Background: Immune checkpoint inhibitor (ICI) therapies that promote T cell activation have improved outcomes for advanced malignancies yet can also elicit harmful autoimmune reactions. The T cell mechanisms mediating these iatrogenic autoimmune events remain unclear.
Objectives: To investigate the immunophenotype, transcriptomic feature and clonotypes of T cells from joints of patients affected by ICI-induced inflammatory arthritis (ICI-arthritis).
Methods: Detailed immunophenotyping was performed on mononuclear cells from synovial fluid (SF) using mass cytometry and flow cytometry to identify significantly altered populations in ICI-A compared to seropositive rhrumatoid arthritis (RA) and psoriatic arthritis (PsA) (p<0.05). Bulk RNA-seq was performed on altered SF CD8 T cell subsets from ICI-A, RA and PsA to investigate their transcriptomic features. Cytokine profile and pathways enriched in ICI-A CD8 T cells were examined using differentially expressed genes, intracellular staining, and in vitro culture. TCR clonotypes were examined using single cell RNA-seq of T cells from synovial fluid, tissue and blood of ICI-A.
Results: Compared to the autoimmune arthritides RA and PsA, ICI-arthritis joints contained an expanded $CD38^{hi}$ $CD127^{-}$ $CD8^{+}$ T cell subset that displays cytotoxic, effector, and interferon (IFN) response signatures. Exposure of synovial T cells to Type I IFN, more so than IFN-γ, induced the $CD38^{hi}$ cytotoxic phenotype. Single cell transcriptomic and T cell repertoire (TCR) analyses indicated that the abundance of $CD38^{hi}$ CD8 T cells in ICI-arthritis resulted from proliferation of a limited number of clones. The $CD38^{hi}$ population appeared distinct from dysfunctional T cells and clonally most related to $TCF7^{+}$ memory populations. Comparison of synovial tissue from bilateral knees of the same patient demonstrated considerable sharing of TCR clonotypes among $CD38^{hi}$ CD8 T cells between the two joints. Further, TCR clonotypes expanded in synovial fluid of ICI-arthritis patients were detected in circulating T cells, and circulating $CD38^{hi}$ CD8 T cells are also expanded in ICI-arthritis patients.
Conclusion: These results define a distinct CD8 T cell subset in the synovial fluid and in the circulation of patients with ICI-A that may be directly activated by ICI therapy to mediate a tissue-specific autoimmune response.

POS0403 DYNAMIC CHANGES IN AUTOREACTIVE MEMORY B CELLS IN RHEUMATOID ARTHRITIS: KEY TO UNDERSTANDING IMMUNOLOGICAL DISEASE ACTIVITY

N. Blomberg[1], H. Kristyanto[1], M. Verstappen[1], S. Neppelenbroek[1], A. S. B. Kampstra[1], A. Van der Helm-van Mil[1], R. Toes[1], H. U. Scherer[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) patients with autoantibodies against citrullinated antigens (ACPA) are characterized by poor chances to achieve sustained DMARD free remission. We have previously observed that autoreactive ACPA-expressing memory B cells (MBC) display an activated phenotype and frequently maintain this state of activation even in patients in clinical remission in whom joint inflammation is absent through treatment. Conceptually, these observations could reflect ongoing immunological activity. In fact, they indicate that most current therapeutic interventions do not induce immunological remission and could explain why disease frequently flares when treatment is stopped. ACPA-expressing MBC display the phenotype of recent germinal centre emigrants, actively proliferating (Ki-67 positive), expressing CD95 and co-stimulatory markers CD80 and CD86, and the signature cytokine IL-8.[1] Notably, in autoantibody-positive individuals with arthralgia that did not progress to inflammatory arthritis within 2 years, the autoreactive B cells were readily detectable in the circulation and proliferated but lacked, in most cases, the upregulation of CD80 seen at the onset of disease. Now, we studied these autoreactive B cells longitudinally in the 'at-risk' phase of clinically suspect arthralgia (CSA) and in a population of patients in sustained (>1 year) drug-free remission (SDFR).
Objectives: To define dynamic changes of the ACPA-expressing B cell compartment throughout clinical disease stages with the aim to evaluate this response as a possibly predictive biomarker of immunological disease activity.
Methods: ACPA-expressing MBC were identified by flow cytometry in peripheral blood of RA patients with chronic disease or at disease-onset (treatment-naïve), in ACPA-positive CSA patients 'at-risk' for RA, and in patients in SDFR. B cells were characterized by a combination of markers to classify B cell subpopulations and activation- and germinal centre related markers. Tetanus-toxoid-specific B cells were analysed in the same individuals as antigen-specific comparators.
Results: In patients in SDFR, significantly less autoreactive B cells expressed CD80 compared to active disease, while they persistently showed signs of proliferation, similar to the phenotype observed in CSA patients that did not progress to RA. ACPA-specific plasmablasts (defined as $CD20^{-}CD27^{hi}$) were practically absent in SDFR and CSA non-progressors, while they were readily detectable in patients with RA at disease onset, during treatment, and in CSA-individuals that later progressed to RA. Notably, two arthralgia patients that developed RA within one year showed high CD80 expression in the autoreactive MBC compartment already in the 'at-risk' phase, whereas patients that so far did not progress to RA during the time of follow-up, showed less CD80-positive autoreactive MBC.
Conclusion: The phenotype of autoreactive B cells is dynamic in different disease phases of RA. By studying extremes of clinical phenotypes ('at-risk' phase, disease onset, SDFR), we found evidence for dynamic expression of CD80 by ACPA-expressing MBC in relation to clinical disease stage. Intriguingly, CD80-positive B cells, but not CD80-negative B cells, have been shown to be able to differentiate into antibody secreting cells in mice.[2] Our finding that plasmablasts were practically absent in ACPA-positive arthralgia patients that did not progress to RA and in SDFR would fit with this notion and suggests that in SDFR autoreactive MBC lack, although actively proliferating, triggers that induce CD80 upregulation, differentiation to plasmablasts and, possibly, their active participation in processes causing joint inflammation. Based on this observation, it is possible that induction of this $CD80^{lo}$ phenotype in autoreactive MBC may be an important step towards achieving immunological remission, a conceptual proxy for cure.

Innate immunity in rheumatic diseases

POS0404 IFNα-MEDIATED METABOLIC REPROGRAMMING IN HUMAN SLE MONOCYTES INVOLVES PERTURBATIONS IN GLYCOLYTIC AND LIPID METABOLISM TO REGULATE PROINFLAMMATORY MARKERS AND CYTOKINES

C. Stathopoulou[1,2], D. Konstantopoulos[3], S. Papanikolaou[1,3], G. Vatsellas[4], G. Panagopoulos[4], P. Sidiropoulos[1,2,5], G. Bertsias[1,2,5]. *[1]University of Crete, Medical School, Heraklion, Greece; [2]Institute of Molecular Biology and Biotechnology-IMBB, Foundation for Research and Technology Hellas, Heraklion, Greece; [3]Institute for Bioinnovation-IBI, Biomedical Sciences Research Center "Alexander Fleming", Athens, Greece; [4]Greek Genome Center, Biomedical Research Foundation Academy of Athens, Athens, Greece; [5]University General Hospital, Rheumatology Department, Heraklion, Greece*

Background: Systemic Lupus Erythematosus (SLE) is a prototype interferonopathy characterized by multiple organ damage[1]. Metabolomic analyses of patient-derived sera indicate distinct metabolic pertubations in oxidative and lipid metabolism[2,3]. Among innate effectors, monocytes (Mo) are implicated in SLE pathogenesis and also display a perturbed metabolic phenotype[4].
Objectives: Based on previous data indicating a prominent IFNα-gene signature in SLE monocytes even during disease remission[5], we herein sought to delineate the metabolic repercussion of IFNα signaling contributing to SLE autoimmunity.
Methods: Using transcriptomic data, we compared the enriched metabolic categories of IFNα(+) and IFNα(-) SLE-Mo[6]. In order to compare metabolic perturbations pertaining to SLE, we performed transcriptomic Gene Set Enrichment Analysis (GSEA)[7] from *in vitro* cultured IFNα-activated Mo. We supplemented the analysis with selective *ex vivo* biochemical inhibition of the metabolic pathways arising from the GSEA and evaluated the effect on inflammatory markers of healthy IFNα-Mo.
Results: We found a statistically significant enrichment of transcripts associated with glycolytic metabolism and lipid biosynthetic and catabolic processes in both IFNα(+)-SLE Mo and healthy IFNα-Mo, but not in IFNα(-)-SLE Mo, which in turn resembled healthy-Mo. Additionally, transcripts associated with cholesterol biosynthetic processes such *PMVK*, *SQLE*, *LSS*, *DHCR7*, and *LDLR*, *MVK*, *FFT1* were significantly upregulated in IFNα(+)-SLE Mo and healthy IFNα-Mo respectively. In accordance, blockade of either glycolysis with the use of 2-DG hexokinase inhibitor, or mevalonic acid synthesis with the use of fluvastatin, attenuated proinflammatory cytokine secretion (IL6, CXCL10) associated with IFN-response in both IFNα(+)-SLE Mo and healthy IFNα-Mo.
Conclusion: Our results link IFNα mediated metabolic shifts in Mo with corresponding metabolic perturbations found in SLE patient-Mo. Pending further confirmation with targeted metabolomics, these data further rationalize the use of IFN blockade and also suggest the potential use of specific metabolites as novel therapeutic targets in SLE.

Background: Intercellular adhesion molecule-1 (ICAM-1) and E-Selectin are adhesion molecules considered as markers of underlying endothelial activity and damage. These molecules are known to play an important role in autoimmune disease (AD) [1]. Accordingly, they may contribute to the development of interstitial lung disease (ILD), one of the main causes of death in patients with AD [2]. In fact, they have been proposed as prognostic biomarkers in idiopathic pulmonary fibrosis (IPF) [3]. However, studies on the role of ICAM-1 and E-Selectin in AD-ILD$^+$ are scarce.
Objectives: To study the role of ICAM-1 and E-Selectin in the pathogenesis of AD-ILD$^+$.
Methods: Peripheral venous blood was collected from 57 patients with AD-ILD$^+$ and three comparative groups: 45 AD-ILD$^-$ patients, 21 IPF patients and 21 healthy controls (HC). All the subjects were recruited from the Rheumatology and Pneumology departments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. ICAM-1 and E-Selectin levels were measured in serum samples by enzyme-linked immunosorbent assay.
Results: Higher levels of ICAM-1 and E-Selectin were found in patients with AD-ILD$^+$ compared to AD-ILD$^-$ patients ($p<0.001$ and $p=0.001$, respectively) and HC ($p<0.001$ in both cases). Likewise, IPF patients showed increased levels of ICAM-1 and E-Selectin in relation to AD-ILD$^-$ patients ($p<0.001$ and $p=0.002$, respectively) and HC ($p<0.001$ in both cases). However, no statistically significant difference in ICAM-1 and E-Selectin concentrations was observed between AD-ILD$^+$ and IPF patients.
Conclusion: Our study suggests that increased levels of ICAM-1 and E-Selectin are associated with the presence of ILD in AD patients.

POS0406 CHARACTERISATION OF ENHANCER RNAS IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

L. Moser[1], M. Houtman[1], O. Distler[1], B. Maurer[2,3], C. Ospelt[1], K. Klein[2,3]. *[1]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland; [2]University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland; [3]University of Bern, Department of BioMedical Research, Bern, Switzerland*

Background: Rheumatoid arthritis synovial fibroblasts (SF) exhibit a prolonged histone 3 lysine 27 acetylation (H3K27ac) after stimulation with TNF, leading to a sustained inflammatory response. Enhancer RNAs (eRNAs) are short-lived non-coding RNAs transcribed from cell type-specific H3K27ac-marked enhancers that facilitate the transcription of their linked coding genes. The interrelation of eRNAs and their linked coding genes in SF has not been studied yet.
Objectives: To analyze the expression and regulation of inflammatory eRNAs in SF.

Methods: The expression of eRNAs in SF (n=9), stimulated with TNF (24h; 10 ng/µl) or left untreated, was detected by cap analysis of gene expression followed by sequencing (CAGEseq). To further investigate eRNA expression in SF, the expression of selected eRNAs and their linked coding genes (*CXCL1*, *CCL20*, *IL6*, *CCL2*, *CXCL12*, *IL8*) was analyzed by real-time PCR in SF that were stimulated with TNF (1, 3, 6, 24h; 10 ng/µl), IL1 (1, 24h; 1 ng/ml), or the Toll-like receptor agonists Pam3 (1, 24h; 1 ng/ml), pIC (1, 24h; 10 µg/ml) and LPS (1, 24h; 100 ng/µl). Samples containing the untranscribed RNA were measured in parallel. To study eRNA regulation, SF were treated with the bromodomain inhibitor I-BET (1 µM; 24h), or silenced for the histone acetyltransferases CBP and p300 by transfection of antisense LNA gapmeRs (12.5 nM) prior to stimulation with TNF (1, 24h).
Results: We have selected four potential eRNAs for CCL2 and IL8, three for CXCL12, two for IL6 and CXCL1 and one for CCL20 from CAGEseq analysis. They were located upstream (eCCL2#1, eCCL2#2, eCXCL1#2, eCXL12#3, eIL6#1+2, eIL8#1-4), downstream (eCCL2#3, eCCL2#4, eCXCL1#1, eCXL12#1) and intronic (eCCL20, eCXL12#2) at distances between 300 bp to 35.6 kb relative to the transcription start sites of the corresponding coding genes. None of the eRNAs was present in all nine samples in CAGEseq data sets, indicating a patient-dependent variability in eRNA expression. The majority of eRNAs were not detected in unstimulated SF, with the exception of eRNAs for CXCL12. By performing TNF time course experiments (Figure 1), we have detected different patterns of eRNAs: (a) eRNAs, that peaked at 1h (eCCL20, eIL8#2, eCCL2#1), (b) at 6h (eCXCL1#1), (c) or at 24h (eIL8#1, eIL8#3, eIL8#4, eCXCL1#2) after stimulation, (d) eRNAs that were stably expressed over the time points (eCCL2#2, 3, 4), and (e) eRNAs that were down regulated by TNF

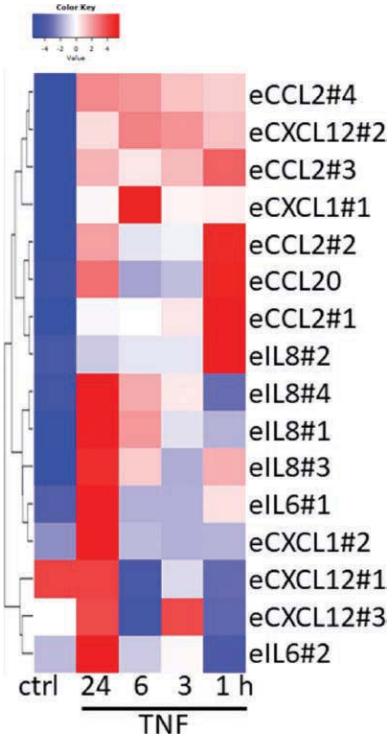

Figure 1.

stimulation (eCXCL12#1, eCXCL12#3). All inflammatory stimuli induced eRNA expression in SF, with LPS and IL1, followed by TNF, being the most potent inducers of eRNAs. I-BET suppressed the TNF-induced expression of all eRNAs tested. The effects on the expression of eRNAs after silencing of p300 but not of CBP mirrored to a large extent those of the respective coding genes.
Conclusion: In SF, the expression of some eRNAs is maintained for up to 24h, contradicting previous reports that eRNAs are short-lived. Our data suggest that different eRNAs orchestrate the early and sustained expression of cytokines and chemokines in SF. eRNA expression is controlled by p300 and BET bromodomain proteins.

OXYSTEROL 7-KETOCHOLESTEROL CAN RE-PROGRAM SYNOVIAL TISSUE MACROPHAGES AND SUPPORT M1 POLARIZATION

V. Drvar[1], D. Legović[2], B. Ćurko-Cofek[3], D. Rukavina[4], E. Babarović[5], T. Kehler[6], V. Persic[6], G. Laskarin[3,6]. *[1]Clinical Hospital Centre Rijeka, Clinical Department of Laboratory Diagnostics, Rijeka, Croatia; [2]Orthopaedic University Hospital Lovran, Orthopaedic University Hospital Lovran, Lovran, Croatia; [3]Faculty of Medicine, University of Rijeka, Department of Physiology and Immunology, Rijeka, Croatia; [4]Croatian Academy of Sciences and Arts, Department of Biomedical Sciences in Rijeka, Rijeka, Croatia; [5]Faculty of Medicine, University of Rijeka, Department of Pathology, Rijeka, Croatia; [6]Hospital for Medical Rehabilitation of Hearth and Lung Diseases and Rheumatism "Thalassotherapia-Opatija", Hospital for Medical Rehabilitation of Hearth and Lung Diseases and Rheumatism "Thalassotherapia-Opatija", Opatija, Croatia*

Background: Oxidized low-density lipoprotein (oxLDL) particles support low-grade inflammation and have been found in synovial fluid from osteoarthritis (OA) joints [1]. Their component is 7-ketocholesterol (7-KC), which arises as the result of the oxidation of cholesterol [1]. 7-KC acts proinflammatory and it binds to Toll-like receptor (TLR) 4 expressed on macrophages [1]. Activation of TLR4 stimulates the classical macrophage maturation program, resulting in a specific phenotype of inducible nitric oxide synthase positive (iNOS+) and macrophage (M) 1 function, which produce and secrete proinflammatory chemokines and cytokines [2]. M2 macrophages are associated with wound healing by the production of arginase-1 [2,3]. Synovial macrophages are of critical importance in the symptomatology and structural progression of OA since M1 polarized macrophages accumulate in human OA synovial tissue during exacerbation [3]. However, it is not known whether 7-KC can re-program synovial tissue macrophages and support M1 polarization.
Objectives: We analyzed the influence of 7-KC on the polarization of CD68+ macrophages in the suspension of synovial mononuclear cells (SMCs) in respect to lipopolysaccharide (LPS), as M1 inducer.
Methods: Mature synovial tissue samples were obtained during alloarthroplasty of the knee (N = 56). Paraffin embedded tissue sections were labelled by double immunofluorescence using a combination of antibodies directed toward CD68 and iNOS, arginase-1, CCL2 or CCL22. Suspension of SMCs was prepared by enzymatic digestion of tissue samples using collagenase IV and gradient density centrifugation. We analyzed intracellular (iNOS, arginase-1, CCL2, and CCL22) and surface (CD91, mannose receptor, HLA-DR, CD80, CD86 and decoy D6) antigens expression in CD68+ cells in the suspension of freshly isolated or 18 hour-cultured SMCs with 7-KC (25 µM), LPS (10 ng/ml), their combination or in the medium only.
Results: iNOS and CCL2 were more frequently labelled in lymphocyte clusters, while arginase-1 and CCL22 were labelled in synovial lining CD68+ cells. Phenotype of CD68+ cells did not change significantly after the 18 hour- culture in the medium only, except the decrease of mannose receptor and CD91, when compared with freshly isolated cells. 7-KC increased the percentage of CD86 expressing CD68+ cells, whereas decreased surface expression of CD91 and chemokine decoy D6, like in the culture with LPS, when compared with cells cultured in the medium only. 7-KC decreased the frequency of arginase-1+/CD68+ cells in the suspension and did not change iNOS+ in CD68+ cells, thus increasing the ratio of iNOS+/arginase-1+ in CD68+ subset. 7-KC was unable to increase CCL2 like LPS in comparison with cells cultured in the medium only. Neither 7-KC nor LPS affected CCL22 expression in the CD68+ subset.
Conclusion: These data provide a new perspective in understanding the polarization of macrophages toward the M1 phenotype mediated with oxysterol 7-KC *in vitro*.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

POS0408 TRANSFER OF HUMAN RHEUMATOID ARTHRITIS MONONUCLEAR CELLS INDUCES ARTHRITIS IN IMMUNODEFICIENT HLA-DR4 TRANSGENIC MICE

J. Rupp[1], J. Fessler[1], S. Hayer[2], B. Dreo[1], A. Lackner[1], P. Fasching[3], W. Helberg[4], P. Schlenke[4], J. Thiel[1], G. Steiner[2], W. Cornelia[5], M. Stradner[1]. *[1]Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria; [2]Medical University of Vienna, Division of Rheumatology, Vienna, Austria; [3]Steiermärkische Krankenanstaltengesellschaft m.b.H., Institut für Krankenhaushygiene und Mikrobiologie, Graz, Austria; [4]Medical University of Graz, Department of Blood Group Serology and Transfusion Medicine, Graz, Austria; [5]Mayo Clinic School of Medicine and Sciences, Division of Rheumatology, Department of Medicine, Rochester, United States of America*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease leading to erosive joint destruction. Although the exact pathogenesis is still elusive, the strong association of certain HLA class II molecules, such as HLA-DRB1*0401 (HLA-DR4), suggest involvement of $CD4^+$ T cells (1,2). Mouse models of RA mimic specific aspects of the disease but are limited by the differences between human and murine immune systems.
Objectives: We aimed to establish a humanized mouse model (humice) carrying $DR4^+$ RA PBMCs to study its role in the pathogenesis of RA without putting patients at risk.
Methods: Peripheral blood mononuclear cells (PBMC) of HLA-DR4 positive RA patients or controls were isolated and injected into NSG-Ab^0 DR4 mice (NOD-scid IL2Rgamma^{null} mice lacking MHC class II while expressing the human HLA-DR4) to create humice. Human immune cell composition within humice was profiled using flow cytometry. Development of RA was monitored by examination of the joints and micro computed tomography analysis. Joints were analysed by histology regarding pannus formation, bone erosions, cartilage damage, and human cell infiltration.
Results: Transfer of RA PBMCs induced arthritis in humice recapitulating hallmarks of RA including immune cell infiltration, pannus formation, increased osteoclastogenesis, cartilage damage, and bone erosions. Arthritis was dependent on the implanted human cells as NSG-Ab0 DR4 mice without transfer of human PBMCs did not develop arthritis. T-helper 1 (Th1) cells, dominated the human immune cell composition in humice, while regulatory T cells (Tregs) were diminished compared to donor PBMC composition. Mice humanized with cells from RA patients were more likely to develop inflammatory joint disease, compared to healthy HLA-DR4 positive controls (RA donor 70% vs. healthy control 20%, p=0.00196). CTLA-4 Ig treatment prevented arthritis development in this model (p=0.0055).
Conclusion: Humice carrying $DR4^+$ RA PBMCs developed an RA-like erosive joint disease driven by the implanted human immune system. The data implies that the disease can be transferred by arthritogenic cells found in the peripheral blood of RA patients. This model will allow new insights into the pathogenesis of RA.

POS0409 INTESTINAL HIF1α EXPRESSION PROTECTS AGAINST EPITHELIAL CELL DEATH IN ARTHRITIS

P. Lyu[1], J. Wen[1], I. Stolzer[2], A. Giessl[3], R. Song[1], X. Meng[1], S. Cao[1], C. Günther[2], G. Schett[1], A. Bozec[1]. *[1]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany; [2]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 1, Erlangen, Germany; [3]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Ophthalmology, Erlangen, Germany*

Background: While a so-called *gut-joint axis* is supported by many clinical observations, the current knowledge on such axis is mostly confined to descriptive and correlative data, e.g. showing the microbiota changes are associated with arthritis. In contrast, mechanistic data on how molecular changes in the intestinal epithelium influence the development of arthritis are scarce.
Objectives: To investigate, whether the mucosal barrier in the intestine dependent of the epithelial cell survival maintenance, influences the development of arthritis.
Methods: Intestinal hypoxia inducible factor (HIF)-1α expression was assessed before, at onset and during experimental arthritis and human rheumatoid arthritis (RA). Intestinal epithelial cell-specific HIF1α conditional knock-out mice were generated ($HIF1\alpha^{\Delta IEC}$) and subjected to collagen-induced arthritis (CIA). Clinical and histological courses of arthritis were recorded, and T and B cell subsets were analyzed in the gut and secondary lymphatic organs, and intestinal epithelial cells were subjected to molecular mRNA sequencing in $HIF1\alpha^{\Delta IEC}$ and littermate control mice. Furthermore, pharmacologic HIF1α stabilization by PHD inhibitor was used for the treatment of arthritis.
Results: Intestinal HIF1α expression peaked at onset and remained high in experimental arthritis and RA. Conditionally deletion of HIF1α in gut epithelial cells strongly exacerbate arthritis and was associated with increased gut epithelial cell death, intestinal and lymphatic Th1 and Th17 activation. Mechanistically, HIF1α inhibits the transcription of necroptotic and apoptotic markers, which leads to a defect in the intestinal barrier integrity. Furthermore, treatment with HIF1α stabilization reinforced the gut epithelial cell survival and inhibited arthritis.
Conclusion: These findings show that the HIF1α regulating epithelial cells survival is critical for the breakdown of the intestinal barrier function in arthritis highlighting the functional link between intestinal homeostasis and arthritis.

POS0410 THE ROLE OF IL-6 IN ENDOTHELIAL DYSFUNCTION: RHEUMATOID ARTHRITIS AND COVID-19, TWO PATHOGENIC MODELS IN COMPARISON

A. I. Celia[1], C. Barbati[1], T. Colasanti[1], M. Speziali[1], G. Pellegrino[1], F. Natalucci[1], F. M. Ucci[1], E. Balbinot[1], C. Ciancarella[1], G. Tripodi[1], G. Buoncuore[1], F. Ceccarelli[1], F. Conti[1], C. Alessandri[1]. *[1]Arthritis Clinic, Department of Clinical internal, anaesthesiological and cardiovascular sciences, Sapienza University of Rome, Rome, Italy*

Background: Rheumatoid arthritis (RA) is the most common systemic autoimmune disease that primarily affects joints but is also often characterized by extra-articular involvement[1]. Cardiovascular diseases are the most important causes of sudden death in these patients, which present a risk of developing cardiovascular events increased by 48%[2]. The causes of increased cardiovascular risk are several and not completely understood, but recent evidence supports the key role of endothelial dysfunction in pathogenesis. In this complex scenario, it is known that IL-6 receptors are present at the endothelial level and can be activated leading to endothelial dysfunction. SARS-Cov-2 is a coronavirus responsible for the disease called 'coronavirus disease 2019' (CoViD-19) characterized by clinical manifestations ranging from a flu-like syndrome up to severe lung damage associated with systemic hyper cytokine syndrome that can lead to multiple organ failure and death. Therefore, both RA and Covid-19 are associated with an increased pro-thrombotic and cardiovascular risk and IL-6 might be crucial in the pathophysiological mechanisms of both diseases.
Objectives: The main hypothesis of this study was to evaluate the possible role of IL-6 as a promoter of endothelial dysfunction in RA and CoViD-19.
Methods: In vitro experiments were conducted on the endothelial cell line EA. hy926. Cells were treated for 24 h with fetal bovine serum (FBS), a pool of RA patients' sera or a pool of CoViD-19 patients' sera. The expression levels of adhesion molecules (V-CAM1/CD-106, I-CAM/CD-54, p-selectine/CD-62, tissue factor/CD-142) and apoptosis were analyzed using cytofluorimetric technique. In addition, the autophagy level, using the autophagy markers p62 and LC3II, were evaluated through a western-blot analysis. The same experiments were conducted co-treating cells with the same pool of sera in addition to tocilizumab (TCZ), an anti-IL-6 drug, to verify the reversibility of the process and test the role of the aforementioned cytokine. Data are reported as interquartile median values. The Kruskal Wallis test was used for unpaired samples and the Mann-Whitney test for paired samples. $P<0.05$ values were considered statistically significant.
Results: EA. hy926 cells, when treated with both RA and CoViD-19 patients' sera, showed increased levels of activation molecules and apoptosis compared to FBS treated cells. In addition, we observed increased levels of both p62 and LC3 proteins after both rheumatoid arthritis and CoViD-19 patients' sera treatment. All these findings were reversible in the presence of TCZ. The results are presented in Figure 1.

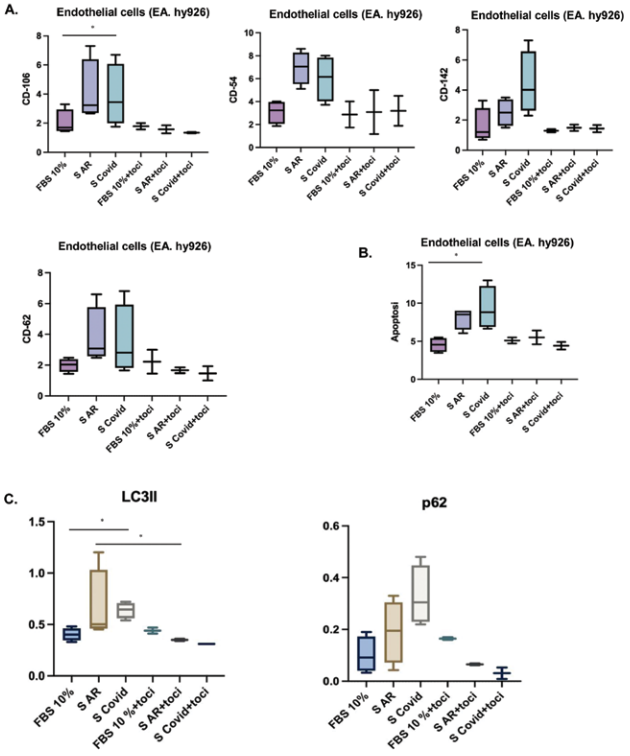

Figure 1. Figures show the adhesion molecules levels (**A**), apoptosis levels (**B**), p62 and LC3II levels (**C**), in all experimental conditions. FBS 10% (cells treated with FBS at 10% concentration), S AR (cells treated with a pool of RA patients' sera); S Covid (cells treated with a pool of COVID-19 patients' sera); FBS 10%+toci (cells co-treated with FBS at 10% concentration and TCZ); S AR+toci (cells co-treated with a pool of RA patients' sera and TCZ); S Covid+toci (cells co-treated with a pool of CoViD-19 patients' sera and TCZ).

Conclusion: Our data showed that treatment with RA and CoViD-19 patients' sera increase the activation and death of endothelial cells in vitro. The increased level of cells death is possibly due to a block of autophagy. The reversibility of the process after blocking IL-6 with TCZ co-treatment confirms the hypothesis that IL-6 can play a key role in the pathogenesis of endothelial damage in patients with RA and CoViD-19.

POS0411

COMPARISON OF MTX-POLYGLUTAMATE ACCUMULATION PROFILES IN PERIPHERAL BLOOD MONONUCLEAR CELLS AND ERYTHROCYTES DURING 6 MONTHS MTX-THERAPY IN THE METHOTREXATE MONITORING (MEMO) TRIAL

R. Hebing[1,2], M. Lin[3], E. Struys[3], S. Mahmoud[1], I. Muller[3], S. Heil[4], P. Griffioen[4], W. Lems[1,2], B. Van den Bemt[5,6], M. Nurmohamed[1,2], G. Jansen[2], R. De Jonge[3].
[1]Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam UMC, locatie VUmc, Rheumatology, Amsterdam, Netherlands; [3]Amsterdam UMC, locatie VUmc, Clinical Chemistry, Amsterdam, Netherlands; [4]Erasmus MC, Clinical Chemistry, Rotterdam, Netherlands; [5]Sint Maartenskliniek, Pharmacy, Ubbergen, Netherlands; [6]Radboud University Medical Center, Pharmacy, Nijmegen, Netherlands

Background: Optimal dosing of methotrexate (MTX) in rheumatoid arthritis (RA) remains challenging. To this end, monitoring of intracellular MTX polyglutamates (MTX-PGs) in red blood cells (RBCs) has been investigated as a potential marker of MTX (non-)response, with contradictory results. As enucleated, non-proliferative cells, mature RBCs lack regulated folate metabolism and are devoid of folylpolyglutamate synthetase (FPGS) activity catalyzing the conversion of MTX to MTX-PGs. Therefore, it has been argued that analysis of MTX-PG in immune-effector cells, represented by peripheral blood mononuclear cells (PBMCs), would be more relevant. However, no prospective study has been performed measuring MTX-PG levels in PBMCs nor in comparison with RBCs.

Objectives: To investigate the pharmacokinetics of MTX-PG accumulation in RBCs and PBMCs in newly diagnosed RA patients in the early phase of MTX treatment.

Methods: In a clinical prospective cohort study (Methotrexate Monitoring (NTR7149)), RA patients were administered MTX op to 25 mg/week, as described before. (1) At 1, 2, 3 and 6 months after start of therapy, blood was collected and RBCs were isolated by centrifugation and PBMCs after Ficoll density gradient centrifugation. MTX-PG_{1-6} concentrations in these cells were analyzed using a UPLC-MS/MS method with including custom-made stable isotopes of MTX-PG_{1-6} as internal standards. (2) UPLC-MS/MS measurements for MTX-PG_{1-6} were performed with a Waters Acquity BEH C18 column coupled to an AB Sciex 6500+ with the ESI operating on the positive mode. MTX dosing and concomitant treatments were in conformity with clinical practice. (3)

Results: 46 consecutive patients were included in this study; 76% female, mean age: 57.8 years, mean baseline DAS28-ESR: 3.5, as described before. (1) Mean dosage was 10.5 mg (SD: 1.5) at baseline, 16.3 mg (2.5) at month 1, 22.7 mg (4.5) at month 2, 19.5 mg (6.3) at month 3 and 19.1 mg (6.2) at month 6.

MTX-PG accumulation in PBMCs and RBCs revealed a disparate profile in both MTX-PG distribution and absolute accumulation levels (Figure 1A/B). Remarkably, MTX-PG distribution in PBMCs was mainly composed of MTX-PG_1 (58%), and to a lesser extent MTX-PG_2 (27%) and MTX-PG_3 (15%). Longer chain MTX-PG_{4-6} were also detectable in PBMCs, but at lower levels (mean: 4.0 – 6.7 fmol/10^6 cells) than MTX-PG_{1-3}. Moreover, this MTX-PG distribution profile in PBMCs remained constant over a MTX therapy period of 6 months (Figure 1A). The RBC MTX-PG accumulation profile shows mainly MTX-PG_1 and lower levels of MTX-PG_{2-6} at 1 month after the start of therapy. After 3 months of therapy, MTX-PG_3 is the main PG-moiety with also MTX-$PG_{4,5,6}$ being detected. This profile is largely similar after 6 months of therapy. With respect to total intracellular MTX-PG_{1-6} accumulation, PBMCs had significantly ($p<0.001$) 10-20-fold higher levels than RBCs at all analyzed time points (Figure 1A/B). Total MTX-PG_{1-6} levels in RBCs and PBMCs at all time points were weakly correlated ($r=0.41$, $p<0.01$) (Figure 1C).

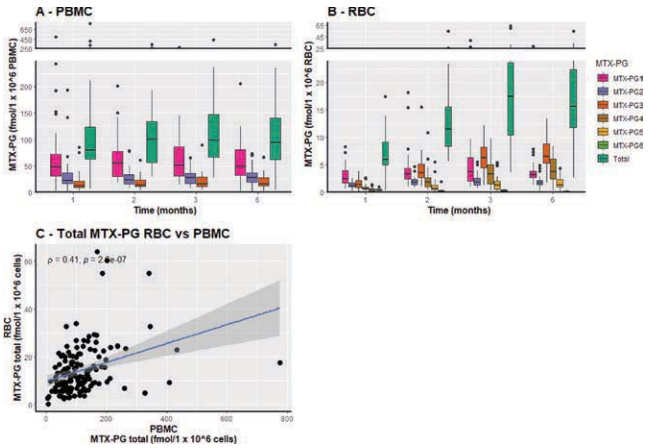

Figure 1. Individual MTX-PG concentrations in PBMCs (A) and RBCs (B) during the first 6 months of MTX administration (note the different scaling of the y-axes). At 6 months, 36 patients were still on MTX treatment. Panel (C): Spearman's correlation plot of total MTX-PGs in RBCs versus PBMCs of all time points.

The disparate MTX-PG accumulation and distribution profiles in PBMCs versus RBCs of RA patients may be associated with the shorter life span of PBMCs and the low FPGS activity in RBCs. (4)

No significant relation between MTX-PGs and DAS28 was found (data not shown).

Conclusion: This study shows that in newly diagnosed RA patients starting MTX therapy, MTX-PG concentrations in PBMCs are significantly 10-20-fold higher than in RBCs over a period of 6 months, with a disparate MTX-PG distribution profile in PBMCs (highest: MTX-PG_1) than RBCs (highest: MTX-PG_3).

POS0412 ENHANCING SURVIVAL AND THERAPEUTIC EFFECT OF MESENCHYMAL STEM CELLS IN RAT MODEL OF RHEUMATOID ARTHRITIS VIA NANOMODIFICATION

Y. Lu[1,2], C. Ding[1,3]. *[1]Zhujiang Hospital, Southern Medical University, Clinical Research Center, Guangzhou, China; [2]Zhujiang Hospital, Southern Medical University, Orthopedic Center, Guangzhou, China; [3]University of Tasmania, Menzies Institute for Medical Research, Tasmania, Australia*

Background: Mesenchymal stem cells (MSCs) have immunomodulatory, multilineage differentiation, and inflammatory/injury site-homing properties. These unique therapeutic features enable MSCs to be used in the treatment of rheumatoid arthritis (RA). However, MSCs therapy is still facing multiple obstacles in RA. First, MSCs are sensitive to inflammatory microenvironment (e.g., high level of reactive oxygen species [ROS]) and hence lose viability and immune regulatory effect when exposed in the inflamed joint. Second, uncontrolled differentiation of MSCs leads to the failure of cartilage repair.
Objectives: The aim of this study was to develop nanoparticle (NP)-modified MSCs that can maintain their biofunctions under the RA-associated oxidized stress and chondrogenically differentiate to repair cartilage.
Methods: Copper sulfide@manganese dioxide (CuS@MnO_2) NPs were sythesized, then modified with an MSC-targeting peptide (VTAMEPGQ, termed VQ) and loaded with metformin (MET) to produce VQ-CuS@MnO_2/MET (termed VCMM) NPs. After cellular uptake, the NP-modified VCMM-MSCs were obtained. The basic functions, chondrogenesis, anti-inflammatory effect and cell viability under oxidized stress of VCMM-MSCs were studied in vitro. Further, VCMM-MSCs were intravenously (i.v.) injected into rat models of collegan-induced arthritis (CIA) and adjuvant-induced arthritis (AIA) to evaluate their survival and therapeutic effect in vivo.
Results: The NP-modified VCMM-MSCs exhibited stronger capabilities of cell migration and chondrogenesis relative to bare MSCs. VCMM-MSCs were also better than bare MSCs in terms of anti-inflammation towards lipopolysaccharide-induced M1 macrophages (RAW264.7). Moreover, VCMM-MSCs could survive under the RA-associated oxidized stress through catalyzing intracelluar ROS into oxygen by the superoxide dismutase (SOD)- and catalase (CAT)-like activities of the NPs, whereas approximately half of bare MSCs were dead. After i.v. injection into CIA and AIA rats, VCMM-MSCs lived longer and accumulated more abundant in the inflamed joints relative to bare MSCs (determined by in vivo fluorescence imaging). They promoted the repolarization of macrophages from M1 to M2 type in synovium, thereby inhibiting synovial inflammation in vivo. Further, VCMM-MSCs enhanced the sythesis of glycosaminoglycan and type II collegan in cartilage and thus promoted joint reapir.
Conclusion: The NP-modified VCMM-MSCs alleviated arthritis syndrome of both CIA and AIA models through reducing synovial hyperplasia and cartilage destruction. Nanomodification of MSCs may provide a new strategy to improve stem cell therapy in RA and other inflammatory diseases.

POS0413 IGURATIMOD AMELIORATES BLEOMYCIN-INDUCED PULMONARY FIBROSIS VIA INHIBITINGEMT PROCESS AND NLRP3 INFLAMMASOME ACTIVATION

W. Liu[1], Q. LI[1], X. Han[1], L. Sun[1], J. Wang[1]on behalf of Rheumatology & Clinical Immunology working group. *[1]The Affiliated Hospital of Qingdao University, Department of Rheumatology & Clinical Immunology, Qingdao, China*

Background: Interstitial pulmonary fibrosis is the deadliest manifestation of rheumatoid arthritis (RA), and its pathogenesis is complicated. As a new drug for controlling RA, clinical studies have found that iguratimod (IGU) has certain advantages in improving lung function and shows great potential for pulmonary fibrosis therapy[1]. However, the specific mechanism of IGU in treating pulmonary fibrosis is not clear.
Objectives: This study was designed to observe and investigate the therapeutic effects of IGU on bleomycin-induced pulmonary fibrosis in mice and further investigate its underlying mechanism, aiming to provide a further theoretical basis for clinical rational drug use.
Methods: A mouse model of pulmonary fibrosis was induced by intratracheal injection of bleomycin (BLM)[2]. Model mice were randomly assigned to receive Sodium carboxymethyl cellulose (CMC) or different concentrations of IGU. HE staining and immunohistochemical staining were performed to observe the therapeutic effects of IGU on mouse fibrosis. TGF-β induced A549 EMT cell model was utilized to investigate the effects of IGU on EMT *in vitro*[3]. NLRP3 inflammasome was activated by the co-stimulation of TGF-β+LPS+ATP (TLA) to evaluate the effects of IGU *in vitro*[4].
Results: We found that IGU resulted in favorable therapeutic outcomes by affecting the inflammation infiltration (Figure 1A) and collagen deposition (Figure 1B). Immunohistochemical results showed that IGU downregulated the levels of α-SM and NLRP3. Additionally, the markers of BLM-mediated EMT (Figure 1C) phenotype and NLRP3-activated (Figure 1D) phenotype in the lung were also attenuated after IGU administration. *In vitro* experiments, the results confirmed its anti-EMT effects of reducing the expression of interstitial proteins Vimentin and α-SMA and restoring the content of epithelial protein E-cadherin. Besides, IGU could inhibit NLRP3 activation by downregulating NLRP3 related marker proteins, reducing the secretion of IL-1β, and attenuating caspase-1 activity. We then found that IGU anti-EMT and anti-NLRP3 effect was accompanied by decreased ROS production.

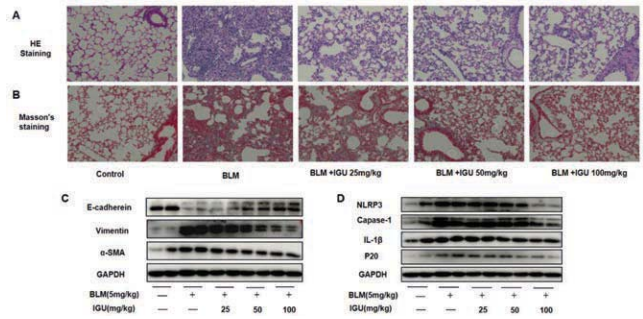

Figure 1. IGU ameliorates BLM-induced pulmonary inflammation and pulmonary fibrosis. **(A)** Representative lung micrographs of lung tissues stained with HE. Magnification, ×200. **(B)** Representative photographs of lung tissues stained with Masson's trichrome staining. Magnification, ×200. **(C)** Representative results of western blot for E-cadherin, Vimentin, α-SMA expression in lung tissues. GAPDH was used as the endogenous control. **(D)** Representative results of western blot for NLRP3, caspase-1, cleaved-caspase-1 p20, IL-1β expression in lung tissues. GAPDH was used as the endogenous control.

Conclusion: IGU can inhibit the EMT process and NLRP3 inflammasome activation, reduce ROS production to ameliorate pulmonary fibrosis, which may provide new insights into the further application of IGU in Interstitial pulmonary fibrosis.

POS0415 PLASMA GALECTIN-9 IS ASSOCIATED WITH CLINICAL DISEASE ACTIVITY IN TREATMENT NAÏVE EARLY RHEUMATOID ARTHRITIS, UNAFFECTED BY DMARD TREATMENT, AND IN VITRO MODULATES THE SECRETION OF MCP-1 AND IL-6 IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

M. A. Nielsen[1,2], D. Køster[2], K. Stengaard-Pedersen[1], P. Busson[3], P. Junker[4], K. Hørslev-Petersen[5], M. L. Hetland[6], M. Østergaard[6], M. Hvid[2,7], T. W. Kragstrup[1,2], B. Deleuran[1,2]. *[1]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [2]Aarhus University, Biomedicine, Aarhus, Denmark; [3]Paris-Saclay University, CNRS-UMR, Orsay, France; [4]Odense University Hospital, Rheumatology, Odense, Denmark; [5]King Christian X's Rheumatism Hospital, Rheumatology, Sønderborg, Denmark; [6]Rigshospitalet, Copenhagen Center for Arthritis Research, København, Denmark; [7]Aarhus University, Clinical Medicine, Aarhus, Denmark*

Background: Fibroblast-like synoviocytes (FLS) are pivotal mediators of rheumatoid synovitis expansive growth and invasiveness which respond insufficiently to disease-modifying antirheumatic drugs. Galectin-9 (Gal-9) is a lectin with well-conserved carbohydrate-recognition domains. Gal-9 has been reported to have both pro- and anti-inflammatory properties based on its ability to modulate RA FLS. Gal-9 levels are elevated in serum of rheumatoid arthritis (RA) patients, and high levels of Gal-9 have been identified in both the synovial fluid and in the inflamed synovial tissue of patients with RA.

Objectives: To investigate the role of Gal-9 as a biomarker for disease severity in treatment naïve patients with early RA and to study aspects of Gal-9 effects on inflammatory RA FLS.
Methods: Soluble plasma Gal-9 was measured in patients with newly diagnosed, treatment-naïve RA (n = 98) and in Healthy (HC) (n = 48) (Table 1). Over a 2-year period patients were randomized to either MTX alone or MTX and anti-TNF antibody treatments. Serial measurements of disease activity (DAS28CRP) were collected to evaluate the disease course. In another cohort of patients with established RA, plasma and synovial fluid samples were also examined for Gal-9 (n = 18) (Table 1). Synovial fluid mononuclear cells (SFMC) from established RA patients were used to harvest RA FLS (n=7). Osteoarthritis FLS were used as disease controls and obtained from patients with knee OA undergoing joint replacement surgery (n = 5). Monocultures of synovial fluid derived FLS (SF-FLS) (n= 6) and autologous co-cultures of SF-FLS and peripheral blood mononuclear cells (PBMC) were established (n=7) and subsequently analyzed by flow cytometry, MTT assay, and ELISA. *In vitro,* cultures were treated with a neutralizing anti-Gal-9 antibody.

Table 1.

Patient characteristics	Early RA (n=98)			Established RA (n=18)	HC (n=48)
Time after treatment initiation (months)	0	3	24	84 (12-288)	
Disease activity					
DAS28CRP (0-10)	5.7 (5.1-6.4)	2.1 (1.8-3.2)	2.0 (1.8-2.7)	5.0 (3.2-5.5)	-
Gal-9 levels (pg/ml)					
Plasma	3315 (2683-4421)	3217 (2706-4250)		2904 (2639-3411)	2190 (1652-2852)
Synovial fluid				21246 (13832-34727)	

Patient characteristics. Data are expressed as median with IQR range unless otherwise indicated.

Results: Patients with early and established RA had increased plasma levels of Gal-9 compared with HCs ($P < 0.05$) (Table 1) and levels of Gal-9 correlated positively with swollen joint counts at baseline (rho = 0.344, $P < 0.05$). The levels remained unaffected by treatment with MTX alone or by a combination of MTX and anti-TNF antibodies. Gal-9 levels were markedly elevated in the synovial fluid of chronic RA patients compared with the corresponding plasma samples ($P < 0.05$) (Table 1). *In vitro,* a neutralizing Gal-9 antibody mediated a 40% decrease in MCP-1 secretion ($P < 0.05$) and a 30% decrease in IL-6 secretion ($P < 0.05$) in RA FLS monocultures. In OA FLS, addition of anti-Gal-9 antibodies comparably decreased the production of both MCP-1 ($P < 0.05$) and IL-6 ($P < 0.05$). The changes in cytokine production were not attributable to reduction in the fraction of inflammatory FLS ($CD34^-PDPN^+THY1^+$), decreased viability or proliferation. We further investigated if the effect of neutralizing Gal-9 persisted in co-cultures between FLS and autologous PBMC. Also in this setting, neutralization of Gal-9 mediated a 40% reduction in both MCP-1 and IL-6 ($P < 0.05$, $P < 0.05$).
Conclusion: Pretreatment plasma Gal-9 levels in patients with newly diagnosed RA were increased and correlated with baseline clinical disease activity but remained elevated during goal directed synovitis suppressive therapy. In addition, in vitro neutralization of Gal-9 decreased MCP-1 and IL-6 production in a subset of FLS linked to RA pathology. Collectively these findings indicate that Gal-9 overexpression is a co-player in the causation of acute and persistent RA synovitis by enhancing pro-inflammatory FLS pathways.

POS0416 PRECLINICAL EFFICACY OF AN OXAZOLOPYRIDINE IRAK4 INHIBITOR IN RODENT MODELS OF INFLAMMATION

A. Ugolkov[1], R. Von Roemeling[2], R. Martell[3]. *[1]Curis, Inc., Translational Science, Lexington, United States of America; [2]Curis, Inc., Clinical Development, Lexington, United States of America; [3]Curis, Inc., Research & Development, Lexington, United States of America*

Background: Interleukin-1 receptor-associated kinase 4 (IRAK-4) is involved in Toll-Like Receptor (TLR) and Interleukin-1 Receptor (IL-1R) signaling pathways regulating innate immunity. Inhibition of IRAK4 could block the expression of cytokines involved in autoimmune disorders such as rheumatoid arthritis. CA-4948 is a member of the oxazolopyridine class of IRAK4 inhibitors and has been shown to suppress TLR agonist-induced NF-kappaB activation, TNF-alpha and IL-1beta expression in the THP-1 monocytic cell line.
Objectives: Determine whether a highly specific oxazolopyridine IRAK4 inhibitor demonstrates efficacy in mouse models of arthritis and systemic inflammation; compared to an isoquinoline inhibitor PF-06650833.
Methods: We used the mouse model of collagen induced arthritis (CIA) and lipopolysaccharide (LPS)-induced cytokine release mouse model of systemic inflammation. Mice were treated with CA-4948 or PF-06650833. In the CIA mouse model, disease activity was determined by measuring inflammation swelling in the affected joints (paw volume) and clinical score over time. Histopathological evaluation of the sum of hindpaws was performed for CIA study. A single oral dose of IRAK4 inhibitor was administered to CD-1 mice followed by intraperitoneal administration of LPS at 3 hours. ELISA kits were used to evaluate cytokine levels in mouse serum samples at 1 and 3 hours after LPS challenge.
Results: Treatment with CA-4948 or PF-06650833 resulted in inhibition of arthritis severity in the CIA mouse model and a decreased expression of proinflammatory cytokines as measured in mouse blood after LPS challenge. Consistent with CIA in-life data, treatment with CA-4948 decreased the score of all histopathological parameters (inflammation, cartilage erosion, synovial hyperplasia and pannus, bone degeneration/resorption, periosteal/exostotic changes, and composite scores) when compared to vehicle control and the differences attained statistical significance for all histopathological parameters. Treatment with CA-4948 resulted in a significant reduction of cytokine levels by 72% for TNF-alpha and 35% for IL-6 in LPS-induced cytokine release mouse model.
Conclusion: A highly specific oxazolopyridine IRAK4 inhibitor, CA-4948, demonstrated potent therapeutic efficacy in mouse models of arthritis and systemic inflammation.

POS0417 LESS ACPA EPITOPE EXPANSION IS FOUND IN ACPA-POSITIVE IMMUNE CHECKPOINT INHIBITOR ARTHRITIS PATIENTS COMPARED TO ACPA-POSITIVE RHEUMATOID ARTHRITIS PATIENTS

D. Rajesh[1,2], N. Ghosh[1,2], J. Kirschmann[3], K. K. Chan[1,2], D. Jannat-Khah[1,2], S. Goodman[1,2], V. Bykerk[1,2], W. Robinson[3], A. Bass[1,2]. *[1]Hospital for Special Surgery, Department of Medicine, New York, United States of America; [2]Weill Cornell Medical College, Department of Medicine, New York, United States of America; [3]Stanford University School of Medicine, Department of Medicine, Stanford, United States of America*

Background: Immune checkpoint inhibitors (ICI) have markedly improved the treatment of many advanced cancers; however, they can result in immune-related adverse events (irAE) including ICI arthritis (ICI-A). ICI-A often resembles rheumatoid arthritis (RA) and ~9% of ICI-A patients are anti-citrullinated peptide antibody (ACPA) positive. In RA, ACPA epitope expansion occurs over the years prior to onset of clinical disease. In this study we examined the degree of ACPA epitope expansion in seropositive ICI-A patients in order to determine whether it is similar to early RA, or more suggestive of the pre-clinical phase of disease[1].
Objectives: To compare the number of ACPA epitopes targeted in seropositive ICI-A versus RA.
Methods: We used clinical data and serum from 12 ACPA+ ICI-A patients enrolled in a prospective registry and 39 ACPA+ RA patients enrolled in the CATCH-US early RA cohort. ACPA screening was done using a commercial ELISA (positive >20 units/mL). A custom, bead-based antigen array was used to identify antibody reactivities to 16 putative RA associated citrullinated proteins. Synovial fluid (SF) samples from 3 of the ICI-A patients were also tested using the bead-based microarray. Hierarchical clustering software was used to create heatmaps to identify ACPA levels. Z-scores for fluorescence intensity were also calculated separately for each peptide, and a fluorescence level above the mean (Z-score>0) was defined as a positive ACPA. The number of positive epitopes for each patient was determined and compared categorically between the ICI-A and RA patients using Fischer's exact test.
Results: Characteristics of ICI-A and early RA patients are listed in Table 1. Compared to RA patients, ICI-A patients were older (mean 71 years vs. 48 years), more likely to have ever smoked (67% vs. 36%) and less likely to have positive rheumatoid factor (RF) (8% vs. 69%). Median symptom duration for ICI-A patients was 3.7 months compared to 6.7 months in RA patients. The median ACPA titer was lower in ICI-A patients than RA patients (42 units/mL vs. 250 units/mL). As demonstrated in Figure 1, lower signal intensities (level of ACPA) and a lower number of distinct ACPA epitopes were seen in the serum of ICI-A patients compared to RA patients. Of ICI-A patients, 67% were positive for 0-4 ACPA epitopes, 8% for 5-10 epitopes and 25% for >10 epitopes, as opposed to

23% of RA patients positive for 0-4 epitopes, 36% for 5-10 epitopes, and 41% for >10 epitopes (p=0.02). The one ICI-A patient who was also RF positive had 12 positive ACPA epitopes. There was no significant difference in the number of ACPA epitopes in ICI-A patients who were smokers vs. nonsmokers, RA-like vs. PMR-like, or who received ICI combination vs. ICI monotherapy. In the 3 ICI-A patients with synovial fluid samples, SF ACPA was not demonstrated.

Table 1. Baseline Characteristics of ACPA+ ICI-A and RA Patients

	ICI-A (N=12)	Early RA (N=39)
Age in years, mean (SD)	71.0 (8.3)	48.2 (14.6)
Female Sex	7 (58%)	33 (85%)
White/Caucasian	9 (75%)	27 (69%)
Symptom Duration in months, median [IQR]	3.7 [1.0,11.3]	6.7 [4.0,9.7]
RF Positive	1 (8%)	27 (69%)
ACPA level (units/mL), median [IQR]	42.2 [29.4,70.5]	250 [107.5,251.0]
Obese (BMI≥30)	3 (25%)	9 (23%)
Current/Past Smoker	8 (67%)	14 (36%)
Cancer Type[†]		
Melanoma	4 (33%)	
Renal Cell Carcinoma	3 (25%)	
ICI Regimen		
PD-1/PD-L1	7 (58%)	
CTLA-4+PD-1	5 (42%)	
ICI-A Phenotype		
RA-like	9 (75%)	
PMR-like	3 (25%)	

[†] *Other cancer types in ICI-A patients included urothelial carcinoma (n=2), non-small cell lung cancer (n=2), and head and neck cancer (n=1).*

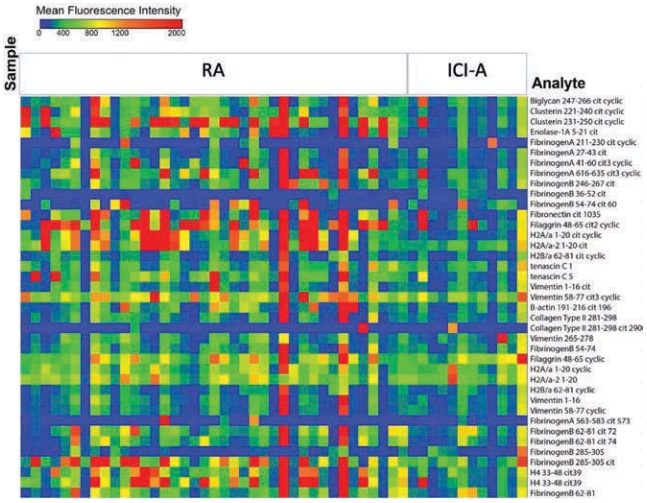

Figure 1. Heat Map of ACPA repertoire in RA Patients and ICI-A Patients.

Conclusion: ICI-A patients had lower ACPA titers and targeted fewer ACPA epitopes than early RA patients. It remains to be determined if ICI-A represents an accelerated model of RA pathogenesis with ICI triggering an early transition from pre-clinical to clinical disease. This would require sequential sampling and analysis.

POS0418 ICE CRYOTHERAPY: A NEW STRATEGY TO REDUCE ARTERIAL INFLAMMATION IN RHEUMATOID ARTHRITIS? A STUDY IN ADJUVANT-INDUCED ARTHRITIS MODEL

C. Peyronnel[1], P. Totoson[1], V. Petitcolin[1], F. Bonnefoy[2], F. Verhoeven[2,3], X. Guillot[4], P. Saas[2], H. Martin[1], C. Demougeot[1]. *[1]PEPITE EA4267, FHU INCREASE, Univ. Bourgogne Franche-Comté, Besançon, France; [2]INSERM UMR 1098, EFS BFC, Univ. Bourgogne Franche-Comté, Besançon, France; [3]Rhumatologie, CHRU Jean-Minjoz, Besançon, France; [4]Rhumatologie, CHU Felix-Guyon, Saint-Denis, French Southern Territories*

Background: Rheumatoid arthritis (RA) is characterized by endothelial activation (EA), endothelial dysfunction and vascular inflammation, leading to accelerated atherosclerosis. In the last decade, a renewed interest in cryotherapy - local or whole body - has emerged. Although growing evidence demonstrated that ice cryotherapy reduces not only pain but also disease progression, whether such therapy might blunt disorders of the systemic vasculature is unknown.

Objectives: The aim of our study was to determine the effects of a subchronic treatment with ice cryotherapy on aortic leucocyte infiltration and markers of endothelial activation in the rat adjuvant-induced arthritis (AIA) model.

Methods: AIA was induced by injection of *Mycobacterium butyricum* in Freund's incomplete adjuvant at the base of the tail in 6-week-old male Lewis rats. AIA rats were treated or not with ice applied on paws, from the onset of arthritis to the acute inflammatory stage of the disease, twice a day for 14 days. Arthritis score and paw skin temperature were daily monitored. At the end of the treatment, leucocyte infiltration and the different cell subsets (monocytes/macrophages, neutrophils, $CD4^+$ and $CD8^+$ T cells producing or not IL-17A) were measured in thoracic aorta using flow cytometry. Relative mRNA expression of cytokines/chemokines (IL-6, TNF-α, CXCL-1, MIP-1α (CCL-3), MCP-1 (CCL-2)) and adhesion molecules (ICAM-1, VCAM-1) was analyzed in thoracic aorta by RT-qPCR. X-Ray analysis of hind paws was performed to assign a radiographic score.

Results: Treatment with ice cryotherapy, that decreased skin surface temperature from 28.6 ± 0.3°C to 18.5 ± 0.2°C, reduced arthritis score (-36%, $p<0.001$) and radiographic score (-34%, $p<0.05$) with a positive effect on osteoporosis, cartilage and bone destruction. These effects were associated with a dramatic decrease in $CD4^+$, $CD8^+$ and Tc17 cell aortic infiltration as compared to untreated AIA. By contrast, ice had no effect on endothelial activation markers except VCAM-1 mRNA expression that was significantly increased ($p<0.05$). A positive correlation was found between the number of total leucocytes, monocytes/macrophages, $CD4^+$ and $CD8^+$ T cells in aorta and arthritis score.

Conclusion: In the model of AIA that reproduces arterial wall inflammation recently characterized in rheumatoid arthritis by PET/CT [1], local ice cryotherapy exerts not only local beneficial effects on the joints but also systemic benefits on vascular inflammation in large vessels. These results suggest that reduction of vascular comorbidities might be a new output of ice cryotherapy used as an adjunctive therapy in RA.

POS0419 DIFFERENTIAL MIRNA EXPRESSION AND ENDOTHELIAL CELL FUNCTION IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

O. Tynan[1], C. Cunningham[1], M. Hanlon[1], A. Floudas[1], M. Canavan[1], U. Fearon[1], D. Veale[2]. *[1]Trinity Biomedical Sciences Institute, Molecular Rheumatology, School of Medicine, Dublin, Ireland; [2]St. Vincent's University Hospital, and University College Dublin, Centre for Arthritis and Rheumatic Disease, Dublin, Ireland*

Background: Rheumatoid arthritis (RA) and Psoriatic arthritis (PsA) constitute forms of inflammatory arthritis (IA) characterised by enhanced angiogenesis, immune cell infiltration, and generation of a hypoxic microenvironment leading to an invasive synovial pannus that results in bone and cartilage destruction. However, significant differences in circulating biomarkers in addition to disease pathogenesis at the clinical, immunological, cellular, and molecular levels have been identified that differentiate the two pathotypes.

Objectives: The aim of this study was to examine circulatory miRNA as cellular biomarkers that can distinguish RA form PsA and to evaluate the potential implication for disease pathogenesis. Furthermore, this study aimed to examine the differential effect of the joint microenvironment on endothelial cell (EC) function in both RA and PsA.

Methods: RA, PsA and healthy controls (HC) were recruited from St. Vincent's University Hospital, and serum was collected. Multiplex analysis of 68 serum miRNAs was performed using the FirePlex miRNA Immunology-V2 panel (FirePlex Bioworks Inc). Receiver operator characteristic (ROC) curves were generated to determine sensitivity and specificity of specific miRNAs whilst DNA intelligent analysis (DIANA)-mirPath and STRING software were used to analyse pathways targeted by the dysregulated miRNAs. Additionally, human umbilical vein endothelial cells (HUVEC) were cultured with RA and PsA synovial fluid (SF). Angiogenesis, invasion, and cellular adhesion were quantified by Matrigel tube formation assays, wound healing assays, and adhesion assays. Real-time cellular bioenergetics was analysed in HUVEC in response to RA and PsA SF using the Seahorse XFe96 Analyser.

Results: 7 miRNAs; miR-126-3p, miR-29b-3p, miR-22-3p, miR-223-3p, miR-320a, let-7g-5e, and let-7g-5p (all**$p\leq0.01$), were significantly elevated in RA

serum compared to both PsA patients and HC, with ROC curve analysis demonstrating the predictive accuracy with which each miRNA differentiated between RA and PsA (all <0.05). Biplot analysis further identified that three miRNA, miR-29b-3p, miR-22-3p, and miR-223-3p demonstrated the greatest separation between RA and PsA (all p<0.05). DIANA and STRING analysis identified the P13K-Akt pathway as being the primary target of these 3 miRNAs with specific gene targets involved in this pathway including factors all importantly associated with endothelial cell migration, proliferation, invasion, and angiogenesis. Next, we examined the effect of the joint microenvironment on endothelial cell function and demonstrated that PsA SF significantly enhanced EC tube formation (p<0.05) and EC leukocyte adhesion (p<0.05), with RASF only significantly inducing EC leukocyte adhesion. Finally, metabolic analysis of endothelial cells demonstrated that PsA SF significantly induced baseline glycolysis (p<0.05), baseline OCR (p<0.05), maximal respiratory capacity (p<0.05) and spare respiratory capacity (p<0.05), with no effect observed for RA SF.

Conclusion: Circulating miRNAs may be valuable as diagnostic biomarkers that can distinguish RA from PsA. Additionally, the joint microenvironment induces EC function and metabolic capacity, with these effects more pronounced in response to PsA SF compared to RA SF.

POS0420 A 10-COLOR FLOW CYTOMETRIC PANEL FOR IDENTIFYING SYNOVIAL FIBROBLAST SUBSETS IN RHEUMATOID ARTHRITIS

S. Lomholt[1], T. W. Kragstrup[1,2]. [1]*Aarhus University, Department of Biomedicine, Aarhus, Denmark;* [2]*Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark*

Background: Synovial fibroblasts are key players in the disease pathology of rheumatoid arthritis and specific fibroblast subsets have been linked to joint inflammation and joint destruction[1]. These synovial fibroblasts can be cultured from both the easily obtained synovial fluid or the more time-consuming synovial biopsy or resection. Recently, cultured synovial fibroblasts from synovial fluid where confirmed to possess a similar phenotype to that of the synovial fibroblast podoplanin+/CD90+/human leukocyt antigen(HLA)-DR+ subset from biopsies[2].

The present advancement in our knowledge of synovial fibroblasts have been spearheaded through bulk and single cell RNA transcriptomics. Expensive techniques that may require supplementary identification of phenotype clusters and cell function on protein level.

Objectives: The objective of this work was to plan, optimise and test a multi-color flow cytometry panel for identification of known synovial fibroblast subsets linked to arthritis pathology. The primary focus was well established markers; podoplanin, CD90, CD55, HLA-DR, CD34 and fibroblast activation protein alpha (FAPa).

Methods: Several cell types were used in optimizing the panel. The majority of antibody titration was conducted on immortalized synovial fibroblasts from a patient with rheumatoid arthritis. Exclusion markers such as CD45 (blood cells) and CD31 (endothelial and monocytes/macrophages) were titrated on synovial fluid mononuclear cells and peripheral blood mononuclear cells. Finally, full panel testing on synovial fibroblasts cultured from synovial fluid was compared with immortalized synovial fibroblasts. All tests were carried out on a commercially available flow cytometer with 4-lasers (405, 488, 561 and 637nm) and 27 detectors.

Results: Several panel iterations were tested during the optimization process. Two markers, cadherin-11 and receptor activator of nuclear factor kappa-b ligand, were abandoned after testing different antibody clones for staining and several detaching solutions on fibroblasts prior to staining. Initial compensation issues were overcome by rearranging fluorochromes and using cells as CD90 compensation controls.

The final flow cytometry panel contained 10 markers; podoplanin, CD90, CD55, CD34, HLA-DR, FAPa, CD45, CD31, complement C3a receptor and a viability marker. Final testing on synovial fibroblasts cultured from synovial fluid yielded an acceptable viability > 90%. Within the synovial fibroblasts cultured from synovial fluid, the panel was able to identify podoplanin+/CD90+/FAPa+ synovial fibroblasts previously linked with joint inflammation. The panel was, furthermore, able to identify a podoplanin+/CD90+/HLA-DR+ population in the immortalized synovial fibroblasts.

Conclusion: The optimized flow cytometry panel presented here enables researchers to identify synovial fibroblasts subsets which have been linked with disease traits in rheumatoid arthritis. This panel could therefore both be useful as a supplement to transcriptomic data and as a primary interrogation tool when investigating fibroblast subsets and cell function on a protein level.

POS0422 A HISTORY OF CHLAMYDIAE INFECTION IN RHEUMATOID ARTHRITIS DEVELOPMENT

C. Lamacchia[1], R. Aymon[1], B. Gilbert[1], O. Studer[1], K. Lauper[1], A. Finckh[1]. [1]*Geneva University Hospital, Rheumatology, Geneva, Switzerland*

Background: Current hypotheses for the ethiopathogenesis of rheumatoid arthritis (RA) postulate an infectious agent initiating autoimmunity, which is thought to be at the mucosal level. *Chlamydiae* infections have been previously associated to development of an acute inflammatory arthritis, which can become chronic in some patients. *Chlamydia trachomatis* was detected in synovial fluid and tissue of RA patients, at least in early disease, suggesting that this organism could be involved in initiating RA onset, at least in a subset of patients.

Objectives: To investigate the association between *Chlamydiae* infection and the development of autoimmunity and pre-clinical manifestations associated with RA.

Methods: This study was performed in an ongoing prospective study of individuals genetically at risk of developing RA, namely first-degree relatives of RA patients (RA-FDR). Individuals without clinical evidence of RA

are enrolled, and assessed yearly, clinically and biologically. We included all RA-FDRs who responded to a *Chlamydiae* infection questionnaire, and the exposure of interest was self-reported *Chlamydiae* infection. The primary outcome was autoimmunity associated with RA (seropositivity) defined by the presence of anti-citrullinated peptide antibodies (ACPA) and/or rheumatoid factors (RF) at the last visit. Seropositive inflammatory arthritis at the last visit was a secondary outcome. We used logistic regression to analyze univariable and multivariable associations, adjusting for age and gender as potential confounders.

Results: A total of 1254 RA-FDRs were analyzed, of which 168 (13.4%) had developed seropositivity. The prevalence of self-reported Chlamydia infection was significantly higher in seropositive individuals as compared to controls (17.9% versus 9.8%, P<0.01) (Table 1). A significant association between the self-reported history of *Chlamydiae* infection and the seropositivity was observed in both univariate and multivariate analyses (OR=2.00, 95% CI: 1.27-3.09; OR=1.91, 95% CI: 1.20-2.95, respectively). A sub-group of 48 RA-FDRs (4 %) presented inflammatory arthritis in conjunction with seropositivity. This subgroup, considered at highest risk for RA, reported significantly more often prior infections with *Chlamydiae* than the negative subgroup (20.8% versus 10.5%, P<0.05). The ORs for the association of self-reported history of *Chlamydiae* infection and inflammatory arthritis coupled to RA-associated autoimmunity were 2.23 (95% CI: 1.03-4.43, P<0.01, univariate analysis) and 1.91 (95% CI: 0.88-3.82, P=0.08, multivariate analysis).

Table 1. A potential association between a self-reported history of *Chlamydiae* infection and RA development

	RA-FDR with a self-reported chlamydia infection anamnesis (n=1254)		
		Univariate analysis	Multivariate analysis[1]
Study Groups	**Self-reported "infection"**	**OR (95% CI)**	**OR (95% CI)**
Seropositive RA-FDR (n=168)	30 (17.9%)	2.00** (1.27 - 3.09)	1.91** (1.20 – 2.95)
Seronegative RA-FDR (n=1063)	104 (9.8%)		
RA-FDR with seropositive inflammatory arthritis [2] (n=48)	10 (20.8%)	2.23* (1.03 – 4.43)	1.91 (0.88 – 3.82)
RA-FDR without seropositive inflammatory arthritis (n = 1206)	127 (10.5%)		

[1]Logistic regression model adjusting for age and gender.[2]Seropositive inflammatory arthritis was defined by being either: seropositive RA; seropositive "arthritis" (defined by at least one swollen joint at physical examination); seropositive with MSUS (musculoskeletal ultrasound) inflammatory activity.* P-value < 0.05** P-value < 0.01

Conclusion: Our results suggest that a history of *Chlamydiae* infection may be a risk factor for the development of RA in a subset of individuals at genetic risk for the disease. Serological analyses to assess the prevalence of antibodies to *C. trachomatis* major outer membrane protein (MOMP) are under way to confirm these preliminary data.

POS0423 CYCLIC CITRULLINATED PEPTIDE APTAMER TREATMENT ATTENUATES COLLAGEN INDUCED ARTHRITIS

S. Khatri[1], J. Hansen[1], N. Pedersen[1], S. Gram-Nielsen[2], A. Mendes[3], I. Chronakis[3], U. Keiding[1], B. Réthi[4], M. H. Clausen[1,5], T. W. Kragstrup[5,6], K. Astakhova[1,5]. *[1]Technical University of Denmark, Chemistry, Lyngby, Denmark; [2]Technical University of Denmark, Health Technology, Lyngby, Denmark; [3]Technical University of Denmark, FOOD, Lyngby, Denmark; [4]Karolinska Institutet and Karolinska University Hospital, Department of Medicine/Solna, Solna, Sweden; [5]IBIO TECH ApS, R&D, Copenhagen, Denmark; [6]Aarhus University, Biomedicine, Aarhus, Denmark*

Background: Anti-citrullinated peptide antibodies (ACPA) appear 10–15 years before the diagnosis of rheumatoid arthritis (RA) and are associated with a more severe disease course. In previous work, we rationally designed and screened ACPA-binding peptide aptamer sequences in silico and constructed a nanoparticle with chitosan and hyaluronic acid(1). A developmental stage version of this nanoparticle was able to reduce disease activity in the collagen-induced arthritis (CIA) and the serum transfer arthritis mouse models (2).

Objectives: Here, we investigated the effect and potential toxicity of three different versions of the aptamer nanoparticle (loading of 20%, 10% and 5% aptamer, respectively) in the CIA rat model.

Methods: Wistar rats (males and females) were given a single intravenous dose (100 mg/kilo) of type II collagen in PBS in the tail vein. The dosing was repeated three times with one day interval, followed by blood sample collection at day 7 after the initial collagen injection. To evaluate route of administration and dosing, we injected a single intravenous and subcutaneous dose (2.5 mg/kg) of aptamer-nanoparticles (A/N ratio 20%) in PBS in the tail vein/abdomen, and plasma concentration–time profiles were followed for 2 days after dosing with weekly blood sampling. To evaluate organ uptake, rats were given a single intravenous and subcutaneous dose (2.5 mg/kg) of aptamer-nanoparticles (A/N ratio 20%) in PBS in the tail vein/abdomen. The procedure was repeated after 24 hours. Blood and urine samples were taken once a week. A group of 10 animals was sacrificed every week over a three-week period, and the organs were processed. To examine efficacy, rats were given a single subcutaneous dose (2.5 mg/kilo) of aptamer-nanoparticles and nanoparticle controls without aptamer or PBS alone in the abdomen. The procedure was repeated once a week over a course of three weeks. Weight, joint measurement, blood, and urine samples were taken once a week. Paw swelling was measured on a weekly basis. In the plasma samples we measured CPEP2 and anti-collagen II by enzyme linked immunosorbent assay (ELISA).

Results: Using a rather high dose of collagen (100 mg/kilo) via an intravenous administration route, ACPA was measurable in all CIA rats with rapid development of RA in 82% of the included animals. Intravenous administration resulted in an immediate high plasma concentration post injection, which decreased rapidly to low levels. The s.c. administration route gave a steady, long-term aptamer release with a maximum availability 8 hours post-injection. After three aptamer-nanoparticle doses (2.5 mg/kg; either 20%, 10% or 5% aptamer), we observed a dose-dependent reduction in swollen joint count for the aptamer-nanoparticle treated groups (10 rats in each group) compared with the healthy control group (10 rats) (P-value = 2,1E-6). We observed decreased ACPA IgG levels in the rats treated with aptamer-nanoparticle. The decrease in ACPA levels correlated with the aptamer-nanoparticle having higher loading. Anti-collagen II IgG levels slightly increased towards the end of the study.

Conclusion: We developed and tested a novel peptide aptamer-based drug candidate for seropositive rheumatoid arthritis in CIA rats. Over a 3-week course of treatment with subcutaneous administration of aptamer-nanoparticles, joint swelling was decreased during treatment, and completely reversed at the end of the observation period. The reduction of joint swelling was associated with decreased levels of ACPA in the blood.

POS0424 THE ROLE OF IL-25 REGULATING IL-17 AND ROR-γT ON TH17 IN RHEUMATOID ARTHRITIS

D. Liu[1], Y. LV[2]. *[1]Xi'an No.5 Hospital, Department of Rheumatology and Immunology, XI'AN, China; [2]Xi'an No.5 Hospital, Department of Rheumatology and Immunology, XiAN, China*

Background: Rheumatoid arthritis (RA) is a prevalent common autoimmune disease characterized by chronic inflammation of the joint and synovial hyperplasia and progressive destruction of articular cartilage and bone, which seriously influences a patient's quality of life.Interleukin-25 belongs to the IL-17 cytokine family newly identified. IL-25 is widely produced between tissues, IL-25 is reported to play an anti-inflammatory role in autoimmune and inflammatory diseases through the downregulation of Th1 and Th17 cell responses[1]. However, the exact role of IL-25 in the pathogenesis of RA remains to be elucidated.
Objectives: Set up CIA model to evaluated IL-25 influence in RA disease. Discuss the molecular mechanism of IL-25 how to regulate IL-17A, ROR-γt and Th17.
Methods: ①male DBA/1 mice (n=12) were induced with immunized intradermally twice with type II chick collagen (2 mg/ml) emulsified in Complete Freund's adjuvant or Incomplete Freund's adjuvant containing by tail intravenous injection.CIA mouse model was constructed. CIA were then divided into two groups, for the use of PBS (n=6) and IL-25 (0.5μg, n=6) respectively, and follow-up daily. After 42 days, mice were sacrificed and collected articular tissues, proceed pathological staining and pathological score of arthritis. ②Male DBA/1 mice were immunized with CII to induce arthritis and consecutively received rmIL-25 (1 μg/mice) or PBS for 5 days beginning from day 1 after the second immunization with CII, and the incidence of arthritis was calculated. Spleen $CD4^+$ T cells were isolated from CIA mice using Mouse $CD4^+$ T Cell Isolation Kit. Cells were stimulated with plate-bound anti-CD3 (5 μg/ml) plus anti-CD28 (2 μg/ml) in the presence or absence of recombinant mouse (rm) IL-25 (100 ng/ml) for 24 h. In some cases, control IgG (10 μg/ml) were added to the cultures. The expression of IL-17A were examined using ELISA assay and ROR-γt mRNA in the cells were measured by real-time quantitative qPCR.
Results: In vivo studies indicated that, the RA incidence and symptoms of arthritis in IL-25-treated mice were significantly reduced compared with PBS controls. Histopathologic examination showed that the knee joints of IL-25-treated mice with CIA exhibited a significant reduction in synovial hyperplasia, cartilage damage and bone erosion compared with PBS controls. The serum levels of IL-17A in IL-25-treated mice were markedly reduced compared with those in WT mice. RT-qPCR also demonstrated that the transcription levels of IL-17A and ROR-γt were decreased in the Spleen of IL-25-treated mice.
Conclusion: Systemic injection of IL-25 can reduce the onset of arthritis and joint injury in CIA mice. IL-25 can inhibit Th17 cells of CIA mice, and its target is to regulate IL-17 cytokines and Expression of ROR-γt mRNA. CIA protection is mediated by the inhibition of Th17 by IL-25.

POS0425 METABOLIC ALTERATIONS IN ACTIVATED FIBROBLAST-LIKE SYNOVIOCYTES FROM NON-INFLAMED SUBJECTS - MIMICKING EARLY STAGE OF RHEUMATOID ARTHRITIS

Y. Zhang[1,2], A. Nguyen[1], A. Rudin[1], C. Maglio[1,2,3]. [1]*Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation research, Gothenburg, Sweden;* [2]*University of Gothenburg, Wallenberg Center for Molecular and Translational Medicine, Gothenburg, Sweden;* [3]*Region Västra Götaland, Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden*

Background: Proliferative cells, such as inflamed cells, depend on altered metabolic pathways to support their active proliferation. Synovial samples from patients with rheumatoid arthritis (RA) show reprogramming of different metabolic pathways such as glucose and glutamine metabolism [1]. However, it is unknown which metabolic pathways are altered in the early phases of RA pathogenesis, when non-inflamed fibroblast-like synoviocytes (FLS) are activated to a pro-inflammatory state. Our group has created an in-vitro cell model using FLS from subjects without inflammatory arthritis (non-inflamed FLS) after activation with adiponectin and tumour necrosis factor (TNF) to mimic the early stage of RA [2].
Objectives: We aim to determine if the stimulation of non-inflamed FLS upregulates the expression of key-enzymes involved in glucose and glutamine metabolism and how the inhibition of those enzymes affects FLS activation.
Methods: FLS (passage 6-8) were isolated from synovial tissues of patients without inflammatory arthritis or osteoarthritis who underwent diagnostic arthroscopy due to a previous injury. FLS were cultured in DMEM medium (high glucose and GlutaMAX) containing 10% FBS and stimulated by known FLS-activators, i.e. TNF, interleukin 1 beta (IL-1 β), or adiponectin. For the inhibition experiments, cells were pre-treated with 25 mM 2-DG or 300 nM CB-839 for 4 hours before stimulation. Expressions of the enzymes were measured by western blot in whole-cell lysates and IL-6 was measured using ELISA in cell culture supernatants at 24 hours after stimulation. Cell proliferation was determined using MTT assay after 48 hours of stimulation.
Results: First, we compared the expression of hexokinase 2 (HK2), glutaminase C (GAC), and PFKFB3 in non-inflamed FLS before and after activation with adiponectin, TNF, and IL-1β. Expression of HK2 and GAC were upregulated in adiponectin- and TNF-activated FLS compared to unstimulated FLS. PFKFB3 was not affected by any of the stimuli. IL-1β did not affect the expression of the analysed enzymes (Figure 1A-C). As IL-1β did not affect the expression of metabolic enzymes, we continued stimulation only with adiponectin and TNF. TNF but not adiponectin significantly enhanced the proliferation of FLS without inhibition (Figure 1D). However, FLS proliferation was significantly reduced by pre-treatment with 2-DG, a glycolysis inhibitor, in unstimulated as well as TNF- and adiponectin-stimulated cells. CB-839, a glutaminase inhibitor, did not affect the proliferation of FLS (Figure 1D). Both TNF and adiponectin significantly upregulated the production of IL-6 in FLS. Pre-treatment with 2-DG significantly reduced the production of IL-6. CB-839 pre-treatment significantly reduced the production of IL-6 only in unstimulated FLS (Figure 1E).

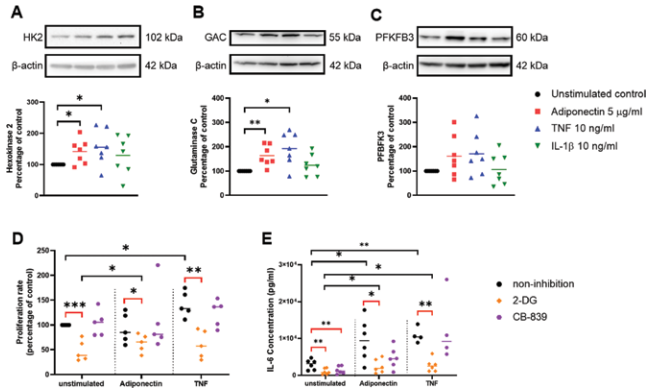

Figure 1. Metabolic alterations in non-inflamed FLS. Expression of hexokinase 2 (HK2; A), glutaminase C (GAC; B) and PFKFB3 (C) in non-inflamed FLS measured by western blot. Proliferation assay (MTT assay; D) and production of IL-6 (ELISA; E) was performed using cells treated with HK2 inhibitor 2-DG and glutaminase inhibitor CB-839. Statistical significance was determined as by one sample t test (A-C; n=7) or paired t test (D-E; n=4-6).

Conclusion: Our results show that the expression of key-enzymes regulating metabolic pathways can be enhanced by adiponectin and TNF in non-inflamed FLS. Moreover, we also show that inhibition of specific metabolic pathways can affect FLS activation differently depending on the cytokine stimulation. These results provide a deeper understanding of metabolic reprogramming in FLS in early RA.

POS0426 BRD3 REGULATES THE INFLAMMATORY AND STRESS RESPONSE IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

M. Maciukiewicz[1,2,3], L. Moser[3], M. Krosel[4], T. Seifritz[3], M. Tomsic[4], B. Maurer[1,2], O. Distler[3], C. Ospelt[3], K. Klein[1,2]. Background: Small molecule inhibitors targeting members of the bromodomain and extra-terminal (BET) protein family (BRD2, BRD3, BRD4) have anti-inflammatory properties in rheumatoid arthritis (RA). BET proteins are readers of acetylated histone side chains and activators of transcription. BRD3 is an understudied member of BET proteins.

Objectives: To analyse individual functions of BET proteins and mechanisms underlying BET inhibition in RA synovial fibroblasts (SF).
Methods: The expression of BRD2, BRD3, and BRD4 was silenced by lenti-viral transduction followed by TNF stimulation (10 ng/µl, 24h). Silencing was confirmed by Western blotting. Transcriptomes were determined by RNA-seq (Illumina NovaSeq 6000, n=3). Pathway enrichment analysis for KEGG and Reactome databases was conducted with significantly affected genes (± fold change > 1.5, FDR < 0.05). SF were treated with I-BET (1 µM) and TNF (10 ng/µl, 24h). Autophagy was evaluated by Western blotting using the conversion of LC3B as a marker (n=9). I-BET-induced global changes on post-translational histone modifications were analysed by mass spectrometry (Mod Spec, Active Motif; n=2; 120h protocol) and Western blotting (H3K27ac, H3K18ac, total acH3; n=7; 24h and 120h protocol). For this purpose, SF were stimulated with I-BET (1 µM) for 24h, and either co-stimulated with TNF (24h protocol), or washed with PBS, followed by a 24h stimulation with TNF 120h after the I-BET treatment (120h protocol).
Results: Silencing of BRD2 and BRD4 in SF was, in contrast to silencing of BRD3, associated with high levels of cell death, and therefore not analyzed further. We detected 257 and 324 differentially expressed genes (DEG) that were affected by BRD3 silencing in unstimulated and TNF-stimulated SF, respectively. 105 DEG overlapped between the two groups. DEG were enriched in inflammatory pathways such as "TNF signaling pathway", "rheumatoid arthritis", "Toll-like receptor cascades", "MAPK signaling pathway", "IL-17 signaling pathway" and "signaling by interleukins". Furthermore, pathway enrichment analysis suggested a role for BRD3 in different stress-associated pathways, including "DNA repair", "chaperone mediated autophagy", "cellular responses to stress", and "autophagy". In line with the pathway enrichment analysis, I-BET induced levels of LC3B-II in unstimulated (4.3 fold, p=0.07) and TNF-stimulated (2.9 fold, p=0.07) SF, indicating a role of BET proteins in the regulation of autophagy. To further study the mechanisms underlying I-BET-mediated suppression of gene expression, we analyzed potential effects of I-BET on histone modifications. Mod Spec analysis indicated that I-BET induced profound changes in chromatin modifications, with a global reduction of acetylation on different histone side chains. We confirmed some of these differences in independent samples. I-BET treatment reduced mean TNF-induced levels of total acH3 by 25.2% (120h; p=0.0303), of H3K18ac by 35.3% (24h; p=0.0288) and by 29.3% (120h; p=0.0373) and of H3K27ac by 41.7% (120h; p=0.0587).
Conclusion: BRD3 acts as an upstream regulatory factor that integrates the response to inflammatory stimuli and stress conditions in SF. Our data suggest that BET inhibitors do not only prevent the reading of acetylated histone side chains, but also directly affect the chromatin structure, in particular by downregulating global levels of histone acetylation.

POS0427 PRE-INFLAMMATORY MESENCHYMAL (PRIME) CELLS IDENTIFIED BY MASS CYTOMETRY IN THE PERIPHERAL BLOOD OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

E. K. Vetsika[1], M. Chatzopoulos[2], G. E. Fragoulis[2], M. Tektonidou[2], G. Kollias[1,3], P. Sfikakis[1,2]. *[1]Centre of New Biotechnologies and Precision Medicine, National and Kapodistrian University of Athens Medical School, Athens, Greece; [2]First Department of Propaedeutic and Internal Medicine & Joint Academic Rheumatology Program, "Laiko" General Hospital, National and Kapodistrian University of Athens Medical School, Athens, Greece; [3]National and Kapodistrian University of Athens Medical School, Department of Physiology, Athens, Greece*

Background: Experimental evidence suggests that synovial fibroblasts (SFs) may play a central pathogenetic role in chronic inflammatory arthritis in humans. RNA of the mesenchymal marker cadherin-11 characterising SFs is overexpressed in the peripheral blood of rheumatoid arthritis (RA) patients compared to healthy donors and correlates with established polyarthritis [1]. Recently, Orange et al. using RNA sequencing and flow cytometry have identified in the peripheral blood of RA patients PRIME (PRe-Inflammatory MEsenchymal) cells, considered as the precursors to inflammatory sublining SFs, that could be used as predictors of RA flares [2].
Objectives: To test the hypothesis that circulating PRIME cells can be identified by mass cytometry in patients with active RA, as well as in patients with active psoriatic arthritis (PsA).
Methods: The expression of markers suggestive of PRIME cells, namely, cadherin-11 and/or podoplanin (both expressed on SFs), and/or CD90 (Thy-1, expressed on sublining SFs), and/or Notch-3 (expressed on endothelial cells and sublining SFs), and/or CD34 (expressed on stem cells and SFs) was evident in all 10 RA and 5 PsA-derived blood samples. Circulating PRIME cell levels were elevated in patients (0.019%±0.003%) than healthy donors (0.008%±0.002%, p=0.004). The increased PRIME cell levels were more pronounced in PsA (0.023%±0.007%, p=0.003) than RA (0.017%±0.003%, p=0.03), when compared to healthy donors. PRIME cells were also present in 2 RA synovial fluid samples, being at three-fold higher levels than in the paired blood samples. Interestingly, a fraction of circulating PRIME cells exhibited expression of HLA-DR, suggestive of antigen-presenting capacity.
Results: The expression of markers suggestive of PRIME cells, namely, cadherin-11 and/or podoplanin (both expressed on SFs), and/or CD90 (Thy-1, expressed on sublining SFs), and/or Notch-3 (expressed on endothelial cells and sublining SFs), and/or CD34 (expressed on stem cells and SFs) was evident in all 10 RA and 5 PsA-derived blood samples. Circulating PRIME cell levels were elevated in patients (0.019%±0.003%) than healthy donors (0.008%±0.002%, p=0.004). The increased PRIME cell levels were more pronounced in PsA (0.023%±0.007%, p=0.003) than RA (0.017%±0.003%, p=0.03), when compared to healthy donors. PRIME cells were also present in 2 RA synovial fluid samples, being at three-fold higher levels than in the paired blood samples. Interestingly, a fraction of circulating PRIME cells exhibited expression of HLA-DR, suggestive of antigen-presenting capacity.
Conclusion: Rare circulating mesenchymal cells with antigen-presenting properties may be of pathogenetic importance in patients with RA and PsA. Whether their measurement is clinically relevant, as well their function during chronic inflammatory arthritis, merits further studies.

POS0428 PATHOGENETIC ROLE OF MICROPARTICLES IN RHEUMATOID ARTHRITIS

F. M. Ucci[1], C. Barbati[1], T. Colasanti[1], E. Balbinot[1], M. Speziali[1], A. I. Celia[1], C. Ciancarella[1], G. Tripdi[1], G. Buonocore[1], F. Ceccarelli[1], F. R. Spinelli[1], G. Riitano[2], S. Recalchi[2], A. Longo[2], V. Manganelli[2], M. Sorice[2], F. Conti[1], C. Alessandri[1]. *[1]Sapienza University of Rome, Department of Clinical internal, anesthesiologic and cardiovascular sciences, Rome, Italy; [2]Sapienza University of Rome, Department of Clinical e molecular medicine, Rome, Italy*

Background: Microparticles (MPs) are fragments of surface membranes of activated eukaryotic cells. They are characterized by different dimensions (from 0.1 to 1µm) and expression of surface antigens, depending on their origin. MPs are important mediators of cell-to-cell communication as they can be internalized in a dose-dependent manner by macrophages, endothelial cells and other cell types, influencing both functional and phenotypic characteristics of the target cells. Even if MPs formation is enhanced by cell activation or apoptosis, constitutive exocytosis is a continuous ongoing process in vivo for many cells, and MPs originating from different cells can be always found in the plasma. In various autoimmune diseases, it has been found an increased number of MPs derived from activated platelets, leukocytes, vascular endothelium cells and other cell types. In Rheumatoid Arthritis (RA) an excessive production of MPs may predispose to autoimmune manifestations. Moreover, it has been speculated that MPs can stimulate the production, secretion, and transport of inflammatory factors in RA.

Objectives: We investigated the presence on the surface of RA-MPs of antigens derived from post-translationally modified proteins (citrullinated peptides and carbamylated peptides). We assumed that these specific antigens carried on the surface of RA-MPs could participate in RA pathogenetic process.
Methods: We enrolled 20 RA patients naïve for biological therapy fulfilling the 2010 American College of Rheumatology RA criteria and 20 healthy controls (HC), matched for age and sex. For each patient, laboratory and clinical data were recorded and clinical indexes were measured (TJ, SJ, CDAI, VAS pain, CDAI, SDAI, DAS28). A fasting blood sample, obtained from RA patients and HC, was centrifugated in order to obtain platelet-poor plasma (PPP), rich in MPs. Thereafter, MPs in RA patients and HC were measured using nanoparticle tracking analysis. Later on, MPs were incubated with unconjugated anti-citrullinated/carbamylated proteins antibodies and processed by flow cytometry and western blot to evaluate the surface expression of citrullinated/carbamylated antigens.
Results: Nanoparticle tracking analysis revealed a significant increase of number of MPs in RA compared to HC. Moreover, densitometric analysis showed a significative higher expression of citrullinated antigens on MPs' surface in RA than controls ($p < 0.0001$), while no substantial difference was found in the expression of carbamylated antigens. The data obtained were confirmed with the western blot which identified the cytoskeletal protein vimentin, the cytoplasmatic glycolytic enzyme alpha-enolase1 and type II collagen as the main citrullinated and carbamylated proteins carried by MPs. Finally, a relevant correlation between the expression of citrullinated and carbamylated antigens and disease activity was found (Figure 1).

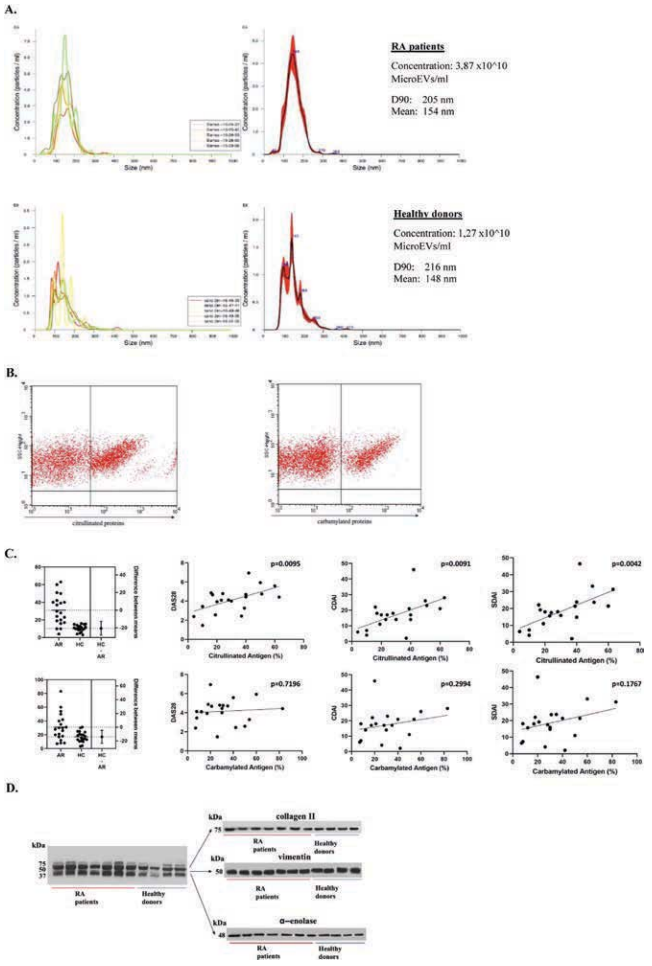

Figure 1. The figure shows: (A) concentration of MPs in RA patients and HC (nanoparticle tracking analysis); (B) expression of citrullinated and carbamylated antigens on MPs' surface in RA patients (flow cytometry analysis); (C) expression of citrullinated antigens in RA patients and HC and correlation between expression of citrullinated and carbamylated antigens on MPs' surface in RA patients and DAS28, CDAI, SDAI; (D) cytoskeletal protein vimentin, cytoplasmatic glycolytic enzyme alpha-enolase1 and collagen type II (western blot).

Conclusion: The results of this study confirm an important role of MPs in the pathogenesis of RA not only as markers of disease activity but also as possible inducers of autoimmunity.

POS0429 ACTIVATED RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS ALTER OSTEOCLAST DIFFERENTIATION AND ACTIVITY

J. Fuchs[1], M. Arnold[1], K. Frommer[1], I. Aykara[1], T. Laibe[1], S. Rehart[2], U. Müller-Ladner[1], E. Neumann[1]. [1]*Justus-Liebig-University Campus Kerckhoff, Department of Rheumatology and Clinical Immunology, Bad Nauheim, Giessen, Germany;* [2]*Agaplesion Markus Hospital, Department of Orthopaedics and Trauma Surgery, Frankfurt, Germany*

Background: In rheumatoid arthritis (RA), osteoclasts are one of the most important mediators of bone erosion. In addition, RA synovial fibroblasts (RASF) have a major influence on joint erosion in RA. They affect osteoclast differentiation e.g. by increased RANKL production or secretion of other pro-osteoclastogenic factors such as IL-6. In addition to the pro-osteoclastogenic effect of soluble factors such as RANKL and IL-1, visfatin inhibits osteoclast differentiation. Furthermore, visfatin increases the secretion of pro-inflammatory factors by RASF, such as IL-6 or matrix degrading enzymes.
Objectives: In this study, the effect of RASF with/without activation by visfatin and IL-1 on osteoclastogenesis was evaluated.
Methods: Blood from healthy donors and RA patients was used for PBMC isolation. RANKL, TGF-β and hM-CSF were added to induce osteoclast differentiation. RASF-conditioned media (CM) were prepared from confluent RASF cultured for 48h. Differentiating PBMCs in monoculture were compared to PBMC cultured with CM from RASF (CM: 10%, 20%, 30%) as well as in direct co-culture with RASF with/without stimulation with IL-1 (0.05ng/ml), visfatin (25ng/ml). After two weeks in culture, cells were stained using TRAP staining. 3-5 images per well were used for quantification dependent on the variability of the wells. IL-6 was measured by ELISA in supernatants collected at day 14.
Results: IL-6 production increased by IL-1 (e.g. co-culture: 2,8-fold) and visfatin (CM-visfatin: 10%=4,3-fold, 20%=5,4-fold, 30%=4,2-fold; co-culture: 9,5-fold) compared to unstimulated control in all settings. In addition, IL-6 was increased with the addition of CM compared to unstimulated controls (healthy donors CM 30%: unstimulated p=0.0342, IL-1 p=0.0133, visfatin p=0,0133; RA: unstimulated p=0.0133, IL-1 p=0.0342, visfatin p=0.0133, n=3 each). Of note, baseline IL-6 concentrations were higher in PBMC from RA patients compared to healthy donors. Co-culture showed an additional increase in IL-6 levels in all settings (e.g. monoculture: IL-1 4.71±5.75pg/ml, visfatin 141.09±182.79pg/ml; co-culture: IL-1 7241±10398pg/ml, visfatin 24535±16994pg/ml;). During osteoclast differentiation, addition of CM showed similar osteoclastogenesis with similar proportion of osteoclasts with 2 and 3-5 vs. higher numbers of nuclei per cell compared to control. In coculture with RASF osteoclasts showed a stronger TRAP signal compared to monoculture especially for unstimulated and IL-1 stimulated co-cultures.
Conclusion: Both, in monoculture with CM and in coculture, IL-6 levels were increased compared to control, whereas in RA patients the IL-6 levels were higher compared to healthy donors. The CM containing secreted factors of RASF did not have a prominent influence on osteoclastogenesis. However, the presence of RASF increased the TRAP signal showing an increased activity of differentiated osteoclasts especially in unstimulated and IL-1 stimulated co-cultures but not with addition of visfatin.

Toxicology Lab, Milano, Italy; [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Neurosciences and Mental Health, Milano, Italy; [6]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milano, Italy

Background: Accumulating evidence suggests that poor mental health is one of the most common comorbidities of both rheumatoid arthritis (RA) and osteoarthritis (OA) [1]. Even if underpinning RA and OA are different genetic, structural, mechanical, and immunologic pathways involved in their pathogenesis, poor mental health, and joint involvement are intertwined and negatively affect their mutual course by contributing to global disability. Thus, new insights into mechanisms that link these disorders are needed to identify new actionable biomarkers to drive more personalized therapeutic strategies. Amidst potential mediators, extracellular vesicles (EVs) play a central role in terms of communication between cells, they cross the blood-brain barrier and based on their cargos can affect the recipient cell function [2].
Objectives: To isolate EVs from synovial fluid (SF) in RA and OA patients and to evaluate if and how these EVs can alter in vitro synaptic transmission of murine hippocampal neurons.
Methods: In this cross-sectional pilot study, consecutive adult RA and primary OA who were referred to the Rheumatology Unit for aspiration of joint effusion were enrolled. Demographic and clinical variables and mental health rating scales were collected. Discarded SF were collected and EVs were isolated and analyzed by Malvern NanoSight NS300 system to obtain information on their number and size. Afterwards, DIV14 cultured wild-type hippocampal neurons were exposed for two hours to OA- and RA-EVs at low and high concentration EVs. Thus, miniature excitatory and inhibitory postsynaptic currents (mEPSCs and mIPSCs), which reflects glutamatergic and GABA-ergic activity respectively, were examined by exploiting patch-clamp recordings in the whole-cell configuration. Frequency and amplitude were analyzed to evaluate potential changes at the presynaptic or postsynaptic compartment. Mann Whitney test was used to compare two different samples.
Results: Eight RA patients (7 female, mean age 57 yrs), and 5 primary OA (4 female, mean age 60 yrs) were recruited for SF aspiration. The mean VAS pain was 7.25 in RA and 6.5 in OA. No statistically significant differences were found between the two groups in mean rating scale scores although patients affected by RA had more severe depressive symptoms (Montgomery Asberg Depression Rating Scale -MADRS- means scores: 16.57) with respect OA group (MADRS mean scores: 10). The Nanoparticle tracking analysis showed that RA-EVs were significantly more in number compared to OA-EVs (Figure 1 A), mimicking more inflammation, while no significant difference in size was observed. Analysis of miniature events revealed the occurrence of two different changes. High concentration of OA-EVs has led to an increased amplitude of excitatory events, meaning an increased susceptibility of neurons to glutamate in the post-synaptic compartment (Figure 1 B). Whereas low concentration of RA-EVs has led to a decreased frequency of inhibitory events, which reflects a reduced function of GABA-ergic synapse in the pre-synaptic compartment (Figure 1 C).

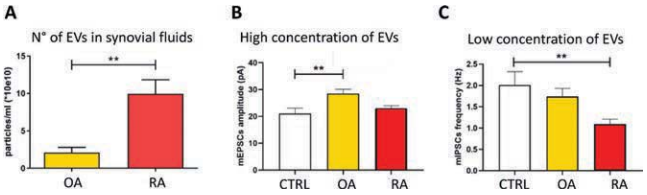

Figure 1.

Conclusion: Our results suggest that SF-derived EVs from OA and RA patients lead to different specific changes of neurotransmission, with different concentration needed to alter neuronal spontaneous activity in post-synaptic and pre-synaptic compartment, respectively. EVs may provide insight into the pathogenesis of joint-brain communication in RA and OA, unraveling specific pathways thus allowing targeted therapies for neuropsychiatric involvement.

POS0431 PDGF-BB, TNF-α, AND LT-β REGULATE FOLLICULAR DENDRITIC CELL DEVELOPMENT IN THE RHEUMATOID SYNOVIUM

M. Elshikh[1], R. El Sayed[1], N. Aly[1], E. Prediletto[1], R. Hands[1], L. Fossati-Jimack[1], M. Bombardieri[1], M. Lewis[1], C. Pitzalis[1]. *[1]Experimental Medicine and Rheumatology, William Harvey Research Institute - Barts and The London School of Medicine and Dentistry - Queen Mary University of London, London, United Kingdom*

Background: Follicular dendritic cells (FDCs) fundamentally contribute to the formation of synovial ectopic lymphoid-like structures in rheumatoid arthritis (RA) which is associated with poor clinical prognosis. Despite this critical role in RA pathogenesis, FDC development in the RA synovium has not been fully elucidated.
Objectives: To investigate the role of TNF-α/LT-β and PDGF-BB in the ontogeny of RA synovial FDCs and the differentiation of lymphoid and fibroid RA synovitis.
Methods: RA Synovial tissues were obtained from the Pathobiology of Early Arthritis Cohort (PEAC) of the Centre for Experimental Medicine and Rheumatology of Queen Mary University of London. RNA-Seq analysis and confocal imaging of early and late FDC differentiation markers were carried out and the stromal cell subsets were sorted by flow cytometry. The stromal cell subsets were treated with TNF-α/LT-β and/or PDGF-BB and the expression of FDC differentiation genes was assessed by qPCR. Germinal centre reactions were setup *in vitro* using TNF-α/LT-β activated stromal cells, and antibody production by naive human B cells stimulated with anti IgM was measured by ELISA.
Results: Our results indicate that PDGF-BB induces the FDC marker CNA.42$^+$ on NG2$^+$/αSMA$^+$ type-1 pericytes, stimulates THY-1 and αSMA gene expression, and strongly correlates with fibroid synovitis using RNA-Seq analysis. On the other hand, TNF-α/LT-β downregulate PDGFR-β, THY-1, αSMA; induce CD21, FcγRIIB expression, and significantly correlate with lymphoid synovial pathotype. Ultrastructural examination of antigen trapping on TNF-α/LT-β-activated RA synovial fibroblasts (RASFs) showed periodically retained surface antigens and these fibroblasts were able to induce T cell independent B cell activation in *in vitro* germinal centre reactions. The transition from an early PDGFR-β$^+$ pre FDCs to a late TNF-α/LT-β-responsive mature FDCs is promoted by PDGF-BB. PDGF-BB induces TNF-αR expression in RASFs and facilitates B cell recruitment via pericyte CXCL13 expression and stromal cell migration.
Conclusion: To the best of our knowledge, this is the first report describing the crosstalks between PDGF-BB and TNF-α/LT-β in FDC development in the rheumatoid synovium and its association with the evolution of lymphoid and fibroid synovitis. Selective targeting of this interplay could inhibit FDC differentiation and potentially ameliorate RA in clinically severe and drug-resistant patients.
Disclosure of Interests: None declared.

POS0432 MDSCS IN THE INFLAMMATORY JOINT OF SKG MICE HAVE BOTH T CELL SUPPRESSIVE ABILITY AND OSTEOCLAST DIFFERENTIATION POTENTIAL

Y. Fujikawa[1], S. Sendo[2], T. Nagamoto[3], Y. Yamamoto[3], H. Yamada[3], T. Okano[3], K. Nishimura[3], Y. Ueda[3], J. Saegusa[3]. *[1]Kobe University, Rheumatology and clinical Immunology, Chuo-Ku, Kobe, Hyogo, Japan; [2]University of California, San Diego, Department of Medicine, San Diego, California, United States of America; [1]Kobe University, Rheumatology and clinical Immunology, Chuo-Ku, Kobe, Hyogo, Japan*

Background: Myeloid-derived suppressor cells (MDSCs) are heterogeneous immature myeloid cells with suppressive functions (1). It is known that MDSCs are expanded in inflammatory sites after migrating from bone marrow (BM) or spleen. Rheumatoid arthritis (RA) is an autoimmune disease characterized as polyarthritis. Although previous reports indicate that MDSCs are increased in BM

and spleen of arthritis model mice, detailed analysis of MDSCs in inflammatory joints is limited.

Objectives: The purpose of this study is to characterize the MDSCs in the joints of autoimmune arthritis.

Methods: We isolated $CD11b^{+}Gr1^{+}$ cells as MDSCs from joints (Jo-MDSCs), bone marrow (BM-MDSCs) and spleen (Sp-MDSCs) of arthritis-induced SKG mice, and investigated differential expressed genes (DEGs) among MDSCs from three tissues by microarray expression analysis. Furthermore, we analyzed the suppressive function of each MDSCs by investigating the effect of them on T cell -proliferation and the osteoclast differentiation of each MDSCs stimulated by M-CSF and RANKL.

Results: Microarray analysis revealed that Jo-MDSCs highly expressed immunosuppressive DEGs (*Pdl1, Arg1, Egr2* and *Egr3*) compared to BM MDSCs or Sp MDSCs. In addition, Jo-MDCSs highly expressed NF-κB non-canonical pathway DEGs (*Nfkb2* and *Relb*), which are related to osteoclast differentiation. BM-MDSCs differentiated into osteoclasts but didn't suppress T cell-proliferation and Sp-MDSCs suppressed T cell-proliferation but didn't differentiate into osteoclasts. On the other hand, Jo-MDSCs was found to have both functions: T cell suppression and osteoclast differentiation potential.

Conclusion: Jo-MDSCs have a strong inhibitory effect on T cell proliferation and have the ability osteoclast differentiation potential.

POS0433 POTENTIAL THERAPEUTIC EFFECTS OF NARINGENIN ON RA THROUGH SUPPRESSING P2X7R/NLRP3 MEDIATED PYROPTOSIS BY TARGETING ESR

H. Wang[1], Y. Zhang[1]. [1]*Qilu Hospital, Department of Clinical Laboratory, Jinan, China*

Background: Naringenin (NAR), a partial agonist on estrogen receptor, is naturally occurring flavonoids in grapes and grapefruits. We previously reported that NAR in patients with Rheumatoid arthritis (RA) have changed significantly [1]. However, the role and mechanism of action of NAR in RA remain unclear.

Objectives: This study aimed to determine the roles and mechanisms of NAR on RA and provides a basis for NAR to become a potential therapeutic agent for RA.

Methods: This study employed bovine type II collagen-induced arthritis (CIA) rats, in vitro mononuclear cells (MNCs) as models to explore the potential therapeutic effects and mechanisms of NAR on RA.

Results: Rats following NAR injections showed significantly alleviated CIA, while the proportion of NK cells decreased. After CIA rats were injected with both NAR and NK cells, the rats remained joint inflammation. NAR decreased the proportion of NK cells in RA MNCs. However, NAR did not directly affect the NK cell activation and their cytokine production. NAR suppress pyroptosis in THP-1 cells (Figure 1). The NAR activate the ESR1 in macrophage. NAR significantly increased histone deacetylase 1 gene (HDAC1) activation in macrophage. NAR significantly increased P2X7R expression and decreased NLRP3 expression in macrophage.

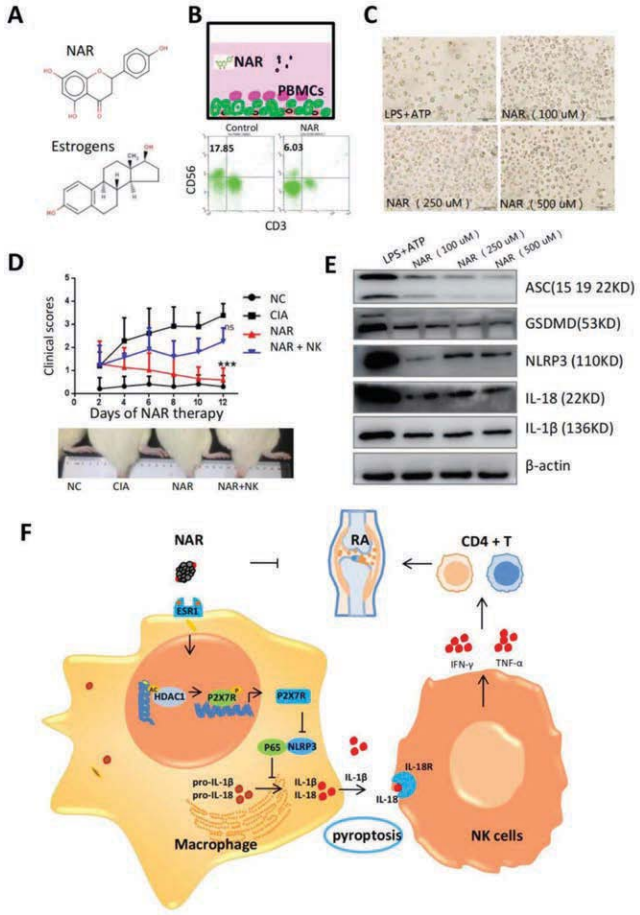

Figure 1. Effect of NAR on RA in vitro and in vivo. A The chemical structures of NAR and Estrogen. **B** Flow cytometry assay of NK cells in MNCs with treatment of NAR. **C** The morphology of THP-1 cells with treatment of NAR. **D** Joint inflammation of CIA rats with treatment of NAR and NK cells. **E** The expression level of pyroptosis -related protein was tested by western blot (WB). **F** Pattern diagram explaining therapy mechanism of NAR to RA.

Conclusion: NAR has therapeutic effects for CIA and RA through suppressing P2X7R/NLRP3 mediated pyroptosis by targeting ESR.

POS0434 A NOVEL TARGET FOR TREATMENT OF INFLAMMATORY JOINT DISEASES

S. Lindquist[1,2], H. Persson[3], A. Roos[3], L. Lundberg[2], O. Hernell[1,2]. [1]*Umeå University, Clinical Sciences, Pediatrics, Umeå, Sweden;* [2]*Lipum AB, R&D, Umeå, Sweden;* [3]*SciLifeLab, Drug Discovery and Development Platform, Uppsala, Sweden*

Background: A significant number of patients with inflammatory joint disorders do not respond or experience a waning effect to currently available pharmaceuticals, which emphasizes a high medical need for new efficacious drugs operating through novel targets and modes of action. One unexplored novel target is Bile Salt-Stimulated Lipase (BSSL). We have shown that patients with rheumatoid arthritis (RA), psoriasis arthritis (PsA), and juvenile idiopathic arthritis (JIA) have increased BSSL plasma levels compared to healthy controls, and that these levels correlate with disease activity scores. Moreover, conventional BSSL knockout mice are protected from developing disease in several recognized in vivo arthritis models and antibodies targeting BSSL prevent or mitigate arthritis in rodent models[1].

