Background: A strong female predisposition is characteristic of Systemic Lupus Erythematosus (SLE), with female-to-male ratio ranging from 7:1 to 15:1. The molecular basis of this gender bias remains incompletely understood. In a previous whole-blood RNA profiling study, we identified genes with differential expression in SLE males versus females but not in their healthy counterparts. Among these genes, the cohesin complex protein SMC1A (Structural Maintenance of Chromosomes 1A) displayed the highest statistical significance [1].
Objectives: To (a) determine the immune cell type that displays the strongest gender-biased SMC1A expression in SLE versus healthy individuals, and (b) elucidate the role of SMC1A in regulating immune/inflammatory responses in the context of SLE.
Methods: Multiple immune cell types ($CD19^+$ B cells, $CD4^+$ T cells, $CD14^+$ monocytes, neutrophils) were purified from peripheral blood specimens of SLE and healthy individuals, followed by Taqman PCR and Western blot to measure SMC1A mRNA and protein levels, respectively. The genome-binding properties of SMC1A were assayed by chromatin immunoprecipitation (ChIP)-sequencing in monocytes cultured under lupus-inducing conditions (lupus-like monocytes) [2]. To recapitulate the female/male difference in SMC1A expression, *ex vivo* cultured lupus-like monocytes were transfected with si-SMC1A (to downregulate SMC1A) versus si-control reagent, followed by genome-wide transcriptome analysis by RNA-sequencing.
Results: Among the various tested immune cell types, $CD14^+$ monocytes best recapitulated the initial whole blood RNA-seq findings, demonstrating significantly decreased SMC1A mRNA and protein expression in male versus female SLE patients but not in their healthy counterparts. In blood monocytes cultured under lupus-inducing conditions and tested by ChIP-sequencing, SMC1A binding was increased on enhancers and promoters of genes associated with inflammation (including type I/II interferon and other inflammatory cytokines) and cell migration. In accordance, lupus-like monocytes with lowered SMC1A expression (i.e., male-like) displayed significantly reduced expression of inflammatory genes like *IL6*, *GBP5*, *ADA* and *IL1A*, as compared to monocytes with unaffected SMC1A (i.e., female-like). Furthermore, *IL6* mRNA synthesis was significantly enhanced in female versus male monocytes cultured under lupus-inducing conditions.
Conclusion: SMC1A may transcriptionally regulate genes associated with the inflammatory response of monocytes. Our findings of gender-biased SMC1A levels in SLE monocytes raise the hypothesis that differential SMC1A expression and function might contribute to the disease gender bias and/or sexual dimorphism.

THE ROLE OF NLRP3 INFLAMMASOME POLYMORPHISMS IN THE GOUT SUSCEPTIBILITY

D. Clavijo-Cornejo[1], A. López-Reyes[2], E. Cruz-Arenas[3], L. Jacobo-Albavera[4], A. Francisco-Balderas[5], M. Domínguez-Pérez[4], J. Vazquez Mellado[6], L. H. Silveira Torre[7], C. Pineda[8], G. Martínez-Nava[2], M. Gutierrez[8]. [1]*Instituto Nacional de Rehabilitación, Division of Musculoskeletal and Rheumatic Diseases, Mexico City, Mexico;* [2]*Instituto Nacional de Rehabilitación, Geroscience Laboratory, Mexico City, Mexico;* [3]*Instituto Nacional de Rehabilitación, Hospital Epidemiological Surveillance Unit, Mexico City, Mexico;* [4]*Instituto Nacional de Medicina Genómica, Laboratory of Genomics of Cardiovascular Diseases, Mexico City, Mexico;* [5]*Instituto Politécnico Nacional, Graduate Studies Department, Mexico City, Mexico;* [6]*Hospital General de México, Rheumatology Department, Mexico City, Mexico;* [7]*Instituto Nacional de Cardiología Ignacio Chávez, Rheumatology Department,, Mexico City, Mexico;* [8]*InsInstituto Nacional de Rehabilitación, Division of Musculoskeletal and Rheumatic Diseases, Mexico City, Mexico*

Background: Recent reports have demonstrated that polymorphisms within NLRP3 inflammasome signaling pathway are key factors in the risk to develop some joint inflammatory diseases (1). To date, there is still uncertain information about the presence of these genetic variants and their association with risk of gout.
Objectives: To determine the association between the single nucleotide polymorphisms (SNPs) within NLRP3 inflammasome genes and the risk of developing gout.
Methods: We included 220 gout patients and 243 healthy subjects as control group. Clinical examination was performed and laboratory including glucose concentration, total cholesterol and triglycerides were obtained. The frequency and the allelic distribution of eight SNPs from seven different genes within the NLRP3 inflammasome signaling pathway were analyzed using the Step One Plus Real-Time PCR Systems. SNPs were selected by the criterion of minor allele frequency (MAF) (above 1 %), using the 1000 Genomes Project. Genetic variation data for all the SNPs were obtained from the HapMap project (http://www.hapmap.ncbi.nlm.nih.gov/) and the public National Center for Biotechnology Information dbSNP database (http://www.ncbi.nlm.nih.gov/snp). The SNPs should not to be in linkage disequilibrium. Ancestry was analyzed using ancestry informative markers differentiating mainly Amerindian, African, and European ancestries.
Results: The missense SNP rs45520937 in PPARGC1B, showed enhanced association with the risk of developing gout when it was analyzed using the dominant model, evidencing that gout patients carried the A/G-A/A genotype have an elevated risk compared to the control group [OR (95% CI) = 2.30 (1.09-4.86), p=0.030]. While, the adaptor molecule CD14 rs2569190 SNP could be associated with lower risk of gout under an additive model [OR (95 % CI)= 0.41 (0.16-1.05), p= 0.064]. No significant association were identified for the remaining SNPs.
Conclusion: Our findings suggest that genetic variant rs45520937 of PPARGC1B is significantly associated with the gout susceptibility.

HOMEOBOX D13 TRANSCRIPTION FACTOR MODULATES THE FORMATION OF THE PRIMARY CILIUM IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

M. Mirrahimi[1], E. Camarillo[1], K. Klein[1,2,3], M. Houtman[1], O. Distler[1], C. Ospelt[1]. [1]*University of Zurich, University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland;* [2]*University of Bern, Department of BioMedical Research, Bern, Switzerland;* [3]*University of Bern, Department of Rheumatology and Immunology, Bern, Switzerland*

Background: Differences in gene expression and functions of synovial fibroblasts between distinct joints might lead to site-specific activation of arthritis-relevant pathways. We previously showed that the transcription factors HOX-D10, -D11 and -D13 are higher expressed in synovial fibroblasts from hands and feet compared to shoulder and knee, and that this expression pattern is epigenetically imprinted[1].
Objectives: To investigate the functional role of HOXD13 in synovial fibroblasts.
Methods: Synovial fibroblasts from patients with rheumatoid arthritis (n=2) were cultured and transfected with HOXD13 antisense LNA GapmeRs (12.5 nM). Transcriptomes were determined by RNA-seq (Illumina NovaSeq 6000). Pathway enrichment analysis of RNA-seq data was performed using web-based tools (ToppGene, EnrichR and Cytoscape) (± fold change > 1.5, FDR < 0.05). The expression of histone deacetylases (HDACs) and sirtuins was measured by quantitative real-time PCR and immunofluorescence staining. Ciliogenesis of synovial fibroblasts was assessed by measuring the expression of *PKD2, ARL13B, KIF3A*, and *IFT88* using qPCR. Acetylation of alpha-tubulin was assessed by immunofluorescence staining. Imaging was performed with the CellInsight™ CX7 platform.

Primary cilia were manually counted. Approximately 500 cells for each replicate were recorded for the presence of a primary cilium. The length of primary cilia was measured using Image J (Version 1.53o). Synovial fibroblasts were treated with Trichostatin A (2μM), an inhibitor of HDACs (HDACi), for 24h.

Results: Pathway enrichment analysis of genes changed after HOXD13 silencing of synovial fibroblasts showed that HOXD13 regulated genes are involved in primary cilia related pathways. We confirmed lower mRNA expression of the ciliary proteins, *PKD2*, *KIF3A* and *IFT88* after HOXD13 silencing (n=4; *PKD2*: 0.65 ± 0.4, p<0.05; KIF3a: 0.6 fold ± 0.3, p<0.05; IFT88: 0.7 fold ± 0.3, p<0.05), and higher expression of *ARL13B (ARL13B*: 1.8 fold ± 0.4, p<0.05). An increase in the number and length of primary cilia, as well as acetylation of alpha- tubulin, a characteristic feature of primary cilia, was seen after HOXD13 silencing (n=4). Accordingly, expression of *HDAC4, -5* and *-7* was decreased after HOXD13 silencing (n=4; *HDAC4*: 0.25 fold ± 0.1, p<0.05*; HDAC5*: 0.4 fold ± 0.1, p<0.05; *HDAC7*: 0.3 fold ± 0.2, p<0.05). *SIRT1* expression was higher (n=4; 1.7 fold ± 0.4, p<0.05), but *SIRT2* expression was lower (n=4; 0.1 fold ± 0.03, p<0.05) in HOXD13 silenced synovial fibroblasts. Trichostatin A treatment increased the acetylation level of alpha tubulin (n=4) as well as the expression of *ARL13B*, *KIF3A*, and *IFT88* in synovial fibroblasts (n=4; *ARL13B*: 2.3 fold ± 0.9, p<0.05; *IFT88*: 1.5 fold ± 0.3, p<0.05; *KIF3A*: 3.7 fold± 1.8, p<0.05). The length and number of primary cilia was not changed by Trichostatin A treatment.

Conclusion: Our data show that HOXD13 plays a role in regulating the assembly of primary cilia in synovial fibroblasts. This effect seems partly mediated by the expression of HDACs and partly by the expression of ciliary proteins. The primary cilium is a sensory organelle mediating reactions to mechanical and chemical signals from the environment. Thus, our results suggest joint specific regulation of synovial fibroblasts in response to stimulation via the primary cilium.

AB0016 GENETIC VARIANTS OF PREDISPOSITION TO RHEUMATOID ARTHRITIS IN BELARUSIAN POPULATION

E. Siniauskaya[1], H. Yatskiu[1], N. Dostanko[2], V. Yagur[2], R. Goncharova[1]. [1]*Institute of Genetics and Cytology of NAS of Belarus, Laboratory of Molecular Basis of Genomic Stability, Minsk, Belarus;* [2]*BSMU; Belarusian State Medical University, 2-nd Department of Internal Medicine, Minsk, Belarus*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by autoimmune inflammatory response focused in the synovium. RA is a complex disorder with significant genetic component and it is also known to have possible environmental triggers. Microbiota and bacterial infections play a significant role in RA etiology. The onset of RA may be accompanied by the previous or ongoing chlamydia infection in some cases.

Objectives: to determine genetic variants of susceptibility to RA in Belarusian population

Methods: 650 individuals were divided into 2 cohorts: 305 patients with RA (59.69 ± 12.20), and 345 controls (mean age 37.42 ± 10.62). Patients with RA were further stratified into two subsets – those with catamnestic *Chlamydia trachomatis*/*Chlamydophila pneumoniae* infection (43, "RAChl+") and those without (262, "RAChl-"). 11 SNPs of 10 genes (*IL6* (rs1800795), *IL6R* (rs2228145 and rs4845618), *STAT4* (rs7574865), *TRAF1/C5* (rs3761847), *RUNX1* (rs9979383), *RUNX3* (rs11249215), *PTPN2* (rs2542151), *PTPN22* (rs2476601), *AGER* (rs1035798), *SLC7A11* (rs13128867)) were genotyped using Real-time PCR or PCR-RFLP.

Results: It was found that homozygous TT genotype at the rs7574865 locus of the *STAT4* gene and CT+TT genotypes at the rs2476601 locus of the *PTPN22* gene are associated with RA in general (OR 2.71 [1.31 – 5.61]; p = 0.005 and OR 2.47 [1.75-3.48] p<0.000, respectively). CC genotype at the rs9979383 locus of the *RUNX1* gene and AG+GG genotypes at the rs11249215 locus of the *RUNX3* gene revealed protective effect (OR 0.63 [0.40-0.98] p=0.036 and OR 0.58 [0.36-0.92] p=0.02, respectively). The lack of association with RA was shown for polymorphic loci of the *IL6* (rs1800795), *IL6R* (rs2228145 and rs4l45618), *SLC7A11* (rs13128867), *AGER* (rs1035798), *PTPN2* (rs2542151) and *TRAF1/C5* (rs3761847) genes. For RA subsets stratified according to presence/absence of the *C. trachomatis*/*C. pneumoniae* infection it was shown that CC genotype at the rs1800795 locus of the *IL6* gene and AA genotype at the rs11249215 locus of the *RUNX3* gene were associated specifically with the risk of developing Chlamydia infection-associated RA (OR 5.22 [1.85–14.71] p=0.0024 and 2.63 [1.09-6.35] p=0.037). In addition, TG+GG genotypes at the rs2542151 locus of the *PTPN2* gene is also associated with RAChl+ clinical phenotype (2.10 [1.10-3.99] p=0.025). No association with either of disease subtypes was revealed for polymorphic loci *RUNX1* (rs9979383), *IL6R* (rs2228145, rs4845618), *AGER* (rs1035798), *SLC7A11* (rs13128867), *TRAF1/C5* (rs3761847).

Conclusion: Thus, the polymorphic variants of *STAT4*, a key gene of autoimmunity, and *PTPN22* gene, that is involved in the JAK/STAT pathway of immune response, increase the RA susceptibility in general cohort for the Belarusian population. At the same time, CC genotype at the rs1800795 of the *IL6* gene, its product being central proinflammatory cytokine, and AA at the rs11249215 locus of the *RUNX3* gene, that is involved in T-cell initiated immune response, as well as the genotypes TG+GG at the rs2542151 locus of the *PTPN2* gene, involved in signaling pathways of immune response through T-cell activation, are associated only with RAChl+ clinical phenotype. Our data may indicate that genetic variants of *STAT4* and *PTPN22* contribute to genetic basis of the pathogenesis of RA through renewal of T-cell initiated immune response.

Adaptive immunity (T cells and B cells) in rheumatic diseases

AB0017 T HELPER /REGULATORY T CELLS RATIOS IMBALANCE IN DIFFERENT STAGING RHEUMATOID ARTHRITIS

R. Su[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University, Taiyuan, Department of Rheumatology, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that results in the destruction of the bone and cartilage of the joints[1]. The imbalance between Th17 and Treg cells has been demonstrated to play a role in RA pathogenesis[2].With the advances in the RA field, curing and even preventing RA has become a new direction of efforts. To explore the immune characteristics in multi-staging RA is helpful for the development of accurate strategies.

Objectives: To observe the immune characteristics in different staging rheumatoid arthritis patients

Methods: A total of 127 patients with RA were recruited for this study, in cluding 30 early RA(newly diagnosed and treatment-naive,duration of disease ≤3months), 30 midddle RA (newly diagnosed and treatment-naive, duration of disease >3months and≤1 year), 30 advanced RA(newly diagnosed and treatment-naive,duration of disease >1 year) and 37 active treated RA (remissioned after target treatment and this time due to disease recurrence in hospital). All patients were hospitalized in the second hospital of Shanxi medical university and diagnosed with RA fulfilled the ACR 1987 or 2010 criteria.The percentage and absolute numbers of lymphocyte phenotypes and CD4+ T subsets in peripheral blood were examined by flow cytometry.

Results: There were no significant difference in the percentage and value of T,B,NK,CD4+T,CD8+T andCD4+T subsets. But the Th1/Th2 cell ratios in active treated RA group were increased than that in early RA, middle RA and advanced RA group.The Th17/Treg cell ratios in middle RA and advanced RA group were higher when compared with those of active treated RA group.In addition, the Th1/Treg cell ratios were decreased in middle and advanced RA group as compared with those in active treated RA.

Conclusion: Th1/Th2,Th17/Treg and Th1/Treg imbalance varied with disease staging.The different disease staging in RA, the immune function is different. Providing targeted immunotherapy according to disease staging is helpful to improve remission rates and even prevent disease.

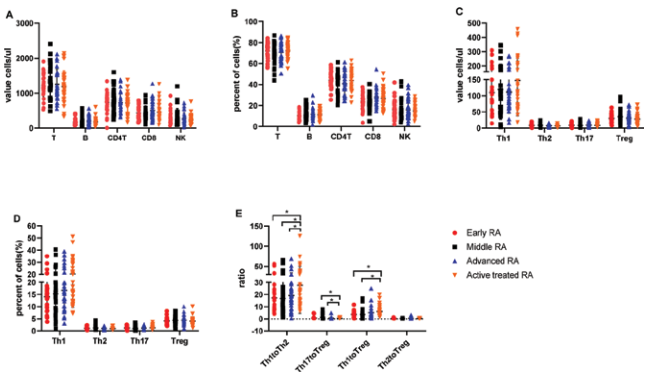

Figure 1. The comparsion about the lymphocyte subsets and cell ratios in peripheral blood of different stage RA patients.(*p<0.05)

AB0018 SERUM ANTIBODIES AGAINST ORAL AND INTESTINAL BACTERIA IN INDIVIDUALS AT RISK FOR RHEUMATOID ARTHRITIS, CHRONIC RA PATIENTS, AND NEW ONSET PATIENTS WITH DIFFERENT RHEUMATIC DISEASES

L. Amend[1], B. Gilbert[2], A. Finckh[2], T. Strowig[1]. *[1]Helmholtz Centre for Infection Research, Microbial Immune Regulation, Braunschweig, Germany; [2]Geneva University Hospitals, Divison of Rheumatology, Geneva, Switzerland*

Background: Evidence about the influence of microbes in autoimmune diseases such as rheumatoid arthritis (RA) has grown in recent years. However, the precise role of specific bacteria remains largely unknown. Previous investigations identified several oral pathobionts to be specifically targeted by serum antibodies in RA patients.[1] In addition, Pianta et al.[2] identified recognition of *Prevotella copri* by the immune system of RA patients. It has to be noted, however, that such findings have neither been reproduced, nor studied in different disease stages. Also, the assumptions made for *P. copri* relied on a single strain, the type strain DSM18205, isolated from a healthy individual.[3] However, there is recent evidence suggesting *P. copri* to be a non-monotypic species, meaning it clusters into several subspecies displaying geno- and phenotypic differences[4].
Objectives: This study aimed to quantify serum antibodies targeting different *P. copri* strains, as well as known oral pathobionts in patients with different rheumatic diseases or in various stages of RA development.
Methods: We used custom-made ELISA assays measuring pathogen-specific IgG levels in patient's serum. Samples were tested against *P. copri* strains isolated from stool samples of healthy donors and RA patients, as well as the following oral pathobionts: *Porphyromonas gingivalis*, *Prevotella intermedia* and *Prevotella melaninogenica*. We analyzed 120 samples from a Swiss cohort of first-degree relatives, individuals in various pre-clinical RA stages (SCREEN-RA), and 45 samples of patients with established RA (SCQM cohort). These participants were categorized as asymptomatic seronegative individuals (FDR), individuals with 'systemic autoimmunity associated with RA' (ACPA and/or RF autoantibodies) (preRA 1), individuals with 'clinically suspect arthralgia' or 'undifferentiated arthritis' with/without autoantibodies (preRA 2) and chronic RA patients (cRA). Additionally, we included 92 serum samples from new-onset patients diagnosed with RA, psoriatic arthritis (PsA) axial spondyloarthritis (SpA), or other non-rheumatic diseases (NRD) recruited via the german RheumaVOR cohort (Table 1).

Table 1. Overview human cohort studies

cohort	SCREEN-RA			SCQM	RheumaVOR			
patient group	FDR	preRA 1	preRA 2	cRA	NRD	RA	PsA	axSpA
total numbers	42	40	38	45	32	14	30	16
age median	54	54	59	56	43.5	51.5	50.5	33
sex (F/M)	32/10	35/5	34/4	35/10	19/13	9/5	15/15	10/6
ACPA positivity	0	25	9	31	0	7	0	0
RF positivity	0	19	8	34	0	7	0	0

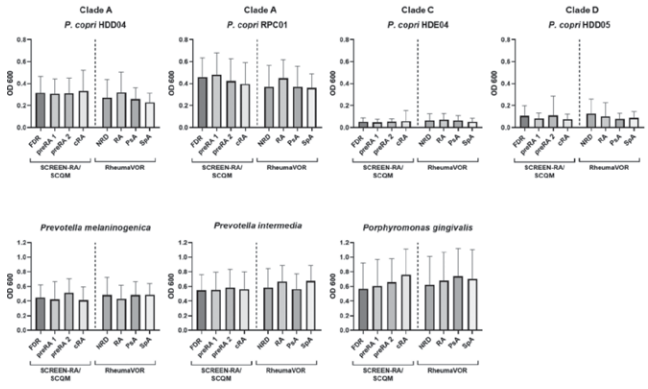

Figure 1. Serum IgG responses against different microbes from individuals recruited via SCREEN-RA, SCQM or RheumaVOR cohort

Results: Overall, there were no significant differences in the IgG reactivity profiles between the patient groups against the distinct *P. copri* strains or oral pathobionts (Figure 1). However, performing this assay with *P. copri* strains from distinct subspecies identified clear differences and revealed important variability in the IgG reactivity.
Conclusion: Our study failed to reproduce previous results and could confirm neither *P. copri* nor the three oral pathobionts to be particularly targeted by systemic IgG immune reactions in RA patients. However, we identified strain-specific differences in the IgG reactivity against *P. copri*, regardless of disease type or state. The latter suggests that the overall immunostimulatory potential of *P. copri* might be dependent on its strain/subspecies level. Our findings underline the necessity of *P. copri* strain-level characterization when studying host-microbiota immune interactions.

AB0019 RITUXIMAB TREATMENT DOES NOT ALTER EXPRESSION OF CO-STIMULATION MARKER CD19 ON B CELLS IN SYSTEMIC SCLEROSIS PATIENTS

B. Dreo[1], B. Prietl[2,3], S. Kofler[2,3], V. Pfeifer[2,3], H. Sourij[2,3], F. Moazedi-Fürst[1], S. Kielhauser[1], M. D'Orazio[1], S. Zenz[1], J. Thiel[1], M. Stradner[1], H. P. Brezinsek[1]. *[1]Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria; [2]CBmed GmbH, CBmed GmbH – Center for Biomarker Research in Medicine, Graz, Austria; [3]Medical University of Graz, Division of Endocrinology and Diabetology, Graz, Austria*

Background: CD19 is a membrane glycoprotein interacting with different surface molecules like the B cell receptor (BCR) and is crucial for antigen-independent development as well as immunoglobulin-induced activation of B cells.[1] Alterations in this signalling pathway can incline autoantibody production and systemic autoimmunity in humans. Rituximab (RTX), a CD20 antagonist appears to be an effective candidate in the treatment of different autoimmune diseases that are partly driven by autoreactive B cells, such as systemic sclerosis (SSc).[2] It has been speculated that RTX might work not only by depleting B cells but also to down regulate activation markers, such as CD19.
Objectives: In-depth analysis of CD19 abundancy and activation on B cells in SSc patients with and without RTX treatment
Methods: Peripheral blood samples from 41 patients suffering from SSc (median ± standard deviation SD, age: 54.3 ± 10.6 years, female ratio: 0.8) and 45 age- and sex-matched healthy controls (HC) (age: 51.0 ± 13.9 years, female ratio: 0.8) were drawn and PBMCs were isolated on-site. We performed flow cytometry analysis on a standardized BD LSRFortessa platform to identify B cell (CD19+CD20+) subpopulations. The geometric mean fluorescence intensity (gMFI) for CD19 in all B cell subtypes was extracted from the data set and used for further statistical analysis. Additionally, a quantitative flow cytometric bead-based assay (QuantiBRITE PE kit from Becton Dickinson) was used for the estimation of CD19 antibodies bound per cell.
Results: 3 out of 41 SSc patients were in high disease activity at the time of blood drawal. 23 SSc patients were under RTX therapy of whom 5 patients still displayed measurable B cells frequencies. Naïve B cells made up the most abundant B cell population in SSc patients. Thus, the frequency of IgM+/IgD+/CD27- B cells was 67.9% ±13.2 (mean ±SD), followed by class-switched memory B cells (IgM-/IgD-/CD27+, 10.5 ± 4.9), non-switched memory B cells (IgM+/IgD+/CD27+, 4.0 ± 3.6) and plasmablasts (0.3 ± 4.4). Pairwise Wilcoxon Tests (Bonferroni-corrected for multiple testing) showed significant differences ($p < 0.001$) between frequencies of naïve B cells and all other cell types. In contrast, naïve B cells displayed the second lowest CD19 gMFI levels (7601.0 ± 1912.0) in the dataset. Non-switched memory B cells in SSc patients showed the highest CD19 gMFI (10620.0 ± 15689.8), followed by class-switched (9388 ± 3048.6). As expected, Plasmablasts displayed the lowest CD19 gMFI levels (4799.0 ± 4185.7). The decrease in CD19 gMFI was again highly significant. This trajectory in decreasing CD19 gMFI was found in both HCs and SSc patients. We saw a significant reduction in percentages of non-switch B cells and class-switched B cells in SSc patients compared to HCs (4.0 ± 3.6 vs 6.5 ± 4.2, $p = 0.029$, 10.5 ± 4.9 vs 13.2 ± 7.2 $p = 0.04$) but an increase in CD19 gMFI in non-switched B cells (HC: 9204.5 ± 2116.8, $p = 0.05$). Interestingly, SSc patients under RTX treatment had significantly lower class-switched memory B cell frequencies compared to HCs (6.4 ± 4.2 vs. 13.2 ± 7.2, $p = 0.015$). However, RTX did not affect CD19 gMFI or bound CD19 in SSc.
Conclusion: RTX treatment in SSc is not associated with downregulation of the co-stimulation marker CD19. Thus, the main effect of this drug is the reduction of B cells, especially class-swtched memory B cells that might have a high capacity to activate other cells involved in the pathogenesis of SSc.

Background: COVID-19, rheumatoid arthritis (RA) and osteoarthrosis (OA) are diseases characterized by the secretion of cytokines related to the stimulation of the inflammatory response.
Objectives: To identify the differences in the cytokine and matrix metalloproteinases (MMP) profile within one acute infectious disease and two chronic inflammatory rheumatic diseases.
Methods: Analytical cross-sectional study. RA patients under a strict follow-up program (T2T evaluated every two months), OA patients without strict clinical follow-up, evaluated once or twice a year, and Severe (mortality) COVID-19 patients were included. Eleven proteins (cytokines, MMPs and its tissue inhibitors) were quantified through Luminex multiplex assay in serum samples. Univariate and bivariate analyzes were performed. Approval of Ethics Committee and informed consent were obtained.
Results: A total of 108 patients with RA and OA were compared with 20 severe COVID-19 patients. There were no significant differences through the method of Kruskall–Wallis, between RA and OA patients. IL1-B and MMP-2 were significantly lower in COVID-19 patients. Levels of IL-10, IL-1RA, IL-6, MMP-1, MMP-9, and TIMP-1 were significantly higher in COVID-19 patients. There were no differences in TNF-A, TIMP-2 and INF-G. (Table 1)

Table 1. Significant correlations between cytokines related to Covid-19, RA and OR.

Cytokine (pg/ml) Median values	RA (%)	OA	COVID-19	P-value
IL-10	54.92	54.49	116.38	<0.0001[a]
Il1-RA	62.19	51.82	110.08	<0.0001[a]
IL1-B	67.09	55.30	46.17	0.045
IL-6	56.09	51.34	84.98	<0.0001[b] 0.003[c]
TNF-A	17.5	14.6	16.3	NS
MMP-1[d]	57.84	54.84	90.81	<0.0001[b] 0.045[c]
MMP-2 [d]	70.38	70.59	48.56	0.040
MMP-9 [d]	66.25	58.16	86.4	0.007 [b]
TIMP-1 [d]	51.59	60.99	111.67	<0.0001[a]
TIMP-2 [d]	45.2	47.7	49.6	NS
INF-G	5.75	5.32	3.07	NS

[a] Between RA and Covid-19 and OA and Covid-19, without differences between RA and OA. [b] Between OA and Covid-19.[C] Between RA and Covid-19. [d] ng/ml.

Conclusion: Compared with RA and OA patients, severe COVID-19 patients have a great impact on the cytokines and MMPs addressed in this study, proving that COVID-19 patients suffer from a cytokine storm [1] when severely infected.

AB0021 FEATURES OF IMMUNOLOGICAL MANIFESTATIONS OF COMMON VARIABLE IMMUNODEFICIENCY COMBINED WITH RHEUMATOID ARTHRITIS

S. Kudryashov[1], L. Karzakova[2], I. Sidorov[1], N. Zhuravleva[1]. *[1]The Chuvash State University named after I.N. Ulyanov, Department of Internal Medicine, Chuvash Republic, Cheboksary, Russian Federation; [2]City Clinical Hospital No. 1 of Public Health Ministry of Chuvashia,The Chuvash State University named after I.N. Ulyanov, polyclinic No. 1, Department of Internal Medicine, Chuvash Republic, Cheboksary, Russian Federation*

Background: The prevalence rate of common variable immunodeficiency (CVID), the most common symptomatic form of primary immunodeficiency disease (PID), is growing every year. In the Republican Register of PID in the Chuvash Republic (Russia) there are 32 patients with CVID, 5 (15.6%) of whom have CVID combined with an autoimmune disease - rheumatoid arthritis (RA). The immunological studies occupy a large place in the diagnosis of PID and autoimmune diseases.
Objectives: The aim of the study was to search for immunological criteria for the differentiation of RA from CVID combined with RA.
Methods: The object of the study were 2 groups of patients. Group 1 consisted of 20 RA patients; group 2 consisted of 5 patients with CVID in combination with RA. Patients with CVID, who had the results of an immunological study conducted before the appointment of immunoglobulin replacement therapy, were selected for this study. The control group consisted of 20 practically healthy people.
Results: The significant changes were revealed in the concentration of serum immunoglobulins in the studied groups of patients, in particular, a sharp decrease in IgG levels in group 2 (1.9±0.3 g/l vs. 15.2±2.3 in group 1, p<0.001), IgA (0.1±0.02 g/l vs. 3.1±0.7 g/l in group 1, p<0.001), IgM (0.2±0.03 g/l vs. 1.7±0.2 g/l in group 1, p<0.001). Immunoglobulin levels in both groups of patients were lower (p<0.001) compared to the control group. In both groups, the number of regulatory cells – Treg (CD4+CD25+FoxP3) was reduced: in group 1 - to 2.5±0.03%; in group 2 - to 2.3± 0.02%, while in the control group it was 4.2± 0.5%, p<0.001. The result of our study confirms that the development of RA and CVID is associated with the decrease in the number of Treg cells responsible for ensuring peripheral tolerance and preventing the development of autoimmune diseases.
Conclusion: CVID and RA have a common immunopathological sign - a decrease in the content of Treg cells in the blood. In the differential diagnosis between RA and CVID, combined with RA, it is necessary to rely on the results of the determination of immunoglobulins in the blood serum.

AB0022 SELECTIVE ESTROGEN RECEPTOR MODULATORS AND TISSUE-SELECTIVE ESTROGEN COMPLEX DO NOT SHARE ESTROGENIC EFFECTS ON IGG SIALYLATION IN AUTOIMMUNE CONDITIONS

P. Gupta[1,2], K. L. Gustafsson[2], H. Carlsten[1], P. Henning[2], C. Engdahl[1,2].
[1]Department of Rheumatology & Inflammation Research, Institute of Medicine, Sahlgrenska Osteoporosis Centre, Centre for Bone and Arthritis Research, University of Gothenburg, Gothenburg, Sweden; [2]Department of Internal Medicine & Clinical Nutrition, Institute of Medicine, Sahlgrenska Osteoporosis Centre, Centre for Bone and Arthritis Research, University of Gothenburg, Gothenburg, Sweden

Background: Women entering menopause, with a decrease in estrogen levels, display an increased incidence of rheumatoid arthritis (RA). Estrogen (E2) treatment has beneficial effects on IgG pathogenicity by altering the sialylation grade which affect the binding ability to FcR[1]. E2 replacement may therefore be beneficial in pre-RA patients having autoantibodies. Exposure to estrogen is associated with negative side effects, therefore selective estrogen receptor modulators (SERMs) have been developed with estrogenic protective effect on bone but minimal impact on the reproductive system[2]. The SERM, Bazeodoxifene (BZA), as well as tissue-selective estrogen complex (TSEC), a combination of conjugated estrogen and BZA, have been approved for treatment of postmenopausal bone loss[3-5]

Objectives: The purpose of this study was to investigate the impact of BZA and TSEC on IgG sialylation grade which affects the pathogenicity as well as to determine the effects on total serum protein sialylation.
Methods: C57Bl6 mice were subjected to ovariectomy to stop the endogenous E2 production and mimicked the postmenopausal status. Mice were then treated with E2, BZA, TSEC, or vehicle, followed by ovalbumin (OVA) immunization to induce the IgG levels. Blood was collected before treatment started and at termination. In serum total IgG, OVA specific IgG and the degree of IgG-sialylation were quantified with ELISA. Sialyation of total serum proteins was determined with sialic acid assay quantification kit. Expression of sialyltransferase protein was analyzed in the bone marrow (BM) and spleen cell compartment using flow cytometry. The mRNA expression of glycosyltransferase was analyzed by qPCR analysis.
Results: Neither BZA nor TSEC significantly altered the total IgG levels or sialylation grade of IgG. Indeed, E2 significantly altered IgG sialylation. We showed that BZA increased sialyltransferase protein in plasma cells in a similar manner as E2. Further, neither E2, BZA or TSEC had any significant impact on sialic acids in whole serum protein and not in the mRNA expression of glycosyltransferase in the liver, BM, or gonadal fat.
Conclusion: In this study, we were not able to detect any alteration by TSEC or BZA treatment on IgG-sialylation grade and thereby pathogenicity of the IgG. Neither E2 nor BAZ or TSEC show any significant alteration on general sialylation, but our results suggest that further studies are required to understand E2, SERM, and TSEC full effect on protein sialylation in autoimmune conditions.

AB0023 JAK-INHIBITORS DISRUPT CD14+/CD4+ CELL INTERACTION SUPPRESSING RHO-GTPASE DEPENDENT LEUKOCYTE RECRUITMENT TO JOINTS OF RA PATIENTS

E. Malmhäll-Bah[1], K. M. Andersson[1], M. Erlandsson[1], V. Chandrasekaran[1], S. Töyrä Silfverswärd[1], M. I. Bokarewa[1,2]. *[1]Gothenburg University, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; [2]Sahlgrenska University Hospital, Rheumatology, Gothenburg, Sweden*

Background: While examining arthritis development due hyperactivated Rho-GTPases in a mouse model, we found that macrophages with hyperactive Rho-GTPases regulate the migration of thymic T regulatory cells to peripheral lymphoid organs, which contributed to arthritis development Interestingly, T cells reciprocally upregulate Rho-GTPases leading to suppression of homing and formation of a mechanosensory complex of centered around β_1-intergrin facilitating migration.
Objectives: In response to the finding in mice we sought to explore this relationship in patients diagnosed with RA, aiming to expand understanding how different treatments affect the molecular mechanisms we observed in mice.
Methods: To confirm if similar interaction mechanisms between macrophages and T cells are present in RA patients, we used paired transcriptome (RNAseq) of $CD14^+$ and $CD4^+$ cells from 80 RA patients active on conventional DMARDs prior to treatment with TNF-inhibitors (exploratory cohort) and from 56 RA patients with inactive disease on various DMARD treatment (confirmatory cohort). In both cohorts, patients were stratified by mean expression of *CDC42* in $CD14^+$ cells to mimic hyper activation of Rho-GTPases. Transcriptomics of $CD14^+$ and $CD4^+$ cells were analyzed and translated into clinical correlates.
Results: Examining the exploratory cohort, we found a reciprocal upregulation of Rho-GTPases across the cell types. The $CDC42^{hi}$ group had upregulation of *RHOA* and *RAC1* in $CD14^+$ cells and *CDC42, RAC1* and *RHOA* in $CD4^+$ cells. Upregulation of *IL6*, *TLR4* and inflammasome units *IL18R1* and *IL1R2*, *NLRP3* signified pro-inflammatory phenotype of those cells. Furthermore, $CDC42^{hi}CD14^+$ and $CD4^+$ cells shared the upregulation of AP-1 TFs, and the circadian rhythm controlling molecules *PER1*, *AHR* and *KLF6* assisting cell migration. Next, $CDC42^{hi}$ cells were enriched with a synovial macrophage marker CD163, and *ITGB1* to facilitate focal adhesion and migration into joints. Moreover, high expression of CXCL-chemokines and *CCL5* on $CDC42^{hi}CD14^+$ cells indicated the ability to recruit T cells, and high *CXCR4* on $CDC42^{hi}CD4^+$ cells suggested their synovial destination. Unexpectedly, $CDC42^{hi}CD14^+$ and $CD4^+$ cells were not recognized by strong production of the key pro-arthritis cytokines TNF-α and IFN-γ. Consequently, the $CDC42^{hi}$ profile of $CD14^+$ and $CD4^+$ cells was not predictive for clinical response to TNF-inhibition in the exploratory cohort.
Examination of the confirmatory cohort revealed the majority of $CDC42^{hi}CD14^+$ cells belong to the patients treated with conventional DMARDS, while $CDC42^{lo}$ group were treated with JAK-inhibitors (20 vs 4, *OR*= 11.87, 95 % CI [3.387, 49.72], $p<0.0001$). We also found a correlation between *CDC42* expression in $CD14^+$ cells and DAS28 in patients treated with JAK-inhibitors ($r=0.5$, $p=0.0072$) pointing at tight relation between the treatment effect and Rho-GTPase dependent processes. This significantly affected the Rho-GTPase dependent interaction between $CD14^+$ and $CD4^+$ cells.
Transcriptional profile of $CDC42^{hi}CD14^+$ cells of the confirmatory cohort showed many similarities with the exploratory cohort including upregulation of the canonical Rho-GTPases, *ITGB1* and the inflammasome activation that were enhanced by upregulation *of* the vast number of ITGA and chemokines. Transcriptional regulation through *AHR* and *KLF6* persisted, while AP-1 and *PER1* was downregulated. In contrast to CD4+ cells of the exploratory cohort, $CD4^+$ cells of the patients with $CDC42^{hi}CD14^+$ cells were low in *CDC42*, *RAC1* and *RHOA* expression. Also, $CD4^+$ cells were deficient in AP-1, *AHR*/*KLF6* and *PER1*.
Conclusion: Taken together, these data show that Rho-GTPases regulate interaction between $CD14^+$ and $CD4^+$ cells and their migration to RA joints. Treatment with JAK-inhibitors suppress the Rho-GTPase dependent recruitment to joints by changing communication between $CD14^+$ and $CD4^+$ cells. This finding opens new perspective to use Rho-GTPase signature to identify patients suitable for treatment with JAK-inhibitors and in predicting the treatment response.

AB0024 PLURIPOTENCY MARKER PBX1 PREDICTS TREATMENT EFFECT IN RHEUMATOID ARTHRITIS

K. M. Andersson[1], E. Malmhäll-Bah[1], M. Erlandsson[1], V. Chandrasekaran[1], S. Töyrä Silfverswärd[1], R. Pullerits[1], M. I. Bokarewa[1]. *[1]Department of Rheumatology and Inflammation Research, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden*

Background: Accelerated immunosenescence with contraction of T cell repertoire, demise of thymic function and expansion of $CD28^{null}$ T cells with poor T cell reconstitution is the hallmark of rheumatoid arthritis (RA)[1].
Objectives: In this study we assessed if PBX1 transcription factor that maintains the pluripotency of hematopoietic stem cells could be used to predict treatment response in RA patients.
Methods: $CD4^+$ T cells of 87 RA female patients (age, median 61y (23-76); disease duration, median 9y (0-45)) were isolated from the perpheral blood, activated with aCD3 and subjected to transcriptional analysis by RNAseq (Illumina). External RNAseq of $CD4^+$ T cells of 80 RA patients (f 56, m 24) was used for validation. The genes differentially expressed (DEG, nominal $p<0.05$) between $PBX1^{hi}$ and $PBX1^{lo}$ groups were identified by R-studio using Benjamini-Hochberg correction (Bioconductor, DESeq2 package). DEGs were clustered by covariance to identify PBX1 associated genes and biological processes. Clinical variates and treatment regimens in $PBX1^{hi}$ and $PBX1^{lo}$ groups were compared.
Results: The patients of $PBX1^{hi}$ and $PBX1^{lo}$ groups were of similar age and disease duration but differed in anti-rheumatic treatment. $PBX1^{hi}$ group was often treated with conventional DMARDs and monotherapy, while $PBX1^{lo}$ group was mostly treated with biologics and/or JAK-inhibitors in combination with cDMARDs (χ^2, $p=0.0099$). This treatment led to sufficient disease control in both PBX1 groups (median DAS28; 2.6 and 2.7, respectively). In the external RA cohort of the patients resistant to conventional DMARDs, $PBX1^{hi}$ patients had significantly fewer frequency of non-responders to anti-TNF treatment compared to $PBX1^{lo}$ (χ^2, $p=0.026$).
Pathway analysis of the DEGs identified strong enrichment for regulation of transcription ($cor.p=10^{-23}$), RNA metabolic processes ($cor.p=10^{-18}$) and differentiation ($cor.p=10^{-7}$) in $PBX1^{hi}$ $CD4^+$ cells, which corresponds to the known biological properties of $PBX1^2$. $PBX1^{hi}CD4^+$ cells in both datasets had imprinted features of pluripotency[3] and expressed higher levels of KIT and CAT, low proliferation

markers Ki67 and BIRC5, and had virtually no cytokine production. In the main cohort, PBX1^{hi}CD4^{+} cells were recognized by naïve T cell marks CD62L (SELL) and CD45 (PTPRC), and also PECAM1, CR2, and CD28, indicating recent thymic egress. In the validation cohort, PBX1^{hi}CD4^{+} cells were enriched with stem cell markers CD34, MEG3, and DNMT3B. Lineage specific TFs (TBET, GATA3, FOXP3, RORC) and cytokines (IFNG, TNF, IL10, IL17F, etc.) were accumulated in PBX1^{lo}CD4^{+} cells indicating terminally differentiated effector CD4^{+} T cells.

Conclusion: This study shows that enrichment with PBX1^{hi} CD4+ cells is associated with naïve pluripotent phenotype of CD4 lymphocytes. Patients with high PBX1 expression are less heavily treated and respond better to treatment. This suggests boosting of PBX1-expression to be a way of treating RA.

AB0025 PERIPHERAL BLOOD CD4+ AND CD8+ RECENT THYMIC EMIGRANTS IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS DISPLAY AN ACTIVATED PHENOTYPE

F. V. Kraus[1], V. Eckstein[2], L. V. Klotz[3], H. Winter[3], H. M. Lorenz[1], M. Souto-Carneiro[1]. *[1]University Hospital Heidelberg, Division of Rheumatology, Dept. of Medicine V, Heidelberg, Germany; [2]University Hospital Heidelberg, dFCCU, Dept. of Medicine V, Heidelberg, Germany; [3]German Center for Lung Research (DZL), Translational Lung Research Center (TLRC), Heidelberg, Germany*

Background: T cells play a major pathogenic role in Rheumatoid Arthritis (RA). Their pro-inflammatory potential, interaction with B-cells (CD4) and cytotoxic capacities (CD8) have a high impact on disease progression, at the site of inflammation as well as in the periphery. T cells in RA have an altered glucose metabolism, which further amplifies their pro-inflammatory and auto-immune profile.[1,2] This phenotype is even displayed by RA naïve CD8 T cells, and several studies propose that defects in RA T cell development occur already during thymic development. Thus, acquisition of an activated (auto)inflammatory phenotype may occur at very early stages of RA T cell development.

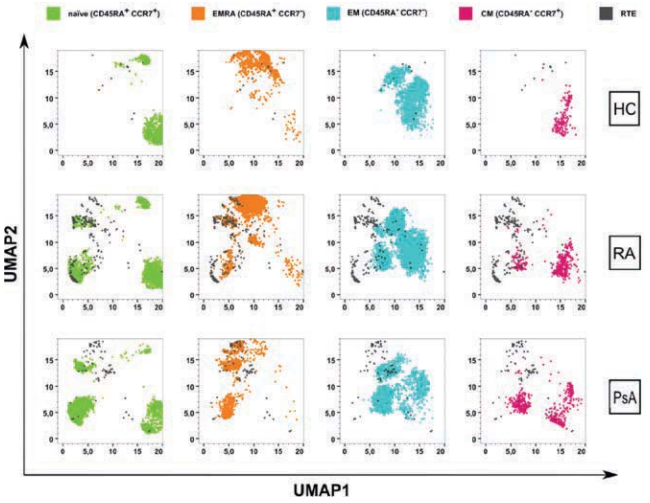

Figure 1. UMAP analysis of total RTEs. Previously downsampled CD4^{+} and CD8^{+} T cells were clustered by UMAP (FlowJo™) and total RTEs were mapped on the naïve, effector (EMRA), effector memory (EM) and central memory (CM) compartments of the respective groups.

Objectives: We studied Recent Thymic Emigrants (RTEs) in peripheral blood to establish, whether the activated pro-inflammatory signature present in naïve RA T cells can already be found at such an early stage of T cell development.

Methods: We analysed previously described RTE surface markers [3] on CD8 and CD4 T-cells of human adult thymus samples, as well as on cord-blood samples and additionally confirmed the identified cells as RTEs based on their TREC (T cell Receptor Excision Circle) content. Next, we phenotypically characterised RTEs in the peripheral blood of 10 RA patients, 6 PsA (Psoriatic Arthritis) patients and 5 healthy donors (HC) by 24-parameter Flow Cytometry. Cell clustering was analysed using the UMAP algorithms.

Ethic approval NR: S-969/2020

Results: As expected, RTEs only made up a small proportion of the total CD4 and CD8 T cells, on average 1.3 % and 2.5 % respectively. Contrary to previous reports [4], we could see no significant differences between patients and controls. A first global analysis of CD45RA and CCR7 on CD4 and CD8 via UMAP revealed that RA and PsA RTEs cluster together with naïve and effector cells (Figure 1).

We further analysed several functional surface markers for homing (CD11a, CD49a), effector functions (CD69, CD27, CD107a), regulatory functions (CD25) and exhaustion (CD95, PD-1, CTLA-4.

In CD4 RTEs we observed more cells expressing homing, effector and exhaustion markers in RA and PsA when compared to HC. CD11a and CD69 were expressed on 3 times more CD4 RTEs in RA and PsA and CD95 and PD1 expressing CD4 RTEs were 2 times more frequent in the arthritic groups compared to HC, while PD1 expressing CD4 RTEs in patients were 10 times more frequent. The CD25^{+} CD4 RTE population was 3 times larger in RA and PsA than in HC.

In CD8 RTEs the frequency of CD11a expression was similar, whereas the CD49a^{+} population was 3 times larger in RA compared to PsA and HC. CD69 expressing CD8 RTEs were increased in RA and PsA compared to HC, while the degranulation marker CD107a was expressed on similar amounts of HC and PsA RTEs and 2 fold increased compared to RA. CTLA-4 and PD1 expressing CD8 RTEs were 5 - and 2 times more frequent in the RA group than in HC.

Conclusion: Overall, the RTE populations of RA and PsA patients displayed a more active and exhausted phenotype than the control group. However, this seemed to be more prominent for CD4 RTEs than CD8 RTEs. According their CD45RA/CCR7 profiles, both CD4 and CD8 RTEs fall into the less active naïve compartment, corresponding to the early developmental stage, but also into the effector compartment. The RTEs from RA and PsA patients also express markers that are usually associated with pro-inflammatory activity and even exhaustion. This implies that indeed even RTEs are already biased towards a more active phenotype in RA and PsA, compared to RTEs from healthy individuals, suggesting alterations in T cell development in the RA and PsA thymus.

States of America; [5]The Janssen Pharmaceutical Companies of Johnson & Johnson,Translational Sciences, Spring House, United States of America

Background: Sjögren's disease (SjD) is a chronic, heterogenous autoimmune disorder characterized by inflammatory destruction of the exocrine glands and Ro autoantibodies. Previous studies, most in whole blood, reported transcriptional and cell type differences between SjD subphenotypes.
Objectives: Evaluate the role of cell type-specific dysregulation in subpopulations of SjD patients having focal lymphocytic sialadenitis and/or anti-Ro/SSA and/or ANA positivity using single-cell RNA-seq (scRNA-seq).
Methods: Peripherical blood mononuclear cells (PBMCs) stored at -120°C from 30 SjD patients and 10 healthy controls (HCs) were selected from our OMRF Sjögren's Research Cohort based on ACR/EULAR 2016 criteria. PBMCs were captured, libraries processed using 10X Genomics Chromium v3.1 and sequenced to a depth of ~45,000 reads/cell. 10X Genomics Cell Ranger (v 6.1.2) cell multiplexing pipeline was used to align reads to the GRCh38 human genome and separate combined data to per-sample output files. Seurat R package was used for quality control (QC), integration, clustering, and cell type assignment. Differential expression (DE) analysis was done using Seurat for genes with 10% or more of the cells showing expression. DE transcripts (defined as p_{adj}<0.05) were evaluated using Ingenuity Pathway Analysis (IPA).
Results: After removing cells with low feature counts, high mitochondrial gene counts, and/or other QC criteria, a total of 331,981 cells were captured. Cells were mapped to 28 clusters using Seurat, then cell types were predicted using marker genes developed from an in-house reference panel of publicly available scRNA-seq datasets. Mapping condensed the 28 observed cell clusters to 19 clusters of specific cell types; 4 clusters remained unidentified. Percentages of each cell type were compared across various subsets of SjD (Ro+; Ro-; Ro-/ANA+; Ro-/ANA-) and HCs. CD14 monocytes were decreased in Ro-/ANA- vs. Ro+ or Ro-/ANA+ cases (p<0.05) and trended downward when compared to HCs (p=0.057). CD8 central memory T cells (TCM) were decreased in Ro+ vs. Ro- or Ro-/ANA- cases (p<0.02) and trended downward when vs. HCs (p=0.076). Conventional dendric cells (DCs) were increased in Ro+ vs. Ro-/ANA- SjD cases (p=0.036) and trended upward in Ro+ vs. Ro- cases (p=0.08) but were not significantly different from HCs. Natural killer (NK) cells were increased in both Ro-/ANA- and Ro- vs. Ro+ (p<0.05).
DE analysis between immune cell subsets revealed potential subphenotype-specific differences in pathophysiology. Interferon signaling was upregulated in CD14 monocytes, naïve B, and CD4 central memory (TCM) cells from the Ro+ subset. Ro+ subset also showed upregulation of genes involved in T cell receptor signaling in CD4 cytotoxic T (CTL), CD4 TCM, and CD4 effector memory T (TEM) cells, but downregulation of this pathway in CD8 TCM cells. Ro+ subset also exhibited increased B cell receptor signaling pathway in naïve and memory B cells. Ro+ subset showed downregulation of autophagy in naïve B, CD4 CTL, CD4 TCM, and CD4 TEM cells. Several cell types in Ro+ and Ro-(ANA+/-) subsets showed decreased DE of genes involved in nitric oxide production and NRF2 oxidative stress pathways. Ro- (ANA+/-) vs. HCs showed increased IL6 and TREM1 signaling pathways in CD14 and CD16 monocytes. While Ro+ subsets showed upregulation of B and T cell pathways (shown previously in lupus), Ro- (ANA+/-) showed dysregulation of osteoarthritis and neuroinflammatory pathways. Interestingly, among the DE long intergenic non-coding (linc)RNAs found herein, we observed that *LINC01871*, which we previously reported as DE in all subsets of SjD, was overexpressed in CD4 CTL and NK cells in both Ro+ and Ro- (ANA-) vs. HCs.
Conclusion: This interim analysis shows similarities and differences in the dysregulation of genes and pathways for specific cell subsets from our Ro+ and Ro- (ANA+/-) subsets of SjD, potentially allowing for more tailored diagnostics and interventions for the disease in the future.

AB0027 XANTHINE OXIDOREDUCTASE: ENZYME PROFILE OF PLASMA AND LYMPHOCYTES IN RHEUMATOID ARTHRITIS

S. Bedina[1], A. Trofimenko[1], E. Mozgovaya[1], S. Spitsina[1], M. Mamus[1]. *[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical biochemistry lab, Volgograd, Russian Federation*

Background: Disorders of acquired and adaptive immunity play an important role in the rheumatoid arthritis (RA) pathogenesis. Important changes can nevertheless be detected at the metabolic level in the immune cells along with immune disorders. The imbalance between generation and neutralization of the free radicals during oxidative stress may cause damage of both cellular structures and components of extracellular matrix. One of principal free radical generators is xanthine oxidoreductase (XOR), the prooxidant enzyme complex which could be active either in its oxidase or dehydrogenase form. The study of plasma and lymphocytic xanthine oxidase (XO) and xanthine dehydrogenase (XDG) activities is of emerging interest because of their putative role in initiation and chronization of RA.
Objectives: Evaluation the relationship between RA activity and XO and XDG activities using both plasma and lysed lymphocyte samples.
Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles after the local ethical board approval. RA diagnosis was verified using ACR/EULAR criteria (2010). RA activity was measured using the Disease Activity Score of 28 joints (DAS28). Blood lymphocytes were isolated by means of density gradient centrifugation in lymphosep (JCN Biomedicals), 1.077-1.079 g/ml. XO (EC 1.17.3.2) and XDG (EC 1.17.1.4) activities in plasma and lysed lymphocytes were measured using spectrophotometric techniques and expressed as nmol/ml/min [1]. Data are presented as median and quartiles (Me (Q_{25}; Q_{75}). Differences were considered significant when p<0.05.
Results: 77 RA patients (57 women and 20 men) were enrolled in the study. Mean age of patients was 45 (37; 49) years, mean RA duration was 8 (6; 10) years. 16 (21%) RA patients had low disease activity, 49 (63%) patients moderate, and 12 (16%) patients had high one. 30 (19 women and 16 men) healthy persons comprised the control group. Reference ranges for plasma XO and XDG activities were 2.60–3.96 nmol/min/ml and 4.49–5.93 nmol/min/ml, respectively. Reference ranges for XO and XDG activities in lysed lymphocytes were 14.11-31.33 nmol/min/ml and 18.62-39.64 nmol/min/ml, respectively. Plasma enzymatic pattern in RA patients was characterized by increase in XO activity (p<0.001) and a somewhat decrease in XDG activity (p=0.059). Lymphocytic enzymatic pattern in RA patients was characterized by decreased activity of both enzymes (p<0.001 for both cases). Plasma XO activity was increased and lymphocytic XO activity was decreased in all the grades of RA activity. XO activity reached its highest changes at maximum disease activity. Plasma XDG activity was increased in low disease activity (p<0.001), while patients with moderate or high disease activities were characterized by decreased activity of this enzyme (p=0.008). Lymphocytic XDG activity was decreased in all the grades of disease activity (p<0.001). XDG activity reached its highest changes at maximum disease activity. Activities of XO and XDG in lymphocytes negatively correlated with RA activity. Activities of XO in plasma positively correlated with RA activity, while XDG activity negatively correlated with RA activity.
Conclusion: Plasmatic and lymphocytic enzymatic patterns in RA patients were characterized by multidirectional changes of XO and XDG activities. Multiple correlations were found between RA activity and enzyme activities in both studied compartments. These changes in oxidant enzyme activities may point at involvement of free radical oxidation in the RA pathogenesis. Free radical generation triggers metabolic cascades that lead to cell damage, premature death, promote endothelial dysfunction, extracellular neutrophil trap formation, support chronic inflammation and joint destruction, and other organs and systems under oxidative stress.

AB0028 IL-2 DEPRIVED PHENOTYPE OF FOXP3+ REGULATORY T CELLS AND PHENOTYPIC ALTERATIONS CONVENTIONAL CD4+ T CELLS IN PATIENTS WITH INFLAMMATORY MYOPATHIES AND PRIMARY SJOGREN´S SYNDROME

L. R. Monne[1], S. Comduehr[1], F. Gerlach[1], A. Müller[1], G. Riemekasten[1], J. Y. Humrich[1]. *[1]University Hospital Schleswig-Holstein - Campus Lübeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany*

Background: A defect in regulatory T cell (Treg) homeostasis due to an acquired deficiency of interleukin-2 (IL-2) plays an important role in the pathogenesis of systemic lupus erythematosus (SLE).[1,2] However, it is still unclear whether a defect in the Treg-IL-2 axis is also involved in other connective tissue disease such as inflammatory myopathies or primary Sjogren´s syndrome (pSS).
Objectives: The aim of our study was to investigate whether Treg from patients with poly- and dermatomyositis (PM/DM) and pSS display typical features of IL-2

deficiency in parallel to phenotypic alterations of conventional CD4+ T cell (Tcon) subsets compared to healthy controls (HC).
Methods: PBMC were isolated from patients with PM/DM (n=22) and pSS (n=17) and from age- and sex-matched HC (n=19) using gradient density centrifugation. Treg and Tcon subsets were analyzed by using multicolor flow cytometry. Mann-Whitney test was used for statistical analyses.
Results: Frequencies of FoxP3+CD127lo Treg among CD3+CD4+T cells were higher in pSS compared to PM/DM patients ($p<0.001$) and to HC ($p<0.05$). However, in both, PM/DM and pSS patients, frequencies of CD25+ cells among FoxP3+CD127lo Treg were significantly lower compared to HC (PM/DM: $p<0.05$, pSS: $p<0.0001$), while the frequencies of Helios+ cells among the CD25- Treg subset were substantially higher in pSS patients compared to DM/PM and HC (both $p<0.001$). Conversely, we found lower frequencies of CXCR5+ follicular Treg only in PM/DM patients ($p<0.05$). In parallel, there were higher frequencies of CD45RO+CCR7- effector/memory cells ($p<0.01$) and of Ki67+ proliferating cells ($p<0.05$) among CD3+CD4+FoxP3- Tcon in pSS patients compared to HC, which was not observed in PM/DM patients.
Conclusion: The loss of the CD25+ Treg subset in PM/DM and pSS patients is similar to previous findings in SLE patients[1] and represents a hallmark of IL-2 deficiency. This suggests that shortage of IL-2 is pathophysiologically relevant also in PM/DM and pSS providing a rationale for low-dose IL-2 therapy in these diseases. In addition, activation and expansion of effector/memory Tcon appears to be more pronounced in pSS compared to PM/DM. The different distribution of Treg and of Tcon subsets between pSS and PM/DM patients might reflect differences in the availability of IL-2 and in the regulation of Tcon responses in these diseases.

AB0029 CIRCULATING CD39+ TREG CELLS IN EARLY RHEUMATOID ARTHRITIS FACILITATE THE ANTIINFLAMMATORY ACTION OF METHOTREXATE AND SERVE AS EARLY BIOMARKERS OF CLINICAL RESPONSE

A. Villalba[1], L. Nuño[1], M. Benito-Miguel[2], I. Monjo[1], M. Novella-Navarro[1], D. Peiteado[1], S. García-Carazo[1], A. Balsa[1], M. E. Miranda-Carus[1]. *[1]Hospital Universitario La Paz -IdiPAZ, Rheumatology, Madrid, Spain; [2]Universidad de Nebrija, Physiology. Centro de Ciencias de la Salud San Rafael. Fundación San Juan de Dios., Madrid, Spain*

Background: FoxP3+ regulatory CD4+ T cells (Tregs) are key to the homeostasis of the immune system [1-3]. Stressed cells at inflammatory foci release adenine nucleotides to the extracellular space[4] that can act as enhancers of inflammation[4] but are rapidly hydrolysed by the sequential action of ectonucleotidases CD39 and CD73 rendering the antiinflammatory agent adenosine[4]. CD39, the rate-limiting enzyme in this cascade, is highly expressed by a subset of human FoxP3+Tregs (Treg39+)[1-3]. Methotrexate (MTX), the first line of treatment in Rheumatoid Arthritis (RA)[4], inhibits AICAR transformylase which results in an enhanced release of extracellular adenine nucleotides[4] to be metabolized by Treg39+ cells; hence MTX may cooperate with Treg39+ cells in the control of inflammation.
Objectives: To examine the relation of CD39 expression on Treg cells of early RA (ERA) patients with the ex vivo and in vivo effect of MTX.
Methods: Peripheral blood was obtained from 63 DMARD- and steroid- naïve ERA patients with a disease duration < 24 weeks and 63 age and gender-matched healthy controls (HC). 33 ERA patients donated blood again 12 months after initiating MTX (ERA-R). The frequency of Treg and Treg cell subsets was assessed by flow cytometry. CD4+CD25+CD127- (total T reg), CD4+CD27+CD127-CD39+ Treg (Treg39+) and CD4+CD25-CD39- responder T (Tresp39-) cells were isolated by sorting. The suppressor potency of Tregs was determined in cocultures of isolated Tregs with Tresp. Proliferation was determined by CFSE dilution; cytokine secretion was measured by ELISA of culture supernatants. Disease activity was assessed using the DAS28-ESR score. Low disease activity (LDA) was defined as a DAS28 ≤ 3.2.
Results: The proportion of Tregs that expressed CD39 (Treg39+) was significantly increased in ERA. Total ERA Tregs were more potent suppressors than HC Tregs, and the difference was reduced by adenosine A2AR antagonists. In vitro, MTX further heightened the total Treg cell potency, with greater amplification in ERA vs HC and this was also reversed by A2AR antagonists. The potency of isolated Treg39+ and its enhancement by MTX were comparable for ERA and HC; the potency of isolated Treg39- was inferior to that of Treg39+ cells in both groups of subjects and was not modified by A2AR antagonists; this further suggests that the differences observed in assays using total Tregs are due to the increased ERA Treg39+ frequency. Patients who achieved LDA had significantly higher basal frequencies of Treg39+ cells and multiple logistic regression (OR 1.93, 95% CI 1.33-4.51) showed that this was independent of basal disease activity, RF or ACPA titres. The Receiver Operating Characteristic (ROC) analysis area under the curve (AUC) was 0.97 (0.94-0.99) for Treg39+ cells. The relative risk (RR) of achieving LDA for patients with a cTreg39+ frequency above the p75 value observed in HC was 13.4 (2.9-75.6) (Fisher's exact test). The proportion of Treg39+ significantly decreased in all patients whether they had or not achieved LDA, and the frequency and function of ERA-R Treg cells were not different from HC. In fact, 12 months after initiating treatment with MTX, the circulating Treg39+ cell frequency was no longer elevated in ERA; however, its association with the clinical response remained: the cTreg39+ cell frequency observed at 12 months was still significantly higher in those patients who had achieved LDA. This suggests that Treg cell expression of CD39 is upregulated during the initial stages of ERA as a negative feedback mechanism of inflammation.
Conclusion: MTX cooperates with Treg39+ cells to control inflammation and the pretreatment Treg39+ frequency in ERA is associated with the clinical response to MTX at 12 months.

AB0030 THE BIOLOGICAL FUNCTION AND MECHANISM EXPLORATION OF TACI IN SJOGREN'S SYNDROME

H. Zhang[1], H. Zhang[1], D. Gao[1], L. Ji[1], Z. Zhang[1]. *[1]Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China*

Background: primary Sjogren's syndrome (pSS) is a chronic autoimmune disease that affects the lacrimal, salivary and other exocrine glands. More and more studies have shown that B cells play a central role in the pathogenesis of SS.
Objectives: We intended to explore the expression of the transmembrane activator, calcium modulator and cyclophilin ligand interactor (TACI) on the B cells, its role in pSS, and possible signal transduction pathways.
Methods: We included 34 naive pSS patients who visited the rheumatology department of Peking University First Hospital, and 37 gender- and age-distribution matched healthy controls (HCs). (1) To compare the B cell subsets, expression of TACI and relevant receptors in pSS patients, peripheral blood mononuclear cells were separated to analyze the ratio of B subsets, TACI, and BAFF-R by flow cytometry; ELISA was applied to detect the serum BAFF and soluble TACI (sTACI) concentration. (2) As for functional research of TACI, CD19+ B cells separated by magnetic sorting were treated under in vitro culture circumstances with raw TACI, TACI knocked down by siRNA, and sTACI analog (telitacicept) intervention with varing doses. The apoptosis, proliferation, differentiation and regulatory capacity on T cells were analyzed by flow cytometry, inflammatory cytokines and immunoglobulin levels in the culture supernatants were detected by CBA. (3) As for TACI-associated signaling pathway exploration, based on our previous miRNA data and relevant report of high quality, miRNA associated with

TACI with significantly biased expression was confirmed by RT-qPCR. Screening the target gene of the candidate miRNA, and miRNA overexpression and inhibition experiments were conducted to validate the targeted relationship in B cells. And TACI-associated signaling pathway was explored via overexpressing and inhibiting the target gene.

Results: (1) Compared to HC, peripheral blood B subsets of pSS patients exhibited a significant bias, manifesting as increased proportion of CD19+CD24hiCD38hi Breg and decreased ratio of CD19+CD24+CD38- memory B cells. The expression of TACI in all B subsets was down-regulated, while that of BAFF-R was up-regulated. Both the serum concentration of BAFF and sTACI in pSS patients increased significantly. (2) As for functional research of TACI, in the setting of raw TACI, B cells in the pSS group showed higher apoptosis rate than HC under culture in vitro, where the ligand of TACI (APRIL or BAFF) addition turned the rate comparable; more active proliferation, and impaired capacity of inducing Treg cells to secrete IL-10. When TACI was knocked down by 50%, B cells performed less late apoptosis, significantly increased proliferation, impaired differentiation, significant dysfunction of Breg itself and impaired induction of Treg cells to secrete IL-10. While telitacicept intervention increased early apoptosis rate of B cells, significantly inhibited proliferation in 500ng/mL group and impaired ability of Breg and Treg cells to secrete IL-10. Besides, increased TACI on B cells treated with telitacicept, decreased IgG and increased IgA in the culture supernatants were observed. (3) As for TACI-associated signaling pathway exploration, hsa-miR-30b-5p showed satisfactory correlation between both transmembrane and sTACI. Besides, the expression of hsa-miR-30b-5p was significantly down-regulated, and inhibition its expression in vitro could lead to differentiation retard, impaired secretion of IL-10 by Breg cells. SMAD1 was screened based on database and validated as its target gene by overexpressing and inhibiting hsa-miR-30b-5p in B cell. After targeted up- or down-regulating the transcription of SMAD1 further, the transcription of ID2 downstream the TGF-β/Hippo signaling pathway changed accordingly.

Conclusion: The expression of TACI on peripheral blood B cells was deficient in pSS patients. TACI deficiency was closely associated with the downregulation of hsa-miR-30b-5p, activating TGF-β/Hippo pathway mediated by its target gene SMAD1 and taking part in the pathogenesis of pSS.

AB0031 DEEP IMMUNE PHENOTYPING OF SLE AND RA BY MACHINE LEARNING

B. Prietl[1,2], J. Vera-Ramos[1], L. Herbsthofer[2], V. Pfeifer[1,2], P. Lopez-Garcia[1], H. P. Brezinsek[3], T. R. Pieber[1,2], M. Stradner[3]. *[1]Medical University of Graz, Division of Endocrinology and Diabetology, Graz, Austria; [2]Center for Biomarker Research in Medicine, Area Data and Technologies, Graz, Austria; [3]Medical University of Graz, Division of Rheumatology and clinical Immunology, Graz, Austria*

Background: Breakdown of self-tolerance is an important common mechanism in autoimmunity. Despite considerable clinical heterogeneity, many autoimmune diseases exhibit common immunological mechanisms leading to a breakdown of self-tolerance. Identification of unique and similar patterns across different autoimmune disease may help to understand their pathophysiology behind.

Objectives: Establishing workflows for the multi-parameter deep immune phenotyping of T- and B-cells by unsupervised machine learning (ML) methods for feature extraction, cluster analysis and anomaly detection.

Methods: We use machine learning to identify common patterns and dissimilarities between type 1 diabetes (T1D, n=69), rheumatoid arthritis (RA, n=63), systemic lupus erythematosus (SLE, n=38) and healthy controls (n=69) samples based on multi-plex immune phenotyping. PBMCs were isolated from patients with T1D, RA, SLE, and controls. A flow cytometry-based approach was applied, and a traditional analysis was compared to a ML method implemented in R [1] and based on self-organizing maps (Figure 1). Our pipeline includes unsupervised pre-gating, normalization, FlowSOM clustering [2], and a statistical model

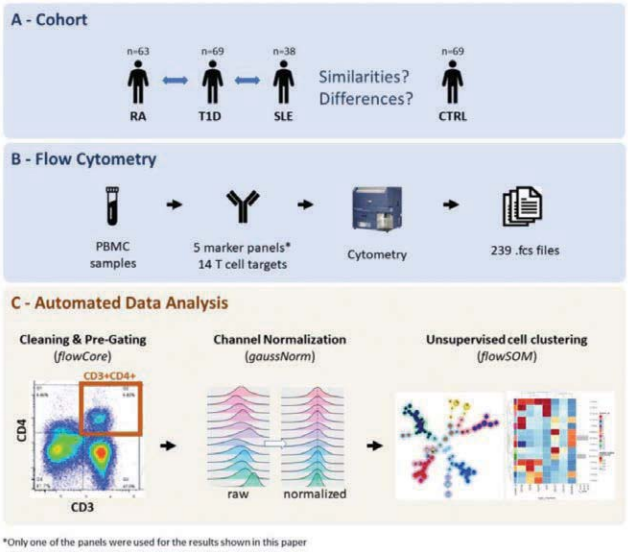

Figure 1.

(GLMM), to check for significant differential abundances of cell populations among the autoimmune conditions.

Results: After applying our automated workflow to one T cell panel we could identify 14 cell clusters present in all the samples. The GLMM test revealed a cluster with a significant difference (p=0.035) and a trending one (p=0.059) on the abundance across the different diseases. In particular, $CD4^{pos}$ T cells expressing high IL-7 receptor (CD127) levels and median amounts of CD15s but low CD25, CD161 and FoxP3 are increased in T1D whereas $CD4^{+}CD25^{++}CD15s^{+}FoxP3^{low-}CD161^{low}CD45RA^{-}$ cells are increased in SLE.

Conclusion: This unbiased, unsupervised ML workflow was able to identify canonical and novel clusters of T cells that are similar in RA, SLE and T1D. Additionally, a novel memory T cell population expressing CD15s was shown. This unsupervised analysis approach for large datasets enables the discovery of new immune cell populations complementing traditional workflows.

AB0032 CHARACTERIZATION OF PERIPHERAL BLOOD B-CELL SUBSET IN UNTREATED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS

E. Gerasimova[1], D. Tabakov[2], A. Aleksankin[2], R. Shayakhmetova[3], T. Popkova[1], A. Avdeeva[2]. *[1]V.A.Nasonova Research Institute of Rheumatology, Department of systemic rheumatic disease, Moscow, Russian Federation; [2]V.A.Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation; [3]V.A.Nasonova Research Institute of Rheumatology, Laboratory of Systemic Sclerosis, Moscow, Russian Federation*

Background: B-cells play a critical role in the regulation of systemic autoimmune diseases pathogenesis, that extends beyond antibodies production.
Objectives: To examine B-cell subsets in peripheral blood of patients (pts) with untreated systemic lupus erythematosus (SLE) and systemic sclerosis (SSc), to analyze of their associations with disease-specific autoantibodies.
Methods: Thirty six untreated SLE pts (31F/5M) and 32 untreated SSc pts (25F/7M) were enrolled. SLE pts had median age of 37(range)(32-41)years, disease duration of 3.5(1-11)years, SLEDAI 2K of 7(4-8), BILAG of 14,5(10,2-23). SSc pts had median age of 42(38-50)years, disease duration of 3.5(1-10) years, Disease Activity EScSG of 2.5 (1-3.2). The control group consisted of 29 volunteers (23F/6M, median age 38(35-48)years. CD19+B cells, memory B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD-), non-switched memory B cells (CD19+CD27+IgD+), naive (CD19+CD27-IgD+), double-negative (CD19+CD27-IgD-), transitional (CD19+CD38++CD10+IgD+CD27-) B cells, and plasmablasts (CD19+CD38+++CD27+IgD-CD20-) were analyzed using multicolor flow cytometry.
Results: Differences in the median percentage and of absolute B-cells subset levels in untreated pts with RA and SLE were not found. The absolute counts of memory B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD-), transitional B cells (CD19+CD38++CD10+IgD+CD27-), and plasmablasts (CD19+CD38+++CD27+IgD-CD20-) were higher in SLE and SSc pts compared to healthy donors, p<0,01 for all cases. The absolute counts of double-negative B cells (CD19+CD27-IgD-) were lower in SLE pts than in donors, p=0,03 (Table 1). At significant correlation was found in SLE pts between anti-dsDNA levels and absolute counts of the following B-cell subtypes: CD19+B cells (r=0,72), memory B cells (CD19+CD27+) (r=0,76), switched memory B cells (CD19+CD27+IgD-) (r=0,75) and naive B cells (CD19+CD27-IgD+) (r=0,73); the a-Sm levels and absolute counts of the switched memory B cells (CD19+CD27+IgD-) (r=0,51); the antibodies to cardiolipin (aCL) IgG levels and absolute counts of CD19+B cells (r=0,64), and with naive B cells (CD19+CD27-IgD+) (r=0,59), p<0,01 for all cases. There was a correlation between the anti-topoisomerase-1 antibodies (a-Topo-1) and the absolute counts of double-negative B cells (CD19+CD27-IgD-) (R=0,62, p=0,01) in SSc pts.

Table 1. Levels of the blood B-cell subsets in SLE pts, SSc pts and in control.

Parameters, n (x10^9/l)	SLE	SSc	Control group

plasmablasts (CD19+CD38+++CD27+IgD-CD20-)	0,001 (0,001-0,002) *	0,001 (0-0,002) *	0,0001 (0,00006-0,0003) *

Note: * - Differences in B-cell subset of the control group with SLE and SSc groups.

Conclusion: Immunophenotyping showed similar levels of B-cell subset in untreated SLE and SSc pts, an increase in the absolute counts of memory B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD-), transitional B cells (CD19+CD38++CD10+IgD+CD27-), and plasmablasts (CD19+CD38+++CD27+IgD-CD20-) in untreated SLE and SSc pts compared with healthy subjects. Positive correlation between the counts of B-cell subsets and values of disease-specific autoantibodies (anti-dsDNA, a-Sm, aCLIgG, a-Topo-1) suggests that B-lymphocytes may be involved in SLE and SSc pathogenesis.

Background: Systemic lupus erythematosus (SLE) and primary Sjogren's syndrome (pSS) are chronic autoimmune diseases with complex pathogenesis. T-lymphosytes are known to be prime effectors of autoimmune diseases, while B-lymphosytes play a key role as sources of antibodies and antigen presenting cells. Considering the implications of T- and B-cells in the pathophysiology of SLE ans pSS, the assessment of their distribution in the blood could be helpful in the complex process of determining a precise diagnosis.
Objectives: The study aimed to compare composition of peripheral blood T- and B-cell subsets and investigate their diagnostic utility in patients with SLE and pSS.
Methods: The study was performed with 37 patients suffering from SLE, 57 patients with pSS, and 49 apparently healthy volunteers (HVs). The diagnosis of SLE was performed according to the 2019 EULAR – ACR classification criteria, the diagnosis of pSS- according to the 2016 EULAR – ACR criteria. 11 patients in pSS group met the criteria for both pSS and SLE. The relative distribution and percentage of T- and B-cell subsets were evaluated by flow cytometry. T helper (Th) and cytotoxic T-cell subsets (Tcyt) were identified by using CD3, CD4, and CD8 antibodies. Regulatory T cells (Tregs) were characterized by the expression of CD3, CD4, and high IL-2R alpha chain (CD25high) levels. All peripheral blood B-cells were identified by using CD19 antibody, detection of subpopulations of B cells based on expression of IgD, CD38, CD27. The absolute and relative values of B-lymphocyte subpopulations were evaluated using three main classifications: based on IgD / CD38 expression (classification Bm1-Bm5), co-expression of IgD / CD27 and CD38 / CD27. The statistical analysis of data was performed with STATISTICA Version 12.0 Inc. Method of discriminant analysis was performed to evaluate diagnostic utility of relative values of T- and B-cell subsets.
Results: In the discriminant model the top significance was documented while assessing the percentage of naive B-cells (Bm1, IgDdimCD38low), germinal center B-cells (Bm 3+Bm4, IgDlowCD38hi), naive B-cells (IgDdimCD27low), unswitched memory B-cells (IgDdimCD27dim), naive mature B-cells (CD27dimCD38low), transient B-cells (CD27lowCD38hi), all T-cells (CD3hi), Tregs (CD3hiCD4hiCD25hi), Tcyt (CD3hiCD8hi) and Th (CD3hiCD4hi), model percent correct was 78%, p <0,05. The discriminant function was either f1 for distinguishing HVs versus ill patients SLE and pSS (all participants are accounted) or f2 for SLE versus pSS (only participants with disease are accounted). During ROC analysis, performed for the differential diagnosis of healthy and sick patients, this discriminant model had a sensitivity of 86,5% and a specificity of 72,8%, the area under the curve (AUC) 0.94, p <0.001. Among the group of ill patients, the differential diagnosis between SLE and pSS had a sensitivity of 69,6% and specificity of 64,8%, AUC 0.87, p <0.001. Graphic representation of the discriminant analysis is performed on Figure 1. The group of patients, meeting the criteria for both pSS and SLE, is between the main groups.

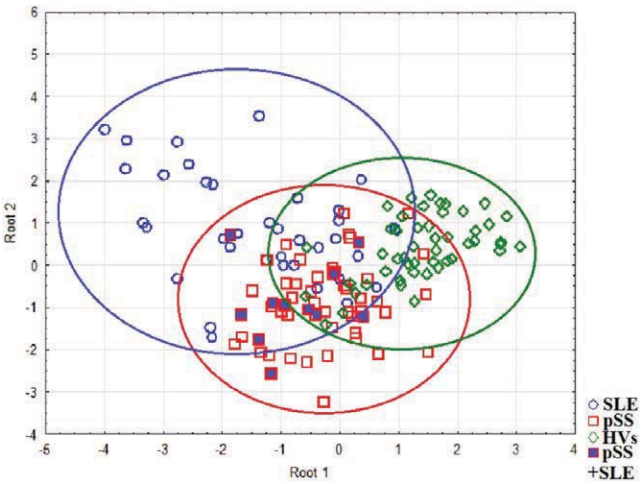

Figure 1. Graphic distribution of SLE, pSS and pSS+SLE patients, as well as HVs analyzed by discriminant analysis.

Conclusion: T- and B-cell peripheral blood subsets might provide an additional diagnostic tool for distinction SLE, pSS and HVs. Differential diagnosis between pSS and SLE is difficult, because this diseases may coexist.

AB0034 INVESTIGATING THE ROLE OF ACCELERATED IMMUNESENESCENCE IN THE PATHOGENESIS OF RHEUMATOID ARTHRITIS

N. Duggal[1], K. Raza[2], A. Sharma-Oates[3], N. Rivera[4], L. Padyukov[4], A. Pratt[5], E. Niemantsverdriet[6], A. van der Helm-van Mil[5], S. Jones[2], J. Lord[2]. *[1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom; [2]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom; [3]School of Biosciences, University of Birmingham, Birmingham, United Kingdom; [4]Department of Medicine, Karolinska Institute, Solna, Sweden; [5]Faculty of Medical Sciences, University of Newcastle, Newcastle, United Kingdom; [6]Department of Rheumatology, Leiden University, Leiden, Netherlands*

Background: Advancing age is recognised as a major risk factor for autoimmune inflammatory conditions, such as Rheumatoid Arthritis (RA). Despite strong associations with older age we understand little of the role ageing processes play in disease pathogenesis in RA. The immune system undergoes a dramatic remodelling with age, termed immunesenescence, which contributes towards increased risk of autoimmunity[1]. Previous research in patients with established RA has shown certain features of immunesenescence, such as thymic atrophy and telomere shortening in T cells, at a younger age[2,3].

Objectives: In this study we aimed to determine if immunesenescence is seen in the very earliest stages of RA and therefore might be a contributor to RA pathogenesis rather than a result of the disease.

Methods: We have assessed aspects of the aged immune phenotype by immunostaining and flow cytometry[4] in adults with arthralgia (n=25), undifferentiated arthritis (UA; n=41), confirmed RA of less than 3 months (n=25) and more than 3 months duration (n=78) and compared these to age and sex matched healthy controls (n=38). Nanostring methodology was used to determine gene expression changes associated with the development of RA.

Results: We observed increased features of T and B cell immunesenescence in DMARD-naïve recently diagnosed RA patients driven by reduced naïve T cells ($p<0.01$) and B cells ($p<0.01$), increased senescent (CD28-ve, CD57+ve, KLRG1+ve) T cells ($p<0.01$), an increased Th17/Treg ratio ($p<0.01$) and increased frequency of age-associated B cells ($p<0.01$). With the exception of naïve T cell frequency, which was reduced in UA patients ($p<0.05$), these changes were not seen in the very early stages of RA, namely patients with arthralgia and UA. These data suggest that immunesenescence only occurs once disease is established. Furthermore, using nanostring we have identified several biological ageing processes (DNA damage, autophagy) associated with this state of immunesenescence in RA.

Conclusion: Accelerated immune ageing is an early feature of RA and biological ageing processes represent novel targets to modulate disease progression.

AB0035 FREQUENCY OF LYMPH NODE STROMAL CELLS HLA-DR+ IS REDUCED IN INGUINAL LYMPH NODES FROM HUMAN DONORS WITH RHEUMATOID ARTHRITIS COMPARED TO CONTROLS

C. Grasso[1]. *[1]Amsterdam Medical Center, Experimental Immunology, Amsterdam, Netherlands*

Background: Rheumatoid arthritis (RA) is an autoimmune disorder where the immune system gradually damages a wide variety of body systems, including the skin, eyes, lungs, heart, and blood vessels[1]. Animal studies have shown that lymph node stromal cells (LNSCs) are key players in peripheral tolerance through their capacity to present self-antigen to T cells thereby controlling auto reactivity and regulating autoimmunity and humoral response[4,5]. Although self-antigen presentation by human LNSCs needs to be formally proven in human, this study speculates that malfunctioning LNSCs might be associated with loss of tolerance in autoimmune diseases like RA.

Objectives: The objective of this study is to assesses and compare the frequency of main LNSC subsets in human lymph node needle biopsies of healthy controls, autoantibody positive individuals at risk of developing RA (RA-risk) and RA patients. We especially focussed on markers for antigen presentation expressed by LNSCs.

Methods: RA at risk, RA and healthy (n=1) participants underwent an ultrasound-guided inguinal LN needle core biopsy as previously described[6]. We included RA-risk participants (n = 6) with elevated IgM-RF and/or ACPA levels, but without any evidence of arthritis upon examination; RA patients (n =13) with established disease based on fulfilment of the American College of Rheumatology and European League Against Rheumatism (ACR/EULAR) 2010 criteria as assessed by the rheumatologist. For comparison we included healthy participant (n = 17) The healthy control was without any joint complaints and without elevated IgM-RF and/or ACPA level and without active viral infection or any history of autoimmunity or malignancy. To increase the number of healthy participants in the control group, we included lymph node biopsies from individuals receiving a kidney transplant (n= 16). After collection, tissue samples were enzymatically digested to obtain a single cell suspension, followed by flowcytometry analysis with the following cell surface markers CD40, CD80, CD86, PD-L1, HLA-DR, CD45, PDPN, CD31, CD235a, Viability dye.

Results: Antigen presentation related co-stimulatory molecules (CD40, CD80, CD86, PD-L1) and HLA-DR were detected at low levels. Blood endothelial cells having the highest expression of HLA-DR followed by LECs, FRCs, DNs. WE observed a reduced frequency of HLA-DR+ lymph node stromal cell (CD45-, CD235a-) in RA and at RA at risk compared to control. After we found that FRCs, DNs, and BECs were reduced in RA and RA at risk compared to healthy control population.

Conclusion: Our findings show that the frequency of HLA-DR positive LNSCs is lower in RA-risk individuals and RA patients compared to controls. As HLA-DR is crucial to present self-antigens and promote self-tolerance, it will be of interest to investigate whether the antigen presenting capacity of LNSCs is diminished already before onset of disease and how we could restore this.

Innate immunity in rheumatic diseases

AB0036 BUTYRIC ACID SUPPRESSES MIGRATION OF MONOCYTE-DERIVED DENDRITIC CELLS BY INHIBITING MDIA1-MEDICATED ACTIN POLYMERIZATION

T. Nagamoto[1], T. Okano[1], Y. Fujikawa[1], Y. Ueda[1], H. Yamada[1], S. Sendo[2], J. Saegusa[1]. *[1]Kobe University, Rheumatology, Kobe, Japan; [2]University of California, Medicine, San Diego, United States of America*

Background: Butyric acid is known to improve chronic inflammation such as inflammatory bowel disease and arthritis [1, 2]. Dendritic cells activate in inflammatory condition, migrate to regional lymph nodes, and activate naive T cells.
Objectives: In this study, we investigated the effect of butyric acid on the migration ability of monocyte-derived dendritic cells (moDC).
Methods: Human CD14+ Monocytes were purified by positive selection from PBMC using CD14 magnetic beads. Cells were cultured in the presence of GM-CSF (50 ng/ml) and IL-4 (20 ng/ml) for 5 days. After culturing for 5 days, cells were matured with LPS (1ug/ml) for 24 hours. Butyric acid was administered at different dose or period. Surface antigen on moDC was analyzed by flow cytometry (BD FACS VERSE). Migration assay was performed on Boyden chamber CytoSelect 24-Well Cell Migration Assay (5um). Actin was stained with Alexa Fluor 488 Phalloidin before and after migration assay. After administration with butyric acid assigned to each period and concentration, moDC were lysed for western blot analysis for evaluating signaling. Chemiluminescent signals were detected and calculated by Amersham Imager.
Results: We demonstrated that butyric acid decreased the CCR7 expression of moDC, which has a key role in DC homing to the lymph nodes and intestinal Peyer's patches. We also showed that butyric acid decreased the migration ability of moDC. Furthermore, moDCs cultured with butyric acid showed a round shape and poor formation of dendrites and pseudopodia. Then we studied the effect of butyric acid on cytoskeleton, which plays an important role in migration and pseudopodia formation of DCs. Polymerized Actin (F-Actin) staining revealed that butyrate suppressed actin polymerization of moDC in a dose dependent manner. CDC42 works important role of lamellipodia and membrane protrusions. RhoA is upstream of mDia1, and mDia1 was reported to accelerate actin nucleation and elongation. We revealed that butyrate decreased the protein expression of mDia1, RhoA, and CDC42, while beta actin was not downregulated, by Western blot analysis. Our results suggested that butyric acid suppresses migration of moDCs by inhibiting mDia1-medicated actin polymerization.
Conclusion: Butyric acid suppresses migration of moDCs by inhibiting mDia1-medicated actin polymerization.

AB0037 APE1 REGULATES THE MIGRATION OF FIBROBLAST-LIKE SYNOVIOCYTES FROM PATIENTS WITH RHEUMATOID ARTHRITIS

H. R. Lee[1,2], J. Kim[2], S. J. Yoo[1,2], J. A. Park[2], H. K. Joo[1,3], Y. R. Lee[1,3], S. Kim[1,3], B. H. Jeon[1,3], S. W. Kang[1,2]. *[1]Chungnam National University School of Medicine, Research Institute for Medical Sciences, Daejeon, Korea, Rep. of (South Korea); [2]Chungnam National University Hospital, Department of Internal Medicine, Daejeon, Korea, Rep. of (South Korea); [3]Chungnam National University, Department of Physiology, College of Medicine, Daejeon, Korea, Rep. of (South Korea)*

Background: The level of apurinic/apyrimidinic endonuclease 1 (APE1) is elevated in synovial fluids from patients with rheumatoid arthritis (RA). However, the role of APE1 in RA pathogenesis remains unclear.
Objectives: To explore whether APE1 affects cell migration through reactive oxygen species (ROS) level, fibroblast-like synoviocytes (FLS) from patients with RA were stimulated with human recombinant APE1.
Methods: Synovial tissues were obtained from RA patients who were undergoing synovectomy or joint replacement. The isolated cells were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum and maintained in a 5% CO_2 incubator at 37 °C. FLS were used for experiments after three to six passages. Cells were stimulated with or without recombinant interleukin 17 (IL-17; 10 ng/ml), tumor necrosis factor alpha (TNF-α; 10 ng/ml), and long-lasting recombinant human APE1 (MR201; 1, 10, 100 ng/ml) for 24 h. ROS levels were analyzed using MitoSOX dye. Cell migratory ability was examined using wound migration assay.
Results: RA FLS treated with APE1 showed slightly decreased level of mitochondrial specific ROS. To induce pro-inflammatory conditions, RA FLS were incubated with IL-17 and TNF-α. These cytokines are highly detected in RA synovium and directly stimulate FLS activation. Stimulation with IL-17 and TNF-α upregulated ROS by 30% compared to control. Cytokines-induced increase of ROS was inhibited by 22% in APE1 treatment. When FLS cultures were approximately 90% confluent, FLS monolayers were wounded with pipette tips and treated with IL-17/TNF-α and APE1 for 24 h. Cell migration was increased after treatment with IL-17/TNF-α. Cytokines-induced cell migration was remarkably attenuated by APE1 treatment.
Conclusion: Recombinant APE1 markedly inhibited mitochondrial specific ROS production and IL-17/TNF-α-induced cell migration in RA FLS.

AB0038 DUAL TARGETING PEPTIDE RLS-0071 REDUCES AND INHIBITS MYELOPEROXIDASE (MPO) IN HEALTHY HUMAN VOLUNTEER

P. Kumar[1], K. Cunnion[1], N. Krishna[1], U. Thienel[1], P. Hair[1], J. Goss[1], C. Gabriel[2]on behalf of ReAlta Life Sciences. *[1]ReAlta Life Sciences, Research, Norfolk, United States of America; [2]Children's Hospital of The King's Daughters, Rheumatology, Norfolk, United States of America*

Background: RLS-0071-101 was a first in human clinical trial to evaluate safety of the peptide RLS-0071 in healthy volunteers in a single ascending dose and multiple ascending dose format. RLS-0071, previously referred to as Peptide Inhibitor of Complement C1 (PIC1) is a dual-targeting peptide being developed for clinical use to moderate humoral and cellular inflammation via inhibition of complement activation and neutrophil effectors including myeloperoxidase (MPO) and Neutrophil extracellular trap formation (NETosis).[1,2] Humans that are otherwise asymptomatic are considered at risk for cardiovascular complications if they have a plasma MPO level of > 420 pmol.[3] A post hoc analysis of plasma samples from subjects participating in RLS-0071-101 identified an individual with mildly elevated baseline MPO level (142 pmol/L).
Objectives: Evaluate if RLS-0071 dosing would change MPO level or activity in a subject with elevated baseline MPO.
Methods: Frozen plasma samples prepared from blood collected by venipunture into K2EDTA tubes (BD) was utilized to determine MPO quantity and activity levels. MPO quantity in the plasma was analyzed using a human MPO ELISA kit (BMS2038INST, Invitrogen) and MPO activity within the plasma was analyzed using a fluorescence-based myeloperoxidase assay kit (K745-100, BioVision).
Results: Upon screening 54 subjects from RLS-0071-101 we identified one individual with a mildly elevated MPO level at baseline, a 21-year-old white female with BMI of 21.7. The subject received 9 intravenous infusions of RLS-0071 each at a dose of 10 mg/kg. Her vital signs and body temperature remained normal

throughout the study and the only blood laboratory abnormality were a mildly low plasma protein concentration of Day 2 and Day 4 which was noted both among recipients of the peptide and placebo subjects. Analysis of MPO blood concentrations demonstrated a mildly elevated baseline plasma MPO concentration that decreased after multiple doses of RLS-0071 with partial recovery to baseline 24 hours after cessation of dosing. MPO activity analyzed using a fluorescence-based myeloperoxidase assay kit demonstrated an elevated baseline plasma MPO activity level that decreased after multiple doses of RLS-0071 with partial recovery after 24 hours.

Conclusion: These results suggest promise for RLS-0071 to reversibly moderate plasma MPO activity and potentially affect MPO-mediated diseases including acute coronary syndrome (ACS), atheromatous plaque vulnerability and auto immune conditions.4,5,6,7.

AB0039 MONOCYTE EXTRACELLULAR TRAPS: A NEW POTENTIAL DIAGNOSTIC BIOMARKER IN RHEUMATOID ARTHRITIS?

I. Zborovskaya[1], S. Bedina[1], E. Mozgovaya[1], A. Trofimenko[1], M. Mamus[1], S. Spitsina[1]. *[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical biochemistry lab, Volgograd, Russian Federation*

Background: Studies demonstrating the important role of neutrophil extracellular traps (NETs) in the pathogenesis of autoimmune diseases, including rheumatoid arthritis (RA), have been published extensively in recent years. The researchers are also discussing the possibility of considering NET as a source of potential diagnostic biomarker in RA. As compared with NETs, the monocyte extracellular traps (METs) formation by mononuclear phagocytes, although they have also been implicated in the development of autoimmune reactions, has been studied insufficiently. No studies have been reported on the MET formation in active RA patients.

Objectives: Assesssment of METs generation by peripheral blood monocytes from RA patients in association with the disease exacerbation.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles after the local ethical board approval. Circulating monocytes were isolated with one-step density gradient centrifugation using double layers of the in-lab-made ficoll-amidotrizoate gradient. Composition of isolated cellular fractions, their viability, and non-specific activation were evaluated by light microscopy using common Romanowsky-Giemsa staining, trypan blue exclusion test as well as NBT test. METs were induced by LPS. Monocyte fractions contained low extents of activated and dead cells. Spontaneous and induced formation of extracellular traps was assessed using fluorescence microscopy [1]. Results were presented as values (95%CI).

Results: 30 healthy volunteers (9 males and 21 females, mean age 37.2 years) were enrolled as a reference group. 37 patients (6 males and 31 females, mean age 42.7 years) with verified RA according to the ACR/EULAR 2010 criteria were included in the study. RA disease activity was assessed using DAS28 score did not exceeded 2.6 in every patient at the inclusion timepoint. In 16 (15.4%) patients, the activity of DAS 28 exceeded 3.2 at subsequent visits (after 3, 8 and 12 months). Spontaneous and induced MET formation by isolated monocytes in RA patients (DAS 28<2.6) was 8.7 (8.3-9.1)% and 26.2 (24.5-27.9)%, respectively. Spontaneous and induced MET formation by isolated monocytes in RA patients (DAS 28>3.2) was 18.1 (17.8-18.4)% and 38.2 (38.0-38.4)%, respectively. Spontaneous and induced MET formation by isolated neutrophils in active RA patients (DAS 28>3.2) was significantly higher than in inactive RA patients and in comparison to the reference group. Induced MET formation was also significantly higher than spontaneous one ($p<0.05$). Monocytes did not demonstrate any difference between ACPA-positive and ACPA-negative RA patients in their MET production. The growth rate of spontaneous MET formation was 114.7%, for induced MET formation – 44.2%. The growth rate of spontaneous MET formation is 2.6 times higher than the induced MET formation.

Conclusion: METs formation by isolated monocytes can be considered as a new potential diagnostic biomarker associated with RA flare. Further study of the mechanisms of MET formation and their composition may improve our understanding of the role of monocytes and METs in the pathogenesis of RA.

AB0040 STUDYING THE MACROPHAGE ACTIVATION AND THE INTIMA-MEDIA THICKNESS OF THE CAROTID ARTERIES IN UNTREATED PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS (PRELIMINARY DATA)

E. Gerasimova[1], T. Popkova[1], T. Kirichenko[2], A. Markin[2], I. Kirillova[3], A. Orekhov[2]. *[1]V.A.Nasonova Research Institute of Rheumatology, Department of systemic rheumatic disease, Moscow, Russian Federation; [2]Research Institute of Human Morphology,, Laboratory of Cellular and Molecular Pathology of the Cardiovascular System, Moscow, Russian Federation; [3]V.A.Nasonova Research Institute of Rheumatology, Laboratory of systemic rheumatic diseases, Moscow, Russian Federation*

Background: Autoimmune Rheumatic Diseases (ARDs) occur with a high risk of atherosclerosis development. The macrophages are at the same time a part of the inflammatory response, and also tightly linked to the foam cell formation, thus taking part in both crucial for atherogenesis processes.

Objectives: To evaluate the macrophage activation, and the intima-media thickness (IMT), subclinical atherosclerosis of the carotid arteries in untreated pts with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).

Methods: Thirty six untreated RA pts (30F/6M) and 36 untreated SLE pts (31F/5M) were enrolled.

RA pts had median age of 39 years (range) (33-45), disease duration of 2.5 years (1-5), moderate clinical disease activity DAS of 28 5.3 (3.5;5.8), SDAI of 17 (15;19), HAQ of 1 (0.75;1).

SLE pts had median age of 37 years (range) (32-41), disease duration of 3.5 years (1-11), SLEDAI 2K of 7 (4-8), BILAG of 14,5 (10,2-23).

Isolation of monocytes was carried out according to the standard procedure for obtaining a leukocyte fraction in a Ficoll gradient and subsequent selection of CD14 + cells using magnetic separation. After isolation, the cells were cultured in X-Vivo medium. To assess the degree of monocyte activation, cells were stimulated by the addition of LPS. The value of monocyte activation was expressed as a ratio of the level of secretion of proinflammatory cytokines by monocytes cultured with and without LPS addition. Secretion levels were determined by ELISA. The belonging of the isolated cells to CD14 + monocytes was additionally confirmed by flow cytometry. All pts undertook carotid duplex ultrasonography.

Results: Macrophage activation was 8.9 (range) (2.7;40.8) in RA pts and 4.8 (2.3;5.6) in SLE pts ($p=0.09$). In RA and SLE pts macrophage activation was independent of age, sex, body mass index, cardiovascular risk (CVR) factors (arterial hypertension, overweight, smoking, family history of cardiovascular diseases), activity scores (DAS28, SDAI, SLADAI 2K), and disease-specific autoantibodies levels.

In RA pts and SLE pts, the carotid mean IMT (m-IMT) was 0.66 ± 0.12mm and 0.61 ± 0.10mm, the maximum IMT (M-IMT) was 0.76 ± 0.16mm and 0.69 ± 0.14mm, respectively, $p>0.05$ in both cases. The prevalence of raised lesions (IMT>0.9 mm) were observed in 5 RA pts (14%) and 2 SLE pts (5%); the atherosclerotic plaques (ASP) (IMT ≥ 1.2 mm) – in 7 RA pts (20%) and 6 SLE pts

(17%). In RA pts, there was a significant correlation between carotid m-IMT and age (R=0.76), level of total cholesterol (R=0.51), LDL cholesterol (R=0.27), systolic blood pressure (R=0.71), diastolic blood pressure (R=0.78), aMCV levels (R=0.79), p<0,05 in all cases. No correlation between carotid m-IMT/M-IMT and the disease's duration, stage or activity was found in RA pts. In SLE pts, carotid m-IMT was associated with the mean SLICC/ACR Damage Index score (R=0.50, p=0.01), with antibodies to cardiolipin (aCL) IgG levels (R=0,42, p=0,02), and with antibodies to beta2-glycoprotein 1 (anti-beta2GP1) IgG levels (R=0.49, p=0.01). No correlation between carotid m-IMT/M-IMT and the traditional CVR factors and disease's activity was found in SLE pts. No association was found between the carotid m-IMT/M-IMT and macrophage activation.

Conclusion: No differences in macrophage activation were found in RA and SLE pts. Macrophage activation was independent of CVR and ARD-related factors. Subclinical atherosclerotic lesions of the carotid arteries were observed in a every fifth untreated RA and SLE pts. Carotid m-IMT correlated with traditional CVR factors in RA pts, and SLICC/ACR Damage Index score in SLE pts. Our results suggest that there is an association between carotid IMT and immunoinflammatory markers: aMCV in RA pts and antiphospholipid antibodies in SLE pts. A study on a larger number of pts will clarify the link between macrophage activation, autoimmune disorders and carotid atherosclerotic lesions.

THE PHENOTYPE OF PERIPHERAL BLOOD DENDRITIC CELLS OF PATIENTS WITH ADULT-ONSET STILL´S DISEASE COMPARED TO HEALTHY DONORS AND PATIENTS WITH PSORIATIC ARTHRITIS

S. Schnitte[1], T. Funk[1], J. Henes[2], S. Saur[2]. *[1]UKT, Department of Medical Oncology, Hematology, Immunology, Rheumatology and Pulmonology., Tübingen, Germany; [2]UKT, Rheumatology and Auto-inflammatory Diseases and Department of Internal Medicine II (Hematology, Oncology, Immunology and Rheumatology), Centre for Interdisciplinary Clinical Immunology., Tübingen, Germany*

Background: Adult-onset still´s disease (AOSD) is a rare autoinflammatory disease. A triad of high fever, arthritis and skin rash is described, but multiple forms of manifestation, as the lack of detectable biomarkers, aggravate making the diagnosis (1).

Psoriatic arthritis (PsA), another autoimmune disease with jointal manifestation, affects approximately 30% of all patients with psoriasis (2).

Dendritic cells (DCs) are potent antigen presenting cells linking adaptive and innate immunity. In various autoimmune diseases alterations of DCs were detected (4).

Objectives: The etiology and effect of peripheral blood DCs on the arthritis in both diseases is not cleared yet (1,3). This project tried to examine alterations of DCs in AOSD patients compared to those with PsA and a healthy control group (HC).

Methods: 13 patients with AOSD were analysed and compared.

Leukocytes were separated with density gradient centrifugation and sorted with flow cytometry. The contingent of DC subsets in the peripheral blood (pDCs, CD1c+DCs, CD141+DCs) was compared between AOSD patients and the other two groups (n=12).

Monocytes of the peripheral blood were incubated with IL-4 and GM-CSF to differentiate to DCs. The addition of lipopolysaccharides helped gaining immature (n=11) and mature (n=9) DCs. Their phenotype was characterized by CD1a, CD206, Osteoactivin (OA), CCR7, CD14, DC sign, CCR7, CD14, CD40, HLA-DR, CD80, CD83, CD86. The expression levels of the surface proteins were again compared.

Results: The DC subset rates did not differ significantly between AOSD patients and both other groups.

The surface markers showed a significant difference in expression of CD80 on mature DCs of AOSD patients and those with PsA. Immature DCs presented a significantly different level of OA on patients with AOSD and HCs. All other measured surface markers did not vary between the groups.

Conclusion: The DC subsets analysis did not show significant differences. An arthritic manifestation in AOSD might not depend on the fraction of DCs in the peripheral blood.

OA inhibits T cell responses strongly as coinhibitory molecule on antigen presenting cells. The lower expression of OA on DCs of patients with AOSD might represent a lower inhibition of T cells in comparison to HCs (5).

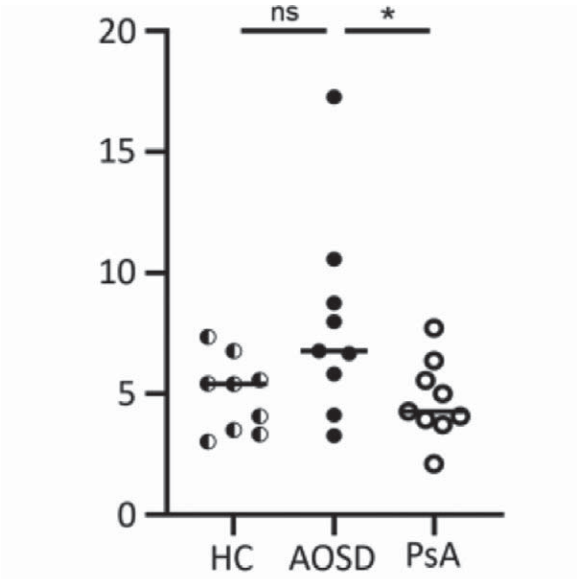

Figure 1: CD80 expression on mature DCs of patients with AOSD compared to patients with PsA is significantly different (p=0,04). HC does not express CD80 differently.

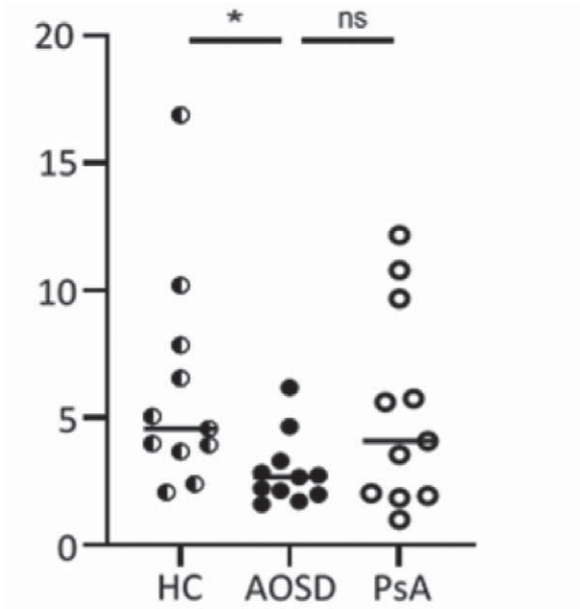

figure 2: OA expression on immature DCs is statistically different between HC compared to patients with AOSD (p= 0,0128). The expression levels of AOSD patients and those with PsA do not differ significantly.

The interaction of CD80 and CD86 with CD28 is necessary to produce IL-6. The pro-inflammatory effect is limited by CD80/ CD86 itself (6). CD80, in contrast to CD86, is expressed differently in patients with AOSD and PsA. As CD80 and CD86 function as cofactors, an alteration of both might have been expected.

AB0042 OPTIMAL CONDITIONS FOR THE DETECTION OF INFLAMMASOME ACTIVATION IN CD14+ CD16- MONOCYTES FROM HUMAN BLOOD BY FLOW CYTOMETRY

N. Wittmann[1], N. Mishra[2], A. K. Behrendt[1], L. Bossaller[2], A. Meyer-Bahlburg[1]. [1]*University Medicine, University of Greifswald, Pediatric Rheumatology, Department Pediatric and Adolescent Medicine, Greifswald, Germany;* [2]*University Medicine, University of Greifswald, Section of Rheumatology, Department of Medicine A, Greifswald, Germany*

Background: The inflammasome activation is linked to the aggregation of the adaptor protein ASC into a multimeric structure, known as the ASC speck. The aggregation of cytosolic ASC into ASC specks is therefore used as a readout parameter for inflammasome activity. The direct detection of ASC speck formation on a single cell basis through flow cytometry, can analyze inflammasome activated cells. This allows the investigation of inflammasome activity in a clinical setting.
Objectives: Investigating the optimal conditions for a reliable identification of inflammasome activated ASC speck positive cells *ex vivo* using flow cytometry.
Methods: Freshly donated blood from five different healthy donors was used for all experiments. The choice of anticoagulant, storage time and storage temperature were examined. PBMCs were isolated from blood collecting tubes with ethylenediaminetetraacetic acid (EDTA) or lithium heparin (LH). PBMCs were also isolated from LH blood stored at 4 °C, room temperature (RT), 37 °C and after different storage times. After isolation, PBMCs were fixed immediately and stained for flow cytometric analysis. ASC speck positive $CD14^+$ $CD16^-$ monocytes and THP-1 cells can be generated through incubation with nigericin in PBS.
Results: We adapted a method for flow cytometric analysis of ASC specks, with was previously described by Sester *et al*. [1]. As expected, we observed ASC speck formation after inflammasome activation, in $CD14^+$ $CD16^-$monocytes through a decrease in ASC fluorescent pulse width and an increase in ASC fluorescent pulse area. Monocytes in PBMCs collected from tubes with EDTA compared with LH showed significantly higher numbers of unspecific ASC speck positive cells. Blood storage at RT for 24 h can lead to an unspecific ASC speck formation. Storage at 37 °C resulted in contamination of the PBMC interface with erythrocytes, while blood stored at 4 °C resulted in severe cell clumping. Since storing LH blood for 24 h at RT lead to unspecific ASC speck formation in $CD14^+$ $CD16^-$ cells, but not monocytes from freshly isolated PBMCs, the determination of the time until unspecific ASC speck signals occur was investigated. A significant increase in ASC speck positive $CD14^+CD16^-$ monocytes was detected after 4 h storage at RT compared to directly processed samples and the number of ASC speck positive monocytes further accumulated over time. The incubation with nigericin in PBS leads to a significant increase in ASC speck positive $CD14^+$ $CD16^-$ monocytes and THP-1 cells compared to incubation in RPMI media.
Conclusion: The flow cytometric detection of ASC specks is adapted for practical clinical usability. To reduce background signals, LH- instead of EDTA blood collecting tubes are recommended. The LH blood should be processed within 2 h after blood collection and be stored at RT. To avoid nonspecific activation and formation of ASC specks, the PBMCs should be isolated directly after venipuncture and fixed immediately. It is also possible to freeze the PBMCs until further usage. However, this will cause some loss of ASC speck positive cells. With these settings, clinical samples can now be examined.

AB0043 THE IMPACT OF ANTI-RO52 ANTIBODIES ON THE EXPRESSION OF ANTIVIRAL RESPONSE-RELATED GENES – PRELIMINARY STUDY

A. Opinc[1], J. Sarnik[1], Z. Łukasik[1], J. Makowska[1]. [1]*Medical University of Lodz, Department of Rheumatology, Lodz, Poland*

Background: Ro52, also known as TRIM21, is an essential agent of the innate host defence, especially of the antiviral responses[1]. It was found to be induced by type I and II interferons. Due to its activity of E3 ligase, TRIM21 is involved in the ubiquitination of several IFN regulating factors (IRFs)[2]. Ro52 enables antibody-dependent intracellular neutralization as a high-affinity Fc immunoglobulin receptor[1]. The auto-ubiquitination of the TRIM21-related complex induces signalling pathways with the production of pro-inflammatory cytokines[1]. Anti-Ro52 autoantibodies are found in versatile autoimmune conditions. The hypothesis of our project assumes that viral infections in genetically susceptible individuals trigger overexpression of Ro52, followed by the production of autoantibodies, which suppress its function as the negative regulator of type I interferon responses, leading to enhanced production of proinflammatory agents that uphold autoimmune process.
Objectives: To compare the expression of antiviral response-related genes in patients with anti-Ro52 autoantibodies and healthy volunteers in order to assess the significance of anti-Ro52 in the antiviral defence.
Methods: Anti-Ro52+ patients, hospitalized at the Department of Rheumatology, Medical University of Lodz or treated in the united outpatient clinic were recruited. 19 patients with anti-Ro52 antibodies were included in the study group (mean age: 54,2 years, F:M ratio 14:5). Among them, 5 patients were diagnosed with primary Sjogren syndrome, 5 with idiopathic inflammatory myopathies, 4 with systemic lupus erythematosus, 1 with rheumatoid arthritis, 3 with overlapping syndromes and 1 was undergoing diagnosis of connective tissue disease at the time of the recruitment. Data on the diagnosis, clinical symptoms and laboratory results were collected from the patients and the available medical records. 10 healthy individuals without autoimmune disorders were recruited to the control group. Whole blood samples were collected from both anti-Ro52+ patients and healthy controls, PBMC were isolated using Biocoll reagent. RNA was isolated from each sample with RNeasy and cDNA synthesis was performed by RevertAid™ H Minus First Strand cDNA Synthesis Kit. The mRNA expression levels of TRIM, IRF3, IRF5, IRF7, NFκB, RIG-1, MDA5 genes were examined by quantitative real-time PCR with TaqMan™ Universal PCR Master Mix according to the manufacturer's instructions. The expression levels of genes relative to that of GAPDH were calculated by delta Ct (ΔCt). The ΔCt value is the Ct value of the target gene subtracted its Ct value of GAPDH, $\Delta Ct = Ct (Gene) - Ct (GAPDH)$. Therefore, the smaller the ΔCt values, the higher the expression levels of the target mRNA. The Mann–Whitney rank sum test was used to compare the control group and anti-Ro52+ patients.
Results: The ΔCt values for TRIM, IRF3, IRF5, IRF7, NFkB, RIG-1, MDA5 were found to be lower in the anti-Ro52+ group as compared to the control group, indicating higher mRNA expression of these genes in anti-Ro52+ patients. Statistical significance was reached for all of the examined genes but IRF3. Detailed results are presented in Table 1.

Table 1. The ΔCt values for antiviral response-related genes in anti-Ro52+ patients and healthy controls. P – statistical significance

	Anti-Ro52+ group ΔCt	Control group ΔCt	*p*
TRIM	4,91	6,64	<0,0001
IRF3	5,70	5,92	0,8482
IRF5	4,45	5,68	<0,0001
IRF7	5,14	6,54	<0,0001
NFκB	4,78	5,66	<0,0001
RIG-1	3,77	4,33	0,0188
MDA5	5,08	6,82	<0,0001

Conclusion: Presented results confirm the enhancement of the antiviral defence in anti-Ro52+ patients. As overexpression is observed independently in various connective tissue diseases, impaired response to viral infections via Ro52 pathways could indicate a common trigger factor of autoimmunity.

AB0044 **REDUCED PERIPHERAL BLOOD MYELOID CELLS IN PATIENTS WITH VEXAS SYNDROME**

V. Jachiet[1,2], L. Ricard[3], P. Hirsch[4], F. Malard[3], L. P. Zhao[5], L. Adès[5], P. Fenaux[5], O. Fain[2], M. Mohty[1,3], B. Gaugler[1], A. Mekinian[1,2]. *[1]Sorbonne Université, AP-HP, Hôpital Saint Antoine, INSERM UMR938, Paris, France; [2]Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service de Médecine Interne et Inflammation-Immunopathology-Biotherapy Department (DMU i3), Paris, France; [3]Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service d'Hématologie Clinique et de Thérapie cellulaire, Paris, France; [4]Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service de Médecine Interne et Inflammation-Immunopathology-Biotherapy Department (DMU i3), Service d'Hématologie Biologique, Paris, France; [5]Université de Paris, AP-HP, Hôpital Saint Louis, Département d'hématologie, Paris, France*

Background: Systemic inflammatory or dysimmune diseases (SIDDs) are encountered in up to a quarter of patients with myelodysplastic syndromes (MDS). Recently identified VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome, associated with somatic mutations in UBA1, encompasses a range of severe inflammatory conditions along with hematologic abnormalities, including myelodysplasia. Only limited data are available on the pathophysiology of MDS-associated SIDDs, and especially about the role of different myeloid cell subsets.

Objectives: The aim of this study was to describe the phenotype of myeloid immune cells (dendritic cells and monocytes) in MDS patients with associated SIDDs, and to compare their distribution with MDS patients without SIDDs and controls.

Methods: Phenotype analysis by flow cytometry from PBMCs of 14 MDS patients with SIDDs, 23 MDS patients without SIDDs and 7 controls without MDS and SIDDs. Eight of the 14 MDS/SIDDs patients (57%) had a somatic *UBA1* mutation.

Results: In this study analyzing peripheral blood myeloid immune cells in MDS patients with and without SIDDs, we observed a quantitative reduction of different DC and monocyte subsets in MDS/SIDDs patients, especially in patients with active SIDDs and above all in patients with newly described VEXAS syndrome.

Conclusion: Further functional studies are warranted to better understand the mechanisms and the consequences of the phenotypic modulations of immune myeloid cells in the pathophysiology of MDS-associated SIDDs, especially in VEXAS syndrome.

Osteo arthritis, aetiology, pathology and animal models

AB0045 **EFFECTS OF AEROBIC EXERCISE AND PREBIOTIC FIBRE SUPPLEMENTATION ON THE VASTUS LATERALIS AND SOLEUS MUSCLES IN A RAT MODEL OF DIET-INDUCED OBESITY**

H. de Brito Fontana[1,2], J. Lourdes Rios[3], R. A. Seerattan[3], V. Joumaa[3], D. A. Hart[3], R. A. Reimer[3], W. Herzog[3]on behalf of Human Performance Laboratory. *[1]Universidade Federal de Santa Catarina, Campus Florianópolis, School of Biological Sciences, Florianópolis, Brazil; [2]University of Calgary, Human Performance Laboratory, Calgary, Canada; [2]University of Calgary, Human Performance Laboratory, Calgary, Canada*

Background: A high-fat/high-sucrose (HFS) diet leads to osteoarthritis-like damage in the knee and shoulder (Collins et al., 2018), and to a low-level systemic inflammation that is accompanied by a decrease in insulin sensitivity. Recently, we demonstrated in a rat model, that when prebiotic fibre supplementation, aerobic exercise, or their combination is started at the onset of the HFS diet exposure, the development of the osteoarthritis-like lesions in the knee joints and the metabolic dysfunction is prevented (Rios et al., 2019).

A central role in the altered metabolic state of rats fed a HFS diet is thought to be played by skeletal muscle (Collins et al., 2018). Besides the detrimental effect on metabolic and inflammatory regulation, muscular dysfunction might be a contributor to the decline in running endurance and coordination observed with prolonged exposure to a low quality diet (Clayton et al., 2022).

Objectives: To evaluate the changes in insulin sensitivity and vastus lateralis and soleus muscle composition in a HFS diet rat model and determine whether the expected muscle alterations can be prevented with a prebiotic fibre supplementation, aerobic exercise, or their combination.

Methods: Twelve-week-old male Sprague Dawley rats fed a high-fat/high-sucrose diet (HFS, Diet #102412, Dyets) were randomized into a sedentary (HFS, n=12), moderate aerobic exercise (HFS+E, n=12), prebiotic fibre supplementation (HFS+F, n=12), or moderate aerobic exercise combined with prebiotic fibre supplementation (HFS+F+E, n=12) group for 12 weeks. Eight chow-fed (Diet #5001) age- and sex-matched animals were used as controls.

Whole body insulin sensitivity (composite insulin sensitivity index – CISI) was determined at the end of the intervention period and, after sacrifice, the VL and soleus muscle composition was evaluated through a triglyceride colorimetric assay and histological analysis of collagen with picrosirius red staining. Non-parametric Kruskal-Wallis testing with pairwise comparisons was used to compare groups.

Results: HFS group rats had less than half (40%, p = 0.001) of the whole-body insulin sensitivity of control rats while rats in the HFS+E, HFS+F and HFS+F+E groups were similar to control.

Rats that were fed the HFS diet showed increased VL (p = 0.033) but not soleus (p = 0.644) triglycerides content compared to control (Figure 1 A). Both VL and soleus showed increased collagen content in the groups fed the HFS diet compared to the control group (p<0.001 for VL and soleus) (Figure 1 B). Moderate aerobic exercise, prebiotic fibre supplementation, or their combination did not prevent the observed alterations in muscle composition in the groups fed the HFS diet.

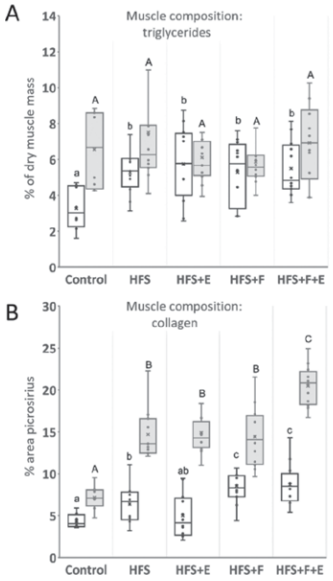

Figure 1. Vastus lateralis (white) and soleus (shaded) composition. In A) intramuscular triglyceride content and B) intramuscular collagen content. Equal letters represent similar values across groups with capital letters used for comparisons regarding the soleus muscle.

HFS: high fat/high sucrose diet; F: prebiotic fibre; E: aerobic exercise.

Conclusion: While a positive effect of prebiotic fibre and exercise in managing metabolic disturbance was present with a clear recovery of insulin sensitivity to control levels in the groups that were fed the HFS diet, the protective effect of exercise and prebiotic fibre that has been previously described for knee joints in this model was not observed for the VL and soleus muscles. The HFS diet led to alterations in muscle composition that seem to be muscle-specific

and cannot be prevented by combining prebiotic fibre or exercise with the HFS diet.

AB0046 RESISTANCE TO OXIDATIVE DEGRADATION OF A FORMULATION COMBINING HYALURONIC ACID AND NIACINAMIDE

F. Hadjab[1]. [1]*Albomed GmbH, Research and Development, Schwarzenbruck, Germany*

Background: Hyaluronic acid plays a major role in the homeostasis of cartilage. In cases of osteoarthritis, hyaluronic acid is subjected to significant oxidative stress linked to the inflammation cascade leading to drastic diminution of its quantity at the level of the joint. This decrease in hyaluronic acid reduces dramatically the lubricating properties of the synovial fluid.

Several preparation methods have been developed to further stabilize the hyaluronic acid used as viscosupplement such as crosslinking or adding adjuvants.

Objectives: A new formulation intended for intra-articular administration has been developed consisting of a combination of hyaluronic acid and vitamin B3 commonly called Niacinamide.

The addition of niacinamide has a protective effect against hyaluronic acid under heat stress and under oxidative stress.

Methods: In order to assess the resistance to free radicals, 4 products were compared (HA 2.2%+vitamin B3 vs HA at 2.2% vs 2 cross-linked HA). 1 gram of sample were placed on Peltier Plate of a Rheometer – TA instrument and submitted to a temperature of 37°C. 50µL of H2O2 was introduced on the sample.

The rheological properties of the mixture were followed-up at a shear stress of 1Hz until full degradation of the sample (i.e. until reaching a viscosity close 0).

The degradation was calculated at each time point and plotted on a graph to compare the enzymatic degradation kinetics.

To assess the thermal resistance, 2 products were compared (HA 2.2%+ vitamin B3 vs HA 2.2%). The samples consisting of 2 grams of gel packaged in glass syringe were placed in a dry oven at 50°C. The viscosity was measured at 3 different timepoints.

Results: This study demonstrates a significant better resistance to free-radical degradation for the HA+Niacinamide vs comparative products.

The viscosity follow-up under heat stress demonstrated that the adjunction of Niacinamide does have a positive effect in preserving the HA viscosity consistently throughout time.

Conclusion: Vitamin B3 commonly called Niacinamide exhibits a dual positive effect when associated with Hyaluronic Acid.

The study demonstrates a better resistance to oxidative degradation for the HA+Niacinamide most probably due to the antioxidant effect of Niacinamide.

This study confirmed the adjunction of the Niacinamide into the HA-based gel formulation does increase the stability of HA against thermal degradation.

AB0047 CARTILAGE DEGRADATION STATUS OF KNEE OSTEOARTHIRTIC PATIENTS CAN BE PREDICTED BY CHONDROCYTE GENE EXPRESSION ANALYSIS

L. Tío[1], L. Triginer[1], A. Ribes[1], P. Camps[1], R. Torres-Claramunt[1,2], J. C. Monllau[1,2], J. Monfort[1,3]on behalf of HOLOA. [1]*IMIM (Hospital del Mar Medical Research Institute), Barcelona, Infammation and Cartilage Cellular Reseach Group, Barcelona, Spain;* [2]*Hospital del Mar, Servei de Cirurgia Ortopèdica i Traumatologia,, Barcelona, Spain;* [3]*Hospital del Mar, Servei de Reumatologia, Barcelona, Spain*

Background: Osteoarthritis (OA) is the most common degenerative joint disease, but its pathogenesis is still poorly understood. OA is characterized by articular cartilage loss due to an imbalance in anabolic and catabolic gene expression of the chondrocyte, together with aberrant expression of transcription factors and inflammatory mediators.

Objectives: We aim to evaluate de genes implicated in the chondrocyte failure regarding the four issues assessed to evaluate cartilage integrity using Mankin score (MkS): surface integrity, cellularity, cell cloning and staining.

Methods: Knee OA (KOA) patients aged 60-75 undergoing a total knee replacement, were recruited. At surgery, tibial plateau and femur condyles were deposited in DMEM medium and sent to the laboratory within 4 hours of the extraction. Punches from areas located at low, medium and high load (1) were excised from each sample (approximately 11 areas per patient). For RNA analysis, punches were kept in RNAlater at -20ºC until analyzed. RNA extraction, cDNA synthesis and cDNA amplification of the selected genes were performed previous to gene expression quantifycation by OpenArray Assay with custom plates. ΔCt was analyzed by ExpressionSuite V1.3 using 6 housekeeping genes. For histology study, punchs were fixated in formalin and embedded in parafin. Sections of 4 µm were stained with hematoxilin eosin and Safranin O-Fast Green. Slices were scored using the modified MkS (2) by 3 independent observers. R (v3.3.2) analysis was used to explored the results with principal components analysis (PCA) and linear regression (LR).

Results: Surgical samples were obtained from a total of 27 patients and 219 different areas were analyzed. ΔCt of the 51 genes analyzed by PCA showed that 9 components were enough to represent >80% of variance of the model. The genes associated with each component are summarized in Table 1. LR shows that second and first component were significantly associated to all or most of the fields included in the MkS, respectively. In contrast, component 4, 5 and 9 were not associated with any field. Lower expression of genes represented in component 1 (mainly related with extracellular matrix content) are associated with higher MkS values. On the other hand, component 2 summarizes data of genes mainly related with factors regulating cell metabolism. In this case, higher expression of TNFαIP6, NGF, IGFBP1, CRLF1, TNFα, and lower expression of ACAN, COL11A2, COL2A1, COL10A1, SOX9 and TGFβ1, among others, are associated with increased MkS values.

Table 1. Genes that most contribute (by order) to component 1 & 2 (due to space limitation). Data of LR analysis for each component and MkS item. Significant association marked in bold.

9		-0.220; 0.096	-0.041; 0.425	-0.101; 0.110	0.020; 0.780

Conclusion: There is a correlation between the expression level of the studied genes and the MkS values, although the role played by each gene might be

different according to the MkS issue evaluated. These results could be useful to describe biomarkers that identify burden of disease in KOA.

AB0048 THE SUPPRESSION OF INFLAMMATORY PROCESSES AND MODULATION OF MAPK SIGNALING BY SHIKONIN DERIVATIVES IN PRIMARY OA CHONDROCYTES

B. Lohberger[1], H. Kaltenegger[1], N. Eck[1], D. Glänzer[1], A. Leithner[1], R. Bauer[2], N. Kretschmer[2], B. Steinecker-Frohnwieser[3]. *[1]Medical University Graz, Department of Orthopedics and Trauma, Graz, Austria; [2]University Graz, Institute of Pharmaceutical Sciences, Department of Pharmacognosy, Graz, Austria; [3]Ludwig Boltzmann Society, Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Saalfelden, Austria*

Background: Osteoarthritis (OA) is one of the most common joint disorders and is characterized by the degeneration and loss of articular cartilage with chronic arthritis of the joint edge and subchondral bone. OA is causally influenced by several factors, including age, gender, familial susceptibility, as well as local biomechanics, cartilage cell apoptosis, and the action of degenerative enzymes. Despite intensive research, there are still few effective therapeutic approaches.
Objectives: In the rat OA model, shikonin was shown to inhibit inflammatory processes and chondrocyte apoptosis by regulating the PI3K/AKT pathway. Therefore, we investigated the effect of shikonin and its derivatives acetylshikonin and cyclopropylshikonin on inflammation, MMP expression, and regulation of MAPK signaling in human OA chondrocytes.
Methods: Viability was analyzed using the CellTiter 96 AQ_{ueous} Luminescence Assay on human healthy chondrocytes (HC) and primary OA chondrocytes (pCH-OA). For the study of inflammatory processes, we performed a proteome profile screening assay. As MAPK signaling pathways play a key role in cartilage destruction in OA, we analyzed the effects of shikonin and its derivatives using protein expression analysis of the phosphorylation pattern and the corresponding downstream gene regulation using RT-qPCR.
Results: Both HC and pCH-OA showed a dose-dependent inhibition of cell viability after treatment with shikonin derivatives, whereby the strongest effects were found for shikonin with IC_{50} values of 1.2 µM and 1.3 µM, respectively. Shikonin counteracts inflammatory response caused by IL-1β by massively reducing the expression of pro-inflammatory mediators.
Phosphorylation level of ERK changed slightly, pJNK and pp38 showed a significant increase after treatment with the shikonin derivatives both in HC and pCH-OA cells. The downstream targets c/EBPs and MEF2c may play a role in the homeostasis of joint cartilage under physiological and pathological conditions. The phosphorylation level of STAT3 significantly decreased in a dose-dependent manner after treatment. STAT3 blockade has a chondroprotective function through a regulation of cyclin D1 or Sox9.
Conclusion: Our results demonstrate for the first time that shikonin and its derivatives acetylshikonin and cyclopropylshikonin have extensive effects on inflammatory processes, MAPKs, and IL6/STAT3 downstream regulation in human healthy chondrocytes and primary OA chondrocytes.

AB0049 ASSOCIATION WITH LEPTINEMIA AND Q223R (RS1137101) POLYMORPHISM OF LEPR GENE IN FEMALE PATIENTS WITH KNEE OSTEOARTHRITIS

L. Shvets[1], V. Novoseletskyi[2], V. Khomenko[3], L. Perebetiuk[3], M. Stanislavchuk[3]. *[1]National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine #1, Vinnytsia, Ukraine; [2]Communal nonprofit enterprise "Vinnytsya Regional Clinical Hospital named after N. I. Pirogov Vinnytsia Regional Council", Regional Centre of Nephrology and Dialysis, Vinnytsia, Ukraine; [3]National Pirogov Memorial Medical University, Vinnytsya, Rheumatology, Vinnytsia, Ukraine*

Background: Knee Osteoarthritis is the most common form of arthritis, affecting millions of people worldwide. Poor early diagnostics, growing share of seniors in the population structure, the need for genetic or other molecular biomarkers to improve safety, efficacy, and outcome of treatment of OA patients make up the key issues of scientific interest.
Objectives: To assess the association between serum leptin concentrations, the *LEPR* gene *Q223R(rs1137101)* polymorphism in patients with knee OA.
Methods: The participants in this study (knee OA patients = 99, control group (healthy women) = 62) underwent blood measurement to *LEPR Q223R(rs1137101)* genotyping assay and leptin serum levels. We analyzed the relationship with multivariate regression models using generalized linear models with binomial link function.
Results: In this way, allele frequency and genotypic variant specificity for polymorphic variant Q223R(rs1137101) of LEPR gene in women with OA of knee joints were determined. The frequency of the variant allele G(Arg) in the group of patients with OA of the knee joints was 0.54 and in the control group 0.43. The results were unreliable, although the nature of the trend was small (p = 0.06). In patients with OA, the genotype Q223R(rs1137101) of the LEPR gene was significantly subdivided according to the Hardy-Weinberg law (p = 0.002), which was due to the higher frequency of homozygotes of both types, while theoretically scoring with the same status. The association of the Q223R(rs1137101) polymorphism of the LEPR gene with the risk of developing OA of the knee joints in the recessive model of decay (GG/AA + AG) was revealed: odds ratio (OR) = 2.15 (95% CI: 1.03-4.50), p = 0.04. There was no correlation between the Q223R(rs1137101) polymorphism of the LEPR gene and such clinical and laboratory indicators as clinical form, body mass index, and blood serum leptin concentration. Carriers of AG (Gln/Arg) + GG(Arg/Arg) genotypes have a significantly higher risk of developing rapid X-ray progression of OA (II and III X-ray stages, due to I) after 5 years of diseases: OR = 5.17 (95% CI: 1.04 - 25.57), p = 0.03.
Conclusion: Our results suggest that the patients with knee OA the *AG (Gln/Arg)* and *GG (Arg/Arg)* genotype carriers have statistically significant higher risk of OA.
Further study of this issue is needed.

AB0050 ALTERED NAMPT, ADIPOKINE AND CYTOKINE LEVELS CHARACTERIZE MONOCYTE ACTIVITY AND CORRELATE WITH DISEASE SEVERITY IN OSTEOARTHRITIS

F. Motta[1,2], B. Durante[2,3], C. Pandolfo[2,3], C. Selmi[1,2], A. Sica[2,3]. *[1]IRCCS Humanitas Research Hospital, Division of Rheumatology and Clinical Immunology, Rozzano, Italy; [2]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy; [3]University of Piemonte Orientale "A. Avogadro", Department of Pharmaceutical Sciences, Novara, Italy*

Background: Osteoarthritis (OA) is a chronic, debilitating, aging-associated disease (1), characterized by chronic low-grade inflammation, the underlying mechanisms of which are poorly understood (2). Intracellular nicotinamide phosphoribosyltransferase (iNAMPT) is the rate-limiting enzyme in the NAD^+ salvage pathway, in charge of maintaining cellular homeostasis through redox reactions. NAD^+ promotes the expression of sirtuin-1 (SIRT1), which regulates the mobilization of myeloid-derived suppressor cells from the bone marrow. Extracellular eNAMPT, the secreted form of NAMPT also known as visfatin, is an adipokine involved in OA pathogenesis (3,4).
Objectives: We aim to analyse the cytokine and adipokine profile and the role of i- and eNAMPT in OA-related inflammation.
Methods: Peripheral blood and, whenever possible, synovial fluid from knee joint were collected from patients with OA older than 50 years. Samples from subjects without OA older than 50 (non-OA>50y) and younger than 30 (non-OA<30y) were used as controls. Serum, plasmatic, and synovial fluid adipokines and cytokines were measured by ELISA. Peripheral blood mononuclear cells were purified with Ficoll gradient and monocytes were selected with anti-human CD14 microbeads; RNA was extracted for polymerase chain reaction for NAMPT, SIRT1 and pro/anti-inflammatory cytokines. Monocyte intracellular NAD^+ was measured at baseline and 1 hour after nicotinamide (a NAMPT substrate and precursor of NAD^+) supplementation. Results were correlated with clinical data.
Results: Peripheral blood was obtained from 51 patients with OA (19 with synovial fluid also), 44 from non-OA>50y, and 35 from non-OA<30y controls. Plasmatic chemerin and leptin were higher in OA patients, visfatin was higher in OA and in non-OA>50y group ($p<0.01$ for all analyses). Plasmatic and synovial levels of leptin and resistin were correlated ($p<0.001$, $r=0.6$ for both comparisons); synovial leptin and resistin correlated with synovial IL-6, VEGF, and TNFα and these were higher in polyarticular OA (vs monoarticular, p=0.01 and p=0.03, respectively) and in OA with more severe Kellgren-Lawrence score (p=0.003 and p=0.03, respectively). Monocyte expression of NAMPT and anti-inflammatory cytokines IL-10 and Arginase-1 was increased in non-OA<30y controls compared to OA patients and non-OA>50y subjects ($p<0.05$ for all analyses). At baseline, monocyte intracellular NAD^+ content was higher in the non-OA>50y cohort; after niacin supplementation, non-OA>50y subjects had the highest content, whereas

OA patients had higher NAD levels than at baseline, but significantly lower than non-OA>50y controls (Figure 1).

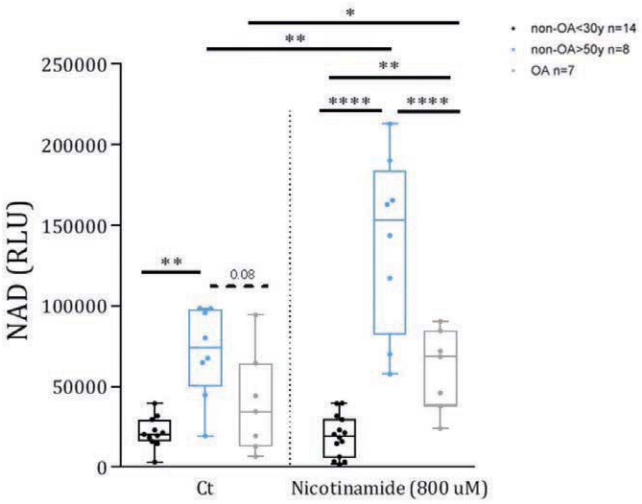

Figure 1. Monocyte NAD^+ content at baseline and 1 hour after nicotinamide supplementation. *p<0.05 **p<0.01 ****p<0.0001.

Conclusion: A specific plasmatic and synovial adipokine signature characterizes OA and patients with more severe disease. In monocytes there is a age-related reduction of iNAMPT and anti-inflammatory cytokine expression, whereas eNAMPT is higher in elderly compared with younger subjects. In non-OA>50y subjects there might be an increase of iNAMPT activity which leads to NAD^+ production, while in OA patients this mechanism seems to be impaired and can be only partially enhanced by nicotinamide supplementation, leading to reduced intracellular redox efficiency. These results suggest that NAMPT activity might be a key component of the mechanisms underlying inflammation in OA patients.

AB0051 EVIDENCE OF VERY EARLY CARTILAGE DAMAGE IN EXPERIMENTAL OSTEOARTHRITIS USING SCANNING ELECTRON MICROSCOPY

V. C. Carneiro Girao-Carmona[1], M. Marques Bezerra[2], F. M. Aragão Ximenes Porto[1], A. C. Matias Dinelly Pinto[3], R. Nunes[3], A. M. Costa Vasconcelos Alves[3], C. Cabral Campello[4], A. C. Rocha de Melo Leite[5], G. A. de Castro Brito[1], F. A. Castro Rocha[3]. *[1]Faculdade de Medicina, Morphology, Fortaleza, Brazil; [2]Faculdade de Medicina - Universidade Federal do Ceará, Pharmacology, Sobral, Brazil; [3]Faculdade de Medicina, Internal Medicine, Fortaleza, Brazil; [4]Faculdade de Medicina Veterinária - Universidade Estadual do Ceará, Morphology, Fortaleza, Brazil; [5]University of International Integration of Afro-Brazilian Lusophony, Pharmacology, Redenção, Brazil*

Background: Early, reproducible, sensitive imaging biomarkers are an unmet need in experimental osteoarthritis (OA) evaluation. Electron microscopy may reveal joint changes prior to soluble biomarkers.

Objectives: This study describes very early, quantitative, articular cartilage surface damage in posttraumatic experimental OA models allowing determination of disease severity.

Methods: Mice (5/group) were subjected to anterior cruciate ligament transection (ACLT), ACLT plus meniscectomy (MNCT), as OA models, or sham surgery and sacrificed 3, 7 or 14 days later. Articular cartilage was collected and processed for optical (H&E; Safranin O staining) or scanning electron microscopy (SEM) analysis. Histology was graded using Osteoarthritis Research Society International (OARSI) parameters whereas cartilage thickness, roughness and damage index were evaluated under SEM.

Results: Optical microscopy did not reveal significantly relevant cartilage changes in OA models *vs* controls. Femoral and tibial cartilage thickness were significantly reduced in mice subjected to ACLT or MNCT at 7 and 14 days postsurgery (P<0.05). Cartilage roughness was significantly increased in MNCT agroup as early as 3 days postsurgery, as compared to sham and ACLT groups, being sustained up to 14 days in both femoral and tibial extremities. Articular damage index using SEM was more severe at 14 days postsurgery in ACLT and MNCT *vs* control groups (P<0.05).

Conclusion: Posttraumatic experimental OA display quantitative cartilage changes at SEM with increased roughness and thickness as early as 3 days post induction. In addition to unravel very early ultrastructural cartilage damage, these changes may be used as early surrogates for joint damage in experimental OA.

Disclosure of Interests: None declared

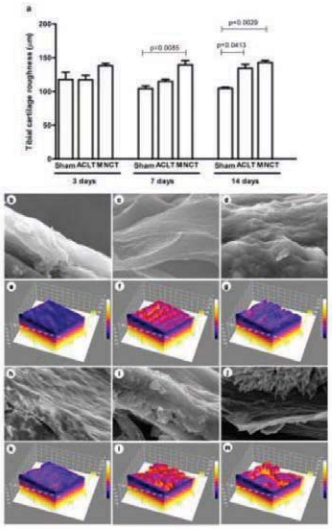

Figure 3. Assessment of roughness of tibial cartilage.
Mice were subjected to a sham procedure or transection of the medial collateral and anterior cruciate ligaments (ACLT) or ACLT followed by transection of the medial meniscus (MNCT). Groups were sacrificed 7 or 14 days post surgery. (A) Data represent mean±sem of cartilage roughness (µm) using scanning electron microscope (SEM) images (9/group), compared using Student's "t" test. Representative SEM imaging and roughness plots of the tibial cartilage of animals of the sham [(B,H) and (E,Q)], ACLT [(C,I) and (F,L)], and MNCT [(D,J) and (G,M)] groups sacrificed at 7 or 14 days post surgery, respectively.

AB0052 CHANGES IN THE MOLECULAR ARCHITECTONICS OF PLASMA MEMBRANES (PM) OF NEUTROPHILIC LEUKOCYTES (NL) FROM SYNOVIAL FLUID (SF) IN GONARTHROSIS (GA)

V. Shishkin[1], Y. Malenkov[1], V. V. Shishkin[1], G. V. Kudryavtseva[1]. *[1]Saint Petersburg state University, Diagnostic of functional systems, Saint Petersburg, Russian Federation*

Objectives: Changes in the spectrum of phospholipids (PL) in NL membranes correlate with the activity of their metabolic and phagocytic processes. The aim of the work was to study PL homeostasis of NL from SF in GA.

Methods: SF of knee joints of 12 patients with GA with active synovitis and 7 conditional donors postmortem (D) were researched. PL analysis: phosphatidylcholine (PC), sphingomyeline (SM), phosphatidylethanolamin (PEA), phosphatidylinositol (PI), phosphatidylserine (PS), lysophosphatidylcholine (LPC) were performed by conventional lipid-gas and fluid chromatography methods. Active forms of oxygen (AFO2) have been registered by applying EPR. Electrokinetic motility (EM) of NL determined by the automatic microscope.

Results: With GA, against the background of the sharp increase (2.7 times) of free radical processes, there are quantitative changes in the FL plasma membranes NL, expressed in the decreases in the percentages of PC, SM, PEA, PI and the increases in PS and LPS.

Table 1. Phospholipids concentration (%), AFO2 (units/mg of protein) and EM (m/v sec) NL from SF in GA

NL	PC	SM	PEA	PI	PS	LPC	AFO2	EM
D	25,8±0,9	18,7±0,3	27,3±0,7	19,7±0,4	9,5±0,9	5,1±0,2	21,7±4,9	1,20 ♦ 10-8
GA	20,4±0,7*	12,3±0,4*	11,7±0,6**	10,9±0,8**	13,2±0,4*	8,9±0,7*	59,4±7,5**	0,27♦ 10-8***

* - p <0.05; ** - p <0.01; *** - p <0.001

A decrease in the level of PC and SM in GA indicates an increase in the sensitivity of NL membranes to reactive oxygen species and a decrease in their structural stability, an increase in microviscosity and fluidity. A decrease in the PEA level in GA is also associated with the sharp increase in the active forms of oxygen radicals, which leads to "loosening" of the membranes and the formation of hydrophilic pores. PI is an effector of many membrane enzyme-substrate complexes, and with GA, the percentage of PI is halved. An increase in the level of PS and LPC in GA indicate the presence of structural rearrangements and loosening of the hydrophobic region of the lipid layer of the NL membranes. The PEA / PS ratio in the control group was 2.87, and with GA - 0.89. This indicates a change in the saturation of the lipid bilayer of the NL membrane, an increases in microviscosity and fluidity. Quantitative shifts in the FL composition in NL membranes during GA lead to their pronounced depolarization and the 4.4 -fold decrease in EM.

Conclusion: FL form the NL apoptotic response, determine their plastic and energy potential. In GA, FL homeostasis of NL is disturbed and membrane-destructive processes development. Modification of the lipid bilayer of plasma membranes NL causes their depolarization, a decrease in plasticity, viscosity, electrical conductivity and EM. The noted changes in the molecular architectonics of NL membranes in GA inhibit their membrane-protective properties, antioxidant potential, and stimulate the apoptotic response.

AB0053 **LNCRNA NUTM2A-AS1 ALLEVIATED OSTEOARTHRITIS BY REGULATING MIR-183-5P/TGFA PATHWAY**

N. Geng[1], D. Yun[1], D. Liu[1], P. Liu[1]. [1]*The First Affiliated Hospital of Xi'an Medical College, Department of Rheumatology and Immunology, Xi'an, China*

Background: Osteoarthritis(OA) is a common comorbidity in the elderly, characterized by articular cartilage degeneration, hyperosteogeny and synovitis. Long non-coding RNAs (LncRNAs) have been shown to be involved in several human diseases, including OA. However, the effect of NUTM2A-AS1 on chondrocytes remains unknown.
Objectives: The purpose of this study was to evaluate the role of LncRNA NUTM2A-AS1 in OA pathological changes in vitro.
Methods: Chondrocyte cells were treated for 24 hours to mimic OA pathological conditions. The experimental center used chondrocytes with interleukin-1 beta (IL-1β) Intervention to simulate the pathological state of OA.The expression levels of LncRNA NUTM2A-AS1, miR-183-5p and TGFA mRNA were detected by quantitative real-time PCR (qRT-PCR), along with CCK-8 to determine cell viability. Inflammatory response was assessed by determining the release of pro-inflammatory factors such as TNF-α and IL-6 using ELISA kits. Cell apoptosis was examined by flow cytometry assay. The binding relationship between miR-183-5p and LncRNA NUTM2A-AS1 or TGFA was confirmed by dual-luciferase reporter assay.
Results: IL-1β induced chondrocytes to express LncRNA NUTM2A-AS1 and TGFA, and the miR-183-5p expression was decreased in IL-1β-treated cells. Low expression of LncRNA NUTM2A-AS1 or TGFA mitigated IL-1β-caused chondrocyte viability reduction and apoptosis promotion. miR-183-5p overexpression alleviated IL-1β-mediated chondrocyte apoptosis and inflammatory injury via decreasing TGFA expression. In addition, our work revealed that miR-183-5p is a target of LncRNA NUTM2A-AS1. Rescue experiments showed that TGFA overexpression could reverse the effects of low expression of LncRNA NUTM2A-AS1 on the pathological changes in IL-1β-induced chondrocytes.
Conclusion: Low expression of LncRNA NUTM2A-AS1 significantly mitigated the chondrocytes damage induced by IL-1β through regulating miR-183-5p/TGFA axis, which might be an important target to regulate the promotion of OA.

Bone diseases, aetiology, pathology and animal models

AB0054 **NEW THERAPEUTICAL TOOLS FOR HETEROTOPIC OSSIFICATION TREATMENT AND PREVENTION**

A. Alonso-Pérez[1], M. Guillán-Fresco[1], E. Franco-Trepat[1], A. Lois-Iglesias[1], A. Jorge-Mora[1], R. Gómez[1]. [1]*Health Research Institute of Santiago de Compostela (IDIS), Musculoskeletal Pathology Group, Santiago de Compostela, Spain*

Background: Heterotopic ossification (HO) consists in abnormal bone growth in soft tissues, in a non-porrostoeblastogenic environment. This pathology origin can be congenital (progressive osseus heteroplasia, progressive osseous fibrodysplasia, …) or acquired (burnt, big traumas, electrocutions, articular replacement surgeries, …). Currently, the available therapies (radiotherapy and removal surgery) are aggressive, associated to multiple adverse effects, and not suitable for every populations. Therefore, new therapeutic tools are needed to HO.
Osteoblast is the cell type in charge of bone growth. These cells share a mesenchymal origin with adipocytes. Interestingly, osteoblastogenesis and adipogenesis are opposed and mutually controlled processes.
Objectives: The aim of this work is to study osteoblastogenesis inhibition through adipogenesis promotion using a new therapy (Tri-therapy) composed by a PPARG agonist, a NSAID, and a corticoid.
Methods: Mice mesenchymal stem cells (C3H10T1/2) were differentiated towards adipogenesis and osteoblastogenesis for 7 days, in the presence of the Tri-therapy compounds alone and combined. Simultaneously, human preosteoblast cells (SaOS2) were differentiated to osteoblast for 14 days, being treated with the Tri-therapy. Human HO cells (acquired HO and congenital HO independently), obtained from HO explants, were exposed to an adipogenic environment in the presence of the Tri-therapy for 7 days.
Osteoblastogenic (ALPL, SPP1, GPNMB, RUNX2) and adipogenic (FABP4, PLIN2, ADIPOQ, PPARG) marker genes mRNA expression measured by RT-PCR was used to evaluate differentiation processes. All the results were expressed as the media± SEM of, at least, 3 independent replicates.
Results: In C3H10T1/2 differentiations Tri-therapy synergically induced FABP4, PLIN2, ADIPOQ expression in both cell fates, demonstrating therefore its ability to promote adipogenesis. In SaOS2, the proposed therapy diminished osteoblastogenic marker genes expression (SPP1, GPNMB, RUNX2), being this effect greater than PPARG agonists' themselves. In HO cells, Tri-therapy augmented adipogenesis markers expression, showing a partial effect in osteoblastogenic marker genes expression.
Conclusion: Pro-adipogenic switch in differentiation marker genes expression induced by the Tri-therapy suggested the clinical use of this drugs combination to treat and prevent HO and abnormal bone growth.

AB0055 **BONE AND MINERAL DISORDERS IN RENAL HEMODIALYSIS PATIENTS**

R. Ben Tekaya[1], H. Hachfi[1], M. Brahem[1], O. Jomaa[1], Z. Atti[2], Y. Mohamed[1]. [1]*University Hospital Tahar Sfar, Rheumatology Department, Mahdia, Tunisia;* [2]*University Hospital Tahar Sfar, nephrology department, Mahdia, Tunisia*

Background: Chronic kidney disease causes many mineral and bone disorders, secondary hyperpathyroidism, adynamic bone disease and osteomalacia which can reduce the bone mineral density (BMD).
Objectives: To analyze the prevalence of osteoporosis in group of patients with chronic renal failure and to evaluate the relation between bone mineral density (BMD) and specific markers of bone turnover in hemodialysis (HD) population.
Methods: This is a cross sectional study conducted in rheumatology department of Taher Sfar university hospital in mahdia, Tunisia. The study involved 61 patients with chronic hemodialysis. they were invited to participate and were included after signing informed consent until the calculated sample size was reached. Patients were asked to undergo a hip and lumbar (L2-L4) densitometry by DXA to measure bone mineral density (BMD). Serum levels of iPTH and alkaline phosphatase (ALP) were measured before the dialysis session.
Results: The studied group of 61 patients was 26 females (42,6%) and 35 males (57.4%), there mean age was 53.9 [17-83] years, with mean dialysis duration 6,1 years. The mean onset age of hemodialysis therapy was 44.7 +/- 15.4 years. It was diabetic nephropathy in 25 cases (41%) vascular nephropathy in 15 cases and tubulointerstitial nephropathy in 21 cases (34,4). 23 patients (37,7%) had osteoporosis using the WHO criteria (T-score < -2,5), 26 patients (42,6%) had osteopenia and 12 patients had normal BMD. The mean serum level of iPTH with normal BMD and lower BMD 167,84 vs 535,71 respectively. the mean serum level of ALP with normal BMD and lower BMD 144,59 vs 271,99 respectively (p<0,001). The mean duration of dialysis therapy with normal BMD and lower BMD 4,57 years vs 6,55 years (p<0,001).
Conclusion: Our study showed that osteoporosis is common in dialysis patients. The main determinants of BMD is PTH activity and the duration of dialysis therapy. the importance of prevention and treatment of metabolic bone disease has become better appreciated.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

AB0056 COMPARATIVE ANALYSIS OF THE DISTRIBUTION OF LYMPHOCYTES, MACROPHAGES AND MAST CELLS IN THE MARGINAL SYNOVIUM AND JOINT CAPSULE IN GENERAL AFTER ANTENATAL ANTIGENIC STIMULATION

A. Fedotchenko[1,2]. [1]*Zaporizhzhia State Medical University, Human Anatomy, Zaporizhzhia, Ukraine;* [2]*Zeisigwaldkliniken Bethanien Chemnitz, Rheumatology, Chemnitz, Germany*

Background: The joint capsule is one of the main pathogenetic points of arthritis development [1]. In addition, the initial signs of the inflammatory joint diseases are identified primarily in the marginal transitional zone [2]. The joint capsule morphology was studied using hip joints of Wistar rats during the postnatal period in norm and after antigenic stimulation. The last one was modeled through the transuterine intrafetal interscapular subcutaneous injection of antigen (0.05 ml of human normal immunoglobulin) for the rat foetus on the 18th day of its antenatal life under general anesthesia and sterile conditions via laparotomy for the pregnant female (Voloshyn's method (1981). The control group of rats was injected with 0.05 ml of physiological saline in the same manner. The earlier recovery of certain parameters (total cells quantity, vessels, collagen fibers and ground substance) to normality in the marginal synovium compared to the rest (larger) part of the joint capsule in antigen-suppressed rats was previously revealed.
Objectives: A comparative analysis of the distribution of lymphocytes, macrophages and mast cells in the marginal synovium in relation to the rest (larger) part of the joint capsule after antenatal antigenic stimulation was conducted.
Methods: Collection of the biomaterial was carried out on the first, seventh, 14th, 30th, 45th, 60th and 90th day of postnatal life under general anesthesia (intact, antigen-suppressed and control rats; six rats in each group, 126 rats in total). The joints were fixed, decalcified and dehydrated. Paraffin-embedded tissue sections were stained with hematoxylin and eosin. Cells of the synovial subintima of the marginal synovium and rest (larger) part of the joint capsule were counted using the light microscopy (x100) and morphometric lattice. The obtained data were processed using the statistical methods. The parameters of intact and control rats did not differ significantly from each other.
Results: In the joint capsule of antigen-suppressed rats compared to intact and control rats, an increased number of lymphocytes till the 90th day (in the marginal synovium – till the 45th day), macrophages till the seventh day (in the marginal synovium – also till the seventh day) and mast cells till the 90th day (in the marginal synovium – till the 14th day) was found. The integrity of the synovium-cartilage barrier is of fundamental importance, failing which it would lead to excessive synovial tissue penetration into the articular cartilage, recognition of it by immunocompetent cells and initiation of immune-mediated cartilage destruction. The previously premature appearance (on the seventh day) of strong expression of receptors for peanut agglutinin (PNA) in the marginal cartilage of antigen-suppressed rats I detected could lead to the assumption about the premature appearance of "chondroprotective substances" such as fibronectin, laminin etc. and their intensive glycosylation. This fact might be considered a compensatory mechanism to create the „defensive wall" for adhesion and deactivation of the immunocompetent cells, therefore reducing their influence on cells and contributing to accelerated return the parameters to normality.
Conclusion: The compensatory defence mechanisms, occurring in the marginal cartilage after the antigenic stimulation, contribute to earlier recovery of parameters in the marginal synovium compared to the joint capsule in general. In so doing, the marginal transitional zone forms the important innate, nonspecific, immunobiological, anatomical and physiological barrier between the joint capsule and articular cartilage.

AB0057 REGULATION OF TYPE I INTERFERON SIGNATURE BY VGLL3 IN THE FIBROBLAST-LIKE SYNOVIOCYTES OF RHEUMATOID ARTHRITIS

Y. Du[1], S. M. Dai[1,1]. [1]*Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Rheumatology and Immunology, Shanghai, China*

Background: The upregulation of interferon (IFN)-stimulated genes (ISGs) induced by type I IFNs (namely type I IFN signature) in RA patients had implications in early diagnosis and prediction of therapy responses. However, factors that modulate the type I IFN signature in RA are largely unknown.
Objectives: To explore the involvement of VGLL3, a homologue of the vestigial-like gene in Drosophila and a putative regulator of the Hippo pathway, in the modulation of the type I IFN signature in RA.
Methods: FLS were isolated from RA and osteoarthritis patients. Expression of VGLL3 in the synovial tissues and FLS was analyzed by immunohistochemistry and PCR. RNA sequencing was performed in RA-FLS upon VGLL3 overexpression. The expression of ISGs was examined by PCR and Western blotting.
Results: VGLL3 was upregulated in the RA synovium and RA-FLS compared to OA. Overexpression of VGLL3 promoted the expression of ISGs in RA-FLS. The expression of STAT1 and MX1 was also upregulated in RA synovium compared to OA. The expression of STAT1 and MX1 was associated with the expression of VGLL3 in RA and OA patients. VGLL3 promoted the IRF3 activation, IFN-β1 expression, and IFN-β1 autocrine signaling in RA-FLS. VGLL3 also modulated the expression of the Hippo pathway molecules WWTR1 and AMOTL2, which mediated the regulation of IRF3 activation and IFN-β1 production by VGLL3 in RA-FLS.
Conclusion: VGLL3 drives the IRF3-induced IFN-β1 secretion in RA-FLS by inhibiting WWTR1 expression and subsequently promotes the type I IFN signature expression through autocrine IFN-β1 signaling.

AB0058 SERUM ANTIGENOME PROFILING REVEALS DIAGNOSTIC MODELS FOR RHEUMATOID ARTHRITIS

P. Han[1,1], C. Hou[2], X. Zheng[1,2], L. Cao[1,2], X. Shi[3], X. Zhang[3], H. Ye[1], T. Li[2], F. Hu[1], Z. Li[1]. [1]*Peking university People's hospital, Department of rheumatology, Beijing, China;* [2]*Peking university Health Science Center, Department of Biomedical Informatics, Beijing, China;* [3]*Peking University, State Key Laboratory of Natural and Biomimetic Drugs, Beijing, China*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that leads to joint damage, systemic inflammation and early mortality. Though the precise molecular mechanism in the triggering immune response are not fully understood, the emergence of antibodies against self-antigens can serve as diagnostic biomarker. Multiple antigens have been confirmed. However, the profiling of serum antigen, antigenome, remains poorly known.
Objectives: The study aimed to investigate the serum antigenomic profiling and determine potential diagnostic biomarkers using label-free proteomic technology implemented with machine-learning algorithm.
Methods: We captured serum antigens from a cohort consisting of 60 RA patients (45 ACPA-positive RA patients and 15 ACPA-negative RA patients), sex- and age-matched 30 osteoarthritis patients and 30 healthy controls. Liquid chromatography-tandem mass spectrometry (LC-MS/MS) was performed. We then trained a machine learning model to classify RA, ACPA-positive RA and ACPA-negative RA based on proteomic data and validated in the cohort.
Results: We identified 62, 71 and 49 differentially expressed proteins (DEPs) in RA, ACPA-positive RA and ACPA-negative RA respectively, compared to OA and healthy controls. Among these DEPs, the pathway enrichment analysis and protein-protein interactions networks were conducted. Three panels were constructed to classify RA, ACPA-positive RA and ACPA-negative RA using random forest models algorithm based on the molecular signature of DEPs, whose area under curve (AUC) were calculated as 0.9949 (95% CI = 0.9792-1), 0.9913 (95%CI = 0.9653-1) and 1.0 (95% CI = 1-1).
Conclusion: This study presented serum antigen profiling of RA. Among them, three panels of antigens were identified to classify RA, ACPA-positive and ACPA-negative RA patients as diagnostic biomarkers.

SRC-LIKE ADAPTOR PROTEIN DEFICIENCY DOSE-DEPENDENTLY PROTECTS MICE AGAINST COLLAGEN-INDUCED ARTHRITIS

P. Királyhidi[1], N. Badari[1], L. Tóth[1,2], Z. Pós[1,3], N. Lupsa[1,3], A. Mocsai[4], D. Csete[4], T. Nemeth[4,5], E. Buzás[1], G. Nagy[1,5]on behalf of Experimental Rheumatology Research Group. *[1]Semmelweis University School of Medicine, Department of Genetics, Cell- and Immunobiology, Budapest, Hungary; [2]University of Pécs, Department of Pharmacology and Pharmacotherapy, Pécs, Hungary; [3]MTA-SE, Experimental and Translational Immunomics Research Group, Budapest, Hungary; [4]Semmelweis University School of Medicine, Department of Physiology, Budapest, Hungary; [5]Semmelweis University School of Medicine, Department of Rheumatology and Clinical Immunology, Budapest, Hungary*

Background: Src-like adaptor protein (SLAP), an adaptor between E3 ubiquitin ligase c-Cbl and the TCR complex, is a negative regulator of T-cell activation. SLAP regulates the expression of the CD3 ζ-chain. In accordance with our previous data, SLAP expression is increased in the CD4+ T-cells of patients with rheumatoid arthritis (RA). Recent data demonstrate that SLAP deficiency can prevent zymosan-induced arthritis in mice.
Objectives: We investigated the role of SLAP in collagen-induced arthritis (CIA).
Methods: Homozygous and heterozygous SLAP knock out and wild type (WT) C57BL/6J mice were used. After the isolation of genomial DNA, the genotype of the mice was determined. Then the animals were injected once (primary immunization) or twice (secondary immunization) with type II. collagen, or left untreated (the first injection was applied together with complete Freund's adjuvant). Mice were monitored twice a week for 70 days, and the severity scores were evaluated. The scores were calculated for each limb (1 limb score: 0=no swelling; 4=the severe swelling).
Results: SLAP deficiency provided almost complete protection from the primary immunization of CIA. By contrast secondary immunization led to similar arthritis of the SLAP-KO, heterozygous or WT mice.
Conclusion: The authors' present data suggest that SLAP deficiency protects dose-dependently from CIA.

SYSTEMIC INFLAMMATORY EFFECT ON HIPPOCAMPAL VOLUME IN RHEUMATOID ARTHRITIS AND ULCERATIVE COLITIS

J. Cox[1], M. de Groot[2], J. Cole[3], S. Williams[1]. *[1]King's College London, Centre for Neuroimaging Sciences, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom; [2]GSK - Stevenage, Clinical Imaging, Stevenage, United Kingdom; [3]University College London, Centre for Medical Image Computing, Department of Computer Science, London, United Kingdom*

Background: Autoimmune diseases represent a large and heterogeneous group of disorders that afflict specific target organs. However, multiple factors point to common links between the differing presentations of autoimmune disorders. With increased interest in further understanding the neuro-immune axis, autoimmune diseases represent an important opportunity to explore whether systemic inflammation from these autoimmune pathways has a central effect and, if so, whether there is a common or discrete central effect caused by different autoimmune diseases.
Objectives: The present study aimed to analyse hippocampal volume in patients with rheumatoid arthritis (RA) and ulcerative colitis (UC) as compared to healthy control groups. The hippocampus was chosen as a region of interest given the regulatory role it exhibits in the hypothalamic–pituitary–adrenal (HPA) axis[2]. Additionally, the hippocampus has been identified as a region that is affected in other autoimmune diseases such as systemic lupus erythematosus (SLE).
Methods: Data from 1,040 individuals in the UKBiobank Imaging sub-study were included in the present study. This was divided into two separate patient populations with separate control groups. Data from 267 individuals (mean age ± SD =65.52 ± 7.02, 70.8% females) were included in the RA patient group with 267 age and sex matched controls (mean age ± SD = 65.51 ± 7, 70.8% females). Data from 253 individuals (mean age ± SD = 64.09 ± 7.03, 51.6% females) were included in the UC patient group with 253 age and sex matched controls (mean age ± SD = 63.4 ± 7.02, 51.6% females).
The UKBiobank is a prospective observational study with a proposed cohort of 500,000 participants. The imaging substudy is planned to scan 100,000 of those participants with a standardised scanning protocol including MRI of the brain. Multi-modal images were acquired on a 3T scanner[3]. From the T1w data, volumetric imaging derived phenotypes (IDPs) are provided using the FMRIB Integrated Registration and Segmentation Tool (FIRST); http://fsl.fmrib.ox.ac.uk/fsl/fslwiki/FIRST. This study utilised the right and left hippocampal volume outputs from that tool.
Results: We observed a smaller hippocampal volume in UC patients when compared to healthy controls (difference right: 99.78 mm^3, SD ± 38.97, p = 0.01; left: 74.30 mm^3, SD ± 39.41, p = 0.06). The Cohen's effect size was *d* = -0.24 [95% CI -0.43, -0.05] for right hippocampal volume and *d* = -0.18 [95% CI -0.36, 0.00] for left hippocampal volume.

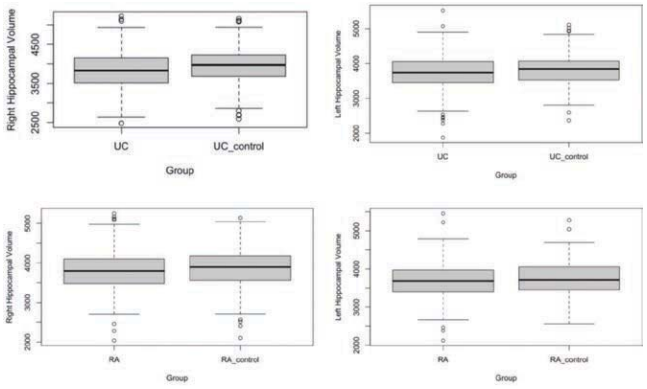

Figure 1. Right and left hippocampal volume in UC patients versus controls and right and left hippocampal volume in RA patients versus controls.

There was no significant difference seen in hippocampal volume in RA patients compared to controls (difference right: 61.32 mm^3, SD ± 40.33, p = 0.13; left: 39.00 mm^3, SD ± 38.19, p = 0.31). The Cohen's effect size was *d* = -0.12 [95% CI -0.30, 0.06] for right hippocampal volume and *d* = -0.08 [95% CI -0.27, 0.10] for left hippocampal volume.
Conclusion: This study provides evidence of moderate reduction in hippocampal volumes in patients with ulcerative colitis as compared to age and sex matched healthy controls. This same effect was not seen in a similarly matched rheumatoid arthritis patient population. Further analysis of additional subcortical regions could provide further context for whether there are alternative regions affected in both RA and UC.

AB0061 PHARMACOKINETICS OF METHOTREXATE POLYGLUTAMATES IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF RA PATIENTS IS SIMILAR AFTER SUBCUTANEOUS OR ORAL ADMINISTRATION IN THE METHOTREXATE MONITORING (MEMO) TRIAL

R. Hebing[1], M. Lin[2], E. Struys[2], S. Mahmoud[1], I. Muller[2], W. Lems[1,3], B. van den Bemt[4,5], G. Jansen[3], R. De Jonge[2], M. Nurmohamed[1,3]. *[1]Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam UMC, locatie VUmc, Clinical Chemistry, Amsterdam, Netherlands; [3]Amsterdam UMC, locatie VUmc, Rheumatology, Amsterdam, Netherlands; [4]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [5]Radboud University Medical Center, Pharmacy, Nijmegen, Netherlands*

Background: Pharmacokinetics of methotrexate (MTX) after oral and subcutaneous administration to RA patients differs: MTX levels in plasma and MTX-polyglutamate (MTX-PG) accumulation in erythrocytes are higher during equidosed subcutaneous compared to oral MTX treatment. (1,2) No data are available whether administration route of MTX differentially impacts the intracellular concentrations of MTX-PGs in peripheral blood mononuclear cells (PBMCs) during MTX therapy.
Objectives: To investigate the pharmacokinetics of MTX-PGs in PBMCs of newly diagnosed RA patients receiving oral or subcutaneous MTX in the early phase (1, 2, 3 and 6 months) of MTX treatment.
Methods: In a clinical prospective cohort study (MeMo study (NTR7149)), RA patients were
administered oral (n=24) or subcutaneous (n=22) MTX up to 25 mg MTX/week, as described before. (1) At 1, 2, 3 and 6 months after the start of therapy, PBMCs were isolated via Ficoll density gradient centrifugation. Individual MTX-PG forms ($MTX\text{-}PG_{1\text{-}6}$) in PBMCs were analyzed by a UPLC-MS/MS method including custom-made stable isotopes of $MTX\text{-}PG_{1\text{-}6}$ as internal standards (3). UPLC-MS/MS measurements of the PBMCs were performed with a Waters Acquity BEH C18 column coupled to an AB Sciex 6500+ with the ESI operating on the positive mode. Dosing, concomitant treatments and DAS28-ESR assessments were in conformity with clinical practice. (4)
Results: 46 consecutive patients were included in this study; 76% female, mean age: 57.8 years, BMI: 25.8, smokers: 20%, mean baseline DAS28-ESR: 3.5, as described before. (1) MTX dose at baseline was 10.5 mg (SD: 1.5) for both groups, 15.4 mg (4.4) and 16.8 mg (1.8) at 1 month, 22.8 mg (3.9) and 22.4 mg (5.2) at 2 months, 20.1 mg (6.3) and 20.8 mg (5.6) at 3 months, and 19.7 mg (6.1) and 18.5 mg (6.7) at 6 months for oral and subcutaneous use, respectively. MTX-PG analyses in PBMCs for individual and total MTX-PGs revealed no significant differences between oral and subcutaneous administration groups at 1, 2, 3, and 6 months (Figure 1). Linear regression of LN transformed MTX-PG levels in PBMCs and administration route, corrected for age, baseline DAS28, smoking, BMI, eGFR and MTX dose, showed a trend towards higher MTX-PG levels in PBMCs after subcutaneous MTX administration compared to oral administration (data not shown). MTX-PG distribution in PBMCs was mainly composed of $MTX\text{-}PG_1$ (58%), and to a lesser extent $MTX\text{-}PG_2$ (27%) and $MTX\text{-}PG_3$ (15%). Longer chain MTX-PGs beyond $MTX\text{-}PG_4$ were detectable in PBMCs, but at levels lower than $MTX\text{-}PG_{1\text{-}3}$ (mean: 4.0 – 6.7 fmol/10^6 cells). Total MTX-PG accumulation in PBMCs was approximately 10-20 fold higher than in erythrocytes. PBMC accumulation was rather stable, whereas RBC MTX-PG accumulation increased between 1 to 3 months to reach a plateau (Figure 1).

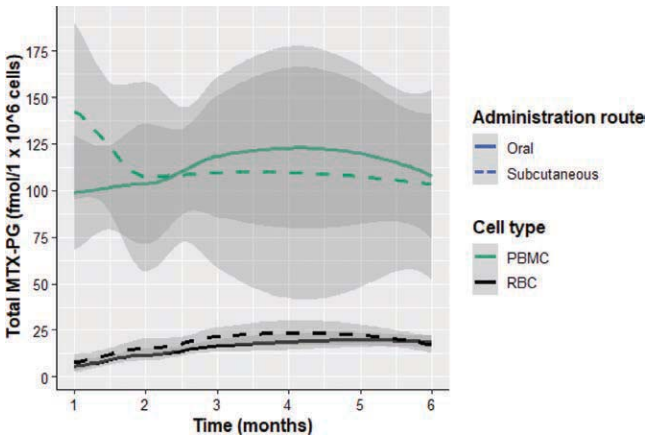

Figure 1. Loess regression of MTX-PG concentrations in PBMCs (MTX-PG1-3) and RBCs (MTX-PG1-6) of RA patients during the first 6 months of oral or subcutaneous MTX administration. At 6 months, 18 patients using oral and 18 patients using subcutaneous MTX were still continuing MTX treatment. Means (lines) and SE (grey areas) are depicted.

Conclusion: This study demonstrated that MTX-PG accumulation in PBMCs early on in the MTX treatment of RA patients was not significantly different between oral or subcutaneous MTX administration routes.

AB0062 ANGIOTENSIN CONVERTING ENZYME ACTIVITY IN ANTI-TNF-TREATED RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS PATIENTS

B. Soós[1], M. Fagyas[2], Á. Horváth[1], E. Végh[2], A. Pusztai[2], M. Czókolyová[2], A. Csongrádi[2], A. Hamar[1], Z. Pethö[1], N. Bodnár[1], G. Kerekes[3], K. Hodosi[1], É. Szekanecz[4], S. Szamosi[1], S. Szántó[1], G. Szücs[1], Z. Papp[2], Z. Szekanecz[5]. *[1]University of Debrecen, Rheumatology, Debrecen, Hungary; [2]University of Debrecen, Cardiology, Debrecen, Hungary; [3]University of Debrecen, Internal Medicine, Debrecen, Hungary; [4]University of Debrecen, Oncology, Debrecen, Hungary; [5]University of Debrecen, Rheumatology, Debrecen, Hungary*

Background: Angiotensin-converting enzyme (ACE) and ACE2 have been implicated in the regulation of vascular physiology. Elevated synovial and decreased or normal ACE or ACE2 levels have been found in rheumatoid arthritis (RA). Very little is known about the effects of tumour necrosis factor α (TNF-α) inhibition on ACE or ACE2 homeostasis.
Objectives: In this study, we assessed the effects of one-year anti-TNF therapy on ACE and ACE2 production in RA and ankylosing spondylitis (AS) in association with other biomarkers.
Methods: Forty patients including 24 RA patients treated with either etanercept (ETN) or certolizumab pegol (CZP) and 16 AS patients treated with ETN were included in a 12-month follow-up study. Serum ACE levels were determined by commercial ELISA, while serum ACE2 activity was assessed using a specific quenched fluorescent substrate. Ultrasonography was performed to determine flow-mediated vasodilation (FMD), common carotid intima-media thickness (ccIMT) and arterial pulse-wave velocity (PWV) in all patients. In addition, CRP, rheumatoid factor (RF) and ACPA were also measured. All assessments were performed at baseline and 6 and 12 months after treatment initiation.
Results: Anti-TNF therapy increased ACE levels in the full cohort, as well as in the RA and AS subsets. ACE2 activity increased in the full cohort, while the ACE/ACE2 ratio increased in the full cohort and in the RA subset ($p<0.05$). Uni- and multivariable regression analyses determined associations between ACE or ACE/ACE2 ratios at different time points and disease duration, CRP, RF, FMD and IMT ($p<0.05$). ACE2 activity correlated with CRP. The changes of ACE or ACE2 over 12 months were determined by treatment together with either RF or FMD ($p<0.05$).
Conclusion: Anti-TNF treatment may increase ACE and ACE2 in the sera of RA and AS patients. ACE and ACE2 may be associated with disease duration, markers of inflammation and vascular pathophysiology. The effects of TNF inhibition on ACE and ACE2 may reflect, in part, the effects of these biologics on the cardiovascular system.

AB0063

AMPA CANNOT BE DETECTED IN FAECES OF SEROPOSITIVE RA PATIENTS: NO EVIDENCE FOR LOCAL AMPA PRODUCTION IN THE LOWER GASTRO-INTESTINAL TRACT

V. Derksen[1], T. Huizinga[1], R. Toes[1], D. van der Woude[1]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) patients harbor antibodies against several post-translational modifications (AMPA), for example anti-citrullinated protein antibodies (ACPA) and anti-acetylated protein antibodies (AAPA). The exact mechanism underlying the development of these autoantibodies is currently unclear, but the mucosal immune system has been hypothesized to play a role. ACPA IgA have been detected in sputum and saliva of seropositive RA patients (1-2), suggesting local production of autoantibodies in the lung and oral mucosa. This raises the question whether ACPA can also be produced at other mucosal sites. The intestines are an interesting candidate, as microbiome dysbiosis has been described in RA patients and intestinal content may represent a source of post-translationally modified antigens. However, it is currently unknown whether AMPA are also produced locally in the intestine.
Objectives: To determine whether AMPA are produced locally in the intestine, we set out to detect ACPA and AAPA in faeces samples of seropositive RA patients. These findings were compared to the ACPA/AAPA levels found in paired serum and saliva samples of the same patients.
Methods: Paired faeces, saliva and serum samples of 16 established seropositive RA patients and 16 healthy volunteers were collected. All patients fulfilled the ACR/EULAR 2010 criteria. Saliva was collected using the passive drooling method. Faeces was self-collected by participants at home and immediately frozen. Faeces samples were homogenized in PBS containing protease inhibitors and supernatants were used in ELISA. Saliva was diluted 1:4. Total IgA and anti-E. Coli IgA were measured using commercial and in-house ELISA, respectively. ACPA/AAPA IgA (serum, saliva) and ACPA/AAPA Ig (faeces) were detected using in-house ELISAs, coated with citrullinated and acetylated CCP2 or the unmodified arginine and lysine variants as control. Saliva samples were considered AMPA positive when the value was above the cut-off (mean + 2 times standard deviation of healthy donors) and the delta OD between the modified and unmodified peptide was larger than 0.1.
Results: 9/16 ACPA IgG-positive RA patients were also ACPA IgA positive in serum. In the faecal supernatants total IgA was clearly detectable by ELISA: the supernatants contained on average 85 µg/ml total IgA, only slightly less compared to the mean 117 µg/ml total IgA found in the pre-diluted saliva. However, in none of the faecal supernatants ACPA Ig could be detected. Differences in optical density (OD) between the CCP2 and unmodified arginine peptide were close to 0 (Figure 1A). On the contrary, 8 RA patients were positive for ACPA IgA in saliva (Figure 1B). Similar results were found for AAPA (Figure 1C-D). To control whether the lack of an AMPA signal is explained by technical difficulties associated with measuring IgA in an antigen-specific manner in faeces, we determined anti-E. Coli IgA in the same samples. Anti-E. Coli IgA was clearly detectable in 11/32 faeces samples, indicating intact antigen-specific IgA was present in the faecal samples (Figure 1E).

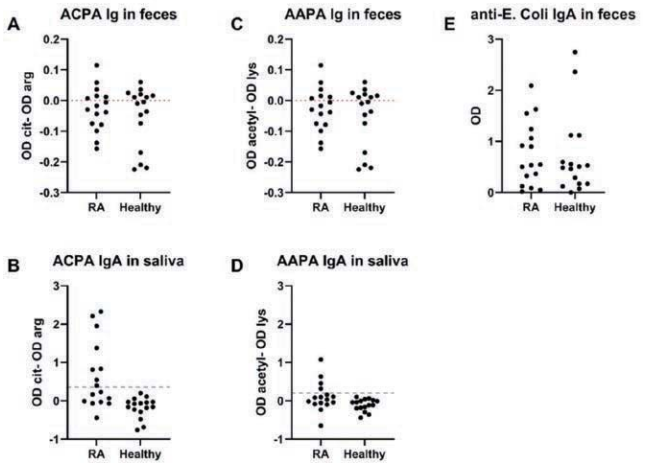

Figure 1.

Conclusion: No ACPA or AAPA Ig antibodies could be detected in faeces of RA patients, even though these patients were positive for ACPA/AAPA IgA in both serum and saliva. The fact that it was possible to detect other antibodies in faeces, indicates that the absence of an AMPA signal is not due to inherent methodological issues. These findings indicate that the lower gastro-intestinal tract does not contain measurable levels of AMPA IgA and suggest that it is not a main site of ACPA production in RA patients.

PHARMACOLOGICAL INHIBITION OF IL-6/JAK/STAT AXIS INCREASES MUSCLE MASS IN AN EXPERIMENTAL MODEL OF SARCOPENIA ASSOCIATED TO RHEUMATOID ARTHRITIS

I. Bermejo[1], S. Pérez-Baos[1], J. P. Medina[1], P. Gratal[1], I. Prieto-Potín[1], R. Largo[1], G. Herrero-Beaumont[1,2]on behalf of Bone and Joint Research Unit. [1]*Instituto de Investigacion Sanitaria FJD, Rheumatology, Madrid, Spain;* [2]*Fundación Jiménez Díaz, Rheumatology, Madrid, Spain*

Background: Sarcopenia is a frequent comorbidity of rheumatoid arthritis (RA) due to an imbalance in muscle remodelling with dominance of catabolism over anabolism. IL-6/JAK/STAT axis is of particular importance in this regulation because of its dual activity. According to local and acute factors, it promotes muscle healing and hypertrophy, whereas in chronic inflammation, this signalling substantially increases muscle catabolism activating pro-atrophic pathways involving atrogene expression and ubiquitin proteasome system (UPS). JAK/STAT blockade suppresses muscle wasting induced by IL-6, through STAT3 activation. Interestingly, different clinical trials have shown that JAK inhibitors produce an asymptomatic increase in serum creatine kinase (CK) and creatinine levels in RA patients, suggesting an impact on muscle.
Objectives: To evaluate the effect of JAK inhibition and its effect in muscle remodelling in an experimental model that accurately mimics human rheumatoid sarcopenia.
Methods: An experimental model of antigen-induced arthritis (AIA) was carried out in 14 rabbits by immunization against ovalbumin followed by 4 intra-articular (i.a) injections of this protein. One week after the first i.a injection, 7 of these rabbits received tofacitinib (TOFA, orally 10mg/kg/day) for 2wk. Animals were euthanized one day after the last i.a injection, when tibialis anterior (TA), extensor digitorum longus (EDL) and gastrocnemius (GN) were isolated from both hind limbs. Histological changes and ATPase staining were analysed in TA, while the number of myonuclei was evaluated in EDL fibres by immunofluorescence studies. C-reactive protein (CRP) and myostatin (MSTN) serum concentration were determined by ELISA. The gene expression of proinflammatory cytokines (IL-1β, IL-6, TNF-α, MCP-1), atrogenes (Atrogin-1, MuRF-1) and MSTN was measured by quantitative PCR, while proliferative muscle marker (PAX-7), differentiation muscle markers (MyoD, Myogenin), pSTAT3, pSTAT1, MSTN and CK protein expression was analysed by western blot in GN. Creatine presence in GN was analysed by a colorimetric assay.
Results: A significant increase in body weight was observed in the AIA+TOFA group vs. AIA at the end of the study. A significant increase in TA cross-sectional area and diameter in the AIA+TOFA, in comparison to AIA, was found, while the decrease in the area of type II fibres observed in the AIA animals was not noticed in AIA+TOFA. Moreover, the number of myonuclei in the EDL that was increased in the AIA group when compared to healthy animals, was significantly decreased in AIA+TOFA. However, systemic inflammation measured by CRP was not modified by TOFA treatment at the end of the study, in comparison to AIA, and so did serum MSTN concentration. TOFA evoked a significant reduction in the gene expression of IL-6, MCP-1, atrogin-1 and MuRF-1 in GN in comparison to untreated AIA rabbits. Notably, AIA+TOFA showed higher protein levels of CK and lower creatine compared to AIA in muscle. Simultaneously, no differences in the proliferative marker PAX-7 were found between groups, while AIA rabbits showed an increase in the differentiation markers MyoD and Myogenin in the muscle that was prevented in AIA+TOFA.
Conclusion: These data provide novel insights into the effects of JAK inhibitors in muscle remodelling during rheumatoid cachexia. Despite an elevated systemic inflammatory status, JAK inhibition was able to rapidly increase muscle mass through attenuating IL-6/JAK/STAT activation, decreasing atrogene expression, and restoring to baseline the muscle cell differentiation markers in the tissue. The increase in muscle mass was accompanied by an increase in CK presence, supporting the role of CK as a valuable marker of muscle gain following treatment with JAK inhibitors. However, the low levels of MCP-1 and the disorganization of muscle fibre myonuclei raise the question of whether these treatments could trigger a complete regeneration of muscle fibre cell or just hypertrophy of cells already present.

ASSOCIATION OF SERUM LEVELS OF NESFATIN-1 WITH RHEUMATOID ARTHRITIS ACTIVITY AND ANXIETY-DEPRESSIVE DISORDERS

J. Polyakova[1], L. Seewordova[1], E. Papichev[1], Y. Akhverdyan[1], T. Kvlividze[1], B. Zavodovsky[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation*

Background: Rheumatoid arthritis (RA) is primarily associated with pain levels and limited function. Depressive disturbances and anxiety levels are not usually assessed, the focus is on the physical aspects of the disease. At the same time, patients with high disease activity often experience a decrease in body weight and lack of appetite, which is referred to as rheumatoid cachexia. Nesfatin-1 (NF-1), discovered as an anorexigenic protein. The participation of NF-1 in the regulation of eating behavior and reactions to emotional stress together with oxytocin, melatonin, serotonin, and histamine receptors has been proven. Elevated levels of NF-1 are detected in more severe forms of depression, correlating with the level of inflammation markers - C-reactive protein and interleukin-6. Recent work confirms an increase in NF-1 levels in RA, although its role in inflammation has not yet been clearly defined.
Objectives: To determine the correlation of the level of NF-1 in the blood serum of patients with RA with the level of anxiety and depression.
Methods: 110 patients with RA were examined. NF-1 level concentration was determined by indirect enzyme-linked immunosorbent assay (RaiBiotech, cat no. EIA-NESF). The PHQ-9 scale was used to assess the severity of depressive symptoms, and the GAD-7 scale was used to assess the severity of anxiety symptoms.
Results: Mood disorders of varying severity were detected in 48% of patients with RA. The highest levels of NF-1 were found in patients with high RA activity according to DAS-28 and disease duration of more than 10 years. The level of anxiety was more correlated with the severity of the disease activity ($r = 0.351$; $p<0.01$), and the level of depression was more correlated with the duration of the disease ($r = 0.273$; $p<0.01$).
Conclusion: In our study depression and high levels of anxiety were found in 48% of patients with RA, which is consistent with well-known data (the prevalence of mood disorders in RA ranges from 30 to 75%). The severity of depression and anxiety correlates with the level of NF-1, the frequency of occurrence depends on the activity and duration of the disease.

EFFECT AND MECHANISM OF QINXITONG ON BIOLOGICAL BEHAVIOR OF SYNOVIAL FIBROBLASTS IN RHEUMATOID ARTHRITIS

Y. Lv[1], J. Zhang[1], Y. Liu[1]. [1]*Xi'an No.5 Hospital, Rheumatology, Xi'an, China*

Background: Chinese medicine has been used widely for the treatment of RA for a long history in China. The Fifth Hospital of Xi'an has treated patients of RA with QinXiTong(QXT) for 40 years which is mainly based on the water extract from Caulis Sinomenii(CS). However, the molecular mechanism of its anti-rheumatism effect remains unclear.
Objectives: To investigate the effects of Qinxitong on proliferation, apoptosis, migration and invasion of synovial fibroblasts in rheumatoid arthritis and its mechanism.
Methods: Taking rheumatoid arthritis synovial fibroblast cell line MH7A as the research object. The cells were divided into four groups according to the different dosage of Qinxitong intervention, namely control group, low dose group (QXT-20), medium dose group (QXT-50) and high dose group (QXT-100). CCK-8 assay was used to detect cell proliferation, flow cytometry was used to detect cell apoptosis, Transwell assay was used to detect cell migration and invasion, and Western blotting was used to detect total Erk protein (t-Erk) and phosphorylated Erk protein (p-Erk) expression levels.
Results: CCK-8 assay showed that Qinxitong could inhibit the proliferation of MH7A cells, compared with the control group, cell proliferation in QXT-50 and QXT-100 groups was significantly reduced ($p<0.05$) after 24h, 48, and 72h intervention, the effect of QXT-100 was even more significant ($p<0.001$); flow cytometry showed that QXT could promote apoptosis of MH7A cells, compared with the control group, the apoptosis rate of QXT-50 and QXT-100 groups was significantly increased ($p<0.05$); Transwell assay showed that QXT could inhibit the migration and invasion of MH7A cells, compared with the control group, the QXT-50 and QXT-100 groups showed significantly higher inhibition of migration and invasion of MH7A cells ($p<0.05$); Western blotting showed that QXT could reduced p-Erk expression level, compared with the control group, the decrease of p-Erk expression level in QXT-50 and QXT-100 groups was statistically significant ($p<0.001$).
Conclusion: Qinxitong can inhibit the proliferation, promote apoptosis, inhibit migration and invasion of rheumatoid arthritis synovial fibroblasts by regulating Erk signaling pathway, providing scientific basis for clinical application of Qixintong.

INTERLEUKIN-1 RECEPTOR ANTAGONIST: RELATION TO CARDIOVASCULAR DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Almeida[1], J. C. Quevedo-Abeledo[1], L. Cáceres Martín[1], V. Hernández Hernández[2], A. Delgado-González[3], I. Ferraz-Amaro[2]. [1]*Hospital Universitario de Gran Canaria Dr Negrín, Division of Rheumatology, Las Palmas de Gran Canaria, Spain;* [2]*Hospital Universitario de Canarias, Division of Rheumatology, La Laguna. Tenerife, Spain;* [3]*Hospital Universitario de Canarias, Division of Central Laboratory, La Laguna. Tenerife, Spain*

Background: The interleukin-1 receptor antagonist (IL1-Ra) belongs to the IL-1 family. IL1-Ra has an inhibitory function on the inflammatory reaction consisting of preventing the binding of IL-1α and β to their respective receptors. IL-1, in its different subtypes, has been implicated in the pathogenesis of both rheumatoid arthritis (RA) and cardiovascular disease (CV) in the general population.
Objectives: In the present work we aim to study the relation of IL1-Ra serum levels to RA's features, and its CV comorbidity and subclinical carotid atheromatosis in a large RA cohort.
Methods: This was a cross-sectional study that included 430 RA patients. A complete panel of clinical and analytical information related to CV disease was collected: CV risk factors, full lipid profile, insulin and C-peptide serum levels, insulin resistance and β-cell function (%B) indexes by Homeostatic Model Assessment (HOMA2). A carotid ultrasound examination was performed to assess carotid intima-media thickness in the common carotid artery and to detect focal plaque in the extracranial carotid tree. Similarly, IL1Ra and IL-6 serum levels were assessed and disease activity indices, extra-articular manifestations and RA therapies were collected. A multivariable regression analysis was performed to determine how IL1Ra serum levels is associated with disease-related characteristics, CV comorbidity and subclinical atheromatosis in RA patients.
Results: Regarding CV risk factors, IL1-Ra serum levels were related with waist circumference (coefficient beta -β- 8 [95% confidence interval -CI- 5-11] pg/ml, $p<0.001$) and obesity (body mass index >= 30 kg/m2) (β 169 [95% CI 78-260] pg/ml, $p<0.001$). After adjusting for confounders, IL1-Ra was related with higher levels of several lipid profile molecules, such as total cholesterol (β 12 [95%CI 2-22] mg/dl, $p=0.023$), apolipoprotein A1 (β 13 [95% CI 0.5-25] mg/dl, $p=0.042$) and apolipoprotein C3 (β 3 [95% CI 2-5] mg/dl, $p<0.001$). Furthermore, higher IL1-Ra serum levels were associated with pancreatic beta cell dysfunction as measured by HOMA2-%B (β 22 [95%CI 2-42], $p=0.031$). Disease activity using different scores showed a positive relationship with IL1-Ra after multivariable adjustment: DAS28-ESR (β 60 [95% CI 28-92] pg/ml, $p<0.001$), DAS28-PCR (β 65 [95%CI 26-104] pg/ml, $p=0.001$) and CDAI (β 99 [95%CI 3-14] pg/ml, $p=0.002$). Likewise, ESR (β 2 [95% CI 0.07-5] pg/ml, $p=0.044$) and IL-6 plasma levels (β 3 [95% CI 1-6] pg/ml, $p=0.003$) were positively associated with IL1-Ra levels after adjusting for covariates. Hydroxychloroquine use, but not other therapies, was associated with lower IL1-Ra serum levels (β -131 [95% CI -260- -2] pg/ml, $p=0.046$), independently of confounding variables. No association was found between IL1-Ra and intima-media thickness or carotid plaque.
Conclusion: In RA patients, IL1-Ra serum levels are related to the clinical and biological disease activity, as well as with different CV comorbidities such as dyslipidemia, beta cell dysfunction and obesity. Our findings highlight the beneficial effect that blocking IL-1 activity can have both in the control of RA disease activity and in the management of the CV disease that accompanies the disease.

INTERLEUKIN 40 SERUM LEVELS ARE ELEVATED IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS AND ASSOCIATE WITH NEUTROPHIL ACTIVATION

A. Navrátilová[1,2], V. Becvar[1], H. Hulejova[1], K. Pavelka[1,2], J. Vencovský[1,2], L. Šenolt[1,2], L. Andres Cerezo[1,2]. [1]*Institute of rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic;* [2]*First Faculty of Medicine Charles University, Department of Rheumatology, Prague, Czech Republic*

Background: IL-40 is a newly described cytokine associated with immune system function and malignant transformation. We have recently shown that IL-40

is up-regulated in rheumatoid arthritis (RA) and associates with disease activity, autoantibodies and NETosis[1].

Objectives: As autoantibodies and neutrophil activation are factors thought to drive the pathological processes at early phase of RA development, we aimed to investigate IL-40 in relation to neutrophils and early stages of RA (ERA).

Methods: The levels of serum IL-40 were determined in a cohort of treatment naïve patients with ERA at baseline (n=60) and three months after initiation of conventional treatment (n=60). Serum IL-40 was also determined in sex- and age- matched healthy controls (n=60). Levels of IL-40, cytokines and NETosis markers (proteinase 3, PR3 and neutrophil elastase, NE) were measured by commercially available ELISA kits. The levels of autoantibodies were analysed by routine laboratory techniques. *In vitro* experiments were performed on peripheral blood neutrophils from patients with ERA (n=15).

Results: Levels of IL-40 were elevated in ERA patients at baseline compared to healthy controls ($p<0.0001$) and normalised after three months of the treatment ($p<0.0001$). Baseline serum IL-40 was associated with the levels of autoantibodies RF (IgM) ($p<0.01$) and anti-CCP ($p<0.01$) and markers of NETosis PR3 and NE) (both $p<0.0001$). Moreover, significant decreases in the serum IL-40 following the therapy correlated with the decrease of NETosis markers PR3 ($p<0.01$) and NE ($p<0.05$). *In vitro*, neutrophils from patients with ERA significantly enhanced the release of IL-40 following NETosis induction ($p<0.05$) or after exposure to pro-inflammatory cytokines such as IL-1β, IL-8 ($p<0.05$), TNF ($p<0.01$) or to LPS ($p<0.05$). Lastly, recombinant IL-40 induced the secretion of IL-1β ($p<0.05$) and TNF ($p<0.05$) by ERA neutrophils.

Conclusion: We demonstrated for the first time that IL-40 is upregulated in ERA and decreases after three months of conventional therapy. Moreover, we showed that neutrophils are an important source of IL-40 in RA and its release is potentiated by pro-inflammatory cytokines and NETosis. Our results suggest that IL-40 may play an important role in early stages of RA.

AB0069 ASSOCIATION OF NUCLEAR FACTOR OF ACTIVATED T CELLS CYTOPLASMIC 1 (NFATC1) EXPRESSION WITH CARDIOVASCULAR RISK IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

F. Genre[1], V. Pulito-Cueto[1], A. Corrales[1,2], V. Portilla[1,2], L. Lera-Gómez[1], B. Atienza-Mateo[1,2], O. Gualillo[3], R. Blanco[1,2], I. Ferraz-Amaro[4], S. Castañeda[5], R. López-Mejías[1], M. A. González-Gay[6,7], S. Remuzgo-Martínez[1]. *[1]IDIVAL, Research group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic bone Diseases of the Musculoskeletal System, Santander, Spain; [2]Hospital Universitario Marqués de Valdecilla, Rheumatology Department, Santander, Spain; [3]Hospital Clínico Universitario de Santiago, SERGAS (Servizo Galego de Saude) and IDIS (Instituto de Investigación Sanitaria de Santiago), NEIRID Lab (Neuroendocrine Interactions in Rheumatology and Inflammatory Diseases), Research Laboratory 9, Santiago de Compostela, Spain; [4]Hospital Universitario de Canarias, Rheumatology Division, Santa Cruz de Tenerife, Spain; [5]Hospital de la Princesa, IIS-Princesa, Rheumatology Department, Madrid, Spain; [6]Medicine and Psychiatry Department, Universidad de Cantabria; Rheumatology Division, Hospital Universitario Marqués de Valdecilla; Research group on genetic epidemiology and atherosclerosis in systemic diseases and in metabolic diseases of the musculoskeletal system, IDIVAL, Santander, Spain; [7]University of the Witwatersrand, Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, Faculty of Health Sciences, Johannesburg, South Africa*

Background: Nuclear factor of activated T cells (NFAT) is a transcription factor family that plays a crucial role in physiological and immune processes, modulating intracellular and extracellular signaling pathways related with several diseases[1,2]. In this regard, it has been involved in the pathogenesis of rheumatoid arthritis (RA) and in the development of cardiovascular (CV) disease[3-5]. Given that CV disease is one of the main causes of morbidity and mortality in patients with RA[6], functional studies focused on the implication of *NFAT* in CV disease in RA are of potential interest.

Objectives: To study the role of the gene expression of two members of the NFAT family, *NFATc1* and *NFATc2*, in the risk of developing CV disease in patients with RA.

Methods: A total of 79 disease-modifying antirheumatic drug-naïve patients with early RA[7] from Hospital Universitario Marqués de Valdecilla (Santander, Spain) were included in this study. The relative mRNA expression of *NFATc1* and *NFATc2* in peripheral blood was determined by qPCR. Carotid ultrasound data were used as surrogate markers of subclinical atherosclerosis. The association between *NFATc1* and *NFATc2* expression in RA patients and their clinical characteristics was evaluated. Results were adjusted by sex, age at the time of the study and traditional CV risk factors.

Results: A statistically significant increase of *NFATc1* mRNA expression was found in women compared to men (fold change=+1.18, $p=0.035$). In addition, a higher *NFATc1* mRNA expression was observed in patients with dyslipidemia compared to those with normal lipid profile (fold change=+1.18, $p=0.006$). With respect to this, we also disclosed a positive correlation between *NFATc1* mRNA expression and low-density lipoprotein cholesterol levels ($r=0.27$, $p=0.039$). No significant associations were detected between *NFATc2* mRNA expression and clinical characteristics of our RA patients. Carotid ultrasound findings were not related to *NFATc1* and *NFATc2* expression.

Conclusion: Our study suggests that a higher expression of *NFATc1* in peripheral blood is associated with abnormalities in the lipid profile and, consequently, with an increased risk of CV disease in patients with early RA.

AB0070 INHIBITION OF STAT3 IN PBMCS FROM RHEUMATOID ARTHRITIS PATIENTS: CLUES TO UNDERSTAND SELECTIVITY OF JANUS KINASE INHIBITORS

F. Cacciapaglia[1], V. Venerito[1], S. del Vescovo[1], S. Stano[1], R. Bizzoca[1], D. Natuzzi[1], N. Lacarpia[1], M. Fornaro[1], F. Iannone[1]. *[1]Rheumatology Unit, Department of Emergency and Organs Transplantation (DETO) - University of Bari., Bari, Italy*

Background: The Janus kinase (Jak) - signal transducer and activator of transcription (STAT) pathway has 4 Jak proteins and 7 STAT factors that mediate intracellular downstream of cytokine receptors. Targeted small-molecule therapies with different bond affinity to Jak proteins have been demonstrated effective in rheumatoid arthritis (RA) treatment, but the clinical significance of selective inhibition remains unclear.

Objectives: To explore the effect of selective inhibition of Jak-STAT pathway in peripheral blood mononuclear cells (PBMC) from RA patients compared to healthy donors (HD).

Methods: In vitro Jak inhibition of the subunit 3 of phosphorylated (p) than activated STAT was measured by flow cytometry in peripheral blood mononuclear cells (PBMC) from RA patients with active disease (DAS28>5.1) naïve to any DMARDs (n.5) and HD (n.5), following recombinant human 0.1 ng/ml IL-6 (Peprotech – NJ, USA) stimulation. After blood separation, PBMC were overnight incubated with IC50 concentrations of selective Jak1-, Jak2-, Jak3- and Tyk2-inhibitors (Biovision Inc. – CA, USA) with or without IL-6 stimulation. Mean fold-increase of pSTAT3 was then compared in presence of different compounds stimulation.

Results: Mean pSTAT3 activity after overnight incubation was significantly higher in RA patients compared to HD (37%; 95CI 8.2-56.7 vs 17.9%; 95CI 4.6-21 – $p=0.01$). After IL-6 stimulation, a 2-fold and a 1.4-fold increase in pSTAT3 levels was observed in PBMC from RA patients and HD, respectively. In unstimulated PBMC from HD Jak-inhibitors didn't significantly reduced pSTAT3 activity. In CD14+ cells from RA patients, pSTAT3 activity was reduced with no differences between all four selective Jak-inhibitors, while in CD4+ cells only Jak1-inhibition was able to reduce by 40% pSTAT3 activity. After IL-6 stimulation, the co-culture with Jak1- or JaK3- selective inhibitors was able to significantly reduce pSTAT3 levels in CD4+ lymphocytes, by an average of 20%. While in CD14+ monocytes Jak1-, Jak2- and Jak3- selective inhibitors were able to reduce pSTAT3 activity by a mean of 30%. Tyk-2 selective inhibitor did not interfere with STAT3 activation by IL-6 stimulation of PBMC from RA patients and HD.

Conclusion: Jak/STAT3 activity of PBMC from RA patients with active disease may be differently modulated by specific inhibitors. Selectivity of Jak-inhibitors seems more relevant in lymphocytes after IL-6 stimulation. These preliminary findings may explain discrepancies in effectiveness of selective Jak-inhibitors and pave the way for different choices in clinical practice.

AB0071 ANTI-ACETYLATED PROTEIN IGM-ANTIBODIES AS THE STARTING POINT OF AUTOANTIBODY FORMATION IN RHEUMATOID ARTHRITIS?

T. J. van Wesemael[1], S. Reijm[1], A. Kawakami[2], T. Maeda[3], S. Y. Kawashiri[4], T. Huizinga[1], M. Tamai[2], R. Toes[1], D. van der Woude[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Nagasaki University Graduate School of Biomedical Sciences, Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences,, Nagasaki, Japan; [3]Nagasaki University Graduate School of Biomedical Sciences, Department of General Medicine, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; [4]Nagasaki University Graduate School of Biomedical Sciences, Community Medicine, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan*

Background: Anti-modified protein antibodies (AMPA) are an important hallmark of rheumatoid arthritis (RA) and the fact that they have consistently been found to develop years before disease onset, has provided important insights into the immunopathology underlying RA. In (auto)antibody development, IgM is the first isotype to be produced. However, it is unclear whether IgM-autoimmunity differs between AMPA targeting different post-translational modifications (citrulline, homocitrulline and acetylated residues), which could provide clues about the starting point of the AMPA response.

Objectives: We therefore investigated IgM-levels of anti-citrullinated protein antibodies (ACPA), anti-carbamylated protein antibodies (anti-CarP) and anti-acetylated protein antibodies (AAPA) in healthy individuals, non-RA and RA patients.

Methods: Autoantibodies were investigated in 2 cohorts:

1) a Japanese cohort of healthy individuals (community based Nagasaki Island study) known to be ACPA-positive (n=65) or ACPA-negative (n=197) were compared to Dutch healthy donors (n=30) and ACPA-positive RA patients (n=29). ACPA, anti-CarP and AAPA IgG were measured by ELISAs using CCP4, CHcitP4 and CAcetylP4 peptides with sequences similar to the commercial CCP2 antigen and native control peptides.

2) early arthritis patients from the Leiden Early Arthritis Clinic who had RA (n=648) or another form of arthritis (non-RA, n=555) and healthy controls (n=80). ACPA and AAPA were determined by ELISAs using CCP2 and cACP2 peptides and their native control peptides, while anti-CarP was measured on homocitrullinated versus native fetal calf serum. Mann-Whitney U-tests were performed for statistical comparisons.

Results: ACPA IgM reactivity was mainly present in established ACPA-positive RA patients (Figure 1A) and to a lesser extent in ACPA-positive healthy Japanese individuals, and non-RA arthritis patients (Figure 1D). A similar picture was observed for anti-CarP IgM reactivity, for which again highest levels were found in established RA patients (1B and 1E) and ACPA-positive compared to ACPA-negative healthy Japanese individuals (1B). Intriguingly, AAPA IgM reactivity-levels displayed a different pattern as these were comparable between healthy individuals and ACPA-positive RA patients (1C and 1F). Likewise, AAPA IgM reactivity-levels were also not increased in ACPA-positive healthy Japanese individuals, who instead had lower levels compared to their ACPA-negative counterparts. Furthermore, the AAPA IgM-reactivity levels did not differ between non-RA arthritis patients, healthy controls and RA patients (1F). AAPA IgG-levels on the other hand were clearly elevated in RA patients compared to healthy controls and non-RA arthritis patients (1G).

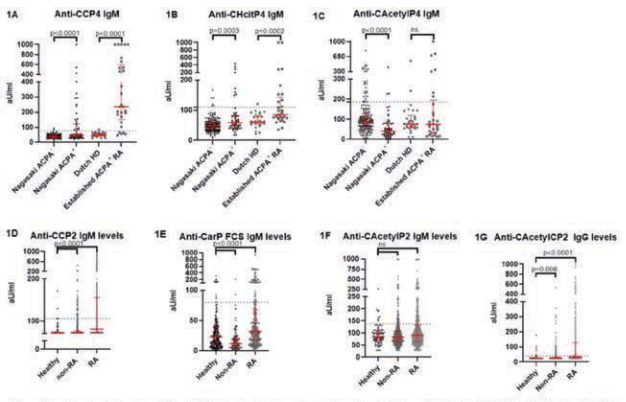

Figure 1. Levels of anti-modified protein antibodies (AMPA) in healthy individuals and rheumatoid arthritis patients. Figure 1A-C: levels of ACPA IgM (anti-CCP4), anti-CarP IgM (anti-CHcitP4) and AAPA (anti-CAcetylP4) IgM in healthy Japanese ACPA-negative and ACPA-positive individuals, as well as Dutch health donors (HD) and established ACPA-positive RA patients. Figure 1D-G: levels of ACPA IgM (anti-CCP2), anti-CarP IgM (anti-CarP FCS),AAPA (anti-CAcetylP2) IgM, AAPA (anti-CAcetylP2) IgG in Dutch healthy controls, non-RA arthritis patients and RA patients.

Conclusion: AAPA are exceptional compared to other AMPA because IgM AAPA-levels are similar among healthy individuals, non-RA arthritis and RA patients. This suggests that AAPA IgM is part of the "normal" immune repertoire and could constitute the starting point for RA-associated AMPA responses, with isotype switching and epitope spreading to other post-translational modifications leading to the typical RA-associated mature AMPA response.

AB0072 GLUCOCORTICOIDS MODIFY NOT ONLY THE PROPERTIES OF DENDRITIC CELLS, BUT ALSO PROGENITOR CELLS

Y. Kurochkina[1], A. Sizikov[2], E. Chernykh[3], T. Tyrinova[3]. *[1]Research Institute of Clinical and Experimental Lymphology - branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Science, Rheumatology, Novosibirsk, Russian Federation; [2]Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Rheumatology, Novosibirsk, Russian Federation; [3]Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Laboratory of cells immunotherapy, Novosibirsk, Russian Federation*

Background: Dendritic cells (DCs) are universal antigen-presenting cells that can have both tolerant and immunosuppressive properties. Tolerogenic properties of DCs are mediated by activation T-regulatory cells, production of anti-inflammatory cytokines and activation T cell apoptosis. Currently, DC is an attractive object of study as a new treatment for rheumatoid arthritis. It is known that glucocorticoids make it possible to control properties of DCs to the tolerogenic side.

Objectives: The aim of the study is to investigate the effect of pulse therapy by glucocorticodes on the properties of DCs and peripheral blood monocytes from which DCs were generated.

Methods: Twenty five patients with rheumatoid arthritis were recruited in this study. All patients follow ACR/EULAR criteria (2010). All studies were performed after receiving informed consent. All patients received conventional synthetic DMARDs. DCs were generated from blood monocytes culturing for 5 days with GM-CSF and IFN-α, LPS as maturation stimuli was added on fourth day. The functions of DCs were evaluated by allostimulatory activity in mixed lymphocyte culture. The properties of DC were studied before pulse therapy (methylprednisolone 500mg №3) and 4 days after pulse therapy.The relative number of monocytes (classical $CD14^{++}CD16^{+}$, intermediate $CD14^{+}CD16^{+}$ and nonclassical $CD14^{+}CD16^{++}$) before and after pulse therapy was also studied in comparison with healthy donors.

Results: Prior to pulse therapy, the DCs from RA patients were characterized by a high ability to stimulate the proliferation of allogenic T-lymphocytes about 20000 cpm. After pulse therapy, the stimulating ability of DCs significantly decreased (9800 vs. 2000 cpm, p=0.04). Evaluation of the relative content of classical ($CD14^{++}CD16^{-}$), intermediate ($CD14^{++}CD16^{+}$) and nonclassical ($CD14^{+}CD16^{++}$) monocytes of healthy donors (n=18) and RA patients (n=25) revealed a decrease in the relative content of $CD14^{++}CD16^{-}$ cells in patients (Me 78 vs. 90%; p=0.02) and an increase in the proportion of $CD14^{++}CD16^{+}$ (Me 4.0 vs. 2.0%; p=0.034) and $CD14^{+}$ $CD16^{++}$ monocytes (Me 5.0 vs. 1.5%; p=0.02). After the end of pulse therapy in RA patients, the relative content of $CD14^{++}CD16^{-}$cells increased (89 vs. 78%), and the proportion of $CD14^{+}CD16^{++}$ monocytes decreased (1 vs. 5%), and RA patients no longer significantly differed in these indicators from healthy donors. Thus, a decrease in the content of $CD14^{+}CD16^{++}$ cells in the monocytes population after pulse therapy was associated with a decrease in the effectiveness of DCs generated to stimulate the proliferation of allogenic T cells.

Conclusion: The effect of pulse therapy of glucocorticoids is associated not only with the ability of glucocorticoids to inhibit the maturation of IFN-DC and induce their tolerant phenotype at the stage of differentiation of monocytes into DCs, but also with the effect on the subpopulation of circulating monocytes that are precursors of DC.

AB0073 NEUTROPHIL EXTRACELLULAR TRAPS: COUPLING WITH RHEUMATOID ARTHRITIS FLARES AND ANTI-CITRULLINE AUTOANTIBODIES PERSISTENCE

S. Bedina[1], E. Mozgovaya[1], A. Trofimenko[1], S. Spitsina[1], M. Mamus[1]. *[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical biochemistry lab, Volgograd, Russian Federation*

Background: Rheumatoid arthritis (RA) is characterized by dysregulation of the adaptive immune system. Detection of subcellular structures with localization of most typical citrulline-containing rheumatoid autoantigens in a single compartment is of special interest considering importance of anticitrulline autoantibodies for autoimmune response in RA. Neutrophil extracellular traps (NETs) can be suggested as a most likely candidate for the role of such structures.
Objectives: To study of peripheral blood neutrophils from RA to generate NETs, associated with diseases exacerbation.
Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles after the local ethical board approval. Circulating neutrophils were isolated with one-step density gradient centrifugation using double layers of ficoll-amidotrizoate gradient. Composition of isolated cellular fractions, their viability, and non-specific activation were evaluated by light microscopy using common Romanowsky-Giemsa staining, trypan blue exclusion test as well as NBT test. Neutrophil fractions contained minute percentages of impurities and low extents of activated and dead cells. NETs were induced by PMA. Spontaneous and induced formation of extracellular traps was assessed using fluorescence microscopy [1]. Results were presented as values (95%CI).
Results: 37 patients (6 males and 31 females, mean age 42.7 years) with verified RA according to the ACR/EULAR 2010 criteria were included in the study. RA disease activity at the inclusion timepoint shouldn't exceed 2.6 DAS28 points. 16 (15.4%) patients had subsequent increase of the DAS28 score above 3.2 at following visits (3, 8 and 12 months after the inclusion). 30 healthy volunteers (9 males and 21 females, mean age 37.2 years) were enrolled as a reference group. Mean proportions of spontaneous and induced NET formation by isolated neutrophils of inactive RA patients (DAS 28<2.6) were 6.0 (5.7-6.3)% and 26.9 (24.0-29.8)%, respectively. Active RA patients (DAS 28>3.2) had dramatic increase of the respective values: 16,6 (16,4-16,8)% and 38,0 (37,7-38,3)%.
Both active and inactive RA patients had significant increase of NET-generating neutrophils proportion comparing to the reference group as well as significant difference of both these parameters between active and inactive phase (p<0.05). The growth rate of spontaneous NET formation in the active RA was 183.8%, the respective value for induced NET formation was 46.7%. The growth rate of spontaneous NET formation is 3.9 times higher than the induced NET formation. Neutrophils from ACPA-positive RA patients were found to have increased spontaneous and induced NETs formation compared to ACPA-negative RA patients (p>0.05).
Conclusion: Thus, our study demonstrated a strong relationship between onset of RA flare and increase of spontaneous and induced NET formation by circulating neutrophils. There was also a clear distinction between ACPA negative and positive RA patients as to higher spontaneous and induced NET formation in the latter subgroup. The comparison using larger group of patients will magnify the differences above significance limit. Continued research in this direction can promote the development of new therapies of RA.

