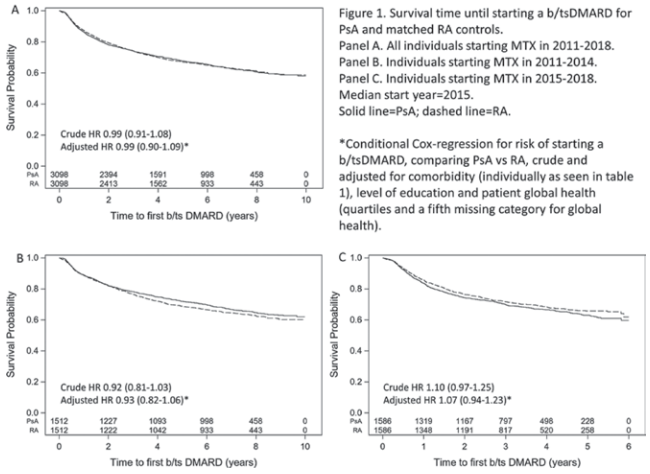

Figure 1. Survival time until starting a b/tsDMARD for PsA and matched RA controls.
Panel A. All individuals starting MTX in 2011-2018.
Panel B. Individuals starting MTX in 2011-2014.
Panel C. Individuals starting MTX in 2015-2018.
Median start year=2015.
Solid line=PsA; dashed line=RA.

*Conditional Cox-regression for risk of starting a b/tsDMARD, comparing PsA vs RA, crude and adjusted for comorbidity (individually as seen in table 1), level of education and patient global health (quartiles and a fifth missing category for global health).

Conclusion: In this study, the risk of escalating treatment from MTX, by adding or switching to a b/tsDMARD, was identical in PsA cases and matched RA controls. This supports a good response to MTX in PsA, similar to that in RA. Due to the matching, neither the results from the PsA nor the RA populations may be fully generalizable.

Dobbin Genetics Research Centre, St. John's, Canada; [14]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; [15]Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America

Background: A better understanding of the immunological differences between psoriatic arthritis (PsA) patients (pts) who are tumor necrosis factor inhibitor (TNFi)-naïve & who have inadequate response to TNFi (TNFi-IR) may guide treatment choices. In DISCOVER-1, benefit of the IL-23p19 subunit inhibitor guselkumab (GUS) every-four-weeks (Q4W) & Q8W vs placebo (PBO) in improving PsA signs & symptoms was seen in adults with active PsA.[1] The Ph3b COSMOS study of GUS Q8W vs PBO in TNFi-IR PsA pts corroborated these findings.[2]

Objectives: Assess baseline (BL) molecular differences between TNFi-naïve & -IR PsA pts & investigate GUS pharmacodynamic (PD) effect on cytokine expression over time in these cohorts.

Methods: Serum samples collected from consenting biomarker substudy pts in DISCOVER-1[1] (TNFi-naïve [n=101] & -IR [n=17]), DISCOVER-2[3] (TNFi-naïve [n=150]), & COSMOS[2] (TNFi-IR [n=76]) were analyzed for selected serum cytokine levels. TNFi-IR pts in this post-hoc analysis had active PsA & discontinued 1-2 TNFi due to inadequate efficacy; these pts required a TNFi-specific washout period prior to starting GUS. PD effect of GUS Q8W on cytokine levels was assessed. Differential BL cytokine expression, associations between BL cytokine levels & clinical response (Psoriasis [PsO] Area & Severity Index 75% improvement from BL [PASI75] & American College of Rheumatology 20% improvement [ACR20]), & GUS effect on cytokine levels were analyzed with a General linear model & Spearman linear regression.

Results: BL pt demographics, disease characteristics, & conventional synthetic disease-modifying antirheumatic drug (csDMARD) use were comparable between TNFi-naïve (DISCOVER-1 & -2, N=251) & -IR (DISCOVER-1 & COSMOS, N=93) pts, with differences in mean PASI score (8.9 v 12.5), swollen joint count (SJC) (11.7 v 10.3), PsA duration (5.8 v 9.8 yrs), & PsO duration (16.7 v 20.4 yrs; Table 1). BL serum IL-22 & TNFα levels for pooled treatment groups were higher in TNFi-IR than -naïve pts ($p<0.05$). At W24, GUS reduced IL-22, IL-17A/F, IL-6, C-reactive protein (CRP), & serum amyloid A protein to similar levels in both cohorts ($p<0.05$; Figure 1). W24 PASI75 responders had higher BL IL-17F levels with GUS in both cohorts ($p<0.05$) & higher IL-22 levels in TNFi-IR pts only ($p<0.05$). A trend of upregulated BL IL-22 expression in W24 ACR20 responders was seen for TNFi-IR pts with GUS ($p=0.07$).

Table 1. BL demographics, disease characteristics, & drug use in TNFi-naïve & -IR cohorts with available cytokine data in DISCOVER-1&2 & COSMOS.*

	TNFi-naïve (N=251)	TNFi-IR (N=93)
Age [yrs]	47.2 (11.3)	48.5 (11.1)
Female, n (%)	132 (52.6)	46 (49.5)
Body mass index [kg/m^2]	29.6 (6.1)	30.3 (6.4)
Median (range) **CRP** [mg/dL]	0.9 (0.0-12.9)	1.0 (0.0-13.2)
Log2 IL-22 / TNFα [pg/mL]	2.0 (1.4) / 1.1 (0.6)	2.5 (1.5) / 1.9 (1.2)
Log2 IL-17A / F [pg/mL]	-0.4 (1.5) / 1.7 (1.5)	-0.1 (1.7) / 2.0 (1.6)
SJC [0-66]	11.7 (7.1)	10.3 (8.3)
TJC [0-68]	20.3 (13.1)	20.6 (14.2)
PsA duration [yrs]	5.8 (5.9)	9.8 (8.2)
PsO duration [yrs]	16.7 (12.8)	20.4 (12.0)
PsO Body surface area (%)	14.8 (18.6)	19.1 (21.3)
Investigator's Global Assessment score [0-4]	2.3 (0.9)	2.3 (1.0)
PASI score [0-72]	8.9 (10.6)	12.5 (12.0)
Enthesitis [Y], n (%)	160 (63.7)	58 (62.4)
csDMARD use [Y], n (%)	164 (65.3)	62 (66.7)
Corticosteroid use (Y), n (%)	45 (17.9)	19 (20.4)
Methotrexate use [Y], n (%)	136 (54.2)	54 (58.1)

Data are mean (SD) unless otherwise noted. *Pts with serum CRP level ≥0.3 mg/dL, SJC ≥3, & TJC ≥3 (to mimic D1 inclusion criteria[1]). *TJC*= tender joint count

Conclusion: Elevated BL IL-22 expression & association between BL IL-22 levels & W24 PASI75 response, & a W24 trend for an association between upregulated BL IL-22 & ACR20 response, in TNFi-IR pts seen in this exploratory analysis may suggest increased involvement of the IL-23 pathway in TNFi-IR pts. GUS showed comparable & significant PD effects for TNFi-naïve & -IR pts, consistent with observed clinical responses.

POS0075

LONG-TERM PERSISTENCE OF FIRST-LINE BIOLOGICS FOR PSORIATIC ARTHRITIS AND PSORIASIS: A COHORT STUDY OF 23,423 PATIENTS FROM THE FRENCH HEALTH INSURANCE DATABASE (SNDS)

L. Pina Vegas[1,2], L. Penso[2,3], E. Sbidian[2,4,5], P. Claudepierre[1,2]. *[1]Henri-Mondor University Hospital, Rheumatology, Créteil, France; [2]Paris 12 Val de Marne University, EpiDermE, Créteil, France; [3]EPI-PHARE, Scientific Interest Group*

in Epidemiology of Health Products From the French National Agency for the Safety of Medicines and Health Products and the French National Health Insurance, Saint-Denis, France; [4]Henri-Mondor University Hospital, Dermatology, Créteil, France; [5]Inserm, Centre d'investigation Clinique 1430, Hôpital Henri Mondor, Créteil, France

Background: Treatment options for psoriasis (PsO) and psoriatic arthritis (PsA) have evolved significantly since the era of biologics. Clinical trials (mainly placebo-controlled for 12 to 16 weeks) are inadequate to assess the relative long-term efficacy of biologics and are often insufficient regarding safety.
Objectives: To assess the long-term persistence of different biologic classes to treat PsA and PsO.
Methods: This nationwide cohort study involved the administrative healthcare database of the French health insurance scheme linked to the hospital discharge database. We included, in two sub-cohorts, all adults with PsA and those with PsO, who were new users of biologics (not in the year before the index date) during 2015-2019. We excluded patients hospitalised for PsO in the PsA cohort and for PsA in the PsO cohort in the year before the index date. Persistence was defined as the time from biologic initiation to discontinuation and was estimated by the Kaplan-Meier method. Comparison of persistence by biologic class involved using propensity score-weighted Cox models (IPTW) and adjustment on specific systemic non-biologics (time-dependant variables).
Results: We included 6,531 patients with PsA (mean age 49±13 years, 45% male): 4,974 (76%) starting a TNFi, 803 (12%) an IL12/23i and 754 (12%) an IL17i. We included 16,892 patients with PsO (mean age 53±17 years, 50% male): 10,199 (60%) starting a TNF inhibitor (TNFi), 3,982 (24%) an IL12/23i, and 2,711 (16%) an IL17i. Overall 3-year persistence rates were 36% and 41% for PsA and PsO (Figure 1). After IPTW and adjustment, IL17i was associated with higher persistence than TNFi for PsA (weighted hazard ratio [HR_w] 0.70, 95% confidence interval [95%CI] 0.58-0.85) and PsO (HR_w 0.78, 95%CI 0.73-0.83) and than IL12/23i for PsA (HR_w 0.69, 95%CI 0.55-0.87). We found no difference between IL17i and IL12/23i for PsO. IL12/23i had better persistence than TNFi for PsO (HR_w 0.76, 95%CI 0.72-0.80), with no difference observed for PsA.

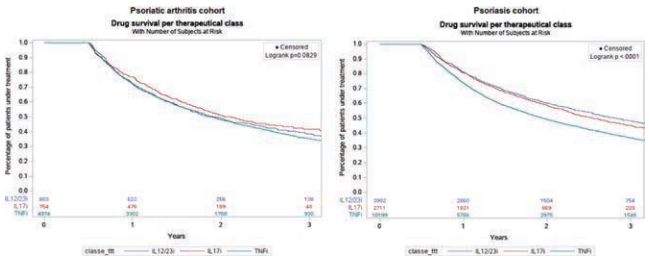

Figure 1. Kaplan Meier estimates of biologic treatment persistence in psoriasis and psoriatic arthritis cohorts *TNFi: tumor necrosis factor inhibitor; ILi: interleukin inhibitor.*

Conclusion: This real-life study suggests a higher persistence of IL17i than TNFi for PsA and PsO. IL17i also has better persistence than IL12/23i for PsA, with no difference for PsO. However, the persistence rates of all biologics remained globally low at 3 years.

POS0076 DRUG SURVIVAL OF BIOLOGICS AND NOVEL IMMUNOMODULATORS FOR RHEUMATOID ARTHRITIS, AXIAL SPONDYLOARTHRITIS, PSORIATIC ARTHRITIS, AND PSORIASIS - A NATIONWIDE COHORT STUDY FROM THE DANBIO AND DERMBIO REGISTRIES

A. Egeberg[1], N. Lippert Rosenoe[1], D. Aagaard[1], E. Lørup[1], L. Nymand[1], L. E. Kristensen[2], J. Thyssen[1], S. F. Thomsen[1], R. L. Cordtz[3], N. Loft[4], L. Skov[4], L. E. Bryld[5], M. Rasmussen[6], P. Højgaard[7], S. Kristensen[3], L. Dreyer[3].
[1]Copenhagen University Hospital - Bispebjerg, Department of Dermatology, Copenhagen, Denmark; [2]The Parker Institute, Department of Rheumatology, Frederiksberg, Denmark; [3]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark; [4]Gentofte Hospital, Department of Dermatology and Allergy, Hellerup, Denmark; [5]Zealand University Hospital, Department of Dermatology, Roskilde, Denmark; [6]Aarhus University Hospital, Department of Dermatology, Aarhus, Denmark; [7]Holbæk Hospital, Department of Rheumatology, Holbæk, Denmark

Background: Drug survival is an important proxy measure for effectiveness of treatments for inflammatory diseases such as rheumatoid arthritis (RA), axial spondyloarthritis (AxSpA), psoriatic arthritis (PsA), and psoriasis [1-4].
Objectives: The objective of this study was to examine the real-life drug survival of biologics and novel small-molecule therapies across various disease entities such as RA, AxSpA, PsA, and psoriasis.
Methods: We performed a nationwide cohort study using the prospective nationwide registries DANBIO and DERMBIO, comprising all patients treated with biologics or novel small-molecule therapies for RA, AxSpA, PsA, and psoriasis between January 2015 through May 2021 (DANBIO) and November 2009 to November 2019 (DERMBIO). Drug survival was visualized using Kaplan-Meier curves, and Cox proportional hazards models were used to calculate adjusted Hazard Ratios (HRs) with 95% confidence intervals (CIs) for risk of discontinuing therapy.
Results: The study comprised a total of 12,089 patients (17,903 treatment series), including 5,104 RA patients (7,867 series), 2,157 AxSpA patients (3,016 series3), 2,551 PsA patients (3,313 series), and 2,577 psoriasis patients (3,707 series). In confounder-adjusted models drug survival in RA was highest for rituximab followed by baricitinib, etanercept and tocilizumab respectively. For AxSpA drug survival was high for golimumab compared to all other drugs, followed by secukinumab and etanercept and lowest for infliximab. For PsA tofacitinib and infliximab had the lowest drug survival compared to all other drugs. All other drugs performed almost equally well with a tendency of a generally higher drug survival for golimumab, followed by secukinumab and ixekizumab. For psoriasis drug survival was generally highest for guselkumab.

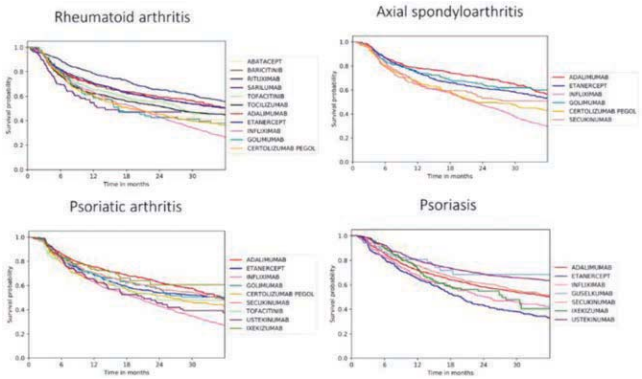

Figure 1.

Conclusion: Differing treatment responses to drugs with various types of action across RA, AxSpA, PsA and psoriasis emphasize that although these diseases have many overlaps in their pathogenesis, there is a need for an individualized treatment approach that considers the underlying disease, patient profile, and treatment history.

Background: Evidence demonstrates sex differences in disease presentation, physical function, treatment response and drug retention in patients with psoriatic arthritis (PsA). Data from observational cohort studies indicate female sex is associated with reduced effectiveness of tumor necrosis factor inhibitors (TNFis)[1,2]. Although, conflicting results are also reported[3,4]. We sought to validate prior studies using data from a large multinational cohort based on real-life clinical practice.
Objectives: To investigate sex differences in treatment response and drug retention rates in clinical practice among patients with PsA, treated with their first TNFi.
Methods: Data from biologic-naïve PsA patients initiating a TNFi in the EuroSpA registries were pooled. In the primary analysis, propensity-score weighting was applied to assess the causal effect of sex on low disease activity (LDA) according to DAS28-CRP at 6 months. A generalized linear regression model was used to estimate the causal risk difference (RD) and relative risk (RR) of sex on LDA. Possible covariates influencing the outcome were determined a priori and selected based on availability in the database (<20% missing). The final covariates included were country, age, conventional synthetic disease-modifying antirheumatic drug use at baseline and TNFi start year. In the secondary analysis, drug retention was assessed over 24 months of follow-up by Kaplan-Meier curves and log-rank test.
Results: In total, 7,679 PsA patients with available data on DAS28-CRP at 6 months were assessed for treatment response. Baseline characteristics are shown in the Table 1. In the adjusted analysis, the probability for females to have LDA was 17% (RR, 0.83; 95% confidence interval [CI], 0.81 to 0.85) lower compared to males and the difference in probability for having LDA was 13 percentage points (RD, 0.13; 95% CI, 0.11 to 0.15). The survival analysis included 18,599 PsA patients with available data on retention rates. The TNFi 6/12/24-month retention rates were significantly lower in females (81%/68%/56%) compared to males (89%/80%/69%), see Figure 1.

Table 1. Baseline characteristics of all biologic-naïve PsA patients treated with their first TNFi and available DAS28-CRP at 6 month, data pooled across all countries

	Female	Male
	Mean (SD), median [IQR] or percentages	Mean (SD), median [IQR] or percentages
Age (years)	49.7 (12.5)	47.8 (11.9)
Disease duration (years)	4.0 [1.0, 10.0]	4.0 [1.0, 10.0]
TNFi start year		
1999-2009	29%	29%
2010-2013	26%	27%
2014-2016	25%	24%
2017-2020	20%	20%
Concomittant csDMARD	75%	77%
DAS28-CRP	4.4 (1.2)	4.2 (1.2)
DAPSA28	32 (16)	29 (16)
CRP (mg/L)	7.0 [3.0, 17.0]	8.0 [3.3, 19.0]
SJC (0-28)	3.0 [1.0, 6.0]	3.0 [1.0, 6.0]
TJC (0-28)	6.0 [2.0, 10.0]	4.0 [2.0, 9.0]
VAS pain, mm	61 (23)	55 (23)
VAS fatigue, mm	62 (26)	53 (27)

Data are as observed, mean (SD), median [IQR] or percentage. TNFi, tumor necrosis factor inhibitor; csDMARD, Conventional synthetic disease-modifying antirheumatic drugs; DAS28-CRP, Disease Activity Score 28-joint count C reactive protein; DAPSA28, Disease Activity in PsA 28; CRP, C-reactive protein; SJC, swollen joint count; TJC, tender joint count.

Conclusion: Treatment efficacy and retention rates are lower among female patients with PsA initiating their first TNFi. Females presented with higher 28-tender joint count and higher scores on patient reported outcomes at baseline, reflecting differences in disease expression. Recognizing these sex differences is of relevance for customized patient care and may improve patient education.

POS0078 COMPARING METHOTREXATE MONOTHERAPY WITH METHOTREXATE PLUS LEFLUNOMIDE COMBINATION THERAPY IN PSORIATIC ARTHRITIS: A RANDOMISED, PLACEBO-CONTROLLED, DOUBLE-BLIND CLINICAL TRIAL (COMPLETE-PSA)

M. L. M. Mulder[1], J. E. Vriezekolk[2], T. Van Hal[1], L. Nieboer[1], N. Den Broeder[1], E. M. G. J. De Jong[3], A. Den Broeder[1], F. Van den Hoogen[1], P. Helliwell[4], M. Wenink[1]. *[1]Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands; [2]Sint Maartenskliniek, Research, Nijmegen, Netherlands; [3]Radboudumc Medical Centre, Dermatology, Nijmegen, Netherlands; [4]Leeds University, Rheumatology, Leeds, United Kingdom*

Background: Conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) are the cornerstone first-line treatment in psoriatic arthritis (PsA), although there is a paucity of evidence for the effectiveness of csDMARDs and especially their combination. Assessing the efficacy and safety of combinations of csDMARDs compared with csDMARD monotherapy has been prioritized on the EULAR research agenda. We hypothesized that combining csDMARDs might be more effective than csDMARD monotherapy.
Objectives: We aimed to investigate whether a combination of methotrexate (MTX) and leflunomide (LEF) is superior to MTX monotherapy on improvement in disease activity in patients with PsA.
Methods: Patients with a clinical diagnosis of PsA and active disease (≥2 swollen joints) were included in this randomised, placebo-controlled, double-blind trial. Patients were randomised (1:1) to MTX plus LEF or MTX plus placebo. Patients received MTX 15 mg/week for four weeks and thereafter 25 mg/week, combined with two LEF 10 mg tablets or two placebo tablets daily. The primary outcome was the difference between the MTX plus LEF group and the MTX plus placebo group on the psoriatic arthritis disease activity score (PASDAS) at week 16 adjusted for baseline PASDAS. Key secondary outcomes included safety and the achievement of minimal disease activity (MDA) criteria and PASDAS low disease activity (LDA) (≤3.2).
Results: A total of 78 PsA patients (MTX + LEF n=39; MTX + placebo n=39) were included. The mean age was 53.1 (SD=12.8) years and 36% (n=28) of the patients were female. The mean PASDAS at baseline was 4.9 (SD=1) in both treatment groups. Table 1 shows that MTX plus LEF was superior to MTX plus placebo at week 16 (PASDAS 3.1, SD=1.4 vs 3.7, SD=1.3; treatment difference= -0.6, 90% CI -1.0 to -0.1, one-sided P-value=0.025). Similar and significant results were found for achievement of MDA criteria (59% vs 33%, one-sided P-value=0.013) and PASDAS LDA (59% vs 35%, one-sided P-value=0.019) (Figure 1 and Table 1). Other favorable and significant outcomes for the MTX plus LEF group included -among others- the improvement in swollen joint count (SJC) (median [IQR] = -3 [-5, -2] vs -2 [-4, 0], one-sided P-value=0.039) and the proportion of patients with active psoriasis (i.e. body surface area score >0) at week 16 (44% vs 68%, one-sided P-value=0.014). Generally mild adverse events and treatment discontinuation (MTX+LEF n/N=10/39; MTX + placebo n/N=3/39) occurred more frequently in the MTX plus LEF group.

Table 1. Primary and secondary outcomes at week 16

	MTX + LEF (N=39)	MTX + placebo (N=38)*	Absolute difference [90% CI]	P-value One-sided
Primary endpoint				
PASDAS at week 16	3.1 (1.4)	3.7 (1.3)	-0.6 [-1.0, -0.1]	**0.025**
Selected secondary endpoints				
Fulfilling PASDAS LDA, N (%)	23 (59)	13 (35)	24% [6, 42]	**0.019**
Fulfilling MDA criteria, N (%)	23 (59)	12 (33)	26% [7, 44]	**0.013**
SJC66, change from baseline, median (Q1, Q3)	-3 (-5, -2)	-2 (-4, 0)	..	**0.039**
TJC68, change from baseline, median (Q1, Q3)	-2 (-4, 0)	-2 (-5, 0)	..	0.457
VAS physician global, change from baseline, mean (SD)	-22.0 (21.9)	-12.2 (19.7)	-9.8 [-17.7, -1.9]	**0.021**
VAS patient global, change from baseline, mean (SD)	-20.9 (24.4)	-13.9 (28.3)	-7.0 [-17.0, 3.0]	0.124
Active psoriasis, N (%)	17 (44)	26 (68)	-25% [-43, -7]	**0.014**

* One patient in the MTX + LEF group was excluded from the efficacy analysis due to change of diagnosis.

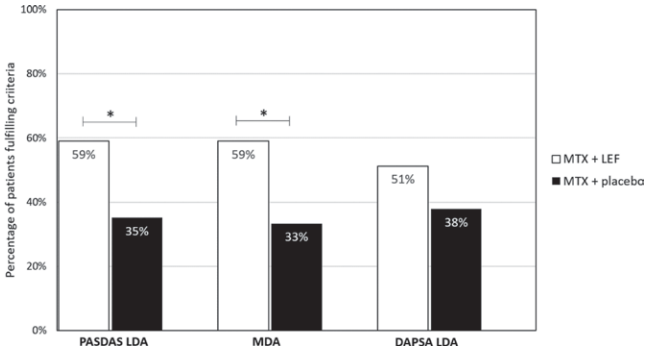

Figure 1. Proportion of patients meeting different PsA responder criteria for low disease activity at week 16* = one-sided P-value <0.05DAPSA = Disease Activity in Psoriatic Arthritis

Conclusion: MTX plus LEF combination therapy resulted in a significantly greater improvement in disease activity according to PASDAS and MDA than treatment with MTX monotherapy in patients with PsA after 16 weeks. In addition, a greater improvement in psoriasis was found for the combination group. However, there are indications that MTX plus LEF combination is less well tolerated than MTX monotherapy.
Acknowledgements: We would like to thank all the patients that participated in this study; all rheumatologists from the Sint Maartenskliniek that helped with the patient inclusion; our patient partners and especially R. van den Griend; Dr. E. Mahler for her suggestions and advice with regard to the study design; Dr. C. Popa and Dr. D. Telgt for being members of our data safety monitoring board and the rheumatology nurses of our center for their assistance with collecting the data.

POS0079 DOES METHOTREXATE IMPACT USTEKINUMAB IMMUNOGENICITY IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS? A POST HOC ANALYSIS OF SAMPLES FROM A RANDOMIZED, PLACEBO-CONTROLLED TRIAL.

S. Mojtahed Poor[1,2,3], M. Henke[4], T. Ulshoefer[1], F. Behrens[2,3,4], M. Köhm[2,3,4], H. Burkhardt[2,3,4], S. Schiffmann[1]. *[1]Fraunhofer, Institute for Translational Medicine and Pharmacology ITMP, Frankfurt, Germany; [2]University Hospital Frankfurt, Rheumatology, Frankfurt am Main, Germany; [3]Fraunhofer, Cluster of Excellence for Immune-Mediated Diseases CIMD, Frankfurt, Germany; [1]Fraunhofer, Institute for Translational Medicine and Pharmacology ITMP, Frankfurt, Germany*

Background: The formation of antidrug-antibodies (ADA) may reduce treatment efficacy or provoke discontinuation due to adverse reactions. Subsequent alterations in the drugs' pharmacodynamics, pharmacokinetics, safety, and efficacy are often unpredictable and can impede clinical discourse. Recent studies gave us some insights regarding the role of ADA formation against the monoclonal IL-12/-23 antibody ustekinumab (UST) and the impact of concomitant MTX treatment on immunogenicity in psoriatic arthritis (PsA) patients [1,2]. Valid measurement of ADA, particularly of neutralizing ADA (nADA) is essential to understand UST-associated immunogenicity and may help to predict clinical outcomes.
Objectives: To examine the impact of concomitant MTX on UST-immunogenicity in patients with active psoriatic arthritis (PsA).
Methods: Plasma samples were collected from a randomized controlled trial in patients with active PsA, treated with open UST and placebo-controlled methotrexate over a 52 weeks. We compared samples of 112 patients treated with

either UST and MTX (n=58) or UST and placebo (n=54). Plasma samples were obtained shortly before UST injection at weeks 0, 4, 16, 40, and 52.
Immunogenicity testing was performed as described by our group elsewhere [3], in a multitiered manner with ELISA and surface plasmon resonance analysis for the detection and quantification of ADA and UST, respectively. Neutralizing capacity was characterized in a cell-based assay. For statistical analysis, a two-way ANOVA with Sidak correction for multiple comparisons was used.
Results: Over the 52 weeks treatment period, 10 (18 %) of patients in the placebo cohort developed UST-specific ADA with one patient having non-neutralizing ADA, whereas 15 (27 %) subjects in the MTX cohort generated UST-specific ADA with 2 patients having non-neutralizing ADA. The ADA rates and concentrations at the different time points (Figure 1A, B) did not differ significantly between MTX and non-MTX users (p< 0.05). Furthermore, the presence of UST-specific ADA was not associated with decreased UST levels (Figure 1C).

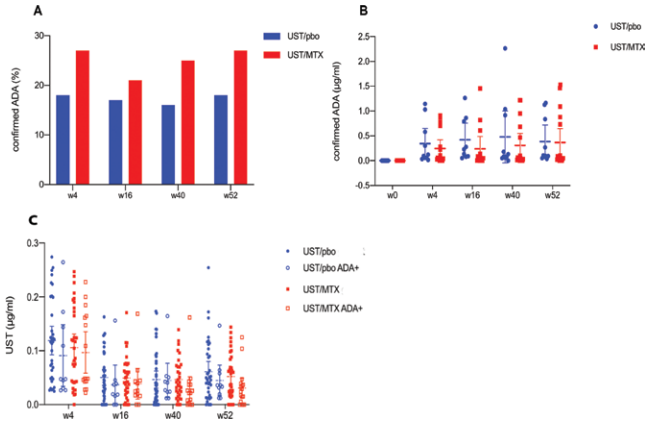

Figure 1. (A) ADA prevalence (%), (B) mean concentration (µg/ml) of confirmed ADA with 95%confidence interval and (C) mean UST concentration (µg/ml) with 95%confidence intervall in the MTX cohort (UST/MTX; n=58) and placebo cohort (UST/pbo; n=54) overall and with confirmed ADA (ADA+), respectively, at week (w) 0, 4, 16, 40, and 52.

Conclusion: The presented data yielded no statistically significant difference in ADA detection between the two analyzed groups. Our findings suggest that concomitant MTX had no impact on UST immunogenicity in PsA patients.

POS0080 PROGNOSTIC FACTORS ASSOCIATED WITH NON-REMISSION OR LOW DISEASE ACTIVITY STATUS AFTER 1 YEAR OF PSORIATIC ARTHRITIS PATIENTS TREATMENT IN REAL PRACTICE

E. Loginova[1], T. Korotaeva[1], E. Gubar[1], Y. Korsakova[1], S. Glukhova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation*

Background: Remission/Low Disease Activity (LDA) are acceptable goal of psoriatic arthritis (PsA) treatment. According to registry data 32.8%- 60.3% of PsA patients (pts) are considered to be in remission under biological (b) DMARDs treatment [1, 2]. Prognostic factors for non-remission/LDA hasn't been fully studied yet and data is limited.
Objectives: to determine the prognostic factors associated with non-remission/LDA status within 1 year of treatment in PsA pts in real practice.
Methods: 292 pts (M/F=122/170) with active PsA fulfilling the CASPAR criteria were included. Mean age 46.1±12.5 years (yrs.), PsA duration 10.4±7.1 months (mos.), psoriasis (Ps) duration 19.32±12.08 mos., body mass index (BMI) 27.7±5.6 kg/m^2, Median (Me) DAPSA 23.8 [14.7; 37.4]. 182 pts was given therapy with synthetic (s) DMARDs predominantly Methotrexate (MTX), 110 pts – bDMARDs as monotherapy or with combination with MTX or other sDMARDs. At baseline (BL) and at 1 year of therapy PsA activity by tender/swelling joint count (TJC)/68, (SJC)/66, Pain (VAS), Patient global assessment disease activity (PtGA, VAS), CRP mg/l, dactylitis, enthesitis by LEI and plantar fascia, BSA (%), HAQ, DAPSA were evaluated. DAPSA>28 indicate high disease activity (HDA), 15-28 - moderate activity (MoDA), 5-14 - LDA, ≤4 - remission. By 1 year of therapy the proportion of pts who had not reached remission or LDA were calculated. The one-factor model of logistic regression was used to identify a group of features that are associated with remission or LDA nonachievement. M±SD, Me [Q25; Q75], Min-Max, %, t-test, Pearson-χ^2, Manna-Whitney tests, ORs with 95% CI were performed. All p<0.05, were considered to indicate statistical significance.
Results: At 1 year of therapy 116 pts of 292 (39.7%) have HDA/MoDA by DAPSA. Remission/LDA was reached in 176 pts (60.3%), 110 of them (62.5%) were treated with bDMARDs. Comparative analysis in both groups and one-factor model of logistic regression showed the following features at BL were associated with non-remission/LDA status: TJC>3 (p<0.001), SJC>5 (p<0.001), CRP> 10 mg/l (p<0.001), HAQ>0.5 (p<0.001), presence of entesitis (p<0.001), dactylitis (p<0.001), BMI>30 (p<0.002) and had to be treated with sDMARDs. PsA pts with combination of these clinical features at first visit have more chance to non-remission/LDA status in comparison to PsA pts without them, OR with CI 95% (Figure 1).

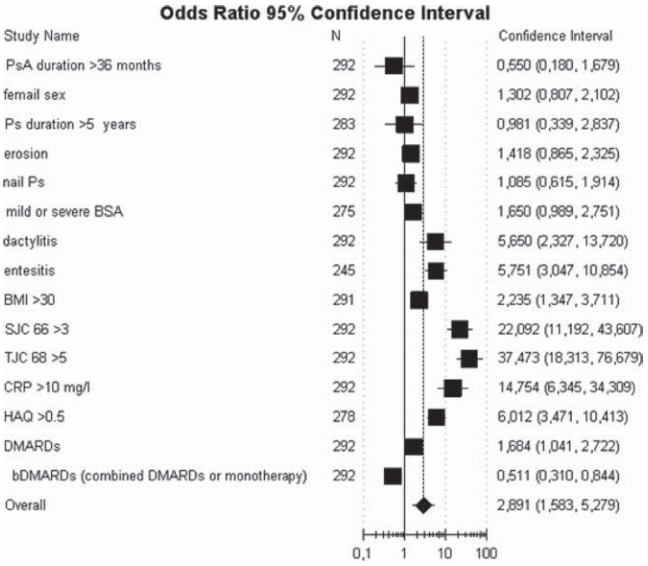

Figure 1. The prognostic factors associated with non-remission/LDA status in PsA pts

Conclusion: In real practice remission/LDA can be seen in 60% of PsA pts treated mostly with bDMARDs. But about 40% of PsA pts still have HAD/MoDA despite going through therapy. It is a combination of clinical features at BL – TJC>3, SJC>5, CRP>10 mg/l, HAQ>0.5, presence of entesitis, dactylitis, BMI>30 kg/m^2 and sDMARDs therapy - that constitutes a prognostic factor with negative impact on achievement remission/LDA after 1 year of treatment.

POS0081 LONG-TERM EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS: 2-YEAR RESULTS FROM THE PHASE 3 SELECT-PSA 1 STUDY

I. Mcinnes[1], K. Kato[2], M. Magrey[3], J. F. Merola[4], M. Kishimoto[5], D. Haaland[6], L. Chen[2], Y. Duan[2], J. Liu[2], R. Lippe[7], P. Wung[2]. *[1]University of Glasgow, College of Medical, Veterinary, and Life Sciences, Glasgow, United Kingdom; [2]AbbVie*

Inc., Immunology, North Chicago, United States of America; [3]Case Western Reserve University School of Medicine at University Hospitals, Cleveland, Rheumatology, Cleveland, United States of America; [4]Brigham and Women's Hospital and Harvard Medical School, Dermatology and Rheumatology, Boston, United States of America; [5]Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan; [6]McMaster University, Hamilton, Ontario and The Waterside Clinic, Rheumatology and Clinical Immunology & Allergy, Barrie, Canada; [7]AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany

Background: In SELECT-PsA 1, patients (pts) with psoriatic arthritis (PsA) and an inadequate response or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug showed improvement in the signs and symptoms of PsA with upadacitinib 15 mg (UPA15) or 30 mg (UPA30), an oral Janus kinase (JAK) inhibitor, through week (wk) 56.[1]
Objectives: To evaluate the efficacy and safety of UPA and UPA vs adalimumab (ADA) at wk 104 from the ongoing long-term extension of SELECT-PsA 1.
Methods: Pts received UPA15, UPA30, ADA 40 mg, or placebo (PBO) for 24 wks, at which point, PBO pts switched to UPA15 or UPA30. Efficacy endpoints were analyzed using non-responder imputation (NRI) and as observed (AO) (binary endpoints) or mixed-effect model repeated measures and AO (continuous endpoints), with nominal *P*-values shown, for continuous UPA and ADA treatment groups. Treatment-emergent adverse events were summarized for pts who received ≥1 dose of study drug using a visit-based cut-off at wk 104.
Results: 1704 pts received ≥1 dose of study drug. At wk 104, 25.4% of patients had discontinued study drug. The proportions of pts who achieved ACR20/50/70, MDA, PASI75/90/100, and resolution of enthesitis or dactylitis showed consistent responses, or further improvements, from wk 56[1] to wk 104 (Table 1). ACR20/50/70 and MDA responses, as well as mean change from baseline (BL) in HAQ-DI, patient's assessment of pain, BASDAI, and ASDAS, were greater with UPA vs ADA. Mean change from BL in modified total Sharp/van der Heijde Score (mTSS) was generally similar across groups and comparable to wk 56.[1] The safety profile of UPA was generally comparable to ADA (Figure 1) and consistent with wk 56[1] data. Rates of serious infection, herpes zoster, lymphopenia, and elevated CPK remained numerically higher with UPA30 vs UPA15; rates in both UPA groups were higher vs ADA. Rates of malignancies, MACE, or VTE were similar across groups, and consistent with wk 56[1] data. Two deaths were reported with UPA15, 1 with UPA30, and 1 with ADA.

Table 1. Efficacy Endpoints at Week 104

Endpoint	UPA15 (n=429)		UPA30 (n=423)		ADA (n=429)	
Proportion of Pts (%)[a]	NRI	AO	NRI	AO	NRI	AO
ACR20	69.0	87.9	69.5	87.9	63.4	85.1
ACR50	53.6	67.4	59.3*	74.1	47.1	62.3
ACR70	38.0*	47.4	43.5*	54.4	29.4	39.1
Minimal Disease Activity (MDA)	42.0	54.8	45.9*	56.8	37.8	50.3
PASI75[b]	57.9	73.4	62.4	78.6	58.8	76.5
PASI90[b]	46.7	59.0	53.3	66.5	48.8	63.3
PASI100[b]	34.1	43.4	42.4	51.4	34.1	44.0
Resolution of enthesitis by LEI[c]	53.3	75.5	52.2	72.0	49.1	73.9
Resolution of dactylitis by LDI[d]	69.9	94.5	71.7	96.2	72.4	95.2
Change from BL[e]	MMRM	AO	MMRM	AO	MMRM	AO
Health Assessment Questionnaire - Disability Index (HAQ-DI)	-0.55*	-0.57	-0.55*	-0.59	-0.45	-0.47
Patient's assessment of pain (numeric rating scale)	-3.3	-3.5	-3.4*	-3.6	-3.0	-3.2
Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)[f]	-3.0	-3.2	-3.3	-3.6	-2.7	-2.6
Ankylosing Spondylitis Disease Activity Score (ASDAS)[f]	-1.6	-1.8	-1.9*	-2.1	-1.5	-1.6
Modified total Sharp/van der Heijde Score (mTSS)	0.03	0.01	0.01	0.00	0.11	0.11

ACR20/50/70, ≥20%/50%/70% improvement in American College of Rheumatology criteria; ADA, adalimumab; AO, as observed; BL, baseline; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; MMRM, mixed effect model repeated measurement; NRI, non-responder imputation; PASI75/90/100, ≥75%/90%/100% improvement in Psoriasis Area and Severity Index; pts, patients; UPA, upadacitinib. [a]Data shown as NRI and AO for binary endpoints. [b]For pts with psoriasis affecting ≥3% of body surface area at BL. [c]For pts with LEI >0 at BL; resolution LEI=0. [d]For pts with LDI >0 at BL; resolution LDI=0. [e]Data shown as MMRM (LS mean) and AO (mean) for continuous endpoints. [f]For pts with psoriatic spondylitis at BL. Nominal *$P<0.05$, UPA15 or UPA30 vs ADA for NRI and MMRM; AO descriptive only.

Conclusion: In PsA pts, efficacy responses were similar or greater with UPA15 or UPA30 vs ADA at wk 104, and inhibition of radiographic progression was maintained. No new safety signals were identified with long-term exposure to UPA up to 2 years.

Deodhar[12]. *[1]Geneva University Hospitals and University of Geneva, Department of Dermatology, Geneva, Switzerland; [2]Icahn School of Medicine at Mt Sinai, Department of Dermatology, New York, United States of America; [3]Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; [4]University of Pennsylvania School of Medicine, Rheumatology, Philadelphia, United States of America; [5]University of Calgary, Division of Rheumatology, Calgary, Canada; [6]McGill University and JSS Medical Research, Inc, Department of Pediatrics, Montreal, Canada; [7]Janssen Research & Development, LLC, Immunology, San Diego, United States of America; [8]Janssen Scientific Affairs, LLC, Immunology, Horsham, United*

States of America; [9]Drexel University College of Medicine, Rheumatology, Philadelphia, United States of America; [10]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; [11]Janssen Inc., Rheumatology and Biologics, Toronto, Canada; [12]Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America

Background: Psoriatic arthritis (PsA) is characterized by a range of musculoskeletal and extra-articular disease manifestations. Composite indices are valuable tools to assess the multidimensional nature of PsA. The Psoriatic Arthritis Disease Activity Score (PASDAS)[1] provides robust assessment of both joint and skin domains but is cumbersome to use in clinical practice. The Disease Activity Index for Psoriatic Arthritis (DAPSA)[2] is relatively easy to use but does not assess skin disease.
Objectives: Using pooled data from the phase 3 DISCOVER-1 and DISCOVER-2 studies of guselkumab (GUS) for the treatment of active PsA:[3,4] (1) Describe the rate of achievement of a new composite endpoint combining DAPSA low disease activity (LDA; score ≤14, including remission) and Investigator Global Assessment (IGA) of psoriasis score ≤1 (range=0 [clear] to 4 [severe]); (2) Determine whether earlier (Week [W] 16) DAPSA LDA + IGA ≤1 is predictive of future achievement of minimal disease activity (MDA) or American College of Rheumatology (ACR) 50 response criteria; and (3) Contrast the performance of DAPSA LDA + IGA ≤1 with that of PASDAS LDA (score ≤3.2).
Methods: Patients (pts) with active PsA despite standard therapies (DISCOVER-1: ≥3 swollen + ≥3 tender joints; CRP ≥0.3 mg/dL; ~30% had prior use of up to 2 TNF inhibitors; DISCOVER-2: ≥5 swollen + ≥5 tender joints; CRP ≥0.6 mg/dL; all pts were biologic-naïve) were randomized 1:1:1 to GUS 100 mg at W0, W4, then Q4W or Q8W; or placebo (PBO) with crossover to GUS Q4W at W24. In both studies, efficacy of GUS vs PBO was compared at W24 (primary endpoint). The number (%) of pts with DAPSA LDA + IGA ≤1 was determined at W24 for pts randomized to GUS or PBO. For all GUS-randomized pts, baseline variables associated with DAPSA LDA + IGA ≤1 and PASDAS LDA at W16 and the predictive value of W16 DAPSA LDA + IGA ≤1 or PASDAS LDA for achieving ACR50, MDA, and DAPSA LDA at W52 were assessed using logistic regression models.
Results: At W24, DAPSA LDA + IGA ≤1 was met by 37% (277/748) of GUS-treated pts vs 13% (48/372) in the PBO group. At W16, 27% (203/748) of GUS-randomized pts had DAPSA LDA + IGA ≤1, and 22% (164/748) had PASDAS LDA. Among the 73% (545/748) of pts who did not have DAPSA LDA + IGA ≤1 at W16, most (77% [418/545]) had IGA ≤1 but not DAPSA LDA; 4% (23/545) had DAPSA LDA but not IGA ≤1, and 19% (104/545) had neither component. Baseline predictors of DAPSA LDA + IGA ≤1 at W16 were male gender, lower dactylitis score, lower Health Assessment Questionnaire-Disability Index (HAQ-DI) score, lower tender joint count (TJC), and higher Psoriasis Area and Severity Index (PASI) score. Baseline predictors of PASDAS LDA at W16 were younger age, lower dactylitis score, lower HAQ-DI score, lower TJC, and higher PASI score. As shown (Figure 1), pts who had DAPSA LDA + IGA ≤1 and PASDAS LDA at W16 were significantly more likely to achieve ACR50, MDA, and DAPSA LDA at W52 than pts without W16 responses; odds ratios (ORs) for achievement of ACR50, MDA, and DAPSA LDA responses at W52 were similar for pts who had DAPSA LDA + IGA ≤1 and for pts who had PASDAS LDA at W16. ORs for achievement of ACR50 and MDA at W52 were higher for pts who had both DAPSA LDA and IGA ≤1 at W16 (9.5 and 10.7) than for pts who had DAPSA LDA but not IGA ≤1 (6.5 and 3.5) or IGA ≤1 but not DAPSA LDA (1.6 and 1.5).
Conclusion: DAPSA LDA at W16 predicted future (W52) achievement of the stringent treatment targets of ACR50 and MDA; associations with W52 response were greater when W16 IGA ≤1 was added to DAPSA LDA. DAPSA LDA + IGA ≤1 at W16 as a predictor of W52 ACR50 and MDA response performed similarly to PASDAS LDA. The novel composite of DAPSA LDA + IGA ≤1 may be a reliable predictor of long-term PsA skin and joint response that is more practical to implement than the PASDAS.

PARE Poster Tour 1

POS0083-PARE DRIVING IMPROVEMENT IN AXIAL SPONDYLOARTHRITIS SERVICES: THE USE OF QUALITY IMPROVEMENT APPROACHES AND TOOLS

D. Webb[1], R. Barnett[2], L. Davies[3]. *[1]National Axial Spondyloarthritis Society, CEO, London, United Kingdom; [2]Bath, Health, Bath, United Kingdom; [3]Salford, NHS Transformation Unit, Salford, United Kingdom*

Background: Quality Improvement (QI) methods have been used in healthcare since the late 1980s across a wide range of healthcare settings. However, in the UK they have not been applied widely within rheumatology including axial Spondyloarthritis (axial SpA). In 2017, the UK healthcare regulator, NICE, produced a national clinical guideline for axial SpA, but there was no mechanism to encourage uptake of its recommendations.
The National Axial Spondyloarthritis Society created a programme to use QI approaches to help encourage uptake of the Guidelines and act as a catalyst for wider improvement in axial SpA care.
Objectives: To encourage service improvement in axial Spondyloarthritis care through the use of quality improvement theory and methods.
Methods: In late 2019 six rheumatology departments were selected to participate in the first cohort. The programme design was underpinned by:
- A framework for management grounded in systems theory[1]
- A learning system that brings healthcare organisations together[2]
- A set of tools to develop, test and implement changes: the Model for Improvement[3].

The teams met four times for training in QI methods, plus team-based online coaching. They had time to develop their projects and networking opportunities to share their data and experiences of implementation.
We conducted a qualitative review of the programme in year one. We interviewed 31 programme participants and reviewed programme documentation.
Results: The review found that:
- A proven QI framework provides a strong basis to build improvement
- A competitive programme helps foster motivation and accountability
- The programme provides the time to use tools to understand the problem and construct improvement aims
- Measurement is key to understand improvement and to create a story of change
- Collaboration and engagement is key within the team and with other stakeholders.

The teams have:
- Trained community–based physiotherapists, leading to improved rheumatology referrals
- Implemented an inflammatory back pain pathway from primary care
- Introduced an MRI spine IBP protocol to reduce variation in imaging
- Established a tertiary referral service which has improved time to diagnosis

- Implemented mental health interventions for patients and reduced the percentage of patients with abnormal scores
- Established a pathway for physiotherapy self–referral and reduced Did Not Attend rates
- Used audit to make the business case for an extended scope practitioner

Conclusion: Despite the challenges of posed by the Covid-19 pandemic, a structured QI programme has enabled clinicians to stay engaged and implement projects to reduce diagnostic delay and improve care.

POS0084-PARE IMPACT OF OSTEOARTHRITIS ON PATIENT QUALITY OF LIFE: IS THERE AN EVOLUTION BETWEEN THE 2013 AND 2021 LARGE-SCALE SURVEYS "STOP OSTEOARTHRITIS" CONDUCTED IN FRANCE AND BELGIUM?

L. Grange[1,2], C. Mathy[3,4], F. Alliot Launois[5], G. Chales[6], L. Seidel[7], A. Albert[7], R. Lories[8], Y. Henrotin[9,10,11]. *[1]CHU Grenoble Alpes/Hôpital SUD, Rheumatology Department, Échirolles, France; [2]Association Française de Lutte Antirhumatismale A.F.L.A.R, Président, Paris, France; [3]Princess Paola Hospital, Vivalia, Department of Physical Therapy and Rehabilitation, Marche-en-Famenne, Belgium; [4]Osteoarthritis Fondation, Treasurer, Boncelles, Belgium; [5]Association Française de Lutte Antirhumatismale A.F.L.A.R, Vice Présidente, Paris, France; [6]Association Française de Lutte Antirhumatismale A.F.L.A.R, Treasurer, Paris, France; [7]Liege University Hospital, Department of Biostatistics, Liège, Belgium; [8]University Hospitals Leuven, Belgium, Skeletal Biology and Engineering Research Center, KU Leuven and Division of Rheumatology, Leuven, Belgium; [9]Princess Paola Hospital, Vivalia, Belgium, Department of Physical Therapy and Rehabilitation, Marche-en-Famenne, Belgium; [10]Osteoarthritis Fondation, Président, Boncelles, Belgium; [11]University of Liège, MusculoSKeletal Innovative Research Lab (mSKIL), Liège, Belgium*

Background: Osteoarthritis (OA) is the most common form of arthritis, affecting more than 500 million people globally. OA is characterized by chronic mechanical pain and stiffness in the joints, limiting patient physical activities, leading to sedentarism, and disability. The results of the French web-based survey "Stop OA" (N=4227 participants) conducted in 2013 were presented at EULAR 2014. They evidenced the heavy burden of OA in France.

Objectives: The survey was repeated in France/Belgium between 2019 and 2021 (N=3465). This study aimed at assessing the impact of OA on patient quality of life and looking at a potential evolution between the two surveys.

Methods: Participants were invited to complete the survey questionnaire online via the website www.stop-arthrose.org. The questions focused on demographic and socio-economic aspects, history of the disease, physical activities, beliefs about OA, its impact on daily life, assessment of health status and the consequences, as well as the needs and expectations of the participants.

Results: 3465 questionnaires (France N = 2822, Belgium N = 643) were thus collected between September 2019 and January 2021. The average filling time of the survey was 40 minutes. In the 2021 survey, 80.8% of participants (mean age 60 years, 80.3% women) declared that OA had a negative impact on their morale and 64.1% that they had a deteriorated self-image due to the disease. 25% of participants thought that difficulties in their couple were caused by OA and 33% reported problems in sexual life. 24.8% found it hard to cope with the discouragement generated by the disease. Even if psychological repercussions were observed in 21.2%, less than 5% consulted a psychologist. The impact on leisure (78.1%) and family life (61.9%) was also significant, as well as on social activities (58.0%) and professional life (43.7%). The disease also hindered walking (67.4%) and prevented daily actions (32.0%). Some help was necessary, mainly for gardening or tinkering (28.7%), picking up or opening objects (22.9%) as well as shopping and household chores (17.7%). 50% reported difficulty falling asleep and 67.6% were being woken up at night during their sleep because of pain caused by OA. Fatigue was difficult to live with for 47.9% of the participants. Compared to the results of the 2013 survey, there was no significant improvement evidenced in any of the areas studied.

Conclusion: OA represents a real burden that affects the mental health of patients, their relationships and the quality of their sleep. There has been no improvement of OA impact in patient' quality of life between the two surveys (i.e., 8 years). This reflects the lack of resources for research to find new treatments and implement evidence-based therapeutic strategies in the current medical practice. A better understanding of these repercussions will allow effective strategies to be adopted in order to deal with these issues.

POS0085-PARE CURRENT NEEDS, IMPACT AND PERSPECTIVE OF PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS

P. Plazuelo-Ramos[1], E. Loza[2]. *[1]Coordinadora Española de Asociaciones de Espondiloartritis, Presidencia, Fuenlabrada, Spain; [2]Instituto de Salud Musculoesquelética, Rheumatology, Madrid, Spain*

Background: The impact of spondyloarthritis (SpA) and psoriatic arthritis (PsA) is enormous.

Objectives: To analyse in patients with SpA and PsA current 1) needs; 2) disease impact, and 3) patients' opinion on treatments, patients-physicians relationship and disease information.

Methods: National survey promoted by CEADE (Spanish Coordinator of Spondyloarthritis Associations). A multidisciplinary working group composed by 1 rheumatologist, 2 patients members of CEADE with SpA and PsA and a methodologist was established. They designed a structured survey (20 minutes long), in electronic format to be answered by patients with SpA and PsA, aged 18 years or above. The survey was launched on April 28, 2021, using CEADE channels to communicate with members and followers, and was closed on June 30, 2021. Sociodemographic and clinical variables were collected (age, sex, disease duration treatments), and variables related to the objectives. A descriptive analysis was performed.

Results: The survey included 543 patients with SpA (55% ankylosing spondylitis, 86% women, 61% aged 48-64 years, 25% with biological therapies) and 291 patients with PsA (89% women, 73% aged 48-64 years, 40% with biological therapies). In the last month, the reported level of fatigue, morning stiffness and sleep problems of patients with SpA and PsA was considerable. In a scale from 0 (no symptoms) to 10 (high level of symptoms) the means were greater than 8. Almost 80% of patients with SpA described low back pain within the last month and 82.5% of patients with PsA pain, stiffness and/or arthritis on the knees, ankles, feet and/or hands, and 51% dactylitis. Regarding to daily activities, practicing exercise and house cleaning were the most affected ones among patients with SpA and PsA. We found that 70%-74% of these patients were concerned about pain and almost 60%-66% about loss of mobility and autonomy. The impact of the disease on work was in general very high very high. The level of satisfaction with treatments was low in SpA, mean 5.5 (scale from 0 no satisfaction to 10 very satisfied), and moderate in PsA, mean 6.2. Across treatments, the level of satisfaction was higher with biological therapies compared with classical synthetic disease modifying antirheumatic drugs in both disease groups. Many patients (70.2% with SpA and 66% with PsA) are used to live with pain every day. Many of the survey participants (over 50%) hope that treatments will help them recover their quality of life and improve pain, stiffness and fatigue. Oral treatments are preferred over subcutaneous and intravenous drugs in SpA and PsA. Patients also consider that oral treatments have more positive influence on adherence to treatments. A total of 22% of surveyed patients with SpA and 14% with PsA said that their rheumatologists never asked them about the factors that limit their life, 14.3% and 6% that they never talked about the impact of the disease on quality of life, and 43.8% (SpA) and 31.2% (APs) that they do not stablish treatment objectives with the rheumatologist. Almost 30% of participants stated that they would like to have more time to express and discuss doubts and concerns with their rheumatologist, and around 25% would like to have more follow-up visits. Table 1 describes the most used.

Table 1. Sources and formats of information about the disease.

	SpA	PsA
Source of information		
Social networks	184 (33.9%)	68 (23.4%)
Patients associations	158 (29.1%)	77 (26.5%)
Scientific societies	70 (12.9%)	36 (12.4%)
Websites created by rheumatologists	165 (30.4%)	82 (28.2%)
Physician	197 (36.3%)	117 (40.2%)
Nurse	33 (6.1%)	10 (3.4%)
Other/s	11 (2.0%)	7 (6.9%)
Format		
Graphic or visual illustrations	184 (33.9%)	78 (26.8%)
Podcasts	47 (8.6%)	12 (4.1%)
Video	175 (32.2%)	72 (24.7%)
Written information (brochures, magazines, newspapers)	200 (37.8%)	100 (34.4%)
News	148 (27.2%)	72 (24.7%)
Chatbots	8 (1.5%)	2 (0.7%)
Other/s	10 (1.8%)	6 (0.7%)

Conclusion: Current impact of SpA and PsA on daily life is still very high. There are areas for improvement in the doctor-patient relationship and on disease treatments.

Disclosure of Interests: None declared

POS0086-PARE PATIENT PREFERENCES FOR SYSTEMIC LUPUS ERYTHEMATOSUS TREATMENTS: A DISCRETE CHOICE EXPERIMENT

H. Collacott[1], A. Phillips-Beyer[2], N. Krucien[1], K. Marsh[1], B. Flamion[3]. [1]*Evidera, London, United Kingdom;* [2]*Innovus Consulting Limited, London, United Kingdom;* [3]*Strategic Development, Idorsia Pharmaceuticals, Allschwil, Switzerland*

Background: Fatigue, chronic pain, and skin and joint manifestations can be debilitating for people with systemic lupus erythematosus (SLE), and managing these symptoms is vital to safeguard their quality of life (QOL). In addition, oral corticosteroids (OCS) and other immunosuppressants can expose patients with SLE to severe adverse events. However, little is known about the relative importance of SLE treatment outcomes including symptom control or the extent to which treatment risks are tolerated in exchange for this.

Objectives: To quantify the relative importance of different SLE treatment outcomes and the trade-offs patients are willing to make between these outcomes.

Methods: This online discrete choice experiment (DCE) assessed how treatment choices varied with treatment outcomes. Subjects were US adults (≥18 years) with a self-reported diagnosis of moderate-to-severe SLE (≥6 months) who experienced ≥1 flare in the past year and were taking ≥1 SLE treatment. Treatment outcomes included four benefits on: 1) fatigue levels, as in the Functional Assessment of Chronic Illness Therapy (FACIT)–Fatigue, described the degree of tiredness felt by a patient in the previous 7 days, while not experiencing a flare and despite adequate sleep or rest, 2) joint and 3) non-joint pain levels as measured using the Brief Pain Inventory–Short Form (BPI-SF) scale; scores of 2, 5, and 8 correspond to mild, moderate, and severe worst daily pain on a scale of 0 (no pain) to 10 (worst imaginable pain),and 4) skin rash and itch levels, as in SLE-QOL, indicated how much patients were troubled by sore, painful, stingy, or itchy skin in the previous 7 days. Treatment outcomes also included three risks: 1) risk of infections represented by the proportion of patients who might experience an infection during treatment, 2) mild-to-moderate OCS-related side effects requiring no or only self-administered treatment and 3) severe, potentially life-threatening OCS-related side effects requiring long-term outpatient or hospital treatment. An error-component multinomial logit model was used to analyze DCE data.

Results: The DCE survey was completed by 342 subjects with SLE (mean age 39.6 years) who were predominantly female (82%). Most participants were diagnosed with SLE ≥1 year prior (84%) and experienced ≥2 SLE flares in the previous 12 months (90%). Nearly all participants experienced joint pain (92%) and non-joint pain (84%). Treatment preferences were modelled using 3,420 subject-generated observations. Over the ranges tested, more importance was attached to symptom improvement than risk reduction (Figure 1). A reduction in joint pain (8 to 2) was most important to patients (marginal utility [MU] 0.84), followed by skin rashes and itching ('extremely' to 'not at all', MU 0.66) and non-joint pain (8 to 2, MU 0.49). Reduction of infection risk (10% to 0%) was least important (MU 0.27). Regarding the maximum acceptable risk, participants would accept a 74% increase in the risk of mild-to-moderate side effects to avoid being 'extremely troubled' by skin rash and itch (Table 1).

Table 1. Maximum acceptable risk of mild-to-moderate oral corticosteroid side effects

Attribute levels	Maximum Acceptable Increase in Risk* [95% CI]
Fatigue	
A little bit	50.06% [32.41, 67.71]
Somewhat	47.51% [29.92, 65.09]
Very much	Reference
Skin rash and itch	
Not at all	73.81% [51.51, 96.11]
Moderately	50.84% [32.37, 69.32]
Extremely	Reference
Joint pain (1-level decrease)	15.63% [11.24, 20.02]
Non-joint pain (1-level decrease)	9.18% [6.06, 12.31]
Risk of infections (1% decrease)	2.99% [1.53, 4.45]
Risk of severe side effects (1% decrease)	1.72% [0.97, 2.47]

*Calculated using an error-component multinomial logit model.

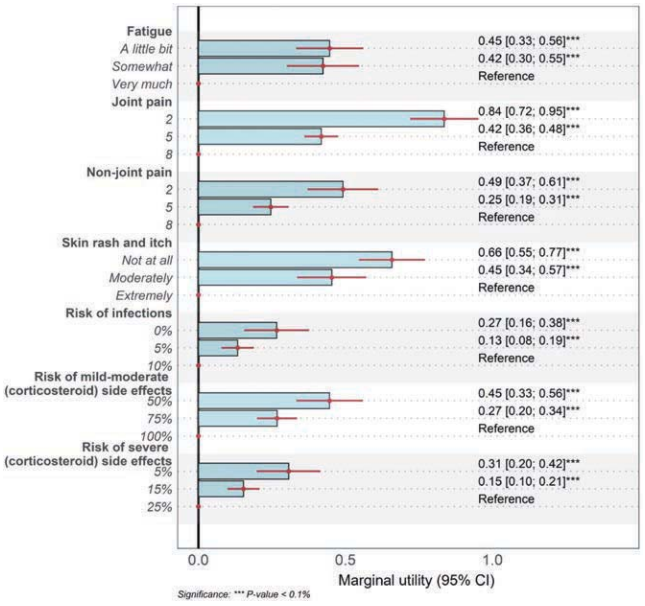

Figure 1. Marginal utilities associated with changes in SLE treatment outcomes

Conclusion: This real-world patient preference assessment provides insights into the relative importance of SLE treatment outcomes and willingness to tolerate SLE treatment risks. These results can guide endpoint prioritization in SLE clinical studies and inform the evaluation of SLE treatments.

POS0087-PARE IMPROVED SELF-MANAGEMENT IN PATIENTS WITH OSTEOPOROSIS AND INFLAMMATORY ARTHRITIS

M. Roffler[1], A. Mueller[1], I. Steeb[1]. [1]*Rheumaliga Schweiz, Dienstleistungen, Zürich, Switzerland*

Background: Self-management care services have received a great deal of attention in Switzerland lately. However, there is still a huge gap in service provision, especially with regard to rheumatic diseases. To fill this gap, the Swiss League against Rheumatism has developed a comprehensive self-management programme for patients with inflammatory arthritis (IA) and osteoporosis. In the course of this programme, eleven medical assistants in outpatient rheumatological and general practitioner clinics were trained to help osteoporosis and IA patients to strengthen their self-management capacity. This programme was implemented within the scope of a three-year pilot project (2019 – 2021) and is continuing as a regular project from 2022 onwards.

Objectives: The ultimate objective was to increase the quality of life and health status of people with osteoporosis and IA by enhancing their capacity for self-management. This included all three components of self-management, i.e. strengthening patients' knowledge of the disease, motivating them to take action

and increasing their ability to manage the disease. Furthermore, the pilot project aimed to close an important gap in the Swiss health care system.

Methods: A questionnaire was designed to measure the change in self-management abilities and the health status of patients. The questionnaire was given to patients at three points in time (t1=enrolment of patient, t2=last session of the self-management programme and t3= two months after the last session) and contained several validated scales such as the heiQ, Self-Efficacy for Managing Chronic Disease 6-Item Scale, RADAI-5 and EQ-5D-5L. Descriptive statistics were applied to analyse the data by comparing the mean values of all relevant indicators at three points in time.

Results: In total 52 patients were enrolled in the pilot project. 48 patients completed the programme and 35 took part in the follow-up questionnaire. Overall, the results show a positive trend in self-management abilities and an improvement in the patients' current health status. The slight increase in *knowledge* remained until the follow-up. Significant changes are seen in *Skill and Technique Acquisition* as well as in *Self-Monitoring and Insight* of the disease, which are two important components of self-management. Other components such as the *knowledge* and *constructive attitudes and approaches* also underwent a small but positive change that lasts up to two months after the last session of the self-management programme. *Self-efficacy* improved as well, but with a slight decrease during the follow-up. The *disease activity* also declined slightly over time. The results also indicate a small and steady improvement of the *current health status*. Using a visual analogue scale as part of the EQ-ED-EL, participants evaluated their current health status as 69 (t=1), 73 (t=2) and 74 (t=3). The *quality of life* has improved too, but the change doesn't seem to be relevant. Furthermore, the *use of health services* indicates a slight decline after taking part in the self-management programme.

Conclusion: The comprehensive self-management programme designed by the Swiss League against Rheumatism embedded in outpatient rheumatological and general practitioner clinics proved to be successful. The three components of self-management in particular, i.e. knowledge, motivation to take action and skills to manage the disease improved significantly. The results also show a positive trend in the patients' current health status, their quality of live and a decline in disease activity. However, based on the study design, it cannot be concluded that there is a correlation between the improved health status/quality of life and the self-management programme. For this purpose, a control group would be necessary to evaluate the programme's effect on the health status and quality of life of people with rheumatic disease. Nevertheless, this pilot project represents an important foundation on which further services and programmes to strengthen self-management in rheumatology can be developed.

POS0088-PARE CHANGES IN PATIENT-REPORTED OUTCOME SCORES DURING COVID-19 PANDEMIC: DATA FROM THE ARTHRITISPOWER REGISTRY

K. Gavigan[1], E. Rivera[1], J. R. Curtis[2], S. Venkatachalam[1], L. Stradford[1], D. Curtis[1], W. B. Nowell[1]. *[1]Global Healthy Living Foundation, Patient-Centered Research, Upper Nyack, United States of America; [2]University of Alabama at Birmingham, Division of Clinical Immunology & Rheumatology, Birmingham, United States of America*

Background: The COVID-19 pandemic causes concern among patients with autoimmune and rheumatic disease (ARD) due to increased risk of infection and heightened isolation from social distancing.[1]

Objectives: Examine how mean patient-reported outcome (PRO) scores for mental, social and physical health fluctuated after COVID-19 vaccine availability was widespread in US.

Methods: We conducted and reported on[2] an initial analysis of January 2020 – April 2021 where US participants (pts) of the ArthritisPower (AP) registry completed PROMIS measures of physical health (Physical Function, Pain Interference, Fatigue, Sleep Disturbance), mental health (Anger, Anxiety, Depression) and social health (Social Isolation, Emotional Support). Follow-up analysis was conducted May – December 2021. Only pts from initial analysis were included in follow-up. Null hypothesis was no change in monthly average scores across 23-month pandemic period. Analysis of means compared monthly assessment mean scores to overall mean score for each measure during study period. Pts with < 2 assessment time points and osteoarthritis with no ARD were excluded from analysis.

Results: Total of 49,940 PRO scores were contributed by 2,266 pts during 23-month period, with 8,393 of the scores contributed from May – December 2021. Mean (standard deviation, SD) number of observations per pt was 5.6 (12.5). Pts were 87.6% female, 86.7% white, mean age of 52.1 (12.7) years. Rheumatoid arthritis (n=1,131, 49.9%) was the most common condition. Most commonly reported measures were Pain Interference, Fatigue, Sleep Disturbance and Physical Function, each with >11,000 total results (Table 1).

Pts' mental and social health assessment scores improved then worsened during last 8 months of 2021 (Figure 1). Overall mean scores were: Anxiety 62.4 (12.5), Social Isolation 61.9 (10.5), and Anger 61.5 (12.8). From July – August, Social Isolation decreased by 1 SD. Compared to overall assessment mean, Anger declined by > ½ SD (53.3 [19.4]) in August and Anxiety declined by ½ SD (57.7 [11.3]) in September. By December, Anger rose by > ½ SD (68.6 [5.0]) of assessment mean. Pain Interference (mean: 63.3 [7.8]), Fatigue (62.6 [9.5]), and Sleep Disturbance (58.1 [9.0]) scores were significantly lower in May, June, July and August compared to the assessment mean, though none decreased by > ½ SD.

Conclusion: ARD members of AP had mental, social and physical health scores improve during summer of 2021, corresponding with widespread availability of vaccines. However mental and social health scores worsened by December as US faced new variants of the virus.

POS0089-PARE THE IMPORTANCE OF ACCURATE INCIDENCE AND PREVALENCE ESTIMATES FOR FAMILIES OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

R. Beesley[1]. [1]*Juvenile Arthritis Research, JAR Project,Tonbridge, United Kingdom*

Background: Juvenile Idiopathic Arthritis (JIA) is a heterogenous group of autoimmune disorders characterised by chronic joint inflammation, affecting children and young people (CYP) under the age of 16. Recent analysis in the UK [1] has provided an update to the estimated incidence and prevalence of JIA.
Objectives: Whilst the policy and health-care benefits of accurate incidence and prevalence rates are understood, this patient- and parent-led qualitative project sought views from parents of CYP with JIA to understand whether knowing accurate estimates of incidence and prevalence are important to them.
Methods: Parents of CYP with JIA, all members of a small online group on social media, were asked whether knowing accurate rates of JIA were important to them, and why. Responses were collated and summarized.
Results: Whilst a few respondents felt it did not matter to them what the overall rates of JIA were, focusing instead on their own personal experience with the condition, the majority did want to know and gave consistent reasoning.
They advised that, when your child is diagnosed with JIA, it is a very isolating experience. Most people have never heard of the condition before, and being told your child has arthritis is a frightening time (especially if you then become aware of some of the significant long-term effects, such as potential continuation of disease into adulthood and possible joint damage, and the side effects of treatment, and social impacts of the disease [2, 3]. Whilst direct support is available to families affected by JIA (www.jarproject.org/hope), understanding prevalence rates can help reduce mental health burdens on patients and parents and reduce feelings of isolation.
Families also advised that they want to know numbers of children with JIA so we collectively can get a better understanding of the cause, the trends, and the possible reasons behind changes. Knowing accurately the numbers of children with JIA can help to raise awareness; current lack of awareness in society and primary care contributes to delays in diagnosis and potentially worse clinical outcomes [4]. In addition they reported the need for appropriate resourcing of paediatric rheumatology and support services, and the political and financial discussions that must take place to enable that to happen need to be supported by evidence.
Conclusion: Overall, parents *do* want to know how many other children have JIA. It takes some of the isolation and anxiety away to know you are not alone. It matters because knowing there are other parents in the same situation as you can help reduce anxiety and loneliness. It matters, because knowing there are researchers focussing on JIA helps remind you that work is underway to better understand JIA, its causes, and improved treatments which will eventually lead to improved care for children with the condition. It matters, because it can help target resources appropriately. It matters, because raising awareness is more effective if we know how many people are affected by a chronic condition. And it matters, because as improved treatments are developed we want to be able to see the number of children categorised as having active JIA to reduce and health outcomes for each child to improve.

POS0090-PARE ORGANIZATION, INFLUENCE, AND IMPACT OF PATIENT ADVISORY BOARD REPRESENTATION IN PRIVATE REHABILITATION INSTITUTIONS – AN EXPLORATIVE CROSS-SECTIONAL STUDY

J. Sagen[1], E. Børøsund[2], A. E. Simonsen[3], A. Habberstad[4], I. Kjeken[1], H. Dagfinrud[1], R. H. Moe[1]. [1]*The Deacon's Home Hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway;* [2]*Oslo University Hospital, Oslo, Norway, Department of Digital Health Research, Division of Medicine, Oslo, Norway;* [3]*Røysumtunet Rehabilitation Center, Patient Advisory Board, Jarem, Norway;* [4]*The Norwegian Federation of Organisations of Disabled People, Research and Patient Participation, Oslo, Norway*

Background: Patient participation (PP) organised as patient advisory boards (PABs) is a statutory part of health care institutions in Norway (1). There is limited agreement on how to engage PABs in a meaningful manner (2). More knowledge on how PAB representatives experience patient engagement (PE) is needed.
Objectives: To explore how PAB representatives engage in PABs with regard to organisation, influence, and impact on decision-making processes and service delivery.
Methods: PAB representatives recruited from rehabilitation institutions, representing all four health regions in Norway completed a PE evaluation tool. The tool is tested for reliability and content validity with good results and comprises 35 items including four main domains *policies and practices, participatory culture, collaboration,* and *influence and impact* that provided responses about PE-levels (3). Categorical data were summarized to modal scores using frequencies and percentages, and response categories were collapsed from five to three. The collapsed categories were divided into PE-levels; barrier, intermediate, and facilitator (Table 1). Free-text responses were analysed according to principles of manifest content analysis, summed up, and used to complete the results of the scores. Free text responses were analysed using Quirkos version 2.4.1.
Results: Of the 150 contacted PAB representatives, 47 (32%) responded. PAB representatives' mean age was 60.5 (min-max 30 - 80), 62% were female and a majority (81%) had prior experience with PP. The results showed that 75% of the participants agreed that patient-centered care was strengthened as a result of PE. Three out of four main domains scored indicating a facilitating PE-level (Table 1). The domain, *influence and impact* scored with an intermediate PE-level. Regarding *influence and impact*, half of the participants did not know if *PE input had influenced management decisions,* and 60% had rarely *identified any PE contributions*. The results from free text analyses showed that PE was coded as a facilitator seven times, and as a barrier to PE 26 times. The most frequent barrier was exclusion of PAB (13 codes), and the most coded facilitator was inclusion of PAB (3 codes).
Conclusion: Findings indicate that PAB representatives are satisfied with how rehabilitation institutions organise PABs. Unclear adherence to the values and principles of PP may hinder influence and visibility from PE contributions.

Table 1

Modal scores of the most common collapsed response category (PE-level) (N=47)

Items (n)	Domain	Modal PE-level	Mode n (%)	(min-max)
5	Policies and practices	Facilitating	125 (53.2)	(18-37)
8	Participatory culture	Facilitating	199 (53)	(14-35)
2	Collaboration	Facilitating	35 (36.5)	(14-19)
6	Influence and impact	Intermediate	125 (44.4)	(10-30)

Questions not presented in the table consist of *background* items, items related to *final thoughts,* and five questions with free text fields. A yes or no question related to the domain policies and practices is not included in the table.

Before collapsed, 15 items were valued: Strongly disagree, disagree, neither agree nor disagree, agree, strongly agree, don't know. Seven items valued 1-5: never, seldom, some of the time, all of the time, don't know.

POS0091-PARE **MIG-NETWORK - A NETWORK FOR PEOPLE WITH RHEUMATISM AGED 35-55 YEARS.**

B. Schmidt Andersen[1]. [1]*Gigtforeningen, Frivilligafdelingen, Gentofte, Denmark*

Background: The MIG network *("MIG" is a shortening for "Midt i gigt" which means "In the middle of Reumatism" as well as mid-life. MIG also means "ME" in Danish*
The existing offers and activities in the Danish Rheumatism Association are primarily targeted towards the age group above 60 years. Often, younger members find it difficult to feel at home and see themselves as part of that particular age group. They miss activities where they can meet up with their peers, who are going through the same challenges in life.
Objectives: The objectives of the MIG network is to create a forum for people with rheumatism, who are roughly between 35 and 55 years old. The network focuses on life with rheumatism and how to keep the balance between job, family life and the disease. The ultimate goal was to create a community based on networking, shared experiences and relevant knowledge from both each other and health professionals.
Methods: First of all, the age group needed to be involved right from the start, so we initially made a series of interviews to learn about their needs and wishes. Then we gathered a group of five volunteers, who agreed to participate in defining the objectives and activities and to start up the network.
The network consists of the following:
I) an online based network with monthly webinars on the platform Zoom, where different health professionals talks about relevant subjects. The obvious advantage being, that people could participate from all over the country, from their sofa, not needing to dress up and travel after a long day of obligations.
II) The Danish Rheumatism Association have created an App for their volunteer community. In this app we offered the members of MIG "a room of resources" where they can find news on the latest research and other relevant news. The members can also ask questions and share written advice and good ideas with each other.
III) Last, but not least it was important for the volunteers to offer physical meetings once or twice a year. They long to meet up, to laugh together and share their stories and experiences on life with arthritis. These meetings always have talks and lectures by eg. Reumatologists, scientists, physiotherapists or psychologists.
Results: I) The participants in the online webinars have been very pleased with the professional presentations and found them to be very useful. At the same time, they gained useful tools to make it easier to live a life with rheumatism. But it has been difficult to create an intimate space. For many, it is difficult to share private feelings of uncertainty and inadequacy on camera in a Zoom meeting. The "room of resources" on our App has only worked and engaged a very small group of people, in spite of a great effort from our volunteers.
The physical meetings have been a great success. And they have covered a need that wasn't met before. The participants have enjoyed the professional lectures, but enjoyed the social networking even more. So now the meetings have less lectures and more networking in the program. As living with a chronic disease can make the whole family and network suffer, we also met the need to invite next of kin to join the meetings and have arranged for them to have their own workshop with a Psychologist.
Conclusion: The MIG network makes sense! And it has met a need for people with a chronic disease to meet up with peers in the same life situation. It has proven to be more difficult than intended to create an online community, whereas the physical meetings have created strong relations on a completely different level. The network continues with both the digital and the physical activities nationally. The goal is also to recruit volunteers locally, so that they can initiate local activities.

Pathogenesis of SLE, Sjöns and antiphospholipid sydrome

POS0092 **HETEROGENEITY OF THE TYPE I INTERFERON SIGNATURE AMONG ANTIPHOSPHOLIPID SYNDROME PATIENTS: A CLUSTER AND CORRESPONDENCE ANALYSIS APPROACH**

I. Cecchi[1], M. Radin[1], A. Barinotti[1], S. G. Foddai[1], E. Rubini[1], A. Suárez[2], D. Roccatello[1], S. Sciascia[1], J. Rodríguez-Carrio[2]. [1]*University of Turin, Department of Clinical and Biological Sciences, Center of Research of Immunopathology and Rare Diseases Coordinating Center of Piemonte and Valle d'Aosta Network for Rare Diseases, University of Turin, Italy, Turin, Italy;* [2]*University of Oviedo, Area of Immunology, Department of Functional Biology, Faculty of Medicine, University of Oviedo, Oviedo, Spain, and Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, Ovied, Spain*

Background: Type I Interferons (IFN) are central players in the pathogenesis, disease activity and evolution of several autoimmune conditions. To date, a limited number of evidences is available on the specific role of IFN activation in antiphospholipid antibodies (aPL) positive patients, including aPL carriers, primary antiphospholipid syndrome (PAPS) and those APS subjects who presented with an associated autoimmune disease (secondary APS, SAPS), such as systemic lupus erythematosus (SLE).
Objectives: The aim of this study was to evaluate the differential expression of IFN stimulated genes (ISG) among different subsets of aPL positive subjects and SLE patients.
Methods: For the purpose of the study, a total of 112 patients attending the San Giovanni Bosco Hospital (Turin, Italy) were enrolled, including 31 PAPS, 25 SAPS, 27 SLE patients without aPL, 29 aPL carriers (mean age 48.3±13.3 years, 76% female)[1,2]. Nineteen subjects were also recruited as healthy controls (HCs). Complete demographic, clinical, and laboratory data were collected at the time of the inclusion. Gene expression was evaluated by RT-PCR in whole blood for the following genes: IFI6, IFI44, IFI44L, MX1,IFI27, OAS1 and RSAD2. Normalized gene expression levels (Z-scores) were averaged into a global IFN signature (IFN score). Differences were measured by Kruskal-Wallis tests and associations among genes were studied by cluster and correspondence analyses. Correlations among genes were plotted by network analyses.
Results: An overall activation of ISG was noted across APS subsets, but certain differences were noted among genes. Whereas some ISG were already upregulated in the aPL positive group compared to HC (IFI44, IFI44L, MX1, IFI27, OAS1 and RSAD2, all $p<0.050$), other ISG were only in increased SLE (IFI6), MX1 differed between SLE and SAPS, and IFI27 and OAS1 showed differences between PAPS and SAPS. The composite IFN score revealed quantitative differences in the IFN pathway activation across APS subsets, being elevated in aPL carriers/PAPS groups compared to HCs (both $p<0.050$) and increasing in SAPS ($p<0.010$) and SLE ($p<0.001$) groups. Network analyses (Figure 1A) revealed qualitative differences in the gene-gene correlation networks: (i) weaker structures were found in HCs and aPL carriers, compared to stronger and higher-degree networks in SAPS and SLE groups; and (ii) the influence of each node was different across groups. Unsupervised cluster analysis identified 3 clusters (I to III) based on ISG patterns (Figure 1B). Clusters usage differed among APS subsets, thus correlating clinical status (Figure 1C). Distinct groups of ISG positively correlate to aPS/PT IgG titre in aPL carriers and PAPS groups (all rho>0.500), whereas no associations were retrieved in SAPS or SLE. No associations with previous thrombotic events were observed in any subset, although IFN composite score and several ISG correlate with the number of thrombotic recurrences under anticoagulation (all rho>0.400). No associations with GAPSS were observed.

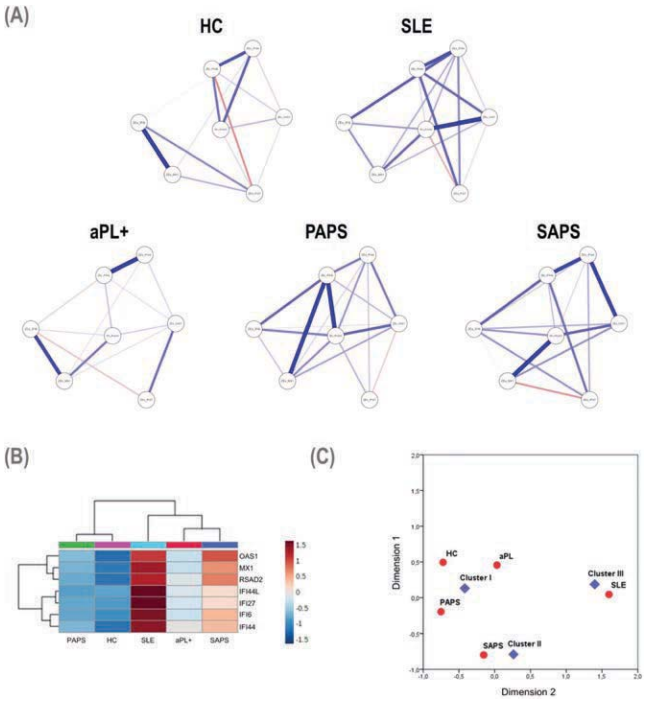

Figure 1.

Conclusion: An overall IFN pathway activation has been observed in aPL positive patients and across all APS subsets. Qualitative and quantitative differences across the APS spectrum can be identified, leading to the identification of distinct IFN signatures with different clinical value.

POS0093 ASSESSMENT OF HISTOLOGICAL FEATURES OF CHRONICITY OF MINOR SALIVARY GLAND BIOPSY IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

S. Garcia-Cirera[1,1], C. Galisteo[1], S. Retamozo[1], M. Moreno[1], E. Casado[1], M. Rusiñol Gonzalez[1], J. Gratacos-Masmitja[1], J. Calvet[1]. [1]*ParcTaulí Hospital Universitari. Institutd'Investigació i Innovació ParcTaulí, Rheumatology, Sabadell, Spain*

Background: The origin of the histological chronic inflammation of the salivary gland in patients with primary Sjogren's Syndrome (pSS) is questionable. It is probably a consequence of both, the evolution of the disease itself and ageing
Objectives: This study aims to evaluate histological data of chronicity of minor salivary gland biopsy with clinical characteristics and time of evolution in a series of patients with pSS.
Methods: A cross-sectional study including 98 subjects fulfilling the ACR-EULAR 2017 classification criteria for pSS. All patients underwent a minor salivary gland biopsy requested as per clinical practice. We collected the age at diagnosis and at biopsy, xeroftalmia and xerostomia evolution time, and stimulated and unstimulated salivary flow as a clinical data. We informed the following features in the minor salivary gland biopsy: the focus score (positive if ≥ 1), atrophy, fibrosis and adiposity all graded in negative, mild, moderate, and severe stages according to pathological criteria.
Results: This study included 98 patients with pSS. the median of all recruited parameters are shown in Table 1. Only 2 patients presented severe fibrosis and adiposity, so we did not consider them for the analysis. Both, the age at diagnosis and at biopsy are significantly higher between none, mild and moderate stages in the three biopsy parameters. The age at biopsy increased in negative, mild, and moderate stages, in median, 10, 9 and 6 years in atrophy, fibrosis and adiposity respectively. Although more evolution time is observed in atrophy and fibrosis regarding classification categories, it does not reach statistical signification. Focus score is associated with atrophy as a high percentage in severe stage shows negative biopsy (78% vs 22%, p = 0.046) while in negative, mild, and moderate atrophy display a positive biopsy (61%, 73% and 64%, respectively). Furthermore, we observe a significant OR of 8.75 [1.7-68] for negative, 6 [1.25-44] in mild and 9.92 [1.8-80] in moderate compared to severe atrophy. Fibrosis and adiposity are not related to focus score. A low unstimulated salivary flow is observed in the atrophy and fibrosis stages, although differences are explained when compared negative with mild and moderate (3.5 vs 2 and 1.4 for atrophy and 3 vs 2 and 1.75 for fibrosis). Regarding adiposity, a lineal statistically significant association is observed for every stage (3.5, 1.65 and 0.7, p< 0.001). No differences in the stimulated salivary flow are shown.

Table 1. Description of variables included in the study.

	Categories	N(%)Median(IQR)
Age at diagnosis(years)		55.220 (51.097, 58.407)
Age at biopsy (years)		57.719 (53.851, 61.333)
Xerostomia (months)		19.614 (10.480, 35.121)
Xeroftalmia (months)		21.487 (8.148, 38.735)
Focus score (positive)		63 (64.3%)
USF (ml/15 min)		2.000 (1.400, 3.000)
SSF (ml/ 5min)		4.500 (3.000, 5.000)
Atrophy	Negative	28 (28.7%)
	Mild	37 (38.1%)
	Moderate	23 (23.7%)
	Severe	9 (9.3%)
Fibrosis	Negative	29 (30.5%)
	Mild	40 (42.1%)
	Moderate	26 (27.4%)
Adiposity	Negative	39 (41.1%)
	Mild	38 (40%)
	Moderate	18 (18.9%)

USF: Unstimulated salivary flow, SSF: Stimulated salivary flow

Conclusion: An older age both, at diagnosis and at biopsy are associated with a severe stage of atrophy, fibrosis, and adiposity. Patient with severe atrophy shows less positive focus score, which might be noticed for biopsy interpretation

POS0094 ALPN-303, AN ENGINEERED DUAL BAFF/APRIL ANTAGONIST, POTENTLY INHIBITS PATHOGENIC LYMPHOCYTE SUBSETS AND FUNCTION IN B-CELL- AND ANTIBODY-RELATED PRECLINICAL MODELS

S. R. Dillon[1], K. E. Lewis[2], S. Mudri[1], K. Kleist[2], L. Griffin[2], L. S. Evans[3], J. Bhandari[4], L. Garrett[4], M. A. Seaberg[1], N. Wang[1], A. Chunyk[1], D. Ardourel[4], L. Hebb[4], M. F. Wolfson[4], M. W. Rixon[4], P. Holland[5], S. L. Peng[6]. [1]*Alpine Immune Sciences Inc,Translational Medicine, Seattle, United States of America;* [2]*Alpine Immune Sciences Inc, Pharmacology, Seattle, United States of America;* [3]*Alpine Immune Sciences Inc, Immunology, Seattle, United States of America;* [4]*Alpine Immune Sciences Inc, Protein Therapeutics, Seattle, United States of America;* [5]*Alpine Immune Sciences Inc, Research, Seattle, United States of America;* [6]*Alpine Immune Sciences Inc, Clinical Development, Seattle, United States of America*

Background: B-cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL) are tumor necrosis factor (TNF) superfamily members that bind TACI (transmembrane activator and CAML interactor), BCMA (B-cell maturation antigen), and/or BAFF-R on B cells and together support B cell development, differentiation, and survival. ALPN-303 is an Fc fusion protein of a human TACI variant TNFR domain engineered by directed evolution[1,2]. It mediates significantly improved combined BAFF and APRIL inhibition in vitro and enhanced pharmacokinetic and immunomodulatory properties in preclinical studies, as compared to wild-type (WT) TACI-Fc molecules. B-cell targeting therapies like the WT TACI-Fc fusions atacicept and telitacicept have demonstrated promising clinical potential in B cell-related diseases like systemic lupus erythematosus (SLE). ALPN-303, with enhanced inhibitory activity against BAFF and APRIL, has previously been shown to demonstrate promising efficacy in an (NZB/NZW) F_1 mouse model of lupus, and may therefore further improve clinical outcomes in such diseases.
Objectives: To further characterize the comparative activity of ALPN-303 versus an Fc matched control, a WT TACI-Fc comparator (telitacicept), and/or a B cell-depleting therapy (anti-mouse CD20 [anti-mCD20] monoclonal antibody [mAb]), in antibody-related preclinical models.
Methods: The functional activity of ALPN-303, as compared to telitacicept or a depleting anti-mCD20 mAb, was evaluated in a sheep red blood cell (SRBC) immunization mouse model. Mice immunized intraperitoneally with SRBC on Study Day 0 were administered 200 µg ALPN-303 or a molar-matched amount (240 µg) of telitacicept on Days 1 and 6 or were treated with 200 µg anti-mCD20 (rat IgG2b) on Day 1. At study termination on Day 15, serum was collected to measure levels of test article and anti-SRBC immunoglobulin (Ig) titers, and spleens and bone marrow (BM) were collected for immunophenotyping by flow cytometry. A study in the inducible bm12 mouse model of lupus was also conducted, with mice treated twice weekly with 200 µg ALPN-303 or a molar-matched dose of Fc control, starting on Day 5 after splenocyte transfer and continuing through Week 13.
Results: ALPN-303 administration rapidly and potently reduced BM plasma cells, splenic germinal center B cells, follicular T helper cells, and plasmablasts in SRBC-immunized mice, often significantly more so than telitacicept and/or anti-mCD20 mAb. ALPN-303 also significantly reduced serum titers of anti-SRBC IgM, IgG1, IgG2a, and IgG2b as compared to all other treatment groups. In the bm12 model, ALPN-303 treatment significantly impacted the same key lymphocyte subsets affected in the SRBC model, and significantly reduced circulating anti-dsDNA antibodies (Figure 1) and total IgA, IgM, IgG1, IgG2b, and IgG3, and inhibited renal IgG deposits (Figure 1).

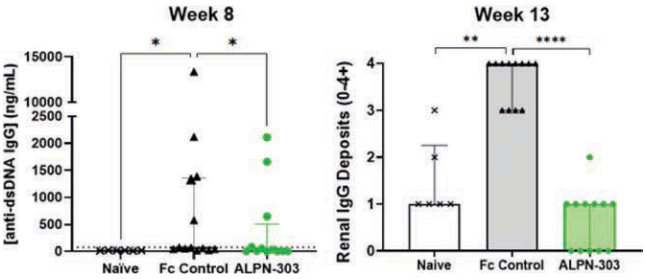

Figure 1. ALPN-303 treatment significantly reduces serum autoantibody titers and renal immune complex deposition in the inducible bm12 mouse model of lupus. *p<0.05, **p<0.01, ****p<0.0001 by the Kruskal-Wallis test.

Conclusion: ALPN-303 is an engineered, potent BAFF/APRIL antagonist that continues to consistently demonstrate encouraging immunomodulatory activity and efficacy in vitro and in vivo, as further demonstrated in the SRBC immunization and bm12 lupus models, with superiority to WT TACI-Fc and anti-CD20 comparators. ALPN-303 may thus be an attractive development candidate for

the treatment of multiple autoimmune and inflammatory diseases, particularly B cell- and/or autoantibody-related diseases such as SLE, Sjögren's syndrome, and other connective tissue diseases. A Phase 1 study of ALPN-303 in adult healthy volunteers (NCT05034484) is ongoing.

POS0095 CAMK4 CONTROLS T REGULATORY CELL METABOLISM AND DEFINES THEIR FUNCTION AND STABILITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Scherlinger[1,2], W. Pan[1], R. Hisada[1], A. Boulougoura[1], M. Vukelic[1,3], G. Tsokos[1]. *[1]Beth Israel Deaconess Medical Center (BIDMC), Rheumatology, Boston, United States of America; [2]Hôpital de Hautepierre - Hôpitaux Universitaires de Strasbourg, Rheumatology, Strasbourg, France; [3]Albert Einstein College, Rheumatology, Bronx, United States of America*

Background: Calcium/Calmodulin-dependent protein kinase IV (CaMK4) is a serine kinase expressed in CD4 T cells whom activity is increased in patients with active systemic lupus erythematosus (SLE). We have shown that CaMK4 negatively impacts T regulatory (Treg) cells differentiation and function in SLE, but the underlying mechanism remains unclear. Recent, data suggest that CaMK4 impacts cellular metabolism.

Objectives: Investigate how CaMK4 impacts Treg cell metabolism and its potential effect on Treg cell function.

Methods: We harvested $CD62L^+CD4^+$ T cells from *wild-type* (WT) or *Camk4*$^{-/-}$ mice and differentiated them *in vitro* into Treg (iTreg) cells. We assessed iTreg metabolism using Seahorse XF analyzer and mass spectrometry (metabolomics). Gene expression was assessed at the mRNA (RT-qPCR) and at the protein level (Western Blot). Phosphofructokinase activity was assessed by a colorimetric assay (Abcam). *In vitro* gene knockdown was conducted by transfecting a guide RNA (gRNA) in CRISPR/Cas9-expressing T cells. Treg cell function was evaluated by *in vitro* immunosuppressive assay and *in vivo* by the adoptive transfer of T conventional T and iTreg cells (8:1 ratio) in *Rag1*$^{-/-}$ mice to induce inflammatory colitis. The relevance of CaMK4 in SLE was evaluated *in vivo* using a T-cell specific knockdown of CaMK4 in the B6.lpr mouse model, and in humans by culturing SLE patient T cells with KN-93, a CaMK4 specific inhibitor.

Results: iTreg cells from *Camk4*$^{-/-}$ mice had decreased glycolysis and increased mitochondrial metabolism compared to WT mice. Metabolomics studies suggested decreased activity of the rate-limiting glycolysis enzyme phosphofructokinase platelet-type (PFKP). While PFKP mRNA and protein levels were similar between WT and *Camk4*$^{-/-}$ iTreg, we found that PFKP activity was significantly decreased in *Camk4*$^{-/-}$ iTreg, suggesting post-transcriptional control of PFKP activity. Mechanistically, immunoprecipitation experiments confirmed that CaMK4 interacted with PFKP, and phosphoproteomic study suggested that CaMK4 phosphorylated serine residue 539 of PFKP, a site known to control PFKP activity. Excitingly, PFKP's endproduct fructose 1,6-biphosphate negatively regulates the activation of the mitochondrial metabolism masterswitch AMPK, therefore linking decreased PFKP activity/glycolysis with increased mitochondrial metabolism in *Camk4*$^{-/-}$ Treg. To confirm the importance of PFKP in Treg biology, we confirmed that PFKP knockdown significantly improved iTreg function *in vitro* ($p < 0.01$) and *in vivo* using an adoptive CD4+ T cell transfer in to *Rag1*$^{-/-}$ mice (colitis model). Interestingly, iTreg lacking PFKP were transferred *Rag1*$^{-/-}$ mice were less likely to lose FoxP3 expression and to produce IL-17A, demonstrating higher Treg stability in an inflammatory environment. On a translational basis, lupus-prone B6.*lpr* mice with a T-cell specific CaMK4 knockdown displayed significantly less lupus manifestations. In human SLE, $CD4^+$ T cells had higher PFKP activity compared to healthy donors, and PFKP activity correlated with the SLE disease activity index (SLEDAI, $r= 0.47$; $p <0.05$). Finally, culture of SLE CD4+ T cells with KN-93 led to a significant decrease in PFKP activity ($p < 0.001$).

Conclusion: Increased CaMK4 activity in human SLE mediates Treg dysfunction and instability by altering PFKP activity. Restoring normal Treg metabolism by inhibition of CaMK4 or its downstream target PFKP represents a novel strategy for the treatment of SLE.

Background: Sjögren's Disease (SjD) and Systemic Lupus Erythematosus (SLE) are autoimmune diseases with several shared characteristics and similar genome-wide significant associations with the *DDX6-CXCR5* locus. DDX6 suppresses interferon-stimulated gene expression and CXCR5 regulates T cell functions implicated in autoimmunity.

Objectives: To identify and characterize functional SNPs in the *DDX6-CXCR5* interval.

Methods: ImmunoChip data from European populations (3785 SLE cases; 1916 SjD cases; 6893 controls) were imputed and SNP-trait associations tested. Bayesian statistics defined a credible SNP set that was refined using bioinformatic analyses (RegulomeDB, Haploreg, ENCODE, promoter capture Hi-C, eQTLs, etc.). Electrophoretic mobility shift assays (EMSAs) and luciferase expression assays were used to test allele-specific SNP function in EBV-transformed B (EBV B) cells, Daudi B cells, Jurkat T cells, THP1 monocytes, and A253 salivary gland cell lines. Chromatin conformation capture with quantitative PCR (3C-qPCR) was used to assess long-range chromatin interactions.

Results: Fine mapping of the SjD and SLE associations found similar SNP associations. Bioinformatic analyses identified 5 common SNPs with strong evidence of functionality in immune cell types: rs57494551 in an intron of DDX6, and rs4938572, rs4936443, rs7117261, and rs4938573 in the promoter/enhancer region of *DDX6* and *CXCR5*. EMSAs and luciferase experiments showed cell type-specific differences in protein binding and promoter or enhancer activity, respectively, at each SNP. Risk allele of rs57494551 increased enhancer activity in B cells and A253 cells ($p<0.001$), but decreased promoter activity in T cells and A253 cells ($p<0.01$). SNP rs4938572 is an eQTL of *DDX6* in T cells, and the risk allele significantly increased protein binding, promoter and enhancer activity in T cells ($p<0.01$). Risk allele of rs4938572 also increased promoter activity in A253 cells ($p<0.001$), but had no effect on promoter or enhancer activity in B cells. SNP rs4936443 showed no promoter or enhancer activity in immune cells, but the risk allele showed

significant promoter and enhancer (p<0.001) activity in A253 cells. SNP rs7117261 showed decreased enhancer activity in EBV B cells, T cells, and A253 cells (p<0.05) and increased promoter activity in A253 cells (p<0.001). SNP rs4938573 showed decreased promoter activity in EBV B cells, T cell and A253 cells (p<0.05), decreased promoter activity in EBV B cells (p<0.05), and increased enhancer activity in A253 cells (p<0.0001). Overall, A253 cells exhibited more allele-specific effects on promoter and enhancer activity across the five SNPs compared to tested immune cells. In addition to *DDX6* and *CXCR5*, rs57494551 and/or rs4938572 are reported eQTLs for several other genes of interest in the local chromatin regulatory network: *IL10RA* in T cells, *TRAPPC4* in salivary gland and activated macrophages, and long non-coding (lnc)RNA *AP002954.1* in T cells and whole blood. 3C-qPCR in EBV B and A253 cells showed that the two regulatory regions carrying rs4938572 or rs57494551 interacted with a region upstream of *DDX6* that includes *AP002954.1*. Hi-C data showed looping between *AP002954.1* and the regulatory region carrying rs4938572 and rs57494551 in T cells.

Conclusion: SjD and SLE share similar genomic architecture across the *DDX6-CXCR5* risk interval with several common SNPs showing immune and salivary gland cell type-specific allelic effects on protein binding and/or enhancer/promoter activity. Extensive bioinformatic analyses suggest that the SNPs likely work within the local chromatin regulatory network to regulate cell type-specific expression of several genes on the interval. Ongoing studies will use 3C-qPCR to assess allele-specific chromatin interactions between the SNPs and these genes in different cells types, and CRISPR to determine how the risk alleles alters expression.

Background: No immunomodulatory drug has ever demonstrated its efficacy in primary Sjögren's Syndrome (pSS). Drug repurposing, or drug repositioning, refers to the use in another disease of an existing drug, originally approved or evaluated in a different disease.

Objectives: The objective of our study was to repurpose existing therapeutic drugs in pSS using a transcriptomic approach.

Methods: We generated pSS transcriptomic signatures from peripheral blood samples of patients with pSS compared to healthy controls in two cohorts (ASSESS and a Norwegian cohort) and data mined available pSS transcriptomic signatures in public databases. We compared each disease signature to transcriptomic signatures, obtained from the biological action of 2837 drugs, 2160 knock-in and 3799 knock-down genes, available in the Connectivity Map database. A median similarity score with regard to disease signatures was computed for each candidate drug/gene. Drugs and genes were selected if p<0.05 and similarity score $>|80|$. If this score is sufficiently high and statistically significant (>80, p<0.05), the tested drug or gene, mimics the signature of the disease. Conversely, if this score is sufficiently low and statistically significant (<-80, p<0.05), the tested drug or gene inverts the signature of the disease and might represent a potential treatment or therapeutic target of interest (Figure 1).

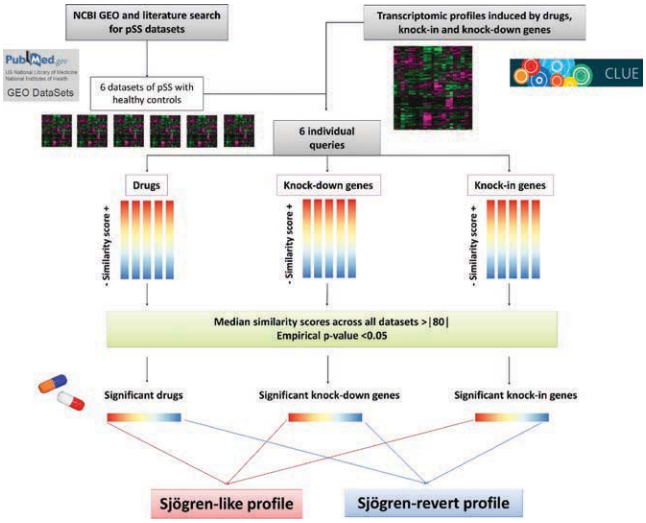

Figure 1. Methods of drug-repurposing transcriptomic analysis (adapted from Toro-Dominguez et al, Arthritis Res Ther 2017;19:54)

Results: 1091 peripheral blood transcriptomes were analyzed from 6 independent studies (906 patients with pSS and 185 healthy controls). Our analysis identified 11 transcriptomic drug signatures significantly associated with pSS signature. We identified 72 transcriptomic knock-in (11) or knock-down (61) gene signatures significantly associated with that of pSS, including 21 with a negative similarity score (Table 1).

Table 1. Knock-down and knock-in genes significantly associated with the pSS transcriptomic signatures

Type of experiment	Similarity score	Genes	Number of genes
Knock-in	+	IFNG, DUSP28, IFNB1, LYN, BCL2L2, TNFRSF1A, CD40, BCL10, NLK, ZNF398	**10**
	-	SLC52A2	**1**
			11
Knock-down	+	SLC25A14, GOLIM4, DTYMK, DCXR, RRM2, IMPA1, CLTB, F12, CAB39, ID1, ISOC1, UBAP1, HIGD2A, UFD1L, SOD2, BTG1, PRKCI, HIST2H2BE, NISCH, TEAD4, MTX2, TYK2, GTF2B, NDUFS7, NNT, ACADSB, GSTP1, HOMER2, SORBS3, PCK2, PHB2, PDXK, TES, TM9SF2, TBX2, HOXA6, KIF2C, MED1, NR2F6, CD14, BECN1	**41**
	-	TM9SF3, E2F3, PRMT3, KD, PKN2, SUCLA2, CD44, GRN, SP3, ATP5S, MYCBP2, TRAF7, POLA2, ADRB2, PSMG1, PPP2R3C, PMAIP1, ETFA, ANKRD37, SPECC1L	**20**
			61

Type I and II interferons were highly ranked (similarity score >99), and their overexpression mimicked the disease signature. CD40 appeared also as a very relevant target (similarity score = 98.8). Three drugs had a significant negative similarity score: ampicillin (-88.69, p=0.0019), amylocaine (-88.28, p=0.0026), and droxinostat (-85.42, p=0.0027). Droxinostat is a HDAC inhibitor. HDAC activity has been shown to be an essential element of the coactivation system for IFN-induced gene regulation and the IFN-induced innate immune response.

Conclusion: This first drug repositioning transcriptomic approach in Sjögren's syndrome confirms the interest of targeting interferons and identifies histone deacetylases as potential therapeutic targets.

Background: Sjögren's disease (SjD) is an autoimmune disease characterized by exocrine gland dysfunction. Long non-coding RNAs (lncRNAs) are a functionally diverse class of non-protein coding RNAs that are longer than 200 nucleotides. Our previous study using whole blood RNA-seq found that lncRNA, *LINC01871*, is overexpressed in SjD relative to controls [1]. CRISPR-Cas9 targeting in HSB2 T cells yielded a *LINC01871*$^{-/-}$ clone with altered expression of many genes implicated in immune regulation [1].
Objectives: The goal of this study was to analyze the gene expression perturbations resulting from the loss of *LINC01871* and to characterize the regulation of LINC01871 in both the *LINC01871*$^{-/-}$ clone and primary human T cells in response to immune stimuli.
Methods: Flow cytometry and LegendPlex bead assays were used to compare surface and secreted protein expression changes, respectively, in *LINC01871*$^{-/-}$ cells and the parental HSB2 cells. Parental HSB2 T cells, *LINC01871*$^{-/-}$ cells, Kasumi-3 myeloid cells, and primary human T cells were stimulated in vitro and changes in gene expression were measured over time using qRT-PCR. Responses to interferons (IFN) were assessed using universal type I IFN (IFNα) or IFNγ. TCR signaling responses were assessed using PMA/Ionomycin (PMA/I) or anti-CD3/CD28 stimulations in the presence or absence of the calcineurin inhibitor, FK506.
Results: Previous RNA-seq analysis found 1166 differentially expressed (DE) transcripts ($\log_2$FC ≥1 or ≤-1; p_{adj} ≤0.05) in *LINC01871*$^{-/-}$ cells compared to parental HSB2 cells, including many prominent immune regulatory genes. Changes in the basal expression of 7 proteins in *LINC01871*$^{-/-}$ cells were confirmed using flow cytometry (significantly decreased: CD8a (p=0.0004), CD30 (p=0.0008), CXCR3 (p=0.037), T-Bet (p=0.0002), and Aiolos (p=0.02); significantly increased: CD226 (p=0.0059) and CD44 (p=0.024)). Analysis of *LINC01871*$^{-/-}$ cells revealed a growth inhibition in *LINC01871*$^{-/-}$ cells (p=0.0014 at 72h), in which multiple secreted growth and adhesion factors were significantly reduced: GM-CSF (p=2.0e-06), M-CSF (p=2.7e-09), IGBPF4 (p=1.2e-07), s-ICAM1 (p=0.015), MMP9 (p=3.0e-14), and MMP2 (p=6e-08). In contrast, the IL-6 cytokine family member, LIF, was significantly increased in *LINC01871*$^{-/-}$ cells (p=1.2e-07). Because HSB2 cells were not responsive to all IFNs, IFN-mediated regulation of *LINC01871* expression was examined in the Kasumi-3 myeloid cell line. While *LINC01871* expression was not modulated by type I IFN stimulation, it was robustly responsive to IFNγ treatment. Since *LINC01871* was expressed in T cells and implicated in T cell pathways, responses to TCR signaling pathways were characterized in HSB2 cells or purified primary human T cells treated with PMA/I. In both cell types, *LINC01871* exhibited a prolonged decrease in expression that was abrogated by concurrent treatment with FK506, indicating that *LINC01871* is regulated by calcineurin signaling. Treatment of primary human T cells with anti-CD3/CD28 to mimic true TCR engagement resulted in a modest decrease of *LINC01871* expression at early time points, followed by an increase in expression with longer stimulation (2d).
Conclusion: Our findings suggest that *LINC01871* is a potential mediator of the dysregulated T cell inflammatory response pathways implicated in SjD pathogenesis. *LINC01871* influences the expression of many important immune cell genes and growth factors, is inducible by IFNγ, and is regulated directly by calcineurin signaling and TCR ligand engagement. Although *LINC01871* functions are still unknown, observed *LINC01871* overexpression in whole blood of SjD cases and after prolonged TCR stimulation in primary human T cells suggests that it could be a biomarker of SjD.

POS0099 THE CELLULAR METABOLISM OF SLE NK CELLS IS PRIMARILY ALTERED AT THE LEVEL OF MITOCHONDRIAL RESPIRATION.

N. Fluder[1], M. Humbel[1], F. Bellanger[1], A. Horisberger[1], C. Fenwick[1], C. Ribi[1], D. Comte[1]. *[1]Lausanne University Hospital, Immunology and Allergy, Lausanne, Switzerland*

Background: Systemic lupus erythematosus (SLE) is an inflammatory autoimmune disease, involving the development of autoreactive cells and autoantibodies. Natural Killer (NK) cells are innate immune cells that mediate the interaction between the innate and adaptive immune system, however their role in SLE is incompletely understood. SLE NK cells are decreased in peripheral blood, exhibit reduced cytotoxicity, and impaired cytokine production (1, 2). Furthermore, SLE NK cells present phenotypic alterations: increased expression of CD38 and altered upregulation of SLAMF7 after activation (3). To date, few studies evaluated the molecular mechanisms underlying NK cell dysfunction in SLE.
Objectives: We examined immunometabolic alterations of SLE NK cells. First, we characterized the cellular metabolism of SLE NK cells by assessing glycolysis and oxidative phosphorylation (OXPHOS) at basal level. Then, we evaluated how cellular metabolism can be manipulated to enhance NK cell function. In this perspective, we examined how the ligation of CD38 with daratumumab (DARA) and SLAMF7 with elotuzumab (ELO) modulate glycolysis and OXPHOS.
Methods: NK cells of cryopreserved PBMC from SLE patients were isolated. Glycolysis and OXPHOS were studied using XF^{e}96 Seahorse. Expression of metabolic receptors (CD71, GLUT-1, CD98), mitochondrial function (mitochondrial membrane potential, mass) and calcium influx were investigated

by FACS. Mitochondrial structure was evaluated by electron and confocal microscopy.

Results: First, we examined the cellular metabolism of SLE NK cells compared to healthy cells. We observed that OXPHOS is significantly increased in SLE NK cells (Figure 1A), whereas glycolysis was normal (Figure 1B). Furthermore, the mitochondrial mass and membrane potential (by FACS (Figure 1C) and confocal microscopy) were increased in SLE. Electron microscope imaging showed profound alterations in SLE NK cell mitochondrial ultrastructure (Figure 1D). No significant differences in the expression of key metabolite transporters involved in mitochondrial fueling (CD71, GLUT-1, CD98) was observed in SLE NK cells compared to healthy controls.

Second, we examined how ligation of DARA and ELO influences the metabolism of healthy NK cells. Our data showed that ELO primarily enhances NK cell OXPHOS (Figure 1E), whereas DARA mainly increases glycolysis. Consistently, ELO also increases mitochondrial membrane potential and expression of metabolite transporters CD71, GLUT-1 and CD98. Next, we examined the effect of DARA and ELO on SLE NK cells. While stimulation with DARA adequately increases glycolysis in SLE NK cells, engagement with ELO fails to properly increase OXPHOS (Figure 1F), expression of cell surface transporters, mitochondrial membrane potential and mass.

Conclusion: Our data suggest that SLE NK cells exhibit alterations in cellular metabolism, primarily involving mitochondrial respiration. In contrast, glucose metabolism is similar to that of healthy NK cells. Additionally, ELO and DARA mediate the activation of healthy NK cells through the engagement of different metabolic pathways: OXPHOS and glycolysis, respectively. Therefore, priming SLE NK cells with ELO is unable to adequately engage their dysfunctional mitochondrial respiration. These findings provide important insights on the alteration present in SLE NK cells and contribute to a better understanding of the pathogenesis of the disease.

POS0100 ACTIVATION OF THE CELLULAR INTEGRATED STRESS RESPONSE IN LABIAL SALIVARY GLANDS FROM SJÖGREN'S SYNDROME PATIENTS.

P. Carvajal[1], V. Bahamondes[2,3], D. Jara[1], M. J. Barrera[4], I. Castro[3], S. Aguilera[5], S. González[6], C. Molina[4], M. J. González[1]. *[1]Universidad de Chile, Programa de Biología Celular y Molecular, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile; [2]Ohio University, Edison Biotechnology Institute, Athens, Ohio, United States of America; [3]Universidad de Chile, Departamento de Tecnología Médica, Facultad de Medicina, Santiago, Chile; [4]Universidad San Sebastián, Facultad de Odontología, Santiago, Chile; [5]Clinica Indisa, Reumatología, Santiago, Chile; [6]Universidad Mayor, Escuela de Odontología, Facultad de Ciencias, Santiago, Chile*

Background: Sjögren's syndrome (SS) is a chronic autoimmune disease characterized by inflammation of the exocrine glands and severe symptoms of eye and mouth dryness. Disorders in the saliva secretion process have been associated with oxidative and endoplasmic reticulum (ER) stress in combination with inflammatory responses. The integrated stress response (ISR) is a mechanism that allows cells to modify their gene expression program to restore homeostasis and promote their survival against various extrinsic and intrinsic stress signals, such as hypoxia, nutrient deprivation, viral infections, inflammatory factors (cytokines, chemokines, inflammasomes), and accumulation of unfolded proteins in the ER, among others (1). The ISR is regulated by four kinases: PERK, PKR, HRI and GCN2, that dimerize and autophosphorylate to become active and each one responds to different stress stimuli. The signaling pathways that are activated in response to stress factors stimulate the phosphorylation of eIF2α, which causes a transient inhibition of global protein synthesis and induction of synthesis of some specific genes like ATF4 and NRF2. ATF4 induces the transcription of genes involved in metabolism and nutrient uptake, redox status, and regulation of apoptosis. Dephosphorylation of eIF2α is the ISR termination signal to restore protein synthesis and is mediated by the PP1 complex, which recruits the catalytic subunit PP1c and one of its two regulatory subunits: GADD34 or CREP.

Objectives: To evaluate the presence and functional state (phosphorylation) of the ISR sensing kinases: PERK, PKR, HRI and GCN2; the levels of eIF2α /p-eIF2α and the key ISR transcription factors ATF4 and NRF2, as well as subunits of the complex involved in the ISR termination: PP1c, GADD34 and CREP in labial salivary glands (LSG) of SS-patients.

Methods: Biopsies of LSG from 12 SS-patients and 11 control subjects were studied. The levels of mRNA, protein and phospho (p)-protein of the ISR components were determined by RT-qPCR and Western blotting.

Results: Our results show increased levels of p-PERK/PERK ratio (11/11), PKR (7/11), p-PKR (7/11), p-PKR/PKR ratio (7/11), eIF2α (5/11), p-eIF2α (5/11) and ATF4 (11/11) in LSG from SS-patients compared to control subjects. No significant changes were found in mRNA levels of HRI, GCN2, and GADD34 between LSG from SS-patients and control subjects. Decreased protein levels of HRI (8/12), p-GCN2 (6/11), eIF2α (6/11), p-eIF2α (6/11), NRF2 (11/12), and p-NRF2 (12/12) were found in LSG showing scarce parenchyma and high fibrosis and fat infiltration. On the other hand, PP1c and CREP showed decreased mRNA and protein levels in all SS-patients LSG. Interestingly, Ro autoantibodies and focus score were negatively correlated with PP1c and NRF2 mRNA and protein levels whereas positively correlated with PKR mRNA levels.

Conclusion: The overexpression and activation of some ISR kinases together with the decrease in the PP1c/CREP phosphatase complex suggests a continuous activation of ISR, resulting in p-eIF2α to remain activated in LSG from SS-patients. This would explain the high protein levels of ATF4 and of target genes involved in the antioxidant response in LSG from SS patients suggesting that ISR activation plays a key role in pro-survival response to cellular stress.

POS0101 POTENTIAL INVOLVEMENT OF IL-40 AND IL-40 PRODUCING CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND LUPUS ASSOCIATED NEPHRITIS

C. Rizzo[1], L. La Barbera[1], M. Lo Pizzo[2], L. Mohammadnezhad[2], V. L. Lentini[3], D. Donzella[1], F. Ciccia[4], S. Fasano[4], G. Guggino[1]. *[1]University of Palermo, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Rheumatology Unit, Palermo, Italy; [2]University of Palermo, Biomedicine, Neuroscience and Advanced Diagnostic, Palermo, Italy; [3]Azienda Ospedaliera Ospedali Riuniti Villa Sofia Cervello, Pathology Unit, Palermo, Italy; [4]University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Naples, Italy*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder, characterized by a remarkable heterogeneity of clinical presentations. Glomerulonephritis (GN) remains a leading cause of morbidity and mortality in SLE, influencing long-term prognosis. The alteration of both innate and adaptive immune responses plays a pivotal role in SLE pathophysiology [1]. B lymphocytes are mainly involved in SLE through the production of autoantibodies but recent evidence suggests an effector role of these cells in cytokine production. IL-40 is a recently discovered cytokine, produced by B cells and involved in their homeostasis, that may participate in the pathogenesis of B-mediated autoimmune diseases, such as SLE [2].
Objectives: The purpose of this study was to evaluate the role of IL-40 in the pathogenesis of SLE, with a specific focus on renal involvement.
Methods: Peripheral blood and urine samples were collected from 10 consecutive SLE patients and 10 healthy controls; kidney biopsy specimens were obtained from 3 SLE patients and 3 controls. The concentration of IL-40 in serum and urine samples was evaluated by ELISA. IL-40 production by monocytes, B cells and T cells was assessed by flow cytometry at day 0 and after *in vitro* stimulation. Immunohistochemistry on kidney tissue was also performed to evaluate IL-40 expression.
Results: IL-40 levels were reduced in the serum of patients with active GN. This reduction was further observed in the serum of patients with previous GN. In the serum of active SLE patients, without renal involvement, the concentration of IL-40 did not change significantly compared to controls. Urinary levels of IL-40 showed no significant changes compared to controls. Consistently, immunohistochemistry on kidney showed the expression of IL-40 only in SLE patients (Figure 1). Flow cytometric analysis on T cells, B cells and monocytes isolated from peripheral blood of SLE patients with active GN did not show production of IL-40.

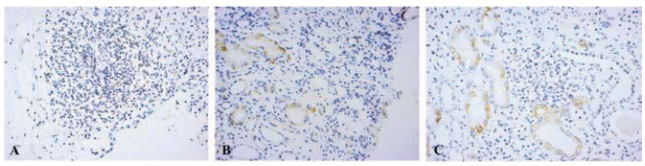

Figure 1. IL-40 overexpression in lupus nephritis at tissue level. Kidney biopsies stained for IL-40 in controls (**A**), Class III lupus nephritis (**B**) and Class V lupus nephritis (**C**) showed intense IL-40 positivity in lupus nephritis (**B, C**) compared to controls (**A**).

Conclusion: To the best of our knowledge this is the first demonstration of IL-40 expression at kidney level in SLE associated nephritis. These preliminary data suggest an active role of IL-40 in SLE, with specific focus on active kidney disease. Our results highlight a potential use of IL-40 as a marker of active GN, although its specific mechanism of action needs to be further elucidated.

POS0102 GLOBAL CHARACTERIZATION OF SALIVARY GLANDS IMMUNE MICROENVIRONMENT IN PRIMARY SJÖGREN'S SYNDROME BY SINGLE-CELL SEQUENCING

N. Xiang[1], X. Hao[2], G. Chuang[2], L. Wang[1], Z. Zhou[1], G. Wang[1], Q. Kun[2], X. Li[1]. *[1]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Department of Rheumatology and Immunology, Hefei, China; [2]University of Science and Technology of China, CAS Center for Excellence in Molecular Cell Sciences, the CAS Key Laboratory of Innate Immunity and Chronic Disease, Hefei, China*

Background: Primary Sjögren's syndrome (pSS) is a heterogeneous, chronic, complex systemic autoimmune disease. The hallmark symptom of the disease is exocrinopathy, chiefly salivary and lachrymal glands, which often results in dryness of the mouth and eyes. As of today, although a lot of genetic and epigenetic studies have reveal the complexity of pSS to a certain extent, but the knowledge of existing pSS disease heterogeneity is still limited and the immune mechanisms of salivary glands (SG) injury have been challenging to clarify.
Objectives: Single-cell RNA sequencing (scRNA-seq) is a powerful tool capable of defining cell types and states on the basis of their individual transcriptome in a given sample from health and disease. To characterize the salivary glands immune microenvironment of patients with pSS, we performed droplet-based single cell mRNA sequencing (scRNA-seq) (10X Genomics) to provide a deeper insight into the cellular and molecular characteristics of salivary glands from pSS patients.
Methods: 11 patients and 5 non-pSS controls were recruited from the The First Affiliated Hospital of USTC. The non-pSS were subjects who had experienced subjective symptoms of dryness, but no not meet any of the classification criteria of pSS. The clinical characteristics and laboratory findings of enrolled patients were also collected. After resection, salivary glands tissue samples were obtained after labial gland biopsy, rapidly digested to a single-cell suspension and subjected to scRNA-seq using the 10X platform. After rigorous quality control (QC) definition, low-quality cells were filtered. Following gene expression normalization for read depth and mitochondrial read count, we applied principle component analysis on genes variably expressed across all 72,853 cell.
Results: A total of 72,853 cells were obtained from all salivary glands samples. Our results revealed 12 major unique cell populations of salivary glands cell, including T cells, B cells, plasma cells, epithelial cells, myoepithelial cells, endothelial cells, myofibroblast, pericytes, melanocytes, fibroblast, myeloid cells and a cluster of unknown cells. As expected, lymphocytes (T and B cell populations) were significant increase in the salivary glands of patients with pSS. For further subsets analysis, we identify 41 subsets, including novel subpopulations in cell types hitherto considered to be homogeneous, as well as transcription factors underlying their heterogeneity. Strikingly, we found that differentially expressed genes (DEGs) that myoepithelial cells uniquely downregulated in pSS patients were involved in regeneration, stem cell population maintenance, cell division, and epithelial cell proliferation. This indicated an impaired stem cell property and regeneration capacity of myoepithelial cells in the SG of pSS patients which may result in the reduction of normal epithelial cells differentiation and proliferation. Our results identified three distinct endothelial subtypes according to the differentially expressed cell markers. *ACKR1*$^{+}$ endothelial cells were expanded in the SG of pSS patients which may enhance Leukocyte transendothelial migration. A clear interferon response was observed in most celltypes. We also found a significantly expand *PD-1*^{hi}*CXCR5*$^{-}$CD4^{+}T peripheral helper (Tph), *GZMK*$^{+}$CD8^{+} T cells and a patient-specific fibroblasts in pSS patients. Cellular interaction analysis of SG revealed a strong interaction between epithelial cells and immune cells from pSS patients through *CD74-MIF, MIF-TNFRSF14* and *HLA-C-FAM3C* receptor/ ligand pairs. Chemokine receptors *CXCR4* were broadly expressed in SG immune cells implying a potentially central role in cell trafficking.
Conclusion: This resource provides deeper insights into pSS salivary glands immune microenvironment that will be helpful in understanding of the disease heterogeneity and advancing pSS therapy.

Rheumatoid arthritis prognosis, predictors and outcome

POS0103 IN RHEUMATOID ARTHRITIS, THE ASSOCIATION BETWEEN ANTI-MODIFIED PROTEIN ANTIBODIES AND LONG-TERM OUTCOMES IS DOMINATED BY THE EFFECT OF ANTI-CITRULLINATED PROTEIN ANTIBODIES

T. J. Van Wesemael[1], M. Verstappen[1], R. Knevel[1], A. Van der Helm-van Mil[1], T. Huizinga[1], R. Toes[1], D. Van der Woude[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: In rheumatoid arthritis (RA) many patients harbor autoantibodies against post translationally modified proteins (anti-modified protein antibodies (AMPA)): anti-citrullinated protein antibodies (ACPA), anti-carbamylated protein antibodies (anti-CarP) and anti-acetylated protein antibodies (AAPA). All three AMPA have been described to be associated with an increase in radiographic joint damage and ACPA also with a lower chance of obtaining sustained drugfree remission (SDFR). However, it is unclear whether the effects of these autoantibodies are independent of each other, and whether testing for all three AMPA offers additional information regarding these clinical outcomes.

Objectives: To investigate the individual and combined associations of AMPA with radiological progression and SDFR in RA.

Methods: In 612 RA patients from the Leiden Early Arthritis Clinic, we measured ACPA IgG with anti-CCP2-assays, anti-CarP IgG using homocitrullinated and native (as a control) fetal calf serum, and AAPA IgG by means of novel assays consisting of cyclic peptides with either acetylated or norleucine residues (as a control). Sharp-van der Heijde scores (SHS) were determined in 2685 sets of radiographs with yearly intervals for 7 years. The association of AMPA with SHS was assessed with a multivariate normal regression model. SDFR was defined as the absence of clinical synovitis after discontinuation of DMARD treatment. The association of SDFR with autoantibody-status was assessed with Kaplan-Meier curves. The very small number of patients single-positive for AAPA (n=4, 1%) precluded analyses in this subgroup.

Results: The prevalence of autoantibodies is shown in Table 1. A higher SHS was found in patients with autoantibodies compared to patients without antibodies, and in triple-positive versus single-positive patients (Figure 1A, p=0.04). To investigate if the higher SHS was due to the number of autoantibodies or a specific autoantibody, analyses were stratified for all three AMPAs. Interestingly, no difference was found in SHS between all ACPA-positive strata (Figure 1B). In the ACPA-negative stratum, a significant difference was found between patients with zero antibodies and solely anti-CarP (p=0.02).

Table 1. Prevalence of autoantibodies in 612 rheumatoid arthritis patients in the EAC cohort

Autoantibody status	n (%)
ACPA-positive	316 (52)
Anti-CarP-positive	270 (44)
AAPA-positive	208 (34)
ACPA-AAPA-CarP-	255 (42)
ACPA+AAPA-CarP-	46 (7)
ACPA-**AAPA+**CarP-	4 (1)
ACPA-AAPA-**CarP+**	37 (6)
ACPA+AAPA+CarP-	37 (6)
ACPA+AAPA-**CarP+**	66 (11)
ACPA-**AAPA+CarP+**	- (0)
ACPA+AAPA+CarP+	167 (27)

EAC: early arthritis clinic, ACPA: anti-citrullinated protein antibodies, anti-CarP/CarP: anti-carbamylated protein antibodies, AAPA: anti-acetylated protein antibodies

The chance to obtain SDFR was lower in all antibody-positive groups compared to the autoantibody negative group. Moreover less triple-antibody-positive patients than single-antibody-positive patients achieved SDFR (P<0.001), Figure 1C. After stratification for AMPA, no difference was found in the percentage of SDFR in all ACPA-positive strata, or in the ACPA-negative stratum, Figure 1D.

Conclusion: In ACPA-positive patients, the presence of other AMPA influences neither radiographic progression, nor the chance of SDFR. Thus, long-term clinical phenotype in RA is particularly dependent on the presence of ACPA, and less on the presence of other AMPA. Therefore, there appears to be no added value of testing the other AMPA for predicting clinical outcome in ACPA-positive patients.

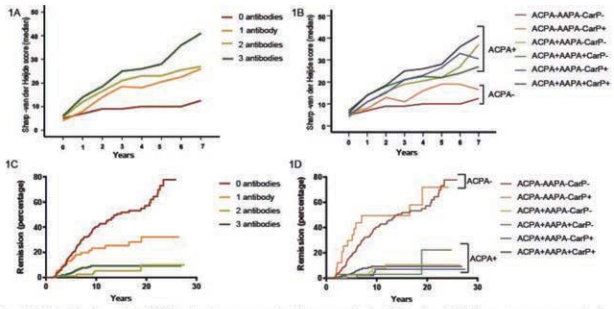

Figure 1. Sustained drug free remission (SDFR) and erosion scores according to the presence of autoantibodies. Figure 1A: Median erosion scores assessed by the Sharp-van der Heijde method (SHS) during the disease course stratified for number of autoantibodies (n=503). All comparisons between groups were statistically significant except between 1 versus 2 and 2 versus 3 antibodies. Figure 1B: Median erosion scores assessed by the SHS during the disease course stratified for anti-acetylated protein antibodies (ACPA), anti-acetylated protein antibodies (AAPA) and anti-carbamylated protein antibodies (anti-CarP) (n=499). SHS did not differ significantly between all ACPA-positive strata, in the ACPA-negative stratum a significant difference was found between 0 antibodies and anti-CarP single-positive patients, (p=0.02). Figure 1C: Kaplan-Meijer curve of the percentage of patients that achieved SDFR stratified for the number of autoantibodies (n=565). All comparisons between groups were statistically significant except between 1 versus 2 antibodies. Figure 1D: Kaplan-Meijer curve of the percentage of patients that achieves SDFR stratified for ACPA, AAPA and anti-CarP (n=561). The percentage of SDFR did not differ between all ACPA-positive strata and did also not differ between the ACPA-negative strata.

POS0104 ACPA-NEGATIVE AND ACPA-POSITIVE RA-PATIENTS ACHIEVING DISEASE RESOLUTION DEMONSTRATE DISTINCT PATTERNS OF MRI-DETECTED JOINT-INFLAMMATION

M. Verstappen[1], X. Matthijssen[1], S. Connolly[2], M. A. Maldonado[2], T. Huizinga[1], A. Van der Helm-van Mil[1,3]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands;* [2]*Bristel Myers Squibb, Immunology and Fibrosis, Philadelphia, United States of America;* [3]*Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: Sustained DMARD-free remission (SDFR), the sustained absence of clinical-synovitis after DMARD-discontinuation, is increasingly achievable in RA. However, prevalence differs significantly between ACPA-negative (40%) and ACPA-positive RA (5-10%). In addition, early-DAS-remission ($DAS_{4months}$<1.6) associates with SDFR in ACPA-negative RA but not in ACPA-positive RA.[1] Based on these differences, we hypothesized that longitudinal patterns of local tissue-inflammation (synovitis/tenosynovitis/osteitis) might also differ between ACPA-negative and ACPA-positive RA-patients achieving SDFR.

Objectives: With the ultimate aim to increase understanding of disease-resolution in RA, we studied MRI-detected joint-inflammation over time in relation to SDFR-development in ACPA-negative RA and ACPA-positive RA.

Methods: 198 RA-patients (94 ACPA-negative and 104 ACPA-positive) underwent repeated MRIs (0/4/12/24-months) and were followed on SDFR-development. The course of MRI-detected total-inflammation, and synovitis/tenosynovitis/osteitis individually, were compared between RA-patients who did and did not achieve SDFR, using Poisson-mixed-models. 170 ACPA-positive RA-patients from the AVERT-1 were studied as ACPA-positive validation-population.

Results: In ACPA-negative RA, patients achieving SDFR had similar baseline total inflammation-levels, which declined 2.0-times stronger in the first-year of DMARD-treatment (IRR 0.50, 95%CI;0.32-0.77, p<0.01) compared to patients without SDFR. This stronger decline was seen in tenosynovitis/synovitis/osteitis. In contrast, ACPA-positive RA-patients achieving SDFR, had already lower inflammation-levels (especially synovitis/osteitis) at disease-presentation (IRR 0.45, 95%CI;0.24-0.86, p=0.02) compared to non-SDFR patients, and remained lower during follow-up (p=0.02). Similar results were found in the ACPA-positive validation-population.

Conclusion: Compared to RA-patients without disease-resolution, ACPA-positive RA-patients achieving SDFR have less severe joint-inflammation from diagnosis onwards, whilst ACPA-negative RA-patients present with similar inflammation-levels but demonstrate a stronger decline in the first year of DMARD-therapy. These different trajectories suggest that mechanisms underlying resolution of RA-chronicity in both RA-subsets might be different and indicates the relevance of the total inflammatory-load in ACPA-positive-RA.

POS0105 IMMUNOLOGICAL AND TISSUE DERIVED BIOMARKERS OF EARLY RESPONSE IN MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS TREATED WITH JAK-INHIBITORS

S. Perniola[1,2], B. Tolusso[2], C. Dl Mario[2,3], M. Gessi[4], D. Bruno[1,2], V. Varriano[1,3], A. Paglionico[1], L. Petricca[5], M. R. Gigante[5], M. A. D'agostino[3,5], S. Alivernini[2,3,5], E. Gremese[1,2,3]. *[1]Clinical Immunology Unit, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Rome, Italy; [2]Immunology Research Core Facility, Gemelli Science and Technology Park (GSTep) - Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Rome, Italy; [3]Department of Medicine, Università Cattolica del Sacro Cuore, Rome, Italy; [4]Institute of Pathology, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Rome, Italy; [5]Division of Rheumatology, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Rome, Italy*

Background: Among Janus kinase inhibitors (JAKi) approved for Rheumatoid Arthritis (RA) treatment, tofacitinib and baricitinib are considered as pan-JAKi (pJAKi) while upadacitinib and filgotinib as selective anti-JAK1 (sJAKi) drugs. To date, despite ≈30% of RA patients exposed to JAKi achieve DAS28-CRP remission at 12 weeks, there is still lack of predictive biomarkers of response in RA treated with distinct JAKi.

Objectives: To determine whether pre-treatment immunological and synovial tissue features can predict clinical improvement in moderate-to-severe RA treated with JAKi.

Methods: Among 174 RA patients treated with JAKi, 84 underwent peripheral blood (PB) drawing and US-guided synovial tissue (ST) biopsy. Demographic, clinical and immunological features were collected for each patient at baseline and after 12 weeks. The distribution of PB-derived B lymphocytes subsets was assessed by flow cytometry, using CD27/IgD classification. Synovitis degree assessment was determined using Krenn score (KSS) by trained pathologist, blinded to clinical characteristics.

Results: Among enrolled RA patients, 82.7% was treated with pJAKi and 17.3% with sJAKi. Moreover, 35.6% of RA patients was b/ts-DMARDs naïve, 18.4% b/ts-DMARDs non-responder and 46.0% was difficult-to-treat (D2T) RA. In the whole cohort, 49.2% and 50.8% of RA patients achieved DAS28-CRP and CDAI low disease activity (LDA), respectively, after 12 weeks of JAKi treatment. Moreover, 37.7% and 5.9% of RA patients achieved DAS28-CRP and CDAI remission (REM), respectively, after 12 weeks of JAKi treatment regardless to JAKi category. Considering the immunological profile, RA patients achieving CDAI LDA were more likely rheumatoid factor (60.0%) and ACPA positive (60.5%) compared to RA patients not achieving this outcome (RF: 40.0%, p= 0.03 and ACPA: 39.5%, p= 0.02). Considering PB-derived B cell phenotype, b/ts-DMARDs naïve RA achieving DAS28-CRP LDA at 12 week had pre-treatment lower unswitched memory B ($IgD^{pos}CD27^{pos}$) cell rate (6.91±7.70%) compared to b/ts-DMARDs naïve RA not achieving the same outcome (13.21±5.68%, p= 0.009). ROC analysis identified a cut-off value of 6.89% for $IgD^{pos}CD27^{pos}$ cells discriminating b/ts-DMARDs naïve RA achieving DAS28-CRP LDA at 12 week [AUC: 0.174±0.086; p= 0.008; OR(95%-CIs): 18.20 (1.761-188.069)]. Furthermore, b/ts-DMARDs naïve RA achieving DAS28-CRP REM at 12-week follow up visit, had PB enrichment of naïve B cells ($IgD^{pos}CD27^{neg}$: 68.08±17.38%) and lower percentage of unswitched memory B lymphocytes (5.10±4.29%) compared to RA not achieving the same outcome ($IgD^{pos}CD27^{neg}$: 54.68±16.16%, p= 0.05; $IgD^{pos}CD27^{pos}$: 13.96±8.34%, p= 0.001) [$IgD^{pos}CD27^{neg}$ cut-off: 62.6%, AUC:0.727±0.101, p=0.05; OR(95%CIs): 7.33(1.272-42.294); $IgD^{pos}CD27^{pos}$ cut-off: 6.89%, AUC: 0.139±0.073, p= 0.002; OR(95%CIs): 12.37 (1.828-83.767)]. Interestingly, considering the D2T RA subgroup, patients achieving DAS28-CRP LDA at 12 week follow up had lower rates of PB-derived $IgD^{neg}CD27^{neg}$ B cells (3.83±0.96%) compared to RA not achieving the same outcome (7.25±2.83%, p= 0.04; cut-off: 5.46%, AUC: 0.083±0.095, p=0.041). Considering the pre-treatment synovitis degree, b/ts-DMARDs naïve RA achieving CDAI LDA status had significantly higher KSS at baseline (3.8±2.2) compared to RA not achieving the same outcome [1.7±1.4, p= 0.02; KSS cut-off: 3.00, AUC: 0.795±0.097; p=0.018; OR(95%CIs): 14.0 (1.39-141.49)]. Finally, no significant associations were observed between PB-derived B cell subpopulations rate and synovitis degree both in the whole RA cohort as well as stratifying patients for disease phase.

Conclusion: Pre-treatment immunological profile, peripheral blood-derived B cell phenotype and synovitis degree are associated with the early achievement of at least DAS28-CRP/CDAI LDA in RA patients receiving JAKi despite their selectivity.

Ohrndorf[1]on behalf of AG Ohrndorf - Imaging (Development and Evaluation of Imaging Approaches in Rheumatic Diseases). *[1]Charité Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [2]Universitätsklinikum Leipzig, Department of Endocrinology, Nephrology, Rheumatology, Leipzig, Germany; [3]Biostatistics Tubingen, Biostatistics, Tubingen, Germany; [4]MC Groep Hospitals, Department of Rheumatology, Lelystad, Netherlands; [5]First Faculty of Medicine, Department of Rheumatology, Prague, Czech Republic; [6]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway; [7]University of Oslo, Faculty of Medicine, Oslo, Netherlands; [8]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [9]Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands; [10]Park-Klinik Weißensee, Department of Internal Medicine - Rheumatology and Clinical Immunology, Berlin, Germany*

Background: There is no international consensus on an optimal ultrasound scoring system in patients with rheumatoid arthritis (RA) yet.

Objectives: To assess the musculoskeletal ultrasound score on seven joints ('US7 score') (1) for the identification of the most frequently pathologic and

responsive joint regions during 3 and 6 months of therapy in order to optimize the score. Furthermore, to evaluate the impact of disease duration on the performance of the score.

Methods: RA patients were recruited from 54 German rheumatology centers when starting or changing DMARD therapy. Patients were assessed by the US7 score in greyscale (GS) and power Doppler (PD) at baseline, after 3 and 6 months. The frequency of pathologic joint/tendon regions and their responsiveness to therapy were assessed including the comparison of palmar vs. dorsal regions.

Differences between the palmar and the dorsal sides were analyzed using Chi-square test, the gradings of the US-joint inflammation were compared between baseline, 3 months, and 6 months by Friedman test with Dunn test as post-hoc test. We used standard response mean to determine the responsiveness of possible reduced scores and linear regression to assess the amount of information retained from the original score. Analyses were also performed separately for early and established RA.

Results: A total of 435 patients (n=138 early RA) were included (56.5 (SD 13.1) years old, 8.2 (9.1) years disease duration, 80% female). The dorsal wrist, palmar MCP2, extensor digitorum communis (EDC) and carpi ulnaris (ECU) tendons out of 7 joints were most frequently affected by GS/PD synovitis/tenosynovitis (wrist: 45%/43%; MCP2: 35%/28%; EDC: 30%/11% and ECU: 25%/11%) and significantly changed within 6 months of therapy (all $p \leq 0.003$ in GS/PD).

The dorsal vs. palmar side of the wrist by GS/PD ($p<0.001$) and the palmar vs. dorsal side of the finger joints by PD ($p<0.001$) were more frequently pathologic. The reduced US7 score (GS and PD: dorsal MCP2, dorsal wrist, EDC and ECU, only GS: palmar MCP2) showed therapy response (SRM 0.433) after 6 months and retained 76% of the information of the full US7 score. No major differences between the groups of early and established RA could be detected.

Conclusion: The wrist, MCP2, EDC and ECU tendons were most frequently pathologic and responsive to therapy, representing an optimized score for monitoring of RA patients for both early and established RA and should therefore be included in comprehensive scores for monitoring RA patients.

Background: The goal of treatment for RA is achieving low disease activity and/or remission[1,2]; however, disease course and management can be complicated by additional factors that may be influenced by serostatus. Anti-citrullinated protein antibodies (ACPAs) and RF contribute to a more severe RA disease pattern[3] and may be useful in predicting response to treatment.[4] ACTION (AbataCepT In rOutiNe clinical practice; NCT02109666) and ASCORE (Abatacept SubCutaneOus in Routine Clinical PracticE; NCT02090556) were 2-year, international, observational, prospective, multicenter studies of IV and SC abatacept, respectively, for the treatment of RA in routine clinical practice.[4,5] Previous analyses have shown that ACPA/RF double-positive serostatus was associated with better treatment outcomes compared with ACPA/RF double-negative serostatus.[4–6]

Objectives: To assess the independent effect of ACPA or RF single seropositivity among patients with RA on achieving remission after treatment with abatacept for 2 years, and to compare outcomes among patients with single versus double serostatus.

Methods: This post hoc analysis included patients from ACTION and ASCORE who initiated IV (body weight–adjusted dosing) or SC abatacept (125 mg once weekly), respectively. Patients were stratified by baseline ACPA/RF status: ACPA+/RF– (ACPA+ only), ACPA/RF double positive (+/+), ACPA–/RF+ (RF+ only), and ACPA/RF double negative (–/–). DAS28 (CRP) and CDAI remission rates (defined as < 2.6 and 0–2.8, respectively) at 2 years for patients who were ACPA+ or RF+ only at baseline were assessed and compared with those who were +/+ and –/–. Patients with missing baseline ACPA/RF status were excluded. Last observation carried forward efficacy analyses were used to impute missing values.

Results: This analysis included 1679 patients from ACTION (ACPA+ only, n = 98; +/+, n = 1028; RF+ only, n = 161; and –/–, n = 392) and 1748 patients from ASCORE (ACPA+ only, n = 184; +/+, n = 1079; RF+ only, n = 142; and –/–, n = 343). Across studies and serogroups, baseline demographics and disease characteristics were similar (data not shown). In both ACTION and ASCORE, a higher proportion of patients who were only ACPA+ achieved DAS28 (CRP) and CDAI remission at 2 years compared with patients who were only RF+ (Figure 1). Additionally, a similar proportion of patients who were only ACPA+ achieved DAS28 (CRP) and CDAI remission at 2 years compared with patients who were +/+. In contrast, a lower proportion of patients who were only RF+ achieved DAS28 (CRP) and CDAI remission at 2 years compared with patients who were +/+.

Conclusion: In this post hoc analysis of real-world data from ACTION and ASCORE, ACPA positivity was associated with an increased likelihood of achieving DAS28 (CRP) and CDAI remission at 2 years. Patients who were ACPA+ only were as likely to achieve remission as +/+ patients, suggesting that RF serostatus had less influence than ACPA serostatus on remission status at 2 years. In line with this, patients who were RF+ only were less likely to achieve remission at 2 years. This is the first large, real-world study to show that ACPA positivity plays a more important role than RF positivity in achieving remission whilst on abatacept. These results highlight the importance of assessing baseline ACPA status when considering treatment options for patients with RA.

POS0108

REMISSION OR NOT REMISSION? THAT'S THE QUESTION, BUT WHAT'S THE ANSWER? - ILLUMINATING ON REMISSION IN ORDINARY OUTPATIENT CLINICAL RHEUMATOID ARTHRITIS PATIENTS

A. Brkic[1,2], K. Łosińska[3], A. H. Pripp[4], M. Korkosz[3,5], G. Haugeberg[1,2].
[1]Sørlandet Hospital Kristiansand, Research Department, Kristiansand, Norway; [2]Norwegian University of Science and Technology, Neuromedicine and Movement Science, Trondheim, Norway; [3]Krakow University Hospital, Rheumatology and Immunology, Kraków, Poland; [4]Oslo University Hospital, Oslo Centre of Biostatistics and Epidemiology, Oslo, Norway; [5]Jagiellonian University Medical College, Rheumatology and Immunology, Krakow, Poland

Background: A recent meta-analysis by Ferreira et al. (2020) has questioned the validity of using Patient Global Assessment (PGA) to define remission in the Boolean remission criteria (4-variable remission, 4vR) [1]. This is because PGA, which presumptively reflects a patient's perception of disease activity, is influenced by both inflammatory and non-inflammatory mechanisms, thus questioning the validity of PGA-related remission definitions when treating patients to target using anti-inflammatory drugs. Further, the impact of PGA differs in the various definitions and algorithms developed to define remission in rheumatoid arthritis (RA).

Objectives: This study aims to examine remission rates by applying different definitions of remission in an outpatient cohort of RA patients and illuminate the impact of PGA on Boolean remission.

Methods: Data were obtained during 2019 from RA patients followed at an outpatient clinic in Southern Norway. The composite disease activity scores simple disease activity index (SDAI), clinical disease activity index (CDAI), and disease activity score with 28 joint count with C-reactive peptide (DAS28(3) and with PGA DAS28(4)), as well as Boolean 4vR and without PGA the 3-variable remission (3vR) were used to define remission. Cut-off remission values for CDAI, SDAI, and DAS28 are ≤2.8, ≤3.2, and ≤2.6, respectively. 4vR is attained when PGA ≤10, C-reactive peptide (CRP) ≤10 mg/L, SJC28 ≤1, and TJC28 ≤1, while 3vR when CRP ≤10 mg/L, TJC28 and SJC28 ≤1 [2]. Remission rates for 4vR were also calculated with the PGA cut-offs of ≤20, 30, 40, 50, 60, 70, 80, 90.

Results: In Figure 1, proportion rates of remission for DAS28(3), DAS28(4), CDAI, SDAI, 3vR, and 4vR with different PGA cut-offs are presented. The proportion of remission were 73% for DAS28(3), 67% for DAS28(4), 37% for CDAI, 38% for SDAI, 23% for 4vR, 65% for 3vR. When comparing the different remissions proportion rate with various cut-offs of PGA in 4vR, SDAI and CDAI lie between a cut-off of ≤20 and ≤30, while DAS28(3), DAS28(4), and 3vR all lies beyond a cut-off of ≤90.

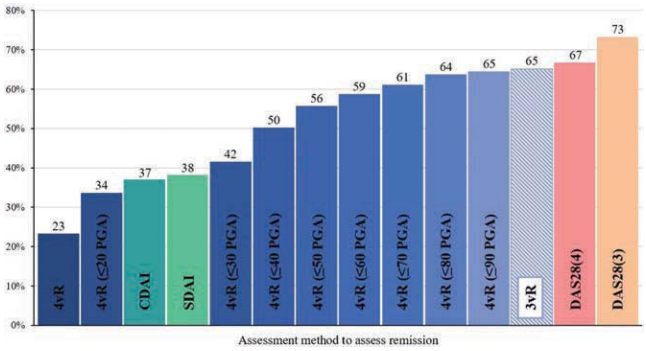

Figure 1. Remission rates using different definitions of remission in an outpatient cohort of 502 rheumatoid arthritis patients

Conclusion: Our data highlights that there is a great variation in remission rates for the different remission definitions, with DAS28(3) having the highest (73%) and the original Boolean remission the lowest (23%) remission rate. While RA patients in DAS28 remission may still have swollen joints, RA patients with no swollen and tender joints and normal CRP may not achieve Boolean remission because of even a minor elevation of PGA above ten, which may not only reflect inflammatory mechanisms. We question the value of using remission definitions where PGA has a large impact when used in ordinary clinical practice to treat patients to remission. Further studies are warranted to illuminate which remission definitions should be used both in studies and in ordinary clinical practice when treating patients with anti-inflammatory drugs.

Is it time for a paradigm shift to focus more on objective than subjective measures reflecting disease status and disease activity when aiming for remission daily clinical practice?

POS0109 IMPACT OF EARLY AGE AT MENOPAUSE ON DISEASE OUTCOMES IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS: RESULTS FROM A LARGE OBSERVATIONAL COHORT OF KOREAN PATIENTS WITH RHEUMATOID ARTHRITIS

E. H. Park[1], S. T. Choi[1], J. S. Song[1], E. H. Kang[2], Y. J. Lee[2], Y. J. Ha[2]. *[1]Chung-Ang University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [2]Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)*

Background: The increased prevalence of rheumatoid arthritis (RA) in women has led to studies exploring how female reproductive factors affect disease outcomes in women RA. While a few studies have investigated how early menopause (EM) affects RA outcomes, they had relatively small sample size and have shown inconsistent results [1, 2]. Moreover, none has evaluated the association between age at menopause and longitudinal changes in validated disease activity indices or patient-reported outcomes (PROs) of RA.
Objectives: We aimed to assess the differences in clinical outcomes between RA patients with EM (age at menopause <45 years) and usual menopause (UM) (age at menopause ≥45 years), and identify potential impact of EM on longitudinal changes in RA activity and PROs during follow-up period.
Methods: A total of 2,878 postmenopausal women with RA were included from the Korean Observational Study Network for Arthritis, a nationwide prospective RA cohort of Korea. Each patient was examined at baseline and for 5 consecutive years using the simplified disease activity index (SDAI), health assessment questionnaire-disability index (HAQ-DI), and other PROs. Among patients with a baseline SDAI >11, generalized estimating equation (GEE) analyses were performed to evaluate the impact of EM on longitudinal changes in RA activity and PROs during follow-up.
Results: The EM group (N=437) was younger than the UM group (N=2,441) [58.0±9.5 vs. 60.8±8.0 years, p<0.001], but RA duration was similar between the two groups. The EM group had higher education level and was more likely to be seronegative at enrollment. Moreover, the EM group demonstrated higher disease activity [SDAI 15.4±11.7 vs. 13.9±10.0, p=0.011] and patient-reported visual analogue scale (VAS) scores for global assessment, fatigue, and sleep disturbance (all p<0.05), and worse EQ-5D-VAS [59.9 ±22.2 vs. 63.0±19.5, p= 0.006] at baseline. The rate of previous fracture and neoplastic disease, especially uterine/cervical neoplasm, was higher while that of hypertension was lower among the EM group. The GEE model revealed that EM significantly influenced the rate of SDAI change (β=1.265, p=0.004), after adjusting for age, RA duration, biologic use, and SDAI at baseline. The EM group was also significantly associated with increase in HAQ-DI (β=0.088, p=0.003), and decrease in EQ-5D utility value (β=-0.031, p=0.016) during 5-year follow-up period.
Conclusion: RA patients with EM demonstrate higher disease activity and poorer health-related quality of life. EM significantly affects longitudinal changes in disease activity and PROs in RA.

Table 1. Longitudinal analysis of predictors of the SDAI, HAQ-DI, and EQ-5D utility value over time using a GEE model among patients with a baseline SDAI >11

Outcome	Independent variables	Regression coefficient (β) (95% CI)	P

Background: ORAL Surveillance was a post-authorisation safety study of tofacitinib vs tumour necrosis factor inhibitors (TNFi) in patients (pts) with rheumatoid arthritis (RA) aged ≥50 yrs with ≥1 additional cardiovascular (CV) risk factor and an inadequate response to methotrexate (MTX).
Objectives: To examine associations between major adverse CV events (MACE) and the geographic region and baseline (BL) CV risk profile of pts in ORAL Surveillance.
Methods: Pts on stable MTX were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (adalimumab 40 mg every 2 weeks in North America [NA] or etanercept 50 mg once weekly in the rest of the world [RoW]). Incidence rates (IRs; pts with first events/100 pt-yrs) were evaluated for adjudicated MACE, as well as myocardial infarction (MI) and stroke. MACE was defined as CV death (excluding CV death due to pulmonary embolism), non-fatal MI and non-fatal stroke. IRs were stratified by geographic region (NA vs RoW) and BL CV risk profile: pts were first categorised by history of coronary artery disease (HxCAD); pts without a HxCAD were then categorised by 10-yr risk of MACE (high [≥20%], intermediate [≥7.5–<20%], borderline [≥5–<7.5%] and low [<5%] risk), per the ASCVD-pooled cohort equations calculator[1] with a 1.5 multiplier applied.[2]
Results: Overall, 4362 pts were included in the study (tofacitinib 5 mg BID, n=1455; tofacitinib 10 mg BID, n=1456; TNFi, n=1451). Across treatments, a higher proportion of pts in NA vs RoW had a HxCAD (Table 1). In pts without a HxCAD, across treatments, higher percentages of pts had a high 10-yr risk of MACE in NA vs RoW (Table 1). Across treatments, overall MACE IRs were higher

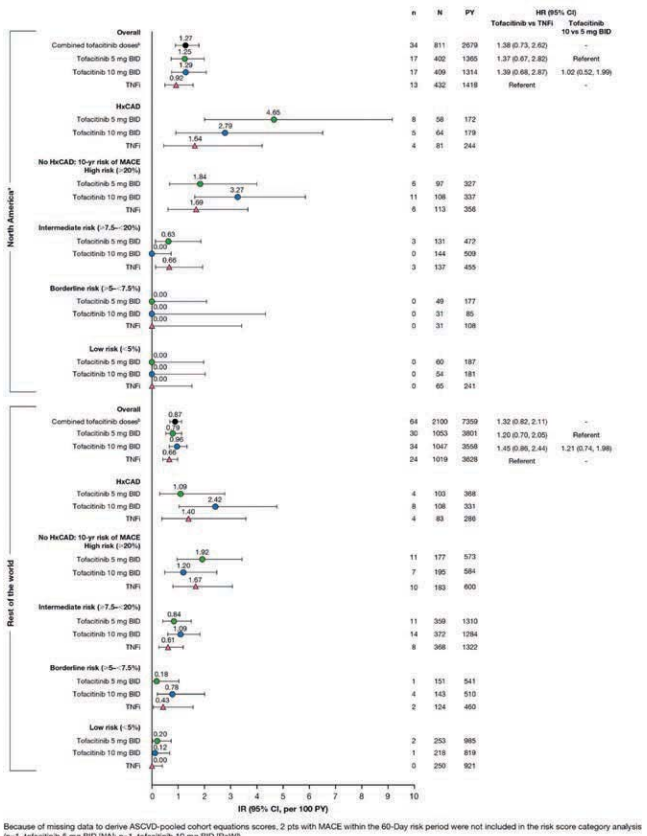
in pts in NA vs RoW (Figure 1). Incidence and risk of MACE were higher with tofacitinib vs TNFi in both NA and RoW (Figure 1). In NA, MACE IRs were higher for tofacitinib 5 mg BID vs TNFi in pts with a HxCAD, and tofacitinib 10 mg BID vs TNFi for pts with a high 10-yr risk of MACE; pts with low or borderline 10-yr MACE risk had no MACE across tofacitinib groups (Figure 1). Compared with NA, similar trends for MACE were generally observed across treatments in RoW, particularly for intermediate, borderline and low CV risk categories (Figure 1).

Table 1. Percentages of pts in NA and RoW with a HxCAD and pts without a HxCAD categorised by 10-yr risk of MACE, per ASCVD-pooled cohorts equation risk calculator[1] with a 1.5 multiplier applied[2]

	NA[a]			RoW		
	Tofacitinib 5 mg BID (N=402)	Tofacitinib 10 mg BID (N=409)	TNFi[b] (N=432)	Tofacitinib 5 mg BID (N=1053)	Tofacitinib 10 mg BID (N=1047)	TNFi[b] (N=1019)
HxCAD, n (%)	58 (14.4)	64 (15.6)	81 (18.8)	103 (9.8)	108 (10.3)	83 (8.1)
No HxCAD: 10-yr risk of MACE, n (%)						
High (≥20%)	97 (24.1)	108 (26.4)	113 (26.2)	177 (16.8)	195 (18.6)	183 (18.0)
Intermediate (≥7.5–<20%)	131 (32.6)	144 (35.2)	137 (31.7)	359 (34.1)	372 (35.5)	368 (36.1)
Borderline (≥5–<7.5%)	49 (12.2)	31 (7.6)	31 (7.2)	151 (14.3)	143 (13.7)	124 (12.2)
Low (<5%)	60 (14.9)	54 (13.2)	65 (15.0)	253 (24.0)	218 (20.8)	250 (24.5)
Missing data	7 (1.7)	8 (2.0)	5 (1.2)	10 (0.9)	11 (1.1)	11 (1.1)

HxCAD was defined as any history of MI, coronary heart disease, stable angina pectoris or coronary artery procedures. [a]United States, Puerto Rico and Canada. [b]For pts randomised to the TNFi group, adalimumab and etanercept were administered in NA and RoW, respectivelyn, number of pts with specified characteristics; N, number of evaluable pts

Fig. IRs (pts with first events/100 pt-yrs; 95% CI) for MACE, stratified by HxCAD, BL CV risk and geographic region in ORAL Surveillance



Because of missing data to derive ASCVD-pooled cohort equations scores, 2 pts with MACE within the 60-Day risk period were not included in the risk score category analysis (n=1, tofacitinib 5 mg BID [NA]; n=1, tofacitinib 10 mg BID [RoW])
Data collected after pts who were randomised to tofacitinib 10 mg BID had their dose reduced to 5 mg BID were included in the tofacitinib 10 mg BID group
Risk period was defined as the time from first study dose to last study dose +60 days, or to the last contact date, whichever was earliest
HxCAD was defined as any history of MI, coronary heart disease, stable angina pectoris or coronary artery procedures
95% CIs for IRs were constructed using Exact Poisson Distribution
ORAL Surveillance (NCT02092467)
[a]United States, Puerto Rico and Canada
[b]Includes pts who received tofacitinib 5 or 10 mg BID in ORAL Surveillance
CI, confidence interval; HR, hazard ratio; PY, pt-yrs

Conclusion: This post hoc analysis of data from ORAL Surveillance suggests that differences in MACE IRs across geographic regions are largely driven by HxCAD and high BL CV risk scores in NA vs RoW. Results should be interpreted with caution due to low pt and event numbers, particularly restricting the evaluation of tofacitinib vs TNFi in NA and RoW. Noting this limitation, these findings emphasise the importance of assessing and addressing BL CV risk when treating pts with RA.

Background: A Treat-to-Target approach (T2T) is broadly considered to lead to better clinical outcomes and recommended in patients with RA. However, very few studies have analyzed the effect of T2T on radiographic progression, and any such studies have provided inconsistent results.

Objectives: To investigate whether meticulously following a treat-to-target (T2T)-strategy in daily clinical practice leads to lower radiographic progression in RA.

Methods: Patients from the multicenter RA-BIODAM cohort with ≥2 consecutive visits with radiographs available were included. In RA-BIODAM patients were enrolled as they were initiating a new csDMARD/bDMARD treatment were followed-up with the intention to benchmark and intensify treatment. The primary outcome of this analysis was the change in Sharp-van der Heijde score (SvdH, 0-448), assessed every 6 months, using average scores from 2 readers (scores with known chronological order). Following a DAS44-T2T remission strategy, which was defined at each 3-month visit, was the main variable of interest. Patients were categorized based on the proportion of visits in which T2T was followed according to our definition: very low (≤40% of the visits, low (>40%, <62.5%), high (≥62.5%, ≤75%) and very high (>75%). Radiographic progression at 2 years was visualized across groups by cumulative probability plots. Per 3-month interval T2T could be followed zero, one or two times (in a total of 2 visits). Associations between the number of visits with T2T in an interval and radiographic progression, both in the same and in the subsequent 6-month interval, were analysed by generalised estimating equations, adjusted for age, gender, disease duration and country.

Results: In total, 511 patients were included (mean (SD) age: 56 (13) years; 76% female). After 2 years, patients showed on average 2.2 (4.1) units progression (median:1 unit). Mean (SD) 2-year progression was not significantly different across categories of T2T: very low: 2.1 (2.7)-units; low: 2.8 (6.0); high: 2.4 (4.5), very high: 1.6 (2.2) (Figure 1). Meticulously following-up T2T in a 3-month interval neither reduced progression in the same 6-month interval (parameter estimates (for yes vs no): +0.15 units (95%CI: -0.04 to 0.33) for 2 vs 0 visits; and +0.08 units (-0.06;0.22) for 1 vs 0 visits) nor did it reduce progression in the subsequent 6-month interval (Table 1).

Table 1. Effect of following DAS44-remission-T2T strategy on 6-month radiographic progression over 2 years

	Change in radiographic damage (regression coefficient (95% CI)) N=506
T2T during 3 months on radiographic progression in the same 6-month period	
2 visits vs 0 followed	0.15 (-0.04; 0.33)
1 visit vs 0 followed	0.08 (-0.06; 0.22)
T2T during 3 months on radiographic progression in the subsequent 6-month period	
2 visits vs 0 followed	-0.09 (-0.28; 0.10)
1 visit vs 0 followed	-0.10 (-0.24; 0.05)

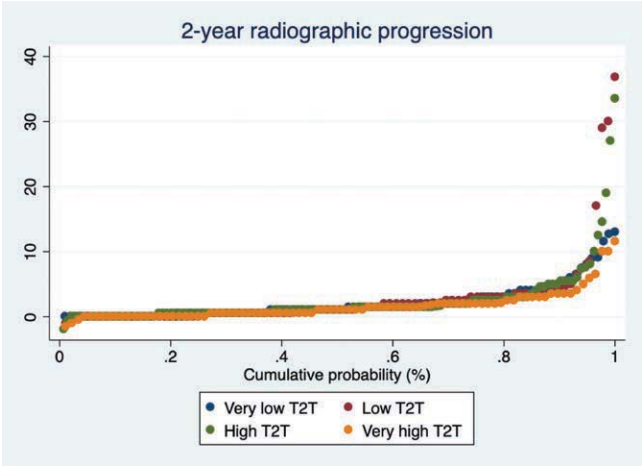

Figure 1. Cumulative probability plot with 2-year radiographic progression according to the proportion of 3-monthly visits with T2T followed

Conclusion: In this daily practice cohort, more meticulously following T2T principles did not result in more reduction of radiographic progression than a somewhat more liberal attitude toward T2T. One possible interpretation of these results is that the *intention* to apply T2T already suffices and that a more stringent approach does not further improve outcome.

POS0112 CLASSIFYING SELF-REPORTED RHEUMATOID ARTHRITIS FLARES USING DAILY PATIENT-GENERATED DATA

J. Gandrup[1], D. A. Selby[1], W. Dixon[1]. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*

Background: Flares are an inherent part of the rheumatoid arthritis (RA) disease course and may impact clinical and patient outcomes. The ability to predict flares between clinic visits based on real-time longitudinal patient-generated data could potentially allow for timely interventions to avoid disease worsening. For intensively-collected patient-generated data, machine learning methods offer benefits over traditional statistical tools for accurate prediction, but examples in rheumatology are sparse.

Objectives: Investigate the feasibility of using machine learning methods to classify self-reported RA flares based on a small dataset of daily symptom data collected on a smartphone app.

Methods: We used data from the Remote Monitoring of Rheumatoid Arthritis (REMORA) study, which aimed to improve monitoring of disease severity in RA. Patients tracked daily symptoms (pain, fatigue, function, sleep, coping, physical and emotional wellbeing) on a 0-10 numerical rating scale, duration of morning stiffness, and weekly flares on the REMORA smartphone app for three months. The outcome was the binary yes/no answer to the weekly flare question "*Have you experienced a flare in the last week?*". Several summaries of the eight daily symptom scores collected in the week leading up to the flare question (the exposure period) were used as predictors. These included the mean, min, max, standard deviation and slope. Where exposure periods overlapped, the intersecting symptom reports were allowed to correspond to multiple outcomes.

We fitted three binary classifiers: logistic regression +/- elastic net regularization, a random forest and naïve Bayes. The models were benchmarked using the R package mlr3 and 10-fold cross-validation, with two participants comprising the test set and the remaining 18 the training set.

Finally, the performance of the classifiers was evaluated according to the area under the curve (AUC) of the receiver operating characteristic curve. The model with the highest AUC in the test dataset was considered as the best final model.

Results: Twenty patients tracked daily symptoms over three months. 60% were female, all but one were white British, and mean age was 56.9±11.1 years. The median number of days in the study was 81 (interquartile range (IQR) 80, 82). The collected data comprised an average of 60.6 daily reports and 10.5 weekly reports per participant over the study period. Participants reported a median of 2 flares (IQR 0.75-4.25) resulting in 57 flares in total.

Classifier performances are visualized in Figure 1. The best performing model was logistic regression with elastic net with an AUC of 0.82. At a cut-off point requiring specificity to be 0.80, the corresponding sensitivity to detect flares was 0.60 for this model, meaning that the prediction model correctly identified three in every five self-reported flares, and four in every five non-flares. At this cut-off, the positive predictive value, i.e. the probability that those with a predicted flare indeed go on to have a flare was 53%. The negative predictive value, i.e. the probability that those with a predicted non-flare indeed do not experience a flare, was 85%.

Conclusion: Predicting self-reported flares based on daily symptom scorings in the preceding week using machine learning methods was feasible, although regularized logistic regression outperformed the other machine learning methods in this small dataset. The perceived advantage of machine learning may therefore be attributed to overfitting. It is possible that the observed predictive accuracy will improve as we obtain more data.

Our results point to a future where regular analysis of frequently collected patient-generated data may allow us to predict imminent flares before they unfold with decent accuracy, opening up opportunities for just-in-time adaptive interventions (JITAIs). Depending on the nature and implications of a JITAI, different cut-off values should be explored: different interventions will require different levels of predictive certainty before an action is triggered (eg self-management advice vs. a patient contact).

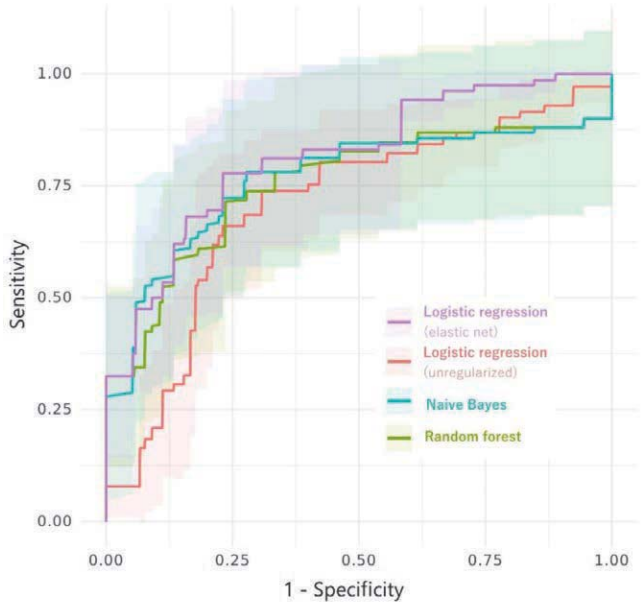

Figure 1. Performance of binary flare classifiers fitted to data from the REMORA study: Logistic regression with and without regularization, naïve Bayes and random forest.

POS0113 THE PREDICTIVE VALUE OF HEALTH LITERACY ON DISEASE ACTIVITY AND MEDICATION USE OVER TIME IN RHEUMATOID ARTHRITIS PATIENTS.

A. Gorter[1], M. M. Bakker[2,3], P. Ten Klooster[4], A. Boonen[2,3], H. Vonkeman[1,4]. *[1]Medisch Spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands; [2]Maastricht University Medical Centre, Internal Medicine, Rheumatology Division, Maastricht, Netherlands; [3]Maastricht University, CAPHRI - Care and Public Health Research Institute, Maastricht, Netherlands; [4]University of Twente, Psychology, Health and Technology, Enschede, Netherlands*

Background: Health literacy is a multidimensional concept comprising various individual skills and situational resources and is increasingly recognized as a critical determinant of health. Limited health literacy has been demonstrated to associate negatively with health outcomes in multiple chronic diseases, but data on the relevance of health literacy for treatment and outcomes in rheumatoid arthritis (RA) is still limited.

Objectives: The aim of this study was to explore the longitudinal association between health literacy profiles, disease activity and medication prescription in patients with RA.

Methods: We conducted a single center, retrospective, cohort study including patients from the Medisch Spectrum Twente hospital (Enschede, the Netherlands) who completed the Health Literacy Questionnaire (HLQ) and were previously clustered into 10 "health literacy profiles".[1] The 10 profiles were further aggregated, based on similarities in profile characteristics, into three groups: "several health literacy limitations", "some health literacy limitations" and "good health literacy". Up to 1 year of follow-up data on disease activity (DAS28-ESR) and medication use were obtained from patients' electronic health records. Linear mixed modelling (LMM) was used to analyze DAS28-ESR scores over time using health literacy group, time and their interaction term as fixed effects and gender and age as random effects. Drug prescriptions were constant over time, therefore chi-square tests were used to compare prescribed medication between the health literacy groups.

Results: 108 patients with RA were included and assigned to "several health literacy limitations" (n=21), "some health literacy limitations" (n=33) or "good health literacy" (n=54). LMM showed a significant main effect of health literacy group on DAS28-ESR scores over time (F (2,105) = 4.941, p=0.009). Post hoc contrast analysis showed that patients with "good health literacy" had significantly lower disease activity scores than patients with "several health literacy limitations". In addition, there was a significant effect of time on DAS28-ESR scores (F (2,141) = 4.601, p=0.012) in the total sample, indicating significantly lower scores at the 6-month follow-up. There was no significant interaction between group and

time (F (4,141) = 0.712, p=0.585). Figure 1 shows the estimated trajectories of DAS28-ESR scores over 12 months time for the three health literacy groups. Patients with "several health literacy limitations" were prescribed prednisolone significantly more often (52.4%) than patients with "some health literacy limitations" (21.2%) or "good health literacy" (22.2%) over time (p=0.019). Patients with "some health literacy limitations" were prescribed conventional DMARDs more often (72.7%) than patients with "good health literacy" (38.9%; p=0.008). There was no difference in biological DMARDs use between the health literacy groups.