We have further shown that BSSL is secreted from activated granulocytes, binds to monocytes and stimulates their migration in vitro. With that knowledge, we developed a humanized anti-BSSL antibody (SOL-116) that blocks BSSL from binding to monocytes and we are now evaluating SOL-116 as candidate drug for treatment of chronic inflammatory joint diseases, including RA, PsA and JIA in man.

Objectives: The aim of the present study was to characterize SOL-116's biological activity in vitro and verify the therapeutic efficacy in the pristane induced arthritis (PIA) rat model.

Methods: The affinity of SOL-116 to human, mouse and rat BSSL was measured by surface plasmon resonance biosensor technology. The epitope on human BSSL was mapped by hydrogen deuterium exchange mass spectrometry (HDX-MS) and confirmed by crystallization of SOL-116 Fab-fragments with human BSSL. For efficacy evaluation, arthritis was induced in DA rats by administration of pristane. SOL-116 at three different doses (10, 30 and 90 mg/kg) or vehicle control were administered subcutaneously on day 5, 10 and 15 after disease induction. Disease activity was evaluated daily from day 7 in a blinded fashion using a macroscopic scoring system of the four limbs. To gain knowledge about the mechanism of action, the effect of SOL-116 on BSSL induced cell migration was evaluated using a transwell migration assay.

Results: SOL-116 binds to human, mouse, and rat BSSL, although a single amino acid deviation in the BSSL epitope results in approximately 80-fold lower affinity to rodent compared to human BSSL protein. In the efficacy validation study, treatment with highest dose SOL-116 (90 mg/kg) significantly mitigated disease severity in the PIA rats (Figure 1A). The relatively high doses of SOL-116 were chosen to compensate the low affinity for rat BSSL. A decrease in disease severity was also seen with SOL-116 at 30 mg/kg and 10 mg/kg, indicating a dose response, albeit not statistically significant. The plasma concentration of SOL-116 at day 19 correlated significantly to the arthritis score (Figure 1B). Mechanistic studies show that BSSL stimulates migration of CD14+ monocytes, and that SOL-116 prevents this effect in a dose dependent manner.

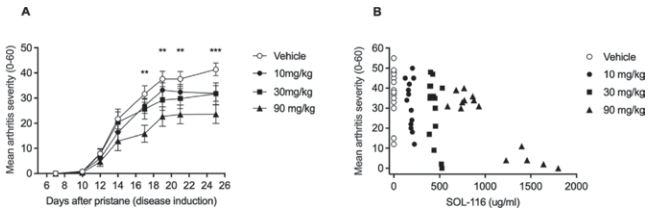

Figure 1. Arthritis development and SOL-116 exposure in rats following pristane injection. (**A**) Animals treated with SOL-116 (90 mg/kg) show significantly lower disease severity compared to vehicle treated animals. Results are presented as mean ± SEM. (**B**) Plasma concentration of SOL-116 at day 19 in animals treated with 90 mg/kg correlates to disease severity.

Conclusion: The present study verifies that BSSL plays an important role in inflammation and that SOL-116 is a promising biologic drug candidate for novel treatment of chronic inflammatory joint diseases.

POS0435

IMPACT OF COMBINATION THERAPY WITH CSDMARDS ON THE EFFECTIVENESS OF BIOLOGIC OR TARGETED SYNTHETIC DMARDS IN A REAL-LIFE SETTING: RESULTS FROM THE SWISS RHEUMATOID ARTHRITIS REGISTER (SCQM-RA)

B. Gilbert[1], D. Mongin[1], E. Nham[1], D. Courvoisier[1], K. Lauper[1,2], C. Laedermann[3], R. Müller[4], A. Finckh[1]. *[1]Geneva University Hospitals, Division of Rheumatology, Geneva, Switzerland; [2]Centre for Musculoskeletal Research University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [3]Eli Lilly, (Suisse) SA, Vernier, Switzerland; [4]Kantonsspital, Division of Rheumatology, Aarau, Switzerland*

Background: Management guidelines of RA suggest to administer biological or targeted synthetic DMARD (b/tsDMARD) in combination with conventional synthetic DMARD (csDMARD). Limited data exists about the impact of such csDMARD combination therapy (co-therapy) in real life settings, in particular for baricitinib use compared to other types of b/tsDMARD.

Objectives: To assess the impact of concomitant csDMARD prescription on b/tsDMARD maintenance, in a real-world setting.

Methods: This is a nested cohort study within the Swiss registry of RA patients (Swiss Clinical Quality Management (SCQM-RA)), of treatment courses with bDMARDs or baricitinib (BARI) initiated between 2017-09-01 and 2020-06-01, with at least one follow-up visit. We compared the time-to-drug-discontinuation (drug maintenance), as a measure of drug effectiveness of b/tsDMARDs, with or without csDMARD co-therapy. Our exposure of interest was the impact of csDMARD co-therapy compared to monotherapy in 3 categories of b/tsDMARDs: baricitinib (BARI), TNFi inhibitors (TNFi) and other modes of action bDMARDs (OMA). Co-therapy was defined as receiving at least one csDMARD during at least 40% of the b/tsDMARD treatment courses (TC) duration. Baseline characteristics were compared using t-tests or χ^2. Survival Kaplan-Meier curves, with Log-rank test, were used to assess time-to-discontinuation. Cox models were applied to obtain adjusted hazard ratios (HR) using age, BMI, corticosteroid treatment, CDAI score, disease duration, smoking, line of therapy, seropositivity, gender as covariates. Missing baseline CDAI values were imputed using linear model with quadratic regression time.

Results: 1065 TC were included (273 BARI, 319 OMA, 473 TNFi), about half of which were initiated with csDMARD co-therapy (Table 1). In the co-therapy groups, csDMARD were taken on average 98% of the TC duration. Methotrexate was the most prescribed csDMARD (Table 1). Even after adjustment, we found no difference in drug maintenance with and without concomitant csDMARD in the BARI group (crude p = 0.67; HR co-therapy 2.17, 95% CI [0.61;7.77], p = 0.16) and in the TNFi group (crude p = 0.13; HR co-therapy 1.24, 95% CI [0.56;2.74], p = 0.60). Adjusted drug maintenance with or without csDMARD was also similar in the OMA group, despite non-adjusted p-value in favor of monotherapy (Figure 1) (crude p = 0.007; HR co-therapy 0.66, 95% CI [0.25;1.80], p = 0.39).

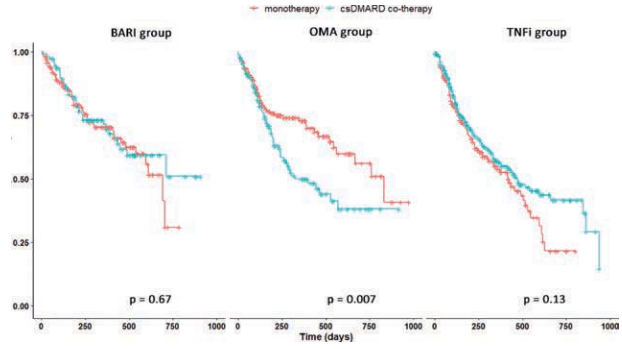

Figure 1. Drug maintenance of monotherapy vs csDMARD co-therapy (Non-adjusted Kaplan-Meier).

Conclusion: Our data suggest that drug maintenance of BARI, OMA and TNFi, were not significantly modified by concomitant csDMARD therapy.

EFFECT OF DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS ON LUNG MICROENVIRONMENT IN RHEUMATOID ARTHRITIS-ASSOCIATED LUNG DISEASE ANIMAL MODELS

S. H. Chang[1], J. S. Lee[2], J. J. Chae[3], J. Y. Choe[4], E. Y. Lee[5].
[1]Soonchunhyang University College of Medicine, Department of Internal Medicine, Division of Rheumatology, Cheonan, Korea, Rep. of (South Korea); [2]Korea Advanced Institute of Science and Technology, KAIST, Graduate school of Medical Science and Engineering, Daejeon, Korea, Rep. of (South Korea); [3]GENINUS Inc.,., Seoul, Korea, Rep. of (South Korea); [4]Catholic University of Daegu College of Medicine, Department of Internal Medicine, Division of Rheumatology, Daegu, Korea, Rep. of (South Korea); [5]Seoul National University College of Medicine, Department of Internal Medicine, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is one of the pivotal extrapulmonary conditions. However, the pathophysiology of RA-ILD, including the effect of disease-modifying anti-rheumatoid drugs (DMARDs) is largely unknown.
Objectives: To study the effect of methotrexate and TNFα inhibitor on lung microenvironment of SKG mice using single-nucleus RNA sequencing.
Methods: At age eight to ten weeks, male SKG mice received a single intraperitoneal zymosan A (ZyA) injection to induce arthritis and pneumonitis. We gave them twice-weekly intraperitoneal injections of PBS, methotrexate (7.5 mg/kg; MilliporeSigma), or TNFα inhibitor (100 μg/kg; R&D Systems, Inc., Minneapolis, MN, USA). Nuclei were prepared from frozen lung tissue under ribonuclease-free conditions by a method adapted from an existing protocol.
Results: Macroscopically, pneumonitis was most evident in SKG mice with ZyA and methotrexate treatment; multiple inflammatory cell aggregations were observed. In mice with ZyA and TNFα inhibitor, there were a few perivascular inflammatory cell aggregations as in the mice with ZyA and PBS, compared with the mice without ZyA. A total of 59,860 nuclei were obtained from sixteen mice, four mice from each of the four groups. We classified each cell type using previous reports on the single-nucleus cells of mouse lungs. The most frequently observed cell was the type 2 alveolar (AT2) cell among all four groups. Alveolar epithelial cells were further subclustered into six clusters (Figure 1). Cluster 2 highly expressed type 1 alveolar (AT1) cell marker genes. In mice without ZyA, cluster 0 predominated relative to cluster 1. This proportion was inverted in mice with the ZyA injection, where cluster 1 predominated. TNFα inhibitor treatment reversed the proportion, with cluster 0 predominating in this group. On the other hand, methotrexate treatment further accentuated the predominance of cluster 1 over cluster 0. Interestingly, a distinct cluster 3 was observed after methotrexate treatment. This distinctive alveolar epithelial cell cluster (cluster 3) showed IL-1, TNF, IFNα, and IFNγ perturbation-response signatures using Library of Integrated Network-Based Cellular Signatures (LINCS) 1000 ligand perturbation analysis. In addition, enrichment analysis revealed that cluster 3, as well as cluster 2 (i.e., AT1 cells) significantly enriched genes of BMI1 knockout mice that fail to self-renew their lung cells after damage.
Conclusion: The current study shows that methotrexate exacerbates lung inflammation via attenuation of the regenerative potential of AT2 cells.

CIRC_ 0003972 STUDY ON FIBROBLAST LIKE SYNOVIAL CELLS IN RHEUMATOID ARTHRITIS THROUGH IMMUNE REGULATION

P. Liu[1], T. Zhang[1], Y. Yu[1]. *[1]The First Affiliated Hospital of Xi'an Medical University, Department of Rheumatology and Immunology, XI'AN, China*

Background: Rheumatoid arthritis (RA) is a common chronic autoimmune disease involving multiple joint symmetry. The main pathological changes are fibroblast like synovial (FLS) cell proliferation and bone destruction. Circular RNA (circrna) is a special type of noncoding RNA formed by reverse splicing of linear RNA, which has high stability in organisms. Research shows that circ_ 0003972 is a circrna found to be significantly up-regulated in RA patients in recent years, and its level is significantly positively correlated with DAS28 score and patients with joint tenderness (Wen et al, 2020b)[1]. However, The role of CIRC_0003972 in the pathological progression of RA synovium has not been confirmed. Our research aims to reveal Role of Circ_0003972.
Objectives: Circular RNAs (circrnas) have been shown to play an important role in the progression of RA. The purpose of this study is to explore Circ_ 0003972 Role and mechanism of in the progression of RA.
Methods: The gene expression was determined by real-time quantitative PCR. The proliferation and apoptosis of human RA fibroblast like synovial (fls-ra) cells were measured by cell counting kit 8, edu staining and flow cytometry. Western blot analysis was performed to measure protein expression, and ELISA was used to check

the concentration of inflammatory factors. Double luciferase reporter gene detection and rip detection confirmed mir-654-5p and Interaction between Circ_0003972.
Results: Circ_0003972 is expressed in RA patients and fls-ra cells. Circ_ 0003972 knockdown inhibits proliferation and inflammation and promotes TNF-α Flra-induced apoptosis. Mir-654-5p is down regulated in RA patients and fls-RA cells, and it can be expressed by Circ_ 0003972 absorption. Mir-654-5p inhibitor reversed Circ_0003972 silencing on TNF-α Effects of induced hfls-RA on cell proliferation, inflammation and apoptosis.
Conclusion: Circ_0003972 may promote the proliferation and inflammation of FLS-RA cells and accelerate the pathological progress of RA by regulating mir-654-5p.

POS0438 IDENTIFICATION OF ANTI-CYTOKINE AUTOANTIBODIES WITH POTENTIAL TO PREDICT FLARE IN RHEUMATOID ARTHRITIS PATIENTS UNDERGOING BIOLOGICAL THERAPIES: A DISCOVERY STUDY

L. Lourido[1], P. Quaranta[1], R. Paz González[1], V. Calamia[1], J. D. D. Cañete[2], B. Fernandez[3], I. González-Álvaro[4], A. Gonzalez[5], J. L. Pablos[6,7], F. J. Blanco[1,8], C. Ruiz-Romero[1,9]. *[1]INIBIC-CHUAC, Grupo de Investigación de Reumatología (GIR), Proteomics Unit, A Coruña, Spain; [2]Hospital Clínic and IDIBAPS, Department of Rheumatology, Arthritis Unit, Barcelona, Spain; [3]Health Research Institute (IdISSC), Hospital Clinico Universitario San Carlos, Rheumatology Department, Madrid, Spain; [4]Hospital de La Princesa, IIS Princesa, Rheumatology Department, Madrid, Spain; [5]Instituto de Investigacion Sanitaria - Hospital Clínico Universitario de Santiago (IDIS), Experimental and Observational Rheumatology and Rheumatology Unit, Santiago de Compostela, Spain; [6]Hospital Universitario 12 de Octubre, Instituto de Investigación Sanitaria Hospital 12 de Octubre (imas12), Department of Rheumatology, Madrid, Spain; [7]Complutense University of Madrid, Department of Medicine, Madrid, Spain; [8]Universidad de A Coruña, Departamento de Medicina, Grupo de Investigación en Reumatología y Salud, A Coruña, Spain; [9]CIBER - Center for Biomedical Research Network, Bioingeniería, Biomateriales y Nanomedicina, Madrid, Spain*

Background: The presence of anti-cytokine autoantibodies (ACAAs) seems to be a physiologic mechanism to control the immune response and regulate cytokine activity. Biological therapies also regulate cytokine activities and have greatly improved the quality of life of RA patients. However, alteration of the cytokine network by the use of these treatments may lead to a disbalance in the regulatory system of ACAAs. We hypothesize the ACAAs network may influence the course of immune response in RA patients and may be useful to predict the therapy efficacy.
Objectives: We aimed to explore the potential of circulating ACAAs to predict flare in a cohort of RA patients treated with biological therapy.
Methods: We employed sera at baseline from 194 RA patients of the clinical trial OPTIBIO[1] (A Coruña), whose primary endpoint is to evaluate the usefulness of standardized protocol strategies of dose reduction in patients with RA in clinical remission treated with biologics. These patients were treated with TNF inhibitors (Etanercept, N=47; Infliximab, N=12; Adalimumab, N=35; Certolizumab (CTZ), N=17; Golimumab, N=5), Tocilizumab (TCZ, N=60) and Abatacept (ABA, N=18). Patients were in clinical remission (DAS 28 <2.6 or SDAI <5 or ACR/EULAR 2011 criteria) at least from 6 months. Patients were followed during a minimum period of one year and maximum period of 3 years. Flare was considered when remission criteria were not fulfilled. The bead-based antigen array MILLIPLEX MAP Human Cytokine Autoantibody Magnetic Bead Panel was used for the simultaneous detection and quantification in sera of anti-BAFF, anti-G-CSF, anti-IFNβ, anti-IFNγ, anti-IL-1α, anti-IL-6, anti-IL-8, anti-IL-10, anti-IL-12 (p40), anti-IL-15, anti-IL-17A, anti-IL-17F, anti-IL-18, anti-IL-22, and anti-TNFα. Non-parametrical tests, ROC curves and logistic regressions were performed for the statistical data analysis using SPSS. P-value < 0.05 was considered statistically significant.
Results: The levels of anti-17A and anti-IL-1α were increased in the sera from patients who suffered a flare during the follow-up period (N= 76), compared to those who remained in remission (N= 118), showing an area under the curve (AUC) of 0.586 and 0.594, respectively. Segregating by treatment, the levels of anti-17A were specifically increased in those relapsing patients under CTZ (N=6), ABA (N=12) and TCZ (N=20) treatment. The AUC of anti-17A within these three therapies was 0.867, 0.903 and 0.682, respectively. Logistic regression analysis also associated the levels of anti-17A with the risk of suffering a flare in TCZ-treated patients (OR=1.11; p=0.015, for 100 MFI increase). In addition, the TCZ-treated patients who suffered a flare also showed higher levels of anti-IL17F, anti-IL-1α, and anti-IL-18 compared to those that remained in remission, showing AUCs of 0.689, 0.657 and 0.698, respectively. Anti-IL-18 was also associated with the risk of flare in these patients (OR=1.65; p=0.028, for 100 MFI increase). The presence of these three ACAAs was also higher in the TCZ-treated patients who suffered a flare compared to those in remission.
Conclusion: Although further validation of our results is needed, we present a ground-breaking study showing the potential of anti-IL17A, anti-IL-1α, and anti-IL18 to predict flare in RA patients under biological therapies.

POS0439 STROMAL B-CELL CROSSTALK PROMOTES THE ESTABLISHMENT OF SYNOVIAL B CELL NICHES THROUGH THE SELECTION, ACTIVATION OF NATURALLY OCCURRING EBV+ B CELLS

M. Caliste[1], E. Prediletto[1], E. Corsiero[1], L. Jagemann[1], C. Pitzalis[1], M. Bombardieri[1]. *[1]William Harvey Research Institute, Experimental Medicine & Rheumatology, London, United Kingdom*

Background: Rheumatoid Arthritis (RA) is characterized by the formation of ectopic lymphoid structures (ELS) in the synovial tissue, which can promote B cells activation and local production of autoantibodies. B cells exert an essential role in RA immunopathogenesis, as demonstrated by therapeutical effects of Rituximab (1). We previously showed that ELS in the RA joints frequently accumulate Epstein Barr virus (EBV)-infected B cells displaying evidence of both latent (LMP2A) and early lytic viral reactivation in locally differentiated plasma cells (PCs)(2). RA synovial fibroblasts (SFs) can sustain B cells activation, proliferation and maturation into high affinity antibodies producing cells, mimicking B cells physiological differentiation in germinal centres (3). Whether RASFs can also promote preferential selection of naturally-occurring EBV+ B cells is currently unknown.
Objectives: Here, we aim to a) demonstrate SFs role in EBV+ B cells selection b) phenotypically characterize B cells after co-culture with SFs c) dissect the molecular mechanisms behind the B cells SFs crosstalk.
Methods: Long-term *in vitro* B cells SFs co-cultures have been established, followed by phenotypical characterization of B cells in flowcytometry. Supernatant were then screened by ELISA at different timepoints, to measure IgG, IgM and IgA production. EBV infection status on B cells were analysed by qRT-PCR after gDNA extraction. Single cells RNA sequencing was finally performed at 28 days of co-culture.
Results: Preliminary results confirmed RASFs role in sustaining B cells activation and maturation, showing B cells survival up to 90 days, production of IgG and an increased IgG/IgM ratio overtime. Interestingly, we identified a particular B cells phenotype occurring in long term *in vitro* co-cultures, characterized by CD38 expression and the subdivision into two functional subsets, CD58+/CD23^{high} and CD58+/CD23^{low}. These two subpopulations - previously described by Megyola et al. in *in vitro* EBV infected B cells - are characterized by two different functional states: an highly proliferating (CD58+/CD23^{high}) population and an IL-6 producers (CD58+/CD23^{low}) one(4). We also observed that RASFs preferentially support EBV+ clones expansion, showing a preferential expression of EBV markers in CD58+/CD23^{high} cells. The high proliferation rate of these B cells allowed – on a specific experiment - the establishment of a cell line, named

"Carejavi", that we are currently employing as tool for functional investigation of RASFs primed EBV+ B-cells. Finally, the transcriptomic analysis revealed the selection of a relatively small number of clonotype at the VDJ analysis at the end of co-culture. In addition, we observed the upregulation of genes related to GC formation (such as EBI3, LTA and LTB), B cells proliferation (mki67) and viral oncogenic transformation (MYC).

Conclusion: Here, we demonstrated that RA SFs not only support B cells maturation and activation in local autoantibodies producing cells, but they are also able to preferentially induce selection and proliferation of EBV+ clones, characterized by a peculiar expression of CD58 and CD23. The molecular mechanisms behind this phenomenon are currently under investigation.

POS0440 THE ANALYSIS OF THE INFLAMMATORY PROTEOME IN RHEUMATOID ARTHRITIS IDENTIFIES COMMON SIGNATURES ASSOCIATED WITH THE CLINICAL RESPONSE TO DMARDS AND TNFI THERAPIES

L. Marenco[6], E. Collantes Estevez[1], C. Lopez-Pedrera[1]on behalf of BIOSAR. *[1]IMIBIC/Reina Sofia Hospital/ University of Cordoba, Rheumatology, Cordoba, Spain; [2]Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain; [3]Hospital Clínico Universitario, Rheumatology, Malaga, Spain; [4]Hospital Regional Universitario de Malaga, Rheumatology, Malaga, Spain; [5]Hospital Regional Universitario de Malaga, Malaga, Malaga, Spain; [6]Hospital Universitario Virgen de Valme, Rheumatology, Sevilla, Spain*

Background: The clinical outcome of the most common therapeutic options of rheumatoid arthritis (RA) patients, such as conventional disease-modifying antirheumatic drugs (DMARDs) and TNF inhibitors (TNFi) is still unpredictable, since a high percentage of patients do not response to the therapy. Innovative analyses combining high-throughput technologies and thorough clinical assessments are needed to gain insight about the management of this prevalent autoimmune disorder.

Objectives: To evaluate the systemic inflammatory proteome of RA patients, to identify useful biomarkers associated with distinctive clinical outcomes.

Methods: Serum samples from 140 subjects, including 40 healthy donors (HC) and 100 RA patients with high activity disease (mean DAS28=4.7), were profiled with the innovative proteomic methodology "proximity extension assay" (Olink) which analyses one panel of 92 pro-inflammatory proteins. Samples from RA active patients included 40 from newly-diagnosed RA patients before taking conventional DMARDs and 60 from biologics-naïve patients (mean disease duration=10 years) before receiving TNFi drugs. Clinical outcomes were evaluated following EULAR criteria after 6 months of treatment and patients were classified as responders or non-responders to the different therapeutic interventions. Unsupervised hierarchical clustering methodologies were applied to identify subgroup pf patients based on the proteomic profiles. Gene ontology enrichment were used to interrogate the biological meaning of the distinctive molecular signatures identified.

Results: The inflammatory proteome analysis identified 33 proteins differentially expressed and upregulated in RA patients compared with HC including several chemokines (CCL-11, -19, -20, -23, -28; CXCL-10, -11, -9; MCP-1, -3), interleukins (IL-6, -8, -18, -10, -17c), and other relevant proinflammatory mediators (VEGFA, CD40, MMP-1, CSF-1, OPG, FGF23) among others (FDR<0.05). Most of these molecules were associated with disease activity (DAS28) and the autoimmunity profile (Rheumatoid factor and ACPAs antibodies) of RA patients. The unsupervised clustering analysis using the proteomic profile of RA patients before TNFi identified two subgroups of patients. Cluster 1 (C1) was characterised by patients with higher levels of several pro-inflammatory mediators compared with Cluster 2 (C2), where a signature of 16 chemokines was significantly enriched (CCL-3, -4, -10, -11, -20, -23; CX3CL1; CXCL-1, -10, -11, -5, -6, -9; MCP-1, -3, -4). Clinically, 25% of the non-responders' patients was included in C2, while 75% was located in C1, suggesting that a prominent circulating chemotaxis profile prior therapy is associated with a poor clinical outcome. These data were similarly observed in patients before receiving DMARDs, where a signature of upregulated chemokines and pro-inflammatory mediators characterised a cluster with a high % of non-responder patients.

Conclusion: A pro-inflammatory signature, where chemokines are predominantly up-regulated in the serum of RA patients before therapy, is associated with a poor clinical outcome. This newly identified signature, which deserves a more in-depth analysis, might be clinically useful guiding precision medicine and novel therapeutic approaches.

POS0441 IN-DEPTH ANALYSIS OF AXL AND MERTK EXPRESSION PATTERNS AND REGULATION BY BIOLOGIC TREATMENTS IN RHEUMATOID ARTHRITIS

A. Nerviani[1], M. A. Boutet[1], G. M. Ghirardi[1], K. Goldmann[1], E. Sciacca[1], F. Rivellese[1], E. Pontarini[1], M. Caliste[1], E. Prediletto[1], M. Bombardieri[1], M. Lewis[1], C. Pitzalis[1]. *[1]William Harvey Research Institute, QMUL, Centre for Experimental Medicine and Rheumatology, London, United Kingdom*

Background: Tyrosine kinases receptors MerTK and Axl have been implicated in the pathogenesis of several autoimmune diseases. Despite sharing significant structural homology and having common ligands, Axl and MerTK have distinct features and biological functions [1]. A growing body of evidence suggests that both Axl and MerTK play a crucial role in Rheumatoid Arthritis (RA) pathogenesis and progression and may be exploited as novel therapeutic targets [2]. However, numerous unanswered questions remain to be addressed.

OBJECTIVES:

i. To define common and distinct gene-partners of Axl/MerTK and quantify their expression in RA synovial tissue.
ii. To assess the co-expression of Axl/MerTK by synovial cells.
iii. To outline the longitudinal variation in Axl/MerTK expression upon treatment intervention.

Methods: Synovial tissue samples were collected by US-guided synovial biopsy from: i. Patients with early (<12 months) RA DMARDs/steroid-naïve [n=87]; and ii. RA patients who failed the first-line biologic with TNF-inhibitors (TNFi) before and 16 weeks after receiving either Rituximab (RTX) or Tocilizumab (TOC) [n=164] [3]. Gene expression was obtained by bulk RNAseq performed on an Illumina HiSeq2500 platform. Axl-/MerTK-modules were defined using STRING networks and the module expression determined by the mean z-score of regularized log transformed expression for all genes in the set. Axl, MerTK, CD55, CD90, CD68 protein expression was analysed by multiplex immunofluorescence staining.

Results: Using STRING network analysis, we defined an Axl- and a MerTK-module composed of 31 predicted gene-partners of either Axl or MerTK. Thirteen genes were common to both modules and included the ligands Gas6 and ProteinS, and EGFR. Conversely, eighteen genes were uniquely present in the Axl-module (e.g., PIK3-family, IGF1R, IFNAR1 and STAT3) or the MerTK-module (e.g., Galectin3 and TULP, recently discovered MerTK ligands, FCGR1A/CD64, PTPN1and MEGF10). Axl/MerTK-modules quantified in the early-arthritis treatment-naïve RNAseq dataset showed a significant negative correlation with the synovitis score (Axl r=−0.33, p=0.0032; MerTK r=-0.33, p=0.003). At protein level, CD68+macrophages of the Lining showed notable heterogeneity between patients: they could express either Axl or MerTK alone, or co-express both. Axl was also present in most CD55+ Lining Fibroblast-Like-Cells (FLS) but not by CD90+ Sublining FLS while MerTK, as expected, was restricted to macrophages, including intra-aggregate tingible-body-macrophages. To define how Axl and MerTK vary depending on disease stage and treatment exposure, we quantified their gene expression in active RA patients inadequately responding to TNFi, prior and 16 weeks after starting second-line biologic (RTX or TOC) [3]. Differently from the early-arthritis cohort, MerTK was significantly up-regulated in synovia characterised by higher degree of tissue inflammation (lympho-myeloid > diffuse-myeloid > pauci-immune, p<0.0001) and significantly positively correlated with several cytokines' genes such as TNF, IL-6, CCL8 and IL-10. MerTK expression was dependent on clinical response to RTX but not TOC as assessed by EULAR response (DAS28CRP, good vs none/mod, FDRresp 0.048). Conversely, Axl expression

significantly increased upon IL-6 blockade by TOC independently of the clinical response (FDRtime 0.016).

Conclusion: Our data further corroborate that Axl and MerTK constitute a dynamic axis influenced by the synovial tissue inflammatory features, the disease stage, the exposure and the response to targeted treatment and the blockade of critical inflammatory pathways over time. A better understanding of the individual features of these tyrosine kinases as well as their interaction would be beneficial to define novel treatment approaches.

POS0442 GLPG4399: SELECTIVE SIK3 INHIBITION AS A NOVEL MODE OF ACTION FOR THE TREATMENT OF INFLAMMATORY ARTHRITIC DISEASES (PRECLINICAL)

S. Lavazais[1], A. Pereira-Fernandes[2], C. Delachaume[1], C. Jagerschmidt[1], M. Drennan[2], D. Merciris[1], C. Peixoto[1], M. Borgonovi[1], N. Desroy[1], D. Amantini[1], S. De Vos[2], K. Nys[2]. *[1]Galapagos, SASU, Romainville, France; [2]Galapagos, NV, Mechelen, Belgium*

Background: Salt-inducible kinases (SIKs) is a family of kinases with immunomodulatory function identified using a proprietary adenoviral shRNA knockdown target discovery platform. Moreover, SIK inhibition has previously been shown to have a role in inflammatory signalling.[1–3] These findings suggest a therapeutic potential for SIK inhibition in inflammatory indications. A medicinal chemistry effort resulted in the development of a first-in-class, oral, selective SIK3 inhibitor: GLPG4399. This compound may be beneficial in inflammatory diseases such as rheumatoid and psoriatic arthritis which are chronic disorders characterized by impaired joint synovial inflammation.

Objectives: Our research aimed to characterize GLPG4399 and explore its impact in arthritis-relevant inflammatory *in vitro* phenotypic cell assays, and to evaluate the therapeutic potential of selective SIK3 inhibition in *in vivo* experimental models of arthritis.

Methods: The selectivity and potency of GLPG4399 was profiled using biochemical and target-based cell assays. The mode of action of selective SIK3 inhibition in inflammation was explored in an *in vitro* panel of innate (monocytes, macrophages, dendritic cells) and adaptive (B and T lymphocytes) immune phenotypic assays and in a lipopolysaccharide (LPS)-stimulated human whole blood assay by measuring the production of inflammatory cytokines. *In vivo* target engagement was evaluated in an acute LPS-stimulated cytokine release mouse model by measuring plasma tumour necrosis factor (TNF) α levels. The therapeutic efficacy of GLPG4399 was evaluated *in vivo* in collagen-induced arthritis (CIA) and IL-23-induced psoriatic arthritis mouse models by assessing disease activity endpoints.

Results: GLPG4399 was shown to be a SIK3 inhibitor with high selectivity against a panel of 370 kinases. The wide effect of SIK3 inhibition on key immune cell types was demonstrated by GLPG4399's reduction of pro-inflammatory cytokines produced by monocytes, macrophages, dendritic cells, B and T lymphocytes in a panel of *in vitro* innate and adaptive immune phenotypic assays. The biological activity and target engagement of GLPG4399 was further demonstrated by dose-dependent inhibition of TNFα production *in vitro* in LPS-stimulated human whole blood and *in vivo* in the blood of LPS-challenged mice. Oral treatment with GLPG4399 in mice resulted in a significant and dose-dependent improvement of disease activity score in both CIA and the psoriatic arthritis disease model. Moreover, bone erosion in CIA and new bone formation in the psoriatic arthritis disease model were significantly reduced.

Conclusion: Our preclinical findings demonstrate the strong immunomodulatory effect of SIK3 inhibition in arthritis-relevant inflammatory cell assays and highlight the significant preclinical efficacy of GLPG4399 in two experimental arthritis mouse models. The novel mechanisms of action of GLPG4399 represents a promising approach for the treatment of arthritis.

POS0443 INSIDE THE JOINT OF INFLAMMATORY ARTHRITIS PATIENTS: HANDLING AND PROCESSING OF SYNOVIAL TISSUE BIOPSIES FOR HIGH THROUGHPUT ANALYSIS

A. Floudas[1,2], A. Gorman[2], N. Neto[3], M. Monaghan[3], Z. Elliott[2], U. Fearon[1,2], V. Marzaioli[1,2]. *[1]Trinity Biomedical Sciences Institute, Molecular Rheumatology, Dublin, Ireland; [2]EULAR Centre of excellence, Centre for Arthritis and Rheumatic Diseases, St Vincent's University Hospital, Dublin, Ireland; [3]Trinity Biomedical Sciences Institute, Trinity Centre for Biomedical Engineering, Dublin, Ireland*

Background: Inflammatory arthritis (IA) is a chronic systemic autoimmune disease of unknown aetiology, which affects the joints. While studies of immune cell populations in peripheral blood have been informative regarding potential immune cell dysfunction and possible patient stratification, there are considerable limitations in identifying the early events that lead to synovial inflammation. The joint, as the site of inflammation and the local microenvironment, exhibit unique characteristics that contribute to disease pathogenesis. The limited availability of synovial tissue (ST) biopsies is a key incentive for the utilisation of high-throughput techniques in order to maximise information gain.

Objectives: This work aims to provide an overview of key methods and novel techniques that are used in the handling, processing and analysis of ST biopsies and the potential synergy between these techniques.

Methods: We describe the utilisation of high dimensionality flow cytometric analysis, single cell RNA sequencing, *ex vivo* functional assays, including T cell activation, endocytosis and two-photon fluorescent lifetime imaging microscopy (FLIM).

Results: When comparing different methods for ST cell suspension generation we observed that the combination of mechanical and enzymatic digestion resulted in the release of considerably higher numbers of total viable cells when compared to mechanical digestion alone, although consideration should be taken in the cleaving of extracellular markers, like CD27. We next compared two different cryopreservation methods to that of freshly digested ST and observed similar viability and frequency of immune cells. Functional characterisation of ST cells can be challenging due to the high number of cells required for analysis, herein, we utilised the above protocols to establish ST viable cell suspensions and optimised different experimental approaches for phenotypical/functional characterisation. To investigate the functional consequence of OxPhos inhibition on ST T-cell polyfunctionality, ex-vivo ST cell suspensions from IA patients were stimulated with PMA/Ionomycin in the presence/absence of FCPP followed by metabolic profile characterisation via FLIM and high dimensionality flow-cytometric analysis for T cell-derived cytokines. Treatment with FCPP resulted in a decreased in T-cell polyfunctionality specifically in co-expression of TNF-α,-IL-2,-IFN-γ,IL-17A, -GM-CSF, an effect associated with a shift in their metabolic profile. In addition, freshly digested ST cell suspensions were subjected to an optimized assay to evaluate endocytosis in multiple populations simultaneously without the need for cell sorting. Briefly, digested cells were incubated in parallel at 4°C (passive endocytosis) and 37°C (active endocytosis) with DQ OVA(Ovalbumin). ST cells were then stained for multiple populations, demonstrating differential endocytosis capacity across pathotypes and disease controls. Finally, utilisation of novel bioinformatics analysis of RNAseq a data showed differential gene expression and pathway enrichment involved in IA pathogenesis and allowed for the comparison of cell specific enrichment scores and transcription factor usage based on pathotype and gender.

Conclusion: The introduction of new powerful techniques in the study of ST inflammation, brings new challenges and significant opportunities. These approaches will accelerate our path towards understanding of the mechanisms involved in the pathogenesis of IA and lead to the identification of new avenues of therapeutic intervention.

POS0444 PROFILING OF CIRCULATING MIRNAS IN DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

J. Baloun[1,2], A. Pekacova[1,2], H. Mann[2,3], J. Vencovský[2,4], K. Pavelka[2,4], L. Šenolt[1,2]. *[1]Institute of rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic; [2]1st Faculty of Medicine of Charles University, Department of Rheumatology, Prague, Czech Republic; [3]Institute of rheumatology, Inpatient department, Prague, Czech Republic; [4]Institute of rheumatology, Research Center, Prague, Czech Republic*

Background: Biologic (b-) and targeted synthetic (ts-) disease-modifying antirheumatic drugs (DMARDs) have brought significant progress in the treatment of rheumatoid arthritis (RA), but a significant proportion of RA patients still remain symptomatic despite treatment according to current recommendations. These patients have recently been defined as "difficult-to-treat (D2T)" RA (1). There is evidence that miRNA expression may play a role in the diagnosis and therapy of RA (2).

Objectives: In a retrospective study, we analyzed patients' blood samples prior to b-/ts-DMARD treatment and profiled circulating miRNAs to predict the development of D2T-RA.

Methods: A total of 36 patients fulfilling the EULAR definition of D2T-RA (1) (mean age 59.1±10.7 yrs, 78% females), 36 patients with RA in sustained clinical remission on b-/ts-DMARDs at two consecutive examinations 12 wks apart (mean age 66.3±9.6 yrs, 78% females), and 36 healthy controls (mean age 61.1±7.7 yrs, 68% females) were included in the study. Blood samples were collected before initiation of b-/ts-DMARD. We profiled circulating miRNAs using the sequencing approach and differential expression analysis was performed using DESeq2 algorithm.

Results: The massive parallel sequencing of circulating miRNAs detected 814 quantifiable miRNAs and DESeq2 algorithm revealed 35 miRNAs with different concentrations in patients who developed D2T-RA compared to patients with RA who achieved sustained remission or healthy controls. Out of these miRNAs, miR-16-5p (1.5x) and miR-451a (2.1x) were downregulated and miR-126-3p (1.4x) was upregulated in D2T RA patients compared to controls. In addition, miR-101-3p (1.5x) was downregulated in D2T RA compared to RA patients. Except for miR-101-3p, these miRNAS have been previously associated with RA and might predict development of D2T disease prior to initiation of b-/ts-DMARD therapy.

Conclusion: We found four miRNAs as potential biomarkers differentiating patients who are at risk to develop difficult-to-treat disease compared to patients who have a chance of sustained remission even before initiation of biological or targeted synthetic DMARDs. Further studies with larger sample size are needed to validated these data.

POS0445 DISSECTING THE ROLE OF PLATELET FUNCTION IN INFLAMMATORY ARTHRITIS

D. Kimpel[1], K. Kannan[2]. *[1]University of Virginia, Rheumatology & Immunology, Charlottesville, United States of America; [2]University of Arkansas, Medicine, Little Rock, United States of America*

Background: Inflammatory autoimmune diseases such as rheumatoid arthritis (RA) show an increase in atherosclerotic cardiovascular disease, and are commonly associated with an increase in platelet counts. Thus, platelets fill a central role in the tenet: Inflammation begets coagulation, and coagulation begets inflammation. We have previously reported that induction of arthritis by the Streptococcal cell wall component peptidoglycan-polysaccharide (PGPS) results in increased platelet numbers, aggregation, activation, and increased expression of P-selectin (CD62-P) and of the costimulatory molecule CD40. These platelets are also more sensitive to stimuli such as ADP and thrombin, which induce dense granule release of serotonin and aggregation. We have also described increased P-selectin expression limited to the joints in mice with acute arthritis. Platelets, generally considered elements of the hemostatic system, are underappreciated for their pro-inflammatory potential.

Objectives: To further understand the role of platelets in inflammatory arthritis, and distinguish their biochemical and adhesive features we set out to characterize the impact of modulating platelet activity in acute and chronic rodent models of arthritis.

Methods: Chronic inflammatory arthritis was induced in Lewis rats by a single i.p. injection of PGPS which results in an early phase non-T cell dependent arthritis, and a chronic T cell dependent phase after day 10. An acute inflammatory arthritis was induced in Balb/c mice by the same method. Joint scoring and volume measurement were carried out daily to determine an arthritis severity score. The role of platelets on PGPS arthritis was assessed using a) depletion of platelets using periodic intraperitoneal (IP) anti-platelet antibody, b) blockade of the integrin GPIIb/IIIa with the monoclonal antibody (mAb) abciximab to inhibit activation and aggregation via vWF and fibrinogen. In the acute murine arthritis c) P-selectin deficient mice were assessed for severity of arthritis, and d) wild-type mice were pre-treated with a single IP injection of anti-CD41 (GPIIb) antibody.

Results: Depletion of platelets in rats during the PGPS treatment resulted in amelioration of both the early and chronic phases of disease. We previously demonstrated that TNF is elevated in this model following PGPS injection, so for comparison animals were treated with infliximab, a monoclonal antibody to TNF, with equivalent suppression of both acute and chronic phases of disease. Abciximab, targeting the dual function adhesion and signaling molecule GPIIb/IIIa, did not decrease arthritis, and in fact increased the severity of the chronic phase of arthritis. In the acute murine model, despite the previously described expression of CD62-P in joints and on platelets, the CD62-P knockout mice had no significant difference in arthritis severity. Conversely treatment of wild-type mice with the anti-CD41 to block GPIIb resulted in suppression of the arthritis.

Conclusion: Platelet depletion had a dramatic impact on both acute and chronic phases of inflammatory arthritis, which is not unexpected given that platelets carry an array of pro-inflammatory and procoagulant mediators including IL-1, chemokines, vWF, and fibrinogen, as well as an array of adhesion molecules for binding to endothelium, leukocytes, and to other platelets. The increase in chronic arthritis severity despite inhibiting platelet aggregation by blockade of GPIIb/IIIa was unexpected, but may have been due to increased platelet-endothelial binding or platelet-leukocyte aggregation thus exacerbating the chronic T cell phase. Lack of CD62-P appeared to have no influence on acute phase arthritis development. Interestingly anti-CD41, which blocks one part of the GPIIb/IIIa integrin, was effective at ameliorating arthritis in the murine model. Platelets play an often underappreciated role in inflammatory processes, but understanding the mechanisms will require further dissection of the complex nature of these cellular elements which have dual inflammatory and hemostatic roles.

POS0446 ARP2/3 AS A LASP1 INTERACTION PARTNER REGULATES CELL-TO-CELL CONTACT FORMATION OF FIBROBLAST-LIKE SYNOVIOCYTES IN RA

D. Beckmann[1], A. Krause[1], U. Hansen[1], H. Kiener[2], J. Kremerskothen[3], H. Pavenstädt[3], T. Pap[1], A. Korb-Pap[1]. *[1]University Hospital Muenster, Institute of Musculoskeletal Medicine, Muenster, Germany; [2]Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria; [3]University Hospital of Muenster, Department of Nephrology and Rheumatology, Internal Medicine D, Muenster, Germany*

Background: In rheumatoid arthritis (RA), fibroblast-like synoviocytes (FLS) undergo a stable transformation resulting in an aggressive phenotype mediating cartilage damage by increased levels of adhesion molecules. In this context, Lasp1 and the Arp2/3 complex are of interest because they modulate actin organization and focal adhesion turnover.

Objectives: In this study, the effects of Arp2/3 on cadherin-11 mediated cell-to-cell contact formation have been investigated using the arthritic hTNFtg mouse model.

Methods: Expression levels of Lasp1 and Arp2/3 protein complex were investigated in synovial tissue of wild type (wt) and hTNFtg hind paws by immunohistochemistry. Primary FLS were analysed, respectively and co-immunoprecipitation experiments were performed. In addition, *lasp1*$^{-/-}$ mice were interbred with hTNFtg animals and offspring were evaluated for disease progression and joint destruction. To further study the role of Arp2/3 in the function of the cadherin-11 adhesion complex, the effects of an Arp2/3 inhibitor (CK666) on cell-to-cell contact formation in FLS derived from hTNFtg and *lasp1*$^{-/-}$hTNFtg mice were investigated by stainings. To assess signaling pathway activation, cells were stimulated with the growth factor PDGF.

Results: Upregulated Lasp1 levels were found in synovial tissue and FLS of hTNFtg compared to wt mice. Assays showed that Arp2/3 is part of the adherens junction (AJ) machinery in FLS although Arp2/3 expression levels were not changed between the genotypes. *In vivo* evaluation of *lasp1*$^{-/-}$hTNFtg mice revealed a milder arthritis score, less cartilage degradation and reduced FLS attachment to articular cartilage compared to hTNFtg mice. *In vitro*, the loss of Lasp1 led to clear alterations in AJ arrangement indicated by altered β-catenin pattern. As expected, β-catenin expression was mainly located at adhesion sites between adjacent cells. In hTNFtg FLS, these structures were characterized by a zipper-like pattern. In contrast, these structures were disrupted in *lasp1*$^{-/-}$hTNFtg FLS. Interestingly, CK666 induced zipper-like structures in hTNFtg FLS comparable to the pattern found in *lasp1*$^{-/-}$hTNFtg cells. Furthermore, *lasp1*$^{-/-}$hTNFtg FLS showed decreased Src phosphorylation following PDGF stimulation in comparison to hTNFtg FLS.
Conclusion: Lasp1 represents an interesting target involved in RA-caused joint destruction, because its loss results in significantly reduced cartilage destruction and altered FLS contacts mediated by Arp2/3.

POS0447 TREATMENT WITH UPADACITINIB IN RA PATIENTS FOR WHICH BIOLOGIC THERAPY FAILED

L. Robles Kirkegard[1], E. Rubio Romero[1], P. León[1]. [1]*Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Sevilla, Spain*

Background: Upadacitinib is a JAK inhibitor recently approved for rheumatoid arthritis treatment with promising results in its studies for severe moderate RA for which conventional therapies failed.
Objectives: To study and describe the evolution of patients diagnosed with RA and treated with Upadacitinib who had inadequate response to biological therapy in association or not with DMARDs and GC for 6 months.
Methods: A population of 23 patients (19 of them female) with RA on treatment with Upadacitinib was analyzed over 6 months. Using patient-reported outcomes (PROs) to measure disease activity by visual analogue scale (VAS), the HAQ Disability Index (HAQ-DI), Disease Activity Score (DAS28), and morning stiffness duration. The age´s (average ± SD) = 53 ± 10 years and time of disease evolution (average ± SD) = 17.6 ± 23.3 years. Pretreatment HAQ (average ± SD) = 2.2 ± 0.5. All patients received previous biologic treatments and 61% (14 patients) combined therapy with DMARDs. Only 2 cases had no glucocorticoid treatment prior to treatment with Upadacitinib.
Results: In 3 months' time, most patients (81%, n = 21) treated with Upadacitinib were able to reduce GC dose, and this reduction was maintained 6 months from the beginning of the treatment. After 3 months of treatment, most patients experienced an enhancement in DAS28 (89%, n = 18), with an average improvement in DAS28 of (± SD) 1.87±1.09 units. Regarding the pain (VAS), 67% of the patients showed improvement after 3 months (n=18), reaching 71% after 6 months (n=17). Sixty-eight percent of treated patients showed a reduction in morning stiffness after 3 months (n = 19), and this improvement increased up to 84% of treated patients at 6 months (n = 19). Side effects were observed in five patients, consisting of dizziness and nausea. In no case were they a reason for the withdrawal of the drug. Treatment was withdrawn in three patients due to primary failure.
Conclusion: Treatment with Upadacitinib allows GS dose reduction, as well as an improvement in DAS28, VAS and morning stiffness at three months and six of treatment. These data are in line with the evidence published in Upadacitinib pivotal studies, meaning a good alternative in the treatment of patients with moderate or severe RA.

POS0448 SYNOVIAL TRANSCRIPTOMIC PROFILES CORRELATE WITH DISEASE ACTIVITY IN EARLY UNTREATED RHEUMATOID ARTHRITIS

C. Triaille[1], T. Sokolova[1], S. De Montjoye[2], A. Nzeusseu Toukap[2], L. Meric de Bellefon[2], A. Loriot[3], B. Lauwerys[1], P. Durez[1], N. Limaye[4]. [1]*UCLouvain Brussels Woluwe, IREC RUMA, Woluwe-Saint-Lambert, Belgium;* [2]*Cliniques universitaires Saint-Luc (UCLouvain), Service de rhumatologie, Bruxelles, Belgium;* [3]*De Duve Institute UCLouvain, Computational Biology, Woluwe-Saint-Lambert, Belgium;* [4]*De Duve Institute UCLouvain, Genetics of Autoimmune Diseases and Cancer, Woluwe-Saint-Lambert, Belgium*

Background: Synovitis is the common feature across all individuals with a diagnosis of rheumatoid arthritis (RA). Yet, cellular and transcriptomic alterations occuring in RA synovium are highly variable amongst patients. So far, most data on clinical-tissue correlations either rely on hypothesis-driven approaches or are potentially biased by heterogeneous clinical characteristics (e.g. disease duration or disease-modifying antirheumatic drugs).
Objectives: We used transcriptomic profiling of synovial tissue from early, untreated rheumatoid arthritis patients (ERA) to 1/ identify the genes with the most variable expression amongst patients and 2/ explore the ability of unbiased (data-driven) approaches to define clinically relevant ERA subgroups.
Methods: Synovial biopsies were harvested from clinically involved joints of ERA patients using needle arthroscopy or ultrasound-guided biopsy. Data on disease activity were collected at inclusion. For each sample, 350ng total RNA was sent for RNAsequencing using a standardized protocol (Macrogen Europe). After quality control (Fast QC) and genome alignement (HiSat2), normalized read counts were analyzed on Qlucore Omics Explorer. To focus on inter-sample heterogeneity, genes were filtered based on variance (σ/σ_{max}). Unbiased approaches (Principal Component Analysis, Unsupervised Clustering) were applied to define patients' clusters. Pathway enrichment analysis were performed on Metascape. CibersortX was used to extrapolate the immune cell subsets relative composition from gene expression data. All other statistical analyses were performed on GraphPad Prism v9.
Results: Total RNA was obtained from synovial biopsies from 74 patients. We first applied variance filtering to identify the genes whose expression showed the greatest variation between patients (n = 894 most variable genes). PCA analysis on the level of expression of these genes did not divide samples into distinct groups, instead yielding a continuous distribution broadly associated with baseline disease activity, as measured by DAS28CRP. Consequently, we used unsupervised clustering to allow for unbiased definition of two patient clusters (PtC): PtC1 (n=52) and PtC2 (n=22) based on their expression of these 894 genes. Pathway analysis of these genes revealed significant enrichment of immune system genes, in the *Inflammatory response* and *Rheumatoid Arthritis* pathways (gene cluster 1: GC1), B cell & plasma cell-related pathways (GC2) and metabolic processes-related genes (GC3). Interestingly, PtC1 and PtC2 were characterized by very different clinical features. More specifically, patients from the group with a strong B & plasma cell signature (PtC1) displayed higher baseline indices of all disease activity score components (median DAS28CRP: 5.56 *vs* 4.09; p-value = 0.0003). They also had higher rates of baseline radiological erosions (erosive disease in 34.6 % *vs* 10%; p-value = 0.0252) but similar rates of seropositive disease. In line with our pathway analyses, we found a higher signature (inferred relative frequency) of B & plasma cells, T cells and M1-like macrophages in PtC1 compared to PtC2 synovia. PtC2 synovia instead had relatively higher M2-like macrophage and resting mast cell signatures.
Conclusion: In this large synovial biopsy study, we found that synovial transcriptomic profiles in ERA patients distribute continuously based on the expression of inflammatory and immune cell transcriptomic pathways. These synovial transcriptomic signatures correlate strongly with systemic disease activity.

Spondyloarthritis - aetiology, pathogenesis and animal models

POS0449 CHARACTERISTICS OF GUT MICROBIOTA AND ITS RELATIONSHIP WITH LYMPHOCYTE SUBSETS AND CYTOKINES IN PATIENTS WITH UNDIFFERENTIATED SPONDYLOARTHRITIS

Q. Wang[1,2], S. X. Zhang[2,3], J. Qiao[2,3], X. LI[3], Q. Yu[4,5], P. F. He[4,5]. *[1]Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China; [2]Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; [3]The Second Hospital of Shanxi Medical University, Department of Rheumatology and Immunology, Taiyuan, China; [4]Shanxi Medical University, School of Management, Taiyuan, China; [5]Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Gastrointestinal microbiota, particularly dysbiosis of gut microbiota composition have been correlated with the progression of autoimmune disorders, such as undifferentiated spondyloarthritis (USPA).
Objectives: This study aimed to identify the changed gut microbiota and its relationship with lymphocyte subsets and cytokines in USPA Patients.
Methods: A total of 210 participants were recruited in this study, comprising 105 USPA patients and 105 age and sex-matched healthy controls (HCs). Microbial genome was extracted from approximately 250mg fresh fecal samples from all participants using QIAamp PowerFecal DNA Kit (Qiagen). The V3-V4 variable regions of bacterial 16S rRNA genes were sequenced with the Illumina Miseq PE300 system. QIIME2 was used to process representative sequence clusters with a similarity cutoff of 100% (ASVs)[1]. Microbial diversity was estimated by the alpha diversity (observed, chao1, ACE, shannon, simpson, and ivsimpson) and beta diversity (bray distance). Biomarker species were identified based on STEMP between USPA and HC group. Correlations were analyzed with the Spearman rank correlation test.
Results: The alpha-diversity indices have no significant different between two groups (P >0.05, Figure 1A). Gut microbial community structure differed between USPA and HC, as revealed by ASV Bray–Curtis distances (P <0.05, Figure 1B). As for composition of gut microbiota, there were the increased levels of Escherichia_Shigella, Flavonifractor, Hungatella in the USPA group, and Lachnospirales, Roseburia, and Lachnospiraceae in HCs (Figure 1C). The relative abundance of Lachnospiraceae_UCG_001 and Enterobacter was negatively correlated with the absolute numbers of Th17 (P<0.05). Bifidobacterium was positively correlated with the absolute number of Th1 and Tregs (P<0.01, Figure 1D). The relative abundance of Fusobacterium, Incertae_Sedis, and Colidextribacter were negatively correlated with the absolute numbers of Il-10, IL-4, and IL-2 (P<0.05). Prevotella and Enterobacter were positively correlated with the absolute number of IL-6 and IL-4 respectively (P<0.05, Figure 1E). Bifidobacterium and Bilophila were neagtively correlated with the absolute number of NK cell (P<0.05, Figure 1F).
Conclusion: Gut dysbiosis in USPA patients mainly characterized by reduced the diversity and impaired abundance of the intestinal flora, which was closely related to the disturbance of lymphocyte subpopulations and cytokines.

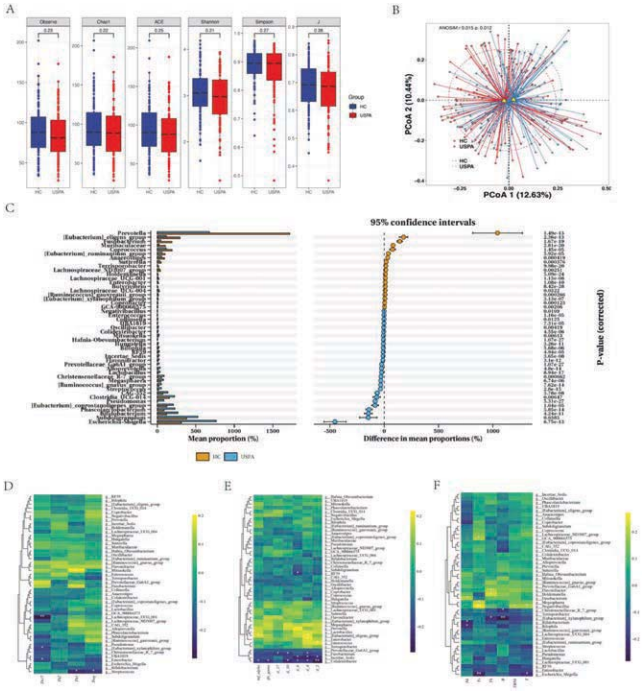

Figure 1. (A) Comparison of alpha-diversity indexs between HC and USPA groups was shown using boxplot. (B) β diversity of the gut microbiome in USPA patients and HCs. Principal coordinate analysis plot generated from the bray distance analyse. (C) STEMP was used to detect difference in Flora according to USPA and HC. (D-F) Relationship between gut microbiota, and Lymphocyte subsets as well as cytokines. *P<0.05, **P<0.01.

POS0450 TEMPORAL MIGRATION OF IMMUNE CELLS FROM PSORIATIC SKIN TO JOINTS INITIATING SYNOVIAL INFLAMMATION IN PSORIATIC ARTHRITIS

Fearon[5], D. Veale[6], M. Sticherling[2,7], J. D. D. Cañete[8], G. Schett[1,2], A. Ramming[1,2]. *[1]Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany; [3]Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitatsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [4]Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitatsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany; [5]Trinity College Dublin, Department of Molecular Rheumatology, Dublin, Ireland; [6]University College Dublin, Centre for Arthritis and Rheumatic Disease, Dublin, Ireland; [7]Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Department of Dermatology, Erlangen, Germany; [8]Hospital Clinic and IDIBAPS, Arthritis Unit, Rheumatology Department, Barcelona, Spain*

Background: Spreading of inflammation from skin to joint is a key question behind the pathogenesis of psoriatic arthritis (PsA). Psoriasis (PsO), being one of the most prevalent skin diseases, usually anticipates joint manifestations, suggesting spreading of skin to joint disease, which happens in about 30% of the patients with psoriasis.[1] To date, it is still obscure why the inflammatory process in some patients with PsO remains restrained to the skin, whereas in other patients it extents to tendons and joints.
Objectives: Using a pre-clinical model of PsA, we aimed to unveil the skin-joint axis, i.e. the spreading of psoriatic inflammation from the skin to the joints.
Methods: KAEDE transgenic mice expressing a photo-convertible fluorescent reporter were used to assess cell trafficking from inflamed skin to other organs in the mouse model of IL-23 overexpression (IL-23OE) induced PsA. Psoriatic skin lesions were irradiated with UV light to trigger the photoswitch from KAEDE^{GREEN} to KAEDE^{RED}. Migration to different organs was determined by flow cytometry. Imaging flow cytometry was used to characterize the type of cells migrating from the skin to the joints. Migrating cells were further characterized by single-cell RNA-sequencing (scRNAseq) and functional analyses.
Results: MRI imaging and histological evaluation of IL-23OE mice revealed skin inflammation preceding joint inflammation in both wild-type and KAEDE-transgenic mice. Specific leukocyte migration from the skin to the joints started shortly after the onset of skin inflammation and before onset of inflammation within the joints of KAEDE transgenic mice. No migration was observed in healthy control animals. Other organs such as spleen or lymph nodes showed no model-dependent migration. Imaging flow cytometry revealed that the cells migrating to the joints were predominantly CD45+ CD11b+ cells. ScRNAseq analysis of sorted KAEDE^{RED} cells from inflamed joints confirmed that approximately 80% of the migrating cells were macrophages. Differential gene expression and pathway analysis revealed an imbalance between pro- and anti-inflammatory macrophages in the joints of experimental psoriatic arthritis.
Conclusion: We describe IL-23-mediated migration of skin-derived macrophages from the skin to the joints during the onset of experimental psoriatic arthritis. This process may explain the spreading from psoriatic skin to joint disease as these cells foster the development by local cytokine production once arrived in the joints.

SLE, Sjöns and APS - aetiology, pathogenesis and animal models

POS0451 DEFICIENCY OF PPM1A IN MACROPHAGE AGGRAVATES PRISTANE-INDUCED LUPUS-LIKE DISEASE

J. E. Kim[1,2], E. Y. Kim[1,2], S. Oh[1,2], M. Lee[1,2], D. Yoon[1,2], H. J. Min[1,2], H. S. Choi[1,2], Y. G. Kim[3], E. J. Chang[1,2,4]. *[1]University of Ulsan College of Medicine, Biomedical Sciences, Seoul, Korea, Rep. of (South Korea); [2]University of Ulsan College of Medicine, Stem cell Immunomodulation Research Center, Seoul, Korea, Rep. of (South Korea); [3]Asan Medical Center, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea); [4]University of Ulsan College of Medicine, Biochemistry and Molecular Biology, Seoul, Korea, Rep. of (South Korea)*

Background: Protein phosphatase Mg^{2+}/Mn^{2+}-dependent 1A (PPM1A) is a phosphatase which regulates various intracellular cell signaling pathways including inflammation. We previously suggested that the inflammatory signal decreased the PPM1A protein level in macrophage and this reduction had correlation with the chronic inflammatory bone disease, implying the possible role of PPM1A in inflammatory responses of macrophage.

Objectives: In this study, we aim to elucidate the potential role of PPM1A in macrophage to regulate inflammatory response during the disease progression of systemic lupus erythematosus.

Methods: We generated macrophage-specific conditional gene-knockout ($PPM1A^{fl/fl}$;LysM-Cre) mice and developed a lupus-like disease with immune complex glomerulonephritis in these $PPM1A^{fl/fl}$;LysM-Cre mice by intraperitoneal pristane injection. Mouse serum was collected every 4 weeks after pristane injection. Serum anti-dsDNA IgG, anti-ssDNA IgG, interleukin-17 (IL-17) and tumor necrosis factor-α (TNF-α) was quantified by ELISA. After 41 weeks from pristane injection, histological changes in the kidney, spleen, and lung tissues were observed. To analyze M1/M2 polarization in vitro, LysM-Cre and $PPM1A^{fl/fl}$;LysM-Cre mouse bone marrow-derived macrophages were cultured with lipopolysaccharide (LPS)/interferon-γ (IFN-γ) or interleukin-4 (IL-4) to check M1 or M2 related genes.

Results: We found that macrophages of $PPM1A^{fl/fl}$;LysM-Cre mice displayed different gene expression with LPS stimulation especially in M1/M2 related genes through the RNA-seq analysis and showed a decrease in both M1 and M2 polarization induced by LPS/IFN-γ or IL-4 stimulation. Notably, we found that $PPM1A^{fl/fl}$;LysM-Cre mice with pristane injection showed a significant increase of anti-ssDNA IgG compared to LysM-Cre mice. $PPM1A^{fl/fl}$;LysM-Cre mice showed severe lupus-like phenotypes such as global glomerular enlargement indicated by endocapillary proliferation and glomerular cellularity in kidney and lung inflammation accompanied by fibrosis, compared to LysM-Cre mouse by pristane injection. Together, serum IL-17 and TNF-α, which are proinflammatory cytokines, were increased in $PPM1A^{fl/fl}$;LysM-Cre after pristane injection. These results indicate that PPM1A depletion in macrophage deteriorates inflammation and contributes to the tissue damage in a lupus-like disease.

Conclusion: Our findings suggest that the deficiency of PPM1A in macrophages impairs M1/M2 macrophage polarization leading to an immune imbalance in lupus-like disease model, providing a potential link between the loss of function of PPM1A in macrophages and its molecular target for treatment of systemic lupus erythematosus.

POS0452 ABNORMALITY OF TYPE I INTERFERON SIGNALLING IN B CELLS IN PRIMARY SJÖGREN´S SYNDROME AND THE IMPACT ON LABORATORY AND CLINICAL FINDINGS

J. Ritter[1,2], F. Szelinski[2,3], A. Aue[3,4], A. L. Stefanski[2,3], E. Schrezenmeier[1,3,4], T. Dörner[2,3]. *[1]Berlin Institute of Health (BIH), BIH, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; [3]German Rheumatism Research Center (DRFZ), a Leibniz Institution, Berlin, Germany; [4]Charité Universitätsmedizin Berlin, Nephrology and Intensive Care, Berlin, Germany*

Background: B cell hyperactivity (1), autoantibody production (anti-SS-A, anti-SS-B) and hypergammaglobulinaemia as well as interferon (IFN) signature (2) play a central role in the pathogenesis of primary Sjögren´s Syndrome (pSS). The link between these hallmarks is still elusive. While treatment of pSS remains limited, an improved understanding of IFN and JAK/STAT signalling on B cells may hold promise to improve potential treatment targets and related biomarkers.

Objectives: To investigate downstream molecules of the IFN signalling pathway on B cells and their clinical impact in pSS.

Methods: Peripheral blood from 47 pSS patients and 36 matched healthy controls (HC) was obtained and permeabilized for intracellular staining. Here B and T cell markers were applied together with Signal Transducers and Activators of Transcription 1 (STAT1), STAT2, pSTAT1 and 2, Interferon Regulatory factor 9 (IRF9), IRF7 and IRF1 and analysed by using flow cytometry. Cell subsets and correlations with all markers and clinical information were subjected to statistical analyses.

Results: Compared to HC the pSS group showed significantly elevated STAT1 expression among all B cell subsets ($p>0.0001$) including naïve (CD27-IgD+), pre-switched (CD27+ IgD+), switched-memory (CD27+IgD-), double negative (CD27- IgD-) B cells and plasmablasts (CD27++ CD38++). Furthermore, IRF9 and STAT2 were increased among most B cell subsets. Positive correlations were found between STAT1 and IRF9 with Siglec-1 (CD169), an IFN signature marker expressed on the surface of CD14+ monocytes ($p>0.0001$; $r=0.633$). Notably, increased levels of IRF9 positively correlates with STAT1. Upregulated STAT1 and IRF9 within pSS B cells were associated to extraglandular manifestations, high anti-SS-A and anti-SS-B autoantibodies, high anti-nuclear antibody titers (ANA) and rheumatoid factors (IgA, IgM) in pSS patients.

Patients treated with prednisolone showed dose dependent inverse correlations of IRF9 expression among naïve-, memory-, and double negative B cells suggesting its treatment responsiveness.

Conclusion: The current data provide evidence of type I IFN on B cell subsets in pSS. Elevated STAT1, STAT2 and IRF9 expression suggest transcriptionally activity, which was evident in patients with extraglandular manifestations and elevated serologic activity.

Targeting JAK/STAT in pSS could be beneficial for patients with high STAT1 levels leading to a personalized approach for this specific subgroup of patients.

POS0453 EXPLORATORY IMMUNOPHENOTYPE OF THE RARE DISEASE JUVENILE SJÖGREN'S SYNDROME REVEALS A DYSREGULATION OF B AND T MEMORY CELL FREQUENCIES

L. Martin-Gutierrez[1], H. Peckham[2], A. Radziszewska[2], J. Peng[2], O. Nette[2], E. Jury[1], C. Ciurtin[2]. *[1]University College London, Centre for Rheumatology Research, London, United Kingdom; [2]University College London, Centre for Adolescent Rheumatology Versus Arthritis, London, United Kingdom*

Background: Sjögren's syndrome (SS) is an autoimmune rheumatic disease characterised by dryness resulting from chronic lymphocytic infiltration of the exocrine glands. Patients also present with other extraglandular manifestations such as arthritis, anemia and fatigue or various organ and systems involvement. The disease is more frequent in women aged 30-50. However, in rare cases, the disease starts in childhood and is known as juvenile SS (JSS) or childhood SS. Children have different clinical manifestations compared to adults, with dryness being less common, making the diagnosis very challenging[1].

Objectives: To investigate in depth the immune cell profile of patients with JSS for better understanding of disease pathogenesis.

Methods: Peripheral blood was collected from a cohort of patients with JSS while attending appointments at UCLH clinics. None had received B-cell depletion therapy. Immune-phenotyping of 29 immune-cell subsets, including B and T cells, in peripheral blood from patients with JSS (n=10) and age and sex-matched healthy controls (n=10) was performed using flow cytometry as we have performed previously for patients with adult onset SS[2]. Data were analysed using multiple t-tests and compared with the adult SS immune phenotype.

Results: Patients with JSS had an average age of 18 years (range 16-21) with an average age of disease onset at 14 years (range 12-18). Up to 60% of patients presented Anti-Ro autoantibodies while 50% presented Anti-La autoantibodies.

Patients with JSS had an altered immune profile compared to age matched healthy controls (average of 18 years, range 15-25). In the B cell compartment,

JSS patients had higher frequencies of Total CD19+ B cells (p=0.0044), Naïve B cells (CD19+IgD+CD27-) (p=0.0183) and bm2 (CD19+IgD+CD38+) (p=0.0490) whereas memory B cell subsets such as early bm5 (CD19+IgD-CD38+) and late bm5 (CD19+IgD-CD38-) were significantly reduced (p=0.0249, and p=0.0117 respectively), similar to the profile seen in patients with adult-SS. Interestingly, in the CD4+ T cell compartment, central memory (CD4+CD27+CD45RA-) T cells were significantly reduced (p=<0,0001) but effector memory (CD4+CD27-CD45-) and effector memory-re-expressing-CD45RA (EMRA, CD4+CD27-CD45RA+) T-cell subsets were significantly elevated (p=0.0171 and p=0.0002 respectively). These changes were not identified in adult-SS patients. Finally, unlike our observations in patients with adult-onset SS there was no widespread deregulation of CD8+ T cell subsets in JSS patients; only a significant increase in CD8+CD25-CD127+ responders T cells (p=0.0392) was observed in JSS patients versus healthy.

Conclusion: This is the first pilot study investigating the immunophenotype profile of patients with JSS. Our preliminary findings suggest altered immune phenotypes in both B-cell and T cell compartments and for B cells are in concordance with previous immunophenotyping studies in adult SS (predominance of naïve and lower frequencies of memory B cells), suggesting an immunological rationale for the use of similar therapies. Further studies, comparing the adult with the juvenile phenotype could help stratify patients for targetted therapies and improve treatment in this rare disease in children for which no evidence-based recommnedations exist.

POS0454 DIGITAL IMAGE ANALYSIS OF INTRAEPITHELIAL B-LYMPHOCYTES AS AN OBJECTIVE ALTERNATIVE TO ASSESS LYMPHOEPITHELIAL LESIONS IN SALIVARY GLANDS OF SJÖGREN'S SYNDROME PATIENTS

M. S. Van Ginkel[1], T. Van der Sluis[2], M. L. C. Bulthuis[2], H. J. Buikema[2], E. A. Haacke[1,2], S. Arends[1], S. Harder[3], F. K. L. Spijkervet[4], H. Bootsma[1], A. Vissink[4], F. G. M. Kroese[1], B. Van der Vegt[2]. *[1]University of Groningen and University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University of Groningen and University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands; [3]Visiopharm, Visiopharm, Hørsholm, Denmark; [4]University of Groningen and University Medical Center Groningen, Oral and Maxillofacial Surgery, Groningen, Netherlands*

Background: Salivary glands of primary Sjögren's syndrome (pSS) patients characteristically contain periductal lymphocytic infiltrates. Associated with these infiltrates, lymphoepithelial lesions (LELs) can be formed. LELs are composed of hyperplastic ductal epithelium with infiltrating lymphocytes and may assist in the diagnostic process of pSS[1]. However, manual identification of LELs on H&E staining is a subjective process and can be challenging. A more objective histological parameter that could assist in identification of LELs is the presence of intraepithelial lymphocytes within striated ducts, since we previously showed an association between intraepithelial B-lymphocytes and hyperplasia of the ductal epithelium[2]. These results, however, warrant validation in a larger cohort. Furthermore, associations between clinical parameters of pSS patients and presence of intraepithelial lymphocytes are not yet known.

Objectives: To investigate if detection of intraepithelial lymphocytes using digital image analysis can be used as an objective alternative to assess LELs, and to correlate presence of intraepithelial lymphocytes to clinical parameters of pSS patients.

Methods: Paired labial and parotid salivary gland biopsies of 109 patients clinically suspected for pSS were serially sectioned and stained for CD3 (T-lymphocytes), high molecular weight cytokeratin (striated ducts) and CD20 (B-lymphocytes). We developed a virtual triple staining digital image analysis (DIA) algorithm using the Visiopharm Integrator System (Visiopharm, Hørsholm, Denmark) to detect intraepithelial T- and B-lymphocytes within regions of interest comprising striated ducts. A maximum of 10 regions of interests was selected per biopsy. Presence of ductal hyperplasia was assessed on consecutive H&E stained slides. Patients were classified as pSS or non-SS according to the ACR-EULAR criteria.

Results: The DIA algorithm presented in this study was an accurate and objective method to detect intraepithelial lymphocytes within striated ducts in salivary gland tissue. Presence of intraepithelial B-lymphocytes, in contrast to intraepithelial T-lymphocytes, was a specific finding in salivary gland biopsies of pSS patients. In total, 59% of labial and 68% of parotid gland biopsies of pSS patients contained intraepithelial B-lymphocytes, against only 2% of patients classified as non-SS. Intraepithelial B-lymphocytes were not only detected within striated ducts with hyperplasia (LELs), but also in around 25% of analyzed striated ducts without hyperplasia of pSS patients (precursor stage of LEL). PSS patients with presence of intraepithelial B-lymphocytes in the labial gland showed lower stimulated whole salivary flow (p=0.011) and higher ocular staining scores (p=0.048), compared to patients without intraepithelial B-lymphocytes. Serological parameters, such as, rheumatoid factor-, IgG- and ESR levels were significantly higher in pSS patients with presence of B-lymphocyte containing ducts, irrespective whether the labial or parotid gland was taken into account.

Conclusion: Presence of B-lymphocyte containing ducts is a specific finding in salivary gland biopsies of pSS patients and is associated with clinical parameters of pSS. Together, identification of B-lymphocyte containing ducts by using DIA could be used as an objective marker in the diagnostic histopathological work-up of patients suspected of pSS.

POS0455 TOFACITINIB DECREASES INFLAMMATORY MARKERS AND MITOCHONDRIAL MORPHOLOGICAL DAMAGE IN SALIVARY GLANDS OF A MURINE MODEL OF SJÖGREN'S SYNDROME

M. J. Barrera[1], I. Castro[2], P. Carvajal[3], S. Aguilera[4], D. Jara[3], S. González[5], C. Molina[1], M. J. González[3]. *[1]Facultad de Odontología, Universidad San Sebastián, Santiago, Chile; [2]Departamento de Tecnología Médica, Facultad de Medicina, Universidad de Chile, Santiago, Chile; [3]Programa de Biología Celular y Molecular, Instituto de Ciencias Biomédicas, Facultad de Medicina, Universidad de Chile, Santiago, Chile; [4]Clínica INDISA, Departamento de Reumatología, Santiago, Chile; [5]Escuela de Odontología, Facultad de Ciencias, Universidad Mayor, Santiago, Chile*

Background: Altered homeostasis of salivary gland (SG) epithelial cells in Sjögren's syndrome (SS) patients could be the initiating factor that leads to inflammation, as well as secretory dysfunction. Mitochondria are important organelles involved in cellular metabolism and their dysfunction can induce a loss of homeostasis and inflammation. Altered mitochondrion can release mitochondrial components that can act as damage-associated molecular patterns (DAMPs) and induce an inflammatory response via pattern recognition receptors (PRRs) such as the NLRP3 inflammasome, TLR9, cGAS/STING, and ZBP1 (1). Previously we determined that SG from SS patients showed and altered autophagy, which is associated to an increased pro-inflammatory cytokines expression. Interestingly, increased expression of pro-inflammatory markers such as IL-6, was reversed by JAK inhibitor tofacitinib in three-dimensional (3D)-acini deficient in autophagy (2). It is not clear whether the alterations in autophagy found in SG patients include alterations in mitochondrial clearance (mitophagy) that may lead to the accumulation of damaged mitochondria and enhanced inflammation. In this context, recent results of our laboratory showed, for the first time, severe ultrastructural alterations of mitochondria in SG cells from SS patients (1). However, it remains to be determined if these alterations are related to inflammation and if an anti-inflammatory agent could regulate these processes.

Objectives: To analyze the effect of tofacitinib on the mitochondrial ultrastructure in submandibular glands of a murine model of SS. In addition, to evaluate the effect of tofacitinib on the expression and activation of some PRRs involved in the recognition of mitochondrial DAMPs in the same murine model.

Methods: Six-month-old female NOD.B10Sn-H2b/J mice (Jackson Laboratories, USA) were used with 4-5 mice per group. Procedures were approved by the Universidad de Chile Animal Care and Use Committee. 30 mg/kg/day tofacitinib citrate was administered by oral gavage. After 28 days of tofacitinib or vehicle administration, their submandibular glands were obtained, which were processed to evaluate the mitochondrial ultrastructure by electron microscopy or lysed in

RIPA buffer to obtain proteins. The protein levels of PRRs: NLRP3, TLR9, ZBP-1, and cGAs, as well as molecules activated downstream of cGAS and ZBP-1 such as TBK1, pTBK1, pSTING, and STING were determined by Western blotting.

Results: The results show that the mitochondria of the glandular epithelial cells of NOD.B10Sn-H2b/J mice treated with vehicle (control) present alterations such as swelling, disruption of membranes and crest disorganization that previously were reported in patients with SS (1). Interestingly, tofacitinib treatment improves the architecture of mitochondria. On the other hand, the protein levels of PRRs such as NLRP3 and cGAS decreased in mice treated with tofacitinib, as well as pTBK1.

Conclusion: The altered morphology of mitochondria together with the increased protein levels of PRRs and downstream markers of these PRRs suggests release of mitochondrial DAMPs in submandibular glands of NOD.B10Sn-H2b/J mice. The improvement in mitochondrial morphology as well as the decrease in PRRs activation under tofacitinib treatment suggest a potential use of this anti-inflammatory agent in mitochondrial alterations associated with inflammation. Many questions remain to be addressed, such as determining which mitochondrial DAMP might be being released and whether this is associated with impaired mitochondrial function in SS.

POS0456 AUTOPHAGY-RELATED RISK LOCI IN SLE AND THEIR ROLE IN NEUTROPHILS

A. Nagel[1], M. Radziszewski[1], B. Khatri[1], M. M. Wiley[1], A. M. Stolarczyk[1], M. L. Joachims[1], Q. Sun[2], K. Kim[3], S. C. Bae[4,5], B. Tsao[2], C. Lessard[1]. *[1]Oklahoma Medical Research Foundation, Genes and Human Disease Research Program, Oklahoma City, United States of America; [2]Medical University of South Carolina, Division of Rheumatology & Immunology, Charleston, United States of America; [3]Kyung Hee University (KHU), Seoul Campus, College of Science, Seoul, Korea, Rep. of (South Korea); [4]Hanyang University, Institute for Rheumatology Research, Seoul, Korea, Rep. of (South Korea); [5]Hanyang University, Hospital of Rheumatic Diseases, Seoul, Korea, Rep. of (South Korea)*

Background: Systemic lupus erythematous (SLE) is an autoimmune disease with ~150 established susceptibility risk loci. Genome wide-association (GWA) studies in SLE cases and controls of Korean ancestry identified the SLE risk locus ATG16L2-P2RY2, and rs11235604 as a SLE-associated missense variant (R220W) of Autophagy Related 16 Like 2 (ATG16L2) [1]. PRDM1-ATG5 is also an SLE risk locus in European populations that is implicated in autophagy. Autophagy plays a crucial role in neutrophil extracellular trap (NET) formation, degranulation, and limiting autoantigens in blood. Dysregulated autophagy has been implicated in SLE pathology and poor disease outcomes. The function of ATG16L2 is unknown, but evidence suggests it may function as a negative regulator of autophagosome formation [2].

Objectives: To identify autophagy-related SLE risk variants shared across different ancestry populations and define the role of ATG16L2 in SLE and autophagy.

Methods: SLE case-control GWA scans from European (7568 cases; 1082 controls), African American (4336 cases; 935 controls), Hispanic (3752 cases; 1840 controls), and Korean (1173 cases; 4213 controls) populations were imputed and SNP associations tested. Meta-analysis was performed, then Bayesian statistics were used to define a credible SNP set. Bioinformatic analyses (RegulomeDB, promoter capture Hi-C, eQTLs, etc.) further prioritized SNPs based on predicted functionality. The functional significance of autophagy SLE risk genes, ATG16L1, ATG16L,2 and ATG5, were tested by CRISPR knockout (KO) in PLB-985 cell line. CRISPR-targeted single cell clones were screened for ATG16L1, ATG16L2 or ATG5 deletion using qPCR, NanoPore sequencing, and Western blotting. Changes in autophagy were assessed by Western blotting and confocal microscopy.

Results: Transracial fine-mapping of PRDM1-ATG5 locus identified two SNP associations shared across the credible sets in all populations: rs56886418 (p=1.38x10-5) located in the intron of PRDM1 and rs77791277 (p=1.38x10-5) that tagged a group of SNPs in strong linkage disequilibrium. Cross comparison of the credible SNP sets and bioinformatic analyses of shared SNPs identified rs533733 and rs9373843 as additional likely functional variants. Bioinformatic analyses prioritized rs56886418, an eQTL for ATG5 (p=0.05) and PRDM1 (p=4.75x10-7) in blood cells positioned in a topologically associated domain (TAD) that may interact with ATG5 and PRDM1 promoters in EBV-transformed B cells. SNP rs533733 is an eQTL for ATG5 in neutrophils (p=0.006) and is in a TAD 6.4kb 3' of PRDM1 that interacts with the ATG5 promoter region where rs9373843 (eQTL of ATG5 in neutrophils (p=0.04)) is positioned. These data suggest that risk SNPs on the PRDM1-ATG5 locus may modulate ATG5 expression and autophagy in specific cell types by modulating the local chromatin regulatory network. To assess the roles of ATG5, ATG16L1 and ATG16L2 in autophagy, PMA/I-induced hallmarks of autophagy, LC3-I and LC3-II conversion and p62 protein aggregation, were assessed in homozygous and heterozygous ATG5, ATG16L1, or ATG16L2 CRISPR KO PLB-985 cells by Western blotting and confocal microscopy. Loss of ATG5 or ATG16L1 impaired PMA/I-induced autophagosome formation in myeloid-like and differentiated neutrophil-like PLB-985 cells. In contrast, loss of ATG16L2 elevated the conversion of LC3-I to LC3-II and p62 protein aggregation in both cell types, suggesting that ATG16L2 may inhibit autophagy.

Conclusion: Functional characterization of SNPs on the PRDM1-ATG5 and ATG16L2-P2RY2 loci, and the functional characterization of ATG16L2 in myeloid and neutrophil cell lines, provide new insights into the mechanisms that regulate autophagy in health and disease. Ongoing studies will focus on in vitro validation of predicted functional SNPs and will introduce ATG16L2 rs11235604 risk variant in PLB-985 cells to assess its importance in autophagy.

POS0457 LABIAL AND PAROTID SALIVARY GLAND HISTOPATHOLOGY IN PRIMARY SJÖGREN'S SYNDROME

U. Nakshbandi[1], M. S. Van Ginkel[1], H. Bootsma[1], S. C. Liefers[1], F. K. L. Spijkervet[2], A. Vissink[2], B. Van der Vegt[3], F. G. M. Kroese[1]on behalf of Sjögren's syndrome center of expertise Groningen. *[1]University Medical Center Groningen, Rheumatology & Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Oral & Maxillofacial surgery, Groningen, Netherlands; [3]University Medical Center Groningen, Pathology & Medical Biology, Groningen, Netherlands*

Background: Salivary gland involvement is a hallmark of disease in primary Sjögren's syndrome (pSS). This is reflected by the prominent role of a positive biopsy within the ACR-EULAR classification criteria, which is solely based on the focus score (FS)[1]. In pSS all salivary glands might be involved in the disease process. For this reason, both labial and parotid salivary gland biopsies can be used for diagnosis and evaluation. Although nearly all clinical centres obtain labial gland biopsies for classification and diagnosis of pSS, a parotid biopsy is also a safe and effective procedure. Furthermore, it has a comparable diagnostic potential in pSS, might be associated with less morbidity, and may even detect presence of subclinical MALT lymphomas[2]. However, histopathological differences between both types of salivary glands should potentially be taken into account.

Objectives: The aim of this study was to get histopathological insight in minor (labial) and major (parotid) salivary glands in pSS patients in comparison with non-SS sicca patients.

Methods: Both labial and parotid salivary gland biopsies were obtained from 99 patients. According to the expert opinion of three experienced rheumatologists, 36 patients were classified as pSS patients and 63 as non-SS sicca patients. Salivary gland biopsies were formalin fixed, paraffine embedded and serially sectioned at 3-4µm. Sections were stained with H&E and for CD3, CD20, CD45, hmwCK, CD21, Bcl6, IgA/IgG and IgM. Focus score (FS), relative area of lymphocytic infiltrate, level of lymphoid organization and presence of a plasma cell shift were determined. In addition, number of lymphoepithelial lesions, germinal centers, follicular dendritic cell networks, B-cells and T-cells were analyzed.

Results: All histopathological parameters differed significantly between pSS and non-SS sicca patients in both labial and parotid salivary gland sections. Comparison of the two salivary gland types of non-SS sicca patients revealed more signs of inflammation in labial gland biopsies as shown by a significantly higher FS, $CD3^+$ T-cells, $CD20^+$ B-cells and relative area of $CD45^+$ infiltrates compared to non-SS parotid salivary gland biopsies. Other histopathological parameters were comparable between the two types of salivary glands. In pSS patients, a higher FS and relative area of $CD45^+$infiltrates was observed in labial gland biopsies compared to parotid gland biopsies. Nevertheless, relative and absolute $CD20^+$ B-cell counts, GCs/mm^2 and LELs/mm^2 were higher in parotid gland parenchyma.

Conclusion: This study shows in labial salivary gland biopsies of non-SS sicca patients more signs of (unspecific) inflammation compared to parotid biopsies. In parotid gland biopsies signs of B-cell hyperactivity, such as number of $CD20^+$B-cells, GCs/mm^2 and LELs/mm^2, are more pronounced, compared to labial gland biopsies. These histopathological differences should be taken into consideration in diagnosis and classification of Sjögren's disease.

POS0458 ENRICHMENT OF COMPLEMENT, IMMUNOGLOBULINS, AND AUTOANTIBODY TARGETS IN THE PROTEOME OF PLATELETS FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

P. Linge[1], A. Jern[1], H. Tydén[1], B. Gullstrand[1], H. Yan[2], C. Welinder[3], R. Kahn[1], A. Jonsen[1], J. Semple[4], A. Bengtsson[1]on behalf of Lund SLE Research Group.
[1]Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden; [2]Swedish National Infrastructure for Biological Mass Spectrometry, BioMS, Lund, Sweden; [3]Lund University, Department of Clinical Sciences Lund, Lund, Sweden; [4]Lund University, Division of Hematology and Transfusion Medicine, Lund, Sweden

Background: Systemic Lupus Erythematosus (SLE) is characterized by autoimmunity towards apoptotic/necrotic cells, complement activation and excessive amounts of circulating immune complexes. Platelets are recognized as immune cells that interacts with innate and adaptive immune functions. They are activated in SLE patients and contribute to an increased susceptibility to thrombosis [1]. Decreased platelet size has been observed in patients with SLE [2], but the mechanism(s) remains unclear. In this study, we have analyzed the complete proteome of platelets with normal and decreased size from SLE patients and from healthy controls (HC).
Objectives: Our aim was to find clues that could explain the morphological differences observed in platelets from SLE patients and to better characterize the role of platelets in SLE.
Methods: We included 23 consecutive patients with SLE, median SLEDAI-2K score was 2, and 10 HC. Blood count, serum complement levels and the presence of antiphospholipid or dsDNA antibodies were analyzed in all patients. Platelet size (forward scatter) and activation status (CD154, PAC1, CD32, PAR1, CD62P and Annexin V) was determined using flow cytometry. The proteome of 10 platelet isolates from SLE (five with smallest and the five with largest average size) and five HC were analyzed using liquid chromatography with tandem mass spectrometry (LC-MS/MS). Data were analyzed using ANOVA, t-test, hierarchical cluster analysis, protein interactions using the STRING software and correlation analysis using spearman correlation.
Results: We identified a total of 2572 proteins from the platelet isolates. Out of the identified proteins, 396 had significantly different levels, meeting an ANOVA q-value ≤ 0.01. Pairwise t-test analysis, using a fold difference (FD) of ≥ 1.5 and a p-value of ≤ 0.05 as cut off reveled significant differences in the distribution of proteins between groups. Platelets of both SLE groups (small and normal sized) shared higher levels of forty proteins and twenty proteins were reduced, compared to HC. Cytoskeletal functions were overrepresentation in the group of reduced proteins, while proteins with higher levels in platelets from SLE patients included proteins associated with complement and autoantibody targets such as Beta-2-glycoprotein 1, Annexin A5, and Prothrombin. Platelets from SLE patients also shared an abundance in immunoglobulin proteins, with even greater accumulation in the normal sized platelets. SLE platelet heavy constant alpha 1 (r -0.85, p=0.003), heavy constant mu (r -0.64, p=0.05) and heavy constant gamma 3 (r -0.80, p=0.008) was inversely correlated with complement C4 in serum and heavy constant gamma 2 (r -0.648, p=0.049) with complement C3.
Conclusion: This study revealed an accumulation of complement proteins, immunoglobulins and known autoantigens in platelets from SLE patients compared to HC. The signature was largely independent of platelet size, but the enrichment of proteins involved in SLE pathogenesis indicates that the composition is influenced by SLE disease mechanisms. This was supported by the inverse correlation between platelet immunoglobulin and serum levels of complement protein C3 and C4. Platelets are known to interact with complement and express the low-affinity immunoglobulin gamma Fc region receptor IIA (CD32), suggesting a role in the clearance of immune complexes [3]. Future studies will have to determine if platelets play a role in the turnover of complement and immune complexes and the potential role of platelets as a source of autoantigens.

POS0459 APTAMER-BASED PROTEOMIC SCREENING IN IDENTIFICATION OF PATHOGENIC SIGNAL PATHWAY AND URINARY BIOMARKERS ASSOCIATED WITH HISTOLOGICAL FINDINGS IN LUPUS NEPHRITIS

K. Hiramoto[1], S. Saito[1], H. Hanaoka[1], K. Suzuki[1], J. Kikuchi[1], H. Fukui[1], R. Takano[2], F. Miyoshi[2], N. Seki[2], K. Sugahara[2], Y. Kaneko[1], T. Takeuchi[1].
[1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; [2]Mitsubishi Tanabe Pharma Corporation Sohyaku, Innovative Research Division, Tokyo, Japan

Background: The current gold standard for the diagnosis and classification, assessment of the severity of lupus nephritis (LN) is a renal biopsy. On the other hand, since the procedure is highly invasive, there is a pressing need to identify biomarkers for predicting the presence and its histological severity of LN. In addition, the background pathogenesis of each histological findings is not clearly understood.
Objectives: The purpose of this study was to elucidate the urine biomarkers for predicting the presence and the severity of histological findings of LN, and to search the pathogenic signal pathway.
Methods: Urine samples from 24 biopsy-proven active LN patients were initially screened for the levels of 1305 distinct human proteins using an aptamer-based-targeted proteomic assay. We developed histological scoring system based on ISN/RPS lesion definitions and classification, NIH activity and chronicity score. Two experienced evaluators assessed the histological scores. Cluster analysis and pathway analysis were performed.
Results: A total of 24 LN patients were included: 20 (83%) had a proliferative histological class (III or IV +/-V), 4 (17%) pure membranous (V). Through cluster analysis, several histological subgroups were extracted according to correlation with each histological finding, and proteins which corelated with each histological scores were analyzed. We focused on two subgroups: one in which including active glomerular histological findings (endocapillary hypercellularity, karyorrhexis, neutrophil infiltration, subendothelial deposits) and the other in which including interstitial histological findings (interstitial inflammation, interstitial fibrosis, tubular atrophy). Histological scores in the former group showed strong positive correlation with protein group which contained 59 proteins (Group A), including CCL21, CXCL10, VCAM1. Histological scores in the latter group corelated with another protein group which contained 85 proteins (Group B), including MCP-1, CCL11. Ingenuity Pathway Analysis showed 16 pathways (PDGF Signaling, Granulocyte Adhesion and Diapedesis, etc) were upregulated in Group A and 11 pathways (IL-17 signaling, Fibrosis signaling pathway, etc) upregulated in Group B. Among group A and group B urine proteins, those showed strong correlation between respective histological findings were validated with ELISA assays.
Conclusion: An aptamer-based-targeted proteomic assay screening by combining with renal histological scoring system suggested several urine proteins can predict the severity and the presence of major renal histological findings, and suggested to be related with the pathogenesis in patients with LN.

POS0460 METABOLOMICS ACROSS AGE IDENTIFIES UNIQUE CHANGES IN THE SERUM METABOLIC PROFILE IN PATIENTS WITH SLE

G. Robinson[1,2], A. Van Vijfeijken[1], L. Martin-Gutierrez[1], D. Isenberg[1], I. Pineda Torra[3], C. Ciurtin[2], E. Jury[1]. *[1]University College London, Rheumatology, London, United Kingdom; [2]University College London, Centre for Adolescent Rheumatology, London, United Kingdom; [3]University College London, Centre for Cardiometabolic and Vascular Science, London, United Kingdom*

Background: Cardiovascular disease (CVD) is a leading cause of mortality in patients with systemic lupus erythematosus (SLE, female:male ratio of 9:1) through accelerated atherosclerosis, the build-up of lipids and inflammation in the major artery walls, compared to age and sex matched healthy individuals. This is due to chronic inflammation, dyslipidaemia and other cardiometabolic defects that exacerbate with age (1). SLE in women aged of 35-44 increases the risk of coronary artery disease by 50 times and there is a 100-300-fold increased CVD-related mortality risk in young patients that develop SLE before the age of 18. Investigating metabolic defects in young patients and how they progress with age could help us understand the progressive mechanisms of atherosclerosis in SLE.

Objectives: This study investigated detailed changes in the metabolomic profile of female patients with SLE and matched healthy controls across age.

Methods: Serum NMR metabolomics (>250 metabolites, Nightingale) covering glycolysis metabolites, amino acids and 130 lipid measures was performed on serum from a cohort of female SLE patients (n=164, 13-72 years of age, median 35) and matched healthy controls (HCs, n=120, 15-76 years of age, median 36) and analysed by linear regression and Venn analysis. Multiple t-tests (corrected for multiple comparisons by false discovery rate) were used to assess unique metabolic changes by age group between SLE patients and HCs (≤25, n=62/43; 26-49, n=50/46; ≥50, n=52/31) and dysregulated metabolic pathways were assessed using metaboanalyst software. The metabolic impact of disease activity measures and treatments was assessed by Spearman correlations and unpaired t-tests respectively.

Results: Twenty-five metabolites were significantly altered in all SLE age groups compared to HCs, dominated by atheroprotective high density lipoprotein (HDL) subsets and their surface-bound peptide, apolipoprotein(Apo) A1, all of which were significantly decreased in SLE compared to HCs ($p<0.0001$ in ages combined). In addition, the concentration of glycoprotein acetyls (GlycA, inflammatory biomarker) was increased in SLE in all age groups compared to HCs ($p<0.0001$ in ages combined). Importantly, ApoA1 correlated negatively with disease activity measures (SLEDAI, p=0.005; BILAG, p=0.0009; dsDNA, p=0.003; ESR, p=0.0006) and positively with lymphocyte count (p=0.0005), whilst GlycA correlated positively with ESR ($p<0.0001$) and CRP ($p<0.0001$). Alternatively, metabolites unique to specific age groups in SLE compared to HCs included reduced amino acid subsets in the ≤25 age group, increased atherogenic very low density lipoproteins and reduced polyunsaturated fatty acids in the 26-49 age group, and increased atherogenic low density lipoproteins in the ≥50 age group. Separately, metabolites associated with the glycolysis pathway (p=0.004, metaboanalyist), including acetone, citrate, creatinine, glycerol, lactate and pyruvate, had significant positive correlations with age in SLE patients, but not in HCs. These metabolites were not significantly associated with disease activity measures. However, pyruvate (p=0.01) and lactate (p=0.009) were significantly upregulated in prednisolone treated patients, whilst citrate (p=0.002) and creatinine (p= 0.005) were downregulated in hydroxychloroquine treated patients.

Conclusion: Increasing HDL (ApoA1) levels whilst maintaining low disease activity in patients with SLE from a young age could improve cardiometabolic risk outcomes. This could be achieved through improved nutrition, lipid targeted therapies and better treatment strategies. Focusing on understanding and monitoring biomarkers of the glycolytic pathway could aid treatment decisions and help avoid adverse metabolic effects of current anti-inflammatory therapies in SLE (1).

POS0461 DISRUPTED HIPPOCAMPAL NEUROGENESIS MEDIATED BY IL-6 AND IL-18 INDUCE NEUROPSYCHIATRIC CHANGES IN MURINE LUPUS

D. Nikolopoulos[1], T. Manolakou[1], A. Polissidis[1], A. Filia[1], Y. Koutmani[1], D. Boumpas[1]. *[1]Biomedical research foundation academy of athens, Center for clinical, experimental surgery and translational research, Athens, Greece*

Background: Systemic lupus erythematosus (SLE) frequently affects the nervous system (NPSLE), however, its pathogenesis is only partly understood. We have previously characterized the behavioral phenotype of the NZB/W-F1 lupus-prone mouse which recapitulates the NPSLE phenotype exhibiting hippocampal-linked behavior including depressive-like disorder, anxiety and cognitive impairment both at early and late stages of the disease characterized by a profound hippocampal inflammatory response1,2. Defective hippocampal neural stem cell (hNSC) response is associated with cognitive dysfunction, depression and anxiety, all of which represent common neuropsychiatric features of both human and murine SLE.

Objectives: To further investigate the hippocampal neurogenesis in lupus mice and determine its involvement in disease pathogenesis.

Methods: All experiments were performed in female NZW/NZB F1 and C57BL/6 (WT) mice at the age of 3 months (pre-nephritic) and 6 months (nephritic stage) (n=5-8/condition/experiment). Neurogenesis was assessed in sagittal sections of hippocampus by immunohistochemical staining (DCX, Sox2, GFAP, Iba1) and morphological criteria. RNA-sequencing was performed in hippocampal tissue followed by pathway and enrichment analysis. Apoptosis (cleaved-caspase 3) and immune cell infiltration (CD11b, CD45, Ly6G, Ly6C, MHC-II, CD4, CD8, B220, Iba1, CD80, CD86, Argianse-1, iNOS) were assessed by flow-cytometry. Cytokines levels were measured by Legendplex. Ex vivo assays were performed in adult hippocampal neural stem cells extracted by 2-month-old female WT mice.

Results: We identified a profound disruption (~2-fold) of hippocampal neurogenesis (decreased DCX+ cells) both at 3 ad 6 month-old lupus mice together with decreased differentiated cells in both time-points, suggesting that lupus mice exhibit impaired neuronal differentiation. Although the number of the neuronal precursors radial glial-like cells (RGLs) was normal at pre-nephritic stage, lupus mice express increased number of both activated RGLs (Sox2+/GFAP+) and proliferating neuronal progenitors (Sox2+ cells) indicating enhanced self-renewal ability of neural precursors and augmented proliferation. Levels of cleaved-caspase 3 were elevated in lupus hippocampus supporting increased hippocampal apoptosis. Transcriptomic analysis of hippocampal tissue revealed a profound inflammatory response in lupus mice. Flow-cytometry analyses showed a pronounced immune cell trafficking in lupus hippocampus with a myeloid predominant response –involving predominantly the microglia- both at early and late stages of the disease. Multiplex assays revealed elevated levels of IL-6 and IL-18 in lupus hippocampus. Ex vivo exposure of adult hNSCs to IL-6 or IL-18 promoted cell proliferation and induced apoptosis.

Conclusion: The NZB/W-F1 mouse model of SLE exhibits defective neurogenesis due to increased apoptosis, and decreased differentiation of neuronal progenitors. Inflammation in lupus hippocampus results in elevated levels of IL-6 and IL-18 with both cytokines negatively affecting the hNSCs response. IL-6 and IL-18 may induce behavioral changes in NZB/W-F1 lupus mediated by altered neurogenesis and may represent therapeutic targets in NPSLE.

Background: Data on fluctuation of antibodies directed against domain 1 (anti-D1) of β_2-glycoprotein I (β_2GPI) are scarce. Patients with antiphospholipid syndrome (APS) and all three criteria tests for antiphospholipid antibodies (aPL) display higher titers of anti-D1, which correlate with anti-β_2GPI levels.
Objectives: This project aims at evaluating predictors of the variation of anti-D1 titers over time in a large international cohort of persistently aPL positive patients.
Methods: AntiPhospholipid Syndrome Alliance For Clinical Trials and InternatiOnal Networking (APS ACTION) Registry was created to study the course of persistently aPL-positive patients with or without autoimmune disorders over at least 10 years. Inclusion criteria are positive aPL by Updated Sapporo Criteria tested within one year prior to enrolment. Patients are followed every 12±3 months with clinical data and blood collection. Patients with available blood samples from at least three time points were included in this analysis. Anti-β_2GPI and anti-D1 IgG were tested by chemiluminescence (BioFlash, Werfen) at APS ACTION core laboratories. Positive results were defined as >20 CU, according to the manufacturer. Clinical data were retrieved from APS ACTION online database. Anti-D1 titers within the same subject were compared by Friedman's test. A mixed linear model was built to identify predictors of the fluctuation of anti-D1 antibody titers over time.
Results: In this longitudinal study, 230 patients with anti-D1 tested at 4 time points were included (Table 1). Patients with thrombotic APS had anti-D1 titers significantly higher than those without thrombosis (p=0.022). Among 135 patients with at least one anti-D1 positive result, anti-D1 titers varied significantly over time (Friedman statistics: 508.5, p<0.0001; anti-D1 geometric mean at baseline 189.0; T1 132.3 [-15%]; T2 113.8 [-17%]; T3 109.2 [-6% versus T2, -38% versus T1]). Anti-D1 titers were significantly higher at baseline compared to T3 (p=0.029). In the 4 years of follow-up, 18 new thrombotic events occurred. Patients with double/triple aPL positivity displayed 12.5 fold increase [95%CI 7.4-20.0] in baseline anti-D1 titers. After adjustment for age, gender and number of positive aPL tests, the fluctuation of anti-D1 titers was associated with treatment with hydroxychloroquine (HCQ) at each time-point. In particular, treatment with HCQ, but not those with conventional immunosuppressors, was associated with a 1.3-fold decrease in anti-D1 titers [95%CI 1.1-1.5]. In the same multivariable model, incident vascular events were associated with a 1.5 fold increase of anti-D1 titers. A concomitant diagnosis of systemic lupus erythematosus did not affect the fluctuation of anti-D1 titers.
Conclusion: Treatment with HCQ and vascular events during follow-up were identified as significant predictors of the fluctuation of anti-D1 antibody titers over time.

Table 1. Demographic and Clinical Characteristics of 230 APS ACTION Registry Patients with anti-D1 tested ≥3 time points during the follow-up

	Anti-D1 pos samples	Anti-D1 neg samples	p-value	Overall sample
	(n=135)	(n=95)		(n=230)
Age [years] *mean (SD)*	42.3 (11.8)	48.8 (13.0)	0.0001	45.0 (12.7)

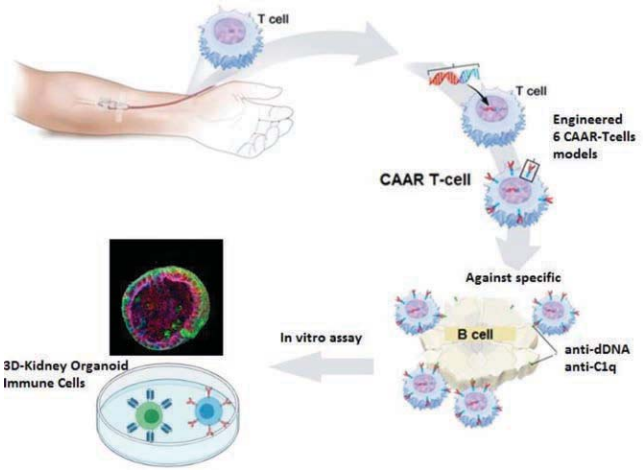
POS0463 REENGINEERING CHIMERIC ANTIGEN RECEPTOR T CELLS FOR TARGETED THERAPY OF LUPUS NEPHRITIS

C. Solé-Marcé[1], T. Moline[2], J. Cortés-Hernández[3]. *[1]Vall Hebron Institute Research, Lupus Unit - Rheumatology, Barcelona, Spain; [2]Vall Hebron Institute Research, Pathology, Barcelona, Spain; [3]Hospital Universitari Vall d'Hebron, Lupus Unit - Rheumatology, Barcelona, Spain*

Background: Although the pathogenesis of lupus nephritis (NL) is not completely clear, it is known that the production of anti-dsDNA or anti-C1q antibodies is related to its activity [1]. Despite treatment, approximately 30-40% of patients continue to present a significant number of renal outbreaks [2]. Therefore, there is a growing interest in the development of more specific drugs. As B cells play a central role in the pathogenesis of SLE, the therapy CAR-T cells has been studied reporting good results for the prevention and also for as treatment in murine lupus models [3,4]. Recently, a new selective immunotherapy for autoimmune diseases has been demonstrated by modifying the T cells with a chimeric autoantigen receptor (CAAR) [5]. This novel therapeutic approach could be beneficial in NL with the aim of depleting only anti-DNA producing B cells. In this way, the benefits of anti-CD20 biologics would be obtained, but it would be much more specific, personalized and, surely, effective since only the self-reactive B cells would be destroyed.
Objectives: To study CAAR-Tcell anti-dsDNA and anti-C1q therapy in NL through *in vitro* experiments (primary cells and kidney organoids).
Methods: Synthesis of 6 CAAR anti-dDNA that will be transfected in the primary T cells extracted from patients with NL and healthy controls (N = 10 per group). Through *in vitro* experiments their ability to lyse the B cells that produce anti-dsDNA or anti-C1q will be evaluated. The two CAAR-Tcell models that is most effective will be evaluated using kidney organoid models obtained from human samples.
Results: We engineered six human T cells models to express a chimeric autoantibody receptor (CAAR), consisting lupus nephritis autoantigen. As antigens for anti-DNA produced B cells, we designed Heparanase1/2, Histone1 and alpha actinin 1/2 CAAR-Tcells. For anti-C1q produced B cells, we used C1q protein fused to CD19-CD3 signaling domains. The CAAR-Tcells models that exhibited specify cytotoxicity *in vitro* againts B cells producing



anti-dDNA were Heparanase2 and alpha actinin1 CAAR-Tcells (selectivity of 75% vs 45%). C1q CAAR-T cells also presented specificy cytotoxicity for anti-C1q B cells (selectivity of 80%). In *vivo* imaging assay reveals that C1q or Heparanase2 CAAR-Tcells depleted completly B cells at 48 hours (ratio 1:10, Bcells:CAAR T-cells). We developed 3D in vitro organoid culture using human kidney organoid and B cells from lupus nephritis patients. We evaluated Heparanase2 and C1q CAAR-Tcells using them and we demostrated that C1q CAAR-Tcells could resolved better local kidney inflammation (reduction of IL6, TNF and INF cytokines levels).

Conclusion: Taken together, these results show that C1q CAAR-Tcells could be an effective and selective immune therapy for treatment of lupus nephritis. Currently, we are evaluated this therapy using NZWB/F1 murine models.

Background: The differential diagnosis of Rheumatoid Arthritis (RA) and Psoriatic arthritis (PsA) is often difficult due to the similarity of symptoms and the unavailability of reliable clinical biomarkers. Molecular alterations have been suggested to contribute to the pathophysiological processes in the knee joint, and it is known that chronic inflammation induces significant changes in the synovial tissue (ST) and synovial fluid (SF) lipidome and proteome.

Objectives: We aimed to evaluate whether specific characteristics in the molecular profiles from ST and SF could support the differential diagnosis of these diseases.

Methods: ST frozen samples of patients affected by RA (n=6), PsA (n=12) and control donors (n=10) were compared using Matrix-Assisted Laser Desorption Ionization Mass Spectrometry Imaging (MALDI-MSI) for spatially resolved lipid analysis. To this end, tissue sections were measured on a RapifleX MALDI-TOF/TOF instrument. Next, a targeted approach based on multiple reaction monitoring (MRM-MS) was performed to further validate the lipidomic alterations reported by MALDI-MSI between RA and PsA tissues. In this case, lipids extracted from SF (control donors (n=4), RA (n=21) and PsA (n=27)) were analyzed in a QTRAP 4000 mass spectrometer for the targeted analysis of 84 lipid species. Finally, a quantitative proteomic analysis was carried out on FFPE ST from RA (n=13), PsA (n=13) and controls (n=8) by nLC-MS/MS analysis using a TimsTOF Pro system (Bruker). Statistical analyses were performed using GraphPad Prism, Metaboanalyst and Perseus software.

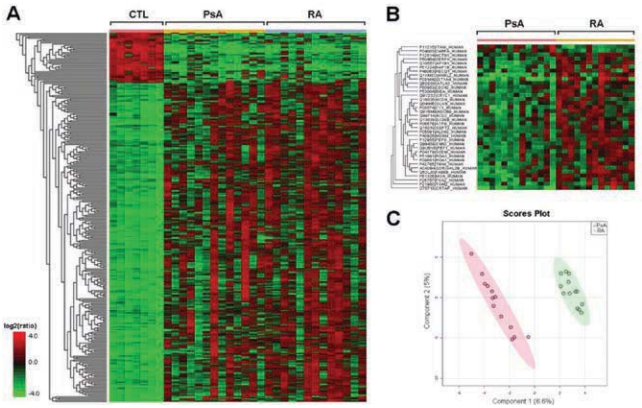

Figure 1. Results from the proteomic analysis carried out on synovial tissues. A) Heatmap showing the differential protein profiles between synovial tissues (PsA and RA) and healthy controls (CTL), at FDR 0.01. B) Characteristic protein panel discriminating PsA and RA tissues (p-value < 0.01). C) Discriminant analysis performed using this protein panel.

Results: Lipid profiles in ST from PsA and RA were unequivocally distinguished by MALDI-MSI followed by PCA-DA, and were also different comparing with control tissues. Interestingly, several lipid species, including sphingomyelins, phosphatidylcholines (PC) and phosphatidylethanolamines (PE), presented the greatest separation power to classify RA and PsA tissue samples. ANOVA analysis found 35 lipid species significantly different among the study groups, most of them significantly increased in RA and PsA compared to controls. Particularly, 11 lipids showed higher levels in PsA tissues compared with RA, including several PC and PE. The spatial distribution of these PE species was associated with areas of the sublining layer with increased vascularity and inflammatory cell infiltrates, according to MALDI-MSI images. On the other hand, RA and PsA patients were also correctly classified based on the SF levels of all quantified lipid species according to PCA and clustering analysis. Finally, the proteomic analysis quantified around 2,500 distinct proteins in the ST, including several related with lipid metabolism. Near 300 proteins showed altered abundance in the pathological tissues compared to healthy controls (FDR 0.01%, Figure 1A), being the small subset increased in controls mainly extracellular matrix proteins. The comparison between RA and PsA ST led to the identification of a panel of 36 proteins discriminating the two tissues with high statistical significance (p-value <0.01). In this comparison, all proteins except two appeared increased in RA (Figure 1B). A discriminant analysis shows the usefulness of this protein panel to differentiate the two diseases (Figure 1C).

Conclusion: Our study shows distinct molecular profiles between RA and PsA synovial tissue and synovial fluid, and reports potential clinically useful lipid and protein markers for the differential diagnosis of these diseases.

POS0465 UNSUPERVISED CLUSTERING ANALYSIS OF THE SERUM PROTEOME IDENTIFIES SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH DISTINCTIVE DISEASE SEVERITY AND LUPUS NEPHROPATHY

C. Lopez-Pedrera[1], M. Á. Aguirre-Zamorano[1], L. Muñoz-Barrera[1], I. Sanchez-Pareja[1], F. U. Pilar[1], M. C. Ábalos-Aguilera[1], N. Barbarroja Puerto[1], E. Collantes Estevez[1], R. Ortega Castro[1], C. Perez-Sanchez[1]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology, Córdoba, Spain*

Background: Systemic lupus erythematosus (SLE) is a remarkably heterogeneous autoimmune disease. Despite great efforts, our knowledge of serum protein patterns in severe SLE phenotypes is still limited.

Objectives: This study investigated the serum proteomic profile of SLE, in order to identify relevant clinical patterns.

Methods: Proximity extension immunoassay (PEA, Olink) was used to assess the serum levels of one hundred and eighty-four inflammation and organ damage-related proteins in patients with SLE (n = 72) and age-matched healthy donors (HD) (n = 18). In parallel, an extensive clinical and analytical profile of recruited subjects was performed. To evaluate the contribution of molecular profiles to the disease severity, unsupervised clustering analyses were developed. Gene ontology enrichment analysis were

also carried out to interrogate the biological meaning associated with the molecular signatures identified.

Results: Several circulating proteins related to inflammation and organ damage were coordinately altered in the serum of SLE patients in relation to HD. Unsupervised clustering analyses differentiated 2 patients clusters presenting different proteomic profiles. Clinically, although no differences were found in terms of age or disease duration, patients belonging to cluster 1 were characterized by a significantly higher status of disease activity (SLEDAI > 6) and prevalence of positivity for anti-ENA and anti-dsDNA antibodies than patients belonging to cluster 2, along with preponderance of patients with biopsy-diagnosed lupus nephritis (LN), abnormal creatinine and proteinuria. Twenty-three serum proteins were found deregulated between clusters. Interestingly, in parallel to well-recognized inflammatory cytokines, chemokines and regulatory proteins of leukocyte activity [Interferon (IFN)-gamma, interleukin (IL)-15RA, IL-20, sCD40, macrophage colony-stimulating factor-1 (CSF-1), leukemia-inhibitory factor receptor (LIF-R), monocyte chemotactic protein (MCP)-1, MCP-4, C-C motif chemokine (CCL)-4, C-X-C motif chemokine (CXCL)-5, CXCL-6, metalloproteinase (MMP)-1, programmed cell-death ligand (PDL)-1, eukaryotic translation initiation factor 4E-bindign protein 1 (4E-BP1)], a number of key proteins involved in renal damage, not previously reported in serum from SLE, were further found significantly deregulated in patients belonging to cluster 1 when compared with cluster 2 (kidney injure molecule 1 (KIM1), Linker for activation of T-cells family member-2 (LAT2), C-type natriuretic peptide (NPPC), Erbin-2 interacted protein (ERBB2IP)].

Conclusion: 1) This highly sensitive proteomic analysis in the serum of SLE identified molecular patterns distinguishing patients with high disease activity and active LN, and including several novel candidate proteins, whose exact role and suitability as biomarkers in SLE deserve further investigation. 2) Combination of novel and traditional disease-specific biomarkers may improve diagnosis and management of SLE.