AB0074 RAPAMYCIN INHIBITS IL-1B INDUCED RA SYNOVIAL FIBROBLAST ACTIVATION, AN EFFECT ASSOCIATED WITH ALTERATION IN THEIR METABOLIC PROFILE

B. Barker[1,2], M. Hanlon[1,2], S. Wade[1,2], D. Veale[1,2], M. Canavan[1,2], U. Fearon[1,2]. *[1]Trinity College Dublin, Molecular Rheumatology, Dublin, Ireland; [2]St. Vincent's University Hospital, EULAR Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland*

Background: Rheumatoid Arthritis (RA) is a common autoimmune disease characterized by systemic polyarthritis affecting the joints, most notably of the hands and feet. A fundamental feature of RA is inflammation within the synovial joint due to neo-angiogenesis which facilitates an influx of immune cells and release of pro-inflammatory mediators.
Objectives: In this study we investigate the effect of metabolic reprogramming on IL-1β regulation of stromal cell activation and invasiveness in RA.
Methods: Primary RA synovial fibroblasts (RAFLS) and human umbilical vein endothelial cells (HUVEC) were cultured with IL-1 β (2 ng/mL) alone or in combination with the metabolic inhibitor rapamycin (100nM). Pro-inflammatory cytokines IL-6, MCP-1 and Rantes were quantified by real-time PCR and ELISA. Cellular adhesion and network formation were quantified by adhesion binding assays and Matrigel invasion assays. pS6 (a surrogate marker of the mTOR pathway) was quantified by flow cytometry. Cellular bioenergetics was assessed using the Seahorse-XFe-technology and key glycolytic genes (HK2, PKM2, G6DP) were quantified by real-time PCR. YAP was measured by Western-Blot.
Results: IL-1β significantly induced secretion of IL-6 (p<0.05), MCP-1 (p<0.01) and Rantes (p<0.01) from RAFLS. IL-1β induced leukocyte adhesion to RAFLS (p=0.062) and HUVEC (p=0.051), in addition to an increase RAFLS and HUVEC network formation. This was accompanied by a change in the cellular bioenergetic profile of cells, where IL-1β increased the ECAR/OCR ratio in favour of glycolysis for RAFLS (p<0.05) and HUVEC, and induced the % frequency in the cell surface expression of pS6 on RAFLS. Rapamycin inhibited IL-1β -induced leukocyte adhesion and network formation in RAFLS (p<0.05; p<0.05 respectively) and HUVEC (p<0.05). Rapamycin inhibited IL-1β -induced Rantes secretion (p<0.05), no effect observed for IL-6 and MCP-1. Rapamycin also inhibited IL-1b-induce YAP protein expression which is involved in FLS invasive capacity through cytoskeletal rearrangement. This was accompanied by a shift in the metabolic profile from a glycolytic/energetic state back towards a more quiescent state.
Conclusion: Rapamycin inhibits IL-1β -induced pro-inflammatory mechanisms in key stromal cells involved in the pathogenesis of RA. Targeting metabolism may lead to new potential therapeutic or adjuvant strategies, particularly for those patients who have sub-optimal responses to current treatments.

AB0075 IDENTIFICATION OF NOVEL ACETYLATED ANTIGENS IN IMMUNE COMPLEXES OF SYNOVIAL FLUID FROM RA PATIENTS

K. Ghannam[1], H. Bang[2], T. Häupl[1], S. Ohrndorf[1], J. Zernicke[1], U. Kuckelkorn[3], E. Feist[4], G. R. Burmester[1] on behalf of group of Prof. Burmester. *[1]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [2]Orgentec Diagnostika GmbH, Orgentec, Mainz, Germany; [3]Charité – Universitätsmedizin Berlin, Institute of Biochemistry, Berlin, Germany; [4]HELIOS clinic Vogelsang Gommern, Rheumatologie, Gommern, Germany*

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterized by genetic predisposition and associated immunological features including the production of autoantibodies against various epitopes. Several pathways have been implicated in the induction of autoantibodies against novel epitopes through post-translational modifications such as citrullination, carbamylation and acetylation (1). However, the contributions of these anti-modified protein antibodies (AMPAs) in the pathogenesis and formation of immune complexes (IC) in the synovial fluid has not been fully uncovered.
Objectives: To analyze reactivity of monomeric and IC antibodies of RA patients to citrullinated, carbamylated and acetylated modified antigens in comparison to disease control group and healthy donors.
Methods: Synovial fluid (SF) was collected from 17 RA patients and 40 individuals from a disease control group (CG) including reactive arthritis and psoriasis arthritis. Paired serum and SF samples were used from 16 RA and 19 CG compared to serum from 70 healthy donors (HD). Immune complexes (IC) were purified from sera and SF by applying a technique using purified human C1q, which was immobilised on magnetic tosylactivated microparticles (Dynabeads M-280) according to the manufacturer's recommendations for activation of amine groups. Additionally, sucrose gradient centrifugation was used to fractionate SF and sera into 21 fractions and according to protein markers, protein G was used to isolate monomeric IgG from fractions 3-9 and IC IgG from fractions 11-22. ELISA kits for anti CCP-IgG, anti-mutated citrullinated vimentin (MCV)-IgG, anti-acetylated Lysine Antibody (anti-HC55)-IgG and anti-carbamylated vimentin (carbVim)-IgG were used to test reactivity against modified proteins. Extracted antigens from the IC were investigated with Western blot for specific modifications or individual antigens with the corresponding antibodies. Citrullinated and acetylated vimentin was identified as part of IC via mass spectroscopy. Purified AMPAs from serum or SF (isolated from IC or as soluble antibodies) were investigated on a custom-made LineBlot array containing 24 different antigens either citrullinated, carbamylated, acetylated or unmodified/native counterparts.
Results: Titers of anti-CCP, anti-MCV and anti-acetylated (anti-HC55) reactivity were higher in SF of RA patients compared to CG. AMPAs were detected in SF in IC as well as free antibodies. Some isolated IgG (monomeric and IC) showed reactivities against citrullinated and acetylated peptides that could not be detected in native samples. Surprisingly, in addition to citrullinated vimentin, the acetelylated form was also detected in the IC eluted fractions. Haptoglobin and fibrinogen fragments were identified as carbamylated modified proteins in small concentrations. The spectrum of identified acetylated proteins included human proteins such as histones as well as fragments of bacterial filament proteins. SF of RA patients showed reactivity against MCV and citrullinated desmin in LineBlot array.

Conclusion: AMPAs recognize different modified antigens and form immune complexes in the SF of RA patients. The elevated titer of anti-acetylated protein antibodies and the inclusion of its epitope in immune complexes in the synovium points to its contribution in the pathogenesis of RA.

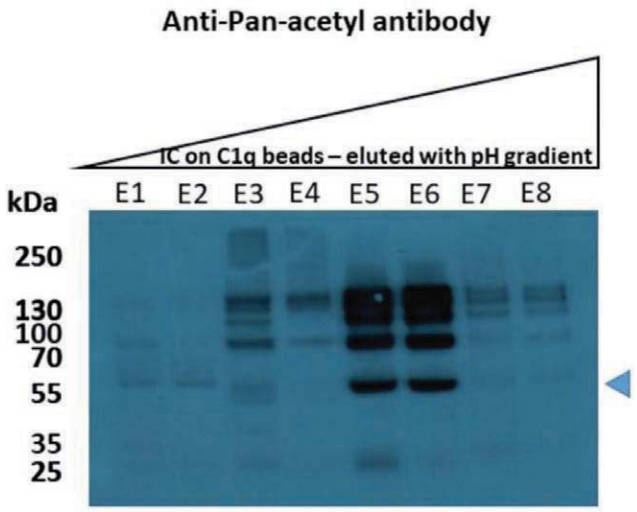

Figure 1. The identification of acetylated antigens in the synovium of RA patients is especially intriguing, as infections (bacteria) are known to not only acetylate their own proteins, but also modify host proteins.

AB0076 DOES HELICOBACTER PYLORI HAVE AN IMPACT ON RHEUMATOID ARTHRITIS?

H. Wu[1,2], C. Wu[1]. [1]*The Eighth Affiliated Hospital of Sun Yat-sen University, Department of laboratory medicine, Shenzhen, China;* [1]*The Eighth Affiliated Hospital of Sun Yat-sen University, Department of laboratory medicine, Shenzhen, China*

Background: Rheumatoid arthritis (RA) is an autoimmune disease of not completely defined pathogenesis. A growing body of studies shows that microbiota may be a critical environmental trigger in the development of RA. Helicobacter pylori (Hp) is a common human pathogenic bacterium and is associated with multiple autoimmune diseases. However, the role of H.pylori in RA is far less well understood.

Objectives: The study aims to investigate the impact of Hp on RA.

Methods: We recruited 81 RA patients (disease duration >1 year) in this study, and all patients met the 2010 ACR/EULAR diagnostic criteria. They were divided into two groups depending on their infection status: the Hp-uninfected group (9 male, 33 female) and the Hp-infected group (10 male, 29 female). C-reactive protein (CRP), Rheumatoid factor (RF), and Anti-citrullinated protein antibodies (ACPA) were measured in serum of patients for assessing disease severity.

Results: The results, as shown in Figure 1, indicated that the serological levels of CRP (P=0.004), RF (P=0.0004), and ACPA (P=0.009) were significantly elevated in the Hp-positive group compared to the Hp-negative group.

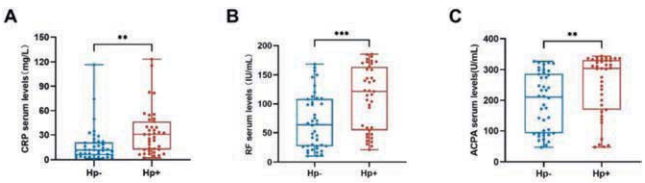

Figure 1. The serological levels of CRP (A), RF (B), and ACPA (C) in two groups. *P<0.05, **P<0.01, ***P<0.001.

Conclusion: Hp-positive RA patients present with higher levels serological of CRP, RF, and ACPA, which suggested that Hp infection could influence the disease progression or severity of RA. Thus, further research is required to investigate the pathogenic mechanism of Helicobacter pylori in rheumatic diseases.

AB0077 IN RHEUMATOID ARTHRITIS PATIENTS, TOTAL IGA1 AND IGA2 LEVELS ARE ELEVATED: IMPLICATIONS FOR THE MUCOSAL ORIGIN HYPOTHESIS

V. Derksen[1], C. Allaart[1], A. van der Helm-van Mil[1,2], T. Huizinga[1], R. Toes[1], D. van der Woude[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands;* [2]*Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: Mucosal surfaces may be involved in the pathophysiology of rheumatoid arthritis (RA) (1). IgA is the most abundant class of immunoglobulin at mucosal sites. Therefore, it is worthwhile to study this isotype in RA patients in more detail. Humans have two IgA subclasses, IgA1 and IgA2, which are not evenly distributed. IgA1 is dominant in serum, whereas IgA1 and IgA2 are more balanced at mucosal surfaces (2). Besides these differences in location, IgA2 has also been ascribed pro-inflammatory properties (3).

Objectives: As IgA subclasses might provide new insights into mucosal involvement and potential pro-inflammatory mechanisms, we investigated total and autoantibody-specific IgA subclasses responses in sera of rheumatoid arthritis patients.

Methods: Sera from two cohorts of RA patients, the IMPROVED (baseline visit) and the EAC (1-year visit), were selected based on previous autoantibody measurements. All patients fulfilled the 1987 (EAC) or 2010 (IMPROVED) ACR criteria for RA. Total IgA subclasses and IgA subclasses of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) were measured using (in-house) ELISA's, and compared to healthy donors. Associations between these IgA subclass levels and markers of inflammation (CRP and disease activity score (DAS)) were investigated using Spearman's rank correlation. Mann–Whitney U tests were performed to investigate the association between IgA1 and IgA2 levels and smoking, a proxy for chronic mucosal inflammation. To correct for confounders, a multivariate linear model including age, gender, CRP and smoking was used.

Results: Total IgA1 and IgA2 levels were increased in RA patients compared to healthy donors in both cohorts (Figure 1A-C, data IMPROVED). This increase was more pronounced in seropositive RA versus seronegative RA. Both total IgA subclasses were raised to the same extent, since the percentage of IgA2 of total IgA in serum did not differ between patients and healthy donors. In seropositive patients, RF and anti-CCP2 IgA1 and IgA2 could be detected, but measurements of anti-CCP2 IgA2 levels proved challenging due to interference of RF IgA. Although IgA2 has been postulated to be more proinflammatory, no correlations were found between total, RF and ACPA IgA subclass levels and DAS. An association between CRP and RF IgA2 was observed, but the effect size was small and did not remain significant after correction for multiple testing in the EAC. In smoking seropositive RA patients, a trend towards a selective increase in total IgA2 and RF IgA1 and IgA2 was observed (Figure 1D, data IMPROVED seropositive RA).

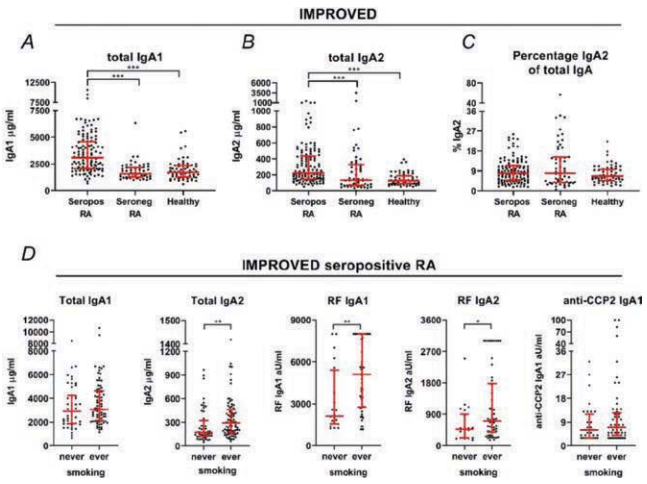

Figure 1.

Conclusion: Seropositive RA patients have raised IgA1 and IgA2 levels and can also harbor RF and ACPA IgA subclasses. No shift towards IgA2 was observed,

indicating that the increase in total IgA is not due to translocation of mucosal IgA into the bloodstream. However, chronic mucosal inflammation might be one of the mechanisms involved in the raise in IgA(2) levels in RA, given the association between smoking and total IgA2 levels. Despite its' pro-inflammatory properties, no strong associations between IgA2 and markers of inflammation were found, which suggests that IgA2 does not play a essential role in the ongoing pro-inflammatory processes in RA patients.

AB0078 NESFATIN-1 EXPRESSION ASSOCIATED WITH A MARKER FOR BONE MATRIX FORMATION P1NP IN RHEUMATOID ARTHRITIS

L. Seewordova[1], J. Polyakova[1], E. Papichev[1], Y. Akhverdyan[1], B. Zavodovsky[1]. *[1]Federal State Budgetary Institution «Zborovsky Research Institute of Clinical and Experimental Rheumatology», lab. methods of treatment and prevention of joint diseases, Volgograd, Russian Federation*

Background: Currently, the role of tissue cytokines in the pathogenesis of various diseases is being actively studied [1,2]. Nesfatin-1 (NF-1) is an endogenous peptide with pleiotropic activity. Recently, there have been works on the involvement of NF-1 in osteogenesis. In the experiment, intravenous administration of NF-1 to ovariectomized rats (OVX) leads to an increase in bone mineral density (BMD). There are works showing inhibition of osteoclastogenesis in mice [3,4]. We assume that the level of NF-1 affects the processes of bone matrix formation. The aim of the study was to determine the relationship between the level of NF-1, bone mineral density, composite body composition and markers of bone metabolism in patients with rheumatoid arthritis (RA).

Objectives: The study randomized 110 patients with RA according to the ACR/EULAR criteria, 2010 and 30 people in the control group.

Methods: All of them underwent osteodensitometry LUNAR DPX-Pro with the determination of composite body composition (BCT) and bone mineral density (BMD). NF-1 levels and bone turnover markers were determined using a commercial ELISA test.

Results: The average concentration of NF-1 in patients with RA was 50.49±34.05 ng/ml, which is significantly higher than in healthy individuals. The average level of NF-1 in the blood serum of healthy individuals was 31.61±3.17 ng/ml (M±σ). The level of reference indicators of NF-1 in healthy individuals, defined as M±2σ, ranged from 25.27 to 37.95 ng/ml.

According to the level of NF-1, all patients with RA were divided into 2 subgroups. The 1st group included patients (n=44) with normal serum NF-1 concentration (less than 37.95 ng/ml), the 2nd group (n=66) included patients with elevated NF-1 levels (more than ng/ml).

During the analysis of the results of the study, we revealed a statistically significant correlation between NF-1 and the N-terminal propeptide of type I procollagen (P1NP)) ($r = 0.218$, $p = 0.022$). The level of CRP and the erythrocyte sedimentation rate positively correlated with the indicators of NF-1.

However, we found no relationship between NF-1 levels and BMD; composite body composition; as well as the level of C-terminal type I collagen telopeptide (β-CTx).

Conclusion: Thus, the relationship between nesfatin-1 and a marker of bone matrix formation (P1NP) was revealed. This may indicate a possible effect of nesfatin-1 on the differentiation and function of osteoblasts.

AB0079 THERAPEUTIC EFFECT OF ANTIGEN B, A PROTEIN FROM ECHINOCOCCUS GRANULOSUS, IN EXPERIMENTAL ARTHRITIS

M. L. Gasparini Vieira[1], M. Farinon[1], R. T. Pedo[1], V. Schuck Clarimundo[1], A. Zaha[2], H. Bunselmeyer Ferreira[2], K. Mariante Monteiro[2], P. Gnieslaw de Oliveira[1], R. Xavier[3]on behalf of Laboratório de Doenças Autoimunes. *[1]Federal University of Rio Grande do Sul, Laboratório de Doenças Autoimunes, Porto Alegre, Brazil; [2]Federal University of Rio Grande do Sul, Departamento de Biologia Molecular e Biotecnologia, Porto Alegre, Brazil; [3]Hospital de Clinicas de Porto Alegre, Serviço de Reumatologia, Porto Alegre, Brazil*

Background: Antigen B (AgB) is a lipoprotein secreted in the hydatic cyst by *Echinococcus granulosus* larval stage and seems to be responsible for regulating the immune balance of host via Th2 response to promote survival of the parasite. A Th2 response can suppress the pro-inflammatory Th1 response generated in several immunopathologies, such as rheumatoid arthritis.

Objectives: To evaluate the anti-inflammatory and immunomodulatory effects of AgB in mice models of Zymozan-induced arthritis (ZIA), Antigen-induced arthritis (AIA) and Collagen-induced arthritis (CIA).

Methods: In all models, mice were divided into three groups: vehicle (saline), AgB 2 µg and AgB 10 µg (intraperitoneal once a day). In ZIA, arthritis was induced in Balb/c mice with an intra-articular (ia) injection of zymosan in the left knee joint thirty minutes after treatment. Nociception was analyzed over a 6h period and mice were euthanized 6h after arthritis induction to assess leukocyte migration into the joint. In AIA, Balb/C mice were sensitized by subcutaneous (sc) injection of methylated bovine serum albumin (mBSA) on day 0. Booster was administered on days 7 and 14. On day 21, arthritis was induced by ia injection of mBSA in the left knee joint. The treatment was performed 24h and 30min before the ia injection of mBSA. Nociception was analyzed over a 24h period and mice were euthanized 24h after arthritis induction to assess leukocyte migration into the joint. Male DBA/1J mice had CIA by subcutaneous injection of an emulsion containing Freund's adjuvant and bovine collagen type II on days 0 and 18. The treatment took place between the 18th and 45th day after induction, as well as the evaluation of clinical arthritis score and nociception. Serum concentrations of IL-2, IL-4, IL-6, IL-10, IL-17, IFN-γ and TNF were evaluated in AIA and CIA.

Results: In ZIA, both doses of AgB diminished leukocytes migration to the knee joint compared with vehicle (AgB 2µg: 5.8±2.7; AgB 10µg: 5.6±2.7; vehicle: 4.8±3.1, $p<0.05$), but did not affect nociception. In AIA, both doses of AgB reduced nociception (AgB 2µg: 7.3±1.6; AgB 10µg: 7.2±1.6; vehicle: 6.0±2.1, $p<0.01$). Moreover, treatment with 2 µg of AgB inhibited in 70% the neutrophils migration (12.0±9.0, $p<0.001$) as well as it was reduced in mice treated with 10 µg of AgB as much as 58% (8.9±7.5, $p<0.001$), compared with control/vehicle (55.9±30.9). In addition, both doses reduced serum levels of IL-6 (AgB 2µg: 2.85±2.63; AgB 10µg: 3.10±3.18; vehicle: 27.07±30.28, $p<0.01$) and the dosage of 2 µg reduced the levels of IFN-γ (AgB 2µg: 0.53±0.27; vehicle: 1.47±0.46, $p<0.05$). In CIA, AgB treatment did not affected clinical score of arthritis (AgB 2µg: 4.6±3.8; AgB 10µg: 2.6±2.9; vehicle: 4.8±3.8, $p>0.05$), but the 2 µg dose improved nociception at day 32 after disease induction (7.1±1.2, $p<0.05$) and diminished serum levels of IL-6 (AgB 2µg: 68.9±71.8; vehicle: 475.7±362.3, $p<0.05$;) and TNF (AgB 2µg: 49.3±31.1; vehicle: 115.9±19.58; $p<0.01$), while the dose of 10 µg improved nociception at days 25, 32 and 34 after CIA induction (7.2±1.2, $p<0.05$).

Conclusion: These results suggest an effect of AgB on the initial pathophysiology of arthritis, reducing the influx of inflammatory cells to the knee joints of mice with acute arthritis. It also showed analgesic and anti-inflammatory potential on murine models of rheumatoid arthritis, highlighting the immunomodulatory role of parasitic helminth proteins on immune-mediated diseases.

AB0080 GDF-11 AND GDF-8 INVOLVEMENT IN MUSCLE IMPAIRMENT OF COLLAGEN-INDUCED ARTHRITIS MODEL

B. Bartikoski[1,2], M. Farinon[1,2], T. Hein da Rosa[1,2], R. T. Pedo[1], T. Karnopp[1,2], R. Cavalheiro do Espírito Santo[1,2], J. Miranda de Souza Silva[1,2], R. Xavier[1,2,3]on behalf of Autoimmune disease laboratory. *[1]Hospital de Clínicas de Porto Alegre, Autoimmune diseases laboratory, Porto Alegre, Brazil; [2]Federal University of Rio Grande do Sul, Medical Sciences program, Porto Alegre, Brazil; [3]Federal University of Rio Grande do Sul, Rheumatology Service, Porto Alegre, Brazil*

Background: Rheumatoid arthritis is an autoimmune, inflammatory disease which affects primarily synovial joints and can induce skeletal muscle wasting (1). It is known that growth differentiation factors 8, 11 plays an important role in muscle homeostasis (2-3).

Objectives: Evaluate muscle mRNA and protein expression of GDF-8, GDF-11 in early and established stages of collagen-induced arthritis.

Methods: DBA1/J mice, were randomized into 5 groups: baseline animals (BL=6); control animals evaluated at days 25 and 50 (CO25=8, CO50=8) and collagen-induced arthritis mice evaluated at day 25 and 50 (CIA 25=8; CIA 50=8). Clinical score, paw edema, and body weight were evaluated. Clinical score, hind paw edema, and body weight were assessed. Grip strength, nociception, fatigue time, and walking speed were assessed on days 0, 18, 25, 50 of experimentation. Animals were euthanized on days zero (BL group), 25 (CIA 25 and CO 25) and 50 (CIA 50 and CO 50) after disease induction. TA muscle was used to myofiber cross-sectional and GA muscle was used to evaluate gene expression of GDF-8, GDF-11 levels via qRT-PCR. Protein expression of GDF-8, GDF-11 levels in GA muscle was performed by ELISA.

Results: RA in the early CIA 25 and established CIA 50 groups was confirmed by high values of clinical score, nociception, paw edema and histological score when compared to the respective controls ($p<0.0001$; $p=0.001$; $p=0.001$). There was a decrease in grip strength in the CIA 25 group and a worsening in this decrease at CIA 50 ($p=0.0021$, $p=0.007$). Fatigue time was shorter in CIA 25 compared to CO 25 ($p= 0.002$) and maintained in CIA 50 ($p= 0.006$). Walking speed showed a decrease in both time points ($p=0.001$; $p=0.000$). After normalization by body weight, only the GA muscle had weight loss in CIA 50 when compared to CO 50 (-34.5%). Similarly, the CSA TA muscle myofiber showed a reduction of 14.04% only at CIA 50 group compared to the CO 50 ($p=0.026$). The GA muscle GDF-11 mRNA levels were higher in the CIA 25 group compared to the CO 25 and BL groups ($p=0.004$; $p=0.0087$, respectively); in CIA 50, there was a trend towards increased muscle GDF-11 mRNA levels ($p=0.07$). The protein expression of GDF-11 in serum samples did not show differences between the analyzed groups; however, in GA muscle, GDF-11 protein expression showed differences at the CIA 25 ($p=0.0023$) and the CIA 50 group ($p=0.017$) compared with the respective controls and a significant difference in muscle protein expression between the CIA 25 groups and CIA 50 ($p=0.0138$). There was a decreased of mRNA content GDF-8 on muscle, in CIA 50 and a decreased between the CIA 25 and CIA 50 in GA muscle ($p= 0.0377$; $p= 0.0019$); GA muscle had an increase of GDF-8 protein levels comparing the CIA 25 and CIA 50 group ($p=0.001$), while protein levels in serum of GDF-8 were decreased in CIA 50 compared with CO 50 ($p= 0.037$). Low muscle strength was associated with higher protein levels of GDF-11 in GA muscle ($r= -0.64$, $p=0.01$) and decreased walking speed ($r=-0.534$, $p=0.04$). Higher serum levels of GDF-8 were associated with higher muscle strength ($r= 0.74$, $p=0.02$) and increased walking speed ($r= 0.64$, $p=0.01$).

Conclusion: At early arthritis, GDF-11 mRNA and protein expressions were increased and are related to the physical impairment, while GDF-8 expression is reduced at established disease and increased in serum over time in CIA model, possibly as GDF-8 had a more systemic role in inflammatory arthritis. Thus, the GDFs may have a role in muscle outcomes in the CIA model and can be involved in muscle atrophy and loss of physical function in RA.

AB0081 BIODISTRIBUTION OF NIPOCALIMAB (ANTI-HUMAN FCRN ANTIBODY) IN HUFCRN TRANSGENIC MICE

A. Vermeulen[1], J. H. Leu[2], S. Sipsey[3], S. Lee[3], L. Ling[4]. *[1]Clinical Pharmacology and Pharmacometrics, Janssen Research and Development, a Division of Janssen Pharmaceutica NV, Beerse, Belgium; [2]Clinical Pharmacology and Pharmacometrics, Janssen Research and Development, Spring House, PA, United States of America; [3]Biologics Discovery, Janssen Research and Development, Cambridge, MA, United States of America; [4]Translational Sciences, Immunology, Janssen Research and Development, Cambridge, MA, United States of America*

Background: Nipocalimab (JNJ-80202135, M281) is a fully human IgG1 monoclonal antibody (mAb) designed to bind to the human FcRn receptor with high affinity at both neutral and acidic pH, and is currently in investigational clinical trials. The primary role of FcRn is to extend the half-life of IgG due to its ability to bind, salvage, and recycle IgG in the circulation. Nipocalimab specifically targets the FcRn IgG binding site, thereby interfering with the binding of native IgG, reducing IgG recycling and accelerating IgG clearance (1).

Objectives: To determine the biodistribution of nipocalimab compared to an isotype control IgG in huFcRn transgenic (Tg32) mice. This type of study is well suited to non-invasively determine the blood PK of labeled antibodies, as well as the kinetic biodistribution into various organ systems.

Methods: Four formulations were prepared for dosing: nipocalimab-VT680XL (N027a), nipocalimab-VT680XL plus 2x unlabeled nipocalimab (N027b), isotype control IgG-VT680XL and control vehicle. The biodistribution assessment experiments were performed in Tg32 mice (n=3/group, strain: B6.Cg-Fcgrttm-1Dcr Tg(FCGRT)32Dcr/DcrJ). A time series of *in vivo* fluorescence-mediated tomography (FMT) imaging sessions of body and brain was collected to follow the biodistribution of antibodies (Abs) after single IV administration. *In vivo*, whole body fluorescence was assessed immediately after administration of each formulation, and at 1, 5, 24, 48, 72, 96 and 144 hrs post administration. Mice were sacrificed after the final *in vivo* imaging timepoint, followed by resection of tissues and *ex vivo* imaging. The *in vivo* tissues were also assessed *ex vivo* at the terminal time point by epifluorescence. *Ex vivo* epifluorescence measurements were obtained for gall bladder, muscle, spleen, pancreas, white blood cells, lymph nodes, and intestines, which were flushed prior to imaging to remove fecal material.

Results: Biodistribution of nipocalimab and control IgG1 mAb were similarly observed to exhibit 2-compartment blood pharmacokinetics, dominant liver accumulation with minimal kidney and bladder signal and a prolonged terminal half-life in circulation (70-90 h). Nipocalimab showed only subtle differences compared to IgG1 control antibody, attributed to specific binding to target antigen. Early tissue accumulation/binding was seen between 1 and 5 hrs post-injection, which yielded an apparent, modest increase in blood clearance and a slightly lower AUC as compared to control IgG. The bulk of increased tissue binding could be attributed to liver retention, with trends for lower accumulation/binding in other tissues, such as pancreas, lung, and muscle. Addition of 2-fold excess of unlabeled nipocalimab to the labeled nipocalimab yielded some small trends of changes in biodistribution of the labeled material.

Conclusion: Whole body biodistribution and blood pharmacokinetics of nipocalimab were similar to that observed for the isotype control IgG1 antibody. Nipocalimab exhibited a subtle trend towards higher liver distribution within the first 5 hours after dosing and a more rapid distribution phase compared to the control antibody. This is possibly related to its FcRn targeting and its shorter anticipated half-life compared to isotype control IgG or other human IgG mAbs. Overall results for both nipocalimab and control IgG were typical for IgG mAbs.

ANTI-INFLAMMATORY EFFECTS OF TOTAL SAPONINS OF PANAX JAPONICUS ON RHEUMATOID ARTHRITIS

J. Zhang[1,2], X. Guo[1,2], Q. Bu[1,2], X. Shen[1,2], Z. Feng[1,2]. *[1]Chinese Medicine Approved by State Administration of Traditional Chinese Medicine, Third-Grade Pharmacological Laboratory, Yichang, Hubei, China; [2]China Three Gorges University, Medical College, Yichang, Hubei, China*

Background: Rheumatoid arthritis (RA) is a common autoimmune disease with inflammation[1]. Total saponins of *Panax japonicus* (TSPJs) are effective components extracted from *Panax japonicus*[2]. They are known to exhibit anti-inflammatory and immunosuppressoive properties, but their effect of anti-inflammation in collagen-induced arthritis (CIA) remains unclear.
Objectives: To investigate the anti-inflammatory targets of TSPJ predicted by bioinformatics and the verification in CIA mice.
Methods: The targets of RA are obtained in the GeneCards database. we used Cytoscape 3.7.2 software to construct a protein-protein interactions (PPI) network and obtain the hub genes. There are four effective components of TSPJ: Araloside A, chikusetsusaponin IVa, ginsenoside Rg2, and ginsenoside Ro. Through molecular docking between the screened hub genes and the four effective components of TSPJ, the possibility of TSPJ treating CIA mice can be predicted. The collagen II (CII) and complete Freund's adjuvant (CFA) were used to induce the CIA model. After establishing the model, 32 DBA1/J mice were divided into C group (n=8), M group (n=8), L group(n=8), and H group(n=8). The L and H groups were gavaged with TSPJ at 30 mg/kg or 150 mg/kg, and the C and M groups were gavaged with normal saline. The thickness of the hind paw, number of swollen joints, and arthritis index were evaluated. After 11 days of treatment, all the mice were sacrificed after anesthesia. Sera were collected to centrifuge tubes and the levels of inflammatory factor were determined by the ELISA kit following the instruction.
Results: A gene list that enriches 263 genes was obtained by searching RA from the GeneCards database. The hub genes of the top 3 obtained from Cytoscape 3.7.2 software were tumor necrosis factor (TNF), interleukin-1β (IL-1β), and interleukin-6 (IL-6). In addition, interleukin-17A (IL-17A), a classical inflammatory index in the top 10, was selected and included in the predicted target. The results of molecular docking between the predicted target and the components of TSPJ showed that the combined pose has good stability. The numerical value of hind paw thickness, swollen joint counts, and arthritis index in the intervention groups were lower than those in the M group, suggesting TSPJ played a critical role in improving pathological changes. Compared to those of the C group, the serum levels of TNF-α, IL-1β, IL-6, and IL-17A were increased in the M group. Compared to those of the M group, the levels of TNF-α, IL-1β, IL-6, and IL-17A in the L and H groups were decreased. Compared to those of the L group, the levels of TNF-α, IL-1β, IL-6, and IL-17A in the H group were decreased. The results suggested that TSPJ may decrease the levels of TNF-α, IL-1β, IL-6, and IL-17A in CIA mice. These results suggest that TSPJ may inhibit the inflammatory effects of CIA mice.
Conclusion: Current study demonstrated a novel inhibitory effect of TSPJ on inflammation in CIA mice, and TSPJ can act on the targets predicted by bioinformatics of CIA mice, suggesting the potential of TSPJ as a therapeutic agent for RA and providing new ideas for the clinical treatment of RA.

AB0083

RELATIONSHIP BETWEEN APOLIPOPROTEIN C-III AND ACTIVATED FACTOR VII-ANTITHROMBIN COMPLEXES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

A. Zielińska[1], E. Zielinska[1], J. Wroński[1], J. Natorska[2], A. Paradowska-Gorycka[3], P. Głuszko[1]. *[1]National Institute of Geriatrics, Rheumatology and Rehabilitation, Rheumatology, Warsaw, Poland; [2]Institute of Cardiology, Jagiellonian University Medical College, Cardiac Surgery, Anesthesiology and Experimental Cardiology, Kraków, Poland; [3]National Institute of Geriatrics, Rheumatology and Rehabilitation, Molecular Biology, Warsaw, Poland*

Background: Both rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are associated with increased cardiovascular risk and thrombosis. Alterations in plasma lipids levels, including apolipoproteins are recognized as the important risk factors of cardiovascular disorders. Activated Factor VII -anti- Thrombin complex (FVIIa-AT) is a marker of the extrinsic coagulation cascade activation, the pathway accelerated by interaction with plasma apolipoprotein C-III (Apo-CIII) (1).
Objectives: To investigate the associations between plasma FVIIa-AT concentration, lipid profile including apolipoprotein CIII, and markers of disease activity in patients with RA and PsA.
Methods: 41 patients with RA, 38 with PsA, and 22 healthy controls, all not taking anticoagulant drugs were selected for the study. The lipid profile comprised triglycerides (TG), total cholesterol (TCh), low (LDL), and high-density lipoprotein (HDL). Serum levels of Apo C-III were measured using a Human ApoCIII ELISA kit CellBiolabs Inc.Austria. FVIIa–AT plasma concentrations were determined using ELISA test. C-reactive protein (CRP) level was measured using the immunoturbidimetric assay. All measurements were performed by a technician blinded to sample origin. The Mann-Whitney test and Kruskal Wallis tests were applied for intergroup comparisons, and correlations were assessed using Spearman's rank tests, due to data non-normal distribution.
Results: The highest serum levels of Apo C-III were found in RA patients (median: 99.9μg/ml, min.-max. 8.7–199) compared to PsA (30.86μg/ml, 12.4–125.8) and controls (9.5 μg/ml, 3.7–29.2), p<0.001. RA and PsA patients revealed higher FVIIa-AT plasma levels than controls (RA median 153.8 pM, min.—max. 57.0–397.8, PsA 157.6 pM, 64.9– 323.8 vs controls 104.5 pM, 68.9–150.9, p<0.001). In RA and PsA patients ApoCIII correlated positively with TG levels (r=0.35, p=0.027 and r=0.38, p=0.018 respectively). In all patients and controls, Apo C-III levels correlated positively with FVIIa-AT concentrations (r=0.45 p<0.001). No significant differences were found in the serum concentrations of TCh, LDL, HDL, TG, and CRP, between the groups of RA and PsA patients.
Conclusion: Elevated concentrations of both, apolipoprotein CIII and activated FVII-AT complexes in rheumatic patients suggest associations between plasma lipoproteins and activation of coagulation cascade leading to a pro-thrombotic state in patients with RA and PsA. Further studies on these relationships are necessary taking into account various clinical conditions of patients and treatment.

INCREASED LIVER DISEASE RISK IN RHEUMATOID ARTHRITIS IS ASSOCIATED WITH DISEASE ACTIVITY, INFLAMMATORY MARKERS, INSULIN RESISTANCE AND ACPAS. INFLUENCE OF METHOTREXATE

I. Arias de la Rosa[1], M. Ruiz-Ponce[2], L. Cuesta López[2], M. D. Gahete[3], N. Herman-Sanchez[3], A. Lucendo-Villarin[4], P. Navarro-Sanchez[4], M. C. Ábalos-Aguilera[2], C. Perez-Sanchez[2], R. Ortega Castro[2], J. Calvo Gutierrez[2], C. Lopez-Pedrera[2], A. Escudero Contreras[2], E. Collantes Estevez[2], N. Barbarroja Puerto[5]. *[1]Pfizer-University of Granada-Junta de Andalucía Centre for Genomics and Oncological Research, Genomic Medicine, Granada, Spain; [2]IMIBIC/University of Cordoba/Reina Sofia Hospital, Rheumatology Department, Cordoba, Spain; [3]University of Cordoba/IMIBIC/Reina Sofia Hospital, Cell Biology, Immunology and Physiology Department, Cordoba, Spain; [4]Hospital General de Tomelloso, Gastroenterology Department, Cuidad Real, Spain; [5]University of Cordoba/IMIBIC/Reina Sofia Hospital, Medicine and surgical sciences, Cordoba, Spain*

Background: Liver alterations, especially nonalcoholic fatty liver disease (NAFLD) are associated with Rheumatoid Arthritis (RA). This abnormality appears as asymptomatic and can progress to a severe liver damage rapidly. Chronic inflammation, treatment with methotrexate (MTX) or even autoimmunity are factors that might be involved, however the mechanisms related to this comorbidity in RA are not completely stablished yet.
Objectives: 1) To evaluate the liver disease risk in RA patients through feasible indexes to be used in the daily clinical practice and its relationship with clinical features of the disease; 2) To analyze the impact of antibodies to citrullinated proteins antigens (ACPAs) on hepatic function; 3) To examine the influence of MTX treatment on classical parameters and new indexes of hepatic dysfunction in a cross-sectional and longitudinal cohort.

Methods: 1) Cross-sectional study in 307 body mass index matched subjects: 55 healthy donors (HDs), 190 RA patients and 62 non-RA patients diagnosed with NAFLD through echography. Obese patients were excluded from the study. 2) Longitudinal study with 50 RA patients treated with MTX for 6 months. Clinical and laboratory parameters, subclinical liver disease biomarkers and 4 indexes to evaluate the presence of fibrosis and steatosis (APRI, "AST to platelet ratio index"; FIB-4, "fibrosis 4 score"; HSI, "hepatic steatosis index" and TyG, "triglycerides and glucosa index") were measured. Association studies of hepatic dysfunction with clinical parameters were performed; A panel of 15 proteins directly involved in hepatic disease was analyzed in serum (C1QTNF1, IL7R, TIE1, CCL5, REG3A, CA3, LCN2, CCL14, NRP1, ICAM3, CD59, TIMP1, CNDP1, GNLY, IGFB6). 3) *In vitro* experiments were carried out in hepatocyte cell line (HEPG2) treated with ACPAs.

Results: Using NALFD patients as positive controls for the four liver disease indexes, RA patients showed significantly higher levels of HSI and TyG biomarkers. In fact, a high proportion of these patients (42.7%) were estimated to suffer NALFD. The association studies in RA patients showed that liver disease biomarkers (HSI and TyG) were related to the insulin resistance state, inflammation, complement component 3(C3), disease activity, and the levels of ACPAs. Serum levels of CNDP1, CCL5, GNLY, TIMP-1, CD59 and CCL14 were significantly increased in RA patients and correlated with hepatic damage indexes. Treatment with ACPAs on hepatocytes promoted the secretion of C3 in parallel with a significant alteration of genes related to glucose and lipid metabolisms, inflammation, fibrosis and apoptosis. MTX treatment, from the point of cross-sectional approach, was not associated with an increase of hepatic enzymes, serum proteins nor liver disease indexes. Treatment with MTX for 6 months did not affect those levels either.

Conclusion: 1) A high proportion of RA patients present an alteration in markers of NAFLD, associated with insulin resistance state, disease activity, inflammation, component C3 and ACPAs levels; 2) the autoantibodies could directly impact hepatocyte biology altering the expression of genes related to glucose and lipid metabolisms, inflammation, fibrosis and apoptosis, 3) Treatment with MTX did not promote any alteration in subclinical liver disease biomarkers after 6 months of treatment. AB0085 TIGLYLCARNITINE AS KEY FACTORS IN LIVER–JOINT AXIS

H. Wang[1], Y. Zhang[1]. [1]*Qilu Hospital, Department of Clinical Laboratory, Jinan, China*

Background: Gut microbiota could promote RA progression metabolites mediated gut–joint axis [1]. We previously reported that liver metabolism has a close linkage with Rheumatoid arthritis (RA) [2]. However, the inter-relational mechanisms between liver and joint are still unclear.

Objectives: This article aimed to explore the shared metabolites signatures of liver, plasma and joint in RA.

Methods: We integrated multiomics datasets metabolites of liver and plasma from in the healthy group (n=10) and CIA group (n=10), and metabolites of knee-joint fluid (synovial fluid) from 40 participants in osteoarthritis (OA) group (n=20) and RA group (n=20). The Weighted Gene Co-Expression Network Analysis (WGCNA) was used to identify the co-expression modules related to liver, plasma and joint.

Results: The blue modules were negativelycorrelated with CIA (r =-0.74, p <0.001), included 200 liver metabolites. The black modules were positively correlated with CIA (r = 0.63, p <0.001), included 78 plasma metabolites. The yellow modules were positively correlated with RA (r = 0.53, p =0.008), included 55 synovial fluid metabolites. There were only 1 metabolite (Tiglylcarnitine) overlapped in RA-related module of liver, plasma and joint.

Conclusion: Tiglylcarnitine may be the key factors to liver–joint axis.

AB0086 PORPHYROMONAS GULAE INFECTION IS NOT RELATED TO EXOGENOUS CITRULINATION OR DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS

C. Castellar[1], D. M. Castillo[2], L. Chila[3], W. Bautista-Molano[3,4], J. M. Bello-Gualtero[4,5], C. Romero-Sánchez[3,4,5]. [1]*Universidad El Bosque, School of Science, Biomedical Master Program, Bogotá D.C., Colombia;* [2]*Universidad El Bosque, Unit of Basic Oral Investigation, School of Dentistry, Bogotá D.C., Colombia;* [3]*Universidad El Bosque, Cellular and Molecular Immunology Group - INMUBO-, Bogotá D.C., Colombia;* [4]*Universidad Militar Nueva Granada, School of Medicine, Clinical Immunology Group, Bogotá D.C., Colombia;* [5]*Hospital Militar Central, Rheumatology and Immunology Department, Bogotá D.C., Colombia*

Background: *Porphyromonas gulae (P. gulae)* is a Gram negative microorganism of the Porphyromonadaceae family. It presents in its structure virulence factors similar to *P. gingivalis*, including the PAD enzyme. An enzyme responsible for catalyzing citrullination, related to the formation of autoantibodies against citrullinated peptides associated with Rheumatoid Arthritis (RA).

Objectives: To evaluate the presence of *P. gulae* and anti-citrullinated peptide antibodies of *P. gulae* PAD in patients with RA and their possible association with clinical markers of activity.

Methods: Ninety RA patients and 90 controls matched for age and sex were included. Serum levels of rheumatological markers such as erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), anti-citrullinated protein antibodies (Anti-CCp/ACPA) and rheumatoid factor (RF) were measured. Disease activity was assessed using Disease Activity Indices-28 (DAS28) and SCDAI. The periodontal diagnosis was according to CDC and American Academy of Periodontology. The presence of *P. gulae* was established by qPCR, verifying the specificity and confirmed due to the high homology between *P. gingivalis* and *P. gulae*. The presence of antibodies against 2 peptides called VDK and LPQ were evaluated in their native structure and citrullinated at one end and inside the PPAD molecule of *P.gulae*. It was determined by ELISA in-house. Prediction of B and T epitopes of PPAD from *P. gulae* was made taking into account the location of arginines within the molecule, restricting it to HLA alleles associated with RA. Associations were established by Kruskal Wallis, Mann Whitney U tests and multiple correspondence discriminant analysis (MCDA) in SPSS V24 and STATA for Windows software, with a significance of 95%,$p \leq 0.05$.

Results: A frequency of *P. gulae* was observed in the RA group of 15.8% versus controls of 9.5%, p=0.1925, A Despite finding a diagnosis of periodontitis in 70.5% of the patients, it was not associated with clinical severity or diagnosis of periodontitis. Comparisons were made classifying the patients according to periodontal diagnosis, the presence of *P. gulae* was observed more frequently in the RA group with a diagnosis of periodontitis, compared to the control group (6.7% vs 2.5%, respectively) without statistical significance (p=0.2576). Of the 180 individuals evaluated, 17 had the presence of anti-citrullinated peptide antibodies of *P. gulae* PAD. Despite a higher frequency in the RA group of antibodies against two citrullinated peptides, the results were not significant (p=0.378 and p=0.346), there was no evidence of a relationship with activity or disease markers in RA. The MCDA test generated two dimensions, one with the clinical activity variables of RA with CC: 0.218, and a second dimension in which the presence of anti-citrullinated peptide antibodies of PAD CC were related to each other CC: 0.749; No positive correlation was found between the clinical variables of RA and the anti-citrullinated peptide antibodies of *P. gulae* PAD.

Conclusion: Despite the presence of *P. gulae* and PPAD citrullinated peptide antibodies from *P. gulae* in patients with RA, it was not possible to establish the relationship with clinical variables, which could indicate a lower contribution of this microorganismto the biological mechanism and molecular of citrullination common between RA and periodontitis. However, an additive effect of *P. gulae* with *P. gingivalis* in the citrullination process cannot be ruled out.

AB0087 THE EFFECT OF BARICITINIB ON STAT1 PHOSPHORYLATION IN MONOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS

C. Garufi[1], G. Tucci[1], I. Pacella[1], M. Zagaglioni[1], A. Pinzon Grimaldos[1], F. Ceccarelli[1], S. Piconese[1], F. R. Spinelli[1], F. Conti[1]. *[1]Sapienza University of Rome, Department of Internal Clinical Sciences, Anesthesiology and Cardiovascular Sciences, Roma, Italy*

Background: Baricitinib is a Janus kinase (JAK)1/JAK2 inhibitor approved for the treatment of rheumatoid arthritis (RA)[1-2]. STAT proteins bind JAK kinase dimers coupled with cytokine receptors and regulate gene transcription. The JAK/STAT system is responsible for the intracellular signaling of different cytokines contributing to the activation process of the monocyte lineage, therefore the use of JAK inhibitors can affect cell functionality[3-6].

Objectives: The aim of the present study was to verify the effects of baricitinib on STAT phosphorylation in peripheral mononuclear cells (PBMCs) of RA patients and to evaluate any correlation between STAT phosphorylation and response to therapy.

Methods: At baseline (BL) and after 4 weeks (w4) of treatment, we evaluated patients' disease activity ($DAS28_{PCR}$, CDAI and SDAI), dividing them into responders and non-responders according to the Minimal Clinically Important Difference for $DAS28_{PCR}$ (1.2 points) at w4. The phosphorylation of STAT1, STAT4 and STAT5 was analyzed at BL and w4 in gated monocytes, Treg, CD8 + and CD4 + lymphocytes from 4 responder and 4 non-responder patients through flow cytometry, at basal conditions and after IL2, IFNα and IL6 stimulation.

Table 1. Clinical and demographic characteristics of Rheumatoid Arthritis patients.

Clinical and demographic characteristics	N=8
Age (years), median (IQR)	59 (8)
Female:Male	7:1
Etnicity	
-Caucasian n (%)	6 (75)
-Hispanic n (%)	2 (25)
Disease duration (months), median (IQR)	156 (201)
Rheumatoid Factor, n (%)	3 (37.5)
ACPA, n (%)	4 (50)
Number of previous csDMARDs, n (%)	
-1	2 (25)
-2	1 (12.5)
-3	1 (12.5)
-≥ 4	4 (50)
Number of previous bDMARDs, n (%)	
-1	2 (25)
-2	2 (25)
-3	1 (12.5)
-≥ 4	3 (37.5)
Baricitinib in monoterapy, n (%)	5 (62.5)
Daily PDN dose, median (IQR)	5 (6)

ACPA: anti-citrullinated protein antibodies; csDMARDs: conventional syntetic disease-modifying antirheumatic drugs; bDMARDs: biological disease-modifying antirheumatic drugs; PDN: prednisone.

Results: Baseline clinical and demographic characteristics of patients are reported in Table 1. We showed that monocyte count decreased from BL to w4 mostly in responders. Basal pSTAT1 phosphorylation tent to be higher in monocytes of non-responder patients; after 4 weeks of treatment, the reduction of the cytokine-induced pSTAT1 was significantly greater in monocytes from responders compared to non-responders (Figure 1). The phosphorylation of STAT4 and STAT5 was not affected by treatment in any cell type and at any time point. We further studied the STAT1 phosphorylation pathway isolating the effect of stimulation with IFNα and stratifying monocytes according to their surface marker expression of CD14 and CD16 in classical, intermediate and non-classical. We observed the same pattern with a significant greater reduction of pSTAT1 in monocytes from responder patients, compared to non-responders, after the treatment with baricitinib.

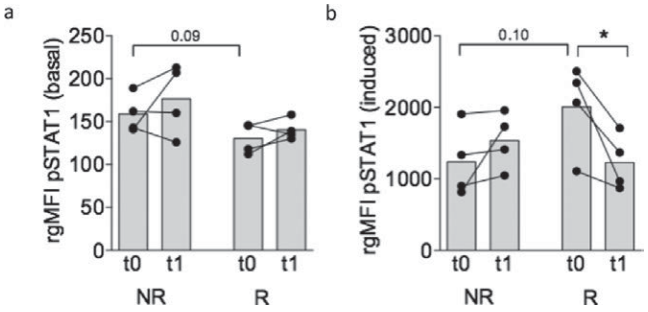

Figure 1. STAT1 phosphorylation in responder (R) and non-responder (NR) patients at basal conditions (before stimulation) (a), and after cytokine (IL2, IFNα and IL6) stimulation (b) at baseline and at T1 (week 4).

Conclusion: These results may suggest that monocyte count and STAT1 phosphorylation in circulating monocytes could represent early markers of response to baricitinib therapy.

AB0088 DOUBLE-STRANDED DNA BREAKS ARE A MARKER OF THE INFLAMMATORY ACTIVITY OF RHEUMATOID ARTHRITIS

A. Avdeeva[1], Z. Verizhnikova[1], V. Rybakova[1], V. Kozlova[1], T. Popkova[2], A. Lila[3], E. Nasonov[4]. *[1]V.A. Nasonova Research Institute of Rheumatology, laboratory of immunology and molecular biology rheumatic diseases, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Department of systemic rheumatic diseases, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Medical Academy of Continuing Professional Education, Rheumatology, Moscow, Russian Federation; [4]V.A. Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Background: Double-strand DNA breaks (DNA-DSB) are one of the most biologically significant DNA damage lesions that leads to chromosome breakage and/or rearrangement, mutagenesis and loss or gain of genetic information. The phosphorylation of H2AX histone proteins which are located in the vicinity of the DSBs is known as one of the earliest responses to DNA DSBs in cells. Induction

of DNA DSBs in live mammalian cells triggers the phosphorylation near the C-terminal of H2AX protein, which results in the phosphorylated form of H2AX, termed yH2AX. [1,2].

Objectives: To examine DNA-DSB among patients with systemic autoimmune rheumatic diseases (SARDs) by evaluating phosphorylation yH2AX and 53BP1 at the site of injury.

Methods: The analysis included 25 patients with SARDs (19 with RA (16 women, Me;IQR the disease duration 60 (20-103) months, DAS28-ESR 5.05(4.06-5.9)); 4 - with systemic lupus erythematosus (4 women, the disease duration 324 (204-372) months, SLEDAI-2K 9.5 (4.5-16.5) and 2 women with Sjogren's disease. The control group consisted of 14 healthy donors, comparable in gender and age with the examined patients. DNA-DSB breaks were determined as a discrete focus during immunofluorescence staining with anti-yH2AX and anti-53BP1 antibodies of the lymphocyte culture, followed by analysis on the automated platform AKLIDES (Medipan, Berlin/Dahlewitz, Germany).

Results: There were no significant differences in the number of DNA breaks among patients with SARDs and healthy donors (p>0.05). There was a positive correlation between % pos. cells by yH2AX and CDAI (r=0.45 p=0.035), Nuclei with foci by 53BP1 and ESR (r=0.53 p=0.02) and IgM RF (r=0.63 p=0.005). Among patients with high CDAI activity (n=10), there was a greater number of Nuclei with foci by yH2AX - (22.5 (6.0-43.0); a higher average number of foci mean (0.39 (0.19-0.62) and a higher % pos. cells (32.6 (18.7-39.1) comparing with patients with low/moderate inflammatory activity (9,0 (2-12); 0,12 (0,02-0,28); 11,5 (1,8-23,5) accordingly, p<0.05, n=9).

Conclusion: The evaluation of double-stranded DNA breaks can be beneficial as an additional marker for assessing the disease activity among patients with RA.

AB0089 INTEGRIN A11B1 DEFICIENCY AFFECTS THE COURSE OF DISEASE IN THE ARTHRITIC HTNFTG MOUSE

A. De Giuseppe[1], A. Deichsel[1], K. Rauwolf[1], I. Zeinert[2], N. Lu[3], D. Beckmann[1], U. Hansen[1], D. Kronenberg[1], D. Gullberg[3], B. Eckes[2], T. Pap[1], A. Korb-Pap[1].

[1]University Hospital Muenster, Institute of Musculoskeletal Medicine, Münster, Germany; [2]University of Cologne, Translational Matrix Biology, Köln, Germany; [3]University of Bergen, Department of Biomedicine and Centre for Cancer Biomarkers, Bergen, Norway

Background: Rheumatoid arthritis (RA) is an autoimmune disorder conducted by fibroblast-like synoviocytes (FLS), which acquire a tumor-like phenotype causing irreversible cartilage and bone damage. FLS attache to the extracellular matrix (ECM) invading the joints, a process mediated by integrins. Integrins are transmembrane proteins regulating several cell functions like cell migration, cell proliferation, tissue invasion and cytokine expression – key mechanisms during the pathogenesis of RA. The collagen-binding Integrin $\alpha 11\beta 1$ ($\alpha 11$) is expressed on FLS mediating their adhesion to the ECM and in this study, we analysed its implication in RA.

Objectives: We examined the pathogenesis of RA in a murine arthritis model (hTNFtg) lacking $\alpha 11$ to analyze its contribution to joint destructions and the disease course.

Methods: Expression levels of $\alpha 11$ were analysed by Western Blot and immunofluorescence staining using FLS and synovial tissue of patients with RA and hTNFtg mice in comparison to their respective controls. Crossbreeding hTNFtg with $\alpha 11$ deficient (*itga11*$^{-/-}$) mice enabled us to evaluate arthritis progression using clinical parameters like paw swelling and grip strength. Inflammation area and cartilage damage were quantified by histomorphological techniques such as toluidine blue staining of in paraffin-embedded sections from hind paws. Bone erosion was visualized by µCT imaging and quantification of the bone volume in the tarsal bone area.

Results: High expression levels of $\alpha 11$ could be detected in hTNFtg and human RA samples in comparison to their controls. The progression of arthritis in *itga11*$^{-/-}$hTNFtg was slower and less severe in comparison to hTNFtg mice, visible in a stronger grip strength and reduced paw swelling at the same timepoint. The histomorphology analysis confirmed these results showing higher cartilage area (3.21% vs 5.22%, $p < 0.05$), less cartilage destruction (51.73% vs 35.65%, $p < 0.05$) and reduced inflammation (28.28% vs 12.00%) in *itga11*$^{-/-}$hTNFtg compared to the hTNFtg mice. Also, the quantification of the tarsal bone area revealed a higher bone volume (77.94% vs 84.92%, $p < 0.01$) in *itga11*$^{-/-}$hTNFtg.

Conclusion: This study showed the important role of $\alpha 11$ in the progression of joint destruction as it is highly expressed in hTNFtg mice and in human synovial tissue of patients with RA. Its absence results in less severe arthritis progression and joint destruction, therefore a possible and interesting target for RA treatment.

AB0090 BASELINE IGG-FC N-GLYCOSYLATION PROFILE IS ASSOCIATED WITH LONG-TERM OUTCOME IN A COHORT OF EARLY INFLAMMATORY ARTHRITIS PATIENTS

T. Sénard[1], I. Flouri[2], F. Vučković[3], G. Papadaki[4], P. Goutakoli[4], A. Banos[5], M. Pučić-Baković[3], M. Pezer[3], G. Bertsias[2,4], G. Lauc[3,6], P. Sidiropoulos[2,4].

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease which causes chronic joint inflammation and functional limitation[1,2]. The diagnosis of rheumatoid arthritis (RA) is mainly based on clinical data and RA specific autoantibodies, while the prediction of long-term prognosis from disease outset is not clinically reliable[3,4]. The importance of immunoglobulin G (IgG) and its Fc *N*-glycosylation in inflammation of RA has been described, with changes in the glycosylation profiles observed years before the diagnosis of RA[5].

Objectives: We herein sought to assess the value of total serum IgG Fc *N*-glycosylation as a diagnostic and prognostic biomarker in patients with early inflammatory arthritis (EIA). Specifically, we aim to assess whether IgG *N*-glycoform levels may predict the diagnosis of RA or undifferentiated arthritis (UA) and the long-term disease's outcome in patients with EIA arthritis patients naïve to treatment.

Methods: The "Early Arthritis Clinic" of the University Hospital of Heraklion is a prospective cohort of patients with inflammatory arthritis. For the present study, we selected a group of patients naïve to any immunosuppressive treatments with available serum at baseline evaluation (n=118). At baseline, demographics, RA clinical characteristics (DAS28, HAQ-DI) and laboratory tests [autoantibodies (RF and/or ACPA)], were also recorded. The patients were prospectively followed for two years, with clinical, laboratory and disease-related treatments documented. A diagnosis of RA or UA was based on established classification criteria[6]. In order to assess long-term prognosis we formulated a combined "index" of favourable outcome if the patients fulfilled all the following at 24 months of follow-up: remission or low disease activity (based on DAS28 < 3.2) and normal functionality (based on HAQ ≤ 0.25) while on treatment with csDMARDs and never use bDMARDs. We applied a state-of-the-art liquid chromatography - mass spectrometry (LC-MS) based workflow for analysis of subclass-specific IgG Fc *N*-glycosylation at the baseline[7].

Results: We studied 118 EIA patients [age (mean, SD) (53, 15.6) years, females (80.5%), symptoms duration (53.8, 8.7) years, ACPA positive (16%), DAS28 (4.8, 0.14)]. During the 2 years of follow-up, 60% of the patients were diagnosed with RA and 40% with UA. Although patients with UA had higher relative abundances of galactosylated and sialylated *N*-glycoforms (H4N4F1, H5N4F1 and H5N4F1S1) in all IgG subclasses at baseline compared to RA patients, differences were not statistically important. Interestingly, we observed a significant association between high levels of IgG2/3 galactosylation for H5N4F1 [effect 0.63, adjusted p=0.036)] and H3N4F1 [effect -0.55122, adjusted p=0.0496) and favorable outcome after two years of treatment.

Conclusion: In our cohort of EIA we found IgG2/3 Fc *N*-glycoforms to be associated with a favorable prognosis after 2 years of follow-up. Should the present data be confirmed in a larger cohort could be of clinical value. Since currently available prognostic tools have significant limitations, further research should aim to the development of a predictive tool of high specificity and sensitivity based on the combination of clinical, serological data and novel biomarkers.

Lord[6,12]. *[1]Birmingham University, School of Biosciences, Birmingham, United Kingdom; [2]Karolinska University Hospital, Department of Medicine, Solna, Karolinska Institute, Stockholm, Sweden; [3]Birmingham University, MRC-Versus Arthritis Centre for Musculoskeletal Ageing Research, Institute of Inflammation and Ageing, Birmingham, United Kingdom; [4]Birmingham University, NIHR Birmingham Biomedical Research Centre, Birrmingham, United Kingdom; [5]NIHR Birmingham Biomedical Research Centre, University Hospital Birmingham and University of Birmingham, rmingham, United Kingdom; [3]Birmingham University, MRC-Versus Arthritis Centre for Musculoskeletal Ageing Research, Institute of Inflammation and Ageing, Birmingham, United Kingdom; [7]Birmingham, Sandwell and West Birmingham NHS Trust, Birmingham, United Kingdom; [2]Karolinska University Hospital, Department of Medicine, Solna, Karolinska Institute, Stockholm, Sweden; [9]Newcastle University, Faculty of Medical Sciences, Newcastle, United Kingdom; [10]Leiden University, Department of Rheumatology, Leiden, Netherlands; [3]Birmingham University, MRC-Versus Arthritis Centre for Musculoskeletal Ageing Research, Institute of Inflammation and Ageing, Birmingham, United Kingdom; [12]Birmingham University, NIHR Birmingham Biomedical Research Centre, Birmingham, United Kingdom*

Background: Immunesenescence in the adaptive immune system, subsequent to thymic involution, results in compromised immunity and increased susceptibility to autoimmune disease and chronic inflammation. There are reports in the literature that immunesenescence, including thymic atrophy and telomere shortening, is accelerated in patients with rheumatoid arthritis (RA)1. What is unclear is whether RA includes accelerated biological ageing overall in addition to immune ageing which may help to explain the increased risk of age-related diseases in RA2. Recent studies have identified a set of DNA methylated sites across the genome that are highly correlated with chronological age and mortality, termed epigenetic clocks3,4 or DNAm age (DNAma), and can be used to determine an individual's biological age.

Objectives: The aim of our study is to determine if the biological epigenetic clocks of RA patients are accelerated.

Methods: We evaluated the Horvath[3] and Hannum[4] epigenetic clocks of control and RA patients using published DNAm data sets, accessions GSE42861 (EIRA, Swedish cohort of 342 RA patients and 328 non-RA controls) and E-MTAB-6988 (77 RA discordant monozygotic twins).

Results: We did not detect significant differences between DNAma of RA and non-RA twins. Similarly, there were no significant differences between the DNAma of RA patients and controls from the Swedish EIRA cohort. However, we detected a significant acceleration in DNAma of male discordant twins, both RA and non-RA, by 5.4 years (p=3.29e-5) and 2.8 years (p=0.04) using the Hannum and Horvath clocks, respectively. Male participants, both control and RA patients, from the EIRA cohort also exhibited an accelerated DNAma, by 1.5 years (p=7.55e-5) using the Hannum clock but using the Horvath clock a significant DNAma acceleration, by 1.4 years (p=0.002) was detected in male RA patients from the EIRA cohort.

Conclusion: Overall, we detected a significant biological age acceleration in male participants from both RA and control groups and only found a significant difference between DNAma of Non-RA controls and RA patients for one of the epigenetic clocks. Further analysis using additional cohort data and biological clock algorithms is needed to confirm our findings.

AB0092 CTLA4-IG PROMOTES THE M1-M2 SHIFT IN CULTURED MACROPHAGES OF RHEUMATOID ARTHRITIS PATIENTS WITH ACTIVE DISEASE: IN VITRO STUDY

M. Cutolo[1], S. Tardito[1], E. Gotelli[1], P. Montagna[1], R. Campitiello[1], S. Paolino[1], C. Pizzorni[1], A. Sulli[1], V. Smith[2,3,4], S. Soldano[1]. *[1]University of Genova, IRCCS San Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, Genova, Italy; [2]Ghent University Hospital, Department of Rheumatology, Ghent, Belgium; [3]Ghent University Hospital, Department of Internal Medicine, Ghent, Belgium; [4]VIB Inflammation Research Center, Unit for Molecular Immunology and Inflammation, Ghent, Belgium*

Background: In rheumatoid arthritis (RA), macrophages play an important role in modulating the immunoinflammatory response through their polarization into "classically" (M1) or "alternatively activated" (M2) phenotypes and the release of pro-inflammatory cytokines (1). In the active inflammatory phase of RA, circulating intermediate monocytes and synovial tissue macrophages show a M1 phenotype, whereas MerTK$^+$M2 macrophages seem to characterize the synovial tissue of RA patients under remission (2-4). In RA, CTLA4-Ig fusion protein (abatacept) reduces the pro-inflammatory activity of macrophages by interacting with the costimulatory molecule CD86 on surface cell membrane of activated cells, including macrophages (2).

Objectives: The *in vitro* study investigated the efficacy of CTLA4-Ig treatment to induce the shift from the M1 phenotype into an M2 phenotype in cultured monocyte-derived macrophages (MDMs) obtained from active RA patients.

Methods: Cultured MDMs obtained from peripheral blood mononuclear cells of 5 active RA patients (mean age 54±13 years) and 5 age-matched healthy subjects (HSs) after overnight stimulation with phorbol myristate acetate (5ng/ml), were treated with CTLA4-Ig at the concentrations of 100mg/mL or 500mg/mL for 3, 12, 24 and 48 hours. A part of cultured RA-MDMs as wells as cultured HS-MDMs were maintained in growth medium (RPMI at 10% of fetal bovine serum) without any treatment and used as unstimulated cells. Gene expression of CD80, CD86 and toll-like receptor-4 (TLR4), as M1 markers, as well as macrophage scavenger receptors (CD163, CD204), mannose receptor-1 (CD206), as surface M2 markers, and MerTK (functional M2 marker) were evaluated by quantitative real-time polymerase chain reaction (qRT-PCR). Protein synthesis of surface M2 markers was investigated by Western blotting. The statistical analysis was performed by Wilcoxon t-test.

Results: Cultured RA-MDMs showed a high basal gene expression of TLR4, CD80 and CD86 compared to HS-MDMs, confirming to be activated M1 macrophages. In these macrophages, CTLA4-Ig treatment downregulated the gene expression of M1 markers at both concentrations and all timings, but significantly limited to TLR4 and CD80 markers (500mg/mL,12 hours: $p<0.05$). Conversely, both concentrations of CTLA4-Ig significantly upregulated the gene expression of CD163, MerTK and CD206 ($p<0.05$), whereas only the high concentration of CTLA4-Ig significantly upregulated CD204 gene expression ($p<0.05$). The protein synthesis of all M2 surface markers was increased after 24 hours of treatment primarily by the high concentration of CTLA4-Ig, and significantly for CD204 and CD206 ($p<0.05$).

Conclusion: CTLA4-Ig treatment seems to exert an important anti-inflammatory effect by promoting the shift from a M1 to an M2 phenotype in cultured RA macrophages The results suggest a further mechanism for CTLA4-Ig in the modulation of the RA synovitis (5).

AB0093 MODELING OF ANTIGEN-COLLAGEN-INDUCED ARTHRITIS IN BALB/C MICE

M. Fisher[1], V. Kurilin[1], S. Sennikov[1]. [1]*Research Institute of Fundamental and Clinical Immunology, Laboratory of Molecular Immunology, Novosibirsk, Russian Federation*

Background: Rheumatoid arthritis (RA) is one of the most common autoimmune diseases. Currently, disease-modifying drugs and biological agents are used to treat RA [1]. The available drugs are not perfect: they have serious side effects and do not always cause a stable improvement or remission [2]. The above sets the task of finding new approaches to treatment that will be effective, more specific and safe. In this connection, it is necessary to develop and apply experimental models as close as possible in pathogenesis to rheumatoid arthritis. One such model, rarely used at present, is the combined antigen-collagen-induced arthritis [3].
Objectives: To show immunological and histological changes similar to RA in the AIA/CIA model and the validity of its application in research activities.
Methods: Experimental AIA/CIA was induced according to 2 different protocols in 50 BALB/c mice. Clinical assessment of arthritis was made by measuring the swelling of the paws with a caliper at different times. The assessment of immunological changes included the analysis of the content of antibodies to type II collagen by ELISA, the content of T-regulatory cells by flow cytometry. Also, a histological analysis of the obtained data was carried out.
Results: On the 10th day, a significant increase in paw thickness was recorded in animals induced both according to the first and second protocols. The intensity of swelling subsided by the 23rd day. A significant increase in the content of antibodies to type II collagen was observed in all experimental groups, but in animals from Protocol No. 1, the amount of antibodies to type II collagen was significantly higher. A high level of T-regulatory cells was registered only in mice induced according to the first protocol on the 10th day. Histological changes in the form of synovial hyperplasia, pannus, usurations were observed to varying degrees in all experimental groups, but the most pronounced changes were in animals from the first protocol.
Conclusion: In experimental animals, in all the presented protocols, changes were observed that were closest to RA, when compared with classical models of experimental arthritis induction. Based on the fact that protocol 1 animals showed an increase in the content of T-regulatory cells, the levels of antibodies to type 2 collagen were consistently high, and the histological changes were the most pronounced, it can be assumed that protocol 1 of the combined AIA/CIA model on the line of Balb/c mice, is the most suitable for testing and developing new methods of RA therapy.

AB0094 DENDRITIC CELLS AS TARGETS OF PATHOGENETIC THERAPY FOR AUTOIMMUNE DISEASES

Y. Kurochkina[1], M. Korolev[1], E. Letyagina[1], A. Akimova[1], N. Banshhikova[1], V. Omelchenko[1], Y. Ubshaeva[1]. [1]*Research Institute of Clinical and Experimental Lymphology - branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Rheumatology, Novosibirsk, Russian Federation*

Background: Dendritic cells (DCs) are known to contribute to the pathogenesis of autoimmune diseases through presentation of cartilage glycoprotein, production of proinflammatory cytokines and activation of Th1/Th17 responses. DCs are a heterogeneous population and can be divided into groups: myeloid (mDCs) and plasmacytoid (pDCs). DCs can induce both immune response and tolerance.
Objectives: The study is aimed at investigating the subpopulations of peripheral blood DCs (myeloid and plasmacytoid) in patients with rheumatoid arthritis (RA) and axial spondyloarthritis (axSpa) under disease-modifying antirheumatic drugs (DMARDs) treatment as a target of pathogenic therapy.
Methods: There are thirty patients were included in the study. Twenty patients with early RA (ACR/EULAR criteria, 2010, duration of the disease up to 12 months,) and ten patients with axSpa (ASAS criteria) were recruited. RA patients received methotrexate, leflunomide, sulfasalazine or their combination. All patients received NSAID in combination with conventional synthetic DMARDs. Analysis of the content of the B-lymphocytes, myeloid and plasmacytoid DCs was carried out by flow cytometry. B-lymphocytes, subtypes of peripheral blood DCs were characterized by the following phenotypes: myeloid DCs (CD3-CD14-CD19-HLA-DR + CD11c + CD123-), plasmacytoid DCs (CD3-CD14-CD19-HLA-DR + CD11c-CD123 +), B-lymphocytes (CD19 +). Analyses were performed before treatment and 6 months later.
Results: RA patients were characterized by high activity of the disease (DAS28=5.46). At the beginning we revealed significant increasing of the population of myeloid DCs (1.6%) and B-lymphocytes (5.4%). No significant differences were observed in the number of plasmacytoid DCs. After 6 months of treatment, most of the patients had a decrease in the activity of the disease (DAS28=3.5vs5.46, p=0.05, n=12) coupled with a significant decrease mDCs (0.85 vs1.6%, p=0.03) and B-cells (4.2 vs 5.4%, p=0.05). In the remaining patients (n=8), there was no clinically significant improvement (DAS28=4.96) or differences in mDCs (1.45 vs1.6%) and B-cells (5.0vs5.4%). Six months later, there was a decrease in ASDAS activity among axSpa patients (2.56 vs 2.09). We were revealed no differences in amount in mDCs between RA and axSpa patients (1.4 vs 1.6%). After 6 month of investigation we detected decreasing mDCs (1.4 vs 0.9%, p=0.05). We have also found a decrease in B lymphocytes among axSpa patients (5.1 vs 4.1%) that is consistent with some authors' data on B lymphocytes in spondyloarthritis pathogenesis.
Conclusion: Reduction in the number of DCs in the context of treatment combined with reduced activity of diseases confirm the role of DCs in the pathogenesis of autoimmune diseases. In addition, probably being a target of pathogenetic therapy, they can serve as a marker of a good clinical response to the therapy.

AB0095 CHARACTERISTICS OF TUMOR NECROSIS FACTOR-ALPHA AND INTERLEUKIN-6-INDUCED OSTEOCLASTS IN PERIPHERAL BLOOD AND BONE TISSUE FROM PATIENTS WITH RHEUMATOID ARTHRITIS

K. Yokota[1], M. Sekikawa[2], S. Tanaka[2,3], Y. Aizaki[1], Y. Kadono[2], H. Oda[4], T. Mimura[1]. [1]*Saitama Medical University, Rheumatology and Applied Immunology, Saitama, Japan;* [2]*Saitama Medical University, Orthopaedic Surgery, Saitama, Japan;* [3]*Japan Community Health care Organization Saitama Northern Medical Center, Orthopaedic Surgery, Saitama, Japan;* [4]*National Hospital Organization Ibusuki Medical Center, Orthopaedic Surgery, Kagoshima, Japan*

Background: We have previously reported that stimulation of mouse bone marrow–derived macrophages with tumor necrosis factor-α (TNF-α) and interleukin-6 (IL-6) induces differentiation of osteoclast-like cells having bone resorption ability[1]. Recently, we have shown that the combination of TNF-α and IL-6 can induce osteoclasts from human peripheral blood mononuclear cells (PBMCs) via RANKL-independent pathways, and that there are functional differences between TNF-α and IL-6-induced osteoclasts (T6-OCs) and RANKL-induced, conventional osteoclasts (cOCs). In particular, the number of T6-OCs differentiated from PBMCs in patients with rheumatoid arthritis (RA) positively correlated with the modified total Sharp score (mTSS)[2]. On the other hands, no such correlation was observed between the number of cOCs from RA and mTSS.
Objectives: Objectives of this study were to compare the differentiational potential into T6-OCs of PBMCs from RA patients with those from healthy donors, to clarify mRNA and protein expressions of T6-OCs derived from PBMCs from patients with RA, and to identify tartrate resistant acid phosphatase (TRACP) positive multinuclear cells with the same characters as T6-OCs histologically in the sub-chondral bone tissues from patients with RA and osteoarthritis (OA).
Methods: PBMCs and CD14+ monocytes derived from RA patients and healthy volunteers were stimulated with TNF-α and IL-6 or RANKL. Real-time quantitative PCR and immunofluorescence staining were used to measure expression levels of osteoclast-associated mRNA and protein. Consecutive sections of the proximal tibial bone tissue from patients with RA and OA (n=6 each) were stained by TRACP, and analyzed expression levels of osteoclast-associated molecules by immunohistochemistry.
Results: The number of T6-OCs differentiated from PBMCs in RA patients was significantly increased compared to that in healthy volunteers. Expression levels of *RANK* mRNA and protein were clearly up-regulated in cOCs differentiated from CD14+ monocytes and were down-regulated in T6-OCs. In contrast, expression levels of *MMP-3* mRNA and protein were obviously up-regulated in T6-OCs and down-regulated in cOCs. Therefore, we believe T6-OCs and cOCs were differently identified on bone tissue as TRACP+RANK-/MMP-3+ cells and TRACP+RANK+/MMP-3- cells, respectively. The numbers of TRACP+ osteoclasts in subchondral cancellous bone were significantly increased in RA patients compared to those in OA patients. Interestingly, numerous TRACP+/

RANK-/MMP-3+ osteoclasts were present in the subchondral bone from patients with RA, on the other hands, no such cells observed in OA patients.

Conclusion: The PBMCs of RA patients have definitely increased differentiation capacity into T6-OCs, which have potential of degrading chondral tissue. Additionally, cells having same characteristics with T6-OCs are observed in subchondral bone of patients with RA. These results suggest that novel T6-OCs may be involved in the pathogenic mechanisms of inflammatory bone destruction in patients with RA.

AB0096 MECHANISM OF SHIP IN NEUTROPHIL EXTRACELLULAR TRAP IN RHEUMATOID ARTHRITIS

Z. Cheng[1], X. Tang[1], H. Zhang[1], L. Sun[1]. *[1]Department of Rheumatology and Immunology,The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

Background: Rheumatoid arthritis (RA) is a common autoimmune disease with unknown etiology. RA is characterized by the destruction of cartilage and bone. Neutrophils are abundant in synovial fluid of RA and are closely related to the development of RA [1]。In recent years, it has been reported that neutrophils can release neutrophil extracellular traps (NET) , which can not only kill different bacteria and viruses, but also closely related to autoimmune diseases [1,2] Studies have shown that NET is involved in the development of RA[3]. The Src homologous 2 domain containing inositol 5-phosphatase 1 (SHIP-1) controls the level of intracellular inositol 3-phosphate kinase product phosphatidylinositol-3,4,5-triphosphate. SHIP can be used as a positive or negative regulatory signal in different stimuli.And So has studied that the inflammation of CIA mouse model is reduced after SHIP is inhibited.

Objectives: Therefore, we want to study whether SHIP is involved in the formation of rheumatoid arthritis NET and its relationship with NET.

Methods: We isolated neutrophils from RA peripheral blood, stimulated NETosis with PMA, and detected the changes of NETosis in the group with SHIP inhibitor by flow cytometry and immunofluorescence. In addition, DBA mice were divided into three groups: HC, CIA and SHIP inhibitor intraperitoneal injection group. The degree of paw swelling and HE staining were used to detect the inflammation of mice, and the release of NET in CIA model was detected by flow cytometry.

Results: In the DBA model, the generation of neutrophil extracellular traps decreased significantly in the intraperitoneal injection group of SHIP inhibitor. SHIP inhibitor can significantly inhibit the formation of NET in RA patients. In addition, we also found TNF- α Monoclonal antibodies reduced NETosis in RA patients, while SHIP inhibitors inhibited the generation of NET in RA patients. The results suggest that SHIP may inhibit the inflammatory factor TNF- α. In turn, it is involved in the release of NET in rheumatoid arthritis

Conclusion: SHIP participates in the formation of NET in rheumatoid arthritis and affects the production of NET through pro-inflammatory cytokines. Therefore, SHIP is expected to become a new target for the treatment of RA.

AB0097 EFFECT OF CYTOCHROME P450 METABOLITES OF ARACHIDONIC ACID IN RHEUMATOID ARTHRITIS

M. Hoxha[1], V. Malaj[2], B. Zappacosta[1]. *[1]Lady of Good Counsel University, Department of Chemical Toxicological and Pharmacological Evaluation of Drugs, Tiranë, Albania; [2]University of Tirana, Department of Economics and Statistics, Tiranë, Albania*

Background: Arachidonic acid (AA) is a polyunsaturated fatty acid, released in inflammatory disease, such as rheumatoid arthritis (RA). Cyclooxygenase (COX) and lypooxygenase (LOX) pathways have received greater attention than cytochrome P450 (CYP) pathway of AA, which also plays a significant role in RA. AA is a substrate of CYP enzymes through two different pathways: the ω-hydroxylase, and epoxygenase pathways, respectively. The epoxygenase gives rise to epoxyeicosatrienoic acids (EETs) (5,6-EET, 8,9-EET, 11,12-EET, 14,15-EET), whereas ω- hydroxylase produces hydroxyeicosatetraenoic acids (HETEs) [1].

Objectives: The aim of this study is to evaluate the role of Cytochrome P450 metabolites of arachidonic acid and their therapeutic targeting in rheumatoid arthritis.

Methods: Pubmed and Scopus databases were the main databases used to identify all the studies conformed to the eligibility criteria.

Results: CYP enzymes (CYP3A, CYP2C19, CYP2C9, CYP1A2) suppression was observed in the synovial fluid of RA patients with higher IL-6 levels. EETs inhibit bone resorption and osteoclastogenesis, have an important role in blocking inflammation by reducing TNFα, and are negatively linked with pro-inflammatory cytokines (IL-1, IL-6, IL-8)[2]. The anti-inflammatory effects of EETs are potentially attributed to peroxisome proliferator–activated receptor gamma (PPARγ) activation. EETs are also metabolized through soluble epoxide hydrolase (sEH) to dihydroxyeicsatrienoic acids (DHETs), which have a pro-inflammatory activity. On the other hand, 20-HETE deriving from CYP ω-hydroxylase pathway has pro-inflammatory effect [3]. Data have shown that the genetic variations of CYP could affect the individual susceptibility to RA [4].

Conclusion: sEH inhibitors (sEHi) can not only block the inflammation caused by EETs metabolite, but can also act on LOX and COX pathway, and can be used in chronic-phase arthritis to reduce both inflammation, and the pain. In a mouse model of RA, sEHi showed decent RA assessment score improvement [5]. Moreover, data suggest that sEHi inhibit also PGE2 production, and exert an additional anti-inflammatory effect in arthritis. Since NSAIDs can lead to gastric and cardiovascular problems, sEHi are considered a better pharmacological approach in inflammatory rheumatic disease. Despite the failure of some of sEHi to reach clinical trials, we believe that CYP-derived eicosanoids should be further studied as potential target in rheumatic disease. Dual inhibitors sEHI/5-LOX activating protein (FLAP) are also very promising compounds as they can inhibit leukotriene formation, without effecting the levels of anti-inflammatory pro-resolving mediators. In perspective we suggest that multiple ligands targeting different AA pathways or mediators should be further explored as potential targets for designing new compounds to treat RA patients.

AB0098

TOFACITINIB IS SUPERIOR TO DEXAMETHASONE IN MODULATING MAIT CELLS, INNATE LYMPHOID CELLS, AND TH9 CELLS IN PSORIATIC ARTHRITIS

M. De Santis[1], N. Isailovic[1], A. Ceribelli[1], F. Motta[1], M. Vecellio[1], M. Caprioli[1], G. M. Guidelli[1], N. Luciano[1], C. Selmi[1]. [1]*Humanitas Research Hospital - IRCCS, Rheumatology and Clinical Immunology, Rozzano, Italy*

Background: Tofacitinib is a potent and selective oral inhibitor prevalently of JAK1 and JAK3and is currently included in the international recommendations for the management of psoriatic arthritis (PsA). Nonetheless, the mechanisms of the immune response to the treatment remain unclear, particularly regarding the effects on overlooked immune cell subpopulations specifically involved in the pathogenesis of PsA, i.e. mucosal-associated invariant T cells (MAIT), innate lymphoid cells (ILCs), both relevant sources of IL-17, and T lymphocytes producing interleukin 9 (Th9). We thus investigated the effect of tofacitinib on these cell population function and compared with glucocorticoids.
Objectives: To investigate the effect of tofacitinib and dexamethasone on MAIT cells, ILCs, and Th9 cells in PsA.
Methods: We investigated synovial fluid and peripheral blood mononuclear cells from patients with PsA that were cultured with phorbol myristate acetate (PMA)/ionomycin in the presence or absence of 100 or 300nM Tofacitinib or 1000uM Dexamethasone for 24 hours and the addition of brefeldin in the last 2 hours. FACS analysis allowed to identify MAIT cells by CD3+CD161+Valpha7.2TCR; ILCs by CD3+CD45+CD127+, from this population ILC1 were arrayed as cKit-CRTH2-; ILC2 as cKit +/- and CRTH2+, and ILC3 as cKit+ and CRTH2-; Th9: CD3+CD4+IL-9+.
Results: A significant decrease in IL-17 production was observed in CD8+ MAIT cells treated with tofacitinib 300 nM compared to untreated conditions, with a magnitude similar to what observed with dexamethasone [mean fluorescence intensity-MFI median 1920 (interquartile range-IQR 1597-2761), 18.6% (3.9-31.4) in untreated cultures; 1481 (1325-3163), 13.4% (4.5-9.3) in tofacitinib-treated cultures; 1511 (1147-2882); 11.5% (2.5-49) in Dexamethasone-treated cultures; Figure 1]. A reduction of IL-17 production was observed also in ILC3 [52.1% (4.2-59.4) in untreated cultures; 25.8% (5.3-40.3) in Tofacitinib-treated cultures; 35.4% (6.3-47.9) in dexamethasone-treated cultures]. A reduction of IL-9 production was observed in peripheral blood T cells [2.19% (1.3-2.3) in untreated cultures; 0.6% (0.0-1.8) in Tofacitinib-treated cultures; 0.97% (0.07-1.13) in Dexamethasone-treated cultures].

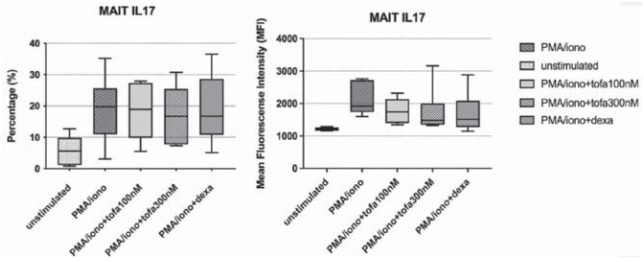

Figure 1.

Conclusion: In PsA, tofacitinib is superior to dexamethasone in reducing the production of IL-17 by synovial fluid MAIT cells and ILC3 cells and of IL-9 by peripheral blood T cells.

KNEE SYNOVIAL FLUID AND SERUM TNF-A IN RHEUMATOID ARTHRITIS: CORRELATION WITH SONOGRAPHIC PARAMETERS

A. H. El Hassaany[1], S. Tharwat[1], M. Mansour[2], A. F. Enein[1]. [1]*Faculty of Medicine, Mansoura University, Mansoura, Egypt, Rheumatology & Immunology Unit, Department of Internal Medicine, Mansoura, Egypt;* [2]*Faculty of Medicine, Mansoura University, Egypt, Department of Clinical Pathology, Mansoura, Egypt*

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory joint condition that affects about 5 out of 1000 persons of the general population [1]. Environment, genetics, and autoimmunity may all have a role in the pathogenesis of the disease [2]. Overproduction of pro-inflammatory cytokines like tumor necrosis factor-α (TNF-α) is the end result of these mechanisms [3].However, little is known about its soluble concentrations in synovial fluid and serum and its association with clinical and ultrasonographic joint parameters.
Objectives: The aim of this study was to assess the presence of TNF-α in serum and synovial fluid of the knee in RA patients with knee effusion and to evaluate its correlation with musculoskeletal ultrasound (MSUS) parameters of the affected knee joint.
Methods: This study included 40 patients (20 RA,10 systemic lupus erythematosus (SLE) and 10 osteoarthritis (OA)) who had knee effusion (unilateral or bilateral) upon clinical examination. The sample size was selected as convenient sample; all patients who fulfilled the inclusion criteria were offered to participate in the study, unless they qualify for any of the exclusion criteria or refuse to participate. The inclusion criteria included the following: a) age ≥ 18 years old, b) patients with knee effusion detected by clinical examination and confirmed by MSUS, c) patients with RA diagnosed according to 2010 ACR /EULAR classification criteria [4],SLE according to SLICC criteria [5] or knee OA diagnosed according to EULAR criteria [6].
Demographic, clinical, and therapeutic data were recruited from all participants. Visual analogue scale (VAS) was used to determine the pain intensity in the affected knee. MSUS examination of the affected knee was performed, and a sample of synovial fluid was aspirated. TNF-α was measured in the aspirated synovial fluid and serum of each patient.
Results: There was a total of 40 patients (20 RA, and 20 age and sex matched non_RA (10 SLE, and 10 OA)). The mean age of RA patients was 48.4 years, most of them were females (80%) with median duration of knee pain of 2 months. Serum TNF-α was barely significantly higher in RA vs. non-RA cases (3.66 ± 0.76 vs 3.24 ± 0.58 U/ml, p= 0.052), while in synovial fluid, difference was not statistically significant (3.73 ± 0.72 vs 3.48 ± 0.58 U/ml, p= 0.252). Also, there was a statistically significantly higher serum TNF-α in RA vs. OA (3.66 ± 0.76 vs 3.06 ± 0.32, p= 0.022). Figure 1 shows that serum TNF-α at cut point of >3.24 U/ml can significantly discriminate RA from OA with 65% sensitivity, and 90% specificity (AUC = 0.725, P = 0.018). There was no statistically significant correlation between synovial TNF-α and MSUS parameters of thee knee either in RA or non_RA patients.

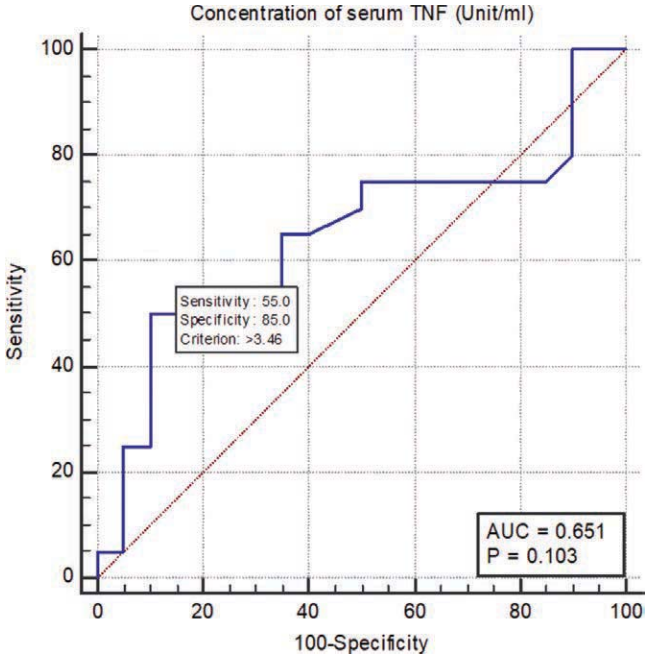

Figure 1. ROC curve for serum TNF as a discriminator of RA from non-RA

Conclusion: Serum TNF-α is higher in RA than non_RA patients. However, synovial fluid TNF-α level do not differ in RA from non_RA patients. No role of synovial TNF-α in knee pathologies in RA patients.

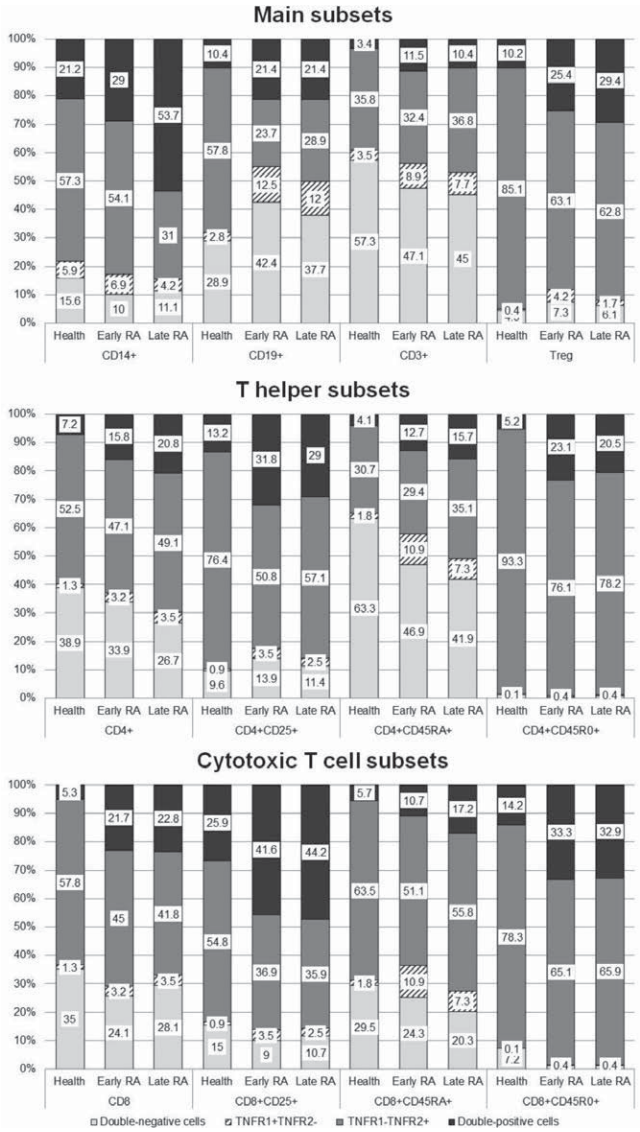
AB0100

LONGER DISEASE DURATION OF RHEUMATOID ARTHRITIS IS ASSOCIATED WITH TNF RECEPTORS REDISTRIBUTION ON IMMUNOCOMPETENT CELLS AND CHANGES IN CELL SENSITIVITY TO CYTOKINE

A. Alshevskaya[1], J. Zhukova[1], J. Lopatnikova[1], O. Chumasova[2], N. Shkaruba[2], A. Sizikov[2], S. Sennikov[1]. *[1]RIFCI, Laboratory of Molecular Immunology, Novosibirsk, Russian Federation; [2]RIFCI, Rheumatology Department, Novosibirsk, Russian Federation*

Background: Longer duration of rheumatoid arthritis (RA) is associated not only with higher disease severity, but also with lower treatment efficacy including anticytokine therapy. One of key mechanisms implementing this is changing in expression of cytokines and their receptors actively involved in the pathological process, such as tumor necrosis factor (TNF).



Objectives: The aim of the study was to study the redistribution of TNF receptors in patients with different duration of RA and depending on the severity of the disease.
Methods: Subanalysis of RA patients with disease duration less than 10 years (Early RA group, n=34) and more than 10 years (Late RA group, n=30) was performed. Late RA patients had DAS-28 activity comparable with Early RA group (4.98 vs 4.69, p=0.68), but had higher radiological stage, higher levels of inflammatory markers, and more often received biologics and had systemic features. As a control group, data from 43 comparable healthy donors were used. Co-expression profile of TNF receptors type 1 and 2 (TNFR1/2) were assessed in main mononuclear subsets: T cells, B cells, monocytes, Tregs, T helpers, cytotoxic T cells. Dynamics of percentage of cells with different co-expression combination was estimated as well as receptors expression density per cell.
Results: The redistribution of receptors on 12 subpopulations of immune cells was studied. Two types of cell responses were associated with disease duration increase. The first trend was presented by monocytes, regulatory T cells and general pool of cytotoxic T cells and consisted in significant decrease in TNFR2 expression density with simultaneously increase of double-positive TNFR1+TNFR2+ cells percentage and decrease of TNFR1-TNFR2+ cells percentage with no changes in proportion of cells without receptors, as compared with health and with disease progression. The second type of response was presented by B cells, T cells, T helper naïve cells and activated T cells and represented a significant increase in TNFR1 expression density and increase of double-positive cells proportion compared to health without influence of disease duration and tendency to decrease in proportion of cells without receptors over time.
Conclusion: Two trends in the response of immunocompetent cells to changes in the level of TNF that occur during chronic inflammation in RA were established. These two trends demonstrate the reactive and adaptive mechanisms of immune cells actively involved in pathological process and are of significant interest for the possibilities of modulating cell sensitivity to the proapoptotic and proinflammatory effects of cytokine and for futher development of targeted RA therapy.

INCREASED DNA DAMAGE AND LACK OF DNA REPAIR IN FIBROBLAST-LIKE SYNOVIOCYTES OF INDIVIDUALS AT RISK OF DEVELOPING RHEUMATOID ARTHRITIS

T. de Jong[1,2], J. F. Semmelink[1,2], R. A. Hoebe[3], P. Krawczyk[3], L. van Baarsen[1,2]. *[1]Amsterdam UMC, Academic Medical Center, Department of Rheumatology & Clinical Immunology, Department of Experimental Immunology, Amsterdam, Netherlands; [2]Amsterdam Rheumatology & Immunology Center (ARC), Amsterdam UMC, Academic Medical Center, Amsterdam, Netherlands; [3]Amsterdam UMC, Academic Medical Center and Cancer Center Amsterdam, Department of Medical Biology, Amsterdam, Netherlands*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory immune-mediated disease leading to synovial tissue inflammation and bone destruction. Inflammation-induced DNA damage in fibroblast-like synoviocytes (FLS) is thought to play an important role in RA pathogenesis. However, since a recent functional genomics study revealed a causal role for FLS in the genetic susceptibility of RA and synovial inflammation is absent in autoantibody positive individuals at risk for RA, we aimed to investigate whether DNA damage in FLS is present before onset of disease.
Objectives: Determine the extent of DNA damage in FLS and their capacity to repair this damage during the earliest phases of systemic autoimmunity.
Methods: We included individuals with arthralgia who were IgM rheumatoid factor (RF) and/or anti-citrullinated protein antibody (ACPA) positive but without any evidence of arthritis (RA-risk individuals, n=6), RA patients (n=6), osteoarthritis (OA) patients (n=6) and controls without inflammatory disease (n=6). Synovial tissue biopsies were collected either during joint surgery or individuals underwent a mini-arthroscopy of a knee joint. Subsequently, FLS were *in vitro* expanded upon enzymatic synovial tissue digestion. DNA damage in FLS (passage 6) was assessed by immunofluorescence staining for γH2AX. DNA damage repair was assessed by first irradiating the cells with 1 gray to induce DNA damage and assess γH2AX staining directly and after 3 and 24 hours of culture to allow for DNA repair.
Results: Preliminary immunofluorescence staining for γH2AX shows that DNA damage is present in RA-risk and RA FLS to more extent compared with FLS from non-inflammatory controls. OA FLS exhibit even more DNA damage and their nuclei show signs of impaired chromosomal segregation, forming micronuclei with high γH2AX staining intensity. Overall, DNA damage repair is slower in FLS from RA-risk individuals, RA and OA patients compared with controls as shown by persistent γH2AX staining after inducing DNA damage.
Conclusion: These findings reveal increased DNA damage and concomitant impaired DNA repair in FLS of not only patients with synovial inflammation but also in FLS from RA-risk individuals, suggesting that DNA damage is already present in absence of overt synovial tissue inflammation and before clinical

disease onset. More research is needed to investigate DNA damage or lack of DNA repair as potential driver in development of RA.

AB0102 GPX4 - ASSOCIATED FERROPTOSIS OF MACROPHAGE EXACERBATES IMMUNE IMBALANCE IN RHEUMATOID ARTHRITIS

Y. Liu[1], Y. Jiang[1], Y. Pan[1]. [1]*The Third Affiliated Hospital of Sun Yat-sen University, Rheumatology department, Guangzhou, China*

Background: Reactive oxygen species accumulation and iron overload are involved in the pathogenesis of rheumatoid arthritis (RA). Ferroptosis, as a non-apoptotic form of programmed cell death, characteristically depends on iron and lipid peroxidation. However, the role of ferroptosis in RA has not been explored.
Objectives: To explore the role of ferroptosis in immune imbalance of rheumatoid arthritis.
Methods: Iron content in synovial fluid was determined by colorimetry. Lipid peroxidation was assessed by flow cytometry and immunofluorescence. MDA and GSH were used as markers to assess iferroptosis. K/BxN spontaneous arthritis mice and serum-induced arthritis mice were used as in vivo animal models of ferroptosis.
Results: Iron overload and hyperlipid peroxidation of mononuclear-macrophages were found in the synovial fluid of RA patients. Liproxstatin-1, the specific inhibitor of ferroptosis, alleviated the progression of arthritis mice model by increasing M2-like macrophage numbers. Mechanistically, iron overload in arthritis lesion induced anti-inflammatory macrophage ferroptosis by promoting glutathione peroxidase 4 (GPX4, a classical anti-ferroptosis molecule) to undergo P62 - dependent autophagy degradation.
Conclusion: Our results provide compelling evidence that macrophages ferroptosis plays a major role in RA. M2-like macrophages are more sensitive to ferroptosis than M1-like macrophages under iron overload circulation. This finding heavily contributes to the immune imbalance of rheumatoid arthritis.

AB0103 SITE SPECIFICITY OF RHEUMATOID ARTHRITIS INFLAMMATION: A SECONDARY ANALYSIS OF BIOPSIES FROM RADIAL AND ULNAR ASPECTS OF MCP JOINTS

K. Skovsgaard Itenov[1], N. Søe[2], E. M. Bartels[1], H. Bliddal[1], M. Andersen[1]. [1]*Copenhagen University Hospital, Parker Institute, Frederiksberg, Denmark;* [2]*Copenhagen University Hospital, Department of Hand Surgery, Gentofte, Denmark*

Background: Ulnar drift is a common complication of Rheumatoid Arthritis (RA) (1,2). There is no clear consensus regarding the etiology of the hand deformity. Observations from corrective hand surgery and other studies have noted more pronounced inflammation in the radial site of the MCP-joints (3,4). This could partly explain the pathophysiology behind the ulnar deviation.
Objectives: To determine if there is more pronounced inflammation, measured by increased CD-68 expression (5) and Krenn-synovitis score (6), at the radial side of the MCP joints when compared to the ulnar side, in patients with verified RA.
Methods: We included RA patients from a previous study who had biopsies taken from the most affected joints based on clinical examination and ultrasound (7). Twenty-nine PIP-, MCP- and wrist-joints were biopsied. Biopsies from the MCP-joints were taken from the dorso-ulnar and dorso-radial concavity. Inflammation was graded by the Krenn-synovitis score (0-9) and the density of CD-68-positive cells (%). The difference between radial and ulnar joint inflammation was calculated by paired t-test. P-value <0.05 was considered statistically significant.
Results: In 8 patients biopsies were taken from both the ulnar and the radial site of the same MCP-joint. The mean difference in inflammation on the radial and ulnar site of MCP-joints was based on differences in CD-68 density: 0,67% (95%-CI -4,77 to 6,10; P = 0,77) (Figure 1) and Krenn-score: 0,83 (95%-CI -1,31 to 2,98; P = 0,36), respectively.

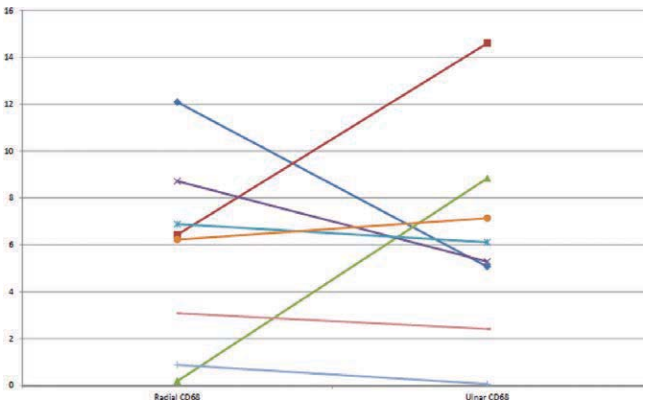

Figure 1. Paired data on CD-68 percentage in radial and ulnar sites

Conclusion: There was no difference in concentration of inflammatory cells or overall synovial pathology between the radial and ulnar site of MCP-joints in RA patients. The impression of a more pronounced inflamed synovium on the radial site of MCP joints, as observed during surgery, does not seem to arise from an immunological preference, but rather to be linked to a larger synovial volume.

Spondyloarthritis - aetiology, pathogenesis and animal models

AB0104 CHANGES IIN SECRETION OF TH17 EFFECTOR CYTOKINES IN SYNOVIAL FLUID CELL CULTURES BY THE ATOPIC DERMATITIS BIOLOGIC DUPILUMAB (ANTI-IL-4 RECEPTOR ALPHA)

M. P. Hundahl[1], S. Lomholt[1], T. W. Kragstrup[1]. [1]*Aarhus University, Institute of Biomedicine, Aarhus, Denmark*

Background: Inflammatory arthritis and enthesitis has been documented as adverse events in patients with atopic dermatitis treated with dupilumab targeting the interleukin 4 (IL-4) receptor alpha subunit (1,2). The disease mechanisms underlying atopic dermatitis are primarily driven by a substantiated Th2 response. Therefore, blockade of IL-4 and IL-13 signaling rationally inhibits Th2-mediated atopy. However, IL-4 and IL-13 are also well-known suppressors Th17 cells. Therefore, we hypothesize that dupilumab-induced arthritis could be caused by increased production of Th17 effector cytokines.
Objectives: Here, we tested the effect of dupilumab on in vivo activated peripheral blood and synovial fluid mononuclear cells from patients with active inflammatory arthritis.
Methods: We used peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) from patients with immune mediated inflammatory arthritis (juvenile idiopathic arthritis, spondylarthritis, polyarthritis, psoriatic arthritis, and arthritis with intestinal bowel disease (IBD), n=8). PBMCs and SFMCs were either unstimulated or stimulated with CD3/Cd28 beads, and then cultured with three different concentrations of dupilumab (0.2 µg/mL, 1.0 µg/mL or 5.0 µg/mL). Supernatants were analyzed by the two MSD Multi-Spot Assay System in the Proinflammatory Panel 1 (INF-γ, IL-1β, IL-2, Il-4, IL-6, IL-8, IL-10, IL-12p70, IL-13 and TNF-α) and the Th17 Panel 1 (IL-17A, IL-21, IL-22, IL-23, IL-27, IL-31 and CCL20). All data were transformed to ratios by dividing the value of the samples treated with dupilumab with the value of untreated samples. Data were then analyzed with repeated measures one-way ANOVA or the paired t-test depending on the number of groups. P-values <0.05 were considered statistically significant.
Results: In SFMCs not cultured with CD3/CD28 beads, dupilumab decreased the production of IL-17A, IL-22, CCL20 and IL-1β (P-values: 0.0007, 0.0002, 0. 0025 and 0.0432 respectively). IL-6 was decreased by dupilumab in both PBMCs and SFMCs not cultured with CD3/CD28 beads (P-value = 0.013 and P-value = 0.001). The concentration of cytokines measured in supernatants from the PBMCs cultured without CD3/CD28 were low in both the Proinflammatory Panel and the Th17 panel. Interestingly, the response to increasing concentrations of dupilumab in PBMCs and SFMCs pre-conditioned with CD3/CD28 showed a biphasic curve. Thus, the low concentration of dupilumab (0.2 µg/mL) resulted in increased concentration while the higher concentrations of dupilumab (5.0 µg/mL) decreased the concentration. This was particularly seen in CD3/CD28-stimulated SFMC cultures for IL-17A, IL-22, IL-4, IL-13, IL-31, IL-10 and IL-1β (P-value for UT vs. 0.2 µg/mL: 0.0117, 0.0379, 0.0052, 0.0002, 0.0456, 0.0003 and 0.0484) In CD3/CD28-stimulated PBMC cultures, the biphasic response curve was seen for TNF-α, IFN-γ, IL-2 and IL-10 (P-value for UT vs. 1.0 µg/mL: 0.4978, 0.3922, 0.0373 and 0.0008).
Conclusion: This data contradicts the hypothesis and indicates that dupilumab does not increase the production of Th17 related cytokines. However, the increase in proinflammatory cytokines seen with the low concentrations of dupilumab suggest that partial blockade of the IL-4 receptor alpha under some conditions could lead to augmented inflammation.

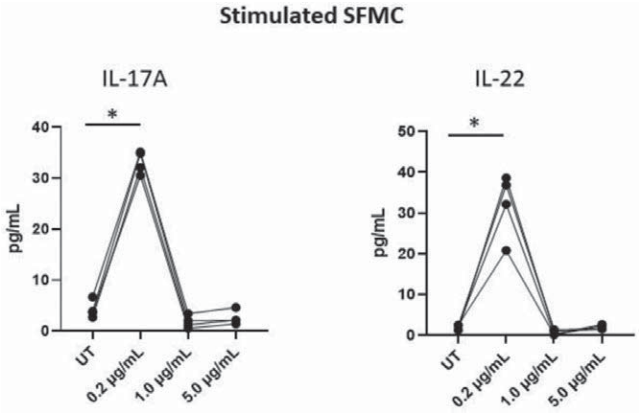

Figure 1. The biphasic response to dupilumab treatment shown for the analytes IL-17A and IL-22. An increase is seen in UT vs. 0.2 µg/mL with a P-value of 0.0117 and 0.0379.

AB0105 A HIGHLY SENSITIVE NEO-EPITOPE BIOMARKER OF TYPE II COLLAGEN C- TERMINAL IS ASSOCIATED WITH CARTILAGE FORMATION

H. Port[1,2], C. Thudium[3], T. Gantzel[4], A. C. Bay-Jensen[1], M. Karsdal[3], S. Holm Nielsen[3]. [1]*Nordic Bioscience A/S, Immunoscience, Herlev, Denmark;* [2]*The University of Copenhagen, Faculty of Health and Medical Sciences, Clinical Medicine, København, Denmark;* [1]*Nordic Bioscience A/S, Immunoscience, Herlev, Denmark;* [4]*Gentofte Hospital, Orthopaedic Surgery Unit, Hellerup, Denmark*

Background: Altered extracellular matrix (ECM) remodeling is a common event in rheumatic diseases. Type II collagen is the most abundant ECM protein in the cartilage and provides tensile elasticity and strength to enable support to the joints. Chondrocalcin, also known as the C-terminal propeptide of type II collagen, is among the most highly synthesized polypeptides in cartilage. It is cleaved off by BMP-1/C-endopeptidase during maturation and plays a role in assembly of type II collagen and in calcification of cartilage matrix. When cleaved off, the chondrocalcin fragments are released into circulation, where they can be quantified in a blood sample.
Objectives: This study aimed at developing an immunoassay targeting a neo-epitope of chondrocalcin, named CALC2. Moreover, we explored its biomarker potential to evaluate type II collagen formation in an *ex vivo* human osteoarthritis (OA) cartilage explant model (HEX) with anabolic treatment, and in serum from healthy controls, patients with rheumatoid arthritis (RA) and patients with ankylosing spondylitis (AS).
Methods: A novel direct immunoassay targeting the neo-epitope of type II collagen C-terminal (PIICP) was developed and technically validated. The technical validation included inter- and intra-variation, linearity, spiking recovery, stability, and specificity. Specificity of the monoclonal antibody was tested using an elongated peptide, a truncated peptide, and a non-sense peptide to exclude possible cross-reactivity. CALC2 levels were measured in supernatant from HEX cultured for 35 days in serum free DMEM/F12 medium with IGF-1 (Insulin-like Growth Factor-1) (100 ng/mL), including a control group without (w/o) treatment. The supernatant was harvested 3 times weekly and replaced with new culture medium with IGF-1. Biomarker results were confirmed by western blot. Serum samples from 18 healthy donors (mean age 35.8 ± SD 3.8, 100% Caucasian), 19 patients with AS (mean age 35.8 ± SD 3.2, 100 % Caucasian) and 18 patients with RA (mean age 35.8 ± SD 3.4), 100% Caucasian) were also measured by CALC2. Linear regression models with pairwise comparisons were performed.
Results: A technically robust and specific assay was developed. The inter- and intra-assay variation of CALC2 was determined as 12% and 7% respectively. CALC2 showed a good dilution recovery, spiking recovery, and storage /freeze-thaw stability (All, 100%±20%). CALC2 showed specificity towards the targeted sequence and did not show any reactivity towards the truncated peptide, elongated peptide, or non-sense peptide. CAL2 neoepitope levels were significantly elevated after 14, 21 and 28 days of IGF-1 treatment compared to untreated ($p<0.01$, $p<0.0001$ $p<0.001$, respectively). The western blot confirmed the CALC2 results by the presence of a band of ~35 kDa in all explants, corresponding to the weight of chondrocalcin previously stablished (1). Furthermore, the bands were more pronounced at day 21 in the IGF-1 treated explant compared to the untreated explant. CALC2 also showed significantly lower levels in patients with RA compared to controls (p=0.003; mean 0.32 ng/mL ± SD 0.16 vs 0.64 ng/mL ± SD 0.31).
Conclusion: Higher levels of CALC2 were detected in supernatants from explants after 14, 21 and 28 days of IGF-1 treatment compared to untreated. Lower levels of CALC2 were present in patients with RA compared to healthy controls. Overall, this suggests that CALC2 may have potential as biomarker for type II collagen formation. However, further preclinical and clinical studies are required to validate these findings.

AB0106 THE PATTERN OF JOINT INFLAMMATION IN THE CAIA MOUSE MODEL OF ARTHRITIS

M. Van Mechelen[1,2], S. Hayer[3], K. Van Laere[4], R. Lories[1,2], B. Neerinckx[1,2]. *[1]KU Leuven, Laboratory of Tissue Homeostasis and Disease, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, Leuven, Belgium; [2]University Hospitals Leuven, Division of Rheumatology, Leuven, Belgium; [3]Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria; [4]KU Leuven, Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, Leuven, Belgium*

Background: Animal models of inflammatory arthritis such as the collagen-antibody induced arthritis (CAIA) have a variable disease incidence in hind paw arthritis, complicating experimental design.
Objectives: To investigate the use of 18FDG µPET/CT as a guide for inflammation in joints otherwise inaccessible for clinical scoring, enabling the use of additional joints for histological analysis.
Methods: CAIA was induced in 8 male DBA/1 mice using the ArthritoMab Antibody cocktail (4 mg/mouse on day 0), followed by 100 µg LPS at day 3. Body weight, clinical signs of arthritis such as paw swelling and grip strength loss were recorded 3 times per week in both front and hind paws. Whole body 18FDG µPET/CT was performed at day 11, the estimated time of peak inflammation, and inflammation was scored visually on images scaled to the same standardised uptake value. At day 28, animals were euthanized and peripheral joints were collected for histological analysis.
Results: Cumulative disease incidence based on paw swelling dropped from 100% to 87.5% when looking only at hind paws, and to 75% when taking into account only the region suitable for histological analysis, namely the ankle and midfoot of the hind paws. Symmetrical, bilateral hind paw arthritis was not observed. While hind paw arthritis showed a tendency to be less severe in comparison to front paw arthritis, grip strength was equally affected, indicating possible involvement of other hind limb joints. µPET/CT images detected inflammation in the hind paws (at least unilateral involvement in 62.5% of the mice, bilateral involvement in 0%), knee joints (at least unilateral in 75%, bilateral in 50%), hip joints (at least unilateral in 50%, bilateral in 0%), elbow joints (at least unilateral in 50%, bilateral in 37.5%) and shoulder joints (at least unilateral in 25%, bilateral in 25%). Histology could confirm this inflammation with the presence of inflammatory infiltrates and bone erosions. Grip strength loss in hind limbs without paw swelling correlated only weakly with knee inflammation detected by µPET/CT.
Conclusion: In the CAIA model, inflammatory arthritis can develop in all peripheral joints, in particular with a high incidence in knee joints, which are highly suitable for subsequent histological analysis. Since clinical scoring seems insufficient for detecting these affected joints, implementation of in vivo imaging modalities such as µPET/CT, offers a substantial benefit in disease monitoring and assessment.

Costa[2]. *[1]Centro Hospitalar Tondela Viseu, Rheumatology Unit, Viseu, Portugal; [2]São João Universitary Hospital Center, Rheumatology department, Porto, Portugal; [3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; [4]Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology department, Vila Nova de Gaia, Portugal; [5]University Hospital Center of Algarve, Rheumatology department, Faro, Portugal; [6]Faculty of Medicine, University of Porto, Medicine, Porto, Portugal*

Background: SARS-CoV-2 infection can lead to severe inflammation and has been suggested to induce Psoriatic Arthritis (PsA) flares.[1] However, the impact on disease activity and response to biological disease modifying anti-rheumatic drugs DMARDs (bDMARDs) remains unknown.
Objectives: To evaluate the effect of SARS-CoV-2 infection on disease activity and bDMARDs responses in patients with PsA.
Methods: We performed a retrospective analysis including all the patients with PsA, meeting the CASPAR criteria and under biologic therapy, followed in the Rheumatology department of a tertiary university hospital. Demographic and clinical data, including occurrence of SARS-CoV-2 infection, were collected from our national database (reuma.pt). Disease activity (CDAI, SDAI, DAS28 4v, BASDAI, ASDAS) and bDMARDs responses (EULAR, ASDAS, ASAS, ACR and PsARC responses) were evaluated before and after SARS-Cov-2 infection. Statistical analysis was performed with SPSS. Continuous variables were compared through paired samples t-test.
Results: A total of 102 patients with PsA were included. Fifty-two were females (51%).The mean age was 53 ± 11.09 years and the median disease duration was 15 years [min 2, max 47]. Overall, 54 (53%) patients had predominant axial involvement, 26 (26%) peripheric and 36 (37%) enthesopathic. The most used bDMARD was etanercept (n=28, 27.5%) followed by adalimumab (n=22, 21.6%) and secukinumab (n=18, 17.6%).
The prevalence of SARS-CoV-2 infection was 15.7% (n=16). Sixty-three per cent received the BNT162b2 (Pfizer/BioNtech) vaccine, 31% received mRNA-1273 (Moderna), 13% received AZD1222 (AstraZeneca) and 13% received AD26.COV2.S (Janssen/Johnson & Johnson). Sixty-three percent were infected before any vaccination, 13% after the first dose and 25% after the second. The most common symptoms were anosmia (65%), dysgeusia (56%) and cough (56%). All patients fully recovered from the infection, with no need for hospitalization.
Regardless of the score used, the difference between the mean disease activity after SARS-CoV-2 infection and that at baseline did not reach statistical significance. At baseline and after infection, mean (SD) disease activity parameters were, respectively: CDAI 8.6±5.7 vs 8.6±5.7, p=0.997; SDAI 9.3±6.6 vs 9.2±6.1, p=0,928; DAS 28 4v 2.9±1.2 vs 2.9 ±1.2, p= 0.818; BASDAI 3.6 ±2.6 vs 3.2±2.7, p=0.506; ASDAS 2.2±1.2 vs 2.2±1, p=0.721.
The number of patients unresponsive to bDMARDs (according EULAR, ASDAS, ASAS, ACR and PsARC) before the infection wasn't different from post-infection.
Conclusion: Our study suggests that SARS-CoV2 infection has no negative impact on PsA disease activity and bDMARD responses. However, more studies are still needed to better understand the long-term effects of SARS-CoV2 infection.

AB0108 INFLAMMATION IN AXSPA AS A DISRUPTOR OF BONE METABOLISM – THE EFFECT OF PATIENTS' SERA ON AN IN VITRO BONE MODEL

E. Sebova[1,2], P. Skubica[1], M. Husakova[3], P. Dankova[1]. *[1]Faculty of Science, Charles University, Department of Anthropology and Human Genetics, Prague, Czech Republic; [2]Institute of Experimental Medicine CAS, Department of Tissue Engineering, Prague, Czech Republic; [3]Institute of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic*

Background: In axial spondyloarthritis (axSpA), two opposing processes of bone resorption and neogenesis are closely related, with a common denominator – chronic inflammation. This pathological condition affects osteoblasts, among other cells, residing in sites of inflamed tissue, but it can also activate mononuclear precursors in the blood to form osteoclasts [1,2]. To this day, it is not

yet clear how the interplay between osteoblasts and osteoclasts affects pathogenesis of axSpA.

Objectives: The aim was to evaluate the effect of sera from patients with different forms of the disease, non-radiographic (nr-axSpA) and radiographic (r-axSpA) including ankylosing spondylitis, in comparison to the effect of sera from healthy individuals (axC) on osteoblasts and osteoclasts co-culture.

Methods: The inflammation characteristic for each diagnose was simulated by age- and sex-matched pools of 12 nr-axSpA and 12 r-axSpA patients' sera, healthy condition by a pool of 12 axC sera. We used THP-1 monocytic cell line and SaOS-2 osteosarcoma cell line co-culture to model bone physiology. After THP-1 adhesion, SaOS-2 cells were added with 10 % of nr-axSpA, r-axSpA or axC sera, respectively, in the media for 14 days. Activity of osteoblastic alkaline phosphatase (ALP) and osteoclastic enzymes tartrate-resistant acid phosphatase (TRAP), cathepsin K (CTSK) and carbonic anhydrase II (CAII) on days (D) 1, 7 and 14 were measured. Simultaneously, we examined metabolic activity (MTS assay), cell proliferation (PicoGreen assay) and mRNA expression of selected genes in co-culture.

Results: In all three studied co-cultures the ALP activity increased with length of the cultivation; nevertheless, the onset of the activity in D1 was more rapid in axC sera compared to nr-axSpA ($P<0.05$) and r-axSpA ($P<0.001$). The ALP activity increase from D1 to D14 was 4.9 fold in axC, 5.7 fold in nr-axSpA and 6 fold in r-axSpA. Moreover, rise of ALP gene expression corresponds well with rise of ALP activity. TRAP activity peaked in all sera on D7 and decreased again towards D14, mirroring the same mRNA expression profile. The TRAP activity on D7 was highest in axC sera and lowest in r-axSpA ($P<0.01$). Gradual drop of CA II activity from D1 to D14 was detected in co-cultures with axC and nr-axSpA sera; in r-axSpA, however, the activity increased 1.42 times from D7 to D14 and was thus significantly higher on D 14 compared to cultures in other two sera ($P<0.0001$). In all cultures, CTSK activity increased from D7 to D14. Activity was highest in culture with axC sera (nr-axSpA D7 and D14 $P<0.0001$; r-axSpA D7 $P<0.0001$, D14 $P<0.05$). A gradual increase in cell proliferation was observed in axC sera and was thus significantly higher compared to both patients' sera on D14 ($P<0.0001$). In contrast, the proliferation in patients' sera peaked on D7 with the significantly highest D7 proliferation observed in r-axSpA ($P<0.05$). While the metabolic activity per cell followed U shape trend in all co-cultures, the changes were more distinct in patients' sera: 2 fold drop in r-axSpA, 1.6 fold in nr-AxSpA and 1.3 fold in axC sera on D7 followed by increase of 3.4 fold in r-AxSpA, 2.9 fold in nr-AxSpA and 1.8 fold in axC on D14.

Conclusion: Data acquired from the *in vitro* bone model point to an imbalance in the enzymatic activity of osteoclasts and to changes in the metabolic activity and proliferation of both, osteoblasts and osteoclasts. These changes seem to be caused by inflammatory agents in patients' sera. However, the changes are not the same in both forms of disease, which may explain differences between nr- and r-axSpA symptoms.

AB0109 INCREASED NEUTROPHIL FREQUENCY IN LYMPH NODES OF PATIENTS WITH PSORIATIC ARTHRITIS

A. M. O'byrne[1,2,3], J. W. Bolt[1,2,3], C. van Ansenwoude[1,2,3], J. F. Semmelink[1,2,3], M. Maas[4], M. G. H. van de Sande[1,2,3], L. van Baarsen[1,2,3]. *[1]Amsterdam University Medical Centre, Clinical Immunology and Rheumatology, Amsterdam, Netherlands; [2]Amsterdam Rheumatology Centre,., Amsterdam, Netherlands; [3]Amsterdam University Medical Centre, Experimental Immunology, Amsterdam, Netherlands; [4]Amsterdam University Medical Centre, Radiology, Amsterdam, Netherlands*

Background: Increased presence of neutrophils in the skin[1], synovium[2,3], and entheses[4] of patients with Psoriatic Arthritis (PsA) and their downregulation upon successful treatment[2,5,6], suggests a role for neutrophils in PsA pathogenesis. As neutrophils have been implicated in Th17 differentiation, gaining insight in the presence and function of neutrophils within lymph nodes, which are the epicentre of T cell activation and differentiation, could be important in unravelling disease pathogenesis.

Objectives: We hypothesize that activated neutrophils migrate from inflamed peripheral tissues to lymph nodes, where they steer inflammation by interaction with tissue resident cells and immune cells, ultimately resulting in activation of IL-17 producing T cells. To investigate this, we studied the presence of neutrophils in lymph node biopsies of patients with inflammatory arthritis, including PsA, and compared their frequencies to controls.

Methods: Ten PsA patients, 34 seropositive individuals at risk of developing rheumatoid arthritis (RA-risk), 26 ACPA- RA patients and 10 healthy controls (HC) underwent ultrasound-guided inguinal lymph node biopsy. These biobanked biopsies were analysed using qPCR and immunohistochemistry. Flow cytometry on fresh biopsies was used to determine cell frequencies in six active PsA patients (defined as arthritis in ≥1 joint) and two RA-risk individuals.

Results: qPCR analyses showed significantly increased mRNA levels of Cathepsin G (CTSG), which is highly expressed by neutrophils, in PsA patients compared to HC ($p = 0.020$). Immunohistochemistry showed that the neutrophil marker CD15 is significantly increased in PsA patients compared to HC ($p = 0.008$). Preliminary flow cytometry analyses indicates a clear population of CD45+CD16+CD66b+ neutrophils in lymph node biopsies of PsA patients while this was not observed in RA-risk individuals.

Conclusion: Overall, we show for the first time an increased presence of neutrophils in lymph nodes of PsA patients when compared to controls. Future studies are needed to investigate their functional role in immunoregulation within lymph node organs.

AB0110 TRANSCRIPTOMICS-BASED INVESTIGATION OF THE MECHANISM OF ANKYLOSING SPONDYLITIS WITH UVEITIS

H. Hai[1], H. Li[2], B. Deng[3]. *[1]Sichuan Provincial People's Hospital, Department of Rheumatology and Immunology, Cheng Du Shi, China; [2]Sichuan Provincial People's Hospital, Department of Health Management, Cheng Du Shi, China; [3]Sichuan Provincial People's Hospital, Department of Ophthalmology, Cheng Du Shi, China*

Background: Spondyloarthritis is a large group of autoimmune diseases that are associated with HLA-B27. Among them, Ankylosing spondylitis is a typical representative of these diseases. In addition to spine and joint involvement, AS has many extra-articular manifestations, among which uveitis is one of the most common extra-articular manifestations of AS.[1]Untreated or inappropriate treatment can lead to serious consequences such as blindness. However, there are few studies on the mechanisms of AS-related uveitis, and the pathogenesis of AS-related uveitis is not fully understood, so there is no way to prevent it.

Objectives: We performed a whole-blood gene expression profiling and then analyzed gene expression differences between AS-associated uveitis patients and normal controls by bioinformatics methods. Protein–protein interaction network was constructed to predict the relationship among the products of the differentially expression genes (DEGs). Furthermore, module mining and function

annotation were applied to assess the interaction network of DEGs.The aim is to find predictive biomarkers for AS-associated uveitis, to further discuss the pathogenesis of AS-associated uveitis in depth, and to provide a reference for clinical precision treatment.

Methods: This microarray-based discovery study used samples from three patients with AS,classified according to the New York criteria,four patients with AS-associated uveitis, and three gender- and age-matched controls. Total RNA was extracted from whole blood samples and enriched for mRNA after DNA digestion using DNase, and then constructed cDNA libraries were quality-checked with an Agilent 2100 Bioanalyzer and sequenced using an Illumina HiSeq TM 2500 sequencer.The data were normalized and initially screened for differential genes using the DESeq R package in R 4.1.0 Prediction of relationships between products of differentially expressed genes (DEGs) using String database prediction and construction of protein-protein interaction networks in Cytoscape. GO with KEGG analysis of differential genes using ClueGO and CluePedia. Screening for hub genes associated with AS-associated uveitis using cytoHubba.

Results: We initially screened 14607 differential genes, from which 112 significantly differential genes with p-values<0.05 and |log2FC|>2 were selected. Among them, 82 were up-regulated genes and 30 were down-regulated genes. Sixty-six relationships between 49 nodes were shown in the PPI network interactions graph constructed from the String database results.The results of GO analysis showed that most genes were involved in biological processes related to immune response, such as positive regulation of inflammatory response, integrated stress response signaling and toll-like receptor 4 signaling pathway. The molecular functions were mainly focused on chemokine receptor binding. the results of KEGG analysis showed that the gene products were mainly involved in cytokine-cytokine receptor interaction, IL-17 signaling pathway. The target genes screened included CXCL8 CXCL2 NFKBIZ NFKBIA IL11 IL1A,all of which have adequate immune response effects(Figure 1)

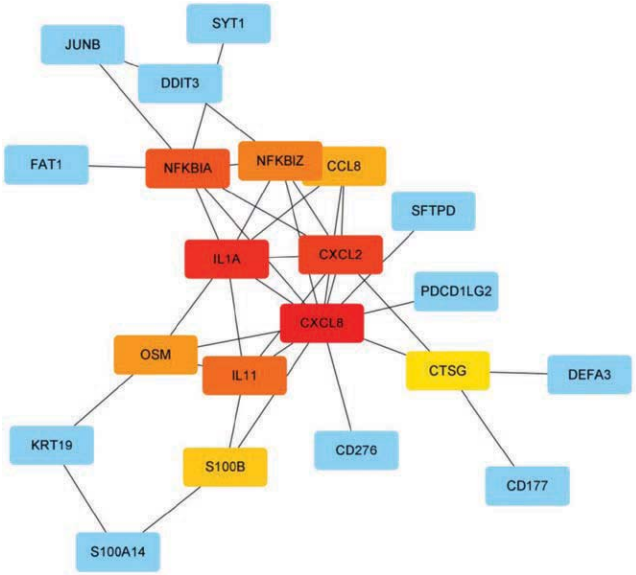

Figure 1. Using the EPC algorithm in cytoHubba to screen hub genes, the graph shows the top 10 scoring genes, with different colors representing higher scores.

Conclusion: We have identified a series of genes associated with immunity in this study.These DEGs may provide a basis for insight into the pathogenesis of AS-associated uveitis. Further experimental studies are needed to confirm our hypothesis.

AB0111 EFFECT OF TOFACITINIB AND GLUCOCORTICOIDS ON INTESTINAL PERMEABILITY, EPITHELIAL DAMAGE AND BACTERIAL TRANSLOCATION IN RAT ADJUVANT-INDUCED ARTHRITIS

S. Hecquet[1,2], P. Totoson[2], M. Tournier[2], C. Prati[1,2], D. Wendling[1,3], C. Demougeot[2], F. Verhoeven[1,2]. *[1]Centre hospitalier régional universitaire de Besançon, Rheumatology, Besançon, France; [2]University of Franche-Comté, UR 4267 PEPITE, Besançon, France; [3]University of Franche-Comté, UR 4266 EPILAB, Besançon, France*

Background: Growing evidence indicated that the intestine is not only a target but also an actor of the pathogenesis in chronic inflammatory rheumatic diseases (CIRD). Consistently, increased intestinal permeability (IP) and damage (ID) as well as bacterial translocation (BT) have been described in patients with CIRD. However, the effects of treatments used in patients with CIRD on gut health are unknown.

Objectives: To determine the effect of glucocorticoids (GCs) and tofacitinib on IP, ID and BT in rats with adjuvant-induced arthritis (AIA).

Methods: AIA was induced in 6-week-old male Lewis rats by a tail injection of *Mycobacterium butyricum* in incomplete Freund's adjuvant. At onset of arthritis, rats were treated daily with prednisolone at low (0.1 mg/kg/day, i.p.) or high dose (10 mg/kg/day, i.p.), or with Tofacitinib (10 mg/kg twice a day, s.c.) or with vehicle. After 21 days, IP, ID and BT were assessed by measurement of plasma levels of zonulin, intestinal Fatty Acid Binding Protein (iFABP) and serum levels of soluble CD14 (sCD14) by ELISA), respectively. Arthritis severity was daily evaluated through the determination of an arthritis score.

Results: Compared to vehicle, Tofacitinib and high-dose of GC both reduced arthritis score ($p<0.001$) and levels of sCD14 (-44%, $p<0.001$ and -41% $p<0.001$ respectively) in AIA. High dose of GC decreased iFABP (-17%, $p<0.05$) levels but had no effect on zonulin levels. Tofacitinib did change nor iFABP neither zonulin levels. As compared to vehicle, the low-dose of GC had no effect on arthritis severity, sCD14, iFABP and zonulin plasma levels.

Conclusion: Prednisolone at a dose efficient on arthritis did not worsen but on the contrary reduced intestinal bacterial translocation and epithelial damage. These results are consistent with the positive effects of GCs on intestinal dysfunction observed in case of sepsis or colitis. The lack of efficacy of the sub-therapeutic dosage of prednisolone suggested that effects of GC are, at least partly, related to their anti-inflammatory effects. Consistent with the positive effect of jakinibs in patients with inflammatory bowel disease, Tofacitinib blunted intestinal bacterial translocation in AIA. Given the suspected pathophysiological link between bacterial translocation and arthritis, our results identified a new mechanism involved in the positive effects of GC and tofacitinib in arthritis diseases.

AB0112 DECOY RECEPTOR 3 AND ITS SIGNAL PATHWAY CONTRIBUTE TO PATHOGENESIS IN ANKYLOSING SPONDYLITIS

Y. Jiang[1], S. B. Wang[1], X. Liao[1], Y. X. He[1], Y. F. Qing[1]on behalf of Institute of Research Center of Gout and Hyperuricemia of the Affiliated Hospital, North Sichuan Medical College. *[1]Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology, Nanchong, China*

Background: Ankylosing spondylitis (AS) is a chronic progressive disease with invasion of spine and sacroiliac joint as the main clinical manifestation, which can be combined with systemic inflammation or abnormalities in multiple parts at the same time. There are complex changes of immune function in patients with AS, and its immune and genetic pathogenesis is still unclear. Decoy receptor 3 (DcR3), as a new immune molecule discovered in recent years, plays an important role in regulating T cell activation, proliferation, differentiation and apoptosis. Studies have confirmed that DcR3 is involved in the immune disorder process of rheumatoid arthritis, SLE, AS and other autoimmune diseases, so that the role of DcR3 in AS has attracted attention. However, the expression of DcR3 related pathway genes[1-3].However, studies evaluating the DcR3 related pathway genes in AS are scarce.

Objectives: To assess the contribution of DcR3 and its signal pathway to AS and the clinical importance of these genes in AS.

Methods: The mRNA expression levels of DCR3 and its signal pathway(DR3、TL1A、Fas、FasL、Ligth、LigthR、LTgthRNA expresured in peripheral blood mononuclear cells (PBMCs) from 50 AS patients and 50 healthy subjects. The relationship between DCR3 related molecular pathway expression levels and laboratory features was analyzed in AS patients.

Results: The expression levels of DCR3、DR3、Fas、Light were much lower in the AS group than in the HC groups ($p<0.05$)(a,b,c,d), and the expression levels of LT The relationship between DCR3 related molecular pathway expression l

Conclusion: Compared with HC group, DCR3 and its signal pathway in PBMCs of AS patients are differentially expressed. It is speculated that DcR3 related molecular pathway gene may be involved in the pathogenesis of AS.

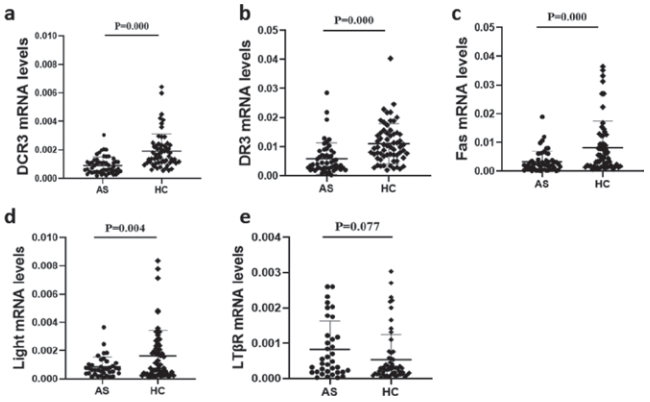

Figure 1. Relative Expression of DcR3 related molecular pathway gene in the PBMCs of Patients. The mRNA levels in PBMCs from AS patients(n=50) and HCs(n=50) were measured by RT-qPCR. The expression levels of DCR3、DR3、Fas、Light were much lower in the AS group than in the HC groups ($p<0.05$)(a,b,c,d), and the expression levels of LTβR was much higher in the AS group than in the HC groups ($p<0.05$)(e).

AB0113 A MINIMAL-INVASIVE METHOD TO RETRIEVE AND IDENTIFY ENTHESEAL TISSUE FROM PSORIATIC ARTHRITIS PATIENTS

M. G. Raimondo[1,2], M. Pachowsky[1,2], C. Xu[1,2], S. Rauber[1,2], K. Tascilar[1,2], H. Labinsky[1,2], A. Soare[1,2], L. Bräuer[3], J. Rech[1,2], D. Simon[1,2], A. Kleyer[1,2], G. Schett[1,2], A. Ramming[1,2]. *[1]Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology & Immunology, Erlangen, Germany; [2]Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany; [3]Friedrich Alexander University Erlangen-Nurnberg, Institute of Functional and Clinical Anatomy, Erlangen, Germany*

Background: Enthesitis represents a hallmark feature of spondyloarthritis, including psoriatic arthritis (PsA).[1] So far, most of the data on enthesitis in PsA are based on clinical assessment of tenderness as well as MRI or ultrasound examinations.[2] These approaches, however, do not allow molecular analysis of entheses, which will require acquisition of entheseal tissue. Up today, it is unknown, which entheseal structure in humans would qualify for a feasible biopsy and how correct sampling of entheseal structures could be ascertained within such biopsy material. These technical challenges have led to substantial lack of knowledge on human entheseal tissues.

Objectives: To establish a minimally invasive biopsy technique of human entheses for the analysis of entheseal tissue in patients with PsA.

Methods: Human cadavers were used for establishing the technique to retrieve tissue from the lateral humeral epicondyle enthesis (cadaveric biopsies). After biopsy, the entire entheses was surgically resected (cadaveric resections). Biopsies and resections were assessed by label-free second-harmonic-generation (SHG) microscopy. The same biopsy technique was then applied in PsA patients with subsequent definition of entheseal tissue by SHG.

Results: Entheseal biopsies were performed in five cadavers and allowed the retrieval of entheseal tissue, validated by analysis of the resection material. Thus, microscopy of biopsy and resection sections allowed differentiation of entheseal, tendon and muscle tissue by SHG and definition of specific intensity thresholds for entheseal tissue. The same method was then successfully applied to 10 PsA patients. Hence, the fraction of entheseal tissue within the PsA biopsy specimens was high (65%) and comparable to the fraction retrieved in cadaveric biospies (68%) as assessed by SHG microscopy.

Conclusion: Entheseal biopsy of the tendon plate of the lateral epicondyle is feasible in PsA patients allowing reliable retrieval of entheseal tissue and its identification by SHG microscopy.

AB0114 IMPROVEMENT OF GUT MICROBIOTA DYSBIOSIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AFTER ONE YEAR OF BIOLOGICAL TREATMENT

V. Rios Rodriguez[1], M. Essex[2,3,4], J. Rademacher[1,5], M. Torgutalp[1], F. Proft[1], U. Löber[2,3], L. Marko[3,4], D. Poddubnyy[1,6], S. K. Forslund[3,4,7,8]. *[1]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Gastroenterology, Infectious Diseases, and Rheumatology (including Nutrition Medicine), Berlin, Germany; [2]Helmholtz Association of German Research Centers e.V., Max Delbrück Center for Molecular Medicine, Berlin, Germany; [3]Max Delbrück Center for Molecular Medicine, Experimental and Clinical Research Center, Berlin, Germany; [4]Charité – Universitätsmedizin Berlin,., Berlin, Germany; [5]Berlin Institute of Health,., Berlin, Germany; [6]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology Unit, Berlin, Germany; [7]Deutsches Zentrum für Herz- und Kreislaufforschung, Partner site Berlin, Berlin, Germany; [8]EMBL Heidelberg, Structural and Computational Biology Unit, Heidelberg, Germany*

Background: Emerging evidence suggests that dysbiosis of the gut microbiota is involved in the initiation and perpetuation of spondyloarthritis (SpA). Biological disease-modifying antirheumatic drugs (bDMARDs) are a successful treatment to improve symptoms and reduce structural damage occurring in SpA; however, non-responders are frequent and few predictive factors for clinical response have been identified. Whether or not a patient responds to treatment could be related to gut microbiota composition.

Objectives: To investigate the gut microbiota changes in patients with radiographic axial SpA (r-axSpA) after receiving one year of treatment with bDMARDs and identify potential microbial biomarkers predictive of treatment response.

Methods: Patients with r-axSpA were recruited between 2015 and 2019 in an extension of the prospective GErman SPondyloarthritis Inception Cohort (GESPIC) before beginning bDMARD therapy. All patients had high disease activity (BASDAI >=4 and/or ASDAS >=2.1) despite previous treatment with nonsteroidal anti-inflammatory drugs, and had not received treatment with bDMARDs for at least three months before enrollment in the study. The choice of bDMARD was left to the discretion of the clinical rheumatologists in accordance with standard practice. Disease activity measures (BASDAI, CRP and ASDAS) and fecal samples were assessed at baseline prior to treatment and after one year of treatment. Patients with back pain negative for inflammatory disease served as a control group. Microbiota composition was determined by 16S rRNA gene sequencing, followed by taxonomic profiling with the SILVA138 database. Response to bDMARD therapy was defined as a clinically important improvement of ASDAS (>=1.1).

Results: A total of 99 patients with r-axSpA and 63 control individuals were included based on the availability of clinical and microbiome samples. Average age (mean±SD) was 36.4±10.4 years and 64 patients were males. The prevalence of HLA-B27 was 89.9% among r-axSpA patients compared to 7.9% among control individuals. Simpson indices showed an increase in alpha diversity between baseline and year 1 in r-axSpA patients which was statistically insignificant (paired Wilcoxon p=0.154) but brought the r-axSpA cohort nearer to controls. Likewise, Bray-Curtis dissimilarities to measure beta diversity showed a qualitative normalization to healthy individuals after treatment when visualized in principal coordinate space.

At the genus level, patients were mainly depleted in Lachnospiraceae taxa such as *Blautia*, *Roseburia*, and *Fusicatenibacter*, and enriched in *Collinsella* compared to the control group at baseline. After one year of treatment, most SpA patients exhibited increased abundances of these taxa, most notably *Blautia*. Patients also exhibited depletions in *Bacteroides* and

Faecalibacterium, which was strongly enriched in HLA-B27+ individuals at baseline (adjusted Wilcoxon p<0.001). *Collinsella* showed a very slight median increase after one year of treatment, with no significant difference between responders and non-responders (adjusted Wilcoxon p=0.33). Shifts in highly abundant *Prevotella* and *Bacteroides* were strongly correlated with the change in ASDAS after one year when controlling for intra-individual variance and overall changes in alpha diversity.

Conclusion: The gut microbiota composition of r-axSpA patients who underwent treatment with bDMARDs for one year more closely resembled the controls. The unique enrichment of *Collinsella* in r-axSpA patients remained stable across time and treatment, suggesting it may be a disease biomarker.

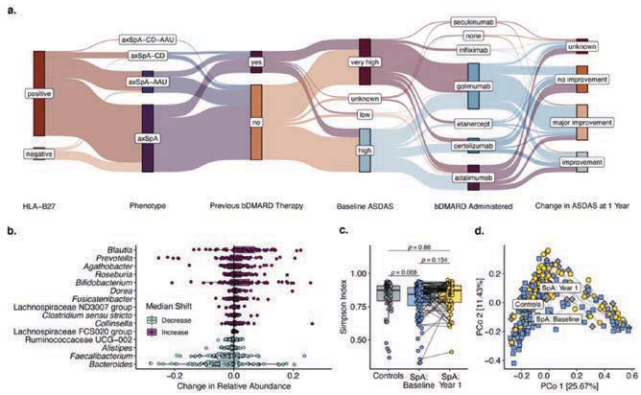

Figure 1. a) Flowchart of axSpA patients summarizing the main clinical and disease activity parameters of the cohort. b) Taxa with the most pronounced shifts in median relative abundance in patients with axSpA after receiving biological treatment for one year. c-d) Alpha and beta diversity analyses, respectively, of axSpA patients before and after treatment compared to control individuals. MONOCYTE CHEMOATTRACTANT PROTEIN-1 IN PATIENTS WITH PSORIATIC SPONDYLOARTHRITIS CORRELATES WITH COMPONENTS OF PATIENT FUNCTIONAL STATUS

T. Kehler[1,2], I. Uravić Bursać[1], V. Drvar[3], V. Persic[1,2], G. Laskarin[1,4]. *[1]Hospital for Medical Rehabilitation of Hearth and Lung Diseases and Rheumatism "Thalassotherapia-Opatija", Hospital for Medical Rehabilitation of Hearth and Lung Diseases and Rheumatism "Thalassotherapia-Opatija", Opatija, Croatia; [2]Faculty of Medicine, University of Rijeka, Department of Medical Rehabilitation, Rijeka, Croatia; [3]Clinical Hospital Centre Rijeka, Clinical Department of Laboratory Diagnostics, Rijeka, Croatia; [4]Faculty of Medicine, University of Rijeka, Department of Physiology and Immunology, Rijeka, Croatia*

Background: Activated monocytes represent the main source of pro-inflammatory chemokine, Monocyte Chemoattractant Protein-1 (MCP-1) in psoriatic skin lesions and synovial tissue during active psoriatic arthritis (PsA) (1). Osteoclast precursors binds MCP-1, implying the involvement of MCP-1 in the pathogenesis of bone erosion (2). MCP-1 is present in the plasma of patients with psoriasis at higher levels than in healthy subjects (3).

Objectives: The aim of this study was to determine the relationship between serum MCP-1 concentration and disease activity in PsA patients.

Methods: We enrolled 52 patients with PsA in the study and assessed Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Disease Activity in Psoriatic Arthritis (DAPSA), Bath Ankylosing Spondylitis Disease Functional index (BASFI), and the spread of psoriasis using Body Surface Area (BSA) method. In the serum, C-reactive protein (CRP) was measured using immunoturbidimetric assay and MCP-1 concentration using ELISA. Relationship between two parameters was analyzed applying Spearman correlation and p<0.05 was considered significant.

Results: Serum MCP-1 concentration did not correlate with the BSA, the DAPSA, CRP, the number of tender joints from 68 evaluated, the number of swollen joints from 66 evaluated, the patient's assessment of the intensity of pain and overall disease activity during the last week. The concentration of MCP-1 did not correlate with the fatigue, the intensity of pain in axial and peripheral joint structures, the sensitivity to touch, the duration of morning stiffness, BASDAI and BASFI.

MCP-1 statistically significantly correlated with the score for getting up from a sitting position without the help of hands, for getting up from a floor without the help, for standing up without supporting for 10 minutes and for performing physically demanding activities (Figure 1).

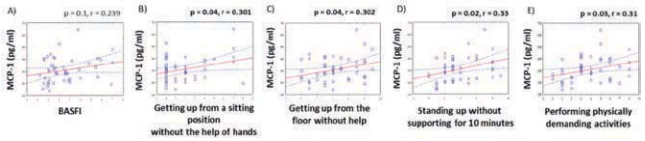

Figure 1. Correlation of serum MCP-1 concentration and BASFI components in patients with PsA.

Conclusion: Serum MCP-1 concentrations in PsA patients seem to reflect some components of patient functional status.

NEW INFLAMMATORY MARKERS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

K. Nurbaeva[1,2], T. Reshetnyak[1,2], F. Cheldieva[1,2], M. Cherkasova[1], E. Samarkina[3], A. Lila[1,2]. *[1]1-V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]2-Russian Medical Academy of Continuing Professional Education of the Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*

Background: Thromboinflammation is a pathological process that is associated with uncontrolled inflammation, leading to hypercoagulability and thrombotic complications. Systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) are prototypical chronic thromboinflammatory diseases. Neutrophils are important cells in the development of systemic inflammation and thrombosis. Neutrophil reactivity (NEUT-RI), neutrophil granularity (NEUT-GI), immature granulocytes (IG), and neutrophil-to-lymphocyte ratio (NLR) are considered as inflammatory markers.

Objectives: To determine the role of parameters of neutrophil activation (NEUT-RI, NEUT-GI), immature granulocytes (absolute (IG#), relative (IG%) counts), NLR, ESR in assessing inflammation in SLE, primary APS (PAPS), and SLE with APS.

Methods: The study included 80 patients and 40 healthy donors (HD). Patients were classified into three groups: Group 1 included 37 patients with SLE. The median age of patients with SLE was 34 years [28-43]. Group 2 included 20 patients with SLE+ APS (45 years [37-49]). Group 3 included 23 patients with PAPS (38 years [34,5-47,5]). Current disease activity was evaluated with SLE-DAI-2K and adjusted GAPSS (aGAPSS).

A complete blood count (WBC-white blood cell, NEUT#-absolute neutrophil count, NEUT-RI, NEUT-GI, IG%, IG count, NLR, thrombocytes, ESR-erythrocyte sedimentation rate) was performed with XN-1000 automated hematology analyzer (Sysmex, Japan).

Results: Patient characteristics are shown in Table 1. IG# and IG% levels were significantly increased in patients with SLE and SLE+APS compared to controls and PAPS. ESR levels was significantly higher in patients with SLE, SLE+APS, and PAPS compared to HD. There was no significant difference between NEUT-RI, NEUT-GI, NLR, fibrinogen and CRP levels in patients with SLE, SLE+APS, PAPS, and HD. The aGAPPS was positively correlated with the IG# (r_s=0.46; p=0.028) and IG% levels (r_s=0.49; p=0.017) in patients with PAPS. No correlation was found between the IG and SLEDAI 2K. The ESR was positively correlated with SLEDAI 2K in SLE patients (r_s =0.54; p≤0.001).

Conclusion: Patients with SLE and SLE+APS had significantly higher levels of immature granulocytes than controls and PAPS patients. In PAPS, immature granulocytes were positively correlated with aGAPSS values.

The study was performed at V.A. Nasonova Research Institute of Rheumatology within the framework of the fundamental research FURS-2022-003.

IMMUNE CELL IMBALANCES IN PLACENTAS OF SYSTEMIC LUPUS ERYTHEMATOSUS AND SJÖGREN'S SYNDROME PATIENTS

J. J. Fierro[1], G. M. Verstappen[1], J. R. Prins[2], J. Westra[1], H. Bootsma[1], K. de Leeuw[1]on behalf of Rheumatology and Clinical Immunology. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands;* [2]*University Medical Center Groningen, Obstetrics and Gynecology, Groningen, Netherlands*

Background: Systemic lupus erythematosus (SLE) and primary Sjögren's syndrome (pSS) are associated with adverse pregnancy outcomes (APOs) [1,2]. During pregnancy, maternal immune activation is related to a higher risk of hypertension, preeclampsia, preterm labor, and fetal growth restriction in SLE patients [1]. Furthermore, these patients have an increased risk of neonatal lupus due to the transplacental passage of maternal anti-RO/SSA antibodies to the fetus [3]. Nevertheless, there is no compelling evidence about the type of immune cell imbalances in the placenta in patients with SLE and pSS.

Objectives: Identify immunologic imbalances, focusing on interferon (IFN) and immune cell subtypes in placenta tissue of patients with SLE or pSS.

Methods: Retrospective analysis of immune cell composition of paraffin-embedded placental tissue from 6 SLE, 4 pSS, and 12 healthy women was conducted. For each case, one full-thickness sample of normal-appearing parenchyma from the central two-thirds of the placental disc was taken. APOs history and pregnancy outcomes were recorded. Placenta immunohistochemistry stainings were done for myxovirus resistance protein A (MxA, an interferon induced protein), CD3, CD20, CD45 and CD68. Statistical analysis was performed with a non-parametric T-test.

Results: A significantly higher MxA expression in the placenta of SLE and pSS patients compared to healthy controls was observed (Figure 1A). SLE patients had an increased MxA expression in decidua and villi compared with controls, while in pSS patients this increase was found in amnion and villi.

The count of T cells, B cells, total leukocytes, and macrophages in the decidua tissue were comparable between groups (Figure 1B). However, a significantly higher macrophage per total number of cells index was observed in SLE and pSS patients compared to healthy controls (Figure 1C). Only two patients had no APOs. Therefore, no analysis was performed comparing patients with or without APO.

Conclusion: A higher macrophage count and an increased IFN expression were identified in the placentas of SLE and pSS patients. These findings suggest a proinflammatory placental environment that could be related to APOs presentation in patients with SLE and pSS. However, to establish the relation with APOs further studies are needed including more patients especially without APOs.

PORPHYROMONAS GINGIVALIS AMOUNT IN THE TONGUE BIOFILM IS ASSOCIATED WITH EROSIVE ARTHRITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

F. Ceccarelli[1], M. Saccucci[2], F. Natalucci[1], G. Olivieri[1], E. Bruni[3], R. Iacono[2], T. Colasanti[1], G. Di Carlo[2], C. Alessandri[1], D. Uccelletti[3], P. Russo[2], A. Pilloni[2], F. Conti[1], A. Polimeni[2]. Background: Several data have demonstrated the occurrence of erosive arthritis in Systemic Lupus Erythematosus (SLE) patients. However, few studies have focused on the pathogenic mechanisms involved in this feature. The implication of oral pathogens has been proved in Rheumatoid Arthritis: in particular, Porphyromonas gingivalis (Pg), by inducing citrullination, could trigger autoimmune response.

Objectives: We evaluated amount of Pg of the tongue in a cohort of SLE patients with arthritis, focusing on the association with the erosive phenotype.

Methods: SLE patients with arthritis were enrolled. We evaluated the presence of ACPA and RF by using commercially enzyme-linked immunosorbent assay kits. SLEDAI-2k was applied to assess disease activity and DAS28 to assess

joint inflammatory status. Erosive damage was evaluated by ultrasound at level of metacarpophalangeal and proximal interphalangeals joints. All subjects underwent a tongue cytologic swab in order to quantify the amount of Pg (real-time PCR). The bacterium expression was obtained from the ratio between the patient's DNA amount and that obtained from healthy subjects.

Results: The present analysis included 33 SLE patients (M/F 3/30; median age 47 years, IQR 17; median disease duration 216 months, IQR 180). Concerning activity at the time of the enrollment, we found a median DAS28 value of 3.8 (IQR 2.8) and a median SLEDAI-2k of 4 (IQR 5). Twelve patients (36.4%) showed US-detected erosive damage in at least one joint, significantly associated with ACPA positivity (p<0.0001). Furthermore, patients with erosive damage showed significantly higher median DAS28 values in comparison with those without [4 (IQR 3.1) versus 3.2 (IQR 2.1), p=0.03]. Moving on the oral pathogen analysis, we found a mean Pg ratio of 19.7±31.1 (median 6.6, IQR 22.3). When dividing patients according to the presence of erosive damage, we found higher Pg amount in SLE patients with this phenotype in comparison with those without (31.4±44.3 versus 12.9±19.2, p=ns; Figure 1A). Thus, we used Pg mean values as threshold, identifying two groups of patients, namely highPg and lowPg. In a receiver operating characteristic curve analysis (ROC), this threshold resulted in the most sensitive and specific one (sensitivity of 85%; specificity of 50%). As reported in Figure 1B, erosive damage was significantly more frequent in highPg patients in comparison with lowPg (60.0% versus 26.0%, p=0.001). Furthermore, highPg patients showed higher prevalence of skin manifestations, serositis and neurological involvement compared to lowPg patients (p=0.005, p=0.03, p=0.0001, respectively).

Conclusion: The possible contribution of oral microbiota in SLE erosive arthritis was here evaluated for the first time, finding a significant association between erosive damage and higher expression of Pg at tongue level.

Figure 1. (A) Box and whisker plot representing Pg ratio in SLE Patients with and without erosive arthritis.
(B) Prevalence of erosive arthritis in SLE patients with HighPg and LowPg ratio.

ROLE OF COSTIMULATORY MOLECULES IN SYSTEMIC LUPUS ERYTHEMATOSUS: FOCUS ON CD137

F. Natalucci[1], A. Di Filippo[2], F. Ceccarelli[1], I. Zizzari[2], G. Olivieri[1], V. Orefice[1], C. Pirone[1], F. R. Spinelli[1], C. Alessandri[1], M. Nuti[2], F. Conti[1]. [1]*"Sapienza" University of Rome, Policlinico Umberto I, Lupus Clinic, Rheumatology Unit, Department of Clinical, Internal, Anaesthesiological and Cardiovascular Science, Roma, Italy;* [2]*"Sapienza" University of Rome, Policlinico Umberto I, Laboratory of Tumour Immunology and Cell Therapy, Department of Experimental Medicine, Roma, Italy*

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease characterized by a wide autoantibodies production. The traditionally concept of a B-cell driven disease has been changed in the last years due to the evidence demonstrating the crucial role of T cells in SLE pathogenesis. In particular, regulatory (Treg) and memory T cells seem act through co-stimulatory and co-inhibitory molecules, such as CD137, PD1-1 and CTLA4. The over-expression of this molecules on lymphocytes may contribute to immune system dysregulation.

Objectives: The primary objective of the present case-control study was to evaluate the expression of CD137, PD1-1 and CTLA4 on T cell surface of SLE patients by using flow-cytometry. Secondly, we evaluated the percentage of Treg and memory T cells.

Methods: We enrolled patients SLE patients (2019 ACR/EULAR criteria) and sex/age-matched healthy subjects (HS). Demographic, clinical, and laboratory data were collected in a standardized computerized electronically filled form. Disease activity was assessed by SLEDAI-2k. Each subject underwent peripheral blood sample collection. By using flow-cytometry we evaluated the expression of FOXP3, CD137, PD1-1 and CTLA4, CD45, CD25, CCR7 to determine the percentage of Treg and memory T cells.

Results: The present analysis included 21 SLE patients [M/F 1/20 median age 48 years (IQR 17), median disease duration 144 months (IQR 204)]. The Treg percentage was significantly lower in SLE compared to HS [median 4.2 (IQR 0.32) *versus* 2.5 (IQR 2.44); p=0.001, Figure 1A]. Moving on effector Treg (eTreg), SLE patients with high disease activity (SLEDAI > 4) showed a significantly higher prevalence for these cells compared to patients with SLEDAI ≤ 4 [1.16 (IQR 0.51) *versus* 0.53 (IQR 0.8), p=0.014, Figure 1B]. Moreover, inverse correlation was found between eTreg percentage and SLEDAI-2k [p=0.029, r=-0.47 (CI 0.75 – 0.04) Figure 1C]. The evaluation of CD137 expression was significantly higher in SLE patients compared to HS on CD3+ cells [median 5.32 (IQR 6.11) *versus* 3.3 (IQR 1.7), p=0.001, Figure 1F]. On CD4+ cells, CD137 expression positively correlated with disease activity [p=0.0082, r=0.58 (CI 0.15-0.82)]. Finally, when analysing memory T cells subpopulations, inverse correlation has been found between effector memory T cells (TEM, CD45RA-CCR7-) and SLEDAI-2k when considering CD3+ [p=0.029, r=-0.56 (CI 0.81 – 0.12)] and CD4+ cells [p=0.016, R=-0.54 (CI -0.80 - -0.1)]. Of note, CD137 expression on T central memory cells (TCM, CD45RA-CCR7+) positively correlated with SLEDAI-2k [(p=0.019, r=0.52 (CI 0.09 – 0.79)].

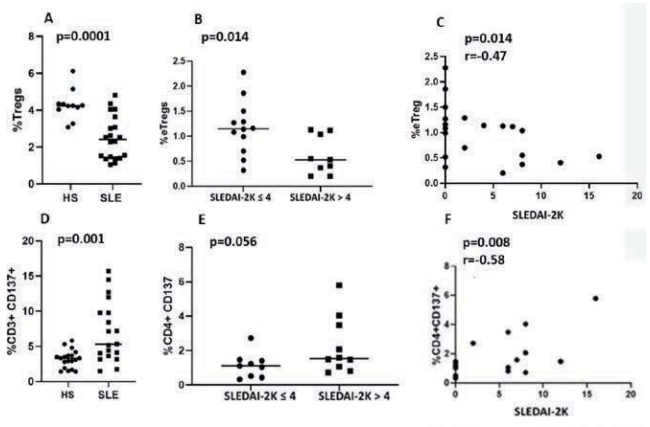

Figure 1. A) Comparison of the percentage of Treg in HS and SLE patients. B) Comparison of the percentage of eTreg in SLE patients with high disease activity and low disease activity C) Correlation between % eTreg and SLEDAI-2k. D) Comparison of the percentage of CD3+CD137+ cells in HS and SLE patients. E) Comparison of % of CD4+CD137+ cells in SLE patients with high disease activity and low disease activity F) Correlation between % of CD4+CD137+ cells and SLEDAI-2k.

Conclusion: Our results suggest a possible role of CD137-CD137L axis in SLE pathogenesis. The stimulatory role of this molecule is indicated by the positive correlation between SLEDAI-2k values and surface expression of CD137. Moreover, inverse correlation between SLEDAI-2k and eTreg percentage suggests a possible Treg dysregulation in SLE.

Table 1. SLE cohort features

Clinical and Laboratory Features	
Mucocutaneous	80.9%
Articular	76.1%

AB0120 ENZYMATIC PATTERN OF CIRCULATING XANTHINE OXIDOREDUCTASE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

E. Mozgovaya[1], S. Bedina[1], M. Mamus[1], A. Trofimenko[1], S. Spitsina[1].
[1]*Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical biochemistry lab, Volgograd, Russian Federation*

Background: Generalized autoimmune inflammation underlies the pathogenesis of systemic lupus erythematosus (SLE). At the same time metabolic disorders at the cellular and subcellular levels are involved in the development of the disease. The literature contains data confirming the role of reactive oxygen species and oxidative stress in SLE multi-organ involvement [1,2].
Objectives: to evaluate the changes in XOR activities in plasma, lysed white blood cells (WBC), and lysed red blood cells (RBC) of SLE patients.
Methods: Diagnosis of SLE was verified using the SLICC criteria (2012). Activities of XOR interconvertible forms, xanthine oxidase (XO) and xanthine dehydrogenase (XDG), were measured in plasma, lysed WBC and lysed RBC by the spectrophotometric method [3]. The enzymatic activities were expressed as nmol/min/ml and normalized to 1×10^7 cells/ml in lysed WBC, and to 1×10^9 cells/ml in lysed RBC. The results were expressed as Me (Q_{25}; Q_{75}). Statistical comparison tests were selected in according to the common guidelines. Differences were considered significant when $p<0.05$. Reference ranges were calculated as 95th percentile interval.
Results: 56 adult SLE patients (mean age 35 (31; 42) years; mean disease duration was 8 (5; 11) years)) and 35 healthy individuals were enrolled in the study. Reference intervals of plasma XO and XDG activities were 2.29 – 4.31 and 4.52 – 5.97 nmol/min/ml, respectively. Reference intervals of XO and XDG activities in lysed WBC were 14.11 – 31.33 and 18.62 – 39.65 nmol/min/ml, respectively. Reference intervals of XO and XDG activities in lysed RBC were 20.62 – 25.46 and 41.89 – 55.04 nmol/min/ml, respectively. Enzymatic activities of SLE patients were significantly different from healthy controls. Increased XO activity and decreased XDG activity were observed in plasma of SLE patients ($p<0.001$ for both enzymes). The activities of both XOR forms were decreased in lysed WBC ($p<0.001$ for both enzymes). Lysed RBC were characterized by a decrease in XDH activity ($p<0.001$).
Conclusion: Significant changes in the balance of XO and XDG activities were revealed in plasma, lysed WBC and RBC of SLE patients., These enzymes can also exhibit NADH oxidase and nitrate reductase activities under conditions of low pH and hypoxia. Such conditions are formed in SLE due to the development of pronounced inflammation and microthrombosis in various tissues. Reactive forms of oxygen and nitrogen, which production is increased as a result of XOR activity, have a damaging effect on cellular structures, initiate the processes of lipid peroxidation, participate in the stimulation of NF-kB, and contribute to the formation of neutrophil extracellular traps. It can be assumed that the imbalance of XOR enzymatic activities in WBC indicates the previous stages of purine metabolism disturbances, which leads to a change in functional state and death of these blood cells. Free radicals generated by the XOR may have a damaging effect on RBC.

AB0121 STUDY OF SLAMF7 EXPRESSION IN PRIMARY GOUGEROT-SJÖGREN SYNDROME

C. Schleiss[1], R. Felten[1,2], F. Monneaux[1], H. Dumortier[1], J. E. Gottenberg[1,2].
[1]*Laboratoire d'Immunologie, Immunopathologie et Chimie Thérapeutique, Institut de Biologie Moléculaire et Cellulaire (IBMC),, CNRS, UPR3572, Strasbourg, France;* [2]*Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Centre National de Référence des Maladies Auto-immunes Systémiques Rares Est Sud-Ouest (RESO), Strasbourg, France*

Background: SLAMF7 (CD319, CS1) is a lymphocyte signaling activation molecule (SLAM) belonging to the CD2 receptor family. It regulates many immune functions following its activation by homotypic interaction (SLAMF7 as ligand and receptor). Its expression is observed on different hematopoietic cells such as plasma cells and NK cells and its activation leads to increased cytotoxic degranulation and IFNg secretion. SLAMF7 is a therapeutic target in multiple myeloma where plasma cells over-express SLAMF7. Elotuzumab, which binds to SLAMF7, induces an antibody-mediated cytotoxicity mechanism and an increase in the anti-tumor activity of NK cells.
Objectives: We investigated SLAMF7 expression in primary Sjögren's syndrome (pSS).
Methods: SLAMF7 expression was studied using flow cytometry on different subpopulations (CD4 T cells, CD8 T cells, NK cells, plasma cells (CD19+ CD38+ CD27high) and naive (CD27-) or mature (CD27+) B cells before (IgD+) or after (IgD-) class switching in pSS patients and healthy donors (HD). SLAMF7 protein expression was measured by the difference in expression (condition with antibody recognizing SLAMF7 - condition without antibody) of the mean fluorescence intensity (delta MFI).
Results: The pSS cohort consisted of 18 patients (17 women). 71% of patients were anti-SSA+, 41% anti-SSB+, 44% had rheumatoid factors (RF). The median IgG level was 13.3 g/l (9.88-21.45). 8/18 patients had evidence of systemic activity (ESSDAI score >0). Twenty-one healthy donors (19 women) were used as controls. No overall difference in SLAMF7 expression was observed between pSS and healthy donors, or among pSS patients between patients with or without systemic complications. SLAMF7 expression was higher in patients with than in patients without autoantibodies or markers of B-cell activation.
1/RF-positive patients had a higher expression of SLAMF7 than RF-negative patients by IgD- CD27+ B cells (median delta MFI: 397 for RF+ pSS vs 185 for RF- negative pSS [p=0.001] vs 187 [p<0.0001] for HD) and by C27+ IgD+ B cells (median delta MFI: 450 for RF+ pSS vs 307 for RF- negative pSS [p=0.005] vs 329 [p=0.001] for HD).
2/ Anti-SSA-positive patients had a higher expression of SLAMF7 than anti-SSA-negative patients by CD27+ IgD- B cells (median delta MFI: 346 for anti-SSA+ pSS vs 149 for anti-SSA-negative pSS [p=0.019] vs 187 [p=0.007] for HD) and by C27+ IgD+ B cells (median delta MFI: 403 for anti-SSA+ pSS vs 264 for anti- SSA negative pSS [p=0.021] vs 329 [p=0.012] for HD). The same association with a higher expression of SLAMF7 was observed for anti-SSB.
3/SLAMF7 expression was correlated with IgG levels in pSS patients on IgD-CD27+ B cells (r=0.51, p=0.044).
Conclusion: This study shows for the first time an overexpression of SLAMF7 on the surface of mature B cells in patients with pSS. This overexpression of SLAMF7 is associated with the presence of markers of B-cell activation. The therapeutic targeting of SLAMF7 therefore deserves further investigation in pSS. A study of its expression in the target tissue of the disease, minor accessory salivary glands, will allow a more precise analysis of the potential pathogenic role of SLAMF7 in pSS.

AB0122 DETECTION OF ANTINUCLEAR ANTIBODY AND ANTIBODIES TO EXTRACTABLE NUCLEAR ANTIGENS IN SERUM-DERIVED EXOSOMES

Y. Huang[1], Q. Huang[1], T. W. Li[1,2]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China;* [2]*Zhaoqing Central People's Hospital, Department of Rheumatology and Immunology, Zhaoqing, China*

Background: Antinuclear antibody (ANA) and antibodies to extractable nuclear antigens (anti-ENAs) are important diagnostic biomarkers for autoimmune disease. In-direct immunofluorescence (IIF) and EUROLINE-Western Blot technology are used to detect ANA and anti-ENAs in serum respectively. However, the sensitivity of some anti-ENAs are not high, which often lead to the misdiagnosed or missed diagnosis of autoimmune disease. Much more methods are needed to increase the sensitivity of anti-ENAs. The protein of serum-derived exosomes have been used to explore the biomarker of many disease. As the level and significance of ANA and anti-ENAs in serum-derived exosomes, it has not been reported yet.
Objectives: Our study aims to detect the level of ANA and anti-ENA in serum-derived exosomes and compare the difference between serum and serum-derived exosomes.
Methods: Twenty-four patients with ANA positive in serum were enrolled into the study. Exosomes were separated from the serum by the ExoQuick^{TM} kit combined with ExoQuick^{TC} kit. ANA and anti-ENAs were further detected by IIF and EUROLINE-Western Blot technology in serum and serum-derived exosomes.
Results: The ANA levels in serum-derived exosomes were the same as serum. The anti-ENAs levels of serum-derived exosomes in 70% (16/24) patients were different from serum. Besides, anti-nRNP, anti-Sm, anti-SSA, anti-Ro52, anti-SSB, anti-Jo1, anti-CENPB, anti-dsDNA, anti-AHA, anti-ARPA levels of serum-derived exosomes in 11.11% (1/9), 33.30% (1/3), 46.15% (6/13), 54.55% (6/11), 50% (1/2), 100% (1/1), 66.67% (2/3), 75.0% (3/4), 66.67% (2/3), 40% (2/5) patients were different from that of serum.
Conclusion: The levels of most anti-ENAs in serum-derived exosomes are higher than that of serum, which may help to improve the sensitivity of diagnose in autoimmune disease.

IMPACT OF TOBACCO ON PRIMARY SJÖGREN SYNDROME: ANALYSIS OF THE FRENCH COHORT ASSESS

L. Pacoureau[1], J. E. Gottenberg[2], G. Nocturne[1,3], E. Dernis[4], M. Couderc[5], V. Le Guern[6], X. Mariette[1,3], R. Seror[1,3]. *[1]APHP Hôpital Bicêtre, Department of Rheumatology and National Reference Center for Rare Systemic Autoimmune Diseases, Le KREMLIN BICETRE, France; [2]Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Centre National de Référence des Maladies Auto-immunes Systémiques Rares Est Sud-Ouest (RESO), Strasbourg, France; [3]Université Paris Sud - Faculty of Medicine, INSERM UMR1184, Le KREMLIN BICETRE, France; [4]CH Le Mans, Service de rhumatologie, le mans, France; [5]Clermont-Ferrand University Hospital, Rheumatology Department, Gabriel-Montpied Hospital,, Clermont Ferrand, France; [6]APHP - Hôpital Cochin, Internal Medicine Department, Paris, France*

Background: It has been shown that smoking could be negatively associated with the risk of developing primary Sjögren's Syndrome (pSS), and that amongst smoking pSS patients, seropositivity for anti SSA antibodies and frequency of focal sialadenitis were lower. However, data are scarce concerning the impact of smoking on disease activity, glandular features, patient reported outcomes (PROs) and disease progression.
Objectives: To describe the impact on smoking on pSS disease characteristics and outcome.
Methods: ASSESS (Assessment of Systemic Signs and Evolution in Sjögren's Syndrome) is a French prospective multicenter, longitudinal cohort involving 395 patients with pSS enrolled in 15 French centers between 2006 and 2009 and followed since then. In these patients, we compared baseline characteristics and outcome (change in activity and PROs) during the first 5 years of follow-up, according to their smoking status (ever/never). For change during follow-up, any change of ≥ 3 points of ESSDAI or ≥ 1 point of ESSPRI or individual VAS, ≥ 25% of unstimulated salivary flow (UWSF) were considered.
Results: Data on smoking at inclusion were available for 394 patients, 106 (26.9%) of them were ever-smokers. Compared to never smokers, ever-smokers were significantly younger (54.0 ± 11.3 vs 59.2 ± 12.2, p < 0.001), and more frequently men (14 (13.2%) vs 12 (4.2%), p = 0.0013). The mean ESSDAI did not differ according to smoking status, (5.0 ± 4.9 vs 5.5 ± 5.8, p = 0.436).
There were no significant differences regarding the use of corticosteroids (49 (46.2%) vs 159 (55.2%), p = 0.113), immunosuppressive drugs (21 (19.8%) vs 77 (26.7%), p = 0.158), or hydroxychloroquine (49 (46.2%) vs 165 (57.3%), p = 0.05), even though numerically less smokers were taking these treatments. Smokers tended to have a lower dryness VAS and were less likely to use treatment for dry mouth (64 (60.4%) vs 210 (73%), p = 0.016).
No difference was observed in PROs (ESSPRI 5.2 ± 2.2 vs 5.5 ± 2.1, p = 0.259), and in UWSF (0.5 ± 0.75 vs 0.4 ± 1.0, p = 0.672) between smokers and non-smokers.
After five years, no difference in change of disease activity (ESSDAI change ≥ 3 points: 12/77 (15.6%) vs 30/207 (14.5%), p = 0.818), or in PROs (ESSPRI change ≥ 1: 30/70 (42.9%) vs 91/198 (46%) p = 0.654) was observed according smoking status, as well as no change in dryness (p = 0.968), pain (p = 0.280), fatigue (p = 0.605) or in UWSF (p = 0.132).

Table 1. ***Baseline characteristics and change in patient-reported outcomes at 5 years***

Baseline	Smokers n = 106	Non smokers n = 288	*p*-value
Age (years)	54.0 ± 11.3	59.2 ± 12.2	0.00008
Sex, females	92 (86.0)	276 (95,8)	0.0013
Disease duration (years) median [IQR]	3.9 [1.1; 8.7]	5.5 [2.6; 9.7]	0.257
ESSPRI	5.2 ± 2.2 (n = 97)	5.5 ± 2.1 (n = 267)	0.259
Dryness	4.9 ± 2.5 (n = 98)	5.5 ± 2.2 (n = 270)	0.053
Fatigue	5.9 ± 2.8 (n =101)	6.0 ± 2.6 (n = 275)	0.924
Pain	4.6 ± 2.8 (n = 101)	4.9 ± 2.9 (n = 274)	0.359
Unstimuled salivary flow (mL/min)	0.5 ± 0.75 (n = 89)	0.4 ± 1.0 (n = 241)	0.672
Treatment for dry mouth	64 (60.4)	210 (73.0)	0.016
ESSDAI	5.0 ± 4.9 (n = 104)	5.5 ± 5.8 (n = 281)	0.436
Corticosteroids	49 (46.2)	159 (55.2)	0.113
Hydroxychloroguine	49 (46.2)	165 (57.3)	0.050
Immunosuppresive drugs	21 (19.8)	77 (26.7)	0.158
Lymphocytes count (/mm^3)	1661.1 ± 919.3	1492.1 ± 1072.0 (n = 280)	0.128
After five years			
Change in ESSDAI ≥ 3	12 (15.6) (n = 77)	30 (14.5) (n = 207)	0.818
Change in ESSPRI ≥ 1	30 (42.9) (n = 70)	91 (46.0) (n = 198)	0.654
Change in salivary flow ≥ 25%	29 (44.6) (n = 65)	55 (34.0) (n = 162)	0.132

Data are given as mean ± SD or n (%) unless otherwise specified. SD, standard deviation; IQR, interquartile range; ESSPRI, EULAR Sjögren's Syndrome Patient Reported Index; ESSDAI, EULAR Sjögren's Syndrome Disease Activity Index.
Continuous variables were compared using student t test and qualitative variable using chi-square

Conclusion: Smokers pSS patients are more likely to be men and younger than non-smokers. Ever smokers tended to have less dryness, and take less frequently treatment for dryness, corticosteroids, hydroxychloroquine or immunosuppressants. After five years, no difference was observed, according to smoking status, in terms of change in disease activity or PROs.

EFFECTS OF INHIBITOR K-CARRAGEENAN ON HAECS INFLAMMATORY RESPONSE TO LDLS ISOLATED FROM SLE PATIENTS

S. Parra[1], A. Avila[2], J. Rivalta[3], M. Guardiola[3], R. Rodriguez[3], A. Castro[1]. *[1]Hospital Universitari Sant Joan de Reus, Internal medicine. Autoimmune diseases unit, Reus, Spain; [2]Hospital Universitari Sant Joan de Reus, Pathology department, Reus, Spain; [3]Rovira i Virgili University, Unitat de Recerca de Lipids i arteriosclerosis, Tarragona, Spain*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with a high risk of atherosclerosis and cardiovascular events. It was previously reported by our group that low-density lipoprotein (LDL) particles isolated from SLE patients, during an active state of the disease ('flare'), promoted an exaggerated inflammatory response in human aortic endothelial cells (HAECs). However, the molecular mechanisms underlying this response still remain elusive.
Objectives: The hypothesis of this study is that these SLE-LDLs would be using receptor LOX-1, associated with inflammatory conditions and altered lipoproteins, to generate the proatherogenic response in HAECs.
Methods: LOX-1 pharmacological inhibitor k-carrageenan was used before the stimulation of HAECs with LDLs isolated from healthy controls (10), non-active (13), or active-SLE patients (13). Gene expression, protein, and cell migration assays were performed to evaluate HAECs inflammatory response.
Results: LOX-1 inhibition with k-carrageenan significantly reduced the expression of vascular cell adhesion molecule 1 (VCAM-1) and restored the gene expression of endothelial nitric oxide synthase (eNOS) in HAECs incubated with non-active SLE LDLs.
Conclusion: While VCAM-1 down-regulation was expected, the immediate next step derived from the observed results will be a deeper understanding of how LOX-1 inhibition may restore the endothelial ability to synthetize NO in the presence

of altered LDL. This will allow gaining insight not only on the development of atherosclerosis but also on the clue mechanisms involved in the pathogenesis of SLE.

AB0125 IL-25 PARTICIPATES IN KERATINOCYTE-DRIVEN DERMAL MATRIX TURNOVER AND IS REDUCED IN SYSTEMIC SCLEROSIS (SSC) EPIDERMIS

B. Russo[1,2], J. Borowczyk[3], P. Cacialli[3], P. Moguelet[4], M. E. Truchetet[5], A. Modaressi[6], N. Brembilla[2], J. Bertrand[3], W. H. Boehncke[2], C. Chizzolini[3]. *[1]University of Geneva, Departement of Medicin, Geneva, Switzerland; [2]Hôpitaux Universitaires de Genève, Dermatology unit, Geneva, Switzerland; [3]University of Geneva, Departement of Pathology and Immunolgy, Geneva, Switzerland; [4]Tenon Hospital APHP, Department of Pathology, Paris, France; [5]University Hospital, Departement of Rheumathology, Bordeaux, Switzerland; [6]Hôpitaux Universitaires de Genève, Plastic, reconstructive & aesthetic unit, Geneva, Switzerland*

Background: Evidence shows that dysfunctional SSc keratinocytes contribute to fibrosis by altering dermal homeostasis (1, 2). Whether interleukin-25 (IL-25), an IL-17 family member regulating many epidermal functions (3), takes part in skin fibrosis is unknown.
Objectives: To investigate the role of IL-25 in skin fibrosis.
Methods: The expression of IL-25 was evaluated by immunofluorescence and *in situ* hybridization in 10 SSc and 7 healthy donors (HD) skin biopsies. Epidermal equivalents (EE) reconstituted by primary HD keratinocytes were used as a model to study transcriptomic changes induced by IL-25 in the epidermis. RNA expression profile in EE was characterized by RNAseq. The conditioned medium (CM) from primary SSc and HD keratinocytes primed with IL-25 was used to stimulate fibroblasts. IL-6, IL-8, MMP-1, type-I collagen (col-I), and fibronectin production by fibroblasts was assessed by ELISA.
Results: SSc epidermis expressed lower levels of IL-25 compared to HD. In EE, IL-25 regulated several molecular pathways related to wound healing and extracellular matrix (ECM) remodeling. Compared to control CM, the CM from IL-25-primed keratinocytes enhanced the fibroblast production of MMP-1, IL-6, IL-8, but not of Col-I nor fibronectin. However, IL-25 significantly reduced the production of Col-I when applied directly to fibroblasts and partially inhibit α-smooth muscle actin (α-SMA) expression promoted by TGFβ. The activation of keratinocytes by IL-25 was receptor-dependent and evident after a very short incubation time (10 min), largely mediated by IL-1, suggesting enhanced and specific release of preformed mediators.
Conclusion: These results show that IL-25 participates to skin homeostasis and its decreased expression in SSc may contribute to skin fibrosis by favoring ECM deposition over degradation.

AB0126 MULTIPARAMETER LINEBLOT IMMUNOASSAY FOR AUTOIMMUNE INFLAMMATORY MYOPATHIES: ADDITION OF CN-1A FOR THE DETECTION OF AUTOANTIBODIES ASSOCIATED WITH INCLUSION BODY MYOSITIS

J. Janz[1], A. Ott[1], M. Richter[1], T. Scheper,[1], W. Schlumberger[1], W. Meyer[1]. *[1]EUROIMMUN Medizinische Labordiagnostika AG, Institute for Experimental Immunology, Lübeck, Germany*

Background: Autoantibodies against cN-1A (Mup44) are primarily used as a biomarker for inclusion body myositis (IBM), they also occur with lower prevalence in systemic lupus erythematosus (SLE) and Sjögren's Syndrome (SjS). cN-1A has been included as a parameter on the multiparameter lineblot Autoimmune Inflammatory Myopathies 16 Ag et cN-1A (EUROIMMUN), allowing the detection of 17 myositis-specific and myositis-associated autoantibodies.
Objectives: The prevalences of anti-cN-1A autoantibodies were determined in different patient collectives and healthy blood donors.
Methods: A lineblot immunoassay containing a highly purified, recombinant cN-1A expressed in *E.coli* was incubated according to the instructions. Sera of 197 patients with IBM, 48 with collagenosis (systemic sclerosis, undifferentiated collagenosis and mixed tissue collagenosis), 52 with polymyositis/dermatomyositis and 75 with SLE/SjS were screened for cN-1A autoantibodies. Additionally, 151 apparently healthy blood donors as well as a disease control collective comprising sera of 20 patients with thyroiditis, 26 with neuromuscular disorders, 24 with primary biliary cholangitis (PBC), 19 with Wegener's Disease, 17 with Coeliac disease, and 2 with autoimmune liver disease (ALD) were analyzed. Signal intensities were automatically evaluated using the EUROLineScan software (EUROIMMUN).
Results: Prevalences of cN-1A autoantibodies were 34.5% in IBM, 10.4% in collagenosis, 7.7% in polymyositis/dermatomyositis, 13.3% in SLE/SjS, 2% in the blood donor cohort and 4.6% in the disease control collective.
Conclusion: The addition of cN-1A to a multiparametric lineblot immunoassay now reduces the risk of underdiagnosing IBM in patients with autoimmune inflammatory myopathies and increases the overall diagnostic sensitivity.

AB0127 BRONCHOALVEOLAR LAVAGE (BAL) FLUID AND SERUM FROM PATIENTS WITH SYSTEMIC SCLEROSIS WITH INTERSTITIAL LUNG DISEASE (SSC-ILD) PROMOTE A PRO-INFLAMMATORY GENE SIGNATURE IN HUMAN PRIMARY LUNG FIBROBLASTS

Y. Al-Adwi[1], J. Westra[2], A. J. Stel[2], H. van Goor[3], D. J. Mulder[1]. *[1]University Medical Center Groningen, Internal Medicine (Vascular), Groningen, Netherlands; [2]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [3]University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands*

Background: While circulating cytokines are frequently investigated in SSc patients, they may also play a role in local tissue, such as the lungs. Although most SSc patients show limited systemic inflammation, some studies have demonstrated that BAL fluid obtained from patients with SSc contains elevated levels of pro-inflammatory and pro-fibrotic cytokines. However, the relevance of the local milieu of the bronchial tree on the development of ILD has not been studied. We hypothesized that the bronchial milieu as represented by BAL fluid will have pro-inflammatory and pro-fibrotic effects on lung fibroblasts as the major effector cells in lung fibrosis. We also anticipated a greater pro-inflammatory and pro-fibrotic effect of BAL fluid obtained from patients with ILD (SSc-ILD) compared to patients without ILD (SSc). Finally, we hypothesized that serum obtained from both SSc-ILD and SSc will have a similar and concordant effect on lung fibroblasts, due to the systemic nature of the disease.
Objectives: To show the differential effect of BAL fluid and serum obtained from SSc patients with and without ILD on mRNA expression of pro-inflammatory and pro-fibrotic markers in human primary lung fibroblasts.
Methods: Serum and BAL fluid were collected from 3 SSc-ILD and 3 without ILD who were all treatment-naïve. ILD diagnosis was based on HRCT and lung function tests. Normal human primary lung fibroblasts were cultured and treated with either BAL fluid (5%) or serum (0.5%) from all individual patients. No treatment (CTRL) or treatment with pooled serum from healthy controls were used as control. After 4h, fibroblasts were harvested in TRIzol. The mRNA expression levels of inflammatory markers (Interleukin-6: IL-6, Interferon gamma-induced protein 10: IP-10), fibrotic markers (Connective Tissue Growth Factor: CTGF, Transforming Growth Factor: TGF-β and Alpha- Smooth Muscle Actin: α-SMA) were assessed using RT-qPCR. Nonparametric Mann-Whitney U test was used for comparison between groups. Correlation between BAL and serum treated fibroblast were calculated for the expression of the markers using Pearson correlation coefficient method.
Results: Fibroblasts treated with either SSc or SSc-ILD BAL fluids showed a significantly higher mRNA expression of IL-6 compared to control (Figure 1 a). The same was observed for IP-10, except for SSc serum which was not significant (Figure 1 b). When comparing the effects of BAL fluids between SSc or SSc-ILD patients, the effect of SSc-ILD BAL fluid was strikingly more profound

than observed with SSc on both IL-6 and IP-10 (Figure 1 a,b). Similar effects were seen when fibroblasts were treated with SSc serum, where serum from SSc-ILD resulted in significantly higher expression of IL-6 and IP-10 compared to SSc (Figure 1 a,b). The effect of serum and BAL on IL-6 gene expression were strongly and significantly correlated (r=0.9; P=0.015) while were weakly correlated regarding IP-10 expression (r=0.4; P=0.3) (not shown). The fibrotic markers TGF-β and α-SMA showed no difference in expression in BAL or serum-treated fibroblasts compared to controls (Figure 1 c,d). Only the fibroblasts treated with SSc-ILD serum showed a significant increase in mRNA expression of the early fibrosis marker CTGF when compared to control or SSc serum (Figure 1 e).

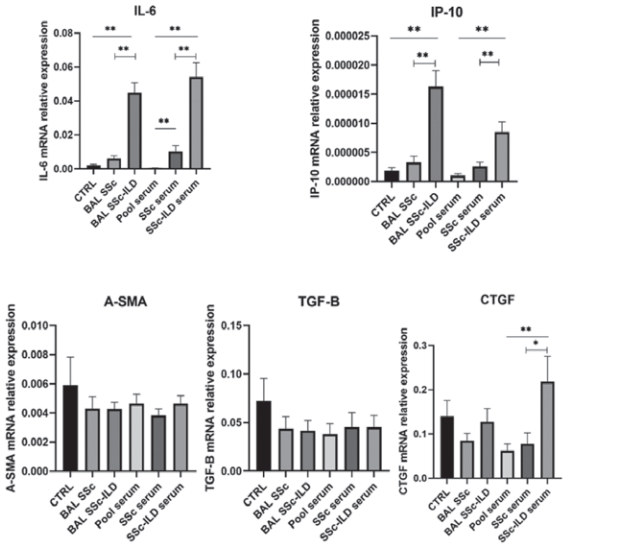

Fig.1: Effects of systemic and local fluids from SSc patients with ILD (SSc-ILD) and those without ILD (SSc) on lung fibroblasts. (a-e) mRNA relative expression of inflammatory (IL-6 and IP-10) and fibrotic (A-SMA, TGF-B and CTGF) genes, respectively, of lung fibroblasts treated with BAL or serum obtained from SSc or SSc-ILD patients, or healthy controls. CTRL, control (untreated); *, p<0.05; **, p<0.01. Three technical replicates were performed (n=3) using materials from 6 patients (N=6) and pooled healthy serum.

Conclusion: We showed a clear pro-inflammatory effect of BAL fluid obtained from patients with SSc on human fibroblasts as demonstrated by mRNA expression of IL-6 and IP-10. This pro-inflammatory effect was 5-10 times more profoundly observed in SSc patients with ILD compared to those without ILD. Similar effects were observed when fibroblasts were treated with serum obtained from the same SSc patients where the BAL fluid and serum of each patient seemed to provoke a concordant pro-inflammatory effect. Although further studies are warranted, our results underline the systemic nature of SSc and provide new insights into the role of and interaction between the local bronchial and systemic milieu in ILD development.

IMMUNE RESPONSE GENE 1 (IRG1) IS DYSREGULATED IN SYSTEMIC SCLEROSIS

S. O'Reilly[1]. [1]*Durham, Biosciences, Durham, United Kingdom*

Background: Systemic sclerosis (SSc) is an autoimmune idiopathic connective tissue disease in which there is inflammation and fibrosis of the skin. The innate immune system is intricately linked in the disease. IRG1 is a gene that codes for an enzyme that is essentially to make itaconate a metabolite of the TCA cycle. Itaconate has recently been ascribed function in immunity by negatively regulating inflammation through mechanism that involve upregulation of nrf2 and possibly downregulation of nf-kb to act as a molecular rheostat to balance the positive and negative aspects of inflammation. IRG1 is known to be robustly upregulated in macrophages after LPS stimulation.

Objectives: To determine the expression of IRG1 in systemic sclerosis macrophages.

Methods: Early diffuse SSc patients (< less than 2 years from first non-Raynaud's symptom) had blood drawn and monocytes were isolated on CD14 using MACS. Healthy controls blood was also taken and CD14+ monocytes were isolated. All female (3 donors each). After isolation cells were differentiated to macrophages using M-CSF for a set period. After which they were treated with ultrapure LPS for 18 hours. Cells were lysed and mRNA expression for IRG1 and Nqo1 was quantified by qPCR. Data is normalized to housekeeping gene 18S for normalization. In some experiments macrophages were stimulated with the itaconate derivative 4 Octyl Itaconate (4OI) at 100 μM for 2 hours, then stimulated or not with LPS for a further 24 hours. IL-1β and IL-6 cytokines were measured by ELISA. Bleomycin mouse model of skin fibrosis was employed by repeated intra dermal injections of bleomycin or sodium chloride vehicle. Skin biopsies were taken in the lesioned skin and H&E performed and fibrosis markers by qPCR was analysed.

Results: Healthy monocytes in response to LPS stimulation robustly upregulated IRG1 expression but in comparison to SSc monocytes this upregulated was significantly attenuated (n=3). Pretreatment of SSc monocytes with the itaconate derivative 4OI prior to LPS stimulation led to significantly reduced IL-1β and IL-6 secretion. The also led to upregulation of the nrf2 target gene Nqo1 6 fold compared to LPS treated alone. No difference in nf-kb was observed. mRNA expression of bleomycin skin found significantly downregulated nrf2 expression in association with elevated fibrosis markers compared to vehicle control treated mice (n=3 per group).

Conclusion: Failed upregulation of IRG1 in SSc macrophages may lead to a failure of inflammatory resolution and subsequent fibrosis. The itaconate derivative 4OI could be a possible anti-fibrotic through restoration of homeostasis via upregulation of nrf2 target genes.

MYOSITIS-SPECIFIC AUTOANTIBODIES IN CLINICAL PRACTICE: IMPROVING THE PERFORMANCES OF THE IMMUNODOT

E. Bories[1], F. Fortenfant[2], G. Pugnet[1], Y. Renaudineau[2], C. Bost[2]. [1]*Toulouse University Hospital Center, Department of Internal Medicine, Toulouse, France;* [2]*Toulouse University Hospital Center, Immunology laboratory, Institut Fédératif de Biologie, Toulouse, France*

Background: Idiopathic inflammatory myopathies (IIM) or myositis are a group of rare autoimmune diseases that combine muscle weakness and multi-visceral damage. The discovery of IIM-specific autoantibodies (aAbs) and their associations with clinical phenotypes has improved diagnostic and classification criteria. Faced with the large number of these aAbs, multiplexed techniques have emerged. Among them, the immunodot is simple, rapid, and inexpensive, but has been several times criticized for its lack of specificity.

Objectives: Our objective was to evaluate the current interpretation criteria of the D-Tek immunodot and to propose new interpretation rules based on clinical criteria in order to improve its reliability.

Methods: Were included in this retrospective study patients tested positive result on the semi-quantitative myositis/synthetase immunodots at manufacturer threshold (≥ 5 UA), for at least one of the 15 aAbs: anti-SRP, anti-NXP2, anti-TIF1, anti-SAE (1 and 2), anti-Mi2, anti-MDA5, anti-Jo1, anti-PL7, anti-PL12, anti-EJ, anti-OJ, anti-KS, anti-ZO, anti-HA. Specificity of the immunodots was further evaluated using 60 healthy and anonymous subjects (French blood bank, Toulouse, France). The clinical diagnosis and sub-classification retained by the clinician in charge of the patient was used as a reference for attribution to the myositis/non-myositis group and subgroups. For the myositis group, 7 subgroups were considered: immune-mediated necrotizing myopathy (n=4); dermatomyositis (n=66); anti-synthetase syndrome (n=36); inclusion body myositis (n=1); overlap myositis with another connective tissue disease (n=7); polymyositis (n=8); and unclassified myositis (n=6). For the non-myositis group, patients were subdivided in 4 subgroups: autoimmune or inflammatory diseases (n=72); isolated and diffuse interstitial lung disease (n=26) not associated with other myositis criteria; other non-inflammatory myopathies (n=8) including genetic, metabolic, and toxic myopathies; and other diseases (n=36). The immunodot interpretation thresholds were evaluated both in relation to the manufacturer's threshold, and by considering the phenotypes and clinical diagnoses using a ROC method (Youden's index).

Results: Among 270 patients included between 01/07/2016 and 30/06/2020, 128 (47%) were classified as myositis (median age 58 years, 60% women, 52% DM and 28% AS) and 142 (53%) in non-myositis. Among the 15 aAbs analyzed, none were detected in the healthy control group but they were represented in both myositis and non-myositis group. Among them only 2 (anti-Jo1, anti-Mi2) predominate in the myositis group, and 1 (anti-TIF1) in the non-myositis group (Fisher's test). As quantitative values were found different for 5 aAbs (Mann Whitney test), a clinical threshold was calculated to discriminate myositis from non-myositis groups (ROC curve) allowing to determine an odds ratio (OR). Accordingly, 4/15 (%) aAbs were found associated with myositis: anti-SRP (at 28UA: OR=3.24 95% CI [1.01-10.46], p=0.048), anti-MDA5 (at 15UA: OR=4.36; 95% CI [1.19-15.99], p=0.048), anti-Mi2 (at 5UA: OR =3.24; 95% CI [1.01-10.46], p=0.026), anti-Jo1 (at 5UA: OR= 12.20; 95% CI [2.78-53.52], p<0.0001). All positive predictive values were improved by using a clinical threshold although some of did not reach significance due to their infrequency.

Conclusion: In this retrospective work, despite missing data, the clinical phenotypes of myositis patients and their distribution according to aAbs were

comparable to those in the literature. Our study confirms the lack of specificity of D-tek immunodots for IIM-specific aAbs and allows establishing new thresholds improving their performance. Our results should encourage medical biologists to establish local rules of interpretation and reinforce the interest of the discussion between Clinicians and Biologists around the interpretation of these immunodots.

AB0130 DEREGULATION OF TFAM EXPRESSION PROMOTES MITOCHONDRIAL DAMAGE AND FIBROBLAST ACTIVATION IN SYSTEMIC SCLEROSIS

X. Zhou[1,2], T. Trinh-Minh[1,2], C. Tran Manh[1,2], A. Giessl[3], C. Bergmann[1,2], A. H. Györfi[1,2], G. Schett[1,2], J. H. W. Distler[1,2]. [1]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Department of Internal Medicine 3 - Rheumatology and Clinical Immunology, Erlangen, Germany;* [2]*FAU Erlangen-Nürnberg and University Hospital Erlangen, Deutsches Zentrum für Immuntherapie (DZI), Erlangen, Germany;* [3]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Ophthalmology, Erlangen, Germany*

Background: Transcription factor A, mitochondrial (TFAM) is a transcription factor with essential function in the mitochondrial homeostasis, such as mitochondria biogenesis and mtDNA replication. Deregulation of TFAM expression has been linked to mitochondrial dysfunction. However, its role in the pathogenesis of rheumatic diseases has not been studied so far.
Objectives: We aimed to study the role of TFAM in the pathological fibroblast activation in SSc.
Methods: The expression of TFAM in SSc skin fibroblast and skin biopsies was analyzed by immunofluorescence and Western blot. The role of TFAM in fibroblast activation was investigated by TFAM knockdown in cultured fibroblasts. The role of TFAM in skin and lung fibrosis was further studied in mice with fibroblast specific knockout of TFAM in three independent mouse models: Bleomycin-induced skin and lung fibrosis as well as TβRI^{act}-induced skin fibrosis.
Results: Dermal fibroblasts from SSc patients express lower level of TFAM in the skin and also after prolonged culture in vitro. The downregulation of TFAM impairs mitochondria homeostasis with decreased mitochondrial number, accumulation of damaged mitochondria with release of mtDNA, accumulation of deletions in mtDNA, metabolic reshaping with impaired OXPHOS and release of the mitokine GDF15. Long time, but not acute exposure of normal fibroblasts to TGFβ mimicked the finding in SSc fibroblasts with downregulation of TFAM and mitochondrial homeostasis disruption and damage. Knockdown TFAM of normal fibroblasts promotes fibroblast activation with increased myofibroblast differentiation and collagen release in a SMAD3 dependent manner. RNA sequencing demonstrated upregulation of pro-fibrotic genes and pathways. Mice with fibroblast-specific knockout of TFAM demonstrate are more sensitive to fibrotic stimuli such as bleomycin injection and TβRIact-overexpression and even demonstrate responses to NaCl instillation.
Conclusion: Alterations in the key mitochondrial transcription factor TFAM in response to prolonged activation of TGFβ and associated mitochondrial damage induce transcriptional programs that promote fibroblast activation and tissue fibrosis.

AB0131 INDUCTION OF COLLAGEN CHAIN FORMATION IN RESPONSE TO FIBROTIC FACTORS IN DERMAL AND PULMONARY FIBROBLASTS

S. F. Madsen[1,2], P. Juhl[3], J. M. B. Sand[3], M. Karsdal[4], A. C. Bay-Jensen[2], C. Thudium[2]. [1]*University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark;* [2]*Nordic Bioscience, ImmunoScience, Herlev, Denmark;* [3]*Nordic Bioscience, Fibrosis, Herlev, Denmark;* [4]*Nordic Bioscience, R&D, Herlev, Denmark*

Background: Systemic sclerosis (SSc) patients who develop pulmonary fibrosis, have an increased mortality rate[1]. Excessively activated fibroblasts deposit extracellular matrix (ECM), which leads to fibrosis resulting in stiffening of the tissue in both skin and lung. Currently there is no cure for fibrosis in SSc, only drugs which can slow the fibrotic process, and there is therefore, a medical need for further understanding of the pathogenesis. Fibrosis is associated with growth factors, including tumor growth factor beta 1 (TGF-β1) and platelet derived growth factor-ab (PDGF-ab).
Objectives: We investigated how TGF-β1 and PDGF-ab stimulation affected the gene and protein expression of specific collagen chains of type I, III and VI collagens in primary healthy human dermal (DF) and pulmonary fibroblasts (PF).
Methods: The fibroblasts were grown in 0.4% fetal calf serum DMEM, ficoll (to produce a crowded environment) and ascorbic acid for up to 12 days. They were stimulated with TGF-β [0.01 nM], PDGF-ab [3 nM] or a combination of TGF-β [0.01 nM] and PDGF-ab [3 nM], while non-stimulated fibroblasts served as control. ECM protein formation was assessed in supernatant from day 0, 4, 8 and 12, by ELISAs which detects the N-terminal of the pro-collagen of type I and III collagen, and the C5 domain of the α3 chain of type VI collagen. Gene expression was analyzed after 4 days and the relative gene expression was calculated based on multiple reference genes[2]. Statistical analysis includes one-way and two-way ANOVA.
Results: TGF-β increased the gene expression of Col1α1 in DF (p<0.0001) and Col1α2, Col3α1 and Col6α3 in both DF (p<0.01, p<0.001, p<0.05, respectively) and PF (p<0.0001) compared to control. PDGF-ab showed no difference in gene expression of the DF but decreased multiple genes in PF (p<0.01). The combination of TGF-β and PDGF-ab increased the gene expression of Col1α1 in DF (p<0.01), Col3α1 in PF (p<0.0001) Col1α2 and Col6α3 in both DF (p<0.05 and p<0.01) and PF (p<0.0001) compared to control. None of the stimulations lead to an increase in the Col6α1 and Col6α2. The TGF-β induced gene expression corresponded with increased ECM formation of type I and VI collagen from day 4 (p<0.01), and type III collagen from day 8 (p<0.05) in both DF and PF. PDGF-ab stimulation led to an increased ECM formation of type I and VI collagen in both DF and PF (p<0.01), and type III collagen in DF (p<0.01). The combination stimulation with TGF-β and PDGF-ab induced a corresponding increase in both gene expression and ECM formation of type I and VI collagen in both DF and PF (p<0.01). While the combination increased the ECM formation of type III collagen in both fibroblast types, the gene expression of Col3α1 were only increased in PF (p<0.0001).
Conclusion: This study demonstrates that TGF-β stimulation alone and in combination with PDGF-ab results in increased gene and protein expression of type I and VI collagen in both DF and PF, and additionally type III collagen in PF. However, there was a disconnect between the gene and protein expression profiles after PDGF-ab stimulation, which have to be investigated further. This study may provide new insights to the differences between fibroblast of different origin and their response to fibrotic factors.

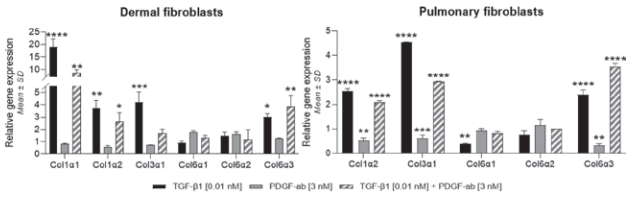

Figure 1: Relative gene expression type I, III and VI collagens of dermal (DF) and pulmonary fibroblasts (PF) after stimulation with TGF-β and/or PDGF for 4 days. The gene expression was calculated based on multiple reference genes.

AB0132 STIMULATION OF SOLUBLE GUANYLATE CYCLASE (SGC) FOSTERS ANGIOGENESIS AND BLUNTS ENDOTHELIAL-TO-MESENCHYMAL TRANSITION (ENDOMT) OF SYSTEMIC SCLEROSIS (SSC) DERMAL MICROVASCULAR ENDOTHELIAL CELLS

E. Romano[1], I. Rosa[1], B. S. Fioretto[1], D. Giuggioli[2], M. Manetti[1], M. Matucci-Cerinic[1,3]. [1]*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy;* [2]*University of Modena and Reggio Emilia, Scleroderma Unit, Department of Medical and Surgical Sciences for Children and Adults, Modena, Italy;* [3]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: In SSc, early abnormalities in microvessel morphology and angiogenic impairment in parallel advance with the development of tissue fibrosis orchestrated by myofibroblasts. Increasing evidence suggests that the EndoMT process, in which endothelial cells transdifferentiate into profibrotic myofibroblasts, may take centre stage in SSc pathogenesis [1,2]. sGC is an enzyme regulating cell growth/proliferation and vascular tone/remodelling by catalysing the production of cyclic guanosine monophosphate. Previous studies reported that sGC stimulation inhibits TGFβ-induced fibroblast-to-myofibroblast differentiation and collagen synthesis by blocking non-canonical ERK-dependent TGFβ signalling, and that sCG stimulators (sGCS) may exert antifibrotic effects in experimental models of fibrotic disorders.
Objectives: To investigate the possible modulatory effects of sGC stimulation on impaired angiogenesis and EndoMT of SSc dermal microvascular endothelial cells (SSc-MVECs).
Methods: To evaluate the effects of treatment with sGCS on endothelial cell viability/proliferation, 5 lines of SSc-MVECs and 5 lines of healthy dermal MVECs (H-MVECs) were challenged with sGCS (here MK-2947) and assayed with both annexin V/PI flow cytometry and WST-1. To analyse the modulation of angiogenesis by sGCS, SSc-MVECs were challenged with MK-2947 and subsequently tested for wound healing and capillary-like tube formation capabilities. To study the effects of MK-2947 on EndoMT, the same cells were assayed for the expression of endothelial and mesenchymal/myofibroblast markers by quantitative real-time PCR, western blotting and immunofluorescence, as well as for their contractile ability by collagen gel contraction assay. Phosphorylation of ERK1/2 was assessed by western blotting.
Results: Treatment with MK-2947 did not affect viability/proliferation of H-MVECs, while it significantly increased the proliferation of SSc-MVECs ($p<0.001$ vs. basal). Compared to basal condition, the MK-2947 challenge ameliorated both wound healing capability ($p<0.001$) and angiogenic performance (number of nodes: $p<0.01$; segments: $p<0.001$; meshes: $p<0.01$; and junctions: $p<0.001$) of SSc-MVECs. Upon stimulation of sGC, SSc-MVECs exhibited increased gene expression of proangiogenic matrix metalloproteinase (MMP)-9 ($p<0.05$) and decreased expression of both antiangiogenic MMP-12 ($p<0.05$) and pentraxin-3 ($p<0.001$) respect to basal SSc-MVECs. A significant increase in both gene and protein expression of the endothelial markers CD31 and VE-cadherin, and a parallel decrease in the expression of the mesenchymal/myofibroblast markers α-SMA, S100A4, and type I collagen were found in MK-2947-treated SSc-MVECs. MK-2947 also downregulated the EndoMT-driving transcription factor SNAIL1 in SSc-MVECs. Stimulation with MK-2947 was able to significantly counteract the intrinsic ability of myofibroblast-like SSc-MVECs to contract collagen gels ($p<0.001$) and effectively reduce phosphorylated-ERK1/2 protein levels ($p<0.01$) respect to basal cells.
Conclusion: Stimulation of sGC effectively ameliorates the angiogenic performance and blunts the pathogenic myofibroblast-like profibrotic phenotype of SSc-MVECs.

AB0133 TARGETING INFLAMMATION RESOLUTION IN SYSTEMIC SCLEROSIS: PRECLINICAL DATA OF A NEW DISEASE MODIFYING BIOLOGIC DRUG CANDIDATE RESOLVIX

F. Bonnefoy[1], S. Perruche[2]. [1]*RIGHT Institut (UMR 1098) /MED'INN'Pharma, EFS B/FC, BESANCON, France;* [1]*RIGHT Institut (UMR 1098) / MED'INN'Pharma, EFS B/FC, BESANCON, France*

Background: Systemic sclerosis (SSc) is a complex immune-mediated connective tissue disorder characterized by microvascular damage, inflammatory cell infiltration, and excessive deposition of extracellular matrix proteins (ECMs) resulting in fibrosis in the skin and various internal organs.
Limited treatment options are currently available in the clinic and are mostly focusing on symptom control with limited impact on disease progression. New treatment approaches are needed to address the complex dysregulated pathways and disease drivers to develop effective therapies.
While the pathophysiology of SSc remains incompletely understood it is well-recognized that progressive chronic inflammation is a part of the disease and its progression. Accumulation of apoptotic cells in tissues and defective clearance of these cells contributing to unresolved tissue repair is emerging as a root cause leading to sustained uncontrolled chronic inflammation and fibrosis. Naturally ending and resolving chronic inflammation to initiate healing and repair processes could present a novel therapeutic approach for SSc.
Resolvix, a next generation biological drug candidate under development, harnesses a complex mix of naturally occurring pro-resolutive factors emitted by human cells, has demonstrated promising disease modifying effects in models of experimental arthritis and inflammatory bowel disease.
Objectives: The objective of our preclinical study presented here, was to evaluate the potential therapeutic effects of Resolvix in experimental models of SSc.
Methods: Two established inducible preclinical models of SSc (bleomycin (BLM) and HOCl) were used to monitor the impact of Resolvix mouse equivalent versus a control treatment on skin (thickness and collagen deposition), lung (leucocyte infiltration and alveolar macrophage efferocytosis) and lymphoid organs/blood (Tregs) as well as selected plasma proteins. A single treatment or respective controls were administrated intra-venously at 3 weeks post disease induction and mice were monitored daily and sacrificed for analysis after 3 weeks post treatment.
Results: In our hands both preclinical models clearly show phenotypes associated with sclerosing processes of SSc. In both models we could show a significant reduction of skin thickening and collagen deposition in skin samples after a single treatment with Resolvix when compared to controls. Leucocyte infiltrates particularly evident in the HOCl model were significantly reduced by the Resolvix treatment in skin and lung tissues. Interestingly, alveolar macrophages collected from broncho-alveolar lavage (BAL) fluids of the diseased mice in both model systems demonstrated a significant reduction of efferocytosis capacity (eliminating apoptotic cells) a sign of uncontrolled ongoing chronic inflammation and recently reported in SSc patients[1]. Resolvix treatment successfully restored the efferocytosis activity to comparable levels detected in healthy mice.
In addition, $Foxp3^+$ regulatory T cells were increased in the blood of BLM-mice treated with Resolvix.
Plasma concentrations of IL-6 and TNF-α were not modified between controls, treated and non-treated mice.
Conclusion: Collectively our preliminary data demonstrate that harnessed pro-resolutive factors making up Resolvix are able to revert skin fibrosing processes, control inflammatory cell infiltration and restore defective macrophage efferocytosis as a novel a therapeutic approach in SSc.
Resolvix should be considered as a next generation disease modifying biological drug candidate for further development for the treatment of SSc.