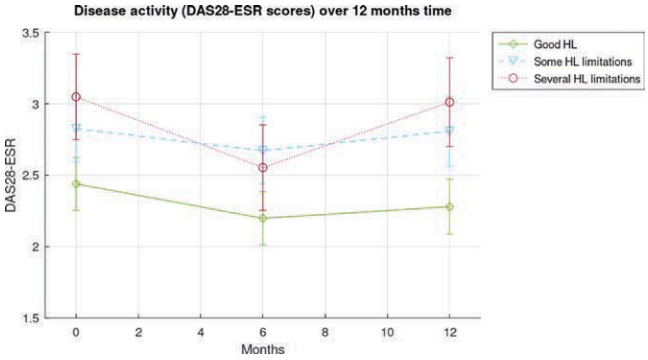

Figure 1. Mean (standard error) DAS28-ESR scores of health literacy (HL) groups over a 12-month time period.

Conclusion: We found that among patients with RA, those with several health literacy limitations have higher disease activity scores over time and use prednisolone significantly more often than patients with higher health literacy levels. No difference was observed in biological DMARD use. These results grant more insight into the role of health literacy for treatment and outcomes in patients with RA and supports existing research in other chronic diseases.

COMPUTATIONAL IDENTIFICATION OF SLE PATIENT RECORDS USING DATA-DRIVEN CLINICAL FINGERPRINTS

M. Barbero Mota[1], J. L. Gamboa[2], J. M. Still[1], C. M. Stein[2], V. K. Kawai[2], T. A. Lasko[1]. *[1]Vanderbilt University Medical Center, Department of Biomedical Informatics, Nashville, TN, United States of America; [2]Vanderbilt University Medical Center, Department of Medicine, Nashville, TN, United States of America*

Background: Systemic lupus erythematosus (SLE) is a chronic relapsing autoimmune disorder that is challenging to diagnose due to its heterogeneous presentation of a combination of non-specific clinical manifestations and laboratory findings. This heterogeneity and lack of granularity is a major cause of treatment failure. With the advent of precision medicine, there is a need for accurate methods to identify cases of SLE in large clinical databases, and to recognize constellations of pathological characteristics (or *fingerprints*) that allow a better understanding of the disease. Computational phenotype discovery aims to solve this problem by using unbiased, data-driven machine learning methods to disentangle the fingerprints of disease that hide within the noisy, sparse and incomplete electronic health record data.

Objectives: To generate data-driven phenotypic fingerprints of SLE and validate them by assessing their ability to distinguish records of patients with SLE vs. 'near miss' patients without the disease.

Methods: Records of 716 patients that published, expert-curated algorithms [1] indicated as likely SLE patients were reviewed by 3 clinicians and labeled as positive (490 records), negative (261), or indeterminate (55). Those labeled positive by an algorithm but negative by clinician chart review were considered 'near misses' and should be among the more difficult cases to classify. We trained an ElasticNet (regularized logistic regression) model to distinguish the true positive records from the near misses and evaluated it under 10x cross validation.

Inputs to the predictive model were the projections of each patient record into the space of 2000 latent variables. These features had been inferred separately by an unsupervised machine-learning algorithm from a much larger dataset of 646,716 randomly sampled temporal cross sections of 63,775 longitudinal records of patients with an antinuclear antibody test. Each of the 2000 variables constitutes the phenotypic fingerprint of an unobserved, independent potential disease mechanism. Formally, they represent linear combinations of demographic data, laboratory test results, billing code intensities, and medication exposures [2].

Results: Our predictive model achieved an area under the Receiver Operating Characteristic Curve of 0.90, 95% CI: [0.879, 0.922], an area under the Precision-Recall Curve of 0.94, 95% CI: [0.926, 0.954], and an Integrated Calibration Index of 0.074, 95% CI: [0.067, 0.080].

The model selected 61 of the 2000 potential latent mechanisms to distinguish positive SLE records from near-misses. All of the phenotypes selected to be predictive exhibit high face-validity from a clinical interpretation perspective. They include recognizable patterns of variables representing different clinical features of SLE (Figure 1).

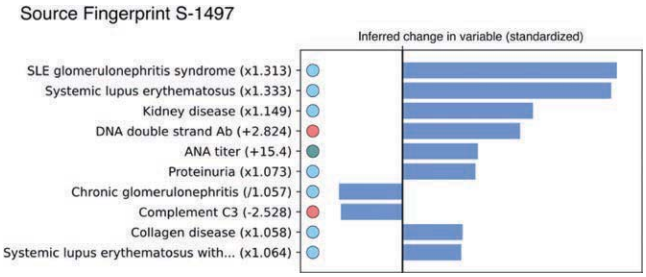

Figure 1. Detail of the estimated changes in the clinical features representing one of the 61 potential fingerprints found to distinguish records of patients with SLE vs. near misses.

Conclusion: We found unbiased, data-driven fingerprints of potential latent disease mechanisms that were highly informative in differentiating records of patients with SLE from near-miss presentations, with performance surpassing existing expert-curated algorithms. Our methods found dozens of variable constellations that may lead to a more precise understanding of this complex and heterogeneous disease. That these results were obtained from cases that should be the most difficult for an algorithm to distinguish (positive vs. near-miss) suggests that our model's accuracy is a lower bound on what would be expected from a more balanced cohort.

POS0115

SERUM PROPROTEIN CONVERTASE SUBTILISIN/KEXIN TYPE 9 (PCSK9) AND CARDIOVASCULAR RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL COHORT STUDY

C. C. Mok[1], K. L. Chan[1], L. Y. Ho[1], S. M. Tse[1], C. H. To[2]. *[1]Tuen Mun Hospital, Medicine, Hong Kong, China; [2]Pok Oi Hospital, Medicine, Hong Kong, China*

Objectives: To study the effect of serum PCSK9 on major cardiovascular adverse events (MACEs) in Chinese patients with systemic lupus erythematosus (SLE).

Methods: Consecutive patients who fulfilled ≥4 1997 ACR criteria for SLE and consented for a biomarker study between 2009 and 2012 were included. Stored serum samples from these patients were assayed for the levels of PCSK9 using a commercial ELISA kit (OKBB00903, Lot# 1344, Aviva Systems Biology, San Diego, US). New MACEs (acute coronary syndrome, ischemic stroke, peripheral vascular disease) documented by imaging and angiographic studies over time was evaluated. Patients were stratified into high/low PCSK9 groups according to the best cut-off level by ROC analysis for the prediction of these events. The cumulative incidence of new MACEs and mortality over time was studied by Kaplan-Meier's analysis and compared between the high and low PCSK9 subgroups. Cox regression was performed to study the effect of the PCSK9 subgroups on new MACEs and mortality, adjusted for other confounding factors.

Results: 539 SLE patients were studied (93% women, age 41.9±14.0 years; disease duration 106±90.4 months at entry). The mean PCSK level at baseline was

265±158ng/ml and a cut-off of 243.25ng/ml best predicted a new vascular event by the maximum Youden's index (ROC analysis: AUC 0.63[0.51-0.74]; sensitivity 69%; specificity 61%). 220 SLE patients had baseline PCSK9 level of ≥243.25ng/ml (high PCSK9) and 319 patients had level below 243.25ng/ml (low PCSK9). Patients with high PCSK9 (n=220) had more active SLE than those with low PCSK9 (n=319) (p<0.001). PCSK9 level was highest in active renal SLE patients and correlated with SLE disease activity index (r=0.55; p<0.001). No significant difference in SLE manifestations and autoantibody profile was observed between the high and low PCSK9 groups except the former had a significantly higher prevalence of lupus nephritis. Over 91.3±18.6 months, 31 new MACEs (13 ischemic stroke, 13 acute coronary syndrome and 5 peripheral vascular disease) developed in 29 patients. Patients with a new MACE had a significantly higher baseline PCSK9 level than those without (350±225 vs 260±153ng.ml; p=0.02). The cumulative incidence of a first MACE at 5 years from study entry was 7.8% in the high PCSK9 group and 1.9% in the low PCSK9 group (log rank test; p=0.003, univariate hazard ratio [HR] 3.08[1.39-6.80]). At last follow-up, 40 patients succumbed (10 due to vascular event [vascular death]). Kaplan-Meier's analysis showed that the high PCSK9 group had a significant higher cumulative risk of all-cause mortality (log rank test p=0.003; HR2.68[1.39-5.14]) and vascular mortality (log rank test p=0.002; HR12.4[1.56-98.4]) over time than the low PCSK9 group. Cox regression analyses showed that high PCSK9 was significantly associated with new MACEs (HR2.74[1.16-6.52]; p=0.02) independent of age, sex, SLE duration, history of nephritis, traditional atherosclerotic risk factors, antiphospholipid antibody, past history of vascular events, and the use of statins, aspirin/warfarin and immunosuppressive drugs (hydroxychloroquine, prednisolone, mycophenolate mofetil, azathioprine and the calcineurin inhibitors) at baseline. High PCSK9 was also independently associated with all-cause (HR2.55[1.27-5.12]; p=0.008) and vascular mortality (HR13.0[1.49-114]; p=0.02).

Conclusion: High circulating levels of PCSK9 increase the risk of MACEs and vascular mortality in patients with SLE.

POS0116 PLASMA AND CEREBROSPINAL FLUID NEUROFILAMENT LIGHT CONCENTRATIONS REFLECT NEURONAL DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS

K. Zervides[1,2], S. Janelidze[3], J. Nystedt[2], B. Gullstrand[1], P. Nilsson[2], P. Sundgren[4,5], A. Bengtsson[1], O. Hansson[3,6], A. Jonsen[1]. *[1]Lund University, Skåne University Hospital, Department of Clinical Sciences, Rheumatology, Lund, Sweden; [2]Lund University, Skåne University Hospital, Department of Clinical Sciences, Neurology, Lund, Sweden; [3]Lund University, Clinical Memory Research Unit, Department of Clinical Sciences, Malmö, Sweden; [4]Lund University, Skåne University Hospital, Department of Clinical Sciences, Diagnostic Radiology, Lund, Sweden; [5]Lund University, Lund University BioImaging Center, Lund, Sweden; [6]Skåne University Hospital, Memory Clinic, Malmö, Sweden*

Background: Neuronal damage in systemic lupus erythematosus (SLE) is common, but the extent and mechanisms are unclear [1-2]. Neurofilament light (NfL) concentrations rise in plasma and cerebrospinal fluid (CSF) during neuronal damage and reach abnormal levels in various neurological disorders [3]. NfL is sparsely studied in SLE [4-7].

Objectives: To explore plasma and CSF concentrations of NfL in SLE patients and investigate the associations between NfL and nervous system involvement, including cognitive dysfunction, imaging findings on magnetic resonance imaging (MRI), laboratory and clinical abnormalities, and to compare the NfL levels of SLE patients with those present in healthy controls.

Methods: In this cross-sectional study, 72 consecutive SLE out-patients and 26 healthy controls, all female, aged <55 years, underwent MRI and neurocognitive testing. NfL concentrations in plasma from all individuals and in CSF from 32 patients were measured with single-molecule array technology. Patients were assessed by a rheumatologist and neurologist to define neuropsychiatric involvement (NPSLE) according to three attribution models.

Results: Plasma and CSF NfL concentrations correlated strongly (r=0.72, p<0.001). Plasma NfL concentrations were higher in SLE patients, both with and without neuropsychiatric involvement, compared with healthy controls (Figure 1A-D). Plasma and CSF NfL concentrations did not differ between NPSLE and non-NPSLE patients (Figure 1B-D). Larger white matter lesion volumes correlated with higher CSF NfL concentrations in patients aged 18-30 (r_s=0.80, p=0.005). Higher plasma NfL concentrations correlated with lower simple attention scores (r_s=-0.42, p=0.007), and were associated with dysfunction of psychomotor speed (p=0.012) and verbal memory (p=0.024). SLICC/ACR-Damage Index ≥1 was independently associated with higher plasma log-NfL concentrations when adjusting for age, SLE Disease Activity Index-2000 ≥1, low complement C3 levels, a history of renal involvement or anti-dsDNA, and ongoing treatment (β=0.080, 95% CI 0.009-0.15, p=0.028).

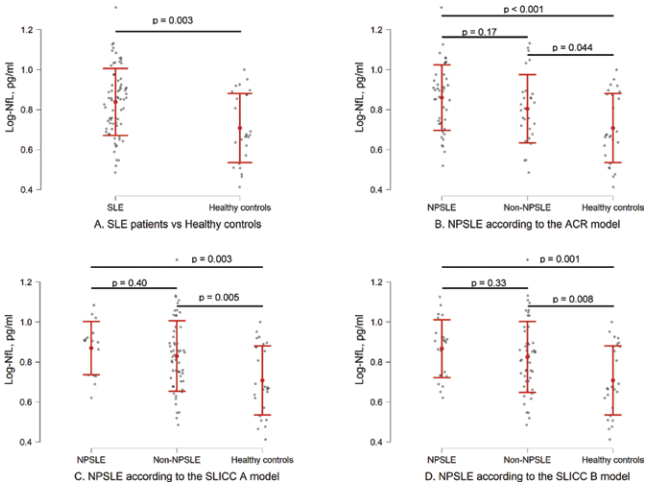

Figure 1. Plasma log-NfL concentrations between groups. The intervals illustrate means and standard deviations.

Conclusion: Higher plasma NfL concentrations in NPSLE and non-NPSLE patients may indicate a higher degree of neuronal damage in SLE in general, particularly in the lower age group, corresponding with cognitive impairment and organ damage development. NfL may serve as an indicator of neuronal damage in SLE in further studies.

POS0117 DISEASE ACTIVITY AND CLINICAL REMISSION IN SYSTEMIC LUPUS ERYTHEMATOSUS: COMPARISON BETWEEN PATIENT AND PHYSICIAN PERSPECTIVES BY MEANS OF PATIENT REPORTED OUTCOMES (PROS)

M. Fredi[1], C. Orlandi[2], M. Salvi[2], C. Bazzani[1], C. Nalli[1], L. Andreoli[1], F. Franceschini[1]. *[1]Reumatologia e Immunologia Clinica, Spedali Civili e Università degli Studi di Brescia, BRESCIA, Italy; [2]Università degli Studi di Brescia,., BRESCIA, Italy*

Background: In daily clinical practice, it is not rare to observe a relevant discordance between patient's global assessment (PGA) and physician's global assessment (PhGA), because of different illness perceptions.

Objectives: To evaluate the presence of PGA/PhGA discrepancy in patients with Systemic Lupus Erythematosus (SLE) who achieved clinical remission and to evaluate how this discrepancy affects PROs. In addition, to explore whether this discordance could be influenced by the presence of additional elements affecting patients' quality of life, such as comorbidities, sleep disturbances and psycho-emotional factors.

Methods: Our study included adult SLE patients consecutively followed in a single Lupus Clinic from March to July 2021 fulfilling at minimum the definition of clinical remission of treatment according to Zen et al. (1) (cSLEDAI=0, corticosteroids ≤5mg/die, stable dosage of DMARD). Medical records including demographic data, clinical characteristics and outcomes measures were collected. Pain assessment, PGA and PhGA were rated on a visual analogue scale

(0-100 mm) on the same day of the clinical evaluation. To analyse the discrepancy between PGA and PhGA, the [PGA-PhGA] variable was calculated, considering as discordant a difference ≥ 25 mm as previously proposed (2) All the subjects completed the following questionnaires: Health Assessment Questionnaire (HAQ), SF36 Health Survey, State-Trait Anxiety Inventory (STAI-Y1/Y2), Self-rating Depression Scale (SDS Zung) and Insomnia Severity Index. Statistical analysis was performed to compare concordant and discordant groups.

Results: The study included 106 patients, (93 women, 13 men) with a median age of 48 (41-58) and a median SLE duration 227 months (124-330). At the last evaluation median SLEDAI was 0 (0-2) and median SLICC was 1 (0-1). According to Zen definitions of remission, 51 patients (48%) and 20 (19%) also fulfilled the criteria of clinical remission off corticosteroids and complete remission respectively. Nevertheless, in 24 patients (22,7%) [PGA-PhGA]≥25. Patients in the discordant group were older (median 58 years, IQR 49-62 vs 46, IQR 39-57; p=0,0043) and less frequently achieved the definition of clinical remission off corticosteroids (n=4, 16,7% vs n=47, 57,3%,p<0.001;OR6,7; CI95%2.1-21) than concordant. No differences were found in gender, SLE duration, serology, disease activity or damage and other treatment. Data about differences in PROs between two groups are reported in Table 1: discordant patients had a worse performance in all the PROs included. At multivariate analysis SF-36 Physical Component Summary (PCS) resulted associated with [PGA-PhGA] ≥25 (p=<0,0001).

Table 1. Data are expressed as median and interquartile range (IQR) and compared using Mann-Whitney test.

	TOTAL N=106 (%)	CONCORDANT GROUP (PGA-PhGA) <25 N=82 (%)	DISCORDANT GROUP (PGA-PhGA) ≥25 N=24 (%)	P value
VAS-pain [0-100],	10 (0-30)	10 (0-20)	50 (40-60)	< 0.001
SF-36 Physical Component Summary (PCS)	50 (37,5-53)	51 (44-54)	30 (27,5-39)	< 0.001
SF-36 Mental Component Summary (PCS)	48 (38-55)	51 (40-55)	40 (36-48,5)	0,015
STAI-Y1 [20-80]	35 (30-47)	33 (28,3-45,5)	42 (36,5-49,5)	0,013
STAI-Y2 [20-80]	37 (30-46)	35 (29-43,3)	42 (36-46)	0,021
Test di Zung [20-80]	34,5 (29-43)	33 (27-43)	39 (35,5-44,5)	0,008
Insomnia severity index [0-28]	6 (2-12)	4 (1-9)	9 (6,8-14,3)	<0,0001
HAQ	0 (0-0,1)	0 (0-0)	0,38 (0-0,6)	< 0.001

Conclusion: In our study we found that, even in patients considered in remission, in more than 20% of patients there is a considerable discordance between the global disease assessment reported by patients and their physicians. Patients that had a higher PGA also presented worse score at PROs. Our data seems to confirm that potential causes for discordance could be more related to the presence of non-inflammatory processes, depression, or anxiety than clinical manifestations or damage related to SLE.

POS0118

SMALL FIBER NEUROPATHY EVALUATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A SINGLE CENTER STUDY.

C. Pirone[1], F. Ceccarelli[1], E. Galosi[2], P. Falco[2], C. Garufi[1], F. Miranda[1], V. Orefice[1], V. A. Pacucci[1], F. R. Spinelli[1], C. Alessandri[1], M. Leopizzi[3], V. Di Maio[1], A. Truini[2], F. Conti[1]. *[1]Lupus Clinic, Reumatologia, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Sapienza Università di Roma, Rome, Italy; [2]Sapienza Università di Roma, Dipartimento di Neuroscienze umane, Roma, Italy; [3]Polo Pontino, Sapienza Università di Roma, Dipartimento di Scienze Medico-Chirurgiche e Biotecnologia, Latina, Italy*

Background: Neuropsychiatric involvement represents one of the most relevant Systemic Lupus Erythematosus (SLE) manifestations and it is characterized by a protean spectrum of clinical disorders. Among them, small fiber neuropathy (SFN) could represent a relevant reason for chronic pain and somatosensorial dysfunctions, even if not included in ACR 1999 nomenclature yet.

Objectives: In the present study we aimed at evaluating the prevalence of SFN among SLE patients with neuropathic pain and identifying significant associations with clinical and laboratory disease features.

Methods: Consecutive SLE patients (according to ACR 1987 criteria), were screened for neuropathic pain through a specific questionnaire (DN4). Subjects were enrolled to the full protocol in the presence of bilateral limb pain and one of the following: hypoesthesia to touch or prick; pain caused or increased by brushing; tingling, numbness and itching; electric shocks, painful cold or burning pain. We excluded SLE patients with other possible explanation for SFN including diabetes, Sjogren's syndrome and kidney impairment (eGFR <30 ml/m). For each patient the following data were collected: demographics, medical history, treatments, disease activity (SLEDAI-2K) chronic damage (SLICC *damage index)*, clinical and laboratory data, including complement level and the main autoantibodies. Each patient enrolled underwent different tools specific for neuropathic pain (such as SFN-SIQ and NPSI), nerve conduction study, quantitative sensory testing (QST) and skin biopsy performed at proximal thigh and distal leg. SFN was diagnosed when intraepidermal nerve fiber density (IENFD) reduction was associated with at least one thermal detection threshold abnormality at QST. A concomitant fibromyalgia (FM) was evaluated by different tools including FIRST, FibroDetect and ACR 2016 criteria.

Results: Among the 114 recruitable subjects, 58 were excluded because of confounding factors and 25 declined the study. Therefore we enrolled 31 patients (M/F 3/28, median age 50.0 years, IQR 21.0; median disease duration 132.0 months, IQR 197.0; median SLEDAI-2k 0, IQR 4 and median SDI 1, IQR 1.2). FM was identified in 81.8% of subjects according to ACR criteria. SFN was diagnosed in 35.5% of patients; among them, in 81.8% a non-length dependent distribution was recognized while in 18.2% a length-dependent pattern and the large fiber dysfunction were found. SFN was associated with anti-Sm (p=0.03), Raynaud's phenomenon (p<0.01), low complement levels (p=0.04) and SLEDAI-2k≥4 (p=0.04). Neurovegetative symptoms and pain intensity correlated with distal (p<0.001) and slightly with proximal IENFD reduction (p=0.02 and p=0.04). No significant association was found between FM and SFN or IENFD.

Conclusion: The present study suggests that SFN is a common finding in SLE and it should be considered in patient with neuropathic pain, somatosensorial and neurovegetative dysfunctions, especially in subjects with low complement levels, high disease activity and Raynaud's phenomenon.

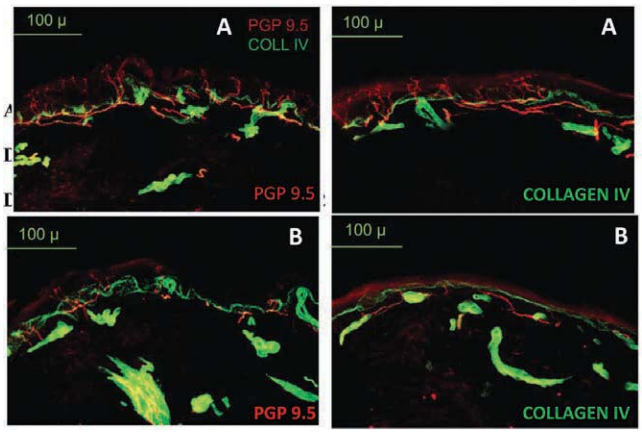

Figure 1. A: SLE patient with normal IENFD. B: SLE patient with low IENFD, consistent with SFN.

POS0119

SLE-DAS REMISSION AND LOW DISEASE ACTIVITY STATES ARE ASSOCIATED WITH IMPROVED HEALTH-RELATED QUALITY OF LIFE AND FATIGUE: POST-HOC ANALYSIS OF THE BLISS-52 AND BLISS-76 PHASE III TRIALS.

D. Jesus[1,2], A. Matos[3,4], C. Henriques[3,5], A. Doria[6], L. Inês[2,7]. *[1]Centro Hospitalar de Leiria, Rheumatology Department, Leiria, Portugal; [2]University of Beira Interior, Faculty of Health Sciences, Covilhã, Portugal; [3]Polytechnic Institute of Viseu, School of Technology and Management, Viseu, Portugal; [4]Research Centre in Digital Services, (CISeD), Viseu, Portugal; [5]University of Coimbra, Centre for Mathematics, Coimbra, Portugal; [6]University of Padova, Rheumatology Unit, Department of Medicine, Padova, Italy; [7]Centro Hospitalar e Universitário de Coimbra, CHUC Lupus Clinic, Rheumatology Department, Coimbra, Portugal*

Background: Accurate and practical outcome measures for clinical trials in systemic lupus erythematosus (SLE) are lacking. The SLE Disease Activity Score (SLE-DAS) is a recently validated 17-item instrument, with high accuracy and sensitivity to changes in SLE disease activity. The SLE-DAS definitions of remission and low disease activity (LDA) were newly validated against disease activity physician-applied measures in the clinical setting [1, 2]. Criterion validity of

SLE-DAS for Patient Reported Outcomes, namely health-related quality of life (HR-QoL) and fatigue needs to be assessed.

Objectives: To evaluate if the attainment of SLE-DAS remission and LDA states is associated with improvements in HR-QoL and fatigue.

Methods: Post-hoc analysis of the merged study population in the BLISS-52 and -76 trials (NCT00424476; NCT00410384) of intravenous belimumab versus placebo for moderate to severe SLE disease activity. We analysed the Functional Assessment of Chronic Illness Therapy (FACIT) and 36-Item Short Form Survey (SF-36) trial data. Fulfillment of SLE-DAS remission (defined as absence of all SLE-DAS clinical items and prednisone ≤5mg/day) and LDA (defined as SLE-DAS≤2.48 and prednisone ≤7.5mg/day) definitions were retrospectively assessed from the individual participants' data. Mean changes from study baseline to week 52 in FACIT and SF-36 physical component summary (PCS) and mental component summary (MCS) and domain scores were compared between patients attaining at week 52 the SLE-DAS remission *vs* non-remission and the SLE-DAS LDA *vs* non-LDA using multivariate regression analysis adjusted for baseline scores.

Results: A total of 1684 SLE patients were included. Few patients were in SLE-DAS remission (0.5%) and LDA (0.8%) at study entry. At week 52, 12.5% patients attained SLE-DAS remission and 17.5% attained SLE-DAS LDA. Mean improvements in SF-36 PCS and MCS scores were greater in patients that attained SLE-DAS remission *vs* non-remission (5.4 *vs* 3.4, and 4.6 *vs* 2.7, respectively; multivariate p<0.005 for both) and SLE-DAS LDA *vs* non-LDA (5.0 *vs* 3.4 and 4.6 *vs* 2.6, respectively; multivariate p<0.005 for both), at week 52 (Figure 1). Similarly, improvements in all individual domain scores were greater in SLE-DAS remission *vs* non-remission patients (all multivariate p<0.005) and SLE-DAS LDA *vs* non-LDA patients (all multivariate p<0.005) (Figure 1). Importantly, improvements in the summary scores and in all the individual domain scores largely exceeded the minimum clinically important differences (MCIDs) of 2.5 and 5 points, respectively, in those patients attaining SLE-DAS remission or LDA.

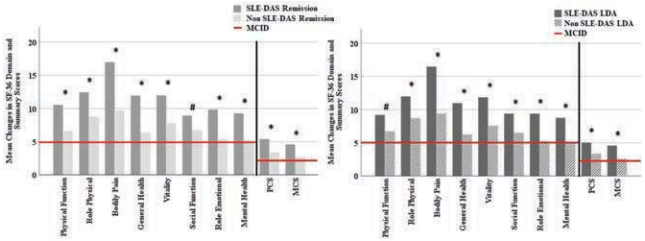

Figure 1. Mean changes in SF-36 domains and summary scores from baseline to week 52. #p<0.005; *p<0.001; MICD, Minimum Clinically Important Difference; MCS, Mental Component Summary; PCS, Physical Component Summary; SF-36, Medical Outcomes Survey Short Form; SLE-DAS, Systemic Lupus Erythematosus Disease Activity Score.

Additionally, mean improvements in FACIT scores were higher in SLE-DAS remission than non-remission (6.3 *vs* 3.6, multivariate p<0.001) and in SLE-DAS LDA than non-LDA (5.9 *vs* 3.6, multivariate p<0.001), and exceeded the MCID of 4 points.

Conclusion: Attainment of SLE-DAS remission and LDA is associated with meaningful improvement in HR-QoL and fatigue.

POS0120 NEUROLOGICAL INVOLVEMENT IN A MONOCENTRIC COHORT OF PATIENTS WITH SERONEGATIVE ANTIPHOSPHOLIPID SYNDROME

L. Rapino[1], S. Truglia[1], S. Mancuso[1], M. De Michele[2], D. Toni[2], I. Berto[2], M. Sorice[3], R. Misasi[3], A. Capozzi[3], C. Alessandri[1], F. Conti[1]. *[1]La Sapienza Università di Roma - Policlinico Umberto I, Medicina Interna e Specialità Mediche - Reumatologia, Rome, Italy; [2]La Sapienza Università di Roma - Policlinico Umberto I, Emergenza e Accettazione - Unità di Terapia Neurovascolare, Rome, Italy; [3]La Sapienza Università di Roma - Policlinico Umberto I, Medicina Sperimentale - Medicina Clinica e Molecolare, Rome, Italy*

Background: The nervous system is affected in a relevant number of patients with antiphospholipid syndrome (APS), being responsible for high morbidity and mortality rates. The identification of neurological manifestations is crucial since those symptoms may benefit from anticoagulation treatment. Noteworthy, the prevalence and the characteristics of neurological manifestations in the subset of patients with "seronegative APS" (SN-APS) still need to be investigated.

Objectives: The aim of this study was to assess the neurological involvement in patients with SN-APS. Secondly, association between non-conventional antiphospholipid antibodies (aPL) and clinical characteristics were investigated.

Methods: We included all consecutive patients referred to the Lupus Clinic and to the Stroke Unit of our Hospital, presenting clinical features consistent with a diagnosis of APS despite the evidence of persistently negative tests for anti-cardiolipin antibodies (aCL), anti-β2 glycoprotein I, and lupus anticoagulant. Patients with an identified cause of thrombosis and/or pregnancy morbidity were excluded. Patients' sera were analyzed for the detection of aCL using thin layer chromatography (TLC), while ELISA test was used to detect antibodies directed against the anti-vimentin/cardiolipin complex (aVim/CL).

Results: From January 2015 to October 2019, 40 patients with SN-APS and neurological involvement were enrolled. Clinical and demographic characteristics are reported in Table 1. Thirty-three patients (82.5%) resulted positive for at least one non-conventional test (62.5% positive on two occasions) while 17.5% were negative. The occurrence of aCL by TLC immunostaining was 33/40 (82.5%), while a Vim/CL were found in 10/40 (25%). Double positivity for aCL by TLC-immunostaining and aVim/CL was observed in 8/40 patients (20%). Patients who tested positive for non-conventional aPL on two occasions had a five-fold increased risk of developing venous thrombosis (LR 5.24; p=0.022). The positivity for aCL by TLC immunostaining determined an augmented risk of sinus vein thrombosis (LR 5.49; p=0.019) while positivity for aVim/CL raised the likelihood of epilepsy (LR 4.133; p=0.042). Almost all (16/18, 88%) patients with ischemic stroke resulted positive at least one test, 15 tested positive for aCL by TLC-immunostaining and 3 for aVim/CL. In this subset of patients, the positivity for non-conventional aPL on two occasions determined an increased risk of venous thrombosis (LR 8.905; p=0.003) and recurrent stroke (LR 6.321; p=0.012). In particular, those who tested positive for aVim/CL were at higher risk of developing recurrent stroke (LR 6.659; p=0.01).

Table 1.

Characteristics	Patients N= 40 (%)
Female/Male	35/5
Mean age in years (S.D.)	48 (12.5)
Thrombosis	34 (85)
Arterial	23 (57.5)
Venous	17 (42.5)
Recurrent	13 (32.5)
Pregnancy morbidity	12 (34.3)
Recurrent miscarriage	11 (31.4)
Foetal deaths	2 (5.7)
Premature births	2 (5.7)
Thrombosis + Pregnancy morbidity	6 (17.1)
Neurological manifestations	
Stroke	18 (45)
Recurrent stroke	7 (17.5)
Transient ischemic attack	4 (10)
Venous sinus thrombosis	5 (12.5)
Headache	18 (45)
Epilepsy	7 (17.5)
Transverse myelitis	2 (5)
Other manifestations	
Livedo reticularis	5 (12.5)
Low platelets	3 (7.5)

Conclusion: The nervous system is one of the most frequently affected in APS, however only few data exist about prevalence, characteristics and outcome of its involvement in SN-APS patients. In this work, using TLC immunostaining and ELISA for aVim/CL, we identified non-conventional aPL antibodies in 62,5% SN-APS patients. This subset of patients presented a wide spectrum of neurological manifestations, with frequencies and features that resemble those observed in APS patients. Furthermore, we demonstrated the association between non-conventional aPL and neurological manifestations, such as sinus vein thrombosis, recurrent stroke and epilepsy. In conclusion, testing for non-conventional aPL antibodies may contribute to the evaluation of the stratification of risk for neurological manifestations in SN-APS.

Background: In SLE patients, episodes of high disease activity state (HDAS, SLEDAI-2K≥10) are associated with worse outcomes even if only experienced once. We investigated whether attainment of the lupus low disease activity state (LLDAS) was associated with protection against adverse outcomes in SLE patients after an episode of HDAS.

Objectives: To compare LLDAS attainment between HDAS and non-HDAS patients.

Methods: Data on 4,106 SLE patients from a multinational cohort, collected prospectively between 2013 and 2020, were analysed. Disease activity was assessed using SLEDAI-2K. Patients who had SLEDAI-2K≥10 at least once were defined as HDAS patients. For the purpose of evaluating long term outcomes, each HDAS patient's first visit with SLEDAI-2K≥10 was assigned as baseline, and for non-HDAS patients, recruitment was considered as baseline. Patients in LLDAS continuously for ≥6 months were defined as in sustained LLDAS (≥6months- and ≥12months-sustained LLDAS). Survival analyses were performed to examine the association between LLDAS attainment and damage accrual and flare.

Results: 1076 patients (26%) had HDAS at least once (HDAS-ever). Compared to patients who never experienced HDAS (HDAS-never), HDAS-ever patients were younger, had shorter disease duration at enrolment, and a longer study follow-up period. HDAS-ever patients had higher disease activity across the observation period measured by time-adjusted mean SLEDAI-2K and PGA; higher PNL and IS use, more flares, organ damage, and damage accrual.

None of the HDAS cohort and 42% of HDAS-never group were in LLDAS at baseline (HDAS-never/not LLDAS BL). 66% of HDAS-ever and 57% of 'HDAS-never/not LLDAS BL' patients attained LLDAS at least once during the study observation period. Proportions of patients in sustained LLDAS and who had cumulative LLDAS ≥ 50% of observed time (LLDAS-50) were lower in HDAS-ever patients (Table 1). LLDAS-50 attainment was protective from damage accrual and flare in both HDAS-ever and HDAS-never patients (Table 1). Sustained LLDAS was similarly protective from damage accrual and flare in both 'HDAS-ever' and 'HDAS-never/not LLDAS BL' groups (Table 1).

Table 1.

	HDAS-never/not LLDAS BL n=1215 n (%)	HDAS-ever n=1076 n (%)
Patients with organ damage accrual	212 (18.8%)	269 (27.5%)
patients with flare	613 (50.5%)	894 (83.1%)
LLDAS-ever (at least once)	688 (56.6%)	713 (66.4%)
≥50% cumulative time in LLDAS (LLDAS-50)	371 (33.1%)	182 (18.6%)
≥6-months in sustained LLDAS	391 (32.2%)	287 (26.7%)
≥12-months in sustained LLDAS	243 (20.0%)	143 (13.3%)
Longitudinal associations with	**HR (95% CI), p-value**	**HR (95% CI), p-value**
Organ damage accrual$_t$		
LLDAS$_{t-1}$	0.54 (0.41,0.71), p<0.001	0.49 (0.36,0.67), p<0.001
LLDAS-50$_{t-1}$	0.67 (0.49,0.90), p=0.009	0.61 (0.38,0.98), p<0.04
≥6m sustained LLDAS$_{t-1}$	0.68 (0.45,1.01), p=0.06	0.43 (0.26,0.73), p=0.002
≥12m sustained LLDAS$_{t-1}$	0.54 (0.31,0.94), p=0.03	0.29 (0.11,0.74), p=0.01
Flare$_t$		
LLDAS$_{t-1}$	0.83 (0.71,0.97), p=0.019	0.67 (0.59,0.77), p<0.001
LLDAS-50$_{t-1}$	0.84 (0.69,1.01), p=0.059	0.59 (0.48,0.72), p<0.001
≥6m sustained LLDAS$_{t-1}$	0.47 (0.37,0.60), p<0.001	0.48 (0.38,0.60), p<0.001
≥12m sustained LLDAS$_{t-1}$	0.41 (0.30,0.56), p<0.001	0.29 (0.20,0.42).p<0.001

Conclusion: Sustained or majority LLDAS was less achievable in SLE patients after an episode of HDAS in HDAS-ever compared to HDAS-never patients, but protective associations of LLDAS against organ damage accrual and flare were similar regardless of HDAS. LLDAS attainment is protective from adverse outcomes even after high disease activity.

Acknowledgements: We thank all patients participating in the Asia Pacific Lupus Collaboration (APLC) cohort, and all data collectors for their ongoing support for APLC research activities.

The APLC has received unrestricted project grants from AstraZeneca, BMS, Eli Lily, Janssen, Merck Serono, and UCB to support data collection contributing to this work.

CENTRAL NERVOUS SYSTEM DEMYELINATING SYNDROMES IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM "ATTIKON" LUPUS COHORT

D. Nikolopoulos[1], D. Kitsos[2], M. Papathanasiou[3], N. Kapsala[1], A. Grivas[1], O. Gioti[4], P. Garantziotis[5], A. Pieta[6], K. Voumvourakis[2], D. Boumpas[1], A. Fanouriakis[1,7]. *[1]National and Kapodistrian University of Athens, Rheumatology and Clinical Immunology Unit, 4th Department of Internal Medicine, Attikon University Hospital, Athens, Greece; [2]National and Kapodistrian University of Athens, 2nd Department of Neurology, Attikon University Hospital, Athens, Greece; [3]National and Kapodistrian University of Athens, 2nd Department of Radiology, Attikon University Hospital, Athens, Greece; [4]Asklepieion General Hospital, Department of Rheumatology, Asklepieion General Hospital, Athens, Greece; [5]Hannover Medical University, Division of Immunology and Rheumatology, Hannover, Germany; [6]University of Ioannina, Rheumatology Clinic, University Hospital of Ioannina, Ioannina, Greece; [7]National and Kapodistrian University of Athens, Rheumatology Unit, First Department of Propaedeutic Internal Medicine, Athens, Greece*

Background: Central nervous system (CNS) demyelinating syndromes that occur in the context of SLE may represent a manifestation of neuropsychiatric lupus, or an overlap of SLE and multiple sclerosis (MS). The differential diagnosis between the two entities has important clinical implications, because the therapeutic management differs between the two conditions.
Objectives: To characterize CNS demyelinating syndromes in a large SLE cohort as neuropsychiatric SLE or SLE-MS overlap, using a multidisciplinary approach and existing diagnostic (MS) and classification criteria (SLE)
Methods: Patients from the "Attikon" lupus cohort (n=707) were evaluated for demyelinating syndromes. Clinical, laboratory and neuroimaging data were recorded for each patient. Following multidisciplinary evaluation and application of criteria, the demyelinating syndrome was attributed to either SLE or MS. Patients with transverse myelitis were not included in this study.
Results: We identified 26 patients with demyelinating syndromes (3.7%) with mean age at diagnosis 46.9 (SD 12.3) years and median disease duration at last follow-up 60 (IQR 52) months. Of them, 12 were diagnosed as primary SLE-demyelination (46.2%) and 14 as overlap SLE-MS (53.8%). The two groups did not differ with respect to rheumatologic and neurologic manifestations, or serologic findings (ANA, dsDNA, C3/C4, aPL, ENA). SLE patients with demyelination manifested mild extra-CNS disease mainly involving joints and skin, while severe non-CNS manifestations were rare. However, patients with SLE-demyelination were less likely to have elevated IgG index (OR 0.055 95% CI: 0.008-0.40) and positive oligoclonal bands (OR 0.09 95% CI: 0.014-0.56). SLE patients with primary demyelinating syndrome were less likely to exhibit brain lesions in the spinal cord, infratentorial, periventricular and juxtacortical regions. A single brain region was affected in 9 SLE-demyelination patients (75%), while all MS-SLE patients had multiple affected brain regions. MS-SLE overlap was associated with increased likelihood of neurologic relapses (OR 18.2, 95% CI: 1.76-188), while SLE-demyelination patients were less likely to exhibit neurological deficits (EDSS>0) at last follow-up visit (50% vs. 78.6%in SLE-MS, respectively).
Conclusion: Demyelination in the context of SLE follows a more benign course compared to a frank SLE-MS overlap. Prolongation of follow-up will ascertain whether SLE-demyelination patients evolve to MS, or this is a *bona fide* NPSLE syndrome.

MAJOR SALIVARY GLAND ULTRASONOGRAPHY AND MRI WITH DIFFUSION WEIGHTED IMAGING (DWI) AS COMPLEMENTARY TOOLS TO IDENTIFY FEATURES OF MALT IN PRIMARY SJÖGREN'S SYNDROME (PSS): A SINGLE CENTER CROSS SECTIONAL STUDY

G. Governato[1], G. Fulvio[1], C. Fanni[2], F. Ferro[1], C. Roncella[2], V. Donati[3], A. Santoro[4], S. Fonzetti[1], G. La Rocca[1], M. Mosca[1], G. Aringhieri[2], C. Baldini[1]. *[1]Rheumatology Unit, Azienda Ospedaliero-Universitaria Pisana, Clinical and Experimental Medicine, Pisa, Italy; [2]Diagnostic and Interventional Radiology, Azienda Ospedaliero-Universitaria Pisana, Department of Traslational Research and of New Technologies in Medicine and Surgery, Pisa, Italy; [3]Unit of Pathological Anatomy 2, Azienda Ospedaliero-Universitaria Pisana, AOUP, Pisa, Italy; [4]Unit of Otolaryngology, Azienda Ospedaliero-Universitaria Pisana, AOUP, Pisa, Italy*

Background: Salivary MALT lymphoma represents the major complication of primary Sjögren's Syndrome (pSS). However, the early recognition of MALT lymphoma may be challenging due to its indolent, slow clinical course.
Objectives: 1. to identify salivary gland ultrasonographic (SGUS) features and magnetic resonance (MRI) abnormal findings with Diffusion Weighted Imaging (DWI) and Apparent Diffusion Coefficient (ADC) of MALT in pSS patients 2. To evaluate the correlation between salivary gland ultrasonography (SGUS) and MRI in pSS patients with suspected lymphoma.
Methods: consecutive patients with pSS (2016 ACR/EULAR criteria) and suspected MALT lymphoma undergoing histological examination were included in this cross sectional study from September 2017 to November 2021. The US echostructure of each gland on B-mode images was graded using the latest 2019 OMERACT semiquantitative SGUS scoring systems (0-3). Sonographic features of focal lesions were described. Conventional MRI techniques (i.e T1WI, T2WI, and STIR images) combined with MR sialography was performed in all the cases. DWI was acquired at b-value 0, 500 and 1000. ADC values were calculated. Patients' clinical and histological data were collected. Data were presented as mean±SD, or percent frequency as appropriate. Intergroup comparisons were made using the t-test/Mann–Whitney test for continuous variables and Fisher's exact test for categorical variables.
Results: 45 pSS (mean age, S.D=55±15 yrs) were included. MALT lymphoma was histologically confirmed in 14/45 pSS patients and, specifically in 18/180 major salivary glands (17 parotids and 1 submandibular glands). At SGUS examination, MALT salivary glands presented an OMERACT grade 3 in 16/18 and a grade 2 in 2/18, significantly higher than the OMERACT scoring observed in no-MALT pSS glands (p=0.0001). The sonographic features more commonly detected in MALT were: hypoecoich macroareas with posterior enhancement, presence of septa or hyperechogenic strands and anarchic intralesional vascularization. At MRI, 15/18 (83.3%) MALT lymphoma appeared as intraglandular solid lesions: 9/15 (60%) were solid-cystic lesions and 6/15 (40%) were solid lesions without cystic changes. The frequency of solid lesions in pSS patients without lymphoma was 3/124 (2.4%), significanlty lower than in MALT-pSS. Furthermore 15/18 (83.3%) MALT lymphoma showed glandular fatty substitution. The presence of fatty substitution did not differ in MALT lymphoma and in no-MALT pSS glands. The mean (SD) ADC value of MALT lesions was significantly lower than the ADC of the parotid glands in pSS without lymphoma (0.63±0.07 x 10^-3 mm^2/s vs 1.13± 0.19 x 10^-3 mm^2/s, p =0.001). A negative correlation between SGUS OMERACT score and mean glandular ADC values (r = – 0.776, p < 0.001) was found; patients with OMERACT score 3 presented the lowest mean salivary gland ADC when compared to the other OMERACT scores (0-2) (p=0.001).
Conclusion: OMERACT semiquantitative SGUS scoring systems and MRI with DWI represent promising complementary tools in the differential diagnosis of pSS MALT lymphoma, particularly useful to guide parotid biopsy. Patients with an OMERACT score 3 in their SGUS deserve a careful screening for lymphoma.

POS0124

DIAGNOSTIC VALUE OF LIVER STIFFNESS AS MARKER OF HEPATIC MARKER OF HEPATIC AMYLOID DEPOSITION IN SYSTEMIC AL AMYLOIDOSIS

A. F. Brunger[1], J. Bijzet[1], H. Blokzijl[2], R. Van Rheenen[3], R. Gans[4], B. Hazenberg[1], H. L. A. Nienhuis[4]on behalf of Amyloidosis Center of Expertise, University Medical Center Groningen, Groningen, The Netherlands.. *[1]University Medical Center Groningen, Rheumatology & Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Gastroenterology, Groningen, Netherlands; [3]University Medical Center Groningen, Nuclear Medicine and Molecular Imaging, Groningen, Netherlands; [4]University Medical Center Groningen, Internal Medicine, Groningen, Netherlands*

Background: Hepatic involvement in AL amyloidosis is often asymptomatic but does affect prognosis and should be taken into account during follow-up. An increased plasma level of alkaline phosphatase (ALP) or increased liver span are part of the conventional diagnostic criteria for establishing hepatic involvement[1], however these markers are nonspecific. ^{123}I-labeled serum amyloid P component (SAP) scintigraphy is a specific and sensitive method to establish hepatic involvement but is not widely available. Liver stiffness measured by transient elastography is increased in AL amyloidosis patients with hepatic involvement and could be useful in establishing liver involvement and monitoring treatment response in AL-amyloidosis.
Objectives: To assess the diagnostic value of liver stiffness (LS) for liver involvement in AL amyloidosis and the utility of LS to monitor treatment effect using SAP scintigraphy as gold standard.
Methods: LS was measured prospectively in 49 treatment naive patients with systemic AL amyloidosis and 9 patients with wild type transthyretin amyloidosis (ATTRwt) with cardiomyopathy (cardiac controls). In addition, LS was longitudinally measured in 10 AL amyloidosis patients of whom 9 patients had liver involvement. SAP scintigraphy, laboratory assessments including ALP and measurement of liver span was performed in all patients.
Results: Of the 49 patients, 27 patients had liver involvement (of whom 24 also had heart involvement), 10 patients had heart involvement, 12 patients had no heart or liver involvement. Median LS was significantly higher in AL amyloidosis patients with liver involvement (22.8 kPa, range 4.3-75), than in AL amyloidosis patients without liver involvement (6.3 kPa, range 4.4-35.8) (p=0.000). Also a significant difference was seen between AL amyloidosis patients with liver involvement (22.8.9, range 4.3-75) versus, heart involvement (9.0, range 4.5-35.8) (p=0.02), no liver or heart involvement (5.7, range 4.4-10.1) (p=0.0001), and ATTRwt patients (9.9 kPa, range 4.0-14.6) (p=0.01). Furthermore, LS values seemed to significantly decrease over time in AL amyloidosis patients with liver involvement with a good hematologic response to treatment.
Conclusion: LS is a non-invasive tool which seems to be useful in clinical practice to establish liver involvement in patients with AL amyloidosis. In addition, it is a promising marker in the follow up of AL amyloidosis patients for establishing hepatic response over time.

Van Herwaarden[2,6]. *[1]Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands; [2]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [3]Radboud University Medical Center, Radiology Nuclear Medicine & Institute for Molecular Life Sciences, Nijmegen, Netherlands; [4]Rijnstate, Rheumatology, Arnhem, Netherlands; [5]Amsterdam UMC, locatie VUmc, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; [6]Radboud University Medical Center, Pharmacology-Toxicology, Nijmegen, Netherlands*

Background: Whole-body Positron Emission Tomography with CT-scanning using fluorine-18 fluorodeoxyglucose (18F-FDG) is occasionally used in Rheumatoid Arthritis (RA) patients. Reasons to use FDG-PET/CT-scans are to diagnose arthritis or guide decisions on systemic therapy, as FDG uptake in affected joints may reflect disease activity [1]. FDG-PET/CT might also detect malignancies, but the frequency of incidental findings and the proportion of relevant malignant disease that could be missed are currently unknown.
Objectives: To study the malignancy screening performance of whole-body FDG-PET/CT in longstanding RA patients with low disease activity.
Methods: FDG-PET/CT-scanning was done in the intervention arm of the Dose REduction Strategy of Subcutaneous TNF-inhibitors (DRESS) study, a randomized controlled trial on dose-tapering of biological Disease Modifying Anti-Rheumatic Drugs (bDMARDs) [3]. Baseline and if applicable follow up whole-body FDG-PET/CT-scans were performed in consenting patients in the tapering arm to assess predictive value of subclinical PET-arthritis for risk of flaring [4]. The scans were also read by experienced nuclear medicine specialists immediately after they were performed for any unexpected extra-articular finding, conform routine clinical care.
The reference standard was clinical diagnosis of malignancy during the 3 year follow-up. Prevalence of extra-articular abnormalities, follow-up, and received treatments were summarized post-hoc.
Results: 121 scans were made in 79 patients. Extra-articular abnormalities were found in 59/121 (48.8%) scans (Table 1) in 45/79 (57%) patients.

Table 1. ***Abnormalities found on FDG-PET/CT scans***

	# abnormal results found on scans (%)
No PET/CT result obtained	3 (2.5)
No abnormalities found on any scan	59 (48.8)
One or more abnormalities found per scan*	59 (48.8)
Total number of scans	**121**
Inflammatory	7 (5.7)
Suspected malignancies	9 (7.4)
Cardiovascular	2 (1.6)
Pulmonary	7 (5.8)
Gastrointestinal	10 (8.3)
Muscles/tendons	3 (2.5)
Bone-related	3 (2.5)
Hypermetabolic lymph nodes (non-specific)	16 (13.2)
Thyroid	4 (3.3)

* Fifteen of these abnormalities were found on the second PET/CT, the rest was found on the first scan. 11 abnormalities on the second PET/CT were the same as the one seen on the first scan, and 7 abnormalities resolved after the first scan. One scan can show multiple abnormalities, from different categories.

Follow-up action occurred in 21 (26.6%) patients, consisting of referral to a specialist or reassessing and/or scheduling diagnostics directly by the treating rheumatologist. In 5 (6.3%) patients, the rheumatologist followed-up. In 17 (21.5%) patients a consultation with a different specialist was scheduled. In five patients surgical/invasive intervention took place. In one patient a hemi-thyroidectomy was performed revealing a follicular adenoma. This resection was complicated by persistent recurrent laryngeal nerve paresis and hoarseness. In a second, an intra-uterine myomectomy took place. In a third, a colonoscopy was performe revealing two low-grade adenomas. In a fourth a benign cyst in the neck was extracted. A fifth patient underwent spinal marginal myotomy which turned out to be a benign schwannoma.
Nine patients (7.4%) were suspected of malignancy, none turned out to be malignant. Six clinical malignancies (bladder, penile, lymphoma, 2x melanoma and prostate) that developed during follow-up were all negative on baseline FDG-PET/CT. The malignancies were diagnosed after an interval of between 5 and 34 months (mean 13 months).
Conclusion: Whole-body FDG-PET/CT-scanning for arthritis imaging in RA patients results in frequent incidental extra-articular findings, while some who apparently had normal scans developed malignancies.

POS0126 UTILITY OF THE SUBCHONDRAL BONE ATTENUATION COEFFICIENT OF THE SACROILIAC MARGINS TO DIFFERENTIATE SPONDYLOARTHRITIS AND OSTEITIS CONDENSANS ILII

A. Terrier[1], O. Fakih[2], M. Chouk3, C. Prati3, D. Wendling[4], S. Aubry[5], F. Verhoeven[6,7]. *[1]CHU Besancon, Musculoskeletal Imaging, Besancon, France; [2]CHU Besancon, Rheumatology, Besancon, France; [2]CHU Besancon, Rheumatology, Besancon, France; [4]CHU Besancon, Rheumatology, Besancon, France; [5]CHU Besancon, Musculo Skeletal Imagina, Besancon, France; [6]CHU Besancon, Rheumatology, Besancon, France; [7]Université de Franche Comte, EA 4267 PEPITE, Besancon, France*

Background: Differentiating ankylosing spondylitis (AS) from osteitis condensans ilii (OCI) remains challenging for clinicians.
Objectives: The aim of this study was to determine whether Subchondral Bone Attenuation Coefficient of the Sacrolliac margins (SBAC-SI) is different in AS, OCI and diffuse idiopathic skeletal hyperostosis (DISH).
Methods: A monocentric retrospective observational study was performed at a French University Hospital. Patients included were followed for AS, DISH or OCI and underwent CT scan including sacroiliac joint. Patients with tumor lesion of bone or a history of pelvic radiotherapy were excluded. AS and OCI patients were matched with a control of the same age and sex. All scans were acquired on the same CT-scan unit (Somatom 64 definition AS+, Siemens Healthineers, Erlangen, Germany), with a slice thickness of 0.625 mm. In the coronal oblique plane of the SIJ, three slices (anterior, middle and posterior) and four quadrants per joint were defined. Twenty-four identical circular regions of interest (ROIs) (30 mm2), 8 per slice, were manually placed separately subcortical to the SIJ, four on the sacral side and four on the iliac side. The distance between the circle of the ROI and the cortical bone was 2 to 3 mm. An overall score was obtained from

the sum of all ROIs. For every ROI, an Attenuation Coefficient was measured and expressed in Hounsfield Unit. The total SBAC-SI score was the sum of the 24 ROI. The sacral and iliac SBAC-SI scores were the sum of the sacral or the iliac ROI.

Results: Thirty AS and AS controls, 31 DISH, 29 OCI and OCI controls were included. SBAC-SI score was 9727 (±2430) in the OCI group (p<0.001), 3563 (±1860) in the AS group, 3899 (±1937) in the DISH group, 4224 (±1693) in the AS control group and 5445 (±1205) in the OCI control group. A threshold of 7500 HU had the best discriminative value between OCI and AS (youden index: 0.89). In AS, disease duration is negatively associated with SBAC-SI (r: -0.623; p< 0.01) and HLA B27 is associated with lower SBAC-SI (6523 [5198; 7137]VS 2809 [1568; 3371]; p <0.001).

Conclusion: SBAC-SI is significatively different between AS and OCI and could help to distinguish these two diseases.

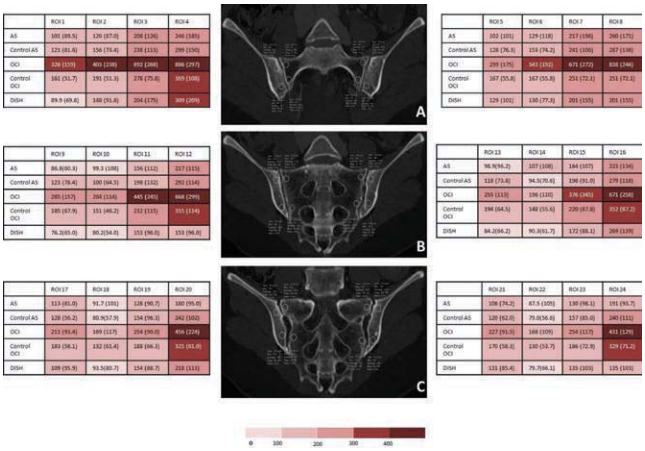

Figure 1. Distribution of the Subchondral Bone Attenuation Coefficients of the Sacroiliac Margins of the 24 ROI in the anterior (A), middle (B) and posterior (C) slices in the coronal oblique plane of the sacroiliac joints

POS0127 QUANTITATIVE ASSESSMENT OF FINGER VASCULARITY IN SYSTEMIC SCLEROSIS PATIENTS WITH RAYNAUD'S PHENOMENON USING ULTRASOUND VASCULAR IMAGING

K. Nam[1], F. Mendoza Ballesteros[2,3], C. Wessner[1], T. Allawh[3], F. Forsberg[1]. *[1]Thomas Jefferson University, Department of Radiology, Philadelphia, United States of America; [2]Thomas Jefferson University, Scleroderma Center and Jefferson Institute of Molecular Medicine, Philadelphia, United States of America; [3]Thomas Jefferson University, Department of Medicine, Division of Rheumatology, Philadelphia, United States of America*

Background: In patients with Systemic Sclerosis (SSc), vasculopathy plays an important pathophysiological role and it is almost universally expressed as Raynaud's Phenomenon (RP). Assessment of vasculopathy/microangiopathy is crucial for early diagnosis of SSc and also is considered in the SSc classification criteria. Currently, this evaluation is performed by nailfold capillaroscopy. However, nailfold capillaroscopy is limited to the nail fold area and is mainly qualitative since is based on the shape, size, and density of the observed capillaries.

Objectives: The objective of this study is to detect and quantify finger vascularity of SSc patients with RP using four ultrasound vascular imaging techniques. Additionally, the diagnostic performance of quantified finger vascularity was assessed.

Methods: This prospective IRB approved study has enrolled 20 SSc patients fulfilling the 2013 ACR/EULAR classification criteria and presenting RP. Age and sex matched normal volunteers (16 subjects) without RP, were also enrolled. All fingers except thumbs were imaged at room temperature in the seated position. The blood flow of each finger was evaluated on the dorsal (showing nail) and ventral (showing palm) sides using an i24LX8 probe (9-24 MHz) on an Aplio i800 system (Canon Medical Systems, Tustin, CA, USA). Blood flow images were obtained using color Doppler imaging (CDI), power Doppler imaging (PDI), monochrome Superb Microvascular Imaging (mSMI), and color-coded Superb Microvascular Imaging (cSMI) keeping the same imaging settings for all subjects. The percent area of vascularity observed by each technique was quantified offline by counting pixels of blood flow in a 5 x 5 mm square centered at the nail fold for the dorsal side and in a 1 x 1 cm square from the fingertip for the ventral side using Matlab (MathWorks, Natick, MA, USA). The percent vascularity areas from dorsal and ventral sides were averaged over fingers, then t-tests and receiver operating characteristic (ROC) analyses were performed (Youden Index) to assess the ability of the different methods for classifying disease status (RP-SSc from normal controls), allowing to assign diagnostic accuracy.

Results: Two patients' data were excluded due to technical errors. The data from 18 RP-SSc patients and 16 normal volunteers were analyzed. The percent vascular areas in patients with RP were significantly lower than those in normal volunteers at both dorsal ($p < 0.03$) and ventral ($p < 0.01$). For each imaging technique, the ventral side vascularity showed a higher diagnostic accuracy compared to the dorsal side. Among the four imaging techniques, CDI showed the highest diagnostic accuracy. The mean percent areas by CDI were 6.8 ± 7.1% (mean ± standard deviation) and 15.3 ± 8.9% on the dorsal side ($p < 0.01$) and 5.3 ± 5.6% and 16.7 ± 7.4% on the ventral side ($p < 0.0001$) for RP patients and normal volunteers, respectively. The ventral side vascularity by CDI showed the highest diagnostic accuracy of 90% with 88% specificity and 78% sensitivity.

Conclusion: Ultrasonic vascular imaging demonstrated the potential to quantify microangiopathy of RP-SSc. Additionally, the mean percent vascular area averaged across the fingers showed to be accurate (70 to 90%) to differentiate patients with RP-SSc from normal controls, albeit based on small sample size.

POS0128 MICROVASCULAR INVOLVEMENT IN BEHÇET'S DISEASE. STUDY OF NAILFOLD CAPILLAROSCOPY AND ENDOTHELIAL PROGENITOR CELLS IN A NATIONAL REFERRAL CENTER

B. Atienza-Mateo[1,2], A. del Peral Fanjul[2], V. Pulito-Cueto[2], D. Prieto-Peña[1,2], M. A. González-Gay[1,2], R. Blanco[1,2]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain; [2]IDIVAL, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic Bone Diseases of the Musculoskeletal System, Santander, Spain*

Background: Ocular manifestations of Behçet's disease (BD) are globally recognized and widely studied **[1]**. Vascular lesions are also frequent but less explored **[2]**. Microvascular involvement may be clinical (as Raynaud's phenomenon) or subclinical. Vascular microcirculation is studied with Nailfold Capillaroscopy (NFC) that may show capillary abnormalities such as dilated loops, megacapillaries and microhemorrhages. Endothelial progenitor cells (EPCs) have been implied in the pathogenesis of multiple cardiovascular disorders and vasculitis, including BD and could be used as biomarkers.

Objectives: To assess the microvascular involvement and EPCs in patients with BD.

Methods: Observational study of unselected consecutive patients with BD assessed in a national referral center from March to May 2021. All patients fulfilled the 2014 ICBD criteria **[2].** They were evaluated sequentially with a scheduled clinic visit after signing an informed consent. The main variables collected were **a)** periungual capillaries features (loop diameter, tortuosity, vascular density, microhemorrhages and blood flow), and **b)** serum EPCs levels. NFC was performed from the second to fifth fingers of both hands using a 500x magnification digital microscope. The following features were considered abnormal: diffuse enlarged capillaries (≥2 capillaries with a diameter of 20-50 µm in at least 2 different fingers), megacapillaries (>50 µm in diameter), reduced vascular density (<9 capillaries/mm or avascular areas), diffuse microhemorrhages (≥2 hemorrhages in at least 2 different fingers) and granular/slow flow. EPCs were studied in unselected BD patients in whom instant blood samples were available and compared with sex-aged matched healthy controls (HC). EPCs from peripheral venous blood were quantified by direct flow cytometry and characterized by simultaneous expression of cell surface markers of stemness (CD34), immaturity (CD133), endothelial commitment (CD309) and a low expression of the pan-leukocyte marker (CD45).

Results: From a cohort of 120 patients with BD, 42 were evaluated during the period of the study (Table 1). NFC was performed in the 42 cases, being abnormal in 54.8% of them. The most common findings were capillary loop dilation (45.2%), capillary tortuosity (31%), megacapillaries (21.4%) and microhemorrhages (16.7%) (Table 1). Instant blood samples to study EPCs levels were available in 18 BD patients and 12 HC. The median [IQR] frequency of EPCs levels were higher in BD than in HC (p=0.011) (Figure 1).

Table 1. Collected data of 42 patients with Behçet's disease.

Demographic data	n (%)
Women/Men	19 (45.2)/ 23 (54.8)
Age (years), mean ± SD	47.86±12.99
Clinical vascular involvement	**n (%)**
Deep vein thrombosis	4 (9.52)
Superficial thrombophlebitis	1 (2.38)
Arterial aneurysms	2 (4.76)
Acute myocardial infarction	3 (7.14)
Arterial thrombosis	1 (2.38)
Raynaud's phenomenon	10 (23.81)
Nailfold capillaroscopy Findings	**n (%)**
Abnormal	23 (54.8)
Dilated loops (20-50 µm) ≥2 in at least 2 fingers	19 (45.2)
Megacapillaries (>50 µm)	9 (21.4)
≥2 in at least 2 fingers	3 (7.1)
Capillary tortuosity	13 (31)
Microhemorrhages	7 (16.7)
≥2 in at least 2 fingers	1 (2.4)
Reduced vascular density	3 (7.1)
Granular flow	1 (2.4)

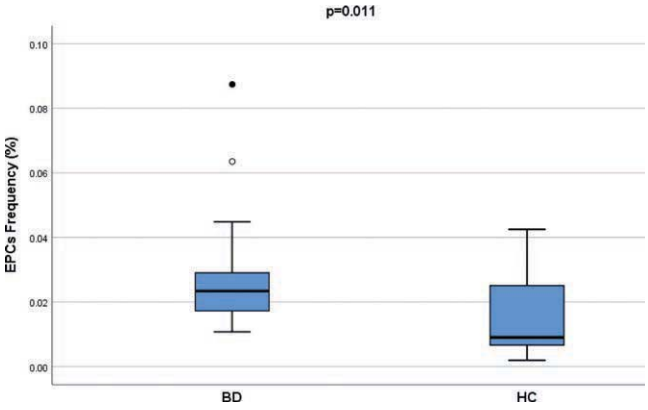

Figure 1. Quantification of endothelial progenitor cells population by flow cytometry in 18 patients with Behçet's disease and 12 healthy controls. Mann-Whitney U test. BD: Behçet's disease. EPCs: endothelial progenitor cells. HC: healthy controls.

Conclusion: Microvascular involvement is common in BD and can be easily assessed by NFC. Furthermore, EPCs quantification may be a useful serum biomarker of the disease.

POS0129 TO CONTRAST OR NOT TO CONTRAST? ON THE ROLE OF CONTRAST ENHANCEMENT IN HAND MRI STUDIES OF PATIENTS WITH RHEUMATOID ARTHRITIS

G. Rübsam[1], M. Frenken[1], A. D. Mewes[1], K. L. Radke[1], L. Le[2], L. Wilms[1], S. Nebelung[3], D. Abrar[1], P. Sewerin[4,5]. *[1]Heinrich Heine University Duesseldorf, Institute of Diagnostic and Interventional Radiology, Düsseldorf, Germany; [2]Ludwig Maximilian University, nstitute for Medical Information Sciences, Biometry and Epidemiology, Munich, Germany; [3]Aachen University Hospital, Department of Diagnostic and Interventional Radiology, Aachen, Germany; [4]Heinrich-Heine University, Department and Hiller Research Unit of Rheumatology, Duesseldorf, Germany; [5]Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany*

Background: Currently, clinical indications for application of gadolinium-based contrast agents (GBCA) in magnetic resonance imaging (MRI) are increasingly being questioned[1]. Rheumatoid arthritis is a disease which is characterised by joint inflammation and due to various existing therapies, early diagnosis and sensitive monitoring is beneficial for assessing disease progression, therapy response and optimizing the individual therapy.

Objectives: This study aimed to evaluate the necessity of contrast enhancement in MRI of the hand in patients with rheumatoid arthritis (RA).

Methods: 31 patients with RA (mean age, 50±14 years [range, 18–72 years]) from the German ArthroMark cohort underwent morphologic high-field MRI scans on a clinical 3T scanner. MRI studies were analyzed based on (1) the Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS[2]) and (2) the GBCA-free RAMRIS version, termed RAMRIS **S**ine-G**a**dolinium-**F**or-**E**xperts (RAMRIS-SAFE), in which synovitis and tenosynovitis were assessed using the short-tau-inversion-recovery (STIR) sequence instead of the post-contrast T1-weighted sequence.

Results: Correlation between RAMRIS and RAMRIS-SAFE in terms of Spearman's ρ was almost perfect (ρ=0.976; p<0.001). The synovitis subscores, as based on RAMRIS and RAMRIS-SAFE, were equally strongly correlated (ρ=0.937; p<0.001), while the tenosynovitis subscores were less strongly correlated (ρ=0.380 p=0.035). Inter-rater reliability in terms of Cohen's κ was high ($0.963 \leq \kappa \leq 0.925$).

Conclusion: In conclusion, RAMRIS-SAFE as the GBCA-free version of the well-established RAMRIS is a patient-friendly and resource-efficient alternative for assessing disease-related joint changes in RA. As patients with RA are subject to repetitive GBCA applications, non-contrast imaging protocols should be considered.

POS0130 NEAR INFRARED FLUORESCENCE OPTICAL IMAGING (NIR-FOI) CAN SUPPORT THE DIFFERENTIAL DIAGNOSES OF CONNECTIVE TISSUE DISEASES

D. Kiesel[1], J. Berger[2], E. Gedat[3], S. Ohrndorf[4], A. Briel[5], V. Failli[2], P. Welker[1]. *[1]Charité - University Medicine Berlin, Functional Anatomy, Berlin, Germany; [2]Xiralite GmbH, R&D, Berlin, Germany; [3]Technical University of Applied Sciences, Engineering and Natural Sciences, Wildau, Germany; [4]Charité - University Medicine Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; [5]nanoPET GmbH, R&D, Berlin, Germany*

Background: Differentiation between degenerative osteoarthritis (OA) and autoimmune caused connective tissue diseases (CTD), or rheumatoid arthritis (RA) is important for effective therapy. Anamnesis, clinical examination, and analysis of laboratory parameters are helpful for diagnosis, but do not always lead to clear results. One problem is that patients often show overlapping symptoms. Particularly, imaging techniques as NIR-based fluorescence optical imaging (FOI) are playing an increasingly role as quantifiable and sensitive diagnostic methods. After injection of a fluorescent dye, changes in the microcirculation caused by inflammation can be detected due to altered blood flow and accumulation in anatomical structures of the hands. Analyses of enrichment features can be used to identify pathological changes and to support the diagnosis of degenerative and autoimmune diseases.

Objectives: The present work investigates the potential of NIR-FOI feature assessment to differentiate between various rheumatic diseases, which are accompanied by pathological changes in connective tissues.

Methods: NIR fluorescence imaging comprised 360 images/6 min. after injection of the dye. Analyses of patients with the clinical diagnosis of OA (n = 236) were compared with RA patients (n = 235), and patients diagnosed with autoimmune CTD (collagenoses) (n = 149). 17 features known to occur in FOI images were analyzed in both hands in three time periods (P1-3) after injection in two independent passes. In some cases, Prima Vista images (PVI), representing the sum of images 1-240 were also analyzed (n = 45, 33, 33 for OA, RA, CTD). Signals compared to the background were assessed as positive or negative (Figure 1). The data were analyzed statistically.

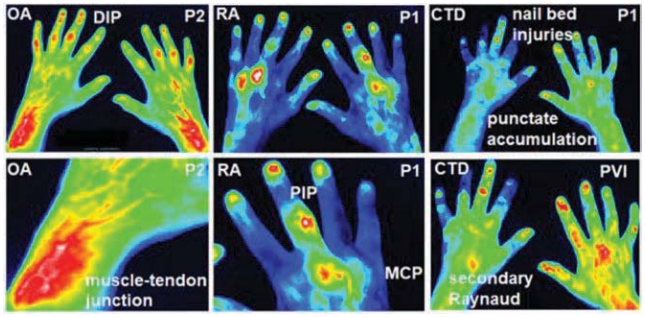

Figure 1. Examples of significantly different features in NIR-FOI images of patients with clinically diagnosed OA, RA, or CTD. Top: the whole hands, also with nail bed injuries in phase 1 (P1) for a CTD patient (right), bottom: increased intensity in muscle-tendon junction in the forearm in phase 2 (P2) for an OA patient, increased intensity in MCP joint in phase 1 (P1) for an RA patient and a secondary Raynaud syndrome for a CTD patient in PVI.

Results: Comparing the analyses of all phases of the OA cohort with those of the RA cohort, 14 of 51 features were identified as significantly different ($p<0.05$). The dye accumulation in metacarpophalangeal joints (MCP) has high specificity and diagnostic odds ratio (DOR) for RA patients (91%, 4.32). Patients in the OA cohort showed an increase in the signal at the muscle-tendon junction in the forearm (80% specificity, DOR 3.11). A comparison of the RA and CTD cohorts revealed 24 significant differences, most prominent changes in the nail bed in P1 (100% specificity, DOR 8.27) and a punctate accumulation pattern in P2 (98% specificity, DOR 2.61) for the CTD cohort. Comparing the RA and CTD cohorts, 22 features were significantly different. The strongest differences were found in the PIP joints of RA patients (78% sensitivity, DOR 2.97) and in the nail bed of CTD patients (100 % specificity, DOR 8.18). In the cumulative PV images a high specificity for a secondary Raynaud's syndrome in CTD patients was found as compared to RA (97%, DOR 17.7) and OA (91%, DOR 5.9). Further, DIP signals for OA comparing to CTD show significant differences (76 % sensitivity, DOR 2,73).

Conclusion: The present work demonstrates the detection and localization of specific, significant features in NIR-FOI of patients with different rheumatic diseases and can thus make an important contribution to diagnosis and optimization of therapy. In future, multivariate analysis and artificial intelligence algorithms can combine these features to further improve the diagnostic value.

POS0131 CONCORDANCE BETWEEN LOCATION OF SELF-REPORTED SITE OF MUSCULOSKELETAL PAIN IN PSORIASIS AND FINDINGS OF INFLAMMATION BY ULTRASOUND

S. Kamp Felbo[1,2], L. Terslev[1,2], I. J. Sørensen[3], O. Hendricks[4,5], D. Kuettel[4,5,6], R. Lederballe Pedersen[7], S. Chrysidis[8], M. Østergaard[1,2]. *[1]Rigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; [2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [3]Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; [4]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; [5]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; [6]Hospital Sønderjylland, University Hospital of Southern Denmark, Medical department, Sønderborg, Denmark; [7]Silkeborg Regional Hospital, Department of Rheumatology, Diagnostic Center, Silkeborg, Denmark; [8]University of Southern Denmark, South West Jutland Hospital, Research Unit of Rheumatology, Department of Clinical Research, Esbjerg, Denmark*

Background: Patients with psoriasis (PsO) often report muskuloskeletal (MSK) pain without clinical findings of inflammation. Ultrasound (US) is more sensitive than clinical evaluation in detecting synovitis and enthesitis, and we have previously found that patients with PsO and pain more often have US signs of inflammation in joints and entheses than patients without pain (1), indicating possible psoriatic arthritis (PsA). Whether the area of reported pain in these patients correspond to inflammation by US has not yet been investigated.
Objectives: In patients with PsO with self-reported MSK pain, to investigate if the area of reported of pain corresponds to synovitis and/or enthesitis.
Methods: PsO patients with self-reported MSK pain (n=79, Table 1), recruited from a Danish nationwide survey, were evaluated in one of four rheumatology departments with greyscale (GS) and color Doppler (CD) US of 48 joints and 12 entheses, applying the OMERACT scoring systems (2) for US synovitis (defined as GS score ≥2 or CD≥1) and enthesitis (defined as ≥1 GS inflammatory finding (hypoechogenicity/thickening) and CD score ≥1). Patients indicated the location of current pain in 21 areas on a homunculus, out of which shoulder (joint), elbow (joint and common extensor enthesis), hand (wrist and MCP, PIP, and DIP-joints 1-5), knees (joint and quadriceps- and patellar entheses), feet (ankle and MTP-joints 1-5) and heel (Achilles- and plantar fascia entheses) were evaluated by US, se Figure 1. Association between self-reported pain and US inflammation (synovitis/enthesitis) was explored using Fisher's exact test and odds ratios (OR) for 2x2 tables. Agreement was calculated using Cohen's kappa (κ).

Table 1. Population characteristics (n=79)

Sex (female)	33 (42)
Age (years)	57 (47-66)
Body Mass Index (kg/m^2)	28.4 (24.8-34.8)
Disease duration PsO (years)	25 (11-39)
Swollen joint count (0-66)	0 (0-1)
Tender joint count (0-68)	2 (0-5)
Tender enthesis count (0-16)	1 (0-2)
Fibromyalgia tender point count (0-18)	1 (0-5)
Psoriasis Area and Severity Index (0-72)	1.5 (0.2-4.2)
Nail psoriasis (presence)	26 (33)
Physician VAS (0-100)	3 (1-6)
CRP (mmol/l)	2.1 (0.5-4.1)
Global VAS (0-100)	16 (4-45)
Pain VAS (0-100)	20 (5-39)
Health Assessment Questionnaire (0-3)	0.25 (0.00-0.69)
DAS28-CRP (0-10)	1.6 (1.5-2.6)
Disease Activity in Psoriatic Arthritis (0-164)	5.2 (4.1-20.7)

Numbers are median (IQR) or no. (%). CRP: C-reactive protein, DAS28: Disease Activity Score - 28 joints, VAS: Visual Analog Scale

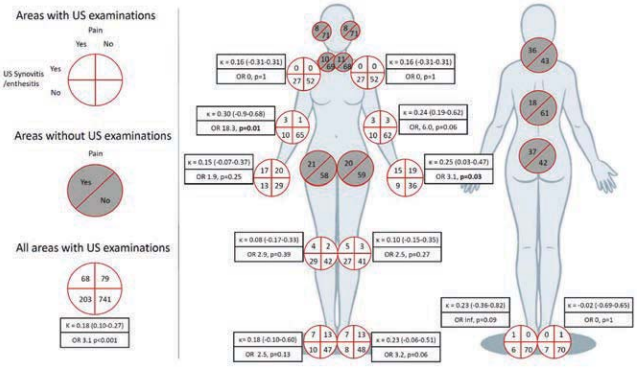

Figure 1. Self-reported pain versus ultrasound (US) inflammation in different areas, and in all areas considered together, presented as 2x2 tables and corresponding odds ratios (OR, p-value) (Fisher's exact test), and agreement (Cohens Kappa (κ (95% confidence interval)).

Results: Of the areas examined by US, pain was most frequent in the knees (41% of patients), while US inflammation was most frequent in the hand/wrist (55%). In total, US inflammation was found in of 72% patients (synovitis in 71%, enthesitis in 17%). In 47% of patients, US inflammation was found in one or more of the painful sites. Figure 1 shows 2x2 tables of pain versus US inflammation in different areas and corresponding ORs and κ-values. Self-reported pain was significantly related to US inflammation in that area, both overall (OR=3.1, p>0.001) and for the specific areas of the left hand (OR 3.1, p=0.03) and right elbow (OR 18.3, p=0.01). Agreement between self-reported pain and US inflammation, as measured by κ, was overall low, κ =0.18(95% confidence interval 0.10-0.27), with highest agreement found for the right elbow (κ = 0.30(-0.9-0.68)). Pain only in areas not examined by US (back/hips/breastbone/jaw) was indicated by 16% of patients.
Conclusion: While US signs of synovitis and enthesitis is frequent in patients with PsO and pain, concordance between US inflammation and the specific location of pain is only seen in half of the patients.

THE FIRST ALGORITHM TO INTEGRATE ULTRASONOGRAPHY IN THE DIAGNOSTIC PROCESS OF DIFFERENTIAL DIAGNOSIS OF INFLAMMATORY ARTHROPATHY IN CLINICAL PRACTICE: A STUDY FROM THE MSUS WORKING GROUP OF THE ITALIAN SOCIETY OF RHEUMATOLOGY

A. Damiani[1], G. Sakellariou[2], A. Adinolfi[3], C. A. Scirè[4], G. Pacini[1], E. Fiorentini[1], D. Carboni[1], S. Sirotti[5,6], P. Sarzi-Puttini[5], J. Madruga Dias[7], A. Iagnocco[8], G. Filippou[5]on behalf of the Italian society for Rheumatology (SIR) Ultrasound group. *[1]University of Florence, Department of Experimental and Clinical Medicine, Division of Rheumatology, Florence, Italy; [2]University of Pavia, Istituti Clinici Scientifici Maugeri IRCCS, Pavia, Italy; [3]ASST Grande Ospedale Metropolitano Niguarda, Rheumatology Unit, Milano, Italy; [4]University of Milano-Bicocca, Epidemiology Research Unit, Società Italiana di Reumatologia, Milano, Italy; [5]Luigi Sacco University Hospital, Rheumatology Department, Milano, Italy; [6]University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy; [7]Cento Hospitalar Médio Tejo, Torres Novas, Portugal & EpiDoc, CEDOC, Nova Medical School, Lisbon, Portugal; [8]Università degli Studi di Torino, Academic Rheumatology Centre, Torino, Italy*

Background: Musculoskeletal ultrasonography (MSUS) is a useful tool for the diagnosis of several Rheumatic and Musculoskeletal Diseases (RMDs) but its role in the diagnostic pathways in clinical practice is still unclear as feasibility issues limit its application as a bed side technique.
Objectives: To optimize the use of US in clinical practice, the MSUS Study Group of the Italian Society for Rheumatology aimed to develop an algorithm combining US with clinical and laboratory findings to improve the differential diagnosis among patients presenting with joint swelling.
Methods: Based on a systematic literature review[1] and experts' opinion, MSUS Study Group Members attempt to identify a set of statements including the main US elementary lesions useful for US scanning in the suspicion of Rheumatoid arthritis (RA), Psoriatic arthritis (PsA), Rheumatic Polymyalgia (PMR), Gout, Calcium Pyrophosphate Deposition Disease (CPPD), Osteoarthritis (OA). Then, the MSUS Study Group defined through a survey and ranked in a 1000minds exercise the most important clinical/laboratory findings for the differential diagnosis of those diseases. Higher-ranked items were fitted in an algorithm driving the differential diagnosis of RMDs to a reduced spectrum of 2 to 4 possible diseases. Finally, the algorithm supported the performance of US according to the established scans for those specific diseases. To assess the algorithm's performance, a pilot study was conducted on 59 patients, comparing the algorithm-based diagnosis with the final diagnosis based on rheumatologist's experience and/or on classification criteria.
Results: Sets of elementary US lesions and a scanning protocol for each included pathology were created (Table 1), optimized towards high sensibility and specificity. Among the findings evaluated, the age (<50 / ≥50 years old), the number of the involved joints (monoarticular/polyarticular), the serology (Rheumatoid Factor [RF] and anti-citrullinated protein antibody [ACPA]); the acute-phase reactants (C-reactive protein [CRP]; erythrocyte sedimentation rate [ESR]) reached the higher ranking in the survey and were introduced in the algorithm, showed in Figure 1. In the pilot study, the algorithm-based diagnosis was consistent with the final diagnosis in 52 cases (accuracy 88.1%). Among the 7 cases in which the algorithm misclassified patients, four patients had a final diagnosis of OA (3 diagnosed by the algorithm as PMR/RA/PSA and one as PSA), one gout (algorithm diagnosis: OA/CPPD/PSA), one RA (algorithm diagnosis: Gout/CPPD/PSA) and one CPPD (algorithm diagnosis: PMR/RA/PSA).

Table 1. Elementary ultrasound lesions and joints to be scanned for each included pathology

Disease	Sites to scan	US elementary lesions
RA	II-IV MCPs	Synovial Hypertrophy (SH), Power Doppler (PD), erosions
	Wrist	
	V MTP	
PsA	II-III MCPs	Peritendonitis
	PIPs	Enthesitis
		Soft tissue oedema
	Flexor tendons of the hands	Tenosynovitis
		Soft tissue oedema
	Achille's tendon enthesis	PD, erosions
	Proximal patellar tendon enthesis	
CPPD	Knees (menisci and Hyaline Cartilage)	CPP deposits
	Wrist (triangular fibrocartilage complex)	
	Any involved sites	CPP deposits, SH, PD
Gout	Knees	Double contour, tophi
	I MTP	
	Involved sites	SH
		PD
OA	Involved sites	Osteophytes
		Cartilage changes
PMR	Shoulders	Bursitis
		Arthritis
		Rotator cuff integrity

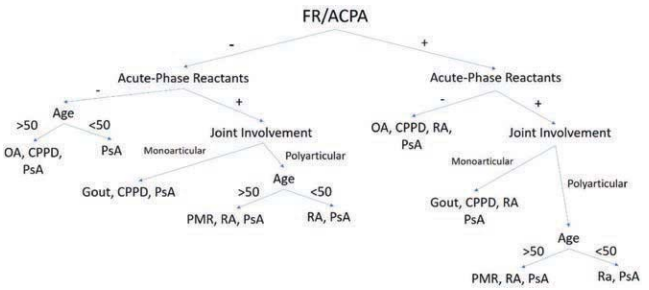

Figure 1. The final algorithm

Conclusion: The diagnostic algorithm produced in this pilot study correctly classified patients with the most prevalent RMDs in clinical practice. A longitudinal study on a large sample size is ongoing to evaluate the added value of US when implemented in this algorithm regarding diagnostic certainty, accuracy and early diagnosis.

HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY FOR THE EVALUATION OF BONE EROSIONS OF METATARSOPHALANGEAL JOINTS IN RHEUMATOID ARTHRITIS: A PILOT STUDY

J. Meinhardsson[1], R. Klose-Jensen[1], J. Therkildsen[1,2], B. Langdahl[2,3], E. M. Hauge[1,2], K. Keller[1,2]. *[1]Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark; [2]Aarhus University Hospital, Department of Clinical Medicine, Aarhus N, Denmark; [3]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark*

Background: Bone erosion in rheumatoid arthritis (RA) is most commonly detected in the wrist, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints. High-resolution peripheral quantitative computed tomography (HR-pQCT) has successfully been used to quantify bone erosions in the wrist and MCP joints. A recent study highlights that HR-pQCT of only two MCP joints has equal accuracy to detect erosive disease in RA patients compared to conventional radiography (CR) of the hands, wrists, and feet (44 joints)[1]. However, no study has evaluated the MTP joints by HR-pQCT.

Objectives: To characterize the localization, size and frequency of erosions in the 4th and 5th MTP joints. Furthermore, to evaluate the sensitivity for the detection of erosion in the 4th and 5th MTP joints by HR-pQCT, compared to CR.

Methods: This single-centre cross-sectional study included 42 patients with established RA (disease duration ≥ 5 years). The right foot was imaged by HR-pQCT in a 2.7 cm long region corresponding to the 4th and 5th MTP joint. Blinded to patient data, the number and volume of bone erosions by HR-pQCT were measured and scored according to the SPECTRA criteria[2]. CR of 44 joints was evaluated according to the Sharp/van der Heijde (SHS) method.

Results: The patients (62% women) had a median disease duration of 12 years (interquartile range (IQR): 7 – 20). HR-pQCT of the 4th and 5th MTP joints identified erosions in 38 (90%) patients. The total erosion volume (V_{tot}) was 2610 mm^3 in all quadrants of the 4th and 5th MTP joints. Erosions were most frequently found at the lateral aspect of the 5th metatarsal head (MH), including 1261 mm^3 (48%) of V_{tot} (Figure 1). CR of 44 joints detected erosions in 30 (71%) patients with a median SHS erosion score of 9 (5 – 28). The sensitivity and specificity (95% CI) of classifying patients with erosive RA by HR-pQCT and CR is displayed in Table 1. McNemar's χ^2 test showed a significantly higher sensitivity of patients classified as having erosive RA by HR-pQCT of the 4th and 5th MTP joints than by CR of 44 joints (4.6, p = 0.03).

Table 1. Comparing CR and HR-pQCT for classifying patients as having erosive RA, and for identifying erosions in the 4th and 5th MTP joints.

Sensitivity & specificity of classifying patients with erosive RA by HR-pQCT when CR of the hands, wrist and feet was used as reference

	CR Hands, wrists, and feet Erosive RA	CR Hands, wrists, and feet Non-erosive RA	Total	Sensitivity (95% CI)
HR-pQCT 4th and 5th MTP joints Erosive RA	27	11	38	90.0 (73.5 – 97.9)
				Specificity (95% CI)
HR-pQCT 4th and 5th MTP joints Non-erosive RA	3	1	4	8.3 (0.2 – 38.5)
Total	30	12	42	

Sensitivity & specificity of classifying patients with erosive RA by CR when HR-pQCT was used as reference

	HR-pQCT 4th and 5th MTP joints Erosive RA	HR-pQCT 4th and 5th MTP joints Non-erosive RA	Total	Sensitivity (95% CI)
CR Hands, wrists, and feet Erosive RA	27	3	30	71.0 (54.1 – 84.6)
				Specificity (95% CI)
CR Hands, wrists, and feet Non-erosive RA	11	1	12	25.0 (0.6 – 80.6)
Total	38	4	42	

Conventional Radiography (CR), High-resolution peripheral Quantitative Computed Tomography (HR-pQCT), Metatarsophalangeal (MTP), Rheumatoid Arthritis (RA), Confidence Interval (CI).

Conclusion: This is the first study to evaluate erosions with HR-pQCT of the 4th and 5th MTP joints, including a comparison to CR. Erosions were frequent at the lateral aspect of the MTP joints, suggesting that mechanical and biomechanical demands may play a role in the development of erosions in the MTP joints. The superiority of HR-pQCT compared to CR for detecting erosions provide a basis for larger studies assessing bone changes in the MTP joints.

RELATIONSHIP BETWEEN RETINAL VASCULAR DENSITY DETECTED THROUGH OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY AND INTIMAL MEDIAL THICKNESS: A NEW POTENTIAL MARKER OF CARDIOVASCULAR INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. Ferrigno[1], P. Conigliaro[1], S. Longo[2], C. Nesi[3], A. Di Stefano[3], E. Santilli[3], C. Giannini[3], S. Rizza[2], M. Federici[2], M. Cesareo[3], A. Bergamini[1]. *[1]University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", Rome, Italy; [2]University of Rome Tor Vergata, Internal Medicine, Department of "Medicina dei Sistemi", Rome, Italy; [3]University of Rome Tor Vergata, Ophthalmology Unit, Department of Experimental Medicine and Surgery, Rome, Italy*

Background: Systemic Lupus Erythematosus (SLE) patients have a 3- fold risk of CV events compared to the general population, mainly due to accelerated atherosclerosis that is not completely explained by the presence of traditional CV risk factors. Individuals with increased Intimal medial thickness (IMT) carry a higher risk to develop carotid atherosclerosis. Accordingly, IMT acts as a marker of subclinical atherosclerosis. In recent studies, SLE patients showed a significant higher IMT compared to healthy subjects. On the other side, SLE retinal involvement can be detected in 7-29% of cases, it is characterized mainly by retinal vasculopathy and it can be a marker of systemic vascular involvement. Optical Coherence Tomography Angiography (OCTA), a new diagnostic technique that can visualize retinal blood flow and evaluate the Fovea Avascular Zone (FAZ), has been investigated as an instrument for early detection of subclinical retinal vascular impairment in SLE.
Objectives: Aim of this study is to examine a possible correlation between IMT and retinal vascular impairment assessed through OCTA in SLE.
Methods: We recruited SLE patients fulfilling 2019 EULAR/ACR classification criteria. Patients with other rheumatic, ophthalmological diseases, diabetes or history of CV diseases were excluded. We also collected patients' demographic and clinical data, including sex, age, smoking habit, BMI, systolic and diastolic blood pressure (BP), C-Reactive Protein (CRP), total cholesterol, LDL, HDL, triglycerides. All patients underwent an ophthalmological evaluation, including OCTA estimation of superficial and deep retinal vessel density (VD), considering both the whole image and the foveal region, and FAZ area. Carotid ultrasound (US) comprising IMT assessment was also performed. Statistical analysis was accomplished using unpaired t-test or Mann Whitney U test, Pearson or Spearman rank correlation when appropriate.
Results: We enrolled 37 SLE patients; demographic, clinical and US data are displayed in Table 1. Nine patients (24.3%) had uncontrolled arterial hypertension. According to US evaluation, carotid plaques were detected in six patients (16.2%). OCTA data were correlated with IMT values showing a negative correlation between IMT and both superficial and deep fovea VD (p=0.003, r=-0.4 and p=0.004, r=-0.4), while a positive correlation was found with FAZ area (p=0.02, r=0.4).

Table 1. Demographic, clinical and US data of the study population

Female sex n(%)	28 (75.6)
Age, yrs	49.2±14.7
Smokers n(%)	12 (32.4)
BMI	25.1±5.2
SBP, mmHg	118.5±15.7
DBP, mmHg	73.3±11.6
IMT, μM	549.6±124

IMT positively correlated with traditional CV risk factors, particularly age (p<0.0001, r=0.7), BMI (p=0.007, r=0.3) and systolic BP (p=0.001, r=0.4). Patients with high BP levels showed not only a significant higher IMT compared to the group with normal BP values (p=0.04), but also a significant increased FAZ area (p=0.02). FAZ area correlated positively with CRP levels (p=0.0001, r=0.5). Triglycerides showed a positive correlation with IMT values (p=0.001, r=0.4) and FAZ area (p=0.04, r=0.3) while correlated negatively with deep fovea VD (p=0.04, R=-0.4). A reduction in deep whole retinal VD was detected among patients with carotid plaques compared to the group without (p=0.02), together with higher IMT values (p=0.04).
Conclusion: Retinal vascular impairment in SLE has been associated with IMT, atherosclerotic plaques and some CV risk factors as hypertension, hypertriglyceridemia and CRP levels. Search for new markers of preclinical CV damage in SLE is currently ongoing and OCTA might be an additional instrument to assess preclinical cardiovascular involvement in SLE.

Biomarkers in pathogenesis, monitoring and treatment of rheumatic diseases

POS0135

DOWNREGULATION OF MIR-885-5P AS A KEY EFFECTOR IN CUTANEOUS LUPUS ERYTHEMATOSUS PATHOGENESIS

S. Domingo[1], C. Solé-Marcé[1], T. Moline[2], B. Ferrer[3], J. Cortés-Hernández[1]. *[1]VHIR - Vall d'Hebron Institut de Recerca, Lupus Unit, Rheumatology, Barcelona, Spain; [2]VHIR - Vall d'Hebron Institut de Recerca, Pathology, Barcelona, Spain; [3]Hospital Universitari Vall d'Hebron, Pathology, Barcelona, Spain*

Background: Skin involvement is common in systemic lupus erythematosus (SLE), with up to 70% of patients developing skin lesions at some point during the course of their disease. Moreover, cutaneous lesions are the first sign of systemic disease in 20% of SLE patients [1]. Skin requires a regulated and undisrupted miRNA profile for a correct development and function. Studies show that miRNAs play a pathogenic role in autoimmune skin diseases such as Psoriasis [2]. Understanding of the role of deregulated miRNAs in CLE may enhance our knowledge about CLE pathogenesis which is currently not understood.
Objectives: Identify differentially expressed miRNAs in skin lesions to determine their role in CLE pathogenesis.
Methods: Paired skin biopsies from CLE lesional (n=20) and non-lesional skin (n=20) were obtained. MiRNA microarray screening was performed using TaqMan MicroRNA Array. Validation was performed in a new cohort of FFPE skin samples by qRT-PCR (n=20). *In situ* hybridization was performed to identify the skin cell type involved in selected miRNAs. Next, *in vitro* experiments using primary skin and immune cells were performed in order to discover their role in CLE pathogenesis. A microarray screening and luciferase assay were performed to find miR-885-5p altered gene expression, molecular pathways and target genes.
Results: MiR-885-5p was found downregulated in CLE lesional skin (-4.45 fold, pvalue<0,01, respectively). Results were confirmed in a validation cohort. *In situ* hybridization revealed miR-885-5p was located in the epidermal keratinocytes in CLE non-lesional skin. Healthy keratinocytes presented an increased miR-885-5p expression compared with other relevant cell types such as fibroblasts (p<0.001) or PBMCs (p<0.001). Moreover stimulation with IFNα and UVB promoted a marked long-lasting downregulation of miR-885-5p (IFNα, 24h -67 fold (p<0.001); UVB, 24h -70 fold (p<0.001)).
Gene microarray of anti-miR-885-5p keratinocytes showed that the unique gene that was upregulated in all anti-miR-885-5p conditions was PSMB5. In *vitro* experiments demonstrated that PSMB5 is a direct target of miR-885-5p (74% of reduction p<0.001) and it is involved in epidermal inflammation by enhancing NFKB and inflammatory cytokines IL-1β, TNFα and CXCL8. In addition, we observed immune recruitment in UVB stimulated anti-miR885-5p keratinocytes and we found that this immune migration is mediated via miR-885-5p

direct binding of TRAF1 and subsequent chemokine CCL5, CCL20, CXCL8 and S100A7 secretion.

Conclusion: Our findings demonstrate that CLE lesions present a downregulation of miR-885-5p that is strongly implicated in CLE pathogenesis. Moreover, miRNA applicability as therapeutics makes the discovered miRNAs promising candidates for novel therapy in CLE, as there is a need to develop new therapies for refractory cases and to avoid current treatment significant side effects.

COMPLEMENT C1Q PROMOTES MITOCHONDRIA RESPIRATION AND SECRETION OF IL-6 AND IL-1B BUT NOT TNF-A BY SYNOVIAL MACROPHAGE IN RHEUMATOID ARTHRITIS

Y. Jiang[1,2], B. Wu[3], T. Huang[3], Y. Liu[1], Z. Hu[3], T. Zhao[3], Y. Pan[1], W. Cornelia[2,3]. *[1]Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China; [2]Stanford University, Department of Immunology and Rheumatology, Palo Alto, United States of America; [3]Mayo Clinic, Department of Rheumatology and Immunology, Rochester, United States of America*

Background: Complement C1q (C1q), predominantly synthesized by myeloid cells such as macrophages, has elusive functions in the pathogenesis of rheumatic arthritis (RA). Binding to its receptor gC1qR, C1q can activate mitochondria, the dysfunction of which may result in tissue inflammatory disease [1]. Bone marrow derived macrophages in RA patients have elevated OXPHOS activity [2], while the reason remains to be discovered.

Objectives: The objectives of the study were to explore the expression of C1q and its receptor gC1qR in synovial macrophages in RA and whether C1q contributes to tissue inflammation via affecting pro-inflammatory cytokines (IL-1β, IL-6 and TNF-α) and mitochondria respiration in synovial macrophages.

Methods: Tissue transcriptome analysis for C1q(C1qA, C1qB and C1qC), C1q receptors (including gC1qR) in rheumatoid synovium and and pro-inflammatory cytokines (IL-6, IL-1β and TNF-α) in rheumatoid synovium and synovium macrophages were quantified by RT-PCR. Concentrations of C1q in the plasma of RA and healthy controls (HC) were analyzed by ELISA and the correlation between plasma C1q and disease activty measured by DAS28 were calculated. gC1qR protein expression was detected by flow cytometric analysis and immunoblotting. Synovial macrophages were isolated and stimulated with or without C1q for 24 h. Function of gC1qR was analysed by knockdown experiment using siRNA. Transcripts for inflammatory cytokines were quantified by RT-PCR. Mitochondrial respirometer was evaluated with Seahorse Bioscience XF96 analyzer after C1q treatment or gC1qR knockdown.

Results: C1qA, C1qB,C1qC and gC1qR were all upregulated in both rheumatoid synovium and synovial macrophages compared to healthy controls. Meanwhile, RA patients had a higher level of C1q concentration in plasma, which positively correlated with DAS28. Moreover, an increased expression of gC1qR protein was confirmed by flow cytometric analysis and immunoblotting. Besides, C1q could increase the expression of IL-6 and IL-1β but not TNF-α in synovial macrophages. We also found that C1q could increase basal OCR, ATP-coupled OCR, max respiration and reserve capacity of healthy macrophages. Comparatively, gC1qR knockout could down-regulate mitochondria respiration of RA macrophages.

Conclusion: Synovial macrophages in RA patients have significantly elevated expression of C1q and its receptor gC1qR. C1q could promote mitochondria respiration through gC1qR, thus leading to hyper-metabolism in macrophages from RA patients. C1q could promote synovitis through enhanced pro-inflammatory cytokines IL-6 and IL-1β but not TNF-α secreted by synovial macrophages, which represents a novel therapeutic target in RA.

POS0137

FREQUENCIES OF WNT PATHWAY GENE VARIANTS ASSOCIATED WITH ANTI CARBAMYLATE PROTEIN IN EARLY RHEUMATOID ARTHRITIS

M. Acevedo-Godoy[1], S. J. Perdomo[2], W. Bautista-Molano[2,3], L. Chila[2], O. J. Calixto[1], J. M. Bello-Gualtero[1], C. Romero-Sánchez[1,2,3]. *[1]Hospital Militar Central, Rheumatology and Immunology Department, Clinical Immunology Group, Bogota, Colombia; [2]Universidad El Bosque, Cellular and Molecular Immunology Group/ INMUBO, Bogota, Colombia; [3]Universidad Militar Nueva Granada, School of Medicine, Clinical Immunology Group, Bogota, Colombia*

Background: Increased bone resorption and impaired bone formation characterize the pathogenesis of rheumatoid arthritis (RA). Wnt/β-catenin pathway regulates osteoblast function. Since bone mineral density (BMD) and RA joint destruction are partially inherited, we studied the association of Dickkopf-1 (DKK-1), sclerostin (SOST), Kremen-1 and lipoprotein receptor-related protein-5 (LRP-5) genes single nucleotide polymorphisms (SNPs).

Objectives: To establish the genotypic frequency of variants of the DKK-1 (rs1896368, rs1896367, rs1528873), SOST (rs6503475), Kremen-1 (rs132274) and LRP-5 (3736228) genes in patients with early RA (eRA) and first degree relative (FDR) with healthy controls (HC), and its association with autoimmunity profile.

Methods: Colombian individuals were matched by age and gender. Serological and clinical indices were measured. Variants associated with the Wnt pathway; DKK-1, SOST, LRP-5, and Kremen were analyzed using High Resolution Melting and confirmed by Sanger sequencing. A bivariate analysis was conducted in eRA and FDR. A logistic regression was performed.

Results: 232 individuals were evaluated; 66 eRA patients, 50 FDR, and 116 HC. For eRA, 78.8% were female, with a median age 52 years (IQR: 38,8-56). Higher levels of CRP: 4,2 (IQR: 1,6-11,6), RF: 30,2 (IQR: 1,2-74,1), anti-CCP: 7,81 (IQR: 7,81-104,9) and anti-Carbamylate protein (CarP): 17,7 (IQR: 12,3-31,8) were observed.

Among eRA, FDR, and HC genotypic frequencies are listed in Table 1, there were significant differences among DKK-1 rs1528873 GA and AA (p<001), Kremen GG and GA (p<0,001), and LRP5 GG and GA (p=0,038), and GG with AA (p=0,023). In haplotype analysis between eRA and HC for DKK-1 rs1896368 GA and LRP-5 AA (p=0,033) and for LRP5 GG and AA DKK-1 rs1528873 (p<0,001).

Table 1. Population genotypic frequencies

	eRA	FDR	HC

SOST rs6503475	51 (77,3)	35 (70)	85 (73,3)	
GG Native	15 (22,7)	15 (30)	31 (26,7)	0,657
GA Homozygous	13 (19,7)	9 (18)	28 (25)	0,580
AA Heterozygous	38 (57,6)	26 (52)	56 (48,3)	0,488
KREMEN rs132274	62 (93,9)	28 (56)	102 (87,9)	
CC Native	4 (6,1)	22 (44)	14 (12,1)	**<0,001**
CT Homozygous	35 (53)	6 (12)	54 (46,5)	**<0,001**
TT Heterozygous	27 (40,9)	22 (44)	48 (41,4)	0,953
LRP-5 rs3736228	23 (34,8)	16 (32)	22 (19)	
CC Native	43 (65,2)	34 (68)	94 (81)	**0,038**
CT Homozygous	3 (4,5)	10 (20)	3 (2,6)	**0,038**
TT Heterozygous	20 (30,3)	6 (12)	19 (16,4)	**0,023**

In eRA SOST rs6503475 was associated with anti-CarP (AOR 3,4 [95%IC 1,1-10,8] p=0,037). LRP-5 with former smoking (AOR 8,6 [95%IC 2,0-36,4] p=0,004). Additionally, in patients with a combination of at least three SNPs with a lower frequency of anti-Carp peptide (AOR 0,09 [95%IC 0,012-0,608], p=0,014), meanwhile a combination of at least five SNPs with a higher frequency of anti-Carp (AOR 4,7 [95%IC 1,27-17,1] p=0,020) were observed. There were no differences in FDR group.

Conclusion: Significant associations between Wnt pathway genes variants, haplotypes, and antibody profile could reinforce evidence to relation of high titters of anti-CarP with decreased BMD in eRA patients.

POS0138 RHEUMATOID SYNOVIAL FIBROBLASTS DISPLAY IMPRINTED MEMORY OF THEIR SYNOVIAL ENDOTYPE WHICH CAN BE PLASTICALLY MODULATED BY B-CELLS CROSSTALK

E. Prediletto[1], C. Cubuk[1], E. Pontarini[1], F. Rivellese[1], A. Nerviani[1], D. Lucchesi[1], M. Caliste[1], E. Corsiero[1], R. Hands[1], M. Lewis[1], C. Pitzalis[1], M. Bombardieri[1].
[1]William Harvey Research Institute, Queen Mary University of London, Centre for Experimental Medicine & Rheumatology, London, United Kingdom

Background: Despite advances in the treatment of Rheumatoid Arthritis (RA), synthetics and biologicals drugs are ineffective in ~40% of patients. The origin of this refractoriness is unclear, but several clues point at the synovial microenvironment (SE) and the relative cellular heterogeneity between patients. We previously described the existence of different RA endotypes such as the lympho-myeloid, LM, which is B-cell rich and the fibroid-paucimmune, FPI, which is devoid of B-cells. While there is clear evidence that the crosstalk between stromal and immune cells in rheumatoid joints is critical for the perpetuation of chronic inflammation and autoimmunity, it is currently unknown whether transcriptional signatures identified in synovial fibroblasts (SFs) derived from different RA endotypes are driven by "imprinted" properties of the SFs or are shaped by the interaction with infiltrating immune cells in the RA joints.

Objectives: I) to identify "imprinted" vs "inducible" RASFs signatures trough the comparison of freshly isolated SFs and primary established SFs cultures obtained from LM vs FPI RA synovial biopsies and ii) to investigate the identified RASF signature as predictive biomarkers of disease evolution and of response to conventional and biological DMARDs.

Methods: We performed flowcytometry and single cell RNA sequencing (sc-RNAseq) on SFs obtained from LM and FPI biopsies, in isolation or in co-culture with RA B cells. Next, supernatant has been screened trough Multiplex and ELISA. Furthermore, we compared our results to publicly available sc-RNAseq datasets on freshly isolated SFs and to our bulk-RNAseq data from clinical trials patients.

Results: Hierarchical clustering from sc-RNAseq transcriptional profiling of LM vs FPI RASF - after several cell passages - identified profoundly different gene signatures: whereby LM-RASF were characterised by genes involved in inflammation, proteoglycan formation and integrin binding, FPI-RASF were defined by genes related to collagen biosynthesis. Comparing the above signatures with those of freshly isolated RASF we identified both imprinted (i.e. maintained through several in vitro passages) and inducible (i.e. loss after long term culture) gene signatures. Notably, RA B-cells co-cultured with FPI-RASF profoundly altered the FPI-RASF transcriptional profile including the ex-novo expression of gene signatures typical of LM-RASF. Consensus gene modules constructed on LM vs FPI RASF imprinted gene signatures could be tracked in longitudinal whole tissue bulk RNA-seq data obtained from both early arthritis and established RA and were associated with synovial pathotype-specific histological and clinical features. Finally, modulation of FPI-RASF related genes following B-cell depletion identified poor responders to Rituximab in the R4RA randomised clinical trial.

Conclusion: Our work demonstrates that RASFs from different endotypes display imprinted memory of their original synovial tissue when maintained in culture over several months. We also demonstrated that imprinted memory typical of RASF isolated from B-cell rich LM synovial tissues can be dynamically modulated in FPI RASF following crosstalk with RA B cells. Finally, consensus gene modules based on FPI vs LM RASF-gene signatures were able inform on response/resistance to targeted biologic therapies.

POS0139 RELATIONSHIP BETWEEN SYNOVIAL FLUID IMMUNE CELL PHENOTYPES AND CLINICAL OUTCOMES IN PATIENTS WITH KNEE OSTEOARTHRITIS

M. Trajerová[1,2], E. Kriegova[1,2], Z. Mikulková[1], J. Savara[1,3], M. Kudělka[3], J. Gallo[1,4]on behalf of OLGEN. *[1]Palacký University Olomouc, Department of Immunology, Olomouc, Czech Republic; [2]University Hospital Olomouc, Department of Immunology, Olomouc, Czech Republic; [3]VSB - Technical University of Ostrava, Department of Computer Science, Ostrava, Czech Republic; [4]University Hospital Olomouc, Department of Orthopaedics, Olomouc, Czech Republic*

Background: Knee osteoarthritis (KOA) is a highly heterogeneous and multifaceted disease with many clinical phenotypes that often overlap. So far, phenotypes based on the composition of immune cells in synovial fluid (SF) have not yet been defined, although these cells, their activation and the mediators they produce play a central role in the pathophysiology of OA.

Objectives: This study aimed to investigate the relation between SF-derived immune cells and SF protein patterns in patients with KOA and its relationship to disease trajectory. Special emphasis was given to chemokine receptor expression on macrophages.

Methods: Immune cell phenotype and protein pattern from 119 KOA patients were analysed using flow cytometry. KOA phenotypes were determined by multivariate network analysis and related to clinical outcome 3-6 months post-sampling. The chemokine receptor pattern on macrophages was analysed using the FlowSOM algorithm and verified by manual gating.

Results: Four KOA-phenotypes were detected based on the distribution of T-lymphocytes, monocyte-macrophage lineage cells and activated CD8+ T-lymphocytes. The "healing" phenotype (n=17) had a high proportion of T lymphocytes, but low NK cells, monocyte-macrophage lineage and neutrophils, showing improved symptoms in 70% of patients. The "pain-less" phenotype (n=31) characterised by a higher percentage of neutrophils and a lower percentage of lymphocytes and monocyte-macrophage lineage as well as its activation, showed lower levels of pain. Next, the "progressive" phenotype (n=35) was represented by high NK percentage and monocyte-macrophage lineage representation yet low lymphocyte percentage and T-lymphocyte activation. From the „inflammatory progressive" phenotype (n=36) with a high proportion of activated lymphocytes, macrophages, NK cells and neutrophils, only 39% of patients improved during follow-up. The phenotypes obtained showed differences in CXCL10 expression, with high levels in the "healing" KOA1 compared to the "inflammatory progressive" KOA4 phenotype (1106 vs 126 pg/ml, p=0.001). In general, high CXCL10 levels were associated with improved disease trajectory compared to patients with

worsening symptoms (339 vs 222 pg/ml, p=0.002). CXCL10 levels in patients with improved symptoms showed a decreasing trend between phenotypes from KOA1 > KOA2 > KOA3 > KOA4. Regarding macrophages, low expression of chemokine receptors CXCR4 and CCR7 on macrophages was associated with improved symptoms regardless of KOA phenotype.

Conclusion: We identified four KOA phenotypes differing in immune cell percentage and activation associated with different clinical trajectories. Low expression of chemokine receptors CXCR4 and CCR7 on macrophages and high CXCL10 in SF was linked to KOA symptom improvement. How these phenotypes can be targeted therapeutically deserves future investigations.

Background: Risk-stratification is key in a heterogeneous disease like systemic sclerosis (SSc). Until now, SSc patients are stratified according to the extent of skin involvement into limited cutaneous, diffuse cutaneous and sine scleroderma subtypes. However, this classification remains inaccurate to capture disease heterogeneity. Autoantibodies are found in more than 90% of the patients and can be detected before onset of the disease. Among them, three predominant and specific antibodies are used: anti-centromere, anti-Scl70 and RNA polymerase III antibodies.

Objectives: To compare the performances of stratification into LeRoy's cutaneous subtypes versus autoantibody status in SSc versus combination of cutaneous subtypes and autoantibodies status.

Methods: Patients from the EUSTAR database were classified either as (i) limited cutaneous, diffuse cutaneous or sine scleroderma (based on the recording made by the treating physician) or (ii) according to autoantibodies with the following subclassifications: (1) no specific autoantibodies, (2) isolated ANA, (3) anti-centromere antibodies, (4) anti-Scl70 antibodies and (5) anti-RNA polymerase III antibodies or (iii) according to combination of cutaneous subset and auto-antibodies. The respective performance of each model to predict overall survival (OS), progression-free survival (PFS), disease progression and different organ involvements was assessed and the three models were compared by the area under the receiver operating characteristic curve (AUC 95%CI) and the net reclassification improvement (NRI). Missing data were imputed through multiple imputation using chain equations.

Results: In all, 10'711 patients were included: 84.6% females, mean age: 54.4±13.8 years, mean disease duration: 7.9±8.2 years. In the prospective analysis (n= 6'467 to 7'829 according to the outcome), after a mean follow-up of 56 months and a mean of three visits per patient, we did not identify any difference in AUC between the cutaneous-based model and the antibody-based model for prediction of OS and disease progression. However, the NRI showed a significant improvement in prediction of OS (0.57 [0.46-0.71] vs. 0.29 [0.19-0.39]) and disease progression (0.36 [0.29-0.46] vs. 0.21 [0.14-0.28]) at 4 years using the antibody-based model. Regarding prediction of each organ involvement in longitudinal analyses, the antibody-based model showed better performance than the cutaneous-one for renal crisis (AUC: 0.719 [0.696-0.742] vs. 0.664 [0.643-0.685]), with the highest association observed with anti-RNA polymerase III (OR: 7.47 [1.63-34.24], p= 0.010). Similarly, the antibody-based model was better than the cutaneous model in predicting lung fibrosis (AUC 0.719 [0.715-724] vs. 0.653 [0.647-0.659]) and restrictive lung fibrosis (AUC 0.759 [0.749-0.766] vs. 0.711 [0.701-0.721]) which were both associated with anti-Scl70 antibodies (OR: 9.29 [8.17-10.55] and 7.92 [5.37-11.69], respectively, p<0.0001 for both). Although there was no difference in the AUC to predict digital ulcers, NRI showed an improvement using the antibody-based model (0.31 [0.29-0.33] vs. 0.24 [0.22-0.26]) with the highest association with anti-Scl70 antibodies (OR: 3.57 [2.68-4.75], p<0.0001). The two models had similar performances in assessing occurrence of intestinal involvement, heart dysfunction or elevated sPAP. Combining both antibody status and cutaneous subtype did not improve the performance of our models. In the exploratory analysis, there was no change using modified Rodnan skin score to define cutaneous form.

Conclusion: Auto-antibody status outperforms the common cutaneous subsetting to risk-stratify SSc patients in the EUSTAR cohort. This easily performed subclassification using autoantibodies specific status can be used by the clinicians to risk-stratify their patients and to adapt disease monitoring in routine practice.

POS0141 PLATELET-SELECTIN PRIME LUPUS NEUTROPHILS TO PRODUCE MITOCHONDRIAL ROS AND PARTICIPATE IN SLE PATHOGENESIS

M. Scherlinger[1,2], V. Guillotin[3,4], P. Vacher[5], I. Douchet[4], E. Lazaro[4,6], C. Richez[4,7], P. Blanco[4,8]. *[1]Strasbourg University Hospital, Rheumatology, Strasbourg, France; [2]Beth Israel Deaconess Medical Center (BIDMC), Rheumatology, Boston, United States of America; [3]Chu Bordeaux - Site Pellegrin, Intensive Care, Bordeaux, France; [4]ImmunoConcept Lab CNRS UMR 5164, UMR 5164, Bordeaux, France; [5]INSERM, U1218, Bordeaux, France; [6]Chu Bordeaux - Site Haut Leveque, Internal Medicine, Pessac, France; [7]Chu Bordeaux - Site Pellegrin, Rheumatology, Bordeaux, France; [8]Chu Bordeaux - Site Pellegrin, Immunology, Bordeaux, France*

Background: In patients with active systemic lupus erythematosus (SLE), circulating platelets have an activated phenotype characterized by the expression of P-selectin (CD62P). We have shown that in human SLE, platelets interact with T regulatory cells and repress their immunosuppressive functions through a P-selectin/CD15s-dependent interaction (1). Preliminary results showed that neutrophils express high level of CD15s, predicting a possible platelet/neutrophil interaction in SLE.

Objectives: Investigate platelet/neutrophils interaction in human SLE and evaluate its impact on neutrophil functions, and lupus pathogenesis.

Methods: Patients with SLE responding to the 2019 ACR/EULAR criteria were recruited for blood sampling (n = 30). Disease activity was measured using

SLE disease activity index (SLEDAI-2K), and patients were considered active if SLEDAI-2K ≥ 6. Platelet-neutrophils aggregates were identified as (platelet) $CD61^+$ (neutrophil) $CD66b^+$ cells using flow cytometry on fresh blood samples. Single-cell cytosolic calcium and ROS imaging was performed by incubating cell with either a fluorescent calcium dye (cali-520), or a mitochondrial specific dye (MitoSox). Coverslips were mounted in an Attofluor cell chamber positioned on the stage of an inverted epifluorescence microscope (Olympus, IX70). Mitochondrial polarization of human neutrophil was evaluated by incubating cells with TMRM (100 nM) for 30 minutes. Platelet-free plasma was isolated by two sequential centrifugations (3500xg) of EDTA-anticoagulated blood and stored for subsequent evaluation of soluble P-selectin (using ELISA) and (platelet-derived) microparticular P-selectin (using flow cytometry).

Results: In healthy donors (HD) and patients with SLE, circulating neutrophils expressed significantly higher levels of the P-selectin ligand CD15s compared to lymphoid subsets ($p < 0.001$), predicting platelet/neutrophil interactions. In contrast to HD and patients with inactive SLE, those with active disease had a significant increase of circulating platelet-neutrophils aggregates ($p < 0.05$), and these aggregates correlated with the SLEDAI ($r = 0.59$, $p < 0.001$). The incubation of human neutrophils with recombinant P-selectin induced a strong intracellular calcium signaling which was inhibited by preincubating neutrophil with anti-PSGL1 antibody (blocking P-selectin/CD15s interaction) or with a Syk kinase inhibitor. Similarly, P-selectin induced a mitochondrial ROS release in a CD15s- and Syk-dependent manner. Interestingly, incubation of neutrophils with anti-dsDNA IgG and P-selectin induced mitochondrial depolarization, which was absent with either stimulus alone. Soluble and platelet-derived microparticular P-selectin levels were significantly increased in patients with active SLE compared to inactive patients or healthy donors ($p < 0.05$ and $p < 0.001$, respectively). In a longitudinal analysis of SLE patients, soluble and microparticular P-selectin levels closely followed clinical (SLEDAI) and biological (C3 levels) markers of SLE disease activity.

Conclusion: P-selectin levels are increased in active SLE and follow hallmark of disease activity. P-selectin induces calcium/mitochondrial ROS signaling in lupus neutrophils which are key players in SLE pathogenesis. We hypothesize that the inhibition of P-selectin pathway might be a promising target in SLE.

POS0142

DISTINCT EXPRESSION CLUSTERS OF INTERFERON-REGULATED GENES ASSOCIATE DIFFERENTLY WITH DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS.

K. Zahid Siddiqi[1], A. H. Zinglersen[1], K. K. Iversen[1], N. S. Rasmussen[1], C. T. Nielsen[1], S. Jacobsen[1]. [1]*Copenhagen University Hospital, Rigshospitalet, Copenhagen Lupus and Vasculitis Clinic, København, Denmark*

Background: Systemic lupus erythematosus (SLE) is a complex multiorgan autoimmune disease that primarily affects women during child-bearing years. The aetiology of SLE involves inadequate clearance of nuclear material released from apoptotic cells. The persistence of host DNA and RNA triggers the immune system to react as seen in a viral infection, causing persistent activation of anti-viral interferon (IFN) signalling pathways. Aberrant production of IFN cytokines, type 1 in particular, results in elevated levels of >1000 IFN-regulated gene (IRG) expression in the blood, termed an IFN signature. The IFN signature is typically measured as a score combining the expression levels of a subset of 3-4 IRGs. Several cross-sectional studies have pointed to an association between the IFN signature and disease activity, however subsequent longitudinal studies and a recent systematic review by our group[1] have failed to reproduce these findings. It was suggested that the lack of association between the IFN signature and disease activity was because the IRGs that are sensitive to disease activity are not typically included in the subset of IRGs used to determine an IFN score[2]. Uncovering the significance of the IFN signature in SLE disease activity is particularly relevant for evaluating the scope of IFN pathway inhibitors and may explain why these fail to have a significance for the primary endpoint in clinical trials[3].

Objectives: -Determine the mRNA expression of a broad subset of IRGs (>100) in a cross-sectional study of SLE patients with diverse clinical manifestations
-Investigate the association between IRG expression and disease activity
-Validate the findings from a cross-sectional study in a longitudinal study of SLE patients with fluctuating disease activity

Methods: In a cross-sectional study, peripheral blood samples from 34 SLE patients and 15 healthy controls were collected in PAXgene tubes. Ten SLE patients were followed longitudinally, and peripheral blood samples were collected in PAXgene tubes at time of inclusion and after 12 months. Disease activity was assessed by SJ in all patients and determined by means of SLE Disease Activity Index 2000 (SLEDAI-2K) and European Consensus Lupus Activity Measurement Index (ECLAM). RNA from peripheral blood cells (PBCs) was extracted using the PAXgene Blood RNA kit. The mRNA transcripts of 128 IRGs were measured using the multiplexed NanoString nCounter Gene Expression platform. Bioinformatics and statistical analyses were performed using nSolver and SPSS software.

Results: Out of 128 IRGs, 46 were highly expressed in SLE patients as compared to controls and seemed to co-express in mainly two distinct clusters, Figure 1. Expression scores for cluster K1 did not correlate with SLEDAI or ECLAM in a cross-sectional setting, whereas K2 expression scores did ($p<0.01$). These findings were confirmed by correlation analysis of changes in K1 and K2 expression scores with scores of disease activity in a longitudinal setting.

Conclusion: Interferon signatures may express differentially with varying associations with disease activity.

COMPOSITION AND ASSOCIATIONS OF THE GUT MICROBIOTAWITH PERIPHERAL LYMPHOCYTE SUBSETS AND CYTOKINES IN IDIOPATHIC INFLAMMATORY MYOPATHIES

Q. Y. Su[1,2,3], J. Q. Zhang[1,2,3], J. Luo[1,2,3], J. Qiao[1,2,3], S. X. Zhang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China;* [2]*Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China;* [3]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*

Background: The idiopathic inflammatory myopathies (IIM) are a group of acquired myopathies characterized by inflammatory lymphocytes infiltrates in muscle tissue[1].Gut microbiota serves as a critical environmental component of autoimmune disease pathogenesis such as IIM[2].

Objectives: This study sought to investigate the composition of gut microbiota and the relationship between microbiota structure and lymphocyte subpopulations and cytokines in IIM patients to recommend feasible intervention strategies.

Methods: Faecal samples were taken from 37 IIM patients and 37 age- and gender- matched healthy controls (HCs) in a sterile environment placed into the Second Hospital of Shanxi Medical University. Microbiome profiling was performed by sequencing of the V3-V4 variable regions of the 16S rRNA gene and the peripheral T lymphocyte subsets of these participants were assessed by flow cytometry. The clinical laboratory data such as erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and immunoglobulin were also determined. In terms of gut microbia, the diversity and richness was evaluated from two aspects: alpha diversity and beta diversity with the indices of ACE, Chao1, Shannon and Simpson. Analyses were conducted using R version 4.0.1. Pearson correlation was applied to assess the relationship between the relative abundances of bacterial genera and clinical parameters, and $p < 0.05$ was considered to be statistically significant.

Results: The α-diversity analysis of the richness (Chao1) and diversity (Shannon and Simpson) were reduced in IIM samples compared with those of HCs (Figure 1A, $p < 0.05$). Bray curtis distance-based beta diversity analysis revealed significant differences in the microbial community between IIM and HCs (Figure 1B, $p = 0.001$,

ANOSIM). Detailly, at the genera level, IIM patients had a higher abundance of Enterococcus, Veillonella, Streptococcus, et al. and a lower abundance of Roseburia, Lachnospira, Klebsiella, et al(Figure 1D, $p < 0.05$). In IIM patients, Fusobacteriota correlated positively with the ratio of Th1 cells (Figure 1E, $p < 0.01$), and there was a significant positive correlation between Synergistota and B lymphocyte (Figure 1E, $p < 0.01$). Besides, Euryarchaeota and Cyanobacteria were both positively and significantly related to IL-6, IFN-γ and C-reactive protein (CRP) (Figure 1E, $p < 0.001$).

Conclusion: Richness and diversity of intestinal flora in IIM patients were impaired, which might participate in the pathogenesis of IIM by disturbing lymphocyte subpopulations and cytokines. Regulating intestinal flora and restoring homeostasis might become a critical therapeutic methods of IIM.

POS0144 NOVEL ANTIBODY BIOMARKERS THAT PREDICT FAILURE TO ACHIEVE EARLY AND SUSTAINED DISEASE REMISSION OR LOW DISEASE ACTIVITY AFTER INTENSIVE FIRST-LINE THERAPY IN RHEUMATOID ARTHRITIS

P. Vandormael[1], A. Pues[1], E. Sleurs[1], J. Liesenborgs[2], P. Verschueren[3], V. Somers[1]. *[1]Hasselt University, Biomedical Research Institute, Immunology and Infection, Diepenbeek, Belgium; [2]Hasselt University, Expertise Centre for Digital Media, Computational Science, Diepenbeek, Belgium; [3]KULeuven, University Hospital Leuven, Rheumatology, Leuven, Belgium*

Background: Current EULAR guidelines for the management of rheumatoid arthritis (RA) recommend the use of classical synthetic disease-modifying anti-rheumatic drugs (csDMARDs), combined with short-term use of glucocorticoids (GC) as first-line therapy. Still, finding out which patients will show a poor response to such intensive first-line therapy is currently based on trial and error. Therefore, we recently performed a screening for novel antibody biomarkers that could predict the lack of response to csDMARD/GC combination therapy, resulting in identification of antibodies to 6 novel University Hasselt (UH)-RA antigens.

Objectives: The aim of this study was to validate these novel antibody biomarkers for their potential to identify at baseline, which RA patients fail to reach remission (rem-), or low disease activity (LDA), after intensive csDMARD therapy.

Methods: Presence of antibodies to the identified UH-RA antigens was measured using ELISA in 179 baseline samples from participants of the CareRA trial, which evaluated the efficacy of different first-line combination therapies[1]. Baseline antibody reactivity was correlated with remission or LDA, over a two-year follow-up period, according to the Disease Activity Score based on 28 joints with C-reactive protein (DAS28CRP), the DAS28 with erythrocyte sedimentation rate (DAS28ESR), and the clinical/simplified disease activity index (CDAI/SDAI).

Results: Baseline antibody reactivity against a panel of 3 antigens was higher in patients failing to reach DAS28CRP (31 vs 15%, p=0.007) or DAS28ESR (30 vs 14%, p=0.007) remission at week 8, or those failing to reach SDAI (36 vs 17%, p=0.018) or CDAI (37 vs 17%, p= 0.01) LDA at week 8, compared to RA patients that did reach these respective disease states. Baseline antibody reactivity correlated with lack of DAS28CRP remission after 8, 16, 40 and 52 weeks of first-line therapy, and was present in one in three DAS28CRP rem- patients, and in one in two DAS28CRP rem- patients that were seronegative for RF and ACPA. For each of the remission criteria studied (DAS28CRP, DAS28ESR, SDAI and CDAI), baseline antibody reactivity against these antigens was significantly higher in RA patients that did not maintain sustained remission (resp. 25 vs 12%, p=0.029; 24 vs 11%, p=0.041; 24 vs 4%, p=0.009; 24 vs 4%, 0.011), or sustained LDA (resp. 29 vs 13%, p=0.007; 27 vs 11%, p=0.008; 29 vs 14%, p=0.018; 29 vs 14%, p=0.013) between week 8 and week 52, compared to patients that did reach these respective disease states.

Conclusion: We have identified a set of 3 antibody biomarkers that predict the failure to achieve early and sustained remission and LDA in response to intensive first-line RA therapy. Therefore, the presence of these antibodies might indicate the need for another first-line treatment option in a personalized medicine approach.

Background: The TRial for Anti-B-Cell Therapy In patients with pSS (TRACTISS) is the largest multi-centre, placebo-controlled, phase-III trial with the administration of 2 cycles of Rituximab (RTX) or placebo at week 0 and 24, with trial clinical endpoints at week 48. Despite the primary endpoints (30% reduction in fatigue or oral dryness) were not met, RTX treated patients showed an improvement in secondary endpoints, such as unstimulated whole salivary flow

(UWSF), and salivary gland (SG) total ultrasound score[1,2]. Additionally, recent post-hoc analysis of TRACTISS using novel CRESS composite endpoints[3], highlighted a significantly increased response rate in the RTX vs placebo arm.

Objectives: To perform the first longitudinal analysis of matched transcriptomic and histological data of SG biopsies of pSS patients treated with RTX vs placebo at 3 time points, over 48 weeks, from the TRACTISS cohort, in order to identify mechanisms of response/resistance to B cell depletion.

Methods: 29 pSS patients randomised to RTX or placebo arm consented for labial SG biopsies at week 0, 16 and 48. Patients received two 1000mg cycles of RTX or placebo at week 0 and 24. SG focus score, inflammatory aggregate area fraction, B-cells (CD20+), T-cells (CD3+), follicular dendritic cells (FDCs) (CD21+) and plasma cells (CD138+) density were assessed using quantitative digital image analysis. RNA sequencing with deconvolution and pathway analysis was performed to identify genes signatures and consensus gene modules as biomarkers of disease evolution and response/resistance to therapy.

Results: Placebo-treated SGs showed worsening of SG inflammation highlighted by the increment of aggregate size, B-cell density, development of new FDC networks, and a higher ectopic GC prevalence over 48 weeks, compared to RTX-treated patients. No difference in focus score, total T-cell and plasma cell infiltration was observed. RTX downregulated genes involved in immune cell recruitment and inflammatory aggregate organisation (e.g. CXCL13, CCR7 and PDCD1). Gene signature-based analysis of 35 immune cell types using XCell highlighted how RTX blocked class-switched and memory-B-cells accumulation in SGs over 48 weeks. Pathway analyses confirmed the downregulation of leukocyte migration, MHC-II antigen presentation, and T-cell co-stimulation immunological pathways, such as the CD40 receptor complex pathway. Among RTX-treated patients, only CRESS-responders demonstrated prevention of worsening B cell-driven molecular pathology signatures over time and a significant improvement in UWSF, in parallel with the upregulation of molecular pathways associated to SG restoration of the glandular epithelium. None of the above effects were observed at week 16 after the first RTX cycle.

Conclusion: Two RTX infusions repeated at week 24 exerted beneficial effects on labial SG inflammatory infiltration in pSS by downregulating genes involved in immune cell recruitment, activation and organisation in ectopic GCs. Conversely, all the above parameters showed significant evolution in placebo treated patients over 48 weeks demonstrating progression of SG immunopathology. Clinical responders to RTX based on CRESS response criteria were characterised by preservation of exocrine function which appear driven by SG epithelial restoration.

Clinical aspect of spondyloarthritis

POS0146 INCREASED RISKS OF AORTIC REGURGITATION AND ATRIAL FIBRILLATION IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS PATIENTS: A 10 YEAR NATIONWIDE COHORT STUDY

H. K. Min[1], K. Y. Kang[2], H. R. Kim[1], S. H. Lee[1], S. Park[3], M. Park[3], Y. S. Hong[2], M. Y. Kim[2], S. H. Park[4]. *[1]Konkuk University Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea); [2]The Catholic University of Korea Incheon St. Mary's Hospital, Rheumatology, Incheon, Korea, Rep. of (South Korea); [3]Hanmi Pharmacy, Data Science Team, Seoul, Korea, Rep. of (South Korea); [4]The Catholic University of Korea Seoul St. Mary's Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Radiographic axial spondyloarthritis (r-axSpA) has increased risk of cardiovascular disease. Other cardiac manifestations such as conduction disturbance and valvular diseases were also suggested as co-morbidities in r-axSpA patients, however, the risk of these cardiac manifestation in r-axSpA were seldomly evaluated in large cohort.

Objectives: To compare the incidences of aortic regurgitation, atrial fibrillation (AF), and atrioventricular (AV) block II–III between r-axSpA patients and the general population (GP).

Methods: National Health Insurance Services data were used. R-axSpA patients (N = 8,877) and the age- and sex-matched GP (N = 26,631) were followed from August, 2006 to December, 2019. Incidence rates and standardized incidence ratios (SIR) of aortic regurgitation, AF, and AV block II–III were compared between these groups. Ten year incidence rates and hazard ratios (HRs) were calculated by the Kaplan–Meier method and Cox regression analysis.

Results: Incidence rates of aortic regurgitation, AV block II–III, and AF in the r-axSpA group were 0.42, 0.21, and 4.0 per 1000 person-years, respectively. In the r-axSpA group, the SIR for aortic regurgitation was highest among 40–49-year-old men (4.11). Incidence rates of aortic regurgitation and AF were higher in the r-axSpA group than in the GP group (both $p < 0.001$), whereas the difference was insignificant for AV block II–III. In multivariate analysis, HRs for aortic regurgitation and AF were higher in the r-axSpA group than in the GP group (HR (95% confidence interval) = 2.55 (1.49–4.37) and 1.20 (1.04–1.39), respectively), but the difference was insignificant for AV block II–III.

Conclusion: Compared with the GP, r-axSpA patients are at increased risk of aortic regurgitation and AF, but not AV block II–III. These patients should be carefully monitored for occurrence of aortic regurgitation and AF.

POS0147 DETERMINANTS OF GENERAL HEALTH AND HEALTH RELATED QUALITY OF LIFE IN AXIAL SPONDYLOARTHRITIS, PERIPHERAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS: RESULTS FROM THE ASAS-PERSPA STUDY

H. Santos[1,2], A. R. Henriques[2], M. Dougados[3], C. López-Medina[3], H. Canhão[2,4], P. M. Machado[5], F. Pimentel Santos[6,7]. *[1]Portuguese Institute of Rheumatology, Rheumatology, Lisbon, Portugal; [2]Nova Medical School, EpiDoc Unit, Comprehensive Health Research Center, Lisbon, Portugal; [3]Cochin Hospital, Rheumatology, Paris, France; [4]Centro Hospitalar Lisboa Central, Rheumatology, Lisbon, Portugal; [5]University College of London, Centre for Rheumatology and Department of Neuromuscular Diseases, London, United Kingdom; [6]Nova Medical School, CEDOC, Rheumatic Diseases Lab, Lisbon, Portugal; [7]Centro Hospitalar Lisboa Ocidental, Hospital de Egas Moniz, Rheumatology, Lisbon, Portugal*

Background: Axial Spondyloarthritis (axSpA), peripheral Spondyloarhritis (pSpA) and Psoriatic arthritis (PsA) are different types of SpA, with large heterogeneity in clinical manifestations. It is crucial to understand which are the determinants of health-related quality of life (HRQoL) and general health (GH, global functioning and health) in axSpA, pSpA and PsA, which can lead to differential approaches and interventions, to attain better outcomes.

Objectives: This study aims to identify and compare determinants of HRQoL and GH in axSpA, pSpA and PsA, using data from the PerSpA study.

Methods: Data from the ASAS-PerSpA study, a cross-sectional and multicenter study with 24 participating countries, was used. Patients with either axSpA, pSpA or PsA were enrolled. Sociodemographic, lifestyle, anthropometric, and clinical characteristics were collected. Univariable and multivariable regression models for the three groups were performed separately, to explore factors associated with HRQoL, assessed by EuroQoL-5 Dimensions 3 level (EQ-5D), and similar analysis was performed for GH, assessed by the Assessment of SpondyloArthritis international Society Health Index (ASAS-HI).

Results: 4185 patients were included in the analyses. For the final models, only patients with complete data were included (results summarized in Table 1). Regarding HRQoL, worse HRQoL in axSpA was associated with female gender, fibromyalgia (FM), peripheral disease (PD), worse function and higher disease activity (DA) and patient's global assessment (PGA), in pSpA with worse function, higher DA and higher non-steroidal anti-inflammatory drugs intake score (NSAIDs-IS), and in PsA with female gender, axial involvement, worse function, higher DA and glucocorticoid therapy. On the contrary, better HRQoL was

associated in axSpA with a history of uveitis, in pSpA with older age (with a trend in axSpA and PsA, but not statistically significant) and in PsA with biologic therapy. Regarding GH, in axSpA, worse GH was associated with female gender, FM, PD, worse function and higher DA and PGA, in pSpA, with female gender, inflammatory bowel disease, worse function, treatment with conventional synthetic disease-modifying anti-rheumatic drug and higher NSAIDs-IS, in PsA with female gender, alcohol intake, FM, axial involvement, worse function and higher DA. On the contrary, better GH was associated in axSpA with university education (UE), higher BMI and higher NSAIDs-IS, in pSpA with UE, and in PsA with older age and UE.

Table 1. Factors associated with HRQoL and GH stratified by diagnostic category (summarized)

NS – not significant in univariable model; NA – not applicable; * - colinear with DAS44-

Conclusion: In all types of SpA, DA and function are major determinants of HRQoL, passible of tight monitoring and therapeutic intervention. In GH, besides DA and function, socio-demographic factors, like gender and education, also play an important role, in all forms of SpA, highlighting the importance of a holistic approach of the individual patient in order to achieve better outcomes.

SPARCC, MASES, LEI AND MEI INDEXES CAPTURE DIFFERENT PATIENTS WITH ENTHESITIS IN AXIAL SPONDYLOARTHRITIS, PERIPHERAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS.

R. E. M. Granados[1], M. L. Ladehesa Pineda[1], M. Á. Puche Larrubia[1], M. Dougados[2], E. Collantes Estevez[1], C. López-Medina[1,2]. [1]*Reina Sofia University Hospital/Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Rheumatology, Córdoba, Spain;* [2]*Cochin Hospital, Rheumatology, Paris, France*

Background: Spondyloarthritis, (axial (axSpA), peripheral (pSpA)) and psoriatic arthritis (PsA)) share enthesitis as a hallmark clinical feature. Reliable clinical instruments have been developed to assess enthesitis: Spondyloarthritis Research Consortium of Canada Enthesitis (SPARCC), Leeds Enthesitis Index (LEI), Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) and MEI (Mander Enthesitis Index). Since these four indexes include different enthesis locations, they may capture a different number of patients with enthesitis in the different SpA entities.

Objectives: a) To describe the individual locations of enthesitis in axSpA, pSpA and PsA; b) to evaluate whether the prevalence of patients with at least one enthesitis across the three groups differs depending on the use of SPARCC, LEI, MASES and MEI indexes; c) to evaluate the level of agreement between these indexes for detecting patients with at least one enthesitis in axSpA, pSpA and PsA populations.

Methods: PerSpA was a multinational observational, cross-sectional study with 24 participating countries worldwide. A total of 4185 patients with a diagnosis of axSpA (2719), pSpA (433) and PsA (1033) according to the Rheumatologist's opinion were included in this analysis. Information on the location of enthesitis collected during the study visit was used according to the SPARCC, LEI, MASES and MEI indexes.

The prevalence of patients with at least one enthesitis according to the different indexes were compared across the diseases (axSpA, PsA and pSpA), and pairwise agreement between indexes were evaluated using the Cohen's kappa in the global population and in the three groups.

Results: Out of 36 locations, the most prevalent enthesitis in the overall population were the lumbar spinous processes (6.5%), the thoracic spinous processes (4.9%) and the insertion of the Achilles tendon right (4.8%) and left (3.9%). A total of 10.7%, 8.3%, 13.5% and 17.2% of patients in the overall population showed at least one enthesitis according to the SPARCC, LEI, MASES and MEI indexes, respectively. Figure 1 shows that, among patients with axSpA, MEI and MASES indexes capture the majority of patients with at least one enthesitis (98.7% and 82.4%, respectively), while in pSpA and PsA, MEI and SPARCC are the indexes which capture the majority of patients with enthesitis (100% and 84.6% for MEI and SPARCC in pSpA, and 97.3% and 77% for MEI and SPARCC in PsA, respectively). In PsA, the LEI only captured 57.2% of the patients with at least one enthesitis. In the total population, MASES and MEI showed the strongest agreement for patients with at least one enthesitis (absolute agreement 96.3%; Cohen's kappa: 0.86). Similarly, among axSpA patients, MASES and MEI showed an almost perfect agreement (97.3%; 0.90), while LEI and MEI showed a moderate agreement (90.4%; 0.54). In pSpA patients, SPARCC and MEI showed the strongest agreement (97.2%; 0.90), as well as among PsA patients (95.4%; 0.82). However, MASES and SPARCC showed a less agreement in PsA patients (94.2%; 0.67).

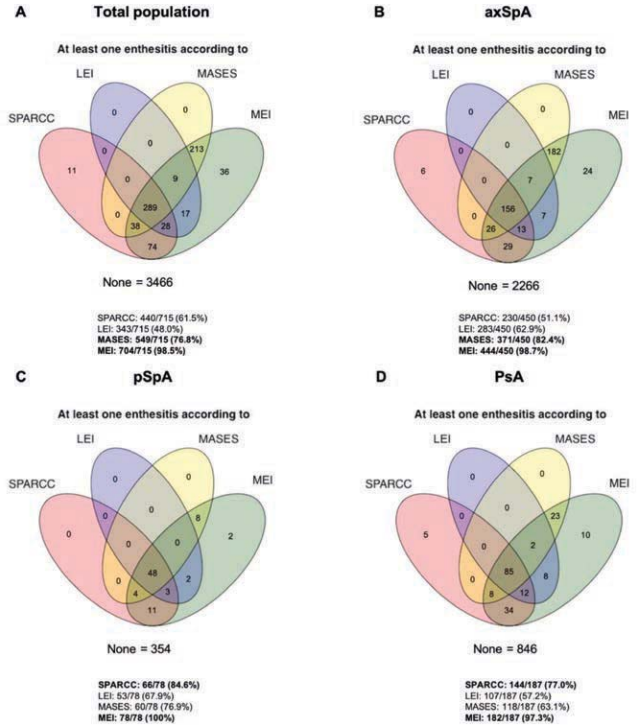

Figure 1. Prevalence of enthesitis captured by different indexes.

Conclusion: The most prevalent locations of enthesitis on the global SpA population are the lumbar spinous processes, the thoracic spinous processes and Achilles tendon. MEI and MASES are the two index that capture more patients with enthesitis in axSpA, while MEI and SPARCC are the two index that capture more patients in pSpA and PsA. The LEI index may underestimate the prevalence of enthesitis in these patients. MASES and MEI showed the largest level of agreement in the overall population and in axSpA, while MEI and SPARCC showed the largest level of agreement in pSpA and PsA. These results suggest that the prevalence of enthesitis across entities differs depending on the disease and on the use of the different index.

WHAT IS BACKFILL? - DETAILED CT / MRI ANALYSIS OF NEW BONE FORMATION IN AXIAL SPONDYLOARTHRITIS

T. Diekhoff[1], C. Niedermeier[1], F. Proft[2], D. Poddubnyy[2], K. G. Hermann[1].
[1]Charité Universitaetsmedizin Berlin, Clinic for Radiology, Berlin, Germany; [2]Charité Universitaetsmedizin Berlin, Divison of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany

Background: Several magnetic resonance imaging (MRI) findings of the sacroiliac joint space in axial spondyloarthritis (axSpA) were previously described such as inflammation or fatty metaplasia inside an erosion, i.e. "backfill". However, it is incompletely understood if one or all of these changes represent calcified bone matrix.
Objectives: This study aims to one-by-one link the aforementioned changes to computed tomography (CT) measurements and to understand, which of those findings represents new bone formation.
Methods: Out of 178 patients from two prospective studies that included CT and MRI of the sacroiliac joints all patients with the final diagnosis of axSpA were selected. MRI was screened by two senior musculoskeletal radiologists in consensus for joint-space related MRI findings and grouped into three categories, Type A: hyperintense in STIR and hypointense in T1 (inflammation inside erosion), Type B: hyperintense in both sequences and Type C: hypointense in STIR and hyperintense in T1 (backfill). By using image fusion techniques and one-by-one comparison, the Hounsfiled Units (HU) of those lesions as well as normal cartilage and spongeous and cortical bone were measured in CT.
Results: Ninety-nine patients with axSpA were identified and 48 Type A, 88 Type B and 84 Type C lesions were assessed. Please see Figure 1 for CT measurements. The HU values of cartilage were 73.6±15.0, spongious bone 188.0±69.9, cortical bone 1086.0±100.3, Type A 341.2±96.7, Type B 359.3±153.5 and Type C 446.8±123.0, respectively. The lesion values were significantly higher than cartilage and spongious bone but lower than cortical bone (p<0.001). Type A and B showed similar HU (p=0.93), whereas Type C lesions where denser (p<0.001).

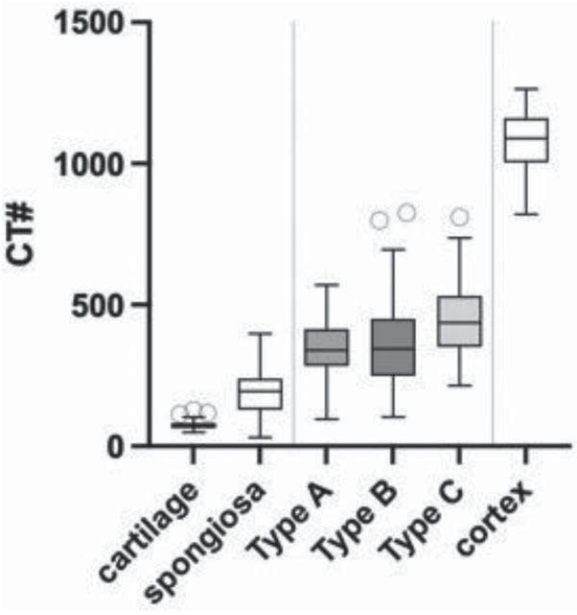

Figure 1. CT-Measurements of cartilage, bone and lesions.

Conclusion: All joint space lesions (Type A to C) show calcified matrix and, thus, resemble new bone formation with gradually more calcified matrix in Type C lesions, i.e. typical backfill. Therefore, the nomenclature of those lesions should be critically re-assessed.

ANKYLOSING SPONDYLITIS RELATED STRUCTURAL CHANGES IN THE SPINE INDEPENDENTLY INFLUENCE PATIENT REPORTED PHYSICAL FUNCTION IN MEN BUT NOT IN WOMEN. A COMPREHENSIVE CROSS-SECTIONAL ANALYSIS OF BATH ANKYLOSING SPONDYLITIS FUNCTIONAL INDEX AND ITS RELATION TO SEX

M. Hallström[1,2], E. Klingberg[1,2], A. Deminger[1,2], J. Backman Renman[3], M. Geijer[4,5], H. Forsblad-D'elia[1,2]. [1]Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; [2]Region Västra Götaland, Sahlgrenska University Hospital, Department of Rheumatology, Gothenburg, Sweden; [3]Umeå University, Department of Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden; [4]Institute of Clinical Sciences, Sahlgrenska Academy, Department of Radiology, Gothenburg, Sweden; [5]Region Västra Götaland, Sahlgrenska University Hospital, Department of Radiology, Gothenburg, Sweden

Background: Patient reported physical function assessed by Bath Ankylosing Spondylitis Functional Index (BASFI) is an important outcome in ankylosing spondylitis (AS) and is associated with health-related quality of life.
Objectives: To improve health care efforts, we aimed to investigate which demographic and disease related factors that influence BASFI in AS patients overall and stratified by sex. Further, we sought to elucidate if there are differences between sexes regarding specific BASFI items.
Methods: Patients fulfilling the modified New York criteria for AS were included in two geographically separate regions in Sweden for this observational cross-sectional study. Patients were assessed with 66/68 joint count and Bath Ankylosing Spondylitis Metrology Index (BASMI) measurements. Lateral X-rays of the spine were performed for modified stoke ankylosing spondylitis spine score (mSASSS) and BASFI, BASDAI, ASDAS CRP were registered. Multiple linear regression analyses were used to investigate influencing factors on BASFI. Independent variables were chosen based on what is previously known and on hypothetical reasoning. Models were performed overall and stratified by sex.
Results: A total of 353 patients, age (median, range) 53 (17-78) years, symptom duration 27 (2-56) years, men 62.3% and HLAB27 91.8 % were included. In multiple linear regression analysis age, BMI, ASDAS CRP, mSASSS, fatigue (BASDAI Q1) and tenderness (BASDAI Q4) were found to significantly associate with BASFI. In models separated by sex, mSASSS independently influenced BASFI in men (p<0.0001) but not in women (p=0.124)(Table 1). Further, separate BASFI items were compared between sexes. The ability to look over shoulder was scored the worst among men while getting up from the floor was hardest for women (Figure 1). Differences between sexes were found in the ability to look over shoulder (p=0.05) and the ability to climb stairs without handrail (p<0.001). Among the separate BASFI items, the ability to look over shoulder showed the highest correlation with mSASSS (r= 0.532, p<0.001).

Table 1. Multiple linear regression analysis exploring factors associated with BASFI

	All		Men		Women	
R^2	0.58		0.62		0.54	
	B (95% CI)	p-value	B (95% CI)	p-value	B (95% CI)	p-value
Age	0.06 (0.04;0.08)	<0.0001	0.05 (0.03;0.07)	<0.0001	0.08 (0.05;0.11)	<0.0001
BMI	0.05 (0.01;0.09)	0.024	0.04 (-0.01;0.09)	0.093	0.05 (-0.03;0.13)	0.209
ASDAS CRP	1.04 (0.74;1.34)	<0.0001	0.84 (0.48;1.20)	<0.0001	1.39 (0.86;1.93)	<0.0001
mSASSS	0.03 (0.02;0.04)	<0.0001	0.03 (0.02-0.05)	<0.0001	0.02 (-0.01;0.06)	0.124
Fatigue	0.34 (0.24;0.43)	<0.0001	0.41 (0.29;0.53)	<0.0001	0.27 (0.11;0.42)	0.001
Tenderness	0.17 (0.07;0.26)	0.001	0.14 (0.02;0.27)	0.027	0.18 (0.02-0.34)	0.027
Women	-0.29 (-0.74;0.17)	0.214	N/A		N/A	

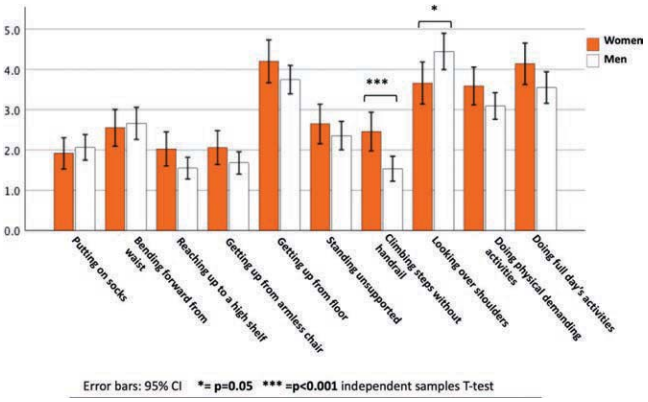

Figure 1. Separate BASFI items women compared to men

Conclusion: AS related self-reported physical function measured by BASFI was influenced by disease activity, fatigue and tenderness in both men and women. Interestingly, structural changes in the spine, evaluated by mSASSS, independently influenced BASFI in men but not in women with AS.
The ability to look over the shoulder was worse in men vs women and excelled as more disease specific than other individual BASFI items in both sexes.

PREGNANCIES IN PATIENTS WITH SPONDYLOARTHRITIS: DATA FROM 2 EUROPEAN CENTERS.

F. Crisafulli[1], A. R. Cruz-Machado[2], J. Rodrigues-Fernandes[3], M. C. Gerardi[1,4], S. C. Barreira[2], S. Grazioli[1], P. Martins[2], C. Zanardini[5], M. Centeno[6], S. Zatti[5], C. Araújo[6], L. Pinto[6], S. Capela[6], L. Andreoli[1], F. Franceschini[1], A. Tincani[1,7]. *[1]ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; [2]Hospital de Santa Maria, Serviço de Reumatologia e Doenças Ósseas Metabólicas, Lisbona, Portuga7l; [3]Curry Cabral Hospital, Central Lisbon University Hospital Centre, Internal Medicine/Autoimmune Diseases Unit, Lisbona, Portugal; [4]ASST Grande Ospedale Metropolitano Niguarda, Rheumatology Unit, Milano, Italy; [5]ASST Spedali Civili and University of Brescia, Obstetrics and Gynaecology Unit, Brescia, Italy; [6]Hospital de Santa Maria, CHULN, Departamento de Obstetrícia, Ginecologia e Medicina da Reprodução, Lisbona, Portugal; [7]I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University),., Moscow, Russian Federation*

Background: There is growing interest in reproductive issues in patients with Spondyloarthritis (SpA) and Psoriatic arthritis (PsA).
Objectives: To describe a real-life cohort of prospectively-followed pregnancies in SpA and PsA patients, focusing on obstetric outcome and on flare during pregnancies and post-partum.
Methods: Data on SpA and PsA pregnancies prospectively-followed in 2 European pregnancy clinics from 2010 to 2021 were retrospectively analysed.
Disease activity was assessed using ASDAS-CRP or DAS28-CRP according to the main involvement (peripheral or axial). Disease flare was defined as the need to treatment modification (introduction or increase ≥5mg/day of prednisone, introduction of cDMARD or bDMARD). Miscarriages were excluded from the analysis of flares.
Results: Data on 122 pregnancies (53 PsA and 69 'other SpA': 39 axialSpA, 20 undifferentiated SpA, 6 IBD-related SpA, 4 reactive arthritis) in 102 patients (median age at conception: 34 [IQR: 31-36] years; median disease duration: 72 [24-132] months) were collected.
We recorded 98 (86%) live births and 16 (14%) miscarriages (8 missing data).
Cesarean section was performed in 15/98 (15%) cases. Median week of gestation at delivery was 39 [38-40]; 8 preterm births (<37 week of gestation) and 2 severe preterm births (<34 week of gestation) occurred. There was no difference between PsA or 'other-SpA' concerning pregnancy outcome and route of delivery.
Fourty-two pregnancies (40%) had at least 1 flare during pregnancy; 7 pregnancies had more than 1 flare. Overall, there were 13, 24 and 12 flares in the 1st, 2nd and 3rd trimester, respectively.
A higher frequency of patients with axial involvement was observed in the 'flare' group as compared to pregnancies without flare (83% vs 59%, p=0.02) (Table 1).

Table 1. Comparison between 'flare' and 'without flare' groups.

	FLARE (42)	WITHOUT FLARE (64)	*p*
Age at conception (years)	33 (31-37)	33 (31-35)	0.88
Disease duration at conception (months)	71 (24-120)	60 (24-137)	0.74
PsA	13 (31%)	31 (48%)	0.11
'Other SpA'	29 (69%)	33 (52%)	0.11
Axial involvement	**35 (83%)**	**38 (59%)**	**0.02**
Peripheral involvement	30 (%)	54 (%)	0.17
bDMARD use			
Any time before pregnancy	16 (38%)	19 (30%)	0.49
Stop at + pregnancy test/1st trimester	8 (19%)	4 (6%)	0.09
Start/continue 1st trimester	7 (17%)	10 (16%)	0.89
Start in 2nd trimester	**5 (12%)**	**0**	**0.02**
Start in 3rd trimester	2 (5%)	0	0.30
Post-partum flare	11/34 (32%)	22/49 (45%)	0.36

Continuous variables were compared using Mann-Whitney test; categorical variables were compared using Chi-square with Yates' correction or Fisher's exact test.

Medications resumed to treat flare were steroids (29 pregnancies), csDMARDs (14 pregnancies) and TNF-inhibitors (7 pregnancies: 5 during the 2nd and 2 during the 3rd trimester).
A post-partum flare was registered in 33/83 (40%) of cases, without difference between 'flare' group vs 'without flare' group (Table 1), as well as between PsA vs 'other SpA' pregnancies (47% vs 33%, p=0.2).
Conclusion: In this cohort of SpA pregnancies, 40% experienced a flare during pregnancy and 40% during post-partum. Flares occurred more frequently in the 2nd trimester and especially in patients with axial involvement, requiring the start of a TNF-inhibitor during the 2nd or the 3rd trimester in 7 pregnancies. Having a flare during pregnancy was not associated with a post-partum flare.

POS0152

DIRECT AND INDIRECT EFFECT OF TNF INHIBITORS ON SPINAL MOBILITY IN PEOPLE WITH AXIAL SPONDYLOARTHRITIS AND THE MEDIATOR ROLE OF DISEASE ACTIVITY

A. S. Pinto[1], B. Yao[2], C. Harris[3], R. Hayward[3], A. Keat[3], P. Machado[3,4]. *[1]Unidade Local de Saúde da Guarda, Rheumatology, Guarda, Portugal; [2]University of Oxford, Statistics, Oxford, United Kingdom; [3]Northwick Park Hospital, London North West University Healthcare NHS Trust, Rheumatology, London, Portugal; [4]University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom*

Background: Although it may be difficult to detect changes in spinal mobility on the short term, spinal mobility is considered an important measure to assess the efficacy of drugs used to treat axial spondyloarthritis (axSpA). However, few studies evaluated the long-term impact of biologic treatment on spinal mobility.
Objectives: To describe the long-term effect of TNF inhibitors (TNFi) on spinal mobility in patients with axSpA, and to determine whether the use of TNFi treatment influences spinal mobility, and if this due to a direct or indirect effect (mediated by disease activity).
Methods: We performed a retrospective observational study, using data collected from patients with a clinical diagnosis of axSpA treated with TNFi at a tertiary care centre where disease activity and metrology assessments are routinely done. Adult patients with at least two Bath Ankylosing Spondylitis Metrology Index (BASMI) measurements were included. Disease activity was measured using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score C-reactive protein (ASDAS). The longitudinal association between TNFi and improvement in BASDAI/ASDAS was tested using a linear mixed effects model with BASMI as dependent variable. To test whether TNFi had a direct effect on BASMI, not mediated by disease activity, we tested that TNFi treatment was not conditionally independent of BASMI given BASDAI/ASDAS (Figure 1). We tested whether the nodes TNFi and BASMI were disconnected if we removed BASDAI and ASDAS. To test this conditional independence, we first built a linear mixed effects model for BASMI given BASDAI or ASDAS when the patient was under TNFi and used this model to predict a 95% confidence interval (CI) for BASMI given the data for BASDAI/ASDAS when the patient was without TNFi. We checked whether the true value of BASMI lay within this 95% CI and performed a hypothesis test for binomial distribution where H0: p=0.95. To test for the indirect effect of TNFi on BASMI reduction, mediated through the disease activity, we regressed BASMI on BASDAI/ASDAS, TNFi (if there was a direct effect), demographics, presence of radiographic (r-) axSpA and HLA-B27 positivity, using a linear mixed effects model adjusted for within-patient correlation.

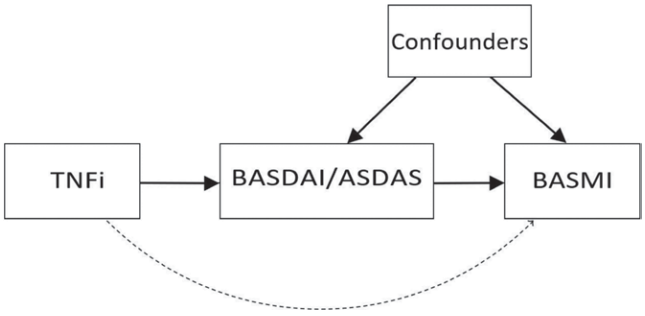

Figure 1. Indirect effect of TNFi on BASMI (represented by the full line), through the influence of TNFi on disease activity, adjusted by other confounders and direct effect of TNFi on BASMI (dashed line), independently of disease activity.

Results: Data from 188 patients and 1326 visits were analysed. Mean age was 45.6 (SD 11.6) years, mean disease duration was 15.8 (SD 9.64) years, 152 (80.9%) were male, 120 (73.6%) had r-axSpA, and 83 (74.8%) were HLA-B27 positive. Mean follow-up time was 8.0 (SD 4.4) years, ranging from 0.8 to 18.2 years. Treatment with TNFi was significantly associated with long-term improvement in BASMI (B=-0.423, 95% CI=[-0.553,-0.292], p<0.001). An indirect effect of TNFi on BASMI improvement was observed, mediated by reduction in disease activity, measured by BASDAI (B=0.146, 95% CI=[0.092, 0.200], p<0.001) or ASDAS (B=0.405, 95% CI=[0.260, 0.549], p<0.001). Using conditional independence tests, a direct effect of TNFi on BASMI improvement was also observed, independently of disease activity, when BASDAI was used (p<0.001) as a covariate, but not when ASDAS was used (p=0.3104). The direct effect of TNFi (B=-0.300, 95% CI=[-0.576,-0.025], p<0.001) on BASMI was estimated in the BASDAI-adjusted mixed effects model.

Ankylosis ≥1	2 (10.5%)	0 (0%)	0.13	2(9.1%)	0(0%)	0.18	0 (0%)	0 (0%)	-

Conclusion: TNFi are effective at improving BASMI in patients with axSpA, in a real-life setting. This effect is mainly explained by the reduction in disease activity. However, a direct effect of TNFi on BASMI could also be demonstrated, when disease activity was measured by BASDAI, suggesting that ASDAS captures additional factors that can influence spinal mobility. These potential factors deserve further investigation, but they could for example include biomechanical properties of tendons and myofascial tissue.

POS0153 MRI SPINAL LESIONS IN PATIENTS WITHOUT MRI OR RADIOGRAPHIC LESIONS IN THE SACROILIAC JOINTS TYPICAL OF AXIAL SPONDYLOARTHRITIS

W. P. Maksymowych[1], M. Østergaard[2], X. Baraliakos[3], P. Machado[4], S. J. Pedersen[2], U. Weber[5], I. Eshed[6], M. De Hooge[7], J. Sieper[8], D. Poddubnyy[8], M. Rudwaleit[9], D. Van der Heijde[10], R. B. M. Landewé[11,12], R. G. Lambert[13]on behalf of ASAS MRImagine. *[1]University of Alberta, Medicine, Edmonton, Canada; [2]Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; [3]Rheumazentrum Ruhrgebiet Herne, Rheumatology, Herne, Germany; [4]University College London, Rheumatology, London, United Kingdom; [5]Practice Buchsbaum, Rheumatology, Schaffhausen, Switzerland; [6]Sheba Medical Center, Radiology, Tel Aviv, Israel; [7]University Hospital Ghent, Rheumatology, Ghent, Belgium; [8]Charité – Universitätsmedizin, Rheumatology, Berlin, Germany; [9]Klinikum Bielefeld, Rheumatology, Bielefeld, Germany; [10]Leiden University Medical Center, Rheumatology, Leiden, Netherlands; [11]Amsterdam University Medical Center, Amsterdam Rheumatology & Clinical Immunology Center, Amsterdam, Netherlands; [12]Zuyderland MC, Rheumatology, Heerlen, Netherlands; [13]University of Alberta, Radiology, Edmonton, Canada*

Background: There are limited data as to the frequency of spinal lesions on MRI in patients without MRI or radiographic features typical of sacroiliac joint (SIJ) disease and to what degree spine MRI might enhance diagnostic evaluation.

Objectives: To assess the frequency of MRI lesions of the spine in the ASAS-Classification Cohort according to the presence of MRI SIJ lesions typical of axSpA and/or radiographic sacroiliitis (mNY+).

Methods: MRI spine lesions were recorded by 9 central readers in an eCRF that captures global assessment of the spine ("Is the MRI consistent with axSpA: yes/no") (yes=MRI_{global} spine+) and detailed anatomical-based scoring of each discovertebral unit plus lateral and posterior structures. Independently, readers globally assessed SIJ scans for active and/or structural lesions typical of axSpA. We compared the frequency of MRI_{global} spine+ and frequencies of different types of spinal lesions according to the presence/absence of axSpA on global evaluation of SIJ scans by ≥5 of 9 readers (MRI_{global} SIJ+) and mNY+ sacroiliitis using Fisher's exact test. Analysis was also stratified by rheumatologist diagnosis.

Results: Among 51 cases with SIJ as well as spine MRI scans and radiographs of the SIJ,19 (37.3%) had MRI_{global} SIJ+, and 12 (23.5%) and 7 (13.7%) had MRI_{global} spine+ by ≥2 and ≥5 reader agreement, respectively. MRI_{global} spine+ occurred significantly more frequently in the presence of mNY+ sacroiliitis and MRI_{global} SIJ+ but was also recorded in 4 of 32(12.5%) (≥2 readers) and 1 of 32(3.4%) (≥5 readers) cases that were MRI_{global} SIJ- ***and*** x-ray negative, all 4 cases being diagnosed with axSpA. Moreover, vertebral corner BME lesions, but not spinal structural lesions, were significantly more frequent in MRI_{global} SIJ- cases that had been clinically diagnosed as axSpA versus non-axSpA (Table 1).

Conclusion: Spinal lesions on MRI indicative of axSpA per majority read occurred in about 3% of patients without positive imaging in the SIJ. Frequency of spinal BME lesions was higher in cases with negative SIJ imaging but clinically diagnosed with axSpA.

POS0154 INFLAMMATION IS ASSOCIATED WITH INCIDENT HYPERTENSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A LONG-TERM FOLLOW-UP STUDY

J. L. H. Shi[1], S. H. M. Lam[2], H. So[2], E. LI[2], T. K. LI[2], C. C. Szeto[2], L. S. Tam[2]. *[1]The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China; [2]The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Axial spondyloarthritis (axSpA) patients have increased risks of developing cardiovascular diseases (CVD) compared to the general population. Hypertension (HT) as the most common CV risk factor in these patients. Whether chronic, low-grade inflammation predispose to the development of incident hypertension in axSpA remained uncertain.

Objectives: To examine the association between markers of systemic inflammation and incident hypertension in axSpA patients.

Methods: A cohort analysis was performed in patients with axSpA who had been followed since January 2001. Patients diagnosed with hypertension and/or on anti-hypertensives at baseline were excluded. The primary outcome was first diagnosis of HT occurring between January 2001 and December 2020. Three different CVD risk scores including Framingham risk score (FRS), QRISK3 and SCORE were computed at baseline. Baseline demographic data and clinical inflammatory and disease activity parameters were assessed using Cox proportional hazard regression. The association between disease activity measures, inflammatory markers, medications, and the occurrence of incident HT was assessed using time-varying Cox proportional hazard models after adjusting for baseline CVD risk scores.

Results: 413 patients [34(25-43) years, male: 319 (77.2%)] were recruited. After a median follow up of 12 (6-17) years, 58 patients (14%) developed incident HT (IHT+group). In baseline multivariable Cox regression analysis, ESR and CV risk scores were significantly associated with developing IHT ($p<0.05$) (Table 1). Using time-varying multivariate analysis, higher inflammatory burden (ESR≥20) was significantly associated with developing IHT after adjusting for FRS and SCORE respectively. Use of csDMARDs was significantly linked to develop IHT after adjusting for baseline FRS, while a trend suggesting that csDMARDs was associated with an increased risk of IHT after adjusting for baseline SCORE was observed (Table 2).

Table 1. Multivariable analysis with Cox proportional hazard regression for the baseline predictors of incident HT.

Table 1a.

	Model 1		Model 2	
	HR (95%CI)	p-value	HR (95%CI)	P-value
BASDAI≥5	1.44 (0.78, 2.67)	0.244	1.39 (0.75, 2.59)	0.3
ESR	1.01 (1.00, 1.02)	0.003*	1.01 (1.00, 1.02)	0.003*
BASFI	1.03 (1.00, 1.02)	0.616	1.03 (0.92, 1.16)	0.572
Baseline disease duration	1.04 (1.00, 1.08)	0.102	1.03 (0.98, 1.08)	0.215
Symptom duration	1.01 (0.98, 1.05)	0.513	1.02 (0.98, 1.05)	0.386
FRS	1.05 (1.03, 1.08)	<.001*		
SCORE			1.23 (1.12, 1.36)	<.001*

Table 1b.

	Model 1		Model 2	
	HR (95%CI)	p-value	HR (95%CI)	P-value
BASDAI≥6	1.53 (0.84, 2.78)	0.166	1.47 (0.81, 2.69)	0.209
ESR	1.01 (1.00, 1.02)	0.003*	1.01 (1.00, 1.02)	0.003*
BASFI	1.03 (0.92, 1,15)	0.646	1.03 (0.92, 1.16)	0.599
Baseline disease duration	1.04 (1.00, 1.08)	0.121	1.03 (0.98, 1.07)	0.244
Symptom duration	1.01 (0.98, 1.05)	0.530	1.02 (0.98, 1.05)	0.391
FRS	1.05 (1.03, 1.08)	<.001*		
SCORE			1.23 (1.11, 1.35)	<.001*

Conclusion: Higher baseline and time-varying inflammatory burden predict the development of IHT in addition to traditional CV risk scores in axSpA patients. While exposure to csDMARDs may be associated with the development of IHT, NSAIDs and biologic DMARDs use were not associated with the development of IHT.