Background: Fiber-poor diets are linked to a reduction in gut microbiota diversity and gut barrier integrity, which is thought to promote the susceptibility to chronic inflammatory disorders[1,2]. We have previously shown that dietary resistant starch (RS) improves lupus-like disease in a murine model of SLE[3] through the modulation of microbiota composition. If similar dysbiotic microbial community structures exist in subsets of SLE patients and if a RS intervention may be efficacious in those patients remains unclear.

Objectives: To test if the dietary RS content in SLE and SLE-related antiphospholipid syndrome (APS) affect gut microbial taxa associated with SLE in published cohorts to date.

Methods: We obtained stool and blood samples as well as diet history for up to 3 visits (0, 4 and 8 weeks) from 12 SLE (n=28) and 15 APS (n=44) patients as well as 20 controls (n=48) as previously published[4-6]. Microbiota composition was defined by 16S rRNA V4 region sequencing on the Illumina platform and correlated with dietary fiber content extracted from a diet questionnaire. We used the FDA reference list to determine dietary RS contents in patients` regular diets and defined RS quantities as being low if less than 2.5 g/day and as medium if 2.5 to 15 g/day. None of the patients achieved high RS greater than 15 g/day. Mann-Whitney or Kruskal-Wallis tests were performed to compare bacteria relative abundances among the different groups. Simple linear regression was performed to relate the bacterial abundance to RS content and other metadata.

Results: Medium intake of RS was associated with beneficial *Bifidobacterium* spp. in SLE patients (p=0.016) but not APS (p=0.509). Instead, APS patients who consumed medium quantities of RS in their diets had less gut bacterial taxa that are capable of producing cardiolipins (among them *Collinsella*; p=0.009) and *Ruminococcus gnavus* (p=0.0142), a species previously associated with lupus nephritis[7]. A recent Japanese metagenome-wide study[8] associated *Streptococcus* spp. and related redox reaction genes with SLE, which may also affect oxidative processes in APS[9]. We therefore also explored *Streptococcus* levels in SLE and APS patients and found unexpectedly a significant reduction of streptococci in a subset of APS (p=0.004) but not SLE patients (p=0.451) in medium compared to low RS dietary content. *Streptococcus* abundance was correlated with both *Collinsella* (R^2=0.3141; p=<0,0001) and *Ruminococcus gnavus* (R^2=0.1687; p=<0,0056) in APS patients.

Conclusion: Medium compared to low RS quantities in the regular diets of SLE and APS patients were associated with unique alterations in gut microbial community structures. *Bifidobacterium* increased in SLE patients with diets containing medium RS whereas APS patients with medium RS carried less cardiolipin-synthesizing taxa and lupus-related pathobionts. In particular, *Streptococcus* species recently strongly associated with SLE and redox reactions in Japanese patients in a metagenome-wide study[8], were significantly suppressed in APS patients on medium RS diets. This modulatory effect was not seen in SLE patients or control subjects consuming medium RS. Together, these findings support distinct dietary effects on autoimmune gut microbiomes depending on the disease state. They also suggest potential beneficial effects of increased RS content on gut microbiota in SLE and APS patients. Fully resolving gut microbial signatures and clinical characteristics in these patients may identify the ideal subset to benefit from an interventional pilot trial with RS.

Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models

POS0467 DERSIMELAGON, A NOVEL ORAL MELANOCORTIN 1 RECEPTOR AGONIST, DEMONSTRATES DISEASE-MODIFYING EFFECTS IN PRECLINICAL MODELS OF SYSTEMIC SCLEROSIS

M. Kondo[1], T. Suzuki[1], Y. Kawano[1], S. Kojima[2], M. Miyashiro[1], A. Matsumoto[1], G. Kania[3], P. Blyszczuk[3], R. Ross[4], P. Mulipa[4], F. Del Galdo[4], Y. Zhang[5], J. H. W. Distler[5]. *[1]Mitsubishi Tanabe Pharma Corporation, Research Unit/Immunology & Inflammation, Souyaku Innovative Research Division, Yokohama, Japan; [2]Mitsubishi Tanabe Pharma Corporation, Discovery Technology Laboratories, Souyaku Innovative Research Division, Yokohama, Japan; [3]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Schlieren, Switzerland; [4]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Faculty of Medicine and Health, Leeds, United Kingdom; [5]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Department of Internal Medicine 3—Rheumatology and Immunology, Erlangen, Germany*

Background: Activation of melanocortin 1 receptor (MC1R) is known to have broad anti-inflammatory and anti-fibrotic effects. The bleomycin (BLM)-induced skin fibrosis murine model is well-established for systemic sclerosis (SSc). α-melanocyte-stimulating hormone, an endogenous ligand of MC1R, inhibits skin fibrosis and MC1R knock-out enhances skin fibrosis in this model. These pieces of evidence suggest that MC1R agonism has potential in the treatment of SSc.
Objectives: Dersimelagon phosphate (MT-7117) is an investigational small molecule that is an orally administered, selective agonist for MC1R. The purpose of this study is to investigate the potential of MT-7117 as a therapeutic agent for SSc by evaluating its efficacy and mechanism of action in complementary preclinical models. The expression and distribution of MC1R in the skin of SSc patients was investigated.
Methods: The effects of MT-7117 on skin fibrosis and lung inflammation were evaluated in BLM-induced SSc murine models that were optimized for prophylactic and therapeutic evaluation. Microarray-based gene expression analysis and serum protein profiling were performed to investigate the mechanism of action of MT-7117 in the BLM-induced SSc models. The effect of MT-7117 on TGF-β-induced activation of human dermal fibroblasts was evaluated *in vitro*. Immunohistochemical analyses of MC1R expression in skin samples from SSc patients were performed.
Results: Prophylactic treatment with MT-7117 (≥0.3 mg/kg/day p.o.) significantly inhibited the increase in collagen content of the skin, the serum level of surfactant protein D, and the weight of the lungs from BLM-induced skin fibrosis and lung inflammation model. Therapeutic treatment with MT-7117 (≥3 mg/kg/day p.o.) significantly suppressed skin thickening and the numbers of myofibroblasts in pre-established BLM-induced skin fibrosis model. Gene array analysis using the BLM-induced SSc model demonstrated changes in numerous categories related to macrophages, monocytes, and neutrophils, followed by endothelial cell-related categories after treatment with MT-7117. In the analysis that focused on biological functions, categories of inflammatory response, activation of antigen-presenting cells, angiogenesis, atherosclerosis, vasculogenesis, and vaso-occlusion were suppressed by MT-7117. In the analysis that focused on molecular signaling pathways, triggering receptor expressed on myeloid cells-1, IL-6, and oncostatin M involved in inflammation, and peroxisome proliferator-activated receptor that is related to fibrosis were all affected by MT-7117. Serum protein profiling using BLM-induced SSc model revealed that multiple SSc-related biomarkers including P-selectin, osteoprotegerin, cystatin C, growth and differentiation factor-15 and S100A9 were suppressed by MT-7117. MT-7117 inhibited the activation of human dermal fibroblasts by suppressing TGF-β-induced *ACTA2* (encoding α-smooth muscle actin) mRNA elevation in vitro. Immunohistochemical analyses showed that MC1R positivity was observed in 40 of 50 diffuse cutaneous SSc patients. MC1R was expressed by monocytes/macrophages, neutrophils, blood vessels (endothelial cells), fibroblasts, and epidermis (keratinocytes) in the skin of SSc patients.
Conclusion: MT-7117 demonstrates disease-modifying effects in preclinical models of SSc. Investigations of its mechanism of action and target expression analyses indicate that MT-7117 exerts its positive effects by affecting the pathologies of inflammation, vascular dysfunction, and fibrosis through inflammatory cells, endothelial cells, and fibroblasts. In view of its potent beneficial impact on all these three main pathologies of SSc, MT-7117 is a potential therapeutic agent for the treatment of clinically challenging SSc, which has diverse and difficult to treat symptoms. A phase 2 clinical trial investigating the efficacy and tolerability of MT-7117 in patients with early, progressive diffuse cutaneous SSc is currently in progress.

POS0468 EXTRACELLULAR VESICLES FROM SERUM OF MYOSITIS PATIENTS AS CIRCULATING BIOMARKERS AND DISEASE MEDIATORS

S. Kivity[1,2], H. Kravitz[3], C. Cohen[3], D. Margoulis[3], M. Amar[3], G. Kazimirsky[3], D. Ozeri[4], A. Dori[5], C. Brodie[3]. *[1]Meir Medical Center, Rheumatology Unit, Kefar Sava, Israel; [2]Tel Aviv University, Sackler faculty of Medicine, Tel Aviv-Yafo, Israel; [3]Bar-Ilan University, The Mina and Everard Goodman Faculty of Life Sciences, Ramat Gan, Israel; [4]Tel-HaShomer The Sheba Medical Center, Zabludowicz Center for Autoimmune Disease, Ramat Gan, Israel; [5]Tel-HaShomer The Sheba Medical Center, Department of Neurology, Talpiot Medical Leadership Program, Sackler Faculty of Medicine, Tel Aviv University, Ramat Gan, Israel*

Background: Inflammatory myopathies (IM) are a heterogeneous group of disorders characterized by autoimmune inflammatory destruction of skeletal muscles. It is many times associated with lung, skin and joint involvement. Identifying biomarkers that can differentiate IM from other muscle disorders may elucidate the pathophysiology of IM, guide novel therapies, monitor disease activity/response to treatments and predict prognosis. Exosomes are membrane-bound nanovesicles with diameters of 30-150 nm that contain multiple proteins, nucleic acid, lipids and other molecules in a tissue- and cell-specific manner. Exosomes are secreted by a large variety of cells, play major roles in cell-cell interactions, and have recently emerged as circulating biomarkers in a variety of pathological conditions, including several autoimmune diseases.
Objectives: To characterize exosomes from serum of IM patients, analyze protein expression and study their potential mediators of disease pathologies.
Methods: Serum was collected from patients suffering from IM(n=5) and from patients suffering from Becker (BMD) and Duchenne (DMD) muscular dystrophies (n=6). Exosomes were isolated by Exoquick precipitation and analyzed for size distribution and by nanoparticle tracking analysis (NTA) and by Western blot for exosome markers. The effects of the isolated EVs on human satellite cell proliferation and differentiation and macrophage activation were examined.
Results: Exosomes from IM patients decreased human satellite cell proliferation (51%, P<0.01) and inhibited their myogenic differentiation as indicated by lower fusion index (24% inhibition, P<0.01) and expression of myosin heavy chain (72% inhibition, P<0.001). Similar results were obtained also with exosomes derived from DMD and BMD patients; however, their inhibitory effect were more pronounced on MyoG expression. Treatment of macrophages with exosomes from IM patients significantly increased the expression of IL-10 (3-fold, P<0.001), compared to exosomes of healthy controls and DMD patients. Another significant difference was in the expression of signaling molecules: Thus, exosomes from BMD patients increased the phosphorylation of Erk and p38, whereas a smaller effect was induced by IM exosomes.
Conclusion: Exosomes from IM patients decrease satellite cell proliferation and myogenic differentiation compared to healthy exosomes. In addition, these exosomes increased the expression of IL-10 in macrophages. These effects are unique to exosomes of IM patients compared to muscular dystrophies. These promising results suggest that serum exosomes should be further investigated as a novel biomarker with potential therapeutic implications.

POS0469 ENDOTHELIAL TO MESENCHYMAL TRANSITION AND SENESCENCE ARE PART OF THE FIBROTIC PATHOGENESIS IN SYSTEMIC SCLEROSIS

Y. H. Chiu[1,2], J. Spierings[1], J. M. Van Laar[1], J. De Vries-Bouwstra[3], M. Van Dijk[4], R. Goldschmeding[4]. *[1]University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands; [2]Tri-Service General Hospital, Division of Rheumatology/Immunology/Allergy, Taipei, Taiwan, Republic of China; [3]Leiden University Medical Center, The Department of*

Rheumatology, Leiden, Netherlands; [4]University Medical Center Utrecht, Department of Pathology, Utrecht, Netherlands

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease characterised by inflammation, vasculopathy and fibrosis. Several mechanisms, including endothelial to mesenchymal transition (EndMT) and cellular senescence, may be included in the fibrosis process, especially in response to inflammation and vasculopathy.
Objectives: Our study aimed to identify how EndMT and cellular senescence manifest in SSc skin fibrosis.
Methods: We performed a cross-sectional biobank study on formalin-fixed, paraffin-embedded skin biopsies from patients meeting the ACR/EULAR 2013 classification criteria for SSc. The extent of dermal fibrosis and inflammatory cell infiltration was scored on haematoxylin-eosin stained samples. Fibrosis severity was semi-quantified by the compactness of collagen bundles and scored from one to three. The presence of senescence was defined by P21 or P16 positivity without co-localised Ki-67. The expression of P16, P21, and CTGF on fibroblasts and endothelia was scored from zero to two. The semi-quantitative score was evaluated independently in the superficial and deep dermis by agreement of two researchers (MRD and YHC). EndMT was assessed by co-localisation of CD31 and α-SMA double staining by immunofluorescence, and enclosure of ERG positive endothelial cell nuclei by α-SMA stained cytoplasm under bright field. Lymph vessels were identified by D2-40 (podoplanin) staining, and density was assessed.

Results: In total, skin biopsies from 18 SSc patients and four age-matched healthy controls were investigated. The characteristics of the patients are listed in Table 1. The dermal fibrosis score revealed a correlation with modified Rodnan skin score (Figure 1A).

Table 1. Clinical features of 18 patients with systemic sclerosis

Age, median (IQR)	47 (21)
Female, n (%)	11 (61)
Biopsy site, n (%)	
Upper limb	3 (17)
Trunk	6 (33)
Lower limb	8 (44)
Type of SSc, n (%)	
Limited cutaneous SSc	13 (72)
Diffuse cutaneous SSc	5 (28)
mRSS, median (IQR)	4 (9)
Anti-topoisomerase I antibody positive, n (%)	3 (17)
Anti-RNA polymerase 3 positive, n (%)	2 (11)
Anti-centromere positive, n (%)	3 (17)

SSc, systemic sclerosis; IQR, interquartile range; mRSS, modified Rodnan skin score.

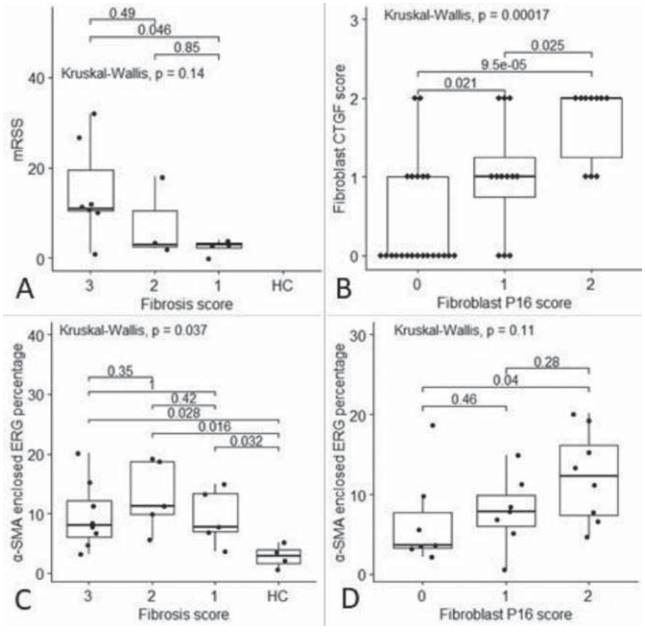

Figure 1. (A) The modified Rodnan skin score (mRSS) was higher in skin biopsies with severe fibrosis. (B) While merging superficial and deep dermis semi-quantitative scores, increased senescence marker was associated with increased CTGF expression on fibroblasts. (C) Endothelial to mesenchymal transition (EndMT) was more in systemic sclerosis skin without difference between groups with various fibrosis severity. (D)EndMT was associated with increased senescence markers on fibroblasts.

Senescence markers showed higher expression on fibroblasts from highly fibrotic dermis than healthy control. The median (IQR) percentage of P16 positive fibroblasts in dermis was 0.7 (0.5) in healthy controls, 0.9 (0.7) in grade one fibrosis, 0.5 (0.5) in grade two fibrosis, and 6.0 (4.6) in grade three fibrosis (p = 0.144). The median (IQR) percentage of P21 positive fibroblasts in dermis was 3.3 (7.0) in healthy controls, 10.3 (11.8) in grade one fibrosis, 33.2 (19.2) in grade two fibrosis, and 32.9 (40.7) in grade three fibrosis (p = 0.042). Moreover, increase of senescence markers on fibroblasts was associated with increased CTGF expression (Figure 1B). The density of blood and lymphatic vessels did not correlate with fibrosis severity. Still, the frequency of EndMT was significantly higher in patients with SSc, although it did not differ between groups with various fibrosis severity (Figure 1C). EndMT was not observed in lymphatic vessels (i.e. there was no co-localisation of D2-40 and α-SMA). Finally, the frequency of EndMT was increased with stronger fibroblast senescence (Figure 1D).
Conclusion: EndMT and fibroblast senescence were more prominent in SSc skin compared to healthy control skin. Strong fibroblast senescence was associated with EndMT. Fibroblast senescence might facilitate EndMT and be involved in SSc fibrosis.

POS0470 FOSL-2 TRANSCRIPTION FACTOR REGULATES MACROPHAGE POLARIZATION AND PHAGOCYTOSIS IN SYSTEMIC SCLEROSIS

A. Hukara[1], T. Tabib[2], M. Rudnik[1], O. Distler[1], P. Blyszczuk[1], R. Lafyatis[2], G. Kania[1]. *[1]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland; [2]University of Pittsburgh, Division of Rheumatology and Clinical Immunology, Department of Medicine, Pittsburgh, United States of America*

Background: Macrophages play a crucial role in the development and progression of systemic sclerosis (SSc). Pathological effects of the AP-1 transcription factor Fos-related antigen 2 (Fosl-2) have been associated with SSc. However, the exact role of Fosl-2 in macrophage function in SSc has not been clarified.
Objectives: To study macrophage functions in SSc with a focus on Fosl-2 as a potential regulator.
Methods: Human monocyte-derived macrophages (hMDM) were differentiated from $CD14^+$ blood-derived monocytes from healthy controls and SSc patients. Published data of single cell RNA sequencing (scRNAseq) of human explanted lung tissue from SSc-ILD patients[1] and skin from dcSSc patients[2] was further analyzed using the R package Seurat V2.3.4. Peritoneal macrophages were isolated from Fosl2 overexpressing transgenic (Fosl2tg), $Csf1R^{Cre}Fosl2^{fl/fl}$, wild-type (wt) and $Fosl2^{fl/fl}$ mice. Protein expression was detected by Western Blot. Phagocytic activity in hMDM was detected using pHrodo Red *E.coli* particles and *in vivo* phagocytosis of phagocytic dye aggregates in peritoneal macrophages was assessed 4 hours post injection and detected by flow cytometry. Surface marker expression was measured using human or mouse macrophage polarization panels by flow cytometry.
Results: SSc hMDM (n=18-25) showed increased Fosl-2 protein expression (untreated: p<0.01, LPS stimulated: p<0.01) compared to healthy hMDM (n=11-18). Phenotypical characterization of untreated SSc hMDM (n=17) displayed an increased percentage of $CD40^+CD86^+CD206^+PD\text{-}L2^+CD163^+$ cells (p<0.05) compared to healthy hMDM (n=7). Additionally, we found enhanced phagocytic activity in untreated (p<0.01) and LPS stimulated (p<0.05) SSc hMDM (n=29-34) compared to healthy hMDM (n=12-16). To assess the role of Fosl-2 in other macrophage types, we performed scRNAseq analysis of the SSc-ILD lung dataset, which lead to the identification of differentially expressed macrophage polarization (*CD206*) and phagocytosis-associated genes (*MARCO*/*C1QA*/*C1QB*/*C1QC*) in $SPP1^{hi}$ macrophages from SSc-ILD patients when comparing $FOSL2^{hi}$ and $FOSL2^{null}$ cells. Moreover, independent of *FOSL2* expression phagocytosis-associated *ARPC1B*/*ARPC2*/*ARPC5* genes were upregulated in $SPP1^{hi}$, $FABP4^{hi}$ and $FCN1^{hi}$ macrophages in SSc-ILD patients (p.adj.≤0.05; log2 ratio≥0.5). Similarly, to the alternatively-activated macrophages in SSc-ILD lungs, scRNAseq of dcSSc skin tissue revealed increased expression of *CD204*/*CD163*/*CD36* in $CCR1^+$ macrophages. Further, $FOSL2^{hi}$ $CCR1^+$ skin macrophages showed higher expression of phagolysosome-associated *CARO1A* and *ARL8B* genes compared to $FOSL2^{null}$ cells (p.adj.≤0.05; log2 ratio≥0.5). In the immunofibrotic animal model of SSc, Fosl2tg peritoneal macrophages showed enhanced expression of alternatively-activated CD206 (p=0.0591) and PD-L2 (p<0.05) polarization markers compared to wt cells (n=5-9). $Csf1R^{Cre}Fosl2^{fl/fl}$ peritoneal

macrophages displayed a reduced expression of CD206 ($p<0.05$) and PD-L2 ($p<0.01$) markers compared to $Fosl2^{fl/fl}$ controls (n=5-9). Preliminary data indicated that Fosl2tg $MHCII^+$ and $CD36^+$ peritoneal macrophages showed a trend towards elevated phagocytic activity compared to wt cells (n=3). $Csf1R^{Cre}Fosl2^{fl/fl}$ peritoneal macrophages did not show a significant difference in phagocytic activity (n=3) compared to $Fosl2^{fl/fl}$ controls.

Conclusion: For the first time, we showed an increased expression of Fosl-2 and boosted phagocytic activity in SSc hMDM. scRNAseq analyses revealed upregulated phagocytosis-related genes with association to alternatively-activated macrophage polarization in different macrophage clusters in SSc-ILD lungs and dcSSc skin. Moreover, our animal data indicated an involvement of Fosl-2 regulating alternatively-activated macrophage polarization and phagocytosis. Therefore, targeting this alternative/pro-phagocytic phenotype represents an effective tool to counteract disease progression.

Background: Antibodies directed to the angiotensin receptor type 1 (AT1R) were found to be increased in patients with SSc ad they predict mortality and SSc complications (1, 2). In vitro studies suggested an involvement in the pathogenesis of systemic sclerosis (SSc).

Objectives: Here, we aim to determine the contribution and functions of AT1R autoantibodies (Abs) in vivo and in vitro as well as their capacity to recognize AT1R from different species.

Methods: C57BL/6J mice were immunized with membrane-embedded human AT1R or empty membrane as control. Phenotypic properties of various organs were examined by immunohistochemistry, immunofluorescence, and TUNEL apoptosis assay. A monoclonal (m)AT1R Ab was generated based upon this mouse model by hybridoma technology and transferred into C57BL/6J mice. Mice deficient for CD4+ and CD8+ T cells, B cells and AT1Ra/b served as controls. In vitro, Abs responses towards AT1R were measured using rat cardiomyocytes, human epithelial cells, AT1R-transfected HEK293 cells and primary human monocytes.

Results: AT1R-immunized mice developed perivascular skin and lung inflammation, lymphocytic alveolitis, weak endothelial apoptosis and skin fibrosis, not present in controls or mice deficient for CD4+ T and B cells. The contribution of AT1R Abs to skin manifestations and interstitial lung disease was demonstrated by application of a mAT1R Ab, which induced skin and lung inflammation, not observed in the AT1Ra/b knockout mice. IgG from immunized mice containing AT1R Abs and/or the mAT1R Ab activated rat cardiomyocytes and human monocytes. Treatment of AT1R-transfected HEK293 cells with the mAT1R Ab enhanced AT1R signaling in the presence of the endogenous agonist Angiotensin II.

Conclusion: Our immunization strategy successfully induced AT1R Abs, contributing to inflammation and most likely to fibrosis via activation of AT1R. Therefore, AT1R Abs are valuable targets for future therapies in SSc and possibly other AT1R Ab-related diseases.

POS0472

AGONISTIC STIMULATION OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AMELIORATED INFLAMMATORY MYOPATHIES THROUGH SUPPRESSING MUSCLE FIBER NECROPTOSIS

M. Kamiya[1], F. Mizoguchi[1], H. Sasaki[1], N. Umezawa[1], S. Yasuda[1]. [1]*Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Department of Rheumatology, Tokyo, Japan*

Background: While glucocorticoids (GC) are the cornerstone of the treatment for polymyositis (PM), GC-induced myopathy is inevitable, which further deteriorates muscle weakness. Therefore, novel therapeutic strategy that not only suppresses muscle inflammation but also improves muscle strength is awaited. We recently found that injured muscle fibers in PM undergo FASLG-mediated necroptosis[1], a form of regulated cell death accompanied with release of pro-inflammatory mediators such as HMGB1, which contributes to accelerate muscle inflammation and muscle weakness. We also showed that inhibition of necroptosis or HMGB1 ameliorated the muscle weakness and muscle inflammation[1] in C protein-induced myositis (CIM), a murine model of PM. Glucagon-like peptide-1 receptor (GLP-1R) agonists, which have been developed as an anti-diabetic therapy, have pleiotropic actions including anti-inflammatory effects[2], suppression of muscle wasting[3], and inhibition of cell death[4]. Accordingly, we hypothesized that GLP-1R agonists have beneficial effects on PM to recover muscle strength and to suppress muscle inflammation.

Objectives: The aims of this study are to examine the role of GLP-1R in PM and the effect of a GLP-1R agonist on in vivo and in vitro models of PM.

Methods: Muscle specimens of PM patients and CIM were examined with immunofluorescence staining for the expression of GLP-1R. The effect of PF1801, a GLP-1R agonist, on CIM was examined in monotherapy or in combination with prednisolone (PSL). As an in vitro model of PM, C2C12-derived myotubes were treated with FAS ligand (FASLG) to induce necroptosis. The levels of HMGB1, TNF-α, and IL-6 in the serum of CIM and in the culture supernatant of the in vitro model were measured by ELISA. The effect of PF1801 on the myotube necroptosis was examined using time lapse imaging [5] and its effect on the activation of AMP-activated protein kinase (AMPK), the expression of PGAM5, and ubiquitination of PGAM5 was assessed with immunoblotting. The levels of reactive oxygen species (ROS) in the myotubes were analyzed with CellROX assay. The

effect of PF1801 on the expression of antioxidant molecules in the myotubes was analyzed with quantitative real-time PCR.

Results: GLP-1R was expressed on the inflamed muscle fibers of PM and CIM. The treatment with PF1801 in monotherapy or in combination with PSL suppressed CIM-induced muscle weakness and the muscle weight loss as well as the severity of histological myositis while the monotherapy with PSL did not suppress muscle weakness and muscle weight loss. PF1801 decreased the levels of inflammatory mediators such as HMGB1, TNF-α, and IL-6 in the serum of CIM. In vitro, PF1801 inhibited FASLG-induced myotube necroptosis and decreased the levels of HMGB1, TNF-α, and IL-6 in the supernatant. PF1801 activated AMPK and decreased the levels of PGAM5, which was crucial for FASLG-induced necroptosis of the myotubes. The inhibitory effect of PF1801 on myotube necroptosis was cancelled by compound C, an AMPK-kinase inhibitor, or MG132, a proteasome inhibitor, suggesting that PF1801 promoted ubiquitin-proteasome-mediated PGAM5 degradation through the activation of AMPK. Furthermore, PF1801 suppressed FASLG-induced reactive oxygen species (ROS) accumulation in myotubes, which was also crucial for the execution of necroptosis, thorough up-regulating the antioxidant molecules such as *Nfe2l2*, *Hmox1*, *Gclm*, and *Nqo1*.

Conclusion: GLP-1R agonist could be a novel therapy for PM that restores muscle strength as well as suppresses muscle inflammation through inhibiting muscle fiber necroptosis.

POS0473 INFLAMMATORY-PRIMED MUSCLE CELLS INFLUENCE MACROPHAGE CYTOKINE SECRETION IN A MYOSITIS CONTEXT

B. Mccord[1], R. Day[1]. *[1]Centre for Precision Healthcare, Division of Medicine, University College London (UCL), London, United Kingdom*

Background: Sporadic inclusion body myositis (sIBM) is a progressive disease causing muscle weakness and mobility issues. It is characterised by inflammatory and degenerative features; however there is no clear single cause for sIBM symptoms. Inflammatory factors include macrophage infiltration into muscle fibres and presence of high levels of inflammatory cytokines such as IFNγ [1]. Degenerative features within muscle fibres include sarcoplasmic inclusions containing aggregated proteins. p62 and TAR DNA-binding protein 43 (TDP-43) are two proteins that are found in inclusion bodies, and these have been suggested as sensitive diagnostic markers differentiating sIBM from other inflammatory myopathies [2]. Currently there is limited understanding of the pathogenic mechanisms underlying sIBM, and no effective treatments.

Objectives: The aim of this study is to investigate the interplay between inflammatory and degenerative features of sIBM with a focus on macrophage secreted factors, p62 and TDP-43 sarcoplasmic aggregation. Firstly, to examine whether skeletal muscle cells that have previously been exposed to an inflammatory environment can in turn influence the inflammatory response of macrophages. Secondly, by investigating if macrophage-secreted inflammatory factors influence p62 and TDP-43 sarcoplasmic aggregates. This will give insight into whether macrophage inflammation precludes skeletal muscle degeneration in an sIBM context or vice versa.

Methods: Primary human myogenic cells from healthy individuals were differentiated into myotubes for 7 days, with further 48-hour 20 ng/mL IL-1β and 750 ng/mL IFNγ incubation to form inflammatory-primed myotubes. Conditioned media (CM) was collected from washed myotubes after 24 hours. $6x10^5$ THP-1 cells/mL were differentiated to unprimed M(PMA) macrophages with 150 nM phorbol 12-myristate 13-acetate (PMA) for 24 hours, followed by 72-hour PMA-free rest. Inflammatory-primed M(IFNγLPS) THP-1 were generated from M(PMA) with 48-hour IFNγ and lipopolysaccharide (LPS) incubation. 20 % CM from myotubes was added to M(PMA) or M(IFNγLPS) THP-1 for 24 hours, before washing and measuring IL-6 and TNFα release from macrophages via ELISA. 20 % CM from M(PMA) or M(IFNγLPS) was added to myotubes for 48 hours before quantifying TDP-43 and p62 aggregates with image analysis.

Results: M(IFNγLPS) THP-1 secreted higher levels of IL-6 and TNFα than M(PMA). M(PMA) or M(IFNγLPS) exposed to conditioned media from control or inflammatory-primed myotubes had no detectable TNFα secretion. For both M(PMA) and M(IFNγLPS), addition of inflammatory-primed myotube CM caused higher IL-6 secretion than adding control myotube CM. Incubating unprimed myotubes with M(PMA) or M(IFNγLPS) CM had no effect on the presence, size, or frequency of p62 or TDP-43 sarcoplasmic aggregates compared to control conditions.

Conclusion: Inflammatory priming myotubes with IL-1β and IFNγ caused a response in macrophages that increased IL-6 production. However, CM from inflammatory-primed myotubes did not influence TNFα secretion from macrophages compared to control myotube CM. IL-6 has pleiotropic effects on skeletal muscle [3], promoting both hypertrophy and atrophy under different conditions. Therefore the effects of macrophage IL-6 upregulation on muscle is unclear. Culturing myotubes in unprimed or inflammatory-primed macrophage conditioned media did not influence p62 or TDP-43 sarcoplasmic aggregation. This suggests macrophage secretory factors are not responsible for the sIBM degenerative features of p62 and TDP-43 aggregation.

POS0474 ACTIVATION AND HYPERSENSITIZATION OF THE ANGIOTENSIN II TYPE 1 AND ENDOTHELIN-1 TYPE A RECEPTORS BY AGONISTIC AUTOANTIBODIES CONTRIBUTES TO VASCULAR INJURY IN SCLERODERMA RENAL CRISIS

B. Hegner[1], R. Schindler[1], G. Riemekasten[2], P. Scheerer[3], A. Philippe[1], R. Catar[1]. *[1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Nephrology and Critical Care Medicine, Campus Virchow Klinikum, Belin, Germany; [2]University of Lübeck, University Clinic of Schleswig-Holstein, Rheumatology and Clinical Immunology, Lübeck, Germany; [3]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Institute of Medical Physics and Biophysics, Group Protein X-ray Crystallography and Signal Transduction, Berlin, Germany*

Background: Scleroderma renal crisis (SRC) is a vascular complication of systemic sclerosis (SSc) with substantial risks for end-stage renal disease and death. Activating autoantibodies (Abs) targeting the angiotensin II type 1 (AT1R) and the endothelin-1 type A receptor (ETAR) are suggested to contribute to the vasculopathy in SSc (1, 2).

Objectives: Here, we sought to determine their pathogenic significance for acute renal vascular injury.

Methods: IgG from patients with SRC was studied for AT1R and ETAR dependent biologic effects on isolated rat renal interlobar arteries and vascular cells including contraction, signaling, and mechanisms of receptor activation. A cohort of ten patients with refractory SRC received multimodal treatment including AT1R and ETAR inhibition and plasma exchange and was followed for improvement of kidney function.

Results: In myography experiments, patient IgG exerted vasoconstriction (mean 6.5% of KCl induced contraction [95% confidence interval (95 CI) 5.0-8.1]) whereas control IgG did not (0.6% [95 CI 0.3-1.0]). The response was sensitive to inhibition of AT1R (3.0% [95% CI 1.4-4.7]) and ETAR (1.0% [95 CI 0.6-1.3]) and relied on MEK-ERK signaling. Contraction induced by angiotensin II and endothelin-1 was amplified by anti-AT1R and anti-ETAR Abs with substantial crosstalk between both receptors implicating autoimmune receptor hypersensitization. Co-immunoprecipitation experiments indicated heterodimerization between both receptor types enabling functional interrelation by structural interactions. 30% of patients with refractory SRC had improved kidney function after multimodal therapy.

Conclusion: We provide experimental and clinical evidence that agonistic Abs may contribute to SRC. Novel therapies targeted at autoimmune hyperactivation of AT1R and ETAR might improve outcomes in severe cases of SRC.

POS0475

ROLE OF IL-33/ST2 AXIS IN SYSTEMIC SCLEROSIS PATIENTS WITH ELECTROCARDIOGRAPHIC ABNORMALITIES

G. Pellegrino[1], T. Colasanti[1], I. Bisconti[1], M. Cadar[1], F. R. DI Ciommo[1], D. M. Reza Beigi[1], K. Stefanantoni[1], A. Gigante[2], E. Rosato[2], F. Conti[1], V. Riccieri[1]. [1]*Sapienza University of Rome, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy;* [2]*Sapienza University of Rome, Department of Translation and Precision Medicine, Rome, Italy*

Background: Electrocardiographic (EKG) abnormalities are described in 25-75% Systemic Sclerosis (SSc) patients and they are associated with other systemic manifestations[1] as well as with a worse prognosis.[2] There is an increasing need for clinical and laboratory biomarkers to ameliorate the diagnostic approaches to patients with EKG abnormalities.[3] In the last decade, many studies focused on the components of the interleukin (IL)-33/ST2 axis. Under physiological conditions, IL-33 is released by apoptotic cardiac cells, promoting a protective mechanism of cell survival, thanks to the binding with its transmembrane receptor ST2.[4] During pathological cardiovascular events, an abnormal secretion of the IL-33 soluble receptor (sST2) by Th2 cells occurs. It binds IL-33 not allowing the physiological mechanism driven by the IL-33/ST2 binding previously described.[4] For these reasons, sST2 has been proposed as a biomarker of cardiac injury in a variety of diseases.[5]

Objectives: Aim of this study was to analyse clinical and demographical parameters in a group of SSc patients, trying to define any possible feature associated with EKG abnormalities. Furthermore, the role of IL-33/ST2 axis components as biomarkers of cardiac injury in patients with SSc-related EKG abnormalities was evaluated, also assessing the possible correlation with serum concentration of NT-pro-BNP, a well-known cardiac injury biomarker in SSc.

Methods: Data from 277 SSc patients, fulfilling the 2013 ACR/EULAR classification criteria,[6] attending our Scleroderma Clinic were retrospectively analysed. We selected patients with EKG trace and a blood sample available, collected after the SSc diagnosis. The sera levels of sST2 (ELISA Kit, Abcam), IL-33 (ELISA kit, RayBiotech) and NT-pro-BNP (ELISA Kit, Abcam) were measured. Patients with a history of heart diseases occurring before the diagnosis of SSc or features of secondary cardiac involvement (pulmonary arterial hypertension, severe interstitial lung disease or renal disease) were excluded.

Results: Forty-six SSc patients showed significant EKG abnormalities (rhythm and conduction disorders). Thirty-one SSc patients without pathologic finding at EKG traces were recruited as the control group. From the analysis of the clinical characteristic of the disease at the moment of serum collection, patients with EKG anomalies have more frequently both a diffuse form of disease (*n*°-%: 23-50 vs 7-23; *p* 0.01), with a mean value of mRSS higher than controls (11±9 vs 6±6; *p* 0.01), and a scleroderma "late" pattern at the nailfold capillaroscopy (*n*°-% 23-50 vs 6-19; *p* 0.027). Significantly higher median values of serum levels of sST2 in SSc patients with EKG disorders compared to the control group (4289pg/mL, IQR 2383 vs 2560 pg/mL, IQR 1455; *p 0.0002*) were detected, while opposite results were found analyzing serum levels of IL-33 (2.89 pg/mL IQR 101 vs 9 pg/mL IQR 277; *p* 0.032) (Graph 1). Serum NT-pro-BNP median values were significantly higher in the group of patients with EKG abnormalities than in the control group (149 pg/mL, IQR 354 vs 26 pg/mL, IQR 62; *p* 0.0007). These values correlated with sST2 serum levels (rho Spearman correlation 0.37; *p* 0.0006).

Conclusion: SSc patients with EKG abnormalities showed an increased skin and vascular involvement with respect to the control group. These associations could help clinicians in clinically stratifying SSc patients at risk of EKG abnormalities. To our knowledge, this is the first report evaluating the serum concentration of sST2 in SSc patients. Based on these results, we can speculate on the role of this molecule as potential biomarkers of early cardiac injury during SSc, although further studies involving a larger cohort of patients are needed.

POS0476

THE NUCLEAR RECEPTOR TR4 ORCHESTRATES CYTOSKELETAL ORGANIZATION IN A Gα12/ ROCK-DEPENDENT MANNER TO PROMOTE MYOFIBROBLAST DIFFERENTIATION AND TISSUE FIBROSIS IN SYSTEMIC SCLEROSIS

L. Shen[1], Y. Zhang[1], Z. Honglin[2], J. H. W. Distler[1]. [1]*Friedrich-Alexander University Hospital University of Erlangen-Nürnberg (FAU), Department of*

Internal Medicine III and Institute for Clinical Immunology, Erlangen, Germany; [2]Xiangya Hospital and Central South University, rheumatology, Changsha, China

Background: Nuclear receptors (NR) are a family of transcription factors. Several members of the NR family are candidates for targeted intervention in inflammatory and fibrotic diseases (1-2). Testicular receptor 4 (TR4), also known as Nr2c2, has been shown to regulate fundamental cellular processes such as differentiation, proliferation and growth factor signaling (3-4). However, its role in fibrotic diseases has not been investigated so far.
Objectives: The aim of the present study was to characterize the role of TR4 in the pathogenesis of fibrotic tissue remodeling in SSc and to interrogate its underlying mechanism.
Methods: Expression of TR4 was quantified by RT-PCR, Western blot and immunofluorescence. The effects of TR4 knockdown on collagen production and myofibroblast differentiation were analyzed in cultured human fibroblasts and in three mouse models with fibroblast-specific knockout of TR4. RNA sequencing was performed in TGFβ-stimulated human dermal fibroblasts transfected with TR4 siRNA or non-targeting siRNA. The implication of TR4 in cytoskeleton regulation was analyzed by ROCK activity assays, stress fiber formation and quantification of the ratio of filamentous (F)-actin/ globular (G)-actin. The functional role of ROCK and Gα12 was analyzed using small molecule inhibitors and siRNA, respectively.
Results: TR4 expression was upregulated in fibroblasts in the skin of SSc patients and fibrotic mouse models. The expression of TR4 was upregulated in a TGFβ- and SMAD3-dependent manner. TR4 knockdown inhibited TGFβ-induced myofibroblast differentiation and collagen release, whereas overexpression of TR4 promoted fibroblast activation. Fibroblastspecific knockout of TR4 ameliorated experimental dermal fibrosis induced by bleomycin, adTBR and in sclGVHD with decreases in dermal thickening, myofibroblast counts and hydroxyproline content. The RNASeq of TR4 knockdown fibroblasts stimulated with TGFβ identified 651 differentially expressed genes as compared to control fibroblasts. Differentially expressed genes included central profibrotic genes such as ACTA2, COL3A1, CCL12. gProfiler enrichment analysis of the TR4-DEGs revealed enrichment of multiple GO, GSEA and Reactome terms related to ECM release, cytoskeleton organization and Rho GTPases activity. Indeed, knockdown of TR4 ameliorated the induction of ROCK activity by TGFβ stimulation and reduced the shift in the ratio from globular (G) actin to filamentous (F) actin. Knockdown of TR4 strongly reduced the expression of the G-protein alpha-12 (Gα12). ROCK inhibition by Y27632 or knockdown of Gα12 inhibited the induction of αSMA and stress fiber formation induced by overexpression of TR4.
Conclusion: TR4 is upregulated in SSc in a TGFβ-dependent manner to promote fibroblast activation. Inhibition of TR4 interferes with TGFβ-induced activation of ROCK, prevents cytoskeletal remodeling and fibroblast-to-myofibroblast transition and ameliorates experimental fibrosis. As nuclear receptors are common targets for therapeutic intervention, TR4 may offer potential for antifibrotic therapies.

POS0477 ATTENUATION OF FIBROBLAST ACTIVATION AND FIBROSIS BY ADROPIN IN A HEDGEHOG-DEPENDENT MANNER

M. Liang[1,2], J. H. W. Distler[1]. [1]*Erlangen, Department of Internal Medicine 3, Erlangen, Germany;* [2]*Huashan Hospital, Department of Rheumatology, Shanghai, China*

Background: Adropin is a secretory protein encoded by the energy homeostasis-associated (*ENHO*) gene. Emerging evidence indicate its role in metabolism and energy homeostasis, which is known to be deregulated in SSc. However, adropin/*ENHO* has not been linked to the pathogenesis of fibrosis, tissue remodeling or fibroblast activation so far.
Objectives: The aim of the current study was to investigate the role of adropin/*ENHO* in the pathogenesis of fibroblast activation and fibrosis in SSc.
Methods: Machine learning and bioinformatics models were used to identify candidate genes regulating fibroblast activation in SSc. The expression of adropin/*ENHO* in skin samples of SSc patients and healthy individuals was analyzed by quantitative PCR, immunofluorescence and western blot, and validated by *in silico* data mining. The effects of adropin were analyzed in cultured human fibroblasts, 3D skin equivalents, and complimentary murine models of SSc, including sclerodermatous GvHD (sclGvHD) and bleomycin-induced lung fibrosis mice. RNA sequencing (RNAseq) was performed to identify downstream regulatory pathways.
Results: Biostatistical screening of publically available datasets identified adropin/*ENHO* as a potential molecular mediator involved in fibroblast activation with pronounced downregulation in SSc skin. We first confirmed the impaired expression of adropin/*ENHO* in SSc patients and SSc models. TGFβ reduced adropin/*ENHO* expression in a JNK-dependent manner. Recombinant Adropin peptides in turn inhibited TGFβ-induced fibroblast activation and subsequent fibrosis. Treatment of biologically active peptides adropin$^{34-76}$ inhibited TGFβ induced fibroblast activation and extracellular matrix (ECM) production in cultured primary dermal fibroblasts, as well as in 3D skin equivalents. Moreover, therapeutical administration of adropin$^{34-76}$ in mice with preestablished fibrosis exerted potent antifibrotic effects in skin and lungs of two complimentary murine SSc models, sclGvHD and bleomycin-induced lung fibrosis mice. RNAseq demonstrated the antifibrotic effects of adropin were functionally linked to hedgehog signaling and GLI1 deactivation, which experimentally confirmed *in vitro* and *in vivo*. Knockdown of *GPR19*, a putative receptor of adropin, abrogated the therapeutic effect of adropin on αSMA- and GLI1-expression in fibroblasts, indicating adropin may regulate GLI1 signaling and fibroblast activation via GRP19.
Conclusion: We demonstrate a novel regulatory loop of adropin/*ENHO* in TGFβ signaling: TGFβ inhibits the expression of adropin/*ENHO*, while recombinant adropin peptides inhibited fibroblast activation by GPR19-dependent inhibition of hedgehog/GLI1 signaling. Our findings characterize adropin peptides as a potential approach to interfere with aberrant fibroblast activation and tissue fibrosis in SSc.

POS0478 TOPICAL CALCIUM CHELATORS FOR TARGETING CUTANEOUS CALCIFICATION: PRECLINICAL EVIDENCE OF EFFICACY

K. Burgess[1], R. Winpenny[2], A. Saiani[3], A. Herrick[4,5], R. Watson[1,6,7]. [1]*The University of Manchester, Centre for Dermatology Research, Manchester, United Kingdom;* [2]*The University of Manchester, Department of Chemistry, Manchester, United Kingdom;* [3]*The University of Manchester, Department of Materials, Manchester, United Kingdom;* [4]*The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom;* [5]*NIHR Manchester Biomedical Research Unit, Musculoskeletal Research, Manchester, United Kingdom;* [6]*Salford Royal NHS Foundation Trust, Centre for Dermatology, Salford, United Kingdom;* [7]*NIHR Manchester Biomedical Research Unit, Dermatology, Manchester, United Kingdom*

Background: Cutis calcinosis, defined as sub-epidermal deposition of calcium salts, is a painful, disabling, disfiguring, problem in 20-40% of patients with systemic sclerosis. Its pathogenesis remains poorly understood and currently there is no effective disease-modifying pharmacotherapy. One potential strategy is topical application of calcium chelating agents, able to penetrate the epidermal barrier and dissolve subcutaneous calcinotic deposits *in situ*. To date, the only

compound reported for this application has been sodium thiosulfate (STS), with often-contradictory results.

Objectives: To test the hypothesis, in pre-clinical studies, that polycarboxylic acids can induce calcium dissolution without skin toxicity, with the long-term aim of developing an effective topical treatment for cutis calcinosis.

Methods: We compared the metal ion-chelating agents citric acid (CA) and ethylenediaminetetraacetic acid (EDTA) - polycarboxylic acids with well-characterised chelation profiles – to STS for their ability to chelate calcium, without inducing cytotoxicity or inflammation (pro-inflammatory cytokine expression and release), using in vitro 2D (keratinocyte [HaCaT]; fibroblast ([HCA2]) and recombinant human epidermal (RHE) models. The resultant data was subsequently used to predict therapeutic concentrations for assessment in a validated skin irritation model (SkinEthicTM; Episkin SA) and to assay maximal percutaneous absorption. At relative dermal concentrations, the dissolution performance of each chelator was further assessed using two different models of calcinosis: 1) pharmaceutical dissolution of a hydroxyapatite (HAp) tablet (1) and; 2) dissolution of a calcified extracellular matrix laid down by mineralising SaOS2 in vitro monolayer culture (2).

Results: Incubation with CA, EDTA and STS induced cytotoxicity in both *in vitro* cell lines studied at concentrations of >10 mM; only EDTA (10 mM) resulted in inflammatory cytokine release (IL8) from cells at these higher concentrations (*cf* positive control, Lipopolysaccharide 10 mg/mL). When applied topically to RHE models as near-saturated solutions, none of the chelators were categorised as skin irritants. Due to differences in their relative aqueous solubility, higher concentrations of CA (1600 mM) and STS (1200 mM) could be delivered through the RHE model than EDTA (200 mM). Using a simple linear regression model, the rate of compound absorption was: CA, 0.43 ± 0.05; STS, 0.26 ± 0.03 and; EDTA, 0.05 ± 0.01 g/L/hr. At each time-point, the cumulative concentration of compound in the receptor media was CA > STS > EDTA. Incubation with chelators had no effect on the integrity of the RHE by standard histology. Based on the rate of percutaneous absorption, the dissolution performance of each chelator was tested at relative dermal concentrations for phosphate dissolution (nmoles) of HAp (CA, 9.61 ±0.97; EDTA, 5.38 ± 0.28; 3.78 ± 0.58) and in the calcified *in vitro* model (Figure 1; CA, 3285 ± 105, STS, 947 ± 95, EDTA, 1174 ± 89), showing the superiority of CA in both model systems.

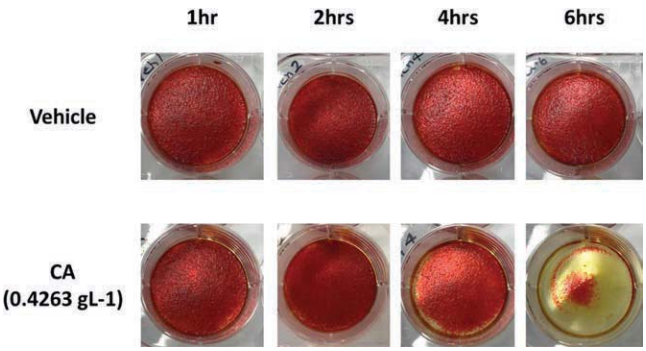

Figure 1. Dissolution of a calcified extracellular matrix by citric acid

Conclusion: Overall, this study highlights the promise of polycarboxylic acids, particularly CA, to target subcutaneous calcification, which are neither toxic nor inflammatory to the skin. Specifically, we have identified CA as a potentially more efficacious alternative to STS for the topical treatment of cutis calcinosis.

POS0479

STAT3 DEGRADERS PROTECT FROM IMMUNOFIBROTIC CHANGES IN PRECLINICAL MODELS

P. Blyszczuk[1,2], G. Kania[1], E. Pachera[1], F. Rolski[2], A. Hukara[1], V. Tela[1], M. Mayo[3], V. Dixit[3], B. Yang[3], J. Gollob[3], N. Mainolfi[3], A. Slavin[3], C. Hubeau[3], O. Distler[1]. [1]*University of Zurich, Department of Rheumatology, Zurich, Switzerland;* [2]*Jagiellonian University Medical College, Department of Clinical Immunology, Cracow, Poland;* [3]*KYMERA THERAPEUTICS, INC., KYMERA THERAPEUTICS, INC., Watertown, United States of America*

Background: The ubiquitin-proteasome system (UPS) is the endogenous intracellular mechanism for maintaining protein homeostasis through protein degradation and turnover. Heterobifunctional small molecules are a new class of compounds that form a ternary complex with an E3 ligase and protein of interest leading to ubiquitination and subsequent degradation of the protein of interest in a process known as Targeted Protein Degradation. This new therapeutic modality enables targeting of "undruggable" proteins such as STAT3, a transcription factor activated in immunofibrotic diseases.

Objectives: Kymera has developed heterobifunctional molecules that potently and selectively target STAT3 for degradation and elimination by the ubiquitin-proteasome pathway. The aim of these studies was to evaluate the therapeutic potential of pharmacologically removing STAT3 by targeted protein degradation in various human cell types in vitro, and to prevent the development of skin and lung fibrosis in vivo.

Methods: Dermal fibroblasts obtained from healthy and systemic sclerosis patients activated with TGF-β were analyzed for development of α-smooth muscle actin (α-SMA)-positive stress fibers and for contractility using collagen gel contraction assay. Contraction assay was also performed using human dermal smooth muscle cells. Human aortic endothelial cells (HAECs) were activated with LPS, and their adhesive properties were assessed in the microcapillary system by the ability to bind peripheral blood mononuclear cells (PBMCs) under shear stress. HAECs proliferation was induced with VEGF. THP-1 cells and $CD14^+$ monocytes were activated with IL-6 or LPS, and secreted cytokines were assessed by CBA. PBMCs activated with LPS, IL-6, IL-21, or IL-23 alone (pSTAT3 induction), or with a combination of anti-CD3/CD38 beads and a pro-Th17 cocktail comprised of cytokines and antibodies to evaluate the development of a Th17 and Treg phenotype by flow cytometry. Cytokines were analyzed by ELISA. All cell types were pre-treated with STAT3 degraders 20h prior to experiment start. Intratracheal instillation of bleomycin was used to induce pulmonary fibrosis. Transgenic Tsk-1 mice were used as a model of spontaneous skin fibrosis.

Results: STAT3 degraders completely ablated STAT3 in all analyzed cell types with DC50 ranging from 0.25-0.8 nM. STAT3 degradation prevented TGF-β-induced formation of α-SMA-positive stress fibers in dermal fibroblasts (IC50 = 0.35nM) and 2 and 10nM degrader completely abrogated their contractility. Similarly, STAT3 degradation reduced the constitutive contractility of dermal smooth muscle cells of 13% ($p<0.05$, n=6). Treatment of HAECs with STAT3 degraders resulted in anti-adhesive 178±21 for LPS and 93±12 for LPS +degrader, $p<0.05$, n=6) and anti-proliferative 1.2±0.1 for VEGF and 0.95±0.1 for VEGF +degrader, $p<0.05$, n=10-11) effects. In monocyte-focused assays (CD14+ monocytes and THP-1 cells), STAT3 degradation potently and dose-dependently inhibited IL-6 and LPS-induced pSTAT3 levels and the ensuing release of MCP-1/CCL2 (24.3±3.7 for LPS and 20.2±3.2 for LPS +degrader, $p<0.05$, n=6). In CD4+ T lymphocytes, STAT3 degradation promoted a Treg phenotype and suppressed the development of Th17 cells. Systemic treatment in vivo showed that prophylactic STAT3 degradation (7 mg/kg twice a week, i.p.) reduced disease severity in the bleomycin-induced pulmonary fibrosis model (Ashcroft's score, 4.7±1.9 vs. 3.1±1.6, $p<0.05$, n=11). In Tsk-1 mice that show co-occurrence of spontaneous skin thickening and robust STAT3 activation, STAT3 degrader treatment (2 or 7 mg/kg twice a week, i.p.) for 7 weeks significantly reduced thickness of the skin (701±238 vs. 480±205 vs. 365±107, $p<0.05$, n=6-8).

Conclusion: STAT3 degraders that selectively and potently eliminate STAT3 show robust anti-inflammatory and anti-fibrotic potential in vitro and in vivo. Our results suggest that targeted protein degradation is a promising approach to modulate the STAT3 pathway, making it a novel therapeutic opportunity to treating multiple immunofibrotic diseases.

POS0480 VITAMIN D AND ITS RECEPTOR (VDR) GENE EXPRESSION IN SKELETAL MUSCLE ASSOCIATE WITH DISEASE AND MUSCLE FUNCTION PARAMETERS IN IDIOPATHIC INFLAMMATORY MYOPATHIES

L. Vernerová[1], M. Vokurková[1], S. Oreska[1,2], M. Špiritović[1,3], M. Klein[1,2], T. Kropackova[1], V. Horvathova[1], M. Tomčík[1,2], J. Ukropec[4], B. Ukropcová[4,5], J. Vencovský[1,2]. *[1]Institute of Rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic; [2]First Faculty of Medicine, Charles University, Department of Rheumatology, Praha, Czech Republic; [3]Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Praha, Czech Republic; [4]Biomedical Research Center, Slovak Academy of Sciences, Institute of Experimental Endocrinology, Bratislava, Slovakia (Slovak Republic); [5]Faculty of Medicine, Comenius University, Institute of Pathophysiology, Bratislava, Slovakia (Slovak Republic)*

Background: Idiopathic inflammatory myopathies (IIM) are chronic inflammatory disorders characterised, apart from extramuscular manifestations, by symmetrical progressive muscle weakness that may persist even after pharmacological suppression of inflammation, suggesting a significant involvement of nonimmune mechanisms. Low levels of vitamin D have been associated with several autoimmune diseases. Vitamin D is essential for the maintenance of skeletal muscle, and mounting evidence supports its relation to muscle damage, regeneration, and energy metabolism.
Objectives: The aim was to analyse vitamin D and the mediators of its function in muscle tissue of IIM patients, and to associate it with muscle health parameters.
Methods: A total of 46 IIM patients (40 females, 6 males; mean age 56.7±12.4; disease duration 6.5±6.0 years; dermatomyositis (21), polymyositis (18), necrotizing myopathy (7)) and 67 healthy controls (HC) (56 females, 11 males; mean age 50.9±14.7) were recruited. In total, 27 IIM patients participated in a 24-week intervention combining activities-of-daily-life, resistance and stability training [1]. Muscle biopsies from *m. vastus lateralis* (by Bergström needle) were obtained from 7 IIM patients before/after the 24-week training program, and from 13 control IIM patients, and 21 HC. Primary muscle cell cultures were established from these samples. Disease-associated parameters were evaluated by MYOACT/MITAX, MDI, VAS, HAQ, MMT8, FI-2 and CK, myoglobin, LD, ALT, AST, and CRP levels. Myostatin, as a myokine involved in muscle atrophy, was determined from serum samples by ELISA. Circulating concentrations of 25(OH) vitamin D (calcidiol) and active 1,25(OH) vitamin D (calcitriol) were measured by routine biochemistry techniques. Gene expression of vitamin D receptor (VDR) and 25-hydroxyvitamin D 1-alpha-hydroxylase (CYP27B1), an enzyme catalysing calcidiol conversion to hormonally active calcitriol, was determined by real-time PCR in muscle tissue and primary muscle cell cultures. Data are presented as mean ± standard deviation.
Results: Decreased levels of active 1,25(OH)D were observed in IIM patients compared to HC (125.0±45.4 vs. 164.7±49.2 pmol/l; p<0.0001). No difference was found for 25(OH)D. The 24-week training program did not have an effect on 25(OH)D or 1,25(OH)D serum levels. 25(OH)D was significantly associated with CRP (r=-0.322, p=0.040), MITAX (r=-0.380, p=0.021) and HAQ (r=-0.370, p=0.017) in IIM patients, even after correction for BMI, gluccocorticoid (GC) and vitamin D daily supplementation dose. After 24 weeks of exercise, active 1,25(OH)D was positively associated with MMT8 (r=0.866, p<0.0001), FI2 (r=0.608, p=0.013) and HAQ (r=-0.537, p=0.032) (corrected for BMI, GC and vit.D supplementation). Numerically higher gene expression of VDR and CYP27B1 was found in muscle tissue and primary muscle cells in IIM compared to HC. After the 24-week training, gene expression of both VDR and CYP27B1 in primary muscle cells decreased (p=0.031 and p=0.078, respectively). Associations of VDR gene expression with myoglobin (IIM: r=0.510, p=0.026; HC: r=0.473, p=0.035), MMT8 (IIM: r=-0.559, p=0.013), myostatin (IIM: r=-0.519, p=0.023; HC: r=0.586, p=0.005), and CK (HC: r=0.484, p=0.031) were observed in muscle tissue. CYP27B1 gene expression in the muscle was also associated with myoglobin (HC: r=0.501, p=0.024), MMT8 (IIM: r=-0.555, p=0.011) and VDR (IIM: r=0.561, p=0.012; HC: r=0.632, p=0.002).
Conclusion: Decrease of the biologically active form of vitamin D in circulation suggests an impairment of its metabolism in IIM. Vitamin D serum levels and gene expression of its receptor and activating enzyme in muscle tissue associate with disease activity and muscle function parameters indicating an important role of vitamin D in physical fitness and disease manifestations in IIM patients.

POS0481 DEFINING DISTINCT RESIDENT AND MIGRATORY FIBROBLAST POPULATIONS FROM SKIN BIOPSIES IN SYSTEMIC SCLEROSIS

K. Clark[1], A. Cole[1], X. Shiwen[1], V. Ong[1], C. D. Buckley[2], C. P. Denton[1]. *[1]University College London, Department for Rheumatology and Connective Tissue Disease, London, United Kingdom; [2]Kennedy Institute, Translational Rheumatology, Oxford, United Kingdom*

Background: Recent studies using single cell RNA sequencing have delineated distinct subpopulations of fibroblasts in skin and other organs. To improve understanding of functional differences between fibroblast subpopulations, we have developed a novel technique to selectively isolate "migratory" fibroblasts, and non-migratory "resident" fibroblasts from heathy control (HC) and SSc skin.
Objectives: To compare migratory and resident populations of dermal fibroblasts in systemic sclerosis by their differential gene or protein expression, and through functional assays of fibrotic potential.
Methods: Forearm skin punch biopsies were collected from dcSSc(n=3), and healthy control skin(n=3).
Migratory fibroblasts were first isolated by standard explant culture, then the residual biopsy fragments underwent collagenase digestion to yield a population of resident fibroblasts that retained in the biopsy fragments. These populations were further expanded for use at passage 3-6. Functional characterisation included 3-D collagen gel contraction, and migratory scratch-wound assays. Expression of pro-collagen I (Col1), CTGF and αSMA was compared by western blot. Bulk RNAseq on each fibroblast population was performed. Statistical analysis was carried out using Rsoftware "tidyverse". Criteria for significant differences in gene expression were a fold change of ≥1.5, and adjusted p-value (FDR) of <0.05
Results: Compared with HC, all SSc fibroblast populations showed a hallmark fibrotic phenotype with increased gel contraction, faster migration, and overexpression of Col1, CTGF and αSMA compared with HC. However, SSc resident fibroblasts showed attenuated contraction, migration, and reduced levels of αSMA compared to migratory SSc fibroblasts. Bulk RNAseq performed on each fibroblast population confirmed 5579 significantly differentially expressed genes between SSc resident and SSc migratory fibroblasts, whereas no genes were significantly differentially expressed between HC resident and migratory fibroblasts. SSc and HC migratory fibroblasts and resident fibroblasts were then compared, to understand disease-related differences between the two fibroblast populations. 739 genes were significantly overexpressed in the migratory fibroblast population (including ASPM, TRIP3), whereas 745 genes were significantly upregulated in the resident fibroblast population. The genes upregulated in resident fibroblasts included CCL2, CXCL8, and ICAM1. Many genes typically associated with SSc (such as SERPINE1, COMP), were not significantly different between the SSc fibroblast subpopulations, but were significantly elevated in both SSc subpopulations compared to HC fibroblast populations, suggesting that these reflect a more generic SSc phenotype.
Conclusion: Migratory and resident SSc fibroblast populations exhibit distinct functional and transcriptional differences that are much less apparent for HC biopsies. Further work is required to understand the precise contribution these distinct SSc fibroblast populations in pathogenesis, and how they might be targeted therapeutically. Our findings also highlight that conventional explant culture techniques may ignore important fibroblasts populations and highlight the importance of more detailed analysis such as single cell analysis to better understand pathobiology of SSc.

Table 1. Table of the most significantly differentially expressed genes with highest fold change and adjusted p-value (FDR) between the migratory and resident SSc fibroblast population

Significantly upregulated genes in SSc migratory fibroblasts			Significantly upregulated genes in SSc resident fibroblasts

POS0482 LONG NON-CODING RNA H19X IS A MEDIATOR OF ENDOTHELIAL CELL ACTIVATION IN SYSTEMIC SCLEROSIS

F. Tirelli[1,2], E. Pachera[1], R. Lafyatis[3], M. Huang[3], S. Assassi[4], E. Camarillo[1], F. Zulian[2], G. Kania[1], O. Distler[1]. *[1]University of Zurich, University Hospital Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland; [2]University of Padova, Department of Woman's and Child's Health, Rheumatology Unit, Padova, Italy; [3]University of Pittsburgh, Department of Medicine, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America; [4]University of Texas Health Science Center at Houston, McGovern Medical School, Department of Internal Medicine, Division of Rheumatology, Houston, United States of America*

Background: In one of our previous studies, we demonstrated that long non-coding RNA (lncRNA) *H19X* plays a crucial role in the development of TGFβ driven fibrosis in systemic sclerosis (SSc) and other fibrotic diseases[1].
Objectives: To define the functional relevance of *H19X* in endothelial cell (EC) activation as a decisive process in SSc vasculopathy.
Methods: Correlation of *H19X* expression and microvascular gene signature was computed on bulk RNA-Seq data derived from SSc skin biopsies of patients enrolled in the multicentre Prospective Registry of Early Systemic Sclerosis cohort (PRESS, n=48 SSc vs. n=33 healthy controls, HCs). Single cell RNA sequencing (scRNA-seq) data were collected from 27 diffuse cutaneous SSc (dcSSc) and 10 HC skin biopsies. Single cells were barcoded and encapsulated in droplets using a 10X Genomics system. After cDNA synthesis, the libraries were prepared and sequenced using Illumina NovaSeq-500 platform. Seurat package in R (v.3.0) was used to perform data analysis. EC were identified by enrichment of EC markers *CLDN5*, *VWF* and *PECAM1*. One thousand five hundred eighty-three and 3398 EC were identified from HC and SSc patients, respectively. Cells were analysed for the expression of *H19X* and EC activation markers. Additionally, differential expression and pathway enrichment analysis between *H19X* expressing cells and *H19X* negative cells was carried out. The function of *H19X* was investigated in human dermal microvascular EC (HDMEC) by silencing, using locked nucleic acid antisense oligonucleotides (LNA GapmeRs). Gene expression was measured by qPCR. Protein levels of endothelial adhesion molecules were analysed by Western Blot. Endothelial adhesion was evaluated by co-culture of HDMEC and fluorescently labelled peripheral blood mononuclear cells (PBMCs).
Results: *H19X* expression was found significantly upregulated in SSc skin biopsies of the PRESS cohort (p<0.0001). The expression of *H19X* positively correlated with the microvascular endothelial cell gene signature in all subjects (SSc and HC, R=0.43, p<0.0001), confirming that *H19X* is expressed in this cell type. To determine if *H19X* might be an important factor in SSc EC dysfunction scRNAseq was performed. This analysis revealed a significant upregulation of *H19X* in SSc EC as compared to HC EC (p=0.0095). *H19X* was found to be upregulated in several EC subclusters including arterial (*SEMA3G*, *HEY1*), capillary (*CA4*, *RGCC*), venous (*ACKR1*, *VCAM1*) and lymphatic (*PROX1*, *LYVE1*). *H19X* displayed highest expression in injured SSc EC and capillary SSc EC. Co-expression analysis of the scRNA-seq data revealed higher expression of several adhesion molecules in EC expressing *H19X*, including *VCAM1*, *ICAM* and *JAM3*. KEGG pathway analysis revealed that differentially expressed genes in *H19X* expressing cells were highly associated with the 'Cell adhesion molecule' pathway (p=2.209e-7). *H19X* silencing lead to a significant downregulation of mRNA levels of genes encoding adhesion molecules VCAM1 (n=7, p<0.05) and E-selectin (n=7, p<0.01) at 48h after transfection. VCAM1, but not E-Selectin, was also reduced at protein level as revealed by Western Blot (n=3). The functional relevance of *H19X* on endothelial adhesion was confirmed by PBMCs with *H19X* silenced HDMEC where we were able to demonstrate a significant decrease in leucocyte-to-endothelial cell adhesion (n=5, p<0.05).
Conclusion: Our results show that lncRNA *H19X* could contribute to EC activation in SSc vasculopathy, acting as a regulator of expression of adhesion molecules in EC.

POS0483 THE EFFECT OF VITAMIN D3 AND A-TOCOPHEROL ACETATE IN THE PRECLINICAL MODEL OF SYSTEMIC SCLEROSIS

B. Doskaliuk[1], L. Zaiats[1], R. Yatsyshyn[2]. *[1]Ivano-Frankivsk National Medical University, Pathophysiology, Ivano-Frankivsk, Ukraine; [2]Ivano-Frankivsk National Medical University, Internal medicine #1 clinical immunology and allergology, Ivano-Frankivsk, Ukraine*

Background: The pathogenesis of systemic sclerosis (SSc) is characterized by complex damage of an organism due to the development of mechanisms of autoimmunity. Dysregulation of immune system, development of fibrosis, and vasculopathy play a significant role in this process.
Objectives: This study aimed to investigate the effect of antioxidant α-tocopherol acetate and immunomodulator vitamin D 3 in the preclinical model of SSc.
Methods: To perform this study, three groups of laboratory animals were formed: a control group (20 animals), an experimental group #1 (25 animals) and an experimental group #2 (25 animals). Experimental animals were mature laboratory rats of the Wistar line weighing 180-220 g. Modeling of SSc was performed in the experimental group #1 using sodium hypochlorite (NaClO) according reported previously method [1]. Laboratory animals of the control group were injected with the isotonic solution according to the same scheme. In the experimental group #2, in addition to NaClO, laboratory rats received a solution of α-tocopherol acetate 10 mg / 100 g of body weight, IV and a solution of vitamin D3 1000 IU / 100 g of body weight, IV for 3 weeks (second half of the experiment). The level of surfactant protein D (Elabscience SP-D ELISA-Kit), the vascular cell adhesion molecule (Elabscience VCAM-1 ELISA-Kit), and interleukin 13 (Elabscience IL-13 ELISA-Kit) was determined by enzyme-linked immunosorbent assay. ELISA was performed on an enzyme-linked immunosorbent assay STAT FAX 303 plus. Data distribution was evaluated with the Shapiro-Wilk test. Mann-Whitney U test and unpaired t test were used for comparisons between groups, a p-value <0.05 was considered statistically significant.
Results: The level of IL-13 (pg/ml) in the experimental group was higher than in the control 136,4± 56,23 vs 9,43± 4,01 (p<0.001). The serum concentration of SP-D (pg/ml) among the experimental group of laboratory animals was significantly higher compared to the control subjects 490,20 [228,75–568,73] vs 70,13±33,21, (p<0,05). VCAM-1(pg/ml) was also higher in the experimental group VCAM-1 91,25 [85,63–143,75] vs 17,35±7,47, (p<0,05). The administration of vitamin D3 and α-tocopherol acetate has shown a positive effect for all three investigated parameters. We have found a statistical difference between the two experimental groups regarding IL-13, SP-D, and VCAM-1. The SP-D level in the experimental group #2 was 124.93 ± 18.96, which was significantly lower than in the experimental group #1 (p=0.04). The concentration of IL-13 and VCAM were also lower in the group of vitamins D3 and α-tocopherol acetate administration (22.88±5.11, p<0.001 and 38.73±12.13, p=0.02 respectively).
Conclusion: This study provided evidence that administration of vitamins D3 and α-tocopherol acetate, given in combination, has a beneficial effect on IL-13, SP-D, and VCAM-1 levels in the organism of the experimental animals.

POS0484 LUNG ORGANOIDS: A NOVEL APPROACH TO STUDY THE MOLECULAR PATHOLOGY OF PULMONARY FIBROSIS IN SYSTEMIC SCLEROSIS

M. Aspari[1], S. R. Greisen[1,2], K. Soendergaard[2], M. N. Dahl[1,2], M. Hvid[1], V. Ong[3], D. Abraham[3], B. Deleuran[1,2]on behalf of Bent Deleruran's group. *[1]Aarhus University, Biomedicine, Aarhus, Denmark; [2]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [3]University College London, Division of Medicine, London, United Kingdom*

Background: Pulmonary fibrosis is one of the major manifestations in Systemic Sclerosis (SSc) associated with high mortality. Mesenchymal transformation of the airway epithelial cells has been implicated as one of the causes for

developing pulmonary fibrosis. Though several animal models shed light towards some of these aspects, an *in vitro* airway epithelial model would provide a novel experimental platform for the understanding and molecular and genetic changes that occur in SSc associated pulmonary fibrosis.

Objectives: To establish a functional model for airway epithelium from patient with diffuse cutaneous SSc (dSSc)and healthy volunteers derived nasal stem cells. Subsequently to induce Epithelial Mesenchymal transformation (EMT).

Methods: Nasal stem cells harvested from healthy volunteers(HV) and dSSc patients were differentiated into ciliated airway epithelium in an Air -Liquid Interface (ALI) using a transwell system. 4 HV cultures were then stimulated with TGF beta (5ug/ml) for 10 days at a basal stage and when differentiated. Markers of mesenchymal transformation including loss of E cadherin, and gain of N cadherin, fibronectin and vimentin were analysed by flow cytometry and image stream, and mean expression intensities given as (MFI). Secreted Type 1 collagen and fibronectin were measured by ELISA.

Results: Ciliated epithelial cultures could successfully be established from nasal stem cells (Figure 1).

TGF beta induced a phenotypic change in the epithelial cells towards a mesenchymal one in HV cultures. This was observed by significantly increased expression of fibronectin and vimentin and loss of expression of E cadherin on the ciliated cells with 7 days of stimulation with TGF beta at a basal stage (Figure 1b). When cells, stimulated with TGF beta for 7 days, were analysed at Day 35 a similar trend was seen in their Delta MFI (Figure 1c). Stimulating the ALI cultures with TGF beta for 20 days completely repressed epithelial cell growth and disrupted their microstructure.

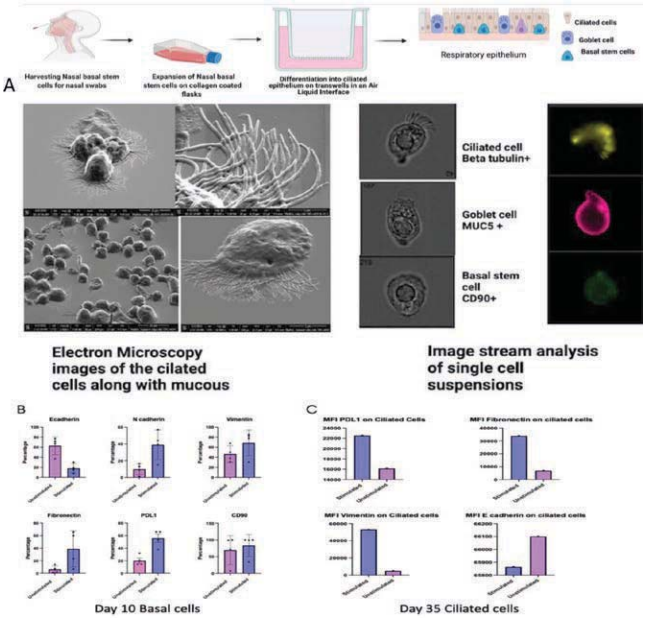

Figure 1.

Conclusion: This novel ALI differentiated Airway epithelial model serves as a functional organoid to test various pulmonary manifestations of Systemic Sclerosis. The ability to induce Epithelial Mesenchymal Transformation of these cultures provides a proof of concept for TGF beta mediated fibrosis in dSSc. Moreover, this model can be utilized to explore, at the cell and molecular level, the impact of various autoantibodies and therapeutics on epithelial cells.

POS0485

PLATELET-DERIVED MICROPARTICLES IN SYSTEMIC SCLEROSIS: POTENTIAL NEW PROFIBROTIC BIOMARKER?

S. Maximiano de Oliveira[1], I. L. De Azevedo Teixeira[2], C. Nunes França[2,3], M. C. De Oliveira Izar[4], C. Kayser[1]. *[1]Universidade Federal de São Paulo (UNIFESP), Rheumatology Department, São Paulo, Brazil; [2]Universidade Federal de São Paulo (UNIFESP), Cardiology Department - Molecular Biology Laboratory - Lipids and Atherosclerosis Sector, São Paulo, Brazil; [3]Santo Amaro University (UNISA), Post-Graduation Program in Health Sciences, São Paulo, Brazil; [4]Universidade Federal de São Paulo (UNIFESP), Cardiology Department, São Paulo, Brazil*

Background: Systemic sclerosis (SSc), the most lethal autoimmune rheumatic disorder, is characterized by vascular damage, immune dysregulation and progressive tissue fibrosis [1]. Microparticles (MP) are membrane-derived vesicles released from cells undergoing activation or apoptosis, that participate in regulation of inflammatory responses, homeostasis and vascular function [2]. Prior studies have reported elevated plasma levels of MP in SSc [3,4], but its association with clinical SSc features and its role in the disease pathogenesis has still not been completely elucidated.

Objectives: We aimed to compare serum levels of platelets-derived microparticles (PMP), endothelial cells-derived microparticles (EMP), and monocytes-derived microparticles (MMP) between SSc patients and healthy controls. Also, we aimed to evaluate the association of MP and SSc clinical features.

Methods: In this cross-sectional study, 70 SSc patients and 35 age- and sex-matched healthy controls were recruited. After staining with fluorescent cell-specific monoclonal antibodies (PMP $CD42^+/31^+$, EMP $CD105^+$, and MMP $CD14^+$), plasma MP were quantified by flow cytometry. Clinical and nailfold capillaroscopy data from patients were obtained. All of them fulfilled the 2013 ACR/EULAR classification criteria for SSc.

Results: Clinical features of studied population are shown on Table 1. Serum MP levels were significantly increased in SSc patients compared to healthy controls (mean ± SD): 79.2% ± 17.3% vs 71.0% ± 19.8% for PMP (p = 0.033); 43.5% ± 8.7% vs 37.8% ± 10.4% for EMP (p = 0.004); and 3.5% ± 1.3% vs 1.1% ± 0.5% for MMP (p < 0.001) (Figure 1). We observed significantly higher PMP levels in patients with positive anti-topoisomerase-I antibodies compared to those with negative anti-topoisomerase-I antibodies (p = 0.030) and in patients with disease duration > 3 years compared to patients with disease duration ≤ 3 years (p = 0.038).

Table 1. Demographic and clinical data of studied population

Variable	SSc (n=70)	Healthy controls (n=35)	*p*
Female/Male	63 (90) / 7 (10)	31 (88.5) / 4 (11.4)	0.68
Age, yr.	48.9 ± 13.4	47.6 ± 14.0	0.63
Limited SSc/Diffuse SSc	44 (62.9) / 26 (37.1)	--	--
Disease duration, yr.	6.4 ± 4.0	--	--
Modified Rodnan skin score	6.5 ± 9.6	--	--
Active digital ulcers	15 (21.4)	--	--
FVC, *(n=63)*	80.9 ± 17.4	--	--
ILD	38 (54.3)	--	--
PAH	4 (5.7)	--	--
Esophageal dyskinesia	42 (60)	--	--
Cardiac involvement	8 (11.4)	--	--
Autoantibodies			
Anticentromere	13 (18.6)	--	--
Anti-topoisomerase-I	13 (18.6)	--	--
Nailfold capillaroscopy, *(n=61)*			
SD Early	23 (37.7)	--	--
SD Active	15 (24.5)	--	--
SD Late	23 (37.7)		
Calcium channel blockers in use	49 (70)	--	--
Phosphodiesterase-5 inhibitors in use	9 (12.9)	--	--
Immunosuppressors in use			
Glucocorticoids	8 (11.4)	--	--
Cyclophosphamide	3 (4.3)	--	--
Mycophenolate	15 (21.4)	--	--
Azathioprine	3 (4.3)	--	--
Rituximab	1 (1.4)	--	--
Methotrexate	12 (17.1)	--	--

Data are mean ± SD or n (%) unless otherwise stated. FVC: forced vital capacity; ILD: interstitial lung disease; PAH; pulmonary arterial hypertension.

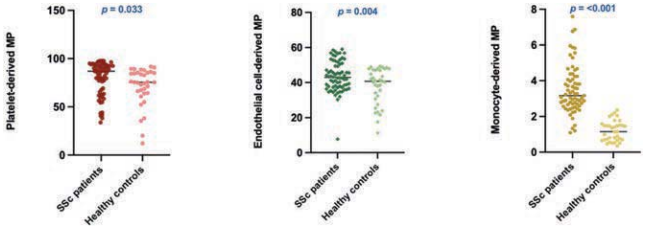

Figure 1. MP plasma levels in SSc patients vs healthy controls

Conclusion: Serum levels of PMP, EMP and MMP are elevated in scleroderma patients, thus indicating a possible role of these agents in SSc pathogenic mechanisms. The higher plasma titles of PMP observed in patients with longer

disease duration and presence of anti-topoisomerase-I, a well-established factor of worse prognosis in SSc, might suggest a profibrotic function for this new potential biomarker.

POS0486 IDENTIFICATION OF NEW CANDIDATE TARGETS INVOLVED IN ACTIVATION OF CARDIAC FIBROBLASTS UNDER IMMUNOFIBROTIC CONDITIONS

I. Kocherova[1], E. Pachera[1], D. Nurzynska[2], F. DI Meglio[2], O. Distler[1], P. Blyszczuk[1], G. Kania[1]. *[1]University of Zurich, University Hospital Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland; [2]University of Naples "Federico II", Department of Public Health, Naples, Italy*

Background: Inflammatory dilated cardiomyopathy (iDCM) often leads to heart failure (HF), which is the main cause of mortality in patients with systemic diseases. Fibroblast activation, driven by the activator protein 1 family member Fos-related antigen 2 (FOSL2), represents a critical step in cardiac fibrogenesis. The existing antifibrotic therapies, based on known fibrotic markers, failed to demonstrate efficacy against myocardial fibrosis.
Objectives: To identify new candidate targets implicated in cardiac fibrogenesis under immunofibrotic conditions.
Methods: Cardiac fibroblasts were isolated from the left atria of patients (n=5) undergoing heart transplantation due to HF associated with iDCM and from unaffected hearts of brain-dead donors (UDs, n=5). Protein identification and quantification was performed using liquid chromatography tandem-mass spectrometry (LC–MS/MS). The data were analysed with MaxQuant v1.6.2.3 software. Bulk RNA sequencing (RNA-seq) was conducted using the Illumina HiSeq platform. Differentially expressed genes were identified using DESeq2. Additionally, we analysed publicly available single-cell (sc) RNA sequencing datasets (GSE109816, GSE121893) [1] on adult hearts from HF patients (n=6) and UDs (n=14) using Seurat package (V.2.3.4). Specific gene knockdown was achieved by siRNA transfection of human foetal cardiac fibroblasts (HCFs, Sigma), untreated or stimulated with TGF-β for 48-72h. The profibrotic marker expression was assessed using RT-qPCR and Western Blot. Cell viability was measured using PrestoBlue HS reagent (Invitrogen), and ATP production was quantified with CellTiter-Glo assay (Promega) in untreated and TGF-β-stimulated HCFs 48h after transfection.
Results: The LC–MS/MS analysis revealed 14 differentially expressed proteins (absolute log2FC>1, adj. p<0.05) in the HF group compared to UDs. The most upregulated protein in HF fibroblasts was dysferlin (DYSF, log2FC=5.78, adj. p<0.004), which is known to play a role in the sarcolemma repair of both skeletal muscle fibres and cardiomyocytes. Bulk RNA-seq analysis identified a total of 67 significantly differentially expressed genes (absolute log2FC>1, adj. p<0.05). The comparative analysis of bulk RNA-seq results and publicly available scRNA-seq datasets revealed two commonly upregulated genes in HF fibroblasts or their subclusters, encoding transcription factor FOXF1 (log2FC=3.51, adj.p<0.05) and matrix remodelling-associated protein MXRA5 (log2FC=2.91, adj. p<0.05). Further *in vitro* studies on HCFs (n=4) showed that TGF-β upregulated *DYSF* (p<0.001) and *MXRA5* (p<0.01) but downregulated *FOXF1* (p<0.05). *DYSF* silencing in HCFs (n=4) upregulated *MXRA5* after 48h of TGF-β stimulation (p<0.05), downregulated *ACTA2* (48h and 72h of TGF-β stimulation, p<0.05), and upregulated FOSL2 protein levels in untreated HCFs and 72h after TGF-β stimulation (n=3, p<0.05). *MXRA5* knockdown (n=8) resulted in the upregulation of *DYSF* (p<0.05), *ACTA2* (p<0.05) and *COL1A1* (p<0.001) in untreated HCFs, and also upregulated *DYSF* (p<0.01) and *COL1A1* (p<0.05) after 48h of TGF-β stimulation. *FOXF1* silencing in HCFs (n=8) followed by 48h of TGF-β stimulation downregulated *MXRA5* (p<0.01) and *ACTA2* (p=0.06), and upregulated *DYSF* (p<0.001) and *COL1A1* (p=0.05). Candidate targets knockdown reduced cell viability in untreated (n=4, *DYSF*: p<0.01, *MXRA5*: p<0.001, *FOXF1*: p<0.01) and TGF-β stimulated (n=4, *DYSF*: p<0.05, *MXRA5*: p<0.05, *FOXF1*: p<0.01) HCFs. ATP levels were decreased in TGF-β-stimulated HCFs after *DYSF* silencing (n=6, p=0.05).
Conclusion: Based on transcriptomics, proteomics and *in vitro* analysis of human cardiac fibroblasts, we identified *DYSF*, *MXRA5* and *FOXF1* as candidate targets implicated in profibrotic phenotype development, including profibrotic transcription factor FOSL2 regulation. These newly proposed candidates may serve as potential therapeutic targets for the treatment of cardiac fibrosis.

POS0487 THE CROSSTALK OF THE SKIN-ORAL-GUT MICROBIOME AXIS IN LIMITED AND DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS

E. Russo[1], D. Carboni[1], S. Baldi[1], B. Fioretto[1], E. Romano[1], K. El Aoufy[1], M. Ramazzotti[2], I. Rosa[1], G. Lepri[1], L. DI Gloria[2], C. Bruni[1,3], D. Melchiorre[1], S. Guiducci[1], M. Manetti[1], M. Matucci-Cerinic[1,4], A. Amedei[1], S. Bellando Randone[1]. *[1]University of Florence, Department of Clinical and Experimental Medicine, 50134, Italy; [2]University of Florence, Department of Experimental and Clinical Biomedical Sciences, 50134, Italy; [3]University Hospital of Zürich, Rheumatology, Zürich, Switzerland; [4]San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare diseases, Milano, Italy*

Background: Systemic sclerosis (SSc) is a complex and still unclear rare disease. Microbiota has recently emerged as an important environmental factor in SSc pathogenesis, either at gut, oral and skin level.
Objectives: To investigate the role of microbiota in SSc subsets, focusing on the skin-oral-gut microbiota axis and serum and fecal free fatty acids (FFA) profile.
Methods: Twenty-six consecutive SSc patients (22 females) (mean disease duration (SD): 13 ± 6.91 yrs), classified according to the ACR/EULAR2013 criteria, were enrolled. Demographic, clinical and laboratory data were recorded. Gastrointestinal symptoms were investigated with UCLA GIT-2.0-questionnaire. Fecal, unstimulated saliva and superficial epidermal samples were collected. Microbiota was assessed through 16S ribosomal RNA Next Generation gene-sequencing analysis. Gas Cromatography-Mass Spettroscopy was used to measure FFAs in serum and fecal samples.
Results: Thirteen patients had limited cutaneous SSc (lcSSc), 13 diffuse cutaneous (dcSSc). The two subsets displayed a different cutaneous and fecal microbiota profile. In detail, the class of cutaneous *Sphingobacteria* was significantly higher in lcSSc (p<0.05), while the phylum of *Lentisphaerae*, the family of *Victivallaceae* and the genus of *Victivallis* were significantly higher in fecal samples of lcSSc (all p<0.05). A significant increase of fecal propionic acid was observed in lcSSc patients (p<0.05). Moreover, all fecal medium-chain FAs and hexanoic acids were significantly higher in lcSSc (p<0.05 and p<0.001, respectively). The analysis of serum FFAs levels showed an increase of valeric and octanoic acids in lcSSc (both p<0.05). A negative correlation between UCLA-GIT-2.0 total score and fecal octanoic acid (rho=-0.61; p=0.03), and a positive correlation with serum propionic acid (rho=0.55; p=0.05) was found in lcSSc.
Conclusion: Our findings show a different microbiota signature in the skin and gut, and a different FFAs profile in lcSSc and dcSSc. Such a differential regulation of microbiota composition and bacterial metabolite production suggests different dynamics of skin-oral-gut microbiota axis in SSc subsets. This data could be useful to develop personalized therapies targeting gastrointestinal and skin involvement.

POS0488 IDENTIFICATION OF NOVEL DISEASE BIOMARKERS IN SYSTEMIC SCLEROSIS THROUGH HIGH-THROUGHPUT PROTEOMICS

R. Ortega Castro[1], F. U. Pilar[1], M. Martinez-Monllor[1], L. Muñoz-Barrera[1], I. Sanchez-Pareja[1], M. C. Ábalos-Aguilera[1], N. Barbarroja Puerto[1], E. Collantes Estevez[1], M. Á. Aguirre-Zamorano[1], C. Perez-Sanchez[1], C. Lopez-Pedrera[1]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology, Córdoba, Spain*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by vasculopathy, tissue fibrosis and activation of the innate and adaptive immune

system. Clinical features of the disease consist of skin thickening and internal organ involvement. Due to the heterogeneous nature of the disease, there is an unmet need of biomarkers for diagnosis, disease progression and response to treatment.

Objectives: The aim of this study was to explore new serum proteomic fingerprints of clinically defined forms of SSc.

Methods: Highly specific detection of nighty two proteins from a panel related to organ damage was performed, by using the breakthrough technology proximity extension immunoassay (PEA, Olink), in the serum of 72 patients with SSC and 18 age-matched healthy donors (HD). Main disease complications in the SSC cohort, including lung fibrosis, skin fibrosis, renal, vascular, and esophageal involvement were assessed, and prevalence of circulating autoantibodies was tested, along with standard demographic and inflammatory parameters. Unsupervised hierarchical clustering methodologies were applied to identify subgroups of patients based on their proteomic profiles. Gene ontology enrichment was used to interrogate the biological meaning of the distinctive molecular signatures identified.

Results: Sixteen circulating proteins related to organ damage were coordinately altered in the serum of SSc patients in relation to HD. Unsupervised clustering analyses differentiated 3 patients clusters presenting different proteomic profiles. Clinically, patients belonging to cluster 1 were characterized by a significant prevalence of multiple organ involvement (84%) in relation to clusters 2 (52%) and 3 (43%), mostly encompassing lung and skin fibrosis and esophageal dysmotility. Immunologically, cluster 1 further displayed the highest percentage of positivity for anti-scl70 antibodies. Nineteen serum proteins, not previously reported in the serum of SSC patients (BANK1, BID, CALR, ERBB2IP, FGR, FOSB, FOXO1, INPPL1, MAEA, MAGED1, MAP4K5, NBN, NCF2, PRKAB1, RASSF2, RCOR1, SMAD1, STXBP3, VASH1) were found deregulated between clusters, with a significant increase in the levels of all of them in cluster 1 compared with clusters 2 and 3. These deregulated proteins were mostly involved in biological processes such as cell proliferation, apoptosis, cell adhesion, migration, and immune response. Among them, two were functionally linked with cutaneous diseases [Calreticulin (CALR) and B-cell scaffold protein with ankryn repeats (BANK1)], two with digestive disorders (Tyrosine-protein kinase Fgr (FGR) and syntaxin-binding protein 3 (STXBP3)] and three with lung disfunction [protein FosB (FOSB), mothers against decapentaplegic homolog 1 (SMAD1) and forkhead box protein O1 (FOXO1)]. Interestingly, levels of some overexpressed proteins in C1 [BH3-interacting domain death agonist (BID), phosphatidylinositol 3,4,5-triphosphate 5-phosphatase 2 (INPPL1), Erbin (ERBB2IP), BANK1 and FOSB] were further related to the positivity for anti-scl70, the specific SSC-autoantibody known to be mostly associated to a bad prognosis and multiple organ involvement in SSC patients.

CONCLUSION:

1) Stratification based on serum proteomic profile could be of use for a better clinical classification of SSc patients, adding new insights to the underlying pathophysiological mechanisms.
2) Combination of disease classifying autoantibodies with principal pathophysiological processes and serum proteomic profiles can help to elucidate and strengthen the diagnosis as well as the prognosis in SSC.

POS0489 CCL24 SERUM CONCENTRATION CORRELATES WITH DISEASE ACTIVITY AND WORSE PROGNOSIS IN DIFFUSE CUTANEOUS SSC: A PROMISING BIOLOGICAL TARGET TO PREVENT DISEASE PROGRESSION

M. Segal Salto[1], A. Mor[1], F. Del Galdo[2]. [1]*Chemomab Therapeutics Ltd., R&D, Tel-Aviv, Israel;* [2]*University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Linking novel therapeutic targets for diffuse cutaneous Systemic Sclerosis (dcSSc) to markers of disease severity and clinical outcome will enable directing the right therapeutic agents to the appropriate patient populations. Such correlation will also support patient stratification in clinical trials, increasing their informative value and success rates. CCL24 is a chemokine within the Eotaxin family, that has been shown to have a dual pro-inflammatory and pro-fibrotic role in SSc. CCL24 and its receptor, CCR3, were found to be over-expressed in SSc skin and serum samples. In-vivo CCL24 blockage was associated with reduction of bleomycin induced skin and lung injury.

Objectives: We aimed to study the role of CCL24 in dcSSc using patient cohorts, by correlating its serum levels to disease activity markers and disease progression.

Methods: Retrospective and longitudinal dSSc patients' cohorts were analyzed for CCL24 circulating levels, clinical measurement and disease related bio-markers.

Results: In a retrospective cohort of 56 dcSSC patients, CCL24 serum levels were significantly higher in patients that had positive anti topoisomerase antibody (ATA) compared to patients with negative ATA. In addition, within the ATA positive patients, ones that had high serum CCL24 levels (≥1500 pg/ml) also presented significantly higher fibrotic activity reflected by a higher enhanced liver fibrosis (ELF) score compared to ATA positive patients with low CCL24 (<1500 pg/ml). In a second longitudinal cohort of 66 patient, baseline CCL24 levels positively correlated with ELF score (r=0.42, p≤0.0005). Patients with high baseline CCL24 serum levels were also more likely to experience lung disease progression, measured by reduction in forced vital capacity (FVC) during 12 months(7 out of 17 patients with CCL24 ≥ 1500 pg/ml had at least -5% reduction of FVC). Consistent with these data, patients with normal FVC at baseline (>80% predicted) which experienced worsening in the next 12 months (at least 7%) had a statistically significant higher baseline serum CCL24 (Average 2,275 pg/ml) compared to patients that had no worsening in FVC over time (average 962 pg/ml, p≤0.001). Interestingly, the same group showed an even steeper reduction in DLCO % predicted (-6.8% vs -0.2%, p≤0.05).

Conclusion: We show here using two dcSSc patient cohorts, that CCL24 serum levels are correlated with disease activity and worse prognosis reflected by high fibrotic activity and deterioration of lung function over time. This reverse translational study supports the role of CCL24 as a therapeutic target for dcSSc and it has informed a phase 2 study testing CM-101, a CCL24 neutralizing antibody, in dcSSc patients to be started in 2022.

POS0490 USEFULNESS OF MHC-II IMMUNO-STAINING ON MUSCLE BIOPSIES IN IDIOPATHIC INFLAMMATORY MYOPATHIES

M. Robert[1], L. Lessard[2,3], T. Fenouil[4,5], A. Hot[1], T. Laumonier[6], A. Bouche[6], B. Chazaud[3], N. Streichenberger[3,5], L. Gallay[1,6]. [1]*Hospital Édouard Herriot, Service de Médecine Interne, Lyon, France;* [2]*Pierre Wertheimer Hospital, Service d'Electroneuromyographie et de pathologies neuromusculaires, Bron, France;* [3]*Institute NeuroMyoGène, Unité Physiopathologie et Génétique du Neurone et du Muscle, UMR 5261 CNRS, U1315 Inserm, Université Claude Bernard Lyon 1, Lyon, France;* [4]*Cancer Research Center of Lyon, UMR Inserm 1052 CNRS 5286, Equipe « Ribosome Traduction et Cancer », Lyon, France;* [5]*Group Hospital Is - Hcl, Institut de Pathologie Multisite des Hospices Civils de Lyon, Bron, France;* [6]*Hôpitaux Universitaires de Genève (HUG), Laboratoire « Cell Therapy & Musculoskeletal Disorders », Département de Chirurgie Orthopédique, Genève, Switzerland*

Background: Idiopathic inflammatory myopathies (IIMs) constitute a group of acquired muscular diseases that occur during childhood and adulthood, exhibit a variety of phenotypes and are potentially life-threatening. IIM diagnosis considers clinical, serological, and histological data. Muscle pathological analysis of IIM patients gives relevant elements for the diagnosis (immune cell infiltrate, vascular and connective tissues, as well as myofiber morphology). Immunochemistry (IHC) labeling for major histocompatibility complex class I (MHC-I), and C5b9, that are negative in normal muscle, appeared of interest in IIM diagnosis and the understanding of IIM pathogenesis. In normal muscle, myofibers are negative for MHC-II IHC. Its interest in the neuropathological exam of IIM muscle remains to be better characterized.

Objectives: This study aims to analyze the pattern of MHC-II expression in various IIMs.

Methods: A historical cohort was designed using the MYOLYON register (IIM patients diagnosed between 2016 and 2020 at the University Hospital of Lyon, France). Inclusion criteria were IIM diagnosis that was established histologically and available frozen muscle samples for additional analyses. Exclusion criterium was any treatment before muscle biopsy. Demographical data and final diagnosis were collected retrospectively from medical records. A centralized, standardized, and blind analysis of muscle MHC-II immuno-staining was conducted to define the various patterns of MHC-II by myofibers and by capillaries. The study complied with ethical requirements.

Results: Seventy-three patients were included: 23 dermatomyositis (DM), 13 anti-synthetase syndrome (ASS), 13 immune-mediated necrotizing myopathies (IMNM), 13 inclusion body myositis (IBM), and 11 overlap myositis (OM). MHC-II immuno-staining of myofibers or capillaries was abnormal for 91.8% of the analyzed biopsies (Figure 1). The analysis of MHC-II myofiber immuno-staining

revealed distinguishable patterns according to IIM subtype: the labeling was diffuse in IBM (69.2%, n=9/13), perifascicular in ASS (61.5%, n=8/13), and variable in OM (patchy for 27.3% n=3/11 or clustered for 36.4%, n=4/11). MHC-II immuno-staining was negative in IMNM (84.6%, n=11/13) and in DM (47.8%, n=11/23). DM exhibiting positive MHC-II myofibers (n=12) were associated with the presence of anti-TIF1γ, anti-NXP2 and anti-SAE auto antibodies (n=5, n=3 and n=2, respectively). Among the 12 patients, there were juvenile cases (n=5, 41.7%) or DM associated with ongoing neoplasia (n=4, 33.3%). Three main architectures were described for capillaries: giant, leaky and capillary dropout. Patterns of MHC-II positive capillaries were the following: DM was characterized by capillary dropout (68.2%), IMNM showed leaky capillaries (75.0%), IBM giant capillaries (66.7%), ASS exhibited both giant (61.5%) and/or leaky (58.3%) capillaries, while OM showed giant (63.6%) or/and leaky (80.0%) capillaries and capillaries dropout (60.0%).

Conclusion: The present work establishes the usefulness of MHC-II immuno-staining for IIM diagnosis, and gives additional elements on the impairment of myofibers and capillaries in the various IIM subgroups. MHC-II expression is known to be induced by inflammatory cytokine such as interferon type II. This could be linked to myofiber and/or capillary impairment in some IIMs, such as IBM, ASS and OM. These results also support the implication of vasculopathy in IIM pathogenesis, with various structural and cellular consequences regarding the different subgroups. Finally, MHC-II immuno-staining in IIM muscle biopsies enables a foremost analysis of myofibers and capillaries, and represents an additional biomarker to distinguish IIM subgroups.

[1] De Bleecker, J.L. et al. 205th ENMC International Workshop: Pathology diagnosis of idiopathic inflammatory myopathies part II 28-30 March 2014, Naarden, The Netherlands. *Neuromuscul Disord* 2015, *25*, 268-272.

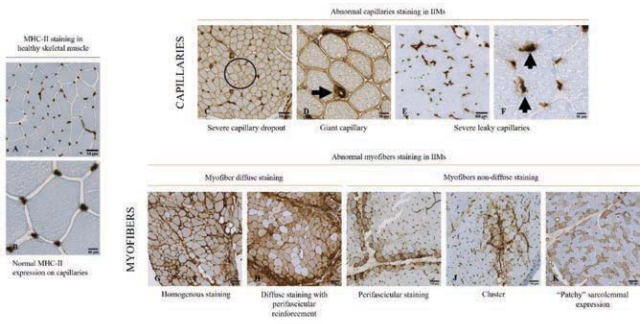

Figure 1. Major histocompatibility complex class II immunostaining in idiopathic inflammatory myopathies.
In normal skeletal muscle, major histocompatibility complex class II (MHC-II) is expressed on capillaries and highlights their regular and "round" shape on axial sections, while there is no sarcolemmal MHC-II expression ((A, scale bar 50μm and B, scale bar 10μm). In idiopathic inflammatory myopathies (IIMs), MHC-II staining highlights either capillary dropout (C, circle, scale bar 50μm)), giant capillaries ((D, arrow, scale bar 10μm) characterized by a widen lumen and a thickened wall, as well as leaky capillaries characterized by a blurred staining with undefined borders (E, scale bar 50μm, and F, arrow, scale bar 10μm). Sarcolemmal expression of MHC-II can be diffuse (G, scale bar 100μm), with for some cases perifascicular reinforcement (H, scale bar 100μm); or non-diffuse: perifascicular (I, scale bar 100μm), clusters (sarcolemmal expression around inflammatory infiltrates) (J, scale bar 100μm), or "patchy" (K, scale bar 100μm).

Vasculitis - aetiology, pathogenesis and animal models

POS0491 A COMPREHENSIVE PROFILE OF CHEMOKINES IN THE PERIPHERAL BLOOD AND VASCULAR TISSUE OF PATIENTS WITH TAKAYASU ARTERITIS

X. Kong[1], S. Wu[1], X. Dai[1], W. Yu[1], J. Wang[1], Y. Sun[1], Z. Ji[2], L. MA[1], X. Dai[1], H. Chen[1], L. MA[1], L. Jiang[1]. *[1]Zhongshan Hospital, Fudan University, Department of Rheumatology, Shanghai, China; [2]Zhongshan Hospital, Fudan University, Department of Rheumatology, Shanghai,*

Background: Takayasu arteritis (TAK) is a chronic granulomatous large vessel vasculitis with multiple immune cells involved [1]. In TAK, vascular lesions originate from the vascular adventitia. The vascular adventitia is rich in vasa vasorum, which can transport peripheral immune cells to active vascular lesions in the early stage of lesion development [2]. Thus, chemokines played critical roles in the pathogenesis of TAK. It has been reported that the levels of RANTES, CCL2, CCL20, CXCL8, and CXCL10 were elevated in TAK, and their levels were correlated with disease activity [3, 4]. However, the profile of chemokines in TAK has not been clearly elucidated.

Objectives: This study aimed to investigate chemokine profile in peripheral blood and vascular tissue of patients with TAK.

Methods: A total of 58 patients with TAK and 53 healthy controls were enrolled. Chemokine array assay was performed in five patients with TAK and three controls. Chemokines with higher levels were preliminarily validated in 20 patients and controls. The validated chemokines were further confirmed in another group of samples with 25 patients and 25 controls. Their expression and distribution were also examined in vascular tissue from 8 patients and 5 controls. Correlations between these chemokines and peripheral immune cells, cytokines, disease activity parameters were analyzed. Their serum changes were also investigated in these 45 patients after glucocorticoids and immunosuppressive treatment.

Results: Patients and controls were age and sex-matched. Twelve higher chemokines and 4 lower chemokines were found based on the chemokine array. After validation, increase of 5 chemokines were confirmed in patients with TAK, including CCL22, RANTES, CXCL16, CXCL11, and IL-16. Their expressions were also increased in vascular tissue of patients with TAK. In addition, levels of RANTES and IL-16 were positively correlated with peripheral CD3+CD4+ T cell numbers. Close localization of CCL22, CXCL11 or IL-16 with inflammatory cells were also observed in TAK vascular tissue. No correlations were found between these chemokines and cytokines (IL-6, IL-17, IFN-γ) or inflammatory parameters (ESR, CRP). No differences were observed regarding with these chemokines between active and inactive patients. After treatment, increase of CCL22 and decrease of RANTES, CXCL16 were found, while no changes were showed in levels of CXCL11 and IL-16.

Conclusion: CCL22, RANTES, CXCL16, CXCL11, and IL-16 were identified as the major chemokines involved in the recruitment of immune cells in the vascular tissue of patients with TAK. Additionally, the persistently high levels of CCL22, CXCL11, and IL-16 observed after treatment indicate their role in vascular chronic inflammation or fibrosis and demonstrate the need for developing more efficacious treatment options.

POS0492 MALADAPTIVE ACTIVATION OF TRAINED IMMUNITY IN THE PATHOGENESIS AND TREATMENT OF GIANT CELL ARTERITIS

E. Cantoni[1], I. Merelli[2], D. Stefanoni[1], A. Tomelleri[3], C. Campochiaro[3], E. Baldissera[3], J. Dominguez Andres[4], M. Matucci-Cerinic[3], A. D'alessandro[5], L. Dagna[3], M. Netea[4], R. Molteni[1], G. Cavalli[3]. *[1]Vita-Salute San Raffaele University, Genetics and Cell Biology, Milan, Italy; [2]IRCCS San Raffaele Scientific Institute, TIGET, Milan, Italy; [3]Vita-Salute San Raffaele University, Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; [4]Radboud University Nijmegen Medical Centre, Department of Internal Medicine and Radboud Center for Infectious diseases (RCI), Radboud Institute for Molecular Life Sciences (RIMLS), Nijmegen, Netherlands; [5]University of Colorado Denver, Biochemistry and Molecular Genetics, Aurora, CO, United States of America*

Background: Trained immunity (TI) is a *de facto* innate immune memory program of monocyte/macrophages, mechanistically characterized by immunometabolic and epigenetic changes sustaining persistent inflammatory activation with enhanced cytokine production. TI evolved as a protective mechanism against infections; however, maladaptive activation can cause detrimental inflammation and might be implicated in the pathogenesis of rheumatic and musculoskeletal diseases (RMDs).

Objectives: In this study, we investigated the role of maladaptive TI in the pathogenesis of Giant Cell Arteritis (GCA), a disease characterized by aberrant macrophage activation.

Methods: Monocytes from a large cohort of clinically active GCA patients (ie, at diagnosis or during disease flares, n=20) and from age- and sex-matched healthy donors were subjected to polyfunctional determinations, including

intracellular metabolomics, chromatin immunoprecipitation PCR, ATAC and RNA sequencing, and cytokine production assays. Arteries from GCA patients were evaluated with immunohistochemistry (IHC) to assess immunometabolic activation. Pharmacologic inhibition of immunometabolic changes underlying TI (ie, glycolysis) was evaluated *ex vivo* as a therapeutic strategy to suppress cytokine production.

Results: GCA monocytes exhibited hallmark molecular features of TI. Specifically, these included typical immunometabolic changes (eg, increased glycolysis and glutaminolysis through the TCA cycle), epigenetic changes promoting transcription of genes governing pro-inflammatory activation, and enhanced IL-6 production upon inflammatory challenge. IHC revealed that GCA lesions are highly glycolytic microenvironments, and pharmacologic inhibition of glycolysis with 2-deoxy-glucose effectively dampened IL-6 production.

Conclusion: This study reveals the deleterious potential of maladaptive TI in the pathogenesis of GCA, and the therapeutic potential of inhibiting TI for the treatment of this condition.

POS0493 1H-NMR BASED METABOLOMIC PROFILE OF PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA IN ACTIVE AND INACTIVE DISEASE STATE

O. Argyropoulou[1], M. Karagiannakou[2], D. Palamidas[1], D. Benaki[2], K. Tsezou[1], P. Vlachoyiannopoulos[1], E. Mikros[2], A. Tzioufas[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece;* [2]*School of Pharmacy, National and Kapodistrian University of Athens, Department of Pharmaceutical Chemistry, Athens, Greece*

Background: Giant cell arteritis (GCA) is the most common form of systemic vasculitis in the elderly. The disease is characterized by a remarkable heterogeneity in terms of clinical picture, histologic pattern of the affected vessels, pathogenetic mechanisms and treatment selection strategies. Approximately half of GCA patients present with polymyalgia rheumatica (PMR), while 20% of PMR patients will develop GCA during follow-up. Organ or life-threatening complications of GCA, include vision loss, strokes, aneurysm formation and accelerated atherosclerosis. The clinical heterogeneity along with the increased relapse rate, even under treatment and the fact that ESR and C-Reactive Protein are the only laboratory tools for the assessment of active disease suggest that the definition of new biomarkers with diagnostic, prognostic and predictive value is an unmet need (1). Among the high throughput approaches towards this direction, ^{1}H NMR spectra of serum samples provides a direct, untargeted, and holistic metabolic profile offering a wealth of information that could be proved useful to discover outcome tools for the management of the disease (2).

Objectives: 1. To characterize and compare the metabolic profile of GCA/PMR serum samples, as captured in ^{1}H NMR spectra, in 3-time points: diagnosis, 1 and 6 months of treatment with steroids (remission), 2. evaluate whether ^{1}H NMR-based metabolomics in serum from patients with GCA/PMR associate with response to treatment and 3. identify potential discriminatory serum metabolic profiles correlating with disease activity.

Methods: One-hundred and ten serum samples from 50 consecutive patients (33-GCA and 17-PMR) were evaluated in the study. GCA serum samples consisted of 33 naïve, 22 in 1 and 21 after 6 months of treatment (25 females, mean age 73.0 ± 7.6 years and 8 males, mean age 69.5 ± 4.9 years), while PMR of 15 naive, 10 in 1st and 8 respectively (9 females, mean age 65.0 ± 5.3 years and 8 males, mean age 77.0 ± 6.6 years). The serum metabolic profiles of patients were obtained at a 600 MHz NMR spectrometer and analysed by means of uni- and multivariate statistical methods.

Results: Multivariate analysis showed metabolic differences between GCA/PMR patients in activity and in remission using unsupervised principal component analysis (PCA: R2X= 0.698, Q2= 0.561) and supervised partial least squares discriminant analysis (PLS-DA: R2X= 0.596, Q2= 0.219) (Figure 1). In accordance with univariate analysis ($p<0.05$), the following discriminatory metabolites were identified: N-acetyl glycoproteins, 3-hydroxybutyric acid and phenylalanine were increased in inflammation, while cholines, lipoproteins, and lipids were decreased in these patients.

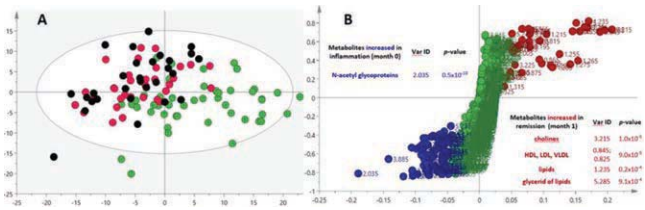

Figure 1. (A) PLS-DA scores plot and (B) S-plot from OPLS-DA of ^{1}H NMR profiling of GCA/PMR serum samples before treatment (green dots) and after 1 (red dots) and 6 months (black dots) of treatment. Characteristic metabolites in inflammation and remission are annotated and the corresponding p-values are given. PLS-DA: partial least square discriminant analysis, OPLS-DA: orthogonal partial least squares discriminant analysis.

Conclusion: ^{1}H NMR-based serum metabolomics revealed a clear discrimination of GCA/PMR metabolic profiles before (active inflammation) and after treatment with steroids (remission), suggesting that the metabolomic analysis may serve as a useful tool to identify potential biomarkers related to disease activity in both GCA and PMR, as well as give further insights into pathogenetic mechanisms mediating the inflammatory response. Further validation studies to dissect the clinical value of specific metabolites are ongoing in our laboratory.

POS0494 ARTERIAL WALL DENDRITIC CELLS IN GIANT CELL ARTERITIS (GCA) AND POLYMYALGIA RHEUMATICA (PMR)

A. Ramon[1,2], H. Greigert[2,3,4], C. Cladière[2], M. Ciudad[2], P. Ornetti[1], B. Bonnotte[2,3], M. Samson[2,3]. [1]*Dijon University Hospital, Rheumatology, Dijon, France;* [2]*Bourgogne Franche-Comté University, INSERM, EFS BFC, UMR 1098, RIGHT Graft-Host-Tumor Interactions/Cellular and Genetic Engineering, Dijon, France;* [3]*Dijon University Hospital, Internal Medicine and Clinical Immunology department, Dijon-Bourgogne University Hospital, Dijon, France;* [4]*Dijon University Hospital, Vascular Medicine department, Dijon-Bourgogne University Hospital, Dijon, France*

Background: Polymyalgia rheumatica (PMR) is an inflammatory rheumatic disease (1) associated in 16 to 21% of cases with giant cell arteritis (GCA). The association of these two conditions raises the question of a pathophysiological *continuum* between PMR and GCA. An early study reported mature arterial wall dendritic cells (DC) in patients with GCA or PMR leading, during GCA, to $CD4^+$ T cell recruitment and the development of vasculitis (2). However, these data have never been confirmed in other studies. There are 3 main types of DC: plasmacytoid DC (expressing CD123), conventional DC (cDC) expressing CD141 (cDC1) or CD1c (cDC2) and monocyte-derived DC (mo-DC) expressing CD14.

Objectives: The aim of this study was to describe the arterial wall infiltrating DCs, their phenotype and maturation state, during PMR and GCA.

Methods: Using temporal artery biopsies (TAB) from patients with PMR, GCA and healthy controls, the level of expression of *CD11c, CD83, CCR7, CCR6, CD1c, CCL18, CCL19, CCL20, CCL21, GM-CSF, CD3, CD68* genes was assessed by RT-PCR. Expression of markers of DC lineage (CD209), DC maturation state (CD83 and CCR7) and DC origin (CD14, CD68, CD1c, CD141) were studied by confocal microscopy.

Results: Fourty-one patients were included (14 GCA, 16 PMR, 11 controls). Within the arterial wall, DCs were identified in GCA patients, with a mature DC phenotype ($CD209^+CD83^+CCR7^+$). DC were present in all three layers of the arterial wall and also expressed CD14 and often CD68 but neither CD1c nor CD141, which could be explained by a monocytic/macrophage origin. TAB from GCA patients were characterized by a high level of expression of *CD83, CCR7, CCR6, CCL18, CCL19, CCL20, CD11c, GM-CSF, CD3 and CD68* gene. This expression was significantly higher ($p<0.05$) compared to the control and PMR groups. Confocal microscopy analyses of arteries from the PMR and controls did not detect the presence of DCs into the arterial wall. In addition, level of

expression of *CD83, CCR7, CCL18, CCL19, CCL21 and CD68* genes in temporal arteries was comparable between PMR and healthy controls.