AB0134 IN-VITRO STUDY ON THE EFFECT OF SELECTIVE JAK-INHIBITORS ON PBMCS STAT3 PHOSPHORYLATION FROM SYSTEMIC SCLEROSIS PATIENTS

F. Cacciapaglia[1], S. Perniola[2], S. del Vescovo[1], S. Stano[1], R. Bizzoca[1], D. Natuzzi[1], M. Fornaro[1], F. Iannone[1]. [1]*Rheumatology Unit, Department of Emergency and Organs Transplantation (DETO) - University of Bari., Bari, Italy;* [2]*Clinical Immunology Unit, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Rome, Italy*

Background: Systemic sclerosis (SSc) is a rare autoimmune connective tissue disease characterized by autoimmunity-driven damage and vasculopathy leading

to fibrosis of the skin and internal organs (1). The Janus kinase (Jak) - signal transducer and activator of transcription (STAT) pathway has been evidenced markedly activated in SSc patients (2, 3), and its inhibition has been proved in preclinical and clinical trials (4), but no data on Jak selective inhibition are available.
Objectives: To explore the effect of selective inhibition of Jak/STAT pathway in peripheral blood mononuclear cells (PBMC) from SSc patients.
Methods: In vitro Jak inhibition of the subunit 3 of phosphorylated (p) than activated STAT was measured by flow cytometry in peripheral blood mononuclear cells (PBMC) from SSc patients naïve to any immunosuppressive and/or corticosteroids (n.5). pSTAT3 activity was also assessed after stimulation with recombinant human 0.1 ng/ml IL-6 (Peprotech – NJ, USA). The PBMC were overnight incubated with IC50 concentrations of selective Jak1-, Jak2-, Jak3- and Tyk2-inhibitors (Biovision Inc. – CA, USA). Percentages of pSTAT3 positive cells were compared in presence of different compounds stimulation.
Results: After overnight incubation, percentage of pSTAT3 positive cells was significantly higher in $CD14^{pos}$ compared to $CD4^{pos}$ (16.3%; 95CI 10-22 vs 10.7%; 95CI 4--18, – p=0.02). $pSTAT3^{pos}CD14^{pos}$ cells were halved only by selective Jak3-inhibitor, while $pSTAT3^{pos}CD4^{pos}$ cells were reduced by 36% by selective Jak1-inhibitor. Selective Jak2- or Tyk2-inhibitors did not interfere with STAT3 phosphorylation in PBMC from SSc patients. After IL-6 stimulation, we observed a 2- and a 1.5-fold increase in percentage of $pSTAT3^{pos}CD4^{pos}$ and $pSTAT3^{pos}CD14^{pos}$ cells, respectively. $pSTAT3^{pos}CD14^{pos}$ cells were reduced in the PBMC co-culture with IL-6 and Jak-selective inhibitors, in contrast no effects were found in $CD4^{pos}$ cells. Specifically, selective Jak1- and Jak3-inhibitors reduced $pSTAT3^{pos}CD14^{pos}$ cells by an average of 37% and 25%, respectively. No effects were observed after co-culture with IL-6 and selective Jak2- or Tyk2-inhibitors.
Conclusion: Jak/STAT3 pathway of PBMC from SSc patients with active disease may be differently modulated by specific inhibitors. Selectivity of Jak1- and Jak3-inhibitors seems more relevant, especially in $CD14^{pos}$ monocytes after IL-6 stimulation. These preliminary findings highlight some evidence for effectiveness of selective Jak-inhibitors in SSc treatment.

AB0135 PROTEIN CONFORMATIONAL CHANGES AND FUNCTIONAL ALTERATIONS IN DERMAL FIBROBLASTS FROM PATIENTS WITH SYSTEMIC SCLEROSIS

J. Li[1], D. Abegg[1], L. Malinovska[2], M. Rudnik[1], O. Distler[1], P. Błyszczuk[1], P. Picotti[2], G. Kania[1]. [1]*University Hospital Zurich, University of Zurich, Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland;* [2]*ETH Zurich, Institute of Molecular Systems Biology, Zurich, Switzerland*

Background: Despite intensive studies and clinical trials, there is still no available precise diagnostic tool and treatment of the patients affected by systemic sclerosis (SSc). Proteopathies are diseases characterized by the production of aberrant conformers of certain proteins that lead to a disturbance of their cellular functions and disease. It is believed that the structure of a protein is principally responsible for its function. By identifying altered protein structures on a proteome-wide scale, there is a possibility to detect protein functional changes.
Objectives: To screen for changes in the protein conformation and to correlate with cell function in SSc dermal fibroblasts compared to fibroblasts from healthy donors (HC) using a novel approach of limited proteolysis followed by functional assays.
Methods: Diffuse cutaneous SSc and HC dermal fibroblasts were used for recently established Limited Proteolysis-coupled Mass-Spectrometry (Lip-MS)[1] to examine protein structural alterations in a proteome-wide scale. A change in conformation was defined as having a foldchange greater than 1 or smaller than -1 and a significant p-value of -log10 > 1.3 (≤0.05). Further, the responsive signalling targets in these cells, including the NF-κB-dependent pathway and energy metabolism, were evaluated. Fibroblasts were stimulated with inflammatory cytokines, highly relevant in SSc, including TNFα, IL-1β, TGF-β, IL-17A, and a combination of IL-17A and TGF-β. To examine the NF-κB activity, cells were transduced with a pseudo-typed HIV-1-based lentiviral vector. The measurements of luciferase signal were analysed. RT-qPCR was used to assess the expression of NF-κB-dependent genes for non-transduced cells. ATP measurements were analysed and presented as the amount of luminescent signal.
Results: LiP-MS analysis detected 53263 common peptides in SSc (n=6) and HC fibroblasts (n=6), of which 41 peptides showed conformational changes in SSc fibroblasts in comparison with HC fibroblasts. The 41 conformationally altered peptides showed significant enrichment in GO pathways for: biological processes (9), molecular function (7) and cellular components (21). SAE1, CTNND1, CDC37, and PPP1R13L were related to the NF-κB-dependent pathways, while ATP5A1, GSTM1, PCK2, ANPEP, GM2A, GNS, CAD, ACOT2 were connected with metabolic processes. There was a tendency of lower levels of mRNA *RELA, NFKBIA, MMP1* and *TNC* expression levels in untreated and stimulated SSc fibroblasts (n=6) compared to HC fibroblasts (n=6). The assessment of the NF-κB activity in untreated SSc fibroblasts (n=9) showed a trend to lower fold change compared to HC fibroblasts (n=9) (0.63 vs 1, SE 0.19, p=0.07). A statistically significant difference between SSc (n=8) and HC (n=8) fibroblasts was found in TGF-β stimulated fibroblasts (0.64 vs 1, SE 0.16, p=0.046). SSc fibroblasts (n=9) showed a lower ATP level compared to HC fibroblasts (n=9) in untreated condition (0.82 vs 1, SE 0.09, p=0.07), after stimulation with IL-1β (0.85 vs 1, SE 0.08, p=0.07) and TGF-β (0.81 vs 1, SE 0.09, p=0.05). Of note, a statistically significant difference between SSc and HC fibroblasts was found in IL-17A stimulated cells (0.82 vs 1, SE 0.07, p=0.02).
Conclusion: LiP-MS approach allowed for the identification of conformational changes in SSc fibroblast mainly related to signal transduction and metabolic pathways. Confirmatory functional studies showed deregulated NF-κB activity and ATP levels in SSc fibroblasts. Therefore, LiP-MS approach may create a distinctive opportunity to discover new disease biomarkers and functionally transformed pathways. This method may advance therapeutical approaches, where only structurally altered proteins could be specifically targeted, without interfering with non-changed proteins.

AB0136 ELUCIDATING THE PATHOGENIC EFFECTS OF ANTI-TOPOISOMERASE-1 ANTIBODIES IN SYSTEMIC SCLEROSIS

M. Aspari[1], K. V. Petersen[2], J. Geertsen Keller[2], S. R. Greisen[1,3], K. Soendergaard[3], J. Hauge Mikkelsen[1], B. Knudsen[2], B. Deleuran[1,3]on behalf of Bent Deleruran's group. [1]*Aarhus University, Biomedicine, Aarhus, Denmark;* [2]*Aarhus University, Molecular Biology, Aarhus, Denmark;* [3]*Aarhus University Hospital, Rheumatology, Aarhus, Denmark*

Background: Prediction of the pattern of organ involvement in patients with diffuse cutaneous systemic sclerosis (dcSSc) is supported by the specificity of autoantibodies. These autoantibodies are generally mutually exclusive and highly specific for dcSSc[1]. The autoantibody reactivity allows patients to be stratified early in the disease course, leading to a tailored approach and management. Anti-topoisomerase I antibodies (ATA) are predictors of the development of interstitial lung disease (ILD) and digital ulcers but appear to be protective against pulmonary artery hypertension (PAH).
Objectives: The aim of this project was to elucidate the functioning of ATA and their role in the pathogenicity of the disease.
Methods: Sera from healthy volunteers (HV) and dcSSc patients with and without ATA were collected from Aarhus University Hospital. Total IgG was purified from the sera using a Protein G column. ATA was further purified from the total IgG fraction by passing it through a column packed with the functional domains of human topoisomerase-1 (TOP1) expressed from *E.coli.*
Sera, total IgG and purified ATA fractions were utilized in preliminary experiments. The ability of ATA to inhibit TOP1 was tested by a in house developed REEAD assay in which the generation of closed DNA circles, by the cleavage-ligation activity of TOP1, is monitored after rolling circle amplification[2].
Results: Serum from patients with dcSSc, but not from HV, could inhibit TOP1 activity at various dilutions. Similarly, purified total IgG fractions from dcSSc patients could also inhibit TOP1 activity. ATA was successfully separated from IgG from dcSSc patients who were positive for ATA. This could inhibit TOP1 activity even at lower concentrations than total IgG. This was the case for both mitochondrial and nuclear TOP1 activity.
Fully in line with presence of ATA, PBMC's from dcSSc patients contained a lower TOP1 activity compared to HVs PBMCs.
Conclusion: To our knowledge we are the first group to be able to successfully separate ATA from total IgG from dcSSc patients. our unique in house developed REEAD assay clearly demonstrates the function of ATA and provides the opportunity to better understand

AB0137 SERA DERIVED EXTRACELLULAR VESICLES FROM SYTEMIC SCLEROSIS PATIENT AND AUTOANTIBODIES MEDIATE PERIPHAL BLOOD MONOCYTES ACTIVATION

A. Hackel[1], A. Müller[1], H. Grasshoff[1], G. Marschner[1], G. Riemekasten[1]on behalf of Rheumatology and Clinical Immunlogy Lab. *[1]University Clinic Schleswig-Holstein, Lübeck, Germany, Clinic of Rheumatology and Clinical Rheumatology, Lübeck, Germany*

Background: In SSc, autoantibodies (abs) directed against G protein-coupled receptors (GPCR) are prominent and for example induce release of inflammatory and profibrotic proteins by monocytes (1-3). Increased levels of autoantibodies against angiotensin II type 1 receptor (AT1R abs) have been found in patients with renal involvement in systemic sclerosis (SSc) (4-5). The elevated amount of anti-GPCR abs is accompanied by increased secretion of extracellular vesicles (EVs) in SSc (6). The importance of EVs in the pathogenesis is also based on packing and horizontal transfer of AT1R to different tissues and immune cells, exemplary shown by activated cardiomyocytes leading to higher responsiveness to Angiotensin II of recipient cells and vessels (7). Taken together, the relevance of studying anti-GPCR abs together with GPCR-EVs in SSc pathogenesis becomes evident (8). Interestingly, CCL18 is found to be upregulated in SSc patients and suggested to be upregulated by AT1R abs (9), indicating CCL18 and CCR8 cross-talk via EVs plays an essential role in the pathogenesis of SSc.
Objectives: Unravel the immune response of peripheral blood monocytes mediated by anti-AT1R abs and EVs to gain new insights into the pathomechanism in SSc.
Methods: Human peripheral blood monocytes of healthy donors were stimulated by the endogenous AT1R ligand angiotensin II as well as by a monoclonal anti-human AT1R ab and, in comparison, by purified IgG from HD (HD IgG) versus those from SSc (SSc IgG). Further, human peripheral blood monocytes of HD were treated with EVs derived from sera of SSc patients versus sera of HD, in the presence or absence of a monoclonal recombinant anti-AT1R ab. Monoclonal AT1R ab has been generated by hybridoma technique, sequenced and recombinantly expressed in HEK cells. The specificity of AT1R abs was tested by using an AT1R blocker (telmisartan, TEL). EVs were isolated from sera by differential centrifugation to exclude large particles and microvesicles and further by one-step polymer precipitation procedure utilising ExoQuick Exosome Precipitation Solution (System Biosciences, Palo Alto, CA) and subsequent purification by size exclusion. Further, primary human peripheral blood monocytes of HD (n=6) were treated with EVs derived from sera of SSc patients (n=6) versus sera of HD (n=6), in the presence or absence of a monoclonal recombinant anti-AT1R ab. The response of the monocytes was measured via CCL18 secretion by ELISA.
Results: The recombinant monoclonal anti-human AT1R antibody induced secretion of CCL18, a profibrotic cytokine, by primary monocytes derived from HD. Similarly, the purified IgG fractions derived from SSc patients also induced an increased CCL18 release by monocytes compared to IgG fractions derived from HD. Further, complete amelioration of the AT1R ab effect on CCL18 secretion was found, when monocytic AT1R expression was blocked with TEL. In addition, antagonistic effects of Angiotensin II to the monoclonal AT1R ab were observed. In line, enhanced CCL18 secretion of human monocytes stimulated with SSc-EVs alone and together with the monoclonal AT1R ab was induced.
Conclusion: The secretion of pro-fibrotic CCL18 by human monocytes in response to a monoclonal AT1R antibody as well as to SSc IgG indicates that anti-AT1R abs are involved in the SSc pathogenesis. Further, this effect could also be due to SSc-EVs potentially presenting anti-GPCR abs to their receptors on immune cells.

AB0138 XANTHINE OXIDOREDUCTASE: BLOOD PROFILE IN SYSTEMIC CONNECTIVE TISSUE DISEASES

E. Mozgovaya[1], S. Bedina[1], A. Trofimenko[1], M. Mamus[1], S. Spitsina[1], I. Zborovskaya[1]. *[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical biochemistry lab, Volgograd, Russian Federation*

Background: Systemic lupus erythematosus (SLE) and systemic scleroderma (SSc) are systemic connective tissue diseases. Their development is based on a generalized immune inflammatory process. Deep immunological and metabolic disorders in these diseases have along with general characteristic distinctive features. XOR is a multifunctional enzyme. The reactions catalyzed by XOR are a source of reactive forms of oxygen and nitrogen, nitric oxide, which are of great physiological importance, and are also responsible for the development of many pathophysiological reactions. Analysis of changes in the activity of interconverting forms of XOR (xanthine oxidase (XO), EC 1.17.3.2 and xanthine dehydrogenase (XDG), EC 1.17.1.4) in plasma and blood cells is of interest.
Objectives: to characterize differences of XO and XDG activities profiles in blood of SLE and SSc patients.
Methods: The researcher was carried out in agreement with the WMA Declaration of Helsinki principles. 56 SLE patients and 51 SSc patients were enrolled in this study. Diagnosis of SLE was verified using the SLICC criteria (2012). SSc was verified according to ACR/EULAR criteria (2013). The reference group consisted of 35 healthy controls. XO and XDG activities were measured in plasma, lysed WBC, lysed RBC using spectrophotometric method [1]. Results were expressed as Me (Q_{25}; Q_{75}). The Mann-Whitney U test was used for statistical analysis, differences were considered significant when $p<0.05$.
Results: Mean age of SLE patients was 35 (31; 42) years, mean duration of disease was 8 (5; 11) years. Mean age of SSc patients was 43 (38; 48) years, mean SSc duration was 8 (6; 9) years. The enzyme indices included in the study did not depend on the sex and age of healthy individuals. XO activity was increased in plasma of SLE and SSc patients ($p<0.001$ for both disease). The activity of XO was higher in SLE ($p<0.001$). XO activity of lysed WBC was decreased in both diseases ($p<0.001$). XDG activity was decreased in lysed WBC and lysed RBC of patients with SLE and SSc (all $p<0.001$). Activity of this enzyme was lower in lysed WBC and higher in lysed RBC in SLE compared with SSc (all $p<0.001$). In contrast to SLE, accompanied by low levels of plasma XDH activity ($p<0.001$), SSc was characterized by increased activity of this enzyme ($p<0.001$). Also, increased XO activity was revealed in lysed RBC of SSc patients ($p<0.001$). The values of this enzymatic activity did not differ between the group of SLE patients and healthy controls ($p=0.977$).
Conclusion: Changes in the activity of oxidase and dehydrogenase forms of XOR were revealed in plasma, lysed WBC, lysed RBC of SLE and SSc patients, which determine characteristic blood profiles in these diseases. Changes in the balance of XOR enzymatic activities can affect the exchange of purine nucleotides, the pool of reactive oxygen and nitrogen species in body tissues, participating in the processes inherent in these diseases.

AB0139 **DEEP IMMUNE PHENOTYPING OF T LYMPHOCYTE SUBSETS IN SYSTEMIC SCLEROSIS PATHOPHYSIOLOGY AND FOLLOWING RESPONSE TO TARGETED CYTOTOXIC TREATMENT**

T. I. Papadimitriou[1], A. van Caam[1], J. Lemmers[1], X. He[2], E. Vitters[1], M. Koenders[1], R. Smeets[2], M. Vonk[1], P. van der Kraan[1], H. Koenen[2], R. M. Thurlings[1]. *[1]Radboud University Medical Center, Rheumatic diseases, Nijmegen, Netherlands; [2]Radboud University Medical center, Laboratory of Medical Immunology, Nijmegen, Netherlands*

Background: Abnormalities in T lymphocyte populations are associated with the pathogenesis of many autoimmune diseases, such as systemic sclerosis (SSc). Various studies report on the aberrations of different T cell cytotoxic (CTL) and helper (Th) subsets that appear to be linked with inflammatory and/or fibrotic manifestations of patients with SSc. Since T cells seem to play a pivotal role in the pathophysiology of SSc, targeting the pathogenic T cell subsets might be a promising therapeutic option.
Objectives: Here we set out to comprehensively compare T lymphocyte phenotypes between SSc patients and healthy donors. We further test the in-vitro efficacy of a combination of anti-CD3/CD7 immunotoxins (CD3/CD7-IT), that have been developed to eliminate activated CD4+ and CD8+ T cells, to study specific sensitivity of T-cell subpopulations to CD3/CD7-IT.
Methods: 30 SSc patients and 15 age and sex matched healthy donors were included. Of these patients, lymphocyte populations were quantified by 17-parameter flow cytometry of peripheral blood mononuclear cells (PBMCs) to identify CD4+ T helper cells (Th1, Th2, Th17, T peripheral helper), CD8+ naïve, memory, effector CTLs and senescent/exhausted subsets. We next developed a cell killing assay to evaluate the effect of T cell depletion. To address this, patients' (N=6) PBMCs were first activated for 24 hours in the presence of phytohemagglutinin, followed by CD3/CD7-IT addition for 48 hours. Subset-specific T cell depletion was assessed by using a combination of CellTiter-Glow luminescent cell viability assay and multi-parameter flow cytometric (FCM) quantification of CD3/CD7-IT-induced cell death.
Results: Frequencies of effector CD8+ CTLs,Th2 and T peripheral helper cells were elevated in SSc patients compared to healthy controls. Furthermore, SSc patients exhibited lower percentages of the anti-fibrotic Th1 subset. A striking expansion of the senescent CD4+CD28- and CD8+CD28- populations was noted in patients, while these subsets were barely detectable in healthy controls. In-vitro adittion of anti-T cell immunotoxins effectively depleted 50 % of patients' CD8+ T cells (including the CD8 effector subset) and 62% of CD4+ T cells (including Th2 and T peripheral helper cells). No difference in cytolytic sensitivity between different T cell subsets was observed.
Conclusion: Our findings demonstrate that deep FCM immunephenotyping reveals pathophysiological differences in peripheral T cell subsets of SSc patients. Strikingly, the developed cytolytic assays show that CD3/CD7-IT is able to target the potential disease-associated T cell subsets in an in-vitro setting.

AB0140 **ROLE OF ENDOGLIN IN THE PATHOGENESIS OF SYSTEMIC SCLEROSIS: A PRISMA-DRIVEN SYSTEMATIC REVIEW**

S. Grignaschi[1,2], B. L. Palermo[1,2], G. Spinozzi[3], A. Sbalchiero[4], C. Cantarini[4], C. Nardiello[4], C. Olivieri[4], L. Cavagna[1,2]. *[1]Fondazione I.R.C.C.S. Policlinico San Matteo, Department of Rheumatology, Pavia, Italy; [2]The University of Pavia, Department of Internal Medicine and Medical Therapeutics, Pavia, Italy; [3]Fondazione I.R.C.C.S. Policlinico San Matteo, Department of Otorhinolaryngology, Pavia, Italy; [4]The University of Pavia, General Biology and Medical Genetics unit, Dept of Molecular Medicine, Pavia, Italy*

Background: Systemic sclerosis (SSc) is a rare autoimmune disease characterized from peculiar vascular alteration and fibrosis of the skin and internal tissues. SSc pathogenetic mechanisms are still partially unclear but an involvement of the TGFβ pathway, known for being responsible of both angiogenesis and fibrosis, has been proven. Endoglin (ENG) is a TGFβ receptor type III involved in signal regulation, and mutations in *ENG* gene cause Hereditary Hemorrhagic Telangiectasia type I, a rare disease that shares with SSc the presence of mucocutaneous telangiectasias and disturbed angiogenesis.
Objectives: The aim of this systematic review is to highlight the role of ENG in the pathogenesis of SSc focusing on a subset of clinical manifestations.
Methods: We performed a systematic review following the PRISMA guidelines, searching the MEDLINE (PubMed), Web of Science and EMBASE databases using as keywords: "Endoglin", "sENG", "CD105", "Systemic sclerosis", "SSc", "Scleroderma", "CREST". The last search was made on November 2nd 2021. This review includes both conference abstracts (without subsequent publication) and articles that evaluated the relationships between SSc and ENG; we excluded the papers that used CD105 only as a cell marker. We then consulted the references from the papers found in order to search possible articles that escaped our first search.
Results: Of the 656 records identified from the database research, 42 were included in our systematic review (16 abstracts and 26 original papers) (Figure). The majority of these studies (25) measured serum ENG (sENG) looking for correlations with cutaneous, pulmonary and cardiac disease in patients with SSc.

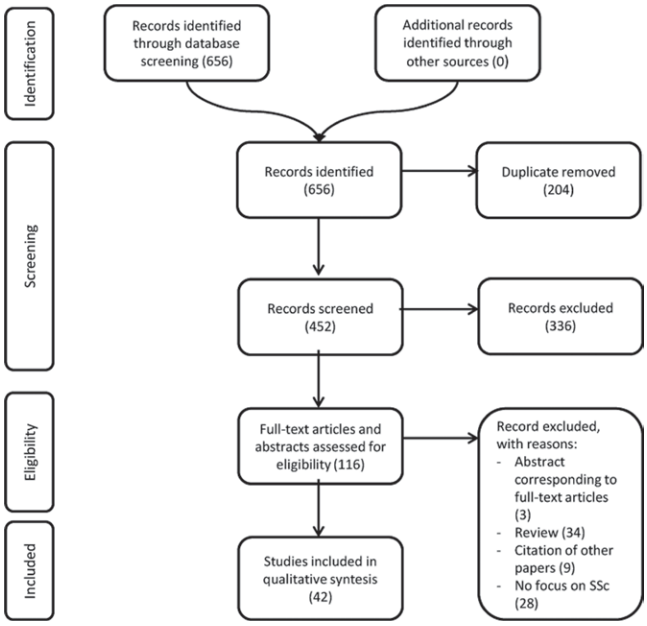

Figure. PRISMA flow diagram.

High levels of sENG demonstrated an independent association with telangiectasia in 2 studies, with the presence of digital ulcers (DU) in 6 studies but was not related to the occurrence of new DU (2 studies) and it was related to scleroderma pattern late in 2 studies. Between limited and diffuse cutaneous SSc, sENG showed no differences in one study and significantly higher values in lcSSc in another, this latter study also found sENG to be higher in lcSSC compared to systemic lupus erythematous and healthy controls (HC). sENG, moreover, demonstrated a positive correlation with anti-centromere antibodies (two studies). Regarding pulmonary involvement, no correlation between sENG and mean pulmonary arterial pressure was recorded, and two studies found sENG elevated in patients with pulmonary arterial hypertension while no correlation was found from two other papers. High sENG concentrations demonstrated a positive correlation with subclinical atherosclerosis and with high sensitivity troponin, but its concentration did not relate to right heart dysfunction (1 study each). Two different groups evaluated sENG concentration in Localized Scleroderma and found no differences with other connective tissue diseases. One study searched for genetic alterations in the expression of *ENG* gene and found no difference between SSc patients and HC. Four studies evaluated Eng expression on fibroblast surface: SSc fibroblasts from both systemic circulation and lung showed higher production of Eng than HC. Tissue Eng, moreover, is up regulated in SSc patients where it acts as a regulator of TGFβ signaling and of extracellular matrix production.
Conclusion: As suggested by the role of Endoglin in the TGFβ pathway, several authors demonstrated an altered expression of Endoglin in SSc patients. A particular focus of interest is the role of ENG in PAH and DU that occur in SSc. A direct involvement of *ENG* in PAH is known as mutation in this gene are one of the genetic causes of PAH. However, particularly in pulmonary vascular disease, there are still controversial and insufficient data to draw definitive conclusions. As PAH is a leading cause of mortality in SSc patients this is an area of clinical interest and the study of the TGFβ pathway could lead to useful clinical findings.

AB0141 DIFFERENTIAL CYTOKINE PRODUCTION PROFILES IN STIMULATED MONONUCLEAR CELLS OF PATIENTS WITH SYSTEMIC SCLEROSIS AND CONTROLS

I. Szabo[1], M. Badii[2,3,4], C. Sirbe[1], O. Gaal[2,3,4], T. Crisan[2], C. Pamfil[1], S. Rednic[1]. *[1]"Iuliu Hatieganu" University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Medical Genetics, Cluj-Napoca, Romania; [3]Radboud University Medical Center, Internal Medicine, Nijmegen, Netherlands; [4]Radboud University Medical Center, Radboud Institute of Molecular Life Sciences, Nijmegen, Netherlands*

Background: Altered innate and adaptive immune responses represent the link between microvascular injury and fibrosis in systemic sclerosis (SSc) pathophysiology. Peripheral monocytes and lymphocytes are responsible for the secretion of cytokines with proven pro-inflammatory and pro-fibrotic activities. Chronic immune activation in SSc is supported by distinct serum and peripheral blood mononuclear cell (PBMC) cytokine profiles in relation to disease duration, autoantibody subtype, as well as severity of clinical manifestations.
Objectives: This pilot study aimed to: (1) evaluate the PBMC cytokine production in SSc patients versus healthy controls (HC) after in vitro stimulation with lipopolysaccharide (LPS) and heat-killed *Candida albicans* and (2) distinguish different SSc clinical phenotypes based on their cytokine signature.
Methods: Eighteen SSc patients (8 limited cutaneous, 9 diffuse cutaneous, 1 sine scleroderma) and 17 age and gender matched HC were enrolled between February 2020 and October 2021. PBMCs were isolated and further subjected to stimulation with LPS and *Candida albicans*. Cytokine production was measured after 24 hours using ELISA kits for interleukin (IL)-1β, IL-1 receptor antagonist and IL-6. IL-17 and interferon gamma (IFN-γ) concentrations were determined at 7 days from samples stimulated with *Candida albicans*-in the presence of 10% human pooled serum. Non-parametric data was analyzed using Mann-Whitney test while T.test was used for parametric data.
Results: Significantly elevated IL-1 β and IL-6 concentrations were detected in SSc patients compared to HC after stimulation with either LPS or *Candida albicans*. IL-17 cytokine production was also enhanced in SSc patients compared to HC after stimulation with *Candida albicans* for 7 days, but no difference was identified with respect to IFN-γ. No significant statistical difference was demonstrated between cytokine levels and extent of cutaneous involvement. Furthermore, no association was observed between autoantibody subtypes and cytokine production. Patients with diffuse cutaneous SSc and those positive for anti-Scl-70 antibodies revealed elevated C-reactive protein (CRP) levels.
Conclusion: SSc patients exhibit a pro-inflammatory phenotype irrespective of the extent of cutaneous involvement or autoantibody profile. This appears to be mediated through increased production of innate immune cytokines, which correlated to elevated Th-17 responses on later time-points. Elevated CRP levels might define a subgroup of SSc patients with specific disease characteristics. Validation of these findings and mechanistic assessment is warranted in larger cohorts of patients.

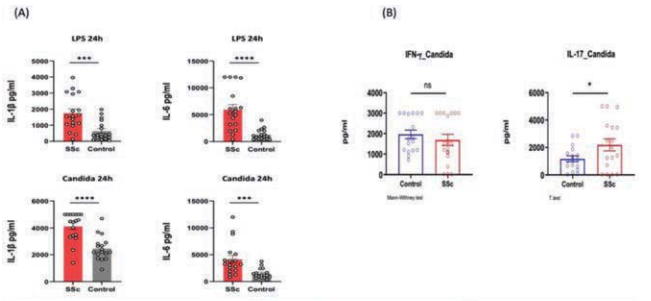

Figure 1. Cytokine production at 24 hours and 7 days respectively after stimulation with LPS and Candida albicans. (A) Higher IL- 1β and IL-6 levels were detected in SSc patients versus HC at 24 hours. (B) IL-17 concentrations are elevated after stimulation with Candida albicans for 7 days in SSc patients compared to HC. No difference was observed with respect to IFN-γ production.

AB0142 EVIDENCE OF TYPE I INTERFERON ACTIVATION DURING VASCULAR MANIFESTATIONS OF SYSTEMIC SCLEROSIS

S. Di Donato[1,2], M. Hughes[3], G. Abignano[4], G. Lettieri[4], R. Ross[1], E. De Lorenzis[1,5], P. O'Connor[4], O. Kubassova[6], F. Del Galdo[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Raynaud's and Scleroderma Programme, NIHR Biomedical Research Centre, University of Leeds, Leeds, United Kingdom; [2]Università Campus Bio-Medico di Roma, Rheumatology, Immunology and Clinical Medicine Unit, Department of Medicine, Rome, Italy; [3]Centre for Musculoskeletal Research, The University of Manchester, Northern Care Alliance NHS Foundation Trust, Manchester Academic Health Science Centre,, Manchester, United Kingdom; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Faculty of Medicine and Health and NIHR Biomedical Research Centre, Leeds, United Kingdom; [5]Catholic University of the Sacred Heart, Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Rheumatology, Rome, Italy; [6]Image Analysis Group, Chief Executive Officer, London, United Kingdom*

Background: Vascular involvement in Systemic Sclerosis (SSc) is known to start even before clinical diagnosis, to drive Digital Ulcer disease and later in the disease natural history to cause Pulmonary Artery Hypertension, among other manifestations. Despite the proven immune origin of Scleroderma, vascular involvement is not currently targeted by immune driven interventions. Similarly, little data is available on immune or inflammatory biomarkers and outcome measures of vascular disease in SSc. Digital Artery Volume Index (DAVIX) has been recently proposed as imaging surrogate outcome measure of vascular disease activity in SSc [1].
Objectives: Here we aimed to determine the value of DAVIX as overall biomarker of vascular involvement and its correlation with Type I IFN activation in patients with SSc.
Methods: Eighty-six patients attending our Scleroderma Program were consecutively enrolled for the evaluation of serum IFN score as previously described [2]. Clinical features including presence or history of Digital Ulcers, Presence of Pulmonary Artery Hypertension (PAH) and DLCO, were recorded. Digital Artery Vascular Index (DAVIX) of the dominant hand's fingers was calculated using time of flight magnetic resonance images analysed through IAG proprietary algorithm, as previously described [1]. Medians were compared by Mann-Whitney-Wilcoxon test, correlation with clinical parameters was performed using Spearman's or Pearson test, as appropriate (R).
Results: Sixty-two patients fulfilled the 2013 ACR/EULAR classification criteria for SSc (diffuse cutaneous 24.6%, limited cutaneous 75.4%) whereas 23 were classified as Very Early Diagnosis of Scleroderma (Criteria score between 6 and 8). Twenty-three patients had DU disease (History of DUs in the previous 24 weeks, presence of DUs at baseline assessment, or onset of new DUs during the following 24 weeks). Eighteen patients had reduced DLCO (<70) with FVC/DLCO>1.8 (suspected PAH). DAVIX showed a negative correlation with disease duration (r=-0.33 and p=.003) and with FVC/DLCO ratio (r=-0.34 and p=.009). Patients with DU disease presented lower DAVIX than patients without (p=.018).
DAVIX showed a significant correlation with Serum IFN score (r=-0.24, p<0.032). Accordingly, patients classified as IFN-HI had lower DAVIX than those within the IFN-LO group (p=0.016).
Conclusion: DAVIX correlated both with presence of Digital Ulcer disease, DLCO and disease duration. The correlation of DAVIX and Serum IFN score does support the notion of innate immune involvement in vascular disease manifestations of SSc. Prospective testing in the context of Randomised controlled trial will determine the value of DAVIX as surrogate outcome measure of vascular disease severity in SSc.

AB0143 CHARACTERIZATION OF CELLULAR INFILTRATE IN TEMPORAL ARTERITIS USING IMAGING MASS CYTOMETRY IN GIANT CELL ARTERITIS

M. Robert[1], H. A. Michaud[2], L. A. Chepeaux[2], A. Sannier[3], T. Papo[1], K. Sacre[1]. *[1]Université de Paris Bichat, Médecine Interne, Paris, France; [2]Institut de Recherche en Cancérologie de Montpellier - INSERM U1194, Equipe Immunité et Cancer, Montpellier, France; [3]Université de Paris Bichat, Pathologie, Paris, France*

Background: Imaging mass cytometry (IMC) is a high-plex imaging technique that incorporates flow cytometry principles while preserving the histological and architectural components of the tissue sample. Characterizing the entire cellular component of temporal artery (TA) in patients with giant cell arteritis (GCA) may provide clues towards novel diagnostic and therapeutic approaches.
Objectives: We aimed at a comprehensive summary of the immune cells and pathways involved GCA by using IMC approach.
Methods: TA samples from biopsy-proven GCA patients (n=2) and controls (CTLs, n=2) were analyzed using IMC with a panel of 15 staining antibodies.
Results: Eleven cell populations were identified in arterial wall from GCA patients including both immune (CD20+ B cells, CD8+ T cells, CD4+ T cells, FOXP3+ Tregs, CD66b+ granulocytes, CD11b+ myeloid cells, CD14+ monocytes, CD68+ macrophages) and non-immune (aSMA+ smooth muscle cells, CD31+ endothelial cells, Vimentin+ fibroblasts) cells (Figure 1). The 3 layers (intima, media and adventitia) of the arterial wall was enriched by all the immune cell subsets in GCA except for granulocytes and myeloid cells. CD8+, CD4+ and FOXP3+ regulatory T cells were significantly increased in any layer of the TA. The proportion of B cells was also enhanced in both intima and adventitia and displayed a high level of Ki67 expression.

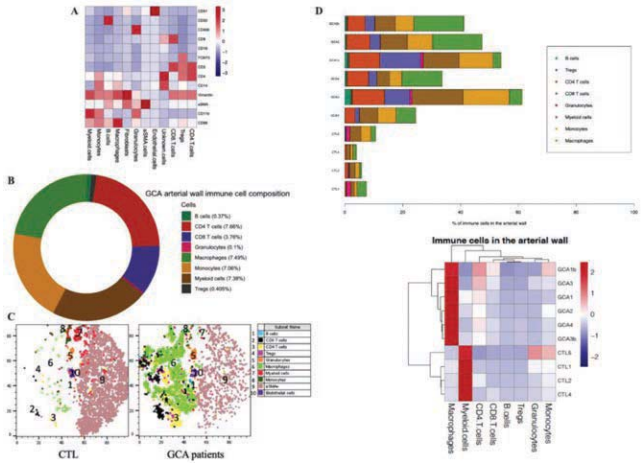

Figure 1. Unbiased clustering of cellular infiltrate in temporal arteritis using Imaging Mass Cytometry.

Heatmap of different cell type markers expressed by the 11 cell populations identified in the arterial wall of GCA patients: CD20+ B cells, CD8+ T cells, CD4+ T cells, FOXP3+ Tregs, CD66b+ granulocytes, CD11b+ myeloid cells, CD14+ monocytes, CD68+ macrophages, Vimentin+ fibroblasts, aSMA+ smooth muscle cells and CD31+ endothelial cells. A population of unidentified cells is also represented (A). Donut chart representing the relative composition of immune cells in the arterial wall of GCA patients (B). tSNE dimensional plots of the different cell clusters identified in the arterial wall of CTL and GCA patients (C). Percent and Heatmap of immune cells identified in the arterial wall of each patient (D).

GCA: giant cell arteritis, CTL: controls, Tregs: regulatory T cells.

Conclusion: Our study provides an exhaustive overview of the distinct cell lineages involved in GCA and supports IMC approach to further characterize the immune networks active in GCA.

AB0144 PD-1 DEFICIENCY IN THE REGULATORY T CELL MAY BE INVOLVED IN THE PATHOGENESIS IN TAKAYASU'S ARTERITIS

N. Gaon[1], L. Pan[1]. *[1]Capital Medical University Affiliated Anzhen Hospital, Rheumatology, Beijing, China*

Background: Regulatory T cell (Treg cell) has been demonstrated decreased in peripheral blood of TAK patients in recent researches. PD-1 may regulate Treg cell differentiation and apoptosis as an important checkpoint molecule.
Objectives: This study aims to investigate whether PD-1 is involved in the abnormal of Treg cell in TAK.
Methods: This study enrolled 49 patients with TAK and 23 healthy controls. Treg cell related serum cytokines IL-10, IL-7, IL-2 and IL-15, as well as serum chemokines CCL2, CCL3 and CXCL10 were detected using cytokine cytometric bead array. The expression of PD-1 in $CD4^+Foxp3^-$ T cells and Treg cells were analyzed by flow cytometry analysis in 15 patients with TAK and 18 healthy controls.
Results: Mean fluorescence intensity of PD-1 in $CD4^+PD\text{-}1^+$ cells decreased in TAK patients [72.2 (45.8, 84.7) vs. 363.00(335, 431), P = 0.000]. The frequency of $CD4^+Foxp3^-PD\text{-}1^+$ cells in $CD4^+$T cells decreased in peripheral blood (9.05 ± 1.06% vs. 12.61 ± 1.17% , P = 0.034) of TAK patients. The percentage of $CD4^+CD25^+Foxp3^+PD\text{-}1^+$ cells in $CD4^+CD25^+$T cells (0.40 ± 0.05% vs. 0.63 ± 0.09% , P = 0.047) is lower in TAK patients than healthy controls. Higher serum levels of IL-10[4.84 (0.07,409.57) vs.3.16 (0,69. 15) , P = 0.004] and IL-7[10.05 (2.68,227.2) vs. 7.4 (2.68,16.77) , P = 0.014] level were observed in TAK patients. Compared to healthy controls, serum CCL2[30.64 (0 , 686.84) vs. 10.31 (0 , 32.92) , P = 0.000] and CCL3[3.01(0.69,19.24)vs.1.84 (0.87 , 4.6) , P = 0.000] increased obviously.
Conclusion: The frequency of $CD4^+Foxp3^-PD\text{-}1^+/CD4^+$T cells and $CD4^+CD25^{+-}Foxp3^+PD\text{-}1^+/CD4^+CD25^+$T cells decreased. This study suggested that PD-1 may contribute to the imbalance of regulatory T cell in TAK.

Background: IgA vasculitis (IgAV) and IgA nephropathy (IgAN) are inflammatory conditions that share pathogenic and molecular mechanisms [1] and may represent different outcomes of a continuous spectrum of the disease [2]. Interleukin (IL)-33 is a cytokine that exerts its biological functions by binding to its receptor, IL-1 receptor like 1 (IL-1RL1) [3]. Several lines of evidence demonstrate that genetic variants located both in *IL33* and *IL1RL1* genes are implicated in the increased risk of numerous immune-mediated diseases [4].

Objectives: To determine whether IgAV and IgAN exhibit a different *IL33-IL1RL1* association pattern.

Methods: Three tag genetic variants within *IL33* (rs3939286, rs7025417 and rs7044343) and three tag polymorphisms within *IL1RL1* (rs2310173, rs13015714 and rs2058660), which cover the major variability of these loci and that were previously associated with several inflammatory diseases were genotyped in 380 Caucasian patients with IgAV, 96 patients with IgAN and 845 sex and ethnically matched healthy controls.

Results: Similar genotype and allele frequencies were observed in the whole cohort of patients with IgAV when compared to those with IgAN when *IL33-IL1RL1* genetic variants were analyzed independently (Table 1). In accordance with that, no *IL33-IL1RL1* genotype or allele differences were detected between IgAV patients who developed nephritis and patients with IgAN (Table 1). Additionally, no statistically significant differences between the whole cohort of patients with IgAV and healthy controls as well as between patients with IgAN and healthy controls were observed when each *IL33-IL1RL1* genetic variant was also analyzed independently (Table 1). Similar results were disclosed when haplotype frequencies were compared between the different comparative groups above mentioned (data not shown).

Conclusion: Our results reveal that IgAV and IgAN share a similar *IL33-IL1RL1* association pattern.

Background: IgA vasculitis (IgAV) and IgA nephropathy (IgAN) are inflammatory conditions [1, 2], that share pathogenic mechanisms [1], in which B-lymphocytes are described as key cells implicated in these processes. BAFF, APRIL and BAFF-R are cytokines implicated in the development of B-lymphocytes [3, 4] and in autoimmune processes [5, 6]. In this regard, an influence of *BAFF, APRIL* and *BAFFR* polymorphisms was observed on several immune-mediated conditions, being *BAFF* GCTGT>A a shared insertion-deletion variant for inflammatory conditions [7, 8].

Objectives: To determine whether *BAFF, APRIL* and *BAFFR* could be used as differential biomarkers between IgAV and IgAN.

Methods: *BAFF* rs374039502 (which colocalizes with *BAFF* GCTGT>A), two tag variants within *APRIL* (rs11552708 and rs6608) and two tag variants within *BAFFR* (rs7290134 and rs77874543) were genotyped in 394 Caucasian IgAV patients, 95 patients with IgAN and 832 matched healthy controls.

Results: Similar genotype and allele frequencies were observed in the whole cohort of patients with IgAV when compared to those with IgAN when *BAFF, APRIL* and *BAFFR* variants were analyzed independently (Table 1). In accordance with that, no *BAFF, APRIL* and *BAFFR* genotype or allele differences were detected between IgAV patients who developed nephritis and patients with IgAN (Table 1). Additionally, no statistically significant differences were observed between the whole cohort of patients with IgAV and healthy controls as well as between patients with IgAN and healthy controls when each when *BAFF, APRIL* and *BAFFR* genetic variant was also analyzed independently (Table 1). Similar results were disclosed when haplotype frequencies of *APRIL* and *BAFFR* were compared between the different comparative groups above mentioned (data not shown).

Conclusion: Our results reveal a similar *BAFF, APRIL* and *BAFFR* genetic distribution in IgAV and IgAN, suggesting that these genes could not be used as differential biomarkers between these pathologies.

AB0147 INFLAMMATORY AND NEUTROPHIL ACTIVATION MARKERS IN PATIENTS WITH BEHÇET'S DISEASE

K. Nurbaeva[1,2], T. Lisitsyna[1], T. Reshetnyak[1,2], R. Goloeva[1], A. Lila[1,2].
[1]1-V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]2-Russian Medical Academy of Continuing Professional Education of the Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation

Background: Behçet's disease (BD) is a systemic variable vessel vasculitis with different clinical manifestations. BD does not have specific laboratory findings. Neutrophil hyperactivation is a major pathogenic factor in BD-related inflammation and tissue damage. Neutrophil reactivity (NEUT-RI), neutrophil granularity (NEUT-GI), immature granulocytes (IG), neutrophil-to-lymphocyte ratio (NLR), mean platelet volume (MPV), and platelet-lymphocyte ratio (PLR) are considered as inflammatory markers. Their role in BD remains unclear.
Objectives: to determine the importance of parameters of neutrophil activation (NEUT-RI, NEUT-GI), immature granulocytes (absolute (IG#), relative (IG%) counts), NLR, MPV, PLR in assessing inflammation in BD.
Methods: 29 patients with a reliable BD according to ICBD 2014 and 40 age-matched healthy donors (HD) without acute infectious diseases or cancer were included in the study (Table 1). Patients with BD were separated into two groups: 22 with active and 7 with inactive BD. Active BD was defined as involvement of at least two of the following features: oral ulcers, genital ulcers, uveitis, intestinal involvement, skin lesions, neurological involvement, arthritis, and vascular involvement. Current disease activity was evaluated with transformed Behçet's Disease Current Activity Form (BDCAF). A complete blood count (WBC-white blood cell, NEUT#-an absolute neutrophil count, NEUT-RI, NEUT-GI, IG%, IG#, NLR, thrombocytes, MPV, PLR, ESR-erythrocyte sedimentation rate) was performed with XN-1000 automated hematology analyzer (Sysmex, Japan).

Table 1. Comparative characteristics of patients with active/inactive BD and healthy controls.

Parameters M±SD, Me [25%; 75%], n (%)	Active BD (n=22)	Inactive BD (n=7)	Healthy donors (n=40)	p
Gender: male/female, n	16/6	4/3	16 /24	NS
Vascular involvement,n	7	3	-	NS
BDCAF	5 [5; 8]	1 [0; 3]	-	p<0.001*
WBC, 10^9/l	7.4 [5.9; 8.6]	6.9 [6.5; 8.4]	6.05 [5.2; 6.9]	p=0.04*

PLR	116.45 [83.5; 138.6]	151.55 [119.5; 171.1]	137.1 [104.4; 160.1]	NS
Fibrinogen, g/l	3.48±0.8	2.88±0.4	-	NS

*a statistically significant test result ($p \leq 0.05$); NS-not significant;FI- fluorescence intensity; SI- scatter intensity; fl- femtoliter.

Results: A WBC count was significantly higher in BD patients compared to controls (Table 1). Patients with active BD had a higher WBC count than inactive. Patients with BD were found to have significantly higher levels of IG#, IG%, and NEUT-RI compared to HD. There was no significant difference between NEUT-GI, NLR, MPV, PLR, and ESR levels in patients with BD and HD. No significant difference in NEUT-RI, NEUT-GI, NLR, IG #, IG%, PLR, or MPV between active and inactive BD was found. These hematological parameters did not correlate with the transformed BDCAF score. IG# levels positively correlated with total leukocyte count (r_s=0.656, p<0.001) and the absolute neutrophil count (r_s=0.548, p=0.002). There was a tendency to a positive correlation between IG# and NEUT-GI (r_s=0.354, p=0.050) and a negative correlation between IG# and PLR (r_s=-0.356, p=0.052).
Conclusion: Patients with BD had significantly higher total WBC counts, immature granulocyte levels, and neutrophil reactivity than controls. Except for the leukocytes, there was no statistically significant difference in the studied parameters between patients with active and inactive BD.
The study was performed at V.A. Nasonova Research Institute of Rheumatology within the framework of the fundamental research FURS-2022-003.

AB0148 COULD THE RENIN-ANGIOTENSIN SYSTEM AFFECT THE PROGNOSIS OF GIANT CELL ARTERITIS? SINGLE-CENTRE RETROSPECTIVE OBSERVATIONAL STUDY

R. Venkateswaran[1,2], K. Gour[3], L. Sorensen4, C. Harden4, S. S. Zhao[5], A. Morgan[2,4], S. Mackie[2,4]. *[1]University of Leeds, School of Medicine, Leeds, United Kingdom; [2]Leeds Teaching Hospitals NHS Trust, Biomedical Research Centre, Leeds, United Kingdom; [3]University of Leicester, School of Medicine, Leicester, United Kingdom; [1]University of Leeds, School of Medicine, Leeds, United Kingdom; [5]The University of Manchester, School of Medicine, Manchester, United Kingdom*

Background: About half of patients with giant cell arteritis (GCA) relapse while tapering glucocorticoid therapy[1]. A previous observational study reported that blockade of the renin-angiotensin system, with angiotensin II receptor blockers (ARBs), was associated with lower relapse risk[2].
Objectives: To determine whether angiotensin blockade, with angiotensin converting enzyme inhibitor (ACEi) or ARB, is associated with differential relapse risk in GCA.
Methods: GCA patients from a tertiary centre diagnosed 2012–2020 with two years follow-up were identified from UK GCA Consortium. All provided written informed consent. Retrospective review of medical records included demographics, comorbidities, drug history, inflammatory markers and relapses. Relapse was defined as return of symptoms, raised inflammatory markers, or active vasculitis on imaging confirmed by the treating clinician. Relapse-free survival was analysed using Kaplan Meier (KM) curves and Cox proportional hazards.
Results: 111 patients were included (Table 1: demographic data), all were initially treated with 40–60mg Prednisolone. 42% received further immunosuppressants due to relapse or disease severity. 50% patients relapsed in two years, presenting with cranial symptoms (72%), PMR-like symptoms (30%) and/or raised inflammatory markers (48%). There was no association between relapse and age, gender, comorbid HTN/IHD or pre-steroid inflammatory markers and relapse. Rate of steroid taper can affect relapse. EULAR recommend 15–20mg of steroid by three months[3]. 9 patients relapsed within that time and were excluded, there was no difference in steriod dose at three months between the two groups. KM analysis showed ACEi did not significantly affect time to relapse compared to no angiotensin blockade (HR 0.57, 95% CI 0.28 – 1.18, unadjusted p-value=0.128), and neither did an ARB (HR 0.78, 95% CI 0.31 – 1.98, unadjusted p-value=0.605).

Table 1. *demographic data at baseline.*

	Relapse (n = 56)	No Relapse (n = 55)
Patient Factors		
Age *median (IQR)*	70 (65-74)	73 (67-78)
Male Sex *n (%)*	16 (29)	20 (36.36)
Medications *n (%)*		
ACEi	9 (15)	16 (29)
ARB	7 (12)	7 (13)
Comorbidities *n (%)*		
CKD	4 (7)	9 (16)
IHD	6 (11)	5 (9)
Prediabetes	11 (20)	10 (18)
DM	1 (2)	5 (9)
HTN	22 (40)	23 (42)
Current Smoker	6 (10)	2 (4)
GCA Factors *median (IQR)*		
CRP pre-treatment	69 (32 – 131)	64 (23 -115)
ESR pre-treatment	50 (37 -95)	4 (22 -72)
Steroid dose at 3 months	19 (15 -20)	15 (10-20)

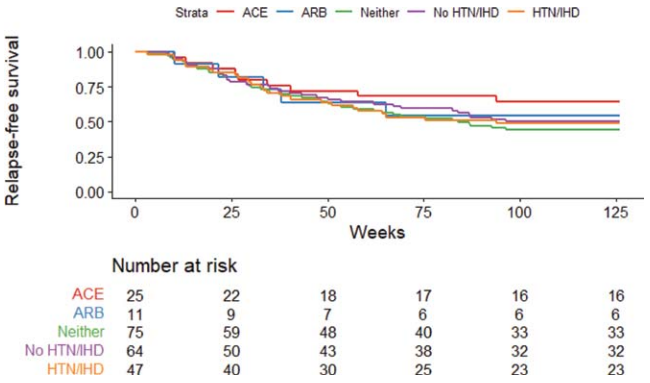

Figure 1. Unadjusted KM survival curve showing probability of relapse in patients 1) taking ACEi, 2) taking ARB, 3) taking neither ACEi or ARB, 4) with no comorbid HTN or IHD at diagnosis, and 5) experienced comorbid HTN/IHD. There was no significant difference in relapse free survival in patients on an ACEi compared to those taking neither ACEi or ARB.

Conclusion: In the two years following GCA diagnosis 50% relapsed. There was no significant difference in the rate of relapse in patients taking an ACEi or ARB. The main limitation, in this retrospective, observational study was the inability to exclude a reluctance of clinicians to diagnose GCA relapse in the presence of cardiovascular comorbidity. A randomised controlled trial would be needed to determine whether starting an ACEi could reduce relapse risk in patients with new-onset GCA.

AB0149 RNA SEQUENCING OF SKIN BIOPSY SAMPLES REVEALS UNIQUE BIOLOGICAL PROCESSES AMONG SPECIFIC GROUPS OF ADULT PATIENTS WITH IGA VASCULITIS

M. Bajželj[1,2], M. Hladnik[3], T. D. Toluay[4], S. Sodin-Šemrl[1,5], A. Hocevar[1,2], K. Lakota[1,5]on behalf of Slovenian Research Agency National research program Systemic autoimmune diseases P3-0314. *[1]University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; [2]Medical Faculty, University of Ljubljana, Internal Medicine, Ljubljana, Slovenia; [3]Faculty of Mathematics, Natural Sciences and Information Technologies, University of Primorska, Department of Applied Natural Sciences, Koper, Slovenia; [3]Faculty of Mathematics, Natural Sciences and Information Technologies, University of Primorska, Department of Applied Natural Sciences, Koper, Slovenia; [5]Faculty of Mathematics, Natural Sciences and Information Technologies, University of Primorska, Department of Biodiversity, Koper, Slovenia*

Background: Immunoglobulin A vasculitis (IgAV) is a small vessel leukocytoclastic vasculitis, characterized by vascular IgA deposits, and clinically by skin, join, kidney and bowel involvement. Renal involvement, present in up to 84% of adult patients, is associated with an increased risk of progression to chronic kidney failure. A skin or renal biopsy is still the golden standard for diagnosis. Omics data from NCBI-GEO and Array Express databanks are lacking from IgAV samples of adult patients.

Objectives: Our aim was to perform RNA sequencing and to identify differentially expressed genes and dysregulated molecular pathways in the affected skin of adult IgAV patients with renal involvement, patients with skin-limited IgAV and healthy controls (HC).

Methods: Skin biopsy samples were collected from treatment-naive adult IgAV patients at time of diagnostic procedure: 1) skin-limited disease (n=3), 2), IgAV with renal involvement (n=3), and age-/sex-matched HC (n=3). RNA was isolated and 100 bp paired-end sequenced using the Illumina HiSeq 4000 platform (25.9 to 30.8 million reads were obtained per sample). Reads were mapped with Salmon tool against the human transcriptome (Ensemble Release 104). Differentially expressed genes (log2 fold change $\geq |1|$, padj < 0.05) were computed using the R package DESeq2. Data were clustered using principal component analysis (PCA), and KEGG pathway over-representation analysis (ORA) was performed with R package clusterProfiler.

Results: We identified 72 differentially expressed genes (34 up- and 38 down-regulated) between skin-limited IgAV and HC, while 686 genes were differentially expressed (421 up- and 265 down-regulated) in the affected skin between adult IgAV patients with renal involvement and healthy controls (HC). PCA distinguished between IgAV (renal and skin-limited) and healthy controls, suggesting specific transcriptome signatures in IgAV. 21 overlapping genes were differentially expressed in both groups of patients in comparison to HC. 196 genes were differentially expressed between IgAV patients with renal involvement compared to skin-limited IgAV.

Genes, differentially expressed in patients with skin-limited disease were enriched in the oxidative phosphorylation (padj = 3.08×10^{-5}) and cell adhesion molecules (padj = 6.32×10^{-4}) KEGG Pathways. Differentially expressed genes in patients with renal involvement exhibited enriched KEGG Pathways involved in the ribosome (padj = 0×10^{-7}), the regulation of lipolysis in adipocytes (padj 9,066 x 10^{-4}), cell adhesion molecules (padj = 8.0008 x 10^{-3}), renin secretion (padj = 4.2882 x 10^{-3}), complement and coagulation cascades (padj = 3.58547 x 10^{-2}), vascular smooth muscle contraction (padj = 3.76132 x 10^{-2}) and aldosterone synthesis and secretion (padj = 3.76132 x 10^{-2}).

Conclusion: Deregulated genes in skin of adult IgAV patients with renal manifestation could serve as biomarkers for organ-specific involvement. Further studies are needed that would support deciphering the involvement of perturbed molecular pathways and the contribution of individual cell types to skin manifestations of adult IgAV patients.

AB0150 CIRCULARRNA AS A POTENTIAL BIOMARKER OF GRANULOMATOSIS WITH POLYANGIITIS

S. Lichołai[1], K. Wójcik[2], K. Wawrzycka-Adamczyk[2], M. Surmiak[1], M. Korkosz[3], J. Musiał[2]. *[1]Jagiellonian University, Medical College, Department of Molecular Biology and Clinical Genetics, Krakow, Poland; [2]Jagiellonian University Medical College, 2nd Chair of Internal Medicine, Krakow, Poland; [3]Jagiellonian University, Medical College, Department of Rheumatology and Immunology, Krakow, Poland*

Background: Granulomatosis with polyangiitis (GPA) belong to ANCA-associated vasculitides, a heterogeneous group of disorders whose clinical presentation ranges from isolated lesions affecting a single organ to life-threatening conditions. The etiology of the disease is not fully understood, and there is a lack of reliable and unambiguous diagnostic and prognostic markers.

Research in recent years points to the potential use of circulating free nucleic acids as a potential biomarkers in human pathology. Circular RNAs (circRNAs) belong to the group of non-coding RNAs, a group of potentially regulatory RNAs generated by linkage between a downstream 3′ splice site and an upstream 5′ splice site in a process known as backsplicing. CircRNAs were found in in nearly all tissues and recently have been reported to regulate gene expression by sponging miRNA. However their role in specific human conditions is largely unknown.

Objectives: The aim of our study was to assess the potential role of circRNA in diagnosis and monitoring of GPA.

Methods: CircRNAs were selected using bioinformatic analysis of RNA-seq data. Serum samples were obtained from 30 patients with GPA and 30 healthy controls. Levels of circRNA weres assessed using qPCR with specific primers

and probes. Statistical analysis was performed using dedicated packages for R and R Studio software.

Results: Levels of at least 10 serum circRNAs distinguished GPA patients from controls and 6 of them reached statistical significance. There was also an apparent difference in the levels of selected molecules between GPA exacerbation and remission (hsa_circ_0015167 – RQ 5.97, p<0.05; hsa_circ_0045266 – RQ 4.53, p<0.05). CircRNAs that differentiate patients from healthy individuals were associated with genes for P-selectin, VCAM and interleukins, among others. In contrast, molecules derived from catherins do not differentiate between the study and control groups.

Conclusion: Our results suggest that circRNA could be potentially used as a biomarker facilitating GPA diagnosis. Moreover, the observed differences depending on the stage of the disease could allow for monitoring the disease and predicting its progression. The association of molecules which levels differ between the test and control groups with genes previously associated with the development of the disease strongly suggests their potential involvement in its pathogenesis, which in turn strengthens the diagnostic specificity of the proposed markers.

AB0151 THE ROLE OF PLASMA MICROVESICLES IN LVVS: NOT ONLY BIOLOGICAL MARKERS

C. Iannone[1,2], J. Mason[3,4], E. Baldissera[5], A. Manfredi[6], E. Tombetti[2,7]. *[1]ASST Pini-CTO - Presidio Gaetano Pini, Rheumatology, Milano, Italy; [2]University of Milan, Rheumatology, Milano, Italy; [3]Imperial College London, Vascular Science, London, United Kingdom; [4]Hammersmith Hospital, Vascular Science and Autoimmunity, London, United Kingdom; [5]San Raffaele Hospital, UniRAR, Milano, Italy; [6]Vita-Salute San Raffaele University, Autoimmunity and Vascular Inflammation, Milano, Italy; [7]Sacco Hospital, Rheumatology, Milano, Italy*

Background: Microvesicles (MVs) are membrane enclosed extracellular vesicles released upon cellular activation and stress, which maintains features and maintain features and constituents of their parental cells. Large vessel vasculitides (LVVs) are inflammatory conditions of the wall of large-sized arteries, mainly represented by giant cell arteritis (GCA) and Takayasu arteritis (TA). Arterial stenosis and dilatation directly affect prognosis and, according to latest EULAR guidelines can be investigated by positron emission tomography and magnetic resonance angiography. Endothelial cells are believed to play a role in the pathogenesis of LVVs and circulating microvesicles could be a biomarker of vessel wall injury.

Objectives: To verify whether arterial wall derived-MVs detectable in the blood of TA patients and expressing bioactive molecules potentially involved in arterial injury, inflammation and remodeling could correlate with clinical and radiological features of those patients.

Methods: Platelet was obtained from 112 LVV pts (73 TA, 39 GCA). Plasma flow cytometry was performed with anti-CD14, CD16, anti-CD144 (VE-cadherin, an endothelial marker), anti-CD140a/b (PDGF receptor A/B a vascular stromal marker), anti-HMGB1, anti-PTX3, Mitotracker green and MitoSox, which are expression of mitochondrial moieties and ROS. Vascular imaging was carried out by angio-RM and PET. Circulating microvesicles from LVVs patients were correlated with disease characteristics, namely CRP, NIH activity, PGA, ITAS2010, ITAS2011 activity, immunosuppressant intake (IS), intake of glucocorticoids (yes/no) and biologics, and daily dose of glucocorticoids as well as radiological parameters. Pearson's and Spearman's correlation tests were used for parametric and non-parametric analysis. The SPSS IBM Software was used for statistics.

Results: The number of total MVs negatively correlate to CRP levels positively correlate to IS (p 0.052 and 0.013). CD 14 and 16 + MVs do not correlate with disease activity, extent or vascular inflammation at either MR or PET. PTX3+ MVs positively correlate to disease activity (NIH criteria and VAS), steroid intake, and disease extent (number of vessels at imaging). CD144+ MVs negatively correlate to IS and positively to SUV max at FDG PET. CD140a+ MVs significantly correlate to disease activity (PGA, VAS, and ITAS2010). Mitotracker+ Mvs negatively correlate to SNR max and positively to FDG-PET positivity.

Conclusion: Monocyte-derived MVs, despite being increased in LVV, do not correlate with disease activity, extent and vascular inflammation. Despite this, endothelial and stromal-derived MVs reflect some disease-related domains including clinical activity and imaging activity at PET. Furthermore, bioactive signals on MVs such as the long pentraxin PTX3 and mitochondria are more promising biomarkers. Accordingly, other studies have shown that systemic pentraxin-3 levels reflect vascular enhancement and progression in Takayasu arteritis, being PCR and ESR more a mirror of the burden of systemic inflammation. However, further studies are required to verify the pathogenic role of MVs in LVVs and to assess the impact of potential confounders such as therapy.

AB0152 MITOCHONDRIAL DNA IS ELEVATED IN PLASMA OF PATIENTS WITH GIANT CELL ARTERITIS

S. Giaglis[1,2], D. Kyburz[1,2], N. Venhoff[3], U. Walker[1,2]. *[1]University of Basel, Department of Biomedicine, Laboratory for Experimental Rheumatology,, Basel, Switzerland; [2]University Hospital Basel, Department of Rheumatology, Basel, Switzerland; [3]University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany*

Background: Giant cell arteritis (GCA) represents the most prevalent form of systemic vasculitis in elderly, and characterized by a remarkable heterogeneity regarding clinical and histological phenotype, pathogenetic mechanisms and treatment choice (1). The pathophysiology of GCA is driven by an interplay between cells of both innate and adaptive immune systems (2). Neutrophils seem to hold a cardinal role in GCA pathology, given their abundance in vicinity to the foci of tissue injury (3). Most importantly, neutrophils eject neutrophil extracellular traps (NETs) which are decorated with a series of immunocompetent epitopes, essential for the dissemination of the inflammatory response (3, 4).

Objectives: The diagnostic and prognostic value of cell-free DNA in GCA is still unknown. The aim of the present study was therefore to examine the clinical utility of cell-free DNA quantification as a biomarker in GCA.

Methods: Total DNA was isolated from platelet-free plasma samples of matched healthy controls (HC) and consecutive GCA patients. Plasma and clinical data were collected at baseline and follow-up. Copy numbers were quantified by quantitative PCR for mtDNA (ATP-6 gene) and nuclear (n) DNA (GAPDH gene) (5).

Results: Twenty-one GCA patients (median age 64.0 ± 9.0, 49% female) and 22 sex matched HC were enrolled for analysis.

mtDNA levels were significantly elevated in GCA plasma ($2.0x10^8$ copies/ml plasma, 95% CI: $7.0x10^7$ to $3.8x10^8$), compared to HC plasma ($7.0x10^6$ copies/ml plasma, 95% CI: $2.8x10^6$ to $1.1x10^7$, p<0.0001). nDNA levels in contrast did not differ between GCA ($5.1x10^6$ copies/ml plasma, 95%CI: $2.5x10^6$ to $9.5x10^7$) and HC ($4.1x10^6$ copies/ml plasma, 95%CI: $2.3x10^6$ to $9.3x10^7$, p=0.74). Receiver *operating characteristic* curve analysis showed that a cut-off value of $2.8x10^7$ mtDNA copy numbers differentiated between GCA and HC with 90.5% sensitivity, 95.2% specificity and an AUC of 0.95.

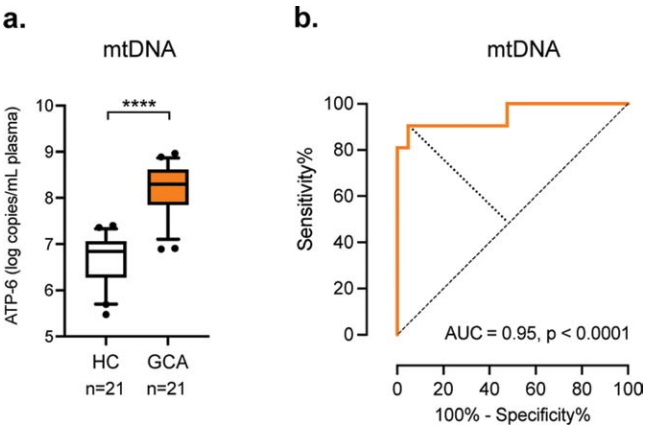

Figure 1. (a.) Plasma mtDNA levels in GCA patients are elevated (2 orders of magnitude) compared to healthy controls. Whiskers represent 95% CI. (b.) Receiver operating characteristic curve for mtDNA plasma concentrations discriminate between HC and GCA patients. AUC: area under the curve.

There was no association of mtDNA elevation with any particular type of intra-, extra-cranial or ocular vessel involvement).
Conclusion: The quantification of cell free mtDNA - but not nDNA - copy numbers allows a sensitive and specific distinction between healthy individuals and patients with GCA and raises the possibility that circulating nucleic acids contribute to the pathogenesis of GCA. Plasma mtDNA quantification may aid in the diagnosis of GCA and in monitoring GCA activity.

AB0153 **EFFECT OF STANDING FRAMES USED IN REAL LIFE ON BONE REMODELING IN NON-WALKING CHILDREN WITH CEREBRAL PALSY**

B. Vincent[1], V. Goeb[2], S. Fritot[1], M. Romuald[3], J. M. Sobhy-Danial[2], P. Fardellone[2], L. Le Monnier[2]. *[1]Chu Amiens-Picardie, paediatric physical medecine and rehabilitation unit, Amiens, France; [2]Chu Amiens-Picardy Site Nord, rheumatology, Amiens, France; [3]Chu Amiens-Picardie, human biology and bone metabolism, Amiens, France*

Background: Children with severe cerebral palsy are prone to low bone mineral density. Standing frames are recommended as postural management for these children. The beneficial effects in promoting bone health remain unclear.
Objectives: To determine whether static standing frames enhance bone remodeling in real life in severe cerebral palsy.
Methods: 24 children with severe cerebral palsy GMFCS IV & V were included in the study and were divided into two groups: 13 were using a passive standing frame and 11 were not. We performed a single center retrospective cross-sectional study comparing the two groups using dual X-ray absorptiometry data and tests on biological samples, including bone remodeling factors.
Results: Total body (less head) bone mineral content was significantly higher in children who used a standing frame for an average of 30 min/day. This was confirmed in the lumbar spine. Although the total body bone mineral density (less head and proximal femur) densitometric data were not significantly higher, a positive trend favored the use of a standing frame in the children. Bone resorptive factors (CTX) were higher in the non standing-frame group, whereas there was no difference among osteoformation factors. No difference in fracture history was found.
Conclusion: Used in real life, we showed that static standing practice improved mineralization by reducing osteoresorption in non-ambulant children with cerebral palsy. Further studies are needed to determine how standing practice could impact bone mineralization over time in real life and to explore more bone remodeling factors.

AB0154 **PHYSICAL FUNCTION ASSESSMENT TOOLS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: JAFAS VERSUS CHAQ**

A. Fazaa[1], M. Kammoun[1], S. Miladi[1], H. Boussaa[1], K. Ouenniche[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. *[1]Hospital Mongi Slim of La Marsa, Department of Rheumatology., Marsa, Tunisia*

Background: Children with juvenile idiopathic arthritis (JIA) frequently experience impairments in one or more body systems. These may include pain, fatigue, muscle weakness, and poor exercise capacity. Functional disability can be evaluated by means of questionnaires and observed performance tests. Only the Juvenile Arthritis Functional Assessment Scale (JAFAS) and the Childhood Health Assessment questionnaire (CHAQ) were developed specifically for children with juvenile arthritis.
Objectives: The aim of this study was to investigate the relationship between JAFAS and CHAQ in the evaluation of physical function.
Methods: This is a cross sectional study including patients with JIA. Assessment of disease activity (DAS28), number of tender joints (NTJ) and swollen joints (NSJ) were determined. The JAFAS (range 0-20) includes 10 items of activities of daily living (dressing, cutting food, getting in and out of bed, picking up an object from the floor while standing, moving from standing to the floor and returning to standing, walking 50 feet unaided, and walking up a flight of 5 steps). The score range for each item is 0–2, based on the time in seconds the child takes to complete each task. Higher scores indicate greater activity limitation (1). The original CHAQ including 30 activities in eight different domains, with a total score ranging from 0 (no limitation) to 3 (maximal limitation) was completed by interviewing the patient (2). Spearman correlation test and Cohen's kappa coefficient (k) were used. Significance level was set at $p \leqslant 0.05$.
Results: Twenty-nine patients with a median age of 25 years [8-40] and median disease duration of 16 years, were included. Age of onset of the disease was 8 years [2-16] years. The median JAFAS score was 3 [0-12] and the median CHAQ score was 0.05 [0-3]. There was a slight agreement between JAFAS and CHAQ k=0.1 (p = 0.05). A positive correlation was found between NTJ and CHAQ (r=0.54, p=0.03) and JAFAS (r=0.5, p=0.05). A correlation was noticed also between NSJ and CHAQ(r=0.51, p=0.05). Both the JAFAS and CHAQ scores correlated with DAS28 (r=0.55, p=0.01and r=0.44, p=0.02, respectively). At the level of the individual joints, coxitis was the most frequent complication (13 patients out of 28), six of them had surgery of total hip prosthesis. There was a linear relationship between JIA complicated with coxitis and the level of functional disability measured with JAFAS (p=0.027).
Conclusion: Our study shows that, even though JAFAS had a slight agreement with CHAQ, both were correlated with the level of disease activity and the number of swollen and tender joints.

AB0155 VASCULAR ENDOTHELIAL GROWTH FACTOR IN JUVENILE IDIOPATHIC ARTHRITIS

O. Pavlova[1], N. Shevchenko[1], T. Holovko[1]. [1]*V. N. Karazin Kharkiv National University, Department of Pediatrics №2, Kharkiv, Ukraine*

Background: Vascular changes are preceding the development of fibrosis in juvenile idiopathic arthritis (JIA). Signs of angiogenesis, the process of new vessel formation, cannot be fully detected, especially in childhood. Vascular endothelial growth factor (VEGF) is considered to play a crucial role for angiogenesis regulation [1,2].
Objectives: To evaluate serum levels of vascular endothelial growth factor in the treatment of juvenile idiopathic arthritis.
Methods: 104 consecutive JIA patients aged 10 to 18 years (13.3 ± 0.3) were included in this 4-years prospective study. VEGF levels were determined by VEGF ELISA kits. Serum levels of VEGF were analyzed depending on patients' gender, age, and age of JIA onset, its variant, duration, activity, and presence of methotrexate (MTX) in treatment and its dose.
Results: We evaluated VEGF level for children with JIA (min: 23.68 pg/ml; Me:244.75 pg/ml; max: 2158.91 pg/ml). VEGF in JIA was related to onset of JIA in patients older than 15 years and high disease activity according JADAS-27 pattern ($p<0.05$). Levels of circulating immune complex (CIC) and antistreptolysin-o (ASL-O) was associated with VEGF level. Mostly VEGF was correlated with CIC (among: girls r=0.53, patients with oligoarthritis r=0.55, inactive disease activity according to JADAS-27 r=0.47, dose of MTX, 10–12,5mg/m2/week r=0.67 $p < 0.05$) and with ASL-O (among: girls r=0.47, inactive disease activity according to JADAS-27 r=0.51, MTX treatment r= 0.36, dose of MTX, 10–12,5mg/m2/week r=0.90 $p < 0.05$).
Conclusion: Children with JIA had a higher VEGF level in patients older than 15 years and high disease activity. Also, CIC and ASL-O showed high impact on VEGF level which is the critical factor of angiogenesis.

AB0156 INTRA-ARTICULAR AGRIN PROVIDES DIRECT PAIN RELIEF IN OSTEOARTHRITIS AND CARTILAGE DEFECTS

S. Eldridge[1], A. Barawi[1], A. S. Thorup[1], B. F. Fernandez[1], S. Bharde[1], S. Sikandar[1], Z. Guan[1], M. Kaneva[1], H. Lydon[2], F. Henson[2], C. De Bari[3], A. McCaskie[4], F. Dell'Accio[1]. [1]*The William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom;* [2]*University of Cambridge, Department of Veterinary Medicine, Cambridge, United Kingdom;* [3]*University of Aberdeen, Aberdeen Centre for Arthritis and Musculoskeletal Health, Aberdeen, United Kingdom;* [4]*University of Cambridge, Division of Trauma and Orthopaedic Surgery, Department of Surgery, Cambridge, United Kingdom*

Background: Osteoarthritis is the leading cause of disability worldwide with a financial burden estimated between 1.5 and 2% of the GDP in all westernised countries. The main driver of progression in osteoarthritis is cartilage loss, which may be associated with bone changes, low degree synovitis and lesions to menisci and ligaments. These pathological features result in pain, which contributes to chronic disability.
Improving cartilage integrity without pain relief does not help patients and results in failure in clinical trials. Therefore, there is a need for therapeutics that induce rapid pain relief and long-term cartilage regeneration.
We previously showed that Agrin results in cartilage regeneration and in this study, following on the serendipitous finding of rapid pain relief after Agrin administration we explore its analgesic effect in animal models of osteochondral defects and osteoarthritis.
Objectives: Test the analgesic potential of Agrin in post-surgical pain associated with osteochondral defects in mice and sheep.
Determine whether Agrin can relieve chronic pain induced by osteoarthritis in mice.
Investigate the therapeutic potential of Agrin in models of primary and injury-induced secondary osteoarthritis.
Methods: Acute post-surgical pain: Surgery was performed on skeletally mature male mice and female sheep to create critical-sized osteochondral defects; defects were filled with collagen gel containing PBS or Agrin. Animals were sacrificed 8 weeks (mice) and 6 months (sheep) after surgery. Pain was measured in mice using von Frey filaments and incapacitance readings. Sheep were fitted with accelerometers for the duration of the study.
Osteoarthritic pain: Osteoarthritis was surgically induced in skeletally mature male mice by menisco-ligament injury (MLI). Control mice received sham surgery. Nine weeks post-surgery, once chronic pain was established, mice were injected intra-articularly with recombinant Agrin. Pain was measured by von Frey filaments and incapacitance.
Treatment in therapeutic regime: Tamoxifen-inducible transgenic mice overexpressing Agrin under the AggrecanCre promotor were generated. Skeletally mature male mice were subjected to menisco-ligament injury surgery. Four weeks later, tamoxifen was administered to overexpress Agrin in the cartilage. Pain was measured by von Frey filaments and incapacitance.
Ex-vivo: MicroCT, X-ray, Kellgren-Laurence scoring, histology, OARSI scoring and immunohistochemistry.
Results: In sheep, Agrin administration induced regeneration in osteochondral defects and, more importantly, reduced the levels of secondary osteoarthritis. This was associated with a rapid and sustained symptomatic relief.
In mice, Agrin expression was lost in the dorsal root ganglia corresponding to the limb subjected to MLI but not in the dorsal root ganglia corresponding to the sham operated limbs.
Intra-articular recombinant Agrin in mice with established OA (9 weeks after MLI surgery) resulted in pain relief as early as three hours after administration. Acute administration of recombinant Agrin does not have any analgesic effects in sham operated mice.
Inducible, cartilage-specific Agrin-overexpression mice were protected from developing pain associated with instability-induced osteoarthritis.
In mice with acute osteochondral defects, intra-articular Agrin administration resulted in pain relief for at least five days.
In humans, the loss of Agrin in the articular cartilage correlated significantly with the Mankin score of patients undergoing knee replacement surgery.
Conclusion: Agrin has analgesic properties in both the acute phases of cartilage damage and in established osteoarthritis. Our findings support the therapeutic use of Agrin for joint surface regeneration and pain relief.

Rheumatoid arthritis - prognosis, predictors and outcome

AB0157 EFFICACY AND SAFETY OF FILGOTINIB IN ACTIVE RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO METHOTREXATE: COMPARATIVE STUDY WITH FILGOTINIB AND TOCILIZUMAB EXAMINED BY CLINICAL INDEX AS WELL AS MUSCULOSKELETAL ULTRASOUND ASSESSMENT (TRANSFORM STUDY): STUDY PROTOCOL

T. Shimizu[1,2], S.Y. Kawashiri[2,3], S. Morimoto[4], Y. Kawazoe[1], S. Kuroda[1], R. Kawasaki[1], Y. Ito[1], S. Sato[1], H. Yamamoto[1], A. Kawakami[2]. *[1]Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan; [2]Nagasaki University Graduate School of Biomedical Sciences, Departments of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences,, Nagasaki, Japan; [3]Nagasaki University Graduate School of Biomedical Sciences, Departments of Community Medicine and, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; [4]Nagasaki University Graduate School of Biomedical Sciences, Innovation Platform & Office for Precision Medicine, Nagasaki, Japan*

Background: The administration of Janus kinase (JAK) inhibitors as well as biological disease-modifying anti-rheumatic drugs has dramatically improved even the clinical outcomes in rheumatoid arthritis (RA) patients with inadequate response to methotrexate (MTX). The dysregulation of JAK- signal transducer and activator of transcription (STAT) pathways via overproduction of cytokines, such as interleukin-6 (IL-6) is involved in the pathogenesis of RA (1). Filgotinib, a preferential JAK1 inhibitor, is effective in suppressing disease activity and preventing the progression of joint destruction due to inhibition of the JAK-STAT pathway. IL-6 inhibitors such as tocilizumab also inhibit the JAK-STAT pathways due to inhibition of IL-6 signaling. Thus, it should be desirable to investigate whether the effectiveness of filgotinib monotherapy is non-inferior to those of tocilizumab monotherapy in RA patients with inadequate response to MTX. In addition, it is important to accurately evaluate disease activity at the joint level by using musculoskeletal ultrasound (MSUS) and clinical disease activity indices, including subjective parameters (2).
Objectives: This study's principal objective is to evaluate the effects of filgotinib monotherapy is non-inferior to those of tocilizumab monotherapy in RA patients with inadequate response to MTX. In addition, we will evaluate changes in patients' parameters, including clinical disease activity indices, MSUS scores, serum biomarkers, patient-reported outcome (PRO), and modified total Sharp score (mTSS) after the administration of filgotinib or tocilizumab. Herein, we describe the study protocol for this study.
Methods: This study is an interventional, multicenter, randomized, open-label, parallel-group and non-inferiority clinical trial with a 52-week follow-up. In total, 400 RA patients with at least moderate disease activity during treatment with MTX will be included. Patients will be randomized in a 1:1 ratio to administration of filgotinib 200mg/day monotherapy or subcutaneous tocilizumab 162mg/biweekly monotherapy switched from MTX (Figure 1). We will evaluate disease activity by measuring clinical disease activity indices and by using MSUS. The primary endpoint is the proportion of patients who achieve an American College of Rheumatology 50 response at week 12. Important secondary endpoints are the changes from the baseline of the MSUS scores, PRO, and mTSS. We will also comprehensively analyze the serum levels of multiple biomarkers such as cytokines and chemokines.

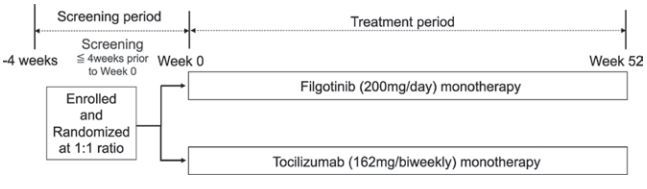

Figure 1.

Results: Although the study results cannot be shown because the research entry is in progress, they are expected to show the non-inferiority of filgotinib monotherapy to tocilizumab monotherapy in RA patients with inadequate response to MTX.
Conclusion: The strength of this study is its prospective evaluation of therapeutic efficacy using not only clinical disease activity indices but also MSUS, which accurately and objectively evaluate disease activity at the joint level among patients drawn from multiple centers with a standardized evaluation by MSUS. In addition, we will evaluate the effectiveness of both drugs by integrating multilateral assessments, i.e., clinical disease activity indices, MSUS findings, and serum biomarkers.

AB0158 PREDICT OF PROGNOSIS AT ONE YEAR AFTER THE ADMINISTRATION WITH B/TSDMARD FOR PATIENT WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

I. Yoshii[1], N. Sawada[2], T. Chijiwa[3]. *[1]Yoshii Hospital, Musculoskeletal Medicine, Shimanto-City, Japan; [2]Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan; [3]Kochi Memorial Hospital, Rheumatology, Kochi, Japan*

Background: Patients with difficult-to-treat rheumatoid arthritis (D2T RA) are the most serious problem in recent systemic RA treatment protocols [1].
Objectives: Prognosis after biologic or targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) is beneficial when predicted in patients with D2T RA. Predictors of post b/tsDMARDs in D2T RA patients were investigated using retrospective cohort data.
Methods: RA patients more than 1 year after the start of newly administered b/tsDMARDs were recruited. The patients were divided into two groups according to the EULAR definition of D2T RA [2]. Patients who met the criteria were classified into the D2T RA group and others into the non-D2T RA group. The incidence of the clinical features described in the criteria of D2T RA and the rheumatoid disease comorbidity index (RDCI) [3] were compared between the two groups at the time of drug initiation (baseline). The primary endpoint was "Success or Failure" 1 year after baseline. Success was defined as b/tsDMARD persisted in remission as the 28 joint disease activity score with erythrocyte sedimentation rate (DAS28) ≤ 2.6, or as b/tsDMARD was discontinued upon achieving clinical remission. The Failure was defined as other decisions such as discontinuation due to failure, adverse events, or characteristic patient problems. In the discontinued cases, the monitoring value at the last observation was carried forward to 1 year.
Cox regression analysis was used to assess each variant as a potential risk factor for Failure. Receiver operating characteristic analysis (ROC) was tested on variants with significantly higher risk ratios, and Kaplan-Meier survival analysis was also tested for cut-off indices.
Results: 71 cases of the D2T RA and 259 cases of the non-D2T RA group were analyzed. As shown in Table 1, the clinical characteristics of the D2T RA group were significantly worse than those of the non-D2T RA group.
Higher DAS28 had a significantly higher risk ratio for the Failure from month 3 in the D2T RA group, whereas from baseline in the non-D2T RA group (Figure 1-A). Other factors in the D2T RA group at and after baseline listed in the Table 1 had no significant risk ratios. PS-VAS and EQ5D score had significant higher risk ratios in the non-D2T RA group using univariate models, however, only DAS28 had significant higher risk ratio using multivariate model. The cut-off index (COI) and the area under the curve (AUC) using ROC for each observational period in the two groups were shown in Figure 1-B. Results of Kaplan-Meier survival analyses were shown in Figure 1-C. Hazard ratios of DAS28 > COI exceeded 2.5 even from months 3 with high sensitivity ($p < 0.001$) in the D2T RA group.

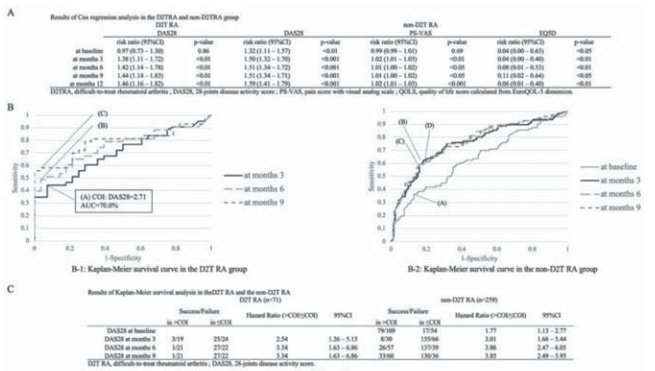

Figure 1

Conclusion: These results indicated that higher DAS 28 suggested a failure prognosis at 12 months after initiation in D2T RA and non-D2T RA patients. Even in patients with D2T RA, strict disease activity control is most important for prognostic management, with 1-year prognosis predictable in the first 3 months. However, this study is a short-term prognostic predictor, and accumulation of short-term predictions is a long-term predictor.

AB0159 HEALTH RELATED QUALITY OF LIFE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS AT TIKUR ANBESSA SPECIALIZED HOSPITAL. A HOSPITAL-BASED CROSS SECTIONAL STUDY

B. A. Adugna[1]. [1]*Addis Ababa university, Internal meicine, Addis Ababa, Ethiopia*

Background: Rheumatoid Arthritis (RA) is a chronic disorder associated with substantial morbidity and mortality. Patients with active RA suffer from significant decline in functional capacity and many become work disabled within five years, from onset of symptoms despite treatment. Measurable outcome of these can be done with the help of HRQoL questionnaires. There is a need to study the HRQoL in RA patients, as there is no available data in Ethiopia.
Objectives: This study was conducted to evaluate HRQoL in patients with Rheumatoid Arthritis and factors associated with it.
Methods: A Cross sectional study was conducted at Rheumatology Clinic in Tikur Anbessa specialized Hospital, Addis Ababa, Ethiopia from June1 to October 31. Data was collected using a structured interviewer administered questionnaire and data extraction form. Data was entered and it was analyzed using SPSS Version 26. To identify associated factors in Health related quality of life of patients with rheumatoid arthritis, bivariable and multivariable analysis were done. Statistical significance was considered at 5%, and beta weight with 95% confidence interval was used to present the estimates of the strength of the association.
Results: A total of 213 participants were included in this study. The mean age of participants was 44.7(±14). Majority 191(89.7%) of participants were female. In this study all the 8 domains of RAND 36 are reduced. The mean value of two scales from physical component and one scale from the mental component are below 50. These are Role limitation due to physical problems, General Health Perception and Role limitation due to emotional problems. Both summary score are affected with the PCS more affected than MCS. The multivariable analysis identified rural residence and modified health assessment questionnaire score as factors associated with PCS. For each shift of a patient from urban to rural residence, the PCS decreases by 9.1. For each one score increase in modified health assessment questionnaire score, the PCS score decreases by 26.25. Whereas factors associated with MCS are rural residence, adherence score, MHAQ score, peptic ulcer disease, and rheumatoid nodule. For each shift of residence from urban to rural, the MCS decreases by 15.2 . For each one score increase in adherence score, the mental component score increases by For each one score increase in MHAQ score, the MCS decreases by 14.3. For each shift of peptic ulcer disease from absent to present, the mental component score decreases by 16.Finally, for each shift of rheumatoid nodule from absent to present, the MCS by 20.8.
Conclusion: This study showed that Rheumatoid Arthritis has a significant effect on the Health Related quality of life of patients. Rural residence and functional disability was the most influencing factor on both the physical and mental function. Routine assessment of the Health Related quality of life in those patients is recommended to detect and monitor the impact of the disease and its medications on different aspects the patient's life.

AB0160 THE RELATIONSHIP BETWEEN THE LEVEL OF FETUIN-A AND LABORATORY MARKERS OF CONNECTIVE TISSUE DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Akhverdyan[1], B. Zavodovsky[1], E. Papichev[1], J. Polyakova[1], L. Seewordova[1]. [1]*Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky", Laboratory of methods of treatment and prevention of joint diseases, Volgograd, Russian Federation*

Background: It is known that there are biochemical markers of cartilage and bone tissue destruction, which reflect the metabolic processes occurring in tissues. For example, in rheumatoid arthritis (RA), routine markers such as CTX-I, a bone degradation marker (C-terminal telopeptide of type I collagen) and CTX-II, a cartilage degradation marker (C-terminal telopeptide of type II collagen), can be used. Also, to assess the state of cartilage tissue, the determination of type II collagen fragments by Urine CartiLaps is widely used, which allows not only primary diagnosis, but also dynamic monitoring of metabolic processes.
Objectives: The aim of our research was to study the relationship between the level of fetuin-A (FeA) and laboratory markers of bone and cartilage tissue degradation in the blood serum of patients with RA.
Methods: We observed 110 patients with a verified diagnosis of RA, the control group consisted of 30 practically healthy individuals without joint diseases. The group of patients with RA and the control group were comparable in terms of age (p=0.083), gender (p=0.116), BMI (p=0.302). The diagnosis of RA was based on the clinical classification adopted at the EULAR/ACR in 2010. The level of FeA in the blood serum was determined once by enzyme immunoassay using commercial test systems (Human Fetuin-A ELISA Biovender Cat No. 191-0371).
Results: We have assessed the FeA level in the group of RA patients and healthy donors. The normal level of FA in healthy individuals, calculated as M±2σ, ranged from 653.55 μg/ml to 972.19 μg/ml. FeA level was normally distributed (K-S d=0.062, p>0.2). We also studied the relationship between indicators of bone metabolism and the concentration of FeA. In patients with normal FeA levels (n=87), the mean CTX-1 level was 35 ng/mL; in patients with reduced FeA levels (n=23), the mean CTX-1 level was 51 ng/ml (t=-2.42 p =0.016). Thus, with a decrease in the FeA level, CTX-I (an indicator of osteodestruction) tended to increase.
Next, we analyzed the relationship between low and normal levels of FeA and the Cartilaps/urine creatinine ratio using intragroup analysis methods. In the group with low FeA level Cartilaps/urinary creatinine was 598.9±223.72 μg/mmol versus 481.17±226.93 μg/mmol in the group with normal FeA level (Z=-2.311; p=0.021). Our data probably allow us to associate the FeA level with the rate of cartilage tissue destruction.
Conclusion: Considering that the levels of laboratory markers of cartilage and bone collagen degradation Cartilaps and CTX-I were statistically lower in the presence of an elevated serum level of FeA, we can conclude that FeA has chondro- and osteoprotective properties. It can also be assumed that the level of this marker can be used to predict the rate of cartilage destruction in patients with RA, but this issue requires further study.

AB0161 THE RELATIONSHIP OF TRYPTOPHAN CATABOLISM WITH RHEUMATOİD ARTHRITIS DİSEASE ACTİVİTY ABSTRACT

A. Kor[1], S. Erten[1], E. F. Yurt[2], I. Dogan[1], H. Apaydın[3], M. A. Serdar[4], C. Bİçer[5]on behalf of ankara city hospital working group. [1]*Ankara Yıldırım Beyazıt University Faculty of Medicine, Rheumatology, ANKARA, Turkey;* [2]*Beypazari Public Hospital,, Medical Biochemistry,, ANKARA, Turkey;* [3]*Ankara Şehir Hastanesi, Rheumatology, ANKARA, Turkey;* [4]*Acibadem Hospital Ankara, Medical Biochemistry, ANKARA, Turkey;* [5]*Ankara Yıldırım Beyazıt University Faculty of Medicine, Medical Biochemistry,, ANKARA, Turkey*

Background: Tryptophan (Trp) is an essential amino acid. The immunosuppressive effect caused by Kynurenine (Kyn) and its metabolites formed by the catabolism of Trp is thought to be an important physiological mechanism.
Objectives: This study aims to evaluate the relationship of Kyn and its metabolites formed in Trp catabolism with rheumatoid arthritis (RA) disease activation and to investigate the usability of these markers in the diagnosis and treatment of RA.
Methods: 50 RA patients followed in our rheumatology clinic and 41 healthy controls without chronic disease were included in this study. Disease Activity Score 28 (DAS28) was used to evaluate the association of Kyn metabolites and Indolamine 2,3 dioxygenase (IDO) enzyme activity with RA disease activity. The task of this enzyme is to provide Kyn formation with Trp catabolism.
Results: In this study, lower Trp levels were found in the RA group compared to the control group (11285.47±2318.93-13320.31±3771.27, respectively) compared to the Trp mean (p<0.01). In terms of the Kyn/Trp ratio, a significantly higher Kyn/Trp ratio (4.42±1.77-3.27±0.71, respectively) was found in the RA compared to the control group (p<0.001). There was no significant difference between the study groups in terms of Kyn averages (p>0.05). A significant correlation was found between Trp levels and morning stiffness (r: -0.321, p<0.05) and the DAS28 score (r:-0.566, p<0.01). A significant positive correlation was found between the Kyn/Trp ratio and C-reactive protein (r:0.317, p<0.05), sedimentation (r:0.319, p<0.05), morning stiffness (r:0.287, p<0.05) and DAS28 score (r:0.322, p<0.01).

Table 1. Comparison of study parameters between RA and control group.

Parameter	Rheumatoid arthritis	Control group	P-Value
Tryptophan (ng/ml)	**11285,47±2318,93**	13320,31±3771,27	**<0.01**
Kynurenine (ng/ml)	477,68±158,38	437,51±162,10	>0.05
Kyn/Trp ratio	**4,42±1,77**	3,27±0,71	**<0.001**

All values were expressed as mean ± SD. All values were calculated using independent sample t-test for normal distribution.

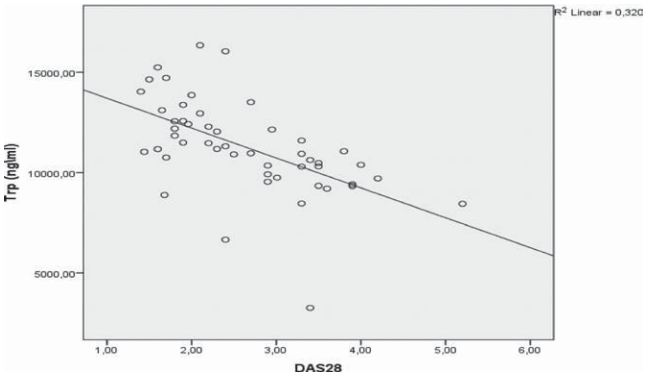

Figure 1. Correlation relationship between DAS 28 and Trp levels (r: -0,321, p < 0.01)

Conclusion: In this study, we observed that RA has a significant relationship with Trp levels and Kyn/Trp ratio. In addition to the literature, we found that RA activation indicator DAS28 score and Kyn/Trp ratio and Trp level showed a statistically significant correlation. Our study has shown that the Trp catabolic pathway can be an important field of study for more effective and safe treatment of RA.

AB0162 PREDICTION OF TREATMENT DISCONTINUATION DUE TO ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS USED BIOLOGICAL DMARDS AND TARGETED SYNTHETIC DMARDS

E. Koltsova[1], G. Lukina[1,2], E. Shmidt[3], K. Lytkina[4], E. Zhilyaev[5,6]on behalf of Moscow Unified Arthritis Registry. *[1]The Loginov Moscow Clinical Scientific Center, rheumatology, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, rheumatology, Moscow, Russian Federation; [3]City Clinical Hospital 1 named after N.I. Pirogov, Rheumatology, Moscow, Russian Federation; [4]City Clinical Hospital 4, Rheumatology, Moscow, Russian Federation; [5]Pirogov Russian National Research Medical University, Rheumatology, Moscow, Russian Federation; [6]CJSC «European Medical Center», Rheumatology, Moscow, Russian Federation*

Background: The main goal of rheumatoid arthritis (RA) patients therapy is to achieve low activity or remission of the disease (T2T strategy). However, it is sometimes necessary to interrupt effective treatment due to the development of adverse events.

Objectives: To reveal predictors of target drug withdrawal due to adverse RA.

Methods: The study includes patients with RA used bDMARDs, total 1217 treatment events. Search for predictors was carried out in two steps. At the first step were selected variables which demonstrated significant correlation with time to treatment discontinuation in Kaplan-Meier analysis. At the second step selected factors were included in the Cox regression model. The final set of independent significant predictors was obtained by backward stepwise variable selection.

Results: Of 661 patients 85,8% were women, the mean age of onset disease 58,7 ± 12,9 years, the mean disease duration 14,6 years. The longest mean time till withdrawal due to adverse events had Abatacept, Toficitinib, Tocilizumab, the shortest time had Infliximab. There were 146 cases of therapy discontinuation due to adverse events. The side effects that caused the cancellation of treatment were: infections of respiratory system, skin, urinary system, allergic and infusion reactions, drug-induced hepatitis, changes in the hematopoietic system, death and other. Presence of rheumatoid nodules ($p < 0.001$), higher doses of glucocorticoids ($p<0.001$), lower doses of methotrexate ($p = 0.009$) were independent significant predictors of increased risk of bDMARDs withdrawal due to adverse events. Used target drug also showed independent significant correlation with this risk. Relative risk (compared to Etanercept) was for Infliximab - 6.57 (CI: 3.69-11.73), Certolizumab pegol - 2.61 (CI: 1.23-5.56), Abatacept - 1.23 (CI: 0.65-2.30), Adalimumab - 1.37 (CI: 0.75-2.50), Rituximab - 0.56 (CI: 0.26-1.20), Tofacitinib - 0.46 (CI: 0.15-1.40), Tocilizumab - 0.77 (CI: 0.37-1.60).

Conclusion: Growth glucocorticoid doses for every 1 mg increases the risk of discontinuation of therapy by 8.7%. Reducing the methotrexate doses for every 1 mg increases the risk of discontinuation of bDMARDs and tsDMARDS by 3%. There are significant differences between target drugs for the risk of cancellation due to adverse events. High risk of infliximab discontinuation was associated more with infusion reactions and infection, discontinuation of certolizumab pegol was associated with infection.

REFERENCES:

[1] The identified predictors for the treatment withdrawal due to side effects may be discussed to identify measures necessary to prevent adverse events in patients with RA who are using bDMARDs and tsDMARDs. These measures are: the use of full doses of methotrexate, avoid long-term use of glucocorticoids, or prescription of the targeted drug with lower risk of adverse events.

AB0163 SERUM LEVELS OF CHEMERIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Akhverdyan[1], B. Zavodovsky[1], E. Papichev[1], J. Polyakova[1], L. Seewordova[1]. *[1]Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky", Laboratory of methods of treatment and prevention of joint diseases, Volgograd, Russian Federation*

Background: Chemerin (Ch) is one of the relatively new representatives of adipokines. Numerous studies have shown that adipokines are actively involved in inflammation and immune responses in rheumatoid arthritis (RA) [1]. Data have been obtained, on the basis of which it can be assumed that an increase in the level of Ch in the blood serum in patients with certain systemic diseases is associated with systemic inflammation [2, 3].

Objectives: The aim of the work was to study the level of chemerin in blood serum in a group of healthy donors and patients with RA.

Methods: The group of patients included 92 patients diagnosed with RA, corresponding to the diagnostic criteria developed by ACR and EULAR (2010). The age of the surveyed ranged from 18 to 75 years. The average duration of the disease was 11 years [(Me) [3(25%);16(75%)]. The control group consisted of 30 practically healthy persons aged 26 to 62 years. The group of patients with RA and the control group were comparable in age (p=0.089) and gender (p=0.121). Serum chemerin levels were determined using the commercial HUMAN CHEMERIN ELISA kit (BioVendor, Cat. No.: RD191136200R) according to the instructions provided.

Results: The level of the normal Ch value in healthy individuals ranged from 134.7 μg/ml to 241.6 ng/ml. The average Ch level in RA patients (calculated as M±2σ) was 462.6±159.82 ng/ml, which is significantly higher than in healthy donors — 169.9±43.47 ng/ml (t=-10.49; p<0.0001). The Ch level was normally distributed (K-S d=0.10653, p>0.2). We also found a moderate correlation between the Ch level and the age of patients with RA (r=0.232008, p<0.05).

Conclusion: Thus, the level of Ch in the blood serum of patients with RA is significantly higher than in healthy individuals. It can be assumed that Ch in RA patients can be used as one of the potential markers of inflammation activity.

AB0164 ARE PATIENTS WITH RA IN REMISSION IN FINLAND DURING THE COVID TIMES? RESULTS FROM THE FINNISH QUALITY REGISTER

L. Weman[1], J. Kärki[2,3], J. Huhtakangas[4], J. Rutanen[5], L. Kuusalo[6], H. Salo[7], T. Sokka-Isler[8,9]. *[1]University of Eastern Finland, Faculty of Health Sciences, Jyväskylä, Finland; [2]Kanta-Häme Central Hospital, Department of Children and Adolescents, Hämeenlinna, Finland; [3]Finnish Institute for Health and Welfare, Finnish Rheumatology Register, Helsinki, Finland; [4]Kuopio University Hospital, Rheumatology outpatient clinic, Kuopio, Finland; [5]Tampere University Hospital, Centre for Rheumatic Diseases, Tampere, Finland; [6]Turku University Hospital, Centre for Rheumatology and Clinical Immunology, Turku, Finland; [7]Finnish Institute for Health and Welfare, Information Services Department, Helsinki, Finland; [8]Central Finland Central Hospital, Rheumatology outpatient clinic, Jyväskylä, Finland; [1]University of Eastern Finland, Faculty of Health Sciences, Jyväskylä, Finland*

Background: Worries have been expressed, concerning the care of chronic diseases during the Covid times (1).

Objectives: To study the current status of patients with RA in the Finnish quality register database.

Methods: Patients who receive care for RA were identified in the database. Clinical and demographic data from the last visits during 2020-21 were collected, including swollen (SJC46) and tender joint counts (TJC46), doctor assessment of disease activity (Dr global), laboratory tests for inflammatory and serology markers, patient reported outcomes (PROs), and DAS28. Regression models were applied to compare measures of clinical status between the health care regions, adjusted for gender, age, ACPA status, and disease duration.

Results: A total of 14163 patients (72% female, mean (SD) age 62 (14) years, median (IQR) disease duration 8.5 (2.6, 20) years, 84% ACPA positive) were identified. For the entire population, the median (IQR) SJC46 was 0 (0, 1), TJC46 0 (0, 2), ESR 8 (5, 18), CRP 3 (1, 6), and dr global 8 (0, 19). Among PROs, median (IQR) HAQ was 0.5 (0, 1), pain 26 (10, 51), fatigue 28 (8, 54) and patient global 29 (11, 51). Between health care regions, statistically significant differences were found for all variables due to a large sample size. The mean (SD) DAS28 was 2.3 (0.9) for the entire group and 69 % of all patients had DAS28<2.6. The median DAS28 ranged from 2 to 2.7 among health care regions (Figure 1) (p<0.001). Majority of patients were taking csDMARDs only.

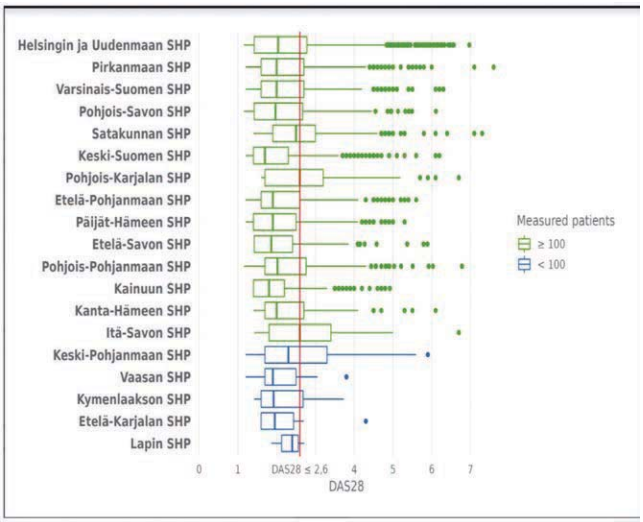

Figure 1. Rheumatoid arthritis in 2020-21: The median DAS28-values in 19 regions in Finland.

Conclusion: The quality register provides comprehensive real-world data on the current status of patients with RA. A majority of patients can be considered being in remission even during the Covid times.

AB0165 MALIGNANCY AS PREDOMINANT CAUSE OF DEATH IN RHEUMATOID ARTHRITIS: REVIEW OF DATA FROM 'BASILDON EARLY ARTHRITIS COHORT'

D. Laila[1], K. Jain[1], A. Nandagudi[1], A. Bharadwaj[1]. *[1]Mid and South Essex Foundation Trust, Rheumatology, Basildon, United Kingdom*

Background: Rheumatoid arthritis is a chronic inflammatory autoimmune condition historically linked to increased mortality with predominant contribution from cardiovascular, respiratory, infectious and neoplastic causes. There is evidence of decreasing cardiovascular mortality through improvements in preventative and treatment strategies. Recent literature has also suggested overall improvement in RA-associated mortality attributed to contemporary advances in disease control. There is a need to assess if such outcomes are reflected in the real world setting and to identify elements that continue to promote poorer outcomes.

Objectives: To assess long-term outcome in patients diagnosed with rheumatoid arthritis from the 'Early Arthritis Cohort' at a district general hospital in UK.

Methods: A retrospective cohort study was conducted on 185 patients newly diagnosed with rheumatoid arthritis between 2009 & 2013. Patients fulfilling the ACR/EULAR 2010 criteria were included. Anonymised data from the Basildon Early Arthritis registry was analysed. Measured parameters included patient demographics, disease activity score (DAS28), treatment regime, development of co-morbidity & mortality.

Results: Complete data was available for analysis in 171 patients. This comprised 60 men & 111 women with median age of 57 years (IQR 47 - 67 years) and median follow-up time of 90 months (IQR 63 - 108 months). Thirty nine percent were current or ex-smokers. At baseline, 40% of patients had DAS28 score > 5.1, this reduced to 2.5% at time of their last follow up. 74% of patients were in clinical remission at last follow up with 11.7% achieving drug-free remission, 40.4% remaining on single csDMARD, 29.8% on combination csDMARD & 18.1% on biologic therapy.

Analysis of new comorbidities revealed cancer burden of 12.9% (22/171) with lung cancer having highest incidence (n= 9). Other comorbidities recorded were cardiovascular 11.1% (19/171), pulmonary 5.8% (10/171) and cerebrovascular disease 5.3% (9/171).

A crude mortality rate of 19.3% (33/171) was observed in our cohort over a median period of 7.5 years follow-up. The incidence mortality rate was 174/10,000 person-years of follow-up and standardised mortality ratio was 2.09 (95% CI 1.44 – 2.86). Majority of patients died five or more years after initial diagnosis (67%) with most deaths occurring in the 6th year after disease onset. Patients in the mortality group had higher disease activity scores at their last follow-up compared to the remaining cohort (p=0.017).

More deaths were recorded from underlying malignancy 7.6% (n= 13) than with cardiovascular disease 4.7% (n= 8). Eight out of 13 cases were identified as lung cancer deaths. Breast, bladder, pancreatic and ovarian cancer constituted remaining cases. Other causes of death were from chronic obstructive pulmonary disease (n= 3), dementia/frailty (n = 3), interstitial lung disease (n= 2), infection (n= 2), stroke (n = 1) and chronic liver disease (n= 1).

Conclusion: Despite achieving remission in majority of patients, long-term analysis reveals that mortality in this cohort is significantly elevated compared to the general population. To best of our knowledge this is the first real-world study showing malignancy as the predominant cause of morbidity and mortality in rheumatoid arthritis.

AB0166

PROTOCOL VIOLATIONS IN AN OPEN, RANDOMIZED, TRIAL IN EARLY RA PATIENTS: POTENTIAL IMPACT OF SHARED DECISION MAKING

L. Hartman[1,2], L. A. Rasch[1], S. A. Turk[3], M. ter Wee[2], P. J. S. M. Kerstens[4], C. J. van der Laken[1], M. T. Nurmohamed[1,3], D. van Schaardenburg[3], L. H. D. van Tuyl[1], A. Voskuyl[1], M. Boers[1,2], W. Lems[1]. *[1]Amsterdam University Medical Centers, Vrije Universiteit, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [2]Amsterdam University Medical Centers, Vrije Universiteit, Department of Epidemiology & Data Science, Amsterdam, Netherlands; [3]Reade, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [4]Dijklander Ziekenhuis, Department of Rheumatology, Hoorn, Netherlands*

Background: Modern trials in RA often have a strict protocolized treat-to-target design, whereas in daily practice shared decision making is the preferred way to manage treatment.
Objectives: To document the protocol violations in an early RA trial that illustrate potential conflicts between these strategies.
Methods: In the COBRA treat-to-target trial, treatment-naive early RA patients were classified into a low- and high-risk group, and treated according to two different protocols. Treatment target was minimal disease activity (DAS44 <1.6) or EULAR good response. Non-responders at 13 weeks were randomized to treatment intensification or continuation, with as primary endpoint the proportion of patients achieving the treatment target at 26 weeks.
Results: In total 190 patients were included. High-risk patients (n=150) were initially treated with COBRA-light (30 mg/day oral prednisolone, tapered in 8 weeks to 7.5 mg/day, and MTX increasing to 25 mg/week): 110 (73%) patients reached the treatment target at 13 weeks. The 31 non-responders were randomized to treatment intensification (n=15) or treatment continuation (n=16) for weeks 14 to 26. Intensification comprised 60 mg/day prednisolone, tapered in 6 weeks to 7.5 mg/day, and addition of sulfasalazine 2000 mg/day and hydroxychloroquine 400 mg/day (COBRA-plus).
The low-risk group (n=40) was treated with MTX monotherapy increasing to 25 mg/week: only 20 (50%) reached the target at week 13. The 15 non-responders were randomized to treatment intensification with a COBRA-light oral pulse of prednisolone (n=8) or continuation (n=7).
Over the whole study period 79 of 190 patients (42%) had a protocol violation. In the first 13 weeks, 27 (18%) high-risk and 8 (20%) low-risk patients had a protocol violation. In the responders at week 13, 15 (14%) high-risk and 3 (18%) low-risk patients had a protocol violation in week 14-26. In the high-risk non-responders, 18 of 31 had a protocol violation (58%) after randomization at 13 weeks, 11 in the intensification group and 7 in the continuation group (Table). Remarkably, increased intensification of therapy was only found in the continuation group (3 patients); decreased intensification was mainly found in the intensification group (11 patients, vs 3 patients in the continuation group). In the low-risk non-responders, violations occurred in 8 out of 15 (53%) patients after randomization, 4 in both groups.

Table Protocol treatment violations after randomization of non-responders at week 13 by risk group.

	High-risk		Low-risk	
	Continuation (16)	Intensification (15)	Continuation (7)	Intensification (8)
Week 14-26				
Number of violations	7	11	4	4
Increased intensity				
Rheumatologist	3			
Other physician			1	
Decreased intensity				
AEs MTX	1		1	
No MTX due to AEs			1	
Rheumatologist	1	3		1
Rheumatologist, patient	1	7		
Patient		1		2
Mixed (increase + decrease)				
AEs MTX, rheumatologist			1	
Rheumatologist, patient	1			1

Violations are categorized by direction of intensification and by reason/initiator.
AE=adverse event; MTX=methotrexate.

Conclusion: In this study almost half of the patients had a protocol violation. The high frequency is most likely related to the open design of the trial, the risk of adverse effects through intensification with high dose prednisolone and other DMARDs, the randomization phase, and, last but not least, by the shared decision making. Shared decision making by physician and patient may jeopardizes protocol adherence in trials with an open treat-to-target design.

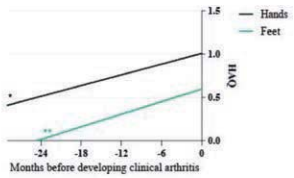
AB0167

FUNCTIONAL DISABILITIES IN HANDS PRECEDE THOSE IN FEET IN PATIENTS PROGRESSING FROM CLINICALLY SUSPECT ARTHRALGIA TO RHEUMATOID ARTHRITIS; A LONGITUDINAL OBSERVATIONAL STUDY

S. Khidir[1], B. van Dijk[1], E. van Mulligen[1,2], A. van der Helm-van Mil[1,2]. *[1]Leiden University Medical Centre, Leiden, Rheumatology, Leiden, Netherlands; [2]Erasmus Medical Centre, Rheumatology, Rotterdam, Netherlands*

Background: In the pre-arthritis phase of Rheumatoid Arthritis (RA), symptoms resulting in physical disabilities already occur. It is unknown whether functional disabilities start in hands or feet, and whether such information on functional disabilities is related to arthritis development.
Objectives: To study the course of functional disabilities in hands and feet during progression from arthralgia to RA, and whether questions assessing specifically these disabilities contribute to predicting progression to RA.
Methods: 600 patients with clinically suspect arthralgia were studied for development of clinical inflammatory arthritis (IA) (median follow-up 25 months). Functioning was measured with the Health Assessment Questionnaire Disability-Index (HAQ) at baseline and after 4,12,24 months. HAQ-items assessing hands-functioning (dressing/eating/grip) and feet-functioning (walking) were studied. In patients who developed IA, the longitudinal course of functional disabilities towards IA-development was studied, using linear mixed models with date of IA-development as timepoint zero. ACPA-stratification was applied. Associations between HAQ-questions at presentation and future IA-development were studied with cox-regression analysis, including age, sex, CRP, ACPA and RF.
Results: 99 patients developed IA. In these patients, feet-functioning at presentation with arthralgia was less impaired than hands-functioning. Disabilities involving hands and feet both rose significantly towards IA-development (hands 0.25units/year, 95%CI=0.04-0.45, p<0.019; feet 0.29units/year, 95%CI=0.08-0.50, p=0.008, on HAQ-scale of 0-3; see Figure). However, hands-disabilities were reported earlier and were more severe than feet-disabilities during the total course (overall difference=0.41units; 95%CI=0.28-0.55, p<0.001). This was similar in both ACPA-subtypes. In the total arthralgia-population, a single question on difficulties with dressing (a HAQ-question involving hands-functioning) was as predictive as total HAQ≥1 for IA-development. This was independent of regularly used predictors; HR 2.3 (95%CI=1.5-3.6, p<0.001).

Figure. Functional disabilities involving hands and feet during progression from CSA to RA



Legend: lines depict the course of functional disabilities involving hands (average of dressing, eating, grip) and feet (walking) in CSA-patients prior to arthritis-development, derived from linear mixed model analyses. In these analyses, date of clinical arthritis is defined as t=0 and functional disabilities prior to clinical arthritis is studied. *Functional disabilities of the hands increased with 0.25 units per year on the HAQ-scale of 0-3, compared to **0.29 units per year for disabilities of the feet. Overall, functional disabilities of the hands was 0.41 units higher than those of the feet.

Conclusion: Functional disabilities in hands precede those in feet during RA-development. A single question on dressing difficulties adds value to risk stratification in patients with clinically suspect arthralgia and is easy to use in practice.

DISEASE BURDEN MEASURED BY PROS: DOES PSORIATIC ARTHRITIS (PSA) FEEL WORSE THAN RHEUMATOID ARTHRITIS (RA)? A CROSS-SECTIONAL STUDY

L. Weman[1], J. Kärki[2,3], J. Huhtakangas[4], J. Rutanen[5], L. Kuusalo[6], H. Salo[7], T. Sokka-Isler[1,1,8]. *[1]University of Eastern Finland, Faculty of Health Sciences, Jyväskylä, Finland; [2]Kanta-Häme Central Hospital, Department of Children and Adolescents, Hämeenlinna, Finland; [3]The Finnish Institute for Welfare and Health, The Finnish Rheumatology Register, Helsinki, Finland; [4]Kuopio*

University Hospital, Rheumatology outpatient clinic, Kuopio, Finland; [5]Tampere University Hospital, Centre for Rheumatic Diseases, Tampere, Finland; [6]Turku University Hospital, Centre for Rheumatology and Clinical Immunology, Turku, Finland; [7]Finnish Institute for Health and Welfare, Information services department, Helsinki, Finland; [8]Central Finland Central Hospital, Rheumatology outpatient clinic, Jyväskylä, Finland

Background: Little comparative research has been done comparing disease burden between PsA and RA. Previous studies from Nordic countries and the US have shown small differences (0-10/100 VAS units) in patients with PsA vs. RA. The mean and median VAS levels for PsA and RA ranged between 30-40 for pain and 40-50 for fatigue and patient global health in cross-sectional settings (1, 2, 3).
Objectives: To study the current differences in PROs between PsA and RA in Finland.
Methods: 3731 patients receiving care for PsA and 14163 for RA were identified in the national quality register for inflammatory arthritides in 2020-21. Patients were divided into groups by sex and age; <50 years, 50-60 years, 60-70 years and ≥70 years. The VAS values of pain, fatigue and patient global health at the most recent visit were compared in PsA vs. RA between the groups. Descriptive statistics and regression models were used for comparison.
Results: Patients with PsA vs RA were younger (mean (sd) age 54(14) vs 62(14)) and less often women (51% vs. 72%). Median (IQR) disease duration after the first symptoms was 8.6 (3.7, 17) years for PsA and 9.5 (3.3, 21) years for RA. The median (IQR) pain was 29 (10, 56) for all patients with PsA and 26 (10,51) for patients with RA. The corresponding values were: fatigue 28 (9, 60) in PsA vs 28 (8, 54) in RA, and patient global health 28 (10, 51) in PsA and 29 (11, 51) in RA.
Median pain was slightly higher in female PsA patients compared to RA patients in all age groups (29 and 18, 35 and 28, 32 and 27 and 48 and 38) (p<0.001). In males, higher levels of pain in PsA vs. RA were seen in age groups older than 50 years old. Figure 1 illustrates the mean (95% CI) pain for PsA and RA in the age and sex groups.
Median fatigue levels were quite similar between the groups. The median patient global health was higher in female PsA compared to RA patients in age groups <50 years and 50-60 years (20 vs. 29 and 30 vs 37) (p<0.001).

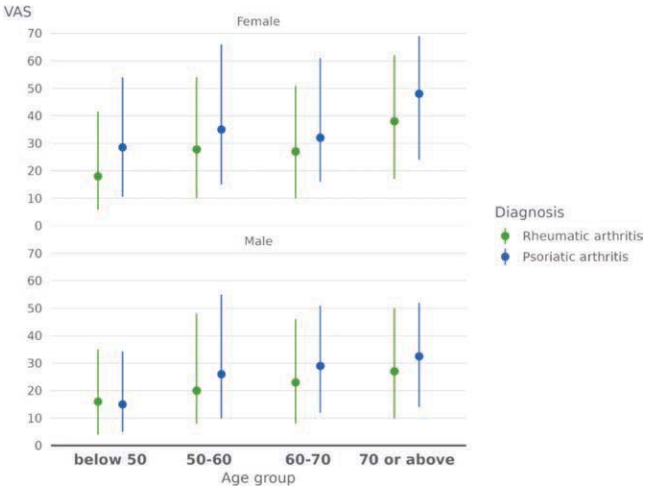

Figure 1. Mean (95 % CI) pain in VAS-units for women and men by age groups in 2020-2021

Conclusion: Female patients with PsA report higher levels of pain in all age groups compared to patients with RA. The same was seen in men >50 years old. Concerning fatigue and patient global health, the differences between PsA and RA were smaller. Compared to earlier research in other countries, disease burden observed by PROs appears lower both in PsA and RA in Finland.

AB0169 EARLY REMISSION AT 6 MONTHS AS A PREDICTOR OF LONGTERM REMISSION IN NEW ONSET RHEUMATOID ARTHRITIS

S. Emilie[1], T. Sokolova[1], A. Avramovska[1], P. Sidiras[2], S. Kleimberg[2], S. Dierckx[3], L. Meric de Bellefon[4], C. Ribbens[5], M. Malaise[5], D. R. Silvana[4], V. Badot[6], P. Durez[1]. *[7]Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium; [2]Hôpital Erasme, Rhumatologie, Brussels, Belgium; [3]CHU UCL Mont-Godinne, Rheumatology, Mont Godinne, Belgium; [4]CHU Saint–Pierre, Rheumatology, Brussels, Belgium; [5]CHU de Liège - Site Sart Tilman, Rheumatology, Liège, Belgium; [6]CHU Brugmann, Rheumatology, Brussels, Belgium*

Background: Early therapeutic intervention is crucial for patients with early rheumatoid arthritis (ERA). The goal of remission is achievable in a large proportion of ERA patients.
Objectives: To evaluate the rate of patients in remission at 6 months and to correlate the 36 and 60 months remission rate in the Belgian CAP48 cohort and the UCLouvain Brussels cohort. To identify baseline characteristics differences between patients achieving remission or not.
Methods: We included patients with ERA from the CAP48 cohort and from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 RA classification criteria. All patients were naïve to csDMARDs therapy. We collected patient characteristics at baseline and clinical response was analysed at 6, 36 and 60 months.
Results: 287 RA patients from our UCLouvain Brussels Cohort and the CAP48 cohort were analysed (211 Females, 76 Males, mean age 46.2 years, 43.4% with baseline erosion, 70.1% with ACPA, 70.3% with Rheumatoid Factor, mean HAQ 1.16, mean DAS28-CRP 4.67, mean SDAI 24.9 and mean CDAI 24.1).

Table 1. The clinical results are summarized in the Table.

	DAS28-CRP Mean(±SD)	SDAI Mean(±SD)	CDAI Mean(±SD)	Remission (DAS28-CRP), %	HAQ Mean(±SD)
Baseline n=287	4.67 (±1.38)	26.5 (±15.5)	24.1 (±14.4)	/	1.16 (±0.70)
Months 6 n=287	2.97 (±1.34)	11.3(±12.3)	10.5 (±11.8)	44,9%	0.60 (±0.62)
Months 36 n=287	2.24 (±1.04)	7.5(±8.6)	6.2 (±7.8)	71,1%	0.52 (±0.59)
Months 60 n=196	2.41 (±1.00)	6.4(±6.5)	5.7 (±6.2)	66,3%	0.56 (±0.63)

We divided the patients according to whether they achieved remission DAS28-CRP < 2.6 (group 1), or not (group 2) at 6 months.
Patient baseline characteristics were similar in the two groups respectively: age (46.7 vs 45.4 yrs); female (68.5 vs 77.3%); smoker (25.6 vs 27.0%); ACPA positive (70.1 vs 75.4%); baseline X-ray erosion (45.0 vs 54.7%).
DAS28-CRP, SDAI and CDAI at 6 months could predict long-term remission at 36 and 60 months, Figure:

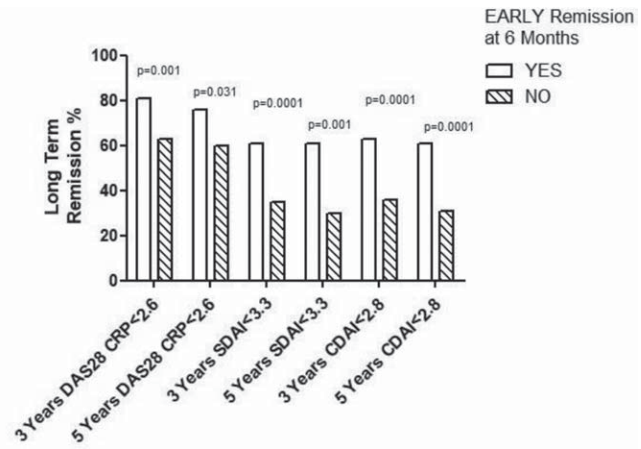

Figure 1.

In group 1 global remission (DAS28-CRP<2.6, HAQ<0.5 and no X-ray progression) was observed in 75.6% at 60 months. The majority of these patients (69.4%) are still treated with Methotrexate, the others were treated with combination therapy.
Conclusion: Early and long term remission is an achievable goal in our two cohorts. Early diagnosis is critical in standard of care. At 6 months, all remission index criteria are good predictor for long term remission and could be used in daily care.

AMCV POSITIVITY AND HIGHER SERUM IP-10 (CXCL-10) LEVEL ARE ASSOCIATED WITH A MORE PRONOUNCED EFFECT OF ABATACEPT THERAPY

M. Borisova[1], G. Lukina[1,2], Y. Sigidin[1], E. Luchikhina[3], D. Karateev[3], A. Novikov[2], E. Aleksandrova[2], M. Cherkasova[1], E. Aronova[1], S. Glukhova[1], E. Nasonov[4,5]. *[1]V.A. Nasonova Research Institute of Rheumatology, laboratory of monitoring safety of antirheumatic treatment, Moscow, Russian Federation; [2]A.S. Loginov Moscow Clinical Scientific Center, Department of rheumatology, Moscow, Russian Federation; [3]Moscow Regional Research and Clinical Institute (MONIKI), Department of rheumatology, Moscow, Russian Federation; [4]V.A. Nasonova Research Institute of Rheumatology, Scientific director, Moscow, Russian Federation; [5]I.M. Sechenov First Moscow State Medical University, Department of Rheumatology, Moscow, Russian Federation*

Background: With the advent of medications with different mechanisms of action in the treatment of rheumatoid arthritis (RA), clinicians face the challenge of personalizing the approach to the treatment of RA patients. One of the steps in this direction is to identify predictors of the effectiveness of the therapy. This work is devoted to the identification of predictors of the therapy effectiveness with the blocker of T cells co-stimulation - abatacept (ABA).
Objectives: Search for clinical and immunological predictors of the effectiveness of ABA therapy.
Methods: 91 patients were included in the study, most of them women, with high disease activity of RA (DAS28=5.1±1.0, SDAI=28±13.4, CDAI=25±12) and failure of previous biologics (51, 6%) and DMARDs (100%). Moreover, in 20% (n=18) of patients the inefficiency more than 2 biologics were recorded. The average duration of the disease was 3.0 (1.4–12) years, most patients were positive for RF 72.5%, ACCP 77%, AMCV 86%. In 44 patients the levels of RF, ACCP, AMCV and MMP-3 were assessed after 24 weeks of ABA therapy. In 36 patients enzyme-linked immunoassay was used to measure serum concentrations of biomarkers IL-1β, IL-6, IL-17AF, TNF-α, VEGF-A, IP-10, YKL-40 at baseline and after 24 weeks of ABA therapy. The effectiveness of therapy was assessed according to the EULAR criteria. ABA IV infusions were performed according to the standard schedule. Methods of parametric and non-parametric statistics were used in statistical analysis.
Results: ABA treatment led to a significant decrease of disease activity assessed by DAS28, SDAI, CDAI starting from 3 months of therapy ($p<0.05$). More than half of the patients were in remission and had low disease activity according to the DAS28 (65.7%, n=35) after 48 weeks of treatment. After 48 weeks, the highest percentage of patients with RA remission was registered by the DAS28 (37.4%, n=20), the lowest — SDAI (21.6%, n=11). After 24 weeks of therapy, ABA led to a significant decrease in the serum levels of IL-6 from 2.4 [1.1 - 6,4] to 1.29 [0.9-2.2] pg/ml, ($p=0.0006$), IP-10 from 21 [12,9-49,8] to 14 [7.5-28] pg/ml, ($p=0.007$) and matrix metalloproteinase 3 (MMP3) from 30.1 [13-82] pg/ml to 10 [7.4-55] pg/ml, ($p = 0.0003$). A decrease in the serum level of IL-6 significantly correlated with a decrease in the DAS28 and SDAI ($r=0.5$ and $r=0.479$, $p<0.05$), IP-10 with DAS28 ($r=0.326$, $p<0.05$). Initially, the serum level of TNF-α was significantly lower in patients who achieved low disease activity by the SDAI (72.6%, n=37) after 48 weeks of therapy, compared with the rest. On the contrary, a significantly higher level of IP-10 before treatment was recorded in patients with a good response according to the EULAR criteria (39%, n=29) after 48 weeks of ABA treatment (Figure 1). The ROC-analysis revealed that an initially high concentration of TNF-α may indicate with 71% sensitivity and 77% specificity about the possible ineffectiveness of ABA therapy after 48 weeks of treatment, the area under the curve was 0.7, 95% CI (0.5– 0.9). In patients initially positive for AMCV, low RA activity by SDAI was significantly more often registered after 24 ($p=0.04$) and 48 weeks. ($p=0.01$). 89% (n=34) of AMCV-positive patients achieved low disease activity after 48 weeks therapy by the SDAI and CDAI. It is noteworthy that a cohort of patients with insufficient effect after 48 weeks consisted entirely of AMCV-negative patients.

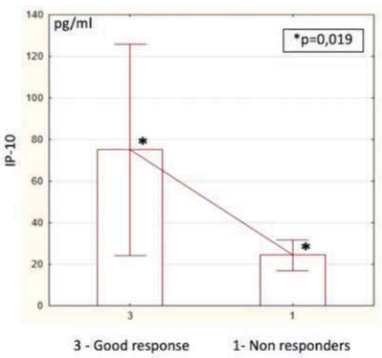

Figure 1 The ratio of the baseline level of IP-10 depending on the response to ABA therapy. The efficacy of therapy was assessed by the EULAR criteria. Error bars represent 95% CI. CI, confidence interval.

Conclusion: ABA therapy led to a significant decrease in disease activity according to the main indices (DAS28, SDAI, CDAI). During ABA treatment, there was a decrease of important immunoinflammatory markers - IL-6, IP-10, MMP-3. AMCV positivity is significantly associated with higher efficacy of ABA therapy. Also, a high basal concentration of TNF-α could use as a predictor of possible failure of ABA therapy, and a high initial level of IP-10, on the contrary, indicates the possible efficacy of ABA therapy.

AB0171

TOWARDS A BETTER IMPLEMENTATION OF TREAT-TO-TARGET STRATEGY IN RHEUMATOID ARTHRITIS: A COMPARISON OF TWO REAL-WORLD COHORTS

H. Huang[1], W. Xie[1], Y. Geng[1], Y. Fan[1], Y. Wang[1], J. Zhao[1], Z. Zhang[1]. *[1]Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Treat-to-target (T2T) strategy has been the core of rheumatoid arthritis (RA) management for over a decade, however implemented distinctly varied in real practices.
Objectives: We tried to investigate the differences in disease activity and target achievement of two cohorts with different T2T implementations.
Methods: We used data of the CENTRA (Collaboratively intENsive Treat-to-target in RA) and TARRA (Treat-to-TARget in RA) cohorts. The CENTRA is a RA cohort prospectively follow-up by a fixed team with tight control, while the TARRA is a longitudinal observational cohort follow-up by a rheumatologist with casual control. Patients from two cohorts were matched 1:3 by propensity score matching (PSM). The primary outcome was simplified disease activity index (SDAI) at 1-year follow-up.
Results: 102 patients from the CENTRA cohort and 271 patients from the TARRA cohort were included. Both groups were comparable in terms of age, gender, disease course, and seropositivity. At the end of 1 year follow-up, the SDAI of patients in the CENTRA cohort was significantly lower than that of patients in the TARRA cohort (2.1 vs 3.4, $p < 0.001$). The follow-up interval of patients in the CENTRA cohort was significantly shorter than that in the TARRA cohort when patients have not achieved remission (3.1 vs. 3.3 months, $p=0.019$).
Conclusion: RA patients may benefit more from a tight control T2T strategy with closer follow-up and appropriate education compared with a casual T2T strategy.

METABOLIC AND LIPOPROTEIN PROFILING IN RHEUMATOID ARTHRITIS WITH THE USE OF NMR-BASED METABOLOMICS

K. Tsezou[1], D. Benaki[2], M. Ghorasaini[3], A. Iliou[2], M. Giera[3], A. Tzioufas[1], E. Mikros[2], P. Vlachoyiannopoulos[1]. *[1]National and Kapodistrian University of Athens, Department of Pathophysiology, Medical School, Athens, Greece; [2]National and Kapodistrian University of Athens, Pharmaceutical Chemistry, School of Pharmacy, Athens, Greece; [3]Leiden University Medical Center, Center for Proteomics and Metabolomics (CPM), Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) remains a disease with high morbidity, due to the greater prevalence of cardiovascular disease. In contrast to the general population, systemic inflammation in RA lowers the circulating levels of lipids, a phenomenon called "the lipid paradox". In addition to that, therapy is withdrawn in 50% of patients within 5 years, due to loss of efficacy or side effects. Momentarily predictive biomarkers for drug efficacy or side effects are missing, while a personalized approach in RA therapy is imperative. Several reports support the notion that specific metabolomic profiles are good predictors for response to MTX and anti-TNF therapy.
Objectives: The aim of this work is to depict in detail the metabolic profile of RA patients at different time-points of therapy DMARDs/bDMARDs in order to retrieve biomarkers related to their response to a given therapy, to monitor the disease progression and to predict the optimal disease management approaches.
Methods: Plasma was collected from fasted RA patients according to their therapy timepoint and organized in the following groups: a) newly diagnosed, without therapy (Naïve, n=15); b) patients having received therapies previously, with unstable disease, who were evaluated before receiving a new therapy (RAb, n=23); c) patients after having received a new therapy (RAa, n=14); and d) patients receiving any standard therapy (RAs, n=54), either DMARD or bDMARD, being in a stable condition. Finally, healthy subjects were enrolled as controls (n=33). Metabolomic profiling was carried out firstly with untargeted ^{1}H NMR spectroscopy, and secondly with in vitro diagnostic (IVDr) NMR spectroscopy with the lipoprotein subclass analysis (B.I.LISA), to quantify absolute concentrations of metabolites and lipoproteins. The acquired data were subjected to univariate and multivariate statistical analysis to investigate clustering of the

groups and define the responsible molecules. Clinical parameters, including inflammation markers, DAS28, and comorbidities, were also included in the analysis, and Spearman correlation coefficient was calculated.

Results: Untargeted NMR data were analyzed with multivariate supervised approach (PLS-DA) revealing distinct metabolic signatures for the 6 groups under investigation. The most defined groups being RAb and RAs, compared to controls, which indicated changes in alanine, tyrosine, lactate and acetone. Besides small molecule, significant changes were also observed in various plasma lipoproteins. For the thorough investigation of these findings, a targeted lipoprotein subclass analysis was conducted and highlighted significantly higher lipoprotein subclass concentrations, including free cholesterol (FC), cholesterol (CH), phospholipids (PL) and apolipoprotein A1 subfractions in RAs compared to controls and Naïve. Concerning metabolite differentiations, RAs patients exhibited reduced ketone bodies and organic acids compared to RAb and control individuals, respectively. All RA groups had lower concentrations of sarcosine. Correlation analysis highlighted the association of DAS28, ESR and CRP with ketone body acetoacetate ($p<10^{-4}$) and sarcosine ($p<10^{-2}$). VAS correlated with HDL triglyceride subfractions (H1TG and H2TG, $p<10^{-5}$) and sarcosine ($p=1.8x10^{-4}$). All therapies were found to correlate with lipoproteins; MTX with LDL-2 subfractions ($p=5x10^{-4}$), intermediate-density lipoprotein ($p=2.7x10^{-5}$) and acetate ($p=5.9x10^{-6}$), Anti-IL-6R with VLDL cholesterol subfraction V1CH, ($p=1.9x10^{-3}$) and V2CH ($p=1.5x10^{-3}$), and Anti-CD20 with triglyceride fractions, IDTG and TPTG ($p<10^{-3}$).

Conclusion: Overall, these data reveal that RA patients have a distinct metabolic signature depending on the time-point of therapy. Clinical parameters correlated with changes in ketone bodies, amino and organic acids, while therapies correlated with lipoproteins. The above analysis indicates that biomarkers revealed by metabolomic profiling can be useful in RA therapy monitoring.

AB0173 MORPHOLOGICAL PARAMETERS ASSESSED BY ULTRASOUND IN QUADRICEPS MUSCLE WERE ASSOCIATED WITH CLINICAL FEATURES, MUSCLE STRENGTH, FUNCTIONAL CAPACITY AND PHYSICAL FUNCTION OF RHEUMATOID ARTHRITIS PATIENTS

L. Santos[1], R. Cavalheiro Do Espírito Santo[1], É. Pena[1], L. Denardi Dória[1], S. Pilotti[1], D. Nóbrega de Moraes[1], M. Marchezan Menezes Da Silva[1], V. Hax[2], C. Brenol[2], O. Monticielo[2], R. Mendonça Da Silva Chakr[2], R. Xavier[2]. [1]*Federal University of Rio Grande do Sul, Laboratório de Doenças Autoimunes, Porto Alegre, Brazil;* [2]*Hospital de Clínicas de Porto Alegre, Serviço de Reumatologia, Porto Alegre, Brazil*

Background: Rheumatoid arthritis (RA) patients usually present extra-articular manifestations (1,2), which affect muscle mass and, consequently, physical function (3). Among the various methods to assess muscle mass we tested muscle morphology by ultrasound (MU) to verify the associations of the quadriceps muscle with clinical features, muscle strength, functional capacity and physical function.

Objectives: To assess the MU of the quadriceps muscle and verify the muscle quality assessed by the pennation angle and its associations with clinical features, muscle strength, functional capacity and physical function in RA patients.

Methods: RA women, age ≥18years and who met 2010 American College of Rheumatology (ACR) criteria were included. Morphological parameters in quadriceps muscle consisted of the pennation angle of rectus femoris (RF), vastus intermedius (VI) and vastus lateralis (VL). RA activity was measured by 28-joint disease activity score (DAS28), muscle strength by handgrip and chair stand tests, functional capacity by health assessment questionnaire (HAQ), and physical function by timed-up-and-go (TUG) test and short physical performance battery (SPPB). Pearson's or Spearman's correlation coefficients were explored. The significance level was set at $p \leq 0.05$ for all analyzes.

Results: Eighty-one patients were included (age: 58.64±9.52 years old; DAS28: 3.24±1.34). Smaller pennation angle in rectus femoris (RF) were associated with lower handgrip strength (r= 0.224, p=0.044), chair stand test (r= -0.372, p=0.004), HAQ (r= -0.404, p=0.001), SPPB (r= 0.262, p=0.047), as well as higher disease activity by DAS-28 (r= -0.415, p<0.0001) and age (r= -0.290, p=0.009). Smaller pennation angle in vastus intermedius (VI) were associated with worse chair stand (r= -0.281, p=0.033), HAQ (r= -0.302, p=0.015) and higher disease activity by DAS-28 (r= -0.304, p=0.006). Lastly, smaller pennation angle in vastus lateralis (VL) were associated with worse chair stand (r= -0.290, p=0.027), as well as higher DAS-28 (r= -0.237, p=0.033) and age (r= -0.272, p=0.014).

Conclusion: The pennation angles of the quadriceps muscle evaluated by ultrasound (RF, VI and VL muscles) were associated with chair stand test and DAS-28. In addition, the level of disease activity assessed by DAS-28 also appears to be affecting the quadriceps muscle. Finally, MU may be a useful method to evaluate the impact of the disease on skeletal muscle.

AB0174 MOST RHEUMATOID ARTHRITIS PATIENTS IN POST–2010 REPORTS FROM ROUTINE CARE REMAIN IN DAS28, CDAI OR RAPID3 MODERATE ACTIVITY/ SEVERITY, NOT LOW/REMISSION: EXPLAINED IN PART BY LIMITS OF INDICES AND/OR STRATEGIES FOR DIAGNOSIS AND TREATMENT?

K. Schroeder[1], S. Kannayiram[2], T. Pincus[1]. [1]*Rush University Medical Center, School of Medicine, Chicago, United States of America;* [2]*John H. Stroger, Jr. Hospital of Cook County, Medicine, Chicago, United States of America*

Background: Availability of powerful biological agents to treat rheumatoid arthritis (RA) has led to a strategy of treat-to-target toward remission or low disease activity according to a quantitative index, although higher levels of disease activity according to shared decisions are recognized as appropriate for certain patients.[1] Substantial improvement in patient status was documented quantitatively in 2000 compared to 1985,[2] maintained in 2008[3] and 2010[4], but few reports in recent years compare patient status in routine care to earlier data.

Objectives: To analyze post-2010 reports concerning mean or median or categories of DAS28, CDAI, and RAPID3 to depict patient status, and compared to pre-2011 reports.

Methods: PubMed searches were conducted for 2011-2021 reports for "DAS28 (disease activity score) categories not trial," and repeated twice, replacing "DAS28" with "CDAI" (clinical disease activity index) and "RAPID3" (routine assessment of patient index data). Activity/severity levels for high, moderate, low, and remission, respectively, are: DAS28 (0-10) >5.1, 3.2–5.1, 2.6–3.2, ≤2.6; CDAI (0-76) >22, 10.1–22, 2.9-10, ≤2.8; RAPID3 (0-30) >12, 6.1–12, 3.1-6, ≤3.0. Mean and/or median DAS28, CDAI, or RAPID3, and/or proportions of patients who were in remission, low, moderate, and high activity/severity were compiled. Results were compared to 3 pre-2011 reports, 2 of which included all 3 indices.[2-4]

Results: Results from 1985 vs 2000 indicate >50% improvement in swollen joints and physical function,[2] maintained in 2008[3] and 2010[4] (data not shown). The

search identified 32 reports with 98 comparisons of 1, 2, or 3 indices for mean or median levels or activity/severity categories (Table). Analyses of 57 means or medians indicated 10 high, 39 moderate, 8 low; for DAS28-ESR 2, 18, 2; for DAS28-CRP 1, 6, 3; for CDAI 4, 9, 3; and for RAPID3 3, 6, 0 (Table). Analyses of 41 reports of comparisons of disease activity/severity categories indicated more high/moderate in 35 vs low/remission in 6, 1 of 5 for DAS28–CRP and 5 of 15 for CDAI (Table). Remission according to DAS28, CDAI, or RAPID3 was reported in 17.1%, 10.2%, and 13.7% of patients, respectively, and low activity/severity or remission in 33.3%, 39.6%, and 29.7%, respectively (data not shown).

Table 1. Means and/or Medians and categories of DAS28-ESR, DAS28-CRP, CDAI and RAPID3.

Index:	# of compa-risons	DAS28-ESR	DAS28-CRP	CDAI	RAPID3
		Mean/Median of Index			
Total means and medians	57	22	10	16	9
High activity/severity	10	2	1	4	3
Moderate activity/severity	39	18	6	9	6
Low activity/severity	8	2	3	3	0
Remission	0	0	0	0	0
		Categories of High or Moderate Activity/ Severity vs Low or Remission			
Total classified by categories	41	12	5	15	9
High or Moderate> Low or Remission	35	12	4	10	9
Low or Remission> High or Moderate	6	0	1	5	0

Conclusion: Most RA patients in post 2011 reports from routine care were in moderate activity according to means or medians or categories, unchanged from 2008 and 2010. Only a minority were classified as in remission or low activity/severity. Optimal RA treatment may require modification of treatment goals, further recognition of differences between patients in clinical trials and routine care, and possible new strategies for earlier identification of RA patients for treatment, in addition to new therapeutic agents.

AB0175 THE ROLE OF MONITORING THE CYTOKINE PROFILE TO PREDICT THE EFFECTIVENESS OF THERAPY IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

A. Avdeeva[1], V. Rybakova[1], E. Nasonov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, laboratory of immunology and molecular biology rheumatic diseases, Moscow, Russian Federation*

Background:

Objectives: To evaluate the changes in cytokine profile in methotrexate (MTX)-naive patients (pts) with early rheumatoid arthritis (RA) during MTX therapy and identify predictors of the effectiveness of therapy.

Methods: The study included 45 early RA DMARD-naive pts (35 females, 10 males with median age 53.5; interquartile range 46-59.5 years, disease duration 7.0;4.0-11.5 months, DAS 28 5.8;4.9-6.4, RF positive 91%, anti-CCP positive 96%). MTX was administered to all patients as the first-line DMARD at 10 mg/week with a rapid escalation of the dose up to 20-25mg/week. The levels of IL-1b, IL-1Pa, IL-2,-4,-5,-6,-7,-8,-9,-10,-12,-13,-15,-17, Eotaxin, FGF-basic, IFN-γ, IP-10, MCP-1, MIP-1α, MIP-1β, RANTES, TNF-α, VEGF (pg/ml) were tested by multiplex technology xMAP at baseline and weeks 12 and 24.

Results: After 3 months the efficacy of SC MTX have met the goal in 23(51%) of pts. MTX induced reduction in proinflammatory (IL-6,-17,TNF-α), anti-inflammatory (IL-4,-5,-9,-13) cytokines, chemokines (IP-10) and growth factors (FGF) at week 12; IL-6,-9, IP-10, PDGF-bb at week 24 (p<0.05). The serum levels of IL-10, IFN-γ increased at week 24 (p<0.05), Figure 1. Among the "respondents" to MT therapy, by week 12, a significant decrease in levels of IL-1Ra, IL-2,-4,-6,-7,-9,-13, IP-10, TNF-α, VEGF was detected. In the "non-responders" group, the level of cytokine profile indices did not change (p>0.05), Figure 2.

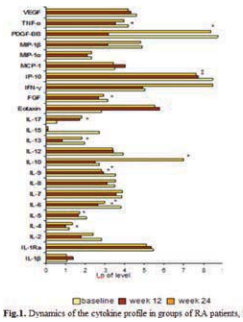

Fig.1. Dynamics of the cytokine profile in groups of RA patients, *p<0,05 from baseline

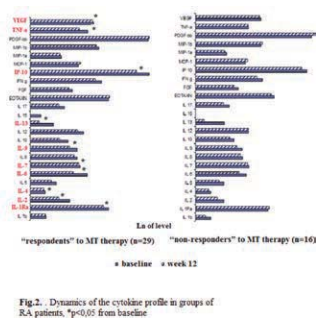

Fig.2. . Dynamics of the cytokine profile in groups of RA patients, *p<0,05 from baseline

Conclusion: Clinical efficacy of SC MTX therapy is associated with reduced of proinflammatory cytokines, chemokines and growth factors at weeks 12-24 of therapy. The dynamics of cytokine profile after 12 weeks of MT therapy can be considered as a predictor of the effectiveness of MT therapy.

AB0176 THE ROLE OF IL-6 IN PREDICTING INFLAMMATORY ACTIVITY BASED ON ULTRASONOGRAPHIC (US) EVIDENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS DURING RITUXIMAB BIOSIMILAR (ACELLBIA «BIOCAD») THERAPY

A. Avdeeva[1], O. Alekseeva[2], V. Rybakova[1], E. Nasonov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, laboratory of immunology and molecular biology rheumatic diseases, Moscow, Russian Federation;* [2]*V.A. Nasonova Research Institute of Rheumatology, Diagnostic department, Moscow, Russian Federation*

Background:

Objectives: To assess the role of laboratory markers in predicting the persistence of inflammatory activity according to US evidence in patients with RA during therapy with a rituximab biosimilar (RTX) – Acellbia.

Methods: 20 RA pts (18 woman, Me;IQR age 61.5[54-66.5] years, disease duration 39.5[20-84] months, mean DAS 28 5.6[4.9-6.8]) received two intravenous RTX infusions (600 mg №2) in combination with DMARDs and glucocorticoids. Ultrasound with gray scale (GS) and power Doppler (PD) were performed at baseline, 12, 24 weeks after initiation of therapy. The wrist, MCP2, MCP3, PIP2, PIP3, MTP2 and MTP5 joints of the clinically dominant side were examined by US according to the European League Against Rheumatism (EULAR) guidelines. ESAOTE MyLabTwice and GE Logiq 9 US machines with 13–18 MHz-transducer were used. The levels of IL-1b, IL-1Pa, IL-2,-4,-5,-6,-7,-8,-9,-10,-12,-13,-15,-17, Eotaxin, FGF-basic, IFN-γ, IP-10, MCP-1, MIP-1α, MIP-1β, RANTES, TNF-α, VEGF (pg/ml) were tested by multiplex technology xMAP at baseline and weeks 12 and 24 after the first infusion of RTX.

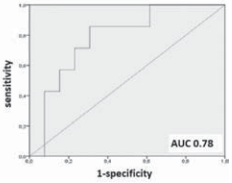
Results: After 24 weeks of RTX therapy values DAS 28 was 4.1 [3.1-4.7]; DAS 28 remission/low disease activity was achieved in 8 (40%) pts, while RTX failure based on EULAR response was documented in 3 (15%) pts. The baseline value of PD was 2.0 [1.0–3.5]; the proportions of PD(+) and PD(–) patients were 65% and 35%, respectively. After 24 weeks of therapy, the PD value was 0.5 [0.0–2.0] points; active inflammation persisted in 7 (35%) patients, p<0.05. Depending on the presence of active inflammation according to PD after 24 weeks of therapy, all patients were divided into two groups (Table 1).

According to the ROC analysis, it was found that the basal level of IL-6 more than 100.0 pg/ml is associated with the preservation of inflammatory activity according to PD by the 24th week of therapy with a sensitivity of 85% and a specificity of 62% (AUC = 0.78, 95% CI 0.57–0.99).

Table 1. Basal clinical and laboratory parameters in groups of patients depending on US changes after 24 weeks of therapy

Parameters	PD (+), *n*=7	PD (-), *n*=13
DAS 28	6.6 [5.4–7.2]	5.4 [4.7–5.7]
ESR, mm/h	62.0 [22.0–130.0]	40.0 [17.0–73.0]
CRP, mg/l	37.1 [9.2–46.0]	10.0 [8.6–44.4]
IgM RF, IU/ml	318.0 [170.0–519.0]	201.0 [79.3–502.0]
Anti-CCP, U/ml	159.6 [17.2–265.1]	119.3 [51.9–264.5]
IL-1β pg/ml	18.5 [4.5–63.3]	10.5 [4.8–30.5]
IL-1Ra pg/ml	3355.7 [448.5–14548.3]	953.2 [475.1–2206.7]
IL-2 pg/ml	253.1 [0.01–850.9]	18.9 [0.01–75.8]
IL-4 pg/ml	7.0 [5.9–9.3]	7.8 [6.5–9.6]
IL-5 pg/ml	15.2 [2.7–30.8]	5.3 [2.7–27.0]
IL-6 pg/ml	**286.4 [106.8–590.7]**	**95.1 [31.5–108.5]** *
IL-7 pg/ml	10.6 [3.8–361.5]	8.5 [5.3–28.8]
IL-8 pg/ml	47.0 [36.4–54.9]	39.2 [33.9–46.2]
IL-9 pg/ml	127.0 [50.8–385.9]	192.3 [62.2–323.2]
IL-10 pg/ml	148.2 [21.2–1877]	66.1 [19.2–332.1]
IL-12 pg/ml	154.4 [35.7–1064.4]	72.1 [46.1–237.7]
IL-13 pg/ml	22.7 [6.2–275.5]	11.6 [2.7–21.1]
IL-15 pg/ml	317.6 [23.5–845.3]	94.9 [58.5–176.5]
IL-17 pg/ml	67.9 [64.0–74.6]	77.8 [74.9–101.6]
Eotaxin pg/ml	857.7 [423.2–3681.3]	340.9 [216.1–584.3]
FGF basic pg/ml	40.9 [35.7–54.1]	43.9 [35.7–48.2]
G-CSF pg/ml	102.3 [94.1–258.5]	130.6 [91.4–382.5]
GM-CSF pg/ml	0.01 [0.01–418.7]	0.01 [0.01–72.7]
IFN γ pg/ml	535.7 [175.2–2939.2]	317.5 [181.3–892.2]
IP-10 pg/ml	2555.2 [1934.8–3289.9]	2471.0 [1764.3–2850.8]
MCP-1 pg/ml	308.7 [42–1119.3]	90.7 [48.7–246.7]
MIP-1α pg/ml	5.0 [4.4–7.7]	5.1 [4.4–8.0]
MIP-1β pg/ml	83.7 [63.6–99.1]	110.9 [84.9–151]
PDGF bb pg/ml	2925.9 [2656.1–3308.7]	3975.8 [3418.5–4275.6]
TNF-α pg/ml	1566.9 [169.9–3472]	324.6 [171.2–705.4]
VEGF pg/ml	116.2 [73.6–599.6]	106.6 [61.2–200.6]

*p<0.05 between groups



Conclusion: IL-6 is the most promising marker for predicting persistent inflammatory activity according to PD in patients with RA on the RTX biosimilar therapy, other analyzed parameters have worse sensitivity and specificity.

AB0177 ASSOCIATION OF SEROLOGICAL STATUS WITH THE FREQUENCY OF CLINICAL AND RADIOLOGICAL REMISSION IN RHEUMATOID ARTHRITIS

O. Iaremenko[1], G. Mykytenko[2]. [1]*O.O.Bogomolets National medical university, internal medicine, Kyiv, Ukraine;* [1]*O.O.Bogomolets National medical university, internal medicine, Kyiv, Ukraine*

Background: Achieving remission is one of the main goal in the management of patients (pts) with rheumatoid arthritis (RA). According to the literature, one of the determining predictor of the disease course is the serological variant of RA [1]. However, there are conflicting data in scientific publications concerning relationship between the presence/titre of antibodies to cyclic citrullinated peptide (ACCP) or rheumatoid factor (RF) and the frequency/rate of remission [1].
Objectives: To examine associations of ACCP- and RF-status with possibility and timing of clinical and radiological remission in Ukrainian pts with RA while taking the main non-biological disease modifying anti-rheumatic drugs (DMARD).
Methods: In enrolled pts RF titer was determined by the latex agglutination method (Humatex, Germany), reference values <20 IU/ml; ACCP level - by ELISA (IBL-Hamburg, Germany), the diagnostic limit of ACCP was ≥15U/ml, the maximum value ≥ 345U/ml. All pts received non-biological DMARD: methotrexate, leflunomide, sulfasalazine or its combination with hydroxychloroquine. At baseline and after 6, 12 and 24 months (mth) of treatment the disease activity and achievement of remission (by DAS28; Sharpe-van der Heide scale) in different subgroups of RA pts were analysed.
Results: 128 pts with RA were included in the study; the mean (SD) age was 54 (12.7) years and follow-up was for 2.0 (1.3) years. Most were women (72.4%), mean disease duration 18.4± 3.18 mth. ACCP-positive were 64.8% and RF - 57.1% pts. According to serological status at baseline, pts were stratified into four classes: ACCP+RF- (n=19), RF+ACCP- (n=9), dual positive (n=64) and dual negative (n=36). There were no significant differences between the analysed groups in age, sex, RA duration, disease activity, radiological changes and prescribed therapy (p>0.05).
During the 2-year follow-up, clinical remission was achieved in a total of 27 (21.1%) pts, including early remission (during first 6 mth) in 25 (19.5%). The percentage of pts in remission were 36.1, 33.3, 15.8, and 12.5 respectively for RF–/ACCP–, ACCP–/RF+, ACCP+/RF–, and ACCP+/RF+ ($\chi 2$ = 7.74, p<0.05 RF–/ACCP– vs ACCP+/RF+; $\chi 2$ = 4.55, p <0.05 ACCP–/RF+ vs ACCP+/RF+). The rate of remission (frequency of early remission in the structure of general remission) in four analysed groups did not differ significantly and was 75%, 66.6%, 66.6% and 84.6%, respectively. The ACCP titer in pts who achieved and didn't achieve remission were respectively 240.8 ± 38.5U / ml and 187.8 ± 13.7U / ml, p>0.05. There also wasn't difference between RF titer and the frequency of remission in these groups (257.9±233.8 IU / ml vs 293.2±257.3 IU / ml, p> 0.05). According to our data, there was no correlation between the level of RF / ACCP and the frequency of remission.
Radiological remission was achieved in 46.7% of ACCP-negative patients and only in 10.6% of ACCP-positive patients (p <0.01). The absence of RF in the blood was also associated with a more frequent achievement of radiological remission (in 34.2% of pts) compared with the RF-positive cohort of pts (in 15.4%, p <0.05). Double seronegative pts achieved remission three times more often (48.1% pts) than double seropositive (13.9%, p<0.01).
Conclusion: Our data suggest that the frequency of clinical remission, including early, is three times higher in patients with RA, negative for ACCP. The rate of clinical remission (ratio of early in the structure of the general) doesn't depend on the serological variant of RA: about two thirds of pts in all analysed groups achieve remission in the first 6 mth of DMARD therapy. ACCP- and RF-titers in the onset of the disease don't influence on the possibility of achieving clinical and radiological remission. Radiological remission is observed three times more often in seronegative (for ACCP or RF) pts. Double seropositivity has an additive effect on subsequent joint destruction.

AB0178 INDICATORS OF DISEASE ACTIVITY DURING HOSPITALIZATION IN A RHEUMATOLOGICAL HOSPITAL IN PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

E. Matianova[1], A. Gordeev[1], Y. Olyunin[1], E. Galushko[1]. [1]*V.A.Nasonova Rheumatology Research Institute, Rheumatoid arthritis evolution laboratory, Moscow, Russian Federation*

Background: Patients (pts) with Difficult-to-Treat Rheumatoid Arthritis (D2T) (EULAR 2021 criteria) are distinguished by a history of failure of two or more biological disease modifying antirheumatic drugs (bDMARDs)/targeted synthetic DMARDs (tsDMARD) with different mechanisms of action and a more aggressive course of RA generally. In this study, we wanted to identify differences in the manifestation of RA activity during an exacerbation of the disease in such pts, compared with similar pts, but not meeting the D2T EULAR criteria.
Objectives: Describe the features of manifestations of rheumatoid arthritis (RA) activity in pts with D2T.
Methods: In pts with RA, with ineffectiveness of bDMARD/tsDMARD taken before hospitalization, admitted to the V.A.Nasonova Research Institute of Rheumatology from January to December 2021 due to an RA exacerbation (n=113), the duration of morning stiffness in the joints, tender joint count (TJC), swollen joint count (SJC), VAS general health pt, ESR, blood CRP levels, and DAS28 calculated indices. Pts Patients Eligible for D2T RA EULAR 2021 were allocated to the D2T group (n=26/23%), the remaining pts were assigned to the C control group (n=87/77%). Pts at D2T and C were matched for sex, age (D2T: 44.6±14.1 years vs. C: 48.8±15.6 years; p>0.05) and duration of RA (D2T: 15.8 ±11.4 years vs. C: 13.7±8.6 years, p>0.05).
Results: Inflammatory activity in terms of CRP in D2T was significantly higher than in C (p=0.04). At the same time, the frequency of taking classical DMARDs in D2T was slightly lower (p>0.05), and systemic glucocorticoids (GC) was significantly higher (OR=3.7 [1.3-10.8]; p=0.01).
TJC, SJC, VAS general health pt, ESR, CRP, duration of morning joint stiffness, as well as the estimated DAS28 indices at the time of admission to the hospital in pts with D2T RA were comparable to those in C. (Table 1)

Table 1. Indicators of disease activity and concomitant therapy in the study groups

	D2T (n=26)	C (n=87)	p
TJC, M±SD	9.1±4.8	10.6±5.7	>0.05
SJC, M±SD	6±3.7	6.6±4.5	>0.05
VAS general health pt, M±SD, мм	66.2±11	66.9±12	>0.05
ESR, Me [25; 75%], mm/hr	53.5 [8;98]	27 [14;56]	>0.05
CRP, Me [25; 75%], mg/l	28.3[3.5;67.7]	7.9[5.7;44.2]	0,04
DAS28^{CO3}, M±SD	5.5±1.3	5.7±1.1	>0.05
DAS28^{CPБ}, M±SD	5.2±0.9	5.3±1	>0.05
Duration of morning joint stiffness, min	120±79	135.5±94	>0.05
Taken classic DMARDs, n/%	18 / 69,2	74 / 85,1	>0.05
Taken GC per os n/%	21 / 80,8	46 / 52,9	OR=3,7 [1,3-10,8]; p=0,01
GC dose in terms of prednisolone, mg/day	7,6±4,1; 5 [5;10]	6,6±3; 5[5;10]	>0.05

Conclusion: Pts with D2T RA during an exacerbation of the disease differed from other RA patients with the ineffectiveness of previous bDMARD/tsDMARD by a higher inflammatory activity in CRP (p=0.04) with a higher frequency of systemic GCs (OR=3,7 [1,3-10,8]; p=0,01).

AB0179 PATIENT'S SATISFACTION WITH TREATMENT IN RHEUMATOID ARTHRITIS: AN UNMET NEED

W. Belhaj[1], S. Miladi[1], A. Fazaa[1], H. Boussaa[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*university of tunis el manar, faculty of medicine of tunis, mongi slim hospital, rheumatology department, tunis, Tunisia*

Background: Shared decision between rheumatologists and their patients has become an overarching principle in current treatment recommendations in rheumatoid arthritis (RA). Therefore, assessing satisfaction with pharmacological therapy, among patients, is becoming increasingly important in clinical settings.
Objectives: In this study, we aimed to assess the satisfaction of patients with RA about their treatment and to investigate the predictive factors.
Methods: A cross-sectional study was conducted including adults diagnosed with RA for more than a year and receiving their current Disease-modifying anti-rheumatic Drug(s) (DMARD(s)) for at least 12 months.
We used the treatment satisfaction questionnaire for medication (TSQM v1.4) to assess the treatment satisfaction among patients. Multivariable regression analysis was applied to determine the factors associated with treatment satisfaction.
Results: We included 70 patients (63F/7M) with a mean age of 57.8 ±10.6 [29-81] years at the time of the study. The mean disease duration was 13.71±7.2 [2-30] years. Twenty-four (34,2%) patients were on a biologic DMARD (bDMARD).
Regarding the Disease Activity Score 28 (DAS28-ESR), 14.3% of patients had a low disease activity, 47.1% a moderate disease activity, 7.1% a high disease

activity, and 31.4% were in clinical remission. The mean (SD) Rheumatoid Arthritis Impact Disease (RAID) overall score was 4.72 ±2.11. Mean (SD) TSQM scores were 65.42±14.77 for convenience, 68.71±18 for effectiveness, 70.60±24.5 for side effects, and 67.95±17.10 for global satisfaction.

Twenty percent of patients were satisfied with convenience, 38.6% were satisfied with effectiveness, 45.7% were satisfied with side effects and 30% were globally satisfied.

The multivariable regression analysis showed that the RAID overall score was inversely associated to global satisfaction (p=0.001) and to satisfaction with effectiveness (p=0.032).

Difficulty of coping (one of the RAID domains) was inversely associated to satisfaction with effectiveness and convenience.

It was, also, showed that satisfaction with side effects was inversely associated to the degree of interference of the RA on domestic work (p=0.020) and positively correlated to the degree of participation in treatment decision-making (p=0.014). In addition, satisfaction with current physician was positively associated to global satisfaction (p=0.029).

Satisfaction with convenience was inversely associated to bDAMARs (p=0.027).

Conclusion: We conclude from our data that despite the diversity of therapeutic strategies, almost two-thirds of patients remain not satisfied with their treatment. A better understanding of patients' unmet needs and an individualized patient-centric approach would improve outcomes in RA.

AB0180 CLINICAL AND ULTRASOUND-BASED COMPOSITE DISEASE ACTIVITY INDICES AND RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS

I. Gessl[1], T. Deimel[1], P. Studenic[1,2], G. Tamborrini[3], P. Zufferey[4], D. Aletaha[1], B. Moeller[5], P. Mandl[1]. *[1]Medical University of Vienna, Dept. of Rheumatology, Vienna, Austria; [2]Karolinska Institutet, Division of Rheumatology, Stockholm, Sweden; [3]Bethesda Hospital Basel, Ultrasound Center and Institute for Rheumatology, Basel, Switzerland; [4]Lausanne University Hospital, Rheumatology Department, Lausanne, Switzerland; [5]Inselspital - Bern University Hospital, Department for Rheumatology, Bern, Switzerland*

Background: Musculoskeletal ultrasound (US) has been reported to predict radiographic progression in rheumatoid arthritis (RA).

Objectives: To test the predictive value of composite disease activity indices (DAI) based on solely clinical as well as clinical and US (USDAI) information to predict radiographic progression in RA.

Methods: Data from the Swiss Clinical Quality Management (SCQM) database were extracted from patients with RA; USDAIs were created based on previous publications (1) (Table 1). In summary, the disease activity score in 28 joints (DAS28) and the simplified disease activity index (SDAI) were modified by supplementing or replacing the clinical swollen JC with joints showing signs of power Doppler (PD) and/or grey scale (GS) synovitis. Series with two standard x-rays of the hands (difference ≥ 183 days) and ≥1 visit with clinical and US data in between were analyzed. Progression was defined as an increase of ≥6.27 points of the Ratingen-Rau x-ray score. Receiver operating curve (ROC) analyses were used to assess predictive ability of every DAI for radiographic progression. As a subanalysis, ROCs using the median DAIs of series with ≥2 DAIs between two x-rays were run. Clinical DAS28/SDAIs were compared to their respective USDAI counterpart with the highest area under the curves (AUC).

Results: We included 649 series in 475 patients. Progression was observed in 84/649 (12.9%) series. Mean difference between the x-rays was 27.6±18.0 months. Mean age was 56.3±12.7 years, 474/649 (73%) series were from female patients. There was no significant difference between the AUC of the ROC of SDAI vs. SDAI_PD (p=0.19) nor between DAS28 vs. DAS28_PD: (p=0.17) (Figure 1A, Table 1). Similarly, when analyzing only series with ≥2 DAIs (143 series) we observed no difference between the AUC of the ROC of SDAI vs. SDAI-PD (p=0.28) nor between that of DAS28 vs. DAS28_PD (p=0.23) (Figure 1B, Table 1).

Table 1. Area under the curves (AUC) of receiver operating characteristic curves for the predictive value of the composite disease activity indices for radiographic progression. ***DAI disease activity index*; *DAS28, disease activity score for 28 joints; GS, grey scale; PD, power Doppler; SDAI, simplified disease activity index; SJC: swollen joint count; + positive***

Disease activity indexes		All series AUC	All series 95% CI Lower	All series 95% CI Upper	Series with ≥ 2 DAIs AUC	Series with ≥ 2 DAIs 95% CI Lower	Series with ≥ 2 DAIs 95% CI Upper
DAS28		.58	.52	.58	.62	.45	.78
DAS28_GS	SJC replaced by GS+ joints	.56	.49	.56	.62	.44	.80

SDAI_GS	SJC replaced by GS+ joints	.53	.46	.53	.47	.23	.71
SDAI_PD	SJC replaced by PD+ joints	.58	.52	.58	.51	.27	.75
SDAI_GSPD	SJC replaced by GS AND PD+ joints	.53	.46	.53	.47	.23	.71
SDAI_plus_GS	SJC supplemented by GS+ joints	.54	.47	.54	.47	.23	.70
SDAI_plus_PD	SJC supplemented by PD+ joints	.58	.51	.58	.48	.25	.72
SDAI_plus_GSPD	SJC supplemented by GS AND PD+ joints	.54	.47	.54	.46	.23	.70

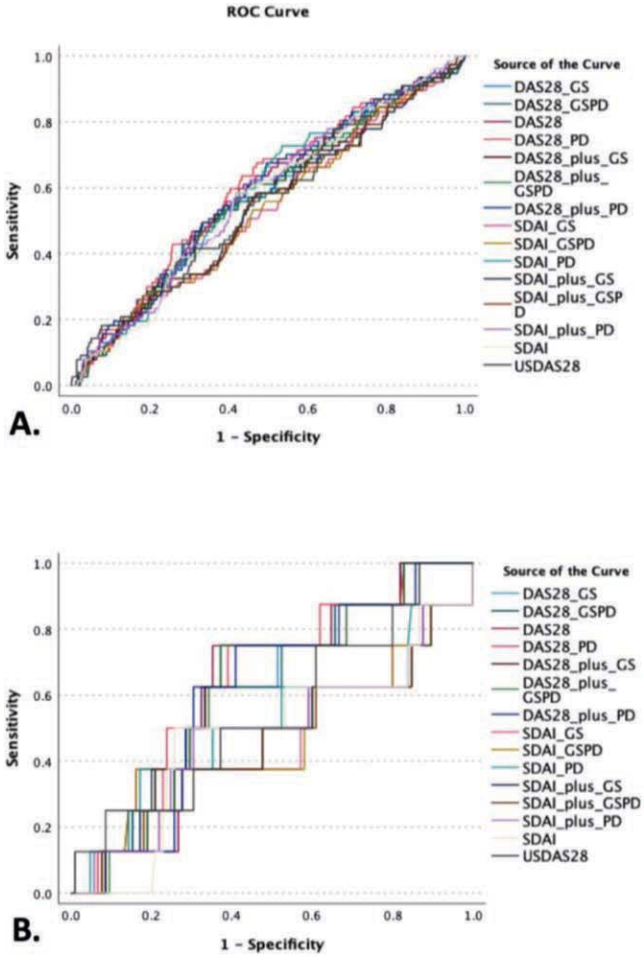

Figure 1. Receiver operating characteristic (ROC) curve of clinical and ultrasound-based composite disease activity indices (A) overall and (B) for the subgroup with series with ≥ disease activity indices. DAS, disease activity score; GS, grey scale; PD, power Doppler; SDAI, simplified disease activity index;

Conclusion: The predictability of radiographic progression by disease activity measures was generally limited. The composite USDAIs containing sonographic JC were not superior for predicting radiographic progression compared to their clinical counterparts although there was a trend for higher predictive value for indices containing PD.

AB0181

RADIOGRAPHIC DESTRUCTION OF CARPAL BONE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

R. Honma[1], Y. Takakubo[1], D. Saito[1], Y. Wanezaki[1], M. Aso[1], R. Monma[1], S. Yang[1], A. Sasaki[1], M. Takagi[1]. [1]*Yamagata University Faculty of Medicine, Orthopedic Surgery,Yamagata city, Japan*

Background: The pharmacotherapy for rheumatoid arthritis (RA) has changed dramatically and caused a paradigm shift with the advent of methotrexate (MTX) and biological disease-modifying antirheumatic drugs (bDMARDs).
Before the paradigm shift of RA therapy, the frequency of carpal collapse was high in patients with RA.
It has been reported that certain numbers of patients with RA rapidly advance the destruction of the carpal bones during the early onset in the natural course of it [1].
Another report showed that hand function was positively correlated with disease activity[2]
In Japan, bDMARDs were approved in 2003, and the maximum allowable dose of MTX was raised from 8 mg/week to 12 mg/week in 2012.
We hypothesize early aggressive therapy for the patients with early RA may have improved outcomes of carpal bone destruction in this last decade.
In this study, we investigated the change of drug therapy and carpal height ratio (CHR) in patients with early RA in the last decade.
Objectives: The aim of this study was to investigate CHR and drugs for the patients with early RA who developed it and started the therapy in 2009, 2014, and 2019.
Methods: Patients with early RA diagnosed in our department in 2009, 2014, and 2019 were included in the study.
The CHR was measured at the first visit and two years later on radiographs of both hands.
The drug history for RA was obtained in the medical records retrospectively.
All statistical analyses were performed with EZR version 1.55.
Results: This study included 43 cases (36 females, 7 males). The number of cases in 2009, 2014, and 2019 was 16, 13, and 14, respectively.
The mean age at the time of initial examination was 55 years (30-72).
There was no significant difference in the mean value of DAS28-CRP at the time of the first visit in each year.
The left hand CHR of initial diagnosis was 0.554 (0.484-0.632), 0.551 (0.490-0.618), and 0.567 (0.517-0.632) in 2009, 2014, and 2019, respectively, with no significant difference.
Two years later, the left-hand CHR was 0.541 (0.475-0.651), 0.549 (0.502-0.617), and 0.562 (0.528-0.591), respectively, with no significant difference.
There was also no significant difference in the amount of change.
The right hand CHR of initial diagnosis was 0.525 (0.475-0.607), 0.539 (0.459-0.589), and 0.557 (0.506-0.635) in 2009, 2014, and 2019, respectively, with no significant difference.
Two years later, the right-hand CHR was 0.532 (0.444-0.627), 0.529 (0.478-0.588), and 0.548 (0.491-0.593), respectively, with no significant difference.
There was also no significant difference in the amount of change.
The DAS28-CRP of initial diagnosis for cases in 2009, 2014, and 2019 was 4.68 (3.11-6.83), 4.19 (1.21-6.15), and 4.23 (2.41-6.38), respectively.
The DAS28-CRP at 2 years after treatment for cases in 2009, 2014, and 2019 was 2.12 (0.96-3.60), 2.25 (1.13-4.81), and 2.04 (0.99-3.45), respectively.
Although DAS28-CRP was improved, there was no significance among the three groups.
The usage rate of MTX was 56.3% in 2009, 76.9% in 2014, and 50% in 2019, with mean doses of 6.2 mg (2-8 mg), 8.6 mg (4-12 mg), and 9.1 mg (4-16 mg), respectively. There was no significant difference in the rate and dosage of MTX use in each year.
bDMARDs were used in one case in 2009, two cases in 2014, and one case in 2019.
Conclusion: In this study, DAS28-CRP showed a trend of improvement in this decade, but there was no obvious improvement in the progression of carpal collapse.
Further early aggressive therapy may be necessary to prevent the destruction of the carpal bones.

AB0182

THE PROFILE OF POOR PROGNOSTIC FACTORS BASED ON EULAR RECOMMENDATIONS IN CHINESE RA PATIENTS: A SINGLE-CENTER OBSERVATIONAL STUDY

Y. Gui[1], Z. Zhang[1], J. Zhao[1]. [1]*Peking University First Hospital, Rheumatology and Clinical Immunology, Beijing, China*

Background: Despite the constant updating of rheumatoid arthritis (RA) treatment strategies, whether poor prognostic factors (PPFs) can guide RA treatment is still controversial. There are limited data about the presence of PPFs in Chinese RA patients.
Objectives: To describe the profile of PPFs based on European League Against Rheumatism (EULAR) recommendations in Chinese RA patients, and explore the significance of these factors in adjusting treatment therapy.
Methods: In this real-world study, RA patients were enrolled from 2012 to 2020. The baseline characteristics and prognostic factors based on EULAR recommendations include acute-phase reactant levels, rheumatoid factor (RF), anti-cyclic citrullinate peptide (anti-CCP antibody), swollen joint counts (SJC), early bone erosions, and responses to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARD) at month 3 or month 6 were collected. Disease activity was assessed by disease activity score of 28 joints-erythrocyte sedimentation rate (DAS28-ESR), DAS28-C-reactive protein (DAS28-CRP), simple disease activity index (SDAI), and clinical disease activity index (CDAI). The association of different factors was represented by a Venn diagram. The number of patients presenting with different combinations of prognostic factors was graphically displayed by UpSetR. Correlation between binary variables was analyzed by the Chi-square test.
Results: 1252 registered RA patients were enrolled. 901/1252 (72.0%) patients had elevated ESR or CRP and 1027/1164 (88.2%) patients had positive RF or anti-CCP antibody. 397/1252 (31.7%) patients had ors was graphicas. 166/444 (37.0%) patients had early bone erosions, which usually coexisted with other PPFs. 394 (34.4%) of the 1105 patients who received csDMARD therapy as prescribed had persistent moderate or high disease activity (MDA/HDA). Failure of two or more csDMARDs was found in 245 (22.2%) patients. 99% of RA patients had at least one PPF. Patients with MDA/HDA usually coexisted with other PPF. MDA/HDA was significantly correlated with elevated ESR/CRP or high SJC and is not correlated with positive RF/anti-CCP antibody or early bone erosion.
Conclusion: PPFs are prevalent in RA patients in real-world data. It is inappropriate to guide treatment strategies just based on the presence or absence of PPFs. The categories of PPFs should be simplified and the role of different combinations of PPFs in guiding treatment therapies remains to be explored.

AB0183 DOWNREGULATION OF TUMOUR NECROSIS FACTOR A GENE EXPRESSION IN CULTURED PERIPHERAL BLOOD MONONUCLEAR CELLS IN THE PRESENCE OF TOFACITINIB PRIOR TO THERAPY AS A PROGNOSTIC BIOMARKER OF CLINICAL REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOFACITINIB

E. Tchetina[1], G. Markova[1], A. Satybaldyev[2]. *[1]Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology, Moscow, Russian Federation; [2]Nasonova Research Institute of Rheumatology, Rheumatoid Arthritis, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial hyperplasia, mononuclear cell infiltration, bone erosion and joint destruction. Recently we have shown that changes in energy generation-related gene expressions in the peripheral blood of tofacitinib (TOFA)-naïve patients with RA are associated with clinical response to treatment [1]. Therefore, considering metabolic status of patients with RA, may be useful for identification of prognostic biomarkers for personal responsiveness to TOFA therapy in TOFA-naïve RA patients by baseline gene expression analysis in peripheral blood mononuclear cells (PBMCs) cultured with TOFA prior to therapy.
Objectives: To examine the association of changes in expression of the genes responsible for cell growth and proliferation [mammalian target of rapamycin, mTOR], bone and articular cartilage resorption [matrix metalloproteinase (MMP)-9, cathepsin K], and inflammation [tumour necrosis factor (TNF)α] in the PBMCs obtained at baseline from patients with RA and cultured with TOFA with therapy outcome.
Methods: 12 patients with RA (median age 55 years), median disease duration 28.5 months (without previous history of therapy with TOFA) were examined. 6 of these patients with RA gained remission after 3 months of TOFA therapy while 6 patients, maintained high and moderate disease activity. Control group consisted of 26 healthy subjects. PBMCs were isolated prior to therapy using Ficoll density gradient and cultured with 10 nM tofacitinib citrate (TOFA) during 48h. Cell viability was monitored with 0.2% Trypan blue staining. Total RNA isolated from these cells was used for mTOR, MMP-9, cathepsin K, and TNFα gene expression studies performed with quantitative real-time RT-PCR.
Results: TOFA was capable of modifying gene expression in cultured PBMCs from the examined patients with RA compared with untreated cells. Baseline expression of all the examined genes was significantly upregulated in cultured with TOFA PBMCs from patients who maintained high and moderate disease activity after TOFA therapy compared with untreated counterparts. In contrast, TNFα gene expression was significantly downregulated in cultured with TOFA PBMCs of patients who gained remission compared with untreated cells. No significant changes in the expression of other examined genes was observed in cultured with TOFA PBMCs from the examined patients with RA who gained remission after TOFA therapy compared with untreated counterparts.
Conclusion: Downregulation of TNFα gene expression in cultured with TOFA PBMCs compared with untreated counterparts in TOFA-naïve patients with RA prior to therapy might serve a prognostic biomarker of personal positive response to TOFA therapy while upregulation in the expression of the same gene suggests non-response to TOFA therapy.

AB0184 IDENTIFYING TRAJECTORIES OF REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED IN A TERTIARY CARE CENTRE

I. Redeker[1,2], N. Gildemeister[1,2], I. Andreica[1,2], D. Kiefer[1,2], X. Baraliakos[1,2], J. Braun[1,2], U. Kiltz[1,2]. *[1]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [2]Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany*

Background: The main goal of treatment for patients (pts) with rheumatoid arthritis (RA) is remission to preserve physical function and prevent radiographic damage. However, less than 50% of pts with early RA have achieved remission in clinical studies and inception cohorts [1]. Little is known about the course of disease and the clinical patterns when remission is tried to be achieved in pts with RA.
Objectives: To identify subgroups with distinct trajectories of DAS28-CRP in pts with RA.
Methods: Longitudinal data from adult RA pts presenting to a tertiary centre were used. Socio-demographic data, disease characteristics and standard assessments including established outcome parameters for disease activity (DAS28-CRP) and physical function (FFbH) were retrospectively analysed. Group-based

RAID (0-10)	6.5 (2.0)	5.3 (2.1)	3.8 (1.9)	1.8 (1.8)	4.6 (1.8)

trajectory modelling (GBTM) was used to identify homogeneous classes of DAS28-CRP trajectories, where the number of classes was selected using Nagin's Bayesian information criterion (BIC). Differences between the identified classes and clinical variables were studied.

Results: Data of 134 pts with 849 DAS28-CRP values were analysed. Retrospective chart data were available for a follow-up of 33.7 (SD 18.0) months. One third of pts already had erosions and severe limitations in physical functioning. About half of the pts were on bDMARDS and <20% on steroids. Five distinct classes of DAS28-CRP trajectories were identified (Figure 1). These groups were subsequently categorized as 1) high-increasing, 2) high-stable, 3) low-increasing, 4) low-decreasing disease activity, and 5) remission. Pts.' characteristics at baseline in each trajectory group are shown in Table 1. Group 4 had a shorter disease duration but more erosions, a better function and a higher educational level than seen in other groups. The increase of disease activity in group 3 was modest.

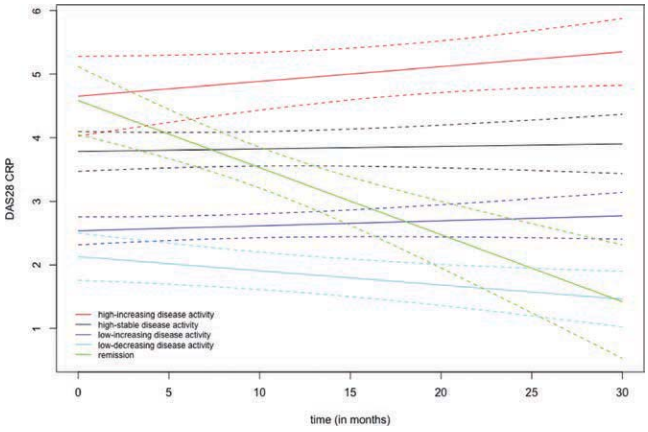

Figure 1. Longitudinal DAS-28-CRP in trajectory groups

Conclusion: Using GBTM five distinct trajectories in pts with RA were identified. Only a small proportion of pts showed a reduction in disease activity over time, whereas the largest proportion of pts showed rather constant high or constant low disease activity. The cohort size may have impacted the modelling and further analyses in larger cohorts are needed. Importantly, even though well established in our hospital it is unclear how consequent the T2T strategy was followed and which intervention was successful to reach remission. The impact of pts global assessment on DAS28 values also needs further study.

PHENOTYPES OF DRUG-FREE RHEUMATOID ARTHRITIS FLARE AND IMPACT OF RESIDUAL SUBCLINICAL ECOGRAPHIC JOINT INJURY IN ACPA POSITIVE AND ACPA NEGATIVE DISEASE

E. Bozzalla Cassione[1,2], S. Grignaschi[1,2], B. Xoxi[1], M. I. Greco[1], T. Luvaro[1], I. Mazzucchelli[2], S. Bugatti[1,2], C. Montecucco[1,2], A. Manzo[1,2]. *[1]IRCCS Policlinico San Matteo Foundation, Rheumatology, Pavia, Italy; [2]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*

Background: The mechanisms of flare across the pathogenic spectrum of RA remain unclear. To what extent RA flare reproduces the dynamics of disease onset or is primarily driven by new dynamics is not known. Furthermore, the hypothesis of a role for circulating auto-antibodies in determining different mechanism behind flare has never been challenged.

Objectives: To evaluate whether RA flare after remission achievement reproduces the phenotype of onset or it is characterized by a different phenotype primarily driven by the pattern of residual joint injury after treatment, in ACPA positive and negative patients.

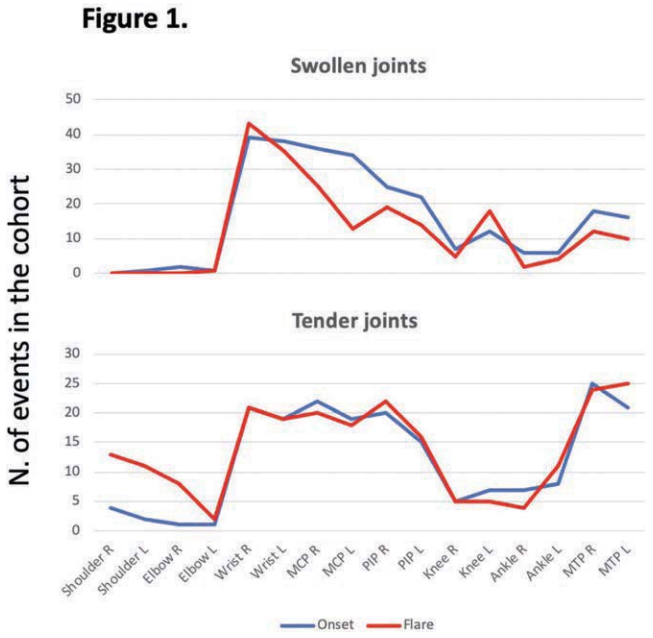
Methods: 53 RA patients, in stable drug-free remission (DFR) after early csDMARDS introduction and displaying clinical flare across 60 months of follow-up were analysed for clinical, laboratory and ultrasound (US) characteristics at diagnosis, treatment discontinuation, and flare (DAS28- and/or physician-based flare). We compared the synovitis clinical phenotype (ACR 1987 criteria defined districts), PROs and the inflammatory status at disease flare versus onset. We then measured the impact of residual subclinical US joint injury (absence of objective synovitis and GS>1 and/or PD>0) at the time of drug discontinuation, on the synovitis clinical phenotype of flare. Finally, we explored differences in the outcomes in ACPA positive and negative RA.

Results: Cohort characteristics are shown in Table 1. As inferred by paired analyses, no significant differences were observed between onset and flare concerning composite indices of disease activity, and subjective/semi-objective domains. However, flare appeared to be significantly less inflammatory in terms of CRP, ESR, SJC, morning stiffness and HAQ ($p<0.05$). These differences remained after adjustment for diagnostic delay including only very early RA patients (<3 months from symptoms' onset). The evaluation of the frequency of articular districts' involvement revealed no difference between onset and flare both for SJC and TJC (Figure 1). However, the percentage of SJs at flare being present at onset showed a high variability among patients. Stratification for ACPA status demonstrated a significantly higher recurrence of synovitis in joints involved at onset in ACPA negative vs ACPA positive patients ($p<0.05$). The percentage of SJs at flare presenting residual subclincal US injury at the time of drug discontinuation was significantly higher in ACPA negative vs ACPA positive patients ($p<0.05$) and negatively correlates with the ACPA titer (R 0.354, $p>0.05$).

Table 1. Comparison between Onset and Flare

	Onset, median (IQR)	Flare, median (IQR)
Sex, female (%)	34 (64)	\
Age at Symptoms onset (yrs)	57 (43-65)	\
Diagnostic delay(months)	3 (2-7)	1.5 (1-2) *
ESR (mm/h)	20.0 (12.0-38.5)	17 (9.00-27.0)§
CRP (mg/dL)	0.640 (0.307-2.11)	0.370 (0.220-1.05) *§
HAQ	0.625 (0.375-1.13)	0.438 (0.125-0.875)
GH	40.0 (26.5-50.0)	40 (30.0-50.0)
PGA	50.0 (27.0-66.5)	49 (20.0-70.0)
EGA	38.0 (27.0-60.0)	40 (30.0-60.0)
SJC/66	7 (4.00-10.0)	4 (3.00-6.00) *§
TJC/68	5 (2.00-10.0)	5 (2.00-11.0)
DAS28-ESR	4.55 (3.29-5.36)	3.98 (3.56-4.61)
DAS28-CRP	3.98 (3.08-4.88)	3.83 (3.00-4.27)
Morning Stiffness (minutes)	60.0 (11.3-90.0)	10 (1.00-30.0) *§

Index: *significant compared to onset, § significant compared to onset considering only VERA



Conclusion: RA flare in patients achieving DFR seems to be less severe in terms of inflammatory markers and synovitis recurrence, despite a similar degree of joint tenderness and patients' perception compared to disease onset. The arthritis phenotype undergoes detectable changes more in ACPA positive than negative patients. The residual subclinical US joint damage seems to drive the localization of synovitis recurrence in ACPA negative more than positive patients, supporting the existence of pathologic differences in the process of disease reactivation in the two groups.

AB0186

IMPROVEMENT OF RADIOGRAPHIC JOINT DESTRUCTION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS IN THE LAST DECADE

D. Saito[1], Y. Takakubo[2], D. Yoshioka[3], R. Monma[1], Y. Wanezaki[1], M. Aso[1], Y. Naganuma[4], H. Oki[3], R. Honma[2], S. Yang[1], A. Sasaki[3], M. Takagi[2]. *[1]Yamagata University Faculty of Medicine, Orthopaedic Surgery, Yamagata, Japan; [2]Yamagata Univ Faculty of Medicine, Rehabilitation & Orthopedic Surgery, Yamagata, Japan; [3]Yamagata Saisei Hospital, Orthopaedic Surgery, Yamagata, Japan; [4]Yamagata Prefectural Central Hospital, Orthopaedic surgery, Yamagata, Japan*

Background: The paradigm shift has caused in the treatment for rheumatoid arthritis (RA) before the last decade [1]. The advent of high-dose MTX and biologics has maked it possible to treat RA with early and aggressive therapy, and prevent the joint destruction [2].
Objectives: To aim of this study, we investigated the joint destruction and clinical outcomes in patients with early RA every 5 years in the last decade.
Methods: 81 patients with early RA (within 1 year from their onset of RA) enrolled retrospectively in this study. The number of patients with early RA were 21 in 2009, 23 in 2014, and 37 in 2019, respectively. They had 17 males and 64 females. Mean age was 59 years (19-92) at the first visit to our department. The following items were investigated: age, disease duration from onset to consultation, anti-cyclic citrullinated peptide antibody (ACPA) positivity (positivity was defined as >4.5 U/ml), CRP, DAS28CRP4, medications, and modified total sharp score (mTSS) at the time of initial consultation and 1 year later. Kruskal-Wallis test was used for statistics (PASW 25 software, SPSS Institute Inc., Chicago, IL, USA, p<0.05).
Results: The ACPA positivity rates were 71.4% (15/21) in 2009, 78.3% (18/21) in 2014, and 78.4% (29/37) in 2019, respectively. The mean value of DAS28CRP4 was 4.7 (2.4-6.8) in 2009, 4.2 (1.2-6.2) in 2014, and 4.2 (2.1-6.7) in 2019 at the time of the first visit to our department respectively. DAS28CRP4 under 2.6 was 29% (6/21) in 2009, 61% (14/23) in 2014, and 54% (20/37) in 2019 1 year after the first visit. The mean improvement of DAS28CRP4 (ΔDAS28CRP4) was -1.2 (-3.9 - 2.1) in 2009, -1.5 (-4.0 - 1.7) in 2014, and -1.7 (-4.1 - 0.4) in 2019, respectively. It had tended to improve gradually, however, it was not significantly different (p= 0.20, Figure 1).

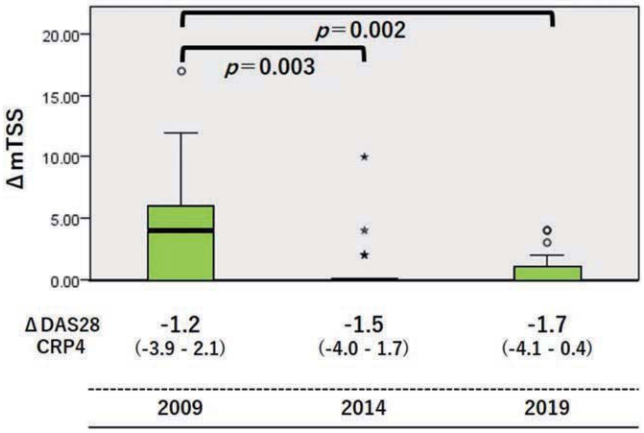

Figure 1. Mean value of improvement of mTSS and DAS28CRP4 (ΔmTSS and ΔDAS-28CRP4) from initial visit to 1 year later at 2009, 2014 and 2019.

The changing of mTSS for a year (ΔmTSS) was 4.2 (0-17) in 2009, 0.9 (0-10) in 2014, and 0.6 (0-4) in 2019, respectivly. ΔmTSS in 2014 and 2019 was significantly lower compared to that in 2009 (p<0.05, Figure 1).
One year after the first visit to our department, the mean dose of MTX increased to 9.2 mg/week (2-14) in 2014 and 8.7 mg/week (4-16) in 2019 compared to 6.6 mg/week (2-8) in 2009 (p=0.19). The mean dose of PSL decreased 4.2 mg/day (1-8) in 2014, and 3.8 mg/day (1-10) in 2019 compared to 4.9 mg/day (2-10) in 2009, respectively (p=0.11). On the other hand, biological DMARDs were introduced in 24% (5/21) in 2009, 13% (3/23) in 2014, and 13% (1/37) in 2019, respectively.
Conclusion: Jonit destruction has been already reported to begin in patients with early-stage of RA [1, 2]. Based on the results of this study, joint desctruction in early RA was decreased in the last decade, because of more early and aggressive therapy for early RA with increasing mean dose of MTX gradually, not biologic DMARDs in real world. In addition, the mean dose of PSL in 2014 and 2019 decreased compared to that in 2009. The intensive therapy for early RA at our hospital has shown the improvement of joint destruction in the last decade.

UNTREATED EARLY RHEUMATOID ARTHRITIS WITH ONSET IN THE YOUNGER (18-49 YEARS) AND OLDER (50 YEARS AND OLDER) AGE ACCORDING TO PRACTICAL HEALTH CARE. COMPARATIVE STUDY

A. Satybaldyev[1], G. Gridneva[2], A. Misiyuk[2], K. Kasumova[3], N. Demidova[3], N. Chichasova[4], E. Nasonov[4]. *[1]FSBI V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Evolution of rheumatoid arthritis, Moscow, Russian Federation; [2]FSBI V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, evolution of rheumatoid arthritis, Moscow, Russian Federation; [3]FSBI V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Clinical Department, Moscow, Russian Federation; [4]FSBI V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Scientifical department, Moscow, Russian Federation*

Background: Comparative characteristics of various clinical manifestations in untreated early rheumatoid arthritis (RA) in younger and older age patients is not sufficiently covered in the literature.
Objectives: To compare the frequency of different clinical manifestations in younger (18-49 years) and older (50 years and older) age patients with early RA who had not received background therapy yet.
Methods: 292 patients (men-65, women - 227, mean age 53.57±16.08 years) with early-stage RA were selected from 5327 patients included in the All-Russian register of patients with arthritis OREL from 01/01/2012 to 31/12-2018. They were studied during the first visit before prescription of background therapy (DMARDs: synthetic, biologics or other targeted drugs and systemic glucocorticoid therapy). 141/227 patients had RA onset at 18-49 years age (group 1): men-25, women-116, mean age (m±SD) 39.27±7.97 years. 151/227 patients had RA onset at 50 years or older age (group 2): men -41, women -110, mean age 66.05±7.34 years. RA was diagnosed according to ACR 1987 and ACR/EULAR 2010 criteria. Disease activity was assessed according to DAS-28 index, radiological stage – Steinbrocker classification, functional disorders - according to functional class (FC).
Results: The male/female ratio in group 1 was 1:4.6, in group 2 - 1:2.8 (p=0.055). Following disorders developed more often in group 2 than in group 1: morning stiffness (82% vs. 59%) (p< 0.05), lesions of small joints of the hands (76% vs. 65%) (p >0.05), wrist joints (65% vs. 52%) (p< 0.05), elbow (33% vs. 17%) (p< 0.05), knee (53% vs. 36%) (p< 0.05), shoulder (44% vs 19%) (p< 0.05), the total number of affected symmetrical pairs of joints (452 vs 285) (p< 0.001). Patients of group 2 showed more pronounced inflammatory process than in group 1: high activity - 66% vs. 35%, respectively (p< 0.05), as well as destructive changes in joints (erosive arthritis - 52% vs. 29%; p< 0.05) and functional disorders (FC 3 - 68% vs. 15%, respectively). RF was detected with equal frequency in both groups (72% vs 72%, respectively; p>0.05), and ACPA was more frequently positive in group 1 (89 vs 78%, respectively; p<0.037).
Conclusion: Comparative study of the clinical characteristics of the natural course of early RA with onset in younger age (18-49 years) and with onset in older age (50 years and older) according to the data of the All-Russian register of patients with arthritis OREL showed that RA with onset in older age is characterized by stronger inflammatory process, destructive and functional disorders in the joints than RA with onset at a younger age.

ULTRASONOGRAPHIC RESIDUAL INTRA-ARTICULAR SYNOVITIS IS MORE SEVERE IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH PREDNISOLONE

T. Okano[1], K. Mamoto[1], Y. Yamada[1], K. Mandai[2], S. Anno[1], M. Tada[3], K. Inui[2], T. Koike[4,5], H. Nakamura[1]on behalf of Osaka City University Rheumatolgy Ultrasoud Group. *[1]Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan; [2]Osaka Saiseikai Nakatsu Hospital, Department of Orthopedic Surgery, Osaka, Japan; [3]Osaka City General Hospital, Department of Orthopedic Surgery, Osaka, Japan; [4]Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [5]Search Institute for Bone and Arthritis Disease, (SINBAD), Wakayama, Japan*

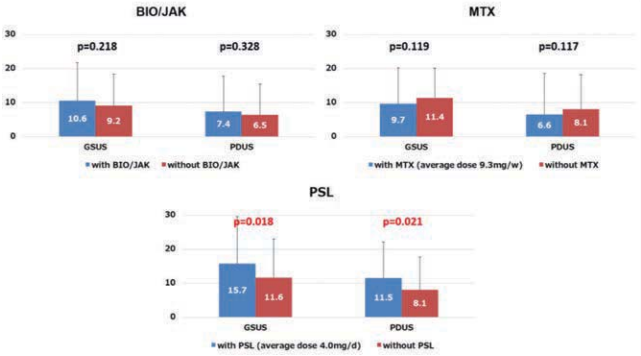
Background: The treatment option including biological DMARDs (BIO) and JAK inhibitor (JAK) was expanded, and the number of patients reached to the

treatment target are increasing in rheumatoid arthritis (RA). On the other hand, it is also true that some patients are still using prednisolone (PSL). Recently, ultrasound has played a role of sensitive imaging modality in the diagnosis and follow-up of patients with RA. It is known that residual synovitis was found in ultrasound even in patients with clinical remission.

Objectives: We investigated the differences of ultrasonographic intra-articular synovitis findings between treatment drugs in patients with RA.

Methods: From January 2017 to August 2020, 750 RA patients who underwent ultrasound examination were included. A US examination was performed at the bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and ulnar) and first to fifth metatarsophalangeal (MTP) joints, by using HI VISION Ascendus (Hitachi Medical Corporation, Japan) with a multifrequency linear transducer (18-6 MHz). The gray scale and power Doppler findings were assessed by the semi-quantitative method (0-3). All patients were divided into with or without BIO / JAK, methotrexate (MTX) and PSL. Then, patients were matched using the propensity score adjusted for gender, age, RA disease duration, disease activity, CRP value, and MMP-3 value. The total gray scale and power Doppler score (GSUS / PDUS) were compared between treatment drugs of RA by using propensity score matching methods.

Results: The average age of 750 RA patients were 64.5 years and an average disease duration of RA was 13.9 years and females were 581 (77.5%). There were 517 patients (68.9%) treated with BIO/JAK and 233 patients treated without BIO/JAK. The 205 patients in each group were matched. GSUS were 10.6±11.1 vs 9.2±10.4 (p=0.218) and PDUS 7.4±9.2 vs 6.5±9.0 (p=0.328). Ultrasound residual synovitis was not different between with or without BIO/JAK in matched patients. There were 525 patients (70.0%) treated MTX, the average MTX dose was 9.3mg, and 225 patients treated without MTX. The 203 patients with or without MTX in each group were matched. GSUS were 9.7±10.6 vs 11.4±12.0 (p=0.119) and PDUS 6.6±8.8 vs 8.1±10.1 (p=0.117). Ultrasound residual synovitis was not different between with or without MTX in matched patients. There were 111 patients (14.8%) treated PSL, the average dose was 4.0mg, and 639 patients treated without PSL. The 105 patients with or without PSL in each group were matched. GSUS were 15.7±13.9 vs 11.6±10.6 (p=0.018) and PDUS 11.5±11.4 vs 8.1±9.6 (p=0.021). Ultrasound residual synovitis was more severe treated with PSL than without PSL in matched patients.



Conclusion: In a comparison between RA patients matched backgrounds such as disease activity, there was no difference in ultrasound residual synovitis between patients with or without BIO/JAK and MTX. However, there was significant difference in patients with or without PSL. This suggests that PSL use suppresses clinical symptoms but does not improve synovitis. Thus, it should be noted that joint destruction may progress in patients treating with PSL.

AB0189 WHAT BIOMARKERS ARE ASSOCIATED WITH LOCAL BONE LOSS AND RISK OF FRACTURES IN RHEUMATOID ARTHRITIS AT LONG-TERM FOLLOW-UP?

P. Kovalenko[1], P. Postnikova[1], I. Dydykina[1], M. Diatroptov[2], S. Glukhova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of evolution of rheumatoid arthritis, Moscow, Russian Federation;* [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology, Moscow, Russian Federation*

Background: Local and generalized bone loss in patients with rheumatoid arthritis (RA) is a manifestation of disease progression or a negative consequence. Various endogenous and exogenous factors have an effect on bone loss.

Objectives: To study the association between the underlying osteoimmunological and immunological RA markers and local bone loss (erosion score) according to the fracture risk.

Methods: There are presented the preliminary results of a prospective long-term research to study the outcomes of local and generalized bone loss in 44 women with rheumatoid arthritis, whose age at baseline was 56.8 ± 6.9 years, the duration of follow-up 8.3 ± 1.5 years. In all patients at baseline and in dynamics serum RF, ACCP, CRP levels were measured by standard methods; serum IL-6, RANKL, CTX-I, osteocalcin and BAP (bone alkaline phosphatase) were measured by ELISA. The immunological control group was composed of healthy donors (n = 12). X-rays of hands and feet were evaluated using the Sharp-Van der Hejde method, in both groups it was observed a significant increase in the erosions score ($p < 0.05$). Bone mineral density (BMD) was measured at lumbar spine (L1-L4) and total hip using dual-energy X-ray absorptiometry (DXA) at baseline and in dynamics (at baseline in all patient by Hologic). The 10-year probability of fractures was measured using the fracture risk assessment tool (FRAX) in 41 (93%) patients. A high risk of fractures was estimated in 25 (61%) patients, a low risk in 16 (39%). Statistical analysis was carried out using standard parametric and non-parametric methods in Statistica. Pearson tests were used for assessing the correlation between serum levels of these molecules and erosion scores in RA.

Results: Over the follow-up period, 12 (48%) patients from high-risk group and 2 (12%) patients of low-risk group has had peripheral fractures ($p = 0.01$). At baseline and in dynamics in the high-risk group it was noted the higher erosion score than in the low-risk group ($p = 0.001$ and $p = 0.002$, respectively), while the delta of erosion between the groups did not significantly differ. The correlation analysis showed that in the high-risk group the erosion score and in dynamics was positively correlated ($p < 0.05$) with the baseline CRP level. In the low-risk group the erosion score was positively correlated ($p < 0.05$) with osteocalcin level (at baseline and in dynamics for both indicators), and the erosion delta was positively correlated with ACCP positivity at the second visit. In the same group, there was a significant positive correlation between the baseline erosion score and CTX-I level in dynamics. No reliable correlation between erosion score and other immunological markers levels was reported.

Conclusion: Preliminary analysis of long-term follow-up results showed an increase in erosion score in the high and low fracture risk groups, and fractures in the high-risk group. Higher baseline CRP values in the high- risk group were associated with a larger count of erosions both initially and in dynamics. The increase in erosion score (delta) in the low-risk group was influenced by ACCP positivity (visit in dynamics) and it was noted that the level of osteocalcin, marker reflecting osteoblast activity, was positively correlated with the erosion score, possibly reflecting remodeling/bone turnover activity.

AB0190 THE LONG-TERM PREDICTORS OF FATIGUE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

D. Santos Oliveira[1,2,3], A. Martins[1,3], B. Samões[4], F. R. Martins[5], F. Oliveira Pinheiro[1,3], M. Rato[1,3], R. Nicolau[6], C. Vaz[1,3], M. Bernardes[1,3], L. Costa[1]. [1]*Centro*

Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; [3]Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal; [4]Centro Hospitalar Vila Nova de Gaia / Espinho, Rheumatology Department, Vila Nova de Gaia, Portugal; [5]Centro Hospitalar Universitário do Algarve, Rheumatology Department, UNIAO FREGUESIAS FARO SE SAO PEDRO, FARO, Portugal; [6]Centro Hospitalar Tondela-Viseu, Viseu, Rheumatology Department, Viseu, Portugal

Background: Fatigue is one of the major complaints of patients with rheumatoid arthritis (RA). However, the literature relating fatigue to other disease-related parameters has presented discrepant results and longitudinal studies with multivariate analyses are scarce.
Objectives: To explore potential associations between fatigue and demographic variables and other patient-reported outcomes (PROMs) in patients with RA treated with biological disease-modifying antirheumatic drugs (bDMARDs) over the time.
Methods: A 24-month (24M) monocentric observational retrospective cohort study was conducted. Patients diagnosed with RA, according to the 2010 American College of Rheumatology (ACR)/ European League Against Rheumatism (EULAR) criteria, and registered on the Rheumatic Diseases Portuguese Register (Reuma.pt) who started their first bDMARD between 2015 and 2021 were included. Age, gender, disease duration, body mass index (BMI) and PROMs were obtained by consulting Reuma.pt. Fatigue was monitored at baseline, 12 and 24M using Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), a 13-item questionnaire with a total score ranging from 0 to 52. A score ≤ 39 indicates the presence of clinically significant fatigue. Health Assessment Questionnaire (HAQ), EuroQol-5D (EQ-5D), 36-Item Short Form Survey (SF-36), patient global assessment visual analogue scale (VAS) and pain VAS were assessed at baseline, 12 and 24M. Multivariate linear regression models were conducted with FACIT-F as the dependent variable.
Results: A total of 40 patients (47.4±11.4 years; 90.2% female) with a BMI of 29.87±8.54 kg/m^2 and a mean disease duration of 10.4±5.6 years were included. A total of 47.5% of patients were treated with an anti-TNF. About 85% of patients had clinically significant fatigue at baseline (FACIT-F 26.9±11.8). At baseline, patient global assessment VAS (β=-0.4, 95%CI [- 0.68; -0.095]) and pain VAS (β=- 0.34, 95%CI [-0.6; -0.068]) predicted fatigue. SF-36 predicted fatigue at baseline (β=0.35, 95%CI [0.14;0.56]), 12M (β=0.23, 95%CI [0.084;0.37]) and 24M (β=0.26, 95%CI [0.13;0.39]). HAQ predicted fatigue at baseline (β=- 12.2, 95%CI [- 19.8; - 4.5]) and 24M (β=- 11.4, 95%CI [- 17.47; - 5.38]). EQ-5D (β=39.5, 95%CI [15.84; 63.22]) predicted fatigue at 24M.
Conclusion: Our results showed that pain levels and patient global assessment of disease activity predicted a higher level of fatigue at baseline. The decrease in physical function and a worse overall health status perceived by patient predicted higher fatigue over the time. Previous research has suggested that disease-related factors, such as inflammation, pain or decreased physical function are associated with greater fatigue in RA (1). These findings encourage the pre-treatment screening of fatigue in patients with RA in order to design individualized non-pharmacological approaches in addition to bDMARDs therapy.

AB0191 OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS: IMPACT ON BIOLOGIC DRUGS TOLERANCE AND SURVIVAL

S. Boussaid[1], K. Saadaoui[1], M. Hassayoun[1], S. Jemmali[1], S. Rahmouni[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]. *[1]Hospital Rabta, rheumatology, Tunis, Tunisia*

Background: Osteoporosis is one of the main comorbidity of RA and leads to an increased risk for fragility fractures, which further impair functional ability, quality of life, and life expectancy. The influence of this condition on the maintenance and survival of biotherapies has rarely been studied.
Objectives: To assess the influence of osteoporosis on efficacy, tolerance, and biologic drugs survival.
Methods: We conducted a cross-sectional and observational study. Files of patients with RA on biologics drugs (archived from the files of patients on the National Health Insurance Fund of Tunis) were studied. Epidemiological characteristics such as age, sex, and comorbidities, were collected. All patients had a bone mineral density measurement. The patients were divided into two groups (a group with G1 osteoporosis and a group without osteoporosis G2). The therapeutic maintenance rate at 12, 24, 36, and 48 months as well as the biologic survival were analyzed using Kaplan-Meier survival curves and compared using the Log-Rank test.
Results: Three hundred and seventy-four files were selected. The average age of our cohort was 55±12.54 years [20-90]. A female predominance was noted with a sex ratio M/F=0.147. The average duration of RA was 11.7±6.76 years [2-41]. Osteoporosis was observed in 78 patients (20.9%). First biogics prescription was: tocilizumab 6% and rituximab 7%, etanercept 54%, adalimumab 14%, certolizumab pegol 13%, infliximab 6%.The maintenance of the first biotherapy was 40.53 [35.64-45.43] in G1 and 41.44 [39.01-43.86] in G2. The biologic survival curve study did not find any significant difference between the two group p= 0.598.
The presence of osteoporosis would increase the risk of stopping biotherapy without being a statistically significant factor (HR = 1.109, p = 0.602)
The therapeutic maintenance of the 1st biotherapy, in the presence of osteoporosis, was on average 40.53 months [35.64-45.43].
Conclusion: Osteoporosis has not hitherto been retained as a determining factor in therapeutic maintenance (1), as was indeed the case in our study. Nevertheless, screening and early management of osteoporosis are necessary since it alone constitutes a risk factor for mortality.

AB0192 ANTIBODIES AGAINST MODIFIED PROTEIN/PEPTIDE SPECIFICITIES IN RECENT-ONSET PALINDROMIC RHEUMATISM MAY DETERMINE THE EVOLUTION TO RHEUMATOID ARTHRITIS

C. García-Moreno[1], R. Morlà[2], B. Frade-Sosa[2], L. Tobalina[1], M. J. Gomara[1], R. Sanmartí[2], I. Haro[1]on behalf of PALABA study investigators.. *[1]Institute of Advanced Chemistry of Catalonia (IQAC-CSIC), Unit of Synthesis and Biomedical Applications of Peptides., Barcelona, Spain; [2]Hospital Clinic de Barcelona, Arthritis Unit. Department of Rheumatology, Barcelona, Spain*

Background: Palindromic rheumatism (PR) may evolve to rheumatoid arthritis (RA), particularly in patients with autoantibodies such as rheumatoid factor (RF) or antibodies against modified proteins (AMPA), anti-citrullinated peptide antibodies (ACPA) or anti-carbamylated antibodies (anti-CarP) (1,2). We hypothesized that the specificities and isotype usage of ACPA and anti-CarP may differ between recent-onset PR and established RA, and this could help ascertain the evolution to RA in PR patients.
Objectives: To determine differences in the recognition of epitopes between patients with recent-onset PR and established RA by analysis of AMPA specificities and isotypes.
Methods: Subanalysis using preliminary data of the PALABA study. Two populations included: patients with recent-onset PR include in the PALABA multicenter randomized clinical trial (abatacept vs hydroxychloroquine) at study entry (NCT03669367) and patients with established RA (ACR/EULAR 2010) as controls previously selected from an observational study(3). Only RF and/or ACPA (CCP2) positive patients were selected. PR patients were DMARD naïve and RA patients receiving rituximab or abatacept were excluded. AMPA specificities and isotypes in sera were determined by in-house ELISA tests using as antigens two carbamylated proteins and a panel of chimeric peptides derived from fibrin and filaggrin proteins bearing one to three post-translational modifications (citrullination, carbamylation and acetylation) (4). The cut-off for ELISA tests was established by ROC curves, with a specificity of 95% compared with a healthy population. The frequency and titers of the AMPA isotypes (IgA,IgG,IgM) was analyzed.
Results: 45 PR patients (77.6% female), with a mean age of 49.3 (±11) years and a mean disease duration of 9.6 (±6.1) months and 125 RA patients (75.6%

Table 1. Anti-CarP autoantibody status in RA vs PR patients.