POS0155

WHAT DRIVES RACIAL DISPARITIES IN GOUT IN THE US? – POPULATION-BASED, SEX-SPECIFIC, CASUAL MEDIATION ANALYSIS

N. Mccormick[1,2,3,4], L. Lu[4], C. Yokose[1,2,3], A. Joshi[2,3,5], T. Merriman[6,7], K. Saag[6], Y. Zhang[1,2,3], H. Choi[1,2,3,4]. *[1]Massachusetts General Hospital, Rheumatology, Allergy, and Immunology, Boston, United States of America; [2]Harvard Medical School, Medicine, Boston, United States of America; [3]The Mongan Institute, Medicine, Boston, United States of America; [4]Arthritis Research Canada, -, Vancouver, Canada; [5]MGH Clinical and Translational Epidemiology Unit, Medicine, Boston, United States of America; [6]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America; [7]University of Otago, Biochemistry, Dunedin, New Zealand*

Background: Traditionally viewed as a disease of White men, global frequency and disability burden of female gout are rising disproportionately to male gout.[1] Moreover, emerging US cohort data suggest gout and hyperuricemia impart larger burdens on Black adults than Whites.[2] These racial disparities may be largely attributable to differences in non-genetic, mainly modifiable gout risk factors e.g., BMI, diet,[3,4] and chronic kidney disease (CKD). However, national-level, general population data on racial differences in burden of gout, and potential mediators, are lacking.

Objectives: To determine and quantify sex-specific mediators of racial disparities in gout prevalence among a nationally representative sample of US adults.

Methods: Using recent decadal data (2007-2016) on physician-diagnosed gout and hyperuricemia from the National Health and Nutrition Examination Survey, we compared contemporary sex- and race-specific prevalences and conducted sequential causal mediation analysis (adjusting for upstream mediators following causal pathways)[5] to determine the proportion of the racial differences attributable to 7 potentially mediating social and clinical factors (see DAG in Figure 1): low education, poverty, body mass index (BMI), alcohol, poor quality diet (poor DASH adherence), diuretic use, and CKD (eGFR <60 mL/min, using the latest equations that do not include a coefficient for Black race[6], per National Kidney Foundation and American Society of Nephrology recommendations.[7])

Results: Age standardised prevalence of gout was 3.5% and 2.0% in Black and White women, respectively (age-adjusted OR =1.8 [95% CI: 1.3 to 2.5]), and 7.0% and 5.4% in Black and White men (age-adjusted OR =1.3 [1.0 to 1.6]). Most risk factors were more frequent/elevated in Blacks than Whites, except alcohol consumption, which was lower in Blacks (both sexes). BMI levels and poverty were higher in Black women, but similar between Black and White men.

Largest mediating factor of excess gout cases among Black women was excess BMI, accounting for 56% of the racial difference (independent of education, poverty, diet, and alcohol), followed by CKD (24%), poverty (17%), and poor diet (12%) (see Table 1).

Table 1. Indirect (mediation) effects of potential mediators, using sequential mediation analysis, for the association between Black race and odds of gout in US women and men.

	WOMEN		MEN	
	Effect Estimate (OR), 95% CI	Proportion Mediated, %	Effect Estimate (OR), 95% CI	Proportion Mediated, %
Indirect (Mediation) Effect				
Education (high school or less)	1.01 (0.98 to 1.03)	2.4%	1.01 (0.98 to 1.03)	3.3%
Poverty	1.07 (1.04 to 1.10)	16.9%	1.00 (0.99 to 1.00)	0.53%
Alcohol consumption *(# drinks/ week, continuous)*	0.99 (0.96 to 1.01)	-3.4%	0.99 (0.98 to 1.00)	-4.5%
DASH diet score *(continuous; higher scores = ↓ adherence)*	1.05 (0.96 to 1.01)	12.0%	1.05 (1.01 to 1.10)	19.8%
Body mass index *(continuous)*	1.25 (1.14 to 1.37)	55.9%	1.03 (1.02 to 1.04)	11.9%
Diuretic use	1.03 (1.01 to 1.05)	7.6%	1.04 (1.02 to 1.06)	14.2%
Chronic kidney disease	1.10 (1.04 to 1.16)	23.9%	1.12 (1.08 to 1.17)	45.6%
Direct Effect	0.94 (0.68 to 1.30)[a]	–15.2%	1.02 (0.83 to 1.26)[b]	9.2%
Total Effect	1.49 (1.12 to 1.98)	100%	1.29 (1.05 to 1.57)	100%

DASH=Dietary Approaches to Stop Hypertension; [a]p=0.52, [b]p=0.83

Among men, CKD was the largest mediator (46%), followed by poor diet (20%) and diuretic use (14%). BMI (12%) and poverty (0.5%) mediated smaller proportions of the racial difference among men compared to women. Mediators of racial differences in hyperuricemia closely agreed with gout results.

Conclusion: Contrasting with historical views, gout is more frequent among Black adults in the US than their White counterparts, especially women (two-times greater in Black women vs. White). Culturally informed efforts to reduce these disparities should focus on excess adiposity, diet quality, and kidney disease while recognising the impact of poverty in female gout.

POS0156 PATIENT INVOLVEMENT IN REGISTRIES BASED RESEARCH

P. Studenic[1,2], M. Sekhon[3,4], L. Carmona[5], M. De Wit[6], E. Nikiphorou[7,8].
[1]Karolinska Institute, Department of Medicine (Solna), Division of Rheumatology, Stockholm, Sweden; [2]Medical University of Vienna, Department of Internal Medicine 3, Division of Rheumatology, Wien, Austria; [3]University of London, Centre for Applied Health and Social Care Research, Kingston and St George's, London, United Kingdom; [4]Kings College, School of Life Course & Population Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom; [5]Instituto de Salud Musculoesquelética (Inmusc), -, Madrid, Spain; [6]EULAR Patient Research Partner, -, Amsterdam, Netherlands; [7]King's College London, Centre for Rheumatic Diseases, London, United Kingdom; [8]King's College Hospital, Rheumatology Department, London, United Kingdom

Background: Patient research partners (PRPs) are increasingly included in research as well as guideline development task forces in rheumatology. In observational and registry studies the role and involvement of PRPs is not clear.
Objectives: We aimed to evaluate current PRP involvement in registry research as well as benefits and barriers of implementation in practice.
Methods: Based on a round table discussion during the EULAR Registries and observational drug studies meeting (RODS) in 2019 we used mixed methods methodology (survey and focus groups) to study the role of PRPs and involvement in research. The survey was sent to investigators of registries across Europe, participants of RODS meetings and members of the EULAR PARE (People with Arthritis / Rheumatism across Europe) network. Interested survey participants were further invited to one of three focus groups. The conduction of the focus groups (FG) was guided by a semi-structured guide based on the survey results. An inductive thematic analysis approach was applied to qualitative data.
Results: We received 45 survey responses with around half of them from patients. The mean importance of PRP involvement was scored VAS±SD: 75±24mm (on a 100mm VAS), but the actual involvement was rather low (VAS: 32±20mm) and 12 participants had no experience with PRPs. The most common current practice was patient involvement in design of studies (32%), cooperation with patient organisation for recruitment (32%) and involvement of PRPs in the management board (32%). The most important need of PRP integration was attributed in the stages of design and preparation before recruitment. 11 survey participants even indicated that PRPs should be involved in all stages/tasks of research. During the focus groups 5 main themes (Table 1) could be identified. Complementary perspectives lead to greater synergy between researchers and patients and further the aim of deriving more valid outcomes. For successful involvement of PRPs, ideally PRPs should be heterogeneous in regard to their lived experience, education ought to be provided and researchers are responsible to offer an environment where PRPs feel comfortable. All FGs elaborated on different roles that PRPs can take on, although the researcher FGs outlined more different tasks of involvement than the PRP group. One theme summarised different barriers for PRP involvement, which have not been a topic of discussion in the FG composed of PRPs only.

Table 1. Overview of themes, sub-themes, and presence of theme according to which focus group discussion.

Theme	Sub theme	Focus Groups		
		Researcher	Researcher and Professionals	PRPs
1.Current experiences of PRPs involvement in research	Researcher experiences of involving PRPs	X		X
	Patient experiences of being involved as PRPs		X	X
2.The role of PRP in registries and research	Complementary perspectives between researchers and PRPs	X	X	X
	The aim of patient involvement in research	X		
3.Points to consider for involving PRPs in research	Consider professional and social backgrounds		X	
	Provide PRPs education and training		X	X
	A welcoming environment for PRPs to contribute		X	X
4.PRP involvement in different phases of the research process	Give PRPs a voice in research committees	X		X
	Identify questions that are most relevant to patients	X	X	
	Select the most relevant outcomes to patients	X		X
	Improve recruitment strategies		X	
	analysis, interpretation and dissemination of results	X	X	
5.Barriers to involving PRPs in research	Recruiting PRPs from ethnic minorities		X	
	Researchers' preconceptions of patients' ability to be involved in research	X		
	Challenging to ask patients to help analyse quantitative data	X		
	Limited financial resources	X		

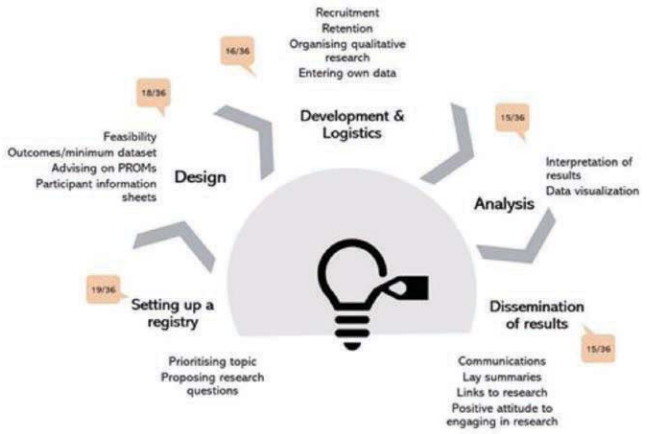

Figure 1. the empirical research cycle - basis for discussion of the role, opportunities & challenges for patient research partners in registry and observational drug study research. X/Y indicates the number of votes for including PRPs at the respective stage.

Conclusion: There is room and much appreciation of PRP involvement in registry research. Researchers and PRPs could use the strategies proposed in this study to define PRP roles and plans of ongoing and future studies.

POS0157

IMPLEMENTATION OF A VACCINATION TOOL IN THE ELECTRONIC PATIENT HEALTH RECORD COINCIDES WITH A SIGNIFICANT INCREASE IN VACCINATION COVERAGE.

J. Joly[1], B. Neerinckx[1,2], K. De Vlam[1,2], L. Fierens[3], E. De Dycker[4], T. Vanhoutvin[5], P. De Haes[5,6], P. De Munter[6,7], J. Sabino[4,8], S. Vermeire[4,8], M. Ferrante[3,4], P. Verschueren[1,2]. *[1]UZ Leuven, Division of Rheumatology, Leuven, Belgium; [2]KU Leuven, Department of Development and Regeneration, Leuven, Belgium; [3]KU Leuven, Department of Chronic Diseases and Metabolism, Leuven, Belgium; [4]UZ Leuven, Division of Gastroenterology and Hepatology, Leuven, Belgium; [5]UZ Leuven, Division of Dermatology, Leuven, Belgium; [6]KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium; [7]UZ Leuven, Division of General Internal Medicin, Leuven, Belgium; [3]KU Leuven, Department of Chronic Diseases and Metabolism, Leuven, Belgium*

Background: Patients with immune-mediated inflammatory diseases (IMID) are at higher risk for infectious diseases. Despite this increased risk and the available guidelines[1,2], we reported a suboptimal vaccination rate of 27 % of IMID patients in 2018. In the meantime, a vaccination module was introduced in the electronic patient medical record (EMR) of our hospital to accurately document and monitor vaccination status of patients.
Objectives: To evaluate the impact of a new vaccination module in the patient health record on vaccination coverage in a previously included IMID cohort.
Methods: Between Aug and Oct 2021, the vaccination status of 1435 (out of the original 1488) IMID patients (45 % male, median age 53.6 years) was collected (790 patients with IBD (inflammatory bowel diseases), 607 with rheumatologic inflammatory conditions (RHEU)(RA or SpA), and 38 with dermatologic inflammatory conditions(DER)) and was compared to that of 2018. The vaccination status for influenza (FLU), pneumococci (Pnc), hepatitis B (Hep B) and tetanus (TT) was obtained mainly through the patients' electronic medical records. Missing data were added after contacting patients or their general practitioner.
Results: From 2018 to 2021, the overall vaccination coverage (excluding TT) of all IMID patients significantly increased from 42 % to 66 % (p<0.001, Figure 1).

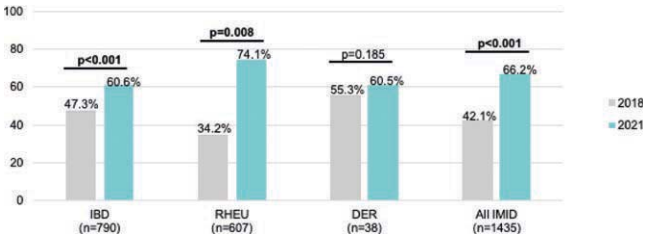

Figure 1. Percentages of total vaccination coverage in 2018 vs. 2021 in patients with IMID – TT vaccination excluded

For patients with RHEU, the vaccination coverage significantly increased, namely from 69.0% to 75 % for FLU (p<0.001), from 36 % to 89 % for Pnc (p<0.001), from 57 % to 73 % for Hep B (p<0.001) and from 34 % to 74 % overall (p=0.008) (Figure 1 and Table 1).

Table 1. Vaccine coverage in 2018 vs. 2021 in patients with IMID

	FLU (%)	Pnc (%)	Hep B*(%)	TT (%)
IBD (n=790)	2018: 76	2018: 73	2018: 67	2018: 80
	2021: 87	2021: 82	2021: 79	2021: 67
	p-value < 0.001	**p-value < 0.001**	**p-value < 0.001**	**p-value < 0.001**
RHEU (n=607)	2018: 69	2018: 36	2018: 57	2018: 65
	2021: 75	2021: 89	2021: 73	2021: 41%
	p-value < 0.001	**p-value < 0.001**	**p-value < 0.001**	**p-value = 0.038**
DER (n=38)	2018: 74	2018: 61	2018: 47	2018: 79
	2021: 71	2021: 82	2021: 65	2021: 71
	p-value = 0.116	p-value = 0.401	**p-value < 0.001**	p-value = 0.394
All IMID (n=1435)	2018: 73	2018: 58	2018: 63	2018: 74
	2021: 81	2021: 85	2021: 77	2021: 56
	p-value < 0.001	**p-value < 0.001**	**p-value < 0.001**	**p-value < 0.001**

*recommended in all seronegative IMID patients with IBD and patients at risk for other IMIDs

Similarly, the vaccination coverage in IBD patients increased significantly from 76 % to 87 % for FLU (p<0.001), from 73 % to 82 % for Pnc (p<0.001), from 67 % to 79 % for Hep B (p<0.001) and from 47 % to 61 % overall (p<0.001) (Figure 1 and Table 1).
For patients with DER, vaccination coverage significantly increased from 47 % to 65 % for Hep B (p<0.001) (Table 1). TT vaccination coverage decreased in all 3 IMID groups from 2018 to 2021.

Conclusion: The implementation of a vaccination tool integrated in the EMR coincided with a significant increase in vaccination rates and also in the total amount of IMID patients that were fully vaccinated according to guidelines. Quite likely, the suboptimal vaccination rate measured in 2018 and the COVID-19 pandemic also raised awareness among patients and healthcare professionals about the importance of following vaccination guidelines.

POS0158

ADHERENCE TO TELEMONITORING DISEASE ACTIVITY BY ELECTRONIC PATIENT REPORTED OUTCOMES IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A PROSPECTIVE COHORT STUDY

J. Wiegel[1], B. Seppen[1], M. Ter Wee[2], M. Nurmohamed[1], W. H. Bos[1]. *[1]Amsterdam Rheumatology & Immunology Center, Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam UMC Location VUmc, Department of Epidemiology & Data Science, Amsterdam, Netherlands*

Background: The use of electronic patient reported outcome measures (ePROM's) enables telemonitoring disease activity in patients with inflammatory arthritis in between consultations. However, recent telemonitoring studies report declining long-term adherence to reporting ePROM's[1,2]. What factors are associated with a decline in adherence is not known.
Objectives: To investigate the factors that are associated with adherence to telemonitoring by an ePROM in patients with inflammatory arthritis.
Methods: We performed a prospective cohort study in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) at Reade Amsterdam, The Netherlands. Patients telemonitored their disease activity weekly for 6 months with a modified Multidimensional Health Assessment Questionnaire including the Routine Assessment of Patient Index Data 3 (RAPID3) that was completed in the "MijnReuma" Reade smartphone application[2]. Adherence was defined as the percentage of weekly completed ePROM and time to dropout as ≥4 weeks nonresponse. Based on literature and through expert meetings, 13 baseline factors were selected to assess their association with dropout through multivariable Cox-regression analysis. The association with the system usability score (measured at 3 months, 1-100) was analyzed with a linear regression for patients who dropped out in month 1, month 2-3 and month 4-6.
Results: A total of 220 consecutive patients was included (mean age 54, 55% females, median disease duration 9 years), of which 99 had RA, 81 PsA, and 40 AS. Adherence to telemonitoring declined from 81% (week 1) to 39% (week 26). Median time to dropout was 17 weeks; a total of 141 patients (64%) stopped

telemonitoring their disease activity. Women had a higher chance to dropout over time compared to men (HR 1.6, p=0.02). The reported usability of the app was higher for patients who were adherent throughout the study (82) compared to patients who dropped out in the 1st month (68, p<0.001), 2nd-3rd month (71, p<0.001) and 4-6th month (78, p=0.18).

Conclusion: Women stopped reporting the ePROM sooner than man and the usability score of the app differed between the adherence and drop-out group. Future research is needed to investigate if the association between the usability score of the app and adherence is causal, and thus if improvements in the usability will lead to lower dropouts. Furthermore, we will perform focus group discussions to identify why women tend to dropout sooner, since this is in contrary to previous research[3].

SEX-RELATED DISPARITIES IN HEALTHCARE UTILIZATION IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A POPULATION-BASED STUDY

S. Tarannum[1,2], J. Widdifield[2,3], F. Wu[4], S. Johnson[5,6], P. Rochon[1], L. Eder[1,2].

[1]Women's College Hospital, Women's College Research Institute, Toronto, Canada; [2]University of Toronto, Medicine, Toronto, Canada; [3]Sunnybrook Research Institute, Health Services Research, Toronto, Canada; [4]ICES, Statistics, Toronto, Canada; [5]Toronto Western Hospital, Rheumatology, Toronto, Canada; [6]Mount Sinai Hospital, Rheumatology, Toronto, Canada

Background: Delayed diagnosis of inflammatory arthritis (IA) such as rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) is associated with joint damage and disability. So regular timely assessment by both family physicians and specialists is necessary for favorable disease outcomes. Sex (biology) and gender (socio-cultural) related factors influence clinical patterns of IA, patient behavior and their interaction with care providers. This influence could be reflected in patterns of healthcare utilization.

Objectives: To compare patterns of musculoskeletal (MSK)-related healthcare utilization before and after diagnosis between male and female patients with IA in Ontario, Canada.

Methods: We assembled 3 inception cohorts of adult RA, AS and PsA patients diagnosed between April 2010 and March 2017 using Ontario health administrative data. MSK-related healthcare utilization patterns in terms of visits to physicians, MSK imaging and laboratory tests were assessed yearly for 3 years before and after the diagnosis date, and compared between male and female patients. Among individuals ≥ 66 years, prescriptions for rheumatic drugs (NSAIDs, corticosteroids, csDMARDs, advanced therapy (bDMARDs and tsDMARDs)) and opioids were ascertained. Regression models were used to compare healthcare utilization indicators between males and females after adjusting for demographics and comorbidities.

Results: A total of 41,277 patients with RA (69% females), 8,150 patients with AS (51% females) and 6,446 patients with PsA (54% female) were analyzed. Male patients were significantly older than female patients only in the RA cohort (mean age M 60.4 y, F 57.1 y). Multimorbidity, depression and osteoporosis were more common in female patients and cardiovascular disease in male patients across the 3 cohorts.

Similar trends of sex-related differences were observed in all three cohorts. Female patients were more likely to visit rheumatologists and family physicians than male patients especially in earlier pre-diagnosis periods (Figure 1). Male patients were more likely to visit emergency department immediately before diagnosis. A similar female predominance was observed in imaging modalities of X-rays and ultrasounds (adjusted ORs for F:M 1.15 - 1.2 for X-rays and 1.07 -1.44 for ultrasounds), and laboratory tests before diagnosis (adjusted ORs for F:M 1.10 to 2.17) across the three cohorts.

Overall DMARD prescription patterns in older male and female patients were similar across the three cohorts except more csDMARD prescriptions in female AS patients (Table 1). Female RA patients were more likely to use NSAIDs and opioids.

Table 1. Odds ratios for prescription patterns in inflammatory arthritis for older female to male patients after diagnosis

Medication Class	Adjusted Odds Ratio (95% Confidence Interval)		
	Rheumatoid Arthritis	Ankylosing Spondylitis	Psoriatic Arthritis
csDMARD			
Yr 1	1.00 (0.92, 1.09)	**1.82 (1.38, 2.41)**	1.05 (0.81, 1.37)
Yr 2	1.00 (0.92, 1.08)	**1.66 (1.24, 2.22)**	0.94 (0.73, 1.20)
Yr 3	1.05 (0.97, 1.14)	**1.51 (1.12, 2.04)**	0.85 (0.66, 1.09)
Advanced therapy			
Yr 1	0.99 (0.78, 1.25)	0.79 (0.49, 1.25)	0.75 (0.47, 1.19)
Yr 2	1.17 (0.99, 1.39)	0.80 (0.53, 1.23)	0.91 (0.61, 1.37)
Yr 3	**1.23 (1.05, 1.45)**	1.04 (0.67, 1.61)	0.88 (0.6, 1.30)
NSAID			
Yr 1	**1.14 (1.04, 1.25)**	1.22 (0.91, 1.63)	0.94 (0.71, 1.24)
Yr 2	1.1 (0.99, 1.22)	1.04 (0.77, 1.43)	0.98 (0.73, 1.32)
Yr 3	**1.16 (1.04, 1.30)**	1.35 (0.96, 1.89)	1.02 (0.73, 1.41)
Opioid			
Yr 1	**1.39 (1.22, 1.58)**	1.23 (0.85, 1.78)	1.32 (0.87, 1.98)
Yr 2	**1.51 (1.32, 1.72)**	1.22 (0.85, 1.76)	1.14 (0.75, 1.75)
Yr 3	**1.46 (1.27, 1.68)**	1.42 (0.96, 2.09)	1.45 (0.95, 2.23)

Bolded results are statistically significant (p < 0.05). Odds ratios for female to male patients adjusted for age, residence, income quintiles, comorbidities and access to rheumatologists

Conclusion: Female patients with IA have higher MSK-related healthcare utilization which may indicate biological differences in disease course or sociocultural differences in healthcare seeking behavior between male and female patients.

POS0160 THE EMPLOYMENT GAP IN PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES COMPARED WITH THE GENERAL POPULATION: A SYSTEMATIC LITERATURE REVIEW

S. Verstappen[1], A. Boonen[2], N. Goodson[3], C. Webers[2], M. Butink[2], N. Betteridge[4], T. Stamm[5], D. Wiek[6], A. Woolf[7], H. Bijlsma[8], G. R. Burmester[9]on behalf of EULAR Task Force on work. *[1]The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; [2]Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands; [3]Liverpool University NHS Foundation Trust, Department of Rheumatology, Liverpool, United Kingdom; [4]Neil Betteridge Associates, N/A, London, United Kingdom; [5]Section for Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Medical University of Vienna, Vienna, Austria; [6]Patient Research Partner, People with Arthritis and Rheumatism (PARE) - EULAR, N/A, N/A, Germany; [7]Bone and Joint Research Group, Royal Cornwall Hospital, Truro, United Kingdom; [8]University Medical Center Utrecht, Dept of Rheumatology & Clinical Immunology, Utrecht, Netherlands; [9]Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Many people with rheumatic and musculoskeletal diseases (RMDs) experience problems at work and some may even have to stop working due to ill health. In most countries, RMDs are a major cause of worker productivity loss. The peak age of onset of many adult onset RMDs is between ~30-50 years, meaning that the majority of patients are still in employment when diagnosed with their chronic disease. Uncertainty about employment prospects and job attainment is also a major concern for young adults with juvenile idiopathic arthritis (JIA) for whom their first job may influence their future employment prospects. From both a societal and patient perspective it is important to gain an understanding about the impact of juvenile and adult onset RMDs on work outcomes. Data comparing productivity loss with the general population are more relevant for care and healthcare planning. However, these data are more scarce and have not been summarized recently across RMDs.
Objectives: To systematically summarize the literature on work outcomes in people with RMDs compared with the general population.
Methods: A systematic literature review (SLR) was conducted to compare work outcomes in people with various RMDs (i.e. JIA, RA, PsA, AxSpA, SSc, SLE, gout, FM, and OA) with the general population or healthy controls as part of the EULAR Task Force on work. A search for eligible observational studies was performed in Medline, Embase and PsycInfo between 2000 and May 2021. Work outcomes were categorizedaccortding to employment status, work disability/stopped working due to ill health, absenteeism, presenteeism and other.
Results: 541 abstracts were extracted and screened for eligibility. Results of 65 studies fulfilling the inclusion criteria were evaluated for this study, including 28 prospective/retrospective longitudinal cohort studies, 34 cross-sectional studies and 3 (nested) case-control studies. The majority of the studies were conducted in Europe (63.1%). The most common RMD evaluated was RA (26.2%) followed by OA (15.4%), SLE (15.4%), AxSpA (12.3%), FM (9.2%), mixed population (7.7%), JIA (7.7%), PsA (3.1%), SSc (1.5%), and gout (1.5%). In papers reporting disease duration (n=38), the majority of the study population had established disease (76.3%). Several work outcomes were evaluated with some papers reporting more than one work outcome: employment/work status (41.5%), unemployment (9.2%), work disability/pension or stopping work due to ill health (38.5%), absenteeism (52.3%), presenteeism (10.8%), and other (e.g. reduced working hours) (29.2%). Fifty-two papers applied statistical tests (e.g. indirect standardisation, logistic regression analysis, Cox regression analysis) to compare work outcomes in people with RMDs with a control/general population. The percentage of papers reporting the work outcomes to be worse, not significantly different or better in the RMD population compared to the control population (n papers included per work outcome; %) was, respectively: employment/work status (n=26; 73.1%, 23.0%, 3.8%), unemployment (n=6; 66.7%, 33.3%, 0%), work disability/stopping work (n=22; 90.9%, 9.4%, 0%), absenteeism (n=26; 92.3%, 7.7%, 0%), presenteeism (n=8; 87.5%, 12.2%, 0%), other (n=19; 84.2%, 15.8%, 0%).
Conclusion: Despite better disease management during the last two decades there is still a significant employment gap between people with RMDs and the general population. It is therefore essential that health professional organisations, policy makers, patient organisations and employers should collaborate to minimize the employment gap and optimize employment opportunities among people with juvenile and adult onset RMDs.

POS0161 WORK STATUS IN PATIENTS WITH INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES: RESULTS OF A BELGIAN COMPARATIVE STUDY

A. S. De Craemer[1,2,3], I. Desimpele[2], L. Delmez[2], L. Deroo[1,2,3], T. Renson[1,2,3], S. De Mits[1,2], V. Smith[1,2,3], P. Jacques[1,2,3], D. Elewaut[1,2,3], P. Carron[1,2,3], F. Van den Bosch[1,2,3]. *[1]Ghent University Hospital, Rheumatology, Ghent, Belgium; [2]Ghent University, Internal Medicine and Pediatrics, Ghent, Belgium; [3]VIB-UGent, Center for Inflammation Research, Ghent, Belgium*

Background: Inflammatory Rheumatic Musculoskeletal Diseases (RMD) constitute a heterogeneous group of chronic disorders with a potential major individual and socio-economic burden. RMD patients often report work-related difficulties (e.g. productivity loss, sick leave, work disability) which contribute significantly to indirect costs and may lead to additional premiums or exclusion when contracting private insurances. However, work-related epidemiological data in Belgium date back to a pre-biologics era, albeit that diagnosis, management and treatment strategies have drastically improved in the last decade.
Objectives: To investigate actual work participation status of inflammatory RMD patients in Belgium, and to benchmark these data to the general Flemish population.
Methods: During an outpatient visit at the rheumatology clinic of Ghent University Hospital, a tertiary hospital in the Flemish region, adult patients with spondyloarthritis (SpA), rheumatoid arthritis (RA), and systemic sclerosis (SSc) were questioned on their socio-economic status (May 2018 to June 2021). SpA patients fulfilled the ASAS classification criteria for axial or peripheral SpA. RA patients fulfilled the 2010 ACR/EULAR classification criteria or had undifferentiated arthritis most suggestive for RA. SSc patients fulfilled the LeRoy and Medsger's criteria. Employment rate, weekly working hours and work disability were compared to the general Flemish population (Dutch-speaking part of the country) in 2019 (https://statbel.fgov.be/en); data on sick leave were deduced from the 2018 national Health Interview Survey.
Results: Among the 483 participants, 262/275 (95%) SpA, 63/102 (62%) RA, and 83/106 (78%) SSc were at a work-productive age (<65 y/o). Table 1 summarizes socio-demographic and clinical characteristics.

Table 1.

	SpA (n=262)	RA (n=63)	SSc (n=83)
Male	148 (56%)	15 (24%)	18 (22%)
Age (y)	40.7±11.0	53.5±10.8	49.9±10.6
Symptom duration (y)*	7.8 (4.7-15.7)	3.9 (1.4-5.8)	5.8 (2.8-11.5)
Age at diagnosis (y)	32.6±11.1	48.3±12.0	43.9±10.7
Biomarker†	170 (70%)	52 (82%)	46 (55%)
Disease activity††	1.9±1.0	2.1±1.0	4 (1-8)
Functional index**	2.3±2.2	67±14	-
EQ-5D scale	0.79±0.22	0.80±0.18	0.74±0.24
Biologics treatment	123 (58%)	15 (24%)	7 (8%)
Educational level			
Low	100 (38%)	36 (57%)	53 (64%)
High	162 (62%)	27 (43%)	30 (36%)
Classification criteria	ASAS: axSpA: 192 (73%) perSpA: 70 (27%)	ACR/EULAR 2010: 46 (73%)	Leroy & Medsger: LSSC: 21 (25%) LcSSc: 47 (57%) DcSSc: 15 (18%)

† HLA B27 (SpA), RF/ACPA (RA), SSc-related auto-antibodies (SSc). †† ASDAS-CRP (SpA), DAS28 (RA), mRSS (SSc). *Disease duration from first non-Rayneud phenomenon in SSc. **BASFI (SpA), Michigan Hand Outcomes Questionnaire (RA).

Crude employment rates were 82% in SpA, 56% in RA and 63% in SSc. Age- and sex-adjusted employment rates (indirect standardization) were respectively 75%, 68%, and 66%, corresponding to a standardized employment ratio of 1.00 (95% CI 0.87 – 1.14) for SpA, 0.89 (0.64 – 1.24) for RA, and 0.88 (CI 0.67 – 1.15) for SSc.

SpA patients worked 39.5±10.9h/week, compared to 40.9±16.9h in RA and 33.0±12.4h in SSc (p=0.003). Flemish employees worked on average 39.7h (full-time) and 25.7h (part-time) per week.

In the working population, 48% of SpA patients, 53% RA and 78% SSc reported sick leave in the previous year, compared to 42% in Flanders. Long-term work disability was reported by respectively 10%, 17% and 20% of patients (p=0.03) compared to 9% in the reference population.

The median retention time on the labour market was not significantly different between SpA (42.1 years), RA (42.1 years) and SSc (41.2 years) (p=0.94, Figure 1).

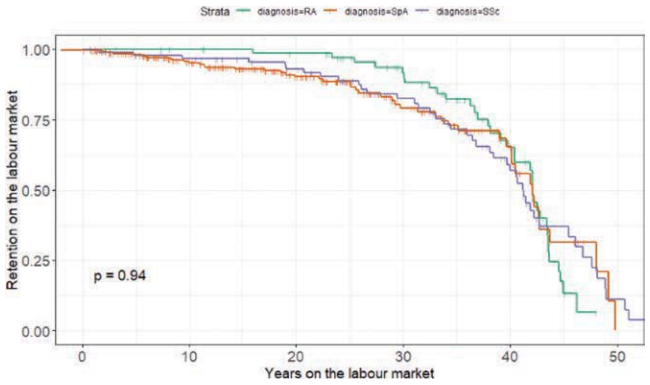

Figure 1. retention time on the labour market since start of patient's professional career.

Conclusion: Our data refute the common perception that patients with RMDs, especially inflammatory joint diseases, have significantly worse work outcomes compared to the general population. In an era of early diagnosis and treatment, more recent datasets could be used to realistically estimate the odds of these important health economic outcomes.

POS0162 HOW ACCURATELY CAN WE IDENTIFY RHEUMATOID ARTHRITIS BY ICD-10 CODES? A LINKAGE OF CROSS-SECTIONAL SURVEY DATA WITH CLAIMS DATA

J. Callhoff[1,2], K. Albrecht[1], U. Marschall[3], F. Hoffmann[4]. *[1]German Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin,; [2]Charité - Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany; [3]BARMER Institute for Health System Research, -, Wuppertal, Germany; [4]Universität Oldenburg, Health Services Research, Oldenburg, Germany*

Background: Claims data from health insurance companies are a valuable source in health services research to provide insights on health care provision for an unselected patient collective. However, the available ICD-10 diagnoses have been collected for billing purposes and their validity is not clear.

Objectives: The aim of this analysis was to assess the positive predictive values (PPV) of a ICD-10 diagnosis of rheumatoid arthritis (RA) and additional criteria (specific medication, measurement of inflammatory markers, contact to a rheumatologist) in German claims data using patient-reported confirmed diagnosis as reference/gold standard.

Methods: Within the PROCLAIR project (Linking Patient-Reported Outcomes with CLAims data for health services research In Rheumatology), data from a large German statutory health insurance with 6.6 million persons aged 18 to 79 were used. We identified a random sample of persons for which an ICD-10 code for RA (M05/M06) was available in at least two quarters in outpatient care. The sample was stratified for age (18 to 49, 50 to 64, 65 to 79 years), sex and seropositive (M05)/ seronegative RA (M06). Persons were asked to confirm their RA diagnosis ("What does your attending physician call the disease you are suffering from?") with answer options "chronic polyarthritis", "rheumatoid arthritis", "rheumatism of the joints" "other (please specify)". The answer was used as the gold standard for RA diagnosis. Analyses were weighted to represent the total RA population of the database. Patient-reported information was linked to the claims data given patient consent. PPVs (% of confirmed RA diagnosis) were calculated for ICD-10-diagnosis or additional examination of inflammatory markers (erythrocyte sedimentation rate/C-reactive protein), prescription of specific medication (disease-modifying anti-rheumatic drugs, non-steroidal anti-rheumatic drugs and glucocorticoids) and contact to a rheumatologist, in the respective year.

Results: We contacted 6,193 persons with a claims diagnosis of RA. Of these 3,184 responding (51%), N=2,535 (81%) confirmed that they had RA. PPVs were 81% for ICD-10 only, 94% in M05 and 76% in M06. When additional criteria were taken into account, PPVs increased to 82% (measure of inflammatory markers), 85% (rheumatologist) and 89% (medication), respectively (Figure 1). However, PPVs ranged from 72% to 76% even if the additional criteria were not fulfilled. PPVs were lowest in men aged 18-49 years and relatively stable among women of all age groups.

Figure 1.

Positive predictive values (PPVs) for different criteria additional to ICD-10 codes to identify rheumatoid arthritis patients in claims data

ESR: erythrocyte sedimentation rate CRP: C-reactive protein

Conclusion: The ICD-10 codes M05 and (less optimal) M06 have high PPVs and are therefore feasible to identify RA in claims data. The prerequisite of specific medication seems to be the most useful one in identifying RA.

POS0163 USEFULNESS OF WEARABLE DEVICES TO ASSESS PHYSICAL ACTIVITY IN NON-INFLAMMATORY AND INFLAMMATORY RHEUMATIC DISEASES: A SYSTEMATIC REVIEW AND META-ANALYSIS.

H. Ocagli[1], R. Agarinis[2], D. Azzolina[1], F. Todino[1], M. Binutti[2], A. Zabotti[2], D. Gregori[1], L. Quartuccio[2]. *[1]Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic, Vascular Sciences, and Public Health, University of Padova, Padua, Italy; [2]Division of Rheumatology, Department of Medicine, Udine, Italy*

Background: In the last years, the rise of personalized medicine has grown up. So, patient-oriented wearable technologies have been developed. Wearable devices (WD) are useful to collect objective data related to physical activity. In the management of rheumatic musculoskeletal disorders (RMDs) a regular physical activity is an important recognized non-pharmacological intervention [1].

Objectives: This systematic review aims at evaluating how the use of WDs impacts physical activity in patients with non-inflammatory and inflammatory rheumatic diseases.

Methods: A systematic review and meta-analysis were performed. A comprehensive search of articles was performed in the following databases: MEDLINE via PubMed, EMBASE, CINAHL, and Scopus. A random-effect meta-analysis has been carried out on the number of steps and moderate to vigorous physical activity (MVPA). Univariable meta-regression models have been computed to assess the possibility that the study characteristics may act as effect modifiers on the final meta-analysis estimate. The primary outcome is the level of physical activity evaluated with a wearable device as a number of daily steps and MVPA. The secondary outcome is the comparison of both a number of steps and MVPA to reference value for healthy people. The number of steps per day and the time spent in MVPA considered as a mean or median were collected. Missing information was calculated from available data when possible.

The reference value for steps was 7000 steps per day, this value was derived by a literature review commissioned by the Public Health Agency of Canada on the number of steps/day suitable for adults [2]. MVPA reference value was of 150 min/week and was derived by WHO guidelines [3].

Results: An overall of 1788 studies was considered in the title/abstract screening. In the analysis, 51 articles were included, with an overall of 7488 participants. Twenty-two studies considered MVPA outcome alone, 16 studies number of steps alone and 13 studies reported information on both outcomes.
The results of this meta-analysis show that there is a high level of I^2 heterogeneity, 99%, according to diagnosis.
Recommended threshold for daily steps was reached for MVPA (36.35, 95% CI 29.39 - 43.31) but not for daily steps (-1092.60, 95% CI -1640.42 - -544.77), with fibromyalgia reporting a higher number (6290, 95% CI 5198.65 – 7381.62) of daily steps compared to other RMDs. Patients affected by chronic inflammatory arthropathies seem to fare better in terms of daily steps than the other categories. Patients with rheumatoid or other chronic arthritis reported a higher number of steps, respectively 6361 (95% CI 5382.51; 7340.35) and 6290.14 (95% CI 5198.65; 7381.62).
Non-elderly people show a higher overall level of physical activity compared to the elderly, 6796.11 (95% CI 5974.10; 7618.13) versus 5431.85 (95% CI 4633.76; 6229.95). Non-elderly group show higher level MVPA compared to the reference value 38.96 (95% CI 18.35; 59.68) vs 11.77 (95% CI 3.32; 20.21).
Conclusion: RMDs suffer of low level of physical activity and WDs are useful and affordable instruments to support the increase of it. WDs can be used in daily monitoring of physical activity in RMDs.

Improving our care and understanding of paediatric RMDs

POS0164 GENETIC ANALYSIS OF WHOLE EXOME SEQUENCING IN A COHORT OF CHILDREN WITH REFRACTORY JIA REVEALS GENETIC RISK FACTORS FOR RARE JUVENILE DISEASES.

M. Tordoff[1], S. Smith[1], G. I. Rice[2], A. Morris[1], T. Briggs[2], W. Thomson[1,3], S. Eyre[1,3], J. Bowes[1,3]. [1]*The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom;* [2]*The University of Manchester, Division of Evolution, Infection and Genomics, Manchester, United Kingdom;* [3]*National Institute of Health Research Manchester Biomedical Research Centre, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: Juvenile idiopathic arthritis (JIA) encompasses a group of heterogeneous rheumatic diseases of childhood onset. JIA can result in long term disability and remission is the main goal of treatment. However refractory disease can occur, which is defined as the absence of response to a standard disease therapy. A genetic basis for refractory disease has yet to be explored, where deleterious rare variants can complicate diagnosis or treatment outcome.
Objectives: To investigate, through genetic analysis, whether children with JIA that is refractory carry rare genetic risk factors in genes linked to monogenic diseases.
Methods: Whole exome sequencing of 99 children with JIA was performed with the Agilent SureSelect Human All ExonV6 kit. All quality control, variant filtering and annotation was performed in Varseq (version 2.2.1). Variants with a read depth <30 and genotype quality <80 were removed. Rarity and pathogenicity filters were then applied to remove variants with an allele frequency >1% (based on ExAC, gnomAD, gnomAD exome, NHLBI and 1KGp phase 3), classified as benign or likely benign on ClinVar, with a CADD PHRED score <15 and a REVEL score >0.7. Variants were annotated if they appeared in a gene from the primary immunodeficiency PanelApp (Martin et al., 2019), in a gene associated with an arthritis phenotype or in a gene that appeared on a paediatric monogenic gene list. The variants were then classified using ACMG guidelines (Richards et al., 2015) and benign, or likely benign, classified variants were removed.
Results: A total of 628 variants were identified and we found that 20 out of the 99 children screened were heterozygous for at least one recognised variant in a gene linked to a monogenic disease. Five of these children carried more than one recognised variant linked to monogenic genes. Here we provide a number of illustrative examples: three genes, *ADAR, ATP7B and MVK,* were prioritised based on prior evidence of associated disease. The variant p.Pro193Ala (gnomAD allele frequency (GAD) $2.2x10^{-3}$) of *ADAR* has previously been deemed pathogenic in a homozygous or compound heterozygous state for Aicardi-Goutières syndrome. Adenosine deaminases (ADARs) catalyse the hydrolytic deamination of adenosine to inosine in dsRNA and is suggested to act as a suppressor of type 1 interferon-stimulated genes. Within *ATP7B*, two distinct variants were detected; p.Gln1142His (GAD $1.6x10^{-5}$) and p.Ile1148Thr (GAD $4.0x10^{-5}$) have previously been reported as pathogenic, in combination with a third variant, for Wilson's disease and were carried by one individual in this cohort. *ATP7B* encodes copper-transporting ATPase 2, which supplies copper to ceruloplasmin. Variant p.Val377Ile (GAD $1.6x10^{-3}$) of *MVK* was detected in eight individuals in this cohort, interestingly five of these individuals also carried at least one *HLA-DRB1* stop-gained variant. This *MVK* mutation has been confirmed as pathogenic in a homozygous or compound heterozygous state for mevalonate kinase deficiency. MVK converts mevalonic acid into mevalonate-5-phosphate in the cholesterol synthesis pathway. Additionally, two stop-gained loss of function *HLA-DRB1* variants, p.Tyr107Ter and p.Gln125Ter, were detected in five and 20 individuals, respectively, in this cohort. *HLA-DRB1* is a recognised susceptibility locus for JIA.
Conclusion: Screening of a cohort of 99 children with JIA that have refractory disease has revealed that individuals carry deleterious variants in genes linked to monogenic forms of disease. These results highlight that the genetic basis for refractory disease needs to be further investigated. Carrying additional genetic risk factors to disease may complicate disease outcome and genetic screening of children with refractory JIA may improve treatment outcome in the future.

POS0165 WHOLE EXOME SEQUENCING TO IDENTIFY RARE INFLAMMATORY VARIANTS IN AN IRISH COHORT WITH CHRONIC NONBACTERIAL OSTEOMYELITIS (CNO)

D. O'Leary[1,2], O. Killeen[1,2], A. G. Wilson[1]. [1]*UCD, Centre for Arthritis Research, Dublin, Ireland;* [2]*Children's Health Ireland, National Centre for Paediatric Rheumatology, Dublin, Ireland*

Background: Chronic nonbacterial osteomyelitis (CNO) is a rare inflammatory disease affecting bone which predominantly occurs in the paediatric population. It is frequently associated with pustulosis, psoriasis, inflammatory bowel disease and arthritis, in particular enthesitis-related arthritis. Activation of the *NLRP3* inflammasome has been implicated in both human and mouse models of the disease.
Objectives: To identify a candidate list of rare, deleterious variants in known inflammatory genes in an Irish cohort with CNO.
Methods: 41 unrelated Irish children with CNO were recruited. Whole exome sequencing was performed on blood using Agilent SureSelect XT Human All Exon V6 kits and Illumina HiSeq 3000 with 150bp paired-end reads. Reads were aligned to the hg19 reference genome. After preprocessing, variants were hard filtered using quality by depth(QD) > 2.0, read depth (DP) >10 and genotype quality (GQ) >20. Synonymous variants and variants with MAF > 0.01 were excluded from further analysis. Remaining variants were filtered against existing databases of genes known to be associated with inborn errors of immunity, autoimmunity or autoinflammation. The Gene Damage Index (GDI) was used to identify genes which are least tolerant to variance and CADD phred-like scores to identify variants predicted to be deleterious. Genes with variants in >=2 CNO patients were included in the candidate list and variants manually checked using the Integrative Genomics Viewer (IGV).
Results: After filtering low-quality, synonymous and common variants, 17,293 variants were filtered against a database of 581 known inflammatory genes. 350 rare variants in 201 genes predicted to be intolerant to variance were identified. After excluding those present in one individual only, ranking by CADD phred-like scores and manual inspection on IGV, a candidate list of 25 genes remained. The same variant in *IL17RA, NLRP1* and *KMT2D* was present in 3 unrelated individuals (Table 1). *IL17RA* belongs to the Th17 pathway which is involved in psoriasis pathogenesis. *NLRP1* is implicated in several autoinflammatory diseases including psoriasis. None of the individuals carrying these variants in *IL17RA* or *NLRP1* have psoriasis. One individual with *IL17RA* variant has 1st-degree family history of psoriasis. Rare variants which are predicted to be deleterious were found in two individuals in each of the following genes in the IL-17 signalling/Th17 differentiation pathway: *IL17RB, IL17RE, IL25, HIF1A* (Table 1). This suggests that the Th17 pathway may play a role in disease pathogenesis in a proportion of children with CNO.
Conclusion: *IL17* +/- the IL-17 signalling/Th17 differentiation pathways, and *NLRP1* provide targets for further investigation in CNO. The role of these candidate genes may be further elucidated through gene-/pathway-based burden testing against a matched control population.

POS0166 POLYARTICULAR JIA HAS A DISTINCT CO-INHIBITOR RECEPTOR PROFILE AMONG OTHER JIA SUBTYPES

E. Sag[1,2], Z. Balik[1], S. Sener[1], U. Kaya Akca[1], S. Demir[1], M. Kasap-Cuceoglu[1], E. Atalay[1], S. Bocutcu[1], T. Vural[2], Y. Bilginer[1], B. Deleuran[3,4], S. Özen[1,2]. *[1]Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey; [2]Hacettepe University, Pediatric Rheumatology Unit, Translational Medicine Laboratories, Ankara, Turkey; [3]Aarhus University, Institute of Biomedicine, Aarhus, Denmark; [4]Aarhus University Hospital, Department of Rheumatology, Ankara, Denmark*

Background: Juvenile idiopathic arthritis (JIA) is the most common inflammatory joint disease in children, driven by continuous T-cell activation.[1] T cell activation is counter-balanced by signals generated by co-inhibitory receptors (co-IRs) such CTLA-4, PD-1, LAG-3, and TIM-3.[2]

Objectives: We aimed to identify the role of co-IRs in the pathogenesis of different subtypes of JIA.

Methods: In total, we included 107 patients with oligoarticular JIA (n=67), polyarticular JIA (n=12), enthesitis related arthritis (n=17), systemic JIA (n=11) and healthy controls (HC, n=10). We collected plasma samples from the patients during the active phase of their disease. We measured the soluble plasma levels of co-IRs by commercial pre-defined cytometric bead array kits and their cellular expression by flow cytometry in blood mononuclear cells. We compared the plasma levels and cellular expressions of different coIRs within different JIA subgroups.

Results: IL-2 levels were lower than HC in all JIA subgroups. The polyarticular JIA group distinguished from the four different JIA subgroups, by having different co-IR pattern. In this specific subgroup, CTLA4, PD-1 and 4-1BB levels were higher than other groups. Polyarticular JIA is the more chronic and severe form of JIA, especially when compared to oligoarticular JIA. (Figure 1).

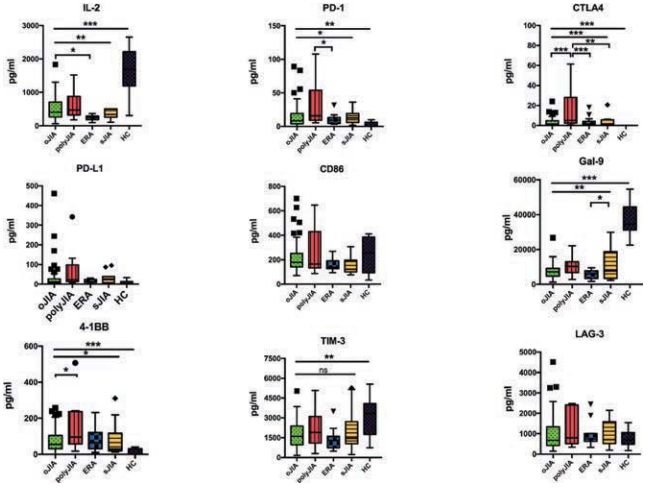

Figure 1.

We investigated the correlations between disease activity markers and plasma co-IRs. Plasma TIM3 levels correlated with erythrocyte sedimentation rate, C-reactive proteins and JADAS in the polyarticular JIA group. In oligoarticular JIA group, JADASs correlated with plasma PD-1 levels, C-reactive protein with PD-L1 plasma levels. Erythrocyte sedimentation rates correlated with IL-2, CD86, PD-L1 and PD-1 plasma levels. There was no correlation between disease activity markers and co-IRs levels in the systemic JIA group and enthesitis related arthritis group.

Finally, we analysed the cellular surface expression of different co-IRs on the PBMCs of different JIA subtypes. Similar to plasma levels, both the percentage and the MFI (mean fluorescence intensity) of CTLA4 expression was higher in polyarticular JIA subgroup.

Conclusion: This is the first report studying the effects of different co-IRs in different subtypes of JIA. Polyarticular JIA patients had a different coIR profile, having more CTLA-4, PD-1 and 4-1BB in their plasma than the other subtypes of JIA

POS0167 A PROTEOGENOMIC MAP OF NATURAL KILLER CELLS IN OLIGOARTICULAR JUVENILE IDIOPATHIC ARTHRITIS

O. Knight[1,2], G. Guerra[3], M. F. Mashreghi[3,4], T. Kallinich[5,6], T. Rückert[1], C. Romagnani[1,2]. *[1]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Innate Immunity, Berlin, Germany; [2]Charité - Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Gastroenterology, Berlin, Germany; [3]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Therapeutic Gene Regulation, Berlin, Germany; [4]Charité Universitätsmedizin Berlin, BIH Center for Regenerative Therapies (BCRT), Berlin, Germany; [5]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Chronic inflammation in Childhood, Berlin, Germany; [6]Charité Universitätsmedizin Berlin, Department of Pediatric Respiratory Medicine, Immunology and Critical Care Medicine, Berlin, Germany*

Background: Natural Killer (NK) cells are innate lymphocytes which are specialised for recognising stressed cells, classically divided into cytotoxic (CD56dim) and cytokine-producing (CD56bright) populations. During oligoarticular Juvenile Idiopathic Arthritis (oligo-JIA), an unknown trigger induces the recruitment of peripheral immune cells into synovial joints, which in turn creates a chronic inflammatory environment. This can result in joint contractures and extraarticular complications, highlighting the requirement for early disease intervention. The contribution of NK cells toward immunopathology during the early stages of disease and in subsequent arthritic flares is unknown, providing a potential avenue for understanding disease course and therapeutic intervention.

Objectives: We aimed to assess the contribution of NK cells to the early pathogenesis of oligo-JIA by identifying inflammatory signatures present in patient synovia, and which signals could induce them.

Methods: Peripheral blood (PB) and synovial fluid (SF) were drawn from 4 patients at the first clinical presentation of oligo-JIA. Flow-cytometry Activated Cell-Sorting (FACS) was used to unbiasedly isolate NK cells (CD3-CD7+), and single cell RNA-sequencing (scRNA-Seq) paired with

oligonucleotide-tagged antibodies (CITE-Seq) performed, allowing us to generate a proteogenomic dataset of 35,609 NK cells. Antibody-derived-tags were used to delineate whether cells were isolated from PB or SF, and a community detection algorithm was used to cluster neighbours of cells for differential gene expression.

Results: We identified 468 differentially expressed genes (>0.2 log2 fold change) between peripheral and synovial NK cells, among which were CD56bright- and CD56dim-specific genes, and a synovia-specific signature. Antibody-tag measurements confirmed the majority of synovial NK cells to be phenotypically CD56bright, with a spectrum of modified gene expression patterns compared of those in the periphery. 6 distinct synovial clusters were identified by community detection, among which were a large number of proliferating cells, a transitionary CD56bright population, and 2 uniquely activated signatures.

Conclusion: Synovial NK cells possess a significantly different transcriptomic identity compared with those in the periphery. However, though they share a gene signature that is most comparable to blood CD56bright NK cells, it is not identical. Uniquely activated subpopulations also provide the first evidence of NK cell activation during oligo-JIA pathogenesis, suggesting that these cells could hold therapeutic potential.

POS0168 NON-INVASIVE IMAGING IN JUVENILE LOCALISED SCLERODERMA: HIGH-FREQUENCY ULTRASOUND, THERMOGRAPHY, LASER DOPPLER & MULTISPECTRAL IMAGING

C. Pain[1], A. Murray[2], G. Dinsdale[3], A. Marsden[4], J. Manning[5], A. Herrick[2]. *[1]Alder Hey Children's Hospital NHS Foundation Trust, Paediatric Rheumatology, Liverpool, United Kingdom; [2]University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; [3]Salford Royal NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; [4]University of Manchester, Division of Population Health, Health Services Research and Primary Care, Manchester, United Kingdom; [5]Salford Royal NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: Outcome measures which can differentiate activity (inflammation) from damage (fibrosis/atrophy) would facilitate development of new treatment strategies in juvenile localized scleroderma (JLS) to target the inflammatory phase of the disease.

Objectives: To evaluate whether in JLS, non-invasive imaging modalities (high frequency ultrasounds (HFUS), multispectral imaging (MSI), laser doppler imaging (LDI) & infra-red thermography (IRT)) can detect differences between affected & non-affected skin, as a next step in developing these as outcome measures. Our hypothesis was that blood flow (and therefore temperature & oxygenation) would be increased in lesional skin.

Methods: Participants aged 4-17 were recruited from 3 paediatric rheumatology centres in the UK. For each participant, a single lesion was selected. HFUS (30MHz), MSI (bespoke camera and tuneable liquid crystal filter, coupled to custom analysis software, 500nm/710nm wavelengths), LDI and IRT imaging were performed at four sites relating to each lesion: two of affected skin (centre & inner edge of lesion) and two of non-affected skin (one cm from edge of lesion ('outer') & contralateral unaffected side). Imaging was performed at 4 visits at 3 monthly intervals. Mean values were compared between the four sites using data from all visits by mixed-effects linear regression to account for individual-level clustering.

Results: 24 participants completed all 4 visits and 1 attended 3. 20 participants were female (80%) & 5 male (20%). Mean age at diagnosis was 7.6 years & disease duration 4.9 years. Subtype of disease was linear head in 5/25 (20%), linear limb 12/25 (48%), generalised morphea 1/25 (4%), mixed 5/25 (20%) and superficial plaque in 2/25 (8%).

Table 1 shows a subset of data. All 4 imaging techniques could detect differences between healthy (outer/contralateral) & affected skin (centre/inner edge). For HFUS, there was strong evidence of a difference between affected & unaffected skin ($p<0.001$) indicating affected skin is thinner than unaffected. Higher mean values of oxygenation, perfusion & temperature were observed in affected compared to non-affected skin in MSI, LDI and IRT respectively. There was no statistical difference seen between inner edge and centre of the lesion in any of the methods.

Table 1. Mean differences between different locations for each imaging technique

Imaging technique	Location	Overall mean difference (95% CI)	p-value
HFUS	Centre - Contralateral	-0.34 (-0.46, -0.22)	<0.001
	Inner edge - Contralateral	-0.30 (-0.40, -0.20)	<0.001
(mm)	Centre - Outer	-0.35 (-0.46, -0.24)	<0.001
	Inner edge - Outer	-0.31 (-0.40, -0.21)	<0.001
	Centre - Inner edge	-0.04 (-0.10, 0.02)	0.168
MSI	Centre - Contralateral	0.06 (0.03, 0.10)	<0.001
	Inner edge - Contralateral	0.06 (0.03, 0.09)	<0.001
(rel units)	Centre - Outer	0.04 (0.01, 0.07)	0.012
	Inner edge - Outer	0.03 (0.00, 0.06)	0.028
	Centre - Inner edge	0.01 (0.00, 0.02)	0.251
LDI	Centre - Contralateral	44.8 (24.4, 65.2)	<0.001
	Inner edge - Contralateral	47.9 (21.0, 74.8)	<0.001
Relative perfusion	Centre - Outer	19.1 (1.0, 37.1)	0.039
units	Inner edge - Outer	24.8 (6.7, 42.9)	0.007
	Centre - Inner edge	-3.5 (-20.3, 13.2)	0.679
IRT	Centre - Contralateral	0.58 (0.24, 0.91)	0.001
	Inner edge - Contralateral	0.44 (0.13, 0.75)	0.005
°C	Centre - Outer	0.44 (0.22, 0.66)	<0.001
	Inner edge - Outer	0.30 (0.09, 0.52)	0.006
	Centre - Inner edge	0.14 (-0.05, 0.32)	0.153

The overall mean difference is the measurement of the first location minus the measurement from the second location (e.g. centre minus contralateral), averaged across the four visits.

Conclusion: Our results suggest non-invasive imaging can detect differences between healthy & unaffected skin in JLS. Whether each technique is only measuring activity & not damage requires further evaluation. The leading edge of lesions has historically been considered as most active compared to the centre. However, no difference was seen between centre & inner edge measurements suggesting that in future studies, imaging protocols can be simplified.

POS0169 OPEN-LABEL, LONG-TERM (10-YEAR) STUDY OF THE SAFETY OF ETANERCEPT IN CHILDREN AND YOUNG ADULTS WITH EXTENDED OLIGOARTICULAR, ENTHESITIS-RELATED, OR PSORIATIC JUVENILE IDIOPATHIC ARTHRITIS

J. Vojinovic[1], J. Dehoorne[1], V. Panaviene[1], G. Susic[1], G. Horneff[1], V. Stanevicha[1], K. Kobusinska[1], Z. Żuber[1], B. Dobrzyniecka[1], J. Akikusa[1], T. Avcin[1], A. Martini[1], C. Borlenghi[2], E. Arthur[3], S. Y. Tatulych[4], C. Zang[5], B. Vlahos[6], N. Ruperto[1]. *[1]Paediatric Rheumatology International Trials Organisation (PRINTO), Paediatric and Rheumatology, Genoa, Italy; [2]Pfizer, I&I Medical Affairs, Buenos Aires, Argentina; [3]Pfizer, Clinical Development and Operations, Peapack, United States of America; [4]Pfizer, Clinical Development, Groton, United States of America; [5]Pfizer, Global Biometrics and Data Management, Collegeville, United States of America; [6]Pfizer, Global Product Development, Collegeville, United States of America*

Background: CLIPPER2 was an 8-year, open-label extension of the phase 3b, multicenter, 2-year CLIPPER study of the safety and efficacy of etanercept (ETN) in the treatment of patients (pts) with juvenile idiopathic arthritis (JIA) categorized as extended oligoarticular arthritis (eoJIA), enthesitis-related arthritis (ERA), or psoriatic arthritis (PsA).

Objectives: The objective of this analysis was to describe the safety of ETN in this population after 10 years of follow up.

Methods: Pts (n=127) with eoJIA (2-17 years), ERA, or PsA (each 12-17 years) who received ≥1 ETN dose (0.8 mg/kg once weekly [max, 50 mg]) in CLIPPER were eligible to enter CLIPPER2. The primary outcome measure was the occurrence of malignancy. Long-term safety was assessed as the total incidence of events from CLIPPER baseline (BL) to month (mth) 120, frequency of events per 100 patient-years (EP100PY), and frequency of events in each study year.

Results: A total of 109/127 (86%) pts entered CLIPPER2; 99 (78%) continued in the active treatment period. At mth 120, 84 (66%) pts had completed the study; 27 (21%) while actively taking ETN; 7 (6%) had withdrawn from treatment due to low/inactive disease; 5 (4%) had re-started ETN following an earlier withdrawal from treatment; and 45 (35%) had stopped ETN (but remained under observation); 25 (20%) pts permanently discontinued from the CLIPPER2 study. In CLIPPER/CLIPPER2, 1 case of malignancy (Hodgkin's disease) was reported (1 pt with eoJIA in Year 3). There was 1 case of uveitis (1 pt with eoJIA in Year 8) and 3 of Crohn's disease (2 pts with ERA, Year 1/Year 6; 1 pt with eoJIA, Year 5). There were 2 cases of opportunistic infections (both herpes zoster), and no deaths. Overall, there were 559 (81.82 EP100PY) treatment-emergent adverse events

(TEAEs) excluding infections and injection-site reactions (ISRs). The overall rate of TE serious infections was low (N=14; 2.05 EP100PY) (Table 1), with the most common TE serious infection being gastroenteritis (N=2; 0.29 EP100PY). The most frequently reported TEAEs (N [EP100PY]) were headache (28 [4.10]), arthralgia (24 [3.51]), pyrexia (21 [3.07]), diarrhea (14 [2.05]), and leukopenia (12 [1.76]). Overall, 39 patients reported serious AEs (excluding infections/ISRs). The number and frequency (N [EP100PY]) of TEAEs (excluding infections/ISRs) decreased over the 10-year study period from 193 [173.81] in Year 1 to 9 [27.15] in Year 10. The number and frequency of TE infections and TE serious infections also decreased over the 10-year study period. There was no clear trend of a decrease over time for the incidence of TE serious AEs (Figure 1).

Table 1. ETN Safety Summary (from CLIPPER BL to mth 120), N (EP100PY) (FAS)*

	eoJIA, n=60 (EXP=313.667 PY)	ERA, n=38 (EXP=206.971 PY)	PsA, n=29 (EXP=162.576 PY)	Total, n=12 (EXP=683.214 PY)

POS0170 EXPERIENCES WITH COVID-19 INFECTIONS IN GERMAN PEDIATRIC RHEUMATOLOGY CENTERS

G. Horneff[1,2], F. Dressler[3], D. Windschall[4,5], S. Mrusek[6], T. Hospach[7], A. Kühn[8], M. Haller[9], P. Von Bismarck[10], W. Emminger[11], P. Ruehmer[12], M. Hufnagel[13], A. Klein[1,2]. *[1]Kinderklinik Sankt Augustin, Pediatrics, Sankt Augustin, Germany; [2]Kinderklinik Uniklinikum Köln, Pediatrics, Köln, Germany; [3]Medizinische Hochschule Hannover (MHH) Klinik für Pädiatrische Nieren- Leber- und Stoffwechselerkrankungen, Pediatric Rheumatology, Hannover, Germany; [4]St. Josef-Stift Sendenhorst, Northwest German Center for Rheumatology, Clinic of Paediatric and Adolescent Rheumatology, Sendenhorst, Germany; [5]Martin-Luther-University Halle-Wittenberg, Medical Faculty, Halle, Germany; [6]Private Practive, Pediatrics, Baden-Baden, Germany; [7]Olgahospital and Women's Clinic, Pediatric Rheumatology, Stuttgart, Germany; [8]Universitätsklinikum Halle (Saale), Pediatric Rheumatology, Halle (Saale), Germany; [9]Private Practice, Pediatrics, Gundelfingen, Germany; [10]Universität Kiel, Pediatrics, Kiel, Germany; [11]Universität Wien, Pediatrics, Wien, Austria; [12]Helios Vogtland-Klinikum Plauen, Pediatrics, Plauen, Germany; [13]Universitätsklinikum Freiburg, Pediatric Rheumatology, Freiburg im Breisgau, Germany*

Background: Although the risk for severe COVID-19 progression in children is low, this may be aggravated by the underlying disease and/or immunosuppressive drugs.

Objectives: We analyzed clinical data of COVID-19 cases among paediatric patients with rheumatic diseases reported to the BIKER registry.

Methods: The main task of the German BIKER (Biologics in Pediatric Rheumatology) registry is to monitor the safety of biologics therapies in JIA. After the onset of the COVID-19 pandemic, the survey was expanded with a standardized form to proactively interview all participating centers about the occurrence, presentation, and outcome of SARS-CoV-2- infections in children with rheumatic diseases. Interviews were conducted with 68 centers initially weekly and later biweekly.

Results: A total of 68 centres participated in the survey. Clinical data from 194 COVID-19 cases reported to the BIKER registry from 41 German and 1 Austrian pediatric rheumatology institutions between February 2020 and December 2021 were analyzed. Juvenile idiopathic arthritis (JIA, n=144) was the most common diagnosis followed by genetic autoinflammation (n=18; i.e. FMF, TRAPS, CAPS, HIDS, DADA2), systemic autoimmune diseases (n=11; i.e. SLE, dermatomyositis, vasculitis) and 16 with other rheumatic diseases (i.e. CRMO, Uveitis). 5 patients with no rheumatic disease were excluded. 104 (54%) patients were receiving conventional DMARDs, 81 (43%) received biologics, mainly TNF inhibitors (n=66 (35%)). Of the 189 rheumatic patients with SARS-CoV2 infection, 123 (63%) were female. The mean age was 12.4+/-4.4 years in females and 13.2+/-4.1 in males. The duration of SARS-Co2 infection associated symptoms was 13.8+/-15.3 days (max. 113 days), in 35 (43%) patients they lasted for > 12 days. 46 (24%) were asymptomatic. Patients with autoinflammation and systemic autoimmunopathies reported more symptoms such as fever, head and throat ache. 4 patients only complained about dyspnea. Only 3 patients were hospitalized and received Oxygen-supplementation. The only patients admitted to ICU, received ventilation but succumbed. This 3½-year-old patient, initially diagnosed with systemic JIA, developed fatal disease with intracranial edema and respiratory failure, as well as typical pulmonary texture changes. Prior to her SARS-CoV-2 infection, the patient was treated with MTX and low-dose steroids. Genetic testing revealed a so far unrecognized congenital immunodeficiency. In the total JIA cohort, treatment with corticosteroids, conventional DMARDs, biologics or combinations did not influence the number of reported symptoms or the favorable outcome of the cohort. However, the duration of symptoms was lower in the TNF-treated cohort (10.4+/-6.4 days vs. 15.7 +/- 19.7 days). In the cohort with autoinflammation, fever was observed in 11 (61%). Those 6 who received IL-1-inhibitors did not show a different outcome than those 12 who did not. No case of PIMS/MISC in children with rheumatic diseases was reported.

Conclusion: Except for one patient with congenital immunodeficiency who died from her COVID-19 infection, no case of severe COVID-19 was reported in our cohort. At the time of infection, over 80% of patients in our cohort had been treated with conventional DMARDs and/or biologics. This did not appear to have a negative impact on the severity or outcome of SARS-CoV2 infection. Interestingly, no case of PIMS/MISC was observed.

Background: The ProKind Commission of the Society for Paediatric and Adolescent Rheumatology (GKJR) has developed evidence- and consensus-based protocols for the diagnosis and therapy of children and adolescents with defined rheumatic diseases (e.g., [1]). In the ProKind-Rheuma project, it is now investigated whether the protocols are followed in everyday clinical practice and what the treatment-associated outcomes are.

Objectives: To investigate the mode of treatment and treatment response in patients with polyarticular juvenile idiopathic arthritis (pJIA).

Methods: ProKind-Rheuma is a multicenter prospective non-interventional observational study. Patients with pJIA enrolled until 17/1/2022 were included into this analysis. Treatments and outcomes up to the 3-month follow-up visit (3FU) were analyzed. Disease states were categorized based on the 2021 cJADAS10 cutoffs [2].

Results: To date, 18 pediatric rheumatology facilities have participated in ProKind-Rheuma. Data from 203 patients with JIA are available. Of those, 44% have oligoarthritis, 36% polyarthritis, 9% systemic JIA, 6% enthesitis-related arthritis and 3% psoriatic arthritis. In total, 76 patients were diagnosed with pJIA, 38 with already completed 3FU: For 23 patients with pJIA and completed 3FU, we were able to analyze the protocol-defined [1] treatment goal of at least "minimal improvement". In total, 18 (78%) achieved minimal improvement, 5 (22%) missed it. For 4 of those 5 patients, the underlying MTX therapy was escalated to a bDMARD (3 changed to MTX+bDMARD-combi, 1 to bDMARD-mono). In 3 other patients, therapy was also escalated to an MTX-+bDMARD-combi. Between baseline and 3FU, 72% achieved cJADAS10-disease state improvement (Table 1) by at least one category (range 1 - 2), 0% decreased.

Table 1.

*based on non-missing values	At Baseline all	At Baseline with 3FU	At 3FU
Total	76	38	
Female, n (%)	58 (76)	30 (79)	
Age (years), *Mdn* (IQR)	9 (3-12)	7 (2-12)	7.5 (3-12)
Time since diagnosis (months), *Mdn* (IQR)	0 (0-1)	0 (0-1)	4 (3-4)
RF-positivity, n (%)	8 (11)	3 (8)	
Number of active joints (arthritis), *Mdn* (IQR)	7 (4-12)	7 (5-12)	2 (0-4)
JADAS10 (0-40), *Mean* (SD) (N_{BL+3FU}= 23)	18.6 (7.4)	19.6 (7.6)	7.2 (4.2)
cJADAS10 (0-30), Mean (SD) (N_{BL+3FU}= 29)	16.3 (5.9)	16.7 (6.1)	7.1 (4.1)
State of inactive disease (cJADAS10≤2.5), n (%*)	0 (0)	0 (0)	4 (13)
State of minimal disease activity (2.5<cJADAS10≤5), n (%*)	1 (2)	1 (3)	9 (28)
State of moderate disease activity (5<cJADAS10 ≤16), n (%*)	33 (54)	17 (50)	18 (56)
State of high disease activity (cJADAS10>16), n (%*)	27 (44)	16 (47)	1 (3)
CHAQ (0-3), *Mean* (SD)	0.8 (0.8)	0.9 (0.8)	0.3 (0.5)
Pain (NRS 0 - 10), *Mean* (SD)	4.3 (3)	4.7 (3)	2.2 (2.7)
PedsQL 4.0 total score, *Mean* (SD)	66.3 (22.2)	65.4 (21.8)	78.4 (17.6)
Intraarticular glucocorticoids > 4 joints (ever), n (%)	12 (16)	5 (13)	7 (18)
Glucocorticoid pulses (ever), n (%)	22 (29)	12 (32)	13 (34)
Methotrexate, n (%)	56 (74)	31 (82)	34 (90)
bDMARDs, n (%)	7 (9)	2 (5)	9 (24)

Within the first 3 months after diagnosis, the treatment pathways proposed by the ProKind Commission [1] were followed in about three-quarters of patients: i) 5 (13%) received MTX and intra-articular glucocorticoid injections in more than 4 joints (IAGC), but no high-dose intravenous glucocorticoid pulse (HDGC) or bDMARD; ii) 8 (21%) received MTX and HDGC (no bDMARD, no IAGC); iii) 16 (42%) patients received MTX, of whom 4 received a bDMARD up to or at the 3FU (no HDGC, no IAGC). Nine (24%) patients were not treated with MTX or did not fit any of these categories, mostly due to starting bDMARD therapy in conjunction with HDGC or IAGC.

Conclusion: In the routine care of JIA patients with polyarthritis, the proposed treatment protocol and treat-to-target strategy are followed in most patients. At 3FU, improvements of JADAS10 and other outcomes were evident, with 41% having achieved inactive or minimal active disease.

Background: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children (1). In adult patients there are significant differences between the clinical presentation of diffuse and limited subtypes (2). We reviewed clinical differences in presentation of subtypes in patients in the juvenile systemic scleroderma inception cohort up to 2021.
Objectives: To study the clinical presentation of jSSc patients with diffuse (djSSc) and limited (ljSSc) subtypes.
Methods: We reviewed the clinical baseline characteristics of the patients, who were recruited to the juvenile scleroderma inception cohort (jSScC) (3, 4) till 1st of December 2021. jSScC is a prospective cohort of jSSc patients, who developed the first non-Raynaud´s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion.
Results: 210 patients with jSSc were included in the cohort, 71% (n=162) had diffuse subtype. The median age at onset of Raynaud phenomenon was 10.4 years (7.3 – 12.9) and the median age at the first non-Raynaud symptom was 10.9 years (7.4 – 13.2). Median disease duration was 2.5 years (1 – 4.4) at the time of inclusion. The female/male ratio was significantly lower in the djSSc subtype (3.7:1 versus 5:1, p<0.001). Antibody profile was quite similar, with the exception of a significantly higher number of anticentromere positive patients in the ljSSc (12% versus 2%, p=0.013). Decreased FVC < 80% was found in approximately 30% and decreased DLCO < 80% was found in around 40% in both subtypes. Pulmonary hypertension assessed by ultrasound was identified in 5% in both groups. Patients with diffuse subtype had significantly higher modified Rodnan Skin Score (mRSS) (16 versus 4.5, p<0.001), sclerodactyly (84% versus 60%, p<0.001), history of digital ulceration (62% versus 31%, p<0.001), decreased Body Mass Index (BMI) < -2 z score (20% versus 4%, p=0.003) and decreased joint range of motion (64% versus 46%, p=0.019). Patients with ljSSc had significantly higher rate of cardiac involvement (13% versus 2%, p=0.001). Regarding patient related outcomes djSSc patients had more severe disease, looking at patient reported global disease activity (VAS 0 – 100) (40 versus 25, p=0.039), patient reported global disease damage (VAS 0 – 100) (40 versus 25, p=0.021) and patient reported assessment of ulceration activity (10 versus 0, p=0.044). Regarding physician related outcomes the physician reported global disease activity (VAS 0 – 100) (32 versus 20, p<0.001) and physician reported global disease damage (VAS 0 – 100) (30 versus 15, p=0.014) was significantly higher in djSSc.
Conclusion: In this jSSc cohort, the largest in the world, djSSc patients have a significantly more severe disease than ljSSc patients. Interestingly, we found no differences regarding interstitial lung disease and pulmonary hypertension.

Background: For classification in juvenile spondyloarthritis (JSpA), it is important to develop cut-offs for active and structural lesions typical of axial disease on MRI that are readily and consistently interpreted. Since the maturing sacroiliac joint (SIJ) looks different from the adult SIJ, the criteria developed for positive MRI in adults may not be applicable in JSpA.
Objectives: As part of a study developing classification criteria for axial disease in JSpA, we aimed to determine quantitative SIJ imaging lesion cut-offs for inflammatory and structural lesions typical of axial JSpA using majority imaging expert decision as the reference criterion.
Methods: Subjects were a retrospective cohort of children with SpA who met the provisional Pediatric Rheumatology International Trials Organization criteria for enthesitis/spondylitis-related juvenile idiopathic arthritis or had a rheumatologist JSpA diagnosis. All subjects had symptom onset prior to age 18 years and underwent MRI as part of a diagnostic evaluation for axial disease. To enable SIJ quadrant-based scoring, all MRIs included semi-coronal slices through the cartilaginous part of the joint on fluid sensitive sequences and on T1-weighted sequences for the assessment of inflammation and structural lesions, respectively. MRIs were reviewed by 6 musculoskeletal imaging experts who were blinded to clinical details. MRI evaluation of the SIJ was based on standardized lesion definitions that were decided by consensus of the central imaging team and represented a mix of definitions from ASAS and the Juvenile Arthritis MRI Score Outcome Measures in Rheumatology working group. Using a web-based interface, raters globally assessed the presence or absence of lesions typical of axial SpA and performed SIJ quadrant or joint based scoring. Lesion scores were generated by averaging the scores of all raters. Sensitivity and specificity of lesion cut-offs were calculated using rater majority (≥4/6 raters) on a global assessment of the presence/absence of active or structural lesions typical of axial SpA with high confidence (confidence of ±3 or stronger on confidence scale from -5, "Definitely No" to +5, "Definitely Yes") as the reference standard.
Results: Imaging from 243 subjects, 61% male, median age 14.9 years, had sequences available for detailed MRI scoring. Active inflammatory lesion typical of axial disease in JSpA was defined as bone marrow edema (BME) in at least 3 SIJ quadrants (sensitivity 98.6%, specificity 96.5%). For structural lesion typical of axial JSpA, the optimal cut-off was erosion in at least 3 quadrants or at least one of the following lesions in at least 2 SIJ quadrants: sclerosis, fat lesion, backfill, ankylosis (sensitivity 98.6%, specificity 95.5%).
Conclusion: We propose data-driven cut-offs for active inflammatory and structural lesions on MRI typical of axial disease in JSpA that have high specificity and sensitivity using central imaging global assessment as the reference standard.

Table 1. Performance of cut-offs for inflammatory and structural lesions of axial disease

Cut-offs for number of SIJ quadrants (any location)	Sensitivity (95% CI)	Specificity (95% CI)
Definite active lesion		
BME score ≥2	100 (95.0-100)	93.5 (88.7-96.7)
BME score ≥3	98.6 (92.5-100)	96.5 (92.5-98.7)
BME, same location on ≥3 consecutive slices	88.6 (78.7-94.9)	98.8 (95.8-99.9)
Definite structural lesion		
Erosion ≥2	95.7 (88-99.1)	96.8 (92.7-99)
Erosion, same location on ≥2 consecutive slices	94.3 (86-98.4)	98.1 (94.5-99.6)
Erosion ≥3	91.4 (82.3-96.8)	98.7 (95.4-99.8)
Sclerosis ≥2	62.9 (50.5-74.1)	98.1 (94.5-99.6)
Fat lesion ≥2	22.9 (13.7-34.4%)	98.7 (95.4-99.8%)
Backfill ≥2	20 (11.4-31.3)	100 (97.7-100)
Ankylosis ≥2	1.3 (0.2-4.7)	100 (94.9-100)
ANY of the following in ≥2 SIJ quadrants: erosion, sclerosis, fat lesion, backfill, ankylosis	98.6 (92.3-100)	93.6 (88.5-96.9)
Erosion ≥3 quadrants *OR* ≥2 quadrants of at least one of the following lesions: sclerosis, fat, backfill, ankylosis	98.6 (92.3-100.0)	95.5 (91.0-98.2)

New insights into the associations of outcomes and biomarkers in OA

POS0174 **PAIN SEVERITY ACROSS HAND OA PHENOTYPES BASED ON A BIOPSYCHOSOCIAL APPROACH**

E. Mulrooney[1], T. Neogi[2], H. Solveig Dagfinrud[1,3], H. B. Hammer[1,3], P. Steen Pettersen[1], T. K. Kvien[1,3], K. Magnusson[4], I. K. Haugen[1,3]. *[1]The Deacon's Home Hospital, Division of Rheumatology and Research, Oslo, Norway; [2]Boston University School of Medicine, Section of Rheumatology, Boston, United States of America; [3]University of Oslo, Faculty of Medicine, Oslo, Norway; [4]Lund University, Department of Clinical Sciences, Lund, Sweden*

Background: Hand osteoarthritis (OA) pain is heterogeneous and multifactorial, involving biological, psychological and social aspects extending beyond the OA disease process. Different phenotypes may differ in prognosis and treatments requirements, and thus be of clinical importance. The presence of hand OA phenotypes has not previously been examined.

Objectives: To explore classes based on a biopsychosocial framework as possible phenotypes in a hand OA population, and examine whether pain severity differ between the classes.

Methods: Biological, psychological, and social domains were assessed including self-reported questionnaires, clinical assessment and imaging in 300 persons with hand OA. Central pain sensitization was tested by pressure pain thresholds (PPT; kg/cm^2) and temporal summation (TS). Variables used for comparison across the classes included age, sex, hand and overall bodily pain severity (Numeric Rating Scales (NRS) last 24h (0-10)). We used Latent Class Analysis followed by posterior fit statistics. Differences in age, sex and pain between classes were assessed by one-way ANOVAs and chi-squared tests.

Results: We identified 4 classes (Table 1): Class 1 had the lowest hand OA severity, high levels of pain sensitization, comorbidities, sleep problems, psychological distress and the lowest frequencies of working participants. Class 2 had the lowest pain sensitization levels and the highest proportion of participants with university education and living with a partner. Class 3 had the highest level of hand OA severity, and the lowest levels of comorbidity burden and psychological distress. Class 4 was similar to class 1 with high levels of pain sensitization, comorbidities and sleep problems and fewer with university education. Compared with class 1 they had less psychological distress and more severe hand OA.

Table 1.

	Class 1: n=25 (8%)	Class 2: n=53 (18%)	Class 3: n=103 (34%)	Class 4: n=119 (40%)	P-value
Biological domain					
OA severity	22.2 (15.8)	28.4 (15.6)	33.6 (20.1)	29.7 (20.0)	0.05
(Kellgren-Lawrence; 0-128)					
PPT tibialis anterior	3.9 (1.8)	9.4 (1.9)	5.6 (1.9)	4.2 (1.6)	< 0.001
PPT trapezius	2.8 (0.9)	7.2 (1.8)	4.5 (1.4)	3.4 (1.5)	< 0.001
TS change	2.6 (1.7)	0.8 (1.0)	1.4 (1.5)	1.9 (1.6)	< 0.001
BMI	28.4 (5.2)	25.7 (4.5)	24.9 (3.6)	27.9 (5.6)	< 0.001
Comorbidity burden (0-45)	10.7 (4.7)	7.2 (3.5)	4.9 (2.9)	9.8 (3.9)	< 0.001
Poor sleep, n (%)	24 (96%)	30 (57%)	57 (55%)	112 (94%)	< 0.001
Psychological domain					
HADS (0-42)	20.9 (5.9)	5.1 (4.4)	4.6 (4.2)	8.0 (4.5)	< 0.001
ASES (10-100)	47.7 (13.6)	73.8 (9.5)	76.6 (12.7)	63.6 (10.1)	< 0.001
PCS (0-52)	23.5 (8.3)	9.6 (7.0)	6.3 (5.3)	12.9 (7.1)	< 0.001
Social domain					
University education, n (%)	13 (52%)	40 (77%)	72 (70%)	48 (41%)	0.01
Working, n (%)	8 (32%)	38 (72%)	68 (66%)	45 (38%)	< 0.001
Living with partner, n (%)	16 (64%)	34 (71%)	70 (61%)	76 (64%)	0.03

SD=standard deviation; BMI= Body Mass Index; HADS=Hospital Anxiety and Depression Scale; PCS=Pain Catastrophizing Scale; ASES=Arthritis Self Efficacy Scale.

Hand and overall pain severity differed significantly between the classes. Class 3 reported the lowest mean (SD) NRS hand and overall pain (2.7 (1.8) and 2.8 (1.7), p=0.01). The highest mean (SD) for NRS hand and overall pain (5.8 (2.7) and 5.8 (2.4), p=0.05) where reported by Class 1, which also had the lowest mean age of 56.9 (SD 6.5), p< 0.001. Class 2 held the highest proportion of men (n=15; 29%), although not significantly different from the other classes.

Conclusion: Four potential hand OA phenotypes that differed in hand and overall pain severity were identified. The phenotypes with higher levels of pain sensitization, comorbidities, psychological and social burden tended to have more severe hand pain than persons with lower levels. The phenotypes with lowest hand OA severity reported the highest pain severity which may reflect the discordance between OA severity and pain experience. Biopsychosocial factors are likely important in defining hand OA phenotypes and may present a possibility for improved clinical outcomes.

Biopsychosocial characteristics across the proposed hand OA phenotypes. Data presented as mean (SD) unless otherwise indicated.

POS0175

ASSOCIATIONS BETWEEN CHRONIC WIDESPREAD PAIN, PRESSURE PAIN THRESHOLDS AND LEPTIN IN INDIVIDUALS WITH KNEE PAIN

M. Andersson[1,2], E. Thoren[1], C. Sylwander[1,3], S. Bergman[1,4]. [1]*Spenshult Reserach and Development Center,., Halmstad, Sweden;* [2]*Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden;* [3]*Halmstad University, School of Health and Welfare, Halmstad, Sweden;* [4]*University of Gothenburg, The Sahlgrenska Academy, Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden*

Background: Previous studies have reported associations between obesity, chronic pain and increased pain sensitivity. The adipokine leptin has been suggested to be involved in the osteoarthritis process as well as in pain sensitisation.
Objectives: The aim was to study associations between chronic widespread pain, pain sensitivity and leptin in individuals with knee pain.
Methods: In all, 306 individuals with knee pain were included in the Halland osteoarthritis cohort, ClinicalTrials.gov NCT04928170. Of those, 265 were included in this cross-sectional baseline study. The mean age (sd) was 51.6 (8.8) years, and 71% was women. The participants marked their painful areas on a pain figure with 18 predefined areas. They were categorised in three different pain groups according to the modified WP2019 definition (1), with knees excluded (due to highest goodness of fit): Chronic widespread pain (CWP), chronic regional pain (ChRP) if CWP was not met, and no chronic pain (NCP). The group with CWP were compared with those reporting no CWP (ChRP and NCP). The pressure pain thresholds (PPT) were measured using a computerised pressure algometry (AlgoMed, Medoc) on eight predefined tender points (trapezius (bilateral), right second rib, right lateral epicondyle, knees, gluteal (bilateral)) (2). Increased pain sensitivity was defined as having PPT in the lowest third in all tender points. Obesity was measured via waistline measurement and a bioimpedance (InBody 770) measuring BMI and visceral fat area (VFA). Serum-Leptin were analysed with an ELISA method (Alpco). Knee Injury and Osteoarthritis Outcome Score (KOOS) was used to describe the groups.
Results: In this baseline study, 16% reported CWP, and 15% had low pain pressure thresholds at baseline in the study. Those fulfilling CWP were more often women, had higher BMI, VFA, and increased leptin levels and worse KOOS in four of five subscores, see Table 1A. The age and gender-adjusted leptin levels were 21.6 ng/ml (95% CI 18.2-25.0) in the group with no CWP vs. 35.5 ng/ml (95% CI 27.6-43.4) in the CWP group, p=0.002. In a logistic regression adjusting for age and gender, leptin was associated with reporting CWP OR 1.015 (95% CI 1.004-1.027, p= 0.008). The participants with low PPT were younger and had a mean (sd) leptin 31.8 ng/ml (31.6) vs 23.0 (26.0), p=0.061 in the group not having low PPT, Table 1B. In a logistic regression adjusting for age and gender, leptin was associated with low PPT OR 1.016 (95% CI 1.004-1.029, p= 0.012).
Conclusion: The pathophysiological mechanism causing widespread pain is probably multifactorial, involving both biological and physical factors. The adipokine leptin could be involved in some of these mechanisms, but longitudinal studies are needed to be able to study causal relationships.

A COMPARISON OF ULTRASOUND-DETECTED PATHOLOGIES IN PERSONS WITH AND WITHOUT KNEE OSTEOARTHRITIS AND THE ASSOCIATIONS WITH PAIN

C. Dekkerhus[1,2], A. Mathiessen[1,2], C. Fjellstad[1], B. Slatwkosky-Christensen[1], H. B. Hammer[1,2], I. K. Haugen[1,2]. [1]*Diakonhjemmet Hospital, Rheumatology, Oslo, Norway;* [2]*University of Oslo, Faculty of Medicine, Oslo, Norway*

Background: Ultrasound can evaluate osteophytes and synovitis in persons with knee OA. However, albeit the literature demonstrates a positive association between knee pain and synovitis, the instruments used to report pain, the number of patients included, the strengths of associations and the overall quality of the studies varies greatly (1).
Objectives: 1) To compare the degree of OA changes by ultrasound among people with and without clinical knee OA according to established classification criteria. 2) Study the associations between ultrasound findings and pain.
Methods: We included 286 of 300 participants from the NOR-HAND study, a hospital-based observational cohort after excluding participants with knee prostheses or arthrodesis.
The participants reported the levels of knee/hip pain using the Western/Ontario McMaster University index (WOMAC) and marked their painful joints (including the bilateral knees) during the last 24 hours and last 6 weeks on two separate homunculi. An experienced rheumatologist (BSC) examined whether the participants fulfilled the clinical ACR criteria for knee OA or not (n=7 missing).
A trained medical student performed the ultrasound examination of the knees using a General Electric (GE) Logic E9 ultrasound machine with a 6-15Mz probe. Both knees were scored for 1) osteophytes in the medial and lateral tibia and femur on 0-3 semi-quantitative scales (0=no, 1=small, 2=medium, and 3=large), and 2) grey-scale synovitis on 0-3 semi-quantitative scales (0=no, 1=mild, 2=moderate, and 3=severe pathology). The highest score of osteophytes and grey-scale synovitis (range: 0-3) and the sum scores of both knees together (range: 0-24 for osteophytes and 0-6 for synovitis) were calculated.
We compared the degree of ultrasound pathologies in persons with vs. without clinical knee OA using Chi square tests and Mann-Whitney U test or T test as appropriate. The associations between ultrasound pathologies and pain scores were explored by logistic regression analyses, adjusted for age, sex and BMI. Generalized Estimating Equations were applied to account for two knees belonging to the same person.
Results: Knee osteophytes, but not grey-scale synovitis, were more common in persons with vs. without clinical knee OA (median sum score of osteophytes: 2 vs. 0, p<0.001) and were associated with higher levels of WOMAC pain (beta=0.18, 95% confidence interval (CI) 0.03-0.32). The same association to WOMAC pain was not found for synovitis (beta=0.03, 95% CI -0.33-0.40). However, in analyses on joint level, both osteophytes and synovitis were associated with pain in the same joint in both a short (24 hours) and longer term (6 weeks), with stronger associations for more severe ultrasound scores (Table 1).

Table 1. Associations between ultrasound pathologies and a) WOMAC pain and b) joint pain in the same joint previous 24 hours and c) previous 6 weeks, adjusted for age, sex and BMI.

	a) WOMAC pain both knees Beta (95%CI)	b) OR (95% CI) of pain in the same knee joint previous 24 hours	c) OR (95% CI) of pain in the same knee joint previous 6 weeks

-Grade 0	0.0 (ref)	1.00 (ref.)	1.00 (ref.)
-Grade 1	0.24 (-0.99, 1.47)	1.00 (0.66, 1.53)	0.95 (0.61, 1.47)
-Grade 2	0.27 (-1.33, 1.87)	1.67 (0.96, 2.91)	1.32 (0.78, 2.25)
-Grade 3	0.46 (-1.73, 2.65)	6.63 (2.26, 19.43)	4.32 (1.59, 11.71)

Conclusion: Both osteophytes and grey-scale synovitis were associated with pain in the same joint, supporting the validity of ultrasound in knee OA. Grey-scale synovitis was commonly present in people not fulfilling the ACR criteria for clinical knee OA and seems to be less specific for clinical knee OA than osteophytes.

POS0177

HETEROGENOUS CARTILAGE DAMAGE SEEN ON MRI AMONG KNEES WITH KELLGREN-LAWRENCE 2 & 3 OSTEOARTHRITIS: WHAT ARE THE IMPLICATIONS FOR CLINICAL TRIALS?

M. Jarraya[1], F. Roemer[2], E. Ashbeck[3], J. Lynch[4], C. K. Kwoh[3], A. Guermazi[5].
[1]Massachusetts General Hospital, Radiology, Boston, United States of America; [2]University of Erlangen-Nuremberg, Radiology, Erlangen, Germany; [3]University of Arizona College of Medicine, Arthritis and Musculoskeletal Population Health Program, Tuscon, United States of America; [4]UCSF, Epidemiology and Biostatistics, San Francisco, United States of America; [5]VA Boston Healthcare, Radiology, Boston, United States of America

Background: The most recent update of the Global Burden of Disease figures (GBD 2013) estimated that 242 million people were living in the world with symptomatic and activity-limiting OA of the hip and/or knee. Many potential disease-modifying osteoarthritis drugs (DMOADs) have been investigated, but to date no DMOADs that slow or stop disease progression have been approved by the Food and Drug Administration (FDA) or the European Medicines Agency (EMA). A potential reason for the lack of demonstrated efficacy may be reliance on radiographs for defining structural inclusion and exclusion criteria for clinical trials, such as use of joint space width and Kellgren-Lawrence (KL) grade as surrogates for cartilage damage.

Table 1.

Cartilage damage seen on 3T MRI, by Kellgren-Lawrence grade

Knee MRI Findlings	Kellgren-Lawrence Grade			
	KL2 (n=2,318)		KL3 (n=1,128)	
	Percent	(95%CI)	Percent	(95%CI)
Medial TFJ				
Normal	52.4	(50.1, 54.6)	14.4	(12.2, 16.6)

PT: Partial-thickness, FT: Full-thickness, TFJ: Tibiofemoral Joint, PFJ: Patellofemoral Joint

Objectives: To estimate the distribution of cartilage damage seen on knee MRI in a sample of knees with radiographic KL 2 and 3 OA that would potentially qualify for a DMOAD trial.
Methods: We selected knees from the Osteoarthritis Initiative (OAI), a longitudinal cohort study of knees with or at risk of developing symptomatic radiographic OA, that met common structural inclusion criteria for DMOAD trial enrollment at OAI baseline: knees with radiographs centrally graded as KL 2 or 3 and medial minimum joint space width (mJSW) ≥ 1.5mm. A musculoskeletal radiologist with 10 years of experience in semi-quantitative MRI assessment scored knee cartilage damage in the medial and lateral tibiofemoral and patellofemoral compartments using WORMS (Whole-Organ Magnetic Resonance Imaging Score). Coronal intermediate weighted (IW) TSE and sagittal fat-suppressed IW TSE sequences on 3T MRI were used. The WORMS cartilage scores, which are based on both the extent and depth of cartilage damage, were collapsed into 4 categories: no cartilage damage (WORMS 0 and 1), focal partial or full-thickness (PT/FT) cartilage damage (WORMS 2 and 2.5), diffuse partial thickness (PT) cartilage damage (WORMS 3 and 4), and diffuse full-thickness (FT) cartilage damage (WORMS 5 and 6). We estimated the prevalence of each category of cartilage damage in KL2 and KL3 knees; 95% confidence intervals (CI) accounted for clustering at the participant-level since some participants contributed two knees to the analysis.
Results: We identified 2,372 participants contributing 3,446 knees with radiographic OA (KL 2 and 3) and medial mJSW ≥ 1.5mm. There were 2,318 KL2 knees and 1,128 KL3 knees. The distribution of cartilage damage in each compartment by KL grade is presented in Table 1. We found no cartilage damage in any compartments in 9.8% (95%CI: 8.5, 11.1) of KL2 knees and 2.0% (95%CI: 1.1, 2.9) of KL3 knees. Cartilage damage was absent in the medial tibiofemoral compartment in 52.4% (95%CI: 50.1, 54.6) of KL2 knees, and 14.4% (95%CI: 12.2, 16.6) of KL3 knees, versus 61% (95%CI: 58.8, 63.2) of KL2 knees and 53.6% (95%CI: 50.4, 56.7) of KL3 knees in the lateral compartment. When medial and lateral compartments were combined, cartilage damage was absent in 34.8% (95%CI: 32.7, 36.9) of the KL2 knees, and 4.3% (95%CI: 3.0, 5.5) of the KL3 knees. Diffuse FT cartilage lesions in the medial compartment were found in 6.1% (95%CI: 5.0, 7.1) of KL2 knees and 42.5% (95%CI: 39.4, 45.6) of KL3 knees.
Conclusion: MRI screening prior to clinical trial enrollment may identify a substantial percentage of knees with normal cartilage, as well as knees with diffuse FT cartilage lesions that may not be responsive to DMOADs, depending on the mode of action of a given pharmacological compound.

POS0178 ASSOCIATION BETWEEN KNEE MR IMAGING MARKERS AND KNEE SYMPTOMS OVER 7 YEARS IN YOUNG ADULTS

B. Antony[1], A. Venn[1], L. Blizzard[1], L. March[2], F. Cicuttini[3], F. Eckstein[4], G. Jones[1], C. Ding[1], A. Singh[1]. *[1]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; [2]University of Sydney, Institute of Bone and Joint Research, Kolling Institute of Medical Research, Sydney, Australia; [3]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia; [4]Chondrometrics GmbH, Paracelsus Medical University Salzburg, Ainring, Germany*

Background: Knee magnetic resonance imaging (MRI)-based morphological markers (quantitative biomarkers) and structural abnormalities (semi-quantitative biomarkers) are known to be associated with the progression of knee osteoarthritis (OA). However, there is conflicting evidence on the association between knee MRI-based morphological markers and knee symptoms. Besides, there is a lack of evidence on the clinical significance of MR imaging markers in the general population-based young adults. Hence, our aim was to investigate the associations between MR imaging biomarkers and knee symptoms in middle-aged adults followed over seven years.
Objectives: To describe the associations of cartilage volume, cartilage thickness, subchondral bone area, cartilage defects, and bone marrow lesions (BML) with knee symptoms in young adults followed up over 6-9 years.
Methods: Knee symptoms (pain, stiffness, and dysfunction) were assessed using the Western Ontario and McMaster University Osteoarthritis Index (WOMAC) scale during Childhood Determinants of Adult Health (CDAH)-knee study at baseline (year: 2008-10, age: 30–40 years) and 6-9 year follow-up (CDAH-3; year: 2014–2019, age: 36–49 years). Knee MRI scans were obtained at baseline and were assessed quantitatively for morphological markers such as cartilage volume, cartilage thickness, subchondral bone area using semi-automated segmentation (Chondrometrics, Germany). Cartilage defects and BMLs were assessed using semi-quantitative scoring systems. Univariable and multivariable (adjusted for age, sex, and body mass index (BMI)) zero-inflated Poisson (ZIP) regression model with random effects were used to describe the cross-sectional and longitudinal associations.
Results: The prevalence of knee pain at baseline (mean age (SD): 34 (2.7); female 49%) was 34% that increased to 50% over 6-9 year follow-up (mean age (SD): 43 (3.2)). Cross sectionally, there was a weak but statistically significant negative association between medial femorotibial compartment (MFTC) [Ratio of Mean (RoM)= 0.99971084; 95% CI: (0.9995525, 0.99986921; p<0.001], lateral femorotibial compartment (LFTC) [RoM=0.99982602; 95% CI: 0.99969915, 0.9999529; p=0.007], and patellar cartilage volume [RoM=0.99981722; 95% CI: 0.99965326, 0.9999811; p=0.029] with knee symptoms.
Similarly, there was a negative association between patellar cartilage volume (RoM=0.99975523; 95% CI: 0.99961427, 0.99989621; p=0.014), MFTC cartilage thickness (RoM= 0.72090775; 95% CI: 0.59481806, 0.87372596; p=0.001) and knee symptoms assessed after seven years.
The total bone area was consistently and negatively associated with knee symptoms at baseline [RoM= 0.9210485; 95%CI: 0.8939677, 0.9489496; p<0.001] and over seven years (RoM=0.9588811; 95% CI: 0.9313379, 0.9872388; p=0.005). Presence of any cartilage defect or BML was associated with higher knee symptoms at baseline and after seven years.
Conclusion: In the middle-aged adult population, BML and cartilage defects were positively associated with knee symptoms, whereas cartilage volume and thickness at MFTC and total bone area were weakly and negatively associated with knee symptoms. These results suggest that the quantitative and semi-quantitative MR imaging biomarkers can be explored as a marker of the clinical progression of OA in a young adult population.

POS0179 IMPLICATIONS OF BRAIN ACTIVITY IN THE TREATMENT DECISION OF KNEE OSTEOARTHRITIS

F. Ojeda[1,2], L. Tío[2], G. Martinez-Vilavella[3], J. Pujol[3,4], L. Blanco-Hinojo[3,4], J. Deus[3,5], J. C. Monllau[2,6], J. Monfort[1,2]on behalf of HOLOA group. *[1]Hospital del Mar, Rheumatology, Barcelona, Spain; [2]Municipal Institute of Medical Research, Grup de Recerca Cel·Lular en Inflamació i Cartílag., Barcelona, Spain; [3]Hospital del Mar, MRI Research Unit, Department of Radiology, Barcelona, Spain; [4]Hospital del Mar, Centro Investigación Biomédica en Red de Salud Mental, CIBERSAM G21, Barcelona, Spain; [5]Autonomous University of Barcelona, Department of Clinical and Health Psychology, Barcelona, Spain; [6]Hospital del Mar, Orthopaedic Department, BARCELONA, Spain*

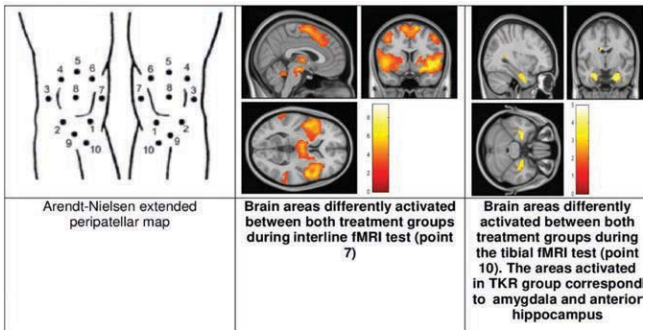
Background: Chronic pain related to knee osteoarthritis (KOA) is a common health problem and functional magnetic resonance imaging (fMRI) is a useful technique which can determine different brain activation (1).
Objectives: The main purpose of our study was to observe whether there is different risk to central sensitization and different brain activation in patients with KOA according to the treatment followed (conservative (CNV) Vs. total knee replacement (TKR))
Methods: Patients diagnosed of primary KOA following a CNV treatment or undergoing TKR were recruited. The two groups were matched by age, sex and BMI. Clinical central sensitization was considered if patients presented spread tenderness, evaluated with an algometer, in more than 1 site of the extended peripatellar map (2) (notice that pain at points 3, 7 and 8 were not counted) fMRI testing involved pressure painful stimulation to the articular interline and to a commonly sensitized site (tibial surface, point 10).To evaluate the associations between central sensitization and the risk to undergo a TKR; logistic regression was performed to estimate OR and 95% confidence intervals (95%CI). Models were adjusted by sex, age and BMI (R (R v.3.5.2).Whole-brain activation maps were compared between groups using Statistical Parametric Mapping software (SPM12 http://www.fil.ion.ucl.ac.uk/spm).
Results: Women have a significant higher risk to present central sensitization than men (OD 12,11 (95% CI 4,32-33,95) p-value:$2,09*10^6$), but no differences were observed between CNV and TKR group (OR TKR 0,69 (95% CI 0,24-1,98)) (Table 1). The differences observed in brain activation between the treatment groups in the interline fMRI test (point 7) did not correspond to any specific brain

area. However, TKR group showed a higher activation that implicated the region of the amygdala and anterior hippocampus during the tibial fMRI test (point 10).

Table 1. Central sensitization Odds Ratio (OR) with 95% Confidence Interval (95%CI)

	O.R. (95% CI)	p-value
Treatment	0.69 (0.24- 1.98)	0,494
Sex	12.11 (4.32- 33.95)	$2{,}09*10^{-6}$
Age	0.72 (0.26- 1.97)	0,525
BMI	1.88 (0.69- 5.17)	0,219

Conclusion: Presenting central sensitization is not a risk for KOA patients to undergo a TKR, but the mechanism underlaying sensitization in both treatment groups might be different, with amygdala playing an important role in TKR patients. The amygdala is an important element of the brain systems that both express emotions and modulate pain. The activation of the amygdala in response to pressure stimulation on a sensitized knee site is interpreted as a failure of the descending pain inhibitory systems, and the occurrence of a major emotional response during the painful experience in patients that ultimately received TKR.



Arendt-Nielsen extended peripatellar map

Brain areas differently activated between both treatment groups during interline fMRI test (point 7)

Brain areas differently activated between both treatment groups during the tibial fMRI test (point 10). The areas activated in TKR group correspond to amygdala and anterior hippocampus

POS0180

THE EFFICACY AND SAFETY OF A FIXED-DOSE COMBINATION OF APOCYNIN AND PAEONOL IN SYMPTOMATIC KNEE OA: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED CLINICAL TRIAL

A. R. Bihlet[1], I. Byrjalsen[2], J. R. Andersen[1], A. Metnik[3], A. Reynolds[4], N. Larkins[4], P. Alexandersen[5], H. Rovsing[6], U. Schmidt[7], R. Moots[8,9], P. G. Conaghan[10,11]. *[1]NBCD A/S, Clinical Science, Herlev, Denmark; [2]NBCD A/S, Biostatistics, Herlev, Denmark; [3]NBCD A/S, Clin Ops, Herlev, Denmark; [4]AKL Research and Development Ltd., Clinical Science, Stevenage, United Kingdom; [5]Sanos Clinic A/S, Vejle, Vejle, Denmark; [6]Sanos Clinic A/S, Gandrup, Gandrup, Denmark; [7]Sanos Clinic A/S, Herlev, Herlev, Denmark; [8]Aintree Hospital, Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom; [9]Edge Hill University, Faculty of Health, Care and Medicine, Ormskirk, United Kingdom; [10]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [11]NIHR Leeds, Biomedical Research Centre, Leeds, United Kingdom*

Background: There is a great unmet need for the development of effective treatments to treat the symptoms of OA. Nuclear-Factor Kappa-B (NF-κB) and Nrf2 play a key roles in OA pathogenesis and have been identified as potential targets. A fixed-dose combination of apocynin and paenol in a ratio of 2:7 (APPA) has been shown to inhibit activation of NF-κB and upregulate Nrf2. [1]

Objectives: We report the results of a phase 2a study evaluating the efficacy and safety of APPA in patients with symptomatic knee OA.

Methods: The trial was a 28-day randomized, placebo-controlled, double-blind study comparing 800 mg of APPA twice daily with matched placebo capsules. Patients with radiographic knee OA KL-grade 2-3, and a WOMAC pain score ≥40 and ≤90/100 of target knee at screening and baseline were randomized 1:1 to APPA or placebo. Main exclusion criteria included recent intraarticular surgery or injection therapy, hip pain greater than the target knee, and BMI ≥40 kg/m^2. The primary endpoint was change from baseline to Day 28 in the WOMAC pain score. Safety outcomes included reported adverse events (AE), clinical laboratory parameters, ECG, and vital signs.

A pre-defined subgroup analysis in subjects with a baseline PainDETECT score >12 indicated a positive effect. Accordingly, post-hoc analyses were undertaken to further assess the effects of APPA in subgroups of participants with higher disease severity.

Results: 152 participants were randomized, and 149 (98%) completed the trial. The mean (SD) WOMAC pain score at baseline was 55.3 (10.2). The two groups were comparable in terms of baseline pain score, gender, age, and BMI.

The primary endpoint was not met, mean difference (MD) between APPA and placebo was -0.89 (95 % CI: -5.62, 3.84, p=0.71, Figure 1A). Similarly, no significant differences were found on other key secondary endpoints (WOMAC Function and WOMAC total Figure 1B and C, respectively.) APPA was well tolerated and no differences in frequencies of reported AEs were noted, apart from a higher proportion of subjects reporting mild to moderate gastrointestinal discomfort reported with APPA compared to placebo (12% vs. 6.5 %).

In the pre-defined subgroup of participants with baseline PainDETECT ≥ 13 (N=45), the difference in mean change in pain from baseline favored the APPA-group (MD: -11.20, 95 % CI: -20.29 to -2.11, p=0.02). Analysis of participants > 50 WOMAC pain at baseline (Group 1, N=95, Figure 1D), and a KL-grade of the non-target knee >2 (Group 2, N=105, Figure 1E), and a combination of these two criteria (Group 3, N=64, Figure 1F) found a positive effect of APPA compared to placebo (Group 1 MD: -2.61, 95 % CI: -8.98 to 3.76, p=0.42, Group 2 MD: -4.01, 95 % CI: -9.35 to 1.33, p=0.14, and Group 3 MD: -8.32, 95 % CI: -15.48 to -1.16, p=0.02).

Conclusion: Treatment with APPA 800 mg twice daily for 28 days in patients with symptomatic knee OA overall was not associated with significantly improved outcomes compared to placebo. The treatment was well-tolerated and safe. Subgroup analyses, however, showed a significant effect of APPA in patients with moderate to severe OA, indicating that further research in the effects of APPA in appropriate patients is warranted.

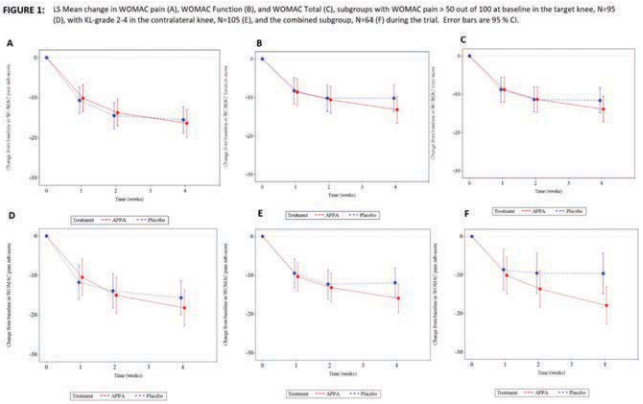

FIGURE 1: LS Mean change in WOMAC pain (A), WOMAC Function (B), and WOMAC Total (C), subgroups with WOMAC pain > 50 out of 100 at baseline in the target knee, N=95 (D), with KL-grade 2-4 in the contralateral knee, N=105 (E), and the combined subgroup, N=64 (F) during the trial. Error bars are 95 % CI.

POS0181

EFFECT OF A MULTIDISCIPLINARY LIFESTYLE PROGRAM ON PATIENTS WITH METABOLIC SYNDROME-ASSOCIATED OSTEOARTHRITIS: THE PLANTS FOR JOINTS RANDOMIZED CONTROLLED TRIAL

W. Walrabenstein[1,2], C. Wagenaar[1,2], M. Van der Leeden[1,3,4], M. Gerritsen[1], M. Van der Esch[1,5], D. Van Schaardenburg[1,3]. *[1]Reade, Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; [2]Amsterdam UMC, University of Amsterdam, Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; [3]Amsterdam UMC, Vrije Universiteit, Department of Rehabilitation Medicine, Amsterdam, Netherlands; [4]Vrije Universiteit Amsterdam, Amsterdam Movement Sciences Research Institute, Amsterdam, Netherlands; [5]Amsterdam University of Applied Sciences, Faculty of Health, Amsterdam, Netherlands*

Background: Metabolic syndrome with low grade inflammation is associated with chronic diseases including osteoarthritis (OA) (1). Nonpharmacological treatment with a combination of an intensive diet and exercise produced better results in people with osteoarthritis (OA) than either treatment alone (2). We further developed the concept of an integrated lifestyle intervention in people with metabolic syndrome-associated osteoarthritis (MSOA) by combining a whole food plant-based diet with physical activity and stress management.

Objectives: To determine the effect of a multidisciplinary lifestyle program on pain, stiffness, and physical function in patients with MSOA.

Methods: In the "Plants for Joints" (PFJ) parallel-arm, randomized clinical trial, patients with MSOA were assigned to the PFJ group or the control group. Patients with metabolic syndrome (according to NCEP criteria) and OA in the knee and/or hip (according to clinical ACR criteria) were eligible for participation. The PFJ group followed a 16-week lifestyle program based on a whole food plant-based diet, physical activity, and stress management in addition to usual care. The control group received usual care.

Prior to the start of the study, it was hypothesized that the lifestyle program would lower pain and stiffness and improve physical function, based on the Western Ontario and McMaster Universities Arthritis Index (WOMAC) score (primary outcome). Secondary outcomes included anthropometric, and metabolic markers. Patient partners selected the patient-reported outcome measures (PROMIS©) depression, fatigue, pain interference and physical function as additional secondary outcomes.

An intention-to-treat analysis with a linear mixed model, adjusted for baseline values (and age, sex, and body mass index [BMI] in additional analyses), was used to analyze the between-group differences of continuous outcomes.

Results: Of the 92 people screened, 66 were randomized and 64 completed the study (PFJ group: n = 32). Participants were 84% female, had a mean (SD) age of 63 (6) and a mean (SD) BMI of 33 (5) kg/m^2. After 16 weeks the PFJ group had a mean 11-point greater improvement of the total WOMAC score (range 0-96) over time (95% CI 6 to 16; p = 0.0001) with significant improvements in all three components pain, stiffness, and physical function compared to the control group (Figure 1). Also, compared to the control group, the PFJ group lost more body weight (–3.9 kg, 95% CI –5.8 to –2.0; p < 0.001), fat mass as measured with dual-energy x-ray absorptiometry (–3.9 kg, 95% CI –5.3 to –2.5; p < 0.0001) and waist circumference (–4 cm, 95% CI –7 to –1; p = 0.01). HbA1c and fasting glucose improved in the PFJ versus control group, but not significantly. LDL decreased by 0.38 mmol/l (95% CI 0.07 to 0.69; p = 0.02) and triglycerides by 0.32 (95% CI 0.01 to 0.63; p = 0.04) in favour of the PFJ group. HDL and blood pressure remained unchanged. Of the patient reported outcome measures (PROMIS©) only fatigue showed a significant improvement. Based on a baseline mean (SD) value of 55 for all the participants, fatigue improved with 4 (95% CI 1 to 6; p = 0.03) in the PFJ group when compared with the control group. Additional analyses adjusted for age, sex, and BMI did not lead to different outcomes.

No serious adverse events occurred.

Conclusion: The 16-week "Plants for Joints" lifestyle program substantially decreased pain and stiffness and improved physical function in people with metabolic syndrome associated osteoarthritis of hip and/or knee. In addition, following the lifestyle program resulted in lower weight, fat mass and smaller waist circumference in comparison with usual care.

POS0182

WHO ARE LIKELY TO BENEFIT FROM THE GOOD LIFE WITH OSTEOARTHRITIS IN DENMARK (GLAD) EXERCISE AND EDUCATION PROGRAM? AN EFFECT MODIFIER ANALYSIS OF A RANDOMISED CONTROLLED TRIAL

M. Henriksen[1], S. M. Nielsen[1], R. Christensen[1], L. E. Kristensen[1], H. Bliddal[1], C. R. Bartholdy[1], M. Boesen[1], D. Hunter[2], R. Altman[3], E. Bandak[1]. *[1]Bispebjerg-Frederiksberg Hospital, The Parker Institute, Copenhagen, Denmark; [2]The University of Sydney, Institute of Bone and Joint Research, Sydney, Australia; [3]UCLA, Ronald Reagan Medical Center, Los Angeles, United States of America*

Background: EULAR clinical guidelines have identified moderators of knee osteoarthritis (OA) outcomes as an important research priority to optimize individualized treatment. In our recent trial the GLAD exercise and education program was proved equivalent to open-label placebo (OLP) in 206 people with knee OA, which calls for evaluation of factors that may predict differential treatment response to GLAD versus OLP.

Objectives: To identify contextual factors that might modify the treatment effect of the '*Good Life with osteoArthritis in Denmark*' (GLAD) exercise and education programme on knee osteoarthritis (OA) pain compared to that of open-label placebo (OLP) in individuals with knee OA, i.e. explore who are likely to benefit from participating in exercise and education programs.

Methods: Secondary effect modifier analysis of a randomised controlled trial, in which 206 adults aged ≥ 50 years, with symptomatic and radiographic knee OA were randomised to either an 8-week exercise and education programme (GLAD; n=102) or OLP in the form of 4 intra-articular saline injections over 8 weeks (n=104). Primary outcome was change from baseline to week 9 in the Knee injury and Osteoarthritis Outcome Score questionnaire (KOOS) pain subscale (range 0 (worst) to 100 (best)). Subgroups were created based on baseline information: BMI, swollen study knee, bilateral radiographic knee OA, sports participation as a young adult, sex, median age, *a priori* treatment preference, regular use of analgesics (NSAIDs or paracetamol), radiographic disease severity, and presence of constant and intermittent pain using the Intermittent and Constant Osteoarthritis Pain questionnaire. Analyses were based on the intention-to-treat principle with simple conservative non-responder imputation of missing outcome data.

Results: Participants who at baseline reported use of analgesics at baseline seem to benefit from the GLAD programme over OLP (subgroup contrast: 10.3 KOOS pain points (95% CI 3.0 to 17.6)). Further, participants with constant pain at baseline also seem to benefit from GLAD over OLP (subgroup contrast: 10.0 KOOS pain points (95%CI 2.8 to 17.2; P=0.007)). Further, *a priori* preference for GLAD also seemed to predict treatment effect in favour of GLAD. Presence of

intermittent pain predicted beneficial effects of OLP, albeit the precision of the estimate was low. See Figure 1.

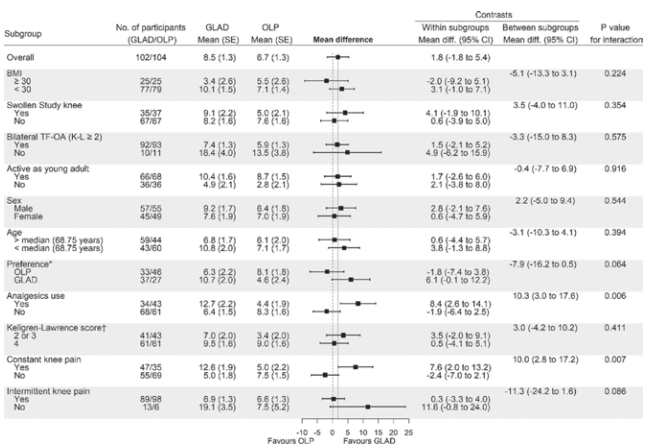

Figure 1. Forest plot showing the results of the subgroup analyses based on the intention-to-treat population with missing outcome data at week 9 replaced with the baseline observation (non-responder imputation). The outcome is change from baseline in KOOS pain at week 9 (after 8 weeks of intervention). GLAD: The Good Life with osteoArthritis in Denmark exercise and education programme. OLP: Open-label placebo consisting of 4 intra-articular saline injections. K-L: Kellgren-Lawrence grading of radiographic disease severity.The full vertical line indicates the overall treatment effect, and the dashed line indicates zero effect. *24 GLAD and 26 OLP had no preference and are not included in the analyses, and 8 GLAD and 5 OLP had missing data; †For study knee.

Conclusion: These results imply that GLAD should not be considered as a one-size-fits-all intervention. For patients who take analgesics for their knee pain or report constant knee pain, GLAD seems to yield clinically relevant benefits when compared to an open-label placebo. The results support a stratified recommendation of GLAD as management of knee OA.

THE EFFECT OF BELIMUMAB ON SRI-4 RESPONSE IN MULTIPLE SUBGROUPS OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A LARGE INTEGRATED ANALYSIS

M. A. Petri[1], G. Bertsias[2], M. Daniels[3], N. L. Fox[4], B. H. Hahn[5], A. Hammer[6], J. Harris[7], H. Quasny[8], C. Tani[9], A. Askanase[10]. Background: Belimumab (BEL) is approved for the treatment of active autoantibody-positive systemic lupus erythematosus (SLE).[1] Four Phase 3 studies have consistently demonstrated greater SLE Responder Index (SRI) response rates with BEL vs placebo (PBO).[2-5] This robust dataset allows for additional exploration of the onset of efficacy of BEL and response rates by patient (pt) characteristics.
Objectives: To perform a *post hoc* analysis evaluating the effect of BEL on SRI-4 response across a large, pooled population and pt subgroups.
Methods: The Belimumab Summary of Lupus Efficacy (Be-SLE) integrated analysis evaluated data from adults with SLE from 5 double-blind, PBO-controlled BEL trials: BLISS-76, BLISS-52, BLISS-NEA, BLISS-SC, and EMBRACE.[2-6] Pts were randomised to BEL (monthly intravenous 10 mg/kg or weekly subcutaneous 200 mg) or PBO, plus standard therapy. Data were collected every 4 weeks (wks) from baseline (BL) to Wk 52. The SRI-4 response rate (a composite measure that includes ≥4-point reduction in Safety of Estrogens in Lupus Erythematosus National Assessment - SLE Disease Activity Index [SELENA-SLEDAI] score, stable Physician Global Assessment [PGA] increase of <0.3, and no new British Isles Lupus Assessment Group [BILAG] 1A/2B organ domain scores) by visit and time to first SRI-4 response maintained through Wk 52 were determined for both treatment groups. SRI-4 response rates at Wk 52 were evaluated by BL characteristic subgroups: SELENA-SLEDAI score; SLE International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) score; disease duration; biomarker levels (anti-dsDNA, complement [C]3/C4); glucocorticoid (GC), immunosuppressant (IS), and antimalarial (AM) use.
Results: Overall, 3086 pts were included (BEL, n=1869; PBO, n=1217). Most were female (94.4%); mean (standard deviation [SD]) age was 37.0 (11.6) years. Mean (SD) SLE duration was 6.4 (6.4) years.
At Wk 52, in the overall population, significantly more BEL vs PBO pts were SRI-4 responders (Figure 1). A significantly greater proportion of SRI-4 responders was observed with BEL vs PBO as early as Wk 8 (38.4% vs 33.3%; odds ratio, OR [95% confidence interval, CI] 1.25 [1.07, 1.46]; p=0.0060), which continued to increase to Wk 52 (54.8% vs 41.6%; OR [95% CI] 1.70 [1.46, 1.98]; p<0.0001). At Wk 52, more BEL vs PBO pts had a 4-point reduction in SELENA-SLEDAI (56.3% vs 43.1%; OR [95% CI] 1.71 [1.47, 2.00]; p<0.0001), no worsening in PGA (76.6% vs 67.9%; OR [95% CI] 1.52 [1.28, 1.79]; p<0.0001), and no new BILAG 1A/2B organ domain scores (77.1% vs 69.4%; OR [95% CI] 1.47 [1.25, 1.74]; p<0.0001). Pts on BEL were 52% more likely to experience an SRI-4 response that was maintained through Wk 52 (hazard ratio, HR [95% CI] 1.52 [1.36, 1.69]; p<0.0001).

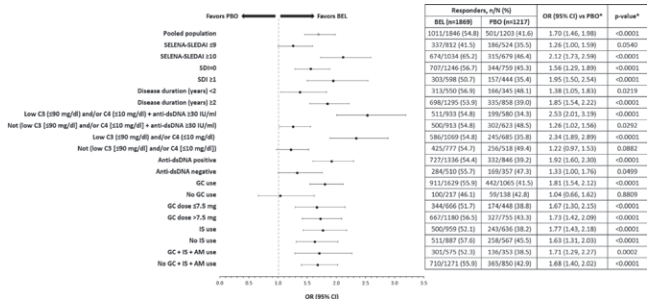

Figure 1. SRI-4 response at Wk 52 in the overall population and by BL characteristic subgroups. *OR (95% CI) and p-value are from a logistic regression model for BEL vs PBO comparison with covariates of treatment group, study and BL SELENA-SLEDAI score (≤9 vs ≥10)

SRI-4 response rates were significantly higher with BEL vs PBO in most subgroups, with the highest response rates observed in pts with SELENA-SLEDAI score of ≥10, low C3 and/or C4 + anti-dsDNA ≥30 IU/ml, and low C3 and/or C4 at BL (Figure 1).
Conclusion: Significantly more pts receiving BEL had SRI-4 response rates that occurred from Wk 8 and were maintained through Wk 52 compared with pts receiving PBO. The efficacy of BEL was consistent across multiple pt subgroups, with higher response rates in pts with SELENA-SLEDAI scores of ≥10, low C3 and/or C4 + anti-dsDNA ≥30 IU/ml and low C3 and/or C4 at BL. These results further substantiate the benefits of BEL in the treatment of adults with SLE.

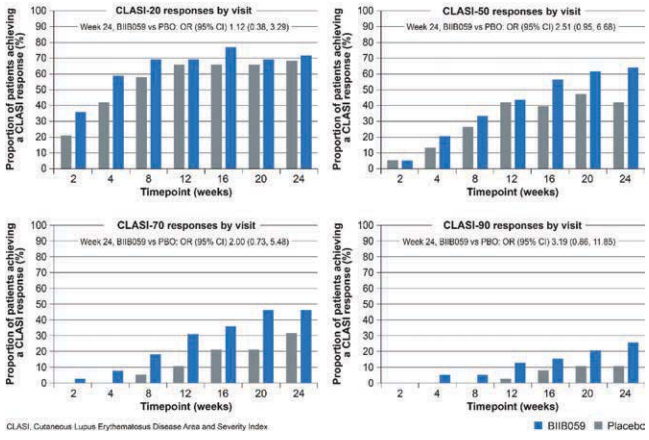
EFFICACY OF BIIB059 ON SKIN MANIFESTATIONS IN PARTICIPANTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN THE PHASE 2 LILAC STUDY (PART A)

R. van Vollenhoven[1], R. Furie[2], V. Werth[3], K. Kalunian[4], X. Huang[5], C. Musselli[6], C. Barbey[7], N. Franchimont[8]. [1]*Amsterdam University Medical*

Centers, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands; [2]Northwell Health, Division of Rheumatology, Great Neck, United States of America; [3]University of Pennsylvania and Corporal Michael J. Crescenz VAMC, Department of Dermatology, Philadelphia, United States of America; [4]University of California San Diego, Division of Rheumatology, Allergy and Immunology, La Jolla, United States of America; [5]Biogen, Biostatistics, Cambridge, United States of America; [6]Biogen, Clinical Development Immunology, Cambridge, United States of America; [7]Biogen, Multiple Sclerosis and Immunology Development Unit, Baar, Switzerland; [8]Biogen, Multiple Sclerosis and Immunology Development Unit, Cambridge, United States of America

Background: SLE is a heterogeneous disease with diverse clinical presentations, and up to 70–80% of patients develop skin manifestations.[1–3] In SLE, plasmacytoid dendritic cells (pDCs), a major source of Type I interferon (IFN), accumulate in the skin.[4] Treatment with BIIB059, a humanized monoclonal antibody targeting blood dendritic cell antigen 2 (BDCA2) that is expressed on pDCs, leads to rapid internalization of BDCA2 from the surfaces of pDCs and inhibits the production of Type I IFNs, pro-inflammatory cytokines, and chemokines.[5] Part A of the randomized, two-part, Phase 2 LILAC study (NCT02847598) enrolled participants with SLE and active skin and joint disease. The primary endpoint was met, with a greater reduction in total active joint count at Week 24 in the BIIB059 treatment group vs placebo (PBO), and more participants achieved a ≥50% improvement from baseline in Cutaneous Lupus Erythematosus Disease Area and Severity Index – Activity (CLASI-A) score with BIIB059 vs PBO.[6]
Objectives: To further evaluate the effect of BIIB059 vs PBO in reducing skin disease activity, as measured by various CLASI-A response thresholds.
Methods: Adults with an SLE diagnosis according to the revised ACR 1997 SLE classification criteria, with ≥4 tender and ≥4 swollen joints (28-joint assessment), active skin disease (as defined by the SLE Disease Activity Index 2000 [SLEDAI-2K]), and positive anti-nuclear antibodies and/or anti-double-stranded DNA antibodies, were enrolled. Participants were randomized to receive BIIB059 450 mg or PBO, administered subcutaneously every 4 weeks with an additional dose at Week 2. Improvements in skin disease were assessed in participants with baseline CLASI-A score ≥8. The proportion of participants achieving a ≥7-point reduction from baseline in CLASI-A score was assessed at Week 24, and CLASI-20, -50, -70, and -90 responses were assessed over time. Achievement of CLASI-A scores of 0–1 was also assessed at Week 24. These analyses used non-responder imputation with logistic regression, without correction for multiplicity. The proportions of participants achieving CLASI-A scores of 0–3 and with resolution of SLEDAI-2K skin rash at Week 24 were evaluated *ad hoc* in the same population. Non-responder imputation was applied to visits post treatment failure and treatment discontinuation. Improvement from baseline in British Isles Lupus Assessment Group index (BILAG-2004) A or B mucocutaneous domains was similarly assessed at Week 24. P-values were calculated based on the odds ratios (ORs) for BIIB059 compared with PBO.
Results: At Week 24, a significantly greater proportion of participants receiving BIIB059 (n=39) vs PBO (n=38) had a ≥7-point reduction in CLASI-A score from baseline to Week 24 (56.4% vs 34.2%, OR [95% confidence interval {CI}] 2.71 [1.03, 7.17], P=0.044). Numerically greater proportions of participants receiving BIIB059 vs PBO achieved CLASI-50, CLASI-70, or CLASI-90 responses (Figure 1). Similarly, the proportion of participants who achieved CLASI-A scores of 0–1 was greater in the BIIB059 group vs PBO (25.6% vs 13.2%), as was the proportion who achieved CLASI-A scores of 0–3 (48.7% vs 28.9%). A greater proportion of BIIB059- vs PBO-treated participants had resolution of SLEDAI-2K skin rash at Week 24 (28.6% vs 10.7%), with similar findings seen in the BILAG-2004 mucocutaneous domain.

Figure. Patients achieving CLASI-20, -50, -70, and -90 responses by visit



Conclusion: Numerically greater reductions in skin disease activity were consistently observed with BIIB059 treatment vs PBO in participants with SLE and active skin disease, supporting a potential benefit of BIIB059 treatment for skin manifestations in SLE.

POS0185 BELIMUMAB DISRUPTS MEMORY B-CELL TRAFFICKING IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

E. J. Arends[1], M. Zlei[2], C. M. Tipton[3], J. Cotic[4], Z. Osmani[1], F. de Bie[2], S. Kamerling[1], A. van Maurik[5], R. Dimelow[6], Y. I. Gregan[7], N. L. Fox[8], T. Rabelink[1], D. Roth[9], I. Sanz[3], J. J. M. van Dongen[2], C. van Kooten[1], Y. K. O. Teng[1]. *[1]Leiden University Medical Center, Department of Nephrology, Leiden, Netherlands; [2]Leiden University Medical Center, Department of Immunology, Leiden, Netherlands; [3]Lowance Center for Human Immunology, Emory University, Department of Medicine, Division of Rheumatology, Atlanta, United States of America; [4]GlazoSmithKline, Clinical Statistics, Brentforf, United Kingdom; [5]GlaxoSmithKline, Clinical Biomarker Group, Stevenage, United Kingdom; [6]GlaxoSmithKline, Clinical Pharmacology Modelling and Simulation, Stevenage, United Kingdom; [7]GlaxoSmithKline, Clinical Science Immunology, Collegeville, PA, United States of America; [8]GlaxoSmithKline, Clinical Development, Collegeville, PA, United States of America; [9]GlaxoSmithKline, Research and Development, Collegeville, PA, United States of America*

Background: Belimumab (BEL), a recombinant human monoclonal antibody directed against B-cell activating factor (BAFF), is the first approved biological agent for patients with active systemic lupus erythematosus (SLE) and lupus nephritis (LN).[1] BEL inhibits primary humoral immune responses by depleting naïve B cells that are dependent on BAFF for their survival while secondary humoral immune responses by memory B cells (MBCs) remain intact. Indeed, some studies reported an increase of circulating MBCs following neutralisation of BAFF.[2-4] So far, these effects of BEL on the MBC compartment in SLE patients have not been investigated.
Objectives: This study aimed to establish the dynamics of circulating MBCs in patients with SLE treated with BEL and to perform an in-depth analysis of the impact of BEL on the MBC compartment.
Methods: First, a retrospective meta-analysis was performed by pooling individual patient MBC flow cytometry data from 1245 patients with SLE treated with BEL 10 mg/kg IV or placebo (PBO) from four randomised clinical trials (NCT00071487, NCT00410384 [BLISS-76],[3] NCT01632241 [EMBRACE],[5] NCT01649765 [PLUTO][6]). Second, extensive B-cell subset phenotyping was performed prospectively by employing high-sensitivity flow cytometry (HSFC) based on EuroFlow protocols[7] in patients with active SLE (from the BLISS-BELIEVE trial [NCT03312907])[8] and with severe SLE/LN (from the SynBioSe-2 trial [NCT03747159])[9] treated with BEL. Additionally, in-depth characterisation of surging MBCs in circulation was performed by single-cell RNA sequencing (scRNA-seq).
Results: By comparing BEL-treated with PBO-treated patients with SLE, a substantial increase in circulating MBC counts was established 4 weeks after BEL initiation, gradually returning to baseline by Week 52. The increase of MBCs was most prominent in BEL-treated patients with higher SLE disease activity (SLE

Disease Activity Index >9), serologically active patients (dsDNA positive and/or low complement levels) and with younger age (below 18 years). HSFC established that the increase was non-specific and observed in a broad range of MBC subclasses peaking as early as 2 weeks after BEL initiation. Subsequent scRNA-seq analysis of the emerging MBCs revealed a non-proliferating phenotype with a prominent decrease in activation status. In these circulating MBCs, a large amount of migration and adhesion genes were downregulated suggesting that the accumulation of MBCs following BEL treatment was related to their impaired cell-cell adhesion, disrupting cell-trafficking and preventing extravasation.

Conclusion: After initiation of BEL treatment, a substantial increase of circulating MBCs was firmly established and was most notable in patients with severe, serologically active SLE/LN. The surge of circulating MBCs appeared to be associated with disrupted lymphocyte trafficking of MBCs, thereby suggesting a new potential therapeutic mechanism of BEL on MBCs in SLE. These findings have important implications to our understanding and consequent improvement of B-cell targeted treatment strategies in patients with active SLE and LN, as MBC accumulation in circulation might allow for more efficient targeting of the B-cell compartment.

POS0186 VOCLOSPORIN FOR LUPUS NEPHRITIS: RESULTS OF THE TWO-YEAR AURORA 2 CONTINUATION STUDY

A. Saxena[1], Y. K. O. Teng[2], C. Collins[3], N. England[4], H. Leher[3]. *[1]NYU Langone Hospital, Internal Medicine, New York, United States of America; [2]Leiden University Medical Center (LUMC), Internal Medicine, Leiden, Netherlands; [3]Aurinia Pharmaceuticals, Medical Affairs, Victoria, Canada; [4]Aurinia Pharmaceuticals, Clinical Development, Victoria, Canada*

Background: Voclosporin (VCS), a novel calcineurin inhibitor, was approved in the US in January 2021 for the treatment of adult patients with active lupus nephritis (LN) in combination with background immunosuppressive therapy. The Phase 3 AURORA 1 study showed that the addition of VCS to mycophenolate mofetil (MMF) and low-dose steroids in patients with LN significantly increased rates of complete renal response at 52 weeks.

Objectives: Here we report the results of the completed continuation study, AURORA 2, which assessed the long-term safety and tolerability of VCS compared to placebo in patients with LN receiving treatment for an additional 24 months following completion of the AURORA 1 study

Methods: Key inclusion criteria for the parent AURORA 1 study included a diagnosis of biopsy-proven active LN (Class III, IV, or V ± III/IV), proteinuria ≥1.5 mg/mg (≥2 mg/mg for Class V) and estimated glomerular filtration rate (eGFR) >45 mL/min/1.73 m^2. Patients who completed AURORA 1 and who elected and were eligible to enter AURORA 2 continued on the same blinded therapy as at the end of AURORA 1 (either VCS or placebo twice daily in combination with MMF and low-dose steroids). Safety and tolerability were monitored, and eGFR, serum creatinine (SCr), and urine protein creatinine ratio (UPCR) were also assessed.

Results: In total, 116 and 100 patients in the VCS and control arms enrolled in AURORA 2, with 92 (79.3%) and 73 (73.0%) patients in each respective arm receiving treatment to the end of AURORA 2. There were no unexpected safety signals in the VCS arm compared to control, with similar rates of serious adverse events reported in both arms (VCS [18.1%] vs. control [23.0%]; Table 1). Eight patients in each arm experienced serious adverse events of infection; serious coronavirus infections were observed in 2 patients in the voclosporin arm and 5 patients in the control arm. There were 4 and 2 adverse events by preferred term of renal impairment reported in the VCS and control arms, respectively, none of which were considered serious, and no reports of acute kidney injury by preferred term in either arm. There were no deaths in the VCS arm during AURORA 2; four deaths were reported in the control arm (pulmonary embolism [n=1], coronavirus infection [n=3]). Mean eGFR and SCr levels remained stable through the end of AURORA 2. The difference between the VCS and control arms in LS mean change from baseline in eGFR was 2.7 mL/min/1.73 m^2 at 4 weeks following study drug discontinuation (Figure 1). The mean reductions in UPCR observed in patients treated with VCS in AURORA 1 were maintained in AURORA 2 with no increase in UPCR noted at the follow-up visit 4 weeks after study drug discontinuation.

Table 1. Overall Summary of Adverse Events

	Control (n=100)	Voclosporin (n=116)
	n (%)	n (%)
Any AE	80 (80.0)	100 (86.2)
Renal Impairment	2 (2.0)	4 (3.4)
Acute Kidney Injury	0	0
Treatment-related AE	21 (21.0)	28 (24.1)
Serious AE	23 (23.0)	21 (18.1)
Serious Treatment-related AE	2 (2.0)	1 (0.9)
AE Leading to Study Drug Discontinuation	17 (17.0)	11 (9.5)
Death	4 (4.0)	0
Treatment-related Death	0	0

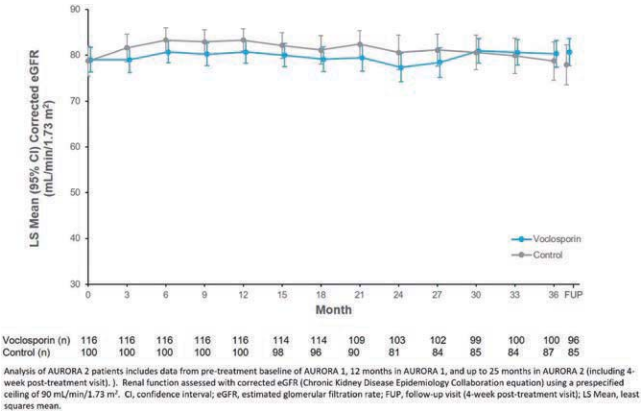

Figure 1. LS Mean eGFR over Time

Conclusion: Voclosporin was well-tolerated over 3 years of treatment with no unexpected safety signals detected. Further, eGFR remained stable throughout the study period, and the significant and meaningful reductions in proteinuria achieved in AURORA 1 were maintained. These data provide evidence of a long-term treatment benefit of VCS in patients with LN.

Includes adverse events starting on or after the first dose of study drug in AURORA 2 up to 30 days after the last dose and all events of death reported during study follow-up. Adverse events were aggregated by System Organ Class and Preferred Term and coded using Medical Dictionary for Regulatory Activities (MedDRA) Version 20.0. AE, adverse event.

Background: Lupus nephritis (LN) is one of the most severe organ manifestations of systemic lupus erythematosus (SLE) and constitutes an important cause of morbidity and death among patients with SLE [1]. The associated renal injury, and ultimately damage, is the result of an immune-mediated process which involves leukocytes, immune complexes, complement and cytokines [2].
Objectives: Lupus nephritis (LN) is one of the most severe organ manifestations of systemic lupus erythematosus (SLE) and constitutes an important cause of morbidity and death among patients with SLE [1]. The associated renal injury, and ultimately damage, is the result of an immune-mediated process which involves leukocytes, immune complexes, complement and cytokines [2].
Methods: We analysed differentially expressed genes (DEGs), pathways and their druggability via the Drug Gene Interaction database (DGIdb) [3] in active LN (n=41) versus healthy controls (HC; n=497), and eQTLs in active or past LN (n=87), based on validated (identified in two independent SLE populations) DEGs in SLE (n=350) vs HC (n=497), in whole blood collected within the frame of the European PRECISESADS consortium [4]. Genome-wide RNA-sequencing and genotyping was previously performed by Illumina assays, and serum levels of 17 cytokines and 18 autoantibodies were analysed using a Luminex assay, ELISA, IDS-iSYS and SPAPLUS analyser [4].
Results: A total of 6 869 significant and validated DEGs were identified in active LN patients compared with HC. Of these, 1010 validated DEGs were tagged to 34 KEGG pathways including 24 DEGs with a lfold change (FC)l > 1.5, genes of 18 cis-eQTLs and 3 trans-eQTLs, and 1 gene from cytokines that differed significantly between active LN and HC. Moreover, 2446 validated DEGs were tagged to 216 Reactome pathways included 85 DEGs with a lFCl > 1.5, genes of 21 cis-eQTLs and 5 trans-eQTLs, and 1 gene from cytokines that differed significantly between active LN and HC. These genes could be targeted by 203 different drugs, with the proteasome inhibitor bortezomib interfering with cathepsin B (CTSB) regulation and cyclophosphamide interfering with the regulation of tumour necrosis factor receptor superfamily member 1A (TNFRSF1A) being of particular interest.
Conclusion: Integrated multilevel omics analysis in LN revealed a set of enriched pathways of potential interest for future drug investigation. A prospect for proteasome inhibition was implicated.

Background: Involvement of the nervous system is a common but poorly understood manifestation of systemic lupus erythematosus (SLE), termed neuropsychiatric SLE (NPSLE). Although studies have reported varying prevalence estimates [1], NPSLE affects at least 20% of patients with SLE within the first years of the disease course [2]. The management of neuropsychiatric SLE (NPSLE) is poorly optimised and specific treatment is lacking.
Objectives: The aim of this study was to investigate expression quantitative trait loci (eQTLs), the transcriptome, and autoimmunity-related cytokines and autoantibodies in patients with central nervous system (CNS) lupus to gain insights into underlying genetics and biologic mechanisms towards identification of novel drug targets.
Methods: We analysed differentially expressed genes (DEGs), pathways and their druggability via the Drug Gene Interaction database (DGIdb) [3] in active CNS lupus (n=26) versus healthy controls (HC; n=497), and eQTLs in active or past CNS lupus (n=53), based on validated (identified in two independent SLE populations) DEGs in SLE (n=350) versus HC (n=497), in whole blood collected within the frame of the European PRECISESADS consortium [4]. CNS lupus was defined according to SLE Disease Activity Index 2000 (SLEDAI-2K) [5] CNS items or by CNS manifestations such as chorea, acute confusional state, transverse myelitis, aseptic meningitis, and optic neuritis in the absence of predisposing conditions unrelated to SLE. Genome-wide RNA-sequencing and genotyping was previously performed by Illumina assays, and serum levels of 17 cytokines were analysed using a Luminex assay and ELISA [4].
Results: Among 5631 significant and validated DEGs in active CNS patients compared with HC, 1922 unique DEGs were tagged to 21 and 176 significant KEGG [6] and Reactome [7] pathways, respectively. Pathways included "Interferon signalling", "TNF signalling" and "Toll-like Receptor Cascades". The pathways included 29 of 59 DEGs with a lfold change (FC)l > 1.5, 6 genes from 14 significant cis-eQTLs and 10 genes from 22 trans-eQTLs, and 2 genes from 8 cytokines that differed significantly between active CNS lupus and HC. These genes could be targeted by 496 different drugs, with the Bruton tyrosine kinase (BTK) inhibitor ibrutinib and the anti-CD20 B cell depleting monoclonal rituximab with ability to interfere with tumour protein P53 (TP53) activity, and a complement C3a Receptor (C3aR) antagonist being of particular interest.
Conclusion: Integrated multilevel omics analysis revealed a set of enriched pathways of potential interest for future drug investigation in CNS lupus, including BTK and C3aR inhibition, and B cell depletion.

POS0189

EFFECT OF ATACICEPT ON RENAL FUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

D. Isenberg[1], C. J. F. Lin[2], A. Kao[3], A. A. Aydemir[4], C. Gordon[5]. [1]*University College London, Div of Medicine, London, United Kingdom;* [2]*Vera Therapeutics,*

Inc., Clinical Development, Brisbane, United States of America; [3]EMD Serono Research & Development Institute, Inc., Translational Innovation Platform (TIP) Immunology, Billerica, United States of America; [4]EMD Serono Research & Development Institute, Inc., Global Biostatistics, Billerica, United States of America; [5]University of Birmingham Institute of Inflammation and Ageing (IIA), Rheumatology Research Group, Birmingham, United Kingdom

Background: Atacicept is a fusion protein that blocks B-lymphocyte stimulator and a proliferation-inducing ligand, which are increased in patients with SLE. APRIL-SLE was a double-blind, placebo-controlled, Phase 2 study that randomized patients with moderate-to-severe systemic lupus erythematosus (SLE) to atacicept 75 mg, atacicept 150 mg, or placebo twice-weekly for 4 weeks, then weekly for 48 weeks.
Objectives: The primary results of the APRIL-SLE study – the effect of atacicept compared to placebo in preventing new flares in patients with moderate-to-severe SLE – have been reported (Isenberg et al., 2013). We performed a post hoc analysis to describe the effect of atacicept compared to placebo on measures of renal function in patients with SLE; this effect has not been reported previously.
Methods: The APRIL-SLE study excluded patients with moderate to severe glomerulonephritis, as defined by either of the following: urinary protein/creatinine ratio (UPCR)>1 mg/mg and/or hematuria or a significant renal impairment as defined by estimated glomerular filtration rate (eGFR)<50 mL/min/1.73 m2. Patients with proteinuria and mild to moderate chronic kidney disease, as assessed by KDIGO criteria were eligible. UPCR and eGFR were measured at baseline, week 2, and then every 4 weeks until week 52. The median change from baseline to each of these timepoints was calculated for eGFR and UPCR using the Safety Analysis Set, comprised of all randomized patients who received at least 1 dose of study medication. Enrollment in the atacicept 150 mg group was discontinued prematurely due to 2 deaths from pneumonias. When treatment was discontinued, 62 of 144 patients in this group had completed 52 weeks of treatment; 27 other patients had already been withdrawn for various reasons; and, in the remaining 55 patients, treatment was stopped early as a safety precaution. Patients in the other two groups completed the protocol.
Results: In total, 111 patients in the placebo group, 112 patients in the atacicept 75 mg group, and 62 patients in the atacicept 150 mg group completed 52 weeks of treatment. The eGFR time course was stable for the atacicept groups compared to a 4.4% decline in the placebo group from baseline at week 52 (Figure 1 and Table 1). UPCR from baseline at week 52 declined in the atacicept groups and increased in the placebo group.

Table 1. Median Percent Change from Baseline of Estimated Glomerular Filtration Rate (eGFR) and Proteinuria at Week 52 – Safety Analysis Set

Variable	Placebo	Atacicept 75 mg	Atacicept 150 mg
eGFR (mL/min)	n=110	n=111	n=62 [b]
median	-4.35	-1.49	0.57
UPCR (mg/mg)	n=108	n=108	n=63
median	6.29	-6.27	-12.72
UPCR (mg/mg) [a]	n=12	n=15	n=8
median	26.11	-54.42	-12.15

eGFR=estimated glomerular filtration rate; UPCR=urinary protein/creatinine ratio. [a]Among patients with screening UPCR ≥0.2 mg/mg. [b]Enrollment in the atacicept 150 mg arm was discontinued prematurely (described in Isenberg et al., 2015).

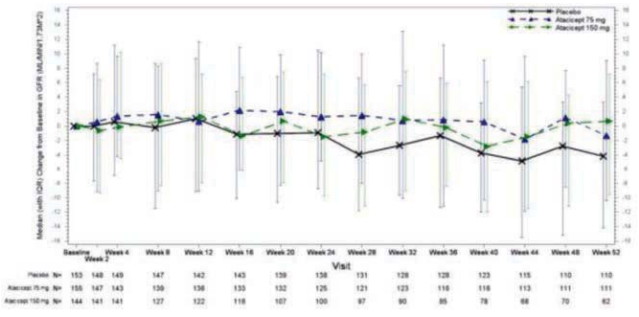

Figure 1. Median Change from Baseline in eGFR. eGFR= estimated glomerular filtration rate; IQR=interquartile range

Conclusion: Results from this double-blind, placebo-controlled, Phase 2 study suggest a potential for improved renal function with atacicept treatment of patients with moderate-to-severe SLE.

POS0190 EFFICACY AND SAFETY OF BARICITINIB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM TWO RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PARALLEL-GROUP, PHASE 3 STUDIES

E. F. Morand[1], Y. Tanaka[2], R. Furie[3], E. Vital[4], R. van Vollenhoven[5], K. Kalunian[6], M. Mosca[7], T. Dörner[8], D. J. Wallace[9], M. Silk[10], C. Dickson[10], I. De La Torre[10], G. Meszaros[10], B. Jia[10], B. Crowe[10], M. A. Petri[11]. *[1]Monash University, Centre for Inflammatory disease, Melbourne, Australia; [2]University of Occupational and Environmental Health, First Department of Internal Medicine, Kitakyushu, Japan; [3]Northwell Health and Zucker School of Medicine, Division of Rheumatology, Northwell, United States of America; [4]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [5]University Medical Centre, Clinical Immunology and Rheumatology, Amsterdam, Netherlands; [6]University of California, Division of Rheumatology, Allergy and Immunology, La Jolla, United States of America; [7]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [8]Charite Universitätsmedizin, Department of Medicine/Rheumatology and Clinical Immunology, Berlin, Germany; [9]Cedars-Sinai Medical Center/University California, Division of Rheumatology, Allergy and Immunology, Los Angeles, United States of America; [10]Eli Lilly and Company, N/A, Indianapolis, United States of America; [11]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America*

Background: In a 24-week, phase 2 clinical study (NCT02708095) in patients with systemic lupus erythematosus (SLE), baricitinib (BARI), an oral selective inhibitor of Janus kinase 1 and 2 approved for the treatment of rheumatoid arthritis and atopic dermatitis, inhibited the type I interferon gene signature, multiple other cytokine pathways, and improved disease activity (1) (2).
Objectives: To further evaluate the efficacy and safety of BARI in patients with SLE.
Methods: Patients with active SLE receiving stable background therapy were randomised 1:1:1 to BARI 2-mg, 4-mg, or placebo (PBO) once daily in two identically designed, 52-week, phase 3 randomised, PBO-controlled studies. In SLE-BRAVE-I (NCT03616912) and -II (NCT03616964), 760 and 775 patients, respectively were enrolled in a balanced manner across regions, although different countries per region participated in each study. The primary endpoint for both studies was the proportion of patients achieving an SLE Responder Index-4 (SRI-4) response at week 52. Glucocorticoid tapering was encouraged but not required per protocol.
Results: The mean Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) at baseline was 10.1 for both SLE-BRAVE-I and -II participants; musculoskeletal and mucocutaneous domains were the most common domains involved at baseline. In SLE-BRAVE-I, the proportion of SRI-4 responders at week 52 among patients treated with BARI 4-mg (56.7%), but not BARI 2-mg (49.8%), was significantly greater than in patients treated with PBO (45.9%, p = 0.016) (Table 1). No difference was seen in SLE-BRAVE-II (47.1%, 46.3%, and 45.6%, BARI 4-mg, 2-mg, and PBO, respectively). None of the key secondary endpoints, including glucocorticoid tapering or time to first severe flare (SFI), were met in either study. The proportions of patients with serious adverse events (SAEs) were 7.1% and 8.6% for PBO, 9.4% and 13.4% for BARI 2-mg and 10.3% and 11.2% for BARI 4-mg in SLE-BRAVE-I and II, respectively.

Table 1. Efficacy and safety of baricitinib in patients with SLE-BRAVE-I and -II

	SLE-BRAVE-I			SLE-BRAVE-II		
Efficacy measure	PBO (N=253)	BARI 2-mg (N=255)	BARI 4-mg (N=252)	PBO (N=256)	BARI 2-mg (N=261)	BARI 4-mg (N=258)
SRI-4 (W52)	116 (45.9)	126 (49.8)	142 (56.7)*	116 (45.6)	120 (46.3)	121 (47.1)
SRI-4 (W24)	99 (39.1)	114 (44.8)	117 (46.5)	98 (38.6)	104 (40.0)	108 (42.1)
Severe Flares (n, events)	38 (15.0)	34 (13.3)	26 (10.3)	26 (10.2)	29 (11.1)	29 (11.2)
HR for time to first severe flare (SFI) HR [CI]	NA	0.8 [0.52, 1.32]	0.65 [0.40, 1.08]	NA	1.1 [0.65, 1.89]	1.1 [0.67, 1.94]
Glucocorticoid sparing	36 (30.8)	31 (29.2)	36 (34.0)	33 (31.7)	34 (29.8)	36 (34.3)
LLDAS (W52)	66 (26.2)	65 (25.7)	74 (29.7)	59 (23.2)	62 (24.0)	65 (25.4)
Safety measure						
TEAE	210 (83.0)	210 (82.4)	208 (82.5)	198 (77.3)	199 (76.2)	200 (77.5)
SAE	18 (7.1)	24 (9.4)	26 (10.3)	22 (8.6)	35 (13.4)	29 (11.2)

Data are n (%) patients, unless otherwise indicated. BARI=baricitinib; CI=confidence interval; HR=hazard ratio compared with PBO; LLDAS=lupus low disease activity state; N=number of patients in the analysis population; n=number of patients in the specified category; PBO=placebo; TEAE=treatment-emergent adverse event; SAE=serious adverse event; W=week. *p≤0.05 vs PBO.

Conclusion: Although phase 2 data suggested BARI as a potential treatment for patients with SLE (2), the SLE-BRAVE-I and -II phase 3 study results were discordant for the primary outcome measure, with only SLE-BRAVE-I positive, making it difficult to elucidate benefit. Additional analyses are being performed to understand this discordance. No new safety signals were observed.

Background: During the first months of the Sars-CoV-2 pandemic, antimalarial drugs were the central axis of the treatment of patients with acute respiratory infection. After that, several studies reported a risk of prolongation of corrected QT interval (QTc) at the electrocardiogram (ECG).
Historically, these drugs, have been the common denominator in the treatment of patients with Systemic Lupus Erythematosus (SLE).

Objectives: To analyze the possible relationship between the use of antimalarial drugs ant the electrocardiographic alterations in patients diagnosed with SLE.

Methods: Cross-sectional study in patients diagnosed with SLE (SLICC 2012). In all of them, we performed a 12-lead ECG at rest. We measured the QT interval: manually and automatically, ant its correction was made according to the Hodge formule (QTc).

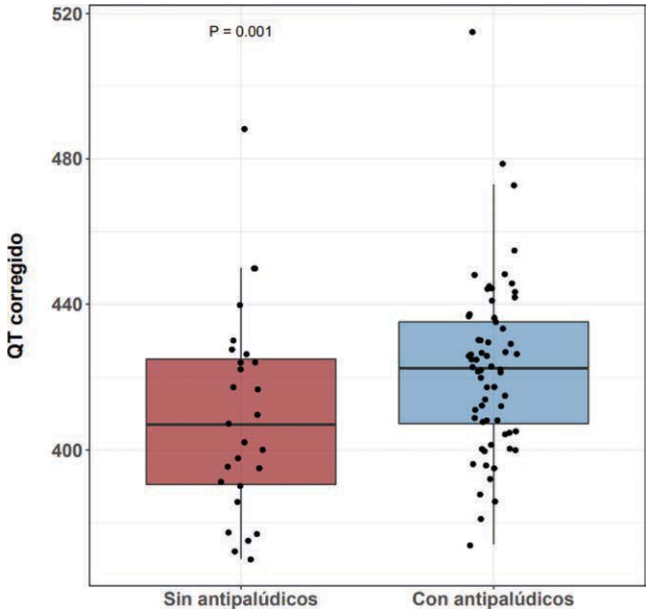
Results: 91 patients diagnosed with SLE were included in the study. Of the total of patients included in the study, 64 were in current treatment with an antimalarial drug, with a mean of 9.09 (5.73) years of treatment, and a mean cumulative dosage of 813.16 (436.12) gr.
Of the patients on current treatment with antimalarial drugs, 4.69% had a prolonged QTc, compared to 3.7% of the patients without current treatment with these drugs.

Table 1.

	NO antimalarial n= 27	YES antimalarial n= 64
Heart disease	7 (25,93%)	5 (7,81%)
Cumulative dosage HCQ (gr)	316,41 (457,28)	813,16 (436,12)
ECG disorders	5 (18,52%)	12 (18,75%)
Structural disorders	1 (3,7%)	6 (9,38%)
Electrical conduction disorders	2 (7,41%)	6 (9,38%)

We analyzed the possible relationship between the QTc interval, the current treatment with antimalarial drugs, and the cumulated dosage of this medication. We corrected the lineal regression models by the years of disease evolution, the presence or absence of known heart disease, the women gender, and other treatments such as antiarrhythmics or beta-blockers.
We found a statistically significant association between taking antimalarial drugs and the elongated QTc interval (p= 0,001). Nevertheless, in the multivariate analysis, we did not found a significant relationship between the ECG alterations and the treatment with antimalarial drugs.

Figure 1.



Conclusion: In our study, we did not observe a direct relationship between the intake of antimalarial drugs and the alteration of the corrected QT interval.

POS0192 IMPACT OF CORTICOSTEROID DISCONTINUATION ON SYMPTOM CONTROL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Phillips-Beyer[1], Q. Li[2], M. E. Stokes[2], M. Pozzobon Da Silva[3], H. Collacott[4]. *[1]Innovus Consulting Limited, London, United Kingdom; [2]Evidera, Waltham, United States of America; [3]Therapeutic Area Units, Idorsia Pharmaceuticals, Allschwil, Switzerland; [4]Evidera Ltd, Research, London, United Kingdom*

Background: Corticosteroid (CS) treatment effectively reduces swelling and pain caused by inflammation in patients with systemic lupus erythematosus (SLE). However, prolonged CS treatment is associated with adverse events including weight gain, infections, bone loss, and premature atherosclerosis. CS treatment should be minimised to ≤7.5 mg/day prednisone or equivalents for chronic use and withdrawn when possible. Available data on the impact of CS discontinuation on patients with SLE are limited.
Objectives: To understand CS treatment patterns and impact of CS discontinuation on flares using a real-world cohort of patients with SLE from the United States.
Methods: This retrospective cohort study used the IBM MarketScan Commercial/Medicare supplemental claims database. Patients with SLE receiving CS who subsequently discontinued treatment during 2015 through 2019 were included. The index date was the completion date of the last CS prescription prior to discontinuation. The duration of CS exposure, daily oral CS dose, and CS medication types prescribed, converted into a prednisone-equivalent dose (PEQ), were evaluated during a 12-month pre-index (baseline) period. Outcomes were evaluated during the follow-up period, which started on the date of CS discontinuation and continued until health plan disenrollment or last day of data. Outcomes included flares, CS treatment restarts, and CS-free period prior to resuming therapy. A published algorithm, which draws on SLE-related healthcare resources and medication use, was used to identify and classify flares as mild, moderate, or severe.[1] Multivariable Cox regression models evaluated the association between oral CS dose and occurrence of flare.
Results: Overall, 17,759 patients were included in the study (Table 1). The most frequently prescribed oral CS treatments were prednisone (62.7%) and methylprednisolone (23.8%). The mean (SD) duration of CS use prior to discontinuation was 104 (130) days. Most patients (86.6%) received ≥6 mg/day oral daily CS PEQ prior to discontinuation. During a mean follow-up of 27.7 months, nearly all patients (90%) had at least one flare and 73.2% resumed CS treatment following discontinuation. Three-quarters of patients (76%) had no CS treatment for a continuous period of ≥6 months after discontinuation. The mean (SD) number of flares during follow-up was 6.9 (6.4) and approximately 50% experienced a severe flare. In Cox proportional hazards models with adjustment for baseline characteristics, the high baseline cumulative oral CS dose tertile was associated with the greatest risk of flare (hazard ratio 1.2 vs. low dose, p<0.001) followed by the middle dose tertile (hazard ratio 1.1 vs. low dose, p<0.001).

Table 1. Outcomes in patients with SLE treated with CS

Measure Mean (SD) or %	Commercial Health /Medicare (N=17,759)
Prior to initial CS discontinuation	
Duration CS use in days	103.6 (129.5)
Oral CS dose tertile	26.6 (126.3)
≤5 mg/day	13.5%
6–20 mg/day	58.6%
>20 mg/day	28.0%
After initial CS discontinuation	
CS treatment restart	73.2%
No CS treatment ≥6 months	76.7%
Any flare	90.4%
Mild to moderate	72.4%
Severe	50.7%
Number flares	6.9 (6.4)

CS, corticosteroid; SD, standard deviation.

Conclusion: Flares were common in patients with SLE who discontinued CS and most patients restarted CS treatment over an average follow-up of 28 months. Patients in the highest cumulative oral CS dose tertile were most at risk of disease flares following CS withdrawal.

POS0193 EVALUATION OF CRESS IN THE PHASE 2 RANDOMISED PLACEBO-CONTROLLED STUDY OF SEQUENTIAL BELIMUMAB/RITUXIMAB ADMINISTRATION IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

H. Bootsma[1], S. Arends[1], L. de Wolff[1], K. L. Clark[2], A. van Maurik[3], P. Mistry[4], P. Shukla[5], S. Nihtyanova[6], N. L. Fox[7], D. Roth[8]. *[1]University Medical Center Groningen, University of Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]GlaxoSmithKline, Clinical Science, Stevenage, Hertfordshire, United Kingdom; [3]GlaxoSmithKline, Clinical Pharmacology and Experimental Medicine, Stevenage, Hertfordshire, United Kingdom; [4]GlaxoSmithKline, R&D Biostatistics, Stevenage, Hertfordshire, United Kingdom; [5]GlaxoSmithKline, R&D Biostatistics, Bangalore, India; [6]GlaxoSmithKline, Clinical Science, London, United Kingdom; [7]GlaxoSmithKline, Clinical Development, Collegeville, PA, United States of America; [8]GlaxoSmithKline, R&D, Collegeville, PA, United States of America*

Background: EULAR Sjögren's syndrome disease activity index (ESSDAI) assesses systemic disease activity in patients (pts) with primary Sjögren's syndrome (pSS); however, weaknesses include exclusion of patient-reported symptoms, tear and salivary gland function, and a marked placebo (PBO) response. Composite of Relevant Endpoints for Sjögren's Syndrome (CRESS) is a recently developed composite outcome measure validated using data from three Phase 3 randomised controlled trials of pts with pSS.[1] Concise CRESS (cCRESS) is used when ocular staining score and salivary gland ultrasonography are unavailable. ESSDAI was an endpoint in a Phase 2, PBO-controlled study, evaluating the safety and efficacy of belimumab (BEL) and rituximab (RTX) sequential administration (BEL/RTX), and BEL and RTX monotherapies in pts with pSS. Although the results numerically favoured BEL/RTX over PBO, this was not statistically significant.
Objectives: To evaluate the efficacy of BEL/RTX and monotherapies using cCRESS overall responses at Weeks (Wks) 24, 52, and 68, and individual item responses at Wk 24 in pts with pSS who completed the Phase 2 study.
Methods: In the Phase 2, double-blind, 68-Wk study (NCT02631538) adults were randomised (2:2:2:1) into 4 treatment arms: BEL/RTX (n=24; weekly BEL 200 mg subcutaneous [SC] to Wk 24 followed by weekly PBO SC to Wk 52 + RTX 1000 mg intravenous [IV], Wk 8 + 10), BEL monotherapy (n=24; weekly BEL 200 mg SC to Wk 52), RTX monotherapy (n=25; RTX 1000 mg IV, Wk 8 + 10), or PBO (n=13). Pts were classified *post hoc* as cCRESS responders when ≥3 of the following 5 items were met: 1) Clinical (Clin)ESSDAI score <5 (low disease state); 2) decrease of ≥1 point or ≥15% from baseline (BL) in EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI); 3) increase of ≥5 mm from BL in abnormal Schirmer's test, or no change to abnormal if normal at BL; 4) unstimulated whole saliva (UWS) increase of ≥25% from BL, or any increase from BL if score was 0 at BL; 5) decrease of ≥25% in the rheumatoid factor (RF) titre from BL, or decrease of ≥10% in IgG from BL.[1]
Results: Of 86 randomised pts, 60 completed follow-up to Wk 68 (completer population) and were included in the analysis. Most pts were female (95%, n=57); mean (SD) age was 49.6 (13.0) years. BL disease characteristics are presented in the Table 1.

Table 1. Clinical, functional, and laboratory parameters at BL and cCRESS responders at Wks 24, 52, and 68 (completer population)

	PBO (n=8)	BEL/RTX (n=17)	BEL (n=19)	RTX (n=16)
Pt parameters at BL, mean (SD)				
ClinESSDAI	11.1 (3.76)	11.7 (5.47)	9.2 (3.77)	11.7 (4.76)
ESSPRI	6.4 (2.05)	6.0 (1.97)	6.5 (1.68)	5.9 (2.20)
Schirmer, mm/5 min	2.7 (3.25)	5.3 (6.44)	3.3 (3.16)	2.8 (3.15)
UWS, ml/min	0.1 (0.11)	0.1 (0.12)	0.1 (0.09)	0.1 (0.14)
RF, KU/l	60.8 (42.24)	30.9 (38.20)	37.0 (34.98)	105.0 (200.97)
IgG, g/l	20.4 (6.65)	16.7 (5.00)	18.1 (7.19)	16.5 (6.09)
cCRESS responders, n (%)				
Wk 24	4 (50.0)	9 (52.9)	7 (36.8)	5 (31.3)
Wk 52	4 (50.0)	10 (58.8)	8 (42.1)	4 (25.0)
Wk 68	1 (12.5)	6 (35.3)	7 (36.8)	3 (18.8)

At Wks 24 and 52, the proportion of cCRESS responders was numerically higher with BEL/RTX than with either BEL, RTX, or PBO, but the difference was not significant (Table 1). At Wk 68, the proportion of cCRESS responders was numerically higher with BEL/RTX than with RTX or PBO (Table 1). The 5 cCRESS items contributed relatively equally to total cCRESS response, with the highest response observed in the RF/IgG item and the lowest in the tear gland item (Schirmer's test; Figure 1).

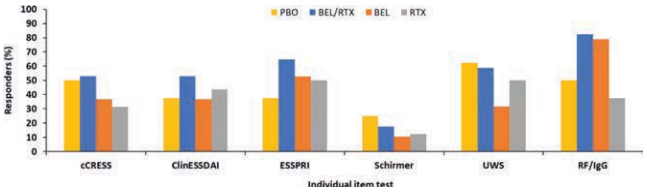

Figure 1. cCRESS and individual item responders at Wk 24 (completer population)

Conclusion: At Wks 24, 52, and 68, BEL/RTX was generally associated with a numerically higher cCRESS response rate compared with the monotherapies or PBO. The PBO response for cCRESS was notable and similar to the PBO response for ClinESSDAI. The PBO response in the tear and salivary gland items was greater than in the other treatment arms, perhaps due to the use of cCRESS instead of CRESS. Due to the small sample size, the results should be interpreted with caution.

Outcome of COVID-19 in patients with rheumatic diseases

POS0194 MORBIDITY AND MORTALITY OF BREAKTHROUGH COVID-19 IN PATIENTS WITH IMMUNE MEDIATED CONDITIONS ON B CELL DEPLETING THERAPIES AND THE EFFECTS OF MONOCLONAL ANTIBODY TREATMENT

C. Calabrese[1], E. Kirchner[1], M. E. Husni[1], B. Moss[2], A. Fernandez[3], Y. Jin[4], L. Calabrese[1]. *[1]Cleveland Clinic, Rheumatic and Immunologic Diseases, Cleveland, United States of America; [2]Cleveland Clinic, Neurological Institute, Cleveland, United States of America; [3]Cleveland Clinic, Dermatology, Cleveland, United States of America; [4]Cleveland Clinic, LRI Quantitative Health Sciences, Cleveland, United States of America*

Background: Among immunocompromised patients with immune mediated inflammatory diseases (IMIDs), those undergoing therapy with B cell depleting agents are among the most vulnerable to both severe COVID-19 disease and sub-optimal response to COVID-19 vaccines(1). Numerous studies have documented suppressed humoral, but relatively maintained cell mediated, responses to COVID-19 vaccines in these patients. However, the clinical significance of such immunity in terms of protection from infection and its sequelae are poorly understood. We have analyzed a large cohort of vaccinated IMIDs patients undergoing B cell depleting therapy for the presence of breakthrough infection and assessed their outcomes.

Objectives: To define the frequency and outcomes of COVID-19 breakthrough infection in fully or partially vaccinated IMIDs patients receiving B cell depleting therapies. To assess the characteristics and risk factors for severe outcomes and death.