Conclusion: This work confirms the presence of mature $CD209^+CD83^+CCR7^+$ DCs within the arterial wall in GCA. The phenotype of these DCs mainly fits with DC of monocytic origin (mo-DCs). However, both by RT-PCR and confocal microscopy, we did not identify DCs in the arterial wall of PMR patients. This discrepancy with previous work (3) could be explained by a better diagnosis of GCA in PMR patients since the development of imaging techniques.

POS0495 CYTOKINE SYNERGY ENHANCES SYNOVIAL FIBROBLAST ACTIVATION IN CHILDREN WITH DOWN'S SYNDROME-ASSOCIATED ARTHRITIS

S. Foo[1], M. Canavan2, V. Marzaioli3, D. Veale[4], S. Wade3, E. Macdermott[5], D. Deely[5], C. Foley[5], O. Killeen[5], U. Fearon3. *[1]Trinity Biomedical Sciences Institute, Department of Molecular Rheumatology, Dublin, Ireland; [1]Trinity Biomedical Sciences Institute, Department of Molecular Rheumatology, Dublin, Ireland; [1]Trinity Biomedical Sciences Institute, Department of Molecular Rheumatology, Dublin, Ireland; [4]University College Dublin, Rheumatology, Dublin, Ireland; [5]Children's Health Ireland (CHI) at Crumlin, Rheumatology, Dublin, Ireland*

Background: We have previously shown that children with Down's syndrome-associated arthritis (DA) display a more aggressive form of inflammatory arthritis compared to that of Juvenile Idiopathic Arthritis (Shih *et al.*, 2019). DA is associated with an increase in polyfunctional T-cells coexpressing TNF-α DA is associated with an increase in polyfunctional T-cells coexpressing TNF-fibroblasts (FLS) (Foley *et al.*, 2019).

Objectives: In this study we examine the effect of cytokine synergy on primary DA FLS function.

Methods: Primary DA FLS were cultured and stimulated with TNF-α (0.1 and 1ng/ml), IL-17A (20 and 50ng/ml), IFN-γ (10 and 50ng/ml) and GM-CSF (20 and 100ng/ml) or a combination of these cytokines and the following functional experiments performed. Chemokine and adhesion molecule cell surface expression were quantified by flow cytometry, in addition to quantification of leukocyte-DA-FLS adhesion assays. Gene and protein expression of proinflammatory and metabolic mediators were quantified by ELISA and RT-PCR. Furthermore, real-time metabolic activity in response to cytokine stimulation was assessed by measuring the two major energy pathways: glycolysis (ECAR) and oxidative phosphorylation (OCR), by the Seahorse XFe96 Analyser.

Results: We examined the effects of T cell derived cytokines, TNF-α, IL-17A, IFN-γ and GM-CSF, alone and in combination on DA FLS function. TNF-α, IL-17A and IFN-γ induced IL-6, RANTES and MCP-1 production, with no effect observed for GM-CSF. Furthermore, TNF-α, IFN-γ and IL-17A increased leukocyte adhesion to DA FLS. TNF-α and IFN-γ induced cell surface expression of CXCR3, CXCR4, ICAM-1 and VCAM-1 on DA FLS. Next, we investigated the potential synergistic relationship that these cytokines could have on proinflammatory mediators. IL-17A and IFN-γ potentiated the effects TNF-α on IL-6 and MCP-1 secretion compared to stimulation alone. Furthermore, cytokine synergy significantly induced IL-6, IL-8, RANTES and LDHA mRNA expression compared to basal. IL-17A and IFN-αL-17A and IFN- eeased ts TNF-α on IL-6 and MCP-1 secretion compared to stimulation alone. Additionally, IFN the ECAR:OCR ratio demonstrating a shift in the metabolic profile of DA FLS to glycolysis. Overall DA FLS are transformed from a quiescent metabolic state to an energetic phenotype.

Conclusion: TNF-αNF-lusion:OCR ratio demonstrating a shift in the metabolhe aggressive phenotype of DA FLS through increased cytokine, adhesion molecule and chemokine expression, which is pathways for the treatment of DA.

POS0496 CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS HAVE ALTERATIONS IN B AND T FOLLICULAR CELL SUBSETS IN PERIPHERAL BLOOD

C. Tomé[1], F. Oliveira-Ramos[1,2], R. Campanilho-Marques[1,2], A. F. Mourão[3], S. Sousa[4], A. P. Martins[5], P. Costa Reis[1,6], R. Pinheiro Torres[3], A. T. Melo[1,2], R. L. Teixeira[1,2], M. Gonçalves[5], M. J. Santos[1,4], L. Graça[7,8], J. E. Fonseca[1,2], R. A. Moura[1]. *[1]Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Rheumatology Research Unit, Lisbon, Portugal; [2]Hospital de Santa Maria, Rheumatology Department, Lisboa, Portugal; [3]Centro Hospitalar Lisboa Ocidental, Rheumatology Department, Lisbon, Portugal; [4]Hospital Garcia de Orta, Rheumatology Department, Almada, Portugal; [5]Hospital de Santa Maria, Pediatric Surgery Department, Lisbon, Portugal; [6]Hospital de Santa Maria, Pediatric Department, Lisbon, Portugal; [7]Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Cellular Immunology Research Unit, Lisbon, Portugal; [8]Instituto Gulbenkian de Ciência, Cellular Immunology Research Unit, Oeiras, Portugal*

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children[1]. Our group has recently demonstrated that extended oligoarticular (eoJIA) and polyarticular JIA (pJIA) mostly evolve to a rheumatoid arthritis (RA) like phenotype in adulthood[2]. Disturbances in B cells, T follicular helper (Tfh) and T follicular regulatory (Tfr) cell immune responses are associated with the pathogenesis of RA[3,4], but their exact role in JIA development is not entirely known.

Objectives: The main goal of this study was to characterize the frequency and phenotype of B, Tfh and Tfr cells in peripheral blood of children with eoJIA and pJIA when compared to healthy controls and children with persistent oligoarticular JIA (poJIA).

Methods: Blood samples were collected from children with eoJIA (n=5), pJIA (n=11) and poJIA (n=19) treated with disease modifying anti-rheumatic drugs. A group of age-matched healthy individuals (n=8) was used as control. Peripheral blood mononuclear cells were isolated and the frequency and phenotype of B, Tfh and Tfr cells were evaluated by flow cytometry.

Results: The frequency of B, Tfh and Tfr cells was similar between JIA patients and controls. Children with eoJIA and pJIA, but not poJIA, had higher levels of naïve B cells and lower frequencies of post-switch memory B cells and plasmablasts when compared to controls. Th17-like Tfh cells were significantly increased in all JIA patients when compared to controls. B cell phenotype was similar between JIA patients and controls, but a reduced activated phenotype of Tfh cells was observed in JIA patients in comparison to controls.

Conclusion: Changes in B and Tfh cell subpopulations, but not in Tfr cells, were found in peripheral blood of children with JIA when compared to controls. The increased frequencies of Th17-like Tfh cells detected in JIA when compared to controls suggests a potential role of these cells in JIA pathogenesis. A treatment effect on the activation state of B, Tfh and Tfr cells cannot be excluded.

POS0497

A STUDY ON THE IMMUNOREGULATORY ROLE OF THE PD1 PATHWAY IN JUVENILE IDIOPATHIC ARTHRITIS - PRELIMINARY RESULTS

A. Koutsonikoli[1], A. Taparkou[1], P. Pratsidou-Gertsi[1], V. Sgouropoulou[1], M. Trachana[1]. [1]*Aristotle University of Thessaloniki, Pediatric Immunology and Rheumatology Referral Centre, 1st Pediatric Dept, Hippokrateio General Hospital, Thessaloniki, Greece*

Background: The Programmed cell Death protein-1 (PD1) pathway promotes self-tolerance, by inhibiting immune responses. The PD1 soluble form (sPD1), by antagonizing the binding of the membrane-bound PD1 with its ligands, may lead to the blocking of the pathway's functions. Data regarding the role of the PD1 pathway in Juvenile Idiopathic Arthritis (JIA) are still limited.
Objectives: To investigate the immunoregulatory role of the PD1 pathway in JIA patients.
Methods: JIA patients and healthy controls participated in this study with peripheral blood (PB) and/or synovial fluid (SF) samples. sPD1 levels in serum and SF were determined by ELISA. The PD1 expression on T-helper (CD4+) and T-cytotoxic (CD8+) cells in PB and SF was analyzed by flow cytometry. A search for any association between the above biomarkers, as well as their relation with JIA activity was then performed. Inactive disease was defined according to Wallace criteria.
Results: 77 Caucasian patients (52 female) participated so far in this study, with a median (range) age of 13 (2-19) years; their JIA subtypes were: oligoarthritis (33%), polyarthritis (26%), psoriatic (12%), enthesitis-related (16%), systemic (10%) and undifferentiated (3%). Ten healthy children served as controls. As compared to controls, a subpopulation of these JIA patients (n=46) had a significantly higher median percentage of PD1+CD4+ (1.15 *vs*. 0.32%, p=0.029) and PD1+CD8 T cells (1.34 *vs.* 0.4%, p=0.006) in PB. In regard to the JIA status, patients with activity (n=33) had a significantly higher median percentage of both PD1+CD4+ and PD1+CD8 T cells in PB, as compared to those with inactive disease (n=13) (1.36 *vs*. 0.87%, p=0.034 and 2.03 *vs*. 0.45%, p<0.001, respectively). Additionally, in a sample of the patients with disease activity (n=22), the median serum sPD1 level was statistically significantly higher, as compared to a sample of those with inactive JIA (n=10) (218.3 *vs.* 186.7pg/ml, p=0.035). In patients with concurrent serum and SF samples (n=7), the median sPD1 level was statistically significantly higher in the SF than in the serum [1104.4 *vs.* 773.4pg/ml, p=0.028). No correlation was though found between the sPD1 levels and the PD1 cellular surface expression (n=16 PB/serum, n=11 SF).
Conclusion: These preliminary results indicated an sPD1 compartmentalization in active JIA, as sPD1 levels were more prominently raised in the inflamed joint than in the PB. A higher number of circulating T-helper and T-cytotoxic cells expressing PD1 were also detected in active JIA. Further investigation in a larger sample of JIA patients may verify these observations and contribute to unraveling the precise role of the PD1 pathway in the pathogenesis and persistence of the joint inflammation.

MOLECULAR DOCKING AND PHARMACOLOGICAL ANALYSIS OF ALPHA-PHELLANDRENE IN CHRONIC PAIN: THE ROLE OF SEROTONINERGIC SYSTEM

Y. M. D. S. Pires[1], J. T. Ciecilinsky[2], L. D. S. Gomes[3], F. D. A. Oliveira[3], F. R. D. C. Almeida[3]. [1]*Federal University of Paraná, Pharmaceutical Sciences, Curitiba, Brazil;* [2]*Universidade do Contestado, Pharmacy, Mafra, Brazil;* [3]*Federal University of Piauí, Biochemistry and Pharmacology, Teresina, Brazil*

Background: Pain is an unpleasant sensory and emotional experience that causes human suffering.[1] Its prevalence has increased, as well as the abuse and dependence on strong opioids.[2,3] The α-phellandrene is a terpene that exerts antinociceptive and immunostimulant effects,[4] however, its mechanisms remain to be elucidated. In this way, bioinformatics may assist in developing new therapeutic approaches for pain management.
Objectives: To investigate the action of a-PHEL in chronic pain, focusing on the role of the serotoninergic system, to develop a new therapeutic tool without the side effects of conventional drugs.
Methods: Molecular docking is an important method for the investigation of the mechanism of action of natural compounds. It is possible to evaluate the molecular dynamics, elucidating the stability of complexes. The software PyMOL and AutoDock Vina 1.5.7 were used to predict interactions of a-PHEL and 5-HT_{2A}R. The mechanism of action of a-PHEL in chronic pain was analyzed *in vivo* as well. The Ethics Committee of UFPI approved this project (protocol n° 305/17). Female Swiss mice (25-30 g) underwent partial sciatic nerve ligation surgery to induce neuropathy. The neuropathic mice (N=6) were pre-treated with 5-HT_{2A} receptor antagonist Ketanserin (0,3 mg/kg, i.p.) or Saline (10 mL/kg, p.o.). After 20min, they were treated with α-phel (6,25 mg/kg, p.o.) and after 1h they were evaluated by the Von Frey test.
Results: The serotoninergic system has a complex and important role in pain modulation especially through descending inhibitory pathways. The Molecular docking predicted the positioning of a-PHEL in the 5-HT_{2A}R, aiding the understanding of its biological activity. The analysis identified 9 key positions for the ligand binding in 5-HT_{2A}R. The lowest Gibbs free energy ΔG= -6.9 kcal/mol. The negative binding energy indicates a strong and stable bond, therefore, α-PHEL has a high affinity for the receptor (Figure 1).

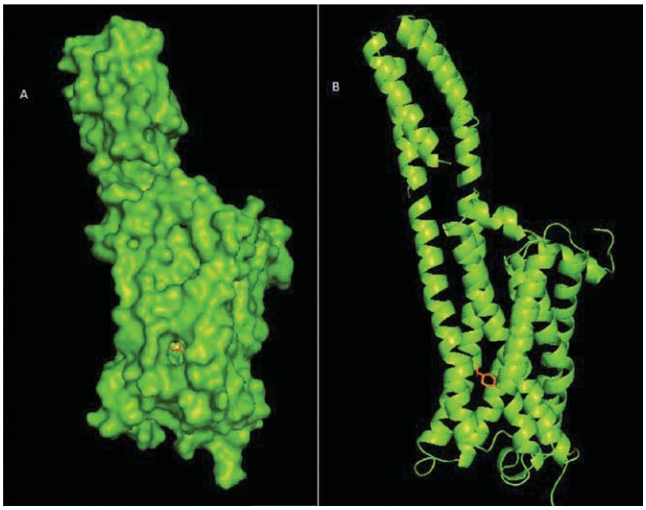

Figure 1. Graphical 3D representation of the binding mode of α-PHEL with 5-HT_{2A}R. A - The ligand (orange) is shown surrounded by a molecular surface of the receptor (green). B – Representation of the best-scoring docked pose (-6.9 kcal/mol) of a-PHEL (orange).

Excellent in vivo therapeutic effects were observed in the animal model of neuropathic pain. Regarding the pharmacological in vivo analysis, the a-PHEL significantly decreased the pain threshold (P<0.05), exhibiting an anti-hypersensitive effect. The inhibition of serotonergic transmission by pretreatment with Ketanserin significantly reduced the antinociceptive effect of a-PHEL in mice. The data indicate that a-PHEL exerts its antinociceptive effect on chronic neuropathic pain model by activation of the 5-HT2AR receptor. Its analgesic effect seems to be mediated by descending inhibitory serotonin system interfering with pain impulse transduction.
Conclusion: Chronic pain is often resistant to medical treatment and the cheminformatics techniques may facilitate the discovery of new compounds, guiding towards specific molecular targets. The a-PHEL may act as a serotoninergic agonist, reducing mechanical sensitivity. It is a promising compound for chronic pain treatment, with lower cost and fewer adverse effects than opioids. Future investigations are expected to highlight the in-depth effects of the interaction of a-PHEL with other receptor subtypes.

Rheumatoid arthritis - prognosis, predictors and outcome

POS0499 A NEW SERUM ASSAY MEASURING SYNOVIAL TURNOVER IN RHEUMATOID ARTHRITIS

P. Garnero[1,2], E. Gineyts[1], J. C. Rousseau[1,2], H. Marotte[3], R. Chapurlat[1]. *[1]INSERM U1033, Rheumatology, Lyon, France; [2]PmoLab, Biomarker, Lyon, France; [3]INSERM 1059, Rheumatology, Saint Etienne, France*

Background: Rheumatoid arthritis (RA) is characterized by synovial tissue (ST) inflammation leading to pain, joint destruction, impaired mobility and ultimately increased morbidity and mortality. These various components of disease etiology can be monitored by pain scores and imaging technologies. Noninvasive assessment of joint tissues metabolism can be performed by measuring serum metabolites of tissue matrix turnover. Specific biochemical markers (BM) of bone and cartilage have been developed, but there is still a lack of a sensitive index of ST metabolism abnormalities, although there are early and key drivers of joint destruction.
Objectives: To develop a sensitive ELISA-based serum BM of ST turnover (SynHelix) and evaluate its performance in patients with RA.
Methods: We identified a 11 amino-acid sequence (HELIX-III) within the triple helical portion of type III collagen, a main component of ST matrix which is released during ST turnover and can be measured in the serum. A highly specific rabbit polyclonal antibody raised against the synthetic HELIX-III peptide was produced to develop a competitive ELISA. Specificity of the antibody was evaluated by competitive inhibitions with homologous sequences of type I, IV and XI collagens which are also present in ST, but in minor quantities for the two later. Immunohistochemistry analysis of human ST obtained during hip surgery was performed to investigate in situ localisation of the HELIX-III peptide. ELISA was then used to quantify serum HELIX-III fragments in two samples of patients with low (n= 40, median DAS 28: 2.1) and moderate (n=11, median DAS28: 3.5) RA activity participating in clinical trials. Levels in RA subjects were compared to sex and age-matched healthy controls randomly selected from epidemiological cohorts (n=70).
Results: The ELISA for SynHelix demonstrated adequate analytical performances with intra and interassay variations below 10 and 15%, respectively; analytical and functional limits of quantification of 0.21 and 2.5 ng/ml, respectively and dilution recovery of human serum ranging from 80 to 108%. Competitive inhibition experiments demonstrated that the antibody does not recognize HELIX-III peptide shortened or elongated by one amino-acid, indicating that immunogenicity is dependent on the presence of a neopitope resulting from the cleavage of the collagen molecule. The antibody does not recognize the homologous sequence of type I collagen, but shows significant immunoreactivity with the homologous sequences of type IV (alpha 5) and type XI (alpha 2) collagens with however a lower affinity than for type III collagen (a 2.2 and 4-fold higher concentration, respectively, is needed to displace 50% of the immune signal). Immunohistochemistry of ST tissue from RA subjects showed increased staining in the interstitial tissue and around vessels which are rich in type IV collagen. Median serum levels of SynHelix were significantly higher in patients with low (p=0027, +17%) and moderate RA activity (+220%, p=00004 vs healthy controls; +164% p=0.16 vs low RA) compared with those in age-matched controls, although CRP did not discriminate RA patients with low and moderate activity (2.2 mg/L for both groups, p=0.90). In RA subjects, serum SynHelix correlates modestly with CRP (r=0.59, p <0.0001), but not with DAS28.
Conclusion: The new SynHelix ELISA measures precisely circulating degradation fragments of Helix-III peptide-containing collagens. Serum SynHelix levels are already increased in patients with low activity RA, values correlating modestly the degree of systemic inflammation. Larger longitudinal studies are needed to further evaluate the value of SynHelix to predict disease outcome in RA.

POS0500 LEVELS OF IL-6 AND OTHER INFLAMMATORY PROTEINS IN EARLY RA PREDICT JOINT DAMAGE PROGRESSION OVER 5 YEARS

E. Rydell[1], K. Forslind[2,3], L. T. H. Jacobsson[1,4], C. Turesson[1,5]. *[1]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Sweden; [2]Lund University, Rheumatology, Department of Clinical Sciences, Lund, Sweden; [3]Spenshult Research and Development centre, Spenshult Research and Development centre, Halmstad, Sweden; [4]Gothenburg University, Rheumatology and Inflammation Research, Sahlgrenska Academy, Göteborg, Sweden; [5]Skåne University Hospital, Rheumatology, Malmö, Sweden*

Background: Joint damage in rheumatoid arthritis (RA) remains a significant problem. Identification of biomarkers associated with joint destruction can improve our understanding of underlying disease processes and future management.
Objectives: To evaluate inflammatory proteins as potential predictors of radiographic progression of joint damage.
Methods: Consecutive early RA patients (symptom duration <12 months), recruited 1995-2005 from a defined area, were followed through 5 years in an observational study. Radiographs of hands and feet were scored in chronological order by a trained reader according to the modified Sharp-van der Heijde score (SHS). Stored plasma samples from the baseline visit were analyzed for levels of 92 inflammatory proteins (Inflammation panel by O-link). Statistical analyses were pre-designated as hypotheses-driven or exploratory. For the latter, principal component analysis was used to identify groups of proteins that explain the variance in the proteome. Within components selected based on Eigenvalues, proteins with a factor loading of >0.50 were investigated as potential predictors of radiographic progression. Logistic and linear regression models were used to assess associations with rapid radiographic progression (RRP; ≥5 SHS/year) and progression of SHS over 5 years.
Results: Data on baseline levels of proteins, and radiographs at baseline and 5 years were available for 114 patients. The median progression of SHS was 11 (interquartile 2-19). For potential biomarkers with an a priori hypothesis, IL-6 significantly predicted both RRP and progression of SHS over 5 years analyzed as a continuous variable [adjusted ß = 0.09 per SD, p=0.032, adjusted for rheumatoid factor (RF) and baseline SHS]. A significant positive association for matrix metalloproteinase 1 (MMP-1) was observed in the unadjusted analysis for SHS progression, but not for RRP (Table 1). In the exploratory analyses, S100 calcium-binding protein A12 (EN-RAGE) was positively, and TNF-related apoptosis-inducing ligand (TRAIL) negatively associated with both outcomes.
Conclusion: Plasma levels of IL-6 at RA diagnosis predict degree of future joint damage. EN-RAGE and TRAIL, both modulators of NF-κB which is known to regulate immune response, are potential biomarkers that need further investigation.

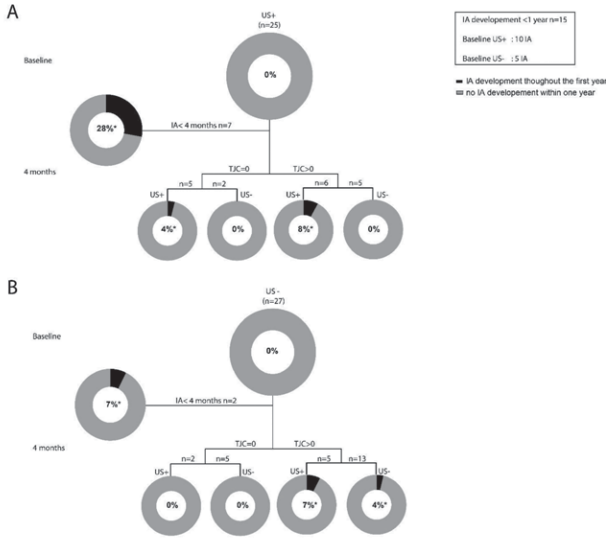
POS0501 SEQUENTIAL ULTRASOUND IN ARTHRALGIA PATIENTS AT RISK FOR INFLAMMATORY ARTHRITIS; IS IT HELPFUL FOR RISK STRATIFICATION IN DAILY PRACTICE?

C. Rogier[1], M. Kortekaas[2], A. Van der Helm-van Mil[1,2], P. De Jong[1], E. Van Mulligen[1,2]. *[1]Erasmus MC, Department of Rheumatology, Rotterdam, Netherlands; [2]Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands*

Background: Musculoskeletal Ultrasound (MSUS) is often used to assess the presence of subclinical joint inflammation in patients presenting with arthralgia suspicious for progression to inflammatory arthritis (IA). Even though evidence-based guidelines for these patients are still absent, presence or absence of subclinical joint inflammation often influences management decisions in daily clinical practice. Studies so far focused on MSUS results at presentation with arthralgia. However, it is unknown if and how MSUS results change over time, and whether repeating MSUS is helpful in demonstrating or ruling out impending RA with greater certainty.
Objectives: To investigate whether sequential imaging at 4-months, in addition to baseline evaluation, is helpful in the risk stratification of arthralgia-patients.
Methods: Arthralgia-patients suspicious for progression to IA were included in the Rotterdam clinically suspect arthralgia cohort. At baseline and at 4-months a bilateral MSUS-examination was performed of the joints and tendons in both hands and feet. Subclinical inflammation was defined as GS>1 and/or PD>0, this was scored according to the latest OMERACT- guidelines.(1, 2) Based on a large US study carried out in a symptom-free population, the cut-off value in MTP 2-3 was considered present if GS ≥3 and/or PD ≥1.(3) Patients were followed for one-year on development of IA, identified with joint examination by experienced rheumatologists. The value of MSUS was studied separately for patients with and without subclinical joint inflammation at baseline. In a sensitivity analysis, ACPA-stratification was applied.
Results: A total of 52 consecutive patients were studied; 29% developed IA after one year. At baseline, 25 patients had subclinical inflammation and 27 patients did not have subclinical inflammation. In these groups respectively 28% and 7% developed IA before the 4-month-visit and therefore did not have repeated MSUS (Figure 1 A/B). In the patients with a positive MSUS at baseline, 28% had a negative MSUS at four months, all these patients did not progress to IA, irrespective of tender joints count(Figure 1A). In the group of patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline and no tender joints at 4-months did not progress to IA, regardless of the MSUS results. Patients with a negative MSUS at baseline and tender joints at 4-months developed IA infrequently, without relevant differences between those that did or did not develop a positive MSUS at 4-monthts. Overall, only a minority of patients whose MSUS progressed from negative to positive indeed developed IA, whereas this repeated MSUS was falsely positive in most cases(Figure 1B). Despite the small numbers, ACPA-stratification was performed, this showed a similar trend.
Conclusion: Within arthralgia patients with a positive MSUS at baseline, a negative MSUS after 4-months may be an incentive to exclude arthralgia-patients from further follow-up. Within the patients with a negative MSUS at baseline, repeating MSUS may induce more false positive than correct positive results.



* percentage IA developement is calculated based on the group at baseline (n=25 for US+ and n=27 for US-)

Figure 1. Sequential ultrasound at baseline and after 4-months of follow-up in arthralgia-patients at risk for inflammatory arthritis with subclinical inflammation at baseline (A) and without subclinical inflammation at baseline(B).

POS0502 ULTRASOUND THRESHOLDS FOR INFLAMMATORY AND STRUCTURAL LESIONS TODISTINGUISH OSTEOARTHRITIC FROM RHEUMATOID ARTHRITIS PATIENTS

S. Honstettre[1], G. Julien[1], E. Allado[1], I. Chary Valckenaere[1], D. Loeuille[1]. *[1]CHRU Nancy, rheumatology, nancy, France*

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatic disease affecting small and medium-sized joints symmetrically, leading to poor functional outcomes and structural damages with time. The RA elementary inflammatory lesions, synovitis and tenosynovitis, have been associated with the development and worsening of bone erosions leading to loss of joint function and pain. The median age at diagnosis of RA patients, ranged between 50-60 years old, age at which degenerative and inflammation lesions relative to osteoarthritis (OA) damages may be present and interfere to establish a diagnosis of inflamed and/or structural RA disease.
Objectives: To assess prevalence, topography and severity of inflammation and erosion on ultrasound (US) in RA and OA patients and to propose US thresholds to classify RA patients.
Methods: Patients fulfilling ACR 1987 and/or ACR/EULAR 2010 criteria for RA or ACR criteria for hand OA were reprospectively included. Synovitis and tenosynovitis (TS) in B and Power Doppler (PD) modes on seven bilateral joints (carpus, MCP2, 3, 5, MTP2, 3, 5) were scored according to a four-grade scale of severity. Erosive disease was defined by the presence of at least one erosion >2 mm confirmed in 2 perpendicular plans on 30 targeted facet joints. Sensitivity, specificity and OR for the diagnosis of RA were calculated for each elementary (inflammatory and erosive) US lesion.
Results: 153 patients were included: 107 (31 early <2 years) RA and 46 OA patients. Synovitis (B and PD modes) was observed in 92 (85.9%) RA and 12 (26%) OA patients, respectively (p <0.0001). TS (B and PD modes) was depicted in 61(57%) RA and 4 (8.7%) OA patients, respectively (p <0.0001). 71 (66%) RA and 5 (11%) OA patients responded to the definition of erosive disease (p<0.001). The combination of US erosion and PD+ synovitis provided the best compromise to classify RA patients: sensitivity 49.1% (39.7-58.4)), specificity 97.8% (87.4-99.5) and OR= 43.8 (CI95: 8.2-230.2). For early RA, PD+ TS provided the best compromise: sensitivity 54.8% (37.8-58.4), specificity 97.8% (87.4 -100) and OR= 54.6 (CI95: 9.3- 320.5).
Conclusion: The combination of PD+ synovitis and erosion in RA and PD+ tenosynovitis alone in early RA offered the best compromise to classify RA versus OA patients.

RISKS OF CARDIOVASCULAR EVENTS AFTER THE INTRODUCTION OF BDMARDS IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS PATIENTS: A POPULATION-BASED INTERRUPTED TIME-SERIES ANALYSIS

Y. V. Zhou[1,2], D. Lacaille[1,3], N. Lu[1], J. Kopec[1,4], Y. Qian[5], B. Nosyk[2,6], J. A. Aviña-Zubieta[1,3], J. Esdaile[1,3], H. Xie[1,2]. *[1]Arthritis Research Canada, Research, Vancouver, Canada; [2]Simon Fraser University, Health Sciences, Burnaby, Canada; [3]University of British Columbia, Department of Medicine, Vancouver, Canada; [4]University of British Columbia, School of population and public health, Vancouver, Canada; [5]University of British Columbia, Sauder School of Business, Vancouver, Canada; [6]Center for Health Evaluation & Outcome Sciences, Research, Vancouver, Canada*

Background: Rheumatoid arthritis (RA) is associated with increased risk of cardiovascular (CV) events. Biological disease-modifying anti-rheumatic drugs (bDMARDs) are effective in suppressing inflammation and preventing joint damage and may help lower the risk of CV events. However, recent epidemiological studies have shown mixed results with some suggesting a lower risk of CV events, while others reporting no significant differences.
Objectives: To determine the impact of the introduction of bDMARDs on incident cardiovascular disease (CVD) among patients newly diagnosed with RA compared with matched non-RA individuals.
Methods: In this age- and gender-matched cohort study using administrative health data for the population of BC, Canada, all incident RA patients diagnosed between 1995–2007 were identified. Non-RA individuals were randomly selected from the general control population to match with RA. Incident RA and non-RA individuals were then divided into quarterly cohorts according to their diagnosis date. The outcome of interest was incident CVD event after RA onset, which include acute myocardial infarction, cerebrovascular accident, and venous thromboembolism. We calculated the 8-year incident CVD rate for each cohort. We conducted interrupted time-series analyses to compare levels and trends of CVD in RA and non-RA individuals diagnosed during pre-bDMARDs (1995–2001) and post-bDMARDs (2003–2007) periods with intervention time set at year of 2002. Adjusted 8-year CVD rates for RA and non-RA cohorts diagnosed five years after bDMARDs introduction were compared with expected rates assuming no bDMARDs introduction, based on extrapolation of pre-bDMARDs trends.
Results: A total of 60,226 and 588,499 incident RA and non-RA individuals were identified. We identified 6,740 and 48,653 incident CVD events in total in RA and non-RA individuals, respectively. We observe no change in the secular trends of the 8-year CVD rates in both RA and non-RA individuals diagnosed in pre- and post-bDMARDS periods (Figure 1): the adjusted difference between the post- and pre-bDMARDs secular trends of 8-year CVD rates was 0.23 (p=0.26) for RA patients and -0.07 (p=0.33) for non-RA individuals (Table 1). However, we observed a reduction in the level of CVD rates among RA patients diagnosed in the post-bDMARDs period and no change in non-RA (Figure 1): the adjusted difference in level comparing points immediately before and after the intervention, and accounting for pre-intervention trend was -1.61 (p=0.03) in RA, while it was -0.02 (p=0.93) in non-RA (Table 1).
Conclusion: Arthritis onset after bDMARDs introduction is associated with a significant reduction in the risk of incident CVD events among RA patients, but not in the matched non-RA individuals.

Verstappen[1,4]. *[1]University of Manchester, Centre for Epidemiology Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; [2]King's College London, Health Psychology section, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom; [3]King's College London, Department of Inflammation Biology, Faculty of Life Sciences and Medicine, London, United Kingdom; [4]Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom; [5]University of Montpellier, Rheumatology, Montpellier, France; [6]University of Montpellier, Laboratory of Biostatistics and Epidemiology, Montpellier, France; [7]Hôpital Purpan, Centre de Rhumatologie, Toulouse, France; [8]Université Toulouse III, Paul Sabatier University, Faculté de Médecine, Inserm UMR1027, Toulouse, France; [9]Pitie Salpetriere Hospital, Department of Rheumatology, Sorbonne University – Assistance Publique Hôpitaux de Paris, Paris, France; [10]Pierre Louis Institute of Epidemiology and Public Health, PEPITES team, INSERM UMRS 1136, Paris, France*

Background: Previous research has identified trajectory groups of people with rheumatoid arthritis (RA) characterised by excess disability (with respect to inflammation)[1]. These excess disability trajectories were relatively fixed from symptom onset, indicating that sociodemographic and lifestyle factors prior to onset may partially determine the disability trajectories of people with RA, potentially mediated by patient reported outcomes (PROMs).
Objectives: To (i) investigate the relationship between social support, financial status and lifestyle factors and excess disability group membership in RA, and (ii) evaluate the mediating effect of pain, fatigue, anxiety and depression on this relationship.
Methods: Data came from the *Etude et Suivi des Polyarthrites Indifférenciées Récentes* (ESPOIR) study, a prospective cohort from 14 centres across France. Inclusion criteria were: >2 swollen joints for 6 weeks-6 months, certain / possible diagnosis of RA, aged 18-70 years, and no disease modifying treatments or glucocorticoids for >2 weeks. A previous study applying trajectory analysis to the 10-year disability and inflammation scores of the ESPOIR participants identified pairs of trajectories characterised by similar inflammation but different disability[1]. For the current analysis, those in the higher disability trajectories of each pair were allocated into the "excess disability" group. At baseline, participants reported demographics, patient reported outcomes (pain / fatigue visual analogue scales;

anxiety / depression: Arthritis Impact Measurement Scales), social support (availability of financial and accommodation support, family contact, married / co-habiting), financial status (personal and family income, job status and level, home owner, ability to go to the cinema/shows / go on holiday) and lifestyle factors (smoking, alcohol, body mass index [BMI; from height and weight], physical activity). Structural equation modelling was used to combine the social support and financial status data into latent variables, and then assess the direct and indirect (mediated by PROMs) effects of these variables as well as lifestyle factors on excess disability (adjusted for age and gender).

Results: In total, 538 people with RA were included (mean [standard deviation] age: 48.3 [12.2] years; 79.2% women), 200 (37.2%) of whom had excess disability over 10 years. The excess disability group were older, included more women, and had worse PROMs at baseline compared with the no excess disability group (Table 1). Less social support (β 0.17, 95% CI 0.08, 0.26) and worse financial status (β 0.30, 95% CI 0.19, 0.41) both predicted excess disability group membership, as did lower physical activity (β 0.17, 95% CI 0.09, 0.25) (Figure 1), whereas smoking, alcohol and BMI at baseline did not. Only a small proportion of this effect was mediated by the PROMs (social support: 21%, financial status: 31%, physical activity: 28%; Figure 1).

Table 1. Baseline characteristics

	Excess disability,	No excess disability,
	Mean (SD) / N (%)	Mean (SD) / N (%)
N	200	338
Age, years	50.4 (10.7)	47.0 (12.8)
Women, N(%)	174 (87.0%)	252 (74.6%)
Symptom duration, months	3.63 (2.02)	3.36 (1.62)
Pain VAS	47.1 (27.4)	37.0 (26.9)
Fatigue VAS	59.3 (27.2)	46.5 (26.5)
AIMS anxiety	5.61 (2.25)	4.71 (2.27)
AIMS depression	4.47 (2.24)	3.47 (1.97)
Health Assessment Questionnaire	1.39 (0.64)	0.93 (0.61)
DAS28-2C	4.04 (1.28)	3.99 (1.34)

AIMS = Arthritis Impact Measurement Scales, DAS28-2C = two-component Disease Activity Score, SD = standard deviation, VAS = visual analogue scale

Conclusion: Disability resulting from RA is a complex phenomenon, arising from more than just joint inflammation. This analysis indicates that lack of social support, financial instability and lower physical fitness at symptom onset may explain the excess disability associated with RA. As only a small portion of the effect is mediated by PROMs, health and social inequalities may need to be targeted directly by interventions.

Figure – SEM diagrams of direct and mediating paths between latent variables (a) less social support, (b) worse financial status as well as (c) lifestyle factors and excess disability group membership (indicates statistical significance)*
Ovals represent latent constructs, rectangles observed variables. The total effects referred to in the abstract combine both the direct effect from the latent constructs to the outcome (excess disability), and the indirect effects through the PROMs. For example, the total effect of social support on excess disability (panel a) was 0.17, calculated as the direct effect (0.13) plus the indirect effects through the PROMs ((0.04 x 0.09) + (0.11 x 0.12) + (0.08 x 0.03) + (0.13 x 0.14)). Proportion mediated by the PROMs is the indirect effect divided by the total effect.
BMI = body mass index, PROMs = Patient reported outcome measures, SEM = structural equation model

NO EXCESS MORTALITY IN CONTEMPORARY UNDIFFERENTIATED ARTHRITIS, IN CONTRAST TO RHEUMATOID ARTHRITIS; A STUDY WITH A FOLLOW-UP OF AT LEAST 10 YEARS

M. Verstappen[1], T. Huizinga[1], A. Van der Helm-van Mil[1,2]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands;* [2]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Undifferentiated arthritis (UA) is traditionally considered an early phase of rheumatoid arthritis (RA),[1] and management strategies of RA are often transferred to UA-patients assuming outcomes are comparable. Importantly, the UA population changed with the introduction of 2010 RA criteria as part of the conventional UA population became classified as RA. Consequently, contemporary UA-patients (not fulfilling the 1987 nor 2010 RA-criteria) are largely autoantibody negative and present with relatively mild disease.[2] Subsequently, contemporary UA might no longer represent a group of patients in a pre-phase of RA but a population with intrinsically different characteristics than RA. We therefore hypothesized that mortality, a long term outcome which is increased in RA, is not increased in contemporary UA.

Objectives: To asses mortality rates in contemporary UA-patients, and to compare this to RA and conventional UA during at least 10 years of follow up.

Methods: We studied 860 conventional UA-patients (no 1987 RA-criteria or other diagnosis), 561 contemporary UA-patients (no 1987/2010 RA-criteria or other diagnosis) and 762 RA-patients according to the 1987 criteria and 826 patients fulfilling the 2010 criteria, included in the Leiden Early Arthritis Clinic (EAC) between 1993-2008 to ascertain 10-years of follow-up. Mortality data were obtained from the civic registries (June 2018). Standardized-mortality-ratios (SMRs) were adjusted for age, gender and calendar-year, and additionally stratified for ACPA-positivity (anti-CCP2, cut-off>10 mg/L) and DMARD-treatment.

Results: The contemporary UA-population was for 93% ACPA-negative and the SJC was 1 (median) and TJC 2. This presentation was milder than that of patients with conventional UA. In RA (both 1987-RA and 2010-RA) we observed excess mortality compared to the general population (Figure 1). In conventional UA, a trend towards excess mortality was observed: SMR 1.11 (95%CI:0.96-1.27). However, part of this UA population is currently classified as 2010-RA. Subsequently, in contemporary UA, which does not include these 2010 RA-patients, no excess mortality was observed: SMR 1.05 (95%CI:0.87-1.26). ACPA-stratification suggested excess mortality in ACPA-positive contemporary UA, but not in ACPA-negative contemporary UA (Figure 1). Mortality rates in contemporary UA-patients who did and did not receive DMARD-treatment were comparable (SMR 0.93 (95%CI:0.66-1.24) and SMR 1.08 (95%CI:0.82-1.36)).

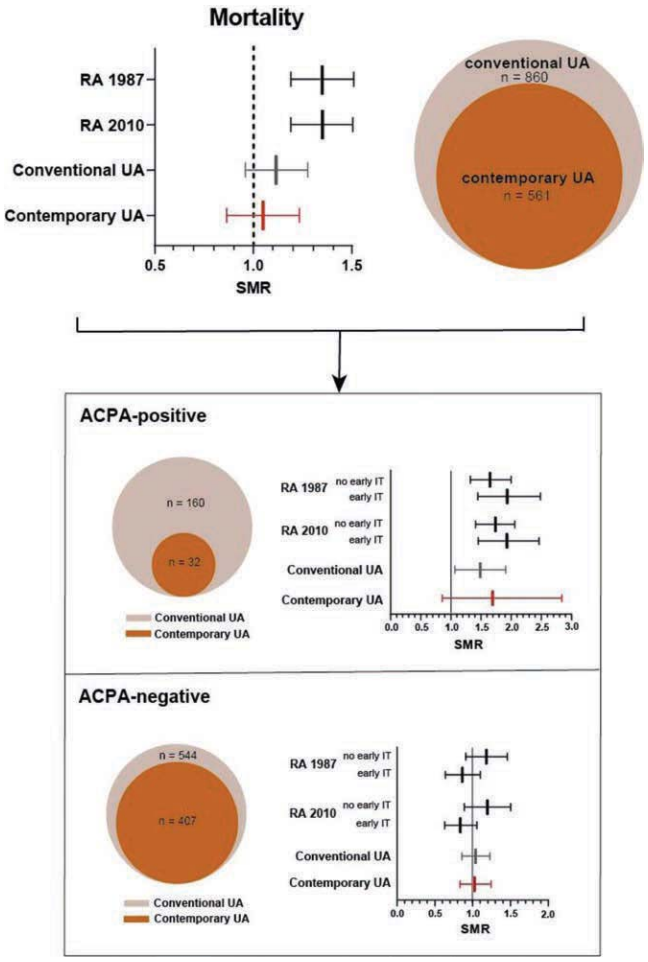

Figure 1. SMRs in UA and RA-patients with minimally 10-years of follow-up. Additionally, mortality was stratified for ACPA-status. In RA, SMRs were also stratified for early treat-to-target DMARD-therapy, which has been shown relevant for mortality analysis in RA.[3] *ACPA: anticitrullinated autoantibody protein, UA: undifferentiated arthritis, RA: rheumatoid arthritis, SMR: Standardized mortality rate, IT: intensive treatment.*

Conclusion: Contemporary UA has no excess mortality, in contrast to RA. So, besides milder disease at presentation within contemporary UA, also the long-term outcome mortality is more favorable and comparable to the general population. This supports the notion that contemporary UA-patients have intrinsically different characteristics than RA-patients, rather than representing an early stage of RA. Future studies are warranted to determine whether contemporary UA should be treated as RA; our results suggest that this population may deserve separate guidelines.

POS0506 DIFFERENT BIOACTIVE LIPID PROFILES PREDICT RESPONSE TO TNF OR IL6 INHIBITORS IN RHEUMATOID ARTHRITIS: RESULT OF THE COREVITAS CERTAIN COMPARATIVE EFFECTIVENESS STUDY

M. Alotaibi[1], R. Coras[1], D. A. Pappas[2], J. M. Kremer[2], G. Thiele[3,4], T. Mikuls[3,4], M. Jain[1], M. Guma[1,5]. *[1]University of California San Diego, Medicine, La Jolla, United States of America; [2]CorEvitas, Medicine, NYC, United States of America; [3]University of Nebraska Medical Center, Medicine, Omaha, United States of America; [4]Omaha VA Medical Center, Medicine, Omaha, United States of America; [5]VA San Diego Healthcare System, Medicine, San Diego, United States of America*

Background: Circulating bioactive lipids can provide information about the pathogenesis of specific diseases and potentially help predict therapeutic response. Choosing the right biological therapy earlier in the course of rheumatoid arthritis (RA) could help reach the goal of remission.
Objectives: We hypothesized that circulating bioactive lipids at baseline would identify specific metabolic profiles that predict patient response to therapy and define elements of metabolic pathobiology in arthritis.
Methods: Bioactive lipids were measured in plasma from two cohorts of RA patients from the CorEvitas (formerly known as Corrona) CERTAIN registry (1) at baseline prior to treatment with TNF inhibitors (all biologic naïve, N=102) or anti-IL6 (all previously exposed to biologics, N=114). Response to treatment was categorized by minimal clinically important difference (MCID) in Clinical Disease Activity Index (CDAI) (2) at 6 months after treatment initiation. Patients had to have a 6 month follow up visit and plasma available at both the baseline and the f/u time points. Liquid chromatography (LC) system coupled with high resolution QExactive orbitrap mass spectrometer (LC/MS) was used for bioactive lipids profiling. Around 300 spectral features were identified as potential oxylipins by searching against an in-house MS/MS library. Logistic regression analyses adjusted for gender, age and BMI was perfomed using R software.
Results: 102 patients (average age 54, standard deviation [SD] 12.6, 82% female [83], average BMI 29.7, SD 6.7, average CDAI 27.1, SD 13.7) starting anti-TNF therapy and 114 patients (average age 57, SD 13, 90% female [102], average BMI 30.5, SD 7.4, average CDAI 28.7, SD 13.8) starting tocilizumab were analyzed. Twenty-five bioactive metabolites discriminated between RA patients classified as anti-TNF responders (R, n = 74) and non-responders (NR, n = 28). Among these, the anti-inflammatory oxylipin maresin 2 was higher in R while the pro-inflammatory oxylipins 15d PGJ2 and 5,6-diHETE were higher in NR. Twenty different metabolites discriminated anti-IL6 R (n=73) and NR (n=41) as shown in Figure 1. The anti-inflammatory oxylipin 14-15EET was higher in R while the pro-inflammatory oxylipins 16-HETE and 5S-HpETE were higher in NR.
Conclusion: Circulating bioactive lipid analysis using LC/MS provided a rapid analysis of a wide range of metabolites and can be used to describe metabolic signatures that predict response to therapies. These results lay the groundwork for more deliberate investigations novel metabolic-based interventions to predict response to therapy and reduce arthritis morbidity.

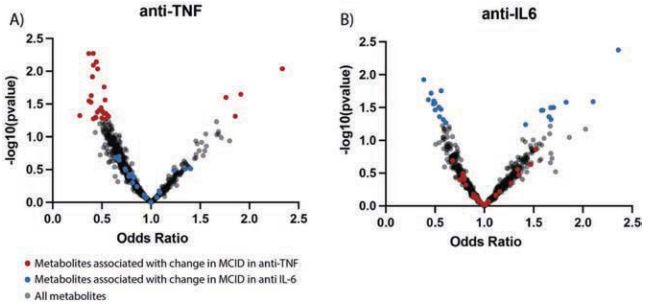

Figure 1. Volcano plots visualizing baseline metabolites associated with responders vs. non responders in a) anti-TNF and b) anti IL-6 therapy groups. Results are derived from multivariate logistic regression analysis of baseline metabolites and response to treatment categorized by MCID. Data plotted as the metabolite against its statistical significance, respectively reported as odds ratio (OR) and -log10(pvalue).

POS0507 TAILORING ORAL THERAPY IN RHEUMATOID ARTHRITIS: THE TUTOR APP

M. Radin[1], M. Arbrile[1], I. Cecchi[1], A. Barinotti[1], S. Baldovino[1], E. Menegatti[1], D. Rossi[1], S. Sciascia[1], D. Roccatello[1]. *[1]University of Turin, Clinical and Biological Sciences, Turin, Italy*

Background: Medication non-adherence has a significant impact on the health and well-being of individuals with chronic diseases. Indeed, with respect to important risk factors of Rheumatoid Arthritis (RA), such as cardiovascular risk factors, it is known that up to 50% of patients will stop taking medication for these conditions during the first year of prescription [1].
Objectives: To support the management of RA patients treated with Tofacitinib, we designed the TuTOR (Tailoring Tofacitinib Oral therapy in Rheumatoid arthritis) Mobile App.
Methods: A prospective-controlled study evaluated the impact of TuTOR App on medical adherence in 20 RA patients, that began treatment with Tofacitinib jointly with the App. We used a crossover design alternating Paper-Diary and TuTOR App, with monthly clinical assessments.
Results: Seventeen patients with RA (mean age at inclusion 59±13yrs; 88% females) the study. A statistically significant decrease of DAS28 was observed since the first month of therapy with Tofacitinib (mean DAS28 at baseline 3.9±1 vs. 1° month 3.1±1, p=0.0016). Similarly, Numerical Rating Scale(NRS) of perceived activity of disease (5.8±2.1 vs.3.7±2.5, p=0.02), and subjective fatigue (6.1±2.3 vs 4.3±2.6; p=0.01) progressively decreased. No differences were reported in DAS28 and in all the NRS between the use of the TuTOR App and the Paper-Diary. A significant decrease was observed also in HAQ during the follow-up (baseline 1.38±1.11 vs.six months 0.83±0.9; p=0.01). Most of the patients (82%) when filling out the self-reporting questionnaires preferred the TuTOR App in helping them to remember to take the pills. Further 82% of patients used the TuTOR App regularly (vs.53% Paper-Diary) and 76% of patients would use it in the future (vs.53% Paper-Diary). Three patients suspended the therapy with Tofacitinib due to gastrointestinal intolerance.
Conclusion: Both digital- and paper-devices can help maximize the adherence to therapy, leading to an improvement in disease's activity, highlighting the need of supports for medication adherence.

PREDICTORS OF PERSISTENT DISEASE IN EARLY ARTHRITIS: 12 MONTHS RESULTS

D. Capelusnik[1], F. M. Dal Pra[2], E. E. Schneeberger[1], E. Soriano[3], J. Rosa[3], O. Rillo[4], Y. M. Ponce Delgado[4], A. Secco[5], E. Velozo[6], A. Berman[7], M. García[8], F. Caeiro[9], S. Paira[10], G. Citera[1]. *[1]Instituto de Rehabilitación Psicofísica, Rheumatology, CABA, Argentina; [2]Instituto de Rehabilitación Psicofiisca, Rheumatology, CABA, Argentina; [3]Hospital Italiano, Rheumatology, CABA, Argentina; [4]Hospital Pirovano, Rheumatology, CABA, Argentina; [5]Hospital Rivadavia, Rheumatology, CABA, Argentina; [6]Universidad Adventista del Plata, Rheumatology, Entre Rios, Argentina; [7]Centro médico privado de reumatología, Rheumatology, Tucuman, Argentina; [8]Hospital San Martin de La Plata, Rheumatology, La Plata, Argentina; [9]Hospital Privado, Rheumatology, Cordoba, Argentina; [10]Hospital José Mcullen, Rheumatology, Rosario, Argentina*

Background: Early arthritis is an inflammatory disease with the potential to progress to persistent arthritis, such as established Rheumatoid Arthritis (RA) or other articular disease, to resolve spontaneously or remain undifferentiated for indefinite periods of time.
Objectives: To identify predictors of persistent RA after 12 months follow up in the Argentinean early arthritis clinic (CONAART).
Methods: We conducted an observational, prospective longitudinal study, including patients with early arthritis (at least 1 swollen joint with <2 years of evolution) who had at least one year of follow-up. Sociodemographic and clinical data and characteristics of the disease were recorded at baseline, at 3, 6 and 12 months. After 1 year of follow-up, each patient was classified according to diagnosis: self-limited arthritis, persistent non-erosive arthritis, or persistent erosive arthritis. The association between the different predictors of diagnosis at 12 months was evaluated using multiple logistic regression, adjusted by potential confounders. Rheumatoid Factor (RF) and Anti Citrullinated Peptide Antibodies (ACPA) were included in separate models in order to avoid multicollinearity. A value of $p<0.05$ was considered significant.
Results: We included 839 patients, 83% females, mean age of 57±14 years and mean disease duration of 8.2±6.2 months; 67.5% were rheumatoid factor positive and 59% ACPA positive. Disease characteristics at baseline were DAS28 5.1±1.4, swollen joints 6±5, erythrocyte sedimentation rate (ESR) 34±25 mm/h, C Reactive Protein (CRP) 4±6 and Health Assessment Questionnaire-Argentinean (HAQ-A) 1.2±0.8. After 12 months follow up, 11% of the patients were diagnosed as self-limited disease, whereas 89% were diagnosed as persistent disease. For the persistent disease, 34% presented radiograph erosions and therefore were catalogued as persistent erosive disease. The seropositivity for both, RF and ACPA, together with baseline DAS28, were the variables independently associated with the development of persistent disease at 12 months. [Model 1a: RF OR 2.33 (95% CI 1.44, 3.78) and DAS28 1.27 (1.06, 1.52); Model 2a: ACPA 2.61 (1.38, 4.93) and DAS28 1.59 (1.24, 2.04)]. (Table 1). In the patient prediction model, it can be observed that a patient with female gender, ACPA negative, and a low activity at baseline (DAS28 <3.1) presents a 62.3% of likelihood of developing persistent arthritis after 12 months, while a male patient, ACPA positive, with a high baseline activity level, the probability of having persistent disease rises to 97.5%. (Figure 1)

Gender	Female	62.3 (42.4, 82.1)	81.3 (67.7, 94.8)	<3.2	**Baseline DAS28**

POS0509 DEVELOPMENT OF A MULITNOMIAL PREDICTION MODEL OF TREATMENT RESPONSE TO ETANERCEPT IN A MULTI-CENTRE COHORT OF PATIENTS WITH ESTABLISHED RA

M. Stadler[1], S. Ling[1], N. Nair[1], J. Isaacs[2], K. Hyrich[3,4], A. Morgan[5,6], A. G. Wilson[7], D. Plant[1,3], J. Bowes[1], A. Barton[1,3]. [1]*Versus Arthritis Centre for Genetics and Genomics, University of Manchester, Manchester, United Kingdom;* [2]*Translational and Clinical Research Institute, Newcastle University and Musculoskeletal Directorate, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom;* [3]*NIHR Manchester BRC, Manchester University Foundation Trust, Manchester, United Kingdom;* [4]*Versus Arthritis Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, University of Manchester, Manchester, United Kingdom;* [5]*Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, Leeds, United Kingdom;* [6]*NIHR Leeds BRC, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom;* [7]*UCD School of Medicine and Medical Science, Conway Institute, University College Dublin, Dublin, Ireland*

Background: Treatment response in rheumatoid arthritis (RA) is assessed through EULAR response groups of good, moderate, and poor response. Clinical prediction models from the literature typically frame this as a binary model, to differentiate poor from good and moderate responders. Here, we develop a multinomial model, to predict each group separately, after 3 months on the anti-TNF drug Etanercept (ETN).
Objectives: Develop and validate a multinomial prediction model of treatment response to ETN in RA, based on baseline clinical covariates.
Methods: We identified patients treated with ETN or biosimilars (N = 778) from the Biologics in RA Genetics and Genomics Study Syndicate (BRAGGSS). Response groups were derived from the CRP based 4C-DAS28 at baseline and 3 month follow up, yielding 310 good, 320 moderate, and 148 poor responders. A multinomial logistic regression model was fitted, using good responders as reference category. Multiple imputation by chained equations was used to impute missing data, and models were internally validated via bootstrapping. We report model accuracy, as well as calibration, and compare effect sizes across response groups. Table 1shows the baseline statistics, and odds ratios for the included covariates.

Table 1. Baseline covariate statistics and odds ratios (in bold: significant at p < 0.05); HADS: Hospital Anxiety and Depression Scale

Variable	Mean (± SD) or % Yes	$OR_{Moderate}$ [95% CI]	p	OR_{Poor} [95% CI]	p
Swollen Joint Count (SJC)	8.8445 (± 5.20)	0.98 [0.95 1.02]	0.35	**0.94 [0.89 0.98]**	**8e-3**
Tender Joint Count (TJC)	14.6877 (± 6.74)	**1.07 [1.04 1.10]**	**6e-6**	**1.05 [1.01 1.08]**	**0.01**
General Health Visual Analog Scale (GHVAS)	74.7429 (±17.79)	1.00 [0.99 1.01]	0.6	**0.98 [0.97 0.99]**	**1e-3**
CRP	19.0739 (±25.07)	1.00 [1.00 1.01]	0.22	0.99 [0.98 1.00]	0.26
BMI	30.3035 (±23.28)	1.00 [0.99 1.01]	0.48	1.00 [0.99 1.01]	0.41
Age of onset	47.3330 (±13.86)	1.01 [1.00 1.03]	0.12	1.02 [1.00 1.04]	0.06
Disease duration	9.9401 (±10.35)	1.00 [0.98 1.02]	0.84	0.99 [0.96 1.02]	0.45
HAQ	1.6085 (± 0.65)	**1.48 [1.06 2.08]**	**0.02**	**2.95 [1.91 4.54]**	**1e-6**
HADS-Anxiety	8.0868 (± 4.54)	1.04 [0.98 1.10]	0.19	1.06 [0.99 1.13]	0.12
HADS-Depression	7.3841 (± 4.02)	1.06 [0.99 1.13]	0.12	0.97 [0.89 1.06]	0.55
Concurrent DMARD	81.49%	**0.41 [0.26 0.66]**	**2e-4**	**0.52 [0.28 0.94]**	**0.03**
Female	78.66%	1.39 [0.92 2.10]	0.12	1.11 [0.65 1.87]	0.71
Seropositive	77.89%	**0.54 [0.33 0.89]**	**0.02**	**0.47 [0.26 0.86]**	**0.01**
1st Biologic	90.62%	1.06 [0.55 2.06]	0.86	**0.48 [0.24 0.94]**	**0.03**

Results: Adjusted for optimism, the multinomial model achieves an accuracy of 50.7% (IQR: 50 – 51.3%), with calibration slopes of 0.574 (IQR: 0.569 - 0.579) and 0.534 (IQR: 0.525 - 0.544) for moderate and poor response, respectively. Figure 1 shows a comparison of odds ratios (OR) for the different outcome groups. The Health Assessment Questionnaire (HAQ) score is the biggest driver of both moderate and poor response. Previous biologic treatment also predicts poor but not moderate response. Compared to the multinomial model, a binary model, that discriminates poor from moderate and good responders, underestimates the effect size of HAQ.

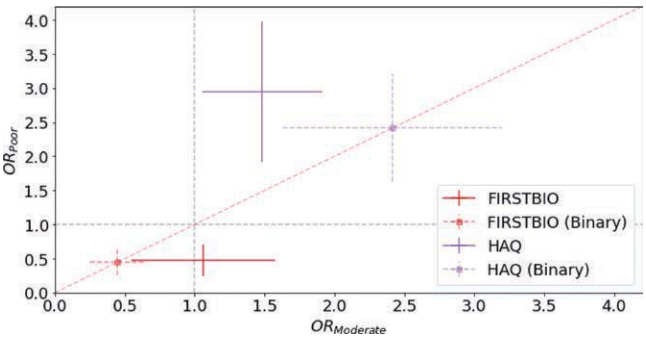

Figure 1. Odds ratios of FIRSTBIO and HAQ for moderate and poor response. Size of crosses indicate 95% confidence intervals.

Conclusion: The model predicts EULAR response groups moderately well but is poorly calibrated, which can partly be explained by the generally higher sample size requirement of multinomial modelling. In the multinomial model, moderate and poor response is largely driven by the same covariates, which leads to blurred boundaries between good and poor responders, when response groups are merged to create a binary problem. Future research should consider the most appropriate model choice to describe data, including the use of multinomial instead of binomial models. More research and bigger sample sizes are required to improve on this multinomial model.

POS0510 INFLUENCE OF CMV INFECTION ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Kippenhahn[1], C. Baerwald[1], C. Pietsch[2], O. Seifert[1]. [1]*Rheumatology Unit, Clinic for Endocrinology, Nephrology and Rheumatology, Department of Internal Medicine, Neurology and Dermatology, University Hospital Leipzig, Leipzig, Germany;* [2]*Institute of Medical Microbiology and Virology, Department of Virology, University Hospital Leipzig, Leipzig, Germany*

Background: The causes of the onset and progression of rheumatoid arthritis (RA) are complex and not yet understood. Some studies suspect viruses as triggers of inflammatory processes (1). Increased numbers of immunomodulatory cells have already been detected in patients with RA infected with the cytomegalovirus (CMV) (2) (3). Understanding the role this infection has on RA-specific disease parameters could help clarify predisposing and prognostic factors.
Objectives: The aim of this study was to determine the relationship between CMV serostatus and disease activity in patients with rheumatoid arthritis.
Methods: We performed a retrospective study in adult patients diagnosed with RA. The data was collected between 2008 and 2021 in the rheumatological outpatient department of the University Hospital in Leipzig, Germany. The parameters examined included age, gender, CMV-IgG and CMV-IgM, and the following parameters to record the disease activity of RA: disease duration, joint erosions, rheumatoid factor, anti-CCP antibodies, CRP, disease activity score (DAS28), visual analog scale (VAS) for pain detection, Health Assessment Questionnaire (HAQ), medication with DMARDs and prednisolone.
Results: A total of 89 RA patients were included, 78.7% of them were female. The mean age was 61.44 ± 10.89 years and the mean duration of illness was 9.48 ± 9.13 years. 56.2% of the patients were CMV-IgG positive, 2.2% CMV-IgM positive. With an OR of 5.04 (95% CI 1.63-15.64), the CMV-IgG titer in women was significantly higher than in men (115.16 vs. 50.75

p = 0.007). This has already been shown in other studies (4). One of the reasons discussed is the women's closer relationship with children at work. It has also been shown that among women those medicated with DMARDs had significantly higher CMV-IgG titers (126.82 vs. 58.84 p = 0.036). This could be explained by an increased predisposition for CMV reactivation due to the intake of medication. Women with joint erosions were also more likely to be CMV-IgG positive (OR = 3.2; 95% CI 1.02-10.03) and had higher CMV-IgG titers (147.44 vs. 97.23 p = 0.024). Furthermore, seropositive RA women were significantly more likely to be CMV-IgG positive (p = 0.05). This association supports the assumption that CMV may play a role in the pathogenesis of RA.

Conclusion: The data presented shows that there is indeed a relationship between infection with CMV and parameters for disease activity in patients with RA. In summary, the integration of a CMV status determination into everyday clinical practice in patients with high disease activity could be quite useful and should be discussed.

POS0511

PERIODONTAL STATUS BEFORE DIAGNOSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS PREDICTS CUMULATIVE DISEASE ACTIVITY IN YEARS AFTER TREATMENT INITIATION

A. Plachokova[1], J. Fransen[2], M. Koenders[2], R. M. Thurlings[2]. *[1]Radboud University Medical Center, Dentistry, Nijmegen, Netherlands; [2]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: Transversal cohort studies demonstrated an association between periodontal disease (PD) and rheumatoid arthritis (RA), but it is unknown how this association evolves during the course and treatment of both conditions[1].

Objectives: In this study we compared RA and PD before and after RA diagnosis in patients versus controls and analyzed the relationships between disease course and treatment of both conditions.

Methods: Retrospective dental and RA data were analyzed of 95 RA patients from 10 years before up to 10 years after RA diagnosis. Dental data were acquired from general practices and matched healthy control patient data from the university dental college. PD was analyzed via radiographic assessment using the new periodontal classification system from 2017. The relationship was analyzed between PD and RA parameters and treatment.

Results: More RA patients had severe or very severe PD compared to matched healthy controls, already before RA diagnosis. The fraction of RA patients with severe/very severe PD increased from 23% before diagnosis to 43% 5-10 years after diagnosis. Patients with a more severe PD before RA diagnosis had more tooth loss at last dental follow-up and a higher cumulative DAS28 in the years after diagnosis. Two-thirds of patients with severe/very severe PD received appropriate dental care less frequently than advised by guidelines. Suboptimal dental care was associated with a higher cumulative DAS28.

Conclusion: PD occurs before RA diagnosis in a proportion of patients. This proportion increases in the years after diagnosis. PD is associated with a decreased response to treatment of RA. A significant number of RA patients with PD receives suboptimal dental care, which is associated with diminished response to RA treatment.

Background: A treat-to-target approach for RA management is recommended.[1,2] However, up to half of patients discontinue DMARD treatment within 18 months.[2] Predictive biomarkers, such as anti-citrullinated protein antibodies (ACPAs) and RF, may be useful to stratify patients to the most appropriate treatment. ACTION (AbataCepT In rOutiNe clinical practice; NCT02109666) and ASCORE (Abatacept SubCutaneOus in Routine Clinical PracticE; NCT02090556) were 2-year, international, observational, prospective, multicenter studies of IV and SC abatacept, respectively, for the treatment of RA in routine clinical practice.[3,4] Higher

retention has been previously reported in patients with double ACPA/RF seropositive RA compared with double ACPA/RF seronegative RA.[3,4]

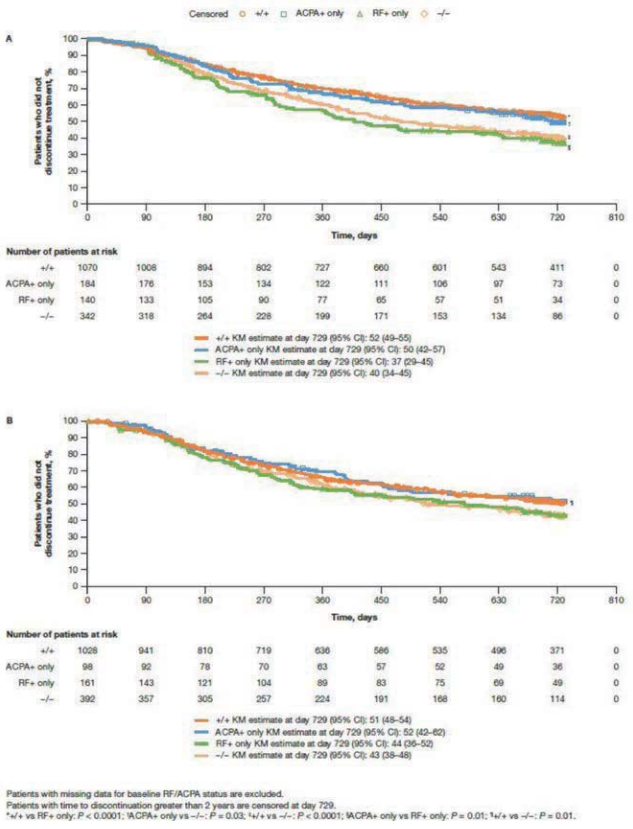
Objectives: To assess the independent effect of ACPA or RF single seropositivity on abatacept retention in patients with RA receiving abatacept in a post hoc analysis of ACTION and ASCORE.

Methods: This post hoc analysis included patients aged ≥ 18 years, with active moderate-to-severe RA (ACR/EULAR 2010 criteria) who initiated IV (body weight–adjusted dosing) or SC (125 mg once weekly) abatacept.[3,4] Patients were stratified by baseline ACPA/RF status: ACPA+/RF– (ACPA+ only), ACPA/RF double positive (+/+), ACPA–/RF+ (RF+ only), and ACPA/RF double negative (–/–). Abatacept retention rate at 2 years was estimated by Kaplan–Meier (KM) analysis.

Results: Patients with ACPA/RF serostatus data from the ACTION and ASCORE studies (N = 1679 and N = 1748, respectively) were evaluated. Baseline demographic and disease characteristics were similar across studies and serostatus groups (Table 1). In patients with ACPA+ only RA, abatacept retention rates were similar to the +/+ group and greater than the RF+ only and –/– groups (Figure 1). In ASCORE (Figure 1A), retention rates were significantly higher in ACPA+ only and +/+ groups when compared with the –/– group. In contrast, retention rates for patients with RF+ only RA were not significantly different vs –/– patients. Results were similar in ACTION, although the higher retention in the ACPA+ group did not reach statistical significance (Figure 1B).

Conclusion: In this post hoc analysis of the real-world ACTION and ASCORE studies, ACPA positivity was associated with an increased likelihood of retention over 2 years. Patients with ACPA+ only RA were equally as likely to be retained on abatacept as patients with ACPA/RF double positivity. In contrast, patients with RF+ only RA were less likely to be retained on abatacept over 2 years. These findings suggest that ACPA positivity played a more important role than RF positivity in abatacept retention. The higher retention seen in patients with ACPA+ only vs RF+ only disease demonstrates the key role of ACPA in RA and supports the importance of precision medicine in treating patients.

Figure 1. Retention rates for patients with ACPA+ only, RF+ only, +/+, and –/– RA treated with abatacept in the (A) ASCORE and (B) ACTION studies



Patients with missing data for baseline RF/ACPA status are excluded.
Patients with time to discontinuation greater than 2 years are censored at day 729.
*+/+ vs RF+ only: $P < 0.0001$; †ACPA+ only vs –/–: $P = 0.03$; ‡+/+ vs –/–: $P < 0.0001$; §ACPA+ only vs RF+ only: $P = 0.01$; ¶+/+ vs –/–: $P = 0.01$.

Clinical Development, Mechelen, Belgium; [7]IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Department of Internal Medicine, Milan, Italy; [8]University of Manchester, Centre for Musculoskeletal Research, School of Biological Sciences, Manchester, United Kingdom

Background: Filgotinib (FIL) is a Janus kinase 1 preferential inhibitor approved for the treatment of moderate to severe rheumatoid arthritis (RA) in patients (pts) with an inadequate response to disease-modifying antirheumatic drugs.[1] In a pooled analysis of Phase 3 FINCH 1–3 studies of FIL in RA, median lymphocyte levels were relatively stable over 1 year with lymphocyte decreases observed in individual FIL-treated pts. Lymphocyte levels should be monitored.[1]
Objectives: To assess the effect of FIL on lymphocyte levels and lymphopenia in the FINCH 4 long-term extension (LTE) study in RA.
Methods: Safety data of FIL 100 mg (FIL100) and 200 mg (FIL200) from LTE baseline to data cut off (01 June 2020) are reported overall and by prior FIL exposure for pts who received ≥1 FIL dose in FINCH 4 (NCT03025308; adults with RA who had completed FINCH 1/2/3). Adverse events (AEs) of lymphopenia were graded based on clinical severity; laboratory abnormalities (decreased lymphocytes) were graded per Common Terminology Criteria for Adverse Events v4.03 (CTCAE). Frequencies of both measures and exposure-adjusted incidence rates (EAIRs) of AEs are reported. Median lymphocyte levels are reported to LTE Week 48.
Results: The safety analysis set included 2729 pts (FIL200: n=1530; FIL100: n=1199). Of these, 75.4% (n=2058) had prior FIL exposure in FINCH 1/2/3. Median FIL exposure to LTE Week 48 was 600 (FIL200: 696; FIL100: 533) days. In both treatment groups, median laboratory lymphocyte levels remained relatively stable to LTE Week 48 for pts with prior FIL exposure. Pts without prior exposure had numerically higher median lymphocyte levels at LTE baseline vs pts with prior exposure (Figure 1). These decreased over time, but medians remained within normal range. The frequency and EAIR of graded decreases in laboratory lymphocyte levels were higher with FIL200 vs FIL100 (Table 1); incidence was slightly higher in pts with vs without prior FIL exposure, with the difference most apparent for Grade 2 decreases.

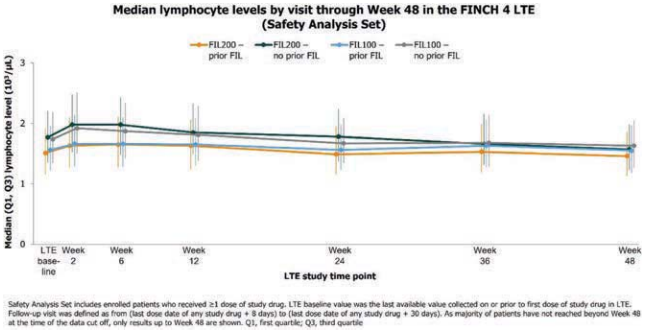

Figure 1.

Of all pts receiving FIL, 43 (1.6%) reported a lymphopenia AE; frequencies and EAIRs of lymphopenia AEs were slightly higher with FIL200 (1.9%; EAIR [95% CI]: 1.2 [0.9–1.8]) vs FIL100 (1.2%; 0.8 [0.4–1.3]). Most were Grade 1 or 2 in severity. Grade 3 lymphopenia AEs occurred in 4 (0.3%) vs 1 (<0.1%) pts receiving FIL200 vs FIL100. There were no Grade 4 AEs in either group. No serious AEs of lymphopenia or treatment discontinuations due to lymphopenia were reported. In total, 8 (0.3%) pts interrupted study treatment due to lymphopenia. Infection rates, but not serious infections, were slightly higher for pts with lymphopenia, however no relationship between lymphopenia severity and infection AE grade was seen.
Conclusion: In FINCH 4, lymphopenia AEs were infrequent but numerically greater with FIL200 vs FIL100, suggesting a dose–response relationship. While exposure at either dose may be associated with decreased lymphocytes, median lymphocyte levels were comparable in both groups and all remained within normal range at LTE Week 48, similar to observations in FINCH 1–3.

POS0514 PREDICTION OF RESPONSE TO METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A MACHINE LEARNING APPROACH USING CLINICAL TRIAL DATA

S. Duong[1], C. S. Crowson[1], A. Athreya[2], E. Atkinson[1], J. M. Davis III[3], K. J. Warrington[3], E. Matteson[3], R. Weinshilboum[2], L. Wang[2], E. Myasoedova[3]. *[1]Mayo Clinic, Quantitative Health Sciences, ROCHESTER, United States of America; [2]Mayo Clinic, Molecular Pharmacology and Experimental Therapeutics, ROCHESTER, United States of America; [3]Mayo Clinic, Internal Medicine, Rheumatology, ROCHESTER, United States of America*

Background: Methotrexate (MTX) is the preferred initial disease-modifying drug (DMARD) for rheumatoid arthritis (RA). However, up to 50% of patients respond inadequately to MTX (1). Clinically useful predictors that effectively identify patients with RA who are likely to respond to MTX are lacking. Whether machine learning (ML) can provide robust and clinically useful prediction of response to MTX monotherapy in the first months of treatment in patients with early RA using uniformly collected baseline demographics and clinical data has not been investigated in large patient populations.
Objectives: We aimed to identify clinical predictors of response to MTX as the first DMARD among patients with RA using ML methods.
Methods: Randomized clinical trials (RCT) of patients with RA who were DMARD-naïve and randomized to placebo plus MTX were identified and accessed through the Clinical Study Data Request Consortium and Vivli Center for Global Clinical Research Data. Studies with available Disease Activity Score with 28-joint count and erythrocyte sedimentation rate (DAS28-ESR) at baseline, 12 and 24 weeks were included. Latent class modeling of MTX response was performed. Least absolute shrinkage and selection operator (LASSO) and random forest were used to identify predictors of response.
Results: A total of 775 patients from 4 RCTs were included (mean age 50 years, 80% female). Two distinct classes of patients were identified based on DAS28-ESR change over 24 weeks: "good responders" and "poor responders" to MTX

Table 1. Frequencies of treatment-emergent laboratory decreases in lymphocytes

	Prior FIL exposure		No prior FIL exposure		Overall		Total
	FIL200	FIL100	FIL200	FIL100	FIL200	FIL100	(N=2729)
	(n=1195)	(n=863)	(n=335)	(n=336)	(n=1530)	(n=1199)	
Decreased lymphocytes (any grade), n (%)	228 (19.1)	125 (14.5)	41 (12.3)	40 (12.0)	269 (17.6)	165 (13.8)	434 (16.0)
Grade 1	48 (4.0)	35 (4.1)	14 (4.2)	7 (2.1)	62 (4.1)	42 (3.5)	104 (3.8)
Grade 2	159 (13.3)	82 (9.5)	21 (6.3)	26 (7.8)	180 (11.8)	108 (9.1)	288 (10.6)
Grade 3	21 (1.8)	8 (0.9)	6 (1.8)	7 (2.1)	27 (1.8)	15 (1.3)	42 (1.5)
Grade 4	0	0	0	0	0	0	0

A treatment-emergent laboratory decrease in lymphocytes was defined as an increase of ≥1 toxicity grade from baseline at any time post-baseline up to and including the date of last study drug dose + 30 days. Severity grades were defined per CTCAE (lower limit of normal: <0.8 × 10^9/L [Grade 1]; <0.8–0.5 × 10^9/L [2]; <0.5–0.2 × 10^9/L [3]; <0.2 × 10^9/L [4]).

treatment (Figure 1). Baseline DAS28-ESR, anti-citrullinated protein antibody (ACPA) and health assessment questionnaire (HAQ) score were the top predictors of good response to MTX using LASSO (Area Under the Curve [AUC] 0.79) and Random Forest models (AUC 0.68) in the external validation set. DAS28-ESR≤7.4, ACPA positive and HAQ≤2 provided the highest likelihood of response (Table 1). Among patients with 12-week DAS28-ESR>3.2, at least 1 point improvement in DAS28-ESR baseline-to-12-week was predictive of achieving DAS28-ESR≤3.2 at 24 weeks.

Table 1. Matrix prediction model: Probability of achieving a good response to methotrexate at 24 weeks

DAS28ESR		HAQ ≤2	HAQ >2	ACPA Status
	≤7.4	80.1 (76.4, 83.8)	77.3 (70.6, 84)	Positive
		77.1 (68.6, 85.6)	74.1 (63.3, 84.9)	Negative
	>7.4	40.3 (32.1, 48.5)	36.5 (29.3, 43.6)	Positive
		36.2 (23.3, 49.1)	32.5 (20.9, 44.1)	Negative

Footnote: The number in each cell represents the percentage and 95% CI of achieving the outcome, based on the combination of predictors at baseline. DAS28-ESR: Disease Activity Score with 28-joint count with erythrocyte sedimentation rate; HAQ: Health assessment questionnaire score; ACPA: Anti-citrullinated protein antibody.

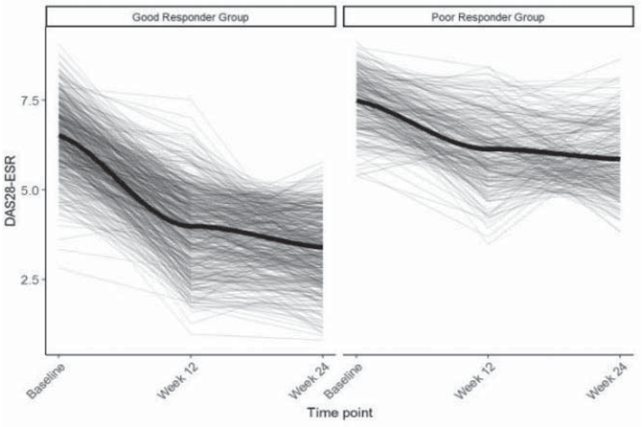

Figure 1. Two patient class trajectories identified with latent class modeling of DAS28-ESR (N=775)

Conclusion: We have developed and externally validated a prediction model for response to MTX within 24 weeks in DMARD-naïve patients with RA, providing variably weighted clinical features and defined cut-offs for clinical decision-making. Trajectory of DAS28-ESR change over 24 weeks in patients with moderate-to-high RA disease activity at baseline who are starting MTX can be predicted by baseline DAS28-ESR, ACPA status and HAQ-score. Patients with at least 1 unit decline in DAS28-ESR within the first 12 weeks of treatment who have not achieved low disease activity by week 12, may be more likely to achieve low disease activity at 24 weeks. These parameters should be considered as part of the clinical decision-making process when initiating MTX in DMARD-naïve patients with RA.

Bang[10], L. Klareskog[1], S. Saevarsdottir[1,11], K. Lundberg[1], C. Grönwall[1], J. Askling[1]. *[1]Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden; [2]Linköping University, Department of Biomedical and Clinical Sciences, Linköping, Sweden; [3]Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden; [4]Karolinska Institutet, Institute of Environmental Medicine (IMM), Stockholm, Sweden; [5]Thermo Fisher Scientific, Thermo Fisher Scientific, Uppsala, Sweden; [6]Université Toulouse III, Institut toulousain des maladies infectieuses et inflammatoires - INFINITY, Toulouse, France; [7]Karolinska Institutet, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden; [8]Leibniz Institute, German Rheumatism Centre, Berlin, Germany; [9]Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [10]ORGENTEC Diagnostika GmbH, Research & Development, Mainz, Germany; [11]University of Iceland, Faculty of Medicine, School of Helath Sciences, Reykjavik, Iceland*

Background: Patients with rheumatoid arthritis (RA) have an increased risk for cardiovascular disease, including venous thromboembolic events (VTE)[1]. The reason behind the increased VTE risk is incompletely understood, but inherent features of RA, such as RA specific autoantibodies, could potentially play a role. For example, studies have linked occurrence and levels of rheumatoid factor (RF) in the general population to increased VTE risk[2]. We and others have demonstrated an association between ACPA and risk of later ischemic cardiovascular events[3]. There are also potential mechanistic links; citrullinated fibrinogen (cFib) has been associated to clot stability[4].

Objectives: We aimed to examine the association between anti-modified protein antibodies (AMPAs) and risk of VTE in RA.

Methods: We included 2809 individuals newly diagnosed with RA and included in the Swedish EIRA study 1996-2009. Through linkage to nationwide health care registers we identified past and incident events of VTE based on validated ICD code algorithms. We centrally typed baseline sera for anti-CCP2, 20 different ACPA sub-specificities, RF isotypes, carbamylated antibodies and 10 additional post-translational modifications. We followed all individuals from RA diagnosis up until their first ever VTE event, migration, death or end of study (2020-12-31) whichever occurred first. We used a Cox regression to estimate hazard ratios (HR) with 95% confidence intervals (CI). Individuals with a history of a VTE event (n=27) at RA diagnosis were excluded.

Results: We included 2782 individuals; 72% were women, median age at RA diagnosis was 54 years (inter quartile range (IQR) 18 years) and median follow-up time was 15.5 (IQR 6.8) years. During follow-up 177 incident VTE events were observed corresponding to an incidence of 5.0 per 1,000 person years.

1797 (64.6%) patients were positive for IgG anti-CCP2 and the HR for VTE (vs. being negative for anti-CCP2) was 1.33 (95%CI 1.00-1.78). The risk of VTE increased with the level of anti-CCP2, with an HR of 1.49 (95%CI 0.99-2.22) for the group with extreme levels compared to those negative for anti-CCP2 (p-value for trend 0.048). For IgA anti-CCP2 the HR was 1.35 (95% CI 0.99-1.84) when comparing those expressing IgA anti-CCP2 against those who did not. Of 20 ACPA fine-specificities studied, 18 occurred with a frequency > 10% in our sample. The median number of fine-specificities expressed was 6 (IQR 11). The risk of VTE increased with the number of ACPA fine-specificities expressed (p-value for trend 0.033). At the 0.05 significance level, two fine-specificities were each associated with VTE; cPept Z1 [HR=1.40 (95%CI 1.06-84)] and cPept-1 [HR=1.47 (95%CI 1.12-1.93)]. None of the six antibodies against cFib assessed were statistically significantly associated with VTE risk. No associations were observed for other AMPAs. Among the three RF isotypes, only IgM RF was statistically associated with VTE [HR=1.38 (95%CI 1.04-1.83)].

Conclusion: RA-related antibodies analysed in clinical practice (anti-CCP2 IgG, RF) are associated not only with risk of myocardial infarction, stroke and cardiovascular death as previously demonstrated but also with VTE. There were no clear specific signals with ACPA fine-specificities, other AMPAs, or IgA RA autoantibodies.

Hammer[2]. *[1]St. Olavs Hospital, Dept of Rheumatology, Trondheim, Norway; [2]Diakonhjemmet Hospital, Dept of Rheumatology, Oslo, Norway; [3]Amsterdam University Medical Center, Amsterdam Rheumatology Clinic, Amsterdam, Netherlands; [4]Karolinska University Hospital, Dept of Rheumatology, Stockholm, Sweden; [5]Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden; [6]Amsterdam University Medical Center, Amsterdam Rheumatology Center, Amsterdam, Netherlands; [7]Karolinska Institute, Dept of Rheumatology, Stockholm, Sweden; [8]Rigshospitalet, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; [9]Amsterdam University Medical Center, Location VUmc, Amsterdam, Netherlands; [10]Kong Chr X's Hospital for Rheumatic Diseases, Dept of Rheumatology, Gråsten, Denmark; [11]Helsinki University Hospital, Divsion of Internal Medicine and Rheumatology, Helsinki, Finland; [12]University of Iceland, Centre for Rheumatology, Reykjavik, Iceland*

Background: Plasma calprotectin is a sensitive inflammatory marker in patients with rheumatoid arthritis (RA) and reflects activation of granulocytes and macrophages. Plasma calprotectin has not previously been studied in a head-to-head trial of multiple biological mechanisms of action versus active conventional therapy (ACT) with methotrexate and prednisolone.

Objectives: To assess the effect of treatment on plasma calprotectin levels in patients with early RA by determining the 24-week change in the four arms of the NORD-STAR Study, a large multicenter randomized head-to-head clinical trial of ACT versus tumor necrosis factor inhibition, T-cell co-stimulation inhibition, and interleukin-6 inhibition (1).

Methods: Calprotectin was analyzed in plasma samples at baseline, week 4 and week 24 from 400 treatment naïve patients with early RA in the NORD-STAR Study. Samples were analyzed using a calprotectin ELISA alkaline phosphatase (ALP) kit from CalproLab (Oslo, Norway) in a Dynex DS2 processing system (normal levels <910 µg/L). Patients were assessed by clinical (CRP, 28 SJC/TJC, physician global) and patients' reported assessments. Crude and adjusted linear regression analyses were performed in R 4.0.3 with calprotectin levels at week 24 as the outcome. The four arms were represented by three dummy variables. The adjustment variables were age, sex, anti-CCP status and country. Both analyses were adjusted for baseline calprotectin levels.

Results: At baseline, the mean time since diagnosis was 15.7 days (SD) (22.9), mean age 53.7 (15.0) years, ACPA positive 81%, and female 66%. Mean calprotectin levels were 1931 (1495) µg/L at baseline, 866 (951) µg/L at week 4, and 629 (661) µg/L at week 24. At baseline, normal calprotectin levels (<910 µg/L) were observed in 27% of all patients (ACT 22%, certolizumab-pegol and methotrexate 30%, abatacept and methotrexate 25%, tocilizumab and methotrexate 31%). At week 24, normal calprotectin levels were observed in 82% of all patients (ACT 68%, certolizumab-pegol and methotrexate 91%, abatacept and methotrexate 80%, tocilizumab and methotrexate 90%). Observed calprotectin levels at week 24 were significantly lower in patients treated with certolizumab-pegol and methotrexate -336µg/L (97) ($p < 0.006$) or tocilizumab and methotrexate -284 (99) ($p < 0.004$), versus ACT when adjusted for age, sex, anti-CCP status, baseline calprotectin level, and country; however, a significant difference was not observed in patients treated with abatacept and methotrexate -110 (96) ($p = 0.25$). The Figure 1 shows the average percentage change in calprotectin levels from baseline to week 24 for all treatment groups.

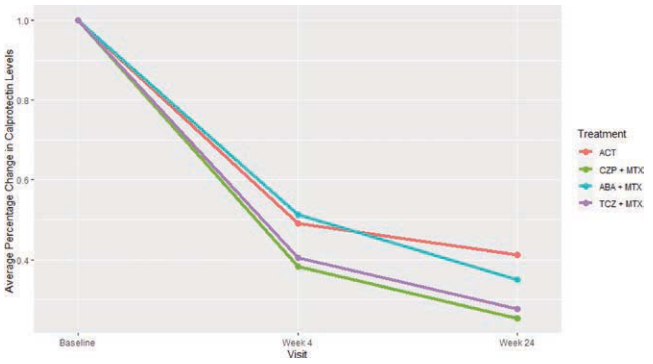

Figure 1. Average percentage change in calprotectin levels from baseline to week 24. ACT: active conventional therapy, CZP+MTX: certolizumab-pegol and methotrexate, ABA+MTX: abatacept and methotrexate, TCZ+MTX: tocilizumab and methotrexate.

Conclusion: Calprotectin, a sensitive biomarker of inflammation, normalized in the majority of patients. The decline differed between treatment groups and was largest in patients treated with a TNF inhibitor and methotrexate, suggesting that calprotectin reflects the activity of specific inflammatory pathways rather than overall inflammation. The findings of this study should be further explored.

POS0517 IGA ACPA ARE ASSOCIATED WITH PROGRESSION TO RHEUMATOID ARTHRITIS IN INDIVIDUALS AT-RISK AND DECLINE IN LEVELS AROUND THE DISEASE ONSET

M. V. Sokolova[1,2], F. Hartmann[1,2], D. Sieghart[3], G. Steiner[3,4], A. Kleyer[1,2], G. Schett[1,2], U. Steffen (Née Harre)[1,2]. *[1]Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany; [3]Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria; [4]Ludwig Boltzmann Institute, Arthritis und Rehabilitation, Vienna, Austria*

Background: Anti-citrullinated protein antibodies (ACPA) can precede the diagnosis of rheumatoid arthritis (RA) up to a decade. However, while some ACPA-positive individuals rapidly develop the disease, a considerable proportion are not progressing to RA, and the events triggering the disease outbreak are still poorly understood. While a lot is known about ACPA of IgG class, the role of IgA ACPA is still not defined.

Objectives: We aimed to look into IgA ACPA isotypes in individuals at-risk for RA and their role in RA development.

Methods: IgA1 and IgA2 ACPA were measured cross-sectionally in 30 seropositive (IgG ACPA-positive) RA patients, 29 seronegative RA patients, 63 individuals at-risk for RA (positive for IgG ACPA and/or anti-modified citrullinated vimentin antibodies and with joint complaints) and 32 healthy controls. In addition, IgA ACPA levels were compared in 24 RA at-risk individuals who developed RA during a follow-up of 14 months and in 21 individuals who did not. Furthermore, longitudinal measurements of IgA1 and IgA2 ACPA levels 1-28 months prior to, at and 1-18 months after the onset of RA were performed in 14 at-risk individuals and in 9 individuals from a confirmation retrospective cohort of RA patients from the Medical University of Vienna. Cut-offs were set based on the comparison of

IgA ACPA levels in RA patients versus healthy controls. Rather than prioritizing specificity, as is done for diagnostic tests, we aimed to define reliably detectable amounts of IgA ACPA, with both sensitivity and specificity not under 70% – 3 µg/ml for total IgA ACPA; 2.46 µg/ml for IgA1 and 0.6 µg/ml for IgA2 ACPA.

Results: Serum levels of both IgA ACPA subclasses were elevated in individuals at-risk, with no significant difference to patients with established IgG ACPA-positive RA. Interestingly, 41.4% of IgG ACPA-negative patients had detectable amounts of IgA ACPA. IgA1 ACPA, but not IgA2 ACPA levels were higher in individuals at-risk who developed RA in the next 14 months than in those who did not (4.54 vs. 2.05 µg/mL, p=0.03); and the percentage of those developing RA was higher in IgA1 ACPA-positive at-risk individuals (64.3% versus 35.3%). Interestingly, during the transition to RA, in the majority of IgA ACPA-positive individuals a decline in IgA1 ACPA levels at the time of RA diagnosis (-26%; p=0.085), as well as in the first months after the RA diagnosis (-38%; p=0.0002) was observed. This observation was confirmed in an independent cohort. IgA2 ACPA declined only after the diagnosis (33%; 10-64%; p=0.0237), and no significant change was observed for IgG ACPA.

Conclusion: Both IgA ACPA subclasses were elevated in individuals at-risk for RA. Positivity for IgA1 ACPA was associated with the progression to RA in the next 14 months. IgA1 ACPA levels declined in the months preceding the diagnosis of RA and in the months after the diagnosis, which might reflect pathophysiological events happening at the time of the disease outbreak.

POS0518 EFFECT OF FILGOTINIB (FIL) ON BODY WEIGHT (BW) AND BODY MASS INDEX (BMI) AND EFFECT OF BASELINE BMI ON THE EFFICACY AND SAFETY OF FIL IN RHEUMATOID ARTHRITIS (RA)

A. Balsa[1], S. Wassenberg[2], A. Tournadre[3], H. D. Orzechowski[4], K. Van Beneden[5], V. Rajendran[6], U. Lendl7, P. J. Stiers[8], C. Watson[5], R. Caporali[9], P. Verschueren[10]. *[1]Hospital La Paz Institute for Health Research, Rheumatology Department, Madrid, Spain; [2]Rheumazentrum Ratingen, Rheumatology Department, Ratingen, Germany; [3]Clermont Ferrand University Hospital, Rheumatology Department, Clermont-Ferrand, France; [4]Galapagos Biopharma Deutschland GmbH, Medical Affairs, Munich, Germany; [5]Galapagos NV, Medical Affairs, Mechelen, Belgium; [6]Galapagos NV, Clinical Development, Mechelen, Belgium; [4]Galapagos Biopharma Deutschland GmbH, Medical Affairs, Munich, Germany; [8]Galapagos NV, Biostatistics, Mechelen, Belgium; [9]The University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [10]University Hospital Leuven, Rheumatology Department, Leuven, Belgium*

Background: FIL is a Janus kinase (JAK) 1 preferential inhibitor approved for the treatment (tx) of moderate to severe RA. Weight gain has been reported with other JAK inhibitors[1–3]; it is important to describe the effect of FIL on BW/BMI for physicians to correctly inform and appropriately treat patients.

Objectives: Our primary aim was to assess the effect of FIL on BW/BMI using data from the FINCH 1–3 studies. Secondary aims were to assess the efficacy and safety of FIL according to baseline BMI.

Methods: FINCH 1–3 (NCT02889796, NCT02873936, NCT02886728) were phase 3, randomised, double-blind, active/placebo (PBO)-controlled studies of FIL 100/200 mg (FIL100/FIL200) ± methotrexate (MTX) in patients with active RA who had an inadequate response to MTX (FINCH 1) or biologic DMARD (FINCH 2), or were MTX naïve (FINCH 3). We assessed changes from baseline (CFB) in BW and BMI by tx group and baseline BMI, and the efficacy and safety of FIL by baseline BMI (<25, 25–<30 or ≥30 kg/m^2). Efficacy measures included American College of Rheumatology (ACR)20/50/70 response, Disease Activity Score 28 with C-reactive protein (DAS28-CRP) and health assessment questionnaire disability index (HAQ-DI). Safety data were from 7 RA clinical trials (FINCH 1–4, DARWIN 1–3)[4].

Results: In FINCH 1–3, baseline disease characteristics such as HAQ-DI, DAS28-CRP and clinical disease activity index were similar across BMI subgroups for each tx group. There were no clinically relevant CFB in median BW or BMI in any tx group or differences between tx groups. Mean CFB in BMI (kg/m^2) were 0.4 with FIL200 and FIL100 and 0.3 with adalimumab (ADA) at Week 52 in FINCH 1; 0.2, 0.6 and –0.1 with FIL200, FIL100 and PBO, respectively, at Week 24 in FINCH 2; and 0.5, 0.6, 1.1 and 0.3 with FIL200+MTX, FIL100+MTX, FIL200 and MTX, respectively, at Week 52 in FINCH 3. CFB in BMI did not appear dependent on baseline BMI. FIL200±MTX was efficacious vs controls regardless of baseline BMI for most measures at each timepoint. In FINCH 1, in the <25, 25–<30 and ≥30 kg/m^2 BMI subgroups, DAS28-CRP <2.6 was achieved by 38%, 29% and 33% of the FIL200 group, 29%, 19% and 21% of the ADA group, and 7%, 10% and 11% of the PBO group at Week 12, respectively. Figure 1 shows ACR20 responders by baseline BMI in FINCH 1–3. Integrated safety data across baseline BMI subgroups are summarised in Table 1. VTE rate was numerically higher with FIL200 in the ≥30 than 25–<30 or <25 kg/m^2 BMI subgroups; serious infection rate was numerically higher with FIL100 in the <25 mg/m^2 subgroup vs other BMI subgroups.

Table 1. Exposure-adjusted incidence rate (95% CI) of AEs per 100 PYE by baseline BMI

	FIL dose (mg)	BMI (kg/m^2)		
		<25	25–<30	≥30
		PYE 3062.8	PYE 2640.1	PYE 2382.2
TEAEs	200	34.5 (32.0, 37.1)	35.7 (33.0, 38.6)	36.6 (33.7, 39.8)
	100	44.3 (40.4, 48.6)	43.0 (38.9, 47.5)	45.3 (41.1, 50.0)
Serious TEAEs	200	5.3 (4.4, 6.4)	5.8 (4.8, 7.1)	7.1 (5.8, 8.5)
	100	7.6 (6.0, 9.4)	6.5 (5.0, 8.4)	8.1 (6.4, 10.2)
Deaths	200	0.3 (0.2, 0.7)	0.5 (0.3, 1.0)	0.5 (0.2, 1.0)
	100	0.4 (0.1, 1.0)	0.3 (0.1, 1.0)	0.2 (0.1, 0.9)
Venous thrombotic and embolic events	200	0.1 (0.0, 0.4)	0.1 (0.0, 0.5)	0.5 (0.2, 1.0)
	100	0.1 (0.0, 0.7)	0.1 (0.0, 0.8)	0.2 (0.1, 0.9)
Major adverse cardiovascular events	200	0.3 (0.2, 0.7)	0.3 (0.1, 0.7)	0.5 (0.2, 1.0)
	100	0.6 (0.3, 1.3)	0.3 (0.1, 1.0)	0.6 (0.2, 1.4)
Serious infections	200	1.1 (0.7, 1.7)	1.7 (1.2, 2.5)	1.8 (1.2, 2.6)
	100	2.6 (1.8, 3.9)	1.2 (0.7, 2.2)	2.2 (1.4, 3.4)
Herpes zoster	200	1.6 (1.1, 2.2)	1.4 (1.0, 2.1)	1.8 (1.2, 2.6)
	100	1.0 (0.5, 1.8)	1.2 (0.7, 2.2)	1.0 (0.5, 2.0)
Malignancy excluding non-melanoma skin cancer	200	0.5 (0.3, 1.0)	0.7 (0.4, 1.3)	0.5 (0.3, 1.1)
	100	0.6 (0.3, 1.3)	0.4 (0.2, 1.2)	0.8 (0.4, 1.7)

BMI, body mass index; FIL, filgotinib; PYE, patient years of exposure; (TE)AE, (treatment-emergent) adverse event

Conclusion: FIL did not substantially affect CFB in BW or BMI. FIL200±MTX was generally more efficacious vs controls regardless of baseline BMI, and the rate of TEAEs was similar across baseline BMI subgroups.

RELATIONSHIP BETWEEN DISEASE ACTIVITY AND MAJOR ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS ON TOFACITINIB OR TNF INHIBITORS: A POST HOC ANALYSIS OF ORAL SURVEILLANCE

G. Karpouzas[1], Z. Szekanecz[2], E. Baecklund[3], T. Mikuls[4], D. L. Bhatt[5], H. Shi[6], C. Wang[7], G. Sawyerr[8], Y. Chen[6], S. Menon[7], C. A. Connell[7], S. R. Ytterberg[9], M. Mortezavi[8]. *[1]Harbor-UCLA Medical Center, Division of Rheumatology, Torrance, CA, United States of America; [2]University of Debrecen, Division of Rheumatology, Faculty of Medicine, Debrecen, Hungary; [3]Uppsala University, Department of Medical Sciences, Uppsala, Sweden; [4]University of Nebraska Medical Center and VA Nebraska-Western Iowa Health Care System, Division of Rheumatology, Omaha, NE, United States of America; [5]Brigham and Women's Hospital and Harvard Medical School, Department of Cardiovascular Medicine, Boston, MA, United States of America; [6]Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America; [7]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America; [8]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America; [9]Mayo Clinic, Division of Rheumatology, Rochester, MN, United States of America*

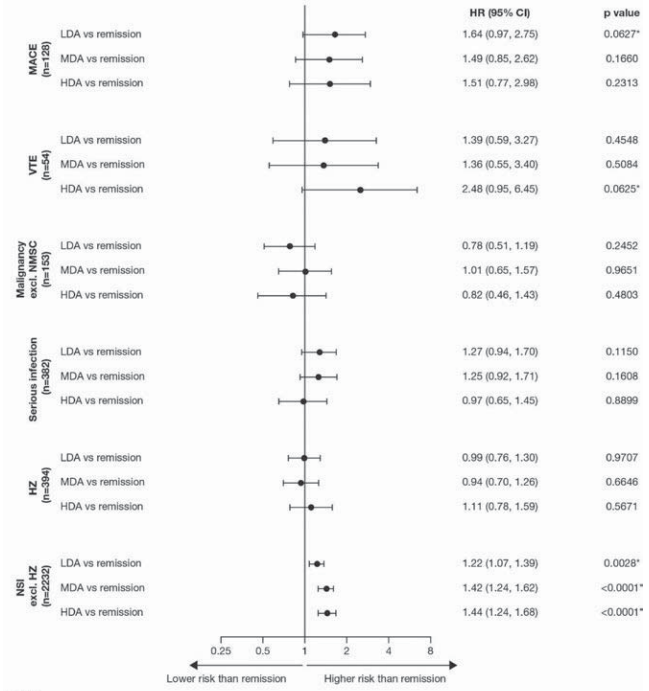
Background: Uncontrolled rheumatoid arthritis (RA) activity and acute disease flares are associated with higher risk of adverse outcomes such as cardiovascular (CV) disease, venous thromboembolism (VTE), malignancy and infection.[1-4]

Objectives: To evaluate associations of acute and cumulative Clinical Disease Activity Index (CDAI) measurements with major CV, malignancy, or infectious adverse events (AEs) of special interest in ORAL Surveillance.

Methods: ORAL Surveillance (NCT02092467) was a post-authorisation safety study of tofacitinib vs TNF inhibitors (TNFi) in patients (pts) aged ≥50 yrs with active RA despite methotrexate (MTX), and ≥1 additional CV risk factor. Pts were randomised 1:1:1 to tofacitinib 5 or 10 mg twice daily (BID) or subcutaneous TNFi. Two post hoc analyses were performed: (1) a time-varying multivariate Cox model examined risks of major AEs when pts were in CDAI-defined low (>2.8–≤10; LDA), moderate (>10–≤22; MDA) or high (>22; HDA) disease activity vs remission (≤2.8). The Cox model also included pt demographics, medical history, RA characteristics, prior treatments, baseline (BL) medications and treatment arm, pre-selected using backward selection; (2) area under the curve (AUC) per yr for CDAI prior to event or to study end (pts without event) was calculated and compared using an analysis of variance model with treatment arm, event status and interaction (supportive). Nominal p values <0.10 were considered evidence of associations.

Results: 4362 pts were included. Mean RA duration at BL was approximately 10 yrs. All pts were on MTX at BL, and 28% had previously been on one other synthetic disease-modifying antirheumatic drug (DMARD). Overall, 10% of pts had been on one biologic DMARD. Hazard ratios suggested that when pts had LDA, MDA or HDA vs remission, they were potentially at higher risk of developing major adverse CV events (MACE), VTE and non-serious infections (NSIs) excluding herpes zoster (HZ), but not malignancies, serious infections or HZ (Figure 1). Similarly, mean CDAI AUC trended higher for MACE, VTE and NSIs (Table 1).

Fig. HRs for major AEs of special interest during active RA vs remission as defined by CDAI



*p<0.10

TNFi	56	5667.2	1291	4875.5	791.8	0.0930*
NSIs excl. HZ						
Tofacitinib 5 mg BID	760	6608.3	463	5122.5	1485.8	<0.0001*
Tofacitinib 10 mg BID	750	6587.8	426	5009.6	1578.2	<0.0001*
TNFi	722	6737.6	521	5217.5	1520.1	<0.0001*

*p<0.10. Data collected after pts who were randomised to tofacitinib 10 mg BID had their dose reduced to 5 mg BID were included in the tofacitinib 10 mg BID groupLS, least squares; n, number of pts in analysis of variance model

Conclusion: In ORAL Surveillance, the risk of MACE, VTE and NSIs excluding HZ appeared higher when pts had active disease than when in remission. Greater cumulative RA disease activity was seen in pts who suffered these AEs vs those who did not. Our findings support treat-to-target recommendations for RA.

Background: ORAL Surveillance (NCT02092467) was a post-authorisation safety study of tofacitinib vs tumour necrosis factor inhibitors (TNFi) in patients (pts) with rheumatoid arthritis (RA) aged ≥50 years (yrs) with ≥1 additional cardiovascular (CV) risk factor and an inadequate response to methotrexate (MTX). Statins are used to treat coronary artery disease (CAD) and are recommended by the American College of Cardiology/American Heart Association (ACC/AHA) for the management of pts at risk of atherosclerotic CV disease (ASCVD),[1] such as those with ≥7.5% 10-yr risk of major adverse CV events (MACE) or diabetes mellitus.

Objectives: To examine the association between baseline (BL) statin use and MACE in ORAL Surveillance.

Methods: Pts with RA on stable MTX were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or TNFi (adalimumab 40 mg every 2 weeks or etanercept 50 mg once weekly). Pts were stratified post hoc by BL statin use (yes/no). Pts were further categorised by history of CAD (HxCAD), BL CV risk score per ACC/AHA guidelines[1] (for pts without HxCAD; 10-yr risk of MACE per the ASCVD-pooled cohort equations risk calculator[2] with a 1.5 multiplier applied[3]), and separately by BL diabetes status. CV risk score/BL diabetes status categories were: high (≥20%)/HxCAD (yes), intermediate (≥7.5–<20%) or low-borderline (<7.5%), and diabetes status (yes). For the overall population and each treatment group, risk of MACE was compared between BL statin use (yes vs no) via Cox analyses for each CV risk category and diabetes status (yes). Incidence rates (IRs; pts with first events/100 pt-yrs) and hazard ratios (HRs; BL statin use: yes vs no) were evaluated for adjudicated MACE.

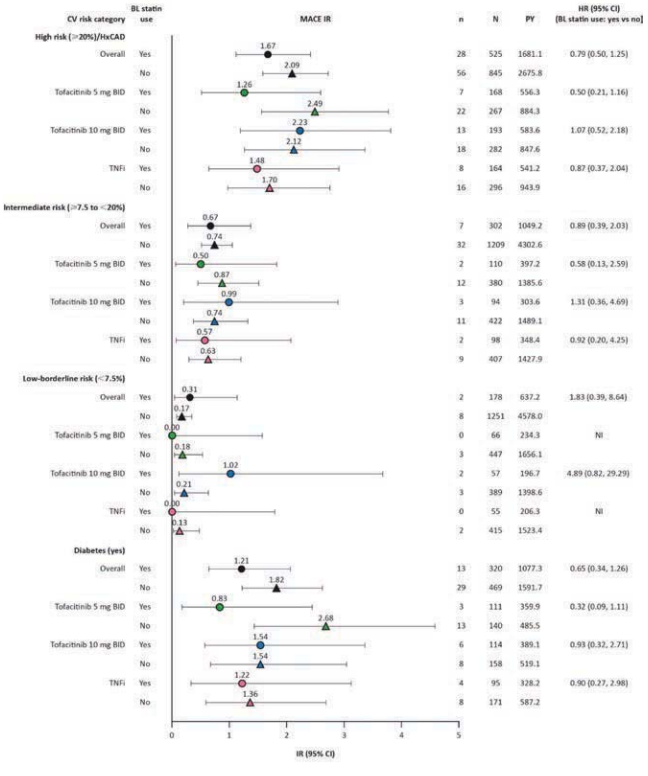
Results: Of 4362 pts (tofacitinib 5 mg BID, n=1455; tofacitinib 10 mg BID, n=1456; TNFi, n=1451), 497 had a HxCAD, and 3813 without a HxCAD had CV risk scores determined; 789 had BL diabetes. Overall, 1020 (23.4%) pts reported BL statin use. Across CV risk score categories for all treatment groups, <50% of pts received statins at BL, with statin use highest in the high/HxCAD category pts (35.7–40.6%) and pts with diabetes (35.7–44.2%) (Table 1). Across categories, no interpretable associations between BL statin use and MACE were found. However, in the overall population, MACE IRs were lower in pts with vs without BL statin use in the high/HxCAD category, and in pts with diabetes (Figure 1). In pts receiving tofacitinib 5 mg BID and TNFi, MACE IRs were lower in pts with vs without BL statin use across all categories (Figure 1).

Table 1. Proportion of pts receiving statins at BL, by CV risk category and presence of diabetes

n/N (%)	Overall	Tofacitinib 5 mg BID	Tofacitinib 10 mg BID	TNFi
High (≥20%)/HxCAD	525/1370 (38.3)	168/435 (38.6)	193/475 (40.6)	164/460 (35.7)
Intermediate (≥7.5–<20%)	302/1511 (20.0)	110/490 (22.4)	94/516 (18.2)	98/505 (19.4)
Low-borderline (<7.5%)	178/1429 (12.5)	66/513 (12.9)	57/446 (12.8)	55/470 (11.7)
Diabetes (yes)	320/789 (40.6)	111/251 (44.2)	114/272 (41.9)	95/266 (35.7)

N, number of pts in each category; n, number of pts receiving BL statins

Fig. MACE IRs (pts with first events/100 pt-yrs) and HRs (BL statin use: yes vs no) across treatment groups, by CV risk category and presence of diabetes in ORAL Surveillance



Data collected after pts who were randomised to tofacitinib 10 mg BID had their dose reduced to 5 mg BID were included in the tofacitinib 10 mg BID group
For MACE, risk period was defined as the time from first study dose to last study dose +60 days, or to the last contact date, whichever was earliest
95% CIs for IRs (per 100 PY) were constructed using Exact Poisson distribution. HRs (95% CIs) comparing BL statin use (yes vs no) were generated using a Cox model with BL statin use as the only covariate at each CV risk category and BL diabetes (yes) within each treatment group
CI, confidence interval; N, number of pts in each category; n, number of pts with events; NI, non-informative (HRs [95% CI] were NI when comparator group had 0 events); PY, pt-yrs

Conclusion: In this post hoc analysis of data from ORAL Surveillance, most pts did not receive BL statin treatment. This suggests suboptimal CV risk management, particularly in pts at high risk of CV events. There was no interpretable association

between BL statin use and MACE. However, pts in the higher risk categories, particularly those receiving tofacitinib 5 mg BID, had lower MACE IRs with vs without BL statin use. This analysis did not take into account initiation or dose adjustment of statin treatment during the study, and had low yrs of exposure in some categories.

RISKS OF SEVERE INFECTION AFTER THE INTRODUCTION OF BDMARDS IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS PATIENTS: A POPULATION-BASED INTERRUPTED TIME-SERIES ANALYSIS

Y. V. Zhou[1,2], D. Lacaille[1,3], N. Lu[1], J. Kopec[1,4], Y. Qian[5], B. Nosyk[2,6], J. A. Aviña-Zubieta[1,3], J. Esdaile[1,4], H. Xie[1,2]. *[1]Arthritis Research Canada, Research, Vancouver, Canada; [2]Simon Fraser University, Health Sciences, Burnaby, Canada; [3]University of British Columbia, Department of Medicine, Vancouver, Canada; [4]University of British Columbia, School of population and public health, Vancouver, Canada; [5]University of British Columbia, Sauder School of Business, Vancouver, Canada; [6]Center for Health Evaluation & Outcome Sciences, Research, Vancouver, Canada*

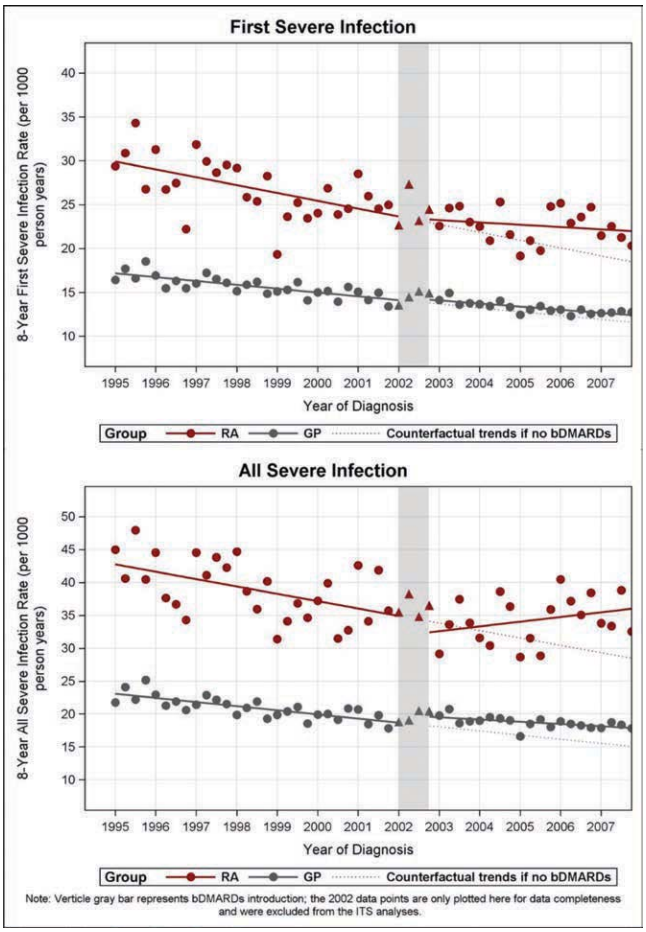

Figure 1. Unadjusted rates.

Background: Biological disease-modifying anti-rheumatic drugs (bDMARDs) are effective in suppressing inflammation and preventing joint damage. But bDMARDs may be associated with increased risk of severe infection. Evidence on this is contradictory with some studies showing increased risk, whereas others reporting no significant changes.

Objectives: To determine the impact of the introduction of bDMARDs on severe infection among patients newly diagnosed with RA compared with non-RA individuals.