		RA (n 125)	PR (n 45)	p value
Fetal calf serum carbamylated (FCS-CarP)	anti-FCS-CarP-IgG positive,n (%)	78 (62.4)	14 (31.1)	<0.005
	median titer, AU/mL (IQR)	238 (571)	75 (249)	<0.005
	anti-FCS-CarP-IgA positive,n (%)	41 (32.8)	2 (4.4)	<0.005
	median titer, AU/mL (IQR)	161 (308)	14 (97)	<0.005
	anti-FCS-CarP-IgM positive,n (%)	30 (24.0)	5 (11.1)	NS
	median titer, AU/mL (IQR)	90 (165)	32 (101)	<0.005
Fibrinogen carbamylated (Fib-CarP)	anti-Fib-CarP-IgG positive,n (%)	87 (69.6)	9 (20)	<0.005
	median titer, AU/mL (IQR)	249 (304)	70 (104)	<0.005
	anti-Fib-CarP-IgA positive,n (%)	25 (20.0)	10 (22.2)	NS
	median titer, AU/mL (IQR)	0 (76)	36 (72)	<0.005
	anti-Fib-CarP-IgM positive,n (%)	33 (26.4)	8 (17.8)	NS
	median titer, AU/mL (IQR)	82 (117)	57 (84)	NS
Chimeric fibrin/ filaggrin homocitrullinated peptide (CFFHP)	anti-CFFHP-IgG positive,n (%)	54 (43.2)	10 (22.2)	<0.05
	median titer, AU/mL (IQR)	9 (227)	0 (12)	<0.005
	anti-CFFHP-IgA positive,n (%)	20 (16.0)	1 (2.2)	<0.05
	median titer, AU/mL (IQR)	0 (5)	0 (0)	NS
	anti-CFFHP-IgM positive,n (%)	14 (11.2)	2 (4.4)	NS
	median titer, AU/mL (IQR)	0 (7)	0 (0)	<0.05

females) with a mean age of 59.6 (±13) years and a mean disease duration of 77.2 (±59.7) months. RF and ACPA (CCP2) were positive in 80% and 91.1% of PR patients and 77.6% and 88% of RA patients (p>0.05). Although both populations presented a similar frequency of RF and ACPA(CCP2), PR patients had fewer AMPA specificities than RA patients. The differences were statistically significant for two IgA ACPA antigens (doubly citrullinated/homocitrullinated peptides) and most anti-CarP specificities and isotypes (Table).

Conclusion: The immune response against post-translational modified peptides/proteins has a lower frequency and less isotype usage in PR for some AMPA specificities in comparison with RA. The absence of IgA ACPA isotypes and, especially, anti-CarP in the early stages of PR may be associated with a lower rate of progression to RA.

AB0193 BIOLOGIC DRUGS RETENTION IN ELDERLY RHEUMATOID ARTHRITIS: WHAT FEATURES?

S. Boussaid[1], K. Saadaoui[1], S. Jemmali[1], M. Hassayoun[1], S. Rekik[1], S. Rahmouni[1], H. Sahli[1], M. Elleuch[1]. [1]*Hospital Rabta, rheumatology, Tunis, Tunisia*

Background: The elderly RA population is expanding. The management of RA in elderly patients can be challenging because of comorbidities, the frequency of adverse events. The efficacy and safety of RA therapies; particularly biologics drugs (bDMARDs); are poorly studied in this age group.

Objectives: To investigate the therapeutic response to bDMARDs in elderly rheumatoid arthritis.

Methods: We conducted a cross-sectional and observational study. Files of patients with RA on biologics drugs (archived from the files of patients on the National Health Insurance Fund of Tunis) were studied. The characteristics of RA, and the current treatments were studied. We have divided our population into two age groups. G1 aging under 65 years and G2 aged 65 or over. The therapeutic maintenance rate as well as the biologics survival was analyzed using Kaplan-Meier survival curves and compared using the Log-Rank test.

Results: Three hundred and seventy-four files were selected. Their average age was 55±12.54 years [20-90]. A female predominance was noted with a sex ratio M/F=0.147. The average duration of RA was 11.7±6.76 years [2-41]. Subjects over the age of 65 represented 22.2% of the workforce, i.e. 83 patients. The first biotherapy prescribed was etanercept in 54% of cases, adalimumab in 14% of cases, certolizumab pegol 13%, infliximab 6%, tocilizumab 6% and rituximab in 7% of cases. The 4-year survival was 54.41% and 60.94% for subjects under 65 and 65 or older, respectively. Treatment maintenance for RA in the elderly (≥ 65 years old) was 42.21 months, [53.51–46.92]. In our study, age did not influence the survival of biologics with a Hazard Ratio (HR) = 0.997 (p=0.667).

Conclusion: RA therapy is generally effective and safe in elderly patients. We did not find any influence of age on survival and therapeutic maintenance of biological treatments. Further studies with a broader spectrum are needed to better understand this notion

AB0194 VALIDATION OF ANDROID OPERATED SMARTPHONE PEDOMETER IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. R. Wagner[1], R. B. Gregersen[1], L. Henriksen[1], E. M. Hauge[2,3], K. K. Keller[2,3]. [1]*Aarhus University, Department of Electrical and Computer Engineering, Aarhus, Denmark;* [2]*Aarhus University, Department of Clinical Medicine, Aarhus, Denmark;* [3]*Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*

Background: Impact of disease and disease activity in RA is measured with questionnaires such as the health assessment questionnaire (HAQ) or composite scores such as the disease activity score (DAS-28). These methods may miss signs of disease activity because they are typically performed only at hospital visits. Measuring physical activity continually may assist in the early discovery of relapses in the future. In addition, measuring physical activity may be relevant for predicting the risk of developing comorbidities such as cardiovascular disease [1]. Activity tracker devices have been tested in RA patients for this purpose, but the disadvantage is that they can only be carried for a limited period of time and are expensive, which makes them unsuitable for long-term cohort studies [2]. As an alternative, obtaining physical activity data from the patient's own smartphone using a dedicated and secure activity tracker app incurs no added costs, but the reliability of this method has never been tested in patients with RA.

Objectives: The aim of this study was to validate the use of the standard Android-operated smartphone step-counter pedometer in patients with RA.

Methods: Clinical characteristics were obtained. Two typical Android smartphones running the Android virtual step counter sensor were tested in a treadmill test-bed setup at 6 different speeds, ranging from 2.5 km/h to 5 km/h. Patients walked 100 steps at each test speed wearing the Android devices placed in a stomach pouch. Software running on a Windows PC communicated in real time with both phones, and the PC software also allowed the investigator to easily record the manually observed steps using clicker functionality, which were then automatically linked to the steps recorded from the smarthphones.

Results: Median (interquartile range) disease duration was 13 (4-21) years, DAS-28 2.2 (1.6-2.9), and MHAQ 0.2 (0-0.9). Seventy-six % of the patients were rheumatoid factor positive, 75% were Anti-citrullinated peptide antibody positive, and 70% had erosive disease.

The overall difference in device step counts versus the observed was 5.9% mean average percentage error for both devices. Most of the error was introduced at the 2.5 km/h speed tests where the mean error of the two devices was 18.5%. From 3 km/h, the mean average percentage error of the two devices was below 5% and from 3.5 km/h and up the mean average percentage error of the two devices was below 3%. A box plot of the data is demonstrated in Figure 1.

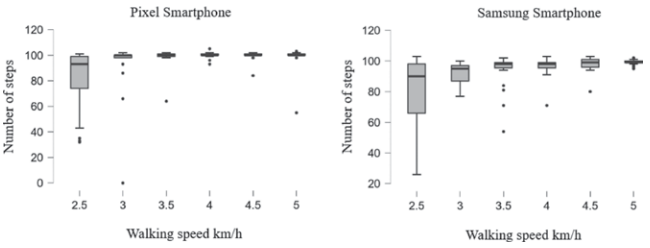

Figure 1. Box plot of number of steps with both devices at the six different speeds.

Both walking speed and walking cadence had a significant impact on the pedometer validity, as both speed and cadence were negatively correlated to the absolute percent error measured by both devices (p<0.001), which indicates, that the greater the speed and/or cadence, the lower the step counting error rate.

Conclusion: The two tested Android pedometer applications were valid in patients with rheumatoid arthritis, but walking with very low speed may represent a challenge. Next step will be field tests evaluating the setup including active measured time in patients with rheumatoid patients.

AB0195 PLATELET TO LYMPHOCYTE RATIO: A BIOMARKER OF STRUCTURAL DAMAGE IN RHEUMATOID ARTHRITIS

F. Maatoug[1,2], M. Slouma[2,3], R. Dhahri[2,3], O. Beskri[2,3], I. Gharsallah[2,3], L. Metoui[2,3], B. Louzir[2,4]. [1]*Military hospital of Tunis, Department of Radiology, Tunis, Tunisia;* [2]*University of Tunis El Manar, Faculty of Medicine of Tunis, Tunis, Tunisia;* [3]*Military hospital of Tunis, Department of Rheumatology, Tunis, Tunisia;* [4]*Military hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia*

Background: A regular monitoring of structural damage in patients with rheumatoid arthritis (RA) is necessary to adjust the treatment. However, the rhythmicity of new radiographs to assess the structural damage is not codified. There is no biomarker able to reflect structural damage.
Objectives: Our study aimed to assess the relationship between the modified Sharp score and the platelet to lymphocyte ratio.
Methods: We performed a cross-sectional study including 53 patients with RA. A cell blood count was performed for each patient, and PLR was calculated. Modified Sharp score and its components (erosion score and joint space narrowing score) were evaluated using the radiograph of hands and feet.
Statistical analysis was performed using SPSS (Statistical Package for Social Sciences).
Results: Of the 53 patients, 39 were female (Sex Ratio: 2.8). The mean age was 53.9 ± 12.7 years. The mean age of the onset of the disease was 43.8±13.5 years. The mean disease duration was 10.1 ± 8.2 years. The mean DAS 28-ESR score was 4.64 ± 1.23.
The mean value of PLR was 161.62 ± 86.59. The mean modified Sharp score was 46.33 ± 37.74. Thirty-two percent of patients had a modified Sharp score greater than 50. The mean scores of joint erosion and joint space narrowing were 12.76 ± 15.05 and 33.57 ± 25.80.
Modified Sharp score was correlated to the PLR (r: 0.501; p <10-3).
Moreover, joint space narrowing score and joint erosion score were correlated to the PLR (r: 0.558; p <10-3 and r: 0.299; p: 0.033, respectively).
Patients with a modified Sharp score ≥ 50 had a higher PLR (203.12 ± 101.71 versus 142.33 ± 74.07).
As shown in Figure 1, the ability of PLR to distinguish patients with a modified Sharp score ≥ 50 was good with an AUC of 0.704 (p= 0.021) with a cut-off of 130.5 (sensitivity=75%, specificity=65.7%).

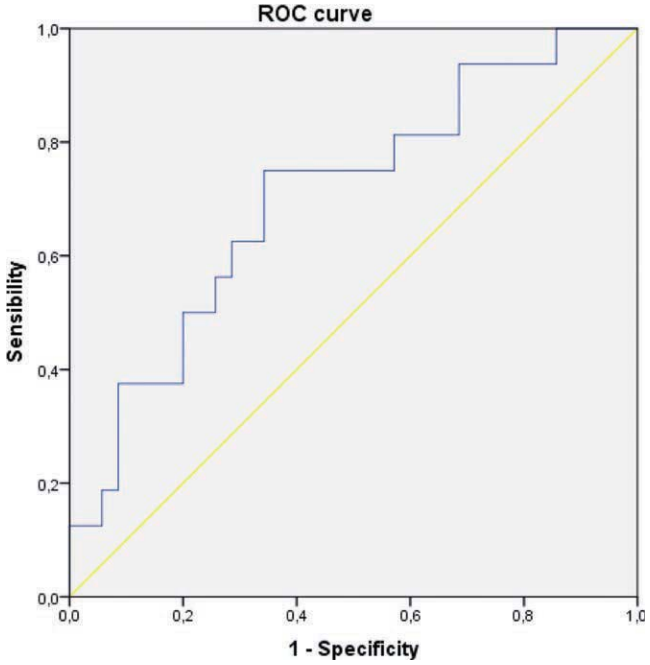

Figure 1. ROC curve assessing the ability of PLR to distinguish patients with a modified Sharp score ≥ 50

Conclusion: Our study showed that the modified Sharp score correlated with PLR, which can be useful to distinguish patients with severe structural damage with a cut-off of 130.5. This finding suggests that this ratio is a reliable marker to reflect radiographic joint damage.

AB0196

ABATACEPT VERSUS HYDROXYCHLOROQUINE IN PALINDROMIC RHEUMATISM: A MULTICENTER RANDOMIZED CLINICAL TRIAL (PALABA STUDY): TRIAL DESIGN AND PATIENTS CHARACTERISTICS

B. Frade-Sosa[1], R. Morlà[1], L. Tobalina[1], C. Perez-Garcia[2], I. Haro[3], R. Sanmartí[3]on behalf of PALABA study investigators. [1]*Hospital Clinic de Barcelona, Arthritis Unit. Department of Rheumatology, Barcelona, Spain;* [2]*Hospital Del Mar, Rheumatoloy, Barcelona, Spain;* [3]*Institute of Advanced Chemistry of Catalonia (IQAC-CSIC),, Unit of Synthesis and Biomedical Applications of Peptides., Barcelona, Spain*

Background: Many patients with palindromic rheumatism (PR), mainly those with positive autoantibodies, evolve to rheumatoid arthritis (RA). Management of PR is empirical, and hydroxychloroquine (HCQ) is the most used antirheumatic drug. Abatacept (ABA) has been investigated in preclinical RA with good results. There are no randomized clinical trials in PR.
Objectives: To present the design of a randomized clinical trial in PR (PALABA study). To describe the characteristics of the patients at study entry. The main objective is to test the hypothesis that ABA can reduce the progression of RA in seropositive (ACPA+ and/or RF+) PR patients in comparison with HCQ.
Methods: Phase IV multicenter open label randomized controlled clinical trial with 42 months duration. The enrollment period was 18 months and the open randomized period 24 months. Fourteen spanish centers were included. The sample size was 70 patients (35 per arm). ABA sc 125mg/week first year, 125mg eow second year and HCQ oral 5mg/Kg daily were administered, both therapies in monotherapy. The main inclusion criteria were age >18 years with PR according to Guerne and Weissman modified criteria and disease evolution >3 and <36 months. Positive ACPA (ELISA or chemiluminescence (CCP2) and/or RF tests are required. Patients with arthritis in ≥1 joint >1 week at baseline, with criteria of other rheumatic diseases, radiographic erosions or previous antirheumatic therapy with synthetic DMARDS were excluded. The main outcome measure is achievement of RA classification criteria (EULAR/ACR 2010) at any time during the 24-month follow-up. Secondary outcomes were the number and intensity of joint attacks, adverse events, and effects on serum ACPA and anti-carbamylated antibodies at 0,3,12,24 months of follow-up. STATISTICS: Modified Full Analysis Set and Per Protocol Population analysis.
Results: Patient one was included in June 2018. The inclusion period has been extended until April 2022 due to low recruitment rates, partly due to the COVID-19 pandemic. As of 15 Jan 2022, 51 patients have been randomized and 49 (37F/12M) have received at least one drug dose. The mean onset of symptoms was 9.9±6.3 months. In 22 patients the follow-up time was greater than 12 months. RF and ACPA (CCP2) were positive in 81.6% and 89.8% of patients respectively; 24 patients were included in the ABA arm and 25 in the HCQ arm. Seven patients withdrew from the study during follow-up due to: progression to RA (n=3), adverse events (n=2) and other reasons (n=2). The demographic, clinical and laboratory characteristics of PR patients at study entry are shown in Table 1. No significant differences in patients' characteristics between arms were observed at enrollment except a higher prevalence of CCP2 in the HCQ arm.

TABLE 1 Baseline demographic, clinical and laboratory characteristics at study entry

Age, mean (sd)	*49.6 (11.2)*	*49.8 (12.0)*	*49.4 (10.7)*	*NS*

PIP: proximal interphalangeal MCP: metacarpophalangeal

Conclusion: We present the design of the first randomized clinical trial in PR of the efficacy of antirheumatic drugs (ABA vs HCQ) to avoid progression towards RA in patients with a high risk (recent onset PR and positive autoantibody status) of persistent arthritis. The characteristics of patients included until now are similar to those reported in recent onset PR.

AB0197 **RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND CERVICAL SPINE INVOLVEMENT**

N. Bahaz[1], F. Mechid[1], C. Makhloufi-Dahou[1]. [1]*Mohamed Lamine Debaghine hospital, Rheumatology, Algiers, Algeria*

Background: The prevalence of cervical spine involvement in rheumatoid arthritis (RA) varies between 17 and 86%. Cervical spine involvement is in third place after hand-wrist and foot involvement. The activity of RA is manifested by inflammation of all joints.
Objectives: To study the characteristics of patients with rheumatoid arthritis and research a relationship between cervical spine involvement and disease activity in rheumatoid arthritis.
Methods: We conducted a multicenter, prospective, descriptive, cross-sectional study in 300
patients with RA between 2013-2018. We collected demographic data, Body mass index (BMI), disease duration, Disease Activity Score of 28 joints (DAS28), (Health Assessment Questionnaire (HAQ), CRP, ESR, the rheumatoid factor (RF), ACPA. A radiological assessment of the cervical spine was requested for all patients, including a radiograph of the cervical spine from the front with the mouth open, a neutral profile, and dynamic flexion and hyperextension views. The activity of RA was assessed by DAS28. We study the relationship between cervical spine involvement (CSI) and disease activity in RA.
Results: 80, 3% were female), sex ratio H/F) was 0,24, the mean age was 51, 17±12,68 years, the BMI was 26,11±5,25, 67, 66 % had comorbidities, the most frequent were osteoporosis (30%), obesity (24%), hypertension (21,7%). RA mean duration was 13±9 years, mean DAS 28 was 4,68±1,5 mean HAQ was 1,01±0,69, mean CRP was 15,50 ±12 mg/L, mean ESR was 41,89 ±26,8mm, rheumatoid factor was positive in 70,6% and ACPA were positives in 77,3%. The standard radiographs of cervical spine found 53 (17, 66%) patients with CSI The various lesions of the cervical spine were atlantoaxial subluxations 13%, 3,66% of lateral atloïdo-axoïd subluxations, vertical subluxations in 0,66%, C1C2 arthropathies in 2,33% spondylolisthesis in 2%, and 0,33% of spondylodiscitis. The results of the univariate and multivariate analysis did not find a relationship between CSI and DAS28A (p=0, 66).
Conclusion: Cervical spine involvement in rheumatoid arthritis was common in our study. We did not find a relationship between cervical spine involvement and disease activity in rheumatoid arthritis.

AB0198 **BASELINE FUNCTIONAL CAPACITY IN RHEUMATOID ARTHRITIS PREDICTS SUBCLINICAL ATHEROSCLEROSIS ON FOLLOW-UP**

M. A. Balderas-Palacios[1], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], A. B. Rodriguez-Romero[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[1], N. Guajardo-Jauregui[1], A. Cárdenas[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Reumathology, Monterrey, Mexico;* [2]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: The main cause of death in patients with rheumatoid arthritis (RA) is due to cardiovascular disease1. Cardiovascular mortality is strongly associated with the cumulative severity of the disease. Functional disability, as measured by the Health Assessment Questionnaire (HAQ), has been used to predict premature mortality in RA2. There are no studies relating its baseline score to the development of subclinical atherosclerosis by carotid ultrasound.
Objectives: To determine whether baseline HAQ score is an independent factor for the development of subclinical atherosclerosis assessed by carotid ultrasound.
Methods: Prospective, observational study. Patients with a diagnosis of RA who met ACR/EULAR 2010 criteria and who were recruited at the Cardio-Rheumatic Clinic in 2014-2015 were included. Patients underwent a clinical history and physical examination and completed the HAQ. The presence of subclinical atherosclerosis was identified by carotid Doppler ultrasound at the end of follow-up. Subclinical atherosclerosis was defined by the presence of carotid plaque or carotid intima-media thickness (c-IMT) ≥0.8mm. Distribution was assessed with the Kolmogorov-Smirnov test. Correlation between cIMT value and baseline HAQ score was determined using Spearman's correlation coefficient. Binary logistic regression was used to determine the independent factor for the development of subclinical atherosclerosis.
Results: A total of 48 patients were followed up. The median follow-up was 4.5 years (4.3-4.9). The baseline characteristics of the patients are shown in Table 1. A correlation was found between the GIMc value and the baseline HAQ score statistically significant (r=0.625, p=<0.001). In multivariate analysis that included scales to assess disease activity (DAS28-CPR, DAS28-ESR, CDAI, HAQ) and disease duration, and HAQ score was found to be an independent factor with MR 5.94 95% CI (1.65-21.41) (p=<0.001). DAS28-CRP with MR 1.52 95% CI (0.39-5.87), DAS28-ESR MR 0.27 95% CI (0.05-1.41), CDAI with MR 0.66 95% CI (0.82-1.12), disease duration 0.32 95% CI (0.07-1.49), but these were not statistically significant.

Table 1. Baseline characteristics.

	Basal (n=48)
Age, years ± SD	55.8 ± 9.7
Female, n (%)	44 (91.7)
Disease duration, years (IQR)	9.5 (4.3-16.5)
DAS28-ESR ± SD	4.4 ± 1.2
DAS28-CPR ± SD	3.3 ± 1.1
CDAI ± SD	13.0 ± 10.2
HAQ, (IQR)	0.87 (0.25-1.25)
HT, n (%)	19 (39.6)
DM, n (%)	2 (4.2)
Active tabaquism, n (%)	4 (8.3)
Obesity, n (%)	19 (39.6)
BMI, kg/m^2 ± SD	29.1 ± 4.6
Methotrexate, n (%)	40 (83.3)
Glucocorticoids, n (%)	30 (62.5)

DAS28, disease activity score using 28 joints; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; CDAI, clinical disease activity index; HAQ, Health Assessment Questionnaire; HT, hypertension; DM, diabetes mellitus; BMI, body mass index.

Conclusion: Our data show that at 4.5 years of follow-up, baseline HAQ score is a significant independent predictor of the presence of subclinical atherosclerosis by carotid ultrasound in patients with rheumatoid arthritis.

AB0199 **RELATIONSHIP BETWEEN EXERCISE AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS**

A. N. Garza-Cisneros[1], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], A. B. Rodriguez-Romero[1], M. A. Balderas-Palacios[1], A. Garcia-Heredia[2], N. Guajardo-Jauregui[1], A. Cárdenas[1]. [1]*Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico;* [2]*Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Cardiology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune, inflammatory disease in which cardiovascular disease is the leading cause of death (1). Exercise has been shown to have certain benefits in chronic diseases such as RA, decreasing symptoms and disease activity (2).
Objectives: To correlate exercise and minutes of physical activity performed per week with the disease activity level in a Mexican RA population.
Methods: This was a cross-sectional study in which a total of 240 Mexican patients with a diagnosis of RA were included. They were divided into two groups (120 in each): those who self-reported performing at least 30 minutes of exercise 3 or more times per week and were matched with patients who did not perform it by age, gender, and comorbidities. The disease activity level was determined with Disease Activity Score 28-joint erythrocyte sedimentation rate (DAS28-ESR) and Disease Activity Score 28-joint C-reactive protein (DAS28-CRP).
Distribution was evaluated with Kolmogorov-Smirnov. Comparisons with Chi-square test, Student's t-test, and Mann-Whitney U test. Correlation between disease activity level and minutes of exercise per day with Spearman-rho coefficient.
Results: DAS28-ESR was significantly higher in patients who did not exercise [4.024 (3.08-5.31) vs 4.73 (3.6-54.82), *p=0.*006]. DAS28-CRP had similar trend [2.76 (1.89-4.14) vs 3.51 (2.28-4.63), *p=0.*004] (Table 1).
The Spearman-rho coefficient showed a significant correlation between the minutes of exercise performed per week and DAS28-ESR (rho=-0.193, *p=0.*003) and DAS28-CRP (rho=-0.207, *p=0.*001) (Figure 1). A multivariate analysis was performed in which minutes of exercise performed per week, treatment, and comorbidities were included, showing an independent association between

minutes of exercise performed per week and the disease activity level assessed by DAS28-ESR (B=-0.001, 95% CI= -0.002- -0.0003, *p=0.*011) and DAS28-CRP (B=-0.001, 95% CI= -0.002- -0.0003, *p=0.*011).

Table 1. Demographic characteristics of the patients.

Characteristics	RA patients who exercise (n=120)	RA patients who do not exercise (n=120)	Value of *p*
Age, mean ± SD	54.4±8.1	54.5±8.2	NS
Female gender, n (%)	106 (88.3)	106 (88.3)	NS
Obesity, n (%)	23 (19. 1)	31 (25.8)	NS
T2DM, n (%)	15 (12.5)	12 (10.0)	NS
Hypertension, n (%)	30 (25.0)	24 (20.0)	NS
Dyslipidemia, n (%)	39 (32.5)	34 (28.3)	NS
Methotrexate, n (%)	93 (77.5)	107 (89.1)	**0.015**
bDMARD, n (%)	6 (5)	5 (4.1)	NS
Glucocorticoid, n (%)	61 (50.8)	74 (61.6)	NS
Minutes of exercise per week, median (p25- p75)	180 (150-300)	0	-
DAS28ESR, median (p25-p75)	4.024 (3.08-5.31)	4.73 (3.6-54.82)	**0.006**
DAS28CRP, median (p25-p75)	2.76 (1.89-4.14)	3.51 (2.28-4.63)	**0.004**

RA, rheumatoid arthritis; NS, not significant; T2DM, type 2 diabetes mellitus; bDMARD, biological disease-modifying anti-rheumatic drugs; DAS28, Disease Activity Score 28-joints; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein.

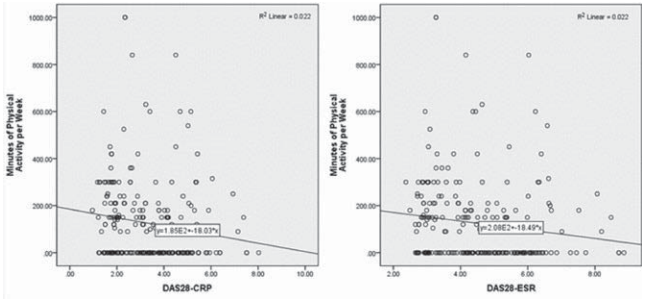

Figure 1. Correlation between exercise time and disease activity level in RA.

RA, rheumatoid arthritis; DAS28, Disease Activity Score 28-joints; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein.

Conclusion: Mexican RA patients who exercise presented lower levels of disease activity. Emphasis should be placed on their practice to improve the patients' symptomatology.

AB0200 COMPARISON OF TREATMENT AND DISEASE ACTIVITY OF BETWEEN EORA AND YORA PATIENTS IN A NATIONWIDE DATABASE OF RHEUMATOID ARTHRITIS IN JAPAN "NINJA"

T. Matsui[1], S. Tohma[2]. *[1]National Hospital Organization Sagamihara National Hospital, Rheumatology, Sagamihara, Japan; [2]National Hospital Organization Tokyo National Hospital, Rheumatology, Tokyo, Japan*

Background: Elderly-onset rheumatoid arthritis (EORA) has different characteristics from younger-onset RA (YORA), however, few reports have conducted large-scale and long-term comparisons of treatment and disease activity between EORA and YORA.

Objectives: To compare the changes in treatment and disease activity of between EORA and YORA patients and to examine the characteristics of patients who achieved remission between them using data of a real-world database in Japan.

Methods: Analysis was performed using data from 2010, 2013, 2016, and 2019 of the National Database of Rheumatic Diseases in Japan (NinJa). Patients were grouped according to age of disease onset into G1: <65 years (divided into G1a <65 years and G1b ≧65 years by the age at analysis), G2: 65-74 years, and G3:≧75 years.

Results: MTX usage rate decreased over time in G2 (58.3% in 2013→55.1% in 2016→54.4% in 2019) and G3 group (41.1→39.5→37.9%). Biologics/JAKi usage rate increased (G1b:24.4→28.2→ 33.3%, G2:19.1→20.3→23.7%, G3:12.3→14.5→19.1%) and steroid usage rate decreased (G1b:49.1→41.8→35.1%, G2:42.2→36.8→29.5%, G3:50.9→45.9→39.2%) in all groups. TNFi usage rate decreased (G1b:19.5→18.0→17.3%, G2:15.4→ 14.1→12.7%, G3:6.2→4.3→5.1%) but IL-6i usage rate increased (G1b:5.2→7.4→9.5%, G2:4.1→4.3→5.9%, G3:2.7→3.4→3.3%) except for the G3 group. CTLA-4Ig usage rate also increased (G1b:3.7→5.3→6.7%, G2:2.7→5.5→5.9%, G3:3.6→6.5→8.1%) in all groups.

The SDAI remission rate was increased over time in all groups (G1a:34.4→41.2→44.6%, G1b:25.1→31.4→35.2%, G2:33.1→37.1→42.2%, G3:30.0→35.9→39.3%) and EORA showed similar rate of remission with YORA. In the analysis stratified by SDAI using NinJa 2019, the positive rate of RF and ACPA decreased (ex RF. G3: 71.0→64.5→53.2%, ACPA. G3: 66.4→56.2→46.5%) and the proportion of male increased (ex G3: 23.0→30.3→35.1%) as the disease activity decreased (moderate / high → low → remission) in all groups. Also, the proportion of patients using two or more DMARDs decreased (ex G3: 43.8→35.2→22.4%) and the usage rate of steroid decreased (ex G3:52.5→37.9→30.2%). Furthermore, in a comparison of remission patients in each group, MTX usage rate (G1b:62.9→G2:61.7→G3:40.9%) and biologics/JAKi usage rate decreased (32.5→23.6→15.3%) as the age of onset increased, but the steroid usage rate increased (20.3→20.6→30.2%).

Conclusion: Disease activity improved over time, regardless of age of onset. EORA showed the same remission achievement rate as YORA, but the treatment content of those who achieved remission differed greatly depending on the age of onset.

AB0201 INTAKE OF FISH RICH IN N-3 POLYUNSATURATED FATTY ACIDS IS ASSOCIATED WITH GOOD RESPONSE TO TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING TARGETED THERAPIES.

M. Tarumi[1], O. Amengual[1], Y. Fujieda[1], M. Navidad Fuentes[2], N. Tsuchida[1], M. Yasuda[1], K. Nishino[1], Y. Kosumi[1], S. Takeyama[1], M. Yoshimura[1], K. Ninagawa[1], K. Aso[1], M. Kono[1], M. Kato[1], R. Cáliz Cáliz[2], T. Atsumi[1]. *[1]Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Sapporo, Japan; [2]Hospital Virgen de las Nieves, Department of Rheumatology, Granada, Spain*

Background: The management of rheumatoid arthritis (RA) has been transformed by the use of molecular targeted therapies. Early treatment and treat-to-target approach leads to good clinical response and remission (responders), but not in all patients.

Environmental factors including diet contribute to the development, activity and severity of RA. Evidence from clinical trials suggested that dietary interventions, such as Mediterranean diet or supplementation with fish oil rich in n-3 polyunsaturated fatty acids (n-3 PUFA), have positive effects on RA. Japanese and Mediterranean diets are associated with longevity and characterized by high fish intake. Clinical studies have identified predictors of treatment response in individual RA patients, however, the influence of fish consumption on treatment response in RA patients treated with targeted therapies has not been elucidated.

Objectives: To assess whether fish consumption is associated with a good response to targeted therapies in RA patients with Japanese and Mediterranean dietary patterns.

Methods: The study is a collaborative international cross-sectional retrospective study enrolling patients with RA on treatment with biologics or JAK inhibitors attending to Hokkaido University Hospital, Japan or Hospital Virgen de las Nieves, Spain.

Enrolled patients were asked to complete a brief-type self-administered diet history questionnaire (BDHQ) and a detailed fish frequency questionnaire (DFFQ) referring to consumption frequency in the previous month. At study entry, alcohol consumption, tobacco habits, educational level and employment status were recorded and RA disease activity evaluated by qualified rheumatologists. Demographic, clinical/laboratory data were retrospectively extracted from the medical records.

By December 2021, 279 patients (Japan 217, Spain 62) returned the questionnaires. A preliminary analysis was carried out with the first 58 Japanese patients in which all clinical and laboratory data could be collected. A descriptive analysis was performed and the relative risks approximated by odds ratios.

Results: Fifty-eight Japanese RA patients, 45 females, median age at entry 66 yrs [IQR 54-73], median disease duration 11yrs [IQR 7-20] were included in this

analysis. Fifty-three (93%) of patients were on biologic therapies and four (7%) on JAK inhibitors with a median treatment duration of 4.5 yrs [IQR 1-7]. Concomitant treatment with conventional DMARDS and glucocorticoids were reported in 69% and 48% of patients, respectively. Forty-two (72%) patients were responders to treatment defined as DASESR ≦3.2. Another systemic autoimmune disease, hypertension, diabetes mellitus, dyslipidemia or gout history were present in 29%, 29%, 9%, 33% and 10% of patients, respectively.

All patients had consumption of fish in the last month and an intake of n3-PUFA rich fish (fatty fish) was indicated by 82% (<1 time/week 34%, ≧ 1 time/week 48%).

The patients' fatty and non-fatty fish intake scores were calculated with a mathematical formula based on the intake of each of the fish included in the DFFQ and number of responses. In the group of high fatty fish score patients (≧ 1 time/week) 94% were responders to treatment vs. 6% non-responders, [OR 8.75, CI [1.0-73.54, p= 0.022] while only 63% of patients in the high non-fatty fish score group respond to the treatment.

Conclusion: Fatty fish intake associated with a good response to treatment in patients receiving targeted therapies, suggesting that fish consumption may have some beneficial effects on RA treatment.

AB0202 GUT MICROBIOTA DYSBIOSIS WERE CLOSELY CORRELATED WITH LYMPHOCYTE SUBSETS AND CYTOKINES IN PATIENTS WITH INFLAMMATORY ARTHRITIS

J. Liu[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], R. Zhao[1,2,3], S. Song[1,2,3], T. Cheng[1,2,3], J. Wang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*

Background: Inflammatory arthritis includes a group of chronic conditions, particularly rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA)[1].Growing evidences link gut microbiota dysbiosis with the development of inflammatory arthritis[2].

Objectives: The aim of this study was to discover the characters of microbiota in inflammatory arthritis patients and compare the relationship between the microbiota and peripheral lymphocyte subsets and cytokines.

Methods: Fecal samples were collected from 73 arthritis patients (13 PsA, 30 AS, 30 RA patients) and 140 sex- and age-matched healthy controls (HCs). The gut microbiota was studied by sequencing the V3-V4 variable regions of bacterial 16S rRNA genes by the Illumina Miseq PE300 system. Peripheral lymphocyte subsets in these participants were assessed by flow cytometry. Measures of disease activity such as erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) were recorded. Alpha and Beta diversity was assessed using results from QIIME2 and gut microbiome profiles were compared using linear discriminant analysis (LDA) effect size (LEfSe). R (version 4.0.1) was used for comparative statistics, using pearson correlation analysis to assess the correlation between the relative abundance of genus in the sample and clinical parameters.

Results: Compared with HCs, the richness of gut microbiota (ACE and Chao 1) was significantly lower ($p < 0.05$) in arthritis patients, and bacterial diversity including Shannon and Simpson indices ($p < 0.001$) was also significant in arthritis decreased (Figure 1A). β-diversity analysis based on Bray-curtis distance revealed significant differences in microbial communities between arthritis and HCs (Figure 1B, r=0.098, p=0.001, ANOSIM). In addition, compared with HCs at the genus level, 9 bacterial groups were significantly different in PsA ($p < 0.05$), 19 bacterial groups in AS ($p < 0.05$), and 17 bacterial groups in RA($p < 0.05$) (Figure 1C). There was a significant positive correlation between CD4+T and Prevotella(p<0.01), T and Prevotella(p<0.05), Blautia(p<0.05) as well as Megamonas(p<0.05), Th17 and Prevotella(p<0.01), CD8+T and Megamonas(p<0.01), Th1 and Megamonas(p<0.05), Prevotella(p<0.01),Coprococcus(p<0.05), B and Erysipelotricbaceae_UCG-003(p<0.01), and Erysipelotricbaceae_UCG-003(p<0.01), Anaerostipes(p<0.01), CRP and Fusobacterium(p<0.05) as well as Roseburia(p<0.05). There were negative correlations between T and Erysipelotricbaceae_UCG-003 (p<0.05),CD8+T and Fusobacterium(p<0.01), CD4+T and Fusobacterium(p<0.05), NK and Fusicatenibacter(p<0.05).

Conclusion: The gut microbiota of patients with inflammatory arthritis differs from HC and also varies among individual arthritis, which was closely related to lymphocyte subsets.

AB0203 25-HYDROXYVITAMIN D [25 (OH) D] LEVEL IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS, ITS RELATIONSHIP WITH THE COURSE OF THE DISEASE, VDR (FOKI) GENE POLYMORPHISM AND BONE MINERAL DENSITY.

Y. Seheda[1], S. Shevchuk[2], O. Galiutina[1], I. Kuvikova[1], O. Shevchuk[2]. *[1]Scientific and Research Institute of Invalid Rehabilitation of VINNYTSA NATIONAL PIROGOV MEMORIAL MEDICAL UNIVERSITY, Rheumatology Department, Vinnitsya, Ukraine; [2]VINNYTSA NATIONAL PIROGOV MEMORIAL MEDICAL UNIVERSITY, Department of Internal Medicine #2, VINNYTSA, Ukraine*

Background: Osteoporosis is known to be a common concomitant state in postmenopausal women with rheumatoid arthritis, but its development cannot be explained only by increasing of age, hormonal disorders, disease duration and glucocorticosteroid intake. Vitamin D deficiency may be one of the major risk factors, but its prevalence in the Ukrainian cohort of postmenopausal RA patients is unknown, and the factors on which it depends have not been established.

Objectives: To analyze the level of 25-hydroxyvitamin D [25 (OH) D] in postmenopausal women with rheumatoid arthritis (RA) and to investigate its relationship with the course of the disease, VDR (FokI) gene polymorphism and bone mineral density (BMD).

Methods: The study included 81 postmenopausal RA patients and 21 postmenopausal age-matched women without RA as a control group. All patients

were screened for demographic, disease course and treatment data. Serum 25-hydroxyvitamin D [25 (OH) D] level and VDR (FokI) gene polymorphism were measured by enzyme-linked immunosorbent assay (ELISA). Levels of 25-hydroxyvitamin D [25 (OH) D] 20-30 ng / ml were defined as insuficiency and less than 20 ng/ml as deficiency. BMD was measured in the lumbar spine and proximal femur using double X-ray absorptiometry. Osteoporosis was diagnosed in case of BMD> -2.5 T.

Results: The analysis has showed that serum vitamin D level in RA group was significantly lower than in control group (11.54 ng/ml vs. 15.25 ng/ml; p <0.01). In addition, the incidence of vitamin D insuficiency and deficiency was higher in RA patients than in control group. In particular, abnormal vitamin D level was diagnosed in 74.1% of RA patients, among whom 25 (30,9%) patients had vitamin D insuficiency and 35 (43.2%) patients had vitamin D deficiency. In control group 8 (38.1%) persons had vitamin D insuficiency, and 6 (28.6%) persons had vitamin D deficiency. There was an inverse correlation between vitamin D levels and RA activity assessed by DAS28 (p <0.001), CDAI (p = 0.001), ESR and CRP (p <0.001) but not with age, daily glucocorticosteroid dose and disease duration. In addition, significant correlation was revieled between VDR (FokI) gene polymorphism and vitamin D deficiency, as well as low BMD in postmenopausal women with rheumatoid arthritis (p <0.001)

Conclusion: Low 25-hydroxyvitamin D [25 (OH) D] level and VDR (FokI) gene polymorphism are independent risk factors of osteoporosis in postmenopausal women with RA. Vitamin D deficiency is associated with RA activity and not depends on age, glucocorticosteroid daily dose and disease duration.

AB0204 DOES THE PRESENCE OF COXITIS IN RHEUMATOID ARTHRITIS CHANGE THE DISEASE SEVERITY PROFILE?

A. Ben Tekaya[1,2], E. Hannech[1,2], O. Saidane[1,2], S. Bouden[1,2], R. Leila[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. [1]*Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia;* [2]*Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by intra-articular manifestations affecting small and large joints. Hip involvement is not common but it can predict a severe disease course [1].

Objectives: Our study aimed to investigate the prevalence of coxitis in RA patients and to compare patients with RA coxitis (+) and RA coxitis (-) according to their clinical, biological outcomes and their therapeutic findings.

Methods: This was a retrospective and comparative study, which include patients diagnosed with RA according to the ACR/EULAR 2010. Sociodemographic, clinical, biological, and therapeutic data were collected. The diagnosis of coxitis was made on plain x-rays or MRI.

Results: Among 255 RA, there were 30 RA coxitis (+) (11.8%). Coxitis was unilateral in 28 patients and bilateral in 2 patients. The mean delay onset of coxitis was about 11.6 ± 8.4 years (1-27). The mean age was 57.5 ± 12.2 years for RA coxitis (+) and 59.1 ± 10.5 years for RA coxitis (-) (p=0.5). The gender distribution was (70% female and 30% male) for RA coxitis (+) and (85% female and 15% male) for RA coxitis (–) (p= 0.04). The mean Body Mass Index was 24.8 ± 4.8kg/m^2 in RA coxitis (+) and 28 ± 5.8 kg/m^2 in RA coxitis (-) (p= 0.03). Comorbidities were present in 46% of RA coxitis (+) and 48% of RA coxitis (–) (p=0.8). Extra articular manifestations were noted in 76% RA coxitis (+) and 66% RA coxitis (–) (p=0.8). RA was seropositive in 76% RA coxitis (+) and in 82% RA coxitis (–) (p=0.4). RA was immunopositive in 51% RA coxitis (+) and 69% RA coxitis (–) (p=0.04). The mean DAS28 (CRP) was respectively 4.6± 1.1 in RA coxitis (+) vs 4.8 ± 1.1 RA coxitis (-) (p=0.7). Atlanto-axial dislocation was noted in 60% RA coxitis (+) and 22% RA coxitis (–) (p<10^{-3}). The use of corticosteroid was noted in 92% RA coxitis (+) and in 90% RA coxitis (–) (p=0.7). Biologic drugs were prescribed in 43% RA coxitis (+) and in 25% RA coxitis (–) (p=0.04).

Conclusion: Our study showed that coxitis in RA patients is associated with a higher risk of Atlanto-axial dislocation and a more frequent use of biologic drugs reflecting a more severe and mutilating disease. We highlight the importance of an early diagnosis and treatment to prevent complications.

AB0205 TENDERNESS AND RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

I. Gessl[1], M. Popescu[2], G. Supp[1], T. Deimel[1], P. Studenic[1,3], M. Durechova[1], M. Zauner[1], J. S. Smolen[1], D. Aletaha[1], P. Mandl[1]. [1]*Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria;* [2]*Hôpital Maisonneuve-Rosemont, Department of Rheumatology, Montreal, Canada;* [3]*Karolinska Institutet, Division of Rheumatology, Stockholm, Sweden*

Background: In inflammatory arthritis swelling is regarded as a sign of synovitis and is associated with radiographic progression. However, the association of tenderness with radiographic progression is not clear.

Objectives: To assess the predictive value of tenderness alone and with consideration of sonographic signs for synovitis, disease duration and baseline radiographic damage for subsequent radiographic progression in rheumatoid arthritis (RA) and psoriatic arthritis (PsA).

Methods: Clinical and sonographic (grey scale (GS) and power Doppler (PD)) examination of 22 joints of the hand were performed cross-sectionally in consecutive patients with RA and PsA with at least one tender joint. Radiographs were scored for erosions and joint space narrowing (JSN) at inclusion and radiographic progression of each joint was assessed after 2 years. The impact of tenderness on progression was analyzed in non-swollen joints for RA and PsA separately with logistic regression analyses. As a second step, the association of PD, GS, disease duration, C-reactive protein, baseline erosions and JSN and global joint counts with subsequent structural damage was assessed using univariate logistic regression in tender non-swollen joints again on the joint level.

Results: We included 1207 joints in 54 RA patients and 396 joints in 18 PsA patients. Tenderness was associated with subsequent radiographic progression in non-swollen joints in PsA (OR 3.44, 95%CI 1.78-6.62, p<0.01) but not in RA (OR 1.60, 95% CI 0.99-2.48, p=0.55) (Figure 1). In tender non-swollen joints in RA patients, PD (OR 3.74, 95% CI 1.10-13.30, p=0.04) and baseline erosions (OR 4.42, 95% CI 1.22-15.95, p=0.02) had a significant impact on radiographic progression. In PsA patients, PD (OR 8.46, 95% CI 1.72-41.72, p<0.01), baseline erosions (OR 6.71, 95% CI 1.43-31.39, p=0.02), baseline JSN (OR 7.27, 95% CI 1.47-35.89, p=0.02) and SJC (OR 1.26, 95%CI 1.07-1.48, p<0.01) were associated with radiographic progression.

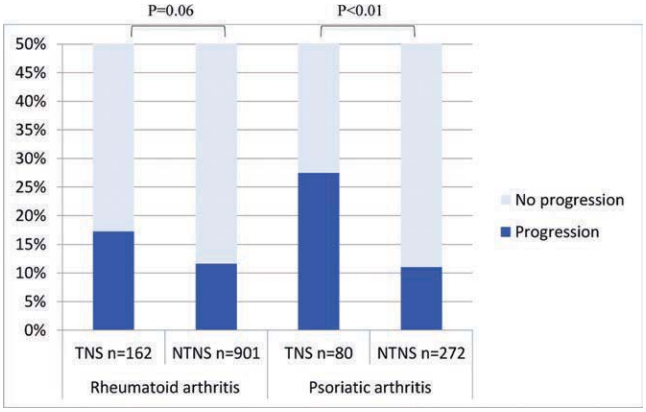

Figure 1. The proportion of joints with progression in tender non-swollen and non-tender non-swollen joints in patients with rheumatoid and psoriatic arthritis; NTNS: non-tender non-swollen; TNS: tender non-swollen

Conclusion: Our findings indicate that tenderness in non-swollen joints is associated with subsequent radiographic progression in PsA, while in RA it is a risk factor for radiographic progression only in the presence of additional factors, such as sonographic signs for synovitis.

AB0206 STUDY ON THE SIGNIFICANCE OF SERUM COMPLEMENT C5 IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Liu[1], Q. Zhou[2], X. Chen[2], H. Guo[2], L. Long[2]. [1]*Zunyi Medical University, Department of Rheumatology and Immunology, Sichuan Provincial People's*

Hospital, University of Electronic Science and Technology of China, Chengdu, China; [2]Sichuan Provincial People's Hospital, Sichuan Provincial People's Hospital, Chengdu, China

Background: Recent studies have pointed out that complement system activation is a major alteration in early atherosclerotic plaques, and complement C5 has promising value as a novel circulating biomarker of atherosclerosis, but the relationship between C5 and carotid atherosclerotic (CAS) plaque in rheumatoid arthritis (RA) is still unclear.
Objectives: To investigate the clinical significance of serum complement C5 and the association with CAS plaque in patients with RA .
Methods: 143 patients with RA were included in the study, and 46 cases with age- and sex- matched healthy physical examination without RA or CAS plaque served as a normal control. All RA patients were divided into RA with CAS plaque group and RA without CAS plaque group according to the presence or absence of plaque formation in the carotid artery. The subject's demographic data, laboratory investigations and serum samples were collected. Body mass index (BMI) and Disease Activity Score 28-joint counts (DAS28) were calculated. Glucocorticoid and DMARDS use were recorded in the past 3 months. ELISA method was used to determine the concentration of complement C5 in the serum of each participation. CAS plaque was determined by color Doppler ultrasound.
Results: Serum complement C5 in RA group was significantly lower than that in control group (P<0.05), whereas C5 level in RA with CAS plaque group was significantly higher than that in RA without CAS plaque group (P<0.05). In RA group, serum C5 level was positively correlated with CAS plaque, high-sensitivity C-reactive protein (hs-CRP) and fibrinogen (FIB) (r=0.204, P=0.017; r=0.225, P=0.009; r=0.186, P=0.029;). In addition, there was no significant correlation between serum C5 and sex, age, BMI, course of disease, DAS28, lipid profile (TG, serum triglyceride; TC, total cholesterol; LDLC, low density lipoprotein cholesterol; HDLC, high density lipoprotein cholesterol; TC/HDLC; LDLC/HDLC), immune markers (RF, rheumatoid factor; anti-CCP, anti-cyclic citrullinated peptide antibodies), cytokine (IL-6, Interleukin-6; TNF-α, Tumor necrosis factor-α), erythrocyte sedimentation rate (ESR) (all P>0.05), or drug therapy (all P>0.05).
Conclusion: C5 may be a novel circulating marker of atherosclerosis in RA patients, it might promise to assist in risk stratification for cardiovascular disease in the future.

AB0207 SOME TARGET JOINTS PERSIST SWOLLEN ACROSS THE FOLLOW-UP IN RHEUMATOID ARTHRITIS: RESULTS FROM A REAL LIFE REGISTRY

E. Buschiazzo[1], M. Aciar[1], E. Picco[1], M. B. Lecumberri[1], N. Cucchiaro[1], A. C. Ralle[1], L. N. Belbruno[1], M. E. Crespo Espindola[1], V. Juarez[1], R. Rojas Tessel[1]. *[1]Hospital Sr Del Milagro, Rheumatology, Salta, Argentina*

Background: Rheumatoid arthritis (RA) is an inflammatory chronic disease, affecting peripheral joints. For the assessment of these joints, rheumatologists use mostly 28 joint swollen and tender count. Although there has been a development of new drugs and therapeutic strategies, there is new information (1) regarding the persistence of some joints that seem to be refractory to treatment.
Objectives: The aim of this study is to describe the pattern of swollen joint affection and its change during followup in real-life RA patients from a rheumatology clinic registry.
Methods: RA patients from an outpatient registry were included if they fulfilled ACR-EULAR 2010 criteria, had ≥ 18 years old, and attended between October 2010 to September 2021. Only those who a 28-joint swollen count available performed by an experienced rheumatologist (EB) in ≥ 5 visits were included. Each joint from the 28-joint count was analyzed individually, the percentage of swollen affection at baseline, last registered visit and during the follow-up was registered. Descriptive statistical analysis and comparisons was performed, depending on the type of data and its distribution.
Results: 403 patients with RA diagnosis were in the registry, 247 (61%) had descriptive 28-joint count, from which 154/247 (62.3%) had ≥ 5 visits and were finally included. When comparing those with < 5 with ≥ 5 visits, the latter had more bDMARD/tsDMARD treatment at baseline (16.9% v 6.5%, p = 0.01). In 154 patients, the mean period between visits was 6.7 months (SD +/- 5.8), the mean follow-up was 5.8 years (SD +/- 3.1), and the mean of visits per patient was 13 (DS +/- 8.8). At baseline the most affected swollen joints were 35.7% right wrist, 35.1% Left Wrist, 35% 2nd right MCP, 32.5% 3rd right PIP. At the last registered visit, the same joints were the most affected, and the percentage of affection persisted across the follow-up. [Figure 1]. When the change from baseline to the last registered visit was analyzed for other variables, a significative improvement was found (baseline v last visit, ESR-DAS28: 3.8 v 3, p = 0.0001, CRP-DAS28: 3.5 v 2.7, p = 0.001).

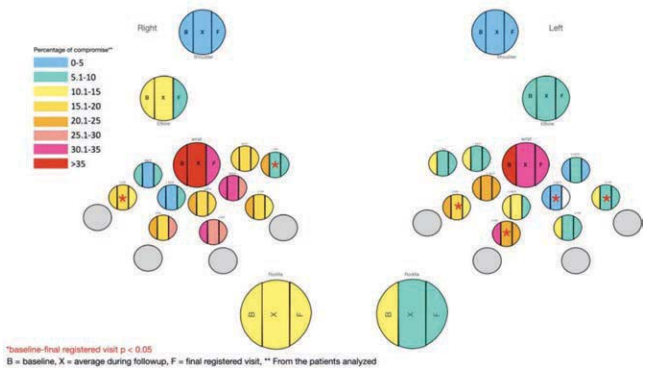

Figure 1. Percentage of swollen joint affection at baseline, final registered visit and average followup

Conclusion: In this registry, some swollen joints were persistently affected across the follow-up, and did not improve from baseline to the last registered visit. However, the burden of the disease improved, measured by DAS28 or its individual components. The improvement of other swollen joints and other components of DAS28 can be the reason. The detection and local treatment (vg: intra-articular injections) of this persistent swollen joints could be the better approach to this issue. Weaknesses of this study: a possible bias in the included patients (they were from single clinic), joint assessment not blind and performed by a single rheumatologist, patients included could be more severe since they were more frequently bDMARD/tsDMARD users.

AB0208 LONG-RUN RELATIONSHIP ASSESSMENT OF AIR POLLUTANTS ON RHEUMATOID ARTHRITIS DISEASE ACTIVITY SCORE: EVIDENCE FROM THE VECM APPROACH

A. Alsaber[1], A. Al-Herz[2], J. Pan[1], A. Al-Sultan[3]on behalf of KRRD. *[1]University of Strathclyde, Department of Mathematics and Statistics, Glasgow, United Kingdom; [2]Al-Amiri Hospital, Rheumatology, Kuwait, Kuwait; [3]Kuwait University, Department of Community Medicine and Behavioral Sciences, Kuwait, Kuwait*

Background: Current findings on the impact of air quality conditions on rheumatoid arthritis (RA) are sparse and not conclusive.
Objectives: To investigate the relationship between air pollutants and RA disease activity scores on a short and a long time period using a multivariate time series model.
Methods: Data on RA patients were extracted from the Kuwait Registry for Rheumatic Diseases (KRRD) from four major hospitals in Kuwait from January 2013 to December 2017. Data on air ambient pollutants (ozone O3, sulfur dioxide SO2, nitrogen dioxide NO2) were extracted from four Kuwait Environmental Public Authority (K-EPA) Air Monitoring Stations through Environmental Monitoring Information System of Kuwait (eMISK), corresponding to the patients residential

areas from January 2013 till December 2020. A multivariate time series approach using Evidence from vector error correction model (VECM) was employed to investigate the effect of air ambient pollutants emissions on DAS28 over that period.

Results: A total of 1,809 RA patients and 10,215 hospital visits were included, 63% females, mean age 54 years, mean disease duration 9.2 years and 77% had rheumatoid factor positive. A significant correlation was found between DAS-28 and SO2, NO2 and O3 (p=0.012, 0.029, 0.039 respectively). According to the Granger causality test and VECM, emissions of NO2, and O3 had a positive short-term effect on DAS28 among RA patients. Impulse response test results showed that for some locations in Kuwait there is a short-term positive causal relationship between emissions of NO2 and DAS28, due to sources of pollution surrounding the locations. The results showed that the short run effect for NO2 with lags 1 to 4 days had a positive relationship with DAS-28 which means, there is 1% increase in DAS-28 for every 0.0182 increase in NO2 emission. Our results revealed that 36% of discrepancy between the overall relationship between DAS-28 and air pollution is corrected each year.

Conclusion: Increased concentrations of air pollutants may increase the risk of RA activity. VECM time series model can be used as a tool to predict changes in disease activity based on air pollutants up to 8 days. We recommend that a regular broadcast is issued by health authorities to RA patients to help predict changes in disease activity. Warning about air pollution may be tailored according to the patient's residential area. Government should take serious decisions to help minimize air pollution in the residential areas.

AB0209 PHYSICIAN TRUST RATHER THAN RHEUMATOID ARTHRITIS KNOWLEDGE RELEVANT IN DISEASE OUTCOMES IN ETHNIC MINORITY PATIENTS WITH RHEUMATOID ARTHRITIS

S. Dowell[1], M. Quinones[1,2], A. Miller[3], O. Kadiri4, T. Jamshidi4, G. Kerr[1,2]. *[1]Howard University College of Medicine, Internal Medicine, Washington, United States of America; [2]Washington DC VAMC, Rheumatology, Washington, United States of America; [3]Howard University, Internal Medicine, Washington, United States of America; [1]Howard University College of Medicine, Internal Medicine, Washington, United States of America*

Background: Ethnic minority (EM) patients with Rheumatoid Arthritis (RA) have more severe disease, more disability, and less use of biologic disease modifying anti-rheumatic drugs (bDMARDs). A Treat to target (T2T) strategy has been recommended to improve clinical outcomes but barriers include patient preference, access to specialty care and increased administrative effort. Additionally, EM patients in the US often have low health literacy, express greater reluctance to accept physician recommendations, in part due to sociocultural preference and mistrust of a historically biased healthcare system. It is unknown whether improving knowledge of RA would improve T2T outcomes in EM active RA patients.

Objectives: To assess the proportion of EM RA patients who achieve low disease activity or remission following implementation of a coordinator-based education program highlighting T2T RA strategy.

Methods: Adult participants with active RA (RAPID3>6 or CDAI > 10) were invited to participate in a series of five one-on-one 20-minute educational sessions, co-occurring with scheduled routine clinic visits (6 -12-week intervals). Sessions were facilitated by a rheumatology care coordinator, a non-healthcare professional with intensive training over 4 weeks to conduct RA patient education. Sociodemographic data was collected, and disease activity measures (TJC, SJC, RAPID3, CDAI) and validated patient questionnaires on RA Knowledge (ACREU), compliance (CQR5), and physician trust (Trust in Physician Scale) were recorded at baseline and after the final educational session. Descriptive statistics were applied and medians and ranges for instrument scores are reported. Paired T-test was used to test for significant differences in scores after the education sessions. Correlations between the ACREU scores and clinical-demographic variables were measured using Pearson's correlation coefficient.

Results: 20 EM patients (75% Female, mean age, 58.8 years (12.2) seen by EM physicians were enrolled, with mean RA disease duration of 7 years and poor prognosticators (75% double seropositivity). ACREU scores were low at baseline (mean 0.45 (0.16)), with no significant improvement on completion of educational sessions, and no correlation with years of education or duration of RA. There was a positive correlation between ACREU and compliance scores at baseline (r=0.3). Average duration of the education period was 9.72 months, with a 33% decrease in average RAPID3 over time, and 42% of patients achieving a target of remission or LDA. Trust in Physician scores were high at baseline and persisted with >50% of patients completing at least one medication change during study period.

Conclusion: RA knowledge did not impact RA patient outcomes in this cohort of EM patients. However, patients had high trust in their providers and achieved clinical remission or LDA despite risk for poor outcomes highlighting the importance of the provider- patient relationship in achieving targeted goals of therapy. Limitations include the small sample size from a single institution, and the lengthy time between initial and final assessment of RA knowledge.

AB0210 REAL-LIFE DAS28-DEFINED REMISSION IN RHEUMATOID ARTHRITIS – INFLAMMATION CONTROL IS NOT ENOUGH

C. Popescu[1,2], E. M. Marin[1,2], C. Codreanu[1,2]. *[1]Carol Davila University of Medicine and Pharmacy, Rheumatology, Bucureşti, Romania; [2]Center for Rheumatic Diseases, Rheumatology, Bucureşti, Romania*

Background: Remission of rheumatoid arthritis (RA) is currently a reachable target in real-life settings under treat-to-target strategies, meta-analytical data

showing an overall success of 16.3% for its 6-month DAS28 definition [1]. Baseline high levels of inflammation and activity markers have been consistently shown to negatively influence this endpoint.
Objectives: The study aimed to evaluate the prevalence of DAS28-defined remission in naïve RA patients after their first 6 months of b/tsDMARD treatment and whether the degree of baseline activity independently predicts treatment outcomes (remission, switch) in a real-life setting.
Methods: Medical records of naïve RA patients who initiated b/tsDMARDs (according to Romanian criteria [2]) from 20.12.2016 to 20.12.2021 were retrieved retrospectively from the database of the Clinical Center for Rheumatic Diseases in Bucharest, Romania. Children, cases with missing data (baseline and 6 months), patients who were previously exposed to b/tsDMARDs, patients exposed to b/tsDMARDs less than 6 months and patients who were not actually exposed to b/tsDMARDs were excluded. Prediction of dichotomous outcomes (remission and switch at 6 months) was evaluated using binary logistic regression.
Results: The study included 157 patients with established RA, mostly women (80.3%), 56.2±11.8 years-old on average. The group included predominantly positive rheumatoid factors (77.7%) and positive anti-citrullinated protein antibodies (81.5%), with only 12.1% both negative. At baseline, 58.0% were receiving one csDMARD (especially leflunomide - 49.7%, and methotrexate - 43.3%), 38.9% were receiving 2 csDMARDs, and 57.3% were on chronic oral glucocorticoids (7.6±4.4 mg/day on average). All patients had high baseline disease activity (average DAS28 of 6.3±0.8). Accordingly, all patients were initiated on either original/biosimilar TNF inhibitors (adalimumab - 22.3%; certolizumab - 7.0%; etanercept - 31.2%; golimumab - 1.3%; infliximab - 17.8%), other bDMARDs (abatacept - 3.8%; rituximab - 1.9%; tocilizumab - 6.4%) or tsDMARDs (baricitinib - 5.7%; tofacitinib - 2.5%). After 6 months, 29.3% of patients were in DAS28-defined remission, 22.9% in LDA, 35.7% in MDA and 12.1% in HDA. Therefore, 12.7% switched their initial bDMARD and 10.8% stopped b/tsDMARDs, because 10.8% exhibited primary non-responsiveness (PNR) and 11.5% had adverse events (7 dermatological conditions, 6 cases of non-tuberculosis pneumonia, 1 case of clinical pulmonary tuberculosis, 1 case of latent tuberculosis, 1 transaminitis, 1 gastric cancer, 1 neutropenia). High baseline levels of DAS28 were associated with a lower probability to attain DAS28-remission after 6 months (OR = 0.64) and with a higher probability to switch the initial b/tsDMARD due to PNR (OR = 2.44), suggesting that pharmaceutically influencing the inflammation cascade is not enough. Addition of b/tsDMARDs reduced at 6 months the prevalence of oral glucocorticoids to 28.0% (5.9±2.6 mg/day on average).
Conclusion: Although reachable, disease remission seems difficult to attain, despite using advanced therapies. High baseline levels of DAS28 are negative predictors for not attaining remission and switching of therapy due to PNR in real-life.

AB0211 FOOT IMPAIRMENT IS NOT A BARRIER TO PHYSICAL ACTIVITY IN RHEUMATOID ARTHRITIS

A. Ben Tekaya[1], C. Ines[1], O. Saidane[1], R. Leila[1], S. Bouden[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. *[1]Charles Nicole Hospital, Rheumatology, Tunis, Tunisia*

Background: Physical activity is increasingly promoted for patients with Rheumatoid arthritis (RA) and strongly recommended. However, adherence to regular physical activity remains low. Identifying the barriers to physical activity is a key element to understanding physical activity behavior in RA.
Objectives: Our objective was to assess the impact of foot involvement on physical activity among patients with RA.
Methods: We conducted a cross-sectional study including patients with RA, fulfilling the ACR-EULAR 2010 criteria. We collected the socio-demographic data and disease characteristics. Regarding the foot involvement, we assessed the presence of foot static disturbances and foot deformities through clinical examination, and radiographic damage. Physical activity was assessed by the Arabic version of validated International Physical Activity Questionnaire (IPAQ). According to this questionnaire, patients were subdivided into three groups: low, moderate and high physical activity.
Results: We included 94 RA (60 rheumatoid factor (RF) positive RA and 57 Anti Citrullinated Peptides Antibodies (ACPA) positive RA) patients. Eighty-six were females, mean age 52,12 ±9,743 years. The mean disease duration was 14,78 years ± 9,425. RA was erosive in 81 cases. Sixty-four patients had extra articular manifestations: pulmonary (n=15), dry syndrome (n=46), rheumatoid nodules (n=7) and osteoporosis (n=25). Mean DAS28CRP score was 3,67 ±1,58 and mean HAQ score was 0,88 ± 0,65. Eighty patients were treated by cs-DMARDS and 31 by biologics: infliximab (n=3), etanercept (n=3), adalimumab (n=2), golimumab (n=3), certolizumab (n=1), tocilizumab (n=11), rituximab (n=4).
Forty-six patients complained of fore foot pain, 34 of mid foot pain and 19 of hind foot pain. Mean visual analogue scale for foot pain was 3,6 ±3,05, and no significant correlation was shown with IPAQ score (p=0,19, r=0,138). Foot static disturbances were present in 66 patients: bilateral flat foot (n=31), hallux valgus (n=59), claw toes (n=33) calcaneal valgus (n=25), peroneal tenosynovitis (n=24), tibialis posterior tenosynovitis (n=18), ankle arthritis (n=15) and mid-foot arthritis (n=18). We didn't find a significant association between lower IPAQ score and foot deformities (p=0,235), the presence of peroneal tenosynovitis (p=0,438) and tibialis posterior tenosynovitis (p=0,113).
As regards X-rays findings, bone erosions were found in 58 patients, joint narrowing in 65 patients, and dislocation of the MTP joints in 17 patients. No positive association with lower IPAQ score was found with structural damage: erosions (p=0,938); joint narrowing (p=0,258) and dislocation of the MTP joints (p=0,884). DAS28 was higher among patients with low physical activity (mean DAS28crp among this population was 4,16 compared to 3,63 among patients with high physical activity), but without reaching a significant threshold (p=0,432, r=-0,85).
Conclusion: Increasing physical activity in RA patients is an ongoing challenge. In this study, no association was found between foot involvement in RA and a lower IPAQ score.

AB0212 COMPARISON OF THE EFFECTS OF POLYPHARMACY IN THE TREATMENT OF RHEUMATOID ARTHRITIS PATIENTS AND PSORIATIC ARTHRITIS PATIENTS WITH PERIPHERAL JOINT INVOLVEMENT

M. Kara[1], S. Palanbek Yavaş[2], A. Taşdemir[3], S. Ketenci[4]. *[1]Republic of Turkey Ministry of Health University of Health Sciences Izmir Bozyaka Education and Research Hospital, Rheumatology, izmir, Turkey; [2]Istanbul University Medicine Faculty, Public Health Department, Istanbul, Turkey; [3]Republic of Turkey Ministry of Health University of Health Sciences Izmir Bozyaka Education and Research Hospital, Internal Medicine, izmir, Turkey; [4]Republic of Turkey Ministry of Health Izmir Katip Celebi University Izmir Atatürk Education and Research Hospital, Rheumatology, izmir, Turkey*

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are chronic, progressive inflammatory diseases that can be accompanied by other diseases. These patients use several medications, especially due to their comorbidities and widespread pain. In recent years, with the increase in the lifespan of individuals, the concept of polypharmacy has become more prominent. Accordingly, in our study, we aimed to present the prevalence of polypharmacy and its effects on these diseases.
Objectives: Demonstrating the prevalence of polypharmacy in RA and PsA, which are among the most frequently encountered inflammatory arthritides, and the effects of polypharmacy on disease activity.
Methods: This study included PsA patients with only peripheral joint involvement and no distal interphalangeal joint involvement and RA patients. The numbers of medications used by the patients at the onset of their treatment and in the sixth month of their treatment were recorded. Non-prescribed (over the counter), topical and herbal/homeopathic medications were excluded. Polypharmacy was accepted as the simultaneous use of at least five medications by the person. Disease activity score in 28 joints C-reactive protein (DAS-28 CRP) was used for disease activity for both diseases. In addition to these, the scores of the patients who attended their follow-ups in the 12th month were calculated and analyzed. The Charlson Comorbidity Index (CCI) scores of the patient were calculated based on their chronic diseases.
Results: The sample of the study included 232 RA and 73 PsA patients. Demographic and some clinical characteristics are shown in Table 1. The mean numbers of medication used by the patients at the onset of their treatment were respectively 5.09±2.89 and 4.03±2.7 for the RA and PsA patients, whereas these mean numbers were found consecutively as 8.67±3.58 and 7.71±3.3 in the sixth month of their treatment. Polypharmacy was present in the sixth month of the treatment in 217 (93.5%) RA and 61 (83.6%) PsA patients.

Table 1. Demographic and some clinical features

	RA (n=232)	PSA (n=73)
Age (mean±SD)	55.2±13.66	48.4±13.43
Age Group		
<65 years	171(73.7)	65(89)
≥65 years	61(26.3)	8(11)
Sex		
Female, n (%)	172(74.1)	50(68.5)
Male, n (%)	60(25.9)	23(31.5)
Current smoker, n (%)	82(35.3)	33(45.2)
The numbers of medication used	8.67±3.58	7.71±3.3
Polypharmacy at the Beginning of Treatment	115(49.6)	28(38.4)
Polypharmacy in the sixth month of treatment	217(93.5)	61(83.6)
CCI (n=232/72) (mean±SD)	1.25±0.88	1.31±0.71
0th month DAS-28 CRP (mean±SD)	4.91±1.28	4.68±1.03
6th month DAS-28 CRP (mean±SD)	3.14±1.06	2.86±0.99
12th month DAS-28 CRP (n=83/29) (mean±SD)	2.73±1.18	2.8±1.12

While the mean ages of the RA and PsA patients who had polypharmacy treatment at the beginning were respectively 59.21±12.65 and 53.5±13.81, their ages were significantly higher than the ages of those who did not receive polypharmacy treatment (respectively, 51.26±13.53 and 45.22±12.3).
In RA ve PsA patients, the status of polypharmacy is higher in the groups in the groups aged 65 and over than those under 65 years of age, and it is statistically significant (p=0.001 and p=0.048, respectively). The risk of polypharmacy in people over 65 years of age in RA patients was 8.2 times, and the risk of polypharmacy in people over 65 years old in PSA patients was increased 6.3 times (p=0.015).
In both the RA and PSA groups, patients with baseline polypharmacy had statistically significantly higher DAS-28 CRP scores at 6 months of treatment than those without baseline polypharmacy. (p<0.001). While the higher DAS-28 CRP score was maintained at 12 months in the RA group with polypharmacy at baseline (p=0.006), this was not significant in the PSA group (p=0.07).
Conclusion: Polypharmacy was present both at the time of diagnosis and in the treatment process in the RA and PsA patients, and the presence of polypharmacy at the beginning of the treatment was among the factors that affected the treatment of these patients by significantly affecting their 6th-month DAS-28 CRP values.

AB0213 CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS UNDERGOING TOTAL JOINT REPLACEMENT: A 20-YEAR TREND ANALYSIS

S. Lapshina[1], I. Akhtiamov[2], I. Gilmutdinov[3]. *[1]Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation; [2]Kazan State Medical University, Department of Traumatology, Orthopedics and Surgery, Kazan, Russian Federation; [3]Republican Clinical Hospital, Orthopedics Department, Казань (Российская Федерация, Республика Татарстан), Russian Federation*

Objectives: To examine time trends in the characteristics of patients with rheumatoid arthritis (RA) undergoing total joint replacement (TJR).
Methods: A total of 271 patients (399 joints) with RA underwent TJR of large joints (hip, knee) at Republican Clinical Hospital, Kazan between 2002 and 2021. Of these, 98 patients were retrospectively examined between 2002 and 2011; 183 patients were observed prospectively in the perioperative period by a rheumatologist and orthopedist from 2012 to 2021. Of the 183 patients, 65,5% underwent one joint replacement, 19,1% underwent two joint replacements, 13,7% underwent three joint replacements, and 1,7% underwent four joint replacements during the study period. All patients met the 1987 ACR classification criteria or the ACR/ EULAR diagnostic criteria. Median [interquartile range (IQR)] age at surgery was 56 (49, 63), the time from the onset of RA to TJR was 11 (7, 18) years. During the study period, total knee replacement was performed most often (67.9%). Joint pain (VAS), disease activity - DAS28, functionality of the HAQ index were assessed before the operation, after 6 and 12 months in the active observation group.
Results: In patients in 2002-2011, TJR were performed earlier from the time of the onset of RA compared to the 2012-2021 group [median (IQR), 10 (7-17) vs. 12 (8-19) years, p = 0.01], and there were more complications of surgery (16.3% vs. 5.4%, p < 0.001). In the later period (2012-2021), there was a decrease in blood loss and operation time, p < 0.05. With respect to RA treatment, a significant increasing trend was observed in the proportion of subjects receiving methotrexate (p 0,006) and biological drugs and biologics (p < 0.001).
In the prospective observation group (n=183), patients were significantly older at the time of TJR with low and moderate activity RA (n=106) compared with high activity (n=77) [median (IQR), 57 (51, 64) vs. 55 (46, 63), p = 0.034]. A significantly less time from RA onset to TJR was observed in patients with high activity, using glucocorticoids. Patients who had the use of glucocorticoids TJR was performed earlier than non-users [median (IQR) 11 (6, 16) and 13 (8, 19) years, respectively, p=0.041] There was no significant difference in time from the onset of RA to TJR, stratified by gender and the use of MTX, biological drugs. At the same time, there was no significant difference in dependence on the activity RA to reduce pain syndrome (VAS), improve function (HAQ) after surgery and presence of postoperative complications.
Conclusion: Over a 20-year period changes were observed in the characteristics of patients with RA undergoing TJR with an increase in the time before surgery. Perioperative management of patients by a rheumatologist and orthopedist can reduce blood loss, the number of complications after surgery. Patients with high RA activity and using glucocorticoids need TJR at an earlier time. Arthroplasty in patients with highly active RA is also effective in improving functional ability.

AB0214 SERUM IMMUNOGLOBULINS LEVEL IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS ON DIFFERENT TREATMENT OPTIONS

C. Mogosan[1,2], E. M. Marin[1], C. Popescu[1,2], L. Enache[1,2], B. Dumitrescu[1,2], M. Agache[1], O. G. Dinache[1], C. E. Ionescu[1], D. Minca[1], C. Codreanu[1,2]. *[1]Clinical Center of Rheumatic Diseases, Rheumatology, Bucuresti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Rheumatology, București, Romania*

Background: Serum immunoglobulins (Ig) A, G, and M (IgA, IgG, and IgM) are not routinely evaluated in rheumatoid arthritis (RA). There are some reports that rituximab (RTX) may induce hypogammaglobulinemia (1). Under normal conditions, IgM provides a rapid immune response and is involved in tissue homeostasis, whereas IgG and IgA are long-lasting high-affinity antibodies, the latter mainly providing mucosal immunity (2).
Objectives: The evaluate serum Ig levels (IgG, IgM, IgA) in a cohort of RA patients and potential therapeutic influences.
Methods: We performed a retrospective study in a cohort of 104 patients with RA exposed to different therapeutic agents, without switch for at least 1 year (conventional synthetic disease modifying drugs - csDMARDs, biologics and JAK inhibitors - JAKi); the collected data included demography, disease characteristics, treatment exposure (molecules, treatment line), serum level of IgA, IgG, IgM.
Results: 104 patients, mean age 60.3 years (±11.9), with a disease duration of 15years (±9.8), 83.7% women; the mean exposure to the current treatment option (without switch) was 3.7 years (±3.8); 20.2% (21 pts) were on csDMARDs, 70.2% (73pts) on biologics and 9.6% (10pts) on JAKi. 90.4% (83pts) used combination therapy along with biologics and JAKi. The biologics used were: 58.9% RTX, 31.5% TNFinhibitors, 8.2% IL-6 blockers and 1.3% abatacept. At cohort level, we found hypogammaglobulinemia in 12.5% for IgG, 9.6% for IgM and 7.7% for IgA, independent of the treatment duration. Low IgG levels were related mostly to RTX exposure (53.8%) followed by TNFi (23.1%) and with equal values anti-IL-6, JAKi and csDMARDs (7.7%). Low IgA levels were noted almost in RTX exposure (75%), followed by TNFi and anti-IL-6 (12.5%, each). Low IgM levels appeared in RTX group (90%) and csDMARDs (10%). No relations between Ig levels and the treatment option (the line of intervention). The Ig mean values were significantly different across treatment groups; for IgG: 9.55g/L in RTX vs 11.68 g/L in TNF inhibitors (p<0.05) and 12.64 g/L in csDMARDs (p<0.05); for IgA: 2.17 g/L in RTX vs 3.35 in JAKi (p<0.05); for IgM: 0.84 g/L in RTX vs 1.82g/L in TNF inhibitors (p<0.001) and 1.58 g/L in JAKi (p<0.05); also IgM were significantly lower in csDMARD group (1.22g/L compared to TNF inhibitors values (1.82g/L), (p<0.05). The serum levels of IgG and IgM (not IgA) were negatively associated with disease duration r = -0.22, p<0.05 and r = -0.2, p<0.05) and age (r =-0.3, r=-0.26, p<0.01). No impact of disease activity, nor patient gender or seropositivity of rheumatoid factor or ACPA.
Conclusion: Low serum levels of IgG, IgM and IgA are seen mostly with RTX exposure, but appear with other treatment exposures as well, which may influence the rate of future infections. Even if our study lacks assessment of baseline Ig levels, it is clear that treatment option has an influence on Ig levels. Future studies are needed to clarify all contributors to these results.

AB0215 DOES THE PARITY IMPROVE THE RHEUMATOID ARTHRITIS ACTIVITY?

E. Rabhi[1,2], H. Ferjani[3,4,5], D. Ben Nessib[3,4,6], L. Kharrat[1,2], W. Triki[3,4,6], K. Maatallah[3,4,6], D. Kaffel[3,4,5], W. Hamdi[3,4,7]. *[1]Kassab Orthopedics Institute, Rheumatology Department, Mannouba, Tunisia; [2]University Tunis el Manar, Faculty of Medicine of Tunis, Beb Saadoun, Tunisia; [3]Kassab Orthopedics Institute, Rheumatology Department, Ksar Said, Tunisia; [4]University Tunis el Manar, Tunisia, Faculty of Medicine of Tunis, Beb Saadoun, Tunisia; [5]Research Unit UR17SP04, Ksar Said, Tunisia; [6]Research Unit UR17SP04, Ksar Said, Tunisia; [7]Research Unit UR17SP04, Ksar Said, Tunisia*

Background: The parity seems to decrease the risk of auto-immune diseases like Rheumatoid arthritis (RA). The risk reduction appeared when the parity number reached two [1]. The activity of RA improved during pregnancy and flares postpartum, but the relationship of parity to RA prognosis is unclear. The impact of childbirth on disease activity is less studied.
Objectives: We aimed to investigate the impact of parity on rheumatoid arthritis activity.
Methods: We conducted a retrospective study including patients fulfilling the American Congress Of Rheumatology / European League Against Rheumatism (ACR EULAR) 2010 criteria.
We collected epidemiological, clinical, biological (C-reactive protein: CRP, erythrocyte sedimentation rate (ESR), immunological status (rheumatoid factor RF and anti-citrullinated protein/peptide antibody ACPA), and disease activity index (The Disease Activity Score 28 DAS 28). We divided our patients into two groups: group (G1): the nulliparous women; group 2 (G2): women who gave birth.
Results: Ninety-two patients were enrolled. There were 14 men and 78 women. The mean age was 59.56 ± 11.7 years. The mean disease duration was 9.32 ± 8.22 years. Among 78 women, we found 50 patients with parity. The main swollen joint was 3.34 ± 3.6 in G2 versus 4.44 ± 4.04 in G1 (p=0.94). The mean painful joints were 6.74 ± 5.12 and 9 ± 9.19 (p=0.28), respectively. However, the inflammatory syndrome is higher among women in G2. The mean CRP level was 15.1 mg/l, and the mean ESR was 37.7 mm. In G1, the RF and ACPA were 131 UI/l and 281 UI/l, respectively compared with 568 UI/L and 315UI/l, respectively in G2.
A significant difference was noted in the DAS28-CRP between the two groups (G2: 4.18 ±1.23 versus G1: 4.49 ± 2.5, p=0.04).
However, no association was found between parity and disease activity using the DAS28-ESR.
Conclusion: Our study showed that parity could have a protective effect on disease activity. It seems to be associated with a lower joint count and a lower rate of RF and ACPA. However, more studies are necessary to conclude these issues.

AB0216 FATIGUE ASSESSMENT IN RHEUMATOID ARTHRITIS, SANTO DOMINGO, DOMINICAN REPUBLIC

R. A. Alvarez Santana[1], D. Garcia[1], J. Santana Peralta[1], A. Cornelio[1], L. Concepción Sanchez[1], T. Polanco Mora[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. [1]*Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Rheumatoid arthritis (RA) is an inflammatory, systemic autoimmune disease affecting the synovial membrane of small joints.[1] Wagan A. et al demonstrated that the frequency of fatigue in rheumatoid arthritis is 62%,[2] Hammam et al described a higher rate of fatigue associated with higher disease activity. Fatigue is as a feeling of exhaustion, also as a reduction in physical and mental capacity,[3,4] it can be measured with the scale FACIT-F (Functional Assessment of Chronic Illness Therapy-Fatigue), which evaluates the last 7 days, with a score of 0-52. For the severity analysis, 4 grades are used: no or mild fatigue (40-52), moderate (27-39), severe (14-26) and extreme fatigue (0-13).[2,5]
Objectives: To evaluate the frequency and degree of fatigue in rheumatoid arthritis.
Methods: Prospective, observational, cross-sectional study of a cohort of patients of the Rheumatology Service of the Hospital Docente Padre Billini. Patients were interviewed in July 2021. Inclusion criteria: ≥ 18 years, diagnosis of RA according to the ACR/EULAR 2010 classification criteria. Exclusion criteria: previous diagnosis of fibromyalgia, depression or anxiety, treatment with antidepressants, antihistamines, beta-blockers. Scales measured: FACIT-F, DAS28, CDAI, and HAQ-DI. Statistical analysis was performed with the Pearson correlation (r_p). Data were analyzed in IBM-SPSS v23.
Results: 597 patients met inclusion criteria. 93% female, mean age 58.5±12.4 years, mean disease duration 7.5 years. HT 73.9% (441), DM 14.2% (85), dyslipidemia 21.3% (127), obesity 17.9% (107), smoking 9.9% (59), high ESR 60.0% (358), high CRP 49.7% (297), scDMARD8 2.7% (494), bDMARDS 36.8% (218), tsDMARDS 18.1 (108). Frequency of fatigue 19.9% (119): moderate 12.9% (77), severe 7.0% (42). Correlation of FACIT-F with DAS28, CDAI and HAQ-DI: No fatigue FACIT-F 80.1% (478): DAS28 remission or low activity 84.9% (406), CDAI remission or low activity 93.5% (447), moderate 4.0% (19), high activity 2.5% (12), HAQ-DI mild 75.9% (363), moderate 16.5% (79), severe 7.5% (36). Moderate FACIT-F 12.9% (77): DAS28 remission or low activity 19.5% (15), moderate 80.5% (62), CDAI moderate 48.1% (37), high activity 51.9% (40), HAQ-DI mild 24.7% (19), moderate 63.6% (49), severe 11.7% (9). Severe FACIT-F 7.0% (42): DAS28 remission or low activity 4.8% (2), high activity 95.2% (40), CDAI low activity or remission 35.7% (15), high activity 64.3% (27), HAQ-DI mild 7.1% (3), moderate 23.8% (10), severe 69.0% (29). Correlation between FACIT-F/DAS28 (r_p= .673, p< .001) and FACIT-F/CDAI (r_p= .701, p < .001) were strong.
Conclusion: The study showed a low frequency of fatigue; the degree of fatigue most found was moderate. The group of patients with fatigue had a statistically significant linear association with disease activity and degree of functional limitation. There were no patients with extreme fatigue.

AB0217 FREQUENCY OF SEXUAL DYSFUNCTION IN RHEUMATOID ARTHRITIS, SANTO DOMINGO, DOMINICAN REPUBLIC

R. A. Alvarez Santana[1], D. Garcia[1], J. Santana Peralta[1], A. Cornelio[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. [1]*Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Rheumatoid arthritis (RA) is an inflammatory, autoimmune systemic disease that affects the synovial membrane of small joints.[1] Kamissoko et al found the frequency of sexual dysfunction in RA to be 69.2%.[2] Pain is considered to have a fundamental role associated with the decrease in the frequency of sexual intercourse.[3] The CSFQ-14 (Changes in Sexual Functioning Questionnaire), evaluates the changes in sexual functioning due to a disease and/or treatment in 5 domains with a score range of 14-70; cut-off point indicating sexual dysfunction <41 men and <47 women.[4]
Objectives: To evaluate the frequency and degree of sexual dysfunction in patients with rheumatoid arthritis.
Methods: Prospective, observational, cross-sectional study of a cohort of patients of the Rheumatology Service at Hospital Docente Padre Billini. Patients were interviewed in July 2021. Inclusion criteria: > 18 years, diagnosis of RA according to the ACR/EULAR 2010 classification criteria, at least 1 sexual intercourse. Exclusion criteria: previous diagnosis of another autoimmune disease, depression, diabetes, treatment with antidepressants, antiepileptics, narcotics. Scales measured: CSFQ-14, DAS28. Statistical analysis was performed with the Pearson correlation (r_p) with p>0.05. Data were analyzed in IBM-SPSS v23.
Results: Of the RA cohort, 483 met inclusion criteria. 93.4% (451) female, mean age 58±12.6 years, mean duration of diagnosis 8 years, married 53.8% (260), single 27.7% (134), widowed 16.6% (80), hypertension 73.9% (357), dyslipidemia 21.5% (104), obesity 18.0% (87), smoking 9.9% (48). Frequency of sexual dysfunction 61.3% (296). Sexual dysfunction in women 93.9% (278) and men 6.1% (18). Global domains: desire/interest 55.7% (165), desire/frequency 56.4% (167), pleasure 58.1% (172), arousal/excitement 67.2% (199), orgasm/completion 50.0% (148). Female: desire/interest 94.5% (156), desire/frequency 93.4% (156), pleasure 93.6% (161), arousal/excitement 93.0% (185), orgasm/completion 93.9% (139). Male: desire/interest 5.5% (9), desire/frequency 11.6% (11), pleasure 6.4% (11), arousal/excitement 7.0% (14), orgasm/completion 6.1% (9). Desire/interest dysfunction: DAS28 remission or low activity 28.5% (47), moderate 53.3% (88), high activity 4.8% (8). Desire/frequency: DAS28 remission or low activity 35.3% (59), moderate 47.3% (79), high activity 3.6% (6). Pleasure: DAS28 remission or low activity 30.2% (52), moderate 50.0% (86), high activity 2.9% (5). Arousal/excitement: DAS28 remission or low activity 25.1% (50), moderate 55.8% (111), high activity 6.0% (12). Orgasm/completion:

DAS28 remission or low activity 43.2% (64), moderate 38.5% (57), high activity 6.1% (9).

Conclusion: The study showed a high frequency of sexual dysfunction, observing greater dysfunction in females. In the population, the most affected global domain was arousal/excitement, and it was the most frequent in female and male.

AB0218 ASSOCIATION OF PULSE PRESSURE AND CAROTID INTIMA MEDIA THICKNESS IN RHEUMATOID ARTHRITIS PATIENTS

N. Guajardo-Jauregui[1], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], A. Cárdenas[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[2], M. A. Balderas-Palacios[1], A. B. Rodriguez-Romero[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; [2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) patients have increased cardiovascular risk than the general population. Systemic inflammation causes a proatherogenic state in this group of patients (1). The carotid ultrasound is a useful diagnostic tool for the detection of subclinical atherosclerosis; however, it is not available for all patients. Pulse pressure, defined as the difference between systolic and diastolic blood pressure, has been associated with atherosclerosis in the general population (2). Information in RA patients is lacking.

Objectives: We aimed to correlate pulse pressure and carotid intima media thickness (cIMT) in RA patients.

Methods: This was a cross-sectional study. We recruited a total of 92 patients with RA diagnosis, according to the 2010 EULAR/ACR classification criteria, aged 40-75 years. Patients with a previous cardiovascular event, another connective tissue disease or pregnancy were excluded. A B-mode carotid ultrasound was performed in all patients by a certified radiologist blinded to clinical information. cIMT was measured in the left and right carotid arteries. An average of both cIMT was obtained for each patient for this analysis. Correlation between pulse pressure and cIMT was determined with the Spearman's correlation coefficient (rs). A p-value <0.05 was considered statistically significant.

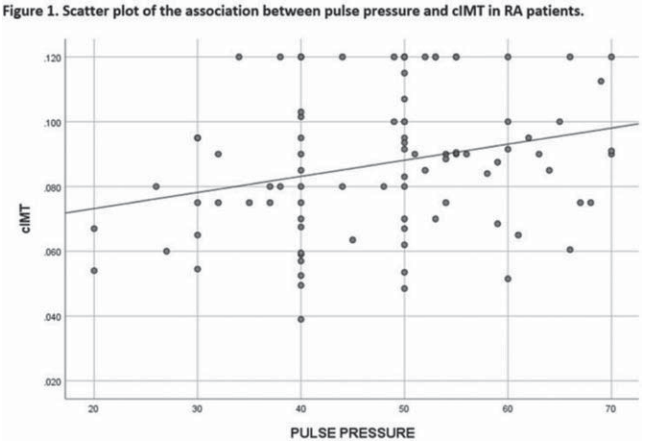
Results: Mean age of RA patients was 58.9 ± 6.6 years. Most of them were women (92.4%), with a median disease duration of 10.5 (4.2-17.5) years. Median cIMT was 0.08 (0.07-0.10) mm, and median pulse pressure was 50 (40-55) mmHg (Table 1). We found a significant positive correlation between pulse pressure and cIMT in RA patients (rs = 0.254, p = 0.015) (Figure 1).

Table 1. Demographic and disease characteristics.

Characteristics	RA patients (n=92)
Age, years, mean ± SD	58.9 ± 6.6
Women, n (%)	85 (92.4)
T2DM, n (%)	17 (18.5)
Hypertension, n (%)	33 (35.9)
Dyslipidemia, n (%)	30 (32.6)
Obesity, n (%)	30 (32.6)
Active smoking, n (%)	11 (12.0)
Disease duration, years, median (IQR)	10.5 (4.2-17.5)
CRP, mg/dL, median (IQR)	0.70 (0.51-1.22)
ESR, mm/h, median (IQR)	21.0 (13.0-33.2)
Pulse pressure, mmHg, median (IQR)	50 (40-55)
cIMT, mm, median (IQR)	0.08 (0.07-0.10)

RA, rheumatoid arthritis; T2DM, type 2 diabetes mellitus; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; cIMT, carotid intima media thickness.

Figure 1. Scatter plot of the association between pulse pressure and cIMT in RA patients.



Conclusion: Higher pulse pressure was associated with higher cIMT in RA patients. Pulse pressure may be useful for the detection of high-risk patients who would benefit from a carotid ultrasound evaluation, to identify patients with high cIMT.

AB0219 ASSOCIATION OF DISEASE ACTIVITY AND THE PRESENCE OF BILATERAL CAROTID PLAQUE IN RHEUMATOID ARTHRITIS PATIENTS

N. Guajardo-Jauregui[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], A. Cárdenas[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[2], M. A. Balderas-Palacios[1], A. B. Rodriguez-Romero[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; [2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*

Background: Cardiovascular (CV) disease is the major cause of death of RA patients. There is a direct association of systemic inflammation and an accelerated process of atherosclerosis, which is related to higher CV morbimortality (1). Additionally, RA patients with bilateral carotid plaque (CP) had a two-fold risk of developing a CV event compared to patients with unilateral CP (2).

Objectives: To compare disease activity and other disease characteristics of RA patients with bilateral and unilateral CP.

Methods: This was a cross-sectional study nested of a RA patients' cohort. We recruited RA patients who fulfilled the 2010 ACR/EULAR classification criteria. Patients with a previous CV event, another connective tissue disease, or pregnancy were excluded. Disease activity was assessed with DAS28-CRP. A carotid ultrasound was performed to all RA patients, and the presence of CP was considered as a carotid intima media thickness ≥ 1.2 mm or a focal narrowing ≥ 0.5 mm. All RA patients with bilateral CP were included in this study and matched by age (± 5 years), gender, and traditional CV risk factors to RA patients with unilateral CP by a rheumatologist blinded to clinical information. Comparisons were done with Chi-square test for qualitative variables and Student's T test or Mann-Whitney's U test for quantitative variables. A p-value < 0.05 was considered statistically significant.

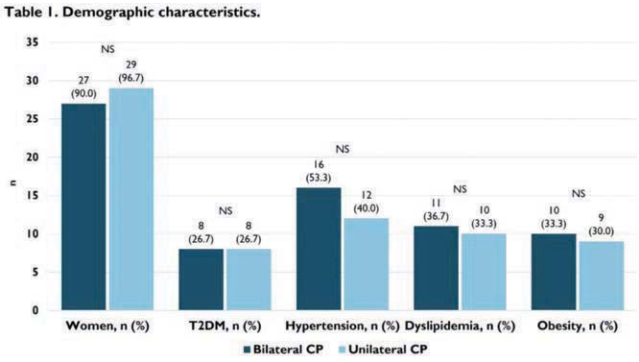
Results: Mean age of RA patients with bilateral CP was 61.98 ± 6.82 years as compared to 59.70 ± 6.74 years in patients with unilateral CP (p = NS). Demographic characteristics are shown in Figure 1. When comparing disease characteristics, we found a difference in C-reactive protein (CRP) levels, higher in patients with bilateral CP (1.06 mg/dl vs 0.64 mg/dl, p = 0.012), in disease activity assessed with DAS28-CRP as a continuous variable, higher in patients with bilateral CP (3.83 vs 3.05, p = 0.023), and as moderate-high disease activity classification, more prevalent in patients with bilateral CP (70.0% vs 43.3%, p = 0.037) (Table 1). A binary logistic regression, including traditional CV risk factors and disease activity, showed that classification of disease activity in the

moderate-high activity category is an independent risk factor for the presence of bilateral CP, OR 3.18, 95% CI 1.033-9.812, p = 0.044.

Table 1. Comparison of disease characteristics.

Variables	RA patients with bilateral CP (n=30)	RA patients with unilateral CP (n=30)	*p-value*
Disease duration, years, median (IQR)	7.86 (2.97-19.18)	9.02 (6.45-13.66)	NS
CRP, mg/dl, median (IQR)	1.06 (0.67-1.93)	0.64 (0.43-1.06)	0.012
DAS28-CRP, mean ± SD	3.83 ± 1.27	3.05 ± 1.32	0.023
Moderate-high activity, n (%)	21 (70.0)	13 (43.3)	0.037
Anti-CCP, median (IQR)	15.30 (3.16-196.15)	115.73 (1.60-196.05)	NS
FR IgG, median (IQR)	5.84 (2.00-17.13)	5.25 (2.00-20.41)	NS
FR IgM, median (IQR)	156.86 (27.91-200.00)	197.22 (65.71-200.00)	NS
FR IgA, median (IQR)	85.87 (13.60-200.00)	46.83 (5.33-129.93)	NS
MTX, n (%)	22 (75.9)	21 (70.0)	NS
GC, n (%)	16 (55.2)	11 (36.7)	NS
bDMARD, n (%)	3 (10.3)	6 (20.0)	NS

NS, no significant; RA, rheumatoid arthritis; CRP, C-reactive protein; anti-CCP, anti-cyclic citrullinated peptide antibodies; RF, rheumatoid factor; MTX, methotrexate; GC, glucocorticoids; bDMARD, biologic disease modifying antirheumatic drugs.



Conclusion: We found that RA patients with bilateral CP had higher levels of CRP levels, higher DAS28-CRP, and a higher prevalence of being classified in the moderate-high disease activity category, which was independently associated to the presence of bilateral CP. Emphasis should be placed on tight disease control to prevent the development of a major CV events in RA patients.

AB0220

FACTORS ASSOCIATED WITH CAROTID INTIMA MEDIA THICKNESS REDUCTION IN RHEUMATOID ARTHRITIS PATIENTS: A FOLLOW-UP STUDY

N. Guajardo-Jauregui[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], A. Cárdenas[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[2], M. A. Balderas-Palacios[1], A. B. Rodriguez-Romero[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico;* [2]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) patients have higher risk of developing cardiovascular (CV) events than the general population. Traditional CV risk algorithms have been shown to underestimate the real CV risk of RA patients (1). For this reason, current CV risk guidelines state that a carotid ultrasound could be considered as part of the CV evaluation of these patients.

Objectives: To describe the carotid ultrasound changes in the follow-up of RA patients, and to compare demographic and disease characteristics in patients who had a reduction of carotid intima media thickness (cIMT) and those who did not.

Methods: Longitudinal, observational, and prospective study. A total of 39 RA patients were included in this study. A first evaluation, including a carotid ultrasound, laboratory analyses, and clinical history, was performed at the time of inclusion. Posteriorly a follow-up carotid ultrasound was performed. Patients were divided into two groups, those with reduction of cIMT in both carotid arteries, and those who remained with the same measurements or had an increase of cIMT. Comparisons were done with Chi-square test or Fisher's exact test for qualitative variables and Student's T test or Mann-Whitney's U test for quantitative variables. A *p*-value < 0.05 was considered statistically significant.

Results: Median follow-up was 4.66 (4.33-5.00) years. When evaluating changes in the carotid ultrasound findings, 15 (38.5%) patients developed CP, 8 (20.5%) patients developed bilateral CP, and 10 (25.6%) patients had a reduction of cIMT at the follow-up (Figure 1). When comparing baseline characteristics, we found that patients with reduction of cIMT were younger (48.88 years vs 59.30 years, $p = 0.004$), with a lower prevalence of dyslipidemia (0% vs 34.5%, $p = 0.040$), had lower levels of erythrocyte sedimentation rate (ESR) (14.50 mm/h vs 28.0 mm/h, $p = 0.024$), and had higher prevalence of normal levels of ESR (<20 mm/h) (80.0% vs 27.6%, $p = 0.007$) than patients who remained with the same measurements or had an increase of cIMT (Table 1). A multivariate analysis was performed, including variables with a *p*-value < 0.05, and we found that normal ESR was an independent factor associated with reduction of cIMT, with an OR 8.63 (1.27-58.33), $p = 0.027$.

Table 1. Baseline characteristics of patients with and without reduction of cIMT.

Baseline characteristics	Patients with cIMT reduction (n=10)	Patients without cIMT reduction (n=29)	*p-value*
Demographic characteristics			
Age, years, mean ± SD	48.88 ± 8.59	59.30 ± 9.46	0.004
T2DM, n (%)	0 (0)	3 (10.3)	NS
Hypertension, n (%)	1 (10)	11 (37.9)	NS
Dyslipidemia, n (%)	0 (0)	10 (34.5)	0.040
Active smoking, n (%)	0 (0)	2 (6.9)	NS
Obesity, n (%)	6 (60)	8 (27.6)	NS
Treatment			
Statins, n (%)	2 (20)	7 (24.1)	NS

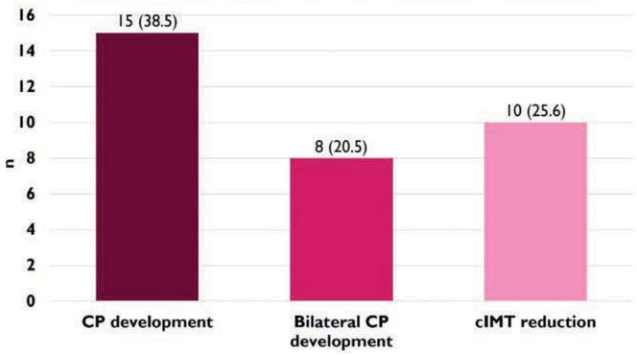
CRP, mg/dl, median (IQR)	0.75 (0.45-1.26)	0.91 (0.66-1.26)	NS
DAS28-ESR, mean ± SD	4.30 ± 1.04	4.66 ± 1.09	NS
DAS28-CRP, mean ± SD	3.23 ± 0.90	3.49 ± 1.06	NS

cIMT, carotid intima media thickness; T2DM, type 2 diabetes mellitus; MTX, methotrexate; GC, glucocorticoids; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; DAS28, disease activity score 28 joints.

Figure 1. Carotid ultrasound changes in follow-up of rheumatoid arthritis patients.



Conclusion: Our results show that patients without dyslipidemia and with lower ESR levels, a proinflammatory biomarker, had a reduction in cIMT, which decreases the risk of developing a major CV event. Emphasis should be placed on tight control of disease activity and traditional CV risk factors. A follow-up carotid ultrasound evaluation in RA patients may be necessary, to identify those who would benefit from an opportune treatment.

AB0221 DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS IN THE CLINICAL PRACTICE OF A RHEUMATOLOGY CENTER

A. Gordeev[1], E. Matianova[1], Y. Olyunin[1], E. Galushko[1]. [1]*V.A. Nasonova Rheumatology Research Institute, Rheumatoid Arthritis Evolution Laboratory, Moscow, Russian Federation*

Objectives: To compare the features of the disease course and the therapy in rheumatoid arthritis (RA) patients who meet and do not meet the difficult to treat (D2T) criteria.

Methods: RA patients admitted to the V.A. Nasonova Research Institute of Rheumatology for therapy correction from March to October 2021were included. All patients fulfilled the RA criteria of ACR/EULAR 2010. According to the opinion of the attending physician, they needed correction of therapy, so they were sent to the expert commission to confirm the expediency of using biologic or targeted synthetic (ts) disease-modifying antirheumatic drugs (DMARDs).

Results: 295 RA patients with high or moderate disease activity according to DAS28 were included. The expert commission in all cases confirmed the validity of administration of biologic or ts DMARDs. 111 (37.6%) patients (group A) were prescribed these drugs for the first time due to the unsatisfactory result of the use of conventional synthetic (cs) DMARDs, 105 (35.5%) patients were planned to continue treatment with previously used biologic or ts DMARDs after a break associated with various reasons (group B). In 54 (18.3%) cases, first biologic or ts DMARD failed so second biologic or ts DMARD was prescribed (group C). The D2T group included 25 (8.4%) patients with a history of inefficiency or intolerance of 2 or more biologic or ts DMARDs of different mechanisms of action. The duration of RA in the D2T group was significantly longer than in the rest of the patients (respectively 15.9±11.8 and 11.9±9 years, p=0.04). Radiological changes of joints in D2T RA were more significant than those in the rest of the patients. The III or IV Steinbrocker stage og RA in the D2T group was detected in 18 (72%) while in the remaining patients - in 130 (48.1%) cases (p=0.02). At the same time, there was a correlation between the duration of RA and the X-ray stage (p<0.0001). At the time of hospitalization, patients with D2T had higher inflammatory activity than group B patients who continued therapy with biologic or ts DMARDs. In groups A and C, all the analyzed signs of inflammation were also significantly higher than in group B (p <0.05). Methotrexate had been most often prescribed as the first cs DMARD in all groups but at the time of hospitalization, patients with D2T RA were more likely than other patients to remain without DMARDs (in 8 (32%) and 39 (14.4%) cases respectively, p=0.03). 73.3 - 84% of patients in all groups earlier received glucocorticoids (GC). At the time of hospitalization, the dose of GC in D2T group was higher than in other patients and averaged 8.3±5.1 mg /day and 6.4±2.9 mg / day, respectively, p=0.02. The proportion of patients taking GC in the D2T group was also higher than that among other patients, but these differences did not reach statistical significance. In D2T RA, adverse events associated with biologic DMARDs occurred more often than in groups B and C (respectively in 9 (36%) and 15 (9.4%) patients; p=0.001).

Conclusion: The formation of D2T RA in our patients could be associated with the prescribing of higher doses of GC and insufficient use of DMARDs. The development of D2T RA was accompanied by a more pronounced progression of radiological changes of the joints than in other patients.

AB0222 THE ALBUMIN TO GLOBULIN RATIO AS A NOVEL INFLAMMATORY MARKER OF RHEUMATOID ARTHRITIS

M. Liu[1,2], Z. Huang[1,2], Y. Huang[1], Z. Huang[1], Q. Huang[1], T. Li[1,2,3]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China;* [2]*Southern Medical University,The Second School of Clinical Medicine, Guangzhou, China;* [3]*Zhaoqing Central People's Hospital, Department of Rheumatology and Immunology, Zhaoqing, China*

Background: The albumin to globulin ratio (AGR) has recently been identified as a new prognostic factor in patients with several types of cancer. However, the correlation of AGR and the disease activity in patients with rheumatoid arthritis (RA) have not been reported.

Objectives: This study aimed to explore the clinical value of AGR in RA and its association with disease activity.

Methods: This retrospective study collected 137 RA patients and 82 age- and sex-matched healthy controls. Neutrophil, lymphocyte, monocyte, platelet, albumin, globulin, AGR, neutrophil to lymphocyte ratio (NLR), monocyte to lymphocyte ratio (MLR), platelet to lymphocyte ratio (PLR), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Disease Activity Score of 28 joints-ESR (DAS28-ESR) and other laboratory parameters were recorded. Receiver operating characteristic (ROC) curves were used to determine the area under curve (AUC) value. The relations between inflammatory indexes and DAS28-ESR were checked.

Results: The AGR was lower in RA patients than in healthy subjects ($P < 0.05$) and decreased significantly along with the disease activity of RA patients ($P < 0.05$). According to the ROC curve which was conducted to discriminate RA patients from healthy individuals, the AGR (0.881, 95% CI: 0.837 - 0.924) showed the highest AUC than albumin (0.868, 95% CI: 0.823 - 0.914), globulin (0.789, 95% CI: 0.729 - 0.849), NLR (0.801, 95% CI: 0.742 - 0.859), MLR (0.762, 95% CI: 0.699 - 0.826) and PLR (0.803, 95% CI: 0.745 - 0.860). Spearman analyses showed that AGR was reversely associated with DAS28-ESR (r = -0.545, $P < 0.001$). Besides, the relevance between AGR and DAS28-ESR was higher than albumin (r = -0.381, $P < 0.001$), globulin (r = 0.492, $P < 0.001$), NLR (r = 0.444, $P < 0.001$), MLR (r = 0.189, $P = 0.027$) and PLR (r = 0.423, $P < 0.001$).

Conclusion: The results demonstrated that the AGR was decreased in RA patients and may be a potential marker for monitoring the disease activity of RA patients.

AB0223 COXITIS AND ATLANTOAXIAL SUBLUXATION IN RHEUMATOID ARTHRITIS: IS THERE A LINK?

A. Ben Tekaya[1], S. Rezgui[1], O. Saidane[1], R. Leila[1], S. Bouden[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology,Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is an autoimmune chronic inflammatory disease that can over time be debilitating and life threatening vital prognosis through Atlantoaxial subluxation(ASS) and functional prognosis through coxitis.

Objectives: The aim of this work was to determine the correlation between coxitis and AAS in RA.

Methods: We performed a cross-sectional comparative study including 182 patients with RA meeting the ACR-EULAR 2010 criteria in a rheumatology department during the period from 2000 to 2021. The socio-demographic, clinical and radiological features were collected.

Results: Among the 182 patient enrolled, 16.4% (n=30) of patients had coxitis: unilateral in (90.24%; n = 27) and bilateral in (9.76%; n = 3). The coxitis was significantly found in males with a percentage of 40% vs 13.5% in females (p=0.01). As it for the AAS, it was noted in 13.3% of our patients more frequently in males 41.2% vs 17.8% in females (p=0.044).

The discovery of AAS on standard radiographs was fortuitous in 70.4% of cases (systematic radiographic assessment for structural assessment of RA) and in 29.6% of cases presenting an inflammatory neck pain.

Cervical MRI was pathological in 63.4%. The abnormalities observed on MRI were: C1 – C2 synovitis (47.6%), confirmed LAA (42.9%) and basilar impression (9.5%).

C1-C2 instability was presumed anterior (90.9%), lateral (6.1%) and rotatory (3%). Two patients had basilar impression.

The occurrence of an atlantoaxial subluxation was significantly correlated to the anterior presence of a coxitis (p=0.000).

Conclusion: Our study suggest that in RA, the presence of a coxitis;mostly in males; can be a predictive factor for the occurrence of AAS but further studies are needed to confirm these results.

AB0224 JAK-INHIBITORS ATTAIN A RAPID AND PERSISTENT EFFECTIVENESS ON SEVERAL PATIENT-REPORTED OUTCOMES IN LONG-STANDING RHEUMATOID ARTHRITIS

S. Monti[1], E. Bozzalla Cassione[1], M. Biggioggero[2], G. Crepaldi[3], C. Bazzani[4], C. Lomater[3], R. Gorla[4], E. Favalli[2], S. Balduzzi[1], R. Caporali[2], C. Montecucco[1]. [1]*University of Pavia, IRCCS Policlinico San Matteo, Department of Rheumatology, Pavia, Italy;* [2]*Istituto Gaetano Pini, Department of Rheumatology,*

Milan, Italy; [3]AO Mauriziano, Università degli Studi di Torino, Academic Rheumatology Centre, Torino, Italy; [4]Spedali Civili di Brescia, Department of Rheumatology, Brescia, Italy

Background: Janus kinase inhibitors (JAKi) are efficacious drugs for the control of disease activity in rheumatoid arthritis (RA). The effect on patient-reported outcomes (PROs) has been shown in randomized clinical trials, but is still largely unknown in real-life scenarios.
Objectives: To assess the time to onset and magnitude of improvement across a number of different PROs in patients with RA treated with JAKi.
Methods: Patients were selected from centres involved in the LORHEN Registry. Patients with a diagnosis of RA initiating a JAKi (Baricitinib or Tofacitinib) between May 2019 and February 2020 were clinically assessed at baseline, 8 weeks and 16 weeks with DAS28 and SDAI. PROs were collected at baseline, 2 weeks, 4 weeks, 8 weeks and 16 weeks from JAKi initiation. The PROs assessed at each timepoint were: Patient Global Assessment (PGA), General Health (GH), 0-100 mm visual analogue scale (VAS)-pain, VAS-fatigue, Health Assessment Questionnaire (HAQ), The Clinical Arthritis Activity (PRO-CLARA) questionnaire.
Results: Thirty-eight patients (female 76%, mean age 57±15) were enrolled for a total of 152 visits for PROs assessments. Patients had received a median of 2 (IQR 1;3) previous conventional synthetic DMARDs (csDMARD) and a median of 2 (0;3) biological DMARDs. Mean disease duration at time of JAKi initiation was 10±9.5 years. JAKi was prescribed as combination therapy with a csDMARD in 20 (53%), concomitant glucocorticoids (GC) in 28 (73%) patients, at a mean dose of 6±2 mg/day. Twenty-one (55) patients were on regular analgesics. DAS28-ESR reduced from 4.5±0.9 at baseline to 2.6±0.9 at 8 weeks (p<0.001). DAS28-ESR remained stable between 8 and 16 weeks (mean values 2.3±0.1; p=0.17). Similarly, DAS28-CRP reduced from 4.1±0.8 to 2.1±0.6 at 8 weeks (p<0.0001). Between 8 and 16 weeks there was a further significant reduction of DAS28-CRP under the effect of JAKi treatment to a mean value of 1.4±0.5 (p<0.0001). SDAI reduced over the period of observation from 19±8 to 6±5 at 8 weeks (p<0.0001), and to 4±3 at 16 weeks (0.03). By week 8 the intake of concomitant GC reduced to 28% of patients (p=0.0001), and of analgesics to 2% of patients (p<0.0001).
By two weeks, all PROs had a significant reduction compared to baseline (Figure 1). For PGA, VAS-pain, VAS-fatigue a further significant reduction was observed by week 4 to then stabilize between week 8 and 16. GH and HAQ had a significant reduction by week 2 and remained stable thereafter. All PROs were significantly lower during all time-points compared to baseline. The PRO-CLARA Road score to assess physical function significantly improved starting from week 2 from a score of 4±2 to 2±2 at the end of follow-up. The PRO-CLARA self-administered tender joint count was stable at week 2 (mean score 4±2) but recorded an improvement from week 4 onwards (p<0.03).

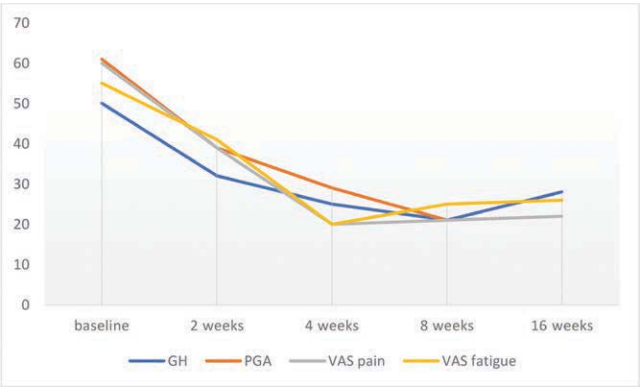

Figure 1. Improvement of patient-reported outcomes over the period of observation

Conclusion: Treatment with JAKi ensures a very rapid and persistent improvement of several PROs, including pain, fatigue and physical function, as early as 2 weeks treatment even in patients with long-standing RA treated with several lines of previous DMARDs.

AB0225 FRAX ASSESSMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS PREDICTED THE REAL INCIDENCE OF CLINICAL FRACTURES FOR 10 YEARS FROM THE RESULTS OF THE 10-YEAR TOMORROW STUDY

K. Mamoto[1], T. Koike[2,3], T. Okano[1], Y. Sugioka[2], M. Tada[4], K. Inui[5], H. Nakamura[1]. *[1]Osaka City University Graduate School of Medicine, Department of Orthopaedic Surgery, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [3]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan; [4]Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan; [5]Osaka Saiseikai Nakatsu Hospital, Department of Orthopaedic Surgery, Osaka, Japan*

Background: To investigate if FRAX in patients with RA can predict the incidence of new clinical fractures for 10 years by using the 10-year data of the TOMORROW study (UMIN000003876) which is a prospective cohort study.
Objectives: To investigate if FRAX in patients with RA can predict the incidence of new clinical fractures for 10 years by using the 10-year data of the TOMORROW study (UMIN000003876) which is a prospective cohort study.
Methods: We calculated ten-year probability of major osteoporotic fracture (FRAX) in 208 RA patients and 205 sex- and age-matched volunteers (Vo), and compared FRAX with the incidence of clinical fractures for 10 years.
Results: The mean FRAX were 14.5 and 8.8% in 175 RA patients and 168 Vo, respectively, in whom we could calculate FRAX at baseline and complete to investigate the incidence of clinical fractures for 10 years from baseline. The mean FRAX in RA patients was significantly higher than that in Vo (P<0.001). The actual incidence of clinical fractures for 10 years in RA patients was significantly higher than that in Vo (33.9 vs 22.9%, P=0.031). In both groups, the actual incidence of clinical fractures was higher than FRAX prediction. Logistic regression analysis revealed that FRAX and FRAX≧15% were the significant risk factors for clinical fractures for 10 years in both groups (Odds ratio (OR), 1.055, P<0.001, 2.943, P=0.043, respectively). The mean FRAX in RA patients with and without clinical fractures for 10 years were 18.5 and 12.5%, respectively (P=0.002). In RA patients, FRAX was also the significant risk factor for clinical fractures (OR, 1.046, P=0.004).
Conclusion: FRAX and the incidence of clinical fractures for 10 years were significantly higher in RA patients than them of Vo. We confirmed that FRAX was the risk factor for clinical fractures in actual clinical practice.

AB0226 CLINICAL SIGNIFICANCE OF SOLUBLE ST2 IN PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE THE APPOINTMENT AND AFTER 12 MONTHS OF TREATMENT WITH BIOLOGICAL DRUGS (PRELIMINARY DATA).

Y. Gorbunova[1], T. Popkova[1], I. Kirillova[1], L. Kondrateva[1], M. Diatroptov[2], A. Lila[3], E. Nasonov[3]. *[1]VA Nasonova Research Institute of Rheumatology, of Systemic Rheumatic Diseases, Москва, Russian Federation; [2]VA Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Москва, Russian Federation; [3]VA Nasonova Research Institute of Rheumatology, Scientific Deparment, Москва, Russian Federation*

Background: The role of soluble ST2, the IL-33 receptor, in the pathogenesis of rheumatoid arthritis (RA) is discussed in the literature.
Objectives: to assess the levels of soluble ST2 marker initially (against the background of ineffective basic anti-inflammatory therapy (DMARD) and after 12 months of combination therapy (DMARD + biological therapy).
Methods: The study included 47pts (39 women /8 men) with RA, 51 [39,0; 63,0] years old. Pts were seropositive for IgM RF (79%) and anti-CCP (62%), with highly active RA (DAS28 5,7 [5,2; 6,4]; SDAI 35,0 [29,1; 43,6], CDAI 34,0 [25,0; 43,0]) scores, and median disease duration of 4.0 [3,0;14.0] years. All patients with RA had a history of insufficient effect or intolerance to two or more basic anti-inflammatory drugs (DMARDs). At the time of inclusion in the study, patients received DMARDs: 44% of patients received methotrexate (median dose - 15 (15; 20) mg /week), 35% - leflunomide (20 mg / day), 9.3 % - sulfasalazine (2000 mg / day), 7% - hydroxychloroquine (200 mg / day), 67.4% - glucocorticoids (5 (4; 8) mg / day). Patients did not receive biological

therapy at the time of inclusion in the study. Due to lack of efficacy or intolerance, patients with RA (n=21) were prescribed biological therapy: 52.4% - anti-B-cell therapy, 38% - TNF-alpha inhibitors, 9.6% - IL-6 inhibitors. The control group consisted of 20 age-matched donors without rheumatic diseases. The concentration of soluble ST-2 was determined by enzyme immunoassay (Cristal Diagnostics, San Diego). The upper limit of normal when testing 20 sera from healthy donors was 17,65 ng/ml, corresponding to the 95th percentile.

Results: The serum level of soluble ST2 in patients with late RA (n=47) was higher than in the control group (n=20) (14.2 [11.5;20.1] ng/ml versus 10.65 [9.3; 13.1 ng/ml) (p<0.001). Patients with RA and elevated serum ST2 levels (≥17.65 ng/mL) were older than patients with ST2 levels ≤17.65 ng/mL (58.5 [50;68] vs 47, 0 [38;59] years) (p=0.007). In the group of patients (n=21) who received combination therapy for 12 months, there was a statistically significant decrease in clinical and laboratory activity, levels of RF IgM and soluble ST2 in blood serum, compared with baseline (13.8 [11.5; 18.4] ng/ml vs 12.5 [9.6;13.8] ng/ml (p<0.05 in all cases).(Table 1). In the group of patients (n=21), after 12 months of combination therapy, direct correlations were noted between the delta (Δ) of the level of soluble ST2 and Δ DAS28 (R=0.59; p=0.006), Δ CRP (R=0.55; p =0.01), Δ anti-CCP (R=0.49; p=0.04).

Table 1.

	Patients with RA (n=21) with insufficient effect of basic anti-inflammatory therapy	Patients with RA (n=21) after 12 months of receiving combination therapy	Δ,%	p
BMI, kg/m^2	24,16 (21,23; 26)	25,15 (23,43;26,7)	+4,1	0,8
DAS28	5,6 (5,3; 6,7)	3,97(3,36;4,63)*	-30,4	**0,0001**
SDAI	38,17 (29,5; 45,8)	17,2(9,57;25,6)*	-54,8	**0,0001**
CDAI	35,0 (26,0; 43,5)	17,0(9,0;23,5)*	-51,4	**0,0001**
CRP,mg/l	20,6 (11,7;34,1)	3,15(1,2;7,2)*	-84,7	**0,003**
ESR,mm/h	27,0 (16,0;45,0)	16,0 (10,0;23,5)*	-40,7	**0,003**
IgM RF, ME/ml	84,4 (20,8;163,0)	32,2(10,6;107)*	-61,8	**0,01**
ST-2, ng/ml	13,8 (11,5;18,4)	12,5(9,6;13,8)*	-9,4	**0,008**

* -p <0.05 reliability of differences in indicators before and after 12 months of combination therapy (Wilcoxon); Δ,% - the difference in indicators between the groups by the 12th month of combination therapy.

Conclusion: In patients with high RA activity and the ineffectiveness of basic anti-inflammatory therapy, the level of soluble ST2 in serum was increased compared to the control group. After 12 months of effective anti-rheumatic therapy, the level of this marker decreased. The association of this marker with the clinical and laboratory activity of RA suggests its role in the development of rheumatoid inflammation.

AB0227 TREATMENT SEQUENCING PATTERNS AND COMPARATIVE EFFICACY IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM A REAL-WORLD SETTING

L. Ai[1], M. Higashi[2], K. Lee[1], Z. Liu[1], L. Jin[1], K. Raja[1], Y. Mai[1], T. Jun[2], W. Oh[2,3], A. Beckmann[1], E. Schadt[1], Z. Schadt[1], R. Wallsten[2], E. Calay[1], A. Kasarskis[1], Q. Pan[1], E. Schadt[1,4], X. Wang[1]. *[1]Sema4, R&D, Stamford, United States of America; [2]Sema4, Medical Sciences, Stamford, United States of America; [3]Icahn School of Medicine at Mount Sinai, Oncology, New York, United States of America; [4]Icahn School of Medicine at Mount Sinai, PRECISION MEDICINE, Stamford, United States of America*

Background: The European League Against Rheumatism (EULAR)[1] recently provided updated guidelines regarding the initiation and modification of disease-modifying antirheumatic drug (DMARD) therapy in patients with Rheumatoid Arthritis (RA). Therefore, real-world evidence studies are warranted to provide insights into first-line DMARD utilization and durability of response in the second-line setting.

Objectives: To analyze RA treatment patterns in real-world data and compare durability of response between second-line DMARDs + anti-TNF (TNFi) therapies vs. TNFi monotherapy.

Methods: Electronic health records (EHRs) from a large health system in the Northeast US were used to identify RA patients. Lines of therapy were defined based on confirmed prescriptions for DMARDs and TNFi therapies. Time to next treatment (TTNT) was the primary outcome to estimate durability of response. Time-to-event analyses were performed using Kaplan-Meier and log-rank test methods. In addition, a Cox Proportional-Hazards (CoxPH) model was used to evaluate covariates as independent predictors of disease progression.

Results: Our study cohort consisted of 8,040 patients who had at least one line of therapy for RA. Conventional synthetic DMARDs (csDMARDs) were the predominant first line of therapy in this dataset (71.3%), followed by TNFi alone (11.1%) or TNFi combined with csDMARD (9.1%) (Figure 1).

For patients who had csDMARD as their first line of therapy, 22.93% progressed to second line treatment. Among them 36.2% patients were TNFi with or without in combination with csDMARDs. In the second-line, TNFi + csDMARDs were associated with a longer TTNT (median time: 13.1 months vs 6.1 months, P < 0.005) compared to TNFi monotherapy. The multiple variable CoxPH model (adjusted for age, gender, and race) demonstrated that second-line TNFi + csDMARDs had a lower hazard rate when compared to TNFi monotherapy (HR = 0.74, 95% CI: 0.36 - 1.12, p < 0.005).

Conclusion: We demonstrated the first comprehensive treatment sequencing patterns in RA from a real-world setting. As a second-line therapy for patients with inadequate response to csDMARDS, the TNFi + csDMARDs combination may improve duration of response when compared to TNFi monotherapy. Results from this study will inform future sequencing strategies to improve patient outcomes.

AB0228 THE CONNECTION BETWEEN NUTRITIONAL STATUS AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

L. Huang[1,2], Y. Huang[1], M. Liu[1,2], Q. Huang[1], Z. Ji[1], S. Sun[1,2], W. Deng[1], T. W. Li[1,2,3]. *[1]Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; [2]Southern Medical University, The Second School of Clinical Medicine, Guangzhou, China; [3]Zhaoqing Central People's Hospital, Department of Rheumatology and Immunology, Zhaoqing, China*

Background: Nutritional status is closely associated with a person's physical condition. As for patients with autoimmune disease, nutritional status may affect the balance of immune system, which successively affects disease activity.

Objectives: The prognostic nutritional index (PNI), nutritional risk index (NRI), controlling nutritional status (CONUT) score and body mass index (BMI) are four widely used nutritional indices [1]. This study aimed to investigate the relationship between nutritional status and disease activity of rheumatoid arthritis (RA).
Methods: 168 RA patients and 50 healthy volunteers were retrospectively enrolled. According to the disease activity score using 28 joint counts-erythrocyte sedimentation rate (DAS28-ESR), the cohort of RA patients was divided into the lower disease activity groups (DAS28-ESR≤3.2) and the higher disease activity groups (DAS28-ESR>3.2). We recorded clinical assessment and laboratory data for further analysis. Spearman's correlation, receiver operation characteristic (ROC) curves, binary logistic regression analysis were carried out.
Results: Compared to the higher disease activity group, the lower disease activity group had low-level total protein (TP), ESR and CRP (all P<0.05), while high-level albumin and PNI (all P<0.05). PNI and NRI were negatively correlated with DAS28-ESR (r=-0.395, and r=-0.200, all P<0.05), while CONUT score was positively correlated with DAS28-ESR (r=0.324, P<0.05). ROC curve illustrated that area under the curve (AUC) of PNI for RA patients with higher disease activity was superior to NRI, CONUT score and BMI. The AUC of PNI was 0.693.

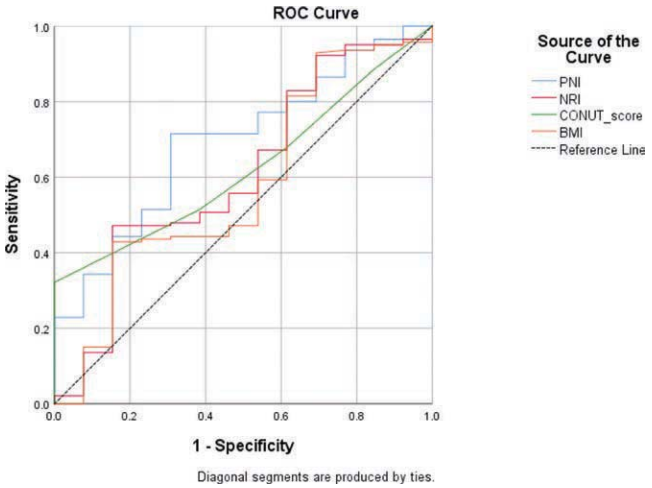

Figure 1. The diagnostic value of variables for disease activity in rheumatoid arthritis using ROC curve

Table 1. The correlation between nutritional indices and disease activity score using 28 joint counts-erythrocyte sedimentation rate (DAS28-ESR)

	PNI		NRI		CONUT score		BMI	
	r	*P* value	r	*P* value	r	*P* value	r	*P* value
Neutrophil(×10^9/L)	-0.061	0.434	0.045	0.568	0.025	0.757	0.079	0.313
Monocyte(×10^9/L)	0.183	0.163	0.145	0.064	-0.104	0.193	0.152	0.052
Lymphocyte(×10^9/L)	0.472	0.000	0.201	0.010	-0.436	0.000	0.208	0.007
ESR (mm/h)	-0.561	0.000	-0.258	0.001	0.393	0.000	-0.182	0.020
CRP (mg/L)	-0.520	0.000	-0.077	0.326	0.391	0.000	0.003	0.967
RF(IU/ml)	-0.224	0.004	-0.116	0.151	0.260	0.001	-0.082	0.306
CCP(IU/ml)	-0.139	0.088	-0.201	0.014	0.195	0.018	-0.188	0.022
DAS28-ESR	-0.395	0.000	-0.200	0.011	0.324	0.000	-0.142	0.072

Conclusion: PNI may become a manageable marker for detector disease activity of RA patients.

AB0229 ACHIEVING GLUCOCORTICOID FREE MIGHT DECREASE RISK FOR CLINICAL FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS - TEN-YEAR FINDINGS FROM THE TOMORROW STUDY

K. Mamoto[1], T. Koike[2,3], T. Okano[1], Y. Sugioka[2], M. Tada[4], K. Inui[5], H. Nakamura[1]. *[1]Osaka City University Graduate School of Medicine, Department of Orthopaedic Surgery, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [3]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan; [4]Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan; [5]Osaka Saiseikai Nakatsu Hospital, Department of Orthopaedic Surgery, Osaka, Japan*

Background: Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falls and fractures.
Objectives: The present study prospectively investigates correlations between decreasing doses of glucocorticoid (GC) and the incidence of clinical fractures in patients with RA based on the ten-year findings of the TOMORROW study (UMIN000003876) that started in 2010.
Methods: We evaluated anthropometric parameters, bone mineral density, disease activity, RA medication, and the incidence of clinical fractures over a period of ten years in 202 patients with RA (mean age, 58.6 years; mean disease duration, 14.0 years). We also investigated the effects of GC doses on the incidence of clinical fractures over the same period in patients with RA using multivariate regression analysis.
Results: The incidence of clinical fractures for ten years in patients with RA was 0.036/person-year. There were 89 patients (44.1%) treated with GC at least once during ten years. The incidences of clinical fractures in patients with RA treated with and without GC during ten years were 0.052 and 0.026/person-year, respectively. After adjusting for fracture risk factors including age, sex, smoking, and body mass index, cox proportional hazard model revealed that GC dose of ≥ 2 mg/day at baseline was a significant risk factor for clinical fractures (Hazard ratio [HR]:2.430; 95%CI, 1.040-5.675, p=0.040). Although the risk for clinical fractures did not decrease by just reducing the dose of GC (HR:4.505; 95%CI, 0.589-34.457, p=0.147), it was significantly lower if the dose of GC could be reduced to zero during ten years (HR:0.407; 95%CI, 0.194-0.857, p=0.018).
Conclusion: Medication with even low dose of GC are apparently significantly associated with an increased frequency of clinical fractures among patients with RA. However, if the dose of GC was reduced to free during ten years, the clinical fracture risk could become lower. We concluded that we should decrease the dose of GC to free after controlling disease activity of RA.

AB0230 THE INFLUENCE OF THE PATIENT'S PSYCHOLOGICAL STATUS ON THE INFLAMMATORY ACTIVITY OF RHEUMATOID ARTHRITIS

V. Rybakova[1], A. Avdeeva[1], E. Nasonov[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology Rheumatic Diseases, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Objectives: To examine the relationship between rheumatoid arthritis (RA) activity indicators and psychological factors of patients receiving the therapy according to the "Treat to target" (T2T) strategy.
Methods: The research included 93 patients with early RA (16 men and 77 women), average age Me;IQR (58 [49; 66] years), the duration of the disease 7 [4-11,5] months. All patients were prescribed a subcutaneous form of methotrexate (MT) at an initial dose of 10 mg / week with a rapid escalation of the dose to 20-30 mg / week. If the effectiveness of the therapy was insufficient, biologics were prescribed. During the first year, patients received the therapy according to the concept of T2T, then they were observed in the «real-life» clinical practice. After 6 years, the patients were re-examined. Clinical examination was performed including patient global assessment (PGA), functional status was determined by HAQ, the nature of pain by painDETECT, the presence of anxiety and depression – by HADS.
Results: Before the start of the therapy, the DAS 28-ESR was 5.31 [4.79; 6.14], SDAI – 28.27 [18.79; 40.73], CDAI-25 [17; 36], HAQ – 1,32 [0,75; 1,25]. After 6 years DAS28-ESR 4 [3,4; 4,59], SDAI-15,06 [9,32; 21], CDAI-15 [9; 21], HAQ - 0.5 [0.25; 1], PGE - 35 [20; 50].; activity of disease according to DAS28-ESR: remission in 7.8%, the low activity in 21.3%, the moderate activity in 60.6%, the high activity in 11.2% of patients.
29 patients had subclinically or clinically expressed anxiety (≥8 according to HADS), of whom10.3% had remission/low disease activity, 89.7% had moderate/high disease activity.
18 patients had subclinically or clinically expressed depression (≥8 according to HADS), of whom remission/low disease activity in 16.6%, the moderate/high activity was in 83.4%. In 35 patients, the painDETECT questionnaire revealed possible or probable neuropathic pain, remission/low disease activity of the was revealed in 20%, moderate/high activity in 80%. Depending on the presence of anxiety and depression, all patients were divided into two groups

(Table 1). Among patients with depression, there was a greater severity of PGE pain, and more expressed functional disorders. In the group of patients with anxiety, there was a higher disease activity (according to DAS28-ESR), the severity of pain according to PGE and functional disorders; there were no significant differences between the groups in terms of ESR and CRP indicators (Table 1).

Table No1. Influence depression and anxiety symptoms of inflammatory activity

Parametres	Depression positive, n=18	Depression negative, n=75
DAS28-ESR	4,4 [3,8; 5]	3,9 [3,1; 4,5]
ESR, mm/hr	16 [13; 25]	16 [9; 27]
CRP, mg/l	1,5[0,6; 2,9]	2,4 [1; 5,9]
HAQ	1[0,75; 1,37]*	0,5[0; 1]*
PGA	52,5 [35; 70]*	30 [15; 50]*
	Anxiety positive, n=29	Anxiety negative, n=64
DAS28-ESR	4,4 [3,8; 4,9]*	3,18[2,9; 4,4]*
ESR, mm/hr	20[11; 33]	15[9; 25]
CRP, mg/l	1,9 [1; 3,3]	2,5[1; 5]
HAQ	1[0,5; 1,37]*	0,5[0; 0,8]*
PGA	50 [35; 70]*	25[10; 40]*

Conclusion: The presence of depression and anxiety negatively influences the activity of RA, leading to an increase in pain and worsening of the functional disorders. To prescribe an adequate anti-rheumatic therapy, it is necessary to take into account not only the activity of RA, but also the psychological status of the patient

AB0231 PROGNOSTIC UTILITY OF METACARPAL BONE MINERAL DENSITY MEASUREMENT IN PATIENTS WITH RECENT-ONSET ARTHRITIS BY ASSESSMENT OF RADIOGRAPHIC PROGRESSION AT 2-YEAR FOLLOW-UP

I. Llorente[1], A. Ortiz[1], A. M. Fernandez Ortiz[2], A. García-Vadillo[3], J. Ivorra[4], L. Rodriguez Rodriguez[5], R. Garcia-Vicuna[1], S. Castañeda[1], I. González-Álvaro[1]. *[1]Hospital Universitario de La Princesa, Rheumatology Unit, Madrid, Spain; [2]Hospital Universitario de Badajoz, Rheumatology Unit, Badajoz, Spain; [3]Hospital Universitario de La Princesa, Rheumatology, Madrid, Spain; [4]Hospital Universitario y Politécnico de La Fe de Valencia, Rheumatology Unit, Valencia, Spain; [5]Hospital Clinico San Carlos, Rheumatology Unit, Madrid, Spain*

Background: Rheumatoid arthritis (RA) and osteoporosis (OP) have a complex interplay in terms of pathogenic mechanisms. In this regard, radiogrammetry (DXR) of the hand, a technique that measures the bone mineral density (BMD) at the central metacarpals (MC), is associated with a worse prognosis in patients with RA (1). However, DXR is an expensive technique, and not very accessible in our environment. Our group demonstrated an excellent reproducibility of the MC measurement by DXA (2) and good correlation between BMD measurements obtained by DXR and DXA (3).

Objectives: To evaluate if baseline BMD of the non dominant MC measured by DXA can be used as a prognostic marker, resembling DXR, in patients with early arthritis (EA).

Methods: A total of 378 subjects from the PEARL (Princesa Early Arthritis Register Longitudinal) study underwent DXA measurement of the 2nd to 4th MC's diaphyseal area of the non dominant hand (Hologic 4500). In PEARL sociodemographic, clinical and laboratory parameters, therapeutic data and radiographic findings are collected by protocol. Radiographic progression was evaluated in hands by a blind expert rheumatologist assessing the erosion scale of modified SvdH index in both the baseline and two year follow-up visit. To study the predictive value of MC baseline BMD by DXA, two multivariate models were fitted using generalized linear models with Stata 14.0 for Windows (Stata Corp LP, College Station, TX, USA). The dependent variables were remission (SDAI<3.3) and radiographic progression after two 2 years of follow-up. Both models were adjusted by the classic variables that affect BMD such as age, sex and body mass index (BMI), cumulative DMARD treatment and baseline disease activity for the remission model.

Results: After adjustment by age, sex and BMI: a) those patients at remission tended to show higher baseline MC's BMD by DXA (p=0.328); and b) those patients with higher radiographic progression had significantly lower baseline MC's BMD as shown in Figure 1(p=0.001).

Conclusion: In our registry of patients with EA, we have detected that a lower basal BMD in the diaphysis of the central MC bones, assessed by DXA, is associated with greater radiographic progression at 2 years of follow-up after adjusting for the main factors influencing BMD. Therefore, we could conclude that a low initial bone mass could constitute a poor prognostic factor in patients with EA.

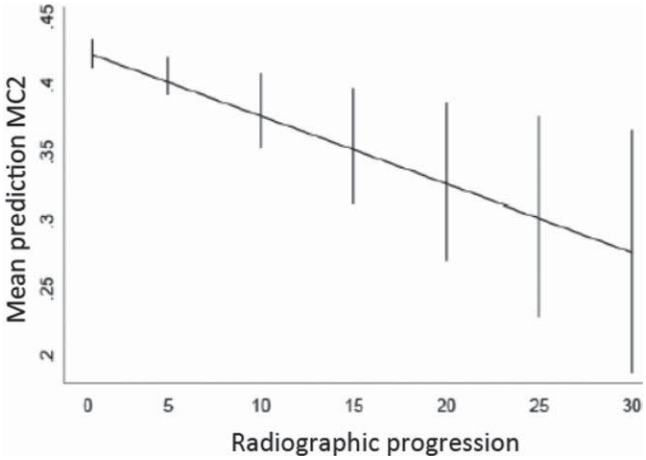

Figure 1. Correlation of mean BMD of 2-4th MC bones with radiographyc progression assesed by the modified SvdH radiological index at 2 years, after adjusting for age, sex and BMI, calculated using Stata margins command base don the data obtained from multivariate analysis.

AB0232 THE USEFULNESS OF THE PROGNOSTIC NUTRITIONAL INDEX (PNI) FOR THE DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Öz[1], H. H. Gezer[2], M. T. Duruöz[3]. *[1]Marmara University School of Medicine, Physical Therapy and Rehabilitation, Rheumatology, Istanbul, Turkey; [2]Umraniye Training and Research Hospital, Physical Therapy and Rehabilitation, Rheumatology, Istanbul, Turkey; [3]Marmara University School of Medicine, Physical Therapy and Rehabilitation, Rheumatology, Istanbul, Turkey*

Background: Many prognostic factors and laboratory biomarkers have been put forward to correlate disease activity in Rheumatoid arthritis (RA). The prognostic nutritional index (PNI) was first established to assess perioperative immunonutritional status and surgical risk in patients undergoing gastrointestinal surgery. The PNI, which reflects albumin concentration and lymphocyte count, is a newly established inflammation-based nutritional score.

Objectives: In this study, we aimed to determine the relationship between this simple risk index, which was first adapted and analyzed in malnourished patients, and disease activity in RA patients.

Methods: This prospective study included 77 RA patients who fulfilled the 2010 revised criteria of the American College of Rheumatology for RA. The demographic characteristics of the patients, duration of the disease and clinic characteristics of the patients such as the 28-joint Disease Activity Score based on the erythrocyte sedimentation rate (DAS28-ESR), Visual Analogue Scale, Health Assessment Questionnaire-Disability Index were collected. Labotaruvary findings including erythrocyte sedimentation rate, C-reactive protein levels, lymphocyte count, albumin were noted. The PNI was calculated using the following formula: 10 x serum albumin value (g/dL) + 0.005 x total lymphocyte count in the peripheral blood (per mm^3). Based on the DAS28-ESR level, the included patients were categorized into two groups, namely, inactive to mild active RA (n=31; DAS28-ESR level <3.2) and moderate to highly active RA (n=46; DAS28-ESR level ≥3.2). These groups were compared with the parameters described above.

Results: Seventy-seven patients (90.9% female) with a mean age of 53.6 (SD:10.2) years were recruited into the study. The age, gender and disease therapy duration of the patients were similar in both groups. Patients who DAS28-ESR ≥3.2 had a significantly lower PNI compared to those who did not [41,57 (SD:3,64) *vs*. 43,78 (SD:2,30), *p*=0.017] (Table 1). Multivariate logistic regression analyses revealed that PNI was an independent predictor of moderate to highly active RA (OR: 0.770, 95%CI: 0.635–0.935; *p*=0.008). A receiver operating characteristic curves analysis yielded that the optimal cut-off value of PNI for moderate to highly active RA was 42.01 with sensitivity 67.7% and specificity 47.9% (AUC: 0.662, 95%CI: 0.541-0.782, p=0.017) (Figure 1).

Table 1. Demographic, clinical features and laboratory findings of the patients with rheumatoid arthritis based on disease activity measured by DAS28-ESR

	DAS28-ESR <3.2 n=(31)	DAS28-ESR ≥3.2 n=(46)	P value
Age (years; mean SD)	55,80 SD 9,39	52,13 SD 10,67	0.124
Female, gender, n (%)	26(%83,9)	44(%95,7)	0.111
Prognostic Nutritional Index (mean SD)	43,78 SD 2,30	41,57 SD 3,64	***0,017***
Disease symptoms duration (month; mean SD)	112,2 SD 97,3	120,9 SD 79,7	0.316
Disease therapy duration (month; mean SD)	93,2 SD 94,2	110,0 SD 76,0	0.126
DAS28-ESR (mean SD)	2,55 SD 0,47	4,47 SD 0,85	<0.001
Visual Analogue Scale (mm, mean SD)	7,38 SD 16,58	20,17 SD 25,76	<0,001
Health Assessment Questionnaire-Disability Index (mean SD)	0,69 SD 0,62	0.84 SD 0,60	0,259
ESR (mm/h, mean SD)	26,35 SD 18,98	31,73 SD 16,95	0.083
CRP (mg/L, mean SD)	6,30 SD 4,49	12,75 SD 19,54	0.106
Albumin (g/dl, mean SD)	4,37 SD 0,23	4,15 SD 0,36	0.010
Lymphocyte (cells/µL, mean SD)	2,01 SD 0,62	2,07 SD 0,65	0.570

Abbreviations: DAS28-ESR, the 28-joint Disease Activity Score based on the erythrocyte sedimentation rate; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein.

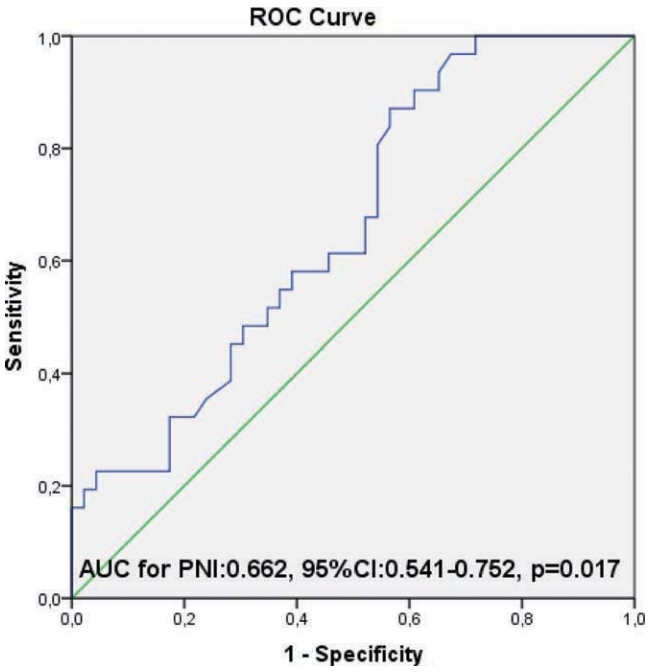

Figure 1.

Conclusion: Based on the study findings, we were able to show that simple and easily obtained PNI could be an independent predictor of disease activity in rheumatoid arthritis patients.

CARDIOVASCULAR EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A TWO YEARS OBSERVATIONAL STUDY.

P. Martinez Calabuig[1], R. González Mazarío[2], J. J. Fragío Gil[3], E. Grau García[3], C. Pávez Perales[3], S. Leal Rodriguez[3], C. Riesco Barcena[3], A. V. Huaylla Quispe[3], L. Mas Sanchez[3], P. Muñoz Martinez[3], J. E. Oller Rodríguez[3], E. Vicens Bernabeu[3], R. Negueroles Albuixech[3], J. Ivorra Cortés[3], F. Ortiz-Sanjuán[3], M. De la Rubia Navarro[3], L. Gonzalez Puig[3], I. Martínez Cordellat[3], C. Nájera Herranz[3], I. Cánovas Olmos[3], J. A. Román Ivorra[3]. *[1]Hospital General Universitario, Servicio de Reumatología, Valencia, Spain; [2]Hospital Arnau de Vilanova, Sección de Reumatología, Valencia, Spain; [3]Hospital Universitari i Politècnic La Fe, Servicio de Reumatología, Valencia, Spain*

Background: The risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) is higher than individuals from the general population due to chronic inflammation. Current CV risk screening and management strategies underestimate the actual CV risk in RA. Thus, an adequate CV risk stratification has special relevance in RA to identify patients at risk of CV disease.

Objectives: To assess the incidence of cardiovascular events in a RA cohort after a 2 years follow-up.

Methods: A cohort study was performed in which inclusion criteria were adult RA patients and matched adults in terms of age, sex and CV risk factors (controls). Population over 75 years old, patients with established CV disease and/or stage III chronic kidney disease were excluded. Controls with other inflammatory diseases, pregnant women or any malignancy were also excluded. This study was performed from July-2019 to January-2022. CV risk assessment included risk factors collection and US evaluation consisted in detection of plaques and measurement of the intima-media thickness in both right and left carotid.

Results: Overall, a total of 200 cases and 111 healthy controls were enrolled in the study. Demographical and clinical variables were comparable between cases and controls and are shown in Table 1. US study revealed a higher IMT in both right and left carotid arteries with greater presence of plaques in patients than in controls (CI 95% [1.542; 3.436], p<0.001). Plaques were found in both carotid arteries in the 32% of cases and 9.91% of controls. The longer duration of RA was related to a higher presence of carotid plaques (95% [1.015; 1.056], p<0.001).

Table 1. Demographic, clinical characteristics and Ultrasound results of patients and controls.

Characteristic	RA cases n=200	Healthy controls n=111
Age - years	62.05 (10.75)	58.3 (12.14)
Female sex – number (%)	163 (81.5)	73 (65.77)
BMI – value (ds)	26.38 (5.03)	26.2 (5.19)
Smoking habit		
Never Smoked	107 (53.5%)	71 (63.96%)
Ex-smoker	51 (25.5%)	20 (18.02%)
Active smoker	42 (21%)	20 (18.2%)
Race – number (%)		
Caucasian	186 (93)	62 (93.94)
Comorbidities – number (%)		
High blood pressure	83 (41.5%)	34 (30.63%)
Dyslipemia	93 (46.5%)	39 (35.14%)
Blood pressure -- mmHg	127.2(18.36)/78.67(10.21)	127.77(19.42)/78.28 (10.59)
Ultrasound findings		
Right carotid cIMT	0.78 (0.15)	0.62 (0.11)
Left carotid cIMT	0.77 (0.14)	0.64 (0.12)
Plaques	101 (50.5%)	32 (28.83%)
Bilateral	64 (32%)	11 (9.91%)
Right carotid	17 (8.5%)	7 (6.31%)
Left carotid	20 (10%)	14 (12.61%)

Eight patients (4%) presented a cardiovascular event, and one of them died (0.5%). The events consisted in 2 angina pectoris, 3 transient ischemic attack, 1 acute myocardial infarction, 1 lacunar stroke and 1 cardiac arrest. Six out those 8 patients demonstrated bilateral plaque presence at baseline. Two patient caused loss of follow up due to death related to Covid-19. Not a single cardiovascular event was reported in the control group.

Conclusion: Our results shows that cardiovascular events are increased in RA patients and US study may be useful in predicting an event.

AB0234 POTENTIAL CREDIBILITY IN RHEUMATOID ARTHRITIS PATIENT REPORTED DAS28 SCORES

S. Cabraal[1]. [1]*Aneurin Bevan University Health Board, Rheumatology, Nepwort, United Kingdom*

Background: Due to COVID-19 and the reduction of face to face clinic, the rheumatology telephone advice line service has been an integral part in identifying patients that need assessment the most (1). This however means relying on a patient's ability to conduct their own disease activity score (DAS28), which clinicians conduct to help drive patients with rheumatoid arthritis (RA) into remission. Current literature suggests that patient self-assessed joint counts are reliable and when compared to the joint count of the physician, have an acceptable level of accuracy (2-5). We present data from an NHS audit where we incidentally found that patients could conduct their own joint counts.
Objectives: Our objective was to compare self-reported DAS28 scores with the clinical opinion of physicians during a face-to-face appointment.
Methods: We identified 10 patients with RA who attended a face-to-face appointment following a call to the helpline where a telephone DAS28 score was undertaken (with guidance from rheumatology specialist nurses). These scores were contrasted against the clinician's assessment of whether synovitis was present or not in a face-to-face consultation. Co-morbidities: fibromyalgia (FM), osteoarthritis (OA) or both, were also recorded to examine whether these conditions influenced a patient's ability to perform an accurate DAS28 score.
Results: There were 10 patient self-reported DAS 28 scores in total. 70% (7/10) of patients DAS 28 scores were over 4.01. In all these cases, clinicians confirmed evidence of synovitis during their face-to-face consultation. 30% (3/10) of patients self-reported DAS 28 score was <4.01. Of these patients 2/3 have no evidence of synovitis according to their clinician. When considering co-morbidities, one individual also suffered from OA. This individual's self-assessed DAS28 score was over 4.01 and was also evidenced to have synovitis during their consultation with the clinician.

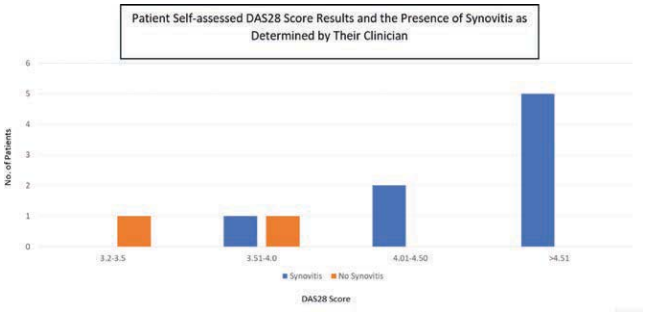

Figure 1. Shows patient's self-assessment DAS28 scores and whether synovitis was identified following a face to face consultation with a clinician.

Conclusion: This regional NHS audit found that patients who self-reported DAS28 scores over 4.01 accurately identified a flare up, as confirmed by a diagnosis of synovitis at a face-to-face appointment. This is significant as it demonstrates that patients who score above 4.01, can reliably assess their own joint count. This may enable the Rheumatology service to become more patient-driven, empowering patients to accurately assess their condition.

AB0235 TREAT TO TARGET PATHWAY (T2T) IN INFLAMMATORY ARTHRITIS-DESIRABLE RESULTS? AND IF CERTAIN GROUPS RESPOND TO TREATMENT BETTER?

Q. Shah[1], E. Ison[1], B. Whelan[1], M. O'sullivan[1], C. Silke[1]. [1]*Saolta Healthcare Group, Northwestern Rheumatology Unit Manorhamiltion, Manorhamilton, Ireland*

Background: There is established evidence that treat to target strategy in inflammatory arthritis helps achieve early remission rates or low disease activity. This approach is more effective for improved outcomes at no additional costs and more likely to achieve rapid and sustained disease control. It is important to aim for early diagnosis to limit the structural damage that occurs with prolonged inflammation. Commencing disease modifying anti-rheumatic drugs (DMARD) therapy and glucocorticoids as early as possible and titrating therapy as appropriate improves clinical outcomes.
Objectives: Aim of this study was to analyse ACR20 response within different subgroups of inflammatory Arthritis patients enrolled in Treat to Target program.
Methods: Data collection was performed by assessing electronic medical records of 374 inflammatory arthritis patients who participated in Treat to Target pathway for inflammatory arthritis between 2014 to 2020.
In total 374 patients were enrolled in treat to target inflammatory pathway led by Rheumatology ANP with consultant supervision. Majority of the patients had diagnosis of Rheumatoid arthritis as per ACR/Eular criteria. 213(51%) were seropositive RF+, 83(19.9%) were seronegative RF-, 44(10.5%) were diagnosed as psoriatic arthritis, and 34(8.1%) were labelled as undifferentiated inflammatory arthritis. In terms of age and gender, 158(42%) were under 50, and 216(58%) were aged 50 and over, majority females 207(55%). Smoking status 118(32%) current, 211(56%) never, 45(12%) ex-smokers. DMARD started at baseline was Methotrexate only and Starting dose was 15mg for all patients. 326(88%) were on oral methotrexate and only 48(12%) were on SC form between weeks 1-20. ACR 20,50,70 responses were analysed for these subgroups with majority (61%) seen at week 6 for their visit 1 after starting T2T pathway while all patients seen by week 20.
Results: ACR 20,50 and 70 responses were calculated for all subgroups enrolled in T2T program. The results showed that ACR 20 response rate was same among patients aged under and over 50(67% responders), ACR 50 (38.3%) responders and ACR 70 (20.1%) responders. There was no significant difference in ACR 20 response among females and males (66.9% response) both groups. In terms of seropositivity, 75% responded to treatment in RF+ group vs 60% in RF-group. Higher response rates were seen among not current smokers vs active smokers(70%vs65%). ACR 20 response was greater in patients on Sc form of methotrexate. Overall, 65 % achieved remission within 15 months of starting T2T pathway while remaining achieved low disease activity. Further analysis and discussion will follow.
Conclusion: Treat to target strategy in inflammatory arthritis are consistent with real world data in achieving early response rates with methotrexate (ACR responses) and specific subgroups within T2T cohort respond better to treatment.

Rheumatoid arthritis - comorbidity and clinical aspects

AB0236 PRESENCE OF ANTI-CITRULLINATED POLYPEPTIDE ANTIBODIES DECREASES BONE MINERAL DENSITY IN BODY OF PATIENT WITH RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY

I. Yoshii[1], N. Sawada[2]. [1]*Yoshii Hospital, Musculoskeletal Medicine, Shimanto-City, Japan;* [2]*Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan*

Background: Presence of anti-citrullinated polypeptide antibodies (ACPA) is one risk factor of bone erosion of the joint in patients with rheumatoid arthritis (RA). However, bone absorption in the whole body is still not clarified in a longitudinal study.
Objectives: The aim of this study is to clarify effects of ACPA on bone mineral density (BMD) decrease using dual-energy X-ray absorptiometry (DXA) in patient with RA using retrospective longitudinal cohort study.
Methods: Patient with RA who were measured BMD in lumbar spine (LS) and total hip (TH) using dual-energy X-ray absorptiometry (DXA) at first consultation (baseline) and were treated for more than five years, were recruited. Follow-up started at BMD measurement and continued until the development of the first fracture or censoring at death, loss to follow-up or end of the study. Every patients have been followed up with monitoring of SDAI and Health Assessment Questionnaire Disability Index (HAQ) at every another to three months. Sharp/van der Heijde Score (SHS) was measured at baseline and every another year thereafter. BMD were measured every six months. Relationship between BMD and candidate risk factors including ACPA positivity and serum titer level, and other variants for BMD loss were evaluated statistically using linear regression analysis. Evaluations were performed for the absolute value of BMD and Z-score at baseline, mean value of these during follow-up, and change from baseline. Change of Z-score during follow-up was also compared between groups what classified according to ACPA positivity (ACPA positive/negative group).
Results: A total of 222 patients were recruited including 17 male (7.7%) and 205 female (92.3%). The mean age of the patients was 69.2 years old. Mean disease duration at baseline and follow-up length after baseline were 6.4 and 63.3 months, respectively. Mean SDAI score, HAQ score and SHS at baseline were 22.2, 0.516, and 6.6, respectively. The mean ACPA level and positive rate were 202.1 and 77.5%, respectively.
Higher ACPA titer level correlated significantly low BMD and Z-score in TH (p<0.05), whereas ACPA positivity significantly correlated with low Z-score in LS and TH during follow-up using univariate models (p<0.05). The ACPA positivity also correlated with decrease of Z-score in both LS and TH using univariate models (p<0.05), whereas no significant correlation demonstrated using multivariate model.
Change of Z-score in the ACPA positive group was significantly lower than in the ACPA negative group despite no significant difference of disease activity between the two groups demonstrated (p<0.05) (Table 1).

Table 1. Comparison of the two groups

	parameters	ACPA-positive (n=172)	ACPA-negative (n=50)	p-value
	female (%)	91.3	96.5	0.10
at baseline	age (year-old)	65.4	71.3	**<0.001**
	disease duration (months)	7.7	4.6	**<0.001**
	RF (IU/L)	138.3 (197.1)	21.5 (49.3)	**<0.001**
	SDAI	26.3 (24.0)	21.0 (17.8)	**<0.05**
	HAQ	0.496 (0.618)	0.553 (0.639)	0.48
	SHS	8.4 (8.2)	3.5 (5.0)	**<0.001**
	BMD in LS (g/cm2)	0.825 (0.167)	0.849 (0.156)	0.23
	BMD in H (g/cm2)	0.700 (0.140)	0.710 (0.132)	0.75
	Z-score in LS	-0.246 (1.300)	0.123 (1.392)	**<0.05**
	Z-score in TH	-0.062 (1.034)	0.261 (1.020)	**<0.05**
at follow-up	follow-up length (months)	64.8	65.4	0.65
	SDAI	4.5 (3.1)	5.1 (4.4)	0.22
	HAQ	0.495 (0.616)	0.516 (0.544)	0.32
	SHS	8.1 (8.2)	3.4 (4.8)	**<0.001**
	BMD in LS (g/cm2)	0.839 (0.171)	0.870 (0.165)	0.16
	BMD in TH (g/cm2)	0.710 (0.118)	0.713 (0.115)	0.99
	Z-score in LS	-0.008 (1.361)	0.368 (1.426)	**<0.05**
	Z-score in TH	0.129 (0.902)	0.396 (0.891)	0.11
	anti-osteoporotic drug administered, ever (%)	73.4	69.8	0.72
	GCS administered, ever (%)	35.8	32.9	0.68

The values are presented as mean (SD) unless indicated otherwise.Statistically significant within 0.05 are shown as bold styles.

Conclusion: Presence of ACPA potentially have an independent risk of BMD decrease. Its action affects regardless gender and age.

AB0237 CHANGES AND CLINICAL SIGNIFICANCES OF PERIPHERAL REGULATORY T CELLS IN RHEUMATOID ARTHRITIS PATIENTS WITH CARDIOVASCULAR DISEASE

H. Q. Niu[1], L. Hao[1]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is an independent risk factor for cardiovascular diseases (CVD), driven by the underlying chronic systemic inflammation [1]. The imbalance of $CD4^+$ T lymphocyte subsets, especially between T helper (Th) 17 cells and regulatory T (Treg) cells, can mediate autoimmune inflammatory process, promoting the overproduction of cytokines and abnormal antibodies [2,3]. However, the levels of peripheral Th17 and Treg cells in RA patients with CVD are still unknown.
Objectives: To explore the expression of circulating Th17 and Treg cells in RA patients with CVD and analyze its clinical significance.
Methods: A total of 192 patients with RA and 86 healthy controls (HCs) were enrolled from January 2019 to January 2021. The peripheral blood $CD4^+$T lymphocyte subsets of all participants were assessed by flow cytometry. Patients were divided into RA-CVD group (n=72) and RA only group (n=120), and the clinical data were recorded. The statistical differences between two groups were analyzed by independent-samples t test, χ^2 test or Mann-Whitney U test, and risk factors of CVD were analyzed using Logistic regression.
Results: ① The median age and the percentage of male patients in the RA-CVD group were significantly higher than those in the RA only group. ② The absolute numbers of peripheral Treg cells in the patients with RA only and RA-CVD were all significantly lower than those in HCs [24.94 (19.32, 34.12) cells/μl *vs.* 33.13 (24.96, 45.83) cells/μl , Z=-4.135 , P < 0.01; 19.13 (13.76, 27.34) cells/μl *vs.* 33.13 (24.96, 45.83) cells/μl , Z=-5.354 , P < 0.01]. While the numbers of peripheral Th17 cells in two groups of patients were not significantly different with those in HCs. The ratios of Th17/Treg cells in two group patients were higher than those of HCs, but only the difference between RA-CVD patients and HCs were significant [0.40 (0.23 , 0.63) *vs.* 0.18 (0.13 , 0.29) , Z=-4.696 , P < 0.01]. ③ Compared to the RA only patients, the absolute counts of Treg cells in RA-CVD patients were significantly lower [Z=-3.047 , P < 0.01], the numbers of Th17 cells were significantly higher [7.48 (3.72, 13.63) cells/μl *vs.* 5.59 (3.49 , 8.91) cells/μl , Z=-1.989 , P < 0.05], and the ratio of Th17/Treg cells was significantly higher [0.40 (0.23 , 0.63) *vs*. 0.23 (0.14 , 0.35) , Z=-4.289 , P < 0.01]. ④ Logistic regression analysis showed that the level of circulating Treg cells (*OR*=0.936, 95%*CI*: 0.906-0.968) was a protective factor, while Th17 cells (*OR*=1.068, 95%*CI*: 1.020-1.119), elder age (*OR*=1.039, 95%*CI*: 1.004-1.076) and hypertension (*OR*=2.712, 95%*CI*: 1.254-5.865) were independent risk factors of RA patients complicated with CVD.
Conclusion: It is suggested that the immune imbalance caused by the deficiency of Treg cells may be involved in the occurrence and development of RA complicated with CVD, and to restore Treg numbers and function may be a promising preventive strategies.

AB0238 HEALTH-RELATED QUALITY OF LIFE AND CORRELATION WITH DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Tzanis[1], K. Klavdianou[1], S. Katechis[1], C. Katsimpari[1], L. Athanassiou[1], O. Gioti[1], I. I. Giannakopoulou[1], S. Koutsoviti[1], I. Sofianos[1], A. Lazarini[1], A. Fanouriakis[1,2], E. Theotikos[1], E. Kalavri[1], A. Elezoglou[1]. [1]*Asklepieion General Hospital, Department of Rheumatology, Athens, Greece;* [2]*National Kapodistrean University of Athens Medical School, 1st Department of Propaedeutic Internal Medicine, Athens, Greece*

Background: Patients with active rheumatoid arthritis (RA) are at risk for poor functional outcomes, affecting quality of life (QoL). SF-36 is a validated instrument to measure health-related quality of life (HRQoL) in various domains of physical and mental health[1], and has been validated in RA. Nevertheless,

data on the impact of RA disease activity on SF-36 scores in Greek patients are lacking.
Objectives: To compare SF-36 scores in Greek RA patients versus the general population and to assess the impact of disease activity on HRQoL.
Methods: Cross-sectional study in RA patients followed in the Department of Rheumatology, Asklepieio Voulas General Hospital (05-10/2021). Demographic characteristics, state of disease activity and current treatment for RA were recorded at most recent visit. All patients completed SF-36 questionnaires and were classified in three subgroups of DAS28-disease activity: i) Remission or Low disease activity (LDA), ii) Moderate disease activity (MDA), and iii) High disease activity (HDA). Data from the SF-36 validation study in the Greek general population with 1007 participants, were used as historical controls[2]. Descriptive statistics, one-way ANOVA and linear regression were used for statistical analyses.
Results: 107 patients participated in the study (80,4% females, mean (SD) age 63.3 (12.1) years, 64.5% seropositive, 72% overweight or obese). One third (n=36) were active smokers and 63% (n=67) were receiving a biologic disease modifying antirheumatic drug (bDMARD).
Patients with RA exhibited low scores in all SF-36 domains and reported significantly worse results compared to the general population (Figure 1).

Figure 1.

Physical component score (PCS) and Mental component score (MCS) of the SF-36 showed a negative correlation with DAS28 (β= -8.28, p= <0.001 and β= -6.2, p= <0.001, respectively). Patients with remission or LDA exhibited better SF-36 scores compared to the other subgroups; moreover, patients with MDA had better SF-36 scores than those with HDA (Table 1). When patients with MDA were further divided into low- and high-moderate disease activity (DAS28: 3,21-4,19 and 4,2-5,1, respectively), no significant difference in any SF-36 domain was found between the two groups.

Table 1.

SF-36 domain mean±SD	RDA or LDA 51%	MDA 37,2%	HAD 11,7%	p-value
PF	48,43 ±34,23	32,14 ±19,83	20 ± 19,75	**0.003**
RP	34,9 ±43,68	20,71 ± 32,92	0 ± 0	**0.015**
BP	51,2 ±30,47	28,24 ± 24,49	18,86 ± 23,54	**<0.001**
GH	48,83 ±45	41,57 ± 24,25	32,27 ± 19,54	**0.043**
VT	49,48 ±22,22	34,14 ± 18,57	30,91 ± 15,94	**0.001**
SF	52,16 ±35,33	40,36 ± 27,13	28,41 ± 14,89	**0.041**
RE	39,01 ±44,68	27,62 ± 40,81	18,18 ± 34,52	0.246
MH	54,08 ±23,24	47,57 ± 21,75	40 ± 18,59	0.124

Conclusion: HRQoL assessed by SF-36 is dampened in RA patients, in both physical and mental component. Disease activity had a negative impact on both physical and mental components of HRQoL. Patients with remission or LDA showed better HRQoL outcomes, suggesting that the treat-to-target approach may also positively affect QoL.

AB0239 **HOW SOLID MALIGNANCIES ARE DETECTED IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS**

A. Aoki[1], H. Kobayashi[1]. [1]*Tokyo Medical University Hachioji Medical Center, Rheumatology, Tokyo, Japan*

Background: According to a meta-analysis reported in 2015[1)], among solid malignancies (cancers), only lung cancer was at an increased risk in patients with rheumatoid arthritis (RA) compared with the general population. A Japanese cohort study reported that the incidence of cancers in patients with RA treated with biological DMARDs was not significantly elevated compared to the Japanese general population[2)]. However, in recent years, malignancy has been one of the major causes of death in Japanese patients with RA[3)]. It has been reported that there was an increased incidence of malignancies in patients treated with tofacitinib compared to TNF-alpha inhibitors. Clinicians need to pay more attention to emerging malignancies.
Objectives: We explored how to detect cancer early in patients attending rheumatology outpatient clinics.
Methods: In this retrospective study, we studied 545 patients with RA who visited our rheumatology clinic between April 2011 and December 2021. Forty-five cases of cancer in 38 patients (31 women, 7 men) with RA were reviewed.
Results: Cancer types: 9 breast, 8 lung, 6 colon, 5 uterus, 4 stomach, 2 prostate, 2 pancreas and 9 others. Five female patients had metachronous or simultaneous double cancers and one male patient had metachronous triple cancers. The median age at diagnosis of 45 cancers was 72 years old (IQR 63–76.5) and the median duration of RA prior to cancer diagnosis was 10 years (IQR 5–20.5).
Lung: Seven cases were found by chest CT at the outpatient clinics; two at the start of bDMARDs and five during RA treatment.
Stomach and Colon: Two cases of four stomach cancers were discovered due to the progression of anemia. Both patients were at an advanced stage with distant metastasis and died 2 months after diagnosis. On the other hand, four of six colon cancers were detected by the fecal occult blood test, and three were in remission.
Of the 45 cases, only 8 cases were detected by cancer screening. In 15 cases, blood samples or imaging tests were the triggers cancer detection. Eight of the 15 cases were detected by routine examinations in the rheumatology outpatient clinic, but five cases were already in the advanced stage.

Table 1. Forty-five cancers in 38 patients with rheumatoid arthritis

		Clue to cancer diagnosis and prognosis at the final visit (death - under treatment - remission)					
Site of cancer	n	noticing symptoms		Various tests in outpatient clinic symptoms(-)		Cancer Screening	
Breast	9	8	(1-4-3)			1	(0-0-1)
Lung	8	1	(1-0-0)	7	(2-3-2)		
Colon	6			1	(1-0-0)	5	(0-1-4)
Stomach	4	1	(0-0-1)	3	(3-0-0)		
Cervix uteri	3	1	(0-0-1)			2	(0-0-2)
Corpus uteri	2	2	(0-2-0)				
Pancreas	2			2	(0-2-0)		
Prostate	2	2	(0-1-1)				
Skin*	2	2	(0-0-2)				
Oral/throat	2	2	(0-2-0)				
Duodenum	1	1	(0-0-1)				
Biliary tract	1	1	(0-1-0)				
Anus	1					1	(0-0-1)
Bladder	1			1	(0-0-1)		
Brain	1			1	(0-1-0)		
Total	45	21	(2-10-9)	15	(6-6-3)	9	(0-1-8)

Conclusion: We have been performing cancer screening before RA treatment and performing routine blood, urine, and imaging tests to identify adverse effects. However, they cannot always find cancers at the early stage. Screening procedures for malignancy are strongly recommended[4)], but the consultation rates for breast and cervical cancer screening are lower in Japan than in European nations. We should encourage our patients to undergo usual age- and sex-appropriate cancer screening.

AB0240 CORRELATION BETWEEN KLOTHO LEVELS AND ANKLE-BRACHIAL INDEX IN FEMALE RHEUMATOID ARTHRITIS PATIENTS

A. Alvarez de Cienfuegos[1], J. A. García-Gómez[2], M. A. González-Gay[3], N. Ortego[4]. [1]*Hospital Vega-Baja, Rheumatology, Alicante, Spain;* [2]*Hopital General Univeritario de Elche, Infectious Diseases, Alicante, Spain;* [3]*Hospital Valdecilla, Rheumatology, Santander, Spain;* [4]*Universidad de Granada, Medicina, Granada, Spain*

Background: Rheumatoid arthritis (RA) that is a chronic systemic and disabling disease affecting 0.5–1% of the general population, have been strongly linked to accelerated aterosclerosis and increased incidence of cardiovascular events and mortality. Klotho is a membrane-bound or soluble antiaging protein, whose protective activity is essential for a proper function of many organs. The association between serum Klotho and the classic risk factors, as well as the clinical history of cardiovascular disease, was also shown. There are a lot of evidences that Klotho deficiency correlates with the occurrence and development of coronary artery disease, atherosclerosis, myocardial infarction, and left ventricular hypertrophy.

Objectives: The aim of this study was to examine the possible association between serum Klotho levels and ankle-brachial index in women with RA.

Methods: This cross-sectional study was performed in Vega-Baja Hospital (Orihuela-Spain) from November 2016 to May 2018. We prospectively enrolled 63 consecutive female patients affected by RA and followed at the Vega-Baja Hospital (Orihuela-Spain). All patients included in this study had normal serum creatinine (Cr) levels and met the 2010 American College of Rheumatology/ European League Against Rheumatism (ACR/EULAR) criteria for RA. Ankle-brachial index were evaluated using a BIDOP model ES-100V3 vascular screening system (Hadeco, Inc, Kawasaki, Japan). Serum Klotho (Elabscience, USA) was analysed using ELISA.

Results: Our study included 63 female patients, with a mean (SD) age of 53 ± 8 years. The majority were Caucasian (90.5%). The mean duration of RA was 8.5 ± 5.8 years. Mean 28-joint disease activity scores (DAS28) based on erythrocyte sedimentation rate (ESR) indicated low disease activity 3.0 ± 1.3. The mean of the health assessment questionnaire (HAQ) was 0.75 ± 0.67. Mean serum Klotho levels were 4.68 ± 1.14 ng/mL. The mean value of the ankle-brachial index was 1.14 ± 0.1.

Lower serum Klotho levels were significantly associated with a lower ankle-brachial index (r 0.27, p<0.05).

Conclusion: Decreased serum Klotho levels are associated with peripheral arterial disease in women with RA.

AB0241 COGNITIVE FRAILTY AND RISK OF FALLS AMONG EGYPTIAN OLDER ADULTS WITH RHEUMATOID ARTHRITIS

R. A. Elziaty[1], R. M. Abdel Kader[2]. [1]*Ain Shams University, Internal Medicine Department, Division of Rheumatology, Cairo, Egypt;* [2]*Ain Shams University, Department of Geriatrics and Gerontology Medicine, Cairo, Egypt*

Background: Rheumatoid arthritis (RA) is chronic autoimmune disease, affecting bone cartilage and predominantly joints, and causing inflammation and pain [2]. RA patients have disease-specific risk factors, including greater impaired balance, tender and swollen joints, lower muscle strength in their lower limbs, fatigability and medication side effects which contributes to a predisposition for falls [1]. Frailty, which was originally considered a geriatric syndrome, is an age-related decline in physiological reserve (3). It is associated with reduced muscle strength, exhaustion and with high inflammatory markers contributing to perpetuation of the frailty cycle (4). The concept of frailty is a recent issue in the rheumatologic field; by now, the prevalence of frailty among elderly individuals with RA has not been extensively examined and few studies on frailty in RA adults have been conducted.

Objectives: To assess the prevalence of cognitive frailty in people with rheumatoid arthritis and the relationship between cognitive frailty and falls.

Methods: In this cross-sectional study we evaluated 105 patients 60 years old or more with rheumatoid arthritis who fulfilled the ACR 2010 criteria and attended to rheumatology outpatient clinic in Ain-Shams University hospitals. Data was collected regarding demography and comorbidities. For cognitive and frailty screening, the Montreal Cognitive Assessment (MOCA) and frail scale were used respectively. Cognitive frailty (CF) is a clinical condition characterized by the simultaneous presence of physical frailty and mild cognitive impairment without functional impairment.

Results: 105 older adult patients with RA were studied of whom (72.4%) were females. The mean age of the study population was 66.03. We found that (12.4%) of the study group were cognitively frail and the prevalence of falls among cognitively frail patients was 92.3%.

Table 1.

		No.= 105
Age	Mean±SD	66.03 ± 4.29
	Range	60 – 77
Gender	Female	76 (72.4%)
	Male	29 (27.6%)
Age/onset	Mean±SD	36.41 ± 4.65
	Range	27 – 48
Education	Not educated	40 (38.1%)
	Educated	65 (61.9%)
Cognitive frailty	No	92 (87.6%)
	Cognitively frail	13 (12.4%)
Frailty sore	Frail	47 (44.8%)
	Pre frail	41 (39.0%)
	Robust	17 (16.2%)

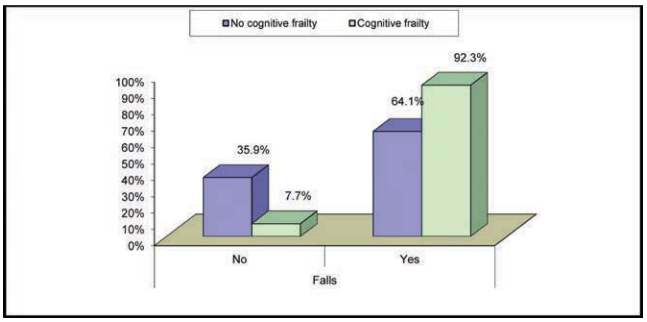

Figure 1.

Conclusion: The prevalence of cognitive frailty in geriatric people with rheumatoid arthritis was high and highly related to falls so screening for cognitive frailty in geriatric practice and the implementation of specific care is recommended.

AB0242 RELATIONSHIP BETWEEN FALLS AND FALL RISK MEDICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Sakurai[1], N. Yajima[2], R. Yanai[2]. [1]*Showa University, Hatanodai Campus, Pharmacy, Shinagawa City, Japan;* [2]*Showa University, Hatanodai Campus, Division of Rheumatology, Department of Medicine, Shinagawa City, Japan*

Background: Falls are a serious event that can lead to disability and death. The use of hypnotics, anxiolytics, and antidepressants has been reported drugs associated with higher risk of falls. Rheumatoid arthritis (RA) is associated with a high risk of falls, which is an important issue because it can lead to fractures. Patients with RA have a higher incidence of sleep disorders, depression, and anxiety disorders. They are likely to be prescribed fall risk medications.

Objectives: We conducted a retrospective study of the incidence of falls in patients with RA, who are more prone to fractures and falls, using fall risk medications, especially hypnotics and anxiolytics, which aimed to determine the relationship between falls and fall risk medications in patients with RA.
Methods: This study is a retrospective cohort study conducted in Showa University Hospital between December 1, 2019 and March 31, 2020. We included of RA patients who visited the outpatient and fulfilled the American College of Rheumatology (ACR) /European League against Rheumatism (EULAR) classification 2010 criteria. The main exposure was the fall risk medication. The fall risk medication group was defined as RA patients who were prescribed fall risk medication (sedative/hypnotic, antidepressants, antipsychotics, and anxiolytic (benzodiazepines) drugs) for all the observational period. The comparison group was defined as RA patients who had never been prescribed any fall risk medications. Outcome measure was the prevalence of fall incidents in the past one year, obtained by using questionnaires to patients. Logistic regression analysis was performed to investigated the relationship between the prevalence of fall incidents and the use of fall-risk medications. The co-variables we selected were as follows: age, sex, stroke, dementia, diabetes and osteoarthritis as covariates.
Results: We obtained data from 331 patients, of which 303 were included in the analysis. Among the 303 patients, the median age was 67 years (56-75), and 78.5% were women. Of the 303 patients, 45 patients used fall risk medication and 69 patients experienced at least one fall in a year. Of the 45 patients who used fall risk medication, 18 patients experienced at least one fall in a year. Of the 69 patients who experienced falls, 30 patients experienced twice or more falls in a year. Of the 18 patients who used fall risk medication and experienced falls, 9 patients experienced twice or more falls. 4 patients were admitted to the hospital as result of falls, 2 patients used fall risk medication. These results are shown as percentages in Figure 1. The group of fall risk medication was significantly higher than using non fall risk medication. (adjusted odds ratio (AOR) 2.31, 95% Confidence Interval (CI) 1.14-4.68, p=0.02).

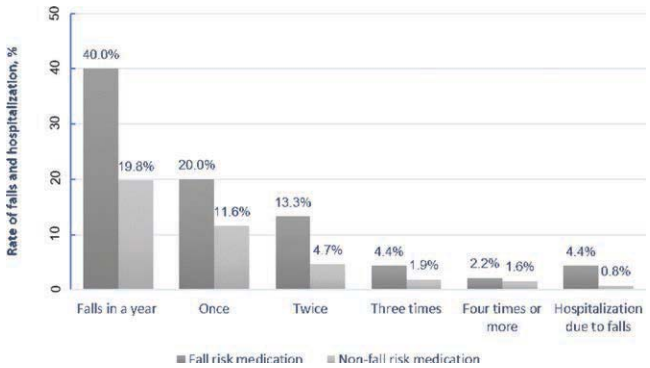

Figure 1.

Conclusion: Use of fall risk medications may have increased falls for patients with RA.

AB0243 **ASSOCIATIONS BETWEEN JOINT DEFORMITY, DISEASE DURATION, DISEASE ACTIVITY, ACTIVITIES OF DAILY LIVING, QUALITY OF LIFE, PAIN, AND FATIGUE IN PATIENTS WITH RHEUMATOID ARTHRITIS**

I. Yoshii[1], N. Sawada[2], T. Chijiwa[3]. *[1]Yoshii Hospital, Rheumatology, Shimanto City, Japan; [2]Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan; [3]Kochi Memorial Hospital, Rheumatology, Kochi, Japan*

Background: Patient with rheumatoid arthritis (RA) have disease-related problems such as joint deformity, disease duration, disease activity, activities in daily life (ADL), quality of life, pain, and fatigue. All these problems correlate interactively.
Objectives: Aim of this study is to clarify association among these problems statistically using retrospective cohort data.
Methods: Patients with RA who were followed up more than three years were recruited. Their EuroQol-5th dimension (EQ5D) as an indicator of quality of life (QOL), simplified disease activity index (SDAI) as an indicator of disease activity, Health Assessment Questionnaire Disability Index (HAQ) as an indicator of ADL, pain score using visual analog scale (PS-VAS), and fatigue score using visual analog scale (FS-VAS), were monitored every three months. Sharp/van der Heijde score (SHS) as an indicator of joint deformity was calculated annually. Association among average values of these factors and patient's sex, age, disease duration (DD), and anti-citrullinated polypeptide antibodies (ACPA) titer were evaluated using multivariate linear regression analysis. Statistical significance was set within 5%.
Results: A total of 447 patients, in whom 120 male and 327 female included, were analyzed. Mean age, disease duration, EQ5D score, SDAI score, HAQ score, SHS, PS-VAS, and FS-VAS during follow-up were 71.6-year-old, 12.9 years, 0.831, 4.26, 0.413, 46.9, 22.5, and 23.2, respectively.
EQ5D score correlated significantly with age, HAQ score, SDAI score, SHS, PS-VAS, FS-VAS, and DD using univariate models. In these, age, HAQ score, and FS-VAS correlated significantly using multivariate model (correlation coefficients (CC): 0.927). HAQ score correlated significantly with age, EQ5D score, SDAI score, SHS, PS-VAS, FS-VAS, and DD using univariate models. In these, EQ5D score, SHS, and FS-VAS correlated significantly using multivariate model (CC: 0.910). SDAI score correlated significantly with female gender, EQ5D score, HAQ score, SHS, PS-VAS, and FS-VAS using univariate models. In these, SHS and PS-VAS correlated significantly using multivariate model (CC: 0.620). SHS correlated significantly with age, female gender, EQ5D score, HAQ score, SDAI score, PS-VAS, and DD using univariate models. In these, HAQ score, SDAI score, and DD correlated significantly using multivariate model (CC: 0.685). PS-VAS correlated significantly with EQ5D, HAQ score, SDAI score, SHS, and FS-VAS using univariate models. In these, SDAI score and FS-VAS correlated significantly using multivariate model (CC: 0.732). FS-VAS correlated significantly with EQ5D score, HAQ score, SDAI score, and PS-VAS using univariate models. In these, EQ5D score, HAQ score, and PS-VAS correlated significantly using multivariate model (CC: 0.715). ACPA did not correlated with any factors significantly.
Conclusion: These results suggested that EQ5D score, namely QOL is influenced by various disease-related factors and aging, especially correlated with ADL and fatigue closely. The HAQ score, namely ADL level is influenced by fatigue level and joint deformity directly. The SDAI score, namely disease activity level correlated with pain level and joint deformity level, and correlates with the other factors indirectly. A schematic figure that represents relationships among factors were shown in Figure 1. These information would beneficial for conducting treatment protocol of RA.

AB0244 **MEDICATION ADHERENCE AND BELIEFS ABOUT MEDICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS.**

C. Jugel[1], C. Baerwald[1], O. Seifert[1]. *[1]University Hospital Leipzig, Department of Internal Medicine, Rheumatology Unit, Leipzig, Germany*

Background: Consistent immunosuppressive treatment of rheumatoid arthritis (RA) with disease-modifying anti-rheumatic drugs (DMARDs) is crucial for reduced progression and improved long-term outcome of the disease. Therefore, drug adherence is a prerequisite, which is often insufficient according to literature.
Objectives: Our aim was to investigate the relationship between adherence and beliefs about medication in patients with RA.

Methods: The study included 137 RA patients (102 female, 35 male; age range 28-86 years, Ø 64.8 ± 12.6 yrs; SDAI Ø 9.9 ± 6.8; 61 % DMARD monotherapy, 31 % DMARD combination therapy, 9 % currently treated without DMARD). Medication adherence was measured with the Compliance-Questionnaire-Rheumatology (CQR). This is a self-report questionnaire with 19 items (4 response options each). The sum score is mapped to a scale from 0 to 100 % (CQR%), where 100 % corresponds to optimal adherence. A CQR% ≥ 80 % was defined as satisfactory adherence. In addition, the specific part of the Beliefs about Medicines Questionnaire (BMQ) was used to assess patients' opinions about the necessity of their medication therapy and their concerns. Besides correlation analyses (Spearman-Rho) multiple linear regression was applied to determine factors influencing adherence (coefficient of determination: adjusted R^2).
Results: Adherence was satisfactory in 93 RA patients (67.9 %) and insufficient in almost one-third (n = 44, 32.1 %). Analyses showed that adherence was significantly related to belief in necessity ($r = 0.46$; $p < 0.001$) and concerns about drug therapy ($r = -0.27$; $p = 0.001$). Furthermore, it became apparent that adherence is closely linked to the age of the patient ($r = 0.30$; $p < 0.001$). Younger RA patients (< 60 yrs) had significantly lower CQR%-scores than older RA patients (≥ 60 yrs; $p < 0.01$). Belief in the necessity of therapy, medication concerns and patient age accounted for almost half of the patient-specific variability in adherence (each $p < 0.001$; $R^2 = 42.9$ %), suggesting a strong dependence of adherence on these three factors.
Conclusion: Adherence is insufficient in about one-third of RA patients. Additionally, adherence appears to be strongly dependent on the patient's belief in the necessity of therapy, medication concerns and age. Physicians should strive for all RA patients to have sufficient knowledge about their medication, strengthen the belief in the necessity of the therapy and be mindful of adherence when talking to patients.

AB0245 PULMONARY INVOLVEMENT IN RHEUMATOID ARTHRITIS AND SECONDARY SJÖGREN SYNDROME

A. R. Halidou[1], K. Nassar[1], S. Janani[1]. [1]*CHU Ibn Rochd, Rhumatologie, Casablanca, Morocco*

Background: Rheumatoid arthritis (RA) is a severe inflammatory disease that affects the joints and other organs such as the lung. Gougerot-Sjögren's syndrome (GSS) is an autoimmune disease. Secondary GSS can be primary or secondary and is defined by (1) the presence of another connective tissue disease, (2) the existence of dry eyes or dry mouth, and (3) objective evidence of ocular or salivary involvement. The presence of anti-SSA or anti-SSB antibodies is not necessary for the diagnosis of secondary SMS (4). The association of the two pathologies (RA-SGS) is frequent, and apart from osteoarticular involvement, various organs can be affected, in this case the lungs, by one or the other pathology with similar pulmonary lesions.
Objectives: To determine the incidence of pulmonary involvement in a population of RA-SGS patients.
Methods: Retrospective study, conducted from January 2019 to October 2021, at the rheumatology department of the CHU Ibn Rochd of Casablanca. Inclusion criteria: patients followed for RA according to the diagnostic criteria (EULAR/ACR 2010) associated or not with secondary GSS. Exclusion criteria: patients followed for primary GSS alone or other inflammatory rheumatic diseases with pneumopathy.
Results: 139 patients were included in our study, with a female predominance of 96.40%. The mean age was 56.31 years, the mean duration of RA was 9.89 years (4 months - 34 years). GSS was associated in about 1/3 of the patients, 33.81%. In the study population 24.46% of patients had pulmonary involvement which was present in the majority of RA-SGS patients (63.83%). Clinically, exertional dyspnea was found in all these patients and chronic dry cough in 66.67%. On standard radiography, an interstitial syndrome was found in all of these patients and on the pulmonary CT scan, 2 patients were at the stage of pulmonary fibrosis, i.e. 6.67% (PR-SGS).
Discussion: Secondary GSS is found in 30% of patients with rheumatoid arthritis (3). Pulmonary infiltrative disease is similar in both conditions. In RA these diseases are in the foreground after pleural involvement. They have the same clinical, radiological and functional characteristics, associated to varying degrees with exertional dyspnea, dry cough, crepitus rales, and digital hippocrasis (5,6). Pulmonary involvement is frequent in SSc, mainly represented by diffuse interstitial lung disease and bronchial and bronchiolar involvement (7). In SSc, the prognosis is rarely life threatening (8). In RA, the overall prognosis of rheumatoid lung disease remains poor with significant morbidity and mortality. A particular evolutionary mode characterized by acute exacerbation of interstitial lung disease associated with connective tissue diseases has been reported, particularly in RA (9,10).
Conclusion: In our series, the frequency of association of secondary SSG with RA is similar to the data in the literature and lung involvement is particularly frequent in these patients. No study in the literature has looked specifically at the clinical and prognostic features of lung involvement in RA-SGS patients.

AB0246 EXAMINATION OF THE FACTORS CONSTITUTING DEPRESSIVE STATE IN RHEUMATOID ARTHRITIS PATIENTS AND THEIR ASSOCIATIONS.

Y. Miwa[1], Y. Mitamura[2], M. Hosaka[3]. [1]*Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan;* [2]*Showa University School of Nursing and Rehabilitation Sciences, Department of Nursing, Tokyo, Japan;* [3]*Katsuyama Clinic, Department of Psychosomatic Medicine, Yamanashi, Japan*

Background: About 15% of patients with rheumatoid arthritis (RA) have depression, with an odds ratio of 1.42 (95% CI: 1.3-1.5) compared with healthy control. In previous reports, depressed mood and sleep disorders were reported separately, and no report has examined the factors that constitute depression. In addition, there is no report that examines the relationship between them.
Objectives: In the present study, we investigated the factors that constitute depression in RA patients.
Methods: One hundred and twenty-four patients with RA attending Showa University Hospital who gave written consent to the study were included in the study. Age, gender, body mass index, smoking history, presence of hypertension, presence of diabetes, steroid use, methotrexate use, erythrocyte sedimentation rate, CRP, and serum MMP-3 levels were investigated. The simplified disease activity index (SDAI) was used to assess disease activity in RA, the health assessment questionnaire disability index (HAQ-DI) was used to assess activity of daily living, and the Hamilton depression rating scale (HAM-D) was used to assess depression. All patients were interviewed for the HAM-D by the same interviewer, and the relationship between each item of the HAM-D and each index was examined.
Results: Forty-two patients (33.9%) reported experiencing "Depressed mood". On the other hand, a higher percentage of patients reported "Anxiety Somatic (79, 63.7%)," " Somatic Symptoms General (69, 55.6%)," "Work and Activities (57, 46.0%)," "Hypochondriasis (53, 42.7%)," and "Genital Symptoms (49, 36.5%)" than depressed mood. Depressed mood" was correlated with SDAI (r=0.31) and HAQ-DI (r=0.26), while " Somatic Symptoms General " was correlated with SDAI (r=0.30) and HAQ-DI (r=0.29). "Somatic Symptoms General" correlated with SDAI (r=0.30) and HAQ-DI (r=0.29). "Anxiety Somatic" correlated only with age (r=0.24), and other factors showed no correlation.
Conclusion: Higher percentage of RA patients reported "Somatic Symptoms" than " Depressed mood " as a factor of depression. These factors were mildly correlated with RA disease activity and HAQ-DI.

AB0247 THE ROLE OF AUTOIMMUNITY ON THE RELATION BETWEEN EROSIONS AND BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS: A CLINICAL RESEARCH

M. Margaux[1], M. Caroline[2], M. De Carvalho Bittencourt[3], E. Allado[4], I. Chary Valckenaere[1], D. Loeuille[2]. [1]*Nancy Regional University Hospital Center, Rheumatology, Nancy, France;* [2]*Nancy Regional University Hospital Center, Rheumatology, NANCY, France;* [3]*Nancy Regional University Hospital Center, Biology and Immunology Laboratory, NANCY, France;* [4]*Nancy Regional University Hospital Center, University Center of Sports Medicine and Adapted Physical Activity F-54000, Nancy, France*

Background: Rheumatoid arthritis (RA) is the most frequent chronic inflammatory rheumatism. It is characterized by peripheral articular destruction and it is

well known that erosions are correlated with the presence and titer of anti-citrullinated peptide antibodies (ACPA)[(1)]. RA is also known to be an independent factor of osteoporosis[(2)] and it has already been demonstrated that ACPA is associated with bone mineral density (BMD) at the hip and spine[(3)]. The physiopathology of erosion and bone loss in RA is related to osteoclast activation via RANK-L pathway stimulation, that can possibly be lead by ACPA[(4)].

Objectives: Our aim was to determine if there is an association between local and systemic bone damage in RA, represented respectively by erosion and BMD, and whether it may be driven by ACPA and/or other autoimmunity-related antibodies.

Methods: Patients followed in the Department of Rheumatology between January 2008 and May 2019 satisfied the 1987 ACR or 2010 ACR-EULAR criteria. To be included, they had to undergo radiographs and biology at intervals of less than 2 years from DXA. Bone mineral density (BMD) was evaluated in g/cm^2 and by T-score at the hip on DXA. Erosions were evaluated by the modified Sharp/van der Heidje erosion score (SHSe) on radiographs and the presence and titers of ACPA, rheumatoid factor (RF) and anti-nuclear antibodies (ANAs) were recorded.

Results: A total of 149 patients met the inclusion criteria, represented by 75.8% of women. They had a mean age of 62 (SD 9.61) and a long median disease duration of 132 [60; 240] months. A total of 61.1% patients were ACPA positive, 79.9% were erosive and 10.7% had a hip or spine T-score ≤-2.5. A higher erosion score was associated with a lower BMD (R^2: 0.049 and value: -0.222; p=0.009) and T-score (R^2: 0.158 and value -0.397; p<0.0001) at the hip. ACPA status, but not titer, was associated with a higher erosion score (63.0 (53.2) *vs.* 45.5 (44.1) for ACPA – (p= 0.04)). ACPA titers were associated with lower BMD at the hip (value -0.216; p=0.01) but not with T-score. In linear regression, erosion and bone mineral density were still associated but this association does not seem to be driven by ACPA status or titer. RF and ANA did not demonstrate any role in this association.

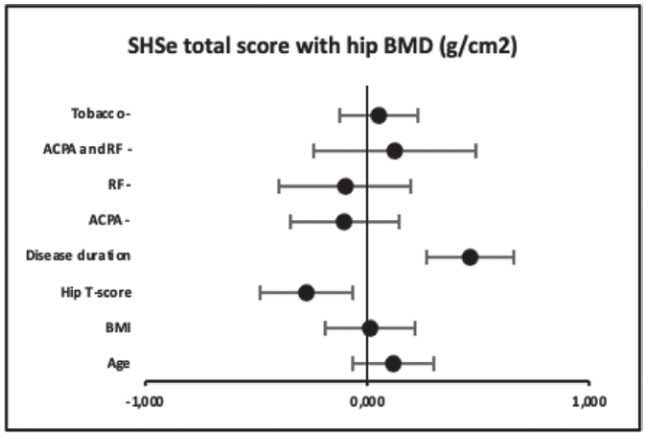

Figure 1. SHSe total score and associated variables in linear regression

Conclusion: We have shown that erosions were associated with lower BMD and T-score at hip but also at spine. Nevertheless that relation does not seem to be driven by ACPA or other autoimmunity-related antibodies. However, the presence of ACPA or erosion should lead to osteoporosis assessment.

AB0248 LIPID PROFILE CHANGES FROM PRE-CLINICAL TO ESTABLISHED RHEUMATOID ARTHRITIS: A 12 YEARS FOLLOWUP PILOT STUDY

R. Raadsen[1], L. Van Boheemen[1], M. Nurmohamed[1,2]. [1]*Amsterdam Rheumatology and Immunology Center, location Reade, Rheumatology, Amsterdam, Netherlands;* [2]*Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Rheumatology, Amsterdam, Netherlands*

Background: Patients with rheumatoid arthritis (RA) have an increased risk for developing cardiovascular diseases (CVD). This is partly due to the systemic inflammation characteristic to the disease, but also due to an increased prevalence of 'traditional' risk factors such as dyslipidemia. The inflammation in RA often leads to an increased catabolism of lipids, resulting in a subsequent decrease in HDL and LDL, while treatment with anti-inflammatory medication reverses these effects. This decreased cholesterol level in active disease is, unexpectedly, associated with an increased incidence of CVD (the lipid paradox). Additionally, we previously demonstrated pro-atherogenic lipid profile changes in preclinical RA patients.

Objectives: To explore the lipid profile changes in RA patients through different phases of the disease, i.e. from the preclinical stage and RA onset through treatment with biological disease modifying anti-rheumatic drugs (bDMARDs).

Methods: Thirty-nine consecutive patients who were previously included in both Reade's RA prevention cohort and biological cohort were included in the current study. The prevention cohort consisted of individuals with arthralgia and rheumatoid factor and/or anti-citrullinated protein antibodies without arthritis, and the biological cohort comprised RA patients using bDMARDs. Lipid spectrum was measured longitudinally, at the following points in the disease course identified in each patient (time from baseline was different in each patient due to the natural course of disease progression):

1.Baseline, months prior to RA diagnosis (Start Prevention cohort)
2.Moment of RA diagnosis (End Prevention cohort)
3.Period between diagnosis and start bDMARD treatment
4.Start treatment with bDMARDs
5-7.Continued treatment with bDMARDs

Results: From baseline, high density lipoprotein cholesterol (HDLc) and apolipoprotein A1 (ApoA1) increased up to the start of biological treatment, thereafter they slightly decreased. Low density lipoprotein cholesterol (LDLc) and apolipoprotein B (ApoB) both decreased with higher disease activity, increasing again after starting bDMARD therapy. Total cholesterol/HDL ratio decreased substantially from baseline and onwards and stabilized in the bDMARDs treatment phase. Lipoprotein(a) (Lp(a)) increased slightly up to treatment with bDMARDs, after which it stabilized. Figure 1 shows the progression of HDLc, LDLc and total cholesterol (TC) plotted against C-reactive protein (CRP) over time.

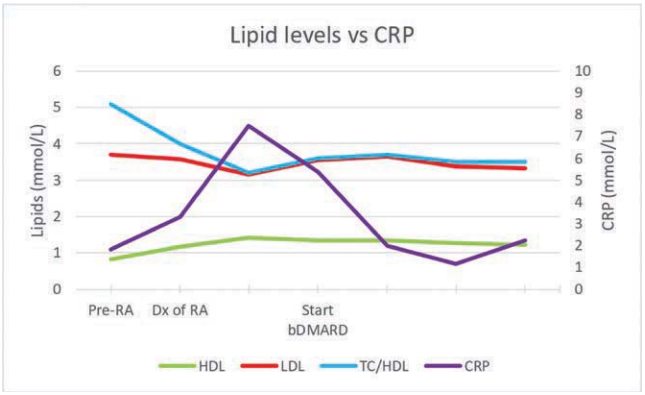

Figure 1. Time course of cholesterol parameters vs disease activity. CRP = C-reactive protein, RA = rheumatoid arthritis, Dx = diagnosis, TC = total cholesterol, HDL = high-density lipoprotein, LDL = low-density lipoprotein

Conclusion: Our study uniquely shows the change of lipid parameters during the course of RA disease. While LDLc, ApoB and cholesterol/HDL ratio decreased with higher disease activity, HDLc and ApoA1 increased, affirming the expectations. Larger cohort studies are necessary to accurately elucidate the development of lipids through different disease stages in RA patients, to better understand one of the key risk factors for CVD in RA.

AB0249 EVALUATION OF BELIEFS AND FEARS DURING RHEUMATOID ARTHRITIS TOWARDS CONVENTIONAL BACKGROUND TREATMENTS: STUDY BY BMQ (BELIEF ABOUT MEDICATION QUESTIONNAIRE)

S. Abdellatif[1], H. Hachfi[1], M. Brahem[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rhumatology, Mahdia, Tunisia*

Background: Poor adherence is one of the main causes of therapeutic failure in chronic inflammatory rheumatism, particularly in rheumatoid arthritis (RA). Thus to improve regular intake especially of conventional background treatments (cs-DMARDs), it is important to assess patients' beliefs and fears about their treatments.
Objectives: Evaluate the beliefs and fears of patients with Rheumatoid arthritis towards their conventional background treatments.
Methods: This is a cross-sectional study with RA follow-up patients meeting the ACR/EULAR criteria. Epidemiological, clinical and paraclinical data were collected. The evaluation of beliefs and fears towards csDMARDs was carried out by the BMQ score which has two five-item scales rated according to a 5-point Likert scale, ranging from 1 (not at all agree) to 5 (strongly agree). The scores of necessity, fear, overuse and nuisance were calculated. Patients were divided into 4 groups according to their beliefs of csDMARDs: accepting, ambivalent, indifferent and septic.
Results: The mean Disease Activity Score (DAS28crp) was 3.5 ±1.54, the mean value of Visual analogue scale of pain (VAS) was 40.5± 20.5, and the mean value of Health Assessment Questionnaire (HAQ) was 1.05± 0.85. All patients were treated with methotrexate and 12.5% with Salazopyrine in combination. The average need score was 20± 2.4, fear score was 16.45± 3, overuse score was 13.67± 2.25 and nuisance score was 10.8± 2.6. Patients' beliefs about the need for their background treatments were more important than their concerns and fears about the potential consequences of these treatments (p=0.03). A higher necessity score was correlated with the number of painful joints (NAD) (p=0.02) and a higher DAS28 (p=0.05). Patients who were more afraid of their treatments had more joint deformities (p=0.03), higher HAQ functional index (0.007) and a higher VAS value (p=0.01). The belief profile study concluded that 60% of patients were ambivalent, 27.5% accepting, 10% indifferent and 2.5% were septic towards their background treatments.
Conclusion: Our study showed that during RA, knowledge of the profiles of our patients, their beliefs and fears about their treatments especially cs-DMARDs is essential, and could help us to adapt strategies for improving compliance.

AB0250 DESCRIPTION OF ARTERIAL STIFFNESS, INFLAMMAGING AND VASCULAR AGE IN A GROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS UNDER A STRICT FOLLOW-UP COMPARED WITH UNCONTROLLED OSTEOARTHRITIS PATIENTS

A. Rojas-Villarraga[1], G. S. Rodríguez-Vargas[1], J. A. Rubio-Rubio[1], P. K. Bautista-Niño[2], D. Echeverri[3], L. D. Gutiérrez-Castañeda[1], F. Sierra-Matamoros[4], S. Navarrete[5], A. Aparicio[5], L. Sáenz[3], P. Santos-Moreno[6]. *[1]Fundación Universitaria de Ciencias de la Salud-FUCS,, Research Institute, Bogotá, Colombia; [2]Fundación Cardiovascular de Colombia – FCV, Research Laboratory, Bucaramanga, Colombia; [3]Fundación Cardioinfantil-Instituto de Cardiología, Hemodynamics and Cardiovascular Function Laboratory, Bogotá, Colombia; [4]Fundación Universitaria de Ciencias de la Salud-FUCS,, Epidemiology, Bogotá, Colombia; [5]Fundación Universitaria de Ciencias de la Salud-FUCS, Basic Sciences Laboratory, Bogotá, Colombia; [6]Biomab IPS, Scientific Direction, Bogotá, Colombia*

Background: The risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) is higher than in individuals in the general population. The fundamental risk factor for CVD is age, related to alterations at the arterial level, called vascular aging reflected by arterial stiffness and endothelial dysfunction
Objectives: The aim of the study was to compare vascular age and arterial stiffness (PWV-Pulse Wave Velocity) in two groups of patients with RA and with osteoarthritis (OA) and to assess the influence of inflammaging (persistent low-grade inflammation that develops with age) and metabolic markers in these outcomes.
Methods: Analytical cross-sectional study. RA patients under a strict follow-up program (T2T evaluated every two months) and OA patients without strict clinical follow-up, evaluated once or twice a year, were included. Patients with history of uncontrolled hypertension, CVD and/or current smoking were excluded. Waist-hip ratio, body mass index (BMI), DAS28 (RA), C-Reactive protein (CRP), Erythrocyte sedimentation rate (ESR), glycemia and lipid profile were measured. PWV and vascular age (in years) were evaluated through oscillometric method, arteriograph-TensioMed. Eleven proteins components of the inflammaging (cytokines, Matrix metalloproteinases - MMPs and its tissue inhibitors), were quantified through Luminex multiplex assay in serum samples. Univariate and bivariate analyzes (Chi-square and non-parametric correlations) were performed. Approval of Ethics Committee and informed consent were obtained.
Results: A total of 106 patients (74% women) were included (52/RA and 54/OA). Mean age was 57±5.6 years without differences between groups. There were significant differences in CRP and ESR (higher in RA) and in BMI, waist circumference and weight (higher in OA). RA patients had low disease activity level (DAS28: Median 2.6, IQR 1.3). There were no differences in PWV, vascular age or inflammaging (except for MMP-1, higher in RA), between the groups. PWV had a positive correlation with LDL (Rho Coef. 0.218 p=0.025). Patients who performed physical activity had a lower vascular age than those who did not [43 Interquartile range (IQR)23 vs 60 IQR 17, p=0.032). Vascular age was higher in RA patients who did not receive methotrexate 60 (IQR 19.3) compared with patients under methotrexate treatment 44.5 (IQR 23) (p = 0.017). Also, vascular age was lower in OA patients under prescribed physical activity (43 IQR 24.8 vs 56.5 IQR 20, p=0.03). MMP-9 in RA patients (Rho 0.283, p=0.042) and IL-10 in OA patients (Rho 0.290, p= 0.036) correlated with diastolic pressure. The components of inflammaging did not correlate with vascular age. The Framingham Risk Score was strongly associated with vascular age.

Table 1. Significant correlations with vascular age

Variable	Spearman's Rho	p-value
LDL levels	0.200	0.040
Systolic blood pressure	0.300	0.002
Mean arterial blood pressure	0.210	0.031
Daily coffee cups intake	-0.212	0. 045
Framingham Risk Score	0.340	<0.0001
MDHAQ score in RA patients	0.417	0.002

LDL: low density lipoprotein; MDHAQ: multidimensional health assessment questionnaire.

Conclusion: In RA strictly controlled patients, there are no differences in endothelial dysfunction, vascular age or inflammaging, when comparing with uncontrolled overweight OA patients. Physical activity, LDL levels and coffee consumption corelate with vascular age in OA and RA patients. OA patients under physiatrists follow-up and RA patients under methotrexate treatment or with low MDHAQ levels have lower vascular age levels.

AB0251 * FATIGUE IN RHEUMATOID ARTHRITIS: DOES PATIENT AGE INFLUENCE?

S. Rodriguez-Muguruza[1], S. Castro[1], M. J. Poveda[1], S. Paredes[2], D. Taverner[2], R. Fontova[3]. *[1]Hospital Universitari de Tarragona Joan XXIII, Rheumatology, Tarragona, Spain; [2]Hospital Universitari Sant Joan de Reus, Rheumatology, Reus, Spain; [1]Hospital Universitari de Tarragona Joan XXIII, Rheumatology, Tarragona, Spain*

Background: Fatigue in RA has a multi-causal pathway. It is recommended that it should be measured in all RA studies using a validated instrument. Fatigue in elderly patients could have a different perception than in younger patients, identifying the associated factors could be a key to the management of this complex symptom.
Objectives: To compare fatigue and its associated factors in young and elderly patients with RA from two university hospitals.
Methods: A cross-sectional analysis was performed in 167 RA patients diagnosed according to the 2010 ACR-EULAR criteria. Patients were divided into two groups based on age (≥60 and <60) for comparative purposes. Fatigue was assessed using 4 instruments: the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ), the fatigue subscale of the Short-form 36 survey (fatigue-SF36), the Visual Analogic scale of fatigue (VASf) and the Functional Assessment of chronic illness Therapy Fatigue Scale (FACIT-F). To compare the mean of fatigue between groups we used a T-Test.
To determine in each group of patients (young and elderly patients) the relationship between the 4 subscales of fatigue (assessed by BRAF-MDQ) and the other variables (DAS28, CPR, ESR, hemoglobin, vitamin D, HAQ, RAID [Rheumatoid Arthritis Impact of Disease], SF36, Hospital Anxiety and depression Scale [HAD] and Brief Pain Inventory) a Spearman correlation was performed. A value of $p < 0.05$ was accepted as statistically significant.
Results: A total of 167 patients were included, 81 (48.5%) young and 86 (51.5%) elderly patients. We found fatigue (using 4 instruments) has not significant differences in young and elderly patients (Table 1). In young and

elderly patients, physical, living, cognitive and emotional fatigue were correlated to RAID, SF36, HAD and pain but they were not associated to CRP, ESR, hemoglobin and vitamin D. In young patients, all dimensions of fatigue were associated with DAS28. Furthermore, in elderly patients we found a relationship between physical (p-value 0.044) and living fatigue (p-value 0.012) with DAS28, nevertheless cognitive and emotional fatigue (p-value 0.078 and 0.079 respectively) were not related.

Table 1. Scores of the Fatigue Questionnaires used to assess fatigue in young and elderly patients with RA.

	Young Mean (SD)	Elderly Mean (SD)	p-value
FACIT-F	36.5 (12.5)	35.9 (11.7)	0.2963
VAS-F	4.3 (2.8)	3.8 (2.8)	0.119
SF36-Fatigue	50.9 (23.9)	51.0 (21.9)	0.628
BRAF-MDQ			
Physical	9.2 (6.2)	8.5 (6.3)	0.4670
Living	5.3 (5.6)	4.2 (4.6)	0.1446
Cognitive	3.3 (3.8)	4.2 (4.6)	0.2932
Emotional	3.5 (3.5)	2.6 (2.7)	0.0932

Conclusion: In young and elderly patients, all dimensions of fatigue appear to be related with subjective but not with objective variables. In young patients, all dimensions of fatigue were associated with DAS28 but in elderly patients only physical and living fatigue were correlate to disease activity. These results could indicate that it is important to evaluate fatigue in a multidimensional perspective in elderly patients.

AB0252 INTOLERANCE TO METHOTREXATE IN RHEUMATOID ARTHRITIS: AN ASSESSMENT WITH THE MISS (METHOTREXATE INTOLERANCE SEVERITY SCORE)

H. Hachfi[1,2], S. Abdellatif[1,2], M. Brahem[2], Y. Mohamed[2]. [1]*Taher Sfar University Hospital, Rhumatology, Mahdia, Tunisia;* [2]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: Methotrexate (MTX) is a cornerstone in the treatment of rheumatoid arthritis (RA), in monotherapy or in combination with biological agents. Its prolonged use requires regular clinical and biological monitoring. The purpose of our study is to assess intolerance to MTX and its consequences.

Objectives: The purpose of our study is to assess intolerance to MTX and its consequences.

Methods: This is a cross-sectional study with RA follow-up patients meeting the ACR/EULAR 2010 criteria. An assessment of MTX intolerance was conducted using the Arabic version of the MISS (Methotrexate Intolerance Severity Score). It is a questionnaire containing 12 items covering four areas: abdominal pain, nausea, vomiting and behavioral disorders. A score of six indicates an intolerance.

Results: Forty patients were included: 35 women (87.5%) and 5 men (12.5%) of average age 51.7 years ±12.7 years. The average duration of disease progression was 12.2 years 9.2 [1-40 years]. All patients were treated with methotrexate and supplemented with folic acid. 50% of patients were under 10mg/week of MTX, 27.5% under 15mg/week and 22.5% under 20 mg/week. Patients had been on this treatment for an average of 8.7 years [1-25 years]. The majority of them (97.5%) received corticosteroids in combination, 12.5% received Salazopyrine and 27.5% received biotherapy. Methotrexate intolerance was observed in 16 patients (42.1%). Nausea was observed in 13 patients (81.2%), vomiting in 5 patients (31.2%), abdominal pain in 11 patients (68.8%) and behavioral disorders in all patients. As a result of this intolerance, 18.8% of patients had to stop their treatment, 12.5% decreased the dose on their own, 6.2% took the MTX irregularly, 12.5% switched from the oral route to the intramuscular route and 50% continued to take their treatment in the usual way. The study of correlations did not reveal statistically significant associations between MTX intolerance and age, sex, dose and duration of MTX, the associated intake of salazopyrin, biotherapy and other symptomatic treatments.

Conclusion: The occurrence of an intolerance to MTX is common in patients followed for RA, which may lead to poor adherence to therapy or even a discontinuation of treatment thus decreasing the effectiveness of management. Hence the need to systematically detect this intolerance and react in time.

AB0253 CARDIOVASCULAR OUTCOMES IN PREVENTION RANDOMIZED CONTROLLED TRIALS IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A SYSTEMATIC REVIEW.