Methods: All pharmacy records from within a large health care system were electronically searched for patients undergoing B cell depleting therapies with approved monoclonal antibodies in 2020. Records with ICD codes for IMIDs but not malignancies were included; patients must also have had at least one documented COVID-19 vaccine. From this cohort all patients with breakthrough COVID-19 disease from time of 1st vaccination through December 15, 2021 were identified; each record was hand-reviewed to extract clinical data including vaccine history, demographics, comorbidities, use of monoclonal antibodies, dose and timing of B cell depleting therapy, and outcomes as assessed by an 8 point NIH ordinal scale. Univariate and multivariable logistic/proportional-odds regression models were used to examine the risk factors for severe outcomes.

Results: A total of 1677 IMIDs patients were identified who received any B cell depleting monoclonal antibody and at least one COVID-19 vaccine in 2021. From this cohort 74 patients (4.4%) experienced a breakthrough COVID-19 infection. Among the breakthrough patients 34 (46%) had a rheumatic disease (RA 11, AAV 15, SLE 2), 34 (46%) had CNS inflammatory disease (MS 32, 2 other), and 6 (8%) had immune hematologic/miscellaneous diseases. Four patients had a previous history of COVID-19 infection. Overall 24 (35%) were hospitalized with 11 patients requiring critical level care (15%) and 6 deaths (8 %). All fatal cases had rheumatic diseases. Monoclonal antibodies were given as outpatient therapy to 21 patients and among these only 1 patient was hospitalized without requiring O2 and none died. In univariate analysis only number of comorbidities had a significant positive effect (p=.001) on severe outcomes (i.e. groups 1-4 vs. groups 5-8: Table 1) while monoclonal antibody therapy was associated with more favorable outcomes (p=.005 group 1-2 vs.3-8, Table 1). There were no associations between the dose, duration or timing of the B cell therapy, concomitant therapies including glucocorticoids, vaccine status (incomplete, complete, boosted) or date of vaccination with severe outcomes.

Conclusion: In IMIDs patients treated with B cell depleting therapies breakthrough infections are common with many experiencing severe outcomes. Concomitant comorbidities were associated with risk of severe disease. Monoclonal antibody therapy was used in only 28% but was associated with enhanced clinical outcomes with only 1 in 21 requiring hospitalization and zero mortality. This population of immunocompromised patients remains vulnerable to COVID-19 disease despite vaccination. More aggressive use of outpatient management with monoclonal antibody therapy and other preventive and therapeutic measures are urgently needed.

POS0195 PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS HAVE AN INCREASED RISK OF MORTALITY, MECHANICAL VENTILATION, AND HOSPITALIZATION FROM COVID-19

S. Bruera[1], X. Lei[2], H. Zhao[2], J. Yazdany[3], M. Chavez-Macgregor[2], S. Giordano[2], M. Suarez-Almazor[2]. *[1]Baylor College of Medicine, Section of Immunology, Allergy, and Rheumatology, Houston, United States of America; [2]The University of Texas MD Anderson Cancer Center, Health Services Research, Houston, United States of America; [3]University of California, San Fransisco, Division of Rheumatology, San Fransisco, United States of America*

Background: Patients with systemic lupus erythematosus (SLE) may have an increased risk of mortality from COVID-19 due to underlying immunosuppression, comorbidities, and abnormalities in the innate immune system. Studies have shown that autoimmune diseases and some immunosuppressive agents are risk factors for hospitalization, ventilation, and mortality from COVID-19.

Objectives: To compare the outcomes of patients with or without SLE who were diagnosed with COVID-19 and to identify the factors associated with 30-day hospitalization, mechanical ventilation, and mortality. We hypothesized that patients with SLE had a higher risk of adverse outcomes.

Methods: This retrospective cohort study used the deidentified Optum COVID-19 electronic health record dataset to identify adult patients with COVID-19 diagnosis from 1/1/2020 – 12/31/2020. The SLE cohort was defined as patients who had two or more international classification of diseases (ICD) 9 or 10 diagnosis codes of 710.0 or M32.xx but not M32.0 within one year before COVID-19 diagnosis and were on either antimalarial or immunosuppressive therapy. The general cohort excluded patients with SLE. We matched SLE cases with controls at a ratio of 1:10 by age, sex, race and ethnicity, and month of COVID-19 diagnosis via a propensity score matching with exact matching for the latter three variables. Outcomes included 30-day mortality, hospitalization, and mechanical ventilation after COVID-19 diagnosis. We performed multivariable logistic regression models to estimate the odds of 30-day mortality,

hospitalization, and mechanical ventilation after adjusting for age, sex, race and ethnicity, COVID-19 diagnosis quarter, insurance, region, severe obesity, smoking status, and comorbidities.

Results: We included 687 SLE cases matched with 6,870 controls. After matching, the 30-day mortality for SLE and control was 3.6% and 1.8% (p <0.001), the 30-day mechanical ventilation was 6.0% and 2.5% (p <0.001), and 30-day hospitalization was 31.0% and 17.7% (p <0.001). After multivariable adjustment (Table 1) for age, sex, race, COVID-19 diagnosis quarter, insurance, region, severe obesity, and smoking status, patients with SLE had higher odds of death (Odds Ratio (OR)=2.09; 95% CI 1.31-3.32), mechanical ventilation (OR=2.43; 95% CI 1.67-3.54) and hospitalization (OR=2.06; 95% CI 1.71-2.49). After additionally adjusting for comorbidities, the OR decreased to 1.39 (95%CI 0.79-2.44), 1.81 (95%CI 1.16-2.82), and 1.32 (95%CI 1.05-1.65) for mortality, mechanical ventilation, and hospitalization respectively. Older age, male sex, Hispanic ethnicity or Black race, severe obesity, and smoking had increased risk of adverse outcomes.

Table 1. Multivariable logistic regression model of 30-day mortality, 30-day mechanical ventilation, and 30-day hospitalization on matched cohort adjusting for demographic and comorbidity score

Variables	Model 1* Odds Ratio (95% CI)	Model 2** Odds Ratio (95% CI)
Mortality		
Control	1	1
SLE	2.09 (1.31 to 3.32)	1.39 (0.79 to 2.44)
30-day mechanical ventilation		
Control	1	1
SLE	2.43 (95% CI 1.67 to 3.54)	1.81 (1.16 to 2.82)
Hospitalization		
Control	1	1
SLE	2.06 (1.71 to 2.49)	1.32 (1.05 to 1.65)

SLE: systemic lupus erythematosus; CI: confidence interval. *Model 1 includes adjustments for age, sex, race, COVID-19 diagnosis date (by quarter), insurance, region, severe obesity, smoking status, and skilled nursing facility stay three months before COVID-19 diagnosis. **Model 2 includes adjustments from model 1 and comorbidities (excluding SLE).

Conclusion: Patients with SLE have an increased risks of mortality, mechanical ventilation, and hospitalization within 30 days of COVID-19 diagnosis. The risks decreased after adjustment for comorbidities but remained statistically significant for mechanical ventilation and hospitalization.

POS0196 NINE PERCENT OF PATIENTS PRESENT WITH MUSCULOSKELETAL SYMPTOMS AFTER A SEVERE SARS-COV2 INFECTION: A DESCRIPTIVE ANALYSIS OF THE ASSISTANCE PUBLIQUE - HÔPITAUX DE PARIS CLINICAL DATA WAREHOUSE.

A. Moltó[1], P. Pinson[1], N. Beeker[1], C. Roux[1]on behalf of AP-HP COVID Clinical Data Warehouse initiative. [1]*the AP-HP/Universities/INSERM COVID-19 Research Collaboration, AP-HP COVID Clinical Data Warehouse Initiative, Paris, France*

Background: the main and most severe manifestation of the SARS-CoV2 infection is pneumonia, but other organ-specific symptoms have been described (myocarditis, encephalitis,..), and some sparse cases have reported musculoskeletal (MSK) symptoms following such an infection.

Objectives: to determine the prevalence of MSK symptoms appearing after a SARS-CoV2 infection.

Methods: this was an observational cohort based on data available at the Assistance Publique-Hôpitaux de Paris (APHP) Clinical Data Warehouse (which includes data from patients admitted in the 39 APHP hospitals). Data collected included both ICD-10 codes in discharge summaries, and 'key-words' search on electronic medical records (EMR). To be included in the analysis, patients had to have a positive RT-PCR for SARS-CoV2 performed in APHP and be admitted in any APHP department between 1st March 2020 until 31st December 2020. Patients with past history of any MSK condition were excluded. MSK conditions were considered only if coded or reported in an EMR up to 90 days after the positive RT-PCR. Demographics and disease characteristics including treatment were compared in both groups (MSK yes/no) by T-test or ChiSquare test, accordingly.

Results: Among the 55872 patients with a positive SARS-CoV2 RT-PCR performed in APHP, 17771 were admitted in APHP hospitals. Among them, 2170 had a previous history of MSK condition and were therefore excluded from this analysis. Among the remaining 15601 patients, 1370 (8.8%) presented with MSK symptoms. The most prevalent MSK symptoms were low back pain (32.9%), followed by joint pain (29.9%), radicular pain (20.2%) and joint effusion/arthritis (22.8%). Patients with MSK symptoms were older (67y vs. 64y, p<0.01), more frequently obese (29% vs. 25%, p=0.03), hypertensive (34% vs. 30%, p<0.01) and with diabetes (21% vs. 18%, p<0.01). There were no differences on gender nor on the ICU admission rate between groups (31% vs. 29%, NS); 30-days mortality was significantly lower in the MSK+ group probably due to selection bias (i.e. only patients who survived could present with MSK symptoms up to 90 days later) (7.8% vs. 16.9%, p<0.01). Treatment for SARS-CoV2 was slightly different in both groups, with higher corticosteroids (40.7% vs. 29.0%, p<0.01), antivirals (21.5% vs. 15.3%, p<0.01) and immunosuppressive drugs (8.5% vs. 4.5%, p<0.01) prescription rates in the MSK+ group.

Conclusion: MSK symptoms occurred in almost 9% of patients admitted to the hospital after a SARS-CoV2 infection, particularly in older and more comorbid patients. Further analysis evaluating the persistence of these symptoms are needed.

POS0197 SARS-COV-2 INFECTION CAUSED THROMBOSIS IN THE LUPUS MODEL WITH ANTIPHOSPHOLIPID ANTIBODY, WHEREAS COVID-19 ASSOCIATED THROMBOSIS WAS IRRELEVANT IN PATIENTS WITH POSITIVE ANTIPHOSPHOLIPID ANTIBODY

S. Oba[1], T. Hosoya[1], D. Kawata[1], W. Lee[1], M. Kamiya[1], Y. Komiya[1], H. Iwai[1], Y. Nukui[2], S. Tohda[3], S. Yasuda[1]. [1]*Tokyo Medical and Dental University, Department of Rheumatology, Bunkyo City, Japan;* [2]*Tokyo Medical and Dental University, Department of Infection Control and prevention, Bunkyo City, Japan;* [3]*Tokyo Medical and Dental University, Department of Laboratory Medicine, Bunkyo City, Japan*

Background: Thrombosis is a unique complication in coronavirus disease 2019 (COVID-19). We have reported that elevated ferritin and D-dimer on admission were the risk factors of thromboses by analyzing the patients sequentially admitted to our hospital due to COVID-19 (1). However, we have not analyzed thrombotic complications in the view of the antiphospholipid antibodies (aPLs), which are frequently detected in the COVID-19 patients.

Objectives: To elucidate the thrombogenic effects of aPLs in COVID-19, we analyzed the development of thrombosis in three lupus models after SARS-CoV-2 infection. Additionally, we evaluated the association of thrombotic events and the serum profile of aPLs in Japanese patients with COVID-19.

Methods: Three animal models of lupus (MRL-*lpr*/*lpr*, NZBxNZW F1 and NZW×BXSB F1) were evaluated in this study. NZW×BXSB F1 was also considered as a model of antiphospholipid syndrome (APS) since aPLs were detected with a high titer (2). Experimental SARS-CoV-2 infection was induced using mouse-passaged virus strain (3). The incidence of thromboses in the lungs and kidneys were identified by evaluating H&E staining and PTAH staining of paraffin-embedded sections. We have experienced 44 thrombotic events in 34 out of 594 patients admitted to our institute. As a non-thrombotic COVID-19, 68 patients were selected to make a 1 to 2 matched-pair based on the propensity score. In total 102 patients, seven types of aPLs (anti-cardiolipin (CL) IgG/IgM, anti-β2GP1 IgG/IgA/IgM, and anti-phosphatidyl serine/prothrombin complex (PS/PT) IgG/IgM) were measured using specific ELISA kits. The patients' clinical characteristics and serological profile of aPLs were further evaluated.

Results: We identified the development of thromboses in the lungs or kidneys in 6 out of 12 (50%) NZW×BXSB F1 mice after the SARS-CoV-2 infection, whereas no thrombosis was observed in non-infected mice. Further, there was no thrombosis in the other lupus models (0%) after the infection. These findings might suggest the pathogenic role of aPLs under the SARS-CoV-2 infection.

Among our COVID-19 patients, 39 out of 102 (38%) were tested positive for one or more aPLs. The positive ratios of any aPLs were statistically indifferent between the patients with or without thrombosis; anti-CL IgG (8.8% vs 5.9%)/IgM (0% vs 5.9%), anti-β2GP1 IgG (21% vs 12%)/IgA (8.8% vs 15%)/IgM (0% vs 1.5%), and anti-PS/PT IgG (0% vs 2.9%)/IgM (12% vs 13%), respectively. In addition, their titers were relatively lower than those observed in APS patients. The patients' characteristics and the prognosis of COVID-19 were comparable

regardless of the detection of any aPLs. These findings suggested that COVID-19 associated aPLs were irrelevant to thrombotic complications.

Conclusion: Thromboses were induced after the infection of SARS-CoV-2 only in the APS model. However, aPLs detected in COVID-19 patients have little impact on the development of thrombosis. SARS-CoV-2 infection might have a high risk of thrombosis, especially in APS patients, as shown in the case report (4). The discrepancy of its thrombogenic effects of aPLs might be explained by the low titer of the antibody or the diversity of antibody epitope. Further analyses are required to clarify the mechanisms of aPLs production and the development of thrombosis in COVID-19.

POS0198 COVID-19 OUTCOMES IN PATIENTS WITH DERMATOMYOSITIS: A REGISTRY-BASED COHORT ANALYSIS

L. Gupta[1,2], H. Pakhchanian[3], H. Khan[4], R. Raiker[5], M. Abbasi[4], C. Deyoung[6], S. Kardes[7], S. Ahmed[8], C. Kavadichanda[9], P. Sen[10], R. Aggarwal[11]. *[1]Royal Wolverhampton Hospitals NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; [3]George Washington School of Medicine & Health Sciences, -, Washington DC, United States of America; [4]Dubai Medical College for Girls, -, Dubai, United Arab Emirates; [5]West Virginia University School of Medicine, -, Morgantown, United States of America; [6]Sidney Kimmel Medical College at Thomas Jefferson University, -, Philadelphia, United States of America; [7]Istanbul University Faculty of Medicine, Department of Medical Ecology and Hydroclimatology, Istanbul, Turkey; [8]Kalinga Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Bhubaneswar, India; [9]Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Clinical Immunology, Puducherry, India; [10]Maulana Azad Medical College, Undergraduate, New Delhi, India; [11]University of Pittsburgh School of Medicine, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America*

Background: Dermatomyositis (DM) patients have fewer risks of COVID-19 infection compared to the general population, however, certain subgroups with DM have worse outcomes. Men. African Americans, those with interstitial lung disease, exhibited higher risks of severe COVID-19. DMARD and glucocorticoid use was associated with frequent hospitalisations and severe sepsis.

Objectives: Rheumatic diseases (RDs) like DM, are previously known to be vulnerable towards various types of infections due to its aggressive activity mandating high dose immunosuppressive therapy. The severity of COVID-19 in RDs is limited in literature due to the heterogeneous nature of the condition. Therefore, specific details on mortality is essential to navigate any precautions required in the treatment.

Methods: Retrospective data of individuals with DM and COVID-19 and the general population with COVID-19 between January 2020 to August 2020 was retrieved from the TriNetX database. A one-to-one matched COVID-19 positive control was selected using propensity score (PS) matching. We assessed COVID-19 outcomes such as mortality, hospitalisation, ICU admission, severe COVID-19, mechanical ventilation (MV), acute kidney injury (AKI), venous thromboembolism (VTE), ischemic stroke, acute respiratory distress syndrome (ARDS), renal replacement therapy (RRT) and sepsis. Subgroup analyses included gender, race, ILD, cancer patients, disease-modifying rheumatic drugs (DMARDs) use, and glucocorticoids (GC) use (Figure 1).

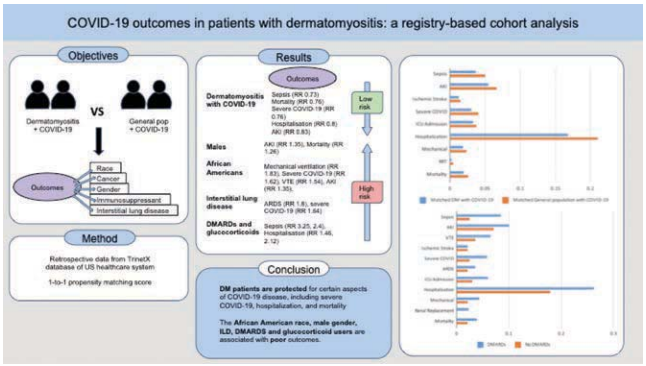

Figure 1. Overview of study

Results: We identified 5,574 DM patients with COVID-19, and 5,574 general population with COVID-19 (controls). DM with COVID-19 had a lower risk of mortality in comparison to controls [RR 0.76], hospitalisation [RR 0.8], severe COVID-19 [RR 0.76], AKI [RR 0.83], and sepsis [RR 0.73]. Males and African Americans were more likely to develop AKI [RR 1.35, 1.65], while African Americans had higher odds for severe COVID-19 [RR 1.62] and VTE [RR 1.54]. DM with ILD group also experienced higher odds for severe COVID-19 infection [RR 1.64], and VTE [RR 2.06] (Figure 1).

DM patients receiving DMARDs and glucocorticoids had higher odds for hospitalisation [RR 1.46, 2.12], and sepsis [RR 3.25] Subgroup analysis of neoplasms amongst DM patients with COVID-19 was inadequate for meaningful comparison (Figure 1).

Conclusion: DM patients are protected for certain aspects of COVID-19 disease, including severe COVID-19, hospitalization, and mortality. The African American race, male gender, ILD, DMARDS and glucocorticoid users, are associated with poor outcomes.

POS0199 DETECTION OF SARS COV-2 ANTIBODIES FOLLOWING VACCINATION IN PATIENTS WITH RHEUMATIC MUSCULOSKELETAL DISEASE (DECODIR) – AN INTERIM REPORT FROM A DANISH PROSPECTIVE COHORT STUDY

C. Graversgaard[1], K. Schreiber[1,2,3], R. Petersen[1], H. Jakobsen[1], A. B. Bojesen[1], N. Steen Krogh[4], B. Glintborg[4,5], M. L. Hetland[4,5], O. Hendricks[1,2]. *[1]University of Southern Denmark, University Hospital of Southern Denmark, Sonderborg, Denmark; [2]University of Southern Denmark, Department of Regional Health Research, Sonderborg, Denmark; [3]Guy's and St Thomas' NHS Foundation*

Trust, Thrombosis and Haemostasis, London, United Kingdom; [4]University Hospital of Copenhagen Rigshospitalet, Glostrup, DANBIO, The Danish Rheumatologic Biobank and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Copenhagen, Denmark; [5]Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Background: During the COVID-19 pandemic, it remains a major concern whether patients with rheumatic musculoskeletal disease treated with conventional (cs) or biologic (b) disease modifying drugs (DMARDs) exhibit an adequate immune response to the currently available SARS-CoV2 vaccines. There remains an urgent need for more data on SARS-CoV-2 vaccine efficacy to inform healthcare providers on the efficiency of the applied vaccination, potential need of and period for booster and/ or re-vaccination.

Objectives: To assess and compare the efficacy of the SARS-CoV2 vaccines BNT162b2 vaccine (Pfizer/BioNTech) and mRNA-1273 vaccine (Moderna). (*The vaccines were administered as part of the Danish vaccine roll out and offered each with two doses and approximately four weeks apart*).

Patients' SARS-CoV2 IgG serum level was used as proxy to determine vaccination response.

Methods: We established the 'Detection of SARS-CoV2 antibodies in Danish Inflammatory Rheumatic Outpatients' study (DECODIR) as a longitudinal prospective cohort study. Patients with rheumatoid arthritis (RA), spondyloarthropathies (SpA) or psoriatic arthritis (PsA) receiving their outpatient treatment and monitored in the Danish DANBIO registry at the Danish Hospital for Rheumatic Diseases (DG), Sonderborg were included (April - June 2021).

Bloods, patient reported outcome measurements (PROMS), clinical data and treatment information (cs/bDMARD) were collected at baseline (prior to vaccination) and after six weeks and six months. SARS-CoV2 IgG levels in serum were assessed by ELISA (ThermoFischer), and manufacturer's cut-off (>=10 EliA U/mL) selected as definition of sufficient IgG response.

Associations between antibody response, age, gender, disease (RA/PsA/SpA), treatment with no or cs/bDMARDs and disease activity were tested using proportional odds regression and bootstrapped tests of medians. Results were reported using mean, median (IqR) and bootstrapped 95% confidence interval (CI) of the median.

Results: A total of 243 patients were included at baseline and after six weeks; at six months' follow-up data were available for 233 patients.

After six weeks, vaccination was followed by a significant increase in IgG levels (median of <0.7 EliA U/mL at baseline *versus* 36.5 EliA U/mL). Patients treated with a combination of both cDMARD and bDMARD had significantly lower IgG levels compared to patients without any DMARD treatment (8,2 EliA U/mL vs 19.5 EliA U/mL (p<0.001)). Patients treated with oral prednisolone (any dose) also showed significantly lower median IgG levels compared to patients without DMARD treatment (3,8 EliA U/mL vs 19.5 EliA U/mL (p<0.01)).

The actual measurements six months after baseline demonstrated a significant decrease of IgG levels for the whole study population (median of 16 EliA U/mL at six month vs 36.5 EliA U/mL at six weeks, p < 0.001) (Figure 1).

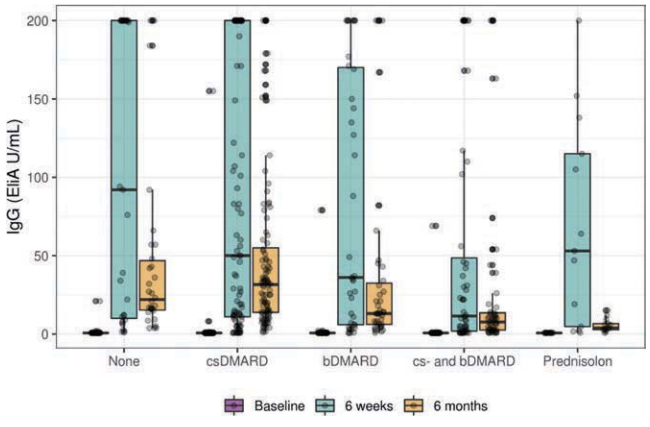

Figure 1. IgG-level stratified by treatment

Similar to week 6, lowest response rates were found in patients treated with prednisolone or combination of csDMARD and bDMARD. After 6 months, the proportional odds model revealed significantly lower median IgG antibody level in patients who received Pfizer compared to Moderna (median 15 EliA U/mL (95%CI: 13-18) vs 44.5 EliA U/mL (95%CI: 36-83) (p<0.001).

Conclusion: IgG levels decreased markedly six months after the initial double dose regimen. Patients treated with a combination of cs/bDMARD or oral prednisolone are at higher risk of inadequate vaccine response as measured by IgG level.

Our results support the decision for the need of a third booster vaccine in patients with inflammatory rheumatic diseases, especially in the case of cs/bDMARD combination treatment and prednisolone. The data may indicate a need for further revaccination in these patients.

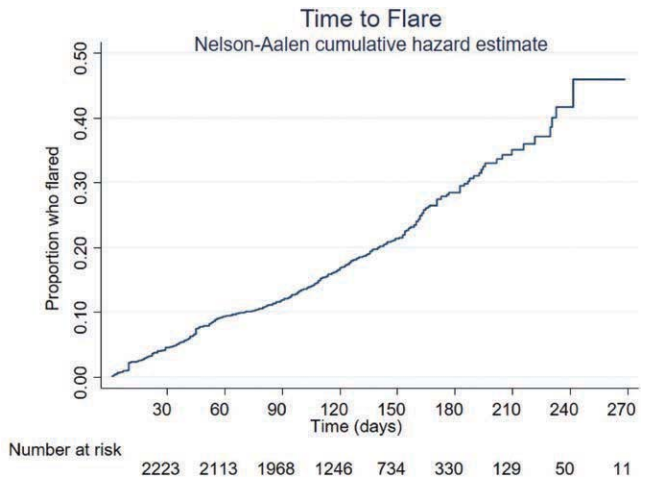

Figure 1. Nelson-Aalen curve of flares over time

Hospital, Rheumatology, Singapore, Singapore; [11]Khoo Teck Puat Hospital, Rheumatology, Singapore, Singapore

Background: Published data suggest no increased rate of flare of autoimmune inflammatory rheumatic diseases (AIIRD) after COVID-19 mRNA vaccination; however, the studies are limited by small sample size, short follow up or at risk of selection bias (voluntary physician reports or patient surveys).
Objectives: To study flares of AIIRD within three months of the first dose of an anti-SARS-COV2 mRNA vaccine.
Methods: A retrospective cohort study of consecutive AIIRD patients ≥ 12 years old, across six public hospitals in Singapore who received at least one dose of an mRNA (Pfizer/BioNTech or Moderna) vaccine. Data were censored at the first post-vaccine clinic visit when the patient had flared or if ≥ three months had elapsed since the first dose of the vaccine, whichever came first. Predictors of flare were determined by Cox proportional hazards analysis and time to flare was examined using a Nelson Aalen cumulative hazard estimate (Figure 1).
Results: 2339 patients (74% Chinese, 72% female) of median (IQR) age 64 (53, 71) years were included in the interim analysis (Table 1). 2112 (90%) had the Pfizer/BioNTech vaccine and 195 (8%) had Moderna, with a median (IQR) interval of 21 (21, 23) days between the two doses. The most common AIIRD diagnoses were Rheumatoid arthritis (1063, 45%), Psoriatic arthritis (296, 12.6%) and Systemic lupus erythematosus (SLE) (288, 12.3%). 186 (8%) were treated with biologics/ targeted disease modifying agents. 2125 (91%) patients were in low disease activity or remission. Treatment was interrupted for vaccination in only 18 (0.8%) patients. Seven (0.3%) patients had previous COVID-19 infection.

Table 1. Patient characteristics

Baseline characteristics	No flares (n = 1887, %)	Flares within 0—3 months of 1st vaccine dose (n= 272, %)	Flares outside of 0 – 3 months after 1st vaccine dose (n = 180, %)
Age (median years, IQR)	64 (53, 71)	61 (50, 69)	65 (55, 71)
Race			
Chinese	1386 (73)	206 (76)	129 (72)
Malay	193 (10)	28 (10)	20 (11)
Indian	195 (10)	27 (10)	26 (14)
Gender	1367 (72)	200 (74)	117 (65)
Female			
Vaccine type			
Pfizer/BioNTech	1713 (92)	239 (90)	160 (90)
Moderna	149 (8)	28 (10)	18 (10)
Diagnosis			
Rheumatoid Arthritis	831 (44)	139 (51)	93 (52)
Systemic Lupus Erythematosus	269 (14)	20 (7)	9 (5)
Psoriatic Arthritis	225 (12)	42 (15)	29 (16)
Spondyloarthropathies	141 (7)	21 (7)	17 (9)
Sjogren's Syndrome	114 (6)	15 (6)	8 (4)
Systemic sclerosis	94 (5)	4 (1)	6 (3)
Baseline Physician Disease Activity			
Remission	1007 (53)	99 (36)	63 (35)
Low Disease Activity	731 (39)	128 (47)	97 (54)
Moderate Disease Activity	134 (7)	40 (15)	20 (11)
High Disease Activity	15 (1)	5 (2)	0

452 (19%) flares were recorded during 9798.8 patient-months [4.6/100 patient-months, median (IQR) follow up duration 4.2 (3.3, 5.3) months], of which 272 (11.6%) patients flared within the 3-month period of interest and 180 (7.7%) flared outside of the 3-month period (Table 1). Median (IQR) time-to-flare was 40.5 (18, 56.6) days. 60 (22.1%) were mild and self-limiting, 170 (62.5%) were mild-moderate and 42 (15.4%) were severe. 190 (69.8%) of those who flared required escalation of treatment and 15 (5.5%) required hospital admission. 239 (10.2%) had improved disease activity after the vaccine.
On multivariate Cox regression analysis, patients in the oldest age tertile [median (IQR) 74 (71, 79) years] were less likely to flare [HR 0.80 (95% CI 0.63, 1.00), p = 0.05] Patients with inflammatory arthritis (compared with connective tissue disease, vasculitis and others) and patients with baseline active disease were more likely to flare [HR 1.72 (95% CI 1.35, 2.20), p < 0.001 and 1.82 (95% CI 1.39, 2.39), p < 0.001 respectively]
Conclusion: There was a moderately high rate of AIIRD flares after mRNA vaccination; however, there was no clustering of flares in the immediate post-vaccine period to suggest causality. Older patients were less likely to flare, while those with inflammatory arthritis and active disease at baseline were more likely to flare.

Background: Significant gaps are present in the evidence of the spectrum and severity of COVID-19 infection in idiopathic inflammatory myopathies (IIM). IIM patients typically require immunosuppressive therapy, may have multiple disease sequelae, and frequent comorbidities, and thus may be more susceptible to severe COVID-19 infection and complications (1). The possibility of attenuated immunogenicity and reduced efficacy of COVID-19 vaccines due to concomitant immunosuppressive medication is a major concern in these patients, and there is little data available on COVID-19 vaccine breakthrough infections (BI) in IIM (2).

Objectives: This study aimed to compare disease spectrum and severity and COVID-19 BI in patients with IIM, other systemic autoimmune and inflammatory diseases (SAIDs) and healthy controls (HCs).

Methods: We developed an extensive self-reporting electronic-survey (COVAD survey) featuring 36 questions to collect respondent demographics, SAID details, COVID-19 infection history, COVID-19 vaccination details, 7-day post vaccination adverse events and patient reported outcome measures using the PROMIS tool. After pilot testing, validation, translation into 18 languages on the online platform surveymonkey.com, and vetting by international experts, the COVAD survey was circulated in early 2021 by a multicenter study group of >110 collaborators in 94 countries. BI was defined as COVID-19 infection occurring more than 2 weeks after receiving 1st or 2nd dose of a COVID-19 vaccine. We analyzed data from the baseline survey for descriptive and intergroup comparative statistics based on data distribution and variable type.

Results: 10900 respondents [mean age 42 (30-55) years, 74% females and 45% Caucasians] were analyzed. 1,227 (11.2%) had IIM, 4,640 (42.6%) had other SAIDs, and 5,033 (46.2%) were HC. All respondents included in the final analysis had received a single dose of the vaccine and 69% had received 2 primary doses. Pfizer (39.8%) was the most common vaccine received, followed by Oxford/AstraZeneca (13.4%), and Covishield (10.9%). IIM patients were older, had a higher Caucasian representation and higher Pfizer uptake than other SAIDs, and HC. A higher proportion of IIM patients received immunosuppressants than other SAIDs.

IIMs were at a lower risk of symptomatic pre-vaccination COVID-19 infection compared to SAIDs [multivariate OR 0.6 (0.4-0.8)] and HCs [multivariate OR 0.39 (0.28-0.54)], yet at a higher risk of hospitalization due to COVID-19 compared to SAIDs [univariate OR 2.3 (1.2-3.5)] and HCs [multivariate OR 2.5 (1.1-5.8)]. BIs were very uncommon in IIM patients, with only 17 (1.4%) reporting BI. IIM patients were at a higher risk of contracting COVID-19 prior to vaccination than ≤2 weeks of vaccination [univariate OR 8 (4.1-15)] or BI [univariate OR 4.6 (2.7-8.0)]. BIs were equally severe compared to when they occurred prior to vaccination in IIMs, and were comparable between IIM, SAIDs, and HC (Figure 1), though BI disease duration was shorter in IIMs than SAIDs (7 vs 11 days, p 0.027). 13/17 IIM patients with BI were on immunosuppressants.

Conclusion: IIM patients experienced COVID-19 infection less frequently prior to vaccination but were at a higher risk of hospitalization and requirement for oxygen therapy compared with patients with HC. Breakthrough COVID-19 infections were rare (1.4%) in vaccinated IIM patients, and were similar to HC and SAIDs, except for shorter disease duration in IIM.

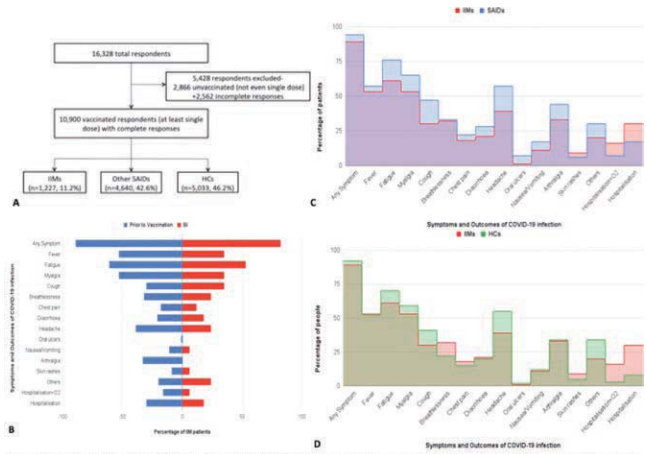

Figure 1. A. Flow diagram of study participants. B. Symptomology of COVID-19 infection in IIM prior to vaccination compared to BI. C. Symptomology of COVID-19 infection prior to vaccination in IIMs compared to other SAIDs. D. Symptomology prior to vaccination in IIMs compared to other HCs. IIMs: Idiopathic Inflammatory myopathies, SAIDs: systemic autoimmune inflammatory diseases, HCs: Healthy controls, BI: vaccine breakthrough COVID-19 infection

Acknowledgements: The authors thank all members of the COVAD study group for their invaluable role in the collection of data. The authors thank all respondents for filling the questionnaire. The authors thank The Myositis Association, Myositis India, Myositis UK, the Myositis Global Network, Cure JM, Cure IBM, Sjögren's India Foundation, EULAR PARE, and various other patient support groups and organizations for their invaluable contribution in the dissemination of this survey among patients which made the data collection possible. The authors also thank all members of the COVAD study group.

Background: A major concern across rheumatology in recent years is how contracting COVID-19 may impact the control of rheumatic diseases.
Objectives: To quantify any difference in rheumatic disease control between those who did and did not contract COVID-19 between March and December 2020 and whether rheumatic disease control changed after COVID-19 was contracted.
Methods: Adults with rheumatic diseases recruited to the COVID-19 European Patient Registry, a patient-led, online, self-referred prospective cohort recruiting participants from around the globe, were included if enrolled between March and December 2020. Rheumatic disease control was self-reported weekly on a scale of 0 (very poor) to 10 (very well). Dates of contracting COVID-19 were self-reported.
Differences in rheumatic disease control trends between those who did and did not contract COVID-19 over the study period were tested via multilevel linear regression. Within those who contracted COVID-19, differences in rheumatic disease control trends were tested via segmented multilevel, multivariable linear regression, adjusting for month of COVID-19 contraction and with the interruption point set at the point of COVID-19 contraction.
Results: Of 3646 adults with rheumatic diseases, the majority were female (89%), most commonly from the UK (82%) and the most common rheumatic disease diagnosis was RA (63%). Between March and December 2020, 3% of the cohort contracted COVID-19 (n=103).
Over the study period, rheumatic disease control for adults who did not contract COVID-19 decreased weekly by 0.01 points (95% CI 0.01, 0.02, p<0.001). In those who contracted COVID-19, rheumatic disease control decreased weekly by 0.03 points (95% CI 0.2, 0.05, p<0.001), with a significant weekly difference of 0.86 points between groups (95% CI 0.28, 1.44, p=0.004) (Figure 1a).
Within those that contracted COVID-19, there were significant differences in rheumatic disease control trends before and after contracting COVID-19 (p=0.001). In the run up to contracting COVID-19, rheumatic disease control significantly decreased weekly by 0.03 points (95% CI 0.02, 0.04, p<0.001), dropped significantly by 0.53 points (95% CI 0.23, 0.83, p=0.001) at the point of COVID contraction and then stabilised with no further reductions or improvement in rheumatic disease control for the remainder of follow-up (p=0.831) (Figure 1b).
Conclusion: People who contracted COVID-19 had initial decreases in rheumatic disease control before contracting the virus, after which their disease control stabilised at a lower level. Those with disease flares should consider increased screening for COVID-19 and COVID-19 mitigation measures. The stabilising lower disease control post-COVID is concerning and should prompt further work into restoring disease control pre-COVID-19 levels.

PREDICTIVE SEVERITY FACTORS OF COVID-19 IN PATIENTS WITH RHEUMATIC IMMUNE MEDIATED DISEASES

D. Martínez-López[1], I. Ferraz-Amaro[2], D. Prieto-Peña[1], F. Benavides-Villanueva[1], C. Corrales-Selaya[1], L. Sanchez-Bilbao[1], A. Herrero-Morant[1], C. Álvarez-Reguera[1], M. Trigueros-Vazquez[1], M. A. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain; [2]Hospital Universitario de Canarias, Rheumatology, Santa Cruz de Tenerife, Spain*

Background: COVID-19 has become a common disease in patients with rheumatic immune-mediated diseases (R-IMID). A risk stratification of the patients at COVID-19 onset is important to predict possible unfavorable results.

Objectives: To identify predictive severity factors in patients with COVID-19 with R-IMID.

Methods: Cross-sectional study in a single University Hospital. We included all consecutive patients with a R-IMID and COVID-19 up to November 6th, 2020. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2.

COVID-19 case severity was divided into mild, moderate, severe and critical according to the United States National Institute of Health (NIH) COVID-19 guidelines **(1).**

We performed a multivariable analysis and calculated de odds ratio of critical COVID in patients with R-IMID, adjusting by age, sex and comorbidities.

Results: We included 274 patients with R-IMID complicated with COVID-19. At COVID-19 onset, the main comorbidities, analytical values, underlying R-IMID and treatments received are shown in Table 1.

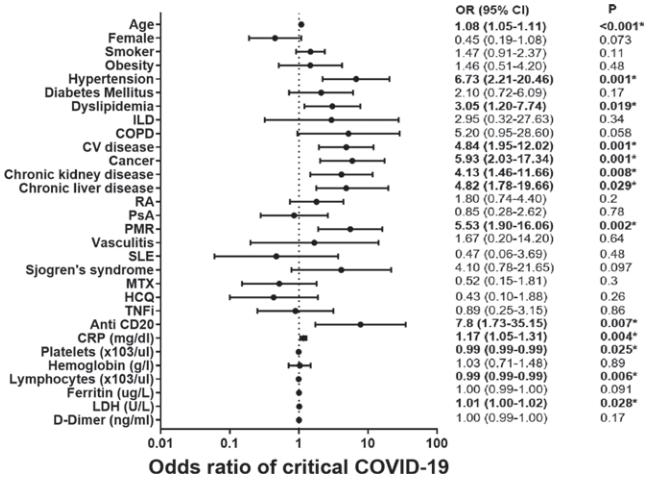

Figure 1. Predictive factors for critical COVID-19 in R-IMID (Multivariable analysis)COPD: Chronic obstructive pulmonary disease; CRP: C-reactive protein; CV: Cardiovascular; HCQ: Hydroxychloroquine; ILD: Interstitial lung disease; LDH: Lactate dehydrogenase; MTX: Methotrexate; PsA: Psoriatic arthritis; RA: Rheumatoid arthritis; SLE: Systemic lupus erythematosus; TNFi: TNF inhibitors. *p< 0.005Data in graphic are presented in a logarithmic scale.

According to COVID-19 severity, patients were mild (n=209; 76.3%), moderate (n=35; 12.8%), severe (n=9; 3.3%) and critical (n=21; 7.7%).

The predictive variables at COVID-19 onset related statistically to critical COVID were older patients, hypertension, dyslipidemia, previous cardiovascular disease, cancer, chronic kidney disease, and chronic liver disease. The only underlying R-IMID and treatment was polymyalgia rheumatica and Rituximab, respectively. Regarding analytical values were higher values of C-reactive protein, LDH, platelets and lymphopenia (Figure 1).

Conclusion: We identified various factors associated with a worse prognosis of COVID-19 in patients with R-IMID. This can help to identify which patients can present a worse course of the disease at the moment of the diagnosis.

RETROSPECTIVE STUDY OF THE COVID-19 COURSE IN CHILDREN WITH RHEUMATIC DISEASES: SINGLE CENTER EXPERIENCE

Z. Kolkhidova[1], I. Nikishina[1], V. Matkava[1], A. Shapovalenko[1], S. Arsenyeva[1], M. Kaleda[1], S. Salugina[1], E. Fedorov[1], T. Pachkoria[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: The study of the features of the course and mutual influence of the new coronavirus disease COVID-19 and various rheumatic diseases (RD) in children can still give us new lessons, warnings and fears.

Objectives: To update the analysis in a retrospective study the course of covid-19 in children with RD based on the results of two years of the pandemic. To analyze the impact of COVID-19 on the course of RD in children.

Methods: Retrospective analysis based on data from single center. The study included patients with RD and confirmed COVID-19 for 2 years (2020-2021).

Results: Were registered 320 cases of COVID-19 in children with RD. 158 (49%) patients were asymptomatically infected, 162 (51%) had clinical symptoms. A detailed description of the groups is presented in Table 1. Clinical symptoms were fever (67%), anosmia (47%), rhinitis (34%), cough (19%), arthralgia/myalgia (16%), dyspepsia (5%), rash (2.5%), pneumonia (3%). In the majority of cases (98%), COVID-19 proceeded in mild to moderate severity. Hospitalization due to COVID-19 was required just in 5 cases. 2 children were admitted to the intensive care unit. First, an 11-year-old girl with sJIA with the history of recurrent episodes of MAS resolved by regular administration of canakinumab. 2nd, a 12-year-old girl with Sjogren's syndrome, who received

*- p<0,05

Rituximab and 1 month later she developed the COVID-19 with MIS-like clinical picture, pneumonia with 25%CT lessions. Both cases have a favorable outcome.

The clinical characteristics of the patients are presented in Table 1. COVID-19 didn`t affect the course of RD in the 86% of pts. However, 15% developed a flare of the RD with average of 3 months after COVID-19. In this group for 13 pts (girls mostly F/M-9/4, mean age 15 years [9;16]), COVID-19 triggered the new onset of RD (non-systemic JIA – 4, Uveitis – 1, non-bacterial osteomyelitis – 3, systemic JIA – 2, Scleroderma – 2, Sjögren's syndrome – 1. 12 from 13 these children had clinical symptoms on COVID-19. Whether this is Long-COVID syndrome or an independent RD is not known.

Conclusion: Our study suggests that the new coronavirus infection in most cases in children with RD, had mild or asymptomatic course, regardless of therapy with immunosuppressive drugs and bDMARD, except of 1 observation with the previous therapy of Rituximab. Worsening of RD after coronavirus infection developed in 15% of cases, regardless of its clinical manifestations. In 13 patients, the RD were started just after COVID-19. The explosive increasing of the incidence of a new strain of COVID-19 for a past month may change the current results and conclusions.

Background: Nintedanib slows the progression of fibrosing ILDs, with a safety profile characterised predominantly by gastrointestinal events.
Objectives: Assess the safety and tolerability of nintedanib in patients with autoimmune disease-related ILDs by sex and age.
Methods: The SENSCIS trial was conducted in patients with ILD associated with systemic sclerosis. The INBUILD trial was conducted in patients with progressive fibrosing ILDs other than idiopathic pulmonary fibrosis. Patients were randomised to receive nintedanib 150 mg bid or placebo. Dose reductions to 100 mg bid and treatment interruptions were permitted to manage adverse events (AEs). Data from all patients in SENSCIS and patients with autoimmune disease-related ILDs in INBUILD were pooled. In subgroups based on sex and age (<65 and ≥65 years) at baseline, we analysed AEs, irrespective of causality, over 52 weeks.
Results: Among 746 patients; 70.1% were female; 29.1% were aged ≥65 years. Mean (SD) exposure to nintedanib or placebo was 10.8 (3.2) and 11.1 (2.9) months in females and males, and 11.0 (3.0) and 10.6 (3.5) months in

Table 1. Adverse events in patients with autoimmune disease-related ILDs in the SENSCIS and INBUILD trials in subgroups by sex and age at baseline.

Serious adverse event(s)	57 (21.3)	53 (20.8)	40 (39.2)	37 (30.6)	63 (23.6)	54 (20.6)	34 (33.0)	36 (31.6)

n (%) of patients with ≥1 such adverse event over 52 weeks. Adverse events were coded based on preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA), except for liver-related investigations, signs and symptoms, which was based on a standardised MedDRA query. *Adverse events reported in >10% of patients with autoimmune disease-related ILDs in the nintedanib or placebo group.

patients aged <65 and ≥65 years, respectively. The AE profile of nintedanib was similar between males and females, but nausea, vomiting, hepatic adverse events and dose reductions were more frequent in females. The AE profile of nintedanib was similar between patients aged <65 and ≥65 years, but nausea, decreased appetite, and weight loss were more frequent in patients aged ≥65 years. AEs leading to treatment discontinuation were more frequent in patients aged ≥65 years in both treatment groups. Serious AEs were more frequent in males and in patients aged ≥65 years in both treatment groups.

Conclusion: In patients with autoimmune-disease related ILDs, the AE profile of nintedanib in subgroups by sex and age was generally consistent with the known safety profile, but certain types of AE and dose reductions were more frequent in female patients, while serious AEs were more common in male patients.

POS0206 EVALUATION OF SALIVARY GLANDS ULTRASOUND IN THE FRENCH RHEUMATOID ARTHRITIS COHORT BCD

R. Rabault[1], A. Saraux[1], E. Courtois Communier[2], D. Guellec[1], T. Marhadour[1], D. Cornec[1], C. Houssais[1], A. Tison[1], P. Kervarrec[1], A. Roudaut[1], J. Allain[1], V. De Saint Pierre[1], G. Carvajal Alegria[3], V. Devauchelle-Pensec[1], S. Jousse-Joulin[4]. *[1]Hospital La Cavale Blanche, Rheumatology Departement, Brest, France; [2]Hospital La Cavale Blanche, Scientific Data Departement, Brest, France; [3]CHU Tours, Rheumatology, Tours, France; [4]Hospital La Cavale Blanche, Rheumatology, Ultrasound Unit, Brest, France*

Background: The prevalence of salivary glands ultrasound (SGUS) abnormalities in Sjögren's syndrom (SS) is well described[(2)]. However, the prevalence is still unknown in rheumatic inflammatory conditions such as rheumatoid arthritis (RA).

Objectives: The main objective of this study was to describe the prevalence of SGUS parenchymal structural abnormalites in patients with RA. Secondary objectives were: i) to study correlation between disease duration and the SGUS OMERACT score and ii) to study correlation between duration of sicca syndrome and the SGUS OMERACT score.

Methods: 561 patients with RA satisfying ACR/EULAR 2010 classification criterias were included in 10 french centers in the prospective cohort BCD, comparing joint ultrasonography to clinical follow-up. Cross sectionnal SGUS examination (parotid and submandibular) was performed in a substudy of this cohort. The new OMERACT-SGUS scoring system[(1)] was used and clinical, biological, immunological and radiological data were collected.

Results: 100 patients agreed to be included in this substudy of BCD cohort, and a total of 98 SGUS patients data were evaluated (lack of SGUS data for 2 patients). Most patients were women (81%), mean age 59 years, with time from RA diagnosis of 11 years on average. The mean CRP-DAS-28 at baseline was at 3.2 with a third of patients in remission at inclusion. Anti-CCP antibodies or RF was positive in 92 patients (92%). 27 patients (27%) complained of eye dryness and 20 (20%) of mouth dryness. 12 (12%) suffered from both. The levels of self-reported fatigue was higher than in the general group of RA included in the study. Two thirds of patients benefited from csDMARD, with a third treated with bDMARDS. 33 (33%) also benefited from a corticosteroid treatment. Among 98 patients, 22 (22.5%) had at least one salivary gland scored grade 1 or more, this number was reduced to 18 patients (18.4%) when considering only the parotid glands. 7 patients (7.1%) had at least one salivary gland scored grade 2 or more, with a number reduced to 4 patients (4.1%) when considering only the parotids. Only one patient (1%) had a parotid gland scored 3. In the 7 patients presenting significant abnormalities in SGUS (grade 2 or more), 5 patients had either dry eye or dry mouth symptoms (71,4%).

Conclusion: Our findings suggest that 7% of RA patients present significant SGUS abnormalities according to OMERACT scoring system, associated with clinical sicca syndrome in 71% of cases. There was no significant association between the duration of rheumatoid arthritis and the OMERACT score (Spearman coefficient for correlation -0,028, p = 0,99). There was also no significant association found between the duration of sicca symptoms and the OMERACT score (Spearman coefficient for correlation 0,025, p = 0,89). This study highlights the importance of SGUS assessment in RA sicca patients to improve monitoring and follow-up in routine clinical practice.

POS0207 UNRAVELING THE COMPLEX INTERACTION BETWEEN DISEASE ACTIVITY AND FATIGUE IN EARLY RA: A MEDIATION ANALYSIS WITH DATA FROM THE CARERA TRIAL

M. Doumen[1,2], S. Pazmino[1], D. Bertrand[1], D. De Cock[1,3], J. Joly[2], R. Westhovens[1,2], P. Verschueren[1,2]. *[1]KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; [2]University Hospitals Leuven, Rheumatology, Leuven, Belgium; [3]KU Leuven, Laboratory of Clinical and Experimental Endocrinology, Leuven, Belgium*

Background: Fatigue is recognized as one of the most important symptoms of rheumatoid arthritis (RA). Although inflammation is often proposed as the predominant pathophysiological mechanism, many patients with RA continue to experience fatigue despite inflammatory disease control. The relationship between RA disease activity and fatigue appears to be complex and is likely confounded by cognitive, emotional and social aspects.

Objectives: To unravel the complex interaction between disease activity and fatigue in early RA.
Methods: Data were analyzed from the 2-year treat-to-target trial Care in early RA (CareRA), which compared different remission-induction DMARD regimens, either with or without bridging glucocorticoids, in treatment-naïve patients with early RA. Fatigue was measured on a visual analog scale (VAS) at every study visit. The association between inflammatory disease activity (DAS28-CRP) and fatigue (VAS) over time was studied with a multilevel mediation analysis, including as mediators the individual components of the DAS28-CRP, pain (VAS), disability (HAQ), psychosocial aspects (Short-Form 36 [SF-36]), illness perceptions (Revised Illness Perception Questionnaire [IPQ-R]), and sleep quality (Pittsburgh Sleep Quality Index [PSQI]).
Results: A total of 356 patients were included in these analyses, with a mean (SD) fatigue (VAS) of 48/100 (24) at study initiation. Although there was a consistently positive association between DAS28-CRP and fatigue over time, this association was fully mediated by patient global assessment (PGA) and pain, and to a lesser extent by SF-36 Mental Health and the PSQI global score (Figure 1). Full mediation implies the absence of a significant direct association between DAS28-CRP and fatigue after adjusting for these mediators. In addition, no mediating effect was found for tender/swollen joint counts or CRP.

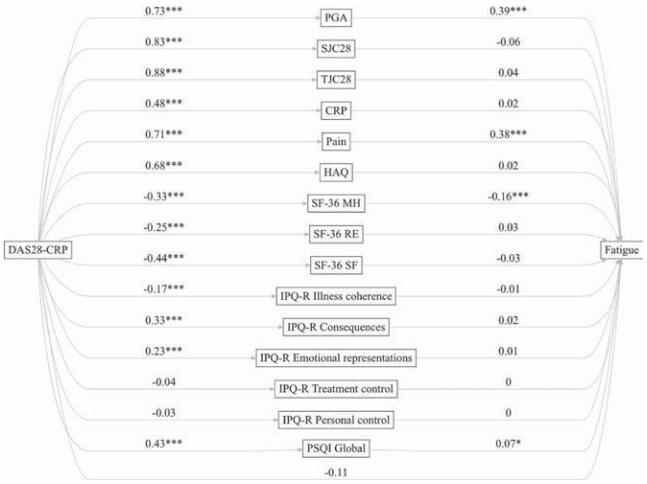

Figure 1. Mediation analysis of the association between DAS28-CRP and fatigue (VAS) over time.Reported are the standardized regression coefficients with indicators of significance (* $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$). *DAS28-CRP = Disease Activity Score in 28 joints with C-reactive protein, SJC28/TJC28 = swollen/tender joint count in 28 joints, HAQ = Health Assessment Questionnaire, SF-36 = Short-Form 36, MH = mental health, RE = emotional role functioning, SF = social functioning, IPQ-R = Revised Illness Perception Questionnaire, PSQI = Pittsburgh Sleep Quality Index*

Conclusion: Our mediation analysis suggests that the relationship between disease activity and fatigue in early RA is complex and fully mediated by aspects of wellbeing like pain, mental health, sleep quality, and the patient's overall assessment of disease. These results imply a mainly indirect relation between fatigue and inflammation. Clinicians should reserve specific attention for the psychosocial determinants of fatigue, particularly when no improvement is seen with DMARDs.

STRESS AT HOME IS COMMON AND HAS SIGNIFICANT ASSOCIATION WITH MARITAL STATUS, HIGHER DISEASE ACTIVITY, COMORBIDITIES, AND WORSE QUALITY OF LIFE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: SINGLE CENTRE RESULTS FROM THE PRIME REGISTRY COHORT

M. Haroon[1], S. Asif[1], S. Ullah[1], F. Hashmi[1], S. Javed[1]. [1]*Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*

Background: In chronic inflammatory diseases like rheumatoid arthritis (RA), psychological stress is widely recognised as an important risk factor to negatively affect the disease course. Perceived stress can potentially induce the disease exacerbation, but on the other hand, the disease itself might produce significant stress to patients thus the vicious circle is formed and maintained.
Objectives: We aimed to examine the prevalence of mental/emotional stress at home and its associations among patients with Rheumatoid arthritis. We addressed this question using real-world data from the PRIME registry.
Methods: This was a cross-sectional study conducted using data collected at the time of patient enrolment in the PRIME registry. The PRIME Registry is a large, independent, prospective, observational cohort initiated in October 2019 that comprises patients diagnosed with RA, SLE, PsA or AS by a rheumatologist, and is being actively followed up. IRB approval and informed consent was obtained. We assessed the data for RA patients. The clinical variables studied were gender, age, smoking habits, body mass index, education status, marital status, disease duration, comorbidities (using Charlson Comorbidity Index). Education status was stratified by whether participants completed secondary (high) school education. The SF-12 Physical Component Score (PCS-12) and Mental Component Score (MCS-12) was also measured. Evaluation of disease activity and severity was made as per internationally agreed definitions, such as: swollen joint counts, tender joint counts, deformed joint counts, and DAS-28. All participants were directly inquired at the interview during the time of patient enrolment about the presence or otherwise of mental/emotional stress at home, and to rate it from 1-3 (mild, moderate, severe). For better understanding and ease of statistical analysis, dichotomous variable was made with moderate-to-severe stress patients were categorised into one group and none-to-mild stress patients into second group.
Results: The data from consecutive 1016 RA patients (mean age 40.8±13 years, 78.6% female, disease duration of 65±67 months) was reviewed. Forty-nine percent of patients accepted to have moderate-severe stress at home. Female gender (p=0.003), low education status (p=0.050), being unmarried (p=0.051), and MCS, PCS, CCI (p<0.001) were associated with moderate-severe stress. However, no statistical association of age and disease duration was noted. On univariate analysis, significant association of moderate-severe stress at home was noted with deformed joint counts (p=0.003), higher DAS-28 scores (p<0.001), low education status (p=0.02) and being married (p<0.001). Weak statistical association of age (p=0.30), disease duration (p=0.12), low education status (p=0.14), female gender (p=0.24) was noted. On multiple logistic regression analysis, a significant association of moderate-severe stress at home was observed with higher DAS-28 scores (OR 2.38, CI 2.00-2.84, p<0.001), MCS-12 (OR 0.65, CI 0.61-0.69, p<0.001), comorbidities-CCI (OR 1.41, CI 1.15-1.74, p=0.001) and being unmarried (OR 0.55, CI 0.36-0.83, p=0.005). The final regression model resulted in a statistically significant improved association/prediction of worse moderate-severe stress at home (R square=71%). Following variables were included in multiple stepwise regression analysis: age, disease duration, gender, education status, marital status, comorbidities index, major trauma/stress in last one year, DAS-28, MCS-12 and PCS-12 scores.
Conclusion: Nearly half of the cohort was noted to have moderate-severe level of stress at home, and is associated with important adverse clinical outcomes. These findings demonstrate an important need for integration of rheumatologic, social workers and mental health services

POS0209

CLINICAL AND DIAGNOSTIC SIGNIFICANCE OF INTIMA-MEDIA THICKNESS, LEVELS OF SOLUBLE CELL ADHESION MOLECULES AND CD40 LIGAND IN RHEUMATOID ARTHRITIS PATIENTS WITH LOW CARDIOVASCULAR RISK

E. Gerasimova[1], T. Popkova[1], D. Gerasimova[2], E. Nasonov[1].
[1]V.A.Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Disease, Moscow, Russian Federation; [2]I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Organization and Economics of Pharmacy, Moscow, Russian Federation

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease leading to significant increase in cardiovascular morbidity and mortality. Development of atherosclerotic lesions of the carotid arteries in RA patients is associated with the accumulation of traditional risk factors and immunological disorders.
Objectives: To evaluate the detection rate of subclinical carotid atherosclerosis and clinical significance of immunoinflammatory markers in RA patients with low cardiovascular risk (CVR) in comparison with the control group.
Methods: The study included 275 RA patients (with low CVR and no established cardiovascular diseases) and a control group comprising 100 people without autoimmune diseases. The groups were comparable in terms of sex, age, traditional risk factors, and CVR value. CVR was calculated using the QRISK3 scale. All study participants had a low CVR (QRISK3<20%). All patients and control group members undertook carotid duplex ultrasonography. Atherosclerotic lesions of the carotid arteries are assessed by the detection of of atherosclerotic plaque (ASP) - the cause of IMT ≥ 1.2 mm. Concentration of sICAM-1, sVCAM, and sCD40L in blood serum was determined by enzyme immunoassay using reagent kits and according to Bender MedSystems protocols (USA).
Results: Carotid ASP were observed more frequently in RA patients (27%) with low CVR than in the control group (17%), p=0.03. ASP were detected more frequently in men with RA than in women with RA (50% versus 24%, p<0.01). The frequency of ASP in RA patients with low CVR did not depend on the disease's stage or activity.
In RA patients, there was a significant correlation between carotid IMT and age (R=0,48), CVR value determined by QRISK3 (R=0,36), level of total cholesterol (R=0,28), LDL cholesterol (R=0,18), systolic blood pressure (R=0,37), diastolic blood pressure (R=0,38), p<0,05 in all cases. No correlation between carotid IMT and blood concentrations of sCD40L, sVCAM, and sIACAM was found in RA patients or controls.
A higher concentration of sVCAM was detected in RA patients compared with the control group (1520 [945; 1915] ng/mL versus 790 [605; 1307] ng/mL, p=0.01); and in RA patients with carotid ASP compared with patients without carotid ASP (1680 [1460; 3350] ng/mL versus 1210 [865; 1810] ng/mL, p=0.01).
In RA patients with carotid ASP, sCD40L level was associated with carotid IMT (R=0.40, p=0.04) and cholesterol concentration (R=0.38, p=0.01). In RA patients without ASP, sCD40L level was associated with cholesterol concentration (R=0.41, p=0.02) and diastolic blood pressure level (R=0.3, p=0.04).
Conclusion: Subclinical atherosclerotic lesions of the carotid arteries were observed in a quarter of RA patients with low CVR and were detected at a significantly more frequent rate compared to the control group. The evaluation of carotid IMT is recommended for RA patients with low CVD. These results suggest that there is an association between carotid IMT and traditional CVR factors and immunoinflammatory markers in RA patients.

A PREDOMINANT NON-SPECIFIC INTERSTITIAL PNEUMONIA PATTERN AND ABERRANT TRANSCRIPTOMIC NEUTROPHIL-MEDIATED IMMUNITY CHARACTERIZE A CONTEMPORARY RA-ILD COHORT

S. Flouda[1,2], A. Grivas[1,2], N. Kapsala[1,2], M. Grigoriou[2], D. Nikolopoulos[2], A. Filia[2], G. Sentis[2], K. Chavatza[1], M. Aggelakos[1], G. S. Moysidou[1], M. Kosmetatou[1], D. Tseronis[1], P. Katsimpri[1], T. Karageorgas[1], A. Fanouriakis[1], D. Boumpas[1,2]. *[1]National and Kapodistrian University of Athens, 4th Department of Internal Medicine, Attikon University Hospital, CHAIDARI, Greece; [2]Biomedical Research Foundation of the Academy of Athens (BRFAA), Laboratory of Autoimmunity and Inflammation, Athens, Greece*

Background: Lung involvement is the most common extra-articular manifestation. Rheumatoid arthritis related interstitial lung disease (RA-ILD) comprises a heterogeneous group of parenchymal lung disorders classified by distinct clinical, pathologic, and radiographic features. According to the current paradigm, circulating immune complexes and aberrant neutrophil extracellular trap formation (NETosis) contribute to disease pathogenesis.
Objectives: To characterize the pattern of lung disease in "Attikon" RA-ILD cohort and develop insights about the pathophysiologic mechanisms via whole blood RNA sequencing.
Methods: Retrospective and prospective study to identify clinical, laboratory and radiologic characteristics of patients with RA and pulmonary manifestations in the "Attikon" RA-ILD cohort. Changes in pulmonary function tests (PFTs), pattern of lung involvement (chest HRCT), disease activity (DAS28-ESR) and incidence of complications and comorbidities, were prospectively analyzed during the one-year follow-up period. Peripheral blood was collected in a subset of RA-ILD (n=11) and control RA patients (n=9) for RNA isolation and RNA sequencing. The gene expression profile of RA-ILD was inferred through differential gene expression analysis, followed by pathway and enrichment analyses.
Results: 114 patients with RA-ILD were included [67% female, mean (SD) age at diagnosis 71.5 (9) years, 58% seropositive]. Non-specific interstitial pneumonia (NSIP) was the radiologic pattern most frequently observed (52%), followed by usual interstitial pneumonia (UIP) (24%). RA was diagnosed after ILD in 40% of patients. Mean (SD) FVC and DLCOsb at baseline was 80.5 (19.2) and 55.4 (19.5), respectively. Disease activity was lower in seropositive compared to seronegative both at baseline and at 1-year follow-up (p=0.025). PFTs at 12 months from baseline had been stabilized. Respiratory infections were observed in 17.6% of patients during the first year of follow-up, more common in the NSIP vs UIP group (p=0.01), possibly due to the higher doses of glucocorticoids in NSIP patients. RNA-sequencing analysis revealed a distinct gene expression profile in RA-ILD, characterized by the activation of type I interferon response, neutrophil activation and degranulation, and CCR1 chemokine interactions.
Conclusion: NSIP is the most frequent pattern of ILD in this RA-ILD cohort, carrying a higher risk for respiratory infections probably related to higher doses of glucocorticoid used. Myeloid cells' migration via CCR1 and the formation of pro-inflammatory and pro-fibrotic NETs by activated neutrophils may contribute to RA-ILD pathogenesis.

ASSOCIATION BETWEEN CARDIOVASCULAR OUTCOME AND RHEUMATOID ARTHRITIS: NATIONWIDE POPULATION-BASED COHORT STUDY

S. Kang[1], K. D. Han[2], S. Lee[1], Y. Eun[1], H. S. Cha[1], E. M. Koh[1], J. Lee[1], H. Kim[1]. *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); [2]Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)*

Background: Many studies have shown increased risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA). Despite a growing burden posed by CVD in RA patients, large scale studies which examined the association between characteristic of RA patients and CVD risks, and studies which adjusted for various confounding factors are lacking.
Objectives: This study aimed to investigate the association between CVD risk and RA in large-scale, nationwide cohort of Korean population, and to examine which characteristics of RA patients are associated with increased CVD risk.
Methods: We enrolled 136,469 patients with RA who participated in national health examinations within 2 years of RA diagnosis between 2010 and 2017 and non-RA controls matched by age and sex (n= 682,345). The cohort was followed until the end of 2019. The outcome was occurrence of myocardial infarction (MI) or stroke. MI was defined as one hospitalization or two outpatient visit with ICD-10-CM codes I21 or I22. Stroke was defined as one hospitalization with ICD-10-CM codes I63 or I64 and a claim for brain imaging (CT or MRI). The Cox proportional hazard model and Kaplan Meier curve were used for the analysis.
Results: Mean follow up duration was 4.7 years. The incidence rate of CVD was higher in RA group than control (MI: 3.20 vs 2.08; stroke: 2.84 vs 2.33 per 1,000 person-years). The risk of CVD was higher in RA patients. (MI: adjusted HR 1.54, 95% CI 1.46-1.61; Stroke: adjusted HR 1.22, 95% CI 1.16-1.28). The association between RA and CVD was prominent in female (MI: adjusted HR 1.41 in male, 1.60 in female, *p* for interaction = 0.0293; Stroke: adjusted HR 1.13 in male, 1.27 in female, *p* for interaction = 0.03) and younger-age subgroups (MI: adjusted HR 2.9 in <40 years, 1.52 in 40-64 years, 1.51 in ≥65 years, *p* for interaction<0.0001; Stroke: adjusted HR 2.35 in <40 years, 1.21 in 40-64 years, 1.21 in ≥65 years, *p* for interaction = 0.0100) after adjusting for confounding variables. The association between RA and risk of MI was significant in those without DM. (adjusted HR 1.30 in DM, 1.61 in non-DM, *p* for interaction = 0.0005)
Conclusion: RA patients had increased risk of CVD events compared to age- and sex-matched control group, and this association was stronger in female and younger-age subgroups. Therefore appropriate screening for CVD would be important in all RA patients including female and younger patients.

POS0212

THE REDUCTION OF TURICIBACTER IN GUT MICROBIOTA ASSOCIATED WITH SJOGREN'S SYNDROME SECONDARY TO RHEUMATOID ARTHRITIS

M. J. Chang[1,2,3], S. X. Zhang[2,3,4], J. Qiao[2,3,4], Q. Wang[2,3,5], R. X. Qi[1], C. Wang[1,2,3], Q. Yu[1,6], P. F. He[6]. *[1]Shanxi Medical University, School of Management Shanxi Medical University, Tai Yuan, China; [2]Shanxi Medical University, Key Laboratory of Cellular Physiology, Tai Yuan, China; [3]Shanxi Medical University, Academy of Microbial Ecology, Tai Yuan, China; [4]The Second Hospital of Shanxi Medical University, the Second Hospital of Shanxi Medical University, Tai Yuan, China; [5]Shanxi Medical University, School of Basic Medical Sciences, Tai Yuan, China; [6]Shanxi Medical University, Medical Data Sciences, Tai Yuan, China*

Background: Secondary Sjogren's syndrome(SS) is a common extra-articular manifestation of rheumatoid arthritis (RA)[1]. RA patients combined with SS have different outcomes from those without SS[2]. However, the studies investigated the characteristics of gut microbiota in patients with RA and SS is limited.
Objectives: To investigate the characteristics of gut microbiome and the associations between flora and peripheral lymphocyte subpopulations in RA patients with or without Sjogren's syndrome.
Methods: A total of 326 samples from 145 RA patients without SS, 23 RA combined with SS patients(RA-SS) and 168 healthy controls (HCs) were recruit in this study from The Second Hospital of Shanxi Medical University (Taiyuan, Shanxi, China). The gut microbiota were investigated via 16s rRNA sequencing and the peripheral T lymphocyte subsets of these participants were assessed by flow cytometry. The Wilcoxon rank-sum test was used to compare alpha diversity indicesbetween groups. Differential abundance analysis was carried out the STAMP software. Spearman's correlation analysis was used to assess the correlations between the relative abundances of bacterial genera and clinical meatures.

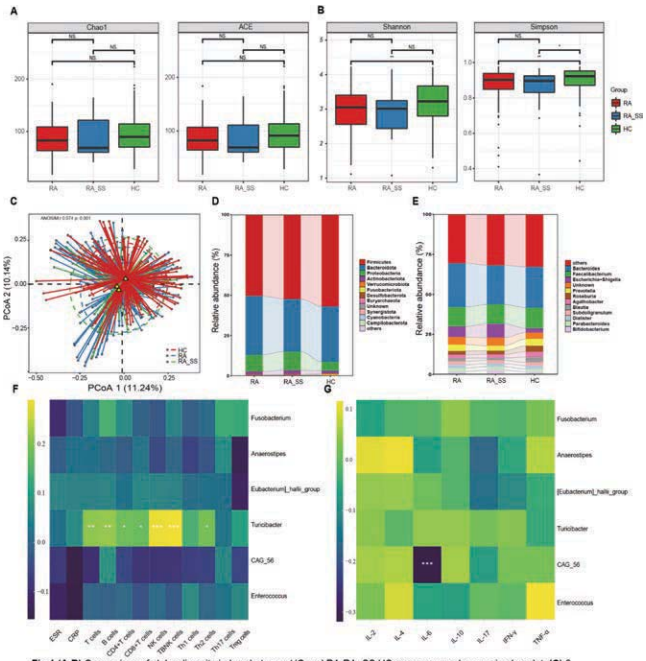

Fig 1 (A-B) Comparison of alpha-diversity indexs between HC and RA,RA_SS,HCs groups was shown using boxplot. **(C)** β diversity of the gut microbiome in RA,RA_SS patients and HCs.**(D-E)** Distribution of gut microbiota at phylum and genus level in RA,RA_SS,HCs.**(F-G)** Relationship between gut microbiota, and Lymphocyte subsets as well as cytokines. the correlation effect is indicated by a color gradient from green (positive correlation) to purple (negative correlation). *p<0.05 **p<0.01 ***p<0.001

Results: Patients with RA and RA-SS exhibited a significant reduction in the richness and diversity of gut microbiota compared with those of HCs (Figure 1 A-B, p < 0.05), whereas there was no significant difference between RA and RA-SS patients. Principal co-ordinates analyses based on bray curtis distance suggested that these there microbiota states explained a definable proportion of observed variance in microbiota composition (ANOSIM R2 = 0.074, p < 0.001; Figure 1 C). Compared with HCs, 58 species of flora were discovered to be distinctly different in RA patients without SS at the genus level of which 6 species of flora unique to RA-SS patients were presented much fewer ([Eubacterium]_hallii_group, Anaerostipes, CAG-56, Fusobacterium, Turicibacter and Enterococcus). Among these RA-SS patients' unique species of flora, it seems that Turicibacter is the key species of flora, owing to whose has a positive correlation with most of lymphocytes such as T, B, CD4+T, CD8+T and NK cells suggesting a close association with intestinal immunity.(Figure 1 F-G,P<0.05)
Conclusion: RA patients with deficiency of Turicibacter in flora had higer occurrence of Sjögren's syndrome sjogren's syndrome complication, which was correlated with peripherial lymphocyte subpopulations and cytokines.

POS0213

EFFECT OF EARLY ETANERCEPT TREATMENT ON CIRCULATING LIPOPROTEINS DIFFERS TO TREATMENT WITH METHOTREXATE AND IS MODULATED BY CLINICAL DISEASE ACTIVITY

R. Shukla[1,2], A. Burska[3], P. Emery[3,4], D. Plant[1,2], M. H. Buch[1,2,3]. *[1]University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, NIHR Biomedical Research Centre, Manchester, United Kingdom; [3]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [4]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: A reduction in serum lipids such as total cholesterol (TC) and low-density lipoprotein (LDL) has been associated with increased risk of cardiovascular events in active RA, paradoxical to the general population[1]. The effect of DMARDs and active inflammation on lipid profiles has been investigated in RA

but detailed lipid profiling has been lacking in very early disease and across the spectrum of disease activity.

Objectives: In a treatment naïve early RA trial cohort, we sought to compare circulating lipid profiles between patients treated with first line etanercept + methotrexate (ETN+MTX) versus methotrexate treat-to-target (MTX-TT) regime and between clinical remission and high disease activity.

Methods: VEDERA trial (Very early Etanercept and Methotrexate versus Methotrexate with/without Delayed Etanercept in RA) randomised 120 treatment-naïve RA patients to either first-line ETN+MTX or MTX-TT regime with escalation to ETN+MTX if not in DAS28ESR remission at week 24[2]. TC, triglycerides (TG), high density lipoprotein (HDL) and LDL were measured; apolipoproteins and atherogenic indices such as TC/HDL, atherogenic index of plasma (AIP) and apolipoprotein B/A-i ratio (aporatio) were calculated at baseline, weeks 12, 24 and 48. Linear mixed effects regression was used to test the effect of treatment on lipids and atherogenic indices in states of remission (DAS28-ESR ≤ 2.6) and high disease activity (DAS28-ESR > 5.1).

Results: Baseline clinical characteristics of individuals[1] and lipid profiles including atherogenic indices were comparable between the two treatment groups (Table 1).

Table 1. Baseline lipids (mmol/L) and atherogenic indices in VEDERA. Median with interquartile range and n/N (%) reported.

	Total, N = 120	MTX_TT, N = 60	ETN+MTX, N = 60
TC	4.69 (4.03,5.25)	4.70 (4.04,5.42)	4.69 (4.01,5.18)
TG	1.15 (0.90,1.41)	1.18 (0.92,1.32)	1.10 (0.89,1.55)
HDL	1.28 (1.04,1.53)	1.29 (1.04,1.57)	1.27 (1.05,1.48)
LDL	2.87 (2.22,3.27)	2.87 (2.27,3.19)	2.84 (2.01,3.29)
TC/HDL	3.53 (3.01,4.16)	3.53 (3.00,4.14)	3.58 (3.08,4.17)
AIP	-0.06 (-0.20,0.09)	-0.06 (-0.22,0.08)	-0.06 (-0.17,0.13)
Aporatio	0.63 (0.54,0.74)	0.62 (0.54,0.74)	0.64 (0.55,0.74)

In clinical remission, a lowering of atherogenic indices and TC, TG, LDL levels as well as a rise in predicted HDL levels were observed. In high disease activity, both HDL and LDL were increased along with the atherogenic indices TC/HDL-C, AIP and aporatio. However, the predicted values at different weeks did not reach statistical significance (not shown).

Treatment with MTX-TT and ETN+MTX had opposing effects on predicted HDL levels in remission and high-disease activity (Figure 1). In remission, MTX-TT treatment resulted in a predicted rise in HDL whilst with ETN+MTX a small reduction was observed (estimate 0.004, p 0.02). Similar trends were observed for HDL in high disease activity (p 0.5). In remission, both treatments resulted in a reduction in LDL (p 0.5), whilst in high disease activity ETN+MTX treatment resulted in a modest rise in LDL compared to MTX-TT (p 0.06). At weeks 24 and 48, significant differences were observed in LDL values between treatment groups in high disease activity (estimate 0.57, p 0.05 and estimate 1.13, p 0.04 respectively).

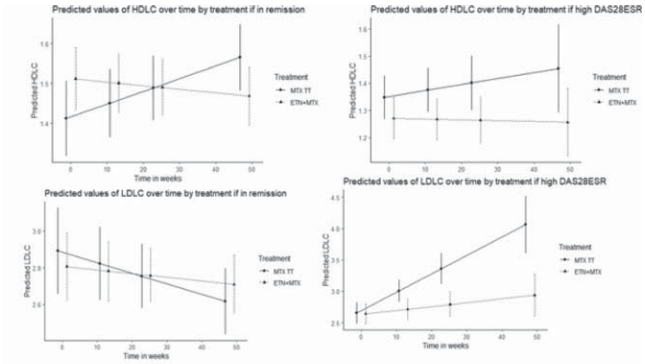

Figure 1: Predicted trends in HDL and LDL if in remission (left) vs high disease activity in MTX-TT and ETN+MTX groups

Conclusion: Effect of early ETN treatment on HDL, and to a lesser extent LDL, differs from MTX and is modulated by clinical disease activity. Further investigation is needed to understand the basis for these findings and the clinical implication of observed differences in LDL and HDL. These data may indicate direct effect of therapies on the qualitative and functional components of metabolic lipid pathway.

POS0214

CORONARY MICROVASCULAR DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS AND DIABETES MELLITUS: A CROSS-SECTIONAL STUDY WITH 13NH3 MYOCARDIAL PET/CT

B. Dijkshoorn[1], R. Knol[2], F. van der Zant[2], M. Nurmohamed[1,3], S. Simsek[4].
[1]Amsterdam Rheumatology immunology Center location Reade, Rheumatology, Amsterdam, Netherlands; [2]Northwest Clinics, Nuclear Medicine, Alkmaar, Netherlands; [3]Amsterdam University Medical Centers, Rheumatology, Amsterdam, Netherlands; [4]Northwest Clinics, Internal Medicine, Alkmaar, Netherlands

Background: Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular disease. This risk is similar to that of diabetes mellitus (DM). There have been no studies comparing the coronary microvascular dysfunction assessed with coronary flow reserve (CFR) of RA patients to both patients with DM and a control group (=patients without RA, without DM and no cardiovascular event).

Objectives: To assess the difference in coronary microvascular dysfunction in patients with RA in comparison to patients with DM and control group.

Methods: From our 13NH3 myocardial PET/CT registry we included all patients that were included from December 2013 until March 2019. A total of 33 patients with RA, 299 patients with DM and 179 control patients (=patients without RA and without DM) were analyzed. Myocardial blood flow was quantified at rest and under stress induced by administrating adenosine. Coronary flow reserve was calculated by dividing MBF under stress by MBF in rest. CFR < 2 was indicative for coronary microvascular dysfunction.

Results: The mean age of patients was 66, with more females in the RA and control group vs the DM group (67% and 69% vs 49% respectively). The total MBF, under adenosine administration, measured in RA patients was higher than DM patients albeit that this did not reach statistical significance (2.26 ± -,70 vs 2,05 ± 0,63 mL/min/g, p=0.08). When compared to controls, the MBF of RA patients was significantly lower (2,94 ± 0,44 vs 2,26 ± 0,70, p < 0.001). The coronary flow reserve (CFR) of patients with RA was similar to patients with DM (2.20 ± 0,69 vs 2,21 ± 0,70 mL/min/g, p=0.977). The CFR of the control group was significantly higher than those of the RA patients (3,03 ± 0,64 vs 2.20 ± 0,69 mL/min/g, p<0.000) and of the DM patients (3,03 ± 0,64 vs 2.21 ± 0,70 mL/min/g, p<0.000). 42% of RA- and 38% of DM patients had coronary microvascular dysfunction, compared to 4% in the control group.

Conclusion: Our results indicate an impaired coronary blood flow in both patients with RA and DM in similar levels. Both patient groups had significantly more coronary microvascular dysfunction.

Background: Milestones in the field of IgG4-related disease (IgG4-RD) include the 2011 Comprehensive Diagnostic Criteria (CDC) (1), the 2019 ACR/EULAR classification criteria (2), and the recent identification of four distinct clinical phenotypes (3). Performance of the criteria and phenotypic disease expression in Scandinavian populations are largely unknown.

*p < 0,05 by one-way ANOVA

Objectives: Describe disease characteristics, phenotypes, and performance of the 2011 CDC and 2019 ACR/EULAR classification criteria in patients with IgG4-RD in Norway.

Methods: Consenting, adult patients with a clinical diagnosis of IgG4-RD, seen at the Department of Rheumatology, Oslo University Hospital were included. Two experts (JV, ØMi) assigned patients to phenotypes ("Pancreato-Hepato-Biliary", "Retroperitoneum and Aorta", "Head and Neck-Limited" or "Mikulicz and Systemic") based on pattern of organ involvement. Fulfillment of the CDC and classification criteria were assessed. Disease activity and damage were scored with the IgG4-RD responder index (IgG4-RD RI). We used descriptive statistics.

Results: We identified 60 patients with IgG4-RD (Table 1). Clinical characteristics were as expected, with approximately equal number of patients in each phenotype group. Of all patients diagnosed by expert opinion, 42 (70%) fulfilled the ACR/EULAR classification criteria. Reasons for not fulfilling the criteria were (i) failure to meet the inclusion criterium (n = 3) due to "atypical" organ involvement: tonsils (n = 1), nasal cavity (n = 1); coronary artery (n = 1); (ii) presence of ≥ 1 exclusion criterium (n = 5): fever (n = 1), leukopenia (n = 1), thrombocytopenia (n = 1), positive anti-MPO-ANCA (n = 3), anti-SSA (n = 1) and/or anti-RNP (n = 1) antibody; and (iii) score < 20 points (n = 10). In the latter group, 8 (80%) were not biopsied, and 1 (10%) had only performed fine needle biopsy. Among the patients not meeting the inclusion criterium or having ≥ 1 exclusion criteria, 1 (33%) and 4 (80%) scored ≥ 20 points, respectively. Of all patients, 56 (93%) fulfilled CDC, with 32 (53%), 10 (17%) and 14 (23%) patients characterized as "definite", "probable" and "possible" IgG4-RD, respectively. Of the 18 patients not fulfilling the ACR/EULAR classification criteria, 15 (83%) fulfilled CDC (4 "definite", 3 "probable", 8 "possible"). Of the 4 patients not fulfilling CDC, 1 fulfilled the ACR/EULAR classification criteria.

Conclusion: Despite expected clinical characteristics, phenotype distribution and fulfilment of CDC in our cohort, the performance of the ACR/EULAR classification criteria was lower than expected, especially in the "Retroperitoneum and Aorta" and "Head and Neck-Limited" phenotypes. This may have important implications for the comparability across studies and inclusion in future clinical trials.

CARDIAC SARCOIDOSIS: AN UNDERDIAGNOSED, LIFE-THREATENING YET TREATABLE DISEASE

P. Webster[1], Y. Rochlani[2], K. Loupasakis3. *[1]Montefiore Medical Center, Albert Einstein College of Medicine, Rheumatology, New York, United States of America; [2]Montefiore Medical Center, Albert Einstein College of Medicine, Cardiology, New York, United States of America; [1]Montefiore Medical Center, Albert Einstein College of Medicine, Rheumatology, New York, United States of America*

Background: Cardiac sarcoidosis (CS) is potentially life-threatening and it typically causes heart failure, ventricular arrhythmia, AV block or sudden death. CS has been reported to account for 25% of sarcoidosis patient deaths, thus highlighting the importance of early diagnosis and treatment. Diagnostic challenges and lack of a unified screening approach make it difficult to estimate its prevalence. Immunosuppression is the mainstay of treatment, but there is paucity of data on optimal dose, duration and efficacy of steroids and synthetic (s) or biologic (b) disease-modifying anti-rheumatic drugs (DMARDs).

Objectives: To describe the demographic and clinical characteristics of our CS patients, and to study their clinical response to steroids, synthetic and biologic DMARDs.

Methods: A retrospective cohort study with a prospective ongoing phase was conducted. ICD-10 codes were used to identify patients over 18 years old with sarcoidosis and CS followed at Montefiore Medical Center from 2017 to 2021. The following variables were recorded: demographics (age, sex, ethnicity), BMI, smoking status, presenting manifestations, histopathology (cardiac and extracardiac), imaging, treatment (corticosteroids and s/bDMARDs), dose and duration of therapy, steroid-sparing effect, response to treatment based on clinical and imaging improvement (echocardiogram, cardiac MRI, PET).

Results: 220 patients with sarcoidosis were identified. 154 (70%) female and 124 (56.4%) Black. 42 out of 220 (19.1%) met diagnostic criteria for CS [1,2]. Mean age of CS patients was 61.6 years. 23 (54.8%) were male and 24 (57.1%) Black. Heart

Table 1. Treatment of cardiac sarcoidosis

Agent	Treated with DMARDs (N=21)*	Duration of treatment (months, x̄)	Max dose (mg, x̄)	Prednisone dose at 12 months (mg, x̄)	Response to treatment
Methotrexate (Weekly)	16/21 (76.1%)	16.0	16.9	3.67	14/16 (87.5%)
Mycophenolate mofetil (Daily)	6/21 (28.6%)	16.9	2000	5.1	3/6 (50%)
Hydroxychloroquine (Daily)	1/21 (4.8%)	17.5	400	5	1/1 (100%)
Infliximab (q 8 weeks)	1/21 (4.8%)	6.0	5 (mg/kg)	5	1/1 (100%)
Adalimumab (q 2 weeks)	2/21 (9.5%)	10.0	40	7.5	2/2 (100%)

*2 patients switched from MTX to MMF and 3 from sDMARDs to bDMARDs

failure (54.8%), arrhythmias (47.6%) and heart block (28.6%) were the most common presenting manifestations. 28.6% had isolated CS. 5 (11.9%) underwent endomyocardial biopsy and 2 of them (40%) had histopathologic evidence of CS. Mean left ventricular ejection fraction (LVEF) was 40.6 % on echocardiogram, and 29 patients (69%) had PPM/ICD placed for arrhythmia prevention. 35 (83.3%) underwent cardiac MRI, 37 (88.1%) cardiac PET scan and 23 (62.3%) had a follow up PET. 33 (78.6%) CS patients were treated with corticosteroids for a mean duration of 17.3 months. 21 of them were also treated with sDMARDs and 3 were subsequently switched to bDMARDs (Table 1). Mean prednisone dose at 12 months was 4.8mg, and 11 patients (33%) were tapered off corticosteroids.

Conclusion: In our sarcoid patient population, the prevalence of CS is 19.1%, which is higher than previously reported in the literature, suggesting CS may be underdiagnosed. There was a greater proportion of male patients in the CS population (54.8%) than the generalized sarcoidosis population (30%). This indicates that males with sarcoidosis may be more likely to have cardiac involvement. Patients treated with s/bDMARDs had a high response rate as reflected by clinical and imaging improvement. Steroid-sparing effect is suggested by the low prednisone dose at 12 months (Table 1). Methotrexate was the most commonly used DMARD (76.2%). Randomized clinical trials are needed to establish robust guidelines for the treatment of CS.

Kang[1]. *[1]Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam-si, Korea, Rep. of (South Korea); [2]Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Behcet's disease (BD) is a systemic vasculitis with multiorgan involvement.

Objectives: To compare the risk of all-cause and cause specific mortality among patients with BD compared to general population

Methods: Using the 2002-2017 Korea National Health Insurance database, we conducted a cohort study among BD patients compared to general population matched on age and sex at a 1:5 ratio. The primary outcome was death of any cause, and the secondary outcomes were cause-specific mortality for top 5 causes of death. Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs), comparing BD patients versus general population.

Results: The PS-matched study cohort (mean age 42.1 years; 32.0% male) included 32288 BD patients and 161440 controls. During a mean follow-up of 9.6 years, 2214 deaths occurred. The HR [95%] for all-cause mortality was 10.6 [9.6-11.6]. The Top 5 causes of death derived from malignancy, cardiovascular disease, infection, respiratory disease, and injury: the HR [95%] for mortality from these causes were 8.5 [7.2-10.1], 10.8 [8.6-13.6], 14.6 [8.1-26.3], 12.0 [8.5-17.0], and 8.0 [5.0-13.0], respectively.

Conclusion: This population-based cohort study warns exceptionally heavy burden of the disease showing approximately 10 times higher mortality of BD patients compared to general population. In line with this, risk of cause specific mortality was also significantly higher among the BD patients, for 5 top causes of death.

POS0218 DECREASED MIR-122-5P IN NEUTROPHIL-DERIVED EXOSOMES ATTENUATED IMMUNOREGULATORY FUNCTION ON MACROPHAGES BY TARGETING IRF5 EXPRESSION IN BEHCET'S DISEASE

X. Yu[1], C. Li[2], J. Liu[1], H. Chen[1], W. Zheng[1]. *[1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology, Beijing, China; [2]Shougang Hospital of Peking University, Department of Rheumatology, Beijing, China*

Background: Behçet's disease (BD) is a chronic systemic vasculitis characterized by the overactivation of neutrophils and macrophages. Exosomes are membrane-derived vesicles that mediate intercellular communications and neutrophil-derived exosomes account for the major portion of serum exosomes in BD. However, the role of neutrophil-derived exosomes in BD remains unknown.

Objectives: 1) To investigate the production of exosomes by BD neutrophils; 2) To elucidate the regulation of macrophage by BD neutrophil-derived exosomes; 3) To explore the mechanism of immunoregulatory functions of BD neutrophil-derived exosomes.

Methods: BD and healthy control (HC) neutrophil-derived exosomes were extracted and quantified. Human monocyte-derived macrophages (HMDM) were stimulated with BD and HC neutrophil-derived exosomes, and TNF-α and IL-6 production were examined. Differently expressed miRNAs in BD neutrophil-derived exosomes were analyzed using miRNA sequencing. LPS-induced HMDM were treated with miRNA mimics or inhibitors, and TNF-α and IL-6 production were detected. miRNA was overexpressed in macrophages, and RNA sequencing was performed to analyze regulating pathways. Dual-luciferase assays were performed to confirm miRNA-mRNA interaction.

Results: BD neutrophils produced a significantly lower level of exosomes than HC ones. Both BD and HC neutrophil-derived exosomes suppressed TNF-α and IL-6 production by macrophages, but to a lesser extent by BD neutrophil-derived exosomes. Six downregulated miRNAs were presented in BD neutrophil-derived exosomes, including miR-122-5p. miR-122-5p mimics inhibited IL-6 and TNF-α production while miR-122-5p inhibitor promoted IL-6 and TNF-α production by HMDMs. Overexpression of miR-122-5p attenuated TLR4 and IFN-β signaling. miR-122-5p directly targeted 3'UTR of IRF5, the TF regulating TLR4 pathway and autocrine of IFN-β, and downregulated IRF5 expression confirmed by dual luciferase assay. Knocking down IRF5 dampened IL-6 and TNF-α production in HMDMs.

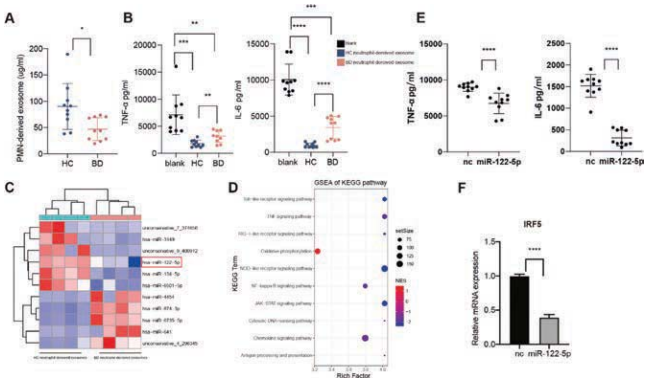

Figure 1. (A) Decreased production of BD neutrophil-derived exosomes. (B) Reduced suppression of macrophage activation by BD neutrophil-derived exosomes. (C) Differentially expressed miRNAs (downregulated) in BD neutrophil-derived exosomes. (D) miR-122-5p suppressed TLR4 and JAK-STAT signaling in HMDM. (E) miR-122-5p inhibited activation of HMDM. (F) miR-122-5p inhibited IRF5 expression in HMDM.

Conclusion: Our findings suggested the reduced production and immunoregulatory function of BD neutrophil-derived exosomes, mediated by lower levels of miR-122-5p in neutrophil-derived exosomes. Impaired BD neutrophil-derived exosomes might be implicated in the overactivation of macrophages in BD.

POS0219 EARLIER AND MORE AGGRESSIVE TREATMENT OF MAJOR ORGAN INVOLVEMENT WITH BIOLOGICS MAY PREVENT RELAPSES OR FURTHER NEW ORGAN INVOLVEMENT IN A SUBGROUP OF BEHÇET'S DISEASE PATIENTS

T. Bozkurt[1], M. Karabacak[2], H. Karataş[1], S. Kutluğ Ağaçkıran[2], T. Ergun[3], H. Direskeneli[2], F. Alibaz-Oner[2]. *[1]Marmara University School of Medicine, Department of Internal Medicine, ISTANBUL, Turkey; [2]Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, ISTANBUL, Turkey; [3]Marmara University School of Medicine, Department of Dermatology, ISTANBUL, Turkey*

Background: Conventional immunosuppressives (cIS) are the choice of treatment for major organ (ocular, vascular, central nervous (CNS) and gastrointestinal (GIS)) involvement to prevent relapses and organ damage in patients with Behcet's disease (BD).

Objectives: We aimed to investigate the rate of new major organ involvement in BD patients under cIS treatments during follow-up and to assess the characteristics and treatment protocols of these patients.

Methods: The files of 1114 patients diagnosed with BD and followed (1992-2019) in the Marmara University Behcet's Clinic were overviewed retrospectively. Patients with follow-up duration less than 6 months were excluded. A total of 806

patients, of whom 56% were male were included in the analysis. Demographic and clinical characteristics, follow-up and treatment data of the patients were recorded from files. Relapse of the same organ and/or new major organ development during the follow-up period of patients receiving cIS was defined as "event under cIS".

Results: Median age at diagnosis was 29 (10-65) years and median follow-up duration was 68 months (6-272). Genital ulcer, erythema nodosum and arthritis/arthralgia were more common in women, whereas papulopustular lesions, vascular and ocular involvement were more common in men (p<0.005 for all). Presence of major organ involvement was 56.9% (n=459) and the frequencies of vascular, ocular, CNS and GIS involvement were 29.8%, 33,5%, 9.7%, and 2%, respectively. At diagnosis 232 (50.5%) patients had major organ involvement, whereas it developed in 227 patients during a follow-up of median 3 years (0.5 - 32) after diagnosis. Major organ involvement developed earlier in males compared to females (median 2 years vs 4 years, p = 0.012). In patients with a first-degree relative history of BD, major organ involvement also developed earlier, however without reaching significance (median 1 year vs 3 years) (p= 0,066). 440 patients had follow-up data under cISs with the follow-up duration of median 65.5 months (6-272). Main reason for cISs use was major organ involvement (86.8%), less frequent reasons were mucocutaneous disease (9.3%) and joint involvement (3.8%). An event under ISs (mainly relapses) occurred in 160 (36.4%) patients with median 23 months after cISs initiation. Majority of events (68%) were relapses of the same major organ (Figure 1). The most commonly used cIS agent was azathioprine (87%). Among patients having an event under cISs, 91% of the relapses and 75% of new major organ involvement developed under azathioprine treatment. In patients with an event under cISs, treatment mostly switched to other ISs such as cyclophosphamide, interferon-alpha, and high dose corticosteroids. In 22% of patients, azathioprine was switched to tumor necrosis factor (TNF) inhibitors.

Conclusion: In our study, major organ involvement developed in 57% of the 806 BD patients. We observed that disease course was more severe under cIS treatment in male patients diagnosed at a younger age and with the history of familial BD. In one third (36%) of the patients under cIS treatment, a relapse or a new major organ involvement developed despite the cISs use, mainly under azathioprine. TNF-inhibitor use was approved for BD treatment within the last decade in Turkey. Therefore, azathioprine was switched to a TNF inhibitor in only 22%. Our results suggest that earlier and more aggresive treatment of major organ involvement with biologics may be an option in young male patients especially with the history of familial BD, who had the highest risk for severe disease course.

Background: The cryopyrin-associated periodic fever syndromes (CAPS) are hereditary monogenic autoinflammatory diseases with severe systemic and organ inflammation due to increased production of Interleukin-1β (IL-1β). The subcutaneously administered monoclonal antibody canakinumab (CAN) effectively inhibits IL-1β and results in rapid remission of CAPS symptoms in clinical trials as well as in real-life.

Objectives: The RELIANCE registry is designed to explore long-term safety and effectiveness of CAN under routine clinical practice conditions in pediatric (≥2 years) and adult patients with CAPS, including Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS), and neonatal onset multisystem inflammatory disease (NOMID)/chronic infantile neurological cutaneous and articular syndrome (CINCA).

Methods: This prospective, non-interventional, observational study with a 3-year follow-up enrolls patients in Germany with clinically confirmed diagnoses of CAPS routinely receiving CAN. In 6-monthly visits, clinical data, physician assessments and patient-reported outcomes are evaluated starting at baseline.

Results: 98 CAPS patients (52% female; 15 [15%] NOMID/CINCA subtypes) were enrolled by December 2021 (Table 1). At baseline, median age was 20 years and median duration of prior CAN treatment was 6 years. At the 36 months visit, 74% of patients reached disease remission by physicians´ assessment along with increasing rates of absent disease activity (patient's assessment, median 2.0 at baseline and 0.0 month 36). In addition, patients reported low levels of fatigue (absent to mild/moderate: 87% at baseline and 95% at month 36). At baseline, CAPS impaired social life in 47% of patients (37% at month 36) and 33% (23% at month 36) reported days off from school/work. Lab parameters were within normal limits. Remission and disease control were sustained as evaluated parameters remained stable or even decreased over time.

Table 1. Patient and physician assessment of clinical CAPS disease activity and laboratory markers over time.

	Baseline	12 months	36 months

POS0221 LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH TRAPS (TUMOR NECROSIS FACTOR RECEPTOR-ASSOCIATED PERIODIC SYNDROME) – INTERIM ANALYSIS OF THE RELIANCE REGISTRY

N. Blank[1], C. Schuetz[2], J. Henes[3], T. Kallinich[4], P. Oommen[5], M. Borte[6], M. Hufnagel[7], A. Janda[8], J. Weber-Arden[9], J. B. Kuemmerle-Deschner[10]. *[1]University Hospital Heidelberg, Rheumatology, Heidelberg, Germany; [2]Technische Universität Dresden, Pediatrics, Medizinische Fakultät Carl Gustav Carus, Dresden, Germany; [3]University Hospital Tuebingen, Centre of Interdisciplinary Rheumatology, Immunology and Auto-inflammatory Diseases and Department of Internal Medicine 2, Tuebingen, Germany; [4]Charité University Medicine Berlin, Department of Pediatrics, Division of Pulmonology, Immunology and Critical Care Medicine, Berlin, Germany; [5]Heinrich-Heine-University Düsseldorf, Clinic of Pediatric Hematology, Oncology and Clinical Immunology, Division of Pediatric Rheumatology, Duesseldorf, Germany; [6]Hospital St. Georg gGmbH Leipzig, ImmunoDeficiencyCenter Leipzig (IDCL), Leipzig, Germany; [7]University Hospital Medical Center, Medical Faculty, University of Freiburg, Division of Pediatric Infectious Diseases and Rheumatology, Department of Pediatrics and Adolescent Medicine, Freiburg, Germany; [8]University Hospital Ulm, Department of Pediatrics, Ulm, Germany; [9]Novartis Pharma GmbH, IHD, Nuernberg, Germany; [10]University Hospital Tuebingen, Department of Pediatrics, Division of Pediatric Rheumatology, Tuebingen, Germany*

Background: Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is a rare hereditary autoinflammatory disease characterized by periodic fever as well as severe systemic and organ inflammation. Successful treatment was achieved with the interleukin-1β inhibitor canakinumab (CAN) in a pivotal phase 3 study, in which 45% of patients reached clinical remission after 16 weeks (primary endpoint)[1]. CAN has been approved and applied for the treatment of TRAPS patients since 2017[2].

Objectives: The present study explores the long-term efficacy and safety of CAN under routine clinical practice conditions in pediatric (age ≥2 years) and adult TRAPS patients.

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany. Patients with clinically confirmed diagnosis of TRAPS who routinely receive CAN are enrolled in order to evaluate efficacy and safety of CAN under standard clinical practice conditions at baseline and at 6-monthly intervals.

Results: The interim analysis of TRAPS patients enrolled by December 2021 includes baseline (N=19, 1 patient with atypical TRAPS) and preliminary 24-month data. Of these patients, N=12 (63%) were females and median age at baseline was 16 years (3–43 years).

Preliminary results indicate stable remission by physicians´ assessment and laboratory parameters. Disease control by patients´ assessment showed no major changes over time (Table 1). In total, N=7 adverse drug reactions where observed, of which none was classified as severe.

Conclusion: Baseline characteristics and interim data of TRAPS patients are available from the RELIANCE study. Further interim and end-of-study data will be analyzed to assess efficacy and safety of long-term treatment as well as dosing effects in TRAPS patients.

POS0222 POLYARTICULAR ARTHRITIS AND ADULT-ONSET OSTEOLYSIS CAUSED BY MUTATIONS IN THE ASAH1 GENE: FARBER DISEASE CLINICAL PRESENTATIONS IN THE CONTEXT OF A FIRST-EVER NATURAL HISTORY STUDY

L. Seefried[1], K. Crosby[2], A. Solyom[3]. *[1]University of Wuerzburg, Musculoskeletal Center Wuerzburg, Wuerzburg, Germany; [2]Aceragen, Patient Engagement, Durham, United States of America; [3]Aceragen, Rare Disease Development, Basel, Switzerland*

Background: Farber disease is frequently misdiagnosed as polyarticular juvenile idiopathic arthritis or seronegative rheumatoid arthritis which leads to a delay in diagnosis for many patients. Farber disease is an ultra-rare lysosomal storage disease caused by mutations in the *ASAH1* gene. The resulting deficiency of the acid ceramidase enzyme leads to accumulation of the pro-inflammatory and pro-apoptotic sphingolipid ceramide. Accumulation of ceramide throughout the body leads to the symptoms of Farber disease. Cardinal symptoms include joint disease (polyarticular arthritis and contractures), subcutaneous nodules, and a hoarse or weak voice due to laryngeal nodules. The phenotypic spectrum of Farber disease ranges from rapidly progressive disease causing death in infancy to moderate or slowly progressive disease with survival into late adulthood. Symptoms may vary in severity across patients and phenotypes.

Objectives: To further define the symptoms of Farber disease, including joint disease, subcutaneous nodules, dysphonia, and osteolysis, which can lead to referral to rheumatology or related specialties. To understand the clinical presentation and broad phenotypic spectrum of this rare disease to aid in clinical diagnosis and reduce diagnostic delay.

Methods: The Observational and Cross-Sectional Cohort Study of the Natural History and Phenotypic Spectrum of Farber Disease (NCT03233841) was the first systematic clinical study of the natural history of Farber disease. The study collected retrospective and prospective data on living and deceased patients, including demographics, clinical presentation, phenotype, diagnostic history, and patient reported outcomes.

Results: 45 patients with Farber disease (27 living, 18 deceased) who had or had not undergone hematopoietic stem cell transplant (HSCT) were enrolled from 16 centers in 9 countries. A cohort of 24 living non-HSCT patients were followed prospectively. The patients represented the broad phenotypic spectrum of Farber disease, from rapidly progressive (severe) to slowly progressive (attenuated). In patients whose data was available for analysis, the average age of patients at enrollment was 7.2 years (range 1 to 28 years). The average age of onset of joint disease (arthritis and/or contractures) was 15 months (range 3 months to 7 years), of subcutaneous nodules was 13 months (range 3 months to 5 years), and of dysphonia was 13 months (range birth to 8 years). The average time from onset of symptoms to Farber disease diagnosis was 2 years (range <1 to 12 years). At baseline, the mean number of joints affected with active arthritis was 11.3 (range 0-36) and the mean number affected with contractures was 18 (range 0-38). 12.5% of patients were reported to have a bone disorder such as osteoporosis or osteolysis. The Child Health Assessment Questionnaire Disability Index (CHAQ) ranging from 0 (no impairment) to 3 (unable to do) was high, with mean scores of 2.62-3.00 across visits.
Conclusion: Data from the Farber disease natural history study further defined the cardinal symptoms, phenotypic spectrum, and high disease-related burden in patients with Farber disease. The large number of joints affected with arthritis or contractures reflects that patients with Farber disease are often referred to rheumatology and can be misdiagnosed with polyarticular juvenile idiopathic arthritis or seronegative rheumatoid arthritis. Demographic information and numbers of patients enrolled indicate that Farber disease is likely not as rare as previously thought. *ASAH1* genetic testing for adult and pediatric patients referred to the rheumatology clinic with symptoms including polyarticular arthritis, subcutaneous nodules, dysphonia, or osteolysis, may shorten the time to diagnosis in patients with Farber disease.

POS0223 AMYLOID BURDEN AND ASSOCIATED FACTORS PREDICT HIGHER MORTALITY AND POOR OUTCOME IN FAMILIAL MEDITERRANEAN FEVER-ASSOCIATED AA AMYLOIDOSIS: DATA FROM A TERTIARY REFERRAL AMYLOIDOSIS CENTER WITH 137 PATIENTS

M. Bektaş[1], N. Koca[1], E. Oguz[1], B. Ince[1], S. Sarı[1], N. Şentürk[2], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], A. Gül[1]. *[1]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*

Background: AA amyloidosis (AA-a) is a rare condition while the most common cause is Familial Mediterranean Fever (FMF) in Turkey. There is limited evidence about the impact of AA-a burden on prognosis and outcome in AA-a.
Objectives: We herein aimed to evaluate the AA-a burden and its association with outcome in patients (pts) with FMF-associated AA-a (FMF-AA)
Methods: We retrospectively evaluated FMF-AA pts from our AA-a cohort. Diagnosis of AA-a was confirmed by histologically. Heart involvement (inv.) was defined by documenting increased (>12mm) septal wall thickness (CSWT) and at least one of three appropriate echocardiography findings (decreased ejection fraction, increased granular echogenicity or valvulopathy, diastolic dysfunction). The pts were divided in three groups according to AA-a burden: pts had only renal inv. (Group 1, G1), renal and gastrointestinal (GIS) (Group 2, G2); renal and GIS and heart (Group 3, G3)
Results: Data of 137 pts with FMF-AA (55% male) were analyzed. We classified 79 pts in G1, 20 in G2, and 14 in G3. CSWT, troponin (trop) and pro-BNP levels were higher in G3 than G1 and G2 but trop levels were not statistically (sts) significant (sig.) between G3 and G2. Overall mortality was in 15.3 %. While mortality rate increased gradually with higher AA-a burden (10 % in G1, 15 % in G2 and 43 % in G3), the difference was sts sig. between G3 and G1.
The number of MEFV variants was lower in pts with higher AA-a burden, especially those with M694V homozygosity were 93% and 72% in G1, 83% and 67% in G2, and 75% and 50% in G3 rsp; but the differences were not sts sig. (p=0.2 and p=0.7 for G1-G2, p=0.06 and p=0.2 for G1-G3, p=0.6 and p=0.4 for G2-G3).
The number of organ inv. was correlated with CSWT (r=0.559' 'p<0.001), trop (r=0.646'), pro-BNP (r=0.572'), bsl creatinine (Cre) (r=0.511'), bsl proteinuria (prt) levels (r=0.321 p=0.008) and negatively correlated with bsl e-GFR (r=-0.437') and biologic DMARD duration (r=-0.235 p=0.03)
ROC analyses revealed 56% sensitivity (SS) and 70 % specificity (SP) for bsl Cre (cut off value [COV] 0.95, AUC=0.726 p=0.03 95% CI 0.56-0.9), 83.3 % SS and 74 % SP for trop (COV 35.5 AUC=0.864 p=0.006 CI 0.73-0.99), 100 % SS and 85.5 % SP for pro-BNP (COV 7246 AUC=0.897 p=0.024 CI 0.79-1.0), 79% SS and 58 % SP for CSWT (COV 11.5 AUC=727 p=0.007 CI 0.61-0.84) to be able to predict higher mortality.
Conclusion: This study showed the association of AA-a burden with higher morbidity such as ESRD and higher mortality in pts with FMF-AA. Bsl Cre, prt, trop and pro-BNP levels were correlated with extent of AA-a burden and predicted higher mortality. Lower frequency of pts with two exon 10 variants or M694V homozygosity in pts with higher AA-a burden indicates that additional genetic and environmental factors may play a role in the development and progression of AA-a in FMF.

POS0224 A NOVEL TNFRSF1A MUTATION ASSOCIATED WITH TNF-RECEPTOR ASSOCIATED PERIODIC SYNDROME AND ITS METABOLIC SIGNATURE

J. Steiner[1], A. Antebi[1], A. Annibal[1], T. Kubacki[2]. *[1]Max Planck Institute, Max Planck Institue for Biology of Ageing, Cologne, Germany; [2]University Hospital Cologne, Cologne, Germany, Department II of Internal Medicine and Center for Molecular Medicine Cologne, Cologne, Germany*

Background: Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal dominant periodic fever syndrome characterized by prolonged episodes of fever, arthralgia, myalgia, abdominal pain and erythematous rash.1 We report a new mutation in the TNFRSF1A gene which is associated with TRAPS and AA-amyloidosis. Furthermore we analyzed the metabolic changes using a metabolomics approach.
Objectives: To describe a novel mutation in the TNFRSF1A gene that causes TRAPS.
Methods: Case series. For pathogenicity predictions we used the PolyPhen-2 web-software2 and PROVEAN3. Metabolomics: Mass spectrometry was performed

on patient plasma and healthy controls using an UHPLC system (Vanquish, Thermo Fisher Scientific, Bremen, Germany) coupled to an HRAM mass spectrometer (Q-Exactive Plus, Thermo Fischer Scientific GmbH, Bremen, Germany).
Results: A 44-year-old man (patient 1) presented to our hospital with abdominal pain, elevated inflammation parameters, renal failure and large proteinuria. Renal biopsy revealed AA amyloidosis. Further anamnesis showed he had suffered from recurrent attacks of abdominal pain with fever and elevation of inflammation markers since he was 16 years old. He also reported that his father, aunt, sister and daughter have had similar problems. His daughter (patient 2) reported recurrent episodes of abdominal pain with fever since she was 11 years old and his 46-year-old sister (patient 3) reported similar symptoms starting at 12 years of age. Upon presentation patient 3 showed proteinuria of 2000 mg/g creatinine (albuminuria 1500 mg/g creatinine) strongly indicating early renal AA-amyloidosis. All symptomatic family members underwent genetic testing that revealed the yet uncharacterized TNFRSF1A-variant c.332A>G (p.Q111R). In silico analysis of the mutation by PolyPhen-2 software and PROVEAN classified the mutation as probably pathogenic culminating in the diagnosis of TRAPS. All patients received canakinumab for treatment and responded with normalization of the inflammatory parameters. Patient 3 showed a marked reduction of proteinuria after 6 months of treatment. Using a metabolomics approach we were able to detect 158 distinct metabolic compounds of which 32 were up- and 35 downregulated, respectively. Two patients were analyzed before and after treatment with canakinumab. The treatment with canakinumab, however, appears to have no effect on the metabolic changes caused by TRAPS. Significantly upregulated metabolic pathways included purine metabolism, glycolysis/glyconeogenesis, glutathione metabolism, pyrimidine metabolism and phenylalanine, tyrosine and tryptophan biosynthesis. Downregulated pathways included Aminoacyl-tRNA biosynthesis, arginine and proline metabolism, arginine biosynthesis among others.
Conclusion: Here we present a novel mutation in the TNFRSF1A gene that causes TRAPS and is associated with AA-amyloidosis. Canakinumab is an effective treatment in this variant and led to improvement in proteinuria in one of the patients with presumed early renal AA-amyloidosis. We observed significant changes in the metabolome in comparison to healthy controls. Treatment with canakinumab appeared to have no effect on these metabolic changes caused by TRAPS.

Remodelling in OA

POS0225 FLUIDIC SHEAR STRESS REDUCES TNFA-MEDIATED CARTILAGE DAMAGE IN A 3D MODEL OF DEGENERATIVE JOINT DISEASE

D. H. Do Nguyen[1], C. Lubahn[1], T. Leeuw[2], F. Buttgereit[1], T. Gaber[1], A. Damerau[1]on behalf of AG Buttgereit. [1]*Charité-Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany;* [2]*Sanofi-Aventis Deutschland GmbH, Immunology & Inflammation Research, Frankfurt am Main, Germany*

Background: Pathomechanisms of degenerative joint diseases such as osteoarthritis (OA) ultimately result in the breakdown of cartilage tissue. To date, the exact underlying mechanisms of both cause and progression of OA remain unclear. Therefore, developing complex and long-lasting *in vitro* components of a human joint including cartilage, subchondral bone, synovial membrane and tendons that simulate the 3D architecture and the metabolic, humoral and cellular interplay of the joint components is needed to study the long-lasting course of OA pathogenesis. Beside the impact of metabolic components and 3D architecture, mechanical forces are well-known to be important modulators of joint health, while aberrant forces are primary etiological factors leading to cartilage degeneration.
Objectives: Here, we aimed to (i) develop a long-lasting human *in vitro* 3D cartilage model using alternated perfused cultivation and (ii) simulate TNFα-mediated cartilage degradation. As a mechanical force we used the perfusion-mediated fluid shear stress (FSS) to enhance chondrogenesis and mimic FSS during joint movement.
Methods: Human bone marrow-derived mesenchymal stromal cells (MSC) were used to develop an *in vitro* 3D cartilage model incubated in a bioreactor with a perfusion cycle that facilitates mechanical stimulation via FSS and daily sampling. Within the bioreactor, MSC mass cultures were subjected to FSS at 10 dyn/cm^2 by medium circulation three times a day for 1.5 hours. The approach of using optimized FSS rate, cycles and cultivation period of 18 days for MSC mass cultures was compared to a non-perfused control based on cell viability (live-dead- and viability-assay), apoptosis (TUNEL-assay, caspase-3/7-activity, *BCL2*/*BAX*), metabolic activity (oxygen and glucose consumption, lactate production), chondrogenic gene expression (*ACAN, COMP*, *COL2A1, COL1A1*, *COL2A1*/*COL1A1*) and matrix metalloproteinase expression *(MMP-1, -3, -13)*.
Results: Alternate perfused long-term cultivation at 10 dyn/cm^2 did not affect cell survival; it rather reduced apoptosis, did not affect oxygen consumption but reduced glucose consumption and lactate production and enhanced chondrogenic gene expression with reduced *MMP13* and *COMP* gene expression compared with non-perfused conditions. Mimicking pathophysiology of OA we stimulated the 3D cartilage model with 100 ng/mL TNFα for 6 hours under non-perfused and perfused long-term cultivation with FSS at 10 dyn/cm^2 as a mechanical stimulus. Compared to untreated perfused conditions, TNFα stimulation (i) did not affect overall cell survival but enhanced apoptosis (demonstrating efficacy of stimulation), (ii) did not affect oxygen consumption and glycolysis, and (iii) enhanced *COMP* and *MMP1* expression as markers of matrix protein turnover. In comparison to TNFα treated cells under non-perfused conditions, TNF stimulation under perfused conditions (i) did not affect cell survival but reduced apoptosis, (ii) did not affect oxygen consumption but reduced glucose consumption and lactate production as a measure of glycolysis, and (iii) reduced the expression of *IL6* and soluble amounts of IL-6 but not of *TNFA* whereas soluble amounts of TNFα were enhanced. Furthermore, TNFα stimulation (iv) reduced the expression of matrix degrading enzymes but (v) enhanced anabolic chondrogenic matrix proteins on mRNA.
Conclusion: In a 3D model that mimics OA, FSS as a mechanical stimulus provides a metabolic "feel-good" niche that reduces chondrocyte apoptosis, metabolic activity, and matrix metalloproteinase expression, increases matrix protein expression and protects against TNFα-mediated cartilage degradation.

POS0226 DEFICIENT CHAPERONE-MEDIATED AUTOPHAGY CONTRIBUTES TO JOINT DAMAGE IN OSTEOARTHRITIS

I. Lorenzo[1], U. Nogueira-Recalde[1], C. Garcia-Dominguez[1], N. Oreiro[2], J. A. Pinto Tasende[2], M. Lotz[3], F. J. Blanco[1,2], B. Carames[1]. [1]*Instituto de Investigación Biomédica de A Coruña (INIBIC), Unidad de Biología del Cartílago, Grupo de Reumatología, A Coruña, Spain;* [2]*Complejo Hospitalario Universitario A Coruña, Grupo de Reumatología Clínica, A Coruña, Spain;* [3]*Scripps Research, Molecular Medicine, La Jolla, United States of America*

Background: In Osteoarthritis (OA), defects in macroautophagy are evident and precede joint damage. Indeed, pharmacological activation of macroautophagy protects against joint damage and disease.
Objectives: Therefore, identifying hallmarks associated with specific autophagy subtypes could shed light to fundamental mechanisms of joint disease and facilitate the development of therapeutic strategies to prevent OA progression.
Methods: A gene expression analysis of 35 autophagy genes was performed from blood from a Prospective OA Cohort of A Coruña (PROCOAC) of non-OA (Age:61,44±1,16 years; BMI:25,25±0,52; Females, n=18) and knee OA subjects (Age:65,50±1,05 years; BMI:29,55±0,67; Females, n=18, OA grade III-IV) by using SYBR green array. The differential expression of candidate genes in blood (n=30/group) and knee cartilage (Non-OA, n=12; Knee OA donors, n=21) was confirmed by using Taqman Technology. HSP90AA1, a chaperone mediated autophagy (CMA) mediator, was evaluated in human knee joint tissues (i.e. cartilage, meniscus, ACL and synovium) with different KL grades (0, 2 and 4, n=3/each KL grade) and in both spontaneous aging mice (2, 6, 12, 18, and 30 months old, n=3/each time) and surgically-induced OA mice (10 weeks after surgery, n=4/each) by immunohistochemistry. The functional consequences of HSP90AA1 deficiency on inflammation, oxidative stress, senescence and apoptosis were studied in human OA chondrocytes by gene and protein expression and flow cytometry. The potential contribution of CMA to chondrocyte homeostasis was studied by assessing the capacity of CMA to restore proteostasis upon macroautophagy deficiency by ATG5 knockdown. To study the therapeutic potential of targeting CMA, HSP90AA1 was overexpressed in human OA chondrocytes.
Results: 16 autophagy-related genes were significantly downregulated in knee OA subjects ($p<0.05$). Macroautophagy-related genes ATG16L2, ATG12, ATG4B and MAP1LC3B, were significantly downregulated ($p<0.05$). Interestingly, HSP90AA1 and HSPA8, CMA mediators involved in stress response and protein folding, were significantly downregulated ($p<0.001$). Confirmatory studies showed a downregulation of MAP1LC3B and HSP90AA1 in blood ($p<0.001$) and cartilage ($p<0.05$) from

knee OA subjects. Moreover, HSP90A was reduced in human joint tissues (i.e. cartilage, meniscus, ACL, $p<0.05$) and associated to OA severity. In mice, HSP90A reduction was observed not only in OA ($p<0.05$) but also in aging ($p<0.01$). LAMP2A, a key CMA mediator, was also reduced in human OA cartilage and associated with aging in mice ($p<0.05$). Remarkably, HSP90AA1 deficiency was functionally linked to inflammation, oxidative stress, senescence and apoptosis ($p<0.05$). Moreover, LAMP2A activity was decreased upon HSP90AA1 deficiency, while mTOR signaling pathway, p62 and active caspase 3 were increased ($p<0.05$), indicating a failure in the autophagy flux that may lead to impaired lysosomal degradation and apoptosis. Human OA chondrocytes with impaired macroautophagy through ATG5 knockdown show reduced LC3II expression and induced activation of prbs6, p16 and p21 ($p<0.05$). Interestingly, HSP90A was increased, suggesting a compensatory activation of CMA in response to specific macroautophagy defects. Remarkably, HSP90AA1 overexpression itself is sufficient to protect against joint damage by decreasing mTOR signaling and senescence in human OA chondrocytes.

Conclusion: Taking together, we identified HSP90A, a marker of CMA, as a key regulator of chondrocyte homeostasis underlying a relevant mechanism in OA. A better definition of the cross-talk between CMA and macroautophagy defects might reveal its role as a hallmark of OA.

POS0227 MUSSEL ADHESIVE PROTEIN-BASED ADHESIVE TO RETAIN STEM CELLS FOR CARTILAGE REGENERATION

J. Y. Ko[1], H. J. Cha[2], G. I. Im[1]. *[1]Research institute of Convergence Live Science, Dongguk University, Goyang, Korea, Rep. of (South Korea); [2]Pohang University of Science and Technology, Department of Chemical Engineering, Pohang, Korea, Rep. of (South Korea)*

Background: Cartilage has limited intrinsic healing capacity, motivating the application of stem cells for regenerative therapies. Therapies to treat osteochondral defects using stem cell therapy-based tissue engineering have been developed and used for more than 20 years; however, the low viability and high possibility of dispersion of injected cells to target defect sites have remained challenge. Mussel adhesive protein (MAP) receiving increasing attraction as functional biomedical materials on tissue and biomedical engineering field. Because of functional underwater adhesive ability if the bioengineered MAP, therefore it could be applied on various environment of lesion site.

Objectives: We developed biocompatible adhesive which enables implanted chondrogenic-enhanced hASCs being strongly fixed to the lesion site of defected cartilage, and thus, the implanted cells can survive lengthily in defect site allowing cells to differentiate directly to chondrocytes.

Methods: MAP was produced and purified for in vivo applications using a bacterial expression system as previously reported [1]. The cell encapsulated coacervate was formulated with two polyelectrolyte, the MAP and 723 kDa hyaluronic acid (HA). The DiD labeled cell was dispensed into the solution in which the MAP solution and the HA solution were mixed in a ratio of 7:3 (v/v). MAP formed liquid microdroplets with hyaluronic acid and subsequently gelated into microparticles, which is highly viscous and strongly adhesive.

In vivo efficacy of MAP in rats - the osteochondral defects were created on the patellar groove of distal femora in rats with sharp excision. After transplantation of human adipose derived stem cells (hASCs), the fluorescents image was taken in every 7 days. Animals were allocated into two groups as follows: MAP with hASCs; fibrin with hASCs.

The MAP with chondro-induced hASCs were implanted on the osteochondral defect created in the patellar groove/condyle of OA-induced rabbits. Rabbits were allocated to three different groups as follows: Group 1 - Fibrin only; Group 2 - Fibrin with hASCs (1.5×10^6 chondro-induced hASCs); Group3; MAP with hASCs. After 12 weeks of implantation, rabbits were sacrificed for analysis.

Results: The fluorescence cell images exhibit the viability of cells under encapsulated condition in coacervate. The cell viabilities were determined with Live/Dead fluorescent staining. The implanted cells were labeled with DiD for in vivo visualization. After 35 days, fluorescent signals were more potently detected for MAP with hASCs group than Fibrin with hASCs group in osteochondral defect model. Implanted hASCs had been remained in target defect rather than diffused to other sites of the knee. Moreover, histological assessment showed that MAP with hASCs group had the best healing and covered with hyaline cartilage-like tissue. The staining image shows that MAP with hASCs group were filled with perfectly differentiated chondrocytes. Although Fibrin with hASCs group had better healing than fibrin only group, it was filled with fibrous cartilage which owes its flexibility and toughness. As MAP with hASCs group has higher possibility of differentiating to complete cartilage, Fibrin only group and Fibrin with hASCs group have failed to treat OA by rehabilitating cartilage. In order to clarify the evidence of remaining human cell proving efficacy of newly developed bioadhesive, human nuclear staining was proceeded with sectioned rabbit cartilage tissue. The results explicitly showed MAP with hASCs group have retained more human cells than Fibrin only and Fibrin with hASCs groups.

Conclusion: We investigated the waterproof bioadhesive supporting transplanted cells to attach to defect lengthily in harsh environment, which prevents cells from leaked to other region of cartilage. Collectively, the newly developed bio-adhesive, MAP, could be successfully applied in OA treatment as a waterproof bioadhesive with the capability of the strong adhesion to target defect sites. Our study suggests a new effective strategy for cartilage regeneration using MAP in tissue engineering fields

POS0228 HYPOXIA AND INHIBITION OF WNT SIGNALING PROMOTE EXPRESSION OF THE PROTECTIVE MOLECULE ANP32A IN CARTILAGE

J. Quintiens[1,2], F. M. F. Cornelis[1], A. De Roover[1], A. Escribano Núñez[1], S. Monteagudo[1], R. Lories[1,2]. *[1]KU Leuven, Laboratory of Tissue Homeostasis and Disease, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, Leuven, Belgium; [2]UZ Leuven, Division of Rheumatology, Leuven, Belgium*

Background: Osteoarthritis (OA) is the most common chronic joint disease and is characterized by damage to the articular cartilage. To date, no cure exists (1). Previously, an association between polymorphisms in the acidic leucine-rich nuclear phosphoprotein-32A (ANP32A) gene and OA was described (2). Our group showed that ANP32A plays a key protective role in OA by preventing oxidative stress (3). In OA cartilage, ANP32A is downregulated as compared to non-OA cartilage (3).

Objectives: Maintaining levels of ANP32A seems crucial to preserve joint health, yet the factors that regulate ANP32A in the joint remain unknown. In this study, we aim to investigate factors that regulate ANP32A expression since such knowledge may lead to the identification of specific novel targets for OA therapy.

Methods: A bioinformatic analysis pipeline was applied to identify potential regulatory factors of ANP32A expression. We then investigated two selected pathways *in vitro*, using pharmacological compounds and incubation in a hypoxia chamber in the human articular chondrocyte cell line C28/I2 and in primary human articular chondrocytes (hACs). The effects on ANP32A expression were evaluated using RT-qPCR and Western blot analysis. For *in vivo* validation, we performed immunohistochemistry to determine ANP32A protein levels in several mouse models.

Results: The bioinformatic analysis pipeline identified the Wnt signaling pathway and the hypoxia pathway as likely regulatory pathways of ANP32A expression. Wnt hyper-activation is known to contribute to OA (4). We found that Wnt hyper-activation with CHIR99021 decreased ANP32A expression at the mRNA level and at the protein level in hACs. *In vivo*, ANP32A protein expression was decreased in *Frzb* knockout mice and wild-type mice that were treated with CHIR99021 intra-articularly (two Wnt gain-of-function mouse models). ANP32A protein levels increased in wild-type mice upon intra-articular injection of the Wnt inhibitor XAV939. In healthy conditions, cartilage is in hypoxic status but in OA, hypoxia is lost (5). Treatment with the hypoxia mimetic IOX2 and incubation in a hypoxia chamber increased ANP32A expression *in vitro* in both the C28/I2 cell line and in hACs. *In vivo*, ANP32A expression was increased in wild-type mice treated with the hypoxia mimetic IOX2 intra-articularly after induction of OA by destabilization of the medial meniscus (DMM).

Conclusion: Limiting activation of Wnt signaling and maintaining the homeostatic hypoxic environment within the joint are strategies to sustain ANP32A levels and its protective effect against the development of osteoarthritis.

POS0229 ELUCIDATING THE MECHANISM OF ACTION DOWNSTREAM OF ROR2 BLOCKADE: A PHOSPHOPROTEOMIC APPROACH

A. S. Thorup[1], J. Wilson[1], P. Cutillas[2], F. Dell'accio[1]. *[1]Queen Mary University of London, William Harvey Research Institute, London, United Kingdom; [2]Queen Mary University of London, Barts Cancer Institute, London, United Kingdom*

Background: Osteoarthritis (OA) affects 12% of the population, and yet we still have no disease-modifying treatment. Cartilage breakdown is the hallmark of OA, and patients suffer from pain and loss of joint function/independence, severely affecting quality of life. Therefore, there is a huge unmet clinical need.
Receptor tyrosine kinase–like orphan receptor 2 (ROR2) is a non-canonical WNT receptor that regulates the planar cell polarity pathway, controlling limb outgrowth. During skeletal development chondrocytes require ROR2 to undergo hypertrophy in the process of endochondral bone formation (1). Loss of function mutations in humans causes Recessive Robinow Syndrome (limb shortening and brachydactyly (2,3)).
Although absent from healthy adult articular cartilage, our initial studies identified high ROR2 expression in chondrocytes from patients with OA, suggesting a role in the disease process.
In a murine model of OA, blocking ROR2 in therapeutic regime using siRNA resulted in reduced cartilage destruction and rapid and sustained pain relief. Due to the limited expression pattern of ROR2 in adulthood, no systemic or local toxicity were expected, nor were any observed. We also found that blocking ROR2 supports cartilage formation in a human cartilage organoid model in nude mice using chondrocytes from patients with OA, and proposed ROR2 blockade as a potential disease-modifying OA treatment.
The mechanism of action of ROR2 blockade was independent of modulation of canonical WNT signaling. YAP inhibition was required, but not sufficient, for the chondrogenic effect (4). Therefore, additional, yet unknown mechanisms must be involved downstream of ROR2 blockade.
Objectives: To study the phosphorylation events downstream of ROR2, to further our understanding of the mechanism of action of ROR2 blockade.
Methods: Phosphoproteomics (label free liquid chromatography tandem-mass spectrometry with TiO2 based phospho-enrichment), in vitro studies in cells, CRISPR.
Results: WNT5A is the most well established ligand for ROR2. We confirmed that WNT5A stimulation leads to time-dependent phosphorylation of ERK in C3H10T1/2 cells.
We then deleted ROR2 in C3H10T1/2 cells by CRISPR, and performed phosphoproteomics analysis on wildtype (control) C3H10T1/2 cells and ROR2-CRISPR C3H10T1/2 cells stimulated with 100ng/ml recombinant WNT5A for 5 or 15 minutes.
ROR2-dependant phosphorylation targets were defined as proteins differentially phosphorylated in control cells upon WNT5A stimulation, but that did not occur in ROR2-CRISPR cells.
YAP was phosphorylated by WNT5A in a ROR2-dependant manner. WNT5A/ROR2 also modulated the YAP signaling pathway at other levels.
KEGG analysis revealed that other pathways with known roles in the pathogenesis of OA were enhanced, including NF-KB, mTOR signaling and cellular senescence.
With the current technology, ROR2 blockade requires intra-articular injections of siRNA conjugated to atelocollagen every 5 days. Preliminary efficacy data of potentially longer-acting ROR2 blockers are promising.
Conclusion: ROR2 blockade has potential as a disease-modifying treatment for OA, resulting in cartilage protection and rapid and sustained pain relief in a murine model. Here, we studied the mechanism downstream of ROR2 blockade using a phosphoproteomics approach. We confirmed that YAP signaling was modulated by ROR2, and identified novel pathways and cellular processes regulated by WNT5A/ROR2. Further studies are needed to clarify their role downstream of ROR2 blockade in OA.
Our current siRNA-atelocollagen based technology requires intra-articular injections too frequently to be acceptable for patients. We are developing ROR2 blockade which can be administered systemically or intra-articularly not more often than every 3 months.

POS0230 THE MIR-320 FAMILY IS UPREGULATED IN FAST-PROGRESSING RADIOGRAPHIC KNEE OSTEOARTHRITIS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

S. Ali[1,2], O. Espin-Garcia[2], A. Wong[2], P. Potla[2], C. Pastrello[2], M. Mcintyre[2], S. Lively[2], I. Jurisica[2], R. Gandhi[2], M. Kapoor[2]. *[1]Henry Ford Hospital, Orthopaedic Surgery, Detroit, United States of America; [2]University Health Network, Schroeder Arthritis Institute, Toronto, Canada*

Background: There is an outstanding need for prognostic biomarkers to reliably detect fast-progressing knee osteoarthritis (OA) such that preventative interventions can be targeted to this patient population. MicroRNA-sequencing is an unbiased approach for comprehensive profiling of circulating microRNAs in liquid biopsies to discover novel biomarkers of disease. As negative regulators of gene expression, microRNAs hold potential not only as biomarkers, but also as mechanistic drivers of knee OA.
Objectives: To apply microRNA-sequencing to identify unique circulating microRNAs as potential biomarkers that distinguish fast-progressing radiographic knee OA from both slow- and non-progressing radiographic knee OA.
Methods: Leveraging the Osteoarthritis Initiative (OAI) longitudinal cohort, we applied our customized microRNA-sequencing pipeline [1] to blood plasma samples collected at both baseline and 4-year follow-up from 106 participants. The disease trajectory for each participant was constructed by plotting their Kellgren-Lawrence (KL) grades over an 8-year follow-up period. Based on these trajectories, we defined fast-progression as an increase from KL 0/1 at baseline to KL 3/4 by 4-year follow-up, slow-progression as an increase from KL 0/1 at baseline to KL 2/3/4 by 8-year follow-up, and non-progression as no increase from KL0/1 at baseline throughout the 8-year follow-up. Following differential expression analysis, we assessed predictive performance and identified putative gene targets for prioritized microRNAs.
Results: Comparing fast-progressors to both slow-progressors and non-progressors, we identified differentially expressed microRNAs within timepoints (i.e., 48 microRNAs at baseline and 2 microRNAs at 4-year follow-up) and across timepoints. Among these microRNAs were four members of the miR-320 family, with miR-320d showing an increase in fast-progressors at both timepoints, compared to both slow- and non-progressors. The predictive models we constructed included miR-320 members and had good accuracy (area under the receiver operating characteristic curves ranging from 82.6 to 91.9) in distinguishing fast-progressors. Putative gene targets of the miR-320 family included members of the 14-3-3 gene family (Table 1), including *YWHAE*, whose downregulation in OA cartilage was reported to promote deterioration [2].

Table 1. Predicted gene targets of the miR-320 family include members of the 14-3-3 gene family.

14-3-3 gene family member	hsa-miR-320b	hsa-miR-320c	hsa-miR-320d	hsa-miR-320e
SFN	M	M	M	L
YWHAB	M	M	M	M
YWHAE	V	**V**	V	**H**
YWHAG	V	V	V	M
YWHAH	**V**	**V**	**V**	M
YWHAQ	**V**	**V**	**V**	M
YWHAZ	**V**	**V**	**V**	M

All mirDIP results with bold text indicating the prediction was among the top 1% for that microRNA/gene target pair. Letters denote the mirDIP score class with V=very high, H=high, M=medium, and L=low.

Conclusion: This microRNA-sequencing study is the first of its kind, profiling circulating microRNAs at two timepoints in 106 participants with data-driven construction of knee OA trajectories. We identify the miR-320 family of microRNAs to be associated with fast-progressing radiographic knee OA over time. While our data suggest this microRNA family could have applications as prognostic biomarkers for knee OA, and could be regulating gene targets to impact OA severity, validation of these findings in independent longitudinal cohorts is required.

POS0231 GENETIC BIOMARKERS, SNP GENES AND MTDNA HAPLOGROUPS, PREDICT OSTEOARTHRITIS STRUCTURAL PROGRESSORS THROUGH THE USE OF SUPERVISED MACHINE LEARNING

H. Bonakdari[1], J. P. Pelletier[1], F. J. Blanco[2,3], I. Rego-Perez[2], A. Durán-Sotuela[2], D. Aitken[4], G. Jones[4], F. Cicuttini[5], A. Jamshidi[1], F. Abram[6], J. Martel-Pelletier[1].

Background: Knee osteoarthritis is the most prevalent chronic musculoskeletal debilitating disease. Current treatments are only symptomatic and to improve this, we need a robust prediction model to stratify patients at an early stage according to the risk of joint structure disease progression. Some genetic factors, including single nucleotide polymorphism (SNP) genes and mitochondrial (mt) DNA haplogroups/clusters, have been linked to this disease.
Objectives: For the first time, we aim to determine, by using machine learning, whether some SNP genes and mtDNA haplogroups/clusters alone or combined could predict early knee osteoarthritis structural progressors.
Methods: Participants (901) were first classified for the probability of being structural progressors. Genotyping included SNP genes TP63, FTO, GNL3, DUS4L, GDF5, SUPT3H, MCF2L, TGFA, mtDNA haplogroups H, J, T, Uk, others, and clusters HV, TJ, KU, C-others. They were considered for prediction with major risk factors of osteoarthritis, namely, age and body mass index (BMI). Seven supervised machine learning methodologies were evaluated. The support vector machine was used to generate gender-based models. The best input combination was assessed using sensitivity and synergy analyses. Validation was performed using 10-fold cross-validation as well as an external cohort (TASOAC).
Results: From 277 models, two were defined. Both used age and BMI in addition for the first one of the SNP genes *TP63, DUS4L, GDF5, FTO* with an accuracy of 85.0%; the second profits from the association of mtDNA haplogroups and SNP genes *FTO* and *SUPT3H* with 82.5% accuracy. The highest impact was associated with the haplogroup H, the presence of CT alleles for rs8044769 at *FTO*, and the absence of AA for rs10948172 at *SUPT3H*. Validation accuracy with the cross-validation (about 95%) and the external cohort (90.5%, 85.7%, respectively) was excellent for both models.
Conclusion: This study introduces a novel source of decision support in precision medicine in which, for the first time, two models were developed consisting of i) age, BMI, TP63, DUS4L, GDF5, FTO and ii) the optimum one as it has one less variable: age, BMI, mtDNA haplogroup, FTO, SUPT3H. Such a framework is translational and would be of benefit to patients at risk of structural progressive knee osteoarthritis.

POS0232 IDENTIFICATION OF THE CORE REGULATORY GENE NETWORKS REGULATING SUBCHONDRAL BONE AND MARROW ADIPOSE TISSUE REMODELING IN HUMAN KNEE OA

L. Ruffieux[1], E. Moradpour[1], A. Antoniadis[2], J. Wegrzyn[2], T. Hügle[1], J. Geurts[1].
[1]Lausanne University Hospital, Rheumatology, Lausanne, Switzerland; [2]Lausanne University Hospital, Orthopaedics, Lausanne, Switzerland

Background: Subchondral bone and the marrow adipose tissue (BMAT) contained therein undergo elevated turnover and remodeling during progression of osteoarthritis (OA). BMAT changes, detected as bone marrow lesions (BML) on MRI images, are considered important diagnostic and prognostic imaging biomarkers for OA. However, a comprehensive understanding of the regulatory mechanisms in individual BMAT-resident cell populations that mediate marrow fibrosis and subchondral bone sclerosis is still lacking. Recently generated single-cell transcriptomic atlas of human adipose tissue has opened new avenues for computational bulk tissue cell type deconvolution and dissecting gene regulatory networks.
Objectives: To infer core gene regulatory networks underlying subchondral bone sclerosis and BMAT remodeling in human knee OA.
Methods: We conducted comparative transcriptomics on bulk transcriptomic profiles of human subchondral bone tissue from three independent studies[1,2,3] comprising tibial plateaus from non-OA controls (*n*=20) and BMLs (*n*=14), non-sclerotic (*n*=45) and sclerotic (*n*=45) regions from patients with medial knee OA. Cell type deconvolution (adipocyte/pre-adipocyte/fibroblast/endothelial/macrophage) of differentially expressed genes (DEGs) was performed using single-cell atlases of human brown and white adipose tissue[4]. Cell type annotated DEGs were functionally annotated using Gene Ontology enrichment. To infer transcription factors (TFs) regulating gene networks we performed ChIP-Seq enrichment analyses and assessed the presence of TF binding sites in the proximal promoter (-500/+100) sequence of DEGs. Tissue explants were stained en bloc with Oil red O and Hoechst to evaluate distribution of neutral lipids and nuclei in BMAT from non-sclerotic and sclerotic regions.
Results: 534 upregulated and 363 downregulated DEGs were shared between at least two independent datasets. Cell deconvolution revealed the majority of upregulated DEGs were expressed in fibroblasts (38%), pre-adipocytes (27%) and endothelial cells (22%). Dowregulated DEGs were predominantly expressed by endothelial (31%), adipocyte (25%) and fibroblast (16%) cell populations. We inferred major TF regulatory networks driving upregulated DEGs in pre-adipocytes (*PRRX1*/*SNAI2*/*TWIST1*) and fibroblasts (*SP7*/*SMAD4*/*RUNX2*/*DLX5*) and loss of *PPARG*/*SOX17*/*SNAI1*-driven gene expression in adipocytes and endothelial cells. Pre-adipocyte genes were functionally enriched for collagen fibril organization, ossification and cell migration. Fibroblast genes associated with biomineral tissue development and negative regulation of angiogenesis. Downregulated DEGs were enriched for triglyceride catabolism and sequestration (adipocytes) and regulation of vascular permeability and endothelial cell differentiation (endothelial). Whole mount staining displayed homogenous distribution of neutral lipids in adipocytes and low cell abundance in BMAT from non-sclerotic tissue. In contrast, BMAT from sclerotic tissue showed heterogeneously distributed and lower neutral lipid content as well as high cell abundance (Figure 1).

Figure 1.

Conclusion: These data provide detailed insight into the cellular and molecular mechanisms underpinning subchondral bone and BMAT remodeling in OA. An expansion of pre-adipocyte populations along altered function of BMAT adipocytes might represent a previously unrecognized mechanism regulating subchondral bone sclerosis. TFs driving core gene regulatory networks might be promising therapeutic targets for knee OA.

POS0233 COMPARISON OF 3D QUANTITATIVE OSTEOARTHRITIS IMAGING BIOMARKERS: A STUDY USING PAIRED CT AND MR IMAGES FROM THE IMI-APPROACH STUDY.

A. Brett[1], M. A. Bowes[1], P. G. Conaghan[2]. *[1]Imorphics Ltd, Clinical Applications, Manchester, United Kingdom; [2]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: MRI bone surface area and femoral bone shape (B-score) measures have been employed as quantitative endpoints in DMOAD clinical trials. The B-score (typical range -2 to +7) has been shown to be an objective, automated assessment of OA status, with clinical risk defined for current and future pain, functional limitation and total knee replacement. Computerized Tomography (CT) imaging is more commonly used for 3D visualization of bony anatomy due to its high bone-soft tissue contrast. Also, CT images are not subject to the geometric distortion in MR images due to field inhomogeneities, a problem addressed in DMOAD clinical trials by positioning the knee near the magnet isocenter. Measurement of 3D joint space width (3DJSW) has been previously reported using CT images but is possible from MR images.

Objectives: To test the robustness of the B-score, bone area and 3DJSW imaging endpoints to the choice of imaging modality, we compared the results of automated analysis of CT and MR image pairs acquired at baseline and 24-month timepoints.

Methods: We used image data from the IMI-APPROACH exploratory, 2-year prospective cohort study. High resolution CT images were acquired at baseline and 24-months. These were matched with 3D T1w MR images with fat-sat or WE sequences. CT and MR images were acquired within a mean of 12 days of each other. Additional test-retest MR images with repositioning were available from 37 subjects. Kellgren-Lawrence Grades (KLG) were read centrally from screening weight-bearing x-rays.

Femur and tibia bones were automatically segmented with sub-voxel accuracy from CT or MR images using active appearance models, a machine learning model trained to search images (Imorphics, Manchester, UK). Bone area measurement was produced for MF.tAB, LF.tAB, MT.tAB and LT.tAB regions. Average 3DJSW was measured in central regions of the medial or lateral tibial plateaus, normal to the tibial surface

Linear regression was used to test for correlation between measures. Limits of agreement and systematic bias were tested using Bland-Altman analysis. Smallest detectable difference (SDD) for MR B-score was computed from test-retest image pairs using Bland-Altman analysis. Images acquired from the same subject at both baseline and 24-month timepoints were treated as independent.

Results: Baseline and 24-month CT-MR pairs of the same knee were available from 231 and 203 subjects respectively. 338 were female knees (78%). KLG was KLG0 (19%); KLG1 (31%); KLG2 (30%); KLG3 (16%); KLG4 (3%) with 5 knees ungraded (1%). SDD of the B-score measure was 0.227. Table 1 presents summary statistics for shape, area, and 3D JSW measures. Figure 1 shows linear regression and Bland-Altman analysis for B-score.

Table 1. Bland-Altman and linear regression statistics.

Measure	Bias [95% CI]	Limits of Agreement	R^2
B-score	0.10 [0.05, 0.14]	-0.90, 1.10	0.94
MF.tAB (mm^2)	-54.983 [-61.22, -48.75]	-184.52, 74.56	0.96
LF.tAB (mm^2)	-42.792 [-47.02, -38.57]	-130.56, 44.98	0.97
MT.tAB (mm^2)	-5.86 [-9.24, -2.48]	-76.00, 64.38	0.96
LT.tAB (mm^2)	-21.33 [-23.90, -18.77]	-74.66, 32.00	0.97
Med 3DJSW (mm)	1.04 [0.98, 1.11]	-0.32, 2.40	0.58
Lat 3DJSW (mm)	0.42 [0.34, 0.51]	-1.30, 2.14	0.47

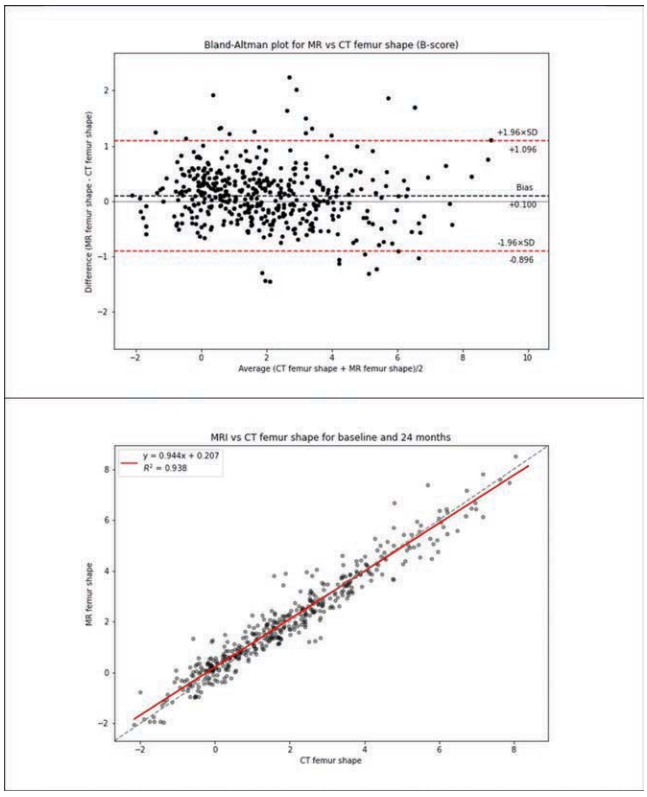

Figure 1. B-score. Top: Bland-Altman plot; Bottom: linear regression

Conclusion: B-score measures were highly correlated with CT and showed good agreement with a relatively small bias of 0.1 suggesting that B-score may be measured reliably using either modality. All 4 area measures were highly correlated and showed negative bias (MR smaller); it is likely that the bone surface identified using MR and CT will be at slightly different positions within the bone/cartilage boundary. A consistent negative bias suggests the MR bone boundary is inside the CT boundary. This is consistent with the positive bias in favour of MR for 3DJSW. However, the MR-CT difference for medial 3DJSW is larger than for lateral 3DJSW, possibly due to a difference in knee pose during acquisition (fully extended for CT, flexed for MR) – the tibia is more externally rotated with respect to the femur in the fully extended knee.

POS0234 HOW CLOSELY DO GERMAN RHEUMATOLOGISTS FOLLOW THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF RHEUMATOID ARTHRITIS WHEN MAKING THERAPEUTIC DECISIONS?

Y. Meissner[1], D. Huschek[1], A. Zink[1], J. Kaufmann[2], M. Bohl-Buehler[3], A. Strangfeld[1]. *[1]German Reumatism Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany; [2]Private Practice, Rheumatology, Ludwigsfelde, Germany; [3]Private Practice, Rheumatology, Potsdam, Germany*

Background: EULAR developed recommendations for the management of rheumatoid arthritis (RA) suggesting treatment escalation and changes at different stages of the disease to reach at least low disease activity with latest updates in 2013[(1)], 2016[(2)], and 2019[(3)]. The recommendation to *consider adding* a biologic disease-modifying anti-rheumatic drug (bDMARD) – or, since 2016, a Januskinase inhibitor (JAKi) – after the first conventional synthetic (cs) DMARD had failed and if poor prognostic factors (PPF) are present, was strengthened 2019. Since then, it is recommended that a bDMARD or a tsDMARD *should be added*.

Table 1. Number and percentages of treatment changes at different stages of the disease.

Patients with	1 previous csDMARD & no PPF	1 previous csDMARD & ≥1 PPF	2 previous csDMARDs	1 previous bDMARD/ JAKi	≥2 previous bDMARDs/ JAKi
EULAR Recommendation	change/add csDMARD	add bDMARD/ JAKi**	add bDMARD/ JAKi	change to another bDMARD/JAKi	
Total numbers of treatment changes	61	2073	2220	1700	1863
Period [I] 01/2014 – 12/2016* N=2,922	n=25	n=848	n=986	n=543	n=520
csDMARD	21 (84.0%)	594 (70.0%)	134 (13.6%)	199 (36.6%)	275 (52.9%)
bDMARD	4 (16.0%)	254 (30.0%)	852 (86.4%)	344 (63.4%)	245 (47.1%)
Period [II] 01/2017 – 06/2020 N=4,580	n=32	n=1,090	n=1,136	n=1,054	n=1,268
csDMARD	16 (50.0%)	469 (43.0%)	96 (8.5%)	261 (24.8%)	274 (21.6%)
bDMARD	13 (40.6%)	509 (46.7%)	822 (72.4%)	403 (38.2%)	288 (22.7%)
JAKi	3 (9.4%)	112 (10.3%)	218 (19.2%)	390 (37.0%)	706 (55.7%)
Period [III] 07/2020 – 04/2021 N=415	n=4	n=135	n=98	n=103	n=75
csDMARD	0	43 (31.9%)	7 (7.1%)	15 (14.6%)	9 (12.0%)
bDMARD	1 (25.0%)	64 (47.4%)	60 (61.2%)	36 (35.0%)	23 (30.7%)
JAKi	3 (75.0%)	28 (20.7%)	31 (31.6%)	52 (50.5%)	43 (57.3%)

*EULAR treatment recommendations are indicated in green. *JAKi were not available. **Recommendation in period [I]: Addition of a bDMARD should be considered; in [II]: Addition of a bDMARD or a tsDMARD should be considered, current practice would be to start a bDMARD; in [III]: a bDMARD or a tsDMARD should be added. PPF, poor prognostic factor.*

Objectives: How closely are EULAR recommendations followed in daily rheumatologic practice in Germany?

Methods: Data were used from the long-term observational cohort RABBIT, which enrols patients with RA starting a bDMARD or JAKi, or a csDMARD after at least one previous csDMARD failure. According to the publication of the recommendations, periods from [I] 01/2014 – 12/2016, [II] 01/2017 – 06/2020 and [III] 07/2020 – 04/2021 were investigated. Patients who were in at least moderate disease activity (DAS28≥3.2) were selected and analysed, if they started a csDMARD, a bDMARD or a JAKi. Patients were further stratified by prior treatments and by the presence of PPF (≥4 swollen joints, positive rheumatoid factor or ACPA, erosions).

Results: Of the 15,150 patients with RA enrolled since 2007, 2,922 treatments were initiated in period [I], 4,580 in [II] and 415 in [III] (see Table 1). The proportion of patients with 1 previous csDMARD and ≥1 PPF who – in agreement with the recommendations – switched to bDMARD or JAKi, increased from 30% (only bDMARDs) in period [I] to 68% (bDMARDs + JAKi) in [III]. The proportions were even higher in patients with 2 previous csDMARDs (86% in [I], 93% in [III]). As recommended, JAKi were used more often as first line therapy (after csDMARD) in period [III].

Conclusion: JAKi have become more established, especially in bionaive patients, but have not reached the significance of biologics in certain patient groups. The early decision for a bDMARD or JAKi has been made more frequently in recent years, yet one third of patients did not receive the recommended treatment escalation. We cannot conclude from the data, which considerations led to the decision not to escalate. Of note, German rheumatologists should rather follow the German treatment guidelines[(4)], which are, however, very similar to the EULAR recommendations.

Background: The preferential Janus kinase-1 inhibitor FIL significantly improved signs and symptoms of RA in Phase 2 and 3 trials.[1–5] FIL is approved for treatment of moderate to severe active RA in Europe and Japan. Integrated safety analysis of FIL with patient data through 2019 was presented at the 2020 ACR virtual meeting.[6]

Objectives: To report updated, as-treated data from the FIL integrated safety analysis with increased study drug exposure.

Methods: Data were integrated from 2 Phase 2 (NCT01668641, NCT01894516), 3 Phase 3 (NCT02889796, NCT02873936, NCT02886728), and 2 long-term extension (LTE) (NCT02065700, NCT03025308) trials. Phase 2 and 3 LTE data were through Nov 2020 and Jan 2021, respectively. The as-treated analysis set included all available data for pts receiving ≥1 dose FIL 200 (FIL200) or 100 mg

Table 1. TEAEs of special interest, as-treated set

TEAE, n (%) and EAIR per 100 PYE (95% CI)	FIL 200 mg n=2267 PYE=5302.5	FIL 100 mg n=1647 PYE=2782.6	Total FIL N=3691 PYE=8085.1
Infectious AEs	1206 (53.2)	747 (45.4)	1927 (52.2)
EAIR	21.1 (19.7, 22.5)	30.2 (26.8, 34.0)	21.0 (19.9, 22.3)
Serious infectious AEs	80 (3.5)	57 (3.5)	137 (3.7)
EAIR	1.5 (1.1, 1.9)	2.7 (1.9, 3.9)	1.6 (1.3, 2.0)
Opportunistic infections	5 (0.2)	4 (0.2)	9 (0.2)
EAIR	0.1 (0, 0.2)*	0.1 (0.1, 0.4)*	0.1 (0.1, 0.2)*
Active tuberculosis	0	3 (0.2)	3 (<0.1)
EAIR	0	0.1 (0, 0.3)*	0 (0, 0.1)*
Herpes zoster	84 (3.7)	30 (1.8)	114 (3.1)
EAIR	1.6 (1.2, 2.0)	1.1 (0.8, 1.5)*	1.4 (1.1, 1.7)
Major adverse cardiovascular events[a]	19 (0.8)	14 (0.9)	33 (0.9)
EAIR	0.3 (0.2, 0.5)	0.5 (0.3, 0.8)*	0.4 (0.2, 0.6)
Venous thromboembolism[b]	11 (0.5)	4 (0.2)	15 (0.4)
EAIR	0.2 (0.1, 0.4)*	0.1 (0.1, 0.4)*	0.2 (0.1, 0.3)*
Atrial systemic thrombotic events[a]	1 (<0.1)	1 (<0.1)	2 (<0.1)
EAIR	0 (0, 0.1)	0 (0, 0.3)	0 (0, 0.1)
Malignancy excluding NMSC	32 (1.4)	17 (1.0)	49 (1.3)
EAIR	0.6 (0.4, 0.9)	0.6 (0.4, 1.0)*	0.6 (0.4, 0.8)
NMSC	15 (0.7)	5 (0.3)	20 (0.5)
EAIR	0.3 (0.2, 0.5)*	0.2 (0.1, 0.4)*	0.2 (0.2, 0.4)*
Gastrointestinal perforations	3 (0.1)	1 (<0.1)	4 (0.1)
EAIR	0.1 (0, 0.2)*	0 (0, 0.3)*	0 (0, 0.1)*

*Except when any study had 0 event within the treatment, the Poisson model was not adjusted by study. PYE was defined as (last dose date – first dose date + 1)/365.25.
[a]Positively adjudicated.
[b]Adjudicated as deep vein thrombosis or pulmonary embolism.
NMSC, nonmelanoma skin cancer

(FIL100), including those rerandomized to FIL for LTE. Exposure-adjusted incidence rates (EAIR)/100 patient-y exposure (PYE) of treatment-emergent adverse events (TEAEs; onset after first dose and no later than 30 days after last dose or new drug first dose date –1 day) and TEAEs of special interest (AESIs) are presented.

Results: 3691 pts received FIL200 or FIL100 for 8085.1 PYE (median 2.2, maximum 6.8 y). In the as-treated set, 61% of FIL200 and 45% of FIL100 pts received FIL for ≥2 y, 19% and 5% for ≥3 y, and 11% and 0.5% for ≥4.5 y, respectively. EAIR for TEAEs was higher with FIL100 than FIL200; EAIRs for deaths were 0.5 and 0.3 for FIL200 and FIL100 (Figure 1). Incidences of infections and serious infections were numerically greater for FIL100 vs FIL200, while EAIRs for other AESIs were comparable between doses (Table 1). EAIRs for AESIs tended to decrease since the previous update, except for venous thromboembolism (total FIL 0.1 to 0.2) and malignancies excluding NMSC (total FIL 0.5 to 0.6).

Conclusion: With 1 additional year of exposure since the 2020 report, FIL continues to be well tolerated with no new safety concerns emerging. EAIRs of TEAEs, including deaths, and AESIs remained stable or decreased since the 2020 report, except for slight increases in rates of NMSC and malignancies excluding NMSC. In the context of demonstrated efficacy, both FIL doses had an acceptable risk/benefit profile.

POS0236 SAFETY AND EFFICACY OF NEUROSTIMULATION WITH A MINIATURIZED VAGUS NERVE STIMULATION DEVICE IN PATIENTS WITH MULTIDRUG-REFRACTORY RHEUMATOID ARTHRITIS: 24-WEEK FOLLOW-UP OF A RANDOMIZED CONTROLLED FIRST-IN-HUMAN TRIAL

N. Gaylis[1], M. C. Genovese[2], D. Sikes[3], A. Kivitz[4], D. M. Horowitz[5], C. Peterfy[6], Y. Levine[7], M. Evangelista[8], D. Chernoff[9]. *[1]Arthritis and Rheumatic Disease Specialties, Rheumatology, Aventura, FL, United States of America; [2]Stanford University, Immunology and Rheumatology, Palo Alto, CA, United States of America; [3]Florida Medical Clinic, Rheumatology, Zephyrhills, FL, United States of America; [4]Altoona Center for Clinical Research, Rheumatology, Duncansville, PA, United States of America; [5]Northwell Health, Rheumatology, Great Neck, NY, United States of America; [6]Spire Sciences Inc, Radiology, Boca Raton, FL, United States of America; [7]SetPoint Medical Inc, Clinical Research and Development, Valencia, CA, United States of America; [8]SetPoint Medical Inc, Clinical Research and Development, Valencia, CA, United States of America; [9]SetPoint Medical Inc, Medical Affairs, Valencia, CA, United States of America*

Background: Vagus nerve stimulation (VNS) activates innate neuroimmune reflexes that have been shown to reduce pro-inflammatory cytokines and clinical disease activity in subjects with rheumatoid arthritis (RA).[1] We previously reported primary clinical outcomes from a first-in-human, double-blind study of a novel, implanted VNS device called a MicroRegulator (MR). That study showed 5/10 subjects with drug-refractory RA met or exceeded the minimal clinically important difference (MCID) in DAS28-CRP; 2 subjects achieved DAS28 remission (DAS28-CRP < 2.6); and pro-inflammatory cytokines were decreased by >30% following 12 weeks of VNS.[2] We now report 24-week efficacy and safety findings from this study.

Objectives: Determine the long-term safety and exploratory efficacy of neurostimulation using a novel, miniaturized VNS device in patients with multiple drug refractory RA who were previously enrolled in a first in human study.

Methods: The primary study enrolled adult patients with active moderate-to-severe RA with incomplete response or intolerability to at least two biologic and/or targeted synthetic DMARDs having at least two different mechanisms of action. The study was enrolled in 2 Stages: Stage 1 (n=3) was open-label, and Stage 2 (n=11) was randomized and sham-controlled (Figure 1). Three weeks after MR implantation, the first 3 subjects in Stage 1 received active VNS for 1 minute, once per day (QD). Following safety review board approval, 11 patients in Stage 2 were implanted with the MR and randomized 1:1:1 into one of two active VNS groups (1 minute of VNS QD or 1 minute of active VNS four times per day [QID]) or a sham group. At Week 12, the blind was lifted, sham subjects were re-randomized and crossed over to either QD or QID active VNS dosing, and all actively treated subjects remained on their dosing through Week 24. Safety and tolerability were determined, and several secondary efficacy endpoints were evaluated measuring the change in disease activity from the start of active VNS to Week 24.

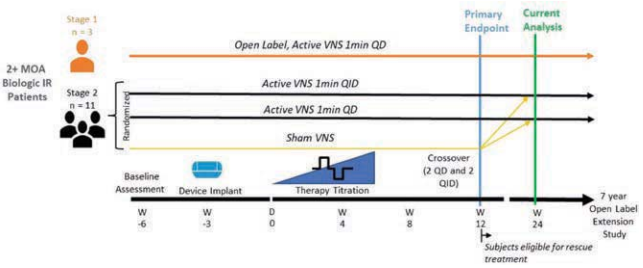

Figure 1. Study Schematic

Results: There were no device-related adverse events from Week 12 through Week 24. Improvement in clinical disease activity was sustained through Week 24: 5/9 patients within the original, active VNS treatment groups met or exceeded

EULAR response criteria for DAS28-CRP at Week 24 (Table 1) vs. 5/10 at Week 12 (one Week 12 responder was lost to follow-up). Similarly, 6/9 patients in the original, active VNS treatment groups met or exceeded the MCID in CDAI at Week 24 vs. 5/10 at Week 12. In the long-term extension, 1/4 sham crossover patients had both EULAR and CDAI response after 12 weeks of VNS (1/2 QD, 0/2 QID). Co-therapy with a b/tsDMARD was initiated in 2 subjects (Table 1). One crossover subject was treated with oral methylprednisolone at week 19 due to worsening RA disease activity. VECTRA composite scores and component analysis revealed an 18-point decrease in median multi-analyte disease activity index in the QD group over 24 weeks of VNS with a decrease in serum levels of several analytes in key component categories (IL-6, serum amyloid A, and VCAM-1). Erosion progression by hand MRI was stabilized or decreased in all but 1 of the stimulated patients at Week 24.

Table 1. Change in DAS28-CRP at Week 24

Subject	Treatment	DAS28-CRP (MCID -1.2) *added b/tsDMARD co-therapy
005-01	QD	-2.4
005-03	QD	-2.21
006-01	QD	-0.07
002-01	QD	-4.95 *
005-06	QD	-0.72 *
006-03	QID	-0.69
008-01	QID	0.49
008-03	QID	-3.14
008-04	QID	1.43
005-05	Sham to QD	0.39
006-04	Sham to QD	-0.78
006-02	Sham to QID	-0.22
008-02	Sham to QID	-0.09

Conclusion: Improvements in clinical disease activity and pro-inflammatory cytokine suppression were maintained through 24 weeks of VNS treatment. Safety outcomes continue to support the risk/benefit profile of VNS as a treatment option for patients with multiple-drug refractory RA.

Background: ORAL Surveillance was a post-authorisation safety study of tofacitinib vs TNF inhibitors (TNFi) in rheumatoid arthritis (RA) patients (pts) aged ≥50 yrs with ≥1 additional cardiovascular (CV) risk factor and an inadequate response to methotrexate (MTX). CV disease has overlapping risk factors with malignancies and venous thromboembolism (VTE), including older age, smoking, hypertension and diabetes.[1,2]

Objectives: To evaluate the impact of pts' baseline (BL) CV risk on the incidence and risk of major adverse CV events (MACE), malignancies and VTE in ORAL Surveillance.

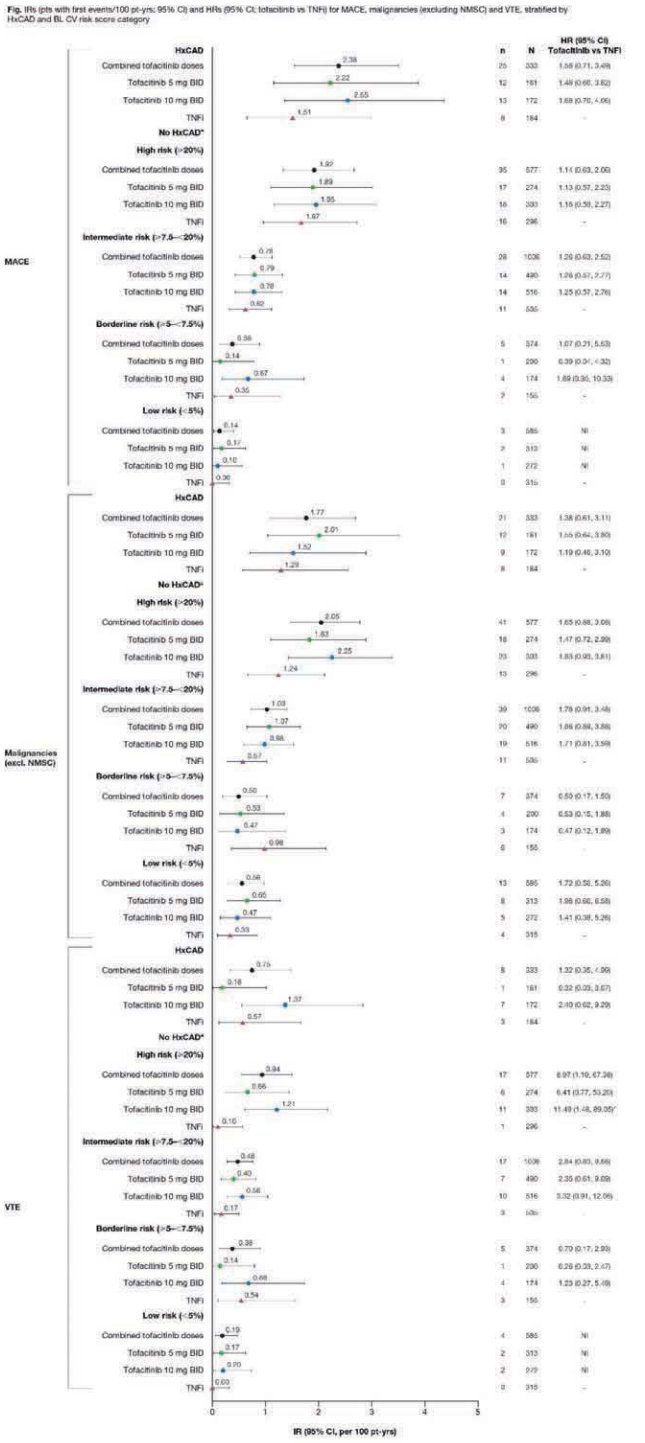
Methods: Pts on stable MTX were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (adalimumab 40 mg every 2 weeks or etanercept 50 mg once weekly). Incidence rates (IRs; pts with first events/100 pt-yrs) and hazard ratios (HRs; tofacitinib vs TNFi) were evaluated for adjudicated MACE (defined as CV death [excluding CV death due to pulmonary embolism (PE)], non-fatal MI and non-fatal stroke), malignancies (excluding NMSC) and VTE (including fatal/non-fatal deep vein thrombosis and PE). Across safety outcomes, IRs/HRs were stratified by BL CV risk score: pts were first categorised by history of coronary artery disease (HxCAD); pts without a HxCAD were further stratified by BL CV risk score categories (high [≥20%], intermediate [≥7.5–<20%], borderline [≥5–<7.5%] and low [<5%] risk), with a 1.5 multiplier applied per EULAR recommendations.[3]

Results: 4362 pts were included: tofacitinib 5 mg BID, n=1455; tofacitinib 10 mg BID, n=1456; TNFi, n=1451. In these treatment groups, during a median follow-up of 4.0 yrs, MACE was reported in 47 (3.2%), 51 (3.5%) and 37 (2.6%) pts, malignancies in 62 (4.3%), 60 (4.1%) and 42 (2.9%) pts, and VTE in 17 (1.2%), 34 (2.3%) and 10 (0.7%) pts, respectively. Approximately two-thirds of pts had intermediate to high CV risk, or HxCAD, and risk was well-balanced across treatment groups (Table 1). Across treatments, MACE and malignancies IRs were highest in pts with a HxCAD or a high BL CV risk score (Figure 1). IRs/HRs for MACE, malignancies and VTE were generally higher with tofacitinib vs TNFi. Differences between tofacitinib vs TNFi in MACE and malignancy IRs/HRs were typically more pronounced in pts with a HxCAD or at least intermediate BL CV risk score, and less so in pts with lower BL CV risk score (Figure 1). In tofacitinib 10 mg BID-treated pts, VTE IRs/HRs (vs TNFi) were clearly highest in pts with a HxCAD or high BL CV risk score; no association between VTE and BL CV risk scores was observed with tofacitinib 5 mg BID or TNFi (Figure 1).