Methods: In this age- and gender-matched cohort study using administrative health data for the population of BC, Canada, all incident RA patients diagnosed between 1995–2007 were identified. Non-RA individuals were randomly selected from the general control population to match with RA. Incident RA/non-RA individuals were then divided into quarterly cohorts according to their diagnosis date. Two outcomes were examined: (1) first severe infection (FSI) after RA onset necessitating hospitalization or occurring during hospitalization; and (2) all severe infections (ASI) after RA onset. We calculated the 8-year FSI and ASI rate for each cohort. We conducted interrupted time-series analyses to compare levels and trends of FSI and ASI in RA and non-RA individuals diagnosed

Table 1. Results of interrupted time-series analysis of FSI/ASI rates, adjusting for age, gender, chronic obstructive pulmonary disease, Romano Charlson Comorbidity Index, diabetes, chronic kidney diseases, alcoholism, cancer, prior hospitalization with infection and socio-economic status at disease diagnosis year, using stepwise model selection

during pre-bDMARDs (1995–2001) and post-bDMARDs (2003–2007) periods. Adjusted 8-year FSI and ASI rates for RA and non-RA cohorts diagnosed five years after bDMARDs introduction were compared with expected rates assuming no bDMARDs introduction, based on extrapolation of pre-bDMARDs trends.
Results: A total of 60,226 and 588,499 incident RA/non-RA individuals were identified. We identified 8,954 FSI and 14,245 ASI in RA, and 56,153 FSI and 79,819 ASI in non-RA. The 8-year FSI rates among RA patients diagnosed in the pre-bDMARDs period decreased over time but leveled off among those diagnosed in the post-period (Figure 1). The adjusted difference between the post- and pre-bDMARDs secular trends of 8-year FSI rates was 0.68 (p=0.03) in RA and 0.03 (p=0.67) in non-RA (Table 1). The 8-year ASI rates among RA patients diagnosed in the pre-bDMARDs period decreased over time but increased significantly among those diagnosed in the post-period (Figure 1). The adjusted difference between the post- and pre-bDMARDs secular trends of 8-year ASI rates was 1.85 (p=0.001) in RA and 0.12 (p=0.29) in non-RA (Table 1). For RA cohort diagnosed 5 years after bDMARDs introduction, ASI rate increased by 20.4% than expected rates assuming no bDMARDs introduction. In contrast, ASI rate in non-RA increased by only 10.9%.
Conclusion: Arthritis onset after bDMARDs introduction is associated with an elevated risk of severe infection in RA patients, compared with matched non-RA individuals.

POS0522 ASSOCIATED FACTORS WITH PHYSICAL DYSFUNCTION OF ELDERLY-ONSET RHEUMATOID ARTHRITIS TREATED WITH A TREAT-TO-TARGET STRATEGY

T. Sugihara[1,2,3,4], T. Ishizaki[2], H. Baba[1,3], T. Matsumoto[1], K. Kubo[1], M. Kamiya[1,3], F. Hirano[1,3], T. Hosoya[1,3], M. Kojima[5], N. Miyasaka[3], M. Harigai[6]. *[1]Tokyo Metropolitan Geriatric Hospital, Department of Medicine and Rheumatology, Tokyo, Japan; [2]Tokyo Metropolitan Institute of Gerontology, Human Care Research Team, Tokyo, Japan; [3]Tokyo Medical and Dental University, Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo, Japan; [4]St. Marianna University School of Medicine, Division of Rheumatology and Allergy, Department of Internal Medicine, Tokyo, Japan; [5]National Center for Geriatrics and Gerontology, Department of Frailty Research, Center for Gerontology and Social Science, Nagoya, Japan; [6]Tokyo Women's Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Achievement of normal physical function is an important outcome for older patients. Previous studies of younger cohorts showed that aging, comorbidities, and joint damage influenced the physical function of patients with RA who achieved clinical remission or low disease activity (LDA). We previously demonstrated that a treat-to-target (T2T) strategy for methotrexate (MTX)-naïve elderly-onset RA (EORA) was effective with an acceptable safety profile. It showed that 60.9% of 197 patients achieved HAQ Disability Index (HAQ-DI) ≤0.5 at three years by following the T2T strategy targeting LDA (1).
Objectives: We aimed to evaluate associated factors with HAQ-DI in the T2T strategy targeting LDA for patients with EORA during three-year observational period.
Methods: Treatment was adjusted to target LDA with conventional synthetic disease-modifying antirheumatic drugs (DMARDs), followed by biological DMARDs (bDMARDs) in 197 MTX-naïve EORA patients (mean age 74.9 years) with moderate-to-high disease activity. HAQ-DI was evaluated at week 0, 24, 52, 76, 104, 128, and 156. To evaluate associated factors with SDAI and HAQ-DI over the 36-month follow-up, Bayesian hierarchical logistic regression modeling was applied for 1067 periods from the 197 patients.
Results: At baseline, the enrolled 197 patients with EORA who had normal physical function (HAQ-DI ≤0.5) in 29.4%, HAQ-DI >0.5 and <1.5 in 36.5%, and HAQ-DI ≥1.5 in 33.0%, and the mean age (standard deviation [SD]) in each group was 72.7 (5.9), 74.8 (7.3), and 75.6 (6.7), respectively. Baseline SDAI increased in the group with higher HAQ-DI. The proportions of patients with each comorbidity and estimated creatinine clearance at baseline were not significantly different across the 3 groups. In the multilevel logistic model, the association of MTX, bDMARDs, and GC use with changes in SDAI in each period was evaluated. Age, sex, and comorbidities (chronic lung disease, cardiovascular disease, history of malignancy, osteoporosis, history of serious infections, and osteoarthritis) were included as inter-individual factors. The model indicated that the use of bDMARDs was associated with a reduction of the SDAI (ΔSDAI: -9.75, SD 0.75, p<0.001), while neither MTX (ΔSDAI: -1.25, SD 1.13, p=0.270) nor GCs (ΔSDAI: -0.78, SD 0.88, p=0.372) was associated with changes in SDAI. Chronic lung diseases (ΔSDAI: 4.64, SD 1.44, p=0.001) and osteoporosis (ΔSDAI: 3.78, SD 1.46, p=0.001) at baseline were associated with the increment of SDAI. The association of age, sex, the comorbidities, and MTX, bDMARDs, and GC use with physical function in each period was evaluated by the multilevel logistic model. The model indicated that older age (ΔHAQ-DI: 0.03, SD 0.01, p <0.001), chronic lung diseases (ΔHAQ-DI: 0.15, SD 0.10, p=0.001), and osteoporosis (ΔHAQ-DI: 0.30, SD 0.10, p=0.010) at baseline were associated with the increment of HAQ-DI. When the mean SDAI during the observation period was added to the model as an inter-individual factor, the associations of HAQ-DI with the chronic lung diseases and osteoporosis at baseline were not statistically significant.
Conclusion: These data indicate that bDMARDs had a central role in reducing disease activity in the T2T strategy targeting LDA in EORA patients. Chronic lung diseases and osteoporosis at baseline were associated with increase in disease activity and worsening of physical function. However, disease activity had a greater impact on physical function than the comorbidities at baseline.

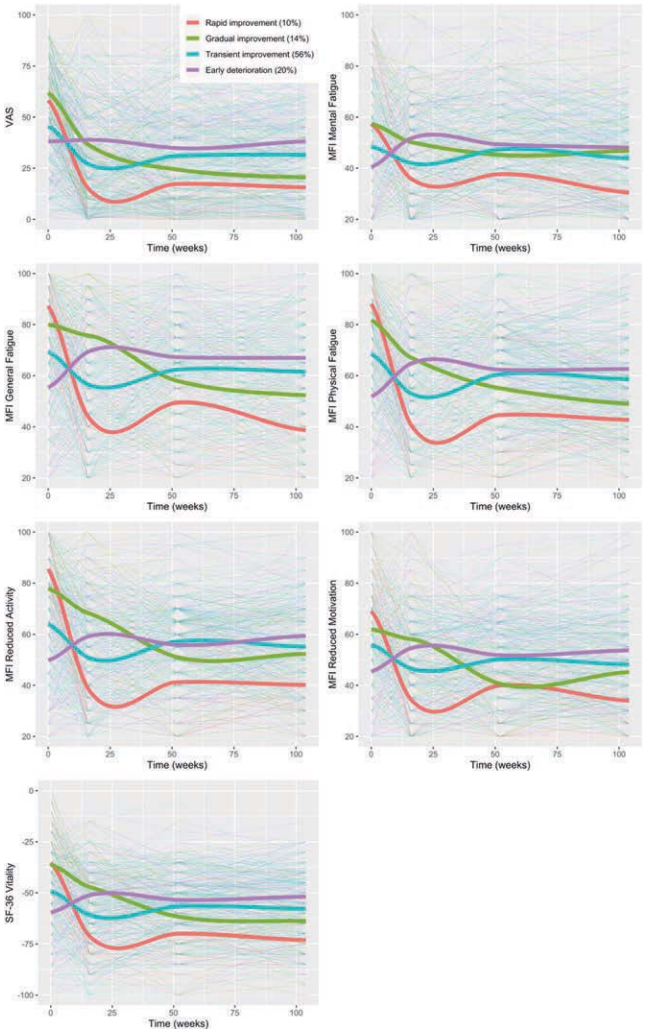

Figure 1. Latent trajectories of fatigue evolution over the first 2 years in CareRA (n = 356).

fatigue and assess these longitudinally with multivariate methods, starting early in the disease.

Objectives: We aimed to explore the longitudinal course of fatigue and its predictors among patients with early RA starting DMARD therapy.

Methods: Data came from the 2-year treat-to-target trial Care in early RA (CareRA) and its 3-year extension. Fatigue was measured based on visual analog scale (VAS), Multidimensional Fatigue Inventory (MFI), and Short-Form 36 (SF-36). Longitudinal fatigue trajectories were identified with multivariable growth mixture modeling. Baseline and early predictors of trajectory membership, including treatment response, were studied with multinomial logistic regression adjusted for age, gender, and treatment type. Patient global assessment (PGA), pain (VAS), and disability (HAQ) were studied in separate models because of collinearity (Spearman r > 0.60). For all models, posterior probabilities of trajectory assignment were included in the regression as weights to account for classification uncertainty. Treatment response was defined, based on whether remission (DAS28-CRP < 2.6) was achieved by week 16 and sustained until year 2, as either early persistent response, secondary failure, or delayed response.

Results: In total, 356 and 244 patients were included in the 2-year and 5-year analyses, respectively. Mean (SD) fatigue (VAS) at inclusion was 48/100 (24). Four fatigue trajectories were identified: Rapid, Gradual, and Transient Improvement, and Early Deterioration, consisting of 10%, 14%, 56%, and 20% of patients, respectively (Figure 1). Higher PGA, pain and HAQ at baseline were associated with increased probability of Rapid Improvement compared to Transient Improvement or Early Deterioration (Table 2). Secondary treatment failure and delayed treatment response strongly increased the probability of less positive fatigue trajectories when compared to early persistent response.

Conclusion: The longitudinal course of fatigue in early RA is dynamic but highly refractory, with less than 25% of patients making lasting improvements and 20% even experiencing worsening fatigue despite intensive DMARD therapy. Remarkably, a higher perceived disease impact at baseline was associated with an increased probability of fatigue improvement, possibly reflecting the fluctuating nature of this complex symptom. However, early inflammatory disease control appears to be the most important contributor to improved long-term fatigue outcomes, illustrating the far-reaching impact of the therapeutic window of opportunity in early RA.

POS0524

THE VALUE OF ULTRASOUND AND MAGNETIC RESONANCE IMAGING SCORING TECHNIQUES FOR DETECTING JOINT INFLAMMATION AND DAMAGE IN RHEUMATOID ARTHRITIS PATIENTS IN EXPLAINING FUNCTIONAL IMPAIRMENT AND HANDGRIP STRENGTH: A PILOT STUDY

F. Salaffi[1], M. Carotti[2], M. DI Carlo[1], L. Ceccarelli[3], S. Farah[1], A. Giovagnoni[2]. *[1]Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale "Carlo Urbani", Ancona, Italy; [2]Università Politecnica delle Marche, Dipartimento di Scienze Radiologiche, Ospedali Riuniti, Ancona, Italy; [3]Azienda Ospedaliero-Universitaria Sant'Anna, Department of Interventional and Diagnostic Radiology, Ferrara, Italy*

Background: Composite disease activity ratings, which are used to assess the severity of rheumatoid arthritis (RA), may not effectively reflect the illness's spatial impact on the hands. In RA, assessments of handgrip strength (HGs) and functional deficits are a kind of objective examination that focuses on the hands.

Objectives: The goal of this study was to see if there was a link between joint inflammation and damage in the wrists and hands, as measured by ultrasound (US) and magnetic resonance imaging (MRI), functional disability as measured by hand-specific self-report questionnaires, and composite disease activity indices.

Methods: Sixty-six female patients with RA were investigated (age 55.6 ± 12.2 years, range 20-80 years; disease duration 4.4 ± 3.0 years). The DAS28-CRP, the SDAI, the CDAI, and US and MRI scoring techniques such as the UltraSound-CLinical ARthritis Activity (US-CLARA) and modified Simplified Rheumatoid Arthritis Magnetic Resonance Imaging Score [SAMIS] were all used as baseline assessments (mod SAMIS) (Figure 1). Without contrast injection, the mod SAMIS score was rated for the presence/absence and semiquantitative assessments of synovitis, bone erosion (ERO), and bone marrow edema (BME). All patients had HGs and completed the shortened Disability of Arm, Shoulder, and Hand Questionnaire (QuickDASH), the Arthritis Impact Measurement Scales hand and finger function subscale, and the upper extremity function sub-score of the ROAD.

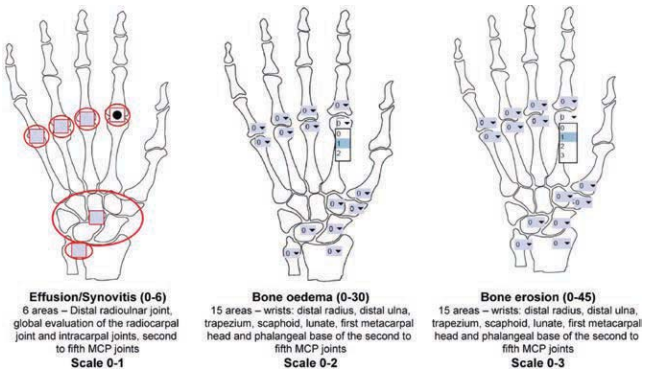

Figure 1. The modified simplified SAMIS magnetic resonance score (mod SAMIS) scoring spreadsheet. The MRI was graded for the presence/absence of synovitis and semiquantitative ratings of bone marrow oedema and bone erosion, without contrast injection.

Results: The mod SAMIS total score and the US-CLARA had a strong correlation (rho=0.377, p=0.0018) for all patients. Among the SAMIS subscores, there was a significant relationship between mod SAMIS bone oedema (SAMIS-BME) and US-CLARA (rho=0.799, p<0.001) and mod SAMIS synovitis (SAMIS-synovitis) and US-CLARA (rho=0.539, p<0.001). There were also significant negative relationships between the HGs score and the mod SAMIS total score and US-CLARA (rho = -0.309, p=0.011 and rho = -0.775, p<0.0001, respectively). The HGs and disease activity composite indices, as well as hand-specific self-report questionnaires, were shown to have high relationships (p<0.0001) in individuals with RA. The hand and finger function sub-scales, as well as the mod SAMIS erosion (SAMIS-ERO) and HGs, exhibited no significant relationship. For each of the three components, interobserver agreement was good to excellent (intraclass correlation values = 0.713, 0.912, and 0.821, respectively) (synovitis, BME, and BME) (Figure 2).

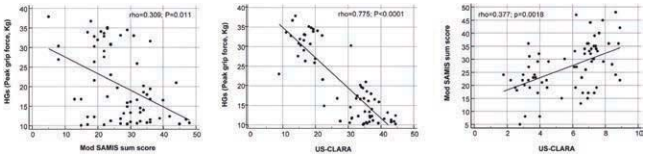

Figure 2. Scatterplot with linear regression lines displays the relationship between (A) mod SAMIS total score vs HGs, (B) US-CLARA vs HGs, and (C) US-CLARA vs mod SAMIS total score.

Conclusion: BME and synovitis have an impact on upper-extremity function. The US-CLARA and mod SAMIS total score are promising solutions for semi-quantitative evaluation of joint inflammation and damage in RA. These shortened scores might cut down on image processing time in US and MRI-controlled RA investigations, as well as make using these imaging modalities in RA treatment response evaluation studies simpler.

POS0525

ARE BIOLOGIC AND TARGETED SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ASSOCIATED WITH WORK PARTICIPATION IMPROVEMENT IN EARLY RHEUMATOID ARTHRITIS? A SYSTEMATIC REVIEW AND META-ANALYSIS

M. L. Marques[1,2], A. Alunno[3], L. Falzon[4], A. Boonen[5,6], S. Ramiro[1,7]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; [3]University of L'Aquila, Internal Medicine and Nephrology Unit, MeSVA Department, L'Aquila, Italy; [4]The University of Sheffield, Health Economics and Decision Science, School of Health and Related Research, Sheffield, United Kingdom; [5]Maastricht University Medical Center, Internal Medicine, Maastricht, Netherlands; [6]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; [7]Zuyderland MC, Rheumatology, Heerlen, Netherlands*

Background: In early RA, the benefit of treatment with b-/tsDMARDs on work participation (WP), a top-three social role in RA, has seldom been studied.

Objectives: To review the effect of treatment with b-/tsDMARDs on employment status (ES), presenteeism and sick leave (SL), in patients with early RA.

Methods: A systematic literature review (SLR) was conducted in key electronic databases up to October 2021, to include RCTs assessing the effect of treatment with b-/tsDMARDs vs any comparator on ES, presenteeism and SL in patients with RA (≤ 3y). Two reviewers independently identified eligible studies and extracted data. Random-effects meta-analysis was only performed if ≥3 studies were conducted in comparable populations, assessing WP outcome similarly. Statistical heterogeneity was assessed with I^2.

Results: From 7129 records (65 full-text articles screened), 11 RCTs were included in the SLR (7 in csDMARD naïve patients; 2 in inadequate responder to csDMARDs; 1 bDMARD tapering after initial combination with MTX, and 1 strategy study). Large heterogeneity was found across WP outcomes, measurement instruments, interventions and comparators (Table 1), which together with insufficient data reporting hampered meta-analysis of most outcomes. For ES, to allow meta-analysis, all outcomes were converted to employment loss, for which individual study Odds ratios (OR) were computed. The pooled OR of 4 studies with 779 patients treated with adalimumab, infliximab or baricitinib (Figure 1) showed a lower likelihood of employment loss at weeks 56 to 104 in those treated with MTX+b/tsDMARDs compared to MTX+PBO (OR: 0.65; 95% CI:0.43-0.99). For presenteeism and SL, 33/40 (83%) between-group comparisons showed improvement in favour of b-/tsDMARDs, but an effect size was reported or possible to compute for only 12 comparisons, of which 8 (67%) were statistically significant.

SCMI – self composed multiple items; **SCSI** – self composed single item; **WPAI –** Work Productivity Activity Impairment questionnaire; [*] $p \leq 0.05$ [**] $p \leq 0.001$ vs C; [‡] non-validated instrument; [$] when > 1 I/C or time-point, between-group comparisons and time-points are presented if I vs C differences were observed; **¶** insufficient data reporting to compute effect sizes.

Conclusion: A protective effect against employment loss was observed in patients with early RA treated with MTX+b-/tsDMARDs compared to MTX monotherapy. The methodological heterogeneity and insufficient reporting hampers clear conclusions regarding the beneficial effects of b-/tsDMARDs on presenteeism and SL. Efforts to uniformize future studies with WP as outcome by following recently developed points to consider are crucial[1].

POS0526

HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY AND PREDICTION OF EROSIVE PROGRESSION AS ASSESSED BY THE GOLD STANDARD CONVENTIONAL RADIOGRAPHY IN ESTABLISHED RHEUMATOID ARTHRITIS: A 1-YEAR COHORT STUDY

J. Therkildsen[1,2], R. Klose-Jensen[1,2], A. B. Blavnsfeldt[2,3], B. Langdahl[2,4], A. Zejden[5], J. Thygesen[6], K. Keller[1,2], E. M. Hauge[1,2]. *[1]Aarhus University Hospital, Dept. of Rheumatology, Aarhus, Denmark; [2]Aarhus University, Dept. of Clinical Medicine, Aarhus, Denmark; [3]Aarhus University Hospital, Dept. of Biochemistry, Aarhus, Denmark; [4]Aarhus University Hospital, Dept. of Endocrinology and Internal Medicine, Aarhus, Denmark; [5]Aarhus University Hospital, Dept. of Radiology, Aarhus, Denmark; [6]Aarhus University Hospital, Dept. of Clinical Engineering, Aarhus, Denmark*

Background: High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) is a promising imaging technique for assessing erosive disease in rheumatoid arthritis (RA). We have shown that the diagnostic accuracy in detecting erosive disease of HR-pQCT of two joints corresponds to conventional radiography (CR) of 44 joints in established RA (1). No data assessing HR-pQCT as a tool for predicting erosive radiographic progression in a large cohort of established RA has been published.

Objectives: To assess the association between erosive disease identified using either CR or HR-pQCT at baseline and erosive progression using CR during 1-year follow-up in established RA.

Methods: This observational cohort study included 220 patients with RA (disease duration ≥ 5 yrs) at the Department of Rheumatology, Aarhus University Hospital, between Mar. 2018 and Oct. 2020. All participants had demographic information collected, together with HR-pQCT at baseline and CR made at baseline and 1-year follow-up. Erosive assessment using HR-pQCT was performed at the second and third metacarpophalangeal (MCP) joint (2). The Sharp/van der Heijde score (SHS) method was used to assess erosive status and erosive progression using CR of hands, wrists and feet (3).

Results: In total, 220 participants with RA (median age 66 yrs, interquartile range (IQR) 57-72; 71% women) were included and 212 completed their follow-up visit in Dec. 2021 (dropout n=8 (4 %)). During follow-up (median 1 yrs, range 0.7-1.4), erosive progression on CR was detected in 24 of 211 (11%) (missing baseline CR, n=1). Characteristics of the study population by erosive progression are shown in Table 1. In unadjusted regression analyses, number of erosions on HR-pQCT at baseline and erosion score (per 10) using CR at baseline were associated with erosive progression (yes/no) on CR at 1-year (Odds ratio (OR) 1.1; 95%CI 1.0-1.1; *p<.05* and OR 1.1; 95%CI 1.0-1.2; *p<.01*). After adjusting for age and sex, erosion score remained associated with erosive progression (OR 1.1; 95%CI 1.1-1.2; *p<.01*), but number of erosions did not (OR 1.0; 95%CI 1.0-1.1; *p=.07*).

Table 1. Demographics at baseline

	Progression on CR	*No progression on CR*	*P value*
No	24/211 (11)	187/211 (89)	
Age, yrs	66 (57-73)	66 (57-71)	*.80*
Women	15/24 (63)	134/187 (72)	*.35*
Disease Duration, yrs	20 (8-28)	15 (9-23)	*.44*
DAS28-CRP	1.7 (1.5-2.5)	1.8 (1.5-2.5)	*.53*
Erosive on CR	24/24 (100)	141/187 (75)	***< .01***
Erosive 2nd/3rd MCP on CR*	17/23 (74)	62/185 (34)	***< .001***
Erosive on HR-pQCT	22/23 (96)	153/185 (83)	*.14*
Erosion score (per 10)	4 (2-7)	1 (0-3)	***< .0001***
Erosion number	10 (5-17)	3 (1-10)	***< .01***
Total erosion volume, mm³	128 (19-201)	26 (2-111)	***< .05***

Data are no. (%) or median with interquartile range. P-values: Mann-Whitney *U* or Fisher's exact test. Missing HR-pQCT, n=3. CR = conventional radiography, DAS28-CRP = disease activity score of 28 joints based on C-reactive protein, HR-pQCT = high-resolution peripheral quantitative computed tomography* Same hand as HR-pQCT scanned

Conclusion: In established RA, baseline CR of 44 joints is superior to baseline HR-pQCT of two joints in identifying individuals at risk of erosive progression on CR. This underlines the need for a head-to-head comparison between progression identified by HR-pQCT and CR to fully assess the clinical utility of HR-pQCT in predicting erosive progression compared to CR.

POS0527

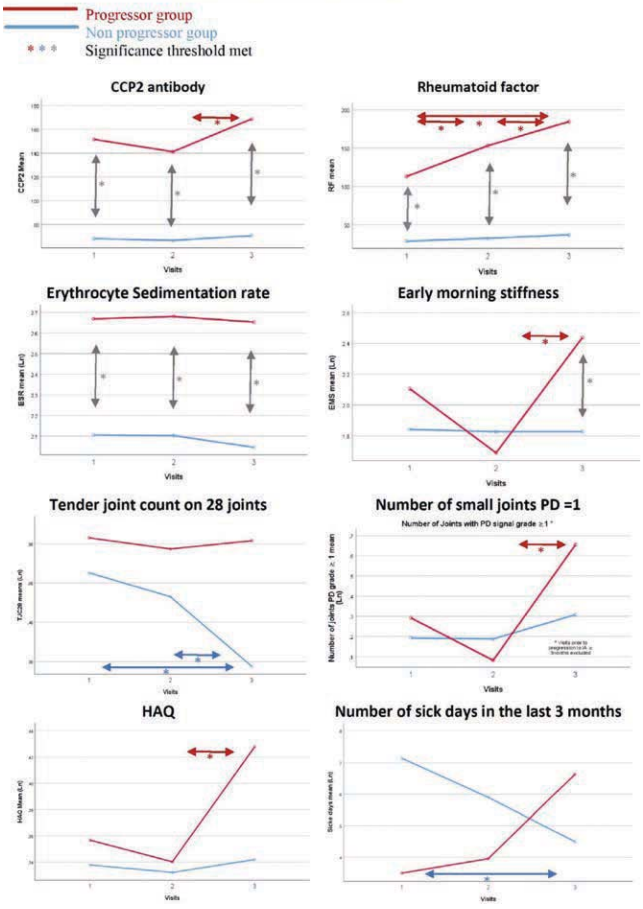
ANTI-CCP POSITIVE INDIVIDUALS AT RISK OF PROGRESSION TO INFLAMMATORY ARTHRITIS: WHAT HAPPENS TO BIOMARKERS PRIOR TO PROGRESSION?

L. Duquenne[1,2], K. Harnden[1,2], L. Garcia-Montoya[1,2], N. Sidhu[1,2], J. Nam[1,2], K. Mankia[1,2], P. Emery[1,2]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, LEEDS, United Kingdom;* [2]*NIHR, Leeds Biomedical Research Centre, LEEDS, United Kingdom*

Background: Although many predictors of progression to inflammatory arthritis (IA) have been identified at first visit in individuals at risk of developing IA, their fluctuation during follow-up is largely unknown.

Objectives: To describe the changes in relevant biomarkers, which precede arthritis development in anti-CCP positive at risk individuals.

Figure 1: Mixed model ANOVA on repeated measures



Methods: In a single centre prospective observational cohort of anti-CCP positive individuals with new musculoskeletal symptoms but without clinical arthritis, 394 individuals with at least 3 available longitudinal datapoints including first, second and last records (progression excluded), were selected. Data on anti-CCP2 antibodies (CCP2), rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), early morning stiffness duration (EMS), tender joint count on examination (TJC28), health assessment questionnaire (HAQ), absence from work in the last 3 months (sick days), and ultrasound power Doppler signal (PD) grade ≥ 1 in small joints, were assessed. Mixed model analysis on repeated measures (MANOVA) were performed, missing data were not imputed.

Results: Of the 394 selected individuals, 82 (21%) progressed to IA. In those who progressed, last visit was at a mean (SD) of 6.1 (8) months prior to progression, and total follow-up duration was 33.7 months (26.7) versus 46.5 months (30.2) for those who did not.

Within group analysis: *in the progressor group* there was a significant increase in the value of biomarkers at the visit prior progression for CCP2 +, RF +, EMS, HAQ, and the number of joints with a PD grade ≥ 1 (Figure 1, Table 1). For sick days from work prior last visit, the increase was non-significant.

Table 1. Mixed model ANOVA on repeated measures: pairwise comparison

		Analysis between groups	Analysis within groups		
Biomarker	Mean (SD) at last visit	P-value between groups at last visit	P-value between second and last visit within the progressor group	P-value between second and last visit within non-progressor group	Within subject effect
CCP2	NP: 71 (108) P: 169 (131)	**p<0.001**	**P=0.008**	P=1.000	F(2/257)=3 $P\eta^2$= 0.017 P=0.077
RF	NP: 37 (73) P: 185 (180)	**P<0.001**	**P=0.012**	P=0.973	F(2/304)=15 $P\eta^2$= 0.084 **P<0.001**
ESR	NP: 11 (9) P: 22 (21)	**p<0.001**	P=1.000	P=0.614	F(2/580)=0.1 $P\eta^2$< 0.001 P=0.877
EMS	NP: 26 (68) P:58 (120)	**P=0.010**	**P=0.006**	P=1.000	F(2/710)=4 $P\eta^2$= 0.018 **P=0.011**
TJC28	NP: 0.5 (1.5) P: 3 (5.5)	**P<0.001**	P=1.000	**P<0.001**	F(2/784)=10 $P\eta^2$< 0.025 **P<0.001**
Number of joints PD ≥1	NP: 0.7 (2) P: 1 (2)	**P=0.020**	**P=0.001**	P=0.055	F(2/318)=4 $P\eta^2$= 0.025 **P=0.014**
HAQ	NP: 0.5 (0.6) P: 0.7 (0.8)	P=0.105	**P=0.016**	P=1.000	F(2/494)=2.5 $P\eta^2$= 0.0.009 P=0.086
Number of sick days	NP: 2 (6) P: 4 (13)	P=0.204	P=0.457	P=0.492 (Between visit 1 and 3: **p=0.042**)	F(2/360)=4 $P\eta^2$= 0.021 **P=0.021**

NP: Non progressors, P: progressors, $P\eta^2$: Partial η^2+ *for these results the assumption of homogeneity of variance was violated, as assessed by Levene's test for equality of variances*.

In the non-progressor group, only TJC28 and sick days showed significant decrease between first and last visit.

Between groups analysis showed significant differences at last visit for the following biomarkers -CCP2 +, RF +, ESR, EMS, TJC28, and number of joints PD grade ≥ 1. The difference in HAQ and sick days was non-significant (Figure 1, Table 1). A significant difference was also shown in all visits for CCP2 + and RF +, and at the second visit for TJC28.

For PD grade ≥ 1, differences at last visit *within progressor group* and *between groups* were only significant after selection of last visits < 3 months before progression.

Conclusion: These results show for the first time significant changes in relevant biomarkers prior to progression to IA with individual biomarkers having different trajectories. Clinical markers (EMS, TJC28, and HAQ) and ultrasound changed late, whilst immunological (CCP2 and RF values) and inflammation biomarkers (ESR) were different from baseline. These data provide valuable information for longitudinal monitoring of biomarkers, further analysis will show if these changes have predictive value for imminent progression to IA.

POS0528 EARLY OPTIMISATION OF METHOTREXATE THERAPY PREVENTS DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: A SINGLE-CENTRE, RETROSPECTIVE COHORT STUDY

A. Giollo[1], M. Zen[1], M. Larosa[2], F. Arru[1], K. Botsios[1], A. Calligaro[1], A. Doria[1]. *[1]University of Padova, Rheumatology Unit, Padova, Italy; [2]ASL3 - Azienda Sanitaria Genovese, SC Reumatologia, Dipartimento Apparato Locomotore, Genova, Italy*

Background: According to the current EULAR recommendations for the management of rheumatoid arthritis (RA), methotrexate (MTX) should be started as soon as RA is diagnosed and rapidly optimized to achieve remission. Nonetheless, it has been estimated that a difficult-to-treat (D2T) disease occurs in 3-10% of RA patients[1]. Herein, we hypothesized that D2T-RA can be prevented with an optimal MTX treatment in early stages.
Objectives: The main objective of this study was to demonstrate an association between successful optimization of MTX treatment within two years of RA diagnosis and development of a status of D2T-RA later in the disease course.
Methods: In 2016 we started a 'Refractory RA' clinic at the Rheumatology Unit, University of Padua, Italy. In this retrospective cohort study conducted in December 2021, we enrolled patients fulfilling both the ACR/EULAR 2010 criteria for RA and the EULAR definition of D2T-RA[2] diagnosed after 2000. We compared D2T-RA patients with non-D2T-RA controls from the same clinic having similar sex distribution and year of diagnosis. The primary outcome was the status of DT2-RA. The exposure was 'MTX optimization' after two years from diagnosis, as assessed with a numeric score (the sum of the following binary variables concerning MTX therapy: started within 3, 12 or 24 months from diagnosis; adequate dose (≥15 mg weekly); treatment duration≥6 months; early intolerance (≤3 months); range 0 to 6, with higher scores reflecting better optimization). We used multiple logistic regression analysis to examine the association (odds ratio (OR)) between MTX optimization scores and the outcome, controlling for potential modifiers (age, sex, body mass index, age at onset, and anti-citrullinated peptides antibodies [ACPA]).
Results: There were 37 DT2 RA patients and 107 non-D2T RA controls for the analysis (mean (SD) disease duration 12.8 (4.1) vs. 12.6 (4.6), p=0.621). Per protocol, gender (females 77.3 vs. 82.0%, p=0.247) and year of diagnosis (median [25th, 75th percentile]: 2008 [2004, 2011] vs. 2008 [2003, 2012]) were comparable between groups. Optimization of MTX therapy was poor overall, yet MTX optimization scores were significantly higher in D2T-RA than in non-D2T-RA patients (1.06 (0.21) vs. 0.56 (0.14), p<0.001). In multiple logistic regression, MTX optimization was protective against DT2-RA. Indeed, the likelihood of D2T-RA was decreased by 34%-54% according to MTX optimization scores. Other disease characteristics significantly associated with D2T-RA were an older age at diagnosis and female sex (Table 1). In December 2021 (last follow-up), D2T-RA patients were receiving a significantly higher daily dose of prednisone (4.3 (1.4) vs. 0.5 (0.2), p<0.001), and had a numerically greater burden of comorbidities (median 3 [1, 4] vs. 2 [1, 3], p=0.252) and disease activity (DAS28-ESR: 3.41 (0.40) vs. 2.6 (0.19), p=0.053) than non-D2T-RA patients.

Table 1. Early factors associated with difficult-to-treat rheumatoid arthritis (multivariable logistic regression)

	B	SE	P-value	Odds ratio	95% IC
MTX optimization score	-0.599	0.092	<0.001	0.549	0.459, 0.657
Age, years	0.033	0.008	<0.001	1.034	1.017, 1.051
Sex (female vs males)	0.723	0.287	0.012	2.061	1.174, 3.615
BMI, kg/m^2	-0.006	0.018	0.748	1.006	0.970, 1.043
ACPA (positive vs negative)	0.431	0.2450	0.079	1.539	0.952, 2.487

ACPA, anti-citrullinated peptide antibodies; B, unstandardised beta coefficient; BMI, body mass index; MTX, methotrexate; SE, standard error.

Conclusion: DT2-RA may be prevented by optimization of MTX therapy within two years of RA management.

POS0529 LONG-TERM LOCAL JOINT DAMAGE PROGRESSION IN RHEUMATOID ARTHRITIS IS RELATED TO CUMULATIVE LOCAL CLINICAL JOINT INFLAMMATION

S. Heckert[1], S. A. Bergstra[1], Y. Goekoop-Ruiterman[2], M. Güler-Yüksel[3], W. Lems[4], M. Van Oosterhout[5], T. Huizinga[1], C. Allaart[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]HagaZiekenhuis, Rheumatology, Den Haag, Netherlands; [3]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; [4]Amsterdam University Medical Center, Rheumatology, Amsterdam, Netherlands; [5]Groene Hart Hospital, Rheumatology, Gouda, Netherlands*

Background: Previously we showed that joint inflammation in rheumatoid arthritis (RA) tends to recur in the same joint, suggesting local factors contributing to joint inflammation. In the same study population, we now investigated whether cumulative local joint inflammation is associated with local radiographic damage progression.
Objectives: To investigate whether there is an association between long-term cumulative joint swelling and progression of radiographic damage in treated-to-target patients with RA.
Methods: Data from the BeSt study were used, in which newly diagnosed patients with RA (ACR 1987 criteria) were treated-to-target (DAS ≤2.4) during 10 years. Local joint swelling (yes/no) was determined by clinical evaluation by trained nurses of all hand and foot joints at 3-monthly study visits. Yearly radiographs of hand and feet were scored for radiographic joint damage (Sharp-van der Heijde method) in random order by two independent readers who were blind for clinical results. Per joint, damage was expressed as the percentage of the maximum possible damage score, to account for differences in maximal scores per joint. Missing values were imputed using the last observation carried forward method. A generalized linear mixed model was used to assess the association between local joint swelling over time (i.e., percentage of study visits with observed local joint swelling) and degree of joint damage at the end of follow-up. Joints were clustered within patients. The model was adjusted for baseline damage and follow-up duration. To test the association between cumulative local joint swelling and joint damage as a local or a general inflammation effect, we did two analyses. First, we additionally adjusted the primary analysis for the mean disease activity score (DAS) over time. Second, we did a permutation test to study whether joint damage progression was better predicted by joint swelling in the joint itself than by joint swelling in randomly selected other joints, which is indicated by a p-value of <0.05.
Results: Of the 16,150 joints of 475 patients with at least one year follow-up with both radiographic and joint swelling assessment available, 16% (2,564) had radiographic joint damage (damage score ≥ 0.5) at the end of follow-up. Median (IQR) follow-up time was 10 (6-10) years. Of the joints with damage at the end of follow-up, 46% (1,163) was swollen at baseline, versus 36% (4,818) of the joints without damage. The median (IQR) percentage of visits at which joint swelling was observed was 6 (0-17) and 3 (0-8) for joints with and without joint damage respectively. We found a β of 0.13 (95% CI 0.12 to 0.14) for the association between cumulative local joint swelling and local progression, that is, with each 1% increase in the number of visits with local joint swelling, local radiographic joint damage progression on average increased with 0.13 percent. In an analysis with 10-years completers only (both baseline and year 10 damage score available, n = 9,520) we also found an association between cumulative local joint swelling and local radiographic damage (β 0.24, 95% CI 0.22 to 0.26). The association was also found in a subset of joints that were swollen at least once (β 0.20, 95% CI 0.18 to 0.22), indicating that joint damage is not only associated with ever-occurrence but also with the frequency of joint swelling. This association was found for both erosions (β 0.07, 95% CI 0.07 to 0.08) and joint space narrowing (β 0.21, 95% CI 0.19 to 0.22). The results of the primary analysis did not change after adjustment for DAS over time. The permutation test showed that local joint damage progression was better predicted by the frequency of joint swelling of that joint, than by joint swelling frequency of other joints (p<0.001). These results indicate a local, rather than a general, inflammation effect.
Conclusion: Cumulative local joint swelling over time is associated with joint damage progression in the same joint in treated-to-target (DAS ≤2.4) patients with RA. Our results indicate that this is a local effect rather than an effect of general disease activity.

POS0530

MOLECULAR SIGNATURE IN SUSTAINED CLINICAL REMISSION INDUCED BY TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Kajio[1], K. Suzuki[1], K. Matsumoto[1], H. Iijima[2], S. Nakamura[2], Y. Ishizawa[2], J. Inamo[1], M. Takeshita[1], K. Yoshimoto[1], Y. Kaneko[1], T. Takeuchi[1]. [1]*Keio University, Division of Rheumatology, Department of Internal Medicine, School of Medicine, Tokyo, Japan;* [2]*DNA Chip Research Inc, Research Division, Tokyo, Japan*

Background: Clinical remission is a clinical goal in the treatment of rheumatoid arthritis (RA). Sustained, biologics-free and true remission is an unachieved goal of the "treat-to-target" approach in most patients, and the determinants for achievement are still unclear. In our recent prospective study using multiomics analysis, we proposed that a molecular signature in peripheral whole blood can be a predictor for subsequent disease activity or activities of daily living.[1] We also showed that tocilizumab (TCZ) induced deep clinical remission associated with gene expression in peripheral CD4+ T cells.[2]
Objectives: To consolidate and expand our hypothesis, we investigated the significance of molecular signatures in sustained remission in a larger scale cohort.
Methods: To build and validate the diagnostic model, we collected 73 peripheral blood samples from 30 patients with active RA, 30 patients in clinical remission induced by TCZ and 13 healthy controls. We then collected another 23 samples at a point before TCZ was halted due to sustained clinical remission. In total, 96 samples were analyzed by a multiomics platform, which included RNA sequencing and comprehensive proteomics.
Results: We first developed an optimized partial least-squares regression (PLSR) model using data from 5,436 genes and 255 proteins extracted in our previous model.[1] The odds ratio in the model clearly reflected the clinical state with high fidelity (Figure 1). In that study, TCZ induced nearly half of the patients with clinical remission into molecular remission, with an odds ratio of less than zero. To clarify the characteristics of the molecular signature at sustained clinical remission under TCZ continuation, 23 samples were applied to the model. The odds ratio was largely the same as that for clinical remission. Next, we investigated the association with disease flare after cessation of TCZ. At some points before cessation, the median odds ratio in patients who experienced disease flare after stopping TCZ tended to be higher than that in patients with sustained remission after stopping TCZ in the transcriptomics model but not in the proteomics model. Thirty-five differentially expressed genes were identified between the two groups under the conditions of a >1.5-fold change and P-value<0.05.

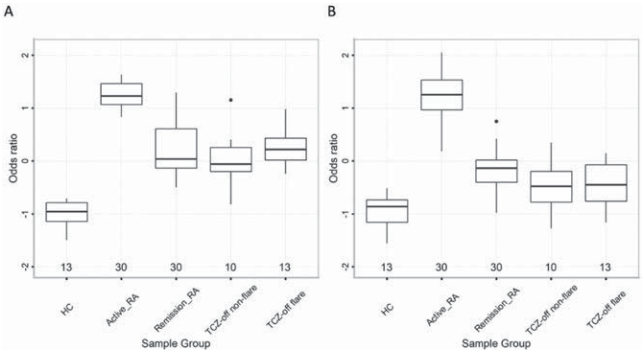

Figure 1. Odds ratio in the partial least-squares regression model using transcriptomics (A) and proteomics (B) data from rheumatoid arthritis and healthy control groups

Conclusion: Our larger scale study validated the idea in our previous study that TCZ induces molecular remission. A certain substantial gap associated with prognosis after quitting TCZ may exist as a molecular signature of sustained clinical remission induced by TCZ. These multiomics data sets enable us to understand sustained clinical remission at a molecular level.

ABATACEPT DELAYS THE DEVELOPMENT OF RA– CLINICAL RESULTS AFTER 18 MONTHS FROM THE RANDOMIZED, PLACEBO-CONTROLLED ARIAA STUDY IN RA-AT RISK PATIENTS

Background: The development of RA is described by a preclinical phase of autoimmunity, that precedes clinical disease. This autoimmune phase is characterized by the presence of anti-modified protein antibodies that recognize citrullinated proteins (ACPA). A subset of individuals with ACPA develops RA, i.e. those with imaging signs of subclinical inflammation in the joints. As T cell mediated B cell activation is a key step in developing autoimmunity and RA, interventions that target this process may be useful for preventing the onset of RA. In this context, abatacept seems being an attractive therapeutic tool as it interrupts the activation of T cells and has a favourable safety profile in the treatment of RA.
Objectives: To test whether treatment of abatacept, as compared to placebo, delays the onset of RA in ACPA positive individuals with a high risk to develop RA.
Methods: ARIAA is an international, randomized double-blinded placebo-controlled multi-center study in RA-at risk individuals, being ACPA positive and showing MRI signs of inflammation. The study was composed of a 6 months treatment phase with either abatacept s.c. 125 mg weekly or placebo and a 12 months observation phase with no treatment. Primary endpoint was the improvement of MRI inflammation after 6 months, secondary endpoints were the progression to RA after 6 and 18 months. The primary analysis was done on the ITT population and missing values were classified as treatment failures.
Results: Between November 2014 and December 2019 139 RA-at risk individuals were included into ARIAA by 14 study sites (11 in Germany, 1 in the Czech Republic and 2 in Spain). Of them, 100 patients were randomized to receive either abatacept or placebo. Two patients were excluded and 98 patients could be evaluated for efficacy and safety. The primary endpoint was met: 61% of abatacept and 31% of placebo treated individuals (p=0.0043) improved in MRI inflammation. Furthermore, only 4 patients (8.2%) in the abatacept group but 17 patients in the placebo group (34.7%) progressed to RA after 6 months (p= 0.0025). Even 1 year after cessation of treatment (18 months after inclusion) the number of patients progressing to RA was lower in the abatacept group (35%) than in the placebo group (57%; p=0.0421). With respect to safety, 12 serious adverse events (each one gastritis, cellulitis, pneumonia, tendinitis calcificans, rotator cuff syndrome,

cholelithiasis, peripheral artery disease, idiopathic pain syndrome, prostate cancer, penile neoplasm; trabeculectomy, cataract surgery) were reported, with only one (pneumonia) being considered to be related to treatment.
Conclusion: Abatacept significantly reduces subclinical joint inflammation and delays the development of RA in at-risk individuals.

Table 1.

	ABA	PBO	All
N	49	49	98
Females, N (%)	31 (63.3)	39 (79.6)	70 (71.4)

Hara[11], K. Hata[12], A. Yoshikawa[12], M. Hashimoto[1]. *[1]Osaka City University Graduate School of Medicine, Department of Clinical Immunology, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan; [3]Kurashiki Sweet Hospital, Department of Health Information Management, Kurashiki, Japan; [4]Graduate School of Medicine, Kyoto University, Department of Advanced Medicine for Rheumatic diseases, Kyoto, Japan; [5]Graduate School of Medicine, Kyoto University, Center for Cancer Immunotherapy and Immunobiology, Kyoto, Japan; [6]Osaka University, Graduate School of Medicine, Department of Musculoskeletal Regenerative Medicine, Osaka, Japan; [7]Graduate School of Medicine, Osaka University, Department of Respiratory Medicine and Clinical Immunology, Osaka, Japan; [8]Kobe University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kobe, Japan; [9]Kansai Medical University, First Department of Internal Medicine, Hirakata, Japan; [10]Osaka Red Cross Hospital, Department of Rheumatology, Osaka, Japan; [11]Nara Medical University, Rheumatology Clinic and Department of Orthopaedic Surgery, Nara, Japan; [12]Osaka Medical and Pharmaceutical University, Department of Internal Medicine (IV), Takatsuki, Japan*

Background: Difficult-to-treat rheumatoid arthritis (D2T RA) is defined as RA in which disease activity is uncontrolled despite the use of two or more biologics or Janus kinase inhibitors (JAKi) with different mechanisms of action (MOA).
Objectives: To explore the optimal treatment strategy for D2T RA, we evaluated the drug retention, efficacy, and reasons for discontinuation of biologics or JAKi used for patients with D2T RA in a longitudinal multicenter cohort.
Methods: RA patients with clinical disease activity index (CDAI) >10 despite the use of at least two biologics or JAKi with different MOA and further treated with biologics or JAKi were included. The drug retention rates of biologics (TNFi, IL-6Ri, and CTLA4-Ig) or JAKi were estimated at 12 months using the Kaplan-Meier method and adjusted for potential confounders (age, sex, disease duration, concomitant MTX and PSL use, and the number of switched biologics or JAKi) using Cox proportional hazards models.
Results: A total of 251 treatment courses (TCs) from 167 patients were included (TNFi: 97 TCs, IL-6Ri: 67 TCs, CTLA4-Ig: 27 TCs, JAKi: 60 TCs). Baseline characteristics showed no difference in age, sex, disease duration, ACPA positivity, CDAI, and concomitant MTX and PSL use between the four groups. Drug retention excluding non-toxic reasons and remission was significantly higher in patients treated with JAKi or IL-6Ri than in patients treated with TNFi or CTLA4-Ig (P=0.00172). Multivariate analysis using Cox proportional hazards models demonstrated that discontinuation of the drug was associated with the use of TNFi or CTLA4-Ig (HR: 3.29, 95%CI: 1.15-9.42, P=0.027) and concomitant PSL use (HR: 1.14, 95%CI: 1.04-1.26, P=0.0084). In terms of disease activity evaluated with CDAI, no difference was observed between the four groups at 3 months (P=0.90), at 6 months (P=0.77), and at 12 months (P=0.75).
Conclusion: In patients with D2T RA, JAKi or IL-6Ri may have treatment advantages compared with TNFi or CTLA4-Ig.

POS0533 REPURPOSING FIB-4 SCORE IN RHEUMATOID ARTHRITIS: DATA FROM THE ESPOIR COHORT

R. Felten[1], T. Fabacher[2], N. Sedmak[2], F. Berenbaum[3], B. Combe[4], J. Sibilia[1], C. Sordet[1], E. Chatelus[1], A. Ruyssen-Witrand[5], O. Vittecoq[6], N. Meyer[2], J. E. Gottenberg[1]. *[1]Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Centre National de Référence des Maladies Auto-immunes Systémiques Rares Est Sud-Ouest (RESO), Strasbourg, France; [2]Hôpitaux Universitaires de Strasbourg, Service de Santé Publique, Strasbourg, France; [3]Hôpital Saint Antoine, APHP, Service de Rhumatologie, Paris, France; [4]Hôpitaux Universitaires de Montpellier, Service de Rhumatologie, Montpellier, France; [5]Hôpitaux Universitaires de Toulouse, Service de Rhumatologie, Toulouse, France; [6]Hôpitaux Universitaires de Rouen, Service de Rhumatologie, Rouen, France*

Background: The Fibrosis-4 (FIB4) score, including age, transaminases and platelets, can detect severe fibrosis (F3-F4) in patients with Non Alcoolic Steato Hepatitis (NASH) and could be of interest in the follow-up of patients with RA. Indeed, platelets contribute to the pathophysiology of RA, transaminases are used in the liver monitoring of our treatments. In addition, retrospective data suggested the association between FIB4 and mortality in RA (1).
Objectives: We aimed to evaluate the value of the FIB4 score as a prognostic factor in RA in the prospective ESPOIR cohort.
Methods: Patients of the ESPOIR cohort diagnosed with RA according to ACR-EULAR criteria were included in our analysis. The formula for the FIB-4 score is as follows: [Age (years) × ASAT (U/L)] / [Platelet count (10^9/L) × ALT (U/L)1/2]. The analyses were based on linear mixed-effects models with a random effect on the subject to account for repeated measures throughout time.
Results: 633 of the 813 patients included met the ACR/EULAR criteria for RA and had a calculable FIB4 score. Median FIB4 was 0.75 IQR (0.53-0.99) and 61 patients (9.6%) had a high FIB4 score at baseline. Baseline FIB4 was significantly higher in patients with a chronic alcohol consumption (p=0.021) or viral hepatitis (p<0.001). In multivariate analysis, including the main baseline prognostic factors for progression of RA (swollen Joint Count, CRP, Presence of ACPA, Rheumatoid Factor and modified Sharp score), FIB4 was not independently associated with progression of DAS28 during 10 years of follow-up, unlike baseline CRP and SJC. Baseline FIB4 was not associated with the modified Sharp score at 10-year follow-up unlike age and the presence of ACPA (Table 1). FIB4 was not associated with mortality (p=0.77) or major adverse cardiovascular events (p=0.22) during the 10-year follow-up. No significant change in FIB4 score over time was related to the use of NSAIDs, methotrexate, tocilizumab or other DMARDs.

Table 1. Associations of FIB4 score with DAS28 and modified Sharp score evolutions in multivariate analyses

Variable	Variables included in model	p-value
DAS28	Time	**<0.0001**
	Age	0.97
	Baseline number of swollen joints	**<0.0001**
	Baseline Rheumatoid Factor	0.51
evolution over time	Baseline ACPA (presence)	0.97
	Baseline CRP	**<0.0001**
	Baseline modified Sharp score > 0	0.15
	Baseline FIB4	0.26
Modified Sharp score	Time	0.052
	Age	**0.0005**
	Baseline number of swollen joints	0.38
evolution over time	Baseline Rheumatoid Factor	0.61
	Baseline ACPA (presence)	**0.012**
	Baseline CRP	0.84
	Baseline FIB4	0.25

Conclusion: Our study was the first to evaluate the value of FIB4 in a prospective cohort of RA patients. The present prospective cohort study with a 10-year follow-up did not find a prognostic role of FIB4 in RA, in contrast to previous retrospective studies. Reassuringly, FIB4 score was not increased by DMARD treatment after 10 years of follow-up, confirming the absence of long-term DMARD-related hepatotoxicity.

POS0534 TRAJECTORY ANALYSIS OF RHEUMATOID ARTHRITIS PROGRESSION USING CLINICAL DATA

D. Van der Bijl[1], T. Maarseveen[1], A. Cope[2], A. Yann[3], R. Knevel[1,4]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]King's College London, Centre for Theumatic Diseases, London, United Kingdom; [3]Johnson & Johnson Santé Beauté France, Discovery Science – AI & Genomics Initiative France, Issy-les-Moulineaux, France; [4]Newcastle University, Rheumatology, Newcastle upon Tyne, United Kingdom*

Background: Given the different symptom duration at first presentation of patients who are developing rheumatoid arthritis, we hypothesize that patients progress towards RA at a different speed, possibly going through different clinical stages. By identifying those stages and the pace at which patients transition from one to the other we could get a better understanding of the disease course as well as define a better timing for medical intervention.
Objectives: To identify clinically distinct disease stages and trajectories within Rheumatoid Arthritis.
Methods: We used clinical data (ESR, TJC, MCH, MCHC, MCV, leukocytes, thrombocytes, hemoglobin, and hematocrit) of 1595 outpatient visits in the first one and a half years of treatment of 426 patients. To facilitate trajectory comparison, we normalized data per patient. Building on previous work in the single-cell analysis field, we employed the Seurat[1] pipeline running an unsupervised cluster

analysis in the higher dimensions using the SLM (smart logical moving) algorithm. Different baseline definitions were explored; the date of first visit, RA diagnosis, and DMARD initiation. Using these different baselines we can examine whether a cluster contains mostly late or early visits.

Results: Using only clinical variables, we identified eleven distinct clinical clusters that represent early, mixed, and late clinical visits (Figure 1) with approximately 105, 220, and 300 days after baseline respectively.

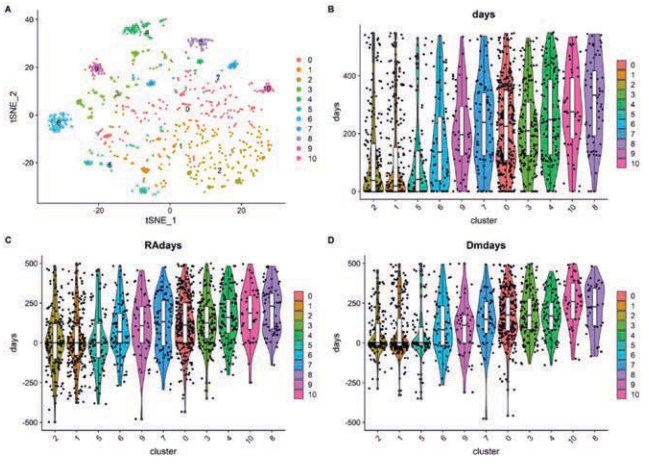

Figure 1. Violin plots for the different baselines. A) tSNE plot color indicating cluster, B) baseline defined by first clinic visit, C) baseline is RA diagnosis, D) baseline is DMARD initiation. The colors correspond to the different clusters. (y-axis: days since baseline, x-axis: cluster)

For each patient, we also had access to the number of days relative to the date of the first visit, RA diagnosis, and DMARD initiation that the different samples were taken from. Using this information we can show that some clusters are enriched for late time points while others are enriched for early time points (Figure 1B, C, and D), suggesting that the different clusters correspond to different disease stages. Considering the clinical values in the different clusters showed a lower disease activity in the later clusters than in the earlier clusters (Figure 2), which is in line with expected treatment efficacy. For example, in cluster 1 which is an early cluster, the average ESR was 28.6 in comparison with late cluster 8 which had an average ESR of 6.0. Interestingly, some clusters are defined by the different clinical variables even when they have a comparable number of days since baseline(Figure 2).

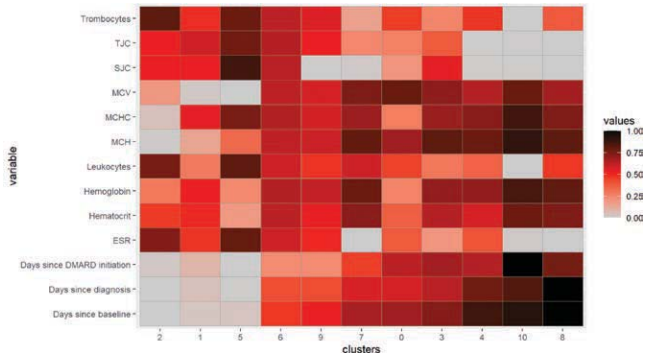

Figure 2. Interpreting the clusters and their values. ESR, Erythrocyte Sedimentation Rate; SJC, Swollen Joint Count; TJC, Tender Joint Count

Conclusion: With unsupervised clustering on clinical parameters, we can differentiate early and late outpatient visits even when the duration between first visit and RA diagnosis or DMARD initiation differed. Subsequently, the clustering identified different clinical groups amongst the first and later clinical visits. Our analysis is the first step into defining disease trajectories in patients who develop RA and represents a new way to integrate longitudinal patient data. The next step is to explore whether patients follow different trajectories.

POS0535 OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING THERAPY WITH ETANERCEPT, ADALIMUMAB, OR JANUS KINASE INHIBITORS

D. A. Pappas[1,2], J. O'brien[2], L. Guo[2], Y. Shan[2], J. Baker[3], G. Kricorian[4], S. Stryker[4], D. Collier[4]. *[1]Columbia University, Department of Medicine, New York, United States of America; [2]CorEvitas, LLC, Research, Waltham, United States of America; [3]Philadelphia Veterans Affairs Medical Center, Rheumatology and Epidemiology, Philadelphia, United States of America; [4]Amgen Inc., Research, Thousand Oaks, United States of America*

Background: Ongoing debate exists regarding the optimal sequence of tumor necrosis factor inhibitors and Janus kinase inhibitors (JAKis) in patients with rheumatoid arthritis (RA) as first-line biologic or targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD) therapy following conventional therapies.

Objectives: To describe baseline characteristics, effectiveness, persistency, and treatment patterns among first-line b/tsDMARD-naive initiators of etanercept (ETN), adalimumab (ADA), or JAKis (tofacitinib, baricitinib, and upadacitinib).

Methods: Data on patients who initiated b/tsDMARD from 11/2012 to 6/2021 were obtained from the CorEvitas RA Registry, a prospective, multicenter, observational, disease-based registry. Patients ≥18 years with rheumatologist-diagnosed RA and 6- and/or 12-months' (M) follow-up were included. We report descriptive statistics at baseline, persistency on therapy, escalation/de-escalation of therapy, details on patterns of drug switching, and effectiveness outcomes using regression models adjusted for baseline covariates (demographic/socioeconomic/lifestyle characteristics, comorbidities, medication history, disease activity, and patient-reported outcomes). Outcomes were evaluated at 6M and 12M follow-up.

Results: First-line initiators of ETN, ADA, and JAKis with baseline and follow-up visits were identified: 803, 984, and 361 patients at 6M, respectively; 589, 749, and 264 patients at 12M, respectively. Baseline characteristics were similar among ETN, ADA, and JAKi initiators with the exception of disease duration, which was longer among first-line JAKi initiators (mean, 8.6 y) versus ETN (5.9 y) and ADA (5.8 y) initiators. Unadjusted mean improvement in Clinical Disease Activity Index (CDAI) was generally similar between groups at 6M and 12M (Table 1). Adjusted effectiveness results were similar at 6M and 12M (Figure 1). At 6M, 68% of ETN, 69% of ADA, and 67% of JAKi initiators remained on the same therapy; at 12M, 53% of ETN, 57% of ADA, and 57% of JAKi initiators remained on the same therapy. The frequency of switching to another b/tsDMARD was similar across initiators.

Table 1. Patient Description at Time of Initiation and Unadjusted Disease Activity Results

	ETN	ADA	JAKis
Age, years	54.4 (12.8)	55.5 (12.1)	60.9 (12.5)

Background: Rheumatoid factor (RF) and anti-cyclic citrullinated protein/peptide antibodies (ACPA) are included in the ACR/EULAR 2010 classification criteria for rheumatoid arthritis (RA)(1). Both markers are given the same weight in the criteria.
Objectives: As the performance characteristics differ significantly between RF and ACPA(2), we set out to refine the serological scores for RA classification.
Methods: Diagnostic samples from 398 RA patients and from 1073 diseased controls were evaluated with five RF assays (two RF IgM isotype-specific assays and three total RF assays) and five ACPA IgG assays from five different manufacturers.
Results: Firstly, we harmonized thresholds between manufacturers based on predefined specificity for low positive (at 92.5% specificity for RF and at 97.5% specificity ACPA) and high positive results (at 97.5% specificity RF and at 99.0% specificity for ACPA). Next, we determined likelihood ratios (LRs) for RF, ACPA, and combinations of both, for negative, low positive, and high positive results. The LR was higher for ACPA than for RF, for high positive results than for low positive results and for double positivity than for single positivity. Based on these data we refined the weights of serological scores for classification (Table 1).

Table 1. Refined weights of serological scores for RA classification

	RF negative	RF low positive	RF high positive
ACPA negative	0	1	1
ACPA low positive	2	3	3
ACPA high positive	3	4	4

Application of such refined serological weights significantly increased the area under the curve of receiver operating characteristics analysis to distinguish RA from controls, significantly reduced the serological scores in the controls as well as the number of RA misclassifications without affecting the diagnostic sensitivity. Besides, we showed that combining predefined specificity thresholds with the refined serological scoring, reduced manufacturer-dependent variability in RA classification impacting RA classification for controls from 18.0-29.0% by ACR/EULAR to 11.0-13.0% (significantly increasing specificity) and for RA patients from 67.8-74.0% to 67.6-71.5% (without significantly affecting sensitivity).
Conclusion: Serological weight factors for RA classification can be improved by taking into account the antibody type (RF versus ACPA), the antibody level, and single or combined positivity.

MORTALITY IN RHEUMATOID ARTHRITIS: CHANGING CAUSES AND PREDICTIVE FACTORS. STUDY OF A COHORT FOLLOWED PROSPECTIVELY

C. Corrales-Selaya[1], F. Benavides-Villanueva[1], I. Ferraz-Amaro[2], N. Vegas-Revenga[3], V. Portilla[4], R. Blanco[1], M. A. González-Gay[1], A. Corrales[1].

Background: Patients with Rheumatoid Arthritis (RA) present an increased risk of mortality. In the last decades, mortality rates tended to decrease but cardiovascular (CV) events remained as the leading cause of death in most series (1).
Objectives: To assess mortality rates and leading causes of death, as well as predictors of mortality related to disease activity in a prospectively followed-up cohort of RA patients.
Methods: We conducted a prospective longitudinal study that included 673 RA patients from a single tertiary center. Univariate and multivariate Cox proportional hazards regression were used to identify predictors of mortality.
Results: We studied 673 patients with RA (75% women), mean age 61±13 years. The main general characteristics, CV risk factors, RA disease activity data and current treatment are summarized in the Table 1.

Table 1. Baseline characteristics of 673 RA patients

Age, years, (mean±sd)	61 ± 13
Female/Male, n (%)	505 (75) /168 (25)
Past or Current smoker, n (%)	338 (50)
Obesity, n (%)	226 (34)
Hypertension, n (%)	310 (46)
Diabetes Mellitus, n (%)	85 (13)
Dyslipidemia, n (%)	310 (46)
BMI, kg/m2 (mean±sd)	28 ± 6
Abdominal circumference, cm (mean±sd)	97 ± 15
Total/HDL/LDL cholesterol, mg/dl (mean±sd)	204±38/62±18/120 ± 31
Disease duration, years (median, [IQR])	13 [10-20]
CRP, mg/l (median, [IQR])	3.0 [0.8-7.0]
ESR, mm/ 1º hour (median, [IQR])	12 [5-21]
Rheumatoid factor/ ACPA, n (%)	376 (56) / 314 (48)
DAS28-ESR/ DAS28-PCR (mean±sd)	3.18 ± 1.41/3.00 ± 1.23
NSAIDs / Prednisone, n (%)	265 (39) /341 (51)
Prednisone dose, mg/day (median, [IQR])	5 (2.5-5)
c-DMARDS: Metotrexate/ Leflunomide/ Hydroxychloroquine/ Salazopyrin, n (%)	406 (60) /52 (8) / 178 (26) / 10 (1)
b-DMARDS: TNFi/ Tocilizumab/ Rituximab/ Abatacept, n (%)	88 (13) / 43 (6) / 13 (2) / 8 (1)
JAK inhibitors, n (%)	12 (2)

After a follow-up of 4,367 person-years (mean 6.4±1.4), 67 deaths were recorded. Considering all causes of mortality, the cumulative incidence was 14% (95% CI 11-18) with a mortality incidence rate of 0.015 (95% CI 0.012-0.020) patient/year. The main causes of mortality in decreasing order of frequency were infections (N=23) (34%), incidence rate-IR: 0.005 [95% CI 0.003-0.008]), cancer (N=18) (27%), IR: 0.004 [95% CI 0.002-0.007]), CV events (N= 12) (18%), IR: 0.003 [95% CI 0.001-0.005]), respiratory diseases (N=2) (3%), IR: 0.0005 [95% CI 0.00007-0.002] and other causes (N=12) (18%), IR: 0.003 [95% CI 0.001-0.005l]. The statistically significant predictive factors of mortality in the univariate analysis were male gender (HR 1.97[95%CI 1.20-3.21, p=0.007), abdominal circumference (HR 1.03 [95% CI 1.01-1.05], p=0,0006), diabetes (HR 2.85 [95%CI 1.68-4.86], p<0.001) and hypertension (HR 2.92 [95%CI 1.73-4.94], p<0.001). Also, baseline data of variables associated with disease activity such as increased CRP, ESR, DAS28-CRP, DAS28-ESR were predictors of mortality (Figure 1). Disease related parameters were adjusted by CV risk factors in a multivariate analysis. Following this procedure, the predictive factors that reached statistical significance; (Hazard Ratio [95%CI]), were an increased in DAS28-VSG (1.40 [1.07-1.83], p=0.016), DAS- 28-PCR (1.40 [1.07-1.83], p=0.016), CRP (1.02 [1.01-1.05] p=0.002), and ESR (1.03 [1.01-1.05], p=<0.001) (Figure 1).

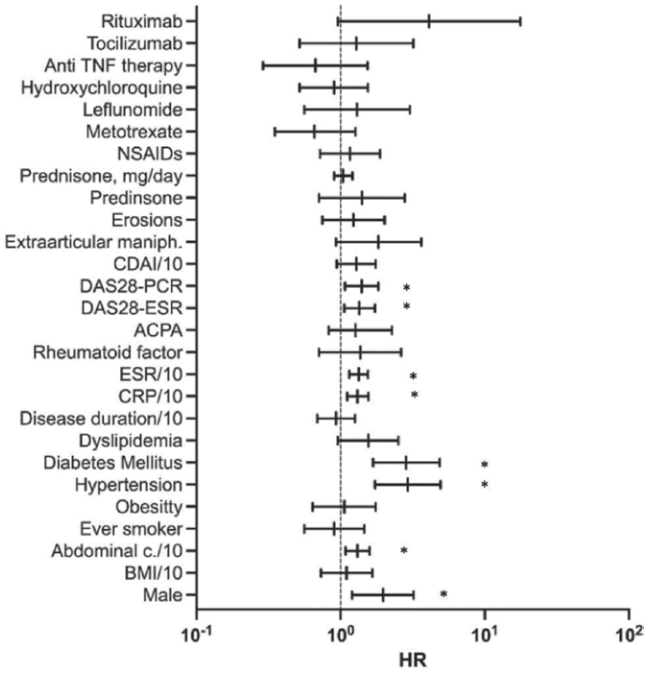

Figure 1. Forest Plot of mortality (Univariate and multivariate analysis). *Results expressed in logarithmic scale. Multivariate analysis: Disease activity related parameters adjusted by age, gender, disease duration, smoker, diabetes, hypertension and abdominal circumference. CDAI, ESR and CPR expressed value/10. (*) p<0.05.*

Conclusion: In a cohort of patients with RA followed prospectively in a tertiary hospital, infections and malignancies are the main cause of mortality rather than CV events. Disease activity parameters are associated with an increased risk of mortality in these patients with RA.

PREDICTING VALUE OF CIRCULATING SEMAPHORIN 4A FOR RHEUMATOID ARTHRITIS PROGRESSION

J. Avouac[1], E. Vandebeuque[1], A. Combier[1], L. Poiroux[1], A. Steelandt[1], M. Boisson[1], V. Gonzalez[2], A. Cauvet[2], Y. Allanore[1]. *[1]Cochin Hospital, Rheumatology, Paris, France; [2]Cochin Institute, INSERM U1016, Paris, France*

Background: The lack of validated tools to predict rheumatoid arthritis (RA) disease course warrants the development of new reliable biomarkers. We have previously detected increased SEMA4A expression in endothelial cells, synovial tissue, and serum of patients with RA. In addition, SEMA4A serum levels correlated with multiple clinical, biological, and power doppler ultrasound markers of disease activity and angiogenesis (1).
Objectives: To evaluate the merit of circulating semaphorin 4A (SEMA4A) for the prediction of disease progression in RA patients.
Methods: Prospective monocentric observational study including consecutive RA patients between May 2016 and February 2018 with available SEMA4A concentrations, measured by quantitative ELISAs (Coud-Clone Corp, Katy, TX). Increased SEMA4A concentrations were defined as values >94 ng/mL, as previously reported (*1*). Patients were followed up on an annual basis until August 2021. Primary endpoints were the occurrence of patient-reported flares with swollen joints and the necessity to initiate or change a targeted biologic or synthetic disease-modifying anti-rheumatic drugs.
Results: A total of 101 patients (85 females, 84%) were included, with a mean age of 58±13 years and a mean disease duration of 14±11 years. During a follow-up period of 41±15 months, disease flares occurred in 38 patients and targeted therapy was added or modified in 26 patients because of insufficient disease control. Increased baseline SEMA4A levels were predictive of flares and treatment escalation (hazard ratio, HR: 2.43, 95% confidence interval, CI 1.27-4.68 and 2.73, 95%CI 1.24-5.96, respectively) (Figure 1**A-B**). Multivariate

Cox analyses confirmed that SEMA4A was an independent predictors of flares and treatment escalation (HR: 2.12, 95%CI 1.04-4.32 and 2.71, 95%CI1.14-6.43, respectively), and revealed that DAS28-CRP and synovial hyperhemia were independent predictors of flares. Baseline age, disease duration, ACPA or RF positivity, smoking status, presence of erosions, line of targeted DMARDs, treatment with corticosteroids and CRP levels were not predictive of these outcomes. SEMA4A remained predictive of flares and treatment escalation in the 58 patients with a DAS28 <3.2 at baseline (HR: 3.68, 95%CI 1.33-10.17 and 3.50, 95%CI 1.02-12.01, respectively). Baseline SEMA4A levels also identified more active and difficult to treat patients who maintained higher mean DAS28-CRP values during the follow-up period (Figure 1**C**). The highest predictive value of flares and treatment escalation was obtained with the combination of increased circulating SEMA4A and/or DAS28-CRP>3.2 and/or the presence of synovial hyperemia on power-doppler ultrasound (HR:4.88, 95%CI 1.50-15.89 and 10.42, 95%CI 1.41-76.94, respectively).

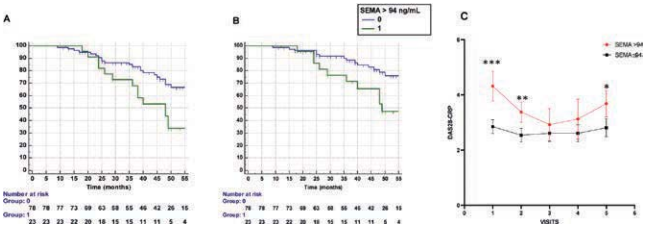

Figure 1. A-C: Predictive value of SEMA4A for the progression of rheumatoid arthritis. A, Disease flare-free survival according to circulating SEMA4A concentrations (≤ or > 94 ng/mL). B, Time to treatment escalation according to circulating SEMA4A concentrations (≤ or > 94 ng/mL). C, Course of the DAS28-CRP during the follow-up period according to baseline SEMA4A concentrations (≤ or > 94 ng/mL). All data are shown as the mean ± SEM. * p<0.05, ** p<0.01 and *** p<0.001, determined by Student's t test.

Conclusion: Circulating SEMA4A was a robust biomarker of disease progression in this cohort, complementary of the DAS28 and synovial hyperemia on power-doppler ultrasound. These results need to be confirmed in replication cohorts.

LATE ONSET RHEUMATOID ARTHRITIS HAS A SIMILAR REMISSION RATE AS YOUNGER ONSET RHEUMATOID ARTHRITIS: RESULTS FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE

X. LI[1], A. Cesta[1], M. Movahedi[1,2], C. Bombardier[1,3,4]. *[1]Toronto General Hospital, system support outcome, Toronto, Canada; [2]University of Toronto - St. George Campus, Institute of Health Policy, Management, and Evaluation (IHPME), Toronto, Canada; [3]Mount Sinai Hospital, Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, Canada; [4]University of Toronto - St. George Campus, Department of Medicine (DOM) and Institute of Health Policy, Management and Evaluation (IHPME), University of Toronto, Toronto, ONen, Toronto, Canada*

Background: The prevalence of rheumatoid arthritis (RA) in persons 60 years or older is estimated to be 2%. Late onset rheumatoid arthritis (LORA) is a sub-group of patients traditionally defined as onset of RA after the age of 60 years. Compared to younger onset rheumatoid arthritis (YORA) which occurs before the age of 60 years, LORA has unique characteristics and disease manifestations. The prognosis of LORA patients is less clear based on prior studies.

Objectives: We compared the clinical characteristics, time to remission and treatment regimen at remission between LORA and YORA patients.

Methods: The Ontario Best Practices Research Initiative (OBRI) is a clinical registry of RA patients followed in routine care. This analysis used the OBRI database from 2008 to 2020. Patients were included if they had active RA disease (≥1 swollen joint) and were enrolled in the study within 1 year of diagnosis. LORA was defined as diagnosis of RA after age of 60, YORA as under age of 60. Remission was defined by Disease Activity Score 28 (DAS28) ≤2.6. A multivariable Cox proportional hazards model was used to estimate time to remission.

Results: The Ontario Best Practices Research Initiative (OBRI) is a clinical registry of RA patients followed in routine care. This analysis used the OBRI database from 2008 to 2020. Patients were included if they had active RA disease (≥1 swollen joint) and were enrolled in the study within 1 year of diagnosis. LORA was defined as diagnosis of RA after age of 60, YORA as under age of 60. Remission was defined by Disease Activity Score 28 (DAS28) ≤2.6. A multivariable Cox proportional hazards model was used to estimate time to remission.

Table 1. Cox proportional hazards model predicting time to remission

	Univariate		Multivariable	
Baseline characteristics	HR (95% CI)	p-value	HR (95% CI)	p-value
Sociodemographic

Ever smoked	0.87 (0.75-1.02)	0.076	0.93 (0.77-1.12)	0.4269
RA family history	0.89 (0.74-1.07)	0.2176	0.87 (0.70-1.70)	0.1817
Disease characteristics				
Positive rheumatoid factor	1.01 (0.85-1.19)	0.9182	0.94 (0.78-1.14)	0.5381
*HAQ-DI	0.62 (0.55-0.69)	<.0001	0.71 (0.61-0.84)	<.0001
Morning stiffness (>30 mins)	0.71 (0.61-0.83)	<.0001	0.89 (0.73-1.08)	0.2366
Joint erosion	0.94 (0.77-1.14)	0.5224	0.87 (0.70-1.08)	0.1954
DAS28	0.77 (0.72-0.82)	<.0001	0.88 (0.80-0.96)	0.0048
Number of comorbidities	0.83 (0.77-0.88)	<.0001	0.88 (0.81-0.95)	0.0019
Treatment				
Biologic or JAK inhibitor (time variant)	0.86 (0.71-1.03)	0.09	1.53 (0.63-3.69)	0.3485
LORA	0.83 (0.71-0.97)	0.0194	1.10 (0.90-1.34)	0.3593

*HAQ-DI = health assessment questionnaire disability index

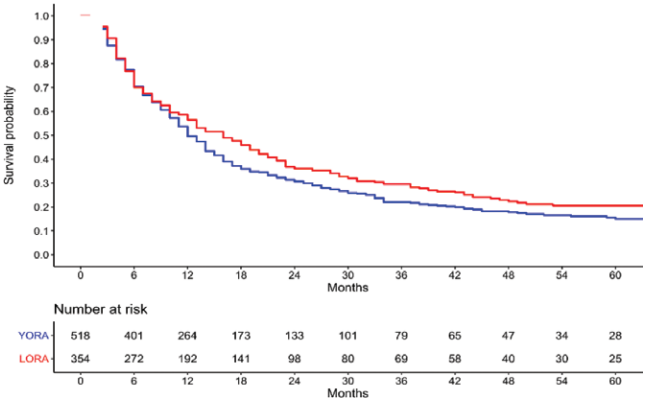

Figure 1. Kaplan Meier survival curve of time to remission.

Conclusion: LORA and YORA patients had similar prognosis in terms of time to remission. At remission, LORA patients were more likely to be on a single csDMARD without biologic or JAK inhibitor. Clinicians should take the same approach for all RA patients targeting remission regardless of age of onset.

CLINICAL OUTCOMES ASSOCIATED WITH GLUCOCORTICOID DISCONTINUATION AMONG PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING UPADACITINIB OR ADALIMUMAB

R. M. Fleischmann[1], B. Combe[2], A. Ostor[3], C. F. Pacheco Tena[4], N. Khan[5], J. Subotickі[5], A. Shmagel[5], Y. Song[5], I. Lagunes-Galindo[5], G. R. Burmester[6].
[1]University of Texas Southwestern Medical Center, Metroplex Clinical Research Center, Medicine, Dallas, TX, United States of America; [2]Montpellier University, Rheumatology, Montpellier, France; [3]Cabrini Medical Center, Monash University, Rheumatology, Malvern, Australia; [4]Universidad Autonoma de Chihuahua, Facultad de Medicina, Chihuahua, Mexico; [5]AbbVie Inc., Immunology, North Chicago, IL, United States of America; [6]Charité – Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany

Background: Patients (pts) with rheumatoid arthritis (RA) are often administered glucocorticoids (GCs) as bridging therapy when initiating or adjusting disease-modifying antirheumatic drugs (DMARDs). Due to their systemic effects, short-term use of GCs at the lowest possible dose is recommended with rapid tapering.[1]
Objectives: We describe GC discontinuation patterns and the associated clinical outcomes in pts with RA receiving upadacitinib (UPA) or adalimumab (ADA).
Methods: SELECT-COMPARE is a randomized phase 3 trial of UPA vs placebo and ADA with a 48-week (wk) double-blind treatment period and a 10-year long-term extension in pts with RA receiving concomitant methotrexate (MTX) who had an inadequate response to MTX.[2] Background GCs (≤10 mg/day prednisone or equivalent) were permitted and could be tapered or discontinued starting at wk 26 per physician discretion. This post hoc analysis included pts who received ≥1 dose of UPA 15 mg once daily or ADA 40 mg every other wk while on concomitant GCs at baseline. The proportion of pts with disease worsening (Clinical Disease Activity Index [CDAI] >2 and Disease Activity Score 28-joint count C-reactive protein [DAS28-CRP] >0.6) following GC discontinuation through follow-up is described. Maintenance of clinical response, including remission and low disease activity based on CDAI ≤2.8 and ≤10, respectively, as well as DAS28-CRP <2.6 and ≤3.2, were assessed among pts who discontinued GCs. Adverse events (AEs) were assessed before and after GC discontinuation through follow-up. Data were analyzed descriptively.
Results: Of 1,629 pts randomized, 978 (60%) used GCs at baseline; 128 (13%) discontinued use at/after wk 26 (UPA, n=97; ADA, n=31). Baseline demographics and clinical characteristics were broadly similar between pts who continued or discontinued GCs. Median follow-up time after GC discontinuation was 60 wks for UPA and 84 wks for ADA. At the time of GC discontinuation, a numerically higher proportion of pts treated with UPA vs ADA were in disease control (CDAI ≤2.8: 55% vs 32%; CDAI ≤10: 85% vs 68%; DAS28-CRP <2.6: 71% vs 48%; DAS28-CRP ≤3.2: 87% vs 62%) (Table 1). Few pts receiving UPA experienced disease worsening following GC discontinuation (1% CDAI increase >2; 7% DAS28-CRP increase >0.6) and none on ADA (Table 1). At 6 months follow-up after GC discontinuation, most pts treated with UPA and ADA maintained CDAI ≤2.8 (74% vs 88%) and ≤10 (92% vs 95%) and DAS28-CRP <2.6 (89% vs 85%) and ≤3.2 (91% vs 94%), respectively (Table 1). GCs were reintroduced (albeit usually temporarily) in 14% of pts on UPA and 19% on ADA (Figure 1). AEs were generally similar across treatment groups. Rates of serious infection before and after GC discontinuation were 0.8 (95% CI 0.0–4.2) and 1.5 (0.2–5.4) events per 100 patient-years (E/100 PY) for UPA and 7.7 (1.6–22.4) and 0 E/100 PY for ADA, respectively. Interpretation of results is limited by small pt numbers and different exposure times.
Conclusion: In pts who achieved disease control and discontinued GCs, disease control was maintained in almost all without worsening disease activity over time following GC discontinuation.

Table 1. Clinical outcomes of pts who discontinued GCs at/after wk 26

	Pts who discontinued GCs N=128	
n/N (%)	UPA n=97	ADA n=31
CDAI		
≤10 at discontinuation	79/93 (85%)	21/31 (68%)
Maintained at 6 months post discontinuation[a]	61/66 (92%)	18/19 (95%)
≤2.8 at withdrawal	51/93 (55%)	10/31 (32%)
Maintained at 6 months post discontinuation[a]	32/43 (74%)	7/8 (88%)
Increase >2 any visit after withdrawal	1/93 (1%)	0
DAS28-CRP		
≤3.2 at withdrawal	78/90 (87%)	18/29 (62%)
Maintained at 6 months post discontinuation[a]	58/64 (91%)	15/16 (94%)
<2.6 at withdrawal	64/90 (71%)	14/29 (48%)
Maintained at 6 months post discontinuation[a]	47/53 (89%)	11/13 (85%)
Increase >0.6 any visit after withdrawal	6/92 (7%)	0

[a]As a proportion of pts achieving outcome at GC discontinuation and with observed data 6 months post GC discontinuation.

PREDICTORS OF REMISSION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH UPADACITINIB OR ADALIMUMAB IN THE SELECT-COMPARE PHASE 3 STUDY: CLINICAL STATUS AT WEEK 12, BUT NOT STANDARD LABORATORY MEASURES, PROVIDES THE BEST CURRENT PREDICTOR OF REMISSION AT WEEK 26

T. Sornasse[1], F. Cai[1], F. Hong[2], S. Anyanwu[3], I. H. Song[4], M. Bukhari[5]. *[1]AbbVie, Precision Medicine Immunology, South San Francisco, United States of America; [2]AbbVie, Data Science and Statistics, Worcester, United States of America; [3]AbbVie, Medical Affairs, North Chicago, United States of America; [4]AbbVie, Immunology Clinical Development, North Chicago, United States of America; [5]Lancaster University, Health and Medicine, Lancaster, United Kingdom*

Background: Upadacitinib (UPA, 15 mg QD), an oral JAK1 selective inhibitor, showed greater efficacy compared to adalimumab (ADA, 40 mg EOW) at week 12 in patients with active rheumatoid arthritis (RA) on background methotrexate (MTX) in the SELECT-COMPARE phase 3 study[1]. Treatment with UPA compared to ADA resulted in a larger proportion of patients reaching CDAI Remission (REM) at week 26 (23% vs. 14%, p-value ≤ 0.001). Because remission is the goal in managing RA, it is of clinical relevance to identify early during the treatment course who might be able to achieve this state. It has been reported that early response to therapy with UPA was associated with achieving CDAI REM at week 26[2]. In parallel, it has been reported that reduction in monocyte can predict DAS28-ESR REM in RA patients treated with anti-TNF therapy[3]. However, the relative predictive values of clinical and standard laboratory measures have not been compared side-by-side.
Objectives: To determine post-hoc the relative predictive values of selected clinical and standard laboratory measures collected at week 12 for identifying RA patients who will be in CDAI REM at week 26 upon treatment with UPA or ADA.

Methods: Clinical (CDAI, SDAI, and DAS28-CRP) and laboratory data (CRP, ESR, CBC with differential, and Lipids) for all available patients enrolled in the SELECT-COMPARE phase 3 study were included in this post-hoc analysis (UPA: n =623 [CDAI REM at wk26 = 23.8%]; ADA: n = 316 [CDAI REM at wk 26 = 14.2%]). Patients who switched treatment between weeks 14 and 22 due to not reaching at least 20% improvement in tender and swollen joints were classified as non-responders for CDAI REM at week 26. The predictive value of clinical and laboratory endpoints recorded at week 12 for determining CDAI REM status at week 26 was assessed by univariate logistic regression. We report the performance of each model as ROC AUC with a cutoff of 0.75 for meaningful predictive value.
Results: For both patients treated with UPA and those treated with ADA, clinical disease activity status measures (CDAI, SDAI, and DAS28-CRP) and relative change in disease activity measures (Percent Change [PCHG] in CDAI, PCHG in DAS28-CRP, and PCHG in SDAI) at week 12 resulted in the highest predictive performance for determining CDAI REM status at week 26 (Figure 1). In contrast, none of the selected standard laboratory measures (CRP, ESR, CBC with differential, and Lipids) reached a meaningful predictive value (ROC AUC < 0.75). Of note, cell numbers and changes in cell numbers (including Neutrophils Lymphocytes, Basophils, Eosinophils, and Monocytes) at week 12 had no meaningful predictive value for determining CDAI REM at week 26.

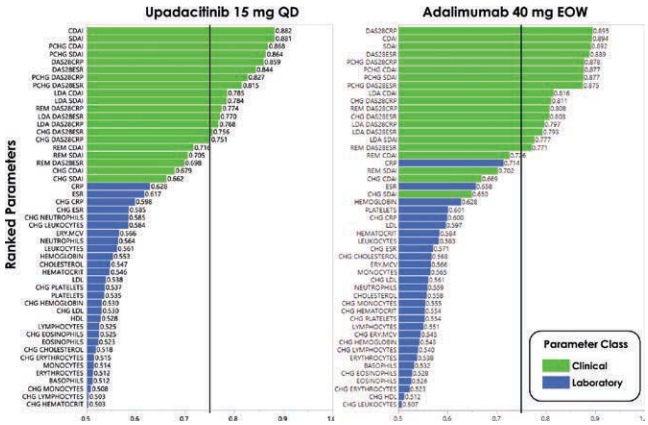

Figure 1. Univariate Logistic Models to Predict CDAI REM at Week 26 in Active RA Patients who had an Inadequate Response to MTX: ROC Analysis AUC. **Legend**: All evaluated parameters were recorded at Week 12; CHG = Change from Baseline to Week 12; PCHG = Percent Change from Baseline to Week 12

Conclusion: This analysis suggests that standard laboratory measures (CRP, ESR, CBC with differential, and Cholesterol) at week 12 do not represent useful predictors for REM at week 26 in csDMARD-IR RA patients. In particular, blood cell numbers and the changes in these measures at week 12 do not provide additional predictive value in our analyses, contrasting with the results from Amarnani and colleagues[3]. Hence, clinical disease activity levels and changes in these measures at week 12 remain adequate predictors of CDAI REM at week 26. Still, the absolute predictive performance of clinical measures remains suboptimal, highlighting the need to dedicate continued efforts to identify and validate improved predictors of long-term REM in RA.

MACHINE LEARNING PREDICTS RESPONSE TO TNF INHIBITORS IN RHEUMATOID ARTHRITIS: RESULTS ON THE ESPOIR AND ABIRISK COHORTS

J. Duquesne[1], V. Bouget[1], P. H. Cournède[2], B. Fautrel[3], S. Hassler[4], F. Guillemin[5], M. Pallardy[6,7], P. Broet[8], S. Bitoun[9], X. Mariette[9]. *[1]Scienta Lab, Research department, Paris, France; [2]CentraleSupélec, Lab of mathematics and computer science (MICS), Gif-sur-Yvette, France; [3]Sorbonne Université – Assistance Publique Hôpitaux de Paris, Groupe Hospitalier Pitié Salpêtrière, Service de Rhumatologie, Paris, France; [4]Assistance Publique Hôpitaux de Paris, Groupe Hospitalier Pitié Salpêtrière, Biotherapy (CIC-BTi), Paris, France; [5]Université de Lorraine, APEMAC, Nancy, France; [6]INSERM, Inflammation microbiome immunsurveillance, Chatenay Malabry, France; [7]ABIRISK, Innovative Medecines Initiative, Paris, France; [8]INSERM, University Paris-Saclay, Hôpitaux Universitaires Paris-Sud, CESP, Villejuif, France; [9]Université Paris Saclay, Assistance Publique-Hôpitaux de Paris, Hôpital Bicêtre, Service de Rhumatologie, Le Kremlin-Bicêtre, France*

Background: Thirteen drugs with different mechanisms of action may be considered to treat patients with methotrexate (MTX) inadequate response in rheumatoid arthritis (RA). TNF inhibitors (TNFi) are frequently the first choice in this situation. Unfortunately, 30% to 40% of RA patients do not respond to TNFi, resulting in a delay for beginning the appropriate targeted DMARD (tDMARD). Predicting the patient response to TNFi before prescribing the treatment is therefore a major goal and could help physicians to prescribe a tDMARD suited to the patient.
Objectives: We aimed to build machine learning models based on simple clinical and biological data to predict patient response to TNFi.
Methods: We used data from the ESPOIR early arthritis cohort (1) to train the models, and the ABIRISK cohort (2) to validate the results. We included patients that fulfilled the EULAR/ACR 2010 criteria and that were treated with a TNFi. The models take as inputs patient's characteristics at treatment initiation and predicts the therapeutic response, defined as the EULAR response 12 months (+/- 6 months) after treatment initiation. We compared the performances of four models (Linear Regression, Random Forest, XGBoost, and Catboost) on the training set by cross-validated them using the Area Under the ROC Curve (AUCROC). The best model was then evaluated on the validation dataset (ABIRISK cohort). We conducted the methodology both on all TNFi together and on etanercept and monoclonal anti-TNF antibodies separated. We analyzed how clinical and biological variables impacted response to provide explainability of the prediction.
Results: We included 164 patients from the ESPOIR cohort and 118 patients from the ABIRISK cohort. Better results were obtained when etanercept and monoclonal anti-TNF antibodies were analyzed separately. These models predict a probability for a patient to respond to TNFi. This probability is compared to a decision threshold to obtain the binary outcome. Two decision thresholds were tested. The first prioritizes a high confidence when identifying responders (Strategy 1) while the second prioritizes a high confidence when identifying non-responders (Strategy 2). The model's results are presented in Table 1.
Using SHAP, we were able to analyze how each variable impacted the predictions. In particular, a DAS28 around 5 had the highest positive impact on response. Higher and lower values of DAS28 had either less impact or even negative impact on the patient response to TNFi treatment (Figure 1). This allows to identify non-linear relations between variables and patient response.
Conclusion: The machine learning models developed in this study can predict RA patients' response to TNFi using exclusively data available in clinical routine. These models also allow to analyze how these variables are used to predict response. Along with similar models for other tDMARDs, such algorithms could lead to a personalized therapeutic strategy.

POS0543 MACHINE LEARNING PREDICTS RESPONSE TO METHOTREXATE IN RHEUMATOID ARTHRITIS: RESULTS ON THE ESPOIR, T-REACH AND LEIDEN COHORTS

V. Bouget[1], J. Duquesne[1], P. H. Cournède[2], B. Fautrel[3], F. Guillemin[4], P. De Jong[5], J. Heutz[5], A. Van der Helm-van Mil[6], M. Verstappen[6], S. Bitoun[7], X. Mariette[7]. *[1]Scienta Lab, Research department, Paris, France; [2]Université Paris-Saclay, CentraleSupélec, Lab of mathematics and computer science (MICS), Gif-sur-Yvette, France; [3]Sorbonne Université – Assistance Publique Hôpitaux de Paris, Groupe Hospitalier Pitié Salpêtrière, Service de Rhumatologie, Paris, France; [4]Université de Lorraine, APEMAC, Nancy, France; [5]University Medical Center, Department of Rheumatology, Rotterdam, Netherlands; [6]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [7]Université Paris Saclay, Assistance Publique-Hôpitaux de Paris, Hôpital Bicêtre, Service de Rhumatologie, Le Kremlin-Bicêtre, France*

Background: Methotrexate (MTX) is the first line of treatment for rheumatoid arthritis (RA) patients. Unfortunately, 30% to 40% of RA patients do not respond to MTX, resulting in uncontrolled joint pain and potential joints destruction. At the same time, many efficient second-line treatments exist and can be given to the inadequate responder patients. Predicting patient response to MTX before prescribing the treatment is therefore a major goal and could enable physicians to directly prescribe second-line treatments if inadequate response to MTX is predicted.
Objectives: We aimed to build machine learning models based on simple clinical and biological data to predict patient response to MTX.
Methods: We used data from the ESPOIR early arthritis (1) and Leiden cohorts (2) to train the models, and the tREACH cohort to validate the results. We included patients that fulfilled the EULAR/ACR 2010 criteria and that were treated with MTX in monotherapy as their first treatment for RA. The models take as inputs patient's characteristics at treatment initiation and predict the therapeutic response, defined as the EULAR response 3 to 12 months after treatment initiation. We evaluated four missing data imputation methods (median, mean, MICE, KNN); we used the backward feature selection algorithm to select the most relevant variables; and compared the performances of four models (Linear Regression, Random Forest, XGBoost, and Catboost) on the training set by cross-validated them using the Area Under the ROC Curve (AUCROC). The best model was then evaluated on the validation dataset.
Results: We included 435 patients from the ESPOIR cohort, 243 patients from the Leiden cohort and 143 patients from the t-REACH cohort. Results of the model are displayed in Table 1. The variables automatically selected to perform prediction were Sex, DAS28, White blood cells, AST, ALT and lymphocytes. Our model performs well on unseen data, this result comes from the fact that we included two different cohorts in our training set which reduces the overfitting of our model and helps him generalize. Our model predicts a probability for a patient to respond to MTX. This probability is compared to a decision threshold to obtain the final binary outcome. Two decision thresholds were tested. The first prioritizes a high confidence when identifying responders (Strategy 1) while the second prioritizes a high confidence when identifying non-responders (Strategy 2). This second strategy would enable physicians to identify highly probable inadequate responders to methotrexate and propose them directly a targeted DMARD such as TNF inhibitors, while still treating more than 70% of patients with MTX as first-line treatment.
Conclusion: The machine learning models developed in this study can predict RA patients' response to methotrexate with a good accuracy exclusively using data available in clinical routine. It paves the way for personalized therapeutic strategies in rheumatoid arthritis.

POS0544 REMOTE MONITORING TOOLS IN RA PATIENTS: FACIT-FATIGUE AND HAQ

E. Grau García[1], P. Muñoz Martinez[1], L. Mas Sanchez[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], S. Leal Rodriguez[1], C. Pávez Perales[1], M. De la Rubia Navarro[1], I. Cánovas Olmos[1], J. J. Fragío Gil[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J. E. Oller Rodríguez[1], F. Ortiz-Sanjuán[1], E. Vicens Bernabeu[1], J. A. Román Ivorra[1]. *[1]HUPLa Fe, Rheumatology Department, Valencia, Spain*

Background: The need to avoid the transmission of COVID19 infection has forced to promote teleconsultations for rheumatic diseases follow-up. However, remote monitoring for rheumatic diseases which require clinical examination, as rheumatoid arthritis (RA), may affect to the evaluation of clinical activity, including the biological therapies follow-up. Due to that, count on tools as Patient Reported Outcomes (PROs) could help the remote monitoring of patients when it is not advisable their physical presence in health centers, being a great help in RA control.
Objectives: We aim to assess the association among the tiredness, disability and pain perception with the clinical activity in RA patients.
Methods: We performed a prospective observational study of three months of follow-up in RA patients (ACR/EULAR 2010) who are newly on biological or anti-JAK therapy. A basal visit and 1, 3 months follow-up visits were conducted. We analyzed changes during follow-up in the PROs parameters reported by patients through FACIT-fatigue and HAQ questionnaires, as well as pain VAS (0-10). Moreover we measured clinical activity through Das28, Das28-CRP, SDAI and CDAI index.
Results: We included 60 patients (83.3% female), with a mean age of 55 (13) and mean disease evolution of 13 (11) years. At the basal visit, 55% of them exhibited increased levels of CRP and the 48.3% of ESR, showing moderate or high clinical activity the 83.3% of the total patients.

Table 1. Sensitivity, Specificity, PPV and NPV are computed on the T-REACH validation cohort for each strategy

AUC (ESPOIR, LEIDEN)	AUC (T-REACH)	STRATEGY 1 (High confidence in responders) SensitivitY	Specificity	PPV	NPV	STRATEGY 2 (high confidence in non-responDeRS) Sensitivity	Specificity	PPV	NPV
0.72 (0.70-0.73)	0.73 (0.64-0.81)	20% (12%-28%)	**98% (83%-100%)**	**95% (82%-100%)**	40% (32%-49%)	**91% (85%-97%)**	33% (20%-47%)	71% (63%-79%)	**68% (48%-86%)**

39 patients started anti-JAK therapy and 21 with TNF-α inhibitors. The 33.34% of patients were under monotherapy, and the 46.67% previously have been treated with biological therapy. The 77.36% of the total number of patients was on the biological therapy at 6 months of follow-up, while the 22.64% discontinued at 6 months of follow-up (9 due to inefficacy and 3 due to adverse effects). 48 patients continued the treatment in the 6 months after, and 12 patients discontinued due to ineffectiveness or drug intolerance. Clinical activity, fatigue, disability and pain perception are shown in Table 1.

Table 1.

Variable	VISIT 0 N=60	VISIT 1 N=57	VISIT 3 N=45
	Mean (SD)	Mean (SD)	Mean (SD)
Pain VAS	6 (2)	4 (3)	5 (3)
HAQ	1.33 (0.61)	1.06 (0.64)	1.06 (0.69)
FACIT-fatigue	25.52 (12.19)	31.03 (12.9)	32.76 (12.46)
DAS28	4.78 (1.2)	3.6 (1.33)	3.54 (1.44)
DAS28-CRP	4.31 (1.06)	3.19 (1.14)	3.05 (1.28)
SDAI	22.72 (9.88)	13.58 (8.58)	12.97 (9.32)
CDAI	21.75 (9.62)	12.88 (7.96)	12.36 (9.11)

Using a mixed linear regression model the association among the fatigue, disability and pain perception with clinical activity was conducted, corrected by age, smoking habits, time of disease evolution, BMI, previous biological/anti-JAK therapy administration and current dose of steroids. We observed a significant association among clinical activity and fatigue (P<0.001), disability (P<0.001) and pain perception (P<0.001). The statistical analyses showed a significant association where a high fatigue is increased in cases with high pain perception (P>0.001) and high number of swollen joints (P=0.002), but not in high levels of CRP and ESR. Fatigue was higher in those cases whom discontinued treatment (P=0.044) regardless of which therapy was chosen. No effect of age, time of disease evolution, steroid dose, BMI or previous therapy and smoking habits in the PROs values was observed.

Conclusion: PROs would be helpful in the disease control in those cases where a remote monitoring is needed, since HAQ or FACIT-FATIGUE index showed a significant association with clinical activity index in RA. Because of its ease for shipping and handling by the health professional, PROs could be a useful tool in the disease control. Its implementation in the remote monitoring of RA patient, as has been the case of Covid19 pandemic, results in an improvement of the clinic evaluation of RA patient, due to required information to clinical management is reported, avoiding presence consultation in those situations when it is required.

Department of Systems and Industrial Engineering, Bogotá, Colombia; [4]School of Medicine - Universidad de los Andes, Department of Internal Medicine, Bogotá, Colombia; [5]School of Medicine - Universidad Nacional de Colombia, Department of Internal Medicine, Bogotá, Colombia*

Background: Rheumatoid Arthritis (RA) is a chronic disease characterized by inflammation and joint pain. In daily clinical practice, it is usual to have multiple variables of different nature to define the current state of the disease, the patient's risk profile, and the subsequent optimal treatment.

Objectives: We aimed to identify the most influential variables from a suitable multivariable clustering and its labeling for an outpatient clinic-based cohort of Colombian RA patients.

Methods: We execute a clustering model (Kohonen's self-organizing map – SOM), applied to 23 variables (17 continuous and 6 discrete) obtained from 14,811 related follow-up visit records hosted on a previously preprocessed database of a cohort with data prospectively collected between 2013 and 2020. The included variables were the disease activity indexes (DAS28-ESR/CRP, CDAI, and SDAI; as outcome variables), serological status (autoantibodies positivity), and patients' sociodemographic and clinical characteristics. Clustering method used for generating the groups was SOM with a size of 25 x 25 neurons and 10000 iterations. SOM allows us to generate the groups by the comparison of the Euclidean distance in the hyperspace generated by the dimensions composed by the variables. After clustering, a discrete label built upon the categorization of the disease activity allowed us to identify the behavior of the included variables regarding the aforementioned outcomes, without affecting the clustering process. We evaluated the corresponding weights and their influence on the proposed neural network.

Results: Data from a total of 1,277 patients were included in the analysis. When both continuous and discrete variables were integrated, discrete data were transformed using the one-hot encoding method, creating new variables according to the corresponding number of categories. Dissimilarity between groups was very low when considering only the continuous variables, and it increases when adding all the other variables; likewise, regardless of the clinimetric index used for labeling, the clustering organization remains (Figure 1a).

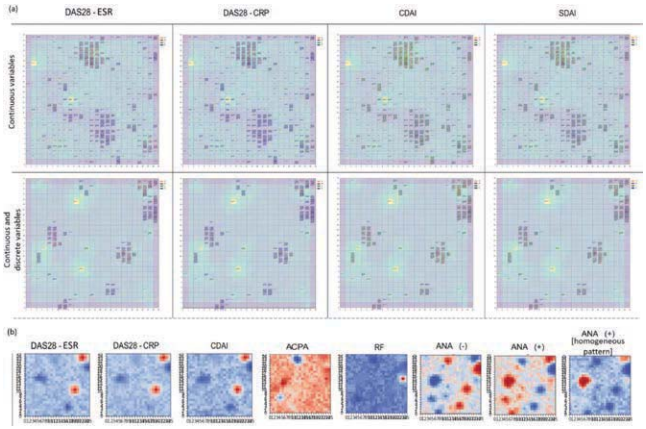

Figure 1. Clusters and heatmaps of variables' weights

In the construction of the groups, the influence of the RF and ACPA positivity was confirmed; furthermore, the antinuclear antibodies (ANAs) delivered a significant effect, especially those with negative ANAs or positive ANAs with a homogeneous pattern, on disease activity (Figure 1b).

Conclusion: SOM, as well as other artificial neural networks (ANN) are important methods for clustering and 2D visualization, due to the multivariate nature of the clinical data and its difficult visualization in the generated n-dimensional hyperspace. The utilized labels confirm that the clustering is adequate when considering that there was an identical grouping behavior for those registers with similar characteristics and an equivalent disease activity score. The findings of this research provide insights into a potentially pivotal role of the influence of RF, ACPA, and ANAs and their interaction with the proposed outcome variables in the understanding and development of future classification or prediction models; based on artificial intelligence and big data methods rather than on classical epidemiological approaches.

POS0546 URINARY METABOLOMIC BIOMARKER CANDIDATES FOR SKELETAL MUSCLE WASTING IN PATIENTS WITH RHEUMATOID ARTHRITIS

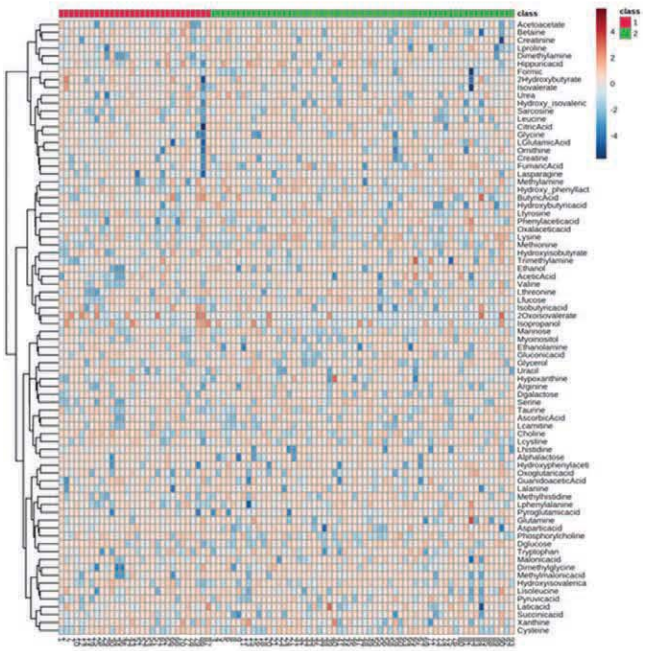
M. De Oliveira[1], R. Cavalheiro Do Espírito Santo[1], R. Xavier[1], P. Alabarse[2], J. Miranda de Souza Silva[3]on behalf of Laboratory of Autoimmune Diseases - HCPA. *[1]Clinicas Hospital, Rheumatology, Porto Alegre, Brazil; [2]University of California, Rheumatology, San Diego, United States of America; [3]University Hospital Münster, University Hospital Münster, Munster, Germany*

Background: Rheumatoid arthritis (RA) is an autoimmune disease that affects the joints, leading to chronic synovial inflammation and local tissue destruction. Extra-articular manifestations may also occur, such as changes in body composition. Skeletal muscle wasting is often observed in patients with RA, but methods for assessing loss of muscle mass are expensive and not widely available, limiting their use in clinical practice and their evaluation in longitudinal studies. Metabolomic analysis has shown great potential for identifying changes in the metabolite profile of patients with autoimmune diseases and can advance our understanding of pathogenic mechanisms, early diagnosis, treatment, and follow-up. In this setting, urine metabolomic profiling in patients with RA may be a useful tool to identify skeletal muscle wasting.

Objectives: To evaluate the urinary metabolomic profile of patients with rheumatoid arthritis and associate it with skeletal muscle loss.

Methods: We recruited patients aged 40–70 years with RA according to the 2010 ACR/EULAR classification criteria. We measured disease activity by the

A.



B.

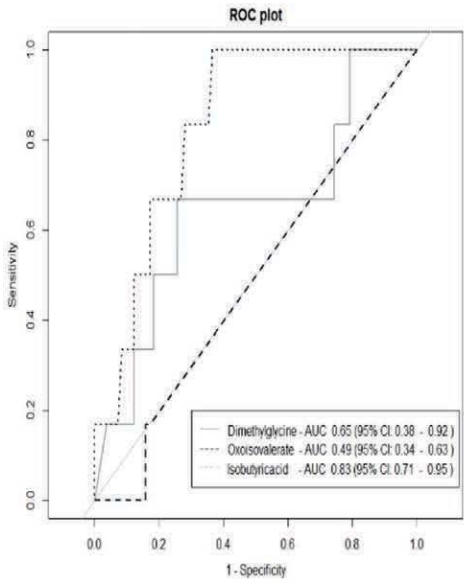


Figure 1.

Disease Activity Score in 28 joints using the C-reactive protein level (DAS28-CRP). We determined muscle mass according to DXA-derived appendicular lean mass index (ALMI) by summing the lean mass measurements for both arms and legs and dividing them by height squared (kg/height^2). We performed urine metabolomic analysis by nuclear magnetic resonance (NMR) spectroscopy using the BAYESIL and MetaboAnalyst software packages. We performed principal component analysis (PCA) and partial least squares-discriminant analysis (PLS-DA), followed by Spearman's correlation analysis. We set the significance level at $p<0.05$ for all analyses. We combined Receiver Operating Characteristic Curve (ROC) and logistic regression analyses to establish a diagnostic model.

Results: We included 90 patients with RA. Most patients were women (86.7%), with a mean age of 56.5 (SD, 7.3) years and a median DAS28-CRP of 3.0 (IQR, 1.0–3.0). We identified 15 metabolites that showed high variable importance in projection (VIP scores) by MetaboAnalyst. Of these, dimethylglycine (r=0.205; p=0.053), oxoisovalerate (r=−0.203; p=0.055) and isobutyric acid (r=−0.249; p= 0.018) were significantly correlated with ALMI. Based on low muscle mass (ALMI ≤6.0 kg/m^2 for women and ≤8.1 kg/m^2 for men), we established a diagnostic model with dimethylglycine (Area Under the Curve - AUC=0.65), oxoisovalerate (AUC=0.49) and isobutyric acid (AUC=0.83), with significant sensitivity and specificity.

Conclusion: Isobutyric acid, oxoisovalerate and dimethylglycine from urine samples were associated with low skeletal muscle mass in patients with RA. These findings suggest that this group of metabolites may be further tested as biomarkers for identification of skeletal muscle wasting.

POS0547

THE ADVANTAGE OF TIGHT CONTROL AND TREAT TO TARGET IN NEW-ONSET RA PATIENTS IN DAILY RHEUMATOLOGY PRACTICE: RESULTS FROM A CONTEMPORARY UNIVERSITY CLINIC INCEPTION COHORT

J. T. Einarsson[1], K. Friberger Pajalic[1], C. Bengtsson[1], E. Mogard[1], E. Lindqvist[1], C. Roseman[1], O. Palsson[1,2], J. K. Wallman[1], T. Olofsson[1], M. C. Kapetanovic[1].

[1]Lund University, Department of Clinical Sciences, Lund, Section for Rheumatology, Lund and Skåne University Hospital, Lund, Sweden, Lund, Sweden; [2]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, Faculty of Medicine, University of Iceland, Reykjavik, Iceland, Reykjavik, Iceland

Background: Since 2018, all patients with new-onset rheumatoid arthritis (RA) at the Department of Rheumatology, Skane University Hospital, Lund, Sweden, are offered to participate in a "tight control" and "treat to target" (TC+T2T) follow-up strategy. This strategy includes regular follow-up visits to a rheumatologist (at diagnosis and 3, 6, 12, 18, 24 months) plus physical/telephone consultations with a rheumatology nurse between physician visits, both with disease activity assessments and, if needed, adjustment/intensification of anti-rheumatic treatment aiming for remission.

Objectives: To explore the possible advantages of integrating this TC+T2T strategy over routine care, aiming more systematically for remission (DAS28<2,6 or CDAI≤2,8), in clinical practice of new-onset RA.

Methods: Patients followed by the TC+T2T strategy were compared to new-onset RA patients followed according to routine care at the same department and during the same period. Data on disease and treatment characteristics, as well as outcome measures during follow-up were retrieved from the Swedish Rheumatology Quality register (SRQ). In total, 156 patients with at least 3 months follow-up between 2018 and 2021 were included; 95 followed according to the TC+T2T strategy and 61 according to routine care. Percentage females/mean age at onset/mean symptom duration at diagnosis were 79%/57 years/4 months (TC+T2T) and 62%/62 years/7 months (routine care). The change in DAS28 and CDAI from baseline to 12 months follow-up were compared between the two strategies by linear regression analyses, adjusted for sex, age, symptom duration, and DAS28 or CDAI, respectively, at baseline. In addition, changes in patient-reported outcomes (fatigue, pain and HAQ) are calculated.

Results: Disease and treatment characteristics at inclusion (diagnosis) are summarized in the Table 1.

Table 1.

	TC+T2T group (n=95)	Controls (n=61)
Swollen 28 joint count,	6,6 (4)	5,1 (5)
Tender 28 join count	8,2 (5)	6,2 (6)
ESR	48,1 (29)	37,7 (25)
CRP	21,3 (29)	16,9 (23)
DAS28	5,5 (1)	4,6 (1)
CDAI	24,5 (11)	18,3 (11)
HAQ	1,01 (0,6)	0,98 (0,7)
Fatigue (VAS)	50,1 (29)	46,6 (30)
Pain (VAS)	57,9 (24)	47,3(30)
ACPA positive (%)	77%	53%
Radiographic changes in hands or feet at inclusion (%)	12%	18%
Smoker (%)	16%	7%
Methotrexate started at inclusion (%)	78%	85 %
Prednisolone started at inclusion (%)	100%	97%

Mean and standard deviation (SD) if not otherwise stated.

The TC+T2T strategy resulted in greater improvements in DAS28 and CDAI scores from inclusion to 12 months follow up (p=0,025 and p=0,026; respectively; Figure 1). Beyond improvements in DAS28 and CDAI, a significant decrease in patient-reported outcomes (fatigue and pain) during 12 months from diagnosis was observed (Figure 1).

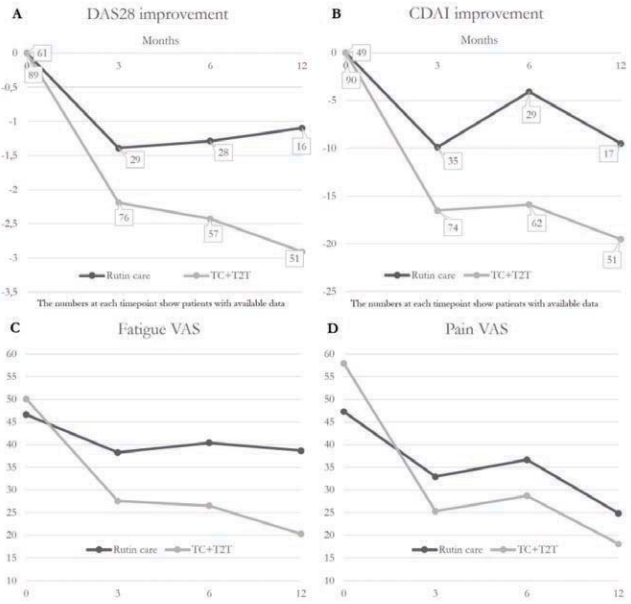

Figure A and B show the mean improvement in DAS28 and CDAI respectively from baseline, 3, 6, and 12 months from diagnosis.
Figure C and D show the mean fatigue and pain respectively at baseline, 3, 6, and 12 months from diagnosis.