C. Garaffoni[1], A. Marangoni[1], M. Govoni[1], C. A. Scirè[2]. [1]*Rheumatology Unit, University of Ferrara and Azienda Ospedaliera-Universitaria S. Anna, Department of Medical Sciences, Ferrara, Italy;* [2]*University of Milano-Bicocca, School of Medicine and Surgery, Milan, Italy*

Background: Cardiovascular disease (CVD) risk in patients with chronic inflammatory arthritis (IA), including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS), is substantially increased compared to the general population. New evidence strengthens the notion that the excess risk of CVD morbidity and mortality in patients with IA is related to both traditional (e.g. hypertension, diabetes, smoking) and novel CVD risk factors, including chronic inflammation, leading to an accelerated atherosclerosis. How to minimize such increased CVD prevalence is still poorly understood, and whether more intensive traditional risk factor control or disease specific risk factor should be targeted is still matter of debate.

Objectives: The aim of this systematic review was to identify intervention targeting CVD or inflammatory arthritis associated with improvement of CV risk outcomes (estimated CV risk, CV events, endothelial function, arterial stiffness, subclinical atherosclerosis) in adult patients with diagnosis of inflammatory arthritis (RA, PsA and AS).

Methods: Two independent reviewers retrieved randomized controlled trials of interest from systematic searches of Medline, Embase and Cochrane database (20th April 2020). Data extraction was performed using standard template; the quality of each included trials was assessed with the Revised Cochrane risk-of-bias tool for randomized trials (RoB 2) [1]. Systematic review was conducted following the Preferred Reporting Items for systematic reviews and Meta-analysis (PRISMA) statement.

Results: Out of total of 4823 articles, 27 met the inclusion criteria. Among these, most (n=22) involved RA patients, one trial was based on mixed IAs patients and the remaining (n=4) were performed on spondylarthritis population. Total number of patients was 8045. Overall risk of bias was high in most of per protocol analysis trials (90%) and in 26.7% of intention-to-treat analysis trials. Four trials evaluated major adverse cardiovascular events (MACE) incidence and one of these demonstrated a significant reduction in incidence of MACE in RA patients underwent a treat-to-target strategy of CV risk factor. The same study also demonstrated a significant reduction in progression of subclinical atherosclerosis (carotid Intima-media thickness, cIMT), while other trials (n= 8) exploring effect of rosuvastatin, enalapril, tocilizumab and TNF-inhibitors failed to reach a similar result. Endothelial dysfunction, predominantly measured as reduce flow mediated dilatation (FMD), was widely used as surrogate outcome of CVD and it appeared to be significantly improved by treatment with statins, ACE-inhibitors, anakinra and tocilizumab. Treatment with pioglitazone, anakinra or tocilizumab in three trials significantly ameliorated arterial stiffness, estimated with pulse wave velocity (PWV), Cardio-ankle vascular index (CAVI) or augmentation index (AI). Two studies explored how a reduction of estimated CV risk could be achieved after treatment with enalapril and tight-control strategy aiming to SDAI ≤ 3.3. Results of both trials didn't demonstrate any variation in QRISK3-2018 and Framingham risk score, respectively.

Conclusion: Optimal CVD management in IA patients remains undefined and it should be implemented as stated in international guidelines. Randomized controlled trials exploring efficacy of prevention strategy are few and predominantly focused on surrogate outcome measures of cardiovascular risk.

Quintana Lopez[2,3,4]. *[1]Universidad Nacional de Colombia, Reumavance Research Group, Bogota, Colombia; [2]Fundacion Santa Fe de Bogota University Hospital, Reumavance Research Group. Department of Internal Medicine, Bogota, Colombia; [3]School of Medicine - Universidad de Los Andes, Department of Internal Medicine, Bogota, Colombia; [4]School of Medicine - Universidad Nacional de Colombia, Department of Internal Medicine, Bogota, Colombia*

Background: Rheumatoid arthritis (RA) represents an essential public health problem regarding vast influence on the individual's global health. Adherence to pharmacological therapy has been shown to be a relevant outcome to ensure the desired therapeutic objectives and thus avoid the recurring concern of flares, the perpetuation of inflammation, and its consequences, not only physiological but also structural and socioeconomic.
Objectives: Our aim was to identify clinical-epidemiological variables associated with treatment adherence in an outpatient clinic-based cohort of Colombian RA patients.
Methods: We conducted a cross-sectional analytic study with data obtained from August 2020 to October 2021. Treatment adherence was assessed on each visit through the Compliance Questionnaire on Rheumatology (CQR); moreover, patients were stratified into those who were adherent to the treatment and those who didn't, according to their CQR score. Additional information regarding the quality of life (QOL-RA), disease activity (DAS28 ESR), and functionality (HAQ) was recovered from electronic clinical charts. Data was gathered on a database stored in REDCap. T-test and Chi-squared test were used for comparisons and a multiple logistic regression with backward selection was performed to build the final fitted model.
Results: Data from a total of 564 patients were included in the analysis. Our population was constituted of 79.1% women with a mean age of 53 (± 13.1); the CQR mean score was 77.7 (± 9.26) and treatment adherence, defined as a CQR score of ≥ 80.7, was seen in 49.3% of the cases. Mean DAS28 ESR, QOL-RA, and HAQ scores were 3.3 (± 1.62), 7.24 (± 1.43), and 0.671 (± 0.716), respectively; with a reported preserved quality of life (QOL-RA >7) in 60,5% of patients. Monotherapy (42.7%) and combined therapy (49-6%) were the two most common treatment schemes, being MTX the more frequent DMARD (58.9% oral, 20.9% subcutaneous). Noncompliant patients showed higher mean disease activity (3.52 (±1.66) vs 3.08 (±1.54); p 0.001) and lower quality of life (6.94 (±1.43) vs 7.56 (±1.35); p <0.001) scores. Having a higher DAS28 score (OR 1,19), drug dispensing delay (OR: 1,71), and infection as an adverse effect (OR 2.53) were recognized as risk factors for an impaired treatment adherence after adjustment for the effects of possible confounders. Complete results of the multiple logistic regression model are shown in Table 1.

Table 1. Associated factors with treatment adherence in RA patients.

	Odds Ratio (95% Confidence Interval)	p-value
Age	0,99 (0,97 – 1)	0,12
Male	**1,54 (0,98 – 2,43)**	**0,065**
Having a stable partner	0,75 (0,52 – 1,09)	0,13
Comorbidities		
Hypothyroidism	0,69 (0,41 – 1,15)	0,16
Dyslipidemia	0,52 (0,22 – 1,16)	0,12
Dyspepsia (AE)	**1,48 (0,97 – 2,28)**	**0,07**
Infection (AE)	**2,53 (1,31 – 5,08)**	**0,007**
Perception of the information received by health professionals		0,45
Unsatisfied	Ref.	
Satisfied	2,23 (0,06 – 28,1)	0,55
Very satisfied	1,37 (0,09 – 17,2)	0,81
Healthcare barriers	**1,98 (0,92 – 4,45)**	**0,088**
Drug dispensing delay	**1,71 (0,99 – 2,99)**	**0,058**
Disease duration (months) until rheumatology consultation	**1,00 (0,99 – 1,00)**	**0,004**
DAS28 ESR score	**1,19 (1,06 – 1,33)**	**0,003**

AE: adverse effect. Bold values indicate a p value < 0,1

Conclusion: In our study population, there were evident trends regarding the effects of dispensing delays, adverse effects, and barriers to access to the health system on reducing treatment adherence. Moreover, there was a subtle association of treatment adherence with the DAS28 score, as well as with a better quality of life. Taken together, these results suggest the need for the implementation of educational programs that will support a comprehensive approach that considers not only patient-related factors but also the proper functioning of the healthcare system itself. Further research with a follow-up period could assess the long-term effects on several clinical outcomes and explore if proposed trends change with time.

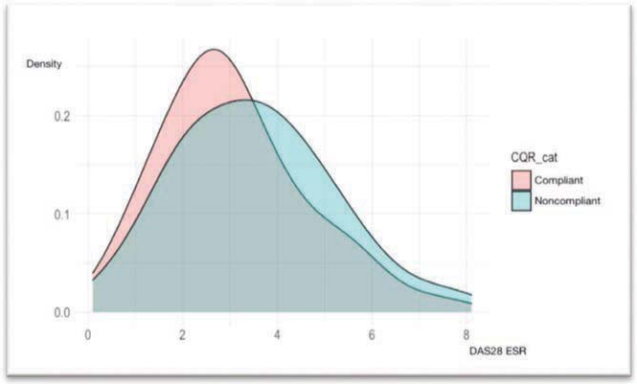

Figure 1. Density plot comparing disease activity in patients that are compliant and noncompliant to treatment.

AB0255 SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS OVER 65 YEARS OF AGE: PREVALENCE AND PREDISPOSING FACTORS.

L. Cano Garcia[1], C. Dominguez[2], P. Armenteros[3], J. Vacas[4], J. M. Martín Martín[5], N. Mena-Vázquez[1]. *[1]Instituto de Investigación Biomédica de Málaga (IBIMA); Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain; [2]Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain; [3]Hospital Universitario Reina Sofía, Instituto Maimónides de Investigación Biomédica (IMIBIC), Universidad de Córdoba, Rheumatology, Córdoba, Spain; [4]Hospital Universitario Reina Sofía, Universidad de Córdoba, Rheumatology, Córdoba, Spain; [5]Hospital Universitario Nuestra Señora de la Candelaria, Rheumatology, Tenerife, Spain*

Background: Sarcopenia is a muscle disease which is characterized by loss of muscle mass and function. This condition is associated with chronic disease and ageing which predicts inability, hospitalization and death.
Objectives: Describe sarcopenia prevalence and risk factors in patients with reumathoid arthritis (RA) over 65 years of age.
Methods: Design:
A case-control study.
Subjects
Cases: Recruitment was performed by random sampling between patients over 65 years of age with RA (ACR/EULAR 2010 criteria) attended at 4 Spanish University Hospitals.
Controls: Recruitment of subjects without rheumatoid disease was performed asking for case patients who attended to medical center with a similar-age (age of range +/- 5 years) and same-gender person from same social or family environment.
Variables: The main variable was sarcopenia which was defined according to European Working Group on Sarcopenia in Older People (EWGSOP) 2019. Sarcopenia risk factors assessed were: economic status, malnutrition, measured with Mini Nutritional Assessment (MNA), dual-energy x-ray absorptiometry (DEXA) in spine and hip to osteoporose screening, toxic habits, comorbidities and Charlson index, physical activity measured with Global physical activity questionnaire (GPAQ) and Short Physical Performance Battery (SPPB).
Other variables were: haemoglobin, calcium, D and B12 vitamins, total proteins, albumin, C reactive protein, body mass index (BMI), polimedication, quality of life measured with EQ-5D and RA related factors, activity disease measured with DAS28, SDAI and CDAI; physical function measured with HAQ (Health assessment questionnaire) and global functional status according ACR criteria.
Statistical analysis:
Descriptive and multivariative analysis was performed to identify factors associated to sarcopenia in RA.
Results: 76 patients and 76 controls were included in the study, 120 were women (78,9%), with media ± SD of age 74,7 ±6,98 of media and 32 (21,1%) were men, with age 70,1 ±3,78 of media. In comparation with controls, RA patients presented more frequency of sarcopenia (30 [19,53%] vs 6 [3,94%]; p=0,005). RA patients who presented sarcopenia, were upper average age (p=0,001), worse results in Short Physical Performance Battery (SPPB) (p=0,037), higher DAS28 (3,55 ± 1,09 vs 2,78 ± 1,05; p=0,017), higher score HAQ (1,18 ± 0,79 vs 1,69 ± 0,68; p=0,024), worse score in EQ5D (0,27 ± 0,28 vs. 0,54 ± 0,25; p=0,001) and Visual analogic scale VAS EQ5D (45,7 ± 17,4 vs. 56,9 ± 17,6; p=0,035).
By the way, RA patients presented lower levels of total proteins (p=0,018), worse results in MNA (p=0,001) and they performed less physical activity by GPAQ (p=0,011). Multivariative models (Table 1) identified as independent predictors of sarcopenia in RA: age (p=0,014), proteins levels (p=0,044) and disease activity measured by DAS28 (p=0,030). This model could explain 37% of sarcopenia in RA (R2=0,37).

Table 1. ***Multivariativeanalysis (VD: Sarcopenia)***

	OR(IC)	p
Age, years	1,213 (1,041-1,414)	0,014
Proteins (g/dL)	0,185 (0,036-0,958)	0,044
DAS28	2,146(1,076-4,881)	0,030

R2=0,37

Conclusion: Sarcopenia is more prevalence in over 65 years-old RA people. Older age and higher activity disease measured by DAS28 more risk of sarcopenia. Proteins levels have a protected association with sarcopenia.

AB0256 EFFECTS OF BIOLOGICAL-DMARDS ON THE SERUM URIC ACID LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Miwa[1], Y. Mitamura[2]on behalf of All Showa University in Rheumatoid Arthritis (ASHURA) group. *[1]Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; [2]Showa University School of Nursing and Rehabilitation Sciences, Department of Nursing, Tokyo, Japan*

Background: Hyperuricemia associated with rheumatoid arthritis (RA) has been reported to be a risk factor for cardiovascular disease. It has been reported that uric acid (UA) levels decrease with the use of leflunomide and increase with tumor necrosis factor (TNF) inhibitor therapy. However, the effects of long-term biological disease-modifying antirheumatic drugs (bDMARDs) therapy and the effects of non-TNF inhibitor biologic therapy on UA levels have not been reported.
Objectives: We aimed to investigate the changes in UA levels during the use of TNF inhibitors and non-TNF inhibitors therapy.
Methods: Patients with RA treated with bDMARDs from 2008 to 2018 were studied based on the All Showa University of RA (ASHURA) database. The association between uric acid level reduction and treatment was evaluated. Of 629 patients treated with the bDMARDs, 256 patients with available uric acid levels medical records were included. The following background factors were investigated: age; sex; type of bDMARDs; dosage of methotrexate and prednisolone; usage of conventional synthetic DMARDs, dyslipidemia drugs and nonsteroidal anti-inflammatory drugs; body mass index; smoking history; HbA1c; presence or absence of hypertension and dyslipidemia; and serum creatinine, C-reactive protein, and matrix metalloproteinase-3 levels. We also used the simplified disease activity index (SDAI) to evaluate RA disease activity. The analysis was performed in two groups, TNF inhibitor-treated group (148 patients) and non-TNF inhibitor-treated group (108 patients, tocilizumab and abatacept). The primary endpoint was UA levels before, and after 6 months and 1 year, which was determined using the repeated-measures analysis of variance (ANOVA) and secondary endpoint was proportion of patients with hyperuricemia (uric acid level of 7.0 or higher was defined), determined using spearman's correlation coefficient by rank test.
Results: In TNF inhibitor-treated group, the UA levels were not increased from 4.9 ± 1.4 (mg/dl) to 4.9 ± 1.4 and 5.1 ± 1.7 before treatment and after 6 months and 1 year, respectively (p=0.50). The number of patients with hyperuricemia increased from 7 to 12 and 16 (p=0.026). In non- TNF inhibitor-treated group, the UA levels were not increased from 5.2 ± 1.4 (mg/dl) to 5.2 ± 1.4 and 5.3 ± 1.4 (p=0.78). The number of patients with hyperuricemia increased from 8 to 16 and 12 (p=0.193). There was a difference in the type of drug, but no difference in the duration of administration by repeated-measures ANOVA.
Conclusion: Our study suggests that TNF inhibitor therapy may affect increased percentage of patients with hyperuricemia. On the other hand, non-TNF inhibitor therapy may not affect increased percentage of patients with hyperuricemia and bDMARD treatment has a mild effect on UA levels in patients with RA.

AB0257 ADHERENCE TO TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Postnikova[1], P. Kovalenko[1], I. Dydykina[1], A. Abolyoshina[1], A. Smirnov[2], A. Lila[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rheumatoid Arthritis Evolution Laboratory, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Instrumental Diagnostics, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Adherence is defined as the degree of agreement between a patient's behavior (taking medication, changing lifestyle, or adhering to treatment recommendations) and the prescriptions of a physician or medical staff. The patient's adherence to treatment is an important factor influencing the effectiveness of therapy, the course of the disease. In Russia, a universal questionnaire was developed to assess the level of adherence to drug therapy, medical care, lifestyle changes, and general adherence to treatment.
Objectives: To analyze the adherence to treatment, medical care and recommendations for lifestyle changes in patients with RA.
Methods: The cross-sectional study included 88 women with RA (ACR/EULAR 2010), the mean age - 63.0±8.1 years, the duration of the disease - 22.4±9.3 years. Adherence was assessed using the Russian questionnaire, which determines the low, average, and high levels of adherence to drug therapy, medical care, recommendations for lifestyle changes, and general adherence to treatment. All patients completed The Hospital Anxiety and Depression Scale (HADS) for the evaluation of anxious and depressive symptoms and HAQ (Health Assessment Questionnaire) to explore functional disability. All patients took a clinical examination, assessment of the anamnestic data, X-ray of hands, feet.

Results: Most of RA patients had an average level of adherence to drug therapy - 51 (58%); medical care - 45 (51%); low level of adherence to lifestyle recommendations – 63 (72%). Assessment of general adherence to treatment showed: 30 (34%) people had a low level of adherence, 51 (58%) - medium, and 7 (8%) - high. Elderly age (p=0.00), anxiety (p=0.02) and depression (p=0.04) were associated with low adherence to medical care. The use of glucocorticoids (GCs) was associated with high adherence to drug therapy (p=0.01). The number of patients taking disease-modifying anti-inflammatory drugs and biologic disease-modifying antirheumatic drugs, functional disability (HAQ) and the radiographic stage of RA (classified according to Steinbrocker) did not differ significantly in patients with different levels of adherence.
Conclusion: Most of RA patients had an average level of adherence to drug therapy, medical care, and a low level of adherence to recommendations for lifestyle changes. Patients taking GCs have a high level of adherence to drug therapy. Mental disorders (anxiety and depression) and elderly age are associated with low adherence to medical care.

AB0258 STATE OF ADIPOCYTOKINES IN PATIENTS WITH RHEUMATOID ARTHRITIS

I. Krivotulova[1], T. Chernysheva[1], K. Korochina[1]. [1]*Orenburg State Medical University,The Department of Internal Diseases, Orenburg, Russian Federation*

Background: Adipose tissue is actively involved in the development of systemic inflammation in rheumatoid arthritis (RA), producing proinflammatory cytokines and adipocytokines that can independently modulate inflammatory and destructive processes in the joints [1-2].
Objectives: To establish the relationship between serum adiponectin and leptin in patients with RA with clinical and laboratory indicators of disease activity and the results of ultrasound examination (US) of the hand joints.
Methods: The study included 72 women with RA according to the ACR / EULAR criteria of 2010 who visited the adaptation therapy clinic of Orenburg State Medical University. The mean±SD age was 46.4±7.5 years and the mean±SD disease duration was 7.9±4.4 years.
Clinical study of patients with RA included an assessment of the tender joint count (TJC) (11.3±6.8), the swollen joint count (SJC) (4.6±2.7), duration of morning stiffness (107.5±49.3 min) and the patient's global assessment according to a 100-millimeter visual analogue scale (46.2±23.5 mm). Disease activity was assessed by the DAS28 index (4.4±1.7).
The mean body mass index (BMI) in patients with RA was 26.3 ± 6.2 kg/m^2.
We evaluated for the following laboratory tests: rheumatoid factor (RF), antibodies to cyclic citrullinated peptide (A-CCP), C-reactive protein (CRP), tumor necrosis factor-α (TNF-α), interleukin-17 (IL-17), adiponectin and leptin in blood serum.
We carried out US to determine the inflammatory and destructive changes in 30 joints in each RA patient (wrist joints, metacarpophalangeal, proximal and distal interphalangeal joints and the first interphalangeal joint on the palmar and dorsal sides of both hands) by the device "Philips Epiq 7" with linear transducer with a frequency of 5-18 MHz and the use of Power Doppler (PD) which included the identification of synovitis, tenosynovitis, erosive changes in the hand joints.
At the time of examination, 30 (41.7%) patients with RA received therapy that included methotrexate (MTX); 9 patients (12.5%) intook glucocorticosteroids (GCS) perorally, MTX+GCS – 15 patients (20.8%).
The program STATISTICA, 12.0 was used for statistical analysis.
Results: The level of serum adiponectin negatively correlated with the level of CRP (r=-0.3, p <0.05). At the same time, significant correlations were found between the number of erosions of the joint space and the level of adiponectin (r=0.5, p <0.0001). Also, additional correlations were noted between adiponectin levels and the intake duration of MTX (r=0.3, p <0.05) and GCS (r=0.4, p <0.001). We found a positive correlation between the level of leptin and BMI (r=0.5, p <0.0001). In addition, there were significant correlations between the level of serum leptin and the morning joint stiffness duration (r=0.4, p <0.0001), TJC (r=0.5, p <0.0001), as well as the level of CRP (r=0.4, p <0.001) and the DAS 28 index (r=0.4, p <0.001) in patients with RA. An increase in IL-17 concentration was associated with an increase in leptin levels (r=0.3, p <0.05) in RA patients. However, we did not find a significant correlations between serum adipokine concentrations and RF and A-CCP levels.
Conclusion: Level of adiponectin is associated with pronounced destructive changes in the joints and the intake duration of MTX and GCS. There is a positive relationship between the level of leptin and indicators of disease activity (TJC, level of CRP, DAS28-CRP index) and an increased blood flow during Doppler imaging, which indicates its role as a proinflammatory cytokine.

AB0259 THE IMPACT OF LOCKDOWN IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Cazzato[1], O. Mazzarella[1], L. Bazzichi[1], F. Subri[1], E. Villa[1], E. Laurino[1], F. D'Alessandro[1], M. Mosca[1]. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy. Azienda Ospedaliero Universitaria Pisana, Pisa, Italy, Pisa, Italy*

Background: The COVID-19 pandemic has impacted on face to face assessments of patients with rheumatic diseases, including rheumatoid arthritis (RA) and telemedicine has offered a valid opportunity to follow these patients. DEDICARE is a Patient Support Program (PSP) which has been active at our center since 2016, which allows the telemonitoring of PROs (Patient Reported Outcomes) for patients being treated with abatacept. Since 2016, 98 RA patients followed at out Unit entered the DEDICARE program. During COVID19 pandemic these patients continued their monitoring using this PSP.
Objectives: To evaluate the impact of the first COVID wave on PROs and CROs (Clinical Reported Outcomes) in patients with RA included in the DEDICARE programme
Methods: Data collected in the dedicated platform three months before (from December 2019 to February 2020, pre-lockdown), during (from March 2020 to May 2020, lockdown) and after (from June 2020 to August 2020, post-lockdown) the first lockdown period in Italy were compared. In detail DAS28 (CRP, ESR), CDAI and SDAI were evaluated before and after the lockdown period; while VAS-pain, Global Health (GH); Patient Global Assessment of Disease Activity (PGA); Health Assessment Questionnaire (HAQ); Functional Assessment Chronic Illness Therapy (FACIT) were evaluated pre, during e post lockdown with the DEDICARE platform.
Results: 36 RA patients, all females, were included in the study; mean age was 62.4 (32-85) years; mean disease duration 15.5 (5-38) years; 18 were ACPA and RF+. All patients were treated with abatacept, 13 as monotherapy and 23 in association with csDMARDs. No patients had COVID19 disease during the evaluated period.
A significant worsening of global health and patient global assessment of disease activity was observed; while no differences were observed regarding the CROs and other PROs (Figure 1)

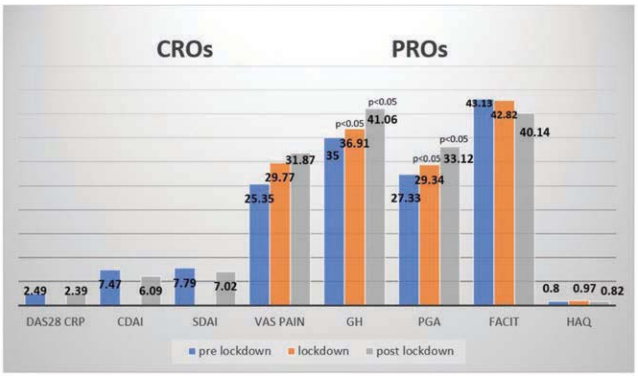

Figure 1.

Conclusion: In the present study we were able to compare PROs in patients with RA before and after the first COVID wave in Italy. While no significant changes in disease activity were observed, patients experienced an increased perception of disease activity and a decline in their overall health status which began during the lockdown and continued over the following 3 months.
This may highlight a discordance between the patient and the physician perception of the disease, which may partly due to the psychological impact of pandemic on the general perception of health particular in patients with chronic diseases.
Since this discrepancy may have consequences on disease management, and particularly on treatment adherence, there is a need to promote studies to better understand the reasons for these discrepancies and to improve the patient perception of their disease particularly in difficult situations such as COVID 19 pandemic.

AB0260 ASSOCIATION BETWEEN INFLAMMATION AND DEPRESSIVE SYMPTOMS IN RHEUMATOID ARTHRITIS PATIENTS.

A. V. Meza Sánchez[1], C. Hernandez-Diaz[2], C. Duarte-Salazar[3], R. E. Barbosa-Cobos[4], I. Romero-Vazquez[4], L. Ventura[2], G. Lugo-Zamudio[4]. *[1]Instituto Politécnico Nacional, Escuela Superior de Medicina, Mexico City, Mexico; [2]Instituto Nacional de Rehabilitacion "Luis Guillermo Ibarra Ibarra", Laboratorio de Ultrasonido Musculoesquelético y Articular, Mexico City, Mexico; [3]Instituto Nacional de Rehabilitacion "Luis Guillermo Ibarra Ibarra", Departamento de Reumatología, Mexico City, Mexico; [4]Hospital Juárez de México, Departamento de Reumatología, Mexico City, Mexico*

Background: Rheumatoid arthritis (RA) is an autoimmune, progressive disease characterized by an inflammatory process mediated by CD4+T lymphocytes leading to damage of the synovial membrane[1]. Its prevalence is estimated between 0.2 and 1.2% worldwide, affecting women in the fourth and fifth decades[2]. In 2013, the Mexican College of Rheumatology estimated a 1.6% prevalence[3] in Mexico.
RA may affect patients´ social, psychological, economic and physical areas. Among its psychological implications, depression is one of the most important (with a prevalence of 40%) beyond the general population[4]. Several studies assess either prevalence or prognosis, despite its higher prevalence and a lesser likelihood of remission in these patients. Some investigations looked for a relationship between inflammation and depressive symptoms considering only clinical or biochemical parameters, despite the evidence supporting better results with imaging methods, such as musculoskeletal ultrasound (MSU).
Objectives: To identify the association between MSU demonstrated inflammation and the presence of depressive symptoms in RA patients.
Methods: In 2021 a cross-sectional study on RA patients (according to ACR/EULAR 2010 criteria) was conducted. The subjects were from the *Instituto Nacional de Rehabilitación "Luis Guillermo Ibarra Ibarra"* and *Hospital Juárez de México* Rheumatology out-patient clinic. Each patient underwent a clinical (SDAI, CDAI, and EVA), psychological (PHQ9 and InCaViSa questionnaires), and MSU assessment (7 joints score). Data described with central tendency and dispersion measures for quantitative variables and frequencies and proportions for qualitative variables. Kruskal Wallis, U Mann-Whitney and Spearman correlation tests for analysis done.
Results: Fifty-two patients (94% women) were evaluated, with a mean age of 56.06 (±12.31) years and duration of disease 13.66 (±9.44) years. Depression prevalence was 54%. Patients with disease activity had the highest depression scores (p=0.009), those with triggering events in the last six months (p=0.177), the leading event was the death of a close relative in 30% of the patients. A moderate correlation between the depression score (PHQ9) and clinical disease activity scores (SDAI, CDAI, VAS, and painful joints) (rho=0.553 [p<0.001], 0.559 [p<0.001], 0.492 [p<0.001], and 0.57 [p<0.001], respectively) were found. Furthermore, we found a moderate correlation between depression scores and psychological, social and physical quality of life. A mild correlation between MSU synovitis and depression scores (rho=0.315 [p=0.03]) found.
Conclusion: Patients with disease activity reported higher depression scores in comparison to remission patients. We demonstrated a relationship between depressive symptoms, social factors, disease perception and ultrasound synovitis. It is crucial to conduct longitudinal studies with a large number of patients, including a control group, and perform an adequate stratification of the demographic characteristics of the patients and their confounding variables.

Ursini[3], R. Giacomelli[2], P. Cipriani[1]. *[1]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy; [2]Campus Bio Medico University of Rome, Department of Medicine, Rome, Italy; [3]Alma Mater Studiorum - Università di Bologna, Department of Biomedical and Neuromotor Sciences, Alma Mater Studiorum, Bologna, Italy*

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease associated with a significant increased rate of cardiometabolic comorbidities contributing to an increased risk of morbidity and mortality of these patients [1,2]. RA patients with cardiometabolic comorbidities might differ from those without in their clinical presentation and prognosis.
Objectives: This "real-life" cross-sectional study was designed to describe disease features of RA consecutive participants affected by cardiometabolic comorbidities than those without, among those attending recruiting centres from January 1, 2021 to December 31, 2021. Our purpose was also the identification of possible associations between these diseases and clinical characteristics of patients (i.e. fulfilment of ACR1987 criteria, ACPA positivity, presence of extra-articular manifestations, remission, and bDMARD failure).
Methods: Consecutive RA patients were assessed, all fulfilling 2010 ACR/EULAR criteria for RA. We have defined the participant as having such comorbidities if affected by 2 or 3 among high blood pressure (HBP), type 2 diabetes (T2D), and/or dyslipidaemia. The presence of cardiometabolic comorbidities for each participant was verified by reviewing the clinical charts, interview, and extensive medical examinations. Patients with and without cardiometabolic comorbidities were grouped and compared. After that, regression models were built to assess the influence of the presence of cardiometabolic comorbidities on RA features of disease severity.
Results: 757 consecutive RA participants were evaluated [(female 56.6%, age 64.7 ± 12.3years, median disease duration 6 years (IQR 12)]. Among assessed participants, 13.5% showed cardiometabolic comorbidities. These were older (63.9 ± 13.1 vs 70.4 ± 9.0 years, p<0.001) and characterised by a longer disease duration with 64.7% between 5 and 10 years (p=0.003). They were more often affected by extra-articular manifestations (8.2% vs 17.7%, p=0.029) and frequently displayed smoking habit (36.6% vs 50.0%, p=0.003). A lower percentage of participants with these comorbidities was in remission (15.7% vs 8.5%, p=0.048) and they showed a higher prevalence of history of bDMARD failure (40.4% vs 78.4%, p<0.001).
Finally, regression models showed that cardiometabolic comorbidities were significantly correlated with RA features of disease severity. Participants with cardiometabolic comorbidities more frequently fulfilled ACR1987 criteria in both univariate (OR: 1.47, 95%CI: 1.15-1.89, p=0.002) and multivariate analyses (OR: 1.48, 95%CI: 1.15-1.91, p=0.002). These participants had a higher probability of ACPA positivity in both univariate (OR: 1.52, 95%CI: 1.10-2.09, p=0.009) and multivariate analyses (OR: 1.47, 95%CI: 1.06-2.04, p=0.020). Cardiometabolic comorbidities also predicted the presence of extra-articular manifestations in both univariate (OR: 3.26, 95%CI: 1.77-5.89, p<0.001) and multivariate analyses (OR: 2.41, 95%CI: 1.30-4.87, p=0.005). Participants with cardiometabolic comorbidities had a higher probability of previous bDMARD failure in both univariate (OR: 1.73, 95%CI: 1.24-2.43, p<0.001) and multivariate analyses (OR: 7.17, 95%CI: 3.61-14.2, p<0.001). Cardiometabolic comorbidities resulted to be a negative predictor of being in remission in both univariate (OR: 0.53, 95%CI: 0.39-0.97, p=0.041) and multivariate analyses (OR: 0.61, 95%CI: 0.41-0.96, p=0.035).
Conclusion: We described disease features of RA participants with cardiometabolic comorbidities, identifying a disease subset characterised by clinical features of disease severity and to be considered as "difficult-to-treat". Thus, cardiometabolic comorbidities may represent a considerable burden for RA patients requiring an appropriate management which should focus, in addition to cardiovascular risk prediction, on targeting these metabolic components.

AB0262 PATIENTS WITH RHEUMATOID ARTHRITIS WHO DEVELOP SARCOPENIA FALL FREQUENTLY: 5-YEAR DATA FROM THE CHIKARA STUDY

Y. Yamada[1], M. Tada[2], K. Mandai[3], N. Hidaka[2], H. Nakamura[1]. *[1]Osaka City University School of Medicine, Orthopedics, Osaka, Japan; [2]Osaka City General Hospital, Orthopedics, Osaka, Japan; [3]Saiseikai Nakatsu Hospital, Orthopedics, Osaka, Japan*

Background: Patients with rheumatoid arthritis (RA) are likely to have sarcopenia due to decreased muscle mass and physical function. Some patients develop sarcopenia even if disease activity is well-controlled. We previously reported that 13.2% of RA patients without sarcopenia at baseline developed sarcopenia over a year[1].
Objectives: The aim was to longitudinally investigate sarcopenia status and the characteristics of RA patients using data from the prospective, observational CHIKARA study.

Methods: Body composition, laboratory data, disease activity, physical function (HAQ), treatment, and history of falls and fractures were investigated in 100 RA patients who participated in the CHIKARA study at baseline and at 5 years. They were divided into 4 groups depending on their sarcopenia status: no sarcopenia developed (N group; sarcopenia absent at baseline and 5 years); sarcopenia developed (S group; sarcopenia absent at baseline, but present at 5 years); cured (C group; sarcopenia present at baseline, but absent at 5 years); and persistent (P group; sarcopenia present at baseline and at 5 years).
Results: Seventy RA patients completed the survey. There were no differences among the 4 groups in disease activity, physical function, and treatment. The N group, accounting for 67.1% of all patients, was young and had high body mass index, muscle mass, fat mass, estimated bone mass, and body metabolic rate at baseline. On the other hand, the S group, accounting for 4.3% of all patients, fell significantly more frequently (p=0.035), 3.3 times during 5 years. The P group, accounting for 18.6% of all patients, had significantly higher MMP-3 at baseline (p=0.006). The C group accounted for 10.0% of all patients (Table 1).

Table 1. Characteristics of 77 RA patients by sarcopenia status at baseline and at 5-year follow-up

	no development (n=47)	development (n=3)	cured (n=7)	persisted (n=13)	p value

AB0263 CLINICAL AND LABORATORY FACTORS ASSOCIATED WITH THE RHEUMATOID CACHEXIA.

E. Papichev[1], L. Seewordova[1], Y. Akhverdyan[1], J. Polyakova[1], B. Zavodovsky[1]. *[1]Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky", Laboratory of Methods of Treatment and Prevention of Joint Diseases, Volgograd, Russian Federation*

Background: Rheumatoid arthritis (RA) is associated with reduced physical performance capacity, leisure activities and self-service [1]. These changes are the results of the destruction of the joints, as well as the decrease in muscle strength, which is known as sarcopenia. However, patients with RA beset with a rheumatoid cachexia (RC), a specific form of sarcopenia, characterized with a decrease in fat-free mass index and an increase in fat mass index [2]. RC leads to a dramatic decrease in the life quality and increase in mortality rate [3].
Objectives: To study the clinical and laboratory factors associated with the RC.
Methods: 110 patients (102 females and 8 males) were enrolled in our study. All patients fulfilled the 2010 ACR/EULAR classification criteria for RA. Standard clinical, laboratory and instrumental examinations were performed. Additionally, hsCRP, ACPA, CTX-1, P1NP and 25(OH)D were defined. Dual-energy X-ray absorptiometry with Total Body program was performed. The diagnosis of RC was based on the next criteria: fat-free mass index less than 10th percentiles with fat mass index above 25th percentiles [2]. Statistical analysis was performed using a software package "Statistica 12.0". Parametric parameters are presented as M±std.dev. (95% CI), non-parametrics as Me (Q1-Q3). Intragroup analysis of quantitative indicators was carried out using Student's or Mann-Whitney test. The multiple logistic regression analysis was performed with a stepwise direct search procedure. Results are presented as odds ratio (OR) and 95% confidence interval (95% CI). ROC curve was plotted to assess the diagnostic significance of quantitative signs in predicting rheumatoid cachexia.
Results: Mean patients age was 53,7±12,07 (10,8-13,7) years. More than 85% had severe of terminal progression of the RA. Most patients were RF (77,3%) and ACPA (67,3%) positive, had moderate disease activity (3,79 [2,89-4,40]), cartilage erosions (79%) and II (56,4%) functional class. RC was diagnosed in 25 patients. Prevalence of RC was lower in RF-negative patients (OR 0,11 (95% CI 0,01-0,83). Also, prevalence of RA was associated with the duration of RA (1,06 (1,01-1,11)). Mean cumulative dose of glucocorticoids (GCs) was higher in patients with RC (8,5 g [6,2-17,5 g]), than without (5,8 g [3,6-13,7 g]) (Z=-1,98; p=0,047). Mean daily dose of GCs was lower in patients with RC (5 mg [4-8 mg] and 8 mg [5-10 mg] (Z=2,58; p=0,01)). The median duration of RA was higher among patients with RC (14,0 years [9,0-22,0] vs 8,0 years [3,0-16,0] (Z=-2,18; p=0,029)).
ROC-curve was employed to assess the significance of the RF-negativity and RA duration in the diagnosis of RC. Results are presented in Figure 1.

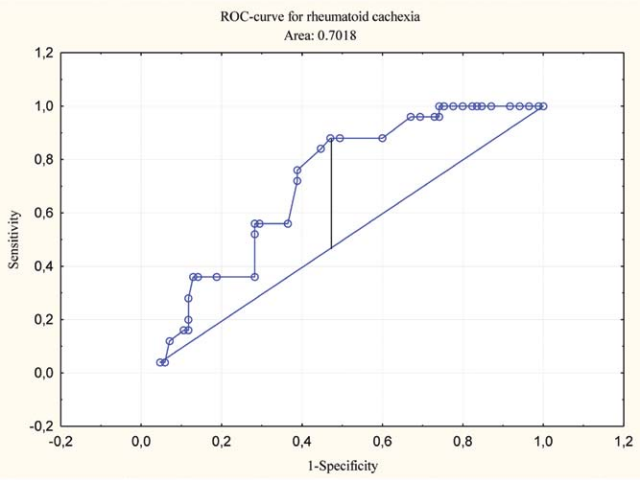

Figure 1. ROC-curve for the RC based on the duration of RA and the presence of RF.

The optimum cut-off point of 9,5 years of RA was defined using Youden's J, with a sensitivity of 88% and specificity of 53%.
Conclusion: RC is associated with the duration of RA, positivity for RF, higher cumulative dose of GCs and lower daily dose of GCs. Due to clinical practice, higher doses of GCs are usually prescribed as a "bridge-therapy" at the start of the treatment or while switching the therapy. On the other side, patients with low daily dose of GCs are more often hormone dependent, with high total cumulative dose. With the sensitivity of 88% patients with the duration of RA 9,5 years and more have RC.

(UCO), Córdoba, Spain, Rheumatology Department, Cordoba, Spain; [2]Reina Sofia University Hospital, 14004 Córdoba, Spain; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), 14004 Córdoba, Spain; Córdoba University (UCO), Córdoba, Spain, Rheumatology Department, Córdoba, Spain

Objectives: To evaluate the association between different HLADRB1 alleles and the development of serious complications in patients with rheumatoid arthritis (RA).
Methods: We performed an observational, longitudinal and retrospective study of a cohort of 134 patients with established RA (ACR/EULAR 2010) from the registry of our department, older than 18 years and without other associated autoimmune pathologies except secondary Sjogren's syndrome and who had the requested HLADRB1 genotype. Patients with ≥ 1 of the following HLA-DRB1 alleles were considered positive shared epitope carriers (SE+): *01:01, *01:02, *04:01, *04:04, *04:05, * 10:01, *03:01 or *07:01. The remaining patients without any of these alleles were considered shared epitope negative (SE-). Serious complications of RA were included: interstitial lung disease, cardiovascular events, cancer, admissions for serious infections, vasculitis, Felty's syndrome, or death. Other severity data: erosions, rheumatoid nodules, multiple resistance to biologicals (3 or more biologicals), secondary Sjogren's syndrome or osteoporosis. Descriptive and bivariate analysis was performed between the different alleles (χ^2/ANOVA). Cox regression analysis was performed to estimate the influence of the different alleles on mortality.
Results: A total of 134 patients (91 SE+ and 43 SE-) were included. The main differences between the different alleles are shown in Table 1. The most frequent alleles were *0101 (n=18), *0301 (n=15) and *0701 (n=17). When the different alleles were compared, it was seen that the carriers of the alleles *04:05 presented positive ACPA more frequently (100%), rheumatoid nodules (50%) and showed higher mortality (50%) together with the carriers of *07:01 (41.2%), in a statistically significant way. There was no difference in the rest of the complications or severity data. The causes of death were varied in patients with both alleles (cardiovascular events, cancer, interstitial lung disease, and infections). There were no differences in age at death [mean 82.8 years (SD 3.8) vs 84.5 (6.6); p= 0.836, respectively]. Cox regression analysis adjusted for sex, age and ACPA showed that patients with alleles *04:05 (HR 9.1 (95% CI 1.1-72.3; p=0.036) and *07:01 (HR 10.9 (95% CI 1.5-81.2; p= 0.019) had a higher risk of mortality from any cause.
Conclusion: Our results suggest that RA patients carrying the *0405 and *0701 alleles have an increased risk of mortality. Studies with larger numbers of patients are needed to confirm these results.

AB0265

RHEUMATOID ARTHRITIS PATIENTS HOSPITALIZED FOR A SERIOUS INFECTION HAVE HIGH INCIDENCE OF SEPSIS WHILE THOSE ON BDMARDS HAVE LOWER MORTALITY COMPARED TO THOSE ON CSDMARDS

E. Tzagkarakis[1], I. Flouri[2], I. Facondi[1], E. Kalogiannaki[2], S. Ilia[3], G. Briassoulis[3], P. Sidiropoulos[2]. *[1]Venizeleio General Hospital of Heraklio, 2nd Internal Medicine Dpt., Heraklion, Crete, Greece; [2]University Hospital of Heraklion, Crete, Rheumatology Department, Heraklion, Crete, Greece; [3]University Hospital of Heraklion, Crete, Pediatric Intensive Care Unit, Heraklion, Crete, Greece*

Background: The treatment of rheumatoid arthritis (RA) includes conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) and biologic DMARDs (bDMARDs). RA is associated with an increased risk of serious infections (SI) and the use of bDMARDs almost doubles this risk. SI can lead to sepsis, a life-threatening condition manifested by organ failure caused by a dysregulated host response to a pathogen. bDMARDs target pro-inflammatory cytokines which mediate the inflammation cascade activated both in RA and sepsis. However, very few data exist regarding the incidence of sepsis in patients with a SI while on treatment with bDMARDs.
Objectives: To assess the outcomes of sepsis and death in RA patients with a SI and compare them between patients on bDMARD and csDMARDs. Secondary aims were the comparison of subgroups of patients treated with different bDMARD classes [Tumor necrosis factor inhibitor (TNFi) vs. non-TNFi] and subgroups based on age (geriatric vs. younger patients).
Methods: Single-center retrospective analysis of adult RA patients registered in the University of Crete Rheumatology Clinic Registry (UCRCR), who were hospitalized for ≥1 SI between 2004-2020. Patients were assigned to "bDMARD group" if they were receiving bDMARDs at the time of the SI or "Control group" if there was no bDMARD exposure at least 3 months before the SI. Demographics, RA characteristics, and comorbidities were retrieved from UCRCR database, while details regarding hospitalization were sought in the patients' electronic and paper files. Together with the "Sequential Organ Failure Assessment" (SOFA) criteria at admission and during 76-92 hours of hospitalization used to define the diagnosis of sepsis, we also analyzed the criteria of septic shock and in-hospital mortality.
Results: A total of 117 hospitalizations for SI in RA patients were included: 66 in patients receiving bDMARDs and 51 in the control group (65% bDMARD-naive and 35% bDMARD-experienced). The majority of the patients (76%) were women in both groups, however, patients on bDMARDs were younger than control patients [70 (IQR 62-77) and 78 (IQR 68-82) years old respectively, p=0.002]. Other demographics, disease characteristics, disease activity at baseline, and comorbidities did not differ between the two groups, except for a higher prevalence of one or more previous hospitalizations for infection in patients on bDMARDs.
During hospitalization, 14 patients (12%) died. Mortality was significantly higher in the control group (19.6% of patients) compared to the bDMARD group (6%) (p=0.025). Sepsis criteria were fulfilled in 56 patients (47.9%) at admission and/or at 76-92 hours of hospitalization. Sepsis was marginally more frequent in the control group versus the bDMARD group (56.9% vs. 40.9% respectively, p=0.087). In the subgroup analysis based on the type of bDMARD, no statistical difference was found for the outcomes of sepsis or death between patients on TNFi versus those on non-TNFi. However, in the subgroup of patients ≥65 years old, there was a tendency for a lower incidence of sepsis or death in patients on TNFi compared to those on non-TNFi or the control group [14% vs 53%, vs 85% respectively (p=0.120) for the outcome of sepsis and 7% vs. 21%, vs. 71% (p=0.138) for the outcome of death].
Receiver operating characteristic (ROC) analysis indicated older age (p<0.001), higher SOFA score at admission (p<0.001), septic shock at 76-92 hours (p<0.001), and non-exposure to TNFi (p=0.040) as predictors of in-hospital death. However, in multivariable logistic regression analysis, older age was the only significant predictor of sepsis and death during hospitalization.
Conclusion: In the present study, we found a high incidence of sepsis (47.9%) and mortality (12%) in RA patients hospitalized for a serious infection. Older age is the most significant predictor of adverse outcomes, however, patients on bDMARDs showed lower mortality and a tendency for a lower incidence of sepsis compared to the control group.

PREGNANCY PLANNING AND FOLLOW-UP IN MULTIDISCIPLINARY UNITS IMPROVES THE OUTCOMES IN WOMEN WITH INFLAMMATORY ARTHROPATHIES

L. Vega[1], O. Ibarguengoitia[2], C. García[1], M. Enjuanes[1], E. Galíndez-Agirregoikoa[1], I. Calvo[2], J. M. Blanco[1], A. R. Inchaurbe[1], I. Torre[1], O. Fernandez[1], C. E. Perez[1], E. Cuande[1], M. R. Exposito-Molinero[1], I. Gorostiza[3], J. Oraa[4], M. L. García Vivar[1], M. E. Ruiz[1]. *[1]Basurto University Hospital, Rheumatology Unit, BILBAO, Spain; [2]Galdakao University Hospital, Rheumatology Unit, Bilbao, Spain; [3]Basurto University Hospital, Investigation Unit, Bilbao, Spain; [4]Basurto University Hospital, Obstetrics and Gynecology Unit, Bilbao, Spain*

Background: Women with inflammatory arthropaties (IA) have fertility problems and complications during pregnancy and frequently biological therapy (BT) is required for the disease control.
Objectives: To evaluate pregnancy in women with IA in a multidisciplinary unit composed of Rheumatologists and Obstetricians: describe disease evolution, complications and treatment.
Methods: Retrospective and descriptive study of the evolution of pregnancy in patients with IA [Rheumatoid Arthritis (RA), Spondyloarthritis (SpA), Psoriatic arthritis (PsA) and Juvenile Idiopathic Arthritis (JIA)] and follow-up in a multidisciplinary unit for more than 15 years (until December 2021). Demographics, maternal disease, time until conception, previous abortions and presence of antibodies were collected. In addition, during follow-up, treatment, abortions, cesarean sections (C-section), preterm births, disease activity and maternal/fetal complications were collected.
Results: We registered 49 pregnancies (39 women): 27 RA (55.1%), 9 SpA (18.4%), 9 PsA (18.4%) and 4 JIA (8.1%). Maternal average age at diagnosis was 26.8±6.7 years and average age at childbirth/abortion was 34.5±5.3 years. It took an average time of 9±7.7 months to conceive. 8.2% received fertility treatment with in vitro fertilization techniques.
AntiRo antibodies were registered in 6.3% of patients and 28.6% had at least 1 antiphospholipid antibody.
At the time of gestational desire/gestation 24 women (13 RA, 5 SpA, 3 PsA, 3 JIA) were receiving BT: 14 certolizumab (CZP), 5 adalimumab (ADA), 4 etanercept (ETN). 1 patient was being treated with baricitinib (BARI). Due to pregnancy, ADA was changed to CZP in 3 women and BT was stopped in 6 cases (3 ETN, 2 ADA, 1 CZP) as well as BARI. In 2 cases, ADA was stopped at week 17 of pregnancy (medical indication). Pregnancy was completed with BT (CZP) in 15 cases. 9 abortions were registered prior to follow-up in the unit (0.23 abortions/mother) and 3 (2 RA, 1 PsA) during follow-up (0.07 abortions/mother): 2 (1 RA, 1 PsA) of them in women with CZP. RA patient had positive antiphospholipid antibodies and was a smoker and the other one had moderate disease activity by the time of the abortion. C-section was performed in 26.1% of cases. Preterm birth (<37 weeks) happened in 8.2% (n: 4) of the pregnancies: 2 in women with CZP.
A total of 19 different fetal/maternal complications were registered during follow-up: 8 in the BT group (42.1%) compared to 11 (57.9%) in the group without BT, being Intrauterine Growth Restriction (IUGR) more frequent among women with BT. Infections were not more common in patients with BT. Table 1.

Table 1.

COMPLICATIONS	WITH BT (n, %) n: 17	WITHOUT BT (n, %) n: 32
IUGR	3 (17.6)	1 (3.1)
LBW	2 (11.8)	2 (6.2)
INFECTION	1 (5.9)	4 (12.5)
CHOLESTASIS	0 (0)	2 (6.2)
PREECLAMPSIA	0 (0)	1 (3.1)
DM	2 (11.8)	1 (3.1)
HIGH BLOOD PRESSURE	0 (0)	0 (0)
NEPHROPATY	0 (0)	0 (0)
NEONATAL LUPUS	0 (0)	0 (0)
HEART BLOCK	0 (0)	0 (0)
MALFORMATION	0 (0)	0 (0)
HELLP SYNDROME	0 (0)	0 (0)
TOTAL	**8**	**11**

Regarding concomitant treatment, low dose prednisone was used in 32.7% of pregnancies, hydroxychloroquine in 44.9%, sulfasalazine in 8.2% and acetylsalicylic acid in 51%. We didn´t find differences in the use of these treatments between the two groups.
Median DAS28 among RA patients with available data was under 2.6 throughout pregnancy as well as previously and posteriorly. No differences in median DAS28 were found between women with BT and without BT. SpA patients had BASDAI lower than 4 in both groups during pregnancy and previously.
Conclusion: In our series, as described in the literature, women with IA are older and more likely to have preterm births compared to general population. Appropriate disease control was maintained during pregnancy, also previously and afterwards. We registered more IUGR, low birth weight (LBW) and diabetes mellitus (DM) among women with BT but lower rate of infections. Given the low number of patients with BT no statistically significant conclusions about complications can be drawn. Therefore, more studies among pregnant women with BT are necessary.

FEATURES OF CARDIAC PATHOLOGY IN PATIENTS WITH SECONDARY OSTEOARTHRITIS ON THE BACKGROUND OF RHEUMATOID ARTHRITIS

L. Feiskhanova[1]. *[1]Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation*

Background: Rheumatoid arthritis, being one of the most common rheumatic diseases, is often accompanied by systemic (extra-articular) manifestations and various complications. In particular, the inflammatory process often leads to damage to the tissues of the joint and the subsequent development of secondary arthrosis. RA is accompanied by a high cardiovascular risk. Patients with OA also have an increased risk of developing cardiovascular diseases.
Objectives: To identify the features of cardiac pathology in patients with rheumatoid arthritis (RA) in combination with osteoarthritis (OA).
Methods: The study involved 282 patients with secondary OA on the background of RA. The first group consisted of 48 patients who underwent endoprosthetics of at least one large joint due to severe OA, the second group consisted of 234 patients with RA and secondary OA of functional class 1-3 who did not require endoprosthetics. The patients underwent determination of the level of rheumatoid factor, circulating immune complexes, C-reactive protein, ESR, ECG with calculation of the QT interval variance, vectorcardiography and echocardiography.
Results: Patients with RA who underwent endoprosthetics due to secondary osteoarthritis were characterized by later clinical and radiological stages ($p<0.0001$), as well as a higher functional class compared to patients of group 2 ($p<0.0005$). Both groups differed in the level of ESR: 1st - 29 [16;40] mm/h, 2nd - 20[12.5;31] mm/h ($p<0.05$). In other words, the severity of osteoarthritis is more associated with the inflammatory component of the underlying disease than with the autoimmune one. During the correlation analysis in group 1, the following correlations were found: inverse, average and reliable relationship between age and the E/a transmittal flow index ($r=-0.63$, $p<0.0001$); direct, average relationship between the DAS level and the relative wall thickness of the left ventricle (LV) ($r=0.39$, $p<0.05$); inverse, average relationship between the level of rheumatoid factor and the vectorcardiographic parameter MV-rise ($r=-0.32$, $p<0.05$); direct, strong the relationship between the relative thickness of the LV wall and the area of the loop P on vectorcardiography ($r=0.76$, $p=0.01$); the inverse, average relationship between the final LV diastolic size and the loop area T ($r=-0.65$, $p=0.03$). Thus, in this group of patients, the older a person is, the more the diastolic function of the left ventricle is impaired. In this study, we found out that with an increase in the activity of the disease, the structural geometry of the heart becomes more concentric, which affects the results of vectorcardiography. In the 2nd group, a direct, average correlation was revealed between the DAS index and the value of the maximum vector according to vectorcardiography ($r=0.6$, $p<0.05$); the inverse, strong relationship between the E/a of the transmittal flow and the dispersion of the QT interval ($r=-0.73$, $p=0.02$). It follows from this that in group 2, an increase in the activity of the disease is accompanied by an increase in the electrical activity of the ventricles of the heart, determined by the maximum vector. And with an increase in diastolic dysfunction of the left ventricle, there is an increase in readiness for the initiation of life-threatening arrhythmias and electrical instability of the myocardium.
Conclusion: In patients with RA and severe secondary OA, high activity of the disease contributes to structural and geometric remodeling of the heart, and in the milder form of secondary OA is accompanied by electrophysiological remodeling in the form of increased electrical activity of the ventricles and, accordingly, the risk of malignant arrhythmias.

AB0268

SURVEY OF ELDERLY RHEUMATOID ARTHRITIS (RA) PATIENTS: REAL-WORLD DATA OF PRE-OLD (65 TO 74 YEARS) AND OLD (≥ 75 YEARS) RA PATIENTS

A. Nakashima[1], H. Fujii2, T. Suda2, I. Mizushima[3], M. Kawano[3], H. Nomura[4]. *[1]Ishikawa Prefectural Central Hospital, Division of Nephrology and Rheumatology, Kanazawa, Japan; [1]Ishikawa Prefectural Central Hospital, Division of Nephrology and Rheumatology, Kanazawa, Japan; [3]Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan; [4]Kanazawa University Hospital, Department of General Medicine, Kanazawa, Japan*

Background: The number of patients (pts) with rheumatoid arthritis (RA) is highest in persons in their late 60s, and the age at onset has increased in recent years. In many countries, including Japan, 'elderly' is defined as 65 years or older, but recently, the Japan Geriatrics Society and Japan Gerontological Society have advocated a newer classification of elderly: pre-old as 65 to 74 years, old as 75-89 years and super old as ≥90 years[1)]. Disease activities, renal functions, treatments and other parameters in thus classified elderly RA pts have not been investigated yet.
Objectives: Elderly pts with RA were classified, and then disease activities, treatments, renal functions and other parameters compared between the groups to clarify the real-world picture of pre-old and old RA pts.
Methods: We enrolled 359 RA patients (85 males, mean age 65.0 ± 13.6 years) treated at our hospital and affiliated hospitals. They were divided into three groups: under 65 years as a control group, 65-74 years as a pre-old (group I), and 75 years or older as an old (group II). Urine examination, serum Cr, eGFR, BUN, other biochemical tests, serological tests, disease activity, treatment, smoking, and comorbidities were evaluated. Difficult-to-treat RA pts (D2T RA) were evaluated according to EULAR criteria[2)].
Results: Group C contained 148 pts (28 males, mean age 51.7 ± 9.6 years), Group I 123 pts (28 males, mean age 70.1 ± 2.9 years) and Group II 88 pts (29 males, average age 80.2 ± 4.5 years). Among the three groups, the frequency of males was 33.0% in group II, which was significantly higher than in the other groups. There was no significant difference in disease activity among the three groups. There was a significant difference in eGFR among the three groups (77.3 ± 17.3 ml/min. in group C, 69.4 ± 15.8 ml/min. in group I, 62.7 ± 18.7 ml/min. in group II). There was a significant difference in frequencies of treatment with NSAIDs (40/133 (30.0%) in group C, 23/102 (22.5%) in group I, 9/67 (13.4%) in group II), methotrexate (MTX) (87/148 (58.8%) in Group C, 62/123 (50.4%) in Group I, 28/88 (31.4%) in Group II). There was no significant difference in frequencies of treatment with prednisolone (55 / 148 (30.2%) in group C, 55/123 (43.1%) in Group I, 45/88 (51.1%) in Group II), with biologics (44/148 (29.7%) in Group C, 29/123 (23.6%) in Group I, 26/88 (29.5%) in Group II) and with JAK inhibitor (15/148 (10.1%) in Group C, 7/123 (5.7%) in Group I, 5/88 (5.7%) in Group II). There was no significant difference in D2TRA pts among the three groups (21/148 (14.2%) in Group C, 12/123 (9.8%) in Group I, 13/88 (14.8%) in Group II). There were significant differences in the frequency of stage IV and comorbidities among the three groups.
Conclusion: In the pre-old and old RA pts, renal function was lower than in the control group. MTX was administered even in them, but less frequently. We were able to clarify the current situation that JAK inhibitors and biologics are actively used even in pre-old and old RA pts with impaired renal function, and the frequency of D2T RA pts could be suppressed to almost that in the control group. Patients with impaired renal function are more likely to develop side effects of MTX, and it is necessary to pay particular attention to pre-old and old RA patients.

AB0269

UTILITY OF DAS28-ΓGT IN THE ASSESSMENT OF DISEASE ACTIVITY AND CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS

M. Lesturgie Talarek[1], A. Deloumeau[1], E. Sorbets[2], Y. Allanore[1], J. Avouac[1]. *[1]Cochin Hospital, Rheumatology, Paris, France; [2]Hôtel Dieu Hospital, Cardiology, Paris, France*

Background: γGT has been identified as a maker of systemic inflammation and cardiovascular (CV) risk. The composite index DAS28-γGT has been developed to allow an evaluation of both joint disease activity and CV risk.
Objectives: To assess the value of the DAS28-γGT in a population of patients with rheumatoid arthritis (RA) requesting cardiologic assessment.
Methods: Retrospective analysis of RA patients referred to cardio-metabolic day hospitalization in the Rheumatology department of Cochin hospital between February 2021 and January 2022. Criteria for referral were age > 50 years and presence of at least one CV risk factor. DAS28-GGT index was calculated as follows: 0,56 * √TJ-28 + 0,28 * √SJ-28 + 2 * ln (γGT) + 0,14 * GH. This index was analysed according to disease activity measured with the DAS28-CRP, CV risk assessed by the Framingham score and the decision taken by the cardiologist (requirement of complementary explorations and/or therapeutic intervention).
Results: We included 22 RA patients (17 women), with a mean age of 66±10 years, a disease duration of 21±12 years. Rheumatoid factor was positive in 15 patients, anti-CCP antibodies in 17, and bone erosions in 16. 15 patients received methotrexate, 13 corticosteroids (dose < 10 mg per day), 15 targeted biologic therapies and 3 JAK inhibitors. The mean DAS28-CRP was 2.5±0.9 and the mean DAS28-γGT was 7.90±1.90.
2 patients had a DAS28-γGT < 5.5, defined in our previous study as high probability of RA remission and low probability of CV risk. These two patients were in remission and their Framingham score was < 10% (low CV risk). No complementary exploration was requested by the cardiologist.
8 patients (6 women, 2 men) had a DAS28-γGT index between 5,5 and 7,5, defined in our previous study as high probability of RA remission or low disease activity (LDA) and increased probability of CV risk. As expected, all patients were in remission or in LDA. This population were at higher CV risk: 2 patients had a Framingham score > 20% (high risk), 3 patients a score ranging from 10 to 20% (intermediate risk), and 3 patients a score < 10%. One patient presented carotid atheroma. 4 patients required additional CV explorations and 3 patients necessitated escalation of blood hypertension therapy.
Twelve patients (9 women, 3 men) had a DAS28-γGT index > 7,5, defined in our previous study as high probability of active RA and/or increased probability of CV risk. 4 patients were in remission, 3 were in LDA and 5 presented moderate disease activity. One patient had a Framingham score > 20%, 4 had a score ranging between 10 and 20% and 6 had a score < 10%. The score was not applicable in an 80-year-old patient. Three other patients had coronary artery disease, including a patient who presented both coronary artery disease and carotid atheroma. 5 patients requested additional CV explorations and 4 required CV therapy escalation (introduction of statin and aspirin in 2 patients and increased blood hypertension therapy in 2 patients). Among these 12 patients, 3 with the highest DAS28-γGT values presented CV complications: a 64-year-old woman with a DAS28-γGT of 12.8 (DAS28-CRP: 2.89) had carotid atheroma and intermediate lesion of the right artery on coroscanner justifying a coronarography; a 81-year-old woman with a DAS28-γGT of 10.67 (DAS29-CRP: 4.62) had atrial fibrillation and aortic stenosis requiring Transcatheter Aortic Valve Implantation; and a 77-year-old woman with a DAS28-γGT of 10.35 (DAS28-CRP: 3.89) had ischemic chest pain necessitating rapid explorations in cardiology.
Conclusion: The DAS28-γGT allowed a reliable classification of patients according to the RA activity disease and CV risk. This index may be relevant for CV risk stratification decision making to refer RA patients to a cardiologist. Its validation is in progress in a prospective cohort.

AB0270

EFFECT OF METHOTREXATE USE ON JOINT AND LUNG DISEASE OUTCOMES IN PATIENTS HAVING RHEUMATOID ARTHRITIS WITH INTERSTITIAL LUNG DISEASE

M. Yoshida[1], T. Zoshima[1], M. Kawano[1]. *[1]Kanazawa University Graduate School of Medicine, Rheumatology, Kanazawa, Japan*

Background: Interstitial lung disease (ILD) is a frequent complication of rheumatoid arthritis (RA). Although methotrexate (MTX) is an anchor drug for RA management, its use may worsen lung disease severity in patients with RA related ILD (RA-ILD). The safety and efficacy of MTX use in RA-ILD treatment have not been elucidated.
Objectives: We aimed to clarify the clinical characteristics of patients with RA-ILD and the effect of MTX use on joint and lung disease outcomes.
Methods: In this retrospective study, we included patients with RA-ILD who visited our department from 2011 to 2019 and underwent chest computed tomography (CT). RA was diagnosed using the 1987 ACR criteria or the 2010 ACR/EULAR classification criteria. During the abovementioned period, we defined the baseline as the time of the first chest CT scan; moreover, the final observation was defined as the time of the final chest CT scan in patients who underwent CT more than once, or as the final visit in those without a second chest CT scan. We excluded patients whose RA-ILD status could not be fully evaluated using chest

CT scans due to other causes, including respiratory infections. Severe infections were defined as infectious events requiring hospitalization.
To identify the clinical characteristics of patients with RA-ILD, we compared the features of RA with versus without ILD at baseline. To clarify the effect of MTX use on RA-ILD outcomes, we compared the outcomes of patients with RA-ILD with versus without MTX use. Furthermore, we investigated factors associated with RA disease activity or ILD deterioration using multivariate analyses.
Results: In this study, we included 452 patients (mean age, 60.2 years; females, 78.5%; mean observational period, 77.5 months), 325 (71.9%) of whom underwent chest CT more than two times.
Patients with ILD (ILD; n=90, 19.9%) were older and had a higher RF positivity rate than those without ILD. Moreover, patients with ILD were treated with lower MTX use (20.2% vs. 52.9%, p<0.001; 1.46 vs. 3.53 mg/week, p<0.001) and TNF inhibitors exposure (21.1% vs. 13.1%, p<0.044) than those without ILD, albeit with similar uses of prednisolone and other bDMARDs, including tocilizumab and abatacept. DAS28-CRP was higher in patients with than in those without ILD at baseline (4.60 vs. 3.42, p=0.063) and at the final observation (2.42 vs. 2.09, p=0.025). Linear regression analysis showed that baseline age and ILD were significantly associated with DAS28-CRP at the final observation (β=0.206 and 0.173, respectively). Kaplan Meier analysis revealed that patients with ILD experienced severe infections and respiratory infections more frequently than those without ILD (log-rank test, p<0.001 and p<0.001).
Seventeen patients (20.2%) with ILD were treated with MTX. At baseline, these patients had similar ages and RF/ACPA positivity rates, as well as prednisolone and tDMARDs exposures, with higher bDMARD exposure (41.2 vs. 13.4%, p=0.016) compared to that in ILD patients without MTX use. DAS28-CRP was comparable in patients with and without MTX use at baseline, but was lower at the final observation in MTX-treated patients with ILD (1.41 vs. 2.73, p<0.001). Kaplan Meier analyses revealed no differences in the frequencies of severe infections, respiratory infections, or ILD deterioration between patients with and without MTX use. Cox regression analysis demonstrated that the risk factors for ILD deterioration included baseline age (hazard ratio [HR] 1.088; 95% confidence interval [CI] 1.037-1.147), but not MTX use (HR 1.666; 95% CI 0.472-5.876).
Conclusion: RA-ILD were treated with lower MTX use, which resulted in higher RA disease activity. In contrast, patients with RA-ILD treated with MTX had lower RA disease activity without ILD deterioration. As RA-ILD is undertreated, appropriate MTX use may be required for effective RA-ILD treatment

AB0271 ALEXITHYMIA IN A PATIENT WITH RHEUMATOID ARTHRITIS: CONNECTION WITH DISEASES AND FUNCTIONAL ABILITY.

Y. Shalkovskyi[1], M. Stanislavchuk[1]. *[1]National Pirogov Memorial Medical University, Vinnytsya, Department of Internal medicine №1, Vinnytsya, Ukraine*

Background: Rheumatoid arthritis (RA) is the chronic, destructive, immune-mediated inflammatory disease that has a progressive course and causes the early disability of approximately 50% over the next five years. Acute pain syndrome in RA often leads to a violation of the psycho-emotional sphere with manifestations in the form of depression, anxiety and alexithymia.[1] Alexithymia is defined as a personal emotional disorder characterized by difficulty in identifying and describing subjective feelings and related to cognitive impairment.
There is insufficient data regarding the prevalence of alexithymia in patients with RA.
Objectives: To investigate the prevalence of alexithymia and the relationship with disease activity and functional ability in patients with RA.
Methods: RA patients diagnosed according to the ACR/EULAR 2010 classification criteria. The presence of alexithymia was determined by the «Toronto Alexithymia Scale» questionnaire (TAS-20). RA activity was assessed by the Disease Activity Score (DAS28-ESR), Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI). Functional ability - by the Health Assessment Questionnaire (HAQ). In the study were included 98 patients with RA (83.7% of women). The mean age was (M±SD) 49.5 ± 11.7 years, the duration of the disease ranged from 1 to 21 years, and averaged 7.8 ± 4.9 years. Statistical analysis was performed by IBM Statistics SPSS 20.
Results: Among 98 examined, alexithymia (≥ 61) was detected in 24 persons (24.5%), including 23 women, mean age (M±SD) 54 ± 7.16 years with disease duration 9.96 ± 5.23 years. The activity of RA in persons with alexithymia was: DAS-28 (6.4 ± 0.71); SDAI (41.15 ± 8.64); CDAI (39.46 ± 9.03) and ESR (27.6 ± 15.1), which was significantly higher than in patients without alexithymia: DAS-28 (5.52 ± 1.05); SDAI (32.72 ± 11.28); CDAI (31.98 ± 11.07) and ESR (22.7 ± 15.27). Functional disability in individuals with RA and alexithymia according to HAQ was (1.7 ± 0.59) in contrast to the group of patients with RA without alexithymia - (1.04 ± 0.62). The value of TAS-20 had a direct correlation with the activity by DAS-28 (0,379; p < 0,01), SDAI (0,39; p < 0,01) and CDAI (0,359; p < 0,01)), radiological stage (0.260; p < 0.01) and HAQ (0.393; p < 0.01).
Conclusion: Alexithymia is quite common comorbid condition in patients with RA associated with disease activity and functional disability. Further studies are needed to assess the clinical significance of alexithymia in this category of patients.

AB0272 DEEP BREATHING INCREASES HEART RATE VARIABILITY IN HEALTHY PARTICIPANTS AND IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS: AN INTERVENTIONAL DOSE-RESPONSE STUDY

C. H. Liboriussen[1], S. S. Andersen[1], M. K. Jensen[1], S. S. Andersen[1], M. R. Jochumsen[1], S. Kristensen[2]. *[1]Aalborg University, Department of Health Science and Technology, Aalborg, Denmark; [2]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark*

Background: Patients with Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) are known to have an autonomic dysfunction, especially reduced parasympathetic activity. The dysfunction can be measured through heart rate variability (HRV), an indicator of vagus nerve tone. Studies have found a potential anti-inflammatory effect of the vagus nerve and proposed vagus nerve stimulation (VNS) as an anti-inflammatory treatment. A way of stimulating the vagus nerve non-invasively could be through deep breathing (DB).
Objectives: The aims of this study were to examine the dose-response of DB on HRV in healthy participants and to examine the reliability of the effect of DB on HRV in patients with RA and SLE across two days.
Methods: The study was designed as an interventional study, more specifically the healthy subjects participated in a dose-response study and the patients with RA and SLE participated in a study of reliability. Forty-one healthy participants performed DB for 5, 15, and 30 minutes (4 seconds of inspiration and 6 seconds of expiration) in a randomized order on three different days. Fifty-two patients with RA and SLE performed the optimal dose of DB found in healthy participants, and the intervention was repeated on two different days to examine the reliability of the effect. The outcome measure was HRV, which was derived from a 5-minute electrocardiogram recording measured twice before and three times after DB. The extracted HRV measures included in the further analysis were the time domain parameters: a) The standard deviation of the R-R intervals (SDNN), b)

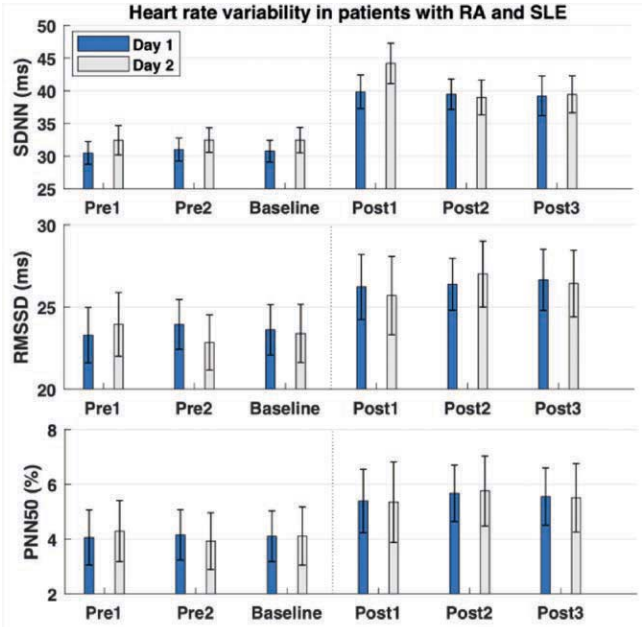

Figure 1. Bar chart showing the heart rate variability-parameters plotted as mean ± standard error in patients with RA and SLE. RA: Rheumatoid Arthritis. SLE: Systemic Lupus Erythematosus. SDNN: The standard deviation of the R-R intervals. RMSSD: The root mean square of successive R-R intervals. PNN50: The proportion of NN50 (pairs of successive R-R intervals that differ more than 50 milliseconds) divided by the total number of R-R intervals.

the root mean square of successive R-R intervals (RMSSD), and c) the proportion of NN50 (pairs of successive R-R intervals that differ more than 50 milliseconds) divided by the total number of R-R intervals (PNN50).
Results: Thirty minutes of DB increased HRV and was the optimal dose of DB in healthy participants. In patients with RA and SLE 30 minutes of DB increased all HRV-parameters similarly across two days indicating reliability, see Figure 1. The effect of DB remained for at least 30 minutes after the intervention.
Conclusion: DB increases HRV in healthy participants and in patients with RA and SLE, indicating a stimulation of the vagus nerve. Future studies are needed to investigate the potential anti-inflammatory effect as well.

AB0273 IDENTIFICATION OF RED FLAGS FOR INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Conigliaro[1], E. De Martino2, E. Cela[1], P. Triggianese[1], M. S. Chimenti[1], A. Luciano[3], M. Chiocchi[3], J. Ora[4], F. Cavalli[4], F. Garaci5, R. Floris[3], P. Rogliani[6], A. Bergamini[1]. *[1]University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy; [1]University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy; [3]University of Rome Tor Vergata, Department of Diagnostic Imaging and Interventional Radiology, Rome, Italy; [4]Tor Vergata Hospital Foundation, Respiratory Medicine, Rome, Italy; [3]University of Rome Tor Vergata, Department of Diagnostic Imaging and Interventional Radiology, Rome, Italy; [6]University of Rome Tor Vergata, Respiratory Medicine, Department of Experimental Medicine, Rome, Italy*

Background: Interstitial lung disease (ILD) in Rheumatoid Arthritis (RA) can be subclinical or underestimated. Data from the literature report male sex, seropositivity and old age as known risk factors for ILD in RA. However, the correct timing for referral to pneumologists and eligibility for CT chest scan is undefined.
Objectives: To identify potential red flags of ILD diagnosis for referral to a multidisciplinary team analyzing clinical and radiological findings associated with the establishment of ILD.
Methods: Retrospective study on CT chest scan from RA patients evaluated and categorized into usual interstitial pneumonia (UIP), nonspecific interstitial pneumonia (NSIP) and unclassifiable RA-ILD (Un-ILD), by two radiologists. RA-ILD was diagnosed by two pneumologists considering radiological and clinical factors.
Results: 80 CT chest scans from RA patients (F 59, age 66,6 ± 11,4, disease duration 7,8 ± 4,4) were evaluated. 36,5% of patients had performed CT-chest scan for suspect of ILD, 11,2% for probable pulmonary infection, 8,7% for oncological screening or follow up, 13,7% for COPD disease, 8,7% for screening or active TBC, 3,7% for screening or previous pleuritis and 17,5% for other reasons. A RA-ILD pattern was identified in 35% of patients, with a defined UIP pattern in 17,8%, a defined NSIP pattern in 42,8% and a 39,3% of Un-ILD, while 65% of patients had a non-ILD lung involvement by CT-scan. The mean age at ILD diagnosis was 67,2 years and the mean time between RA diagnosis and onset of ILD symptoms was 7,4 years.
In the multivariate analysis female sex (HR=0,33; p=0,006) and disease duration (HR=0,8; p=0,06) were protective factors for ILD diagnosis. Age (HR=1,1; p=0,03), use of leflunomide (HR=10,1; p=0,03) were negative prognostic factors for ILD. Pulmonary clinical symptoms as dry cough (HR=17,6; p=0,02), bibasilar inspiratory crackles (HR=11,5; p=0,01) and pleural rubs (HR=18,1; p=0,03) predicted ILD while negative predictors were the presence of linear opacities (HR=99,9; p=0,006), interstitial abnormalities (HR=12,1; p=0,07) and cystic areas (HR=33,3; p=0,06) at chest CT scan.
Conclusion: In our cohort the first ILD symptom appeared 7.4 years after RA diagnosis. Clinical variables and radiological abnormalities were identified as highly predictive of ILD diagnosis and may represent red flags for an early diagnosis and referral to pneumologists and radiologists in a multidisciplinary approach.

AB0274 PRESCRIPTION, SWITCH RATE AND THERAPEUTIC RESPONSE DURING BIOLOGIC THERAPY IN INFLAMMATORY RHEUMATIC DISEASES: AN OBSERVATIONAL STUDY IN SOUTHERN MOROCCO

H. Tebaa[1], F. Idrissi Zaki[1], H. Arabi[1], A. Mougui[1], I. El Bouchti[1]. *[1]CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rhumatology, Marrakech, Morocco*

Background: The use of biological treatment has improved the prognosis of patients with rheumatic diseases. It is important to know the different effects leading to switch in order to adapt the prescription to the patients' profile.
Objectives: To study the prescription profile of biological agents (bDMARD) during chronic inflammatory rheumatic diseases, their impact on disease activity, frequency and causes of switch.
Methods: This is a retrospective study including 106 patients followed for chronic inflammatory rheumatism treated by biological agents.
Results: We included 106 patients, sex ratio (0.44), mean age was 41.5 (±12 .97). 64.4% were followed for spondyloarthritis (41 cases of ankylosing spondylitis, 10 cases of psoriatic arthritis, 11 cases of spondyloarthritis and chronic inflammatory bowel disease). 35.6% of the cases had rheumatoid arthritis, Seropositive in 32%, associated with (Sjorgen's syndrome in 7.5% of cases, lupus in 1.9% of cases, vasculitis in 2% of cases). The mean time between diagnosis and initiation of biotherapy was 54 months (±57.34). The first biologic prescribed for rheumatoid arthritis was Rituximab (94%), Infliximab was the first choice for spondyloarthritis (71%). Conventional treatment was combined with biotherapy in 79% versus 21% just treated by a biological treatment, the switch rate was high in the in the group receiving monotherapy with a significant difference (P=0.024). The initial mean DAS-28 and BASDAI were 4.01 (±2.12) and 4.76 (±2.2) respectively, versus 2.45 (±1.98) and 3.78 (±2.01) after initiation of biologic therapy (P=0.0082). The first cause of switch was therapeutic escape in (82.36%), followed by ineffectiveness in (11.76%) and a paradoxical reaction such as skin psoriasis in (5.85%). Switching was made to an Anti TNF alpha in 14 patients and to another therapeutic class in 3 patients.
Conclusion: Regular monitoring of the efficacy and tolerance of biological treatment is an integral part of the management of chronic inflammatory rheumatism.

AB0275 THE FREQUENCY, PREVALENCE OF CORONARY ARTERY DISEASE AND PRE-MATURE CAD IN PSA AND RA PATIENTS

G. Ayan[1], G. Sandal Uzun[1], O. D. Tatar[1,2], N. E. Gezerer[2], E. Bilgin[1], G. K. Yardımcı[1], E. C. Bolek[1], B. Farisogullari[1], E. Duran[1], Z. Özsoy[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdogan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. *[1]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; [2]Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey*

Background: An increased incidence of coronary artery disease (CAD) is known in inflammatory arthritis patients compared to the normal population. In the Veterans With Premature Atherosclerosis (VITAL) registry, the frequency of premature CAD (CAD < 55 in men, < 65 years in women) in autoimmune rheumatic diseases was 1.72 (95% CI 1.63-1.81) in Rheumatoid arthritis (RA) compared to the healthy population in approximately 135,000 patients, while a similar situation was not observed in Psoriatic arthritis (PsA) patients 1.09 (95%CI 0.98-1.21) (1).
Objectives: In this study, we aimed to compare the frequency of CAD and premature CAD in RA and PsA patients using bDMARDs.
Methods: The Hacettepe University biological database (HUR-BIO), database was established in 2005 and prospective follow-up of patients using bDMARDs is being carried out. The frequency of CAD was recorded in 486 PsA and 524 RA patients using bDMARDs. CAD was determined according to the angiography reports or Coronary Computed-Tomography results. Premature CAD is defined as a history of CAD before the age of 55 in men and before the age of 65 in women. Demographic characteristics and other comorbid conditions of the patients were also noted. Disease activity (DAS-28) and functional status (HAQ-DI) of the patients before the first DMARD initiation were recorded.
Results: 581 (75.4% female) RA and 520 (69.4% female) PsA patients were evaluated. The ages of the patients and the duration of the disease are as follows; RA, mean (SD) years of age 52.1 (13.9), disease duration 5.3 (2.1) years, PsA mean (SD) years of age 48.7 (12.5), disease duration 9.2 (6.4). At the time of first bDMARD initiation, 43/581 (7.4%) patients with RA and 12/486 (2.4%) patients with PsA had CAD (p<<0.001). After a median (IQR) follow-up of 32 (23) months in RA patients and 49 (88.5) months in PsA patients, CAD was detected in 59 (11.2%) patients, 32 (6.6%) in PsA patients, p=0.01. While 39/59 (66.1%)

Table 1. Characteristics of RA and PsA patients with/without premature CAD

	RA			PsA		
	Premature CAD n=38	Non-premature CAD n=21	p	Premature CAD n=18	Non-premature CAD (n=14)	p
Gender, n (%)	29 (76.3)	9 (42.8)	0.01	10 (55.5)	10 (71.4)	0.36
Age, mean (SD), years	56.6 (8.9)	72.7 (7.1)	<0.001	59.9 (8.2)	69.1 (6.3)	0.002
PsA duration, mean (SD), years	5.5 (2.1)	6.0 (1.7)	0.34	13.3 (8.9)	12.6 (9.5)	0.83
Smoking (ever), n(%)	22 (57.9)	11 (52.4)	0.80	16 (88.9)	5 (35.7)	0.002
BMI > 30, n(%)	19 (52.3)	7 (35.0)	0.20	8 (44.4)	11 (78.5)	0.051
HT (ever), n(%)	23 (63.9)	14 (66.7)	0.89	11 (61.1)	13 (92.8)	0.040
DM (ever), n(%)	20 (57.1)	9 (52.9)	0.77	4 (22.2)	6 (42.8)	0.45
LDL > 130 (ever), n(%)	29	12	0.13	11 (61.1)	5 (35.7)	0.14
DAS-28	4.7 (1.1)	4.2 (1.2)	0.11	4.7 (1.4)	4.5 (1.5)	0.72
HAQ (0-3)	1.41 (0.7)	1.05 (0.8)	0.079	0.7 (0.6)	1. 3 (0.7)	0.13

RA: Rheumatoid arthritis, PsA: Psoriatic arthritis, CAD; Coronary artery disease, BMI; Body-mass index, HT: Hypertension, DM: Diabetes mellitus

of RA patients had premature CAD, 18/32 (56.3%) PsA patients had premature CAD (Table 1).

Conclusion: While the frequency of premature CAD is 10% in the normal population, CAD has a premature character in two-thirds of RA patients and 55% of PsA patients (2). In a large community-based study, the frequency of premature CAD was found to be increased in RA patients compared to the normal population, but no similar difference was observed in PsA patients (1). In real-life data in which we examined a large group of patients using bDMARDs, it is seen that the subtype of CAD is of pre-mature character in both RA patients and PsA patients.

AB0276

COMPARISON OF METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE WITH NON-ALCOHOLIC FATTY LIVER DISEASE IN IDENTIFYING CARDIOVASCULAR RISK IN CHINESE INDIVIDUALS WITH RHEUMATOID ARTHRITIS

Y. W. Zou[1], Q. H. Li[1], J. W. Gao[2], J. Pan[1], J. D. Ma[1], L. F. Chen[1], J. Lin[1], Y. Mo[1], X. Zhang[1], P. M. Liu[2], L. Dai[1]. *[1]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Department of Rheumatology, Guangzhou, China; [2]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Department of Cardiology, Guangzhou, China*

Background: The nomenclature from non-alcoholic fatty liver disease (NAFLD) to metabolic dysfunction-associated fatty liver disease (MAFLD) is considered to identify more cardiovascular disease (CVD) risk in general population, and patients with rheumatoid arthritis (RA) carry an excess risk for CVD.

Objectives: To compare MAFLD with NAFLD in identifying CVD risk in RA patients.

Methods: Clinical data from a Chinese RA cohort were retrospectively analyzed. Hepatic steatosis was defined by abdominal ultrasound examination. CVD risk in RA patients was estimated by the Prediction for Atherosclerotic Cardiovascular Disease Risk in China.

Results: Among 513 included RA patients, 78.4% were female and the mean ± SD age was 51.8 ± 12.6 years. The prevalence of MAFLD and NAFLD was 21.4% and 20.5%, respectively. 10.9% RA patients concomitated with CVD events and 32.4% had a high 10-year CVD risk. Multivariate logistic regression analysis showed that both MAFLD and NAFLD were associated with an increase in CVD events (MAFLD: AOR = 2.303 [95% CI 1.197, 4.429]; NAFLD: AOR = 2.478 [95% CI 1.185, 4.779] and high 10-year CVD risk (MAFLD: AOR = 3.184 [95% CI 1.777, 5.705]; NAFLD: AOR = 2.870 [95% CI 1.597, 5.156]; all p < 0.05). The NRI and IDI was -0.011 (95% CI -0.025, 0.003) and -0.002 (95% CI -0.007, 0.002) for CVD events, and 0.012 (95% CI -0.014, 0.038) and 0.005 (95% CI -0.003, 0.013; all p > 0.05) for high 10-year CVD risk, which indicated no additional CVD events and high 10-years CVD risk were identified when replacing NAFLD with MAFLD in RA patients.

Conclusion: Both MAFLD and NAFLD are associated with an increased CVD risk which implies the importance of early detection and management of MAFLD or NAFLD in RA patients. However, new nomenclature of MAFLD identify no additional CVD risk in RA patients.

AB0277

DYSLIPIDEMIA TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS USING BDMARDS IS BETTER THAN PSA, BUT THERE IS STILL A WAY TO GO

G. Sandal Uzun[1], O. D. Tatar[1], N. E. Gezerer[1], E. Bilgin[1], G. K. Yardımcı[1], E. C. Bolek[1], B. Farisogullari[1], E. Duran[1], Z. Özsoy[1], G. Ayan[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], U. Kalyoncu[1], A. İ. Ertenli[1]. *[1]Ankara, Hacettepe University, Faculty of Medicine; Division of Rheumatology, Department of Internal Medicine; Hacettepe University Medical Faculty Department of Internal Medicine Division of Rheumatology, Çankaya, Turkey*

Background: Patients with inflammatory arthritis have an increased risk of cardiovascular disease. Dyslipidemia is one of the primary modifiable risk factors.

Objectives: Comparasion of the frequency of dyslipidemia and the use of anti-hyperlipidemic agents in patients with Rheumatoid Arthritis (RA) and Psoriatic arthritis (PsA) receiving bDMARDs.

Methods: The Hacettepe University biological database (HUR-BIO), was established in 2005 and 581 (75.4% female) patients with RA and 520 (69.4% female) patients with PsA enrolled up to 2021 were analyzed. Dyslipidemia was defined according to the Turkish Endocrine and Metabolism society criteria (TC > 240, Triglycerides (Tg) > 150, LDL-C > 160, HDL-C (< 40 in men, < 50 in women) (1). The anti-hyperlipidemic (anti-HL) agents used by the patients during follow-up and at their last visit were recorded.

Results: The mean (SD) age of the patients and diseases duration were as follows; RA vs. PsA [age: 52.1 (13.9) vs. 48.7 (12.5) years; disease duration: 5.3 (2.1) vs. 9.2 (6.4) years]. Lipid profiles were known in 289 (49.7%) patients with RA and in 175 (33.6%) patients with PsA at the initiaiton of bDMARD. Lipid profiles were evaluated in 356 (61.2%) patients with RA and 226 (43.4%) patients with PsA during follow-up and at the last visit. Lipid profiles were similar in patients with RA and PsA at the initiation of bDMARDs (Table 1). At the initiation of bDMARD, 29 (5.0%) of RA patients and 10 (3.2%) of PsA patients were receiving anti-HL agents. During the entire follow-up, 65 (12.6%) patients with RA and 22 (4.8%) patients with PsA have used anti-HL agents (p<0.001).

Table 1. Lipid values in patients with RA and PsA at the initiation of bDMARD and at the last visit

	Rheumatoid arthritis, n (%)		Psoriatic arthritis, n (%)		p1*	p2**
Lipid values	bDMARD initiation	Last visit	bDMARD initiation	Last visit		
Total Cholesterol > 240	47/270 (17.4)	98/339 (28.9)	32/161 (19.8)	57/203 (28.1)	0.30	0.13
Triglyseride > 150	62/242 (25.6)	108/320 (33.7)	45/159 (28.3)	80/193 (41.4)	0.79	0.20
HDL-C < 40 (males), < 50 (females)	88/267 (32.9)	70/343 (20.4)	57/157 (36.3)	20/207 (9.6)	0.48	0.001
LDL-C > 160	53/289 (18.3)	91/356 (25.6)	43/175 (24.5)	65/226 (28.7)	0.38	0.55

*p1, bDMARD initiation visit comparison **p2, last visit comparison

Conclusion: In real-life cohort, lipid profile was not assesed in half of the patients during entire follow-up. Although, LDL-C levels are high in about a quarter of the patients in both groups, use of anti-hyperlipidemic drug was inadequate. This is even more evident in PsA patients. Despite the significant emphasis on comorbidities in treatment guidelines, there is still a long way to go in real life.

AB0278 IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING BDMARDS, THE CHARLSON COMORBIDITY INDEX IS MORE PRONOUNCED THAN PSORIATIC ARTHRITIS

G. Sandal Uzun[1], O. D. Tatar[1], N. E. Gezerer[1], E. Bilgin[1], G. K. Yardımcı[1], E. C. Bolek[1], B. Farisogullari[1], E. Duran[1], Z. Özsoy[1], G. Ayan[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], U. Kalyoncu[1], O. Karadag[1], A. Akdoğan[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1]. *[1]Ankara, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey*

Background: According to international recommendations, co-morbidities must be taken into account in the management of patients with inflammatory arthritis.

Objectives: To evaluate the distribution of pre-treatment comorbidities in the bDMARD cohort including patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA).

Methods: The Hacettepe University biological database (HUR-BIO) was established in 2005, 581(75.4% female) patients with RA and 520 (69.4%female) patients with PsA enrolled up to 2021 were analyzed. Diagnosis of RA and PsA were based on the clinical evaluation of the rheumatologist who followed the patients. Comorbidities of the patients were reviewed retrospectively from the biological database, hospital electronic records, ICD-10 diagnostic codes and prescriptions of patients. Diabetes mellitus (DM), Hypertension (HT), Dyslipidemia (DL), Coronary artery disease (CAD), Body mass index (BMI) and smoking were recorded. DL was grouped in terms of lipid values according to the classification of the Turkish Society of Endocrinology and Metabolism Dyslipidemia Guide(1). Detection of coronary artery disease before the age of 55 in men and of 65 in women was classified as premature - CAD. Data on Chronic Kidney Disease, obstructive pulmonary disease, Cerebro-vascular disease, Thyroid Diseases were also recorded. The Charlson comorbidity index (CCI) was calculated by summing the comorbidities in the patients' medical history before the bDMARDs.

Results: The distribution of comorbidities in patients with RA and PsA prior to initiation of bDMARDs was given in Table 1. Patients with RA were older and smoking was more common. HT(28.5% for RA, 21.9% for PsA) and thyroid diseases (22.7% for RA, 14.7% for PsA) were the most comorbidities in both groups. Compared to PsA, patients with RA had higher rate of comorbidities (64.8% vs. 40.4%, p<0.001). Multimorbidity was detected in 231/581 (39.7%) of patients with RA, and it is significantly more common than the patients with PsA (21.8%) (p<0.001). There was no difference between the groups in terms of cardiovascular comorbidities such as BMI, DM, and dyslipidemia. When adjusted for age, the comorbidity burden according to CCI was 3.96 (2.57-6.13, p<0.001) times higher in patients with RA than in patients with PsA.

Table 1. Comorbidities in RA and PsA patients

Features	RA n=581	PsA n=520	p
Gender, female n (%)	438 (75.4)	361 (69.4)	0.027

*TC > 240, TG 150-499, LDL-C> 160, HDL-C erkek < 40, kadın < 50CCI: Charlson comorbidity index, CAD: Coronary artery disease, CKD: Chronic Kidney Disease, COPD: Chronic Obstructive pulmonary disease

Conclusion: The burden of comorbidities in patients with RA before bDMARDs is more pronounced than in patients with PsA. Although, cardiovascular risk factors were similar, with the exception of hypertension and smoking, the age-adjusted CCI was 3.96 times higher in patients with RA than in patients with PsA.

Background: Patients with Rheumatoid arthritis (RA) have an increased risk of infections due to the disease itself, and/or immunosuppressive therapy. The risk of herpes zoster (HZ) including disseminated HZ is also increased**(1)**

Objectives: In an unselected series of RA patientswe assess**a)**prevalence, **b)**general features and **c)** predictive factors of HZ.

Methods: Study of 393 RA patients included in the prospective vaccination program of the Preventive Medicine and Rheumatology department of a University hospital, from October 2011 to October 2016. The minimum follow-up was of 12 months; therefore, it was made until December 2020. HZ vaccination is not included in our vaccination program.

RA was diagnosed according to the ACR/EULAR 2010 criteria. HZ was diagnosed if presented: characteristic skin rash and blisters, paresthesia and local pain, in one (localized) or more dermatomes (generalized).

Information on patients and HZ characteristics was retrieved from the hospital and general physician records.

Results: We studied 393 patients (310 women), mean age 61.5±11.9 years. They were followed-up during a mean period of 82.6±15.2 months(range; 50 months-9 years).

HZ infection was observed in 31 of 393 patients (7.9%) (26 women); mean age 67.5±11.6ys. Prevalence of HZ in this period (122months) was 7.88% with an annual incidence rate of 0.73/100 patients/year. A comparison between patients with and without HZ was performed (Table 1**).**

HZ locations were intercostal (n=6), dorsal (5), abdominal (3), lumbar (3), facial (3), cervical (1), gluteus (1), submmamary fold (1), intermmamary fold (1) and upper extremity (1). Main HZ complications were post-herpetic neuralgia (n=7), visual alteration in facial HZ (n=1) and disseminated HZ(n=1).

HZ treatment was anitiviral agents (n=23) (brivudine=7; acyclovir 6; famciclovir6; valaciclovir4), topic (n=2) and none (n=6).

Predictive factors for HZ(Figure 1) were older age (>65 years), hypertension and treatment with high prednisone dose and antiTNF.

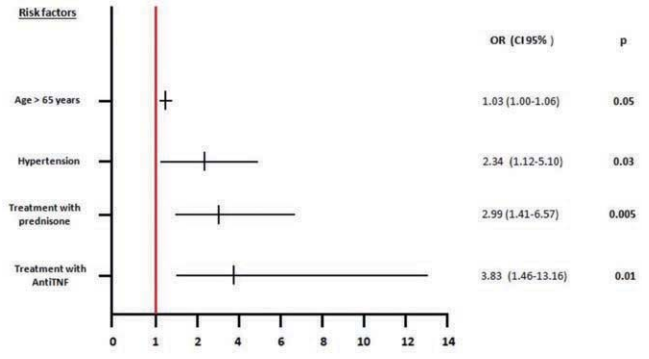

Figure 1. Predictive factors for Herpes zoster

Conclusion: HZ is a relative frequent complication of RA. In our series, although are usually localized, post-herpetic neuralgia is relatively frequent. Probably to include HZ vaccine in our vaccination program of RA may be useful.

AB0280

SERIOUS INFECTIONS-RELATED HOSPITALIZATION IN RHEUMATOID ARTHRITIS. OBSERVATIONAL STUDY OF 392 PATIENTS FROM A SINGLE UNIVERSITY CENTER

L. C. Domínguez-Casas[1], P. Rodriguez Cundin[2], T. Dierssen-Sotos[3], N. Vegas-Revenga[1], A. Corrales[1], M. A. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain; [2]Hospital Universitario Marqués de Valdecilla, Preventive Medicine, Santander, Spain; [3]Universidad de Cantabria, Universidad de Cantabria, Santander, Spain*

Background: Patients with Rheumatoid Arthritis (RA) have an increased risk of infections. This may belinked to disease-related, the immunosuppressive therapy and the co-morbidities.

Objectives: in an unselected group of RA patients, our aim was to assess the **a)**incidence **b)**features of disease and **c)**predictive factors of serious infections-related hospitalization.

Methods: Observational study of all patients diagnosed with RA that were included in the vaccination program of our university hospital between October2011 and October 2016.The minimum follow-up was of 12 months; therefore, it was made until December 2020.

Patients with serious infections-related hospitalization were **a)** compared with those not requiring hospital admission and, **b)**identified predictive factors (multivariate analysis adjusted by age and sex).

Vaccination program in our hospital includes vaccination for Influenza, Streptococcus pneumoniae and Haemophilus influenzae.

Information on patients, infections and hospitalizations was retrieved from the hospital and general physician records.

Table 1. Comparative study of different groups

	Patientswithserious infections-related hospitalization N=88	Patients without serious infections-related hospitalization N=304	p
Demographic features and comorbidities			
Age (years),mean±SD	69.7±11.2	59.2±12.6	0.005
Women, n (%)	60 (68.2)	249 (81.9)	0.33
Active smokers, n (%)	41 (46.6)	114 (7.5)	0.32
Hypertension, n (%)	56 (63.6)	109 (35.8)	0.004
Hypercholesterolemia, n(%)	47 (53.4)	101 (33.2)	0.02
Diebetes Mellitus, n(%)	25 (28.4)	30 (9.9)	0.0002
RA features			
Duration of RA (months) mean±SD	165.8±130.1	128.6±102.6	0.005
Positive RF, n (%)	52(59.1)	171(56.2)	0.80
Positive ACPA, n (%)	48 (54.5)	158 (52.6)	0.81
Erosive disease, n (%)	32 (36.4)	113 (51.9)	0.89
Associated Sjögren Syndrome, n (%)	4 (4.5)	16 (5.3)	0.79
Interstitial lung disease n (%)	11 (12.5)	9 (2.9)	0.0008
Subcutaneousnodules n (%)	6 (6.8)	16 (5.3)	0.57
Prednisone (or equivalent) dose mg/day, mean±SD	5.3±4.5	3.3±3.8	0.001
Number of convencional DMARDs, mean±SD	1.9±1.4	1.5±1.3	0.05
Number of biologic DMARDs, mean±SD	0.1±0.2	0.1±0.4	0.03
Number of JAK inhibitors, mean±SD	69.7±11.2	59.2±12.6	0.1

Results: We studied 392RApatients (309women/83men); mean age 63.1±13.7 years. After a mean follow-up of 71.8±20.6 months, in 88 of 392patients (22.4%) (60 women) 187serious infections-related hospitalizations were required. The median [IQR] number of hospitalizations were 1.5 [1-2]. The main serious infections were respiratory (44 patients; 78 hospitalizations), urinary (33 patients; 48 hospitalization), cutaneous (19 patients; 28 hospitalizations), abdominal (17 patients, 20 hospitalizations), septic arthritis (7 patients; 8 hospitalizations), maxillofacial(2 patients, 2 hospitalizations), bacterial endocarditis (2 patients, 2 hospitalizations) and genital (1 patient, 1 hospitalization).
Patients with serious infections-related hospitalization were older, with a longer RA, with more co-morbidities (hypertension, hypercholesterolemia diabetes mellitus, and Interstitial lung disease) and with more conventional and biological DMARDS (Table 1).
The predictive factors for hospitalization were hypertension and Diabetes Mellitus, RA related interstitial lung disease and treatment with biologic DMARDs. (Figure 1)

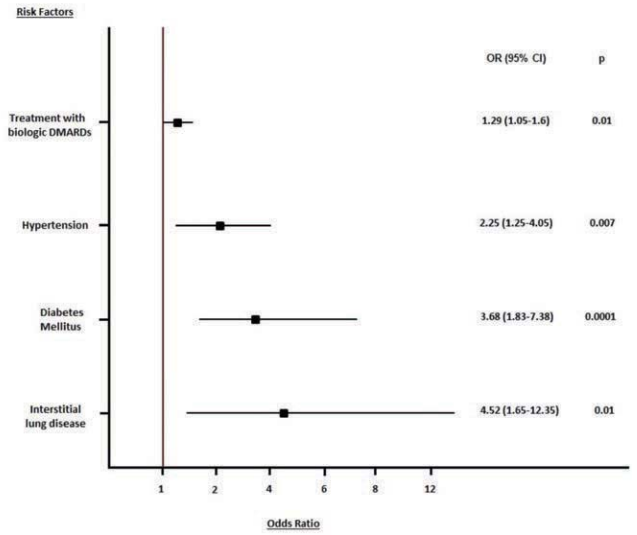

Figure 1. Predictive factors for serious infections-related hospitalization

Conclusion: Despite to be included in a vaccination program up to 22% of patients required hospitalization due to serious infection. The main predictive factors were co-morbidities, interstitial lung disease and treatment with biologic DMARDs. Serious infections in RA remain to be an unmet need.

AB0281 THE 2016 REVISED ACR FIBROMYALGIA CRITERIA IDENTIFY A HIGHER PREVALENCE OF FIBROMYALGIA IN RHEUMATOID ARTHRITIS PATIENTS: A CROSS-SECTIONAL STUDY FROM INDIA.

D. Malgutte[1], S. Upadhyaya[1], R. Handa[1], S. J. Gupta[1], S. Budmuru[1].
[1]*Indraprastha Apollo Hospitals, Rheumatology, New Delhi, India*

Background: Fibromyalgia (FM) prevalence in rheumatoid arthritis (RA) is reported around 5-50% as per older American College of Rheumatology (ACR) FM Criteria, while in India reported around 15% (1). The Revised 2016 ACR FM criteria has greater sensitivity and specificity of 94% and 91% respectively compared to older criteria (2). To best of our knowledge, no study has evaluated presence of FM in RA as per revised 2016 ACR FM criteria.
Objectives: 1) To study prevalence of FM as per revised 2016 ACR FM criteria in RA patients.
2) To compare Disease activity, Disability status, Quality of life, Anxiety and Depression in RA with and without FM.
Methods: This cross-sectional study included 200 RA patients and equal number of controls. FM was diagnosed using revised 2016 ACR FM Criteria. Disease activity, quality of life and functional disability in RA patients was assessed using disease activity scores (CDAI, SDAI, DAS-28 CRP, WHO-Qol BREF and Health Assessment Questionnaire CRD HAQ-DI). Presence of depression and anxiety was determined using validated Hospital Anxiety and Depression Scale (HADS).
Results: FM was present in 31% and 4% of RA patients and healthy controls respectively in our study using 2016 ACR FM criteria. This is significantly higher compared to the 15% and 2.5% in RA and healthy control populations respectively of the study by Dhir V. et studying a similar population of Indian patients, using 1990 ACR FM criteria. RA patients with FM were older, predominantly females, had longer disease duration, were more on steroids, had higher disease activity and more functional disability. In a multivariable linear regression analysis, FM was important predictor of DAS28 score & CDAI, even after adjusting for other independent variable like disease duration, CRP, SJC, functional disability. RA patients with FM had a poorer quality of life and had higher prevalence of anxiety and depression. No difference was noted in use of disease modifying agents, biological or ts-DMARDs in RA patients with or without FM.

Table 1. Characteristics of RA with FM and RA without FM patients.

	RA without FM (n=138)	RA WITH FM (n=62)	P VALUE
	Mean ± sd	Mean ± sd	
Age, yrs.,	47.17±12.44	51.37±12.33	0.028
Duration of RA	4.1±3.59	6.46±6.09	0.006
TJC, 0-28	4.57±2.86	6.87±3.08	<0.001
SJC,0-28	2.3±2.37	3.37±2.87	0.011
Pain VAS,0-100	36.38±16.16	55.24±11.18	<0.001
ESR	39.01±20.67	46±20.39	0.028
CRP	11.61±11.15	16.43±15.72	0.032
CDAI	14.6±6.69	19.68±6.71	<0.001
SDAI	15.74±7.33	21.34±7.48	<0.001
DAS-28 CRP	4.1±1.1	4.85±0.84	<0.001
PDS,0-31	8.68±3.22	16.27±2.33	<0.001
Physical score*, 0–100	54.83±12.16	34.37±9.41	<0.001
Psychological score, 0–100	59.78±14.34	39.84±12.74	<0.001
Social score, 0–100	60.68±12.75	51.5±12.76	<0.001
Environmental score, 0-100	59.21±11.04	49.35±9.73	<0.001
CRD HAQ-DI	1.04±0.64	1.8±1.03	<0.001
Anxiety, n (%)	23(17%)	53(85%)	<0.001
Depression, n (%)	44(32%)	59(95%)	<0.001

TJC: tender joint count (28 joints); SJC: swollen joint count (28 joints); CDAI: Clinical disease activity index; SDAI: Simplified disease activity index; DAS 28: disease activity score (28 joints); PDS: Polysymptomatic distress score of fibromyalgia; *Domain scores of quality of life (WHO-Qol BREF).

Conclusion: The prevalence of FM in RA patients is significantly higher with 2016 ACR FM Criteria as compared to older criteria in similar population of RA patients. A significant number of patients had anxiety and depression that needs to be clinically attended. The presence of FM in RA adversely affects the Disease activity, quality of life, functional disability.

AB0282 COMORBIDITIES ARE MORE IMPORTANT THAN JAK INHIBITORS: VENOUS THROMBOEMBOLISM IN RHEUMATOID ARTHRITIS

G. Sandal Uzun[1], M. Bahap[2], O. Yucel[1], Y. Kaygusuz[1], E. Bilgin[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1].
[1]*Ankara, Hacettepe University, Faculty of Medicine; Division of Rheumatology, Department of Internal Medicine; Hacettepe University Medical Faculty Department of Internal Medicine Division of Rheumatology, Ankara, Turkey;*
[2]*Hacettepe Univercity, Faculty of Pharmacy, Department of Clinical Pharmacy, Çankaya, Turkey*

Background: The risk of Venous thromboembolisim (VTE) is increased and is an important cause of mortality and morbidity in rheumatoid arthritis. In addition to the underlying Rheumatoid arthritis(RA), there are a number of predisposing risk factors for VTE(1).
Objectives: In this study, we aimed to evaluate the demographic and clinical features of rheumatoid arthritis patients with VTE.
Methods: Patients who were refered to Hacettepe University Medical Rheumatology department from January 2021 to December 2021 retrospectively analyzed. A total 981 RA patients were detected according to the ICD code(M05, M06, MO07). RA diagnosis was confirmed in 400 patients according to 2010 ACR/EULAR criteria. Venous thrombosis was confirmed by ICD code(I26,I74,I82), computed torax tomography, lower extremity venous doppler and medical treatment report in these 400 patients with RA. Thromboembolism was detected in 58 patients during follow-up. The patients' clinical characteristics, serological features, co-morbidities, and treatment were systematically analysed.

Results: VTE was diagnosed in 58 patients with RA. Of these patients, 84,5% was female and mean (SD) age was 67.5 ± 11,1 years. The majority of patients had deep venous thrombosis (53.4%). Rate of rheumatoid factor and/or anti-cyclic citrullinated peptid positivity was 72.5% and ANA positivity was 68% respectively. Distribution of cDMARDs and bDMARDs before VTE was as follows: methotrexate 18 (45%), leflunomide (35%), sulfasalazine (22.5%), hydroxychloroquine (47.5%), steroid (47.5%), biological agents (22.5%). Comorbidities were common and The Charlson Comorbidity Index score was ≥3 in 89.6% of patients with VTE. VTE frequency of patients in the last 1 year was %1.27.

Conclusion: All RA patients with VTE had at least one comorbidity and 89% of patients had multi-morbidities. RA patients with multimorbidity may have an increasded risk of VTE. In the management of RA, comorbidities should be taken into account.

AB0283 FATIGUE AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS. A RESIDUAL FATIGUE OF HIGH LEVEL CAN BE OBSERVED EVEN IN LOW DISEASE ACTIVITY.

R. Morlà[1], B. Frade-Sosa[1], N. Sapena[1], J. A. Gómez-Puerta[1], R. Sanmartí[1]. [1]*Hospital Clinic de Barcelona, Rhematology, Barcelona, Spain*

Background: Fatigue is a major symptom suffered by patients with rheumatoid arthritis (RA), with a high prevalence (40%-70%)[1]. Different questionnaires and scales (BRAF, FACIT, SF36v, MDHAQ, VAS...) have been validated, but none have been standardized to measure it. In observational studies, the VAS (0-10) scale was reported as a good measure for fatigue; cut-off>5/10 indicates high level[2]. A residual fatigue in low activity/remission of the disease has been described in a significant proportion of patients[3].

Objectives: We studied the association with high level of fatigue and the clinical disease activity in non-selected RA patients.

Methods: RA patients (ACR/EULAR criteria, 2010) were included consecutively in our Arthritis Unit during a period of 3 months. Patients completed 2-pages MDHAQ that includes a VAS 0-10 for fatigue at question 9, in addition to other queries: physical function (FN) + pain (PN) + patient global assessment (PATGL), checklist of 60 symptoms (ROS60) and self-assessment 48 joint count (RADAI48). VAS for Fatigue was calculated with a cut-off point ≥5/10 to obtain the group with high fatigue. Demographic variables (age, sex, BMI) and clinical variables: disease duration, treatment with bDMARDs and glucocorticoids, joint physical examination (TJC 0-28, SJC 0-28), acute phase reactants (ESR, CRP), physician global assessment (PhyGL), and the rates of clinical activity with their respective clinically significant differences (DAS28-ESR>0.6; SDAI>10; RAPID3>3.8) were also calculated.

A descriptive analysis (mean and SD) of all the variables, a bivariate analysis to compare groups (Student t for quantitative and Chi^2 tests for categorical variables) and calculation of numerical differences between indices was performed.

Results: A total of 75 RA patients (84% females) were recruited, of mean age of 62 (SD:11.6) years, with media BMI of 22.8 (SD:8.0), mean disease duration of 14.6 (± 5) years, 16% depressed (PHQ9≥10), treated with bDMARD (64%) and glucocorticoids (45,3%). Means of disease clinical indexes were as follows: DAS28-ESR (2.55, SD:1.21), SDAI (8.7, SD:8.00) and RAPID3 (5.97, SD:5.85).

In 31 (41.2%) of patients we observed high fatigue (VAS-fatigue≥5/10). When comparing with those with low or no fatigue levels, these patients have higher disease activity measured by the composite activity indices and acute phase reactants except for the SJC. All self-reported variables evaluated by MDHAQ (FN, PN, RADAI48, ROS60) were also higher in patients with high fatigue levels (Table 1).

Table 1. Descriptive and comparison variables between groups, expressed as mean and SD.

	All patients, n=75	Non-high fatigue group, n=44 (58.6%)	High fatigue group, n=31 (41.3%)	p value

PN (0-10)	3,56 (3,12)	1,90 (2,28)	5,30 (2,98)	<0.001
PATGL (0-10)	3,27 (2,86)	2,07 (2,24)	5,18 (2,77)	0.001
RADAI48 (0-48)	7,85 (8,81)	4,14 (5,50)	12,87 (9,99)	<0.001
ROS60 (0-60)	10,06 (8,84)	5,78(5,03)	15,71 (9,64)	<0.001
PhyGL (0-10)	2,43 (1,94)	1,90 (1,47)	3, 18 (3,27)	0.004
DAS28-ESR	2,55 (1,21)	2,13 (0,97)	3,15 (1,27)	0.001
SDAI	8,7 (8,0)	6,18 (4,80)	12,33 (10,01)	0.001
RAPID3 (0-30)	5,97 (5,85)	3,08 (3,48)	10,29(0,06)	<0.001

The mean differences in the three activity indices between both groups were statistically significant, in the DAS28-ESR and RAPID3 were also considered clinically relevant: 1.02 (>0.6) and 7.2 (>3.8) respectively, but not for SDAI: 6.15 (>10).

Conclusion: Even non-selected RA patients but with low disease activity, high fatigue level was common. For a better approach to fatigue in RA patients, it would be interesting not to forget this residual fatigue.

AB0284 COGNITIVE AND DEPRESSIVE DISORDERS IN PATIENTS WITH RA, THEIR CONNECTION WITH THE LEVEL OF BRAIN - DERIVED NEUROTROPHIC FACTOR

L. Perebetiuk[1], I. Shapoval[1], V. Khomenko[1], O. Ostapchuk[1], L. Shvets[1], M. Stanislavchuk[1]. [1]*National Pirogov Memorial Medical University, Vinnytsya, Department of Internal Medicine #1, Vinnytsya, Ukraine*

Background: Rheumatoid arthritis (RA) is a common pathology among other rheumatic diseases. Chronic inflammation, prolonged pain, early disability of

patients - all these factors contribute to the development of depressive and cognitive disorders in this category of patients. Still, the mechanisms of these disorders remain poorly understood. Recently, the role of brain-derived neurotrophic factor (BDNF) as one of the factors of cognitive and depressive disorders in various pathological conditions has been widely discussed in the literature.

Objectives: To study cognitive and depressive disorders in RA patients and their association with serum BDNF levels.

Methods: 79 women with RA, aged 21 to 74 years, on average (M ± SD) 48.7 ± 10.2 were examined. Diagnosis RA was established according to EULAR / ACR criteria (2010). Patients' cognitive function was assessed by the MMSE (Mini Mental State Examination). The presence and severity of depression were determined by the QIDS-SR16 (Quick Inventory of Depressive Symptomatology Self-Report). Serum BDNF was detected by enzyme-linked immunosorbent assay (ELISA) using standard BDNF Quantikine ELISA kits (R&B Systems, USA). The control group consisted of 30 age matched healthy women.

Results: It was found that the level of BDNF in the serum of women with RA was 1.5 times higher than in healthy individuals and was 16.8 ± 10.8 ng/ml and 11.32 ± 4.89 ng/ml, respectively. Cognitive disorders (MMSE <28 points) were registered in the majority (78.5%) of patients with RA, while in the control group, there were only 10%. The mean MMSE values in RA patients and the control group were 27.2 ± 1.45 and 29.1 ± 0.99, respectively. Depressive disorders (QIDS-SR16 ≥ 6 points) were reported in 53% of patients, while in the control group, it was 3.3%. It was found that depressive disorders in RA patients were associated with BDNF levels ($r = 0.208$; $p<0.05$) and age ($r = 0.159$; $p<0.05$). There was no significant association between BDNF levels and MMSE in RA patients. In the control group it was found negative correlation (-0.257; $p <0.05$). We found also close negative correlation between MMSE and age in patients with RA ($r = -0.689$; $p<0.001$). A significant relation with age was also registered in the healthy group ($r = -0.257$; $p<0.05$).

Conclusion: Patients with RA had an increased level of BDNF compared with the control group. Most of them had cognitive and depressive disorders. Depressive disorders in RA patients are associated with higher levels of BDNF in the blood and with age. No association of cognitive impairment with BDNF has been established in patients. Cognitive disorders in RA patients are most closely associated with age. Moderate association between MMSE and BDNF levels was established in control group.

AB0285 MTX REDUCED THE CARDIOVASCULAR RISK IN RHEUMATIC DISEASES

H. Ferjani[1], M. Abbes[1], H. Riahi[2], E. Labbene[2], W. Triki[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], M. Bouaziz[2], W. Hamdi[1]. *[1]Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia; [2]Kassab Institute of Orthopedics, Radiology, Tunis, Tunisia*

Background: The relationship between cardiovascular risk (CVR) and inflammatory rheumatic diseases (IRD) remains certain [1].

The aggressive suppression of systemic inflammation by the CsDMARDs or biologics may lower this risk.

Objectives: The purpose of this study was to assess the protective role of the different treatments in rheumatoid arthritis (RA) and spondyloarthritis (SpA).

Methods: We carried out 107 patients followed up for IRD between March and December 2020. We collected the socio-demographic data of patients, the clinical and biological characteristics of the disease. Prescribed treatments were specified.

CVR was assessed by measuring, in centimeters, the Intima-media Thickness (IMT) at the level of the left (LCC) and right (RCC) common carotid arteries and by calculating the Framingham risk score (FRS) for each patient. Individuals with IMT≥0.9 mm or an FRS≥20% were considered as those with high CVR (HCVR).

Results: Of the 107 surveyed patients, 56% had RA (n=47) and 44% had SpA (n=60). Among them, 55% were male. The mean age was 43.9±14.2 years. The mean disease duration was 117.3±89 months. The mean BASDAI was 4.98 ±2.7. The mean DAS28 was 4.13±1.5. Seventy percent of patients had active disease. Conventional DMARDs were prescribed in 54.7% of cases: Methotrexate (95% in RA versus 5% in SpA) and Sulfasalazine (13% in RA versus 30% in SpA), NSAIDs in 57.3% of patients (4.5% in RA versus 96.6% in SpA), corticosteroids (CT) in 25% (47.5% in RA versus 8.5% in SpA), and biotherapy in 9% of cases (12.8% in RA versus 6.7% in SpA).

The mean FRS was 5.98 ± 6.6. The mean IMT was 0.58±0.15. About 60% of patients were considered with HCVR.

NSAIDs were associated with an increase in IMT in the LCC ($p<0.001$) and in the RCC ($p<0.001$). MTX had a significant protective effect on IMT in LCC ($p=0.001$). However, there was no association between CT use and IMT. Regarding FCS, no significant association was found based on MTX ($p=0.09$), NSAIDs ($p=0.11$), CT ($p=0.45$) nor biologic use ($p= 0.74$).

Conclusion: In our study, patients taking MTX had a lower IMT than those not taking this molecule. NSAIDs were associated with an increase in IMT. However, we didn't observe any effect of CT and biologic treatment on CVR in our population.

AB0286 BENEFICIAL EFFECT OF OLIVES AND OLIVE OIL CONSUMPTION ON RHEUMATOID ARTHRITIS DISEASE ACTIVITY

F. Ingegnoli[1,2], R. De Vito[3], R. Caporali[1,2], M. Parpinel[4], G. Grosso[5], M. Ferraroni[6], V. Edefonti[6]on behalf of RANDIE study group. *[1]Università degli Studi di Milano, Dept. of Clinical Sciences & Community Health, Milano, Italy; [2]ASST Gaetano Pini-CTO, Dept. of Rheumatology, Milano, Italy; [3]Brown University, Dept. of Biostatistics, Providence, Rhode Island, United States of America; [4]University of Udine, Dept. of Medicine, Udine, Italy; [5]University of Catania, Dept. of Biomedical and Biotechnological Sciences, Catania, Italy; [6]Università degli Studi di Milano, Dept. of Clinical Sciences & Community Health, Branch of Medical Statistics, Biometry, and Epidemiology G. A. Maccacaro, Milano, Italy*

Background: The main goal for the management of rheumatoid arthritis (RA) is to control symptoms to reach clinical remission or low disease activity as the best possible alternative [1]. Although the number of available therapeutic options, a substantial proportion of patients remain symptomatic. Recent EULAR recommendations [2] shift focus to lifestyle interventions whose concurrent approach could help in controlling potential inflammatory triggers. In this context, olives and olive oil have beneficial properties on health mainly attributed to their high monounsaturated fatty acid content, and to the presence of phenolic compounds. To our knowledge, very few studies addressed the anti-inflammatory effects related to olives and olive oil consumption on RA disease activity.

Objectives: To study the attitude of consumption of olives and olive oil in RA patients from northern Italy, and to assess the effect on disease activity.

Methods: In this observational cross-sectional study, all consecutive adult RA with disease duration ≥ 3 months were enrolled. Disease Activity Score on 28 joints (DAS28-CRP), Simple Disease Activity Index (SDAI) were recorded. Dietary habits in the previous six months were collected with a with a 110-item food frequency questionnaire. In this analysis, we focus on olive oil consumption with original response categories ranging from "never" to "more than 2 times per day" (in spoon units). We created a food group composed by olive oil, black and green olives (frequencies/day). Olive oil consumption was entered as the independent variable into multiple regression models. When disease activity was entered in continuous in the regression models, we estimated the effect on a 1-point increment/decrease in RA disease activity. When disease activity was modeled as a dichotomous variable, we estimated the odds ratios (ORs) of disease activity and the corresponding 95% confidence intervals (CIs) within unconditional multiple logistic regression models. We included in each model the potential confounding variables: age, sex, education, body mass index (BMI), cigarette smoking status, alcohol drinking intensity, disease duration, rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA), and therapies.

Results: 365 RA patients (median age: 58.46 years, 78.63% females) were included. Most of the patients (60.55%) finished the high school and/or the university. The median BMI was 23.63 (IQR: 21.00-26.78) Kg/m^2; never smokers or drinkers were 51.64% and 29.04%, respectively. The median disease duration was 12.81 (IQR: 8.08-20.72) years, with RF positivity being 53.70% and ACPA positivity 50.96%. Disease activity measures DAS28-CRP and SDAI showed medians of 2.21 (IQR: 1.613.02) and 6.30 (IQR: 3.01-11.81), with high disease activity present in 3.84% and 5.75% of the sample, respectively. Major comorbidities included arterial hypertension (33.42%), gastro-esophageal reflux (19.18%), and gastritis (8.77%). After adjustment for the mentioned confounding factors, the ORs (and the corresponding 95% confidence interval) of RA disease activity was equal to 0.78 (95% CI: 0.76-1.31) for DAS28-CRP and to 0.76 (95% CI: 0.75-1.34) for SDAI, suggesting significant protection of about ~20% for both outcomes. Similarly, robust

regression models for estimating the increment in the mean outcome disease activity scores, DAS28-CRP and SDAI in continuous, provided beta coefficients equal to -0.17 (Standard Error, SE: 0.06) with a p-value equal to 0.06 for DAS28-CRP and a beta coefficient of -1.13 (SE: 0.37) with a p-value equal to 0.04.

Conclusion: Increasing frequency of consumption of a food group composed by olive oil, black and green olives is significantly associated to a lower risk of disease activity, as measured by both DAS28-CRP and SDAI, after adjustment for socio-demographic factors, therapy, disease duration and severity. Robust regression models allowed to quantify the mean reduction of DAS28-CRP in 0.17 points and that of SDAI in 1.13 points.

AB0287 INFLUENCE OF COPING ON RHEUMATOID ARTHRITIS RELATED PAIN

O. Saidane[1], M. Haddad[1], A. Ben Tekaya[1], R. Leila[1], S. Bouden[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. *[1]Charles Nicolle Hospital, Rheumatology,Tunis, Tunisia*

Background: Most patients with rheumatoid arthritis (RA) have chronic pain. Nowadays dealing with pain is no more focused on traditional treatment only.

Objectives: Our study aimed to assess the impact of coping strategies on the chronic pain in RA subjects.

Methods: We performed a 6-month study including patients followed for RA according to ACR / EULAR 2010 criteria. The visual analogue scale (VAS) was used to assess the perception of pain. Coping was assessed by the Brief COPE questionnaire according to which five grouped strategies were identified: Problem solving that includes active coping and planning. Cognitive restructuring that combines humour, acceptance and positive reinterpretation. Support seeking that combines the search for instrumental support, the search for emotional support and religion. Avoidance that includes denial, blame, substance use and behavioural disengagement. Distraction that includes distraction and expression of feelings.

Results: We included 65 RA patients with 58 women and 7 men, the sex ratio was 0, 12 H/F. Mean age of the patients was 58, 6 [24 – 73 years]. Disease duration was superior to 10 years in 66, 2% of patients. RA was immunopositive in 87, 7% of cases and erosive in 83, 1 % of cases. The DAS28 (ESR) was on average 3, 4(IQR 25-75: 2, 8- 4, 6). The average of VAS was 5 ± 2,2. The perception of pain was positively associated with coping strategies based on problem solving, negatively associated to cognitive restructuring and distraction (Table 1).

Table 1. Impact of coping strategies on chronic pain RA subjects

	B	p
Problem solving	0,411	**0,001**
Cognitive restructuring	-0,371	**0,002**
Support seeking	-0,095	0,452
Avoidance	0,243	0,252
Distraction	-0,292	**0,018**

Conclusion: Our study revealed that having coping strategies based on problem solving increased the perception of pain whereas strategies based on distraction and cognitive restructuring decreased it.

AB0288 ECHOCARDIOGRAPHIC FINDINGS BY SPECKLE TRACKING IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. A. Rosal Arteaga[1], S. Cerpa-Cruz[1], E. Purón González[1], G. Martinez-Bonilla[1], V. Gonzalez-Diaz[1], J. Hernandez-del Rio[2], M. E. Ventura Valenzuela[1], S. Contreras Sánchez[1]. *[1]Hospital Civil Fray Antonio Alcalde, Rheumatology, Guadalajara, Mexico; [2]Hospital Civil Fray Antonio Alcalde, Echocardiography, Guadalajara, Mexico*

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory joint disease characterized by infiltration of the synovial membrane by B cells, T cells, and monocytes. Among the most important extra-articular manifestations are those of the cardiovascular system. Cardiovascular involvement in this group of patients is highly relevant as it is an important cause of morbidity and mortality (1,2). Subclinical involvement is underestimated and currently, conventional cardiovascular risk stratification methods are insufficient to detect early stages of cardiovascular disease. Speckle tracking has emerged as a tool to measure early myocardial dysfunction and has been shown to be useful as a predictor of cardiovascular events. Normal reference values have recently been published (3).

Objectives: To describe the echocardiographic findings by speckle tracking (ST) of the left atrium (LA) and left ventricle (LV) in patients with RA without prior known cardiovascular disease and to compare it with healthy controls. To establish if there is an association of echocardiographic findings with characteristics of the disease.

Methods: Thirty-four patients with RA without a history of previous cardiovascular disease and 50 healthy controls were included. Echocardiographic measurements were made by Speckle Tracking of the LA in its 3 phases and of the LV expressed as Global Longitudinal Strain (GLS), in addition to conventional measurements. Quantitative variables were expressed as proportions, continuous data were reported as means and standard deviations. Both groups were compared with t-student test and a linear regression model was used to evaluate age and RA presence in relation to the abnormality or normality of Speckle tracking findings. SPSS was used for statistical analysis.

Results: A significant difference was found in LA global longitudinal strain compared to controls (45.14% vs 57.34%, p=0.020), LA conduit strain (25.69% vs 36.74%, p=0.002) and LV global longitudinal strain (- 17.6% vs. -22.62%, p=0.000). There was no significant difference in LA contractile strain and LA strain rate. In the echocardiographic measurements by conventional technique, no differences were found in the measurement of the LV ejection fraction or LA volume index, but LA ejection fraction was lower in the RA group (53.8% vs 78.2%, p=0.000). Rheumatoid arthritis was associated with LA speckle tracking abnormality in the reservoir, conduit, and LV global longitudinal phases.

Conclusion: The patients with rheumatoid arthritis presented subclinical echocardiographic alterations of myocardial deformation measured by speckle tracking both in the left ventricle (assessed as GLS) and in the left atrium, these were associated with RA regardless of age.

AB0289 DEPRESSION AND METABOLIC DISORDERS PREVENT REMISSION IN RHEUMATOID ARTHRITIS

A. Aleksandrov[1,2], L. Shilova[1], V. Aleksandrov[1,2], I. Alekhina[3], N. Aleksandrova[2]. *[1]Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation; [2]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Clinical and Laboratory Diagnostics, Volgograd, Russian Federation; [3]Stavropol State Medical University, Department of Hospital Therapy, Stavropol, Russian Federation*

Background: Epidemiological data and clinical observations suggest an increased risk of depressive disorders in rheumatoid arthritis (RA) patients with metabolic syndrome (MS) [1, 2].

Objectives: To study the prevalence of depressive symptoms depending on the presence of MS components in RA patients and to evaluate their combined effect on achieving remission of RA.

Methods: 100 RA patients aged 18 to 69 years old (91% women; mean duration of disease 9 [3.5;15] years; body mass index (BMI) 28.8 [IQR 25.1-32.8]) were examined. MS was confirmed in RA patients with three or more harmonized National Cholesterol Education Program/ Adult Treatment Panel III (NCEP/ ATPIII; 2004) criteria. RA patients were assigned a binary MS score ("yes/no") and a categorical MS score (from 0 to 5 criteria) was calculated. The severity of depression in patients with RA was determined using the Beck Depression Inventory (BDI).

Results: 46% of RA patients met the criteria for MS. The presence of three categorical signs of MS was noted in 26%, four - in 16% and of all five signs - in 4% of cases. The combination of elevated fasting glucose, elevated triglycerides (TG), and decreased high-density lipoproteins (HDL) was the most frequent (19.6%; 9/46). The combination of the four MS criteria (increased waist circumference (WC), elevated TG, decreased HDL, and arterial hypertension) occurred in 17.4% (8/46) of cases. RA patients with MS had more severe systemic inflammation (C-reactive protein 9.3[3.9; 23.1] versus 3.35[2.3; 12.0] mg/L, p=0.028), higher levels of TG (p=0.001) and total cholesterol (p=0.003), and higher BMI (p=0.018) and WC (p=0.007).

Depression scores of BDI ≥10 were noted in 64 RA patients: 26% were mild, 28% were moderate and 10% were severe. Symptoms of depression were more frequent in RA patients with longer duration (β=0.25, p=0.012) and high activity (β=0.37; p=0.001) of the disease. There were statistically significant differences in the incidence of depression (BDI ≥10 points) depending on the absence or presence of MS in RA patients (Phi-square=0.42; association coefficient φ=0.65). When comparing groups of RA patients stratified by the presence of MS, significant differences in the severity of depressive disorders according to BDI were found (RA without MS: 8,35 ± 5,1 points; RA with MS: 23,6 ± 12,8 points, p < 0,001). In RA patients without MS, only mild (26%) and moderate (9.3%) depression were detected. In RA patients with MS, depressive symptoms from mild to severe were present in almost equal poportions. Two-factor analysis of variance showed no significant effect of BDI and MS on DAS28-ESR activity in RA patients (p>0.05). The presence of MS had a significant effect on BDI depression (p<0.001), and there was no relationship between MS and the degree of disease activity (p=0.33).

Re-examination (6-7 months later) of patients with initially moderate RA activity (n=58) revealed that remission of the disease was not achieved in 25% of patients from the group with no signs of depression and MS. In the group of RA patients with MS and BDI ≥10 there were almost 2.5 times more cases of deterioration (63.3%) (χ2 with Yates correction = 4.7, p=0.03).

Conclusion: Progression of depression against the background of marked metabolic disorders can lead to a decrease of RA patients' quality of life and complicate disease prognosis [3, 4, 5]. This requires an early multidisciplinary treatment and increased knowledge of the risks associated with depression and MS among health care professionals and patients. Identification and correction of symptoms of depression and MS in RA patients should be a part of the optimal patient care.

AB0290 COMPARATIVE FEATURES AND LONGITUDINAL BEHAVIOUR OF RHEUMATOID ARTHRITIS-ASSOCIATED UIP VERSUS IDIOPATHIC PULMONARY FIBROSIS: A SINGLE CENTRE COHORT STUDY

C. Mazeda[1], J. Antao[2], M. Ferreira[3], R. Aguiar[1], A. Barcelos[1], P. G. Ferreira[4]. *[1]Centro Hospitalar Baixo Vouga, Rheumatology, Centro Académico Clínico Egas Moniz, Aveiro, Portugal; [2]Universidade de Aveiro, Centre for Research and Development in Mathematics and Applications, Aveiro, Portugal; [3]Centro Hospitalar Baixo Vouga, Radiology, Aveiro, Portugal; [4]Centro Hospitalar e Universitário de Coimbra, Pneumology, Coimbra, Portugal*

Background: Interstitial lung diseases (ILDs) are a group of heterogeneous lung disorders with variable prognosis. Idiopathic pulmonary fibrosis (IPF) is the main idiopathic interstitial pneumonia and rheumatoid arthritis (RA) is the commonest cause of connective tissue disease related-ILD. In fact, ILD is the most frequent form of respiratory involvement in RA, with 10% patients having clinically significant disease, frequently imposing significant morbi-mortality. RA-ILD can potentially comprise different disease patterns with distinct prognosis, with usual interstitial pneumonia (UIP) being the most frequent radio-histological pattern. Several studies have suggested that the RA-UIP disease course and survival may be clinically similar to IPF.

Objectives: This study aimed to investigate comparative clinical features, longitudinal behaviour and healthcare resource utilization between local cohorts of RA-UIP and IPF patients.

Methods: Retrospective and descriptive study including all IPF and RA-ILD cases diagnosed and followed in the ILD outpatient clinic of secondary hospital between 2015 and 2020. All patients with RA diagnosis met classification criteria of 2010 ACR/EULAR and IPF patients were diagnosed according to 2018 ATS/ERS/JRS/ALAT clinical guidelines. Socio-demographic, clinical data and longitudinal lung function (functional vital capacity (FVC) and lung diffusion capacity for carbon monoxide (DL_{CO})) were collected. A statistical analysis was performed; p-value <0.05 was statistically significant.

RESULTS:

Table 1. Baseline clinical characteristics of all patients are listed in table.

	IFP n=22	RA-UIP n=14	*p*
Age, years (mean±SD)	74.5±1.8	75.5±9.4	0.75

4 (%)	13.6	0	
Cough (%)	86.4	42.9	**0.01**
Time from respiratory symptoms until diagnosis (months)	20.5±3.4	11.6±9.7	0.09
Elevated titers of Rheumatoid Factor, n	-	10	
Elevated titers of anti-CCP, n	-	11	
Baseline lung function			
FVC, % predicted	73.0±14.9	91.3±19.8	**0.007**
DLCO, % predicted	42.1±18.6	60.3±21.2	**0.04**
6-minute walking distance at baseline (meters)	341.8±147,7	346.2±132.3	0.95

In RA-UIP group, 86% of patients reported preceding articular symptoms, with lung disease being diagnosed after a median of 11 years (IQ range 2-13). All patients had a UIP/probable UIP pattern in HRCT. Regarding baseline FVC and DLCO, the RA-UIP group revealed better lung function compared to the IPF group. All patients with RA-UIP received some form of immunomodulation treatment. Around 78.4% of patients were on low dose prednisolone. Additionally, 64.2% received treatment with mycophenolate mofetil, 21.4% with rituximab, 7.1% with azathioprine and 7.1% with hydroxychloroquine. Regarding IPF patients, about 86.4% were treated with antifibrotics (nintedanib or pirfenidone). From the global population study only 27.3% and 14.3% of IPF and RA-UIP patients, respectively, were referred for respiratory rehabilitation. There were significant differences regarding FVC (p=0.002) and DLCO (p=0.003) decline over time between groups. Comparing to RA-UIP, IPF patients experienced a greater number of acute exacerbations (4 vs 27;p=0.06) and had more respiratory-related emergency visits. IPF patients also had a higher rate of hospitalizations, most of them respiratory-related. There was a clear trend towards higher mortality during follow-up in the IPF group compared to the RA-UIP group (40% vs 21,4%;p=0.23), although not reaching statistical significance.

Conclusion: RA-UIP patients appear to be less symptomatic and have a shorter symptomatic period at diagnosis. IPF patients had worse lung function at diagnosis. IPF patients showed a higher tendency to acute exacerbations and had a greater unplanned health care resources utilization. There was also a non-significant trend towards higher mortality during follow-up in the IPF group.

AB0291 COMORBIDITIES PROFILES IN SEROPOSITIVE RHEUMATOID ARTHRITIS VERSUS SERONEGATIVE RHEUMATOID ARTHRITIS

E. Hannech[1,2], A. Ben Tekaya[1,2], O. Saidane[1,2], S. Bouden[1,2], R. Leila[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. *[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; [2]Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia*

Background: Patients with seropositive rheumatoid arthritis (RA) (positive Rheumatoid Factor (RF)) are more susceptible to extra-articular manifestations [1]. The role of RF in the occurrence of comorbidity is not clear.
Objectives: We aimed to compare comorbidities among patients with seropositive RA versus patients with seronegative RA.
Methods: We conducted a retrospective study in our rheumatology department including 255 patients with established RA according to the ACR/EULAR 2010 criteria. Patients were divided in two groups according to their Rheumatoid Factor (RF) profile: seropositive RA (positive RF), seronegative RA (negative RF). Comorbidities were investigated and compared between the two patients groups.
Results: There were 206 seropositive RA and 49 seronegative RA. Gender distribution was similar in the two groups: 82% female and 18% male in seropositive RA; 85% female and 15% male in seronegative RA (p=0.5). Smoking was noted in 15% patients with seropositive RA and in 11% patients with seronegative RA without any difference (p=0.5).
Comorbidities were noted in 49% of seropositive RA and in 45% of seronegative RA without any significant difference (p=0.6). Obesity (BMI ≥ 30kg/m^2) was noted in 31% of seropositive RA and in 36% of seronegative RA (p=0.7). Diabetes was noted in 18 % seropositive RA and in 26% seronegative RA patients (p=0.1). Hypertension was noted in 31% seropositive RA patients and in 30% seronegative RA (p=0.8). Heart disease was present in 6% seropositive RA and in 7% seronegative RA (p=0.9). Dyslipidemia was noted in 40% seropositive RA and in 20% seronegative RA (p=0.1). Gastrointestinal comorbidities were observed in only seropositive RA patients (11%). Respiratory comorbidities were noted in 27% seropositive RA and in 28% seronegative RA without any significant difference (p=0.6). Regarding mental health problems, depression was noted in 7% seropositive RA and in 14% seronegative RA without any significant difference (p=0.4).
Conclusion: Our study showed that comorbidities were comparable in seropositive and seronegative RA. It seems that RF does not influence the prevalence of comorbidities in RA patients.

AB0292 ASSOCIATION OF RHEUMATOID CACHEXIA WITH BONE, VERTEBRAL FRACTURES, AND STRUCTURAL JOINT DAMAGE IN MOROCCAN RHEUMATOID ARTHRITIS PATIENTS

M. Mahroug[1], H. Azzouzi[1], H. Boutaibi[1], F. Chennouf[1], I. Linda[1]. [1]*Mohamed I University, Rheumatology Department, Oujda, Morocco*

Background: The concurrent decrease in the fat-free mass index (FFMI) and increase in the fat mass index (FM) in rheumatoid arthritis (RA) is called rheumatoid cachexia (RC). There is limited data on RC association with osteoporosis, vertebral fracture (VF), and structural joint damage in RA.
Objectives: To explore rheumatoid cachexia association with bone, vertebral fractures, and radiographic damage in RA patients.
Methods: This was a cross-sectional study on RA patients fulfilling the ACR/EULAR 2010 criteria and recruited from December 2021 at our rheumatology department. Patients with prior cancer, chronic kidney disease, severe heart failure, severe chronic obstructive pulmonary disease, cirrhosis, hyperparathyroidism, thyroid dysfunction, diabetes, dysphagia, illicit drug use, alcohol abuse, and a body mass index (BMI) above 36kg/m^2 were excluded. RC was defined according to Engvall et al. (1) (as a fat-free mass index (FFMI) below the 10th percentile and a fat mass index (FMI) above the 25th percentile) and Elkan et al. (FFMI<25 and FMI>50) (2). Body composition, bone mineral density (BMD), and trabecular bone score (TBS) were obtained by dual-energy X-ray absorptiometry (DXA). Osteoporosis was defined as a T-score under 2.5. The radiographic joint damage was measured by the modified total Sharp /van der Heijde score (mTSS) using standard X-ray images of hands and feet. VFs were defined using the Genant semiquantitative approach as grade 2 or higher.
Results: We included 82 RA patients with a mean age of 51.90 ± 13.12 years. Their mean disease duration under treatment was 7.54 ± 5.69 years, and the mean mTSS was 93.84 ± 56.77. RC was observed in 11 (13.4 %) and 9 (11%) patients using both definitions, respectively. Osteoporosis was observed in 44 (53.7 %) patients. BMD was numerically lower in rheumatoid cachexia patients without significance while mean TBS was similar. The mTSS and particularly the mTSS erosion scores were significantly lower in RC patients (p < 0.01). RA patients with RC (according to Elkan's definition) had significantly more VF (p = 0.039).
Conclusion: RC was positively associated with VF, and RC patients were less erosive.

AB0293 INDICATIONS AND THERAPEUTIC IMPLICATIONS OF HAND AND WRIST JOINT ULTRASOUND IN RHEUMATOID ARTHRITIS

S. Ben Dhia[1], S. Miladi[1], A. Fazaa[1], H. Boussaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Department of Rheumatology, La Marsa, Tunisia*

Background: Ultrasound (US) has been increasingly used in the recent years for the diagnosis and follow-up of rheumatoid arthritis (RA) [1]. It is considered as a complement to physical examination with high sensitivity, specificity, and accuracy in detecting synovial thickening, synovial hypervascularization as well as cortical bone erosions [2].
Objectives: We aimed to study the indications of hand and wrist joint ultrasound and the implications of its findings on the management of RA.
Methods: A cross-sectional study was conducted on a sample of RA patients, fulfilling the ACR/EULAR 2010 RA classification criteria. We collected data about characteristics of the disease, its activity assessed by the Disease Activity Score 28 using C-Reactive Protein and erythrocyte sedimentation rate (DAS28-CRP, DAS28-ESR), treatment of RA (conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), biologics (bDMARDs), and corticosteroids (CS)), indication of hand and wrist joint US and the implications of its findings.
Results: Fifty-eight patients were enrolled in the study with 83% females, with a mean age of 58.5±11.8 years and a mean age at diagnosis of 46.8±12. years. RA was seropositive in 89.7% of patients and erosive in 84.5%. Most patients underwent csDMARDs treatment (67.3%), 29.3% underwent bDMARDs treatment, and 67.3% used oral CS with a mean dose of 4.9±4.4 mg/day of prednisone equivalent. Mean DAS28-CRP was 4.1±1.4, and mean DAS28-ESR was 4.9±1.5. Hand and wrist joint US was performed for RA activity assessment in 93.1% of patients (n=54), for erosion assessment in recently diagnosed RA in 5.2% of patients (n=3), for erosion assessment in established RA in 1.7% of patients (n=1).
In patients who had US signs of active RA, treatment was modified in 73% of patients with initiation of a 3-day parenteral CS pulses (18.9%), initiation of oral CS (2.7%), escalation of oral CS dose (2.7%), escalation of csDMARD's treatment (24.3%), adjunction of another csDMARD (5.4%), reintroduction of a csDMARD (2.7%), initiation of bDMARDs (24.3%), and switch of bDMARDs (5.4%). US findings had no implication in 27% of these patients. When inactive RA was assessed (31,5%), there was no implication on treatment strategy in 82.4% of patients, a decrease of oral CS dose in 11.8% and a single intra-articular CS injection in 5.9%.
Detecting ultrasonographic activity signs of RA in hand and wrist joint was more likely to have implications on treatment strategy than finding no activity signs (75% vs 22%, $\chi 2=14.25$, $p<10^{-3}$).
The group of patients who had an implication of US findings on treatment strategy had significantly higher DAS28-ESR (5.53 vs 4.18, p=0.002).
Conclusion: Hand and wrist US had significant implications on treatment strategy of RA especially in patients with higher disease activity. However, it had no implications in some patients suggesting the complementary role of US compared to clinical determinants in RA treatment decision.

AB0294 VITAMIN D LEVEL AND LOCOMOTIVE FUNCTIONS IN WOMEN WITH RHEUMATOID ARTHRITIS

N. Toroptsova[1], O. Dobrovolskaya[1], A. Sorokina[1], O. Nikitinskaya[1], E. Samarkina[2], M. Cherkasova[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Department of Immunology and Molecular Biology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Department of Thromboinflammation, Moscow, Russian Federation*

Background: Muscle health is an important aspect of rheumatoid arthritis (RA). A decrease in muscle mass and physical performance is a frequent complication of RA that contributes to inability to work and reduced quality of life. Vitamin D deficiency is also common in these patients.
Objectives: To assess the relationship between vitamin D level, muscle strength and physical performance in RA patients.
Methods: 135 women (mean age 58.5±8.9) with confirmed RA according to ACR/EULAR criteria (2010) were enrolled in the study. Muscle strength of upper extremities was measured using a mechanical dynamometer, of lower extremities – using "Chair stand test" (CST) – assessment of the ability to rise from a chair and sit back down 5 times. Handgrip strength 16 kg and less or CST for more than 15 seconds were the criteria for low muscle strength. All patients underwent "Gate speed test" (GST) and "Timed Up and Go test" (TUG) to assess the physical performance. Serum level 25 (OH)D was performed using the Cobas E411 immunochemiluminescence analyzer and Elecsys Vitamin D total kit, Roche.
Results: Median 25(OH)D level was 23.7 [18.2; 30.7] ng/ml in RA women with minimum 7.9 ng/ml and maximum 70.0 ng/ml.
Insufficiency and deficiency of vitamin D were detected in 56 (41,5%) and 42 (31,1%) women, respectively, with median level 24.1 [21.8; 26.6] ng/ml in the patients with insufficiency and 15.6 [13.6; 17.9] ng/ml – in deficiency group.
Vitamin D level was compared between patients with low muscle strength and/or physical performance and women with normal locomotive functions (Table 1). 25(OH)D level was significantly higher in RA women with normal CST and GST >0,8 m/s than in patients with the worst results of these tests. At the same time, we didn't find differences in handgrip strength and TUG depending on vitamin D level.

Table 1. 25(OH)D in women with RA according to locomotive functions

Test	25(OH)D	*p*
CST		
≤15 seconds	26,7 [20,4; 32,2]	0,036
>15 seconds	21,0 [17,9; 25,1]	
GST		
>0,8 m/s	26,1 [19,6; 32,0]	0,043
≤0,8 m/s	21,1 [17,0; 26,8]	
Handgrip strength		
≥16 kg	23,8 [17,8; 30,2]	>0,05
<16 kg	27,7 [19,5; 32,2]	
TUG		
<20 seconds	23,7 [17,9; 30,1]	>0,05
≥20 seconds	18,8 [18,1; 21,0]	

Conclusion: The frequency of low vitamin D level was 72,6% in women with RA including deficiency in 31,1% patients. Patients with reduced lower limb strength and low walking speed had significantly lower vitamin D levels, but there were no differences in 25(OH)D and other tests (handgrip strength and TUG).

AB0295 HIGHER PREVALENCE OF DEPRESSION WITH LINK TO CHILDHOOD TRAUMA IN AN EARLY ARTHRITIS COHORT – A SELECTIVE DATA ANALYSIS (PSYRA-STUDY)

A. Konjikusic[1], S. Ohrndorf[1], T. Braun[1], V. Köhler[1], V. Höhne-Zimmer[1], G. Schmittat[1], C. Heim[2,3], J. Detert[1], G. R. Burmester[1], D. Schaumburg[1]. *[1]Charité University Medicine, Rheumatology and Clinical Immunology, Berlin, Germany; [2]Charité, Institute of Medical Psychology, Berlin, Germany; [3]Pennsylvania State University,, Department of Biobehavioral Health, University Park, United States of America*

Background: In patients with arthritis, psychological co-morbidities are very common. Previous studies have found a relatively high prevalence of depression, anxiety, and post-traumatic stress disorder (PTSD), especially in long-term disease. Recent research has begun to study psychiatric co-morbidities not just as an outcome, but also as a probable risk factor, evaluating patients in the early disease stages. [1] Furthermore, some sources suggest that childhood adversities could impact the autoimmune process in adulthood. [2]
Objectives: To compare the prevalence of depression, anxiety, PTSD, and childhood trauma in a prospective early arthritis cohort to a healthy age- and gender-matched control group. Moreover, to explore whether these factors may contribute to the early arthritis development.
Methods: This selective data analysis of prospective single-centre, observational study included 60 patients with an early arthritis and 60 healthy controls. The control group was defined as no inflammatory joint pain and further subdivided into 2 subgroups, differentiating 24 patients with arthralgia and 36 with no arthralgia and not from the outpatient consultation. Early arthritis was defined as the presence of at least one inflammatory joint from 4 weeks to 12 months, independent of rheumatic diagnosis. For the assessment of current and prior psychological co-morbidities, included patients underwent semi-structured interview and received the standardized questionnaires for depression/anxiety (Hospital Anxiety and Depression Scale (HADS)), childhood trauma (Childhood Trauma Questionnaire (CTQ)) and PTSD (Posttraumatic Diagnostic Scale (PDS)) respectively. Differences among the groups were analyzed with Chi Square and Mann-Whitney U tests. A backwards binominal logistic regression model in reference to the healthy patients was performed to identify the significant factors for the early arthritis group.
Results: The mean age of the total group was 47.4 ± 16.0 (♀ 58.3%, mean symptom duration 4.5±3.3 months). Depression rate of 41.7% according to interview was significantly higher in early arthritis group compared to 16.7% in healthy patients (p=0.03). Regarding arthralgia subgroup, depression was also high with 34%. HADS-D score was also significantly higher in early arthritis (5.4±4.8) to healthy cohort (3.6±3.3) (p=0.047). Compared to 3.3% in healthy patients, PTSD rate of 13.3% was also significantly higher in the arthritis group (p=0.048). We could not detect a significant difference between these two groups using the U test while evaluating CTQ dimensions. We performed a subsequent subgroup analysis and found that childhood trauma dimensions were relevant in arthralgia group, as 25% presented with high emotional abuse score. The logistic regression model showed that emotional neglect, sexual abuses in childhood as well as HADS-D were significant covariates for early arthritis. (p=0,048 OR=1.2; p=0.040 OR=1.4, p=0.025 OR=1.2 respectively).
Conclusion: As the rates of depression and PTSD, as well as HADS-D score were significantly higher in the early arthritis cohort compared to healthy individuals, our findings suggest a potential link between psychiatric outcomes and inflammation. According to our regression model certain childhood adversities and depression are significant factors for an early arthritis group. Arthralgia group had similar aberrant scores regarding childhood trauma, implying that early-life stress might be an important factor in understanding this condition.

AB0296 RELATIONSHIP BETWEEN OBESITY AND ACUTE PHASE REACTANTS IN RHEUMATOID ARTHRITIS

A. N. Garza-Cisneros[1], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], A. B. Rodriguez-Romero[1], M. A. Balderas-Palacios[1], A. Garcia-Heredia[2], N. Guajardo-Jauregui[1], A. Cárdenas[1], D. E. Flores Alvarado[1]. *[1]Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico; [2]Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Cardiology, Monterrey, Mexico*

Background: Obesity plays an important role in autoimmune and inflammatory diseases such as rheumatoid arthritis (RA). It has been demonstrated a paradoxical relationship between increased body mass index (BMI) and disease activity (1). Acute phase reactants (APR) play an essential role in determining the disease activity level (2).
Objectives: To compare APR levels in obese and non-obese patients with RA, and to establish their relationship with the disease activity level.
Methods: A total of 272 patients with a diagnosis of RA were included in a cross-sectional study. They were divided in two groups, 136 obese patients and 136 non-obese patients, matched by age, gender and comorbidities. The C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) level were measured, and the activity level was determined with Disease Activity Score 28-joint erythrocyte sedimentation rate (DAS28-ESR) and Disease Activity Score 28-joint C-reactive protein (DAS28-CRP).
The distribution was evaluated with Kolmogorov-Smirnov. Comparisons with Chi-square test for qualitative variables, Student's t-test, and Mann-Whitney U test for quantitative variables. Correlation between BMI and APR with Spearman-rho coefficient.
Results: The Spearman-rho coefficient showed a significant correlation between CRP level and BMI (rho=0.187, *p=0.*002) (Figure 1). No difference was found between activity level when comparing both groups (Table 1).

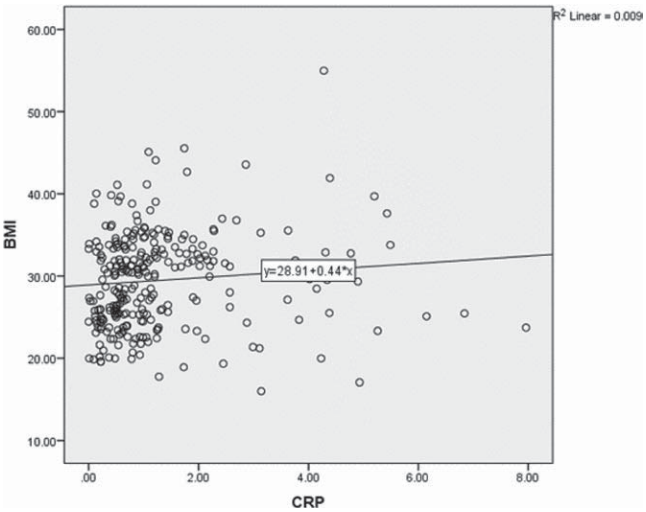

Figure 1. Correlation between BMI and CRP
BMI, body mass index; CRP, C-reactive protein

Table 1. Demographic Characteristics of the Patients

Characteristics	Obese RA Patients (n=136)	Non-Obese RA Patients (n=136)	*P* Value
Age, mean ± SD	55.32±8.67	55.38±8.64	NS
Female, n (%)	130 (95.5)	130 (95.5)	NS
BMI, mean ± SD	34.22±3.74	24.70±2.89	-
T2DM, n (%)	30 (22.0)	23 (16.9)	NS

AB0297 EVALUATION OF FACTORS RELATED TO POSITIVE THORACIC COMPUTERIZED TOMOGRAPHY FINDING IN RHEUMATOID ARTHRITIS

S. Acer Kasman[1], M. E. Tezcan[1]. *[1]Kartal Dr. Lütfi Kırdar Şehir Hastanesi, Rheumatology, Istanbul, Turkey*

Background: Lung involvement is one of the common extra-articular involvements in rheumatoid arthritis (RA). There are some studies in the literature evaluating the risk factors related to lung involvement in RA. Male gender, smoking, seropositivity, uncontrolled disease activity, and long disease duration are the characteristics known for increased lung involvement in RA. There is ongoing debate about when and how we should screen RA patients for lung involvement. In addition, little is known about the importance of patients' comorbidities as a risk factor for RA lung involvement.
Objectives: In this study, we evaluated the role of demographic and disease-related features and comorbidities as risk factors for positive lung computed tomography (CT) findings associated with RA lung involvement. Our aim here was not to evaluate the risk factor for RA lung involvement. Instead, we try to guide clinicians to risk stratification of RA patients for possible lung involvement. In previous studies, the authors compared risk factors between RA patients with and without known lung involvement. In addition, not all patients in these RA cohorts had thoracic CT. Therefore, they may miss preclinical or asymptomatic patients. In our study, we compared the characteristics of two groups of patients with and without positive thoracic CT findings.
Methods: We included 76 RA patients from our cohort who applied to our outpatient clinic for routine follow-up and had thoracic CT for any purpose in the past year. All RA patients met the 2010 ACR-EULAR RA criteria. Thoracic CT findings were classified as associated with RA according to the article by Esposito AJ et al. Patients with any known pulmonary involvement, malignancy, nursing, and known COVID-19 infection in the past year were excluded from the study. We divided the patients into two groups (positive or negative) according to thoracic CT findings. We compared the two groups in terms of patient and disease-related characteristics. We used qi-square test for comparing categorial variables and Mann-Whitney U test for comparing continuous variables. We then performed multivariate analysis with a model that includes significantly different features in univariate analyses and age to find the amount of risk attributed to the factors for positive thoracic CT. P<0.05 was accepted as significant.
Results: Of the 76 (56.5 %) RA patients, 43 (56.5 %) had positive findings related to RA in thoracic CT (Table 1). Male gender (p=0.008), ACPA positivity (p=0.04), thyroid diseases (p=0.03) were found significantly more common in the patients with positive thoracic CT findings. The frequencies of all other demographic and disease related features and comorbidities are similar between the groups. Additionally, multivariate analyses found thyroid diseases (OR 6.1, %95 CI 1.5-24.3, p=0.009) and male gender (OR 7.8, %95 CI 1.6-35.7, p=0.008) were related to positive CT findings.

Table 1. Positive thoracic CT features of RA patients

	n=43 (%)
Pulmonary nodules	15 (34.8)
Ground glass opacities	13 (30.2)
Bronchial diseases	12 (27.9)
Pleural diseases	9 (20.9)
Mosaic attenuation	7 (16.2)
Mediastinal lymphadenopathy	6 (13.9)
Honey combing	5 (11.6)
Emphysema	5 (11.6)
Interstitial fibrosis	3 (6.9)
Pulmonary vascular diseases	2 (4.6)

Conclusion: In our study conducted in our cohort, we found that male gender and thyroid disease were risk factors for positive thoracic CT findings associated

with RA. Clinicians may consider these factors when classifying RA patients for lung involvement and planning thoracic CT for screening.

AB0298 THE RISK OF SULPHA ALLERGY IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Higashida-Konishi[1], K. Izumi[1,2], T. Shimada[1,2], S. Hama[1], T. Oshige[1,2], H. Oshima[1], Y. Okano[1]. *[1]National Hospital Organization Tokyo Medical Center, Division of Rheumatology, Department of Medicine, Tokyo, Japan; [2]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Sulpha drugs have been used such as sulfasalazine for the treatment of rheumatoid arthritis (RA), and trimethoprim-sulfamethoxazole (TMP-SMX) for the treatment or prevention of pneumocystis pneumonia. However, some patients with RA delay treatment because of allergy to sulpha drugs[1]. We reported that 16.7% of RA patients presented drug allergies[2]. It was not clear what is a risk factor for drug allergies in patients with RA.

Objectives: The aim of this study was to evaluate the clinical features with sulpha allergy in patients with RA.

Methods: We prospectively examined consecutive patients diagnosed with RA in our hospital from March 2021 to January 2022. The patients with RA met the EULAR/ACR 2010 criteria. We included patients with RA with other rheumatic diseases. A careful allergic history was obtained from patients with RA and physical examination performed.

The first analysis was performed on patient baseline laboratory data at diagnosis of patients with RA with or without sulpha allergy. Sulpha allergy (rash, angioedema and anaphylaxis after drug exposure) was allergy to sulfasalazine or TMP-SMX. The second analysis was performed on seven types of allergic reactions: (1) drug allergies other than sulpha drugs (rash, angioedema and anaphylaxis after drug exposure), (2) food allergy (rash, angioedema and anaphylaxis after foods exposure), (3) allergic contact dermatitis such as metals, and other cosmetics, (4) seasonal allergic rhinitis and/or conjunctivitis (AR and/or AC), and AR and/or AC associated with house dust, (5) asthma, and (6) atopic dermatitis.

Results: There were 513 patients with RA in our study. In the first analysis, 17 patients with sulpha allergy and 496 patients without sulpha drugs were enrolled (Table 1). The median ages (with supha allergy and without sulpha allergy) were 66.0 and 72.0 years old (p=0.40). Females were 82.3% and 77.0%(p=0.4). The median observation period was 97.0 and 69.0 months (p=0.20). Patients with other rheumatic diseases were 11.6 and 6.8% (p=0.34).

Table 1. Characteristics of RA patients at diagnosis of RA

	With sulpha allergy (n = 17)	Without sulpha allergy (n = 496)	P
Female	83.4%	76.9%	0.77
Age, year, y	66.0 (56.0-78.5)	72.0 (60.0-80.0)	0.40
Observation period, m	97.0 (45.5-182.0)	69.0 (31.0-123.8)	0.20
Patients with other rheumatic diseases	11.8%	6.8%	0.34
ANA-positive patients(>1:80)	52.9%	28.2%	0.052
Anti-SSA antibody-positive patients	46.2%	18.2%	0.02
RF-positive patients	40.0%	66.8%	0.049

The RA patients with sulpha allergy had higher positivity rate of anti-nuclear antibody (ANA) (>1:80) (52.9%, 28.2%: p=0.052), higher positivity rate of anti–Sjögren's-syndrome-related antigen A autoantibody (anti-SSA antibody) than those without sulpha allergies (46.2%, 18.2%: p = 0.02) and lower positivity rate of rheumatoid factor(RF) than those without sulpha allergies (40.0%, 66.8%: p = 0.049).

In the second analysis drug allergies other than sulpha allergy were more frequent in patients with sulpha allergy. Drug allergies other than sulpha allergy were such as antibiotics and nonsteroidal anti-inflammatory drugs. There were no significant differences in other allergies.

Conclusion: Among patients with RA, patients with sulpha allergy had higher positivity rate of ANA and anti-SSA antibody, and lower positivity rate of RF than those without sulpha allergy. RA patients with sulpha allergy had a higher prevalence of the other drug allergies than those other than sulpha allergy.

Table 2. Allergic disorders in RA patients with and without sulpha allergy

	With sulpha allergy (n = 17)	Without sulpha allergy (n = 496)	P
drug allergies other than sulpha allergy	61.6%	12.7%	<0.01
food allergy	11.8%	13.5%	1.00
allergic contact dermatitis	23.5%	24.2%	1.00
AR and/or AC	58.8%	46.6%	0.34
asthma	17.7%	13.1%	0.48
atopic dermatitis	5.9%	6.3%	1.00

AB0299 ASSOCIATION OF RHEUMATOID CACHEXIA WITH DISEASE PARAMETERS IN MOROCCAN RHEUMATOID ARTHRITIS PATIENTS

M. Mahroug[1], H. Azzouzi[1], I. Linda[1]. *[1]Mohamed I University, Rheumatology Department, Oujda, Morocco*

Background: Low muscle mass occurs in patients with rheumatoid arthritis without weight loss. This condition has been studied lately (1) and was referred to as rheumatoid cachexia (RC).

Objectives: To study the prevalence of rheumatoid cachexia and its associated factors in rheumatoid arthritis (RA) patients.

Methods: We designed a cross-sectional study on RA patients recruited from December 2021 at our rheumatology department. Exclusion criteria were patients with prior chronic kidney disease, severe heart failure, severe chronic obstructive pulmonary disease, acute liver failure, uncontrolled diabetes, thyroid dysfunction, dysphagia, illicit drug use, and alcohol abuse. Body composition was measured with dual-energy X-ray absorptiometry (DXA), and patients' data were collected. RC was defined by Engvall et al. (2) as a fat-free mass index (FFMI) below the 10th percentile (under lean) and a fat mass index (FMI) above the 25th percentile (fat excess). Inflammatory activity was measured by C-reactive protein (CRP) and used to assess disease activity score for 28 joints (DAS28CRP). The physical disability was assessed by the Health Assessment Questionnaire (HAQ) and the physical activity by the International Physical Activity Questionnaire (IPAQ). Nutrition was evaluated by the Mini Nutritional Assessment (MNA).

Results: We included 91 RA patients with a mean age of 52.61 ± 12.99 years. The prevalence of rheumatoid cachexia was 12.1 %. Twenty-six patients (28.6 %) were under lean, and six patients (6.6 %) had excess fat. DAS28CRP (p = 0.004) and fasting glucose (p = 0.03) were significantly lower in RC patients. RC did not show any significant association with HAQ, MNA, physical activity, gender, menopause, seropositivity, lipid levels or BMI. RC was significantly associated with DAS28CRP (p = 0.01, OR = 0.305, 95%IC [0.114, 0.818]) and fasting glucose level (p = 0.02, OR = 0.0002, 95%IC [0.00000001, 0.311]) when adjusting on IPAQ categories and ACPA seropositivity.

Conclusion: Rheumatoid cachexia was frequent in our RA patients. This condition was significantly associated with low fasting blood sugar levels and disease activity.

AB0300 REDUCTION OF LACHNOSPIRA IS CLOSELY RELATED TO AUTOIMMUNE DISEASE COMPLICATED WITH PULMONARY FIBROSIS

C. Wang[1,2,3], S. X. Zhang[3,4,5], Q. Wang[6], Y. Li[1], Y. Li[1], D. Y. Xue[1], P. F. He[1,7], Q. Yu[1,7]. *[1]Shanxi Medical University, School of Management, Taiyuan, China; [2]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; [3]Shanxi Medical University, Academy of Microbial*

Ecology, Taiyuan, China; [4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [5]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; [6]Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China; [7]Shanxi Medical University, Medical Data Sciences, Taiyuan, China

Background: Autoimmune diseases (AD) are a group of heterogeneous disorders caused by both genetic and environmental factors. Rheumatoid arthritis (RA) and Sjögrens syndrome (SS) are typical autoimmune diseases[1], Pulmonary fibrosis (PF) is the most common complication of AD. Despite the extensive study of the human gut microbiome in AD complicated with PF(AD-PF),the question of whether there are common microbial features characterizing AD-PF still remains[2].
Objectives: This study focused on exploring differences between the microbiota diversity and peripheral lymphocyte subpopulations as well as cytokine in AD with PF is different from that of AD without PF.
Methods: A total of 64 AD patients (44 AD without PF and 20 AD with PF) as well as 100 age- and sex- matched healthy controls (HCs) were enrolled in this study. The peripheral lymphocyte subsets were analyzed by flow cytometry and the gut microbiota were investigated via 16s rRNA sequencing. Alpha and Beta diversity (bray curtis distance-based) analysis was used to define the difference of gut microbiota profiles between patients and HCs. To explore the specific bacterial taxa associated with AD-PF, the STAMP software was used to compare the fecal microbiota composition. Spearman correlation analysis was used to determine the similarities in the microbiota community with clinical meatures among fecal samples.
Results: There is a decrease that the richness and diversity index between HCs, AD and AD-PF patients. Principal co-ordinates analyses suggested that these three microbiota states explained a reasonable proportion of observed variance in gut microbiota composition (ANOSIM R2 = 0.113, p < 0.001; Figure 1b). Compared with HCs, there are obvious differences among 19 species of flora in AD without PF at the genus level, of which 2 species of flora (Lachnospira,Muribaculaceae) belong to AD-PF patients were showed much fewer. The relative abundance of Lachnospira was positive correlated with the absolute numbers of Th17, IL-6 and THF-α (P<0.05,Figure 1D-E) , which indicated Lachnospira may be the most critical among the AD-RF patients' own species of flora. Therefore, the reduction of Lachnospira may influence the immune status of the intestinal tract of patients by producing less short-chain fatty acids.
Conclusion: Our results suggest that the decrease of Lachnospira may lead to the occurrence of AD with pulmonary interstitial fibrosis, which was closely correlated with lymphocyte subsets and Cytokines, maintaining the flora balance might be a potential therapeutic target for AD-PF.

AB0301 ANALYSIS OF INTESTINAL MICROBIOTA IN PATIENTS WITH OSTEOPOROSIS SECONDARY TO RHEUMATOID ARTHRITIS

A. M. Cabezas-Lucena[1], M. Morales-Águila[1], P. Ruiz-Limon[2], I. Moreno-Indias[2], N. Mena-Vázquez[1], S. Manrique Arija[1], A. Fernandez-Nebro[1]. *[1]Hospital Regional Universitario de Málaga. Institute for Biomedical Research in Malaga (IBIMA), UCG of Rheumatology, Málaga, Spain; [2]Hospital Universitario Virgen de la Victoria. Instituto de Investigación Biomédica de Málaga (IBIMA)., UGC of Endocrinology and Nutrition, Málaga, Spain*

Objectives: To analyse of intestinal microbiota in patients with osteoporosis (OP) secondary rheumatoid arthritis (RA).
Methods: Design: A cross-sectional observational study nested in a prospective cohort of incident RA patients.
Patients: Patients with RA (ACR/EULAR 2010) from a prospective baseline cohort (incident cases between 2007-2011), >16 years, from whom information on bone mineral densitometry (BMD) was collected.
Protocol: all subjects were evaluated in a specialized outpatient unit. Clinical-analytical variables of the cut-off date and clinical history were registered. Blood, urine and faeces samples were obtained from all subjects. A BMD was done by dual energy X-ray absorptiometry (DXA) for osteoporosis diagnosis.
Variables: Dependent variable: osteoporosis according World Health Organization (WHO) definitions. The fecal microbiota (continuous var., 0-100%) was analysed using the Ion Torrent S5 next-generation sequencing platform, and the sequences obtained were processed using the QIIME2 (Quantitative Insights Into Microbial Ecology 2) software. Others variables included demographics characteristics, comorbidities, inflammatory activity measured by mean accumulated Disease Activity Score-28 (DAS-28) throughout the disease, severity variables: smoking, erosions, anticitrullinated peptide antibody (ACPA) titres, rheumatoid factor (RF) and physical function measured by HAQ. Treatment with bDMARD (biological disease-modifying antirheumatic drug) and/or sDMARD (synthetic disease-modifying antirheumatic drug).
Statistical Analysis: descriptive, bivariate using $\chi 2$ and T-Student followed by logistic multivariant regression model in patients with RA. (Vd: Osteoporosis).
Results: 110 patients with RA were included. The majority of the subjects were women (80%) with an average age of 56 years. The majority of patients were seropositive (81.8% with positivity for RF and 80% with positive for ACPA) and the accumulated DAS-28 average was 3. A total of 49/110 (44.5%) had normal BMD, 46/110 patients (41.8%) had densitometric osteopenia and 15/110 OP (13.6%). Patients with OP were older (p=0.025), higher RA length (p=0.003), higher CRP (p=0.046), higher inflammatory by DAS-28 (p=0.051) and higher ACPA titres (p=0.043). Furthermore, they showed higher levels of Lentisphaerae (p=0.035), Synergistetes (p<0.001), Actinobacteria (p=<0.001) y Verrucomicrobia (p=0.034).

Table 1. Epidemiological, clinical and analytical characteristics of patients

Variable	Patients n=110
Epidemiological characteristics	
Age in years, mean (IQR)	55.9 (49.3-64.4)
Sex, female; n (%)	88 (80.0)
Tobacco	
Never smoker, n (%)	47 (42.7)
Ex-smoker, n (%)	30 (27.3)
Active smoker, n (%)	33 (30.0)
Comorbidities	
High blood pressure, n (%)	28 (25.5)
Diabetes Mellitus, n (%)	6 (5.5)
Dyslipidemia, n (%)	25 (22.7)
Cardiovascular Disease, n (%)	18 (16.4)
BMI (Kg/m^2), mean (SD)	28.4 (5.1)
Clinical and analytical characteristics	
RA evolution time, months, median (IQR)	93.2 (77.6-123.4)
Diagnosis delay, months, median (IQR)	8.1 (4.5-17.0)
Erosions, n (%)	68 (61.8)
RF >10, n (%)	90 (81.8)
ACPA >20, n (%)	88 (80.0)
DAS-28 average, mean (±SD)	3.0 (0.7)
HAQ average, median (IQR)	0.71 (0.3-0.9)
sDMARD, n (%)	93 (84.5)
bDMARD, n (%)	42 (38.1)
Osteopenia, n (%)	46 (41.9)
Osteoporosis, n (%)	15 (13.6)

The variables independently associated with OP in RA were: age (OR [IC 95%],1.099 [1.012-1.193]; p=0.025), ACPA (OR [IC 95%],1.005 [1.001-1.010]; p=0.036), RA length (OR [IC 95%],1.039 [1.016-1.062]; p=0.001) y Actinobacteria (OR [95% CI] 1.124 [1.004-1.257]; p=0.042), R2=0.367.

Conclusion: Osteoporosis in Rheumatoid Arthritis is associated with severity factors as the age, the disease length or the presence of ACPA, as well as the *Actinobacteria* predominance in the intestinal microbiota.

AB0302 DIASTOLIC DYSFUNCTION IN RHEUMATOID ARTHRITIS PATIENTS: A COMPARATIVE CROSS-SECTIONAL STUDY

M. Brahem[1], H. Ibn Hadj Amor[2], R. Sarraj[1], S. Kraiem[2], R. Rouabhia[2], E. Hmaier[2], A. Ben Salem[1], R. Grassa[1], G. Haj Mbarek[2], H. Hachfi[1], Y. Mohamed[1]. *[1]Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia; [2]Taher Sfar University Hospital, Cardiology, Mahdia, Tunisia*

Background: Cardiac failure is an independent risk factor for mortality in Rheumatoid arthritis (RA) and diastolic dysfunction (DD) may act as a precursor for cardiac failure.

Objectives: The aim of our study is to determine the frequency of diastolic dysfunction in rheumatoid arthritis (RA) patients compared to a control group and to focus on associated factors.

Methods: This was a comparative cross-sectional study, including patients diagnosed with RA according to the ACR/EULAR 2010 criteria and control subjects. Each patient underwent transthoracic echocardiography and the DD was assessed by E/A and E/a ratio.

Results: Seventy-two patients with RA and 72 control subjects were included. In our study, there was a clear female predominance in both groups (93.1% vs 94.4%). The mean age of RA patients was 52.9 ± 11.72 years [21-75 years] and that of the control group was 49.26 ± 10.74 years [19-76 years]. In RA group, the mean duration of disease was 12.4 ± 9.9 years [6 months-40 years]. The means of DAS 28 (CRP), DAS 28 (ESR) and HAQ score were respectively 3.4 ± 1.4 [1.2-6.7]; 3.9 ± 1.4 [1.4-7.4] and 0.9 ± 0.7 [0-2.5]. 51.4% of patients had an increased ESR and 37.5% of cases had an increased CRP (CRP>6). In RA group, DD was present in 26 patients (36.1% of cases). The mean value of the impaired E/A ratio was 0.7 ± 0.1 [0.4-0.9] and the mean value of the impaired E/a ratio was 9.8 ± 1.5 [8.5-14.4]. These patients (23 women and 3 men) had a mean age of 56 ± 10.4 years [33-74 years]. Among them, 7 patients had hypertension, 9 patients had cardiac symptoms, 21 patients had a long-standing RA, 17 patients had positive ACPAs and 11 patients had positive RF. In control group, DD was present in 10 patients (13.9% of cases). The mean value of the impaired E/A ratio was 0.6 ± 0.1 [0.4-0.9] and the mean value of the impaired E/a ratio was 9 ± 0.6 [8.4 to 10.1]. Left ventricular diastolic dysfunction was more frequent in RA patients compared with the control group with a significant difference (p<0.01). No significant association was found between diastolic impairment and RA parameters.

Conclusion: Subjects with RA have a higher frequency of diastolic dysfunction than those without RA. Therefore, correct assessment of diastolic function should be considered of pivotal importance in the routine follow-up of RA patients. The identification of predictor factors requires further study.

AB0303 RELATION BETWEEN CLINICAL ANTHROPOMETRIC MEASUREMENTS AND MALNUTRITION IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

M. Ardhaoui[1], J. Mahbouba[1], F. Naffati[2], M. Ghali[1], F. Fhima[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. *[1]Fattouma Bourguiba, Rheumatology, Monastir, Tunisia; [2]Fattouma Bourguiba, Biochemistry, Monastir, Tunisia*

Background: Rheumatoid arthritis (RA) is associated with an increased risk of malnutrition, especially among the elderly. However, nutritional assessments in this population are scarce in the clinical situation. Various anthropometric measurements can help to assess malnutrition.

Objectives: To evaluate the nutritional status using anthropometric measurements in elderly patients with RA.

Methods: A prospective study was conducted, including RA patients aged 65 years or older and followed in rheumatology department. Clinical findings, disease activity and nutritional profile were studied. The mini-nutritional assessment (MNA) was used to identify altered nutritional status. The anthropometric measurements studied were: Weight loss, Body mass index (BMI), Triceps skin fold thickness (TSF) which reflects fat mass, Mid-arm circumference (MAC), Arm muscle circumference (AMC) which indicates lean mass and the calf circumference (CC).

Results: Sixty-three patients were included, 82% were female. Their mean age was 68.17±4.35 years. The mean duration of RA was 11 years. The average DAS28 was 3.72±1.48. The mean MNA total score was 20.19 ± 4.71 with a range of 8 to 27.5. The prevalence of malnutrition in our population was 20.6%. 55.6% of the patients were at risk of malnutrition. Only 23.8% had a normal nutritional status. The average BMI was 27.97 ± 5.44 kg/m2 [14.85 - 43.2]. The diagnosis of malnutrition according to the BMI (< 21 kg/m2) was made for 7.9% of patients, of which 4.8% were severely malnourished. The average weight loss was 2.26 ± 2.51 kg during the last month [0 – 10]. The average percentage of weight loss in the last month was 3.39 ± 4% [0-11%]. Among our patients, 26 patients (41.3%) did not report a weight loss, 19 patients (30.2%) had a weight loss of less than 5%. Eighteen patients (28.6%) had malnutrition defined as weight loss greater than or equal to 5% in one month, of whom 7 patients (11.1%) had severe malnutrition with a loss of at least 10% of their habitual weight. The mean TSF was 18.38 ±6.77 mm [5 - 30] (19.15±6.72 mm in women and 14.72±6 mm in men). 28.6% of patients had decreased values of TSF. The mean MAC was 29.48 ± 4.52 cm [18 - 40]. The mean AMC was 23.7 ± 3.64 cm [15.86-34.43] (24±3.57 cm in women and 22.19±3.75 cm in men). The AMC was decreased in 20.6% of cases. The mean CC was 33.25 ± 4.62 cm [20-43]. 31.7% of patients had a decreased CC. There were significant association between the nutritional status using the MNA and BMI, loss of weight and TSF (p=0.013, p<0.001 and p=0.05, respectively). MNA was not associated with MAC, ACM or CC (p=0.6, p=0.8 and p=0.4, respectively).

Conclusion: This study showed that the prevalence of malnutrition varies depending on the used anthropometric tool. BMI, weight loss and TSF are, according to our study, reliable tools to detect the malnutrition in elderly patients with RA.

AB0304 CHRONIC KIDNEY DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY

M. J. Mantilla Ribero[1,2], J. C. Sarmiento Monroy[3], C. Villota-Eraso[4], D. C. Varela[5], J. C. Hurtado[2], M. Rodriguez-Jimenez[6], R. D. Mantilla Hernández[2]. *[1]Universidad de la Sabana, Rheumatology Department, Chía, Colombia; [2]Center of Dermatology and Rheumatology (FUNINDERMA), Rheumatology, Bogotá, Colombia; [3]Hospital Clínic, Villarroel 170, 08036, Rheumatology Department, Barcelona, Spain; [4]IPS Servicio Integral de Reumatología e Inmunología, Rheumatology Department, Pasto, Colombia; [5]Universidad Pontificia Bolivariana, Rheumatology Department, Medellin, Colombia; [6]Center for Autoimmune Diseases Research (CREA), Universidad del Rosario, Rheumatology, Bogotá, Colombia*

Background: Prevalence and incidence estimates for chronic kidney disease (CKD) in rheumatoid arthritis (RA) vary and it may result from comorbidities, chronic inflammation, aging, or effects of drugs used for the disease.

Objectives: To calculate the prevalence and incidence of CKD in a cohort of patients with RA.

Methods: This was a retrospective cohort study in which well-characterized patients with RA (fulfillment of 1987 ACR criteria) were included from 2014 to 2021. Patients were evaluated at a single rheumatology outpatient center in Bogotá, Colombia. Baseline and follow-up estimated glomerular filtration rate (eGFR) were calculated according to CKD-EPI equation. CKD was defined as an eGFR <60 mL/min/1.73 m2.

Results: A total of 783 outpatients were included. Baseline characteristics were as follows: female gender 81.6%, mean age 51.8±11 years, mean disease duration 8 (IQR 3-15) years, RF positive 80.1%, ACPA positive 58.2%, and erosions 24.9%. Most patients have received glucocorticoids (89.8%), and conventional synthetic DMARDs (97.8%), being prednisone and methotrexate the most frequently prescribed. Hypertension was the most frequent comorbidity (27.7%). CKD was found in 43 (5.5%) patients at the time of inclusion, being hypertension the most common cause (24, 55.8%). Only 12 (1.5%) patients had a documented history of CKD at the beginning of the

follow-up. The median of follow-up was 73 months. Fifteen incident cases of CKD were found (15/358, 4.1%) in patients with follow-up data of at least 1 year and without prior CKD. Main characteristics of the patients are shown in Table 1.

Table 1. Cardiovascular disease and main comorbidities in RA patients.

	Baseline (n/783)	Prevalent CKD (n/43)	Incident CKD (n/15)
Cardiovascular Disease	n (%)	n (%)	n (%)
Hypertension	217 (27,7)	24 (56)	6 (40)
Coronary artery disease	27 (3,4)	3 (7)	2 (13)
Thrombosis	14 (1,8)	2 (5)	2 (13)
Stroke	11 (1,4)	1 (2)	-
Chronic occlusive arterial disease	4 (0.5)	1 (2)	1 (7)
Comorbidity	n (%)	n (%)	n (%)
Dyslipidemia	209 (26,7)	16 (37)	9 (60)
Diabetes mellitus type 2	55 (7)	3 (7)	-

Conclusion: There is an underestimation of the prevalence of CKD in patients with RA in routine clinical practice due to the absence of a systematic estimation of eGFR. The incidence of CKD is low in the Colombian population.

AB0305 RELATIONSHIP BETWEEN IMMUNOLOGICAL ASSESSMENT AND PERIODONTAL STATUS IN RHEUMATOID ARTHRITIS

A. Ben Salem[1], M. Brahem[1], C. Baccouche[2], R. Sarraj[1], O. Jomaa[1], R. Grassa[1], H. Hachfi[1], Y. Mohamed[2]. *[1]Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia; [2]Taher Sfar University Hospital, Dentistry, Mahdia, Tunisia*

Background: Rheumatoid arthritis (RA) and Periodontitis are two chronic inflammatory diseases, which can share similarities such as the patho-physiological progression and immune regulation.

Objectives: The present study aimed to determine the link between immunological assessment and periodontal status in RA.

Methods: A cross sectional study including RA patients, which consulted or were hospitalized in Rheumatology department in Taher Sfar University Hospital of Mahdia Tunisia, between March 2020 and February 2021. The diagnosis of RA was based on ACR/EULAR 2010 criteria. Oral and periodontal examination was practiced by a trained dentist in the same hospital. Oral hygiene, teeth status (missing teeth) and paradental parameters (bleeding index of Loe and Silness (GI), plaque indexed O'Leary (PI)) were determined for each patient, to assess oral and periodontal diseases in RA.

Results: Our study included 73 patients with an average age of 51.7 years ±11.8 [21-74years]. Sixty-two patients (93.9 % of cases) were women, in which 35 (54.7%) were menopausal. Only one patient was a smoker. Nine patients (13.6% of cases) were diabetic. The mean duration of RA was 11.2 years ± 8.4 [10 months-37 years]. Rheumatoid factor (RF) was positive in 31 Patients (57 % of cases). Anti-citrullinated peptide antibodies (ACPA) were positive in 39 patients (72 %). Antinuclear antibodies (ANA) were positive in 5 patients (9.3%). Fifty patients (80.6%) had radiological impairments and 36 (54.5%) had specific deformations of RA. The disease activity score (DAS28-VS) and (DAS28-CRP) were very high (>5.1) in respectively 14 patients (21.2%) and 8 patients (12%).

Oral examination revealed xerostomia in 37 patients (62.7% of cases). Three patients (4.7% of cases) were toothless. Gingivitis was diagnosed in 45 Patients (65.2% of cases): localized in 13 patients (31.7%) and generalized in 28 patients (68.3%). Periodontitis was seen in 36 (50.7% of cases). Basing on bleeding index of Loe and Silness (GI), 36 patients (51.4%) had degree 2 and 11 patients (15.7%) had degree 3. Supragingival plaque and subgingival plaque were detected respectively in 62 patients (88.6 %) and 60 patients (88.2 %).

We performed statistical analysis which showed that the positivity of ACPA was significantly associated with the presence of gingivitis. The RF or the ANA were not associated with periodontal abnormalities.

Conclusion: In addition to the functional handicap, rheumatoid arthritis has an impact on the oral status, which may be related to the immunological status of patients.

AB0306 PNEUMOCOCCAL VACCINATION REDUCES THE RISK OF RESPIRATORY INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TARGETED THERAPY. DATA FROM MOSCOW UNIFIED ARTHRITIS REGISTRY (MUAR)

E. Zhilyaev[1,2,3], G. Lukina[4], E. Koltsova[4], D. Murtazalieva[4], E. Shmidt[5], K. Lytkina[6], A. Shmitko[7], D. Blagovidov[7], M. Kostinov[7]. *[1]European Medical Center, Rheumatology, Moscow, Russian Federation; [2]Pirogov Russian National Research Medical University, Department of Faculty Therapy named after Academician A.I. Nesterov, Moskva, Russian Federation; [3]Russian Medical Academy of Continuous Professional Education, Rheumatology, Moskva, Russian Federation; [4]A.S. Loginov Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation; [5]City Clinical Hospital 1 named after N.I.Pirogov, Rheumatology, Moscow, Russian Federation; [6]City Clinical Hospital 4, Rheumatology, Moscow, Russian Federation; [7]Mechnikov Research Institute of Vaccines and Sera, Laboratories of Vaccination and Immunotherapy of Allergic Diseases, Moscow, Russian Federation*

Background: The incidence of infections, mainly pneumonias, is significantly increased in patients with rheumatoid arthritis (RA). The risk increases more in persons treated with targeted anti-inflammatory drugs (tDMARDs), biological or targeted synthetic.

Pneumococcal vaccination is recommended for most patients with rheumatic diseases. However, only the immunological effectiveness of such vaccination has been sufficiently confirmed. There is sparse evidence of its clinical efficacy in patients with rheumatic diseases.

Objectives: to evaluate the effect of 23-valent pneumococcal polysaccharide vaccine (PPV23) and 13-valent pneumococcal conjugate vaccine (PCV13) on the risk of infections in RA patients receiving tDMARDs.

Methods: The data from the Moscow Unified Arthritis Registry (MUAR) for the period 2018-2020 were analyzed. We included patients with RA, over 18 years old, received tDMARDs (all available biologics or tofacitinib).

The analysis included episodes of observation from the moment of vaccination with pneumococcal vaccine until the development of the analyzed event (any infection, respiratory infection or serious infection) or until the end of follow up. For unvaccinated patients, episodes began since October 20, 2018 (the average date of vaccination of persons who received immunization).

The risks were compared using Cox regression. An adjustment was made for confounders identified in an earlier study: age and smoking.

Results: The analysis included 832 patients: 40 were vaccinated with PCV13, 35 – with PPV23. There were 144 men (17.3%). The mean age was 55.4 ± 12.1 years. The duration of observation was 319 ± 198 days.

A total of 237 infectious events were registered, of which 201 were respiratory and 21 serious (Table 1). There was a significantly lower risk of any infection (relative risk (RR) – 0.39 CI: 0.18 - 0.84, p = 0.015) and the risk of respiratory infection (RR - 0.32; CI: 0.13 -0.79; p = 0.014) in the group of patients vaccinated with PCV13 compared with unvaccinated. The differences remained statistically significant after adjusting for the age and smoking, Figure 1.

Table 1. Registered infectious events

Event groups	Localisation	Number	Of them serious
Respiratory infections	Ear, paranasal sinuses, tonsils	16	2
	Upper respiratory tract	166	0
	Pneumonia	18	14
	Lung abscess	1	1
Other infections	Eye and appendages	3	0
	Skin and subcutaneous tissue	7	1
	Bones and joint	2	2
	Urogenital tract	6	0
	Digestive system, including the oral cavity	2	1
	Herpes infections*	16	0

* - events are included in the group, regardless of localization, these events were not included in other sections

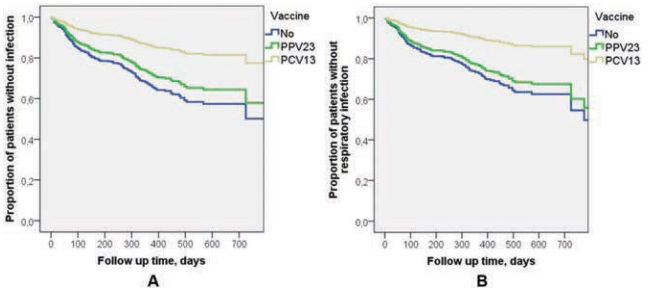

Figure 1. Survival without infectious events (A) and without respiratory infections (B) adjusted for age and smoking

The interaction of the effects of vaccination with the factor of the used tDMARD, as well as with the factor of the use of methotrexate in their effect on the risk of any and respiratory infections was evaluated. There was no significant interaction between these variables.

There were no significant differences in the risk of serious infections due to a small number of events of this kind. No serious infections were registered among patients vaccinated with PCV13.

Conclusion: Vaccination with 13-valent conjugated pneumococcal vaccine in patients with rheumatoid arthritis receiving tDMARDs can significantly reduce the risk of infectious complications, mainly due to acute respiratory infections. We found no significant effect of targeted drug and treatment with methotrexate on the effectiveness of vaccination.

AB0307 MERKEL CELL CARCINOMA RECURRENCE RISK IS LOWER IN PATIENTS WITH AUTOIMMUNE DISEASE THAN IN THOSE WITH OTHER TYPES OF IMMUNE SUPPRESSION

S. Park[1], D. Hippe[1], L. Zawacki[1], M. Bierma[1], S. Bhatia[1], L. Zaba[2], P. Nghiem[1], N. Singh[3]. *[1]University of Washington, Dermatology, SEATTLE, United States of America; [2]Stanford University, Dermatology, Stanford, United States of America; [3]University of Washington, Medicine, SEATTLE, United States of America*

Background: Merkel cell carcinoma (MCC) is twice as likely to recur in immunosuppressed (IS) patients as in immunocompetent (IC) patients. Iatrogenic IS due to autoimmune disease (AD) may influence prognosis differently than intrinsic IS such as due to hematologic malignancy. Moreover, modification of IS medication may improve prognosis.

Objectives: Our objective was to evaluate the risk of MCC recurrence among patients with AD diseases relative to other immunosuppressive conditions among 762 MCC patients from an Institutional review board-approved registry.

Methods: We categorized patients into 3 groups: IS due to AD (IS^{AD}); IS from other causes ($IS^{non\text{-}AD}$) such as hematologic malignancy, solid organ transplant, human immunodeficiency virus; or immune competent (n=31, 70, and 661 respectively). IS^{AD} patients were subcategorized into rheumatoid arthritis (RA) (AD^{RA}, n=13) vs. AD except for RA ($AD^{non\text{-}RA}$, n=18). Descriptive statistics were used to compare the features of different characteristics in each group. Kaplan-Meier survival curves were constructed to assess the cumulative incidence of recurrence in different patient groups. In order to estimate the associations between baseline patient characteristics and the risk of MCC recurrence, Fine and Gray regression models were used with death as a competing risk for recurrence. The multivariable models adjusted for age, sex, and extent of MCC at initial presentation.

Results: Patients with IS^{AD} had lower stage disease (local disease: 58% vs. 36%, p = 0.003) and smaller primary tumors than $IS^{non\text{-}AD}$ (<= 2 cm: 83% vs. 57%, p=0.023). After adjusting for age, sex, and stage, IS^{AD} patients (AD^{RA} and $AD^{non\text{-}RA}$) overall had a 54% higher recurrence rate (hazard ratio (HR): 1.54, p=0.21) than IC patients. In comparison, $IS^{non\text{-}AD}$ group had a 165% higher recurrence rate (HR: 2.65, p<0.001) than IC patients (Figure 1). When considered separately, AD^{RA} pts appeared to have a similar recurrence rate as IC pts (HR: 1.19, p=0.76) while $AD^{non\text{-}RA}$ pts had a higher recurrence rate (HR: 1.83, p=0.16) relative to IC pts. At the time of MCC diagnosis, 80% (n=24) of AD pts were on IS medication including conventional disease modifying drugs, biologics, or oral steroids. After MCC diagnosis, 22% (5 patients) stopped all immunosuppressive medications. Among patients on biologics, 89% (8/9 pts) elected to stop the drug. Eleven pts with AD experienced recurrences. Our study was underpowered to demonstrate associations regarding use of a particular immunosuppressive medication and MCC recurrence.

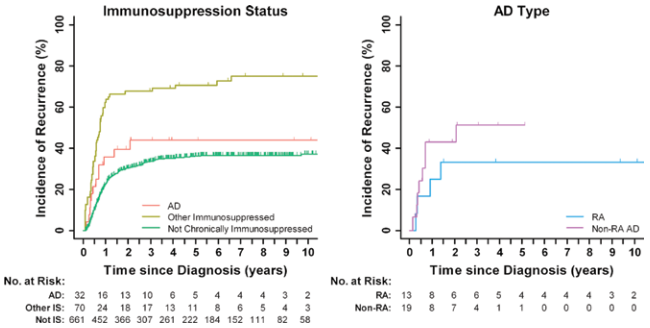

Figure 1. Cumulative incidence of Merkel cell carcinoma recurrence in different patient groups.

AD = autoimmune disease; IS = immunosuppressed; RA = rheumatoid arthritis.There were 4/13, 8/18, 49/70, and 217/661 recurrences in the RA, $AD^{non\text{-}RA}$, other immunosuppressed, and not chronically immunosuppressed groups, respectively. Follow-up time ranged from 26 days to 16 years, with median follow-up times of 4.7 years, 1.6 years, 1.6 years, and 3.9 years for the RA, $AD^{non\text{-}RA}$, other immunosuppressed and not chronically immunosuppressed groups, respectively.

Conclusion: In this cohort, pts with AD appeared to have a better prognosis than intrinsic IS, with RA conferring very little risk above that for immune competent pts.

AB0308 FALL RISK EVALUATION WITH COMPUTERIZED DYNAMIC POSTUROGRAPHY IN RHEUMATOID ARTHRITIS PATIENTS

E. Baran[1], M. A. Dündar[2]. *[1]Hitit University, Physiotherapy and Rehabilitation, Corum,Turkey; [2]Necmettin Erbakan University, Faculty of Medicine, Konya, Turkey*

Background: Patients with rheumatoid arthritis (RA) have a higher risk of falling due to pain and physiological/biomechanical deformities (decreased muscle density, decreased functional stability, changes in gait, etc.) [1]. Although high incidences of falls have been reported in RA patients [1], there are not sufficient data regarding patient-specific fall risk.

Objectives: The aim of this study was to evaluate patient-specific fall risk, via computerized dynamic posturography, in RA patients, and to compare the results with those of age-matched healthy participants.

Methods: A total of 29 patients with RA (9 males, 20 females; mean age: 54.4±6.5 years) and 18 healthy participants (7 males, 11 females; mean age: 53.6±7.1) were included in the study. Detailed demographic, physical, and medical characteristics of the participants were recorded. Dynamic balance was tested with a computerized dynamic posturography, which assesses balance responses to induced postural disruption [2]. A translational ramp test (speed: 0.1 m/s), sinusoid tests (frequencies: 0.25 Hz - 0.50 Hz), and limits of stability evaluations were applied. Ramp and sinusoid tests were evaluated with the eyes open and closed, in the antero-posterior direction, and the participants were instructed to keep their balance during the tests. Limits of stability was evaluated on a static platform, with the eyes open. During the test, the participants were told to carry their pressure center as far as possible by performing the movement only from the ankle (in all directions), without lifting their feet, and trying not to fall.

Results: The groups were similar in terms of demographic and physical characteristics (p>0.05). Patients with RA showed statistically significant dynamic balance alterations compared to healthy participants (p<0.05) (Table 1). The fall test was positive in 31% of the RA patients and 5.6% of the control group (Figure 1).

Table 1. Comparison of the groups in terms of the fall risk assessment criteria

Test Parameters		RA Group (n=29)	Control Group (n=18)	p
1.Ramp	Energy in AP (J)	2051 (1071-2258)	1409 (1224-1644)	0.005*
Eyes Open				
1.	Energy in ML (J)	213 (122-414)	208 (138-259)	0.369
1.	Time in ML (s)	3.9 (3.0-4.4)	3.5 (2.6-3.9)	0.083
2.Ramp	Energy in AP (J)	1939 (1856-2147)	1718 (1334-1929)	0.024*
Eyes Closed				
1.	Energy in ML (J)	224 (174-364)	189 (155-381)	0.539
1.	Time in ML (s)	3.9 (3.5-4.9)	3.4 (3.2-4.5)	0.007*
3.Sinusoid	Gain in AP	1.1 (1.0-1.3)	1.1 (1.0-1.3)	0.809
Eyes closed	Gain in ML	0.3 (0.3-0.4)	0.2 (0.2-0.3)	<0.001*
Eyes open	Gain in AP	1.0 (0.8-1.3)	0.7 (0.6-0.8)	0.003*
4.Limits of Stability	Surface (cm^2)	13.0 (10.0-15.0)	21 (17.7-21.5)	<0.001*

Data are presented as median and interquartile range. p value; Mann Whitney U Significance Test results between groups. (*): statistically significant difference (p<0.05). AP: Antero-posterior, ML: Medio-lateral

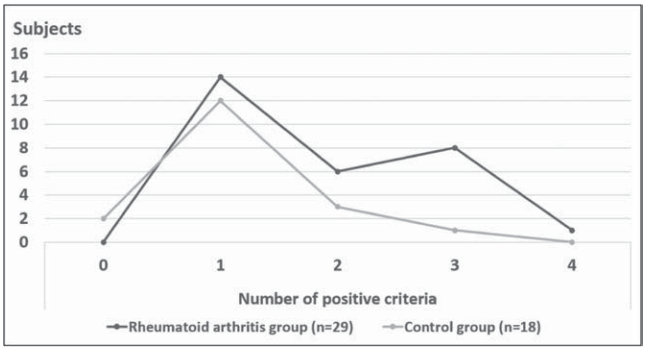

Figure 1. Distribution of participants according to the number of positive criteria. The fallers met at least three criteria.

Conclusion: The results of this study showed that dynamic postural responses to destabilizing conditions are significantly altered in patients with RA compared to healthy controls. Determining the patient-specific fall risk is important in designing personalized rehabilitation programs and reducing the risk of injury.

AB0309 ASSOCIATION BETWEEN RHEUMATIC DISEASE COMORBIDITY INDEX AND PULMONARY INVOLVEMENT IN RHEUMATOID ARTHRITIS

E. Hannech[1,2], A. Ben Tekaya[1,2], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. *[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; [2]Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia*

Background: Pulmonary involvement is one of the primary contributors of morbi-mortality among patients followed for Rheumatoid Arthritis (RA) [1]. Comorbidities are also independent factors of poor outcomes on those debilitated population.

Objectives: We aimed to assess association between comorbidity and pulmonary involvement in rheumatoid arthritis

Methods: We conducted a retrospective study in our rheumatology department including patients with established RA according to the ACR/EULAR 2010 criteria. Rheumatic Disease Comorbidity Index (RDCI) was calculated for each patient. Clinical characteristics, radiological findings, and respiratory function tests (PFTs) for pulmonary involvement were collected.

Results: There were 255 patients: 212 female (83.1%) and 43 male (16.9%). The mean age was 58.92 ± 10.72 years [25-85]. The mean RDCI was 1.14 ± 1.25 [0-6]. Pulmonary involvement was noted in 115 patients (45.3%). It was asymptomatic in 50.6% of cases. Reported clinical symptoms were dyspnea (36.1%), chronic cough (8.4%), and dyspnea with chronic cough (4.8%).

PFT showed a restrictive syndrome in 34.9% of cases, an obstructive syndrome in 4.8%, a mixed syndrome 3.6% and was normal in 56.6% of patients. Non-specific interstitial pneumonia was noted in 26.6% of patients, followed by nodular lung disease in 11.4 %, usual interstitial pneumonia in 11.4%, BOOP in 6.3%, and then pleural nodules in 6.3%.

An association was noted between RDCI and pulmonary involvement (presence: 1.7 ± 1.3 vs absence: 0.6 ± 0.8, $p<10^{-3}$).

Conclusion: In conclusion, there was an elevated comorbidity index in patients with pulmonary involvement. Comorbidities may be a predictive factor of extra-articular manifestations. The early management may improve outcomes in RA patients.

Background: Given the progressive change in the management of inflammatory diseases,an observational study was conducted on the management of Early Rheumatoid Arthritis (ERA) in Catalonia.

Objectives: To know the management of ERA in Catalonia, to assess whether the recommendations of the EULAR/ACR guidelines are followed and to study the causes of management variability,to set improvement objectives.

Methods: An observational,descriptive,and cross-sectional study was conducted,with data collection from June 15 to 30, 2021.The rheumatologists' partners of the Catalan Society of Rheumatology were the object of study. An online survey was conducted with 304 members on the management of the ERA. Variables related to the characteristics of the respondents,the derivation and variables of the disease including clinical variables,type of treatment and outcomes used for follow-up including the impact of the SARS-CoV2 pandemic were included. The univariate study was performed using a study of proportions with Pearson's correlation.

Results: A total of 105 members (34.5%) responded to the survey.11.6%>60 y, only 7.8% <30y. 99% were in public assistance.The number of rheumatologists per service is 7.2[1-17],but 34.2% had< 5 rheumatologists,with a reference population of 200,000-300,000p in 42% of respondents.The number of weekly visits made is 67.5[20-130].42.2% do not have a monographic RA or ERA dispensary and 30.4%not have specialized nursing.**Characteristics of ERA**:77.5% are derived from primary care(PC),52% have been between 6 weeks,42.1%>3 months.54.9% make a first visit within 2-4 weeks of PC referral and 14.7%> 8 weeks.100%provide previous analysis,only 47% had had RX performed.98% were previously treated(50.4%NSAIDs + CG,36.1%NSAIDs,12.3% CG).4.3% had GC doses>10 mg/day,11.3%> to 20mg/day.**The treatment**:DMARDs of choice in 100% is MTX,44.1% start doses of 10mg/week and 3.9%7.5 mg/week.The route of choice is oral(55.9% vs 44.1%).92.2% associate GC and 31.7% have not withdrawn them after 6 m.57.8% consider the maximum of MTX 25mg/W.87.1% use doses<10 mg/day,with the most used dose being 5 mg/day(35.6%).Follow-up after the

start of DMARDs is performed 72.5% between 4-6 weeks and 12.7% is performed by nursing.100% use DAS 28 and 53.5% also CDAI.31.4% perform **PROs**(HAQ 83.3%,RAPID 3 14.3%).The use of **systematic ultrasound** is collected in 33%, being himself who performs it in 59.9% and an expert rheumatologist in 46.1%.Finally, when asked about **incidence of pandemic** in the follow-up,53.3% consider that it is doing the same as before. 46.1% consider that telephone visits are not suitable for the follow-up of the ERAvs14.7% who consider that Yes.When questioning the situations in which they consider them to be appropriate,75.9% that it was adequate in the control after the beginning of the DMARDs.Regarding the treatment of ERA, 66% delayed the onset of biological DMARDs, 72.1% due to difficulty of follow-up and only 8.8% due to an increased risk of infection. When performing the **univariate analysis**, it is evident that having a monographic dispensary is associated with earlier onset of MTX($p< 0.001$)and at doses≥15 mg/W($p = 0.05$),greater nursing intervention($p< 0.001$),greater use of PROs($p = 0.008$)and there is a tendency to a shorter waiting time for first visits($p = 0.07$).It is also associated with not considering telephone visits($p< 0.001$), making them in less than 25%($p< 0.0001$).Similarly,hospital level is directly proportional to initiation at higher doses of MTX($p< 0.0001$),lower use of GC<10mg.Among the rest of the variables, no association has been found.

Conclusion: The recommendations of EULAR/ACR in the treatment and follow-up of ERA are consistently followed,although the wide use of MTX orally is striking.It is evident that the variable that most influences the early onset of FAME and at higher doses,is a monographic dispensary,as well as greater presence of nursing and performance of PROs.

AB0311 RHEUMATOID ARTHRITIS AND OSTEOPOROSIS: FREQUENCY AND ASSOCIATED FACTORS

M. Brahem[1], R. Sarraj[1], A. Ben Salem[1], R. Grassa[1], S. Abdellatif[1], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: In rheumatoid arthritis (RA), persistent systemic inflammation may cause bone and cartilage destruction and systemic osteoporosis (OP).

Objectives: We conducted this study to determine the frequency of OP in RA patients and to focus on associated factors.

Methods: This is a retrospective descriptive and analytic study including consecutive RA patients. The epidemiological, clinical, biological data and the measurement of bone mineral density were collected from patients' records. A statistical analysis was performed to study the clinico-biological profile of osteoporotic patients and determine factors associated with the development of OP in RA patients.

Results: Seventy-one of RA patients were recruited: 67 females (94.4%) and 4 males (5.6%) with a mean age of 54.28 years ± 11.09 [30-75]. OP was noted in 45.1% of cases (32 patients). The mean T-scores at the lumbar and femoral sites were -2.7 ± 0.6 SD and -1.3 ± 1 SD, respectively. Patients with OP were older (58.8 ± 7.6 years vs 50.5 ± 12.1 years; p <0.01) and with a greater number of postmenopausal women than patients with normal bone density (68.7% vs 41%; p=0.02). Osteoporotic patients had RA duration longer than the other group (15.2 ± 12.5 years vs 11.9 ± 8.2 years; p=0.02) and more extra-articular manifestations associated with RA (100% vs 76.9%; p < 0.01). Both groups were treated with corticosteroid drugs with similar frequency, although patients with normal bone density received biotherapy more frequently than patients with OP (23% vs 18.7%; p= 0.03). The two groups had almost similar disease activity DAS28 ESR (44,3 ± 34 vs 42.7 ± 30.7; p=0.2). The following parameters were not associated with the occurrence of OP in our series: gender, smoking, BMI, ESR, CRP, ACPA, RF, erosive and deforming character of RA.

Conclusion: OP is an extra-articular disease that must be systematically screened throughout the follow-up. In our study, there was no significant difference in disease activity at both groups of patients. However, patients with OP had longer duration of RA, more extra-articular manifestations and were less frequently treated with biotherapy.

AB0312 BODY COMPOSITION AND BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

O. Dobrovolskaya[1], A. Feklistov[1], N. Demin[1], A. Sorokina[1], O. Nikitinskaya[1], N. Toroptsova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Osteoporosis, Moscow, Russian Federation*

Objectives: To assess body composition and bone mineral density (BMD) in rheumatoid arthritis (RA) women compared to patients with osteoarthritis (OA).

Methods: 133 women with RA and 45 women with OA aged 50 and over were enrolled in the study. Body composition (fat mass (FM), lean mass and bone mineral component (BMC)) and BMD of the lumbar spine, femoral neck and total hip were measured using dual-energy X-ray absorptiometry (DXA). Appendicular muscle mass (AMM) and appendicular mass index (AMI) were calculated. Muscle strength was assessed in all patients. The criteria of the European Working group on Sarcopenia in Older people 2 (EWGSOP2) were used for low muscle mass and sarcopenia. Osteoporosis was determined in accordance with WHO criteria.

Results: Mean age of RA patients and women with OA was 61.3±7.1 and 61.9±6.2 years, respectively ($p>0.05$). BMC and AMM were lower in RA patients than in women with OA: BMC - 1948.6±425.7g and 2167.1±398.1g, respectively ($p=0.004$); AMM - 17.5±2.9 kg and 20.1±2.7 kg, respectively ($p<0.001$). 27 (20.3%) RA women and only 1 (2.2%) person with OA had low AMM ($p=0.004$). The mean value of AMI was 6.8±1.0 kg/m^2 and 7.5±0.9 kg/m^2 in RA and OA patients, respectively ($p<0.001$). Total FM was 28.3±8.5 kg and 33.2±9.8 kg in RA and OA women, respectively ($p=0.003$). At the same time, we found no differences in the percentage of fat mass: 39.2±5.7% in RA patients and 39.9±5.8% in persons with OA ($p>0.05$). Overfat was discovered in 99 (77.4%) and 38 (84.4%) in women with RA and OA, respectively ($p>0.05$). All women with low AMM/AMI had low muscle strength and were diagnosed with confirmed sarcopenia.

In RA patients BMD at any region was less than in women with OA: in the lumbar spine – 1.026±0.174 g/cm^2 and 1.114±0.177 g/cm^2, respectively ($p=0.009$); in the femoral neck – 0.844±0.151 g/cm^2 and 0.914±0.137 g/cm^2, respectively ($p=0.005$) and in the total hip 0.878±0.148 g/cm^2 and 0.986±0.117 g/cm^2, respectively ($p<0.001$). Normal BMD was found in 33 (24.8%) and 24 (53.3%) women with RA and OA, respectively ($p=0.0004$). 42 (31.6%) patients with RA and 6 (15.4%) women with OA had osteoporosis ($p=0.017$).

Conclusion: RA patients had lower BMC, AMM/AMI, total FM and BMD compared to women with OA, and they were significantly more likely to have sarcopenia and osteoporosis.

AB0313 CLINICAL FEATURE OF 100 CASES OF METHOTREXATE ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS WITH RA PATIENT

T. Kameda[1], Y. Ushio[1], S. Nakashima[1], H. Shimada[1], R. Wakiya[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Kita-gun, Japan*

Background: Lymphoproliferative disorders (LPDs), including malignant lymphoma, are known to occur in RA patients treated with disease modified antirheumatic drugs (DMARDs). In particular, LPD associated with methotrexate (MTX)-treated RA is often referred to as MTX-associated LPD (MTX-LPD). MTX-LPD have various clinical feature and histological findings[1)]. We have accumulated MTX-LPD cases in patients with rheumatoid arthritis (MTX-RA-LPD).

Objectives: We clarified the clinical characteristics of MTX-RA-LPD. In addition, we examine the prognosis of MTX-LPD in RA patients.

Methods: We enrolled 100 RA patients who diagnosed MTX-LPD from 2005 to 2021. We collected as follow data based on clinical reports retrospectively; 1) age, 2) gender, 3) duration from RA onset to LPD onset, 4) total dose of MTX, 5) duration of MTX administration, 6) presence of extranodal lesion 7) histological findings, 8) treatment for LPD, 9) 5-year survival rate.

Results: The mean age of 100 MTX-RA-LPD patients (M:F=30:70) were 66.7 ± 10.7 years old, and the duration from RA onset to LPD onset were 25.2 ± 11.0 years. The total dose of MTX and duration of MTX administration were over 2,600mg and over 5 years, respectively. The extranodal lesions were found in 51%, and diffuse large B cell lymphoma was the most common histological findings. Spontaneous regression was observed in 68%. The 5-year survival rate of MTX-RA-LPD was as high as over 85%.

Conclusion: The clinical features of MTX-RA-LPD were similar to those previous reports. Furthermore, we suggested a good prognosis for MTX-RA-LPD.

AB0314 MULTIMORBIDITY BURDEN IN RHEUMATOID ARTHRITIS

D. C. Varela[1], J. C. Sarmiento Monroy[2], M. J. Mantilla Ribero[3], C. Villota[4], M. Rodriguez-Jimenez[5], R. D. Mantilla Hernández[6]. *[1]Universidad Pontificia Bolivariana, Rheumatology Department, Medellín, Colombia; [2]Hospital Clinic, Rheumatology, Barcelona, Spain; [3]Universidad de la Sabana, Rheumatology, Bogotá, Colombia; [4]IPS Servicio Integral de Reumatología e Inmunología Dr Orlando Villota, Rheumatology, Pasto, Colombia; [5]Universidad del Rosario, Rheumatology, Bogotá, Colombia; [6]Center of Dermatology and Rheumatology (FUNINDERMA), Rheumatology, Bogotá, Colombia*

Background: Multimorbidity in patients with rheumatoid arthritis (RA) has been described as the coexistence of two or more chronic diseases and is the most common cause of death in this population.

Objectives: To describe the prevalence of multimorbidity and mortality trends in a well-characterized cohort of patients with RA.

Methods: A retrospective cohort study of patients with RA (1987 ACR criteria) was conducted. Each patient was evaluated and followed by a rheumatologist in a single outpatient private center in Bogotá, Colombia, from 2014 to 2021. Categorical variables were expressed in frequency and percentage and quantitative variables in mean and standard deviation or median with interquartile range, depending on the distribution of the data. Statistical package: SPSS 25.