Table 1. Percentages of pts with a HxCAD and pts without a HxCAD categorised by BL CV risk scores, per ASCVD-PCE risk calculator[4] with a 1.5 multiplier applied[3]

	Tofacitinib 5 mg BID (N=1455)	Tofacitinib 10 mg BID (N=1456)	TNFi (N=1451)
HxCAD, n (%)	161 (11.1)	172 (11.8)	164 (11.3)
No HxCAD: BL CV risk score, per ASCVD-PCE risk calculator, n (%)			
High (≥20%)	274 (18.8)	303 (20.8)	296 (20.4)
Intermediate (≥7.5–<20%)	490 (33.7)	516 (35.4)	505 (34.8)
Borderline (≥5–<7.5%)	200 (13.7)	174 (12.0)	155 (10.7)
Low (<5%)	313 (21.5)	272 (18.7)	315 (21.7)
Missing data	17 (1.2)	19 (1.3)	16 (1.1)

HxCAD is defined as any history of MI, coronary heart disease, stable angina pectoris or coronary artery procedures n, number of pts with specified characteristics; N, number of evaluable pts



Conclusion: In this post hoc analysis of data from ORAL Surveillance, IRs for MACE and malignancies (excluding NMSC) were highest across treatments, and increased with both tofacitinib doses vs TNFi, in pts with a HxCAD or high BL CV risk score; a similar finding was observed for VTE IRs in pts treated with tofacitinib 10 mg BID. These findings support recommendations to regularly assess and address CV risk in RA pts.

POS0238

SIDE EFFECT PROFILE OF HYDROXYCHLOROQUINE USE IN PATIENTS WITH RA, SLE, AND OTHER RMDS OVER 20 YEARS

K. Michaud[1,2], S. Pedro[2]. [1]*University of Nebraska Medical Center, Internal Medicine, Omaha, United States of America;* [2]*FORWARD, The National Databank for Rheumatic Diseases, Research, Wichita, United States of America*

Background: During the pandemic, hydroxychloroquine (HCQ) became a household name, yet despite more than 70 years as a csDMARD treatment, relatively little is known about its overall side effect (SE) profile.
Objectives: To understand the types, severity, and rates of patient-reported side effects of HCQ in adults with RA, SLE, and other RMDs alone and in comparison with methotrexate (MTX).
Methods: Adult participants in the Forward Databank observational registry reported all medication use and medication side effects through biannual questionnaires from 1999 through 2021. Incident use of HCQ and MTX were measured at enrollment and longitudinally with additional reporting of severity of side effects, certainty of medication as cause of side effect, and affected body systems. We analyzed incident rates of side effects overall and by HCQ or MTX categorical use, respectively: monotherapy, with concomitant use of another csDMARD, or with concomitant use of a bDMARD or tsDMARD. Finally, the likelihood of having any side effects was analyzed in Cox regression models by comparing HCQ initiators to MTX initiation, and within each, combination MTX or HCQ with csDMARD or bDMARD to monotherapy; these

Table 1. Incidence rates (IR) per 1000 patient-years of SEs by diagnoses for HCQ and MTX initiators

	RA		SLE		Other	
	Pt-yrs	IR (95% CI)	Pt-yrs	IR (95% CI)	Pt-yrs	IR (95% CI)
Any HCQ SE	12711	26 (23, 29)	1305	25 (18, 36)	567	41 (27, 61)
Mono HCQ	3397	28 (24, 33)	797	28 (18, 42)	347	52 (32, 82)
HCQ + csDMARDs	5473	28 (24, 33)	416	24 (13, 45)	127	32 (12, 84)
HCQ + bDMARDs	3841	22 (17, 27)	93	11 (2, 77)	93	11 (2, 76)
SE stopping HCQ	12711	13 (11, 15)	1305	12 (7, 19)	567	14 (6, 35)
Mono HCQ	3397	12 (9, 16)	797	11 (6, 22)	347	14 (6, 35)
HCQ + csDMARDs	5473	15 (12, 18)	416	13 (5, 31)	127	24 (8, 73)
HCQ + bDMARDs	3841	12 (9, 16)	93	0	93	0
HCQ SE hospitalization	12711	0.31 (0.12, 0.84)	1305	0.77 (0.1, 5.4)	567	0
Any MTX SE	81234	51 (49, 52)	1516	59 (48, 72)	2145	72 (61, 84)
Mono HCQ	22980	49 (46,52)	369	41 (25, 67)	802	62 (47, 82)
MTX + csDMARDs	15447	72 (68, 77)	872	69 (53, 89)	229	131 (91, 187)
MTX + bDMARDs	42748	43 (41, 45)	265	49 (29, 85)	1106	67 (53, 84)
SE stopping MTX	91477	26 (25, 27)	1638	41 (32, 52)	2335	44 (36, 53)
Mono MTX	26060	19 (17, 20)	390	33 (19, 57)	885	27 (17, 39)
MTX + csDMARDs	17430	38 (36, 42)	933	48 (36, 65)	255	90 (60, 136)
MTX + bDMARDs	47832	25 (23, 26)	305	26 (13, 53)	1188	47 (36, 61)
MTX SE hospitalization	96436	2.4 (2.1, 2.8)	1674	5.4 (2.8, 10.3)	2502	3.2 (1.6, 6.4)

By body system, the patterns of any SE were similar between HCQ or MTX initiators. Gastrointestinal SEs were the most common for both. Only ocular SEs were higher for HCQ vs. MTX. Multivariable Cox regression models of HCQ vs MTX SEs had a HR 0.46 (0.41 - 0.51) for RA, HR 0.47 [0.27 – 0.82] for SLE, and HR 0.51 [0.25 – 1.02] for other RMDs. While there was no difference in HCQ SEs by concomitant category or diagnoses, there was consistently higher SE rates in MTX for those on concomitant csDMARD vs monotherapy: RA HR 1.27 (1.16 - 1.38), SLE HR 1.97 (1.03 - 3.52), and other RMDs HR 2.04 (1.28 - 3.24).

models were adjusted for age, sex, RD Comorbidity Index, patient global, pain, disease duration, and number of bDMARDs used.

Results: Overall, 5874 patients initiated HCQ and 10420 initiated MTX, with RA as the predominant diagnosis. Mean baseline characteristics were similar for RA: 59 years old, 80% female and 12 years of RA duration. HCQ was mostly used with other csDMARDs, while MTX was mostly used with bDMARDs. In the other RMD and SLE groups, most were on HCQ monotherapy. For all RMDs, SE incidence for HCQ (16 – 17%) was lower than MTX (26 – 39%). The Table 1 provides incidence rates by HCQ/MTX for any SE, a SE that forces medication discontinuation, and SE leading to hospitalization. Reported SE rates were always higher for MTX vs. HCQ for all SE severity and diagnoses.

Conclusion: This is the largest study yet to review patient-reported SEs from HCQ and MTX in RA and other RMDs over a 20-year period. While validating SEs was beyond the scope of the current study, we found an overall low incidence of SEs from HCQ use, with an adjusted rate half of those reported for MTX, and that this low rate did not differ by diagnosis or concomitant DMARD use.

POS0239

RISK OF VENOUS THROMBOEMBOLIC EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS AGED ≥50 YEARS WITH ≥1 CARDIOVASCULAR RISK FACTOR: RESULTS FROM A PHASE 3B/4 RANDOMISED STUDY OF TOFACITINIB VS TUMOUR NECROSIS FACTOR INHIBITORS

C. Charles-Schoeman[1], R. M. Fleischmann[2], E. Mysler[3], M. Greenwald[4], C. Wang[5], A. S. Chen[5], C. A. Connell[5], J. Woolcott[6], S. Menon[5], Y. Chen[7], K. Lee[7], Z. Szekanecz[8]on behalf of ORAL Surveillance Investigators.

[1]University of California, Department of Medicine, Los Angeles, CA, United States of America; [2]Metroplex Clinical Research Center; University of Texas Southwestern Medical Center, Department of Internal Medicine, Dallas, TX, United States of America; [3]Organización Médica de Investigación, Rheumatology, Buenos Aires, Argentina; [4]Desert Medical Advances, Rheumatology, Palm Desert, CA, United States of America; [5]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America; [6]Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America; [7]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America; [8]University of Debrecen, Division of Rheumatology, Faculty of Medicine, Debrecen, Hungary

Background: ORAL Surveillance (NCT02092467) was a randomised, open-label, non-inferiority, Phase 3b/4 study assessing the relative risk of major adverse cardiovascular (CV) events (MACE) and malignancies with tofacitinib vs TNF inhibitors (TNFi) in patients (pts) with moderate to severe rheumatoid arthritis despite methotrexate (MTX) and a high risk of MACE (aged ≥50 yrs; ≥1 additional CV risk factor).

Objectives: To assess risk of venous thromboembolic events (VTE; including deep vein thrombosis [DVT] and pulmonary embolism [PE]) in ORAL Surveillance.

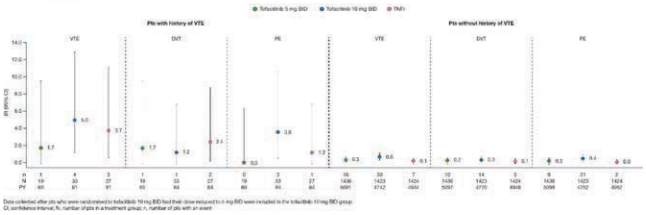
Methods: Pts on stable MTX received tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (etanercept 50 mg weekly or adalimumab 40 mg once every 2 weeks). Incidence rates (IRs; pts with first events/100 pt-yrs [PY]) and 95% CIs were calculated for adjudicated VTE, DVT and PE (overall by 6-month interval and for pts with/without history of VTE). For overall VTE, DVT and PE, numbers needed to harm (NNH; tofacitinib 5 or 10 mg BID vs TNFi) were calculated post hoc. Multivariate Cox models were used post hoc to identify overall independent baseline (BL) risk factors for PE. Censoring time was a 28-day on-treatment period (minimum of last contact date or last study treatment dose date +28 days).

Results: Analysis included 1455, 1456 and 1451 pts receiving tofacitinib 5 mg BID, 10 mg BID and TNFi, respectively. Generally, across 6-month intervals to >54 months, VTE, DVT and PE IRs were numerically higher with both tofacitinib doses vs TNFi, and with tofacitinib 10 vs 5 mg BID; IRs were consistent across time (data not shown). Across treatments, VTE, DVT and PE IRs were higher in pts with vs without history of VTE; however, only a small number

Table 1. Multivariate Cox analyses to identify overall independent BL risk factors for PE across treatments

	HR (95% CI)	p value
BL covariate		
History of VTE	7.06 (2.46, 20.25)	0.0003
Antidepressant use[a]	2.94 (1.44, 6.02)	0.0032
Body mass index ≥30 kg/m^2	2.97 (1.40, 6.32)	0.0047
Corticosteroid use[b]	3.01 (1.40, 6.46)	0.0047
Proton pump inhibitor use	0.32 (0.15, 0.71)	0.0052
Male sex[c]	2.18 (1.06, 4.48)	0.0340
Age ≥65 yrs	2.00 (1.03, 3.88)	0.0401
Oral contraceptives/HRT use	3.56 (1.05, 12.10)	0.0422
History of hypertension	2.57 (0.98, 6.76)	0.0554

[a]BL antidepressant use was an indicator of an underlying condition of depression, and subgroup analysis did not identify the difference in HRs for depression across treatments[b]Proxy for elevated BL disease activity; HRs for BL corticosteroid use were similar between all tofacitinib doses combined and TNFi; includes any BL corticosteroid use[c]Impact of sex on PE risk considered inconclusiveMultivariate Cox model using backward selection included treatment effects (not subject to model selection) and overall potential independent risk factors (those affecting PE IRs equally across treatments; subject to model selection) identified from a prior set of Cox regression analyses (which included treatment and a single candidate risk factor in each model fitting, cycling through a predetermined set of risk factors); cut-off for risk factor to stay in multivariate model was p<0.10; nominal p value and HR (95% CI) based on this modelHR, hazard ratio



of pts per treatment had history of VTE (Figure 1). NNH for tofacitinib 5 and 10 mg BID, respectively, vs TNFi were 763 and 198 PY for VTE, 1347 and 589 PY for DVT, and 870 and 229 PY for PE, or, over 5 yrs, 153 and 40 pts for VTE, 269 and 118 pts for DVT, and 174 and 46 pts for PE. Identified BL risk factors for PE across treatments included history of VTE, antidepressant use, body mass index ≥30 kg/m^2, corticosteroid use, male sex, age ≥65 yrs, oral contraceptives/hormone-replacement therapy (HRT) use, and history of hypertension (Table 1).

Conclusion: Generally, in ORAL Surveillance, VTE, DVT and PE IRs were numerically higher for tofacitinib (10 > 5 mg BID) vs TNFi across 6-month intervals, and for pts with vs without history of VTE. Multivariate Cox models identified BL risk factors for PE that may help support future treatment decisions.

POS0240 WHICH FACTORS DRIVE THE CHOICE BETWEEN A 1ST AND 2ND GENERATION TSDMARD THERAPY IN RA THERAPY?

D. De Cock[1], P. Durez[2,3], V. Badot[4], R. Westhovens[1,5], P. Verschueren[1,5]on behalf of TARDIS Working Group. *[1]KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium; [2]Université catholique de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Louvain La Neuve, Belgium; [3]Cliniques Universitaires Saint-Luc, Department of Rheumatology, Brussel, Belgium; [4]CHU-UVC Brugmann, Division of Rheumatology, Brussels, Belgium; [5]University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium*

Background: Tofacitinib and Baricitinib are Janus Kinase Inhibitors (JAKi) considered first generation targeted synthetic DMARD (tsDMARDs) for the treatment of Rheumatoid Arthritis (RA). The second generation of JAKi (Upadacitinib and Filgotinib) seem to target JAK1 more selectively. Choice of JAKi is left to the treating rheumatologist as no head-to head-study or guidelines exist on this choice in RA.

Objectives: To investigate differences in demographics and clinical variables of patients with RA receiving either a 1st or a 2nd generation JAKi in daily practice.

Methods: Patients were included from the electronic platform "Tool for Administrative Reimbursement Drug Information Sharing" (TARDIS). Data from all Belgian RA patients on biologic (b) and tsDMARDs are here collected for drug reimbursement. Patients were selected for this analysis if starting a JAKi in 2021. Differences in demographic and clinical data were compared by χ^2-tests and t-tests. Stepwise logistic regression models with tsDMARD choice as dependent variable was constructed with variables with $p<0.05$ in univariate analyses. Sensitivity analyses for bionaïve and bioexperienced patients were performed.

Results: In total, 1643 patients with RA starting JAKi therapy in 2021 were included. Of these, 433 (26.4%) were 1s generation and 1210 (73.6%) were 2nd generation. Patients starting a 1st generation JAKi were older, had higher Health Assessment Questionnaire (HAQ) scores, had a higher erythrocyte sedimentation rate (ESR), and less patients starting a 1st generation JAKi were bioexperienced (Table 1).

The final logistic regression model included older age (OR(95%) =1.0(1.0-1.0)) and number of previous b/ts DMARDs ((OR(95%) =0.9(0.8-0.9))) as predictors of choice of 1st generation tsDMARDs (Table 2). In bionaive patients, only ESR (OR(95%) =1.0(1.0-1.0)) was predictive. In bioexperienced patients, older age (OR(95%) =1.0(1.0-1.0)), number of previous b/ts DMARDs ((OR(95%) =0.8(0.7-0.9)) and TJC (OR(95%) =1.0(1.0-1.1)) were predictors for choice of 1st generation tsDMARDs. HAQ was not included as it was missing in 90% of patients.

Conclusion: The high uptake of 2nd generation JAKi, just launched in 2021, is remarkable. Some variables effecting the choice of JAKi were found, yet these effects seemed to be small-sized. These drug choices could also be driven by other factors such as socio-economic status, illness perceptions or other patient reported outcomes, and also by marketing and sales.

JAK INHIBITORS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: EXPLORING EARLY RESPONSE ON CENTRAL SENSITIZATION AND CATASTROPHISM SYMPTOMS

F. Salaffi[1], M. DI Carlo[1], M. Carotti[2], L. Ceccarelli[3], S. Fulginei[1], S. Farah[1], A. Giovagnoni[2]. [1]*Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale "Carlo Urbani", Jesi, Italy;* [2]*Università Politecnica delle Marche, Dipartimento di Scienze Radiologiche, Ospedali Riuniti, Ancona, Italy;* [3]*Azienda Ospedaliero-Universitaria Sant'Anna, Department of Interventional and Diagnostic Radiology, Ferrara, Italy*

Background: Catastrophizing has been demonstrated to be linked with central sensitization (CS), although few studies have investigated the potential of interactions between catastrophizing and CS in patients receiving JAK inhibitors.

Objectives: To explore the link between changes in Simplified Disease Activity Index (SDAI) and changes in pain catastrophizing, pain intensity, neuropathic pain component (NPC) and CS symptoms that occur with the introduction of a novel treatment targeting the JAK/STAT signalling pathway.

Methods: 115 patients in an ongoing prospective observational analysis filled out questionnaires at the start and conclusion of the research, using the Pain Catastrophizing Scale (PCS) and Central Sensitization Inventory (CSI). The study included 22 patients on tofacitinib monotherapy (5 mg BD), 19 on tofacitinib and MTX, 19 on baricitinib monotherapy (4 mg OD), 14 on baricitinib and MTX, 17 on upadacitinib monotherapy (15 mg OD), 16 on upadacitinib and MTX, and 8 on filgotinib (200mg OD) and MTX. The disease activity index was evaluated by the simplified disease activity index (SDAI). The US scoring system validated in the US-CLARA was used. The Semantic Questionnaire for Rheumatology (SQR) and PainDETECT questionnaire (PDQ), were used to assess pain severity and NPC. Using multivariable linear regression models, we investigated the connection between changes in SDAI and in CSI, PCS, PDQ, SQR and US score.

Results: At baseline, the percentage of RA patients who exceeded the thresholds for the presence of NPC (PDQ > 19 points) of the CSI (> 40 points) and PCS (> 30 points) were 43.5%, 36.5%, and 62.6%, respectively. After 4 weeks of treatment, the patient-reported scores and the disease composite index decreased significantly, SRQ (p<0.0001), PDQ (p=0.0084), PCS (p=0.0066), CSI (p=0.0165) and SDAI (p<0.0001).The US score did not change significantly (5.25 to 5.03; p=0.248). SDAI achieved 10.6% remission and 15.2% low disease activity at week 4. Multivariate regression analysis indicated that changes in SDAI were exclusively connected to changes in catastrophizing (coefficient=0.500, P=0.0224).

Conclusion: After starting a Jak inhibitor, pain catastrophizing, but not articular inflammation on US, diminishes along with disease activity. These findings provide credence to the concept of catastrophizing as a dynamic construct that may be adjusted by therapy aimed at reducing inflammatory disease activity and pain levels in the RA patient.

THE EFFECT OF ANTIMALARIALS ON THE OVERALL SAFETY AND PERSISTENCE OF TREATMENT WITH BIOLOGIC AGENTS OR JAK INHIBITORS IN RHEUMATOID ARTHRITIS

M. Bredemeier[1], A. Duarte[1], M. Pinheiro[1], B. Stadler[1], J. C. Macieira[1], R. Ranza[1], J. Miranda[1], V. Valim[1], G. Castro[1], M. Bertolo[1], M. D. F. Sauma[1], V. Fernandes[1], A. C. Medeiros-Ribeiro[1], R. Botelho[1], C. Brenol[1], H. M. Da Silveira DE Carvalho[1], S. Studart[1], G. Da Rocha Castelar Pinheiro[1], L. Rocha[1], H. De Leon de Lima[1], I. Pereira[1], M. Ohira Gazzeta[1], A. Kakehasi[1], P. Louzada Jr[1], A. L. S. Hayata[1], F. Pina[1], M. Alves Ferreira[1], L. Balarini[1], I. G. Silveira[1], S. Kowalski[1], D. Titton[1], R. Mendonça Da Silva Chakr[1], A. Ranzolin[1], I. Laurindo[1], R. Xavier[1]on behalf of BiobadaBrasil. [1]*Brazilian Society of Rheumatology, Register BiobadaBrasil, São paulo, Brazil*

Background: Antimalarials (AM) are frequently part of the initial scheme of conventional synthetic DMARDs in the treatment of rheumatoid arthritis (RA), and have been associated with lower incidence of diabetes and better lipid profile in these patients (1). However, the role of AM in schemes involving biologic (b-) or targeted synthetic (ts-) DMARDs has been much less extensively studied. In addition, a recent large scale study (2) and a consensus article (1) casted doubt on the long-term cardiovascular safety of AM.

Objectives: To evaluate the association of concomitant use of AM with the overall safety and survival of
treatment course among patients receiving one or multiple courses of bDMARDs or tsDMARDs

Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting their first bDMARD or tsDMARD (3). The present analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over one or multiple (up to six) courses of treatment (latest date, Nov 19, 2019). A treatment course is defined as a period during which the medication scheme does not change. The primary outcome was the incidence of serious adverse events (SAEs). Total and system-specific adverse events (AEs), treatment interruption for any reason, interruption due to AEs and due to inefficacy served as secondary outcomes. Negative binomial regression with generalized estimating equations (to calculate the incidence rate ratios [IRRs]) and extended (frailty) Cox proportional hazards models were used for statistical analyses (both types of analyses including time-varying covariates over multiple courses of treatment).

Results: In total, 1316 patients (2335 treatment courses, 6711 patient-years [PY]) were enrolled. The overall incidence of serious adverse events was 9.2/100 PY. AM were used over 354 courses (1254.5 PY) of therapy. The IRRs for the primary and secondary outcomes are presented in Table 1. AM were also associated with better treatment course survival (Figure 1), reducing the risk of interruption due to AEs (multivariate hazard ratio: 0.56, 95% CI: 0.39 to 0.81, P=0.002) and inefficacy (0.65, 0.48 to 0.87, P=0.003).

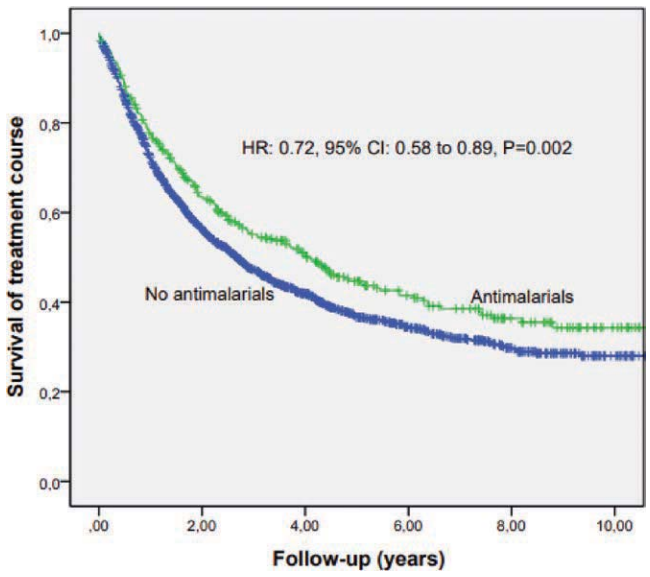

Figure 1.

Table 1. Univariate and multivariate incidence rate ratios (IRRs) of adverse events comparing use versus non-use (reference category) of antimalarials. Results are IRRs, 95% CIs, and P values.

Type of adverse event (n of events)		Crude analysis	Adjusted covariates*
Serious adverse events (617)		0.60 (0.41 to 0.87), P=0.007	0.51 (0.37 to 0.69), P<0.001
Any adverse event (3494)		0.65 (0.54 to 0.77), P<0.001	0.68 (0.57 to 0.81), P<0.001
Cardiovascular‡	Serious (52)	1.04 (0.49 to 2.20), P=0.924	1.06 (0.45 to 2.50), P=0.891
	Total (163)	0.90 (0.59 to 1.38), P=0.642	0.93 (0.59 to 1.45), P=0.737
Infections	Serious (277)	0.78 (0.44 to 1.39), P=0.404	0.53 (0.34 to 0.83), P=0.006
	Total (1400)	0.77 (0.61 to 0.98), P=0.033	0.75 (0.60 to 0.94), P=0.014
Hepatic‡	Total (66)	0.20 (0.07 to 0.64), P=0.007	0.16 (0.04 to 0.57), P=0.005
Glicemic control-related	Total (34)	0.74 (0.29 to 1.92), P=0.540	0.73 (0.26 to 2.00), P=0.535
Dyslipidemia	Total (83)	0.60 (0.31 to 1.13), P=0.114	0.55 (0.28 to 1.06), P=0.074

*Age, baseline DAS28, disease duration, gender, smoking, seropositivity (RF or anti-CCP), previous malignancy, interstitial lung disease, diabetes, hypertension, hypercholesterolemia, renal failure, ischemic cardiomyopathy, COPD, heart failure, concomitant use of each cs-, b-, and tsDMARDs, corticosteroids, starting year, osteoporosis, hepatitis B and C, and treatment sequence. ‡ Excluding infections.

Conclusion: Among RA patients on treatment with bDMARDs or tsDMARDs, concomitant use of antimalarials reduced the incidence of serious and total AEs, including infections and hepatic AEs, and prolonged treatment course survival. No significant increase in the risk of cardiovascular AEs was observed.

POS0243

THE EFFECT OF A MEDITERRANEAN DIET ON PHYSICAL FUNCTION AND QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS – THE MEDRA STUDY

T. Raad[1], A. Griffin[1], L. Larkin[1], N. Kennedy[1], A. Tierney[1,2]. *[1]University of Limerick, School of Allied Health, Limerick, Ireland; [2]La Trobe University, Department of Rehabilitation, Nutrition and Sport, Melbourne, Australia*

Background: The immunomodulatory and anti-inflammatory effects of the Mediterranean Diet (MedDiet) suggest a protective role in rheumatic conditions[1]. A small but increasing body of evidence from randomised controlled trials demonstrates that increased adherence to a MedDiet in patients with Rheumatoid Arthritis (RA) can have a beneficial effect on disease activity, pain levels and physical function[2].

Objectives: The primary aim of the MEDRA study was to determine the effects of a MedDiet compared to the current food based dietary guidelines in Ireland (Healthy Eating Guidelines/HEG) on the physical function and quality of life in patients with RA.

Methods: In this randomised controlled trial, 44 patients with RA were randomly allocated to either the MedDiet or the HEG arm of the study. The 12-week dietary intervention study was delivered online by a Registered Dietitian (RD) and included data collection at three time points: baseline, mid-intervention (6 weeks) and post-intervention (12 weeks). Participants in both dietary intervention groups attended three video consultations with the RD, at baseline, weeks 6 and 12, and two follow up reviews by telephone at weeks 3 and 9. All participants were provided resources designed to specifically explain the assigned diet and how it can be successfully adhered to. Primary outcomes were changes in physical function and quality of life measured using the validated Health Assessment Questionnaire - Disability Index (HAQ-DI) and Rheumatoid Arthritis Quality of Life Questionnaire (RAQoL), respectively. Secondary outcomes included changes in physical activity and patient-reported pain levels.

Results: Forty patients with RA completed the study (mean age:47.5 SD10.9 years, females: 87.5%). No significant differences were found in the distribution of age, anthropometric measures, disease duration, physical activity, and quality of life between the two diet groups at baseline. However, the group assigned to the MedDiet had better mean values for quality of life compared to the HEG group; 0.9 ± 0.5 vs. 1.4 ±0.7, p<0.001, respectfully. Compared to baseline, there was a significant improvement in HAQ-DI scores in participants following both the MedDiet (0.9 ±0.5 to 0.5 ± 0.4, p<0.001) and HEG (1.4 ± 0.7 to 1.0 ± 0.6, p<0.001). Significant improvements in RAQoL scores were also seen in both the MedDiet (10.1 ±7.5 to 4.0 ± 4.7, p<0.001) and HEG (11.25 ± 7.2 to 7.9 ± 6.4, p=0.02) groups. At 12 weeks, participants in the MedDiet group reported a significantly better physical function status (mean difference -0.5, 95% CI -0.8 to -0.1, p=0.007) and quality of life (mean difference -3.9, 95% CI -7.5 to -0.2, p=0.04) compared to the HEG group. Participants in the MedDiet group demonstrated a significant increase in physical activity levels (56.7 ± 28.6 to 70.6 ± 33.5, p=0.01). Conversely, a non-significant decrease in physical activity levels was observed in the HEG group from baseline to post-intervention.

Conclusion: The study indicates positive effects of a Mediterranean and low-fat diet as per the Healthy Eating Guidelines on physical function and quality of life in patients with RA. The MedDiet may be superior in improving physical activity levels. Further studies and a larger cohort are needed to confirm these findings.

St. Clair[11], J. H. Stone[12], M. Prunotto[13], P. Grayson[2], U. Specks[1]. *[1]Mayo Clinic, 1Thoracic Disease Research Unit, Division of Pulmonary & Critical Care Medicine, Department of Medicine, Rochester, United States of America; [2]National Intitute of Health, Translational Autoinflammatory Diseases Section (TADS), NIAID/NIH, Bethesda, United States of America; [3]Genentech Inc., a member of the Roche Group, I2O Technology & Translational Research, San Francisco, United States of America; [4]Mayo Clinic, Division of Nephrology and Hypertension, Departement of Medicine, Rochester, United States of America; [5]University of Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; [6]Cleveland Clinic, Rheumatology, Cleveland, United States of America; [7]University of Pennsylvania, Division of Rheumatology, Department of Medicine, Division of Clinical Epidemiology, Department of Biostatistics, Epidemiology, and Informatics, Philadelphia, United States of America; [8]University of Boston, Rheumatology, Boston, United States of America; [9]Johns Hopkins Medicine, Rheumatology, Baltimore, United States of America; [10]Weill Cornell Medical College, Hospital for Special Surgery, Rheumatology, New York, United States of America; [11]Duke University, Rheumatology, Durham, United States of America; [12]Massachusetts General Hospital, Rheumatology Unit, Boston, United States of America; [13]University of Geneva, Medicine, Geneva, Switzerland*

Background: The frequency of the proteinase 3 gene (PRTN3) polymorphisms in patients with ANCA-associated vasculitis (AAV) is not well characterized. We hypothesize that PRTN3 gene polymorphisms induce allosteric changes in PR3 conformation which may alter its interaction with ligands and PR3-ANCA during inflammation with potential implications for disease presentation and clinical outcomes.

Objectives: To analyze the association of PRTN3 Val119Ile polymorphism (SNP rs351111) with risk of relapse risk among homozygous patients with PR3 ANCA-associated vasculitis.

Methods: DNA variant calling for SNP rs351111 (chr.19:844020, c.355G>A) in PRTN3 gene assessed the allelic frequency in patients with PR3-AAV included in the Rituximab versus Cyclophosphamide (RAVE) trial. This was followed by RNA-seq variant calling to characterize the mRNA expression. We compared clinical presentation and outcomes between patients homozygous for PR3-Ile^{119} or PR3-Val^{119}.

Results: Serum samples for DNA calling were available in 188 of the 197 patients with AAV in the RAVE cohort. 75 PR3-AAV patients had the allelic variant: 13 patients were homozygous for PR3-Ile^{119} and 62 patients were heterozygous PR3-Val^{119}Ile with an allele frequency threshold of 29.3 – 55.1% of reads (Figure 1A and 1B). RNA-seq was available for 89 patients and the mRNA corresponding to the allelic variant was found in 35 PR3-AAV patients: 13 patients were homozygous for PR3-Ile^{119} and 22 patients were heterozygous PR3-Val^{119}Ile with an allele frequency threshold of 11.1 – 62.8% of reads (Figure 1A and 1C). The agreement between the DNA calling results and the mRNA expression of the 86 patients that overlapped was 100%. We found an additional homozygous patient for PR3-Val^{119} in which blood was not available for DNA calling.

We compared the clinical presentation and outcomes of 74 patients with PR3-AAV: 13 homozygous for PR3-Ile^{119} and 51 homozygous for PR3-Val^{119} (Table 1). The frequency of severe flares at 18 months in homozygous PR3-Ile^{119} was ≥ 2x higher when compared with homozygous PR3-Val^{119} (46.2% vs. 19.6%, p=0.048). We found no differences in clinical presentation.

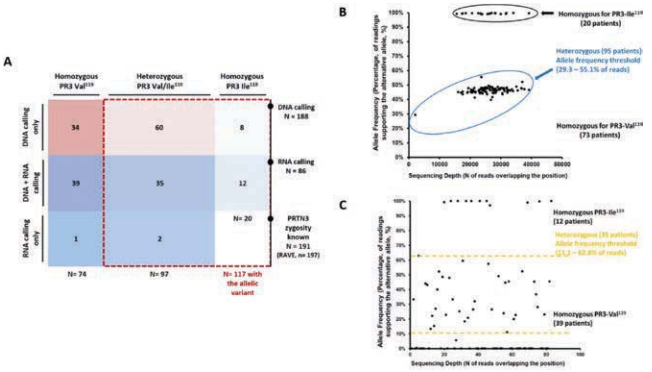

Figure 1. RAVE trial population distribution according to the zygosity status for PRTN3 gene (PR3 and MPO-ANCA patients) and DNA or RNA variant calling (panel A). Allelic frequency for rs351111, chr.19:844020 (c.355G>A) in PRTN3 among patients with AAV (PR3 and MPO-ANCA) in the DNA (panel B) and RNA (panel C) variant calling.

Table 1. Outcomes of patients with PR3-ANCA according with PRTN3 zygosity.

PR3-ANCA (n=64)	Homozygous PR3-Val^{119} (n=51)	Homozygous PR3-Ile^{119} (n=13)	p-value
Remission, n (%)	45 (88.2)	13 (100)	0.194
Complete remission, n (%)	36 (70.6)	10 (76.9)	0.650
Any flare 18 months, n (%)	30 (58.8)	7 (53.8)	0.746
Severe Relapse* 18 months, n (%)	10 (19.6)	6 (46.2)	0.048

* Relapse was considered "Severe" if Birmingham Vasculitis Activity Score for Wegener's Granulomatosis (BVAS/WG) > 3 or one major item as per the RAVE trial definition.Abbreviations: ANCA - anti-neutrophil cytoplasmic antibody; Ile – isoleucine; n- number; PR3 - proteinase 3; Val - valine.

Conclusion: In patients with PR3-AAV the presence of PRTN3 Val^{119}Ile polymorphism was associated with higher frequency of severe relapse. Further studies are necessary to understand the association of this observation with the risk of severe relapse.

POS0245 PROTEIN PROFILING IN PRE-SYMPTOMATIC ANCA-ASSOCIATED VASCULITIS INDIVIDUALS.

M. Brink[1], E. Berglin[1], A. J. Mohammad[2,3], A. Alexeyenko[4], K. Lejon[5], S. Rantapää Dahlqvist[1]. *[1]Umeå university, Public Health and Medicine/ Rheumatology, Umeå, Sweden; [2]Lund University, Clinical Sciences/ Rheumatology, Lund, Sweden; [3]University of Cambridge, Department of Medicine, Cambridge, United Kingdom; [4]Karolinska Institute, Department of Microbiology, Stockholm, Sweden; [5]Umeå universitet, Department of Clinical Microbiology, Umeå, Sweden*

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a rare chronic relapsing condition, with unknown etiology.

Objectives: This study was undertaken to gain insight to the molecular processes and to find potential biomarkers in blood samples collected prior to the onset of symptoms of AAV.

Methods: The National Patient Register and Cause of Death register were searched for AAV-ICD codes and linked to the registers of five biobanks. Eighty-five AAV cases were identified (34 males, 51 females) with samples >1month <10years from AAV symptom onset. For each case two controls matched for sex, age, and sampling date were included. Samples were analyzed using ELISAs for PR3- or MPO-ANCA specificities. Ninety-two protein markers were analyzed using Olink Inflammation panel, (OLINK, Uppsala, Sweden) with 73 eligible after quality control.

Results: Eight protein markers were significantly altered between pre-AAV and controls, with higher levels of CCL23, CXCL5 (p< 0.01-0.05) and lower levels of Flt3L, STAMBP, ADA, TNFB, CX3CL1 and IL-15RA (p< 0.01-0.05) in the pre-AAV individuals. Nine protein markers were found significantly associated with time to symptom onset; CXCL9, CD244, VEGFA, CXCL1, TNFSF9, OPG, CSF-1, IFN-gamma and CD40 (p< 0.01-0.05). In pre-AAV individuals, six proteins were associated with MPO-ANCA-positivity compared with the MPO-ANCA-negative pre-AAV individuals which showed no overlap with the seven proteins related to PR3-ANCA-positivity.

Conclusion: To our knowledge our study is the first to analyze for and identify protein markers before symptom onset in AAV. This allowed for further studies of underlying cellular and molecular mechanisms in AAV pathogenesis as well as the diversification into PR3-ANCA and MPO-ANCA subphenotypes.

Background: Rituximab (RTX) is an effective remission-induction treatment in ANCA-associated vasculitides (AAVs). Some reports have suggested that it might be effective also in Eosinophilic Granulomatosis with Polyangiitis (EGPA), to induce and maintain remission of vasculitic manifestations [1,2]. However, its effects for preventing respiratory relapses seem to be poor. Mepolizumab (Mepo) (both 100 and 300mg/month) is effective in improving respiratory manifestations and lung function, while partially controlling also systemic activity [3,4]. Isolated case reports further indicate that the sequential therapy with RTX and Mepo might be effective [5-7].

Objectives: The study aimed to investigate the efficacy and safety of a therapeutic regimen based on sequential RTX and Mepo for the control of EGPA.

Methods: A multicenter, retrospective, cohort study was conducted on adult patients diagnosed with EGPA according to the ACR classification criteria [8] or MIRRA trial criteria [3]. Only patients who received induction therapy with RTX (any dosage), and subsequent treatment with Mepo (100-300 mg/4 weeks) within 12 months from last RTX administration were included. Patients receiving other induction therapies between RTX and Mepo were excluded. The effectiveness of sequential RTX and Mepo was assessed in terms of disease activity (by the Birmingham Vasculitis Activity Score, BVAS) and daily corticosteroid dosage. Safety data were also collected.

Results: Thirty-four EGPA patients treated with sequential RTX and Mepo were included (59% females, median age of 51 years (IQR 40-58); 41% ANCA positive).

In most cases (26/34; 76%), RTX was started at the dosage of 1g q2w, and all except two patients had active disease at time of RTX beginning [median BVAS of 9 (IQR 6-14)]. Specifically, most patients started RTX for the control of

systemic manifestations (19/34; 56%), or of both systemic and respiratory symptoms (11/34; 32%). All except one patient were receiving oral corticosteroids, at a median dosage of 25 mg/day (10-38).
Mepo was started after a median of 14 months (6-23) from RTX initiation and after a median of 5 months (IQR 3-11) from the last RTX administration. Mepo was used at the dosage of 100mg/4 weeks in 32/34 (94%), mostly for the control of respiratory manifestations (25/34, 74%). At the time of starting Mepo, the median BVAS was 4 (2-8), and median prednisolone dose 10 mg/day (7-15). After a median follow-up of 28 months (IQR 23-33) from starting Mepo, the median BVAS decreased to 1.5 (IQR 0-4) and the median corticosteroid dosage to 5 mg/day (2.5-5), with 7/34 (21%) patients being off steroids. At last follow-up, most patients were off-RTX (28/34), typically due to stable disease remission (20/34; 59%).
Both RTX and Mepo were well-tolerated; 5 patients had adverse events on RTX (none serious), and 5 on Mepo (including one serious infection).
Conclusion: Sequential use of RTX and Mepo seems to be effective for remission induction and maintenance in EGPA.

Background: Antineutrophil cytoplasmic antibody -associated vasculitis (AAV) is usually treated with combination of high-dose glucocorticoid (GC) and immunosuppressive agents, followed by tapering GC dose. Although the European League Against Rheumatism (EULAR) has specific recommendations for tapering the GC dose, clinicians often taper it slower than recommended due to concerns of potential disease relapse. However, such slower taper may prolong GC exposure for the patients, increasing the risk of adverse events, particularly infection.
Objectives: The aims of our study were (1) to clarify GC dose tapering in the treatment of AAV in a real-world setting, in contrast to the EULAR recommendation of 2015 and (2) to compare the incidence of AAV relapse and severe infection between patients underdoing EULAR-recommended tapering and those undergoing slower tapering than the recommendation.
Methods: In this multicenter (25 sites in Japan), observational, retrospective study of AAV, 541 patients who had initial or severe relapse were enrolled between January 2017 and June 2020. Of these, 349 patients with microscopic polyangiitis (MPA) or granulomatosis with polyangiitis (GPA) who entered in GC tapering phase after successful induction treatment were included. These patients were then grouped on the pace of GC tapering, defined as the GC dose at 12 weeks after treatment initiation: (1) EULAR group: 7.5-10 mg/day of GC, according to the EULAR recommendation of 2015, and (2) SLOWER group: >10 mg/day of GC. Their baseline characteristics and clinical outcomes were compared. Primary outcome was defined as relapse-free days from treatment initiation, whereas secondary outcome included the incidence of infectious events requiring hospitalization within 48 weeks from treatment initiation. Multivariable analysis was performed to assess the relationship between tapering pace and clinical outcomes.
Results: There were 44 patients (12.6%) in the EULAR group and 290 (83.2%) in the SLOWER group. Regarding baseline characteristics, compared with the EULAR group, the SLOWER group had significantly higher serum C-reactive protein level (EULAR, 5.89 ± 6.89 mg/dL vs SLOWER, 7.56 ± 6.01 mg/dL; p = 0.03), as well as a trend toward higher Birmingham Vasculitis Activity Score

(version 3) (EULAR, 11.80 ± 7.01 SLOWER, 13.93 ± 7.06; p = 0.08) We did not observe any significant differences in the frequency of relapses between the two groups (EULAR, 8/44, 18.2% vs SLOWER, 55/290, 19.0%; p = 0.63). Multivariable Cox proportional hazard analysis revealed no relationship GC dose at 12 weeks from treatment initiation and incidence of relapse. However, upon logistic regression analysis, the SLOWER group was found to have significant higher risk of a severe infectious event within 48 weeks from treatment initiation (p = 0.046; hazard ratio, 1.27; 95% confidence interval, 1.004 – 1.601).

Conclusion: Our finding indicates that clinicians tended to taper GC slower for patients with higher disease activity. However, slower GC taper was not found to reduce the frequency of relapse. In addition, slower GC taper was found to increase the risk of a severe infection. Hence, clinicians should pay attention not only relapsing but also late GC taper resulting in the risk of serious infection, especially in patients with higher disease activity of AAV.

POS0248 SUBCLINICAL GIANT CELL ARTERITIS IN PATIENTS WITH POLYMYALGIA RHEUMATICA SHOWS A DIFFERENT ULTRASONOGRAPHIC PATTERN THAN PATIENTS WITH CLASSICAL GIANT CELL ARTERITIS

E. De Miguel[1], P. Macchioni[2], E. Conticini[3], C. Campochiaro[4], R. Karalilova[5], S. Monti[6], C. Ponte[7], G. Klinowski[2], I. Monjo8, P. Falsetti[3], A. Tomelleri[4], Z. Batalov[5], A. Hocevar[9]on behalf of GCA/PMR study group. Background: Polymyalgia rheumatica (PMR) can be associated with giant cell arteritis (GCA), even in the absence of clinical suspicions of vasculitis. In addition, some studies have shown an association of PMR with the predominantly large vessel involvement.

Objectives: The objective of our study was to assess the presence of subclinical GCA in patients with PMR and to compare its pattern of vascular involvement to patients with classical GCA.

Methods: Eight rheumatology European centers participated in the study. Cohort A represented consecutive newly diagnosed patients with PMR who fulfilled the 2012 EULAR/ACR Provisional Classification Criteria for Polymyalgia Rheumatica[2] and had no symptoms or signs suggestive of GCA. Ultrasound (US) examination of four vessel territories (i.e. temporal, carotid, subclavian and axillary arteries) was performed bilaterally. Cohort B included all consecutive patients with the diagnosis of GCA evaluated on the fast-track clinic of one of the hospitals (HULP). The halo sign was considered as positive US finding for GCA[3]. In addition, intima-media thickness of arteries was measured, with a cut-off ≥0.34 mm for temporal arteries (TA) frontal and parietal, 0.42mm for common TA, and ≥1 mm for common carotid, axillary and subclavian arteries for positive result. The clinical characteristics of PMR patients were recorded and the frequency of subclinical GCA determined.

Results: Cohort A included 41 PMR patients with subclinical GCA. Cohort B was formed by 97 GCA. The characteristics of the patients are shown in the Table 1. Figure 1 shows the different subtypes of vessel involvement in patients with PMR and subclinical GCA and in patients of the fast-track clinic with the diagnosis of GCA in a single hospital.

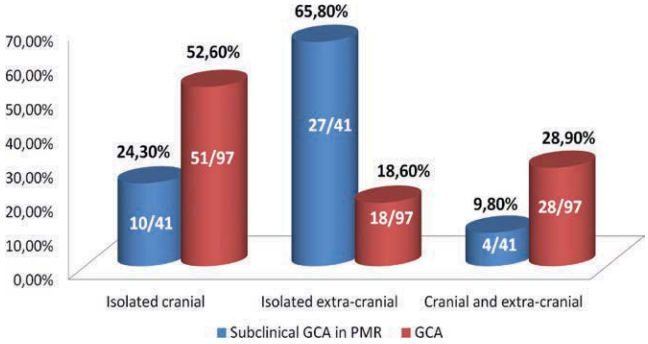

Figure 1. Subtypes of vessel affectation in Subclinical GCA in PMR and in classical GCA

Table 1. Clinical characteristics of patients of Cohort A (Subclinical GCA in PMR n = 41/216) and B (GCA in the fast-track clinic n = 97)

	Cohort A (n = 41)	Cohort B (n = 97)
Sex female (%)	17 (41.5%)	53 (54.6%)
Age (years) mean ± SD	74±6.7	79 ± 12
CRP mg/L	49.6±49.1	46 ± 81.6
Polymyalgia rheumatica	41 (100%)	47 (48.5%)
Constitutional symptoms	19 (35.18%)	35 (36.1%)

Subclinical PMR has a predilection for affectation of large vessels, followed by isolated cranial pattern (ie. Isolated temporal artery involvement) and by the mixed (cranial and extra-cranial) form. On the contrary, in classical GCA an isolated cranial involvement represents the more common pattern, followed by the mixed and finally isolated large vessel involvement.

Conclusion: Subclinical GCA in PMR shows a principal isolated extra-cranial involvement and with clearly different pattern than classical GCA.

POS0249 FIBROBLAST ACTIVATION PROTEIN AS A LINK BETWEEN INFLAMMATION AND VASCULAR REMODELING IN GIANT CELL ARTERITIS

S. Xu[1], W. F. Jiemy[1], A. Boots[1], Y. Van Sleen[1], K. Van der Geest[1], P. Heeringa[2], E. Brouwer[1], M. Sandovici[1]. [1]*University Medical Center Groningen, University of Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands;* [2]*University Medical Center Groningen, University of Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) can present with serious complications such as blindness, stroke and aortic aneurysm that are related to both inflammation and remodeling of the vessel wall. GCA frequently overlaps with polymyalgia rheumatica (PMR). The pathogenesis of GCA starts in the adventitia where fibroblasts are the major stromal cell population. A preliminary study [1] reported the migration of adventitial fibroblasts to the intima, contributing to intimal hyperplasia in GCA. Fibroblast activation protein (FAP) is a non-classical serine protease which can be present in both a membrane-bound form and a soluble form and has been demonstrated to promote inflammation and fibrosis in coronary artery disease and rheumatoid arthritis [2-3]. We hypothesize that FAP is involved in GCA vasculopathy due to its pro-inflammatory and pro-fibrotic effects.

Objectives: As a first step to unravel the contribution of FAP to the vasculopathy in GCA, we determined FAP plasma levels and FAP protein expression at the site of vascular inflammation in GCA.

Methods: In our prospective cohort of GCA, PMR and healthy elderly (GPS), we measured the plasma FAP levels with ELISA in new-onset, treatment-naïve GCA (N=62), and PMR (N=63) patients and 42 age-matched healthy controls (HC). In addition, we measured the plasma FAP levels at follow-up (3-months, 1-year, 1.5-year and treatment-free remission (TFR)). Temporal artery biopsies (TAB) from treatment-naïve GCA patients (n=9) and non-GCA patients (n=9), aorta samples from GCA-related aneurysm (n=9) and atherosclerosis (n=11) were stained for FAP using immunohistochemistry. Immunofluorescence staining for CD90, CD68, αSMA and FAP was performed to detect FAP expression in fibroblasts, macrophages and vascular smooth muscle cells (VSMC), respectively.
Results: Baseline plasma FAP levels were significantly lower in GCA patients (52.72±2.93 ng/ml) than in PMR patients (66.42±2.86 ng/ml) and HC (80.47±3.38 ng/ml). FAP levels at baseline correlated inversely with C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), interleukin (IL)-6, macrophage-associated protein YKL-40 (Chitinase 3-like 1/CHI3L1) levels and monocyte counts. Plasma FAP levels in GCA patients decreased even further at 3 months (37.23±2.10 ng/ml) upon glucocorticoid-induced remission, and gradually increased to the level of HC (76.84±5.43 ng/ml) when patients were in TFR. Increased FAP expression in GCA TAB (adventitia, media, intima) and aorta (media) compared with tissues from non-GCA was documented. FAP was abundantly expressed in fibroblast- and macrophage-rich areas but not in VSMC-rich areas in TAB and aorta of GCA patients.
Conclusion: FAP expression is clearly modulated both in plasma and at the site of vascular inflammation in GCA and may represent a pathogenic link between the inflammatory and remodeling processes in GCA. As such, FAP may have utility as a biomarker and should be further investigated as target for therapeutic intervention.

POS0250 PLASMA MITOCHONDRIAL DNA AS A BIOMARKER IN THE DIAGNOSIS AND FOLLOW-UP OF ANCA-ASSOCIATED VASCULITIDES

S. Giaglis[1,2], D. Kyburz[1,2], J. Thiel[3], N. Venhoff[3], U. Walker[1,2]. *[1]University of Basel, Department of Biomedicine, Experimental Rheumatology Laboratory, Basel, Switzerland; [2]University Hospital of Basel, Department of Rheumatology, Basel, Switzerland; [3]University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) include granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) (1, 2). ANCA recognize the antimicrobial proteins proteinase 3 (PR3) or myeloperoxidase (MPO) (1,2) and trigger the formation of neutrophil extracellular traps (NETs), which release DNA into the extracellular space and systemic circulation. This cell-free (cf)DNA induces endothelial damage, vascular inflammation and necrosis (3).
Objectives: The nature, diagnostic and prognostic value of cfDNA in AAV is still unknown. The aim of the present study was to examine the clinical utility of cfDNA quantification as a biomarker in AAV.
Methods: Total DNA was isolated from platelet-free plasma samples of healthy controls (HC) and consecutive AAV patients. Plasma and clinical data were collected at baseline and follow-up. Copy numbers were quantified by qPCR for mtDNA (ATP-6 gene) and nuclear (n) DNA (GAPDH gene) (4). Patients with eosinophilic GPA (EGPA) were excluded.
Results: Ninety-two HC (median age 51 ± 9, 48.2% female) and 104 AAV patients (median age 64 ± 10, 48% female, mean BVAS: 0; range: 0-40) were available for analysis. Eighty-four (80.8%) of these patients were diagnosed with GPA, and 20 with MPA (19.2%).
mtDNA levels were significantly elevated in AAV plasma ($8.7x10^7$ copies/ml plasma, 95% CI: $5.3x10^7$ to 1.3 $x10^{8)}$), compared to HC plasma ($6.7x10^6$ copies/ml plasma, 95% CI: $5.4x10^6$ to $9.1x10^7$, p<0.0001). nDNA levels in contrast did not differ between AAV ($4.0x10^6$ copies/ml plasma, 95%CI: $2.7x10^6$ to $5.0x10^6$) and HC ($3.3x10^6$ copies/ml plasma, 95%CI: $2.4x10^6$ to $4.7x10^6$, p=0.30). ROC analysis showed that a cut-off value of $1.3x10^7$ mtDNA copy numbers differentiated between AAV and HC with 89.4% sensitivity, 82.6% specificity and an AUC of 0.94. For AAV patients with active AAV, a cut-off value of $2.9x10^7$ mtDNA copy numbers differentiated between AAV and HC with 96.1% sensitivity, 98.9% specificity and an AUC of 0.99 (Figure 1a).

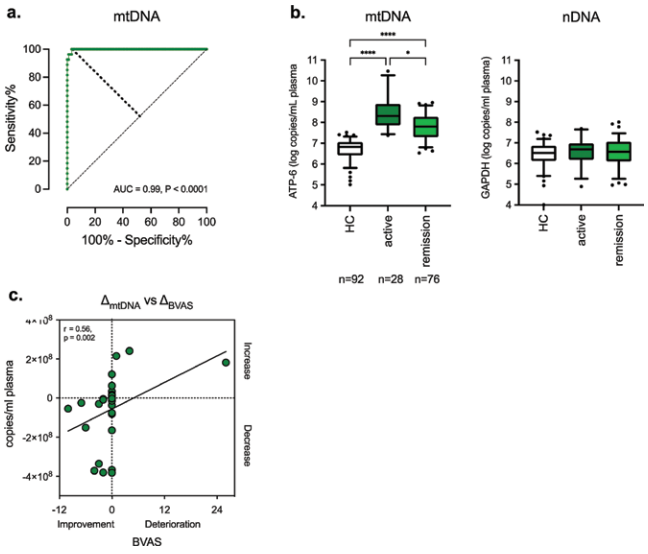

Figure 1. (**a.**) ROC curve for mtDNA plasma concentrations to discriminate between HC and active AAV patients (BVAS>0). AUC: area under the curve. (**b.**) Plasma mtDNA levels distinguish between AAV patients with active disease versus patients in a state of remission. Whiskers represent 95% CI. (**c.**) Plasma mtDNA levels in AAV patients correlate with the evolution of disease activity at follow-up.

With the exception of the peripheral nervous system involvement, there was no association of mtDNA elevation with any particular type of active organ involvement at the time of blood sampling. A positive correlation between all cell-free DNA species and anti-MPO antibody titres was observed, as expected (for cfDNA, nDNA and mtDNA - r=0.25, p=0.01; r=0.21, p=0.02; r=0.22, p=0.02, respectively).
AAV patients with active disease (BVAS>0) had a mean of $2.0x10^8$ copies/ml of mtDNA in plasma which was higher compared to HC (p<0.0001) and AAV patients in remission (BVAS=0) ($6.2x10^7$copies/ml, p=0.03). For nDNA on the other hand, there were similar levels in active disease as in remission ($5.3x10^6$ and $4.8x10^6$ copies/ml, respectively; p=0.64) (Figure 1b).
Follow-up data were available for 27 AAV patients (median follow-up: 6 ± 6 months, IQR: 12). Longitudinal changes in mtDNA levels robustly correlated with changes in BVAS (r=0.56, p=0.002, Figure 1c).
Conclusion: The quantification of cell free mtDNA - but not nDNA - copy numbers allows a sensitive and specific distinction between healthy individuals and patients with active AAV. mtDNA levels correlate cross sectionally with disease activity in AAV patients. Plasma mtDNA quantification may therefore aid in the diagnosis of AAV and in monitoring AAV activity.

POS0251 TRANSCRIPTOMIC CHANGES INDUCED BY MAVRILIMUMAB VERSUS TOCILIZUMAB IN EX-VIVO CULTURED ARTERIES FROM PATIENTS WITH GIANT-CELL ARTERITIS

M. Corbera-Bellalta[1], F. Kamberovic[1], F. Araujo[2], R. Alba-Rovira[1], G. Espigol-Frigole[1], M. Alba[1], S. Prieto-González[1], J. Hernández-Rodríguez[1], P. Pérez-Galán[2], K. Bondensgaard[3], J. F. Paolini[3], M. C. Cid[1]. *[1]Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vasculitis Research Unit, Department of Autoimmune Diseases, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), Department of Hemato-Oncology, Barcelona, Spain; [3]Kiniksa Pharmaceuticals Corp., Kiniksa Pharmaceuticals Corp., Lexington, United States of America*

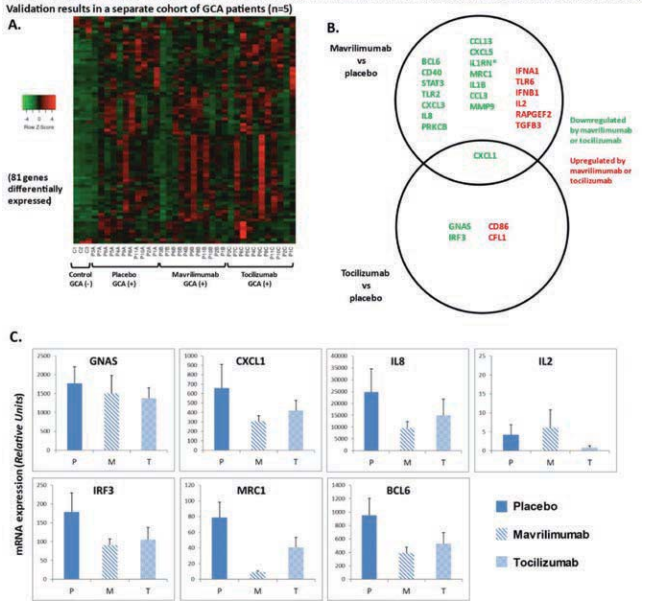
Background: Giant cell arteritis (GCA) is a chronic disease, and affected patients suffer from relapses and glucocorticoid (GC)-related toxicity. Targeted therapies are emerging with the aim of achieving better disease control and reducing GC exposure. Blocking IL-6 receptor with tocilizumab has been a major advance in the treatment of GCA. However, approximately 40% of patients treated with tocilizumab in combination with GCs experience a flare or tocilizumab-related adverse event. Blocking GM-CSF receptor α with mavrilimumab significantly reduced risk of relapse and improved sustained remission at week 26 vs placebo in a Phase 2 trial. Not all patients satisfactorily respond to any therapy, indicating heterogeneity in leading pathogenic pathways among patients. For these reasons, it is crucial to understand the specific impact of targeted therapies on vascular lesions.

Objectives: In this study we investigated transcriptomic changes induced by tocilizumab or mavrilimumab in *ex-vivo* cultured arteries from patients with GCA.

Methods: Temporal artery sections obtained for diagnostic purposes from 11 patients with histopathologically-confirmed GCA and 3 controls were cultured *ex-vivo* and exposed to placebo, mavrilimumab, or tocilizumab (both at 20 µg/mL) for 5 days. Of 11 GCA donors, 2 had received no treatment prior to biopsy, 2 had received a single prednisone (60 mg) dose, 1 had received 2 daily doses, and the remaining 6 had extended treatment; in prednisone-treated patients, mean (SEM) treatment duration was 17.9 ±8.7 days. A separate cohort of patients (consisting of five newly diagnosed patients with GCA, age- and sex-matched with the previous cohort) was used to validate 7 transcripts by real time PCR. Genes were selected for validation based on high level of expression and differential expression with each treatment. All samples were homogenized, and total RNA was extracted with TRIzol reagent. 100 ng of RNA per sample were processed with Nanostring Inflammation gene expression assay (256 transcripts) and hybridized using nCounter Prep Station. Barcode counts from nCounter Digital Analyzer were processed with nSolver 4.0 Software. Normalised data were analyzed using R Studio 4.0.5 and IBM SPSS 22.0, and paired Wilcoxon tests were applied individually to each treatment comparison group for each analysed gene. One µg of RNA per sample from the validation cohort was retrotranscribed; subsequent real time PCRs were normalised against endogenous control GUSb and analysed using SDS 2.3 software.

Results: 67 out of 250 transcripts were differentially expressed between arteries from GCA patients and arteries from control patients (all placebo-treated).

Figure 1. (A) Heat map of differential expression of 81 genes in GCA (-) control and GCA (+) treated with placebo, mavrilimumab, or tocilizumab. (B) Venn diagram of genes differentially expressed in mavrilimumab versus placebo and tocilizumab versus placebo. (C) Validation results in a separate cohort of GCA patients (n=5)



Of those, only 9 transcripts remained significant after correction for multiple comparisons, with a false discovery rate ≤0.05. 81 transcripts were differentially expressed in at least one comparison across groups (Figure 1A). 15 transcripts were lower, and 6 were higher in the mavrilimumab group vs placebo; 3 transcripts were lower, and 2 were higher in the tocilizumab group vs placebo. Most changes elicited between treatments were unique, but CXCL-1 was common (Figure 1B). None remained significant after correction for multiple comparisons. The effects of mavrilimumab and tocilizumab on GNAS, CXCL1, IL8, IL2, IRF3, MRC1 and BCL6 expression by Nanostring were consistent with the effect assessed using real time PCR in the separate validation cohort (Figure 1C).

Conclusion: Mavrilimumab and tocilizumab have a different transcriptomic impact on cultured arteries from patients with GCA, with some overlapping effects, although differential effects may have been attenuated by prior GC use. A better understanding of the impact of targeted therapies on vascular inflammation is needed to improve treatment options for patients with GCA.

Background: Giant cell arteritis (GCA) is a large-vessel vasculitis mainly involving the aorta and cranial arteries. It is the most frequent vasculitis in adults over 50 years. When they are stimulated by interferon-gamma (IFN-γ), vascular smooth muscle cells (VSMC) contribute to GCA pathogenesis by producing chemokines triggering the recruitment of pro-inflammatory T cells and monocytes (1).

Objectives: Current knowledge about the interaction between resident cells of the vascular wall (VSMC, myofibroblasts [MF]) and immune cells is limited. The aim of our research was to better characterize the interactions between VSMC, MF and T cells in GCA.

Methods: Fresh fragments of temporal artery biopsies (TAB) performed at Dijon university hospital (France) were prospectively sent to our research unit. Fresh sections of positive and negative TAB were fixed and embedded in optimal cutting temperature OCT and stored at -80°C. Then, cryostat sections were fixed, permeabilized, blocked and incubated with primary antibodies (anti-alpha smooth muscle actin [α-SMA], anti-myosin heavy chain 11 [MHC11], anti-Desmin, anti CD90, anti-CD45, anti-HLA-DR, anti-phospho STAT1 [pSTAT1] and anti-pSTAT3) and secondary antibodies for confocal microscopy analyses. Fresh sections of healthy TAB were embedded in MATRIGEL and covered by DMEM to obtain vascular cells in culture. Cells were treated with trypsina-EDTA between each passage. Vascular cells were used after 4-7 doubling passages. Cells were analyzed by immunofluorescence, flow cytometry and RT-PCR and their proliferation was evaluated by impedancemetry (iCELLigence system). Peripheral blood

mononuclear cells (PBMC) and vascular cells thus obtained were co-cultured for 7 days in different conditions. Vascular cells were cultured in the presence or absence of IFN-γ and tumor necrosis factor alpha (TNF-α) or interleukin-6 (IL-6) and soluble receptor of IL-6 for 72 hours. When cells reached confluence, they were cultured alone or with allogenic PBMC activated with anti-CD3/CD28 microbeads. After 7 days of culture, cells were separated with a treatment with EDTA and studied by flow cytometry.

Results: Confocal microscopy analyses of GCA arteries showed that neointima was mainly composed of myofibroblasts (MF) (α-SMA$^+$Desmin$^+$MHC11^{low}CD90$^+$) in contact with CD45$^+$ cells and that MF expressed HLA-DR, the phosphorylated form of STAT1 (pSTAT1) and in a lesser extent pSTAT3, strongly suggesting the activation of the IFN-γ signaling pathway rather than the IL-6 pathway. The phenotype of cultured vascular cells isolated from fresh TAB was consistent with MF. When MF were exposed to IFN-γ and TNF-α *in vitro*, their proliferation capacity decreased and their levels of expression of HLA-DR and CD86 increased (median fluorescence intensity [MFI] from 0 to 57 [p=0.03] and from 34 to 103 [p=0.03], respectively). In addition, co-cultures of MF and activated PBMC revealed that MF maintained the polarization of T cells into Th1 and Tc1 cells (p≤0.001) and to a lesser extent into Th17 and Tc17 cells (p=0.03). This effect was even more significant when MF were previously exposed to IFN-γ and TNF-α but not when they were exposed to IL-6.

Conclusion: Our results show that myofibroblasts are present in the neointima of GCA patients and that these MF activate signaling pathways indicative of IFN-γ exposure. Moreover, these MF, especially when exposed to IFN-γ, maintain the polarization of T cells into Th1 and Tc1 cells, which contributes to amplify the production of IFN-γ and thus initiate a pro-inflammatory amplification loop that likely participates in vascular inflammation and remodelling.

Background: ANCA associated vasculitides (AAV) are a heterogeneous group of rare diseases with unknown etiology. In the most severe cases AAV can lead to end stage kidney disease or death. Since etiology and detailed pathogenesis of AAV is not known, the prediction of disease outcome at the time of diagnosis is challenging. Thus, there is an unmet need for tools to identify patients with the highest risk of organ dysfunction and death and apply effective personalized therapy.

Objectives: The aim of this work was to search for tools allowing outcome prediction at the time of AAV diagnosis. Early identification of patients, who are likely to develop severe organ dysfunction and death is crucial for appropriate disease management. Induction therapy in AAV relays on immunosuppressive drugs characterized by a high risk of severe side effects. Thus, their administration in high doses should be limited only to individual patients with an especially high risk of poor outcome.

Methods: We applied here two methods of identification of AAV patients at risk to develop severe organ dysfunction and death. First method (latent class analysis [LCA] followed by logistic regression) was meant to subcategorize patients and identify a subgroup at subjects at risk to develop chronic renal replacement therapy (CRRT) and death [1]. Second, served to assess individual poor outcome risk and was based on two machine learning (ML) classifiers, which by analyzing clinical information allow assigning computed risk for CRRT and death in an individual patient allowing to identify subjects with high risk of chronic replacement therapy (CRRT) and death. We have evaluated a number of different approaches to build the ML models (including logistic regression, support vector machines, random forests), and obtained the best results for the gradient boosting algorithm implementation called LightGBM [2]. It works as a sequential ensemble of so-called weak learners (decision trees) finally combined in a one prediction model. Both analyses were based on retrospective data from Polish national AAV registry (POLVAS) [3] including presently 565 GPA and 135 MPA patients. The parameters used were: demographic data and laboratory parameters, specific organ involvement, ANCA specificity and time between selected stages of the disease.

Results: LCA used on our AAV cohort identified four subphenotypes – three already previously proposed - and revealing a fourth clinically relevant subphenotype. This new subphenotype includes only GPA patients, usually diagnosed at a younger age as compared to other groups, and characterized by multiorgan involvement, high relapse rate, relatively high risk of death, but no end-stage kidney disease. Logistic regression analysis revealed significant differences in the risk of CRRT and death between those subphenotypes – the worst prognosis was found for severe MPO AAV. On the other hand, using ML approach we obtained an individual prediction model with potentially relevant clinical performance (ROC AUC of 0.85 for CRRT and 0.82 for death).

Conclusion: We consider results obtained encouraging. They may offer a new insight into AAV course based on data available at diagnosis, and create a solid foundation for potential clinical decision support system.

Background: Rheumatic musculoskeletal diseases (RMD) are pathological conditions characterized by an impaired immunological system that is determinant both in the pathogenesis and in the inadequate response to infections. The use of disease-modifying anti-rheumatic drugs (DMARDs), which include conventional synthetic (cs) or biologic and targeted synthetic (b/ts) DMARDs, contribute to compromise immunological reactivity.

Objectives: To analyze the immune response to SARS-CoV-2 in patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA) receiving treatment with DMARDs and to investigate the effect of the different classes of drugs on humoral and cellular response.

Methods: Patients were tested for anti-SARS-CoV-2 IgG, IgM and IgA antibodies to nucleoprotein (N) and receptor-binding domain (RBD) through ELISA and neutralization assays. Then, we performed a flow cytometry analysis of monocytes, NK cells, B and T lymphocytes from PBMCs of serologically positive patients. We also included a cohort of non-RMD individuals recovered from COVID-19 as a reference group of non-immunosuppressed subjects. A first recruitment occurred in May-June 2020 (T1) and a second recruitment, 3-4 months after (T2), allowed to evaluate the persistence of the antibody response over time and to investigate the cellular immune response to SARS-CoV-2 in RMD patients having resolved the infection.

Results: During T1, 358 patients with RA (n=200) or SpA (n=158) were recruited. Mean age was 52.8, 64% were female. All patients were treated with DMARDs, 299 with b/tsDMARDs and 59 received csDMARDs alone. One third was also receiving corticosteroids (CS). At T2, 36 subjects were recruited. We found a seroprevalence rate of 18.4%, which did not significantly differ between RA and SpA groups, and between patients treated with b/ts-DMARD or csDMARDs, either alone or in combination with CS (Table 1). Antibody levels of RMD patients were lower than non-RMD individuals (Figure 1), with CTLA4-Ig-treated patients having the lowest IgG levels. This difference was less marked in symptomatic RMD patients. 72% of seropositive patients elicited neutralizing sera. Despite an overall decrease in anti-RBD and anti-N titers, more than two-third of patients maintained antibodies titers above positivity threshold at T2. Concerning cellular response, we found that CD8+ T-cells frequency was overall comparable between RMD and non-RMD convalescents, and did not differ in b- or cs-DMARD treated ones. Conversely, CD4+ T-cell frequencies were significantly lower in RMD patients, especially those treated with anti-IL6R and CTLA4-Ig. B-cell subpopulations (class-switched, memory, and IgG+ memory B-cells) had sustained frequencies in anti-TNFα treated patients, while they had a trend of reduction in patients treated with anti-IL6R and CTLA4-Ig.

Table 1. Anti-RBD seroprevalence

	Total	Seropositive, n	(%)	IgM (n)	(%)	IgG (n)	(%)	IgA (n)	(%)
COVID19 symptomatic	**77**	25	32.5	19	24.7	17	22.1	17	22.1
COVID19 asymptomatic	**281**	41	14.6*	23	8.2*	13	4.6 *	26	9.3*

**P value < 0,005*

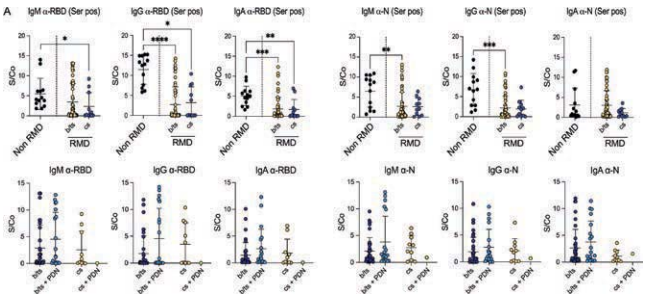

Figure 1. Magnitude of the anti-RBD and anti-N antibody response

Conclusion: Our data provide a comprehensive picture of the humoral and cellular immune responses to SARS-CoV-2 infection in RMD patients. We showed that DMARDs treatments did not alter a successful antibody response to the virus and did not hamper the antibody neutralizing ability. However, the magnitude of antibody response was slightly reduced compared to non-RMD individuals, especially in patients receiving CTLA4-Ig. We did not observe marked differences in the B- and T-cell populations between RMD patients compared to non-RMD individuals. However, in patients receiving anti-TNFα we found a higher relative abundance of effector adaptive population compared to other bDMARDs.

Background: In line with other reports, our group showed that patients treated with rituximab had significant impaired antibody response compared to patients treated with other biologic and targeted and synthetic disease modifying anti-rheumatic drugs (csDMARD).

Objectives: To investigate predictors of response to COVID-19 vaccination (2 doses of mRNA vaccines, 2 doses of virus vector vaccines or combinations of these) in patients with inflammatory rheumatic diseases (IRD) treated with rituximab and controls.

Methods: Antibody levels to three antigens: Spike protein full length, Spike S1 and Nucleocapsid C-terminal fragment (to confirm previous COVID-19 infection) were measured in sera collected before vaccination and 2-12 weeks after the second vaccine using a multiplex bead-based serology assay. The antigen-specific cut-off was defined as the median fluorescence intensity signal plus 6x standard deviations across 12 pre-pandemic controls. A good vaccine response was defined as having antibodies over the cut-off level for both spike antigens. Proportion (%) responders was compared between patients and controls (Chi2 test). Patients with IRD receiving last rituximab treatment within a mean (range) 193 (23-501) days before first vaccination participated. Individuals without IRD served as a control group. Predictors of a good vaccine response were explored using multivariate logistic regression analysis adjusted for age, sex, disease duration, diagnosis (systemic vasculitis/RA/JIA/other), concomitant csDMARD, rituximab dose and prednisolone dose. Hazard ratio (chanse) of a good antibody response in relation to time between the last rituximab treatment and vaccination was studied by Kaplan-Meier survival analysis.

Results: In total, 145 patients receiving rituximab and 61 controls were inclyded. Of these, 82 received rituximab as monotherapy (67% women; mean age 66 years, mean disease duration 13 years; 33% had RA/JIA and 60% vasculitis) and 63 received rituximab+csDMARD (62% women; mean age 66 years; mean disease duration 17 years; 76% had RA/JIA and 10 % vasculitis). Controls (n=61) were 74% women and mean age 49 years. Compared to controls, rituximab patients had lower antibody levels for both spike proteins (p<0.001). Proportion (%) responders among patients receiving rituximab as monotherapy (40.2%) and rituximab+DMARDs (25.4%) was significantly lower than in controls (98.4%) (p<0.001, Chi2). Higher age, concomitant csDMARD at vaccination and shorter time from last rituximab treatment predicted impaired antibody response (multivariate logistic regression model) (Table 1). Longer time between the last rituximab course and vaccination was associated with better antibody response (Figure 1).

Table 1. Predictors of good antibody response to two doses of COVID-19 vaccine defined as antibodies over the cut-off level for both spike antigens

	B	p-value	OR	95% CI
Age at vaccination (years)	-0.04	0.009	0.96	0.93-0.99
Sex (male/female)	-9.55	0.209	0.58	0.24-1.36
csDMARD at vaccination (yes/no)	-1.08	0.026	0.34	0.13-0.88
Prednisolone (mg/dag)	-0.10	0.103	0.90	0.80-1.02
Rituximab dos (1000 mg vs 500 mg)	-0.01	0.370	0.99	0.99-1.00
Time between the last rituximab and vaccination (months)	**0.20**	**0.001**	**1.31**	**1.11-1.55**
Diagnosis at vaccination (systemic vasculitis vs others)	-0.51	0.315	0.60	0.21-1.64

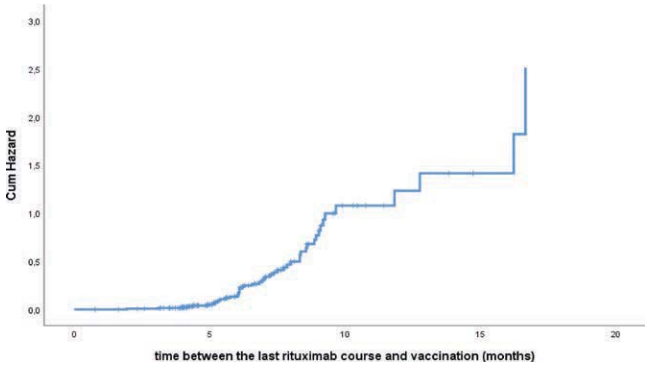

Figure 1. The chance of good antibody response following two doses of COVID-19 vaccine in relation to time between the last rituximab course and vaccination.

Conclusion: Patients with IRD getting vaccinated with two doses of COVID19 vaccine during the treatment with rituximab have the ability to develop antibody response although the response is impaired. For each month passed after the last rituximab course, the chance of good antibody response increases with 30%. Younger patients receiving rituximab as monotherapy and vaccinated preferably several months after the last rituximab treatment have the highest chance of achieving a good antibody response.

CLINICAL PREDICTORS OF ATTENUATED ANTIBODY RESPONSE TO PRIMARY SARS-COV-2 VACCINATION IN A LARGE PROSPECTIVE STUDY OF PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES

C. Connolly[1], T. P. Y. Chiang[2], M. Teles[2], S. Frey[2], J. Alejo[2], A. Massie[2], L. Christopher Stine[1], W. Werbel[1], D. Segev[2], J. Paik[1]. *[1]Johns Hopkins University, Medicine, Baltimore, United States of America; [2]Johns Hopkins University, Surgery, Baltimore, United States of America*

Background: An attenuated humoral response to SARS-CoV-2 vaccination has been observed in some patients with rheumatic and musculoskeletal diseases (RMD) (1). We sought to identify clinical factors associated with poor humoral response following primary (two-dose mRNA or single adenoviral vector dose) SARS-COV-2 vaccination in patients with RMD on immunosuppression.

Objectives: To identify clinical predictors of an attenuated antibody response to primary SARS-CoV-2 vaccination in RMD patients on immunosuppression.

Methods: We included patients ≥18 years old with RMD on immunosuppression who received either two-dose mRNA or single dose Janssen/Johnson and Johnson (J&J) vaccination. Demographics, diagnoses, and therapeutic regimens were collected via participant report; those with prior COVID-19 infection were excluded. One month after vaccination, participants underwent SARS-CoV-2 antibody testing on the semi-quantitative Roche Elecsys anti-SARS-CoV-2 S enzyme immunoassay, which measures antibody to the SARS-CoV-2 S-receptor binding domain (RBD) protein (ceiling >250U/mL later expanded to >2500U/mL). Associations were evaluated using Fisher's exact and Wilcoxon rank sum tests. Logistic regression analyses were performed to evaluate for clinical factors associated with antibody response. We adapted survival methods to address right-truncation of titers; this methodology was used to calculate medians. Participants provided informed consent electronically and the study was approved by the local Institutional Review Board.

Results: We studied 1138 RMD participants on immunosuppression; most were female (93%) and white (91%) (Table 1). One-hundred and fifteen (10%) had anti-RBD response in the negative range at a median (IQR) of 29 days (28-34) following completion of vaccine series. A greater proportion of participants with negative response were non-white, received J&J vaccine, reported use of mycophenolate, rituximab, or glucocorticoids. Antibody response differed by immunosuppressive regimen, with those receiving rituximab having poorest response (Figure 1). Use of mycophenolate (aOR 9.92, p=0.001), rituximab (aOR 56.99, p=0.001), glucocorticoids (aOR 2.99, p=0.001) or receipt of J&J (aOR 3.13, p=0.039) were associated with negative antibody response.

Table 1. Clinical characteristics stratified by anti-SARS-CoV-2 RBD response

	Negative (n=115)*	Positive (n=1023)*	p-value†
Age,median(IQR)	49(42, 58)	47(37, 58)	0.07
Female sex,no.(%)	108(94%)	952(93%)	0.78
Non-white,no.(%)	16(13.9%)	83(8.1%)	0.04

POS0257 COMPARISON OF SARS-COV-2 VACCINE RESPONSE IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASE; MRNA-1273 VACCINE INDUCES HIGHER HUMORAL IMMUNOGENICITY THAN BNT162B2

Y. Kondo[1], M. Takeshita[1], Y. Uwamino[2,3], H. Namkoong[3], S. Saito[1], J. Kikuchi[2], H. Hanaoka[1], K. Suzuki[1], N. Hasegawa[3], M. Murata[2], Y. Kaneko[1]. *[1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; [2]Medicine, Keio University School of Medicine, Department of Laboratory, Tokyo, Japan; [3]Keio University School of Medicine, Department of Infectious Diseases, Tokyo, Japan*

Background: The SARS-CoV-2 messenger RNA (mRNA) vaccines BNT162b2 (Pfizer-BioNTech) and mRNA-1273 (Moderna) have benefitted all countries amid the coronavirus disease 2019 (COVID-19) crisis. Whereas both of them have shown efficacy in preventing COVID-19 illness in healthy participants, there is paucity of data about immunogenicity and safety of mRNA COVID-19 vaccines in patients with autoimmune, inflammatory rheumatic disease. Recent observational studies evaluated mainly BNT162b2, suggesting that glucocorticoids, immunosuppressive agents impair SARS-CoV-2 vaccine responses. However, difference in immune reactions and safety between BNT162b2 and mRNA-1273 have not been clarified in patients with inflammatory rheumatic diseases.
Objectives: To assess humoral and T cell immune responses and safety profiles after two doses of different mRNA vaccine against SARS-CoV-2; BNT162b2 and mRNA-1273.
Methods: We enrolled consecutive, previously uninfected patients with inflammatory rheumatic diseases receiving mRNA vaccine including BNT162b2 and mRNA-1273. Healthy participants receiving BNT162b2 were also recruited as control. Blood samples were obtained 3weeks, 2 months, 3 months, 4 months, and 6 months after second dose of vaccines. We measured titres of neutralizing antibodies against SARS-CoV-2 and calculated seroconversion rates to evaluate humoral responses. We also assessed T-cell immunity responses by using interferon releasing assay against SARS-CoV-2 in a part of the patients. Answers to questionnaires about adverse reactions were obtained from participants.
Results: A total of 974 patients with inflammatory rheumatic diseases and healthy 630 control participants were enrolled. Among them, 796 patients received BNT162b2, 178 patients received mRNA-1273, and all control participants received BNT162b2. Seroconversion rates and neutralizing antibody titres 3 weeks after vaccination were significantly higher in patients with mRNA-1273 and healthy participants with BNT162b2 compared with patients with BNT162b2; seroconversion rates, 97.2% vs 99.5% vs 83.3%, p<0.001; titers of neutralizing antibodies, 29.4±33.9 IU/mL vs 23.9±14.2 IU/mL vs 10.8±16.5 IU/mL, p<0.001, respectively. On another front, T cell reaction against SARS-CoV-2 was similar in both patients with mRNA-1273 and BNT162b2; interferon gamma levels for antigen 1, 1.2±2.1 IU/mL vs 0.8±2.5 IU/mL, p=0.23; and for antigen 2, 1.4±1.9 IU/mL vs 1.0±2.1 IU/mL, p=0.11, respectively. Regarding adverse reaction of each mRNA vaccine, the frequency of systemic adverse reactions including fever and general fatigue are also significantly higher in patients with mRNA-1273 and healthy controls than patients with BNT162b2; fever, 48.0% vs 44.9% vs 10.2%, p<0.001; general fatigue, 70.4% vs 61.8% vs 31.2%, p<0.001, respectively). In longitudinal measurement, neutralizing antibody titres in patients with BNT162b2 were decreased more rapidly than those in healthy controls; 3.3±3.2 IU/mL in patients with BNT162b2 at 4 months and 3.2±4.7 IU/mL in healthy controls with BNT162b2 at 6 months. We identified age, glucocorticoid dose (prednisolone > 7.5mg), use of immunosuppressants including methotrexate, mycophenolate, cyclophosphamide, and tacrolimus are associated with rapid attenuation of humoral responses in patients with BNT162b2.
Conclusion: Our results demonstrated a significant higher humoral immunogenicity and frequency of systemic adverse reaction of the SARS-CoV-2 mRNA-1273 (Moderna) compared with the BNT162b2 (Pfizer-BioNTech) in inflammatory rheumatic disease patients. Glucocorticoid and immunosuppressive agents impaired induction and sustention of neutralizing antibody, and earlier third booster vaccination may be required within 4 months, especially for those receiving BNT162b2.

POS0258 SAFETY AND IMMUNOGENICITY OF BNT162B2 MRNA COVID-19 VACCINE AMONG ADOLESCENTS WITH RHEUMATIC DISEASES TREATED WITH IMMUNOMODULATORY MEDICATIONS

M. Heshin-Bekenstein[1,2], A. Ziv[2,3], N. Toplak[4], D. Hagin[2,5], D. Kadishevich[6], Y. Butbul[7], E. Saiag[8], G. Shefer[9], O. Sharon[9], S. Pel[10], O. Elkayam[2,10], Y. Uziel[2,3]on behalf of PReS Vaccination Working Group. *[1]Dana Dwek Children's Hospital of Tel Aviv Sourasky Medical Center, Pediatric Rheumatology Service, Tel Aviv, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; [3]Meir Medical Center, Pediatric Rheumatology Unit, Kfar Saba, Israel; [4]University Children's Hospital, University Medical Center Ljubljana, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia; [5]Tel Aviv Medical Center, Allergy and Clinical Immunology Unit, Tel Aviv; [6]Meir Medical Center, Pediatrics, Kfar Saba, Israel; [7]Ruth Rappaport Children's Hospital of Rambam Medical Center, Pediatric Rheumatology Service, Haifa; [8]Tel Aviv Sourasky Medical Center, Hospital Management, Information and Operation Branch, Tel Aviv, Israel; [9]Tel Aviv Sourasky Medical Center, Department of Endocrinology Metabolism and Hypertension, Tel Aviv, Israel; [10]Tel Aviv Sourasky Medical Center, Rheumatology Department, Tel Aviv, Israel*

Background: Adolescents with juvenile-onset autoimmune inflammatory rheumatic diseases (AIIRD) could be at risk for disease flare secondary to SARS-CoV-2 infection or to withholding anti-inflammatory therapy. While vaccination can protect against COVID-19, safety and immunogenicity data regarding anti-SARS-CoV-2 vaccines among adolescents with AIIRD are limited.
Objectives: This international, prospective, multicentre study evaluated the safety and immunogenicity of the BNT162b2 anti-SARS-CoV-2 vaccine among adolescents and young adults with juvenile-onset AIIRD, 80% of whom are on chronic immunomodulatory therapy.
Methods: Vaccine side effects, disease activity, and short-term efficacy were evaluated after 3 months in 91 patients. Anti-spike S1/S2 IgG antibody levels were evaluated in 37 patients and 22 controls, 2–9 weeks after the second dose.
Results: Ninety-one patients and 40 healthy controls were included. Safety profile was good, with 96.7% (n=88) of patients reporting mild or no side-effects, and no change in disease activity. However, 3 patients had transient acute symptoms: 2 following the first vaccination (renal failure and pulmonary haemorrhage) and 1 following the second dose (mild lupus flare vs. viral infection). Seropositivity rate was 97.3% in the AIIRD group compared with 100% among controls. However, anti-S1/S2 antibody titres were significantly lower in the AIIRD group compared with controls (242±136.4 vs. 387.8±57.3 BAU/ml, respectively; p<0.0001). No cases of COVID-19 were documented during the 3-month follow-up.
Conclusion: Vaccination of juvenile-onset AIIRD patients demonstrated good short-term safety and efficacy, high seropositivity rate, but lower anti-S1/S2 antibody titres compared to healthy controls. These results should encourage vaccination of adolescents with juvenile-onset AIIRD, even while on immunomodulation.

Bonfa[1]on behalf of COVID-19 CoronaVac in Patients With Autoimmune Rheumatic Diseases and HIV/AIDS (CoronavRheum).

[1]Faculdade de Medicina da Universidade de São Paulo, Rheumatology, Sao Paulo, Brazil; [2]Faculdade de Medicina da Universidade de São Paulo, Pediatric rheumatology, Sao Paulo, Brazil

Background: Patients with rheumatoid arthritis (RA) on methotrexate have reduced vaccine responses. Temporary discontinuation has improved immunogenicity of anti-influenza vaccine, but this strategy has not been evaluated in anti-SARS-CoV-2 vaccines.

Objectives: To evaluate the effect on immunogenicity and safety of 2-week methotrexate (MTX) discontinuation after each dose of the Sinovac-CoronaVac vaccine versus MTX maintenance in rheumatoid arthritis (RA) patients.

Methods: This was a single-center, prospective, randomized, investigator-blinded, intervention study (#NCT04754698, CoronavRheum), including adult RA patients (stable CDAI≤10, prednisone ≤7.5mg/day), randomized (1:1) to withdraw MTX (MTX-hold) for 2 weeks after each vaccine dose or maintain MTX (MTX-maintain), evaluated at D0, D28 and D69. Co-primary outcomes were anti-SARS-CoV-2 S1/S2 IgG seroconversion(SC) and neutralizing antibody (NAb) positivity at D69. Secondary outcomes were geometric mean titers (GMT) and flare rates. For immunogenicity analyses, we excluded patients with baseline positive IgG/NAb, and, for safety reasons, those who flared at D28 (CDAI>10) and did not withdraw MTX twice.

Results: Randomization included 138 patients with 9 exclusions (5 COVID-19, 4 protocol violations). Safety evaluation included 60 (MTX-hold) and 69 (MTX-maintain) patients. Further exclusions: 27 patients [13 (21.7%) vs. 14 (20.3%), p=0.848] with positive baseline IgG/NAb and 10 patients (21.3%) in MTX-hold with CDAI>10 at D28. At D69, MTX-hold (n=37) had a higher rate of seroconversion than MTX-maintain (n=55) group [29 (78.4%) *vs* 30 (54.5%), p=0.019], with parallel augmentation in GMT [34.2 (25.2-46.4) *vs* 16.8 (11.9-23.6), p=0.006]. No differences were observed for NAb positivity [23 (62.2%) *vs* 27 (49.1%), p=0.217]. At D28 flare, rates were comparable in both groups (CDAI, p=0.122; DAS28-CRP, p=0.576), whereas CDAI>10 was more frequent in MTX-hold at D69 (p=0.024).

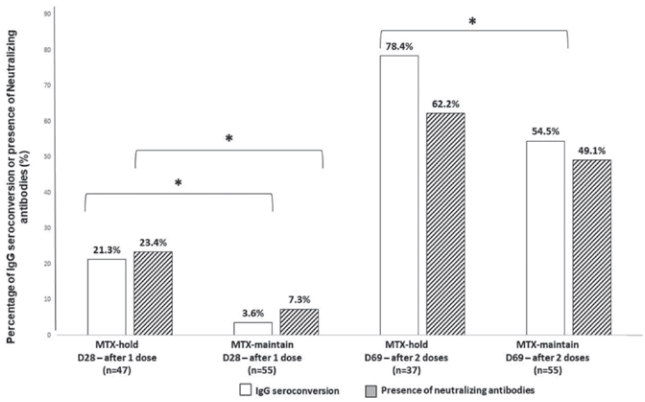

Figure 1.

Conclusion: We provide novel data that 2-week MTX withdrawal after each Sinovac-CoronaVac vaccine dose improves anti-SARS-CoV-2 IgG response. The increased flare rates after second MTX withdrawal may be attributed to the short-term interval between vaccine doses. This strategy requires close surveillance and shared decision making due to the possibility of flares.

Schett[1]. *[1]Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany; [2]Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Dermatology, Erlangen, Germany; [3]Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 1, Erlangen, Germany; [4]Rheumatology Clinical Practice, Erlangen, Erlangen, Germany; [5]Paracelsus University Nürnberg., Clinic for Internal Medicine 5, Nürnberg, Germany; [6]Rheumatology Practice, Bamberg, Bamberg, Germany*

Background: The first vaccine against SARS-CoV-2 was approved in December 2020. Immunogenicity of SARS-CoV2 vaccines in patients with immune-mediated inflammatory disease (IMID) have so far been evaluated in the 2-6 weeks following complete vaccination and risk groups for poor early vaccine response have been identified leading to specific vaccination recommendations. However, data on the long-term course and persistence of vaccine response in IMID patients, as well as the outcomes of the specific recommendations are lacking.

Objectives: To evaluate the long-term course of humoral response to SARS-CoV-2 vaccination in a large prospective cohort of IMID patients and non-IMID controls with a follow-up duration of up-to to 10 months after the first vaccine dose.

Methods: We have initiated a prospective dynamic cohort of IMID patients and healthy controls in February 2020 to monitor immune response to SARS-CoV-2 and respiratory infections including COVID-19 (1). Participants who contributed data starting from the 4 weeks before their first vaccination onwards were included in this analysis. Antibodies against SARS-CoV-2 spike protein were quantified with an ELISA from Euroimmun (Lübeck, Germany) with an optical density cutoff of 0.8. We fitted linear mixed-effect models for log-transformed antibody levels using time splines with adjustment for age and sex. Marginal mean antibody levels with 95% confidence intervals (CI) were estimated at selected time points for IMID patients and controls with double vaccination. We descriptively analyzed the observed antibody levels over time in cohort participants receiving two vaccinations vs. three vaccinations.

Results: Among 5076 cohort participants, 3147 IMID patients and healthy controls (mean (SD) age 49 (16)) provided 4756 samples for this analysis between December 2020 and 2021, with a median (IQR) 28 (14-31) weeks of follow-up after the first vaccination (Table 1). 2965 (94%) participants had received at least 2 and 223 (7%) participants had received three vaccine doses by the date of their latest sampling.

In IMID patients, age and sex-adjusted estimated marginal mean antibody levels waned after week 16 and were substantially reduced at all time points compared to the controls, finally dropping to the borderline range (1.01, 95%CI 0.86 to 1.19) at week 40 (Figure 1A, Table 1). A third dose was given to 128 (7%) of IMID patients with a poor response to 2 vaccine doses after a median 20 weeks of the second dose (IQR 10 to 26 weeks). After the third dose, antibody levels in IMID patients were comparable to those of healthy controls at 40 weeks who had three vaccine doses. These were also higher than that of IMID patients and controls who did not receive a third dose (Figure 1B).

Table 1. Participant characteristics and antibody levels

	Healthy controls	IMID
N	1199	1948
Age, mean (SD)	40.8 (13.5)	54.3 (14.8)
Follow-up, weeks, median (IQR)	31.1 (23.8-36.6)	19.6 (12.3-26.6)
Follow-up range, weeks,	1.6-46.1	1.7-46.3
Sex, n(%)		
Female	554 (46.2)	1136 (58.3)
Vaccine intervals, ´median (IQR)		
1st to 2nd dose	4.6 (3.0-6.0)	6.0 (5.0-6.1)
2nd to 3rd dose	29.6 (26.9-36.4)	19.9 (10.0-26.1)
Diagnosis, n (%)		
Spondyloarthritis	-	713 (36.6)
Rheumatoid arthritis	-	489 (25.1)
Autoimmune disease, systemic+	-	420 (21.5)
Inflammatory bowel disease	-	219 (11.2)
Psoriasis	-	107 (5.5)
Mean* antibody levels after 1st dose		
Week-8	4.16 (3.89 to 4.45)	2.97 (2.83 to 3.12)
Week-16	8.39 (7.81 to 9.02)	5.04 (4.81 to 5.28)
Week-32	5.02 (4.73 to 5.33)	2.52 (2.32 to 2.74)
Week-40	2.14 (1.95 to 2.35)	1.01 (0.86 to 1.19)

+ Systemic lupus, systemic sclerosis, Sjögren's syndrome, vasculitis* Estimated marginal means adjusted for age and sex.

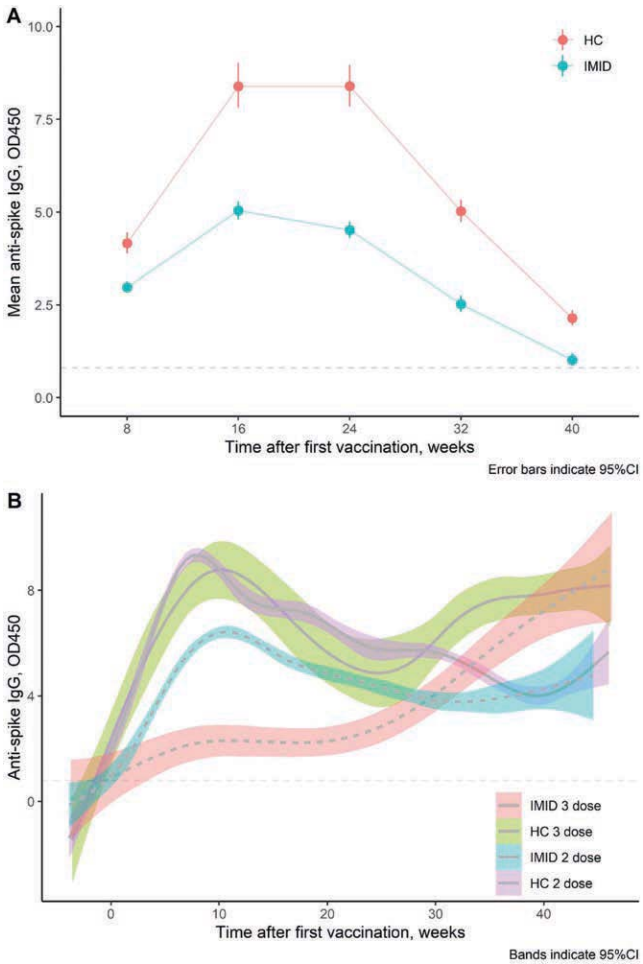

Figure 1.

Conclusion: Humoral response to vaccination against SARS-CoV-2 was weaker in IMID patients compared to controls at all time points after the first vaccine dose and practically disappeared after 1 year. IMID patients can still achieve a good antibody response with a third dose even after a weak response with two doses.

POS0261

TIME SINCE LAST RITUXIMAB TREATMENT IS ESSENTIAL FOR DEVELOPING A HUMORAL RESPONSE TO THE COVID-19 MRNA VACCINE IN PATIENTS WITH RHEUMATIC DISEASES.

A. Troldborg[1,2,3], M. K. Thomsen[1,4], L. E. Bartels[2], J. B. Andersen[2], S. R. Vils[2,3], C. M. Jørgensen[2,3], A. D. Johannesen[2], M. L. F. Hermansen[2], S. Mikkelsen[5], C. Erikstrup[1,5], E. M. Hauge[1,2], C. Ammitzbøll[1,2]. *[1]Aarhus University, Clinical Medicine, Aarhus, Denmark; [2]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [3]Aarhus University, Biomedicine, Aarhus, Denmark; [4]Aarhus University Hospital, Clinical Microbiology, Aarhus, Denmark; [5]Aarhus University Hospital, Clinical Immunology, Aarhus, Denmark*

Background: Concerns about Rituximab (RTX) treatment and potentially inadequate vaccine response were aired early in the pandemic, and initial data seem to support this concern (1). So far, studies regarding rheumatic patients and the COVID-19 vaccines have included a relatively small number of patients receiving rituximab.

Objectives: We aimed to investigate if patients with rheumatic diseases treated with RTX raise a serological response towards the COVID-19 mRNA vaccines and to elucidate the influence of time since the last dose RTX before vaccination on this response.

Methods: We included 201 patients followed at the Department of Rheumatology, Aarhus University Hospital. All had been treated with RTX in the period 2017-2021, and had finished a two-dose COVID-19 mRNA vaccination. All patients and 44 blood donors had total antibodies against SARS-CoV2 spike protein measured. Univariate and multivariate logistic regression were used.

Results: Patients were predominantly female (67%) with a median age of 62 years. The most frequent diagnosis was ANCA-associated vasculitis (32%), rheumatoid arthritis (31%), and myositis (14%), and 97% had the Pfizer/Biontic vaccine. Median number of RTX infusions were 5 (IQR 2-8), with a cumulative dose of 4g (2-8), and 72% had received RTX within the last 15 months. Prednisone was used by 43%, followed by methotrexate (25%), hydroxychloroquine (11%) and azathioprine (10%). We observed a time-dependent increase in antibody response as the interval from the last RTX treatment to vaccination increased (Table 1). Only 17.3% of patients developed a detectable antibody response after receiving their vaccination 6 months or less after their previous RTX treatment (Figure 1). Positive antibody response increased to 66.7% in patients who had RTX 9-12 months before vaccination. Neither cumulative treatment time nor cumulative RTX dose seemed to influence the serological response to the vaccine (Table 1). Thus, even in patients who have received RTX for a substantial time, expanding time-since-last-RTX treatment could prove beneficial for increasing the chance of a serological response. We further found that "months between last Rtx and vaccination", prednisone and azathioprine treatment were alle negatively associated with antibody response in a multivariate logistic regression analysis(Table 1). All blood donors (100%) had detectable antibodies after vaccination.

Table 1. Logistic regression analysis with precense of SARS-CoV-2 antibodies after mRNA vaccination as dependent varaible.

Univariate	OR	95% CI	P-value
Sex, female = ref.	0.91	0.50 - 1.67	0.77
Age, years	0.98	0.96 - 1.00	0.09
Diagnosis	1.05	0.99 – 1.13	0.08
Months between last RTX and vaccination	1.06	1.03 - 1.09	**<0.001**
Total number of RTX infusions	0.96	0.92 - 1.01	0.10
Total dose of RTX, mg	0.97	0.92 - 1.02	0.18
Time from first to last RTX treatment	1.00	1.00 - 1.00	0.57
No DMARD treatment	0.94	0.50 - 1.78	0.85
Prednisone, dose in mg	0.91	0.85 - 0.99	**0.02**
Methotrexate	1.71	0.90 - 3.25	0.10
Hydroxychloroquine	0.87	0.35 - 2.19	0.77
Azathioprine	0.23	0.06 - 0.80	**0.02**
Multivariate model			
Months between last Rtx and vaccination	1.08	1.04 - 1.11	**<0.001**
Prednisone treatment, mg	0.91	0.84 - 0.99	**0.03**
Azathioprine treatment	0.10	0.02 - 0.44	**0.002**

All significant variables in the univariate analysis were included in the multivariate model.

Conclusion: In conclusion, patients with rheumatic diseases treated with RTX have a severely impaired serological response towards the COVID-19 mRNA vaccine. This is especially true if the interval between RTX treatment and vaccination is

less than 9 months. For the majority of RTX treated patients, the recommended six months since last RTX is insufficient to develop a humoral response to COVID-19 mRNA vaccines. Our data suggest that the current recommendations of a 6 months interval should be revised.

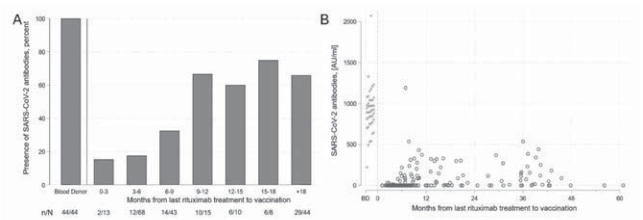

Figure 1. Total SARS-CoV-2 antibody response after receiving two vaccinations with COVID-19 mRNA vaccine in patients with rheumatic diseases treated with rituximab and controls. A) Percent of patients and controls with a measurable antibody response post-vaccination. B) Levels of measured total anti-SARS-CoV-2 antibodies in patients (circles) and controls (crosses). The X-axis shows time since the patients' last treatment with rituximab prior to vaccination. n=number of individuals with SARS-CoV-2 antibodies, N= total number of individuals. Blood donors (BD)

POS0262 HUMORAL AND CELLULAR SARS-COV-2 VACCINE RESPONSES IN PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA

Y. Van Sleen[1], K. Van der Geest[1], R. Reitsema[1], I. Esen[1], J. H. Terpstra[1], E. Raveling-Eelsing[1], M. Van der Heiden[2], J. Jansen[3], A. Buisman[4], D. Van Baarle[2], M. Sandovici[1], E. Brouwer[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Medical Microbiology and Infection Prevention, Groningen, Netherlands; [3]Pharmacovigilance Centre Lareb, Tilburg, Netherlands; [4]National Institute for Public Health and the Environment (RIVM), Centre for Infectious Disease Control, Bilthoven, Netherlands*

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are overlapping autoinflammatory diseases affecting people over 50 years. The diseases are treated with immunosuppressive drugs such as prednisolone, methotrexate, leflunomide and tocilizumab. Even though GCA and PMR patients have a substantially higher risk for infections, little is known about humoral and cellular immune responses after vaccination in these patients.
Objectives: In this study we assessed the immunogenicity and safety of SARS-CoV-2 vaccinations in these diseases.
Methods: Patients (n=45 GCA, n=33 PMR) visited the outpatient clinic twice: pre-vaccination and 4 weeks post-vaccination (BNT162b2 or ChAdOx1 vaccine). Patients with previous SARS-CoV-2 infection were excluded. In both pre- and post-vaccination samples, anti-Spike antibody concentrations were assessed and compared to age-, sex- and vaccine-matched control groups (n=98). In addition, the frequency of SARS-CoV-2 Spike-specific T-cells was assessed by IFN-γ ELIspot assay, and side-effects and disease activity were recorded.
Results: The GCA/PMR patients, as a group, did not have reduced antibody concentrations compared to controls. However, linear regression analysis revealed a significant association of methotrexate and >10mg/day prednisolone use with lower antibody concentrations in GCA/PMR patients. Evidence of cellular immunity, as assessed by ELIspot assay, was found in 67% of GCA/PMR patients, and was correlated with humoral immunity (Figure 1). Patients using >10mg/day prednisolone had reduced cellular immunity. Importantly, vaccination did not lead to significant side-effects or changes in disease activity.

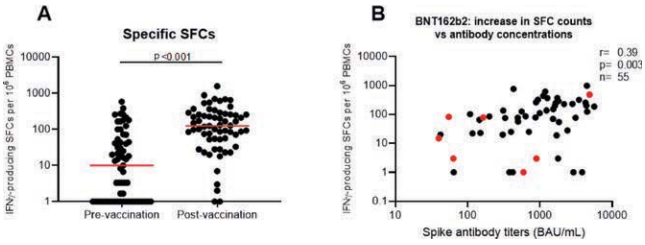

Figure 1. Spot-forming cell (SFC) counts in the ELIspot assay. SFC counts, indicating IFNγ producing cells, increased significantly (Mann Whitney U) at post-vaccination compared to pre-vaccination. Red line indicates the median (A). SFC counts correlated with Spike antibody concentrations in GCA/PMR patients vaccinated with BNT162b2 (B). GCA/PMR patients using >10 mg/day prednisolone are indicated in red. For the correlation, the specific SPC counts are used in the post-vaccination sample after subtracting the SPC count in the pre-vaccination sample. Statistical analysis by the Spearman correlation coefficient. BAU: binding antibody units

Conclusion: SARS-CoV-2 vaccination was safe for GCA/PMR patients and immunogenicity was comparable to other older individuals. However, patients using methotrexate and particularly >10mg/day prednisolone did show lower vaccine responses, which corroborates findings in other autoinflammatory patient populations. These patients may therefore be at higher risk of (potentially even severe) breakthrough SARS-CoV-2 infection.

POS0263 RE-VACCINATION COMPARED TO BOOSTER COVID-19 MRNA VACCINATION SIGNIFICANTLY INCREASES THE SEROLOGICAL RESPONSE IN RITUXIMAB-TREATED PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES WITHOUT A PRIMARY DETECTABLE SEROLOGICAL COVID-19 VACCINE RESPONSE

C. Ammitzbøll[1,2], M. K. Thomsen[2,3], M. L. F. Hermansen[1], S. R. Vils[1,4], J. B. Andersen[1], A. D. Johannesen[1], F. Szabados[1], C. M. Jørgensen[1,2,4], M. C. L. Larsen[1], C. Erikstrup[2,5], E. M. Hauge[1,2], A. Troldborg[1,4]. *[1]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [2]Aarhus University, Clinical Medicine, Aarhus, Denmark; [3]Aarhus University Hospital, Clinical Microbiology, Aarhus, Denmark; [4]Aarhus University, Biomedicine, Aarhus, Denmark; [5]Aarhus University Hospital, Clinical Immunology, Aarhus, Denmark*

Background: Reports of an impaired humoral response after COVID-19 vaccination in patients treated with rituximab (RTX) have raised particular concern for patients with inflammatory rheumatic diseases (IRD) receiving RTX (1). This calls for strategies to enhance a humoral response in RTX-treated patients. At present, there is no data on whether it is best to increase the humoral response with a third vaccine dose (a booster) or with a third and fourth dose (re-vaccination).
Objectives: In IRD patients treated with RTX, without a detectable humoral response after the first vaccination course (two shots), we aimed to investigate the difference of either a booster vaccine (dose 3) or a new re-vaccination course (dose 3+4) on the serological response of the COVID-19 mRNA vaccines.
Methods: We included 84 patients with IRD treated with RTX, all without measurable total SARS-CoV-2 antibodies after a full primary COVID-19 vaccination course (2 doses three weeks apart). All patients were offered a new re-vaccination course with the mRNA vaccine not used primarily (Pfizer/Biontec or Moderna). A small number of patients declined the revaccination, and recieved a booster with the mRNA vaccine used initially. Serum total antibodies were measured before and six weeks after the last dose against recombinant SARS-CoV-2 spike S1 protein (VITROS). In addition, CD19+ B-cells were measured at inclussion.
Results: Patient characteristics are in Table 1. The median age was 64 years; 68% were female with a disease duration of 5 years. Sixty-nine out of 84 were re-vaccinated (3+4 dose). Details previous exposure to RTX are given in Table 1. CD19+ B-cells were measurable in 12/81 at inclussion.

Table 1. ***Patient Characteristics***

	Booster, n=15	Revaccination, n=69
Age, years median (IQR)	60 (45 - 69)	65 (54 - 70)
Female	47%	72%
Disease duration, years (IQR)	5 (2-8)	6(2 - 13)
ANCA-vasculitis	47 %	45 %
Rheumatoid Arthritis	47 %	17 %
Poly- Dermatomyositis	6 %	19 %
SLE, Scleroderma, other diagnoses	-	19 %
No DMARD treatment	27 %	35 %
Prednisone	33 %	46 %
Methotrexate	40 %	16 %
Azathioprine	7 %	12 %
Mycophenolate	7 %	7 %
Other	20 %	9 %
Rituximab treatment, (IQR)		
Months from last RTX to vaccination	3.9 (1.3 - 9.3)	5.4 (4.2 - 7.3)
Number of infusions	6 (4 - 8)	7 (5 - 12)
Cummulativ total dose, gram	4 (2.5 - 7.5)	6 (3.5 - 10)
Total treatment time with RTX, months	15 (9 - 54)	27 (13 - 63)
Patients with measurable CD19+ B-cells in peripheral blood at the time of booster or re-vaccination (positive/total)	3/14	9/67

We found a combined seroconversion rate of 33% six weeks after the last shot. There was no statistical difference between the booster (38,5%) and the re-vaccination group (32,3%), p=0.67 (Pearson's chi-squared). IRD patients with a humoral response in the re-vaccination group had significantly higher levels of total SARS-CoV-2 antibodies (median(IQR) 306(49-464) AU/ml) compared to the booster group (14(4-15) AU/ml) p=0.02, Figure 1A. In multiple logistic regression model, we found that levels of CD19+ B-cells were the only variable able to predict a humoral response, Figure 1B. However, only 39% of the patients with

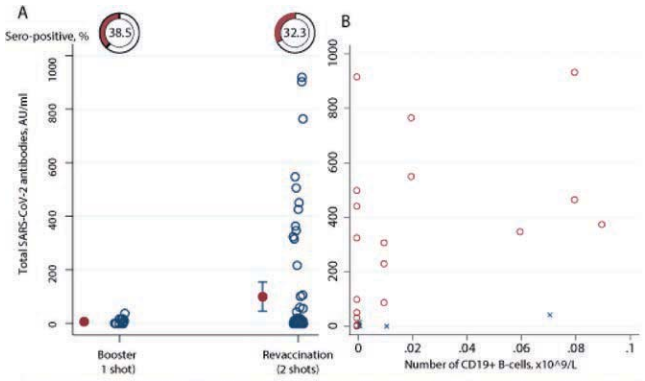

Figure 1. Concentration of total SARS-CoV-2 antibodies measured 6 weeks after last COVID-19 revaccination or booster shot. A) Total antibody concentration presented by vaccination group, either 1 shot (booster) or 2 shots (revaccination). Pie chart present percent of patients with a positive total antibody measurement post-vaccination. Circle with whiskers indicate mean concentration with confidence intervals. B) Total antibody concentration presented by pre-vaccination measurement of circulating CD19+ B-cells in peripheal blood. (x) indicate booster and (0) indicate revaccination group.

Figure 1.

a humoral response to vaccination had measurable CD19+ B-cells before vaccination. We found no effect of age, sex, diagnosis, treatment, and RTX exposure on the chance of seroconversion in multiple logistic regression models when corrected for CD19+ B-cells.

Conclusion: We found that re-vaccination (dose 3+4) with COVID-19 mRNA vaccines favored a high humoral response in patients with IRD treated with RTX, who did not have a detectable humoral response after the first two vaccine doses, compared to a booster shot (dose 3). A detectable humoral response after re-vaccination was seen in more than half of the patients with no measurable CD19+ B-cells before vaccination. Presence of circulating CD19+ B-cells are a significant predictor of humoral response to mRNA COVID-19 vaccination.

POS0264

CHARACTERIZATION OF THE IMMUNE RESPONSE IN PATIENTS WITH INFLAMMATORY IMMUNE-MEDIATED DISEASES ON IMMUNOSUPPRESSIVE TREATMENT AFTER ONE MONTH OF SARS-COV-2 VACCINATION

A. Martínez-Feito[1], P. Nozal[1], M. Novella-Navarro[2], E. Fernández-Fernández[2], L. Del Pino Molina[3], M. Casas Temprano[1], I. Akatbach Bousaid[1], M. D. Martin Arranz[4], A. Balsa[2], C. Plasencia[2]. *[1]La Paz University Hospital, Immunology, Madrid, Spain; [2]La Paz University Hospital, Rheumatology, Madrid, Spain; [3]IdiPAZ, Lymphocyte Pathophysiology in Immunodeficiencies, Madrid, Spain; [4]La Paz University Hospital, Gastroenterology, Madrid, Spain*

Background: The relevance of studying immune response after SARS-CoV-2 vaccination in patients with inflammatory immune-mediated diseases (IMIDs) represents a deep concern regarding the risk estimation and management of patients with these diseases on immunomodulatory drugs. It is well known that certain treatments as anti CD20 therapies results in a diminished immunogenicity against common vaccines but it is a scarce data regarding the cellular protection obtained upon vaccination between patients with different IMID and between different treatments.

Objectives: To compare a potential detriment on cellular and antibody-mediated protection upon SARS-CoV-2 vaccination in patients with IMIDs treated with immunosuppressive drugs.

Methods: We recruited 73 patients with rheumatoid arthritis-RA-(n=49), spondylarthritis-SpA-(n=19), inflammatory bowel disease-IBD-(n=5), idiopathic juvenile arthritis-IJA- (n=2) and heterogenous group composed of sclerodermia, lupus, uveitis…(n=6). They were treated mainly with rituximab (n=27), TNFi (n=37) or JAKi (n=3). We collected data of age,sex, csDMARDs, previous SARS-CoV-2 infection, last RTX infusion and prednisone use.

After one month of vaccination, we assessed the humoral response performing the Thermo Scientific EliA SARS-CoV-2-Sp1 IgG Test (positivity cut-off >0.70 IU/ml) which was also compared with the data with of 35 healthy controls. In addition, in 40 patients who had serum antibody levels under 100UI/ml, we analysed the cellular response by the use of the QuantiFERON SARS-CoV-2 Starter Pack (Quiagen). A cut-off value of 0.15 IU/ml discriminate between positive or negative cell-mediated immune responses. We compared differences among the different IMIDs and between the different immunosuppressive treatments through non-parametric test (p<0.05)

Results: Regarding demographic characteristics of patients, older patients (>56 years) and female sex were factors which were associated with low titles of serum antibodies.

Anti-spike IgG antibodies were present in an 86% of the IMIDs patients and in 100% healthy controls with significant different IgG titre (median [IQR]): 51[11-184] vs 700[440-940]; p<0.0001.

The differences between (median [IQR]) serum antibody levels were statistically different between IMID type: 33[1-138] in RA vs 94[34-191] in SpA vs 204[187-204] in IBD vs 133[61-204] in IJA vs 13[1.5-31.8] in the rest; p=0.04. Remarkably, patients with IBD who had the highest antibodies titles were the youngest compared with the other patients.

Target of the therapy played also an important role in serum antibody levels being these: 3.6 [0.7-51] in RTX patients vs 156 [45-204] in TNFi vs 40 [18-58] in JAKi patients; p<0.0001. In those patients who the last infusion of rituximab was, at least, one year before vaccination presented CD19+ B cells detected by flow cytometry and anti-spike IgG antibodies as well.

Cell-mediated responses to SARS-CoV-2 were positive in 33% of IMIDs patients, indeterminated in 3% and negative in 65% of the patients. Strikingly, out of the 33% positive patients, 85% were treated with RTX. A 61% of the RTX patients had inducible cell-mediated responses vs 14% of the patients treated with TNFi; p<0.01. On the other hand, there were not differences in cell-mediated responses between positive and negative antibody patients.

Conclusion: Titres of serum antibodies against spike protein of SARS-CoV-2 were lower in IMIDs patients than in controls. Patients with RTX had lower rates of positivity humoral response as well as lower serum titles than patients treated with other therapies regardless the patients 'age. Neverthless, in those patients in whom RTX infusion was delayed because of vaccination they conserved a humoral response.

On the other hand, more patients treated with RTX had inducible cell-mediated responses compared with patients with TNFi.

POS0265

SERUM PROTEOMICS IN GIANT CELL ARTERITIS IN RESPONSE TO A THREE-DAY PULSE OF GLUCOCORTICOID FOLLOWED BY TOCILIZUMAB MONOTHERAPY (THE GUSTO TRIAL)

L. Christ[1], A. Gloor[2], F. Kollert[1], S. Reichenbach[1,3], P. Villiger[4]. *[1]Inselspital, Bern University Hospital, Department of Rheumatology and Immunology, Bern, Switzerland; [2]Inselspital, Bern University Hospital, Department of General Internal Medicine, Bern, Switzerland; [3]University of Bern, Institute for Social and Preventive Medicine, Bern, Switzerland; [4]Medical Center Monbijou, Rheumatology, Bern, Switzerland*

Background: Measuring disease activity in Giant Cell Arteritis (GCA) remains a challenge, particularly, if Tocilizumab (TCZ) is prescribed which blunts the acute phase response. A proteome analysis may not only serve to identify biomarkers, but also to shed light on pathophysiology. The sequential administration of Glucocorticoids (GC) and TCZ as done in the GUSTO study (GCA treatment with ultra-short GC and TCZ) provides a unique opportunity to dissect the effects of GC and TCZ.

Objectives: To investigate the effects of pulse GC-treatment and of ensuing long-term TCZ monotherapy on serum proteins in GCA; to compare the serological findings with clinical response; to search for proteins which are not under control of IL-6 and may be suitable as biomarkers of disease activity.

Methods: Eighteen patients with newly diagnosed GCA received 500 mg methylprednisolone intravenously for 3 consecutive days (NCT03745586). Thereafter, GC treatment was discontinued and a single dose of TCZ (8 mg/kg body-weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162 mg) from day 10 until week 52. Serum samples were collected prior to treatment (day 0), at day 3 (after GC treatment), day 10 and at weeks 4, 24, and 52

(Lancet Rheumatology, https://doi.org/10.1016/S2665-9913(21)00152-1). Sera of patients were analyzed on Olink Explore 1536, capturing over 1400 proteins. Protein wise t-tests (threshold, adjusted p-value < 0.05) with adjustment for multiple testing (Benjamini-Hochberg) were performed to identify differentially expressed proteins (DEPs) between day 0 vs day 3 (referred to as GC treatment) and day 0 vs week 52 (referred to as TCZ treatment, remission). DEPs were grouped in pathways identified in the KEGG database.

Results: Successful treatment resulted in the upregulation of 254 proteins and the downregulation of 245 proteins from day 0 to week 52. Protein levels did not change between week 24 and 52 during established full remission.

In response to GC pulse therapy the ten most significant DEPs included ANGPTL7, AREG, IL1RL1, MATN3, MMP3, SPARCL1 (upregulated) and IL12A, IL12B, KLK10, SIGLEC6 (downregulated). Conversely, under treatment with TCZ, SIGLEC6 was continuously up- and MMP3 and AREG were continuously down-regulated from day 3 to week 4.

KEGG pathways of interest in GCA (day 0 vs day 3 and day 0 vs week 52, respectively) included: cytokine-cytokine receptor interaction, the PI3K-AKT, JAK-STAT, IL17, TNF, NF-kappa B, Toll-like receptor and MAPK signaling pathways. Figure 1 displays the top 5 KEGG pathways enriched in TCZ-treated GCA patients in remission.

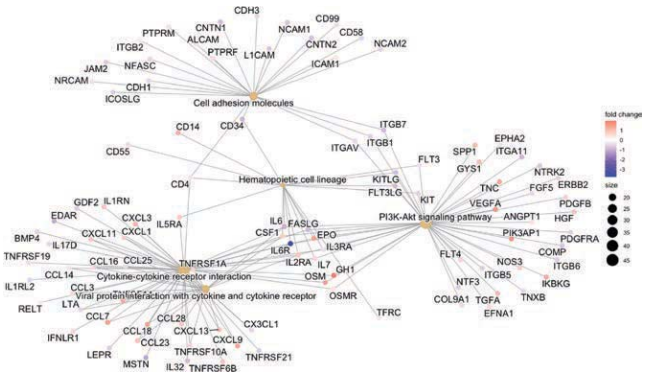

Figure 1. Network plot of the top 5 KEGG pathways from day 0 vs week 52. Size in the figure legend refers to the number of proteins in each pathway. Estimate in the figure legend indicates the log2 fold change from day 0 vs week 52.

Conclusion: One third of the measured proteins covering a wide spectrum of pathways changed in response to pulse GC-treatment followed by TCZ monotherapy. Several proteins were inversely induced by GC or TCZ. Osteopontin, CSF1 and CCL18 as markers of macrophage activation should be explored as biomarkers of disease activity in TCZ-treated GCA-patients.

POS0266 EFFECTIVENESS OF A SPACING-UP STRATEGY AFTER ONE-YEAR COURSE OF WEEKLY TOCILIZUMAB IN PATIENTS WITH GIANT CELL ARTERITIS: A SINGLE-CENTRE PROSPECTIVE STUDY

A. Tomelleri[1], C. Campochiaro[1], S. Sartorelli[1], L. Mariotti[1], E. Baldissera[1], M. Matucci-Cerinic[1], L. Dagna[1]. [1]*IRCCS San Raffaele Hospital, Unit of Immunology Rheumatology Allergy and Rare Diseases, Milan, Italy*

Background: Although tocilizumab (TCZ) is extensively used for the treatment of giant cell arteritis (GCA), there is still uncertainty with regard to optimal treatment duration. The GiACTA open-label extension phase showed that 58% of patients treated with a 12-month course of weekly TCZ had a disease flare in the 2 years following therapy suspension[1], suggesting that some patients may need a more prolonged duration of this therapy.

Objectives: To evaluate efficacy and safety of low-dose TCZ maintenance in GCA patients who achieved remission after one year of standard TCZ therapy.

Methods: GCA patients eligible for TCZ according to the 2018 EULAR recommendations[2] and who achieved remission after one year of weekly subcutaneous TCZ were prospectively enrolled. TCZ was administered every-other-week (EOW) for additional 12 months, and eventually suspended. Patients were evaluated 4-monthly during TCZ therapy, and 1 and 6 months after TCZ suspension (Figure 1). In patients with large-vessel (LV) involvement at baseline, PET scan was performed 12 and 24 months after TCZ start. Primary outcome was relapse-free survival at month 6 since TCZ suspension. Relapse-free survival during TCZ therapy and imaging response at PET scan were also evaluated. Adverse events were recorded.

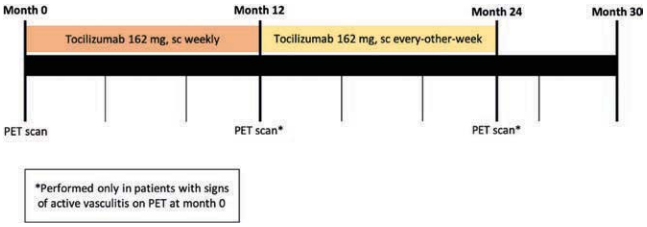

Figure 1. Study design.

Results: 17 patients were enrolled (12 women, 71%; mean age 71.5±8.7 years). Disease features at diagnosis and TCZ start are listed in Table 1. Reasons for TCZ start were clinical or imaging disease flare (n=9), persistence of disease activity (n=5), and steroid-related adverse events (n=3). At TCZ start, median disease duration was 8 (3-22) months, serum C-reactive protein (CRP) was 13 (6-22) mg/L, daily prednisone (PDN) dose was 25 (15-37.5) mg; 4 patients were already on methotrexate (MTX) which was maintained in 1 of them; 10 patients (59%) had LV involvement on PET scan. At TCZ EOW start, no patient was on PDN and 1 patient was on MTX; MTX was added in another patient due to persistence of LV involvement at PET scan. All patients completed the 24-month TCZ course. Two patients (12%) had a polymyalgic flare while on EOW TCZ: one patient at month 1 and one patient at month 6; of note, one of them had a polymyalgic flare also while on weekly TCZ. Both flares were managed with a PDN course with complete clinical remission. No patient had active LV involvement at 24-month PET scan. Adverse events on EOW TCZ were zoster reactivation (n=1) and neutropenia (n=1). At TCZ stop, no patient was on PDN and 2 patients were on MTX. One month after TCZ stop, all patients were in remission. Six months after TCZ stop, 4 patients (24%) experienced a flare, which was successfully managed in all cases with TCZ weekly re-introduction; in 2 patients, a PDN course was also started.

Table 1. ***Patients' characteristics at giant cell arteritis diagnosis and at study entry.***

	GCA diagnosis, n=17 n (%)	TCZ start, n=17 n (%)
Headache	16 (94)	5 (29)
Scalp tenderness	11 (65)	5 (29)
Jaw claudication	9 (53)	2 (12)
Ocular ischemic manifestations	3 (17)	0 (0)
Polymyalgia rheumatica	8 (47)	0 (0)
Constitutional symptoms	14 (82)	7 (47)
Active vasculitis on PET	10 (59)	10 (59)
Modality of diagnosis		
Vascular ultrasound	7 (47)	-
Temporal artery biopsy	3 (17)	-
PET	10 (59)	10 (59)

Conclusion: In this proof-of-concept study, low-dose TCZ maintenance in GCA showed excellent disease control, which was maintained in most patients after therapy suspension. Longer follow-up and replication in larger cohorts are required.

POS0267 OUTCOMES DURING AND AFTER LONG-TERM TOCILIZUMAB TREATMENT IN PATIENTS WITH GIANT CELL ARTERITIS

M. Matza[1], N. Dagincourt[2], S. Mohan[3], A. Pavlov[2], J. Han[4], J. H. Stone[1], S. Unizony[1]. [1]*Massachusetts General Hospital - Harvard Medical School, Vasculitis and Glomerulonephritis Center, Boston, United States of America;* [2]*Everest Clinical Research, Statistical Operations, Markham, Canada;* [3]*Genentech, Inc., US Medical Affairs, South San Francisco, United States of America;* [4]*Genentech, Inc., Biometrics, South San Francisco, United States of America*

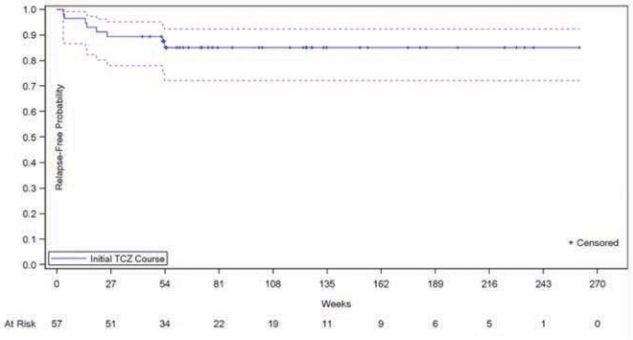
Background: Data on the long-term efficacy and safety of tocilizumab (TCZ) for giant cell arteritis (GCA), including incidence and timing of disease relapse after TCZ discontinuation, is limited.
Objectives: We aimed to evaluate the long-term outcomes of GCA patients treated with TCZ in a real-world setting.
Methods: Retrospective analysis of GCA patients treated with TCZ for >9 months at a single center between 2010-2021. Time to relapse and annualized relapse rate during and after TCZ treatment, prednisone use and safety were assessed. Relapse was defined as the re-appearance of clinical manifestations of GCA that required treatment intensification regardless of the erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) levels. The duration of TCZ treatment was determined as per the best clinical judgement of the treating rheumatologist.
Results: A total of 57 GCA patients were followed for a mean (SD) period of 3.4 (1.7) years. Baseline characteristics and treatments received are shown in Table 1. Patients were maintained on their initial TCZ course for a mean (SD) period of 2.0 (1.3) years. The initial TCZ course lasted >12 months in 50 (88%) patients. During the initial TCZ course, 8 (14.0%) patients relapsed. Kaplan-Meier (KM) estimated relapse rates on TCZ were 10.5% and 14.9% at 12 and 18 months, respectively (Figure 1**A**). TCZ was discontinued due to long-term remission in 37 (64.9%) patients and after an adverse event in 6 (10.5%) patients. Of the 43 patients stopping TCZ due to remission or adverse event, 19 (44.2%) subsequently relapsed. KM estimated relapse rates after TCZ discontinuation were 30.4% and 44.0% at 12 and 18 months, respectively (Figure 1**B**). Overall, 12 patients received more than one TCZ course. The aggregation of all TCZ courses (mean 2.5 years) and all periods off TCZ following the initial TCZ treatment (mean 0.9 years) showed that 11 (19.3%) patients relapsed while on TCZ and 20 (35.1%) patients relapsed during time off TCZ. An analysis adjusting for age, sex, prednisone dose at initiation of first TCZ course, and disease type (new onset vs. relapsing) at initiation of first TCZ course showed an annualized relapse rate (95% CI) of 0.1 (0.0-0.2) during TCZ treatment and 0.4 (0.3-0.7) off TCZ (rate ratio 0.2, p<0.0001). By the end of follow up, 42 (73.7%) patients were able to wean off prednisone. During the study, 12 serious adverse events occurred in 11 (19.3%) patients. Among those 12 events, 3 (25%) were related or possibly related to TCZ exclusively (i.e., soft tissue infection, bacteremia, and COVID-19), 3 (25%) to prednisone exclusively (i.e., osteoporotic fracture, diabetic ketoacidosis and stroke), and 2 (16.7%) to either TCZ or prednisone (i.e., pneumonia and sepsis).
Conclusion: Long-term TCZ treatment was efficacious in maintaining disease remission and sparing the use of prednisone in patients with GCA. Over 40% of patients stopping TCZ after long-term remission or adverse event relapsed following TCZ discontinuation.

Table 1. Baseline characteristics and treatments

	GCA patients (n = 57)
Age, mean (SD)	70.1 (9.3)
Female sex	39 (68.4)
New onset disease at TCZ initiation	18 (31.6)
Initial TCZ treatment	
4 mg/Kg intravenously monthly	2 (3.5)
8 mg/Kg intravenously monthly	13 (22.8)
162 mg subcutaneously every 2 weeks	6 (10.5)
162 mg subcutaneously weekly	36 (63.2)
On prednisone at TCZ initiation	57 (100)
Prednisone dose (mg) at TCZ initiation, mean (SD)	32.3 (21.7)
Patients receiving >1 TCZ course	12 (21.1)
Duration of initial TCZ course (years), mean (SD)	2.0 (1.3)
Total duration of TCZ treatment (years), mean (SD)	2.5 (1.6)*

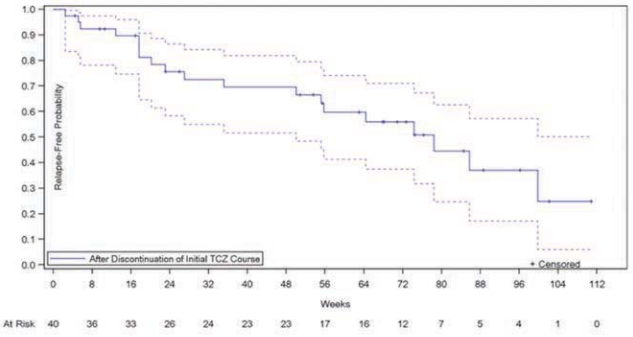
Values represent number and (%) unless otherwise specified. *Aggregated time on tocilizumab (TCZ)for those patients that received more than 1 TCZ course. GCA, giant cell arteritis; SD, standard deviation.

Figure 1A. Time to relapse on initial TCZ treatment*



* Patients were censored if tocilizumab (TCZ) was discontinued for any reason or the patient was lost to follow-up.

Figure 1B. Time to relapse after discontinuation of initial TCZ treatment*



* Time to relapse in patients that discontinued TCZ due to either long-term remission or an adverse event and who had follow-up beyond their TCZ discontinuation date. Patients were censored if TCZ was re-started for any reason other than relapse or the patient was lost to follow-up

Background: Subcutaneous (SC) tocilizumab (TCZ), a recombinant humanized anti-interleukin-6 receptor (IL-6R) monoclonal antibody, is approved globally for

the treatment of giant cell arteritis (GCA), with once weekly injections, based on the GiACTA trial.

Objectives: This Phase Ib study (NCT03923738) investigated the pharmacokinetics (PK), pharmacodynamics (PD), safety and exploratory efficacy of 2 doses of TCZ given intravenously (IV) in patients with GCA. The purpose was to explore an IV dose resulting in a minimum exposure level within the range of effective trough concentrations achieved with TCZ SC dosing in GCA and not exceeding the exposure of the well-tolerated 8 mg/kg IV every 4 weeks (Q4W) in rheumatoid arthritis (RA).

Methods: This study enrolled patients with GCA in Switzerland who had received ≥5 consecutive doses of TCZ IV 8 mg/kg (off label) Q4W and were in remission. Patients received 5 or 6 doses of TCZ IV 7 mg/kg Q4W in period 1 and, if still in remission, then received 5 or 6 doses of 6 mg/kg Q4W in period 2. Glucocorticoid use was at the investigator's discretion. PK endpoints were maximum concentration (C_{max}), minimum (trough) concentration (C_{trough}), area under the curve (AUC_τ) over a dosing interval (τ) and average concentration (C_{mean}) calculated as AUC_τ/τ of TCZ after the last dose of each period. Other endpoints included PD markers (IL-6, soluble IL-6R [sIL-6R], C-reactive protein [CRP] and erythrocyte sedimentation rate [ESR]), safety (adverse events [AEs], serious AEs [SAEs]) and exploratory efficacy (rates of flare and remission).

Results: In 24 patients enrolled, median (range) age was 65.5 (57-90) years and the majority were female (62.5%). All patients had a history of elevated ESR and/or CRP and evidence of GCA by temporal artery biopsy and/or evidence of large vessel vasculitis at GCA diagnosis. The mean PK profile following TCZ IV 7 mg/kg Q4W in Period 1 was of a similar shape to mean PK profile following TCZ IV 6 mg/kg Q4W in Period 2, with a slightly lower exposure at the 6-mg/kg dose level (Figure 1). Compared with the 7-mg/kg dose, TCZ exposures (C_{max} and AUC_τ) were on average 11.2% and 20.0% lower at the 6-mg/kg dose (Table 1). Mean IL-6 serum concentrations were elevated at baseline due to previous TCZ treatment and remained elevated throughout the study, with slightly higher concentrations in Period 1 (7 mg/kg) than Period 2 (6 mg/kg). Mean sIL-6R concentrations were elevated at baseline and comparable between the 2 doses at steady state. As expected for patients in remission, CRP levels and most ESRs were within the normal ranges at baseline and throughout the study. Overall, 22 patients (91.7%) had ≥1 AE; infections were the most frequently reported AEs. Two patients (8.3%) experienced a Grade ≥3 AE. The majority of AEs (70.8%) were not TCZ-related. Four patients (16.7%) reported an SAE; 1 (pneumococcal pneumonia) was considered TCZ-related by the investigator and 3 led to treatment interruption. There were no deaths. No patients experienced a GCA flare, and all patients remained in remission throughout the study.

Table 1. Steady-State PK Parameters of TCZ IV 7 and 6 mg/kg Q4W

PK Parameters, mean, median (range)	7 mg/kg IV (Period 1) n=22*	6 mg/kg IV (Period 2) n=22
C_{max}, µg/mL	205	182
	197 (118-352)	178 (115-320)
AUC_τ, day•µg/mL	2150	1720
	2130 (1120-4300)	1610 (921-3070)
C_{mean}, µg/mL	76.9	61.5
	76.0 (40.1-154)	57.5 (32.9-110)
C_{trough}, µg/mL	35.3	22.7
	37.2 (6.59-69.0)	22.7 (3.38-54.5)

AUC_τ, area under the curve over a dosing interval (τ); C_{max}, maximum concentration; C_{mean}, mean concentration (AUC_τ/τ); C_{trough}, minimum (trough) concentration; IV, intravenous; PK, pharmacokinetics; Q4W, every 4 weeks; TCZ, tocilizumab. *n=21 for C_{max}.

Conclusion: Both dose levels of TCZ-IV (6 and 7 mg/kg) Q4W were generally well tolerated in patients with GCA. The C_{max} and C_{mean} achieved with 6 mg/kg IV Q4W in patients with GCA were similar to those seen in patients with RA treated with 8 mg/kg IV Q4W, and C_{trough} was within the range observed in patients with GCA treated with once weekly and every 2 weeks SC dosing.

POS0269 RESULTS OF ONE YEAR OBSERVATIONAL EXTENSION OF THE BRIDGE-PMR STUDY, A RANDOMIZED DOUBLE-BLIND PLACEBO CONTROLLED TRIAL WITH RITUXIMAB IN POLYMYALGIA RHEUMATICA.

T. Bolhuis[1], D. Marsman[1], A. Den Broeder[1], N. Den Broeder[1], A. Van der Maas[1].
[1]*Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*

Background: Glucocorticoids (GC) are the cornerstone of treatment in Polymyalgia rheumatica (PMR) [1]. However, they are associated with considerable toxicity and inefficacy in part of the patients. Rituximab (RTX) was effective for PMR in a 21-week randomized controlled trial (RCT), however results from longer follow-up is still absent [2].

Objectives: To assess, in a randomized double blinded fashion, the clinical and GC-sparing effects one year after RTX.

Methods: In the BRIDGE-PMR, an RCT of 38 recently diagnosed and 9 relapsing PMR (2012 EULAR/ACR classification criteria) patients recruited from the Sint Maartenskliniek, patients were randomly allocated in a 1:1 ratio and treated with 1x 1000mg RTX / placebo (PCB) iv, identical pre-medication and an accelerated GC tapering protocol. After the 21-week study, patients were assessed in a double blinded prospective extension study up to one year after infusion. The primary outcome at one year was between group difference in GC-free remission (PMR-activity score < 10). Analysis was performed with Fischer's exact test and a two-tailed p-value < 0.05 was considered significant. Secondary outcomes were proportion of relapsing patients during the extension, proportion of patients with CRP > 5mg/l during the extension, cumulative GC dose, DMARD use, EQ-5D score, and adverse events (AE).

Results: The proportion of patients in GC-free remission after one year was significantly higher in the RTX group (48%, 11/23) compared to the PCB group (17%, 4/24), with an absolute difference of 31% (95%-CI 6-56), a relative risk of 2.9 (95%-CI 1.1-7.7), p=0.03. The secondary outcomes showed statistically significant differences in RTX versus PCB in median GC cumulative dose: 1595 versus 2302 mg (p = 0.04) and median PMR-AS: 6 versus 15 (p = 0.02) (Table 1 and Figure 1). No differences were seen in other secondary outcomes.

Table 1. Primary and Secondary Outcomes for Rituximab Versus Placebo Treatment One Year After Infusion

	Placebo [n=24]	Rituximab [n=23]	p-value
Remission, number (%)	10 (42%)	15 (65%)	0.15
GC-free remission, number (%)	4 (17%)	11 (48%)	0.03
Cumulative GC dose 0-52 weeks, in mg	2302 (1595 - 2881)	1595 (1275 – 2260)	0.04
Cumulative GC dose 21-52 weeks, in mg	959 (91 – 1442)	160 (0 - 902)	0.10
Relapse patient 21-52 weeks, number (%)*	14 (58%)	12 (52%)	0.77
PMR-AS**	15.25 (7.75 - 22.5)	6.3 (4.7 - 12.1)	0.02
CRP serum level, in mg/L	3.5 (2 - 5)	3 (1 - 4)	0.29
physicians' VAS, 0-10	2 (0.2 - 3.7)	1 (0 - 2)	0.08
Morning stiffness, in minutes	25 (4 - 60)	10 (0 - 30)	0.06
VAS pain, 0-10	3 (1.45 - 6.4)	1.8 (0.7 - 5)	0.16
EQ5D-5L, score at week 52#	0.71 (0.65 – 0.77)	0.71 (0.63 – 0.77)	0.87
EQ5D-5L, change week 21-52#	0 (-0.03 - 0.09)	0.07 (-0.05 - 0.10)	0.56
Methotrexate use, number (%)	4 (17%)	2 (9%)	0.67
Adverse events, total, % of patients	8, 26%	6, 33%	0.75

Notes. * Relapse was defined as therapy intensification, based on either a) an increase in oral prednisolone, b) adding intramuscular methylprednisolone, or c) starting or switching a DMARD due to treatment inefficiency ** Remission is based on the PMR-AS, calculated by CRP +VASp +VASph + (MST *0.1) + EUL, and a PMR-AS < 10 was considered remission or low disease-activity. # Number of patients for placebo versus RTX were n=23 versus n=23 respectively at week 52, and for comparison of change between week 21-52 total number of patients were n=21 versus n=23 respectively

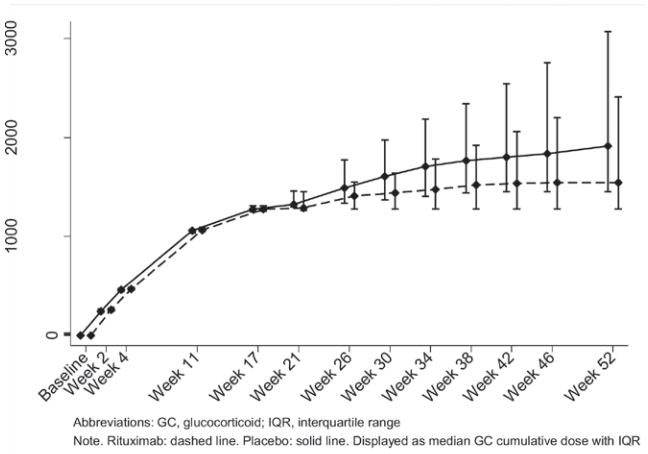

Figure 1. Cumulative GC Dose 0-52 Weeks, in mg

Conclusion: Efficacy of 1x1000 mg RTX in PMR was maintained up to 1 year follow-up, while also demonstrating a GC sparing effect. A larger trial, also assessing effect of on demand retreatment, is needed to confirm our results, and provide insight in which patients most likely benefit from RTX.

DEVELOPMENT OF AORTIC ANEURYSM/DILATATION IN A PROSPECTIVE COHORT OF PATIENTS WITH BIOPSY-PROVEN GIANT-CELL ARTERITIS: EARLY IDENTIFICATION OF PATIENTS AT RISK.

J. Marco Hernandez[1], A. García-Martínez[1], S. Prieto-González[1], A. Suso[1], G. Espígol-Frigolé[1], P. Arguis[2], R. Gilabert[2], M. Alba[1], J. Hernández-Rodríguez[1], M. C. Cid[1]. [1]*Hospital Clínic de Barcelona,Vasculitis Research Unit, Barcelona, Spain;* [2]*Hospital Clínic de Barcelona, Radiology Department, Barcelona, Spain*

Background: Up to 10-33% of patients with giant-cell arteritis (GCA) develop aortic structural damage (ASD) (aneurysm or dilatation), typically involving the ascending aorta (1,2). Systematic use of imaging reveals radiological features of aortitis in 45-65% of patients at diagnosis (3). This finding has been associated with future aortic dilatation in retrospective studies (4).

Objectives: To investigate the prevalence of thoracic ASD in a large prospective cohort of patients with GCA subjected to periodic imaging. To evaluate the association between features at diagnosis with ASD development.

Methods: Patients were included in the study if consented, had biopsy-proven GCA and met the 1990 ACR criteria for GCA classification. Patients were prospectively followed and treated according to uniform criteria. Since 1995 patients were subjected to systematic imaging screening aimed to detect thoracic ASD. Until November 2006 it consisted of a chest X-ray that was performed at least 4 years after diagnosis and repeated every 4 years. When aortic dilatation was minimally suspected, patients underwent contrast-enhanced computed tomography (CT) scan. Since November 2006, most of patients were prospectively studied with CT angiography at diagnosis, after 1 year and every 4 years.

The diagnosis of ASD was confirmed by CT, defined as an aortic diameter > 4 cm at the ascending aorta or ≥4 cm at the aortic arch or the descending aorta. Data regarding demographic characteristics, cardiovascular risk factors, GCA symptoms, laboratory tests, chronic medication at time of GCA diagnosis and corticosteroid tapering were recorded.

Kaplan-Meier survival plot was used to present the cumulated incidence of thoracic ASD over time and patients were censored at the time of ASD diagnosis or at the time of the last screening in those without ASD.

We also investigated which variables present at the time of GCA-diagnosis were associated with future development of ASD. Patients were classified in two groups according to whether they developed ASD or not during a follow-up period of 8 ± 1 years from the time of diagnosis.

Results: Thoracic ASD was confirmed by CT in 58 patients (21.6% of the patients with systematic screening diagnosed from 1994 to 2018) after a median follow-up of 4.7 years (0.05-7.5). Ascending aorta was involved in 56 patients (96.5%), followed by the aortic arch in 11 patients (18.9%), and descending aorta in 5 (8.6%). 14 patients (24.1%) had more than 1 aortic segment involved. Figure 1 shows the number of patients with thoracic ASD detected during follow-up.

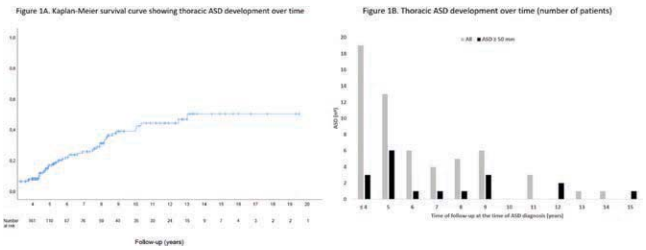

Figure 1. Thoracic ASD was detected within the fir

st 4 years from GCA-diagnosis in 19 out of the 58 patients who developed ASD (32.7%) but was severe (≥ 50 mm) in only 3 (15.8% out of those 19 patients). Most ASD was detected between 5 and 9 years after GCA-diagnosis.

Patients who developed ASD during follow-up experienced less often cranial ischemic symptoms (14.8% vs 41.1%; p=0.003) or polymyalgia (33.3% vs 51.8%; p=0.057), and less frequently had a previous diagnosis of hypertension (66.7% vs 82.1%; p=0.081). Age, sex, clinical or laboratory findings or chronic therapies used at time of GCA-diagnosis were not significantly different between groups.

After multivariate analysis, the presence of cranial ischemic symptoms (HR 0.180, 95% CI 0.065-0.495, p=0.001) and polymyalgia rheumatica (HR 0.329, 95% CI 0.136-0.793, p=0.013) remained inversely associated with thoracic ASD development.

Conclusion: ASD is frequent and probably an underdiagnosed complication of GCA. There is no consensus yet regarding the optimal screening protocol during follow-up and early identification of patients at risk is crucial for this purpose. The presence of cranial ischemic symptoms or polymyalgia rheumatica were inversely associated with thoracic ASD development in our prospective cohort.

CLINICAL SYMPTOMS AT GIANT CELL ARTERITIS DIAGNOSIS AS PREDICTORS OF PERMANENT VISUAL LOSS.

J. Mestre-Torres[1], B. Escalante[2], E. Fonseca[3], A. Martinez-Zapico[4], M. Monteagudo[5], M. Abdilla[6], M. Perez Conesa[7], B. Gracia Tello[2], S. Prieto-González[8], G. Fraile[9], R. Solans-Laqué[1]on behalf of Spanish Registry of Systemic Vasculitis (REVAS). *[1]Hospital Vall d'Hebron, Internal Medicine, Barcelona, Spain; [2]Hospital Clínico Lozano Blesa, Internal Medicine, Zaragoza, Spain; [3]Hospital de Cabueñes, Internal Medicine, Gijón, Spain; [4]Hospital Central de Asturias, Internal Medicine, Oviedo, Spain; [5]Hospital Parc Taulí, Internal Medicine, Sabadell, Spain; [6]Hospital La Ribera, Internal Medicine, Alzira, Spain; [7]Hospital Miguel Servet, Internal Medicine, Zaragoza, Spain; [8]Hospital Clínic de Barcelona, Internal Medicine, Barcelona, Spain; [9]Hospital Ramon y Cajal, Internal Medicine, Madrid, Spain*

Background: Giant cell arteritis (GCA) is the most prevalent vasculitis in the elder. Nearly 20% of patients experience transient or permanent visual loss (PVL). It has been reported that erythrocyte sedimentation rate (ESR), haemoglobin (Hb), constitutional syndrome (CS) and fever are prognostic factors that predict PVL but models have shown poor diagnostic performance.
Objectives: To evaluate if clinical signs, symptoms and blood tests can predict PVL at GCA diagnosis.
Methods: We retrospectively included patients from the Spanish Vasculitis Registry (REVAS) from 2005 to 2009. Clinical and blood tests data were obtained from medical records. We randomly split the cohort using shrinkage function to create a derivation and a validation cohort. In the derivation set we compared data and we built a multivariable logistic regression model to predict PVL. Internal validity was evaluated with 1000 bootstrap. External validity was evaluated using the validation set of data. Performance of the model was determined using the area under the curve (AUC) with 95% confidence interval. Calculations were done using StataBE 17.0.
Results: We included 620 patients (derivation cohort: 397 patients). Clinical signs, symptoms and blood tests results according to the presence or absence of PVL (Table 1). Mean age at diagnosis was 76.3 years and PVL was present in 86 (21.7%) patients. Significant predictors at baseline were age (p=0.000), hypertension (p=0.04), fever (p=0.001), jaw claudication (0.000), transient visual loss (TVL, p=0.000) and decreased temporal artery (TA) pulse (p=0.004). Multivariable logistic regression showed that age older than 75 years (OR 2.7, p=0.000), jaw claudication (OR, 2.75; p=0.000) and TVL (OR 7.2, p=0.000) were risk factors for PVL. CS was the only protective factor (OR 0.57, p=0.017). Hypertension (OR 1.4, IC95%: 0.88 – 2.3) and diabetes (OR 1.63, IC95%: 0.94 – 2.8) were not statistically significant. Our model showed an AUC 0.8 (IC 95%: 0.75 – 0.84). A 1000 bootstrap analysis showed good internal validity (AUC 0.79, IC95%: 0.74 – 0.83). Validation cohort comprised 223 patients and the AUC of the model in this dataset showed an AUC 0.81. We compared our model to previously published models and we found that our model had a higher AUC (AUC 0.8, IC 95%: 0.75-0.84 vs. AUC 0.65, IC95%: 0.6 – 0.7; p < 0.0001).

Table 1. Baseline date according to the presence or absence of permanent visual loss.

	Permanent Visual Loss		No Permanent Visual Loss		
Variable	Mean/ Proportion	SD	Mean/ Proportion	SD	Significance
Female	69.8%		72.0%		0.68
Age >75 y.o.	72.1%		53.4%		**0.000**
Hypertension	64.3%		51.6%		**0.04**
Diabetes	25.9%		16.9%		0.06
Fever	18.6%		36.8%		**0.001**
Constitutional syndrome	42.4%		53.2%		0.075
Polymyalgia	40.7%		39.7%		0.87
Headache	79.1%		79.2%		0.987
Jaw claudication	68.2%		39.7%		**0.000**
Tenderness of the TA	38.6%		31.4%		0.22
Transient visual loss	39.0%		10.5%		**0.000**
Stroke	3.5%		3.9%		0.86
Transient ischaemic attack	0.0%		4.2%		0.053
Decreased TA pulse	66.7%		48.0%		**0.004**
TA enlargement	55.1%		50.9%		0.51
Haemoglobin	11.1	1.2	11.4	1.4	0.37
Erythrocyte sedimentation rate	95.0	26.2	96.4	26.8	0.67
C Reactive protein	9.7	6.2	10.4	8.6	0.8

SD: Standard deviation. TA: Temporal artery.

Conclusion: Age > 75 years, jaw claudication and TVL can predict PVL, being the CS a protective factor for this complication. Blood test data are not good PVL predictive factors.

Background: Tocilizumab (TCZ) has shown efficacy in large-vessel vasculitis, including Giant Cell Arteritis (GCA) **(1-3)**. Clinical trials with TCZ in GCA was performed with intravenous (iv) TCZ in a phase 2 trial **(3)**, and with subcutaneous (sc) TCZ in the phase 3 GiACTA **(4)**. However, in GCA there are no studies comparing IV vs SC TCZ.
Objectives: To compare the efficacy of TCZ in GCA patients according to the route of administration IV-TCZ vs SC-TCZ.
Methods: Multicentre study of 471 patients diagnosed with GCA and treated with TCZ. They were divided into 2 groups according to the route of administration: **a)** IV, and **b)** SC. GCA was diagnosed by: **a)** ACR criteria, and/or **b)** temporal artery biopsy, and/or **c)** imaging techniques. Sustained remission was established according to EULAR definitions **(5)**.
Results: We studied 471 patients (mean age, 74±9 years) treated with TCZ, 238 with IV-TCZ and 233 with SC-TCZ (Table 1). The time between diagnosis of GCA and TCZ onset was shorter in the SC TCZ group. Regarding acute phase reactants at the beginning of TCZ, no differences were found between both groups. There were no significant differences in sustained remission or in glucocorticoid-sparing effect of TCZ (Figure 1). Patients on IV TCZ treatment suffered more relevant adverse effects during follow-up.

Table 1. Main characteristics of GCA patients treated with intravenous and subcutaneous tocilizumab

	IV TCZ (n= 238)	SC TCZ (n=233)	P
Baseline characteristics at TCZ onset			
Age(years), mean±SD	73.3±8.7	73.7±9.3	0.63
Sex, female/male (% female)	175/63 (73)	167/66 (72)	0.65
Time from GCA diagnosis to TCZ onset (months), median [IQR]	8 [3-23.5]	5 [2-15]	**0.016**
ESR, mm 1st hour, median [IQR]	30.5 [12.5-53]	28 [10-56.5]	0.66
CRP, mg/dL, median [IQR]	1.4 [0.5-2.8]	1.4 [0.4-4]	0.92
Prednisone dose, mg/day, median [IQR]	20 [10-40]	20 [10-36.2]	0.69
Safety after TCZ onset			
Follow-up, (months), median [IQR]	27 [16-44]	14 [6-26.7]	**<0.001**
Relevant adverse events, n (%)	80 (34)	46 (19)	**<0.001**
Relevant adverse events per 100 patients-year	12.7	15.2	NS
Serious infections, n (%)	44 (18)	21 (9)	0.44
Serious infections per 100 patients-year	6.7	7.2	NS
MACEs, n (%)/	1 (0.4)	0 (0)	-
MACEs per 100 patients-year	0.1	0	NS
Malignancies, n (%)	4 (1.7)	1 (0.4)	0.20
Malignancies per 100 patients-year	0.6	0.3	NS

Abbreviations: CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; GCA: giant cell arteritis; IQR: interquartile range; IV: intravenous; MACEs: major adverse cardiovascular events; NS: non significant; SC: subcutaneous; SD: standard deviation

Conclusion: In GCA, TCZ seems equally effective and safe regardless of the route of administration IV or SC.

POS0273 THE ROLE OF FACIAL, OCCIPITAL, SUBCLAVIAN AND CAROTID ARTERIES ULTRASOUND IN THE DIAGNOSTIC ASSESSMENT OF GIANT CELL ARTERITIS

J. Martinho[1,2], M. J. Sousa Bandeira[1,2], T. Fontes[1,2,3], S. C. Barreira[1,2], N. Khmelinskii[1,2], C. Ponte[1,2]. *[1]Centro Hospitalar Universitário Lisboa Norte, Rheumatology Department, Lisbon, Portugal; [2]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Unidade de Investigação em Reumatologia, Lisbon, Portugal; [3]Hospital Divino Espírito Santo, Rheumatology Department, Ponta Delgada, Portugal*

Background: Giant cell arteritis (GCA) is the most common form of primary systemic vasculitis in patients aged >50 years. It predominantly affects the cranial arteries; however, extra-cranial disease involving the aorta and its major branches can also be present. Currently, ultrasound of the temporal (TA) and axillary (AX) arteries is the first imaging modality recommended in patients with suspected predominantly cranial GCA. Nevertheless, other arteries such as facial (FA), occipital (OC), subclavian (SC), and common carotid (CC) arteries can also show vasculitic changes on ultrasound. However, there are still conflicting data to support the inclusion of these arteries in the routine ultrasound assessment of patients with suspected GCA.

Objectives: To assess the value of adding the evaluation of the FAs, OCs, SCs and CCs in the ultrasonographic diagnosis of patients with GCA.

Methods: Single-center observational retrospective study, using data from patients diagnosed with GCA registered at the Rheumatic Diseases Portuguese Registry (Reuma.pt). All patients underwent ultrasound of the TAs and AXs ± FAs, OCs, SCs or CCs at the time of diagnosis. The halo sign was considered a positive ultrasonographic finding for GCA. Only patients with the presence of halo sign in at least one of the arterial segments evaluated were included. Binary logistic regression modelling was performed to explore associations between the presence of halo sign in different arterial segments.

Results: We included 84 patients, 57 (67.9%) females, with a mean ± standard deviation age at diagnosis of 75.6 ± 8.8 years. Halo sign was found in the TAs of 66/84 (78.6%) patients, AXs of 40/84 (47.6%) patients, FAs of 37/74 (50.0%) patients, OCs of 15/61 (24.6%) patients, SCs of 30/49 (61.2%) patients and CCs of 13/60 (21.7%) patients. Of the 18/84 patients with GCA without the presence of TA halo, 17/18 (94.4%) showed halo in the AXs, 1/18 (5.6%) in the FAs, 3/18 (16.7%) in the OCs, 15/17 (88.2%) in the SCs and 6/16 (37.5%) in the CCs. Of the 44/84 patients with GCA without the presence of AX halo, 43/44 (97.7%) showed halo in the TAs, 24/39 (61.5%) in the FAs, 12/32 (37.5%) in the OCs, 4/18 (22.2%) in the SCs and 3/33 (9.1%) in the CCs. A total of 83/84 (98.8%) patients had halo sign on the ultrasound of either the TA or AX arteries. The patient with normal TA and AX ultrasound had the presence of halo sign in the SCs. Table 1 shows the proportion of patients with positive TA and AX ultrasounds according to the presence of halo in the FA, OC, SC or CC arteries. Patients with involvement of the cranial arteries were more likely to have a TA halo (FA: OR 30.6, 95%CI 3.8-247.3; OC: OR not applicable) and less likely to have an AX halo (FA: OR 0.37, 95%CI 0.14-0.95; OC: OR 0.19, 95%CI 0.05-0.77). As opposed to patients with involvement of the extra-cranial arteries in whom the halo sign was more frequently found in the AXs (SC: OR 18.2, 95%CI 4.2-78.9; CC: OR 5.9, 95%CI 1.4-24.4) but not in the TAs (SC: OR 0.12, 95%CI 0.02-0.60; CC: OR 0.32, 95%CI 0.09-1.15).

Table 1. Differences in the presence of halo sign in the temporal and axillary arteries according to the arterial segment affected.

Arterial segment with halo	Temporal arteries with halo	Axillary arteries with halo
Facial arteries (n=37)	36/37 (97.3%)	13/37 (35.1%)
Occipital arteries (n=15)	15/15 (100.0%)	3/15 (20.0%)
Subclavian arteries (n=30)	15/30 (50.0%)	26/30 (86.7%)
Common carotid arteries (n=13)	7/13 (53.8%)	10/13 (76.9%)

Conclusion: Our results support the need to assess both TAs and AXs in patients with suspected GCA, resulting in a diagnostic sensitivity of 99%. Only by adding the evaluation of the SCs to the already recommended TAs and AXs increased the diagnostic sensitivity of ultrasound to 100%. All patients with a positive FA, OC or CC ultrasound for GCA also showed a halo sign in either the TAs or AXs. Hence, the additional assessment of these arteries did not improve the diagnostic yield of ultrasound and, therefore, should not be recommended in routine practice.

POS0274 PREDICTION OF VASCULAR COMPLICATIONS IN TAKAYASU ARTERITIS BY MACHINE LEARNING: A PROOF-OF-CONCEPT STUDY BASED ON A PROSPECTIVE COHORT

X. Dai[1], Y. Li[2], Y. Sun[1], L. Jiang[1]. *[1]Zhongshan Hospital Fudan University, Rheumatology, Shanghai, China; [2]Vanderbilt University Medical Center, Otolaryngology-Head and Neck Surgery, Nashville, United States of America*

Background: Vascular complications are common poor prognosis in Takayasu arteritis (TAK). A reliable prediction model for this outcome has not been performed using machine learning (ML) due to the lack of a dataset with sufficient sample size.

Objectives: We aimed to develop ML models for prediction of vascular complications in TAK based on the prospective data of the largest sample in China from the East China Takayasu Arteritis (ECTA) cohort.

Methods: Data were collected from the ECTA cohort in which patients were enrolled from January 2009 to August 2020 and followed till February 2021 (n = 517). Predictor variables included 53 baseline features and outcome of interest was incident vascular complications. Data were randomly split into a training (85%) and test (15%) set. Logistic regression (LR), support vector machine, random forest (RF), k-nearest neighbors, XGBoost (XGB), and light gradient boosting machine models were trained using five-fold cross validation, and evaluated on the test set for recall, specificity, precision and area under ROC (AU-ROC) and precision-recall curves (AU-PRC). Permutation score was applied to assess feature importance to the outcome.

Results: Over a median follow-up of 30 (15–44) months, incident vascular complications were observed in 29.0% (150/517) patients. The RF model demonstrated the best overall predictive performance (AU-ROC = 0.84, AU-PRC = 0.63). Both the RF and LR models had the highest specificity (0.98), and the XGB model had the highest recall (0.87). Progressive clinical course was an important feature significantly associated with the outcome for all models.

Conclusion: It demonstrated the feasibility of developing ML models for prediction of vascular complications in TAK. The XGB model could help for early identification of high-risk patients, and RF and LR models could further confirm.

POS0275 SEROLOGICAL RESPONSE FOLLOWING THREE DOSES OF SARS-COV-2 MRNA VACCINE IN PATIENTS WITH GIANT CELL ARTERITIS: EXPERIENCE OF A SINGLE-CENTRE COHORT

A. Bartoletti[1], G. Franchi[1], C. Fornara[2], P. Delvino[1,3], F. Baldanti[2], D. Lilleri[2], C. Montecucco[1], S. Monti[1]. *[1]Fondazione I.R.C.C.S. Policlinico San Matteo, Rheumatology, Pavia, Italy; [2]Fondazione I.R.C.C.S. Policlinico San Matteo, Microbiology and Virology, Pavia, Italy; [3]University of Pavia, PhD in Experimental Medicine, Pavia, Italy*

Background: The spread of COVID-19 pandemic raised the need to perform an additional vaccine dose to overcome the diffusion of the infection and possible

life-threatening disease complications. Certain population subsets seem to be at increased risk of developing such complications, such as elderly and/or immunocompromised patients.

Objectives: To assess the persistence of immunity following SARS-CoV-2 mRNA vaccine and the magnitude of the humoral response after the booster dose in a cohort of patients affected by giant cell arteritis (GCA).

Methods: Patients with GCA regularly followed at the Rheumatology Department of the University of Pavia, Italy, who received a booster dose of SARS-CoV-2 mRNA vaccine (BNT162b2 Pfizer/BioNtech or mRNA-1273 Moderna) between October 1st and December 31st, 2021 were included. Humoral response was assessed by measuring SARS-CoV-2 Trimeric S (TSAbs) and Neutralizing (NAbs) antibodies, with a cut-off of 33.8 Binding Antibody Units (BAU)/mL and 1:10 dilution, respectively. Blood samples from each patient were drawn at least 4 months after the second and three weeks after the third vaccine dose.

Results: Forty-two patients who received the booster dose of SARS-CoV-2 mRNA vaccine were enrolled. Thirty (71.4%) were females, mean age 73.2±4.7 years, disease duration 58±38 months, 19 (45.2%) had large-vessel vasculitis. Thirty-two (76.2%) were on glucocorticoids (GCs) at a mean dose of 4.9±7.8 mg/day prednisone equivalent, with 7 (16.7%) receiving ≥7.5 mg/day. Eighteen (42.9%) were on methotrexate (MTX) (mean dose 14.2±3.5 mg/week) and 8 (19.0%) were treated with subcutaneous tocilizumab (TCZ) 162 mg/week.

SARS-CoV-2 serology was tested prior to the third vaccine dose at an average of 5.4±0.4 months from the former vaccination scheduled: 37 (88.1%) retained TSAbs and 30 (71.4%) NAbs. The median TSAb titre was 134 BAU/mL (IQR 97-292). Four out of 5 patients (80.0%) without TSAbs and 7 out of 12 (58.3%) without NAbs were on both GCs and MTX. Moreover, those on GCs plus MTX had lower pre-third dose TSAb titres as compared to other treatment subgroups (Figure 1A). GC doses ≥7.5 mg/day prednisone equivalents seemed to blunt NAb levels along time: 28.6% patients on GCs ≥7.5 mg/day prednisone equivalents had negative NAbs before the third dose vs. 80.0% of those taking <7.5 mg/day (p=0.007) as well as lower NAb titres (Figure 1B).

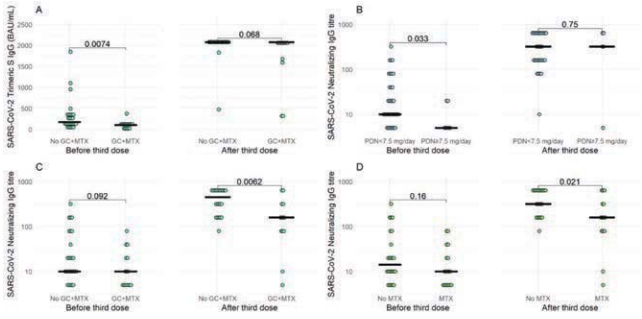

Figure 1. (A) TSAb levels before and after the booster dose among patients on GC + MTX. (B) NAb titres before and after the booster dose according to treatment with prednisone ≥7.5 mg/day or (C) MTX in combination with GCs or (D) MTX alone.

Data regarding antibody response after the booster dose were available for 35 patients (83.3%). Blood collection occurred at a median of 25 days (IQR 24-32) after the third vaccine dose. All patients developed TSAbs, even those who did not respond to the previous shots. The median TSAb titre rose to 2080 BAU/mL (IQR 2080-2080) (p<0.001), while the median NAb titre increased from 1:10 to 1:320 (p<0.001). One patient (2.9%) treated with prednisone 8.75 mg/day plus MTX 12.5 mg/week did not develop NAbs. NAb levels were lower in patients taking MTX as compared to those who did not (Figure 1C,D), whereas treatment with TCZ or GCs, along with the GC dose, did not affect the magnitude of the antibody response.

There were no serious adverse events from the vaccine. However, 3 patients (8.6%) experienced a disease relapse 24±5 days after the booster dose.

Conclusion: In our cohort, most patients who seroconverted after the second dose of vaccine retained the humoral immunity, with excellent seroconversion rates following the booster dose. However, GCs, especially at doses ≥7.5 mg/day prednisone equivalents, may contribute to the waning of NAb titres. On the other hand, immunosuppressants like MTX, especially when combined with GCs, might impair the magnitude of the humoral response to the booster dose.

Background: Conventional radiography (CR) is widely used as the first-line investigation for calcium pyrophosphate deposition (CPPD) disease, given its widespread use and the low cost. Next to it a series of advanced imaging techniques have been evaluated for accuracy and reliability. Among them, ultrasound (US) has been thoroughly tested and demonstrated to be accurate and reliable for CPPD diagnosis. However, even if there are data on the diagnostic accuracy of US and CR alone, it is not clear if performing both diagnostic tests and in which sequential order provides an added value for the diagnosis of CPPD.

Objectives: The aim of this study was to assess which diagnostic test performs better for the diagnosis of CPPD and if a combination of the two exams provides an additional value.

Methods: This is an ancillary study of the criterion validity of US in CPPD study[1]. Consecutive patients with knee osteoarthritis requiring total joint replacement were enrolled in 8 centres. Participants underwent US and CR of the affected knee prior to surgery. US was performed by experienced sonographers following the same scanning protocol described in the main study, while CR were performed in weight bearing AP and lateral views and were read by 2 experienced radiologists that reached a consensus on the presence/absence of CPPD. The evaluation of CPPD at the level of menisci and hyaline cartilage (HC) was based on the OMERACT definitions for US and on the new definitions developed by the ACR/EULAR CPPD classification criteria working group for CR [paper under submission]. Patients were classified as having CPPD considering histological examination as reference standard. Diagnostic indexes were calculated for US and CR alone and combined. Poisson models with robust estimation were used to estimate the best sequence of these diagnostic methods for a more accurate diagnosis of CPPD.