Conclusion: Compared to routine rheumatology practice, the implementation of a "tight control" and "treat to target" strategy resulted in a greater improvement in disease activity and an early and sustained improvement in patient-reported outcomes. Our results suggest that this type of strategy should be integrated into daily clinical practice of new-onset RA.

POS0548

EVALUATION OF PHYSICIAN GLOBAL ASSESSMENT IN PATIENTS WITH B/TSDMARD THERAPY SELECTION ALIGNED WITH A MOLECULAR SIGNATURE RESPONSE CLASSIFIER RESULTS: AN ANALYSIS FROM THE STUDY TO ACCELERATE INFORMATION OF MOLECULAR SIGNATURES (AIMS) IN RHEUMATOID ARTHRITIS

E. Connolly-Strong[1], L. Zhang[2], S. Asgarian[1]. [1]*Scipher medicine, Medical Affairs, waltham, United States of America;* [2]*Scipher medicine, Data Science, waltham, United States of America*

Background: Despite drug therapies that improve lives, tens of millions of patients annually are prescribed therapy using a "trial and error" approach because, until recently, it was not possible to personalize treatment using a patient's unique molecular profile. A blood-based molecular signature response classifier (MSRC) was shown to predict non-response to TNFi therapies in patients. MSRC integrates disease-associated RNA transcripts, and clinical features (anti-CCP, sex, BMI, PGA).[1] A recent study demonstrated that patient response to treatment informed by MSRC was more than 3 times better when MRSC informed therapy selection (predicted non-responders [alt-MOA] =34.8% vs predicted non-responders [TNFi] = 10.3%, p-value = 0.05).[1] Furthermore, when patients without a non-response signal from MSRC were prescribed a TNFi for treatment, their outcomes were improved by 5 times compared to the cohort receiving TNFi therapy despite a signal of non-response from MSRC (no prediction -[TNFi] = 45.8% vs predicted non-responder[TNFi]= 10.3%, p-value = 0.005) [1]

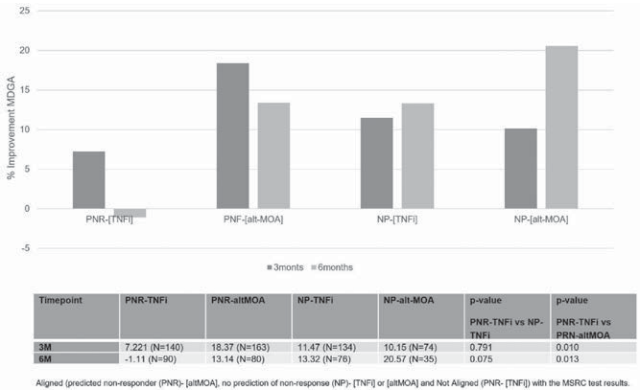
Objectives: The objective of the Study to Accelerate Information of Molecular Signatures (AIMS) in RA is to build a clinical/molecular database of longitudinal data from RA patients managed a real-world, settings with a focus on utilization of the MSRC test (PrismRA Scipher Medicine). Physician Global Assessment scores were measured and assessed as the objective of this analysis.

Methods: This analysis reports on data from patients enrolled in AIMS who initiated a new b/tsDMARD, or continued existing therapy, following MSRC testing (n = 560). Patients were ≥18 years of age with a clinical diagnosis of RA. The cohort was divided into patients whose targeted therapy selection was Aligned (predicted non-responder (PNR)- [altMOA], no prediction of non-response (NP)- [TNFi] or [altMOA] and Not Aligned (PNR- [TNFi]) with the MSRC test results. Improvement from baseline of MDGA was evaluated at 3 & 6ms and swollen joints at 3ms.

Results: Predicted non-responders prescribed an alt-MOA had significant improvement in MDGA scores at 3 & 6ms compared to predicted non-responders prescribed a TNFi (3m: PNR-[altMOA]- 18.4% (n=163) vs PRN-[TNFi] 7.2% (n=140), p-value – 0.010, 6m: PNR-[altMOA]- 13.1% (n=80) vs PRN-[TNFi] -1.11% (n=90), p-value – 0.013). Patients without the molecular signature prescribed a TNFi showed a trend of more improvement in MDGA scores at 3 & 6ms compared to patients with the molecular signature prescribed a TNFi (3m: NP-[TNFi]- 11.5% (n=134) vs PRN-[TNFi] 7.2% (n=140), p-value – 0.791, 6m: NP-[TNFi]- 13.3% (n=76) vs PRN-[TNFi] -1.11% (n=90), p-value – 0.075) (Figure 1). Moreover, predicted non-responders prescribed an alt-MOA showed a trend of improvement in swollen joints at 3ms compared to predicted non-responders prescribed a TNFi (PNR-[altMOA]- 3.15% (n=163) vs PRN-[TNFi] 1.7% (n=140), p-value – 0.08). Patients without the molecular signature prescribed a TNFi showed significantly more improvement in swollen joints at 3ms (NP-[TNFi]- 3.71% (n=134) vs PRN-[TNFi] 1.7% (n=140), p-value – <0.001). Characteristics of the cohort are reported in the Table 1.

Table 1.

Characteristic	PNR-TNFi n=159	PNR-altMOA n=176	NP-TNFi n=145	NP-altMOA n=80	P-value (PNR-TNFi vs NP-TNFi)	P-value (PNR-TNFi vs PNR-altMOA)
Age,mean (SD)	53.5 (13.8)	57.6 (12.9)	55.9 (14.4)	59.7 (13.2)	0.135	0.005
Race, n (%)					0.346	0.896
White	128 (81)	142 (81)	124 (86)	64 (80)		
Black	11 (7)	11 (6)	9 (6)	5 (6)		
Other	20(13)	23(13)	12(8)	11 (14)		
CDAI at baseline (SD)	34.1 (15.8)	38.5 (16.3)	28.5 (15)	26.5 (15.6)	0.002	0.012
TNFi Navie at baseline, n (%)	128 (81)	148 (84)	120 (83)	71 (89)	0.672	0.473



Timepoint	PNR-TNFi	PNR-altMOA	NP-TNFi	NP-alt-MOA	p-value PNR-TNFi vs NP-TNFi	p-value PNR-TNFi vs PRN-altMOA
3M	7.221 (N=140)	18.37 (N=163)	11.47 (N=134)	10.15 (N=74)	0.791	0.010
6M	-1.11 (N=90)	13.14 (N=80)	13.32 (N=76)	20.57 (N=35)	0.075	0.013

Aligned (predicted non-responder (PNR)- [altMOA], no prediction of non-response (NP)- [TNFi] or [altMOA] and Not Aligned (PNR- [TNFi]) with the MSRC test results.

Figure 1.

Conclusion: The incorporation of MSCR testing into the b/tsDMARD selection process can improve patient outcomes and can help identify which patient may be more or less responsive TNFi therapies.

IMBALANCED TFR/TFH IN PERIPHERAL BLOOD OF NEW-ONSET RHEUMATOID ARTHRITIS

R. Wu[1], R. Su[1], T. Ding[1], H. Xue[1], X. F. LI[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University, the department of rheumatology, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is a kind of autoimmune disease characterized with chronic aggressive arthritis, presence of abnormal antibodies and persistent synovitis[1]. However, the pathogenesis of RA remained unclear by now. Several observations have showed that the breakdown of immune tolerance was involved in the development of RA. T follicular regulatory (Tfr) cells and T follicular helper (Tfh) cells, as a new subset of CD4+T cell, can exert an opposite effect in the regulation of humoral immunity[2]. Intensive researches have showed that the imbalance of Tfr/Tfh cell is related to the pathogenesis and development of autoimmune disease. There is still a lack of understanding of the relationship between Tfr/Tfh and RA, which needs further exploration.

Objectives: To detect the expression of Tfh and Tfr cells in thr peripheral blood of patients with new-onset RA and healthy controls, and to explore the role of Tfh and Tfr cells in the pathogenesis and development of RA.

Methods: We enrolled 26 patients with new-onset RA who hospitalized at the Second Hospital of Shanxi Medical University from the June 2021 to the November 2021. And 17 age and gender-matched healthy adults were anticipated as controls. The absolute number of Tfh and Tfr cells in peripheral blood was detected by flow cytometry. Disease activity indicators were collected including erythrocyte sedimentation rate (ESR, mm/h) and Disease Activity Score in 28 joints (DAS28). Then we compared the expression of Tfh and Tfr cells between the patients and healthy controls and conducted the correlation analysis with disease activity.

Results: There was significant decreased level of Tfr cells in the patients with new-onset RA compared with healthy controls (P<0.001) and a lower ratio of Tfr/Tfh in the patients (P<0.01). The reduced Tfr cells and Tfr/Tfh were significant negative correlation with the disease activity indicators including ESR and DAS28 (r=-0.305, P=0.033). There was no statistically significant in the absolute number of Tfh cells between patients and healthy controls, but the level of Tfh cell showed an increasing trend in new-onset RA.

Conclusion: The results we investigated here showed that new-onset RA exhibited an imbalance of Tfr/Tfh, specifically reduced Tfr cells, compared with healthy controls, which were negatively correlated with higher disease activity in RA. It was likely that the imbalance of Tfr/Tfh in peripheral blood played an important role in the development of RA, which may be a target to treat RA.

Table 1. A summary of data of all enrolled patients with RA and healthy controls

	HC(n=17)	New-onset RA(n=26)	P value
Age(years)	51.94±13.03	55.88±13.56	P=0.35
Sex(male/female)	4/13	7/19	P=0.81
ESR(mm/h) [a]	-	54.85±32.71	-
DAS28 [a]	-	5.09±1.56	-
Tfh cell count(cell/UL)[b]	43.156(23.277,106.638)	83.914(38.133,119.662)	0.214
Tfr cell count(cell/UL)[b]	1.422(0.882,1.893)	0.441(0.116,2.888)	0.025*
Tfr/Tfh[b]	0.030(0.014,0.049)	0.011(0.001,0.024)	0.001**

[a] Results are expressed as the mean ± standard error. [b] Results are expressed as the median(Q1,Q3).Normally distributed continuous variables were analyzed by the independent-samples Student's t-test. And nonparametric variables were analyzed by Mann–Whitney U test

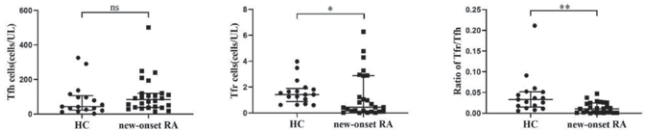

Figure 1. The differences of Tfr and Tfh cells in peripheral blood between the healthy controls and patients with RA. Tfr cells were higher in new-onset RA leading to an imbalance of Tfr/Tfh. Statistical analyses were performed by the Mann-Whitney U test. (*P<0.05, **P<0.01)

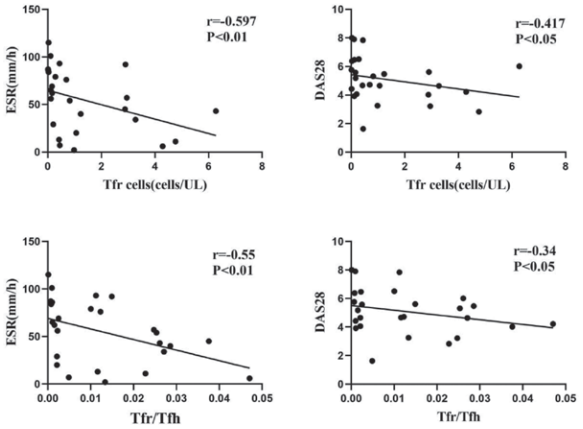

Figure 2. The correlation of disease activity with the level of Tfr cells and Tfr/Tfh. Tfr cells and Tfr/Tfh were negative associated with ESR and DAS28. Statistical analyses were performed by the Spearman correlation analysis.

Background: Targeting MRI remission in rheumatoid arthritis (RA) patients in clinical remission may improve long term clinical, functional and MRI outcomes.

Objectives: To investigate whether a 2-year treat-to-target (T2T) strategy, based on structured MRI assessments targeting absence of osteitis combined with clinical remission, compared with a conventional clinical T2T strategy targeting clinical remission only, improves disease activity, physical function and suppresses MRI-inflammation over 5 years in RA patients.

Methods: The IMAGINE-more trial was designed as an extension protocol to the 2-year IMAGINE-RA randomised controlled trial (RCT). IMAGINE-RA included 200 RA patients, in clinical remission (DAS28-CRP<3.2 and no swollen joints), who received conventional synthetic disease-modifying antirheumatic drugs (csDMARD) and investigated whether an MRI T2T strategy targeting absence of osteitis in combination with clinical remission (DAS28-CRP≤3.2 and no swollen joints) could increase remission rates and prevent erosive progression compared with a conventional T2T strategy targeting clinical remission only. If target was not met, treatment was escalated according to a predefined treatment algorithm starting with increment in csDMARDs and then adding biologics. At the end of the study, participants were invited to participate in the IMAGINE-more follow-up study. Patients were managed in routine outpatient clinic and had three IMAGINE-more visits including clinical examination (year 3, 4 and 5) and contrast-enhanced MRI of the dominant wrist and 2nd-5th metacarpophalangeal joints (year 3 and 5). The primary clinical endpoint was the proportion of patients achieving DAS28-CRP remission (DAS28-CRP<2.6) at year 5. Predefined key secondary outcomes were disease activity (DAS28-CRP), and changes in MRI osteitis (OMERACT RA MRI scoring system (RAMRIS)) and functional level (Health Assessment Questionnaire (HAQ)) from baseline to 5-years follow up. Endpoints were analysed by logistic regression models and repeated measures mixed effects models adjusted for propensity scores corresponding to (remaining in) group allocation.

Results: Fifty-nine patients in the MRI T2T arm and 72 patients in conventional T2T arm consented to participate. Of these, 47 patients (80%) in the MRI T2T group and 54 patients (75%) in the conventional T2T group reached the primary clinical endpoint (p=0.161) (Table 1 and Figure 1). No statistically significant differences between treatment strategies in key secondary outcomes were seen.

Table 1. Primary and key secondary outcomes at 5 years

	MRI T2T	Conventional T2T	Difference between groups	P value
	N=59	N=72		
Primary endpoint				
DAS28-CRP remission (DAS28-CRP<2.6), No. (%)	47 (80%)	54 (75%)	2.00 (0.76 to 5.28)	0.161
Key secondary endpoints				
DAS28-CRP	1.79 (0.08)	1.94 (0.08)	-0.15 (-0.38 to 0.07)	0.176
Change from baseline in MRI osteitis (RAMRIS)	-0.17 (0.58)	0.18 (0.54)	-0.35 (-1.96 to 1.25)	0.663
Change from baseline in HAQ	-0.02 (0.03)	0.05 (0.03)	-0.07 (-0.15 to 0.01)	0.080

Group estimates are presented as No. (%) for dichotomous data and least squares means (SE) for continuous data. For the primary endpoint, adjusted odds ratio and 95%CI between groups were calculated from a logistic regression model including a fixed factor for treatment arm, and an adjustment for propensity score as a covariate. For endpoints with continuous data, least squares mean differences between groups were calculated based on repeated-measures mixed linear models adjusted for baseline values and propensity scores.

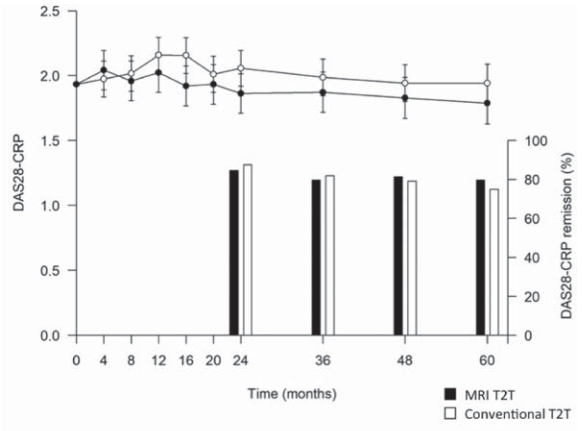

Figure: Absolute scores from baseline to 5 years in DAS28-CRP and proportions in remission
Illustrating the trajectory of absolute scores from baseline to month 60 (i.e. 5 years) in DAS28-CRP based on a mixed model with adjustment for baseline and propensity scores, as well as proportions in DAS28 remission over time for each group, with non-responder imputation.

Conclusion: A 2-year MRI T2T strategy targeting absence of MRI osteitis combined with clinical remission as compared to a conventional clinical T2T strategy in RA patients had no effect on the long-term probability of achieving DAS28-CRP remission. These findnings do not support the use of an MRI-guided strategy for treating patients with RA.

POS0551 CLINICAL SIGNIFICANCE OF SERUM MPO-DNA COMPLEX IN RHEUMATOID ARTHRITIS

B. LI[1], J. Zhao[1], G. LI[1], Z. Zhang[1]. [1]*Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China*

Background: Tumor necrosis factor inhibitors (TNFi) have been widely used in the treatment of RA. Few researches offered solid solution to predict the response of TNFi treatment. NETs formation (NETosis) is a key process participant in RA. NETs and their components also work as a source of auto-antigens for RA.

Objectives: To explore the relationship between serum MPO-DNA complex, which is one of the components of NETosis, and disease activity of RA, and to explore the possibility for serum MPO-DNA complex to predict the therapy response of anti-TNF therapy in RA patients.

Methods: RA patients were enrolled from a randomized controlled clinical trial (EScoRT study, ClinicalTrials.gov identifier: NCT02320630) conducted from Oct. 2014 to Oct. 2018. The clinical and demographic data and blood samples were collected at baseline and every 4 weeks. Serum levels of MPO-DNA complex were detected by a modified enzyme-linked immunosorbent assay (ELISA) kit. The Association between MPO-DNA complex level and disease activity was analyzed. The predictive value of baseline MPO-DNA complex for treatment response of RA patients was analyzed.

Results: 86 RA patients were enrolled. The level of serum MPO-DNA was higher in patients with high disease activity (HDA) than that in patients with medium disease activity (MDA) (1.10±0.32 vs. 0.86±0.29, p=0.001). After 4 weeks of treatments, the level of seurm MPO-DNA complex decreased significantly (1.0±0.3vs. 0.6±0.2, p<0.001). Changes of MPO-DNA complex at week 4 (ΔMPO-DNA) was postively and linearly correlated with changes of TJC, SJC, PGA, EGA, ESR, CRP, DAS28ESR, DAS28CRP, SDAI and CDAI(r 0.270-0.495, all p-value<0.05). Receiver operating characteristic (ROC) analysis revealed that baseline MPO-DNA complex (95% CIs 0.57-0.79 for ACR50 and 0.66-0.85 for ACR70, all p-value<0.05) and ΔMPO-DNA complex at week 4 against baseline (95% CIs 0.63-0.83 for ACR 50 and 0.74-0.97 for ACR70) could predict the achievement of ACR50 and ACR70 within 12 weeks. ΔMPO-DNA complex at week 4 against baseline could predict the achievement of low disease activity (LDA) (95%CIs 0.57-0.79, p=0.03) and remission (95%CIs 0.54-0.8, p=0.024) within 12 weeks.

Conclusion: Serum MPO-DNA is associated with disease activity and can predict treatment response of RA.Serum MPO-DNA could serve as a powerful tool for clinicians to forecast the effectiveness of anti-TNF treatment in RA patients.

Disclosure of Interests: None declared.

POS0552

RELATIONSHIP BETWEEN PAINLESS MYOCARDIAL ISCHEMIA WITH LEVEL WILLEBRAND FACTOR AND INFLAMMATORY MARKERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Galiutina[1], M. Stanislavchuk[2], O. Bychak[3], Y. Seheda[1]. [1]*Scientific and Research Institute of Invalid Rehabilitation (Educational Scientific Treatment Complex) of National Pirogov Memorial Medical University, Rheumatology, Vinnytsya, Ukraine;* [2]*National Pirogov Memorial Medical University, Internal Medicine Chair #1, Vinnytsya, Ukraine;* [3]*Vinnytsya Regional Center for Medical and Social Expertise, Neurology, Vinnytsya, Ukraine*

Background: In a patient with rheumatoid arthritis (RA) manifestations of coronary heart disease occur gradually, at the same time "painless" myocardial ischemia is detected in 50 - 70% of cases according to the literature. According to modern ideas, the formation of endothelial dysfunction, development of early atherosclerosis and vascular thrombosis are closely associated with the increase level of von Willebrand factor (VWF) and inflammatory markers.
Objectives: The aim of this study was to investigate the frequency and duration of painless myocardial ischemia and its association with VWF levels and inflammatory markers in patients with RA.
Methods: 63 patients with RA (44 women) aged 27 - 65 years (mean age - 46.8 ± 9.8 years) and 69 ages and sex-matched controls were examined. Serum levels of VWF, CRP and TNF-α were determined by enzyme-linked immunosorbent assays. Daily (Holter) ECG monitoring was performed by Holter ECG monitoring systems "DiaCard", registrar: model 02100, software version 1.0.40, developed by JSC "Solveig" (Ukraine).
Results: It was found, that the part of patients with painless myocardial ischemia among patients with RA was significantly higher (58.7%) than in the control group (13%). At the same time, in patients with RA the duration of painless myocardial ischemia was in averaged 10.9 ± 8.1 minutes per day. It was significantly more than in the control group 2.88±1.25 minutes per day (p <0,05). It was found, that in patients with RA there was an increased levels of VWF (162.2 ± 9.3% vs. 86.2 ± 2.7% in control). It was found, that the duration of painless myocardial ischemia had close correlations with VWF (r = 0.28), CRP (r = 0.41) and TNF-α (r = 0.40).
Conclusion: The severity the duration of painless myocardial ischemia in RA patients is associated with elevated levels of VWF, CRP, and TNF-α, indicating the possible involvement of VWF and inflammatory markers in cardiovascular disease in RA patients.

POS0553

NEW BIOMARKERS IN RHEUMATOID ARTHRITIS: ROLE OF HOMOCYSTEINYLATED ANTI-ALPHA1 ANTITRYPSIN ANTIBODIES

M. Speziali[1,1], F. Ceccarelli[1], F. Natalucci[1], A. I. Celia[1], T. Colasanti[1], C. Barbati[1], G. Olivieri[1], E. Balbinot[1], C. Ciancarella[1], F. M. Ucci[1], G. Buoncuore[1], G. Tripdi[1], F. R. Spinelli[1], F. Conti[1], C. Alessandri[1]. [1]*Arthritis Clinic, Internal Medicine, Anesthesiology and Cardiovascular Sciences, Sapienza University of Rome, Rome, Italy*

Background: Rheumatoid Arthritis (RA) is a multifactorial, chronic, systemic, inflammatory disease that can lead to progressive joint destruction (Alamanos et al, Autoimmun Rev 2005). Positivity for Rheumatoid Factor (RF) and antibodies against citrullinated proteins (ACPA) is useful for diagnostic and prognostic purposes. Nevertheless, in about 20% of patients, it is not possible to detect the presence of these autoantibodies. This has led to the identification of new antibody specificities, such as antibodies directed against carbamylated proteins (Mastrangelo A et al, J Immunol Res 2015) and, more recently, against homocysteinylated alpha 1 antitrypsin (anti-HATA) (Colasanti T et al, J Autoimmun 2020).
Objectives: To evaluate the prevalence of anti-HATA in a large cohort of patients with RA and their correlation with serological, clinical and erosive bone damage assessed by musculo-skeletal ultrasound (US).
Methods: Consecutive outpatients with RA, diagnosed according to the 2010 ACR/EULAR criteria, were enrolled. Demographic and clinical-laboratory data were recorded, including FR and ACPA determination. Disease activity was assessed by DAS28. The presence of anti-HATA antibodies was investigated by homemade ELISA using native alpha 1 antitrypsin modified *in vitro* to obtain homocysteinylated alpha 1 antitrypsin. US assessment was performed at the level of bilateral metacarpophalangeal and proximal interphalangeal joints; the presence of erosions and inflammatory features was identified according to OMERACT definitions (Wakefield RJ et al, J Rheumatol 2005).
Results: The present analysis included 91 RA patients (M/F 22/69; mean age 62 years; mean disease duration 12.5 years). Overall, the prevalence of anti-HATA was 69.2%. Anti-HATA antibodies were found in 63/91 (69.2%) of the entire patient cohort, whereas 68/91 (74.3%) patients were positive for ACPA and 63/91 (69.4%) for FR. 41.4% of patients had concomitant positivity for the three autoantibodies (FR, ACPA, anti-HATA). The analysis of patients with triple positivity for related arthritis antibodies (FR, ACPA, anti-HATA) was particularly interesting: indeed, in this subgroup, 80% of patients presented erosive damage, compared to 42.1% of patients who did not present simultaneously the three autoantibodies (p=0.0001). Patients with simultaneous positivity for RF, ACPA and anti-HATA showed a more aggressive disease phenotype (p=0.0001). Finally, a positive correlation was also found between disease activity (expressed by DAS28) and total inflammatory and erosive ultrasonographic score (p=0.005 and p=0.001, respectively).
Conclusion: The results of the present study confirm a high prevalence of anti-HATA in RA patients; furthermore, patients with concomitant presence of anti-HATA, ACPA and RF showed a more aggressive disease phenotype, in terms of erosive damage. Our analysis underlines as the characterization of new antibody specificities in RA could help in the early diagnosis of this disease and in the characterization of the different severity degrees.

POS0554

CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS IN PRE-DIFFICULT-TO-TREAT STATUS

I. Yoshii[1], N. Sawada[2], T. Chijiwa[3,3]. [1]*Yoshii Hospital, Musculoskeletal Medicine, Shimanto-City, Japan;* [2]*Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan;* [3]*Kochi Memorial Hospital, Rheumatology, Kochi,*

Background: Patients with rheumatoid arthritis (RA) who have a difficult-to-treat condition (D2T RA) are often a burden to both patients and rheumatologists.
Objectives: The aim of this study was to determine the risk factors for failure to treat in patients with refractory conditions and to find them relevant to prevention.
Methods: Patients with RA who were treated under treat-to-target (T2T) strategy more than one year were picked up. Their background characteristics such as sex, age, disease duration, anti-citrullinated polypeptide antibodies titer (ACPA), and disease duration, were collected, and their simplified disease activity index (SDAI) score, Health Assessment Questionnaire Disability Index (HAQ) score, pain score measured with visual analog scale (PS), EuroQol 5th-dimensions score (EQ5D) were monitored every three months. Sharp/van der Heijde score (SHS) was calculated annually. Difficult-to-treat status was determined in according to the EULAR definition of D2T RA [1], and pre-D2T RA status was determined as follows: (Category-1) a failure history of one kind of action in biologic or targeted synthetic disease modifying anti-rheumatic drug (b/tsDMARD) and switched to another b/tsDMARD with other action mechanism or (Category-2) one or more of following status; mean SDAI score in recent three months exceeded 11 (MDA), three consecutive administration of glucocorticoid steroid no less than 7.5mg in prednisolone equivalent (GCS), rapid radiographic progression with 5 or more in SHS than last time (RRP), or decrease of EQ5D score less than -0.2 in recent 6 months (dEQ5D). Patients were recruited when Category-1 or -2 was matched in treating, and their results were determined in the last observation for each category. When second d/tsDMARD was failed until last observation in patient matched Category-1, the patient was judged as "failure," and the other patient was judged as "success." When Category-2 continued until last observation, the patient was judged as "failure," and escaped from the category, the patient was judged as "success." Risk factors for failure in background characteristics and monitored items in treating were evaluated for each category using binary logistic regression analysis.
Results: A total of 47 in Category-1 and 491 patients in Category-2 were recruited. In Category-1 matched patients, female were 83.0% and mean age was 71.3. Mean SDAI score, HAQ score, PS, EQ5D score, and SHS at failure of b/tsDMARD (baseline) were 15.5, 0.457, 40.1, 0.811, and 72.9, respectively. Numbers of the first b/tsDMARD were 32 TNF inhibitors, 8 IL-6 inhibitors, 6 abatacepts, and 1 JAK inhibitor. Numbers of the second after the first were 13 IL-6 inhibitors and 19 JAK inhibitors after THF inhibitor, whereas 3 TNF inhibitors, 2 abatacepts, and 3 JAK inhibitors after IL-6 inhibitor failure, 1 TNF inhibitor, 1 IL-6 inhibitor, and 4 JAK inhibitors after abatacept failure, and 1 TNF inhibitor after 1 JAK inhibitor failure. In these, success counted 18 and failure counted 29. Significant risk factors for Category-1 failure were higher ACPA, higher SDAI score, higher HAQ score, and higher SHS at baseline ($p<0.05$). There was no significant difference between drugs.
In Category-2 matched patients, numbers of each status at first (baseline) were 455 MDAs, 20 GCSs, 17 RRPs, and 9 dEQ5Ds. Numbers in success and failure for each status at baseline were 315 and 140 for MDA, 16 and 4 for GCS, 9 and 0 for RRP, and 7 and 2 for dEQ5D, respectively. Significant risk factors for each failure status were higher mean SDAI score after baseline for MDA, higher HAQ score at baseline for GCS, and higher mean PS after baseline for dEQ5D ($p<0.01$).
Conclusion: Clinical background factors besides disease activity such as ACPA, HAQ score, and SHS at baseline were important for preventing fall-in D2T_RA. However, most weighted factor was disease activity control after falling in MDA status. Tight disease activity control is the overriding factor.

POS0555

THE NON-APOPTOTIC PROGRAMMED-CELL-DEATH-RELATED SIGNATURE PREDICTS ANTI-TNF THERAPY NONRESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. Wang[1], Q. Che[2,3], J. Chen[2,3], Y. Zhang[1], Q. Shu[2,3]. *[1]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Clinical Laboratory, Jinan, China; [2]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China; [3]Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Qilu Hospital, Department of Rheumatology, Jinan, China*

Background: EULAR guideline in rheumatoid arthritis (RA) recommended the primary failure of the first-line conventional synthetic modifying anti-rheumatic drugs (csDMARDs) patients switching to tumor necrosis factor alpha inhibitors (TNFi) [1]. Nevertheless, approximately 30-40% csDMARDs-IR patients also experience inefficacy of TNFi [2]. There is still no index to predict whether TNFi would be responded or not. Moreover, only few studies had focused on the relationship between TNFi nonresponse and other cell programmed deaths except apoptosis.
Objectives: To predict the possibility of TNFi response prior to prescript in RA patients with the biomarkers of non-apoptotic programmed cell death in synovial cells.
Methods: The datasets of 22 TNFi treated RA synovial samples were enrolled from the Gene Expression Omnibus (GEO) database (GSE140036 and GSE15602). And the differentially expressed genes (DEGs) and modules related to TNFi treatment through weight gene correlation network analysis (WGCNA) were identified with the R packages "limma" and "WGCNA". Then the enrichment analysis among the shared genes was performed through the R.4.1.2, Metascape website, and WebGestalt website. Following with the confirmation of the non-apoptotic programmed cell death (NAPCD) genes in the shared genes with Student's T-Test. Furthermore, the TNFi treatment cohort was clustered based on the hub genes, making the receiver operating characteristic (ROC) curve analysis. Moreover, the least absolute shrinkage and selection operator (LASSO) model was constructed to identify the predictive genes.
Results: 2624 DEGs were identified significantly, including 161 upregulated genes and 2463 downregulated genes. One module with TNFi treatment was constructed in WGCNA, significant in both response and nonresponse. Then the gene signatures for TNFi nonresponse were collected from overlaps 2260 genes in above. And we found 38 NAPCD genes might play role in TNFi nonresponse, but reserved 33 genes which statistically significant with T-Test. 22 TNFi treated synovial samples in GEO database could be classified into response or nonresponse subgroups. The ROC curve showed that the AUC for 32 genes in these samples ranged from 0.7 to 0.9, expected for CD46. At last, the LASSO model indicated that CASP5, CAPN10, ITGB4, NLRP2, and SLC2A8 could predict the TNFi nonresponse, as the risk score = CASP5 × 0.028 + CAPN10 × 0.064 + ITGB4× 0.080+ NLRP2 × 0.317+ SLC2A8 × 0.090 (Figure 1).

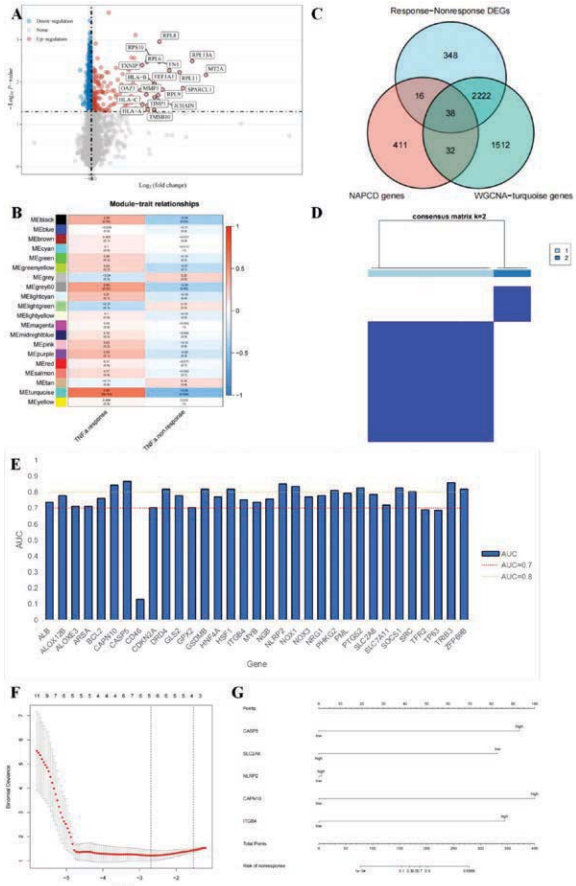

Figure 1. Predictive model of TNFi nonresponse based on NAPCD genes. (A) Volcano map of differential expressed genes; (B) Correlation heat map of gene modules and phenotypes, the red is positively correlated with the phenotype, blue is negatively correlated with the phenotype; (C) The shared 38 genes of TNFi response & nonresponse DEGs, among the WGCNA turquoise module and cell programmed death genes; (D) Consensus clustering matrix for k = 2; (E) The ROC curve of 33 genes; (F) LASSO regression of the 32 genes,except for CD46; (G) Nomogram for predicting TNFi nonresponse in TNFi treatment RA cohort, indicated five possible indicators (CASP5, CAPN10, ITGB4, NLRP2, and SLC2A8) were closely related to TNFi nonresponse.

Conclusion: Our study firstly screened out the 38 NAPCD candidate genes signatures in RA synovial tissues which took part in TNFi nonresponse through WGCNA and DEGs. Further analysis confirmed that five possible indicators (CASP5, CAPN10, ITGB4, NLRP2, and SLC2A8) were closely related to TNFi nonresponse.

ALTERATION OF THE GUT MICROBIOTA IN CHINESE POPULATION WITH RHEUMATOID ARTHRITIS

J. Qiao[1,2,3], M. J. Chang[2,3,4], S. X. Zhang[1,2,3], R. Zhao[1,2,3], S. Song[1,2,5], T. Cheng[1,5,6], Q. Y. Su[1,5,6], X. Li[1,5,6]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Shanxi Medical University, Key laboratory of Cellular Physiology, Ministry of Education, Taiyuan, China; [3]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [4]Shanxi Medical University, School of Management, Taiyuan, China; [3]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [2]Shanxi Medical University, Key laboratory of Cellular Physiology, Ministry of Education, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is an aggressive immune-mediated joint disease characterized by synovial proliferation and inflammation, cartilage destruction, and joint destruction. Growing evidences suggests a chronic inflammatory response induced by gut microbiome critically contribute to the development of rheumatoid arthritis.
Objectives: The aim of this study was to evaluate and quantify differences in the composition of gut microbiota in RA patients and investigate the associations between flora and clinical variables in RA patients.
Methods: Fecal samples from 145 RA patients and 145 age- and gender-matched healthy controls (HCs) were collected for bacterial 16S rRNA genes sequencing. The alpha-diversity, beta-diversity and the microbial composition (at the phylum and genus level) analysis of the gut microbiome were used to define the difference of gut microbiota profiles between RA patients and HCs. The peripheral lymphocytes of these patients were assessed by flow cytometry, and inflammatory biomarkers (ESR, CRP), auto-antibodies(ACPA, MCV) and cytokines measured by ELISA were recorded. Correlations between different taxa and clinical variables, were calculated by Spearman's rank test.
Results: Consistent with trends observed for diversity, patients with RA had a lower richness compared with those of HCs ($p < 0.01$, Figure 1a), suggesting gut microbiome was markedly less diverse in composition in RA. Bray curtis distance-based beta diversity analysis revealed significant differences in the microbial community between RA and HCs (ANOSIM, R2=0.061, p=0.001, Figure 1b). Ten selected taxonomic biomarkers at different phylogenetic levels showed great discriminant ability, with Log10 LDA score > 4.0 (Figure 1e-g). Detailly, at the phylum level, RA patients had a lower frequency of Firmicutes while higher Proteobacteria. RA patients presented fewer Faecalibacterium but more Escherichia_Shigella at the genus level (Figure 1c-d). PICRUSt analysis found that in the KEGG pathways, the microbial gene functions related to Propanoate metabolism were higher in the fecal microbiome of RA patients (Figure 1h). Escherichia_Shigella positively correlated with ACPA antibodies ($r=0.176$, $p < 0.05$) and IL-4 ($r=0.204$, $p < 0.05$, Figure 1i), wheras Faecalibacterium as a probiotic showed no significant correlation with our clinical measures.

Conclusion: Specific gut microbiota played an important role in the pathogenesis of RA, which may aid in the diagnosis or determination of the susceptibility of individuals to RA via detection of the gut microbiome.

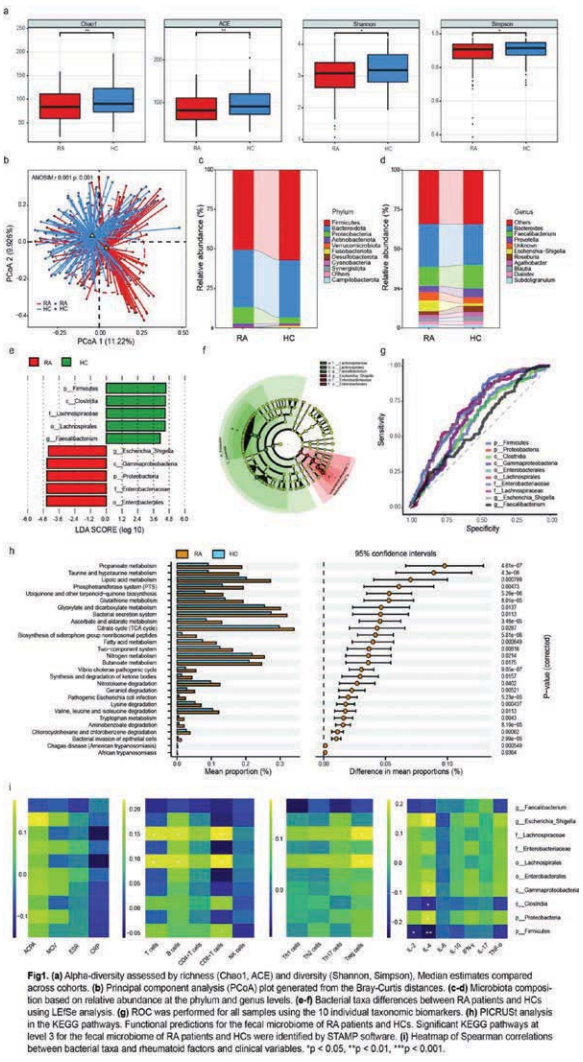

Fig1. **(a)** Alpha-diversity assessed by richness (Chao1, ACE) and diversity (Shannon, Simpson). Median estimates compared across cohorts. **(b)** Principal component analysis (PCoA) plot generated from the Bray-Curtis distances. **(c-d)** Microbiota composition based on relative abundance at the phylum and genus levels. **(e-f)** Bacterial taxa differences between RA patients and HCs using LEfSe analysis. **(g)** ROC was performed for all samples using the 10 individual taxonomic biomarkers. **(h)** PICRUSt analysis in the KEGG pathways. POS0557

ASSOCIATION BETWEEN ANTI CITRULLINATED PEPTIDES ANTIBODIES, BONE MINERAL DENSITY, AND FRACTURE RISK IN RHEUMATOID ARTHRITIS PATIENTS

O. Lamkhanat[1], H. Azzouzi[1], I. Linda[1]. *[1]Mohamed I University, Rheumatology department, Oujda, Morocco*

Background: Recent literature reported Anti Citrullinated Peptides Antibodies (ACPA) associated with bone loss in patients with rheumatoid arthritis (RA).
Objectives: To study if ACPA positivity was associated with bone mineral density and the ten-year probability of fracture (FRAX) in RA patients.
Methods: We performed a cross-sectional study on patients with RA diagnosis according to ACR-EULAR 2010 classification recruited from January 2021 till January 2022. Patients aged from 40 to 90 years were included. Those with prior cancer, hyperparathyroidism, hyperthyroidism, diabetes, chronic kidney disease, and cirrhosis were excluded. Clinical data and results of laboratory tests were collected simultaneously with bone mineral density (BMD) acquisition. The latter was measured with dual-energy X-ray absorptiometry (DXA). BMD of the femoral neck (FN) was used to calculate the ten-year probability of major osteoporotic fracture (FRAX MOF) and femoral neck risk fracture (FRAX FN). Patients were grouped by positivity or quartile of ACPA level (I-IV). We used logistic regression, parametric and non-parametric tests for statistical analysis with SPSS20.
Results: Eighty-two RA patients were enrolled. In total, 69 (84.1%) were women, 16 (19.5%) reported a previous personal fracture, and 37 (45.1%) had osteoporosis. Seventy-two (87.8%) patients were ACPA positive. The mean body mass index (BMI; kg/m^2) and lumbar spine BMD in ACPA-positive patients were 25.44 ± 4.79 and 0.791 ± 0.138, respectively. We found a significant association between ACPA positivity and BMI over 25 ($p = 0.01$; OR = 0.132 [1.527; 6.785]). Comparison between ACPA positive/negative patients did not find a significant difference for osteoporosis, history of fracture, DAS28CRP, lumbar spine BMD, FN BMD, FRAX MOF BMD, and FRAX FN BMD. Lumbar spine BMD was significantly different ($p = 0.035$) among subgroups of ACPA levels, whereas there was no significant difference for FRAX MOF, FRAX FN, and FN BMD.
Conclusion: In this study, lumbar spine BMD was significantly different among subgroups of ACPA levels.

Disclosure of Interests: None declared.

POS0558

A INFLAMMATORY FACTOR-BASED NOMOGRAM PREDICTS FIRST REMISSION TIME OF RHEUMATOID ARTHRITIS PATIENTS WITH BASELINE GALECTIN-9

Z. Sun[1,2], X. Liu[3], F. Wang[4], J. Sun[5], Y. Sui[6], Q. Che[1,2], Q. Shu[1,2]. *[1]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China; [2]Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Department of Rheumatology, Jinan, China; [3]Tianjin Medical University General Hospital, Department of Rheumatology, Tianjin, China; [4]Women and Children's Hospital, Department of Hematology, Qingdao, China; [5]Shandong Provincial Third Hospital, Department of Nephrology and Immunology, Jinan, China; [6]YanTaiShan Hospital, Department of Rheumatology and Immunology, Yantai, China*

Background: Rheumatoid arthritis (RA) is an autoimmune disease. The core treatment principle of RA is to achieve remission or low disease activity as soon as possible to ensure optimal outcomes. Predicting the first remission time according to the patient's risk factors is very important for the choice of treatment scheme.
Objectives: We aimed to verify the prognostic value of inflammatory factors in RA and establish a nomogram based on Human Interleukin-6(IL-6), Galectin-9(Gal-9)and disease activity to predict the first remission time after conventional synthetic DMARDstreatment.
Methods: 184 RA active patients(DAS28-ESR> 3.2, ACR 1987 criteria or EULAR 2010 criteria) were enrolled in the rheumatology department of Qilu Hospital of Shandong University from June 2014 to June 2020.129 patients were assigned to the development cohort and 55 patients were assigned to the validation cohort randomly. Baseline clinical data and plasma were collected. The expressions of Tumour Necrosis Factor α (TNF-α), Vascular Endothelial Growth Factor (VEGF), IL-6 and Gal-9 in plasma of RA patients were detected by ELISA. All patients were treated with csDMARDs and we recorded activity of each follow-up visit until 36 months. Lasso regression and Cox regression analysis were used to screen the 14 variables (including activity indices and cytokines) at baseline, and the prediction model was established to draw the nomogram.
Results: Patient age, CRP, IL-6, Gal-9, HAQ and DAS28-ESR were the significant prognostic factors in the lasso and Cox regression analyses, especially Gal-9. The multivariate analysis revealed that IL-6≤ 9.04 pg/ml(*HR* =0.54, 95% *CI*:0.31–0.95), Gal-9≤ 4490 pg/ml(*HR* =0.43, 95% *CI*:0.21–0.89) were independent protective factors (Table 1). Above-mentioned six factors were included in our model as predictors (Figure 1). The resulting model containing six factors had good discrimination ability in both the development cohort (C-index, 0.729) and the validation cohort (C-index, 0.710). Time-dependent ROC curve (Figure 2), calibration analysis (Figure 3) and decision curve analysis (DCA) show that the nomogram has significant discriminant power, stability and clinical practicability in predicting the first remission time.
Conclusion: We constructed and validated a nomogram with baseline activity indices and cytokines that can predict first remission time in RA patients after csDMARDs treatment. Using this simple-to-use model with plasma Gal-9 at baseline, the remission rate can be determined for an individual patient and could be useful for the early identification of high-risk patients.

Figure1. The nomogram for predicting first remission time of RA after treatment.

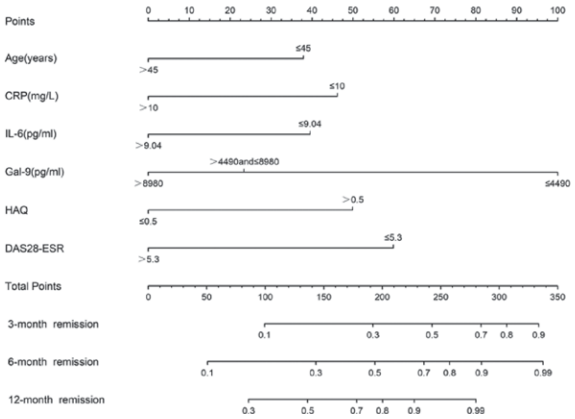

Figure2. ROC curve analysis showed the discriminatory ability of nomogram for predicting 3, 6, 12 months remission rate after treatment.

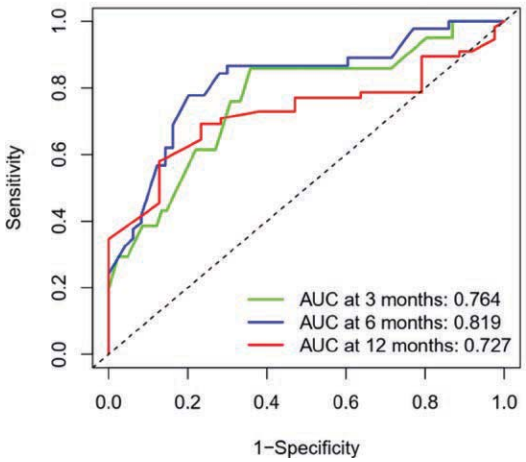

Figure3. The calibration curves for predicting RA patients' postoperative 3, 6, and 12 months remission rate.

POS0559

COMPLIANCE WITH RECOMMENDATIONS OF LOW INTAKE OF RED MEAT AND HIGH FIBER INTAKE IS ASSOCIATED WITH A REDUCED RISK OF RHEUMATOID ARTHRITIS

R. Bäcklund[1,2], I. Drake[3], E. Sonestedt[4], M. Compagno[1,2], U. Bergström[1], C. Turesson[1,2]. *[1]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; [2]Skåne University Hospital, Department of Rheumatology, Malmö, Sweden; [3]Lund University, Diabetes and Cardiovascular Disease-Genetic Epidemiology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Malmö, Sweden; [4]Lund University, Nutritional Epidemiology, Department of Clinical Sciences, Malmö, Malmö, Sweden*

Background: Diet has received much attention as a factor that may contribute to the development of rheumatoid arthritis (RA). Several different nutrients, food components and dietary patterns have been studied in different populations. There is limited information on the importance of compliance with diet recommendations in this context.
Objectives: The aim of this study was to investigate the relation between overall dietary quality, diet components, and the risk of RA.
Methods: Participants in a population-based survey conducted in 1991-1996 who were subsequently diagnosed with RA (from inclusion until December 2004) were identified through register linkage and validated in a structured process. Four controls for each case, matched for sex, year of birth, and year of inclusion, were selected from the study cohort. The controls were alive and RA-free when the index person was diagnosed with RA. At inclusion, diet was assessed using a modified diet history method, consisting of a seven-day food record, a food questionnaire, and a supplementary interview. The New Diet Score (NDS) reflects the recommendations in the Swedish dietary guidelines (SDG) from 2015, produced developed by the Swedish Food Agency, which in turn are based on the Nordic Nutrition Recommendations from 2012. According to the SDG, it is recommended to eat more fiber, vegetables and fruits and fish, and less red meat and added sugars. The mentioned dietary components are all included in the NDS, with a range 0-5. A score of 1 was assigned to each component where the individual complied with the recommendation. Non-compliance was assigned a score of 0. The cutoff values for the

recommendations are based on a previously validated Diet Quality Index, except for red meat (based on SDG) and added sugars (based on World Health Organization guidelines from 2015 for sugar intake).
We used conditional logistic regression analysis to study the relation between NDS, its components, and RA. The NDS was divided into categories, defined as low (0–1), moderate (2–3) and high (4-5), with "low" as reference, and also assessed as a continuous variable. All models were adjusted for reported total energy intake, and potential misreporters of total energy intake were excluded.
We designed multivariable-adjusted models in which we included covariates that had been associated with diet and RA (smoking, alcohol and leisure time physical activity).
Results: In the study population, 172 RA cases were identified. Low red meat intake (<500 g/week) was significantly associated with a decreased risk of RA (Table 1). Compliance with the recommendations for intake of fiber and vegetables and fruit were inversely associated with RA, with a similar trend for the total NDS (Table). In additional multivariable analysis, including both variables and relevant confounders, compliance with recommendations for red meat intake (odds ratio (OR) 0.43; 95% CI 0.22-0.85) and for fiber intake (OR 0.53; 95% CI 0.30-0.94) were both associated with a reduced risk of RA.

Table 1. Multivariable-adjusted odds ratios (ORs) describing the relation between New Diet Score (NDS) and its components and the risk of developing rheumatoid arthritis

		Adjusted for reported energy intake, smoking, alcohol, leisure time physical activity	
NDS components	Recommendation	OR	95% CI
Fibre	≥2.4 g/MJ	**0.51**	**0.29–0.90**
Vegetables and fruits	≥400 g/day	**0.55**	**0.32–0.95**
Fish	≥300 g/week	1.25	0.76–2.05
Added sugar	≤10 E%	1.10	0.68–1.78
Red meat	<500 g/week	**0.42**	**0.22–0.81**
NDS			
0–1		**1.00**	**(Ref)**
2–3		0.65	0.38–1.10
4–5		0.67	0.30–1.46
Per point increment		0.82	0.67–1.00

Conclusion: These preliminary results indicate that low intake of red meat and higher fiber intake, in line with current recommendations, are independently associated with reduced risk of developing RA, suggesting that components found in meat and fiber-rich foods may affect very early disease mechanisms.

POS0560 ASSESSMENT OF THE SWOLLEN TO TENDER JOINT COUNT RATIO AS A PREDICTOR OF RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS: A COHORT STUDY

F. Oliveira Pinheiro[1], P. Madureira[1], M. Rato[1], D. Fonseca[2], A. Martins[1], D. Santos Oliveira[1,3], F. R. Martins[4], B. Samões[2], R. Nicolau[5], M. Bernardes[1,6], L. Costa[1].
[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; [2]Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology Department, Porto, Portugal; [3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; [4]Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal; [5]Centro Hospitalar Tondela Viseu, Rheumatology Department, Viseu, Portugal; [6]Faculty of Medicine, University of Porto, Medicine Department, Porto, Portugal

Background: Several response predictors have already been studied in rheumatoid arthritis, especially since the introduction of biological therapies. The swollen to tender joint count ratio (STR) has been proposed as a predictor of response in patients receiving anti-TNF therapy, but its usefulness in other therapies is not yet well established.
Objectives: To assess whether STR can be a predictor of response in patients with rheumatoid arthritis under b/tsDMARD.
Methods: Longitudinal and retrospective study that included patients diagnosed with rheumatoid arthritis followed in the Rheumatology Department of a tertiary hospital, under therapy with b/tsDMARD. Demographic, laboratory, and clinical data were collected, including tender and swollen joint counts (as included in DAS 28), Visual Analog Scale (VAS), DAS28 4V, SDAI, CDAI, ACR and EULAR responses, and HAQ. All patients were evaluated at 0, 6 and 12 months after starting the first b/tsDMARD therapy performed after 2015. The variation in each parameter compared to baseline was calculated at 6 and 12 months and represented as a delta. A cutoff of 1 was defined for comparison between STR groups. The correlations between the continuous variables were assessed by Pearson's test and comparison between groups of ratios using t test (continuous variables) and chi-square test (categorical variables). Multiple linear regression and multivariate logistic regression were performed to determine response predictors.
Results: A total of 287 patients were included, 238 (82.9%) females, aged 55.7±10.8 years and diagnosed with rheumatoid arthritis for 11.2±8.1 years. Two hundred and sixty-nine (93.7%) were on csDMARD; with regard to b/tsDMARD therapy, 66 started etanercept (23.0%), 62 tocilizumab (21.6%), 58 rituximab (20.2%), 44 adalimumab (15.3%), 17 golimumab (5.9%), 14 abatacept (4.9%), 7 certolizumab (2.4%), 5 upadacitinib and baricitinib (1.7%), 4 infliximab (1.4%), 3 tofacitinib (1.0%), and 2 anakinra (0.7%). At the start of therapy with b/tsDMARD, the mean DAS28 4V was 4.7±1.5, CDAI 20.4±12.2, SDAI 22.8±16.4, erythrocyte sedimentation rate 31.8±24.4, C-reactive protein (CRP) 1.5±1.7, patient VAS 62.6±1.5, physician VAS 41.4±29.7, pain VAS 62.5±24.8, and HAQ 1.5±0.6; median tender joint count was 4 (interquartile range - IQR - 6), swollen joint count was 3 (IQR 6), and STR joint count was 0.9 (IQR 0.5). When the STR < 1 and STR ≥1 groups were compared, it was found that there were no differences in these variables when starting b/tsDMARD, nor in the therapies they performed. At 6 months, the STR ≥1 group showed a higher proportion of patients in CDAI remission (CDAI ≤2.8 – 15.3% vs 6.9%, p=0.033) and in DAS28 4V remission or low disease activity according to DAS28 4V (DAS28 4V ≤3.2 – 36.5% vs 22.4%, p=0.008). At 12 months, the STR ≥1 group exhibited less disease activity (mean DAS28 4V 3.2±1.2 vs 3.6±1.3, p=0.028) and a higher proportion of patients in DAS28 4V remission (25.2% vs 19.7%, p=0.047). No significant differences were found between the groups in the other variables studied. In the correlation studies, a weak correlation was identified between STR and CRP at 12 months (r=0,28, p<0,001). In multiple linear regression studies, when adjusted for sex, age, prednisolone, csDMARD, inflammatory parameters, b/tsDMARD, STR was not shown to be a predictor of DAS28 4V disease activity at 1 year; in multivariate logistic regression studies, when adjusted for the same variables previously described, STR was not shown to be a predictor of remission or remission or low disease activity according to DAS28 4V at 1 year.
Conclusion: The STR is a practical, easy-to-use index that can be used as an adjunct in clinical practice in the evaluation of patients with rheumatoid arthritis, as it is associated with a better response to b/tsDMARD therapy, regardless of patient status and therapy, although it should not be used alone, as it does not appear to be a predictor of response, according to the indices that are currently used.

POS0561 PREVALENCE AND CHARACTERISTICS OF PATIENTS WITH "ARTHRALGIA AT-RISK" DEFINED ACCORDING TO THE RHEUMATOLOGIST AND THE NEW EULAR DEFINITION: A PILOT RETROSPECTIVE STUDY FOCUSSED ON REFERRAL TO A STRUCTURED EARLY ARTHRITIS CLINIC

S. Grignaschi[1,2], B. Xoxi[1], E. Bozzalla Cassione[1,2], T. Luvaro[1], M. I. Greco[1], I. Mazzucchelli[2], S. Bugatti[1,2], C. Montecucco[1,2], A. Manzo[1,2]. *[1]Fondazione I.R.C.C.S. Policlinico San Matteo, Division of Rheumatology, Pavia, Italy; [2]The University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*

Background: The phase preceding the development of rheumatoid arthritis (RA) may contain a novel window of opportunity for disease prevention and control. Investigation of this phase at population level remain, however, very challenging in epidemiological terms due to the rarity of the events. Patients seeking medical attention with arthralgia at-risk, defined by an expert rheumatologist (clinically suspect arthralgia, CSA) or by the recent EULAR definition represent an attractive platform for the identification of both seropositive and seronegative disease subsets.
Objectives: The objective of this study was to explore the prevalence and characteristics of patients with different types of arthralgia, focusing on referral to the screening visit of an early arthritis clinic (EAC) as a putative enrichment strategy for pre-RA.
Methods: EAC first referrals from January 1st 2019 to June 30th 2021 were systematically reviewed through a retrospective evaluation of medical charts. Patient's history, comorbidities, PROs and clinical examination were recorded by two expert rheumatologists blind to immunological, ultrasound and radiological data. Arthralgia cases, sub-classified according to risk-definitions, were recorded. Categories at-risk, according to the rheumatologist's opinion and the EULAR definition, were characterized and compared to other arthralgia cases for clinical characteristics, imaging data and autoantibody status.
Results: Of the 363 patients referred to the EAC, 178 were characterized by peripheral arthralgia (swollen joint count=0) at screening visit (49%). Of these patients, 130 cases were characterized by recent-onset arthralgia (ROA) (<12 months symptoms' duration) (73% of the total). CSA, according to the rheumatologist's opinion, was applicable to 71/178 total arthralgia patients (40%) and to 61/130 ROA patients (47%, recent-onset CSA, RO-CSA). Patients without

CSA were characterized by undefined concomitant conditions or by "clinically suspect psoriatic or spondylarthritis arthralgia" (20/178, 11%). EULAR definition of arthralgia at-risk (>2 items) was fulfilled by 53/71 CSA patients (74.6%) and by 52/107 (49%) patients not characterized by CSA (p=0.001 Chi-square test) (Figure 1).

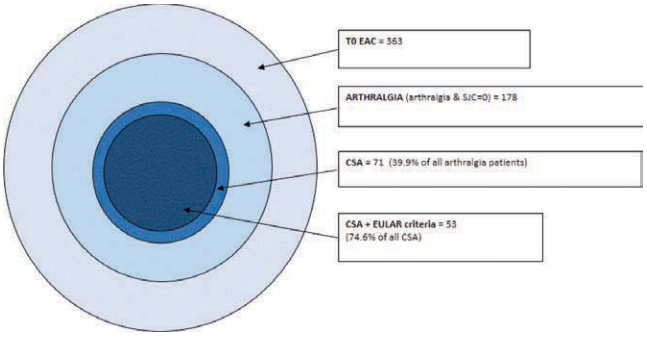

Figure 1. Early Arthritis Clinic first referrals from January 1st 2019 to June 31th 2021.

Despite a similar clinical phenotype, comparative analysis between different arthralgia categories demonstrated a significant enrichment of RF and ACPA positivity (21% vs 4%, p=0,001, and 15% vs 3%, p=0.01) in both CSA and RO-CSA vs other groups. RO-CSA showed also an enrichment of hypogammaglobulynemia compared to other groups (13% vs 3%, p=0.03). After a stratification according to the fulfillment of the EULAR definition, both CSA and RO-CSA increased their differences compared to other groups regarding the elevation of C-reactive protein (CRP ≥0.5 mg/dl, p=0.006 and p=0.02 respectively). No epidemiological, clinical or imaging differences were observed through patient stratification according to the EULAR definition *per se* in the whole population.

Conclusion: Results of our pilot study provide evidence of the applicability of patient selection according to current arthralgia at-risk definition in the real-life setting of an EAC. Both CSA and RO-CSA appears as suitable niches for the enrichment of primary immunological and serological risk factors for RA (RF/ACPA, hypogammaglobulynemia and C-reactive protein). Current data confirm in an independent setting the importance of the rheumatologist's perspective as a platform for appropriate application of the EULAR definition.

POS0562 AUTOANTIBODIES TO JOINT PROTEINS AS NOVEL BIOMARKERS FOR THE DIAGNOSIS OF UNTREATED EARLY RHEUMATOID ARTHRITIS

E. Lönnblom[1], M. Leu Agelii[2], O. Sareila[2], I. Hafström[3], M. Andersson[4], L. Cheng[1], G. Bergström[5], A. K. H. Ekwall[2], A. Rudin[2], A. Kastbom[6], C. Sjowall[6], B. Xu[1], L. T. H. Jacobsson[2], J. Viljanen[7], J. Kihlberg[7], I. Gjertsson[2], R. Holmdahl[1]. [1]*Karolinska Institute, Section of Medical Inflammation Research, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden;* [2]*Institute of Medicine, Gothenburg University, Rheumatology and Inflammation Research, Gothenburg, Sweden;* [3]*Karolinska Institute, Division of Gastroenterology and Rheumatology, Department of Medicine Huddinge, Stockholm, Sweden;* [4]*Spenshult Research and Development Center, Halmstad, Halmstad, Sweden;* [5]*Institute of Medicine, Gothenburg University, Department of Clinical Physiology, Region Västra Götaland, Sahlgrenska University Hospital, Göteborg, Sweden;* [6]*Linköping University, Department of Rheumatology and Department of Biochemical and Clinical Sciences, Linköping, Sweden;* [7]*Uppsala University, Department of Chemistry-BMC, Uppsala, Sweden*

Background: Autoantibodies to citrullinated protein (ACPA; measured as anti-CCP; aCCP) and rheumatoid factor (RF) appear years before clinical onset of RA and are essential tools in today's classification criteria for RA. In animal models, antibodies to joint specific proteins (JP) can induce arthritis, and they are also present at onset of RA [1]. As there is a need for increased precision for early diagnosis of RA as well as identification of different subtypes of the disease, we aim to assess whether autoantibodies to native or modified JP can be used for early and precise diagnosis of RA.

Objectives: To study whether antibodies to JP, alone or in combination with ACPA/RF, could increase the diagnostic sensitivity and specificity in untreated early (ue)RA patients.

Methods: Antibodies to JP were analysed in serum from patients in three independent ueRA cohorts as well as from population controls without rheumatic diseases (WINGA, Gothenburg and MFM-ÅUS, Malmö n=1062). ERAp (n=66), the smallest and most recent cohort was chosen for screening, and BARFOT and TIRA-2 (n=1939) for validation. We have developed a bead-based multianalyte flow immunoassay [2] and screened approx. 350 peptides derived from JPs of interest. We included monoclonal antibodies as assay calibrators and determined limit of detection (LoD). To assess positivity for autoantibodies to JP of interest above LoD, we used 5MAD (median absolute deviation) of the control populations as the cut-off.

Results: In the ERAp cohort, 5 autoantibodies discriminated RA patients from controls with 81% sensitivity and 100% specificity (Table 1). The same autoantibodies had 68% sensitivity and 98% specificity in the combined BARFOT and TIRA-2 cohorts. Together with RF and aCCP, only 2 of the 5 autoantibodies added statistically significant diagnostic value, increasing the sensitivity from 48% to 61% with 99% specificity. In aCCP- and RF-negative ueRA patients (n=536), the novel biomarkers identified 22.5% of the patients with 99% specificity compared to controls.

Table 1. Diagnostic capacity of the joint-specific antibodies

	Test panel			Performance		
Group of patients	**aCCP+**	**RF+**	**JP+**	**Sensitivity**	**Specificity**	**AUC(ROC)**
ERAp						
All patients (n=66)	-	-	X	81%	100%	89%
RF and aCCP-neg patients (n=7)[1]	-	-	-	-	-	-
BARFOT and TIRA-2, combined data						
All patients (N=1939)	-	-	X	68%	98%	86%
All patients (N=1939)	X	-	-	58%	99%	78%
All patients (N=1939)[2]	X	X	-	48%	100%	84%
All patients (N=1939)[2, 3]	X	X	X	61%	99%	86%
RF and/or aCCP-pos patients (N=1403)	-	-	X	84%	99%	93%
RF and aCCP-neg patients (N=536)	-	-	X	22%	99%	67%
RA, literature values						
Anti-CCP test	X	N/A	N/A	53–71%	95–96%	N/A

[1]*Not analysed due to lack of power* [2]*This patient population is both aCCP+ and RF+* [3]*Only 2 of the 5 autoantibodies added statistically significant to the diagnostic valueAUC, Area under the curve; ROC, receiver operating characteristic curve; N/A, not applicable. Controls without rheumatic diseases: N=935 for BARFOT / TIRA-2 and N=27 for ERAp.*

Conclusion: Autoantibodies to JP discriminate ueRA patients better then aCCP and RF alone and add an increased diagnostic value in particular for seronegative patients.

POS0563 INFLUENCE OF ACTIVE VERSUS PLACEBO CONTROL ON TREATMENT RESPONSES IN RANDOMIZED CONTROLLED TRIALS IN RHEUMATOID ARTHRITIS

N. M. Stimakovits[1], A. Kerschbaumer[1], J. S. Smolen[1], T. Stefanova[1], E. Chwala[2], D. Aletaha[1]. [1]*Medical University of Vienna, Division of Rheumatology, Department of Medicine III, Vienna, Austria;* [2]*Medical University of Vienna, University Library, Vienna, Austria*

Background: Randomised placebo controlled double-blind clinical trials are the mainstay of testing drugs for efficacy and safety and ultimately drug approval in medicine.[1] They are performed to ensure the efficacy of the active intervention against the effects of interventions without expected efficacy (placebo). Patients have to be fully consented to the risk of being (randomly) allocated to placebo by good clinical practice guidelines.[2] Knowledge about this risk may reduce the expectations about efficacy on both the patient and the investigator side.

Once many therapeutic options are available, active control interventions are often used as comparators instead of placebo in trials. In such studies, placebo

effects are still in place by the mere expectation of a response, but one could hypothesise that the observable effect of each intervention may be higher simply because of patients' awareness of an active treatment (i.e. no risk of placebo).
Here we investigated this hypothesis by comparing the effects of active controlled trials versus placebo controlled trials on the efficacy for the same therapeutic intervention in patients with rheumatoid arthritis (RA), in a systematic approach using all published trials in the field.
Objectives: To assess whether there is a systematic difference in response rates when investigating treatments in randomised controlled trials (RCTs) with active control compared to placebo control in RA clinical trials.
Methods: A systematic literature search was performed. We identified and matched RCTs that used comparable regimens, patient populations, background therapy and outcome reporting, but were different in terms of control group (active or placebo). Included studies were explored for potential risk of bias and mixed-model logistic regression was used to estimate odds ratios (OR) for achieving an American College of Rheumatology (ACR) 20, 50 and 70% response at week 12 in active-controlled studies compared to corresponding placebo-controlled studies.
Results: 7477 studies were screened, 576 of which underwent detailed review. Finally, 39 studies (45 study arms) were included for analysis. ACR response rates were higher in active controlled trials. The OR for achieving an ACR response when investigating the same treatment was consistently higher in studies with active control group than in corresponding studies with placebo control group: ORs were 1.64 (95% Confidence Interval, CI: 1.44-1.86; p<0.001) for ACR20 (Figure 1), 1.46 (95% CI: 1.28-1.71, p<0.001) for ACR50 and 1.61 (95% CI: 1.28-2.02; p<0.001) for ACR70 at week 12.

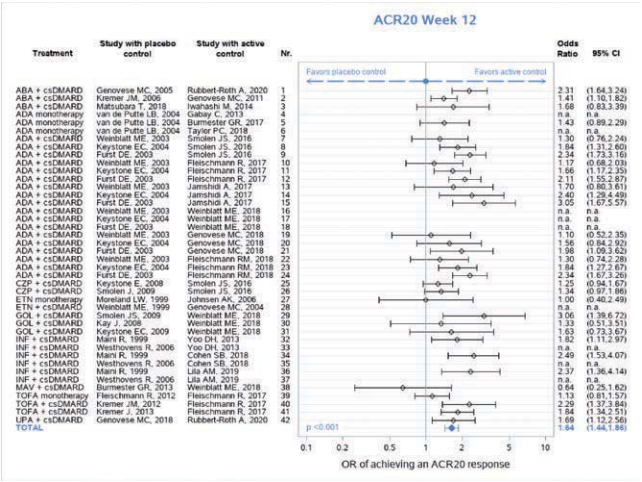

Figure 1. Forest plot showing ORs (with 95% CI) of achieving an ACR20 response at week 12 in studies with active control compared to studies with placebo control.

Conclusion: A systematic difference in response rates favouring head-to-head trials compared to placebo-controlled trials exists in RA clinical trials. This finding calls for consideration when interpreting and planning clinical trials and has implications for patients, investigators, sponsors and regulatory agencies.

Background: The definitions of remission play a crucial role in the treat-to-target strategy in rheumatoid arthritis.The patient's and physician's global assessment (PGA|PhGA) of disease activity are considered in current definitions, but PGA has been criticized for its poor relationship with actual disease activity. This leads to a considerable risk of overtreatment in patients who are otherwise in remission but fail this target solely because of PGA: PGA-near-remission. A dual-target strategy, excluding PGA from the definition of biological remission and the creation of a second target focused on disease impact has been proposed.[1] Another proposal is to substitute PGA by PhGA with the purpose of strengthening the definition with a fourth variable capable of conveying relevant unaccounted factors, such as comorbidity.[2]
Objectives: To assess the relationship of PGA and PhGA with objective measures of disease activity (DAS3v) and their impact upon near-remission and risk of overtreatment.
Methods: This is a cross-sectional analysis of data from RAID.PT, an observational, prospective and multicenter study, including adult patients fulfilling RA classification criteria. Tender (TJC28) and swollen (SJC28) 28 joint counts, C-Reactive Protein (CRP), Pain score, Health Assessment Questionnaire (HAQ), the Rheumatoid Arthritis Impact of Disease (RAID) total score, Hospital Anxiety and Depression Scale (HADS) scores, PGA and PhGA were collected. Disease Activity Score (DAS28-3v-CRP) was calculated and taken as the reference measure of current disease activity. Correlation between PGA and PhGA with other continuous variables was evaluated through Pearson´s Correlation Coefficient and variables with p<0.10 in univariate analysis were included in multivariable linear regression models.
Results: We included 299 patients, 81.3% women, mean age of 57.4±12.0 years and disease duration 9.4±9.5 years. Average DAS28-3v-PCR 2.4 (±1.9).
DAS3v-CRP is the strongest factor associated with PhGA, explaining 45% of its variance. Inversely, it only explains 2% of the variance of PGA, which is more affected by disease impact. In this clinical cohort, 13% of patients were in full Boolean remission and 41% in PGA-near-remission. Only 49 of 123 patients in the latter group had a PhGA >1. Considering PhGA instead of PGA in the Boolean definition of remission would increase the proportion of remission from 13 to 37.5% of the whole cohort.

Table 1. Factors Associated with PGA and PhGA in multivariate regression analysis

	PGA	PhGA(β, 95% CI)
	(β, 95% CI)	(β, 95% CI)
	ΔR^2	ΔR^2
DAS28-3v-CRP	**3.7 (1.9-5.5)**	**10.9 (9.4 to12.5)**
	0.02	**0.45**
RAID	**7.7 (6.7-8.8)**	**3.4 (2.5 to 4.3)**
	0.61	**0.09**
HAQ	**5.6 (1.0-8.1)**	**-3.4 (-6.4 to -0.4)**
	0.01	**0.01**
R^2	**0.64***	**0.55***

DAS28-3v-CRP: Disease Activity Score-3 variables C-Reactive Protein. PGA: Patient global assessment; PhGA: Physician Global Assessment; HAQ (health assessment questionnaire); RAID: Rheumatoid Arthritis Impact Disease score. ΔR^2 change of R^2associated with the inclusion of the variable in the model. *p<0,01

Conclusion: PhGA is a closer representation of actual disease activity than PGA, thus providing a more valid basis for treatment decisions aimed at disease activity. These observations support the substitution of PGA by PhGA in the Boolean definition of remission as it would strengthen the representation of disease activity and significantly reduce the risk of overtreatment in comparison to current definitions. The consequences of this change upon the prediction of long-term function and structural stability warrant evaluation. The patient's perspective will remain central to disease management in the form of a distinct target.

POS0565 WORSE OUTCOMES LINKED TO ETHNICITY FOR EARLY INFLAMMATORY ARTHRITIS IN ENGLAND AND WALES: A NATIONAL COHORT STUDY

M. Adas[1], S. Balachandran[1], S. Norton[1,2], E. Alveyn[1], M. Russell[1], T. Esterine[3], P. Amlani-Hatcher[3], S. Oyebanjo[4], H. Lempp[1], J. Ledingham[5], K. Kumar[6], J. Galloway[1], S. Dubey[7]. *[1]King's College London, Centre for Rheumatic Disease, Department of Inflammatory Biology, London, United Kingdom; [2]King's College London, Psychology Department, London, United Kingdom; [3]British Society for Rheumatology, NEIAA Patient Panel, London, United Kingdom; [4]British Society for Rheumatology, NEIAA, London, United Kingdom; [5]Portsmouth Hospitals University NHS Trust, Rheumatology Department, Portsmouth, United Kingdom; [6]University of Birmingham, Institute of Clinical Sciences, Birmingham, United Kingdom; [7]NHS Foundation Trust, Oxford University Hospitals, Oxford, United Kingdom*

Background: Patients from ethnic minority backgrounds suffer considerable health inequality, with generally poorer health outcomes relative to the rest of the population.[1] Further exploration of these differences is essential if we are to deliver the best care for all, and close the health gap for our patients.
Objectives: We used the National Early Inflammatory Arthritis Audit (NEIAA) to assess variability in care quality and treatment outcomes across ethnicities for patients diagnosed with early inflammatory arthritis (EIA) in England and Wales.
Methods: NEIAA is an observational cohort design. Data were from adult patients newly diagnosed with EIA, and seen by rheumatology in England and Wales between May 2018 and March 2020. Quality of care outcomes were assessed against six metrics contained within the National Institute for Health and Clinical Excellence (NICE) Quality Standard for Rheumatoid Arthritis.[2] Clinical outcomes were measured using DAS28. Outcomes were compared between ethnic groups (White, Black, Asian, Mixed, Other), and adjusted for confounders (age, sex, smoking, comorbidity, seropositivity and disease severity at presentation) using Logistic regression models with multiple imputation for missing data.
Results: Data for 35,807 eligible patients were analysed, of whom 30,643 (85.6%) were White and 5,164 (14.6%) were from ethnic minority backgrounds: 1,035 (2.8%) Black; 2,617 (7.3%) Asian; 238 (0.6%) Mixed; 1,274 (3.5%) Other. A total of 12,955 patients had confirmed EIA. Of those, 11,315 were White and 1,640 were from ethnic minority backgrounds: 314 (2.4%) Black; 927 (7.1%) Asian; 70 (0.5%) Mixed; 329 (2.5%) Other. Of 35,160 eligible patients who had data available, 14,803 (42.1%) were assessed by rheumatology within three weeks of referral. Of 9,900 EIA-eligible patients with data available, 5,642 (57.0%) started treatment within six weeks of referral. There were no significant differences in these outcomes by ethnicity. Ethnic minority patients did, however, have lower odds of disease remission at three months, relative to patients of White ethnicity (adjusted odds ratio 0.79; 95% CI: 0.65-0.96; p=0.02). This difference was due to lower odds of disease remission in Black and Asian patients, relative to White patients (Table 1). Ethnic minority patients were significantly less likely to receive initial treatment with methotrexate (0.68; 95% CI: 0.52-0.90; p=0.008) or with glucocorticoids (0.63, 95% CI: 0.49-0.80; p< 0.001).

Table 1. Associations between ethnicity and disease remission at three months in EIA patients

Model	Odds ratio	95% CI	P-value
Unadjusted			
All ethnic minority backgrounds	0.76	(0.62,0.93)	0.01
Black	*0.48*	*(0.34,0.67)*	*<0.001*
Asian	*0.74*	*(0.59,0.93)*	*0.01*
Mixed	*0.61*	*(0.28,1.35)*	*0.22*
Other	*1.09*	*(0.71,1.68)*	*0.67*
Age and sex-adjusted			
All ethnic minority backgrounds	0.78	(0.63,0.96)	0.01
Black	*0.49*	*(0.35,0.69)*	*0.00*
Asian	*0.75*	*(0.60,0.94)*	*0.01*
Mixed	*0.63*	*(0.28,1.39)*	*0.25*
Other	*1.11*	*(0.71,1.71)*	*0.63*
Fully-adjusted			
All ethnic minority backgrounds	0.79	(0.65,0.96)	0.02
Black	*0.57*	*(0.41,0.79)*	*0.001*
Asian	*0.76*	*(0.62,0.93)*	*0.009*
Mixed	*0.63*	*(0.27,1.46)*	*0.29*
Other	*1.04*	*(0.71,1.54)*	*0.80*

Conclusion: The results from this large cohort demonstrate that some minority ethnic groups are less likely to reach disease remission in the early months following an EIA diagnosis. Our results are not explained by delays in referral or treatment. Intitial treatment strategies varied across ethnic groups. These data highlight the need for investigation into the possible drivers of these inequitable outcomes and reappraisal of EIA management pathways.

POS0566 PREDICTORS OF RESPONSE TO METHOTREXATE MONOTHERAPY IN ACTIVE RHEUMATOID ARTHRITIS: RESULTS FROM A MULTICENTRE, RANDOMIZED CONTROLLED TRIAL (MEIRA)

S. Jain[1], V. Dhir[1], A. Aggarwal[2], R. Gupta[3], B. Leishangthem[1], G. Naidu[1], A. Khullar[1], V. Dhawan[4], S. K. Sharma[1], A. Sharma[1], S. Jain[1]. *[1]PGIMER, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, Chandigarh, India; [2]SGPGIMS, Department of Clinical Immunology and Rheumatology, Lucknow, India; [3]AIIMS, Department of Rheumatology, New Delhi, India; [4]PGIMER, Department of Experimental Medicine and Biotechnology, Chandigarh, India*

Background: Methotrexate (MTX) is the gold standard, first-line therapy for rheumatoid arthritis (RA). However, not all patients respond to MTX, and the predictors of its response or non-response have not yet been reliably identified. Identification of these predictors will facilitate personalized therapeutic choices, and improve patient outcomes.
Objectives: To identify the clinico-laboratory predictors of response to MTX monotherapy in active RA.
Methods: This study included patients with active RA (SJC≥2 and TJC≥4) aged 18-55 years, with disease duration <5 years, who were not receiving DMARDs (except HCQ and low-dose prednisolone) and had been enrolled in the multicentre, parallel group RCT comparing two different MTX escalation strategies in RA (MEIRA)[1]. All these patients received MTX monotherapy which was started at 15 mg/week, escalated to 25 mg/week by 4-8 weeks, and continued till 16 weeks. MTX response was defined as EULAR good or moderate response (based on DAS28-CRP-3v) at 16 weeks. Stepwise, multivariable logistic regression was done using key demographic (age, gender, BMI, comorbidities), clinical (disease duration, DAS28, HAQ), and laboratory parameters (RF, anti-CCP, ESR, CRP, RBC MTX-polyglutamates 1-4, IL-6, MMP-3) as independent variables to identify predictors of MTX response. A two-tailed p-value <0.05 was used for defining statistical significance. (Trial Reg: CTRI/2018/12/016549)
Results: Out of a total of 178 included patients [84% females, mean age 40 (9) years, mean DAS28-CRP=5.4 (1.1)], 113 (63.5%) were classified as MTX responders at 16 weeks. Age (OR=0.95, p=0.01), BMI (OR=1.12, p=0.006), and RF (OR=0.34, p=0.045) were found to be independent predictors of MTX response on multivariable analysis (Table 1). On sensitivity analysis with DAS28-ESR-based EULAR response, age (OR=0.94, p=0.003) and RF (OR=0.42, p=0.059) were replicated as independent predictors of MTX response, in addition to pre-treatment swollen joint count (OR=0.94, p=0.05).

Table 1. Results of multivariable logistic regression analysis for prediction of response (as defined by DAS28-CRP-based EULAR good or moderate response) to methotrexate monotherapy in RA

Variable	OR (unadjusted)	Unadjusted p-value	OR (adjusted)	Adjusted p-value
Age	0.97 (0.93-1.002)	0.06	0.95 (0.91-0.99)	0.01
Male sex	0.78 (0.35-1.76)	0.55	-	
BMI	1.1 (1.02-1.19)	0.01	1.12 (1.03-1.22)	0.006
Presence of comorbidities	0.67 (0.31-1.44)	0.31	-	
Disease duration	0.98 (0.79-1.22)	0.87	-	
Baseline DAS28	1.1 (0.81-1.49)	0.54	-	
Baseline HAQ	1.04 (0.66-1.64)	0.86	-	
Baseline TJC	1.01 (0.96-1.05)	0.72	-	
Baseline SJC	0.97 (0.91-1.02)	0.24	-	
Baseline ESR	1.01 (1.00-1.02)	0.27	-	
Baseline CRP	1.00 (0.99-1.01)	0.85	-	
RF positive	0.31 (0.11-0.85)	0.02	0.34 (0.12-0.98)	0.045
Anti-CCP positive	0.73 (0.27-1.99)	0.54	-	
MTX PG1 (16 weeks)	0.99 (0.94-1.04)	0.69	-	
MTX PG2 (16 weeks)	0.98 (0.95-1.02)	0.37	-	
MTX PG3 (16 weeks)	0.99 (0.96-1.02)	0.43	-	
MTX PG4 (16 weeks)	0.99 (0.95-1.03)	0.62	-	
Serum IL-6 (baseline)	0.98 (0.95-1.02)	0.33	-	
Serum MMP-3 (baseline)	1.00 (1.00-1.00)	0.48	-	

BMI= Body Mass Index, CCP= Cyclic Citrullinated Peptides, CRP= C-reactive protein, DAS= Disease Activity Score, ESR= Erythrocyte Sedimentation Rate, HAQ= Health Assessment Questionnaire, MTX= Methotrexate, PG= polyglutamate, OR=Odds Ratio, RF=Rheumatoid Factor, SJC= Swollen Joint Count, TJC= Tender Joint Count Note: Only variables with p-value <0.2 on univariable analysis were included in the multivariable analysis.

Conclusion: Younger age, RF negativity, higher BMI, and lower pre-treatment swollen joint count are potential predictors of response to MTX monotherapy in RA.

POS0567 SELF-PERCEIVED GENERAL HEALTH AT START OF ANTI-TNF THERAPY PREDICTS THERAPEUTIC RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS: ANALYSIS FROM THE CZECH BIOLOGICS REGISTRY ATTRA

J. Zavada[1], L. Nekvindova[2]on behalf of Collaborators of the ATTRA registry.
[1]Institute of Rheumatology, Rheumatology, Prague, Czech Republic; [2]Instititute of Biostatistics and Analyses spinn off, Faculty of Medicine, Masaryk University, Biostatistics, Brno, Czech Republic

Background: SF-36 and its components, as well as other PROs have been shown to predict various disease outcomes. We hypothesized that positive responses to questions (Q) 11A "I seem to get sick a little easier than other people" and 11C "I expect my health to get worse" from the general health (GH) domain of the SF-36 v1 questionnaire may correspond to a more fragile self-perceived GH status, and thus serve as possible predictors of future disease outcomes in patients with rheumatoid arthritis (RA).

Objectives: We aimed to investigate whether these 2 questions could predict therapeutic response in patients with RA starting their first anti-TNF therapy.

Methods: We have used two separate datasets from the Czech biologics registry ATTRA to validate our hypothesis. Dataset D1 included RA patients with at least 1 year follow-up and all relevant data available starting their first-line anti-TNF treatment within period 01/01/2012-31/12/2017 (N=1808), and dataset D2 pts starting in in 01/01/2018–01/01/2020 (N=734). Our primary outcome was DAS28-ESR remission (REM) at 12 months. REM was defined as DAS28<2.6. Patients were grouped according their response (definitely/mostly yes vs. definitely/mostly no) to Q11A and Q11C at baseline. REM rates after 12 months of 1st-line anti-TNF treatment were compared across patients' groups with Pearson chi-squared test. Firstly, odds ratios (ORs) using logistic regression (univariate, and then adjusted to baseline DAS28 and HAQ) were calculated to predict REM at 12M. Secondly, ORs were calculated after matching pts with positive or negative responses by a propensity score (PS) using sex, age, disease duration, baseline DAS28, calendar year and co-medication to balance baseline differences.

Results: At baseline, 79% and 80% pts were female, mean (SD) age was 52(12) and 54(13) years, DAS28 6.3 (0.9) and 6.2 (1.1), HAQ 1.5(0.6) and 1.5(0.6), 74% and 68% were RF+, 70% and 69% ACPA+ in D1 and D2 resp. In D1 34% and 31% pts, and in D2 32% and 30% responded positively to Q11A and 11C resp. Patients with positive responses to Q11A and 11C tended to have slightly (but statistically significantly) higher DAS28, HAQ, CRP or ESR, and patient- and physician global activity assessment at baseline. At 12 months, 40% (49%), 31% (37%), and 30% (40%) patients with positive, negative and neutral response to Q 11A reached REM; p<0.001 (p=0.018) in D1 (D2) resp. At 12 months, 42% (51%), 31% (37%), and 30% (40%) patients with positive, negative and neutral response to Q 11C reached REM; p<0.001 (p=0.04) in D1 (D2) resp. Crude and adjusted ORs for reaching REM according to responses to Q11A and Q11C are shown in the Table 1.

Conclusion: We provide a robust evidence that self-perceived general health at start of anti-TNF therapy predicts reaching remission at 12 months in pts with RA.

Dataset	D1 (N=1808)		D2 (N=734)	
Baseline parameter	**OR (95% CI)**	**p**	**OR (95% CI)**	**p**
Analysis 1: Patients' responses and occurrence of DAS28 remission after 12 months - Univariate logistic regression models (Remission (DAS28-ESR < 2.6) after 12 months (1 – yes vs. 0 – no)

POS0568 HOW DOES INSTANTANEOUS RA DISEASE ACTIVITY AFFECT THE SHORT-TERM RISK OF ACUTE CORONARY SYNDROME? – A REGISTER-BASED STUDY

B. Delcoigne[1], S. Aarrestad Provan[2], E. Kristianslund[2], J. Askling[1], L. Ljung[1].
[1]Karolinska Institute, Medicine Solna _ Clinical Epidemiology Division, Stockholm, Sweden; [2]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway

Background: Rheumatoid arthritis (RA) patients have a reduced life expectancy, with cardiovascular disease (CVD) being the most frequent cause of death. The mechanisms behind the increased CVD morbidity and mortality in RA are not fully understood. Systemic inflammation is an important contributor to the accelerated arteriosclerosis in RA, and traditional risk factors for CVD are usually more prevalent in RA patients than in the general population. How much the current state of RA disease control impacts the short-term risk of CVD events remains unclear.

Objectives: To estimate the short-term risks and relative risks of acute coronary syndrome (ACS) in patients with RA as a function of RA disease activity, with particular focus on remission.

Methods: We identified patients with RA from the clinical rheumatology registers (CRR) in Sweden (SE) and Norway (NO), and for these patients we retrieved all registered clinical rheumatology visits from January 1st, 2012 to December 31st, 2020. At each visit, we assessed whether the patient was in remission or not according to multiple definitions including DAS28, ACR criteria, and SDAI. We also categorised the disease activity at each visit into categories (remission, low, moderate and high) using DAS28-ESR. Patients had to be free of any history of ACS in a five-year look back window (assessed at the visit date), and were followed for 6 months from each visit date until ACS event (defined as hospitalization due to ACS or death due to either ACS or sudden death) or censoring (death due to other causes, migration, end of the study). We compared the risk of ACS between patients who were (vs. were not) in remission using Cox regression with robust standard errors (accounting for the correlated data structure), adjusted for covariates (including age at the visit, sex, number of previous treatment courses, use of prednisolone, the expanded risk score in RA (ERS-RA), and defined co-morbidities: diabetes, malignancy, respiratory failure, liver failure and kidney disease) and stratified by country.

Results: We included 43,338 RA patients and their 223,197 visits (211,158 (SE), 12,039 (NO)). 74% of the visits were from women, with a mean age (SD) at visit of 62 (14) years. Several clinical characteristics including treatments and

comorbidity history varied with disease activity (Table 1). By contrast, age, number of previous DMARDs, disease duration and smoking habits were relatively similar across categories of disease activity (Table 1).

Table 1. Median [Q1-Q3] or percentage for clinical characteristics in remission (DAS28-ESR<=2.6) and high disease activity (DAS28-ESR>5.1) categories

Variable	Remission	High disease activity
N (visits)	91,497	25,364
Age, years	65[53-72]	63[53-72]
Disease duration	10[4-18]	8[2-17]
N treatment courses	0[0-0]	0[0-1]
Prednisolon	28%	58%
Tender joint count, 28-joints (TJC)	0[0-0]	10[6-14]
Swollen joint count, 28-joints (SJC)	0[0-0]	7[4-10]
Erythrocyte sedimentation rate, ESR	10[6-18]	28[15-47]
C-reactive protein (CRP)	3[1-4]	14[5-32]
Patient global assessment, PGA	13[4-27]	70[55-82]
Pain	12[4-27]	70[55-82]
ERS-RA	8[3-16]	12[5-23]
Ischemic heart disease	6%	7%
Diabetes	9%	13%
Hypertension	39%	42%
Hyperlipidemia	23%	25%
Ever smoking	45%	50%

We observed 598 ACS events (in 554 patients) during the 6-month follow-up window. Comparing patients not in remission to patients in remission, adjusting for the covariates described above, indicated that not being in remission increased the risk of ACS occurrence (Figure 1). Similarly, there was an association between DAS28-ESR at the visit and the risk of ACS during the coming six months.

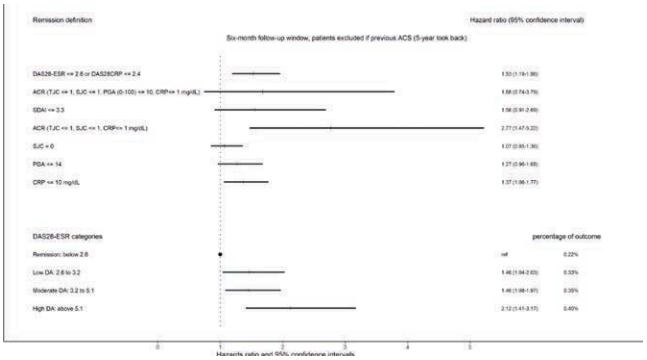

Figure 1. Hazard ratio (95% confidence interval) comparing patients not in remission to patients in remission, using several remission definitions. Percentage of visits with an ACS event within 6 months (bottom panel).

Conclusion: Being in RA remission at any visit is associated with a noticeably lower risk of ACS during the following months, suggesting that RA disease activity not only affects CVD risk in the longer term but also in the short term.

POS0569 IDENTIFICATION OF JOINT LOCATIONS IN AN EARLY RHEUMATOID ARTHRITIS COHORT AS A CHARACTERISTIC OF DISEASE SEVERITY. DATA FROM THE ERA-UCLOUVAIN BRUSSELS COHORT

L. Bricman[1], S. Emilie[1], T. Sokolova[1], A. Avramovska[1], P. Durez[1]. *[1]Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium*

Background: Early RA patients (ERA pts) often present with different areas of joint involvement, but limited data exist to identify which specific joint locations may be indicative of greater disease severity[1].
Objectives: This analysis investigated the baseline (BL) prevalence of swelling in individual joint locations and their possible association with disease characteristics and prognostic factors in a cohort of ERA pts.
Methods: This analysis was based on data from the ERA UCLouvain Brussels cohort in which patients were included according the ACR/EULAR 2010 criteria, naïve to DMARDs and followed in our daily clinic. The physician assessed prevalence of baseline individual swollen joint status (present, absent) through a physical examination. The joint count includes 44 joints. Similarly, all patient and RA characteristics were analyzed.The association between BL swelling and disease characteristics was investigated for each individual joints.
Results: 453 ERA pts were analyzed, BL swelling was most frequently observed in the wrist (71.1%) followed by IPP 3 and 2 joints (52.5 and 50.1%) (Table 1). MTP4 et 5 was more present in younger and MCP 2-4 in older pt *. BL swelling in the large size joint (knee, elbow, shoulder and ankle), in the medium size joint (wrist) and the small size joint (only MCP3, IPP 1, 2 and MTP5) was highly associated with higher DAS28 (CRP) *. Pts with BL swelling MCP1, 3, 4; MTP 1,2, 5 was associated with erosive disease*. In contrast, swelling of the knee was correlated with non erosive and also seronegative RA*. Swelling of many joints locations (knee, shoulder, ankle, MCP 1-5, MTP1, 5 and IPP 1, 2) were correlated significantly with a higher HAQ*. Only swelling of MTP1, 2, 5 was associated with the presence of ACPA antibodies*. No difference was observed for smoking habits and gender. *(*) - p≤0.001.*
Conclusion: In our cohort of ERA, small joints swelling was associated with erosive and seropositive RA (only MTP). Swelling of the large joint and the wrist seems to be associated with higher disease activity. In ERA, a difference in joint location presentation may identify pts with poor pronostic factors to be eligible for an intensive treatment or a personalized treatment approach. Further analysis are planned to analyze the correlation with erosion in each joint location and response to Methotrexate.

POS0570 UNSUPERVISED DEEP-LEARNING IDENTIFIES SIX CLINICAL SUBTYPES OF RHEUMATOID ARTHRITIS AT BASELINE THAT ASSOCIATE WITH METHOTREXATE FAILURE DURING FOLLOW-UP

T. Maarseveen[1], M. Maurits[1], T. Huizinga[1], M. Reinders[2,3], E. Van den Akker[2,3], R. Knevel[1,4]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Delft University of Technology (TU Delft), Bioinformatics Lab, Delft, Netherlands; [3]Leiden University Medical Center (LUMC), Molecular Epidemiology, Leiden, Netherlands; [4]Newcastle University, Rheumatology, Newcastle upon Tyne, United Kingdom*

Background: Currently methotrexate (MTX) is the prevailing baseline treatment for Rheumatoid Arthritis (RA). Treatment response varies since RA is a highly heterogeneous disease. A tantalizing idea is that the factors causing clinical heterogeneity can already be elucidated at baseline.
Objectives: Disentangle clinical heterogeneity of RA patients at baseline to identify likely MTX failure during follow-up.
Methods: We constructed patient-specific profiles, featuring baseline clinical measurements which we split into three layers: 1) joint counts, 2) numerical hematology work up, and 3) categorical features (binary serological markers (aCCP/RF) and localization of joint inflammation and tenderness). We applied Z-score scaling on the numerical data and one hot encoding on the categorical features. To identify hidden structure across these layers we used Maui (Multi-omics Autoencoder Integration) [1], and Phenograph [2] for subsequent clustering of patients within the extracted latent space. We examined the most discriminatory features post-hoc with SHAP. With Kaplan Meier curves we assessed MTX efficacy using treatment switch as proxy for failure. We calculated hazard ratios (HR) with univariate Cox-regression.
Results: We had 944 RA patients with baseline health record data. MAUI identified 23 latent factors from 335 baseline variables. Phenograph showed 6 RA-subgroups (Table 1 & Figure 1).
The baseline clusters (C) are characterized by a different joint involvement or lab value: C1 had a low aCCP-positivity (37%) and high median ESR of 33. C1 had the most affected joints (primarily the small joints) with a swollen- (SJC) and tender joint count (TJC) of 15 and 19 respectively. C2 had mediocre aCCP-positivity (50%) and low median SJC=6 and TJC=9. C3 had MTP involvement, high aCCP-positivity (64%), and low ESR=19 but relatively high joint counts; SJC=9 and TJC=12. C4 had no wrists, high aCCP-positivity (65%), high ESR=28 and low joint counts; SJC=2, TJC=4. C5 had low lymphocyte numbers and a low median ESR=23, SJC=4 and TJC=3. C6 had MCP1 involvement, was mostly aCCP-positive (59%) and had a slightly higher median ESR=25, SJC=9 and TJC=11.

Table 1. Baseline characteristics of the different clusters

	C1	C2	C3	C4	C5	C6

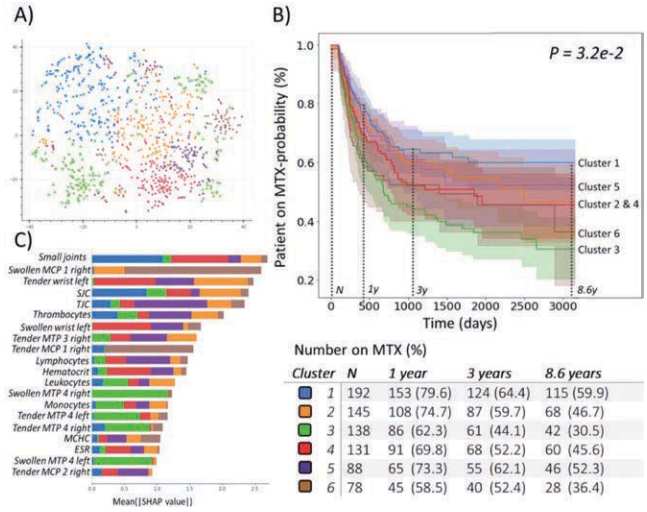
Symptom duration (days)	124 (52-334)	155 (46-537)	155 (62-365)	217 (77-775)	186 (62-548)	155 (62-365)

Presented are *binary variables as n(%) and continuous as median (Q1-Q3) or mean (SD).



Number on MTX (%)

Cluster	N	1 year	3 years	8.6 years
1	192	153 (79.6)	124 (64.4)	115 (59.9)
2	145	108 (74.7)	87 (59.7)	68 (46.7)
3	138	86 (62.3)	61 (44.1)	42 (30.5)
4	131	91 (69.8)	68 (52.2)	60 (45.6)
5	88	65 (73.3)	55 (62.1)	46 (52.3)
6	78	45 (58.5)	40 (52.4)	28 (36.4)

Figure 1. Overview of the distinct RA-clusters: A) 2D UMAP, B) Kaplan Meier plot of MTX-probability across 8.6 years (defined by cluster with shortest follow up), C) SHAP plot of most discriminatory features per cluster.

Clusters differed in MTX failure: 40%, 53%, 69%, 54%, 48% and 64% (for cluster 1-6, *P=3.2e-2*). Examining the local differences, we observed the biggest difference between C1 and C3 (HR 0.5 (95% CI 0.36-0.7), *P=4.4e-5*).

Conclusion: Using baseline data, we identified 6 putative novel RA subtypes which were associated with differences in MTX failure. Our study demonstrates the applicability of unsupervised deep learning and cluster analysis to elucidate hidden structure in the multi-modal EHR.

POS0571

THE ROLE OF PROINFLAMMATORY CYTOKINES (IL-6 AND IL-17) IN PREDICTING 6-YEAR RESULTS OF EARLY RA THERAPY

V. Rybakova[1], A. Avdeeva[1], E. Nasonov[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, laboratory of immunology and molecular biology rheumatic diseases, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Objectives: To evaluate the dynamics of indicators of the cytokine profile and determine their role in predicting long-term results of early rheumatoid arthritis (RA) therapy.

Methods: The research included 93 patients with early RA (16 men and 77 women), average age Me;IQR (58 [49; 66] years), the duration of the disease 7 [4-11,5] months, DAS28-ESR high 59.7% and moderate activity 38.8%. All patients were prescribed a subcutaneous form of methotrexate (MT) at an initial dose of 10 mg / week with a rapid escalation of the dose to 20-30 mg / week. If the effectiveness of the therapy was insufficient, biologics were prescribed. The concentration of 27 cytokines in the blood serum: IL-1b, IL-1Pa, IL-2,-4,-5,-6,-7,-8,-9,-10,-12,-13,-15,-17, Eotaxin, FGF-basic, IFN-γ, IP-10, MCP-1, MIP-1α, MIP-1β, RANTES, TNF-α, VEGF (pg/ml) were determined with the help of the multiplex xMAR technology on the Bio-Plex array system analyzer (BIORAD, USA).

Results: Before the start of the therapy, the DAS 28-ESR was 5.31 [4.79; 6.14], SDAI – 28.27 [18.79; 40.73], after 6 years, the DAS28-ESR was 4.0 [3.4; 4.59], SDAI - 15.06 [9.32; 21]; remission of the disease: DAS 28-ESR was detected in 7.8%, SDAI-5.3%; the low activity: DAS28-ESR in 21%, SDAI in 30.1 %, moderate activity: 60% according to DAS28-ESR, 56% according to SDAI, high activity: 11.2% according to DAS28-ESR, 8.6% according to SDAI. Prior to the start of therapy, the group of patients with RA had a higher level of pro-inflammatory cytokines (IL -6, IL -12, IL -15, IL -17), anti-inflammatory (IL -5, IL -13), chemokines (IP- 10, MIP-1ß, IL-8) and growth factors (IL -7, PDGF-BB, VEGF) compared with healthy donors ($p<0.05$) Table 1. After 6 years, the patients were divided into groups: remission/low activity and moderate/ high activity. Among the patients who achieved remission/low SDAI activity by the 6th year after the initiation of the therapy, a lower level of IL -6, IL -17 after 12 weeks, IL -9 after 24weeks $p<0.05$ was observed. There was a low level of IP-10 ($p=0.06$) 12 weeks after the start of therapy. (Table 2)

Table No. 1 Initial cytokine level of patients with early RA compared with healthy donors (pg/ml)

Parameters	Patients with RA(n=23)	Donors (n=30)
IL-1b	2,52 [2,21; 4,95]	4,07 [2,61;4,9]
IL-1Pa	219,36 [100,29;599,77]	150,64 [111,19; 253,83]
IL-2	7,12 [2,94; 23,12]	10,765 [5,53; 13,87]
IL -4	2,71 [2,33; 4,4]	3,315 [0,21;5,85]
IL -5	6,06 [3,65; 7,66]	2,92 [0,2; 5,24] *
IL -6	36,09 [20,38; 82,02]	7,78 [4,5;13,09] *
IL -7	33,83 [24,74; 64]	8,15 [0,5; 21,52] *
IL -8	27,99 [22,92; 40,54]	12,47 [4,76; 16,25] *
IL -9	23,01 [14,78; 46,54]	34,17 [26,3; 42,36]
IL -10	13,61 [5,24; 33,46]	13,22 [5,83; 37,47]
IL -12	38,14 [19,98; 92,89]	5,775 [2,24; 9,94] *
IL -13	4,53 [0,01; 14,99]	16,685 [9,93; 22,44] *
IL -15	0,37 [0,01; 2,28]	6,695 [3,92; 17,42] *
IL -17	11,24 [5,81; 16,71]	22,87 [5,23; 90,3] *
Eotaxin	263,51 [179,96; 442,95]	102,415 [19,39; 585,69]
FGF-basic	20,83 [15,79; 23,89]	27,25 [19,32; 44,3] *
IFN-γ	111,21 [86,27; 358,6]	285,345 [112,29; 1037,9] *
IP-10	5616,05 [3123,44; 9901,46]	717,8 [188,68; 4064,81] *
MCP-1	36,99 [19,81; 93,85]	48,595 [22,26; 120,74]
MIP-1α	9,51 [8,62; 10,09]	10,815 [8,84; 18,1]
MIP-1β	140,72 [116,05; 174,44]	66,045 [49,36; 99,42] *
PDGF-BB	4975,53 [3031,33; 8994,55]	26024,51 [5854,75; 58715,04]*
TNF-α	42,66 [34,01; 110,11]	38,9 [17,2; 64,87]
VEGF	84,02 [56,71; 160,84]	205,56 [63,85; 312,77] *

p<0,05 from baseline

Table No. 2. The relationship between the dynamics of the cytokine concentration (after 12 and 24 weeks) and the results of therapy after 6 years

	After 12 weeks		After 24 weeks	
Parameters	Remission/low activity according to SDAI (n=30)	Moderate/ high activity according to SDAI (n=63)	Remission/low activity according to SDAI (n=30)	Moderate/ high activity according to SDAI (n=63)
IL -6, pg/ml	7,7 [7,4; 23,3] *	23,5 [12,4; 69,5]	13,8 [5,8; 28,6]	33 [17,4; 45,8]
IL -9, pg/ml	13,5 [9,1; 18,9] *	17,8 [15; 29]	12,6 [6,8; 16,2] *	18,5 [14,2; 22,8]
IL -17,pg/ml	0,01 [0,01; 5,5] *	12,4 [0,01; 24,2]	3,7 [1,4; 9,2]	12,4 [0,01; 23,1]
IP-10, pg/ml	1319 [936; 2586]	2430 [2074; 4023],p=0,06	1358,1 [817; 2504]	1489 [1332; 3005]

*p<0,05 from baseline

Conclusion: The evaluation of the level of proinflammatory cytokines (IL -6, IL -17), chemokines IP-10, immunoregulatory cytokine IL -9 after 12 weeks and 24weeks of the initiation of therapy allows to identify a group with the worst long-term prognosis.

Disclosure of Interests: None declared.

POS0572 ARE WOMEN WITH RHEUMATOID ARTHRITIS REALLY LESS LIKELY TO ACHIEVE REMISSION WITH BIOLOGICS? A COHORT STUDY IN THE SWISS CLINICAL QUALITY MANAGEMENT COHORT

E. Vallejo-Yagüe[1], J. N. Pfund[1], T. Burkard[1], C. Clair[2,3], R. Micheroli[4], B. Moeller[5], A. Finckh[6], A. M. Burden[1]. *[1]ETH Zurich, Department of Chemistry and Applied Biosciences, Institute of Pharmaceutical Sciences, Zürich, Switzerland; [2]Center for Primary Care and Public Health (Unisanté), Department of Training, Research and Innovation, Lausanne, Switzerland; [3]University of Lausanne, Faculty of Biology and Medicine, Lausanne, Switzerland; [4]University Hospital of Zurich, Department of Rheumatology, Zurich, Switzerland; [5]Inselspital, University Hospital of Bern, Rheumatology, Immunology and Allergy, Bern, Switzerland; [6]University Hospitals of Geneva, Division of Rheumatology, Geneva, Switzerland*

Background: Rheumatoid arthritis (RA) affects women three time more frequently than men. However, compared to men, women may have a lower likelihood of achieving clinical response, but data related to this topic are controversial.

Objectives: We aimed to compare the likelihood of achieving remission across men and women with RA, who started their first biologic or targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARDs).

Methods: This observational cohort study in the Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) registry included adult RA patients who started their first b/tsDMARDs (from 1997 to 31/April/2018). Patient characteristics at start of the b/tsDMARD were compared between men and women. Subsequently, logistic regression was used to assess the likelihood of achieving remission during the first year after b/tsDMARDs start, defined by disease activity score 28 (DAS28) <2.6, in men compared to women (reference group). Secondary analyses were adjusted for age and seropositivity as prognostic factors, and we investigated the role of potential mediators or factors that could explain the findings from the main analysis.

Results: The study included 3722 RA patients, of which 2839 (76.3%) were women and 883 (23.7%) were men. Compared to women, men were older at diagnosis and start of b/tsDMARDs, and had shorter time from diagnosis to their first b/tsDMARD (3.4 vs 5.0 years, p<0.001). At baseline (b/tsDMARD initiation), women had significantly more active disease activity (DAS28) and worse patient-reported outcomes (Health Assessment Questionnaire, tender joints). Concomitant osteoporosis and depression/anxiety were more frequent among women, while men had more frequent diabetes and prior or current smoking record. Physician's global disease assessment and swollen joints were similar across groups. Compared to women, men were 21% more likely to achieve DAS28-remission, with an odds ratio (OR) 1.21, 95% confidence interval (CI) 1.02-1.42. Secondary analyses adjusting by for age and seropositivity did not change the findings (adjusted OR 1.24, 95% CI 1.05-1.46). Our analyses of potential mediators suggested that the observed effect may be explained by the shorter disease duration and lower DAS28 at treatment initiation in men vs women.

Conclusion: Men started b/tsDMARDs at an earlier stage of disease than women, particularly regarding disease duration and disease activity (DAS28) at b/tsDMARD initiation, and they presented higher odds of remission. This highlights the importance of an earlier treatment, and it suggests to target an earlier stage of disease in women to match the benefits observed in men.

POS0573 MUSCULOSKELEATAL ULTRASOUND STUDIES ARE CRITICAL FOR DETECTING SERONEGATIVE INFLAMMATORY ARTHRITIS

C. Lin[1], R. Chou[1]. *[1]University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Division of Allergy, Immunology, & Rheumatology, Department of Medicine, Buffalo, New York, United States of America*

Background: The autoantibody status of rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP Ab) has gained widespread recognition for its role in the diagnosis of rheumatoid arthritis (RA) based on the latest diagnostic criteria for RA.[1] However, in early disease, the rates of antibody expression have been reported as low as 50%[2], rendering early diagnosis of RA difficult. Furthermore, the nature of seronegative rheumatoid arthritis is unknown, though it is presumed to have less aggressive disease course as compared to its seropositive counterparts. Musculoskeletal (MS) ultrasound studies have been widely used in recent clinical practice to assess soft-tissue abnormalities of the joints and disease states in RA, such as synovitis and bone erosions. MS ultrasound studies were recently shown to be more sensitive to detect early synovial changes and erosions than other radiographic methods while maintaining cost-effectiveness.[3-5] We hypothesize that MS ultrasound studies are more sensitive to detecting inflammatory changes in seronegative inflammatory arthritis, which is often subclinical in presentation.

Objectives: To assess the role of MS ultrasound studies in detecting early inflammatory changes in the joints and diagnosing seronegative inflammatory arthritis.

Methods: A retrospective electronic medical record review was performed of all patients at the two University at Buffalo rheumatology clinics who underwent MS ultrasound studies after complaining of multiple joint pain. All these patients were previously seen and evaluated by at least one other medical provider, who found no evidence of inflammatory arthritis on physical examination. These patients did not meet diagnostic criteria for rheumatoid arthritis due to a lack of gross joint swelling and/or positive serological makeup. As part of their clinical care, they were referred to obtain MS ultrasound studies to rule out inflammatory arthritis. All patients were de-identified at initial data collection. Information pertaining to the patients' 1) demographics (gender, age, ethnicity, etc.), 2) findings of MS ultrasound studies, and 3) serological studies (RF, anti-CCP Ab, HLA-B27) was collected and tabulated.

Results: Of the 363 patients who underwent MS ultrasound studies, 280 of them (77.1%) of them were found to have synovial hypertrophy [minimal = 23%, mild = 46%, moderate = 29%, severe = 2%] in bilateral MCP, PIP, carpal, and/or MTP joints, therefore conferring a diagnosis of inflammatory arthritis. The average age of these 280 patients was 48.35 ± 14.86 years old at the time of diagnosis, with female to male ratio of 4.38:1. Surprisingly, of these 280 patients with evidence of inflammatory arthritis, 69 (24.6%) of them were found to have joint erosions with either MCP or MTP joints, supporting a diagnosis of advanced inflammatory arthritis with erosive disease. The erosions were predominantly located in MTP joints (77.1%) as compared to MCP joints (22.9%). Therefore, our findings clearly demonstrated distinct clinical and ultrasonography features of seronegative inflammatory arthritis (SNIA) as compared to seropositive RA.

Conclusion: MS ultrasound studies are more sensitive to and critical for detecting inflammatory changes and joint damages in SNIA due to its subclinical presentation. Based on our findings, SN IA is underdiagnosed in individuals who complain of joint pain without gross synovitis. SNIA also likely has distinct pathophysiology that needs further characterization.

POS0574 FEMALE GENDER AND STRESS ARE MAIN DETERMINANTS OF NON-ADHERENCE AND NEGATIVE ILLNESS PERCEPTION AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: SINGLE CENTRE RESULTS FROM THE PRIME REGISTRY COHORT

F. Hashmi[1], M. Haroon[1], S. Asif[1], S. Ullah[1], S. Javed[1]. [1]*Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*

Background: Adherence to medications among patients with RA is traditionally considered to be low. Little is known about the indicators and the outcomes of patients having good adherence to medications among Pakistani RA patients.
Objectives: We aimed to assess the level of non-adherence and its associations with clinical indicators and outcomes using validated measures in a large consecutive Pakistani RA population. Moreover, we measured illness perception using additional validated tools to help us better understand this concept.
Methods: This was a cross-sectional study conducted using data collected at the time of patient enrolment in the PRIME registry. IRB approval and informed consent was obtained. The clinical variables studied were gender, age, smoking habits, body mass index, education status, marital status, disease duration, Charlson Comorbidity Index. Education status was stratified by whether participants completed secondary (high) school education. Evaluation of disease activity and severity was made as per internationally agreed definitions. To measure adherence, the instrument used in the study was the Urdu version of the General Medication Adherence Scale (GMAS), which has been validated for RA patients. Brief Illness Perception Questionnaire (BIPQ) is the simplified version of the Illness Perception Questionnaire (IPQ). BIPQ is a nine-item scale designed to rapidly assess the cognitive and emotional representations of illness. To facilitate interpretation of results in daily clinical practice and to identify patients with the most negative illness perception, we dichotomized the BIPQ scores using the 75th interquartile range score as cutoff, as previously done.
Results: The data of consecutive 320 RA patients enrolled in PRIME registry (mean age 37.4±13.4 years, 74% female, disease duration of 73±68 months, 30% rural residents, 32.5% had low education status of ≤primary school, and 35% of the cohort was employed) was reviewed. Thirty six percent of the cohort (n=116) was noted to have non adherence. On multiple logistic regression analysis, a significant association of moderate-severe stress (OR 1.85, CI 1.04-3.2, p=0.03), DAS-28 scores (OR 1.83, CI 1.52-2.21, p<0.001), HAQ scores (OR 1.77, CI 1.07-2.92, p=0.02), deformed joint counts (OR 1.30, CI 1.15-1.46, p<0.001). We further examined the concept of non-adherence among our cohort across three domains or components of GMAS questionnaire individually. Firstly, on multivariate regression analysis showed that non-adherence due to patient behavior had significant association with male gender (OR 0.48, p=0.01), unemployment (OR 1.82, p=0.02), stress (OR 2.17, p=0.001), DAS-28 (OR 1.15, p=0.050), worse HAQ scores (OR 1.83, p=0.005). Secondly, multivariate regression analysis showed that non-adherence due to comorbidity and pill burden was associated with age of onset of arthritis (OR 1.02, p=0.006), DAS-28 (OR 1.18, p=0.03), and HAQ (OR 1.81, p=0.008). Thirdly, multivariate regression analysis showed that cost-related non-adherence had no significant association with patient related demographics and traits, but was noted to have significant association with worse DAS-28 and HAQ scores. The mean total BIPQ score of the cohort was 62±8.8. Twenty six percent of the cohort (n=86) was noted to have the most negative illness perception (BIPQ score of >68). On multiple logistic regression analysis, a significant protective association of male gender (OR 0.24, CI 0.11-0.53, p<0.001) and age of onset of arthritis (OR 0.96, CI 0.94-0.99, p=0.01), along with significant association of worse HAQ scores (OR 3.7, CI 2.2-6.1, p<0.001) was noted with the most negative illness perception.
Conclusion: Non-adherence is common and its main determinants were female gender and stress, along with associated adverse clinical outcomes. Gender-based discrimination in low socioeconomic states along with associated stress is a plausible explanation.