Results: A total of 783 patients were included. 11% of patients with RA present multimorbidity. Baseline characteristics were as follows: female gender 81.6%, mean age 51.8±11 years, mean disease duration 8 (IQR 3-15) years, RF positive 80.1%, ACPA positive 58.2%, and erosions 24.9%. Most patients have received glucocorticoids (89.8%), and conventional synthetic DMARDs (97.8%), being prednisone and methotrexate the most frequently prescribed. Hypertension was prevalent in 27.7%, osteoporosis 19.3%, malignancies in 5.5% and principal infection was urinary infection 14.3%. Polyautoimmunity was present in 5.7% most frequently Autoimmune thyroid diseases 10.6% and Sjögren syndrome 9%. After a median of 73 months of follow-up, the mortality rate was 1% of the entire cohort, being cardiovascular disease and COVID-19 infection the main causes.

Conclusion: Patients with RA have an important multimorbidity burden and this increased risk of adverse outcomes and mortality.

AB0315 HYPERURICEMIA AS A FACTOR INTERRELATED WITH COMORBIDITY AND TREATMENT RESULTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Fonturenko[1,2], V. Mazurov[1,3], R. Bashkinov[1,3], M. Petrova[1,4], O. Inamova[1,4], I. Gaydukova[1,2]on behalf of group for the study of hyperuricemia in patients with rheumatic diseases. *[1]North-Western State Medical University named after I.I. Mechnikov, Chair of Therapy and Rheumatology of Temporary Disability and Medical Care Quality Expertise named after E. E. Eichwald, Saint-Petersburg, Russian Federation; [2]St. Petersburg State Budgetary Healthcare Institution Clinical Rheumatology Hospital No. 25, Ambulatory-Consultative Department, Saint-Petersburg, Russian Federation; [3]St. Petersburg State Budgetary Healthcare Institution Clinical Rheumatology Hospital No. 25, City Clinical Center of Gout, Saint-Petersburg, Russian Federation; [4]St. Petersburg State Budgetary Healthcare Institution Clinical Rheumatology Hospital No. 25, Chief Medical Officer, Saint-Petersburg, Russian Federation*

Background: Uric acid (UA) is a risk factor of cardiovascular comorbidity in total population [1,2]. However, data about role of hyperuricemia (HU) in rheumatoid arthritis (RA) are limited.

Objectives: to evaluate the interrelations between HU and disease activity, comorbidity, treatment results in patients (pts) with RA.

Methods: Three age and sex matched groups of the pts were formed on the base of Saint-Petersburg rheumatological register (01JAN 2011 - 31DEC2021): group of RA pts with HU (n=292, criteria EULAR2010), group of RA pts without HU (n=292), and group of pts with gouty arthritis (GA, n=300). HU registered if patient had serum level of UA ≥360 μmol/l in ≥3 tests in absence of GA. Pts with secondary HU excluded. RA activity was measured with DAS28. Statistics was performed with SPSS 2020.

Results: Demographic, clinical characteristics, RA treatment in both RA groups were comparable, however decrease of DAS28 during 6-month RA treatment in RA pts with HU was lower than in RA with absence of HU, Table 1.

Table 1. Clinical, laboratory characteristics, and treatment efficacy in RA and GA

Parameter	RA with HU (n=292)	RA without HU (n=292)	GA (n=300)
Age (Mean±SD), years	60.53±12.47	58.07±13.24	57.7±11.85
Female, n (%)	253 (86,64)	282 (96.57)	275 (91.67)
Duration of clinical manifestation, years (mean±SD)	3.56±1.58	4.13±1.75	3.42±2.12
ESR, mm/h (mean±SD)	29.25±14.67	28.22±14.39	30.14±14.43
C-reactive protein, mg/l (mean±SD),	21.10±20.88	23.69±29.93	22.48±21.49
6 months decrease of DAS28 (mean±SD)	1.09±0.28	1.48±0.35*	NA
Medicamental ULT, n (%)	25	NA	100
Efficacy of ULT, n (%)	68 (23.29)	NA	160 (53.33)

ESR – Erythrocyte Sedimentation Rate; ULT – urate-lowering treatment; DAS28 – Disease activity score; NA – not applicable; intergroup difference with p<0.001.

Presence of the HU in RA pts was associated with increased comorbidity as compared with age, sex and activity matched RA pts without HU, and with GA, Figure 1.

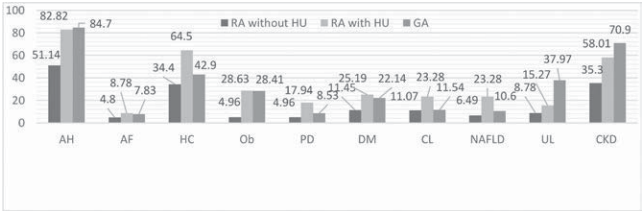

Figure 1. Comorbidity in pts with RA without and with HU, and in GA pts.

Intergroup difference of comorbidities between pts with RA without and with HU or with GA is significant with p <0.000. Intergroup difference between RA with HU and GA is significant with p<0.01.

AH - arterial hypertension, AF - atrial fibrillation, HC – hypercholesterolemia, Ob – obesity, DM - diabetes mellitus type 2, CL – cholelithiasis, NAFLD - non-alcoholic fatty liver disease, UL – urolithiasis, CKD – chronic kidney disease (st.1-4).

ULT was administered to pts with RA and HU 4 times less frequently than to pts with GA. The effectiveness of ULT in RA and HU is two times lower than in GA.

Conclusion: 1) HU negatively affects the decrease of RA activity. 2) HU in RA is associated with increased comorbidity 3) ULT is assigned to pts with RA and HU 4 times less frequently than to pts with GA and is ineffective in 76.71% of cases.

Additional research is needed to evaluate the influence of UAs' serum levels' normalization as factor that could improve results of RA treatment and comorbidity.

AB0316 SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: PREVALENCE AND ASSOCIATED FACTORS

N. Toroptsova[1], O. Dobrovolskaya[1], A. Sorokina[1], A. Feklistov[1], N. Demin[1], O. Nikitinskaya[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*

Objectives: To evaluate the prevalence of sarcopenia (SP) and associated factors in patients with rheumatoid arthritis (RA).

Methods: 159 women (mean age 58.7±8.8) with confirmed RA according to ACR/EULAR criteria (2010) were enrolled. Hand grip strength was measured using mechanical dynamometry. Dual-energy X-ray absorptiometry (DXA) was performed to assess the body composition and bone mineral density (BMD) of the lumbar spine, femoral neck and total hip. SP was defined as muscle strength < 16 kg and appendicular lean mass index (ALMI) <5.5 kg/m^2 or appendicular lean mass (ALM) <15 kg. RA activity was assessed by C-reactive protein (CRP) and disease activity score using 28 joint counts and erythrocyte sedimentation rate (DAS28-ESR). The relation between low ALM with disease parameters was analyzed using Spearman's r. Factors associated with SP were evaluated using regression analysis.

Results: SP was diagnosed in 33 (20.8%) women with RA. Patients with SP did not differ in age from those without it (59,0±8,9 and 58,7±8,8 years, respectively, p>0,05). 75.8% patients with SP and only 27.8% women without SP had normal BMI (p<0.001). Osteoporosis was diagnosed significantly more often in patients with SP than in women without SP (54.5% and 23.0%, respectively, p<0.001). In women with RA, ALM and ALMI correlated with body mass index (BMI), bone mineral component, BMD and total fat mass. ALM and ALMI did not correlate with age, disease duration, the use of glucocorticoids, DAS28, CRP, total protein, and creatinine levels. In univariate regression analysis, SP was associated with BMI, bone mineral component, BMD of lumbar spine and proximal femur, total fat mass. In multivariate regression analysis, SP was positively associated with the presence of osteoporosis [OR 2.98, 95%CI (1.22-7.30), p = 0.017] and BMI < 25 kg/m^2[OR 6.75, 95%CI (2.45-18.56), p <0.001]. No other significant associations were found.

Conclusion: Among patients with RA, 1/5 of them had SP, which was positively associated with BMI and the presence of osteoporosis, but not with the age, activity and duration of the disease.

AB0317 QUALITY OF LIFE AND LOCOMOTIVE FUNCTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Dobrovolskaya[1], O. Nikitinskaya[1], A. Feklistov[1], N. Demin[1], A. Sorokina[1], N. Toroptsova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*

Objectives: To evaluate quality of life and its relationship with muscle strength and physical performance in patients with rheumatoid arthritis (RA).

Methods: 157 women with RA (median age was 58.6±8.8 years, median duration of RA was 8.0 [4,0; 14] years) were included in the study. Assessment of functional disability and quality of life was carried out using Health Assessment Questionnaire Disability Index (HAQ), EQ-5D (index and visual analog scale, VAS), Hospital Anxiety and Depression Scale (HADS, with two subscales for anxiety and depression, HADS-A and HADS-D), Rheumatoid Arthritis Impact of Disease (RAID). Also, all patients underwent tests to determine muscle strength by hand dynamometry and test "Chair stand" and physical performance by the Short Physical Performance Battery (SPPB). Dual-energy X-ray absorptiometry of the whole body, lumbar spine and proximal hip was done. Spearman's correlation test was performed.

Results: 88.5% of RA patients had low muscle strength, 61.1% of people had low physical performance. No correlation was found between physical performance and age, RA activity, body composition and BMD. In persons with reduced physical performance, HAQ, EQ-5D index, VAS and RAID were worse than in women with normal physical function (p<0.0001; p<0.0001; p=0.004; p=0.010, respectively). Also, these patients had more pronounced signs of anxiety and depression, assessed using HADS-A (p=0.004) and HADS-D (p=0.001). HAQ positively correlated with the number of comorbidities (r=0.35, p<0.001) and negatively correlated with the SPPB and gait speed (r=0.35, r=-0.39 and r=-0.37, respectively, p<0.001). EQ-5D index positively correlated with SPPB and gate speed (r=0.44 and r=0.39, respectively, p<0.001). HADS-A and HADS-D positively correlated with the number of comorbidities (r=0.35 and r=0.34, respectively, p<0.001). HADS-A negatively correlated with the biological therapy duration (r=-0.36, p=0.032) and with BMI (r=-0.34, p<0.001). HADS-D negatively correlated with the SPPB (r=-0.36, p<0.001). RAID negatively correlated with the biological therapy duration (r=-0.35, p=0.032) and with SPPB (r=-0.35, p<0.001).

Conclusion: 88.5% of RA patients had low muscle strength and 61.1% - low physical performance. Quality of life negatively correlated with physical performance.

AB0318 PREVALENCE OF SECONDARY SJOGREN'S SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS- A SINGLE CENTER STUDY FROM NORTHERN INDIA

S. Mehra[1], N. Hariharan[2], S. Deka[2]. *[1]Jaypee Hospital, Rheumatology, Noida, India; [2]Technology | Healthcare | Big Data Analytics, Real World Evidence, Haryana, India*

Background: Sjogren's syndrome (SS) is a systemic autoimmune disease characterized by lymphocytic infiltration of salivary and lacrimal glands leading to dry eyes and dry mouth. Sjogren's syndrome either present alone (primary Sjogren's syndrome) or sometimes can occur with other autoimmune diseases like rheumatoid arthritis, systemic lupus erythematosus, and scleroderma. In such instances, the condition is termed secondary Sjogren's syndrome. SS may be a marker of more aggressive joint disease in patients with RA, and hence it is essential to characterize the symptoms in the RA cohort, which may help in the management and treatment of the disease.

Objectives: Primary Objective

The primary objective of the current study is to estimate the prevalence of secondary Sjogren's syndrome in a cohort of patients with rheumatoid arthritis.

Secondary Objective

To compare the clinical characteristics in rheumatoid arthritis patients with Sjogren's syndrome and in rheumatoid arthritis patients without Sjogren's syndrome.

Methods: The study was conducted from 2016-2018 in a tertiary care hospital in the Department of Rheumatology, New Delhi, India. Patients with a rheumatologist-diagnosed RA were enrolled. There were 726 patients with rheumatoid arthritis. Patients were enquired about their symptoms. Out of 726, 193 had secondary Sjogren's syndrome (26.58%). In patients without Sjogren's syndrome, complete clinical data were available only for 377 patients hence the analysis on the comparison of clinical characteristics was limited to 377 patients. The other patients were excluded due to lack of the data required for the study.

Results: It was identified that out of 726 patients, 193 had symptoms of secondary Sjogren's like dry eyes dry mouth, or both. It was found that in patients with secondary Sjogren's syndrome (n=193), the mean age was significantly higher than those patients without secondary Sjogren's syndrome (n=377) [52.58 ± 12.36 Vs. 48.42 ± 13.98, p=0.0005]. Similarly, the mean disease duration was significantly higher among RA patients with secondary SS than those without SS [10.76 ± 8.34 Vs. 6.81 ± 7.29, p<0.0001]. Similarly, co-morbidities like hypertension, diabetes mellitus, and hypothyroidism were more seen in patients with rheumatoid arthritis with Sjogren's syndrome.

In a meta-analysis involving 18 studies[1], it was identified that the prevalence of SS in RA was 19.5%. The differences in the prevalence of secondary SS in RA patients could be attributable to inter-ethnic variation, disease duration, and clinical scores employed in the studies. Similar to our study, Santhosh et al.[2] reported that patients with secondary SS had a longer disease duration than those without secondary SS.

Conclusion: The prevalence of Sjogren's syndrome among patients with rheumatoid arthritis in the North Indian cohort of patients with RA was 26.58%.

AB0319 PREALBUMIN SERUM LEVEL AS A USEFUL TOOL IN THE ASSESSMENT OF MALNUTRITION IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

M. Ardhaoui[1], J. Mahbouba[1], F. Naffati[2], F. Fhima[1], M. Ghali[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology, Monastir,Tunisia;* [2]*Fattouma Bourguiba hospital, Biochemistry, Monastir,Tunisia*

Background: Protein-energy malnutrition is a common condition among elderly patients with RA associated with a poor prognosis. Although many screening tools are developed, there's no consensus on which test is more reliable in clinical practice. Serum prealbumin (PAB) may be a useful malnutrition biomarker.
Objectives: Our objective is to evaluate the usefulness of serum PAB in the assessment of malnutrition in elderly patients with RA.
Methods: We conducted a prospective study including RA patients who were followed in rheumatology department and aged 65 years or older. We studied malnutrition prevalence, risk of complications related to malnutrition and PAB serum concentrations. The mini-nutritional assessment (MNA) score was used as the reference method to determine malnutrition. We also dosed inflammatory proteins: Orosomucoide (Oroso), C-reactive protein (CRP) and Haptoglobine (Hapto). For the prognosis assessment, we calculated the Geriatric nutritional risk index (GNRI) and the Prognostic Inflammatory and Nutritional Index (PINI).
Results: Sixty-three patients (52 female and 11 male) were included. Their mean age was 68.17±4.35 years. The average DAS28 was 3.72±1.48. The mean MNA total score was 20.19 ± 4.71. According to MNA, the prevalence of malnutrition was 20.6%. 55.6% of the patients were at risk of malnutrition and only 23.8% of patients had a normal nutritional status. The median PAB was 0.16 g/L with an IIQ of [0.04-0.24] and extremes ranging from 0.01 to 0.37 g/L. According to PAB, 35.8% of patients had a normal level above 0.20 g/L, 17% had PAB levels between 0.15 and 0.19 g/L, indicating moderate malnutrition and 47.2% of patients had PAB levels below 0.15 g/L, indicating severe malnutrition. Concerning inflammation proteins: the mean CRP was 18.96 ± 27.8 mg/L. 28.6% of patients had a CRP > 15 mg/L, of which 9.5% had a CRP > 50 mg/L. The mean Oroso was 1.29 ± 0.46 g/L [0.6-2.2]. 52.5% of our patients had an elevated oroso value. The mean Hapto was 2.07 ± 0.97 g/L [0.31-5.29]. 42.9% of patients had an increased value above 2.5 g/L. Concerning prognosis indexes, the median GNRI was 116.47 with an IIQ of [106.6-125.12] and extremes ranging from 70.06 to 145.02. The median PINI was 1.77 with an IIQ of [0.47-10.21] and extremes ranging from 0.05 to 222.16. Statistical analysis showed a significant association between PAB and MNA with p=0.05. Negative correlation was found between PAB and inflammatory proteins; with Oroso (p=0.001), CRP (p=0.006) and Hapto (p=0.03). By analysing prognosis indexes, significant negative correlation of the serum PAB was found with the GNRI (p=0.003) and the PINI (p=0.001).
Conclusion: We conclude that PAB could represent a feasible and reliable tool in the diagnosis of malnutrition. It is a good biomarker for the prognosis and the assessment of the risk of complications related to malnutrition among the elderly patients with RA.

AB0320 ASSOCIATION OF THE BIOMARKERS SOLUBLE ST2, GALECTIN-3, N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE, PENTRAXIN WITH MYOCARDIAL DYSFUNCTION DETECTED BY SPECKLE TRACKING ECHOCARDIOGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS PRIOR TO BIOLOGICAL THERAPY

I. Kirillova[1], T. Popkova[1], Y. Gorbunova[1], M. Diatroptov[1]. [1]*V.A. NASONOVA RESEARCH INSTITUTE OF RHEUMATOLOGY, Moscow, Russian Federation, Laboratory of Systemic Lupus Erythematosus, Moscow, Russian Federation*

Background: Risk of developing cardiovascular complications and death in rheumatoid arthritis (RA) is 50% higher than in the total population. The biomarkers soluble ST2 (sST2), galectin-3, pentraxin and N-terminal pro-brain natriuretic peptide (NT-proBNP) provide prognostic information in pts with heart failure.
Objectives: To determine the frequency of myocardial dysfunction (lower global longitudinal epicardial strain of left ventrical (GLES LV) using echocardiographic method of speckle tracking, the level of NT-proBNP, pentraxin, galectin-3 and sST2 in patients (pts) with RA prior to therapy with bDMARDs.
Methods: A total of 41 pts with RA (ACR/EULAR criteria, 2010) were included in the study: 63% of women, age 56 [37;66] years, disease duration 24 [8;96] months; DAS28 6,01 [5.3;6.3], positive for ACCP (92%), RF (78%), without cardiovascular diseases and prior administration of bDMARDs. All pts underwent echocardiography, tissue Doppler imaging and the speckle tracking assessment of GLES LV. 44% of RA pts received methotrexate (median dose - 15 (15;20) mg / week.), 35% - leflunomide, 9.3% - sulfasalazine, 7% - hydroxychloroquine, 67.4% - glucocorticoids (median dose - 5 (4;8) mg / day.), 74% - nonsteroidal anti-inflammatory drugs. In each RA pts, we measured plasma concentrations of sST2 (Cristal Diagnostics, San Diego), galectin-3 (Bender MedSystems GmbH Biocenter, Vienna Austria) NT-proBNP (Roche Diagnostics, Switzerland) and pentraxin (Hycult Biotech, Netherland). The control group consisted of 10 healthy subjects, which were matched by sex and age.
Results: : In pts with RA speckle-tracking method detected lower global longitudinal epicardial strain (GLES)(–16.5 [-14.6; -18.5]%), compared to the healthy control group (–21.58 [-22.1;-20.4] %, p=0.0001). 27(67%) RA pts showed a decrease GLES. RA pts also had higher levels of NT-proBNP (114.8 [45.1; 277.5] pg/ml vs 52 [40.5; 69.1] pg/ml, p<0.05), lower levels of sST2 (10.6 [9.2; 13.1] ng/ml vs 13.5 [11.0; 19.7] ng/ml, p<0.04) compared to control group.
All RA pts were divided into 2 groups: group 1- with low GLES, group 2 - with preserved GLES. In group 1, the levels of ST2 were significantly lower than in group 2 (Table 1). There were no differences in left ventricular ejection fraction, LV sizes, LV myocardial mass index, NT-proBNP, pentraxin, galectin-3 levels between groups.

Table 1. Levels of biomarkers in groups

	low GLES, (n=27)	Normal GLES, (n=14)	p
sST2, ng/ml	13.2 [10.6;17.0]	18.3 [13.7;60.9]	<0.05
Pentraxin, ng/ml	0.29 [0.05;0.42]	0.3 [0.02;0.79]	>0.05
galectin-3, ng/ml	4.0 [2.6;6.9]	4.3 [3.2;5.3]	>0.05
NT-proBNP, pg/ml	105 [42;260]	94 [35.5;378.8]	>0.05

There were negative correlations between the global longitudinal epicardial strain and age (r=-0,9, p<0,02), E velocity LV (r=-0,5, p<0,04), sST2 (r=-0,5, p<0,02). Galectin-3 correlates with left atrial volume (r=0,4, p<0,04), septal e' velocity (r=0,6, p<0,008). ST2 levels correlate with ESR (r=0,6, p<0,04), CRP (r=0,5, p<0,002).
Conclusion: In pts with RA frequently (67%) were detected lower global longitudinal epicardial strain, higher levels of NT-proBNP and lower levels of sST2. In RA pts the sST2 biomarker is better associated with inflammatory activity and myocardial dysfunction.

AB0321 ADHERENCE TO MEDITERRANEAN DIET AND PREVALENCE OF CARDIOVASCULAR RISK FACTORS IN RHEUMATIC DISEASES

S. Rekik[1], S. Nouicer[1], S. Boussaid[1], S. Jemmali[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta, Rheumatology,Tunis,Tunisia*

Background: Rheumatic diseases (RD) are autoimmune inflammatory arthritis. However involvement to other organs can occur and leads to atherosclerosis and cardiovascular (CV) risk factors. Mediterranean diet (MD) has attracted considerable interest because it seems to offer significant benefits to that end.
Objectives: To evaluate the role of MD in the development of the cardiovascular risk factors in RD.
Methods: We conducted a cross-sectional study including patients with RA (ACR-EULAR 2010 criteria) or with SA (ASAS 2009 criteria), in remission or in low activity disease and with no history of cardio vascular risk factors before the diagnosis of their RD. Sociodemographic and disease related data were collected: Disease Activity Score (DAS28-CRP), Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) and medication. We asked the patients to complete the 14-items MD adherence questionnary. We evaluated the association of adhrence to MD with cardiovascular risk factors: obesity, type-2 diabetes, hyperlipidemia and hypertension. We estimated odds ratios for each cardiovascular risk factors and their 95% confidence intervals. In all analyses, the

high adherence category of MD adherence score [10–14) was considered the reference category.

Results: We included 61 patients (40 women and 21 men) with a mean age of 42.2 ± 1.1 years old [20-66]. Among them, 32.7% belong to urban environment and 26.2% were professionally active. The mean disease duration was 83.2 months [9-180]. The mean DAS28-CRP was 1.2 [0.8-1.9] and the mean ASDAS-CRP was 1.8 [1.1-2.01]. Methotrexate was used by 52.4%, either as monotherapy or combination and biological in 47.6 %. Thirty patients had high adherence to MD (H-MD) and thirty-one had medium or low adherence to MD (L-MD). We found that higher adherence to the MD is inversely associated with the prevalence of each of the four cardiovascular risk factors, results are shown in Table 1.

Table 1. Prevalence of cardiovascular risk factors and odds ratio in high adhrence to Mediterranean diet in rheumatic diseases.

	Prevalence %	Odds ratio	95% confidence intervals
Obesity	57.4	0.017	[0.03-0.93]
Type-2 diabetes	50.8	0.01	[0-0.019]
Hyperlipidemia	50.8	0.126	[0.04-0.3]
Hypertension	42.6	0.13	[0.43-0.4]

Conclusion: Our results suggest that the healthy effects of the MD observed in epidemiologic studies are exerted partly through plausible mechanisms: low prevalence of obesity, of type2 diabetes, of hyperlipidemia and of hypertension. Interventional studies may eventually provide stronger evidence. In the meantime, an increasing of knowledge supports the Mediterranean diet as a useful tool in managing individuals with RD, who are at high risk ofcardiovascular diseases.

AB0322 INTESTINAL DISBIOSIS IS ASSOCIATED WITH INADEQUATE RESPONSE TO MULTIPLE ANTIRHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS.

M. Morales-Águila[1], A. M. Cabezas-Lucena[1], P. Ruiz-Limon[2], I. Moreno-Indias[2], S. Manrique Arija[1], N. Mena-Vázquez[1], A. Fernandez-Nebro[1]. [1]*Hospital Regional Universitario de Málaga (HRUM). Institute for Biomedical Research in Malaga (IBIMA), UCG of Rheumatology, Málaga, Spain;* [2]*Hospital Clínico Virgen de la Victoria. Institute for Biomedical Research in Malaga (IBIMA), UCG of Endocrinology and Nutrition, Málaga, Spain*

Objectives: To evaluate the relationship between inadequate response to multiple antirheumatic biologic or targeted synthetic drugs (IRM-b/tsDMARDs) and intestinal microbiota and other inflammatory and severity factors in patients with rheumatoid arthritis (RA).

Methods: Design: A case-control study nested in a prospective cohort of RA patients.

Patients: Patients with RA (ACR/EULAR 2010) from a prospective baseline cohort (incident cases between 2007-2011), >16 years. Controls: subjects without inflammatory disease matched by sex and age.

Protocol: All subjects were evaluated in a specialized outpatient unit. Clinical, analytical and therapeutic variables were registered using a data collection protocol. Blood, urine and faeces samples were obtained from all subjects.

Variables: Dependent variable: "RA patients with IRMD", defined as failure >2 different bDMARDs (biological disease-modifying antirheumatic drug) or dsDMARDs (targeted synthetic disease-modifying antirheumatic drug). Faecal microbiota (continuous var., 0-100%) was analysed using the Ion Torrent S5 next-generation sequencing platform, and the sequences obtained were processed using the QIIME2 (Quantitative Insights Into Microbial Ecology 2) software. Inflammatory activity was measured by mean DAS-28 (disease activity score-28) throughout the disease and RA severity variables included erosions, anticitrullinated peptide antibody (ACPA) titres and HAQ (health assessment questionnaire). Other variables included socio-demographic, clinical-analytical characteristics, type of treatment with bDMARDs and reason for suspension.

Statistical Analysis: descriptive, bivariate using χ^2 and T-Student followed by two logistic regression model in order to identify the factors associated with both bDMARDs and IRM-b/tsDMARDs in patients with RA.

Results: 220 subjects, 110 RA patients and 110 controls, were included. A total of 90/110 RA patients were seropositive (81.8%) and 68/110 were erosive (61.8%). A total of 61/110 (55.5%) were treated with any bDMARD, being more frequent the anti TNF (35.5%). Ninety-three (84.5%) of RA patients took associated sDMARD. Thirteen patients (21.3%) presented IRMD. The variables independently associated with biological therapy in RA were: physical activity (OR [95% CI], 0.990 [0.989-0.999]; p=0.043), erosions (OR [95% CI], 2.450 [1.056 -4.683]; p=0.037) and Actinobacteria family (OR [95% CI], 1.182 [1.016-1.375]; p=0.030), R2= 0.283. The variables that were independently associated with IRMD in patients with RA were: ACPA (OR [95% CI], 1.005 [1.001-1.010]; p=0.039), diagnostic delay (OR[95% CI] 1.025 [1.001-1.050]; p=0.044), age (OR [95% CI], 0.933 [0.872-0.998];p=0.032), *Bacterioidetes* (OR [95% CI],1.080 [1.014-1.150]; p=0.016), *Synergistetes* (OR [95% CI], 2.277 [1.094-4.741]; p=0.028), R2=0.329.

Table 1. Epidemiological, Clinical and analytical characteristics of patients and controls.

Variable	Patients n=110	Controls n=110	p-value
Epidemiological characteristics			
Age, mean (IQR)	55.9 (49.3-64.4)	56.2 (48.3-65.3)	0.917
Sex, female; n (%)	88 (80.0)	88 (80.0)	1.000
Clinical and analytical characteristics			
Erosions, n (%)	68 (61.8)	-	-
RF >10, n (%)	90 (81.8)	0 (0.0)	<0.001
ACPA >20, n (%)	88 (80.0)	0 (0,0)	<0.001
CRP (mg/dl), median (IQR)	2,9 (2.9-6.2)	2.9 (2.9-3.3)	<0.001
ESR (mm/h), median (IQR)	13.0 (8.0-21.0)	11.0 (6.0-16.0)	0.008
DAS28 average, mean (±SD)	3.0 (0.7)	-	-
HAQ average, median (IQR)	0.71 (0.3-0.9)	-	-
sDMARD, n (%)	93 (84.5)	-	-
bDMARD, n (%)	61 (55.5)	-	-
Anti TNF-α, n (%)	39 (35.5)	-	-
Anti IL-6, n (%)	9 (8.2)	-	-
Rituximab, n (%)	7 (6.4)	-	-
Abatacept, n (%)	2 (1.8)	-	-
JAK inhibitor, n (%)	4 (3.6)	-	-
Multiresistance, n (%)	13 (21.3%)	-	-

Conclusion: Biological treatment in RA was associated with less physical activity, erosions and a greater presence of *Actinobacteria.* Bad prognosis factors such as delayed diagnosis and elevated ACPA titres were associated with multiresistance in RA patients, in addition to higher levels of *Bacteriodetes* and *Synergistetes.*

AB0323 FACTORS ASSOCIATED TO CLINICAL INERTIA IN RHEUMATOID ARTHRITIS

S. Miladi[1], O. Boudrigua[1], A. Fazaa[1], H. Boussaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology Department, La Marsa,Tunisia*

Background: Clinical inertia in rheumatic diseases is defined as inability or undue delay to initiate or intensify therapy when the disease is active or de-escalate therapy when the disease is in remission. Understanding the various contributory factors to clinical inertia is helpful in ensuring appropriate planning to tackle the issue and achieving Treat-To-Target (T2T) goals.

Objectives: We aimed to identify medical therapeutic inertia in Rheumatoid Arthritis (RA) patients and to assess its contributing elements.

Methods: We conducted a monocentric study including 42 patients, fulfilling the 2010 ACR/EULAR classification criteria for RA, who consulted our outpatient department from november 2021 to January 2022. Study data collection included demographics, clinical and disease characteristics, and treatment history. The survey also contained the Satisfaction Questionnaire for Medication (TSQM) which provides validated score for four subscales: effectiveness, side effects, convenience, and global satisfaction. Treatment satisfaction was measured using a cutpoint global satisfaction score ≥ 80.

Results: Most patients were female (86%) with a mean age of 57±13 years and a mean disease duration of 10.8±4.7 years. The education level for most patients (62%) was secondary school education or less. Fifteen percent of patients were in full-time work, 27% were unemployed, and 54% were retired. RA impact on patients' work-life was considerable, as 14.3% had retired early due to RA. Patients had moderate-to-high disease activity, with a mean DAS28 with C-reactive protein (CRP) of 4.2±1.4. Radiographic structural damage was apparent in 79% of patients. RA was immunopositive in 92% of patients. Most

common comorbidities were cardiac disorders (32%), pulmonary disorders (13%), and metabolic/nutrition disorders (11%). Psychiatric disorders was present in 9.5% of patients. CsDMARDs were the most frequently prescribed medications, used in 69% cases, followed by bDMARDs used in 34% cases. A total of 54% received the anchor drug methotrexate as part of their treatment regime. Only 12% of patients used systemic glucocorticoids for RA. Only half (52%) of all patients had a planned switch of medication, despite long-standing disease and suboptimal symptom control with current DMARD therapy. Statistical analysis revealed that factors for switch decision to a different DMARD by the treating physician was: younger patient age (p=0.002), having a high disease activity by DAS28-ESR (p<0.001), worse HAQ score (p<0.001), lower global satisfaction score (p<0.001), and patient preference for oral administration (p=0.006). Predictors for not switching to a different DMARD included a higher number of comorbidities (p<0.001), lower current DAS28-ESR score (p<0.001) and lower number of concomitant medications (p=0.002). Mean TSQM scores were 62 for effectiveness, 45 for side effects, 65 for convenience, and 60 for global satisfaction. Only 16 % of patients were satisfied with their RA treatment.
Conclusion: Our study showed that patients with active RA may not be managed in consistency with recommendations. This phenomenon defined as clinical inertia, is multi-factorial including healthcare set-ups and providers, patients and their caregivers. That's why before labelling management of rheumatic disease in an individual as a 'failure', careful consideration of relevant factors linked to clinical inertia may be helpful.

AB0324 SAFETY PROFILE OF JAK INHIBITORS IN REAL WORLD FROM A SINGLE CENTER COHORT

R. González Mazarío[1], J. J. Fragío Gil[2,3], L. Mas Sanchez[3], P. Muñoz Martinez[3], F. Ortiz-Sanjuán[3], C. Pávez Perales[3], S. Leal Rodriguez[3], C. Riesco Barcena[3], A. V. Huaylla Quispe[3], M. De la Rubia Navarro[3], L. Gonzalez Puig[3], E. Grau García[3], J. E. Oller Rodríguez[3], I. Martínez Cordellat[3], R. Negueroles Albuixech[3], E. Vicens Bernabeu[3], J. Ivorra Cortés[3], C. Nájera Herranz[3], I. Cánovas Olmos[3], J. A. Román Ivorra[3]. *[1]Hospital Arnau de Vilanova, Sección de Reumatología, Valencia, Spain; [2]Instituto de Investigación Sanitaria La Fe (IIS La Fe), Grupo de Investigación de Reumatología, Valencia, Spain; [3]Hospital Universitari i Politècnic La Fe, Servicio de Reumatología, Valencia, Spain*

Background: Recent published data have emerged some concerns about safety of Janus kinase (JAK) inhibitors and FDA have established prescribing restrictions.
Objectives: The aim of this study was to analyze the safety profile of current approved JAK inhibitors in Europe with data from a Real World cohort.
Methods: A single center observational study was performed including patients who had initiated treatment with Tofacitinib, Baricitinib or Upadacitinib from September, 2017 to January, 2022. Demographic, clinical, laboratory and safety variables were collected from baseline and at months 1, 3, 6 and every six months. Safety data was collected including any adverse event (AE) due to any cause. An AE was considered serious if it was life-threatening or result in hospitalization, disability or in death. All AE and SAE were expressed adjusted by exposure (E/100 PY).
Results: A total of 194 patients were included whom baseline demographic and disease characteristics are exposed in Table 1. Drug exposure was 265.5 patient-years. Overall, 214 AE were detected being mild upper tract respiratory infection the most frequently registered (15.82 E/100PY) followed by Urinary tract Infection accounting 7.16 E/100PY. 10 Serious Infections were detected in 10 patients of which 5 were pneumonia (1.88 E/100PY), 1 cellulitis (0.38 E/100PY) and 2 COVID-19 (0.76 E/100PY). 12 herpetic infection were detected in 9 patients (4.52 E/100PY) of which 7 were caused by herpes zoster (2.64 E/100PY) and 5 by herpes simplex (1.88 E/100PY) 3 cases were mono-metameric and 4 multi-metameric. Moreover, 2 patient developed postherpetic neuralgia. A patient with RA developed Miliary Tuberculosis (0.38 E/100PY) with a negative IGRA test prior to the JAKi. A patient with RA suffered a Myocardial Infarction (0.38 E/100PY). 7 RA patients developed malignancy (2.64 E/100PY), one with oral squamous cell carcinoma, two Bowen carcinoma, one breast cancer, 2 basal cell carcinoma and a colorectal metastatic cancer. Not a single case of thromboembolic event nor Hepatitis B Virus reactivation were registered. 2 patients died, one with cancer and the other suffered a severe COVID-19 (unvaccinated).

Table 1. DEMOGRAPHIC, DISEASE AND TREATMENT BASELINE CHARACTERISTICS.

Characteristic	Rheumatoid arthritis n=163 (84.02%)	Psoriatic arthritis n=18 (9.28%)	Juvenile idipathic arthritis n=7 (3.61%)	Other n=6 (3.09%)
Age - years	55.23 (16.84)	54.71 (11.89)	27.14 (5.18)	48 (12.95)
Female sex – number (%)	142 (87.12)	12 (66.66)	6 (85.71)	4 (66.67)
Race – number (%)				
Caucasian	135 (82.82)	16 (88.89)	7 (100)	6 (100)
Asian	2 (1.23)	0 (0)	0 (0)	0 (0)
Latin	26 (15.95)	2 (11.11)	0 (0)	0 (0)
Comorbidities – number (%)				
High blood pressure	118 (72.39)	11 (61.11)	0 (0)	0 (0)
Dyslipemia	54 (33.13)	6 (33.33)	0 (0)	1 (16.67)
Diabetes Mellitus	10 (6.13)	3 (16.66)	0 (0)	1 (16.67)
Positive HBV serology	12 (7.36)	1 (5.55)	0 (0)	0 (0)
Latent Tuberculosis	15 (9.20)	1 (5.55)	0 (0)	0 (0)
JAKi				
Baricitinib	61 (37.42)	0 (0)	2 (28.57)	1 (16.67)
Tofacitinib	83 (50.92)	15 (83.33)	4 (57.14)	3 (50)
Upadacitinib	19 (11.66)	3 (16.67)	1 (14.29)	2 (33.33)
Patients taking glucocorticoids – number (%)	112 (68.71)	9 (50)	3 (42.86)	1 (16.67)

Conclusion: In this updated analysis of 194 patients treated with JAKi, the three approved JAKi showed a safety profile consistent with data from RCT. The patients under JAK therapy should be carefully evaluated on their follow-up.

AB0325 SERUM HEPCIDIN LEVEL IN REFRACTORY RHEUMATOID ARTHRITIS: ITS RELATIONSHIP TO DISEASE ACTIVITY AND CHRONIC HYPOXIA

E. Galushko[1], A. Semashko2on behalf of Topic No. AAAA-A19-119021190149-0. *[1]V.A. Nasonova Research Institute of Rheumatology, V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; [1]V.A. Nasonova Research Institute of Rheumatology, V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Difficult-to-treat rheumatoid arthritis (D2T RA) was recently defined by a EULAR study group and, as a disease category it is largely complicated and under-researched. Patient multimorbidities, in particular chronic hypoxia, may play a significant role in the response to therapy with biologic disease-modifying antirheumatic drugs (bDMARDs) and in the disease classification as D2T RA. Iron metabolism disorders are the leading pathogenic factors in progression of anemia of chronic disease and chronic hypoxia. Hepcidin is a key negative acute-phase regulator of duodenal iron absorption, mobilization and considered as a mediator of anemia in inflammation. However, present studies on serum hepcidin levels in patients with RA and multimorbidity are inconsistent
Objectives: To investigate the relationship between hepcidin levels, markers of inflammatory activity and hemoglobin (Hb) levels in patients with RA and multimorbidity.
Methods: The investigation enrolled 71 patients (mean age, 54.8±14.8 years) with RA according to the 2010 ACR/EULAR criteria, who had been examined and treated at the V.A. Nasonova Research Institute of Rheumatology. The median disease duration was 5.0 [1.5; 9.5] years; the mean DAS28 score was 5.0±1.3. Documentation and anamnesis data were analyzed with emphasis on associated diseases. The Cumulative Illness Rating Scale (CIRS) was used to assess the profile of multimorbidity.
Anemia of inflammation (AI) was diagnosed in 42 patients. Anemia was defined as hemoglobin <12g/dL and <13.5g/dL, in men and women, respectively. AI was diagnosed on the basis of a combination of the following: a) normal or elevated ferritin b) lowered serum iron and total iron binding capacity and c) normal percent iron saturation. Serum hepcidin, as well as IL-6 levels were also measured. Patients with iron-deficiency anemia were excluded.
Results: Chronic kidney disease that occurred in almost half (42.5%) of cases was most commonly undiagnosed in the cohort under study; on average, every three patients were not found to have signs of metabolic syndrome (hyperglycemia in 29%, hypercholesterolemia in 20%, obesity in 13.5%), chronic hypoxia (new-onset anemia verified in 24% of cases).

RA patients with AI and with normal Hb levels (n=29) were comparable (p>0.05) in age (44.4±14.8 and 49.8±9.3 years), disease duration (73.5±65.4 and 59.8±48.3 months) and DAS28 (6.3±1.6 and 5.9±1.9).

In RA patients with AI we found a strong positive correlation between serum hepcidin and ferritin levels (r=0.623, p=0.009). There was a positive correlation between serum hepcidin and IL-6 levels (r=0.546, p=0.023). We found a strong negative correlation between serum hepcidin concentrations and Hb levels (r=0.528, p=0.029), but reliable correlation between DAS28, CRP and ESR was not revealed.

In RA patients without anemia, the level of hepcidin positively correlated with the inflammatory activity parameters including CRP, ESR and DAS28, no correlation between the Hb and ferritin levels was revealed.

Conclusion: Our data support the hypothesis that IL-6-driven hepcidin production mediates AI in RA patients and might play a role in the pathogenesis of anemia associated with RA. In RA patients with chronic hypoxia, serum hepcidin level was significantly higher and perform better than traditional yardsticks in identifying anemia inflammation.

AB0326 EVALUATION OF BONE DENSITY PARAMETERS IN A COHORT OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS: HOW THERAPY WITH GLUCOCORTICOIDS, METHOTREXATE AND BDMARDS CHANGES BONE MINERAL DENSITY, T-SCORE AND TRABECULAR BONE SCORE

A. Altomare[1], C. Rotondo[1], D. Cici[1], A. Trotta[1], A. Corrado[1], F. P. Cantatore[1]. *[1]Azienda Ospedaliero-Universitaria "Policlinico Riuniti", Rheumatology Clinic, Foggia, Italy*

Background: Osteoporosis (OP) can affect patients with Rheumatoid Arthritis (RA). This can be due to long-time use of glucocorticoids (GCS) or to the activation of proinflammatory pattern, via TNFα signalling, that leads to osteoclast (OC) activation with bone resorption.

Objectives: Aim of this study is to assess how therapy with GCS, methotrexate (MTX) and bDMARDs may change bone density parameters.

Methods: 66 RA patients were enrolled in this study. Bone Mineral Density (BMD), T-score of spine and femur, Trabecular Bone Score (TBS) and TBS T-score were evaluated at baseline and after 18 months of treatment with GCS, MTX, bDMARDs. Comparison among different patient groups were evaluated by ANOVA. P-value < 0.05 was considered significative.

Results: At baseline, 66% of patients were female and 44% male, mean age was 62.2 (± 8.4) years, mean disease duration was 17.8 (± 11.2) years, 76% of patients were Rheumatoid Factor (RF) positive and 24% were RF negative, 71% were ACPA positive and 29% were ACPA negative, mean DAS-28 was 3.67 (± 1.34), mean L1-L4 BMD was 0.930 (± 0.175) g/cm^3, mean neck's femur BMD was 0.705 (± 0.102) g/cm^3, mean L1-L4 T-score was -1.11 (± 1.54), mean neck's femur T-Score was -1.17 (± 1.02), mean TBS was 1.239 (± 0.132) and mean TBS T-score was -2.36 (± 1.42). Among the entire population in study, 24.4% were affected by OP, 74.6% were in therapy with GCS, 57.8% with MTX and 16.6% were under OP treatment with bisphosphonate or teriparatide or denosumab. At baseline, 51.6% of patients started an TNFi treatment, 3.1% started an anti IL-6 treatment, 9.3% started an anti-CTLA4 treatment and 23.4% started a JAKi treatment. By ANOVA analysis, patients at baseline in therapy with MTX had mean L1-L4 BMD and L1-L4 T-score higher than those not in therapy with MTX, respectively 0.985 (± 0.184) g/cm^3 vs 0.866 (± 0.144) g/cm^3 (p < 0.05) and -0.73 (± 1.70) vs – 1.62 (± 1.13) (p < 0.05). At 18 months patients treated with MTX had higher L1-L4 T-score than those not in therapy with MTX, respectively -0.48 (± 1.68) vs – 1.68 (± 1.18) (p < 0.05). Percentage variations in BMD, T-score, TBS and TBS T-score between baseline and 18-month endpoint were not significative; nevertheless, we observed a positive trend in lumbar and femur BMD percentage variations in patients treated with JAKi (2.89%), and in TBS percentage variations in patients in TNFi treatment (2.98%).

Conclusion: In this study we confirmed the high prevalence of OP in RA-patients. Therapy with MTX seems to prevent bone resorption, but it does not improve bone density parameters. Moreover, we observed a positive trend in JAKi-patients BMD and TNFi-patients TBS percentage variations, even though these data are not statistically significative due to the small sample.

AB0327 CARDIOVASCULAR RISK ASSESSMENT IN RHEUMATOID ARTHRITIS WITH CAROTID ULTRASONOGRAPHY AND CARDIOVASCULAR RISK SCORES: A CASE CONTROL STUDY

R. González Mazarío[1], P. Martinez Calabuig[2], J. J. Fragío Gil[3], E. Grau García[3], C. Pávez Perales[3], S. Leal Rodriguez[3], C. Riesco Barcena[3], A. V. Huaylla Quispe[3], L. Mas Sanchez[3], P. Muñoz Martinez[3], J. E. Oller Rodríguez[3], E. Vicens Bernabeu[3], F. Ortiz-Sanjuán[3], R. Negueroles Albuixech[3], M. De la Rubia Navarro[3], I. Martínez Cordellat[3], L. Gonzalez Puig[3], J. Ivorra Cortés[3], C. Nájera Herranz[3], I. Cánovas Olmos[3], J. A. Román Ivorra[3]. *[1]Hospital Arnau de Vilanova, Sección de Reumatología, Valencia, Spain; [2]Hospital General Universitario de Valencia, Servicio de Reumatología, Valencia, Spain; [3]Hospital Universitari i Politècnic La Fe, Servicio de Reumatología, Valencia, Spain*

Background: The risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) is higher than individuals from the general population. This excess risk might be explained by the chronic inflammation.

Objectives: To assess the Cardiovascular Risk (CV) in Rheumatoid Arthritis (RA) patients using the Framingham Score, SCORE (systematic coronary risk evaluation) and carotid ultrasound additionally to the traditional cardiovascular risk factors.

Methods: A single center case control study was performed. Inclusion criteria were adult RA patients (cases) and matched healthy adults in terms of age, sex, and CV risk factors (controls). Population over 75 years old, patients with established CV disease and/or stage III chronic kidney disease were excluded. Controls with other inflammatory diseases, pregnant women or any malignancy were also excluded. This study was performed from July-2019 to January-2020. The US study included presence of plaques, plaque number and measurement the intima-media thickness in both right and left carotid. Scores were multiplicated x1.5 according to EULAR recommendations.

Results: Overall, a total of 200 cases and 111 healthy controls were included in the study. Demographical and clinical variables were comparable between cases and controls and are shown in Table 1. In both groups a relationship between age, BMI and high blood pressure was detected (p<0.001). RA patients had a Disease duration of 18.93 years (11.36); 163 (81.5%) Erosions (X-Ray of hands/feet), Extra-articular symptoms 44 (22%), Prednisone use 103 (51.5%) with Median dose of Prednisone last year 2.34 (2.84). In treatment with Methotrexate 104 (52%), bDMARDs 89 (44.5%) and JAK inhibitor 26 (13%). US study revealed a higher IMT in both right and left carotid arteries with greater presence of plaques in

Table 1. Demographic, clinical characteristics, Ultrasound Results, SCORE and Framingham of patients and controls.

Characteristic	RA cases n=200	Healthy controls n=111
Age - years	62.05 (10.75)	58.3 (12.14)
Female sex – number (%)	163 (81.5)	73 (65.77)
BMI – value (ds)	26.38 (5.03)	26.2 (5.19)
Smoking habit		
Never Smoked	107 (53.5%)	71 (63.96%)
Ex-smoker	51 (25.5%)	20 (18.02%)
Active smoker	42 (21%)	20 (18.2%)
Race – number (%)	186 (93)	62 (93.94)
Caucasian		
Comorbidities – number (%)		
High blood pressure	83 (41.5%)	34 (30.63%)
Dyslipemia	93 (46.5%)	39 (35.14%)
Blood pressure -- mmHg	127.2(18.36)/78.67(10.21)	127.77(19.42)/78.28 (10.59)
Ultrasound findings		
Right carotid cIMT	0.78 (0.15)	0.62 (0.11)
Left carotid cIMT	0.77 (0.14)	0.64 (0.12)
Plaques	101 (50.5%)	32 (28.83%)
Bilateral	64 (32%)	11 (9.91%)
Right carotid	17 (8.5%)	7 (6.31%)
Left carotid	20 (10%)	14 (12.61%)
SCORE		
Very Hihg	13 (6.5%)	5 (4.5%)
High	31 (15.5%)	15 (13.51%)
Low	156 (78%)	91 (81.98%)
Framingham		
High	76 (38%)	33 (29.7%)
Low	124 (62%)	78 (70.3%)

patients than in controls (CI 95% [1.542; 3.436], p<0.001). Plaques were found in both carotid arteries in the 32% of cases and 9.91% of controls. The longer duration of RA was related to a higher presence of carotid plaques (95% [1.015; 1.056], p<0.001). US and blood test results are shown in Table 3. SCORE and Framingham correlated with the CV estimation with US (p<0.001), however, seemed to underestimate the global findings in cases (p<0.001).

Conclusion: Cardiovascular risk calculators such as Framingham and SCORE are useful in RA risk estimation. However, those tools may underestimate the real risk, so carotid US might be valuable.

AB0328 ASSESSING THE MULTIMORBID PROFILE (CIRS) IN REFRACTORY RHEUMATOID ARTHRITIS

A. Gordeev[1], E. Galushko2. *[1]V.A. Nasonova Research Institute of Rheumatology, V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; [1]V.A.Nasonova Research Institute of Rheumatology, V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: The World Health Organization assigns cardiovascular diseases, cancers, chronic respiratory diseases, as well as diabetes mellitus and some other nosological entities, including mental and musculoskeletal disorders, to main non-communicable diseases. These are considered to be a major public health challenge of the 21st century. In this case, one patient frequently has a set of several age-related chronic diseases that develop simultaneously or sequentially. The management of these patients requires an integrated approach based on the multimorbid nature of pathology. Unlike the definition of comorbidities, which assumes to identify the underlying and related diseases, the concept of multimorbidity of such gradations fails to provide and interprets a patient's chronic diseases as equivalent.

Objectives: To assess the presence and nature of multimorbidity in patients with refractory rheumatoid arthritis (RA) and the impact of multimorbidity on disease activity

Methods: The investigation enrolled 153 patients (mean age, 54.8±14.8 years) with RA according to the 2010 ACR/EULAR criteria, who had been examined and treated at the V.A. Nasonova Research Institute of Rheumatology in 2019–2020. The median disease duration was 5.7 [1.5; 10.5] years; the mean DAS28 score was 5.0±1.3. Documentation and anamnesis data were analyzed with emphasis on associated diseases. The Cumulative Illness Rating Scale (CIRS) was used to assess the profile of multimorbidity.

Results: The patients with RA had a high index of the spectrum of multimorbidity; concomitant diseases were detected in 125 (82%) patients with RA. Their number ranged from 0 to 8 and increased in direct proportion to the age of the patients. The average total score of CIRS was 6.7 ± 3.3 points, the maximum score was 18, the minimum score was 2; The multimorbidity index is 2.5 [1; 6], the maximum number of categories with a score of ≥2 points is 6, the minimum is 1.

The number of concomitant diseases diagnosed in patients with RA before using CIRS was significantly lower (by 52%; p <0.01) than the results of our study showed. Most often, the following disorders were observed in patients at the time of inclusion in the study: comorbid cardiovascular diseases in 44%, anemia in 14.5%, hypercholesterolemia in 18%, obesity in 9.5%, thyroid disease in 11.5% (hypothyroidism criterion – in 3.5%) and diabetes – in 4%. CIRS allowed the first time to identify chronic pathology. The results reflect the cautiousness of doctors regarding comorbid cardiovascular diseases in RA: only 4% of patients were diagnosed with hypertension for the first time. At the same time, before inclusion in the study, no patient with RA revealed chronic kidney disease(CKD), which occurred in almost half of the cases (44.5%). On average, every third person had no previous signs of metabolic syndrome (hyperclycemia in 29%, obesity in 13.5%) and chronic hypoxia (anemia first diagnosed was verified in 24% of cases)

There was a correlation of the quantitative equivalent of multimorbidity with the clinical and laboratory measures of RA activity, including the number of painful joints (r = 0.39; p<0.001), overall patient assessment (r=0.37; p=0.03), physician's global assessment of disease activity (r = 0.37; p < 0.01), DAS28 (r = 0.42; p<0.001), CDAI (r=0.37; p<0.001), SDAI (r=0.34; p< 0.001), HAQ (r=0.34; p<0.001).

Conclusion: Systematic screening for multimorbidity should be performed in each patient with RA. It is advisable to use CIRS in subsequent studies to assess the prevalence of multimorbidity and its consequences. CIRS allows you to more accurately determine the contribution of each chronic disease or syndrome to the development of «multimorbid disease»

AB0329 IS THERE A LINK BETWEEN INFLAMMATION AND AN ABNORMAL LIPOPROTEIN PROFILE IN RHEUMATOID ARTHRITIS?

B. Touil[1], N. Akasbi[2], I. EL Harch[3], I. El Mezouar[2], T. Harzy[2]. *[1]HASSAN II UNIVERSITY HOSPITAL, SIDI MOHAMMED BEN ABDELLAH UNIVERSITY, FACULTY OF MEDECINE, RHEUMATOLOGY, FEZ, Morocco; [2]HASSAN II University Hospital, SIDI MOHAMMED BEN ABDELLAH UNIVERSITY, Faculty of Medecine, RHEUMATOLOGY, FES, Morocco; [3]EPIDEMIOLOGY LABORATORY OF SIDI MOHAMMED BEN ABDELLAH UNIVERSITY, FACULTY OF MEDECINE, EPIDEMIOLOGY, FES, Morocco*

Background: The management of cardio vascular risk in rheumatoid arthritis (RA) is essential and involves the assessment of the blood lipid profile. Studies have shown that patients with active untreated RA, by the presence of a pro-inflammatory state, have a decrease of total cholesterol (TC), HDL cholesterol (HDLc) and LDL cholesterol (LDLc) [1]. The relationship between blood lipids and inflammation is the so-called `lipid paradox' in RA [2].

Objectives: To study the lipoprotein profile of patients with RA and its association with markers of inflammation and disease activity.

Methods: We conducted a cross sectional study among patients with established RA. We analyzed their lipoprotein profile. We further evaluated possible associations between dyslipidemia, disease activity score using the DAS28 and markers of inflammation C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR)]. A disturbed lipid profile was defined by a Total Cholesterol level (TC) ≥ 5.17 mmol/L or High density lipoproteins (HDLc) ≤ 1.03 mmol/L or Low Density Lipoproteins (LDLc) ≥ 4.13 mmol/L or Triglycerides (TG) ≥ 1.69 mmol/L.

Results: The mean age of the 136 patients included was 55.19±11.84 years, with a female predominance (n=120). Disease duration was 16.27±11.84 years. Mean lipid concentrations were 4.73±0.95 mmol/L for TC, 1.29±0.36 mmol/L for HDLc, 2.87±0.72 mmol/L for LDLc and 1.19±0.54 mmol/L for TG. The inflammatory syndrome was present in 70% of patients. Mean ESR and CRP values were 32.81±22.19 mm at H1 and 26.17± 6.17 mg/L.

A significant association was objectified between the inflammatory syndrome and low concentrations of TC (4.57 ±0.93 vs 5.09 ±1.06; p=0.010) and LDLc (2.74 ±0.69 vs 3.15 ±0.85; p=0.007). However, no relationship was found between lipid profile and disease activity.

Conclusion: Although there was no relation between lipids plasma levels and disease activity in our population, inflammation was linked to a decrease in CT and LDLc. Contrary to the general population, this decrease is at high cardiovascular risk joining the lipid paradox theory in RA.

Rheumatoid arthritis - biological DMARDs

AB0330 EXPERIENCE IN THE CURRENT PRACTICE WITH BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INTERSTICIAL LUNG DISEASE OF THE DONOSTIA UNIVERSITY HOSPITAL

J. A. Valero Jaimes[1], A. De Diego Sola[1], N. Alcorta Lorenzo[2], C. A. Egües Dubuc[2], J. M. Belzunegui Otano[2], E. Uriarte Isacelaya[2], J. J. Cancio Fanlo[2], L. M. Lopez Dominguez[2], O. Maiz-Alonso[2]. *[1]Hospital Bidasoa, Rheumatology, Irún, Spain; [2]Donostia University Hospital, Rheumatology, San Sebastian, Spain*

Background: Baricitinib (BARI) is a selective and reversible oral Janus kinase (JAK) inhibitor for the treatment of moderate to severe active rheumatoid arthritis (RA) in adult patients with inadequate response or intolerance to one or more antirheumatic drugs disease modifiers (DMARDs). Interstitial lung disease (ILD) is a common extra-joint manifestation of RA. Symptomatic ILD occurs in 5-17% of patients with RA and influences the natural course of the disease and substantially affects morbidity and mortality, which is why we wanted to review our patients with RA and ILD who are under treatment with BARI.
Objectives: To assess the safety and persistence of BARI, as well as the evolution of lung function in patients with RA and ILD who are undergoing treatment with BARI, in the Rheumatology Service of the Donostia University Hospital.
Methods: A retrospective search was carried out of all patients undergoing BARI treatment until June 2020. The electronic medical records were reviewed. The variables collected were: sex, age, date of diagnosis of RA, history of smoking, presence of erosions, positivity for rheumatoid factor (RF), citrullinated cyclic antipeptide (anti-CCP) and previous treatments. Regarding BARI, the dose, the time since the start of treatment, related adverse effects, reason for suspension and other relevant data were collected. The quantitative variables are shown with the median and interquartile range, the qualitative variables are shown with the absolute value and its percentage.
Results: 17 patients with RA and ILD treated with BARI were found. Table 1 shows the clinical characteristics, Table 2 shows the treatments and Table 3 shows the respiratory function tests (RFT). All patients were positive for RF and anti-CCP, the presence of erosions was observed in 10 (59%), a history of smoking in 8 (47%), the most frequent type of ILD was Usual Interstitial Pneumopathy (UIP) 7 (41%), at the diagnosis of ILD Abatacept was the most used drug 14 (82). Before the start of BARI, the median FVC 90% (80.5-111), DLCO 69% (57-83.5) and the last control after the use of BARI the median FVC 94% (87-107), DLCO 63% (51-87), the median time of exposure to BARI was 34 months. To date, 10 (59%) patients continue with BARI and the most frequent cause of suspension was failure 2º.
Conclusion: A good persistence of BARI was observed (59%), it also proved to be a safe drug and kept lung function stable in these patients, so BARI can be a therapeutic option in these cases, although more studies are needed to better elucidate these findings.

AB0331 REDUCED C-REACTIVE PROTEIN LEVEL AT HOSPITAL ADMISSION IN PATIENTS TREATED WITH TOCILIZUMAB IN COMPARISON WITH OTHER ADVANCED ANTIINFLAMMATORY TREATMENTS- AN ATTENTION MAY BE REQUIRED

M. Berman[1], S. Berliner[2], N. Bashouti[3], O. Elkayam[1], T. Ziv-Baran[4]. *[1]Tel Aviv Sourasky Medical Center, Department of Rheumatology, Tel Aviv, Israel; [2]Tel Aviv Sourasky Medical Center, Internal Medicine E, Tel Aviv, Israel; [3]Tel Aviv Sourasky Medical Center, Clinical Pharmacology Unit, Tel Aviv, Israel; [4]Sackler Faculty of Medicine, Tel Aviv University, Department of Epidemiology and Preventive Medicine, School of Public Health, Tel Aviv, Israel*

Background: C-reactive protein (CRP) is a marker of inflammation and infection. The main proinflammatory cytokine that leads to CRP gene expression is IL-6[1]. Different DMARDS may influence CRP levels due to their specific mechanisms of action and alter its usage as an important indicator of acute infection/inflammation
Objectives: The study aimed to compare CRP level between patients who were treated with Tocilizumab (TCZ), an il-6 receptor blocker, and other advanced anti-inflammatory treatments (AAIT), as well as with other admitted and non-admitted populations.
Methods: A cross-sectional study of all patients (≥18 years) hospitalized at tertiary medical center between 12/2009 and 02/2020 and treated before hospitalization with (AAIT). Data on background DMARDS treatment was collected and then categorized to one of the two following groups: tocilizumab treatment and other treatments. In further investigation, the other treatments groups were divided into 3 subgroups: anti-TNF subgroup which included Infliximab (IFX), Adalimumab (ADA), etanercept (ETN), Golimumab, and Certolizumab, JAK-inhibitor subgroup which included Tofacitinib and Baricitinib, and another subgroup which included Rituximab, Abatacept and Anakinra Only the first hospitalization of each patient was included. Women admitted to obstetrics department were excluded. Demographic data, first blood tests results, and comorbidities were collected.
Results: The study included 563 patients treated with AAIT (2.5% received TCZ). Patients treated with TCZ were older (median 75 vs. 50 years, p<0.001), had higher Charlson score (median 5 vs. 1, p<0.001) and more infectious diseases at admission (50% vs. 23.4%, p=0.05). Patients treated with TCZ had lower CRP levels (median 0.5 vs. 25mg/l, p<0.001) and more common normal values (64.3% vs. 20.8%, p<0.001) compared to patients treated with other AAIT. CRP level in patients treated TCZ (median 0.5mg/l) was lower than that of 58,548 patients admitted to the hospital between 2010-2020 (median 12.55mg/l, p<0.001) and not statistically different from 140 non-admitted randomly selected individuals without acute disease (1.33 mg/l, p=0.294).
Conclusion: When compared to other anti-inflammatory drugs, tocilizumab is associated with lower CRP levels in individuals admitted to an acute care hospital. This finding must be considered by treating physician to avoid misinterpretation of CRP results.

AB0332 EVALUATION OF THE RABBIT RISK SCORE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS NEWLY TREATED WITH BIOLOGIC DMARDS: DATA FROM THE IORRA COHORT

T. Higuchi[1,2], E. Tanaka[1], E. Inoue[1], M. Abe[1], K. Saka[1], E. Sugano[1], N. Sugitani[1], Y. Shimizu[1], M. Ochiai[1], R. Yamaguchi[1], K. Ikari[2,3], Y. Hisashi[1,4], M. Harigai[1]. *[1]Tokyo Women's Medical University Hospital, Department of Rheumatology, Institute of Rheumatology, Tokyo, Japan; [2]Tokyo Women's Medical University School of Medicine, Division of Multidisciplinary Management of Rheumatic Diseases, Department of Internal Medicine, Tokyo, Japan; [3]Tokyo Women's Medical University Hospital, Department of Orthopedic Surgery, Tokyo, Japan; [4]Sanno Medical Center, Rheumatology, Tokyo, Japan*

Background: Serious infection is one of the most critical adverse events in patients with rheumatoid arthritis (RA) using biologic disease-modifying antirheumatic drugs (bDMARDs). During the first year, infections occur more frequently. Therefore, estimating the risk of developing a serious infection is important for the safe use of bDMARDs. The Rheumatoid Arthritis Observation of Biologic Therapy (RABBIT) risk score predicted the incidence rate of serious infection during 1 year in patients with RA taking DMARDs. Moreover, it has been validated using data from various observational cohort studies and nationwide registries with favorable results, with a reported area under the receiver operating characteristic curve (AUROC) of 0.68–0.87[1–5]. However, the RABBIT risk score has not been validated in RA patients starting a first bDMARD.

Objectives: To investigate the discriminatory ability of the RABBIT risk score for predicting the development of serious infection during 1 year after starting first bDMARDs in Japanese patients with RA using data from the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort.
Methods: The IORRA cohort is a large observational cohort at the Institute of Rheumatology, Tokyo Women's Medical University. Japanese patients with RA visiting our institute were registered and clinical parameters were assessed biannually. This study enrolled patients with RA who were registered in the IORRA cohort and treated with a first bDMARD. Patients who were missing data needed to calculate the RABBIT risk score were excluded. The RABBIT risk score was calculated using the patient's age, comorbidities, Japanese-Health Assessment Questionnaire score, history of previous infections, and types of DMARDs used. Serious infections were defined as those requiring hospitalization or treatment with intravenous antibiotics. The occurrence of serious infection during 1 year after starting the first bDMARDs was identified using data from the biannual IORRA cohort and confirmed using medical records. The discriminatory ability of the RABBIT risk score was analyzed by the AUROC.
Results: A total of 1,081 patients with RA and a median age of 55.3 years, in which females were the majority (88.2%), were included. Serious infection occurred in eight patients during 1 year before starting their first bDMARDs. The number of patients starting a TNF inhibitor, IL-6 inhibitor, and abatacept were 830 (76.8%), 170 (15.7%), and 81 (7.5%), respectively. A total of 23 patients (1.7%) had serious infections during 1 year after starting the first bDMARD; the most frequent infection was pneumonia (n=16, 69.6%). The median RABBIT score was 2.3 (IQR 1.6–5.4) in patients with serious infections during the follow-up period, and 1.6 (IQR 1.2–2.5) in patients without serious infections. The discriminatory ability of the RABBIT risk score was slightly poor, with an AUROC of 0.67 (95% CI, 0.52– 0.79).
Conclusion: The RABBIT risk score is highly practical; however, our present study suggested that some adjustments may be required to predict the risk of serious infection in Japanese patients with RA starting a first bDMARD.

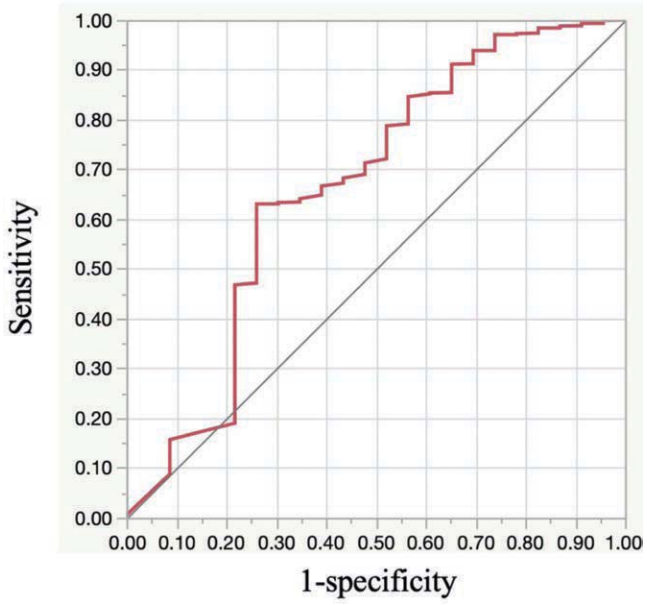

Figure 1. ROC curve of serious infection and RABBIT score with an AUROC of 0.67 (95% CI, 0.52– 0.79).

AB0333

SUSTAINABILITY OF RESPONSE TO UPADACITINIB AMONG PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS REFRACTORY TO BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

R. van Vollenhoven[1], S. Hall[2], A. F. Wells[3], S. Meerwein[4], Y. Song[5], J. Subotticki[5], R. M. Fleischmann[6]. *[1]Amsterdam Rheumatology and Immunology Center, Rheumatology and Immunology, Amsterdam, Netherlands; [2]Emeritus Research and Monash University, Rheumatology, Melbourne, Australia; [3]Rheumatology and Immunotherapy Center, Rheumatology, Franklin, United States of America; [4]AbbVie Deutschland GmbH & Co. KG, Global, Ludwigshafen, Germany; [5]AbbVie Inc., Immunology, North Chicago, United States of America; [6]University of Texas Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, United States of America*

Background: Sustained clinical remission (REM) is the primary treatment goal for patients with rheumatoid arthritis (RA), with low disease activity (LDA) being an appropriate target for treatment-refractory patients.[1,2]
Objectives: To evaluate the sustainability of response to the JAK inhibitor, upadacitinib (UPA) 15 mg once daily (QD), among patients with prior inadequate response or intolerance to biologic DMARDs.
Methods: Data come from the 12-week, phase 3 randomized, placebo (PBO)-controlled SELECT-BEYOND trial of UPA 15 mg or 30 mg QD in patients with moderate to severe RA on stable background conventional synthetic (cs) DMARDs. Initiation, change, or discontinuation of background RA medications, including ≤2 csDMARDs, was allowed starting at Week 24. Patients completing the 12-week trial were able to enter a long-term extension of up to 5 yrs with all PBO patients switching to UPA.[3] This post hoc analysis evaluated REM (CDAI ≤2.8; SDAI ≤3.3), LDA (CDAI≤10; SDAI≤11), and DAS28(CRP) <2.6/≤3.2 at first occurrence of response before Week 60, as well as at 3, 6, and 12 months following initial response in patients randomized to UPA 15 mg. For those patients who achieved REM/LDA, Kaplan-Meier was used to define the time from when the response was first achieved to the earliest date at which the response was lost at two consecutive visits or discontinuation of study drug. The predictive ability of time to REM/LDA was evaluated using Harrell's concordance (c)-index (range: 0 to 1, where 0.5 indicates a model that is no better at predicting an outcome than random chance). The date of the last follow up was 16 April 2018, when all patients had reached the Week 60 visit. Non-responder imputation was used for missing data. Only data from the approved 15 mg dosage are reported here.
Results: In patients with active RA despite prior treatment with at least one bDMARD, 34% and 79% of those receiving UPA 15 mg + background csDMARD(s) achieved CDAI REM or LDA through Week 60, respectively. Sustained CDAI REM was attained by 30%, 26%, and 16% of patients randomized to UPA at 3, 6, and 12 months post initial response, while CDAI LDA was achieved by 68%, 61%, and 50% of patients during the same time points (Figure 1). Time to initial clinical response weakly predicted sustained REM but did not predict sustained LDA, with a c-index (95% CI) of 0.62 (0.49, 0.74) and 0.52 (0.44, 0.61), respectively. Through the last follow-up visit at Week 60, 39/61% of patients on UPA remained in CDAI REM/LDA (Figure 2). Of those who lost CDAI REM, 58% remained in CDAI LDA, and 22% recaptured REM by the cut-off date; 18% of patients who lost CDAI LDA recaptured response. Similar results were observed for REM and LDA based on SDAI and for DAS28(CRP) <2.6/≤3.2.
Conclusion: Among patients with inadequate response or intolerance to bDMARDs, over three-quarters on UPA 15 mg achieved CDAI LDA, a relevant therapeutic target for these treatment-refractory patients, and nearly two-thirds of those maintained this response through 60 weeks. Additionally, about one-third of UPA-treated patients attained CDAI REM and maintained that response over 60 weeks.

EFFICACY AND SAFETY OF ABATACEPT IN CHINESE PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: REAL-WORLD DATA

Y. F. Qing[1], Q. Huang[2], Z. Y. Zhao[3], Q. B. Zhang[2], L. Q. Li[1], Z. Wen[3], Z. X. You[2], H. Tang[1], H. Xu[3]. *[1]Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Rheumatology and Immunology, Nanchong, China; [2]Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Geriatrics, the Affiliated Hospital of North Sichuan Medical College, Nanchong, China; [3]Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Rheumatology and Immunology, the Affiliated Hospital of North Sichuan Medical College, Nanchong, China*

Background: Abatacept (ABA) has demonstrated efficacy and safety in active rheumatoid arthritis (RA) patients in Europe and the United States as one of bDMARDs [1]. However, the clinical activity of Abatacept (ABA) has not been sufficiently investigated in patients with RA from a real-world clinical setting in China.
Objectives: This study was designed to investigate the efficacy and safety of Abatacept in the RA patients in Chinese population who were refractory to csDMARDs, aiming to provide further reference for clinical rational drug use.
Methods: Clinical data of 55 patients with active RA who were admitted in the Affiliated Hospital of North Sichuan Medical College from June 2020 to June 2021 and did not respond to csDMARDs was retrospectively analyzed. Patients in this study were treated with Abatacept (125 mg by subcutaneous injection once weekly combined with csDMARDs. Changes in clinical manifestations, including DAS28-ESR, CDAI, ACR 20/50/70 at week 12 and 24 from baseline and AEs during 24 weeks were observed and recorded.
Results: 55 patients (46 women and 9 men) were included in this study with a mean age 50.80 ± 12.46 and a mean disease duration of 6.29 ± 6.22 years. The ACR 20 response at week 12 and 24 was 50.91% (28/55) and 87.27% (48/55), respectively. Besides, DAS 28-ESR score were significantly lower at week 12 and 24 compared to baseline (P <0.05) with 19 patients (34.55%) achieving clinical remission or low disease activity. Changes in CDAI scores revealed that 80% patients achieved clinical remission or low disease activity at week 24. DAS28-ESR score was significantly lower in previously untreated patients (Biologic-naive) (n=36) (3.40 ± 0.81) than in the previously treated patients (Biologic non-naive) (n=19) (3.83 ± 0.68) (P = 0.02) (Figure 1). RF, CCP antibody and GLOB levels were significantlyreduced in RA patients after 24-week ABA treatment compared to baseline (*P*<0.05) (Table 1). Two hepatitis B virus (HBV) carriers, two patients with active tuberculosis and one patient with latent tuberculosis status showed no reactivation of HBV and no new active tuberculosis lesions 24 weeks after treatment with ABA. AEs were reported in 9.1% (5/55), but no serious infections occurred.

Table 1. Analysis of clinical and serological parameters at baseline and after treatment with Abatacept.

Indexes	Baseline	12 weeks	24 weeks
TJC	6 (4 , 10)	3 (2 , 4)*	2 (1 , 3)**

RF-IgA (U/mL)	90.18 (25.63, 99.12)	-	58.20 (16.81, 59.09) *
CCP (RU/mL)	1095.45 (66.79, 1033.28)	-	782.0 (58.49, 857.5) *

*p<0.05,TJC=Tender joint count, SJC=Swollen joint count, GLOB= immunoglobulin.

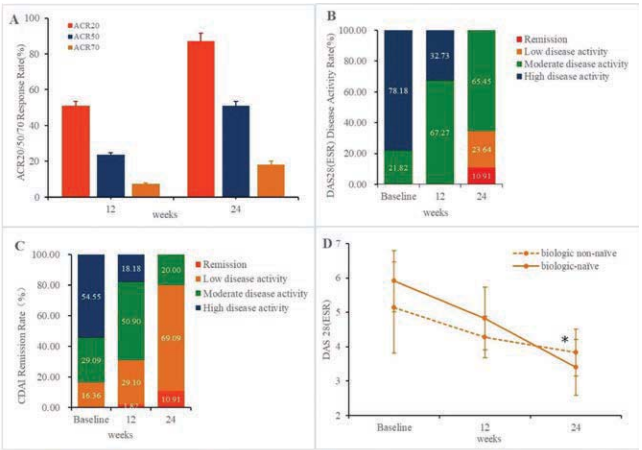

Figure 1 Efficacy of Abatacept at week 12 and week 24. (A) ACR20/50/70 response rate of all patients at week 12 and week 24. (B) DAS28 (ESR) disease activity of patients at baseline, week 12, and week 24; (C) CDAI remission rate of patients at baseline, week 12, week 24; (D) Efficacy of abatacept with biologic-naïve and biologic non-naïve. *P < 0.05 compared with week 24.

Conclusion: In the Chinese patients with active RA refractory to csDMARDs, the combination of ABA and csDMARDs showed great clinical efficacy and a favorable safety profile. Moreover, ABA resulted in better efficacy in patients previously untreated with biologics than previously treated with biologics.

AB0335 THE FREQUENCY OF SWITCH FROM ANTI-TNF ORIGINATORS TO BIOSIMILARS AND THE CLINICAL OUTCOMES – REAL-WORLD RETROSPECTIVE STUDY IN FOUR ITALIAN CENTRES

F. Atzeni[1], M. Bardelli[2], P. Moscato[3], M. Giallanza[1], D. Birra[3], F. Pistillo[4], A. Carletto[4]. *[1]Rheumatology Unit, University of Messina, Messina, Italy; [2]Rheumatology Unit, University of Siena, Siena, Italy; [3]UOC of Internal Medicine - Rheumatology Outpatients Unit, Azienda Ospedaliero-Universitaria San Giovanni di Dio e Ruggi D'Aragona, Salerno, Italy; [4]AOUI di Verona UOC di Reumatologia, Dipartimento di Medicina, Verona, Italy*

Background: Biologics, such as tumor necrosis factor inhibitors (TNFi), are highly effective in the treatment of inflammatory arthritis, i.e., rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA). The importance of collecting real-world evidence data on switching patients from an originator to a corresponding biosimilar is well recognized in the field (1).

Objectives: The aim of the study was to evaluate the frequency and clinical outcomes of the switch in patients with RA, PsA and axSpA to determine whether a switch could cause a reactivation of the disease.

Methods: We searched electronic patient's records in four Italian centers for consecutive adult patients treated with TNFi for RA, PsS and axSpA. For these patients, we extracted data on age, gender, age and diagnosis and disease duration, the history of a switch from a TNFi originator to a biosimilar, and swollen joints, tender joints, global health, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP). We calculated composite indices of disease activity, DAS28-ESR, DAS28-CRP, CDAI and SDAI, at baseline, and at 3 and 6 months of follow-up. Response was calculated as the difference between DAS28 at baseline and at 3 or 6 months and stratified into good, moderate, no response according to EURAL response criteria. Chi-square test was used to assess if lower response rates were encountered in the switch versus no-switch groups. The Generalized Linear Regression Model was used to study the relationship between DAS28-ESR/CRP responses at 3 and 6 months and DAS28-ESR/CRP, age, sex, smoke or switch at baseline as predictors.

Results: We identified 195 patients; cohort's descriptive statistics are given in Table 1. A total of 140 (74%) patients were switched from adalimumab to a biosimilar. At 3 months after the switch, 25 (19%) and 17 (13%) of patients were defined as good responders, 48 (36%) and 41 (31%) as moderate responders and 61 (46%) and 76 (57%) patients as non-responders, on DAS28-ESR and DAS28-CRP, respectively. At 6 months, 28 (24%) and 22 (19%) of patients had a good response, 29 (25%) and 32 (28%) – a moderate response and 59 (51%) and 62 (53%) patients did not respond, on DAS28-ESR and DAS28-CRP (Figure 1), respectively. The results of the Chi-squared test indicated no difference in the frequency of good/moderate/no response at 3 and 6 months on DAS28-ESR/CRP between patients switched and not. There was a significant association between age and DAS28-ESR/CRP response at 6 months ($p<0.001$ and $p=0.025$) respectively.

Table 1. Patients characteristics

Variables	N = 195[1]
Age	
Mean (SD)	55.05 (13.95)
Median (IQR)	57.00 (48.00, 64.00)
Minimum	18.00
Maximum	86.00
(Missing)	6
Sex	
F	120 (62%)
M	74 (38%)
(Missing)	1
Smoke	
no + ex-smokers	150 (79%)
yes	39 (21%)
(Missing)	6
ANTI-CCP	
neg	130 (75%)
pos	40 (23%)
(Missing)	25

[1]Mean (SD), Median (IQR), Min, Max or Frequency (%)

Conclusion: About three quarters of the patients included in this study underwent a switch from an originator to a biosimilar TNFi. The response rates were similar in those who did and who did not undergo a switch. The switch did not determine a reactivation of the disease.

AB0336 MANAGEMENT OF INFLAMMATORY ARTHROPATHIES IN SUSTAINED REMISSION: UNIFICATION OF TAPERING CONCEPT IS ON TIME (THE RESULTS OF E-SURVEY OF UKRAINIAN RHEUMATOLOGISTS)

I. Biliavska[1], V. Kovalenko[1]. *[1]SI NSC "Institute of Cardiology named after acad. M.D. Strazhesko" NAMS of Ukraine, Non-Coronary Heart Disease and Rheumatology, Kyiv, Ukraine*

Background: Changes in the management paradigm (early diagnosis, new therapeutic options, implementation treat-to-target (T2T) concept) in patients with inflammatory arthropathies (IA) have led to the fact that disease activity in most cases is suppressing effectively. On the one hand, this improves of long-term outcomes of IA; on the other - it increases risks of overtreatment, adverse events, and financial costs.

Objectives: The study aimed to estimate trends and approaches among Ukrainian rheumatologists to the tapering disease-modifying antirheumatic drugs (DMARDs) in patients with IA in sustained T2T remission.

Methods: The anonymous and validated e-survey, based on the initial research hypothesis, was conducted by the Ukrainian Association of Rheumatologists. Its structure consists of 10 questions agreed by the members of the Task Force and approved by the ethics committee. E-survey was designed with digital toll SurveyMonkey and disseminated via email among rheumatologists of Ukraine from the national database. All data received is stored and processed per privacy protection laws. Descriptive statistics were used for the analysis.

Results: During one month period, 107 responses had received. 82.2% of Ukrainian rheumatologists used validated diseases activity measures in their daily clinical practice regularly. To assess the trends for DMARDs tapering for further analysis, 71 (66.4%) responses are taken from specialists who often/very often prescribe bDMARDs to patients with IA. Only 12 (17.1%) rheumatologists rarely taper DMARDs; 39 (55.7%) - periodically and 20 (28.2%) - very often deescalate DMARDs therapy in their practice. For 35 (49.3%) of responders, the decision doesn't depend on the type of IA. In the case of combined therapy, 43 (60.6%) start tapering of synthetic DMARD, 19 (26.8%) – of bDMARDs, and 9 (12.7%) with simultaneously tapering of bDMARDs and cDMARDS, respectively. The main criteria for Ukrainian rheumatologists to start dose reduction of DMARDs were state of sustained remission - 30 (42.3%), significant disease activity suppression - 17 (23.9%), financial inability to purchase the drug - 17 (23.9%), adverse events development - 7 (9.9%). The optimal remission duration before tapering for 23 (32.4%) responders was 6-12 months, for 17 (23.9%) – up to 6 months, and for 12 (16.9%) more than 12 months, respectively. Only 19 (26.8%) believe that disease activity suppression and improvement of patient status are enough to start tapering DMARDs. During tapering DMARDs, it was found that for clinical status monitoring, 30 (42.3%) of rheumatologists examine patients monthly, 31 (43.7%) – every 3-months, 7 (9.9%) - on-demand, and only 3 (4.2%) – every 6-months. 43 (60.6%) of specialists had noted that due to the loss of T2T response - full-dosing regimens have to be restored. Financial inability to purchase the drug for 49 (69%) responders is the strong argument to start a dose reduction due to the lack of bDMARDs reimbursement in Ukraine.

Conclusion: DMARDs dose reduction has become a part of clinical rheumatology practice. The lack of unified recommendations leads to decisions tapering

DMARD based mainly on rheumatologists' knowledge and experience. The standardized approach introduction to DMARD de-escalation would help clinicians support treatment decisions.

AB0337 BASELINE C-REACTIVE PROTEIN PREDICTS ADHERENCE TO ADALIMUMAB THERAPY AT 3 MONTHS IN AN OBSERVATIONAL COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS

A. W. Ramli[1,2], N. Nair[3], K. Hyrich[4,5], J. Isaacs[6], A. Morgan[7,8], D. Plant[3,4], A. G. Wilson[9], A. Barton[3,4,10]. *[1]The University of Manchester, Centre for Musculoskeletal Research, School of Biological Sciences, Manchester, United Kingdom; [2]Wrightington Hospital, Wrightington, Wigan and Leigh Teaching Hospitals NHS Foundation Trust, Department of Rheumatology, Wigan, United Kingdom; [3]The University of Manchester, Versus Arthritis Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester, United Kingdom; [4]Manchester University NHS Foundation Trust, NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester, United Kingdom; [5]The University of Manchester, Versus Arthritis Centre for Epidemiology, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; [6]Newcastle upon Tyne Hospitals NHS Foundation Trust, Translational and Clinical Research Institute, Newcastle University and Musculoskeletal Directorate, Newcastle upon Tyne, United Kingdom; [7]University of Leeds, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; [8]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; [9]University College Dublin, UCD School of Medicine and Medical Science, Conway Institute, Dublin, Ireland; [10]Manchester Royal Infirmary, Manchester University NHS Foundation Trust, The Kellgren Centre for Rheumatology, Manchester, United Kingdom*

Background: Adherence to biologic treatment in rheumatoid arthritis (RA) is often self-reported and little is known about the predictors of adherence to biologic medications. Many studies have reported the predictors of adherence to be linked to psychological factors. A systematic review [1] identified several predictors of adherence to methotrexate in RA patients with the strongest predictors related to psychological factors including beliefs in medication necessity and absence of low mood. Mild disease activity was also found to be a significant predictor of adherence from this study. It is unknown whether similar factors will predict adherence in an established cohort of patients with RA starting biologic therapy.

Objectives: To investigate levels of self-reported adherence to adalimumab treatment and identify the contribution of demographic, physical and psychological factors to medication adherence in an RA cohort.

Methods: Patients with RA who were commencing on adalimumab were recruited through the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS), a large UK multicentre prospective observational cohort study. Demographics, baseline clinical and psychological measures including illness and medication beliefs were collected. Self-reported adherence, defined as the patient has never stopped, altered, missed, forgot to take, or took a lower dose than prescribed of adalimumab, were recorded at 3 months. Potential baseline predictors of adherence to adalimumab therapy were determined using logistic regression analyses.

Results: 202 patients were included; 76% female, median (IQR): age 59 (52-67) years, pre-treatment DAS28-CRP score 5.6 (5.1-6.1) and disease duration 5 (2-15) years. During the first 3 months following commencement of adalimumab, 176 (87%) patients reported full adherence. Univariable analyses found that high baseline C-reactive protein (CRP) [odds ratio (OR) 1.04 per mg/L, 95% CI 1.01, 1.09] was associated with adherence to adalimumab at 3 months. However, there were no associations identified from the psychological variables and this includes perceived necessity towards medication [OR 0.92, 95% CI 0.79, 1.05], hospital depression score [OR 0.94, 95% CI 0.84, 1.06] and hospital anxiety score [OR 0.97, 95% CI 0.88, 1.08].

Conclusion: These findings suggest that the psychological measures were less able to predict adherence to adalimumab therapy. The high percentage of adherence during the first three months of therapy may limit power to detect small effects in this cohort. Further research to investigate whether psychological variables correlate with drug levels as an alternative surrogate for adherence and to consider including other biological agents with a longer follow-up timeline are needed.

High baseline CRP levels were associated with adherence. This finding suggests active disease with higher levels of inflammation in RA may be a factor for adherence in patients who are commencing biologic therapy.

AB0338 BELIEFS ABOUT BIOLOGIC DRUGS AMONG RHEUMATOID ARTHRITIS PATIENTS

E. Hannech[1,2], S. Boussaid[1,2], S. Rekik[1,2], S. Rahmouni[1,2], S. Jemmali[1,2], H. Ajlani[1], H. Sahli[1,2], M. Elleuch[1,2], R. Dhahri[2,3], I. Gharsallah[2,3]. *[1]Rheumatology Department, La Rabta Hospital, Tunis, Tunisia; [2]Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; [3]Rheumatology Department, Military Hospital of Tunis, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease requiring a long-term follow-up and the use of chronic therapies. The management of this disease is based on a multidisciplinary care, requiring total patient involvement. Previous personal experiences, the experiences of others and the daily impact of the disease on patients fuel their perceptions of the treatment especially biologic one. There are few studies evaluating patient's beliefs about these drugs [1,2].

Objectives: The aim of our study was to investigate beliefs about biologic Disease-Modifying Anti-Rheumatic Drugs (bDMARDs) among patients with RA and to identify factors related to specific beliefs.

Methods: We conducted a bi-centric cross-sectional study, including patients with RA fulfilling the ACR/EULAR 2010 criteria. All patients were on bDMARDs associated or no to conventional synthetic (sc) DMARDs. Sociodemographic, clinical, biologic, and therapeutic data were collected. Patients were interviewed about their medication beliefs using the Beliefs about Medicines Questionnaire (BMQ).

Results: There were 75 RA patients: 60 female (80%) and 15 males (20%). The sex ratio was about 0.25. The mean age was 56.92 ± 9.06 years [34-80]. Thirty-three percent of patients were illiterate. Twenty patients were employed. Sixty-four patients (85.3%) were married. The mean disease duration was 14.85 ± 8.5 years [2-39]. Thirty-three patients had joint deformities. Twenty-seven patients had extra-articular manifestations and thirty-six patients had comorbidities. The mean disease activity scale (DAS28 CRP) was 3.94 ± 1.32 [1.21-7.15]. Fifteen patients (20%) had high disease activity, 11% had low disease activity, and 19% were in remission. The mean functional impairment scale (HAQ) was 0.64 ± 0.48 [0-2.2]. Twelve patients had moderate to severe disability and only one patient had severe to very severe disability. The mean duration of the current bDMARD was 37.17 ± 39.44 months and the mean rank of the current biotherapy was 1.41 ± 0.9 [1-5].

Regarding the BMQ, the mean score for General Overuse was 14 ± 2.37 [6-20]. The mean score for General Harm was 10.82 ± 4.42 [4-20].

The mean score of patients' specific beliefs regarding the necessity of taking the current bDMARD (Specific Necessity) was 20.62 ± 5.71 [5-25]. The mean Specific Concerns score regarding the current bDMARD was 10.33 ± 3.29 [5-25]. Necessity about taking bDMARD was reported by 77.3% patients in the present and 61.3 % patients consider maintaining the bDMARD in the future.

There were 4% of patients who reported concerns about taking bDMARD. Twenty four percent of patients reported concerns about long term effects, and 16% about becoming too dependent on bDMARD.

Beliefs about the necessity to stop occasionally chronic therapies were reported by 13.3% of patients.

Specific necessity was correlated to the current bDMARD duration (p=0.01), Patient Global Evaluation (p=0.03), VAS pain scale ($p<10^{-3}$), the number of nocturnal awakenings (p=0.01), tender joint count ($p<10^{-3}$), swollen joint count (($p<10^{-3}$), HAQ (p=0.005), DAS28 (CRP) ($p<10^{-3}$). Specific concerns were correlated to the actual bDMARD rank (p=0.01).

Conclusion: Our study showed stronger beliefs in the necessity of taking biologic drugs if indicated. Disease activity parameters and functional impairment influence those beliefs. Further studies are required to evaluate the impact of beliefs on biologic drug adherence.

EFFICACY, PHARMACOKINETICS AND SAFETY BETWEEN CT-P13 AND CHINA-APPROVED INFLIXIMAB: 54 WEEK RESULT FROM A PHASE III RANDOMIZED CONTROLLED TRIAL IN CHINESE PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

J. Kay[1], X. Zeng[2], L. Chen[3], K. Tang[4], G. Shi[5], L. Liu[6], L. Wu[7], Y. Liu[8], J. Hu[9], S. Liu[10], Z. Yi[11], S. H. Kim[12], Y. Bae[13], J. Suh[13], S. Rhee[13], S. Lee[14], C. Hwang[14]. *[1]UMass Chan Medical School and UMass Memorial Medical Center, Rheumatology, Worcester, MA, United States of America; [2]Peking Union Medical College Hospital, Rheumatology, Beijing, China; [3]Jilin Province People's Hospital, Rheumatology, Changchun, China; [4]Liuzhou Worker's Hospital, Rheumatology, Liuzhou, China; [5]The First Affiliated Hospital of Xiamen University, Rheumatology, Xiamen, China; [6]Xuzhou Central Hospital, Rheumatology, Xuzhou, China; [7]People's Hospital of Xinjiang Uygur Autonomous Region, Rheumatology, Urumqi, China; [8]West China Hospital, Sichuan University, Rheumatology, Chengdu, China; [9]Jiangxi Pingxiang People's Hospital, Rheumatology, Pingxiang, China; [10]The First Affiliated Hospital of Zhengzhou University, Rheumatology, Zhengzhou, China; [11]Beijing Chaoyang Hospital, Rheumatology, Beijing, China; [12]Celltrion, Inc, Medical Science, Incheon, Korea, Rep. of (South Korea); [13]Celltrion, Inc, Clinical Planning, Incheon, Korea, Rep. of (South Korea); [14]Celltrion, Inc, Clinical Statistics, Incheon, Korea, Rep. of (South Korea)*

Background: CT-P13 is an approved biosimilar to EU-approved and US-licensed Infliximab (INX) for the indications of rheumatoid arthritis (RA), adult and paediatric Crohn's disease, adult and paediatric ulcerative colitis, ankylosing spondylitis, psoriatic arthritis and psoriasis.

Objectives: The purpose of this study was to demonstrate equivalence of efficacy and compare PK and safety profiles of CT-P13 and China-approved INX.

Methods: In this randomized, double blinded, multicenter, parallel-group, phase III study, patients with active RA who had been responding inadequately to methotrexate for at least 3 months, were randomized to receive either CT-P13 or China-approved INX. Patients were treated with doses of 3 mg/kg at Weeks 0, 2, 6, then every 8 weeks up to Week 54. Prior to dosing at Week 30, patients randomized to China-approved INX underwent a second randomization either to continue China-approved INX or to switch to CT-P13 at Week 30. Results of patients who underwent transition to CT-P13 were included in the China-approved INX group. The primary efficacy endpoint was change in DAS28 (CRP) from baseline to Week 14, which was analyzed using an analysis of covariance. Equivalence was determined if the 90% CI for the estimate of treatment difference was entirely contained within the predefined equivalence margin of -0.6 to 0.6.

Results: 270 patients were randomly assigned to 2 treatment groups in a 1:1 ratio (136 and 134 patients in the CT-P13 and China-approved INX groups, respectively) and 184 patients completed the study. The least square mean change (standard error) of DAS28 (CRP) from baseline to Week 14, -1.566 [0.1419] and -1.547 [0.1491], was similar between the CT-P13 and China-approved INX groups, respectively. The 90% CI for the estimate of treatment difference (-0.29, 0.25) was contained within the predefined equivalence margin, which demonstrated therapeutic equivalence between the groups. The mean actual values for DAS28 (CRP) decreased from baseline to Week 54 and were similar between the groups (Figure 1). Additional efficacy endpoints, including ACR responses (ACR20 at Week 14; 60.6%, 54.8% and at Week 54; 65.1%, 60.6% in the CT-P13 and China-approved INX groups, respectively), EULAR responses, CDAI, and SDAI, were similar between the groups, even after switching at Week 30. During the study, mean serum INX concentrations were similar between the groups. Between Weeks 14 and 22, mean (percent coefficient of variation) AUC_{τ} were 11156333.615 (44.796) ng·h/mL and 11462884.280 (51.057) ng·h/mL, and $C_{max,ss}$ were 66577.2 (31.4) ng/mL and 66356.1 (21.0) ng/mL in the CT-P13 and China-approved INX groups, respectively, which were similar between the groups. Most treatment-emergent AEs were grade 1 or 2 in intensity. One malignancy was reported in the CT-P13 group and no deaths were reported. The proportions of patients with anti-drug antibodies were similar between the groups, even after switching at Week 30. The overall safety profile of CT-P13 was comparable to that of China-approved INX and no new safety issues were observed (Table 1).

Table 1. Summary of Safety Results

Number of patients (%)		CT-P13 (N=136)	China-approved Infliximab (N=133)
Treatment-emergent AEs	Total	115 (84.6%)	107 (80.5%)
	Related	97 (71.3%)	86 (64.7%)
Treatment-emergent serious AEs	Total	17 (12.5%)	12 (9.0%)
	Related	10 (7.4%)	6 (4.5%)
Infusion related reaction/ hypersensitivity/ anaphylactic reactions	Total (=Related)	20 (14.7%)	19 (14.3%)
Infections	Total	45 (33.1%)	43 (32.3%)
	Related	36 (26.5%)	40 (30.1%)

Note: Summary is presented for the safety population who received at least 1 dose (full or partial) of study drug.

Conclusion: The study demonstrated that efficacy of CT-P13 is equivalent to that of China-approved INX. Also, the PK and safety profiles of CT-P13 were comparable to those of China-approved INX. No loss of efficacy or difference in safety or immunogenicity was observed after switching from China-approved INX to CT-P13 at Week 30.

AB0340

SHORTENING THE DOSING INTERVAL OR DOSE ESCALATION OF BIOLOGICAL DMARDS SUPPRESSED RESIDUAL ULTRASOUND SYNOVITIS AND JOINT DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS -STARBOARD STUDY-

Y. Yamada[1], T. Okano[1], K. Mamoto[1], K. Inui[2], K. Mandai[2], T. Koike[3], H. Nakamura[1]. *[1]Osaka City University School of Medicine, Orthopedics, Osaka, Japan; [2]Saiseikai Nakatsu Hospital, Orthopedics, Osaka, Japan; [3]Osaka City University School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*

Background: In patients with rheumatoid arthritis (RA) who have residual synovitis even after using biological disease modified anti-rheumatic drug (bDMARDs), joint destruction may progress[1]. The enhanced treatment such as shortening the dosing interval or dose escalation of bDMARDs are recommended for these patients, if allowed in package inserts[2, 3].

Objectives: We investigated the effects of enhanced treatment in RA patients with residual synovitis under treatment with standard dose of bDMARDs.

Methods: Forty RA patients treated with standard dose of infliximab, tocilizumab or golimumab were included in this study. Ultrasound (US) examination was performed at the bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three parts of radial, medial and ulnar) and first to fifth metatarsophalangeal (MTP) joints, by using HI VISION Ascendus (Hitachi Medical Corporation, Japan) with a multifrequency linear transducer (18-6 MHz). Residual synovitis was defined as Power Doppler score (PD) ≥2. In patients with residual synovitis, we recommended enhanced treatment. The patients were divided into 3 groups, PD≥2/ET+ group (patients agreed enhanced treatment), PD≥2/ET- group (patients rejected enhanced treatment), and PD<2 group. We assessed ultrasound (PD score), laboratory data

(CRP, MMP-3), disease activity (Simplified Disease Activity Index; SDAI), physical function (Health Assessment Questionnaire; HAQ), and joint destruction (modified Total Sharp Score; mTSS) at baseline and 1-year follow-up.

Results: There were 9 patients in PD≥2/ET+ group and 31 patients in PD<2 group. PD≥2/ET+ group had significantly higher SDAI (p=0.027), MMP-3 (p=0.005), and PD (p<0.001) at baseline compared with PD<2 group, but their MMP-3 (p=0.019) and PD (p=0.042) were significantly decreased over 1 year. PD≥2/ET+ group had joint destruction before ET (p=0.022), but it was suppressed after ET and there was no significance in change in mTSS compared with PD<2 group (p>0.99) (Figure 1).

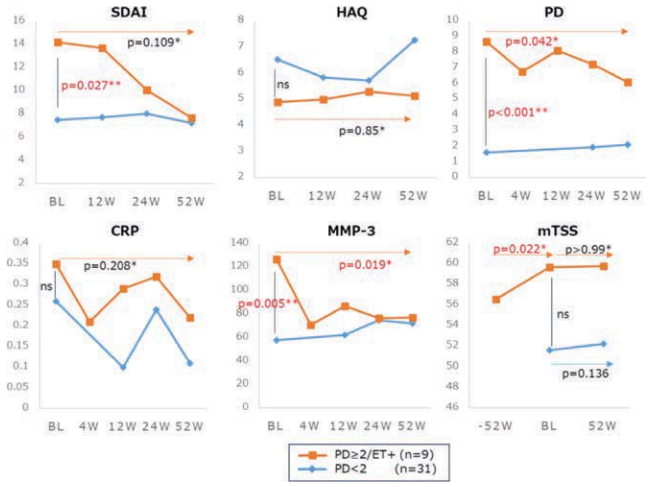

Figure 1. Disease activity, ultrasound assessment and radiographic change from baseline (BL) to 1-year follow-up in RA patients with residual synovitis who had enhanced treatment (PD≥2/ET+) and those without active synovitis (PD<2). *Each parameter at BL and 1-year was statistically analyzed by Wilcoxin signed rank test only in PD≥2/ET+ group.**Difference in two groups at BL was statistically analyzed by Student t test or Mann-Whitney U test. SDAI: simplified disease activity index, HAQ: health assessment questionnaire, PD: Power Doppler, MMP-3: matrix metalloproteinase 3, mTSS: modified Total Sharp Score.

Conclusion: In RA patients with the residual synovitis under treatment with standard dose of bDMARDs, enhanced treatment decreased the synovitis and suppressed the joint destruction.

EFFICACY AND DRUG SURVIVAL AFTER MULTIPLE-SWITCHING FROM ADALIMUMAB ORIGINATOR TO THE BIOSIMILARS ABP501 AND SB5: A REAL-LIFE STUDY

S. Parisi[1], A. Becciolini[2], M. C. Ditto[1], A. Ariani[2], A. Ianniello[3], M. Priora[4], M. Paroli[5], C. Realmuto[1], C. L. Peroni[1], C. M. Centanaro Di Vittorio[1], R. Degiovanni[1], A. Laganà[1], E. Fusaro[1]. *[1]Azienda Ospedaliero Universitaria Città Della Salute e della Scienza di Torino, Rheumatology Unit, Turin, Italy; [2]Azienda Ospedaliero Universitaria di Parma, Department of Medicine, Internal Medicine and Rheumatology Unit, Parma, Italy; [3]Azienda Sanitaria Locale Novara, Rheumatology Unit, Novara, Italy; [4]Department of General and Specialist Medicine, Rheumatology Unit, Mondovì, Italy; [5]Department of Medical-Surgical Sciences and Biotechnologies, Sapienza University of Rome, Polo Pontino, Latina, Italy*

Background: AntiTNF-α biosimilars are broadly available for the treatment of inflammatory arthritis. There are a lot of data concerning the maintenance of clinical efficacy after switching from originators to biosimilars. However, there is lack of data on the switch between biosimilars. The current evidence on the safety, efficacy, and immunogenicity of switching multiple times from a biosimilar to another biosimilar comes from a limited number of randomized-controlled trials and real world evidence studies.

Objectives: The aim of our work was to evaluate the disease activity trend after multiple switching from ADA originator-Humira (oADA) to its biosimilars (bsADA; ABP 501 and SB5 subsequently) in a cohort of inflammatory arthritis patients.

Methods: In this real-life study, we selected patients with clinical diagnosis of rheumatoid Arthritis (RA), psoriatic Arthritis (PsA) and ankylosing spondylitis (AS). Patients had been previously treated with oADA and switched to the bsADA (first ABP 501 and then SB5). At each outpatient visit, we recorded demographic features (age, sex, and time since diagnosis) and the following disease activity measures: DAS28, DAPSA, BASDAI and the HAQ. Rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA), C-reactive protein (CRP) and HLAB27 were also measured over the observational period (visits 0, 12, 24 and 36 months). The disease activity was evaluated during the year before the introduction of the bsADA, and then evaluated in the following 36 months during the first and the second bsADA treatment. We also examined whether some baseline characteristics, such as the duration of ADA treatment, concomitant therapy, comorbid disease and baseline disease activity, could influence the bsADA discontinuation.

Results: We evaluated the 3-year drug survival and efficacy of the multiple switch of bsADA in RA, PsA and AS patients, previously treated with oADA in 127 patients (Table 1). All the patients enrolled underwent a first switch lasting one year and then a second switch with a follow up of one year too. The 1-year retention rate for ABP501 was 84.4%, 78% and 76% in AS, RA and PsA patients, respectively. The 1-year retention rate for SB5 was 82.1%, 78,7% and 77,5% in AS, RA and PsA patients, respectively. Disease activity, as measured by DAS28, DAPSA and BASDAI remained stable over the 3 years (Figure 1). Comorbid disease (HR: 3.04, $p < 0.001$) and HAQ at baseline (HR: 2.12, $p = 0.001$) significantly increased the risk of ADA discontinuation, while previous ADA duration was positively associated with bsADA retention rate (HR: 0.83, $p = 0.0024$). 27.4% patients left the study due to the interruption of the bsADA, 76.5% discontinued due to inefficacy and 23.5% due to adverse events.

Table 1. Baseline characteristics of RA, PsA and AS patients

Characteristics	Total cohort N=127	RA N=41	PsA N=52	AS N=34
Female gender (%)	75 (60)	35 (85)	31 (59)	9 (26)
Age (years)	61.7±12.78	60.5±12.64	61.55±11.6	56.3±10.71
Disease duration (years)	15.86±9.49	17.23±10.64	13.75±6.57	14.92±9.50
Comorbidities, (%)	17,8 (14)	5,7 (14)	9,8 (19)	2 (6)
ACPA+, n (%)	-	25 (63.3)	-	-
RF+, n (%)		24 (62.5)		
HLAB27+, n (%)	-	-	8 (15)	17 (50)
CRP (mg/L)	1.65±2.27	2.31±1.90	0.42±0.27	1.36±1.91
DAS 28	-	2.65±0.75		
DAPSA	-		8.25±3.69	
BASDAI	-			3.23±1.58
HAQ	0.73±0.57	0.72±0.55	0.73±0.52	0.76±0.69
Prednisone, n (%)	46 (36)	23 (55)	20 (44)	3 (13)
Combo Therapy	65 (51)	29 (68)	25 (48)	11 (32)
oADA duration (months)	49.74±40.75	56.43±41.27	25.00±13.67	40.08±37.78
ABP501 duration (months)	12.42±2.41	12.77±2.34	12.82±1.49	12.49±2.95
SB501 duration (months)	11.92±1.41	12.47±1.74	12.72±1.49	12.41±1.95

ABP501 (Adalimumab biosimilar, Amgevita), SB501 (Adalimumab biosimilar, Imraldi)

Conclusion: No difference was found between oADA and bsADA in terms of efficacy. This real-life study confirms the similar efficacy profile of multiple switch bsADA with long-term retention and a good safety profile in inflammatory arthritis patients.

AB0342 EVALUATION OF SELF-CARE SAFETY SKILLS AND THERAPEUTIC KNOWLEDGE OF RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGIC DRUGS

E. Hannech[1,2], S. Boussaid[1,2], S. Rekik[1,2], S. Jemmali[1,2], S. Rahmouni[1,2], H. Sahli[1,2], M. Elleuch[1,2], R. Dhahri[2,3], I. Gharsallah[2,3]. [1]*Rheumatology Department, La Rabta Hospital, Tunis, Tunisia;* [2]*Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia;* [3]*Rheumatology Department, Military Hospital of Tunis, Tunis, Tunisia*

Background: The management of rheumatoid arthritis (RA) was revolutionized by the use of biologic therapies (bDMARD). Nevertheless, bDMARDs may carry some specific risks such as infection. However, data about self-care safety skills are poor [1]. An assessment of the level of information and education is therefore essential for patients followed for RA.
Objectives: The purpose of our study was to assess knowledge and safety skills of RA patients under bDMARDs.
Methods: We conducted a descriptive, bi-centric, and cross-sectional study, including RA patients receiving intravenous (IV) or subcutaneous (SC) bDMARD for at least 3 months. Sociodemographic, clinical, and paraclinical data were collected. Knowledges and self-care safety skills were assessed by a pre-specified questionnaire.
The questionnaire was divided into three domains:
- Five questions about general theoretical knowledge domain: assessing patient's knowledge of the name of the current bDMARD, duration and rate of intake, and a question on annual cost estimation.
- Three questions about the current bDMARD management: assessing cold chain compliance and management of the biologic in SC emphasizing adherence to the steps to be taken prior to giving the injection.
- Tow questions about knowledge regarding safety skills in special situations: infection, cough, contraception, surgery, vaccination, and regarding the need to inform others about the use of bDMARD.
Based on the data analysis, patients were divided into 3 groups according to their knowledge level:
- Group A (low knowledge level: percentage of correct answers <40%)
- Group B (moderate knowledge level: percentage of correct answers >40% and <60%)
- Group C (high level of knowledge: percentage of correct answers > 60%).
Results: Seventy-five patients with RA were collected. Their mean age was 56.92 ± 9.06 years [34-80]. The mean duration of bDMARD was 37.17 ± 39.44 months [4-248] with a mean rank of 1.41 ± 0.9 [1-5]. The SC route was used in 41 patients (54.7%) followed by the IV route in 34 patients (45.3%)
The most prescribed molecules were Infliximab, Certolizumab and Tocilizumab (22.7% respectively). The average order of the current biologics was 1.41 ± 0.9 [1-5] in combination with a csDMARD in 48 patients (64%).
Safety skills were low in 24 patients (32%), moderate in 36 patients (48%), and high in 15 patients (20%).
The mean percentage of correct answers for each domain was respectively: 56.53 ± 18.4% [20-100] for general theoretical knowledge domain, 68.44 ± 26.21% [0-100] for the management of current biologic treatment domain, and 40.8 ± 16.87% [6.67-80] for knowledge regarding safety skills in special situations.
Safety skills levels were significantly related to occupational status (p=0.001), DAS28 CRP (p=0.04), joint deformities (p=0.01) and radiographic erosions (p=0.006), number of previous bDMARDs (p=0.009), and the rank of the current bDMARD (p=0.009).
Conclusion: The major finding of our study was the insufficient level of knowledge and safety skills of RA patients under bDMARDs. We highlight the importance of involving patients in the decision-making process and emphasize the role of the therapeutic patient education programs.

AB0343 LONG-TERM TOCILIZUMAB TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS IN DAILY CLINICAL PRACTICE

Y. Ono[1], Y. Hirano[1]. [1]*Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan*

Background: Tocilizumab (TCZ) is a humanized anti-IL-6 receptor monoclonal antibody that improves the signs and symptoms of rheumatoid arthritis (RA). In previous clinical trials, long-term outcomes have been increasingly evaluated in daily clinical practice. We report the five-year outcomes of TCZ treatment at our institute.
Objectives: This retrospective study determined the long-term trends in TCZ use in clinical practice.
Methods: Data from the Toyohashi RA database (TRAD) were used. The TRAD is single-center retrospective data. Last observation carried forward was used as a complementary method for missing data. Participants were 59 RA patients in whom TCZ therapy was started at our institute from September 2009 to May 2016. Subsequent items, baseline patient characteristics, disease activity, treatment continuation rates of TCZ using the Kaplan-Meier method, reasons for stopping TCZ, concomitant use of methotrexate (MTX) and prednisolone (PSL) were investigated.
Results: Baseline characteristics at the start of TCZ treatment were 17 men and 42 women with a mean age of 58.6 years (30–81). The mean RA duration was 8.7 years (0–31). The mean SDAI score was 27.9 ± 11.6; the mean DAS28-CRP was 5.0 ± 1.0. CRP was 4.1 ± 3.0 mg/dl and MMP-3 388.3 ± 311.5 ng/ml. Methotrexate (MTX) was administered in 37 patients (62.7%, mean 6.0 mg, mean MTX dose administered in cases, 9.6 mg/week). Prednisolone (PSL) was administered in 37 patients (62.7%, mean 3.6 mg; the mean PSL dose administered in cases 5.7 mg/day).
Regarding disease activity, the mean SDAI was 27.9 at baseline; 12.3 at three months; 8.1 at one year; 7.3 at two years; 6.5 at three years; 46.7 at four years; 5.6 at five years, and 5.2 at final observation. The SDAI significantly improved after two years compared to baseline. Remission and low disease activity also significantly improved at one year and gradually improved after one year (Figure 1). The remission rate at the final observation was 55.2%, with an SDAI ≦3.3. TCZ continuation rates were 86.9% at one year, 78.7% at three years, and 68.9% at five years (Figure 2). TCZ was discontinued due to adverse events in 11 cases (18%), and inadequate efficacy occurred in 9 (14.8%). The adverse events were respiratory infection (5), purulent arthritis (1), infectious endocarditis (1), subarachnoid hemorrhage (1), breast cancer (1), pruritis (1), and skin ulcer (1). Other reasons for discontinuation were dialysis (2), suspension of hospital visits (2), kidney transplant (1), and financial difficulties (1). Concomitant use from baseline to final observation declined from 62.7% to 15.3% for MTX and from 62.7% to 23.7% for PSL.
Conclusion: Long-term treatment with TCZ was acceptable. We found that with TCZ therapy, the remission and low disease activity rates significantly improved at one year and continued to improve after one year. Treatment persistence was high, but careful monitoring for infection is necessary.

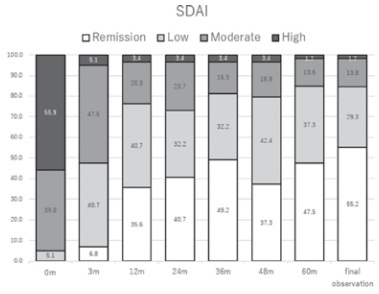

Figure 1 Time-course of Disease Activity Category in RA patients who passed 5 years afterTCZ initiation (Last Observation Carried Forward, including cases who stopped TCZ therapy before 5 years after initiation)

Background: Subcutaneous (SC) CT-P13 is the first and only subcutaneous formulation of infliximab (IFX) approved by the EMA.[1] In the pivotal study (NCT03147248), non-inferiority of SC IFX to intravenous (IV) was demonstrated in rheumatoid arthritis (RA) patients using 28-joint Disease Activity Score (DAS28) C-reactive protein (CRP) improvement at Week 22, with a statistically significant treatment difference of 0.27 (95% CI 0.02, 0.52) favoring the SC versus the IV arm.[2,3] At Week 30, numerical differences in efficacy outcomes were shown between SC and IV IFX favoring SC IFX. IV group patients switched to SC IFX by Week 30, and the difference between the groups was reduced at Week 54.[2]
Objectives: To investigate whether there was a statistically significant difference between SC and IV IFX at Weeks 30 and 54 in the phase 3 pivotal study of CT-P13 SC using conservative missing imputation methods.
Methods: Patients with active RA who had an inadequate response to MTX received IV IFX 3mg/kg at Weeks 0 and 2 for induction and were randomized at a 1:1 ratio to receive SC IFX 120mg every 2 weeks or IV 3mg/kg every 8 weeks thereafter for maintenance. Patients who were randomized to receive IV IFX switched to SC at Week 30. In this post-hoc analysis, non-responder imputation (NRI) and last observation carried forward (LOCF) methods were used to investigate whether the difference in efficacy outcomes between SC and IV IFX at Weeks 30 and 54 was statistically significant. Assessments included EULAR (CRP/ESR)/ACR response; remission rate and low disease activity (LDA) rate based on DAS28 (CRP/ESR), Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI); Boolean remission rate; and the proportion of patients achieving a minimal clinically important difference (MCID) in Health Assessment Questionnaire (HAQ).
Results: Of the 343 randomized patients, 165 patients who received SC IFX and 174 patients who received IV IFX from the efficacy population were included in the analysis. There was a statistically significant difference in SC IFX compared to IV treated patients at Week 30 using both NRI and LOCF methods in almost all the clinical variables. However, the difference in efficacy outcomes between SC IFX and IV was reduced at Week 54 after the IV group switched to SC. This supports the improved efficacy of SC IFX at Week 30. Some of the key results (EULAR [CRP] responses, LDA rates based on DAS28 [CRP], CDAI, and SDAI) were presented in Figure 1. Analysis using LOCF and NRI methods yielded consistent results across most of the efficacy outcomes.

Figure 1. Comparison of clinical outcomes between SC IFX and IV IFX in patients with active rheumatoid arthritis. *P<0.05. P-value for difference in proportion between SC and IV treatment group was obtained by asymptotic Wald test. Low disease activity based on DAS28 (CRP) (< 3.2), CDAI (eatment group AI (≤ 11.0).

Conclusion: Statistical analyses using conservative missing imputation methods showed significantly greater improvements in clinical outcomes with SC IFX compared to IV at Week 30 in patients with RA. Between-group differences was reduced at Week 54, suggesting improved responses after switching from IV to SC.

THERAPEUTIC DRUG LEVELS TO ACHIEVE GOOD EULAR RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING ADALIMUMAB: RESULTS FROM THE BIOLOGICS IN RHEUMATOID ARTHRITIS GENETICS AND GENOMICS STUDY SYNDICATE (BRAGGSS) COHORT

R. M. Hum[1,2,3], P. Ho[1,2,3], N. Nair[2,3], D. Plant[2,3], A. Morgan[4], J. Isaacs[5], A. G. Wilson[6], K. Hyrich[1,2,3], A. Barton[1,2,3]on behalf of BRAGGSS. *[1]Manchester University NHS Foundation Trust,The Kellgren Centre for Rheumatology, Manchester, United Kingdom; [2]The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; [3]The University of Manchester, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; [4]University of Leeds, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; [5]Newcastle University, NIHR Newcastle Biomedical Research Centre, Newcastle, United Kingdom; [6]University College Dublin Centre for Arthritis Research, Conway Institute, Dublin, Ireland*

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease often treated with biologic disease-modifying anti-rheumatic drugs (bDMARDs) such as Adalimumab (ADL), a tumour-necrosis factor inhibitor (TNFi). However, it is known that about a third of patients do not respond to ADL treatment. Previous studies have reported associations between poor response, decreased serum drug levels (SDLs) and poor adherence, but a therapeutic SDL has not been defined nor applied in clinical practice.
Objectives: To assess median ADL SDLs in RA European Alliance of Associations for Rheumatology (EULAR) good vs non/moderate responders, and to determine cut-off SDLs associated with a "Good" response in fully adherent RA patients.
Methods: In a prospective observational cohort study, patients with RA were treated with ADL. At baseline, 3-, 6-, and 12-months patients had 4-component DAS28 scores, self-reported treatment adherence data and SDLs measured. Median drug levels and receiver-operator characteristics (ROC) curves were used to compare SDLs between responders and non-responders, and to establish cut-off SDLs in

self-reported fully adherent patients. Serum drug levels were measured using a sandwich ELISA produced by Progenika Biopharma. Patients were considered fully adherent if they self-reported never having altered, forgotten or omitted any dose of their biologic drug at follow-up. Between group comparisons were assessed using Fisher's exact test, with a threshold for significance set at p<0.05. Statistical analyses were performed in R Version 4.1.0 and RStudio Version 1.4.1106.

Results: A total of 283 RA patients taking ADL were included in the analysis. Baseline characteristics are shown in Table 1. Of these patients 93 (32.9%) self-reported being fully adherent to treatment at 3 months follow-up and had SDLs measured.

Table 1. Baseline characteristics of patient cohort with RA taking ADL (n=283)

Characteristic	n	Missing (%)
Age at baseline, median years (IQR)	58 (51, 64)	0
Disease duration, median years (IQR)	7 (3, 16)	0
Female Sex, n (%)	206 (73)	0
BMI, median (IQR)	27.4 (23.7, 31.9)	0
Smoking Status		132 (46)
Current, n (%)	57 (38)	-
Ex, n (%)	32 (21)	-
Non, n (%)	62 (41)	-
On concurrent DMARD(s)		1 (0.4)
No, n (%)	34 (12)	-
Yes, n (%)	248 (88)	-
Baseline DAS Score, median (IQR)	5.61 (5.18, 6.14)	
On MTX at baseline		38 (13)
No, n (%)	44 (18)	
Yes, n (%)	201 (82)	

In 93 fully adherent RA patients taking ADL at 3 months, good EULAR responders had significantly higher SDLs compared to non/moderate EULAR responders (p=0.0234). In 47/93 (50.5%) fully adherent good responders median SDL at 3 months was 10.94mg/L (IQR 7.75 to 12.0), whereas in 46/93 (49.5%) non/moderate responders, median SDL at 3 months was 9.014 (IQR 6.96 to 11.1).

ROC analysis (see Figure 1) reported a 3-month non-trough ADL SDL cut-off of 7.5mg/L in fully adherent RA patients which discriminated Good EULAR responders compared to non/moderate responders with an AUC of 0.63 (95% CI 0.52 – 0.75), 39.1% specificity, and 80.9% sensitivity.

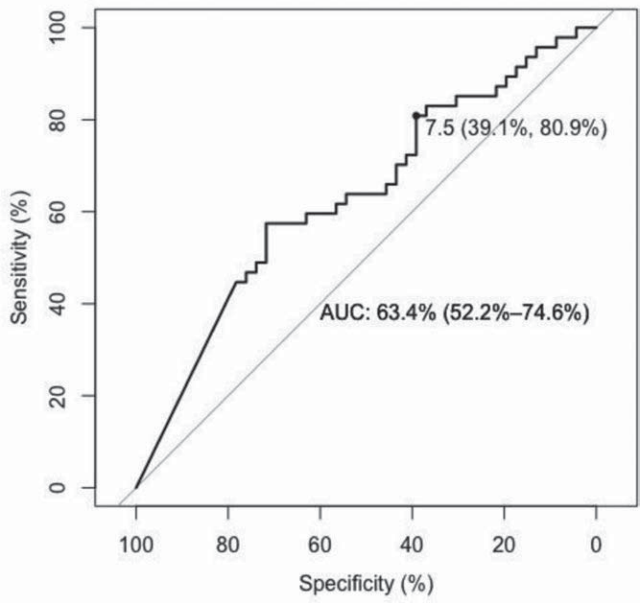

Figure 1. ROC curve analysis: EULAR non/moderate vs good responders with 3 month ADL SDLs.

Conclusion: In keeping with previous work, SDLs were higher in adherent compared with non-adherent patients, but this is the first study to demonstrate that SDLs are higher in fully adherent good EULAR responders compared with non/moderate responders. Based on our methods, cut-offs of 7.5mg/L for ADL may be useful targets in clinical practice to achieve good EULAR response.

AB0346 REASONS FOR DISCONTINUATION OF TNF INHIBITORS IN PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS ACCORDING TO DRUG HISTORY

E. Matianova[1], A. Gordeev[1], E. Galushko[1]. [1]*V.A. Nasonova Rheumatology Research Institute, Rheumatoid Arthritis Evolution Laboratory, Moscow, Russian Federation*

Background: TNF-alpha inhibitors (TNFi) are considered the drugs of choice for initiating biological therapy in rheumatoid arthritis (RA). Rreview of the reasons for their cancellation is included in a comprehensive study of the group of patients (pts) with Difficult to Treat RA (D2T).

Objectives: To make a comparative assessment of the reasons for discontinuation of TNFi in pts meeting the international EULAR (2021) criteria for D2T, comparing them with other pts who had experience in taking a biological disease modifying antirheumatic drugs (bDMARDs)/targeted synthetic DMARDs (tsDMARDs).

Methods: We analyzed the drug history of 505 pts with RA who were hospitalized at the V.A.Nasonova Research Institute of Rheumatology hospital from January to December 2021(inclusive) due to an RA exacerbation, and who were approved for the introduction of bDMARD/tsDMARD. Pts with no prior experience with bDMARD/tsDMARD were excluded from the analysis (n=179/35.4%). Pts meeting the EULAR criteria for D2T RA (the main of which: failure of two or more bDMARDs/tsDMARDs of different mechanisms of action) were allocated to the D2T group (n=35/6.9%), the rest of the pts made up the control group C (n=291/57.6%). The middle age (±SD) of patients in D2T was less than in C (D2T - 46.3±15.1 years vs. C - 51.6±14.8 years, p=0.047), the duration of RA in the groups was comparable (D2T - 15 .7±10.7 years vs. C – 13.1±8.9 years, p>0.05).

Results: The frequency of prescribing a history of TNFi in D2T (85.7%) was higher than in C (38.5%; OR=2.9 [1.3-6.6]; p<0.0001). The total duration of their intake (in cases of prescription) and the average number of TNFi drugs in the groups were comparable (p> 0.05), but in D2T pts more often had the experience of taking 3 or more TNFi (OR = 6.4 [2 -20.4]; p=0.002) (Table 1).

Table 1. Reasons for discontinuation of TNFi in study groups (n/%)

		D2T (n=35)	C (n=291)	p
Pts taking TNFi in anamnesis, n/%		**30** / 85,7	**112** / 38,5	<0,0001; OR=9,6 [3,6-25,4]
Total duration of taking TNFi M±SD, Me [25; 75 percentile], months		22,8±22,5* 15[6;35]	23,2±27,5* 11[4;34]	>0,05
Pts taking 3 or more TNFi, n/%		8 /26,7*	6 /5,4*	0,002; OR=6,4 [2-20,4]
Cancellation for administrative reasons, n/%		2 /6,7*	37 /33*	0,004 $^{CHI\text{-}Square}$;OR=6,9 [1,6-36,6]
Adverse reactions, n/%		9 /30*	23 /20,5*	>0,05
insufficient efficiency	Total	28 /93,3*	49 /43,8*	<0,0001 $^{CHI\text{-}Square}$; OR=18 [4,1-79,3]
	Secondary non-responsiveness to TNFi	**17** /56,7*	**35** /31,3*	0,01; OR=2,9 [1,3-6,6]
	Gradual fading effect	7 /41,2**	22 /62,9**	>0,05
	After the break	9 /52,9**	7 /20**	0,02; OR=4,5 [1,3-15,9]
	After changing to generic	1 /5,9**	7 /20**	>0,05

*the percentage is calculated from the number of pts who took TNFi

**percentage calculated from the number of pts with a history of secondary efficacy of any TNFi

Withdrawal of TNFi due to their ineffectiveness was more often performed in D2T (93.3%/n=28) than in C (43.8%/n=49; OR=18 [4.1-79.3];p<0.0001). At the same time, secondary non-responsiveness (NR) prevailed in D2T - in 56.7% (17 of 28 cases of NR), which is more often than in C (31.3% / 35 of 49 cases of NR; OR = 18 [4.1-79.3]; p<0.0001).

Secondary NR in D2T in 59.9% of pts (9 of 17 cases of secondary NR) developed after the break for administrative reasons in taking a previously effective drug, which is significantly more common than in C (20%/7 of 35 cases of secondary NR; OR = 4.5 [1.3-15.9], p=0.02).

Withdrawal of TNFi for administrative reasons was more common in C (33%/n=37 vs. in D2T -6.7%/n=2; OR=6.9 [1.6–36.6]; p =0.004). The incidence of adverse reactions in both groups was comparable (in D2T 30%/n=9 vs. in C - 20.5%/n=23; p>0.05).

Conclusion: In patients with D2T RA, TNFi were discontinued more often due to their ineffectiveness (93.3%; compared with C: p<0.0001). This inefficiency was more often secondary (56.7%; compared with C: p=0.01). In the structure of secondary inefficiency, the variant of its development after a break in reception for administrative reasons prevailed (52.9%; compared with C: p=0.02). The incidence of adverse reactions in both groups was comparable.

AB0347 TREATMENT RESPONSE WITH ABATACEPT PLUS METHOTREXATE TREATMENT FOR RHEUMATOID ARTHRITIS: REAL-WORLD EVIDENCE FROM THE UK

E. Choy[1], S. Henning[2,3], M. Brazil[3], K. Pollock[3], L. Groves[4], D. Sugrue[4], J. Houghton[4]. *[1]Cardiff University, CREATE Centre, Cardiff University School of Medicine, Cardiff, United Kingdom; [2]nzyme Educate,, Portsmouth, United Kingdom; [3]Bristol-Myers Squibb Pharmaceuticals Limited, Middlesex, United Kingdom; [4]Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom*

Background: A previous real-world study has reported the characteristics, treatment patterns and clinical outcomes of patients with rheumatoid arthritis (RA) who received abatacept in UK clinical practice.[1,2] However, many of the eligible population received abatacept monotherapy rather than as indicated. A subgroup analysis of patients treated with abatacept in combination with methotrexate (ABA + MTX) was therefore undertaken to explore the treatment effect in this specific patient population.

Objectives: Present a subgroup analysis describing the clinical outcomes of patients with RA treated with ABA + MTX in UK real-world clinical practice.

Methods: A multi-centre, retrospective observational study was undertaken in patients with RA treated with abatacept at any line of therapy between 1 January 2013 and 31 December 2017, across four UK centres. Data were collected from patient medical records from index date, defined as the date of first bDMARD initiation, to most recent RA clinic visit, death or end of study (31 December 2017). Clinical outcomes (disease activity and response to treatment) were measured using the 28-joint Disease Activity Score based on erythrocyte sedimentation rate (DAS28-ESR) and European League Against Rheumatism (EULAR) response criteria. Patients that received abatacept outside indication (i.e., without concomitant methotrexate) were retrospectively excluded from the analysis dataset. Statistical analyses for the ABA + MTX subgroup were repeated in line with the methodology previously reported.[1,2]

Results: This subgroup analysis included 133 patients, of 213 patients included in the original study, with RA that received ABA + MTX (mean age 54.6 years, 77.4% female, 7.5 years mean duration of RA at index date). At index date, 64.8% of patients were positive for both anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF), where data were available. In total, 77.8% of patients were categorised with high disease activity at index, with mean DAS28-ESR of 6.2 (SD 1.1).

Irrespective of line of treatment (LOT), patients tended to have a more favourable distribution of good/moderate/no EULAR response when receiving ABA + MTX (31.8%/34.1%/34.1%; n=44) compared with receipt of other bDMARDs (12.7%/36.4%/50.9%; n=55) at 6 months. Similarly, a favourable distribution of good/moderate/no EULAR response in favour of those receiving ABA + MTX compared with other bDMARDs was observed at 12 months (30.6%/41.7%/27.8% versus 20.0%/35.0%/45.0%, respectively).

Patients receiving ABA + MTX remained on treatment for significantly longer than patients in receipt of other bDMARDs as first LOT (median time on treatment 53.4 vs 18.1 months; p<0.01). A similar trend was observed at second LOT, although differences were not statistically significant (median time on treatment 40.1 vs 19.7 months; p =0.08).

Conclusion: Patients with RA who received treatment with any bDMARDs, including ABA + MTX, experienced reduced disease activity. However, those receiving ABA + MTX persisted with treatment significantly longer than when receiving other bDMARDs.

Switzerland; [8]Biogen Idec Ltd, Clinical Research, Maidenhead, United Kingdom

Background: SB5, a biosimilar to reference adalimumab (ADL), received EU marketing authorisation in 2017, based on pre-clinical and clinical phase I and III studies that demonstrated bioequivalence and comparable efficacy, safety and immunogenicity to ADL.
Objectives: The real-world study 'PROPER' is designed to provide insights into outcomes of the transition from ADL to SB5 outside the randomised, controlled, clinical trial setting.
Methods: Under an umbrella design, 1000 patients with immune-mediated inflammatory disease were enrolled at centres in Belgium, Germany, Ireland, Italy, Spain and the UK, and followed for 48 weeks post-transition. Eligible patients with a diagnosis of rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA), ulcerative colitis or Crohn's disease had been transitioned to SB5 as part of routine treatment following a minimum of 16 weeks' treatment with ADL. Data were captured from patient charts retrospectively for 24 weeks prior to and prospectively and/or retrospectively up to 48 weeks after SB5 initiation. This analysis of the rheumatology cohort reports clinical characteristics, disease scores, persistence on SB5, clinical management and safety up to the closing date of November 30th, 2021.
Results: Of the 496 patients included in this analysis, the majority were enrolled in UK (n=174), Germany (n=145) and Spain (n=73); Italy, Ireland and Belgium enrolled 45, 44 and 15 patients respectively. At study close, 487 patients had completed 48 weeks of follow-up; 397 of those remained on SB5 throughout.
Methotrexate was received as concomitant therapy by 37% of patients and 20% had received a biologic therapy prior to reference ADL. Most patients (89.3% of RA, 92.1% of axSpA, 97.3% of PsA) transitioned to SB5 at the same dose regimen received for ADL.
Clinical characteristics, SB5 dose and flare are detailed in Table 1, disease scores in Figure 1.

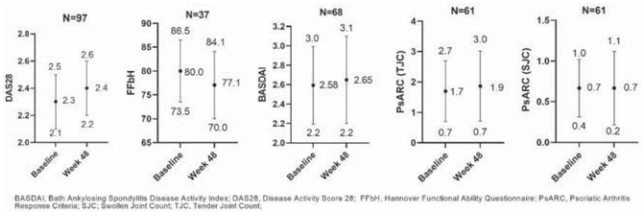

Figure 1. Disease scores (paired patients), mean (95% CI)

Fifteen patients each experienced one unrelated Serious Adverse Event (SAE): 2 in the axSpA cohort [tachycardia, intracranial haemorrhage]; 6 in the PsA cohort [myocardial infarct (2), breast carcinoma, COVID-19, gallbladder calculus, dyspnoea]; 7 in the RA cohort [facial numbness, depression, COVID-19, pneumonia, diverticulitis, parvovirus, coronary occlusion]. Two patients reported SAEs considered causally related to SB5: Herpes zoster and pneumonia (RA cohort), and ALS with worsening (PsA cohort).
Conclusion: This analysis of a large, contemporary cohort of EU patients with established RA, axSpA or PsA shows treatment effectiveness maintained at 48 weeks after switching from ADL to SB5, with most patients continuing on SB5 Q2W throughout. Episodes of flare were uncommon, and the importance of patient-reported symptoms in recognition of flare is evident. No new safety signals were observed.

Nasonova Research Institute of Rheumatology, Scientific Director, Moscow, Russian Federation; [5]I.M. Sechenov First Moscow State Medical University, Department of Rheumatology, Moscow, Russian Federation*

Background: Despite the high efficacy of rheumatoid arthritis (RA) therapy, in routine clinical practice, clinicians face questions about the choice of a second biologics, as well as the possibility of biologics monotherapy. Therefore, the specialties of biologics use in these categories of patients are of great clinical interest. This work is devoted to the study of the effectiveness of abatacept (ABA) therapy in biologic-naïve and biologic-experienced patients and in the subgroup of ABA monotherapy.
Objectives: To evaluate the effectiveness of ABA therapy between biologic-naïve and patients who had experienced an inadequate response to biological agents and in the subgroup of ABA monotherapy.
Methods: We prospectively enrolled and followed 91 patients with high RA activity (SDAI=28±13.4, CDAI=25±12) and an inadequate response of conventional synthetic DMARDs (mainly methotrexate, 70.3%) and biologics (mainly TNF-α blockers, 93%) were included in the study. Most of the patients were middle-aged (49±13.5), positive for RF (72.5%) and ACCP (77%) with moderate functional impairment - 1.4 (0.9-2). Patients were divided into two groups: biologic-naïve (48.4%, n=44) and biologic-experienced patients (51.6%, n=47). 18% (n=17) of patients had a history of an inadequate response of 2 or more biologics. The ABA monotherapy group (13%, n=12) was assessed separately. ABA were administered IV, 10 mg/kg according to the standard scheme. The evaluation of the effectiveness of the therapy was carried out according to the EULAR/ACR 2011 criteria using the intention-to-treat approach and SDAI, CDAI and the functional state using the HAQ.
Results: ABA led to a significant ($p<0.05$) decrease in RA activity after 3 months of ABA therapy in all groups. After 6 months of treatment, there was a tendency towards an increase in the number of patients who achieved remission and low RA activity in the group of biologic-naïve patients, which continued to 12 months of therapy. So, after 6 months and 12 months in the group of biologic-naïve patients, the frequency of remission and low disease activity was 71% (n=25) and 76% (n=19) by SDAI, 75.6% (n=28) and 81.5% (n=24) by CDAI, respectively. Whereas, in the group of biologic-experienced patients - SDAI - 61.8% (n=21) and 69.2% (n=18), CDAI - 64.8% (n=22) and 77.8% (n=21), respectively. However, these differences didn't reach significance. Similar results were obtained according to the EULAR criteria: after 12 months of treatment, the percentage of patients with a good response in both groups did not differ, 38% (n=14) in biologic-naïve and 38.4% (n=15) in biologic-experienced patients. ABA significantly improved functional status of patients, after 12 months the median HAQ of biologic-naïve and biologic-experienced patients were 0.7 (0.2–0.8) and 1.18 (0.7–1.6), respectively. More biologic-naïve patients achieved functional remission by HAQ after 6 and 12 months compared with biologic-experienced patients: 67% (n=23) vs. 33% (n=17), 62.5% (n=11) vs. 37.5% (n=9), respectively, but these differences didn't reach significance. In the ABA monotherapy group after 6 months treatment, a good response by EULAR criteria was achieved in 10% (n=1) patients, while in the group of ABA+csDMARDs therapy in 43.5%, p=0.04. After 12 months the trend towards a more pronounced response in the combination therapy group persisted (11%, n=1 and 42%, n=28, respectively), but no significant differences were obtained.
Conclusion: Abatacept has shown significant improvement clinical and functional status in all studied groups. There were no significant differences in response to ABA therapy between biologic-naïve and biologic-experienced patients. ABA monotherapy were significantly worse compared with the combination therapy of ABA and csDMARDs after 6 months. After 12th month observation, this tendency continued, but no significant differences were achieved. This is probably due to the small number of patients on ABA monotherapy and, as a result, to the insufficient statistical representativeness of the sample.

AB0350

ASSESSMENT OF REAL-LIFE PATIENT HANDLING EXPERIENCE OF AVT02 ADMINISTERED SUBCUTANEOUSLY VIA AUTOINJECTOR IN PATIENTS WITH MODERATE-TO-SEVERE ACTIVE RHEUMATOID ARTHRITIS: AN OPEN-LABEL, SINGLE-ARM CLINICAL TRIAL, THEN AN EXTENSION PHASE OF AVT02 ADMINISTERED WITH A PRE-FILLED SYRINGE (ALVOPAD-PEN)

N. Damjanov[1], H. Stroissnig[2], M. Steiger[3], J. Sobierska[3], E. Guenzi[2], H. Otto[2], A. Sattar[4], H. N. Haliduola[2], E. Edwald[5], F. Berti[3]. *[1]Belgrade University School of Medicine, Department of Rheumatology, Belgrade, Serbia; [2]Alvotech Germany GmbH, Clinical and Medical Affairs, Jülich, Germany; [3]Alvotech Swiss AG, Clinical and Medical Affairs, Zürich, Switzerland; [4]Alvotech UK Ltd, Clinical and Medical Affairs, London, United Kingdom; [5]Alvotech hf, Combination Products & Devices, Reykjavik, Iceland*

Background: AVT02 is an investigational biosimilar to adalimumab. It is approved in Europe, Canada, and the UK. It is not approved by the US Food and Drug Administration (FDA).
Objectives: To assess the real-life patient handling of an autoinjector (AI) in adult patients with moderate-to-severe active rheumatoid arthritis (RA) who self-inject AVT02 subcutaneously (s.c.).
Methods: This open-label study enrolled 107 adalimumab-naïve subjects with moderate-to-severe active RA to self-inject AVT02 with the proposed AI 40 mg s.c. in Week 1, and every other week thereafter through Week 8. In an optional extension phase through Week 56, subjects were switched from AVT02 AI to pre-filled syringe and followed for safety and efficacy. The primary endpoint was the percentage of successful self-injections as reported by both the trial site and by subjects using standardized questionnaires at Week 8. Additional endpoints included ease of use and robustness of the AI at Week 8, and efficacy in RA, assessment of serum trough levels of AVT02, and detection of antidrug antibodies (ADA) throughout the study.
Results: The AI success rate was 100% as reported by both the trial site and by subjects. No handling events were noted through Week 8. Approximately 80% (78.1–84.9%) of subjects found the AI 'very easy' to use and, in general, less difficulty was reported as the study progressed. The first 110 AIs used were inspected for robustness and none showed any sign of damage or malfunction.
All subjects who completed Week 8 (n = 106) took part in and completed the optional extension phase through Week 56.
At Week 8, 49.1%, 5.7% and 0.9% subjects achieved ACR20, -50 and -70 responses, respectively. Improvement was also reported for the SDAI, DAS28 CRP and HAQ, with scores consistently decreasing through Week 8. In the extension phase, 70.8%, 47.2% and 13.2% subjects achieved ACR20, -50 and -70 responses at Week 56. Improvement was also reported for the SDAI, DAS28 CRP and HAQ, with scores consistently decreasing through Week 56.
From Baseline through Week 8 the mean serum concentrations of investigational AVT02 increased consistently at each visit, reaching a peak at Week 24. There was no significant difference in serum concentrations of AVT02 based on injection subsite (abdomen or thigh).
ADAs were detected in 65.1% of subjects through Week 8, reducing to 49.1% by Week 56. Of ADA-positive subjects, most were also positive for neutralizing antibodies through Week 8 (62.3%) increasing through Week 56 (90.4%). Subjects who were ADA-positive had lower serum concentrations of study drug compared with the overall population at Week 8 and Week 56 as expected.
There were no clinically relevant safety or tolerability issues. Overall, treatment-emergent adverse events reported in at least 5% of subjects at the PT level were anaemia and influenza (6 subjects [5.6%)] reported 6 events each), and no local ISRs were reported.
Conclusion: The fully successful self-injection with the AI in this study supported the use of the device while administering AVT02. Furthermore, subjects typically found the AI easy to use, with ease of use increasing as time progressed.
The ACR20, -50, and -70, SDAI, DAS28 CRP and HAQ results supported the use of AVT02 to treat adult patients with moderate-to-severe RA, with the treatment effect persisting beyond Week 8 and through Week 56.
The safety and immunogenicity profiles were as expected for adalimumab.

AB0351

IMPACT OF FCGR2A, FCGR3A AND FCGR3B POLYMORPHISM ON RITUXIMAB EFFICACY IN RHEUMATOID ARTHRITIS

M. Moalla[1], I. Mahmoud[1], A. Ben Tekaya[1], L. Rouached[1], S. Bouden[1], R. Tekaya[1], Y. Gorgi[2], L. Abdelmoula[1], O. Saidane[1], I. Sfar[2]. *[1]Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; [2]Charles Nicolle Hospital, Laboratory of Research in Immunology, Renal Transplantation and Immunopathology (LR03SP01), Tunis, Tunisia*

Background: Identifying reliable biomarkers of response to biologics in rheumatoid arthritis (RA) is necessary to improve responsiveness, preserve functions and structure of joints, as well as to reduce treatment's cost. Single nucleotide polymorphisms (SNP's) of Fc-gamma receptors genes (FCGRs), by inducing a variation of receptors' affinity to Fc fragment of Gamma immunoglobulin, might influence the efficacy of therapeutic monoclonal antibodies by modifying their clearance.
Objectives: The aim of this study was to investigate whether FCGR2A, FCGR3A and FCGR3B SNP's were predictive factors of response to rituximab (RTX) in Tunisian RA patients.
Methods: A cross-sectional, observational and analytic multicentric cohort study was conducted in a group of patients suffering from RA treated with RTX. Treatment outcome was evaluated after 6 months, using DAS_{28} variation from baseline and EULAR response criteria. R131H-FCGR2A, F158V-FCGR3A and NA1/NA2-FCGR3B SNPs were studied using PCR-SSP and direct sequencing process.
Results: Thirty-four patients were enrolled with a sexe ratio M/F=5/29. The mean age at inclusion was 54,24±11,78 years [29-77]. All patients received at least one cs-DMARDS priorly to the prescription of RTX. Concomitant treatment with methotrexate was pursued in 77,3% of patients. As shown in Table 1, an

DAS**: disease activity score, **ΔDAS**: mean variation of DAS at 6 months, **:Comparison of the global distribution of the 3 genotypes, ******: p while comparing the prevalence of R/R genotype to R/H and H/H genotypes, **R+**: good or moderate EULAR response, **R-**: bad EULAR response*

association, that tend to signification, was found between R/R FCGR2A receptors and a greater variation in DAS28 score (p=0,053). This association was also found using EULAR criteria, since all patients with R/R genotypes had a good or moderate response to RTX but was not significative (p=0,131).

Conclusion: The low affinity receptor R/R FcgRIIa might be predictive of good response in RA patients treated with RTX. More studies need to be conducted in larger cohorts to confirm this association, with the aim of identifying reliable biomarkers of response to biologics to improve responsiveness, preserve joints functions and structure, as well as reduce treatment's cost.

AB0352

IMPACT OF SEROLOGIC STATUS ON CLINICAL RESPONSES TO UPADACITINIB OR ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PRIOR INADEQUATE RESPONSE TO BIOLOGIC DMARDS: SUB-GROUP ANALYSIS FROM THE PHASE 3 SELECT-CHOICE STUDY

A. Rubbert-Roth[1], J. Sparks[2], A. Constantin[3], R. Xavier[4], Y. Song[5], J. Suboticki[5], R. M. Fleischmann[6]. *[1]Division of Rheumatology, Cantonal Clinic St Gallen, St Gallen, Switzerland; [2]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, United States of America; [3]Rheumatology Department, Purpan University Hospital and Toulouse III - Paul Sabatier University, Toulouse, France; [4]Division of Rheumatology, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [5]AbbVie Inc., Immunology, North Chicago, United States of America; [6]University of Texas Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, United States of America*

Background: In patients with RA who had a prior inadequate response or intolerance to biologic DMARDs, the oral Janus kinase inhibitor, upadacitinib (UPA), demonstrated superiority in change from baseline in DAS28(CRP) and DAS28(CRP)<2.6 at week 12 and improved responses across additional endpoints compared to abatacept (ABA) in the phase 3 SELECT-CHOICE study. Seropositive patients have been reported to respond better to treatment than seronegative patients.

Objectives: To evaluate clinical responses with UPA versus ABA among RA patients based on serologic status.

Methods: In SELECT-CHOICE (24-week, phase 3, double-blind, controlled trial), RA patients were randomized to oral UPA (15 mg once daily) or intravenous (IV) ABA (at day 1 and weeks 2, 4, 8, 12, 16, and 20; <60 kg, 500 mg; 60-100 kg, 750 mg; >100 kg, 1000 mg).[1] UPA patients also received IV placebo and ABA patients also received oral placebo. All patients continued stable background conventional synthetic DMARDs. Starting at week 12, background RA medications were adjusted or added if patients did not experience ≥20% improvement compared to baseline in tender and swollen joint counts at two consecutive visits. For this sub-group analysis, patients were categorized as follows: RF+ and ACPA+, RF+ and/or ACPA+, and RF- and ACPA-. Mean change from baseline in DAS28(CRP), Clinical Disease Activity Index (CDAI), ACR responses, HAQ-DI, patient's assessment of pain, and Functional Assessment of Chronic Illness Therapy - Fatigue scale (FACIT-F) were evaluated at weeks 12 and 24. Statistical inference was conducted using Chi-square tests or analysis of covariance (ANCOVA) with non-responder imputation or multiple imputation used for missing data and nominal *P*-values shown.

Results: Of the total population (N=612), the majority of patients were seropositive for RF and/or ACPA at baseline (80.4%) (Table 1). Most patients were female (~80%), ~55 years old, and one-third had previously experienced ≥2 biologic DMARDs. Mean change from baseline in DAS28(CRP) and CDAI were numerically higher with UPA vs ABA at weeks 12 and 24 across all sub-groups (Figure 1). Regardless of serologic status, UPA demonstrated numerically higher responses vs ABA for ACR 20/50/70 and proportions of patients in low disease activity and remission at both timepoints (Table 1). Mean change from baseline in the HAQ-DI and the patient's assessment of pain was numerically higher with UPA compared to ABA across all sub-groups and timepoints (data not shown). Clinical responses were generally numerically higher at week 24 compared to week 12, and for the seropositive groups compared to the seronegative group, with both UPA and ABA.

Conclusion: Across serologic statuses, clinical responses with UPA 15 mg vs ABA were numerically higher at weeks 12 and 24 among RA patients with prior inadequate response or intolerance to biologic DMARDs. In addition, clinical responses were numerically higher for seropositive patients compared to seronegative patients across all endpoints assessed, although the seronegative group had a smaller sample size in this post-hoc analysis.

Figure: Mean Change from Baseline in DAS28(CRP) and CDAI with UPA 15 mg or ABA Across Serologic Status Sub-Groups at Weeks 12 (A, C) and 24 (B, D)†

AB0353 BDMARD CHOICES FOR INFLAMMATORY ARTHRITIS WITH CHRONIC KIDNEY DISEASE; HUR-BIO REAL-LIFE REGISTRY

G. Sandal Uzun[1], A. Taghiyeva[2], İ.Y. Çakır[2], K. Moral[2], E. Bilgin[1], G. K. Yardımcı[1], B. Farisogullari[1], E. C. Bolek[1], E. Duran[1], Z. Özsoy[1], G. Ayan[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. *[1]Ankara, Hacettepe University, Faculty of Medicine; Division of Rheumatology, Department of Internal Medicine; Hacettepe University Medical Faculty Department of Internal Medicine Division of Rheumatology, Çankaya, Turkey; [2]Ankara, Department of Internal Medicine, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey*

Background: Rheumatic disesases may involve multiple systems and chronic kidney disease (CKD) can be seen during the course of diseases. Accompanying CKD affects the the choice of treatments in patients with rheumatic disease. There is limited data on the use of biological DMARDs in rheumatic patients with chronic kidney disease.
Objectives: To determine the preferred first and second bDMARDs in patients in the CKD in the bDMARD cohort.
Methods: The Hacettepe University biological database (HUR-BIO), was established in 2005. A total of 2160 RA patients, 3744 SPA patients, were registered in HUR-BIO until November 2021. The CKD was confirmed and classified according to 2012 Kidney Disease: Improving Global Outcomes (KDIGO) guidelines. . Patients were evaluated for the presence of CKB before the initiation of bDmard and during follow-up under bDMARDs. Age and sex matched RA patients without CKD were selected for the control group.
Results: 142/5904 (2.4%) patients have CKD. 102(%71.8) patients had CKD prior to initiation of bDMARD and 40 (28.1%) patients had developed during follow-up. The median time to CKD development after starting bDMARD was 4.13 years(±4.05). Of the patients with CKD, 98 (69.0%) had RA and 44 (31.0%) had SpA. RA patients followed for CKD were older than SpA (66.0 (±11.1) vs 59.1 (±13.0) years, p=0.001), female gender was more common (73.5% vs 36.4%, p<0.001), disease duration was similar (19.3 (±13.8) vs 17.1 (±10.5) years, p=0.40). The first bDMARD choices of patients with and without CKD in RA and SpA patients were shown in Table 1. There was no difference between the SPA patients with or without CKD regarding TNF-i preferences. In patients with rheumatoid arthritis there was no difference in terms of TNFi and non-TNF-i preferences, but tocilizumab was more prefered in CKD group.

Table 1. Relationship between remission according to bDMARD and CKD

	Rheumatoid arthritis		p	Spondyloarthritis		p
	w CKD n=98	wo CKD n=91		w CKD n=44(%)	wo CKD n=80(%)	p<0,05
Etanercept, n(%)	34 (34.6)	30 (33.0)	0.46	17 (38.6)	22 (27.5)	P=0.14
Adalimumab, n(%)	17(17.3)	17 (18.7)	0,48	10 (22.7)	22 (27.5)	P=0.36
Infliximab,n(%)	3 (3)	8 (8.8)	0.85	14(31.8)	32 (40.0)	p=0.24
Golimumab, n(%)	4 (4)	3 (3.3)	0,54	1 (2.2)	3 (3.8)	p=0.55
Certolizumab, n(%)	0 (0)	3 (3.3)	0,11	1 (2.2)	1 (1.3)	p=0.58
Anti-TNF therapy, n(%)	58 (59.2)	61 (67.0)	0,61	43	80	0.352
Non-TNF biologics, n(%)	40 (40,8)	30 (33.0)	0,13	1	0	0.355
Rituximab, n(%)	14 (14.3)	12 (13.2)	0,57			
Abatacept, n(%)	14(14.3)	12 (13.2)	0,49			
Tocilizumab, n(%)	**6 (6.1)**	**1**	**0.041**	1(2.2)		p=0.35
Jak-kinase inhibitors, n(%)	6(6.1)	5 (5.5)	0.55			

Conclusion: In our biologic cohort, 2% of patients with RA and SpA had accompanying CKD. In one-third of the patients with CKD, it was developed during the follow-up after bDMARDs. In patients with RA, there was no difference in terms of TNFi and non-TNF-i preferences. It should be kept in mind that CKD may develop during the follow-up of patients using bDMARDs.

AB0354 THERAPEUTIC DRUG MONITORING: PERFORMANCE OF THE FIRST LATERAL FLOW-BASED POINT OF CARE TEST FOR THE QUANTIFICATION OF INFLIXIMAB IN A FINGER PRICK

A. Ametzazurra[1], J. Pascual[1], L. Del Rio[1], A. Maguregui[1], D. Nagore[1], M. B. Ruiz-Argüello[1]. *[1]Progenika Biopharma - Grifols, Research and Development, Derio, Spain*

Background: Promonitor Quick IFX is a lateral flow test (LFT) for the quantification of infliximab (IFX) in human whole blood (finger prick or venous) or serum in 20 minutes. This LFT is based on a sandwich immunoassay to quantify either the reference IFX or biosimilars.
Objectives: The objective of this study was to perform the required analytical studies to establish the specifications of the product.
Methods: Clinical and Laboratory Standards Institute (CLSI) guidelines were followed for the evaluation of the analytical specifications of the LFT in whole blood and serum matrices: Linearity (EP-06-A), Detection capability (EP17-A2), Interfering substances (EP07, 3rd Edition) and Intermediate precision (EP05-A3). Results were obtained in combination with the automated portable reader PQreader. A Datamatrix provided with each Promonitor Quick IFX kit contains the calibration information required for the PQreader to measure the Control and Test lines and report the IFX concentration.
Results: The linear assay range was determined to be 1-58 µg/mL in whole-blood and 0.6-67 µg/mL in serum according to the processes indicated in the Package Insert. The Limit of Blank is 0.8 µg/mL, the Limit of Detection and Lower Limit of Quantification (LLoQ) are 1.1 µg/mL, and the Upper Limit of Quantification (ULoQ) is 15.4 µg/mL. There was no effect on assay performance when each of the following substances were added to samples with 0, 3, and 7 µg/mL of IFX: Haemoglobin (>1000 mg/dL), Bilirubin (>40 mg/dL), Triglycerides (>1500 mg/dL), HAMA (160 AU/mL), Rheumatoid factor (200 IU/mL), EDTA (5.4 mg/mL), Heparin (51 U/mL), Citrate (11.4%), Vedolizumab (60 µg/mL) and Adalimumab (20.25 µg/mL). Repeatability and within-device precision results obtained for the positive samples are shown in Table 1.
Conclusion: Promonitor Quick IFX is the first LFT available for true Point of Care testing of patients treated with IFX with just a finger prick sample. It provides quick turnaround time to facilitate therapeutic drug monitoring and aid immediate decision making in the doctor office or hospitals with an excellent analytical performance.

Table 1.

	Whole blood samples					Serum samples				
IFX theoretical concentration (µg/mL)	Mean observed IFX concentration (µg/mL)	Repeatability		Within-device precision		Mean observed IFX concentration (µg/mL)	Repeatability		Within-device precision	
		SD	CV%	SD	CV%		SD	CV%	SD	CV%
3	3.2	0.6	18	0.8	25	3.6	0.5	15	0.6	17
7	7	1.3	18	1.7	24	8.3	1.4	16	1.8	21
10	9.8	1.8	18	2.7	28	10.9	1.8	16	2.3	21

The negative samples showed a negative result in all the measurements.

AB0355

THE DIFFERENCES BETWEEN THE FIRST PREFERRED BIOLOGICAL DMARD AND THE DRUG SURVIVAL IN GERIATRIC AND YOUNGER ADULT POPULATION WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS: TREASURE REAL-LIFE DATA

Background: Inflammatory musculoskeletal diseases are frequent in the elderly population, and this number is expected to increase significantly near future. The exclusion of older adults from the studies due to their age and comorbidities causes insufficient data about this population. Insufficient data cause clinicians to have difficulties using and selecting biological therapy in the elderly patient group. In real life, physicians' approaches to the selection and use of biological disease modifying anti-rheumatic drugs (DMARDs) in the geriatric population with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) have not been well studied.

Objectives: To compare the clinicians' first choice of biological DMARDs in elderly and younger RA and PsA patients and investigate the drug survival of first biological DMARDs in both populations.

Methods: The traditional chronological age for the human to be classified in the geriatric population is ≥ 65 years (1). The TReasure web-based registry, created in 2017, is a multicenter observational cohort established to collect data on RA and spondyloarthritis (SpA) patients from the participating 17 rheumatology centers in different regions of Turkey. Physicians' first choice biological and targeted synthetic DMARDs in younger and elderly patients with RA and PsA was evaluated using the descriptive statistical method. The survival of the first b/tsDMARDs was assessed using the Kaplan-Meier method.

Results: 3136 RA and 738 PsA patients were evaluated. 12% of 3136 patients with RA were in the geriatric population. In patients with RA, the first choice of biologic DMARDs was adalimumab (20.6%), followed by etanercept (19.9%), and tofacitinib (13.6%) in patients < 65 years of age, while rituximab (24%) was the first choice in patients ≥ 65 years, tofacitinib (20.9%) in the second place and etanercept (13%) in the third. Of 738 PsA patients, 3% were over 65 years. Adalimumab (41.1%) was the first choice of <65 years of age, etanercept (17.6%) was the second choice, and infliximab (15.5%) was the third choice, while adalimumab (28.6%) was the first choice in patients ≥ 65 years followed by etanercept (17.9%) and certolizumab (17.9%). In RA group, drug survival was significantly higher in patients ≥ 65 years (estimated median drug survival; <65 age: 37.5 (34.1-41.1) months vs ≥65 age: 53.5 (24.9-82.2) months; log-rank p=0,016) (Figure 1). In PsA group, drug survival was significantly higher in patients < 65 years (estimated median drug survival; <65 age: 31.2 (26.4-36.1) months vs ≥65 age: 9.1 (0.4-17.7) months; log-rank p<0,001) (Figure 1).

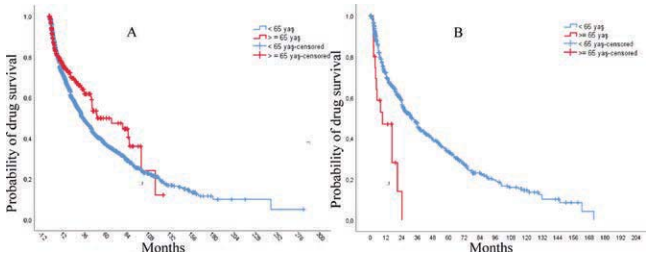

Figure 1. Comparison of first bDMARD retention rates between <65 years and ≥ 65 years. A: In rheumatoid arthritis patients, B: In psoriatic arthritis patients

Conclusion: With these findings, it is thought that in Turkey, the limited socioeconomic support in the geriatric patients has led physicians to prescribe treatments such as rituximab, which are administered in the hospital under the supervision of a physician, are relatively preferred in malignancies, and are considered to be relatively less risky in terms of tuberculosis. Adalimumab and etanercept were chosen in the first two lines in both geriatric and young populations in the patient group with PsA. While the drug survival was significantly higher in patients with RA geriatric age group than the younger group, in PsA in which tumor necrosis factor-alpha (TNF-α) inhibitors were chosen as initial therapy in both age groups was lower in the geriatric population.

AB0356

THERAPEUTIC DRUG MONITORING: STANDARDIZATION OF PROMONITOR QUICK IFX AND PROMONITOR QUICK ADL POINT OF CARE TESTS WITH WHO INTERNATIONAL STANDARDS FOR THE QUANTIFICATION OF INFLIXIMAB AND ADALIMUMAB IN WHOLE BLOOD AND SERUM

A. Ametzazurra[1], J. Pascual[1], L. Del Rio[1], A. Urigoitia[1], D. Nagore[1], M. B. Ruiz-Argüello[1]. *[1]Progenika Biopharma - Grifols, Research & Development, Derio, Spain*

Background: Promonitor Quick IFX and Promonitor Quick ADL are rapid point of care lateral flow tests (LFT) based on a sandwich immunoassay for the quantification of infliximab (IFX) and adalimumab (ADL), respectively, in human whole blood (finger prick or venous) or serum. These tests are to be used as an aid in Therapeutic Drug Monitoring (TDM) of rheumatic and inflammatory bowel disease patients under anti-TNFα therapy. The international standards (IS) developed by World Health Organization (WHO) for IFX and ADL allow harmonization and comparability among different assays.

Objectives: The aim of this study, was to show that Promonitor Quick IFX and Promonitor Quick ADL can measure either reference or biosimilar drugs, as well as to evaluate the agreement of Promonitor Quick IFX and Promonitor Quick ADL tests and the WHO IS.

Methods: Clinical and Laboratory Standards Institute EP10-A3 guidelines were followed to estimate the bias of Promonitor Quick assays when used to quantify IFX or ADL in samples containing the reference drugs, biosimilars or the WHO IS. Briefly, whole blood was spiked with four known concentrations of IFX or ADL, including current clinical decision levels. Ten replicates were measured of each level along two days. Promonitor Quick IFX was evaluated using the reference drug, SB2 and CT-P13 biosimilars, and the WHO IS (NIBSC 16/170). Promonitor Quick ADL was evaluated using the reference drug, ABP501 and SB5 biosimilars, and the WHO IS (NIBSC 17/236). Results were obtained in combination with the automated portable reader PQreader.

Results: Bias was estimated by comparing the observed concentration of drug spiked whole blood samples. Each biosimilar was compared to the reference at the different drug levels tested. Results showed that Promonitor Quick IFX and Promonitor Quick ADL are able to measure equivalently any molecule (see Table 1).

Table 1.

Promonitor Quick IFX bias results in whole blood samples. Each molecule was compared to the reference drug.

IFX concentration (µg/mL)	Bias (%)			
	CT-P13	SB2	GP1111	WHO IS
3	14%	3%	4%	8%
7	9%	0%	5%	15%
10	1%	5%	6%	8%

Promonitor Quick ADL bias results in whole blood samples.
Each molecule was compared to the reference drug.

ADL concentration (µg/mL)	Bias (%)		
	ABP501	SB5	WHO IS
3	17%	2%	3%
5	13%	3%	12%
8	2%	2%	7%
10	5	17%	2%

Similar results were obtained when serum matrix was used.

The accuracy or closeness of the agreement between the result provided by Promonitor Quick IFX and Promonitor Quick ADL and the true value of the measur- and was assessed by measuring the IS developed by the WHO (see Table 1).

Conclusion: Promonitor Quick IFX and Promonitor Quick ADL allow monitoring of patients treated with IFX and ADL, respectively, with just a finger prick sample. Both tests can quantify reference and biosimilar drugs with equivalent results. Moreover, comparable results were obtained with the WHO IS, and thus, demonstrate that Promonitor Quick tests are suited to accurately determine drug levels at the clinical decision points in both whole blood and serum, proving to be an effective and valuable tool in TDM and immediate decision making in the doctor office or hospitals.

AB0357 INCIDENCE AND DETERMINANTS OF INFECTION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH GOLIMUMAB IN REAL-WORLD PRACTICE

L. Bessette[1], P. Rahman[2], J. Kelsall[3], J. Purvis[4], E. Rampakakis[5], A. Lehman[6], M. Rachich[6], F. Nantel[7], M. Marrache[6], O. Asin Milan[6]. *[1]Université Laval, Département de Médecine. Faculté de Médecine., Quebec City, Canada; [2]Memorial University of Newfoundland, Medicine, St. John's, Canada; [3]The University of British Columbia, Faculty of Medicine. Department of Medicine, Vancouver, Canada; [4]300-270 Charlotte St, Rheumatology, Peterborough, Canada; [5]JSS Medical Research, Clinical Research, Montréal, Canada; [6]Janssen Inc, Rheumatology, Toronto, Canada; [7]Retiree, Janssen Inc, Rheumatology, Toronto, Canada*

Background: Although biologic use in rheumatoid arthritis (RA) has a well-characterized infections risk factor, most studies evaluating this association were conducted on first-generation anti-tumor necrosis factor (TNFi) agents or in early years post-drug development (early 2000).

Objectives: To (i) characterize the long-term incidence of infection in a real-world cohort of RA patients treated with subcutaneous golimumab (GLM) in Canadian routine care; (ii) assess the impact of infections on GLM retention, and (iii) explore factors associated with the risk of infection.

Methods: BioTRAC registry was a prospective, multicenter study that collected real-world clinical, laboratory, safety and patient-reported data from TNFi naïve patients or treated with biologics for a period of <6 months before enrolment. This post-hoc analysis included patients with RA who initiated GLM treatment. The incidence density rates (IDR) of total serious (SI) and non-serious (NSI) infections were calculated for the overall follow-up (90 months) period as well as by 6-month interval. Time to first infection and time to treatment discontinuation were assessed with the Kaplan-Meier estimator of the survival function. Determinants of infection over time or within the first 6 months were explored using generalized estimating equation models and logistic regression, respectively.

Results: 530 patients were included with a mean (SD) age of 57.7 (13.0) years and disease duration of 8.0 (8.3) years. Of these, 404 (76.2%) were females, 74 (14.0%) were treated with ≤15mg/week MTX, 280 (52.8%) with >15mg/week MTX, while 173 (32.6%) were not on MTX. In terms of corticosteroids (CS), 72 (13.6%) were treated with ≤5mg/day, 63 (11.9%) with >5mg/day, and 391 (73.8%) were not on CS. Diabetes (4.5%), pulmonary disease (8.9%), and renal disease (18.5%) were present.

Over a mean follow-up duration of 27.0 months, the IDR for total infections, NSI, and SI was 35.10 events/100 PYs, 32.90 events/100 PYs, and 2.23 events/100 PYs. Median estimated time to first infection was 52.9 months (SI: 84.9 months; NSI: 55.1 months) (Table 1). The incidence of total infections was 44.0, 37.3, 35.1, 29.4, 31.1, 35.7, 19.3 and 7.4 events/100 PYs at 0-6 months, 6-12 months, 12-24 months, 24-36 months, 36-48 months, 48-60 months, 60-72 months, 72-84 months, respectively and no infections between 84-90 months. In terms of determinants, no significant associations were identified for the incidence of infections within the first 6 months. However, presence of pulmonary disease was identified as a significant determinant of total infections (OR [95%CI]: 2.19 [1.36-3.52]) and NSI (2.22 [1.35-3.66]) over time, while higher age (1.08 [1.00-1.26]) and high (≥5 mg/day) CS dose (7.25 [1.12-46.80]) were associated with significantly higher odds of SI. Incidence of SI (6.48 [1.16-36.13]), but not NSI, was associated with significantly higher odds of GLM discontinuation; additional predictors of discontinuation were increased baseline CDAI (1.06 [1.04-1.08]) and use of concomitant MTX at low dose (0.52 [0.30-0.91]) or high dose (0.71 [0.49-1.04]).

Table 1. Incidence Density Rate (IDR) by Infection Type.

Infection Type	IDR (Events/100 PYs)	Median Time to 1st Infection (months)
Total Infections	35.1	52.9
Non-serious Infections	32.9	84.9
Serious Infections	2.2	55.1

Conclusion: The infection rates reported with GLM in this cohort are low compared to the rates reported in earlier registry studies with TNFi. Changes in the characteristics of patients starting TNFi (lower disease activity, shorter disease duration, less exposure to CS) in recent years may explain the decreased risk of infection. Compared to the available literature, treatment with GLM was associated with relatively low infection rate. Most infections occurred during the first 6 months of treatment and decreased thereafter. Presence of pulmonary disease, higher age, and higher CS dose were identified as significant predictors of infections. SIs, but not NSIs, were associated with significantly higher odds of treatment discontinuation-TNFi.

AB0358 SAFETY, TOLERABILITY, PHARMACOKINETICS, RECEPTOR OCCUPANCY, AND SUPPRESSION OF T-CELL-DEPENDENT ANTIBODY RESPONSE IN A PHASE 1 STUDY WITH KPL-404, AN ANTI-CD40 MONOCLONAL ANTIBODY

M. Samant[1], A. Wheeler[2], G. L. Jiang[1], M. Njenga[1], M. Spiers[1], A. Pano[1], J. F. Paolini[1]. *[1]Kiniksa Pharmaceuticals Corp., Kiniksa Pharmaceuticals Corp., Lexington, United States of America; [2]Kiniksa Pharmaceuticals, Ltd., Kiniksa Pharmaceuticals, Ltd., Hamilton, Bermuda*

Background: T-cell priming and T-cell-dependent B-cell responses require an intact cluster of differentiation (CD)40/CD40L pathway. CD40 is expressed on the surface of B-cells, dendritic cells, antigen-presenting cells, and non-immune cell types; its ligand, CD40L (CD154), is expressed on the surface of activated

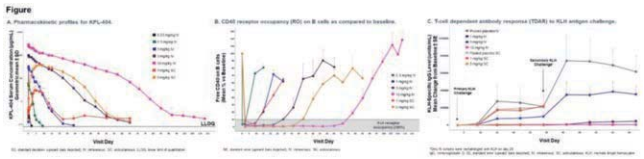
T-cells, platelets, and other cell types. Blockade of CD40/CD40L interaction has been shown to ablate primary and secondary T-cell dependent antibody response (TDAR).

Objectives: We hypothesized that KPL-404, an anti-CD40 monoclonal antibody which inhibits interaction between CD40 and CD40L, would block T-cell dependent, B-cell-mediated autoimmunity in this Phase 1 study in healthy participants.

Methods: This randomized, double-blind, placebo-controlled, first-in-human study of KPL-404 in healthy participants was designed with two single-ascending-dose arms: single intravenous (IV) doses of 0.03 mg/kg, 0.3 mg/kg, 1 mg/kg, 3 mg/kg, or 10 mg/kg and single subcutaneous (SC) doses of 1 mg/kg or 5 mg/kg. The primary objective was safety and tolerability of KPL-404; secondary and exploratory objectives included pharmacokinetic (PK) parameters, TDAR inhibition, and receptor occupancy (RO). To evaluate TDAR inhibition, participants post-KPL-404 administration were immunized with 1 mg intramuscular injection of the test antigen *Keyhole* Limpet Hemocyanin (KLH) on day 4 and day 29 to elicit a primary and secondary Immunoglobulin (Ig) response, respectively. To evaluate RO, free and total CD40 receptor levels (percent change from baseline) on B-cells (whole blood) were measured using flow cytometry.

Results: There were no dose-limiting or dose-related safety findings in healthy participants after KPL-404 administration. One unrelated serious adverse event (patella fracture following a fall) occurred in the 10 mg/kg IV arm. The PK profile of KPL-404 in serum after IV or SC administration had low to moderate variability between individuals; elimination was dose-dependent and consistent with target-mediated drug disposition (TMDD) (Figure 1a). For participants receiving 10 mg/kg IV, full receptor occupancy was observed through day 71 (Figure 1b), complete TDAR suppression was observed through Day 57 (Figure 1c), and anti-drug antibodies to KPL-404 were suppressed for at least 57 days; the suppression of antibody responses to the drug itself is an independent indicator of target engagement and pharmacodynamic effect. For participants receiving 5 mg/kg SC, full receptor occupancy was observed through day 43 (Figure 1b), and complete TDAR suppression was observed through Day 29 (Figure 1c). The TDAR response to KLH antigen correlated with the observed full RO.

Figure



Conclusion: The safety and tolerability data and the PK/PD profile of KPL-404 support further investigation of KPL-404 in a broad range of autoimmune diseases, including rheumatoid arthritis. These data support the optionality for studying chronic KPL-404 dosing in patients with subcutaneous and/or intravenous administration.

TOCILIZUMAB IN AFRO-CARIBBEAN RHEUMATOID ARTHRITIS: THE MARTINICAN EXPERIENCE

L. S. Fabienne[1], C. Costecalde[1], M. Dramé[2], C. Deligny[3], P. Numeric[1], M. Blettery[1], C. Petit[1], M. De Bandt[1], B. Suzon[3]. *[1]Hospital Center University Of Fort De France, Rheumatology, Fort-de-France, Martinique; [2]Hospital Center University Of Fort De France, Public Health, Fort-de-France, Martinique; [3]Hospital Center University Of Fort De France, Internal Medicine, Fort-de-France, Martinique*

Background: Mortality and morbidity related to rheumatoid arthritis (RA) has remarkably improved over the last twenty years since using biologics DMARDs[1]. However, their effectiveness remains questionable in Afro-descendants (AD) due to their large under-representation in RA clinical trials[2,3]. Martinique is a French Caribbean region with a majority of AD population[4], with free access to healthcare, including biotherapies, and a unique university hospital and rheumatology unit.

Objectives: To evaluate effectiveness of Tocilizumab (TCZ), an interleukin-6 inhibitor, in an afro descendant RA population.

Methods: Retrospective cohort of 171 patients who received at least 1 infusion of Tocilizumab (IV TCZ) at Martinique University Hospital Center between 2008 and 2019. Inclusion Criteria: Patients over 18 y/o meeting RA 2010 ACR/EULAR criteria, having received at least 4 courses of IV TCZ starting at 8mg/kg every 4 weeks, with available baseline clinical/biological data. Exclusion criteria: Patients having received subcutaneous TCZ (SC TCZ) prior to IV TCZ, not living in Martinique. Primary endpoint was proportion of patients in remission (R) and low disease activity (LDA) according to DAS28 CRP at 12, 24, 36 weeks. Secondary endpoint was proportion of patients achieving good (GR) and moderate (MR) EULAR response criteria [5] at 12, 24 and 36 weeks, and TCZ retention at 1 year defined as the proportion of patient receiving TCZ at 1 year follow up.

Results: Out of 171 patients receiving IV TCZ, we identified 138 RA and 80 patients met inclusion criteria: 90% were women, mean age was 56.8 (± 11.8) y/o, mean duration of RA was 11.6 (± 8.9) years, ACPA and Rheumatoid Factor were positive in 72.1% and 73% of cases, 69.6% of patients had erosions and 77.8% had received at least 1 biologic prior to IV TCZ. At baseline, 8 patients were in R, 8 had LDA but presented steroid dependency over 10 mg per day of prednisone and mean dose of prednisone was 6.9 (+/- 6.7) mg per day.

At 12, 24, 36 weeks, R was achieved in 44.8%, 55.2% and 51.2% of patients and LDA in 37.3%, 17.2% and 20.9%, respectively (Figure 1). At 12, 24, 36 weeks, GR was achieved in 44.8 %, 60.3% and 48.8% of patients respectively, MR was achieved in 20.9%, 20.7% and 27.9% of patients respectively (Figure 1) and mean dose of prednisone per day was 5.1 (± 4.9) mg, 4.9 (± 5.6) mg and 3.3 (± 5.1) mg respectively. At 1 year, 78.8% of patients were still on TCZ. During follow up: 15 patients experienced 19 infectious events; 6 patients liver cytolysis; 12 patients neutropenia. No patient died.

Conclusion: This is the first study evaluating efficacy and safety of TCZ in an AD RA cohort. TCZ is safe and effective in our AD population with comparable data observed in other ethnicities[6,7].

THE LONG-TERM IMPACT OF FATIGUE ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

D. Santos Oliveira[1,2,3], A. Martins[1,3], F. R. Martins[4], B. Samões[5], M. Rato[1,3], F. Oliveira Pinheiro[1,3], R. Nicolau[6], C. Vaz[1,3], M. Bernardes[1,3], L. Costa[1].

Background: Fatigue is common among patients with rheumatoid arthritis (RA) with a substantial impact on quality of life (1). Biological disease-modifying antirheumatic drugs (bDMARDs) have been shown to significantly improve fatigue in these patients. However, fatigue is under-assessed by the physicians and evidence is still scarce regarding a possible impact of fatigue on disease activity over time.
Objectives: To explore the long-term impact of fatigue on the disease activity in patients with RA treated with bDMARDs.
Methods: A monocentric observational retrospective cohort study was conducted with 24 months (M) of follow-up. Patients diagnosed with RA, according to the 2010 American College of Rheumatology (ACR)/ European League Against Rheumatism (EULAR) criteria, and registered on the Rheumatic Diseases Portuguese Register (Reuma.pt) who started their first bDMARD between 2015 and 2021 were included. Demographic, clinical and laboratory data were obtained by consulting Reuma.pt. Fatigue was monitored at baseline, 12 and 24M using Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F). This scale is a 13-item self-reported questionnaire with a total score ranging from 0 to 52. A score ≤ 39 indicates the presence of clinically significant fatigue. Disease Activity Score for 28 joints with erythrocyte sedimentation rate (DAS28), DAS28 with C-reactive Protein (CRP) [DAS28-CRP], DAS28 delta, Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI) were calculated to measure disease activity. Clinical response was evaluated by EULAR criteria in three response categories-good, mild and no response- and by ACR criteria (0 to 100%) at 12 and 24M. To correlate fatigue score with EULAR clinical response Chi-square test was used. Multivariate linear regression models adjusted for age, gender and disease duration were used to assess the effect of fatigue on disease activity and ACR clinical response over time.
Results: A total of 40 patients with RA were included, with a mean age of 47.4±11.4 years old and disease duration of 10.4±5.6 years. Most patients were female (90.2%). Rheumatoid Factor was positive in 70% of patients. The majority of patients (85%) had clinically significant fatigue at baseline moment (FACIT-F 26.9±11.8). Treatment characteristics and baseline disease activity scores are described in Table 1. Fatigue at baseline moment predicted DAS28(CRP) (β=-0.061, 95%CI [-0.12; -0.003]) and CDAI (β=- 0.30, 95%CI [-0.57; -0.029]) at 12M. Additionally, fatigue predicted SDAI (β=-0.38, 95%CI [-0.72; -0.047]) and CDAI (β=- 0.39, 95%CI [-0.73; -0.051]) at 24M. In general, for these models, fatigue as a symptom was shown to have negative effects on the different outcomes analysed. Fatigue did not associate with EULAR and ACR responses over time.

Table 1. Baseline characteristics of sample. LEGEND: SD: Standard deviation; DAS28: Disease Activity Score for 28 joints; CRP: C-reactive Protein; CDAI: Clinical Disease Activity Index; SDAI: Simplified Disease Activity Index.

Variable	Descriptive statistic
Treatment options	**n(%)**
Glucocorticoids	37(92.5)
Conventional DMARDs	37(92.5)
Anti-TNF	19(47.5)
Etanercept	13(32.5)
Rituximab	4(10)
Tocilizumab	4(10)
Disease activity score	**Mean±SD**
DAS28	5.4±0.87
DAS28-CRP	4.9±0.69
CDAI	27.6±8.5
SDAI	28.9±8.7

Conclusion: These findings showed that, in our sample, the most RA patients had severe fatigue and its presence may be a predictor of increased disease activity. Indeed, previous research observed a positive association between fatigue and disease activity over the time in patients with RA (2). Therefore, fatigue should be regularly monitored in patients with RA and its impact on treatment must be considered. Moreover, further research with larger samples is needed to explore the impact of fatigue on clinical response and the potential of fatigue relief as an outcome measure of RA treatment.

TOCILIZUMAB VERSUS TOFACITINIB IN THE 12-MONTH TREATMENT OF BIOLOGICAL-NAIVE PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

D. Gerasimova[1], E. Gerasimova[2], T. Popkova[2], O. Zakharova[1], V. Medvedeva[1].
[1]I.M. Sechenov First Moscow State Medical University (Sechenov University), Institute of Pharmacy, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Deseases Laboratory, Moscow, Russian Federation

Background: The choice of the most effective disease-modifying antirheumatic drug (DMARD) for the treatment of rheumatoid arthritis (RA) remains relevant. There are several comparative studies between tocilizumab (TCZ), an antibody against interleukin 6 receptor, and tofacitinib (TOFA), a potent selective Janus kinase inhibitor, regarding their efficacy [1,2].
Objectives: To compare the effectiveness of TCZ and TOFA for treatment of biological-naive patients (pts) with active RA according to various indicators of disease activity, physical function, and quality of life during a 12-month (m) follow-up period.
Methods: A total of 80 biological-naive pts with high and moderate RA activity were enrolled (40 pts with TCZ and 40 pts with TOFA). The groups were comparable in terms of sex, age, BMI, and DAS28. All pts were measured: for disease activity using DAS28, SDAI, and CDAI; for quality of life and physical function using EQ-5D, HAQ, and RAPID 3 questionnaires at the beginning of the study and after 12 m of TCZ/TOFA therapy. The EULAR response criteria for treatment of RA were used.
Results: Significant positive changes in major disease activity, clinical and laboratory parameters were found in RA pts after 12 m of TCZ infusion and TOFA intake: DAS28, SDAI, and CDAI decreased significantly in both groups ($p<0.01$ in all cases). There were more good responders among TCZ pts compared to TOFA pts: by DAS28 35 pts (87.5%) vs. 20 pts (50%), $p<0.01$; by CDAI 38 pts (95%) vs. 26 pts (65.7%), $p=0.02$, respectively. There was a more pronounced decrease in DAS28 and CRP levels in TCZ pts (ΔDAS28=-3.8[-4.5;-2.7], ΔCRP=-26.5[-45;-10.7] mg/L) compared to TOFA pts (ΔDAS28=-2,3[-3.2;-1.5]; ΔCRP=-10.1[-32;-8] mg/L, $p<0.01$ in all cases). Both drugs equally improved quality of life and physical function indicators EQ-5D, HAQ, and RAPID during a 12-m follow-up period. Correlations of ΔEQ-5D with ΔESR (R=0.43: $p<0.01$) and with ΔCRB (R=0.46; $p=0.03$) were found after 12 m of TCZ therapy.
Conclusion: TCZ and TOFA both significantly reduce disease activity and improve quality of life and physical function in bDMARD-naive RA patients. Compared with TOFA, TCZ can induce greater improvements during the first 12-m treatment. No unequivocal conclusions on the drugs' effect on pts' quality of life could be made.

NEUTROPHIL COUNT REDUCTION 1 MONTH AFTER INITIATING SARILUMAB AND BASELINE SERUM SOLUBLE GP130 LEVELS CAN INDEPENDENTLY PREDICT CLINICAL REMISSION WITHIN 3 MONTH IN RHEUMATOID ARTHRITIS PATIENTS

T. Yoshikawa[1], K. Azuma[1], T. Furukawa[1], T. Hashimoto[1], M. Morimoto[1], N. Azuma[1], K. Matsui[1]. [1]*Hyogo College of Medicine College Hospital, Division of Allergology and Rheumatology, Department of Internal Medicine, Nishinomiya, Japan*

Background: IL-6 contributes significantly to the chronic inflammatory process of rheumatoid arthritis (RA) and is elevated in serum and synovial fluid of RA patients. Sarilumab (SRL), a human anti-human IL-6 receptor alpha monoclonal antibody that blocks the signaling originated by the IL-6/IL-6R complex like tocilizumab (TCZ),is an effective treatment. Recently, an association between the therapeutic effect of TCZ and neutropenia after TCZ initiation was reported[1]. Neutropenia is a common adverse event of SRL in patients with RA, but the relationship between reduced neutrophil count and clinical response to SRL is still inconclusive. In EULAR 2020, we reported the association between serum soluble gp130 levels before SRL treatment and the efficacy of SRL[2]. It is also unclear whether there is a relationship between IL-6 axis cytokines and SRL-induced neutropenia.
Objectives: The purpose of this study was to determine whether neutropenia at 1 month by SRL predicts clinical remission within 3 months and whether there is an association between IL-6 axis cytokines levels and SRL-induced neutropenia.
Methods: This research is a retrospective study. We reviewed medical records of RA patients initiating SRL between February 2018 and August 2021 in our hospital. The Clinical Disease Activity Index (CDAI) was evaluated at baseline (before initiating SRL) and 3 months after administration. Clinical remission was defined when CDAI decreased ≤ 2.8. Of the 66 patients treated with SRL, 42 patients with 3 months follow-up, valid CDAI and serum available were enrolled. The ratio of neutrophil counts 1 month after initiating SRL to those at baseline (neutrophil ratio) was also calculated. Serum samples were tested for IL-6 (Human IL-6 Quantikine ELISA Kit, R&D systems), sIL-6R (Human soluble IL-6R alpha Quantikine ELISA Kit, R&D systems) and sgp130 (Human soluble gp130 Quantikine ELISA Kit, R&D systems) using specific ELISAs according to the manufacturer's instructions. The statistical analyses were performed with EZR 1.55, and p values less than 0.05 were considered significant.
Results: The median age of patients was 69.0 (IQR: 59.3 - 73.8) years and the median of disease duration was 9.0 (3.0 - 16.0) years. Eighteen (42.9%) patients were biologics and Jakinibs naive. The baseline CDAI was median 16.7 (11.5 - 25.8). When comparing CDAI-remission group (clinical remission: CR) and non-CR group, Patients in the CR group had significantly shorter disease duration, were more Biologic and JAKinib naive, and had greater neutropenia 1 month after starting SRL (0.71 vs 0.94, P=0.0252). There was no significant difference in the baseline serum levels of IL-6, sIL-6R between the CR and non-CR groups, but baseline serum sgp130 levels in the CR group tended to be higher than in the non-CR group (264.9 vs 234.2 ng/mL, P=0.0592). Univariate logistic regression analysis suggested Biologics and JAKinibs naive (odds ratio (OR) 6.68, p = 0.0317), baseline serum sgp130 levels (OR 8.608, P=0.0312) as predictors of CDAI remission treated with SRL at 3 months. Although not significant, neutrophil ratio ≤ 0.8 was associated with achieving remission (OR 6.67, P=0.0537). Univariate logistic regression for neutrophil ratio ≤ 0.8 did not show any relevant factors, including higher baseline serum sgp130 levels (OR 1.25, P=0.782).
Conclusion: A 20% or greater decrease in neutrophil count after 1 month of SRL treatment and a high baseline serum sgp130 level independently predict clinical remission within 3 months.

COMPARING THE ULTRASONOGRAPHIC EVALUATION IN PATIENTS WITH JAPANESE RHEUMATOID ARTHRITIS BETWEEN JAK AND TNF INHIBITOR THERAPY

Y. Kanayama[1], A. Nagata[2], M. Shimotake[2], F. Miyachi[2], K. Fujita[2], M. Koyama[2], S. Uno[2]. [1]*Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan;* [2]*Toyota Kosei Hospital, Clinical Technology, Toyota, Japan*

Background: JAK inhibitor (JAK) and TNF inhibitor (TNF) are the important therapeutic agent for the treatment of rheumatoid arthritis.However there is still few studies of improvement of ultrasonographic findings in RA treated comparison with JAK and TNF.
Objectives: To evaluate the clinical efficacy of JAK and TNF therapy patients with rheumatoid arthritis (RA) using ultrasonography (US).
Methods: Participants comprised 32 and 39 Japanese RA patients who had recently received JAK (BAR23, PEF9) and TNF. All patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria. Patients underwent clinical and laboratory assessments every 4 weeks from baseline to 24 weeks, and US assessments at baseline, 4, 12 and 24 weeks. Gray scale (GS) and power doppler (PD) signals were scored using a semi-quantitative scale from 0 to 3 at 26 (0-78) synovial sites (22 joints) in the following joints: bilateral first to fifth metacarpopharangeal (MCP) joints (dorsal recess); first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) (dorsal recess) joints; and the wrists (dorsal radial, median and ulnar). We evaluated the improvement of GS and PD score from baseline to week 24.
Results: In the patients receiving JAK (n=32) and TNF (n=39), the mean age was 54.7 vs 55.1 years old (p=0.871), disease duration was 7.4 vs 6.1 years (p=0.290), the rate of MTX use was 75% vs 87% (p=0.187), the mean MTX dose was 9.9 vs 10.2 mg/w (p=0.813), the rate of ACPA positive was 94% vs 79% (p=0.086), DAS28-ESR was 4.79 vs 4.65 (p=0.435), CDAI was 22.4 vs 19.1 (p=0.239), GS score was 20.8 vs 18.3 (p=0.995) and PD score was 14.0 vs 11.0 (p=0.940). The degree of improvement respective changes in GS and PD score after 4, 12 and 24 weeks were as follows: GS: -5.1 vs -4.3 (p=0.817) and PD: -5.3 vs -2.7 (p=0.855) after 4 weeks, GS: -9.1 vs -6.6 (p=0.880) and PD: -7.9 vs -4.5 (p=0.476) after 12 weeks, GS: -10.4 vs -9.5 (p=0.463) and PD: -8.1 vs -6.7 (p=0.968) after 24 weeks between JAK and TNF (Figures 1 and 2). Next, The improvement rate of respective changes in GS and PD score after 4, 12 and 24 weeks were as follows: GS: -13.7% vs -18.3% (p=0.489) and PD: -20.4% vs -16.5% (p=0.777) after 4 weeks, GS: -29.7% vs -26.0% (p=0.922) and PD: -30.9% vs -30.8% (p=0.890) after 12 weeks, GS: -38.1% vs -36.4% (p=0.567) and PD: -33.4% vs -50.1% (p=0.977) after 24 weeks between JAK and TNF.
Conclusion: The present study provides evidence supporting the JAK and TNF therapy improved similarly the inflammatory synovitis of US findings.

AB0364

THE EFFECT OF BIOLOGIC AND TARGETED SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ON WORK PARTICIPATION IN LONGSTANDING RHEUMATOID ARTHRITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

A. Alunno[1], M. L. Marques[2,3], L. Falzon[4], S. Ramiro[2,5], A. Boonen[6]. *[1]Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy; [2]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [3]Coimbra University Hospital, Department of Rheumatology, Coimbra, Portugal; [4]University of Sheffield, Health Economics and Decision Science, School of Health and Related Research, Sheffield, United Kingdom; [5]Zuyderland Medical Center, Department of Rheumatology, Herleen, Netherlands; [6]Maastricht University Medical Center, Department of Rheumatology, Maastricht, Netherlands*

Background: Work participation (WP) is a top priority for people with RA and a determinant of patients' quality of life. Therefore, assessing the effect of interventions on WP outcomes is important.
Objectives: To review the effect of b/tsDMARDs on employment status (ES), sick leave (SL) and presenteeism in patients with longstanding RA.
Methods: A systematic literature review up to October 2021 was conducted using the PICOT framework (Figure 1). Two researchers independently screened abstracts, then full texts were reviewed to determine eligibility. Data from eligible articles were extracted. Heterogeneity and insufficient reporting of data precluded meta-analysis.
Results: We included 42 studies:16 randomized controlled trials (RCT) and 26 longitudinal observational studies (OBS). All studies were conducted with background therapy with csDMARDs; 33 (78%) in csDMARD-IR patients. RCTs provided short-term data only (≤24 weeks (w)) which have limited relevance for WP outcome domains such as ES[1]. OBS reported long-term data (≤ 5 years), albeit imposing challenges due to lack of random allocation to interventions and often lack of a comparator. Regarding ES, 6 RCTs and 4 OBS did not report significant differences in bDMARD-treated patients vs background csDMARDs. For SL (19 studies), 1 RCT showed that etanercept significantly reduced RA-related SL up to 12-16w; however, one OBS showed no such effect on the long-term. Conflicting results were obtained by 2 RCTs on baricitinib. Most compounds assessed in the 12 OBS without comparator reported improvement in SL up to 104w. For presenteeism (11 studies; Table 1), 4 RCTs showed that etanercept, golimumab, certolizumab pegol, baricitinib and peficitinib were superior to PBO+csDMARDs up to 12w. Two H2H studies assessing sarilumab and baricitinib vs adalimumab observed comparable presenteeism in all treatment arms at 12-16w.
Conclusion: Short-term data from RCTs with background therapy with csDMARDs showed adding b/tsDMARDs was more effective than PBO in improving presenteeism. However, data on SL are conflicting and the positive results come from OBS without comparator. Future studies should consider existing guidance on the assessment of WP outcome domains to allow pooling and meta-analysis[1].

AB0365 BELIEFS AND ADHERENCE IN RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGIC DRUGS

E. Hannech[1,2], S. Boussaid[1,2], S. Rekik[1,2], S. Jemmali[1,2], S. Rahmouni[1,2], H. Ajlani[1], H. Sahli[1,2], M. Elleuch[1,2], R. Dhahri[2,3], I. Gharsallah[2,3].
[1]Rheumatology Department, La Rabta Hospital,Tunis,Tunisia; [2]Faculty of Medicine of Tunis, University Tunis El Manar,Tunis,Tunisia; [3]Rheumatology Department, Military Hospital of Tunis,Tunis,Tunisia

Background: Patients with chronic rheumatic diseases play an important role in their disease management. Adherence to their long-term therapies may depend on their therapeutic beliefs [1].
Objectives: The purpose of our study was to investigate the relationship between beliefs and adherence among patients with rheumatoid arthritis (RA) on biologic therapies (bDMARDs).
Methods: We conducted a multi-centric cross-sectional study, including patients with RA fulfilling the ACR/EULAR 2010 criteria. All patients were on bDMARD. Sociodemographic, clinical, biologic, and therapeutic data were collected. Patients were interviewed about their medication beliefs using the Beliefs about Medicines Questionnaire (BMQ) and about their therapeutic adherence.
Results: There were 75 RA patients: 60 female (80%) and 15 males (20%). The sex ratio was about 0.25. Their mean age was 56.92±9.06 years [34-80]. Thirty-three percent of patients were illiterate. Twenty patients were employed (15%). The mean disease activity scale (DAS28 CRP) was 3.94±1.32 [1.21-7.15]. Fifteen patients (20%) had high disease activity, 11% had low activity, and 19% were in remission. The mean duration of the current bDMARD was 37.17±39.44 months [4-248]. The mean Specific Necessity score was 21.02±5.38 [5-25] for adherent patients and 13.5±7.54 [5-19] for non-adherent patients.
The mean Specific Concerns score was 10.07±3.13 [5-15] for adherent patients and 15±2.82 [5-20] for non-adherent patients.
A statistically significant association was found between Specific Concerns beliefs and adherence behavior (p=0.009) and between Specific Concerns beliefs and adherence behavior (p=0.003). No statistically significant association was noted between general beliefs (General Harm and General Overuse) and adherence behavior (p=0.4 and p=0.6 respectively).
Conclusion: Beliefs about therapeutic were identified as a key factor of adherence among rheumatic disease patients. Practitioners should detect negative patient beliefs and perceptions earlier to prevent nonadherence.

AB0366 A PROSPECTIVE OBSERVATIONAL STUDY TO ASSESS THE REAL-WORLD EFFECTIVENESS OF GOLIMUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND PREVIOUSLY TREATED WITH INITIAL TNFA INHIBITORY THERAPY

C. Gaujoux-Viala[1], J. Sellam[2], F. Tubach[3], N. Harid[4], B. Combe[5], R. M. Flipo[6].
[1]CHU Nimes, IDESP UMR UA11 INSERM - Université de Montpellier, Montpellier, France; [2]Hôpital Saint-Antoine, Paris 12, Paris, France; [3]CHU de Montpellier, Hôpital Lapeyronie, Montpellier, France; [4]MSD, France, Puteaux, France; [5]CHU La Pitié-Salpêtrière, Paris 13, Paris, France; [6]CHRU de Lille, Hôpital B Roger Salendro, Lille, France

Background: TNF inhibitor (TNFi) treatment is standard for RA patients even though many reasons may lead to TNFi therapy failures such as lack of effectiveness, patient dissatisfaction or limited therapy adherence, or even safety. As a consequence, patients may switch to a different TNFi. The efficacy of golimumab (GLM) in RA patients with inadequate response to TNFi was demonstrated in the Go-AFTER phase III clinical trial.
Objectives: The objectives of the present Go-BEYOND study were to provide real-world data to evaluate disease activity and treatment persistence with GLM as a second line TNFi therapy in RA patients over a one-year follow-up.
Methods: Go-BEYOND is an observational French multicenter prospective cohort study. All consecutive patients over 18 years of age with a diagnosis of active RA were eligible at the time of initial GLM prescription. To be included, patients had to be previously treated with only 1 TNFi (discontinued for any reason) other than GLM. Patients were ineligible if they had been previously treated with other "non-TNFi" biologics or more than one TNFi.
The study's primary outcome was the percentage of RA patients with a Disease Activity Score (DAS28-CRP score) ≤ 3.2 at the 6-month visit (M6 visit). Patients who permanently discontinued their treatment over the 1-year follow-up were considered as non-responders. The secondary outcomes were analyzed descriptively and included (but not limited to) DAS28-CRP score at 12-month visit (M12 visit), EULAR criteria assessment, treatment persistence analysis, HAQ score, RAPID3 score, and patient acceptable symptom state and satisfaction with the injection. The study was approved by a French Ethics Committee in July 2017.
Results: A total of 128 patients (72.7% female, median age 58.2 years, and duration of RA 13.2 ± 11.4 years) met the inclusion criteria. Anti-CPP antibodies and rheumatoid factors were present in 80 (62.5%) and 81 (63.3%) patients, respectively. In the majority, the initial TNFi was etanercept (n=88, 68.8%), then adalimumab (n=25, 19.5%). The reasons for switching to GLM were secondary non-response (*i.e.,* lack of effectiveness after an initial response to the treatment) for 75 (58.6%) patients, then safety (n=22, 17.2%), primary non-response (n=21, 16.4%), and other personal or medical reasons (n=10, 7.8%).
At the M6 and M12 visits, a small number of patients, 27 (21.1%) and 48 (37.5%) had respectively permanently discontinued their GLM treatment and were considered as non-responders. At the M6 visit, 48 patients over the 128 included (37.5%) had a DAS28-CRP ≤ 3.2 and 32 (25%) < 2.6. At M12 visit, 41 (32%) patients had a DAS28-CRP ≤ 3.2 and 31 (24.2%) < 2.6. According to EULAR response criteria thresholds, 49 (38.3%) and 45 (35.2%) patients had a good or moderate response to GLM at the M6 and M12 visits.
Conclusion: The Go-BEYOND study confirms that in RA, a non-response to a first TNFi does not exclude a response to GLM as a second-line biologic in a substantial proportion of patients in real-life settings.

AB0367 THE PARADIGM OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: SUBTYPES AND EARLY IDENTIFICATION.

M. Novella-Navarro[1], V. Ruiz[2], G. Torres Ortiz[1], C. A. Chacur[2], C. Tornero[1], A. Villalba[1], R. Sanmarti[2], C. Plasencia[1], A. Balsa[1]. *[1]Hospital Universitario La Paz, Rheumatology, Madrid, Spain; [2]Hospital Clìnic, Rheumatology, Barcelona, Spain*

Background: Difficult-to-treat rheumatoid arthritis (D2TRA)[1] is an emerging concern for rheumatologists. Multiple failures to biologic or targeted specific disease modifying antirheumatic drugs (b/tsDMARDs) may be due to multi-drug inefficacy or difficulties in the optimum management of treatments due to adverse events, comorbidities, poor adherence, among others. In a previous study[2] we identified that younger patients with erosive disease and especially the early absence of clinical response to the first b/tsDMARDs were associated to multiple drug inefficacy but it is worth knowing whether these factors are the same for those patients who receive multiple b/tsDMARDs due to causes other than inefficacy.
Objectives: i) To describe the characteristics of a cohort of D2TRA patients in clinical practice. ii) To analyze the differences between D2TRA due to inefficacy vs D2TRA to other causes. iii) To compare the different subtypes of D2TRA with non-D2TRA.
Methods: This study involved patients with D2TRA from La Paz Hospital and Clìnic Hospital between 2000 and 2021. D2TRA group included patients who had received ≥2b/tsDMARDs due to inefficacy (D2TRA-inefficacy) or due to: adverse events, poor adherence, contraindications, comorbidities, drug-intolerance etc. (D2TRA-other causes). Patients who achieved low disease activity or remission (by DAS28) with the 1st bDMARD and remained with the same drug for at least 5 years were non-D2TRA patients. For all patients, demographic, clinical characteristics and laboratory parameters were assessed at baseline visit (prior to start the 1st b/tsDMARD) and after 6 months. Descriptive analysis was performed and bivariate logistic regression models were assembled. P<0.05 was considered statistically significant. Odds Ratio (OR) and Confidence Intervals (CI) were calculated. IBM SPSS 21.0
Results: In total, 253 patients were included, 131 were non-D2TRA and 122 D2TRA [86 (70.5%) D2TRA-inefficacy and 36 (29.5%) D2TRA-other causes]. Comparison between both groups of D2TRA patients: no differences in gender, age at b/tsDMARD starting or age at RA diagnosis were found and neither between socioeconomic status, frequency of anxiety-depression or other comorbidities. Patients D2TRA-other causes had less extra-articular manifestations

than D2TRA-inefficacy (8.3% vs 26.7%; p=0.02); lower values of DAS28 at starting 1st b/tsDMARD (4.9±1.4 vs 5.7±1.2; p=0.01), and also at 6 months of treatment (3.5±1.5 vs 4.5±1.5; p=0.02) than those with D2TRA-inefficacy. 2) Comparison between Non-D2TRA patients and D2TRA-other causes: no differences in sociodemographic characteristics were found and neither differences in baseline disease activity, only differences in DAS28 at 6 months were observed, being higher D2TRA-other causes than in non-D2TRA (3.54±1.54 vs 2.93±0.99; p=0.03). Bivariate analysis only showed that high DAS28-6m was slightly associated with D2TRA-other causes (OR=1.45 CI95% 1.11-2.16).

Conclusion: In this cohort, around 3 out of 10 D2TRA patients dropped out multiple b/tsDMARDs for reasons other than inefficacy In contrast to D2TRA-inefficacy, patients with D2TRA-other causes are indistinguishable from non-D2TRA patients at baseline, indicating that patients with D2TRA-other causes does not seem predictable in the early stages of treatment with b/tsDMARDs, unlike what occurs with multidrug ineficacy.

AB0368 EFFECTS OF SWITCHING FROM ETANERCEPT ORIGINATOR TO ETANERCEPT BIOSIMILAR ON DISEASE ACTIVITY, PHYSICAL FUNCTION, AND PATIENT-REPORTED OUTCOME REGARDING A SELF-INJECTION DEVICE IN PATIENTS WITH WELL-CONTROLLED RHEUMATOID ARTHRITIS

Y. Hirano[1], Y. Ono[1]. [1]*Toyohashi Municipal Hospital, Rheumatology,Toyohashi, Japan*

Background: Although biological drugs have dramatically changed and improved the outcome of patients with rheumatoid arthritis (RA), a lot of unresolved problems still exist. Although comorbidity by which enough treatment drugs cannot be prescribed or RA patients refractory to biological agents are representatives, financial difficulty is another representative. There are RA patients who hesitate biological treatment or treatment with Janus-kinase inhibitor due to financial difficulty. Although biosimilar disease-modifying anti-rheumatic drugs (DMARDs) are promising treatment options for such patients, real-world clinical experiences are still lacking in respect to exchanging from biological originator DMARDs to biosimilar DMARDs.

Objectives: This retrospective study investigated the effects of switching from etanercept originator (ETN-OR) to ETN biosimilar (ETN-BS: LBEC0101 developed by LG Chem) on disease activity, physical function, and patient reported outcome (PRO) regarding a self-injection device in patients with well-controlled RA.

Methods: Data from the Toyohashi RA Database (TRAD) was used, which is a collection of single-center retrospective data. We retrospectively investigated disease activity, modified health assessment questionnaire (mHAQ), and patient characteristics in 42 RA patients that switched from ETN-OR to ETN-BS at least 6 months prior. Patients were also requested to answer the Toyohashi Self-Injection Assessment Questionnaire (T-SAQ), originally designed to assess PRO. T-SAQ consisted of 18 questions about self-injection device such as burden, learning, pain, convenience, handling and so on. Best was 0 and worst was 4 in each question and mean score of 18 questions was called total T-SAQ score.

Results: All the patients were female. The mean age, RA duration, and ETN-OR treatment duration were 63.1 years, 18.3 years, and 3107 days, respectively. Mean disease activity and mean mHAQ after switching were as follows (baseline-3 months-6): DAS28-CRP (1.86-2.00-2.03), SDAI (4.3-5.0-5.3), and mHAQ (0.43-0.44-0.46). SDAI after 6 months was significantly elevated compare to baseline. Among each parameter, tender joints count at 3 months and patients' global assessment at 6 months after switching are significantly increased compared to baseline (Table 1). Other parameters such as swollen joint counts, physician global assessment and CRP were not significantly changed. Total T-SAQ scores before and after switching were 1.3 and 1.1 ($p < 0.01$), respectively. Ease of use, mental tension, and pain were especially improved after switching to ETN-BS.

Conclusion: Switching from ETN-OR to ETN-BS worsened disease activity in well-controlled RA patients in our real-world clinical practice due to not objective findings, but subjective complaints by RA patient. We thought that nocebo effect was one of the reasons to explain the results. On the other hand, the PRO regarding the injection device was improved. This improvement may be due to Finer needle of ETN-BS (ETN-OR: 27G, ETN-OR: 29G).

Table. Time-course of parameters on disease activity

	At starting of ETN-OR (n=34)	At switching to ETN-BS (n=42)	At 3 months	At 6 months
Tender Joints Counts	7.5 (5.0)	1.1 (2.2)	**1.8 (3.3)***	1.4 (2.5)
Swollen Joints Counts	4.7 (4.5)	0.2 (0.6)	0.3 (0.7)	0.2 (0.5)
Patient's Global Assessment (mm)	38.6 (22.3)	14.6 (12.6)	13.5 (12.1)	**21.8 (18.2)***
Physician's Global Assessment (mm)	39.4 (16.6)	10.7 (8.2)	11.4 (8.2)	12.2 (7.9)
CRP (mg/dl)	2.6 (2.7)	0.4 (1.0)	0.3 (0.6)	0.3 (0.6)

Data lacking at starting of ETN-OR exist due to ETN-OR initiation at another institute.
Data is expressed mean value (standard diviation).

* $p<0.05$ compared with data at switching to ETN-BS by Wilcoxon signed-rank test)

Disclosure of Interests: None declared

AB0369 CORRELATION OF THE FIRST LATERAL FLOW-BASED POINT OF CARE TEST TO QUANTIFY INFLIXIMAB AND ANTI-INFLIXIMAB ANTIBODIES IN A FINGER PRICK SAMPLE WITH THE REFERENCE ELISA TECHNIQUE

M. B. Ruiz-Argüello[1], J. Pascual[1], L. Del Rio[1], A. Urigoitia[1], C. Balo-Farto[2], C. Fernández-López[3], A. Mera Varela[2], F. J. de-Toro-Santos[3], D. Nagore[1], A. Ametzazurra[1]. [1]*Progenika Biopharma - Grifols, Research and Development, Derio, Spain;* [2]*Hospital Clínico Universitario de Santiago, Servicio Reumatología, Santiago de Compostela, Spain;* [3]*Complexo Hospitalario Universitario A Coruña, Servicio Reumatología, A Coruña, Spain*

Background: Current techniques to monitor clinical response may require several days and centralised facilities, which may cause delays in effective therapeutic decisions. Therefore, the use of a rapid decentralized test will facilitate patient management and improve patient care.

Objectives: The goal of this study was to validate the use of capillary blood in a real point-of-care (POC) setting for rheumatic patients under infliximab treatment by using Promonitor Quick lateral flow (LF) tests. Results were compared to the Promonitor ELISA reference technique in serum samples used by centralised laboratories.

Methods: A prospective, observational study was designed to evaluate the performance of a rapid LF test (Promonitor Quick IFX, Progenika, Spain). 160 infliximab treated rheumatology consecutive patients (400 samples) were recruited in two hospitals in Galicia, Spain. Prior to the infusion, a finger prick sample was obtained and analysed. Anti-infliximab antibodies were also determined with Promonitor Quick ANTI-IFX[1-4]. Results were read with the automated portable PQreader instrument. Additionally, a serum sample was collected for subsequent comparative analysis with either LF or ELISA tests.

Qualitative (positive (PPA) and negative (NPA) agreements) and quantitative (Pearson correlation and bias) performance of the LF test was compared to ELISA, as well as between different specimens following CLSI EP09-A3.

Results: Overall agreement between Promonitor Quick IFX finger prick and ELISA test was 91% (88% PPA; 100% NPA). The quantitative comparison showed a good correlation (Pearson correlation coefficient: 0.85 and observed bias: 25%) (Table 1).

Table 1.

Performance results: infliximab drug				
Qualitative Comparison				
	N*	**PPA**	**NPA**	**overall**
POC finger prick vs ELISA	274	88%	100%	91%
POC serum vs ELISA	281	98%	100%	98%
Quantitative Comparison				
	N*	**Pearson correlation**	**Bias**	
POC finger prick vs ELISA	165	0.85	25%	
POC serum vs ELISA	181	0.91	6%	
**Only samples in the common measurement range for both methods considered.*				
Performance results: anti-infliximab anti-drug antibodies				
Qualitative Comparison				
	N*	**PPA**	**NPA**	**overall**
POC finger prick visual vs. PQreader	396	100%	99%	99%
POC serum visual vs PQreader	398	100%	100%	100%
POC finger prick PQreader vs ELISA	393	90%	99%	98%
POC serum PQreader vs ELISA	395	89%	100%	99%

Similar results were also observed when serum was used with either the LF or the ELISA tests (98% overall agreement, 0.91 correlation coefficient; 6% bias) (Table 1). Overall agreements for visual and automated (PQreader) interpretations with Promonitor Quick ANTI-IFX were 99% and 100% for finger prick and serum specimens, respectively (Table 1).

Conclusion: Promonitor Quick can be used to reliably quantify infliximab in capillary blood samples and results are comparable to those obtained with the reference ELISA technique. The use of the rapid POC test with finger prick will allow clinicians to monitor their patients in a fully decentralized mode to aid in the decision making process. PQreader is a sensitive portable equipment to report drug as well as antibody levels in the patient samples.

AB0370 COMPARISON OF A NEW RANDOM-ACCESS SOLUTION FOR THERAPEUTIC DRUG MONITORING OF ADALIMUMAB TO THE REFERENCE ELISA TEST

A. Ruiz del Agua[1], R. El Hamss2, M. Moneo[1], M. B. Ruiz-Argüello[3], D. Nagore[3]. *[1]Progenika Biopharma SA, PDS, Derio, Spain; [1]Progenika Biopharma SA, PDS, Derio, Spain; [3]Progenika Biopharma SA, R&D, Derio, Spain*

Background: Despite numerous studies, Therapeutic Drug Monitoring (TDM) of biological therapies is still debated partly motivated by the accessibility to a ready-to-use monotest device capable of delivering accurate results in a timely manner without the burden of sample batching, therefore allowing immediate decision making.

Objectives: We aimed at comparing the new Chorus Promonitor Adalimumab monotest running in the fully automated random-access Chorus TRIO system to the reference ELISA test Promonitor ADL run in a Triturus system.

Methods: Chorus Promonitor Adalimumab (Diesse Diagnostica Danese, Italy) is an immunoassay kit for the automated quantitative detection of adalimumab (ADL) in human serum using a ready-to-use disposable monotest device applied on the Chorus TRIO (Diesse Diagnostica Danese, Italy) instrument, a random-access single test multiparametric system for immuno-colorimetric assays. The new device implements the same specific reagents as in the reference ELISA test Promonitor ADL (Progenika, Spain) run in a Triturus (Grifols, Spain) system, therefore ensuring the same analytical specificity and applicability for patient monitoring previously demonstrated with the predicate ELISA. The new monotest device contains all the reagents necessary to perform the assay, and a lot-specific master curve method is used for calibrating. The comparison was performed in a set of 53 serum samples from patients under ADL therapy that covered the entire drug trough concentrations found in clinical practice (up to 30 ug/mL). Pearson's correlation, Bland-Altman and Passing-Bablok regression analysis were used to study the association and quantitative comparison between the methods.

Results: Time to first result for the Chorus Promonitor Adalimumab test was 2 hours and 45 min minutes and after this a new result was delivered every 30 seconds. Positive and negative percent agreements between both tests were 100%. A high correlation between both tests was found (coefficient of correlation of 0.959, p<0.01). The Passing-Bablok regression analysis determined an excellent comparability of both data sets with a slope of 1.032 (0.952-1.129) with an intercept of -0.428 (-1.292-0.053).

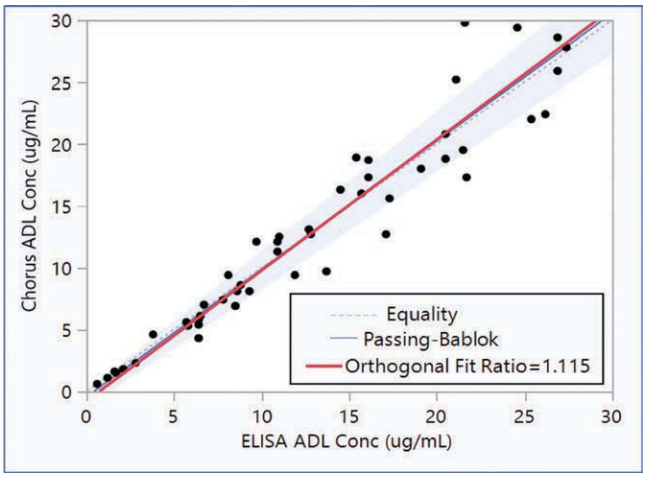

Figure 1.