Results: 51 pts were enrolled (63% F, mean age 74y ± 8). Diagnostic indexes of US and CR alone and combined are indicated in Table 1. Compared to histology, US demonstrated to be a sensitive tool for identification of CPPD at the knee, with a good sensitivity in all sites and in the overall evaluation. Instead, CR was less sensitive, but it was a highly specific exam for CPPD identification. Combining US and CR led to a higher sensitivity compared with CR alone, but a lower specificity compared to both CR and US alone, and it offered no additional increase in diagnostic accuracy. The Figure 1 shows the results of the

appropriate sequence of use of US and CR in patients with suspected CPPD: in case of a positive CR at any of the 3 sites (menisci and HC) no additional exam is necessary, and the same in case of a positive US in at least two sites; however in case of a negative CR, US could help in a statistically significant way to identify CPPD patients, and further in case of a positive US in a single site CR can offer additional information.

Table 1. ***diagnostic indexes of US, CR and US + CR in the identification of CPPD. MM: medial meniscus, LM: lateral meniscus, HC: hyaline cartilage, SN: sensitivity, SP: specificity, PPV: positive predictive value, NPV: negative predictive value, ACC: accuracy.***

US		SN	SP	PPV	NPV	ACC
	MM	0.88	0.81	0.82	0.88	0.84
	LM	0.88	0.73	0.76	0.86	0.80
	HC	0.78	0.86	0.82	0.83	0.82
	Overall	**0.92**	**0.64**	**0.73**	**0.89**	**0.78**
CR	MM	0.32	1	1	0.61	0.67
	LM	0.40	0.96	0.91	0.63	0.69
	HC	0.48	0.93	0.85	0.68	0.73
	Overall	**0.54**	**0.92**	**0.88**	**0.66**	**0.73**
US + CR	MM	0.88	0.81	0.82	0.88	0.84
	LM	0.92	0.69	0.74	0.90	0.80
	HC	0.87	0.82	0.80	0.89	0.84
	Overall	**0.92**	**0.56**	**0.67**	**0.88**	**0.75**

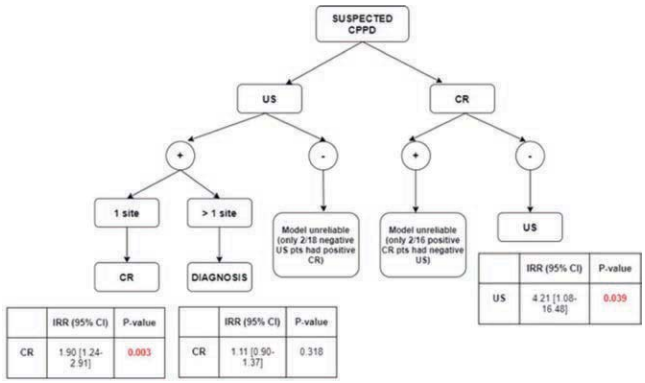

Figure 1. evaluation of sequence of US and CR

Conclusion: US confirmed a high diagnostic accuracy in identifying patients affected by CPPD at knee level, while CR demonstrated a high specificity but a low sensitivity. Performing both diagnostic tests could make sense in case of a negative CR or in case of an inconclusive US (only one positive site). To our knowledge, this is the first study that investigates the role of the combination of the two exams in CPPD. Further studies in a large number of patients and in different joints would be helpful to address this point.

POS0277 EFFECT OF COLCHICINE THERAPY ON ATHEROSCLEROSIS-RELATED CARDIOVASCULAR OUTCOMES IN PATIENTS WITH CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE

E. Cheremushkina[1,2], M. Eliseev[1], O. Sheliabina[1], A. Novikova[3], S. Glukhova[4]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation; [2]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation; [3]Lapino Clinical Hospital, Rheumatology, Lapino, Russian Federation; [4]VA Nasonova Research Institute of Rheumatology, Laboratory Axial Spondyloarthritis, Moscow, Russian Federation*

Background: anti-inflammatory therapy supposed to influence the rate of cardiovascular events development in pts with calcium pyrophosphate deposition disease (CPPD).

Objectives: To assess the effect of colchicine, hydroxychloroquine, and methotrexate on cardiovascular outcomes (CVO) in CPPD pts.

Methods: The study included 305 pts with CPPD: 115 (37.70%) men, 190 (62.30%) women. The average follow-up period was 3.9±2.7 yrs. Among the factors influencing CVO were considered: gender, age, smoking, alcohol intake ≥20 standard doses/week, hypertension, history of cardiovascular disease (CVD): (ischemic heart disease (CHD), acute myocardial infarction myocardial infarction (AMI), acute cerebrovascular insufficiency (ACV), chronic heart failure (CHF) >3 grade, NYHA), diabetes mellitus (DM), BMI >25 kg/m^2 and >30 kg/m^2, cholesterol level >5.1 mmol/l, GFR <60 ml/min/1.73 m^2, serim uric acid (sUA) > 360 µmol/l, hypercalcemia (serum calcium> 2.62 mmol/l), CRP> 2 mg/l, hyperparathyroidism (parathyroid hormone> 65 pg/ml), phenotypes of CPPD (asymptomatic, osteoarthritis with calcium pyrophosphate crystals (OA with CPP crystals), chronic arthritis, acute arthritis), taking colchicine, hydroxychloroquine and methotrexate, glucocorticoids (GCs) and non-steroidal anti-inflammatory drugs (NSAIDs).
Information about mortality, regardless of cause, was noting down throughout the follow-up period.
The causes of death were determined on the patient's death certificate, and then classified according to the International Classification of Diseases of the 10-th Revision (ICD-10) All newly developed cases of non-fatal cardiovascular events were identified on the basis of medical documentation. The odds ratio (OR) with a 95% confidence interval of developing cardiovascular events was calculated. Statistica 12.0 package was used for statistical data processing.

Results: The mean age at inclusion was 58.9±12.5 yrs. 264 patients were available for follow-up. Any of the studied cardiovascular events were registered in 79 (29.9%) pts. During the follow-up period, 46 (17.4%) pts died; 35 of 46 (76.1%) pts died because of CVD; 11 (23.9%) pts died due to other causes. Non-fatal cardiovascular events were registered in 44 (16.7%) pts.
The risk of cardiovascular events was higher for ps aged >65 years (OR 5.97, 95% CI 3.33-10.71), serum cholesterol level ≥5.1 mmol/l (OR 1.95, 95% CI 1.04-3.65]), GFR <60 ml/min/1.73 m^2 (OR 2.78, 95% CI 1.32-5.56]), history of CVD (OR 2.32, 95% CI 1.22-4.44) Colchicine therapy was associated with the lower risk of cardiovascular events (OR 0.20, 95% CI 0.11-0.39]). Therapy with methotrexate and hydroxychloroquine did not exert an influence on opportunity of CVO.

Conclusion: Adverse CVD outcomes in CPPD pts are associated with age, hypercholesterolemia, CKD, and a history of CVD. The intake of colchicine, but not methotrexate and hydroxychloroquine, by patients with CPPD is associated with decline of risk of cardiovascular events.

POS0278 COMPARISON OF ULTRASOUND BEAM ATTENUATION BY CALCIUM PYROPHOSPHATE, HYDROXYAPATITE AND MONOSODIUM URATE CRYSTALS: A PROOF-OF-CONCEPT STUDY

G. Pacini[1], G. Filippou[2], S. Sirotti[2,3], M. Zadory[4], D. Carboni[1], A. Damiani[1], E. Fiorentini[1], E. Filippucci[5], E. Cipolletta[5], J. M. Froehlich[4], P. Sarzi-Puttini[2], F. Becce[6]. *[1]University of Florence, Department of Experimental and Clinical Medicine & Division of Rheumatology, Azienda Ospedaliero Universitaria Careggi, Firenze, Italy; [2]Sacco Hospital, Rheumatology Department, Luigi Sacco University Hospital, Milano, Italy; [3]University of Milan, Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milano, Italy; [4]KlusLab, Kluslab Research, Zürich, Switzerland; [5]Hospital "Carlo Urbani", Rheumatology Unit, Department of Clinical and Molecular Sciences, Polytechnic University of Marche "Carlo Urbani" Hospital Jesi, Jesi, Italy; [6]Lausanne University Hospital, Department of Diagnostic and Interventional Radiology, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland*

Background: Ultrasound (US) demonstrated to be reliable and accurate for the diagnosis of crystal induced arthropathies, especially gout and calcium pyrophosphate deposition disease (CPPD) and validated definitions for uric acid and calcium pyrophosphate deposition in joints were released by the Outcome Measures in Rheumatology (OMERACT) US group. Less is known regarding hydroxyapatite (HA) deposition disease (HAAD) and the role of US in the assessment of HA crystal deposition.
It is general belief that HA crystals create posterior acoustic shadowing, monosodium urate could create or not US beam attenuation while CPP crystals generally do not attenuate the US beam.

Objectives: Aim of this proof-of-concept study was to investigate the US appearance in terms of beam attenuation due to increasing concentrations of MSU, CPP and HA crystals.

Methods: Sixteen synthetic crystal suspensions with known concentrations of CPP (26-109 mg/mL), HA (31-153 mg/mL) and MSU (90-500 mg/mL) were prepared. These specific concentrations were selected to replicate the X-ray attenuation characteristics of those crystals when imaged by conventional radiography,

computed tomography (CT) and dual-energy CT (DECT) in vivo[1]. The density of the agar-based lipogel background was intentionally increased to mimic the X-ray attenuation of hyaline cartilage (i.e., 100-120 HU at 120 kVp). Each crystal suspension was placed in a plastic container filled with US gel, next to the control (i.e., crystal-free background) calibration phantom. We acquired all US images using a Samsung RS80A system equipped with a high-frequency linear array transducer (4-18 MHz) set at the maximum frequency, by applying the same settings. US scans were performed by a single experienced sonographer, blinded to the crystal type and concentration. For each of the 16 crystal suspensions, at least two images were recorded both in the long- and short-axis views, the latter including the control phantom in the field of view. Interpretation of US images for the extent of US beam attenuation and the presence of acoustic shadowing was performed in consensus with a second experienced sonographer.

Results: None of the five CPP phantoms generated posterior acoustic shadowing or US beam attenuation regardless of CPP concentration. HA 31mg/mL did not generate US beam attenuation, while HA 62, 92 and 123mg/mL generated a progressively increasing US beam attenuation with posterior acoustic shadow clearly generated by HA 153mg/mL. Similarly, MSU 90mg/mL did not generate US beam attenuation. MSU 195mg/mL generated only a very faint US beam attenuation that became progressively more visible at 270 and 345mg/mL even if a clear posterior acoustic shadow was detectable only with MSU 420 and 500mg/mL (Figure 1).

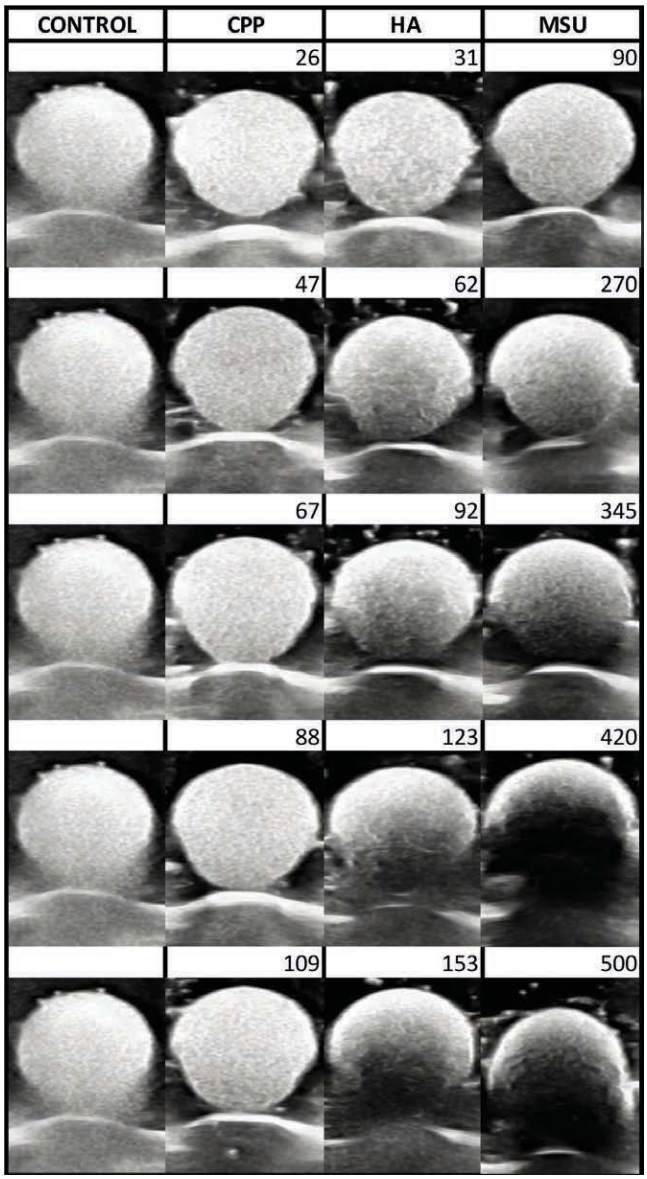

Figure 1. Short-axis views comparing the US attenuation characteristics, including acoustic shadowing, of increasing concentrations (in mg/mL) of CPP, HA and MSU crystals. The left column shows the US attenuation of the crystal-free (0mg/mL) agar-based lipogel background for reference

Conclusion: This proof-of-concept study confirmed that in the concentrations of crystals encountered in vivo, CPP do not generate posterior shadowing, while MSU and HA determine US beam attenuation proportionally to the concentration of the crystals. Being this a proof-of-concept study, attenuation of the US beam was assessed empirically and not in a quantitative or semi-quantitative way. However, this study highlights the potential of US to differentiate between CPP, MSU and HA crystals based on their appearance on gray scale imaging. Future studies should be carried out with different crystal concentrations, different US equipment and settings, in order to create a scoring system for US beam attenuation that is actually lacking.

POS0279

THE ABCG2 RS2231142 POLYMORPHISM ARE ASSOCIATED WITH RISK OF NEPHROLITHIASIS IN A TAIWANESE POPULATION.

C. T. Lin[1,2], Y. H. Chen[3], I. C. Chen[3], W. N. Huang[1,4], Y. H. Chen[1,2,4], C. H. Lin[3,4], Y. M. Chen[1,2,3,4]. *[1]Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; [2]School of Medicine, National Yang Ming Chiao Tung University, Department of Internal Medicine, Taipei, Taiwan, Republic of China; [3]Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China; [4]National Chung Hsing University, Department of Post-Baccalaureate Medicine, Taichung, Taiwan, Republic of China*

Background: In genome-wide association studies (GWAS), the strong association of ABCG2 *rs2231142* variant with hyperuricemia and gout was confirmed in Asian population. Additionally, the obesity, diet, lifestyle, genetics and underlying comorbidities are important risks factors predisposing to hyperuricemia and gout. The systematic reviews revealed a significant link between obesity, systemic comorbidities and hyperuricosuria for predisposition of kidney stones (nephrolithiasis). However, whether ABCG2 plays an important role in the phathogenesis of nephrolithiasis remain unclear. The interaction between genetic factors and other risk factors of nephrolithiasis is still elusive.

Objectives: In this study, we want to explore the association between *ABCG2* rs2231142 variant and the risk of nephrolithiasis in modern Taiwanese population, and clarify the role of uric acid in nephrolithiasis formation.

Methods: This retrospective case-control study was conducted using the Taiwan Biobank database. A total of 120,267 individuals of Taiwanese Han Chinese aged 30-70 years were enrolled in the study. The primary outcome was the incidence of self-reported nephrolithiasis. Odds ratio (OR) of incident nephrolithiasis was analyzed by multiple logistic regression models and the interaction between ABCG2 *rs2231142* variants, serum uric acid level, on the nephrolithiasis was explored. The multifactorial confounding factors for prediction of nephrolithiasis were also re-examined in our study.

Results: Finally, we identified 8,410 participants with nephrolithiasis and the prevalence was 11.52% and 4.37% in men and women, respectively. Older age (OR=1.08, 95% CI: 1.02-1.03, p<0.001) and male gender (OR=2.21, 95% CI: 2.08-2.36, p<0.001) showed an independent predictor for development of incident nephrolithiasis. The risk of nephrolithiasis markedly increased resulting from the interaction of ABCG2 rs2231142 and nephrolithiasis. In comparison with GG genotype, the risk of nephrolithiasis also demonstrated a significant association with TT and GT genotype (TT: OR=1.18, 95% CI: 1.09-1.28, p<0.001; GT: OR=1.12, 95% CI: 1.06-1.18, p<0.001). The variant comorbidities significantly associated with susceptibility to nephrolithiasis are hyperlipidemia (OR=1.40, 95% CI: 1.29-1.51, p<0.001), hypertension (OR=1.67, 95% CI: 1.57-1.78, p<0.001), diabetes mellitus (OR=1.16, 95% CI: 1.06-1.26, p=0.002), and hyperuricemia (OR=1.06, 95% CI: 1.04-1.08, p<0.001) with significant difference. The interaction of lifestyles and the risk of nephrolithiasis revealed significant differences in smoking (OR=1.15, 95% CI: 1.09-1.22, p<0.001) and overweight (OR=1.22, 95% CI: 1.15-1.28, p<0.001) rather than alcohol use(OR=0.92, 95% CI: 0.84-1.01, p=0.083). Participants with regular physical exercise is a protective factor from nephrolithiasis (OR=0.95, 95% CI:0.9-1.0, p=0.048).

Conclusion: Our study demonstrated the risk of nephrolithiasis is significant association with ABCG2 *rs2231142* variants. This risk also increased with systemic comorbidities (hyperlipidemia, hypertension, diabetes mellitus, and hyperuricemia), and lifestyle (obesity, and smoking). Regular physical exercise is associated with protective factor for incident nephrolithiasis.

POS0280 EXCESS RISK OF ALL-CAUSE AND CARDIOVASCULAR MORTALITY IN FEMALES WITH GOUT – A PROSPECTIVE COHORT STUDY OF 105,502 WOMEN

C. Yokose[1,2], N. McCormick[1,2], N. Lu[3], A. Joshi[4], G. Curhan[5], H. Choi[1,2]. *[1]Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; [2]Massachusetts General Hospital, Clinical Epidemiology Program, Mongan Institute, Boston, United States of America; [3]Arthritis Research Canada, n/a, Vancouver, Canada; [4]Massachusetts General Hospital, Clinical and Translational Epidemiology Unit, Mongan Institute, Boston, United States of America; [5]Brigham and Women's Hospital, Division of Renal Medicine, Boston, United States of America*

Background: Despite the disproportionately worsening disease burden of female gout in recent years[1] and its frequent associations with key cardiovascular risk factors (more often than male gout[2,3]), there remains a paucity of specific data about female gout, particularly about its impact on mortality and fatal coronary heart disease (CHD).
Objectives: To prospectively examine the relation of female gout and risk of all-cause and cardiovascular and coronary heart disease-specific deaths.
Methods: Using data from the Nurses' Health Study (NHS), an ongoing prospective cohort study in which female nurses in the United States completed detailed mailed questionnaires regarding their medical history, lifestyle, and other risk factors at baseline and every two years thereafter, we prospectively analyzed the relation between gout status at baseline and during the follow-up period and the risk of all-cause and cardiovascular mortality using Cox proportional hazards regression to adjust for cardiovascular risk factors such as comorbidities, body mass index, postmenopausal status, medication use, and dietary factors.
Results: The analysis included 105,502 women without gout and 1602 women with gout. Women with gout at baseline in 1982 tended to be older (mean age 54 vs. 50 years), and more likely to report a history of hypertension (44% vs. 22%), hypercholesterolemia (17% vs. 8%), and diabetes (11% vs. 6%). During 24 years of follow-up, we documented 15,255 deaths from all causes, including 3,128 deaths from cardiovascular disease (CVD) and 1,405 deaths from coronary heart disease (CHD). Compared to women without history of gout or CHD at baseline, the multivariable relative risks (RRs) among women with history of gout at baseline were 1.33 (95% CI, 1.21 to 1.46) for total mortality, 1.40 (95% CI, 1.17 to 1.67) for CVD deaths, and 1.49 (95% CI, 1.17 to 1.91) for fatal CHD (Table 1). The corresponding RRs for gout at baseline and during the follow-up were 1.33 (95% CI, 1.23 to 1.44), 1.43 (95% CI, 1.24 to 1.66), and 1.34 (95% CI, 1.08 to 1.66), respectively.

Table 1. Relative Risks of Death from All-Causes, Cardiovascular Disease, and Coronary Heart Disease According to Gout Status at Baseline in 1982 in the Nurses' Health Study

	No CHD	
	No Gout	Gout
Deaths from all causes		
Cases, n	14,810	445
Age-adjusted RR (95% CI)	1.0	1.58 (1.43, 1.73)
Multivariable-adjusted* RR (95% CI)	1.0	1.33 (1.21, 1.46)
All cardiovascular deaths		
Cases, n	3,001	127
Age-adjusted RR (95% CI)	1.0	2.06 (1.72, 2.46)
Multivariable-adjusted* RR (95% CI)	1.0	1.40 (1.17, 1.67)
Fatal CHD		
Cases, n	1,335	70
Age-adjusted RR (95% CI)	1.0	2.53 (1.99, 3.22)
Multivariable-adjusted* RR (95% CI)	1.0	1.49 (1.17, 1.91)

*Adjusted for age (continuous), history of hypertension, history of hypercholesterolemia, history of diabetes, aspirin use (yes, no), diuretic use (yes, no), smoking (never, past, current <15, current ≥15 cigarettes/day), body mass index (<23, 23-24.9, 25-29.9, 30-34.9, ≥35), physical activity (quintile), alcohol intake (nondrinker, <5, 5-9, 10-29, ≥30g/day), family history of MI (yes, no), menopausal status (premenopause, post menopause), hormone replacement therapy use (premenopause, never user, current user, past user). total energy intake (quintile), trans fat (quintile), dietary cholesterol (quintile), protein (quintile), linoleic fatty acid (quintile), and ratio of polyunsaturated fat/saturated fat.CHD = coronary heart disease; CI = confidence interval; RR = relative risk.

Conclusion: These prospective data indicate that women with gout have a higher risk of all-cause mortality, which is primarily driven by higher risk of CVD deaths. These findings closely agree with the UK general population data of both sexes that showed unclosing mortality gap over the past two decades.[4] Together, these findings provide support for rigorous cardiovascular risk factor modification specifically in female gout to help curtail the rising disease burden of gout worldwide.[1]

POS0281 FLUCTUATIONS IN SERUM URATE ARE RELATED TO GOUT FLARES IN THE NOR-GOUT STUDY

T. Uhlig[1], L. Karoliussen[1], J. Sexton[1], T. K. Kvien[1], E. A. Haavardsholm[1], F. Perez-Ruiz[2], H. B. Hammer[1]. *[1]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway; [2]Osakidetza Cruces University Hospital, Rheumatology, Barakaldo, Spain*

Background: Urate lowering therapy (ULT) is expected to prevent new gout flares, but flares still do occur during the first year, and could be related to fluctuations in serum urate (SUA), being a result of proinflammatory signals. Knowledge on the relationship between fluctuation in SUA and gout flares is limited.
Objectives: To study how fluctuation in SUA is related to gout flares in the first year of ULT.
Methods: In a prospective observational 2-year study 211 included patients with crystal-proven gout were evaluated for flare frequency. Patients were frequently followed during ULT (allopurinol or febuxostat) with monthly dose escalation until SUA was at target (<360 µmol/L or <300 µmol/L if tophi), and met also for visits at 3, 6, 9, 12 during year 1 and at year 2. Self-reported flares were continuously registered at all study visits.
Fluctuations in SUA were defined with various measures of SUA: a.) sum of changes between all consecutive visits over the whole 2-year period as a global measure, b. SUA change during 3-month visits at year 1 and during year 2. Further, the frequency of patients exceeding SUA changes with threshold >30, >60 and >90 µmol in these periods was calculated.
Fluctuations in SUA were then related to self-reported flares during the same 3-month periods year 1, and the whole years 1 and 2.
Results: Age was 56.4 (SD 13.7) years, 95.3% were males, disease duration 7.8 (SD 7.6) years.

SUA decreased from mean 500 µmol/L at baseline to 311 µmol at 1 year and 324 µmol/L at year 2. Flares were seen in year 1 in 81.2% (155/186) and year 2 26.0% (45/173) of patients.
The total sum of SUA changes over 2 years as a global measure for individual SUA fluctuation was related to flares in all 3-month periods during year 1 (Table 1) and for year 1 overall (Figure 1), but not for year 2.

Table 1. Flares and fluctuation of serum urate (SUA) measures during defined observation periods.

Flare period (Mths)		N	Sum of all SUA changes (mean)	SUA change (mean)	>30 µmol/L SUA change (% patients)	>60 µmol/L SUA change (% patients)	>90 µmol/L SUA change (% patients)
0-3	Flare +	63	467*	141*	88.1	83.1	67.8
	Flare -	148	388	165	95.5	91.5	80.8
3-6	Flare +	91	459**	19	38.8	28.2	10.6
	Flare -	120	375	17	39.4	24.5	14.9
6-9	Flare +	56	482*	10	49.0**	25.5	25.5
	Flare -	155	386	26	26.5	15.5	15.5
9-12	Flare +	70	470*	4	32.2	16.9	11.9
	Flare -	116	406	9	22.6	9.4	6.6
0-12	Flare +	155	445*	193	98.0	94.0	90.7*
	Flare -	36	345	160	91.7	86.0	75.0
12-24	Flare +	45	411	13	24.4	11.1	6.7
	Flare -	128	449	14	25.8	11.7	4.7

*P<0.05, **P<0.01 for comparisons +/-Flare

Other measures of SUA fluctuation (SUA change during periods, and exceeding thresholds of change) were generally not related to incidence of flares, neither were sensitivity analyses for incidence of flares in periods succeeding observed SUA fluctuations.
Conclusion: Fluctuation in SUA, defined as the total sum of mean SUA changes between all study visits, was related to gout flares during year1. Our findings support that a pattern of SUA fluctuation is related to gout flares.

Figure. Fluctuation of serum urate and flare during months 0-12

POS0282 UPDATE ON COMPARATIVE CARDIOVASCULAR SAFETY OF FEBUXOSTAT VERSUS ALLOPURINOL AMONG PATIENTS WITH GOUT

A. Shin[1], Y. J. Ha[1], Y. J. Lee[1], E. B. Lee[2], E. H. Kang[1]. *[1]Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam-si, Korea, Rep. of (South Korea); [2]Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Gout is associated with an increased risk of cardiovascular (CV) disease.
Objectives: To update comparative CV safety of febuxostat versus allopurinol among patients with gout
Methods: Using the 2011-2019 Korea National Health Insurance database, we conducted a cohort study comparing gout patients initiating febuxostat versus allopurinol, with study participants matched on a propensity score (PS) for>60 covariates at a 1:1 ratio. The primary outcome was composite CV outcome of myocardial infarction, coronary revascularization, and stroke. Secondary outcomes were CV and all-cause mortalities in addition to individual components of the primary outcome. Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs), comparing febuxostat versus allopurinol initiators.
Results: We included 160,930 febuxostat users PS-matched on 160,930 allopurinol users (mean age 59.3 years, 79.6% male). During a mean follow-up of 250 days, the incidence rate of the primary outcome was 2.27 and 2.06 per 100 person-years for allopurinol and febuxostat users respectively, with the PS-matched HR [95% CI] of 1.03 [0.95-1.12]. Analysis on secondary outcomes also showed a similar result except for all-cause mortality with a significantly reduced risk among febuxostat users with a PS-matched HR [95% CI] of 0.84 [0.78-0.91] (Table 1).

Table 1. Comparative cardiovascular safety between febuxostat and allopurinol

	Febuxostat N = 160,930			Allopurinol (Ref) N= 160,930			HR
	Events	PY	[a]IR [95% CI]	Events	PY	[a]IR(95% CI]	(95% CI)
Composite CV endpoint	2635	128,193	2.06 [1.98-2.13]	2,099	92,512	2.27 [2.17-2.37]	1.03 [0.95-1.12]
MI	468	129,873	0.36 [0.33-0.39]	341	93,808	0.36 [0.33-0.40]	1.13 [0.91-1.39]
Coronary revascularization	1085	129,233	0.84 [0.79-0.89]	856	93,293	0.92 [0.86-0.98]	1.10 [0.96-1.26]
Stroke or TIA	1490	129,163	1.15 [1.10-1.21]	1,187	93,252	1.27 [1.20-1.35]	0.99 [0.90-1.10]
Death	2558	130,176	1.97 [1.89-2.04]	2,201	94,007	2.34 [2.24-2.44]	0.84 [0.78-0.91]

[a]IR is per 100 person-years. IR=incidence rate, HR=hazard ratio, CI=confidence interval, MI=myocardial infarction, PY=person-years, TIA=transient ischemic attack

Conclusion: This large population-based cohort study showed a similar CV safety profile between febuxostat and allopurinol users but found a 16% reduced all-cause mortality among febuxostat users compared to allopurinol, primarily derived from non-CV death reduction.

POS0283 DOES A GOUT STIGMA AMONG RHEUMATOLOGISTS INFLUENCE PERCEPTIONS OF PATIENTS AND TREATMENT DECISIONS?

N. L. Edwards[1], B. Lamoreaux[2], A. Magerman[3], J. Hunger[4], J. Vitriol[5]. *[1]University of Florida College of Medicine, Rheumatology, Gainesville, United States of America; [2]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [3]Saint Joseph's University, Haub School of Business, Philadelphia, United States of America; [4]Miami University, Psychology, Oxford, United States of America; [5]Stony Brook University, Political Science, Stony Brook, United States of America*

Background: Gout is an inflammatory condition caused by chronic hyperuricemia, often causing physical and emotional distress and a lower quality of life (QOL).[1-3] Gout stigma is common and impactful,[4] with physicians often perceiving gout as a "lifestyle" disease caused by personal dietary and exercise choices. Further, patients can internalize and anticipate this stigma, influencing how they seek healthcare and adhere to medical therapies.[5]
Objectives: This study investigated whether or not a gout stigma exists among rheumatologists and, if so, how it influences physicians' perceptions of patients and treatment decisions. Rheumatoid arthritis (RA) was used as a comparator disease.
Methods: 106 practicing rheumatologists completed an online survey regarding perceptions of, experiences with, and recommendations for patients with controlled gout, uncontrolled gout, and rheumatoid arthritis (RA). Disease states were presented in random order. Each set of measures examined rheumatologists' perceptions and judgments of each disease condition on a range of dimensions, including (a) perceptions of patient's compliance with treatment recommendations and responsibility for their disease condition, (b) causal attributions for contributing factors to disease condition, and (c) efficacy of recommended treatment decisions. Answers were provided using a 7-point Likert scale (e.g., patient compliance: 1 = will not comply, 7 = will comply; patient responsibility for condition: 1 = not responsible, 7 = responsible). Prior to analyses, all responses were converted to a 0 to 1 scale for ease of comparison and interpretation.
Results: Responses regarding controlled and uncontrolled gout patients were not significantly different, so these two groups were pooled. Compared to patients with RA, rheumatologists perceived patients with gout as significantly more responsible for their disease (p<0.05) and significantly less likely to comply with prescribed treatment regimens (p<0.05, Figure 1). Further, rheumatologists perceived patient personal behavior, diet, BMI, and patient adherence as

greater contributing factors to gout than to RA (all p<0.01). Similarly, change in diet, increased exercise, and weight loss were perceived as more beneficial for managing gout than RA (all p<0.01), and biological treatments were perceived as more effective for managing RA than gout (p<0.01).

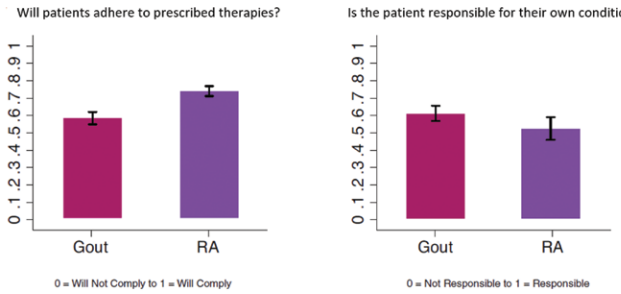

Figure. Rheumatologist's mean-level perceptions of patient treatment compliance (left) and responsibility for their condition (right). Error bars represent 95% confidence interval.

Conclusion: Despite good intentions when treating gout patients, rheumatologists appear to have causal beliefs and illness perceptions that reflect negative gout-related stereotypes. Compared to RA patients, gout patients were perceived as being more responsible for their condition and were expected to be less compliant with medications and less likely to benefit from biological therapies. Interestingly, there were no differences in rheumatologists' judgments between patients with controlled and uncontrolled gout, suggesting that their beliefs may refer to gout itself rather than the degree of control or management. Educating physicians, particularly rheumatologists, on the myths surrounding gout may improve clinical care and, therefore, patient outcomes.

POS0284 CHANGES OF ESTIMATED GLOMERULAR FILTRATION RATE AFTER LONG-TERM FEBUXOSTAT OR ALLOPURINOL TREATMENT IN GOUT PATIENTS

B. Ghang[1], J. Kim2, B. Yoo[3]. *[1]Jeju National Univ. Hospital, Rheumatology, Jeju-si, Korea, Rep. of (South Korea); [1]Jeju National Univ. Hospital, Rheumatology, Jeju-si, Korea, Rep. of (South Korea); [3]Asan Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Under the hypothesis that hyperuricemia is a potentially modifiable risk factor for progression of CKD, there has been numerous small, single-center studies that have shown that use of urate-lowering therapy (ULT) delayed CKD progression in patients with hyperuricemia or CKD. However, recent three multicenter, randomized controlled trials have not shown beneficial effect of ULT on the progression of CKD among CKD patients without gout and in DM patients with albuminuria.

Objectives: We investigated whether ULT may have a beneficial effect on the progression of CKD in gout patients.

Methods: Gout patients who took the study medication for more than 1 year were identified from the Cardiovascular Safety of Febuxostat or Allopurinol in Patients with Gout (CARES) trial, which is a large, multicenter, randomized controlled trial. We analyzed the estimated glomerular filtration rate (eGFR) slope (mL/min/1.73 m^2 per year) using the CKD-EPI equation. Using logistic regression, we investigated risk factors for CKD progression, defined as eGFR slope of lower than 0 mL/min/1.73 m2 per year.

Results: During the study period [median (interquartile range, IQR) 3.1 (2.0-4.8) year], 4,144 patients performed median (IQR) 12 (9~15) creatinine tests, the GFR slope was analyzed as median (IQR) 0.5 (-0.8-1.6). The median (IQR) values of the GFR slope were -1.2 (-2.3--0.5) in the CKD progression group (n=1,590) and 1.3 (0.7-2.2) in the CKD progression delayed group (n=2,554). After adjusting well known factors associated with CKD progression, average level of serum uric acid ≥ 6 mg/dL during study period was significantly associated with CKD progression (adjusted odds ratio 1.73; 95% confidence interval 1.49-2.01, p < 0.0001).

Conclusion: This study showed that eGFR did not decrease in more than half of gout patients after long term febuxostat or allopurinol administration. ULT may have a beneficial effect on slowing the progression of CKD in gout patients.

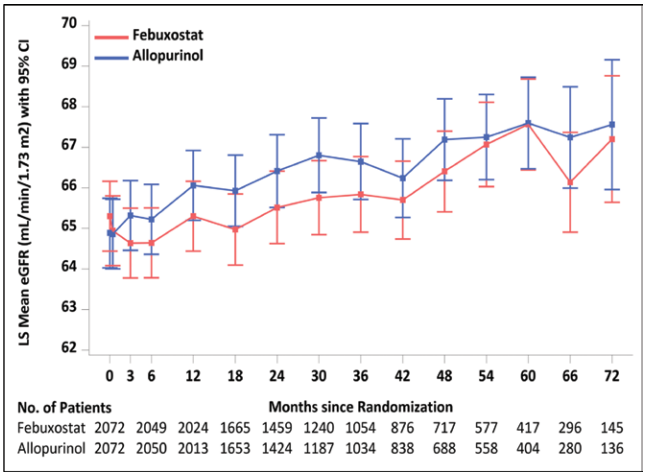

Figure 1. Changes of estimated glomerular filtration rate during febuxostat or allupurinol administration.

POS0285 SUB-STANDARD CARE FOR PATIENTS WITH GOUT, DESPITE UPDATED GUIDELINES: A UK-WIDE, POPULATION-BASED COHORT STUDY

M. Russell[1], A. Rutherford[1], B. Ellis[2], S. Norton[1], A. Douiri[3], M. Gulliford[3], A. Cope[1], J. Galloway[1]. *[1]King's College London, Centre for Rheumatic Diseases, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, Department of Rheumatology, London, United Kingdom; [3]King's College London, School of Population Health and Environmental Sciences, London, United Kingdom*

Background: Treat-to-target urate-lowering therapy (ULT) is highly effective at preventing flares and improving quality of life for patients with gout.[1] However, in 2012, only 27% of patients with gout in UK primary care received prescriptions for ULT within 12 months of diagnosis.[2] Since then, EULAR and BSR gout management guidelines have been updated, to recommend that all patients with gout should have ULT discussed and offered to them, with uptitration of dosing until target urate levels are achieved. We investigated whether gout management has improved in recent years.

Objectives: To assess temporal trends in the initiation of ULT and attainment of serum urate targets following new gout diagnoses in UK primary care from 2004 to 2020.

Methods: The Clinical Practice Research Datalink (CPRD) Gold database was used to assess the management of patients with index diagnostic codes for gout in UK primary care between January 2004 and October 2020. We analysed the proportion of patients with the following outcomes within 12 months of diagnosis: i) initiation of ULT (allopurinol, febuxostat, benzbromarone, probenecid or sulfinpyrazone); ii) serum urate ≤360 µmol/L; iii) serum urate ≤300 µmol/L; iv) treat-to-target urate monitoring (defined as two or more serum urate levels performed within 12 months of diagnosis and/or one or more urate ≤300 µmol/L). Interrupted time-series analyses (ITSA) were used to estimate the impact of updated EULAR and BSR gout management guidelines on these outcomes. Multivariate logistic regression was used to analyse predictors of ULT prescription and target attainment following new gout diagnoses.

Results: 129,972 patients had index gout diagnoses between January 2004 and October 2020, of whom only 37,529 (28.9%) had ULT initiated within 12 months of diagnosis. ULT initiation improved modestly over the study period, from 26.8% for those diagnosed in 2004 to 36.6% in 2019, decreasing to 34.7% in 2020 (Figure 1). Of patients diagnosed in 2020 who had a serum urate performed within 12 months of diagnosis, 36.0% attained a urate ≤360 µmol/L, while 17.1% attained a urate ≤300 µmol/L. Of all participants, 18.9% received treat-to-target urate monitoring. In ITSA models, no statistically significant improvements in ULT prescription or urate target attainment were observed after publication of updated

EULAR (2016) or BSR (2017) gout management guidelines, relative to before publication of these guidelines. In multivariate logistic regression models, comorbidities including chronic kidney disease, heart failure and obesity, and diuretic use were associated with increased odds of ULT initiation but decreased odds of attaining target urate levels by 12 months.

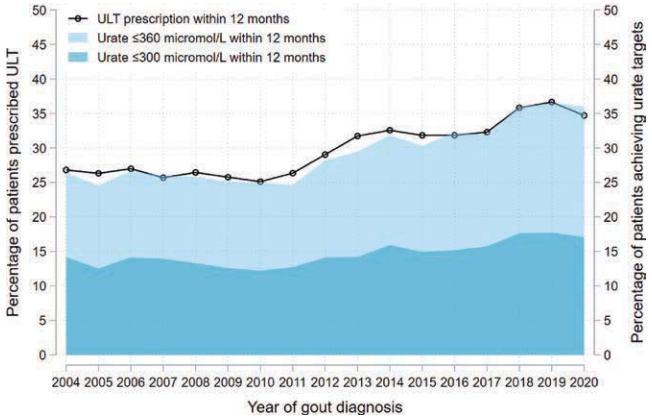

Figure 1. Proportion of patients newly diagnosed with gout who: i) were initiated on urate-lowering therapy (ULT) within 12 months of diagnosis (black line); ii) had a serum urate performed and attained a level ≤360 µmol/L (light blue) or ≤300 µmol/L (dark blue) within 12 months of diagnosis.

Conclusion: In this UK-wide study, we demonstrate that the initiation of ULT and attainment of serum urate targets following new gout diagnoses remain poor, despite the introduction of updated management guidelines. If the evidence-practice gap in gout management is to be bridged successfully, strategies to implement best practice gout care are urgently needed.

POS0286

CAN PATIENTS WITH CONTROLLED RA RECEIVING ANY CLASS OF TARGETED THERAPY WITH METHOTREXATE (MTX) SUSTAIN DISEASE CONTROL AFTER TAPERING MTX? A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Meng[1], D. Rajesh[2], D. Jannat-Khah[2], O. Bruce[3], B. Jivanelli[4], V. Bykerk[5]. *[1]Hospital For Special Surgery, Rheumatology, New York, United States of America; [2]Hospital for Special Surgery Main Hospital, Rheumatology, New York, United States of America; [3]Hospital for Special Surgery Main Hospital, Biostatistics, New York, United States of America; [4]Hospital for Special Surgery Main Hospital, Kim Barrett Memorial Library, New York, United States of America; [5]Hospital for Special Surgery Main Hospital, Rheumatology, 10021, United States of America*

Background: Patients with RA frequently struggle with intolerance of MTX and adherence to MTX remains highly variable. Guidelines conditionally recommend the tapering of MTX before tapering biologic (b)DMARDs, but acknowledge there is an absence of direct evidence. Prior reviews on this topic have focused on tapering of MTX from combination treatment with TNF-inhibitors(i) only[1]. There have been no updated reviews addressing MTX tapering from other targeted therapies such as IL6-i or JAK-i, nor has there been a systematic review addressing this question.

Objectives: To determine the feasibility of tapering MTX to targeted therapy (bDMARDs or JAKi) alone in patients whose RA is controlled (LDA or remission).

Methods: A systematic literature search combing MeSH terms and keywords was conducted in Medline, Embase and Cochrane Library for studies reporting remission outcomes after tapering MTX from targeted therapies in RA. Non-English and animal studies were excluded. Meta-analyses were conducted using random effects models. Forest and funnel plots were created and heterogeneity was calculated.

Results: Our search identified 5762 citations. After removal of duplicates and screening title/abstract using the COVIDENCE platform, 504 full-text articles were reviewed. Of the 10 articles meeting our inclusion criteria of tapering MTX to monotherapy with a targeted therapy, 3 studies tapered to etanercept, 3 to tocilizumab, 1 to tofacitinib, 1 to certolizumab pegol, 1 to adalimumab and 1 to abatacept monotherapy. Nine studies were RCTs and one was a long-term extension study (LTE) (Table 1). Disease duration was longer in 7 studies (6-11 years) and early in 3 studies (1-9 months). The MTX tapering strategy was gradual in 2 and rapid in 8 studies. Follow-up ranged from 3 -18 months in RCTs, and up to 3 years in the LTE. Studies reporting outcomes up to 1 year after tapering had remission rates ranging 48-76%, but this dropped to 40% in one study reporting 18- month remission outcomes. Our meta-analysis conducted in 2000 RA participants from 10 studies showed that patients who tapered MTX to targeted therapy alone could maintain remission with an overall pooled OR of 0.81 (0.68, 0.97) (Figure 1). There was no heterogeneity among the studies in this group (I^2=0.0%, p=0.788). Our funnel plot indicated high precision and potentially less publication bias. No significant difference in remission outcomes between early RA [OR 0.63 (0.33, 1.18)] and established RA [OR 0.84 (0.69, 1.03)] was observed.

Table 1. Included Studies

Keystone 2016	205	no	ETA+MTX	Stop	DAS28	18 mos
Keystone 2018	140	yes	ADA+MTX	Stop	DAS28-CRP	3 years

ETA etanercept, ABA abatacept, TOFA tofacitinib, TCZ tocilizumab, CZP certolizumab pegol, ADA adalimumab, REM remission, wk week, mo month, DAS28 Disease Activity Score 28, SDAI Simplified disease activity index.

Conclusion: Patients with controlled RA have a high probability of maintaining disease control after tapering their MTX to targeted therapy alone, up to 18 months. This review may inform patients with controlled disease on any of a range of targeted therapies and MTX, but who are struggling with MTX-related adverse effects and wish to taper it. Longer follow-up studies with attention to radiographic, functional and patient reported outcomes are needed. The possibility of disease worsening must be discussed with the patient in advance with careful follow-up and prompt re-treatment of disease worsening.

POS0287

A PHASE III, RANDOMISED, DOUBLE-BLIND, ACTIVE-CONTROLLED CLINICAL TRIAL TO COMPARE BAT1806/BIIB800, A PROPOSED TOCILIZUMAB BIOSIMILAR, WITH TOCILIZUMAB REFERENCE PRODUCT IN SUBJECTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS WITH AN INADEQUATE RESPONSE TO METHOTREXATE THERAPY

X. Leng[1], P. Leszczynski[2], S. Jeka[3], S. Liu[4], H. Liu[5], M. Miakisz[6], J. Gu[7], L. Kilasonia[8], M. Stanislavchuk[9], X. Yang[10], Y. Zhou[11], Q. Dong[11], M. Mitroiu[12], J. Addison[13], X. Zeng[14]. *[1]Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China; [2]Poznan University of Medical Sciences, Department of Rheumatology, Poznan, Poland; [3]Clinic and Department of Rheumatology and Connective Tissue Diseases University Hospital No 2 in Bydgoszcz Collegium Medicum UMK in Toruń, Department of Rheumatology and Connective Tissue Diseases, Toruń, Poland; [4]First Affiliated Hospital of Zhengzhou University, Department of Rheumatology and Immunology, Zhengzhou, China; [5]Qilu Hospital of Shandong University, Department of Rheumatology, Jinan, China; [6]Twoja Przychodnia Medyczne Centrum, Internal Medicine and Rheumatology, Nowa Sol, Poland; [7]The Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology, Guangzhou, China; [8]Tbilisi Heart and vascular Clinic Ltd, Rheumatology, Tbilisi, Georgia; [9]National Pirogov Memorial Medical University, Internal Medicine, Vinnytsya, Ukraine; [10]Biothera Solutions Ltd., Medical Affairs, Guangzhou, China; [11]Biothera Solutions Ltd., Research and Development, Guangzhou, China; [12]Biogen International GmbH, Evidence Generation Biosimilars, Baar, Switzerland; [13]Biogen Idec Ltd., Clinical Research, Maidenhead, United Kingdom; [14]Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China*

Background: BAT1806/BIIB800 is a proposed biosimilar to reference tocilizumab (TCZ). A Phase III randomised, double-blind, active-controlled clinical trial was conducted as part of a biosimilar development programme.
Objectives: To evaluate the efficacy, pharmacokinetics (PK), safety and immunogenicity of BAT1806/BIIB800 in comparison with EU-sourced TCZ in subjects with moderate to severe rheumatoid arthritis with inadequate response to methotrexate (MTX).
Methods: The study was conducted at 55 centres in China and Europe, between June 2018 and January 2021. Eligible subjects were randomised in a 2:1:1 ratio to one of three treatment groups: (1) BAT1806/BIIB800 up to Week 48, (2) TCZ up to Week 48, or (3) TCZ up to Week 24, followed by BAT1806/BIIB800 from Week 24 to Week 48, administered intravenously every 4 weeks at a dose of 8mg/kg. The primary endpoint was the proportion of subjects achieving an ACR20 response at timepoints pre-specified to meet the requirements of different Regulatory Agencies: Week 12, for EMA; Week 24, for FDA and NMPA. Equivalence margins applied to differences in ACR20 response rates in the BAT1806/BIIB800 and TCZ treatment groups were pre-specified as follows: +/- 14.5% for EMA (95% confidence interval (CI)); -12.0%,15% for FDA (90% CI); +/- 13.6% for NMPA (95% CI). Secondary endpoints included pharmacokinetics, safety and immunogenicity.
The ICH E9(R1) estimands framework including intercurrent events (related or unrelated to the COVID19 pandemic) was implemented for the ACR20 evaluation. A logistic regression model including 'region' (China and Eastern Europe) and 'previous biologic or targeted synthetic DMARD use' (Yes/No) as captured in Interactive Web Response System as stratification factors was utilised to assess equivalence for the primary endpoint. The difference in response rates was estimated and corresponding confidence intervals were derived to assess equivalence for the primary endpoint. This abstract presents results up to Week 24.
Results: In total, 621 subjects were randomised to receive BAT1806/BIIB800 (N=312), TCZ (N=155), or TCZ followed by BAT1806/BIIB800 (N=154). The groups were comparable in terms of baseline demographics and disease characteristics, including age, gender, disease activity and disease duration. The estimated proportions of subjects achieving an ACR20 response in the BAT1806/BIIB800 vs. the TCZ groups, respectively, were 68.97% vs. 64.82% at Week 12 and 69.89% vs. 67.94% at Week 24. The estimated difference between ACR response rates was 4.15% (95% CI -3.63, 11.93) at week 12, and 1.94% (90% CI -4.04, 7.92; 95% CI -5.18, 9.07) at Week 24. The CIs for the estimated differences between the treatment groups were within the pre-defined equivalence margins (Figure 1). The treatment groups were comparable in terms of serum trough levels, incidence of TEAEs and ADA/NAb positivity (Table 1).

Table 1. Safety and Immunogenicity up to Week 24, and Pharmacokinetics at Week 24

	TCZ (N =309) n (%)	BAT1806/BIIB800 (N=312) n (%)
TEAE	196 (63.4)	201 (64.4)
Related TEAE	151 (48.9)	148 (47.4)
Serious TEAE	13 (4.2)	11 (3.5)
Related Serious TEAE	7 (2.3)	2 (0.6)
Fatal TEAE	1 (0.3)	3 (1.0)
ADA positive [a]	42 (13.6%)	64 (20.5%)
NAb positive [a]	42 (13.6%)	63 (20.2%)
PK, n	271	276
Serum trough level (ug/mL), mean (SD)	15.4 (17.1)	15.8 (12.3)
Serum trough level (ug/mL), geometric mean (CV%)	12.3 (140.3)	12.9 (121.3)
Below limit of quantification, n (%)	43 (15.9)	28 (10.1)

TEAE, treatment emergent adverse events[a] subjects with ≥1 ADA/NAb positive results up to week 24

Conclusion: BAT1806/BIIB800 has demonstrated equivalent efficacy at Week 12 and Week 24 and a similar PK, safety and immunogenicity profile as reference tocilizumab up to Week 24.

POS0288

A CANADIAN RETROSPECTIVE CHART REVIEW EVALUATING CONCOMITANT METHOTREXATE DE-ESCALATION PATTERNS IN RA PATIENTS TREATED WITH BIOLOGIC OR TARGETED SYNTHETIC DMARDS

L. Bessette[1], B. Florica[2], P. A. Fournier[3], T. Girard[3], L. Naik[4], D. Sholter[5], P. Baer[6]. *[1]Faculty of Medicine - University Laval, Department of Medicine, Québec, Canada; [2]University of Toronto, Department of Internal Medicine, Toronto, Canada; [3]AbbVie Corporation, Medical Affairs, St-Laurent, Canada; [4]University of Saskatchewan, Department of Adult Rheumatology, Saskatoon, Canada; [5]University of Alberta, Department of Medicine, Edmonton, Canada; [6]Baer Weinberg MPC, Medicine, Scarborough, Canada*

Background: Rheumatoid arthritis (RA) guidelines recommend methotrexate (MTX) as anchor therapy in combination with biologic or targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs). However, its tolerability is challenging with a significant proportion of patients not adhering to their prescribed MTX regimen following b/tsDMARD initiation. Rates of MTX tapering and withdrawal have been reported elsewhere but Canadian data are lacking.
Objectives: This multi-centre, retrospective chart-based cohort study assessed the frequency of MTX withdrawal or tapering following initiation of a b/tsDMARD in Canadian adults with RA.

Methods: Patients were eligible if they received MTX for ≥3 months before initiation of a b/tsDMARD that was then prescribed continuously for ≥18 months and was initiated in combination with MTX. Patients taking oral prednisone or equivalent at a dose >10 mg per day, and those whose b/tsDMARD was prescribed prior to 2014, were excluded.
Results: Data from 889 patients were included in the analysis. Mean age was 50.6 years and 72.6% were female. Mean time since diagnosis was approximately 8 years. Of the 46.1% of patients with a documented assessment of disease status at baseline, 62.7% of patients had high disease activity. Baseline mean (SD) MTX dose was 18.9 (6.63) mg/week, administered orally (57.4%), subcutaneously (41.3%), or intramuscularly (1.2%). Overall, 270 (30.4%) patients either tapered (123, 13.8%) or discontinued (147, 16.5%) their MTX within 2 years of initiating the b/tsDMARD. Methotrexate dose was unchanged for 582 (65.5%) subjects and increased for 37 (4.2%) subjects. The prescribed b/tsDMARD was most often a tumor necrosis factor inhibitor (TNFi,52.1%), followed by a Janus kinase inhibitor (JAKi, 18.3%), other modes of action (OMA) which included abatacept and rituximab (17.7%) and interleukin-6 inhibitor (IL-6i, 11.9%). The b/tsDMARD type with the highest frequency of MTX Taper or Discontinued was IL-6i (37 patients, 34.9%) followed by TNFi (144 patients, 31.1%), JAKi (47 patients, 28.8%) and OMA (44 patients, 28.0%). In the MTX Discontinued group, the most common reasons for MTX discontinuation were patient decision (27.2%) and adverse events (24.5%). In the MTX Tapered group, the most common reasons for MTX dose change were planned tapering (36.6%) and adverse events (29.3%). In the MTX Increased group, insufficient clinical response (73.0%) was the most common reason provided for MTX dose change. Baseline factors associated with MTX dose discontinuation and tapering by multiple logistic regression were a shorter time since diagnosis (Odds ratio [OR]: 0.981; 95% confidence interval [CI]: 0.964 – 0.999. P=0.0401), use of non-DMARD medications excluding steroids (OR: 0.683; 95%CI: 0.503 – 0.929. P=0.0150) and a greater number of comorbidities (OR: 1.054; 95%CI: 1.001 – 1.110. P=0.0444). The mean (SD) weekly MTX dose at the end of the data extraction period was 14.13 (4.81) mg for the MTX Tapered group, with 109 (88.6%) subjects taking a weekly MTX dose ≥10 mg. In the MTX Increased group the mean (SD) weekly MTX dose was 22.3 (3.74) mg. Interpretation of the effect of MTX dose on disease activity, fatigue, pain and functional status is challenging due to missing data, but most patients in all 4 groups transitioned to low disease activity or remission during the study period.
Conclusion: Methotrexate withdrawal or tapering occurred in 30.4% of Canadians with RA within two years following b/tsDMARD initiation. There was no evidence of worsening disease activity in these patients. These proportion of Canadian RA patients who reduce or discontinue MTX after the initiation of a ts/bDMARD are generally consistent with those reported in other regions of the world.

A CONCEPTUAL FRAMEWORK OF THE COURSE AND TIMEFRAME OF PATIENT-REPORTED ADVERSE DRUG REACTIONS OF BIOLOGICS IN IMMUNE-MEDIATED INFLAMMATORY DISEASES

J. Van Lint[1], N. Jessurun[1], S. Tas[2], H. Vonkeman[3,4], F. Hoentjen[5], M. Van Doorn[6,7], M. Nurmohamed[8], B. Van den Bemt[9,10]. *[1]Netherlands Pharmacovigilance Centre Lareb, Dutch Biologic Monitor,'s-Hertogenbosch, Netherlands; [2]Amsterdam UMC, Location AMC, University of Amsterdam and Amsterdam Rheumatology & Immunology Center (ARC), Department of Rheumatology & Clinical Immunology,Amsterdam, Netherlands; [3]University of Twente, Department of Psychology, Health & Technology, Enschede, Netherlands; [4]Medisch Spectrum Twente, Department of Rheumatology & Clinical Immunology, Enschede, Netherlands; [5]University of Alberta, Division of Gastroenterology, Edmonton, Canada; [6]Erasmus Medical Center, Department of Dermatology, Rotterdam, Netherlands; [7]Centre for Human Drug Research, Leiden, Netherlands; [8]Reade, Amsterdam Rheumatology & immunology Center (ARC), Amsterdam, Netherlands; [9]Sint Maartenskliniek, Pharmacy, Nijmegen, Netherlands; [10]Radboudumc, Pharmacy, Nijmegen, Netherlands*

Background: Patients with immune-mediated inflammatory diseases (IMIDs) need chronic drug treatment, including biologics, which may cause adverse drug reactions (ADRs). Information about ADRs is usually restricted to the type of ADRs that may occur with drug use. Common patterns in the course and timeframe of ADRs are often not described while this information may provide valuable insights for patients and healthcare professionals.
Objectives: To identify common and corresponding items with thematic analysis in the described course of ADRs of biologics reported by patients with IMIDs.
Methods: We used qualitative data from the Dutch Biologic Monitor (DBM) to assess the patient's descriptions of the course of ADRs they experienced. IMID patients were asked to fill out a bimonthly questionnaire on experienced ADRs they attributed to the use of a biologic [1, 2]. Inclusion criteria were: patients reporting an ADR and elaboration on the course of the ADR in an open-ended text field. Answers of the patients on the course of the experienced ADR were analysed by two pharmacovigilance assessors with a thematic analysis with an inductive approach to develop a conceptual framework which was visualised using an Ishikawa diagram.
Results: From 1382 consecutive participants, 730 patients reported 2035 ADRs. Six themes with multiple subthemes were identified from patient descriptions on the course of the ADRs they experienced (Figure 1). Four themes included descriptive items of the course of ADRs: the moment or period of ADR occurrence (e.g. a specific moment of the day or in a specific season), the frequency of an ADR episode (e.g. once, sometimes, often, always or recurring with or without specified frequency), the duration of an ADR episode (e.g. specified duration, constant, variable increasing or decreasing duration) or an association in time with the administration moment (e.g. before, during or after biologic administration or a specific time to onset in relation to the moment of biologic administration). Two themes included factors influencing the course of ADRs: triggering factors for ADR occurrence or aggravation (e.g. administration method, social, physical or mental status, nutrition, external factors, (co)medication or daily activities) and improving factors (e.g. administration method, treatment, physical or mental status, nutrition or selfcare).

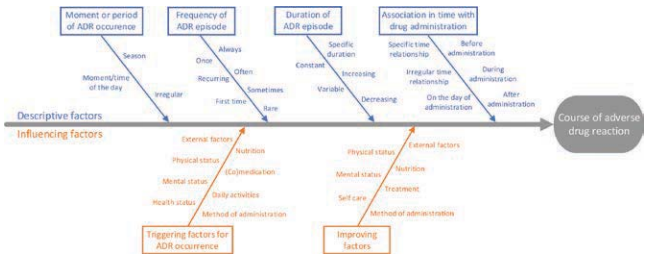

Figure 1. A conceptual framework of descriptions of the course and timeframe of adverse drug reactions reported by patients using a biologic for immune-mediated inflammatory diseases

Conclusion: We identified six themes in patient-reported descriptions of the course of ADRs of biologics. These themes provide information about ADRs on a broader level than the currently available information on nature and frequency. Information about ADRs enriched with details on the course and timeframe of ADRs may support healthcare professionals in improving clinical practice by discussing ADRs with patients and finding practical solutions in dealing with ADRs. This will ultimately lead to more optimised medical treatment.

POS0290 THE EFFECTS OF TREATMENT RESPONSE AND RISK FACTOR TO INHIBIT THE CLINICAL RESPONSE IN PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS TREATED WITH IL-6 RECEPTOR INHIBITOR, ABATACEPT AND JAK INHIBITOR

S. Anno[1,2,3], T. Okano[1], K. Mandai[4], K. Orita[3], Y. Yamada[1], K. Mamoto[1], T. Iida[5,6], M. Tada[7], K. Inui[4], T. Koike[8,9], H. Nakamura[1]. *[1]Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan; [2]Osaka social medical center, Orthopaedic Surgery, Osaka, Japan; [3]Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; [4]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan; [5]Koryokai Hospital, Orthopaedic Surgery, Osaka, Japan; [6]Takahiro Clinic, Orthopaedic Surgery, Osaka, Japan; [7]Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan; [8]Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [9]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan*

Background: Recently, the disease activity of rheumatoid arthritis (RA) was improved due to the 'treat-to-target' strategy. However, some patients remain various symptoms despite recommended treatment was performed. Then, the term of 'difficult-to-treat RA (D2TRA)' is widely recognized. It is unknown how the difference of type of biological disease-modifying anti rheumatic dugs (bDMARDs)/Janus kinase inhibitor (JAKi) will affect clinical efficacy in patients with D2TRA. Moreover, the risk factor to inhibit the clinical response in patients with D2TRA is unknown.

Objectives: The aim of this study was to evaluate the treatment response in patients with D2TRA who were treated with interleukin 6 receptor inhibitor (IL-6Ri), abatacept and JAKi.

Methods: This study used the multicenter database included 673 RA patients treated with bDMARDs/JAKi (tocilizumab 240, sarilumab 67, abatacept 146, tofacitinib 101, baricitinib 83, upadacitinib 20, peficitinib 14, filgotinib 2). Two hundred forty-two patients were treated as first line bDMARDs/JAKi (IL-6Ri 117, abatacept 63, JAKi 62), 211 patients were treated as second line bDMARDs/JAKi (IL-6Ri 117, abatacept 37, JAKi 57), 220 patients were treated as third and more bDMARDs/JAKi. In these 220 patients, 82 patients did not meet D2TRA criteria (IL-6Ri 42, abatacept 15, JAKi 25) and 138 patients met D2TRA criteria (IL-6Ri 31, abatacept 31, JAKi 76). In all patients, we analyzed 138 patients with D2TRA (113 female, mean age was 63.1 ± 13.7 years). Drug retention rate and effectiveness of bDMARDs/JAKi in patients with D2TRA were evaluated for 24 weeks. Multivariate linear regression analysis was performed to clarify the risk factors to inhibit the clinical response.

Results: Drug retention rate of patients with D2TRA at 24 weeks was 67.7% in IL-6Ri group, 74.2% in abatacept group, 61.8% in JAKi group. Drug retention rate in patients with D2TRA was not different between groups (IL-6Ri vs abatacept: p=0.86, IL-6Ri vs JAKi group: p=0.39, abatacept vs JAKi group: p=0.33). DAS28-CRP at 4, 12, 24 weeks decreased in all group (Figure 1). Abatacept showed lower improvement ratio of DAS28-CRP at 24 weeks compared to IL-6Ri group (IL-6Ri vs abatacept: p<0.01, IL-6Ri vs JAKi: p=0.1, abatacept vs JAKi: p=0.07). Good responder (defined as decrease in DAS28-CRP score > 1.2 with a score < 3.2) was 52.4% patients in IL-6Ri, 17.4% patients in abatacept, 29.8% patients in JAKi. SDAI and CDAI at 4, 12, 24 weeks decreased in all group (Figure 1). There were no diferences between the groups in improvement ratio of SDAI (IL-6Ri vs abatacept: p=0.11, IL-6Ri vs JAKi: p=0.81, abatacept vs JAKi: p=0.08) and CDAI (IL-6Ri vs abatacept: p=0.31, IL-6Ri vs JAKi: p=0.82, abatacept vs JAKi: p=0.13) at 24 weeks. HAQ was 1.42, 1.15, 1.39 at baseline, 1.27, 1.07, 1.22 at 4 weeks, 1.17, 1.07, 1.17 at 12 weeks, 1.26, 1.06, 1.14 at 24 weeks in IL-6Ri group, abatacept and JAKi, respectively. Multivariate linear regression analysis revealed that high HAQ (β=0.28, p=0.02) and high dosage of glucocorticoid (β=0.67, p<0.01) inhibited the improvement of DAS28-CRP. Type of bDMARDs/JAKi (β=-0.09, p=0.36) did not affect the DAS28-CRP improvement for 24 weeks.

Figure. Clincal responce in patients with D2TRA treated with different type of bDMARDs/JAKi

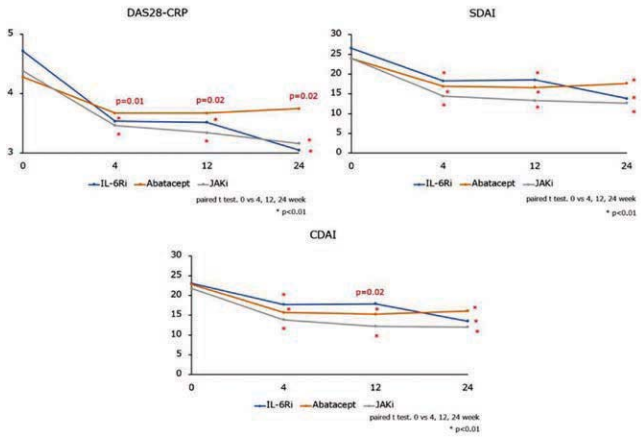

Table 1. Multivariate linear regression analysis of risk factor to inhibit the clinical response in patients with D2TRA.

	β	95% CI	p
Age (years)	-0.037	-0.025, 0.017	0.74
male	-0.047	-0.788, 0.486	0.64
Disease durations (years)	-0.048	-0.028, 0.017	0.63
RF (IU/ml)	-0.082	-0.0004, 0.0002	0.41
Anti CCP antibody (U/ml)	0.111	-0.0005, 0.002	0.26
DAS28-CRP	-0.063	-0.265, 0.142	0.55
HAQ	0.279	0.059, 0.717	0.02
MTX (mg/day)	0.136	-0.018, 0.081	0.21
Glucocorticoid dose (mg/day)	0.669	0.174, 0.324	< 0.01
Type of bDMARDs/JAKi	-0.088	-0.415, 0.151	0.36

Conclusion: Drug retention rate and clinical efficacy of D2TRA patients were not different among IL-6Ri, abatacept and JAKi. DT2RA patient with functional disorder and high dosage of glucocorticoid were risk factor to inhibit the clinical response.

POS0291 OLOKIZUMAB IMPROVED PATIENT REPORTED OUTCOMES IN TNF INCOMPLETE RESPONDER (TNF-IR) RHEUMATOID ARTHRITIS PATIENTS: RESULTS FROM THE PHASE 3 RANDOMIZED CONTROLLED TRIAL, CREDO 3

V. Strand[1], E. Choy[2], E. Nasonov[3], T. Lisitsyna[4], A. Lila[3], S. Kuzkina[5], M. Samsonov[5], E. Feist[6]. *[1]Stanford University, Division of Immunology/Rheumatology, Palo Alto CA, United States of America; [2]Cardiff University, CREATe Centre, Section of Rheumatology, Cardiff, UK, United Kingdom; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [4]V.A. Nasonova Research Institute of Rheumatology, Thromboinflammation, Moscow, Russian Federation; [5]R-Pharm, Medical, Moscow, Russian Federation; [6]Helios Fachklinik Vogelsang-Gommern; Helios Clinic, Rheumatology, Vogelsang-Gommern, Germany*

Background: Olokizumab (OKZ) is an interleukin-6-inhibitor for treatment of rheumatoid arthritis (RA). In these analyses we present patient reported outcomes (PROs) reported by TNF-IR patients with moderate to severely active RA receiving OKZ or placebo in a phase 3 randomized controlled trial (RCT) (ClinicalTrials.gov number, NCT02760433).

Objectives: To assess the effect of OKZ treatment compared with placebo in patient global assessment of disease activity (PtGA), pain, physical function (HAQ-DI), fatigue (FACIT-F) and health related quality of life (SF-36 physical (PCS) and mental (MCS) component summary and domain scores) at 12 weeks.

Methods: 368 patients were randomized 2:2:1 to receive subcutaneously administered OKZ 64 mg once every 2 weeks (q2w), OKZ 64 mg q4w, or placebo, plus

Table 1. Mean baseline values and LSM changes from baseline to week 12 for PROs

Footnotes: NRI for Missing data.†, secondary endpoint; *p≤0.05, **p<0.01, ***p<0.001 vs placebo;

MTX. PROs were assessed at baseline, weeks 12 (primary endpoint) and 24. At week 16, all patients receiving placebo were switched to either OKZ dose. Between groups differences in least-squares mean (LSM) changes from baseline were analyzed, p < 0.05 considered significant; nominal p-values for PROs not in the hierarchy.

Results: Baseline demographics and disease characteristics were comparable between groups. At week 12, treatment with OKZ q2w compared with placebo resulted in significantly greater LSM changes from baseline in Pain, HAQ-DI, FACIT-F, SF-36 PCS, MCS and 4 domains; with OKZ q4w in PtGA, Pain, SF-36 MCS and 4 domains (Table 1, Figure 1). Improvements reported at week 12 in PROs continued or increased with both doses of OKZ until week 24. Post hoc analyses demonstrated that a higher proportion of patients receiving OKZ reported improvements ≥minimum clinically important differences vs placebo (p<0.05) in FACIT-F, SF-36 PCS and MCS scores, indicating that these changes translated into clinically meaningful benefits on an individual patient basis. Numbers needed to treat to gain these benefits in fatigue and physical function ranged from 9.2 - 15.4 with OKZ q2w vs 10.5 - 13.3 with OKZ q4w, respectively.

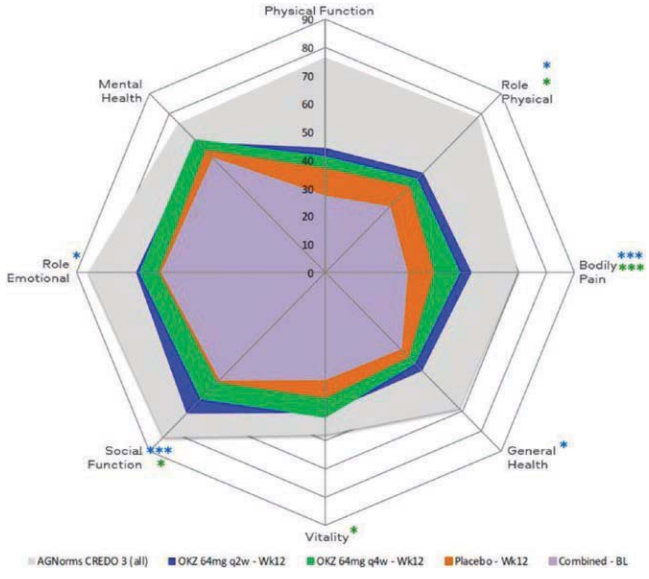

Figure 1. SF-36 domain changes from baseline to week 12. *p≤0.05, **p<0.01, ***p<0.001 for OKZ q2w vs placebo; *p≤0.05, **p<0.01, ***p<0.001 for OKZ q4w vs placebo; AGNorms, age- and gender-matched normative values; BL, baseline.

Conclusion: Treatment with OKZ over 12 weeks resulted in statistically significant improvements in PROs vs placebo reported by TNF-IR RA patients. Benefits were more frequently reported by patients receiving OKZ q2w than q4w in this phase 3 RCT of limited size in treatment experienced patients.

POS0292

INCREASE OF PRO-INFLAMMATORY CYTOKINES IS ASSOCIATED WITH ANTI-IDIOTYPE EVENTS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH INFLIXIMAB OR ADALIMUMAB

D. X. Xibille Friedmann[1], S. M. Carrillo Vazquez[2], J. González Christen[3], D. Vega Morales[4], M. Garza Elizondo[4], R. Hernández[5], J. E. Ortíz Panozo[6], J. L. Montiel Hernández[3]. *[1]Hospital General de Cuernavaca, Rheumatology, Cuernavaca, Mexico; [2]Hospital Regional 1 de Octubre, Rheumatology, CDMX, Mexico; [3]Universidad Autónoma del Estado de Morelos, Facultad de Farmacia, Cuernavaca, Mexico; [4]Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; [5]Hospital de Especialidades, Centro Médico NAcional S. XXI, Rheumatology, CDMX, Mexico; [6]Instituto Nacional de Salud Pública, Epidemiology, Cuernavaca, Mexico*

Background: A significant percentage of rheumatoid arthritis (RA) patients undergoing Infliximab (IFX) or Adalimumab (ADA) treatment develop antidrug antibodies with potential negative effects over their clinical activity; however, it is unknown if these anti-idiotype events could be associated with changes in cytokines levels

Objectives: To evaluate the association between blood cytokine levels, anti-idiotype events and clinical activity in RA patients treated with IFX or ADA.

Methods: All patients complied with ACR/EULAR 2021 criteria for RA and received anti-TNFa agents. Blood samples were collected during the drug trough and kept at -75ºC until analysis. Clinical activity was based on DAS28-ESR. Specific anti-drug antibodies to IFX and ADA were evaluated by sandwich ELISA. Cytokine blood levels were quantified using a multiplex system or sandwich ELISA.

Results: 57 patients with RA were recruited, 17 treated with IFX and 40 with ADA. According to the presence of anti-drug antibodies and sub-optimal levels of the biologic drug, patients were classified as immunogenic (29.8%; n=17) and non-immunogenic (70.2%; n=40), the first showed significantly higher ESR (p<0.001) and DAS28 (p<0.005). A significant association was seen between antidrug antibodies and increases of IFNg (2.1 OR, CI95%:1.2-3.8, p<0.01); MCP-1 (3.9 OR, CI95%:1.1-14.5, p<0.05); MIF (2.8 OR, CI95%:1.3-5.7, p<0.01) and TNFa 3.0 OR, CI95%:1.3-6.6, p<0.01 (see Table 1). Although anti-idiotype events were more frequent in IFX treated patients (41%), a significant difference was not seen when comparing with ADA treated patients (25%).

POS0293 IN VITRO RESPONSE TO DISEASE MODIFYING ANTIRHEUMATIC DRUGS LINK MOLECULAR DRUG TARGET WITH SYNOVIAL TRANSCRIPTIONAL SIGNATURE

M. B. Kristensen[1], U. Ahmadov[1], M. A. Nielsen[1,2], L. S. Kristensen[1], T. W. Kragstrup[1,2]. [1]*Aarhus University, Department of Biomedicine, Aarhus C, Denmark;* [2]*Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*

Background: Immune-mediated inflammatory arthritis (IMIA) is a group of diseases characterized by chronic synovitis including rheumatoid arthritis (RA), psoriatic arthritis (PsA), and spondyloarthritis (SpA). Some disease modifying antirheumatic drugs (DMARDs) have demonstrated efficacy in several of these diseases (e.g. TNFα inhibitors) while others have not (e.g. IL-17A inhibitors in RA). Furthermore, within each disease there are patient subgroups experiencing different responses to the same drug, which underlines the need for further elucidation of pathogenic processes to guide personalized in IMIAs.

Objectives: Here we investigated if clinical features and synovial transcriptional signature could predict *in vitro* efficacy of specific DMARDs across different IMIAs.

Methods: Synovial fluid mononuclear cells (SFMCs) from patients with SpA (n=13), RA (n=16), PsA (n=13), juvenile idiopathic arthritis (JIA) (n=7) or undifferentiated arthritis (n=5) were included. SFMCs from each patient were cultured for 48 hours (drugs listed in Table 1). Culture medium and DMSO were used as negative controls. In vitro drug response was assessed by measuring monocyte chemoattractant protein 1 (MCP-1) by ELISA. SFMC baseline gene expression of 270 genes related to inflammation was measured using the NanoString nCounter Human Inflammation V2 Panel. Drug responses (ΔMCP-1) were compared with clinical diagnosis, serostatus in RA patients, HLA-B27 status in SpA patients, DAS28-CRP score, years since diagnosis, failed modes of action and transcriptional signatures.

Table 1.

Drug	Target
Adalimumab	TNFα
Etanercept	TNFα
Tocilizumab	IL-6
Anakinra	IL-1β
Ustekinumab	IL-12/23
Secukinumab	IL-17A
Tofacitinib	JAK1/3
Baricitinib	JAK2/3

Results: DMARDs with a similar molecular target had comparable effects on ΔMCP-1. The TNFα inhibitors adalimumab and etanercept (r=0.86) had similar drug responses, and so had the JAK inhibitors tofacitinib and baricitinib (r=0,71). In contrast, drugs with different modes of action had diverse responses (Figure 1). High HLA-DRA gene expression associated with high responses to TNFα inhibitors (both p<0.05). JAK inhibitors reduced MCP-1 secretion significantly more in SFMCs from seropositive than seronegative RA patients (p<0.05). Drug response was greater in SFMCs from patients with low DAS28-CRP scores (DAS28-CRP <2.5) compared with patients with a high DAS28-CRP score (DAS28-CRP >5.2) for TNFα inhibitors, tocilizumab and JAK inhibitors (all p<0.05). Patients clustered with either an overall high or an overall low response to almost all DMARDs, or with a significant response to only one or a few of the DMARDs. Transcriptional signature of patient SFMCs primarily responding to TNFα inhibitors was different compared with the signature of patient SFMCs primarily responding to JAK inhibitors. Diagnosis, HLA-B27 status, failed modes of action and years since diagnosis did not affect ΔMCP-1 in this in vitro setup.

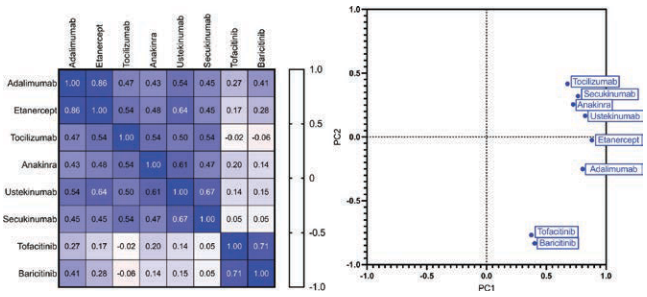

Figure 1. *Association between DMARD molecular target and in vitro response as measured by change in MCP-1 secretion.*

Conclusion: Similarities and differences in mode of action for 8 different DMARDs were captured in drug response as measured by MCP-1 change in SFMC cultures from 54 patients with inflammatory arthritis. We were able to identify interesting differences in gene expression when comparing cells responding to TNF inhibitors to cells responding to JAK inhibitors. Drug responses were only to a minor extent associated with clinical features.

POS0294 ARTIFICIAL INTELLIGENCE TO CONNECT THE USE OF BIOLOGICS AND SMALL MOLECULES IN RHEUMATOID AND PSORIATIC ARTHRITIS WITH A MULTIDISCIPLINARY EVALUATION: A REAL WORLD EVIDENCE APPROACH THROUGH NATURAL-LANGUAGE PROCESSING

P. Moranding[1], F. Maffia[1], F. Puggioni[2], F. Motta[3], M. Vecellio[3], A. Costanzo[4], V. Savevski[1], C. Selmi[3]. [1]*Humanitas Research Hospital - IRCCS, Artificial Intelligence, Rozzano, Italy;* [2]*Humanitas Research Hospital - IRCCS, Asthma, Allergy, and Personalized Medicine, Rozzano, Italy;* [3]*Humanitas Research*

Hospital - IRCCS, Rheumatology and Clinical Immunology, Rozzano, Italy;
[4]Humanitas Research Hospital - IRCCS, Dermatology, Rozzano, Italy

Background: The management of rheumatoid arthritis (RA) and psoriatic arthritis (PsA) is often relying on a multidisciplinary approach with different specialists evaluating the patient for treatment choices. The ultimate impact of such management on the use of systemic glucocorticoids and more innovative drugs such as biologics and small molecules, however, is unclear. Artificial intelligence tools, particularly natural language processing and machine learning, allow to manage large datasets and investigate associations between variables.
Objectives: To use a natural language processing approach to demonstrate whether a multidisciplinary approach to RA or PsA changes treatment choices.
Methods: We analysed the clinical notes of hospital encounters between 2017 and 2020 of patients with a terminated or ongoing care process at outpatient clinics included in the Humanitas Center for immune-mediated disease. To extract structured information from text data we used regular expressions (RegEx), a technique that allows to define elastic search patterns. RegEx were also used to detect negations to consider only affirmative citation of diseases or prescribed therapy. Care processes were described by binary flags which express the presence of RA or PsA and the prescription of glucocorticoids and biologics /small molecules for each patient. Working with only categorical data, we relied on the chi squared test to detect possible correlations between prescribed treatments and the characteristics of the care process, including whether a multidisciplinary evaluation had occurred.
Results: Our analysis included 1839 patients with RA (77% women, mean+-standard deviation age 58±16 years) and 1652 patients with PsA (46% women, age 57±15 years), accounting for 5517 and 3992 outpatient visits with different specialists over the study period, respectively. Among patients with RA and PsA, 378 (22%) and 371 (25%) were prescribed biologics or small molecules, respectively, while 830 (47%) RA and 431 (29%) PsA cases received a prescription for systemic glucocorticoids during one of the visits and patients seen three of more times by the rheumatologists received significantly more biologics / small molecules. Importantly, 4.5% of patients with RA and 9.4% of patients with PsA were evaluated also by dermatology, gastroenterology, allergy and pulmonary disease specialists and these patients were treated more frequently with glucocorticoids (70% vs.47% for RA, P<0.001; 60% vs. 29% for PsA, P<0.001) as well as with biologics / small molecules (42% vs. 22% for RA, P<0.001; 58% vs. 25% in PsA, P<0.001).
Conclusion: Natural language processing and machine learning were applied to unstructured electronic clinical charts in a large Center dedicated to immune-mediated diseases and allowed to demonstrate that patients with RA or PsA undergoing multiple evaluations are more likely to receive biologics or small molecules.

POS0295

OCCURRENCE OF SERIOUS INFECTIONS IN RHEUMATOID ARTHRITIS PATIENTS CONCURRENTLY TREATED WITH A BIOLOGIC AGENT AND DENOSUMAB: A RETROSPECTIVE STUDY WITH PROPENSITY SCORE

D. Renna[1,2], V. Venerito[1], M. Fornaro[1], F. Cacciapaglia[1], M. G. Anelli[1], C. Scioscia[1], G. Lopalco[1], F. Iannone[1]. *[1]Policlinico di Bari, Rheumatology Unit, Department of Emergence and Organ Transplantation (DETO), Bari, Italy; [2]IRCSS Humanitas Research Hospital, Rheumatology and Clinical Immunology Unit, Rozzano, Italy*

Background: Denosumab is a monoclonal antibody used in patients with osteoporosis. It inhibits the receptor activator NF-kB ligand (RANKL), an essential cytokine mediator of osteoclastogenesis. Some concerns have been raised about Denosumab safety profile, especially when it is administered concurrently with biologic drugs for rheumatoid arthritis (RA) (1,2). Indeed, RANK and RANKL have a known immunomodulatory effect (2). In a retrospective study, Lau et al. (1) showed that patients concurrently treated with Denosumab and biologic disease modifying anti-rheumatic drugs (bDMARDs) had a higher rate of serious infections compared to patients taking bDMARDs only, but no adjustment was made for any observed imbalances in potential confounders, such as age and disease activity, between the groups.
Objectives: This study aims to evaluate, in a monocentric cohort of RA patients concurrently treated with bDMARDs and Denosumab, the safety of such combination.
Methods: We retrospectively observed RA patients on bDMARDs ± methotrexate and denosumab (DEN group) for comorbid osteoporosis and RA patients treated with bDMARDs±methotrexate (noDEN group) who started treatment in a tertiary care centre from 2015 to 2020. Clinical characteristics were gathered at baseline and at 12-month follow up. We also recorded the occurrence of serious infections between groups (defined as infections requiring hospitalization and/or parenteral antibiotics). We deployed the nearest-neighbour matching algorithm (1:4), based on Propensity Score (PS), in order to adjust for non-randomization. The McNemar's test was used to compare the frequency of serious infection in the two groups.
Results: DEN group consisted of 36 patients were recruited, while the cohort of patients in noDEN group consisted of 547 individuals (Table 1). After PS matching only 58 patients were noDEN group, matched for disease duration, presence/absence of ACPA antibodies, baseline BMI, baseline DAS28 and daily prednisone dosage. In the matched cohort, we found an increase in terms of frequency of serious infections in DEN group, even if not statistically significant (Figure 1). All the infections were completely resolved after hospitalization and/or parenteral antibiotic treatment, without fatal events or irreversible complications. Both groups were not stratified for bDMARDs mechanism of action (MoA). Of note, in the DEN group Rituximab therapy was admnistered in 22% of patients, while in noDEN group in 12% of them.

Table 1. Patients' characteristics at baseline.

	Av. Obs.	bDMARDs Only	Av. Obs.	bDMARDs + Denosumab
Female, n (%)	547	466 (85.2%)	38	34 (89.4%)
Age, y (mean±sd)	547	53.3±13.2	38	63.4±11.1
Disease duration, m (mean±sd)	472	120.2±105.3	38	207.9±126.5
DAS28, n(mean±sd)	532	4.55±1.39	38	2.90±1.44
PCR, mg/dL (mean±sd)	539	1.77±4.51	38	0.81±1.22
HAQ, n (mean±sd)	516	1.28±0.86	38	1.54±0.87
ACPA, n. (%)	541	416 (76.8%)	38	17 (44.7%)

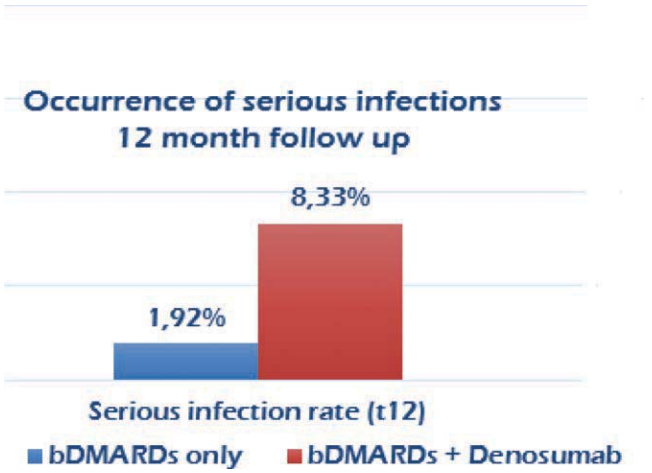

Figure 1. Occurrence of serious infections at 12-months follow-up.

Conclusion: The occurrence of serious infections among RA patients receiving denosumab in combination with bDMARDs ± MTX for RA was not significantly increased compared to those receiving bDMARDs ± MTX alone at 12 months from treatment baseline. Further studies powered for detecting difference between bDMARDs MoA are necessary in order to assess the infection risk of denosumab co-administration.

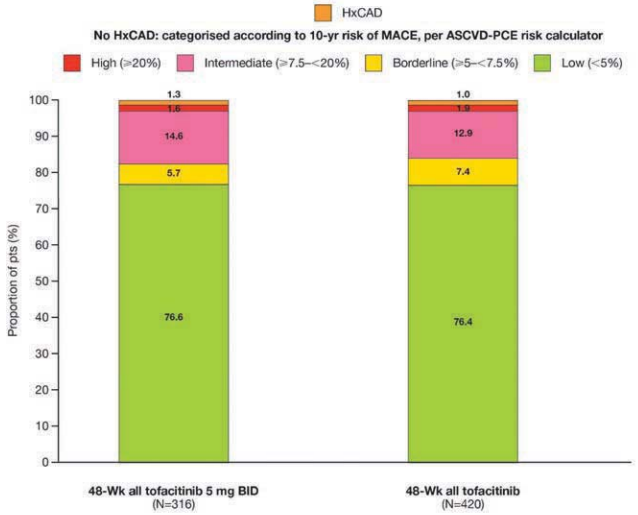
Background: Tofacitinib is an oral JAK inhibitor for the treatment of adults with ankylosing spondylitis (AS).
Objectives: To describe the tofacitinib safety profile from an integrated analysis of randomised controlled trials (RCTs) in patients (pts) with active AS.
Methods: Pooled data from Phase (P)2 (NCT01786668) and P3 (NCT03502616) RCTs in pts with AS were analysed in 3 cohorts (Table 1): the 16-Week (Wk) placebo (PBO)-controlled cohort (pts receiving tofacitinib 5 mg twice daily [BID] or PBO from Wks 0–12 [P2 RCT] or Wks 0–16 [P3 RCT]), the 48-Wk all tofacitinib 5 mg BID cohort and the 48-Wk all tofacitinib cohort (pts receiving ≥1 dose of tofacitinib 2, 5 or 10 mg BID), including pts receiving tofacitinib from Wks 0–12 (P2 RCT) or Wks 0–48 (P3 RCT). Pts receiving tofacitinib 5 mg BID were included in the 16-Wk PBO-controlled cohort and both 48-Wk tofacitinib cohorts. Adverse event (AE)/AEs of special interest incidence rates (IRs; pts with events/100 pt-yrs) were reported based on a 28-day risk period (time of first to last study drug dose +28 days). Baseline (BL) cardiovascular (CV) risk was calculated post hoc by the atherosclerotic CV disease (ASCVD)-pooled cohort equations calculator for pts without history of coronary artery disease (48-Wk tofacitinib cohorts).
Results: At BL, most pts (>76%) in the 48-Wk tofacitinib cohorts had <5% (low) 10-yr ASCVD risk (Figure 1). The most common treatment-emergent AEs were nasopharyngitis/upper respiratory tract infection. Serious AE IRs were higher with tofacitinib 5 mg BID vs PBO in the 16-Wk PBO-controlled cohort, and similar in the 48-Wk tofacitinib cohorts (Table 1). Discontinuation due to AEs was similar between groups in the 16-Wk PBO-controlled cohort and between the 48-Wk tofacitinib cohorts (Table 1). One pt receiving tofacitinib 5 mg BID (included in the 16-Wk PBO-controlled and both 48-Wk tofacitinib cohorts) had a serious infection (SI; meningitis; Table 1). No SIs with PBO. Herpes zoster (HZ; all non-serious) occurred in the 48-Wk all tofacitinib 5 mg BID (5 pts [1.6%]) and 48-Wk all tofacitinib cohorts (7 pts [1.7%]; Table 1) only. Most cases involved a single dermatome, but 1 pt (tofacitinib 10 mg BID) had HZ involving 2 adjacent dermatomes. Across cohorts, there were no deaths or adjudicated opportunistic infections (OIs), OIs excluding tuberculosis (TB), TB, malignancies excluding non-melanoma skin cancer (NMSC), NMSC, major adverse CV events, thromboembolic events, gastrointestinal perforation or interstitial lung disease. Uveitis was reported in 1 (0.5%), 3 (1.6%), 4 (1.3%) and 6 (1.4%) pts in the tofacitinib 5 mg BID, PBO, 48-Wk all tofacitinib 5 mg BID and 48-Wk all tofacitinib groups, respectively; all but 1 pt (tofacitinib 2 mg BID) had history of uveitis. Psoriasis occurred in 1 (0.5%) pt (PBO) with history of psoriasis. There were no AEs of inflammatory bowel disease.

Fig. Proportions of pts with a HxCAD and pts without a HxCAD categorised according to their 10-yr risk of ASCVD, per the ASCVD-PCE risk calculator, in the 48-Wk all tofacitinib 5 mg BID and 48-Wk all tofacitinib cohorts



CAD was defined as having ≥1 of the following: myocardial infarction, coronary heart disease, coronary artery procedure or stable angina pectoris
Pts without a HxCAD were scored according to the ASCVD-PCE calculator, developed by the ACC and the AHA. Scores were calculated based on pts' age, sex, race (White, Black, other), smoking status (yes/no), systolic blood pressure, antihypertensive treatment (yes/no), total cholesterol, high-density lipoprotein cholesterol and diabetes (yes/no). Pts were assigned to one of the following categories based on these risk scores (per ACC/AHA guidelines): high risk (≥20%), intermediate risk (≥7.5–<20%), borderline risk (≥5–<7.5%) and low risk (<5%)
The proportion of pts without a HxCAD, but with missing ASCVD-PCE risk category data, are not shown in the figure: 48-Wk all tofacitinib 5 mg BID, n=1 (0.3%); and 48-Wk all tofacitinib, n=2 (0.5%)
ACC, American College of Cardiology; AHA, American Heart Association; CAD, coronary artery disease; HxCAD, history of CAD; N, number of pts per cohort in the Safety Analysis Set; PCE, pooled cohort equations

Conclusion: Tofacitinib 5 mg BID was well tolerated over 48 Wks in pts with AS, and safety was consistent with the established safety profile of tofacitinib.

Background: Axial Spondyloarthritis (axSpA) can be distinguished in radiographic axSpA (r-axSpA) and non-radiographic (nr-axSpA). Secukinumab (SEC) is a novel treatment for axSpA, but data from real-life are still missing.

Objectives: To evaluate, in a multicentric-Italian-cohort of axSpA patients on SEC followed for 24-months: a)the long-term effectiveness and safety of SEC; b)the drug-retention-rate and low-disease-activity (LDA) measured as BASDAI<4/ASDAS<2.1 and very-low-disease-activity (VLDA) measured as BASDAI<2/ASDAS<1.3; c)any differences in outcomes according to: line of biological treatment (naïve/non-naïve), gender (male/female), subtype of axSpA (r-axSpA/nr-axSpA).

Methods: Consecutive patients with active axSpA (diagnosis according Assessment of SpondyloArthritis International Society ASAS criteria), who started SEC treatment, were evaluated prospectively. Data on disease characteristics, previous/ongoing treatments and imaging were collected. Disease-activity/functional/clinical scores and biochemical values were recorded at baseline (T0), at 6 (T6), 12 (T12), and 24 (T24) months. Effectiveness was evaluated over-time with descriptive statistics; multivariate Cox and logistic regression models were used to evaluate predictors of drug-discontinuation and LDA at T6. Infections, adverse events were recorded.

Results: 249 patients (47.8% male; median age 51 years) were enrolled; 40.9% had HLA-B27; 53.8% had r-axSpA and 46.2% nr-axSpA. SEC was prescribed in 28.9% naïve and in 71.1% non-naïve patients. SEC effectiveness was shown as an improvement in several outcomes, such as ASDAS [T0=3.5(2.9-4.4) vs. T24=1.9(1.2-2.4);p=0.02] and BASDAI [T0=6.5(5.0-7.5) vs. T24=2.8(1.8-4.0);p=0.03]. After 24-months of treatment, 90.7% of naïve and 75.3% of non-naïve patients achieved LDA (BASDAI<4). At T24 naïve-patients showed better physical-functioning and lower disease-activity than non-naïve (Table 1). Similarly, at T24 we observed better physical functioning and lower inflammatory activity in males vs. females and in nr-axSpA vs. r-axSpA subjects. Retention-rate at T24 was 75% in the whole population, with some difference depending on gender (log-rank 9.319; p=0.002) (Figure 1). Treatment was discontinued in 61 patients (24.5%), mainly due to primary/secondary loss of effectiveness events (20 and 24 subjects, respectively), and only 17 patients (6.8%) due to adverse events (7 for reactions at the injection site or skin manifestations, 1 for gastro-intestinal complications, 1 for relapsing uveitis, 1 for hypertransaminasemia, 4 for severe recurrent infections, 3 due to the onset of new cancer).

Table 1. Clinical, functional, disease activity and serological parameters of *naïve* (n=72) and *non-naïve* (n=177) axSpA patients during the 24-month follow-up

	T0	T6	T12	T24

naïve	14.0 (6.0-27.0)	10.0 (4.0-19.5)	8.0 (3.1-12.8)	5.0 (2.0-15.0)
non-naïve	18.5 (10.0-31.3)	15.0 (8.0-25.0)	12.0 (6.0-20.0)	12.0 (6.0-19.0)
p	*p=0.04*	*p=0.04*	*p=0.04*	*p=0.04*

Legend: BASMI: Bath Ankylosing Spondylitis Metrology Index; HAQ: Health Assessment Questionnaire modified for spondyloarthritis; ASDAS: Ankylosing Spondylitis Disease Activity Score; ESR: erythrocyte sedimentation rate

Conclusion: In a real-life clinical-setting, SEC proved to be safe and effective in axSpA, mainly in naïve-patients, with a notable drug-retention-rate. No differences were observed between r-axSpA and nr-axSpA.

Background: Patients with axial spondyloarthritis (axSpA) in clinical remission tapered Tumor Necrosis Factor inhibitor (TNFi) therapy according to a clinical guideline and had 2 years´ follow-up [1].

Objectives: We aimed to investigate flare frequency, dose at which flare occurred, type of flare (clinical/ Bath ankylosing spondylitis disease activity index (BASDAI)/magnetic resonance imaging (MRI)) and predictors of flare.

Methods: Patients in clinical remission (BASDAI<40, physician global score<40 and without disease activity the previous year) tapered TNFi to 2/3 standard dose at baseline, 1/2 at week (w)16, 1/3 at w32 and 0 (discontinuation) at w48. Patients who flared were increased to previous dose. Predictors of flare at each dose step were investigated by regression analyses.

Results: Of 108 patients, 106 (99%) flared before year 2 (flare occurring mean (SD) 99(44.3) days after last tapering). Twenty-nine patients (27%) flared at 2/3 standard dose, 21 (20%) at 1/2 dose, 29 (27%) at 1/3 dose and 27 (25%) after discontinuation. One-hundred-and-five (99%) had clinical flare, 25 (24%) BASDAI flare and 23 (29% of patients with MRI at flare) MRI flare; and forty-one patients (41%) fulfilled the ASAS-definition of clinically important worsening (≥0.9 increase since baseline) (Figure 1). Most common flare symptoms were back/buttock pain (n=93 (89%)) and pain in peripheral joints/entheseal regions (n=48 (46%)). Higher baseline physician global score was an independent predictor of flare after tapering to 2/3 (Odds ratio=1.19 (95% Confidence Interval=1.05-1.41); p=0.011) (Table 1). Changes in clinical and/or imaging variables in the 16 weeks prior to tapering did not predict flare (data not shown).

Conclusion: Almost all (99%) axSpA patients in clinical remission flared during tapering to discontinuation, but above half not before receiving 1/3 dose or less. Higher physician global score was the only independent predictor of flare.

Figure 1. Venn diagram showing flare types (n=106)

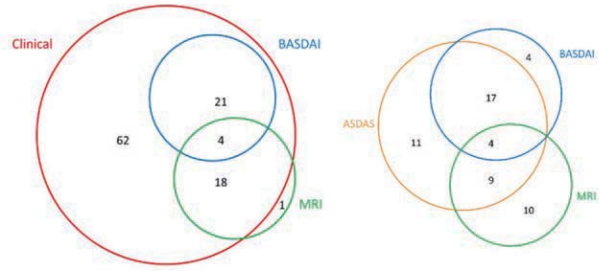

Figure 1. The left schematic shows the overlap between the 3 flare types (i.e BASDAI, clinical and MRI flare). The right schematic shows overlap between BASDAI flare, MRI flare and clinically important worsening according to ASDAS. BASDAI flare: change in BASDAI ≥20 since inclusion and an absolute BASDAI ≥40. Clinical flare: signs of inflammatory back pain, development of musculoskeletal manifestations such as peripheral arthritis, enthesitis or dactylitis and/or development of extra-articular manifestations as anterior uveitis, psoriasis or inflammatory bowel disease, and/or an increase in ASDAS-CRP ≥0.9. MRI flare: ≥2 new or worsened inflammatory lesions in the sacroiliac joints or spine according to a predefined MRI-flare definition.

Background: Axial spondyloarthritis (axSpA) is characterised by inflammation of the sacroiliac joints (SIJ) and the spine. Secukinumab (SEC) treatment was clinically efficacious and reduced SIJ bone marrow oedema as detected by magnetic resonance imaging (MRI) in patients (pts) with non-radiographic (nr)-axSpA through 52 weeks in the PREVENT (NCT02696031) study.[1]

Objectives: To report radiographic progression and the course of inflammation as assessed by X-ray and MRI of SIJ and spine over 2 years in the PREVENT study.

Methods: Study design and key endpoints have been reported earlier.[1] In total, 555 pts were randomised (1:1:1) to receive SEC 150 mg, with (LD) or without loading (NL) doses, or placebo (PBO). Switch to open-label (OL) SEC or standard of care (SoC) was permitted after Week (Wk) 20. All pts (except those who switched to SoC) received OL SEC from Wk 52. Radiographs of the spine and SIJ were collected at baseline (BL) and Wk 104; MR images of the spine and SIJ were collected at BL, Wk 16, 52, and 104. Spinal radiographs were scored using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) and SIJ radiographs according to modified New York criteria (mNYC). Pts whose screening SI joint radiographs fulfilled mNY criteria during the eligibility reading session were excluded from the study. Spinal MR images were assessed for signs of inflammation with the Berlin score. SIJ bone marrow oedema was assessed according to the Berlin Active Inflammatory Lesions Scoring. All images were evaluated in blinded fashion independently by 2 central readers. All data are reported from the Wk 104 reading session and are presented as observed.

Results: The vast majority (98%) of pts treated with SEC 150 mg (pooled LD and NL) showed no structural progression, defined as change in total mSASSS score ≤ smallest detectable change (SDC) of 0.76 (80% agreement level) over 2 years. At BL, 62 pts (43 in SEC, 19 in PBO) presented with ≥1 syndesmophyte (≥1 vertebral unit scored by ≥1 reader). Among these pts, 9 in SEC (20.9%) and 7 in PBO (36.8%) groups had developed ≥1 new syndesmophyte by Wk 104. Among 237 SEC and 117 PBO pts without syndesmophytes at BL, only 4 pts on SEC (1.7%) and 4 pts on PBO (3.4%) developed ≥1 new syndesmophyte by Wk 104. SIJ radiographs showed that 88% of pts on SEC and 86% on PBO had no progression in SIJ (defined as change ≤ SDC (0.46) in total mNYC score) by Wk 104. No patient had an increase in total mNYC score of 2 or more. When screening radiographs of eligible pts were scored alongside post-BL images in the final reading campaign, approximately 25% of pts (68/277 and 34/139 pts in the SEC and PBO groups, respectively) were evaluated as mNY-positive at screening (pts were considered mNY-positive if ≥1 reader evaluated them as mNY-positive). Of these, 11/68 pts in the SEC (16.2%) and 5/34 in the PBO (14.7%) groups were evaluated as mNY-negative at Wk 104. In the SEC and PBO groups, 202 (96.7%) and 102 (97.1%) pts who were mNY-negative at screening stayed negative through Wk 104, respectively. Only 7 pts in the SEC (3.3%) and 3 in the PBO (2.9%) groups who were mNY-negative at BL were scored as mNY-positive at Wk 104. In both groups, fewer pts progressed from mNY-negative to mNY-positive than had a change in the opposite direction (from positive to negative), resulting in an overall negative net progression. Spinal inflammation on MRI (Berlin score) was low at BL with a mean of 0.82 in SEC and 1.07 in PBO groups with no meaningful change up to Wk 104 (mean of 0.56, SEC). SEC reduced SIJ bone marrow oedema score versus PBO at Wk 16 and Wk 52 with sustained reduction through Wk 104 in the overall patient population, with greater reduction in pts with BL score >2 (Figure 1).

Conclusion: Most pts initially randomised to SEC or PBO showed no radiographic progression through 2 years. There was some discrepancy between SIJ eligibility and efficacy reads. SEC reduced SIJ inflammation (bone marrow oedema) on MRI in pts with active nr-axSpA.

Background: While data on real-life SEC retention rate in patients (pts) with axSpA is accumulating, there are no data on predictive factors for this retention. Presence of objective sign of inflammation (OSI) are known to be predictive of efficacy of anti-TNFs and their retention in axSpA.
Objectives: To assess whether OSI were predictive of SEC retention at 1 year in axSpA.
Methods: French retrospective study collecting between October 2019 and September 2020 data from axSpA pts a) having initiated and received at least one dose of SEC between August 11th 2016 and August 31st 2018, b)with at least a one year follow-up period. Retention of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following: CRP> N, MRI-inflammation at the sacroiliac or spine level. Preselected factors of SEC retention at 1 year (≥1 OSI, age, sex, BMI, smoking, HLA B27, non-radiographic vs radiographic axSpA, past or present uveitis / Inflammatory Bowel Disease (IBD) / psoriasis / arthritis or synovitis, diagnostic delay, disease duration, SEC line of biologic therapy, SEC maintenance dose, concomitant csDMARD / oral corticosteroids / proton pomp inhibitor, history of depression / fibromyalgia) were analyzed by multivariate cox model regression. Only variables with <20% missing data were included in the model after imputation and stepwise selection (significance level for entering variables = 20%; for removing variables = 10%). OSI was forced into the model whatever its significance level or rate of missing data.
Results: In total, 906 pts from 47 centers (male: 42.2%, mean age: 46.2 ± 11.7 years, mean disease duration: 9,3 ± 9.1 years), were included in the analysis. At initiation of SEC, 86.3% of pts had ≥ 1 OSI and respectively 8.0%, 14.9% and 77.1% were in 1st, 2nd and ≥ 3rd line (L) of biologic/targeted synthetic DMARD. The 1 year KM survival rate for SEC was 59% [95%CI:55%-62%] overall, 58% [54%-62%] and 63% [53%-73%] for pts with or without OSI, and was numerically greater in 1st L vs 2nd and ≥3rd L (70% [59%-81%], 62% [54%-70%], 57% [53%-61%] respectively). In multivariate analysis absence of OSI, lack of prior exposure to anti-TNF inhibitors, absence of IBD, and absence of history of depression were associated with a better SEC retention at 1 year (Table 1).

Table 1. Predictive factors of SEC 1 year retention identified by multivariate cox regression analysis (multiple imputation + stepwise selection)

Predictive factors (* reference)		Still on SEC at 1 Year (%)#	HR [95% CI]	p vs ref	p type III
≥ 1 objective sign of inflammation	No (N=165)*	65.3%			
	yes (N=711)	58.8%	1.44 [1.08; 1.93]	0.014	
SEC treatment line	1st L (N=68)*	72.2%			0.084
	2nd L (N=132)	62.7%	1.53 [0.91; 2.57]	0.107	
	≥ 3rd L (N=676)	57.6%	1.67 [1.06; 2.62]	0.028	
Past or present history of IBD	No (N=854)*	59.8%			
	Yes (N=22)	40.9%	1.76 [1.01; 3.07]	0.047	
History of depression or anti-depressive concomitant treatment	No (N=716)*	60.8%			
	Yes (N=160)	54.5%	1.25 [0.97; 1.60]	0.090	

without imputation for missing dataInterpretation HR > 1: the hazard of discontinuation at 1 year is X times higher vs reference

Conclusion: The overall retention of SEC at 1 year in daily practice at the time of its launch in France was 59% for axSpA patients and OSI, prior exposure to TNF inhibitors, IBD and history of depression were identified as predictive factors of SEC retention.

STRUCTURAL OUTCOMES IN THE SACROILIAC JOINT AFTER IXEKIZUMAB TREATMENT FOR 16 WEEKS IN PATIENTS WITH ACTIVE NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS STRATIFIED BY GENDER, HLA-B27, AND BASELINE MRI INFLAMMATION

W. P. Maksymowych[1], X. Baraliakos[2], R. G. Lambert[3], R. B. M. Landewé[4], D. Sandoval[5], H. Carlier[6], J. Lisse[5], X. LI[5], M. Hojnik[5], M. Østergaard[7]. *[1]Division of Rheumatology at the University of Alberta, Department of Medicine, Alberta, Canada; [2]Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany; [3]University of Alberta, Department of Radiology & Diagnostic Imaging, Alberta, Canada; [4]Amsterdam Rheumatology and Immunology Center, Department of Clinical Immunology and Rheumatology, Amsterdam, Netherlands; [5]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America; [6]Eli Lilly and Company, Immunology Medical, Brussels, Belgium; [7]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, and Department of Clinical Medicine, University of Copenhagen, Glostrup, Denmark*

Background: Ixekizumab (IXE) has demonstrated clinical efficacy in patients with active non-radiographic axial spondyloarthritis (nr-axSpA) together with significant repair of structural lesions in the sacroiliac joint (SIJ) on MRI. There is, however, a paucity of data as to which patients may be most responsive.

Objectives: We aimed to evaluate whether patients' gender, HLA-B27 status, and presence of MRI inflammation impacted the effect of treatment with IXE versus placebo (PBO) on MRI structural lesions in the SIJ in patients with nr-axSpA.

Methods: Patients with active nr-axSpA, biologic-naïve (COAST-X, NCT02757352) were randomized 1:1:1 to ixekizumab 80 mg every 4 (Q4W) or 2 weeks (Q2W) or PBO. Structural lesions on SIJ MRI were assessed by the Spondyloarthritis Research Consortium of Canada (SPARCC) MRI SIJ structural score (SSS). Treatment comparisons used analysis of covariance based on observed cases. SPARCC SSS subgroup analyses were performed according to baseline gender, HLA-B27 status, and SPARCC MRI SIJ bone marrow oedema (BME) <4 and ≥4 subgroups, which reflects a definite MRI for inflammation in the SIJ typical of axSpA.

Results: Of 303 randomized patients, 266 patients (Q4W: n=85, Q2W: n=91, PBO: n=90) had an MRI scan at baseline and week 16. At baseline, SPARCC scores were consistently higher in males, and mostly higher in HLA-B27 and BME≥4 positive subgroups. Significant differences between patients treated with IXE versus PBO were observed for male patients, HLA-B27 positives, and those with baseline SPARCC BME ≥4. Numerically similar changes were observed in female patients, patients with negative HLA-B27, and patients with SPARCC BME<4, though not statistically significant.

Conclusion: Effects of IXE on structural repair are most evident in males, HLA-B27 positives, and patients with definite MRI inflammation at baseline.

CFB=change from BL. BL=baseline, LS=least squares.

Background: So far, no consensus has been reached on a definition of early SpA. The ASAS-SPEAR (SPondyloarthritis EARly definition) project aims to develop a consensual definition. Therefore, it is important to know whether treatment earlier in the disease course compared to treatment of established disease leads to better outcomes in axSpA.

Objectives: To summarize the evidence on the relationship between symptom duration or the presence of radiographic damage and clinical response in patients with axSpA treated with NSAIDs, bDMARDs or tsDMARDs.

Methods: A SLR was conducted using Medline, EMBASE and the Cochrane Library (April 28, 2021), supplemented by hand-searches in the FDA website. Randomized controlled trials (RCTs) and cohort studies in patients with axSpA addressing the impact of symptom duration or disease duration and presence of radiographic damage on treatment response (to NSAIDs, b/tsDMARDs) were included. Based on a cut-off of symptom/disease duration or the absence/presence of radiographic damage, groups of 'early' and 'established' disease were compared. Treatment outcomes were measures of disease activity, function or quality of life. Two reviewers independently identified eligible studies and extracted the data, including the risk of bias (RoB) assessment. For categorical outcomes we calculated relative risk (RR), relative risk ratio (RRR) and number needed to treat (NNT), and differences in differences (DID) for continuous outcomes.

Results: From the 8769 articles retrieved, 23 were included and 3 added by hand-search, most of them with low RoB. Nineteen studies (9 RCTs) compared groups based on symptom (n=6)/disease duration (n=13) and 7 studies (4 RCTs) based comparisons on absence/presence of radiographic damage in posthoc analyses. When early axSpA was defined by symptom duration in RCTs (n=4), in patients with nr-axSpA, early treatment was associated with higher RR and RRR and lower NNT for ASAS40 in two studies (Table 1); a third study showed that patients achieving ASDAS-ID and ASAS-PR had shorter symptom duration than those not achieving this. Lastly, in one study including patients with axSpA patients, no difference in treatment response was observed based on symptom duration. In most of the cohort studies using a definition based on symptom/disease duration (n=10), no association was found between symptom/disease duration and treatment response (n=8). Only in one cohort study, disease duration was a significant predictor of quality of life, and in another cohort study, it was a predictor of functional improvement.

Table 1. Assessment of treatment response in RCTs based on symptom duration

Study	Population	Early vs established (years)	RR (early vs established)	RRR (95%IC)	NNTs (early vs established)
ASAS20					
Landewé 2014	axSpA	<5 vs ≥5	1.5 vs 1.5	0.96 (0.53-1.73)	5.5 vs 4.8
ASAS40

ASAS-PR					
Sieper 2019	nr-axSpA	5.3±5.7	8.0±7.8		<0.001
Cell colours	In favor of early disease	In favor of established disease	Non significant		

When early axSpA was defined based on disease duration or the presence of radiographic damage, there was no significant difference in response to treatment between early and established axSpA.

Conclusion: Studies addressing treatment response based on symptom duration or radiographic damage in axSpA are scarce. When defining early axSpA based on symptom duration, in nr-axSpA, treatment with bDMARDs may lead to better outcomes compared to established axSpA whereas in axSpA there is no difference in response to treatment between early and established disease. When early axSpA is defined based on disease duration or radiographic damage, no differences in response to treatment are found between early and established disease.

POS0303 TREATMENT DECISIONS IN AXIAL SPONDYLOARTHRITIS ARE MORE THAN TREAT TO TARGET

J. W. Bolt[1,2], C. Aalbers[1,2], L. H. Walet[1,2], L. Van Mens[1,2], J. C. Van Denderen[2,3], I. Van der Horst-Bruinsma[4], L. Van Baarsen[1,2], R. B. M. Landewé[1,2], M. G. H. Van de Sande[1,2]. *[1]Amsterdam UMC, University of Amsterdam, Department of Rheumatology & Clinical Immunology and Department of Experimental Immunology, Amsterdam Institute for Infection & Immunity, Amsterdam, Netherlands; [2]Amsterdam Rheumatology and Immunology Center (ARC), Amsterdam, Netherlands; [3]Reade, Department of Rheumatology, Amsterdam, Netherlands; [4]Radboud University Medical Centre, Department of Rheumatology, Nijmegen, Netherlands*

Background: Several guidelines advise treating axial spondyloarthritis (axSpA) patients according to the 'treat-to-target principles' (T2T)1 although a clear target has not yet been defined. Disease activity measures, which are often used as targets, do not always reflect pure inflammatory disease activity. Currently is it not known if T2T is applied in axSpA clinical practice and what factors influence treatment decisions.

Objectives: To assess residual disease activity according to the physician's opinion, patient's opinion and disease activity measures and the subsequent treatment decisions made in axSpA patients.

Methods: This cross-sectional multicentre study included 249 patients with a clinical diagnosis of axSpA ≥ 6 months. Remission and low disease activity according to Bath Ankylosing Spondylitis Disease Activity Index (BASDAI <1.9 and <3.5 respectively), physician's, and patient's opinion was assessed. Questionnaires including patient reported outcomes (PROs) such as the Patient Global Assessment (PGA) of disease activity, Bath Ankylosing Spondylitis Functional Index (BASFI), ASAS-Health Index (ASAS-HI), central sensitization inventory (CSI), Brief Illness Perception Questionnaire (B-IPQ), and satisfaction with treatment; or questions regarding motivations for treatment decisions were filled in by patients and physicians respectively.

Results: In this cohort, 115/249 patients were in remission according to the physician. Of these 115 patients, 67% (n=80) indeed perceived their disease as being inactive, but only 37% (n=43) reached remission according to the BASDAI. This shows a significant level of discrepancy in comparison with the physician's opinion. Of note, 30% (n=35) even reported a BASDAI >3.5. In 93% (n=107) treatment-intensity remained unchanged and in 6% (n=5) treatment was tapered. Physicians motivated that treatment was left unchanged in the majority of these patients because of remission (n=55, 48%), low disease activity (n=28, 24%), or complaints not related to axSpA (n=13, 12%). The latter two motives were most frequently mentioned for the patients with a BASDAI >3.5 (respectively n=13, 39% and n=9, 27%). Residual disease activity was present in 134/249 patients according to the physician's opinion and 67% (n=90) of these patients also perceived their disease as active. In 89% (n=119) BASDAI score was >1.9 and in 62% (n=83) >3.5. In 61% (n=51) of these patients with residual disease and a BASDAI >3.5, treatment remained unchanged, as well as in 84% (n=43) of the patients with a BASDAI between 1.9 and 3.5. Physician's most frequently mentioned motives for not changing treatment in the residual disease activity group were: low disease activity achieved (n=29, 25%), the need to await the effect of the current treatment (n= 23, 20%), or complaints that were not related to axSpA (n=9, 8%). The second (n=20, 39%) motive was most frequently mentioned for unchanged treatment in the BASAI >3.5 group and additionally, physicians mentioned that these patients had a preference to continue their current treatment despite high disease activity (n=5, 10%). Analyses of PROs showed significantly higher scores for PGA of disease activity, several subdomains of the B-IPQ, general fatigue and morning stiffness in patients with remission according to the physician despite a

BASDAI >3.5 compared to patients with residual disease according to the physician with a BASDAI <1.9.

Conclusion: This study shows that physicians in daily clinical practice do not always adjust treatment according to the T2T-principles in patients with residual disease activity when measured by BASDAI scores, either because low disease activity is achieved, because they classify the patient as being in remission, as having low disease activity, or because there was a need to await the efficacy of the current treatment. Further studies are needed to investigate if treatment choices made in clinical practice result in under-treatment of axSpA patients with worse outcome in comparison to the T2T approach.

POS0304 THE EFFECT OF ANTI-INFLAMMATORY TREATMENT ON DEPRESSION IN SPONDYLOARTHRITIS: DOES THE TYPE OF DRUG MATTER?

C. Webers[1,2], U. Kiltz[3,4], J. Braun[3,4], D. Van der Heijde[5], A. Boonen[1,2].
[1]Maastricht University Medical Centre, Rheumatology, Maastricht, Netherlands; [2]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; [3]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [4]Ruhr-Universität Bochum, Rheumatology, Bochum, Germany; [5]Leiden University Medical Centre, Rheumatology, Leiden, Netherlands

Background: Patients with spondyloarthritis (SpA) are at increased risk of depression compared to the general population. Currently, it is unknown whether this increased risk is only secondary (due to SpA-related symptoms), or also due to a shared inflammatory pathway. From both clinical and pathophysiological perspectives, it is relevant to know whether comorbid depressive symptoms improve with treatment of SpA, and if so, whether such an improvement depends on drug type/mechanism of action.

Objectives: To investigate the effect of pharmacological treatment of SpA on depressive symptoms, and to explore whether this effect differs between drug types.

Methods: Data from the international ASAS Health Index Validation Study were used. Included patients had a diagnosis of SpA and fulfilled the ASAS classification criteria for axial/peripheral SpA. Patients were assessed at baseline, and for those who required a therapeutic change (initiation of NSAID, conventional synthetic (cs)DMARD or TNFi) due to high disease activity, a follow-up assessment was conducted. The current analysis included only those with a therapeutic change. Data on demographics, disease characteristics and disease activity (ASDAS, BASDAI, CRP) were available. Depressive symptoms were assessed with the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D, range 0-21 [best-worst]). HADS-D scores ≥8 and ≥11 indicated possible and probable depression, respectively. Change in depressive symptoms from baseline was compared between treatments (NSAID, csDMARD, TNFi) with ANOVA and linear regression analysis, adjusting for potential confounders.

Results: In total, 1548 patients were assessed at baseline. A therapeutic change was initiated in 304 patients (n=102/45/157 initiated an NSAID/csDMARD/TNFi). Of these, 260 (85%) had axSpA, 190 (63%) were male, mean age was 37.3 (SD 12.6) years and mean ASDAS at baseline 3.3 (1.1). The mean HADS-D was 6.9 (4.2); 126 (42%) were possibly depressed and 66 (22%) probably depressed. At baseline, there were no significant differences in demographics, disease parameters or depressive symptoms between treatment groups. At follow-up, mean HADS-D had improved to 5.1 (change -1.9 (3.8), p<0.01). Improvement in HADS-D was greater for TNFi (-2.4) than NSAIDs (-1.3, p=0.05) or csDMARDs (-1.2, p=0.15). Also, the proportion of patients with possible depression decreased more for TNFi (from 48% at baseline to 29% at follow-up) compared to NSAIDs (from 38% to 32%). In multivariable regression, initiation of TNFi was associated with greater improvement in HADS-D compared to NSAID (B = -1.27, 95%CI -2.23 to -0.32, base model) (Table 1). However, after additional adjustment for change in ASDAS/BASDAI, drug type was no longer associated with HADS-D improvement (Table 1). Adjustment for CRP in addition to BASDAI did not change results, and CRP itself was not associated with depressive symptoms (not shown). Of note, csDMARDs did not differ from NSAIDs in any of the analyses regarding their effect on HADS-D.

Table 1. Multivariable regression analysis of change in HADS-D from baseline

	Base model		ASDAS model		BASDAI model	
Variable	**B**	**95%CI**	**B**	**95%CI**	**B**	**95%CI**
Age, years	**0.04**	**0.00 to 0.07**	0.03	-0.01 to 0.07	**0.03**	**0.00 to 0.06**
Male gender	0.23	-0.67 to 1.14	0.55	-0.39 to 1.49	0.28	-0.54 to 1.10
HLA-B27 (vs negative)						
Positive	**1.56**	**0.46 to 2.67**	**1.38**	**0.27 to 2.49**	**1.17**	**0.17 to 2.18**
Unknown	**1.70**	**0.19 to 3.22**	**2.21**	**0.66 to 3.75**	**1.41**	**0.04 to 2.77**
Therapy initiated (vs NSAID)						
csDMARD	0.19	-1.16 to 1.54	0.02	-1.34 to 1.39	0.14	-1.07 to 1.36
TNFi	**-1.27**	**-2.23 to -0.32**	-0.51	-1.58 to 0.55	-0.23	-1.13 to 0.67
ASDAS, change			**1.27**	**0.84 to 1.71**	†	
BASDAI, change			†		**0.78**	**0.60 to 0.96**

Associations in bold are statistically significant (p<0.05) †Due to collinearity, ASDAS and BASDAI were tested in separate models

Conclusion: Treatment of active SpA also improves depressive symptoms. TNFi have a larger effect than NSAIDs, which can mainly be explained by a stronger effect on disease activity. This analysis did not find evidence for a direct link between CRP-mediated inflammation and depressive symptoms in SpA.

POS0305 TIME TO IMPROVEMENT OF FATIGUE IN PATIENTS WITH ANKYLOSING SPONDYLITIS IN A STUDY OF TOFACITINIB

L. Gossec[1,2], D. Cella[3], J. A. Walsh[4,5], R. Sengupta[6], A. G. Bushmakin[7], J. C. Cappelleri8, A. Yndestad[9], O. Dina[10]. *[1]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France; [2]Pitié-Salpêtrière Hospital, AP-HP, Rheumatology Department, Paris, France; [3]Northwestern University Feinberg School of Medicine, Department of Medical Social Sciences, Chicago, IL, United States of America; [4]University of Utah, Salt Lake City, UT, United States of America; [5]George E. Wahlen Veteran Affairs Medical Center, Salt Lake City, UT, United States of America; [6]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; [7]Pfizer Inc, Statistical Research and Data Science Center, Groton, CT, United States of America; [7]Pfizer Inc, Statistical Research and Data Science Center, Groton, CT, United States of America; [9]Pfizer Inc, Inflammation and Immunology, Oslo, Norway; [10]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*

Background: Fatigue is common in patients (pts) with ankylosing spondylitis (AS) and is associated with higher levels of pain and functional disability.[1] Tofacitinib is an oral JAK inhibitor approved for the treatment of AS. In pts with AS, greater improvements in fatigue were seen with tofacitinib vs placebo (PBO).[2]

Objectives: To estimate the time to improvement in fatigue in pts with AS treated with tofacitinib.

Methods: This post hoc analysis used data from a Phase 3 trial (NCT03502616) in pts with AS receiving tofacitinib 5 mg twice daily (BID) or PBO for 16 weeks; after Week (W)16, all pts received open-label tofacitinib until W48.[2] Fatigue was assessed by Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) total score (range 0–52; higher scores indicate less fatigue[3]). A series of time to event analyses were performed using non-parametric Kaplan–Meier models. Median times to initial improvements in FACIT-F total score were assessed based on different thresholds. The initial improvement event was defined as time to first post-baseline week with an improvement in FACIT-F total score of at least 5%, 10%, 15% etc, up to 100%. Median times to events based on absolute changes in FACIT-F total score were also investigated.

Results: Overall, 269 pts were assessed; baseline demographics/disease characteristics have been previously reported.[2] The median times to initial improvements in FACIT-F total score were significantly (p<0.05) shorter in pts receiving tofacitinib 5 mg BID vs PBO (Figure 1). For example, median time to

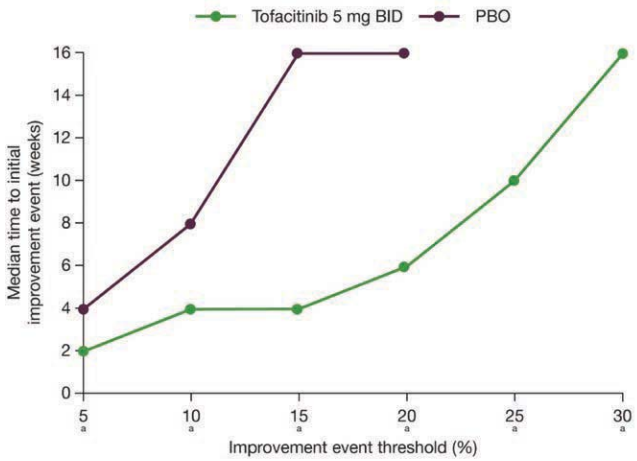
initial improvement of 30% in FACIT-F total score was 16 weeks in pts receiving tofacitinib 5 mg BID; however, in pts receiving PBO, the median time for this event was not achieved up to W16. More pts receiving tofacitinib 5 mg BID vs PBO experienced initial improvement events up to W16 (Table 1). For example, 36.1% of pts receiving tofacitinib 5 mg BID experienced 50% improvement of fatigue up to W16, compared with 19.9% of pts receiving PBO.

Table 1. Proportions of pts who experienced initial improvement events in FACIT-F total score up to W16

Fatigue improvement threshold	Initial improvement, n (%)	p value[a]
25%		
Tofacitinib 5 mg BID	82 (61.7)	0.0009
PBO	58 (42.6)	
50%		
Tofacitinib 5 mg BID	48 (36.1)	0.0031
PBO	27 (19.9)	
75%		
Tofacitinib 5 mg BID	30 (22.6)	0.0626
PBO	19 (14.0)	
100%		
Tofacitinib 5 mg BID	23 (17.3)	0.1233
PBO	15 (11.0)	

N=133 (tofacitinib 5 mg BID); N=136 (PBO) [a]Test of equality over strata log-rank test, p<0.05
n, number of pts achieving an initial improvement event; N, total number of pts in each treatment group

Fig. Median times to initial improvement events in FACIT-F total score



[a]Test of equality over strata log-rank test, p<0.05
Initial improvements in fatigue were evaluated from baseline based on the first post-baseline week with an improvement in FACIT-F total score of at least 5%, 10%, 15% etc, up to 100%

Conclusion: In pts with AS, initial improvements in fatigue, as determined by FACIT-F total score, occurred faster and were larger in magnitude with tofacitinib vs PBO up to W16. These results may help physicians better understand the speed and magnitude for fatigue benefit in pts receiving tofacitinib.

Background: Upadacitinib (UPA) was shown to be safe and effective through 2 years in patients (pts) with active ankylosing spondylitis (AS) naïve to biologic disease-modifying antirheumatic drugs (bDMARDs) in the pivotal phase 2/3 SELECT-AXIS 1 trial.[1,2]

Objectives: To assess the efficacy and safety of UPA in pts with active AS with an inadequate response (IR) to bDMARDs.

Methods: SELECT-AXIS 2 (NCT04169373) was conducted under a master protocol and includes two separate studies (one for AS bDMARD-IR and one for non-radiographic axial spondyloarthritis [nr-axSpA]). The AS bDMARD-IR study is a randomized, double-blind, placebo (PBO)-controlled, phase 3 trial that enrolled adults ≥18 years with AS who met modified New York criteria, had BASDAI and pt's assessment of total back pain scores ≥4 (numeric rating scale 0–10) at study entry, and had an IR to one or two bDMARDs (TNF inhibitor or IL-17 inhibitor). Pts were randomized 1:1 to receive oral UPA 15 mg once daily (QD) or PBO during the 14-week (wk) double-blind treatment period. The primary endpoint was ASAS40 response at wk 14. Multiplicity-controlled secondary endpoints evaluated at wk 14 were improvements from baseline in disease activity (ASDAS [CRP], ASDAS ID [<1.3], ASDAS LDA [<2.1], BASDAI50, ASAS20, and ASAS PR), pain (total and nocturnal back pain), function (BASFI), objective measure of inflammation (SPARCC MRI score of the spine), spinal mobility (BASMI), enthesitis (MASES), and quality of life (ASQoL and ASAS HI). Non-responder imputation incorporating multiple imputation (NRI-MI) was used to handle intercurrent events and missing data for binary endpoints. Cochran-Mantel-Haenszel (CMH) test and mixed-effect model for repeated measures (MMRM) were used for analyzing binary and continuous endpoints, respectively. Treatment-emergent adverse events (TEAEs) assessed through wk 14 are reported for pts who had ≥1 dose of study drug.

Results: All 420 randomized pts with active AS received assigned treatment (UPA 15 mg, n=211; PBO, n=209); 409 (97%) received study drug through wk 14. Baseline demographic and disease characteristics were generally similar between treatment groups and reflective of an active AS bDMARD-IR population (74% male; mean age 42.4 years; mean disease duration 7.7 years; 83% HLA-B27 positive; mean BASDAI 6.8). Significantly more pts achieved the primary endpoint of ASAS40 response at wk 14 with UPA vs PBO (45% vs 18%; $P<0.0001$; Figure 1); UPA showed onset of effect in ASAS40 as early as wk 4 (nominal $P\leq0.05$). All multiplicity-controlled secondary endpoints met statistical significance for UPA vs PBO at wk 14 across multiple clinical domains of AS ($P<0.0001$; Figure 1). The rate of TEAEs was similar between treatment groups through wk 14 (UPA, 41%; PBO, 37%). TEAEs led to discontinuation in 3 (1.4%) pts treated with PBO and none with UPA. Serious infections occurred with UPA (2.4%) but not with PBO and included 4 events of COVID-19 and 1 event of uveitis. Additional events of uveitis were reported in 3 (1.4%) pts treated with PBO. Inflammatory bowel disease (IBD) occurred in 1 (0.5%) pt on UPA and none on PBO. No malignancy, major adverse cardiovascular events, venous thromboembolic events, or death were reported with UPA; 1 event of malignancy was observed with PBO.

Conclusion: UPA 15 mg QD was significantly more effective than PBO over 14 wks of treatment in pts with active AS and IR to bDMARDs. No new safety risks were identified with UPA compared with its known safety profile.[3,4] These findings are consistent with and complementary to those of SELECT-AXIS 1 (bDMARD-naïve AS population),[1,2] and support the use of UPA in pts with active AS, including those who had a previous IR to bDMARD therapy.

Clinical aspects in Psoriatic Arthritis

POS0307

IMPAIRED GLYCAEMIC CONTROL IS ASSOCIATED WITH INCREASED RISK OF PSORIATIC ARTHRITIS: MENDELIAN RANDOMISATION STUDY

S. S. Zhao[1], A. Barton[2], J. Bowes[2]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom;* [2]*The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom*

Background: Psoriatic arthritis (PsA) and psoriasis are both strongly associated with impaired glycaemic control and type 2 diabetes. The risk of developing type 2 diabetes is estimated to be ~40% higher in PsA compared to controls [1]. However, these observational findings are susceptible to bias from reverse causation: Insulin resistance and impaired glycaemic control are evident well over a decade before clinical onset of type 2 diabetes [2]. Therefore, whether impaired glycaemic control is a cause or consequence of PsA is unclear. Testing this hypothesis using traditional observational designs is challenging since longitudinal assessments of glycaemic control before PsA onset are often not available. Mendelian randomisation (MR) is an epidemiologic method that provides evidence about putative causal relationships between modifiable exposures and disease outcomes using genetic variants as instrumental variables. MR is less likely to be affected by confounding or reverse causation than conventional observational designs because genetic variants are randomly allocated at conception.
Objectives: To estimate the effect of genetically predicted glycaemic traits - glycated haemoglobin (HbA1c), 2-hour glucose after oral glucose challenge (2hG), fasting glucose (FG), and fasting insulin (FI) - on risk of PsA and psoriasis compared to controls using two-sample MR.
Methods: We selected 320 independent (r^2<0.001) genome-wide significant ($p<5x10^{-8}$) variants as instruments for HbA1c from a UK biobank genome-wide association study (GWAS) of 344,182 individuals, and 14 variants for 2hG, 67 for FG and 38 for FI from up to 200,622 individuals from a MAGIC consortium meta-analysis that adjusted for body mass index. Genetic associations for PsA were obtained from a GWAS comprising 3,609 cases (majority fulfilling CASPAR criteria) and 9,192 controls. Psoriasis data were obtained from 5,278 cases (96% European, defined using ICD and phecodes) and 650,391 controls from the UK biobank, FinnGen and BioBank Japan [3]. We used the inverse-variance weighted method to combine effect estimates from each variant using fixed-effect meta-analysis.
Results: Genetically predicted HbA1c increased risk of PsA (OR 1.18 per standard deviation (6.7 mmol/mol) increase in HbA1c; 95%CI 1.02, 1.36). 2hG (OR 1.55 per SD (0.6 mmol/L) increase; 95%CI 1.26, 1.89) and FG (OR 1.73 per SD (1.6 mmol/L) increase; 95%CI 1.35, 2.21) similarly increased PsA risk (Figure 1). FI was not associated with PsA risk. 2hG was the only glycaemic trait significantly associated with psoriasis (OR 1.21; 95%CI 1.04, 1.40).

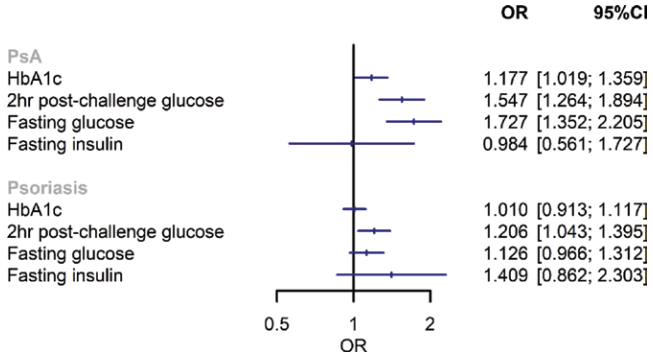

Figure 1. Mendelian randomisation estimates of the effect of glycaemic traits on risk of psoriatic arthritis and psoriasis.

Conclusion: This study provides supportive genetic evidence that impaired glycaemic control increases risk of PsA. By contrast, estimates were smaller when comparing psoriasis against controls with confidence intervals including the null. Improving glycaemic control may reduce PsA risk, although further studies are required to confirm these findings and to compare PsA directly against cutaneous only psoriasis.

EFFECT OF GUSELKUMAB ON SERUM BIOMARKERS IN PSORIATIC ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE OR INTOLERANCE TO TUMOR NECROSIS FACTOR INHIBITORS: RESULTS FROM THE COSMOS STUDY

G. Schett[1], W. Chen[2], S. Gao[2], S. D. Chakravarty[3,4], M. Shawi[5], F. Lavie[6], E. Theander[7], M. Neuhold[8], L. Coates[9], S. Siebert[10]. [1]*FAU Erlangen-Nürnburg,*

Internal Medicine 3, Erlangen, Germany; [2]Janssen Research & Development, LLC, Biostatistics, Spring House, United States of America; [3]Drexel University College of Medicine, Department of Medicine, Philadelphia, United States of America; [4]Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America; [5]Janssen Pharmaceutical Companies of Johnson & Johnson, Global Medical Affairs, Horsham, United States of America; [6]Janssen Cilag Global Medial Affairs, Global Medial Affairs, Issy les Moulineaux, France; [7]Janssen Scientific Affairs, LLC, Immunology, Solna, Sweden; [8]Janssen Scientific Affairs, LLC, Immunology, Zug, Switzerland; [9]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [10]University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom

Background: Guselkumab (GUS), a selective IL-23 inhibitor, is efficacious in treating bio-naïve and TNFi-experienced active PsA patients (pts).[1,2] In the COSMOS study of active PsA pts with lack of efficacy/intolerance, i.e., inadequate response (IR), to 1-2 TNFi, GUS demonstrated significantly greater response rates and mean improvements in PsA signs and symptoms vs. placebo (PBO) at Week (W) 24.[3]

Objectives: Evaluate baseline (BL) serum levels of pro-inflammatory biomarkers (CRP, serum amyloid A [SAA], TNFα, IFNγ, IL-6, IL-10, IL-17F, IL-17A, IL-22) and their relationship to BL disease activity, GUS treatment (tx), and clinical response in COSMOS TNFi-IR pts.

Methods: TNFi-IR pts ≥18 yrs with active PsA (≥3 swollen & ≥3 tender joint counts [SJC/TJC]) were randomized 2:1 to GUS 100 mg every 8W (Q8W) through W44 or PBO with early escape (W16) or crossover (W24) to GUS Q8W. Samples for serum biomarker analyses, collected at W0, 4, 16, 24, and 48 from consenting pts, were compared with healthy controls (HC; independent of COSMOS). Associations between early biomarker changes and BL disease activity, GUS tx, and clinical response at W24 were assessed.

Results: Among 285 COSMOS pts, 50/95 PBO and 100/190 GUS pts had available biomarker data. BL characteristics of the biomarker cohort were similar to the overall COSMOS population and well balanced across tx arms. At BL, levels of TNFα, IFNγ, IL-6, IL-10, IL-17A, IL-17F, and IL-22 were significantly upregulated in TNFi-IR pts vs. HC (Table 1). IL-6, CRP, and SAA levels were associated with BL joint disease severity per Disease Activity Score (DAS) 28-CRP (but not with SJC [0-66]/TJC [0-68]). IL-17A and IL-17F levels were associated with BL PASI score. Through W24, significant decreases from BL in levels of CRP, SAA, IL-6, IL-17A, IL-17F, and IL-22 were seen in GUS-, but not PBO-tx pts. Reductions in IL-17A, IL-17F and IL-22 with GUS were significant by W4, decreased further by W16, and were sustained through W24 and W48. In GUS-tx pts, serum levels of IL-17F (from W16) and IL-22 (from W4) were not significantly different vs. HC. At W48, reductions in these same markers were seen in PBO-tx pts who crossed over to GUS at W16/24 (Figure 1; IL-17A, IL-17F, & IL-22 data shown). In these TNFi-IR pts, GUS-tx pts achieving ACR20 at W24 exhibited higher IL-22 and IFNγ levels at BL than nonresponders (NR). All other biomarkers evaluated were not significantly associated with ACR20 response to GUS. In the subset of pts with IGA of psoriasis assessed, BL IL-6 and SAA levels were upregulated in W24 IGA 0/1 responders (R) vs. NR in the GUS arm. ACR20 and IGA 0/1 R at W24 exhibited an early greater reduction in IL-6 expression (at W4) than did respective NR in the GUS arm. No BL biomarkers were associated with ACR50 or PASI75 responses to GUS at W24.

Table 1. Select Serum Biomarkers at BL in TNFi-IR pts vs. HC¤

Biomarker, pg/mL	HC N=24	TNFi-IR N=150	Fold difference	p-value
CRP	22.1 (1.5)	22.8 (2.2)	1.6	0.2895
SAA	21.7 (1.2)	22.8 (2.4)	2.1	0.0794
IL-6	0.07 (1.1)	0.98 (1.7)	**1.9**	**0.0314***
IL-10	-2.3 (1.1)	-1.7 (1.0)	**1.5**	**0.0272***
IL-17A	-2.1 (1.3)	-0.3 (1.5)	**3.3**	**<0.0001***

TNFα	0.5 (0.75)	1.4 (1.1)	**1.8**	**0.0002***
IFNγ	2.4 (0.84)	2.9 (1.3)	**1.5**	**0.0259***

Data are mean (SD); *p<0.05 and |fold difference| >1.4; ¤adjusted for confounding factors age & sex.

Conclusion: GUS-tx TNFi-IR pts showed response-specific associations with BL biomarkers (IL-22, IFNγ, IL-6, and SAA). GUS resulted in decreased levels of elevated CRP, SAA, IL-6, IL-17A, IL-17F, and IL-22, while no significant change was observed with PBO tx. Reductions in these biomarkers were evident as early as W4 and approximated levels seen in HC from W16 onward (W4 for IL-22), suggesting apparent normalization of effector cytokines associated with the IL-23/Th17 axis following GUS tx.

POS0309 ARE PATIENTS' AND RHEUMATOLOGISTS' PERCEPTIONS OF THE BURDEN AND TREATMENT OF PSORIATIC ARTHRITIS ALIGNED? RESULTS FROM THE UPLIFT SURVEY

P. Richette[1], W. Tillett[2], A. Ogdie[3], A. B. Gottlieb[4], S. Jardon[5], S. Richter[5], A. Flower[5], J. Merola[6]. *[1]Hôpital Lariboisière, AP-HP, Paris, France; [2]University of Bath, Department of Pharmacy & Pharmacology, Bath, United Kingdom; [3]University of Pennsylvania, Rheumatology, Philadelphia, United States of America; [4]Icahn School of Medicine at Mount Sinai, Dermatology, New York, United States of America; [5]Amgen Inc, Medical Affairs, Thousand Oaks, United States of America; [6]Brigham and Women's Hospital, Dermatology, Boston, United States of America*

Background: Alignment of patient and clinician goals and perceptions of psoriatic arthritis (PsA) burden and treatment are important to improving disease management.

Objectives: To describe patient and rheumatologist perceptions on factors contributing to PsA severity, treatment goals, and attributes of ideal therapy.

Methods: Understanding Psoriatic Disease Leveraging Insights for Treatment (UPLIFT) was a multinational Web-based survey that included adults who reported a healthcare provider (HCP) diagnosis of PsA and/or psoriasis, as well as rheumatologists and dermatologists. This analysis focused on survey responses from patients with PsA and rheumatologists. Respondents ranked their top 3 contributing factors for PsA severity, treatment goals, and ideal attributes for therapy. Results were analyzed using the sum of scores.

Results: In all, 1256 patients with PsA and 450 rheumatologists completed the respective surveys between March and June 2020. An oligoarticular (≤4 joints involved) pattern of involvement was prevalent in 43.8% of patients (Table 1). Involvement of large joints (78.8%) was most common, followed by intermediate (69.3%) and small (51.8%) joints. Only half of patients reported seeing an HCP for PsA in the last year (Table 1). Patients and rheumatologists agreed that joint pain is a top factor contributing to disease severity; patients also ranked the impact on quality of life and type of symptoms as top factors whereas rheumatologists placed greater importance on the number of joints involved and joint erosion or deformity (Figure 1). Top treatment goals for patients were reducing joint pain and stiffness and stopping the progression of joint damage or erosion (Figure 1). Rheumatologists agreed that inhibiting progression of joint damage or erosion and reducing joint pain were among the top treatment goals, and they rated disease remission or low disease activity (LDA) as the most important goal (Figure 1). Rheumatologists identified consistent treatment goals for patients

regardless of degree of joint involvement (oligoarthritis vs polyarthritis). Patients and rheumatologists agreed that long-term safety and efficacy are key attributes of an ideal PsA therapy. The top attribute for patients was joint pain reduction, whereas achievement of remission or LDA was the top attribute identified by rheumatologists (Figure 1). Despite general alignment between patient and rheumatologist responses across metrics, 87.1% of patients reported they did not feel that their treatment goals matched those of their current HCP.

Table 1.

Characteristic	UPLIFT Global PsA Patient Subgroup N=1256
Age, mean (SD), years	42.9 (15.3)
Men, n (%)	674 (53.7)
Joint count, n (%)	
>4 joints (polyarthritis)	706 (56.2)
≤4 joints (oligoarthritis)	550 (43.8)
Seen an HCP in the past year, n (%)*	626 (49.8)
Type and location of practice, n (%)	**UPLIFT Rheumatologists N=450**
Single or solo specialty	267 (59.3)
Multi-specialty	183 (40.7)
Canada	41 (9.1)
France	53 (11.8)
Germany	50 (11.1)
Italy	54 (12.0)
Japan	50 (11.1)
Spain	51 (11.3)
United Kingdom	50 (11.1)
United States	101 (22.4)

The N represents the total sample. The number of patients with data available may vary. *COVID-19 restrictions may have impacted a patient's ability to have an HCP visit from March 2 to June 3.

Conclusion: In the UPLIFT survey, patients with PsA and their rheumatologists generally agreed on the top factors contributing to disease severity, treatment goals, and attributes of ideal PsA therapy. However, the majority of patients with PsA did not feel aligned with their current HCP regarding treatment goals. Development of methods for treatment goal discussion and alignment are important to improving patient outcomes.

POS0310 DO AXIAL PSORIATIC ARTHRITIS PATIENTS MEET ASAS CLASSIFICATION CRITERIA FOR AXIAL SPONDYLOARTHRITIS?

E. Gubar[1], T. Korotaeva[1], E. Loginova[1], Y. Korsakova[1], S. Glukhova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation*

Background: There isn't any generally accepted definition and diagnostic criteria for axial psoriatic arthritis (axPsA). According to most recent data, classification criteria for axial spondyloarthritis (axSpA) may not be applied to axPsA (1).
Objectives: To analyze, in clinical practice, whether axPsA patients (pts) meet classification criteria for axSpA and ankylosing spondylitis (AS).
Methods: 52 pts (M/F–32/20), a hospital cohort, with PsA according to CASPAR criteria were observed. All pts had back pain at one time or another, which rheumatologist suspected to be axial involvement. Pts' age 43.0 [35.0; 54.0], disease duration 3.4 yrs [0.2; 32.0]. Me BASDAI 5.3 [3.6; 7.0]; ASDAS-CPБ 3.3 [2.2; 4.1]; DAPSA 36,3 [19,3; 50,5]; CRP 9.6 [0.1; 86.6] mg/L; ESR 31 [3; 99] mm/h. Enthesitis was found in 69.2% and dactylitis in 61.5% of pts. All pts had psoriasis with Me BSA (body surface area) of 4 [1; 9]%, Me PASI (Psoriasis Area Severity Index) of 9.6 [5.6; 17.4]. Nail psoriasis was found in 38 (73.1%) pts, 40.4% of them had onycholysis. All pts were evaluated for presence of inflammatory back pain (IBP) by ASAS criteria. Pts underwent sacroiliac joints (SIJ) X-ray (pelvic radiographs), cervical and lumbar spine, hands and feet X-rays, so that 50 pts had complete sets of radiographs. Radiographic sacroiliitis (rSI) was defined as bilateral grade ≥ 2 or unilateral grade ≥ 3. Pts without rSI underwent SIJ MRI on Philips Multiva 1.5 T scanner. Active MRI sacroiliitis (MRI-SI) was categorized using ASAS 2016 criteria. Radiographic spondylitis (rSp) was defined as ≥1 marginal/paramarginal syndesmophyte(s) of the cervical and/or lumbar spine. All radiographs and MRI results were interpreted by two experienced musculoskeletal radiologists. 45 pts underwent HLA B27 examination. Me [Q25; Q75] and Pierson-χ2 tests were performed. All $p<0.05$ were considered to indicate statistical significance.
Results: IBP was found in 34 (66.7%) and rSI in 30 (57.7%) pts. 15 (30.0%) pts had rSI along with rSp, while in 15 (30.0%) pts rSI was without it, and 9 (18.0%) pts had rSp alone. 2 pts of the 17 examined, had MRI-SI. HLA B27 was present in 15 (33.3%) pts examined. 37 (71.2%) pts met ASAS criteria for axSpA as follows: 22 pts met the imaging arm (rSI or MRI-SI + ≥ 1SpA feature), 5 pts met the clinical arm (HLA B27+ ≥ 2 other SpA features) and 10 pts met both of those. 10 (19.2%) pts didn't meet ASAS criteria for axSpA: they had neither rSI/MRI-SI nor HLA B27; however, 9 of them had syndesmophytes. 30 pts had rSI with 21 of them (40.4% of all pts) meeting modified New York (mNY) criteria for AS, because along with rSI, they had at least 1 of the 3 clinical criteria (IBP for > 3 months, limitation of lumbar motion in sagittal and frontal planes, limitation of chest expansion). The pts who met both CASPAR and mNY criteria, however had typical axPsA features: 85.7% of them had polyarthritis with multiple joint erosions, 61.9% had osteolysis and/or juxtaarticular new bone formation, 61.9% dactylitis, 33.3% non-marginal asymmetrical syndesmophytes, 44.4% were HLA B27 negative, 43.3% didn't have IBP; all pts developed psoriasis many years before the onset of PsA.
Conclusion: Among PsA pts with axial involvement there is an alternative phenotype group (18% of our cohort) with neither sacroiliitis (rSI/ MRI-SI) nor HLA B27. Such pts do not meet ASAS criteria for axSpA. The alternative phenotype is characterized by isolated spondylitis (syndesmophytes) without sacroiliitis. Axial disease cannot be ruled out in PsA pts without spinal radiographs, regardless of symptoms. Pts meeting both CASPAR and mNY criteria and featuring typical axPsA symptoms cannot be diagnosed as having AS along with concomitant psoriasis, because axPsA and AS with psoriasis seem to be two different diseases. There is an urgent need for a unified definition of axial involvement in PsA.

POS0311 FLARES IN PATIENTS WITH RECENT-ONSET PSORIATIC ARTHRITIS. PREDICTIVE MODEL BASED ON MACHINE LEARNING

R. Queiró Silva[1], D. Seoane-Mato[2], A. Laiz[3], E. Galíndez-Agirregoikoa[4], J. D. D. Cañete[5], J. Gratacos-Masmitja[6], X. Juanola-Roura[7], J. Fiter[8],

A. González Marcos[9]on behalf of Proyecto REAPSER Study Group.
[1]Universidad de Oviedo, Rheumatology Service & the Principality of Asturias Institute for Health Research (ISPA), Faculty of Medicine, Oviedo, Spain; [2]Spanish Society of Rheumatology, Research Unit, Madrid, Spain; [3]Hospital Universitari de la Santa Creu i Sant Pau, Rheumatology and Autoimmune Disease Department, Barcelona, Spain; [4]Hospital Universitario Basurto, Rheumatology Service, Bilbao, Spain; [5]Hospital Clinic & IDIBAPS, Arthritis Unit, Rheumatology Department, Barcelona, Spain; [6]Hospital Universitario Parc Taulí, Rheumatology Service, Sabadell, Spain; [7]Hospital Universitari Bellvitge, Rheumatology Service, Barcelona, Spain; [8]Hospital Universitario Son Espases, Rheumatology Service, Palma de Mallorca, Spain; [9]Universidad Autónoma de Madrid, Knowledge Engineering Institute, Madrid, Spain

Background: An important aspect in the clinical care of patients with PsA is to be able to predict the occurrence of a flare using tools and information that are readily available in daily clinical practice. This information would provide added value in disease management, yet, unfortunately, scarcely any studies provide it.
Objectives: To identify patient- and disease-related characteristics that make it possible to predict flares in recent-onset PsA.
Methods: We performed a multicenter observational prospective study (2-year follow-up, regular annual visits), promoted by the Spanish Society of Rheumatology [1]. The study population comprised patients aged ≥18 years who fulfilled the CASPAR criteria [2], with less than 2 years since the onset of symptoms. The intention at the baseline visit was to reflect the patient's situation before disease progress was modified by the treatments prescribed in the rheumatology department.
All patients gave their informed consent. The study was approved by the Clinical Research Ethics Committee of the Principality of Asturias.
Flares were defined as inflammatory episodes affecting the axial skeleton and/or peripheral joints (joints, digits or entheses) and diagnosed by a rheumatologist between the previous and the current visit.
The dataset contained data for the independent variables from the baseline visit and from follow-up visit number 1. These were matched with the outcome measures from follow-up visits 1 and 2, respectively. We trained logistic regression models and a random forest–type machine learning algorithm to analyze the association between the outcome measure and the variables selected in the bivariate analysis (statistical significance was defined as p value <0.05). We used a confusion matrix to visualize the performance of the final model. This matrix shows the real class of the data items, together with the class predicted by the machine learning algorithm, and records the number of hits and misses.
Results: The sample comprised 158 patients. 14.6% were lost to follow-up. At the first follow-up visit, 37.6% of the patients who attended the clinic had experienced flares since the baseline visit. Of those who attended the second visit, 27.4% had experienced flares since the first visit. Table 1 shows the results of the logistic regression analysis. The variables predicting flares between visits selected in this analysis were age-adjusted Charlson comorbidity index, PsAID score, number of digits with onychopathy, and level of physical activity. The direction of the association was negative for the Charlson index and physical activity and positive for PsAID score and onychopathy.

Table 1. Variables associated with flares between visits selected in the logistic regression analysis.

Variable	Regression coefficient	95% CI	p value (Wald test)
Age-adjusted Charlson comorbidity Index	-4.655	(-7.021, -2.289)	<0.001
PsAID score	2.212	(1.171, 3.254)	<0.001
No. of digits with onychopathy	1.420	(0.331, 2.511)	0.011
Level of physical activity	-1.221	(-1.87, -0.572)	<0.001

When the random forest machine learning algorithm was trained with these 4 variables, the order of importance (from more to less) attributed by the model was as follows: PsAID score, number of digits with onychopathy, age-adjusted Charlson comorbidity index, and level of physical activity. The percentage of hits in the confusion matrix was 78.38%.
Conclusion: PsAID score was the first variable in the predictive hierarchy generated in our model, supporting its importance in the management and follow-up of PsA patients.

POS0312 REAL-WORLD EVIDENCE ON ASSESSING PSORIATIC ARTHRITIS BY DISEASE DOMAIN: AN EVALUATION OF THE COREVITAS PSORIATIC ARTHRITIS/ SPONDYLOARTHRITIS REGISTRY

P. J. Mease[1], T. Blachley[2], J. O'brien[2], N. Middaugh[2], G. Kricorian[3], S. Stryker[3], D. Collier[3], A. Ogdie[4]. *[1]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Rheumatology, Seattle, United States of America; [2]CorEvitas, LLC, Research, Waltham, United States of America; [3]Amgen Inc., Research, Thousand Oaks, United States of America; [4]University of Pennsylvania, Rheumatology, Philadelphia, United States of America*

Background: Psoriatic arthritis (PsA) is a burdensome, chronic disease that can impact patient functionality and quality of life. Real-world data are limited regarding the most common disease domain combinations in patients with PsA receiving biologic disease-modifying anti-rheumatic drugs.
Objectives: The objective of this study was to describe PsA disease domain frequency, the most common disease domain combinations of PsA manifestations, and pairwise disease domain prevalence in patients initiating treatment with tumor necrosis factor inhibitors (TNFis) or interleukin-17 (IL-17) inhibitors.
Methods: The CorEvitas PsA/Spondyloarthritis (SpA) Registry is a prospective, observational registry for patients with PsA or SpA under the care of a rheumatologist. The current analysis included adults with PsA who initiated treatment with a TNFi (adalimumab, etanercept, certolizumab pegol, infliximab, golimumab), etanercept (ETN; independent exploratory evaluation as a subset of the TNFi group), or an IL-17 inhibitor (ixekizumab, secukinumab) from January 2013 through December 2020. Baseline disease characteristics among the total population and by therapy group were examined for 6 PsA domains, including enthesitis (ET), dactylitis (DA), peripheral arthritis (PA), nail psoriasis (NP), axial PsA (AX), and skin disease (SD). The top 5 most common domain combinations and frequency of other concomitant disease domains within each domain subpopulation are presented.
Results: Among 1005 patients initiating treatment for PsA (mean age, 52.9 years; 57% female, 90% white), the prevalence of disease domains was PA (86%), SD (82%), NP (57%), ET (38%), DA (23%), and AX (20%); these proportions were similar among the therapy groups. The frequency of high skin disease (body surface area [BSA] ≥10%) at baseline was highest in IL-17 initiators (23% vs 16% for TNFi and 9% for ETN). TNFi (40%) and ETN (48%) were more frequently observed as first-line therapy compared with IL-17 inhibitors (14%). The most common disease domain combination overall (14%) was PA, NP, and SD; frequency of the top 3 most common domain combinations were similar among therapy groups (Table 1). Overall, PA and SD were the most common concomitant disease domains observed within each PsA disease domain subpopulation (Figure 1). Results were similar by therapy group (data not shown).

Table 1. Most common PsA domain combinations overall and by therapy

Domain Combination Ranking by Frequency, n (%)	Overall (N=1005)	TNFi[a] (n=631)	ETN (n=112)	IL-17 (n=374)
#1	PA, NP, SD 138 (14)	PA, NP, SD 91 (14)	PA, SD 17 (15)	PA, NP, SD 47 (13)
#2	PA, SD 122 (12)	PA, SD 84 (13)	ET, PA, NP, SD 13 (12)	ET, PA, NP, SD 41 (11)
#3	ET, PA, NP, SD 95 (9)	ET, PA, NP, SD 54 (9)	PA, NP, SD 12 (11)	PA, SD 38 (10)
#4	ET, PA, SD 64 (6)	DA, PA, NP, SD 38 (6)	SD 7 (6)	ET, PA, SD 33 (9)
#5	DA, PA, NP, SD 61 (6)	ET, PA, SD 31 (5)	ET, PA, NP, AX, SD 6 (5)	ET, PA, NP, AX, SD 24 (6)

Matching domain combinations are shaded across each therapy group.ET, enthesitis; DA, dactylitis; PA, peripheral arthritis; NP, nail psoriasis; AX, axial PsA; SD, skin disease; TNFi, tumor necrosis factor inhibitors; ETN, etanercept; IL-17, interleukin-17 inhibitors.[a]TNFi includes ETN initiators.

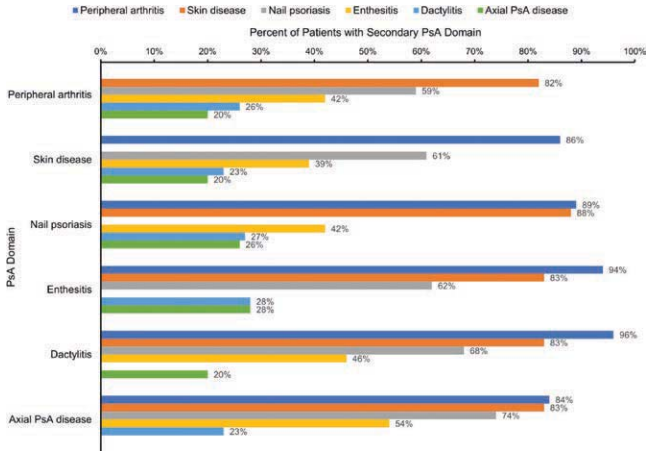

Figure 1.

Conclusion: The most common disease domains and domain combinations were similar among initiators of TNFis, ETN, and IL-17s. IL-17 initiators had high skin disease (BSA ≥10%) more often and initiated as first-line therapy less frequently than TNFi initiators. Assessing all PsA domains is important for optimal disease management.

POS0313 THE ASSOCIATION BETWEEN BODY COMPOSITION AND PHYSICAL ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS: THE TRØNDELAG HEALTH STUDY

A. A. Osman[1], M. Hoff[2,3], V. Videm[1,4]. *[1]Norwegian University of Science and Technology's, Department of Clinical and Molecular Medicine, Trondheim, Norway; [2]Norwegian University of Science and Technology's, Department of Neuromedicine and Movement Science, Trondheim, Norway; [3]St. Olav's University Hospital, Department of Rheumatology, Trondheim, Norway; [4]St. Olav's University Hospital, Department of Immunology and Transfusion Medicine, Trondheim, Norway*

Background: Persons with psoriatic arthritis (PsA) have an altered body composition compared to the general population, including overweight, which may increase the risk of several comorbidities. However, the associations of physical activity (PA) with body composition among persons with PsA is not well described.

Objectives: The aim of the study was to investigate the relationship between visceral fat mass (VFM) and percentage body fat (PBF), respectively, with PA in persons with PsA.

Methods: The study utilized data from the population-based Trøndelag Health Study (HUNT4, 2017-2019), where all inhabitants ≥ 20 years of age in northern Trøndelag were invited. Data comprised questionnaires, measurements, and blood sample analyses. Persons with PsA (n=291, CASPAR criteria) were identified from hospital case notes. The remaining participants with complete data for relevant variables (n=38 955) were used as controls.

Body composition was measured using bioelectrical bioimpedance including 30 values for 5 body segments. The primary outcomes were VFM (Model 1) and PBF (Model 2). PA was quantified using an index based on self-reported frequency, duration, and intensity (1), and categorized as low, moderate, or high.

Data were analyzed with multivariable linear regression including PsA and PA as exposures. The models were adjusted for age (<40, 40-59 >60 years), sex, alcohol consumption (once a week/more vs. less/none), smoking status (present/former vs. never smoker), diabetes, hypertension, heart disease, lung disease and cancer; and height (Model 1 only). To achieve appropriate model fit, an interaction term between age and PsA was included.

Results: Persons with PsA had higher weight, body mass index, VFM and PBF than controls, and they were less physically active (Table 1). The interaction term between PsA and age was statistically significant in both models (p<0.05), showing that the difference in VFM and PBF with PsA compared to controls was relatively larger in persons < 40 years (VMF difference: 3.6kg (95% CI 1.4, 5.9 kg) vs. ~1.1 kg in older age groups, PBF difference: 5.2% (1.9, 8.5%) vs. ~1.5% in older age groups).

Table 1. Demographic and clinical characteristics

Variable	PsA (n=291)	Controls (n=38 955)	p-value
Age (years), mean (±SD)	58 (12)	53 (17)	p<0.001
Male, n (%)	174 (59.8)	21 875 (56.2)	p =0.21
Diabetes, n (%)	28 (9.7)	1 876 (4.8)	p<0.001
Cardiovascular disease, n (%)	11 (3.8)	1 349 (3.5)	p=0.77
Lung disease, n (%)	45 (15.5)	4 904 (12.6)	p=0.14
Cancer, n (%)	29 (10.0)	2 746 (7.1)	p=0.053
Alcohol (once a week/more), n (%)	71 (24.4)	8 234 (21.1)	p=0.18
Smoking (present/former), n (%)	208 (71.5)	20 915 (53.7)	p<0.001
Education (college or higher), n (%)	164 (56.4)	25 166 (64.6)	p=0.003
Height (cm), mean (±SD)	171 (9.1)	171 (9.2)	p=0.31
Weight (kg), mean (±SD)	83 (16.5)	79 (15.7)	p<0.001
Body mass index (kg/m^2), mean (±SD)	28.3 (4.7)	26.9 (4.5)	p<0.001
Percentage body fat, mean (±SD)	33.7 (8.8)	30.5(9.3)	p<0.001
Visceral fat mass (kg), mean (±SD)	13.5 (5.5)	11.4 (5.4)	p<0.001
Physical activity			p=0.004
Low	139 (47.8)	16 648 (42.8)	
Moderate	104 (35.7)	14 491 (37.2)	
High	48 (16.5)	7 816 (20.1)	

The associations between PA and VFM or PBF were similar with and without PsA. In Model 1 (R^2=0.17), moderate or high physical activity was significantly associated with lower VFM. The moderate activity group had 0.8 kg (0.7, 0.9 kg, p<0.001) and the high activity group had 2.6 kg (2.5, 2.7, p<0.001) lower VFM compared to the low physical activity group. In Model 2 (R^2=0.38), moderate or high physical activity was significantly associated with lower PBF. The moderate activity group had 1.4% (1.2, 1.5%, p<0.001) and the high activity group had 4.3% (4.1, 4.5%, p<0.001) lower PBF compared to the low physical activity group.

Conclusion: Patients with PsA had increased PBF and VFM, and moderate or high physical activity was associated with significant reductions in both endpoints. Physical activity may reduce the comorbidity burden among persons with PsA and should be a focus in clinical treatment plans.

Rheumatology, Rheuma-Zentrum Wien-Oberlaa, Vienna, Austria; [3]Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [4]Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany; [5]TAmiRNA, GmbH, Vienna, Austria; [6]Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Departement of Dermatology, Erlangen, Austria

Background: MicroRNAs (miRNAs) are small non-coding RNAs that control gene expression. Specific miRNA signatures have been identified in numerous diseases and may serve as potential biomarkers or new drug targets. Whether certain miRNA signatures are associated with psoriatic joint disease is currently unknown.
Objectives: To search for circulating miRNA signatures in psoriasis patients with subclinical joint disease and in patients with psoriatic arthritis (PsA).
Methods: Analyses of serum miRNA were done in three groups: (1) PsA patients fulfilling CASPAR criteria (PsA), (2) healthy controls without past or present signs of musculoskeletal disease (HC) and (3) psoriasis patients with musculoskeletal pain but no signs of clinical PsA (PsO). PsO and PsA patients received a hand MRI, which was scored according to PsAMRIS method. miRNA analysis of serum samples was performed stepwise using RT-qPCR (TAmiRNA Vienna). In the discovery phase 192 miRNA assays were analyzed in 48 samples (N=16 each group). In the validation phase 17 miRNAs (Table 1) were selected and analyzed in 94 samples (N=35 PsA, N=24 PsO, N=35 HC) based on results of discovery phase and previous reports in literature. Results presented as mean±SD/median (IQR), p-values are adjusted for multiple testing.
Results: 51 PsA patients (age: 51.3±11.4 years; 56.9% females), 40 PsO patients (51.4±11.0; 37.5%) and 50 HC (51.0±10.5; 52.9%) were assessed. Duration of psoriasis was 12(25) years in PsA and 15(22.8) years in PsO. Duration of joint disease in PsA was 1.0(4.8) year. 51% of PsA and 5% of PsO patients were on biological disease modifying drugs (bDMARDs), 49% vs. 10% on conventional DMARDs. The most frequent findings in the MRI were erosions (PsA 59.6%; PsO 40%) and synovitis (PsA 48.9%; PsO 42.5%). PsA patients had higher number of tenosynovitis compared to PsO (p=0.04). In discovery phase 51 miRNAs in PsO and 64 miRNAs in PsA were down- or upregulated compared to HC, with an overlap of 33 miRNAs changed in PsA and PsO (p<0.05). Results of the selected 17 miRNAs are presented in Table 1. The top candidates to differentiate PsA and HC were miR-29b-3p (AUC=0.87), miR-93-5p (AUC=0.83) and let-7b-5p (AUC=0.79). For differentiating PsO and HC, they were miR-29b-3p (AUC=0.82), miR-140-3p (AUC=0.81) and miR-19b-3p (AUC=0.80) and for PsO vs. PsA miR-92a-3p (AUC=0.87), let-7b-5p (AUC=0.72) and miR-21-5p (AUC=0.70). miR-93-5p was lower in patients with erosions (p=0.01). miR-92a-3p, let-7b-5p and miR-21-5p were lower in patients with tenosynovitis, bone proliferations or erosions.
Conclusion: PsA and PsO patients show miRNA signatures different from HC. Top candidate miRNAs differentially regulated in PsA and PsO have been previously reported in alteration of bone metabolism and osteoarthritis indicating the intimate association of psoriatic inflammation with bone and cartilage changes.

POS0315 DIAGNOSTIC PERFORMANCE OF CASPAR CRITERIA FOR PSORIATIC ARTHRITIS WITH OR WITHOUT INTEGRATION OF ULTRASOUND

Y. Geng[1], Z. Song[1], X. Zhang[1], X. Deng[1], Y. Wang[1], Z. Zhang[1]. *[1]Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Although the CASPAR criteria in the diagnosis of psoriatic arthritis (PsA) have been validated, CASPAR based on physical examination (PE) is not "gold standard". The ultrasound (US) could improve the diagnostic accuracy as compared to clinical examination alone.
Objectives: To evaluate the diagnostic performance of CASPAR criteria for psoriatic arthritis (PsA) with or without integration of ultrasound (US).
Methods: The patients with hint of PsA were enrolled. Tender and swollen joint counts, presents of enthesitis and dactylitis were collected by physical examination (PE). US was performed to evaluate peripheral joints, entheses and tendons. The additional value of US to CASPAR criteria were analysed.
Results: 326 consecutive patients were enrolled, with 164 PsA and 162 non-PsA. Significantly higher frequencies of tenosynovitis and enthesitis on US and new bone formation on X-ray were found in PsA than non-PsA patients (56.7% vs. 13.0%; 62.2% vs. 14.2%; 62.2% *vs*. 8.0%, $p<0.01$ for all). Logistic regression analysis showed that dactylitis (OR=12.0, $p<0.01$), family history of PsO/PsA (OR=3.1, $p<0.05$), nail involvement (OR=3.5, $p=0.01$), new bone formation (OR=14.8, $p<0.01$) and tenosynovitis on US (OR=21.3, $p<0.01$), enthesitis on US (OR=21.7, $p<0.01$) were independent risk factors for PsA. Adding US tenosynovitis and/or enthesitis to CASPAR criteria showed better performance by improving the specificity (91.4% *vs.* 67.9%) and meanwhile keeping sensitivity (92.1% *vs.* 96.3%). When replacing hand X-ray by US in CASPAR criteria, the sensitivity and specificity were comparable to CASPAR criteria adding with US. The diagnostic accuracy was 82.2% for CASPAR criteria based on PE, 91.7% for CASPAR integrated with US, and 91.4% for CASPAR with US to replace X-ray.
Conclusion: CASPAR criteria based on US improve the diagnosis utility of PsA than CASPAR criteria based on PE. US assessment is valuable in the diagnosis of PsA.