POS0575 CAPACITY OF SIX DIFFERENT CARDIOVASCULAR RISK ALGORITHMS FOR THE DETECTION OF CAROTID PLAQUE IN RHEUMATOID ARTHRITIS

N. Guajardo-Jauregui[1], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], A. Cárdenas3, A. N. Garza-Cisneros3, A. Garcia-Heredia[2], M. A. Balderas-Palacios3, A. B. Rodriguez-Romero3. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico;* [2]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico;* [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*

Background: Current EULAR recommendations for cardiovascular risk (CVR) assessment in rheumatoid arthritis (RA) indicate that the CVR evaluation should be performed according to national guidelines; however, there was no algorithm designed for the Mexican population until 2019, when the World Health Organization (WHO) published the CVR charts for 21 world regions, including Mexico (1).
Objectives: To determine the capacity of the WHO and other five algorithms for the detection of carotid plaque (CP) in RA patients.
Methods: Cross-sectional study. We included 164 patients with RA diagnosis according to the 2010 ACR/EULAR classification criteria, aged 40-75 years. CVR was calculated with six algorithms: WHO, FRS-lipids, FRS-BMI, SCORE, ACC/AHA and QRISK3. Carotid ultrasound was performed in all patients to identify the presence of CP. A ROC-curve analysis was performed, and the cutoff points of each algorithm were determined using the Youden Index. Area under the curve (AUC), sensitivity, specificity, and likelihood ratios (LR) were calculated. A *p*-value <0.05 was considered statistically significant.
Results: The prevalence of CP was 35.9%. The WHO algorithm showed AUC: 0.729 (0.649-0.809), cutoff point: 5.25, sensitivity: 72.9%, and specificity: 64.8%. FRS-lipids showed AUC: 0.684 (0.601-0.767), cutoff point: 8.62, sensitivity: 67.8%, and specificity: 61.0%. FRS-BMI showed AUC: 0.700 (0.618-0.781), cutoff point: 11.55, sensitivity: 72.9%, and specificity: 61.0%. SCORE showed AUC: 0.687 (0.601-0.773), cutoff point: 1.5, sensitivity: 79.7%, and specificity: 45.7%.

Table 1. Capacity of cardiovascular risk algorithms to detect presence of carotid plaque in rheumatoid arthritis patients

		CI 95%					Likelihood radio	
Algorithms (cut-off points)	**AUC**	**Inferior limit**	**Superior limit**	*p*	**Sensibility**	**Specificity**	**+**	**-**
WHO (5.25)	0.729	0.649	0.809	<0.001	72.9%	64.8%	2.07	0.42
FRS-lipids (8.62)	0.684	0.601	0.767	<0.001	67.8%	61.0%	1.74	0.53
FRS-BMI (11.55)	0.700	0.618	0.781	<0.001	72.9%	61.0%	1.87	0.44
SCORE (1.5)	0.687	0.601	0.773	<0.001	79.7%	45.7%	1.47	0.44
ACC/AHA (3.82)	0.687	0.604	0.770	<0.001	62.7%	61.0%	1.61	0.61
QRISK3 (6.05)	0.733	0.654	0.811	<0.001	71.2%	61.0%	1.82	0.47

AUC, area under the curve; WHO, World Health Organization; FRS, Framingham Risk Score; BMI, body mass index.

ACC/AHA showed AUC: 0.687 (0.604-0.770), cutoff point: 3.82, sensitivity: 62.7%, and specificity: 61.0%. QRISK3 showed AUC: 0.733 (0.654-0.811), cutoff point: 6.05, sensitivity: 71.2%, and specificity: 61.0%. All algorithms had a *p*-value <0.001 (Figure 1 and Table 1).

Conclusion: The WHO calculator was one of the best algorithms for the detection of CP, with the best positive and negative likelihood ratios; however, like the other algorithms, a lower cut-off point than the one established by official guidelines was needed to identify high-risk patients with the presence of CP, who were initially classified as low-moderate risk by the CVR algorithm.

POS0576

ASSOCIATION BETWEEN POTENTIAL PROGNOSTIC FACTORS AND ADVERSE HEALTH OUTCOMES IN RHEUMATOID ARTHRITIS: A STUDY OF 5658 UK BIOBANK PARTICIPANTS

J. Canning[1], S. Siebert[2], B. Jani[1], F. Mair[1], B. Nicholl[1]. [1]*University of Glasgow, General Practice and Primary Care, Glasgow, United Kingdom;* [2]*University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom*

Background: There is a pressing need to identify simple prognostic factors, which are readily available in primary and secondary care settings, that can predict adverse health outcomes in people with rheumatoid arthritis (RA). Exploring various clinical, physiological and patient-reported measures as prognostic factors may enhance risk stratification and promote more personalised care for RA patients.

Objectives: To determine the association, if any, between selected prognostic factors and all-cause mortality and major adverse cardiovascular events (MACE; including myocardial infarction and stroke) in an RA population.

Methods: UK Biobank participants that self-reported RA were included in this study. Prognostic factors were selected from the literature based on relevance, predictive potential, simplicity and accessibility in a primary/secondary care setting. Those included were categorised into the following domains: anthropometric measures (body mass index (BMI), body fat percentage, waist circumference, waist-to-hip ratio), functional measures (hand grip strength (HGS), usual walking pace (UWP)), inflammatory markers (C-reactive protein (CRP)), patient-reported measures (pain), physiological measures (blood pressure (BP), heart rate (HR)) and serological markers (rheumatoid factor (RF)), with normal ranges used as reference categories. Associations between individual factors and outcomes were explored using Cox proportional hazards models. Models were adjusted for age, sex, socioeconomic status, number of additional long-term conditions and smoking status in the first instance to identify potential individual predictors. Models were then further adjusted for any identified individual predictors to determine the most important prognostic factors.

Results: 5658 (1.1%) UK Biobank participants self-reported RA (mean age 59 (standard deviation 7.13); 69.8% female). 670 deaths (median 11 years) and 370 MACE (median 8 years) were recorded during the follow-up period. Several significant individual associations with all-cause mortality (Figure 1A) and MACE (Figure 1B) were found. After further adjustment for these significant individual predictors, the following factors demonstrated significant associations with risk of all-cause mortality, independent of the other significant predictors: underweight BMI (<18.5kg/m^2) (hazard ratio (HR) 2.96 [95% confidence intervals (CI) 1.59-5.51]), obese BMI (≥30.0kg/m^2) (HR 0.52 [95% CI 0.36-0.76]), 3-10mg/L CRP (HR 1.41 [95% CI 1.14-1.75]), >10mg/L CRP (HR 1.77 [95% CI 1.39-2.26]), low HGS (<16kg female or <27kg male) (HR 1.28 [95% CI 1.05-1.56]) and slow UWP (patient-reported) (HR 1.31 [95% CI 1.06-1.62]). Likewise, the following factors were found to be significantly associated with MACE, independent of other significant factors: >10mg/L CRP (HR 1.62 [95% CI 1.19-2.20]), low HGS (HR 1.61 [95% CI 1.26-2.07]) and slow UWP (HR 1.50 [95 % CI 1.15-1.97]).

Conclusion: In this RA population, the risk of all-cause mortality was approximately three-fold higher in those who have an underweight BMI when compared to those who have a BMI in the normal range, when adjusted for all other significant factors, while an obese BMI appeared to lower this risk, consistent with the "obesity paradox" reported in RA [1]. Increased levels of CRP, low HGS and slow UWP were also all independently associated with an increased risk of all-cause mortality and MACE. Our findings highlight the potential value of these factors for predicting adverse outcomes in RA populations. A simple, yet multidimensional approach to risk assessment, combining well-tolerated, easily repeatable measures such as those included here may provide important prognostic information at both primary and secondary care levels, while limiting excessive and overly invasive testing on RA patients.

POS0577 COMPARISON OF THE WHO AND ACC/AHA CARDIOVASCULAR ALGORITHMS TO DETECT CAROTID PLAQUE IN RHEUMATOID ARTHRITIS

N. Guajardo-Jauregui[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], A. Cárdenas[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[2], M. A. Balderas-Palacios[1], A. B. Rodriguez-Romero[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; [2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*

Background: Cardiovascular disease is the major cause of death in rheumatoid arthritis (RA) patients. Cardiovascular risk algorithms are used to estimate the probability for the development of a cardiovascular event in 10 years, according to patients' characteristics, however, no algorithm existed for the Hispanic population until the World Health Organization (WHO) published the cardiovascular disease risk charts for 21 regions (1).
Objectives: To compare the capacity of the 2019 WHO algorithm and the 2013 American College of Cardiology/American Heart Association (ACC/AHA) algorithm for detecting the presence of carotid plaque (CP) in RA patients.
Methods: Cross-sectional study. We recruited a total of 164 patients with RA diagnosis, according to the 2010 ACR/EULAR classification criteria, aged 40-75 years. Patients with a previous cardiovascular event were excluded. Cardiovascular risk was evaluated with the 2019 WHO algorithm for the Mexican population and the 2013 ACC/AHA cardiovascular algorithm. The results were multiplicated by 1.5, according to current guidelines. A carotid ultrasound was performed to all study subjects by a certified radiologist blinded to clinical information. Distribution was evaluated with the Kolmogorov-Smirnov test. Correlations were performed with the Spearman-rho coefficient (rho). A ROC-curve analysis was performed for both algorithms. The areas under the curve (AUC) of the algorithms were compared using the method of DeLong.
Results: The presence of CP was detected in 59 (36.0%) patients. Demographic characteristics are shown in Table 1. There was a large positive correlation between the WHO and the ACC/AHA algorithms (rho=0.880, p=<0.001). Both algorithms showed significant discrimination for the presence of CP in RA patients, the WHO algorithm had an AUC 0.729 (95% CI 0.649-0.809, p=<0.001) and the ACC/AHA algorithm had an AUC 0.687 (95% CI 0.604-0.770, p=<0.001). However, there was a difference when comparing both AUC, which was higher with the WHO algorithm (p=0.042) (Figure 1).

Table 1. Demographic characteristics of RA patients

Characteristics	RA patients (n=164)
Age, years, mean ± SD	55.82 ± 8.94
Women, n (%)	157 (95.73)
T2DM, n (%)	27 (16.46)
Hypertension, n (%)	53 (32.32)
Dyslipidemia, n (%)	58 (35.36)
Obesity, n (%)	56 (34.15)
Active smoking, n (%)	15 (9.15)
WHO algorithm, median (IQR)	4.5 (3.0-9.0)
ACC/AHA algorithm, median (IQR)	3.75 (1.80-9.26)
Carotid plaque, n (%)	59 (36.0)

RA, rheumatoid arthritis; T2DM, type 2 diabetes mellitus; WHO, world health organization; ACC/AHA, American College of Cardiology/American Heart Association.

Conclusion: Our results showed that although both algorithms had significant discrimination for the presence of CP, the 2019 WHO algorithm had a better capacity for the detection of CP than the 2013 ACC/AHA algorithm, for this specific Hispanic RA population. This could be attributed to the fact that the WHO algorithm was designed for 21 different regions, including the Mexican population.

POS0578 RISK AND RISK FACTORS OF MORTALITY IN RHEUMATOID ARTHRITIS PATIENTS WITH INTERSTITIAL LUNG DISEASE: A NATIONWIDE, POPULATION-BASED COHORT STUDY

H. H. Chen[1], D. Y. Chen[2]. *[1]Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China; [2]China Medical University Hospital, Center of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China*

Background: Recent meta-analysis by Meihua Qiu et al [6] has shown ten factors associated with increased risk of mortality in rheumaoitd arthritis associated interstitial lung disease (RA-ILD): older age, male sex, smoking history, lower diffusing capacity of the lung for carbon monoxide, lower forced vital capacity predicted, higher composite physiological index, usual interstitial pneumonia pattern on high-resolution computed tomography, emphysema presence and acute exacerbation of ILD. However majority of the studies were single-centre studies. There were very limited studies on influence of treatment, especially disease-modifying anti-rheumatic drugs on mortality in RA-ILD.
Objectives: To examine the risk and risk factors of mortality among RA patients with ILD.
Methods: Using the 1997-2013 Taiwanese National Health Insurance Research Database, we identified 32,289 newly diagnosed RA patients from 2001 to 2013. Of them, 214 subsequently developed ILD. We then matched RA patients with ILD at a ratio of 1:10 to RA patients without ILD by sex, age at RA diagnosis, year of RA diagnosis date and disease duration. We further conducted propensity score matching (PSM) at a 1:1 ratio for selected comorbidities using the greedy algorithm to select RA-ILD patients and controls. We examined the association of mortality with ILD in RA patients using the Cox proportional hazard model shown as adjusted hazard ratios (aHRs) with 95% confidence intervals (CIs). Among 214 RA-ILD patients, we assessed factors associated with mortality using the multivariable Cox regression analysis.
Results: Before PSM, a total of 164 RA-ILD patients and 1,640 RA patients without ILD were selected. After PSM, 155 RA-ILD patients and non-ILD RA controls were included. The incidences of mortality were 2,975 per 10^5 years and 2,981 per 10^5 years in the RA-ILD group before and after PSM, respectively. The incidence rate ratios (95% CIs) of mortality were 2.66 (1.95–3.63) and 2.55 (1.51–4.29) in the populations before and after PSM, respectively. Using the multivariable Cox regression analysis and the conditional Cox regression analysis, the risk of mortality was associated with ILD in RA patients (before PSM: aHR, 3.17 [2.17–4.63]; after PSM: 7.16 [1/76–29.15]). Among 214 RA-ILD patients, significant predictors for mortality included male gender (aHR, 2.59), age (aHR, 1.04), residence in suburban region (aHR, 2.29), peripheral vascular disease (PVD) (aHR, 83.26) and chronic pulmonary obstructive disease (COPD) (aHR, 2.73). The risk of mortality was not associated with use of non-steroidal anti-rheumatic drugs, corticosteroid, methotrexate, sulfasalazine, leflunomide, hydroxychloroquine, immunosuppressants, tumor necrosis factor inhibitors and rutixumab.
Conclusion: This population-based, cohort study demonstrated that ILD was associated with increased risk of mortality in RA patients, and risk factors for mortality in RA-ILD patients included male, age, residence in suburban region, PVD and COPD. Use of DMARDs was not associated with the risk of mortality in RA-ILD patients.

ABSENCE OF ASSOCIATION BETWEEN ABATACEPT EXPOSURE LEVELS AND INITIAL INFECTION IN PATIENTS WITH RA: A POST HOC ANALYSIS OF THE RANDOMIZED, PLACEBO-CONTROLLED AVERT-2 STUDY

P. Emery[1,2], R. Fleischmann[3], R. Wong[4], K. Lozenski[5], Y. Tanaka[6], V. Bykerk[7], C. Bingham[8], T. Huizinga[9], G. Citera[10], Y. Elbez[11], V. Perera[12], B. Murthy[12], K. Maxwell[13], J. Passarell[14], W. Hedrich[12], D. Williams[12]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [2]Leeds Teaching Hospitals NHS Trust, Leeds NIHR Biomedical Research Centre, Leeds, United Kingdom; [3]University of Texas, Division of Rheumatology, Dallas, United States of America; [4]Bristol Myers Squibb (at the time of analysis), Immunology and Fibrosis, Princeton, United States of America; [5]Bristol Myers Squibb, Immunology and Fibrosis, Princeton, United States of America; [6]University of Occupational and Environmental Health, First Department of Internal Medicine, Kitakyushu, Japan; [7]Hospital for Special Surgery, Department of Rheumatology, New York, United States of America; [8]Johns Hopkins University, Divisions of Rheumatology and Allergy, Department of Medicine, Baltimore, United States of America; [9]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [10]Instituto de Rehabilitación Psicofísica, Department of Rheumatology, Buenos Aires, Argentina; [11]Significence, Biostatistics, Paris, France; [12]Bristol Myers Squibb, Clinical Pharmacology and Pharmacometrics, Princeton, United States of America; [13]Cognigen Corporation, a Simulations Plus company, Pharmacometrics, Buffalo, United States of America; [14]Cognigen Corporation, a Simulations Plus company, Statistics, Buffalo, United States of America*

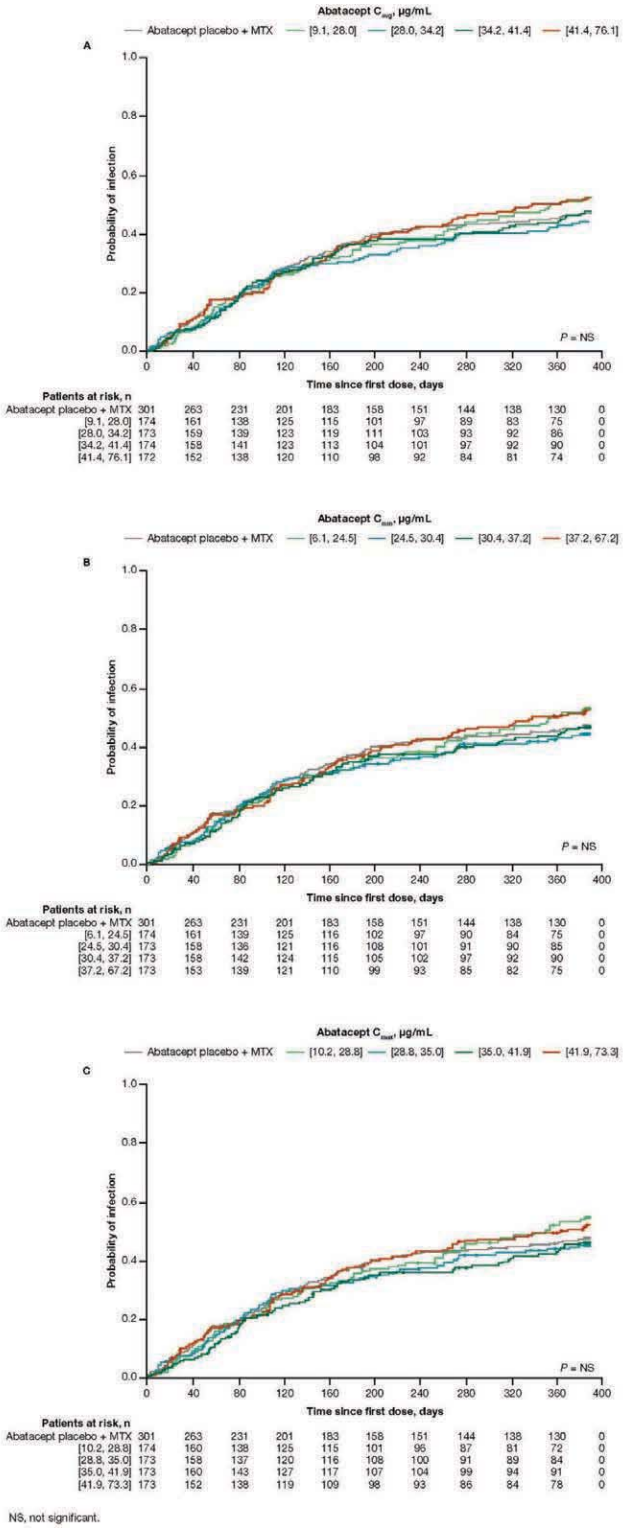
Background: Infections are the most commonly reported AE observed in patients with RA treated with immunosuppressive therapies and can be clinically significant. A recent review reported differences in the risk of infection for some biologics such as tocilizumab and TNF inhibitors.[1] Abatacept selectively modulates T-cell co-stimulation and is approved for the treatment of RA. In patients with polyarticular-course juvenile idiopathic arthritis, no association was found between higher serum abatacept exposure and the incidence of infection.[2] This has not been evaluated for adult patients with RA.

Objectives: To determine if higher serum abatacept exposure during treatment with SC abatacept was associated with increased risk of infection in adult patients with RA.

Methods: AVERT-2 (Assessing Very Early Rheumatoid arthritis Treatment-2) was a randomized, placebo-controlled study of SC abatacept + MTX vs abatacept placebo + MTX in MTX-naive, anti-citrullinated protein antibody–positive patients with early, active RA.[3] A post hoc population pharmacokinetic (PK) analysis was performed using PK-evaluable patient data from the induction period (year 1) of AVERT-2. Association between steady-state abatacept exposure (min plasma concentration [C_{min}], max plasma concentration [C_{max}], and average plasma concentration [C_{avg}]) and first infection was evaluated using Kaplan–Meier plots of probability vs time on treatment by abatacept exposure quartiles and Cox proportional-hazards models.

Results: PK of SC abatacept was defined as a linear 2-compartment model with first-order absorption and first-order elimination. The findings of the updated PK analysis were consistent with those reported in prior population analyses of abatacept PK in adults with RA. The final model included effects of baseline body weight, estimated glomerular filtration rate, sex, age, albumin, MTX use, NSAID use, SJC, and race on abatacept clearance. The only covariate with a clinically relevant effect was higher body weight, which caused an increase in clearance and volume. Infections occurred in a total of 330/693 (47.6%; serious, 1.6%) patients treated with abatacept, and 134/301 (44.5%; serious, 1.3%) with placebo during the first year of AVERT-2. In patients taking abatacept, the mean (SD) study exposure to abatacept was 376 (60) days, while mean (SD) prednisone equivalent dose was 6.7 (3.8) mg/day and mean (SD) MTX dose was 9.6 (3.0) mg/week. No exposure–response relationship was observed between the probability of first infection and steady-state abatacept exposure quartiles (C_{avg}, C_{min}, and C_{max}), or compared with placebo (Figure 1A–C). Kaplan–Meier assessment also showed no increase in risk of infection with concomitant use of MTX and glucocorticoids.

Conclusion: No association was found between initial infection and steady-state abatacept exposure (C_{avg}, C_{min}, C_{max}) or MTX and glucocorticoid use in patients with RA treated with SC abatacept.



NS, not significant.

TRENDS IN THE OCCURRENCE OF ISCHEMIC HEART DISEASE OVER TIME IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY FROM NORWAY OF 1821 PATIENTS FROM 1972 TO 2014

C. L. Alsing[1,2], T. W. Nystad[3], J. Igland[4,5], C. G. Gjesdal[2,3], H. Midtbø[6], G. S. Tell[4,7], B. T. Svanes Fevang[2,3]on behalf of BEaBiRD - Bergen group of Epidemiology and Biomarkers in Rheumatic Disease. *[1]Haraldsplass Deaconess Hospital, Department of Internal Medicine, Bergen, Norway; [2]University of Bergen, Department of Clinical Science, Bergen, Norway; [3]Haukeland University Hospital, Department of Rheumatology, Bergen, Norway; [4]University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway; [5]Western Norway University of Applied Science, Department of Health and Social Science, Centre for Evidence-Based Practice, Bergen, Norway; [6]Haukeland University Hospital, Department of Heart Disease, Bergen, Norway; [7]Norwegian Institute of Public Health, Division of Mental and Physical Health, Bergen, Norway*

Background: Previous studies have shown that rheumatoid arthritis is associated with a 1.5 to 2.0 times increased risk of acute myocardial infarction (AMI) and ischemic heart disease (IHD) compared with the general population [1,2]. RA treatment has improved vastly over the last two decades, due to the focus on early and aggressive treatment and the use of synthetic and biologic DMARDs. Several studies have documented higher rates of remission and better long-term outcomes in patients with early introduction of DMARDs [3]. This "window of opportunity" may also be a critical phase for intervention against the development of atherosclerosis in RA. There is little information about the occurrence of AMI and IHD in RA patients diagnosed after the introduction of modern RA treatment.
Objectives: To evaluate trends of AMI and IHD in RA patients compared with the general population over time.
Methods: We performed a retrospective cohort study of 1821 RA patients diagnosed from 1972 to 2013. The total population of Hordaland, Norway was used as a comparison cohort. Information on AMI and IHD events was obtained from hospital patient administrative systems or cardiovascular registries during 1972-2014. Aggregated counts of AMI, IHD and population counts of the comparison cohort were used to calculate expected counts of AMI and IHD in the RA cohort per 5-year age group, sex and calendar year. We then used Poisson regression with expected counts as an offset to estimate standardized event ratios (SER) as a measure of excess events.
Results: The difference in events (excess events) in RA patients compared with the general population declined on average 1.3% per year for AMI and 2.3% for IHD from 1972 to 2014. There was no significant excess AMI (SER 1.05, 95% CI 0.82–1.35) and IHD events (SER 1.02, 95% CI, 0.89–1.16) for RA patients diagnosed after 1998 compared with the general population.
Conclusion: RA patients have historically had an excess risk of IHD compared with the general population. Our study did not find excess AMI or IHD events in RA patients diagnosed after 1998. Our findings may reflect improved management of RA, CVD prevention or changes in the case-mix of RA patients over time.

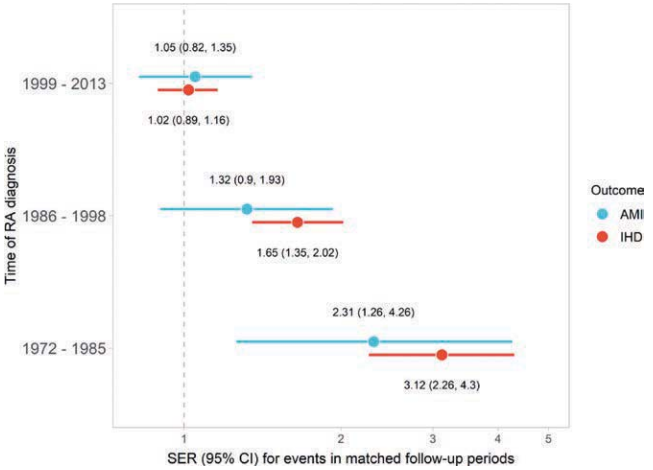

Figure 1. Excess AMI and IHD events in RA patients compared with the general population. RA patients are divided into three groups by the time of RA diagnosis. End of follow-up was set to 1 year after the end of each diagnostic period (1986, -99 and 2014 respectively) to allow for equal RA duration between groups. Point estimates are standardized event ratios comparing the number of events in the RA cohort to the expected number of events calculated from reference rates in the general population and standardized for age, sex and year of the event. All estimates are given with robust 95% confidence intervals (CI). Both the RA and general population were obtained from Hordaland, Western Norway. AMI, acute myocardial infarction; IHD, ischemic heart disease.

POS0581

HIGHER SKIN AUTOFLUORESCENCE IN INDIVIDUALS AT RISK FOR RHEUMATOID ARTHRITIS: RESULTS FROM A LARGE POPULATION BASED COHORT

H. Hinkema[1], S. Arends[1], D. J. Mulder[2], J. Westra[1], E. Brouwer[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Internal Medicine, Groningen, Netherlands*

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease which is associated with increased mortality, mostly because of a higher incidence of cardiovascular disease (CVD), which cannot be explained by traditional risk factors alone. (1,2) Also studies showed that the cardiovascular events can already occur at a higher than expected rate shortly after the first symptoms of RA. (3)This raises the question if individuals with clinical suspect arthralgia (CSA) but not yet diagnosed with RA, already have an increased risk for developing cardiovascular disease compared to healthy controls and if this is also true for ACPA positive individuals without symptoms of clinical suspect arthralgia. In our study we used skin autofluorescence (SAF), measured with the AGE reader, as an early non-invasive tool to identify subjects who are at increased risk for developing cardiovascular disease. (4) SAF measures the accumulation of AGEs in the skin and thereby offers a simple alternative to invasive measurement of AGE accumulation. (5)
Objectives: To investigate skin autofluorescence (SAF) levels, as an early indicator for cardiovascular disease, in relation to the presence of anticitrullinated

protein antibodies (ACPA), clinical suspect arthralgia (CSA) and rheumatoid arthritis (RA) in a large population-based cohort.
Methods: Cross-sectional data were used from 17346 participants of the Dutch Lifelines Cohort Study, of whom baseline SAF and ACPA levels were available. The presence of CSA was determined using EULAR questions from the connective tissue disease screening questionnaire (CSQ). Individuals were divided into four groups: ACPA negative controls (n=17211), ACPA positive without CSA (n=49), ACPA positive with CSA (n=31) and defined RA (n=52). Multinomial regression was used to compare SAF levels and correct for potential confounders.
Results: SAF levels were higher in the ACPA positive with CSA group (OR 2.04, p=0.034) and the defined RA group (OR 3.10, p<0.001) compared to controls, but not in the ACPA positive without CSA group (OR 1.07, p=0.875). The difference in SAF levels remained statistically significant in the defined RA group after adjusting for age (OR 2.09, p=0.011), smoking status, renal function or HbA1c. In the ACPA positive with CSA group, the effect was found to be comparable (corrected for age: OR 2.09).
Conclusion: Our results indicate that ACPA positive individuals with CSA have elevated SAF levels, which is regarded as an early marker for oxidative stress and a possible indicator for development of cardiovascular disease. Therefore it is important to conduct further studies to explore if, in individuals with clinical suspect arthralgia, cardiovascular risk management should be considered in future clinical practice.

RHEUMATOID ARTHRITIS BENEFITS FROM FASTING AND PLANT-BASED DIET: AN EXPLORATORY RANDOMIZED CONTROLLED TRIAL (NUTRIFAST)

A. M. Hartmann[1,2], F. I. Kandil[1,3], N. Steckhan[1,4], T. Häupl[1,5], C. S. Kessler[1,6], A. Michalsen[1,6], D. A. Koppold-Liebscher[1]. *[1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Institute of Social Medicine, Epidemiology and Health Economics, Berlin, Germany; [2]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Dermatology, Venereology and Allergology, Berlin, Germany; [3]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Paediatric Oncology/Haematology, Otto-Heubner Centre for Paediatric and Adolescent Medicine (OHC), Berlin, Germany; [4]Hasso Plattner Institute, University of Potsdam, Connected Healthcare, Potsdam, Germany; [5]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [6]Immanuel Hospital Berlin, Department of Internal and Integrative Medicine, Berlin, Germany*

Background: Fasting has been shown to be beneficial in many diseases, including rheumatoid arthritis (RA). Among other effects, fasting stimulates ketogenic metabolism, induces autophagy, and harbors immunomodulatory functions. Recent studies have highlighted the role of the intestinal microbiota in the still unclear etiology of RA[1]. This could be a potential target for additional dietary therapy in RA.
Objectives: To investigate the effect of therapeutic fasting followed by a plant-based diet compared to standard dietary recommendations in patients with RA.
Methods: In this pilot study[2] patients with RA were randomized to either a 7-day fast (≤250kcal/d) followed by 11 weeks of plant-based diet or to conventional nutritional counselling according to the recommendations of the German Society for Nutrition (Deutsche Gesellschaft für Ernährung, DGE) for 12 weeks. Disease activity and treatment response in RA (including Health Assessment Questionnaire, HAQ; EULAR Response Criteria, ACR Response Criteria) were measured at baseline (T0), day 7 (T1), 6 weeks (T2) and 12 weeks (T3).
Results: A total of 50 from 53 enrolled participants were included into the per-protocol analysis. The mean age was 51.98 ± 9.4 years with symptoms duration of 6.8 ± 8.1 years; 92% were females and 78% were ACPA and/or RF IgM positive. At baseline, participants presented HAQ 0.8 ± 0.5, DAS28CRP 4.0 ± 1.3, CRP 3.1 ± 3.8 mg/L, and a BMI of 25.0 ± 3.7 kg/m^2. The primary endpoint did not become significant. However, post-hoc analyses revealed clinically relevant improvements in the HAQ after 12 weeks in both the fasting and the DGE group (Δ-0.29; 95% CI, -0.45 to -0.13; p = 0.001; and Δ-0.23; 95% CI, -0.45 to -0.22; p = 0.032; respectively). Furthermore, the effect already set on by day 7 in the fasting group compared to week 6 in the DGE group (Figure 1). This effect was independent of antibody status, delivery mode of the intervention or previous dietary forms. CV risk factors including weight and total cholesterol levels improved stronger in the fasting group compared to the DGE group (Δ-3.9 kg vs. -0.7kg; 95% CI, 1.4 to 5.0; p = 0.001 and Δ-18.60 mg/dl vs Δ6.44 mg/dl; 95% CI, 7.3 to 42.8, p=0.007).

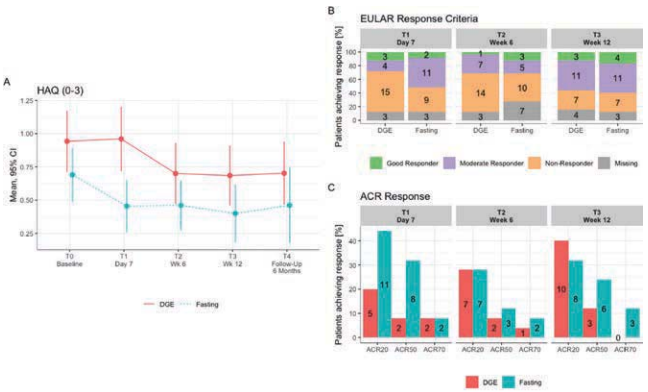

Figure 3. EULAR and ACR Response until week 12 and HAQ up to 6 months. ACR, American College of Rheumatology; CI, confidence interval; HAQ, health assessment questionnaire.

Figure 1. EULAR and ACR Response until week 12 and HAQ up to 6 months. ACR, American College of Rheumatology; CI, confidence interval; HAQ, health assessment questionnaire.

Conclusion: Fasting followed by a plant-based diet positively impacts disease activity and CV risk factors in RA, comparable to and no lesser than those of an anti-inflammatory diet according to the DGE. These results may open new perspectives by dietary interventions in an integrative therapeutic approach. Further confirmatory clinical studies with larger patient numbers are needed to confirm these exploratory findings.

Ramlan[12], G. R. Ling[13], R. Nasadurai[14], S. Ch'ng Suyin[6], S. Ahmad Maulana[14], M. Mohd Zain[6], S. C. Gun[1]. *[1]Tuanku Ja'afar Hospital, Seremban, Rheumatology, Seremban, Malaysia; [2]Melaka Hospital, Rheumatology, Melaka, Malaysia; [3]Hospital Pulau Pinang, Rheumatology, Georgetown, Malaysia; [4]Hospital Putrajaya, Rheumatology, Putrajaya, Malaysia; [5]Sarawak General Hospital, Rheumatology, Kuching, Malaysia; [6]Selayang Hospital, Rheumatology, Batu Caves, Malaysia; [7]Raja Permaisuri Bainun Hospital, Ipoh, Rheumatology, Ipoh, Malaysia; [8]Queen Elizabeth Hospital, Kota Kinabalu, Rheumatology, Kota Kinabalu, Malaysia; [9]Hospital Tengku Ampuan Afzan, Kuantan (HTAA), Rheumatology, Kuantan, Malaysia; [10]Sultan Ismail Hospital, Rheumatology, Johor Bahru, Malaysia; [11]Raja Perempuan Zainab II Hospital, Kota Bharu, Rheumatology, Kota Bharu, Malaysia; [12]Hospital Sultanah Bahiyah, Rheumatology, Alor Setar, Malaysia; [13]Sibu Hospital, Rheumatology, Sibu, Malaysia; [14]Tengku Ampuan Rahimah Hospital, Klang, Rheumatology, Klang, Malaysia*

Background: Patients with rheumatoid arthritis (RA) are at increased risk of developing malignancies, particularly hematologic malignancies. This predisposition for malignancy is attributed to the immune dysregulation, chronic inflammation and the long-term use of disease-modifying anti-rheumatic drugs(DMARDs).

Objectives: This study was undertaken to determine the incidence, patterns of malignancy and identify risk factors of malignancy among RA patients.

Methods: Individuals diagnosed with cancer after the onset of RA between year 2008 and 2020 from the NIAR RA registry were retrospectively examined. Standardized incidence ratios (SIR) and 95% confidence intervals of various cancers were calculated based on the expected and observed frequencies. The expected number of cases were extracted from the Malaysian National Cancer registry report. ANOVA, Chi-squared, and Student's t test were used to analyze the risk factors for developing malignancy.

Results: Of the 3995 patients in the registry, 97 patients developed malignancies at a mean interval of 9.1 years after RA onset. The total follow-up time was 26841.9 person-years. The mean age of patients was 59.3 (± 9.25) years, of which 89.7%(n=87) were women and 40%(n=39) were Chinese. 87.6%(n=84) had solid-organ tumours while 12.4%(n=13) had hematological malignancies. Women showed increased risks of non-Hodgkin's lymphoma (SIR = 13.1, 95% CI = 9.78 – 17.08), followed by lung cancer (SIR = 12.7, 95% CI = 10.01-15.77) and breast cancer (SIR = 8.8, 95% CI = 7.84 – 9.83). Men showed increased risks of lung cancer (SIR = 3.79, 95% CI = 2.81 – 4.92) and colorectal cancer (SIR = 1.69, 95% CI = 1.09 – 2.42). The risk factors for developing malignancy ($p<0.05$) include age above 60 years, long duration of RA disease, and higher disease activity states. There were no associations between gender, ethnicity, autoantibodies and DMARDs exposure.

Conclusion: The overall malignancy incidence was increased among RA patients, with women having a 4-fold higher risk. Though the incidence of solid-organ malignancies is higher, the SIR once adjusted was highest for non-Hodgkin's lymphoma which is consistent with literature review. Hence, cancer screening with continued vigilance among RA patients is recommended.

DIAGNOSIS OF MENTAL DISORDER COMPLICATED BY RHEUMATOID ARTHRITIS: A STUDY OF THE VALIDITY OF A PSYCHIATRIST'S DIAGNOSIS AND QUESTIONNAIRE METHOD

Y. Miwa[1], H. Tomioka[2], M. Hosaka[3], Y. Mitamura[1]. [1]*Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan;* [2]*Showa University School of Medicine, Department of Psychiatry, Yokohama, Japan;* [3]*Katsuyama Clinic, Department of psychosomatic medicine, Yamanashi, Japan*

Background: It has been reported that about 15% of patients with rheumatoid arthritis (RA) have depression, and most of these studies have used questionnaire methods. Most of the studies have used questionnaires for depression. Because the depression questionnaire includes questions about physical symptoms, it is necessary to be careful in interpreting the results when there is an underlying disease. In addition, there are no studies on other mental disorders.
Objectives: In this study, we examined the validity of the questionnaire method for the diagnosis of RA complicated by psychiatric disorders.
Methods: Forty-nine outpatients with RA who agreed to participate in this study were included. Age, gender, type of Disease-modifying anti-rheumatic drugs, prednisolone use, presence of diabetes, hypertension, dyslipidemia, and CRP were investigated. The Patient Health Questionnaire-9 (PHQ-9) and Center for Epidemiologic Studies Depression Scale (CES-D) questionnaires were used; a score of 10 or more on the PHQ-9 and 16 or more on the CES-D was considered a cutoff. The psychiatrist was blinded to the results of the questionnaire and conducted a structured interview in a separate room. The psychiatrist's diagnosis was defined as the Gold Standard, and was compared with the PHQ-9 and CES-D.
Results: Psychiatrist's diagnosis was abnormal in 9 patients. This included one patient with major depression, one patient with moderate depression, two patients with minor depression, and two patients with adjustment disorder. The PHQ-9 had a specificity of 98%, a sensitivity of 33%, a positive predictive value of 75%, and a negative predictive value of 87%. The CES-D had a specificity of 82%, a sensitivity of 100%, a positive predictive value of 56%, and a negative predictive value of 100%.
Conclusion: The PHQ-9 and CES-D may be useful in screening for psychiatric disorders including associated with RA.
Disclosure of Interests: None declared.

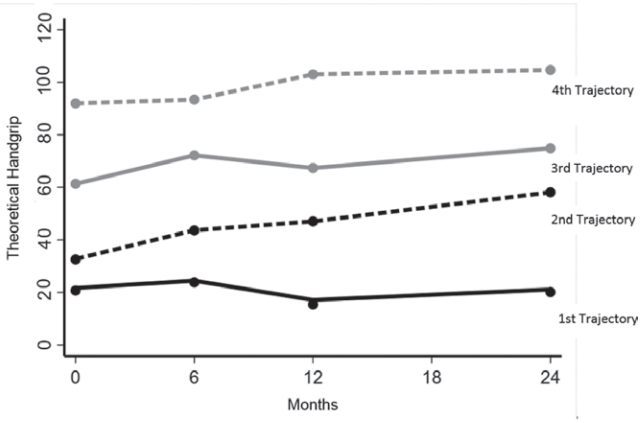
POS0587

TRAJECTORIES AND FACTORS INFLUENCING THE EVOLUTION OF HAND GRIP AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

B. Squercioni[1], B. Pereira[2], M. Beauger[1], M. Couderc[1], F. Ladouce[1], S. Malochet[1], S. Mathieu[1], P. Marie-Eva[1], M. Soubrier[1], A. Tournadre[1]. [1]*CHU Clermont-Ferrand, Rheumatology, Clermont Ferrand, France;* [2]*CHU Clermont-Ferrand, Biostatistics department DRCI, Clermont-Ferrand, France*

Background: Rheumatoid arthritis (RA) is characterized by an early reduced grip strength which persists over time despite the remission of the disease suggesting the presence of a sarcopenia.
Objectives: To study the evolution of the grip strength measured by the handgrip. by identifying different trajectories and associated factors.
Methods: Patients with active RA who visited the Rheumatology Department of Clermont-Ferrand University Hospital for initiating bDMARD were invited to participate to the longitudinal cohort RCVRIC analyzing cardiovascular risk and chronic inflammatory rheumatic disease. Within the RCVRIC cohort 175 RA initially underwent a handgrip determination. 143 patients had at least 2 handgrip measurements over 2 years, allowing analysis of trajectories by the "Group Based Trajectory Modeling" method. For the trajectories, handgrip was expressed in terms of percentage of the theoretical value defined according to age and sex. The clinical characteristics of the disease, the therapeutic response, and the body composition associated with each trajectory were analyzed.
Results: At inclusion, the handgrip was normal among only 4% of patients, with an alteration of 51% of its theoretical value. After 2 years of follow-up, a majority of patients improved their handgrip trajectory to reach an average of 68% of the theoretical one, but only 15.7% of the patients normalized their handgrip. Four trajectories have been identified along with associated factors:



1st trajectory consists of low handgrip with little improvement and was composed of: 9 patients (6.3%), median age 60 years [53.6;69.3], 88% women, disease duration 17.99 years [6.78;24.9], DAS 28 ESR 4.68 ± 1.29, and initial handgrip 21% of the theoretical value [8;24].
2nd trajectory shows good improvement (+72%) and was composed of: 70 patients (49%), median age 58.9 years [54.4;64.3], 84% women, disease duration 5.99 years [1.46;14.8], DAS 28 ESR 4.43 ± 1.07, and initial handgrip 32% of the theoretical value [17.8;46.4].
3rd trajectory shows moderate improvement (+25%) and was composed of: 43 patients (30%), median aged 60.7 years [45.7;69.4], 79% women, disease duration 3.5 years [1.25;9.9], DAS 28 ESR 4.0 ± 1.03 and initial handgrip 60% of the theoretical value [48.2;76].
4th trajectory shows high handgrip and was composed of: 21 patients (14.7%), 57% women, median age 57.9 years old [49.7; 67.4], disease duration 3.81 years [2.14; 10.7], DAS 28 ESR 3.68 ±1.29 and initial hand grip 92% of the theoretical value [85; 100].
Significant differences at inclusion between the 4 trajectories were observed. The 4th trajectory was characterized by a higher proportion of men (p=0.05), lower disease activity (DAS 28 ESR (p=0.02), SDAI (p=0.04)), better initial handgrip (p=0.03) and 6 min walk test (p=0.0001), and a lower percentage of fat mass (p=0.04). In contrast, a higher disability (HAQ, p=0.002), a lower total lean body mass (p=0.001) and poorer therapeutic response (p=0.04) were noted in trajectories 1 and 2.
Conclusion: After 2 years of follow-up, a majority of patients improved their handgrip trajectory. However, very few patients normalized their hand grip. Four trajectories of handgrip were identified; the main indicators of hand grip's improvement were the control of the disease activity, low functional disability, walking performance, a low percentage of fat mass and high lean mass.

POS0588 SEASONALITY OF FLARE AND REMISSION PATTERNS IN RHEUMATOID ARTHRITIS: A POPULATION-BASED COHORT STUDY

R. Javed[1], C. S. Crowson[2], J. M. Davis III[1], E. Myasoedova[2]. [1]*Mayo Clinic, Division of Rheumatology, Rochester, United States of America;* [2]*Mayo Clinic, Division of Rheumatology, Department of Quantitative Health Sciences, Rochester, United States of America*

Background: Flare of rheumatoid arthritis (RA) disease activity is an important aspect of RA disease experience for patients with RA, associated joint damage and comorbidity. Major advancements in treatment of RA in recent decades resulted in improving trends in RA disease activity and increasing rates of remission. However, flares in RA remain common and some patients are still unable to achieve remission. Disease-modifying antirheumatic drugs have a major impact on controlling RA disease activity, minimizing the likelihood of flares. The effect of environmental factors on the pattern of flares and remissions in RA is less studied. Previous studies showed conflicting results regarding the likelihood of flare and remission occurrence across the seasons of the year.

Objectives: To assess the seasonal pattern in the occurrence of flares and remissions in a population-based cohort of patients with RA.

Methods: This retrospective population-based cohort study included patients with RA (age ≥30 years) who met 1987 ACR criteria in 1988-2007. A retrospective review of each clinical visit in the medical records was performed to ascertain flare or remission status. A flare was defined as an episodic worsening of RA disease activity that leads to initiation, change or increase of treatment. Remission was defined as the absence of disease activity based on a tender joint count of 0, a swollen joint count of 0 and an ESR less than 10 mm/h. Seasons were defined as: winter (Dec, Jan, Feb), spring (Mar, Apr, May), summer (June, July, Aug) and autumn (Sep, Oct, Nov). All subjects were followed until death, migration or July 1, 2012. Generalized linear models with random effects to account for multiple visits per patient were used for data analyses.

Results: The study included 650 RA patients (mean age 55.8 years; 69% female) with a mean follow up of 10.3 years. In a total of 17,323 clinical visits, patients were flaring in 2887 (17%) visits. The incidence of RA flares was 15% higher in the spring than in the winter (OR 1.15: CI: 1.02-1.29, p=0.045) after adjusting for age, sex and RA duration. There was no change in flare pattern between winter and summer or autumn. Remission rate did not differ between the seasons. (3df test p=0.65).

Conclusion: Patients with RA were more likely to experience flares in spring as compared to winter, and there were no differences in flare rates for the rest of the seasons. Remission rates were similar between the seasons of the year. The reasons for this seasonal effect on flare pattern is unknown, and the role of patient-related and environmental risk factors remains to be investigated. Our findings on the seasonality in flare occurrence can be used to inform patients about the risk of RA disease flares throughout the year.

POS0589 CARDIOVASCULAR DISEASE RISK IN INFLAMMATORY ARTHRITIS STILL ELEVATED IN 2021!

R. Raadsen[1], F. Hooijberg[1], L. Boekel[1], G. J. Wolbink[1], W. Lems[1,2], A. Van Kuijk[1], M. Nurmohamed[1,2]. [1]*Amsterdam Rheumatology and Immunology Center, location Reade, Rheumatology, Amsterdam, Netherlands;* [2]*Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Rheumatology, Amsterdam, Netherlands*

Background: Patients with inflammatory rheumatic diseases as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA) are at higher risk for developing cardiovascular diseases (CVD) than the general population. This is due to a higher prevalence of 'traditional' CV risk factors as hypertension and dyslipidemia, and the underlying systemic inflammation. During the past two decades, the burden of inflammation has been reduced by more efficacious anti-rheumatic treatment, leading to a reduced CVD risk, albeit still elevated in comparison to the general population. Therefore, it remains important to monitor the presence of CVD in rheumatic patients in systematically controlled cohorts.

Objectives: To evaluate whether, nowadays, the CVD risk of patients with inflammatory rheumatic diseases still differs from the general population.

Methods: In March 2020, all adult patients with an inflammatory rheumatic disease from the Amsterdam Rheumatology and Immunology Center, location "Reade" were systematically asked to participate in a prospective cohort study, which focused on the impact of the COVID-19 pandemic. The patients were compared with age and sex matched controls. In the third questionnaire, sent out in January 2021, questions regarding CV risk factors and comorbidities were added. Baseline characteristics and prevalence of CV risk factors and CVD were compared between RA, PsA or SpA patients, and healthy controls.

Results: 2050 consecutive patients with an inflammatory rheumatic disease (1312 RA patients, 353 PsA patients, 385 SpA patients), and 939 healthy controls completed the questionnaires (Table 1). The prevalence of at least one CV comorbidity was more frequently reported in RA, PsA and SpA patients compared to healthy controls: 69 (5%), 24 (7%), 17 (4%) compared to 31 (3%), respectively. Events were primarily cardiac (i.e. myocardial infarction and coronary angioplasty). Inflammatory arthritis patients more often had hypertension or hypercholesterolemia than healthy controls, which were untreated in nearly half the cases. RA patients most often used anticoagulant medication.

Table 1. Baseline characteristics. Values are displayed as mean ± standard deviation (SD) or frequencies with percentages (%). RA = rheumatoid arthritis, PsA = psoriatic arthritis, SpA = spondyloarthritis, CV = cardiovascular, DMARD = disease modifying anti-rheumatic drug

Patient characteristics	All patients (n = 2050)	RA (n = 1312)	PsA (n = 353)	SpA (n = 385)	Control (n = 939)
Mean age – yr	57 ± 13	60 ± 12	57 ± 12	51 ± 13	55 ± 13
Female sex - no (%)	1266 (63)	923 (70)	164 (47)	179 (47)	636 (69)
CV risk factors - no (%)					
Hypertension	746 (37)	482 (38)	134 (39)	130 (34)	213 (23)
Antihypertensive med	411 (20)	271 (21)	78 (22)	62 (16)	131 (14)
Hypercholesterolemia	594 (30)	391 (31)	102 (30)	101 (27)	197 (21)
Statins	335 (16)	223 (17)	59 (17)	53 (14)	98 (10)
Anticoagulants	246 (12)	180 (14)	34 (10)	32 (8)	74 (8)
CV diseases - no (%)					
Overall	110 (5)	69 (5)	24 (7)	17 (4)	31 (3)
Cardiac	91 (4)	60 (5)	17 (5)	14 (4)	26 (3)
Cerebral	27 (1)	12 (1)	9 (3)	6 (2)	4 (0)
Peripheral	14 (1)	10 (1)	3 (1)	1 (0)	3 (0)
Anti-rheumatic drugs - no (%)					
Prednisone	202 (10)	175 (13)	17 (5)	10 (3)	n/a
Conventional synthetic DMARD	1118 (55)	902 (69)	184 (52)	32 (8)	n/a
Biological DMARD	895 (44)	512 (39)	166 (47)	217 (56)	n/a
Targeted synthetic DMARD	20 (1)	11 (1)	5 (1)	4 (1)	n/a

Conclusion: The prevalence of CVD was approximately 1.5 times higher in patients with inflammatory rheumatic diseases compared to healthy controls (5% vs 3%), similar to older investigations. The prevalence of CV risk factors also remained elevated, and often undertreated. This indicates that the CVD risk in arthritis patients is still elevated in 2021 compared to the general population, despite improved anti-rheumatic treatment. Therefore, adequate and timely treatment of CV risk factors and optimization of anti-rheumatic drug treatment remains important in all inflammatory arthritis patients.

POS0590 ASSOCIATIONS BETWEEN SELF-REPORTED RHEUMATOID ARTHRITIS, RHEUMATOID FACTOR POSITIVITY AND STRUCTURAL BRAIN PHENOTYPES IN UK BIOBANK

I. Stanciu[1], S. Siebert[2], D. Mackay[1], D. Lyall[1]. [1]*University of Glasgow, Public Health, Glasgow, United Kingdom;* [2]*University of Glasgow, Infection Immunity & Inflammation, Glasgow, United Kingdom*

Background: There is very limited research on structural brain health in people with rheumatoid arthritis (RA).

Objectives: To investigate whether there are differences in brain volume in people with self-reported RA or positive rheumatoid factor (RF+).

Methods: Cross-sectionally tested for associations with several MRI brain volume measures in UK Biobank (n=37,379 of whom 432 RA and 1833 RF+). The partially adjusted regression models controlled for age and sex, while the fully adjusted models further controlled for deprivation index, smoking status and

cardiometabolic diseases. For all subcortical volumes analyses we also controlled for total brain volume.

Results: Those that self-reported RA were more likely to have increased WMH (White Matter Hyperintensities) (β= 0.08, 95% CI= 0.022; 0.14, p<0.01), and smaller volumes of the amygdala (β=-0.09, 95% CI= -0.16; -0.02, p<0.01), pallidum (β=-0.07, 95% CI= -0.13; -0.005, p<0.05) and thalamus (β= -0.06, 95% CI= -0.12; -0.01, p<0.05) in the partially adjusted analyses. In the fully adjusted model only amygdala volume remained negatively associated with RA (β=-0.09, 95% CI= -0.16; -0.02, p<0.01).

Conclusion: We provide evidence of differences in structural brain phenotypes known to underpin cognitive and psychological health, in RA. Since the amygdala may play an important role in pain modulation and mental health, while WMH are associated with a higher risk of stroke, the observed differences may be of clinical relevance in RA which is associated with a higher prevalence of these conditions. Further research is required to confirm these findings and asses their functional implications.

POS0591 TREATMENTS TO PREVENT RHEUMATOID ARTHRITIS IN FIRST DEGREE RELATIVES: DEMOGRAPHIC AND PSYCHOLOGICAL PREDICTORS OF RISK TOLERANCES

G. Simons[1], E. Janssen[2], J. Veldwijk[3], R. Disantostefano[2], M. Englbrecht[4], C. Radawski[5], L. Valor[6], J. Humphreys[7,8], I. N. Bruce[7,8,9,10], B. Hauber[11], K. Raza[12,13,14], M. Falahee[1]. *[1]University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, Queen Elizabeth Hospital, United Kingdom; [2]Janssen R&D, NJ, United States of America; [3]Erasmus University Rotterdam, Erasmus School of Health Policy and Management and Erasmus Choice Modelling Centre, Rotterdam, Netherlands; [4]Freelance data scientist, Eckental, Germany; [5]Eli Lilly & Company, Indianapolis, United States of America; [6]Friedrich-Alexander-University Erlangen, Erlangen, Germany; [7]University of Manchester, Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre, Manchester, United Kingdom; [8]Manchester University NHS Foundation Trust, Kellgren Centre for Rheumatology, Manchester, United Kingdom; [9]Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; [10]University of Manchester, Division of Musculoskeletal and Dermatological Sciences, School of Biological Sciences, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; [11]Pfizer Inc., New York, United States of America; [12]University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, Birmingham, United Kingdom; [13]University of Birmingham, Research into Inflammatory Arthritis Centre Versus Arthritis and MRC-Versus Arthritis Centre for Musculoskeletal Ageing Research, Birmingham, United Kingdom; [14]Sandwell and West Birmingham NHS Trust, Rheumatology Department, Birmingham, United Kingdom*

Background: There is a growing research focus on the development of interventions to reduce risk of rheumatoid arthritis (RA) in at-risk groups.(1) RA patients' first-degree relatives (FDRs) have an elevated risk of developing RA and are potential candidates for preventive interventions. Recent studies have quantified the preferences of at risk groups for preventive treatments. (2-4) Little is known about predictors of preference heterogeneity in this context.

Objectives: Assess the extent to which FDR characteristics and beliefs predict risk tolerances for preventive treatments.

Methods: Adult FDRs of patients with confirmed RA in the UK were invited to take part in a web-based survey. FDRs enrolled in a UK prospective cohort (PREVeNT-RA) were also invited. Survey development, including attribute selection and presentation, was informed by qualitative research, ranking surveys, literature review, and expert opinion including patient research partners. Respondents received information about RA, questions to check comprehension, and an introduction to the survey. Participants were asked to imagine they were experiencing arthralgia and had positive autoantibody tests indicating a 60% chance of developing RA within two years. Using a probabilistic threshold technique, participants made choices between no treatment (no benefit and no risks) or a preventive treatment option. Treatment options were defined by a fixed level of benefit (reduction in risk of RA from 60% to 20%) and varying levels of risks (Table 1). For each treatment risk, participants made a series of choices where the risk was systematically increased or decreased until they switched their choice. This procedure was repeated for each of the remaining risks. Participants also completed items assessing demographics, perceived risk of developing RA, health literacy, subjective numeracy, the Brief Illness Perception Questionnaire (IPQ) and the Beliefs about Medicines Questionnaire General (BMQ-G). The maximum acceptable risk (MAR) respondents were willing to accept for a 40% (60% to 20%) point risk reduction in developing RA was summarized across participants using descriptive statistics. Associations between MARs and participants' characteristics and illness/medication beliefs were assessed using interval regression. Independent variables were dichotomized and effects coded.

Table 1. Attributes and levels of treatment options

Treatment attribute	Levels describing no treatment option	Levels describing treatment option
Chance of developing RA	60%	20%
Chance of mild side effects	0%	2%; 4%; 5%; 7% or 10%
Chance of a serious infection due to treatment	0%	1%; 1.5%; 2%; 3% or 5%
Chance of a serious side effect that is potentially irreversible	0%	0.001%; 0.01%; 0.02%; 0.05% or 0.1%

Results: 289 FDRs (80 male) responded. The mean (SE) MAR for mild side effects, serious infection, and serious side effects was 29.08 (1.52), 9.09 (0.60) and 0.85 (0.27), respectively. Participants aged over 60 years were less tolerant of risk of serious infection than average (mean MAR - 2.06 (0.78)) and younger participants were more tolerant of risk of serious infection than average (mean MAR + 2.06 (0.78)). Risk of mild side effects was less acceptable to participants who perceived they were likely/very likely to develop RA (mean MAR - 3.34 (1.55)) than to those who did not (mean MAR + 3.34 (1.55)). Education level, health literacy, numeracy, IPQ and BMQ-G subscales were not predictors of risk tolerance.

Conclusion: Age and perceived risk of RA had a significant impact on FDRs' tolerance for specific, but not all, included risks. Cognitive ability and beliefs about RA/medicine did not explain preference heterogeneity. This is informative for drug development and the development of tailored risk communication resources to support preventive approaches.

POS0592 PREDICTING LIVER ENZYME ELEVATION IN PATIENTS WITH RHEUMATOID ARTHRITIS ON TREATMENT WITH METHOTREXATE USING SUPERVISED MACHINE LEARNING

V. Gilvaz[1], S. Surendran[2], M. Cb[2]. *[1]Rhode Island Hospital, Rheumatology, Providence, United States of America; [2]Amrita Hospital, Rheumatology, Kochi, India*

Background: Methotrexate (MTX) is the most used disease-modifying anti-rheumatic drug (DMARD) in the treatment of rheumatoid arthritis (RA). (1) Chronic use of this medication warrants close laboratory monitoring given its propensity for liver damage and myelosuppression. (2) MTX associated hepatic dysfunction is a well-described adverse effect and has been seen in up to a quarter of

patients on long term treatment. (3) Recent advances in health care coupled with the extensive use of electronic health records (EHR) has resulted in the accumulation of large amounts of patient data. Approaches like machine learning (ML) allows us to leverage these large data sets to predict outcomes and support clinical decision making. (4) We hypothesized that a ML model trained on conventionally available EHR data would be able to identify patients at the greatest risk of developing MTX related hepatotoxicity.

Objectives: To develop a machine learning model to accurately predict liver enzyme elevation in rheumatoid arthritis (RA) patients on treatment with methotrexate (MTX) using electronic health record (EHR) data from a real-world RA cohort.

Methods: Demographic, clinical, biochemical, as well as prescription information from 569 RA patients were retrospectively collected. Liver transaminase elevation above the upper limit of normal following initiation of MTX, was the primary outcome. The total dataset was randomly split into a training (80%) and test set (20%) and used to develop a Random Forest Classifier model. The best model was selected after hyper-parameter tuning and fivefold cross-validation.

Results: 104 patients (18.2%) developed hepatic dysfunction while on MTX therapy. The best performing predictive model had an accuracy/F1 score of 0.87. The top ten predictive features were then used to create a limited feature model that retained most of the predictive accuracy, with an accuracy/F1 score of 0.86.

Conclusion: Our proof-of-concept study suggests the possibility of building a well-performing ML model to predict liver enzyme elevation in RA patients being treated with MTX. Similar ML models could be used to identify 'high risk' patients who can then be potentially targeted for closer monitoring with the aim of preventing these adverse outcomes. Conversely, patients at low risk can avoid extra outpatient visits, thereby reducing costs.

POS0593

THE COURSE OF FATIGUE AND ITS RELATION WITH INFLAMMATION DURING THE DEVELOPMENT OF RHEUMATOID ARTHRITIS: A LONGITUDINAL STUDY

S. Khidir[1], F. Wouters[1], E. Van Mulligen[1,2], A. Van der Helm-van Mil[1,2]. [1]*Leiden University Medical Centre, Leiden, Rheumatology, Leiden, Netherlands;* [2]*Erasmus Medical Centre, Rheumatology, Rotterdam, Netherlands*

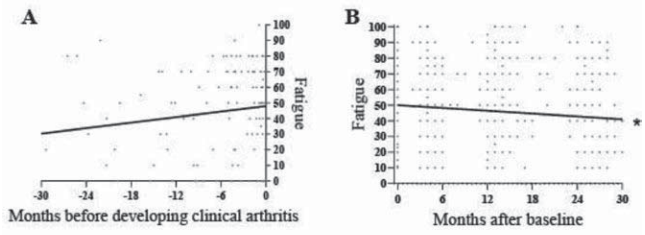
Background: Fatigue is a prominent and disabling symptom in patients with rheumatoid arthritis (RA), that is only partially explained by inflammation and responds poorly to DMARD-therapy. We hypothesized that inflammation explains fatigue to a larger extent in the phase of clinically suspect arthralgia (CSA), when clinical arthritis is still absent and fatigue has not yet become chronic.

Objectives: To study the course of fatigue in CSA during progression to RA and the association with inflammation at CSA-onset and at RA-diagnosis.

Methods: 600 consecutive CSA-patients were followed for RA-development (median follow-up 25 months). Additionally, 710 early RA-patients were studied at diagnosis. Fatigue was assessed every study visit and expressed on a scale of 0-100. The DAS44-CRP was used to measure inflammation (with SJC=0 in CSA). The course of fatigue over time was studied with linear mixed models. Associations between fatigue and inflammation were studied with linear regression, corrected for sex. Analyses were stratified by ACPA-status.

Results: In 88 CSA-patients who developed RA, pre-arthritis fatigue-levels increased gradually with 7/year (95%CI= -2 to 16, p=0.13), towards 48 at RA-development. Fatigue decreased in CSA-patients who did not develop RA (-4/year, 95%CI= -6 to -3, p<0.001) (see Figure 1). At CSA-onset, inflammation was associated with fatigue (β=18, meaning 18 points more fatigue

Figure 1. Course of fatigue in CSA-patients developing RA (A) and in CSA-patients not developing RA (B)



Legend: lines depict the average course derived from linear mixed model analysis. Timepoint zero was defined as time of clinical arthritis in CSA-patients who developed RA and as the first visit in the CSA-patients who did not develop RA. Figure 1B contains data of 475 patients at baseline (t=0), but most dots overlap. Fatigue increased in CSA-patients who developed RA with 7/year. *Fatigue decreased in CSA-patients who did not develop RA with -4/year.

per point increase DAS-score, 95%CI=7-28, p=0.001). This association was stronger than at RA-diagnosis (β=5, 95%CI=3-7, p<0.001). Fatigue-levels increased towards RA-development in both ACPA-subtypes, but were on overall average higher in ACPA-negative CSA than ACPA-positive CSA (mean difference in fatigue of 13, 95%CI=1-24, p=0.027). However, the association between fatigue and inflammation was stronger in ACPA-positive compared to ACPA-negative CSA.

Conclusion: Fatigue increased gradually during progression from arthralgia to clinical arthritis, and fatigue was better explained by inflammation in CSA than in RA. This implies a 'phase-dependent relation' between inflammation and fatigue.

POS0594 FACTORS ASSOCIATED WITH THE 6-MINUTE WALK TEST AMONG PERSONS WITH RHEUMATOID ARTHRITIS

I. S. Houge[1,2], M. Hoff[3,4], V. Videm[1,5]. *[1]Norwegian University of Science and Technology, Department of Molecular and Clinical Medicine, Trondheim, Norway; [2]Levanger, Department of Rheumatology, Levanger, Norway; [3]Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Trondheim, Norway; [4]St. Olav's University Hospital, Department of Rheumatology, Trondheim, Norway; [5]St. Olav's University Hospital, Department of Immunology and Transfusion Medicine, Trondheim, Norway*

Background: Persons with rheumatoid arthritis (RA) are less physically active than the general population. A 6-minute walk test (6MWT) measures how far a person can walk in 6 minutes, testing overall functional capacity. This can inform clinicians before initiating potential interventions.

Objectives: To assess psychological, patient- and disease-related factors associated with 6MWT results among persons with RA.

Methods: Patients were recruited in 2019 and 2021 from the Rheumatology outpatient clinics at St. Olavs Hospital and Levanger Hospital, Norway (n=225). They answered questionnaires, and a subgroup (n=86) performed a 6MWT according to guidelines from the American Thoracic Society (1). Diagnostic characteristics and medical history were collected from hospital records. Participants with data for 6MWT but missing data for other variables in the main model were excluded (n=7). Physical function was measured with the Modified Stanford Health Assessment Questionnaire (mHAQ, range 0-3, lower score indicating better physical function). For the patient global assessment (PGA) patients rated their overall disease activity in the past week on a 100 mm visual analogue scale; higher score indicates more symptoms. Presence of depressive symptoms was measured with the Hospital Anxiety Depression Index Depression score (HADS-D, range 0-21, higher value implying more depressive symptoms). Perceived stress was measured with Cohen's Perceived Stress Scale (range 0-40, higher score indicates more stress). The belief in one's ability to be physically active under different circumstances was measured by the Self-Efficacy for Exercise score (range 5-35, higher score indicates higher self-efficacy). Data were analyzed with multiple regression with 6MWT as dependent variable. Model 1 included age (categorized into tertiles to improve model fit: <59, 59-69, or ≥70 years), sex, mHAQ, PGA, HADS-D, Cohen's Perceived Stress Scale, Self-Efficacy for Exercise, smoking habit and body mass index (BMI, categorized ≤25 or >25 kg/m^2). Model 2 included only the variables significantly associated with 6MWT in Model 1, but keeping adjustment for sex. The regression coefficients of Model 2 were standardized.

Table 1. Patient characteristic

	Rheumatoid arthritis patients (N=79)
Female sex, n (%)	60 (76)
Age (years), median (IQR)	65 (55, 71)
Ever smoker, n (%)	49 (62)
Body mass index (kg/m^2), median (IQR)	26.3 (23.6, 28.9)
Rheumatoid arthritis duration (years), median (IQR)	10 (5, 23)
Seropositive (anti-CCP and/or RF), n (%)	68 (86)
Uses conventional DMARDs, n (%)	67 (85)
Uses biological DMARDs, n (%)	42 (53)
Uses corticosteroids, n (%)	21 (27)
Cardiovascular disease (HT, angina, MI, arrhythmia or stroke), n (%)	38 (48)
Respiratory disease (COPD, CRPD or asthma), n (%)	21 (27)
DAS28-CRP	2.3 (1.8, 2.9)
Modified Health Assessment Questionnaire, median (IQR)	0.38 (0.13, 0.63)
Patient global assessment (mm), median (IQR)	27 (12, 40)
Hospital Anxiety Depression Scale Depression score, median (IQR)	3 (1, 4)
Cohen's Perceived Stress Scale, median (IQR)	15 (9, 19)
Self-Efficacy for Exercise, median (IQR)	25 (17, 30)
6-Minute Walk Test (m), mean (±SD)	507 (±88)

Results: In model 1, the variables associated with 6MWT were mHAQ (p=0.04), Self-Efficacy for Exercise (p=0.001), BMI (p=0.01) and age (oldest versus youngest age tertile p<0.001, middle versus youngest age tertile p=0.11). Sex was not significantly associated with 6MWT (p=0.82). The standardized coefficients in Model 2 were: mHAQ -0.27 (p=0.002), Self-Efficacy 0.27 (p=0.002), categorized BMI -0.27 (p-value=0.002), middle age group versus youngest age group -0.17 (p=0.08), oldest age group versus youngest age group -0.55 (p<0.001), male gender 0.08 (p=0.33). The R^2 of Model 1 and Model 2 were 0.54 and 0.52 respectively.

Conclusion: Self-Efficacy for Exercise, mHAQ, BMI and age had the largest impact on 6MWT, explaining 52 % of the observed variation in 6MWT in a model adjusted for sex.

POS0595 THE ASSOCIATION BETWEEN AXIAL AND PERIPHERAL BONE IN PATIENTS WITH RHEUMATOID ARTHRITIS, INCLUDING THE IMPACT OF EROSIVE DISEASE. A HR-PQCT STUDY.

A. B. G. Blavnsfeldt[1,2], R. Klose-Jensen[1], J. Therkildsen[1,2], K. Keller[1,2], S. G. Hansen[3,4], B. Langdahl[2,5], E. M. Hauge[1,2]. *[1]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [2]Aarhus University, Clinical Medicine, Aarhus, Denmark; [3]Odense University Hospital, Endocrinology, Odense, Denmark; [4]University of Southern Denmark, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark; [5]Aarhus University Hospital, Internal Medicine and Endocrinology, Aarhus, Denmark*

Background: The severity of Rheumatoid Arthritis (RA) is associated with increased fracture risk (1). Areal bone mineral density (aBMD) by dual-energy absorptiometry (DXA) is the gold standard for diagnosis of osteoporosis as well as fracture risk assessment. High resolution peripheral quantitative computed tomography (HR-pQCT) of the distal radius yields volumetric BMD (vBMD) of trabecular and cortical bone compartments, as well as micro-architectural parameters and may prove useful for fracture risk prediction. The association between aBMD by DXA and HR-pQCT derived vBMD and microarchitecture have only been sparsely investigated in patients with RA, and it is not known if erosive disease, measured by the gold standard Heijde-modified Sharp Scores (HSS) (2) affects HR-pQCT derived parameters.

Objectives: To assess the associations between aBMD by DXA and bone parameters of the distal radius by HR-pQCT, in both male and female patients with RA, and the impact of erosive disease on the bone parameters of the distal radius.

Methods: We measured aBMD by DXA of the lumbar spine and hip, HR-pQCT of the distal radius and assessed HSS in 162 patients with RA. Using multivariate linear regression models, we explored the association between HSS and HR-pQCT parameters, adjusted for sex and age. The associations between aBMD by DXA and vBMD and microarchitecture by HR-pQCT were assessed by Spearman correlation coefficients, interpreted as negligeable (0.00-0.10), weak (0.10-0.39), moderate (0.40-0.69), strong (0.70-0.89) or very strong (0.90-1.00).

Results: Mean age for the included patients was 63 years, 75% were women and median disease duration was 18 years. Erosive disease (HSS) was negatively associated with trabecular number and density, but not with cortical bone parameters. This association was stronger for HSS of the wrist joints, than for HSS of the hands and total HSS (Table 1). Trabecular density of the distal radius correlated moderately with aBMD at the total hip, and weakly with aBMD at the lumbar spine. Trabecular numbers also correlated moderately with aBMD at the total hip. Cortical bone parameters at the distal radius correlated weakly with aBMD at the hip, but only among women.

Table 1. Multivariate linear regression model exploring the effect of Heijde-modified Sharp Score on selected HR-pQCT (distal radius) parameters, adjusted for age and sex.

	Tb. BMD (mg HA/cm^3)	0.273	-0.467	0.003
	Tb. N (1/mm)	0.311	-0.010	<0.001

HR-pQCT: high resolution peripheral quantitative computed tomography,HSS: Heijde-modified Sharp Score, Tt.: total, Ct.: cortical, Tb.: trabecular, BMD: bone mineral density, HA: hydroxyapatite, Th.: Thickness, N: number

Conclusion: Among patients with RA, the correlation between axial and peripheral bone is strongest between trabecular bone parameters of the radius and aBMD at the hip, which suggests that prediction of hip fractures is maintained. However, the degree of erosive disease negatively impacts the trabecular bone parameters. This may potentially interfere with the hip fracture prediction abilities of HR-pQCT in patients with high degree of erosive disease.

POS0596 SERUM CHOLESTEROL LOADING CAPACITY ON MACROPHAGES IS LINKED TO OXIDIZED LOW-DENSITY LIPOPROTEIN AND REGULATED BY SEROPOSITIVITY AND C-REACTIVE PROTEIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Karpouzas[1,2], B. Papotti[3], S. Ormseth[2], M. Palumbo[3], E. Hernandez[2], C. Marchi[3], F. Zimetti[3], M. Budoff[1,2], N. Ronda[3]. *[1]Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America; [2]The Lundquist Institute, Rheumatology, Torrance, United States of America; [3]University of Parma, Department of Food and Drug, Parma, Italy*

Background: Excessive cholesterol accumulation in macrophages underlies foam cell formation, initiation and progression of atherosclerosis. LDL oxidation and unregulated uptake of oxidized LDL by macrophages are critical in foam cell development. Cholesterol loading capacity (CLC) is the ability of serum to deliver cholesterol to cells and is related to foam cell formation. Rheumatoid arthritis (RA) serum increased cholesterol content in macrophages and promoted foam cell formation significantly more than control serum[1]. Although inflammation, LDL oxidation and antibodies to oxidized LDL (anti-oxLDL) may be higher in RA, their relationships and their individual and synergistic contributions to CLC in RA are unknown.

Objectives: To explore determinants and moderators of serum CLC in patients with RA. We also investigated whether oxidized LDL influences CLC directly or indirectly through anti-oxLDL IgG and proprotein convertase subtilisin/Kexin type-9 (PCSK9), independently or conditionally on RA-related autoantibodies such as rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) or level of inflammation.

Methods: In an observational study of 104 patients, CLC was measured fluorimetrically as intracellular cholesterol content in human THP-1-derived macrophages after incubation with patient serum. Oxidized LDL was measured as oxidized phospholipids on apoB100 particles (oxPL-apoB100). Anti-oxLDL, PCSK9 and C-reactive protein (CRP) were also quantified. Associations of oxPL-apoB100, anti-oxLDL IgG and PCSK9 with CLC were examined with multivariable linear regression. A two-stage dual moderated mediation model explored whether an indirect association of oxPL-apoB100 with CLC through parallel mediators anti-oxLDL IgG and PCSK9 varied as a function of moderators CRP and RF/ACPA positivity.

Results: OxPL-apoB100, anti-oxLDL IgG and PCSK9 positively associated with CLC (all adjusted p<0.020). In the final dual moderated mediation model oxPL-apoB100 was directly linked to CLC only in dual seropositive patients (unstandardized b [95% bootstrap confidence interval]=2.08 [0.38-3.79], Figure 1). An indirect effect of oxPL-apoB100 on CLC through anti-oxLDL IgG was present and increased along with level of CRP (index of moderated mediation=0.55 [0.05-1.17]). CRP also moderated the other indirect effect of oxPL-apoB100 on CLC through PCSK9, but only in dual seropositive patients (conditional indirect effect=0.64 [0.13-1.30]).

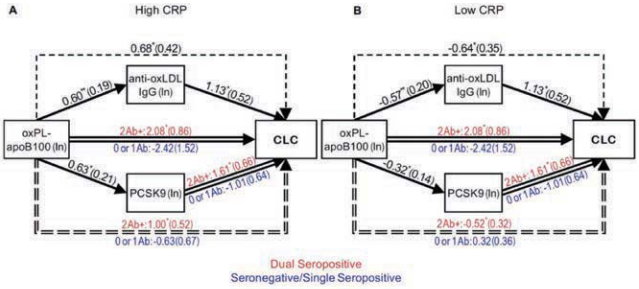

Figure 1. Determinants of CLC in RA. Unstandardized regression coefficients (standard errors) for paths of the dual moderated mediation model at **(A)** high (+1 SD above the mean) and **(B)** low (-1 SD below the mean) levels of the moderator CRP. ASCVD score, statin use, LDL-C, anti-oxLDL IgM, obesity, and age at diagnosis were included as covariates. Double lines are paths moderated by RF/ACPA seropositivity. Single dashed lines are the indirect effect of oxPL-apoB100 on CLC through anti-oxLDL IgG. Double dashed lines are the indirect effect of oxPL-apoB100 on CLC through PCSK9.
*p<0.05, **p<0.01

Conclusion: Oxidized LDL can directly influence CLC in dual seropositive RA patients, regardless of CRP. This suggests that targeting LDL oxidation in addition to inflammation may enable a more comprehensive reduction of atherosclerotic risk in these patients. Depending on CRP level, oxidized LDL also affected CLC indirectly via anti-oxLDL IgG and via PCSK9 in dual seropositive patients. If externally validated, our findings may have clinical implications for cardiovascular risk stratification and prevention.

POS0597 PREDICTORS OF PERCEIVED RISK IN FIRST DEGREE RELATIVES OF RHEUMATOID ARTHRITIS PATIENTS

S. Bunnewell[1], I. Wells[2], D. Zemedikun[3], G. Simons[2], C. Mallen[4], K. Raza[2,5,6], M. Falahee[2]. *[1]Sandwell and West Birmingham Hospitals NHS Trust, Department of Rheumatology, Birmingham, United Kingdom; [2]University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, College of Medical and Dental Sciences, Birmingham, United Kingdom; [3]University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom; [4]Keele University, Primary Care Centre Versus Arthritis, School of Medicine, Keele, United Kingdom; [5]University Hospitals Birmingham NHS Foundation Trust and University of Birmingham, NIHR Birmingham Biomedical Research Centre, Birmingham, United Kingdom; [6]University of Birmingham, MRC Versus Arthritis Centre for Musculoskeletal Ageing Research and the Research*

Into Inflammatory Arthritis Centre Versus Arthritis, Birmingham, United Kingdom

Background: Risk of rheumatoid arthritis (RA) is 3-5 times higher in first-degree relatives (FDRs). Efforts are increasing to develop preventive interventions for this at risk group. Risk perception is a key predictor of health behaviours, including FDRs' interest in predictive testing[1] and preventive intervention for RA. Effective risk communication is essential for RA prevention studies and clinical translation[2].
Objectives: To define variables associated with perceived risk of developing RA in FDRs of RA patients.
Methods: RA patients attending outpatient clinics (West Midlands, UK) were asked to invite their FDRs to complete a cross-sectional printed survey. Patients were also invited to complete a survey. Unique survey numbers enabled linkage of FDR and proband responses. FDRs' perceived absolute risk, comparative risk, experiential risk, and worry about risk were assessed using 5-point Likert scales. Predictor variables included demographics, the Single Item Literacy Screener, Brief Illness Perception Questionnaire, Brief Approach/Avoidance Coping Questionnaire, Life Orientation Test Revised and the Short Health Anxiety Inventory. Patient predictors of FDR perceived risk included demographics, time since RA diagnosis and Rheumatoid Arthritis Impact of Disease Score. Outcome measure responses were grouped into 'low' and 'high' for regression analyses. Univariable analysis used independent samples T-tests, chi-square tests and Mann-Whitney U Tests. Backwards stepwise binary logistic regression examined the relationship between FDR characteristics and perceived risk of RA. Generalised Estimating Equations assessed whether patient variables predicted FDR's perceived risk.
Results: 396 FDRs returned a survey. Paired data from 213 patients were available for 292 of these FDRs. The distributions of risk perception scores are shown in Figure 1. All measures of perceived risk were inter-correlated ($p<0.001$; ranging from r=0.48 to r=0.80). 65.2% of FDRs perceived themselves to be 'Likely' or 'Very Likely' to develop RA in their lifetime. FDR's ethnic group, deprivation index, employment status, education level, smoking status, cohabitation with index patient status, coping style and dispositional optimism were not significantly different between high and low perceived risk groups. Characteristics significant in univariable analyses were used in multivariable analyses (Table 1). Children were 3.89 times more likely than siblings to perceive themselves at high risk of RA. Higher health anxiety scores were associated with increased perceived risk. Female gender, and beliefs that RA would last a long time, and cause higher concern and negative emotional impact predicted increased risk perceptions. Higher perceptions of how well treatment would control RA was associated with a reduced likelihood of perceiving oneself at high risk.Index patient characteristics did not associate with FDRs' risk perceptions.

Table 1. Multivariable analysis

FDR Characteristic	Perceived Risk [Odds Ratio (95% Confidence Interval)]			
	Absolute	**Comparative**	**Experiential**	**Worry about Risk**
Gender				1.98 (1.19-3.27)*
Male[$]				
Female				
Relationship to index patient	2.80 (1.70-4.61)***	3.43 (2.04-5.78)***	3.89 (2.24-6.75)***	2.26 (1.30-3.94)**
Child

Illness Perceptions	0.89 (0.79-0.99)*	1.25 (1.05-1.48)*	1.17 (0.99-1.38)	0.84 (0.74-0.94)**
Timeline		0.91 (0.81-1.01)	0.87 (0.77-0.98)*	1.36 (1.13-1.63)**
Treatment control				1.20 (1.02-1.40)*
Concern				
Emotion				
Health Anxiety	1.04 (1.01-1.07)*	1.05 (1.01-1.07)*	1.07 (1.03-1.11)**	1.06 (1.02-1.09)**

* $p<0.05$, ** $p<0.01$, *** $p<0.001$, [$] Reference

Conclusion: FDRs' perceived risk of RA was high. Key predictors included being a child of a patient with RA, higher health anxiety and lower perceptions of RA treatment control. An understanding of these predictors will inform the development of effective risk communication and preventive strategies.

POS0598

PERSISTING PAIN IN RHEUMATOID ARTHRITIS: DO WE NEED TO RECONSIDER OUR IDEA OF PAIN ALLEVIATION DESPITE ANTI-INFLAMMATORY TREATMENT?

C. Baerwald[1], E. Stemmler[2], S. Gnuechtel[3], K. Jeromin[3], C. Holland[3], B. Fritz[3], D. Adolf[4], P. C. Taylor[5], R. Baron[6]. *[1]University Hospital Leipzig, Department of Medicine, Neurology and Dermatology, Rheumatology Unit, Leipzig, Germany; [2]AbbVie Germany GmbH & Co. KG, AbbVie Deutschland GmbH & Co. KG, Wiesbaden, Germany; [3]AbbVie Deutschland GmbH & Co. KG, AbbVie Deutschland GmbH & Co. KG, Wiesbaden, Germany; [4]StatConsult GmbH, Biometrics and Datamanagement, Magdeburg, Germany; [5]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Headington, Oxford, United Kingdom; [6]University Hospital Schleswig-Holstein, Division of Neurological Pain Research and Therapy, Department of Neurology, Kiel, Germany*

Background: Pain significantly impacts life of patients with rheumatoid arthritis (RA) (1). Besides articular pain due to systemic inflammation, neuropathic pain (NeP) represents another challenge that can pose a considerable burden on the life of patients (2).
Objectives: To investigate persisting pain in RA patients and to analyse NeP along with patient-reported outcomes (PROs).
Methods: PAIN-CONTROL is a prospective, non-interventional study in rheumatology centres in Germany. Inclusion criteria were fulfilment of the 2010 ACR/EULAR RA classification criteria, disease duration ≤ 8 yrs, DAS28 > 3.2, SJC > 3, CRP normal or above reference range, and pain rating ≥ 50 (0-100 VAS). Eligible subjects had to be scheduled for escalation of anti-inflammatory treatment according to national guidelines. At wk 24 subjects were allocated to three subgroups given DAS28-CRP change and VAS pain: i) reference group: VAS pain < 50 with either DAS28 improvement > 1.2 or DAS28 ≤ 3.2, ii) non-responders: DAS28 improvement ≤ 1.2 and DAS28 > 3.2 with or without pain alleviation, iii) persisting pain: VAS pain ≥ 50 with either DAS28 improvement > 1.2 or DAS28 ≤ 3.2. For groups 1 and 2 end of study was at week 24, patients with persisting pain continued until wk 48. Patients were assessed for NeP using a score of ≥ 19 in the painDETECT questionnaire (PD-Q) (3). Pain-related PROs, i.e. the Rheumatoid Arthritis Impact of Disease Questionnaire (RAID) and the Patient Health Questionnaire (PHQ-9), were analysed along with demographic background information (1,4). Descriptive results are presented as mean (SD) or mean (SD) | N_{valid}, as well as n (%) or n (%) | N_{valid}, respectively.
Results: 567 subjects were analysed with the following distribution: Reference group 337 (59.4%), non-responders 102 (18.0%), and persisting pain 128 (22.6%), of which 115 patients were available at wk 48. Subgroups showed similar demographic baseline characteristics but differed in PROs (Table 1). Until wk 24, proportion of patients with NeP indication decreased in the reference group (-19.8%) and slightly in non-responders (-6.0%) and persisting pain group (-9.5%). Non-responders showed the highest NeP proportion at wk 24 (35.0%) (Table 1). Of 115 patients with

persisting pain at wk 24, 47 (40.9%) tested NeP negative at wk 48, 21 (18.3%) tested unclear, 28 (24.3%) were missing and 19 (16.5%) tested positive. Of the latter 9 patients (47.4%) still had persisting pain at week 48, while this was the case for 14 patients (29.8%) in the former group. 49 (42.6%) of 115 patients with severe persisting pain at wk 24 reported pain alleviation at wk 48 and fulfillment of reference group criteria. RAID and PHQ-9 scores improved in the reference group but only slightly in the other two subgroups.

Table 1. Demographic background and PROs

Characteristic	Reference group (N = 337)	Non-responders (N = 102)	Persisting pain (N = 128)
Gender (f/m)	233 (69.1%) / 104 (30.9%)	65 (63.7%) / 37 (36.3%)	87 (68.0%) / 41 (32.0%)
Age	57.1 (13.2) | 337	59.9 (12.0) | 102	57.1 (13.0) | 128
Disease duration (yrs)	2.5 (2.6) | 337	2.7 (2.8) | 102	2.5 (2.5) | 128
PD-Q (≥ 19) (BI)	82 (28.6%) | 287	32 (41.0%) | 78	40 (36.0%) | 111
PD-Q (≥ 19) (wk 24)	21 (8.8%) | 239	28 (35.0%) | 80	27 (26.5%) | 102
PD-Q (BI)	14.0 (6.8) | 287	15.5 (7.1) | 78	15.5 (6.5) | 111
PD-Q (wk 24)	8.8 (5.8) | 239	14.8 (6.7) | 80	13.8 (7.2) | 102
RAID (BI)	5.8 (2.0) | 332	6.0 (1.9) | 100	6.6 (1.7) | 125
RAID (wk 24)	2.4 (1.8) | 321	5.4 (1.9) | 97	5.1 (1.9) | 123
PHQ-9 (BI)	7.3 (5.1) | 328	8.4 (5.4) | 98	7.9 (5.1) | 123
PHQ-9 (wk 24)	3.8 (3.5) | 318	7.3 (4.5) | 95	6.6 (4.5) | 122

Conclusion: NeP is common among RA non-responders to anti-inflammatory treatment and in patients with persisting pain, meriting a routine NeP screening to more adequately address persisting pain in these patients. However, even late improvements (after 24 wks) regarding persisting pain seem likely during anti-inflammatory treatment.

POS0599 IMPACT OF TREAT-TO-TARGET THERAPY ON BONE MINERAL DENSITY LOSS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE COHORT STUDY

H. Huang[1], Y. Wang[1], W. Xie[1], Y. Geng[1], D. Gao[1], Z. Zhang[1]. *[1]Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Osteoporosis is a common comorbidity of rheumatoid arthritis (RA). Although RA disease activity has been demonstrated to be associated with bone loss in previous studies, most of them were cross-sectional studies and not in the context of treat-to-target (T2T) strategies.

Objectives: To evaluate the association of disease activity with bone mineral density (BMD) changes in the context of T2T strategies in a prospective RA cohort.

Methods: RA patients were enrolled from a prospective CENTRA cohort of Peking University First Hospital. BMD was repeated at baseline, 1-year and then every other year. Time-adjusted mean disease activity scores were adopted to reflect the overall disease activity during follow-up. The influence of univariable associations between predictors and BMD was investigated using linear regression.

Results: A total of 268 patients were included in our analysis. Their mean age was 50 (12.9) years old. At enrollment, the mean (SD) DAS28-ESR was 3.70 (1.17), and the median (IQR) CDAI and SDIA was 10 (14.45) and 10.30 (16.53), respectively. Osteoporosis at lumbar spine was observed in 23.1% patients and 9.3% at femoral neck at enrollment. Older age, higher SDAI score and lower BMI were found to be associated with osteoporosis at baseline. Reevaluations of BMD at 1 year was applied in 144 patients. Mean decreases of BMDs were 1.75 % at the lumbar spine and 1.40 % at femoral neck at 1 year form baseline, respectively. Patients who achieved remission had less yearly bone loss at lumbar spine (p=0.036). Female gender was identified as a risk factor in the multiple linear regression analyses, and lower disease activity and bisphosphonates were protective factors of continuous bone loss.

Conclusion: Disease activity is associated with bone loss in RA patients in the context of T2T strategies, and those who achieved remission had less yearly bone loss.

POS0600 ANGIOGENIC T-CELL DEPLETION OCCURS DURING THE EARLIEST PHASES OF RHEUMATOID ARTHRITIS LINKED TO SUBCLINICAL VASCULAR STIFFNESS

J. Rodríguez-Carrio[1,2], M. Alperi-López[2,3], P. López[2,2], Á. Pérez-Álvarez[4], A. Suárez[1,2]. *[1]University of Oviedo, Area of Immunology, Oviedo, Spain; [2]Instituto de Investigación Sanitaria del Principado de Asturias, Research Group on Basic and Traslational Research of Chronic Inflammatory Diseases, Oviedo, Spain; [3]Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain; [4]Hospital Universitario Central de Asturias, Neurology, Oviedo, Spain*

Background: vascular insult accounts for the cardiovascular (CV) risk excess in rheumatoid arthritis (RA). Angiogenic T cells (Tang), which are responsible of vascular repair, have been described to be reduced in established RA with overt CV disease. However, whether Tang are altered during the earliest stage of the disease and related to subclinical CV findings is unknown.

Objectives: to evaluate circulating Tang levels in the very early stage of RA, including clinically suspect arthralgia (CSA), and their associations with subclinical CV endpoints (subclinical atherosclerosis and vascular stiffness).

Methods: 84 RA patients (2010 EULAR/ACR classification criteria), 14 CSA individuals (EULAR criteria) and 28 matched healthy controls (HC) were recruited. All patients were untreated at the time of sampling. Tang (CD3+CD31+CXCR4+) frequency was assessed by flow cytometry in peripheral blood samples. Plaque occurrence, cIMT and stiffness parameters were analyzed by Doppler ultrasound in internal carotid, middle cerebral and basilar arteries. Lipoprotein analyses were performed by NMR.

Results: Tang were decreased in RA and CSA groups compared to HC (both p<0.010). Whereas Tang frequency was negatively correlated with very low density lipoproteins features (cholesterol and triglyceride content, size distribution and particle number) in HC and positively with HDL (cholesterol content and particle number), these associations were lacking in RA

and CSA groups. Tang levels were not related to individual traditional CV risk factors, body mass index, wait circumference (all p>0.050) nor with the modified SCORE (r=-0.070, p=0.542) or Framingham Risk Score (r=-0.013, p=0.907). On the contrary, disease activity accounted for the Tang depletion observed in RA (b[95% CI]; DAS28: -0.436 [-0.306, -0.109], p=<0.001; SDAI: -0.020 [-0.032, -0.008], p=0.002). Tang levels were unrelated to the duration of the symptoms both in RA and CSA. In RA patients, Tang frequency was not associated with atherosclerosis plaque occurrence (p=0.556) or cIMT (r=0.136, p=0.245). However, Tang paralleled stiffness parameters: vascular strain (VS, r=0.373, p=0.013), vascular distensibility (VD, r=0.479, p=0.004), vascular stiffness (VSf, r=-0.400, p=0.007) and pressure-strain elastic modulus (PSEM, r=-0.373, p=0.013). Finally, Tang frequency was an independent predictor of stiffness parameters after adjusting for mSCORE, body mass index, DAS28, RF and ACPA positivity: VS (β=0.415, p=0.035), VD (β =0.361, p=0.028), VSf (β =-0.322, p=0.033) and PSEM (β =-0.346, p=0.016).

Conclusion: Tang depletion is an early event along RA development, associated with disease-related parameters and unrelated to traditional risk factors. Tang may be the missing, functional link between disease activity and CV outcomes. Altered Tang levels may be an early biomarker of premature vascular stiffness during the first stages of the disease.

POS0601 CRANIOCERVICAL JUNCTION INVOLVEMENT ASSESSED BY COMPUTED TOMOGRAPHY AND/OR MAGNETIC RESONANCE IMAGING IN INFLAMMATORY ARTHRITIS: SINGLE CENTER CASE-CONTROL STUDY

F. Yalçınkaya[1], Ş. Parlak[2], E. Bilgin[3], K. Karlı Oğuz[2], U. Kalyoncu[3]. *[1]Hacettepe University, Internal Medicine, Ankara, Turkey; [2]Hacettepe University, Radiology, Ankara, Turkey; [3]Hacettepe University, Rheumatology, Ankara, Turkey*

Background: Craniocervical involvement is generally overlooked clinically.

Objectives: The aim of this study is to investigate the craniocervical involvement in inflammatory arthritidies and compare with patients without inflammatory arthritidies.

Methods: In this retrospective analysis, cervical CT and/or MRI scans -taken for any reasons between 2010 and 2020 - of patients with rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsA) (M05, M06, M07 and M45) according to ICD-10 codes were scanned from the hospital database. The diagnosis of RA, AS, and PsA was confirmed by an experienced clinician with medical history, laboratory, and treatment history. Of these patients, those who underwent CT and/or MRI before the definitive diagnosis of inflammatory arthritis were included in the analyses. Demographic data of the included patients were recorded. Craniocervical involvements (anterior, posterior, lateral, and rotational atlantoaxial subluxation; vertical subluxation; subaxial subluxation; odontoid process involvement [resorption or pannus], atlantoaxial and atlantooccipital involvement) were evaluated by an experienced radiologist on CT or MRI, as appropriate. Control group was consisted of consequent patients without inflammatory arthritidies and who undergone cervical CT or MRI with any reasons out of trauma. p<0.05 was considered statistically significant.

Results: From a total of 4442 records (1558 individual patients), 459 patients (204 RA, 200 SpA, and 55 PsA patients) and 78 patients for control group were included in the study. **In** Table 1, comparison of RA, SpA and control groups was given. The percentage of female gender and age at diagnosis were lower in SpA patients. Craniocervical junction involvement was detected in 101 (49.5%) RA, 53 (26.5%) SpA, 4 (5.1%) of control group, p<0.001. The odontoid process appears to be one of the main targets at the craniocervical junction, especially in RA patients (69 (33.8%)) which was significantly higher than SpA and control groups. Atlantoaxial subluxation and atlantoaxial joint involvement were significantly higher in RA and SpA groups than control group. Although vertical subluxation (VS) was numerically higher in RA nd SpA groups compared to control group, VS-related brainstem compression was relatively uncommon (6 (2.9%) in RA, 1 (0.5%) in AS, none of the control group. Spinal cord compression was detected in 8 (7.9%) RA patients and 2 (1.0%) AS patients and none of the control group. Regarding PsA, percentage of overall craniocervical involvement was higher than control group (16.4% vs 5.1%) without precedence of any specific involvement.

Table 1. Comparison of RA, SpA and control groups for spesific types of craniocervical involvements

	RA (n=204)	SpA (n=200)	Control group (n=78)	p; RA vs SpA vs Contol	p; RA vs Control	p; SpA vs Control	p; RA vs SpA
Female, n (%)	166 (81,4)	124 (62,0)	55 (70.5)	<0,001	0.048	0.18	<0,001
Age at the time of CT	50 (41-60)	38 (32-47)	46 (18-86)	<0,001	<0,001	0.45	<0,001
Any type of involvement	101(49,5)	53 (26,5)	4 (5.1)	<0,001	<0,001	<0,001	<0,001
Odontoid process involvement	69(33,8)	24 (12,0)	0	<0,001	<0,001	0,001	<0,001
Odontoid process resorption	62(30,4)	19(9,5)	0	<0,001	<0,001	0,005	<0,001
Odontoid process pannus	37(18,1)	9(4,5)	0	<0,001	<0,001	0.065	<0,001
Atlantoaxial subluxation (AAS)	17(8,3)	10 (5,0)	0	0.022	0.004	0.067	0.018
Spinal cord compression due to AAS	5 (2,5)	1 (0,5)	0	0.12			
Vertical subluxation (VS)	24 (11,8)	20/197 (10,2)	3 (3.8)	0.13			
Brainstem compression due to VS	6 (2,9)	1 (0,5)	0	0.06			
Subaxial subluxation (SAS)	12 (5,9)	4 (2,0)	1 (1.3)	0.054			
Spinal cord compression due to SAS	3 (1,5)	1 (0,5)	0	0.38			
Atlantoaxial joint involvement	23/186 (12,4)	13 (6,5)	0	0.002	0.001	0.023	0.32
Atlantooccipital joint involvement	6/187 (3,2)	3 (1,5)	0	0.19			

CT: Computarized tomography, RA: Rheumatoid arthritis, SpA: Spondyloarthritis

Conclusion: Craniocervical junction involvement can often be detected in patients with inflammatory arthritis, especially in patients with RA. Odontoid process seems as the main target of inflammation. Craniocervical involvement has the potential to be overlooked clinically, and needs to be evaluated more carefully.

POS0602 PULMONARY RHEUMATOID NODULES: DOES SEROLOGIC STATUS MATTER?

Y. Sarıkaya[1], G. Sandal Uzun[2], E. B. Ata[2], S. Arslan[1], M. Ekici[2], G. Durhan[1], E. Bilgin[2], U. Kalyoncu[2], M. Arıyürek[1]. *[1]Hacettepe University, Radiology, Ankara, Turkey; [2]Hacettepe University, Rheumatology, Ankara, Turkey*

Background: The frequency of pulmonary rheumatoid nodules closely relates to the diagnostic modality and changes from <0.4% to 32%. Also, it is known that seropositive RA patients tend to have more extra-articular disease.

Objectives: We aimed to compare the disease and pulmonary rheumatoid nodule characteristics of seropositive and seronegative RA patients.

Methods: In this study, all RA patients - according to ICD-10 code - and had at least one chest computerized tomography (CT) were examined and revealed 4117 individual patients. First, RA diagnosis was confirmed according the patients' history, physical examination, radiography and laboratory assessment. Then, chest CTs were examined by an experienced radiologist. To classify pulmonary nodules as ''pulmonary rheumatoid nodule'', following inclusion and exclusion criteria were used; For inclusion: 1) nodules with changing dimension on follow-up, 2) At least two nodules with different dimensions, 3) Cavitary nodule at any chest CT. For exclusion: 1) Solitary nodules OR all nodules ≤ 5mm and without follow-up OR no change on follow-up. Biggest nodule was named as **dominant nodule.** Then, patients were grouped according to rheumatoid factor and anti-CCP status as seropositive (RF ± anti-CCP) and seronegative. Demographics, comorbidities, RA-spesific treatments and nodule characteristics were compared.

Results: Of 680 RA patients who had pulmonary nodule in chest CT, 208 (30.6%) patients were classified as having pulmonary rheumatoid nodule. 167 (80.3%) patients were seropositive. Demographic and comorbidity characteristics were similar among seronegative and seropositive patients (Table 1). Regarding RA-spesific treatments, methotrexate, leflunomide and rituximab were prescribed more frequently in seropositive patients. For nodule characteristics, seropositive patients had higher number of nodules (5 [1-48] vs 3 [1-27]; p=0.004), bigger dominant nodule (8 [3-95] vs 6 [3-45] mm; p=0.011), and higher percentage of cavitary nodule (28.7% vs 12.2%; p=0.03). Localization of the nodule was compareble.

Table 1. Comparison of demographic, disease and nodule characteristics of seropositive and seronegative patients (n=208)

	Seropositive (n=167, 80.3%)	Seronegative (n=41, 19.7%)	P value
Female, n(%)	113 (67.7)	28 (68.3)	0.94
Age at the time of CT (median, min-max)	61 (24-83)	59.7 (20-83)	0.28
Smoking (n=73)	26 (43.3)	4 (30.8)	0.40
- **Never smoked**	34 (56.7)	9 (69.2)	
- **Ever smoked**			
Comorbidity (n=188)	127 (84.7)	30 (78.9)	0.40
- **Hypertension**	72 (55.0)	18 (58.1)	0.91
- **Diabetes (n=166)**	25 (18.5)	7 (22.6)	0.79
- **CAD (n=165)**	30 (22.6)	7 (21.9)	0.93
- **Heart Failure (n=164)**	15 (11.4)	6 (18.8)	0.41
- **COPD (n=163)**	20 (15.2)	1 (3.2)	0.13
- **Asthma (n=160)**	15 (11.6)	5 (16.1)	0.54
- **CKD (n=169)**	20 (14.5)	8 (25.8)	0.22
- **ILD (n=202)**	54 (33.1)	10 (25.6)	0.37
RA-spesific treatments (ever)	90 (72.6)	16 (55.2)	0.07
- **Methotrexate (n=153)**	105 (64.0)	12 (30.8)	**0.001**
- **Leflunomide (n=208)**	117 (70.5)	25 (61.0)	0.06
- **Hydroxchloroquine (n=169)**	65 (47.4)	11 (36.7)	0.28
- **Sulfasalazine (n=167)**	39 (39.0)	6 (27.3)	0.30
- **TNFi (n=122)**	41 (39.8)	2 (9.5)	0.008
- **Rituximab (n=124)**	11 (9.9)	2 (8.0)	0.77
- **Tofacitinib (n=136)**	12 (11.9)	2 (10.5)	0.86
- **Abatacept (n=120)**	9 (8.5)	2 (8.7)	0.98
- **Tocilizumab (n=129)**			
Number of nodules at baseline CT (median, min-max)	5 (1-48)	3 (1-27)	**0.004**
Diameter of dominant nodule (median, min-max) (mm)	8 (3-95)	6 (3-45)	**0.011**
Localization of dominant nodul	64 (38.3)	15 (36.6)	0.84
- **Left or right?**	64 (38.3)	12 (29.3)	0.48
◦ **Left**	51 (30.5)	16 (39.0)	0.28
- **Upper, middle or lower?**	52 (31.1)	13 (31.7)	
◦ **Upper**	69 (41.3)	21 (51.2)	
◦ **Middle**	22 (13.2)	7 (17.1)	
◦ **Lower**	76 (45.5)	13 (31.7)	
-Peripheral, central or subpleural			
◦ **Peripheral**			
◦ **Central**			
◦ **Subpleural**			
Cavitation	48 (28.7)	5 (12.2)	**0.03**
Calcification	54 (32.5)	12 (29.3)	0.69

CAD: Coronary artery disease, CKD: Chronic kidney disease,; ILD: Interstitial Lung Disaese,

Conclusion: Autoantibodies seem to have impact on the characteristics of pulmonary rheumatoid nodules. As there were different prescription patterns were seen in our study, effects of these treatment differences need to be determined.

POS0603 CARDIOVASCULAR RISK FACTORS BEFORE ONSET OF RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH CARDIOVASCULAR EVENTS AFTER DISEASE ONSET – A CASE CONTROL STUDY

H. Kokkonen[1], L. Johansson[1], H. Stenlund[2], S. Rantapää Dahlqvist[1].
[1]Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden; [2]Public Health and Clinical Medicine, Epidemiology and Global Health, Umeå, Sweden

Background: Increased comorbidity and mortality in rheumatoid arthritis (RA) patients are highly due to cardiovascular disease (CVD). The etiology of this increased morbidity and mortality in patients with RA compared with the general population is not fully understood. We have previously shown that individuals who subsequently develop RA have increased frequencies of several risk factors for CVD, such as elevated BMI, elevated Apoliprotein (Apo) B/ApoA1 ratio, and cigarette smoking compared with matched controls, already before symptom onset of RA.
Objectives: We aimed to assess the impact of CV risk factors, already present before onset of symptoms of RA, for future CV events (CVE) in comparison with matched controls.
Methods: A case-control study including 521 individuals before symptoms of RA and 1,566 matched controls identified in the Health Surveys of the Medical Biobank of Northern Sweden was performed. Information regarding the presence of the selected risk factors for CVD was based on surveys with data collected in the Västerbotten Intervention Programme (VIP) and the Northern Sweden Multinational Monitoring of Trends and Determinants in Cardiovascular Disease (MONICA). Selected CVD risk factors were: hypertension, elevated Apolipoprotein B/A1 ratio, elevated body mass index, diabetes, and smoking. Information on comorbidities (coded according to the International Statistical Classification of Diseases and Related Health Problems ninth or tenth revision (ICD-9 and/or -10)) was requested from the Swedish National Patient Register and the Cause of Death Register. Statistics were performed using SPSS version 26.0 (IBM Corp., NY, USA), Cox proportional hazard regression was used and presented with calculated hazard ratios (HRs) and 95% confidence intervals (CI). Adjustments were performed for risk factors developed after RA onset.
Results: Pre-RA individuals had a higher risk for CVE after RA onset compared with matched controls (HR (95% CI)= 1.70 (1.31-2.21)) which remained after adjustment for various risk factors for CVD, (HR (95% CI)= 1.69 (1.24-2.30)). Also, treatment with biological disease modifying anti rheumatic drugs (bDMARDs) were associated with CVE (HR (95% CI)=2.06 (1.05-4.03), adjusted for CV risk factors). Most of the risk factors present prior to RA were associated with CVE after diagnosis, The significant association of risk factors present before RA onset for a CVE after onset remained after adjustments for risk factors that developed after RA onset. A combination of risk factors resulted in a higher risk in RA compared with controls (OR (95% CI); two risk factors 3.30 (1.16-9.36), vs. 1.21 (0.62-2.37), and three-four risk factors, 7.32 (2.71-19.74), vs. 4.16 (2.27-7.67).
Conclusion: Known risk factors for CVD present in individuals prior to onset of RA were associated with future CVE and even after adjustments for the risk factors, patients with RA had a higher risk for CVE compared with controls. In addition, risk factors present before RA was associated with future CVE even after adjustment for risk factors developed after RA onset. These findings further enlighten the importance of early assessment of risk for CVD in RA.

POS0604 THE EFFECT OF TRANSCUTANEOUS AURICULAR VAGUS NERVE STIMULATION AND DEEP BREATHING EXERCISES ON HEART RATE VARIABILITY IN HEALTHY PARTICIPANTS AND PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

M. K. Jensen[1], S. S. Andersen[1], C. H. Liboriussen[1], S. S. Andersen[1], M. R. Jochumsen[1], S. Kristensen[2]. *[1]Aalborg University, Department of Health Science and Technology, Aalborg, Denmark; [2]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark*

Background: Rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) are chronic autoimmune diseases associated with a reduced function of the autonomic nervous system including an impaired function of the vagus nerve (VN). The VN has potential anti-inflammatory effects, which could be utilized in a new treatment approach using vagus nerve stimulation (VNS). Different types of VNS exist, but no direct comparison has been made of the methods in patients with RA and SLE.
Objectives: The aim of this study was to compare the effect of transcutaneous auricular VNS (taVNS) and deep breathing (DB) on vagal tone in patients with RA or SLE and healthy participants and to investigate the washout effect assessed through time domain heart rate variability (HRV) measures (RMSSD (root-mean-square of successive differences), SDNN (standard deviation of N-N intervals), and PNN50 (percentage of adjacent N-N intervals that differ from each other by more than 50 milliseconds)).
Methods: The study was designed as an open label cross-over study. 42 healthy participants and 52 patients with RA or SLE performed two interventions, 30 minutes of taVNS and 30 minutes of DB. The interventions were separated by at least 24 hours. Before each intervention, two 5-minutes ECG-recordings were made to determine the participants' baseline HRV. After each intervention three 5-minutes ECG-recordings were conducted in the following 30 minutes to investigate the potential washout effect.
Results: Healthy participants: A significant increase in SDNN, RMSSD, and PNN50 were found after DB. SDNN increased significantly immediately after taVNS. SDNN was significantly higher after DB compared to taVNS. Otherwise, there were no significant differences between the effects of the two interventions. Patients: A significant increase in SDNN, RMSSD, and PNN50 were present after both DB and taVNS. No significant differences were found between the effects of the two interventions. The effects of the interventions were still measurable 30 minutes after intervention, indicating no washout.

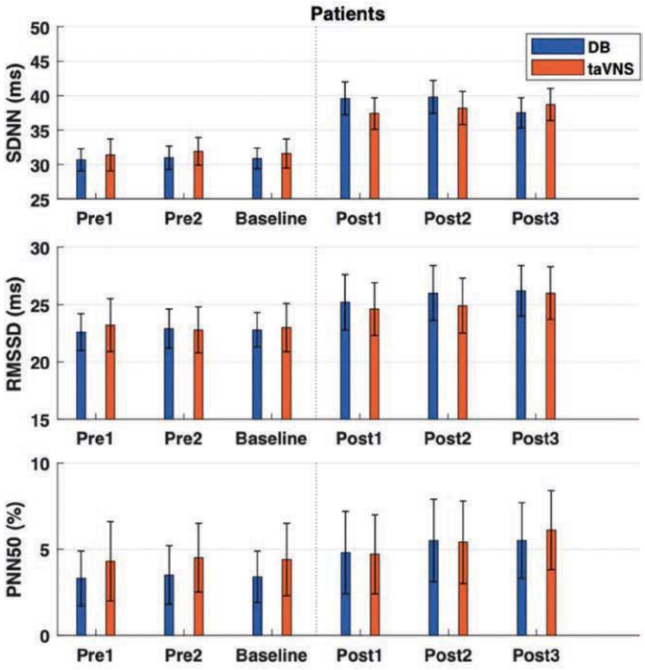

Figure *HRV-data for the patient population. Baseline shows mean values of Pre1 and Pre2. Data are displayed as mean ± standard er ror across participants.*

Conclusion: DB causes the greatest increase in HRV for healthy participants, while both DB and taVNS can equally elevate HRV in patients with RA and SLE, which support their use as a potential new treatment approach. However, their clinical effect needs to be investigated in future studies.

POS0605

IN PATIENTS WITH RHEUMATOID ARTHRITIS, CLINICAL EXAMINATION OF THE FEET IS IMPORTANT FOR UNDERSTANDING INDIVIDUAL DISEASE BURDEN, BUT DOES NOT PROVOKE A CHANGE IN THERAPY IN MOST CASES

N. Leuchten[1], C. Weinert[1], M. Aringer[1]. [1]*University Medical Center and Faculty of Medicine TU Dresden, Division of Rheumatology, Department of Medicine III, Dresden, Germany*

Background: Disease activity scores like CDAI, SDAI or DAS28, are essential for measuring rheumatoid arthritis (RA) disease activity. These do not contain foot joints. However, foot pain is an important aspect of morbidity for RA patients, which leads to reduced mobility and quality of life.

Objectives: To analyse the impact of synovitis in ankle and metatarsophalangeal joints on RA scores and RA disease activity states.

Methods: Joint scores of 545 RA outpatients were followed from August 2004 through December 2020. Informed consent for the analysis of their routine data was obtained for every patient. The standard CDAI cut-offs used were CDAI ≤ 2.8 for remission (REM), CDAI > 2.8 - 10.0 for low disease activity (LDA), CDAI > 10.0 - 22.0 for moderate disease activity (MDA) and CDAI > 22.0 for high disease activity (HDA). Foot involvement (FI) was defined as having at least one swollen (SJ) or tender (TJ) foot joint in patients who ever had palpable synovitis in any of these joints. The visits were grouped according to the number of swollen joints (SJ 0-28). The mean Physician Global Assessment of disease activity (PhGA) was calculated for each SJ group and the difference between the mean PhGA in patients with and without FI (as defined above) was calculated for each SJ group (ΔPhGA). Statistical analysis was performed in IBM SPSS Statistics Version 28.0.1.0.