Conclusion: The Chorus Promonitor Adalimumab represents the first evolution of the gold-standard Promonitor ELISA technology into a monotest random-access technology that enables quick turnaround time to facilitate TDM for ADL and aid immediate decision making.

AB0371 CLINICAL SIGNIFICANCE OF GALECTIN-3 IN PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE THE APPOINTMENT AND AFTER 12 MONTHS OF TREATMENT WITH BIOLOGICAL DRUGS (PRELIMINARY DATA).

Y. Gorbunova[1], T. Popkova[1], I. Kirillova[1], T. Panafidina[1], M. Diatroptov[2], E. Nasonov[3]. *[1]VA Nasonova Research Institute of Rheumatology, of Systemic Rheumatic Diseases, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Scientific, Moscow, Russian Federation*

Background: The role of galectin-3, a pro-inflammatory mediator involved in autoimmune disorders in patients with rheumatoid arthritis (RA), is discussed in the literature.

Objectives: To clarify the relationship of clinical and laboratory manifestations of RA with galectin-3 with the ineffectiveness of basic anti-inflammatory therapy and after 12 months of treatment with biological drugs.

Methods: The study included 47pts (39 women /8 men) with RA, 51 [39,0; 63,0] years old. Pts were seropositive for IgM RF (79%) and anti-CCP (62%), with highly active RA (DAS28 5,7 [5,2; 6,4]; SDAI 35,0 [29,1; 43,6], CDAI 34,0 [25,0; 43,0]) scores, and median disease duration of 4.0 [3,0;14.0] years. All patients with RA had a history of insufficient effect or intolerance to two or more basic anti-inflammatory drugs (DMARDs). At the time of inclusion in the study, patients received DMARDs: 44% of patients received methotrexate (median dose - 15 (15; 20) mg /week), 35% - leflunomide (20 mg/day), 9.3 % - sulfasalazine (2000 mg/day), 7% - hydroxychloroquine (200 mg/day), 67.4% - glucocorticoids (5 (4;8) mg /day). Patients did not receive biological therapy at the time of inclusion in the study. Due to lack of efficacy or intolerance, patients with RA (n=21) were prescribed biological therapy: 52.4% - anti-B-cell therapy, 38% - TNF-alpha inhibitors, 9.6% - IL-6 inhibitors. The control group consisted of 20 age-matched donors without rheumatic diseases. Galectin 3 concentration was determined by ELISA (Bender MedSystems GmbH, Biocenter, Vienna Austria). The upper limit of normal when testing 20 sera from healthy donors was 5.32 ng/ml, corresponding to the 95th percentile.

Results: The serum level of galectin-3 in RA patients (n=47) and in the control group (n=20) did not differ statistically significantly (4.27 [2.3;5.26] ng/ml vs 3.83 [2.57;4.11] ng/ml (p=0.1). In the whole group of RA patients (n=47) with inefficiency (insufficient effect) of basic anti-inflammatory therapy, correlations were noted between the level of galectin-3 and age (R=0.34; p=0.02), BMI (R=0.36; p=0.02), SDAI (R=0.33; p=0.02), CDAI (R=0.31; p=0.03). RA patients were divided into 2 groups: group I (n=27) - patients with galectin-3 ≥ 5.32 ng/ml; II (n=20) - less than <5.32 ng/ml. Group I patients were older in age (59.0 (46;67) years vs 42.5(38;53) years), had higher activity according to SDAI (38.2 (30; 48.4) vs 29.7 (26.6; 40.6)), CDAI (35.0 (29; 43) vs 27.0 (23;38)) (p<0.05 in all cases). In the group of patients (n=21) who received combination therapy (DMARDs + biological therapy) for 12 months, there was a significant decrease in clinical and laboratory activity, IgM RF levels (p<0.05 in all cases). (Table 1). The serum level of galectin-3 in RA patients (n=21) decreased by 19% statistically insignificantly after 12 months of combination therapy (4.24 [2.8;5.1] ng/ml vs 3.42 (2.56; 4.36) ng/ml (p=0.2).

Table 1.

	Patients with RA (n=21) with insufficient effect of basic anti-inflammatory therapy	Patients with RA (n=21) after 12 months of receiving combination therapy	Δ,%	p
DAS28	5,6 (5,3; 6,7)	3,97(3,36;4,63)*	-30,4	**0,0001**
SDAI	38,17 (29,5; 45,8)	17,2(9,57;25,6) *	-54,8	**0,0001**
CDAI	35,0 (26,0; 43,5)	17,0(9,0;23,5) *	-51,4	**0,0001**
CRP,mg/l	20,6 (11,7;34,1)	3,15(1,2;7,2) *	-84,7	**0,003**
ESR,mm/h	27,0 (16,0;45,0)	16,0 (10,0;23,5) *	-40,7	**0,003**
IgM RF, ME/ml	84,4 (20,8;163,0)	32,2(10,6;107) *	-61,8	**0,01**
Galectin-3, ng/ml	4,2 [2,8;5,1]	3,42 (2,56; 4,36)	-19	0,2

* -p <0.05 reliability of differences in indicators before and after 12 months of combination therapy (Wilcoxon); Δ,% - the difference in indicators between the groups by the 12th month of combination therapy.

Conclusion: There were no differences in the level of serum galectin-3 in patients with RA and with the ineffectiveness of basic anti-inflammatory therapy and in the control group. At the same time, the association of this marker with RA activity (according to the SDAI, CDAI indices) does not exclude its role in the development of clinical manifestations of rheumatoid arthritis.

AB0372 BIOLOGIC THERAPY IN CHILDREN WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS ACCORDING TO THE FEDERAL REGISTER OF THE RUSSIAN FEDERATION.

M. Botova[1], E. Alexeeva[1,2], T. Dvoryakovskaya[1,2], R. Denisova[1], A. Mamutova[1], K. Isaeva[1], A. Chomakhidze[1], O. Lomakina[1], A. Fetisova[1], M. Gautier[1], K. Chibisova[1], E. Krekhova[1,2], I. Kriulin[1,2], I. Tsulukiya[1], T. Kriulina[1,2], N. Kondratyeva[1]. [1]*National Medical Research Center of Children's Health, Rheumatology, Moscow, Russian Federation;* [2]*Sechenov First Moscow State Medical University, Pediatric, Moscow, Russian Federation*

Background: Systemic juvenile idiopathic arthritis (sJIA) is the rarest variant of juvenile idiopathic arthritis, characterized by severe course, frequent exacerbations, the development of life-threatening extra-articular manifestations and complications, which requires the use of expensive medications and frequent hospitalizations of patients. In the Russian Federation, the provision of medicines to patients with sJIA is carried out at the expense of the federal budget, in this regard, the Federal Register of sJIA was created in 2018.

Objectives: To analyze biologic therapy in patients with sJIA according to the data of the Federal Register of the Russian Federation.

Methods: Retrospective analysis of epicrisis of patients receiving biologic therapy with a diagnosis of sJIA included in the Federal Register of the Russian Federation. The analysis included patients receiving the following drugs of biologic therapy: tocilizumab, canakinumab, etanercept, adalimumab.

Results: In 2018, 582 patients receiving biologic therapy were included in the Federal Register. Since 2019, the number of patients has steadily increased: in 2019 there were 796, in 2020 - 949, in 2021 - 1041 patients. The Federal Register of the Russian Federation includes patients under the age of 18 (in 2018 – 471, in 2019 – 666, in 2020 – 806, in 2021 – 790 patients) and patients over the age of 18 (in 2018 – 111, in 2019 – 130, in 2020 – 143, in 2021 – 250 patients). During the four-year follow-up, patients receiving tocilizumab predominate - on average 72.25% (in 2018 – 74%, in 2019 – 73.1%, in 2020 – 70.3%, in 2021 – 71.6% of patients). Therapy with using of TNF-α inhibitors remains without statistically significant dynamics: in 2018 – 38 (6.5%) received etanercept, in 2019 – 42 (5.3%), in 2020 – 44 (4.6%), in 2021 – 46 (4.4%); in 2018 – 22 (3.8%) received adalimumab, in 2019 – 25 (3.1%), in 2020 – 27 (2.9%), in 2021 – 29 (2.8%) patients. The number of patients receiving canakinumab has more than doubled since 2018 (in 2018 – 91 (15%), in 2019 – 147 (18.5%), in 2020 – 210 (22.3%), in 2021 - 220 (21.1%) patients.

Conclusion: The number of patients receiving biologic therapy with sJIA in the Russian Federation has increased, which is due to the natural growth of the disease and more affordable provision of patients with sJIA by the state.

AB0373 ABATACEPT IN MONOTHERAPY OR IN COMBINATION WITH CONVENTIONAL DISEASE-MODIFYING DRUGS: TREATMENT PERSISTENCE IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS.

P. Muñoz Reinoso[1], I. García Hernández[1], B. Hernández-Cruz[1], J. J. Pérez Venegas[1]. [1]*Hospital Universitario Virgen Macarena, Reumatología, Sevilla, Spain*

Background: Abatacept is a selective T-cell co-stimulation modulator indicated for the treatment of moderate to severe active rheumatoid arthritis in patients with inadequate response to previous treatment. It is used in routine clinical practice in combination with other conventional synthetic disease-modifying drugs, with some records showing worse results when used in monotherapy[1].

Objectives: To analyse the persistence and efficacy of ABA in monotherapy vs. combined with conventional DMARDs. To determine the prescription patterns and clinical characteristics of patients who have received at least one dose of the drug.

Methods: Retrospective observational study of a cohort of RA patients under treatment with ABA reviewed in Rheumatology consultations at Virgen Macarena University Hospital, from 2010 to 2020. STATA statistical software was used. The study was conducted in accordance with the standards of the CEIC.

Results: 69 patients were included, 80% female. The average age was 63 (53-63) years. RA evolution time was 10 (4-16) years. 92% RF +, 86% ACCP + and 84% double +. 81% with erosions and 47% had extra-articular manifestations: 16 ILD, 10 Dry Syndrome and 9 Rheumatoid Nodules. 96% had relevant comorbidities such as Osteoporosis 33, Hypertensión 31, dyslipidaemia 26, Fibromyalgia 16, Depression 14 or Diabetes 9. Prior to ABA start, all were treated with NSAIDs, GC and conventional DMARDs, 32% with one conventional DMARDs, 31% with two and 37% with three or more; The conventional DMARDs used were MTX 90%, LFN 45%, HCQ 38%, CyA 13%, Gold salts 9% and SSZ 7%. 71% were previously treated with biologic DMARDs; 44% with one biologic DMARDs and 39% with two or more biologic DMARDs. The most commonly used biologic DMARDs were ETA 63.3%, ADA 30.6%, IL-6 inhibitors 20.4% and RTX 24.3%. Of the 29% who started ABA as a first-line. S.C. administration was used in 78%, with the standard dose. ABA was introduced together with conventional DMARDs in 67% patients: MTX 70%, LFN 17%, HCQ 13%, SSZ 4%. Of the 16 patients with ILD, 9 continued with conventional DMARDs in combination. The average ABA persistence was 65.5 (43-100) months; monotherapy 56 (17-76) and associated with conventional DMARDs 73 (59-101), p=0.904 (Figure 1). The differences between ABA in monotherapy or in combination are shown in Table 1. On the last visit, 67% patients with ABA had CG. At the end of the study 38% remained on ABA; 62% discontinued treatment, 68% due to secondary failure, 16% primary failure and 12% adverse events (skin toxicity, haematological toxicity and infections). Six patients died, four due to disease complications, five of whom were on monotherapy.

Table 1.

Variables	Global n=69	ABA monotherapy n=23	ABA + conventional DMARDs n=46	
		Median (p25-p75)		
Age	63 (54 – 70)	70 (63 – 74)	57 (52 – 67)	0,001
Duration of illness	10 (7 – 16)	12 (5 – 20)	10 (4 – 19)	0,04
Exposure time	66 (43 – 100)	56 (20 – 76)	73 (59 – 106)	0,04
DAS28 Basal	4.9 (3.9 - 5.7)	5.3 (3.8 – 6.3)	4.8 (3.8 – 5.5)	0,1
DAS28 Final	4.2 (2.8 – 5.6)	4 (2.7 – 5.4)	4.7 (2.8 – 5.7)	0.4
Basal GC (mg/d)	6 (5 – 10)	6 (5 – 11)	6 (5 – 10)	0,5
Final GC	6 (5 – 10)	7 (5 – 10)	6 (5 – 10)	0,4
	n (%)			
ABA as a first-line	20 (29)	6 (26)	14 (30)	0,7
ABA + GC at the start	54 (78)	18 (78)	319 (63)	1
At the end	31 (67)	12 (75)	6 (78)	0,4
ABA Discontinuation	43 (62)	13 (57)	30 (65)	0,4
ABA Persistence	26 (38)	10 (43)	16 (35)	0,4
EULAR response				
None	32 (64)	11 (64)	21 (63)	0,9
Moderate	11 (22)	4 (23)	7 (21)	
Good	7 (14)	2 (12)	5 (15)	

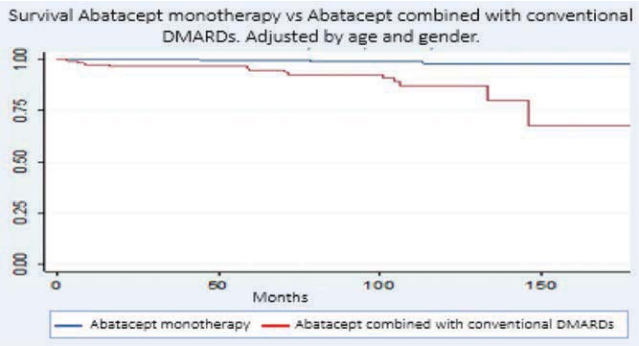

Figure 1.

Conclusion: The results show that Abatacept is mainly used after failure of conventional DMARDs and biologic DMARDs, in patients with long-standing RA and poor prognostic criteria. Combination therapy is used in patients with a higher risk profile (males, antibody positivity, erosions, extra-articular manifestations, comorbidity) and leads to a reduction in the number of patients treated with GC. Survival of ABA in combination is higher than in monotherapy, but this difference is less statistically significant when adjusted by age and gender.

Background: Limited data have been published on tolerance and efficacy of biotherapy in elderly patients with rheumatoid arthritis (RA) [1]

Objectives: To assess in real life the efficacy and safety of biological treatments in elderly patients with rheumatoid arthritis (RA) and to identify predictive factors for a good therapeutic response.

Methods: A cross-sectional observational study was conducted, the main data source was the Moroccan registry of biological therapies in rheumatic diseases (RBSMR registry). The duration of this study was 12 months. Patients included were all elderly patients (age > 65 years old), presenting RA,according to ACR /EULAR classification criteria for RA 2010.Demographic and clinical characteristics, disease activity, radiographic damage and functional ability have been compared between two groups of patients: those with response to biotherapy and those without response to biotherapy. Clinical and biological tolerance of biotherapy was assessed at 12 months of follow-up in all patients

Results: Among 224 patients included in the RBSMR registry, 23 patients were over 65 years. The average age of patients was 69,57 years ±4.33 with a sex ratio women/man: 4.75. The mean duration of the disease was 964,79 weeks +/-588,8. RA was seropositive in 87% of patients, with positive anti-cyclic citrullinated antibodies (ACPAs) in 60.9%. It was erosive in 83.3%, with carpitis in 50% of our cases. Concerning biological features, the mean erythrocyte sedimentation rate (ESR) was 55,05 mm H1± 26 and the mean C - reactive protein (CRP) was 26.79 mg/l ± 18. The average initial disease activity score 28-ESR (DAS 28 ESR) was 4,08+/-1,60. The average 12-month DAS was 2,67+ /-1,49. The Health Assessment Questionnaire (HAQ) average was 1.22. Concerning the treatment taken, 8.7% of patients were under Etanercept,4,3% were under Golimumab,69,6% were under Rituximab and 17,4% of patients received Tocilizumab. The analysis did not reveal any statistically significant difference between the two groups regarding demographic, clinical characteristics, disease activity, radiographic damage, biological feature and therapeutic data. 78.3% of our patients had a good tolerance to biotherapies, on the other hand 21.7% had presented undesirable effects.

Conclusion: RA is a common and even more common disease in the elderly, our study as well as The literature data confirms the efficacy of biotherapy and its good tolerance in our Moroccan patients with RA. It represents a therapeutic alternative of choice. Our results further encourage its use in our Moroccan context.

AB0375 IN PATIENTS STARTING ETANERCEPT, MALE SEX, ABSENCE OF COMORBIDITIES AND NO CSDMARDS CO-ADMINISTRATION ARE INDEPENDENT PREDICTORS OF LONG-TERM (MORE THAN 3 YEARS) PERSISTENCE TO THERAPY, IRRESPECTIVELY OF THE CLINICAL DIAGNOSIS.

I. Flouri[1], A. Repa[1], N. Avgustidis[1], A. Eskitzis[1], A. Molla Ismail Sali[1], S. Pitsigavdaki[1], K. Pateromichelaki[1], A. Bertsias[1], E. Kalogiannaki[1], M. Terizaki[1], G. Bertsias[1], P. Sidiropoulos[1]. *[1]University Hospital of Heraklion, Crete, Rheumatology Department, Heraklion, Crete, Greece*

Background: Comparative data among rheumatoid arthritis (RA), spondylarthritis (SpA) and psoriatic arthritis (PsA) patients regarding long-term survival of etanercept (ETN) in clinical practice are limited.

Objectives: The first aim of this study was to analyze the long-term (>3 years) ETN survival comparatively between its three main indications. We also aimed to analyze for predictors of long term ETN survival.

Methods: We analyzed data from the University of Crete Rheumatology Clinic Registry (UCRCR), a single center prospective cohort study. All patients with a diagnosis of RA, SpA or PsA starting treatment with a biologic DMARD are recorded prospectively based on a common follow-up protocol. For the first aim, ETN survival >3 years was compared among the 3 diseases. For the 2nd aim patients on ETN >3 years were compared to those stopping ETN during the first 2 years. We analyzed baseline and early on treatment (first 6 months) characteristics, comedications, comorbidities as predictors for long term survival applying univariate and multivariate models.

Results: A total of 711 patients who were started on ETN were analyzed (RA: 450, SpA: 177, PsA: 84). As expected, patients' and disease characteristics at baseline differed significantly between the 3 diagnoses (Table 1). Patients' function was compromised irrespective of the diagnosis, while inflammatory activity was significant across diseases.

Table 1. Baseline parameters [Medians (IQR) unless otherwise specified]

	RA (n=450)	SpA (n=177)	PsA (n=84)	p
Women N (%)	370 (82)	66 (37)	46 (55)	**<0.001**
Age	61.5 (53-70)	44.5 (35-54)	51 (41-62)	**<0.001**

Nr of previous csDMARDs	2 (1-3)	1 (0-2)	1 (1-2)	**<0.001**
Co-administered MTX N(%)	284 (63)	65 (37)	50 (60)	**<0.001**
Monotherapy, N (%)	60 (13)	100 (56.5)	25 (30)	**<0.001**
Ongoing corticosteroids N(%)	153 (34)	25 (14)	17 (20)	**<0.001**
DAS28 - ESR	5.8 (5.0-6.5)	3.7 (2.9-4.7)	5.3 (4.5-6.4)	**<0.001**
ASDAS-ESR	-	3.4 (2.8-4.1)	3.6 (3.2-4.7)	0.067
CRP (mg/dl)	0.4 (0.3-1.1)	1.1 (0.3-2.4)	0.8 (0.4-2.0)	**<0.001**

During a follow-up of 1371 patient-years, 466 (65.5%) patients stopped therapy. The estimated percentage of patients persisting on ETN therapy for > 3 years was 28.4%, 42.8% and 44% of RA, SpA and PsA respectively. The main reason for therapy discontinuation was inefficacy (75% of stop reasons in RA vs. 58% in SpA vs. 69% in PsA). In multivariable Cox regression analyses the most important predictor for ETN survival was the achievement of LDA/remission at 6 months based on DAS28 for RA or ASDAS for SpA [Odds Ratio (OR) 1.98, p=0.008 and 3.02, p=0.001 respectively]. Prognostic factors for ETN discontinuation specifically due to inefficacy were comorbidities number and csDMARDs coadministration (p<0.05 for both), while older age and no co-therapy with MTX predicted ETN stop due to adverse events (p<0.05 for both). Logistic regression analysis indicated that male sex [OR: 2.08, p=0.004], calendar year of treatment start [OR per 3 years: 0.74, p=0.001], comorbidities' number [OR: 0.82, p=0.045] and monotherapy [OR: 1.81, p=0.027] predict persistence on ETN therapy beyond 3 years, while the clinical diagnosis or other baseline parameters are not significant predictors.

Conclusion: In this prospective cohort study, we found that ETN survival was higher for patients with SpA/PsA as compared to RA. Male sex, absence of comorbidities and no csDMARDs co-administration are independent predictors of long-term persistence to therapy, irrespectively of the clinical diagnosis. Notably, both in RA and SpA, 6-month response predicted ETN survival in the long term.

AB0376 DIFFERENCES IN IMMUNOGLOBULIN LEVELS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS AND RHEUMATOID ARTHRITIS TREATED WITH RITUXIMAB

M. Sanz[1], C. M. Oñoro López[2], G. Bonilla[1], D. Peiteado[1], A. Noblejas Mozo[2], Á. Robles Marhuenda[2], J. J. Rios[2], D. Benavent[1], C. Plasencia[1], L. Nuño[1], I. Monjo[1], A. Villalba[1], A. Balsa[1]. *[1]Hospital Universitario La Paz, Rheumatology, Madrid, Spain; [2]Hospital Universitario La Paz, Internal Medicine, Madrid, Spain*

Background: Hypogammaglobulinemia (HGGS) is one of the adverse effects of Rituximab (RTX), a chimeric monoclonal antibody directed against the CD20 receptor, frequently observed in ANCA-associated vasculitis (AAV) patients.

Objectives: To study the characteristics of patients with AAV on RTX treatment and to analyze the factors associated with HGGS, as well as to compare them with patients with rheumatoid arthritis (RA) on the same treatment.

Methods: Retrospective descriptive study of patients with a diagnosis of AAV or RA treated with RTX who had immunoglobulin levels prior to treatment and after each cycle were included. Demographic, clinical and analytical variables were analyzed. Patients who developed HGGS versus those who did not were compared using Student's t and Mann-Whitney U for continuous variables and chi-square for categorical variables.

Results: Ninety-five patients were included, 19 (20%) with AAV and 76 (80%) with RA. Of the 34 (35.8%) who developed HGGS, 19 had RA (25%) and 15 AAV (79%) (p<0.001). The 6 patients who presented with severe HGGS (IgG<500) belonged to the AAV group.

The overall sample was divided into patients with HGGS and patients without (Table 1). Significant differences were obtained in relation to diagnosis (p<0.001), age at diagnosis and at the start of treatment, being higher in patients with HGGS (p 0.005 and p 0.001) and years of disease evolution (p 0.036). Patients with HGGS had a lower mean baseline IgG (p<0.001). The HGGS group had more severe infections (infections requiring admission) (p 0.005) and the time from RTX administration to the development of infection was shorter in this group (p 0.017). The frequency of abdominal infection was higher in the HGGS group (p 0.050), and there were no significant differences with the other types of infection.

Table 1.

	Total sample (n= 95)	HGGS IgG (n= 34)	No HGGS IgG (n= 61)	P
Women n/N(%)	70/95(73.7)	23/34(67.6)	47/61(77)	0.318

Age at start of treatment (m±SD)	57±12	62±10	54±12	0.001
Years of evolution (m±SD)	11±9	8±9	12±10	0.036
RA n/N(%)	76/95(80)	19/34(55.9)	57/61(93.4)	<0.001
AAV n/N(%)	19/95(20)	15/34(44.1)	4/61(6.6)	<0.001
Glomerular filtration rate <60 n/N(%)	7/91(7.7)	4/34(11.8)	3/61(4.9)	0.164
GCS AD in the previous year (m±SD)	2918±3102	3265±3050	2690±3155	0.238
GC AD during treatment (m±SD)	4656±17713	2889±2778	5576±21775	0.271
Total GC AD (m±SD)	56411±326716	117050±484186	5879±6089	0.159
CFM AD (m±SD)	0.51±2.25	1.1±3.1	0.2±1.5	0.032
Baseline IgG (m±SD)	1107±340	933±346	1203±297	<0.001
Infection n/N(%)	58/95(61.1)	23/34(67.6)	35/61(57.3)	0.325
Severe infection n/N(%)	19/95(20)	12/34(35.3)	7/61(11.5)	0.005
Time to infection (months)(m±SD)	43±43	30±36	57±45	0.017
Exitus n/N(%)	8/95(8.4)	2/34(5.9)	6/61(9.9)	0.270

Conclusion: A significantly higher percentage of HGGS is observed in patients with AAV treated with RTX compared to patients with RA. The development of HGGS seems to be influenced by age at diagnosis and at the start of treatment, years of disease evolution and low levels of IgGs prior to the start of treatment. In addition, there is a higher frequency of severe infections in the HGGS group. Studies with larger sample sizes are needed to confirm these results.

AB0377 DIFFERENCES OF EFFICACY OF TNF-A INHIBITORS AND THEIR IMMUNOGENICITY IN RHEUMATOID ARTHRITIS AND INFLAMMATORY BOWEL DISEASES

T. Nuriakhmetova[1], D. Abdulganieva[1], A. Vasiliev[2], N. Cheremina[3], J. Shevnina[4]. *[1]Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation; [2]City Clinical Hospital #7, Rheumatology, Kazan, Russian Federation; [3]Republican Clinical Hospital, Gastroenterology, Kazan, Russian Federation; [4]Republican Clinical Hospital n.a. N.A. Semashko, Outpatient Clinic, Simferopol, Russian Federation*

Background: The immunogenicity of TNF-α inhibitors (TNFi) and its effect on their efficacy can depend on the underlying disease. To date, no studies were performed to directly compare this relation between different groups of immune-mediated diseases.

Objectives: To compare the effect of immunogenicity of TNFi on their efficacy in rheumatoid arthritis (RA) and inflammatory bowel diseases (IBD) (Crohn's disease (CD) and ulcerative colitis (UC)).

Methods: 20 patients with RA and 53 patients with IBD (38 (30.9%) with CD and 15 (12.2%) with UC) were observed for 17 [10; 27] months. 26 (35.6%) of them received infliximab (INX) infusions, 23 (31.5%) – adalimumab (ADM) and 24 (32.9%) – certolizumab pegol (CZP). The following criteria were used for the evaluation of the response to TNFi: EULAR criteria for RA, decrease of CDAI for CD and Mayo Score for UC. Trough level of TNFi and the level of anti-drug antibodies (ADAb) were measured in the serum samples drawn directly before the planned drug administration. The threshold for low trough level was determined as follows: 1 μg/mL for INX[1] in RA group and 5 μg/mL for INX[2] in IBD group, 5 μg/ml for ADM[3], and 20 μg/l for CZP[4].

Results: 17 (85%) patients with RA and 35 (66%) patients with IBD responded well to the treatment. Loss of response to the treatment developed in 3 (15%) cases of RA and 18 (34%) cases of IBD (p>0.05). The median trough level of INX was 0.22 [0.17; 6.19] μg/ml in RA and 1.56 [0.79; 3.87] μg/ml in IBD. The median trough level of ADM was 5.45 [1.05; 12.07] μg/mL in RA and 11.17 [3.19; 13.01] μg/mL in IBD. The tendency toward lower median trough level of CZP in IBD was observed (28.17 [20.69; 42.95] μg/mL in IBD vs 16.92 [8.31; 30.96] μg/mL in RA (p=0.09)). Low trough level of TNFi was found in 11 (55%) patients with RA and 27 (50.9%) patients with IBD. It did not differ significantly either between the diseases or between the TNFi (p>0.05). Loss of response was associated with low trough level of TNFi in all 3 cases of RA and in IBD – in 9 (50%) cases (p>0.05). Positive ADAb were detected in 6 (30%) patients with RA and 8 (15.1%) patients with IBD. The rate of positive ADAb was comparable between different TNFi and immune-mediated diseases (p>0.05). A tendency toward lower prevalence of ADAb to ADM in CD than in RA was observed

(0% vs 40%, OR 0.6, 95%CI 0.362 to 0.995, p=0.08). Association of loss of response to the treatment with ADAb was observed in 2 (66.7%) patients with RA and 2 (11.1%) patients with IBD. Inefficacy of TNFi due to immunogenicity was 6 times more frequent in RA than in IBD (OR 6.0, 95%CI 1.296 to 27.769, p=0.08).

Conclusion: All RA patients not responding to TNFi treatment had either low trough level of the drug or ADAb as opposed to IBD patients with inefficacy, half of which did not have ADAb or low trough level.

AB0378 EFFECT OF RITUXIMAB ON BONE MINERAL DENSITY IN WOMEN WITH RHEUMATOID ARTHRITIS

O. Dobrovolskaya[1], N. Demin[1], N. Toroptsova[1], A. Sorokina[1], D. Kusevich[2], O. Nikitinskaya[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoarthritis, Moscow, Russian Federation*

Objectives: To compare the effect of rituximab (RIT) treatment on bone mineral density (BMD) in women with rheumatoid arthritis (RA) and those with RA without biological therapy.

Methods: 78 women over 40 years with confirmed RA according to ACR/EULAR criteria (2010) were enrolled in the study: 48 patients treated with RIT and methotrexate (RIT+) and 30 women received only methotrexate (RIT-). The patients did not differ in the glucocorticoid therapy duration and cumulative dose. BMD was determined in the lumbar spine, femur neck and total hip using dual energy x-ray absorptiometry (DXA, Hologic 4500A) at baseline and after 1 year. RA activity was evaluated by disease activity score using 28 joint counts and erythrocyte sedimentation rate (DAS28 ESR). Nonparametric statistic tests were performed.

Results: There were no differences between patients RIT+ and RIT- in age (median - 58 [53; 63] years and 52 [50; 69] years, p>0.05), RA duration (median – 15 [4; 21] year and 9 [3; 11] year, p>0.05) and DAS28 ESR (median – 5.18 [4.35; 6.25] and 5.71 [4.66; 5.94]). The percentage BMD changes from baseline in lumbar spine, femoral neck and total hip were 0.2% [-3.9%; 4.0%], -1.8% [-6.2%; 2.4%] and -0.3% [-3.5%; 4.5%], respectively, in patients RIT+ and -1.0% [-4.9%; 3.3%], -2.5% [-5.8%; -0.4%], -1.7% [-4.3%; 4.2%], respectively, in persons RIT-. There were no differences in BMD changes in the pair matching test both patients RIT+ and RIT-. No correlations between BMD changes with age, RA duration and DAS28 ESR were found.

Conclusion: RIT had no effect on BMD in women with RA after 1 year therapy. BMD changes were not associated with age, RA duration and disease activity.

AB0379 DOSE-DEPENDENT SUPPRESSION OF T CELL-DEPENDENT ANTIBODY RESPONSE IN HEALTHY VOLUNTEERS BY KPL-404, AN ANTI-CD40 MONOCLONAL ANTIBODY, SUPPORTS CHRONIC DOSING STUDY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Papandrikopoulou[1], G. R. Burmester[2], F. Fang[1], A. Kivitz[3], M. Njenga[1], A. Pano[1], C. Pitzalis[4], M. Samant[1], S. Schmitz[1], M. Spiers[1], E. Tessari[1], J. Ziemniak[5], J. F. Paolini[1]. *[1]Kiniksa Pharmaceuticals Corp., Kiniksa Pharmaceuticals Corp., Lexington, United States of America; [2]Charité Universitaetsmedizin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [3]Altoona Center for Clinical Research, Altoona Center for Clinical Research, Duncansville, United States of America; [4]University of London, The William Harvey Research Institute - Barts and The London School of Medicine Queen Mary, London, United Kingdom; [5]Kiniksa Pharmaceuticals, Ltd., Kiniksa Pharmaceuticals, Ltd., Hamilton, Bermuda*

Background: An unmet need remains in patients with failure and/or inadequate response (IR) to biological disease-modifying antirheumatic drugs (bDMARD-IR) and/or Janus kinase inhibitors (JAKi-IR). The CD40/CD40L (CD154) costimulatory pathway is linked to inflammation and joint destruction in RA via production of autoantibodies and inflammatory mediators. KPL-404 is a humanized IgG4 antibody engineered to bind CD40 without triggering Fc effector functions (Muralidharan, 2019), which are known to have been associated with thromboembolic events seen in the first generation of CD40L-targeting therapies. In a first-in-human Phase 1 single ascending dose study, 52 healthy volunteers received single doses of KPL-404 administered either subcutaneously (SC) or intravenously (IV) with no dose-limiting safety findings, infectious episodes, or toxicities (Samant, 2021). The study demonstrated that with 10 mg/kg IV, full receptor occupancy (RO) was observed through day 71, and there was complete suppression of T-cell dependent antibody response (TDAR) to keyhole limpet hemocyanin challenge on day 1 and re-challenge on day 29 through day 57. With 5 mg/kg SC, full RO was observed through day 43, and there was complete suppression of TDAR through at least day 29. Complete suppression of ADA to KPL-404, an independent indicator of target engagement, was also observed while KPL-404 serum concentrations were above approximately 0.1 to 0.2 µg/mL and continued for at least 50 days and 57 days after 5 mg/kg SC and 10 mg/kg IV administration, respectively.

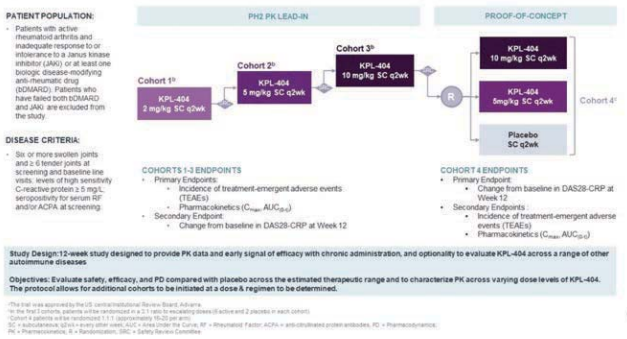
Objectives: Using Phase 1 and nonclinical data, identify chronic dosing regimens anticipated to yield PK in the sub-therapeutic, therapeutic, and supra-therapeutic ranges to be utilized in a Multiple Ascending Dose Phase 2 Study.

Methods: A PK model was used to simulate multiple dosing scenarios, including: 2.5, 5, and 10 mg/kg SC qwk, q2wk, and q4wk, as well as 10 mg/kg IV q4wk. The model was used to identify optimal Phase 2 dosing schedules by generating 1000 virtual subjects using the typical parameter estimates with between-subject variability included.

Results: Following SC administration, all subjects were predicted to achieve complete ADA suppression for the full dosing interval at/above 2.5 mg/kg SC q2wk. At 2 mg/kg SC q2wk (starting dose level), simulated steady-state 8-week data predicted PK in a sub-therapeutic range for most subjects and an approximately 31- and 18-fold safety margin relative to preclinical NOAEL dose. At 5 mg/kg SC q2wk, 100% of patients were predicted to be in a therapeutic range, indicating a potential practical efficacious dose level. At 10 mg/kg SC q2wk, 100% of patients were predicted to be in the supratherapeutic range.

These results support a Multiple Ascending Dose (MAD) Phase 2 study design, with PK lead-in comprised of 3 Cohorts at 2, 5, or 10 mg/kg SC q2wk (each randomized 6:2) and Proof-of-Concept phase (Cohort 4) comprised of 48-60 subjects randomized 1:1:1 to 10 mg/kg, 5 mg/kg, and placebo SC q2wk. The ongoing study will evaluate efficacy (Disease Activity of 28 joints using C-reactive protein [DAS28-CRP]), safety, PK, and pharmacodynamics (PD) of escalating doses levels of KPL-404 compared with placebo in patients with moderate to severe RA (bDMARD-IR or JAKi-IR). The study also allows the flexibility of optional cohorts including additional dosing regimens and/or subpopulations identified based on clinical response and biomarkers.

Figure 1. Study Design of the Phase 2 Trial[a] of KPL-404 in Rheumatoid Arthritis



Conclusion: Inhibition of the CD40-CD154 co-stimulatory interaction holds promise for the management of a spectrum of autoimmune diseases. KPL-404 demonstrated prolonged absorption/excretion capable of suppressing TDAR for extended periods allowing for use of extended dosing intervals irrespective of IV or SC dosing. These analyses supported the design of the ongoing Phase 2 study assessing the efficacy and safety KPL-404 in RA.

AB0380 ANTI-TNFA: ORIGINATORS VS BIOSIMILARS, COMPARISON IN CLINICAL RESPONSE ASSESSMENT IN A MULTICENTER COHORT OF PATIENTS WITH INFLAMMATORY ARTHROPATHIES

C. Gioia[1], A. Picchianti-Diamanti[1], R. Perricone[2], M. S. Chimenti[2], A. Afeltra[3], L. Navarini[3], A. Migliore[4], U. Massafra[4], V. Bruzzese[5], P. Scolieri[5], C. Meschini[6], P. Scapato[7], M. Paroli[8], R. Scrivo[1], F. Conti[1], B. Laganà[1], M. Di Franco[1]. *[1]Sapienza University Rome, Rheumatology, Rome, Italy; [2]TorVergata, Rheumatology, Rome, Italy; [3]Campus Biomedico, Rheumatology, Rome, Italy; [4]San Pietro Fatebenefratelli, Rheumatology, Rome, Italy; [5]Nuovo Regina Margherita, Rheumatology, Rome, Italy; [6]Belcolle Hospital, Rheumatology, Viterbo, Italy; [7]S. Camillo de Lellis Hospital, Rheumatology, Rieti, Italy; [8]Sapienza University, Rheumatology, Latina, Italy*

Background: Tumor necrosis factor (TNF)-α is one of principal proinflammatory cytokines involved in pathogenesis of different inflammatory arthropathies as Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS). Biotechnological drugs, represented among others by monoclonal antibodies directed against TNF-α, lead to a revolution in RA and spondylarthritis treatment. They were the first biological drugs used to treat these diseases, with good results in terms of safety and efficacy. Also because of high cost of these drugs, for some years biosimilars have been introduced in clinical practice. Biosimilars are less expensive (in Italy, less of 30% than bioriginators); they underwent to a severe process of "*comparability*" to assess safety and efficacy like their originators. In Italy, AIFA authorized SB4 (etanercept biosimilar), SB5 and ABP501 (adalimumab biosimilars) after passing III-phase randomized clinical trials; but *real-life* data and registers are lacking.

Objectives: Aim of this study is to compare biosimilars and bioriginators in terms of safety and efficacy in a real-life contest.

Methods: We consequently enrolled patients, affected by inflammatory arthropathies (RA, PsA, AS) and treated with biosimilars (SB4, ABP501), belonging to any of the main biological prescribing centers in the Lazio region, from 2017 to 2020. Moreover, we enrolled patients, affected by same inflammatory diseases, but treated with corresponding originator. Clinical and laboratory data as well as disease activity indices, were collected at recruitment (T0) and after 4 (T1), 8 (T2), 12 (T3) and 24 (T4) months of therapy. Adverse events were registered.

Results: The multicenter cohort was composed by 455 patients treated with biosimilars (SB4/ABP501 276/179; F/M 307/146; naïve 56%, median age/IQR 55/46-65) and 436 treated with originators (etanercept/adalimumab 186/259, F/M 279/157, naïve 67,2%, median age/IQR 53/43-62). No differences were found about safety, but biosimilar group presented a higher number of discontinuations due to inefficacy (p<0.001), observed at all time-points. Female gender, to be smoker and b-DMARDs naïve, the initial non-response to the drug were predictive factors of reduced drug survival (p=0,05, p=0,046, p=0,001 respectively). Retention rate at 24 months was 81.1% for bioriginators and 76.5% for biosimilars (with a median retention time of 20.7 and 18.9 months, respectively) (p=0.002). Patients with remission/low disease activity achievement at T1 showed a cumulative survival of 90% to biosimilar therapy until at T4 (p=0.001); early adverse reactions instead represented an important cause of subsequent drug discontinuation (p=0.001).

Conclusion: Real-life data demonstrated the same safety between biosimilars and originators but a reduced biosimilar retention rate at 24 months, about 76%. Despite their loss efficacy, biosimilars could be considered valid and safe, and a good and less expensive alternative to the originators, allowing access to these innovative treatments to a wider patient population.

AB0381 ULTRASONOGRAPHY TO PREDICT FLARE AFTER DISCONTINUATION OF BIOLOGICS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REMISSION

T. Ogura[1], A. Hirata[1], T. Kagtagiri[1], Y. Takakura[1], H. Kameda[1]. *[1]Toho University, Division of Rheumatology, Department of Internal medicine, Tokyo, Japan*

Background: Ultrasonography (US) has been suggested to be useful in predicting flare in patients with rheumatoid arthritis (RA) after discontinuation of biological disease-modifying antirheumatic drugs (bDMARDs).

Objectives: This study aimed to investigate whether US can predict flare after discontinuation of bDMARDs in RA patients who have achieved stringent remission criteria.

Methods: We prospectively enrolled RA patients who maintained a simplified disease activity index ≤ 3.3 and discontinued bDMARDs and measured clinical assessment and US every 2-3 months for 2 years. The US examination was performed on 40 joints using the semi-quantitative method of 0-3 on the Grey-scale (GS) and Power Doppler (PD), and the total values for each patient were used as the GS score and PD score. Joints graded as GS score ≥ 2 or PD score ≥ 1 were counted as US arthritis. In addition, tendons at 36 sites were counted with or without tendinitis/tenosynovitis to obtain a tendon score.

Results: Thirty-six patients were enrolled and two patients who dropped out early without flare were excluded from the comparative analyses. At baseline, the median GS score was 7, PD score was 0, US arthritis was 0, and tendon score was 0. The total PD score was 0 in 26 patients (72%) and it was 1 in 5 patients (14%). There were no significant differences in US findings between the relapse group (20 patients) and the non-relapse group (14 patients). Positive and negative predictive value for PD-positive findings (total PD score ≥1) were 60% and 42%, and for total PD score ≥2 were 60% and 41%, respectively.

Conclusion: The PD score in the US findings at the time of bDMARDs discontinuation was not predictive for future disease flare.

Rheumatoid arthritis - non biologic treatment and small molecules

AB0382 COMPARISON OF ADVERSE EVENTS (AES) RELATED TO MAJOR ANTI-RHEUMATIC DRUGS, REPORTED TO THE OFFICIAL JAPANESE ADVERSE DRUG EVENT REPORT DATABASE (JADER)

N. Tsuda[1], S. Inokuma[1,2], H. Noguchi[1], M. Yamaji[1], T. Harada[1], M. Misaki[1], Y. Masui[1], T. Kano[1]. *[1]Kohnodai Hospital, National Center for Global Health and Medicine, Rheumatology, Ichikawa, Chiba, Japan; [2]Chiba Central Medical Center, Allergic Diseases and Rheumatology, Chiba, Japan*

Background: Currently, many disease-modifying anti-rheumatic drugs (DMARDs) are available for the treatment of rheumatoid arthritis (RA). Among them, methotrexate (MTX), biologic DMARDs (bDMARDs) and Janus kinase inhibitors (JAKi) are the major options. AEs related to these are major concerns. In Japan, the AEs data spontaneously reported to and summarized by Pharmaceuticals and Medical Devices Agency (PMDA) are freely accessible.

Objectives: The major AEs relating to MTX, bDMARDs, and JAKi observed in the real world were compared.

Methods: The number of AEs listed by JADER from 2014 to 2020 was collected. The AEs were classified by System Organ Class (SOC) of Medical Dictionary for Regulatory Activities (MedDRA) and compared using the chi-square test. The bDMARDs included were etanercept (ETN), adalimumab (ADA), golimumab (GOL), tocilizumab (TCZ), and abatacept (ABT), and JAKi was tofacitinib (TOF) and baricitinib (BAR).

Results: The total number of AEs was 27,604. The number was significantly increasing in total and MTX, GOL, TOF during these years, although the number of cases that have each DMARD is not known in this study. The proportion of SOCs among each DMARD was similar throughout the period.

The most frequent was infections/infestations in all DMARDs except for MTX, in which neoplasms were the most. The primary cause of infection was bacterial, including pneumonia. Varicella-zoster virus infection in JAKi, and tuberculosis in ADA and GOL were conspicuous.

Neoplasms were the second major in many DMARDs. Lymphoproliferative disorders were most common in MTX-related neoplasms, whereas solid tumors were more in other DMARDs like ABT or BAR.

Other SOCs include all other categories such as the musculoskeletal, nervous system, cardiac, and vascular disorders. Among them, major adverse cardiovascular events (MACE, including cardiovascular death, myocardial infarction and stroke) and venous thromboembolism (VTE) were both reported in small numbers. However, more MACE was noted in BAR and GOL, and more VTE was in BAR and TOF compared to other DMARDs.

Conclusion: The number of AEs cases related to DMARDs was increasing. Significant difference among AEs related to DMARDs was noted in the JADER database, especially regarding MTX and JAKi.

AB0383 COMPARISON OF EFFICACY AND SAFETY IN JAK INHIBITOR DUE TO A DIFFERENCE OF SELECTIVITY – TOFACITINIB VS. BARICITINIB –

I. Yoshii[1], N. Sawada[2], T. Chijiwa[3]. *[1]Yoshii Hospitalshii, Musculoskeletal Medicine, Shimanto-City, Japan; [2]Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan; [3]Kochi Memorial Hospital, Rheumatology, Kochi, Japan*

Background: Each Janus Kinase Inhibitor (JAK-i) has different selectivity of JAKs, such as JAK1, JAK2, JAK3, and TIK2. However, little has been known regarding mode of action due to the selectivity difference in clinical practice for treating rheumatoid arthritis (RA).

Objectives: The aim of this study is to compare difference of efficacy and safety in two JAK-i; between tofacitinib (TOF) and baricitinib (BAR) in clinical practice using one-center retrospective cohort.

Methods: Within the case which administered TOF or BAR to the RA patient who the effect was insufficient in the existing treatment and the disease activity was over the middle disease activity using simplified disease activity index (SDAI). At the start of administration (baseline), 5 mg tablets of TOF were taken twice a day or 4 mg tablets of BAR were taken one a day. Patients were divided by drug and included their sex, age at onset, anti-cyclic citrullinated polypeptide antibodies (ACPA) titer, length of RA history at onset, Sharp/van der Heijde score (SHS) at onset, Naïve/Not Naive for biologic DMARDs or JAK-i, 28-joints disease activity score (DAS28), SDAI, Health Assessment Questionnaire Disability Index (HAQ-DI), and pain score with visual analog scale (PS-VAS). It was classified into large joint and small joint, and the point was independently scored by swelling and pressure pain by size and position in each joint. Total score of the

Background colors indicate: comparing to the total cases, higher with *p<0.05*, light pink; higher with *p<0.00001*, dark pink; higher with *p<1E-10*, red. Lower with *p<0.05*, light blue; lower with *p<0.00001*, blue; lower with *p<1E-10*, dark blue, using chi-square test. Yellow indicates System Organ Classes.

involved joints for each part; upper-extremities, lower extremities, big joints, and small joints (UES/LES/BJS/SJS), rheumatoid factor (RF) titer, serum matrix metalloprotease-3 (MMP-3) level, serum creatinine (Cr) level, and estimated glomerular filtration rate (eGFR) of each part were measured. The mean values of each group were obtained at baseline, 1, 2, 3, 6, 9, and 12 months, and the two groups were statistically compared using the Mann-Whitney U-test. As a sub-analysis, each drug group was divided into bio or JAK-i naive, age ≥ 70 years, disease duration ≥ 10 years, SHS ≥ 100. The change of DAS28 under each 2 divided condition was compared using Mann-Whitney U-test. Similar comparison was carried out with RA patient who administered golimumab (GOL) as a control group. The significance level was less than 5%.

Continuation rate (the withdrawal after the remission introduction is put in the continuation) in 12 months after baseline was also compared.

Results: A total of 82 patients were picked up, in whom 22 TOF group, 31 BAR group, and 29 GOL group included. Both DAS28 and SDAI were consistently lower in the BAR than in the other 2 groups from 1 month after baseline. SDAI in the BAR was significantly lower than in the GOL at 3 months after the baseline. The HAQ-DI score at 6 months after baseline was significantly lower in the BAR than in the GOL. PS-VAS in the GOL was significantly higher than the other two groups at 2, 3 and 6 months after baseline. In the joint point, BJS in the BAR was significantly lower than that in the GOL at 2, 3, and 6 month after baseline. SJS in the GOL was significantly lower than that in the TOF at 6 and 12 months after baseline. There was no significant difference in MMP -3, RF, Cr and eGFR between the 3 groups in any observation month, but Cr increased after the start in the BAR group and eGFR tended to decrease.

In the sub-analysis, the decrease of DAS28 at 1 year after baseline with a history of ≥ 10 years was significantly greater than in those with a history of < 10 years in the TOF, as well as DAS28 at 1 year in those with SHS ≥ 100 decreased significantly more than that in those < 100. These phenomena was not observed in the BAR group.

The continuation rate at 12 months after the start of administration was 86.4% in the TOF, 89.3% in the BAR and 69.0% in the GOL.

Conclusion: Even JAK-i characteristics in action differs for each drug. It is needed to choose appropriate drug based on these drug characteristics.

THE EFFECT OF A LIFESTYLE PROGRAM ON PATIENTS AT RISK FOR RHEUMATOID ARTHRITIS:THE "PLANTS FOR JOINTS" PILOT RANDOMIZED CLINICAL TRIAL

C. Wagenaar[1,2], W. Walrabenstein[1,2], M. van der Leeden[3,4,5], F. Turkstra[1], J. Twisk[6], M. Boers[6], H. van Middendorp[7], P. Weijs[8], D. van Schaardenburg[1,2].

[1]Amsterdam Rheumatology Center, Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam Rheumatology Center, Amsterdam University Medical Centers, Universiteit van Amsterdam, Rheumatology, Amsterdam, Netherlands; [3]Amsterdam Rheumatology Center, Reade, Rehabilitation Medicine, Amsterdam, Netherlands; [4]Department of Rehabilitation Medicine, Amsterdam University Medical Centers, Vrije Universiteit, Rehabilitation Medicine, Amsterdam, Netherlands; [5]Amsterdam Movement Sciences Research Institute, Rehabilitation Medicine, Amsterdam, Netherlands; [6]Amsterdam University Medical Centers, Vrije Universiteit, Department of Epidemiology and Data Science, Amsterdam, Netherlands; [7]Institute of Psychology, Health, Medical, & Neuropsychology Unit, Leiden University, Social and Behavioral Sciences, Leiden, Netherlands; [8]Department of Nutrition and Dietetics, Center of Expertise Urban Vitality, Amsterdam University of Applied Sciences, Department of Nutrition and Dietetics, Amsterdam, Netherlands

Background: An unhealthy lifestyle increases the risk of developing rheumatoid arthritis (RA). Interventions including plant-based diets, physical activity, and stress management have shown benefits for RA patients but have not yet been evaluated in a program for patients at risk for RA.

Objectives: To investigate preliminary effectiveness of a multidisciplinary lifestyle program on RA risk in patients at risk for RA, in comparison to usual care.

Methods: In the "Plants for Joints" (PFJ) pilot RCT, patients with anti-citrullinated protein antibody (ACPA) positive arthralgia were randomized to the PFJ or control group. Both groups received usual care while the PFJ group additionally followed a 16-week lifestyle program based on a whole food plant-based diet, physical activity, and stress management.[1] The primary outcome was risk of developing RA as quantified by the RA risk score (including family history, symmetry, stiffness, pain level, RF/ACPA level).[2] The maximum score (13 points) was given to participants who developed RA. Secondary outcomes included self-reported pain intensity, inflammatory, anthropometric, and metabolic markers, and serum levels of ACPA and rheumatoid factor (RF). A linear mixed model for between group analysis was used, adjusted for baseline values.

Results: 14 out of 17 included patients completed the study (all female, mean age 47 years). Three patients (n = 2 PFJ group, n = 1 control group) were diagnosed with RA after mean 9.6 weeks and remained in the study. After 16 weeks there was no significant difference in RA risk score between PFJ and control groups (Figure 1). Compared to the control group, the PFJ group had significantly lower fat mass and LDL-cholesterol after 16 weeks (Table 1). After the intervention the PFJ group had an average weight loss of 4.9 kg, of which 2.7 kg was fat mass.

Conclusion: The results of this pilot study do not suggest the PFJ lifestyle program influenced RA risk score, pain, or autoantibody levels, although possible effects cannot be excluded due to the small sample size. However, metabolic health clearly improved in the PFJ group.

BARICITINIB LEADS TO RAPID AND PERSISTENT RESOLUTION OF SYNOVITIS AS MEASURED BY HAND MRI IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS (RA) FAILING CS/BDMARD THERAPY

S. Kemenes[1,2], S. Bayat[1,2], D. Simon[1,2], G. Krönke[1,2], D. Bohr[1,2], L. Valor[1,2], F. Hartmann[1,2], L. Schuster[1,2], K. Tascilar[1,2], G. Schett[1,2], A. Kleyer[1,2]on behalf of https://www.medizin3.uk-erlangen.de/en/research/research-main-focus/research-group-pd-dr-a-kleyer-and-pd-dr-d-simon/. *[1]University Hospital Erlangen and Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]Deutsches Zentrum Immuntherapie, University Hospital Erlangen, Friedrich-Alexander University (FAU) Erlangen-Nuremberg, Erlangen, Germany*

Background: RA is characterized by synovial inflammation resulting in local bone loss [1]. Inhibitors of JAK/Stat pathways, such as baricitinib, demonstrated efficacy in reducing signs and symptoms of RA in clinical trials, however, little is known about their effects on synovitis and bone structure [2]. Preclinical and clinical observations suggest a positive effect JAK inhibitors on bone mass and microstructure, however no prospective, interventional clinical trial has been performed so far [3].
Objectives: The aim of this study is to evaluate the effect of baricitinib on local inflammation (synovitis and osteitis) and bone structure (erosions) in RA patients failing on cs/bDMARD therapy using hand MRI.
Methods: BAREBONE is a prospective, interventional, open label, monocentric single center study (EUDRACT 2018-001164-32 / NCT03701789) to assess the effect of baricitinib (4mg/day) on local MRI inflammation and structure in patients with active RA. Besides demographic and clinical characteristics, hand joint inflammation was assessed by magnetic resonance imaging (MRI) using a 1.5 Tesla scanner (Siemens Magnetom Aera T1w TSE cor, T2w TIRM cor, T2w TSE fat-sat trans, T1w TSE fat-sat trans + cor after KM;). at baseline, week 24 and week 48. Scans were assessed for synovitis, osteitis and bone erosions using the RAMRIS scoring system using two independent blinded readers (SK and SB). Intraclass correlation coefficients were calculated for total RAMRIS and synovitis, erosion and osteitis subscores and in a second step differences between cs and bDMARD failure were elaborated. Variables are summarized descriptively using means and 95% bootstrap confidence intervals for continuous outcomes and as number and percentages for categorical outcomes.
Results: Thirty- two RA patients were screened and 30 patients were included (age: 53.4 [SD 12.6] years; sex: f/m N 24/6; disease duration: 3 [IQR 2.0 – 8.0] years; biologic naïve/bDMARD failure 16/14). 27 patients completed the trial while MRI data was available for 24 patients at week 48. Demographics and clinical characteristics can be seen in Table 1. Total RAMRIS scores slightly decreased from 20.6 (95% CI 14.4 -27.8) at baseline (BL) to 18.3 (11.5 -26.5) at week 48. The synovitis subscore mainly contributed to total RAMRIS reduction by significantly improving from 5.3 (4.0 - 6.8) at BL to 2.7 (1.5 - 4.0) at week 48 with a score change of -2.9 (-4.0 to -1.8). At week 48, 12 patients (44.4%) had no signs of synovitis compared to only 3 patients at BL. In contrast, RAMRIS osteitis subscores only marginally decreased from 4.9 (2.2 - 8.4) at BL to 4.0 (1.9 - 6.7) at week 48. RAMRIS erosion score remained stable over the 48-week observation time. A significant difference in RAMRIS synovitis change for biologic naïve -3.8 (-5.2 to -2.6) vs biologic failure -1.0 (-2.2 to 0.4 could be observed at week 48). With respect to clinical disease activity, DAS 28 score decreased from 4.8 (4.5 – 5.1) at BL to 2.9 (2.5 – 3.3) at week 48. Detailed results can be found in Table 1 and Figure 1. Intraclass coefficient (95%CI) for RAMRIS scoring was high for both readers 0.997 (0.994 to 0.998).
Conclusion: Our study shows that baricitinib primarily reduces MRI synovitis in RA patients that have previously failed csDMARD and bDMARD therapy and particularly in patients who are biologic naïve.

AB0386 ANALYSIS OF THE RELATIONSHIP BETWEEN THE METHOTREXATE PHARMACOKINETIC PARAMETERS AND RESPONSE TO METHOTREXATE THERAPY IN RHEUMATOID ARTHRITIS

G. Gridneva[1], E. Aronova[1], E. Samarkina[1], S. Glukhova[1], Y. Muraviev[1], N. Baymeeva[2]. *[1]V.A. Nasonova Rheumatology Research Unstitute, Drug Safety Department, Moscow, Russian Federation; [2]Mental Health Research Centre, Research, Moscow, Russian Federation*

Background: The key link in the therapeutic drug monitoring of methotrexate (MTX) is the measurement of the concentrations of its most stable metabolites, as well as products of the early and late stages of MTX conversion (short-chain polyglutamates). Metabolic rate of MTX can depend on the clinical characteristics of patients and concomitant drug therapy.
Objectives: To reveal the regularity of the distribution of various metabolites in patients who responded and did not respond to MTX therapy. To compare groups of patients with different responses to MTX according to clinical characteristics.
Methods: The study included 79 RA diagnosis according to ACR/EULAR 2010 criteria, 65 (82%) women and 14 (18%) men, aged 53 ± 11 years, naiive to MTX. All patients had normal renal excretory function (GFR more than 60 ml / min). All patients were prescribed MTX of 10-15 mg/m2 of body surface. Achievement of therapy targets was established according to the EULAR therapy response criteria. The determination of MTX monoglutamate in erythrocytes (ER) and mononuclear cells (MO), as well as the main metabolites of MTX-polyglutamates with 2,3 and 4 glutamate residues (MTXPG 2-4), as well as 7-hydroxymethotrexate (7-OH-MTX) was measured by the tandem chromatomass spectrometry after 4, 12 and 24 weeks of therapy, the result was expressed in nmol/L. The calculation was performed using the statistical data analysis package Statistica 10 for Windows (StatSoft Inc., USA) using the methods of parametric and nonparametric statistics.
Results: By the 24th week of therapy, 34 (43%) (group 1) patients achieved the targets of therapy, 36 (46%) did not achieve (group 2). MTX withdrawn in 5 (6%) patients - due to adverse reactions. 4 (5%) were unable to continue to participate due to SARS-CoV2 pandemic. After 4 weeks of treatment, the concentration of various MTX metabolites did not differ in the groups. After 12 weeks of therapy, significant differences were found in the content of 7-OH MTX in the ER: 28.19 [7.28;58.07] and 5.89 [0.79;20.03], respectively (p=0.002); the concentration of the remaining fractions did not differ. Group 1 showed a higher concentration of 7-OH-MTX in MO after 24 weeks of therapy - 5.23 [1.39;12.52] and 1.05 [0.07;3.55], respectively (p = 0.006). No differences between the concentrations of other MTX metabolites were found. The groups were matched for age, body mass index, duration of RA, and disease activity at the baseline. In group 2, patients used statins more often (2 (6%) versus 6 (37%), p = 0.01), however, there were no statistically significant differences in the concentration of MTX metabolites in the groups of patients taking and not taking statins.
Conclusion: The concentration of 7-OH-MTX after 12 and 24 weeks of therapy is statistically higher in the group of patients who responded to therapy. 7-OH-MTX appears to be a more persistent metabolite of MTX, therefore, it is more applicable for therapeutic drug monitoring of MTX. Patients taking statins may be potential nonresponders to MTX therapy.

AB0387 THE RELATIONSHIP BETWEEN JAK INHIBITORS AND CREATINE KINASE ELEVATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A REAL-WORLD CLINICAL STUDY

M. Tada[1], T. Okano[2], K. Mamoto[2], Y. Yamada[2], K. Orita[3], K. Mandai[4], S. Anno[2], T. Iida[5], K. Inui[4], T. Koike[6]. *[1]Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan; [2]Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan; [3]Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; [4]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan; [5]Koryokai Hospital, Orthopaedic Surgery, Osaka, Japan; [6]Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*

Background: Some cases of creatine kinase (CK) elevation caused by Janus kinase (JAK) inhibitor treatment for rheumatoid arthritis (RA) have been reported in clinical trials[1]. However, the frequency and patients' background characteristics in clinical practice are unknown.
Objectives: The correlation between JAK inhibitor treatment for RA and changes in CK levels in clinical practice were investigated using a multicenter database.
Methods: The multicenter database of JAK inhibitors was used, and 103 (tofacitinib 46, baricitinib 44, upadacitinib 11, peficitinib 1, filgotinib 1) of 265 RA patients were followed up at 24 weeks, and their CK levels were evaluated. The time-dependent change of CK was evaluated by sex and analyzed by the Wilcoxon signed-rank test. The percentage abnormal from the standard titer was calculated. The factors related to an elevated CK at 24 weeks were investigated using patients' background characteristics at the time of starting JAK inhibitors by univariate analysis.
Results: Women accounted for 85.4% of the patients, the median age was 68 years, disease duration was 15 years, and the mean DAS28ESR was 5.00. The CK levels of both men and women were significantly elevated at 4 weeks and maintained until 24 weeks (men, women: 63, 62 (0 weeks), 101, 95 (4 weeks), 119, 96 (12 weeks), 155, 99 (24 weeks), U/L, P<0.001) (Figure 1). The percentage abnormal was also significantly increased at 4 weeks and maintained until 24 weeks (5.8% (0 weeks), 20.7% (4 weeks), 26.3% (12 weeks), 24.3% (24 weeks), P=0.002). The factors significantly positively related to elevated CK levels at 24 weeks were male, CK, creatinine, and lactate dehydrogenase (LDH), and stage, class, modified health assessment questionnaire, estimated glomerular filtration rate (eGFR), and glucocorticoid use were significantly negatively correlated (Table 1). There were no significant differences in CK elevation among the agents.

Table 1. Characteristics at the time of starting JAK inhibitors related to elevated creatine kinase levels at 24 weeks

	Univariate	
Data at stating JAK inhibitors	R value	P value
Creatine kinase	0.653	<0.001
Gender, men	0.247	0.012
Steinbrocker stage	-0.215	0.039
Steinbrocker class	-0.277	0.008
modified health assessment questionnaire	-0.268	0.008
Creatinine	0.289	0.003
eGFR	-0.231	0.019
LDH	0.201	0.041
Glucocorticoid use	-0.409	0.008

Analyzed by Spearman rank correlation coefficient

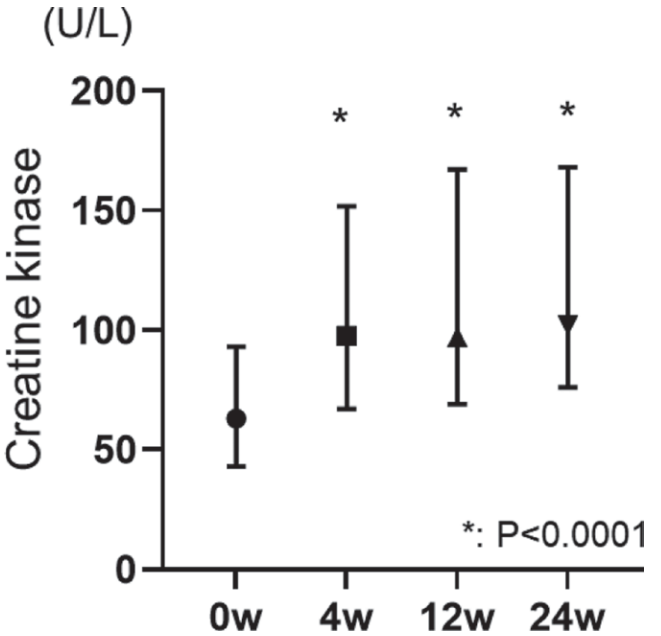

Figure 1. Time-dependent changes of CK in all RA patients

Conclusion: CK was significantly elevated at 4 weeks and maintained until 24 weeks. However, no patients complained of muscle pain and stopped JAK inhibitors. Patients with high CK, low eGFR, high LDH, or maintained activities of daily

living at the time of starting JAK inhibitors tended to have high CK levels at 24 weeks.

AB0388 FRENCH REAL LIFE SAFETY DATA ON THE USE OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL STUDY, DEFACTO

C. Gaujoux-Viala[1], A. Basch[2], S. Lassoued[3], F. Coury-Lucas[4], M. Kessouri[5], N. Mammar[6], Y. Brault[7], T. Lequerre[8], C. Salliot[9]. *[1]CHU Nimes, Rheumatology, Nimes, France; [2]Infirmerie Protestante Clinic, Lyon, Rheumatology, Caluire-et-Cuire, France; [3]Cahors Hospital Centre, Rheumatology, Cahors, France; [4]Lyon Sud Hospital, Rheumatology, Pierre-Bénite, France; [5]Pfizer, Medical, Paris, France; [6]Pfizer, Medical, Paris, France; [7]Pfizer, Statistics, Paris, France; [8]Rouen University Hospital (CHU) & Inserm U905, Rheumatology,, Rouen, France; [9]Orléans Regional Hospital Centre (CHR),, Rheumatology,, Orléans, France*

Background: Tofacitinib, an oral Janus Kinase inhibitor, is indicated in the treatment of adult patients (pts) with active, moderate to severe rheumatoid arthritis (RA).

Objectives: The objective of this work is to describe the tofacitinib's safety profile in the DeFacTo study (French prospective observational study).

Methods: The safety profile of tofacitinib was assessed on the basis of interim data from a descriptive analysis of pts having taken at least one dose of tofacitinib in the context of the DeFacTo study.

Results: Of the 313 pts enrolled in the study, 301 had received tofacitinib and were included in the safety analysis. Of these, 276 fulfilled the eligibility criteria and included 219 who had ≥ 1 year follow-up and a mean exposure period of 368 ± 197.1 days. As of 15 March 2021, 122 patients are continuing to take tofacitinib therapy (76 missing prescription data). On inclusion, 77.9% of the 276 pts were females of mean (± SD) age 59.7 ± 11.7 years and a median disease duration of 9.1 years [Q1;Q3: 4.1; 19.2]. A history of cardiovascular disease was found in 12.5% of cases, (4.4% myocardial infraction, 5.5% stroke/transient ischemic attack, 1.5% heart failure and 1.5% peripheral arterial occlusive disease); 5.5% had a history of cancer, 17.5% a prior infection and 46% were smokers/former smokers. Tofacitinib was prescribed in combination with a csDMARD in 58.3% of pts and with corticosteroids in 54.3% of cases. At the cut-off date of 15 March 2021, of the 301 patients, adverse effects (AE) had been reported in 44.9% of cases of which 10.6% were considered serious (SAE). Infections were detected in 18.6% of pts (Table 1).

Table 1. Real life safety data for tofacitinib according to age

N, (%)	< 65 years (n=190)	≥ 65 years (n=110)	Total (n=301*)
Adverse effect	80 (42.1)	55 (50.0)	135 (44.9)
Serious adverse effect	16 (8.4)	16 (14.5)	32 (10.6)
Infection	33 (17.4)	23 (20.9)	56 (18.6)
Severe infection	3 (1.6)	4 (3.6)	7 (2.3)
AE of interest (number of events)			
Infection			
Herpes zoster	5	5	10
Severe infection			
Herpes zoster	1	0	1
Tuberculosis	0	2	2
Cancer			
Small-cell carcinoma	0	1	1
MACE			
Stroke	1	0	1
Thromboembolic events			
Venous thrombosis	0	1	1
Death	0	0	0

*1 patient for whom age is unknown but is counted in the total.

Conclusion: These purely descriptive interim results reveal a safety profile for tofacitinib in patients with RA, similar to that previously reported in clinical and observational studies. [1-2]

AB0389 EVOLUTION OF MONOTHERAPY IN RHEUMATOID ARTHRITIS: IMPACT OF THE RISE OF JAK INHIBITOR

R. Garcia Salinas[1], F. Sommerfleck[2], A. Vargas Caselles[3], L. Palomino Romero[3], J. Rosa[3], M. Benegas[2], E. Saturansky[2], P. Giorgis[4], F. Martinez[5], M. Abdala[5], J. Sanchez Alcover[6], E. E. Civit De Garignani[6], G. V. Espasa[7], V. I. Bellomio[7], J. M. Bande[8], S. Papasidero[8], V. Saurit[9], L. Ibañez Zurlo[10], E. Buschiazzo[10]. *[1]Hospital Italiano La Plata, Rheumatology, La Plata, Argentina; [2]Sanatorio Dr. Julio Méndez, Rheumatology, Buenos Aires, Argentina; [3]Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; [4]Psychophysical Rehabilitation Institute, Rheumatology, DQG, Argentina; [5]Hospital Provincial del Centenario, Rheumatology, Santa Fe, Argentina; [6]Hospital El Carmen, Rheumatology, Godoy Cruz, Argentina; [7]Hospital Ángel C. Padilla, Rheumatology, San Miguel de Tucumán, Argentina; [8]Dr. Enrique Tornú Hospital, Rheumatology, Buenos Aires, Argentina; [9]Hospital Privado Universitario de Córdoba, Rheumatology, Córdoba, Argentina; [10]Sr Hospital del Milagro, Rheumatology, Salta, Argentina*

Background: According to different international registries, the frequency of use of biological agents in monotherapy in RA ranges from 12 to 39%. Targeted synthetic DMARDs (tsDMARDs-Jaki) have shown great efficacy when used as monotherapy. The rationale for this study is based on the fact that the frequency has increased with the appearance of the Jaki.

Objectives: To estimate the frequency and reason of the use of biological drugs (bDMARDs) or tsDMARDs in monotherapy since 2013 (Year the Jaki were available in Argentina). To describe the frequency of monotherapy by treatment class and analyze the differential characteristics.

Methods: Retrospective and cross-sectional multicenter study (10 reference centers from Argentina). Consecutive patients, ≥18 years, diagnosis of RA (ACR / EULAR 2010), who were under treatment with bDMARDs or tsDMARDs, started after 2013. Socio-demographic, disease and therapeutic data were collected.

Statistical analysis: descriptive statistics, Chi2 test, Fisher's exact test, Student's T test and Mann Whitney were performed, according to the nature of the variables. A p <0.05 was considered significant.

Results: Total 505 patients were included, 87.7% women, with a mean age 58 years (SD ± 13.5) and disease duration of 13 years (SD ± 7.8). Treatment: TNF blocker 42.1%, JAKi 30.3%, IL-6 blocker 10.9% and other treatments 16.8%.

Since 2013, the frequency of monotherapy was 49% (95% CI: 45-53), in the last visit the current frequency was 41% (95% CI 37-45),of this 40% received JAKi. JAKi and IL-6 blocker were the treatments that were used more frequently in monotherapy vs combination modality (Figure 1).

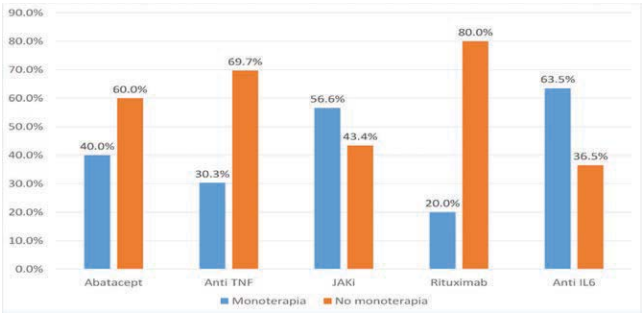

Figure 1.

The main causes of monotherapy were intolerance (39.9%), adverse event (22%), physician's decision (20.2%) and lack of adherence (17.7%) to DMARDs. Patients who were active workers (64% vs 55%, p <0.05), with higher socioeconomic

status (31.4% vs 17.2% p <0.01), better mean HAQ at diagnosis (1.1 vs 1.3, p <0.05) an association was observed with monotherapy. In addition, an association was observed with the use of monotherapy in patients in the 2nd biological line or higher vs 1st line (53% vs 33%, p <0.01), lower polypharmacy (45.6% vs 60%, p <0.02) and a shorter mean time of biological treatment (47 months vs 39 months, p <0.01). These variables were entered in a logistic regression model, the results of the independently associated variables are shown in Table 1.

Table 1.

Variable	p	OR	CI 95%	
Employment status (active).	0,191	1,327	0,868	2,029
Socioeconomic level (medium-high stratum)	**0,002**	**2,15**	**1,323**	**3,494**
HAQ at diagnosis, M (SD)	**0,019**	**0,704**	**0,524**	**0,944**
First Line of biological treatment or Jaki (yes)	**0,02**	**0,459**	**0,3**	**0,7**
Polypharmacy (>4 drugs) (yes)	**0,018**	**0,603**	**0,395**	**0,918**
bDMARDs or tsDMARDs exposure time (months)	0,054	0,994	0,987	1

Conclusion: The frequency of monotherapy, since the Jaki's emergence, was 49% (all follow-up) and 41% (current-last visit). Intolerance to cDMARDs doctor and the patient decision were the main cause. The monotherapy use pattern was greater in those who received JAKi and anti IL6. The use of monotherapy was associated with work activity, socioeconomic status, and functional capacity at diagnosis. An association was also observed with less polypharmacy.

AB0390 COST-EFFECTIVENESS OF IGURATIMOD IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) BY USING A CLAIMS-BASED ALGORITHM: RETROSPECTIVE ANALYSIS OF REAL-WORLD DATA

Y. Wang[1], T. Shi[1], J. Deng[1], J. Wu[1], Y. Qu[1], Y. Zhang[1], X. Zhu[1], B. Liang[1], Q. Yu[1], H. Du[2], L. Jie[1]. *[1]Southern Medical University, Department of Rheumatology and Clinical Immunology, Guangzhou, China; [2]Southern Medical University, School of Laboratory Medicine and Biotechnology, Guangzhou, China*

Background: Iguratimod (IGU), as one of the conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), has been approved by National Medical Products Administration (NMPA) to treat Rheumatoid arthritis (RA).

Objectives: This study aimed to compare the cost-effectiveness of well-established RA therapies using a claims-based algorithm in RA patients.

Methods: An electronic medical record (EMR) database from Zhujiang Hospital was utilized to estimate the cost-effectiveness of medication for RA patients, including IGU with MTX, biological DMARDs (bDMARDs) with MTX, and MTX alone for more than 6 months from 2014 to 2020. Patients who were deemed effective must meet all the following criteria according to the algorithm, high adherence; no bDMARDs or IGU switch or addition; no prescription of new csDMARDs; no increase in dose or frequency of index drug; no new use of chronic glucocorticoids or increase in glucocorticoid dose; and no more than one glucocorticoid injection. Average cost was calculated by summing total cost of effective treatment and dividing by number of patients achieving efficacy in each group.

Results: A total of 263 patients were included in the analysis. Based on a claims-based algorithm, the effective rate was 27.1 % (26/96) for IGU with MTX group, 11.2% (7/62) for bDMARDs with MTX group, and 13.3% (14/105) for MTX alone group, respectively. Average cost of effective treatment was $833.46 for IGU with MTX therapy, $2554.57 for bDMARDs with MTX therapy, and $171.48 for MTX alone (Table 1).

Table 1. Effectiveness and Cost per Effectively Treated Patient with RA

Criteria	All patients (n=263)	IGU with MTX group (n=96)	bDMARDs with MTX group (n=62)	MTX (n=105)
Effectiveness:no. of patients (%)[a]	47(17.87%)	26 (27.1%)	7 (11.2/%)	14 (13.3%)
Cost of all RA-related medication per effectively treated patient(SD)	$892.75(911.57)	$833.46 (252.67)	$2554.5 (1273.13)	$171.4 (110.33)
Average cost of all RA medications postindex (excluding biologic DMARDs) per patient (SD)[b]	$146.38(114.60)	$148.81 (123.12)	$86.90 (74.53)	$171.4 (110.33)
Average cost of only biologicDMARDs postindex per patient (SD)[b]	$746.38(926.35)	$684.27(188.67)	$2468.67(1285.91)	/

[a] χ^2showed significant difference in percentage effectiveness for the original algorithm ($p<0.05$). [b]Medication cost was 2020 U.S. dollars.

Conclusion: IGU with MTX therapy was revealed to be both effective and modestly priced, which seemed to be a cost-effective strategy for RA therapy and warranted further cost-effectiveness investigation.

AB0391 ANALYSIS OF CLINICAL IMPROVEMENT BY 5 JAK INHIBITORS AGAINST JAK INHIBITOR IR RA PATIENTS IN JAPANESE CLINICAL PRACTICE

K. Katayama[1], M. Yuichi[2], H. Ito[3]. *[1]Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan; [2]Asahikawa Medical University, Integrated Medical Education Center, Asahikawa, Japan; [3]Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan*

Background: Recently, Eular recommended different mode of therapeutic tool to get clinical remission. JAK inhibitors are considered to be one of candidates. Several JAK inhibitors have been used, however there are almost little informations about selection of JAK Inhibitors, especially, informations about secondary JAK for JAK inhibitor iR RA patients.

Objectives: To analyze clinical response by second JAK inhibitors against JAK inhibitor iR RA patientsin in clinical practice.

Methods: In Japan, five JAK inhibitors have been mainly used in MTX iR or biologics iR patients from 2013 (tofacitinib, JAK1,3), 2017 (baricitinib, JAK 1,2), 2019 (Peficitinib, Pan JAK, in Asia, Japan), 2020,April (upadacitinib, JAK1,2, mainly JAK1) and 2020.Nov (filgotinib, JAK1). In our clinic, these JAK inhibitors were sequentially used to get clinical remission. Numbers of patients who used JAK inhibitors are 28 patients in tofacitinib, 38 patients in baricitinib, 27 patients in peficitinib, 34 patients in upadacitinib, and 13 patients in filgotinib. Among them, 22 JAK inhibitor iR RA patients were investigated for clinical effectiveness.

Results: Summery of study were shown in Tables 1 and 2. Biologics were used in 14 patients and satisfied D2T RA (1st row, green color). For pre JAK inhibitors, 12 tofacitinib, 6 baricitinib, 4 peficitinib have been used. JAK inhibitor for JAK inhibitor iR patients, 13 upadacitinib, 3 baricitinib, 3 peficitinib and 3 filgotinib were used. Six months later, 9/13 patients in upadacitinib, 2/3 in filgotinib, 2/3 in peficitinib, 0/3 in baricitinib, totally 13/22 improved clincal disease activity (Eular good+ moderate response). Clinical improvement about ACPA negative (6th row, yellow color) patients, especially RF negative (5th row, blue color) patients, are incomplete. Double negative (ACPA, RF)or RF negative may be a predicter for clinical response about 1st and successive response for upadacitinib treated patients. Since, first JAK in 4 patients (8 th row, dark green)- 3 tofacitinb, 1 baricitinib respond well firstly (secondary unresponsiveness), tofacitinib may be useful for double negative or RF negative RA patients.

Table 1.

No	sex	age(yrs)	Dur (Mo)	RF (IU/ml)	ACPA (U/ml)	pre BIO	pre JAK	csDMARDs	JAK	dose(mg)	Eular response
1	m	67	180	358	1381	TCZ	BARI	n	FIL	200	G
2	f	62	156	287	163.9	ADA,TCZ	BARI	MTX,LEF	UPA	15	M
3	f	62	110	209	163.9	ADA,TCZ	TOF	MTX,LEF	BARI	4	N
4	f	64	144	175	159	ADA.	TOF	MTX	PEF	150	M
5	f	82	348	150	12.5	ADA	PEF	TAC	UPA	7.5	N
6	f	67	192	141	1.7	IFX,TCZ	BARI	n	UPA	15	G
7	f	39	72	59	1.3	n	PEF	n	UPA	15	M
8	f	74	396	56	240	n	TOF	MTX	PEF	100	N
9	f	77	108	51	51.6	GOL,TCZ	TOF	MTX	UPA	15	M
10	f	77	108	51	51.6	GOL,TCZ	TOF	MTX	UPA	15	M
11	f	78	360	44	2.2	TCZ	PEF	n	UPA	15	G

Conclusion: Jak inhibitors are useful for another JAK inhibitor iR RA patients in clinical practice. However, to get good response, baseline immunogenicity, RF/ACPA positivity, JAK specificity need to be considered. To solve, prospective clinical study may be required.

AB0392 EFFICACY AND SAFETY OF UPADACITINIB IN A CHINESE SUBGROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

X. Zeng[1,2], Y. Liu[3], J. Hu[4], J. Li[5], Y. Wang[6], D. Zhao[7], L. Wu[8], Z. Xiao[9], Z. Li[10], J. Xu[11], S. Meerwein[12], Y. Xie[13], P. Liang[14]. *[1]Peking Union Medical College Hospital (PUMCH), Chinese Academy of Medical Sciences, Rheumatology, Beijing, China; [2]National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Key Laboratory of Rheumatology & Clinical Immunology, Beijing, China; [3]West China Hospital, Sichuan University, Rheumatology, Chengdu, China; [4]Pingxiang People's Hospital, Rheumatology, Pingxiang, China; [5]Zhuzhou Hospital Affiliated to Xiangya School of Medicine, Rheumatology, Zhuzhou, China; [6]First Affiliated Hospital of Baotou Medical College, Rheumatology, Baotou, China; [7]Shanghai Changhai Hospital, Rheumatology and Immunology, Shanghai, China; [8]People's Hospital of Xinjiang Uygur Autonomous Region, Rheumatology, Urumqi, China; [9]First Affiliated Hospital of Shantou University Medical College, Rheumatology, Shantou, China; [10]First Affiliated Hospital of Bengbu Medical College, Rheumatology, Bengbu, China; [11]First Affiliated Hospital of Kunming Medical University, Rheumatology, Kunming, China; [12]AbbVie Deutschland GmbH & Co. KG, Immunology, Ludwigshafen, Germany; [13]AbbVie Inc, Immunology, Illinois, United States of America; [14]AbbVie China, Immunology, Shanghai, China*

Background: Upadacitinib (UPA) was effective in global Phase 3 trials in rheumatoid arthritis (RA) patients (pts) with inadequate response (IR) to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs).

Objectives: To assess the efficacy and safety of UPA in csDMARD-IR pts with RA in Chinese subgroup from a Phase 3, randomized, double-blind, placebo (PBO)-controlled study (NCT02955212) [1].

Methods: Pts were randomized to 12 weeks of blinded treatment with UPA 15 mg once daily (QD) or PBO, in combination with csDMARDs. Primary and secondary endpoints were analyzed in a Chinese subgroup, including American College of Rheumatology criteria (ACR) responses, remission and low disease activity measures. Safety was analyzed for pts who received ≥1 dose of study drug.

Results: 228 Chinese pts (67.5% of overall trial population) were randomized and took at least one dose of study drug. Baseline characteristics were generally balanced between UPA and PBO. 46% and 35.1% used methotrexate (MTX) alone as concomitant csDMARD in UPA and PBO group, respectively. 38.9% in UPA and 43.0% in PBO group used concomitant csDMARDs other than MTX and 15.0% and 21.9% respectively used a combination. At week 12, more Chinese pts receiving UPA achieved the primary endpoint of ACR20 compared with PBO (71.9% vs 31.6%, nominal p<0.001). UPA also showed greater improvements in all secondary endpoints vs PBO at Week 12 (Table 1), including ACR50 and ACR70, mean change in Disease Activity Score in 28 joints using C-reactive protein (DAS28-CRP), Health Assessment Questionnaire-Disability Index (HAQ-DI), Short-Form 36-item Health Survey-Physical Component Summary (SF-36 PCS), as well as proportion of pts achieving low disease activity based on DAS28-CRP ≤3.2 and Clinical Disease Activity Index (CDAI) ≤10, and clinical remission based on DAS28-CRP <2.6. Onset of response was rapid with more pts receiving UPA achieving ACR20 by Week 1 versus PBO (25.4% vs 5.3%, nominal p<0.001). Through Week 12 treatment-emergent adverse events (TEAEs) occurred in 57.9% of pts on UPA and 49.1% on PBO. The rate of pts with serious AEs (SAEs) was numerically higher with UPA than with PBO (6.1% vs 4.4%). TEAEs reported in ≥ 3% of subjects and with a higher rate on UPA vs. PBO were: upper respiratory tract infection, alanine aminotransferase increased, aspartate aminotransferase increased, hypertension, diarrhea, and leukopenia. Overall safety was consistent with the trial population[1] and similar with the reported safety profile of the global clinical program[2].

Table 1. Summary of Efficacy Endpoint Results at Week 12 in Chinese Subgroup

Endpoint [a]	UPA 15mg (N=114)	PBO (N=114)
Primary endpoint		
ACR20, %	71.9***	31.6
Secondary endpoints		
Δ DAS28-CRP	-2.42***	-0.75
Δ HAQ-DI	-0.55***	-0.11
Δ SF-36 PCS	7.63 [b]***	2.94 [c]
DAS28-CRP ≤3.2, %	46.5***	9.6
DAS28-CRP <2.6, %	28.1***	1.8
CDAI ≤10, %	33.3***	7.0
ACR50, %	39.5***	7.0
ACR70, %	16.7***	2.6
ACR20 at Week 1, %	25.4***	5.3

***Nominal p<0.001 vs PBO [a]Non-responder imputation for binary endpoints; ANCOVA with multiple imputation for DAS28(CRP) and HAQ-DI; mixed model repeated measures for other continuous endpoints. Δ: mean change from baseline [b]N=106 [c]N=104

Conclusion: UPA demonstrated clinical and functional improvement in Chinese csDMARD-IR RA pts. The safety of UPA was comparable with the overall study population and with the safety seen in the global Phase 3 program.

AB0393 SURVIVAL ON JANUS KINASE INHIBITORS VERSUS OTHER ADVANCED THERAPIES IN RHEUMATOID ARTHRITIS

N. Bakhtiar[1], L. Gray[2], S. M. Bilgrami[2], L. Ottewell[2], F. Wood[2], M. Bukhari[2,3]. *[1]University Hospitals Morecambe Bay NHS Foundation Trust, General Medicine, Lancaster, United Kingdom; [2]University Hospitals Morecambe Bay*

NHS Foundation Trust, Rheumatology, Lancaster, United Kingdom; [3]Lancaster University, School of Medicine, Lancaster, United Kingdom

Background: Four Janus Kinase inhibitors (JAKi) are licensed in the UK for treating rheumatoid arthritis (Upadacitinib, Tofacitinib, Filgotinib and Baricitinib). Several analyses have examined the survival in these groups of drugs and found them more likely to be tolerated more or equivalently than other modes of action. Recent data suggested an age influence on survival on these drugs.
Objectives: To study the overall survival rates of JAKi compared to the other biologic treatments in a single centre cohort.
Methods: We analysed patients commencing advanced treatments (anti-Tumour necrosis factor, Interleukin 6 blocker, Rituximab and Abatacept) between February 2011 and October 2021. Variables examined included gender and age. The time on drug was compared between JAKi and other treatments using student's T test. Chi squared test was used to compare categorical variables. A Cox regression model was fitted to compare length of stay on each agent JAKi length of stay was compared to length of stay on other agents combined.
Results: 592 patients were included in the analysis. 168 (28%) were started on JAKi. 435 (73.48%) were females. Mean age at drug start was 60.6 years (SD 13.5). The numbers on drug were Filgotinib n=10, Tofacitinib n=35, Upadacitinib n=37, Baricitinib n=86, Adalimumab n=211, Abatacept n=36, Certolizumab n=18, Etanercept n=112, Golimumab n=21 and Tocilizumab n=26. 93 (15.7%) discontinued their drug, mostly due to lack of efficacy. Mean number of days on any biologic treatment was 918.9 (SD 711.5). Patients on JAKi had a significantly shorter survival on drug 652.7 days vs 1024.4 days (P<0.001).
There were no significant differences in age and gender between the groups. Univariate regression showed a hazard ratio of 1.19 (95%CI 0.75,1.98). This remained non-significant after adjusting for age and gender (1.18 95%CI 0.71,1.95). The only predictor of stoppage was age (HR 1.03 95%CI 1.01,1.04).
Conclusion: In this relatively large observational study, there was no difference in predictors of stoppage between JAKi and other advanced therapies. Increasing age was found to be a predictor for stoppage. This is in line with other reports in the literature. Further work looking at the impact of serology and disease activity will be performed.

AB0394

CLINICAL OUTCOMES UP TO WEEK 48 OF ONGOING FILGOTINIB (FIL) RHEUMATOID ARTHRITIS (RA) LONG-TERM EXTENSION (LTE) TRIAL OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG (BDMARD) INADEQUATE RESPONDERS (IR) INITIALLY ON FIL OR PLACEBO IN A PHASE 3 PARENT STUDY (PS)

M. H. Buch[1], T. Takeuchi[2], V. Rajendran[3], J. E. Gottenberg[4], A. Pechonkina[5], Y. Tan[5], Q. Gong[6], K. Van Beneden[7], R. Caporali[8]. *[1]University of Manchester, Centre for Musculoskeletal Research, Division of Musculoskeletal & Dermatological Sciences, Faculty of Medicine & Health, Manchester, United Kingdom; [2]Keio University School of Medicine, Department of Internal Medicine, Tokyo, Japan; [3]Galapagos NV, Clinical Development, Mechelen, Belgium; [4]Strasbourg University Hospital, Department of Rheumatology, Strasbourg, France; [5]Gilead Sciences, Inc., Clinical Development, Foster City, United States of America; [6]Gilead Sciences, Inc., Biostatistics, Foster City, United States of America; [7]Galapagos NV, Medical Affairs, Mechelen, Belgium; [8]Policlinico S. Matteo, Rheumatology Department, Pavia, Italy*

Background: The preferential Janus kinase-1 inhibitor FIL is approved for treatment of moderate to severe active RA in Europe and Japan.
Objectives: Efficacy and safety of FIL were assessed in patients (pts) with IR to bDMARDs in a LTE trial (NCT03025308) enrolled from a Phase 3 PS (NCT02873936).[1]
Methods: bDMARD-IR pts received FIL 200 mg (FIL200), FIL 100 mg (FIL100), or placebo (PBO), all with stable conventional synthetic (cs)DMARDs up to 24 weeks (W). At W14 of the PS, pts with IR to FIL or PBO (<20% improvement in swollen [66] and tender [68] joint counts) switched to standard of care (SOC; investigator's choice of treatment). Pts completing the PS on FIL, PBO, or SOC could enter the LTE. PS FIL pts were maintained, blinded, on their FIL dose; PS PBO and PS SOC pts were rerandomized, blinded, to FIL200 or FIL100. Efficacy data to LTE W48 and safety data to data cutoff (June 1, 2020) are reported.
Results: The PS included 147, 153, and 148 pts on FIL200, FIL100, and PBO. Pts continuing on LTE FIL200 and FIL100 at data cutoff: 80/121 (66%) and 76/110 (69%) from PS FIL200 and FIL100; 35/47 (75%) and 32/46 (70%) from PS PBO, and 13/23 (57%) and 13/22 (59%) from PS SOC. LTE baseline (BL) characteristics were similar in FIL200 and FIL100 pts. During LTE, PS FIL ACR20/50/70 response rates decreased modestly by W48 (Figure 1). Among PS PBO pts, response rates were lower at LTE BL, reaching similar levels to PS FIL pts by W48; rates increased to W48 in PS SOC pts on either FIL dose but not to levels of other groups. Percentages of pts attaining DAS28(CRP) ≤3.2, DAS28(CRP) <2.6, CDAI ≤10, and CDAI ≤2.8 were maintained up to W48 for FIL/FIL pts. PBO/FIL and SOC/FIL pts showed similar patterns to ACR responses (Figure 1). Exposure-adjusted incidence rates (EAIRs)/100 pt-years of exposure for treatment-emergent adverse events (TEAE), serious AEs, and serious infection were higher in SOC/FIL pts vs FIL/FIL or PBO/FIL pts, but samples were small and confidence intervals overlapped. There were 5 deaths (Table 1).
Conclusion: Efficacy was mostly maintained in PS FIL pts up to W48. Response among PS PBO and SOC pts increased from BL to W48, but response in PS SOC pts continued to be lower than in other groups; these pts may represent a refractory population. FIL safety was largely consistent between PS and LTE.

AB0395 DE-ESCALATION OF DMARDS IN ELDERLY PATIENTS WITH RA

L. Robson[1], F. Hayes[2]. *[1]Lister Hospital, Rheumatology, Stevenage, United Kingdom; [2]Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom*

Background: Rheumatoid Arthritis is the most common form of inflammatory arthritis in older adults, with the mainstay of treatment being the conventional DMARDs (Tutuncu & Kavanaugh, 2007). These drugs are not without side effects, and as elderly people have higher rates of adverse drug reactions and less long-term benefits, the risk/benefit ratio is different compared to other age groups. This research sought to evaluate if the rheumatology department at Southend hospital was sufficiently acknowledging the changing circumstances of their elderly patients and de-escalating conventional DMARDs accordingly. As the average age of rheumatology patients is only likely to increase in the future, contextualising a patients treatment plan for their rheumatological disorder with their overall health status will become an increasingly important skill for clinicians and the observations from this study will be applicable to all who treat elderly patients with inflammatory disorders.

Objectives: 1. Evaluate if major new diagnoses were acknowledged in the rheumatology clinic and if conventional DMARD treatment was reduced in response. 2. Record and compare the outcomes of when conventional DMARD was stopped abruptly vs when it was tapered down slowly.

Methods: Evaluated 10 year's worth of clinic letters from rheumatology and other specialities in 50 patients with a diagnosis of RA over the age of 89. Noted new diagnoses of dementia, cancer and frailty (multiple falls, care home admission or becoming newly house bound) as well as acute hospital admissions and declining renal function and evaluated if this was acknowledged in clinic letters and whether treatment was changed in response. Recorded all instances where conventional DMARDs were stopped or had a dose reduction and evaluated if these dose drops were successful (patient stayed at reduced dose with no flares in disease activity), semi-successful (patient had mild RA flare treated with short course corticosteroids, or stayed at reduced dose for at least a year before returning to original dose) or unsuccessful (patient suffered flare and went back to original dose within 1 year.)

Results: Of the 50 patients, 31 received methotrexate monotherapy, 12 methotrexate and other conventional DMARDs, and 5 DMARDs other than methotrexate. 36 out of 45 patients receiving methotrexate had some decrease in dose by the end of the 10 year period, with the median decrease being 5mg. Patients on multiple DMARDs saw a greater average decrease in methotrexate compared to those on monotherapy. 15 abrupt cessations in methotrexate were recorded, with acute hospital admission being the most common trigger. Of these 3 were successful, 5 were semi-successful and 7 were unsuccessful. 55 planned methotrexate dose reductions in the rheumatology clinic were recorded, with 38 being successful, 9 being semi-successful and 8 being unsuccessful (Figure 1.). Clinic letters did generally acknowledge both new physical diagnoses and changes in social circumstances, but some diagnoses were more likely to trigger a change in treatment, for example in 8 new cancer diagnoses, there were 5 changes to treatment, whereas in 12 dementia diagnoses there were 3 changes to treatment. 6 patients received more methotrexate than guidelines suggest for their level of CKD, with 3 of these having it acknowledged in clinic letters.

Conclusion: Most patients had a reduction in dose of methotrexate over a 10 year period. Planned de-escalations were mostly successful, whereas abrupt stops to treatment were generally less successful. Rheumatologists are good at acknowledging changes to health status but were more likely to change DMARD therapy in response to a cancer diagnosis than a dementia diagnosis or frailty. There is still some work to be done in acknowledging declining renal function and changing methotrexate in response. Overall, these results suggest de-escalation is mostly successful and clinicians can be confident in further expanding this into their day to day practice.

AB0396 EFFECT OF A MULTIDISCIPLINARY LIFESTYLE PROGRAM IN PATIENTS WITH RHEUMATOID ARTHRITIS: THE PLANTS FOR JOINTS RANDOMIZED CONTROLLED TRIAL

W. Walrabenstein[1,2], C. Wagenaar[1,2], M. van der Leeden[2,3,4], F. Turkstra[2], J. Twisk[5], M. Boers[5], H. van Middendorp[6], P. Weijs[7], D. van Schaardenburg[1,2]. *[1]Amsterdam UMC, University of Amsterdam, Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; [2]Reade, Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; [3]Amsterdam UMC, Vrije Universiteit, Department of Rehabilitation Medicine, Amsterdam, Netherlands; [4]Vrije Universiteit Amsterdam, Amsterdam Movement Sciences Research Institute, Amsterdam, Netherlands; [5]Amsterdam UMC, Vrije Universiteit, Department of Epidemiology and Data Science, Amsterdam, Netherlands; [6]Leiden University, Institute of Psychology, Health, Medical, & Neuropsychology Unit, Leiden, Netherlands; [7]Amsterdam University of Applied Sciences, Department of Nutrition and Dietetics, Center of Expertise Urban Vitality, Amsterdam, Netherlands*

Background: Lifestyle factors have been associated with the development and progression of rheumatoid arthritis (RA). Interventions involving whole food plant-based diets (WFPDs), physical activity or stress management have shown promising results for people with RA but were not yet evaluated in an integrated program.

Objectives: To determine the effect of a 16-week multidisciplinary lifestyle program on disease activity in patients with RA.

Methods: In the "Plants for Joints" (PFJ) parallel-arm, assessor-blind randomized clinical trial, patients with RA and a 28-joint Disease Activity Score [DAS28] score ≥ 2.6 and ≤ 5.1, were assigned to the PFJ group or the control group. The PFJ group followed a lifestyle program based on a WFPD, physical activity, and stress management in addition to usual care. The control group received usual care. Medication was kept stable three months before and during the trial. Secondary outcomes included anthropometric, and metabolic markers. An intention-to-treat analysis with a linear mixed model, adjusted for baseline values was used to analyze between-group differences of continuous outcomes.

Results: Of 115 people screened, 85 were randomized and 79 completed the study. Participants were 91% female with a mean (SD) age of 55 (12) and body mass index of 26 (4) kg/m^2. After 16 weeks the PFJ group had a mean 0.85-point greater improvement of the DAS28 versus the control group (95% CI 0.40 to 1.30; p < 0.001) (Figure 1). Subgroup analyses showed significant improvements in the seropositive as well as the seronegative subgroup, although the effect was more profound in the seronegative group. Weight, fat mass, HbA1c, LDL and triglycerides also showed significant improvements in the PFJ versus control group, while blood glucose and HDL remained unchanged (Table 1). No serious adverse events occurred.

Seropositive subjects: positive for rheumatoid factor [RF] or anti-citrullinated protein antibodies [ACPA], seronegative subjects: negative for RF and ACPA. DAS28 = 28-joint disease activity score, SD = standard deviation, ESR = erythrocyte sedimentation rate, patient's global assessment based on a visual analogue scale (0-100 mm), CI = confidence interval, OR = odds ratio.
[1] P-values based on linear mixed model with random effect for between group analyses, adjusted for baseline values.

Conclusion: The 16-week PFJ lifestyle program substantially decreased disease activity in people with RA with low-moderate disease activity.

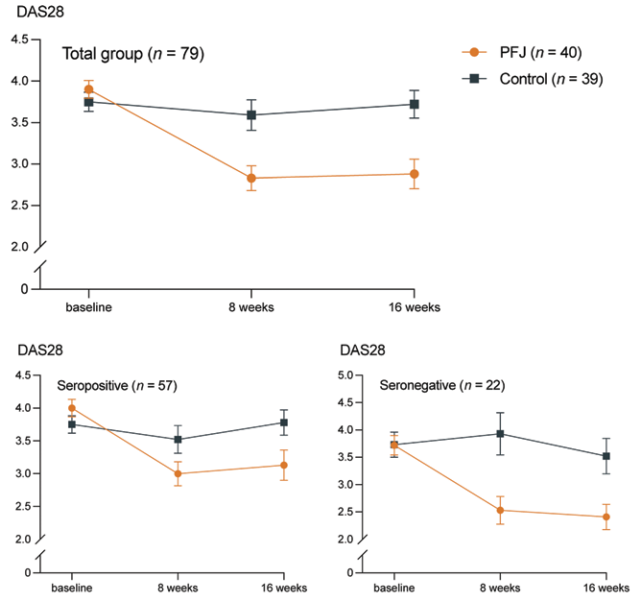

Figure 1. Change in disease activity score based on 28 joints (DAS28, primary outcome) for the total group ($p = 0.0005$) is presented in the top panel with mean ± standard error. The panels below present the same for seropositive subjects (positive for rheumatoid factor [RF] and/or anti-citrullinated protein antibodies [ACPA], $p = 0.02$) and seronegative subjects (negative for RF and ACPA, $p = 0.005$).

AB0397

DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS WERE SIGNIFICANTLY DECREASED BY SWITCHING JAK INHIBITOR TO ANOTHER JAK INHIBITOR

T. Miyagi[1], R. Wakiya[1], S. Nakashima[1], H. Shimada[1], M. Kato[1], K. Sugihara[1], M. Mizusaki[1], R. Mino[1], T. Kameda[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa, Japan*

Background: With the availability of multiple Jak inhibitors (JAKi) for treatment, patients with RA who have had inadequate response to conventional therapies, including biologics, can now achieve favorable outcomes such as remission and low disease activity. However, it is also true that no single JAKi therapy is effective for all RA. Some RA treatment guidelines recommend a switch strategy from current JAKi to other JAKi or biologics in patients with inadequate response to JAKi therapy [1]. There is insufficient evidence to support the efficacy of switching to another JAKi in patients with inadequate JAKi response (JAKi-IR).
Objectives: The aim of this study is to clarify the effectiveness of the strategy of controlling disease activity by switching to other JAKi in RA cases with JAKi-IR and to analyze the effect on serum cytokines related to the pathogenesis of RA.
Methods: RA patients who switched to other JAKi during treatment with JAKi between September 2017 and January 2022 were included in this retrospective study. The clinical characteristics of the included RA patients were collected from their medical records. The efficacy of the JAKi switch strategy was assessed by changes in composite measure scores of disease activity, including DAS28-CRP, SDAI, and CDAI, at 4 and 12 weeks after the switch. In addition, changes of serum cytokines associated with RA pathogenesis (IL-6, TNF-α) were measured and analyzed by ELISA (Simple Plex, Protein Simple).
Results: Twenty-nine RA patients who received the JAKi switch treatment strategy were included in the analysis. The clinical characteristics of the included patients are shown in Table 1. All patients were receiving JAKi due to inadequate response to biologics. JAKi were switched to control disease activity including 3 cases (10%) who achieved temporary remission. Figure 1 shows the effect of the JAKi switch strategy on the disease activity category. Evaluation using SDAI showed that 65% of patients achieved the immediate treatment goal of low disease activity at 4 weeks after switch, and 69% of patients maintained this goal at 12 weeks. SDAI remission was also observed in 17% of patients at 4 weeks and 31% at 12 weeks, demonstrating the efficacy of the JAKi switch strategy. The efficacy of the JAKi switch strategy was also observed in other measures of disease activity. Changes in serum cytokines (IL-6, TNF-α) associated with disease activity in RA before and after JAKi switch were analyzed in 10 patients. Regardless of the type of JAKi, serum IL-6 was decreased by JAKi switch in most cases at 12weeks (average change of serum IL-6: -27.25pg/ml). However, no trend was observed for changes in serum TNF- disease acti (average change of serum TNF-ed for change) . There was no clear association between changes in these two cytokines and the efficacy of the JAKi switch strategy.
Conclusion: The composite disease activity index showed that about 60% of JAKi-IR patients achieved low disease activity, one of the treatment goals, at 4 weeks after switching to JAKi, and the effect was maintained up to 12 weeks. This effect did not appear to be related to the type of JAKi. The effects of biologic therapy on serum cytokines associated with RA activity differed from the effects of the JAKi switch strategy.

Table 1. Baseline characteristics of the 29 patients enrolled this study

Clinical characteristics	n=29
Age	57 [48.0-66.0]
Sex (F/M)	22/7 (75.9)
Disease duration, years	13 [8.6-18.8]
RF positive	26 (89.7)
ACPA positive, (n=22)	20(90.0)
Concomitant medications	
Methotrexate, dose(mg/week)	10 (34.5), 8.0 [6.0-10.5]
Corticosteroid, dose(mg/day)	17 (59.0), 4.0 [2.0-5.0]
Disease activity	
DAS28-CRP	3.77 [3.2-4.6]
SDAI	15.5 [9.8-21.1]
CDAI	14.5 [9.5-20.0]

AURICULAR TRANSCUTANEOUS HI-FREQUENCY E-MMUNOTHERAPY SEQUENCES (ATHENS) FOR THE TREATMENT OF RHEUMATOID ARTHRITIS: 1-YEAR CHANGES IN SYNOVITIS, OSTEITIS, AND BONE EROSION

C. Peterfy[1], H. Corominas[2], J. J. De Agustin[3], C. Perez-Garcia[4], M. Lopez Lasanta[3], H. Borrell Paños[3], D. Reina-Sanz[5], R. Sanmartí[6], J. Narváez[7], J. A. Narvaez[8], V. Sharma[9], K. Alataris[9], M. C. Genovese[10], M. Baker[11], S. Marsal[3]. [1]*Spire Sciences, Clinical Research, Boca Raton, United States of America;* [2]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain;* [3]*Hospital Universitari Vall d'Hebron, Rheumatology, Barcelona, Spain;* [4]*Hospital Universitari Parc Salut Mar, Rheumatology, Barcelona, Spain;* [5]*Hospital Moisès Broggi, Rheumatology, Barcelona, Spain;* [6]*Hospital Clinic de Barcelona, Rheumatology, Barcelona, Spain;* [7]*Hospital Universitari de Bellvitge, Rheumatology, Barcelona, Spain;* [8]*Clinica Diagonal, Imaging, Barcelona, Spain;* [9]*Nesos Corp, Research, Redwood City, United States of America;* [10]*Gilead, Clinical Development, Foster City, United States of America;* [11]*Stanford*

University, Division of Immunology and Rheumatology, Stanford, United States of America

Background: Current pharmacological treatments remain inadequate for a significant proportion of patients with rheumatoid arthritis (RA), and thus alternative treatment approaches are needed. Prior results from the first 12 weeks of a proof-of-concept (POC) study showed that ATHENS, a non-invasive high-frequency vagus nerve therapy, was well-tolerated with meaningful reductions in RA disease severity as measured by the American College of Rheumatology response criteria (ACR) and the Disease Activity Score using 28 joints (DAS28)[1].
Objectives: The current analysis assessed long-term changes (52 weeks total follow-up) in disease activity as measured by ACR, DAS28, and the following MRI-assessed changes: synovitis, osteitis, bone erosion, and cartilage loss.
Methods: Following the completion of the 12-week POC study, patients achieving a reduction in DAS28-CRP of ≥1.2 were given the option to enroll in the 9-month open-label extension (OLE) study. During the extension phase, patients were to use the wearable device for 15 minutes per day. Adjustment of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) or biologic disease-modifying antirheumatic drugs (bDMARDs) were allowed during the OLE. Changes from baseline were assessed at 12 weeks (end of initial POC) and 52 weeks (end of the OLE). Structural damage and disease progression were evaluated by standardized MRI of the wrist and hand, with and without intravenous gadolinium-based contrast. MRIs were evaluated by two independent, central readers, blinded to clinical information and visit-order of the images, and were scored for synovitis, osteitis and bone erosion using the OMERACT-RAMRIS method. Cartilage loss was also determined using the 9-point cartilage loss scale (CARLOS).
Results: Twenty-seven of 30 patients completed the initial 12-week study, of whom 19 consented and entered the OLE. Of those 19 patients, 4 (21%) discontinued due to lack of efficacy, while the remaining 15 completed the 9-month extension. Due to the COVID-19 pandemic, 7 patients were unable to complete a 52-week MRI scan; MRI evaluations at baseline, 12 weeks, and 52 weeks were available for 8 patients. DAS28-CRP mean (standard deviation [SD]) change from baseline was -1.78 (1.01) at 12 weeks (n=19; p<0.0001) and -2.30 (1.22) at 52 weeks (n=15; p<0.0001). ACR20, ACR50, and ACR70 response rates were 68%, 42%, and 21% at 52 weeks (n=19; discontinued participants were deemed non-responders). MRI analysis of synovitis, osteitis, bone erosion, and cartilage loss showed no evidence of disease progression through 52 weeks compared with baseline (Table 1).

Table 1. Change in MRI OMERACT-RAMRIS from baseline to week 52

Score	Baseline (n=8)	Week 12 (n=8)	Week 52 (n=8)	Change Week 12 vs BL (n=8)	Change Week 52 vs BL (n=8)
CARLOS, mean (SD)	3.9 (5.6)	3.9 (5.6)	3.9 (5.6)	0.0 (0.0)	0.0 (0.0)
Erosion, mean (SD)	10.8 (10.3)	10.5 (10.3)	10.6 (10.3)	-0.3 (0.4)	-0.1 (0.8)
Osteitis, mean (SD)	2.8 (4.1)	2.3 (3.7)	1.0 (1.1)	-0.5 (1.1)	-1.8 (3.1)
Synovitis, mean (SD)	4.0 (4.2)	4.1 (4.7)	3.3 (4.0)	0.1 (0.6)	-0.7 (1.0)

CARLOS = Cartilage loss score; OMERACT = Outcome Measures in Rheumatology; RAMRIS = Rheumatoid Arthritis Magnetic Resonance Imaging Scoring System

During the 9-month extension study, two new adverse events were reported (cornea transplant and right hand dysesthesia) in 2 (11%) patients; neither was treatment-related and both resolved without intervention. No serious adverse events were reported.
Conclusion: In patients with an initial treatment response to the Nēsos ATHENS therapy in the 12-week POC study, reductions in DAS28-CRP were sustained through 52 weeks. Although results should be interpreted cautiously given the small sample size and lack of control arm, MRI evaluation of synovitis, osteitis, bone erosion, and cartilage loss suggested no disease progression.

AB0399

COMPARISON OF RITUXIMAB VERSUS LEFLUNOMIDE IN COMBINATION WITH METHOTREXATE IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DESPITE METHOTREXATE TREATMENT- AN OPEN LABEL, RANDOMISED CONTROLLED TRIAL

R. Roongta[1], G. Sircar[1], P. Ghosh[1], H. Sit[1], D. Ghosh[1]. [1]*IPGME&R and SSKM Hospital, Clinical Immunology and Rheumatology, Kolkata, India*

Background: Active rheumatoid arthritis (RA) despite methotrexate monotherapy is seen in about 43% of patients[1]. The current American College of Rheumatology (ACR) guidelines recommend adding a biologic or targeted synthetic Disease Modifying Anti-rheumatic Drug (DMARD) to methotrexate (MTX) therapy in such cases. The European Alliance of Associations for Rheumatology (EULAR) guidelines recommend combination DMARDs but the most commonly used combination is that of MTX with sulphasalazine and hydroxychloroquine. In a resource limited country like ours, it is not always possible to give a biological or a targeted synthetic DMARD, and a more cost effective method needs to be implemented. Often, leflunomide (LEF) is added in such cases and is effective.
Objectives: We aimed to study if LEF with MTX combination is non inferior to rituximab (RTX) and MTX combination in patients with active RA despite MTX.
Methods: This open label, randomised controlled trial, carried out on patients with moderate to high disease activity despite MTX therapy for atleast 3 months (Clinical Trials Registry- India - REF/2021/04/042755) was conducted in a tertiary care centre in India. Patients were randomised to receive either LEF (10-20mg/day) or RTX (2 doses of 1gm, 2 weeks apart) along with background MTX (10-25mg/week) and followed up at 12, 18 and 24 weeks. The primary outcome ACR20 response at 24 weeks and secondary outcomes were ACR50 and 70 responses at 24 weeks.
Results: There were 21 patients in each arm. At baseline, all patients in both groups had seropositive RA and had high disease activity according to Disease Activity Score (DAS)28 scores. The ACR20 response at 24 weeks was achieved by 14 (66.6%) and 16 (76.19%) patients respectively in the LEF and RTX arms. The ACR50 response was achieved by 11 (52.38%) patients in both groups and ACR70 response by 4 (19%) and 7 (33.3%) in the LEF and RTX arms respectively (Figure 1). The mean dose of LEF at week 24 was 17.6 mg/day. Improvement of various parameters at week 24 as compared to the baseline values were similar in both groups (Table 1). No major adverse events were noted. Two patients receiving RTX had a mild infusion reaction. Elevation in liver enzymes (<3 times the upper limit of normal) were noted in 4 patients in the LEF arm which normalised subsequently. No patient required drug withdrawal.

Table 1. Responses in both groups at week 24 (p= Not significant for all)

	Leflunomide, n=21	Rituximab, n=21
Mean ±SD reduction in SJC	-4.57 ± 3.4	-5.43 ± 4.6
Mean ±SD reduction in TJC	-6.2 ± 3.9	-7.1 ± 6.1
Mean ±SD reduction in PhGA	-3.42 ± 1.8	-4.04 ± 2.5
Mean ±SD reduction in PGA	-3.05 ± 1.8	-3.42 ± 2.4
Mean ±SD reduction in pain VAS	-33.57 ± 23.2	-38.57 ± 24.4
Mean ±SD reduction in DAS28-ESR	-1.95 ± 1.2	-2.08 ± 1.4
Mean ±SD reduction in DAS28-CRP	-1.81 ± 1.2	-2.07 ± 1.4
Mean ±SD reduction in HAQ-DI	-0.65 ± 0.5	-0.82 ± 0.6
EULAR good response (%)	1 (4.76%)	1 (4.76%)
EULAR moderate response (%)	15 (71.43%)	14 (66.6%)
EULAR non-responders (%)	5 (23.81%)	6 (28.57%)

CRP, C- Reactive Protein; DAS, Disease Activity Score; ESR, Erythrocyte Sedimentation Rate; HAQ-DI, Healthy Assessment Questionnaire-Disability Index; PGA, Patient's global assessment of disease activity; PhGA, Physician's global assessment of disease activity; SJC, Swollen Joint Count; TJC, Tender Joint Count; VAS, Visual analogue scale.

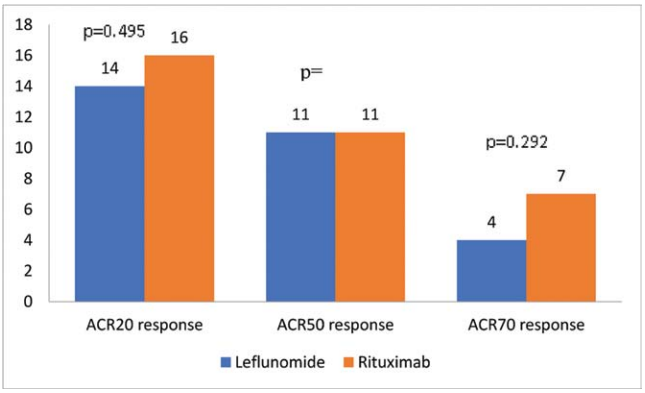

Figure 1. Number of patients achieving ACR20, 50 and 70 responses at week 24

Conclusion: In our study, LEF was comparable to RTX for achievement of ACR20/50/70 responses at 24 weeks. LEF can be considered as an add-on option to MTX instead of more expensive biologic agents in MTX refractory RA. Larger studies are needed to confirm this hypothesis.

AB0400 A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS INTO THE SUCCESS RATE OF GLUCOCORTICOID DISCONTINUATION AFTER THEIR USE AS INITIAL BRIDGING THERAPY IN RHEUMATOID ARTHRITIS PATIENTS IN OBSERVATIONAL COHORTS AND CLINICAL TRIALS

L. van Ouwerkerk[1], A. Palmowski[2], I. Nevins[1], F. Buttgereit[2], P. Verschueren[3], J. Smolen[4], R. B. M. Landewé[5], H. Bijlsma[6], A. Kerschbaumer[4], R. Westhovens[3], T. Huizinga[1], C. Allaart[1], S. A. Bergstra[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany; [3]UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium; [4]Medical University of Vienna, Rheumatology, Wien, Austria; [5]Zuyderland MC, rheumatology, Heerlen, Netherlands; [6]UMC Utrecht, Rheumatology, Utrecht, Netherlands*

Background: Glucocorticoids (GC) are widely used for the initial treatment of rheumatoid arthritis (RA), to induce rapid suppression of inflammation and clinical symptoms and thereby limit radiographic damage progression. There are concerns that GC use in the long term is associated with a dose and duration dependent risk of serious side effects. Therefore, international guidelines have recommended to start GC when initiating a csDMARD, but to discontinue GC as rapidly as clinically feasible, preferably within 3 months (bridging therapy). In contrast, due to the concerns of GC side effects, the ACR guidelines published in 2021 conditionally recommend to start csDMARD monotherapy without GC bridging therapy.

Objectives: We aim to evaluate the success rate of GC discontinuation after using temporary GC as part of initial therapy ('bridging') both in observational cohorts and clinical trials in newly diagnosed RA patients.

Methods: Systematic literature searches were conducted to identify observational cohorts (scoping search) and clinical trials (in-depth search) that included RA patients who were treated with initial GC bridging therapy. GC bridging was defined as oral or intramuscular GC treatment that was discontinued within one year, alongside conventional DMARD therapy. Patient percentages still or again using GC were considered to represent the reverse of successful discontinuation. Random-effects meta-analyses were performed stratified by time point.

Results: The literature search on observational cohort studies could not identify any study answering the research question, since it remained unclear which patients had received GC as part of the initial treatment. The literature search for clinical trials identified 7160 abstracts, resulting in 10 included studies, with varying type and dose of GC and varying tapering schedules (Table 1). Of these included studies, 4 reported sufficient data on GC discontinuation or GC use after the bridging phase. The pooled proportion of patients who were still using GC was 22% (95% Confidence Interval (CI) 8; 37, based on 4 trials) at 12 months and 10% at 24 months (95% CI -1; 22, based on 2 trials) (Figure 1). Thus, the vast majority had stopped GC. Heterogeneity was substantial ($I^2 \geq 65\%$).

Table 1. Overview of included clinical trials.

Study (publication year)	Tapering schedule (mg/day)
COBRA (1997)	In 7 weeks to 7.5. Stop after 28 weeks.*
BeSt (2005)	In 7 weeks to 7.5. Stop in 8 weeks after week 28 if DAS persistently ≤2.4
IDEA (2014)	N.A.
COBRA-light (2015)	arm 1: in 7 weeks to 7.5 arm 2: in 9 weeks to 7.5 Stop after 32 weeks if DAS<1.6.
IMPROVED (2014)	In 7 weeks to 7.5. Stop after 20 weeks if DAS <1.6 at 4 months.
ARCTIC (2016)	In 7 weeks to 0 if DAS <1.6 and no swollen joints present.
tREACH (2013)	In 10 weeks to 0.*
CareRA (2017)	- in 7 weeks to 7.5, further tapered from week 28, stop after 34 weeks.
- *Classic*	- in 6 weeks to 5, further tapered from week 28, stop after 34 weeks.
- *Slim*	- in 6 weeks to 5, further tapered from week 28, stop after 34 weeks.
- *Avant garde*	All if DAS28(CRP) ≤3.2.
Hua et al. (2020)	Tapering after 4 months to 5, stop after 6 months.*
NORD-STAR (2020) - *arm 1A (oral prednisolone)*	In 9 weeks to 5. Stop after 9 months.*

DAS=disease activity score; mg=milligram; N.A.=not applicable. *GC tapered and stopped according to protocol, not depending on disease activity score.

Conclusion: The success rate of GC discontinuation after bridging as part of initial treatment of RA has been described in a limited number of studies. Reports on observational cohorts did not answer the research question and in clinical trials reports, GC (dis)continuation data were also scarce. However, the available data show that GC can be discontinued successfully in a large majority of patients. The paucity of data also reveals that more efforts are needed to provide data towards identifying the optimal GC bridging and discontinuation strategy, combining Treatment to Target with Starting to Stop.

AB0401 THE BASELINE SERUM SOLUBLE TNF RECEPTOR LEVELS ARE ASSOCIATED WITH THE RESPONSE OF RHEUMATOID ARTHRITIS PATIENTS TO JAKINIBS

T. Yoshikawa[1], T. Furukawa[1], T. Hashimoto[1], M. Morimoto[1], N. Azuma[1], K. Matsui[1]. *[1]Hyogo College of Medicine College Hospital, Division of Allergology and Rheumatology, Department of Internal Medicine, Niahinomiya-city, Japan*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that primarily affects the multiple joints.

The elucidation of the pathogenesis of RA has progressed dramatically in recent decades, and among the many cytokines involved in the pathogenesis of RA, interleukin (IL)-6 and TNF-α are known to be the major pro-inflammatory cytokines that are abundant in the bloodstream and synovial tissue. JAK inhibitors (JAKinibs) such as tofacitinib and baricitinib are used in the treatment of RA by inhibiting JAK, which in turn inhibits the signaling of various cytokines including IL-6. However, predictors of the response to JAKinibs are still required.

Objectives: We aimed to combine soluble TNF receptor (sTNFR) I, sTNFR II, IL-6, soluble IL-6R (sIL-6R) and soluble gp130 (sgp130) levels to identify groups of JAKinibs responses in RA patients.

Methods: This research is a retrospective study. We reviewed medical records of RA patients initiating JAKinibs between July 2013 and July 2021 in our hospital. The Simplified Disease Activity Index (SDAI) was evaluated at baseline and 3, 6 months after JAKinibs administration. Clinical remission was defined when SDAI decreased ≤ 3.3. Of the 125 patients treated with JAKinibs, 89 patients with 6 months follow-up, valid SDAI and serum available were enrolled. Serum samples were tested for IL-6 (Human IL-6 Quantikine ELISA Kit, R&D systems), sIL-6R (Human soluble IL-6R alpha Quantikine ELISA Kit, R&D systems) and sgp130 (Human soluble gp130 Quantikine ELISA Kit, R&D systems), sTNFR I (Human TNF RI/TNFRSF1A Quantikine ELISA Kit DRT100) and sTNFR II (Human sTNF RII/TNFRSF1B Quantikine ELISA Kit DRT200) using specific ELISAs according to the manufacturer's instructions. The statistical analyses were performed with EZR 1.55, and p values less than 0.05 were considered significant.

Results: The median age of patients was 62 (IQR: 51 - 72) years and the median of disease duration was 6.0 (2.0 - 16.0) years. Twenty-seven (30.3%) patients were biologics and Jakinibs naive. The baseline SDAI was median 18.9 (12.7 - 27.9). When comparing SDAI-remission group (clinical remission: CR) and non-remission group, there were no significant differences in any of the baseline clinical parameters. There was no significant difference in the serum levels of IL-6, sIL-6R and sgp130 between the CR and non-CR groups, but the serum levels of sTNFR I and sTNFR II in the CR group were significantly lower than non-CR group. Univariate logistic regression analysis suggested Biologics and JAKinibs naive (odds ratio (OR) 3.58, p = 0.015), baseline Log sTNFR II levels (OR 0.013, P=0.034)

as predictors of SDAI remission treated with JAKinibs at 6 months. Although not significant, Stage IV (OR 0.211, P=0.082) and baseline Log sTNFR I serum levels (OR 0.013, P=0.065) were associated with clinical remission.
Conclusion: RA patients could be easily stratified prior to JAKinibs intervention with serum sTNFR II and sTNFR I levels, not but IL-6 axis cytokines (IL-6, sIL-6R and sgp130).

Univariate logistic regression analysis for clinical remission in patients treated with JAKinibs.

AB0402 THERAPEUTIC ADHERENCE AND PERSISTENCE OF TOFACITINIB AND BARICITINIB IN RHEUMATOID ARTHRITIS PATIENTS IN DAILY CLINICAL PRACTICE.

H. Codes-Mendez[1], C. Martinez-Molina[2], M. Masip[2], P. Riera[2], N. Pagès Puigdemont[2], A. Riera Magallón[2], D. Lobo Prat[1], L. Sainz Comas[1], H. Corominas[1], C. Díaz-Torné[1]. *[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; [2]Hospital de la Santa Creu i Sant Pau, Pharmacy, Barcelona, Spain*

Background: The use of Janus kinase inhibitors (JAKi) is approved for adults with rheumatoid arthritis (RA) with moderate to severe activity. Although there is increasing data about baricitinib and tofacitinib in daily clinical practice, data about adherence and persistence in real-life is scarce.
Objectives: (i) To evaluate the adherence and persistence of tofacitinib and baricitinib in RA patients in a real-life setting. (ii) To assess the influence of treatment adherence to therapeutic persistence.
Methods: Retrospective longitudinal observational study that included all patients with RA who were treated with tofacitinib and/or baricitinib between 2017/10 and 2021/05 in a tertiary hospital. Demographic, clinical and pharmacological data were collected from electronic medical and pharmacy claim records. Kaplan-Meier survival analysis and log-rank test were performed to calculate and compare treatment persistence, respectively. Drug adherence was assessed with the Medication Possession Ratio (MPR). The effect of therapeutic adherence on treatment persistence was evaluated with a linear regression model.
Results: We included 136 cases: 30 treated with tofacitinib [28.6%], 44 with baricitinib [41.9%] and 31 with both [29.5%] corresponding to 105 RA patients. In our sample 86.7% of the patients were women with a mean age (± SD) of 63 (± 13) years. At the start of treatment, patients had a mean disease activity score DAS28-ESR (± SD) of 5.1 (± 1.2) and they had previously received a median (range) of 3 (0-8) biologic agents for RA.
During the study period, 40 (29.4%) and 38 (27.9%) patients treated with tofacitinib and baricitinib, respectively, discontinued the treatment.
Mean treatment persistence was 363 days (95%CI=2-1.282) in tofacitinib group and 406 days (CI95%=8-1.300) in baricitinib group. There were no statistical differences in treatment survival (HR=1.01 [95CI%=0.59-1.71]; p=0.97).
Mean MPR was 91% in both groups. There was no statistically significant correlation between therapeutic adherence and treatment persistence (p=0.21).
Conclusion: The results showed no significant differences between treatment persistence and adherence of tofacitinib and baricitinib in our patients with rheumatoid arthritis. In our cohort, therapeutic adherence was high and it did not influence treatment persistence.

AB0403 EVALUATION OF THE SAFETY AND EFFICACY OF 13-VALENT PNEUMOCOCCAL VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Lukina[1,2], D. Murtazalieva[1], E. Koltsova[1], M. Kostinov[3], A. Shmitko[3], D. Blagovidov[3], E. Zhilyaev[4]. *[1]A.S. Loginov Moscow Clinical Scientific Center, Rheumatology, Москва, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [3]I.I Mechnikova Research Institute of Vaccines and Sera, Moscow, Russian Federation., Laboratories of Vaccination and Immunotherapy of Allergic Diseases, Москва, Russian Federation; [4]CJSC «European Medical Center», Rheumatology, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is accompanied by a significant increase in the risk of infection and serious infections, among which pneumonia occupies a leading place. (1) The use of targeted anti-inflammatory drugs is accompanied by an additional increase in the risk of infectious complications. In this regard, vaccination is crucial in the management of such patients.
Objectives: To evaluate the safety and efficacy of the 13-valent pneumococcal vaccine in patients with RA undergoing various types of antirheumatic therapy.
Methods: The study included 60 patients with a reliable diagnosis of RA, according to the criteria of ACR/EULAR, among them 8 men and 52 women, average age 63 years (from 29 to 69 years) with disease activity at the time of inclusion of Das-28 – 4.9 (2.2-7.7), bionaive patients with insufficient response to DMARDs who will be prescribed tofacitinib (TOFA) for the first time or receiving TOFA for at least 3 months (30 patients in each group). Both groups of patients were further subdivided into two groups, 15 vaccinated and unvaccinated patients in each. The exclusion criteria were: age over 70 years; patients with infectious diseases in the acute stage; having a history of intolerance to diphtheria toxoid, patients who had previously been vaccinated with pneumococcal vaccines. For the prevention of pneumococcal infection, a pneumococcal 13-valent polysaccharide conjugated adsorbed vaccine was used. Visits to assess the condition were made in the period of 0-3-12 months. The activity of the disease was assessed by the DAS 28, CDAI, SDAI indices.
Results: Among vaccinated patients with PCV 13 the most common adverse events were: pain at the injection site (16%), fever up to 37.6C (13%), redness at the injection site (6%), infiltration at the injection site (2%), myalgia (2%). These adverse events resolved spontaneously within 3 days. In a comparative assessment of infectious events during 12 months before vaccination and the next 12 months after it, there were no significant differences between vaccinated and unvaccinated patients. In patients who had a history of pneumococcal etiology infections after vaccination, the incidence decreased by 33%.
Conclusion: Vaccination against pneumococcal infection is a safe and effective method of preventing pneumococcal infection in patients with rheumatoid arthritis.

AB0404 DEPENDENCE OF COMPLICATIONS IN TOTAL HIP AND KNEE ARTHROPLASTY ON THE TREATMENT OF RHEUMATOID ARTHRITIS.

A. Khramov[1], M. Makarov[1], S. Makarov[1], V. Amirdzhanova[1], S. Maglevaniy[1], I. Kushnareva[1], T. C. Phan[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Orthopaedic, Moskva, Russian Federation*

Background: Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications. This is due to the presence of an inflammatory process, a variety of variants of the course of the disease, reduced physical activity, the severity of functional disorders, prolonged therapy with glucocorticoids, disease-modifying and genetically engineered biological drugs, osteoporosis, as well as the activity of the underlying disease.
Objectives: to conduct a comparative analysis of the effect of RA treatment on local complications, such as periprosthetic infection, periprosthetic fractures, wound complications, ligamentous disorders in hip and knee total arthroplasty in patients with RA.
Methods: 1113 arthroplasties of large joints in patients with RA, which were performed in the period from 2002 to 2020, were analyzed. Of these, 649 total knee replacements (TKA) and 464 total hip replacements (THA) were performed.
Results: In patients with therapy of methotrexate at an average dose of 12.5 mg per week, the incidence of local complications was 7.87%. In patients receiving Leflunomide (Arava), complications were detected in 9.29% of cases. In group

of patients with Sulfasalazine (SSZ) intake, local complications were detected in 7.73% of cases. The complication rate of 7.01% was determined in group of patients who received Glucocorticoids (GC) at an average dose of 7.5 mg (recalculation in Prednisone). 1.87% of complications were observed in patients with intake of genetically engineered biological drugs (bDMARD). The highest incidence of local complications was found in patients with RA who had no therapy (27.27%).
Statistical data analysis revealed a significantly higher number of complications in the group of RA patients ($p<0.005$). Analyzing each type of complications, significant differences were also obtained ($p<0.005$).
Conclusion: The risk of local complications was 3 or more times higher in group of patients with RA without any treatment. So, arthroplasties of large joints in patients with RA without treatment are often accompanied by a high risk of intra- and postoperative complications.

AB0405 JAK INHIBITORS IMPROVE PATIENT-REPORTED OUTCOMES SUCH AS PAIN AND HAQ EARLIER THAN ANTI-IL-6 INHIBITORS

T. Okano[1], T. Koike[2,3], K. Inui[4], M. Tada[5], K. Mamoto[1], Y. Yamada[1], K. Orita[6], K. Mandai[4], S. Anno[1], T. Iida[7,8], H. Nakamura[1] on behalf of Osaka City University Team RA. *[1]Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [3]Search Institute for Bone and Arthritis Disease (SINBAD),, Wakayama, Japan; [4]Osaka Saiseikai Nakatsu Hospital, Department of Orthopedic Surgery, Osaka, Japan; [5]Osaka City General Hospital, Department of Orthopedic Surgery, Osaka, Japan; [6]Yodogawa Christian Hospital, Department of Orthopedic Surgery, Osaka, Japan; [7]Koryokai Hospital, Department of Orthopedic Surgery, Osaka, Japan; [8]Takahiro Clinic,, Nishinomiya, Japan*

Background: Clinical feature of Janus kinase (JAK) inhibitor is recognized as not only suppress inflammation but also improve patient-reported outcomes (PRO) such as pain and health assessment questioner (HAQ) in patients with rheumatoid arthritis (RA). This representative clinical feature was known as a results of phase 3 trial compared to TNF inhibitor. One of the mechanisms of JAK in RA is to suppresses interleikin-6 (IL-6). However, the effect for PRO in JAK inhibitor compared to IL-6 inhibitor have not been known.
Objectives: We investigated the effect for patient-reported outcomes such as pain and HAQ in patients with RA treated with JAK inhibitor compared to IL-6 inhibitor.
Methods: This study was analysed a multicenter database included RA patients treated with biological disease-modifying anti rheumatic dugs (bDMARDs) and JAK inhibitors. In 307 patients treated with IL-6 inhibitor (tocilizumab 240 and sarilumab 67) and 220 patients with JAK inhibitor (tofacitinib 101, baricitinib 83, upadacitinib 20, peficitinib 14 and filgotinib 2), 155 patients were treated as first-line bDMARDs/JAK inhibitor (IL-6R inhibitor 104 and JAK inhibitor 51). In this first-line patients, patients treated with IL-6R inhibitor and JAK inhibitor were matched using the propensity score adjusted for gender, age, RA disease duration, baseline charactristics of disease activity, CRP level, and MMP-3 level. The beaseline data and the change of clinical and laboratory data at 4, 12 and 24 weeks were compared between IL-6 inhibitor and JAK inhibitor.
Results: Thirty-six patients in each group were matched and analyzed. The average age was 62.4 and 62.6 years and the average disease duration of RA was 13.2 and 10.1 years in IL-6 inhibitor and JAK inhibitor. The baseline characteristics were not significantly different in both groups. At week 4, tender joint count (TJC) was significantly improved in JAK inhibitor than IL-6 (IL-6: -1.86 vs JAK: -4.12, p= 0.036) and HAQ was significantly improved in JAK inhibitor than IL-6 (IL-6: -0.04 vs JAK: -0.27, p= 0.041). Moreover, Clinical Disease Activity Index (CDAI) was also improved in JAK inhibitor than IL-6 (IL-6: -6.6 vs JAK: -10.9, p= 0.026) at week 4. However, pain VAS and patient global VAS were not significantly different in each group in week4. TJC, HAQ and CDAI was not different in both groups at week 12 and week 24. On the other hand, ESR was significantly decreased in IL-6 inhibitor than JAK inhibitor at week 4, 12 and 24 (IL-6: -26.6 vs JAK: -14.1, p=0.018 at week 4, IL-6: -32.7 vs JAK: -16.5 p=0.004 at week 12, IL-6: -31.3vs JAK: -17.7 p=0.014 at week 24).

SDAI	22.8	22.4	0.872	-7.5	-11.5	0.075	-11.7	-13.5	0.494	-11.6	-14.8	0.266
CDAI	21.3	21.1	0.955	-6.6	-10.9	0.026	-10.2	-12.6	0.358	-10.1	-13.7	0.181

Conclusion: In a comparison between IL-6 inhibitor and JAK inhibitor as a first-line molecular-targeted drug matched baseline charactristics of disease activity, TJC and HAQ was improved in JAK inhibitor earlier than IL-6 inhibitors. JAK inhibitor suppress multi cytokine that might be the reason why JAK inhibitor improve pain. Improvement of patient reported outcome in JAK inhibitor was found also in comparison with IL-6 inhibitor.

AB0406 LIPID-LOWERING THERAPY IN THE TREATMENT PROFILE OF THE RHEUMATOID ARTHRITIS PATIENTS

K. Fedorovych[1], R. Yatsyshyn[1], B. Doskaliuk[2]. *[1]Ivano-Frankivsk National Medical University, Internal Medicine #1 Clinical Immunology and Allergology, Ivano-Frankivsk, Ukraine; [2]Ivano-Frankivsk National Medical University, Pathophysiology, Ivano-Frankivsk, Ukraine*

Background: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disorder characterized by inflammatory changes in the synovial membranes of the joints, leading to their progressive damage and deformity. Inflammation occupies a prominent place in the pathogenesis of RA making it an essential target to improve the patient's condition.
Objectives: The purpose of this study was to evaluate the influence of lipid-lowering therapy on RA patients given its anti-inflammatory effect.
Methods: We involved 80 patients with established RA diagnosis based on 2010 ACR/EULAR Classification Criteria. The inclusion criteria for our study were the age of patients ≥18 years and the DAS28 index > 2,6. We have excluded from investigation individuals with any prior medical history of myopathies, liver diseases or increased transaminase levels, pregnant or breastfeeding women and patients taking lipid-lowering drugs. The accepted patients were randomized into 2 groups numbering 40 individuals each. The first group of subjects received just basic DMARDs and the second had atorvastatin 40 mg/day in addition. The atorvastatin admission lasted 3 months. To evaluate the possible anti-inflammatory effect of atorvastatin the ESR, CRP, Visual Analogue Scale (VAS), swollen joint count (SJC), tender joint count (TJC) and Disease Activity Score (DAS-28) were used. Moreover, the lipid panel indexes in both groups of patients were assessed. We used the Kolmogorov-Smirnov test for data distribution evaluation. Mann-Whitney U test and unpaired t test were employed for groups comparison, p-value <0.05 was considered as statistically significant.
Results: We found that the administration of atovastatin had a positive effect on pro-inflammatory parameters of patients. In the atorvastatin group the levels of ESR (mm/h) and CRP (mg/L) were significantly lower in comparison with the controls (25.38±9.43 vs 31.85±10.54, p=0.02 and 12.26 [8.21-17.54] vs 15.89 [11.32-21.54], p=0.04 respectively). SJC (p<0.01) and TJC (p<0.05) and DAS-28 (p<0.05) indexes have been improved more significantly in the investigation group as well. The results of lipid panel assessment were better in the atorvastatin group as well. The LDL (mg/dl) level differed between the two groups the most significantly (143.7±23.2 in the control group and 109.8±21.4 in the atorvastatin group, p=0.02).
Conclusion: With this study, we managed to demonstrate the beneficial effect of atorvastatin not only on the lipid profile but also on an inflammatory level and disease course in patients with RA.

AB0407

EFFICACY AND SAFETY OF 144-WEEK TREATMENT WITH TACROLIMUS AS THE FIRST-LINE CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG (CSDMARD) FOR PATIENTS WITH ACTIVE REFRACTORY RHEUMATOID ARTHRITIS： A PROSPECTIVE, COHORT STUDY

Y. Li[1,2], F. Wang[3], Y. Sui[2], J. Chen[4], T. Zhang[4], Q. Shu[1,5]. *[1]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China; [2]YanTaiShan Hospital, Department of Rheumatology, Yantai, China; [3]Women and Children's Hospital, Qingdao University, Department of Hematology, Qingdao, China; [4]School of Public Health, Cheeloo College of Medicine, Shandong University, Department of Biostatistics, Jinan, China; [5]Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Qilu Hosptial, Department of Rheumatology, Jinan, China*

Background: The T2T guideline in RA recommended the normal csDMARDs irresponsive patients (pts) switching to other treatment target. Tacrolimus (TAC), the inhibitor of T cell activation, is candidate for these pts, especially with extrarticular complications (EC).
Objectives: To observe the efficacy and safety of TAC-based csDMARDS regimen refractory RA (RRA) pts and the characteristics of TAC combined treatment.
Methods: This prospective cohort study (ClinicalTrials.gov Identifier NCT02837978) was conducted in China. According to baseline DAS28-ESR, RRA pts (ACR 1987 criteria [1]) were classified to severe (>5.1, S) or moderate (> 3.2,≦5.1, M) groups. The efficacy indicators and AE were recorded untill 144w. The combined medicine with TAC was based on the past history of csDMARD prescription and EC, including TAC with/wo MTX (T+M or T group), Pred, HCQ.
Results: 150 pts (52±14y) were involved, 15 finished 144w observation, 50 still following up and 85 lost.
As shown with GEE analysis, DAS28-ESR, CRP, HAQ were decreased significantly in all pts within 24ws, and maintained stable in later period (Figure 1). The REM or LDA, achieved ACR20, good or moderate EULAR response (G+M) proportion of 103 pts completed the 24w were 41.75%, 56.31%, 76.70%.

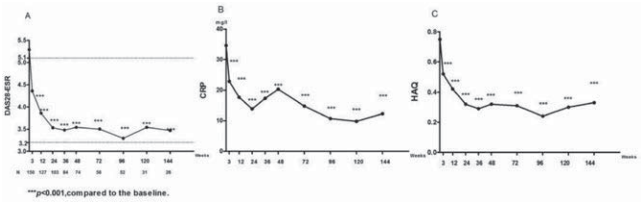

Figure 1. Disease activity index of 150 RRA pts decreased in 144weeks

Similar to the Japanese study [2], DAS28-ESR, CRP and HAQ typically declined rapidly in S group, but still higher than M (Figure 2A-C). According to GBTM analysis, S group, longer disease course or higher HAQ had a higher ACR20 remission rate (Figure 2D).

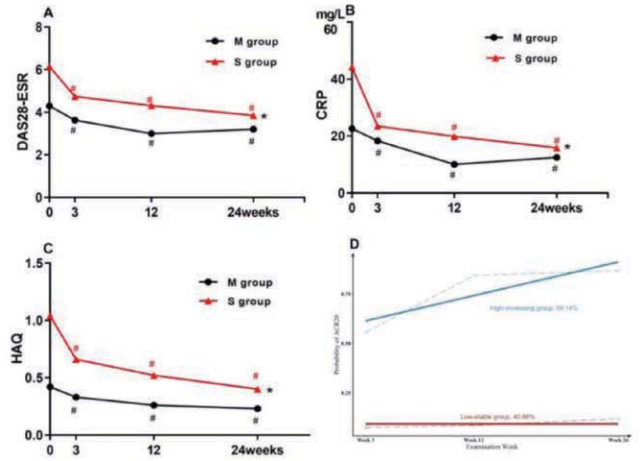

Figure 2. Disease activity index of 103 pts declined rapidly in 24weeks. **(A)**. DAS28-ESR; **(B)** CRP; **(C)**. HAQ declined significantly in S (n=53) than M (n=50) during 24ws. **(D)**.higher increased ACR20 remission group (90.6%), compared with low-stable (0%) in 24ws. *p< 0.05, compared to M; #p< 0.05, compared to baseline.

A total of 69 RA pts (46.0%) had 177 times (23.07%) AE, including 2 SAEs. Infection was the dominating AE (30%) due to asymptomatic positive urinary leucocyte and cold were classified, higher than (3.4%) Japanese study [3]. AEs were mainly happened in pts with higher TAC blood concentration 4.55(3-14.5) ng/ml, compared to No AE group 3.8(2.4-7.8) ng/ml, p=0.048, extremely in those abnormal glucose tolerance and hypertensive pts, p=0.002, 0.022.
The most common reasons of lost were drug ineffective (32.94%), economic reasons (29.1%). There was no difference in efficacy of TAC combined treatment. Combination MTX reduce AE, decrease the usage rate and dosage of Pred. Combination Pred increased AE.
Pts that achieved REM+LDA, G+M, had better TAC survival rate (Figure 3A-B). The combination of MTX, HCQ reduce lost rate (Figure 3C-D).

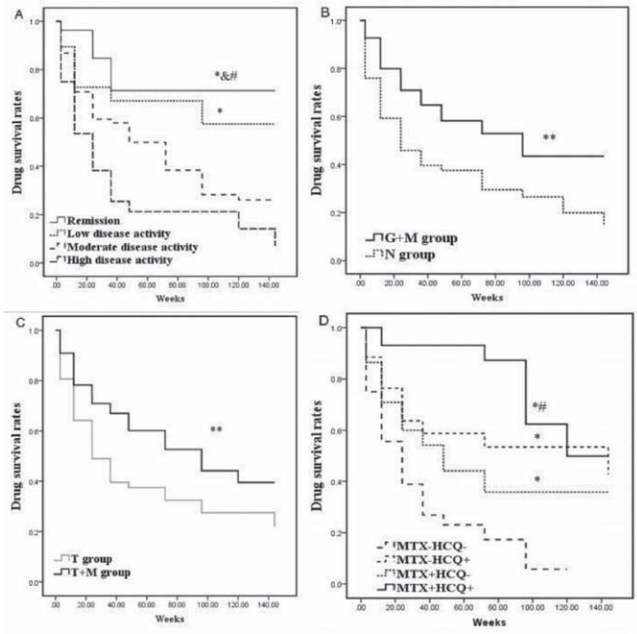

Figure 3. TAC survival ratio were compared in different response and csDMARDs combination groups. **(A)**.The pts acquired remission (n= 31) or LDA (n= 18) had higher TAC survival rate than high (n=28) & moderate (n=73) group, * p < 0.05, compared to group High; # p < 0.05, compared to Moderate; & p < 0.05, compared to Low; **(B)**. The pts G+M (n=95) had better TAC survival rate, compared with no response (N, n=55), ** p < 0.01; **(C)**. Combine MTX reduced lost rate, ** p < 0.01, compared to T; **(D)**. Combine MTX and HCQ reduced lost rate, * p < 0.05 compared to MTX-HCQ-; # p < 0.05 compared to MTX+HCQ-.

The Logistic regression showed baseline DAS28-ESR was an independent protective factor for poor response. Baseline DAS28-ESR and previous Perd use were independent protective factors for ACR20 remission.
Conclusion: TAC-based combined therapies are effective and tolerable for RRA, especially to the higher disease activity pts. TAC blood concentration related to AE. The lower disease activity index and better respond, the higher TAC survival ratio. MTX is recommended as TAC combined treatment.

AB0408

EXOSOMAL MICRORNAS AS BIOMARKERS FOR VIRAL REPLICATION IN TOFACITINIB-TREATED RHEUMATOID ARTHRITIS PATIENTS WITH HEPATITIS C

T. L. Liao[1], H. W. Chen[1], K. T. Tang[2], W. N. Huang[2], Y. H. Chen[2], Y. M. Chen[1]. *[1]Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China; [2]Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China*

Background: Despite recent advances of direct-antiviral agents (DAA) for Hepatitis C virus (HCV), it is still a prevalent worldwide issue and therapeutic challenge in patients with rheumatoid arthritis (RA). HCV viral replication may respond differently to biological disease-modifying antirheumatic drugs (bDMARDs) and targeted synthetic DMARDs (tsDMARDs) of different mechanism of action. Exosomal microRNA 155 (exo-miR-155) and exo-miR-122 have been implicated in modulating the host immune response and transmit anti-HCV factors to HCV-infected hepatocytes in patients with RA. However, it remains unknown how

exosomal miRNAs may respond following bDMARDs and tsDMARDs treatment in HCV-infected patients with RA.

Objectives: We aimed to study the changes of exo-miR-155 and exo-miR-122 following bDMARDs and tsDMARDs treatment in HCV-infected RA patients.

Methods: We prospectively enrolled RA patients taking anti-tumor necrosis factor-α (TNF-α) inhibitors, rituximab and tofacitinib. The effect of bDMARDs and tsDMARDs on HCV viral replication were assessed using an HCV-tricistronic replicon cell system. Exo-miR-155 and 122 were detected by quantitative PCR.

Results: HCV RNA replication in hepatocytes were not affected by tofacitinib treatment. Exo-miR-155 and exo-miR-122 were significantly increased in RA patients with HCV infection compared with those without HCV infection. We observed a dramatically increase of exo-miR-122 and decreased of exo-miR-155 in patients taking rituximab compared with the TNF-α inhibitors, tofacitinib and conventional synthetic DMARD groups. Finally, a reduction of exo-miR-122 and increase of exo-miR-155 levels were detected following DAA therapy for HCV.

Conclusion: Exo-miR-155 and exo-miR-122 were potential biomarkers for RA patients with HCV infection. Further studies are needed to confirm our findings.

AB0409 FRENCH REAL LIFE EFFECTIVENESS DATA FOR TOFACITINIB AT 1 YEAR IN PATIENTS WITH RHEUMATOID ARTHRITIS: INTERIM RESULTS OF THE OBSERVATIONAL STUDY, DEFACTO

C. Gaujoux-Viala[1], A. Basch[2], S. Lassoued[3], F. Coury-Lucas[4], M. Kessouri[5], N. Mammar[5], Y. Brault[6], T. Lequerre[7], C. Salliot[8]. *[1]Desbrest Institute of Epidemiology and Public Health (IDESP), Univ Montpellier, INSERM,, Rheumatology, Nimes, France; [2]Infirmerie Protestante Clinic, Lyon, Rheumatology, Caluire-et-Cuire, France; [3]Cahors Hospital Centre, Reumatology, Cahors, France; [4]Lyon Sud Hospital, Rheumatology, Pierre-Bénite, France; [5]Pfizer, Medical, Paris, France; [6]Pfizer, Statistics, Paris, France; [7]Rouen University Hospital (CHU) & Inserm U905, Rheumatology, Rouen, France; [8]Orléans Regional Hospital Centre (CHR), Rheumatology, Orleans, France*

Background: Tofacitinib, an oral Janus Kinase inhibitor, is indicated in the treatment of adult patients (pts) with active, moderate to severe rheumatoid arthritis (RA). At the present time we have no data concerning its efficacy in a French RA population in a real-life setting.

Objectives: DeFacTo, is an on-going observational study the principal goal of which is to identify factors predictive of Tofacitinib drug survival in RA patients in real life.

Methods: These are the results of interim descriptive analyses of effectiveness data after 1 year of follow up.

Results: Of the 313 pts enrolled in the study, 276 pts were included in the effectiveness analysis (POP1), 219 of whom were patients with a ≥1-year follow-up (POP2) including 122 patients who, as of 15 March 2021, were continuing to take Tofacitinib therapy. At inclusion, POP1 (n=276) was composed of 77.9% females of mean (± SD) age 59.7 ± 11.7 years, having a median disease duration of 9.1 years [Q1;Q3: 4.1; 19.2], TJC 7.5 ± 5.9 and SJC 5.3 ± 5.1; 115 patients presented with erosions, 206 had RF+ and 202 had ACPA+. The median CRP value was 7.4 [: 3.0; 20.0] mg/l, DAS28-4-CRP was 4.6 ±1.1, and the FACIT-Fatigue score was 28.3 ± 11.3. In all, 96.7% of the pts had received prior treatment with ≥1 csDMARDs, 65.2% with b/tsDMARDs (median = 2 [1; 4]). Tofacitinib was prescribed in combination with a csDMARD in 58.3% of cases. The baseline characteristics of the 122 patients still taking tofacitinib at 12 months were comparable to those of POP1. Results showed continued treatment with tofacitinib in 85.3% of pts with mean duration of treatment of 368 ± 197.1 days and reductions from baseline in the parameters of inflammatory markers, pain and the DAS28 activity scores; 20% of 122 pts were in DAS28-CRP remission (Table 1). Safety findings were similar to those reported previously in clinical studies[1 2].

Table 1. Baseline characteristics and effectiveness at 12 months Patient characteristics

Variables: mean ± SD or % pts	Inclusion, n=219	At 12 months, n=122*
PtGA (VAS, mm)	60.6 ± 20.8	29.8 ± 22.8
Pain (VAS, mm)	57.3 ± 24.8	30.1 ± 25.7
CRP (mg/l)	15.5 ± 21.9	7.9 ± 13.3
DAS28-4-CRP	4.6 ± 1.0	2.8 ± 1.1
DAS28-4-ESR	4.9 ± 1.1	3.3 ± 1.2
Effectiveness		
	Inclusion. n=219	At 12 months. n=219‡
LDA, % pts		
- DAS28-CRP ≤3.2	6.8	28.8
- DAS28-ESR ≤3.2	4.6	21.5
Remission, % pts		
- DAS28-CRP <2.6	3.7	20.1
- DAS28-ESR <2.6	2.7	9.6

Conclusion: These real-life interim results for Tofacitinib in RA patients provide information on its use in France: with prescriptions for single drug therapy in 41.7% of cases, the effectiveness of Tofacitinib is confirmed as comparable to that found in clinical studies[1-3].

AB0410 EVOLUTION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE IN PATIENTS TREATED WITH JAK INHIBITORS FOR RHEUMATIC DISEASES (JAKPIC STUDY)

D. Faganello[1], P. Meunier[1], A. Bertrand[2], E. Toussirot[3], F. Coury-Lucas[4], R. Seror[5], G. Le Meledo[6], J. Avouac[7], V. Germain[8], D. Shima[1], C. Richez[1], M. E. Truchetet[1], T. Schaeverbeke[1], M. Kostine[1]. *[1]Bordeaux University Hospital, Rheumatology, Bordeaux, France; [2]Hôpital Suburbain du Bouscat,*

Rheumatology, Le Bouscat, France; [3]Besançon University Hospital, Rheumatology, Besançon, France; [4]Lyon University Hospital, Rheumatology, Lyon, France; [5]Hospital Bicetre, Rheumatology, Le Kremlin-Bicetre, France; [6]Brest University Hospital, Rheumatology, Brest, France; [7]Cochin Hospital, Rheumatology, Paris, France; [8]Pau Hospital, Rheumatology, Pau, France

Background: Monoclonal Gammopathy of Undetermined Significance (MGUS) is common in patients with inflammatory rheumatic diseases but there are scarce data regarding the effect of disease-modifying antirheumatic drugs (DMARDs) on this pre-malignant condition. Recently, preclinical data and phase I trial have shown efficacy of JAK inhibitors (JAKi) in multiple myeloma.
Objectives: We aimed to evaluate the impact of JAKi on MGUS when initiated for an active rheumatic disease.
Methods: Patients with monoclonal abnormality prior to JAKi initiation for an active rheumatic disease were identified through the MAJIK-SFR Registry, a french multicentre prospective study, and a call for observation via the "Club Rhumatismes et Inflammations" Clinical and biological data were collected using a standardised case report form.
Results: Nineteen patients were identified, 10 women and 9 men, with a mean age of 65 years and a diagnosis of rheumatoid arthritis (n=14), psoriatic arthritis (n=3) or spondyloarthritis (n=2). The JAKi prescribed was baricitinib (n=8), tofacitinib (n=6) or upadacitinib (n=5), with a mean duration of 13 months.
Sixteen patients had individualized serum monoclonal protein (IgG Kappa n=9; IgG Lambda n=6; IgM Kappa n=3; IgA Lambda n=1) ranging from 0,16g/dL to 2,3g/dL. With a follow-up of 2 to 47 months, 8 of 16 patients experienced a decrease in serum monoclonal protein level and 8 had a stable serum monoclonal protein level. The maximal decrease observed was an initial IgG Kappa of 2.3g/dL decreasing to 0.2g/dL at month 14. During follow-up, two patients did not have any detectable serum monoclonal protein on serum electrophoresis (initial value of 5.2g/l and 1.6g/l), but still a positive immunofixation. One patient had bone marrow aspirate with 8% of plasma cells before JAKi introduction and 3% after 4 months of treatment. Three patients did not have initial measurable spike but a positive immunofixation that became negative at month 8 and 11 (IgG Lambda, n=2) or stable (IgG Kappa, n=1).
Conclusion: This study brings reassuring and promising data on the MGUS evolution in patients treated with JAKi for rheumatic diseases, which may guide the choice of treatment in patients with both conditions.

AB0411 IMPACT OF GENDER IN JAK INHIBITORS PRESCRIPTION: ANALYSIS FROM A SINGLE CENTER COHORT

E. Grau García[1], J. J. Fragío Gil[1], R. González Mazarío[2], P. Muñoz Martinez[1], L. Mas Sanchez[1], C. Pávez Perales[1], S. Leal Rodriguez[1], A. V. Huaylla Quispe[1], C. Riesco Barcena[1], M. De la Rubia Navarro[1], F. Ortiz-Sanjuán[1], I. Martínez Cordellat[1], J. E. Oller Rodríguez[1], R. Negueroles Albuixech[1], J. Ivorra Cortés[1], L. Gonzalez Puig[1], E. Vicens Bernabeu[1], I. Cánovas Olmos[1], C. Nájera Herranz[1], J. A. Román Ivorra[1]. *[1]Hospital Universitari i Politècnic La Fe, Servicio de Reumatología, Valencia, Spain; [2]Hospital Arnau de Vilanova, Sección de Reumatología, Valencia, Spain*

Background: Gender differences in demographic and clinical features may have a direct impact in patient prognosis.
Objectives: We aimed to investigate gender differences in disease manifestations, comorbidities and treatment among patients who had started treatment with Janus Kinase Inhibitors.
Methods: A single center observational study was performed including patients who had initiated treatment with Tofacitinib, Baricitinib or Upadacitinib from September, 2017 to January, 2022. Demographic and clinical data was collected and subgroup analysis was performed.
Results: A total of 190 patients were included (84%) and their characteristics are exposed in Table 1. Discontinuation rate was 33% in men and 39% in women. In female patients, age of diagnosis was younger (p=0.04) and the disease evolution, longer (p<0.01). Rheumatoid Arthritis was more frequent in women and Psoriatic Arthritis in men. Smoking habit was more seen in females (p<0.01). High Blood Pressure and Diabetes Mellitus were more frequent in men but dyslipidemia was more seen in women with no statistical signification. Men were more likely to receive a JAKi in first indication (p<0.02). At the time of first dose of JAKi, DAS28 and SDAI were similar between both sexes but HAQ was higher in women. All the laboratory markers (CRP, ESR, RF and ACPA) were higher in women than in men.

Table 1. POPULATION CHARACTERISTICS.

	Men group n=30 (16%)	Women n=160 (84%)
Age – years (ds)	55.73 (14.66)	53.57 (17.29)
Age at diagnosis	46.93 (15.64)	39.9 (15.71)
Disease evolution (years)	10.73 (7.04)	16.79 (11.88)
Rheumatoid Arthritis	21 (70%)	139 (86.88%)
Psoriatic Arthritits	6 (20%)	11 (6.88%)
Juvenile Idiopathic Arthritis	1 (3.33%)	6 (3.75%)
Other	2 (6.67%)	4 (2.5%)
Baricitinib	3 (10%)	59 (36.88%)
Tofacitinib	22 (73.33%)	81 (50.62%)
Upadacitinib	5 (16.67%)	20 (12.5%)
Race – number (%)		
Caucasian	24 (88.89%)	137 (86.16%)
Latin	3 (11.11%)	21 (13.21%)
Other	0 (0%)	1 (0.63%)
Smokers – number (%)	3 (17.65%)	30 (27.03%)
Mean glucocorticoid dosage – mg of prednisone or equivalent	2.85 (3.37)	4.53 (4.24)
Comorbidities – number (%)	10 (33.33%)	39 (24.38%)
High blood pressure	3 (10%)	11 (6.88%)
Diabetes Mellitus	7 (23.33%)	53 (33.12%)
Dyslipidemia	0 (0%)	6 (5.45%)
Fibromyalgia		
Prior bDMARD– number (%)		
Naïve patients	17 (60.71%)	55 (34.59%)
1 bDMARD failure	2 (7.14%)	33 (20.62%)
2 bDMARD failure	3 (10.71%)	21 (13.12%)
3 or more bDMARD failure	6 (21.43%)	45 (28.12%)
DAS 28 – mean total score	5.01 (1.13)	5.02 (0.98)
SDAI – mean total score	22.31 (8.43)	25.21 (9.24)
HAQ – median total score	1.38 (0.91, 1.5)	1.62 (1.25, 1.88)
CRP – mg/L	5 (3.02, 11)	7 (2, 18.9)
ESR – mm/h	16 (8, 32)	29.5 (17, 49.5)
Rheumatoid Factor	16 (10, 166)	37 (10, 169.5)
ACPA	138 (0.7, 340)	204.5 (1.08, 340)

Conclusion: In this analysis of 190 patients treated with JAKi we detect that the men uses JAKi more frequently in first indication than women. Women seems to have a longer disease evolution, more smoking habit and less cardiovascular risk than men.

AB0412 CYCLING OF JAK-INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTRE EXPERIENCE

C. Vassallo[1], L. Sammut[1]. *[1]Queen Alexandra Hospital, Rheumatology, Portsmouth, United Kingdom*

Background: Despite the availability of multiple effective disease-modifying antirheumatic drugs (DMARDs), discontinuation/switching of treatment is common for many patients with rheumatoid arthritis (RA). Janus kinase (JAK) inhibitors or JAKi, are the latest class of DMARDs approved for RA. Data on the outcomes of cycling JAKi in RA patients is still limited to this day.
Objectives: To assess the outcomes of switching between JAKi baricitinib, tofacitinib and upadacitinib in a real-world cohort of RA patients.
Methods: This was a hospital-based, retrospective observational study of all RA patients treated in a single-centre. Data was collected between 2016 and 2021 for all patients who failed JAKi and were treated with another JAKi. Demographic data, antibody status, history of DMARD use and clinical outcomes were assessed according to change in disease activity scores, time to JAKi discontinuation and reason for switching based on DAS 28-CRP scores.
Results: We identified 26 RA patients, 23 (88%) of which were RhF and/or anti-CCP positive, that failed JAKi and were cycled to another JAKi. 23 (88%) patients had failed treatment with one or more biological therapies prior to initiating JAKi. 13 (50%) patients were prescribed baricitinib and the other 13 patients Tofacitinib as their initial JAKi. During their RA treatment pathway, 9 (35%) of the patients on tofacitinib switched to baricitinib, and 4 (15%) switched to upadacitinib. 7 (27%) patients who started on baricitinib were switched to upadacitinib, and 6 (23%) were switched to tofacitinib. 3 (12%) patients cycled between all 3 JAKi. Reasons for switching first JAKi included primary treatment failure at initial 3-month rescore due to lack of efficacy (7/26; 27%), secondary failure (9/26; 35%), adverse drug reactions (ADR) (2/26; 8%) and others (1/26; 4%). Additionally, 7 (27%) patients on tofacitinib were switched following a drug safety update published by the Medicines and Healthcare products Regulatory Agency (MHRA), in an effort to minimize risk of major adverse cardiovascular events and malignancies. The median time to switching first JAKi was 11.5 months (range 3-23 months). After switching JAKi, 17 (65%) patients were found to have improved DAS 28-CRPs

at their 3-month rescore and continued treatment with their second JAKi. Following their switch, a total of 8 (31%) patients stopped their second JAKi due to inefficacy, 3 (12%) due to ADRs and 2 (8%) for other reasons. Of the 3 patients that went on to receive treatment with a 3rd JAKi (2/3 for primary failure; 1/3 for secondary failure), 2 patients were found to improve at their 3-month rescore.

Conclusion: Cycling through JAKi is an appropriate and safe treatment strategy in RA patients that discontinue first JAKi therapy due to lack of efficacy or ADR.

AB0413 STEROID SPARING EFFECT OF JAK-INHIBITORS ACROSS MULTIPLE PATIENTS POPULATION

P. Conigliaro[1], C. Minerba[1], A. Vendola[1], E. Greco[1], B. Kroegler[1], S. Modica[1], P. Triggianese[1], M. S. Chimenti[1], A. Bergamini[1]. [1]*University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy*

Background: JAK-inhibitors (JAK-i) represent an effective choice in achievement of therapeutic target in bio-naïve (bnaïve) and bDMARD-insufficient responders (bDMARD-IR) patients. However, oral glucocorticoids (OGC) are commonly used in clinical practice in combination with b/tsDMARDs in Rheumatoid and Psoriatic Arthritis (RA and PsA) patients in order to reach clinical remission.

Objectives: To assess, in a real-life clinical setting, the reduction of OGC dose during JAK-i treatment in RA and PsA patients that were b-naïve or ≥1-bDMARD-IR or ≥2-bDMARDs-IR with different mechanisms of action.

Methods: Patients with active RA or PsA treated with first JAKi were prospectively enrolled in a single center. Disease activity (DAS28-CRP or DAPSA), pain visual analogic scale (VAS-pain), general health (GH) and mean prednisone dosage (PDN dose) were collected at baseline and after 4, 8 and 12 months (T4, T8, T12) of treatment.

Results: 89 patients with active arthritis (77 RA, 12 PsA) were treated with JAK-i (43 patients received Baricitinib, 41 Tofacitinib and 5 Upadacitinib), with all patients reaching T4, 65 patients T8 and 50 patients T12 (Table 1). 27% patients were b-naïve, 73% ≥1-bDMARD-IR and 34% ≥2-bDMARDs-IR. A mean OGC dose of 4.0 ± 4.6 (mg per day) was used and 39% of patients received JAK-i without csDMARDs. We observed a significant improvement of disease activity by DAS28-CRP or DAPSA, VAS-pain and GH at all time points in whole population (respectively p<0.01, p<0.05, p<0.0001, p<0.001), in b-naïve (p<0.03, p<0.001, p<0.001, p<0.0001), in ≥1-bDMARD-IR (p<0.0001 for all the measures at all time points) and in ≥2-bDMARDs-IR (p<0.006 for DAS28-CRP, p<0.0001 for the others) patients. In all the cohort we reported a statistically significant reduction of PDN dose at T4 (p <0.0001), T8 (p=0.02) and T12 (p=0,002). Likewise, b-naïve patients were able to reduce PDN dose at all time points (p=0.01 for all comparisons); ≥1-bDMARD-IR patients were able to significantly reduce PDN dose at T4 (p<0.0001) and T12 (p=0.03); ≥2-bDMARDs-IR ones also spared steroids at all time points (T4 p=0.0004, p=0.02 at T8 and T12). In patients who completed the follow-up withdraw of OGC was observed at T4 in 42% of patients (44% b-naïve, 41% ≥1-bDMARD-IR and 43% ≥2-bDMARDs-IR patients), at T8 in 31% of patients (25% b-naïve, 33% ≥1-bDMARD-IR and 35% ≥2-bDMARDs-IR patients) and at T12 in 40% of patients (67% b-naïve, 32% ≥1-bDMARD-IR and 38% ≥2-bDMARDs-IR patients).

Table 1.

Women	75% (67)
Age (years)	60 ± 12
Seropositive	66% (51)
Disease duration (months)	132 ± 88
DAS28 CRP	4.0 ± 1.0
DAPSA	40.6 ± 19.7
VAS-pain	67.7 ± 15.8
GH	68.1 ± 15.2

Conclusion: JAK-i administration allows to reduce concomitant OGC regardless of line of b-DMARDs treatment. Chronic OGC may have detrimental bone, metabolic, cardiovascular and infective side effects; therefore JAK-i steroid-sparing effect may be beneficial for patients in long-term treatment.

AB0414 DRUG PERSISTENCE ON JANUS KINASE (JAK) INHIBITORS COMPARED TO BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS: RETROSPECTIVE STUDY IN THE AUSTRALIAN POPULATION

L. Scheepers[1], G. Jones[1]. [1]*University of Tasmania, Musculoskeletal Health and Disease, Hobart, Australia*

Background: In rheumatoid arthritis (RA) persistence on disease modifying anti-rheumatic drugs (DMARDs) can be interpreted as a composite measure of effectiveness, safety, and tolerability. There is limited data available on real-life use of the newest class of drugs, the Janus Kinase (JAK) inhibitors. JAK inhibitors are small-molecule treatments which are administered orally on a daily basis and offer a long-term option in RA treatment.

Objectives: To compare drug persistence on JAK inhibitors tofacitinib, baricitinib and upadacitinib to tumor necrosis factor-α (TNF) inhibitors and other DMARDs in RA patients in Australia.

Methods: A retrospective observational study was conducted among RA patients in the Australian Medicare Database (from January 2006 till October 2021), aged ≥18 and for whom a JAK inhibitor or biologic DMARDs were dispensed. Data were provided by the Australian Department of Health and Aging through PROSPECTION, an Australian healthcare consulting company. A deidentified 10% sample of the database was taken as a random representation of RA patients in Australia.

Kaplan-Meier analysis was used to calculate drug persistence rates, defined as the time from treatment initiation until the date of the last dose when there had not been a script dispensed for 6 months; except for rituximab, where a 12-month gap was applied.

Results: Data from 5,455 patients were analysed. For all patients the 12-month persistence rates were 61% for JAK inhibitors (baricitinib, tofacitinib, upadacitinib), 62% for tocilizumab, 52% for TNF inhibitors (adalimumab, certolizumab, etanercept, golimumab, infliximab), and 51% for abatacept. The JAK inhibitors baricitinib (64%) and upadacitinib (78%) were superior to tofacitinib (54%). Median treatment persistence for upadacitinib was not reached (n = 430); was 27.1 months for baricitinib and 15.2 months for tofacitinib. For TNF inhibitors, treatment persistence was 15.1 months for adalimumab, 14.1 months for certolizumab, 14.0 months for etanercept, 11.1 months for golimumab and 4.5 months for infliximab.

Persistence rates on first-line JAK inhibitors were 70% for baricitinib and 57% for tofacitinib; persistence rates dropped to 63% for baricitinib and 47% for tofacitinib in the second-line setting. First-line persistence rates were 54% for TNF inhibitors and 65% for tocilizumab, rates were sustained for tocilizumab, but dropped to 48% for TNF inhibitors in the second-line setting.

Conclusion: This real-world data highlights that in an Australian clinical practice setting treatment persistence rates on 12 months on JAK inhibitors, in particular baricitinib and upadacitinib, were superior to TNF inhibitors, but not to tocilizumab. Suggesting that persistence rates might differ according to biologics mode of action and line of treatment.

Table 1. Persistence rates at 12 months post treatment initiation

	All patients	First line	Second line
JAK inhibitors			
Overall	61% (2155)	60% (616)	60% (554)
Baricitinib	64% (537)	70% (158)	63% (124)
Tofacitinib	54% (1188)	57% (441)	47% (294)
Upadacitinib	78% (430)	28% (17)	84% (136)
TNF inhibitors			
Overall	52% (6339)	54% (4227)	48% (1561)
Adalimumab	55% (2710)	56% (2030)	48% (590)
Certolizumab	51% (593)	54% (251)	47% (147)
Etanercept	52% (2079)	55% (1354)	47% (623)
Golimumab	49% (814)	49% (506)	47% (174)
Infliximab	35% (143)	23% (86)	53% (27)
Other DMARDs			
Abatacept	51% (952)	56% (263)	46% (310)
Rituximab	49% (284)	41% (70)	65% (79)
Tocilizumab	62% (1156)	65% (279)	65% (351)

In brackets are number of patients.

AB0415 UPADACITINIB. EFFECTIVENESS AND SAFETY IN PATIENTS WITH REFRACTORY RHEUMATOID ARTHRITIS

N. Roldan Ruiz[1], C. Ramos Giráldez[1], C. Azabal Perez[1], R. Martínez[1], M. L. Velloso Feijoo[1], J. L. Marenco[1]. [1]*Seville, Rheumatology Department, Seville, Spain*

Background: Upadacitinib is the third janus kinase (JAKi) inhibitor approved for rheumatoid arthritis after baricitinib and tofacitinib. Upadacitinib is a selective JAK1 inhibitor, and is indicated for the treatment of moderate to severe active RA in adult patients with inadequate response or intolerance to one or more DMARDs.
Objectives: To describe the effectiveness and safety data of upadacitinib in patients with moderate-severe RA refractory to multiple synthetic and/or biologic DMARDs.
Methods: Descriptive and retrospective observational study conducted in patients who met RA classification criteria, refractory to synthetic and/or biologic DMARDs in the Rheumatology department of the Valme Hospital. Epidemiological, clinical, analytical, and safety and treatment-related variables were collected. A descriptive quantitative analysis of the data was performed.
Results: Forty five patients were included (37 women and 8 men), with a mean age of 53 years and mean time of RA evolution of 11 years. Of the patients, 44.4% had some cardiovascular risk factor. With respect to previous treatment, 100% were on DMARDsc, with a median of 2 DMARDsc per patient. Regarding biologic or targeted therapy, 77.8% had a history of biologic therapy failure with a median of 1 biologic; in addition, 8 patients had received at least 3 previous biologic drugs prior to upadacitinib. A total of 28.9% (13 patients) had previously received JAKi, discontinued due to secondary failure or from clinical trials at other centers. In terms of disease activity at the start of upadacitinib, patients had a mean of number of swollen joints (SJC) 3, number of tender joints (TJC) 4, CRP 11 mg/dl, DAS28 of 4.23 and CDAI of 21.5. When starting upadacitinib, 80% of the patients were on steroid therapy, 51% with doses > 5 mgr/day of prednisone. Combination therapy with DMARDs was maintained in 76.3% of patients (56.7% MTX, 36.7% LFN and the rest with SSZ). The results were analyzed after a median of 7 months from the start of upadacitinib: DMARDsc were discontinued in 4 patients and the steroid dose was reduced in 58.3% of the total, being discontinued in 21.2%. With respect to disease activity analyzed post-treatment in patients who maintained the drug, a mean of SJC 0, TJC 2, CRP 0.8 mg/dl, DAS28 2.7 and CDAI 12.5 were observed (Table 1). The drug was discontinued in 11 patients: 5 for adverse events (headache, hypersensitivity, gastrointestinal discomfort, instability accompanied by photopsia, lymphopenia and irritative cough) that resolved after drug discontinuation, 5 for primary failure and 1 for secondary failure. No cases of herpes, thrombosis or cardiovascular events were recorded.

Table 1. Medians pre-treatment and post-treatment outcomes in patients who maintained upadacitinib: SJC, TJC, C-Reactive Protein (CRP) and disease activity indices DAS28 and CDAI.

	Pre upadacitinib	Post-treatment (medians 7 months)	Statistical significance
SJC	3	0	< 0,05
TJC	4	2	0,03
CRP	11	0,8	< 0,05
DAS28	4,23	2,7	< 0,05
CDAI	21,5	12,5	< 0,05

Conclusion: Upadacitinib managed to control disease activity in a high percentage of our series of patients resistant to multiple synthetic and/or biologic DMARDs, making it possible to reduce or even suspend steroid treatment in a significant number of patients, so it may be an option to consider in patients with refractory RA. Longer-term studies are needed to continue evaluating the effectiveness, safety and survival of the drug in real clinical practice.

AB0416 CARDIOVASCULAR EVENT, VENOUS THROMBOEMBOLIZM, AND INFECTION RISK WITH TOFACITINIB IN RHEUMATOID ARTHRITIS PATIENTS AGED ≥ 60 YEARS

E. Duran[1], E. Unaldi[1], E. Bilgin[1], E. C. Bolek[1], G. K. Yardımcı[1], B. Farisogullari[1], Z. Özsoy[1], G. Ayan[1], G. Sandal Uzun[1], M. Ekici[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], A. I. Ertenli[1], U. Kalyoncu[1], S. Kiraz[1]. [1]*Hacettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, ANKARA, Turkey*

Background: Tofacitinib is a targeted synthetic DMARD that selectively inhibits Janus kinase (JAK) and is approved for the treatment of RA by the FDA in 2012. In recent years, an important safety concern related to incidence of adverse events after treatment with tofacitinib has emerged.
Objectives: To evaluate the risk of major adverse cardiovascular events (MACE), venous thromboembolism (pulmonary embolism or deep vein thrombosis), serious infections requiring hospitalization, and herpes zoster with tofacitinib in RA patients aged ≥ 60 years.
Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological and targeted synthetic DMARD registry since 2005. We analyzed RA patients aged ≥ 60 years receiving tofacitinib who had at least 1 control visit registered in the HURBIO database. Phone calls were made with these patients for the current health status information until the end of January 2022. The data of the patients who lost the follow-up in our clinic were obtained from the personal health record system of the Republic of Turkey Ministry of Health by patients' permission. The coprimary end points were adjudicated MACE, VTE, serious infections, and herpes zoster. These events were identified using patients' medical records. Crude incidence rates were expressed in patients with first events per 100 patient-years, with two-sided 95% confidence intervals.
Results: A total of 132 RA patients (109, 82.6% female) aged ≥ 60 years received tofacitinib at a dose of 5 mg twice daily. The median (25–75% percentiles) age was 67 (63-73) years and median duration under tofacitinib was 18 (5-33) months. Approximately 70% of patients were biologically naive. During a median follow-up of 1.5 years, the incidences of serious infection requiring hospitalization and herpes zoster were higher (5.5% [95%CI 3.12-9.86] and 3.4% [1.67-7.17], respectively) while there was no increase in the incidences of MACE and VTE. The causes for hospitalization were as follows: COVID-19 (n=4), pneumonia (n=3), soft-tissue infection (n=3), and GIS infection (n=1). Two of these patients deceased.
Conclusion: Older patients with RA are at increased infection risk because of age and comorbid conditions. Although adverse events are reported with 10 mg tofacitinib twice daily, clinicians should be careful against the risk of infection at a dose of 5 mg twice daily, especially in elderly patients.

AB0417 SHORT-TERM EFFECT OF METHOTREXATE ON APOLIPOPROTEINS AND LIPID PROFILE IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

S. Jain[1], V. Dhir[1], B. Leishangthem[1], M. Kalyan[2], I. Verma[2], G. Naidu[1], S. K. Sharma[1], A. Sharma[1], S. Jain[1]. [1]*PGIMER, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, Chandigarh, India;* [2]*PGIMER, Department of Biochemistry, Chandigarh, India*

Background: Methotrexate (MTX) forms the first line therapy for rheumatoid arthritis (RA). The cardioprotective effect of MTX is well established, but whether this is just due to control of inflammation, or is also via an effect on serum lipoproteins, is unclear. Although a few studies have studied the effect of the MTX on the

traditional lipid profile in RA[1], there is no data on the effect of MTX on apolipoproteins (Apo A1, Apo B, ApoB/ApoA1), which are considered better cardiovascular risk predictors than the traditional lipid profile.
Objectives: To determine the short-term effect of MTX on apolipoproteins and traditional lipid profile in patients with active RA.
Methods: DMARD-naïve patients with active RA (SJC≥2 and TJC≥4) who had been enrolled in the multicentre, RCT comparing two different MTX escalation strategies in RA (MEIRA)[2] and for whom paired serum samples were available before and after MTX treatment were included. All these patients received MTX monotherapy started at 15 mg/week and escalated to 25 mg/week by 4-8 weeks. Serum levels of apolipoprotein A1 (Apo A1), apolipoprotein B (Apo B), total cholesterol (TC), low-density lipoprotein (LDL), high-density lipoprotein (HDL), and triglycerides (TG) were measured before starting MTX and after 16 weeks of MTX monotherapy. Proatherosclerotic indices (TC/HDL and ApoB/ApoA1) were also calculated.
Results: A total of 103 patients [mean age 40 (8) years, 93 (90%) females, mean BMI 25.1 (4.8) kg/m^2, all non-smokers and non-alcoholics] were included. No study participant had comorbid diabetes mellitus or coronary artery disease; none of them were taking glucocorticoids or hypolipidemic drugs. An increase in Apo A1 levels [by a mean of 5.6 mg/dL (p=0.02)], and HDL levels [by a mean of 1.6 mg/dL (p=0.04)] was seen after 16 weeks of MTX monotherapy. Although a numerical increase in levels of TC (mean 4.6 mg/dL, p=0.07), LDL (mean 2 mg/dL, p=0.34) and TG (mean 6.6 mg/dL, p=0.35) was also noted, none of these were statistically significant. No obvious change in Apo B levels and TC/HDL ratio occurred due to MTX therapy. However, the ApoB/ApoA1 ratio decreased significantly from 0.8 to 0.7 (p=0.002) with 16 weeks of MTX therapy (Table 1).

Table 1. Baseline and end of treatment values of apolipoprotein A1 (Apo A1), apolipoprotein B (Apo B), total cholesterol (TC), low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglycerides (TG), and proatherosclerotic indices (TC/HDL and ApoB/ApoA1).

Parameter (mg/dL)	Baseline	After 16 weeks of MTX therapy	p-value
Apo A1	126.0 (25.1)	131.6 (23.4)	**0.02**
Apo B	92.3 (18.9)	92.0 (20.9)	0.84
ApoB/ApoA1	0.8 (0.2)	0.7 (0.2)	**0.002**
TC	164.5 (32.4)	169.1 (36.8)	0.07
HDL	40.9 (9.8)	42.5 (9.7)	**0.04**
TC/HDL	4.2 (1.1)	4.1 (1.1)	0.34
LDL	88.8 (25.2)	90.8 (29.8)	0.34
TG	139.8 (69.6)	146.4 (91.3)	0.35

All values represented as mean (SD). Apo A1=apolipoprotein A1, ApoB=apolipoprotein B, TC=total cholesterol, LDL=low-density lipoprotein, HDL=high-density lipoprotein, TG=triglycerides

Conclusion: MTX therapy led to a mild but significant increase in HDL, ApoA1 and a reduction in ApoB/ApoA1 over short-term. This could potentially represent one of the mechanisms by which MTX exerts its cardioprotective effect; however, these changes need to be carefully interpreted over longer term and in context of the lipid paradox operating in RA.

AB0418 INCREASED THROMBOEMBOLIC RISK OF JAK INHIBITORS AFTER SWITCHING FROM BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Eun[1], G. H. Seo[2], S. Y. Kang[3], S. Lee[3], H. Kim[3,4], H. S. Cha[3], E. M. Koh[3], J. Lee[3]. *[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); [2]Health Insurance Review and Assessment Service,, Wonju, Korea, Rep. of (South Korea); [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); [4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Rep. of (South Korea)*

Background: Safety concerns regarding JAK inhibitors have grown since the ORAL surveillance trial reported that their use was associated with an increase in major adverse cardiovascular events compared to TNF inhibitors. However, real-world data on the association between JAKi and thromboembolic events are sparse.
Objectives: We compared the incidence of thromboembolic events (TEs) before and after switching to Janus kinase inhibitors (JAKi) from biologic disease-modifying anti-rheumatic drugs (bDMARDs) in patients with rheumatoid arthritis (RA).
Methods: Among patients with a diagnostic code for RA taking bDMARDs, patients who switched to JAKi or another bDMARD between March 2015 and December 2020 were included in this self-controlled case series study. The outcome was the occurrence of TEs. The incidence rate ratios (IRRs) for TEs in the period after switching to JAKi or another bDMARD compared with the period before switching were calculated based on an assumed Poisson distribution.
Results: There were 1,150 and 2,254 patients who switched to JAKi and another bDMARD, respectively. The mean follow-up duration was 4.5 ± 1.8 years. In the JAKi group, the IRR for TE after drug switching was 1.56 (95% confidence interval [CI] 1.22–1.98, $P < 0.001$) compared with the period before the drug switch; in the bDMARD group, the IRR was 1.16 (95% CI 0.98–1.38, $P = 0.079$).
Conclusion: Switching from bDMARDs to JAKi was associated with an increase in TE incidence in RA patients in a real-world setting.

AB0419 RHEUMATOID ARTHRITIS SWITCHING PATTERNS AND THE GROWTH OF SMALL MOLECULE TREATMENT IN THE EU5

M. Yarnall[1], P. C. Taylor[2], P. Pouliot[1], E. Hettel[1], K. Murray[1]. *[1]Spherix Global Insights, Rheumatology Market Research, Exton, United States of America; [2]The Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: TNF-α inhibitor therapy has long been the standard of care for adult patients diagnosed with moderate to severe rheumatoid arthritis (RA) across the EU5, though several new biologics, biosimilars, and small molecules have become available for the treatment of RA.
Objectives: This research sought to understand the factors influencing treatment changes when patients are switched from one biologic or small molecule to another, including the reason(s) for their treatment selection.
Methods: An independent market analytics firm collaborated with EU5 rheumatologists (n=250 across France, Germany, Italy, Spain, and the UK) to conduct a retrospective chart review of patients diagnosed with RA (n=1,268) who had switched from one biologic therapy or small molecule agent to another in the prior twelve weeks. Data were collected in August and September 2021 and included clinical and non-clinical patient demographics as well as physician demographics and attitudinal survey responses. This study was a non-longitudinal trending analysis to 2020 (n=1,288), 2019 (n=1,294), 2018 (n=1,312) and 2017 (n=1,235) audits following the same methodology.
Results: 70% of surveyed rheumatologists reported recent changes to the management of their RA patients, with the most recalled treatment shift being an increased use of small molecule agents (JAK inhibitors, 30%), attributable to the introduction of upadacitinib and filgotinib in December 2019 and September 2020, respectively. Despite a plethora of RA treatment options in the EU5, annual physician-reported rates of RA patient switching have remained stable since 2017, with 25% of biologic/small molecule-treated patients switching brands within a given year.
There has been a steady increase in switches from TNF inhibitors to JAK inhibitors over the last few years (2% in 2017 to 19% in 2021). At the same time, the rates of TNF cycling have been on a downward trend (43% in 2017, 40% in 2018, 39% in 2019, 34% in 2020, and 32% in 2021). Rheumatologists indicate 44% of their RA switch patients were switched from a TNF to a JAK inhibitor due to secondary efficacy failure, and their primary reason for selecting a JAK was due to the specific MOA (40%) and dosing delivery (19%).
TNF cycling (both branded and biosimilar) represent one-third of all switches in the EU, making it the most common switch pattern. TNF cycling remains most common in Germany and Spain, while France observes the lowest switch rates between TNFs. The incidence of switches from TNFs to JAK inhibitors is more consistent across countries but remains highest in Germany.

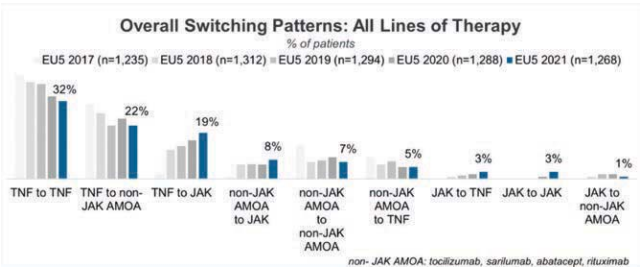

Figure 1.

Conclusion: The introduction of small molecule agents in the EU over recent years (upadacitinib and filgotinib) has provided new options for the treatment of RA, creating a shift in the switching arena from TNF cycling to more utilization of alternate mechanisms of action post first line therapy in favor of JAK inhibitors.

Background: Combination of MTX with a bDMARDs or tsDMARDs is considered the most effective treatment regimen currently available for patients with RA who have failed to respond to conventional DMARDs. However, approximately 30% of patients receive bDMARDs as monotherapy in daily clinical practice. Studies in the literature do not assess unintentional monotherapy in general. However, it is thought that some patients may switch to monotherapy unintentionally. In other words, some patients who are prescribed combination therapy switch to monotherapy without informing their physicians.
Objectives: To determine the rate of unintentional monotherapy in rheumatoid arthritis (RA) patients receiving tofacitinib and to evaluate tofacitinib survival rate.
Methods: This national, multicentre, retrospective study included patients' data from the TURKBIO Registry. Data on demographics, clinical characteristics, disease duration and activity, comorbidities, and treatment were analysed.
Results: Data of 231 RA patients (84.8% female, median age, 56 years) were included; 153 were initially prescribed combination therapy and continued to their therapies; 31 were initially prescribed combination therapy but switched to monotherapy of their own will (unintentional monotherapy); 21 were initially prescribed monotherapy and switched to combination therapy; 26 were initially prescribed monotherapy and continued to their therapies. The combination and unintentional monotherapy groups did not differ regarding remission rate assessed by DAS28-CRP (60.5% and 70%, respectively, p=0.328). The rate of comorbidities at the time of data retrieval was significantly higher in the unintentional monotherapy group compared with the combination group (83.3% vs. 60.3%, p=0.031). Presence of comorbidities was a significant factor affecting switching to monotherapy (p=0.039, Odds ratio: 3.29, 95% CI: 1.06-10.18). Drug survival rates of the unintentional monotherapy and combination groups did not differ. The median drug survival duration of tofacitinib was 27+ months with a 1-year and 4-year drug survival rates of 89.6% and 60.2%, respectively, in the unintentional monotherapy group.
Conclusion: Although 13.4% of the study population started monotherapy unintentionally, drug survival rates of the unintentional monotherapy and combination groups were not different. Comorbidity was an important factor affecting transition from combination therapy to monotherapy. This study was sponsored by Pfizer.

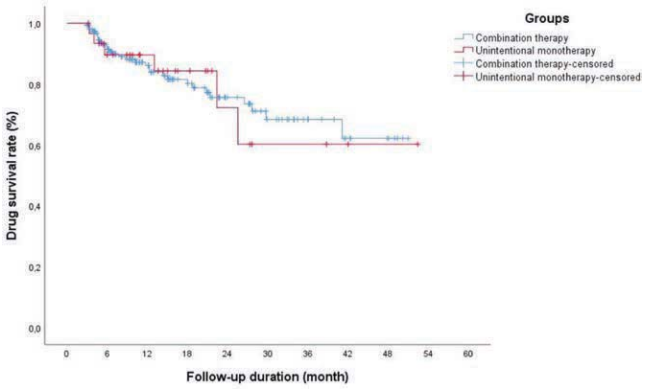

Figure 1.

AB0421 ASSESSEMENT OF LIVER STIFFNESS IN RHEUMATOID ARTHRITIS PATIENTS UNDER METHOTREXATE

W. Lahmar[1], M. Slouma[1], G. Mohamed[2], R. Dhahri[1], L. Metoui[1], I. Gharsallah[1], N. Abdelli[2]. *[1]Military Teaching Hospital, Rheumatology, Tunis, Tunisia; [2]Military Teaching Hospital, Gastroenterology, Tunis, Tunisia*

Background: Methotrexate (MTX) is recommended as a first-line disease-modifying antirheumatic drug for treating rheumatoid arthritis (RA) in monotherapy or combinational therapy. A concern about MTX-related liver fibrosis in patients with rheumatoid arthritis (RA) is still unsolved.
Objectives: The aim of the study cutoff of cumulative dose discriminating patients with normal from those with abnormal liver stiffness.
Methods: We conducted a cross-sectional study including consecutive RA patients diagnosed according 2009 ACR-EULAR criteria. Liver stiffness (LS) was assessed by Fibroscan in the gastroenterology department by an experienced operator. The LS is measured in kilopascals (kPa). It is normal when < 6.2 kPa. Above this rate it is considered pathological. Substantial liver fibrosis was defined as liver stiffness of greater than 8 kPa. We collected the following parameters: age, disease duration, disease activity assessed by DAS28, cumulated dose of MTX and duration of this treatment, and the body mass index (BMI). Patients underwent blood testing exploring hepatic function: alkaline phosphatase (ALP), alanine transaminase (ALT), aspartate aminotransferase (AST), and gamma-glutamyl tansferase (GGT), total bilirubin (TB), albumin (ALB) and prothrombin time (PT). Statistical analysis was performed using SPSS software.
Results: There were 18 men and 36 women. The mean age was 51.9 + 11.49 [22-83]. The mean BMI was 27.27 + 3.40. The mean disease duration 8.08 + 6.28 years. The mean DAS28CRP was 3.96 + 1.49. The mean cumulative dose of MTX was 3670 + 3432.61mg and mean MTX duration was 55.75 + 50.89 months. The mean of LS was 4.6 + 1.64 kPa. The means of the liver blood tests are as follows: AST 20.83 + 8.58 UI/L, ALT 19.60 + 9.39 UI/L, ALP 84.65 + 38.68UI/L, TB 9.50 + 4.79 UI/L, GGT 25.88 + 14.26UI/L, ALB 35.19 + 5.47 g/L, PT 94.60 + 9.02. Eight patients had abnormal LS values and two patients had advanced liver fibrosis. However, hepatic blood tests (AST, ALT, GGT, TB, ALB, PT) were normal in these patients. A correlation was found between LS and following parameters: cumulative dose of MTX (r: 0.347, p: 0.013), the methotrexate duration (r: 0.363, p: 0.010) and total bilirubin rate (r:0.390, p: 0.005). Receiver Operator Curve (ROC) analysis showed the cut-off point of cumulative dose of MTX with the best accuracy in distinguishing patients with normal LS from those with LS higher than 6.2 kPA was 7330 mg, with a sensitivity of 50% and specificity of 91.3% (air under the curve (AUC) value: 0.732 (p=0.03).
Conclusion: Our study showed that LS correlated to both MTX duration and cumulative dose. Patients with a cumulative dose of MTX higher than 7330 mg required a close follow up of liver elastometry and monitoring of hepatic function.

SLE, Sjögren's and APS – treatment

AB0422 SODIUM BICARBONATE MOUTH RINSE IS A USEFUL SELF-CARE METHOD FOR DRY MOUTH IN PATIENTS WITH SJÖGREN'S SYNDROME

N. Azuma[1], K. Matsui[1]. [1]*Hyogo College of Medicine, Division of Diabetes, Endocrinology and Clinical Immunology, Nishinomiya, Japan*

Background: Patients with Sjögren's syndrome (SS) present various symptoms related to dry mouth. While hyposalivation is believed to be the main cause, saliva has various beneficial physiological effects on the intraoral environment, and qualitative changes in its composition should also be considered as a cause of the refractory intraoral manifestations in SS. One of the physiological effects of saliva is buffering, and salivary bicarbonate (HCO3-) is the main determinant of salivary buffering capacity. Since salivary concentration of bicarbonate heavily depends on the rate of salivary secretion, salivary buffering capacity and oral pH decrease in patients with dry mouth; this is associated with the development of dental caries and oral candidiasis. It is considered that sodium bicarbonate mouth rinse is effective for suppressing these intraoral disorders. It is also a practical self-care method because it is inexpensive and can be made at home.
Objectives: To investigate the usability and changes in symptoms associated with dry mouth after use of sodium bicarbonate mouth rinse in SS patients.
Methods: The subjects were 27 SS patients (female: male =24:3, mean age 62.9 years, primary SS: secondary SS =24:3, mean disease duration 12.3 years) who had used sodium bicarbonate mouth rinse (dissolve about 5 g of commercially available baking soda in 500 cc of water in a plastic bottle. Put this sodium bicarbonate water in the mouth and rinse the mouth for 30 seconds to 1 minute so as to reach throughout the oral cavity). We investigated usage status, usability, and changes in subjective symptoms using a questionnaire. During their using the mouth rinse, medication and countermeasures against dry mouth in the daily life continued as usual.
Results: More than half of the patients had no knowledge of sodium bicarbonate mouth rinse (n=15; 55.6%). Highest frequency of use was twice a day (n=9; 33.3%), and common use situations were before bedtime (n=18; 66.7%), after meals (n=17; 63.0%), and at waking up (n=11; 40.7%). Twenty patients (74.1%) had "very good" or "good" sense of use. Eighteen patients (66.7%) had relief of symptoms related to dry mouth. Pros were "feeling refreshed in the mouth" (n=14; 51.9%), followed by "becomes less sticky" (n=8; 29.6%), "easy to make" (n=7; 25.9%), and "inexpensive" (n=6; 22.2%). Some respondents said they had less glossitis, stomatitis, and angular cheilitis (n=4; 14.8%). For cons "troublesome" was the highest (n=10; 37.0%), followed by responses regarding "taste" (n=6; 22.2%). There were also many responses to "none in particular" (n=7; 25.9%). No obvious accidents occurred, and 20 (74.1%) of them replied that they would like to continue to use the sodium bicarbonate mouth rinse.
Conclusion: In addition to the inhibition of dental caries and oral candidiasis, removal of tongue plaque and refreshing feeling in the mouth after rinsing due to its mucolytic effect, reduction of halitosis-causing volatile sulfur compounds, and improvement of gingivitis have been reported as effects of sodium bicarbonate. However, reports on the effects of sodium bicarbonate on dry mouth in SS patients are scarce. These results suggest that sodium bicarbonate mouth rinse is considered to be a useful self-care method that can compensate for the salivary buffering capacity that is impaired in SS patients and may reduce dry mouth symptoms. Since it is easy to continue and safe, it is worth actively incorporating it into the standard treatment for SS. Evaluation in more patients with objective indices is desired in the future.

AB0423 STRATEGIES FOR GLUCOCORTICOID TREATMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS FLARES: A REAL-LIFE EXPERIENCE

L. Scagnellato[1], M. Maffi[1], C. Tani[1], E. Elefante[1], F. Trentin[1], F. Ferro[1], D. Zucchi[1], C. Stagnaro[1], L. Carli[1], M. Mosca[1]. [1]*Università di Pisa, Rheumatology, Pisa, Italy*

Background: Glucocorticoids (GC) are a cornerstone for the treatment of Systemic Lupus Erythematosus (SLE) manifestations but there is still open debate concerning their optimal therapeutic employment.
Objectives: To describe and compare the GC therapeutic strategies used in a real-life setting for the initial treatment of SLE flares.
Methods: This study is a retrospective analysis of data from a monocentric cohort of SLE patients who registered a disease flare between 2015 and 2020. Flares were first categorized in "pulse-treated" (PT) and "non pulse-treated" (NPT). PT flares were then divided into "low-dose regimen" (250 mg iv 6MP for 3 consecutive days or less) and "high-dose regimen" (more than 250 mg iv 6MP for 3 days). GC daily and cumulative 6MP doses, rate of remission and relapse were evaluated at 3, 6 and 12 months.
Results: 101 flares were analyzed (30 PT and 71 NPT). PT flares were more severe in terms of median SLEDAI (PT 16(12-22) vs NPT 8(5-10) p=0,00) and BILAG score index (BILAG A PT 71% vs NPT 30% p=0,001). PT patients received significantly higher GC doses at 1 month (PT median cumulative dose 1372 IQR 1028 – 3076 mg of 6MP vs NPT median 160 IQR 120-288 mg of 6MP, p=0,000), 6 months (PT median cumulative dose 2964 IQR 2294 – 4305 mg of 6MP vs NPT 880 IQR 720 – 1284 mg of 6MP, p=0,000) and 12 months (PT median cumulative dose 3510 IQR 3014-5025 vs NPT median cumulative dose 1571 IQR 1098 – 2122 mg of 6MP, p=0,000). Characteristics of flares that were treated with low-dose (N=19) or high-dose (N=11) pulse regimen are summarized in Table 1. As expected, the "low-dose regimen" subgroup received lower cumulative GC dosage over time. However, no statistically significant differences were found neither in term of disease severity at baseline nor in term of disease activity, remission rates or new flares over time.

Table 1. Comparison between low-dose pulse regimen and high-dose pulse regimen in terms of cumulative GC dose and outcome in the first year after a SLE flare

Median GC doses (6MP)	Low-dose regimen N=19 (63,33%)	High-dose regimen N=11 (36,67%)	P value
Median SLEDAI	16 (12 -20)	18 (8-24)	0,6186
BILAG score (A, B, C)	A=14, B=4, C=1	A=10, B=1, C=0	0,488
Cum. dose 1 mo	1350 (1028 – 1534)	1752 (960 – 2356)	0,126
Cum. dose 3 mos	1858 (1604 – 2463)	2784 (2184 – 3240)	0,040
Cum. dose 6 mos	2450 (2218 – 3586)	3456 (2906 – 4380)	0,029
Cumulative doses 12 mos	3150 (2851 - 4448)	4246 (3591 – 5772)	0,011
Remission 3 mos no – (%)	2 (10%)	0 (0%)	0,265
Remission 6 mos no – (%)	8 (42%)	1 (9%)	0,057
Remission 12 mos no – (%)	12 (63%)	5 (45%)	0,346
Median SLEDAI 3 mos	4 (2 – 9)	9 (4 – 12)	0,138
Median SLEDAI 6 mos	3 (0 - 4)	4 (0 – 9)	0,154
Median SLEDAI 12 mos	2 (0 – 5)	2 (0 – 12)	0,363
New flares 6 mos no – (%)	2 (10%)	1 (9%)	0,900
New flares 12 mos no – (%)	2 (10%)	2 (18%)	0,552

GC=glucocorticoids, 6MP=6-methylprednisolone, no=number, Cum.=cumulative, mos=months

Conclusion: These data suggest that in a real-life setting, pulse GC therapy is preferred over oral administration for severe SLE flares and entails administration of high cumulative doses of GC. However, the experience outlined suggests that the low-dose pulse regimen is as effective in remission induction of severe flares as the high-dose regimen, allowing significant GC sparing. Since the cumulative GC dose is a known strong predictor of organ damage, strategies aimed to minimize the GC dosage should be encouraged.

WHAT DOES IT MEAN TO BE A DUAL BICLA AND SRI(4) RESPONDER? A POOLED ANALYSIS OF TWO PHASE 3 TRIALS IN PATIENTS WITH SLE

I. N. Bruce[1], K. Psachoulia[2], E. Maho[3], D. Isenberg[4], R. van Vollenhoven[5], R. Furie[6], E. F. Morand[7], C. Lindholm[8], M. Hultquist[2], R. Tummala[2]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom;* [2]*AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America;* [3]*AstraZeneca, BioPharmaceuticals R&D, Cambridge, United Kingdom;* [4]*University College London, Centre for Rheumatology, London, United Kingdom;* [5]*University of Amsterdam, Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands;* [6]*Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, NY, United States of America;* [7]*Monash University, Faculty of Medicine, Nursing & Health Sciences, School of Clinical Sciences, Melbourne, VIC, Australia;* [8]*AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*

Background: The BILAG–based Composite Lupus Assessment (BICLA) and SLE Responder Index ≥4 (SRI[4], based on SLEDAI-2K) are validated composite global measures of clinically meaningful improvement in SLE disease activity. BICLA and SRI(4) responses were endpoints in the phase 2b MUSE and phase 3 TULIP-1/-2 trials.[1–3] In a post hoc analysis, more patients met both the BICLA and SRI(4) response criteria at Week 52 (dual responders) with anifrolumab 300 mg vs placebo across trials (MUSE: 48.5% vs 19.9%; TULIP-1: 42.2% vs 27.9%; TULIP-2: 43.4% vs 26.4%; all nominal $P<0.01$).[4] Whereas the clinical benefit of BICLA responses alone have been characterized,[5] the added benefit of dual BICLA/SRI(4) responses remains unknown.

Objectives: To understand the clinical benefits (SLE clinical assessments, patient-reported outcomes [PROs], and healthcare utilization) of having a dual BICLA/SRI(4) response vs a response for just one endpoint or nonresponse for both, irrespective of treatment assignment.

Methods: This was a post hoc analysis of pooled data from the randomized, 52-week, double-blind TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) trials in which patients with moderate to severe SLE despite standard therapy received intravenous anifrolumab (150/300 mg) or placebo every 4 weeks for 48 weeks.[1,2] Patients were categorized as dual responders (met both BICLA and SRI[4] response criteria at Week 52), single responders (met one of either BICLA or SRI[4] response criteria), or dual nonresponders (did not meet either response criteria). SLE clinical assessments, PROs, and healthcare utilization through Week 52 were evaluated for each group. Statistical comparisons were conducted for dual responders vs single responders and dual nonresponders.

Results: Patient demographics and baseline characteristics were generally balanced across dual responders (n=288), single responders (n=122), and dual nonresponders (n=409). At Week 52, dual responders had greater improvements in SLE-related measures compared with dual nonresponders across all evaluated clinical, PRO, and healthcare utilization outcomes (Figure**, A–E).**

Compared with single responders, dual responders had a significantly greater mean change from baseline in SLEDAI-2K score (–8.2 vs –5.1; nominal $P<0.0001$), PGA score (–1.3 vs –0.9; nominal $P<0.0001$), and swollen joint counts (–6.2 vs –4.5; nominal $P<0.0001$) (**Panel A**); there was also a numerically greater proportion with ≥50% reduction in CLASI-A score (91% vs 76%; nominal $P=0.078$) (**Panel B**). Dual responders had a greater mean reduction in baseline oral glucocorticoid (GC) daily dose (–5.6 vs –3.4; nominal $P=0.006$) vs single responders (**Panel A**).

For PROs, compared with single responders, dual responders had a greater mean change in baseline PtGA score (–17.7 vs –8.6; nominal $P=0.001$), and a higher proportion had clinically meaningful improvements from baseline to Week 52 in fatigue (FACIT-F; 56% vs 43%; nominal $P=0.014$) and SF-36 physical component scores (60% vs 34%; nominal $P<0.0001$) (**Panel C–D**). Healthcare utilization (ED visits and hospitalizations) was lower in dual responders vs single responders; however, this comparison did not reach nominal significance (nominal $P=0.462$ and 0.311, respectively) (**Panel E**).

Conclusion: Patients with SLE with dual responses in two validated outcome measures have significantly better outcomes across a range of clinical, PRO, and healthcare utilization measures compared with dual nonresponders. The higher degree of improvement in disease activity, especially in arthritis, and the greater reduction in oral GC dose compared with single responders is reflected in improved patient well-being, physical functioning, and fatigue. Being a dual responder offers a profound and clinically meaningful outcome for both the clinician and patient.

AB0426 THERAPY WITHOUT GLUCOCORTICOIDS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Mesnyankina[1], E. Aseeva[1], N. Nikishina[1], A. Lila[1], T. Popkova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Federal State budgetary Scientific Institution, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Federal State Budgetary Scientific Institution, Moscow, Russian Federation*

Background: The effectiveness of glucocorticoid (GC) therapy in SLE is beyond doubt and has been confirmed by the experience gained over many decades of their use. However, with prolonged use of GC, even in low and medium doses, there are many problems. In particular, the development of organ damage associated with GC significantly worsens the prognosis, leads to a decrease in the quality of life, social adaptation. Currently, attempts are being made to use therapeutic programs without the use of GC or with their appointment in minimal doses.
Objectives: Achieving stable remission in patients with SLE. Cancellation of oral GC or the use of therapy without GC in patients with SLE.
Methods: 3 clinical cases. Two patients (N1, N2) had a combination of SLE with Sjogren's syndrome with predominantly musculoskeletal syndrome. In these patients, severe organ lesions (lupus nephritis, vasculitis, central nervous system damage) were excluded. SLEDAI-2K in these patients was 9 and 8 points. Both patients had a decrease in C3, C4 complement component, ANA positivity, arthritis, hematological disorders. In N2, an increase in at to ds-DNA was determined. Therapy with oral GC, immunosuppressive drugs was not carried out in them. Patient N3 with lupus nephritis (hematuria, leukocyturia), exudative pleurisy, polyarthritis, high immunological activity (SLEDAI-2K - 16 points) was prescribed GC at a dose of 2 tab per day. Creatinine and urea were within normal limits. The patient had high immunological activity: low C3, C4 complement, at to dsDNA 200 IU/ml, ANA positivity (1:1280). Due to the presence of lupus nephritis, the patient received mycophenolate mofetil 1500 mg per day. All patients received double anti-B-cell therapy with the sequential use of Rituximab (RTX) 1000 mg intravenously in patients N1 and N2, and N3 at a dose of 2000 mg per day with premedication of 6-methylprednisolone at a dose of 250-500 mg intravenously. After 1-3 months, belimumab infusions were started at a dose of 10 mg/ kg / month. The observation period is 1 year
Results: Anti-B-cell therapy allowed patients to be treated without oral GC. A patient with LN (N3) was prescribed low doses of GC at the time of initiation of therapy with RTX, however, they were subsequently completely canceled by the 6th month of therapy. Clinical remission of the disease was achieved in all three patients. Clinical manifestations of the disease were stopped. SLEDAI-2k was 0-2 points due to minor hypocomplementemia (Figure 1). No new irreversible organ damage and relapse of the disease were registered. Patients continued to receive monthly infusions of BLM, there were no repeated courses of RTM. The patient with kidney damage continued to take MM.
Conclusion: Consistent therapy of **RTX** and BLM allowed to achieve not only a high clinical and immunological effect, but also the possibility of reducing and even abandoning the oral dose of GC, which is consistent with the concept of "Treat to target" in SLE. In addition, all patients were closely monitored by a rheumatologist once a month, which was partly achieved thanks to monthly infusions of BLM, which were carried out in the clinic.

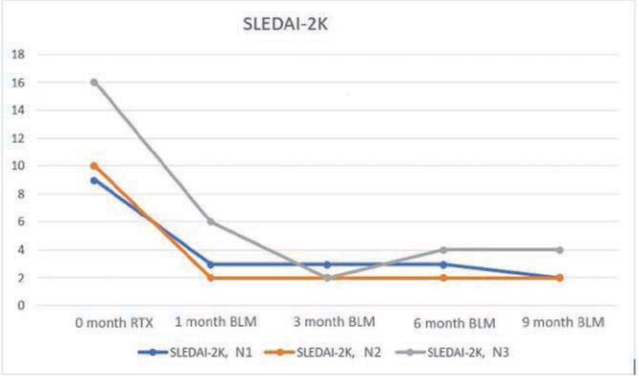

Figure 1.

AB0427 RENAL INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: A DIFFICULT-TO-TREAT CLINICAL CASE

R. Santangeli[1], S. Salvucci[1], L. Gamba[1], G. Montozzi[1], L. Manfredi[2], G. Moroncini[1,2]. *[1]Ospedali Riuniti Ancona University Hospital, Internal Medicine Residency Program, Ancona, Italy; [2]Ospedali Riuniti Ancona, Internal Medicine, Ancona, Italy*

Background: Lupus nephritis (LN) is one of the major organ involvement of Systemic Lupus Erythematosus (SLE), causing significant increase of morbidity, mortality and healthcare impact.[1] According to international guidelines, immunosuppressive therapy is indicated for LN class III and IV, while class V usually do not require this treatment, less than there is a proteinuria in the nephrotic range, and so for class II, also with a risk of evolution in a more aggressive form.[2] Immunosuppressive drugs commonly used are mycophenolate mofetil/mycophenolate acid (MMF/MPA) and cyclophosphamide for the initial treatment and MMF/MPA or azathioprine for the maintenance of remission. LN treatment is often difficult because of the drug adverse events and the comorbidities that make therapeutic choices very challenging.
Objectives: We describe the case of a young woman with SLE and other major systemic comorbidities who developed severe LN. This case emphasizes the importance of considering patients in their complexity and the delicate role of the physician in tailoring the treatment strategy on the individual patient.
Methods: A 36-year-old woman presented to our Department for lymphadenopathy, headache, epistaxis, fever and weight loss. In her past medical history, she had a cerebral abscess caused by Streptococcus Constellatus with residual left hemiplegia and cervical HPV-related high-grade dysplasia, treated by ring biopsy. Upon admission, blood tests revealed severe neutropenia and lymphocytopenia, thrombocytopenia and low complement; blood cultures were negative. A total body CT scan showed multiple lymphadenopathies. Lymph node and bone marrow biopsies were performed and histological examination was negative for hematological disease. The autoimmune panel was positive for antinuclear, anti-DNAn, anti-Sm, anti-U1RNP, anti-cardiolipin and anti-beta2glycoprotein antibodies. According to clinical and laboratory results, a diagnosis of SLE was made.
Results: High-dose corticosteroid therapy was started with good clinical response and improvement of blood tests. Because of the gynecological history, immunosuppressive therapy was not started, and a wait-and-see strategy with steroid tapering and careful follow-up was started. A few months later, the patient developed an increase of serum creatinine with proteinuria at nephrotic range. Thus, a kidney biopsy was performed with evidence of class III LN. Following this result, we started high-dose corticosteroid therapy, with only partial response. After executing colposcopy with biopsy, that was negative for HPV-related lesions, we decided to start MMF, continuing with a careful follow-up. After six months, proteinuria reduced but maintained on levels around 1 gr per day. Bearing in mind the growing number of studies reporting the efficacy of belimumab in LN 3,4, we added this drug to achieve a better disease control, continuing to closely monitor the patients and potential adverse events.
Conclusion: In patients with LN the choice of the immunosuppressive therapy can be very challenging. A tailored approach to the individual patient may be the best option to improve the management of this complex disease.