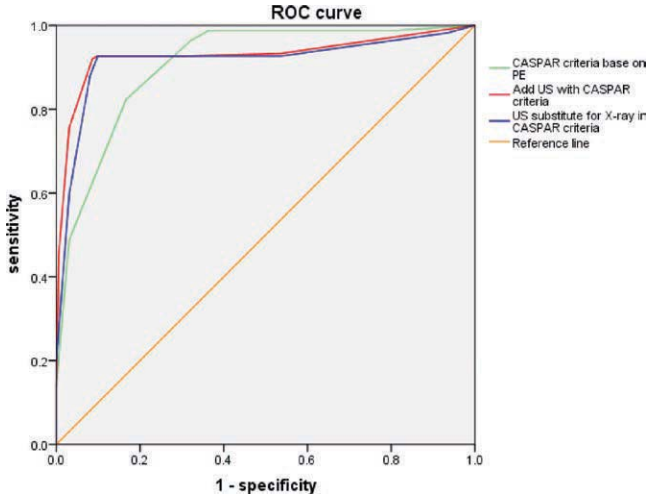

Figure 1. ROC curves for adding US or substituting X-ray by US in CASPAR criteria. Receiver operating characteristic (ROC) curve illustrates the diagnosis performance of CASPAR criteria adding US or substituting X-ray by US in CASPAR criteria and CASPAR criteria based on PE alone. The area under the curve of the ROC curve (AUC) was 0.929 (95%CI 0.897, 0.961) (p<0.01) for adding US to CASPAR criteria. AUC was 0.908 (95%CI 0.876, 0.940) (p<0.01) for CASPAR criteria based on PE. And AUC was 0.916 (95%CI 0.880, 0.951) (p<0.01) for substituting X-ray by US in CASPAR criteria. CASPAR: ClASsification criteria for Psoriatic ARthritis; PE: physical examination; US: ultrasound.

Gemelli IRCCS - Rome, Rome, Italy; [4]Department of Medicine, Università Cattolica del Sacro Cuore - Rome, Rome, Italy; [5]Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli IRCCS - Rome, Rome, Italy; [6]Division of Clinical Immunology, Fondazione Policlinico Universitario A. Gemelli IRCCS - Rome, Rome, Italy*

Background: Ultrasound (US)-guided minimally invasive Synovial Tissue (ST) biopsy serves as a safe and well tolerated procedure for basic and translational research on chronic inflammatory joint disease.
Objectives: (i) to assess the diagnostic value of the Krenn score (KSS) on ST samples obtained from US-guided biopsies in a large bio-samples dataset of patients with Psoriatic Arthritis (PsA) across different disease phases; (ii) to develop a multiparametric nomogram integrating clinical and histological characteristics enabling treatment response prediction in naïve to treatment PsA.
Methods: 410 patients fulfilling the CASPAR criteria for PsA who underwent US-guided ST biopsy were enrolled. At baseline, patients were categorized based on their disease phase and treatment: n=207 naïve to DMARDs; n=101 resistant to c-DMARDs; n=48 resistant to b-DMARDs and n=54 in sustained clinical and ultrasound remission or in low disease activity (LDA) state (DAPSA ≤ 4 or among 4-14, respectively). Clinical, demographic, and immunological characteristics were recorded for each patient. All ST specimens were stained with H&E and classified by a pathologist, blinded to clinical characteristics, using the Krenn score to assess ST inflammation degree (1) implemented with the determination of lymphocytes, plasma cells, granulocytes and tissue oedema presence. Each naive to treatment PsA was treated according to the EULAR recommendations (2) and DAPSA remission rate at 6 months was recorded.
Results: Considering the whole enrolled cohort, the distribution of KSS was significantly different among patients across the different PsA phases (ANOVA p<0.001). In particular, among the different phases, KSS was significantly higher in b-DMARDs resistant (p<0.0001) and c-DMARDs resistant (p<0.0001) compared to remission/LDA disease patients as well as naive to treatment PsA (p<0.0001). Interestingly, regardless to the disease phase, KSS of the biopsied joint directly correlated to disease activity in terms of DAPSA (r=0.476, p<0.001) and DAS28 scores (r=0.476, p<0.001). Considering the naïve to treatment PsA cohort, patients achieving DAPSA defined-LDA/remission had, before treatment, significantly lower KSS (p<0.001), lower rate of ST plasmacells presence (p<0.001) and shorter symptoms duration (p=0.01) as compared to naïve to treatment PsA not achieving this clinical outcome. Moreover, considering distinct clinical phenotype domains, naive to treatment PsA patients with concomitant dactylitis and skin disease were less likely to achieve DAPSA LDA/remission (p<0.001), regardless of treatment scheme. On logistic regression, at baseline, having a KSS <5 [OR: 5.30 (95%CI:2.21-12.74) p<0.001], absence of plasma cells ST infiltrate [OR: 3.87 (2.11-7.10 95%CI) p<0.001], concomitant dactylitis [OR: 2.55 (95%CI:1.24-5.25) p=0.01] and skin involvement [OR: 2.06 (95%CI:1.17-3.62) p=0.01] were independent factors associated with DAPSA score-LDA/remission achievement at 6 months. Finally, a multiparametric nomogram integrating baseline clinical and histological characteristics of naïve PsA enabling to predict up to 75% of probability to achieve DAPSA remission at 6 months was developed.
Conclusion: KSS is a reliable tool for synovitis assessment in PsA, being contingent on disease phases, related to disease burden and included within a treatment response predictive multiparametric nomogram in naïve PsA.

Mortality, Co-morbidity and disease burden

POS0317

WORLD MORTALITY OF SPONDYLOARTHRITIS AND INFLAMMATORY BOWEL DISEASES IN 2015 AND ITS EVOLUTION BETWEEN 2001 AND 2015

O. Fakih1, C. Prati[1,2], D. Wendling[1,3], F. Verhoeven[1,2]. *[1]Centre Hospitalier Régional Universitaire de Besançon, Rheumatology, Besançon, France; [2]UFR Santé, Université de Franche-Comté, EA 4267 'PEPITE', Besançon, France; [3]UFR Santé, Université de Franche-Comté, EA 4266 'EPILAB', Besançon, France*

Background: There is little epidemiological data on mortality in spondyloarthritis (SpA).
Objectives: To determine countries' mortality rates of ankylosing spondylitis (AS) and psoriatic arthritis (PsA), as well as chronic inflammatory bowel diseases (IBDs), which are physiologically related to SpA, and to describe their evolution between 2001 and 2015.
Methods: We used mortality data from the World Health Organisation (WHO), freely available on its website, which shows the number of deaths classified by age, sex, and cause of death coded by ICD-10. The code M45 was used for AS, L405 for PsA, K50 for Crohn's disease (CD), and K51 for ulcerative colitis (UC). Age-standardized mortality rates (ASMR) were constructed using the 2015 WHO reference population and are expressed as deaths per million inhabitants. Temporal trend analyses of ASMR were performed between 2001 and 2015, considering only countries with up to 3 years of missing data, using joinpoint regression.
Results: In 2015, the global ASMR of AS was 0.13 (0.11-0.14), ranging from 0.02 in Japan to 2.00 in Iceland (Figure 1A). The ASMR was 0.20 (0.18-0.23) for men and 0.07 (0.06-0.09) for women (p<0.0001). The trend analysis did not show any significant variation between 2001 and 2015. The ASMR in Europe (0.17 (0.15-0.20)) was significantly higher than in North America (0.12 (0.09-0.14)) (p=0.008), South America (0.09 (0.06-0.12)) (p=0.0001) and Asia (0.08 (0.05-0.10)) (p<0.0001).

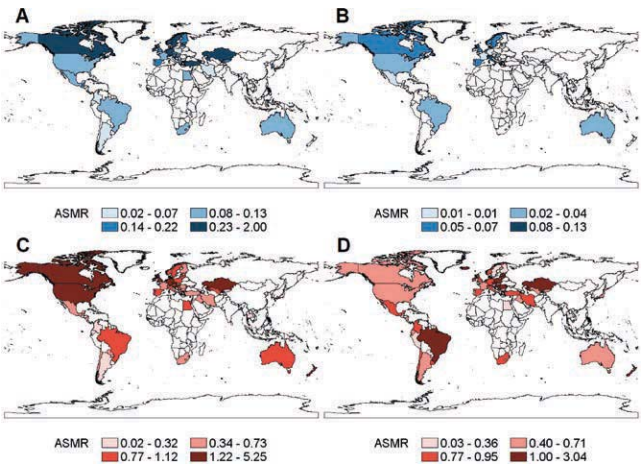

Figure 1. 2015 ASMR by country for ankylosing spondylitis (A), psoriatic arthritis (B), Crohn's disease (C) and ulcerative colitis (D).

For PsA, the global ASMR in 2015 was 0.04 (0.03-0.05), ranging from 0.01 in Mexico to 0.13 in Greece (Figure 1B). The ASMR was 0.06 (0.04-0.07) for men and 0.03 (0.02-0.04) for women (p=0.01). The trend analysis showed a significant increase from 2004 to 2015 with a mean annual percent change (APC) of 5.94% (p=0.02). The ASMR in Europe (0.05 (0.03-0.06)) was significantly higher than in South America (0.02 (0.00-0.03)) (p=0.02).

For CD, the global ASMR in 2015 was 0.86 (0.82-0.89), ranging from 0.02 in Thailand to 5.25 in Luxembourg (Figure 1C). The ASMR was 0.41 (0.38-0.43) for men and 0.38 (0.36-0.41) for women (p=0.17). The trend analysis showed a significant decrease from 2001 to 2015 with a mean APC of -0.82% (p=0.048). The ASMR in Europe (1.12 (1.05-1.19)) was significantly lower than in North America (1.31 (1.21-1.41)) (p=0.001), but significantly higher than in Latin America (0.57 (0.51-0.64)) (p<0.0001) and Asia (0.27 (0.23-0.32)) (p<0.0001).

For UC, the global ASMR in 2015 was 0.76 (0.73-0.79), ranging from 0.03 in Thailand to 5.48 in Saint Lucia (Figure 1D). The ASMR was 0.37 (0.35-0.39) for men and 0.23 (0.21-0.24) for women (p<0.0001). The trend analysis showed a significant decrease from 2001 to 2015 with a mean APC of -1.29% (p=0.01). The ASMR in Europe (1.00 (0.93-1.06)) was significantly higher than in North America (0.64 (0.57-0.71)) (p<0.0001), Africa (0.57 (0.41-0.72)) (p<0.0001), South America (0.84 (0.76-0.91)) (p=0.003)), Asia (0.47 (0.93-1.06)) and Oceania (0.58 (0.38-0.79)) (p=0.003).

Conclusion: ASMR for IBD are higher than those for SpA and are decreasing over time, in contrast to SpA where they remain essentially stable. There are geographical disparities which must be interpreted with caution due to the declarative nature of the data.

POS0318 CHRONIC WIDESPREAD PAIN AND MORTALITY - A 25 YEAR FOLLOW UP

A. J. Dahlqvist[1,2], M. Andersson[1,3], S. Bergman[1,2,3]. *[1]Spenshult Research and Development Center, NA, Halmstad, Sweden; [2]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Primary Health Care/ Department of Public Health and Community Medicine, Gothenburg, Sweden; [3]Faculty of Medicine, Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden*

Background: Chronic widespread pain (CWP) has been suggested as a risk for mortality in especially cardiovascular diseases and malignancies (1, 2). Most studies are based on the CWP definition that is part of ACR1990 criteria for fibromyalgia (3). The ACR1990 definition has been criticized for being too including, and recently a more stringent definition, the WP2019, has been suggested (4). It is yet to be investigated how the more stringent WP2019 definition compares to the ACR1990 definition regarding excessed mortality and certain causes of death.

Objectives: To study if overall mortality and common causes of death are increased among people with CWP in a 25 year follow up of a cohort from the general population. Additionally, to study if the definition of CWP, according to ACR1990 or WP2019, influences these outcomes.

Methods: A 25-year follow up of the EPIPAIN cohort study that in 1995 included 2425 person from the general population (5). They were at baseline divided into three pain groups: CWP, chronic regional pain (CRP) and no chronic pain (NCP). CWP was defined according to both the ACR1990 ($CWP_{ACR1990}$) and the more stringent WP2019 (CWP_{WP2019}) criteria. Deaths and causes of death were derived from the official national Swedish register. Mortality, adjusted for age, sex, socioeconomic status, and smoking habits, was analyzed with Cox regression and presented as Hazard Ratios (HR).

Results: An overall increased mortality was predicted by CWP_{WP2019} (HR 1.32, p = 0.033), but not by $CWP_{ACR1990}$ (HR 1.08, p = 0.484), compared to NCP. An increased mortality in diseases of the circulatory system was predicted by CWP_{WP2019} (HR 1.70, p= 0.016), but not by $CWP_{ACR1990}$ (HR 1.35, p=0.128). Neither definition of CWP, CWP_{WP2019} (HR 1.35, p= 0.176) or $CWP_{ACR1990}$ (HR 1.21, p=0.327) predicted a significantly increased mortality for neoplastic diseases overall.

Conclusion: The WP2019 definition of CWP enhanced the association between CWP and increased mortality, and especially mortality in diseases of the circulatory system. This suggests that the CWP_{WP2019} definition captures a more vulnerable subset of the population that should be assessed for other cardiovascular risk factors in the clinic.

POS0319 DISEASE BURDEN OF PRIMARY SJOGREN SYNDROME: A RETROSPECTIVE UNITED STATES CLAIMS DATABASE STUDY

L. Kalouche-Khalil[1], R. Gandhi[2], L. Hao[3], E. Smolkina[4], F. Schumacher[5]. *[1]Sanofi Genzyme, MS Global Medical Affairs, Paris, France; [2]Sanofi Genzyme, MS Medical Affairs, Cambridge, United States of America; [3]Sanofi, GenMed RWE, Bridgewater, United States of America; [4]Sanofi, Gobal HEVA Neuro Immunology, Amsterdam, Netherlands; [5]Sanofi, Translational Medicine and Clinical Pharmacy, Frankfurt, Germany*

Background: Primary Sjögren's syndrome (pSjS) is a chronic and complex systemic autoimmune disease, primarily characterised by inflammation and progressive destruction of the exocrine glands (ie, autoimmune epithelitis) [1].

Objectives: We evaluated disease progression, treatment patterns, mortality, and healthcare resource utilization (HCRU) of pSjS patients in the United States (US) to understand the real-world experiences of patients with pSjS.

Methods: This retrospective cohort study utilised data from US Optum Clinformatics claims between 01 May 2000 and 31 December 2020. The study included pSjS patient cohort and general population cohort, matched (1:1) on age, sex, and index date. Baseline period of 365 days prior to the index date was used for assessment of baseline comorbidities. Descriptive statistics were used to describe baseline characteristics, HCRU, and treatment pattern while multivariable models were used to assess hazard ratios (HRs) and risk factors.

Results: Overall, 23,168 patients with pSjS (ICD-9 710.2 Sicca syndrome and ICD-10 M 35.0 Sjogren Syndrome and excluding patients with Rheumatoid arthritis [RA], Systemic sclerosis [SS] and Systemic lupus erythematosus [SLE] diagnoses codes) were included in the cohort (mean [SD] age: 61.5 [15.3] years; females: 85%). At baseline, 79.4% and 8.2% of pSjS patients had systemic complications and organ-specific autoimmune comorbidities, respectively. In a subset of the cohort including patients with at least 5 years of follow-up, by the end of 5 years 96.8% and 16.5% of patients developed systemic complications and organ-specific autoimmune comorbidities, respectively (Table 1). The most frequently occurring organ-specific autoimmune comorbidities over the 5-year follow-up included Graves disease (5.4%), Hashimoto disease (3.7%), and discoid/ subacute cutaneous lupus erythematosus (3.5%). Mortality was reported in 7.4% of the patients during 5-year follow-up. Risk factors associated with higher mortality included systemic complications in renal (HR [95% CI]: 2.29 [2.09–2.52]), cardiovascular (HR [95% CI]: 2.42 [2.19–2.67]), lungs (HR [95% CI]: 3.73 [3.41–4.09]) and haematological domains (HR [95% CI]: 2.83 [2.56–3.13]), non-Hodgkin's lymphoma (HR [95% CI]: 2.58 [2.12–3.14]), and primary biliary cirrhosis (HR [95% CI]: 2.17 [1.60–2.96]). Corticosteroids (28.2%), hydroxychloroquine (15.7%), and cyclosporine (10.9%) were most frequently used medications. During the year following the first pSjS diagnosis, defined as the first claim with the Sjogren Syndrome ICD code (index date), the mean all-cause healthcare costs have increased by 27% from $21,634 to $27,526 per patient per year.

Table 1. Occurrence of systemic complications and organ-specific autoimmune comorbidities over follow-up of 5 years

Variable, n (%)	Baseline (N=6000)	Within 5 years (N=6000)
Any systemic complication	**4,555 (75.9%)**	**5,806 (96.8%)**
Articular involvement	3,176 (52.9%)	5,026 (83.8%)
Renal involvement	352 (5.9%)	1,185 (19.8%)
Cardiovascular complications	342 (5.7%)	826 (13.8%)
Muscles	1,390 (23.2%)	2,732 (45.5%)
Pancreatic	31 (0.5%)	88 (1.5%)
Lungs	373 (6.2%)	1,383 (23.1%)
Peripheral nervous system	766 (12.8%)	2,109 (35.2%)
Haematological	1,016 (16.9%)	2,507 (41.8%)
Glandular	542 (9.0%)	2,274 (37.9%)
Central nervous system	212 (3.5%)	556 (9.3%)
Biological	153 (2.6%)	408 (6.8%)
Skin	517 (8.6%)	1,327 (22.1%)
Lymphadenopathy	374 (6.2%	959 (16.0%)
Non-Hodgkin's lymphoma	59 (1.0%)	131 (2.2%)
Any organ-specific autoimmune disease	**464 (7.7%)**	**992 (16.5%)**

Conclusion: These results provide additional evidence that pSjS is associated with substantial morbidity and clinical burden supporting the need for safe and efficacious disease modifying treatment options in this patient population.

POS0320 EPIDEMIOLOGY AND HEALTHCARE RESOURCE UTILIZATION OF PATIENTS WITH EGPA IN THE UNITED KINGDOM

J. Hwee[1], Q. Fu[2], L. Harper[3], K. Nirantharakumar[3], R. Goel[3], R. Jakes[4]. *[1]GSK, Value Evidence Outcomes, Mississauga, Canada; [2]GSK, Value Evidence Outcomes, Collegeville, United States of America; [3]University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom; [4]GSK, Epidemiology, London, United Kingdom*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by eosinophilic inflammation of small with or without medium arteries. EGPA is a rare disease with varying prevalence and incidence rates globally. To date, limited information is available on the prevalence, incidence and burden of disease in the United Kingdom (UK).

Objectives: The objectives were to estimate the prevalence and incidence of EGPA, and to describe the healthcare resource utilization (HCRU) among patients with EGPA in the UK.

Methods: This retrospective database study used the UK-based Clinical Practice Research Datalink (CPRD)-AURUM database linked to the Hospital Episode Statistics (HES). Prevalence was estimated from 2005 to 2019, and incidence was estimated from 2006 to 2019. HCRU was assessed in the 12-months following the first recorded diagnosis of EGPA (index date), and included hospitalizations, emergency room visits, procedures, outpatient specialist visits, primary care visits, and oral corticosteroid use.

Results: 764 people were identified with EGPA in the UK. The prevalence of EGPA, reported in the database, increased from 22.7 to 45.6 per 1,000,000 persons from 2005 to 2019 (Figure 1), whereas the incidence of EGPA from 2006 to 2019 ranged from 2.28 to 4.00 per 1,000,000 person-years. 377 patients with EGPA were successfully linked to the CPRD-HES database. Patient characteristics were as follows: mean age (SD) was 57 years (14.2); 49% were male; 81% had asthma; and 11% had peripheral neuropathy prior to the index date. For patients with EGPA, 19% had an EGPA-related hospitalization and 50% had any-cause hospitalization within 1 year of the index date (Table 1). The mean length of stay was, 18 days and 16 days for EGPA-related and any-cause hospitalizations, respectively. 52% of patients with EGPA had undergone a medical procedure, 89% of patients with EGPA had an outpatient visit to a specialist. Almost all patients with EGPA visited a general practitioner within 1 year of their EGPA diagnosis (97%) and averaged 16.0 visits in 1 year. A significant proportion of the EGPA population were prescribed OCS; most EGPA patients had a prescription in the 0–3 months after the index date (64%), and patients on average had a prescription for OCS for 6 out of the 12 months after the index date.

Table 1. HCRU among patients with EGPA

HCRU	Number of patients N (%) [total days]	Number of events per patient, Mean (SD)
Total EGPA cohort (N)	377	
EGPA-specific hospitalizations	72 (19.10)	1.2 (1)
EGPA-specific hospitalizations	[1283]	17.8 (23.3)
length of stay		
Any-cause hospitalizations	188 (49.87)	1.7 (1)
Any-cause hospitalizations length of stay	[2992]	15.9 (23.7)
Any-cause A & E events	19 (5.04)	1.8 (2)
Any-cause outpatient visits	334 (88.59)	9.8 (7)
Any procedures undertaken	196 (51.99)	6.8 (6)
General Practitioner visits	366 (97.08)	16.0 (11)

A&E, Accident and Emergency; EGPA, eosinophilic granulomatosis with polyangiitis; HCRU, healthcare resource utilization.

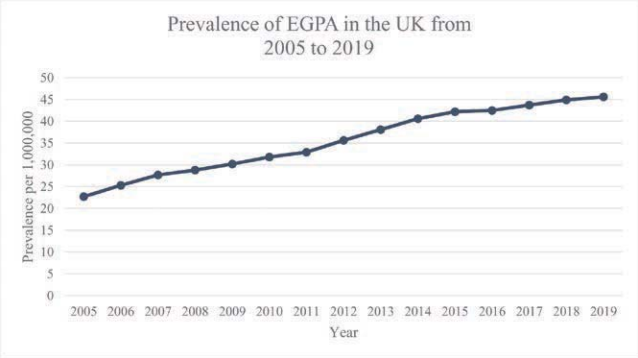

Figure 1. Prevalence of EGPA in the UK from 2005 to 2019Prevalence is expressed as cases per 1,000,000 persons. EGPA, eosinophilic granulomatosis with polyangiitis; UK, United Kingdom.

Conclusion: The prevalence of EGPA increased over the study period in the UK, and the data show significant HCRU within 1 year of the first recorded diagnosis of EGPA. Almost all of the patients with EGPA were found to frequently visit the primary care physician and seek specialist care, and almost half required hospitalization. Funding: GSK [207888]

POS0321 CO-MORBIDITY IN POLYMYALGIA RHEUMATICA

M. Yates[1,2], A. Iftikhar Talib[1], C. Aldus[3], J. Brown[3,4], A. Macgregor[1,2]. *[1]University of East Anglia, Centre for Epidemiology, Norwich, United Kingdom; [2]Norfolk and Norwich University Hospital, Rheumatology, Norwich, United Kingdom; [3]Prescribing Services Limited, Eclipse, Buxton, United Kingdom; [4]Litcham Medical Practice, General Practice, Litcham, United Kingdom*

Background: Polymyalgia rheumatica (PMR) is the most common autoimmune musculoskeletal condition in the developed world, with UK prevalence of 1.7% in those aged older than 55 years. Current guidelines recommend glucocorticoid treatment for one to two years. Since PMR affects older individuals and is associated with prolonged treatment with glucocorticoids, patients are at risk of developing or worsening co-morbidity.

Objectives: This national study aimed to establish the prevalence of PMR from routinely recorded administrative care records from community-based primary care practices; secondly to calculate the most common comorbidities and their relative risk amongst those diagnosed with PMR.

Methods: The ECLIPSE databased covers over 23m patients across 2400 general practices in England and provides insights for enhanced clinical pathway management and to support patient safety in primary care. Routinely recorded diagnoses from primary care data are updated daily, along with administrative prescribing data. Using standardised nationally agreed disease coding frameworks, all diagnoses of PMR were retrieved from the live patient population of 23.3m individuals registered with general practices across England. Comorbidity was recorded similarly. Diagnoses of PMR were categorised in 12-month bands since their date of diagnoses to examine the rates of prednisolone prescription by time since diagnosis.

Results: Amongst the 23.3 million patient care records there were 146,252 diagnoses of PMR, resulting in a prevalence of 2.2% for those aged older than 55 years. The average age of those with PMR was 77.5 years. There were between 9863 to 11036 diagnoses of PMR made each year over the past five years. The proportion of those receiving prednisolone were highest amongst those most recently diagnosed: 76.4% for those in the last year; 48.4% for those diagnosed between a year and two years ago; 33.0% for those diagnosed between two to three years ago; 28.8% for those diagnosed between three to four years ago, and 24.9% for those diagnosed between four to five years ago. On average each patient with PMR had 3.5 co-morbid conditions and was prescribed 5.4 different medications. The top ten co-morbid conditions were, in rank order: hypertension (53.6%), osteoarthritis (48.6%), anxiety and depression (27.5%), chronic kidney

disease (24.3%), type II diabetes (18.9%), ischaemic heart disease (14.9%), atrial fibrillation (13.7%), asthma (12.7%), COPD (7.9%), and heart failure (6.2%).
Conclusion: Routinely recorded GP records provide prevalence estimates that are similar to previously published descriptive epidemiological studies, and despite guidelines recommending shorter courses of treatment, show the rates of prednisolone prescription remain high, years after diagnosis. Furthermore, due to the age of onset of PMR, this results in a patient population with high levels of co-morbidity many of whom are at increased risk due to prolonged glucocorticoid use. These data are crucial for developing risk stratification and population health management tools.

POS0322 CARDIOVASCULAR RISK FACTORS AND RISK OF GIANT CELL ARTERITIS AND/OR POLYMYALGIA RHEUMATICA: RESULTS FROM THE FRENCH E3N COHORT STUDY

F. Barde1, C. Macdonald[1], C. Salliot[2], S. Ascione[1,3], F. Artaud[1], X. Mariette[4,5], M. C. Boutron-Ruault[1], Y. Nguyen[1,6], R. Seror[1,4]. *[1]Université Paris-Saclay, UVSQ, Inserm, Institut Gustave Roussy,"Exposome and Heredity"Team, CESP, Villejuif, France; [2]Centre Hospitalier Régional d'Orléans, Rheumatology, Orléans, France; [3]Hôpital Lariboisière AP-HP, Rheumatology, Paris, France; [4]Université Paris-Saclay, AP-HP, Hôpital Bicêtre, Rheumatology, Le Kremlin Bicêtre, France; [5]Université Paris-Saclay, France, AP-HP, Hôpital Bicêtre, National Reference Center for Rare Systemic Autoimmune Diseases, INSERM UMR1184, Le Kremlin Bicêtre, France; [6]AP-HP. Nord, Hôpital Beaujon, Université de Paris, Internal Medicine, Clichy, France*

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are two associated inflammatory diseases with incompletely known common pathophysiological mechanism. Cardiovascular (CV) risk factors have been thought to play a role in the underlying chronic vascular inflammation involved in GCA and PMR pathophysiology. However, available data on CV risk factors are conflicting.
Objectives: To investigate the association between CV risk factors and the risk of GCA and/or PMR in a large prospective cohort of French women.
Methods: The E3N cohort study (*Etude Epidémiologique auprès des femmes de la Mutuelle générale de l'Education Nationale*) is a French prospective cohort including 98,995 French women born between 1925 and 1950, recruited in 1990. They completed biennially mailed questionnaires to update their health-related information. A validation study based on the use of a specific GCA/PMR questionnaire and medication reimbursement database was conducted prior to this study. The history of CV risk factors (hypertension, type 2 diabetes, dyslipidemia, active smoking status and family history of cardiovascular disease) was self-reported at each questionnaire. Hazard ratios (HRs) and their 95% confidence intervals (95%CIs) for incident GCA and/or PMR were estimated by Cox proportional hazards regression models with age as the time scale. Multi-adjusted models included all CV risk factors and educational level. Further analyses were conducted to separately analyse the risk of incident GCA and of PMR.
Results: The overall population included 79,804 women, during a total follow-up of 1,899,742 person-years. Among them, 399 incident GCA and/or PMR cases were identified (incidence 31/100,000 person-years): 282 PMR alone, 112 GCA cases, and 5 patients who could not be classified. Incident GCA/PMR cases were diagnosed after a mean of 17.9 (± 5.2) years after recruitment. Mean age at diagnosis was 69 (± 7.2) years. Type 2 diabetes was inversely associated with risk of incident GCA/PMR in age-adjusted and multivariable models (HR 0.41; 95%CI 0.2–0.9 in multivariate model). Other CV risk factors such as hypertension, smoking status, dyslipidaemia, familial history of cardiovascular events were not associated with incident GCA/PMR (Table 1). The inverse association remained statistically significant when studying separately the risk of incident PMR (HR 0.3; 95%CI 0.09–0.91) but no longer with incident GCA (HR 0.5; 95%CI 0.1–2.0), probably due to a reduced statistical power.
Conclusion: Type 2 diabetes was associated with a decreased risk of subsequent GCA/PMR development. Further work should be carried out to determine potential mechanisms, and especially to analyze the respective role of diabetes itself and its treatments.

POS0323 RISK FACTORS FOR MAJOR CARDIOVASCULAR EVENTS (MACE) IN INFLAMMATORY ARTHRITIS: A TIME-DEPENDENT ANALYSIS ON INFLAMMATORY BURDEN, USE OF NSAIDS, STEROID AND DMARDS

H. Meng[1], S. H. M. Lam[1], H. So[1], L. S. Tam[1]. *[1]The Prince of Wales Hospital, The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Inflammatory arthritis (IA) including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylarthritis (AS) are associated with accelerated atherosclerosis due to systematic inflammation.
Objectives: To elucidate whether inflammatory burden (c-reactive protein [CRP] and erythrocyte sedimentation rate [ESR] levels) and drugs used to suppress inflammation (disease modifying anti-rheumatic drugs [DMARDs] and non-steroidal anti-inflammatory drugs [NSAIDs]) over time are independently associated with major cardiovascular events (MACE) in patients with IA.
Methods: A population-based cohort of IA patients were identified in the city-wide Clinical Data Analysis and Reporting System (CDARS) of the Hong Kong Hospital Authority. IA patients recruited from 2006 to 2016 were followed until the end of 2018. The outcome was occurrence of a first MACE, defined as unstable angina, acute myocardial infarction, stroke/transient ischemic attack or death from cardiovascular causes. Cox proportional hazard models with time-varying

CRP and ESR levels and drugs used were analyzed to identify the risk of having MACE in IA patients.

Results: A total of 17,732 (12050 RA patients, 1789 PsA patients and 3893 AS patients) patients with IA were recruited. After a mean follow-up of 8.7 ± 3.1 years, 1,069 (6.0 %) patients developed a first MACE. At baseline, the MACE group were older (68±12 vs 53±15, p<0.001), had more traditional cardiovascular risk factors, higher levels of CRP (2.7±1.5 vs 1.7±1.3, p<0.001) and ESR (57.8±32.4 vs 42.5±29.2, p<0.001), and less exposure to biologic DMARDs (bDMARDs) (1.0% vs 3.0%, p<0.001) and non-selective NSAIDs (nsNSAIDs) (63.4% vs 71.1%, p<0.001). After adjusting for age, sex, baseline cardiovascular comorbidities using multivariable Cox regression analysis, IA patients with higher inflammatory burden (as reflected by the time-varying CRP [hazard ratio {HR} 1.11, 95% confidence interval {CI} 1.10-1.12, p<0.001] and ESR levels (HR 1.02, 95% CI 1.01-1.01, p<0.001) and the use of steroid (HR 1.79-1.88) were independently associated with a higher risk of developing MACE (Table 1). In contrast, exposure to nsNSAIDs had a protective effect against MACE (HR 0.76, 95% CI 0.66-0.89, p<0.001), while bDMARDs were not associated with MACE.

nsNSAIDs	0.76 (0.66-0.89)	<0.001*	0.76 (0.66-0.88)	<0.001*
Steroids	1.88 (1.63-2.17)	<0.001*	1.79(1.56-2.04)	<0.001*

*Statistically significant at p < 0.05. † and ‡ Adjusted for Age, Sex, Hypertension at baseline, diabetes mellitus at baseline, dyslipidemia at baseline, bDMARDs, CoxII, non-selective NSAIDs, Steroids. CRP, C-reactive protein; ESR: Erythrocyte sedimentation rate; HT: hypertension; DM: diabetes mellitus; LP: Dyslipidemia; bDMARD, biological disease-modifying anti-rheumatic drug; COXII: cyclooxygenase -2 inhibitors; nsNSAIDs: non-selective nonsteroidal anti-inflammatory drugs.

Conclusion: Increased inflammatory burden as reflected by elevated ESR and CRP level over time, and increased exposure to steroid were independently associated with increased risk of MACE, while the risk was significantly reduced with non-selective NSAIDs use in IA patients.

POS0324 RISK OF CARDIOVASCULAR COMORBIDITIES IN RHEUMATIC DISEASES

H. K. Aaramaa[1], P. Isomäki[1], N. Mars[2], M. Helminen[3,4], A. Kerola[5], A. Palomäki[6,7], K. Eklund[5], J. Gracia Tabuenca[8], J. Sinisalo[9]on behalf of FinnGen. *[1]Tampere University Hospital, Rheumatology Centre, Tampere, Finland; [2]Helsinki Institute of Life Science (HiLIFE), Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland; [3]Tampere University Hospital, Tays Research Services, Tampere, Finland; [4]University of Tampere, Faculty of Social Sciences, Health Sciences, Tampere, Finland; [5]Helsinki University Central Hospital, Inflammation Center, Rheumatology Division, Helsinki, Finland; [6]Turku University Hospital, Centre for Rheumatology and Clinical Immunology, Turku, Finland; [7]University of Turku, Faculty of Medicine, Turku, Finland; [8]University of Tampere, Faculty of Medicine and Health Technology, Tampere, Finland; [9]Helsinki University Central Hospital, Heart and Lung Center, Cardiology division, Helsinki, Finland*

Background: Cardiovascular diseases (CVD's) are the most significant comorbidities in rheumatic diseases, causing also increased mortality. [1,2] However, there is only limited data on how the risk of CV comorbidities varies between different rheumatic diseases.

Objectives: The aim of our study was to estimate the risk of certain CV comorbidities across rheumatic diseases.

Methods: The ongoing FinnGen project links nationwide healthcare register data with genome data. The study (data freeze 7) included 321 302 individuals, and from this group we identified patients with seropositive (N=4293) and seronegative (N=1733) rheumatoid arthritis (RA), ankylosing spondylitis (AS, N=1247), psoriatic arthritis (PsA, N=1235), systemic lupus erythematosus (SLE, N=386), primary Sjogren's syndrome (pSS, N=557) and gout (N=2178). Each patient was matched based on age, sex and municipality of residence with twenty individuals without any rheumatic conditions. The CV comorbidities studied were any CV disease (CVD), major coronary heart disease event (myocardial infarction and/or revascularization; CHD), ischemic stroke, atrial fibrillation and flutter (AF), deep vein thrombosis of lower extremities (DVT) and pulmonary embolism (PE), chronic heart failure (CHF) and valvular heart disease excluding rheumatic fever (VHD). From the prevalence of each CV disease among rheumatic disease cohorts, we calculated the risk ratio (RR) for each CV disease by comparing the prevalence of these diseases between rheumatic diseases and controls.

Results: The average age at the time of diagnosis ranged from 39.6 to 64.4 years, and the average duration of follow-up varied from 9 to 19.5 years in different rheumatic diseases. The risk for any CVD was elevated in all rheumatic disease cohorts with RR varying from 1.14 in seropositive RA to 1.65 in SLE. SLE patients carried the highest relative risk for CV comorbidities, demonstrating over 2.5-fold risk for DVT/PE (RR 3.57), stroke (RR 2.57), CHF (RR 2.64) and VHD (RR 2.98). At least two-fold risk compared to controls was identified for AF (RR 2.03), DVT/PE (RR 2.44) and CHF (RR 3.03) in patients with gout, for DVT/PE (RR 2.15) and CHF (RR 2.0) in patients with pSS, and for DVT/PE (RR 2.03) in patients with PsA. Seropositive and seronegative RA demonstrated similar CV risk profiles. In patients with seropositive or seronegative RA, PsA, pSS or SLE, DVT/PE demonstrated the highest RR's among various CV comorbidities.

Conclusion: The risk of CV comorbidities is increased in all studied rheumatic diseases, with the largest effects observed in patients with SLE and gout. Among CV comorbidities, DVT/PE displayed the largest effect sizes in several rheumatic diseases. The current results further strengthen the importance of evaluating and treating risk factors for CV comorbidities across rheumatic diseases, focusing also to the excess risk for thromboses.

POS0325 THE ASSOCIATION BETWEEN OBESITY, SOCIOECONOMIC POSITION AND KNEE JOINT REPLACEMENT SURGERY IN PATIENTS WITH OSTEOARTHRITIS: RESULTS FROM THE ENGLISH LONGITUDINAL STUDY OF AGEING

R. Witkam[1], S. Verstappen[1], J. Gwinnutt[1], M. Cook[1], T. O'neill[1], R. Cooper[2], J. Humphreys[1]. *[1]University of Manchester, Centre for Epidemiology Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; [2]Manchester Metropolitan University, Department of Sport and Exercise Sciences, Musculoskeletal Science and Sports Medicine Research Centre, Manchester, United Kingdom*

Background: Evidence suggests that associations of lower socioeconomic position (SEP) with increased incidence of osteoarthritis (OA) are partially mediated by obesity. Obesity and lower SEP are also associated with increased symptoms in OA (i.e. pain/function). However, few studies have investigated whether obesity and lower SEP are also associated with increased risk of knee joint replacement surgeries (kJRS).

Objectives: To investigate the relationships of obesity and SEP at time of diagnosis with kJRS at follow-up in people with knee OA (kOA).

Methods: The English Longitudinal Study of Ageing is a nationally representative panel study of adults aged ≥50 years with biannual waves of data collection (2002–2019). Participants who self-reported OA diagnosis for the first time

in waves 2–8 and knee pain in the same or previous wave of diagnosis were defined as having kOA (baseline). Participants with at least one body mass index (BMI) measurement and one follow-up assessment were included. Underweight/normal weight, overweight and obesity were defined using BMI <25 kg/m^2, 25–30 kg/m^2 and ≥30kg/m^2, respectively. Education, occupation (current or last occupation if retired), wealth quintiles (all individual-based) and index of multiple deprivation quintiles (area-based) were used as SEP indicators. Outcome was the first self-reported kJRS (left or right knee) in waves 3–9. Cox proportional hazards models were used to investigate the associations of obesity and SEP with kJRS, controlling for baseline covariates. Person year follow up was calculated from baseline to either a) date of self-reported kJRS, b) loss to follow-up, c) end of follow-up (wave 9).

Results: The analysis sample included 1499 people who reported kOA and had ≥1 BMI measure (62.3% female; mean age 66.5y (SD 9.4); 96% white; 47.4% obese). Number of person-years included in the analysis was 8427. Over a mean follow-up of 4.7 years (SD 2.8), 144 (9.6%) reported having kJRS. Obese kOA patients were more likely to report kJRS than non-obese patients (adjHR 1.89 (95% CI 1.33, 2.68)), independent of age, gender, SEP, cardiovascular disease (self-reported) and HbA1c values (measured from collected blood samples). Education and occupation were not associated with kJRS. However, those living in the most deprived areas and with the least amount of wealth were less likely to undergo kJRS compared with the least deprived and wealthiest (HRs adjusted for age and gender 0.37 (95% CI 0.19, 0.73) and 0.55 (95% CI 0.33, 0.93), respectively). There was no evidence of interactions between obesity and SEP indicators.

Conclusion: Obesity increased the likelihood of undergoing kJRS in kOA patients. Therefore, reducing obesity in kOA patients may help to reduce the need for kJRS. Area-deprivation and lower wealth were associated with lower likelihood of kJRS. Taken together with findings from other studies which report associations between lower SEP and worse OA symptoms, our results suggest that there may be social inequalities in the provision of kJRS in England.

Table 1. The relationships between obesity at baseline and rates of knee joint replacement surgery over a mean of 4.7 (SD 2.8) years in follow-up in those with knee OA at baseline in the English Longitudinal Study of Ageing

	HR (95% CI)

New data on pathophysiology of spondyloarthritis including psoriatic arthritis

POS0326 THE TRANSCRIPTOMIC LANDSCAPE OF ACTIVE PSORIATIC ARTHRITIS: ACTIVATED INNATE IMMUNITY, EXTRACELLULAR MATRIX (ECM) TURNOVER, ABERRANT METABOLISM AND HEMOPOIETIC CELL - SKIN CROSSTALK.

A. Grivas[1,2], M. Grigoriou[2], G. Sentis[2], A. Filia[2], P. Katsimpri[1], P. Verginis[3], D. Boumpas[1,2]. *[1]National and Kapodistrian University of Athens, 4th Department of Internal Medicine, Athens, Greece; [2]Biomedical Research Foundation of the Academy of Athens (BRFAA), Laboratory of Autoimmunity and Inflammation, Athens, Greece; [3]Medical School, University of Crete, Laboratory of Immune Regulation and Tolerance, Division of Basic Sciences, Heraklion, Greece*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease whereby activated T lymphocytes and myeloid cells interact with tissue-resident cells in the skin and joints. Gene expression studies, mainly based on the microarray platforms, have provided an initial glimpse into disease pathogenesis highlighting, among others, the role of the TNFα and IL17 cytokine axis. Yet, the transcriptomic landscape of PsA remains largely unexplored, and the specific contribution of skin fibroblasts to disease pathogenesis remains elusive.

Objectives: To comprehensively characterize the gene expression profile in PsA, specifically in the blood and skin fibroblasts through next-generation RNA sequencing.

Methods: Peripheral blood (PB) was collected from PsA patients (n=30) after informed consent. Healthy individuals (HC) and patients with rheumatoid arthritis (RA) were used as healthy and disease controls (n=10/group) respectively. Psoriatic skin biopsies were obtained from a subset of three PsA patients and three HC. All PsA patients fulfilled the CASPAR criteria and displayed peripheral polyarthritis of moderate- to high- disease activity. Patient's clinical and laboratory data were recorded at the time of sampling. Disease activity in PsA and RA was assessed using the Disease Activity Index for Psoriatic arthritis (DAPSA) and the Disease Activity Score-28 (DAS28), respectively. RNA from PB and skin fibroblasts was extracted, RNA libraries were prepared and sequenced. EdgeR package was used to call differentially expressed genes (DEGs). Statistical significance was set at p value<0.05 and fold-change |FC| >1.5. Functional enrichment analysis and weighted gene co-expression network analysis (WGCNA) was implemented. Inference and analysis of blood immune cells-skin fibroblasts communication were performed with CellChat.

Results: 8 males and 22 female patients with PsA were included with median age 49 years old and median disease duration 4 years. The median DAPSA score was 44.3 and the median DAS28 score was 5.5 for RA patients, suggesting high disease activity in both groups. We found 466 DEGs in PsA versus HC blood (303 up- and 163 down-regulated). DEGs were significantly enriched in biological pathways related to immunity (i.e. *inflammatory response, TNFa signaling via NFkB, IFNa & IFNγ response, complement, IL2 signaling*), metabolism (i.e. *oxidative phosphorylation, adipogenesis, fatty acid metabolism*) and other signaling cascades of pathophysiologic relevance (i.e. *WNTb catenin signaling, TGFβ signaling, MTORC1 signaling*). WGCNA in blood revealed four gene modules containing highly correlated genes. These modules were enriched in *myeloid leukocyte mediated immunity*, *neutrophil-mediated immunity*, *ECM and collagen metabolism, TGFβ and PDGF signaling*. Next, we characterized the "PsA specific activity signature", taking the intersection of DEGs in 'PsA vs. HC' and 'PsA vs. RA', which resulted in 67 DEGs enriched in *response to TGF* and *PDGF*, *ECM organization and degradation.* CellChat analysis identified a higher number of interactions between blood immune cells and skin fibroblasts and increased strength of interactions in PsA compared to healthy state. Aberrant interactions between blood and skin fibroblasts in PsA included, among others, ligand-receptor pairs of the WNT, Notch, and GDF11 signaling pathways.

Conclusion: Our findings confirm the presence of an IFNα signature and complement activation in PsA. The increased cardiometabolic burden and enhanced bone remodeling are reflected by the presence of pathways related to aberrant metabolism and ECM metabolism, respectively. The myeloid cell signature in active disease supports the emerging role of monocytes/macrophages in driving inflammation in PsA, while the aberrant blood-skin fibroblast interactions suggest a novel role for these resident cells in disease pathophysiology.

Background: Axial spondyloarthritis (axSpA) is an inflammatory disease with detrimental effects on the health status of the individuals affected by this condition [1]. axSpA patients also exhibit high cardiovascular (CV) risk, mainly due to accelerated atherosclerosis [2]. Interestingly, the adipomyokine irisin was described to play a beneficial role in several physiological and pathophysiological processes such as inflammation, angiogenesis, oxidative stress, as well as lipid and bone metabolism [3]. However, studies on the role of irisin in CV risk in the setting of axSpA or in the pathogenesis of axSpA are limited [4].

Objectives: In this study we evaluated the role of irisin as a genetic and serological biomarker of subclinical atherosclerosis and CV risk in a large cohort of patients with axSpA. We also assessed its role as a marker of axSpA susceptibility and severity.

Methods: 725 patients who fulfilled the Assessment of SpondyloArthritis international Society classification criteria for axSpA were included in this study [5]. In these patients, the presence of subclinical atherosclerosis (plaques and/or abnormal carotid intima-media thickness values) was assessed by carotid ultrasound. Four *irisin* polymorphisms (rs16835198 G/T, rs3480 A/G, rs726344 G/A and rs1570569 G/T) were genotyped by TaqMan probes in all the patients and in 656 age, sex and ethnically-matched healthy controls. Additionally, serum irisin levels were determined by ELISA in all the patients. All analyses were performed using STATA v.11.1 statistical software, adjusting for potential confounding factors. The strength of associations is indicated as odds ratios (OR) [95% confidence intervals].

Results: Low levels of serum irisin were linked to the presence of plaques ($p=0.002$) and with atherogenic index values indicative of an adverse lipid profile ($p=0.01$). Serum irisin levels also negatively correlated with visual analogue scale (VAS) patient, VAS physician and Bath Ankylosing Spondylitis Metrology Index (BASMI) values ($p<0.05$). Moreover, the presence of sacroiliitis was related to lower serum irisin levels ($p<0.001$). Furthermore, the minor alleles of rs3480 (G) and rs1570569 (T) were associated with higher values of Ankylosing Spondylitis Disease Activity Score (ASDAS) in axSpA patients ($p\leq0.01$ in both cases). In this line, the frequency of the minor allele of rs1570569 (T) was higher in patients with ASDAS values >2.1 (indicative of high disease activity) (OR: 1.46 [1.08-1.97], $p=0.01$), while the minor allele of rs16835198 (T) was less frequent in this group of patients (OR: 0.73 [0.57-0.92], $p=0.01$).

Conclusion: Low serum irisin levels could be indicators of the presence of subclinical atherosclerosis, high CV risk and more severe disease in axSpA patients. In addition, irisin may also constitute a genetic biomarker of disease activity in axSpA.

POS0328 AUTOPHAGY MODULATION BY TOFACITINIB IMPROVES PSORIATIC ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES FUNCTION.

E. Silvagni[1], S. Missiroli[2], S. Patergnani[2], C. Boncompagni[2], M. S. Ciliento[1,3], G. Lanza[4], M. Perrone[2], A. Bortoluzzi[1], M. Govoni[1], C. Giorgi[2], C. A. Scirè[5,6], P. Pinton[2]. *[1]Rheumatology Unit, University of Ferrara and Azienda Ospedaliero-Universitaria S. Anna, Department of Medical Sciences, Cona (Ferrara), Italy; [2]Section of Experimental Medicine, University of Ferrara; Laboratory for Technologies of Advanced Therapies (LTTA), Department of Medical Sciences, Ferrara, Italy; [3]University della Campania L. Vanvitelli, Department of Precision Medicine, Naples, Italy; [4]Anatomic Pathology, University of Ferrara, Department of Translational Medicine, Cona (Ferrara), Italy; [5]Italian Society for Rheumatology, Epidemiology Unit, Milan, Italy; [6]University of Milano Bicocca, Rheumatology Unit, Milan, Italy*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory systemic disease, and peripheral joints involvement is responsible of significant morbidity for patients, leading to damage accrual. Different drugs are available for the systemic management of this condition, with different mechanisms of action. Nevertheless, the rules driving the correct therapeutical choice in each individual patient are not completely defined. Janus kinases (JAK) inhibitors are a class of drugs able to reduce synovial inflammation, and tofacitinib, a JAK1/3 inhibitor, is the most studied. Preliminary evidence suggest an effect of tofacitinib on fibroblast-like synoviocytes (FLS) from PsA patients, reducing pro-invasive and pro-inflammatory properties. The link

between JAK inhibition and FLS function improvement at synovial level is not fully understood.

Objectives: To evaluate the effect of tofacitinib on spontaneous autophagic activity of PsA FLS, and to confirm its effect on anti-inflammatory and anti-invasive properties of PsA FLS and synovial explants.

Methods: This is an in vitro study. Patients with active PsA underwent ultrasound-guided synovial biopsy. Histological evaluation was performed according to Krenn's synovitis score. FLS, PBMCs and synovial explants cultures were set up, and cells were treated in vitro with tofacitinib 1 µM or vehicle control for 24h. Protein levels in cellular homogenates were analysed by western blot for relevant autophagy markers. Autophagy was also studied by fluorescence microscopy using GFP-LC3. Chemokines/cytokines levels into culture supernatants were quantified by ELISA. Migration assays were used to investigate the effect of tofacitinib on invasive properties of FLS. Differences were determined adopting the non-parametric Wilcoxon signed rank test.

Results: 16 patients with moderately active PsA were enrolled (Table 1). Mean (SD) Krenn's synovitis score was 4.4. (1.9). Tofacitinib significantly increased LC3-II and ATG7 levels in PsA FLS compared to vehicle control, while p62 levels were not significantly affected, suggesting an increase in spontaneous autophagy activity, confirmed by LC3-autophagic vesicles count (Figure 1). No effect was highlighted in PBMCs and synovial explants cultures. Tofacitinib significantly reduced migration properties of PsA FLS, as well as MCP-1 and IL-6 release into FLS and synovial explants cultures supernatants.

Table 1. Baseline demographic and clinical data of included patients (N=16).

Variables	Frequency
Age (years), mean (SD)	59.8 (7.9)
Female, N (%)	5 (31.3%)
Disease duration (years), mean (SD)	9.7 (7.9)
CRP (mg/dl), mean (SD)	1.5 (2.0)
Patient Global Activity (0-100), mean (SD)	73.4 (16.9)
Physician Global Activity (0-100), mean (SD)	56.3 (18.1)
DAPSA, mean (SD)	25.6 (6.8)
HAQ (0-3), mean (SD)	0.9 (0.5)
Previous csDMARDs treatment, N (%)	13 (81.3%)
Previous bDMARDs treatment, N (%)	6 (37.5%)
Grey scale synovitis - joint to be biopsied (0-3), mean (SD)	1.9 (0.8)
Joint effusion - joint to be biopsied (0-3), mean (SD)	1.4 (0.7)
Power Doppler - joint to be biopsied (0-3), mean (SD)	0.5 (0.6)
Krenn's synovitis score (0-9), mean (SD)	4.4 (1.9)

Abbreviations: SD, standard deviation; CRP, C reactive protein; DAPSA, Disease Activity Index for Psoriatic Arthritis; HAQ, Health Assessment Questionnaire; csDMARD, conventional synthetic disease modifying antirheumatic drugs; bDMARD, biological disease modifying antirheumatic drugs.

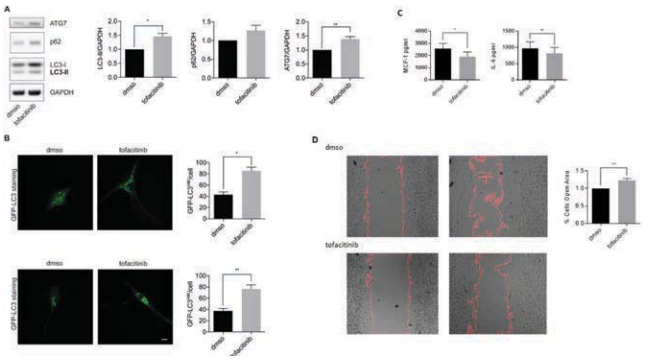

Figure 1. Tofacitinib significantly increased LC3-II and ATG7 levels in PsA FLS homogenates (A), and LC3-autophagic vesicles (B). Tofacitinib significantly reduced MCP-1 and IL-6 release into FLS cultures supernatants (C), and reduced PsA FLS migration properties at 24h (D).

Conclusion: The induction of autophagy by tofacitinib might permit a better functioning of PsA FLS, with a coherent reduction in pro-invasive and pro-inflammatory properties. This may contribute to the rationale for tofacitinib use in PsA management.

POS0329 ABERRANT GLOBAL DNA METHYLATION IN PERIPHERAL BLOOD CELL SUBPOPULATIONS OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS

E. Toussirot[1], S. Pasquereau[2], C. Vauchy[3], D. Wendling[4], J. C. Balblanc[5], C. Laheurte[6], M. Puyraveau[1], G. Herbein[2]. *[1]INSERM CIC -1431, Biostatistics, Besancon, France; [2]University of Franche Comté, EA EPILAB, Besancon, France; [3]INSERM, CIC 1431, Besancon, France; [4]University Hospital, Rheumatology, Besancon, France; [5]Hôpital Nord Franche Comté, Rheumatology, Besancon, France; [6]EFS Bourgogne Franche Comté, Biomonotoring Plateform, Besancon, France*

Background: Axial spondyloarthritis (axSpA) corresponds to a group of chronic inflammatory diseases mainly affecting the axial skeleton. TNFα and IL-17A have been identified as key inflammatory mediators driving the inflammatory process of axSpA. Epigenetics refers to different mechanisms that alter gene expression without involving changes in DNA sequence. DNA methylation is an important epigenetic mechanism, playing a role in gene expression regulation. It is recognized that aberrant DNA methylation can result in immune cell autoreactivity.

Objectives: epigenetic features have been rarely evaluated in axSpA. Prior studies have identified DNA methylation changes at both the gene-specific and genowe-wide levels in radiographic ax-SpA (r-axSpA). In this study, we aimed to evaluate the global DNA methylation of patients with axSpA.

Methods: case-control study (NCT03092583). Patients with r-axSpA or non radiographic (nr) axSpA (ASAS criteria) and healthy controls (HC) were evaluated. All the patients were biologic naïve and under NSAIDs. Disease activity was evaluated by BASDAI and ASDAS. CD4+T cells and CD14+ monocytes were isolated from peripheral blood and then DNA was extracted. Global DNA methylation (5-mC) was determined using MethylAmp global DNA methylation quantification kit (Epigentek) using 150 ng of total DNA.

Results: 104 patients with axSpA including 59 with r-axSpA (45 M; age [mean ± SD]: 47.1 ± 15 y; disease duration: 15.2 ± 13 y; B27: 86.4%) and 45 nr-axSpA (21 M, age: 39.6 ± 13.2; disease duration: 7 ± 7.8; B27: 65.1%) and 79 healthy controls (HC) (51 M; age: 43.4 ± 12.2 y) were evaluated. Patients had active disease (BASDAI and ASDAS in r-axSpA and nr-axSpA: 5.1 ± 1.8 and 3.04 ± 1.1; 5.04 ± 1.1 and 2.8 ± 1.0, respectively). In CD4+ T lymphocytes, global DNA methylation was higher in the whole SpA group compared to HC (1.45 ± 3.6 *vs* 0.44 ± 0.9 of 5-mC (p= 0.0092). Similarly, DNA methylation was higher in monocytes from patients with ax-SpA compared to HC (1.94 ± 2.3 *vs* 0.62 ± 0.9 of 5-mC)(p= 0.0004). When analysing the results between ax-SpA subgroups, DNA methylation remains higher in both CD4 T lymphocytes and monocytes of each patient subgroup compared to HC (p< 0.05 for all comparisons) (Figure 1). The levels of DNA methylation did not correlate with laboratory (ESR, CRP) or clinical (BASDAI) measures of disease activity, excepting ASDAS which was weakly correlated with DNA methylation in CD4+ T lymphocytes from the whole group of axSpA (r = 0.18, p = 0.08). History of uveitis was associated with higher DNA methylation in monocytes (p= 0.017). Previous smoker patients had higher DNA methylation in their monocytes compared to current or never smoker patients (p = 0.06). In a limited number of patients (N = 15) who started a TNFi, DNA methylation decreased in both CD4 T lymphocytes and monocytes after 3 months of treatment.

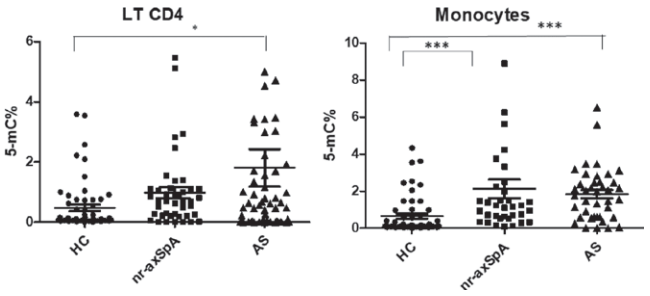

Figure 1. global DNA methylation of CD4+ T lymphocytes and monocytes from patients with ankylosing spondylitis (AS or radiographic axial spondyloarthritis) and non radiographic axial spondyloarthritis (nr-axSpA) and healthy controls (HC) (* p <0.05; *** p <0.001)

Conclusion: a global DNA hypermethylation was observed in patients with axSpA, both in T CD4 lymphocytes and monocytes. These modifications involved both the radiographic and non radiographic forms. These results were weakly correlated with disease activity and only in monocytes. Collectively, these changes in DNA methylation could alter recruitment of methyl binding proteins (MBP) that regulate chromatin structure and/or impair binding of transcription factors, resulting in down regulation of gene expression relevant to the pathogenesis of axSpA. We currently evaluated the level of expression of DNA methyltransferase (DNMT) and MBP proteins and specific DNA methylation status of the promoters of gene involved in inflammation such as TNFa.

POS0330

DIFFERENCES IN GUT MICROBIOTA ASSOCIATED WITH LYMPHOCYTE SUBSETS, CYTOKINES AND DISEASE ACTIVITY IN ANKYLOSING SPONDYLITIS

Z. Song[1,2,3], S. X. Zhang[1,2,3], T. Cheng[1,2,3], R. Zhao[1,2,3], J. Qiao[1,2,3], S. Song[1,2,3], Y. LI[2,3], X. LI[1,2,3], C. Wang[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*

Background: Ankylosing spondylitis (AS), a common chronic inflammatory disease, is a prototype of spondyloarthritis affecting sacroiliac joints and spine with or without peripheral arthritis and other systemic symptoms[1]. Environmental factors, especially microorganisms have been suggested to implicate with AS pathogenesis[2].

Objectives: Utilizing 16S rRNA genes sequencing on the feces of untreated AS patients and healthy controls (HCs), our study aimed to provide an in-depth understanding of AS gut microbiota and identifying a feasible diagnostic strategy for AS.

Methods: Fecal samples were collected from 62 AS patients and 62 age-and-gender- matched HCs. Microbial genome was extracted from approximately 250mg fresh fecal samples from all participants using QIAamp PowerFecal DNA Kit (Qiagen). The V3-V4 variable regions of bacterial 16S rRNA genes were sequenced with the Illumina Miseq PE300 system. QIIME2 based pipeline was used to process the raw sequence data. Alpha and beta diversities were assessed using result from QIIME2, and comparisons of gut microbiome profile were performed using linear discriminant analysis (LDA) effect size (LEfSe) to examine differences between AS and HCs. R (version 4. 0.1) was used for comparative statistics, and pearson's correlation was used to assess the correlations between the relative abundances of bacterial genera and clinical parameters; correlations with p<0.05 were considered significant.

Results: AS for alpha-diversity, ACE and Chao1 indices were lower in AS compared with those HCs(Figure 1**A**, p<0.05), though no significant differences observed in Shannon and Simpson index. Bray curtis distance-based beta-diversity analysis revealed significant differences in the microbial community between AS and HCs (Figure 1**B**, p=0.003, ANOSIM). Fecal microbial communities in AS differed significantly from those in HCs, driven by higher abundances of Escherichia-Shigella, Turicibacter, Enterococcus, et al. and a lower abundance of Agathobacter, Roseburia, Eubacterium_eligens_group, et al (Figure 1**C**, p<0.05). There was a significant positive correlation between ESR and Klebsiella, Butyricicoccus, Roseburia, CRP and Faecalibacterium, Muribaculaceae, ASDAS-CRP score and Faecalibacterium, Ruminococcus, total lymphocyte cells and Agathobacter, Ruminococcus, T cell and Agathobacter, $CD4^+$T cell and Agathobacter, B cell and Agathobacter, Streptococcus, Th1 and Prevotella, CAG–352, Th2 and Agathobacter, Th17 and Prevotella, Agathobacter, IL-2 and Agathobacter, IL-4 and Agathobacter, IL-6 and Lachnospiraceae_UCG–004, Muribaculaceae, IL-17 and Eubacterium_hallii_group, IFN-gama and Phascolarctobacterium.There were negative correlations between total lymphocytes and Escherichia–Shigella, $CD4^+$T cell and Enterobacteriaceae, Th2 cell and Escherichia–Shigella, IL-10 and CAG–352, Ruminococcus (Figure 2, p<0.05).

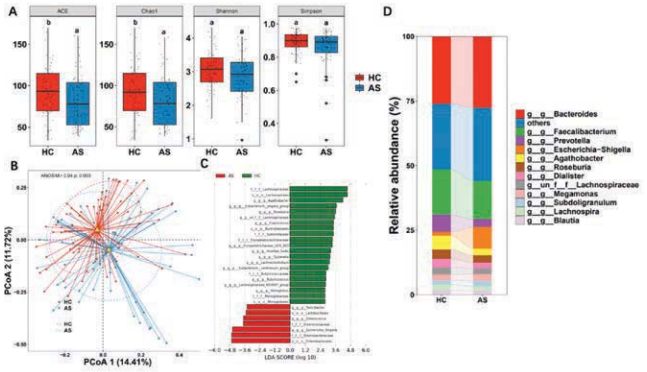

Figure 1. Feature of gut microbiota in AS patients and HCs. (A) Alpha-diversity assessed by richness (Chao1, ACE) and diversity (Shannon, Simpson), Median estimates compared across cohorts. (B) PCoA plot based on the Bray curtis distance of gut microbiota samples from AS patients vs. HC group(p=0.003, ANOSIM). (C) Panel demonstrated the average relative abundance of different genus in AS and HCs. (D) Distribution of gut microbiota at genus level.

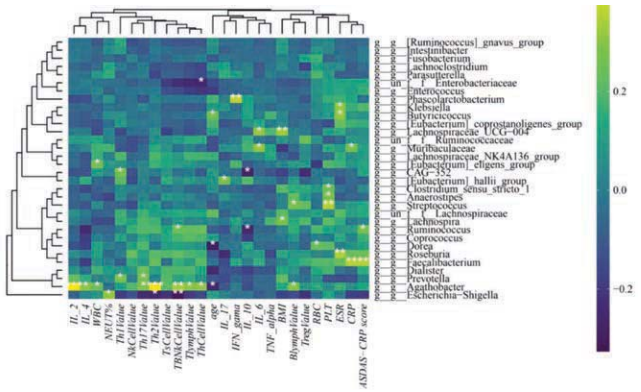

Figure 2. Correlations between the relative abundance of significantly different bacteria and clinical variables. *p<0.05, **p < 0.01, ***p <0 .001, ****p < 0.0001.

Conclusion: Human gut microbiome in patients with AS differed from that of the HCs. Characters of bacteria communities were associated with disease activity.

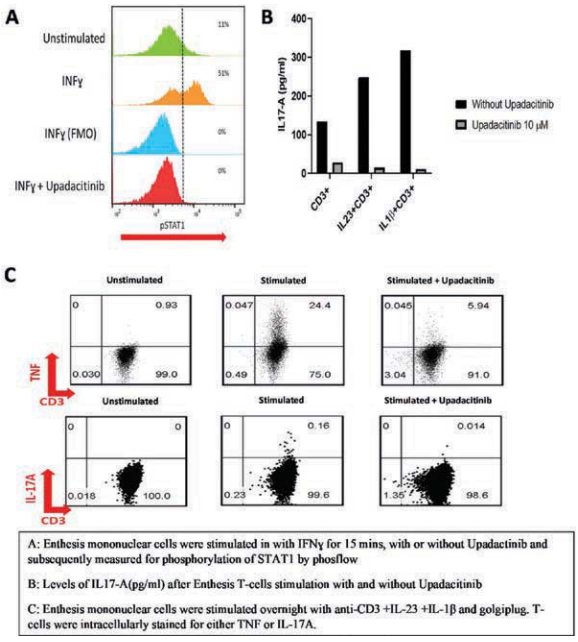
POS0331

UPADACITINIB EFFECTIVELY LIMITS IL-23 DRIVEN INFLAMMATION AT THE ENTHESIS BY INHIBITING T CELL STAT1 PHOSPHORYLATION, IL-17A AND TNFA PRODUCTION

S. Giryes[1], C. Bridgewood[1], C. Wong[1], T. Macleod[1], D. Mcgonagle[1,2].
[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), Leeds, United Kingdom; [2]Leeds Teaching Hospitals, National Institute for Health Research (NIHR) Leeds Biomedical Research Centre (BRC), Leeds, United Kingdom

Background: Enthesitis or inflammation of the tendon/ligament anchorage points is the cardinal lesion in spondyloarthritis (SpA)[1]. Several key mediators have been shown to have a role in SpA including TNFα, IL-23, IL-17A and IL-17F [1]. There is a need for new therapeutic agents to treat SpA as current therapeutics fail to adequately target all its manifestations. Janus kinase (JAK) inhibitors have shown promise as disease modifying drugs and by targeting signaling components shared amongst several inflammatory pathways may be advantageous in treating inflammatory diseases with complex overlapping pathological mechanisms, as seen in SpA[2]. Upadacitinib is an oral selective JAK inhibitor (JAK1 over JAK2/3) which in phase II/III trials has shown efficacy for both psoriatic arthropathy and ankylosing spondylitis, suggesting specific JAK1 targeting may be superior[3, 4]. The role of JAK/STAT signaling in enthesis has not been extensively explored and given the importance of the enthesis in the development of SpA it is crucial to gain a mechanistic understanding of how JAK inhibitors affect entheseal inflammation.
Objectives: To determine if upadacitinib could suppress innate and adaptive immune responses in an in vitro human enthesis model and elucidate mechanisms of suppression.
Methods: Normal spinous process enthesis was obtained from patients undergoing spinal decompression or surgery for scoliosis correction as previously described[5]. Enthesis cells were subsequently isolated by mechanical digestion. Entheseal cells were stimulated with IFNγ (JAK1 activator) with and without upadacitinib and STAT 1 activation measured by phos-flow cyometry. Entheseal T-cells were stimulated with anti-CD3, anti-CD3 with IL-23 and anti-CD3 with IL-1β with and without upadacitinib. IL-17A and TNFα were quantified using intracellular flow cytometry and ELISA of supernatants. Entheseal cells were also stimulated with LPS with and without upadacitinib, and IL-23 and TNFα quantified by ELISA.
Results: Upadacitinib inhibited phosphorylation of STAT1 in entheseal cells, following IFNγ stimulation (Figure 1-A). Following stimulation of entheseal T cells upadacitinib inhibited both TNFα and IL-17A production as assessed by both ELISA and intracellular flow cytometry (Figure 1-B, 1-C). Upadacitinib did not attenuate LPS induced IL-23 or TNFα from entheseal myeloid cells.
Conclusion: Upadacitinib inhibition of entheseal T cell derived TNFα and IL-17A, therefore interrupting the IL-23/IL-17/TNFα axis so prominent in SpA, may offer a mechanistic explanation for upadaticintib's efficacy treating enthesitis.



A: Enthesis mononuclear cells were stimulated in with IFNγ for 15 mins, with or without Upadactinib and subsequently measured for phosphorylation of STAT1 by phosflow

B: Levels of IL17-A(pg/ml) after Enthesis T-cells stimulation with and without Upadacitinib

C: Enthesis mononuclear cells were stimulated overnight with anti-CD3 +IL-23 +IL-1β and golgiplug. T-cells were intracellularly stained for either TNF or IL-17A.

CD71 RECEPTOR APICAL EXPRESSION IN ILEUM IS RELATED WITH HIGH LEVELS OF SERUM SIGA AND ACTIVITY DISEASE IN SPA PATIENTS

J. De Avila[1], A. Ramos-Casallas[1], D. Acero-M[2], C. Florez[3], V. Parra-Izquierdo[3], L. Chila[1], W. Bautista-Molano[1,4], A. Beltrán[1], D. Jaimes[5], J. M. Bello-Gualtero[4,6], C. F. Pacheco Tena[7], P. Chalem[8], C. Romero-Sánchez[1,4,6]. *[1]Universidad El Bosque, Cellular and Molecular Immunology Group - INMUBO, Bogotá D.C., Colombia; [2]Universidad El Bosque, School of Science, Biomedical Master Program, Bogotá D.C., Colombia; [3]Grastroadvanced SAS, Endoscopy Department, Bogotá D.C., Colombia; [4]Universidad Militar Nueva Granada, School of Medicine, Clinical Immunology Group, Bogotá D.C., Colombia; [5]Clínicos IPS, Rheumatology Department, Bogotá D.C., Colombia; [6]Hospital Militar Central, Rheumatology and Immunology Department, Bogotá D.C., Colombia; [7]Biomedicina de Chihuahua, Rheumatology Department, Chihuahua, Mexico; [8]Fundacion Instituto de Reumatología Fernando Chalem, Rheumatology Department, Bogotá D.C., Colombia*

Background: Currently, mucosal immunity research has been investigated whether the serum levels of SIgA reflects the over-activation immune system in gut associated lymphoid tissues (GALT) and if the antigenic stimuli in the mucosa are responsible for inducing and maintaining the inflammatory response in Spondyloartrhitis (SpA). Based on our previous results, variances on levels of SIgA might influence in disease activity. SIgA Reverse transcytosis (retrotranscytosis) has been demonstrated as a GALT mechanism which enhance systemic inflammation in some autoimmune pathologies such as celiac disease.
Objectives: This study proposes the evaluation of receptors associated with retrotranscytosis CD71 and Dectin-1 (Dec-1) in gut tissues from SpA without IBD patients to explore a possible mechanism responsible of gastrointestinal inflammatory imbalance.
Methods: In total, 180 patients with SpA (ASAS/criteria) were assessed by rheumatologists, of which (n=65, 36.1%) met the selection criteria and from them (n=41, 63.1%) by a gastroenterologist to perform digital chromoendoscopy with magnification for colon e ileum and histological analysis. Pregnant and lactating women, and cancer patients, patients with other autoinflammatory diseases, autoimmune diseases, immunodeficiency, chronic pancreatitis, or chronic liver disease, and those who had received antibiotic treatment in the last 3 months were excluded from the study. Furthermore, those patients with SpA and concomitant IBD were excluded. All included patients were between 18 and 65 years old. CD71 and Dec-1 apical expression were identified by indirect immunofluorescence. Fecal Calprotectin (FC), Serum SIgA in house and clinical indices BASDAI, BASFI, ASDAS-CRP, ASDAS-ESR were measured. The association were evaluated using the Chi-square or Fisher's exact test and a multiple correspondence discriminant analysis (MCDA) was performed including those variables with significant associations from bivariate analysis and some that are considered clinically relevant to explain the impact of SIgA and CD71 in SpA.
Results: The average age of the patients included was 44,6±10.2 years, 56.1% were men, 39.0% were HLA-B*27:05 positive, 90.2% had axial involvement. Serum levels of SIgA were 62.3±24.1 gr/mL, CRP 1.7±2.4 and ESR 14.1±12.0 mm/h. Positive levels of FC (>120ng/mL) were observed in 31.7%. BASDAI >4 was found in 58.5% of patients and ASDAS-CRP >2.1 in 75.6%. Apical expression of CD71 and Dec-1 in the ileum was observed in 48.8% and 36% respectively, the expression of both receptors in colon tissues were irrelevant. CD71 expression was associated with high levels of serum SIgA (p=0.05). However, no associations were observed between retrotranscytosis receptors and any of the clinical and histological variables. The MCDA showed a Cronbach's Alpha reliability coefficient of 0.763 and showed two dimensions: a main

dimension (Dim 1) related to the presence of loss of the vascular pattern in the ileum (CC 0.325), FC + diarrhea (CC 0.695), FC + abdominal distension (CC 0.883) and FC + abdominal pain (CC 0.885) and a secondary dimension (Dim 2) that collected the variables serum SIgA (CC 0.513), ASDAS-CRP >2.1 (CC 0.311), CD71 (CC 0.424), please see Figure 1.

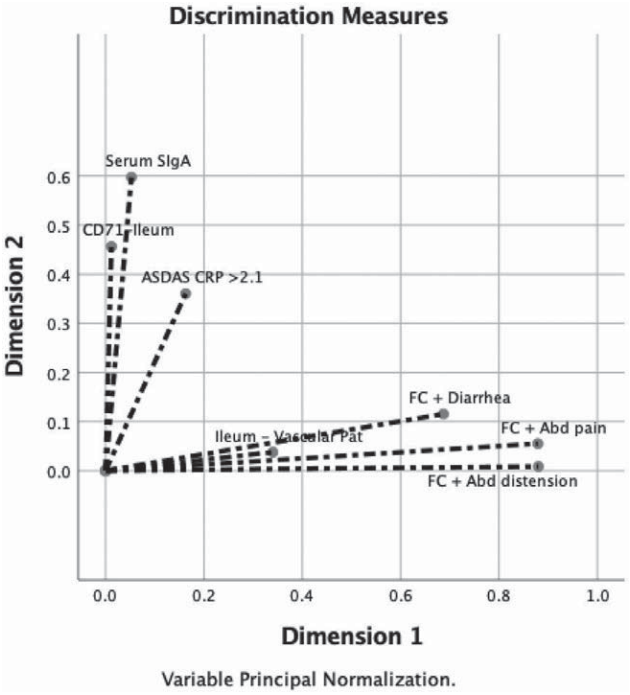

Figure 1. Multiple correspondence discriminant analysis for CD71, serum SIgA and activity index in SpA patient

Conclusion: The findings reflect a possible relationship among the apical expression of CD71in ileum with high levels of serum SIgA and activity, suggesting that retrotranscytosis mediated by this receptor might be a mechanism that mediate the intestine-joint axis in SpA.

POS0333

CIRCULATING NON-CLASSICAL CD14LOW/-CD16+ MONOCYTES AND THEIR EXPRESSION OF ARGINASE-1 ARE ASSOCIATED WITH THE ACTIVITY OF AXIAL SPONDYLOARTHRITIS

T. Tyrinova[1], A. Morenkova[1], M. Tikhonova[1], O. Chumasova[2], N. Ilina[2], A. Fedorova[2], A. Sizikov[2], A. Ostanin[1], E. Chernykh[1]. *[1]Research Institute of Fundamental and Clinical Immunology, Laboratory of Cellular Immunotherapy, Novosibirsk, Russian Federation; [2]Research Institute of Fundamental and Clinical Immunology, Department of Rheumatology, Novosibirsk, Russian Federation*

Background: Human peripheral blood monocytes represent heterogeneous population and can be divided into three major populations, classical ($CD14^{++}CD16^{-}$), intermediate ($CD14^{++}CD16^{+}$) and non-classical ($CD14^{+}CD16^{++}$) monocytes. All three monocyte populations are thought to have different functional activity, including their pro- and anti-inflammatory activity. The ratio between monocyte populations could change in inflammatory conditions that it is thought to be important for the development of adequate immune responses. Axial spondyloarthritis (axSpA) being autoimmune diseases is currently classified as an autoinflammatory disease based on a strong inflammatory component. It is accepted that increased concentration of pro-inflammatory mediators can cause an impairment of myelopoiesis.

Objectives: The present study aimed to analyze the frequency of blood monocyte subpopulations and their expression of the suppressor molecule arginase-1 (Arg1) in patients with axSpA.

Methods: The study included 14 healthy donors and 19 axSpA patients aged 23 to 59 years, including 15 men and 4 women. Ankylosing Spondylitis Disease Activity Score (ASDAS) was used to assess disease activity and high activity was determined as ASDAS≥2.1. The disease duration at the time of the study was 12 years (median). Phenotypic analysis of blood monocytes was performed by flow cytometry based on CD14 and CD16 expression.

Results: The frequency of monocyte subpopulations in patients with low/moderate activity of axSpA did not differ from the donor group. Patients with high/very high disease activity showed an increased relative number of non-classical $CD14^{low/-}CD16^{+}$ monocytes (vs donors p_U=0.007). All donor monocyte subpopulations expressed suppressor intracellular molecule Arg1 with higher expression in intermediate and non-classical monocytes. The expression of Arg1 in $CD14^{low/-}CD16^{+}$ monocytes was significantly reduced in patients with high activity (vs donors Me 41.5 vs 76.5%, p_U=0.01). Patients with the presence of peripheral articular manifestations of axSpA were characterized by a decreased Arg1 expression in non-classical monocytes compared with the donor group (p_U=0.02). However, patients without peripheral manifestations demonstrated a significant reduction of Arg1 expression in all monocyte subpopulations (p_U<0.05).

Conclusion: Shifting of monocyte subpopulation toward a higher number of non-classical monocytes with the decrease in the expression of the suppressor molecule Arg1 in the high activity of axSpA can play important role in terms of the possible involvement of monocytes in maintaining inflammation and its regulation in autoinflammatory disease.

New insights into the management of JIA

POS0334

DRIVERS OF NON-ZERO PHYSICIAN GLOBAL SCORES DURING PERIODS OF INACTIVE DISEASE IN JUVENILE IDIOPATHIC ARTHRITIS

A. I. Rebollo Giménez[1], A. Alongi[2], G. Giancane[1], R. Naddei[1], V. Natoli[1], N. Ruperto[1], A. Consolaro[1], A. Ravelli[3]on behalf of Pediatric Rheumatology Internationals Trials Organization (PRINTO). *[1]Istituto Giannina Gaslini, Pediatric and Rheumatology Clinic, Genoa, Italy; [2]Azienda Ospedaliera di Rilievo Nazionale e di Alta Specializzacione Civico Di Cristina e Benfratelli, Pediatric Clinic, Palermo, Italy; [3]Istituto Giannina Gaslini, Scientific Director, Genoa, Italy*

Background: The ACR provisional criteria for defining inactive disease (ID) in Juvenile Idiopathic Arthritis (JIA) requires that the physician's global assessment of disease activity (PhGA) is marked as 0 on the visual analog scale (VAS). However, some investigators have noticed the tendency of some clinicians to mark the PhGA>0 even on resolution of active disease. Due to the fact that the PhGA and the count of active joints are the two main physician-centered measures included in ID criteria the analysis of their discordance may be of importance to address the issue.

Objectives: To investigate the frequency in which the physician provides a global assessment of disease activity (PhGA)>0 and an active joint account (AJC)=0 in children with juvenile idiopathic arthritis (JIA) and search for determinants of divergence between the two measures.

Methods: Data were extracted from a multinational cross-sectional dataset of 7265 patients who had JIA by ILAR criteria, were recruited between 2011 and 2016 and had both PhGA and AJC recorded by the caring paediatric rheumatologist at the study visit. Determinants of discordance between PhGA and AJC=0 were searched for by multivariable logistic regression and dominance analysis.

Results: The PhGA was scored >0 in 1211 (32,4%) of 3668 patients who had an AJC of 0. In 536 patients (14,6%) the PhGA was the single most frequent reason for not meeting the ID definition in patients with AIJ=O. Independent associations with discordant assessment were identified for tender or restricted joint count>0, history of enthesis, presence of active uveitis or systemic features, enthesitis-related or systemic arthritis, increased acute phase reactants, pain visual analog scale (VAS)>0, and impaired physical or psychosocial wellbeing. In dominance analysis, tender joint count accounted for 35,43% of PhGA variance, followed by VAS>0 (17,72%), restricted joint count >0 (16, 14%) and physical health score >0 (11,42%) (Figure 1).

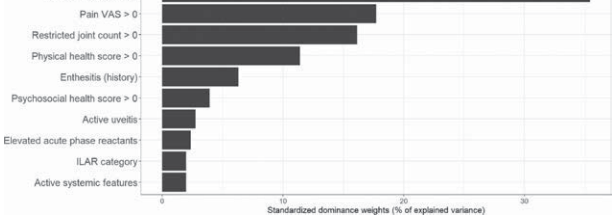

Figure 1. Dominance analysis of relative importance of predictive factors in explaining the variance in PhGA.

Conclusion: We found that many paediatric rheumatologists did not mark a score of 0 for patients who they found not to have active joints. The presence of pain in joints not meeting the definition of active joint used in JIA was the main determinant of this phenomenon.

Background: Pain can be a problem in a subgroup of juvenile idiopathic arthritis (JIA) patients even though in clinical remission. This can at least partly be due to their pain coping strategy of catastrophizing [1]. In a chronic disease such as JIA, the quality of coping with pain is crucial. The importance of coping with pain is well recognized in children [2]. The understanding of the parental role in supporting the child in pain is growing [3]; yet measuring the precise mechanism of parental pain coping is less studied. Thus, it seems important to measure also parental coping quality.

Objectives: The aim of this study was to develop a pain coping scale (PCSpar) for assessing the parents' coping strategies to their child´s pain and a shorter improved PCSped for children feasible for use in clinical practice.

Methods: The original pain coping questionnaire (PCQ) [4] has been validated in Finnish [5] resulting in a 38-item, eight-factor structured PCQ. The items in the new version of PCQ were reduced into twenty by an interdisciplinary team (mPCQped). A corresponding scale was created for parental use (mPCQpar). Consecutive patients aged 8-16 years, visiting pediatric rheumatology outpatient clinic, reporting musculoskeletal pain during the last week before visit or longer, were recruited to participate in this study. Both the patient and the caregiver rated the child's pain VAS from 0 to 100, completed the mPCQped /the mPCQpar and Children´s Depression Inventory (CDI) [6]/the Beck´s depression Inventory (BDI) [7] as appropriate. The selection process of pain questionnaire items was performed with factor analyses. The construct validity, the associations of the mPCQ factors, CDI, BDI and pain VAS, were tested by Spearman´s correlation coefficient.

Results: The study was conducted in all five tertiary and four secondary hospitals evenly distributed throughout Finland. Of the 153 families invited to the study, 130 attended. The average (SD) age of the attending patients was 13.0 (2.3) years. Of the patients, 91 (70%) were girls. Several steps in the exploratory factor analyses preceded the final factor analyses mPCQped and mPCQpar results. The four factors retained in the new improved Pain Coping Scale for children (iPCSped) were named positive cognitive distraction, catastrophizing (CATped), seeking social support (SSSped) and behavioral distraction. The factors in the improved Pain Coping Scale for caregivers (iPCSpar) were positive self-statement, catastrophizing (CATpar), seeking social support and distraction. In both iPCSped and iPCSpar there are a total of 15 items, 2-5 items/factor. The factor´s Cronbach´s alpha reliability coefficients were satisfactory, and the goodness-of-fit statistics were good. The CATpar correlated to BDI Rs= 0.33, $p<0.05$ and parent's assessment of the child's pain Rs= 0.23, $p<0.05$ in caregivers. The CATped correlated to CDI Rs= 0.49, $p<0.05$ and SSSped Rs= 0.26, $p=0.05$ but not to patient pain VAS Rs= 0.08, $p>0.05$.

Conclusion: In this study, we created a shorter pain coping scale for children (iPCSped) and a novel scale for caregivers (iPCSpar). Both showed good validity and reliability.

Background: Uveitis is an extra-articular manifestation of Juvenile idiopathic arthritis (JIA) with a prevalence of up to 20% developing most frequently in young girls and patients positive for antinuclear antibodies (ANA). Untreated and uncontrolled uveitis may lead to vision-threatening complications and even blindness.

Objectives: The main objectives of the analyses were to determine the visual prognosis, uveitis complications and necessity of ocular surgery during the first five years of ocular disease. The likelihood of achieving an inflammation-free phase or even a remission without medication were investigated.

Methods: The Inception Cohort of Newly diagnosed patients with JIA (ICON) was initiated in 2010 in order to prospectively follow JIA patients up to 10 years after JIA disease onset. 953 Patients were assessed at enrollment, three-monthly during the first year, and six-monthly afterwards by a standardized physician's and patient's case report form including clinical parameters, treatment data and several laboratory parameters such as ESR, CRP or S100A12. Patients who developed uveitis underwent a regular ophthalmological assessment. The treating ophthalmologist three-monthly completed an additional questionnaire, documenting the anterior chamber (AC) cell grade, current uveitis activity (UA) and UA during the previous three months, best corrected visual acuity (BCVA), uveitis-related complications, previous ocular surgery, current topical treatment

and clinical course of uveitis and additional parameters. Inactive uveitis was defined by AC cell grade of 0, quiescence of uveitis by inactive uveitis for at least 6 months, and remission by inactive uveitis for at least 6 months without topical steroids or systemic anti-inflammatory medication (steroids or DMARDs).

Results: A total of 133 children developed uveitis in the JIA disease course, of which 97 patients were documented via the ophthalmological questionnaire for at least two years resulting in a mean follow-up of 5.8 years (SD 1.8). 76% were female, 86% ANA positive, 70% oligoarthritis, and 22% rheumatoid factor negative polyarthritis and mean age at JIA onset was 3.1 (SD 2.1) and uveitis onset at 4.4 (SD 2.2) years. The mean duration between JIA onset and uveitis onset was 15.7 (SD 15.6) months. At least one ocular complication was reported for 24% of patients at first uveitis documentation and 47% of patients had at least one ocular complication until the five year follow-up. Among those, posterior synechiae (31%) and cataract (27%) were the most frequent, followed by an increased IOP (12%) with or without glaucomatous changes. Ocular surgery was rarely necessary, and visual acuity remained quite good in the majority of patients: After five years, >90% had BCVA of <0.4 LogMAR (Logarithm of the Minimum Angle of Resolution), and 63.5% even of <0.1 LogMAR. About half of the uveitis patients were already treated with DMARDs at uveitis onset. The rate of treatment with biological DMARDs increased from 10% at first uveitis documentation up to 20% at 5-year follow-up. Three in four patients were treated with topical steroids at first assessment, whereas this proportion decreased to 43%. 80 of 97 patients (83%) achieved uveitis quiescence during the first five years of disease, with more than 50% experiencing more than one episode (mean 1.5 episodes (SD 1.0)) during this time period. The mean duration of uveitis quiescence was 23.2 (SD 15.6) months. A total of 39 (40%) patients achieved uveitis remission during follow-up. The likelihood of remission was associated with a lower JIA disease activity (cJADAS10), lower erythrocyte sedimentation rate (ESR) and a higher age at JIA disease onset.

Conclusion: The rate of ocular complications is already remarkable at uveitis diagnosis, and increases during uveitis disease course despite anti-inflammatory treatment. However, the visual acuity frequently remains unaffected, and the majority of patients achieve uveitis quiescence and even 40% uveitis remission within 5 years of follow-up.

POS0337 DISTINCT CLUSTERS OF JIA AT METHOTREXATE INITIATION IDENTIFIED USING TOPOLOGICAL DATA ANALYSIS

S. Shoop-Worrall[1,2], K. Hyrich[1,3], L. Wedderburn[4,5,6], N. Geifman[7]on behalf of The CLUSTER Consortium, BSPAR-ETN Study, BCRD Study, CAPS, CHARMS. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [2]The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom; [3]Manchester University NHS FT, NIHR Manchester BRC, Manchester Academic Health Science Centre, Manchester, United Kingdom; [4]UCL Great Ormond Street Institute of Child Health, University College London, Centre for Adolescent Rheumatology Versus Arthritis at UCL, London, United Kingdom; [5]Great Ormond Street Hospital NHS Foundation Trust, Paediatric Rheumatology, London, United Kingdom; [6]NIHR Great Ormond Street Hospital Biomedical Research Centre, NIHR Great Ormond Street Hospital Biomedical Research Centre, London, United Kingdom; [7]University of Surrey, School of Health Sciences, Faculty of Health and Medical Sciences, Guildford, United Kingdom*

Background: Stratified medicine requires the identification of unique strata of a disease within which to base prognostic and treatment decisions. Juvenile idiopathic arthritis (JIA) offers a unique challenge in its inherent heterogeneity. The current ILAR classification, whilst useful for clinical categorisation, does not correlate with treatment outcomes. Therefore, further refinement, clustering and correlation of patient characteristics with treatment response are urgently required.

Objectives: To identify novel, phenotypically consistent subgroups of children and young people (CYP) with JIA at the point of starting methotrexate, across 19 patient and disease characteristics.

Methods: MTX-naïve CYP with JIA were selected if enrolled prior to April 2021 in one of four national JIA studies contributing to the UK CLUSTER consortium. Data from 19 harmonised study variables were extracted at point of starting MTX. Topological data analysis using a Gower similarity metric was used to identify clusters with distinct characteristics. Intervals and percent overlap between clusters were varied until an optimal model identified stable, potentially clinically plausible clusters. Significant differences in characteristics between identified clusters were tested using Kruskall-Wallis and Chi-Squared statistics.

Results: Of 2915 CYP included, the majority were female (68%), of white ethnicity (90%); with the most common ILAR categories being oligoarthritis (35%) and RF-negative JIA (34%).

The optimal TDA model identified six clusters which significantly differed across 16 of the 19 clinical variables at MTX initiation: Adolescents with low-moderate disease (Cluster 1, 41%), adolescents with predominantly sJIA and moderate-high disease (Cluster 2, 4%), children with predominantly sJIA and high disease (Cluster 3, <1%), children with oligo/RF-polyarthritis and low-moderate disease (Cluster 4, 43%) and two ANA-positive groups of largely females with moderate (Cluster 5, 11%) and high (Cluster 6, 1%) disease (Figure 1). Clustered groups also significantly differed in gender proportions (p<0.001), ethnicities (p<0.001), history of uveitis (p<0.001) and disease duration to both diagnosis (p<0.001) and MTX initiation (p<0.001), but did not differ in limited joint count (p=0.117), height (p=0.245) or BMI (p=0.394) z-scores.

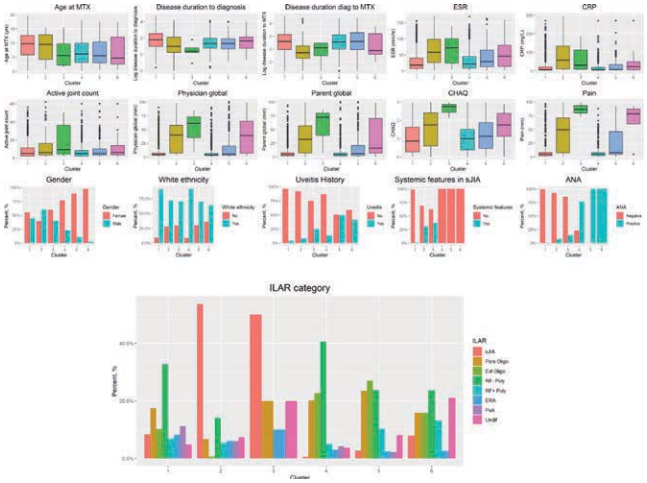

Figure 1. Clusters identified at MTX initiation in children and young people recruited to the UK BSPAR-ETN, BCRD, CAPS and CHARMS studies.

Conclusion: This study shows substantial heterogeneity in JIA at the point of MTX initiation, with six clusters identified across 19 demographic and clinical variables. ILAR categories across clusters were not always indicators of disease activity or symptom burden. Future analyses will correlate MTX treatment response within each cluster to understand what role these combined factors may have on initial treatment response.

Background: In recent years, transition clinics have been set up at an increasing number of paediatric rheumatology sites in Germany to reduce identified deficits in the care of young people with rheumatic diseases[1]. In addition, the German Rheumatic Diseases League (Deutsche Rheuma-Liga, DRL), the largest self-help organisation in Germany, has been offering support services for young people in transition since 2016, including the interactive website www.mein-rheuma-wird-erwachsen.de.

Objectives: To assess the transition competence of young people with juvenile idiopathic arthritis (JIA) and their knowledge of self-help services.

Methods: Cross-sectional data of the National Paediatric Rheumatology Database (NPRD) from 2016 to 2020 were used to evaluate the health-related transition competence of young people with JIA aged ≥16 years. Health-related knowledge and health-care competence were assessed using a modified self-report instrument[2] on a 4-point Likert scale as part of routine documentation in the NPRD. Young people were also asked about their information behaviour and knowledge of new support services. Linear mixed models were used to determine whether health-related transition competence changed between 2016 and 2020, adjusted for disease duration.

Results: During the years 2016 to 2020, between 1.908 to 2.536 patients with JIA aged ≥16 years were annually recorded in the NPRD from 56 to 61 paediatric rheumatology sites. The annual patient collectives comprised 34-39% oligoarthritis, 23-26% RF-negative or RF-positive polyarthritis and 22-27% enthesitis-related arthritis cases. In the years from 2016 to 2020, about one-third of patients had inactive disease (cJADAS-10≤1) and about 60% had no functional limitations (CHAQ=0).

Over the years, the proportions of patients who rated their disease knowledge and health care competence as "very well" increased significantly in most areas. Although over time, no increase in numbers of patients seeking information about their disease outside of rheumatology consultations were recorded (2016: 22.8%; 2020: 20.9%), awareness of the DRL's new website for young people with rheumatic diseases increased from 7.7% in 2016 to 26.9% in 2020. Compared to those who were unaware of the new website, those who knew about the website were more likely to have received care in rheumatology settings that offer transition clinics and were more likely to be girls (75% vs 65%), to attend high school (51% vs 46%) and to be slightly older (17.6 vs 17.1 years).

Conclusion: The transition competence of young people with JIA seems to have improved over the last five years. During this time, more transition services were made available for young people with rheumatic diseases. However, most young people are not yet aware of these services. Moreover, the effectiveness of the different measures/interventions has yet to be evaluated.

POS0339 POINTS TO CONSIDER AT THE EARLIEST STAGES OF THE DIAGNOSIS AND MANAGEMENT OF HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS/ MACROPHAGE ACTIVATION SYNDROME (HLH/MAS)

B. Shakoory[1], A. Geerlinks[2], M. Wilejto[3], K. Kernan[4], E. Demirkaya[3], A. Ravelli[5], R. Sinha[6], R. Goldbach-Mansky[1], F. De Benedetti[7], R. Marsh[8], S. Canna[9] on behalf of EULAR/ACR HLH/MAS Working Group. *[1]NIAID/NIH, Translational Autoinflammatory Disease Section, Bethesda, United States of America; [2]London Health Sciences Centre, Hematology/Oncology, London, Canada; [3]London Health Sciences Centre, Rheumatology, London, Canada; [4]University of Pittsburgh, Critical Care Medicine, Pittsburgh, United States of America; [5]Instiuto Gaslini, Rheumatology, Genoa, Italy; [6]Systemic JIA Foundation, Head, Cincinnati, United States of America; [7]Ospedale Bambino Gesu, Rheumatology, Rome, Italy; [8]Cincinnati Children's Hospital Medical Center, Bone Marrow Transplantation and Immune Deficiency, Cincinnati, United States of America; [9]The Children's Hospital of Philadelphia, Rheumatology & Immune Dysregulation, Philadelphia, United States of America*

Background: Hemophagocytic Lymphohistiocytosis (HLH) and Macrophage Activation Syndrome (MAS) are life-threatening systemic hyperinflammatory syndromes that occur in many contexts and are often called by many names. They nevertheless can progress rapidly, and early identification and management are critical for preventing organ failure and mortality.

Objectives: The purpose of this effort was to develop a series of 'points to consider' to assist clinicians at the earliest stages of evaluation and diagnosis, management, and monitoring of patients with HLH/MAS in order to improve patient outcomes.

Methods: A working group of adult and pediatric rheumatologists (14), hematologist/oncologists (4), immunologists (2), infectious disease specialists (2), intensivists (3), allied health care professionals (1), and patients/parents (2) formulated relevant research questions for a systematic literature review (SLR). We then used the SLR results, Delphi questionnaires, and consensus methodology to devise and refine overarching and specific 'points to consider' statements.

Results: The group arrived at six overarching statements and 24 specific points-to-consider relevant to early decision-making in diagnostics, initial management, and monitoring of HLH/MAS. Major themes included the a) need for prompt recognition, evaluation, and management of underlying triggers and conditions, b) multi-disciplinary/expert input, and c) early, tailored intervention with the goals of halting disease progression and preventing life- and organ-threatening immunopathology

Conclusion: These 2022 EULAR/ACR Points to Consider provide guidance on the initial evaluation, management, and monitoring of patients during the initial consideration of HLH/MAS.

Background: For children with polyarticular juvenile idiopathic arthritis (pJIA) and inadequate response or intolerance to initial treatment with MTX, treatment options include abatacept.[1] Abatacept, a selective T-cell co-stimulation modulator, has a distinct mechanism of action from other current treatments for rheumatic diseases,[2] and factors predicting clinical response can help determine optimal treatment strategy. Two phase 3 studies demonstrated the efficacy and safety of IV and SC abatacept in patients with pJIA and an inadequate response to other DMARDs.[2,3]

Objectives: To determine baseline and post-baseline factors that may predict a clinical response in children and adolescents with pJIA treated with abatacept for 2 years.

Methods: Baseline demographic and disease characteristics and post-baseline factors (50% and 70% improvement in ACR criteria [ACR50, ACR70] at days 57 and 85) were analyzed using data from 2 phase 3 studies of abatacept in patients with JIA aged 2–17 years (SC administration) and 6–17 years (IV administration). Efficacy endpoints were Juvenile Arthritis Disease Activity Score in 10 joints based on CRP (JADAS10-CRP) inactive disease (ID; score of ≤ 2.7),[4] and remission, defined as 6 consecutive months of post-baseline JADAS10-CRP ID. Data were analyzed over the entire 2-year study period. The earliest time point at which patients achieved these outcomes was reported. The aforementioned study factors were subjected to a time-to-event analysis, including Cox proportional hazards univariate regression analysis and Cox proportional hazards multivariate regression analysis using stepwise regression; results of the multivariate analysis are reported. Kaplan–Meier analysis was used to estimate time to achieve clinical response. Receiver operating characteristic curves were used to determine threshold values for continuous variables.

Results: Overall, 347 patients were included in the analysis (SC, n = 219; IV, n = 128; 73.8% female; mean [SD] age, 11.3 [4.0] years). Following abatacept treatment, both time to JADAS10-CRP ID and time to JADAS10-CRP remission were predicted (nominal $P \leq 0.05$) by age (≤ 11 years: hazard ratio [HR], 1.52 [95% CI, 1.14–2.02] and ≤ 10 years: HR, 1.73 [95% CI, 1.20–2.48], respectively), high-sensitivity CRP (hsCRP; ≤ 0.6 mg/dL: HR, 1.67 [95% CI, 1.22–2.28] and ≤ 0.21 mg/dL: HR, 1.67 [95% CI, 1.15–2.42], respectively), Parent/Patient Global Assessment of well-being (≤ 35.86: HR, 1.88 [95% CI, 1.41–2.51] and ≤ 43.16: HR, 2.05 [95% CI, 1.35–3.10], respectively), and Childhood HAQ-DI (CHAQ-DI; ≤ 1.63: HR, 2.23 [95% CI, 1.47–3.39] and ≤ 0.75: HR, 1.84 [95% CI, 1.24–2.73], respectively) (remission data shown in Figure 1). Disease duration ≤ 2 years from baseline (HR, 1.66 [95% CI, 1.25–2.21]) and SC route of administration (HR, 2.05 [95% CI, 1.45–2.91]) also predicted ID. Among the post-baseline factors, ACR50 at days 57 and 85 predicted both ID (HR, 1.57 [95% CI, 1.04–2.36] and HR, 1.88 [95% CI, 1.41–2.51], respectively) and remission (HR, 1.96 [95% CI, 1.11–3.45] and HR, 3.05 [95% CI, 1.47–6.34], respectively); ACR70 at day 57 also predicted ID (data not shown). Patients with predictive factors for age, hsCRP, Parent/Patient Global Assessment of well-being, and CHAQ-DI, and with lower disease activity achieved ID and/or remission earlier than patients with high disease activity.

Conclusion: We identified baseline and post-baseline factors that predicted JADAS10-CRP ID and remission in patients with pJIA treated with abatacept for 2 years. Screening of abatacept-treated patients with pJIA for such factors may help predict earlier achievement of ID and/or remission.

POS0341 CONSENSUS-DRIVEN DEFINITION FOR UNEQUIVOCAL SACROILIITIS ON RADIOGRAPHS IN JUVENILE SPONDYLOARTHRITIS

P. F. Weiss[1,2], T. G. Brandon[2], R. G. Lambert[3], D. M. Biko[4,5], N. A. Chauvin[6], M. L. Francavilla[4,5], N. Herregods[7], A. M. Hendry[8], W. P Maksymowych[9]. [1]*Perelman School of Medicine at the University of Pennsylvania, Center for Clinical Epidemiology and Biostatistics, Philadelphia, United States of America;* [2]*Children's Hospital of Philadelphia, Department of Pediatrics, Division of Rheumatology, Philadelphia, United States of America;* [3]*University of Alberta, Department of Radiology and Diagnostic Imaging, Edmonton, Canada;* [4]*University of Pennsylvania, Department of Radiology, Philadelphia, United States of America;* [5]*Children's Hospital of Philadelphia, Department of Radiology, Philadelphia, United States of America;* [6]*Penn State Health, Department of Radiology, Hershey, United States of America;* [7]*Ghent University Hospital, Department of Radiology and Nuclear Medicine, Ghent, Belgium;* [8]*Middlemore Hospital, General Medicine - (Incl. Obstetric Medicine and Adult Rheumatic Fever), Auckland, New Zealand;* [9]*University of Alberta, Department of Medicine, Edmonton, Canada*

Background: Radiographs are not a sensitive or reliable imaging tool for detection of early sacroiliitis in juvenile spondyloarthritis (JSpA). However, radiographs are still commonly performed in some areas due to difficulty in accessing MRI. As such, radiographs were included in the imaging data considered for an axial disease classification criteria development study, but only when there was no suitable MRI available.
Objectives: We aimed to define criteria for unequivocal evidence of sacroiliitis on pelvic radiography in skeletally immature children and adolescents for use in classification criteria.
Methods: Subjects were a cohort of JSpA patients with suspected axial disease. All subjects had symptom onset prior to age 18 years and underwent MRI as part of a diagnostic evaluation for axial disease; a subset of subjects also had a dedicated pelvic radiograph. Using a web-based interface, 6 musculoskeletal imaging experts, blinded to clinical details, reviewed the radiographs and graded them according to the modified New York (mNY) criteria. A two-way random effects intraclass correlation coefficient (ICC) was used to assess agreement. Next, the central imaging team underwent an iterative consensus process to define unequivocal evidence of sacroiliitis on pelvic radiography in skeletally immature children. Radiographs with at least two raters assigning a non-zero mNY grade were re-reviewed for the presence/absence of "unequivocal evidence of sacroiliitis" according to the consensus definition. Agreement was assessed with Fleiss's kappa statistic with agreement interpreted as poor ≤0.40, fair 0.41-0.59, good 0.60-0.74, and ≥0.75 excellent. Sensitivity, specificity, and positive and negative predictive values (PPV, NPV) were calculated to assess performance of the novel definition using structural lesion typical of juvenile axial disease on MRI as the reference standard (erosion in ≥3 sacroiliac joint (SIJ) quadrants *or* at least one of the following lesions in ≥2 SIJ quadrants: sclerosis, fat lesion, backfill, ankylosis).
Results: Radiographs from 120 subjects, 61% male, median age 14.7 years (range 6.7-20.1 years), had an AP dedicated pelvic radiograph available for scoring. The ICC for mNY grade amongst 6 central raters was fair for joints with at least one rater reporting a non-zero grade (0.45, 95% CI: 0.34-0.57). After multiple iterations and discussion, the consensus definition of unequivocal sacroiliitis by radiograph in skeletally immature children and adolescents was deemed "Unequivocal lesion (erosion, sclerosis, or ankylosis [partial or complete]) that must include at least one iliac bone. When sclerosis is present in isolation, if measurable, should extend ≥5mm from the joint surface. The decision may be influenced by the presence of other lesions, which in themselves do not suffice to meet the criterion." Sixteen radiographs were assessed using the consensus definition. 8 (50%) were rated as unequivocal sacroiliitis and Fleiss' kappa statistic was good at 0.61 (95% CI: 0.41-0.80). Across raters, the sensitivity, specificity, PPV and NPV of the consensus definition on radiograph using structural lesions typical of sacroiliitis on MRI as the reference standard were 80% (95%CI: 44.4-97.5), 100% (95% CI: 54.1-100), 100% (63.1-100) and 75% (95% CI:34.9-96.8), respectively.
Conclusion: We propose a consensus-derived definition of unequivocal sacroiliitis by radiography in skeletally immature children and adolescents with good expert rater agreement. Additionally, the consensus-definition had moderate to high sensitivity and PPV and high specificity and NPV with typical structural lesions on MRI as the reference standard. This definition has applicability to JSpA axial disease classification criteria when MRI is unavailable.

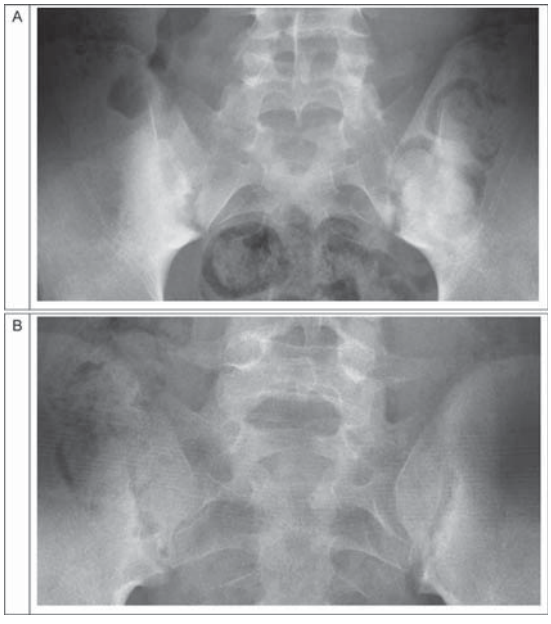

Figure 1. Examples of radiographs with unequivocal evidence of sacroiliitis in skeletally immature children as indicated by definite erosions of both iliac bones (A and B) and definite iliac sclerosis (A).

POS0342 ANTI-TUMOUR NECROSIS FACTOR (ATNF) WEANING STRATEGY IN JUVENILE IDIOPATHIC ARTHRITIS (JIA): DOES LONGER DURATION MATTER?

T. Arkachaisri[1,2], K. L. Teh[1], Y. X. Book[1], X. Gao[1], L. Das[1]. *[1]KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore; [2]Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore*

Background: The efficacy of aTNF in the treatment of children with JIA has been demonstrated. However, once the disease is under control, strategy towards discontinuing aTNF should be considered. Thus far, there is no convincing information regarding how biologics should be weaned.
Objectives: To compare the outcomes of a short- and long-weaning strategies of aTNF in our prospective observational JIA cohort
Methods: Children with JIA taking aTNF with at least 6 months follow-up duration were recruited from our JIA registry (May 2010-Jan 2022) at KK Women's and Children's Hospital, Singapore. Once remission on medication, ROM[1] (including no enthesitis and sacroiliitis by MRI for ERA) was achieved, aTNF was weaned according to 2 different protocols– short (Etanercept every 2 weeks, and Adalimumab every 4 weeks, for 6 months) and long (extending frequency by every 2 weeks for 3 cycles until reaching 12 weekly interval for another 3 cycles then stop biologic thereafter) protocols. Flare (recurrent of arthritis, enthesitis or uveitis) rates were compared, and potential predictors were assessed. Nonparametric statistics were used to described data and logistic regression and Kaplan-Meier analyses were used to assess clinical parameters and outcome association and cumulative probability of disease flare, respectively.
Results: Out of 143 JIA patients, 105 (78% male, 82% Chinese; enthesitis related arthritis 78%, oligoarticular JIA 9%, polyarticular JIA 11%, psoriatic arthritis 1%, undifferentiated JIA 1%) underwent aTNF weaning with 53% on short- and 47% on long-weaning protocol. Median disease duration at aTNF start was 13.5 (10.6-15.8) and duration of follow-up was 6.6 (3.9-9.5) years. There was no significant difference in demographic and clinical parameters between groups. There was none of the short- but 49% of the long-weaning group flared during the weaning period, Table 1. However, no significant difference in the total flare rate (during and after stopping aTNF) was observed between the 2 groups despite less patient flare after stopping aTNF in the later, p=0.004. Median time to flare after stopping aTNF was not different, p=0.270. Furthermore, probability of flare after stopping aTNF was not different as well, Log Rank p=0.095, Figure 1. Positive ANA predicts flare during weaning (OR 5.2, 95%CI: 1.224-22.416, p=0.026), but none of clinical parameters were associated with risk of flare after discontinuing aTNF therapy in our cohort.

Table 1. Rate of flare and duration related to aTNF between short- and long-weaning groups

FLARE	Total (n=105)	Short (n=56)	Long (n=49)	p
Number of JIA patients flared during wean (%)	24 (22.9)	0 (0.0)	24 (49.0)	<0.001
Time to flare during aTNF weaning after starting (month)*			6.5 (4.5-14.5)	
Number of JIA patients flared after DC aTNF (%)	50 (47.6)	34 (60.7)	16† (32.7)	0.004
Time to flare after stopping aTNF (month)*		6.2 (2.7-11.8)	6.9 (5.5-11.6)	0.270
Total number of patients who flared	68 (64.8)	34 (60.7)	34 (69.4)	0.353

*Median (interquartile range), †included 6 patients who flare during weaning and after stopping aTNF, aTNF = anti-tumour necrosis factor

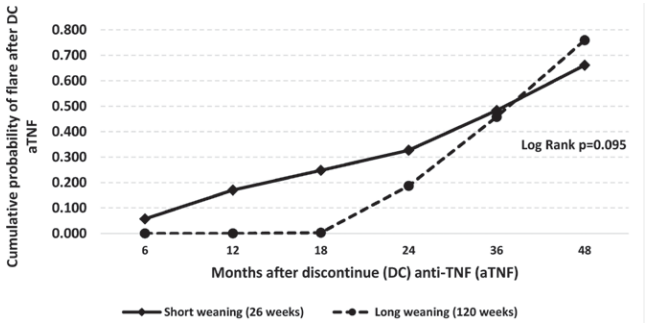

Figure 1. Cumulative probability of flare between the short- and long-weaning group after discontinuing aTNF therapy

Conclusion: Duration of spacing out the aTNF therapy after achieving ROM may not minimize the flare rate or delay time to flare after stopping the therapy in JIA patients. Further validation in larger multinational longitudinal cohorts is required to confirm our initial findings.

POS0343 TREATMENT PERSISTENCE AND ADHERENCE AMONG PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS RECEIVING ABATACEPT OR TNF INHIBITORS USING US CLAIMS DATA

C. A. Wang[1], R. Wong[2], T. D. Kou[3], H. Zheng[4], K. Wittstock[5], V. Khaychuk[6], V. Patel[7]. *[1]Bristol Myers Squibb, Business Insights & Analytics Research & Development, Princeton, United States of America; [2]Bristol Myers Squibb (at the time of analysis), Immunology and Fibrosis, Princeton, United States of America; [3]Bristol Myers Squibb, Immunology, Cardiovascular and Fibrosis, Worldwide Patient Safety, Princeton, United States of America; [4]Bristol Myers Squibb, Worldwide Health Economics and Outcomes Research – United States Market, Princeton, United States of America; [5]Bristol Myers Squibb, Immunology US Medical, Princeton, United States of America; [6]Bristol Myers Squibb, US Medical Immunology and Fibrosis, Princeton, United States of America; [7]Bristol Myers Squibb, Worldwide Health Economics and Outcomes Research, Princeton, United States of America*

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic condition among children and teens[1] and contributes to a diminished quality of life.[2] Previous data underscore the potential for abatacept to improve health-related outcomes in patients with JIA after demonstrating poor responses to other DMARDs.[3] Patients with RA show greater persistence on abatacept vs TNF inhibitors (TNFi), and this should also be confirmed in patients with JIA.[4]

Objectives: To evaluate treatment persistence and adherence at 12- and 18-month follow-up in patients with JIA newly initiating either abatacept or a TNFi.

Methods: This analysis used data from the IQVIA PharMetrics Plus claims database from Jan 2008–Apr 2021. We identified patients with ≥ 1 claim of JIA diagnosis after Jan 2008, who were < 18 years old at initial diagnosis, had ≥ 1 claim of abatacept or TNFi treatment (adalimumab, etanercept, golimumab) following diagnosis, had continuous enrollment in medical and pharmacy benefits for ≥ 12 months before index date (first prescription of abatacept or TNFi), and had 12 or 18 months' continuous medical and pharmacy enrollment after index date. Patients receiving abatacept or TNFi treatment ≤ 12 months prior to index date and patients initiating combined abatacept + TNFi treatment on the index date were excluded. Specific outcomes included: discontinuation (absence of a new prescription for index treatment within the gap of 5× treatment half-life), persistence rate (proportion of patients continuing index medication without any gaps exceeding 5× treatment half-life), and treatment adherence (defined as medication possession ratio [MPR, proportion of follow-up period where medication supply is available] and proportion of days covered [PDC, proportion of follow-up period where a patient is covered by a given drug]). All outcomes were reported at 12 and 18 months. All statistical analyses are descriptive with the intent for hypothesis generation.

Results: There were 2847 patients (abatacept, n = 111; TNFi, n = 2736) at 12-month follow-up; fewer completed the 18-month follow-up (2403 patients: abatacept, n = 94; TNFi, n = 2309). At index date, treatment groups were similar for sex, geographic location, and comorbidities (Table 1). Numerically higher persistence was observed in patients prescribed abatacept compared with TNFi overall at both time points. Abatacept persistence was higher than etanercept but similar to adalimumab (Figure 1). At 12 months, the percent of patients with PDC ≥ 0.8 was 57% for abatacept, 51% for adalimumab, and 38% for etanercept, while MPR ≥ 0.8 was 63% for abatacept, 55% for adalimumab, and 42% for etanercept. Patients prescribed abatacept had numerically greater proportions of PDC ≥ 0.8 (abatacept, 48%; adalimumab, 40%; etanercept, 29%) and MPR ≥ 0.8 (abatacept, 53%; adalimumab, 44%; etanercept, 33%) at 18 months.

Table 1. Baseline characteristics of patients with 12-month follow-up data

Characteristic	Abatacept (n = 111)	TNFi (n = 2736)
Age, years, mean (SD)	14.4 (3.8)	12.6 (4.6)
Female sex	89 (80.2)	1930 (70.5)
Geographic region		
South	43 (38.7)	865 (31.6)
Midwest	40 (36.0)	818 (29.9)
West	9 (8.1)	408 (14.9)
East	19 (17.1)	540 (19.7)
Unknown	0 (0)	105 (3.8)
Comorbidities		
Asthma	9 (8.1)	275 (10.1)
COPD	11 (9.9)	323 (11.8)
Cardiovascular disease	14 (12.6)	222 (8.1)
Uveitis	14 (12.6)	321 (11.7)
Iridocyclitis[a]	12 (10.8)	216 (7.9)
CCI score, mean (SD)	0.58 (0.73)	0.46 (0.68)

Data are shown as n (%) unless otherwise specified. [a]Subgroup disease under uveitis. CCI, Charlson Comorbidity Index; COPD, chronic obstructive pulmonary disease.

Conclusion: The present findings suggest that patients with JIA initiating abatacept treatment display numerically higher persistence and adherence compared with patients treated with TNFis at both 12- and 18-months' follow-up.

Novel molecular regulators of bone turnover

POS0344 O-GLCNACYLATION ON NUP153 REGULATES THE EARLY STAGES OF OSTEOCLASTOGENESIS THROUGH MYC NUCLEAR TRANSLOCATION

Y. N. Li[1], C. W. Chen[1], T. Trinh-Minh[1], Z. Honglin[2], P. Hubel[3], J. Pfannstiel[3], G. Schett[1], J. H. W. Distler[1]. [1]*University Hospital Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany;* [2]*Xiangya Hospital, Central South University, Department of Rheumatology, Changsha, China;* [3]*University of Hohenheim, Core Facility Hohenheim, Stuttgart, Germany*

Background: Bone homeostasis is maintained by the balance between bone formation and resorption. In inflammatory arthritis, such as rheumatoid arthritis (RA), the pro-inflammatory environment promotes osteoclast differentiation and skews this balance towards bone resorption, leading to destructive bone erosion and bone loss. O-GlcNAcylation is one of the most common post-translational modifications, which attaches a single N-acetylglucosamine (GlcNAc) molecular to the serine or threonine of the target protein. O-GlcNAcylation is controlled by the activities of a single pair of enzymes: OGT, which facilitates the transfer of GlcNAc onto proteins; OGA, which removes GlcNAc from proteins. The activity of O-GlcNAcylation has been reported to be involved in several cellular events, such as transcription, translation, intracellular trafficking, and differentiation. We previously showed that the dynamics of O-GlcNAcylation are essential for osteoclast differentiation. TNF-α, a key pro-inflammatory factor in RA, intensified the O-GlcNAcylation dynamics. Inhibition of OGT arrests osteoclast precursors at early stages, whereas OGA inhibition blocks osteoclast maturation. However, the molecular mechanism of these regulations remains unclear.

Objectives: We aimed to identify the O-GlcNAcylation targets in osteoclast precursors in a pro-inflammatory milieu and to decipher the molecular mechanism of O-GlcNAcylation mediated regulation of osteoclastogenesis.

Methods: We first identify the O-GlcNAc-dependent molecular pathways in osteoclast precursors with pharmacological OGT and OGA inhibition by RNA sequencing. Then, we identified the O-GlcNAcylated proteins by mass spectrometry-based proteomics analysis and confirmed by immunoprecipitation. We found the potential molecular mechanism by combining the data from transcriptomics and proteomics. The proposed mechanism was further validated through siRNA-mediated knockdown and high-content screening analysis.

Results: Our transcriptomics data showed that OGT inhibition arrested osteoclast differentiation at early stages through interfering the cytokine signaling and metabolic adaption. The upstream analysis proposed MYC as the most potent regulator for the transcriptomic profile under OGT inhibition. Recent studies proposed MYC as a master regulator for metabolic reprograming during osteoclast differentiation. However, O-GlcNAcylation of MYC was not detected by mass spectrometry, suggesting indirect effects of O-GlcNAcylation on MYC signaling in osteoclast precursors. We detected upregulated levels of O-GlcNAc on NUP153, MTDH, RBM27, IFI207 upon RANKL+TNFα stimulation. An integrated analysis of transcriptomic and proteomic data by Ingenuity Pathway Analysis indicated that NUP153 might regulate the most DEGs among all the identified targets and indicated potential of NUP153 to regulate nuclear shuttling of MYC. Subcellular fractionation and confocal microscopy showed enhanced MYC nuclear translocation upon RANKL+TNFα stimulation, which could be blocked by NUP153 knockdown or OGT inhibition. Functionally, knockdown of NUP153 arrested cells at similar stages to OGT inhibition and reduced bone resorption ability. Together, these results suggest a model, in which O-GlcNAcylation regulates the shuttling activity of the nuclear pore component NUP153 to control the access of MYC to the nucleus during osteoclast differentiation.

Conclusion: Our results indicated that OGT inhibition arrests osteoclastogenesis at early stages through hampering MYC-dependent metabolic adaption. NUP153 was proposed as the most potent O-GlcNAcylation target by multi-omics data integration. NUP153-mediated MYC nuclear trafficking is required for osteoclast differentiation. These findings reveal the molecular mechanism of O-GlcNAcylation-dependent osteoclastogenesis and provide therapeutic insights on targeting O-GlcNAcylation in pathologic bone resorption.

POS0345 ASSESSMENT OF THE EFFECT OF TOFACITINIB ON BONE MARROW ADIPOCYTES AND BONE-FORMING OSTEOBLASTS UNDER NON-INFLAMMATORY AND INFLAMMATORY CONDITIONS

J. G. Letarouilly[1], J. Paccou[1], S. Badr[2], R. M. Flipo[3], C. Chauveau[4], B. Cortet[2], O. Broux[4], A. Clabaut[4]. [1]*Université de Lille, CHU Lille, MABLab ULR 4490, Service de Rhumatologie, Lille, France;* [2]*Université de Lille, CHU Lille, MABLab ULR 4490, Service de Radiologie et Imagerie Musculosquelettique, Lille, France;* [3]*Université de Lille, CHU Lille, Service de rhumatologie, Lille, France;* [4]*Université Littoral Côte d'Opale, MABLab ULR 4490, Boulogne-sur-Mer, France*

Background: Systemic inflammation is the main factor underlying secondary osteoporosis in patients with rheumatoid arthritis (RA). The JAK inhibitors, such as Tofacitinib (Tofa), can control systemic inflammation and have beneficial effects on bone in various models. This might be due to direct effects on the bone microenvironment and not exclusively based on their anti-inflammatory function. Bone marrow adipocytes (BMAds) are abundant in the bone microenvironment. The effect of JAK inhibitors on BMAds is unknown, but evidence suggests that there is competition between human bone marrow-derived stromal cell (hBMSCs) differentiation routes toward BMAds and osteoblasts (Ob) in osteoporosis.

Objectives: To determine in various models whether Tofa influences directly bone marrow cell committment toward adipogenesis and osteoblastogenesis. Then, in a prospective pilot study, to investigate the potential effects of Tofa on bone marrow adiposity in patients with RA.

Methods: To study the effect of Tofa on cellular commitment, hBMSCs were cultured for 3 days in appropriate Ob- and BMAd- differentiation media (Ob-3d and BMAd-3d), together with Tofa at 200, 400 (equivalent to a therapeutic dose of 5 mg twice a day in RA patients) or 800 nM. To mimic inflammatory conditions, TNFα was added to the media at a dose of 1 ng/ml. This study was also conducted on mature BMAds and a similar treatment was applied for 6 days to mature BMAds at 14 days of differentiation (BMAd-20d). The impact of Tofa was determined by gene expression profile analysis, western-blot analysis and cell density monitoring. In parallel, in a pilot study of 9 RA patients treated with Tofa 5 mg twice a day (TOFAT study: NCT04175886), proton density fat fraction (PDFF) was measured by MRI (Dixon technique) at the lumbar spine at the start of treatment and at 6 months.

Results: In non-inflammatory conditions, the gene expression of Runx2 decreased in Ob-3d treated with Tofa 400 and 800 nM($p<0.05$). Conversely, BMAd-3d treated with Tofa (at 200, 400 and 800 nM) exhibited a substantial increase in the gene expression of PPARγ2, C/EBPα and Perilipin 1 (a marker associated with lipid droplet formation) compared to controls ($p<0.05$). The increase in the expression of Perilipin 1 was also confirmed at the protein level. In inflammatory conditions, BMAd-3d and Ob-3d markers decreased considerably (PPARy2 and RUNX2, respectively, $p<0.05$), but the addition of Tofa did not change the expression profiles of Ob-3d compared to TNFα controls. On the contrary, the analysis of PPARy2 gene expression showed that Tofa limited the negative effect of TNFα on BMAd differentiation ($p<0.05$). The positive effect of Tofa on mature adipocyte (BMAd-20d) under inflammatory conditions was also supported by an increase in the density of differentiated BMAds ($p<0.001$). These findings were consolidated by an increase in PDFF at 6 months of treatment with Tofa in RA patients (+6.9%, $p<0.01$).

Conclusion: Overall, *in vitro* and clinical results suggest a stimulatory effect of Tofa on BMAds commitment and differentiation, which does not support a positive effect of Tofa on bone

POS0346

IDENTIFICATION OF NEW MUTATIONS IN THE SQSMT1 GENE IN PATIENTS WITH PAGET'S DISEASE OF BONE. GENOTYPE-PHENOTYPE CORRELATION

A. Conesa[1], N. García Giralt[2], D. Bedoya Sanchis[3], M. Á. Belmonte Serrano[1]. *[1]Hospital General Universitario de Castellón, Rheumatology, Castellón de la Plana, Spain; [2]IMIM-Instituto Hospital del Mar de Investigaciones Médicas, Rheumatology, Barcelona, Spain; [3]INCLIVA -Hospital Clínico Universitario de Valencia, Rheumatology, Valencia, Spain*

Background: The Paget's disease of Bone (PDB) is characterized by a chronic and focal disorder of bone remodeling. PDB is currently considered a complex and multifactorial disease, as a result of a synergistic association of genetic variants with environmental risk factors. The genetic component would explain certain epidemiological traits such as the predisposition to develop in certain ethnic groups and the strong tendency to family aggregation. The most important susceptibility gene for PDB is the Sequestosome-1 (*SQSTM1*), and encodes a 440-amino-acid protein called p62 protein. *SQSTM1* gene occur in between 20 and 40% of patients with a family history of PDB, and 5 and 10% of patients with 'sporadic' disease, according to the series studied. Thus far, 29 *SQSTM1* mutations have been identified in patients with PDB[1-4].
Objectives: To analyze the importance of SQSTM1 gene (p62) variants in the susceptibility to develop PDB, as well as to evaluate the genotype-phenotype correlation in our PDB population.
Methods: The molecular study was carried out by sequencing the SQSTM1 gene (p62) in a population of 200 PDB affected patients and 200 *hypernormal* controls. An "*in silico*" functional analysis of the different genetic variants was performed using the information provided by the splicing prediction algorithms, the miRNA target prediction algorithms, the gene-specific algorithms for predicting pathogenicity (SIFT, PolyPhen, PMut) and the interspecific evolutionary conservation study. The statistical analysis was *performed using SPSS statistical software* Windows (v23) and the R software version 2.15.0 for Windows. The study was approved by the CEIC (Hospital del Mar-Parc de Salut Mar (2007/2885/I)) and all participants signed an informed consent agreeing to participate in the study.
Results: The 27% of the PDB affected patients were carriers of different gene *SQSMT1* mutations, being the most frequent identified the p.P392L, described in the 20% of cases. In terms of genotype-phenotype relation, being a carrier of gene *SQSMT1* mutations is associated to a more severe phenotype based on a greater disease activity and a greater extent at diagnosis as well as higher complications during the course of it, without the presence of an associated family history positive. In our patient cohort 17 mutations have been identified in coding regions of the SQSMT1, with six newly described "*missense*" genetic variants (p.R161W, p.H163Y, p.K238E, p.G262R, p.E274D,p.G405S), all of them associated to a greater susceptibility in the development of PDB and distributed in the different structural and functional domains of the p62 protein, being able to cause dysfuntions in the different cell signalling processes where intervenes (apoptosis, autophagy, proteic degradation through the ubiquitin-proteasome system, the regulation of antioxidant response and the cell survival mediated by RANK-TRAF6-NF-κB signaling pathway), implicated in the pathogenesis of Paget's disease of bone.
Conclusion: In the molecular study of the *SQSTM1* gene, seventeen mutations were identified in the coding regions of the gene, being six "*missense*" genetic variants of new description, associated all of them to a higher risk of developing PDB and distributed in different structural and functional domains of the p62 protein.

POS0347

CHARACTERIZATION OF THE TRANSCRIPTOMIC SIGNATURE OF BONE MARROW CELLS IN OSTEOPOROSIS ASSOCIATED WITH SYSTEMIC MASTOCYTOSIS

Y. Degboe[1,2], A. Constantin[1,2], A. Ruyssen-Witrand[1], C. Paul[3,4], P. Dubreuil[4,5], C. Bulai Livideanu[3,4]. *[1]CHU Toulouse, Rheumatology, Toulouse, France; [2]INSERM, INFINITY U1291, Toulouse, France; [3]CHU Toulouse, Dermatology, Toulouse, France; [4]CHU Toulouse, CEntre de REférence des MASTocytoses (CEREMAST), Toulouse, France; [5]INSERM, Centre de Recherche en Cancérologie de Marseille - U1068, Marseille, France*

Background: Systemic mastocytosis (SM) is a rare monoclonal mast cell disease, associated with vertebral osteoporosis (OP) in ~30% of the patients. This OP frequently leads to multiple vertebral fractures, in particular in young or premenopausal patients. Soluble mediators secreted by the pathogenic mast cells and subsequent activation of osteoclasts are thought to explain the development of such OP. However, data about the nature and the regulation of the pro-osteoporotic factors is limited. We hypothesize that a transcriptomic approach, assessing bone marrow cells involved in this pathological condition, can identify the specific determinants of fragility fractures in SM.
Objectives: To identify a bone marrow transcriptomic profile associated with osteoporosis in SM.
Methods: We analysed clinical data and bone marrow samples collected at diagnosis in SM patients from our Reference Centre for Mastocytosis (CEREMAST) and fulfilling the SM WHO criteria. All patients signed an informed consent. Twelve SM patients with OP and fragility fracture (OP group) were age- and gender-matched with 12 SM patients without OP or fragility fracture (non-OP group). We used a Nanostring nCounter approach to compare the bone marrow mRNA profile. We used a predefined panel of 800 transcripts relevant for an osteo-immunological analysis. Genes expressions were normalized and compared by a Wilcoxon test with R software. We performed a pathway analysis with C5, C7, KEGG and Reactome databases.
Results: Both OP and non-OP groups included 8 women and 4 men, with similar average age (OP 56.1 +/- SD 8.7 vs non-OP 57.1 +/- 9.3). The 12 patients from the OP group had at least 1 vertebral fracture (VF) with an average number of VF of 4.9 +/- 2.6. Lumbar and hip bone mineral density was significantly lower in the OP group. The transcriptomic analysis revealed a specific profile associated with osteoporotic vertebral fractures in SM, with 26 differentially expressed genes (see Figure 1). The analysis highlighted an involvement of NECTIN2 and of IL6/STAT3. Pathway analysis suggested a role for genes involved in cell cycle regulation, T cell activation, protein kinase activity and differentiation and activation of monocytic cells.

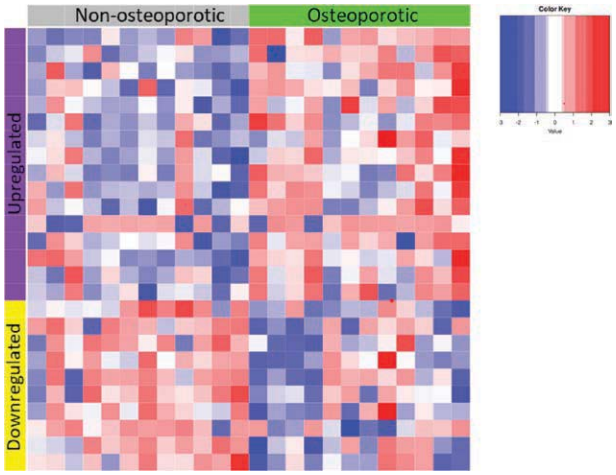

Figure 1. Heatmap of the differentially expressed genes in bone marrow from SM patients with osteoporosis and fragility fracture versus without osteoporosis

Conclusion: Our results highlight that a transcriptomic analysis of bone marrow is relevant to identify biomarkers associated with OP in SM. In addition to the pathogenic role of clonal mast cells and of monocytic lineage, this condition may involve non-clonal immune cells such as T cells.

POS0348

DEVELOPING A WHOLE MOUNT FLUORESCENT OSTEOCLAST ACTIVITY ASSAY USING THE ELF97 PHOSPHATASE SUBSTRATE TO VISUALISE AND QUANTIFY IN SITU OSTEOCLAST ACTIVITY IN ZEBRAFISH (DANIO RERIO)

E. L. S. Fong[1], E. L. Prabha[1], T. Carney[1]. *[1]Lee Kong Chian School of Medicine (LKCMedicine), Singapore, Singapore*

Background: Osteoporosis is a mineral bone disease arising from the predominance of osteoclastic bone resorption. Bisphosphonates which inhibit osteoclasts are commonly used in osteoporosis treatment, but are not without severe adverse effects like osteonecrosis of the jaw. The mechanisms behind the development of such phenomena is not well understood. Bone homeostasis is achieved through an intimate cross-talk between osteoclasts and osteoblasts. Thus, it is important to visualise activities of these cells simultaneously in situ. Currently, there are means to visualise osteoclast shape and numbers with tartrate-resistant alkaline phosphatase (TRAP) staining but no practical and accurate methods to quantify osteoclast activity *in situ*.

Objectives: This investigation aims to establish the use of ELF97, a substrate of TRAP, to visualise and quantify osteoclast activity. This provides vital clues to mechanisms of various bone disorders. TRAP dephosphorylation of ELF97 results in a detectable fluorescent product at areas of osteoclast activity.

Methods: Osteoclastic activity was initiated in zebrafish by inducing crush injuries in tail fin rays. Colocalisation of ELF97 fluorescence with osteoclast-specific DsRed in transgenic zebrafish, visualised under confocal microscopy, is used to further establish the specificity of ELF97 to sites of osteoclastic activity. Quantification is established by comparing fluorescence between wild type, osteoclast-deficient mutants and bisphosphonate-treated zebrafish. The utility of ELF97 will also be investigated in terms of the stability of the florescent product.

Results: The investigation revealed that ELF97 and DsRed fluorescence were found commonly at crush sites with osteoclastic activity. Wild type zebrafish had greater fluorescence compared to osteoclast-deficient ($p<0.0001$) and bisphosphonate-treated zebrafish ($p<0.0001$) after 7 and 14 days post-crush, revealing that fluorescence from ELF97 corresponds to expected osteoclastic activity. Fluorescence of tail fins treated with ELF97 did not diminish over a period of 21 days of storage, demonstrating its stability.

Conclusion: ELF97 is thus a useful means to visualise osteoclast activity, potentially crucial in more advanced investigations to understand bone disorders. It could be used in combination with other cellular markers in whole biological samples to study and experimentally manipulate bone remodelling.

POS0349 DECOY RECEPTOR 3 AND ITS SIGNAL PATHWAY CONTRIBUTE TO PATHOGENESIS IN PRIMARY GOUTY ARTHRITIS

Y. Jiang[1], X. Liao[1], S. B. Wang[1], Y. X. He[1], Y. F. Qing[1]on behalf of Institute of Research Center of Gout and Hyperuricemia of the Affiliated Hospital, North Sichuan Medical College. *[1]Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology, Nanchong, China*

Background: Gouty arthritis (GA) is an autoinflammatory disease caused by the deposition of monosodium urate crystal (MSU) in the joints and surrounding tissues, which lead to a series of complex inflammatory cascade amplification reactions.The clinical symptoms of acute GA attack rapidly, but often alleviate spontaneously within 7 ~ 10 days, which is one of the significant characteristics different from other joint diseases or autoimmune diseases. However, the exact molecular mechanism of its inflammatory self limitation is still unclear. The phenotypic imbalance of Th1 / Th2 cells and the M1/ M2 polarization of macrophages may be involved in the inflammatory self limitation of gout[1].Decoy receptor 3 (DCR3) can differentiate T cells into Th2 phenotype, promote M2 polarization of macrophages, and play the functions of immune regulation and repair[2].DCR3 and its Signal Pathway are involved in the pathogenesis of tumors and a variety of autoimmune diseases, and have become an important research target of tumors and immune related diseases.However, studies on DcR3 related molecular pathway and GA are scarce, and the specific regulatory mechanism is unknown.

Objectives: To assess the contribution of DcR3 and its signal pathway to gout and the clinical importance of these genes in primary gouty arthritis.

Methods: The mRNA expression levels of DCR3 and its signal pathway(DR3, TL1A, Fas, FasL, Ligth, LigthR, LTgthRNA expression levels of DCR3 and its signal pathway(DR3gout and the clinical importance of these genes in primary gouty arthritis.nt research target of tumors and immune related diseases.However, studies on DcR3 related moathway expression levels and laboratory features was analyzed in GA patients.

Results: The expression levels of DCR3, FasL were much lower in the AG and IG group than in the HC groups ($p<0.05$), and no significant difference was detected between AG and IG groups($P>0.05$)(a,e). The expression levels of DR3 were much lower in the AG and IG group than in the HC groups ($p<0.05$), and much lower in the AG group than in the IG groups ($p<0.05$)(b). The expression levels of TL1A were much higher in the AG group than in the IG and HC groups ($p<0.05$), and no significant difference was detected between IG and HC groups($P>0.05$)(c).The expression levels of Light, LightR were much lower in the AG group than in the HC groups ($p<0.05$), and no significant difference was detected between AG and IG groups, IG and HC groups($P>0.05$)(f,g).The expression levels of LTlower in the AG and IG group than in the HC groups ($p<0.05$($p<0.05$), and no significant difference was detected between AG and IG groups, IG and HC groups($P>0.05$)(h).In GA patients, the levels of DcR3 related molecular pathway gene correlated with laboratory inflammatory and metabolic indexes.

Conclusion: Altered DCR3 and its signal pathway expression suggests that DCR3 related molecular pathway is involved in the pathogenesis of GA and participates in regulating inflammation and metabolism.

POS0350 MICRORNAS ASSOCIATED WITH OSTEOPOROSIS IN PATIENTS WITH HAEMOCHROMATOSIS ARTHROPATHY

S. Finzel[1], A. Diendorfer[2], B. Butzeck[3], M. Hackl[2], R. Voll4. *[1]Freiburg im Breisgau, Department of Rheumatology and Clinical Immunology, University Medical Centre, Freiburg im Breisgau, Germany; [2]TAmiRNA GmbH, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Vienna, Austria; [3]Hämochromatose-Vereinigung Deutschland e.V. HVD, European Federation of Associations of Patients with Haemochromatosis EFAPH, Hattingen, Germany; [1]Freiburg im Breisgau, Department of Rheumatology and Clinical Immunology, University Medical Centre, Freiburg im Breisgau, Germany*

Background: Haemochromatosis arthropathy (HA) is one of the most frequent manifestations of hereditary haemochromatosis (HH). Moreover, frequency of osteoporosis is increased in HH. MicroRNAs (miRNAs) are small non-coding RNAs involved in gene silencing, and onset and progression of disease is often reflected in aberrant miRNA expression patterns including osteoarthritis and osteoporosis. Active or passive release of miRNAs from cells enables minimal-invasive detection in biofluids such as plasma (“circulating miRNAs”).

Objectives: We aimed to investigate whether circulating miRNAs involved in osteoporosis as well as liver disease in healthy elderly individuals are also elevated in patients with HH.
Methods: Plasma of 28 HA patients homozygeous for C282Y (60.71% female), 8 HA patients heterozygeous for C282Y (50% female), and 12 controls (66.67% female), was analyzed using the osteomiR and the hepatomiR RT-qPCR kits. Levels were normalized using spike-in controls and non-parametric analyses were performed to associate miRNAs to other clinical parameters and test for differential regulation of miRNAs between the groups.
Results: Even though mean age was different between the three groups (70.64, 52.38, 61.92 years), correlation analysis identified only weak or no associations to miRNA levels. In patients with osteoporosis (n=9, all female, all homozygeous) miR-203a-3p, 214-3p (both bone-related), and 122-5p (liver-related) were significantly downregulated (Kruskal Wallis p=0.024, p=0.037, and p=0.00024). Interestingly, miR-122-5p also showed a clear trend for down-regulation in homozygous HH compared to heterozygous HH and controls (p=0.087).
Conclusion: This is the first study reporting miRNAs involved in osteoporosis and liver diseases in patients homozygeous for C282Y.
Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2022-eular.4044

POS0351 **NEITHER ANTI-CITRULLINATED PROTEIN ANTIBODIES (ACPA) NOR POLYCLONAL IGG ARE ASSOCIATED WITH BONE MASS, IN ELDERLY MEN**

M. Nurkkala[1], M. Lagerquist[2], P. Gupta[1,2], D. Mellström[2], C. Ohlsson[2], C. Engdahl[1,2]. *[1]University of Gothenburg, CBAR, Dep. of Rheumatology and Inflammation, Göteborg, Sweden; [2]University of Gothenburg, CBAR, Dep. of Internal Medicine, Göteborg, Sweden*

Background: Bone loss is associated with anti-citrullinated protein antibodies (ACPA) positivity in rheumatoid arthritis (RA) patients. This is shown in both in pre-clinical RA, and in more pronounced bone loss in serum positive patients compared to serum negative patients. Further, both ACPA and activated IgG stimulate osteoclastogenesis *in vitro* and in murine arthritis-mediated bone loss.
Objectives: Whether polyclonal IgG or autoantibodies are important for general bone architecture, and not only in arthritis-mediated bone loss, has not been determined but they may represent an important link between the immune system and bone.
Methods: Polyclonal IgG and ACPA were measured with ELISA in serum of 600 elderly men (mean age 80.2±3.5 years), in the cohort MrOS Gothenburg. In this cohort, bone was investigated with Dual-energy-x-ray absorptiometry (DXA) and high-resolution 3D peripheral quantitative computed tomography (HR-pQCT). In C57/BL6 mice, high dose heat-activated polyclonal IgG was repetitively injected systemically or intraarticularly, and the bone was investigated with DXA and micro-CT.
Results: No association was determined between existing serum polyclonal IgG and ACPA, with the measured bone parameters, not total bone density, trabecular or cortical bone in the MrOS cohort. Systemic injection of activated IgG in mice did not affect general bone health, not total, trabecular, or cortical bone. Intraarticular injection of activated IgG was shown to give a local reduction in trabecular bone density of the tibia.
Conclusion: These data indicate that serum polyclonal IgG and ACPA do not influence general bone health in elderly men. However, in mice injection with activated IgG intraarticularly leads to a local reduction in trabecular bone. In conclusion, our data imply that ACPA and activated IgG need to be present in close connection to the bone, e.g., in the synovial area, to be able to mediate a reduction in bone mass.

PARE Poster Tour 2

POS0352-PARE **PODCAST FOR RHEUMATISM SUFFERERS AND THEIR RELATIVES**

M. Siber[1], T. Spichtig[2]. *[1]Swiss League Against Rheumatism, Communication, Zurich, Switzerland; [2]Swiss League Against Rheumatism, Communication & Fundraising, Zurich, Switzerland*

Background: Two million people in Switzerland suffer from rheumatic diseases. The Swiss League against Rheumatism is committed to helping those affected. It provides them and their relatives with professional, neutral information on the subject of rheumatism. The Swiss League against Rheumatism has been publishing the podcast series "Rheumatism in person" since 2021. In it, affected people discuss relevant and current topics about living with rheumatism with experts. Another aim is to devote time to the personal experiences of sufferers. The pool of experts includes medical specialists, nutritionists, social counsellors and psychologists.

Objectives: The Swiss League against Rheumatism, as the national umbrella organisation, is expanding its communication services via the podcast in order to reach even more people with rheumatism in Switzerland. This makes it is possible to increasingly address a younger, digital-savvy target group and to expand the service proposed for this target group. The podcasts are primarily aimed at people with chronic forms of rheumatism between the ages of 25 and 50 and their relatives in German-speaking Switzerland. A further aim is to bring the opinions of those affected to the attention of the public, as well as to provide information from specialists, thereby creating greater awareness of the disease.

Methods: Each podcast episode is about 30 minutes long. According to experience, this length is the most popular with most listeners, whilst also allowing complex topics to be explored in depth. The podcasts are issued monthly. This enables listeners to be prepared for a fixed release date. The episodes are produced in cooperation with a podcast agency. The advantage of an agency lies in its expertise and experience, especially in the technical field. Funding for the podcast episodes can be secured from sponsors.

"When things get complicated – social counselling for rheumatism", "Sport and rheumatism – anything but a contradiction" or "Rare forms of rheumatism – lupus, EDS & co." are popular episode titles, to name but a few.

The podcasts are available on various international podcast platforms. The episodes are distributed via blog posts, existing newsletters and social media (Facebook, Instagram and LinkedIn). External distribution channels are used in the form of the interviewees' networks, the "Junge mit Rheuma" (young people with rheumatism) group, national patient organisations, cantonal/regional rheumatism leagues, the Swiss Society of Rheumatology and any media coverage attracted.

Results: So far, the eleven episodes and accompanying trailer have been downloaded or streamed over 8,200 times by 5,300 unique listeners.

All eleven topics were of great interest. The episode on "Anti-inflammatory nutrition" generated the most downloads (1,550), closely followed by the episode on "The coronavirus pandemic with rheumatism", which reached just under 1,300 downloads (as of 21 January 2022). On 15 March 2021, the podcast series also made it onto the podium of a well-known podcast chart in the field of medicine. This clearly shows that there is a need among rheumatism sufferers and their relatives to obtain information via podcasts.

The large quantity of positive feedback from patients, rheumatologists and other health professionals is particularly noteworthy. "From the first second: very interesting topics, well produced and a great voice," shared a listener.

Conclusion: The podcast series has proved successful and will therefore be continued as a complementary communication tool for the Swiss League against Rheumatism. In addition to the episodes already released, another ten episodes are planned in German.

The Swiss League against Rheumatism is keen to extend the podcast series to the French-speaking part of Switzerland. The idea is therefore to include French episodes in 2022. There are specific plans to record three episodes, which will be broadcast in the second half of the year. The aim is to add more episodes to the French podcast series in the long term.

POS0354-PARE **THE POLITICAL WORK FOR BETTER TREATMENT OF MUSCULOSKELETAL DISEASES IN DANISH MUNICIPALITIES**

K. Hammenfors[1] on behalf of The Danish Rheumatism Association. [1]*The Danish Rheumatism Association, Department for Politics and Knowledge, Gentofte, Denmark*

Background: Historically most treatment of musculoskeletal diseases in Denmark has taken place in hospitals. Today, treatment is split between different sectors, where the requirements are widely different.

Physiotherapists, occupational therapists and dietitians are, to a certain extent, no longer found in the rheumatic sections of the hospitals, but rather expected to take care of rehabilitating treatment in one of the 98 municipalities. With the clinical guidelines, the Health Authorities has indicated which treatment areas the individual groups of patients will benefit from – however, there is lack of provision of these in many of the municipalities across the country.

Objectives: To secure that treatment guidelines - within the field of musculoskeletal diseases - made by The National Board of Health, are transformed into national quality standards for treatment in the municipalities.

Methods: To ensure that patients get the treatment needed, we have worked with external consultants resulting in two research papers (visible at link) on the subject at hand. One paper mapped how many of the 98 municipalities provides each of four treatment guidelines made by The National Board of Health. The four being – weight loss, education and physical training for hip- and knee osteoarthritis, education and physical training for patients with back conditions and interdisciplinary treatment for people with pain conditions. The other paper uncovered the potential economic gains for the public sector by introducing the treatment guidelines.

The Danish Rheumatism Association has used these research papers as a significant driver for a large conference in October 2021 at the Danish Parliament – Christiansborg. Essential national politicians where present and they acknowledged the need for an increased focus on the treatment areas.

The results of the reports has also been shared with government officials, an existing commission on labor supply as well as municipalities etc.

In connection with the recently held elections in Danish municipalities and regions, we have reached out to the local politicians experiencing a gap in the offerings either directly or through local media which will hopefully result in an uplift of the focus. In addition, we have made debate posts with among others - unions sharing our point of view.

Results: Essential national politicians acknowledged the need for an increased focus on the treatment areas.

We hope that both from the municipalities as well as from a national level initiative will be taken to introduce a set of national quality standards within the field of musculoskeletal diseases because of our forceful approach.

Conclusion: The increased focus on treatment of musculoskeletal diseases is the result of strong collaboration between The Danish Rheumatism Associations department for Politics and Knowledge, Internal Communications and external partners.

We believe that our work can inspire other European NGO's who has a need to increase their political agenda and awareness. We made a long-term goal, allocated the finances and employees needed and it seems that the structured approach we have taken have increased the focus for our patients in the public debate and will help us achieve the goals.

POS0355-PARE **LONGITUDINAL INVESTIGATION AND VISUALIZATION OF COURSE AND BURDEN OF ADVERSE DRUG REACTIONS IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES USING TNFα INHIBITORS**

M. De Boer[1], H. Gosselt[1], J. Jansen[1], M. Van Doorn[2,3], F. Hoentjen[4,5], M. Nurmohamed[6], P. Spuls[7], S. Tas[8,9], H. Vonkeman[10,11], N. Jessurun[1]. [1]*Netherlands Pharmacovigilance Centre Lareb, Netherlands Pharmacovigilance Centre Lareb, 's-Hertogenbosch, Netherlands;* [2]*Erasmus MC, Department of Dermatology, Rotterdam, Netherlands;* [3]*Centre for Human Drug Research, N/A, Leiden, Netherlands;* [4]*Radboud University Medical Center, N/A, Nijmegen, Netherlands;* [5]*University of Alberta, Division of Gastroenterology, Department of Medicine, Edmonton, Canada;* [6]*Amsterdam Rheumatology Immunology Centre | Reade, N/A, Amsterdam, Netherlands;* [7]*Amsterdam UMC, Department of Dermatology, Amsterdam Public Health/Infection and Immunology, Amsterdam, Netherlands;* [8]*Amsterdam UMC, Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands;* [9]*Amsterdam Rheumatology and Immunology Centre (ARC), N/A, Amsterdam, Netherlands;* [10]*Medisch Spectrum Twente, Department of Rheumatology & Clinical Immunology, Enschede, Netherlands;* [11]*University of Twente, Department of Psychology, Enschede, Netherlands*

Background: Patients are increasingly involved in the decision process regarding their medicines, but a discrepancy exists between the information provided and preferred. Information on adverse drug reactions (ADRs) focuses on frequency, but little is known about the course and burden of ADRs.

Objectives: We aimed to investigate the course and burden of ADRs over time attributed to using TNFα-inhibitors in patients with inflammatory rheumatic diseases (IRDs) and to assess whether Sankey diagrams and polar plots are suitable to provide visualization of these aspects.

Methods: We used data of the Dutch Biologic Monitor [1], in which biologic users with an immune-mediated inflammatory disease filled out bimonthly surveys about ADRs experienced and specifically the ADR course and burden. ADRs were coded according to the MedDRA terminology. ADR course was scored as worsening, improving, remaining stable or resolving over time, with room to give a description. Furthermore, it was assessed whether an ADR was recurrent or not. Patients scored burden on a scale ranging from 1 (no burden) to 5 (very high burden). We selected patients with rheumatoid arthritis (RA), psoriatic arthritis or axial spondyloarthritis using a TNFα inhibitor (adalimumab, certolizumab pegol, etanercept, golimumab or infliximab). They also had to report an ADR belonging to the system organ classes 'Infections and infestations' or 'Skin and subcutaneous tissue disorders', or the high-level term 'Injection site reactions' and completed ≥2 consecutive questionnaires (representing circa ≥4 months). These types of ADRs were chosen as they impose the highest burden for patients. [2]

Results: A total of 202 patients met the inclusion criteria (71.8% female, mean age 54.8 years (±12.7 years)). The majority of the patients (61.9%) was diagnosed with RA. Most frequently used TNFα inhibitors were adalimumab (37.1%) and etanercept (54.0%). In total 353 ADRs were reported, of which 76 (21.5%) were categorized as 'Skin and subcutaneous tissue disorders', 122 (34.6%) as 'Infections and infestations' and 155 (43.9%) as 'Injection site reactions'. The course of the ADRs is visualized in Sankey diagrams (Figure 1a-c); the flows show possible ADR courses, the width of each is proportional to the number of ADRs following that course. Most skin reactions did not change during follow-up (25.0%, Figure 1a), only a few were recurrent. Most infections resolved over time (50.8%, Figure 1b), with some remaining stable and some being recurrent. Most injection site reactions (72.3%, Figure 1c) were recurrent, and resolved in only a minority of the patients (13.4%) during follow-up. The polar plots (Figure 1d-f) visualizes the burden of the ADRs over time. For skin reactions and infections a decreasing trend was observed, represented by fading of the colors to the periphery. Infections had the highest burden at the start of the ADR, indicated by the darker colors in the inner circle. Injection site reactions had a relatively low and stable burden over time, shown by the lighter colors continuing over the circles.

Conclusion: Skin reactions attributed to the use of TNFα-inhibitors by IRD-patients show a stable course over time with a slightly diminishing burden over time. Infections have the highest burden at start but decrease over time and most of them resolve during follow-up. Injection site reactions are mostly recurrent with a low and stable burden over time. We propose that Sankey diagrams and polar plots are suitable to visualize the course and burden of ADRs over time.

POS0356-PARE IN OUR HAND – SELF MANAGEMENT COURSE (FOR PEOPLE WITH CHRONIC RHEUMATIC DISEASES

M. Nudel[1]. [1]*Mifrakim Tze'rim, None, Haifa, Israel*

Background: Since 2016 we had a dream to construct a self-management course for members of The Israeli association for RMDs patients *Mifrakim Tz'eirim*. On September 2018, our CEO heard a lecture by Mrs. Mary Vella, the president of ARAM Malta, and the rest is history.

We approached PARE through AGORA for the Knowledge Transfer Program Grant and got approved in February 2019. The need to develop such a course came from members of the association, as well as posts in Facebook groups. Concerns, fears, and uncertainties about how to live with a chronic illness.

Mifrakim Tz'eirim is committed to reaching out to children, youth, adults and seniors with autoimmune and inflammatory joint diseases and rare autoimmune and various inflammatory diseases and to their families. The association assists its members and provides them with support and available tools on a personal, family, and social level. Our goal is to act for increasing public awareness of these diseases and their day-to-day impact on patients, to expand knowledge and disseminate information about them, patient rights and innovations in treatment, as well as to promote access to a variety of advanced treatments and medications for the members.

Objectives: Providing tools for daily coping and optimal conduct in chronic illness situations in a wide range of aspects: a self-management triangle:

a. Medical / biological (better / helpful understanding of the situation)
b. Emotional (Identify and manage the emotional impact)
c. Social (adjusting the way you manage your daily life)

METHODS:

1. Receiving a grant from PARE - The Knowledge Transfer Program Grant, through AGORA
2. Cooperation with ARAM - Arthritis & Rheumatism Association Malta
3. A study visits to Malta
4. Monitoring the process in Israel by ARAM
5. Founding a management team for the course
6. Localizing adaptation of the learned content for Israelis and introducing new content of our own
7. Promotion of the course to the association members, selecting participants
8. December 2019 the first course started. In 2020-2021 we had 3 more cycles of the course to the members. We had 40 participations
9. Following the pilot course - generating conclusions, lessons, and adjustment of the syllabus accordingly
10. Three more courses are planned for 2022

RESULTS:

1. Excellent feedback from ARAM during the control performed
2. Participants provided outstanding feedback on the course
3. Course graduates established designated WhatsApp groups for ongoing mutual support, thus creating empowerment circles, including periodic physical meetings

CONCLUSION:

1. *In My Hands* course provides a highly efficient and relevant toolbox.
2. The course should be continually offered to people coping with chronic diseases
3. *Finger on the pulse* - ongoing drawn conclusions to be implemented for adjusting the syllabus
4. The course should be promoted gently, since it marks a change in life, which can threat some people's perception
5. We have expanded and offered participation to members of other patient associations that we collaborate with
6. Graduates of the course become ambassadors, spreading the benefits received by the course
7. Graduates of the course are a vivid example of the chance of improving your life even when you cope with chronic diseases
8. Graduates of the course influence their immediate circles to adapt and adopt changing habits

POS0357-PARE EXPLORING THE IMPACT OF THE PANDEMIC ON ITALIAN RHEUMATIC DISEASE PATIENTS: A PATIENT ADVOCACY SURVEY

A. Celano[1], D. Cafiero[2], S. Lopatriello[2], F. Tedone[2]. [1]*APMARR, APMARR, Lecce, Italy;* [2]*Helaglobe srl, Helaglobe srl, Firenze, Italy*

Background: Patients with rheumatic diseases show impaired quality of life (QoL): disease activity, comorbidities and treatment-related side effects contributes to decrease physical, emotional, and social functioning. The COVID-19 pandemic challenged health care systems and patients with chronic conditions: hospital and outpatient clinics delayed access, unpredictable changes like non-adherence to medication, but also negative emotions, psychological conditions recognized as risk factors for the poor QoL [1-2].
Objectives: To describe the impact of the COVID-19 pandemic on the Qol of Italian patients with rheumatic diseases in the first period of the national lockdown.
Methods: APMARR (Associazione Nazionale Persone con Malattie Reumatolgoche e Rare) invited Italian patients and caregivers to participate to an online structured survey in the period March-June 2020. Informed consent was retrieved. The questionnaire, promoted by the patient advocacy website, collected demographics, emotional and healthcare pattern information.
Results: 87,44% (N=215) complete questionnaires were retrieved (96.3% patients; 3.7% caregivers; 87.77% female; 2% aged <18 years, 16% aged 18-30 years, 82% aged >31 years; 0.53% missing data). Respondents were illustrative of the Patient Advocacy regional distribution (Puglia Region predominant). Rheumatoid arthritis regarded 29% of respondents, ankylosing spondylitis 17%, psoriasis 16%, remaining 38% other rheumatoid diseases. 96% of respondents were employed, 39% of which had to discontinue/change working activity during pandemics.
60% of respondents reported being worried about their disease. The deriving sense of fragility was the main cause of anxiety, which was not controlled even by compliance to the treatment plan (88%). 30% of respondents was worried about virus infection. Irritability, appetite and sleep disorders were also reported: anxiety had effects on irritability (46% sometimes more irritable) and sleep quality (38% always disturbed). GPs visits access was limited (40% considered it absent and 76% had to postpone it). Only 32% of specialist centers provided facilitated patterns of care.
Respondents suggested possible solutions to improve QoL during COVID-19 pandemic and over it. Psychologist support was suggested as useful by 44% of respondents to manage therapies and by 56% to effort daily life. The home infusion would be of support according to 44% of respondents (18% already got access to it).
Patient Advocacy had a main role in the new care and life context: 80% would consider it useful to participate to and 81% was satisfied by the prompt and continuous support received during pandemics.
Conclusion: Similar results as far as distress were reported by Italian and foreign evidence, which demonstrated considerable COVID-19 related psychosocial burden in rheumatic disease patients [3-5]. Potential solutions are also with EULAR recent guidelines, which underlined how psychological interventions were found to reduce pain and fatigue even in difficult-to-treat patients [6] and how mental health needs should be periodically assessed, due to the link between better emotional well-being and better self-management [7]. Besides, the reported picture of reorganised care during pandemic corresponded to the real-world experience of the Italian Regions [8]. New approaches of care like home infusions and telemedicine supported by patient organisations should become routinary and may therefore benefit patients.

POS0358-PARE THE IRISH 'WEAR RED' FOR VASCULITIS CAMPAIGN – LAUNCHING AN ANNUAL AWARENESS CAMPAIGN IN A RESTRICTED PANDEMIC WORLD.

S. Skeffington[1]. [1]*Irish Vasculitis Organisation (IVO), Founder, Cashel, Ireland*

Background: Vasculitis is an umbrella term for a number of conditions which are caused by inflammation of the blood vessels. It presently affects approx. 1,000 people in Ireland. Vasculitis is one of the rare rheumatic diseases which are quite often overlooked and unknown as it does not have the recognition that Lupus has created especially with the recent celebrity diagnoses. It is often mistakenly thought to be a heart condition among members of the public due to the vasc sound in the word Vasculitis often being associated with the word vascular. May is Vasculitis Awareness month and the 15th of May is now celebrated as World Vasculitis Day. Due to being in a pandemic due to Covid 19 we couldn't plan face to face events for our first awareness day due to restrictions within Ireland and medically enforced restrictions for members of our committee so online was the only viable option.
Objectives: To celebrate May as Vasculitis month on behalf of those with Vasculitis. To increase awareness among the public of Vasculitis nationally in a memorable way on World Vasculitis Day May 15th 2021. To create brand awareness of our organisation the Irish Vasculitis Organisation (IVO) and increase our Facebook page membership.
Methods: We decided to celebrate the month by posting a fact about Vasculitis every second day starting the 1st of May until the end of the month skipping the 15th which is when we would run our first Wear Red campaign. We approached a number of famous Irish buildings to light up in red to support the day. We also ran a Facebook campaign which looked for people's support on the day by wearing red and posting it online on May 15th encouraging people to wear red and we reposted their efforts on our Facebook page.
Results: We had six famous Irish buildings across Ireland including the Rock of Cashel and the Dublin Mayor's residence light up in red to support the day.
The Vasculitis facts were interesting to some but the Wear Red campaign was the most successful activity we did. In the 14 days running up to the 15th we were reaching on average 28 people a day and on the 15th, we reached an amazing 526 people. We also saw our interactions (comments, shares, likes) go from an average of one a day in the 14 days prior to the campaign to 167 people on the 15th. The videos with children achieved the most interactions.
Unexpectedly the campaign received support from abroad as well with many of the 15% increase in members joining our Facebook page on the 15th being from the UK The Vasculitis Foundation in the USA heard about one of our light up buildings and they advertised it on the newsletter to their many subscribers.
Conclusion: The Wear Red campaign was evidence that even in a pandemic while there were severe limitations to people meeting up and having no ability to go out to advertise, a successful awareness campaign could still be run from a volunteer's kitchen as long as there was careful planning and support.
It is also clear to see that while informative facts may be the answer to those who run organisations and have the condition in order to educate the public it is important to recognise that the public learn through fun activities and if you want to generate real interest keeping it light fun and informative is the way to go.

POS0359-PARE YOUTUBE AS A SOURCE OF INFORMATION ON AUTOINFLAMMATORY DISEASES

M. Sasse[1], S. Ohrndorf[1], A. Palmowski[1], A. D. Wagner[2], G. R. Burmester[1], A. Pankow[1], M. Krusche[3]on behalf of Digitale Medizin in der Rheumatologie. [1]*Charité-Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany;* [2]*Hannover Medical School, Department of Nephrology, Hannover, Germany;* [3]*Universitätsklinikum Hamburg-Eppendorf, Center for Internal Medicine and Rheumatology, Hamburg, Germany*

Background: Getting access to specialists for autoinflammatory diseases (AIDs) is challenging. Therefore, an increasing number of patients and healthcare professionals are seeking information on this topic via the internet, e.g., on the video platform YouTube, which has attracted a huge audience in recent years (1). However, not much is known about the quality of videos pertaining on AIDs.
Objectives: To assess videos about AIDs uploaded on YouTube and to evaluate the quality and usefulness of available information from both the patient's and professional healthcarer´s perspective.
Methods: A YouTube.com search was conducted in January 2022: Selected keywords were "autoinflammatory diseases" (AID), "periodic

fever syndrome" (PFS), "familial mediterranean fever" (FMF), "cryopyrin associated periodic syndrome" (CAPS), "tumor necrosis factor associated periodic syndrome" (TRAPS), "adult onset of still´s disease" (AOSD) and "systemic juvenile idiopathic arthritis"(sJIA). For every keyword, the top 20 videos in their order of relevance were included. Video duration, number of views, likes, dislikes, comments and uploading source were extracted. The quality of a video´s information was evaluated independently by two physicians based on the modified global quality scale (GQS) (2). Subgroup analyses were performed classifying healthcare professionals and patients as target group.

Results: In total 140 videos were screened. We excluded 5 videos due to language other than English, 7 duplicates and 23 not suitable ones. 105 videos met the inclusion criteria for further analysis. Video characteristics are presented in Table 1. Based on the GQS, overall quality of videos for patients was found to be low in 64,8%, intermediate in 27,6%, and high in 7,6% of videos. The quality of videos for professionals was similar: 54,3% were judged to be of low, 23,8% of intermediate, and 21,9% of high quality (Figure 1). Subgroup analyses focusing on videos for professionals found sJIA videos to achieve the highest scores (31,6% with high quality) whereas videos regarding CAPS were rated the least useful ones (15,4% with high quality). In videos for patients, sJIA videos also ranked highest (42,1% with high quality) whereas no high quality videos could be identified for TRAPS. Videos are more often aimed at specialists such as doctors or medical students (65.7%) and less often at affected patients or relatives (34.3%). Video duration was significantly longer in videos targeting a professional audience ($p < 0.001$). In videos for professionals, length was significantly correlated with higher quality ($p < 0.001$).

Table 1. Video Characteristics

	Median (range)							
	Total included (n=105)	AID (n=19)	PFS (n=15)	FMF (n=16)	CAPS (n=13)	TRAPS (n=3)	AOSD (n=20)	SJIA (n=19)
Video duration (minutes)	6,75 (0,58-86,33)	16,13 (0,63-75,18)	3,78 (1,18-54,02)	10,80 (1,58-51,35)	3,48 (0,58-23,27)	6,10 (3,03-86,33)	9,88 (1,47-48,28)	7,28 (1,65-59,67)
Total views	1569 (24-102928)	1672 (223-32930)	2560 (24-36732)	2182,50 (40-24842)	635 (26-32932)	1392 (520-2963)	1029 (192-20011)	2317 (202-102928)
No. of likes	15 (0-1275)	18 (0-357)	26 (0-271)	22 (0-323)	8 (0-357)	11 (8-14)	20,50 (3-133)	15 (0-1275)
No. of dislikes	0 (0-17)	0 (0-7)	0 (0-0)	0 (0-17)	0 (0-7)	0 (0-0)	0 (0-0)	0 (0-0)
GQS (patients)	2 (1-5)	3 (1-4)	3 (1-4)	2 (1-5)	2 (1-4)	2 (1-2)	1,50 (1-4)	2 (1-3)
GQS (professionals)	2 (1-5)	3 (1-5)	1 (1-5)	2 (1-5)	1 (1-5)	2 (1-4)	2 (1-4)	3 (1-5)

Abbrevations: GQS= Global Quality Scale 1(low quality) - 5 (high quality)

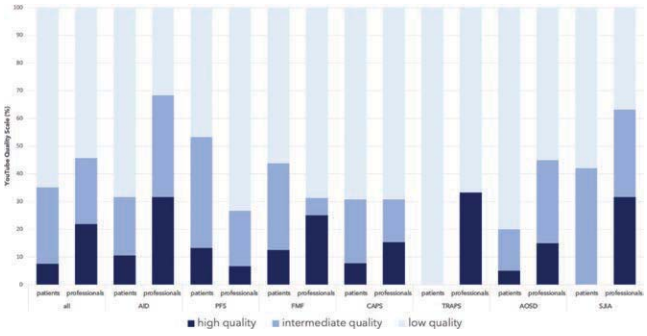

Figure 1. Quality Scale

Conclusion: YouTube as a source of information could have great potential for rare diseases. However, this study demonstrates that the majority of videos regarding AIDs is of limited quality and available videos more often adress users with a professional medical background. Only a small proportion of existing videos provide understandable and useful information for AID patients.

POS0360-PARE EDUCATIONAL NEEDS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS AND HEALTH PROFESSIONALS IN RHEUMATOLOGY: A SWISS CROSS-SECTIONAL QUALITATIVE ANALYSIS

A. Grosjean[1,2], C. Madelaine-Bonjour[3]. *[1]University of Geneva, Patient Education, Geneva, Switzerland; [2]Sjögren Europe, Federation of European Sjögren's Patient Associations, Bienne, Switzerland; [3]Lausanne University Hospital, Rheumatology, Lausanne, Switzerland*

Background: The content and delivery of patient education (PE) should be individually tailored and needs-based for people with inflammatory arthritis[1]. Therefore, a patient trained in PE joined forces with a rheumatology clinical nurse specialist to explore the needs for the management of patients with RA in a Swiss local context (rheumatology department of a university hospital).

Objectives: To identify the difficulties and needs of patients with RA regarding their disease and its management in a local context, from both perspectives: patients and health professionals (HPs).

Methods: We developed 2 different semi-structured questionnaires for each surveyed group. They were distributed to 93 patients and 62 HPs during Summer 2020. Only the fully completed surveys were analysed. A qualitative analysis of the answers to the open questions was carried out and the phenomena thus highlighted were then quantified.

Results: We collected 38 patient (40%) and 35 HP (56%) questionnaires, and 23 patients (25%) and 21 HPs (34%) filled them completely out.

Participants among patients were mostly female (74%) with a mean (SD) age of 54,8 (10,9). Mean (SD) number of years of illness after diagnosis was 11,9 (12,6). HPs were nurses (57,1%), medical doctors (19%), occupational therapists (14,3%), physiotherapists (4,8%) and assistant nurses (4,8%).

Almost half of HPs (48%) and 39% of patients experience difficulties to talk about sensitive topics like sexuality, financial or emotional difficulties.

A third of patients (30%) wished a more supportive attitude from HPs and HPs (62%) would like patients to be more involved in their care, more specifically regarding autonomy and treatment adherence. A few HPs (9%) and patients (19%) want to improve patient-centred and personalised care. Most of HPs (81%) and patients (87%) state that they have no objection or reluctance to PE being developed in the department. Some HPs see PE as an additional workload (19%) and others as a tool to involve the patients more in their care (43%).

HPs (43%) express a need for patient's and disease's management training and wish to acquire additional tools and methods to better assist their patients (43%). A third of them (33%) report a lack of communication, collaboration and interdisciplinarity to support patients. Furthermore, due to the lack of time and availability, 67% of them are not able to provide adequate time for meeting the patients' needs. Some HPs feel powerless to help their patients (19%). Some others (18%) highlight the difference of perspectives and concerns between patients and HPs.

Patients and HPs agreed on most of the main difficulties related to the disease and follow-up. It should be noted that HPs were not aware of the difficulties related to their patients' sleep. The painful and distressing psychological and emotional impact of RA is the difficulty most cited by patients (74%) and the second most mentioned by HPs. More than half of patients (61%) have difficulty managing their pain.

Conclusion: The results of this study confirm the need for PE in the department. Communication is a challenge for both populations. HPs know their patients well, but patients and HPs have different expectations regarding disease's management and follow-up. This work shows the importance of analysing educational needs: it brings out dimensions of the disease and its management that are sometimes hidden or underinvestigated. It thus helps to have a better understanding of the reality and difficulties as they are experienced by people in order to propose appropriate solutions. This work provides a basis for reflection and discussion for the future development and implementation of a PE program, based on the paradigm of the patient-HP partnership. In addition to being an example of an advanced and successful patient-HP partnership, it also demonstrates the benefits of such collaboration.

POS0361-PARE **THE MEDIATING EFFECT OF PAIN CATASTROPHIZING ON WORK PRODUCTIVITY**

C. Ines[1], A. Ben Tekaya[1], A. Gharbi[1], R. Leila[1], O. Saidane[1], S. Bouden[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. *[1]Charles Nicole Hospital, Rheumatology,Tunis,Tunisia*

Background: Work disability is a major patient outcome for spondyloarthritis (SpA) patients since SpA mostly appears in younger adults.
Objectives: we examined the influence of catastrophizing as a negative psychological factor on work productivity and activity impairment in SpA.
Methods: We conducted a cross-sectional study over a 3 months period. We included patients treated with SpA (Assessment of SpondyloArthritis International Society (ASAS) 2009 criteria). Patients related data, and disease characteristics were collected. Pain catastrophizing were assessed by the pain catastrophizing score (PCS). Work productivity and activity impairment were evaluated by Work productivity and Activity Impairment Questionnaire (WPAI). WPAI score examined four aspects of the patient's life: Absenteeism due to SpA and presenteism at work, work productivity loss and activity impairment.
Results: Sixteen SpA patients were enrolled (22 females and 38 males). Mean age was 39,4 years ± 11,08. Mean disease duration was 11,37 years ±7,23; 28 were unemployed. Among workers, absenteeism due to SpA was reported in 7 cases (21,9%). Mean absenteeism rate was 2,35% [0-20]. Both mean work productivity loss and mean activity impairment were 50,23% [20-90].
Mean PCS was 15,73 ± 13,893. Thirteen patients (21,7%) had PCS >30 which indicates a clinically relevant level of catastrophizing, and only two of them reported absenteeism at work. PCS score was higher in patients with absenteeism (mean score=26), compared to patients without absenteeism (mean score=16,96), (p=0,166). Presenteeism was lower in patients with higher pain catastrophizing scores, without reaching a significant difference (p=0,066). A higher PCS was significantly correlated with a greater work productivity loss (p= 0,036, r=0,371) and greater activity impairment (p=0,005, r=0,36).
Conclusion: In our series, pain catastrophizing affected work productivity and daily activity in patients with SpA.

Systemic Lupus Erythematosus: monitoring and management

POS0362 **FACTORS ASSOCIATED WITH CHANGES IN COPING BEHAVIOUR IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS - A LONGITUDINAL STUDY OF THE LULA COHORT**

E. Reutemann[1], R. Brinks[2], J. G. Richter[1], R. Fischer-Betz[1], B. Winkler-Rohlfing[3], M. Aringer[4], M. Schneider[1], G. Chehab[1]. *[1]Policlinic for Rheumatology & Hiller Research Unit for Rheumatology, Medical Faculty, Heinrich-Heine-University Duesseldorf, University Clinic, Duesseldorf, Germany; [2]Chair for Medical Biometry and Epidemiology, Witten/Herdecke University, Faculty of Health/School of Medicine, Witten, Germany; [3]German Lupus Self-Help Community, Wuppertal, Germany; [4]Department of Medicine III, Division of Rheumatology,TU Dresden, Dresden, Germany*

Background: Patients with Systemic Lupus Erythematosus (SLE) experience both physical and psychosocial restrictions that negatively impact their quality of life. Coping mechanisms have turned out to be important contributors to health-related outcomes, not only in SLE but also other chronic conditions. However, there is limited understanding of factors that enhance or hamper coping in SLE.
Objectives: To analyse parameters associated with longitudinal changes in coping behaviour in patients with SLE who take part in a long-term SLE patient cohort study.
Methods: Since 2001, the German nationwide SLE patient longitudinal (Lupus Langzeit 'LuLa') study annually administers self-reported questionnaires to SLE patients.
In addition to demographic and the annually probed extended clinical data (e.g., medication, disease activity, fatigue, depression), in both 2009 and 2014 we assessed the Pain-related Self Statements Scale (PRSS) to perceive information related to coping behaviour. This includes 'positive coping' as well as catastrophizing as a dysfunctional form of coping behaviour.
Statistical analysis was accomplished by a linear regression model adjusting for age, pain, number of comorbidities and net income. The PRSS score difference from 2009 and 2014 was used as the dependent variable. Factors from the i) medical (involvement of the skin, pain, fatigue), ii) activity (basic, leisure, sports), iii) intrinsic (depression, kinesiophobia, perceived health control), and iv) social participation categories were entered as independent variables.
Results: 272 patients (96.7% female) provided valid PRSS questionnaires in both 2009 and 2014. In 2009 the mean age in this cohort was 51 years (SD 11.2) with an average disease duration of 16.2 years (SD 8.3). The mean reported lupus activity (VAS 0-10) during the last three months was 3.7 (SD 2.4). During the six-year observation period, the proportion of improvement (46.2%) and deterioration (47.4%) in coping score was almost balanced, while in catastrophizing score more participants improved (50.0%) than deteriorated (37.0%).
A perceived high internal control, thus the belief that health outcomes are contingent on personal behaviour, was associated with an improvement in the coping score [HLC, b=0.061 (95%-CI 0.014; 0.109), p=0.012]. Conversely, high external control convictions, e.g., the belief that doctors and other third parties determine health outcomes, were associated with a worse coping score [HLC, b=-0.090 (95%-CI -0.154; -0.026), p=0.006]. Deterioration in depression [ADS-L, b=0.015, (95%-CI 0.006; 0.025), p=0.002] and impaired social participation [IMET, b=0.043, (95%-CI 0.000; 0.085), p=0.050] were associated with a deterioration of catastrophizing, whereas better internal control [HLC, b=-0.046, (95%-CI -0.080; -0.012), p=0.009] was associated with its improvement.
Mucocutaneous involvement, fatigue and the extent of physical activity were not significantly associated with either coping or catastrophizing scores in the regression analysis.
Conclusion: In line with data from other chronic diseases, our findings in a longitudinal SLE cohort emphasise the role of intrinsic factors, such as mental health status and self-efficacy, improving the quality of life in SLE patients via successful coping behaviour. Affirmative action measures and programs to improve social participation may yield additional benefits.

POS0363 **THE SIMPLE INDEX FOR SELF-ASSESSMENT OF DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL COHORT VALIDATION**

C. C. Mok[1], L. Y. Ho[1], K. L. Chan[1], J. Meenakshi[2]. *[1]Tuen Mun Hospital, Medicine, Hong Kong, China; [2]Rush University, Medicine, Chicago, United States of America*

Background: The SIMPLE (SIMple Disease Assessment for People with Lupus Erythematosus) index is a composite numeric tool that captures disease activity from patients' self-assessment with minimal physicians' input. The SIMPLE index consists of 2 components: patient self-reported survey questionnaire (3 items from the lupus symptoms domain from the validated LupusPRO, 10 items from Lupus Impact Tracker [LIT], change in the health status and current glucocorticoids use [and dose]) and two laboratory tests (low complements [C3/C4] and urine protein-creatinine ratio >0.5). The values are put in an equation to derive a number, which is transformed to a 0- to 100-point scale by a formula using weighted scores of the above parameters. The SIMPLE index has been validated in US with good correlation with physicians' assessment of disease activity.
Objectives: To validate the SIMPLE index for systemic lupus erythematosus (SLE) disease activity assessment in a longitudinal cohort of Chinese patients.
Methods: Adult patients (age ≥18 years) who fulfilled the 2012 SLICC criteria for SLE and were followed in the Rheumatology clinics of Tuen Mun Hospital, Hong Kong were recruited. Patients were followed for a total of 3 consecutive visits, including hospitalization. Participants were invited to complete the SIMPLE questionnaire before seeing doctors on the same day of clinic visit or hospital stay. The two laboratory results were supplemented by research nurses. Physicians, who were blinded to the SIMPLE results, were asked to complete disease activity assessment by the SELENA-SLEDAI and physicians' global assessment (PGA) after consultation. Correlation was made between the SIMPLE score and the SLEDAI/PGA scores by Spearman's rank correlation test. Correlation was also performed for the changes in total/clinical SLEDAI, PGA with the change in SIMPLE index during subsequent visits relative to baseline.
Results: 399 SLE patients were studied (93.7% women; age 45.3±13.4 years; disease duration 13.3±8.0 years). The proportion of patients having a history of neuropsychiatric and renal disease that required immunosuppressive therapies was 9.8% and 55.6%, respectively. At visit 1, 18 (4.5%) patients had

clinical SLEDAI ≥5 and 98 (24.6%) had clinical SLEDAI 1-4. The mean total SLEDAI was 3.02±2.87 and PGA score was 0.60±0.53. A total of 178 patients (44.6%) had SDI score ≥1. The mean SIMPLE index was 25.6±12.8. SIMPLE index correlated significantly with clinical SLEDAI (ρ=0.56; p<0.001), total SLEDAI (ρ=0.75; p<0.001) and PGA score (ρ=0.41; p<0.001). At visit 3, 87 and 38 patients, respectively, had a drop in total SLEDAI score by ≥1 and ≥4, and the corresponding change in SIMPLE index was 35.3±13.7 to 25.0±10.1 (p<0.001) and 42.9±11.9 to 26.0±11.1 (p<0.001). Conversely, 103 and 29 patients, respectively, had an increase in total SLEDAI score by ≥1 and ≥4. The corresponding increase in SIMPLE index was 23.5±11.3 to 25.7±10.1 (p=0.007) and 25.3±13.7 to 27.3±11.6 (p=0.27). Change in SIMPLE index from visit 1 to 3 correlated significantly with the change in total SLEDAI (ρ=0.35; p<0.001), clinical SLEDAI (ρ=0.19; p<0.001) and PGA (ρ=0.14; p=0.005). ROC analysis performed with pooled data from all the 3 visits showed that a SIMPLE index of >24 points best predicted a clinical SLEDAI score of 1-4 (area under the curve [AUC] 0.72[0.68-0.75]; sensitivity 0.65; specificity 0.64), and >31 points best predicted a clinical SLEDAI score of ≥5 (AUC 0.84[0.77-0.91]; sensitivity 0.76, specificity 0.81).

Conclusion: The SIMPLE index shows a good correlation with SELENA-SLEDAI and PGA. It is also sensitive to change in SLEDAI and PGA score during subsequent visits. The SIMPLE index is a simple tool that enables patients to self-report disease activity and communicate with the health care team more efficiently.

POS0364 UNMET NEEDS IN THE TREATMENT OF EXTRA-RENAL FLARES IN SLE PATIENTS: REAL LIFE EXPERIENCE VS ARTIFICIAL APPROACH

M. Maffi[1], L. Scagnellato[1], A. Collesei[2,3], E. Elefante[1], C. Stagnaro[1], F. Ferro[1], L. Carli[1], V. Signorini[1], D. Zucchi[1], F. Trentin[1], C. Tani[1], M. Mosca[1]. *[1]University of Pisa, Rheumatology, Pisa, Italy; [2]University of Padua, Surgery, Oncology and Gastroenterology, Padua, Italy; [3]Familial Cancer Clinics, Veneto Institute of Oncology, IOV-IRCCS, Padua, Italy*

Background: Systemic lupus erythematosus (SLE) is a heterogeneous disease which can affect various organs and is characterized by different clinical phenotypes. While the treatment of renal involvement is quite standardized, the therapeutic approach to extra-renal manifestations is subjected to a degree of variability.

Objectives: 1. To describe extra-renal disease flares in terms of clinical phenotype and outcomes in SLE patients 2. To compare data from a real-life setting with a machine learning (ML) approach.

Methods: This study is a retrospective analysis of data from a monocentric cohort of SLE patients who experienced a disease flare between 2015 and 2020. Each flare was followed for one year and was classified according to the organ involvement and categorized according to the BILAG definition of flare. At baseline and at 3,6,12 months the following variables were collected: disease activity (SELENA-SLEDAI score), ongoing therapy and disease state (DORIA definition of remission). Demographic data and previous organ involvement were retrieved from clinical charts. Flares' features at baseline and during follow up were analyzed in terms of explained variance across the dataset's Principal Components and clustered with a hierarchical unsupervised learning approach. A ML model based on neural networks was built to early detect flares' therapeutic difficulty: it was validated after data augmentation to satisfy statistical requirements during the training phase.

Results: 66 extra-renal flares were investigated (Table 1); 5 flares (7.5%) were treated with glucocorticoid (GC) pulses and 61 (92.5%) with oral GC therapy, while an immunosuppressive (IS) treatment was prescribed in 44 flares (66.7%). The remission rate at 12 months for the whole group was 50%, with musculo-skeletal (MS) flares, mucocutaneous (MC) flares and others (neuropsychiatric, cardiopulmonary, constitutional, haematologic) that was respectively 63.6%, 31.3% and 41.2%, showing lower rate of remission for MC flares. In 12 months, 17 flares (25.8%) did not respond to treatment (non-responders), requiring an increase in the dose of GC or the introduction of a new IS therapy. Using a machine learning approach, we were able to identify 4 flare clusters, grouping flares in relation to phenotypic characteristics (Figure 1), and recognized statistically relevant features for patients' stratification (cluster 1 "flare in systemic disease with high activity", cluster 2 "outcast flares", cluster 3 "flare in polymorphic disease with mild activity" and cluster 4 "recurrent skin flares"). Interestingly, cluster 4 (recurrent skin flares) was associated with the lowest rate of remission at 12 months with respect to clusters 1, 2, and 3 (33% vs 40%, 76.5% and 56% respectively). Moreover the neural network model correctly predicts difficult to treat flares in up to 80% of the cases

Figure 1. Flare clusters.

Conclusion: These data suggest that, in a real-life setting, the clinical response rate to therapy of patients with an extra-renal flare is not satisfactory, thus identifying an unmet need in the treatment of SLE and highlighting the absence of a standard treatment. Both the real-life data and the machine learning approach identify flares with MC manifestations as the most difficult to treat with the lower rate of remission after one year. Further prospective studies are necessary to improve the neural network model; ML techniques could help in the early identification of difficult to treat flares to be candidates for new and more aggressive therapeutic strategies for extra-renal manifestations.

POS0365 RELAPSES ARE COMMON IN SEVERE HEMATOLOGICAL SLE: REAL-LIFE EXPERIENCE FROM THE "ATTIKON" LUPUS COHORT

G. S. Moysidou[1], S. Flouda[1], M. Kosmetatou[1], N. Kapsala[1], D. Tseronis[1], M. Aggelakos[1], T. Karageorgas[1], D. Nikolopoulos[1], K. Chavatza[1], A. Filippopoulou[1], K. Zoupidou[1], P. Katsimpri[1], A. Fanouriakis[1], D. Boumpas[1]. *[1]National and Kapodistrian University of Athens, 4th Department of Internal Medicine Attikon University Hospital, Athens, Greece*

Background: Hematological manifestations are common in systemic lupus erythematosus (SLE), and are thought to result from immune-mediated peripheral cell destruction or bone marrow failure(1,2).

Objectives: To assess the clinical characteristics and outcomes of severe hematological disease in a large cohort of lupus patients.

Methods: Retrospective analysis of the "Attikon" lupus cohort (over 800 patients total) (3) for the identification of patients with a history of severe hematological manifestation. The latter were defined as: thrombocytopenia with a platelet count <30.000/mm3, hemolytic anemia with an hemoglobin <8 g/dL, neutropenia with less than 500 neutrophils/mm3, history of thrombotic microangiopathy (TMA) or macrophage activation syndrome (MAS). Treatments and long-term outcomes (relapses, mortality) were recorded.

Results: Among 300 patients with hematologic manifestations, 40 patients had severe disease. Most of them were women (75%). Mean age at SLE diagnosis was 41,1 years and mean disease duration at diagnosis of cytopenia was

Table 1.

	WHOLE GROUP	MUSKEL	MUCOCUT	CONSTITUTIONAL	CARDIOPULM	HAEMATOL	NEURO	p
NUMBER (%)	66	33 (50)	16 (24.2)	7 (10.6)	4 (6.1)	5 (7.6)	1 (1.5)	
SLEDAI at baseline median (IQR)	7 (4-29)	8 (6-10)	5.5 (4-10)	5 (4-9)	9 (4.5-12)	5 (5-6)	29 (29-29)	
SLEDAI 12 mos median (IQR)	2 (0-20)	0.5 (0-4)	3 (0-4)	3 (2 – 4)	0 (0-0)	2 (0-3)	14 (14 – 14)	
REMISSION 12 mos number (%)	33 (50)	21 (63.6)	5 (31.3)	4 (57.1)	2 (40)	2 (40%)	1 (100)	0.217
NON RESPONSE 12 mos number (%)	17 (25.8)	8 (25)	5 (31.3)	2 (28.6)	1 (20)	1 (20%)	1 (100)	0.467

3.8 years. Hematologic manifestation preceded SLE diagnosis in 13 patients (32,5%).
Autoimmune thrombocytopenia was the most common (57,5%), followed by hemolytic anemia (17.5%), TMA (12.5%) and Evans syndrome (7,5%). All patients received glucocorticoids (GC). Rituximab (15%) and cyclophosphamide (12,5%) were the most frequently used GC-sparing agents during the first episode. Nine patients (22,5%) received intravenous immunoglobulin (IVIg). Relapse occurred in 23 patients (57,5%), most of which (N=17, 73,9%) were treated with GC alone or in combination with IVIg or plasma exchange at initial presentation, without the use of GC-sparing agents. Most of the flares (60,8%) were severe. No deaths were observed.
Conclusion: Hematological disease in SLE is treatment-responsive. GC remain the mainstay of treatment, but the high relapse rates underscore the need for more efficient GC-sparing agents.

POS0366 MODERATE RATES OF TREATMENT INTENSIFICATION IN SLE PATIENTS WITH RESIDUAL DISEASE ACTIVITY

O. Gioti[1], M. Nikoloudaki[2], K. Chavatza[3], E. Kalavri[1], A. Elezoglou[1], P. Sidiropoulos[2], G. Bertsias[2], D. Boumpas[3], A. Fanouriakis[4]. [1]*"Asklepieio" General Hospital, Department of Rheumatology, Athens, Greece;* [2]*University Hospital Heraklion, Rheumatology, Clinical Immunology and Allergy, Crete, Greece;* [3]*"Attikon" University Hospital, Athens, Greece, Rheumatology and Clinical Immunology, Athens, Greece;* [4]*"Laikon" General Hospital, 1st Department of Propaedeutic Internal Medicine, Athens, Greece*

Background: The treat-to-target (T2T) strategy has gained significant attention in SLE,[1] while EULAR has set remission or low disease activity as the goal of treatment.[2] Nevertheless, the degree to which T2T is followed in real-life clinical settings has not been extensively studied.
Objectives: To assess the proportion of lupus patients with residual disease activity that had their therapy intensified during their most recent visit, identify associated factors, and assess the validity of the SLEDAI-2k as a predictor of this intensification.
Methods: Cross-sectional study of SLE patients who were evaluated in three tertiary centers in Greece during their last visit. Patients were categorized in four disease activity states (remission on and off treatment, low disease activity and non-optimally controlled), according to definitions used in previous studies.[3] Intensification of treatment was defined as addition/increase of glucocorticoids (GC) or addition/increase of immunosuppressive (IS) agent (conventional or biologic). Logistic regression analysis was used to identify factors associated with treatment intensification and ROC analysis to calculate sensitivity, specificity of different SLEDAI-2k cut-off values to predict this escalation.
Results: 332 patients were included [93.1% female, mean (SD) age 48.5 (14.7) years, median (IQR) disease duration 6.5 (12.4) years]. Regarding disease activity states, 23.2% (n=77) of patients were in remission (off or on therapy), 36.7% (n=122) were in LDA, while 40.1% (n=133) were categorized as non-optimally controlled disease.
Within patients with residual disease activity, therapy intensification was offered to 25.8% and 48.9% of those with low disease activity and non-optimally controlled disease, respectively. In multivariable analysis, proteinuria (OR 6.78, 95% CI 2.06 – 22.25), arthritis (OR 5.48, 95% CI 3.20 - 9.40) and rash (OR 3.23, 95% CI 1.81 - 5.75), were associated with intensification of therapy. The AUC of the ROC analysis for total SLEDAI-2k to predict therapy escalation was 0.761, indicating only fair accuracy; the cut-off value with the best combination of sensitivity and specificity was 3 (sensitivity 87%, with a specificity of 55%). For clinical SLEDAI-2k, the respective AUC was marginally better (0.779), with a cut-off of 3 being associated with the best sensitivity (80%), with compromised specificity (64%). (Figure 1).

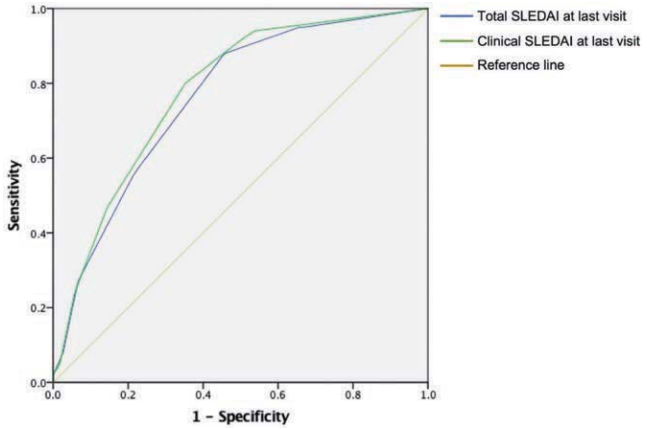

Figure 1. ROC analysis of total and clinical SLEDAI to predict any increase in therapy

Conclusion: In real-life clinical settings, no therapy intensification was offered in more than half of patients categorized as non-optimally controlled disease. Total and clinical SLEDAI-2k showed only fair accuracy to predict therapy escalation, reflecting the role of additional parameters in the decision to escalate therapy in an individual patient.

POS0367 IMPROVEMENT OF INDIVIDUAL MUCOCUTANEOUS MANIFESTATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH ANIFROLUMAB

V. Werth[1], J. Wissmar[2], A. Strömbeck[2], R. Tummala[3], C. Kleoudis[4], M. Albulescu[5]. [1]*University of Pennsylvania and Corporal Michael J. Crescenz Veterans Administration Hospital, Department of Dermatology, Philadelphia, PA, United States of America;* [2]*AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden;* [3]*AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America;* [4]*AstraZeneca, BioPharmaceuticals R&D, Durham, NC, United States of America;* [5]*AstraZeneca, BioPharmaceuticals R&D, Cambridge, United Kingdom*

Background: Patients with cutaneous lupus erythematosus (CLE) experience disfiguring and painful lesions that can lead to psychological distress and significant impacts on quality of life.[1] Treatment of patients with systemic lupus erythematosus (SLE) with anifrolumab, a type I interferon receptor antagonist, was associated with CLE Disease Area and Severity Index–Activity (CLASI-A) improvements compared with placebo through Week 52 in the phase 3 TULIP-1

and TULIP-2 SLE trials.[2,3] CLASI assesses overall skin improvement and may be driven by erythema over the other components.[4]

Objectives: To better understand the effect of anifrolumab on mucocutaneous SLE manifestations by analyzing the individual domains of CLASI-A using pooled data from the TULIP trials.

Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) were randomized, double-blind, placebo-controlled, 52-week trials that evaluated efficacy and safety of intravenous anifrolumab administered every 4 weeks in patients with moderate to severe SLE despite standard therapy.[2,3] In a post hoc analysis, individual CLASI-A domains (erythema, scale/hypertrophy, alopecia, and mucosal) were assessed at Week 24 (time point chosen to ensure adequate duration for improvement in slow-remitting manifestations [eg, scale, alopecia]) in 2 patient subgroups: 1) the "chronic" mucocutaneous subgroup (resembling chronic/discoid CLE), defined as patients with a baseline erythema score ≥4 and scale score ≥2, and alopecia score ≥1 or baseline mucosal lesions or ulceration score of 1; and 2) the "extended" mucocutaneous subgroup (resembling all CLE subtypes), defined as patients who met the "chronic" criteria or those who had a baseline erythema score ≥8.

Results: Across the pooled TULIP trials, 360 patients received anifrolumab 300 mg and 366 patients received placebo. In patients with assessments at Week 24 in the "chronic" (anifrolumab n=58, placebo n=50) and "extended" (anifrolumab n=104, placebo n=96) subgroups, anifrolumab led to a greater mean percent reduction from baseline compared with placebo in erythema (chronic: −63.6% vs −39.9%; extended: −63.7% vs −41.2%) and scale/hypertrophy (chronic: −72.2% vs −42.6%; extended: −45.3% vs −7.3%). Anifrolumab-treated patients in both subgroups had no worsening in alopecia (chronic: 93.3% [56/60] vs 96.0% [48/50]; extended: 95.3% [102/107] vs 95.8% [92/96]) or mucous membrane (chronic: 95.0% [57/60] vs 96.0% [48/50]; extended: 96.3% [103/107] vs 94.8% [91/96]) from baseline vs placebo (Table 1).

Table 1. Skin Responses at Week 24 Compared With Baseline

Criteria, n (%)	Chronic subgroup		Extended subgroup	
	Anifrolumab 300 mg (n=60)	Placebo (n=50)	Anifrolumab 300 mg (n=107)	Placebo (n=96)
Erythema score reduction				
≥25%	53 (88.3)	32 (64.0)	93 (86.9)	68 (70.8)

≥10%	49 (81.7)	34 (68.0)	55 (51.4)	38 (39.6)
≥25%	47 (78.3)	30 (60.0)	53 (49.5)	34 (35.4)
≥50%	46 (76.7)	28 (56.0)	51 (47.7)	31 (32.3)
No new/worsened lesions in any individual body area	44 (73.3)	26 (52.0)	81 (75.7)	56 (58.3)
Alopecia				
≥1-point decrease[a]	25 (41.7)	19 (38.0)	35 (32.7)	27 (28.1)
No worsening	56 (93.3)	48 (96.0)	102 (95.3)	92 (95.8)
Mucosal lesion/ulceration				
1-point decrease[b]	25 (41.7)	13 (26.0)	39 (36.4)	23 (24.0)
No worsening	57 (95.0)	48 (96.0)	103 (96.3)	91 (94.8)

[a]If baseline score ≥1. [b]If baseline score =1.

Conclusion: In the phase 3 TULIP trials, SLE patients with mucocutaneous manifestations treated with anifrolumab experienced numerical improvements in erythema and scale/hypertrophy and no worsening in alopecia or mucous membrane CLASI-A domains compared with placebo, regardless of whether skin disease was classified by chronic or extended definitions. These encouraging data support further evaluation of anifrolumab in patients with CLE.

POS0368

EARLY (3 MONTHS) IMPROVEMENT IN PHYSICIAN GLOBAL ASSESSMENT OF DISEASE ACTIVITY PREDICTS LONG-TERM RETENTION OF BELIMUMAB TREATMENT IN SLE: A MULTICENTRE OBSERVATIONAL STUDY OF 184 PATIENTS

M. Nikoloudaki[1], D. Nikolopoulos[2], S. Koutsoviti[3], I. Flouri[1], N. Kapsala[2], A. Repa[1], P. Katsimpri[2], E. Theotikos[3], S. Pitsigavdaki[1], K. Pateromichelaki[1], A. Eskitzis[1], A. Elezoglou[3], P. Sidiropoulos[1], A. Fanouriakis[3,4], D. Boumpas[2], G. Bertsias[1]. *[1]University of Crete Medical School, Rheumatology, Clinical Immunology, Heraklion, Greece; [2]National and Kapodistrian University of Athens, 4th Department of Internal Medicine "Attikon" University Hospital, Athens, Greece; [3]"Asklepieio" General Hospital, Rheumatology, Athens, Greece; [4]National and Kapodistrian University of Athens, 1st Department of Propaedeutic Internal Medicine, "Laikon" General Hospital, Athens, Greece*

Background: Belimumab has been introduced in the management of SLE for more than 10 years, however long-term efficacy and safety data are still limited and mostly derive from the extended phase of randomized clinical trials.

Objectives: To evaluate the long-term survival of belimumab treatment, reasons for treatment cessation and associated predictors in routine care setting.

Methods: Multicentre observational study of adult SLE patients who were treated with belimumab according to physician discretion and in line with the EULAR recommendations. Disease activity (Physician Global Assessment [PGA]: scale 0-3; SLE disease activity index-2000 [S2K]), flares (SELENA-SLEDAI Flare Index), organ damage (SLICC damage index [SDI]), co-administered treatments and dosage, adverse events and causes of belimumab discontinuation were monitored prospectively at 3–6-month intervals. Cox-regression analysis was performed to identify factors associated with reduced drug survival.

Results: A total 184 patients treated with belimumab for at least 3 months were included (women 95.6%; mean ± SD age 48.8 ± 13.4 years; disease duration 9.2 ± 11.3 years). Baseline S2K and PGA were 7.5 ± 3.0 and 1.64 ± 0.42, respectively, both demonstrating significant improvement at 6 months (4.5 ± 3.5 and 1.02 ± 0.69, respectively; p<0.001) and 12 months (3.5 ± 3.1 and 0.68 ± 0.55, respectively; p<0.001). Of patients receiving glucocorticoids at onset, 49.0% tapered the dose and 17.6% completely withdrew them. After a median (interquartile range) follow-up of 15.1 (16.9) months, 44.0% of patients discontinued belimumab due to suboptimal efficacy as judged by the treating physician (28.3%), adverse events (including infections) (9.8%) or other causes (e.g., pregnancy, patient decision). Accordingly, efficacy-related drug survival rates at 1 and 2 years were 70% and 61%, respectively, with corresponding safety-related survival rates of 94% and 87%, respectively. Baseline factors associated with belimumab discontinuation due to suboptimal efficacy included PGA >1.50 (hazard ratio [HR] 3.66; 95% confidence interval [95% CI] 1.14–11.73; p=0.029) and severe (RA-like) arthritis (HR 2.56; 95% CI 1.16–5.68; p=0.020) but not disease duration, use of glucocorticoids, active serology or organ damage. Notably, patients with early (3 months) improvement (i.e., any decrease in PGA) showed significantly lower risk for treatment cessation (HR 0.38; 95% CI 0.22–0.67; p=0.001) (Figure 1) and this effect was independent of the initial PGA level. Baseline use of hydroxychloroquine was associated with prolonged safety-related belimumab survival (HR 0.32; 95% CI 0.12–0.88; p=0.028).

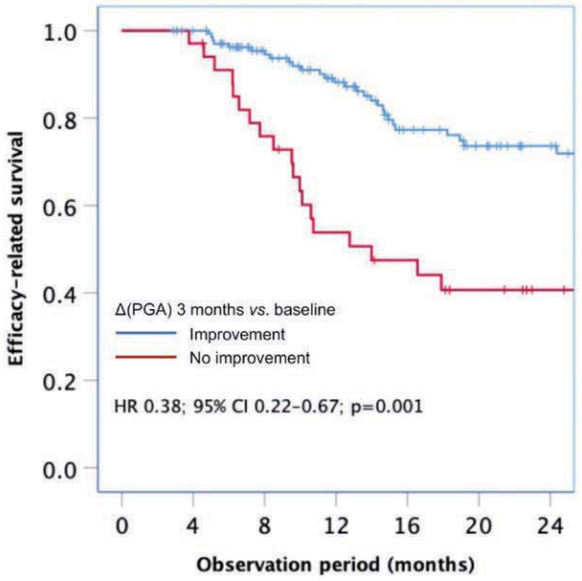

Figure 1. Efficacy-related survival of belimumab according to improvement or not of PGA at 3 months since treatment initiation.

Conclusion: In real-life setting, about 28% of SLE patients discontinue belimumab due to suboptimal treatment response per physician judgement, especially those with moderate-to-high activity and severe arthritis. Improvement in PGA at 3 months predicts long-term drug maintenance, therefore suggesting its value for patient monitoring. Our data confirm the very good tolerability of belimumab and identify hydroxychloroquine co-administration as a predictor for prolonged safety-related drug survival.

POS0369 IMPACT OF HYDROXYCHLOROQUINE LEVEL ON ECG QTC INTERVAL IN PATIENTS WITH RHEUMATIC SYSTEMIC AUTOIMMUNE DISEASES: A REAL-LIFE STUDY

C. Raya-Santos[1], J. Rosas[1], M. Marco[2], A. Pons[1], J. C. Cortés-Quiroz[1], M. Shalabi[2], J. M. Senabre-Gallego[1], G. Santos Soler[1], J. A. Bernal[1], M. Lorente Betoret[1], X. Barber[3], J. A. García-Gómez[3]on behalf of AIRE-MB. *[1]Hospital Marina Baixa, Rheumatology, 03570, Spain; [2]Hospital Marina Baixa, Laboratory, Villajoyosa, Spain; [3]Miguel Hernández University, CIO, Elche (Alicante), Spain*

Objectives: To analyze the impact of the serum level of hydroxychlroquine (OHCLQ) on the QTc interval of the ECG, in patients with rheumatic systemic autoimmune diseases (SARD), treated with this drug for a long time

Methods: Retrospective study, among patients with SARD, treated with OHCLQ ≥ 1 year, dose 200-400 mg/day. Serum OHCLQ level was measured by liquid chromatography and QTc interval by ECG (Welch Allyn 200; SF, N York, USA). Two control groups for QTc are included: Group-1: patients with SARD not treated with OHCQ; Group-2: healthy subjects without SARD. In both, weight and current treatment and an ECG were recorded.

In patients with SARD was collected: 1) Epidemiological data: age, sex, weight, concomitant diseases, current treatment. 2) SARD: diagnosis, year of diagnosis, disease evolution time, clinical and autoimmunity data, treatment and dose. 3) OHCLQ: time in treatment, toxicity, symptoms (dizziness, syncope) and serum level. 4) ECG; QTc and heart rate (HR).

Results: 65 patients treated with OHCLQ, mean 10.8 (6.5) years are included, diagnosed with SLE: 43 (66%) patients, RA: 15 (23%), palindromic rheumatism: 4 (6%), SS1º: 2 (3 %) and PsA: 1 (1%). 63 (97%) patients are women, with a mean age (SD): 58 (14.7) years, weight: 69 (15) kg. Mean dose of OHCLQ: 221 mcg/L (64), 3.24 (1) mg/kg/day.

Mean serum OHCLQ level: 166 mcg/L (6.5): 18 (28%) patients with level <100 mcg/L (mean: 63 [0.7] mcg/L) and 47 (72%) with level >100 mcg/L L (mean 195 mg/XX [94]). On ECG, mean HR: 69 bpm (10) and mean QTc interval: 429.7 (84) ms, prolonged (>440 ms) in 23 (35%) of the patients.

12 (18%) patients reported dizziness at some time and 29 (45%) were being treated with a drug related to the risk of QTc prolongation: Possible (P: at authorized doses no risk of TdP): 1 (2%) patient, Conditional (C: risk under excessive dose, interactions): 13 (20%), P+C: 4 (8%), C+C: 11 (17%).

When comparing the mean QTc result of the group with OHCLQ and the control groups without OHCLQ (n: 41), the QTc is higher (p=0.062) than the group of healthy subjects (n: 23) and without differences with the control group EASR (n: 18), not treated with OHCLQ (p=0.70). Among patients with OHCLQ level >100 mcg/L (n: 47) vs <100 mcg/L (n: 18), patient weight (p=0.012), level (p<0.0001), and dose in mg /kg (p=0.03), is significantly higher at levels >100 mcg/L. No relationship was observed between the OHCLQ level and the QTc result.

In 6 (9%) patients the OHCLQ dose is >3 mg/kg (mean: 5.35 [1] mg/kg, HR: 73 [14] bpm, OHCLQ dose: 367 [71] mcg/L), no detected significant differences in QTc (1 patient presented QTC >440). In patients with QTc >440 ms, older patient age, QTc result, and heart rate were significant. However, the dose in mg/kg of OHCLQ was lower in the group with QTc <440 ms (p=007).

Conclusion: In patients with SARD treated with maintenance doses of OHCLQ of about 3 mg/kg/day, 1) The serum level of OHCLQ is not associated with QTc prolongation on the ECG. 2) QTc is significantly related to age and heart rate. 3) The EASR per se does not affect the QTc result.

Table 1. Characteristics of patients with QTc greater than or less than 440 ms and with an OHCLQ level greater than or less than 100 mcg/L.

POS0370 COMPARATIVE RETINOPATHY RISK OF HIGH- VS LOW-DOSE HYDROXYCHLOROQUINE AMONG 4,677 INCIDENT LONG-TERM USERS: EMULATED TARGET TRIAL ANALYSES

A. Jorge[1], R. Melles[2], M. Marmor[3], C. Conell[4], B. Zhou[1], J. Niu[5], Y. Zhang[1], H. Choi[1]. *[1]Massachusetts General Hospital, Division of Rheumatology, Allergy, & Immunology; Department of Medicine, Boston, United States of America; [2]Kaiser Permanente Northern California, Ophthalmology, Redwood City, United States of America; [3]Stanford University, Ophthalmology, Palo Alto, United States of America; [4]Kaiser Permanente Northern California, Division of Clinical Research, Oakland, United States of America; [5]Baylor College of Medicine, Medicine-Nephrology, Houston, United States of America*

Background: Hydroxychloroquine (HCQ) is a key treatment for patients with lupus, but the major long-term toxicity is HCQ retinopathy. A large cross-sectional study found a prevalence of HCQ retinopathy of 7.5% overall and 5 times higher odds associated with HCQ dose >5 mg/kg/day, which led to ophthalmology guidelines recommending the avoidance of HCQ dosing >5 mg/kg.[1] However, whether this dosing recommendation is applicable to the future risk of HCQ retinopathy is unknown, as is the incidence of severe bullseye retinopathy vs. the mild, pre-symptomatic stage. Furthermore, recent studies have indicated that the use of lower doses of HCQ may increase the risk of lupus flares and hospitalizations.[2]

Objectives: To determine the incidence of HCQ retinopathy associated with long-term HCQ use and compare them according to HCQ dose.

Methods: We emulated a hypothetical target trial using observational data[3] from the US integrated health network Kaiser Permanente Northern California to compare two HCQ weight-based dosing strategies, >5 vs ≤5 mg/kg/day, based on dispensed tablets per year. A secondary analysis evaluated >80% of prescription days covered by dispensed tablets per year with HCQ dose >5 vs ≤5 mg/kg. We included 4,677 patients who initiated and continued HCQ for at least 5 years between 1997-2020. We emulated randomization of treatment strategy by cloning each subject and assigning a replicate to each treatment group.[3] We censored replicates if and when they deviated from the assigned treatment group, assessed as the average dose in the first 5 years and annually thereafter. We used inverse probability weighting to account for censoring. The primary outcome was HCQ retinopathy, assessed by expert adjudication of spectral domain-optical coherence tomography (SD-OCT) and graded by severity. All SD-OCTs were prospectively reviewed by an expert ophthalmologist (RM), and a second expert ophthalmologist (MM) reviewed all abnormal scans and a random subset of normal scans. We assessed intra-rater reliability of SD-OCT findings. We used pooled logistic regression to estimate the cumulative incidence of HCQ retinopathy for each HCQ dose strategy from initiation. The odds ratios approximated hazard ratios (HRs) because the outcome at each one-year time block is <5%.

Results: Among 4,677 patients, the mean age at HCQ initiation was 52 years; 83% were female. The racial/ethnic composition included 51% non-Hispanic White, 19% Hispanic, 14% Asian, and 11% Black patients. 756 (16.2%) and 3,921 (83.8%) patients initiated HCQ with the primary definition of the treatment strategies >5 and ≤5 mg/kg/day, respectively. The weighted kappa was 0.80 for SD-OCT reliability. 164 patients developed HCQ retinopathy (100 mild, 38 moderate, and 26 severe cases). The cumulative incidence of retinopathy over 18 years was 37.6% for >5 and 5.7% for ≤5mg/kg of HCQ in our primary analysis. The corresponding risk was 26.5% for >5 and 3.2% for ≤5 mg/kg in our secondary analysis using >80% of prescription days. Compared with ≤5 mg/kg of HCQ, the HRs of retinopathy were 9.65 (95% CI 5.73-16.65) and 10.79 (95% CI 6.40-20.07) for >5 mg/kg using the primary and secondary definitions of HCQ dose categories, respectively (Figure 1).

Conclusion: The risk of HCQ retinopathy associated with long-term adherence to >5 mg/kg dosing was high, approximately 10 times that of ≤5 mg/kg dosing. However, most cases identified during the study were mild and pre-symptomatic, supporting the value of regular screening. These data should be incorporated into individualized decisions about long-term use of HCQ.

POS0371 CAN WE ENHANCE ADHERENCE TO MEDICATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS? RESULTS FROM A QUALITATIVE STUDY

S. Emamikia[1], C. Gentline[1], Y. Enman[1], I. Parodis[1,2]. [1]*Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine, Solna, Sweden;* [2]*Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden*

Background: Medication non-adherence is common among patients with systemic lupus erythematosus (SLE) [1] and may lead to poor clinical outcomes [2,3].

Objectives: Our aim was to identify influenceable contributors to medication non-adherence to suggest interventions that could increase adherence.

Methods: Patients with SLE from two Swedish tertiary referral centres (N=205) participated in a survey assessing self-reported adherence to medications. Medication adherence was self-reported and measured using the generic instrument Medication Adherence Self-Report Inventory (MASRI) and the rheumatic disease-specific instrument Compliance Questionnaire Rheumatology (CQR). Responses were used to select patients for qualitative interviews (N=15). Verbatim interview transcripts were analysed by two researchers using content analysis methodology.

Results: The mean age of the interviewees was 39 years, 87% were women, and their mean SLE duration was 11.6 years. Patients' medications and adherence levels are detailed in Table 1. We categorised reasons for non-adherence thematically into (i) patient-related e.g., unintentional non-adherence due to forgetfulness or intentional non-adherence due to disbelief in medications, (ii) healthcare-related e.g., untrustworthy relationship with the treating physician, authority fear, and poor information about the prescribed medications or the disease, (iii) medication-related e.g., fear of side-effects, and (iv) disease-related reasons e.g., lacking acceptance of a chronic illness or perceived disease quiescence. Interventions identified that healthcare could implement to improve patients' adherence to medications included (i) increased communication between healthcare professionals and patients, (ii) patient education, (iii) accessible healthcare, preferably with the same personnel, (iv) smooth transition from paediatric to adult care, (v) regularity in addressing adherence to medications, (vi) psychological support, and (vii) involvement of family members or people who are close to the patient.

Table 1. Characteristics of the fifteen interviewees.

Patient	Prescribed medications	Overall medication adherence according to: MASRI (0–100%)	CQR (0–100%)	Direct question (Y/N) *	Intentional non-adherence (Y/N)

POS0372

USE OF TELEMEDICINE FOR FOLLOW-UP OF LUPUS NEPHRITIS IN THE COVID-19 OUTBREAK: ONE-YEAR, PRAGMATIC RANDOMISED CONTROLLED TRIAL

H. So[1], E. Chow[1], I. T. Cheng[1], S. L. Lau[1], T. K. LI2, C. C. Szeto[1], L. S. Tam2. *[1]The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR); [1]The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Patients with systemic lupus erythematosus (SLE) are at increased risk of severe COVID-19 due to the underlying disease, comorbidities and use of immunosuppressants (IS). An alternative option would be to adopt telemedicine (TM) to maintain medical care while minimizing exposure. Despite being widely adopted during the pandemic, the evidence supporting the use of TM in rheumatology has been limited.
Objectives: We primarily aimed to evaluate the effectiveness to maintain disease activity control using TM delivered care compared to conventional in-person follow-up in patients with lupus nephritis (LN). The secondary objectives were to compare the patient reported outcomes, safety and cost-of-illness from the patient's perspective between the 2 modes of health care delivery.
Methods: This was a 1-year, single-center, RCT conducted at a regional hospital in Hong Kong. From May 2020, consecutive adult patients with a SLE according to the 2019 EULAR/ACR classification criteria followed up at the LN clinic were invited to participate in the study. Participants were randomized 1:1 to either TM (TM group) or standard FU (SF group). Patients randomized to receive TM FU were scheduled for a video consultation via a commerical software ZOOM. Patients in the SF group received standard in-person outpatient care. SLE disease activity at each consultation was assessed by SLEDAI-2k and physician global assessment (PGA).
Results: A total of 144 patients with LN were randomized and 3 patients self-withdrew from the study. The mean age was 44.5±11.4 years and the median time from diagnosis to randomization was 168 months (range: 1-528). Most of the patients had class III, IV or V LN (87.2%) and were on prednisolone (89.4%, median dose 5mg daily). Many of them (68.1%) were on IS. While 66.0% of the patients were in lupus low disease activity state (LLDAS), none had disease remission. There were no baseline differences, including demographics, SLEDAI-2k (TM: 3.8±2.3, SF: 3.2±2.2, p=0.13, PGA (TM: 6.2±6.5, SF: 4.6±5.9, p=0.13) and SLE damage index (TM: 1.1±1.3, SF: 0.8±1.1, p=0.10), between the 2 groups.
At one year, 80.0% and 80.2% of the patients in the TM group and SF group were in LLDAS or remission respectively. SLE disease activity indices including SLEDAI-2k, PGA, proteinuria amount and serum anti-ds-DNA level remained similar between the 2 groups. Within the study period, 28 (40%) patients in the TM group and 21 (29.6%) patients in the SF group had disease flare (p=0.20). There were no differences in the SF-36, lupusQoL and HADS scores between the 2 groups at the end of the study. The overall patient satisfaction score was higher in the TM group with a significantly shorter waiting time before seeing doctors. At the end of the study, 67.9% of the overall participants agreed to (versus 15.0% who did not agree to) use TM as a mode of future FU. The mean indirect costs of illness (HKD26,681 vs HKD12,016, p=0.20) and the out-of-pocket costs for health care services were similar between the 2 groups (TM: HKD13,547 vs SF: HKD12,297, p=0.83) in one year. The total number of FU was similar (TM: 6.0±2.0, SF: 5.7±1.7, p=0.40). However, significantly more patients in the TM group (29/70, 41.4% vs 4/71, 5.6%; p<0.01) requested change mode of FU. The proportion of patients requiring hospitalization during the study period was also higher in the TM group (TM: 23/70, 32.9% vs 11/71, 15.5%; p=0.02). After adjusting for age and prednisolone dosage, not being in LLDAS at baseline was the predictor of hospitalization (OR 3.4, 95%CI 1.20-9.65). None of the participants was tested positive for COVID-19.
Conclusion: TM FU resulted in similar 1-year disease activity control and better satisfaction in patients with LN compared to standard care. However, a significant proportion of patients cared by TM required in-person visits or were hospitalized. The results of the study suggest that TM delivered care could help minimizing exposure to COVID-19, but it needs to be complemented by physical visits, particularly in those with unstable disease.

Background: Digital solutions for online monitoring of chronic diseases are increasingly implemented in health care, but not all patients might have access, skills, or interest in using them. Fueled by the COVID-19 pandemic and the urgent need for remote consultations, an online website to enter patient-reported outcomes (PROs) from home (DANBIO-from-home, https://danbio.dk) was implemented on May 15th 2020 for patients with inflammatory rheumatic diseases (IRD) followed in the Danish nationwide DANBIO registry.
Objectives: To explore the use of DANBIO-from-home during the first 1½ year after launching, with focus on a) characteristics of patients who did versus who did not access the webpage, and b) impact of patient age on time to first entry.
Methods: DANBIO-from-home allows PROs to be entered remotely by computer, tablet, or smartphone after secure log-on. All patients followed in DANBIO were informed about this option by invitations sent through eBoks, a national infrastructure for electronic communication, available to 80-90% of Danish citizens. Patients were encouraged to access DANBIO-from-home before planned rheumatology consultations, or when participating in the voluntary questionnaire survey 'You and your rheumatic disease during times with corona-virus' (on three occasions: May 2020, Nov 2020, June 2021) (ref). Follow-up ended Dec 1st 2021. Characteristics of patients who did/did not access DANBIO-from-home during follow-up are explored by multivariable logistic regression analyses adjusted by clinical factors (gender/age-group/diagnosis/disease duration/use of biologics/HAQ/PASS). Time to first entry of PRO using DANBIO-from-home is presented as cumulative incidence curves by age group.
Results: Among 33,776 patients with inflammatory rheumatic diseases followed in DANBIO, 68% used DANBIO-from-home at least once during follow-up (Table 1). Patients who used the system were less frequently below 40 years or above 80 years old, more frequently biologically treated and had lower HAQ-score than patients who did not use it.

Table 1.

		Data entry, DANBIO-from-home solution N=33,776	
		YES, 68%	NO, 32%
Gender, female		64	36
Gender, male		78	22
Age strata, yrs	< 40	62	38
	40-60	73	27
	61-80	72	28
	>80	39	61
Diagnosis	RA	67	23
	AxSpA	69	31
	PsA	70	30
Biologic treatment, yes*		73	27
PASS, yes		71	29
Age, yrs, median (IQR)		62 (52-71)	65 (50-77)
Time since diagnosis, yrs, median (IQR)		9 (5-16)	10 (5-17)
HAQ, median (IQR)		0.5 (0.125-1.0)	0.625 (0.125-1.25)

Row percentages unless otherwise shown* latest visit before March 2020AxSpA: Axial spondyloarthritis, HAQ: health assessment questionnaire, PASS: patient acceptable symptom scale, PsA: psoriatic arthritis, RA: rheumatoid arthritis

In logistic regression analyses, factors associated with DANBIO-from-home access were: female gender (odds ratio, OR 1.2 (1.1;1.3)), age group 40-60

(1.8 (1.6;2.0)) or 61-80 yrs (1.9 (1.7;2.19) and not age >80 yrs (0.6 (0.5;0.7) with age <40 as the reference), biologic treatment (1.4 (1.3;1.5)), higher HAQ (1.3 (0.3;1.4)), scoring PASS 'no' (1.1 (1.02;1.2)) (all p <0.001), whereas disease duration and diagnosis had no impact.

Time to first entry was longest in in patients >80 yrs followed by the <40 yrs group. For all age-groups, and most pronounced for age <40 yrs, the use increased when invitations to questionnaire surveys were sent out. (Figure 1)

Conclusion: A web-based system for secure remote entry of PROs was well-received after a nationwide launch. Patient-related factors had a substantial impact on the use. Lower use in the elderly might indicate lack of technical skills or facilities, whereas low use in younger age groups, which improved over time, is likely driven by other factors. Further analyses are planned to explore if lack of use impacts treatment outcomes.

POS0374

MONITORING CHRONIC INFLAMMATORY MUSCULOSKELETAL DISEASES WITH A PRECISION DIGITAL COMPANION PLATFORM(TM)–RESULTS OF THE DIGIREUMA FEASIBILITY STUDY

D. Benavent[1], F. J. Núñez-Benjumea[2], L. Fernández-Luque[2], V. Navarro-Compán[1], M. Sanz[1], E. Calvo Aranda[3], L. Lojo[3], A. Balsa[1], C. Plasencia[1].
[1]Hospital Universitario La Paz, IdiPaz, Department of Rheumatology, Madrid, Spain; [2]AdheraHealth Inc., Palo Alto, United States of America; [3]Hospital Universitario Infanta Leonor, Department of Rheumatology, Madrid, Spain

Background: Patients with rheumatic and musculoskeletal diseases (RMDs) require a tailored follow-up that is limited by the capacity of healthcare professionals. Innovative tools need to be implemented effectively in the clinical care of patients with RMDs.

Objectives: To test the feasibility of a Precision Digital Companion Platform™ for real-time monitoring of disease outcomes in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA).

Methods: Digireuma was a prospective study including patients with RA and SpA, using the digital Precision Digital Companion Platform, Adhera for Rheumatology (ISRCTN11896540). During a follow-up of 3 months, patients were asked to report disease specific electronic patient reported outcomes (ePROs) on a regular basis in the mobile solution. Two rheumatologists monitored these ePROs and, patients were contacted for online or face-to-face interventions when deemed necessary by clinicians (Figure 1). Assessment measures included patient global assessment (PGA) of disease activity, tender joint count (TJC), swollen joint count (SJC), Health Assessment Questionnaire (HAQ) and pain visual analogue scale (VAS), for patients with RA; VAS, PGA, TJC, SJC, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and ASAS Health Index (ASAS-HI), for patients with SpA. In addition, flares, changes in medication and recent infections were asked. Usability of the digital solution was measured by the Net-Promoter Score (NPS).

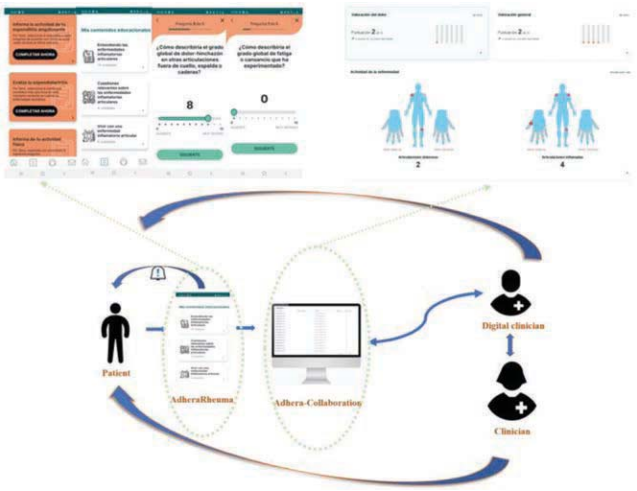

Figure 1. Digital monitoring in the study powered by Adhera for Rheumatology. Screenshots in top depict the mobile interface (left) and clinical web application (right)

Results: Forty-six patients were recruited of whom 22 had RA and 24 SpA. Mean age was 48 ± 12 and 42 ± 9 years in the RA and SpA groups, respectively. 18/22 (82%) patients with RA and 9/24 (38%) with SpA were female. Among the total included patients, 41 (89%) completed the onboarding (18/22 (82%) RA, 23/24 (96%) SpA) and 37 (80%) submitted at least one entry. In the RA group who completed the onboarding (n=18) there were a total of 4019 total interactions (2178 questionnaire items, 648 accesses to educational units, 105 quizzes, 1088 rated messages), while patients with SpA (n=23) had a total of 3160 interactions (1637 questionnaire items, 684 accesses to educational units, 77 quizzes, 762 rated messages). ePROs measurements completion rates for RA and SpA patients that completed any data during follow-up are shown in Table 1. Patients with RA completed a median of 9.5 ePROs during follow-up, whereas patients with SpA completed a median of 3. Regarding alerts, 15 patients generated a total of 26 alerts, of which 24 were flares (10 RA, 14 SpA) and 2 were problems with the medication (1 RA, 1 SpA). 18 (69%) of the alerts were managed remotely, 5 (19%) required a face-to-face intervention and in 3 (12%) patients did not respond before the consultation. Regarding usability and patient satisfaction, 14 patients provided feedback. According to the NPS, 9/14 were considered promoters, 4/14 passives and 1/14 detractor. The overall rating of these 14 patients for the app was 4.3 out of 5 stars.

Table 1. Onboarded patient engagement with regards to e-PROs

Rheumatoid Arthritis (n=18)						
	PGA	TJC	SJC	VAS	HAQ	Total
ePROs completed	1.5 (0.25, 3)	2 (0.25, 3)	2 (0.25, 3)	2 (0, 3)	2 (1, 3)	9.5 (4.3, 15.8)
Patients with ≥ 1 entry	13 (72.2)	13 (72.2)	13 (72.2)	12 (66.7)	16 (88.9)	16 (88.9)
Spondyloarthritis (n=23)						
	PGA	TJC	SJC	BASDAI	ASAS-HI	Total
ePROs completed	1 (0,3)	1 (0,3)	1 (0,3)	1 (0,2)	1 (0,2)	3 (1, 12)
Patients with ≥ 1 entry	16 (69.5)	16 (69.5)	16 (69.5)	14 (60.8)	14 (60.8)	21 (91.3)

Follow-up period was 3 months. Results are expressed in median (Q1, Q3) and n (%)

Conclusion: This study shows that the use of a digital health solution is feasible in clinical practice. Based on these preliminary results, the next step will be to further implement the Precision Digital Companion Platform, Adhera for Rheumatology, in a multicentric setting to analyze the added value for monitoring patients.

POS0375 EVALUATION OF PATIENTS WITH RHEUMATOID ARTHRITIS IN TELECONSULTATION DURING THE FIRST WAVE OF THE COVID-19 PANDEMIC

J. Avouac[1], A. Moltó[1], C. Frantz[1], S. Wanono[1], E. Descamps[1], O. Fogel[1], A. Combier[1], L. Poiroux[1], C. Miceli Richard[1], Y. Allanore[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*

Background: The sudden emergence of SARS-CoV-2 onto the world stage has accelerated a major change in the management of patients with chronic rheumatic diseases and has catalyzed the rapid emergence of telemedicine.
Objectives: Our aim was to describe which parameters were used by rheumatologists to monitor patients with rheumatoid arthritis (RA) in teleconsultation during the first wave of the pandemic and identify the most relevant for decision making.
Methods: Retrospective monocentric routine care cross-sectional study including RA patients seen in teleconsultation between March and September 2020. Available parameters assessing disease status were collected in teleconsultation files. Clinician intervention was defined by treatment escalation and/or the need for a rapid face-to-face consultation or day hospitalization.
Results: 143 RA patients were included (117 females, mean age of 58±16 years, mean disease duration of 14±11 years). The presence or absence of patient self-reported RA flares was mentioned in all medical files, followed by the presence and/or the number of tender joints (76%), the duration of morning stiffness (66%), the number of pain-related nocturnal awakenings (66%) and the CRP value (54%). Patient self-reported RA flares concerned 43/143 patients (30%). The presence of self-reported RA flares was associated with a more detailed evaluation of patient in teleconsultation: The presence (or number) of tender joints and swollen joints were more significantly reported in patients who presented a flare (39/43, 91% vs. 70/100, 70%, p=0.008 and 25/43, 58% vs. 23/100, 23%, p<0.001, respectively).
Teleconsultation led to a clinician intervention in 22/143 patients (14%), representing 51% of patients with self-reported flares (22/43 patients). Therapeutic escalation was necessary in 13 patients: introduction or dose increase of corticosteroids in 8 patients, introduction or dose increase of methotrexate in 4 patients and introduction of hydroxychloroquine in 1 patient. Face-to-face consultation or day hospitalization were organized for 10 patients. Active disease was confirmed during this next face-to-face visit in 9 patients, with DAS28 ranging from 3.35 to 5.62, leading to therapeutic modification. The 133 other patients were seen in face-to-face consultation 6±2 months after the teleconsultation. No DMARD modification was recorded during this next face-to-face consultation.
The following variables were associated with clinician intervention during the teleconsultation in univariate analysis: patient self-reported RA flares since the last visit (p<0.001), CRP >10 mg/mL (p=0.012) and a morning stiffness > 30 minutes (p<0.001). Multivariate analysis confirmed RA flares (Odds Ratio, OR: 15.6 95% CI 3.37-68.28) and CRP values >10 mg/L (OR: 3.32, 95% CI % 1.12-13.27) as the variables independently associated with clinician intervention.
Conclusion: Our study identified patient reported RA flares and increased CRP values as 2 red flags in teleconsultation, independently associated with therapeutic modification and/or the need for a rapid face-to-face consultation. These indicators may help clinician's decision making in teleconsultation.

POS0376 THE ROLE OF ELECTRONIC CONSULTATION IN THE EARLY DIAGNOSIS OF INFLAMMATORY ARTHROPATHIES IN A THIRD LEVEL HOSPITAL

D. V. Mendoza Mendoza[1], D. Ruiz-Montesinos[1], V. Moreira Navarrete[1], J. J. Pérez Venegas[1]. [1]*Hospital Virgen Macarena, Rheumatology, Seville, Spain*

Background: The relevance of early diagnosis in rheumatic inflammatory diseases is well known. Electronic consultation (e-Consults) is a tool for communication between primary health care (PHC) and hospital care (HC) physicians in order to present the cases of patients. It has proven to resolve cases without on-site consultations and to facilitate quick access to conventional consultations.
Objectives: To evaluate whether e-Consults is an effective tool in the early diagnosis of inflammatory arthropathies
To evaluate whether the clinical suspicion of the rheumatologist correspond to the final diagnosis.
Methods: Retrospective, observational study of all e-Consults carried out during 2021 in the hospital area *Virgen Macarena*. All e-Consults were carried out by means of a computer program as a clinical extension of the research project E-Hermes for the implementation of e-Consults. The analysis focused on those e-Consults in which the rheumatologist suspected rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondylarthritis (SpA) in comparison with the final diagnosis. The on-site consultations and waiting time for appointments were also analyzed.
Results: During 2021, the number of e-Consults received was 733. Inflammatory arthropathy was suspected in 54 (7.4%). RA was suspected in 55.9% of the cases, PsA in 17.6% and SpA in 26.5% of the cases. 67.6% of the patients were women with an average age of 53.15 (± 17.06). 87.3% were recalled for an on-site consultation. Of these, 76.5% were given a preferential appointment and 11.8% were given a regular appointment. The waiting time for the preferential appointment was 18.5 days on average and 39 days for the regular appointment.
73.7% of the patients with suspected RA were women with an average age of 55.16 years (± 16.8). The reasons for consultation were: joint swelling (89.5%), polyarthralgia (5.3%) and hand pain (5.3%). The diagnosis of RA was confirmed in 47.4% of the suspected cases and only 27.7% showed no inflammatory joint pathology.
83.3% of the suspected PsA cases were women with an average age of 53 years (± 12.6). Joint swelling was the most frequent reason for consultation (50%) followed by polyarthralgia, lumbar back pain and hand pain (16.7%, respectively). The diagnosis of PsA was confirmed in 33.3% of the suspected cases.
55.6% of the patients with suspected SpA were men with an average age of 49 years (± 20.8). The most frequent reasons for consultation were: joint swelling (44.4%) and lumbar back pain (33%). The suspected diagnosis of SpA was confirmed in consultation in 44.4% of the patients and only 33.3% of the suspected cases showed no inflammatory pathology.
After all 733 e-Consults performed in 2021, 14 patients (2%) were diagnosed with RA, 5 (0.7%) were diagnosed with PsA and y 6 (0.9%) with SpA, which means a 3.5% diagnosis of inflammatory arthropathy by means of e-Consults.
The hospital area *Virgen Macarena* serves 481,296 inhabitants. Considering that the incidence per 100,000 patients/year is 8.3 for RA, 3.6 for PsA and 7.2 for SpA [1-2], the number of new cases expected in our area are as follows: 40 for RA, 17 for PsA and 5 for SpA. The proportion of cases diagnosed by TC were 36% for AR, 27.7% for PsA and 18.5% for SpA, corresponding to the reference population.
Conclusion: The suspected diagnosis of the rheumatologist in the e-Consults was confirmed for inflammatory joint pathologies in almost half of the cases.
E-Consults is a useful tool to identify inflammatory joint processes that need evaluation in an on-site consultation.
E-Consults is an efficient method for the early detection of high-impact rheumatic diseases, facilitating quick access to those patients and minimizing diagnostic time.

ONE YEAR OF DIGITAL HEALTH APPLICATIONS (DIGA) IN GERMANY – RHEUMATOLOGISTS' PERSPECTIVES

J. G. Richter[1], G. Chehab[1], P. Stachwitz[2], J. Hagen[2], D. Larsen[2], J. Knitza[3], M. Schneider[1], A. Voormann[4], C. Specker[5]. [1]*Medical Faculty, Heinrich-Heine-University Duesseldorf, Policlinic for Rheumatology and Hiller Research Unit for Rheumatology, Düsseldorf, Germany;* [2]*Health Innovation Hub of the Federal Ministry of Health, Health Innovation Hub of the Federal Ministry of Health, Berlin, Germany;* [3]*Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3-Rheumatology and Immunology, Erlangen, Germany;* [4]*German Society for Rheumatology, German Society for Rheumatology, Berlin, Germany;* [5]*Clinic Essen-Mitte, Clinic of Rheumatology and Clinical Immunology, Essen, Germany*

Background: Based on given legislation (§§ 33a and 139e SGB V, Social Code Book V) the German approach to digital health applications (Digitale Gesundheitsanwendungen, DiGA) allows reimbursed prescription of approved therapeutic software products (listed in the DIGA directory https://diga.bfarm.de/de/verzeichnis) for patients since October 6th, 2020.
Objectives: To evaluate the level of knowledge on DiGA among members of the German Society for Rheumatology (DGRh) after one year of DiGA under the conditions of the COVID-19 pandemic using the DiGA Toolbox of the 'health innovation hub' (hih), a think tank and sparrings partner of the German Federal Ministry of Health.
Methods: Anonymous cross-sectional online survey using LimeSurvey (https://limesurvey.org). The survey was promoted by newsletters sent out to DGRh newsletter recipients and Twitter posts. Ethical approval was obtained.
Results: 75 valid participants reported that they care more than 80% of their working time for patients with rheumatic diseases. Most were working in outpatient clinics (54%) and older than 40 years of age (84%). Gender distribution was balanced (50%).
70% were aware of the possibility to prescribe DiGA. Most were informed on this for the first time via trade press (63%), and only 8% via the professional society. 46% expect information on DiGA from professional societies and the medical chambers (36%) but rarely from the manufacturer (10%) and the responsible ministry (4%). Respondents would like to be informed about DIGA via continuing education events (face-to-face 76%, online 84%), trade press (86%), and manufacturers test accounts (64%).
Only 7% have already prescribed a DiGA, 46% planned to do so, and 47% did not intend DiGA prescriptions. Relevant aspects for prescription are given in Figure 1.

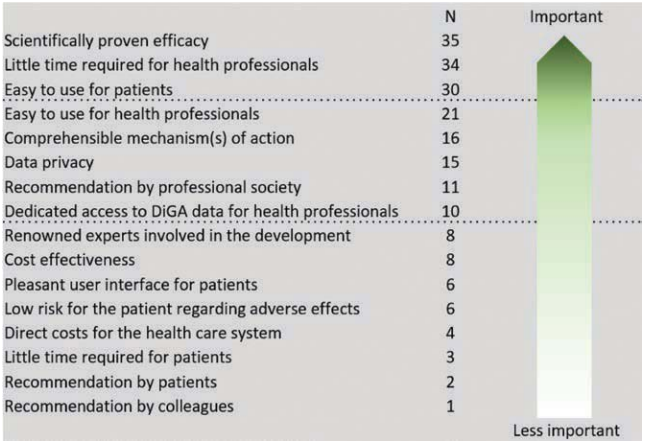

Figure 1. Aspects relevant for DiGA prescriptions; sorted by importance/number of mentions (participants needed to pick their three most relevant aspects from a pre-given list)

86% believe that using DiGA / medical apps would at least partially be feasible and understandable to their patients.
83% thought that data collected by the patients using DiGA or other digital solutions could at least partially influence health care positively.
51% appreciated to get DiGA data directly into their patient documentation system resp. clinical electronic health record (EHR) and 29% into patients' owned EHR.
Conclusion: DiGA awareness was high whereas prescription rate was low. Mostly, physician-desired aspects for DiGA prescriptions were proven efficacy and efficiency for physicians and patients, risk of adverse effects and health care costs were less important. Evaluation of patients' barriers and needs are warranted. Our results will contribute to the implementation and dissemination of DIGA.

POS0378

EVALUATION OF THE USE OF VIDEO CONSULTATION IN GERMAN RHEUMATOLOGY CARE BEFORE AND DURING THE COVID-19 PANDEMIC WAVES

J. Reiter[1], G. Chehab[1], P. Aries[2], F. Muehlensiepen[3], M. Welcker[4], A. Voormann[5], M. Schneider[1], C. Specker[6], J. G. Richter[1]. [1]*Medical Faculty, Heinrich-Heine-University Duesseldorf, University Clinic, Duesseldorf, Policlinic & Hiller Research Unit for Rheumatology, Duesseldorf, Germany;* [2]*Immunologikum Hamburg, Rheumatologie & Klinische Immunologie, Hamburg, Germany;* [3]*Faculty of Health Sciences, Brandenburg Medical School Theodor Fontane, Ruedersdorf, Center for Health Services Research, Brandenburg, Germany;* [4]*MVZ für Rheumatologie Dr. Martin Welcker GmbH & RheumaDatenRhePort (RHADAR), Geschäftsführung, Planegg, Planegg, Germany;* [5]*German Society for Rheumatology, German Society for Rheumatology, Berlin, Germany, Berlin, Germany;* [6]*Clinic Essen-Mitte, Clinic of Rheumatology and Clinical Immunology, Essen, Germany, Essen, Germany*

Background: During the COVID-19 pandemic telemedicine tools rapidly and widely gained acceptance as indispensable management tools for the continuum of clinical care in rheumatic diseases. They have been adopted in position papers and guidelines for the management of rheumatic diseases in adult patients.
Objectives: Evaluation of the use of video consultation as one form of telemedicine before and during the COVID-19 pandemic and associated lockdowns among Rheumatology physicians in Germany. The survey results are expected to support the optimization and implementation of video consultation (VC) into routine clinical practice in rheumatology, providing long-term benefits for both parties, patients and their treating rheumatologists.
Methods: Cross-sectional nationwide online survey among German rheumatologists and rheumatologists in training. The survey was promoted by newsletters sent by means of mail and Twitter posts to members of the German Society for Rheumatology (n=1,650) and German Professional Society for Rheumatology (n=527).
Results: Reported data refer to 205 participants. The majority of respondents was male (59%), older than 40 years (90%) and specialized in internal medicine/rheumatology (85%).
They were divided into two groups: 'digital users' (38%) and 'digital non-users' (62%). Users employing telemedicine (TM) but never VC were defined as 'TM-users' (10%). Those using TM and VC were classified as 'VC-users' (27%). 'Non-users' negated the use of VC and TM respectively.
Knowledge on telemedicine was self-rated as 4 (median on a Likert Scale 1 (very high) to 6 (very low)) with a significant difference between user (VC-user 2.7±1.2, TM-user 3.2±1.1) and non-user (4.4±1.3).
The Figure 1 shows a significant increase in the use of VC during the lockdown periods. Even between the lockdown phases, VC use was higher than in the pre-pandemic phase.

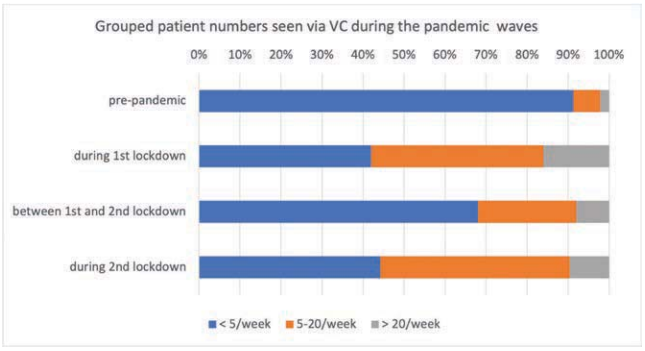

Figure 1. Grouped patient numbers seen via VC during the pandemic waves

Reasons for VC non-use in TM-user and non-user were administrative/technical efforts (21%), lack of technical equipment (15%), time constraints (12%), time required for individual VC sessions (12%), inadequate reimbursement (11%), lack of demand from patients (11%), data security concerns (9%), poor internet connection (8%), and lack of scientific evaluation/evidence (5%).
Based on the experience gained, physicians considered the following clinical situations to be particularly suitable for VC: follow-up visits (VC-user 79%, TM-user 62%, non-user

47%), emergency consultations (VC-user 20%, TM-user 33%, non-user 20%), and patients presenting for the first time (VC-user 11%, TM-user 19%, non-user 8%).

Table 1. Evaluation of the VC in comparison to other patient interaction (VC-user) on a Likert Scale with 1 (I agree completely) to 6 (I do not agree at all)

VC is	Mean ± standard deviation (median)
… comparable to a face to face meeting (n=52)	4.3 ± 1.3 (4.5)
… comparable to a telephone consultation (n=51)	3.3 ± 1.3 (3.0)
… suitable as an additional means of communication with the patient (n=51)	2.3 ± 1.5 (2.0)

Conclusion: Despite the fact that the current pandemic situation, with social distancing and several lockdowns, provides an ideal environment for the implementation of new remote care forms such as VC, their use and acceptance remained below expectations. Given the reported decline in physician face-to-face consultations during the pandemic, these findings are even more concerning. The identified reasons for non-utilization should be addressed by policy makers, payers and medical societies to provide better foundations for future innovative care models.

SMARTPHONE-ASSISTED PATIENT-INITIATED CARE VERSUS USUAL CARE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND LOW DISEASE ACTIVITY: A RANDOMIZED CONTROLLED TRIAL

B. Seppen[1,2], J. Wiegel[1,2], M. Ter Wee[3], D. Van Schaardenburg[1,4], L. Roorda[5], M. Boers[3], M. Nurmohamed[1,2], W. H. Bos[1,2]. *[1]Amsterdam Rheumatology and Immunology Center | Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam UMC, location VUmc, Rheumatology, Amsterdam, Netherlands; [3]Amsterdam UMC, location VUmc, Epidemiology and Data Science, Amsterdam, Netherlands; [4]Amsterdam UMC, location AMC, Rheumatology, Amsterdam, Netherlands; [5]Reade, Rehabilitation, Amsterdam, Netherlands*

Background: Most patients with rheumatoid arthritis (RA) visit their rheumatologist every 3-6 months to evaluate their disease activity. This may be inefficient, as research shows that many patients have minimal disease activity.[1] When patients monitor their disease and initiate care at the right moment, they may be able to reduce the number of clinic visits, with a lower health care burden and costs. We developed a smartphone app that allows patients to self-monitor their disease activity through a weekly assessment of patient index data (RAPID-3).

Objectives: To assess safety (non-inferiority in disease activity, DAS28) and efficacy (reduction in number of visits) of patient-initiated care assisted by a smartphone app compared to usual care.

Methods: A twelve month, randomized, non-inferiority clinical trial was conducted in RA patients with low disease activity, on stable treatment for at least 6 months prior to entry. Patients were randomized (1:1) to either app supported patient-initiated care with a scheduled follow-up consultation after a year (app-group), or usual care, see Figure 1. The primary outcomes were non-inferiority in terms of change in disease activity (ΔDAS28) after 12 months and the number of consultations with a rheumatologist. The non-inferiority limit was set at 0.5 difference in ΔDAS28 between the groups.

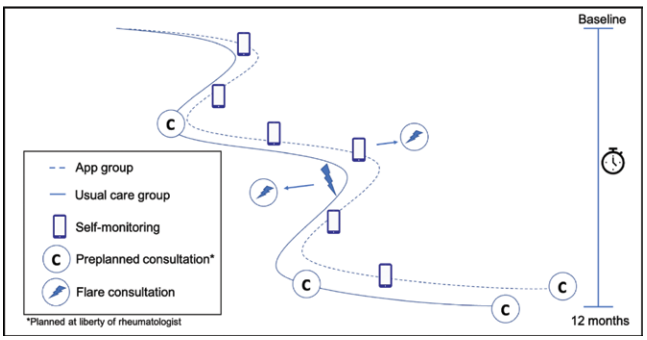

Figure 1. Typical routine care versus app-supported self-initiated care.

Results: 102 of 103 randomized patients completed the study. The mean age was 58, 60 were female and the mean disease duration was 12 years. At baseline mean (SD) DAS28 was 1.67 (0.68) in the app group, and 1.54 (0.72) in the usual care group. After a year, ΔDAS28 was 0.27 in the app group vs 0.35 in the usual care group: the difference in ΔDAS28 was –0.04 in favor of the app group (95%CI –0.39; 0.30) documenting non-inferiority. The number of rheumatologist consultations was significantly lower in the app group: mean (SD) 1.7 (1.8) vs 2.8 (1.4) visits/year; visit rate ratio: 0.62 (95% CI 0.47;0.81, p<0.001).

Conclusion: Patient-initiated care supported with self-monitoring via a smartphone app was non-inferior to usual care in terms of ΔDAS28 and led to a 38% reduction in rheumatologist consultations rate.

POS0380

EFFECTIVENESS OF REMOTE CARE INTERVENTIONS: A SYSTEMATIC REVIEW INFORMING THE 2022 EULAR POINTS TO CONSIDER FOR REMOTE CARE IN RHEUMATIC AND MUSCULOSKELETAL DISEASES

A. Marques[1,2], P. Bosch[3], A. De Thurah[4], Y. Meissner[5], L. Falzon[6], C. Mukhtyar[7], H. Bijlsma[8], C. Dejaco[3,9], T. Stamm[10]on behalf of EULAR task force on Points to Consider for the for remote care in rheumatic and musculoskeletal diseases. *[1]Higher School of Nursing of Coimbra, Health Sciences Research Unit Nursing, Coimbra, Portugal; [2]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; [3]Medical University of Graz, Rheumatology and Immunology, Graz, Austria; [4]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [5]German Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin, Germany; [6]The University of Sheffield, School of Health and Related Research, Health Economics and Decision Science, Sheffield, United Kingdom; [7]Norfolk & Norwich University Hospital, Rheumatology, Norwich, United Kingdom; [8]UMC Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands; [9]Hospital of Bruneck (ASAA-SABES), Rheumatology, Bruneck, Italy; [10]Medical University of Vienna & Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Vienna, Austria*

Background: While the number of patients with rheumatic musculoskeletal diseases (RMDs) is increasing worldwide, there is no adequate increment in the number of health care professionals, leading to the urgent need for new forms of care to take pressure from health care systems.[1] [2] Telehealth comprises a number of different types of interventions with the scope of performing certain steps of care, ranging from diagnostics to follow-up visits, in a remote manner. The use of remote care is heterogenous and guidance is needed to optimize the combination with conventional face-to-face (F2F) visits.

Objectives: To perform a systematic literature review (SLR) on different outcomes of remote care compared to F2F care, its implementation into clinical practice and to identify drivers and barriers in order to inform a task force formulating the European Alliance of Associations for Rheumatology (EULAR) Points to Consider for remote care in RMDs.

Methods: Prospective, retrospective, and qualitative studies testing different types of remote care in patients with RMDs were included. Medline, Embase and the Cochrane Library were searched through February 28th, 2021. Two reviewers independently performed standardized data extraction, synthesis, and risk of bias assessment.

Results: A total of 2,240 references were identified. Forty-seven studies, consisting of 26 randomized controlled trials, 8 prospective cohort studies, 8 cross sectional studies, and 5 qualitative studies were included.

Fifty-one percent of the studies involved patients with inflammatory RMDs, including rheumatoid arthritis, and spondyloarthritis, while 49% were on patients with non-inflammatory conditions, such as osteoarthritis and fibromyalgia. Remote monitoring (n=35) was most frequently studied, with telephone/video calls being the most common mode of delivery (n=30). Thirty-four studies investigated outcomes of remote care in comparison to F2F care. The most frequently assessed outcomes concerned efficacy and user perception of remote care, with 34% and 21% of studies, respectively, reporting superior results for the remote care intervention.

Time savings and flexibility were reported as major drivers, while inadequate technical knowledge and concerns in data security were the main barriers to

implementing remote care. Implementation of remote care methods into clinical practice was not reported by the included studies. The main limitations were the heterogeneity of outcomes and interventions, and the substantial risk of bias (50% of studies with high risk of bias).

Conclusion: Studies on remote care reported similar to partially better results compared to F2F care concerning efficacy, and user perception outcomes, with the limitation of heterogeneity and considerable risk of bias.

POS0381 ALLOCATION OF VISITS ACCORDING TO NEED: SCREENING RHEUMATOID ARTHRITIS PATIENTS WITH PATIENT REPORTED OUTCOMES

B. Seppen[1,2], S. Verkleij[1], J. Wiegel[1,2], M. Ter Wee[3], M. Nurmohamed[1,2], W. H. Bos[1,2]. *[1]Amsterdam Rheumatology and Immunology Center | Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam UMC, locatie VUmc, Rheumatology, Amsterdam, Netherlands; [3]Amsterdam UMC, locatie VUmc, Biostatistics and Data Science, Amsterdam, Netherlands*

Background: Currently, patients with rheumatoid arthritis (RA) require frequent consultations to monitor their disease activity. However, since a majority of patients is in remission during routine follow up, it should be possible to reduce the number of consultations for them.[1] Patients that are meeting their treatment goal, based on the results of their electronic patient reported outcome measures (ePROMs), could be eligible to skip their visit. Research revealed that patients who indicate to be in remission or have a low disease activity (remission/LDA) on their ePROMs, such as the routine assessment of patient index data (RAPID3), also have a low disease activity score 28 (DAS28).[2] However, in clinical practice the decision to intensify treatment is more complex than not meeting a DAS28 threshold. Therefore, ePROM-results should be compared with treatment intensifications to assess the safety of screening with ePROMs.

Objectives: To assess the probability that patients with low scores on disease activity assessment with ePROMs do not need medication intensification.

Methods: This retrospective study compared results of three ePROMs (RAPID3, patient acceptable symptom state (PASS) and asking patients if they experienced a flare (flare question)) answered during routine care with (disease modifying anti-rheumatic drug) DMARD or steroid intensifications collected from anonymised electronic medical records at Reade. We calculated the positive predictive value (PPV) for not receiving a DMARD or steroid intensifications within two weeks and three months for 1) being in remission/LDA according to the RAPID3, 2) being in PASS and 3) not reporting a flare. The secondary aim of the study was to assess which combination of ePROM-results led to the best PPV for DMARD or steroid intensifications.

Results: A total of 321 records were included that regarded 302 unique patients (77% female, mean age (SD) was 60 (12) years). The PPV for not receiving a DMARD or steroid intensification within 2 weeks of the RAPID3, PASS and flare-question were 99%, 95% and 83%, respectively, and after 3 months 95%, 88%, 85%, for all test characteristics see Table 1. The combination of a RAPID3 < 2 and a negative flare-question resulted in a PPV of 100%; this combination was present in 29% (93/321) of the total study population.

Table 1. Predictive values of ePROMs for DMARD or steroid intensifications

ePROMs	PPV	Specificity	NPV	Sensitivity
Direct (<2 weeks)				
RAPID3	99	99	28	37
PASS	95	85	42	71
FLARE	93	74	52	83
RAPID3 + Flare	100	100	36	29
Follow up (<3 months)				
RAPID3	95	95	39	40
PASS	88	75	54	74
FLARE	85	62	63	85
RAPID3 + Flare	96	96	39	39

All numbers are percentages. ePROMs: electronic Patient Reported Outcome Measures, NPV: Negative Predictive Value, PPV: Positive Predictive Value, RAPID3: Routine Assessment of Patient Index Data-3, PASS: Patient Acceptable Symptom State.

Conclusion: Our results show that the RAPID3, PASS and flare have a high diagnostic accuracy to identify individuals that will not receive a DMARD or steroid intensification up to 3 months after their initial consultation and are therefore possibly eligible to skip their outpatient clinic visit. The combination of the RAPID3 and the PASS yielded the best combination of diagnostic accuracy and highest number of eligible patients.

What's new in scleroderma and myositis?

POS0382 RNA-SEQUENCING ANALYSIS TO IDENTIFY POTENTIAL FUNCTIONAL PATHWAYS INVOLVED IN SYSTEMIC SCLEROSIS PATHOGENESIS: OUR PRELIMINARY EXPERIENCE

A. Spinella[1], D. Lo Tartaro[2], L. Gibellini[2], M. Starnoni[3], M. de Pinto[1], G. Amati[1], G. De Santis[2,3], A. Cossarizza[2], C. Salvarani[1,4], D. Giuggioli[1,2]. *[1]University Hospital of Modena and Reggio Emilia, Modena, Italy., Scleroderma Unit, Rheumatology Unit, Modena, Italy; [2]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy; [3]University of Modena and Reggio Emilia, Division of Plastic Surgery, Modena, Italy; [4]University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy*

Background: Systemic Sclerosis (SSc) is a connective tissue disease, characterized by endothelial dysfunction, autoimmunity abnormalities and fibrosis of the skin and internal organs. The exact pathogenetic mechanisms that propagate SSc vasculopathy are still not completely understood. A complex network of interactions between endothelial cells, pericytes, myofibroblasts, and the extracellular matrix (ECM) has been implicated but it is currently unclear what drives the activation of fibroblasts and the increased ECM deposition responsible for the fibrotic changes well known in SSc.

Objectives: Using RNA sequencing (RNA-seq), our goal was to identify potential functional pathways possibly involved in SSc pathogenesis and markers that could potentially be used to better understand endothelial dysfunction and fibrosis mechanisms in SSc patients.

Methods: RNA-seq analysis was performed on RNA obtained from biopsies from 3 SSc patients and 3 age- and sex-matched healthy controls (HC) enrolled in our University Hospital between January 2019 and December 2020. The samples were transferred to a labelled cryovial and immediately stored in liquid nitrogen. RNA extraction followed standard methodologies. RNA from each sample was used to generate sequencing libraries that were sequenced according to proper transcriptomic analyses. To identify potential functional pathways that could be involved in SSc pathogenesis, we performed gene set enrichment analysis (GSEA) of differentially expressed genes (DEGs). GSEA was applied on the entire list of genes that compose the RNA-seq expression matrix. Genes were ranked based on their fold change calculated between groups of each pairwise comparison and analyzed by GSEA in pre-ranked mode. We adopted the

"classic" enrichment statistic, the recommended approach for RNA-sequencing data.

Results: According to GSEA analysis of DEGs applied to SSc and HC, we identified 305 DEGs that were upregulated or downregulated at least 2-fold. In particular, 175 genes were upregulated and 130 genes were downregulated. A marked upregulation of genes involved in Wnt signaling, including Wnt family members, was present in HC if compared with SSc. The upregulation of collagen type VI, extracellular matrix protein 2, vascular endothelial growth factor D, among others, was also observed. Conversely, a marked downregulation of late cornified envelope and of genes encoding for keratins, was present in HC versus SSc samples. GSEA revealed that HC were characterized, among others, by gene signatures related to stromal stem cells proliferation, cytokine-cytokine receptor interaction, macrophage-enriched metabolic network, whereas SSc tissues were enriched in signatures related to keratinization, cornification, retinoblastoma (RB) 1 and tumour suppressor (TP) 53 signaling. Figure 1 displays GSEA in HC *vs* SSc tissues.

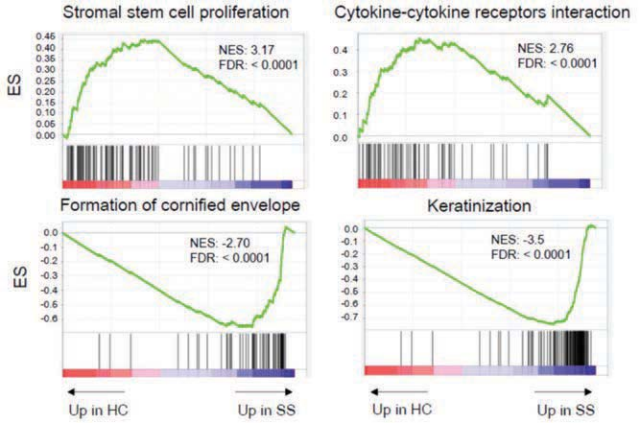

Figure 1. GSEA in HC vs SSc tissues.Enrichment of gene signature was analyzed in transcriptomic data from HC and SSc samples.ES=enrichment score. NES=normalized enrichment score. FDR=false discovery rate.

Conclusion: According to our preliminary data, RNA-seq, differential gene expression and pathway analysis revealed that SSc patients show a discrete pattern of gene expression associated with keratinization, extracellular matrix generation, and negative regulation of angiogenesis and stromal stem cells proliferation. Further analysis on larger numbers of patients are needed; however, our results provide an interesting framework for the development of biomarkers representing vascular injury and fibrotic changes in SSc in order to explore potential future therapeutic targets.

Background: LeRoy's classification defines two main subsets of Systemic Sclerosis (SSc) based on the extent of skin fibrosis: limited cutaneous SSc (lcSSc) with skin thickening sparing the trunk and distal to the elbow and knees, and diffuse cutaneous SSc (dcSSc) with proximal and distal skin thickening. These two subsets notably differ in terms of survival and frequency of visceral involvement, dcSSc being less prevalent but having a higher mortality rate with more frequent visceral manifestations. SSc sine scleroderma (ssSSc) is a third subset initially described by Rodnan *et al.* and characterized by the absence of skin fibrosis but with the existence of SSc-associated visceral manifestations.

Objectives: This study aimed to characterise the main clinical features of patients with ssSSc in comparison with the lcSSc and dcSSc subsets within the international EUSTAR database.

Methods: All patients from the EUSTAR database fulfilling the ACR2013 or 1980 classification criteria for SSc assessed by the modified Rodnan Skin score (mRSS) at inclusion and with at least one follow-up visit were eligible. Sine scleroderma (ssSSc) was defined by the absence of skin thickening (mRSS=0 and no sclerodactyly) at all available visits. The clinical characteristics of these ssSSc patients were compared to those of patients with lcSSc and dcSSc with similar disease duration at last follow-up visit. Descriptive statistics were applied.

Results: Among the 4263 patients fulfilling the inclusion criteria, 376 (8.8%) were classified as ssSSc. Among them, 40.3% had puffy fingers, 39.4% had interstitial lung disease (ILD), 1.6% had a history of scleroderma renal crisis at inclusion visit. At last available visit, in comparison with 708 lcSSc and 708 dcSSc with the same disease duration, ssSSc patients had a lower prevalence of previous or current digital ulcers (28.2% versus 53.1% in lcSSc (P<0.001) and 68.3% in dcSSc (P<0.001)), of joint synovitis (16.9% versus 24.3% in lcSSc (P<0.01) and 30.8% in dcSSc (P<0.0001)), and of elevated sPAP on echocardiogram (15.2% versus 23.9% in lcSSc (P<0.01) and 28.7% in dcSSc (P<0.0001)). Despite similar disease duration, disease activity at follow up visit (assessed by the EScSG disease activity index 2001 and 2016) was lower in ssSSc in comparison with lcSSc and dcSSc. By contrast, the prevalence of ILD was almost similar in ssSSc and lcSSc (49.8% and 57.1% (P=0.03)) but significantly higher in dcSSc (75.0%, P<0.0001). Based on forced vital capacity, ILD was less severe in ssSSc in comparison with the other subsets (mean FVC 100% (SD=22)(%pred) versus 93% (SD=21) in lcSSc and 82% (SD=23) in dcSSc (P<0.0001 for both)). Anti-centromere antibodies were most represented in ssSSc (61.7% versus 41.9% in lcSSc (P<0.0001) and 16.3% in dcSSc (P<0.0001), whereas the opposite distribution was observed for anti-Scl70 antibodies. Survival was significantly higher in ssSSc patients compared to lcSSc (P<0.05) and dcSSc (P<0.0001).

Conclusion: This study highlights that ssSSc patients account for almost 10% of SSc patients with milder disease severity compared to both lcSSc and dcSSc.

POS0384 ULTRA SHORT ECHO TIME MRI (UTE) SEQUENCE IN THE ASSESSMENT OF INTERSTITIAL DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS: CORRELATION WITH DISEASE EXTENSION AT CT AND WITH PULMONARY LUNG FUNCTION TESTS.

M. Orlandi[1], N. Landini[2], C. Nardi[3], G. Morana[2], S. Colagrande[3], M. Matucci-Cerinic[1,4]. *[1]University of Florence, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; [2]Ca' Foncello General Hospital, Radiology, Treviso, Italy; [3]University of Florence, Radiology, Firenze, Italy; [4]RCCS San Raffaele Hospital, Immunology, Rheumatology, Allergology and Rare diseases, Firenze, Italy*

Background: Interstitial lung disease (ILD) is the major cause of death in Systemic sclerosis (SSc). Computed tomography (CT) is the gold standard imaging

technique to diagnose ILD and to assess ILD prognosis. ILD extent assessment at lung CT has shown to correlate with functional lung capacity: extensive lung disease (> 20%) correlate with significant lung capacity decline (forced vital capacity ((FVC) <70%) that is, in fact, associated with a higher mortality. Unfortunately, it is burdened by exposure to ionizing radiations that limits its use for the follow-up. For this reason, new MRI sequences were recently investigated, and Ultra Short Echo Time (UTE) emerged promising for ILD assessment.

Objectives: The aim of the study is to evaluate the reliability of an MRI-UTE sequence in the assessment of ILD extent in patients with SS in comparison with standard high-resolution CT images and to correlate the extension with pulmonary function tests (PFT).

Methods: Patients with SSc and ILD underwent a CT and UTE-MRI (1.5 T) acquisition on the same day. In the same week, they carried out PFT, with FVC and the diffusion capacity of carbon monoxide (DLCo) evaluation. Two thoracic radiologists assessed in consensus, on CT and UTE-MRI, the extent of ILD. Extensions were calculated as the mean percentage of lung involvement, evaluated at five levels, with an approximation of 5%. ILD extension were classified as limited (<20%) or extensive (> 20% or 20% with FVC <70%). The ANOVA test was adopted to compare the CT and MRI extensions of the ILD. Correlations of the extent of CT and UTE-MRI alterations with FVC and DLCo were calculated with Pearson's correlation coefficient *r*. Sensitivity, Specificity, Positive Predictive Value (PPV) and Negative Predictive Value (VPN) of UTE-MRI were also calculated for UTE-MRI in determining ILD extension.

Results: The mean ILD extension was 20.9% in CT and 17.9 % in UTE-MRI (p-value=0.64). The correlation of ILD extension in CT with FVC and DLCo were significant (r=-0.66 (p<0.0001) and r=-0.59 (p<0.0008), respectively). The correlation of ILD extension in UTE-MRI with FVC and DLCo were significant (-0.68 (p<0.0001) and -0.57 (p<0.002), respectively) too. The UTE-MRI assessments agreed with CT in identifying limited or extensive ILD in 25/29 patients (19 limited and 6 extended) and discordant in 4 (1 limited and 3 extended to CT). UTE-MRI sensitivity and specificity in identifying extended ILD were high (86.4% (65.1% -97.1%) and 85.7% (42.1% -99.6%), respectively). PPV and NPV were 95.0% (75.4% -99.2%) and 66.7% (40.7% -85.7%), respectively.

Conclusion: UTE-MRI sequence, compared to CT, has shown high correlation with PFR and comparable ability in identifying patients with extensive ILD. Therefore, UTE-MRI seems new promising imaging sequence for the evaluation of ILD extension in SSc patients.

POS0385 "EFFECTIVE LUNG AGE" IN SUBJECTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD) IN THE SENSCIS TRIAL

T. Maher[1], A. Bourdin[2], E. Volkmann[3], S. Vettori[4], J. H. W. Distler[5], M. Alves[6], C. Stock[7], O. Distler[8]on behalf of The SENSCIS trial investigators. *[1]University of Southern California, Keck School of Medicine, Los Angeles, CA, United States of America; [2]University of Montpellier, INSERM U1046, CNRS UMR 9214 and University of Montpellier, CHU Montpellier, PhyMedExp and Department of Respiratory Diseases, Montpellier, France; [3]University of California, David Geffen School of Medicine, Department of Medicine, Division of Rheumatology, Los Angeles, CA, United States of America; [4]Ospedale Monaldi, UOC di Fisiopatologia e Riabilitazione Respiratoria, Napoli, Italy; [5]Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Universitätsklinikum Erlangen, Department of Internal Medicine 3-Rheumatology and Immunology, Erlangen, Germany; [6]Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim, Germany; [7]Boehringer Ingelheim Pharma GmbH & Co. KG, Global Biostatistics and Data Sciences, Ingelheim am Rhein, Germany; [8]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*

Background: FVC declines gradually with aging. The loss of lung function in patients with progressive SSc-ILD mimics an accelerated ageing process.

Objectives: Using reference equations, we estimated the "effective lung age" of subjects in the SENSCIS trial (*i.e.* the age of healthy individuals with the same FVC) and compared these estimates to their real age.

Methods: The SENSCIS trial enrolled subjects with SSc-ILD with first non-Raynaud symptom within the prior ≤7 years, extent of fibrotic ILD on HRCT ≥10%, FVC ≥40% predicted, DLco 30–89% predicted. Evidence of recent decline in FVC was not an inclusion criterion. Subjects were randomised to receive nintedanib or placebo. Using reference equations published by the European Respiratory Society Global Lung Function Initiative, based on FVC data from over 70,000 healthy individuals aged 3–95 years from 26 countries, [Quanjer et al. Eur Respir J 2012;40:1324–1343], we estimated the effective lung age of subjects at baseline and at week 52 based on their FVC, sex, ethnicity and height, and compared these effective lung ages with the subjects' real ages. Three subjects aged <25 years were excluded. The upper limit of effective lung age was considered to be 95 years.

Results: Mean time since onset of first non-Raynaud symptom was 3.5 years in both the nintedanib and placebo groups. At baseline, mean (SD) effective lung age was 83.1 (14.4) years in the nintedanib group (n=287) and 82.9 (14.8) years in the placebo group (n=286). In these groups, respectively, the mean (SD) difference between effective lung age and real age was 28.4 (17.7) and 29.3 (18.5) years and the difference was >20 years in 71.4% and 72.4% of subjects. In the nintedanib and placebo groups, respectively, median (Q1, Q3) effective lung age was 88.4 (74.6, 95.0) and 88.5 (74.7, 95.0) years at baseline and 91.0 (75.2, 95.0) and 95.0 (75.9, 95.0) years at week 52.

Conclusion: At entry into the SENSCIS trial, subjects with SSc-ILD had an effective lung age that was much higher than their real age. Over 52 weeks, the increase in effective lung age was numerically lower in subjects treated with nintedanib than placebo. These data show that marked loss of lung function that can occur in the few years following onset of SSc-ILD and support a benefit of nintedanib in slowing the progression of SSc-ILD.

POS0386 A NOVEL ECHOCARDIOGRAPHY METHOD FOR THE DETECTION OF SUBCLINICAL MYOCARDIAL FIBROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY.

A. Giollo[1,2], G. Cioffi[2,3], F. Ognibeni[2], F. Aldegheri[2], R. Bixio[2], I. Gavioli[2], D. Rotta[2], E. Bertoldo[2], G. Orsolini[2], D. Gatti[2], M. Rossini[2], O. Viapiana[2]. *[1]University of Padova, Division of Rheumatology, Padua, Italy; [2]University of Verona, Rheumatology Section, Department of Medicine, Verona, Italy; [3]San Pancrazio Hospital, Division of Cardiac Rehabilitation, Arco di Trento, Italy*

Background: Scar imaging echocardiography with ultrasound multi-pulse scheme (eSCAR) is a novel technique allowing detection of myocardial scars. eSCAR has never been explored in patients with systemic sclerosis (SSc).

Objectives: The aim of our study was to examine whether eSCAR may detect subclinical myocardial fibrosis in SSc.
Methods: In this cross-sectional study conducted between 11/2020 and 02/2021, consecutive SSc patients from the University of Verona underwent cardiovascular disease (CVD) screening procedures including standard transthoracic echocardiography (TTE) and myocardial scars detection through the eSCAR technique. We excluded patients with prior history of structural heart disease and pulmonary hypertension. To validate eSCAR findings, we assessed myocardial function through global longitudinal strain (GLS) analysis by speckle tracking echocardiography (STE). We also conducted a case-control study comparing eSCAR findings in randomly selected SSc patients and non-SSc controls matched 1:1 for age, sex and number of CVD risk factors. The primary outcome was the proportion of patients with myocardial scars. Principal component analysis (PCA) was used to determine main eSCAR patterns. Multivariable linear regression analysis was used to minimise confounding.
Results: Scar imaging echocardiography revealed that 42/92 (44%) SSc patients had myocardial scars involving a median [25th-75th percentile] of 4 [1-7] segments. PCA identified that myocardial scars localised mostly at the inferior and septal segments (inferoseptal pattern; Figure 1). STE validation confirmed that GLS was significantly reduced in SSc patients with inferoseptal scars (Table 1). Otherwise, all standard echocardiography measures were normal in both groups. In multivariable regression analysis, prior digital ulcerations (B=0.41, 95% CI 0.008 to 0.809, p=0.045) and body mass index (B=-0.06, 95% CI -0.113 to -0.015, p=0.012) were both significantly and independently associated with inferoseptal myocardial scars. Myocardial scars were found in 38% of SSc patients and no matched controls (p<0.0001).

Table 1. Comparison of speckle tracking echocardiography (longitudinal myocardial strain) in eSCAR-positive (inferoseptal pattern) and eSCAR-negative (no inferoseptal pattern) patients.

Speckle tracking echocardiography	eSCAR-positive (n= 8)	eSCAR-negative (n=31)	P-value
GLS global (%)	- 20.24 (2.39)	- 20.42 (3.65)	0.895
GLS 4-chambers (%)	- 20.66 (1.91)	- 20.09 (4.12)	0.720
GLS 2-chambers (%)	- 23.02 (5.23)	- 21.97 (3.89)	0.924
GLS 3-chambers (%)	- 17.11 (2.60)	- 19.31 (5.26)	0.015
GLS apical			
- anterior	- 19.60 (6.12)	- 17.72 (4.42)	0.857
- inferior	- 26.89 (7.79)	- 23.65 (5.46)	0.581
- lateral	- 18.91 (2.04)	- 18.13 (5.12)	0.508
- septal	- 22.68 (7.14)	- 21.76 (7.04)	0.844
GLS basal			
- anterior	- 23.35 (3.82)	- 22.75 (8.36)	0.752
- anteroseptal	- 14.09 (4.74)	- 18.66 (7.46)	0.109
- inferior	- 22.69 (8.49)	- 22.78 (6.94)	0.818
- lateral	- 19.99 (7.68)	- 22.55 (7.01)	0.218
- septal	- 14.26 (4.63)	- 18.07 (8.79)	0.081
GLS mid			
- inferior	- 23.09 (6.12)	- 22.58 (5.07)	0.917
- septal	- 14.80 (5.69)	- 17.50 (7.53)	0.056
- anterior	- 20.54 (3.28)	- 19.73 (6.52	0.026
- anteroseptal	- 14.70 (4.96)	- 18.13 (5.20)	0.010
- lateral	- 18.64 (5.79)	- 20.09 (5.73)	0.270

Data are reported as mean (S.D.). GLS, global longitudinal strain.

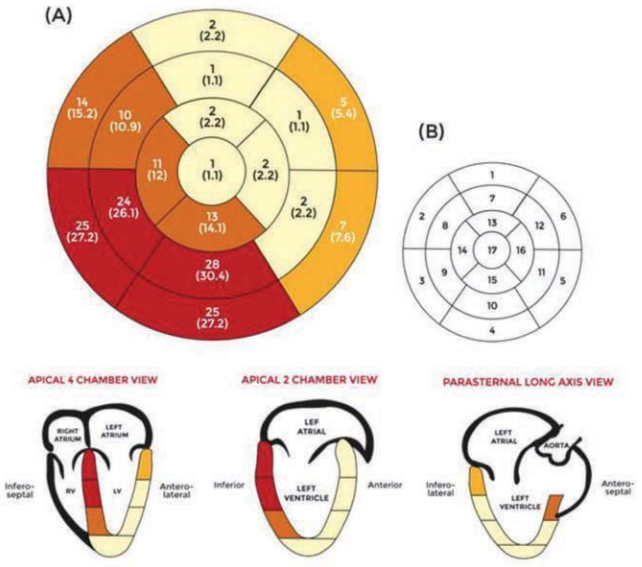

Figure 1.

Conclusion: This simple ultrasound technique allows detection of myocardial dysfunction associated with scars in SSc patients, or its absence in matched controls. Patients with prior digital ulcerations and low body weight have the strongest association with inferoseptal myocardial scars. eSCAR may help detect subclinical myocardial fibrosis in SSc.

Background: Pulmonary arterial hypertension (PAH) is a major clinical challenge in systemic sclerosis (SSc), and is associated with high mortality. Risk stratification provides an estimate for individual patient risk of 1-year mortality. The aim is to detect patients with the worst prognosis to optimize management strategies. Nine risk stratification approaches have been proposed in PAH, but have not been validated in SSc-PAH.
Objectives: To assess four risk stratification models and their performance to predict 1- and 3- year mortality and to identify the best risk assessment approach for SSc-PAH.
Methods: We included all patients with SSc diagnosed with PAH by right heart catheterization (RHC) from the European scleroderma trial and research (EUSTAR) database from 2001 to February 2021. PAH was defined as mean pulmonary arterial pressure (mPAP) ≥25 mmHg, pulmonary artery wedge pressure (PAWP) ≤15mmHg, and pulmonary vascular resistance (PVR) >3 Wood units (WU) in the absence of significant interstitial lung disease. We applied four different approaches for risk stratification at time of PAH diagnosis. Risk parameters included New York Heart Association (NYHA) class, 6-minute walk distance (6MWD), NT-proBNP or BNP, and echocardiographic and hemodynamic parameters with cut-off values based on the 2015 ESC/ERS Guidelines. Model 1 and 2 stratified patients into low, intermediate and high-risk categories; while Model 3 and 4 stratified the patients into four categories (low, intermediate-low, intermediate-high and high).
Model 1: Patients with ≥ 1 high-risk parameter were considered at high risk; with ≥ 1 intermediate-risk parameter at intermediate risk, otherwise at low risk[1]
Model 2: Each variable was graded from 1 to 3 representing low to high risk. The mean of available risk parameters was rounded to the nearest integer to define the risk category[2]
Model 3: Equals Model 2, but the intermediate risk group was divided into intermediate-low and intermediate-high based on the mean score[3]
Model 4: Stratifies patients into four risk categories based on the proportion of low-risk parameters[3]
We performed analysis of 1- and 3- year mortality in patients with a minimum follow-up of 1 and 3 years, respectively.

Table 1. Demographic and clinical characteristics of patients segregated by risk stratification (Model 3)

	N	All patients (n=273)	Low-risk (n=78)	Intermediate-low (n=118)	Intermediate-high (n=56)	High-risk (n=21)
Age, years (SD)	273	65 (10.7)	65 (10.3)	65 (10.7)	65 (10.8)	67 (12.8)
Female sex, n (%)	273	230 (84)	64 (82)	98 (83)	48 (86)	20 (95)
lcSSc, n (%)	263	221 (84)	60 (80)	99 (86)	47 (90)	15 (71)
NYHA 3 or 4, n (%)	261	155 (59)	12 (16)	75 (68)	49 (89)	19 (95)
NT-proBNP, pg/ml (IQR)	111	1941 (230-1485)	215 (103-377)	763 (325-1418)	1926 (1051-5681)	3314 (1129-6553)
6MWD, m (SD)	196	321 (124.1)	404 (119.7)	314 (99.9)	262 (128.6)	215 (96.0)
RHC:						
- mPAP, mmHg (SD)	273	40 (11.0)	35 (8.8)	41 (11.5)	41 (10.8)	45 (11.6)
- PAWP, mmHg (SD)	273	9 (3.2)	9 (3.0)	9 (3.4)	9 (3.2)	8 (3.1)
- Cardiac index, l/min/m^2 (SD)	260	2.8 (0.8)	3.2 (0.7)	2.7 (0.8)	2.6 (1.0)	2.0 (0.5)
- PVR, WU (SD)	273	7.4 (4.1)	5.3 (2.8)	7.9 (4.0)	7.9 (4.2)	11.3 (4.7)

Results: Of 911 patients who conducted RHC, 273 (30%) were diagnosed with SSc-PAH according to the inclusion criteria (Table 1). Median follow-up time was 2.8 years (IQR 1.3-5.3). The models varied in their ability to predict mortality (Figure 1). Model 1 and 4 either over- or underestimated mortality. Model 2 stratified patients according to the expected 1-year mortality of <5%, 5-10% and >10% suggested by the ESC/ERS Guidelines. Model 3, which divided the intermediate risk group in two different risk groups, segregated the risk of mortality further within this group.

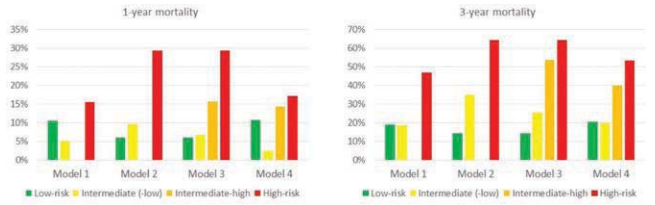

Figure 1. 1- and 3-year mortality according to risk category in the four different models

Conclusion: Model 3 provides signals for a better risk stratification of patients with newly diagnosed SSc-PAH, with progressively increasing mortality across the categories. This may provide guidance for optimized management in clinical practice.

Background: High resolution computed tomography (HRCT) is the gold standard for the diagnosis of systemic sclerosis associated interstitial lung disease (SSc-ILD). Although there is agreement in performing HRCT as a screening test at time of SSc diagnosis, some physicians do not regularly perform baseline HRCTs. In addition, it is unclear according to which criteria HRCTs should be repeated during the follow-up of baseline ILD negative patients.

Objectives: To develop a risk score for the presence of SSc-ILD (the ILD-RISC), to guide physicians in ordering both baseline and follow-up HRCTs.

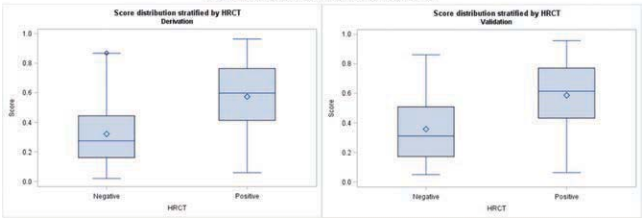
Methods: The steering board included six SSc-ILD experts from referral centers, two fellows and a patient research partner. Items for regression analysis were selected according to face validity, feasibility, scientific background, and personal experience using the nominal group technique (NGT). The prediction model for the presence of ILD was developed from baseline visits of SSc patients from the six centers using multivariable logistic regression with backward selection. Patients were randomly divided into a derivation and validation cohort consisting of 66% and 34% of patients respectively. Patients with missing data in the selected covariates and in the ILD status (outcome) were excluded. After identifying a cut-off favoring sensitivity >85% from the ROC curve analysis, the derived ILD-RISC score was applied first in the validation cohort and then longitudinally in a cohort of SSc patients with negative baseline HRCT.

Results: The steering board selected 13 variables deemed important in the identification of SSc-ILD: sex, age, disease duration from first non-Raynaud's phenomenon symptom, skin subset (diffuse/limited), presence of esophageal symptoms, digital ulcers (DU) ever, arthritis ever, smoking ever, increased inflammatory markers, NYHA functional class, SSc autoantibody status (SSc_Atb), FVC% and DLCO%. Among 780/3240 patients fulfilling the inclusion criteria, 533 (43% ILD) and 247 (48% ILD) respectively constituted the derivation and the validation cohort. In the derivation cohort, a model including FVC%, DLCO%, DU ever, age and SSc_Atb (Table 1A) showed an OR of 133.9 (95% CI 53.4-335.9) and an AUC of 79.1% (95% CI 75.3-83.0%) for the presence of ILD on HRCT (Figure 1). An ILD-RISC score ≥0.3 showed sensitivity of 85.6% and specificity of 53.6%, NPV of 83.2% and PPV of 58.2%, which were replicated in the validation cohort (Table 1B). Among 819 patients with negative baseline HRCT, 170 (20.8%) developed ILD during a 3.8±3.0 years follow up (1988 visits). Longitudinally, the ILD-RISC score showed comparable sensitivity and specificity (Table 1B).

Table 1.

A)ILD-RISC MODEL VARIABLES	OR	95% CI	p value
Digital ulcers, ever	2.058	1.347-3.145	<0.001
Age	1.026	1.010-1.042	0.001
SSc_ATB			
Anti-centromere	0.334	0.198-0.563	<0.001
Anti-topoisomerase I	2.379	1.326-4.267	0.004
Anti-RNA-polymerase III	1.407	0.636-3.113	0.399
Anti-Pm/Scl	2.556	0.916-7.135	0.073
None of the above	Comparator		
FVC%	0.990	0.979-1.002	0.091
DLCO%	0.971	0.960-0.982	<0.001
B)ILD-RISC SCORE PERFORMANCE	**Derivation cohort**	**Validation cohort**	**Longitudinal cohort**
All Patients/ILD patients	533/229	247/119	819/170
AUC %, 95% CI	79.1 (75.3 – 83.0)	76.4 (71.0 – 82.7)	72.6 (68.9 – 76.2)
Sensitivity %, 95% CI	85.6 (80.4 – 89.9)	85.7 (78.1 – 91.5)	80.4 (73.9 – 86.0)
Specificity %, 95% CI	53.6 (47.8 – 59.3)	49.2 (40.3 – 58.2)	50.5 (48.2 – 52.9)
Negative Predictive Value %, 95% CI	83.2 (77.2 – 88.1)	78.8 (68.2 – 87.1)	96.3 (94.9 – 97.4)
Positive Predictive Value %, 95% CI	58.2 (52.7 – 63.5)	61.1 (53.2 – 68.5)	13.9 (11.8 – 16.1)

Figure 1. Distribution of the ILD-RISC score between patients with and without ILD on HRCT, in the derivation and validation cohorts.



Conclusion: We developed and validated the ILD-RISC score to predict the presence of ILD at time of diagnosis and evaluated its performance during follow-up. The ILD-RISC may be useful in routine practice when resources for HRCTs might be limited. In particular, it may also help to decide when to order HRCTs at follow up, thus limiting unnecessary HRCTs and reducing the burden for patients and institutions.

POS0389 MUSCULAR EXPRESSION OF CD163 AND MAJOR HISTOCOMPATIBILITY COMPLEX CLASS I AS DIAGNOSTIC MARKERS IN IDIOPATHIC INFLAMMATORY MYOPATHIES

B. Ghang[1], B. Yoo[2], S. J. Nam[3]. *[1]Jeju National Univ. Hospital, Rheumatology, Jeju-si, Korea, Rep. of (South Korea); [2]Asan Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea); [3]Asan Medical Center, Pathology, Seoul, Korea, Rep. of (South Korea)*

Background: Various inflammatory markers have been suggested for detecting idiopathic inflammatory myopathies (IIMs); however, their diagnostic utility remains inconclusive.

Objectives: Muscle tissues from patients diagnosed with IIMs from January 2001 to March 2017 in a tertiary hospital were investigated. Muscular expression of CD3, CD4, CD8, CD20, CD68, CD163, MX1, MHC class I, MHC class II, and HLA-DR in muscle biopsy specimens from patients with IIMs and controls were evaluated using immunohistochemical staining. Classification and regression tree analyses were used to classify patients with IIMs who met the 2017 European League Against Rheumatism/American College of Rheumatology classification criteria for adult and juvenile idiopathic inflammatory myopathies (2017 EULAR/ACR criteria for IIMs) using various staining results as predictor variables.

Methods: Muscle tissues from patients diagnosed with IIMs from January 2001 to March 2017 in a tertiary hospital were investigated. Muscular expression of CD3, CD4, CD8, CD20, CD68, CD163, MX1, MHC class I, MHC class II, and HLA-DR in muscle biopsy specimens from patients with IIMs and controls were evaluated using immunohistochemical staining. Classification and regression tree analyses were used to classify patients with IIMs who met the 2017 European League Against Rheumatism/American College of Rheumatology classification criteria for adult and juvenile idiopathic inflammatory myopathies (2017 EULAR/ACR criteria for IIMs) using various staining results as predictor variables.

Results: Among the total 146 patients diagnosed with IIMs by expert neurologist or rheumatologist, 129 patients with IIMs met the 2017 EULAR/ACR criteria for IIMs. Histopathologic features consistent with IIMs using HE staining was observed in 104 of 129 (80.6%) patients who met the 2017 EULAR/ACR criteria for IIMs (dermatomyositis, n = 46/66, 69.7%; polymyositis n = 58/63, 92.1%; sensitivity 80.6%, specificity 100.0%). Muscular expression of CD163 (99.2% vs. 20.8%, p < 0.001) and MHC class I (87.6% vs. 23.1%, p < 0.001) were significantly higher in patients with IIMs who met the 2017 EULAR/ACR criteria for IIMs than in controls. Combined CD163 and MHC class I expression provided the most significant stratification for the control group (sensitivity 96.1%, specificity 94.5%). This combination was able to classify 16 of 17 (94.1%) patients who were diagnosed with IIMs by an expert physician but did not meet the 2017 EUALR/ACR criteria for IIMs.

Conclusion: Combined CD163 and MHC class I muscular expression may be useful in diagnosing IIMs.

Table 1. Sensitivity, specificity, and predictive values of various inflammatory marker expressions and their optimal combinations for the diagnosis of idiopathic inflammatory myopathies.

	Sensitivity	Specificity	PPV	NPV	Patients who were diagnosed by an expert physician but did not meet the 2017 EULAR/ACR classification criteria for IIMs are classified by each combination
Muscle biopsy features consistent with IIMs on H/E staining	80.6%	100.0%	100.0%	74.5%	7/17 (41.2%)
CD3 expression	91.5%	51.4%	77.6%	76.6%	7/17 (41.2%)
CD163 expression	99.2%	79.2%	89.5%	98.3%	16/17 (94.1%)
MHC class I on myofibers	87.6%	76.9%	88.3%	75.8%	12/17 (70.6%)
HLA-DR on myofibers	69.8%	81.5%	88.2%	57.6%	8/17 (47.1%)
MHC class II on myofibers	13.2%	72.3%	45.6%	29.6%	6/17 (35.3%)
Combination of CD163 pattern and MHC class I on myofibers	96.1%	94.5%	96.9%	93.2%	16/17 (94.1%)
Combination of histopathologic examination using HE staining, CD163 pattern, and MHC class I on myofibers	97.7%	94.5%	95.8%	96.5%	16/17 (94.1%)

POS0390 GENES OF "DEFENSE RESPONSE TO VIRUS" IN PERIPHERAL BLOOD OF ANTI-MDA5 POSITIVE DERMATOMYOSITIS WERE UPREGULATED AS COMPARE WITH OTHER FORMS OF DERMATOMYOSITIS. ~SUPPRESSING RIG-I LIKE RECEPTOR SIGNALING OR TYPE 1/2 INTERFERON SIGNALING WERE THE KEYS FOR SURVIVAL.

Y. Koyama[1], Y. Sato[2], M. Sakamoto[1]. *[1]Japanese Red Cross Okayama Hospital, Rheumatology, Center for Autoimmune Diseses, Okayama, Japan; [2]DNA Chip Research Inc, N/A, Tokyo, Japan*

Background: Anti-melanoma differentiation-associated gene 5–positive dermatomyositis (MDA5 DM) is a rare but distinct subtype of idiopathic inflammatory myopathy (IIM) that is characterized by high mortality due to rapid progressive interstitial lung disease (ILD). MDA5 is a cytosolic protein and a family of retinoic-acid inducible gene-I (RIG-I) like receptor, which functions as a virus RNA sensor and induces the production of type I interferons (IFN-I) and proinflammatory cytokines. This leads to the death of infected cells and the activation of the antigen-specific antiviral immune response. Although the pathogenesis of MDA5 DM is largely unknown, a hypothesis that pathogenic involvement of anti-MDA5 antibodies has been proposed. Recently, similarities have been noted between multifaceted features of COVID-19 and MDA5 DM, which suggests shared underlying autoinflammatory mechanisms.
Objectives: To detect the critical actors in the pathogenesis of MDA5 DM by gene expression analysis of peripheral blood.
Methods: Total of 31 DM cases were investigated, including anti-aminoacyl-tRNA synthetase positive (ARS) DM (n=12), MDA5 DM (n=7, survivor=3) and others (n=12). Peripheral blood was drawn at baseline and 2 to 3 months after treatments. Total RNAs were then extracted with using PAXgene miRNA kit. After quantifying the expressions of transcripts by multiplex sequencing. And then, hierarchical clustering analysis, enrichment analysis using gene ontology (GO) terms, single sample gene set enrichment analysis (ssGSEA) and weighted gene co-expression network analysis (WGCNA) were performed.
Results: The hierarchical clustering with expression profiles of peripheral blood at baseline showed major 3 clusters. Interestingly, ARS DM cases were segregated into right side of the 3rd cluster while MDA5 DM cases fell into 1st and 2nd clusters. ARS and MDA5 DM were clearly discriminated if differentially expressed genes (DEGs) between these subtypes of DM were analyzed. By GO enrichment analysis, the terms, such as related to "defense response to virus" including "type1 interferon signaling pathway" were found in the DEGs. In the MDA5 DM cases, ssGSEA revealed that genes of "Fcγ receptor mediated phagocytosis pathway" or "complement and coagulation cascade" were significantly enriched and WGCNA showed that pathways of "T-cell antigen receptor signaling" or "lung fibrosis" were significantly upregulated. Next, we also investigated the DEGs of peripheral blood at 2-3 months after treatment between survival and fatal cases in MDA5 DM. We found that suppressing RIG-I like receptor and type 1 and type 2 interferon (IFN) signaling were the keys for survival.
Conclusion: MDA5 is a key sensor of several RNA viruses including coronavirus families and then activate antiviral gene transcription such as type 1 IFN genes, leading to establish an antiviral host response. As the pulmonary damage of COVID-19 is known to be difficult to distinguish from the ILD associated with anti-MDA5 DM, the life-threating ILD of MDA5 DM may be caused by the over-activation of RIG-I like receptor signaling via MDA5. The hypothesis is supported by our findings that the defining features of MDA5 DM are activation of "type 1 IFN pathways" and antigen-specific antiviral immune responses including "Fcγ receptor mediated phagocytosis pathway" or "T-cell antigen receptor signaling". As the levels of anti-MDA5 antibodies reported to be important prognostic parameter, it may be involved in pathogenesis of MDA5 DM. As we found that suppression of type 1 and type 2 IFN signaling were the keys for survival, it seems to be reasonable to use inhibitors of Janus Kinases (JAK) for treatment of MDA5 DM.

POS0391 TRENDS IN THE DIAGNOSIS OF MYOSITIS AND ASSOCIATION WITH THE CORONAVIRUS-19 PANDEMIC AND VACCINES: DATA FROM THE VENETO RARE DISEASE REGISTRY, 2014-2021

A. Giollo[1], M. Zen[1], M. Gatto[1], E. Zanatta[1], L. Iaccarino[1], A. Doria[1]. [1]*University of Padova, Division of Rheumatology, Padova, Italy*

Background: There are uncertainties regarding the occurrence of idiopathic inflammatory myopathies (IIM) after infection by Severe Acute Respiratory Syndrome (SARS)-CoronaVirus2(CoV2) or in recipients of Coronavirus disease-19 (Covid-19) vaccines.
Objectives: Herein, the main objective was to assess temporal trends of newly diagnosed IIM in the past eight years, including the effects of the Covid-19 pandemic.
Methods: We extracted data of IIM patients from the Veneto Rare Disease Registry from 01/01/2014 and 31/12/2021. This regional registry has to be considered comprehensive of all patients with IIM in a specific geographical area. Hence, we extracted the following information: age; sex; date of diagnosis; type of IIM including dermatomyositis (DM), polymyositis (PM), anti-synthetase syndrome (ASS), inclusion body myositis (IBM); place of residence. We restricted the analysis to IIM patients certified by expert rheumatologists belonging to the Regional Centre for Study and Treatment of Connective Tissue and other Rare Diseases at the Division of Rheumatology, University of Padua, Veneto, Italy. Finally, we compared new IIM cases before and after 04/01/2021 as the starting date for the vaccination campaign in Veneto. We reported descriptive statistics (median and interquartile range) and results of non-parametric tests to compare cases of IIM across the study period.
Results: Database extraction retrieved 192 people with IIM diagnosed during the study period (DM 85, PM 82, ASS 23, IBM 2; females 67.2%; median [25th-75th percentile] age at diagnosis 58.5 [49.6-68.5] years). There was a median of 2 [1-4] newly-diagnosed IIM monthly, with a non-significant increase in the post-pandemic two-year period 2020-2021 (Figure 1**A**). Numerically, 2020 had the most IIM diagnosis (N=30), mainly clustered in the second (N=12) and third (N=11) trimesters. Trends of new IIM diagnoses over one year course were similar during the study period, with visually identified higher IIM occurrence in February, April and September (Figure 1**B**). There was no difference in incident IIM cases in the 12 months before (N=31) and after (N=29) the initiation of the vaccination campaign (7 [5-9.8] vs 8 [3-12] new cases for each trimester; Mann-Whitney U test p=0.884). Finally, there was a significant trend for median age at diagnosis increasing by 6.46 years from 55.4 to 61.8 years between 2014 and 2021 (p=0.015, R^2=0.344; repeated measures ANOVA with post test for linear trend).

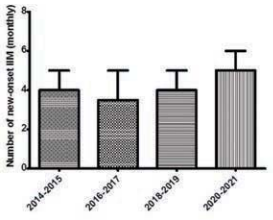

Figure 1A. New diagnoses of IIM certified at the Division of Rheumatology, University of Padua, for each biannual period between 2014 and 2021. Boxes represent median and error bars interquartile range. Kruskal-Wallis statistic (4.699, p=0.195) with Dunn's multiple comparison test (p>0.05 for all comparisons). IIM, idiopatic inflammatory myopathy.

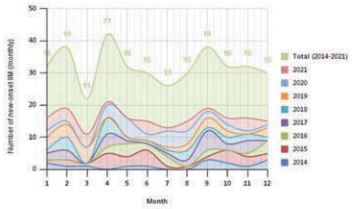

Figure 1B. Seasonal trends of idiopatic inflammatory myopathies. Data are presented as the number of new cases of myositis diagnosed each month (horizontal axis: from 1 [January] to 12 [December]) and total counts between 2014 and 2021.

Conclusion: We found no significant change in patterns of IIM diagnoses between 2014 and 2021 besides a slight numerical increase in the second and third trimesters of 2020. In addition, we noted no signals of increased IIM diagnoses after introducing Covid-19 vaccines. This data encourage further analyses of larger, multicentre datasets from other geographical areas to clarify whether there has been variation in specific myositis subtypes across new-onset IIM after the pandemic.

POS0392 ROLE OF SEMIQUANTITATIVE THIGH MAGNETIC RESONANCE IMAGING (TMRI) IN DETERMINING SKELETAL MUSCLE OUTCOMES AT BASELINE AND ON FOLLOW UP IN IDIOPATHIC INFLAMMATORY MYOPATHIES (IIMS)

M. Gorijavolu[1], D. Bairwa[1], C. Kavadichanda[1], A. Gopal[1], S. K. Dunga[1], M. M. Thabah[1], V. Negi[1]. [1]*Jawaharlal Institute of Postgraduate Medical Education and Research, Clinical Immunology, Pondicherry, India*

Background: Idiopathic Inflammatory Myopathies (IIMs) are characterized by muscle inflammation and associated muscle weakness. Semiquantitative scoring of thigh Magnetic Resonance Imaging (tMRI) has shown contradictory results in associating muscle inflammation, damage, and clinically assessed muscle weakness. Moreover, there are no studies assessing the role of tMRI detected muscle damage in determining long-term recovery of muscle strength and endurance.

Objectives: To correlate tMRI scores for muscle edema, fascial edema, muscle atrophy, and fatty infiltration with consecutively collected manual muscle testing 8 (MMT-8) scores and muscle enzymes. To determine the role of baseline tMRI changes in achieving maximum muscle power during follow-up.

Methods: This is a retrospective analysis of a single-center myositis cohort. IIM patients (n=55) who underwent baseline tMRI (STIR and T1 sequences) at the time of diagnosis were included. Baseline demographic, clinical, and serological parameters were noted. MRI T1 weighted sequence and STIR sequence axial and coronal images were assessed for intramuscular and fascial edema, atrophy and fatty replacement using a semiquantitative score and the percentage of muscle involvement for each parameter was calculated. MMT-8 values and muscle enzyme levels which remained unchanged at least for 6 months during follow-up were noted for 42 patients. MMT-8 ≥74 was taken as near normal muscle power based on the fact that 75% of IIM patients in remission for a long duration achieved MMT-8 of≥74 in our cohort. Spearman correlation was done between clinical parameters, muscle enzymes, and tMRI scores. Baseline parameters of patients who achieved and did not achieve MMT8≥74 were compared. Multiple linear regression was performed to assess the tMRI variables predicting a higher MMT-8 during follow-up

Results: The median age was 36 (27.25-44.75) years, median duration of disease at presentation was 4 months (2-10), median duration of follow up was 24 months (6.75-38.25). Dermatomyositis, Polymyositis and Antisynthetase syndrome comprised of 58.2%, 7.3% and 30.9% cases respectively. Baseline muscle enzymes CPK(r=0.531), AST(r=0.535) and ALT(r=0.442) showed significant positive correlation($p<0.01$) with muscle edema. Baseline MMT-8 showed significant negative correlation with muscle edema(r=-0.657) and fascial edema(r=-0.522) ($p<0.01$). Follow up MMT-8 showed significant negative correlation with muscle edema(r=-0.359), muscle atrophy (r=-0.319) and fatty infiltration(r=-0.308) ($p<0.05$) (Figure 1). Baseline MMT-8 and MRI fatty infiltration were significantly different between patients who achieved and did not achieve MMT-8 of ≥74 on follow-up (Table 1). Multiple regression analysis revealed adjusted R^2 value of 0.386. Baseline MMT-8(β=0.372) and muscle atrophy(β=-0.459) significantly predicted MMT-8 on follow-up

Table 1. Comparison between those who achieved near-normal muscle power versus others

	Follow up MMT-8<74 (n=8)	Follow up MMT-8 ≥74 (n=34)	P-value
Age (years) (median, IQR)	36.5(27-47.5)	36(28.75-44.25)	1.000
Duration of disease (months) (median, IQR)	6(4-10.5)	3.5(2.75-9.75)	0.459
Baseline muscle enzymes and MMT-8 (median, IQR)			
CPK (IU/L)	1758(116-6160)	680(57.5-3595)	0.410
LDH (IU/L)	496(240-823)	616.50(289.25-753)	0.672
AST (IU/L)	112(76-201.5)	69.5(40.5-226.25)	0.352
ALT (IU/L)	74.50(65.5-139.75)	69(36-142.25)	0.560
MMT-8 baseline (0-80)	49.5(47.25-56)	63(53.75-73.25)	**0.007**
MRI thigh scores (median, IQR)			
Muscle edema%	22.41(5.65-63.33)	10.37(0.00-28.70)	0.070
Fascial edema %	43.33(18.61-78.06)	33.89(11.49-50.56)	0.478
Muscle atrophy %	2.22(0.28-20.83)	0.00(0.00-2.50)	0.081
Fatty infiltration %	6.67(2.78-18.61)	0.56(0.00-3.61)	**0.010**

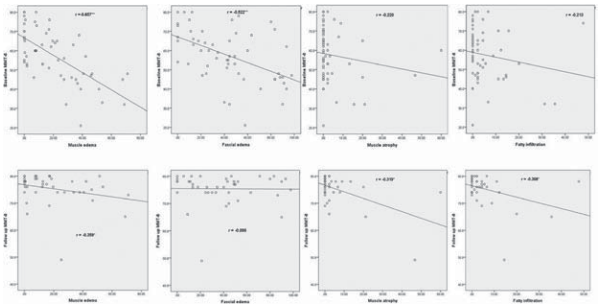

Figure 1. Correlation between baseline and Follow up MMT-8 with tMRI scores.

Conclusion: Low baseline MMT-8 and presence of muscle atrophy at baseline are predictors of poor outcome. Hence performing a baseline MRI will help in the prognosis.

POS0393 ASSOCIATION BETWEEN GENETICALLY PREDICTED EXPRESSION OF TPMT AND AZATHIOPRINE ADVERSE EVENTS IN PATIENTS WITH INFLAMMATORY CONDITIONS

A. Davis[1], A. Dickson[1], L. Daniel[1], P. Nepal[1], J. Zanussi[1], T. Miller-Fleming[1,2], P. Straub[1,3], W. Q. Wei[3], G. Liu[1], N. Cox[1,2], A. Hung[1], Q. Feng[1,2], C. M. Stein[1], C. P. Chung[1,2]. *[1]Vanderbilt University Medical Center, Department of Medicine, Nashville, United States of America; [2]Vanderbilt University School of Medicine, Vanderbilt Genetics Institute, Nashville, United States of America; [3]Vanderbilt University Medical Center, Department of Biomedical Informatics, Nashville, United States of America*

Background: Azathioprine is a widely used immunosuppressant for the treatment of inflammatory conditions such as systemic lupus erythematosus (SLE), systemic vasculitis, dermatomyositis, and inflammatory bowel disease. However, its use is often limited by myelotoxicity. Variants in the gene encoding thiopurine-S-methyltransferase (TPMT), an enzyme in the metabolic pathway of azathioprine, increase the risk for myelotoxicity[1]. We know little about the relationship between the genetically predicted expression of *TPMT* and side effects of azathioprine.
Objectives: To examine whether genetically predicted expression of *TPMT* in liver tissue is associated with azathioprine adverse effects.
Methods: We assembled a retrospective cohort of new users taking azathioprine for inflammatory conditions at a tertiary care center. We performed genotyping with Illumina Infinium Expanded Multi-Ethnic Genotyping Array plus custom content data, and we then used Michigan Imputation servers for genetic imputation and PrediXcan models trained with GTEx/Genotype-Tissue Expression Project version 8 data to impute *TPMT* expression in liver tissue. We prespecified nine groups of phecodes (comprised of ICD9 and ICD10 codes) corresponding to known adverse effects of azathioprine. We then tested the association between the predicted expression of *TPMT* and these adverse events; for outcomes significant in the Wilcoxon ranksum tests ($p<0.05$), each case was reviewed in clinical records for confirmation. Finally, we grouped the predicted expression of *TPMT* in liver tissue into tertiles and conducted logistic regressions to assess the associations between predicted expression and side effects. We conducted a sensitivity analysis restricted to patients with EHR-reported White race.
Results: The cohort included 1034 patients (Table 1). Phecodes for 3 side effects—leukopenia (n=29), skin cancer (n=13), and rash (n=52)—were identified as associated with predicted *TPMT* expression in liver tissue. Of these, cases of side effects attributed to azathioprine were validated by chart review: leukopenia (96.6%; n=28), skin cancer (92.3%; n=12), and rash (9.6%; n=5) and used for analysis. When assessed by tertile of predicted *TPMT* expression, patients in the highest tertile had lower odds of having leukopenia (OR=0.35, 95%CI: 0.12-0.98, p=0.045) and a trend towards higher odds for skin cancer, but the number of cases was small (OR=3.56, 95%CI: 0.73-17.27, p=0.115). Confirmed cases of rash attributed to azathioprine were too few for meaningful analysis. We found similar results when restricted to patients with reported White race.

Table 1. Characteristics of patients by *TPMT* expression

	Lowest Tertile	Middle Tertile	Highest Tertile
	N=345	N=345	N=344
Female sex, n (%)	228 (66.1)	244 (70.7)	238 (69.2)
EHR-reported White race, n (%)	306 (88.7)	293 (84.9)	290 (84.3)
Age, median [IQR]	42 [29-58]	43 [30-55]	46 [30-56]
Indication, n (%)			
Systemic lupus erythematosus	38 (11.0)	42 (12.2)	38 (11.0)
Inflammatory bowel disease	191 (55.3)	185 (53.6)	190 (55.2)
Other connective tissue disorder/autoimmune	92 (26.7)	96 (27.8)	100 (29.1)
Other	24 (7.0)	22 (6.4)	16 (4.7)
Verified leukopenia attributed to azathioprine, n (%)	14 (4.1)	9 (2.6)	5 (1.5)
Verified skin cancer attributed to azathioprine, n (%)	2 (0.6)	3 (0.9)	7 (2.0)
Verified rash attributed to azathioprine, n (%)	2 (0.6)	3 (0.9)	0 (0)

Conclusion: This analysis suggests that PrediXcan may be useful for examining the association between gene expression and side effects of medications. Moreover, this approach successfully identified leukopenia as a side effect associated with predicted *TPMT* expression.

POS0394 VALIDATION OF THE SLE SUSCEPTIBLE GENE LOCI IN THE MULTI-ETHNIC MALAYSIAN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) COHORT AND THEIR ASSOCIATIONS WITH CLINICAL MANIFESTATION

A. K. A. Abd Talib[1], S. S. Shaharir[2], N. A. Abdul Murad[1], N. Abdullah[1], E. A. Azizan[2], A. H. Abdul Gafor[2], R. Mustafar[2], M. S. Mohamed Said[2], S. Rajalingham[2], A. R. A. Jamal[1], Z. Abdul Latiff[3]. *[1]Universiti Kebangsaan Malaysia Medical Molecular Biology Institute, UMBI, Kuala Lumpur, Malaysia; [2]Universiti Kebangsaan Malaysia Medical Centre (UKMMC), Internal Medicine, Kuala Lumpur, Malaysia; [3]Universiti Kebangsaan Malaysia Medical Centre, Paediatric, Kuala Lumpur, Malaysia*

Background: Systemic Lupus erythematous (SLE) is an autoimmune disease with a wide spectrum of clinical manifestations. Asian patients including Malaysia tend to have more severe disease with renal involvement. The differences could be due to the interactions between genetic and environmental factors. Thus, identifying the genetic associations from diverse populations provides a better understanding on the genetic architecture of this heterogeneous disease.
Objectives: The primary objective of this study was to validate the previously described SLE susceptibility gene loci among other population in the multi-ethnic Malaysian SLE patients. The secondary objective was to determine the association between the gene loci with organ-specific involvement across different Malaysian ethnicities.
Methods: This was a case-control study involving the recruitment of SLE patients who attended the outpatient clinic in Universiti Kebangsaan Malaysia Medical Centre (UKMMC) from July 2019 until March 2021. Their medical records were reviewed to record the socio-demographic characteristics and SLE clinical manifestations. The SLE susceptible gene loci from the NHGRI-EBI Catalog of human genome-wide association studies were reviewed. The gene loci with *p* values less than $5x10^{-8}$ tested in a total sample size of at least 1000 individuals were included in the genotyping study in our SLE patients. Healthy controls with frequency matching by gender and ethnicity-matched were also recruited in this study. Their peripheral blood samples were genotyped using the Agena MassARRAY system (Agena Bioscience). The genotype frequencies of susceptibility loci in all patients and controls were tested for Hardy–Weinberg equilibrium. Associations between phenotype and genotype were performed by logistic regression analysis.
Results: A total of 202 SLE patients and 206 healthy controls were recruited. The SLE cohort consisted of predominant Malay ethnicity (n=126,62.6%) followed by Malaysian Chinese (n=69, 34.2%) and Indian (n=7, 3.5%). After quality control and Hardy–Weinberg equilibrium test, a total of 27 candidate SNPs were genotyped in our study population. Meta-analysis revealed 5 gene loci at SNP rs4544377 (*RNU6-546P*), rs4917014 (*IKZF1*), rs1878186 (*SLC12A1*), rs4728142 (*IRF5*) and rs5029937 (*TNFAIP3*) were associated with SLE in Malaysian population (all *p* value <0.05). In Malay group, rs4544377 (*RNU6-546P*) and rs4728142 (*IRF5*) were found to be associated with SLE with adjusted OR 0.42 (95% CI: 0.24-0.74), *p*=0.002 and OR 3.08 (95% CI: 1.71-5.54), p=0.000169, respectively. In Malaysian Chinese group, rs4917014 (*IKZF1*) was found to be associated with SLE with OR 0.45 (95% CI: 0.23-0.86), *p*=0.016. Among Malay patients, rs1878186 (*SLC12A1*) was found to be associated with skin rash with OR 2.01 (95% CI: 1.20-3.35), *p*=0.008 while rs4544377 (*RNU6-546P*) and rs4917014 (*IKZF1*) were associated with lupus nephritis, with OR 0.48 (95% CI: 0.24-0.96), *p*=0.039 and OR 3.29 (95% CI: 1.18-9.20), *p*=0.023. In Malaysian Chinese patients, rs4544377 (*RNU6-546P*) was associated with muco-cutaneous manifestation with OR 2.82 (95% CI: 1.15-6.92), *p*=0.023 while rs4728142 (*IRF5*) was associated with haematological manifestation with OR 5.61 (95% CI: 1.69-18.60), *p*=0.005.
Conclusion: Our exploratory study demonstrates the associations of the established SLE genes in Malaysian SLE populations. There are variations in the SLE susceptible gene loci with clinical manifestations of SLE between Malay and Malaysian Chinese populations.

POS0395

EXPLORING THE POTENTIAL OF GENOMIC RISK PREDICTION FOR CORONARY ARTERY DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Soomro[1], M. Stadler[1], S. Viatte[1], J. Bowes[1], A. Barton[1], S. Verstappen[2], A. Macgregor[3]. *[1]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Faculty of Biology, Medicine and Health, Greater Manchester, United Kingdom; [2]The University of Manchester, Centre for Epidemiology Versus Arthritis, Faculty of Biology, Medicine and Health, Greater Manchester, United Kingdom; [3]University of East Anglia, Rheumatology Department, Norfolk and Norwich University Hospitals NHS Trust, Norwich, UK, Norwich, United Kingdom*

Background: Patients with rheumatoid arthritis (RA) have a higher prevalence of coronary artery disease (CAD) than the general population which contributes to early mortality. However, CAD screeing tools developed in the general population are less effective for estimating CAD risk in RA patients. This is mainly due to the differing contribution from traditional risk factors and the contribution from disease-specific factors. Understanding of the genetic basis of CAD has improved over recent years and shows promise for improving risk prediction in the form of genetic risk scores (GRs), in particular with the development of the metaGRS approach, which combines multiple polygenic risk scores.
Objectives: This study hypothesise that the metaGRS approach can help us improve CAD risk prediction in patients with RA.
Methods: Patients were recruited from the Norfolk Arthritis Register (NOAR), a longitudinal observational study focused on the cause and outcome of inflammatory polyarthritis. Analysis was restricted to patients who satisfied the 2010 ACR criteria cumulatively over five years and had detailed clinical history at baseline and follow-up for ten years. We developed a prediction model based on traditional risk factors[1], and explored the inclusion of a metaGRS. We used a meta-analytic approach to calculate a new metaGRS for CAD, using the effect-sizes from three large-scale, genome-wide, and targeted GRs derived from 1,745,179 [2], 6,630,150 [3], and 40,079 SNPs [4]. We tested the metaGRS in combination with available data on traditional risk factors in a subset of patients with available genetic data. Cox proportional hazards models were used to derive risk equations for evaluation of 10-year risk of CAD. We applied multiple imputations with chained equations to replace missing values. Calibration and discrimination were determined in a separate cohort of 423 individuals.
Results: A total of 2123 patients were included in the analysis with 136 incident cases of self-reported CAD (defined as a composite outcome of myocardial infarction, angina, heart attack, arrhythmia, angioplasty, and coronary artery bypass grafting). The model using only traditional risk factors achieved an AUC of 0.81 (95% CI 0.80, 0.82), with a calibration slope of 1.10, and explained approximately 71% (95% CI 69, 72%) of the variance of the outcome. The hazard ratio for age was found to be 1.00 (95% CI 0.99, 1.01) indicating risk remains the same across all age groups. Inclusion of a CAD metaGRS improves the AUC to 0.82 (95% CI 0.80, 0.83), explains more of the variance at 81% (95% CI 79, 82%) but worsens calibration slope to 0.93. A likelihood ratio test indicates that the integrated model is a better fit (p = 0.04).
Conclusion: An integrated risk score, that combines traditional risk factors with a metaGRS, improves CAD prediction in patients with RA. Further research is required to better understand the role of heritable components contributing to CAD risk in RA patients. By refining the underlying GRS, we hope to further improve risk prediction, through this integrated approach.

IDENTIFICATION OF DIFFERENTIALLY EXPRESSED GENES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. H. Jung[1], A. Kim[2], B. Y. Kim[3], G. G. Song[1]. *[1]Korea University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea); [2]CHA University School of Medicine, Medicine, Seongnam, Korea, Rep. of (South Korea); [3]Gangneung Asan Hospital, Internal Medicine, Gangneung, Korea, Rep. of (South Korea)*

Background: Characterizing differentially expressed genes (DEGs) of systemic lupus erythematosus (SLE) is necessary to understand immunogenic interactions, and how several key immune genes were closely associated with the susceptibility of SLE.
Objectives: This study aimed to identify DEGs of SLE using gene expression-based computational methodologies to analyze disease-immune interactions, which affect the development and progression of SLE.
Methods: Twenty-six patients with SLE and 46 healthy controls were selected from the Gene Expression Omnibus database. The significantly enriched immune and virus related gene lists were computed and visualized by using the DEGs from the Gene Set Enrichment Analysis. Quantification of 38 immune cells were performed in determining the impact of immune cells on the virus mediated immunity in SLE by using ImmQaunt algorithm.
Results: Thirty nine upregulated and 57 downregulated were identified in SLE patient compared to the healthy controls. Upregulated genes were significantly implicated in Gene Ontology gene sets as cytokine mediated signaling, secretion, and exocytosis in immune response pathways. In addition, these genes were enriched in hepatitis C, influenza A, measles, Epstein–Barr virus, and

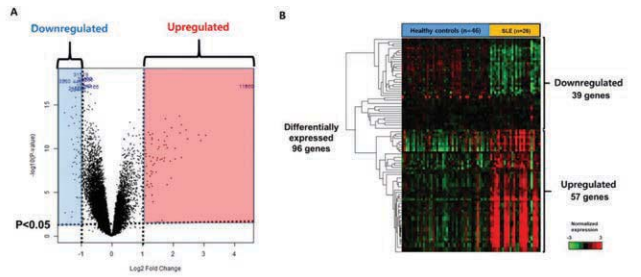

Figure 1. Gene expression analysis of SLE patients vs. healthy control samples. (A) The volcano plot represents differentially expressed gene expression with the significance criteria (adjusted p < 0.05, |Log2 (fold change)| ≥ 1). The x-axis indicates the log 2-fold change of gene expression (SLE patients/healthy controls), and the y–axis indicates the –log 10 (p-value). (B) Heatmap of the expression of selected differentially expressed genes with the computed p-value between the SLE and healthy control samples.

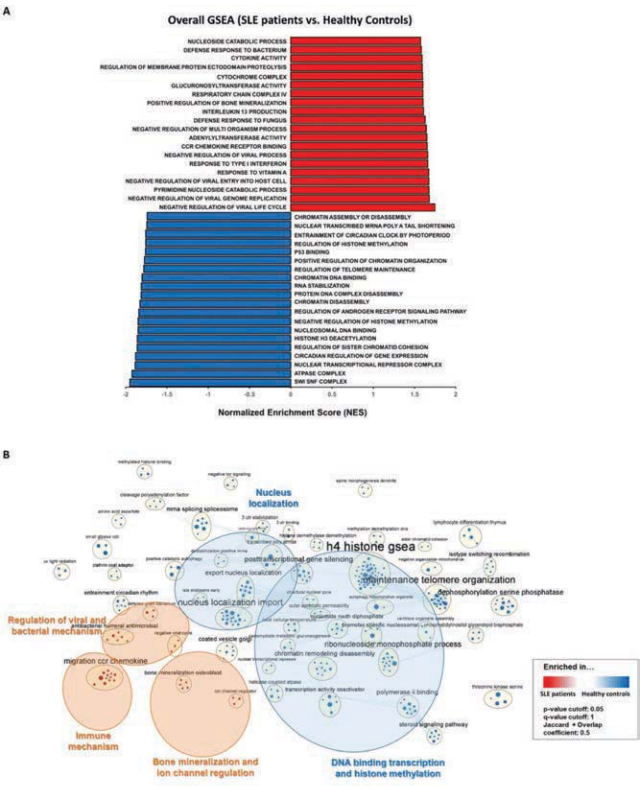

Figure 2. Gene set enrichment analysis (GSEA) of SLE patients vs. healthy control samples. (A) A forest plot was generated showing the overall GSEA pathways that were positively or negatively enriched according to the normalized enrichment score. (B) Network visualization based on the gene enrichment analysis. Blue and red nodes represent the downregulated and upregulated gene sets in SLE patients, respectively. Genes in significant networks were annotated and grouped with simplified Gene Ontology terms.

herpes simplex virus 1 infection in Kyoto Encyclopedia of Genes and Genomes pathways. Especially, FCGR1A, IRF7, OAS2, CAMP, MX1, OAS3, OAS1, DEFA3, ISG15, and RSAD2 were involved in virus mediated SLE mechanism, and the expression for OAS1, OAS2, and IRF7 was closely associated with the quantities of colony forming unit-monocyte and colony forming unit-granulocyte.
Conclusion: Identifying virus mediated SLE genes and quantifies of immune cells were used to understand the pathological process and perform early diagnosis of SLE, and will lead to clinical tools for treating SLEs in patients.

Adaptive immunity (T cells and B cells) in rheumatic diseases

POS0397 SSD6453, A NOVEL AND HIGHLY SELECTIVE BTK/JAK3 DUAL INHIBITOR IS EFFICACIOUS IN MULTIPLE PRE-CLINICAL MODELS OF INFLAMMATION

F. Zhou[1], L. Jiang[1], Y. Yan[2], W. Yang[2], F. Tang[3], P. Chen[4], R. Tang[5]. *[1]Simcere Pharmaceutics, in vitro pharmacology, Shanghai, China; [2]Simcere Pharmaceutics, in vivo pharmacology, Shanghai, China; [3]Simcere Pharmaceutics, Pharmaceutical Chemistry, Shanghai, China; [4]Simcere Pharmaceutics, DMPK, Shanghai, China; [5]Simcere Pharmaceutics, R&D, Shanghai, China*

Background: The mechanism of inflammatory diseases is complicated and dysfunction of multiple immune cells is thought to be directly related to the pathogenesis. Targeting either JAK-STAT or BCR signaling has been proved solid clinical efficacy in multiple inflammatory diseases, such as rheumatoid arthritis (RA) and multiple sclerosis (MS). And the combination of BTK and JAK inhibitors demonstrated synergistic effects for the treatment of inflammation models in pre-clinic. JAK3 expression is largely restricted to leukocytes and involves functions in JAK1/JAK3 heterodimer in signal transduction, it might be a more effective and safer target. Meanwhile, both BTK and JAK3 possess a cysteine residue in their active site and this feature makes it possible to design a dual inhibitor. SSD6453 is a highly selective and irreversible JAK3/BTK dual inhibitor which may have synergistic effects for the treatment of RA and other inflammatory diseases such as MS.
Objectives: To develop a potent, oral, highly selective JAK3/BTK inhibitor for treatment of multiple inflammatory diseases.
Methods: ADP-GLO based biochemical assays were performed to determine the enzymatic inhibitory effect and selectivity for JAK family. The target engagement was evaluated by IgM induced pBTK and IL-2 induced pSTAT5 in human PBMCs. In vivo efficacy was evaluated by rat collagen-induced arthritic (CIA) model and mice experimental autoimmune encephalomyelitis (EAE) models induced by MOG1-125 or MOG35-55, respectively. BTK occupancy in spleens post last dose 24h and IL-2 induced pSTAT5 in whole blood post last dose 0.5h were used to evaluate targets inhibitions. Osteoclast was stained by IHC in pathological section of rat paws.
Results: In biochemical assays, SSD6453 inhibited BTK and JAK3 with the IC_{50} values of 3.4 nM and 1.1 nM, respectively. Notably, SSD6453 displayed high selectivity against JAK1 (510 fold), JAK2 (75 fold) and TYK2 (525 fold). In cellular assays, SSD6453 inhibited anti-IgM induced pBTK and IL-2 induced pSTAT5 in human PBMCs with the IC_{50} values of 18.8 nM and 168.8 nM, respectively. SSD6453 demonstrated favorable PK properties in broad pre-clinical species. Single oral administration of SSD6453 in rat or mouse, resulted in dose-dependent inhibition of BTK and JAKs concurrently. In the rat CIA model in which disease development was accompanied by a robust T-cell and B-cell inflammation response to collagen, SSD6453 dose-dependently inhibited paw edema. And SSD6453 at 10mpk achieved complete (95%) BTK occupancy and JAK3 inhibition and superior efficacy in comparison of tofacitinib (JAK@10 mpk) or evobrutinib (BTK @30mpk) alone, suggesting that concurrent inhibition of JAK3 and BTK lead to synergistic anti-inflammation effects. In addition, ED-1+ osteoclast count decrease was observed in paws, suggesting the prevention of SSD6453 in joint destruction. In two EAE models either induced by MOG1-125 or MOG35-55, which represented T or B dominant inflammation model, respectively, SSD6453 robustly ameliorated disease in both two models. In comparison, BTK inhibitor is efficacious only in the MOG1-125 induced model.
Conclusion: SSD6453 is a novel and high selective BTK/JAK3 dual inhibitor, and demonstrated synergistic efficacy in multiple pre-clinic inflammation models. SSD6453 showed good pharmacokinetic characteristics and well-tolerant in multiple pre-clinical species, and is moving to IND in 2022.

POS0398 IDENTIFICATION OF THE HLA-B*51:01 IMMUNOPEPTIDOME IN BEHÇET'S DISEASE

Y. J. Lee[1], K. C. Cho[2], S. H. Kim[2], B. K. Cho[2], E. C. Yi[2], E. B. Lee[1,2]. *[1]Seoul National University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea); [2]Seoul National University, Molecular Medicine and Biopharmaceutical Sciences, Seoul, Korea, Rep. of (South Korea)*

Background: Immunopeptidomes are peptides, bound to human leukocyte antigens (HLA), that play a key role in immune responses. HLA-B*51:01 is an HLA allele associated with Behçet's disease (BD)[1]. However, the characteristics and the role of HLA-B*51:01 immunopeptidome are not revealed in Behçet's disease.
Objectives: To investigate the difference of HLA-B*51:01 immunopeptidome between Behçet's disease and healthy controls (HCs) and to select candidate peptides which have a pathogenic role in Behçet's disease.
Methods: HLA-bound peptide profiles were established through analysis of plasma samples from HLA-B*51:01–positive BD patients and HCs. HLA-class I molecules were immunoprecipitated, and liquid chromatography-tandem mass spectrometry (LC-MS/MS) was performed. Then, HLA-B*51:01–binding peptides were assessed in terms of binding affinity using NetMHCpan. Finally, the

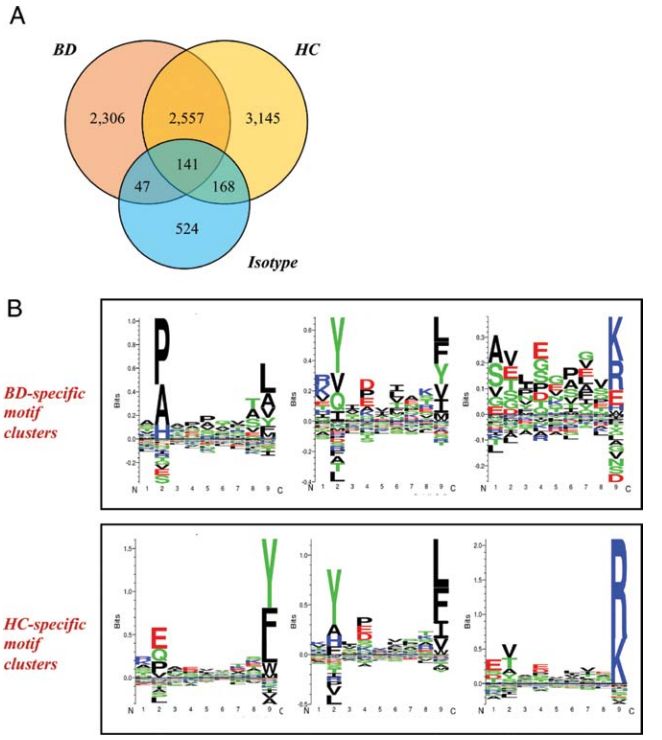

Figure 1. Venn diagram of the identified 8–13-mer peptides and graphs showing the motif clusters. (A) Venn diagram showing the numbers of peptides detected by immunoprecipitation with BD patients or HCs. The number of peptides isolated with isotype antibodies were also depicted. (B) Motif clusters of human leukocyte antigen (HLA)-B*51:01-positive BD patients and HCs.

immunological characteristics of selected peptides were analyzed in BD patients and HCs, using ELISpot, flow cytometry, and dextramer staining.
Results: 2,306 peptides were present only in BD patients, while 3,145 peptides were detected only in HCs. Immunopeptidome of BD patients preferentially showed hydrophobic amino acids at amino acid position 2 (Figure 1). Ten peptides were selected which were confirmed to be preferentially expressed in BD patients compared with HCs. When bound to HLA-B*51:01 in monocyte-derived dendritic cells (Mo-DCs) or peripheral blood mononuclear cells, these peptides activated T cells and induced surface expression of CD69 and CD107, as well as the secretion of inflammatory cytokines such as interferon (IFN)-γ and tumor necrosis factor (TNF)-α.
Conclusion: HLA-B*51:01 immunopeptidome can play a critical role in the development of BD by activating T cells and inducing the secretion of inflammatory cytokines.

POS0399 CHARACTERIZATION OF HSP60, A STROMAL-DERIVED AUTOANTIGEN, RECOGNIZED BY RA SYNOVIAL RECOMBINANT MONOCLONAL ANTIBODIES

E. Corsiero[1], M. Caliste[1], L. Jagemann[1], E. Prediletto[1], C. Pitzalis[1], M. Bombardieri[1]. *[1]William Harvey Research Institute, Queen Mary University of London, Centre for Experimental Medicine & Rheumatology, London, United Kingdom*

Background: Up to 50% of rheumatoid arthritis (RA) patients display synovial ectopic lymphoid structures (ELS) supporting B-cell autoreactivity toward locally generated citrullinated and other translationally modified antigens. Recently, screening a large number of recombinant monoclonal antibodies (rmAbs, n=71) which we derived from locally differentiated B-cells from RA ELS+ synovium [1], we identified a subset of antibodies which specifically recognise fibroblast-like-synoviocytes (FLS) (10 out of 71), suggesting FLS as a cellular source of autoantigens fuelling the local autoimmune response. We reported that calreticulin is one of the antigenic targets of these anti-FLS rmAbs, while the nature of other FLS-derived autoantigens is still unclear [2].
Objectives: Here we aimed to define other stromal-derived autoantigens from RA-FLS targeted by RA-rmAbs.
Methods: Western blotting/mass-spectrometry were used to identify potential autoantigens from RA-FLS protein extracts. Putative candidates were validated using colocalization immunofluorescence confocal microscopy/ELISA/immunoprecipitation assay. Finally, both serum and synovial fluid (SF) from RA patients (OA patients used as control) were tested for immunoreactivity towards the putative antigen.
Results: Following immunoprecipitation and mass-spectrometry analysis, among the anti-FLS antibodies we identified a subset of RA-rmAbs which display strong reactivity towards heat shock protein 60 (HSP60). Three RA-rmAbs confirmed a clear immunoreactivity towards HSP60 in ELISA assay in a dose-dependent manner. Confocal microscopy did not show co-localization between anti-HSP60 RA-rmAbs and HSP60, suggesting that HSP60 act as autoantigen when released from the RA-FLS in stress condition. Finally, anti-HSP60 Abs were preferentially detected in RA-SF versus OA-SF, with an accumulation of HSP60 in RA-SF versus RA sera.
Conclusion: Here, we identified synovial B cell-derived RA-rmAbs locally differentiated within the ELS+ RA synovium reacting toward HSP60, suggesting that FLS-derived HSP60 may contribute to fuel the local autoimmune response. Elucidating the mechanisms involved in RA-FLS activation *in vitro/in vivo* will be important to clarify the anti-FLS rmAbs functional role in modulating inflammation.

POS0400 MODULATION OF HUMAN EARLY B CELL DEVELOPMENT THROUGH TARGETED DEGRADATION OF IKAROS AND AIOLOS WITH IBERDOMIDE

I. Janowska[1], J. Korzhenevich[1], J. Staniek[1], R. Lorenzetti[2], L. Konstantinidis[3], M. Erlacher[4], P. Schafer[5], R. Voll[1], J. Thiel[2,6], N. Venhoff[1], M. Rizzi[1]. *[1]Freiburg im Breisgau, Rheumatology and clinical Immunology, Freiburg im Breisgau, Germany; [2]Medical Center, Rheumatology and Clinical Immunology, Freiburg im Breisgau, Germany; [3]Medical Center-University of Freburg, Department of Orthopedics and Trauma Surgery, Freiburg, Germany; [4]Medical Center - Albert-Ludwigs-University of Freiburg, Department of Pediatrics and Adolescent Medicine, Freiburg, Germany; [5]Bristol Myers Squibb, Translational Medicine, Princeton, United States of America; [6]Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria*

Background: B differentiation in the bone marrow (BM) is impaired in patients carrying mutation in the IKFZ1 gene, coding for Ikaros a zinc-finger transcription factor. High Ikaros expression is on the contrary associated with systemic lupus erythematosus[1] and multiple myeloma[2]. Targeted treatment with iberdomide, a cereblon modulator which enhances degradation of Ikaros and Aiolos, is under clinical investigation in multiple myeloma patients and systemic lupus erythematosus. However, consequences of the treatment on human early B cell development remain elusive. Immature B cells develop in the BM from hematopoietic stem cells. An intricate network of transcription factors regulates the maturation process. Ikaros and Aiolos regulate gene expression during B cell development. As reported in mice, Ikaros is essential for the commitment to the lymphoid lineage and later, together with Aiolos, ensures the transition from pre-BII large to pre-BII small cells.
Objectives: Investigate the effect of iberdomide (CC-220) on human early B cell development simulated in vitro.
Methods: We tested the impact of iberdomide on short term culture of BM-derived lymphocytes and in a unique in vitro modeling of early B cell development starting from cord blood (CB)- CD34+ progenitors [3, 4]. We used multi-dimensional spectra flow cytometry (17-color pan-el) to dissect early B cell subpopulations.
Results: Iberdomide treatment led to enhanced degradation of Ikaros and Aiolos in both BM- and CB-derived cultures. Addition of iberdomide early (day 7) to the CB-derived culture impaired the specification to the lymphoid lineage and later also the commitment to the B cell lineage. These observations were confirmed by reduced E2A and PAX5 gene expression, respectively. Treatment with iberdomide on B cell precursors (pro- and pre-B cells, day 28 of culture) on one side it enhanced the proliferation of early progenitors resulting in increased amount of CD10+CD38+ lymphoid-committed cells. On the other side, it resulted in a accumulation of pre-B cells and inefficient development of immature B cells.
Conclusion: Iberdomide impairs the commitment to the lymphoid lineage by enhancing Ikaros' degrada-tion. When targeting already committed B cells, iberdomide treatment undermines the transition of pre-BII large to pre-BII small cells due to increased Aiolos' degradation, conse-quently impairing the development of immature B cells. Our data can instruct immunologi-cal monitoring of patients treated with iberdomide, and provide insights in the mechanisms of therapeutic efficacy.

POS0401 SERUM ANTIBODIES TO TYPE I COLLAGEN IN PERIPHERAL ARTHROPATHY ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE

D. Abdulganieva[1], D. Mukhametova[1], O. Zinkevich[2], N. Saphina[3], M. Korovina[2], A. Odincova[4]. *[1]Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation; [2]Kazan State Medical Academy, Central Research Laboratory, Kazan, Russian Federation; [3]Kazan State Medical University, biochemistry and clinical laboratory diagnosis, Kazan, Russian Federation; [4]Republican Clinical Hospital, gastroenterology, Kazan, Russian Federation*

Background: Immunological disorders play an important role in the pathogenesis of inflammatory bowel disease (IBD). Type I collagen (COL1) is the main component of the intercellular matrix of connective tissue. It can be assumed that the immune disorders leading to the production of autoantibodies to collagen play a role in the pathogenesis of arthropathy associated with IBD.
Objectives: to study the level of IgM and IgG to type I collagen (COL1) in peripheral arthropathy associated with IBD.

Methods: We prospectively included 91 patients with IBD [61 ulcerative colitis (UC), 30 Crohn's disease (CD)] and 30 healthy controls. 82 patients with IBD were in disease attack and 9 in the remission Mean age in IBD was 36 [28; 47] years and in control group – 35 [25; 48]. Joint involvement (arthralgia, arthritis) was observed in 33 patients (36%). Affected joints were the knees 17 (51%), shoulders 6 (18%), feet 6 (18%), hands 5 (15%), elbows 4 (12%), ankles 3 (9%), wrists 2 (6%). Levels of serum IgM and IgG to COL1 were assessed by enzyme immunoassay.
Results: Levels of IgM to COL1 in active IBD (0,18 [0,10; 0,2] mkg/ml; p<0,01) and in remission (0,15 [0,11; 0,20] mkg/ml; p<0,05) were increased compared with healthy (0,09 [0,07; 0,12] mkg/ml). There were no differences between stage of disease (remission and exacerbation), IBD severity (p>0,05). IgM antibodies to COL1 in patients with peripheral arthropathy (0,174 [0,12; 0,28] mkg/ml) were significantly higher than in patients without joint involvement (0,12 [0,08; 0,19] mkg/ml; p<0,01). The levels of IgG to COL1 in active IBD (14,4 [10,22; 33,34] mkg/ml; p<0,05) and in remission (28,82 [16,36; 78,9] mkg/ml; p<0,005) were higher than in the control group 11,36 [6,93; 19,83] mkg/ml. We didn't find any differences in IgG levels depending on the severity of disease. IgG levels to COL1 in patients with peripheral arthropathy (16,18 [9,46; 26,21] mkg/ml) were higher, than without them (12,78 [8,81; 28,31] mkg/ml), also not significant.
Conclusion: In active IBD the level of serum antibodies of class IgM and IgG to COL1 increased compared with healthy. The maximum increase was found in the patients with peripheral arthropathy, which can be explained by the high content of this collagen in the structural components of the joints and by joint inflammation in patients with IBD.