TREATMENT PATTERNS OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN TAIWAN – A POPULATION-BASED ANALYSIS

Y. S. Chang[1], W. N. Huang[2], C. H. Tang[3], K. Ng[4], P. Y. Chuang[5], W. Furnback[5], B. Wang[5], C. Y. Wei[6], B. Wang[4], T. Treuer[7]. *[1]Shuang-Ho Hospital, Division of Rheumatology, Immunology and Allergy, Department of Internal Medicine, New Taipei, Taiwan, Republic of China; [2]Taichung Veterans General Hospital, Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China; [3]Taipei Medical University, School of Health Care Administration, Taipei, Taiwan, Republic of China; [4]Eli Lilly and Company (Taiwan), Inc, Medical Affairs, Taipei, Taiwan, Republic of China; [5]Real Chemistry Inc., Value and Access, New York, United States of America; [6]Eli Lilly and Company (Taiwan), Inc, Price, Reimbursement and Market Assess, Taipei, Taiwan, Republic of China; [7]Eli Lilly and Company, Value, Evidence, and Outcomes, Budapest, Hungary*

Background: Systemic lupus erythematosus (SLE) is a chronic, autoimmune disease of an unknown etiology with a broad spectrum of organ manifestations, and patients with SLE have limited treatment options to NSAIDS, glucocorticoids, hydroxychloroquine and immunosuppressants. There is a lack of real-world evidence related to treatment patterns of SLE patients in Taiwan.
Objectives: To describe the real-world patient demographics, clinical characteristics, and treatment patterns of patients with SLE in Taiwan.
Methods: A retrospective observational study using Taiwan's National Health Insurance Research Database (NHIRD) from 1/1/2014 to 12/31/2019 was undertaken. Patients holding catastrophic illness certificates for SLE in 2015-2017 were identified. Enrolled patients aged ≥ 18 years were then divided into three groups (mild, moderate, and severe) based on the highest severity patients experienced in the one year following the enrollment date using a published claims-based algorithm (Garris et al 2013) that incorporates the Systemic Lupus Erythematosus Disease Activity Index, Systemic Lupus Activity Measure, British Isles Lupus Assessment Group Index and expert clinical opinion, and indexed upon the first date of entering the severity group. Baseline patient characteristics and treatment patterns during the follow-up period were measured. The types of treatment considered were NSAIDs, glucocorticoids, hydroxychloroquine and immunosuppressants.
Results: A total of 20,181 patients with catastrophic illness certificates for SLE were included in this study. The mean age of all SLE patients was 46.5 years and patients were mostly female (89.1%). The mean Charlson Comorbidity Index (CCI) score of all SLE patients was 1.5 (SD 1.3). Of these patients, 29.3% (n=5,918) had mild SLE activity, 60.7% (n=12,253) moderate and 10.0% (n=2,010) severe. During the one-year follow-up period, moderate to severe patients had numerically higher utilization rate of all types of treatment compared with mild patients (Table 1). Of all oral glucocorticoid users,27.8% of severe patients used high-dose glucocorticoids (> 15 mg/day) compared to <0.1% for mild and 9.7% for moderate patients. More than 70.0% of moderate to severe patients were prescribed 2 or more types of treatment at the same point of time. Of these patients having concomitant treatment of glucocorticoids with immunosuppressants, glucocorticoid dosage increased with the number of immunosuppressant used, especially in severe patients. 80.4% of moderate to severe patients received glucocorticoid-based therapy as the first-line treatment and the median treatment duration was 3.1 months. The median treatment duration of each first-line immunosuppressant ranged from 0.9 to 4.8 months in moderate to severe patients.

Table 1. SLE treatment utilization during the 1-year follow-up period

	Total (n=20,181)`		Mild (n=5,918)		Moderate (n=12,253)		Severe (n=2,010)	
	n	%	n	%	n	%	n	%
NSAID	7,212	35.7	1,405	23.7	4,983	40.7	824	41.0
Glucocorticoid	14,019	69.5	2,015	34.1	10,297	84.0	1,707	84.9
Hydroxychloroquine	13,278	65.8	2,867	48.5	8,970	73.2	1,441	71.7
Immunosuppressant	7,630	37.8	0	0.0	6,319	51.6	1,311	65.2
Methotrexate	898	4.5	0	0.0	786	6.4	112	5.6
Azathioprine	5,642	28.0	0	0.0	4,843	39.5	799	39.8
Leflunomide	132	0.7	0	0.0	117	1.0	15	0.8
Cyclosporin	854	4.2	0	0.0	715	5.8	139	6.9
Mycophenolate	959	4.8	0	0.0	774	6.3	185	9.2
Cyclophosphamide	790	3.9	0	0.0	17	0.1	773	38.5

Conclusion: The complexity and intensity of therapeutic approaches in SLE were associated with increased disease severity and patients were often resistant to treatment. These findings reflect the disease burden in SLE patients and suggest there is a substantial unmet need in the SLE treatment paradigm for moderate to severe SLE patients.

SAFETY AND OBSTETRIC OUTCOMES OF BELIMUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED IMMUNE THROMBOCYTOPENIC PURPURA PATIENTS WITH PREGNANCY

T. J. Lee[1], W. H. Tsai[2], S. C. Hsieh[1]. *[1]National Taiwan University Hospital, Division of Rheumatology, Immunology, and Allergy, Department of Internal Medicine, Taipei, Taiwan, Republic of China; [2]National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: Immune thrombocytopenia purpura (ITP) is not uncommon in systemic lupus erythematosus (SLE) patients and may lead to severe complications during pregnancy, such as pregnancy loss, and peripartum hemorrhage. [1] However, the treatment options during pregnancy was limited due to fetal safety concerns. Belimumab was approved for SLE and appeared to be safe in pregnant patients [2]. A phase II trial also reported efficacy of rituximab-belimumab combination in treating ITP [3]. However, the safety, influence on pregnancy outcomes, and effects on ITP in SLE patients with pregnancy was unclear.
Objectives: To evaluate the safety and obstetrics outcomes of SLE patients with pregnancy receiving belimumab for ITP.
Methods: This was a retrospective study in National Taiwan University Hospital. Eligible patients were more than 20 years old, had history of ITP, and fulfilled either the 1997 American College of Rheumatology or 2012 Systemic Lupus International Collaborating Clinics classification criteria. The belimumab was administered at 400 mg every 3-4 weeks. The serial full blood counts and immunological markers, unintended hospitalizations, infection episodes, pregnancy complications, and pregnancy outcomes were recorded.
Results: From April 2018 to November 2021, 7 SLE patients were identified. The median (IQR) age at conception was 35.6 (33.0 - 39.5) years. Three (43%) patients had secondary antiphospholipid syndrome, and none had lupus nephritis. The median (IQR) platelet count at conception was 187,000 (146,000 - 195,000) per microliter. The median (IQR) cycle of belimumab was 5 (4.5 - 8.5). Successful delivery was achieved in all patients. The median (IQR) gestational age was 36 (34 - 37) weeks, and four (57%) patients had preterm labor. The median birth weight was 2362 (2269-2477) grams, and three (43%) were small for gestational age. Pre-eclampsia developed in one patient, and none had premature preterm rupture of membrane or peripartum infections, or postpartum hemorrhage.
The median platelet count at labor was 75,000 (59,000 - 116,000) per microliter. During the pregnancy, severe thrombocytopenia with a platelet counts less than 10000 per microliter occurred in two (29%) patients, and one received prophylactic preoperative platelet transfusion. None of the patients had major or minor bleeding episodes throughout the pregnancy. Remarkably, one patient developed severe thrombocytopenia to 15,000 per microliter in the first trimester of pregnancy, and the platelet count recovered to normal range after 4 doses of belimumab administration. (Figure 1)

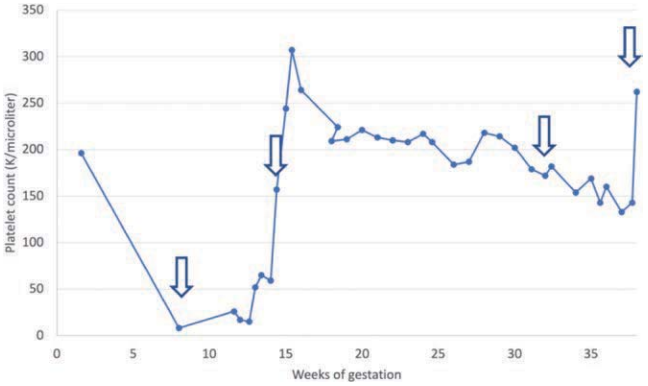

Figure 1. Serial blood platelet count during pregnancy in one patient. Arrow: belimumab 400 mg infusion.

During the pregnancy courses, no patient developed bacterial infections, two (29%) patients developed viral infections (one with upper respiratory tract infection and the other with acute gastroenteritis), and two (29%) had herpes zoster reactivation, which resolved smoothly after five-day course of oral valacyclovir.
Conclusion: The belimumab appeared to be safe in ITP patients with pregnancy, with no obvious increase in the infections and obstetric complications. Based on these observations, belimumab may be considered as one of the pharmacological options for SLE with ITP patients during pregnancy.

AB0430 EFFECTIVENESS OF RITUXIMAB TREATMENT IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME.

M. Pavía Pascual[1], O. Rusinovich[1], N. de la Torre Rubio[1], P. Navarro Palomo[1], M. Machattou[1], H. Godoy[1], J. Campos Esteban[1], C. Barbadillo Mateos[1], J. Sanz[1], C. Merino Argumánez[1], M. Espinosa[2], B. Garcia-Magallon[1], J. L. Andréu Sánchez[1], A. M. Huerta Arroyo[3], M. Fernandez Castro[1]. *[1]Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain; [2]Hospital Virgen Del Rocio, Internal Medicine, Sevilla, Spain; [3]Puerta de Hierro Majadahonda University Hospital, Nephrology, Majadahonda, Spain*

Background: The therapeutic management of Sjögren's Syndrome remains challenging in clinical practice. Randomized clinical trials with rituximab (RTX) fail to submit primary outcomes; nevertheless, some case series show improvement with this treatment.
Objectives: To evaluate the effectiveness of therapy with RTX in patients with primary Sjögren's Syndrome (pSS).
Methods: A retrospective chart review was conducted among patients with pSS who fulfilled 2002 AECG and 2016 ACR/EULAR criteria and had received RTX in the last 6 years. Patients with Sjögren's Syndrome associated with other autoimmune diseases were not included. Clinical, serological and radiological variables were analyzed (prior and 6 months after RTX therapy). A descriptive statistical analysis was performed.
Results: 18 patients were analyzed, 72.2% women, with a mean age of 60.9 years (36-83) and a mean duration of disease of 9.7 years (2-28). Reasons for treatment initiation were pulmonary involvement (n=5), renal involvement (n=4), arthritis (n=3), severe ocular/oral dryness (n=3), recurrent mumps (n=2) and autoimmune hepatitis with lymphadenopathy (n=1). Initial regimen was 2 doses of 1 g each administered 15 days apart. In 8 patients the dose was reduced in subsequent cycles to a single dose of 1 g or 500 mg. The mean number of cycles received was 3.2 (1 - 12). In 7 patients its administration persists as maintenance treatment every 6 months. In 5 patients, treatment was suspended because of clinical improvement/stability; in 2 it was stopped due to adverse effects (one for psychosis and the other for infusion reaction).; in 1 patient it was discontinued due to lack of efficacy in dryness; in 1 patient with pulmonary involvement, it was replaced by mycophenolate due to COVID-19 pandemic and clinical stability; in 1 patient it was suspended due to initiation of radiotherapy for epidermoid carcinoma of the scalp and 1 died of large cell neuroendocrine carcinoma. RTX was effective in 5 (100%) patients with pulmonary involvement (clinical, radiological and functional stability and/or improvement); in 4 (100%) patients with renal involvement (clinical and analytical improvement); in 3 (100%) patients with arthritis complete improvement was obtained; in 2 (100%) patients with recurrent mumps relapse was avoided; in 1 (100%) patient with autoimmune hepatitis and lymphadenopathy clinical and radiological improvement was obtained. Of the three patients with dryness: 1 experienced subjective clinical improvement, 1 reported improvement coinciding with the use of therapeutic contact lenses and 1 improved only at the beginning. Subjective improvement in asthenia was observed in 4 patients. Complement levels normalized in 4 of 5 patients with hypocomplementemia as well as in 4 of 4 with increased B2-microglobulin; 3 of 6 patients with hypergammaglobulinemia normalized IgG value. No changes were observed in the four patients who were rheumatoid factor positive. 6 of 6 patients receiving corticosteroid treatment, reduced the dose by half and 1 achieved corticoid withdrawal.
Conclusion: The observed data suggest that RTX may be useful in selected patients with pSS. Further research is needed to determine its efficacy.

AB0431 THE EFFICACY OF BELIMUMAB (BEL) AS A SPARING CORTICOSTEROID AGENCY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

K. Inoue[1,2], K. Misaki[1,2], N. Dobashi[1,2], M. Yabe[1,2], Y. Mako[1,2], Y. Tarutani[1,2], Y. Imaizumi[2]. *[1]Kita-Harima Medical Center, Rheumatology, Ono, Japan; [2]Kita-Harima Medical Center, Rheumatology Center, Ono, Japan*

Background: Patients with SLE are recommended to continue the maintenance therapy with as less glucocorticoid as possible.1) However, tapering glucocorticoid often results in the recurrence of SLE. Current reports suggested that adding BEL to the standard therapy could lead to the reduction of glucocorticoid and the recurrence of SLE.2)
Objectives: The aim of this study is to evaluate the efficacy and the safety of BEL as co-treatment in the standard therapy of SLE.
Methods: Fourteen patients receiving the maintenance therapy of SLE were enrolled in this study. Dose of prednisolone (PSL), titer of anti-DNA antibody, WBC count, serum complement and SLE disease activity index (SLEDAI) were examined retrospectively at baseline and 24 months after administration of BEL.
Results: At the baseline, the mean age of patients was 48 years old, 11 patients were female, and the mean disease duration was 8.6 years. The mean dose of PSL was significantly reduced (meansease apre-administration of BEL:6.1±1.1 mg/day, 24 months after administration of BEL: 1.2 the baseline,*p=0.001*). Furthermore, six patients (43 %) could withdraw PSL without the flare of the disease. There were also statistical significance about SLEDAI between baseline and after treatment by BEL(2.1patients (43 %) c*p=0.03*) and the titer of anti-DNA antibody (6.8 withdraw PSL without t*p=0.03*). There were no statistical significant in WBC count (6177out the fla7e of the d*p=0.24*) and serum complement (C3 87significant in WBC count (61*p=0.78*, C4 20erum complement (C3 87signif*p=0.54*). As for adverse event, bacterial pneumonia (n=1) and pulmonary cryptococcosis (n=1) was revealed.
Conclusion: Our study is suggested that co-treatment with BEL on standard SLE therapy was enable to prevent the flare of SLE and reduce the dose of PSL with statistical significance among the patients under the maintenance treatment of SLE. In almost half of the cases, patients could withdraw PSL without the flare.

AB0432 EFAVALEUKIN ALFA, A NOVEL IL-2 MUTEIN, SELECTIVELY EXPANDS REGULATORY T CELLS IN PATIENTS WITH SLE: FINAL RESULTS OF A PHASE 1B MULTIPLE ASCENDING DOSE STUDY

N. Tchao[1], N. Sarkar[2], X. Hu[2], R. Zhang[3], C. Milmont[3], Y. Shi Jin[4], V. Chow[5], M. Kroenke[6], K. Gorski[2], R. Furie[7], A. Kivitz[8], S. Cohen[9]. *[1]Amgen Inc., Early Development, South San Francisco, United States of America; [2]Amgen Inc., Clinical Biomarkers, South San Francisco, United States of America; [3]Amgen Inc., Global Biostatistical Science, Thousand Oaks, United States of America; [4]Amgen Inc., Global Patient Safety, Thousand Oaks, United States of America; [5]Amgen Inc., Clinical Pharmacology M&S, Thousand Oaks, United States of America; [6]Amgen Inc., Clinical Immunology, Thousand Oaks, United States of America; [7]Northwell Health and Donald and Barbara Zucker School of Medicine at Hofstra-Northwell, Rheumatology, Great Neck, United States of America; [8]Altoona Center for Clinical Research, Rheumatology, Duncansville, United States of America; [9]Metroplex Clinical Research Center, Rheumatology, Dallas, United States of America*

Background: Defects in regulatory T cell (Treg) number and function are associated with autoimmune diseases including SLE. Interleukin (IL)-2 is essential for the development and suppressive function of Treg, and therapies that exploit the ability of IL-2 to expand Treg have shown disease-modifying potential in SLE[1]. However, low-dose IL-2 has a short half-life and narrow selectivity for Treg over conventional CD4+ T cells (Tcon) and natural killer (NK) cells. Efavaleukin alfa is an IL-2 mutein Fc fusion protein; an introduced mutation decreases binding to IL-2Rβ and increases dependence on IL-2Rα (CD25). This preferential binding to the high-affinity IL-2R, constitutively expressed at high levels on Treg, leads to increased cell surface retention and sustained Treg signaling compared with recombinant IL-2. In healthy subjects, a single dose of efavaleukin alfa was well tolerated and led to robust and selective Treg expansion[2].
Objectives: This final analysis of a phase 1b, double-blind, placebo-controlled, multiple ascending dose study (NCT03451422) reports the safety, tolerability, pharmacokinetics (PK), and pharmacodynamic effects of efavaleukin alfa in patients with SLE.
Methods: The study included five ascending dose cohorts (cohort 1=lowest dose; cohort 5=highest dose). A total of 35 patients with SLE (age 24–71 years; 85.7% female; SLE diagnosed using SLICC or ACR criteria with ANA ≥1:80 and/or elevated anti-dsDNA antibodies) were randomized to receive efavaleukin alfa or placebo (5:2 ratio for cohorts 1–3; 3:1 ratio for cohorts 4–5) subcutaneously every 2 weeks (Q2W; cohorts 1, 2, 4, and 5) or every week (QW; cohort 3) in addition to standard of care therapy for a total of 12 weeks, with 6 weeks of follow-up. The primary endpoint was the incidence of treatment-emergent adverse events (TEAEs). Additional endpoints included serum PK of efavaleukin alfa and changes in numbers of Treg, CD4+ Tcon, CD8+ T cells, and NK cells in peripheral blood.
Results: The most commonly reported TEAEs (occurring in ≥25% of efavaleukin alfa-treated subjects) included non-serious, mild or moderate (grade 1–2) injection site reactions. No grade 4 TEAEs or deaths occurred. Two serious AEs were reported in efavaleukin alfa-treated subjects: one event of syncope (grade 3) was observed in cohort 2 and was not considered related to treatment, and one case of eosinophilia (grade 2) was observed in cohort 5 and was considered related to treatment. Efavaleukin alfa PK was generally linear and dose-proportional, with a terminal half-life ranging from 18–30 hours. Peak Foxp3+ Treg expansion was observed at 8 days post-dose, and the magnitude of the peak was generally sustained after multiple QW or Q2W doses. The mean peak increases in Foxp3+ Treg were 14.8-, 17.4-, 5.7-, 2.4-, and 1.1-fold above baseline for efavaleukin alfa Q2W dosing cohorts 5, 4, 2, and 1 and placebo, respectively. At the final study assessment (42 days after the last dose), the mean Treg count was 1.3-fold above baseline (95% CI, 0.9–1.9). Treatment with efavaleukin alfa also expanded CD25^{bright} Treg (peak 53.8-fold change) and CD31+ recent thymic emigrant (RTE), naïve, and memory Treg subsets. At the highest dose (cohort 5), low-level increases in numbers of CD4+ Tcon (peak 2.3-fold), CD8+ T cells (peak 2.1-fold), and NK cells (peak 2.9-fold) were observed.
Conclusion: Multiple ascending doses of efavaleukin alfa were safe and well tolerated and led to selective and prolonged Treg expansion in SLE patients. Results at the highest dose suggest a plateau in Treg expansion with low-level increases in other IL-2–responsive cells, although interpretation is limited due to small subject numbers. The highest tested dose may be outside the therapeutic window and thus will not be assessed in phase 2 clinical studies. These findings confirm and extend previous results in healthy subjects and support the ongoing phase 2b adaptive randomized controlled trial in patients with SLE.

AB0433 ANTI-RITUXIMAB ANTIBODIES DEMONSTRATE NEUTRALISING CAPACITY, ASSOCIATE WITH LOWER CIRCULATING DRUG LEVELS AND EARLY RELAPSE IN PATIENTS UNDERGOING TREATMENT FOR SYSTEMIC LUPUS ERYTHEMATOSUS

C. Wincup[1], N. Dunn[2,3], C. Ruetsch-Chelli[4,5], A. Manouchehrinia[2,3], N. Kharlamova[2], M. Naja[1], B. Seitz-Polski[4,6], D. Isenberg[1], A. Fogdell-Hahn[2,3], C. Ciurtin[1], E. Jury[1]. *[1]University College London, Rheumatology, London, United Kingdom; [2]Karolinska Institute, Department of of Clinical Neuroscience, Stockholm, Sweden; [3]Karolinska University Hospital, Center for Molecular Medicine, Stockholm, Sweden; [4]Université Côte d'Azur, Laboratoire d'Immunologie, Nice, France; [5]Université Côte d'Azur, Centre Méditerranéen de Médecine Moléculaire (C3M), Nice, France; [6]Université Côte d'Azur, Unité de Recherche Clinique de la Côte d'Azur (UR2CA), Nice, France*

Background: A major limitation of biologic therapy is formation of anti-drug antibodies (ADA). We previously found ADA to rituximab (RTX) are more prevalent in patients undergoing treatment for systemic lupus erythematosus (SLE) than rheumatoid arthritis and vasculitis (1). In addition, we demonstrated that ADA to RTX predict subsequent infusion related reactions (2). However, little is known regarding the long-term dynamics of ADA to RTX in patients undergoing treatment for SLE.
Objectives: In this study we evaluated the longitudinal impact of ADA positivity with particular focus on; 1) Risk factors for development of ADA. 2) Impact of ADA on treatment response. 3) Influence of ADA on RTX drug kinetics over time. 4) The capacity of ADA to neutralise RTX.
Methods: Patients with SLE undergoing treatment with RTX were recruited to this study (n=35). Serum samples were collected at the following intervals post-treatment; 1-3 months (defined as 'early' post-treatment), 6 months, 12 months, 36 months (n=114).
Clinical and laboratory data was collected pre-treatment and at each follow-up time point. Response to treatment was assessed by improvement in SLEDAI-2K score from baseline and also according to BILAG as previously described (3).
ADA were detected using an electrochemiluminescent immunoassay. Serum RTX levels were measured by ELISA. ADA status was defined according to the following patterns over time; persistently negative, persistently positive (0-15 AU/ml) and persistently high positive (≥16 AU/ml, upper quartile). A complement dependent cytotoxic assay was used to determine neutralising capability of ADA in a subgroup of positive samples (n=38).

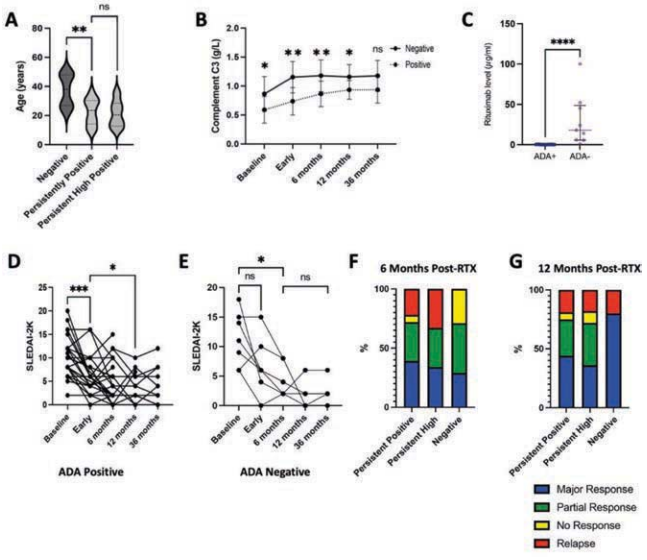

Figure 1.

Results: ADA to RTX were found to be persistently positive in 64.3% of patients over the 36-month follow-up period and there was no significant difference in baseline disease activity (BILAG / SLEDAI-2K) between those who were subsequently ADA positive vs negative. ADA positive patients had a younger age at diagnosis of SLE when compared with ADA negative (mean 22.50 ± 9.10 vs 37.29 ± 11.31 years, p=0.002, Figure 1 A). Multivariate logistic regression found a 22% decrease in risk of ADA positivity for each addition year after diagnosis (p=0.03).

ADA positive patients had a significantly lower C3 level at baseline (mean 0.61 ± 0.23 g/L vs 0.87 ± 0.30 g/L, p=0.026), which remained lower at each subsequent time point post-treatment up to 12 months post-treatment (Figure 1B).

At 1-3 months post-RTX, patients who were ADA positive had a significantly lower circulating drug level than ADA negative (p<0.001, Figure 1 C).

In terms of clinical response, ADA positive patients had an initial significant improvement in disease activity (SLEDAI-2K) by 3 months (p<0.001). However, response was not maintained at 12 months (Figure 1 D). In comparison, ADA negative patients showed a significant improvement in SLEDAI-2K at 6 months and this was maintained across the 36-month follow-up period (Figure 1 E).

BILAG defined relapse was more common at six months post-treatment in ADA positive patients (22%) and ADA highly positive patients (33%) than those who were ADA negative (in which there were no cases of relapse within the first six months, Figure 1 F). At 12-months post-RTX, a higher rate of BILAG defined Major Response was seen in those who were ADA negative (80%) when compared with ADA positive (44%) and high positive (36%) as shown in Figure 1 G.

Finally, antibodies derived from all ADA positive samples (38/38) were found to neutralise RTX *in vitro*.

Conclusion: ADA to RTX were common and persisted over the 36-month period of this study. ADA associated with earlier serum drug elimination, increased relapse rates and demonstrated neutralising capacity suggesting that ADA could be a significant limitation to sustained response to treatment in clinical practice.

AB0434 EFFICACY AND SAFETY OF OBINUTUZUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH SECONDARY NON-RESPONSE TO RITUXIMAB.

J. Arnold[1,2], S. Dass[1,2], S. Twigg[3], C. Jones[4], B. Rhodes[5], P. Hewins[6], M. Chakravorty[7], P. Courtney[7], M. Ehrenstein[8], M. Y. Md. Yusof[1,2], E. Vital[1,2].

Background: Secondary inefficacy characterized by infusion reactions and anti-drug antibodies occur in 14% of SLE patients treated with repeat rituximab courses(1). Obinutuzumab is a next-generation humanized type-2 anti-CD20 therapy licensed for hematological malignancies which may overcome this issue(2).

Objectives: We set out to evaluate the clinical efficacy and safety of obinutuzumab in a cohort of rituximab resistant SLE patients.

Methods: We collated data from SLE patients receiving obinutuzumab for secondary non-response to rituximab in BILAG centres. Disease activity was assessed using BILAG-2004, SLEDAI-2K and serology before, and 6 months after, obinutuzumab 2x1000mg infusions alongside methylprednisolone 100mg. Flow cytometry where possible was carried out using a multiple gating highly sensitive strategy.

Results: All 9 patients included in the study received obinutuzumab alongside concomitant oral immunosuppression. At 6 months post-obinutuzumab, there were significant reductions in median SLEDAI-2K from 12 to 6 (p=0.014) and total BILAG-2004 score from 21 to 2 (p=0.009). Complement C3 and dsDNA titres improved significantly (both p=0.04). Non statistically significant numerical improvements were seen in C4 levels.

Of 8/9 patients receiving concomitant oral prednisolone at baseline (all >10mg/day), 5/9 had their dose reduced at 6 months; 4/8 were on 5mg/day and were in Lupus Low Disease Activity State. After obinutuzumab, 6/9 patients with peripheral B-cell data achieved complete depletion including 4/4 assessed with highly sensitive assays. 1/9 obinutuzumab non-responder required cyclophosphamide therapy. 1 unvaccinated patient died from COVID-19.

Conclusion: Obinutuzumab appears to be effective and steroid-sparing in renal and non-renal SLE patients with secondary non-response to rituximab. Obinutuzumab was shown to be effective in patients with severe renal and non-renal disease. Therefore, in those with previous responsiveness to B-cell depletion, switching to humanised type-2 anti-CD20 therapy is a logical approach following loss off efficacy.

since 2011, but it had no lupus nephritis (NL) indication. Recently, promising results from a controlled Belimumab trial in LN were published.

Objectives: To analyze effectiveness of Belimumab in LN patients under follow-up by the rheumatology department of a tertiary hospital.

Methods: Observational, retrospective and cross-sectional study including SLE patients (SLICC/ACR 2012 criteria) treated with subcutaneous and/or intravenous Belimumab. Demographic and serological data, concomitant treatment, kidney function and urine sediment were collected.

Results: Sixteen patients with a median age of 47.56 (11.66) years and with 5.40 (0.55) years since Belimumab onset were included. Five patients had LN demonstrated by kidney biopsy and they were included on analysis data. In this group, median age was 39 (6.96) years, patients had 17.80 (10.38) years since SLE diagnosis and 6.6 (0,89) years since Belimumab onset. The most prevalent nephritis type was III and IV, only one patient presented V type.

Regarding the treatment, every patient received antimalarial drugs (cloroquine 40%, hydroxicloroquine 60%) and mycophenolic acid. Concerning the corticosteroid therapy, all patients receive prednisone, with an average dose of 4 mg per day.

The results obtained were included in the Table 1.

Conclusion: Belimumab can improve LN, in terms of serological activity, kidney function and urine sediment. It could be a promising option associated to standard therapy for SLE patients with kidney affection.

AB0436 EFFECTIVENESS OF BELIMUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A REAL-LIFE ANALYSIS

L. Picciariello[1], F. Ceccarelli[1], F. Natalucci[1], G. Olivieri[1], C. Pirone[1], V. Orefice[1], C. Garufi[1], F. R. Spinelli[1], R. Priori[1], C. Alessandri[1], F. Conti[1]. [1]*Sapienza University of Rome, Rheumatology, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*

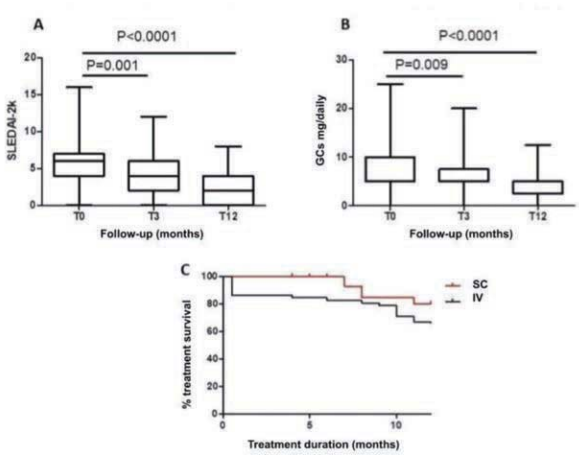
Background: Efficacy and safety of belimumab (BLM) in Systemic Lupus Erythematosus (SLE) patients with active disease have been demonstrated by RCTs [1,2] and confirmed by several observational studies [3-8]. Most of these data have been obtained by the use of BLM intravenous formulation (IV); on the contrary, very few findings are available on the use of the drug subcutaneous formulation (SC).

Objectives: Efficacy and drug survival of BLM have been assessed in a monocentric cohort of SLE patients, exploring any difference between the two routes of administration, IV or SC.

Methods: A longitudinal study on SLE patients (according to ACR 1997 classification criteria [9]) candidates for treatment with BLM has been performed. Demographic, clinical-laboratory and therapeutic data - including glucocorticoid dosage in prednisone-equivalent - have been collected. Disease activity has been assessed by SLEDAI-2k [10]; in patients with inflammatory articular involvement, DAS28-PCR [11] has been used. In compliance with the study protocol, patients were assessed at baseline and at 3 and 12 months after starting treatment.

Results: A total of 85 patients treated with BLM were enrolled, most of whom were female (male/female 2/83), with a median age of 48 years (IQR 13) and a median disease duration of 127 months (IQR 151). Fifty-one patients (60%) were treated with IV formulation and the remaining 34 (40%) with SC route. BLM was prescribed due to the following clinical manifestations: joint involvement (61.2%), cutaneous manifestations (20.0%), renal involvement (for residual proteinuria, 5.9%), haematological modifications (5.9%), constitutional involvement (3.5%), pericarditis (1.2%), headache (1.2%). In both the formulations, joint involvement was the most frequent indication of BLM (IV: 64.7%, SC: 58.8%). Median treatment duration was 15 months (IQR 24). Moving on drug efficacy, after 3 and 12 months of follow-up BLM has determined a significant reduction of SLEDAI-2k median values ($p=0.001$, $p<0.001$ respectively, Figure 1A) as well as of daily prednisone dose ($p=0.009$, $p<0.0001$ respectively, Figure 1B). In patients treated because of musculoskeletal manifestations, DAS28-PCR reduced significantly at 3 and 12 months after treatment ($p<0.0001$). Drug survival at 12 months was 70% in the total cohort (Figure 1C) and was higher in patients treated with SC formulation than with IV route (75.8% *versus* 66.5%, p=ns). During the period of follow-up, 39 patients (45.9%) discontinued BLM: 38.4% of patients due to adverse events, 41% for primary or secondary inefficacy, 15% lost to follow-up, 5.1% for pregnancy. BLM withdrawal for adverse events was more frequent in the group of patients treated with IV formulation than SC one (25.9% *versus* 5.9%, p=0,0001). 11 patients switched from IV formulation to SC one after a median period of 40 months (IQR 20) without loss of efficacy or adverse events.

Figure 1: Change of SLEDAI-2k values (A) and glucocorticoids dosage (GCs - B), graphically represented by Box and Whisker plot; treatment survival calculated by Kaplan-Meier curve (C).



Conclusion: Our results confirm BLM efficacy also in a real-life setting. Notably, our data highlight a better drug survival in patients treated with SC formulation, mainly secondary to a less frequency of adverse events.

AB0437 MONTELUKAST AS A TREATMENT FOR REFRACTORY CUTANEOUS LUPUS ERYTHEMATOSUS: A CASE SERIES AND PROOF-OF-CONCEPT STUDY

F. A. Castro Rocha[1], I. Nogueira[1], R. Nunes[1], G. da Silva[1], C. Martins[2]. [1]*Faculdade de Medicina, Internal Medicine, Fortaleza, Brazil;* [2]*Faculdade de Medicina, Morphology, Fortaleza, Brazil*

Background: Treatment of cutaneous lupus relies mostly in avoidance of exposure to sunlight, steroids and hydroxychloroquine. A diverse array of cytokines and chemokines released by resident and migrating inflammatory cells have been implicated in the pathogenesis of skin damage in patients with systemic lupus erythematosus (SLE). Leukotrienes are potent lipid mediators involved in hypersensitivity reactions but very few data exist on their involvement in SLE.

Objectives: Our aim is to report a case series of SLE patients with refractory skin lesions that were successfully treated with sodium montelukast (MLK), a cysteinyl-leukotriene antagonist.

Methods: We present 4 consecutive female SLE patients with refractory skin lesions that were treated with MLK (10mg/d). Skin lesions were scored using

CLASI criteria. Peripheral blood mononuclear cells (PBMC) from those 4 SLE patients and 4 healthy age-matched female controls were collected and the relative expression of the 5-lipoxigenase (ALOX5) and 15-lipoxigenase (15LOX1R) genes against a reference gene (GAPDH) was assessed using a quantitative polymerase change reaction (qPCR) protocol.

Results: All four patients experienced improvement of skin lesions 2-4 weeks following initiation of MLK with over 50% reduction in severity using CLASI score. The response was sustained for at least 3 months follow-up and no adverse events were recorded. All but one of the patients relapsed following MLK withdrawal but response was recovered after restart of MLK. Expression of the ALOX5, but not of 15LOX1R, was significantly ($p<0.001$) increased in PBMC from SLE patients as compared to controls.

Conclusion: This is the first report of a fast and sustained successful response of cutaneous SLE to MLK. There were no safety issues. PBMC from SLE patients showed increased expression of the ALOX5gene. This case series suggests the involvement of MLK in cutaneous lupus and encourage designing a randomized trial.

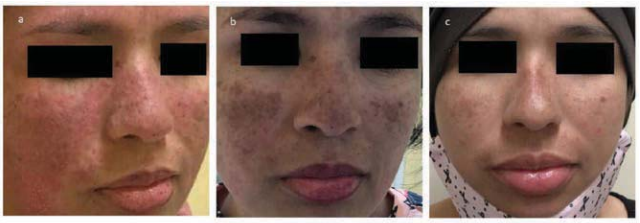

Figure 1 – Severe refractory butterfly rash prior (a) and after (b, c) MLK administration to a lupus patient

AB0438 EFFICACY OF BELIMUMAB TREATMENT FOR SYSTEMIC LUPUS ERYTHEMATOSUS AT OUR HOSPITAL

M. Mizusaki[1], R. Wakiya[1], S. Nakashima[1], H. Shimada[1], K. Sugihara[1], M. Kato[1], T. Miyagi[1], Y. Ushio[1], R. Mino[1], K. Chujo[1], T. Kameda[1], H. Dobashi[1].
[1]Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan

Background: Belimumab (BEL), a monoclonal antibody against the soluble counterpart of B-cell activating factor (BAFF) has been recommended to be added in patients with SLE who do not respond adequately to standard therapy [1]. In addition to antibody production, belimumab may also affect other functions of B cells, such as antigen presentation and excretion of inflammatory cytokines. Belimumab may also have an effect on immune cells other than B cells, as they express BAFF receptors. These facts suggest that BEL administration in SLE may have an effect on various pathological conditions including cytokine production, not just antibody production. However, there are few reports on whether cytokine production is actually related to the efficacy of BEL administration in SLE.

Objectives: The purpose of this study was to determine the efficacy of BEL administration in patients with SLE and its effect on cytokines.

Methods: Patients with SLE who were started on BEL between December 2018 and December 2021 at our institution were included in this study. We retrospectively analyzed the reasons for additional BEL administration, adverse events, disease activity indicators (SLE Disease Activity Index (SLEDAI)-2K, lupus low disease activity state (LLDAS) achievement rate, anti-dsDNA antibody titer, serum complement titer, and treatment agents including glucocorticoid dose. Serum cytokine (interferon-alpha, interleukin (IL)-6, IL-10, and IL-17A) levels were measured using ELISA at the start of BEL administration, 3 months, and 6 months later.

Results: Five cases of SLE were included in the study. Four of the five patients were female, with a mean age of 51.4±9.6 years and a mean duration of disease of 17.4±10.0 years. The reasons for additional BEL administration were glucocorticoid reduction in five patients, refractory pericarditis in one patient, skin rash and arthritis in two patients, and immunological activity in two patients. Four of the five patients had decreased renal function below eGFR50 at the baseline. Concomitant medications at the time of BEL induction included steroids in five patients (mean prednisolone dose 12.2±12.2 mg/day), hydroxychloroquine in three patients, mycophenolate mofetil in three patients, tacrolimus in one patient, and methotrexate in one patient. The mean disease activity before the introduction of BEL was SLEDAI 4±4, and LLDAS was achieved in three patients.

Twelve weeks after the start of BEL treatment, two patients had improved SLEDAI, including one patient who achieved LLDAS. Immunological activity parameters improved in one of the two patients. However, two patients flared after BEL administration and were treated with increased glucocorticoid doses. One patient with SLE on hemodialysis had thrombocytopenia, an adverse event that may have been related to belimumab treatment.

Conclusion: At our institution, BEL was additionally administered to SLE patients with refractory disease and was effective; with the exception of one case. Serum cytokine analysis before and after BEL treatment will be included in the discussion.

AB0439 COMPARATIVE EFFECTIVENESS OF RAPID AND CONVENTIONAL GLUCOCORTICOID TAPERING REGIMENS IN TREATING PATIENTS WITH PROLIFERATIVE LUPUS NEPHRITIS IN THE REAL WORLD SETTING

H. Shimizu[1,2], H. Oka[1,2], S. Sumitomo[1], M. Kanamori[2], C. Miyakoshi[3], A. Yoshimoto[4], H. Nishioka[2], K. Ohmura[1]. *[1]Kobe City Medical Center General Hospital, Department of Rheumatology, Kobe, Japan; [2]Kobe City Medical Center General Hospital, Department of General Internal Medicine, Kobe, Japan; [3]Kobe City Medical Center General Hospital, Department of Pediatrics, Kobe, Japan; [4]Kobe City Medical Center General Hospital, Department of Nephrology, Kobe, Japan*

Background: Rapid glucocorticoid (GC) tapering is recommended for lupus nephritis (LN) by 2019 EULAR/ERA-EDTA recommendations [1]. However, slower conventional GC tapering regimen is still common in the real world setting, and it is controversial whether a rapid GC tapering regimen is as effective as the conventional regimen.

Objectives: We aimed to compare the renal outcomes between rapid and slower GC tapering regimens in patients with LN.

Methods: We retrospectively surveyed the medical records of 27 patients with proliferative LN (class III or IV) at Kobe City Medical Center General Hospital. These patients were divided into two groups (rapid GC tapering group and conventional GC tapering group) according to GC dosage at month 6. Logistic regression analyses were performed to examine the association of GC tapering regimens with achievement of primary efficacy renal response (PERR) and complete renal response (CRR) which were defined by Furie et al. [2] at month 24.

Results: Twenty-seven patients (19 women and 8 men) with class III or IV LN were included. The mean age was 43 years. The mean eGFR and urine protein-to-creatinine ratio at baseline were 66.7 mL/min/1.73m^2 and 3.125 g/gCr, respectively. Concomitant class V LN was present in 26.0%. The rapid GC tapering group (PSL≦10 mg/day at month 6) and the conventional GC tapering group (PSL>10 mg/day at month 6) were 11 and 16 patients, respectively. Baseline characteristics were balanced between the two groups except for use of cyclophosphamide or mycophenolate mofetil. Mean urine protein-to-creatinine ratio at month 24 were 0.46 g/gCr in the rapid GC tapering regimen group and 1.08 g/gCr in the conventional GC tapering regimen group ($p=0.790$). Achievements of PERR and CRR at month 24 were 54.0% and 43.8% in the rapid GC tapering group and 54.5% and 25.0% in the conventional GC tapering group, respectively. After adjustment of cyclophosphamide or mycophenolate mofetil usage and urine protein-to-creatinine ratio at baseline, adjusted odds ratio was 1.52 (95% confidence interval [0.126 to 18.29], $p=0.743$) and 2.99 (95% confidence interval [0.34 to 28.52], $p=0.341$), respectively.

Conclusion: Our results suggest rapid GC tapering regimen is as effective as conventional slower tapering regimen for patients with proliferative LN.

AB0440 USE OF BELIMUMAB IN CLINICAL PRACTICE. CLINICAL AND SEROLOGICAL EFFECTIVENESS AND CORTICOSTEROID-SPARING ACTIVITY

S. Vela-Bernal[1], E. Fuertes[1], P. Albiol[1], I. de la Morena[2], C. Bea[1], A. I. de Gracia[1], A. de Castro[1], L. Navarro[1], M. J. Forner[1]. *[1]Hospital Clínico Universitario de Valencia, Internal Medicine, Valencia, Spain; [2]Hospital Clínico Universitario de Valencia, Rheumatology, Valencia, Spain*

Background: Since 2011, the use of Belimumab for the treatment of Systemic Lupus Erythematosus (SLE) has demonstrated efficacy and safety in several randomised clinical trials. However, strict inclusion criteria may restrict those results limiting the interpretation of these results to routine clinical practice populations.
Objectives: The aim of this study was to analyse the profile of patients using Belimumab as well as the clinical, serological and corticosteroid-sparing outcomes that may result from it use.
Methods: Retrospective cohort study including patients diagnosed with SLE and treated with Belimumab. Epidemiological, clinical and analytical data were collected at 6, 12 and 24 months before and after starting treatment with Belimumab. To assess effectiveness, the SELENA-SLEDAI, SLICC, clinical changes, concomitant treatments, corticosteroid dose and ds-DNA and C3-C4 levels were used.
Safety was evaluated by assessing the need and cause for discontinuation of Belimumab.
Results: Thirty-one patients were included, mostly 28 (90.32%) women, with a mean age of 48.55 ± 1.95 years and a mean time of disease progression since diagnosis of 16.13 ± 1.77 years. The most prevalent affection before initiation of Belimumab were joint (83.87%), systemic (58.06%), skin (29.03%) and nephropathy (22.58%). The mean SELENA-SLEDAI score before Belimumab was 5.32 ± 0.46; 64.5% had elevated anti-dsDNA, 48.39% and 54.84% had low C3 and C4 levels, respectively. Before starting Belimumab, the most used treatments were both antimalarials (72.4%) and corticosteroids (80.6%). The main reason for starting Belimumab was the ineffectiveness of previous treatments (67.7%). The vast majority of patients were treated subcutaneously (90.3%) and there were no major adverse events leading to drug withdrawal, with a median duration of use of 19.3 months (IQR: 9.75-35.55).
Conclusion: After starting Belimumab, a decrease in the SELENA-SLEDAI activity scale, an increase in C3 and C4 levels, and a significant decrease in anti-dsDNA levels at 6 months were observed. At 12 and 24 months, continuity of this trend was observed, although statistical significance was not reached. As concerns corticosteroids, we observed a decrease in steroid use below 7.5mg/day and even 5mg/day after the introduction of Belimumab avoiding the undesirable effects of prolonged steroid use.

Table 1.

	BEFORE BELIMUMAB (n=31)	6 MONTHS (n=28)	12 MONTHS (n=22)	24 MONTHS (n=9)
ESLEDAI x̄ (SD)	5,32 (0,46)	2,28 (0,44) P<0,001	2,90 (0,72) P<0,005	3,44 (1,39) p>0,05

Background: Over 80% of patients affected with SLE experience skin involvement. The anti-BLyS drug belimumab was shown effective in ameliorating mucocutaneous SLE manifestations in clinical trials and real-life studies. Cutaneous response is quantified through the CLASI (cutaneous lupus erythematosus area and severity index). Clinically relevant improvements are defined as decreases of ≥50% (CLASI50) or 70% (CLASI70) from baseline values.
Objectives: To assess rates and predictors of CLASI50 and CLASI70 in the Berliss multicentric SLE cohort[1] of patients treated with belimumab.
Methods: Baseline and ongoing features of patients with baseline active skin involvement (CLASI>0) were assessed in relationship to the chosen outcomes CLASI50 and CLASI70 at 24 and 52 weeks. A subanalysis on patients with CLASI≥5 was as well conducted. Logistic regression was employed to identify predictors of response.
Results: 172 patients displayed skin involvement at baseline (CLASI>0). Of those, 124 displayed at least a 12-month-follow-up and were included in the analysis. Seventy-seven (62.1%) patients reached CLASI50 at 24 weeks and 91 (77.8%) at 52 weeks; 87 (70.2%) reached CLASI70 at 24 and 99 (79.8%) at 52 weeks. Baseline predictors of CLASI50 at 24 weeks were CLASI-damage (CLASI-d) (OR [95%CI], p; 0.79 [0.65-0.98] 0.03) and disease duration (0.93[0.86-0.99], 0.011). No baseline predictors of CLASI70 at 24 weeks emerged, however having achieved a CLASI50 response at 24 weeks portended CLASI50 and 70 response through week 52 (p<0.01, Table 1). In the subgroup of patients with CLASI≥5, longer disease and increased CLASI-d at baseline confirmed as negative predictors of CLASI50 at 24 weeks. In this subset, use of antimalarials and active smoking at baseline predicted CLASI70 at 24 weeks (Table 1).

Table 1. Predictors of CLASI-A Response at Week 24 and 52 by Baseline CLASI-A at 50% and 70% Response Thresholds

Timepoint	Outcome	Variable	OR[95%CI] p
CLASI>0			
24 weeks	CLASI50	CLASI-d	0.79 [0.65-0.98] 0.030
		Disease duration	0.93[0.86-0.99], 0.011
	CLASI70	CLASI-d	0.93 [0.74-1.16], 0.51
		Disease duration	0.97 [0.97-1.02], 0.18
52 weeks	CLASI50	CLASI50 at 24 weeks	14.3[4.88-44.42], <0.001
	CLASI70	CLASI50 at 24 weeks	6.22 [2.00-19.34], 0.002
CLASI≥5			
24 weeks	CLASI50	CLASI-d	0.72 [0.53-0.98], 0.037
		Disease duration	0.93 [0.66-1.00], 0.071
	CLASI70	Antimalarials	6.61 [1.20-36.29] 0.032
		Smoking	0.15 [0.03-0.83], 0.034
52 weeks	CLASI50	CLASI50 at 24 weeks	22.0 [2.47-196.05], 0.006
	CLASI70	CLASI50 at 24 weeks	1.24 [0.06-25.08], 0.88

CLASI, cutaneous lupus erythematosus area and severity index; CLASI-d, CLASI damage; CLASI50 and CLASI70: decrease ≥50% or ≥70% in CLASI from baseline. OR and 95%CIs are estimated using a logistic regression model with stratification factors as covariates (SLEDAI-2K at baseline, baseline prednisone dosage).

Conclusion: Earlier use of belimumab favors achievement of skin response among SLE patients and attainment of a prompt response predicts further response. Use of antimalarials reinforces while smoking hampers a more profound CLASI improvement over time.

AB0442

EVEN IN SYSTEMIC LUPUS ERYTHEMATOSUS THAT HAS ACHIEVED SUSTAINED LLDAS, ADDITIONAL ADMINISTRATION OF HYDROXYCHLOROQUINE SHOULD BE CONSIDERED.

R. Wakiya[1], K. Ueeda[1], H. Shimada[1], S. Nakashima[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], M. Mizusaki[1], R. Mino[1], T. Kameda[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa, Japan*

Background: Hydroxychloroquine (HCQ) therapy is recommended as a baseline treatment for all patients with systemic lupus erythematosus (SLE) due to its various benefits (1). However, it is not clear to what extent HCQ contributes to improvement in SLE patients with stable disease activity. It has also been reported that HCQ is effective in improving the prognosis of life caused by atherosclerotic lesions in SLE, but the mechanism of this effect has not been fully elucidated.

Objectives: The purpose of this study was to determine the benefit of additional HCQ administration in SLE with controlled disease activity, who achieved the sustained LLDAS.

Methods: The study included patients with SLE who started additional HCQ treatment between January 2016 and December 2019 at our institution, those who sustained LLDAS achievement for at least 3 months prior to starting HCQ treatment. These patients did not change their immunosuppressant and glucocorticoid regimens for more than three months after starting HCQ. The effect of HCQ was assessed at the beginning and 3 months after administration. The disease activity was measured by SELENA-SLEDAI, SLE-DAS, and immunoserological parameters including serum complement levels and anti-DNA antibodies. The factors that are known to associated with pathogenesis of atherosclerosis, such as serum TNF-α, IL-6, IL-8, MCP-1, adiponectin, leptin, resistin, S100A8, and S100A9, were measured by ELISA.

Results: Of the 110 SLE patients who received additional HCQ at our institution, 27 patients who had achieved LLDAS from at least 3 months prior to HCQ administration were included in this study. Patient characteristics are represented in Table 1. SLEDAI scores, SLE-DAS scores and serum anti-dsDNA antibodies were observed to be significantly reduced after HCQ treatment compared to baseline. After 3 months of HCQ treatment, serum lipid markers such as triglyceride (TG), low-density lipoprotein (LDL) cholesterol and atherosclerotic index, which are associated with the development of atherosclerosis, were significantly reduced compared to baseline (TG, LDL and atherosclerotic index: p<0.05). Cytokines such as TNF-α, IL-6, MCP-1, S100A8, S100A9, leptin, and resistin were found to be significantly decreased, and serum adiponectin was significantly increased. (TNF-α, IL-6, MCP-1, leptin: p < 0.05. S100A8, S100A9, adiponectin, resistin: p < 0.0001, Figure 1).

Table 1. Characteristics of patients with SLE enrolled in this study.

Characteristics	N = 27
Female, no. (%)	24 (88.9)
Age, years, mean ± SD	44.4 ± 11.6
Disease duration, years, mean ± SD	18.3 ± 12.2
BMI, mean ± SD	21.9 ± 3.0
Concomitant immunosuppressive treatments	
Prednisone, no. (%)	n = 23
Median dosage, mg/day[#]	5 (3.0–5.0)
Triglyceride, mg/dL[#]	102 (73–149)
High-density lipoprotein cholesterol, mg/dL[#]	59 (43–66.5)
Low-density lipoprotein cholesterol, mg/dL[#]	108 (96–122)
Arteriosclerotic index[#]	2 (1.7–2.5)
Disease activity	
SLEDAI score[#]	4 (2–4)
SLE-DAS score[#]	2.076 (1.12–3.50)
Anti-dsDNA antibody, IU/ml[#]	5.2 (5–15.6)
dsDNA positive, no. (%)	10 (37.0)
C3, mg/dL[#]	76 (61–100)
C4, mg/dL[#]	14 (10–22)
CH50, U/mL[#]	34.1 (29.7–39.6)

[#]Nonparametric distributions were represented as median (interquartile range). Anti-dsDNA positive means that anti-dsDNA titer increases to >12 IU/mL.

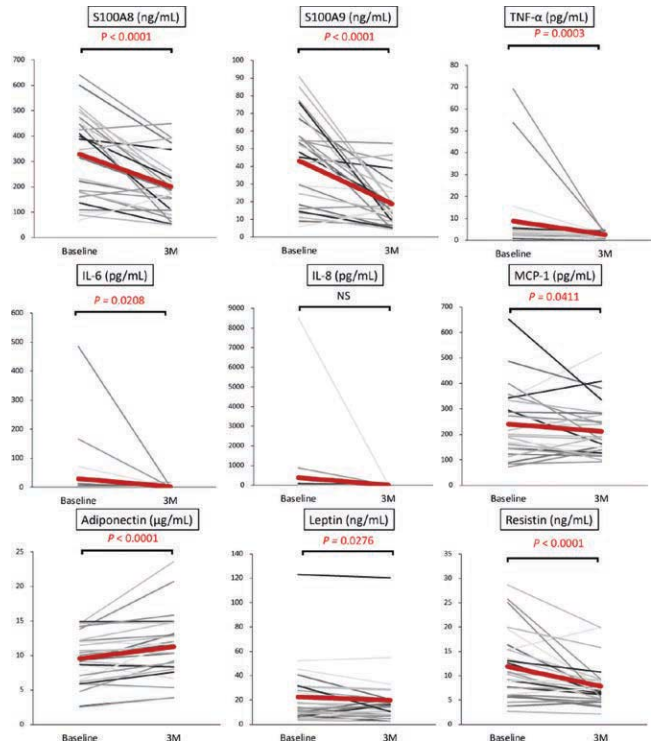

Figure 1. Serum cytokine levels before and after hydroxychloroquine treatment

Serum levels of the indicated cytokines and factors were measured at baseline and after 3 months (3M) of treatment with HCQ. The gray lines show the values for individual patients, and the thick red line shows the average value. P-values were determined using the Wilcoxon signed-rank test. A p-value of less than 0.05 was considered statistically significant.

Conclusion: The addition of HCQ medication to SLE patients who achieve the clinical therapeutic goal of LLDAS without HCQ may prevent progression of atherosclerosis in addition to further reducing disease activity.

AB0443 LONG-TERM OUTCOMES OF MULTITARGET THERAPY OF MYCOPHENOLATE MOFETIL AND TACROLIMUS IN LUPUS NEPHRITIS: A SINGLE CENTER RETROSPECTIVE ANALYSIS

Y. Imai[1], H. Ikeuchi[1], J. Suwa[1], Y. Ohishi[1], M. Watanabe[1], M. Nakasatomi[1], H. Hamatani[1], T. Sakairi[1], Y. Kaneko[1], K. Hiromura[1]. *[1]Gunma University Graduate School of Medicine, Gunma, Department of Nephrology and Rheumatology, Maebashi, Japan*

Background: Recent studies showed the efficacy of multitarget therapy with mycophenolate mofetil (MMF) and calcineurin inhibitor for induction therapy for lupus nephritis (LN)[1]. However, long-term outcomes have not been well elucidated.
Objectives: We retrospectively analyzed the long-term outcomes of multitarget therapy of MMF and tacrolimus.
Methods: We examined 27 LN patients (4 male, 23 female) treated with multitarget therapy for induction therapy between Oct. 2009 and Nov. 2018 in our department. Complete remission (CR) was defined as 1) UPCR<0.5 g/gCr, and 2) serum creatinine (S-Cr) normal or if abnormal, within 15% of baseline; 1) and 2) were observed in 2 consecutive visits. Relapse was defined as UPCR>1.0 g/gCr or intensification of immunosuppressive treatment after achievement of CR.
Results: The mean age was 38.6±11 . 6 years old. 17 patients were new-onset LN, and 10 patients were relapse LN. UPCR and eGFR before treatment were 4.42±2.98 g/gCr and 71.5±32.9 mL/min/1.73m^2, respectively. Renal histology was Class III in 1, III+V in 4 , IV in 12. IV+V in 9 and V in 1 by ISN/RPS 2003 classification. CR at 6 and 12 months were 59% and 74%, respectively. Patients were treated by multitarget therapy for median of 25 months (IQR, 5.5-37). Finally, 26 (96%) patients achieved CR. During multitarget therapy, there were 15 serious adverse events: deep vein thrombosis in 2, myocardial infarctions in 2, cervical intraepithelial neoplasia in 2, heart failure in 1, herpes zoster in 1, viral myocarditis in 1, cytomegalovirus gastroenteritis in 1, cholecystitis in 1, pyelonephritis in 1, bacterial enteritis in 1, sepsis in 1, and breast cancer in 1. During the median observation period of 94 months (IQR, 63-111.5) after the initiation of multitarget therapy, 1 patient died due to sudden death. No patient reached end-stage kidney disease or doubling S-Cr. 16 patients relapsed at median of 32 months (IQR,13.8-64.5) after CR; 8 patients relapsed on multitarget therapy, and 8 patients relapsed after cessation of multitarget therapy. Relapse was associated with chronic lesions in renal biopsy and normal or higher C4 levels at treatment initiation by Kaplan Meier analysis (Log-rank, P=0.006, P<0.001, respectively).
Conclusion: Multitarget therapy effectively induced CR and maintained renal function in long-term period. However, relapse was often observed during or after withdrawal of multitarget therapy.

AB0444 ENPATORAN: PRECLINICAL EVIDENCE SUPPORTING GLUCOCORTICOID DOSE REDUCTION AND PHASE II STUDY DESIGN IN PATIENTS WITH SLE AND/OR CLE (WILLOW)

E. F. Morand[1], A. Bender[2], A. Deshpande[2], B. Vaidyanathan[2], C. Vazquez Mateo[3], M. Przetak[2], F. Moreau[4], M. Khursheed[5], S. Roy[6], D. Pearson[7]. *[1]Centre for Inflammatory Disease, Monash University, Melbourne, Australia; [2]EMD Serono Research & Development Institute, Inc., an Affiliate of Merck KGaA, TIP Immunology, Billerica, United States of America; [3]EMD Serono Research & Development Institute, Inc., an Affiliate of Merck KGaA, Global Clinical Development, Billerica, United States of America; [4]EMD Serono Research & Development Institute, Inc., an Affiliate of Merck KGaA, Global Biostatistics, Billerica, United States of America; [5]Merck Serono Ltd., an Affiliate of Merck KGaA, Global Patient Safety, Feltham, United Kingdom; [6]Ares Trading SA, an Affiliate of Merck KGaA, Global Clinical Development, Eysins, Switzerland; [7]University of Minnesota, Department of Dermatology, Minneapolis, United States of America*

Background: Enpatoran is a potent selective dual inhibitor of toll-like receptor (TLR) 7 and TLR8, aberrant activation of which may be involved in systemic lupus erythematosus (SLE) pathogenesis and glucocorticoid resistance.[1,2,3] Enpatoran suppressed disease development in lupus mouse models, improving survival and reducing proteinuria, autoantibodies, and the interferon (IFN) gene signature.[1] In healthy participants and patients hospitalized with COVID-19 pneumonia, enpatoran was well tolerated and demonstrated effective TLR7/8 engagement.[4] Enpatoran is potentially glucocorticoid sparing and may help avoid the detrimental effects of long-term corticosteroid use in SLE management.[5,6]
Objectives: To evaluate the glucocorticoid-sparing effect of enpatoran and design a basket trial to assess its efficacy and safety in patients with SLE and/or cutaneous lupus erythematosus (CLE).
Methods: Cytokine concentrations and gene expression changes were measured in stimulated human peripheral blood mononuclear cells (PBMCs) from healthy donors after treatment with dexamethasone, TLR7/8 inhibitor, or both. A Phase II, basket design proof-of-concept, dose-finding study in patients with SLE and/or CLE (WILLOW) was designed.
Results: In healthy donor PBMCs, synergy was observed between TLR7/8 inhibitor and dexamethasone. Combination treatment inhibited cytokine release (IL-6) with greater potency than either treatment alone and reduced the expression of nuclear factor-kappa B and IFN-regulated genes. WILLOW is a Phase II, basket proof-of-concept, dose-finding, randomized, double-blind, placebo (PBO)-controlled 24-week study with two cohorts (NCT05162586, Figure 1). The primary objectives of WILLOW are to evaluate the dose–response relationship of enpatoran in reducing disease activity based on Cutaneous Lupus Erythematosus Disease Area and Severity Index-A (CLASI-A) or BILAG-Based Composite Lupus Assessment (BICLA) response rate. The secondary objectives are to investigate effects on both BICLA response and clinically meaningful corticosteroid reduction and evaluate disease control (including clinically meaningful corticosteroid reduction) in patients with predominantly active CLE or SLE. Cohort A will enroll patients with CLE (active subacute CLE and/or discoid LE) or SLE with predominantly active lupus rash. Cohort B, in two parts, will enroll SLE patients with moderate to severe systemic disease activity. Part 1 will assess clinical signal and Part 2 may be adapted to improve dose finding. Glucocorticoid-sparing will be evaluated by mandatory tapering to a prednisone-equivalent dose of ≤5 mg/day.

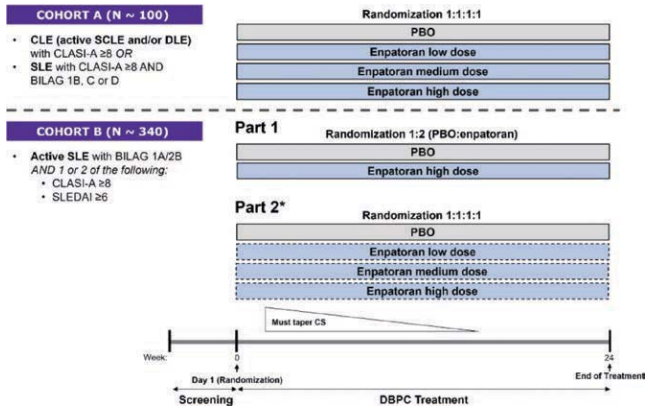

Figure 1. WILLOW study design. Cohort A and Cohort B Part 1 will start in parallel. *Part 2 will be initiated after a pre-specified number of patients are enrolled in Part 1; enpatoran doses in Part 2 may be adapted to improve dose finding (dashed boxes). BILAG, British Isles Lupus Assessment Group; CLASI-A, Cutaneous Lupus Erythematosus Disease Area and Severity Index-A; CLE, cutaneous lupus erythematosus; CS, corticosteroid; DBPC, double-blind placebo-controlled; DLE, discoid lupus erythematosus; PBO, placebo; SCLE, Subacute cutaneous lupus erythematosus; SLE, systemic lupus erythematosus; SLEDAI, Systemic Lupus Erythematosus Disease Activity Index.

Conclusion: Enpatoran is a novel TLR7/8 inhibitor and may enable glucocorticoid dose reduction in patients with SLE and CLE. The WILLOW study incorporates multiple novel elements including a basket design and evaluation of glucocorticoid-sparing.

AB0445 THE BENEFICIAL EFFECTS OF THERAPY ON OBSTETRICAL OUTCOME AND PLACENTAL HISTOLOGY IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: THE EXPERIENCE OF A SINGLE ITALIAN REFERENCE CENTER

V. Canti[1,1,2], G. Inguscio[1], N. P. Tenace[1], R. Lucianò[3], R. De Lorenzo[1], M. B. Cilona[1], M. Pozzoni[4], P. I. Cavoretto[1,1], M. T. Castiglioni[4], P. Rovere-Querini[1,2]on behalf of 'Pregnancy at risk' multidisciplinary outpatient clinics.
[1]Università Vita-Salute San Raffaele, Università Vita-Salute San Raffaele, Milan, Italy; [2]IRCCS Ospedale San Raffaele, Internal Medicine, Milan, Italy; [3]IRCCS Ospedale San Raffaele, Pathological Anatomy, Milan, Italy; [4]IRCCS Ospedale San Raffaele, Obstetrics and Gynecology, Milan, Italy

Background: Abnormal placentation plays a crucial role in the pathogenesis of obstetric morbidity in antiphospholipid antibodies syndrome (APS). Placenta is the main target of aPL in obstetric APS, inducing placental thrombosis, inflammatory response and placental dysfunction.
Standard treatment for APS patients during pregnancy includes low-dose aspirin (LDA) plus low molecular weight heparin (LMWH) and, in refractory cases, additional therapies such as hydroxychloroquine (HCQ).
A systematic review of the literature has found five main pathological lesions in the placenta of APS patients: placental infarction, decidual vasculopathy, decidual inflammation, increase of syncytial knots due to syncytiotrophoblast death, and decrease in vasculosyncytial membranes.
Objectives: To analyze placental histology in a group of 23 spontaneously conceived pregnancies in patients with definite APS prospectively followed in a single Italian reference center.
Methods: We analyzed 25 placenta in 23 spontaneously conceived pregnancies in patients with definite APS prospectively followed in the 'Pregnancy at risk' multidisciplinary outpatient clinics at San Raffaele Hospital, Milan, Italy from January 2017 to May 2021. During each trimester of gestation, ultrasonography with Uterine artery Doppler velocimetry was performed. Histological analysis of the placenta was carried out after delivery and placental tissues were examined for the main aforementioned histopathological findings. Statistical relations among clinical and ultrasound evaluations during each trimester, therapeutic approach and placental histology were performed.
Results: 19/25 (76%) patients had primary APS, while 6 patients had APS secondary to SLE. All patients were treated with LDA and LMWH. HCQ was added in a group of patients with concomitant systemic lupus erythematosus (SLE) or in refractory APS. Mean placental weight was 441 ± 129 grams. Histological analysis of placental tissues revealed increased syncytial knots in 17/25 (68%) placenta, decreased vasculosyncytial membranes in 11/25 (44%), infarction in 8/25 (32%), presence of macrophages and decidual inflammation in 2/25 (8%), and atherosis or reduction of spiral arteries remodelling in 3/25 (12%) placenta. Moreover, we observed at least 2 concomitant placental lesions in 12/25 (48%) placentas.
No statistical association between mean UtA-PI values and the number and type of placental lesions described at the histologic analysis were observed. We found a positive correlation between mean titer of aCL IgG, aβ2GPI IgG, aPS/PT IgM and/or aPS/PT IgG and number of placental lesions, and a significant association between aPS/PT IgM and/or IgG mean titer and presence of infarcted areas at placental histology. Moreover, in the placenta of patients treated with HCQ we did not observe any decidual inflammation at histology.
Conclusion: In our study we found some important clinical-pathological correlations between placental histology, clinical evaluations, ultrasound assessments and treatment received during pregnancy. Specifically, it is tempting to speculate that HCQ may have beneficial effects on pregnancy by decreasing the risk of deciduitis in patients with APS.
Further studies on larger numbers of placenta in APS patients will be needed to confirm our findings.

AB0446 IMPROVEMENT OF BELIMUMAB ON QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Yi[1], S. Zheng[1], X. Guo[1], M. Liu[1], T. Li[1,2]. *[1]Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; [2]Zhaoqing Central People's Hospital, Department of Rheumatology and Immunology, Zhaoqing, China*

Background: Accumulating evidence supports an impaired quality of life in patients with systemic lupus erythematosus (SLE). A study reported the patients concerns centred on fatigue[1].
Objectives: We investigated the effect of belimumab on quality of life in patients with SLE.
Methods: SLE patients from Guangdong Second Provincial General Hospital treated with belimumab (n=19) or control group (n=22) were included. Patients in control group were in traditional treatment without belimumab. Data were collected prospectively at treatment initiation and now, including Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), Pittsburgh Sleep Quality Index (PSQI) and the SF-36 (Table 1).

Table 1.

	SLEDAI		P	PSQI		P	SF-36		P
Group	Pre-treatment	Post-treatment	-	Pre-treatment	Post-treatment	-	Pre-treatment	Post-treatment	-
Belimumab group	11± 4.67	6.11± 3.55	0.001	6± 3.83	3.58± 2.01	0.02	519.47± 187.79	685.62± 141.78	0.004
Control group	8.82± 5.69	3.55±2.11	0.000	6.5± 3.52	5.86± 3.24	0.536	541.73±185.22	700.42± 123.90	0.002
P	0.199	0.007	-	0.665	0.011	-	0.705	0.723	-

Results: Belimumab group showed improvement in SLEDAI, PSQI and the SF-36 ($P < 0.05$). Control group was improvement in SLEDAI and the SF-36 ($P < 0.05$), no changes in PSQI (P=0.536). However, the improvement of belimumab group in SLEDAI and PSQI observably outperformed the improvement of control group.
Conclusion: Belimumab effectively improve quality of life in patients with SLE. Further study of pediatric patients with SLE is still warranted.

AB0447 LUPUS NEPHRITIS OUTCOMES AFTER DISCONTINUATION OF IMMUNOSUPPRESSION

F. Alenzi[1], S. Sangle[2], D. D'cruz[2]. *[1]College of Medicine, Princess Nourah bint Abdulrahman University, Clinical Sciences Department, Riyadh, Saudi Arabia; [2]Guy's and St.Thomas' Hospital, NHS Foundation Trust, Louise Coote Lupus Unit, London, United Kingdom*

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupuserythematosus (SLE).Immunosuppression (IS) is the standard of care therapy for lupusnephritis(LN).Data on the outcomes of LN patients after discontinuation ofimmunosuppression remain uncertain.

Objectives: To assess the outcomes of patients with LN after discontinuation of immunosuppression.
Methods: Clinical and laboratory data were retrospectively collected on LN patients attending our Lupus Unit.We included 45 patients(41had biopsy confirmedLN)who were treated with immunosuppression including cyclophosphamide, mycophenolate, azathioprine,methotrexate, and/or rituximab.Numeric response variables(median and range)including age, disease duration and length of treatment were collected.Frequencies and percentages categorical variables including gender, ethnicity, lupus nephritis class, autoantibodies, laboratory features, IS therapy used and patients' outcomes (stable versus flared) were analysed.LN flares were defined as: doubling of serum creatinine concentrations and increases in proteinuria after discontinuation of IS.Chi-square tests were applied to comparethese categorical variables between patient's outcomes.Reasons for IS discontinuation: remission, pregnancy planning and patients preference.
Results: We identified the outcomes of 45LN patients who stopped IS therapy. The median age of patients was 55(29 -78)years. The median durationof diseasewas 26.5(15-58)years whereas the median treatment duration was 4(1/2-14) years.Thirty (66.7%)patients were Caucasian ethnicity.Seventeen of 45patients received treatment for more than 5 years.There was only 1(2.2%)male patient in our study. At IS discontinuation, creatinine levels were elevated in9/45 (2%) patient and median creatinine values were 73(41-117umol/L).Median proteinuria values were 20mg/mmol (5-934)(p=0.00).LN histology: classV(24.4%),IV 17.8%and III(17.8%)and eleven patients had a combination of class III IV. Thirteen of 45 (28.9%)patients had relapses after discontinuation of IS. Median time to LN flare was 3(1-17) years and median age of the flared patients was58 years(41-70)years.Median creatinine values and median proteinuria of the flared patients were78(41-111umol/L),361.5 mg/mmol(12-908)respectively.Of these 13relapsed LN patients,4had class III,4had class V and the other patients had combinations of classes.Anti-Sm antibodies were more likely to be associated with relapses(6 patients) compared to stable patients(4 patients)(6% vs.40%) (p=0.030).Anti-*dsDNA* antibodies were positive in 22/32 stable patients(68.8%)compared to 10/13(31.3%)relapsed patients (p=NS).Among 13flared patients, 5 (38.5%)had high creatinine levels and 8(61.5%)had normal serum creatinines(p=0.048)on discontinuation of IS. Of 45 patients,12 had low complement C3, of whom 7(58.3 %) flared and 5(41.7%) were stable(p=0.009).Similarly, of 12patients with lowC4, 8(66.7%)flared compared to 4with stable outcomes(33.3%)p=0.001 .A higher proportion of patients previously taking azathioprine relapsed compared to those with previous use of cyclophosphamide or MMF 30.8%vs15.4%(p=0.011) respectively.
Conclusion: Our data suggests that two thirds of our patients experienced clinical remission with stable LN following cessation of IS therapy for LN.Patients who had elevated serum creatinine values, persistent proteinuria, low complement, positive anti Sm antibodies and previous azathioprine use were more likely to flare after stopping IS.Anti-*dsDNA* antibodies levels did not predict flares after stopping IS.Further prospective studies with larger sample sizes and longer follow-up are needed to estimate LN outcomes after discontinuation of immunosuppression.

Table 1. Patient's characteristics and lupus nephritis outcome

Parameters n (%)	Flared patients (N=13)	Stable patients (N=32)	P value
Abnormal creatinine	5(55.6%)	4(44.4%)	0.048
Significant UPCR	8(88.9%)	1(11.1)	0.000
Anti-sm	6(60%)	4(40%)	0.030
Low C3	7(58.3%)	5(41.7%)	0.009
Low C4	8(66.7%)	4(33.3%)	0.001

AB0448 **ADVERSE PREGNANCY OUTCOMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: THE ROLE OF THERAPY.**

M. B. Cilona[1], V. Canti[1,2], I. Dalpiaz[1], R. De Lorenzo[1], G. Inguscio[1], C. Asperti[1], S. Rosa[3], M. T. Castiglioni[3], P. Rovere-Querini[1,2]. *[1]Vita-Salute San Raffaele University, Internal Medicine, Milano, Italy; [2]San Raffaele Hospital, Internal Medicine, Milano, Italy; [3]San Raffaele Hospital, Obstetrics and Gynecology, Milano, Italy*

Background: Our study supports that treatment with glucocorticoids at medium-high doses during pregnancy adversely affects pregnancy outcome with an increased risk of both APO and birth of SGA infants. These data can be related to a direct role of the drug in determining maternal-fetal outcome and to the presence of an incomplete control over disease activity. The comparison between pregnancies followed before 2010 and since 2010 conducted in our study shows that the introduction of drugs such as hydroxychloroquine and azathioprine from the beginning of the pregnancy can reduces the frequency of APO in general. These medications could represent a safety therapeutic strategy both for the mother and for the fetus in order to control autoimmune disease during pregnancy and minimize the occurrence of complications. Further studies on larger numbers of placenta in APS patients will be needed to confirm our findings.
Objectives: To investigate whether treatment in SLE patients during pregnancy may influence the occurrence of APO events and, in particular, the birth of SGA infants.
Methods: We performed a monocentric observational study in SLE pregnant patients prospectively followed at the 'Pregnancy at risk' multidisciplinary outpatient clinics at San Raffaele Hospital, Milan, Italy from January 2003 to June 2021. We collected data from 79 pregnancies in 58 patients with a diagnosis of SLE.
Results: 13/79 (16%) pregnancies ended in a spontaneous abortion. In the other 66/79 (84%) APOs occurred in 29/66 (44%) pregnancies. 17 of the 66 (26%) pregnancies that did not end in spontaneous abortion ended with the birth of SGA infants. Glucocorticoid treatment at medium-high doses (e.i. prednisone ≥ 5 mg) was associated to an increased risk for APO (OR 4.431, p-value 0.018) and for the birth of SGA infants (OR 4.401, p-value 0.019). Preterm delivery (7/43, 16% versus 7/23, 30%), hypertension and/or preeclampsia (4/43, 9% versus 5/23, 22%) were observed with low incidence in pregnancy followed since 2010 than before 2010, even if without reaching statistical significance.
Conclusion: Our study supports that treatment with glucocorticoids at medium-high doses during pregnancy adversely affects pregnancy outcome with an increased risk of both APO and birth of SGA infants. These data can be related to a direct role of the drug in determining maternal-fetal outcome and to the presence of an incomplete control over disease activity. The comparison between pregnancies followed before 2010 and since 2010 conducted in our study shows that the introduction of drugs such as hydroxychloroquine and azathioprine from the beginning of the pregnancy can reduces the frequency of APO in general. These medications could represent a safety therapeutic strategy both for the mother and for the fetus in order to control autoimmune disease during pregnancy and minimize the occurrence of complications. Further studies on larger numbers of placenta in APS patients will be needed to confirm our findings.

SLE, Sjön-s and APS - clinical aspects (other than treatment)

AB0449 THE PREVALENCE OF AUTOANTIBODIES AGAINST IFNA IS HIGH IN SLE AND ASSOCIATED WITH A HIGH FREQUENCY OF TUBERCULOSIS

M. Beydon[1], P. Nicaise Roland[2], A. Mageau[1], T. Goulenok[1], C. Farkh[2], P. Dieudé[3], E. Daugas[4], V. Descamps[5], J. F. Timsit[6], T. Papo[1], K. Sacre[1]. *[1]Université de Paris, Médecine Interne, Paris, France; [2]Université de Paris, Immunologie, Paris, France; [3]Université de Paris, Rhumatologie, Paris, France; [4]Université de Paris, Néphrologie, Paris, France; [5]Université de Paris, Dermatologie, Paris, France; [6]Université de Paris, Réanimation, Paris, France*

Background: IFNα and anti-IFNα autoantibodies have been implicated in susceptibility both for systemic lupus erythematosus (SLE) and viral infection.
Objectives: We aimed to analyze the SLE disease phenotype and risk for infection associated with anti-IFN-α IgG autoantibodies in SLE patients
Methods: In this multidisciplinary retrospective single referral center study, all consecutive patients with SLE admitted between January 1st and November 30th 2020 were considered. All subjects fulfilled the ACR/EULAR 2019 criteria for SLE. Anti-IFNα IgG autoantibodies were quantified at admission by ELISA. Demographic, medical history, laboratory, treatment, and outcome data were extracted from electronic medical records using a standardized data collection form.
Results: 180 patients [female 87.2%, median age of 44.4 (34-54.2) years] were included. The median disease duration was 10 years [4-20] with a median SLEDAI score of 2 [0-4] at study time. Fifty-four (30%) patients had a past-history of lupus nephritis. One hundred and forty-four (80%) had received long-term glucocorticoids and 99 (55%) immunosuppressive drugs. Overall, 127 infections - mostly bacterial and viral - were reported in 95 (52.8%) patients. Twenty SLE patients (11.1%) had positive anti-IFNα IgG autoantibodies with a titer ranging from 10 to 103 UA/mL. Age, sex, SLE phenotype and treatment did not significantly differ between SLE patients with or without anti-IFNα. Infection rate was similar in both groups except for tuberculosis which was more frequent in patients with anti-IFNα (20% vs 3.1%, p = 0.01).
Conclusion: The prevalence of autoantibodies against IFNα is high in SLE and associated with a higher frequency of tuberculosis

AB0450 SOLUBLE CD163 IS A BIOMARKER FOR CARDIOVASCULAR EVENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. David[1], N. Costedoat-Chalumeau[2], D. Belhadi[3], V. Leguern[2], C. Laouenan[3], A. Boutten[4], J. Chezel[1], N. Morel[2], A. Mathian[5], Z. Amoura[5], T. Papo[1], K. Sacre[1]on behalf of PLUS Study group. *[1]Université de Paris Bichat, Médecine Interne, Paris, France; [2]Université de Paris Cochin, Médecine Interne, Paris, France; [3]Université de Paris Bichat, URC, Paris, France; [4]Université de Paris Bichat, Biochimie, Paris, France; [5]Sorbonne Université Pitie, Médecine Interne, Paris, France*

Background: Prediction models based on traditional cardiovascular risk factors underestimate the risk of cardiovascular events (CVE) in systemic lupus erythematosus (SLE).
Objectives: We aimed to determine whether sCD163, a biomarker for SLE-associated atherosclerosis, may predict CVE in SLE.
Methods: All SLE patients included between 2007 and 2010 in the randomized, double-blind, placebo-controlled, multicenter PLUS trial were screened. Patients with no past history of CVE at inclusion and a follow-up period of >20 months were analyzed. sCD163 level was measured using enzyme-linked immunosorbent assay on serum collected at PLUS inclusion. The primary outcome was the incident CVE. Factors associated with incident CVE and sCD163 level were analyzed.
Results: Overall, 442 SLE patients (of the 573 included in the PLUS study) were analyzed for the primary outcome with a median follow up of 110 (interquartile range: 99–120) months. Among them, 29 (6.6%) experienced at least one CVE that occurred at a median of 67 (interquartile range: 31–91) months after inclusion. In the multivariate analysis, dyslipidaemia, age and increased sCD163 were associated with CVE onset. Multivariate Cox models analysis showed that a concentration of sCD163> 263 ng/mL at inclusion increased by 2.7 [hazard ratio 2.7 (95% CI: 1.0, 7.0)] the risk of CVE in SLE. Increased sCD163 was also associated with immunosuppressive treatment, higher body mass index (BMI) and SLEDAI score.
Conclusion: Macrophage-specific sCD163 serum level reflects lupus disease activity and predicts CVE in SLE.

AB0451 FACTORS ASSOCIATED WITH ADVERSE PREGNANCY OUTCOMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

C. Sieiro Santos[1], C. Moriano[1], I. González Fernández[1], X. E. Larco Rojas[1], C. Álvarez Castro[1], E. Diez Alvarez[1]. *[1]Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Pregnancies in systemic lupus erythematosus (SLE) are considered high risk and associated with maternal and obstetric complications.
Objectives: Our goal with this study was to determine the most important predictors for each of the main adverse pregnancy outcomes in SLE patients.
Methods: We conducted a retrospective case-controls study by including multiparous women diagnosed with SLE from 1980 to 2020 followed in our unit and compared the clinical profile of patients with adverse pregnancy outcomes to control SLE patients. We excluded elective terminations of pregnancy and cases lost to follow-up. Qualitative data were analyzed by Chi-square test and Fisher's exact test and continuous variables were analyzed by using Student's t test. Multiple logistic regression models were performed to determine the predictive factors for adverse pregnancy outcomes with adjustment of confounding factors. In all tests, P values less than 0.05 were considered to be statistically significant.
Results: 135 multiparous women were included (43% with adverse pregnancy outcomes). The mean age of patients at inclusion was 55.8 (46-64) years. Abortion occurred in 33 patients (57%), pre-eclampsia in 10 patients (17%), ectopic pregnancy in 5 patients (8%), preterm labor in 5 patients (8%), placental abnormalities in 4 patients (6%), stillbirth in 4 patients (6%), premature rupture of membranes (PROM) and neonatal lupus in 3 patients (5%), respectively. 121 patients (89%) have pre-existing lupus and 14 (11%) referred with SLE onset in pregnancy. Renal involvement (p=0.03), anti-DNAds positivity (p=0.002), antiphospholipid antibody (APA) positivity (p=0.001), anti-Ro/SSA (p=0.003) and a younger age at disease onset (p=0.01) were significantly associated with unfavorable pregnancy outcomes. Abortion was correlated with anti-DNAds (β=0.71. p=0.04), renal involvement (β=0,28, p 0.03) and APA (β=0.2, p 0.03). Stillbirth was also correlated with renal involvement (β= 0.26, p =0.04) and APA (β=0.22, p=0.03). Preeclampsia was correlated with direct Coombs positivity (β=0.42, p=0.01) and serositis (β=0.31, p=0.02). Neonatal Lupus was correlated with anti-RNP (β=0.16, p=0.03) and anti-Ro/SSA (β=0.16, p 0.02). Renal involvement and APA had a 2.6-fold increased risk of unfavorable pregnancy outcomes (OR 2.6 95% (1.1-6.1), p 0.03) and APA had a 4.3-fold increased risk of unfavorable pregnancy outcomes (OR 4.3 95% IC 2.1-8.8), p 0.002).
Conclusion: The most unfavorable pregnancy outcomes in women with SLE was spontaneous abortion. Renal involvement, anti-DNAds and anti-Ro/SSA, antiphospholipid antibody positivity, and a younger age at disease onset increased the risk of pregnancy complications.

Table 1. Multiple logistic regression analysis

	Abortion	Stillbirth	Pre-eclampsia	PROM	Ectopic pregnancy	Neonatal Lupus
Anti-DNAds	β =0,71, p=0.04	β =0.26, p=0.04	β =0.12, p=0.38	β =0.15, p =0.24	β = 0.10, p =0.64	β = 0.16, p=0.24
APA	β = 0.2, p = 0.03	β = 0.22, p=0.03	β = 0.11, p = 0.85	β = 0.26, p = 0.04	β = 0.16, p = 0.21	β = 0.83, p = 0.08
Renal involvement	β=0,28, p 0.03	β = 0.26, p = 0.38	β = 0.33, p = 0.83	β = 0.07, p = 0.53	β = 0.17, p = 0.20	β = 0.58, p = 0.07
Serositis	β = 0.85, p = 0.95	β = 0.11, p = 0.41	β=0.31, p=0.02	β = 0.06, p = 0.46	β = 0.13, p = 0.35	β = 0.08, p = 0.46
Direct Coombs positivity	β =0.11, p = 0.41	β = 0.03, p = 0.81	β = 0.42, p=0.01	β=0.03, p =0.83	β= 0.14, p = 0.81	β=0.03, p=0.83
Anti-Ro/SSA	β=0.19, p = 0.13	β=0.03, p = 0.83	β=0.07, p =0.62	β=0.11, p=0.39	β=0.09, p=0.52	β= 0.16, p 0.02
Anti-RNP	β =0.5, p=0.69	β = 0.09, p=0.49	β = 0.16, p= 0.23	β = 0.09, p= 0.81	β=0.03, p=0.81	β=0.16, p=0.03

AB0452 AGE RELATED DIFFERENCES IN NEUROPSYCHIATRIC MANIFESTATIONS AMONG SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS – A SINGLE RHEUMATOLOGY CENTRE EXPERIENCE IN MALAYSIA

C. R. Ng[1]. [1]*Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia*

Background: The prevalence of SLE in Malaysia was reported as 43/100,000 individuals and Chinese (57/100,000) have the highest prevalence followed by Malays (33/100,000) and Indians (14/100,000) [1,2].
The American College of Rheumatology established case definitions and categorised neuropsychiatric syndromes into two groups: central and peripheral system involvement. There were studies showed that cognitive impairment is the commonest neuropsychiatric manifestations with a prevalence of 66% [3].
Objectives: To determine the association between neuropsychiatric manifestation with different age group among SLE patients.
Methods: This was a retrospective study. The electronic medical records of all SLE patients seen in rheumatology clinic of Hospital Sultan Ismail, Malaysia from 1/1/2007 to 31/12/2021 were reviewed. SLE patients with neuropsychiatric manifestations were selected and categorised by age into children (< 12 years old), adolescents (aged 12-18 years), young adults (aged >18 to 35 years), middle-aged adults (>35 -55 years) and elderly (>55 years). The association between neuropsychiatric manifestation with different age group was analysed by using SPSS-Fisher's exact test.
Results: There was a total of 86 patients and female were 77. The majority were Malay (49/86) followed by the Chinese (33/86), Indians (2/86) and others (2/86). Patients were categorized into children (n:6), adolescents (n:18), young adults (n:43), middle-aged adults (n:16) and elderly (n:3) with the mean age of 28.
Our study showed the onset of neuropsychiatric manifestations occurred most during young adulthood (43/86) followed by adolescents (18/86). Seizure disorders is the commonest manifestations (36/86) followed by psychosis (17/86), poly/mononeuropathy (7/86), cognitive dysfunction (7/86), myelopathy (5/86), cranial neuropathy (4/86), mood disorders (3/86), cerebrovascular disease (3/86), movement disorders (2/86), and lastly headache and myasthenia gravis, 1 patient each. 60% of the patients had onset of neuropsychiatric manifestation during first diagnosis and another 7% developed symptoms within 1 year of diagnosis. There was no association between type of neuropsychiatric manifestation with different age group (p = 0.195). Comparison of neuropsychiatric manifestations according to age group was showed in Table 1.

Table 1. Neuropsychiatric manifestations according to age group

Age group (years)	Central nervous system	Peripheral nervous system
Children < 12	Seizure (4), CVD (1), Cognitive dysfunction (1)	
Adolescents 12-18	Seizure (9), Psychosis (5), Mood disorders (1), Cognitive dysfunction (1)	PN/MN (2)
Young adults >18-35	Seizure (18), Psychosis (10), Cognitive dysfunction (4), movement disorders (2), myelopathy (4), CVD (2)	PN/MN (2) CN (1)
Middle-aged adults >35-55	Seizure (4), Psychosis (2), Mood disorders (2), Cognitive dysfunction (1), Myelopathy (1), Headache (1)	PN/MN (3) CN (2)
Elderly >55	Seizure (1)	MG (1), CN (1)

CVD: Cerebrovascular disease, PN/MN: Polyneuropathy/Mononeuropathy, CN: cranial neuropathy

Conclusion: Seizure disorders is the commonest manifestations amongst SLE patients in our study group and there was no association between neuropsychiatric manifestation with the age group.

AB0453 ROLE OF COMBINATION AUTOANTIBODIES (ANTI-SMITH, RO AND RNP ANTIBODIES) AND ETHNICITY IN ACCELERATED DEVELOPMENT OF LUPUS NEPHRITIS

C. R. Ng[1]. [1]*Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia*

Background: Lupus nephritis (LN) is an important concern among SLE patients in Asia and its mortality rate was reported to be 6 times higher compared to the general population [1]. A study by McCarty et al suggested that African women with serology showed combination of anti-Smith, Ro and RNP antibodies were at increased risk of developing LN [2]. This is further supported by study done by Majed et al showed this unusual combination accelerated development of LN within the first 5 years after SLE onset [3].
Objectives: To determine the correlation between the combination of autoantibody profile: Smith, Ro and RNP in development of LN amongst Asian ancestry and any association with the duration of LN development from onset of SLE.
Methods: This was a retrospective study. The electronic medical records of all SLE patients seen in the rheumatology clinic Hospital Sultan Ismail, Malaysia from 1/1/2007 to 30/4/2021 were reviewed. Patients who had LN were identified and selected. Data on demography, serology, duration of development of LN from SLE onset were obtained and analysed using SPSS Pearson Chi square and binary logistic regression.
Results: There were a total of 197 patients and 183 were females. The majority were Malays (96/197) followed by the non-Malay (101/197) which included Chinese (86/197) and others (15/197). The mean age group for the studied subjects was 34 (14-80). Of the 197 (100%) patients, 23 (11.7%) patients had the triple combination of Sm, Ro and RNP antibodies while 174 (88.3%) patients did not have the triple combination. For patient with the triple combination, regardless ethnicity, 20/23 (87%) developed LN within 5 years from the SLE onset while the remaining 3/23 (13%) developed LN after 5 years. For patients without this combination, regardless ethnicity, 142/174 (81.6%) of them developed LN within 5 years and 32/174 (18.4%) of them more than 5 years. This showed combination autoantibody does not significantly accelerated development of LN amongst Asian ancestry patients, P = 0.092. There was also no association between the positivity of triple antibody with the duration of development LN from SLE onset, P =0.772. Further stratification was based on ethnicity showed compare to Non-Malay ethnicity, the Malay patients is 3.966 higher odds of developing LN within the 5 years from SLE onset, P = 0.002.
Conclusion: Patient with triple serology combination did not showed significant in accelerating development of LN. Our data showed Malay patients are 4 higher odds of developing LN within the first 5 years after SLE onset compare to Non-Malay patients.

AB0455 DRUGS, AUTOANTIBODIES AND GENES CONTRIBUTE TO THE DEVELOPMENT OF CHRONIC DAMAGE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Olivieri[1], F. Ceccarelli[1], C. Pirone[1], L. Picciariello[1], F. Natalucci[1], C. Ciccacci[2], C. Perricone[3], F. R. Spinelli[1], C. Alessandri[1], P. Borgiani[4], F. Conti[1]. [1]*Rheumatology, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Sapienza University of Rome, Roma, Italy;* [2]*Genetica Medica, UniCamillus, Saint Camillus International University of Health and Medical Sciences, Rome, Rome, Italy;* [3]*Rheumatology, Dipartimento di Medicina e Chirurgia, University of Perugia, Perugia, Italy;* [4]*Genetica Medica, Department of Biomedicine and Prevention, Genetics Section, University of Rome Tor Vergata, Rome, Italy*

Background: Genetic contribution to development of chronic damage have been scarcely investigated in systemic lupus erythematosus (SLE). In fact, whereas most studies have looked for an association between genetic variants and SLE susceptibility or disease phenotypes, only few have focused on the relationship between these biomarkers and damage development.

Objectives: Moving from these premises, we firstly analyzed the distribution of organ damage in a cohort of SLE patients and secondly we evaluate the role of clinical and genetic factors in determining the development of chronic damage.
Methods: Caucasian SLE patients, diagnosed according with 1997 ACR criteria, were enrolled, and clinical and laboratory data were collected. Based on literature data, we selected a panel of 17 SNPs of following genes STAT4, IL10, IRAK1, HCP5, MIR146a, ATG16L1, IRGM, ATG5, MIR124, MIR1279, TNFSF4, CD40. Genotyping was performed by allelic discrimination assays. A phenotype-genotype correlation analysis was performed by evaluating specific domains of SLICC Damage Index (SDI).
Results: Among 175 Caucasian SLE patients, 105 (60%) exhibited damage (SDI ≥1) with a median value of 1.0 (IQR 3.0). The musculoskeletal (26.2%), neuropsychiatric (24.6%) and ocular domains (20.6%) were involved most frequently. The presence of damage was associated with higher age, longer disease duration, neuropsychiatric (NP) manifestations, anti-phospholipid syndrome and the positivity of anti-dsDNA antibodies. Concerning therapies cyclophosphamide, mycophenolate mofetil and glucocorticoids resulted associated with the development of damage. The genotype/phenotype correlation analysis showed an association between renal damage, identified in 6.9% of patients, and rs2205960 of TNFSF4 (p=0.001; OR 17.0). This SNP resulted significantly associated with end-stage renal disease (p= 0.018, OR 9.68) and estimated GFR<50% (p=0.025, OR 1.06, Figure 1). The rs1463335 of MIR1279 gene was associated with the development of NP damage (p=0.029; OR 2.783). The multivariate logistic regression analysis confirmed the associations between TNFSF4 rs2205960 SNP and renal damage (p=0.020, r=2.53) and between NP damage and rs1463335 of MIR1279 gene (p=0.013, r=1.26)].

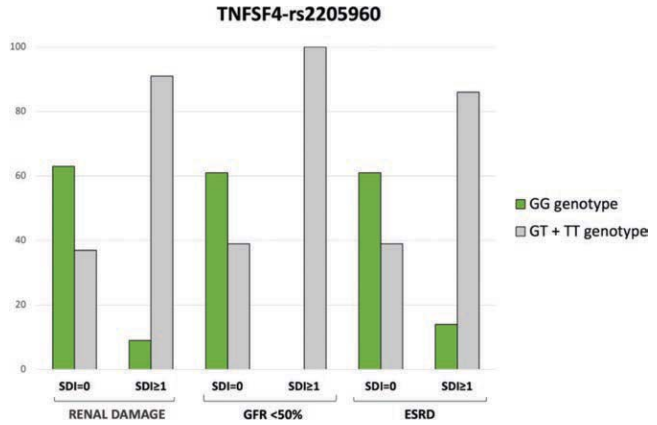

Figure 1. Association between renal damage and rs2205960 of TNFSF4 (p=0.001). In addition, this SNP resulted significantly associated with the development of two specific items of SDI renal domain: estimated glomerular filtration rate (GFR) <50% and end-stage renal disease (ESRD) (p=0.025, p=0.018 respectively).

Conclusion: We showed the role of age, drugs, and autoantibody profile in determining chronic damage.
Our data suggest a possible role of genetic background in determining the development of renal and neuropsychiatric damage, as demonstrated by the association with polymorphisms of TFNSF4 and MIR1279, respectively. These results agree with previous studies suggesting the involvement of TNFSF4 in Lupus nephritis and microRNA in neuroinflammation.

AB0456 DISEASE FLARE OF SYSTEMIC LUPUS ERYTHEMATOSUS IN PATIENTS WITH END-STAGE RENAL DISEASE ON DIALYSIS

Y. E. Kim[1], S. J. Choi[2], D. H. Lim[2], S. M. Ahn[1], J. S. Oh[1], Y. G. Kim[1], C. K. Lee[1], B. Yoo[1], S. Hong[1]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); [2]Ulsan University Hospital, Department of Rheumatology, Ulsan, Korea, Rep. of (South Korea)*

Background: The systemic lupus erythematosus (SLE) disease activity in patients with lupus nephritis (LN) generally declines after the initiation of renal replacement therapy (RRT); this is known as the "burn out" phenomenon that possibly occurs due to the suppression of cellular and humoral immunity in the end-stage renal disease (ESRD) state and elimination of disease pathogenic factor by dialysis [1-4]. However, several studies showed that SLE flares could occur even during RRT [5-8]. Nevertheless, the details of disease flares of SLE in patients under dialysis have not been studied yet.

Objectives: This study aimed to investigate the clinical features, risk factors, and treatment details of SLE patients experiencing disease flare under RRT.
Methods: The medical records of SLE patients who received dialysis at two tertiary referral hospitals in Seoul and Ulsan, South Korea were reviewed. All patients in this study were either clinically or histologically diagnosed with LN
Results: Of a total of 121 patients with SLE on dialysis, 96 (79.3%) were on hemodialysis (HD) and 25 (20.6%) were on peritoneal dialysis (PD). During a median follow-up of 45 months (IQR, 23–120) after the initiation of dialysis, 32 (26.4%) patients experienced SLE flare (HD, n = 25; PD, n = 7). The most common features of SLE flare were hematologic (40.6%) and constitutional manifestations (40.6%). Treatments for disease flares were based on corticosteroids, and 11 (34.3%) patients required additional immunosuppressants including cyclophosphamide and mycophenolate mofetil. There was no case of severe adverse events related to medication. non-renal SLE Disease Activity Index (SLEDAI) score before dialysis initiation (HR 1.235; 95% CI, 1.122–1.359; P = 0.001) was a significant risk factor for disease flare during dialysis.

Table 1. Multivariable analysis of factors associated with SLE flare under dialysis

	Hazard ratio	95% CI	*P*-value
Non-renal SLEDAI at the initiation of dialysis	1.235	1.122–1.359	0.001
Hematologic manifestation prior to dialysis	1.256	0.690–2.826	0.150
Cumulative amount of steroid during 1 year prior to the initiation of dialysis	1.040	0.995–1.087	0.086
Dialysis modality: hemodialysis	0.766	0.262–2.243	0.630

Conclusion: More than one-quarter of SLE patients experienced disease flare during dialysis, which most commonly had hematologic manifestations. Continued follow-up and appropriate treatments including immunosuppressants should be considered for patients with SLE under dialysis.

AB0457 IMPROVED PREGNANCY OUTCOMES IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY OF PREGNANCIES FROM A SINGLE CENTER IN DENMARK FROM 2010-2020 COMPARED WITH THE PERIOD 1990-2010

M. Gohr[1], I. M. Jakobsen[2], R. B. Helmig[3], K. Stengaard-Pedersen[4], T. B. Laurberg[1], A. Troldborg[3]. *[1]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [2]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark; [3]Aarhus University Hospital, Department of Gynecology and Obstetrics, Aarhus, Denmark; [4]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*

Background: Over the past decades, the approach to follow and treat pregnant SLE patients has changed. Today it is recommended that pregnant patients are monitored closely in a multi-professional team throughout pregnancy (1). The importance of low disease activity before pregnancy and continued treatment

during pregnancy has been established (2). Even though many improvements in the management of SLE pregnancies has been made, there is still a high risk of adverse pregnancy outcome (APO).

Objectives: We aimed to evaluate APO in a Danish SLE cohort followed from 2010-2020 and compare the results with a previous study cohort from the same referral area followed from 1990-2010 (3).

Methods: This retrospective cohort study used the local patient registry to identify pregnancies in SLE patients followed at the Department of Rheumatology, Aarhus University Hospital, Denmark from January 2010 to October 2020. All patients were followed regularly and fulfilled at least four of the 1997 American College of Rheumatology (ACR) criteria for SLE classification. Data included demographic, clinical, and laboratory data. Demographics included ethnicity, smoking habits, body mass index (BMI), and concomitant APS (recognized before pregnancy). Data were compared with data from a previous study (1990-2010) from the same department.

Results: In total, 66 pregnancies were registered in 41 women. APO occurred in 65 % of pregnancies. Forty-seven pregnancies resulted in a live birth, while 15 ended in miscarriage. Compared to the 1990-2010 cohort, a reduction in preterm deliveries (7.58 % vs. 17.9 %), acute caesarean (6.1 % vs. 15.5 %), and higher average birth weight (3045 g vs. 2870 g) were found (Table 1). Further, we observed more pregnancies and live births per year (Figure 1). A change in the approach to treatment was found, i.e., significantly more patients were treated with hydroxychloroquine (73 %) compared to the 1990-2010 cohort (6 %).

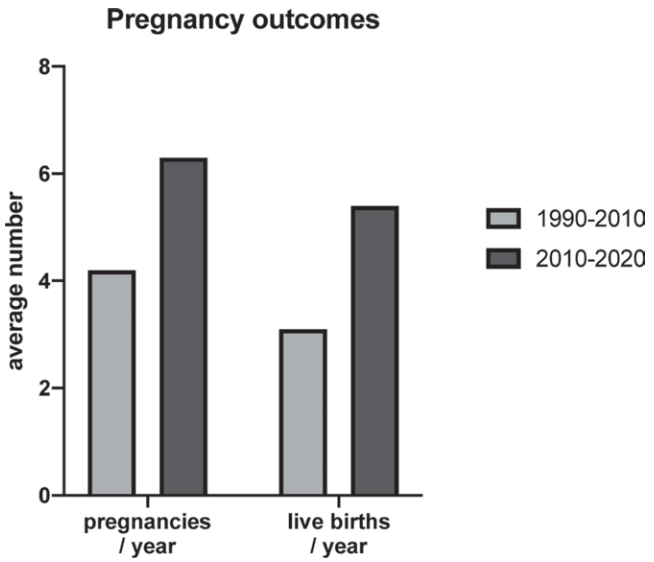

Figure 1. Pregnancy outcome. Average number of pregnancies and live birth per year in the Aarhus SLE cohort in the period 1990-2010 compared with 2010-2020

Table 1. Maternal and fetal/neonatal adverse pregnancy outcomes in our study population (2010-2020) compared with previous study at Aarhus University Hospital (1990-2010).

	1990-2010 n=84	2010-2020 n=66	p-value
Pre-eclampsia/eclampsia, n (%)	7 (8.3)	8 (12.1)	0.59
HELLP syndrome, n (%)	4 (4.8)	0	-
Gestational hypertension, n (%)	20 (23.8)	9 (13.6)	0.05
Preterm deliveries (<37th gestational week), n (%)	15 (17.9)	5 (7.58)	0.07
Acute caesarean delivery, n (%)	13 (15.5)	4 (6.1)	0.07
Elective caesarean delivery, n (%)	11 (13.1)	8 (12.1)	-
Total caesarean delivery, n (%)	24 (28.6)	12 (18.2)	-
Total fetal loss, n (%)	22 (26.2)	19 (28.8)	0.72
Spontaneous abortion <22 weeks, n (%)	18 (21.4)	15 (22.7)	0.85
Therapeutic abortion	3 (3.6)	4 (6.1)	0.47
Still birth	1 (1.2)	0	-
Fetal death after birth	2 (2.4)	0	-
Birth weight, mean ± SD g	2870 (SD,NA)	3045 ± 611	-
IUGR	10 (11.9)	NA	-
SGA	NA	12 (18.18)	-
Congenital heart block, n (%)	1 (1.2)	0	-
Neonatal Lupus Syndrome, n (%)	2 (2.4)	0	-

Conclusion: Improvements in the frequency of APO were found in 2010-2020 compared with 1990-2010. However, even though a specialized multi-professional team closely follows pregnant women with SLE, pregnancy in SLE still carries a high risk of APO.

AB0458

DISEASE ACTIVITY AT CONCEPTION PREDICTS LUPUS FLARE UP TO 2 YEARS AFTER BIRTH: A MULTICENTRE LONG TERM FOLLOW-UP STUDY

M. Radin[1], K. Schreiber[2], I. Cecchi[1], F. Signorelli[3], G. De Jesùs[3], K. Aso[4], M. Kono[4], M. L. Urban[5], B. Bacco[1], S. Gallo Cassarino[1], L. Lo Sardo[1], S. G. Foddai[1], A. Barinotti[1], I. Gómez García[6], M. I. Quaglia[7], Y. Tissera[7], F. Gervasoni[1], M. Á. Aguirre-Zamorano[6], P. Alba[7], C. Benedetto[1], T. Atsumi[4], O. Amengual[4], G. Emmi[5], D. Andrade[3], L. Marozio[1], D. Roccatello[1], S. Sciascia[1]. *[1]University of Turin, Clinical and Biological Sciences, Turin, Italy; [2]Guy's and St Thomas' Hospital, Department of Thrombosis and Haemophlia, London, United Kingdom; [3]Universidade do Estado do Rio de Janeiro, Department ofRheumatology, Rio de Janeiro, Brazil; [4]Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Sapporo, Japan; [5]University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy; [6]University of Cordoba, Rheumatology Service, Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [7]Universidad Nacional de Córdoba, Hospital Córdoba and Materno Neonatal, Cordoba, Argentina*

Background: Systemic lupus erythematosus (SLE) often affects women in their childbearing years, and pregnancy may affect SLE disease activity during pregnancy and post-partum (1,2). Limited data assessing the likelihood and characteristics of SLE activity in an extended time period post-partum which may be relevant as patients may wish further pregnancies exist.

Objectives: To assess predicting factors that might influence SLE disease activity in women in an extended follow-up period of 2 years after giving birth and clinical assessment every three months.

Methods: The study was design as an international retrospective, data-driven case collection study, enrolling 119 women with a first birth and with a strictly monitored follow-up period of 2 years.

Results: Table 1 shows pregnancy outcomes of all pregnancies. When considering disease manifestations, joint involvement was present in 80% of patients, acute cutaneous in 64%, haematological in 54%and renal in 41%; 75% of patients were positive for anti-dsDNA, 49% for anti-ENA and 37% for anti-Ro/SSA positive. The mean SLE disease activity index 2000(SLEDAI-2k) at diagnosis was 13.5±6.8 and at first birth was 2.8±4.4.

Table 1. Pregnancy outcomes of all pregnancies and relative breastfeeding data

Pregnancy Characteristics	All (214)	%
Outcomes		
Live births	169	79
Miscarriages	37	17.3
Stillbirths	8	3.7
Maternal and Foetal Complications		
Prematurity	39	18.2
Pre-eclampsia	23	10.7
HELLP syndrome	4	1.9
Placental Infarction	12	5.6
Breastfeeding (all pregnancies)		
Any breastfeeding (n, %)	109	64.5*
Exclusive breastfeeding (n, %)	87	51.5*
Breastfeeding (after first birth)		
Any breastfeeding (n, %)	87	73.1**
Any breastfeeding duration (months) (m±sd)	10.29±10.04	
Exclusive breastfeeding*** (n, %)	62	52.1**
Exclusive breastfeeding*** duration (months) (m±sd)	6.07±6	

Percentages are calculated considering viable babies (total= 169) Percentages are calculated considering first birth (total= 119)***Exclusive breastfeeding was defined as feeding infants only breast milk*

At follow-up, 51.3% of patients had at least one flare after a mean time after birth of 9±6.3 months(mean flare per patient 0.94±1.1). The most frequent flare manifestations were joint involvement(48%), followed by renal(33%), cutaneous(28%)

and haematologic(20%). Patients with remission of disease(SLEDAI-2K=0; no clinical or laboratory manifestations of SLE) at conception had significantly lower rates of flares than those not in remission (18/49–37% vs. 43/70–61%;p=0.008) (Figure 1).

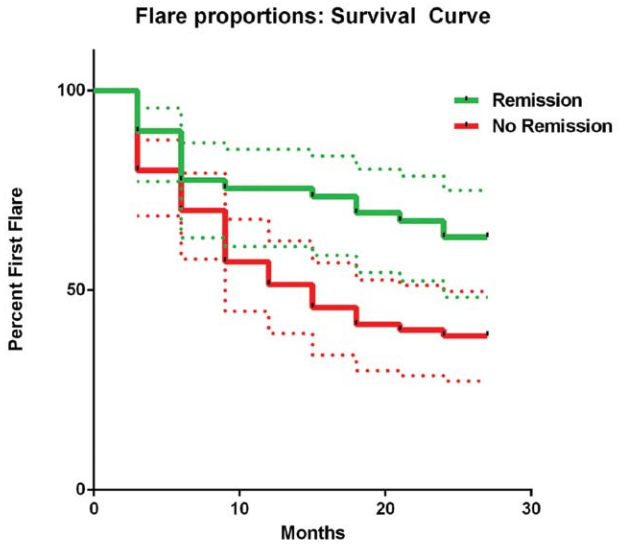

Figure 1. Flare proportion: Survival Curve based on remission status at conception of the patients included in the study.

Patients who experienced a flare during pregnancy (17 patients), when compared to those who did not, had higher rates of flares during follow-up (76% vs. 47%, respectively, p=0.019), lower time for first flare (4.4±2.3 months vs. 10.3±6.5, respectively, p<0.001), lower rate of remission of disease at conception (12% vs. 46%, respectively, p<0.001), lower rates of SLEDAI 2K at conception (5.9±5.6 vs. 2.3±4, respectively, p<0.001) and lower rates of exclusive breastfeeding (24% vs. 57%, respectively, p=0.009). Remission of disease and flares during pregnancy remained significantly associated with the development of flares during follow-up after multivariate analysis.

Conclusion: Remission at conception can influence SLE disease positively, even at long-term. Planned pregnancy counseling is fundamental when managing SLE patients.

AB0459 NATIONAL TEMPORAL TRENDS IN ALL-CAUSE MORTALITY IN PATIENTS WITH SYSTEMIC SCLEROSIS IN MEXICO BETWEEN 1998-2017

P. Munguía-Realpozo[1], M. García Carrasco[1], I. Etchegaray-Morales[1], J. Ayón-Aguilar[2], O. Navarro-Milán[1], C. Mendoza Pinto[3]. *[1]Facultad de Medicina BUAP, Rheumatology Department, Heroica Puebla de Zaragoza, Mexico; [2]IMSS, Research in Health Coordination Assistant, Cholula, Mexico; [3]IMSS Specialty Hospital, Systemic Autoimmune Diseases Research, Heroica Puebla de Zaragoza, Mexico*

Background: Systemic sclerosis (SSc) is a rare chronic connective tissue disease characterized by vascular injury, immune dysregulation, and extensive fibrosis of several organs. Due to its rarity, epidemiological data for SSc are sparse.

Objectives: To investigate national temporal trends over time in all-cause mortality rates in patients with systemic sclerosis (SSc) in Mexico between 1998 and 2017.

Methods: All-cause deaths between 1998 to 2017 were extracted from the General Board of Health Information (DGIS) Open Access datasets. We identified all persons aged ≥18 years with a diagnosis of SSc (ICD-10 code M34). We calculated the age-standardized mortality rate (ASMR) for SSc and non-SSc (information provided by the National Institute of Statistics, Geography and Informatics). A Joinpoint regression model was used to determine mortality trends by sex and geographic regions. Annual percentage change (APC) and average APC (AAPC) were calculated using Joinpoint analysis.

Results: From 1998 to 2017, the overall ASMR of SSc increased (AAPC= 2.5%), whereas the ASMR for non-SSc remained stable. By subpopulations, females and males with SSc had a significant uptrend in the ASMR (APC= 4.6% and 4.4%, respectively), between 1998 and 2008 for the former and between 1998 and 2010 for the later. Females had a non-significant ASMR uptrend and males a non-significant ASMR decline. Some variations among geographic regions were found. Women had a higher SSc AMSR to non-SSc ASMR ratio than males. The relative cumulative change between 1998 and 2017 differed between females (78.1%) and males (50.8%), and residents of the Southern region had the largest cumulative change (147.8%).

Conclusion: SSc mortality rate increased in Mexico between 1998 to 2017, with SSc mortality higher than non-SSc mortality with variations by sex and geographic regions.

AB0460 METABOLOMIC PROFILE OF INSULIN RESISTANCE IN NON-DIABETIC WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

P. Munguía-Realpozo[1], C. Mendoza Pinto[2], I. Etchegaray-Morales[1], S. K. Vélez-Pelcastre[1], Á. D. Osorio-Peña[1], S. Méndez-Martínez[3], M. A. Escamilla-Márquez[4], M. García Carrasco[1]. *[1]Facultad de Medicina BUAP, Rheumatology Department, Heroica Puebla de Zaragoza, Mexico; [2]IMSS Specialty Hospital, Systemic Autoimmune Diseases Research, Heroica Puebla de Zaragoza, Mexico; [3]Puebla State Delegation IMSS., Research in Health Coordination, Heroica Puebla de Zaragoza, Mexico; [4]Facultad de Medicina BUAP, Endocrinology Department, Heroica Puebla de Zaragoza, Mexico*

Background: Systemic lupus erythematosus (SLE) is associated with an increased risk of insulin resistance (IR). Metabolomics offers an opportunity to examine markers of IR and their relationship with SLE.

Objectives: 1) to compare the metabolomic profile of IR in SLE patients and controls; 2) to correlate the metabolomic profile with other IR surrogates and 3) to evaluate the relationship between the metabolomic profile of IR and SLE disease variables, vitamin levels and subclinical atherosclerosis in patients with SLE.

Methods: In this cross-sectional analysis, serum samples were collected from patients with SLE (n= 64) and gender- and age-matched controls (n= 71). Serum metabolomic profiling was performed using ultra-high performance liquid chromatography and tandem mass spectrometry (UPLC-MS-MS). Homeostasis model assessment (HOMA) and the quantitative insulin sensitivity check index (QUICKI) were also carried out. Serum 25(OH)D concentrations were assessed by chemiluminescent immunoassay. Carotid IMT was quantified by ultrasound.

Results: In non-diabetic patients with SLE, the metabolomic Quantose score significantly moderately correlated with HOMA-IR, HOMA2-IR and QUICKI. Although levels of IR metabolites did not differ between SLE patients and controls, fasting plasma insulin levels were higher and insulin sensitivity lower in SLE patients. The Quantose IR score was significantly correlated with complement C3 levels (r= 0.7; p= 0.001). Neither 25 (OH)D nor IMT was correlated with any metabolite or Quantose IR index.

Conclusion: This exploratory study found that Quantose IR may be a useful tool for IR assessment. There was a possible correlation between the metabolomic profile and complement C3 levels. The implementation of this metabolic strategy may help develop biochemical insight into metabolic disorders in SLE.

AB0461

TRIPLE POSITIVE PROFILE IN ANTIPHOSPHOLIPID SYNDROME: PROGNOSIS, RELAPSE AND MANAGEMENT FROM A RETROSPECTIVE MULTICENTER STUDY.

L. Charlotte[1], L. Ricard[1], N. Yann[1], O. Fain[1], A. Mekinian[1]. [1]*Saint Antoine, Internal Medicine, Paris, France*

Background: The antiphospholipid syndrome (APS) is defined by the development of vascular thrombosis, or pregnancy morbidity in the presence of persistent antiphospholipid antibodies (APL). Antinuclear antibodies (ANA) can be detected in primary APS patients without any clinical systemic autoimmune disease. The presence of ANA antibodies could confer a specific phenotype in primary APS.
Objectives: Antiphospholipid syndrome (APS) is defined by the association of thromboembolic and/or obstetrical clinical manifestations and the presence of antiphospholipid antibodies (APL). Patients with all three APL are referred to as triple positive (TP). The objective of our study was to evaluate the impact of the TP profile in a cohort of 204 patients.
Methods: Clinical and biologic data from 195 APS were retrospectively collected. ANA test was considered to be positive when titers were superior or egal to the 1/80 dilution. ANA-positive APS patients did not fulfilled SLE ACR/EULAR classification criteria
Results: 204 patients were included in our study, 68 were TP and 136 were single or double positive (NTP). 122 patients (59.8%) had primary APS. 67 patients (32.8%) had obstetrical APS, with a higher rate among TP patients (45.6% versus 26.5%, P=0.010), and 170 patients (83.3%) had thrombotic APS, without difference between TP and NTP patients. TP patients had more placental complications than NTP patients (17.6% versus 2.9%, P=0.001) and more non-criteria events (48.5% versus 25.7%, P=0.002). 97 patients (47.5%) presented at least one relapse, and the relapse rate was significantly higher in TP patients than in NTP patients (63.2% versus 39.7%, P=0.002). Of the relapses, 30 were obstetric and 74 thrombotic, and the rate of obstetric relapses was significantly higher in TP patients. During follow-up, 21 patients (10.3%) died and this rate did not differ between the two groups. In univariate analysis, TP patients (HR 1.77; 95% CI 1.17-2.68; P=0.007), venous APS (HR 1.74; 95% CI 1.13-2.69; P=0.013), a history of premature birth (HR 2.47; 95% CI 1.24-4.93; P=0.010), and curative anticoagulation (HR 4.91; 95% CI 1.55-15.5; P=0.007) are associated with the risk of relapse. The serological profile was also a factor in relapse: the presence of the anti-β2GP1 antibody (HR 1.70; 95% CI 1.09-2.64; P=0.018) and LA (HR 1.59; 95% CI 1.01-2.50; P=0.046). The non-criteria manifestations of APS are associated with a higher risk of relapse, although not statistically significant (HR 1.49; 95% CI 1.00-2.23; P=0.052). In multivariate analysis, the TP profile remained associated with a risk of relapse (HR 1.63; 95% CI 1.04-2.55; P=0.031), as well as venous APS (HR 2.05; 95% CI 1.30-3.23; P=0.002), and the antecedent of premature delivery (HR 2.33; 95% CI 1.10-4.92; P=0.027). The risk factors associated with relapse in multivariate analysis are summarized in Figure 1.

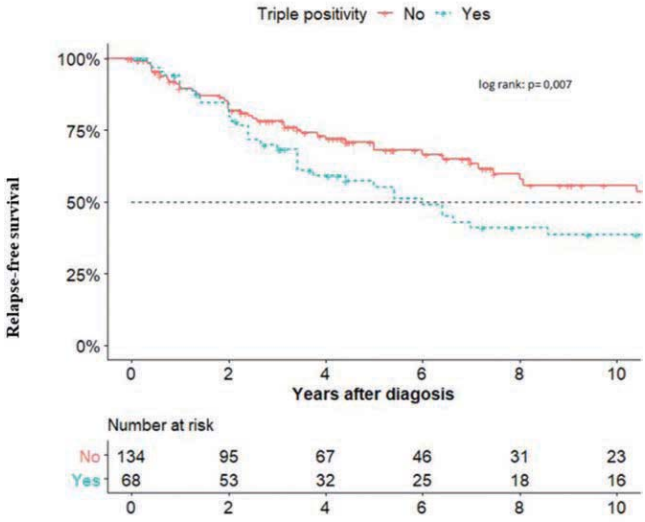

Figure 1.

Conclusion: The TP profile is associated with a higher risk of relapse and obstetrical complications.

CORRELATION BETWEEN SAXON TEST AND UNSTIMULATED SALIVARY FLOW RATE IN PATIENTS WITH SUSPECTED SJÖGREN´S SYNDROME

M. J. Santos Bórnez[1], M. Fernandez Castro[1], J. Sanz[1], J. Campos Esteban[1], H. Godoy[1], C. Merino Argumánez[1], O. Rusinovich[1], N. De la Torre Rubio[1], M. Pavía Pascual[1], M. C. Sánchez Fernández[1], P. D. Briongos Díaz[1], B. Garcia-Magallon[1], C. Barbadillo Mateos[1], L. F. De Villa[1], C. Isasi Zaragoza[1], J. L. Andréu Sánchez[1], A. Sánchez[1]. [1]*Hospital Universitario Puerta de Hierro Majadahonda, IDIPHISA. Madrid, Spain, Rheumatology, Majadahonda (Madrid), Spain*

Background: Sjögren syndrome (SS) is a chronic systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands, which alters their function producing dryness of the mouth, eyes and other mucous membranes. The method used to quantify glandular hypofunction is by whole saliva flow stimulated and unstimulated (UWSF) [1], which takes between 5 and 15 minutes (min). The Saxon test [2], is another tool with the same objective but requires less time: 2 minutes. In the literature, we only have found one study that compares the Saxon test with other diagnostic methods although it is developed in patients without SS [3].
Objectives: To compare the Saxon test and UWSF in a cohort of patients with suspected SS.
Methods: In a consecutive cohort of patients who attended the rheumatology department for suspected SS, UWSF was measured (mL/5 min) and the Saxon test (gr/2 min) was performed. The Index Reported by Patients with Sjögren's Syndrome of the EULAR (ESSPRI) was collected too. This is a patient-reported index designed to assess the severity of patients' symptoms (dryness, pain, somatic and mental fatigue) in SS through an average of single 0–10 numerical scale for each domain. To measure the UWSF, patients were asked to swallow their saliva before the start of the test and then to spit into a container for 5 min. The Saxon test was performed by calculating the difference in the weight of two pieces of sterile gauze that the patient chews for two minutes. An UWSF >0.25 mL/min, a Saxon test >2.75 g/2min and an ESSPRI<5 were considered normal. Spearman's rank correlation coefficient (r_s) was used to determine the correlation between both quantitative variables. The Chi-square test and the Gamma test were used in the comparisons between the groups (altered and normal) and the Mann-Whitney U in the comparisons of the quantitative variables based on the groups (altered and normal) previously defined. *P* values <0.05 were considered statistically significant.
Results: We enrolled 70 patients (63 women/7 men), with a mean age ± standard deviation of 54±13 years. The medians (Me) and interquartile ranges (IQR) obtained were 1.500 (0.6750 – 2.5000) mL/5min for the UWSF, 2.405 (1.6775-3.4925) g/2min for the Saxon test, 6.67 (3.67-7.67) for ESSPRI and 7.00 (4.00-8.00) for ESSPRI-dryness score. A direct and significant correlation between the Saxon test and the UWSF (r_s=0.325; *P*=0.006) was observed. Twenty-four patients (34.3%) presented an altered UWSF and forty-two patients (60%) had an altered Saxon test. When we analysed the intensity of the association between the different groups (altered/normal) of both variables, we observed a direct and significant association (Gamma value=0.583, *P*=0.010) between both tools. We also detected differences in the Saxon test between patients with altered UWSF (Me: 1.89 gr/2min.; IQR: 1.47-2.68) and those with normal UWSF (Me: 2.78 gr/2 min.; IQR: 1.77-3, 75) (*P*=0.029). Similarly, we observed significant differences in UWSF values between patients with altered Saxon test (Me: 1.30 mL/5min IQR: 0.50-2.13) and those with a normal Saxon test (Me: 2.00 mL/5min IQR: 1.5-2.88) (*P*=0.008). Regarding the ESSPRI, 42 (62,7%) patients presented an altered ESSPRI and 49 (73,1%) had an altered ESSPRI-dryness score. The group patients with ESSPRI-dryness score≥5 obtained significantly worse scores on the Saxon test (Me: 2.10 g/2min IQR: 1.58-3.07) and on the ESSPRI (Me:7.33 IQR:5.83-8.00) than the normal ESSPRI-dryness score group: Me:3.02 g/2min, IQR:2.20-3.84, on Saxon test (*P*=0.026); Me: 2.66 IQR:1, 00-4.08, on the ESSPRI (*P*=0.000).
Conclusion: In patients with suspected SS, there is a direct and significant correlation between the Saxon test and the UWSF. Therefore, the Saxon test could be useful in the initial assessment of oral gland dysfunction, to save time and/or to select patients who require performing the UWSF.

PREVALENCE AND PREDICTORS OF COGNITIVE DYSFUNCTION IN PATIENTS WITH LUPUS NEPHRITIS: A CROSS-SECTIONAL COMPARISON WITH PATIENTS WITH OTHER CHRONIC KIDNEY DISEASES

S. Fasano[1], F. Riccio[1], V. Buonincontri[2], M. Patrone[1], A. Milone[1], D. Viggiano[2], A. Perna[2], F. Ciccia[1]. [1]*University of Campania "Luigi Vanvitelli", Napoli, Italy,*

Rheumatology, Naples, Italy; [2]University of Campania "Luigi Vanvitelli", Napoli, Italy, Nephrology, Naples, Italy

Background: Cognitive dysfunction (CD) is among the most frequent neuropsychiatric manifestation of systemic lupus erythematosus (SLE) that has a considerable impact on quality of life, but still lacks adequate screening in clinical routine.
Objectives: Our aim was to investigate the distribution and determinants of CD in patients with lupus nephritis, and to compare cognitive function with that in patients with other forms of glomerular chronic kidney disease (CKD) by the Montréal Cognitive Assessment (MoCA).
Methods: We carried out a cross-sectional case-control study with consecutive patients with SLE who fulfilled the 2012 SLICC (Systemic Lupus International Collaborating Clinics) classification criteria(1) and have history of lupus nephritis, using a similarly derived CKD control population matched by age and sex, to assess cognitive function using MoCA scale(2). CD was defined as score < 26/30, adjusted for duration of formal education. Demographic data and disease characteristics were collected. SLE disease activity was evaluated by using Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI2K) (3). The effect of disease-related parameters on the MoCA was examined by regression analysis.
Results: A total of 35 patients with SLE and 35 CKD controls were included in our study (Table 1). Among SLE patients, 7 (20%) patients had biopsy proven active nephritis, 7 (20%) had kidney failure and one a kidney transplant. CD according to MoCA score was found in 64.2% (n=45) patients (Figure 1). The proportion of patients with CD according to MoCA between patients with lupus nephritis and CKD controls was not statistically significant (62.8% vs 65.7%, p>0.05). SLE patients performed bad in all cognitive domains. Memory, abstraction and language skills were the most affected domains. Our study showed that active nephritis and disease duration were associated with poor cognitive performance (OR=1.4, p = 0.03; OR=1.2, p = 0.03). GFR values and other parameters evaluated (end stage renal disease, damage, age at diagnosis, use of glucocorticoids, hydroxychloroquine and immunosuppressive drugs) had no significant effect on development of CD in SLE patients.

Table 1. Demographics and clinical characteristics of SLE patients

	mean	%
Age	44	
Women		94.2
Education		
>16 yrs		51.4
16 -13 yrs		37.1
<13 yrs		11.4
Disease duration (yrs)	16	
Kidney failure		20
Prednisone (% use)		
<20 mg		11.4
≥20mg		88.5
Hydroxychloroquine (% use)		65.7
Immunosuppressants (% use)		57.1
SLEDAI	2.4	
SDI	0.8	

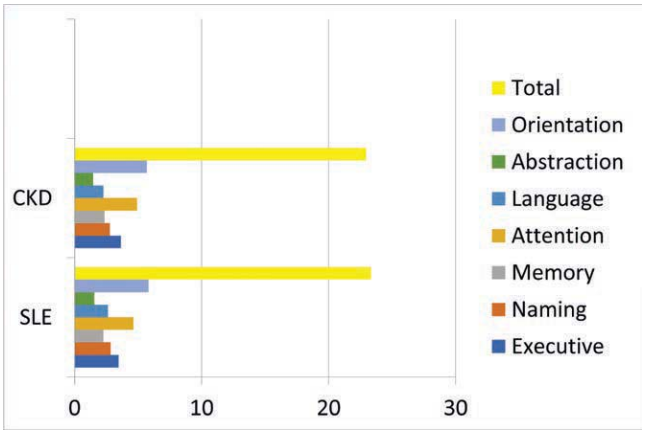

Figure 1. Montréal Cognitive Assessment (MoCA) results in patients with systemic lupus erythematosus (SLE) compared to hemodialysis and chronic kidney disease (CKD) patients.

Conclusion: In this study, two thirds of SLE patients had CD. Patients with lupus nephritis have comparable cognitive function than patients with other CKD. Decline in renal function was not associated with CD in SLE, suggesting that the CD in this population may represent a consequence of lupus itself rather than kidney-related central nervous system damage.

AB0464 ULTRASONOGRAPHIC FEATURES OF THE PAROTID AND SUBMANDIBULAR SALIVARY GLANDS IN SJÖGREN'S SYNDROME

M. I. González-Nieto[1], A. Portella Alegre[2], M. Planes-Conangla[2], S. Bujan Rivas[1], X. Serres-Créixams[2], R. Solans-Laqué[1]. *[1]Hospital Universitari Vall d'Hebron, Internal Medicine, Barcelona, Spain; [2]Hospital Universitari Vall d'Hebron, Radiology, Barcelona, Spain*

Background: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by the presence of "sicca syndrome", secondary to the involvement of the exocrine glands. Different studies have been published and have shown that salivary gland ultrasound (SGUS) could be used as a tool for the diagnosis of pSS, especially the score of parenchymal inhomogeneity of salivary glands (SG) [1].
Objectives: To identify relevant ultrasonographic features associated with glandular involvement in patients with pSS, such as size measurements, vascularization, and the characteristics of adjacent lymph nodes of parotid and submandibular SG, and their association with the score of parenchymal inhomogeneity.
Methods: We enrolled patients with pSS (n=53), based on the 2002 American–European Consensus Group (AECG) pSS classification criteria, and non-Sjögren's sicca subjects (n=25), who exhibited sicca symptoms but did not fulfill the AECG pSS classification criteria. We considered SGUS score based on parenchymal homogeneity, presence of hypoechogenic areas, and clearness of posterior glandular border of SG. The score of the highest graded gland was considered and a score ≥2 was defined as a positive SGUS, according to OMERACT US-SG scoring [1]. The size measurements of the SG were the diameters in anterior-posterior, medio-lateral, and vertical directions during dental occlusion, and length and width of anterior prolongation of parotid glands. The vascularization was ranked according to the color doppler ultrasonography pattern without salivary stimulation. For the lymph nodes examination we considered the shape, number, and size of submandibular, superficial parotid (preauricular), and intraparotid lymph nodes, and the jugulodigastric lymph node, considering also that lymph nodes may not be detected. Categorical variables were compared using the Chi-square test and continuous variables were compared using Student's t-test with Welch's correction. p-values <0.05 were considered significant.
Results: SGUS was positive in a higher proportion of patients with pSS, in comparison to non-Sjögren's sicca subjects (60% vs. 24%, p=0.003). The size measurements showed a smaller antero-posterior diameter of both the right (mean 31.3 mm vs. 35.4 mm, p=0.037) and left (mean 30.1 mm vs. 34.2 mm, p=0.004) submandibular glands in pSS patients. A smaller antero-posterior diameter of the left parotid gland was also observed (mean 30.2 mm vs. 34.2 mm, p=0.046) in pSS patients. The lymph nodes evaluation showed that superficial parotid lymph nodes were detected in a lower proportion in pSS patients (45% vs. 72%, p=0.027). No significant differences were found between pSS patients and non-Sjögren's sicca subjects regarding the rest of the size measurements, the vascularization pattern, nor the shape, number, nor size of lymph nodes when they were detected. In addition, positive SGUS in pSS patients was also associated with smaller antero-posterior diameter of both the right (mean 29.9 mm vs. 35.4 mm, p=0.009) and left (mean 32.8 mm vs. 34.2 mm, p=0.008) submandibular glands, and a smaller antero-posterior diameter of the left parotid gland (mean 27.5 mm vs. 34.2 mm, p=0.044).
Conclusion: Ultrasonographic features are a valuable resource for the evaluation of pSS. The score of parenchymal inhomogeneity is associated with clinical diagnosis, and other indices such as the antero-posterior diameter of the submandibular glands and a lower detection of the superficial parotid lymph nodes may be used to assist the evaluation. However, no other macrostructural features of the parotid and submandibular SG, and the adjacent lymph nodes, seem to be different between pSS patients and non-Sjögren's sicca subjects.

AB0465 COMPARISON OF ULTRASOUND STRUCTURE CHANGES OF SALIVARY GLANDS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME WITH POSITIVE AND NEGATIVE ANTICENTROMERE ANTIBODIES

J. Khvan[1], A. Torgashina[1], E. Sokol[1], B. Chalcev[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Rare Rheumatic Diseases and Primary Sjögren's Syndrome, Moscow, Russian Federation*

Background: Apart from anti-Ro and/or anti-La positive primary Sjögren's syndrome (pSS), there is a unique subtype of pSS with anticentromere antibodies (ACA). At the present time salivary gland ultrasonography (SGUS) is widely used to assess the structure of the salivary glands in pSS, but there are few publications about SGUS changes in ACA-positive patients [1].
Objectives: To investigate SGUS changes in ACA (ACA+) positive pSS patients and compare with ACA-negative (ACA–).
Methods: We examined 141 patients with pSS, including 103 ACA– patients (pSS-ACA–) with the mean age 49,8 ± 14,1 years and 38 ACA+ positive (pSS-ACA+) with the mean age 59,1 ± 10,2 years. All patients underwent standard examination for the diagnosis of pSS (stomatological, ophthalmological, immunological), and SGUS performed using GE LOGIQ 9 of two parotid and two submandibular glands. Ultrasound images were evaluated with the OMERACT SGUS scoring system (SGUS SS) from grades 0 to 3 [2]. Statistical analyses (chi-squared test, p <0.05) were performed using STATISTICA version 12.
Results: Characteristics of patients with pSS-ACA+ and pSS-ACA– are presented in Table 1.

Table 1.

Parameters	ACA–		ACA+	
	N	%	N	%
Oral dryness	86	83,5	36	94,7
Ocular dryness	76	73,8	30	78,9
Enlargement of parotid salivary glands	36	34,9	7	18,4
Recurrent parotitis	23	22,3	7	60,5
ANA ≥1:320	103	100	38	100
Stimulated saliva flow test < 2.5 ml/5 min	65	63,1	30	78,9
Sialectasia on parotid sialography	103	100	38	100
Stimulated Schirmer's test <10 mm/5 min	67	65,0	26	68,4
Tear breakup time <10 seconds	59	57,3	20	52,6
Focus score ≥ 1foci/4 mm2	94	91,3	12/13	92,3
MALT-lymphomas	8	7,7	5	13,1

Characteristics of SGUS SS in pSS-ACA+ and pSS-ACA– are shown in Figure 1.

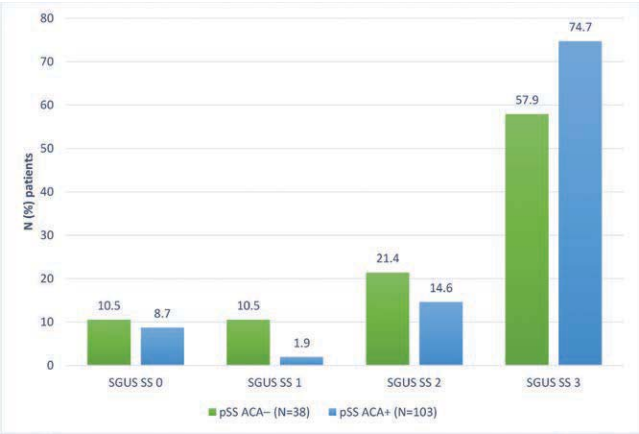

Figure 1.

We did not find significant differences when comparing SGUS SS in patients with pSS-ACA+ and pSS-ACA–.
Conclusion: We did not find significant differences in SGUS and SGUS SS in patients with pSS-ACA+ and pSS-ACA–.

AB0466

DYSFUNCTION OF THE AUTONOMIC NERVOUS SYSTEM IS ASSOCIATED WITH LOW-GRADE INFLAMMATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS.

A. Hempel Zinglersen[1], K. K. Iversen[1], J. Eugen-Olsen[2], J. Fleischer[3], S. Jacobsen[1]. *[1]Copenhagen Lupus and Vasculitis Clinic, Copenhagen University Hospital Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; [2]Department of Clinical Research, Copenhagen University Hospital Amager and Hvidovre, Hvidovre, Denmark; [3]Steno Diabetes Center Aarhus, Aarhus University Hospital, Aarhus, Denmark*

Background: Systemic lupus erythematosus (SLE) is characterized by chronic, systemic inflammation, organ damage and -dysfunction. Autonomic nervous system dysfunction is highly prevalent in SLE patients (up to 54%); compared to controls the prevalence may be up to 12 times increased.[1] These numbers parallel findings in other chronic conditions such as diabetes.[2]
Heart rate variability (HRV) reflects autonomic activity, and low variability indicates impaired activity, denoted as autonomic dysfunction (AD). AD is associated with low-grade inflammation in healthy subjects and patients with diabetes or cardiovascular disease.[3] The causality hereof is not fully understood: AD may impair the vagally mediated anti-inflammatory reflex, thus leading to increased systemic inflammation, but inflammatory mediated microvascular and neuronal damage may also impair autonomic function.
Objectives: To determine if markers of low-grade inflammation are associated with AD in SLE patients.
Methods: SLE patients (n=111) from the Copenhagen based PLUSheart (Prospective Lupus Study on Cardiovascular Risk Factors) cohort were included for this cross-sectional analysis. The cohort has previously been described[1] with the following characteristics in 2018-2019: 89.2% women, mean age: 51.5 (SD ±12.7) years, mean BMI: 25.1 (±5.0), mean disease duration: 19.9 (±9.5) years, median SLEDAI 2K score: 3 (IQR 1-4), and median SLE Damage Index score: 2 (1-4).
Low-grade inflammation was evaluated by plasma levels of C-reactive protein (CRP) and soluble urokinase-type plasminogen activator receptor (suPAR). Autonomic function was assessed with 5-min resting lead-I electrocardiograms using the Vagus™ device. Subsequent HRV analyses comprised RMSSD (the root mean square of successive interval differences between normal heartbeats), reflecting parasympathetic function, and SDNN (standard deviation of normal-to-normal heartbeat intervals), reflecting mixed parasympathetic-sympathetic function.
Results: All HRV- and inflammatory markers were non-normally distributed. The median SDNN was 30.4 (IQR 24.1-40.4), the median RMSSD was 19.7 (12.6-31.7). The median CRP level was 1 (1-3) and suPAR level was 3.2 (2.5-4.6).
For parametric analyses, all markers were logarithmically transformed. Both SDNN and RMSSD associated with CRP and suPAR levels in univariate analyses. When adjusting for age and SLE disease activity as per the SLEDAI-score, SDNN remained associated with suPAR and CRP and RMSSD with suPAR only (Table 1).

Table 1. Association between low-grade inflammation and autonomic nervous system function

	SDNN *				RMSSD *			
	Univariate		Adjusted		Univariate		Adjusted	
	β	P	β	P	β	P	β	P
CRP *	-0.241	**0.011**	-0.197	**0.035**	-0.215	**0.024**	-0.168	0.072
suPAR *	-0.239	**0.014**	-0.197	**0.038**	-0.268	**0.006**	-0.227	**0.016**

Univariate and multivariate linear regression analyses adjusted for age and disease activity of correlations between log-transformed (*) low-grade inflammation markers (CRP and suPAR) and heart rate variability markers (RMSSD and SDNN). β=standardized coefficients. Statistically significance (P<0.05) is marked with bold.

Conclusion: In SLE, HRV impairments reflecting both decreased parasympathetic and mixed parasympathetic-sympathetic autonomic function were associated with markers of low-grade inflammation independently of SLE disease activity and age. Longitudinal prospective studies are needed to determine causality.

AB0467

COMPARISON OF 2002 AECG AND 2016 ACR/EULAR CLASSIFICATION CRITERIA AND ROLE OF SALIVARY GLAND ULTRASONOGRAPHY IN A SICCA COHORT

R. Solans-Laqué[1], A. Portella Alegre[2], M. Planes-Conangla[2], J. Mestre-Torres[1], X. Serres-Créixams[2], M. I. González-Nieto[1]. *[1]Hospital Universitari Vall d'Hebron, Internal Medicine, Barcelona, Spain; [2]Hospital Universitari Vall d'Hebron, Radiology, Barcelona, Spain*

Background: For the last 20 years, different classification criteria have been used in clinical practice to improve the diagnosis of primary Sjögren's syndrome (pSS) and for research purposes. Several recent studies have assessed major salivary gland ultrasonography (SGUS) as a tool for diagnosing pSS and its inclusion in the classification criteria sets. In addition, some research suggests that it may be important to distinguish between monospecific antibody assays to Ro60 or Ro52.

Objectives: To compare the new 2016 American College of Rheumatology/ European League Against Rheumatism (ACR/EULAR) criteria to the revised 2002 American–European Consensus Group (AECG) criteria in a cohort of subjects with sicca symptoms and to assess the diagnostic accuracy of SGUS. We include monospecific antibody determination to Ro60 or Ro52.

Methods: Patients ≥ 18 years old with diagnosis of sicca syndrome without other associated collagen diseases were included. The initial cohort compromised 72 patients. We assessed features of salivary and lacrimal gland dysfunction and autoimmunity as defined by tests of both AECG and ACR/EULAR criteria. We included separate antiRo52 and antiRo60 antibodies determination, and considered only antiRo60 for the ACR/EULAR criteria as recommended [1]. All the patients underwent SGUS. Agreement between the criteria sets was assessed using Cohen's κ coefficient, and categorical variables were compared using the Chi-square test.

Results: Application of the AECG criteria resulted in the classification of 50 (69%) subjects with pSS, among whom 48 (67%) subjects also met ACR/EULAR criteria. All these patients received a physician diagnosis of pSS. No patients met ACR/EULAR only, and 22 (31%) subjects met neither criteria set. The concordance between AECG and ACR/EULAR criteria was almost perfect (κ = 0.94). The concordance group presented 8% antiRo60+, 4% antiRo52+, and 75% antiRo60+/ antiRo52+, among whom 56% had antiRo60+/antiRo52+/antiLa+. No patients presented antiLa in the absence of both antiRo60 and antiRo52 antibodies. SGUS was abnormal in 63% of these patients. The 2 patients fulfilling only AECG criteria had antiRo52+, and SGUS was abnormal in one of them. SGUS was abnormal in 27% of the 22 patients fulfilling no criteria sets. Thus, SGUS was abnormal in a significantly higher proportion of patients with pSS, in comparison to non-Sjögren's sicca subjects (62% vs. 27%, p=0.007). Including SGUS among the ACR/EULAR criteria would increase the concordance from κ = 0.94 to κ = 0.97 between the criteria set.

Conclusion: The two sets of classification criteria yielded concordant results with an almost perfect agreement in our sicca cohort. The presence of both antiRo60 and antiRo52 antibodies was the most characteristic autoimmune pattern, with no detection of antiLa in the absence of them. SGUS was positive in a higher proportion of patients with pSS and may improve the classification criteria.

AB0468

COMPARISON OF THE DIAGNOSTIC PERFORMANCE OF SALIVARY GLAND SCINTIGRAPHY AND ULTRASOUND IN SJÖGREN'S SYNDROME

M. I. González-Nieto[1], A. Portella Alegre[2], A. García-Burillo[3], S. Asadurova[3], J. Mestre-Torres[1], X. Serres-Créixams[2], R. Solans-Laqué[1]. *[1]Hospital Universitari Vall d'Hebron, Internal Medicine, Barcelona, Spain; [2]Hospital Universitari Vall d'Hebron, Radiology, Barcelona, Spain; [3]Hospital Universitari Vall d'Hebron, Nuclear Medicine, Barcelona, Spain*

Background: The 2002 American-European Consensus Group (AECG) criteria included salivary gland scintigraphy (SGS) as one of the possible objective methods for assessing salivary gland involvement in primary Sjögren's syndrome (pSS). However, this test as well as the sialography were not included in the 2016 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria and considered obsolete. On the other hand, salivary gland ultrasound (SGUS) is a simple and non-invasive procedure that is readily available and provides important information on the major salivary glands. Several recent studies have assessed SGUS as a tool for diagnosing pSS.

Objectives: To compare the diagnostic performance of SGS and SGUS for pSS patients.

Methods: We included 63 patients with sicca symptoms and suspected pSS. Diagnosis of pSS was established following the 2002 AECG criteria. The patients' scintigraphic grade was determined according to Schall classification (I-IV scale) [1], establishing Schall grade ≥III (moderate functional impairment) as the cut-off. We considered SGUS score based on parenchymal homogeneity, presence of hypoechogenic areas, and clearness of posterior glandular border of salivary glands. The score of the highest graded gland was considered, and a score ≥2 was defined as a positive SGUS, according to OMERACT US-SG scoring [2]. The area under the receiver operating characteristic (ROC) curve was employed to evaluate the screening method's performance.

Results: pSS was diagnosed in 40 (63%) patients, and the remaining 23 sicca subjects (37%) constituted the control group. Abnormal SGS was established in 26/40 (65%) pSS patients and 10/23 (43%) controls. Positive SGUS was established in 24/40 (60%) pSS patients and 6/23 (26%) controls. Thus, the sensitivity and specificity of SGS were 65% and 57%, respectively, and 60% and 74% for SGUS, respectively. The area under the ROC curve (Figure 1) of scintigraphy was 0.73, while for the SGUS was 0.83.

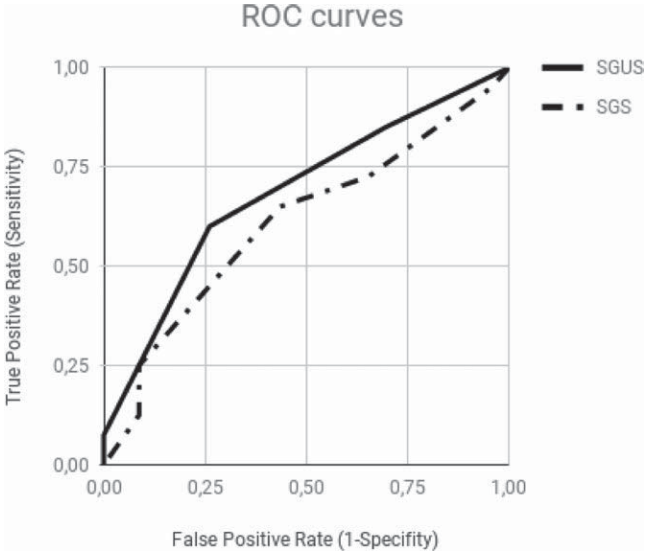

Figure 1. ROC curve comparison of SGS and SGUS for the diagnosis of pSS.

Conclusion: The diagnostic accuracy of SGUS is not only comparable with scintigraphy in pSS patients but also results in a better performance. This result indicates that SGUS is a useful method for evaluating salivary gland involvement in pSS and could be an alternative tool to other diagnostic techniques, such as SGS.

AB0469

EVALUATION OF SALIVARY GLAND ALTERATIONS IN SJÖGREN'S SYNDROME WITH MULTISPECTRAL OPTOACOUSTIC TOMOGRAPHY

B. Hofauer[1], F. Johnson[1], Z. Zhu[1]. *[1]Klinikum rechts der Isar, Technical University of Munich, Otorhinolaryngology / Head and Neck Surgery, Munich, Germany*

Background: More than half of all patients with Sjögren's syndrome (SjS) show characteristic sonomorphological changes in the salivary glands. The relevance of this alterations for diagnosis and follow-up has been investigated in multiple studies. However, it is still not known which parenchymal changes cause this sonomorphological picture. Multispectral optoacoustic tomography (MSOT) is based on the photoacoustic effect – by exciting different chromophores with lasers of different wavelengths, information on tissue composition can be generated. With the help of MSOT, knowledge about tissue changes in salivary glands in patients with SjS should be gained for the first time.

Objectives: Can MSOT be applied in the area of the salivary glands and provide new information on the parenchymal changes in SjS?

Methods: In patients with SjS, classified according to the ACR/EULAR classification criteria, the ESSPRI and ESSDAI were recorded and tear flow and unstimulated salivary flow were determined. The sonomorphological changes in the salivary glands were evaluated using the OMERACT scoring system. Using MSOT, collagen, lipids and (de)oxygenated hemoglobin of the parotid and submandibular glands on both sides were measured (MSOT Acuity Echo).

Results: Twenty-three patients were included in the study (21 women, age: 62 years). At the time of the study, the ESSPRI averaged 47 points and the ESSDAI 8.5 points. The Schirmer test gave an average value of 6.4 mm/5 min, the unstimulated salivary flow (UWSF) 0.2 ml/5 min. The evaluation of the B-mode sonography showed predominantly hypoechoic lesions and less hyperechoic bands. In the evaluation of the tissue information obtained by means of MSOT, a correlation between increased lipid content and salivary flow measurement was shown as well as a significant difference between collagen proportion between parotid and submandibular glands.
Conclusion: With the help of MSOT, statements about the actual tissue changes within the salivary glands in SjS can be made for the first time. This project demonstrated for the first time a correlation between tissue composition and clinical parameter. The evaluation of other wavelengths in order to obtain further information on the tissue composition is planned.

AB0470 THE ASSOCIATIONS OF ANTI-DNA ANTIBODIES WITH DISEASE ACTIVITY INDICES AND PATIENT REPORT OUTCOME PARAMETERS OF SLE IN KYOTO LUPUS COHORT.

Y. Nakakubo[1], H. Tsuji[1], Y. Takase[1], T. Iwasaki[1], M. Shirakashi[1], H. Onizawa[2], R. Hiwa[1], K. Kitagori[1], S. Akizuki[1], R. Nakashima[1], A. Onishi[2], H. Yoshifuji[1], M. Tanaka[2], A. Morinobu[1,2]. *[1]Kyoto University Graduate School of Medicine, Rheumatology and Clinical Immunology, Kyoto, Japan; [2]Kyoto University Graduate School of Medicine, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan*

Background: Since the goals of remission or low disease activity are becoming more realistic with advances in treatment for SLE, there is a need to examine the measurements for SLE especially in patients with low disease activity. It has been known that disease activities in SLE are correlated with anti-DNA antibodies (Abs). However, it was not clear which measurements of disease activities or patient reported outcomes correlate better with anti-DNA Abs.
Objectives: To examine the association between parameters for SLE and anti-DNA Abs measured with RIA in Kyoto Lupus Cohort, a SLE registry in Kyoto University Hospital from 2019 to 2021.
Methods: 1)Correlations between anti-DNA Abs with SLEDAI, M-SLEDAI (SLEDAI without anti-DNA Abs), VAS, LupusPRO, SF-36, and Systemic lupus erythematosus Symptom Checklist (SSC) were evaluated cross-sectionally (n = 310).
2)The alterations in SLE parameters and anti-DNA Abs between two visits were examined (n = 106). Further, the correlations within 3 months were examined in cases with flare-ups of SLE (the alteration in SLEDAI > 0 and anti-DNA Abs≧0, n = 39). The associations of the alterations of anti-DNA Abs with each item of SLEDAI classified by organs were also examined.
Results: 1)31 percent of the cases in the entire registry was classified as remission or low disease activity (Table 1). SLEDAI (mean±SD) was higher in patients positive for anti-DNA Abs (7.94±5.20) than that in patients negative for anti-DNA Abs (4.56±4.65) ($p < 0.0001$). Anti-DNA Abs were weakly correlated with SLEDAI (R = 0.24 [$p < 0.0001$]), M-SLEDAI (R = 0.15 [$p = 0.014$]), and Physician-VAS (R = 0.19 [$p = 0.0016$]). On the other hand, there were no significant correlations between anti-DNA Abs and LupusPRO and SSC. Some dimensions in SF-36 had weak correlations with anti-DNA Abs, while no component summary scores had significant correlations with anti-DNA Abs.

Table 1. Patients' demographics and disease characteristics in the cohort (n = 310).

Variable	Results
Age (years)	47.7 (39.4, 57.5)
Female sex	n = 284 (91.6%)
Disease duration (years)	15.9 (9.4, 24.5)
Anti-DNA Ab positivity†	n = 106 (34.2%)
Anti- DNA Ab titer (U/mL)	4 (0, 8)
SLEDAI	4 (2, 8)
SLEDAI<=4	n = 162 (52.1%)
SSC	31 (16.2, 52.5)
Remission or LDA	n = 95 (30.7%)
Patient-VAS	38 (15, 52)
Physician-VAS	13.3 (3.3, 23.3)
SF-36 PCS	45.4 (36.6, 52.4)
SF-36 MCS	48.2 (41.5, 53.6)
SF-36 RCS	51.3 (42.6, 58.6)
LupusPRO HQOL	70.2 (54.8, 86.5)
LupusPRO NHQOL	41.7 (31.3, 51.0)
Glucocorticoid (mg/day)	5 (4, 8)

* Data are n (%) or median (Q1, Q3). † Anti-DNA Ab positivity at the time of the cross-sectional observation.

2)No significant correlations were observed between the alterations of SLEDAI and anti-DNA Abs (R = 0.00 [95% CI: -0.23 – 0.22, p = 0.95]) in the total of patients with various range of observation periods (Figure 1A). In contrast, a significant correlation was observed (R = 0.32, p = 0.04) within 3 months after the flare-ups of SLE (Figure 1B). No significant correlations were found between the alterations in VAS and anti-DNA Abs, or the alterations of SSC and anti-DNA Abs. They showed the following organ symptoms: renal involvement, 62.8%; musculoskeletal, 17.1%; neuropsychiatric, 11.4%; hematological, 5.7%; mucocutaneous, 11.4%; serositis, 2.9%, and fever, 2.9%.

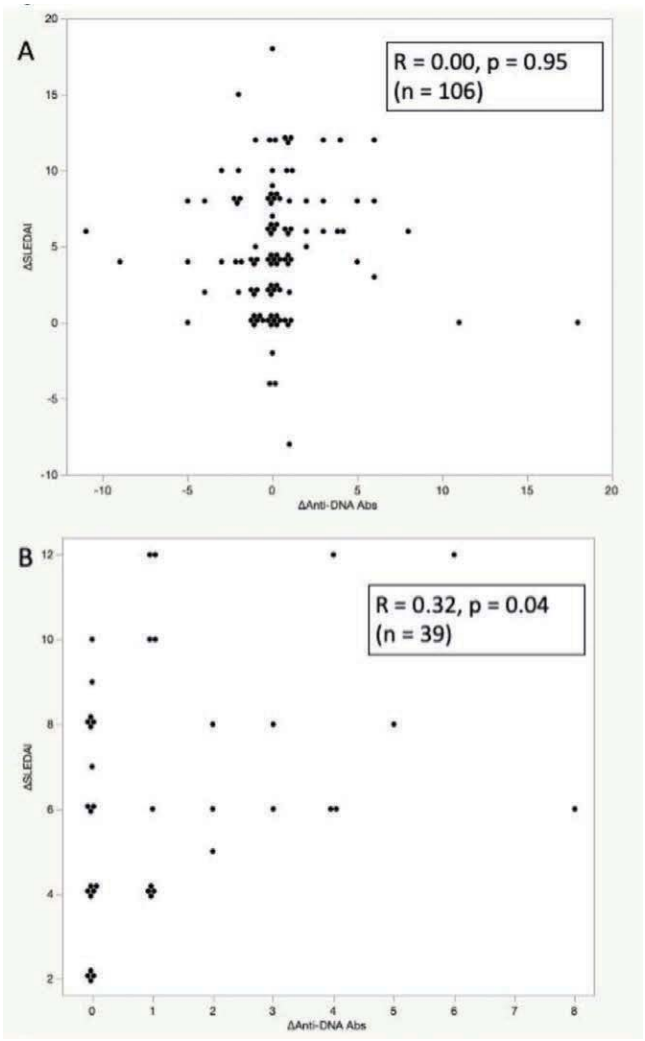

Figure 1. The associations between the alteration in anti-DNA Ab and SLEDAI

Conclusion: The associations between anti-DNA Abs with several parameters of SLE were examined. Anti-DNA Abs correlated with disease activities (SLEDAI) in SLE patients, especially when observed in the condition of flare-up.

AB0471 FIRST SYMPTOMS AT THE ONSET OF PRIMARY SJÖGREN'S SYNDROME – THE PATIENTS' PERSPECTIVE OF A SNEAKY DISEASE

A. Lackner[1], J. Fessler[1], S. Zenz[1], J. Hermann[1], J. Thiel[1], M. Stradner[1]. *[1]Medical University of Graz, Department of Rheumatology & Immunology, Graz, Austria*

Background: Primary Sjögren Syndrome (PSS) is an autoimmune disorder with a diverse spectrum of clinical manifestations ranging from sicca symptoms to severe systemic organ involvement. Little is known about the symptoms at the onset of PSS, as these are often ignored by both, patients and physicians leading to a substantial delay of diagnosis.
Objectives: The aim of this study was to investigate patients' recollection of the first symptoms before diagnosis of PSS in qualitative interviews. The second aim was to verify and quantify these aspects in a representative cohort.

Methods: All PSS patients fulfilled the EULAR/ACR 2016 classification criteria. In the first part of the study, consecutive PSS patients were recruited for individual, semi-structured interviews. A discussion guide with five open-ended questions was developed to explore patients' experiences on the onset of PSS. All interviews were audio-recorded and transcribed verbatim, and an inductive thematic data analysis was performed using MAXQDA software (VERBI, Berlin, Germany).

In the second part, the identified aspects of the qualitative analysis were grouped to a checklist with ten items. Patients were asked to complete the checklist before their routine clinical assessment.

Results: One-hundred and thirty-four patients participated in the study. The qualitative part was completed by 31 PSS patients; 90.3% (n=28) were female and patients had a mean disease duration of 6.9 years (±5.7(SD)) and a mean age of 58.1 years (±12.6).

Four different major aspects emerged of how patients experienced the beginning and first symptoms of PSS: (1) sicca symptoms started after initial swelling of parotis and/or lymph nodes (2) "Classic" PSS symptoms (fatigue, pain, dryness): patients reported wandering joint pain before diagnosis with a long time apart from first symptoms until diagnosis. Patients described joint pain, chronic malaise, and fatigue over months. (3) Hormonal changes (e.g. after birth, hysterectomy) or infections before the onset of PSS symptoms. (4) Slowly progressing discomfort due to sicca: patients reported a slow progression of symptoms with no initial recognition of sicca discomfort. In these patients recurrent dental problems and loss of teeth in the years prior to diagnosis was common.

In the second part of the study, the four themes were verified in an independent cohort of 103 PSS patients. Patients were 59.9 (±13.7) years old and six patients were male. The main symptom before diagnosis was dryness (n=77, 74.8%) with wandering joint pain (n=51, 49.5%) and fatigue (n=47, 45.6%). In 38.8% (n=40), patients reported a swelling/inflammation of the parotid gland at the onset of disease.

Conclusion: We identified four themes describing the initial symptoms of PSS. Raising awareness of these symptoms among physicians and among the general public may allow earlier diagnosis of PSS.

AB0472 DEFINING AN ACCEPTABLE STATE OF QUALITY OF LIFE IN PRIMARY SJÖGREN'S SYNDROME

A. Lackner[1], A. Sanz[1], S. Zenz[1], J. Hermann[1], J. Thiel[1], M. Stradner[1]. [1]*Medical University of Graz, Department of Rheumatology & Immunology, Graz, Austria*

Background: The PSS-QoL (the Primary Sjögren's Syndrome Quality of Life Questionnaire) is a disease-specific health-related quality of life (HRQL) questionnaire in primary Sjögren Syndrome (PSS). The psychometric testing showed a valid and reliable assessment, which allows a comprehensive evaluation of the patients' perspective and the extent of the disease in PSS.

Objectives: To define the threshold of an acceptable QoL state (AQLS) and the minimal detectable change (MDC) of the PSS-QoL.

Methods: Data of patients from the PSS registry of the Medical University of Graz fulfilling the 2016 ACR/EULAR classification criteria for PSS were analysed. Patients completed the PSS-Qol and ESSPRI (EULAR Sjögren's syndrome patient-reported index), disease activity was assessed by the ESSDAI (EULAR Sjögren's syndrome disease activity index) and an evaluator's global assessment (EGA, scale from 0 to 10). Receiver operating characteristic curve analyses were used to estimate the AQLS based on patients' assessment on the extent of HRQL. We selected the optimal cut-off of PSS-QoL by the maximal Youden index. At the follow – up visits after 12 months, patients assessed, whether their HRQL had changed. An anchoring method based on this evaluation was used to estimate the MDC of PSS-QoL. Furthermore, clinical data were compared in AQLS and non-AQLS groups.

Results: Data from 152 PSS patients were analysed which of 91.4% (n=139) were female. The mean age was 59.65±12.3 years (± standard deviation) and the mean disease duration was 5.6±5.3 years. The AQLS estimate was defined as PSS-QoL≤29.5. 40.1% (n=61) were categorized to be in AQLS. Although AQLS patients were significantly younger (56.9±13.1years vs 61.5±11.4 years, $p<0.01$) they had a longer disease duration (6.9±5.8 years vs. 4.7±4.7 years, $p<0.05$) compared to non-AQLS patients. AQLS patients had a lower EGA (2 [0-5] vs 3 [0-7], $p<0.01$ (median [range]), higher IgG (15.7[7.7-33.8, range] vs 13.1 [6.5-38.1], $p<0.05$) and higher rheumatoid-factor IgA (84 [0-500] vs 20 [0-500], $p<0.01$). AQLS patients showed significantly lower burden of sicca (measured by ESSPRI and sicca VAS scores). The MDC for PSS-QoL was defined as 12.2 points. After one year, patients' HRQL did not change in 83.3% and got worse 7.1%.

Conclusion: This study determined the AQLS and the minimal detectable change for HRQL. These results will help evaluating the HRQL of patients in clinical practice, as well as possible assistance designing future clinical trials. Patients in AQLS show lower dryness scores but higher immunological activity compared to non-AQLS patients. Longitudinal studies are needed to determine factors affecting patients' HRQL in PSS.

AB0473 EFFECT OF THYROID LESIONS ON THE COURSE OF SYSTEMIC LUPUS ERYTHEMATOSUS

A. Trofimenko[1], O. Emelyanova[1], O. Rusanova[1]. [1]*Federal State Budgetary Institution « Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Laboratory of Clinical Immunology, Volgograd, Russian Federation*

Background: Thyroid disease is a common complication of systemic lupus erythematosus manifesting in 30% of cases due to a disturbance of autoimmune mechanisms.

Objectives: evaluating the effect of thyroid lesion on the course of systemic lupus erythematosus based on clinical and laboratory parameters, and the level of antibodies to thyroid hormones.

Methods: Among 65 examined patients with SLE (63 women and 2 men aged 19-65) we revealed a thyroid disorder in a third of patients. Patients were diagnosed with autoimmune thyroiditis in 16 cases, nodular goiter (degree I and II), and single diffuse toxic goiter in 5 cases. The duration of the disease was 5 years, that concomitant thyroid diseases — 3 years. The concentration of antibodies to thyroid hormones was determined by enzyme immunoassay using immobilized thyroxine and triiodothyronine.

Results: When the thyroid gland (TG) gets involved, there is a pronounced discordance in the parameters of immune and hormonal status in patients with SLE compared with patients without thyroid complications. It was found that 68% of patients had antibodies to nDNA, compared with 46% without concomitant thyroid lesion, CIC - 77% and 32%, respectively, IgG - 54% and 25%. The SLICC/ACR damage index in the SLE group with thyroid involvement was higher than in the second group: 4.55 and 3.6 points. This indicates an increase in the severity of SLE in patients with involvement of the thyroid gland. Joint involvement was seen in 79% with thyroid involvement, and 49% without thyroid involvement. A lesion of serous membranes in the form of pleurisy was in 39% and in 3% without involvement, that of the heart in 66/24%. Lupus erythematosus cell phenomenon in 44 / 31%. Immunological activity prevailed in the group of SLE patients with combined autothyroid disease. Among these patients, 100% had an elevated level of antibodies to thyroid-stimulating hormones, versus 15% in the group without autothyroid disease.

Conclusion: The involvement of the thyroid gland increases the severity of the course of SLE, antibodies to thyroid hormones are produced actively, which is indicative of thyrocyte destruction and of blocking the normal process of hormone synthesis by their antibodies.

Background: Information technology has expanded the gap in patient health literacy (HL), and HL has various implications on the trust in patient-doctor relationship. Previously, only functional HL, the ability to interpret health information through reading and writing skills, has been studied in patients with SLE (1).
Objectives: We examined how trust in physicians is affected by the broader concept of HL, including communicative HL, the ability to extract health information from communication to use, and critical HL, the ability to discern and use such information (2).
Methods: This cross-sectional study enrolled 362 SLE patients at 5 sites between June 2020 and August 2021. Three domains of HL (i.e., functional HL, communicative HL, and critical HL) were assessed using the 14-item FCCHL scale (range: 1-4 points for each domain). The outcomes were patients' trust in their physicians and physicians in general and were measured using the Japanese version of the 5-item Wake Forest Physician Trust scales (range: 0-100 points for each scale). General linear models adjusted for age, gender, education, income, SLEDAI, disease duration, depression, and hours of Internet use were conducted. Subsequently, a series of general linear models were then fit to each of the three domains of HL to examine whether or not it was associated with the aforementioned covariates.
Results: The median age of the patients was 45 (interquartile range [IQR],34-55), 88% were female. The median value of SLEDAI was 4 ([IQR], 2-8), Trust in one's physician was 80 ([IQR], 70-95) and trust in physicians generally was 65 ([IQR], 50-80). Trust in one's physician increased with higher functional and communicative HL (per 1-pt increase, 3.2 [95%CI 0.7 to 5.9]; 5.4 [95%CI 1.6 to 9.3]). Trust in doctors generally increased with higher communicative HL and decreased with higher critical HL (per 1-pt increase, 6.8 [95% CI 2.0 to 12]; -6.7 [95% CI -12 to -1.9]). Lower functional HL was associated with older age and depression, while higher HL was associated with higher educational level. Higher communicative HL and critical HL were each associated with longer Internet use.
Conclusion: In patients with SLE, higher trust in one's physician was associated with both functional and communicative HL, while higher trust in physicians generally was associated with higher communicative HL and lower critical HL. Our findings suggest that trusting relationships may be fostered by the encouragement of rheumatologists to cultivate patients' ability to share their health problems with their physicians and family members and to obtain useful health information (i.e., communicative HL), rather than to improve their ability to discern health information (i.e., critical HL).

AVASCULAR NECROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF LONG-TERM FOLLOW-UP FROM A SINGLE CENTRE

B. Bulat[1], D. Sahin Eroglu[2], T. M. Turgay[2], G. Kınıklı[2], A. Ates[2]. *[1]Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Avascular necrosis (AVN) is a major cause of morbidity and loss of quality of life in systemic lupus erythematosus (SLE) patients. AVN is often diagnosed at advanced stages and treatment options are limited.
Objectives: To identify the differences of demographic, clinical, and serological factors in SLE patients with and without AVN, and to investigate associated risk factors of AVN in patients with SLE.
Methods: In this single-centre retrospective cohort study, we included 533 SLE patients [88.6% female, mean (standard deviation, (SD)) age at diagnosis 34.6 (14.3) years] who fulfilled SLICC 2012 classification criteria. AVN diagnosis was confirmed by radiological imaging techniques in symptomatic patients. To investigate the correlation between maximum daily steroid dose and AVN development, we divided our patients into four groups according to the highest dose of prednisolone used for a month or longer during their follow-up (Group 1: 0-19mg/day, Group 2: 20-39mg/day, Group 3: 40-59mg/day, Group 4:≥60mg/day). Pulse steroid administration was also recorded. Multivariable logistic regression analyses were performed to demonstrate the associated factors with AVN. Clinical parameters found to be related to AVN development in univariable analyses were analyzed both in the sex- and age-adjusted model, and the model including sex, age, time to AVN or last follow-up, immunosuppressive therapy, and steroid dosages (multivariable model). To determine the relation of different steroid groups and pulse steroids with AVN, odds ratios (OR) were calculated in the sex- and age-adjusted model and multivariable model.
Results: After a median disease duration of 9.1 years, AVN was detected in 46 (8.6%) patients. There were 85 AVN sites involved, the hips being the most commonly affected (71.7%) (Figure 1). The mean age at SLE diagnosis was significantly younger in the AVN group (mean (SD) 26.8 (11.7) vs. 35.3 (11.4), p<0.001). Fever (21.6% vs. 10.9%), malar rash (52.2% vs. 36.3%), serositis (26.1% vs. 14.6%), renal involvement (65.2% vs. 35.1%) and hemolytic anemia (32.6% vs. 19.3%) were found more frequently in the AVN group compared to non-AVN group, respectively (p<0.05). In the multivariable logistic regression analyses, malar rash was found to be the only clinical feature associated with AVN (OR 2.01, 95% confidence interval (CI) 1.02-3.97). The steroids had an association with AVN development in a dose-dependent manner (Table 1). Pulse steroids did not increase the risk of AVN (Table 1).

Table 1. Factors associated with avascular necrosis.

Association between maximum daily steroid dose and AVN			
	OR Crude (95% CI)	OR Age-sex adjusted (95% CI)	OR fully adjusted* (95% CI)
0-19 mg/day (reference group)	1.00 (reference group)		
20-39 mg/day	7.22 (1.29-40.31)	6.63 (1.18-32.28)	5.86 (1.00-34.37)
40-59 mg/day	14.08 (3.02-65.63)	10.69 (2.25-50.75)	8.79 (1.77-43.61)
≥60 mg/day	31.50 (7.39-134.19)	26.03 (6.02-112.59)	13.93 (3.07-63.16)
Association between pulse steroid treatment and AVN			
	OR Crude (95% CI)	OR Age-sex adjusted (95% CI)	OR fully adjusted* (95% CI)
No pulse steroids	1.00 (reference group)		
Pulse steroids	6.29 (3.35-11.81)	4.86 (2.53-9.37)	1.51 (0.69-3.32)

*In addition to the age at SLE diagnosis and sex, immunosuppressant use, and follow-up duration were also added to the final model.

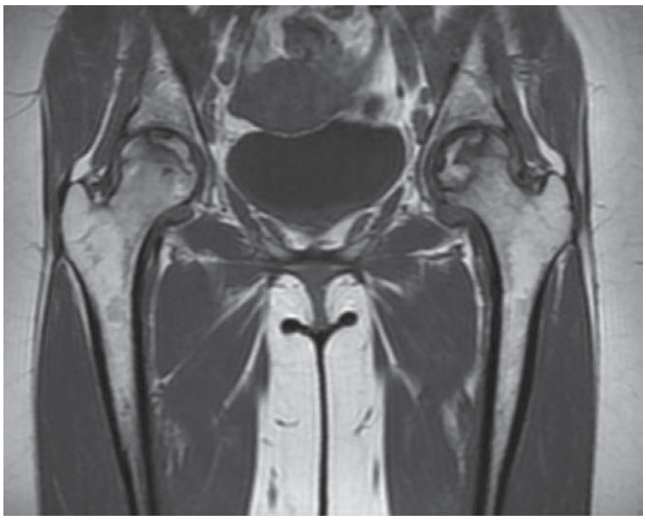

Figure 1. Magnetic resonance imaging of avascular necrosis of bilateral femoral heads in a patient with SLE.

Conclusion: High-dose daily steroid use was associated with an increased risk of AVN in SLE patients. Therefore, to prevent AVN in patients with SLE, the aim should be minimizing the dosage and duration of steroid use as much as possible. Furthermore, we showed that malar rash independently increased the risk of AVN development. Further research is required to explain this finding.

AB0476 PREDICTIVE FACTORS FOR THE DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

S. M. Ahn[1], J. S. Oh[2], Y. G. Kim[1], C. K. Lee[1], B. Yoo[1], S. Hong[1]. [1]*Asan Medical Center, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea);* [2]*Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)*

Background: Patients with immune thrombocytopenia (ITP) have a risk of developing systemic lupus erythematosus (SLE). We sought to examine the clinical characteristics of patients with primary ITP who later developed SLE, and identified the risk factors for the development of SLE.
Objectives: We retrospectively examined patients who were diagnosed with primary ITP at a tertiary hospital between August 2001 and November 2019. We compared the clinical characteristics according to the development of SLE. Logistic regression analysis was performed to identify the factors associated with the development of SLE.
Methods: Of 130 patients with primary ITP, 10 (7.7%) were later diagnosed with SLE during follow-up (median, 30 months [IQR, 15.5–105]). The presence of skin bleeding, organ bleeding, lymphopenia, anemia, and positive antinuclear antibody (ANA) titer (> 1:160) were more common among patients who later developed SLE than did those who did not develop SLE. Multivariate analysis showed that young age (< 40 years; odds ratio [OR], 8.359 [95% confidence interval (CI), 1.230–56.793]; p = 0.033), organ bleeding (OR, 18.349 [95% CI, 2.771–121.517]; p = 0.003), and ANA positivity (>1:160; OR, 7.692 [95% CI, 1.482–39.910]; p = 0.015) were significantly associated with the development of SLE.
Results: Young age (< 40 years), organ bleeding, and ANA positivity (> 1:160) were risk factors for the development of SLE in patients with primary ITP.
Conclusion: These results suggest that continued follow-up for the detection of SLE development is needed for patients with ITP, particularly those with young age, ANA positivity, or organ bleeding.

AB0477 REMISSION AND CLINICAL PATTERNS OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN SOUTHERN PAKISTAN: RETROSPECTIVE COHORT STUDY

M. Saeed[1], A. Pasha[2], S. H. A. Rizvi[1], M. Munawar[1], Z. Abaad Elias[1], M. I. Shafi[3], T. Gazdar[4], M. P. A. Lakhdir[2]. [1]*ImmunoCure, Rheumatology, Karachi, Pakistan;* [2]*Aga Khan University, Community Health Sciences, Karachi, Pakistan;* [3]*BenchMatrix Pvt Ltd., Information Technology, Karachi, Pakistan;* [4]*ImmunoCure, Clinical Laboratory, Karachi, Pakistan*

Background: SLE is a difficult to treat autoimmune disease due to clinical heterogeneity, unpredictability of disease flares and limited therapeutics. These challenges are worsened in a low-middle income country (LMIC) setting, yet clinical epidemiology from LMIC may have global benefits.
Objectives: To determine (i) the clinical pattern of SLE and (ii) the effect of SLE severity and treatment regimen on time to remission.
Methods: A retrospective cohort study of 200 SLE patients' medical records (Mar 2014 to Mar 2020) from ImmunoCure clinic was conducted. Patients fulfilled American College of Rheumatology criteria 1997 for SLE classification. Inclusion criteria were active SLE disease, as measured by SLEDAI-2K [1]. SLEDAI categories were used as outcome measure: mild (score ≤6), moderate (7-10), severe (>10) to evaluate clinical pattern of SLE. ANA subsets and disease phenotypes were used to describe the clinical pattern in each SLEDAI category. ANA was performed using Immunofluorescence on Human Hep2 cells. ANA subsets were performed using immunoblot from Euroimmun [2]. Statistical analyses were performed using STATA v16.0. Kruskal-Wallis test was used for continuous measures, and Pearson's chi square test was used to compare categorical variables across SLEDAI severity. Remission status and time to remission was the secondary outcome. Remission was based on DORIS 4 criteria [3]: immunosuppressives (IS) with Prednisolone (Pred) 5mg or 2.5mg and finally off all drugs (Pred 0 and no IS), along with follow up duration > 1-year. Total doses of all drugs were calculated [4]. Survival regression was used, along with Kaplan Maier curve to estimate median remission time (months).
Results: ANA Speckled pattern is associated with mild to moderate disease (P=0.02). Most frequent antibodies are anti-dsDNA (63%), SSA (24%) and Ku (17.5%). Anti-cardiolipin (aCL) antibodies are significantly associated with severe disease (OR = 3.6, CI: 1.5-8.5, P<0.01). Most common presentations of SLE in this cohort are arthritis (85%), alopecia (53%), anemia (38%), rash (35%) and CNS disease (28%). Nephritis, CNS disease, cytopenias and oral ulcers are significantly associated with severe disease activity (P<0.01). ILD is in 10% of our cohort. Frequency of severe SLE was 47.5%, whereas mild disease was 16.5%. Mean duration of follow up was 41±19 months. For every 1- month increase in duration of follow up, the odds of remission increase by 6% (CI: 1.04-1.09, P<0.05). Clinical remission on treatment (at Pred≤5mg) was successfully achieved in 62% patients. Complete remission (off all IS & Pred) was achieved in 24 patients (14 in severe SLEDAI category) out of 200, with a mean post remission follow-up of 18 ± 15 months. Importantly, no statistical difference was found in SLEDAI category and remission status (p=0.3). However, the hazard of time to remission is 61% (CI: 0.21-0.77, P=0.01) less in severe SLE as compared to mild SLE disease activity (Figure 1).

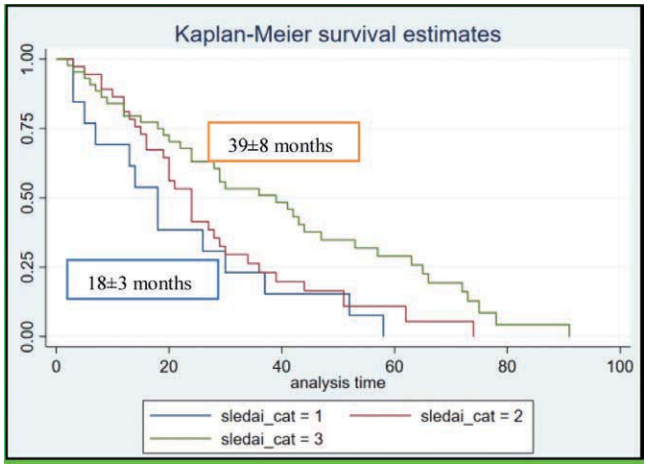

Figure 1. Kaplan Meier curve for remission time in 94 SLE patients followed for >1-year.

Conclusion: Presence of aCL is associated with severe SLE. Sustained remission is possible even in severe SLE in a LMIC setting if adequate immunosuppression is provided with persistent clinical follow-up.

LUPUS ANTICOAGULANT IS ASSOCIATED WITH PROSPECTIVE ECHOCARDIOGRAPHIC CHANGES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A FIVE-YEAR FOLLOW-UP STUDY

K. A. Myhr[1], M. M. Jepsen[2], A. Hempel Zinglersen[3], K. K. Iversen[3], M. L. F. Hermansen[4], A. T. Ngo[5], R. Pecini[1], S. Jacobsen[3]. *[1]Copenhagen University Hospital Rigshospitalet, Department of Cardiology, Copenhagen O, Denmark; [2]Bispebjerg University Hospital, Department of Clinical Pharmacology, Copenhagen, Denmark; [3]Copenhagen University Hospital Rigshospitalet, Department of Rheumatology and Spine Diseases, Copenhagen, Denmark; [4]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [5]Zealand University Hospital, Department of Cardiology, Koge, Denmark*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with increased risk of cardiovascular complications such as coronary artery disease, myocarditis, pericarditis, and valvular dysfunction (1–3). The pathophysiological mechanisms are poorly understood and markers to identify high risk patients are warranted.
Objectives: We aimed to identify SLE-characteristics that are associated with progressive cardiac dysfunction.
Methods: A total of 108 patients with SLE (90 % female, mean age 46±13 years, median disease duration of 14 (7-21) years) were included from 2013 to 2014. Blood samples were collected with inclusion of biomarkers, and a standard echocardiography was performed at baseline and at a five-year follow-up. Multivariate regression analyses with five independent lupus-specific baseline variables of interest (disease activity, lupus nephritis, anti-cardiolipin and/or anti-beta-2 glycoprotein I antibodies, and lupus anticoagulant (LAC)) were performed for the association with baseline echocardiographic parameters as well as for changes during follow-up.
Results: During the five-year follow-up period, left ventricular (LV) end-diastolic volume index increased from 43.5±13.9 to 52.5±15.7 ml/m^2 (p <0.001) (Figure 1 A1), and LV diastolic parameters declined (E/A ratio 1.4±0.5 vs. 1.3±0.5, p=0.002; e' velocity 12.8±3.8 vs. 12.0±3.7 cm/s, p=0.02; mitral valve deceleration time 227.9 vs. 200.8 ms, p=<0.001), except for E/e' (7.5±3.8 vs. 6.8±3.4, p=0.02) (Figure 1B1) in the entire SLE population. LV ejection fraction remained stationary (59.5±6.8 vs. 59.6±6.4 %, p=0.81). Presence of LAC was associated with progressive LV dilatation during the follow-up period (p=0.005) (Figure 1 A2) but not baseline LV volumes (p=0.35). LAC was associated with lower E/A ratio at baseline (p=0.006) but did not predict a decrease of E/A ratio during follow-up (p=0.09) (Figure 1 B2). Follow-up changes of other echocardiographic parameters were not associated with any of the lupus-specific variables.

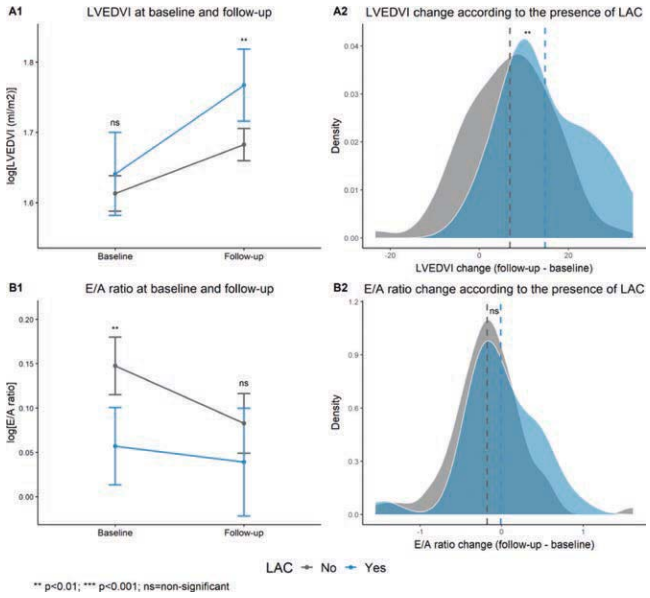

Figure 1. Left ventricular end-diastolic volume index (LVEDVI) (A) and E/A ratio (B) at baseline and follow-up (A1, B1) as well as paired longitudinal changes as density plots (A2, B2) with mean values (dashed lines) according to the presence of LAC (blue). LVEDVI and E/A ratio at baseline were log-transformed due to non-normality.

Conclusion: Presence of LAC was associated with lower E/A ratio at baseline as well as progressive left ventricular dilatation during a five-year follow-up period. Hence, LAC might be a predictor of progressive cardiac dysfunction in SLE patients. LAC is known to have implications for the microvascular circulation, but the clinical significance of the present findings is yet to be elucidated.

AB0479 RELATIONSHIP BETWEEN DISEASE ACTIVITY, ORGAN DAMAGE AND HEALTH-RELATED QUALITY OF LIFE AS ASSESSED BY LUPUSQOL AND SF-36 IN 400 RUSSIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

E. Aseeva[1], S. Solovyev[2], S. Glukhova[1], A. Lila[1]. *[1]Federal State Research Institution (FSRI) named after V.A. Nasonova, Systemic Lupus Erythematosus Department, Moscow, Russian Federation; [2]JSC Group of companies Medsi, Rheumatology Department, Moscow, Russian Federation*

Objectives: We conducted this study to compare the efficiency of LupusQoL with the 36-item Short-Form Health Survey (SF-36), a generic quality of life (QoL) scale, in Russian patients with lupus.
Methods: Both questionnaires were conducted for one visit to the clinic. Disease activity was evaluated by the SLEDAI-2K, while the chronic damage was assessed by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI). Associations between the LupusQoL and SF-36 domains were examined according to SLEDAI 2K and SDI.
Results: A total of 400 patients with lupus (F/M 363:37, mean age 34,2±11.5 years, mean disease duration 106,3±91,9.0 months) were included. All patients were divided into 4 groups: SLEDAI 2K ≤4 – 136 pts, SLEDAI-2K ≥4 – 264 pts, SDI =0 – 177 pts, SDI ≥1 – 223 pts.
QOL as assessed by SF-36 and LupusQoL was low in all groups of patients with SLE. The mean scores for each of the domains of the LupusQoL and SF-36 are shown in Table 1.
It was shown that the domain of pain of the LupusQoL questionnaire ($p<0.007$) statistically significantly responds to disease activity in contrast to the comparable SF-36 scale. The domains MH ($p<0.001$) and VT ($p<0.007$) of the SF-36 are more sensitive to change of disease activity.
It was found that in patients with SLE with a high activity of the disease, the noncomparable domains such as Planning ($p<0.0004$), Intimate relationship ($p<0.003$), Burden to others ($p<0.03$), Body image ($p<0.007$) significantly change. The QOL in patients with SLE with SDI ≥1 was poor in the domain of Physical health of the LupusQoL and in the comparable domain of the SF-36 PF. Higher QOL in these domains was in patients without damages. The domains Fatigue and VT are also significantly affected by the damage. So, in patients with SDII ≥1, there was a significant decrease of QOL in these domains up to 60.35±24.0 and 49.55±20.32, respectively, as compared with patients without damages 65.7±25.3 ($p\leq0.03$) and 55.69±20.32 ($p\leq0.02$) respectively.
Conclusion: LupusQoL is more sensitive to changes in SLE activity. Both SF-36 and LupusQoL are equally sensitive to changes in organ damage.

AB0480 LUPUS ORGAN DAMAGE: WHAT IS DAMAGED IN PATIENTS OF THE RUSSIAN FEDERATION, KIRGIZSTAN AND KAZAKHSTAN?

E. Aseeva[1], G. Koilubaeva[2], B. Issayeva[3], A. Mesnyankyna[1], N. Nikishina[1], S. Solovyev[4], A. Lila[5]. *[1]Federal State Research Institution (FSRI) named after V.A. Nasonova, Systemic Lupus Erythematosus Department, Moscow, Russian Federation; [2]National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Rheumatology Department, Bishkek, Kyrgyzstan; [3]Asfendiyarov National Medical University, City Rheumatology Center, Almaty, Kazakhstan; [4]JSC Group of companies Medsi, Rheumatology Department, Moscow, Russian Federation; [5]Federal State Research Institution (FSRI) named after V.A. Nasonova, Rheumatology Department, Moscow, Russian Federation*

Background: Assessment of organ damage has become the standard outcome measure for morbidity and mortality in patients with lupus over the world including the Russian Federation (RF), Kirgizstan and Kazakhstan.
Objectives: The aim of this study was to compare organ damage of patients with systemic lupus erythematosus in the Russian Federation, Kirgizstan and Kazakhstan in real clinical practice.
Methods: 1102 SLE pts who fulfilled SLICC 2012 criteria were enrolled into the study. Disease activity was evaluated by SLEDAI-2K, while chronic damage was assessed by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI).
Results: 400/600/102 Lupus pts from RF, Kirgizstan and Kazakhstan respectively were studied. Pts were predominantly female (91%/93%/98%) with a mean±SD age of 34,2±11,5/35,07±12,2/33,8±10,5 years ($p=0,36$; $p=0,96$) respectively. The mean disease duration (Me) in RF/ Kazakhstan was 6 [3;12]/ 5[2;9] years ($p=0,15$), in Kirgizstan- 2[0,6; 7] years($p\leq0,05$). Kazakh pts ($p=0,00$) had higher disease activity (SLEDAI 2K) 17,6±8,8 than Kirghiz pts 15,1±8,3 and Russian pts 9,4±8,1.
Patients from RF and Kazakhstan appeared to have a higher prevalence of damage compared with patients in Kirgizstan (Table 1). The Russian pts had a higher prevalence of Cataract 27%, damages in Cardiovascular system 77(19%), Diabetes mellitus 4% and premature gonadal failure 4%.
The pts from Kazakhstan had a higher prevalence of Neuropsychiatric 27% and renal 18% failures, skin 71% and Musculoskeletal 39% damages. The fewest damage was found out in Kirgiz pts. The risk factors for damage in our SLE pts such as age, disease duration, number of exacerbations, dosage of corticosteroids, duration of corticosteroids were determined by comparing pts with DAI SLICC =0 (676) with pts with DAI SLICC >1 (426) (*Mann — Whitney test)*
Conclusion: Identification of variations in target organ predilection and accrual of damage across patients of differing ethnicity has implications for treatment, monitoring and prognostication.

AB0481

HEALTH-RELATED QUALITY OF LIFE ASSESSED BY LUPUSQOL AND SF-36 IN 400 RUSSIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS.

E. Aseeva[1], S. Solovyev[2], S. Glukhova[1], A. Lila[1]. *[1]Federal State Research Institution (FSRI) named after V.A. Nasonova, Systemic Lupus Erythematosus Department, Moscow, Russian Federation; [2]JSC Group of Companies Medsi, Rheumatology Department, Moscow, Russian Federation*

Background: The LupusQoL is a disease-specific health-related quality of life (HRQoL) measure for patients with lupus.
Objectives: We conducted this study to compare the efficiency of LupusQoL with the 36-item Short-Form Health Survey (SF-36), a generic quality of life (QoL) scale, in Russian patients with lupus. Both questionnaires were conducted for one visit to the clinic.
Methods: Disease activity was evaluated by the SLEDAI-2K, and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI). Associations between the LupusQoL and SF-36 domains were examined, while also examining age, disease duration, and disease activity for each questionnaire. Descriptive statistics, Spearman's correlation coefficients, and Students t test were performed to analyze the data.
Results: A total of 400 patients with lupus (F/M 363:37, mean age 34,2±11.5 years, mean disease duration 106,3±91,9.0 months) were included, and 63 % of these were active and 56 % of these had SDI≥1. The mean SLEDAI 2K score was 9,6±8,0.
QOL as assessed by SF-36 and LupusQoL was low in this group of patients with SLE. The mean scores for each of the domains of the LupusQoL and SF-36 are shown in Table 1. The mean scores are < 60 in 8 domains of the SF-36 but not in social functioning (62,03±27,19) and physical function (62,35±28,53).

Table 1. Descriptive statistics and correlation coefficient for SF-36 and LupusQoL

LupusQoL domains	Mean (SD)	SF-36 domains	Mean (SD)	r	P
Comparable					
Physical health	66,20±23,18	PF	62,35±28,53	0,77	0,96
Emotional health	64,65±24,75	MH	50,51±8,40	0,38	0,94
Pain	70,03±24,68	BP	47,0±8,86	-0,33	0,02
Fatigue	62,7±24,73	VT	53,04±22,59	-0,70	0,83
Noncomparable					
Planning	63,90±28,46	SF	62,03±27,19		
Intimate relationships	72,92±30,93	GH	49,14±20,51		
Burden to others	50,68±27,79	RE	49,84±43,86		
Body image	65,18±27,60	RP	40,46±41,35		
		PCS	45,15±7,65		
		MCS	48,46±5,41		

The MCS and PCS scores were both < 50. Despite the fact that the mean score in LupusQoL was always higher than in SF-36 for each of the comparable domains, 3 standardized p values were not statistically significant (mean score in 400 patient visits: physical health/physical function, 66,20±23,18/62,35±28,53, p = 0.96; emotional health/mental health, 64,65±24,75/50,51±8,40, p = 0.94; and fatigue/vitality 62.70 ± 24.73/53.04 ± 22.59, p = 0.83), 1 standardized p value was statistically significant - pain/bodily pain 70.03 ± 24.68/47.00 ± 8.86, p = 0.02. The correlation of the comparable domains of LupusQoL and SF-36 was studied. There was a strong correlation between comparable domains in LupusQoL and SF-36 in 400 patient visits (physical health and physical functioning, r = 0.77; emotional health and role emotional, r = 0.38; pain and bodily pain, r = -0,33; and fatigue and vitality, r =- 0.70; all p values < 0.0001).
For the 4 non-comparable domains of the LupusQoL, there was a correlation between 3 domains of LupusQoL and 1 of the component scores of SF-36: body image and SF-36 MCS, r = 0.20; planning and SF-36 MCS, r = 0.13, r = 0.73; and burden to others and SF-36 MCS, r = 0.19; body image and SF-36 PCS,r=0,38; planning and SF-36 PCS,r=0,66; and burden to others and SF-36 PCS,r=0,38.
Conclusion: The LupusQoL-Russian is sensitive to change in SLE patients with active SLE. LupusQoL and SF-36 were equivalent in assessing the HRQOL in the Russian SLE patients. Both LupusQoL and SF-36 are easily completed by patients and correlate very well with each other.

AB0482

FACTORS AFFECTING QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN 1102 LUPUS PATIENTS FROM THE RUSSIAN FEDERATION (RF), KIRGHIZSTAN AND KAZAKHSTAN

E. Aseeva[1], S. Solovyev[2], G. Koilubaeva[3], B. Issayeva[4], S. Glukhova[1], A. Lila[1]. *[1]Federal State Research Institution (FSRI) named after V.A. Nasonova, Systemic Lupus Erythematosus Department, Moscow, Russian Federation; [2]JSC Group of Companies Medsi, Rheumatology Department, Moscow, Russian Federation; [3]National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Rheumatology Department, Bishkek, Kyrgyzstan; [4]Asfendiyarov National Medical University, City Rheumatology Center, Almaty, Kazakhstan*

Background: Patients with systemic lupus erythematosus (SLE) have a better survival as compared to decades ago; nevertheless, they still experience a low health-related quality of life (HRQoL). The study of factors affecting the quality of life will improve medical care for patients in future.
Objectives: The aim of this study was to determine factors affecting quality of life of 1102 Lupus patients (pts) from the Russian Federation (RF), Kirghizstan and Kazakhstan.
Methods: 1102 SLE pts who fulfilled SLICC 2012 criteria were enrolled into the study. The SLEDAI 2K index activity, SLICC damage index, HRQo*L* using the LupusQo*L* (validated for the Russian-speaking population in 2018) and HADS questionnaires were evaluated.
Results: 400/600/102 Lupus pts from RF, Kirghizstan and Kazakhstan were studied, respectively. *The* pts were predominantly female (91%/93%/98%) and of indigenous nationality (Russian 83%/ Kirghiz 88%/ Kazakh 76%) with a mean±SD age of 34,2±11,5/35,07±12,2/33,8±10,5 years (p=0,36; p=0,96), respectively. The mean disease duration (Me) in RF/ Kazakhstan was 6 [3;12]/ 5[2;9] years (p=0,15), in Kirgizstan - 2[0,6; 7] years(p≤0,05). Kazakh pts (p=0,00) have a higher disease activity (SLEDAI 2K) 17,6±8,8 as compared to Kirghiz 15,1±8,3 and Russian 9,4±8,1 pts. SLICC damage index 2,39±1,61 in Kazakh pts (p=0,00) was higher than in Russian 1,57±1,54 and Kirghiz 0,79±0,32 pts.
The mean scores for each of the domains of LupusQoL are shown in Figure 1.

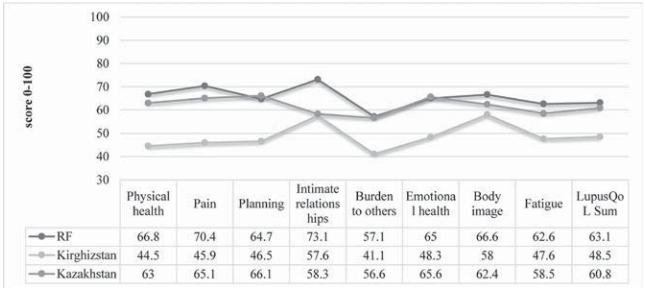

Figure 1. HRQoL in 1102 Lupus Patients from the Russian Federation (RF), Kirghizstan and Kazakhstan

As regards the Sum LupusQoL, 1102 pts were divided into two groups. The first group included 93 pts with SLE with the Sum LupusQoL<20. The second one included 484 pts with SLE with the Sum LupusQoL≥60. Such factors as age, duration of illness before verification of SLE diagnosis, pregnancy, pts without disability, high education, working\ unemployed, SLEDAI 2 K, SLICC damage index, HADS (T), HADS(D) were included into the analysis.

The worst HRQol (Sum LupusQol<20) was associated with older age, duration of illness before verification of SLE diagnosis, unemployed status, high disease activity, organ damage, anxiety and depression (Table 1).

Table 1. Factors affecting quality of life in patients with systemic lupus erythematosus in Lupus Patients from Russian Federation, Kirghizstan and Kazakhstan.

Factors	Sum LupusQol<20 (n=93)	Sum LupusQol>60 (n=484)	P
Age, years, (M±SD)	37,06±12,38	30,09±9,96	0,04
Duration of illness before verification of SLE diagnosis, month., Me [Lower,Upper Quartiles]	36 [12; 84]	10 [4; 24]	<0,0001
Pregnancy, n (%)	0	71(14%)	0,002
Pts without disability, n (%)	30(32%)	242(50%)	0,02
High education, n (%)	38(41%)	281(58%)	0,01
Working, n (%)	33(35%)	266(55%)	0,03
Unemployed, n (%)	46(49%)	131(27%)	0,01
SLEDAI 2 K, score, (M±SD)	11,32±8,16	8,50±7,47	0,04
SLICC damage index, score, (M±SD)	1,83±1,72	1,09±0,96	0,004
HADS (T)≥11, n (%)	30(32%)	19(4%)	<0,0001
HADS(D)≥11, n (%)	26 (28%)	1(0,4%)	<0,0001

**p <0,05 Mann — Whitney test*

Much better HRQoL (LupusQol≥60) was associated with younger age, pregnancy, absence of disability, high education, availability of work.

Conclusion: The most consistent predictors of low HRQoL in SLE Patients from the Russian Federation (RF), Kirghizstan and Kazakhstan are socio-demographic factors such as older age, poverty and lower educational level, working\unemployed. There are some more important factors such as SLE activity, damage and prevalent comorbidities (anxiety and depression).

AB0483 THE ROLE OF PENTRAXIN-3 AS PREDICTOR OF PREGNANCY COMPLICATIONS IN PATIENTS WITH SLE AND/OR ANTI-PHOSPHOLIPID SYNDROME

M. Larosa[1], A. Calligaro[2], M. Tonello[3], A. Ghirardello[3], T. Del Ross[2], M. Favaro[2], L. Iaccarino[3], A. Doria[3]. *[1]Division of Rheumatology, Department of Locomotor System, ASL 3, Genoa, Italy; [2]Division of Rheumatology, Department of Medicine-DIMED, Azienda Ospedaliera di Padova, Padua, Italy; [3]Division of Rheumatology, Department of Medicine-DIMED, Azienda Ospedaliera di Padova, University of Padova, Padova, Italy*

Background: Pentraxin-3 (PTX3) seems to be implicated in placentation and foetus tolerance, being mostly secreted in response to inflammatory stimuli by dendritic cells, macrophages, and endothelial cells (1). Although several studies have recently focused on this molecule (2-4), no data on women with SLE/APS are available to date.

Objectives: To assess the role of serum PTX3 and anti-PTX3 Abs as predictors of pregnancy complications in SLE and/or APS.

Methods: This case control study included pregnancies in women with SLE (SLICC, 2012) and/or APS (Miyakis, 2006), recruited at University of Padova in the Out-patient Clinic shared by Obstetrics and Gynaecologists and Rheumatologists. The control group included pregnancies of patients with other rheumatic diseases rather than APS and/or SLE. All pregnancies were recruited from 2015 to 2021 (conception date< 1st Apr 2021). At first-trimester consultation, demographics, clinical, and serological variables were recorded. First-trimester serum PTX3 levels (ng/ml) were detected by a commercially available sandwich ELISA (Alexis, UK); IgG anti-PTX3 Abs were detected by home-made validated ELISA and expressed as Optical Density values, measured at 405 nm by microplate spectrometer. Cut-off of positivity corresponded to 0.234 OD. Maternal complications included SLE flares (increase of ≥1 point in SLEPDAI); preeclampsia/eclampsia, HELLP, pregnancy induced hypertension, maternal death, gestational diabetes mellitus (GDM). Foetal complications included: miscarriage<10 week of gestation (WG); intra-uterine foetal death (IUFD) (≥10 WG); preterm delivery (<37 WG); intra-uterine growth restriction (IUGR); neonatal death within 28 days from birth.

Results: 79 pregnancies occurred in 79 patients (Table 1). Serum IgG anti-PTX3 Abs were found in 11 women (13.9%, 95% CI 7.2-23.5), and they did not differ between cases and controls (p=0.08, 4 SLE/APS women vs. 7 controls). Anti-PTX3 were associated with GDM (p=0.04, stratified for maternal age) but not with IUGR (p=0.09). No other statistical associations were found between anti-PTX3 Abs and other maternal/foetal complications. PTX3 serum levels did not statistically differ between cases and controls (p=0.63, 0.37 ± 0.26 ng/mL in cases vs. 0.33 ± 0.24 ng/mL in controls). Serum PTX3 levels were lower in patients with GDM (0.3 ± 0.2 ng/mL) compared to non-GDM patients (0.4 ± 0.2) but it did not differ between IUGR and non-IUGR, although the mean PTX3 ± SD was lower in the IUGR group (0.25 ± 0.2 in IUGR vs 0.35 ± 0.2 in non-IUGR).

Table 1. Clinical and serological characteristics of our cohort (N=79)

	Patients (N, %)
Age at pregnancy, years (mean ± SD)	35.1 ± 3.9
Cases	13 (16.5)
SLE	9 (11.4)
APS	7 (8.9)
SLE with secondary APS	3 (23.1)
Control Group	66 (83.5)
Serological features	
LAC	11 (13.9)
IgG/IgM anti-cardiolipin	20 (25.3)
IgG/IgM antibeta2-Glycoprotein I	25 (31.6)
Triple positive aPL tests	6 (7.6)
Primiparous	23 (29.5)
IgG anti-PTX3 Abs	11 (13.9)
IgG anti-PTX3 level (cut-off 0.234 OD), (median, IQR)	0.2 (0.1-0.2)
PTX3 ng/mL (mean ± SD)	0.3 ± 0.2
Concomitant treatment	
Heparin	15 (19.0)
Aspirin	44 (55.7)
Immunosuppressants	3 (3.8)
Hydroxychloroquine	21 (26.6)
Prednisone	9 (11.4)
Prednisone dosage (mg/day) (median, IQR)	5 (2.5-7.5)

Legend to Table 1: SD: standard deviation; SLE: Systemic Lupus Erythematosus; APS: antiphospholipid syndrome; LAC: Lupus anticoagulant; aPL: antiphospholipid antibodies; PTX: Pentraxin-3; Abs: antibodies; OD: optical density; IQR: interquartile range.

Conclusion: To our knowledge, this is the first study which assessed the frequency of anti-PTX3 Abs in a cohort of SLE and/or APS pregnant women. These Abs occurred in the minority of patients (13.9%) and did not differ between SLE/APS women and controls. Due to our sample size, these findings need to be confirmed in larger cohorts.

AB0484 CLINICAL EFFICACY OF 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Tarasova[1], B. Belov[2], O. Egorova[1], T. Reshetnyak[1,3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinal Prevention, Moscow, Russian Federation; [3]Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation*

Background: Patients with systemic lupus erythematosus have an increased risk of detecting respiratory diseases.

Objectives: To study the efficacy of 23-valent polysaccharide pneumococcal vaccine (PPV-23) in patients with systemic lupus erythematosus (SLE).

Methods: The study enrolled 72 patients diagnosed with SLE, including 64 women and 8 men aged 19 to 68 years with the disease duration ranging from 9 months to 42 years. Nine patients had high activity of disease, 17 - moderate, 40 - low, 6 - remission. Therapy: 68 patients received glucocorticoids (GC) 5-40 mg/day, 55-hydroxychloroquine (HC), 38 -cytostatics (CS), 26 - bDMARD: 14-rituximab (RTM), 10-belimumab (BLM), 2-RTM + BLM. Only 4 of 72 patients received monotherapy (GC-1, HC-1, CS-1, bDMARD-1); the remaining 68 received combined immunosuppressive therapy. PPV-23 in an amount of 0.5 ml (1 dose) was administered subcutaneously. Patients were observed and examined for 1 year after vaccination. Standard clinical and laboratory examinations were performed during the visits, and the serum antibody (AB) level to S. pneumoniae was determined. The presence of respiratory infections, including lower respiratory tract infections, during the year before and after vaccination was detected by questioning, as well as by studying medical records (hospital discharge papers, specialist reports, radiological and CT examinations). 25 patients were followed up for 5-6 years after vaccination.

Results: A year after vaccination, a more than twofold increase in the concentration of antibodies to pneumococcus persisted in 56% of patients. The clinical efficacy of the vaccine was superior to the resulting immunogenicity of PPV-23.

Table 1. Respiratory infections in SLE patients at one year before and after vaccination (n=72)

Respiratory infections	1 year before vaccination	1 year after vaccination	p
Lower respiratory infections	31(43%)	9(12,5%)	0,0001
Pneumonia, (including recurrent,	12(16,7%)	4(5,6%)	0,06
2-5 episodes)	5(7%)	-	
Acute bronchitis	13(18%)	4(5,6%)	0,04
Exacerbation of chronic bronchitis	6(8,3%)	1(1,4%)	0,1
Upper respiratory infections	14(19,4%)	6(8,3%)	0,04
Acute sinusitis,	11(15,3%)	5(7%)	0,1
(Including recurrent)	1(1,4%)	-	
Exacerbation of chronic tonsillitis	2(2,8%)	-	
Acute otitis media	1(1,4%)	1(1,4%)	

During the year after vaccination, a decrease in episodes of infections of the lower respiratory tract by more than 3 times was recorded compared with the year preceding immunization (43% and 12.5%, respectively), p=0.0001. Not a single case of recurrent pneumonia was noted (before vaccination - in 5 patients). The number of infections of the upper respiratory tract has more than halved (19.4% and 8.3%, respectively). In 4 (5.6%) patients, non-severe pneumonia developed within a year after vaccination, all of these patients had risk factors for the development of respiratory infections: anti-B-cell therapy with the absence of an adequate vaccine response (3), interstitial lung damage (1), work activities and home environments associated with an increased risk of viral or bacterial infection (3). After a year of observation, 25 patients were followed up for another 4-5 years, the development of pneumonia was not registered in any case (2 out of 25 had pneumonia in the year prior to vaccination). At the same time, 5 years after vaccination, only 18% of patients had more than a 2-fold excess of the initial anti-pneumococcal antibodies.

Conclusion: Sufficient immunogenicity and clear clinical efficacy of PPV-23 have been demonstrated in SLE patients receiving combined immunosuppressive therapy.

AB0485 TRIGGERS OF DISEASE FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. Skhiri[1], A. Baya Chatti[1], S. Toujani[1], Z. Meddeb[1], C. Abdelkefi[1], A. El Ouni[1], S. Hamzeoui[1], T. Larbi[1], K. Bouslama[1]. *[1]Mongi Slim Hospital, Internal Medecine, Marsa, Tunisia*

Background: Systemic lupus erythematosus (SLE) is a chronic relapsing-remitting disease characterized by a clinical heterogeneity, an unpredictable pattern and a capricious course. Despite great advances in diagnosis and treatment strategies, lupus flares of varying severity still occur, leading to an increased risk of organs damages and a poorer prognosis. Preventing flares, achieving and maintaining remission represent the main objective in SLE management and remain a major challenge for practitioners.

Objectives: Our study aimed to describe lupus flare-ups and identify its triggering factors, in a cohort of patients with active SLE, in order to optimize disease control.

Methods: We conducted a retrospective study including patients with SLE followed for a period of 20 years. SLE diagnosis was retained according to the American college of Rheumatology classification criteria (ACR) of 1997 and/or to the SLICC 2012 criteria. A lupus flare was defined by the occurrence of new or worsening lupus manifestation, justifying treatment intensification. We evaluated potential flare triggers, disease activity at each outbreak according to the SLEDAI-2K score and flare types. Patients considered at full clinical remission or at low disease activity state (SLEDAI ≤ 3 in patients treated with antimalarials drugs / SLEDAI ≤ 4 in patients treated with a low glucocorticoids dose <7.5 mg of Prednisone per day ± immunosuppressant) during the study period were excluded (31/102; 30.4% of patients).

Results: A total of 72 patients, with a mean age at SLE diagnosis of 31 years [11-66] and a gender ratio (F/M) of 8:1, were enrolled. During follow-up, 186 flares occurred. The average number of flares per patient was 3 [1-13]. The mean SLEDAI score during flare-ups was 8 [6-21]. At least one triggering factor was found in 62.9% of flares. The identified triggers for lupus flares were medication nonadherence in 54.7% of cases (discontinuation of antimalarial drugs and corticosteroid therapy in 38.46% and 16.2% of cases, respectively), an intercurrent infection in 30.7% of cases, a hormonal factor in 11.96% and inadequate photoprotection and/or excessive sun exposure in 8.5% of flares. Elsewhere, lupus flare-ups could be explained by therapeutic inertia or corticosteroid dependence (mean dose of 12.5mg per day) in 3.4% and 13.7 % of cases, respectively. Frequencies of general symptoms, cutaneous and haematological flare-ups were higher in relapses with objectified triggering factors (26.5% vs 8.7%, p=0.02; 40.2% vs 26.1%, p=0.036; 32.5% vs 14.5%, p=0.005). In contrast, renal flare-ups were more frequent in the group of flares in which no triggering factors were identified (21.4% vs 33.3%, p=0,005). Disease activity was comparable in both groups. The average follow-up time was 8 years [1-26].

Conclusion: In our cohort, an avoidable trigger, dominated by poor medication compliance and infections, preceded more than one out of two lupus flares. Formalized and organized therapeutic education should be one of the pillars of SLE management.

AB0486 INFLAMMATORY MUSCULOSKELETAL ABNORMALITIES BY CONTRAST ENHANCED MRI IN SLE PATIENTS

P. Corzo Garcia[1], I. Garcia-Duitama[2], A. Agustí Claramunt[2], I. Carrión Barberà[3], S. Marsico[2], J. Monfort[3], T. C. Salman Monte[3]. *[1]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; [2]Hospital del Mar, Radiology, Barcelona, Spain; [3]Hospital del Mar, Rheumatology, Barcelona, Spain*

Background: Joint involvement in SLE is the most frequent manifestation and shows a wide heterogeneity[1]. It has not a valid classification and it is often underestimated. Subclinical inflammatory musculoskeletal involvement is not well known[2].

Objectives: We aim to describe the prevalence of joint and tendon involvement in hand and wrist of SLE patients, either with clinical arthritis, arthralgia or asymptomatic and compare it with healthy subjects using contrasted MRI.

Methods: SLE patients fulfilling SLICC criteria were recruited and classified as follows: group (G) 1: hand/wrist arthritis, G2: hand/wrist arthralgia, G3: no hand/wrist symptoms. Jaccoud arthropathy, CCPa and RF positivity, hand OA or surgery were excluded. Healthy subjects (HS) were recruited as controls: G4. Contrasted MRI of non-dominant hand/wrist was performed. Images were evaluated following RAMRIS criteria extended to PIP, Tenosynovitis score for RA and peritendonitis from PsAMRIS. Groups were statistically compared.