Results: A total of 7,577 visits of 545 patients were included, for a mean of 14 visits per patient. 413 (75.8%) of the patients were female, the mean age at visit was 59 years, mean disease duration was 13 years, 284 (52.1%) were ACPA positive. 247 (45.3%) were on glucocorticoid therapy, 50 (9.2%) were on biological DMARDs. The median CDAI at visit was 4.3 (interquartile range IQR 1.6 - 9.0), the median DAS28 was 2.56 (IQR 1.89 - 3.37), the median CRP was 2.5 (IQR 1.0 - 6.2) mg/L. At 2,853 (37.7%) visits the patient was in REM, at 3,134 (41.4%) visits in LDA, at 1,265 (16.7%) visits in MDA and at 324 (4.3%) visits in HDA. Patients with FI were more active and scored higher on CDAI (9.1 vs. 3.4, p<0.001) and DAS28 (3.19 vs. 2.45, p<0.001), even though the indices do not include the foot joints. This was mainly due to higher patient global assessment of disease activity (3.1 vs. 2.0, p<0.001). Involvement of the feet also led to a higher physician estimate of global disease activity. The mean difference of PhGA between patients with and without involvement of their feet (ΔPhGA) was meaningful for joint counts 0-10, with an unweighted mean ΔPhGA of 0.273. Of the 217 patients with FI, 3,776 visits were analyzed. For patients with FI, the potential change in disease activity was calculated by subtracting ΔPhGA from the CDAI at each visit. For 3,662 (97.0%) of the visits, this did not result in a change of disease activity state. For 90 (2.4%) visits, disease activity changed from LDA to REM, for 21 (0.6%) from MDA to LDA, and for only 3 (0.1%) visits from HDA to MDA. At 83 (1.1%) visits of a total of 59 (10.8%) patients, only swollen foot joints without tender foot joints were recorded.

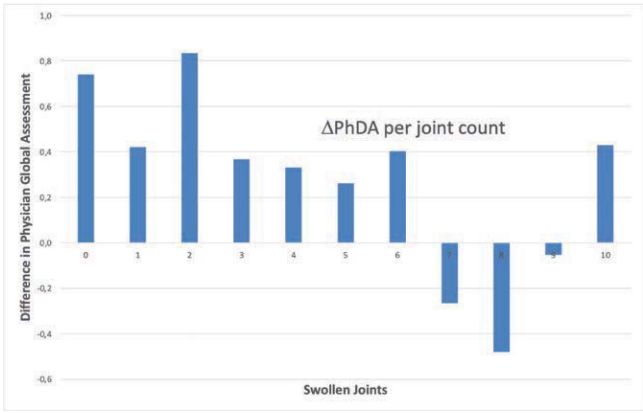

Figure 1.

Conclusion: Patients with foot involvement are more active and score disproportionally high on disease activity indices, even though these do not include foot joints. While patients suffer significantly from foot involvement, underestimating disease activity by not assessing the feet would have changed the disease activity state for 3.1% of the visits only. Palpable synovitis without tenderness, which would be missed by performing only a metatarsophalangeal squeeze test, was found at one in a hundred visits.

HOW DO GLUCOCORTICOIDS, BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS AND DISEASE ACTIVITY IMPACT THE RISK OF STAPHYLOCOCCUS AUREUS BACTEREMIA IN RHEUMATOID ARTHRITIS PATIENTS? A NATIONWIDE NESTED CASE CONTROL STUDY IN THE DANISH DANBIO COHORT

Background: *Staphylococcus aureus* bacteremia (SAB) has high mortality and rheumatoid arthritis (RA) patients are at increased risk,[1] however, the role of anti-rheumatic treatments and disease activity is unclear.[2,3]
Objectives: To explore the impact of treatment with glucocorticoids and biologic disease-modifying anti-rheumatic drugs (bDMARDs) and disease activity on the risk of SAB in RA patients.
Methods: Nested case control study in a nationwide cohort of RA patients (DANBIO) with no history of SAB. Cases had a first-time microbiologically verified SAB between 2010-2018. Controls were incidence density matched (age and sex) at time of SAB (index date). We linked data from DANBIO (e.g. disease activity, anti-rheumatic treatment) to other national registries (comorbidities, prescriptions, socioeconomic status, etc). Treatments were redeemed prescriptions or registrations in DANBIO (oral glucocorticoids, bDMARDs) 0-2 years before the index date. Dose of oral glucocorticoids was retrieved from either DANBIO or estimated from the latest prescription. Risk associated with treatment and disease activity was assessed by multivariate conditional logistic regression. For treatments, excess cases/10,000 exposed/year were calculated by multiplying the fully adjusted OR (95%CI) with the incidence rate in the cohort. Missing data was handled by multiple imputation.
Results: We identified 180 cases in 30,479 RA patients (IR 106.7/100,000 person-years) and matched 720 controls (53% women, median age 73 years, IQR 65;80). For cases, orthopedic implants were frequent (53%/34% for cases/controls), many had recent surgery (38%/5%), longstanding RA (13 years (6;21)/8 (4;14)), joint erosions (48%/39%), moderate (29%/16%) or high (10%/7%) disease activity, and used glucocorticoids (41%/19%) and bDMARDs (31%/20%). Adjusted ORs were high for current use of oral glucocorticoids, especially for doses >10mg/day (OR=14.5 (4.0; 52.2)). For bDMARDs, adjusted OR was 1.9 (1.1; 3.2). Correspondingly, the treatments increased risk with 144 and 9 excess cases/10,000/year, respectively (Table 1). For disease activity, adjusted ORs were >1 (non-significant) for moderate and high disease activity compared with remission (Figure 1).

[a] >3 to 24 months before (rituximab >12 to 24 months), [b] 0-3 months before (rituximab 0-12 months)*adjusted for sex, age, comorbidities, implants, recent surgery, RA disease duration, time since entry, csDMARDs, socioeconomic-, sero-, erosive-, functional- and smoking status, body mass index, and disease activity (high/low/moderate/remission)

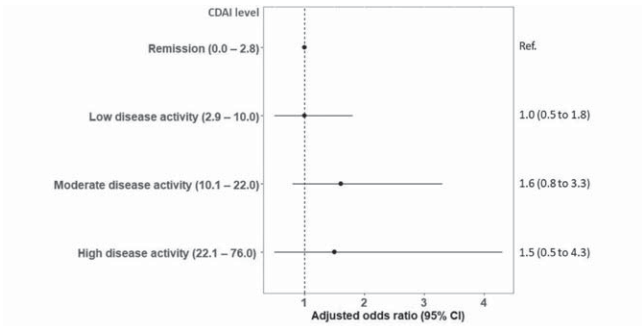

Figure 1. Disease activity and risk of *Staphylococcus aureus* bacteremia

Conclusion: Oral glucocorticoids and bDMARDs increased relative risk of SAB, with number of excess cases being high for oral glucocorticoids (>10 mg/day) and low for bDMARDs. Disease activity had minor impact on the risk. This emphasizes that high dose glucocorticoids should be used with caution.

IMPROVING TREAT-TO-TARGET IMPLEMENTATION IN RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW OF BARRIERS, FACILITATORS, AND INTERVENTIONS

L. Gossec[1], L. Bessette[2], R. Xavier[3], E. G. Favalli[4], A. Ostor[5], M. H. Buch[6]. *[1]Sorbonne Universite, Pitié-Salpêtrière Hospital, Paris, France; [2]Laval University, Rheumatology, Quebec City, Canada; [3]Universidade Federal do Rio Grande do Sul, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [4]ASST Gaetano Pini-CTO Institute, Division of Clinical Rheumatology, Milan, Italy; [5]Monash University and Emeritus Research, Cabrini Medical Center, Melbourne, Australia; [6]University of Manchester, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*

Background: Treat-to-target (T2T) is integral to international recommendations for managing patients with rheumatoid arthritis (RA),[1,2] but its implementation in clinical practice is suboptimal.[3] Understanding T2T barriers and facilitators may inform strategies for improving T2T implementation in RA.
Objectives: To review published evidence on barriers to and facilitators of T2T implementation in RA, and interventions designed to improve T2T implementation.
Methods: Two systematic literature searches were conducted to identify barriers to or facilitators of, and interventions designed to improve, T2T implementation in RA (Jan 1, 2015–Mar 1, 2021 and Jan 1, 2010–Jul 1, 2021, respectively). The quality of each study was assessed using the appropriate Critical Appraisal Skills Programme (CASP) checklist.[4] Barriers/facilitators and interventions were grouped into categories and summarized descriptively.
Results: The barriers/facilitators literature search retrieved 235 articles. Seventy-seven of these, which described primary studies mentioning a total of 331 T2T barriers/facilitators in RA, were included in the analysis. The interventions literature search identified 451 articles, including 70 primary studies reporting a total of 56 unique interventions to improve T2T implementation in RA. The quality of the studies varied; however, most addressed at least half of the information evaluated in the CASP checklists. Barriers/facilitators were categorized into 18 key target areas for patients (n=7), healthcare professionals (HCPs; n=6), or patients and HCPs (n=5). These related to: HCPs' or patients' knowledge or perceptions; patients' clinical or social conditions; patient–HCP communication or alignment; and time or resources (Figure 1). The 56 interventions were grouped into 18 types (Table 1). More than half of the interventions (n=30; 53.6%) were designed to improve or streamline disease activity or patient-reported outcome assessments or increase patient–HCP alignment on disease activity. Interventions designed to improve shared decision-making were also common (n=23; 41.1%); these included patient and HCP education (n=15), decision aids (n=7), and shared decision-making prompts (n=3). Of the 56 interventions, 20 (35.7%) reported improvements in T2T implementation and/or patient outcomes in RA. However, as most interventions were evaluated in single centers, their effectiveness, feasibility, and generalizability across other regions or healthcare settings were unclear.

Table 1. Interventions for improving T2T implementation in RA, by type

Type of intervention	Number of unique interventions (n=56)[a]
Electronic disease assessment recording	11
Disease assessment process/quality improvement initiative	8
Allied HCP-supported T2T strategy	8
Patient educational tools	7
Patient decision aid	7
HCP performance feedback	7
Integrated PRO assessment	6
Ultrasound assessment	5
HCP learning collaborative (structured learning sessions + performance feedback)	4
Patient PRO dashboard/visual feedback tool	4
Telehealth monitoring	3
HCP T2T/shared decision-making prompt	3
Nurse-led patient education	3
Multidisciplinary team program	3
HCP training	2
Patient telehealth education	2
HCP decision-making tool	1
Patient group sessions	1

[a]Interventions may be assigned to more than one categoryPRO, patient-reported outcome

Conclusion: While practical methods designed to improve T2T implementation in RA are available, their effectiveness and feasibility will likely vary by region and healthcare setting. More primary research is required to identify the most relevant barriers/facilitators and prioritize the most appropriate interventions to optimize T2T implementation both globally and locally.

POS0608

PROGRESSIVE INCREASE IN THE DIAGNOSTIC DELAY AND PERSISTENTLY SEVERE CLINICAL PRESENTATION OVER THE YEARS IN AUTOANTIBODY-NEGATIVE PATIENTS WITH RHEUMATOID ARTHRITIS IN THE SETTING OF AN EARLY ARTHRITIS CLINIC

L. De Stefano[1,2], B. D'Onofrio[1,2], G. Sakellariou[2,3], A. Manzo[1,2], C. Montecucco[1,2], S. Bugatti[1,2]. *[1]IRCCS Policlinico San Matteo Foundation, Division of Rheumatology, Pavia, Italy; [2]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy; [3]Istituti Clinici Scientifici Maugeri, Medicina Interna, Pavia, Italy*

Background: Over the past 20 years, despite the widespread diffusion of dedicated early arthritis clinics (EAC) and more sensitive classification criteria, the percentage of patients seen within the window of opportunity remains low, and the new RA criteria, heavily weighted on autoantibodies, may have further hindered the recognition and treatment of seronegative patients.
Objectives: we analysed changes in the diagnostic delay and clinical presentation of patients with RA admitted to the EAC of the Division of Rheumatology of the San Matteo University Hospital, Pavia, Italy, from its institution in 2005 to 2017.
Methods: Referral criteria to the EAC have remained stable over the years and include ≥3 swollen joints (SJs) or, in case of <3 SJs, a positive squeeze test or morning stiffness >30 min. From all early arthritis patients (n=1.553), we selected 668 patients fulfilling at enrolment at least the 1987 ACR criteria for RA before

December 2010 (n=345, 88.4% also fulfilling 2010 criteria), and at least the 2010 ACR/EULAR criteria after January 2011 (n=323, 63.5% also fulfilling 1987 criteria). Time from first self-reported joint symptom to referral (diagnostic delay) was compared across different time periods: (i) 2005-2007; (ii) 2008-2010; (iii) 2011-2013; (iv) 2014-2017. Clinical characteristics were collected according to standardised assessments. Data were analysed in the total population and after stratification for the autoantibody status (double negative for rheumatoid factor, RF, and anti-citrullinated protein antibodies, ACPA vs RF and/or ACPA positive).
Results: In all, the diagnostic delay collectively increased from a mean (SD) of 20.8 (20.5) weeks before 2010 to 24.4 (20.6) weeks thereafter (p=0.02), and the proportion of patients diagnosed within 12 weeks non-significantly decreased from 39.3% to 35.3%. Still, patients presented with progressively milder inflammatory markers despite unchanged joint tenderness and patient-reported outcomes (PROs). Trends were, however, remarkably different in different autoantibody subgroups. In RF/ACPA-positive patients, a stable proportion of 41-44% was diagnosed within 12 weeks (Figure 1**A**). At presentation, patients had fewer SJs and lower C-reactive protein (CRP) levels; the mean decrease of SJs and CRP from 2005-2007 to 2014-2017 were -5.6 and -1.1 mg/dl, respectively (Figure 1**B**). The improvement in PROs was smaller but still significant over time (Figure 1**C**). In contrast, in autoantibody-negative patients, the proportion of patients diagnosed within 12 weeks progressively decreased from 37.9% to 25.6% (p=0.08) (Figure 1**D**). Furthermore, the improvement over time of inflammatory features, especially of SJs, was significant but smaller than autoantibody-patients, and PROs such as pain and global assessment of disease activity remained severely impacting with mean values of up 60 mm even in recent times (Figure 1**E,F**).

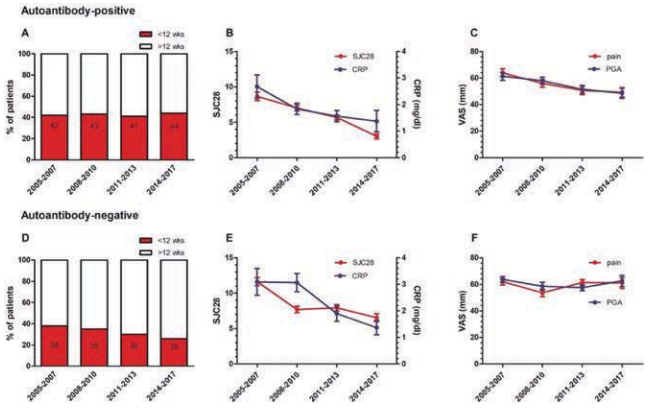

Figure 1. Time to diagnosis and clinical presentation of autoantibody-positive and –negative patients with early rheumatoid arthritis. (**A**, **D**) Proportion of patients diagnosed within 12 weeks from symptoms' onset among autoantibody-positive (**A**) and autoantibody-negative (**D**) rheumatoid arthritis (RA) in different time periods. (**B**, **C**, **E**, **F**) Values of swollen joints (SJC28), C-reactive protein (CRP) (**B**, **E**), and visual analogue scales (VAS) for pain and patient global assessment (PGA) of disease activity (**C**, **F**) in autoantibody-positive (**B**, **C**) and autoantibody-negative (**E**, **F**) RA in different time periods. Values are expressed as means and standard errors.

Conclusion: Collectively, our data indicate that a large proportion of patients with RA still lack early diagnosis despite dedicated early access to rheumatology care; from 2010 onwards, autoantibody-positive patients are diagnosed with a milder and less disabling disease, while autoantibody-negative patients are at increased risk of delayed diagnosis, and remain burdened with severe disease

POS0609 STRESS-ASSOCIATED INCREASES IN RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND FLARES DURING THE COVID-19 PANDEMIC

D. Furst[1], N. T. Morris[1], A. Q. Pham[2], T. Woodworth[1], D. Elashoff[3], J. Brook[3], V. Ranganath[1]. *[1]University of California, Los Angeles, Rheumatology, Los Angeles, United States of America; [2]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, United States of America; [3]University of California, Los Angeles, Medicine Statistics Core, Los Angeles, United States of America*

Background: The novel coronavirus disease 2019 (COVID-19) pandemic has spurred global action. Beginning in March of 2020, the Southern California COVID-19 pandemic response to limit virus transmission was characterized by mandated lockdowns and quarantines, resulting in significant stressors for rheumatology patients and potentially threatening their disease.
Objectives: To examine factors associated with changes in rheumatoid arthritis (RA) disease activity and flares in the COVID-19 pandemic.
Methods: RA patients identified by ICD-9/10 codes and active email addresses within a University of California, Los Angeles (UCLA) Rheumatology database were sent surveys via email in July and November of 2020. The survey was UCLA Institutional Review Board approved and included electronic consent and questions related to: perceptions of disease activity/remission via Routine Assessment of Patient Index Data 3 (RAPID3), flare frequency, RA flare questionnaire (RA-FQ), Perceived Stress Scale (PSS-4), and pandemic impact on stress (i.e. emotional state, apprehension, panic, helplessness, work, home, financial, and social distancing stress). Demographics were extracted from electronic medical records. Results were examined via descriptive analyses, Pearson correlations, and chi-square test for comparisons plus linear stepwise regressions where appropriate to evaluate the relationship between stress measures, RA disease activity, and flare frequency and severity.
Results: Among 5037 patients surveyed, 361 in July and 4676 in November,1128 (22.4%) responded. The study population demographics were: mean age of 57.5 ± 15.1 years, 79.4% female, racially diverse (69.6% Caucasian, 13.7 % LatinX, 9.5 % Asian, and 4.9% Black), and 62% seropositive (CCP and/or RF). Perceived disease activity and remission remained stable in most patients with 719 reporting no flares, and 409 in current flares at the time of the survey (Table 1). A minority reported perceived increases in disease activity which were associated with multiple aspects of perceived stress. At survey completion, 346 had not experienced flares, 290 had experienced one flare, and 492 had experienced multiple flares. Use of DMARDs was associated with lack of flare versus current flare (77.8% versus 71.6%, p = 0.02). The use of conventional synthetic, biologic, or targeted synthetic DMARDs were not associated with flare while current corticosteroid use was associated with flare (9.3% without flare and 20.8% with flare, p < 0.0001). Current flare was associated with increased PSS-4 scores (odds ratio (OR): 1.17 (95% confidence interval: 1.12 – 1.22, p < 0.0001). Figure 1 describes the odds ratio of experiencing aspects of stress with the presence of RA flare.

Table 1. Current RA flare at time of survey completion

	Current Flare No N=719	Current Flare Yes N=409	P-Value
RA duration (mean ± SD) years	15.6 ± 12.3	14.9 ± 11.6	0.3133
Patient Global (mean ± SD), range 0-10	3.5 ± 2.5	6.1 ± 2.2	<0.0001
RAPID3 (mean ± SD) range 0-30	6.1 ± 5.6	13.7 ± 5.7	<0.0001
Patient-Reported Remission, no. (%)	404 (57.1%)	49 (12.1%)	<0.0001
RA-FQ Score, (mean ± SD), range 0-50	13.4 ± 11.4	29.7 ± 10.8	<0.0001
PSS-4, (mean ± SD)	5.2 ± 3.1	6.9 ± 3.1	<0.0001
Overall stress level (%)			0.0004
Increased	62.3%	72.9%	
Unchanged	26.9%	21.8%	
Decreased	10.7%	5.4%	
Current RA Therapy			
Any DMARD	77.8%	71.6%	0.0218
csDMARD Only	31.4%	26.7%	0.0911
bDMARD Only	18.1%	16.9%	0.6082
tsDMARDs Only	3.3%	3.4%	0.9394
bDMARD + csDMARD Only	19.8%	19.8%	0.9823
tsDMARD + csDMARD Only	4.6%	4.9%	0.8188
Current Corticosteroid	9.3%	20.8%	<0.0001

SD = standard deviation; No. = number; RA = rheumatoid arthritis; RAPID3 = routine assessment of patient index data 3; RA-FQ = rheumatoid arthritis flare questionnaire; PSS-4 = perceived stress scale; D/C = discontinued; DMARD = disease modifying antirheumatic drugs; csDMARD = conventional synthetic DMARD; bDMARD = biologic DMARD; tsDMARD = targeted synthetic DMARD

Conclusion: In a large survey population of RA patients during the COVID-19 pandemic, multiple aspects of stress were found to correlate with RA disease activity and flare.

POS0610 THE RELATIONSHIP BETWEEN SYSTEMIC MANIFESTATIONS OF RHEUMATOID ARTHRITIS AND THE STRUCTURAL GEOMETRY OF THE MYOCARDIUM.

L. Feiskhanova[1], D. Abdulganieva[1]. [1]*Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation*

Background: In recent years, chronic inflammatory diseases, including rheumatoid arthritis (RA), have been perceived as independent risk factors for cardiovascular diseases. In addition to influencing the development of atherosclerosis, rheumatic diseases are accompanied by changes in the myocardium.
Objectives: to determine the relationship between systemic manifestations of RA and structural changes of the heart.
Methods: The 282 patients (240 women and 42 men) with verified RA were examined. In addition to standard diagnostic tests, all patients underwent echocardiography with tissue Dopplerography of the myocardium.
Results: Structural and geometric remodeling of the heart was detected in 146 patients (51.8%), of which 29 had concentric remodeling, 35 had concentric hypertrophy, and most often, 82 people had eccentric hypertrophy. The average age was 57.9±8.55 years in the group with cardiac remodeling and 47.2±11.92 years in individuals with normal heart geometry, respectively (p<0.0001). Among 136 patients (48.2%) with normal heart geometry, 39 people suffered from arterial hypertension, 79 patients had various systemic manifestations of rheumatoid arthritis (Sjogren's syndrome, rheumatoid nodules and/or cryoglobulinemia). Among those with cardiac remodeling, arterial hypertension was diagnosed more often – in 107 people (p<0.0001), and systemic manifestations of rheumatoid arthritis - in 87 patients (p<0.1). A comparison was made between a group with eccentric hypertrophy (82 people) and a combined group of patients with concentric remodeling and concentric hypertrophy (64 people). In the first group, the age was higher and amounted to 58.6±8.52 years, and in the second – 57.2±7.96 years (p<0.05). In the first group, systemic extra-articular manifestations of rheumatoid arthritis were found in 56 individuals (68.3%), and in the second group – in 33 people (51.6%) (p=0.04).
It is worth noting that in the second group, patients with concentric hypertrophy made the greatest contribution: out of 35 people, systemic manifestations of rheumatoid arthritis were detected in 23 people (65.7%), which is comparable to the frequency among people with eccentric hypertrophy. In this regard, for the research purpose, we combined individuals with normal geometry and concentric remodeling into one group (165 people), and patients with concentric and eccentric hypertrophy into another group (117 people). When compared, it was found that regardless of the type of myocardial hypertrophy these individuals are significantly more likely to suffer from systemic manifestations of rheumatoid arthritis: 53,9% and 67.5%, respectively (p=0.02).
Conclusion: the formation of myocardial hypertrophy in patients with rheumatoid arthritis is associated with more frequent development of extra-articular manifestations of this disease.

POS0611 THE SIGNIFICANCE OF DETERMINING THE LEVEL OF THE ST-2 MARKER OF HEART FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Feiskhanova[1], D. Abdulganieva[1]. [1]*Kazan state Medical University, Hospital Therapy, Kazan, Russian Federation*

Background: The heart failure in patients with rheumatoid arthritis differs in its genesis from that in the general population. It has been established that the increased risk of congestive heart failure in patients with RA cannot be explained by the high frequency of risk factors for cardiovascular diseases, including coronary heart disease. While 80% of chronic heart failure in the general population is associated with classical risk factors for cardiovascular diseases, in RA these same predictors explain only 40% of cases
Objectives: to establish the prevalence of diastolic dysfunction of preclinical signs of heart failure in patients with rheumatoid arthritis.
Methods: The 282 patients with verified rheumatoid arthritis were examined, including 240 women and 42 men. All patients underwent standard diagnostic tests, two-dimensional transthoracic echocardiography with tissue dopplerography of the myocardium, determination of the level of ST-2, stimulating growth factor, a marker of heart failure, in blood serum.
Results: The Tissue Dopplerography in combination with two–dimensional echocardiography allowed us to identify patients with diastolic myocardial dysfunction and form the following subgroups. 1 – with normal heart geometry and without diastolic myocardial dysfunction (91 people), 2 – with normal heart geometry and with diastolic dysfunction (45 people), 3 - with structural and geometric remodeling of the heart and without diastolic myocardial dysfunction (73 people), 4 – with structural -geometric remodeling of the heart and with diastolic dysfunction (73 people). Among patients with altered heart geometry (3rd and 4th subgroups), the prevalence of diastolic dysfunction was higher than among those with normal geometry (1st and 2nd subgroups): 50% and 33.1%, respectively (p=0.004). We conducted a comparison between the subgroups depending on the presence of diastolic myocardial dysfunction. The average age of patients with rheumatoid arthritis who showed signs of diastolic dysfunction with normal heart geometry was higher (54 [49; 57] years) than in the compared subgroup (45.5 [33.5; 53.5]) (p<0.0001). They also had significantly higher levels of the ST-2 marker, which indicates an early preclinical sign of heart failure: 70.1 [39.5; 106.5] and 42.2 [29.6; 61.5]ng/ml (p<0.01). Apparently, despite the absence of cardiac remodeling, with age, patients with rheumatoid arthritis are more likely to develop not only diastolic dysfunction, but also diastolic type of heart failure.
Conclusion: Thus, in patients with rheumatoid arthritis, it is advisable to conduct tissue Dopplerography in addition to standard echocardiography to detect diastolic dysfunction, which in these patients may develop in the absence of structural and geometric changes.

POS0612 COMORBIDITIES IN RHEUMATOID ARTHRITIS DO NOT INFLUENCE BIOLOGICS DRUG RETENTION: DATA FROM THE NATIONAL HEALTH INSURANCE FUND OF TUNIS

S. Boussaid[1], K. Saadaoui[2], S. Rekik[2], S. Jemmali[2], S. Rahmouni[2], H. Sahli[2], M. Elleuch[2]. [1]*Hospital Rabta, Rheumatology, Tunis, Tunisia;* [1]*Hospital Rabta, Rheumatology, Tunis, Tunisia*

Background: The advent of biologics in the late 1990s radically changed the profile of inflammatory diseases, in particular rheumatoid arthritis (RA). The survival of these innovative therapies is an indicator, in clinical practice, of their long-term efficiency in patients with RA.
Objectives: To study the influence of comorbidities on biologics drugs retention rates.
Methods: We conducted a cross-sectional, observational study. Data were identified from the files of the National Health Insurance Fund of Tunis. It included patients with RA on biologics. Epidemiological characteristics such as age, sex, and comorbidities, were collected. Comorbidities were assessed by the Charlson Comorbidity Index (CCI). The therapeutic maintenance rate at 12, 24, 36, and 48 months as well as the biologics survival were analyzed using Kaplan-Meier survival curves and compared using the Log-Rank test.
Results: Three hundred and seventy-four files were selected. The average age of our cohort was 55±12.54 years [20-90]. A female predominance was noted with a sex ratio M/F=0.147. The average duration of RA was 11.7±6.76 years

[2-41].First biogics prescription was: etanercept 54%, adalimumab 14%, certolizumab pegol 13%, infliximab 6%, tocilizumab 6% and rituximab 7%. First-line survival rates at 12, 24, 36, and 48 months were 85.8; 69.9; 60.6, and 55.9% respectively. Biologics drug survival was, on average, 41.7 months [39.47-43.91]. Comorbidities were assessed by the CCI in 373 patients (99.7%). Ninety patients had an ICC of 0 and 103 patients had an ICC of 1. Only one patient had an ICC of 8. The median value of this score was equal to 1, the mean was 1.64 ± 1.48. Osteoporosis was the most observed comorbidity with 78 patients (20.9%). The study of drug survival according to the ICC did not show any significant difference between the different curves (p=0.809). The Hazard Ratio was 0.999. Similarly, we did not find a discriminating threshold for the Charlson score, allowing it to be decisive for the survival of biologic drugs.

Conclusion: This study did not identify the influence of comorbidities on the biologics survival during RA. Comorbidities can have an impact not only on our therapeutic choice but also on the efficacy and maintenance of biomedicines as well as the quality of life of patients and consequently the prognosis of RA (1). The few studies that have looked at this subject have produced variable results.

POS0613 IDENTIFICATION OF PREDICTORS OF SUDDEN CARDIAC DEATH IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Feiskhanova[1], D. Abdulganieva[1]. *[1]Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease with a high cardiovascular risk, increasing the incidence of coronary artery disease, ventricular arrhythmias and sudden cardiac death (SCD). The annual incidence of SCD among the general population is 0.2%, and patients with RA are twice as likely to develop it as healthy people. The well-known predictors of the development of SCD are the variance of the QT interval and the alternation of the T-wave.

Objectives: to study the prevalence of predictors of the risk of SCD among patients with RA.

Methods: 282 patients with verified RA were examined, including 240 women and 42 men. All patients underwent standard laboratory and instrumental diagnostic tests. In addition, electrocardiography was performed with the calculation of the QT interval variance and determination of the T-wave alternation, two-dimensional transthoracic echocardiography with tissue Dopplerography of the myocardium.

Results: The echocardiography allowed us to identify patients with diastolic dysfunction and form the following groups. 1 group – with normal heart geometry and without diastolic myocardial dysfunction (91 patients), 2 – with normal heart geometry and with diastolic dysfunction (45 pts), 3 - with structural and geometric remodeling of the heart and without diastolic myocardial dysfunction (73 pts), 4 – with structural -geometric remodeling of the heart and with diastolic dysfunction (73 pts). Both groups of patients with rheumatoid arthritis, who had remodeling of the heart, practically did not differ in age. But in the group with diastolic dysfunction, a high variance of the QT interval was significantly more often detected than among individuals without myocardial dysfunction, 54.8 and 38.4%, respectively (p<0.05). Thus, the development of diastolic dysfunction with altered heart geometry is more often accompanied by an increase in the variance of the QT interval, which is a predictor of sudden death in people with heart failure. In this regard, we conducted a comparison between individuals with a high variance of the QT interval (1st subgroup - 139 people) and without it (2nd subgroup - 143 people). We did not obtain significant differences between the subgroups in the prevalence of structural and geometric myocardial remodeling (51.8% and 51.7%, respectively), left ventricular hypertrophy (40.3% and 42.7%, respectively) and diastolic dysfunction (45.3% and 38.5%, respectively). However, in the subgroup with high QT interval variance, T wave alternation was more often recorded: 55.6% and 29.3%, respectively (p=0.0001).

Conclusion: The presence of diastolic dysfunction in patients with cardiac remodeling on the background of rheumatoid arthritis is accompanied by an increase in the variance of the QT interval, which, in turn, is associated with a more frequent occurrence of T-wave alternation. Therefore, patients with diastolic dysfunction and myocardial remodeling on the background of RA belong to the category of increased risk of SCD.

POS0614 THE RELATIONSHIP BETWEEN DISEASE ACTIVITY AND FINANCIAL TOXICITY IN PATIENTS WITH RHEUMATOID ARTHRITIS ON BIOLOGICS: A CROSS-SECTIONAL STUDY USING THE JAPANESE RHEUMATOID ARTHRITIS REGISTRY

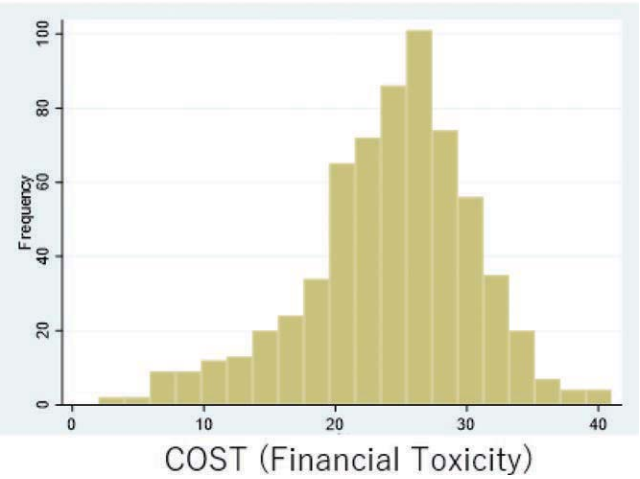
R. Inoue[1], N. Yajima[1,2,3,4], T. Matsui[2,5], S. Tohma[2,6]. *[1]Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; [2]National Hospital Organization Sagamihara National Hospital, Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, Kanagawa, Japan; [3]Fukushima Medical University, Center for Innovative Research for Communities and Clinical Excellence, Fukushima, Japan; [4]Kyoto University, Department of Healthcare Epidemiology, School of Public Health in the Graduate School of Medicine, Kyoto, Japan; [5]National Hospital Organization Sagamihara National Hospital, Department of Rheumatology, Kanagawa, Japan; [6]National Hospital Organization Tokyo National Hospital, Department of Rheumatology, Tokyo, Japan*

Background: As the number of rheumatoid arthritis (RA) patients using biologics increases, the health financial issues posed by biologics become more important. The health financial issues posed by biologics have been discussed using health economic indicators such as incremental cost-effectiveness ratios (ICERs), but have not been evaluated using the financial burden of medical expenses (financial toxicity). In the field of malignancies, evaluations using financial burden have been conducted and have shown that the stage of malignancy is associated with financial toxicity. It is not known whether disease activity and financial toxicity are similarly associated in RA patients.

Objectives: This study aims to evaluate the relationship between RA activity and financial toxicity in RA patients using biologics, who are especially likely to feel the financial burdens.

Methods: We conducted a cross-sectional study of biologic users enrolled in NinJa2020, a database of rheumatoid arthritis patients in Japan collected from April 1, 2020 to March 31, 2021. We defined the users of TNF inhibitor, IL-6 receptor antagonists, T-cell costimulation blocker, Janus kinase inhibitor and biosimilar as biologic users. The main exposure was the disease activity of RA and was measured using DAS28-CRP. Outcome measure was a financial toxicity and was measured using COmprehensive Score for financial Toxicity (COST). This scale is a patient-reported outcome measure (PROM) consisting of 11 items. The responses are recorded on 5-point Likert Scales (ranging from 0 = strongly disagree to 4 = strongly agree). The score by domains ranges from 0 to 44. Higher scores indicated better results and lower financial toxicity. Multiple linear regression models adjusted for age, sex, disease duration, co-payments for anti-rheumatic drugs, work status, financial support systems were conducted to assess the relationship between the disease activity of RA and financial toxicity. As a

Figure.1



secondary analysis, we excluded patients with zero copayments and performed the same analysis as in the main analysis. We used multiple imputation to deal with missing values.
Results: Among 15553 cases in the NinJa database, 649 cases for which RA disease activity and COST were available were included. The median age of the patients was 70 (interquartile range [IQR],56 -77), 83.7% were female. The median copayment amount was ¥12978 per month (IQR 637.2 to 24204.1). The median DAS28-CRP was 1.99 (IQR, 1. - 2.72). The median financial toxicity (COST score) was 21 (IQR 0-27) (Figure 1). In the main analysis using multiple linear regression, COST significantly decreased with disease activity of RA (per 1-pt DAS28-CRP, -1.16 [95% CI -2.04 - -0.28]). In the secondary analysis, COST significantly decreased with disease activity of RA (per 1-pt DAS28-CRP, -1.69 [95% CI -2.29 - -1.10]). Statistical significance was defined as a two-sided p-value < 0.05. All statistical analyses were conducted using STATA 17.0 (Stata Corp LP, College Station, TX). The National Hospital Organization's research ethics committees evaluated and authorized the NinJa study.
Conclusion: High disease activity of RA was associated with high financial toxicity in biologic users. We reaffirmed the importance of financial considerations and empathy for RA patients using biologics, and suggested a potential demand for more financial support for RA patients who are refractory to treatment.

POS0615 CLINICAL DEMOGRAPHICS AND FACTORS AFFECTING DRYNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Yamada[1], T. Sakai[1], I. Mizushima[2], R. Hoshiba[3], F. Suzuki[4], K. Mizutomi[3], M. Kawano[2], Y. Masaki[1]. *[1]Kanazawa Medical University, Department of Hematology and Immunology, Uchinada, Japan; [2]Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan; [3]Kaga Medical Center, Department of Internal Medicine, Kaga, Japan; [4]Kim Clinic, Department of Internal Medicine, Sakai, Japan*

Background: Sjogren's syndrome (SS) is known to coexist with rheumatoid arthritis (RA). However, the prevalence of RA with SS varies widely, from 2.4% to 30%, and some patients with RA without SS also show dryness. The prevalence and clinical demographics of dryness in patients with RA are not well recognized.
Objectives: The aim of this study was to clarify the prevalence, clinical demographics, and related factors of dryness in patients with RA who have not been diagnosed with (SS).
Methods: We enrolled 166 patients with RA (129 females, 37 males; mean age 65.8±14.3 years; disease duration 14.1±10.9 years; DAS28-CRP 2.30±0.92) who were not diagnosed with SS. We analyzed CRP, the estimated glomerular filtration rate (eGFR), RF, anti-CCP antibody, antinuclear antibody, anti-SS-A antibody (SSA), and disease activity score (DAS) 28-CRP, and identified treatments for RA. We used each question item of the EULAR SS Patient Reported Index (ESSPRI) to clarify dryness, somatic and mental fatigue, and pain. History of smoking, comorbidities, such as interstitial pneumonia, fibromyalgia, and psychiatric disorders, and narcotic and/or psychotropic medication use were determined from the medical records. We defined patients with dryness as greater than or equal to one point, and those with severe dryness as greater than or equal to five points, of the visual analog scale (VAS).
Results: Dryness was observed in 93/166 (56.0%) patients and severe dryness was identified in 57/166 (34.4%) patients, and SSA was positive in 23/139 patients(13.9%). We divided our patients into dryness and non-dryness groups and compared their clinical demographics. The dryness group was relatively younger (64.0±14.5 vs. 68.1±13.8 years, p=0.052), had a female predominance (89.2% vs. 63.0%, p<0.001), had severe fatigue (4.06±2.59 vs 2.60±2.78, p<0.001), and had severe pain (3.52±2.41 vs. 2.73±2.32, p=0.020). However, the prevalence of SSA did not significantly differ in this cohort, compared with the non-dryness group (19.3% vs. 11.8%, p=0.248). Next, we analyzed the clinical characteristics of the patients with severe dryness. The severe dryness group was younger (61.9±15.5 vs. 67.9±13.2 years, p=0.022), had higher eGFR (76.1±15.5 vs. 68.9±22.7, p=0.020), had more severe fatigue (4.89±2.42 vs. 2.85±2.63), p<0.001), and had more severe pain (4.16±2.51 vs. 2.65±2.18, p<0.001), compared with non-severe dryness group. The prevalence of SSA was also significantly higher in the severe dryness group (91.2% vs. 70.6%, p=0.002). We then performed a multifactorial analysis using logistic regression analysis with a stepwise method. Female sex (OR 3.739, 1.247-11.207) and VAS of fatigue (OR 1.269, 1.054-1.526) were found to independently relate to dryness.
Conclusion: More than half of the patients with RA had dryness, although only 13.9% of patients were SSA positive. Dryness was related to female predominance and fatigue. Simon et al. reported that SS was found in 2.42% of patients with RA (1). On the other hand, Harrold et al. reported that SS was found in 30% of patients with RA, and the prevalence of SS increased with duration of RA (2). Our data indicate that patients with fatigue, regardless of pain, tend to have dryness, which may be a key factor in diagnosing SS in patients with RA.

POS0616 EFFECT OF TOCILIZUMAB ON THE TRIGLYCERIDES METABOLISM PATHWAYS CONSTITUTED BY ANGIOPOIETIN LIKE-PROTEIN 4, APOLIPOPROTEIN CIII AND LIPOPROTEIN LIPASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Santos-Concepción[1], J. Castro-Hernández[2], V. Hernández-Hernández[1], C. Luna-Gomez[3], I. Ferraz-Amaro4, F. Diaz-Gonzalez[1]. *[1]Hospital Universitario de Canarias, Division of Rheumatology, Santa Cruz de Tenerife, Spain; [2]Universidad de La Laguna, Departamento de Ciencias Médicas Básicas. Área de Anatomía y Embriología Humana, Santa Cruz de Tenerife, Spain; [3]Hospital Nuestra Señora de la Candelaria, Division of Rheumatology, Santa Cruz de Tenerife, Spain; [1]Hospital Universitario de Canarias, Division of Rheumatology, Santa Cruz de Tenerife, Spain*

Background: Tocilizumab is a humanized immunoglobulin G antibody to the interleukin 6 (IL-6) receptor that is used in the treatment of patients with rheumatoid arthritis (RA). Patients receiving TCZ are more likely to experience an elevation in total cholesterol, triglycerides and the ratio of low-density lipoprotein to high-density lipoprotein cholesterol. Elevated triglycerides or triglyceride-rich lipoproteins are cause of cardiovascular disease. Although the pathways for the synthesis and metabolism of triglycerides are complex and diverse, three molecules play a central role in their metabolism: apolipoprotein C-III (ApoC3), angiopoietin-like protein 4 (ANGPLT4), and lipoprotein lipase (LPL). LPL hydrolyzes the triglycerides core of chylomicrons and has a crucial role in regulating plasma triglycerides levels. Besides, ApoC3 and ANGPLT4 participates in the regulation of triglycerides metabolism by the inhibition of LPL, thereby also decreasing the lipolysis of circulating triglycerides.
Objectives: The objective of this study was to evaluate the influence that TCZ has on the TG metabolism axis constituted by ANGPTL4, ApoC3 and LPL. In a second step we have assessed whether the changes that TCZ exerts on the lipid profile can be justified by a modification of this axis.
Methods: TOCRIVAR (*ClinicalTrials.gov:* NCT01752335) is a one-year prospective clinical trial that analyzes the influence of TCZ on different cardiovascular risk factors including lipid pattern. Twenty-seven RA patients receiving TCZ (8 mg/kg IV/q4w) were assessed at baseline and weeks 12, 24, and 52. Disease activity indexes, serum levels of ApoC3, ANGPLT4 and LPL, and lipoproteins serum concentrations were assessed at every visit.
Results: Acute phase reactants and disease activity were significantly reduced during study visits and at the end of treatment after one year with TCZ. While total and LDL cholesterol initially increased in plasma concentration, then decreased to baseline, lipoprotein (a) was significantly lower, and HDL higher, than baseline at all study visits. TG showed a trend to be significantly higher at 6 months (net increase 29 (95%CI -45-68) mg/dl, percentage increase 36 (95%CI -27-52) %, p=0.079). However, TG did not show significant differences at any visit compared to baseline levels. ANGPLT4 (baseline 387 ± 203 vs final 257 ± 32 wk52 ng/ml, p=0.016) and ApoC3 (baseline 10.1 ± 6.7 vs final 6.3 ± 3.7 mg/dl, p=0.023) were significantly lower at the end of the study (week 52) compared to their initial concentrations. LPL also showed a gradual decrease at each visit (baseline 345 ± 289 vs. final 291 ± 197 ng/ml, p=0.57), although statistical significance was not reached (trend test p=0.56). The decrease in DAS28-ESR at each visit was not associated with the changes produced in the three molecules, thus showing that the decrease in the TG metabolism axis does not depend on the lower activity of the disease produced by TCZ. In contrast, the decline in ApoC3 was significantly correlated with the increase in TG at month 3 (Pearson r -0.494, p=0.037) but not at 6 and 12 months.
Conclusion: TCZ decreases serum levels of ANGPTL4, ApoC3 and LPL. At 3 months, the increase that occurs in TG seems to depend on the inhibition that TCZ exerts over ApoC3. Our findings suggest that the effect of TCZ on the lipid profile in patients with RA could be mediated by the modification that this drug exerts on the ANGPTL4-ApoC3-LPL axis.

POS0617 SYNOVITIS OF THE FIRST METACARPOPHALANGEAL JOINT HAS A MAJOR IMPACT ON GRIP FORCE IN EARLY RHEUMATOID ARTHRITIS

M. Rydholm[1,2], A. Sharma[2], I. Wikström[1,2], L. T. H. Jacobsson[2,3], C. Turesson[1,2]. *[1]Skåne University Hospital, Department of Rheumatology, Malmö, Sweden; [2]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; [3]Gothenburg University, Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, Gothenburg, Sweden*

Background: Rheumatoid arthritis (RA) has a major impact on hand function in many patients. Information on the contribution of individual joints to impaired grip strength may be helpful for guiding individualized management.
Objectives: The objective of this study was to investigate the relation between swelling and tenderness of individual finger joints and grip force in patients with early RA.
Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in 1995-2005, was investigated and followed in a structured program, with follow-up evaluations after 1 and 5 years. All patients were examined by the same rheumatologist according to a structured protocol. Grip force (Newton) was measured using the electronic instrument Grippit (AB Detektor, Gothenburg, Sweden). Average grip force values of each hand were evaluated and compared to the expected, based on age- and sex-specific reference values from the literature (1). Grip force was expressed as % of expected values. Linear regression analyses were used to assess the relation between involvement of individual finger joints and grip force. Synovitis and joint tenderness were assessed in separate models. As wrist involvement, high erythrocyte sedimentation rate (ESR) and severe patient reported pain have been independently associated with reduced grip force in early RA (2), the analyses were adjusted for these covariates.
Results: A total of 215 patients with early RA (71 % women; mean age 60 years) were investigated. The median symptom duration at inclusion was 7 months; interquartile range 5-10. In the right hand, synovitis of the first metacarpophalangeal (MCP) joint was consistently associated with reduced grip force at all evaluations (Table 1). Patients with MCP II and MCP III synovitis also had reduced grip force at inclusion, but not after 1 and 5 years. Proximal interphalangeal (PIP) joint swelling (Table 1), and tenderness of MCP or PIP joints, had a lower impact on grip force. Results were largely similar for the left hand.

Table 1. Relation between synovitis of individual MCP and PIP joints and grip force of the right hand (% of expected) in patients with early RA; β (95 % CI), adjusted for wrist synovitis, ESR and VAS pain

	Inclusion	1-year follow-up	5-year follow-up
MCP I	**-10.8 (-17.1 to -4.4)**	**-8.0 (-14.8 to -1.2**)	**-8.2 (-16.4 to 0)**
MCP II	**-7.5 (-13.9 to -1.1)**	-0.6 (-7.6 to 6.4)	-0.6 (-8.2 to 9.5)
MCP III	**-7.4 (-13.5 to -1.3)**	-1.3 (-9.4 to 6.8)	-4.5 (-13.4 to 4.5)
MCP IV	-8.9 (-18.5 to 0.7)	-8.8 (-25.7 to 8.1)	-4.0 (-22.1 to 14.0)
MCP V	-2.5 (-12.6 to 7.6)	-2.6 (-16.5 to 11.2)	7.4 (-5.2 to 20.0)
IP I	2.0 (-6.4 to 10.9)	-1.6 (-14.0 to 10.7)	-5.1 (-23.3 to 13.2)
PIP II	-0.8 (-7.7 to 6.2)	-3.9 (-13.3 to 5.5)	-3.2 (-16.2 to 9.8)
PIP III	-5.6 (-12.1 to 1.0)	2.5 (-6.5 to 11.6)	1.9 (-9.0 to 12.9)
PIP IV	-4.1 (-11.8 to 3.6)	-1.9 (-12.8 to 9.0)	-0.1 (-14.2 to 14.1)
PIP V	-7.2 (-16.0 to 1.7)	-10.3 (-22.8 to 2.3)	-5.6 (-21.2 to 9.9)

Conclusion: MCP I synovitis is a major contributor to reduced grip force in patients with early RA during the first 5 years after diagnosis, independent of wrist synovitis, general pain and systemic inflammation. This underlines the importance of involvement of the thumb for impaired hand function in RA.

POS0618 CLASSICAL PATHWAY OF THE COMPLEMENT SYSTEM RELATES TO SUBCLINICAL ATHEROMATOSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Garcia Gonzalez[1], J. C. Quevedo-Abeledo[2], I. Ferraz-Amaro[1]. *[1]Hospital Universitario de Canarias, Division of Rheumatology, Santa Cruz de Tenerife, Spain; [2]Hospital Universitario Doctor Negrín, Division of Rheumatology, Las Palmas de Gran Canaria, Spain*

Background: Rheumatoid arthritis (RA) is associated with arteriosclerosis. The inflammation present in the disease is responsible for this cardiovascular (CV) comorbidity. The complement system (C) is an essential component of the immune response that has the function of enhancing the inflammatory response. C has been implicated in the etiopathogenic mechanisms of CV disease and RA.
Objectives: Our objective was first to determine the serum levels of different molecules of the classical C pathway to fully characterize it in patients with RA. In a second step, we analyzed the relationship of this classic C pathway with the CV comorbidity and subclinical atheromatosis of a large series of patients with RA.
Methods: Cross-sectional study of 430 patients with RA. Clinical and analytical information related to CV disease was collected: presence of CV risk factors, lipid profile, indices of insulin resistance (HOmeostatic Model Assessment - HOMA2-), as well as measurement of intima media thickness and detection of carotid plaque by ultrasound. Plasma levels of C3, C4, C1-inhibitor and CH50 assay were assessed. Multivariable linear and logistic regressions was performed to study the relation of these molecules of the classical C pathway to the characteristics of the disease, CV comorbidity and subclinical atheromatosis.
Results: C3, C4 y C1-inh were highly and positively correlated with each other ($p<0.001$). However, although CH50 functional test was strongly interrelated to C3 and C1-inh, correlation index to C4 was found to be weak (Pearson r 0.126, $p=0.049$). In the univariable analysis the four parameters (C3, C4, C1-inh and CH50) were, in general, associated with classical CV risk factors. In this sense, C3 and C4, but not C1-inh and CH50, were positively associated with body mass index, and abdominal circumference. Similarly, hypertension and the use of statins were associated with significant higher serum levels of C3, C4 and C1-inh, but not CH50; and the presence of dyslipidemia was related to higher circulating C3 and CH50. Likewise, in non-diabetic RA patients, C3, but not the other parameters, were significantly related to higher HOMA2-insulin resistance, and beta cell function indices after adjustment for covariates. Besides, after fully multivariable analysis, disease activity and acute phase reactants were positively related with significant higher serum levels of the three C component and the CH50 assay. Similarly, the use of NSAIDs, anti-TNF therapies, and tocilizumab, but not other therapies, were related to lower circulating C3, C4 and C1-inh, but not CH50. After adjustment for covariables that included traditional CV risk factors, CH50, but not the other C components, was positively associated with higher carotid intima-media thickness (beta coef. 1 [CI95% 1-2] microns, $p<0.001$). Similarly, C3 (OR 1.01 [CI95% 1.00-1.02], $p<0.021$), C1-inh (OR 1.05 [CI95% 1.01-1.08], $p<0.007$), and CH50 (OR 1.02 [CI95% 0.99-1.03], $p=0.067$) were associated with the presence of carotid plaque.
Conclusion: Classical pathway of the C system is activated in patients with RA. Its serum components and functional assay are associated with disease activity and several disease-related data. Moreover, C's classical pathway is related to traditional CV risk factors and to the subclinical carotid atherosclerosis present in the disease. Our findings highlight the role of C system in RA, and propose its therapeutical inhibition as a tool to control both the disease activity and the CV comorbidity that accompanies the disease.

POS0619

CLINICAL AND SUBCLINICAL INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS: ASSOCIATED FACTORS.

M. Rojas-Giménez[1], J. Calvo Gutierrez[2], R. Ortega Castro[1], M. L. Ladehesa Pineda[1], A. Escudero Contreras[1]. *[1]Reina Sofia University Hospital, 14004 Córdoba, Spain; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), 14004 Córdoba, Spain; Córdoba University (UCO), Córdoba, Spain, Rheumatology Department, Cordoba, Spain; [2]Reina Sofia University Hospital, 14004 Córdoba, Spain; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), 14004 Córdoba, Spain; Córdoba University (UCO), Córdoba, Spain, Rheumatology Department, Córdoba, Spain*

Objectives: To evaluate the differences between patients with rheumatoid arthritis (RA) with and without interstitial lung disease (ILD), to identify factors associated with the development of ILD and to evaluate subclinical ILD; prevalence and factors associated with its development.
Methods: Observational and cross-sectional study of a cohort of patients with RA (ACR/EULAR 2010) and with ILD and a control group of patients without ILD. Both groups with HRCT performed in the last 18 months. The date of the last HRCT was considered as the study date. The % of patients who had subclinical ILD was retrospectively evaluated, defining this as pulmonary involvement due to a requested HRCT without any previous respiratory symptoms. Demographic variables, activity data (DAS28VSG, SDAI and CDAI on the study date), RF and ACPA levels, RA severity data and treatments they were receiving were collected. Descriptive analysis, χ^2 or t-Student and multivariate logistic regression analysis was performed to find predictive variables of the development of ILD.
Results: 66 patients with RA (41 with ILD and 25 without ILD) were included. The main differences between both groups are shown in Table 1. In the group of patients with ILD, the male sex predominated, they were older, with a longer duration of the disease and a longer diagnostic delay of RA. They made more use of biological therapies with better control of the disease by DAS28, SDAI and CDAI. Pulmonary function preserved by respiratory function tests. Of the total number of patients with ILD, 15 (36.6%) did not present any respiratory symptoms when the HRCT was requested. The reasons for their request were: finding abnormalities on chest X-ray (66.7%) and dry crackles on examination (33.3%). Subclinical ILDs were diagnosed with less evolution time of RA than clinical ones. In the rest of the variables there were no differences with the clinical ILD. The variables independently associated with the development of ILD, adjusted for age, tobacco use and ACPA at high titers, were male sex [OR = 4.2 (95% CI 1.05-19.7), p = 0.049] and time of evolution of RA [OR = 1.08 (95% CI 1.02-1.17), p = 0.014].
Conclusion: In our cohort, the prevalence of subclinical ILD was high (36%). Clinical characteristics, disease activity and ILD data (PFT and HRCT patterns) were similar between clinical and subclinical ILD, but prospective studies are needed to assess whether the course and prognosis in both groups is also similar. Bearing in mind that ILD is an important cause of death in our patients, we must actively search for this condition in order to treat it early and improve its prognosis.

Table 1. Differential characteristics between the different groups.

Variables	RA with ILD (n= 41)	RA with clinical ILD (n=26)	RA with subclinical ILD (n=15)	RA without ILD (n=25)	*p-value ILD vs. no ILD*	*p-value clinical ILD vs. subclinical ILD*

POS0620

RHEUMATIC DISEASE COMORBIDITY INDEX: IT IS A PREDICTOR OF OUTCOMES IN RHEUMATOID ARTHRITIS?

A. Ben Tekaya[1,2], E. Hannech[1,2], O. Saidane[1,2], S. Bouden[1,2], R. Leila[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. *[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; [2]Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia*

Background: Comorbidities are frequent among patients with rheumatoid arthritis (RA). They influence clinical outcomes and treatment response. Comorbidity indices are developed to study their impact on different outcomes [1].
Objectives: The aim of our study was to assess comorbidity among RA patients and to explore the association between comorbidities and the clinical profile of the rheumatic disease.
Methods: We conducted a retrospective study in our rheumatology department including 255 patients with established RA according to the ACR/EULAR 2010 criteria. The Disease Activity Scale (DAS28) and the functional impairment (HAQ) were noted. Comorbidities were collected. Rheumatic Disease Comorbidity Index (RDCI) was calculated for each patient. It is rated from 0 to 9 and comprises 11 comorbid conditions including lung disease, cardio-vascular disease, hypertension, diabetes, fracture, depression, cancer, and gastrointestinal ulcer [2].
Results: There were 255 RA with sex ratio M/F at 0.2. The mean age was 58.92 ± 10.72 years [25-85]. The mean age at onset of disease was 43.78 ± 14.28 years [13-81]. The mean disease duration was 16.32 ± 14.3 [1-72]. Identified comorbidities were: hypertension (31.4%), lung disease (27.1%), diabetes (19.6%), cardio-vascular disease (16.8%), gastrointestinal ulcer (9.2%), depression (8.8%), and chronic renal failure (8%). The mean RDCI was 1.14 ± 1.25 [0-6]. A statistically significant correlation was found between RDCI and age ($p<10^{-3}$, r=0.277), RDCI and age at disease onset ($p<10^{-3}$, r=0.3). RDCI was not correlated to the disease duration (p=0.27). RDCI was not associated with the DAS28 (p=0.5) nor with the HAQ (p=0.4). RCDI was not significantly different in terms of sex (female: 1.2 vs male: 1.3, p=0.09). This comorbidity index was associated with the presence of extra articular manifestation (presence: 1.4 vs absence: 0.8, p=0.004). It was associated with pulmonary involvement (presence: 1.7 vs absence: 0.6, $p<10^{-3}$). There was an association between the presence of radiographic erosions and RDCI (1.2 vs 1, p=0.001). RDCI was also associated with atlanto-axial dislocation (p=0.009) and with coxitis (p=0.009). Comorbidity index was statistically different between patients on biologic drugs and patients without biologic drugs (1.6 vs 0.9, $p<10^{-3}$).
Conclusion: Our study showed that comorbidity index was associated with a severe disease and signs of poor prognosis (erosions, coxitis, andatlanto-axial dislocation). This confirmed the hypothesis that comorbidity can be a threat to the improvement in the long-term prognosis in RA patients.

Moltó[1]on behalf of the GR2 Group. *[1]Cochin Hospital, Rheumatology, Paris, France; [2]CHU Gabriel-Montpied, Rheumatology, Clermont-Ferrand, France; [3]University Hospitals Pitié Salpêtrière - Charles Foix, Rheumatology, Paris, France; [4]Chu De Lille, Rheumatology, Lille, France; [5]University Hospital of Saint-Étienne, Rheumatology, Saint-Priest-en-Jarez, France; [6]Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France; [7]Lariboisière Hospital AP-HP, Rheumatology, Paris, France; [8]Hospital Saint-Antoine AP-HP, Rheumatology, Paris, France; [9]Poitiers University Hospital, Rheumatology, Poitiers, France; [10]CHU Brest, Rheumatology, Brest, France; [11]Chu Grenoble Alpes, Internal Medicine, La Tronche, France; [12]Bicetre Hospital, Rheumatology, Le Kremlin-Bicêtre, France; [13]Intercommunal Hospital Group Le Raincy Montfermeil, Rheumatology, Montfermeil, France; [14]Centre Hospitalier du Pays d'Aix, Rheumatology, Aix-en-Provence, France; [15]Hospital Center University De Montpellier, Rheumatology, Montpellier, France; [16]CHRU Strasbourg, Rheumatology, Strasbourg, France; [17]Cochin Hospital, Internal Medicine, Paris, France*

Background: Rheumatoid arthritis (RA) is one of the most common chronic inflammatory diseases and regularly affects women of childbearing age[1]. However, there is limited knowledge about the impact of the disease and its treatment on fertility.
Objectives: The aim of the study was to determine factors associated with time-to-conception in women with RA.

Methods: All RA patients (diagnosis according to the Rheumatologist) included in the national multicenter GR2 cohort from 2015 to June 2021 were included in the analysis. Patients could be included either with a pregnancy wish (i.e., preconceptional period) or because of a clinical pregnancy (<12 weeks of gestation): for this analysis, only patients included preconceptionally were included. The main endpoint was time-to-conception, and the secondary endpoints were the number of subfertile patients (i.e., time-to-conception >12 months or non-achievement of pregnancy), as well as the number exposed to csDMARDs and biologics in the preconception period. We performed survival analyses, using a Cox model including a random effect for the center to account for heterogeneity of practices among participating centers. We used a multiple imputation to address missing data among the explanatory variables. Results are presented as a hazard ratio (HR) with confidence interval (CI) to assess associations between the factors studied and time-to-conception.

Results: Among the 167 patients with RA included in the GR2 cohort, 78 were selected for the main analysis of time-to-conception. Of these, 40 (51.3%) had a clinical pregnancy during follow-up. Subfertility was observed in 33 (42.3%) women and median time-to-conception was 19.1 months; mean preconception DAS28-CRP score was 2.3 (+/- 1.2). Patients were treated during the preconceptional period with NSAIDs, corticosteroids, csDMARDs and biotherapy in 10 (12.8%), 35 (44.9%), 24 (30.8%), and 32 (41.0%) cases, respectively. The multivariate model adjusted for age, BMI, DAS28-CRP, disease duration, ACPA positivity, and exposure to corticosteroids and biologics in the preconception period found an association between increased preconception delay and age (HR (per year) 1. 12 95% CI [1.04-1.16] p = 0.01) as well as disease duration (HR (per year) 1.06 95% CI [1.02-1.15] p = 0.03).

Conclusion: This study provides original results on fertility in women with RA. It found a median time-to-conception of 19.1 months, with a subfertility rate of 42.3%, which is significantly higher than the general population[2]. In this context, it seems essential to discuss this topic from the beginning of the disease in women of childbearing age.

POS0622 ASSOCIATION OF DIURNAL FLUCTUATION OF THE SOLUBLE TOLL-LIKE RECEPTORS 2 (STLR2) WITH COMORBIDITY AND QUALITY OF LIFE IN WOMEN WITH RHEUMATOID ARTHRITIS

K. Zaichko[1], N. Zaichko[2]. *[1]Vinnytsia National Pirogov Medical University, Internal Medicine #2, Vinnytsia, Ukraine; [2]Vinnytsia National Pirogov Medical University, Clinical Biochemistry, Vinnytsia, Ukraine*

Background: Disorders of circadian rhythms in the production of inflammatory mediators play an important role in the pathogenesis of rheumatoid arthritis (RA) [1]. Innate immune factors, in particular toll-like receptors 2 (TLR2), are involved in the formation of the inflammatory pattern in RA. Recently was shown that TLR2 play an important role in the development of atherosclerosis and hypertension [2]. Chronobiological aspects of innate immunity, in particular circadian rhythms of the soluble form of TLR2 (sTLR2) in RA and its comorbidity, requires further study.

Objectives: The aim of the study was to assess the daily variability of sTLR2 in RA patients depending on comorbid conditions and quality of life indexes.

Methods: In the study were enrolled 173 females with RA aged 45.9 (8.79) years and disease duration 7.96 (6.38) years. High activity of the RA (DAS28-ESR > 5.1) were registered in 114 (66%) cases, moderate activity (DAS-28 3.2-5.1) - in 59 (34%) cases. 144 (83%) patients were seropositive by anticyclic citrullinated peptide (ACCP). Among enrolled subjects 140 (81%) had II-III radiographic stage. There were 89 (51%) patients with comorbid pathology, including arterial hypertension (AH) - 59 (34%). Serum sTLR2 level was determined at 8:00 and 20:00 using Cloud-Clone Corp kits (USA). All stages of the study were carried out in compliance with bioethical standards and provisions of the WHO, Helsinki Declaration of the General Assembly of the World Medical Association (1989), Bioethical protocol No 1, 01 November 2016. *Data are mean (SD) or n (%).

Results: In patients with RA, daily fluctuations in sTLR2 levels were detected: indexes at 8:00 at 20:00 were lower than at 8:00 (343 (93.7) vs 272 (99.2) ng/L, p<0.001). The mean difference between sTLR2 levels at 8:00 and 20:00 was -21.6 (13.2) %. In RA patients with AH, the average daily level of sTLR2 was higher (in 1.42 times, p <0.001) than in RA patients without AH. Differences between RA with AH and RA without AH groups were more significant in the evening sTLR2 level (320 (112) vs 246 (81.3) ng/L, p<0.01), than in the morning (378 (90.6) vs 321 (89.0) ng/L, p<0.05). In the group RA with AH decrease in sTLR2 in the evening was less than in the group RA without AH (1.36 times, p <0.05). An increase in sTLR2 at 20:00 was associated with a deterioration in mental health according to SF-36 (VT, SF, MH) in 1.2-1.3 times (highest quartile vs lowest quartile, p<0.01). An increase in sTLR2 at 8:00 was associated with a decrease in physical health PF, RP, BP and GH (in 1.3-1.6 times, p<0.01). Patients with high levels of sTLR2 showed more severe pain, impaired function, fatigue and sleep, decreased physical and emotional comfort, and control of symptoms according to RAID (in 1.3-1.4 times, p<0.01).

Conclusion: In RA patients daily fluctuations in sTLR2 levels has been registered with the decrease of this index in the evening. In the case of comorbid AH production of sTLR2 is higher, especially in the evening time. Disorders of sTLR2 production are one of the factors that deteriorate the quality of life in patients with RA.

POS0623 SUBCLINICAL ATHEROSCLEROSIS IS NOT RELATED WITH ACID URIC IN RHEUMATOID ARTHRITIS. STUDY OF 1005 PATIENTS OF A SINGLE UNIVERSITY HOSPITAL

F. Benavides-Villanueva[1], C. Corrales-Selaya[1], I. Ferraz-Amaro[2], N. Vegas-Revenga[3], V. Portilla[1], R. Blanco[1], M. A. González-Gay[1], A. Corrales[1]. *[1]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; [2]Hospital*

Universitario de Canarias, Rheumatology, San Cristóbal de La Laguna, Spain; [3]Galdácano Hospital, Rheumatology, Galdakao, Spain

Background: Rheumatoid Arthritis (RA) and Gout are associated with an increase of cardiovascular (CV) disease **(1,2).** Carotid plaques and increased carotid intima-media thickness (cIMT) are surrogate markers of CV mortality **(3)**. The association of serum uric acid (SUA) levels as an independent factor of subclinical Atherosclerosis and mortality in RA remains not fully clarified **(4,5).**
Objectives: In a wide cohort of patients with RA our aims were to assess the relationship of SUA with **a)** CV risk factors and **b)** presence of atherosclerosis.
Methods: Cross-sectional study including 1005 patients with RA from a Single University Center. The presence of Atherosclerosis (c-IMT and carotid plaque) was explored by Carotid Ultrasonography. The relationship between SUA and markers of subclinical atherosclerosis was studied through linear regression and logistic multivariate analysis.
Results: We studied 1005 RA patients (741 women, 74%), mean age 61±13. The main general features, CV risks factors, RA activity data and current therapy are summarized in Table 1.

Table 1. Main features of 1005 RA patients

GENERAL FEATURES	RESULTS	GENERAL FEATURES (CONTINUATION)	RESULTS (CONTINUATION)
Age, years, mean±SD	60±13	**RA features**	
Female/ Male, n (%)	741 (74) / 264 (26)	RA duration, years; mean±SD	17±12
		CRP, mg/L, median, [IQR]	3.0 [0.9-7.5]
CV risk factors		ESR, mm/ 1st hour; median, [IQR]	14 [6-24]
Past or Current smoker, n (%)	539 (54)	Rheumatoid factor, n (%)	528 (53)
Obesity/ Dyslipidemia, n (%)	307 (31)/ 560 (56)	ACPA, n (%)	492 (50)
Hypertension, n (%)	453 (45)	DAS28-ESR; mean±SD	3.3 ± 1.5
Diabetes Mellitus, n (%)	127 (13)	DAS28-CRP; mean±SD	3.1 ± 1.3
BMI, kg/m2, mean±SD	28±5/93±15	**Uric acid**	
Abdominal circumference cm; mean±SD		Uric acid level (mg/dl); mean±SD	4.8 ± 1.4
Previous CV Events, n (%)	125 (12)		
Chronic Kidney Disease, n (%)	58 (6)	**Carotid Ultrasonography**	
Gout / using drugs for hyperuricemia; n (%)	20 (2)	cIMT microns; mean±SD	708 ± 157
Total cholesterol, mg/dl; mean±SD	201±39	Carotid plaque¸ n (%)	617 (62)
HDL cholesterol, mg/dl; mean±SD	61±17		
LDL cholesterol, mg/dl; mean±SD	119 ± 32		

Abbreviations: ACPA: Anti–citrullinated protein antibody; BMI: Body mass index; CV: Cardiovascular; cIMT: carotid intima-media thickness; cm: centimeter; CRP: C Reactive protein; DAS28-ESR: Disease Activity Score-28 for Rheumatoid Arthritis with Erythrocyte Sedimentation Rate; DAS28-PCR: Disease Activity Score-28 for Rheumatoid Arthritis with C reactive protein; dl: deciliter; ESR: Erythrocyte Sedimentation Rate; HDL: high-density lipoprotein; IQR: Interquartile range; Kg: kilogram; LDL: Low-density lipoprotein; mg: milligram; m2: square meter; n: number; RA: Rheumatoid Arthritis; SD: Standard Deviation.

SUA as a dependent variable was significantly correlated with age, male gender and most of CV risk factors (body mass index, abdominal circumference and obesity) (single-variable analysis). Similarly, a significative beta coef. [95%CI] positive relationship with SUA was observed with hypertension (0.7 [0.5-0.8], p<0.001), diabetes (0.5 [0.2-0.7], p<0.001), dyslipidemia (0.2 [0.04-0.4], p=0.016), renal chronic insufficiency (1.5 [95CI 1.1-0.8], p<0.001) and previous CV events (0.8 [0.4-1.2], p<0.001). Subclinical Atherosclerosis, as dependent variable, was significantly correlated with SUA (single-variable analysis). In addition, SUA showed a positive significative beta coef. [95%CI] relationship with cIMT (18 [12-25], p<0.001) and the presence of carotid plaques (1.29 [17-1.42], p<0.001). However, statistical significance was not observed in the multivariable analysis adjusted by Classic CV Risk Factors.
Conclusion: In RA, SUA is related with most of CV risk factors. However, SUA is not associated with Subclinical Atherosclerosis.

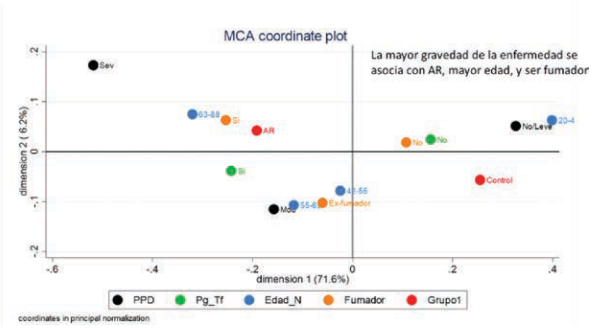
POS0624 RHEUMATOID ARTHRITIS AND ORAL MICROBIOME RELATED TO PERIODONTAL DISEASE

R. Dos-Santos[1], F. Otero[1], M. Varela García[1], E. Perez-Pampín[1], A. Mera Varela[1]. [1]*Clinical University Hospital in Santiago de Compostela, Spain, Rheumatology Department, Santiago de Compostela, Spain*

Background: Rheumatoid Arthritis (RA) is a prevalent systemic autoimmune disease with an unknown etiology. Its onset has been related with chronic immune activation.[1] Oral microbiome (OM) could be one trigger for this beginning, due to its implication in periodontal disease (PD) and chronic gum inflammation.[2]
Objectives: To correlate OM species potentially harmful and RA disease activity.
Methods: During a 6-month period (June to December 2021), RA patients (from the daily practice in a Rheumatology Department) and healthy controls were recruited. Healthy controls proceed from outpatient Orthopaedic Surgery Department (with no autoimmune diseases). A specialized odontologist made an oral evaluation and took samples. OM was assessed by a semiquantitative reactive-chain protein. Species evaluated were Porphyromonas gingivalis, Tanerella forthsytia, Treponema denticola, Prevotella intermedia y Aggregatibacter actinomycetemcomitans (PerioPOC, Austria).
Results: 237 RA patients and 83 healthy controls were recruited. 100% RA patients have, at least, one oral germ, as opposed to healthy controls (57.8%, p<0.001). P. gingivalis was present in 60.2% RA patients treated with biological therapies, most of them anti-TNF. No healthy patients were carriers of P. gingivalis. 41% RA patients had the association of T. denticola and P. gingivalis, regardless of therapies used. The association of T. denticola, T. forsythia and P. gingivalis was also frequent. No relationship between biological therapies used and germs were found (p<0.12). The coexistence of P. gingivalis and T. forsythia increases exponentially the risk of having a severe PD (x5, Figure 1). This is influenced also by higher age and smoking status. As well, this association was observed more frequently in RA patients versus healthy controls (x2.5).

Figure 1:



Conclusion: RA is related with OM, regarding healthy controls. P. gingivalis is more frequent in RA patients that needed biological therapies. These therapies seem to not influence the presence of OM, being frequent the association of several species (symbiosis) causing PD. An OM and PD examination in RA patients could be beneficial to assess disease development and response to treatments, mainly if an eradication protocol is developed (based on local hygiene and periodontal treatment).

POS0625 VASCULAR EFFECT OF INFLAMMATORY BURDEN IN EARLY RHEUMATOID ARTHRITIS PATIENTS - A 5-YEAR PROSPECTIVE STUDY

H. Meng[1], I. T. Cheng[1], B. P. Yan[1], A. P. W. Lee[1], H. So[1], L. S. Tam[1]. [1]*The Prince of Wales Hospital,The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are associated with accelerated atherosclerosis driven by chronic Inflammation. We have previously reported that cumulative inflammatory burden, as reflected by cumulative averages of repeated measures of erythrocyte sedimentation rate (ca-ESR), was associated with increased arterial stiffness in PsA patients (1).

Table 1. Univariable analysis on baseline clinical characters and progression of subclinical atherosclerosis parameters

	AP+				ba PWV change			
	Univariate model		Multivariate model		Univariate model		Multivariate model	
	OR		OR		β		β

ca-ESR	1.02 1.00-1.04	0.106	1.03 1.00-1.06	0.038*	3.12 0.97-5.27	0.005*	2.78 0.73-4.82	0.008*

*Statistically significant at $p < 0.05$.RF positive: Rheumatoid factor positive, FRS, 20%: Framingham risk score ≥20%, caESR: cumulative average-Erythrocyte sedimentation rate.

Objectives: To ascertain whether inflammatory burden over time is associated with long-term vascular outcome in early RA (ERA) patients.

Methods: In this 5-year prospective study, consecutive ERA patients without overt cardiovascular disease were recruited. All patients received tight-control treatment in the first year followed by stand-of-care management subsequently. Subclinical atherosclerosis and arterial stiffness progression were assessed using high-resolution carotid ultrasound (US) and brachial-ankle pulse wave velocity (PWV) respectively at baseline, year 1 and year 5. The primary outcome was subclinical atherosclerosis progression (AP+), defined as incident plaque in a segment without plaque before, or an increased number of plaques in a segment, and/or maximum carotid intima-media thickness (max cIMT) over 0.9 mm at year 5. Secondary outcome was the change in PWV over a period of 5 years. ESR level was measured during each clinic visit. Inflammatory burden was measured by cumulative averages of the area under the curve for erythrocyte sedimentation rate (ESR) over a period of 5 years.

Results: One-hundred and four ERA patients (age: 52±11 years, 81(78%) female) who completed 5 years of follow-up were included in this analysis. Significant improvement in disease activity was observed (DAS-ESR at baseline: 5.8±0.9 vs 3.2±1.2 at year 5, $p<0.001$). Forty-two patients (40.4%) had AP+. The AP+ group had higher ca-ESR (37.6±16.4 vs 32.0±17.1, $p=0.106$) and baseline Framingham risk score (FRS) (13.3±12.5 vs 5.5±6.6, $p<0.001$). Multivariate logistic regression analysis revealed that a higher ca-ESR was associated with AP+ (OR=1.03, 95%CI: 1.00-1.06, $p=0.038$) after adjustment for baseline high risk Framingham risk score (FRS≥20%) and baseline triglycerides level (Table 1). Similarly, PWV increased from 1461±285cm/s to 1559±309cm/s ($p<0.001$) after 5 years. Higher ca-ESR correlated with PWV progression (r=-0.211, $p=0.032$). Using multivariate logistic regression analysis, ca-ESR was associated with arterial stiffness progression ((β=2.94, 95%CI: 0.80 to 5.08, $p=0.007$) after adjusting for symptom duration, presence of rheumatoid factor and FRS.

Conclusion: Persistent inflammation was an independent predictor of subclinical atherosclerosis and arterial stiffness progression in ERA. Effective long-term suppression of inflammation is required to minimize cardiovascular risk.

POS0626 CREATININE-BASED CKD-EPI EQUATION LEADS TO OVERESTIMATION OF GLOMERULAR FILTRATION RATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. Aleksandrov[1,2], I. Alekhina[3], A. Aleksandrov[1,2], L. Shilova[1], N. Aleksandrova[2], I. Zborovskaya[1,2]. *[1]Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation; [2]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Clinical and Laboratory Diagnostics, Volgograd, Russian Federation; [3]Stavropol State Medical University, Department of Hospital Therapy, Stavropol, Russian Federation*

Background: Accurate calculation of glomerular filtration rate (GFR) is an important aspect of clinical care for rheumatologic patients [1, 2, 3].

Objectives: To choose the optimal method of determining the GFR to assess the severity of renal dysfunction in patients with rheumatoid arthritis (RA).

Methods: An open cross-sectional study was performed involving 96 patients with a reliable diagnosis of RA (mean age 54.4±11.6 years, duration of disease 10.7±8.56 years, 57.3% with moderate RA activity).

For comparative assessment of renal function, we used the estimated glomerular filtration rate (eGFR) using the CKD-EPI formulas on the National Kidney Foundation website (USA): creatinine-based equation (eGFRcr), cystatin C-based equation (eGFRcyst) and calculated creatinine and cystatin C equation (eGFRcr-cyst). The 2009 CKD-EPI creatinine equation (eGFRcr) was used as a reference for comparative calculations of GFR. Based on the eGFRcr measurements, patients with RA were divided into four groups: I, >90 ml/min/1.73 m^2; II, 89-60 ml/min/1.73 m^2; III, 45-59 ml/min/1.73 m^2; and IV, <45 ml/min/1.73 m^2.

Results: The mean eGFRcr, presented as a reference in this study, was 70.0±18.7 ml/min/1.73 m^2. Signs of hyperfiltration using eGFRcr (>90 ml/min/1.73 m^2) were observed in 16 (10.1%) patients with RA, mild decrease of renal function (60-89 ml/min/1.73 m^2) was registered in 52 (32.9%), moderate/severe decrease (<59 ml/min/1.73 m^2) - in 28 (17.8%) patients with RA. Decreased eGFRcr was differentially associated with increased patient age (r=0.46; p=0.003), disease duration (r=0.24; p=0.017), cumulative dose of hormones (r=0.66; p=0.007), lower height (r= 0.35; p=0.001).

Analysis of eGFR values demonstrated significant differences using the selected methods (χ^2=9.91, p= 0.007). Intergroup differences (in degree of decrease in eGFR) were statistically significant for all variants of eGFR calculation (eGFRcr, eGFRcyst, eGFRcr-cyst; H-test and Median-test, p<0.001). According to the eGFRcr formula, an absolute majority of patients with RA (83.3%) had a decrease in GFR of varying severity (a slight decrease was registered in 54.2% of cases) (Table 1).

Table 1. Group distribution of RA patients according to eGFR, n(%)

	Group I	Group II	Group III	Group IV
eGFRcr	16 (17.0)	52 (54.2)	20 (20.8)	8 (8.33)
eGFRcr-cys	22 (22.9)	39 (40.6)	20 (20.8)	15 (15.6)
eGFRcyst	29 (30.2)	29 (30.2)	22 (22.9)	16 (16.7)

The use of eGFRcyst showed that only 12 of 29 people in the first group had optimal (>90 ml/min/1.73 m^2) eGFRcr (p=0.031), and 17 patients entered the group with slightly decreased (60-89 ml/min/1.73 m^2) eGFRcr. A similar, but less significant situation (12 of 22 people and 10 patients, p=0.02) was also observed with eGFRcr-cyst. In the second group of RA patients 19 patients corresponded to the chosen criteria in determination of eGFRcyst, and 8 patients entered groups (III and IV) with more severe decrease of renal function (2 patients were included into group I) (p=0,011). Significant differences in this group were also noted when comparing the proportions according to eGFRcr with eGFRcr-cyst (p=0.044). A probable decrease in renal filtration function with eGFRcr (compared with the alternative use of eGFRcr-cyst or eGFRcyst) can be observed in 11-18% of RA patients in group 1 (high/optimal renal function) and up to 10% of RA patients in group 2 (slight decrease). No significant differences were found using the three estimated CKD-EPI formulas in RA patients with moderate/significant decrease in GFR (p>0.05).

Conclusion: Currently, the overall diagnostic performance of the CKD-EPI equation based on creatinine and cystatin C may be the most optimal (in comparison with other calculated CKD-EPI formulas) in patients with RA, and may also be useful for confirming eGFRcr results >60 ml/min/1.73m^2.

POS0627 SUBOPTIMAL MANAGEMENT OF RHEUMATOID ARTHRITIS IN FRANCE: A REAL-WORLD STUDY BASED ON DATA FROM THE FRENCH NATIONAL HEALTH DATA SYSTEM

C. Gaujoux-Viala[1,2], J. F. Bergmann[3], M. Goguillot[4], A. Melaine[4], M. Guérin[5], A. Edouard[5], S. Benard[4], B. Fautrel[6]. *[1]Nîmes University Hospital, Department of Rheumatology, Nîmes, France; [2]Montpellier University, UA11 INSERM, Desbrest Institut of Epidémiology and Public Care, Montpellier, France; [3]APHP, Lariboisière Hospital, Paris, France; [4]Stève Consultants, -, Oullins, France; [5]Galapagos, -, Puteaux, France; [6]APHP, La Pitié Hospital, Paris, France*

Background: Currently, real-world data on rheumatoid arthritis (RA) treatment patterns in France are limited.
Objectives: The aim of this study was therefore to describe, between 2013 and 2017, the sequence of therapies used in the treatment of patients with RA and to characterize RA treatment patterns using real-world data.
Methods: A non-interventional, longitudinal study was conducted using the Echantillon Généraliste des Bénéficiaires (EGB) between 1 January 2013 and 31 December 2017. EGB is a 1/97th representative random sample from the French National Healthcare Database (SNDS) which includes claims data covering 99% of the total French population. Treatment patterns, adherence and persistence of RA treatments were described in a cohort of patients with RA, identified between 2013 and 2017.
Results: Between 2013 and 2017, 2,553 patients with RA were identified, including 2,314 in 2017. Of the 2,314 RA patients identified in 2017 (mean age 66.2 ± 15.4 years; 73.7% female; mean Charlson comorbidity score 4.2), 1,102 (47.6%) did not receive any disease-modifying anti-rheumatic drug (DMARD). Of these, 944 (85.7%) had received at least one symptomatic treatment, including 862 (91.3%) an analgesic, 509 (53.9%) an oral corticosteroid and 384 (40.7%) non-steroidal anti-inflammatory drugs. Of the 2,553 RA patients monitored between 2013 and 2017, 1,512 (59.2%) patients received a DMARD, of which 721 (47.7%) patients received only one treatment sequence, mainly methotrexate (n=529, 35.0%), and did not discontinue or switch treatment. Switching treatment to a targeted DMARD was reported for 144 (9.5%) patients. During follow-up, 377 (25%) patients discontinued treatment. In total, 1,142 RA treatment initiations were recorded, 62.4% of which were conventional synthetic DMARDs (csDMARDs). Persistence rates (95% confidence interval) for csDMARDs, TNF inhibitors (TNFi) and other targeted DMARDs (tDMARDs) were 63.4% (59.6–67.0), 55.9% (49.2–62.0) and 59.4% (51.2–66.6) at 12 months, respectively; Medication Possession Ratio (MPR), an adherence indicator, was 80.5%, 90.8% and 71.9%, respectively. Long-term oral corticosteroids (≥6 months) were also associated with csDMARD for 42.6% of cases (n=304/713), TNFi for 39.7% (n=100/252) and another tDMARD for 53.1% (n=94/177). The average doses of long-term oral corticosteroids were 7.5 mg, 6.5 mg and 7.8 mg of prednisone equivalent per day, respectively.
Conclusion: Using data obtained from the EGB, this study estimated the number of patients with RA in France to be 307,612 in 2017. Approximately half of the patients identified in the EGB cohort were not treated with a DMARD. For a substantial proportion of patients receiving DMARDs, therapeutic escalation, a switch in treatment, or long-term corticosteroid co-therapy with an average daily dose greater than 5 mg were needed. Furthermore, median persistence for most targeted DMARDs was less than 2 years, and the early discontinuation rates of up to 46.6% suggest poor DMARD tolerance in many patients.
This study highlights that the medical need for RA treatment is not covered by current therapeutic strategies.

Table 1. Characteristics of DMARD treatments initiated between 2013–2017 in the EGB database (N=1,142)

	csDMARD	TNFi	Other targeted DMARD
Treatments initiated, n (%)	713 (62.4)	252 (22.1)	177 (15.5)
Median duration of treatment, months	26.7	18.5	14.6
Rate of early treatment discontinuation (≤2 dispensations within 2 months of initiation), %	15.5	10.7	11.9
Mean treatment adherence (MPR), %	80.5	90.8	71.9

POS0628 CLINICAL AND LABORATORY FEATURES OF RHEUMATOID ARTHRITIS IN COMBINATIONS WITH SJOGREN'S SYNDROME IN CLINICAL PRACTICE OF RHEUMATOLOGICAL HOSPITAL.

A. Torgashina[1], E. Matianova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Disease and Sjogren's Syndrome, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Rheumatoid Arthritis Evolutuon Laboratory, Moscow, Russian Federation*

Background: Overlap syndrome of rheumatoid arthritis (RA) and Sjogren`s syndrome (SjS) characteristically manifested with more visceral involvements and has his own features of the articular syndrome. This issue is not well covered in the literature.
Objectives: To determine the clinical and laboratory features of RA in combination SjS, in cases where biologic therapy was prescribed.
Methods: 505 patients (pts) were enrolled in observational cross-sectional study. These patients were examined and treated in our clinic in 2021 year. RA was diagnosed according to the 2010 ACR/EULAR criteria. SjS was diagnosed on ECR/EULAR 2016 criteria in 155 (30.7%) pts. Thus, 2 groups (grs) were identified for comparative analysis: pts with RA in combination with SjS (n=155) (group S) and pure RA (n=350) as a control group (gr C).
Results: In gr S there were two times less men (8.4% and 17.7%, p=0.004) and pts were older (53.6±12.5 and 48.8±15, p<0.001), while the duration of disease didn`t differ significantly and amounted 10 (5-16) years. Tender joints score and the duration of morning stiffness in the joints were comparable. Other indicators of RA activity (swollen joints score, VAS of pts, ESR, CRP), as well as calculated activity indices (DAS28ESR, DAS29CRP) in gr S were significantly lower than in gr C (Table 1). The frequency of erosive arthritis was similar for this grs. Leukopenia was more common in the gr S (p=0.004). Pts of gr S had positive values of RF and ACCP more often (p≤0,005).

Table 1. Indicators of RA activity at study entry.

	S (n=155)	C (n=350)	p
tender joints score, M±SD; Me [25; 75]	9,1±5,3; 8[4;12]	9,5±5,8; 8[5;13]	p>0.05
swollen joints score, M±SD; Me [25; 75]	5±4,5; 4[2;7]	6±4,1; 5[3;9]	0,02
VAS pts, M±SD; Me [25; 75], mm	58,9±16,1; 60[50;70]	63,9±13,2; 65 [60;70]	0,0003
ESR, M±SD; Me [25; 75], mm/h	27,9±28,4; 18[9;34]	36,3±35; 22[11;51]	0,009
CRP, M±SD; Me [25; 75], g/l	14±20,2; 5[1,4;17,8]	23,8±29,5; 11,7[3,5;33,8]	0,0002
DAS28COЭ, M±SD; Me [25; 75]	5±1,3; 4,9[3,9;6,2]	5,4±1,2; 5,4[4,5;6,3]	0,005
DAS28CPБ, M±SD; Me [25; 75]	4,7±1,2; 4,6[3,7;5,6]	5±1,1; 5,1[4,3;5,8]	0,0007
Morning stiffness M±SD; Me [25; 75], min	109,8±98; 60[30;140]	122,7±96,4; 90[42,5;180]	p>0.05

The frequency of prescribing methotrexate or leflunomide at the onset of the disease was comparable. Hydroxychloroquine was more often prescribed in the gr S at the onset of the disease (16% and 6%, p<0.001) and at the time of analysis (22.6%, 8.6%, p<0.001). The frequency and duration of oral glucocorticoids (GCs) in the grs were comparable, but at the time of hospitalization GCs were received at lower doses in gr S (p=0.02). The first biological drugs,

prescribed at the onset of the disease were more often TNFα blockers in gr C and rituximab in gr S.
Conclusion: According to our observations, the combination of RA with SjS leads to a milder course of the RA. Early diagnosis of SjS in RA pts is important for understanding the course of the disease and determining the prognosis.

POS0629 PREVALENCE AND FACTORS ASSOCIATED WITH SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Bertelle[1], R. Bixio[1], E. Bertoldo[1], A. Giollo[2], S. Framarin[1], F. Pollastri[1], G. Orsolini[1], O. Viapiana[1], M. Rossini[1], G. Adami[1]. *[1]University of Verona, Reumatology Section, Verona, Italy; [2]University of Padova, Reumatology Section, Padova, Italy*

Background: Sarcopenia is a progressive and generalized skeletal muscle loss associated with falls, fractures, physical disability, and mortality, described as age-related or secondary. Systemic inflammatory diseases, such as rheumatoid arthritis (RA), are well-known causes of secondary sarcopenia. However, the exact prevalence of sarcopenia in patients with RA is still unknown, partly due to the heterogeneous definitions of sarcopenia adopted in different studies.
Objectives: To assess the prevalence of sarcopenia in a cohort of patients affected by RA, and to evaluate the influence of age, sex, comorbidity, disease duration and activity, antibody status and therapies on sarcopenia.
Methods: We conducted a retrospective observational study on adult patients affected by RA undergoing evaluation at our outpatient clinic from January 2009 and July 2021. All patients underwent dual-energy X-ray absorptiometry (DXA) for assessment of body composition; diagnosis of sarcopenia was defined using Skeletal Muscle Mass Index (SMI), as proposed by consensus EWGSOP2 (1). We collected relevant demographic, clinical, therapeutic, and laboratory data at the time of DXA. We excluded patients affected by neoplastic disorders and/or malnutrition. Binary logistic regression analysis was employed to define predictors and protective factors of developing sarcopenia.
Results: A total of 266 patients (82.7% women) with a median age of 58.4 (IQR 14.4) years were included in the study. The prevalence of sarcopenia was 27.44%. From the binary logistic regression analysis, we found that the use of oral glucocorticoids (GCs) at a daily dose > 3.25 mg of prednisone-equivalent was significantly associated with sarcopenia (β 0.68, p = 0.047, aOR 1.98, 95% CI 1.009 – 3.881) (Figure 1). We found a significant inverse correlation between conventional disease-modifying antirheumatic drug (c-DMARDs) and sarcopenia (β -0.71, p = 0.027) as well. Age, sex, disease duration, mean disease activity - expressed as disease activity score based on 28 joints (DAS-28), erosive and seropositive disease - and biologic disease-modifying antirheumatic drug (b-DMARDs) therapy were not predictors of sarcopenia, albeit seropositive status showed a correlation trend with increased prevalence of sarcopenia (p = 0.092).

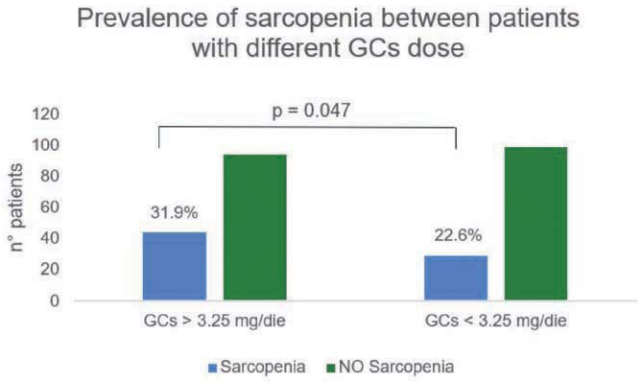

Figure 1.

Conclusion: Our study showed that sarcopenia is a common complication in RA. Glucocorticoid therapy was associated with an increased prevalence of sarcopenia, while c-DMARDs acted as protective factors, possibly decreasing chronic inflammation. No correlation was found with b-DMARDs, possibly due to association with longer and more aggressive rheumatic disease.

POS0630 INCIDENCE AND ASSOCIATED FACTORS OF CANCER IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Tasci[1], M. Aysin[2], D. Sahin Eroglu[3], A. K. Aydogan[1], A. Ateş[3], T. M. Turgay[3], G. Kınıklı[3]. *[1]Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Izmir Katip Çelebi University, Department of Public Health, Izmir, Turkey; [3]Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Rheumatoid arthritis (RA) is an autoimmune disease primarily characterized by joint inflammation along with systemic manifestations and increased risk of cardiovascular disease. Furthermore, it has been suggested that RA itself and medications administered might increase the risk of cancer.
Objectives: To assess cancer incidence in RA patients and factors associated with cancer development in RA patients.
Methods: In this single centre retrospective cohort study, the data of 2000 patients (76.3% female, mean age at the last follow-up: 59.5 ± 13.4 years) who were followed up between 2005 and 2020 and fulfilled 2010 ACR/EULAR classification criteria were scrutinised. Patients' demographic, clinical and serological characteristics, and smoking history were recorded. Multivariable logistic regression analysis was performed to determine the associated factors with cancer development. The standardized incidence rate (SIR) was calculated by dividing the number of cancer cases observed in a given age and gender group by the expected number.
Results: After a median follow-up of 9 years, 71 (3.6%) patients were diagnosed with cancer and the number of patients with more than one malignancy was 5 (0.5%). Cancer types in each sex were demonstrated in Table 1. Seropositivity rate of the cohort was 86.0% and 376 out of 1102 (34.1%) patients were smokers. Glucocorticoids were the most common used agent in the treatment of RA (75.2%), followed by methotrexate (68%), hydroxychloroquine (65.1%), sulfasalazine (37.7%), leflunomide (35.5%), biological disease-modifying antirheumatic drugs (11.4%) and tofacitinib 4%. In multivariable logistic regression analysis performed of 1102 patients without missing data of smoking history, only smoking and age were independently associated with malignancy (Odds Ratios were 2.11 (95% Confidence Interval (CI) 1.07-4.14 and 1.05 (95% CI 1.02-1.07), respectively). Treatment modalities and RA-related clinical factors were not related to cancer development (data not shown). When compared with the 2017 Cancer Statistics of Turkey, the incidence of malignancy in our RA cohort was similar to the corresponding age and gender groups. The SIRs in male and female patients were calculated as 0.93 (95% CI: 0.82-1.05 p= 0.25) and 0.92 (95% CI: 0.77-1.09 p= 0.34), respectively.

Table 1. Number of malignancy distribution by gender of patients

	Female	Male
	n=47	n= 24
Breast, n (%)*	15 (100.0)	0 (0.0)
Urogenital system, n (%)*	8 (53.4)	7 (46.6)
Prostate, n (%)*	0 (0.0)	5 (100.0)
Lung, n (%)*	3 (30.0)	7 (70.0)
Lymphoma, n (%)*	4 (57.1)	3 (42.9)
Thyroid, n (%)*	6 (100.0)	0 (0.0)
Skin, n (%)*	5 (83.3)	1 (16.7)
Colorectal, n (%)*	2 (50.0)	2 (50.0)
Head and Neck, n (%)*	0 (0.0)	3 (100.0)
Multipl Myeloma, n (%)*	1 (50.0)	1(50.0)
Others, n (%)*	7 (87.5)	1 (12.5)

*Row Percent

Conclusion: Our results show that patients with RA do not require additional screening beyond the nationally recommended guidelines. Medications used, including tumor necrosis factor inhibitors, did not increase the risk of cancer. In conclusion, all patients with RA should receive standard age- and sex-appropriate cancer screening.

POS0631 EVEN LOW-DOSE GLUCOCORTICOID USE IS A RISK FACTOR FOR CLINICAL FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS: TEN-YEAR FINDINGS OF THE TOMORROW STUDY

C. Yoshimura[1], T. Koike[2,3], K. Mamoto[4], T. Okano[4], Y. Sugioka[2], M. Tada[5], K. Inui[6], H. Nakamura[4]. *[1]Shiraniwa Hospital, Department of Orthopaedic Surgery, Nara, Japan; [2]Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [3]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan; [4]Osaka City University Graduate School of Medicine, Osaka, Japan, Department of Orthopaedic Surgery, Osaka, Japan; [5]Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan; [6]Osaka Saiseikai Nakatsu Hospital, Department of Orthopaedic Surgery, Osaka, Japan*

Background: Patients with rheumatoid arthritis (RA) who have sarcopenia and stiff or painful joints might be at increased risk of falls and fractures.
Objectives: The present study aimed to prospectively identify the incidence of clinical fractures and associated risk factors in patients with RA in a cohort study named the TOMORROW (UMIN000003876) that started in 2010.
Methods: We evaluated anthropometric parameters, bone mineral density (BMD), disease activity, RA medication at entry and observed the incidence of clinical fractures during ten years in 202 patients with RA (mean age, 58.6 y; medication with biological agents, 54.9%) and 202 age- and sex-matched non-RA volunteers (Vo) (mean age, 57.4 y). We compared the incidence of clinical fractures between patients with RA and Vo for ten years, and analyzed the risk factors for clinical fractures using Cox proportional hazard model.
Results: The incidences of clinical fractures were 0.036 and 0.024/person-year in patients with RA and Vo, respectively. Cox proportional hazard model revealed that low BMD at the thoracic vertebrae (< 0.7 g/cm^2) and history of fractures at entry were significantly associated with the incidence of clinical fractures (Hazard ratio [HR]1.737, p=0.020 and HR1.514, p=0.047, respectively) in all participants. RA morbidity, however, was not (HR1.398, p=0.112). In patients with RA, medication with GC at entry was a significant risk factor for clinical fractures (HR1.898, p=0.017). Additionally, a mean GC dose (≥ 2 mg/day) at entry and during the ten-year period increased risk for fractures (HR 2.189, p=0.004, 1.866, p=0.022, respectively).
Conclusion: RA per se was not a risk factor for clinical fractures in this cohort. Low BMD at the thoracic vertebrae at entry and the use of GC with even low dose at entry and during ten years were significantly associated with an increased frequency of clinical fractures among patients with RA.

POS0632 EXPRESSION OF PD-1 AND PD-L1 IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS WITH PRE-EXISTING RHEUMATOID ARTHRITIS – A POSSIBLE ASSOCIATION WITH HIGH RHEUMATOID ARTHRITIS DISEASE ACTIVITY

E. Hellbacher[1], C. Sundström[2], D. Molin[3], E. Baecklund[1], P. Hollander[2]. *[1]Uppsala University and Uppsala University Hospital, Medical Sciences, Rheumatology, Uppsala, Sweden; [2]Uppsala University and Uppsala University Hospital, Clinical and Experimental Pathology, Department of Immunology, Genetics and Pathology, Uppsala, Sweden; [3]Uppsala University and Uppsala University Hospital, Experimental and Clinical Oncology, Department of Immunology, Genetics and Pathology, Uppsala, Sweden*

Background: Patients with rheumatoid arthritis (RA) are at increased risk of developing diffuse large B-cell lymphoma (DLBCL). Immunotherapy blocking programmed cell death protein 1 (PD-1) and its ligand PD-L1 has substantially improved outcome in a number of malignant diseases but has so far been disappointing in DLBCL. However, current research seeks to identify DLBCL subgroups responsive to PD-1 blocking agents. Whether patients with pre-existing rheumatoid arthritis (RA) might constitute such a subgroup is unknown. Expression of PD-1 and PD-L1 has not previously been studied in a cohort of RA-DLBCL patients.
Objectives: To determine intratumoural expression of PD-1 and PD-L1 in DLBCL patients with pre-existing RA and relate the expression to clinical characteristics and survival outcome.
Methods: We included 103 RA-DLBCL patients and 74 DLBCL controls without rheumatic disease. PD-1 and PD-L1 immunohistochemical markers were applied on tumour tissue microarrays. The number of PD-1+ tumour infiltrating leukocytes (TILs) and proportions of PD-L1+ tumour cells and TILs were calculated and correlated to clinical data. For RA patients, disease activity had been individually scored repeatedly over time based on swollen and tender joint counts, erythrocyte sedimentation rate (ESR), and the treating physician's global assessment of disease activity from onset of RA until lymphoma diagnosis(1). Values of cumulative disease activity for each patient were calculated as area under the curve (AUC). To investigate a possible influence of RA disease severity on the expression of PD-1 and PD-L1, RA patients with DLBCL were divided in two groups using the upper quartile of the AUC values as cut off for the highest disease activity group.
Results: Expression of PD-1 in TILs and PD-L1 in tumour cells was similar in RA-DLBCL and DLBCL controls. In RA-DLBCL, high expression of PD-L1 in tumour cells was significantly more common in patients with the most severe RA disease (45% vs 20%, p=0.04) (Table 1) and was associated with inferior overall survival in multivariable analysis (HR 4.62, 95% CI, 1.55-13.71).

Table 1. Clinical and lymphoma related parameters and their distribution in the RA-DLBCL patients according to high and low expression of PD-L1 in tumour cells

	Entire cohort	High PD-L1 in tumour cells[1]	Low PD-L1 in tumour cells	P-value*
All patients, n (%)	**103 (100)**	**11 (100)**	**89 (100)**	
Women, n (%)	**61 (59)**	**6 (55)**	**54 (61)**	**0.70**
Age ≥60, n (%)	**85 (83)**	**10 (91)**	**72(81)**	**0.68**
DLBCL subtype, n (%)				**0.35**
GCB	**30 (29)**	**2 (18)**	**27 (30)**

Missing	**3 (3)**	**1 (10)**	**2 (2)**	

RA, rheumatoid arthritis; DLBCL, diffuse large B-cell lymphoma; GCB, germinal centre B-cell like;EBV, Epstein-Barr virus; DMARD, disease modifying anti-rheumatic drug; TIL, tumour-infiltrating leukocytes; [1] High expression ≥17% PD-L1+ tumour cells of all tumour cells; *According to chi-square or Fischer's exact test; †Active RA treatment= DMARD and/or corticosteroids;

Conclusion: Our results indicate an association between a more severe RA disease and increased expression of PD-L1 in DLBCL tumour cells. This might have implications for the prognosis of the lymphoma as well as the chance of response to immunotherapy and warrants further studies also in other chronic inflammatory condidions.

POS0633 HIGH SENSITIVITY TROPONIN I IS ASSOCIATED WITH FOCAL FIBROSIS AS DETECTED BY CARDIAC MR IN EARLY, TREATMENT-NAIVE RA

R. Shukla[1,2], R. Ark[1,3], A. Burska[4], S. Plein[5], M. H. Buch[1,2,4]. *[1]University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, NIHR Biomedical Research Centre, Manchester, United Kingdom; [3]University Hospitals of Morecambe Bay NHS Foundation Trust, Royal Lancaster Infirmary, Lancaster, United Kingdom; [4]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [5]University of Leeds, 5. Multidisciplinary Cardiovascular Research Centre (MCRC) and Leeds Institute of Cardiovascular and Metabolic Medicine, Biomedical Imaging Science Department, Leeds, United Kingdom*

Background: RA individuals are known to have excess CVD risk, equivalent to that of type 2 diabetes mellitus[1]. We recently reported vascular and

myocardial abnormalities on cardiac magnetic resonance imaging (CMR) in an early RA cohort compared with control subjects, and improvement with DMARD treatment[2]. Non-invasive assays for high-sensitivity troponin and NT-pro-BNP have been evaluated in RA cohorts. No study has investigated these in early, treatment-naïve RA and in association with subclinical CMR findings.

Objectives: In a treatment-naïve, early RA trial cohort, we examined serum cardiac markers of ventricular stretch (NT-pro-BNP) and myocardial injury (high-sensitivity troponin-I (hs-Tn-I)) and change with treatment, and whether these associated with cardiac MRI abnormalities.

Methods: In CADERA (a unique early RA RCT derived study), out of a total of 120 patients randomised to either first-line TNFi+MTX (n=60) or MTX and conventional synthetic DMARDs (n=60), 81 subjects with no previous history of CVD or diabetes and with only a maximum of 1 other traditional risk factor, underwent baseline and year 1 CMR. Corresponding levels of NT-pro-BNP (pg/ml) and hs-Tn-I (ng/L) were measured at baseline and year 1. CADERA reported CMR measures of vascular stiffness [aortic stiffness index (AoSI), and aortic distensibility (AD)]; tissue oedema/fibrosis [native T1 values (T1), myocardial extracellular volume (ECV), and late gadolinium enhancement (LGE)] and ventricular function [2]. Bayesian linear and logistic regression models with mixed effects for overall data were used to test association between serum cardiac markers and CMR parameters.

Results: CADERA trial already reported baseline demographics and comorbidity data of patients. The most common risk factor was smoking history (55%) followed by hypertension (7%) and family history of ischaemic heart disease (5%)[2]. 7 patients had abnormal findings on LGE imaging at baseline and 4 at year 1.[2] From baseline to year 1, NT-pro-BNP remained within normal limits although a numerical improvement was noted at year 1(76.4 to 59.4, p = 0.038). Hs-Tn-I was within normal limits (<3ng/L) with no significant change noted (1.62 to 1.7). At baseline, median hs-Tn-I was 2 (IQR 1.4 - 3.05) in patients with abnormal LGE findings compared to 1.60 (0.95 – 2.52) in those without (p = 0.3). At year 1, median hs-Tn-I was 2.70 (IQR 1.08 – 4.82) in patients with abnormal LGE findings versus 1.7 (IQR 1 – 2.5) in those without (p = 0.5). Table 1 outlines the association of serum cardiac markers with CMR parameters. At baseline, hs-Tn-I positively associated with LGE. This association was also demonstrated when considering overall data (baseline + week 48). Association of NT-pro-BNP with CMR was not significant.

Table 1. Association of serum Hs-Tn-I with CMR parameters (posterior estimates with 95% credible intervals reported)

	Hs-Tn-I		
CMR parameter	Overall	Baseline	Year 1
Measures of myocardial tissue oedema/fibrosis			
LGE	**0.56(0.1 to 1.11)**	**0.6(0.04 to 1.27)**	0.54(-0.13 to 1.17)
T1	-4.42(-10.5 to 1.5)	-0.38(-6.7 to 6.2)	-6.02(-14.9 to 3.15)
ECV	0.002(-0.04 to 0.08	0.001(-0.05 to 0.07)	0.001(-0.04 to 0.04)
Measures of vascular stiffness			
AoSI	0.01(-0.23 to 0.25)	0.05(-0.22 to 0.33)	0.05(-0.33 to 0.42)
AD	-0.05(-0.23 to 0.13)	-0.02(-0.18 to 0.14)	-0.06(-0.37 to 0.25)

Conclusion: Our data suggest hs-Tn-I is within normal limits in a treatment-naïve, RA cohort but with numerical differences that associated with presence of focal fibrosis on CMR. Modest numbers of those with focal fibrosis may account for normal range values for hs-Tn-I.

Background: In real-life setting, a greater number of elderly rheumatoid arthritis (RA) patients with impaired glomerular filtration rate (GFR) needs treatment with biologic or target synthetic disease-modifying anti-rheumatic drugs (b/tsDMARD) to achieve disease control and reduce NSAIDs intake. Long-term observational data from the real-life on the use of b/tsDMARD in these patients are scarce.

Objectives: The aim of this study was to evaluate the retention rate of b/tsDMARD in RA patients with impaired GFR in real-life setting.

Methods: Data of RA patients treated with at least one b/tsDMARD were retrospectively analyzed form the national Italian GISEA registry from January 2016 to December 2021. Estimated-GFR (eGFR) was calculated with the Cockcroft-Gault equation at the time of any b/tsDMARD prescription. For the purpose of this study, patients were divided in two groups, patients with impaired GFR (eGFR ≤60) and patients with normal GFR (eGFR >60). The retention rate was calculated by the Kaplan-Meier method and compared between these two groups by a log-rank test.

Results: The study population included 2443 treatment-line with b/tsDMARD from 1888 patients (female 80.4%, age 57±12 years, mean baseline CDAI 17±12, FR/ACPA+ 69.5%) who started a new b/tsDMARD. Disease characteristics are shown in Table 1. 288 treatments with b/tsDMARD were started in patients with impaired eGFR and 2155 in patients with normal eGFR. Compared to patients with eGFR >60, patients with eGFR ≤60 showed higher HAQ-DI (1.3±0.8 vs 1±0.8, p<0.001) at the start of b/tsDMARD treatment. Glucocorticoids were more prescribed in patients with impaired eGFR (80.2% vs 72.8%, p<0.01), while csDMARDs were more prescribed in association with b/tsDMARD in patients with normal eGFR (83.1% vs 76.4%, p<0.01). Of note, CTLA4-Ig treatment was more prescribed in patients with impaired eGFR (26% vs 17.1%, p<0.05), while no difference in b/tsDMARD prescription was observed for other mechanism of actions. Drug survival was similar between RA patients with impaired eGFR [58.2%, mean survival time 35 months (CI95% 31-39)]and RA patients with normal eGFR [55%, mean survival time 34.4 months (CI95% 33-36), log rank: 0.88] (Figure 1). Cox regression model adjusted for age, sex and b/tsDMARD showed no impact of eGFR on drug survival [HR: 0.9 (CI95%: 0.7-1.2).

Conclusion: Our data show that impaired eGFR seems to not influence the persistence of b/tsDMARD treatment in RA patients.

POS0635 DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: EXPERIENCE IN A RHEUMATOLOGY OUTPATIENT PRIVATE CENTRE

C. Villota-Eraso[1], J. C. Sarmiento-Monroy[2], D. C. Varela[3], M. J. Mantilla Ribero[4]. *[1]IPS Servicio Integral de Reumatología e Inmunología Dr Orlando Villota, Rheumatology Department, Pasto, Colombia; [2]Hospital Clínic, Villarroel 170, 08036, Rheumatology Department, Barcelona, Spain; [3]Universidad Pontificia Bolivariana, Rheumatology Department, Medellin, Colombia; [4]Universidad de la Sabana, Rheumatology Department, Chia, Colombia*

Background: Patients with difficult-to-treat rheumatoid arthritis (D2T RA) have not achieved treatment target despite treatment according to EULAR recommendations. Information on the incidence rates of D2T RA in a real-life setting is lacking.

Objectives: To estimate the prevalence of D2T RA in a well-characterized cohort.

Methods: This was a cross-sectional analytical study of patients with RA (1987 ACR criteria). Each patient was evaluated and followed by a rheumatologist from January 2014 to December 2021 in a single rheumatology outpatient private center in Bogotá, Colombia. RA patients were classified as D2T RA according to EULAR definition.

Results: A total of 783 patients were evaluated. Baseline characteristics were as follows: female gender 91.1%, mean age 54.4±13 years, mean disease duration 13.9±9.3 months, RF positive 92.4%, ACPA positive 59.5%, and erosions 44.3%. 32.9% have extra-articular manifestations and 31.6% at least one comorbidity. Most of patients have received conventional synthetic DMARDs (97.8%), being prednisone and methotrexate the most frequently prescribed. Seventy-nine (10%) patients were classified as D2T RA. The current treatments were conventional synthetic DMARD alone 18.9%, combination with bDMARD 79.4%, and 78.5 with glucocorticoids. Main characteristics of the patients are shown in Table 1.

Table 1.

	D2T RA (n=79)
Demographics	
Age, years	54.4
Female, %	91.1
Comorbidity	31.6
Smoking	37.9
Disease characteristics	
Disease duration, months	13.9
RF positivity, %	92.4
ACPA positivity, %	59.5
PAI	10.1
EAM	32.9
Drugs	
Number of previous bDMARDs, mean	2.89
Glucocorticoid therapy, mean dose per day (mg)	18.4

RF: rheumatoid factor; ACPA:anti-citrulinated protein antibodies; PAI: poliautoimmunity, EAM: extra-articular manifestations, bDMARD: disease-modifying biologic antirheumatic drug; D2T: difficult-to-treat; n: number; mg miligrams

Conclusion: D2T AR is common and represents a phenotype with a significant burden of comorbidities and a high prevalence of poor prognostic factors. This concept should be recognized and taken into account to bring a personalized approach.

Rheumatoid arthritis - biological DMARDs

POS0636

PATIENT GROUPS IN RHEUMATOID ARTHRITIS IDENTIFIED BY DEEP LEARNING RESPOND DIFFERENTLY TO BIOLOGIC OR TARGETED SYNTHETIC DISEASE MODIFYING ANTIRHEUMATIC DRUGS

M. Kalweit[1], A. M. Burden[2], T. Hügle[3], T. Burkard[2]. [1]*University of Freiburg, Department of Computer Science, Freiburg im Breisgau, Germany;* [2]*ETH Zürich, Department of Chemistry and Applied Biosciences, Zürich, Switzerland;* [3]*Lausanne University Hospital, Department of Rheumatology, Lausanne, Switzerland*

Background: Cycling of biologic or targeted synthetic disease modifying antirheumatic drugs (b/tsDMARDs) in rheumatoid arthritis (RA) patients due to non-response is a problem preventing and delaying disease control.
Objectives: To assess and validate treatment response of b/tsDMARDs among RA patient groups identified by deep learning.
Methods: In the Swiss Clinical Quality Management of Rheumatic Diseases registry (SCQM), between 1998 and 2018, we identified all RA patients with a DAS28-erythrocyte sedimentation rate (esr) record within 6 months before start of the first b/tsDMARD. This first-time b/tsDMARD was the cohort entry at which patients were clustered through several runs of deep embedded clustering. Features, measured at cohort entry, included demographics, RA disease burden/duration, life-style factors, and other RA medication. To increase robustness of the obtained clusters, we grouped similar patient clusters together (further referred to as groups). Our outcomes were b/tsDMARD stop due to non-response, and separately a ≥20% reduction in DAS28-esr (RA disease activity in 28 joints using esr measures) as a proxy for treatment response. We followed all patients from cohort entry until b/tsDMARD stop or a maximum of 15 months follow-up. We assessed comparative effectiveness of b/tsDMARDs (ref. adalimumab) using Cox proportional hazard regression in each patient group by estimating hazard ratios (HR) with 95% confidence intervals (CI). We validated results obtained per patient group through stratified analyses according to most distinctive patient characteristics of the respective group, i.e. the characteristics that led to the respective grouping were also used to stratify the overall population by in this validation analysis.
Results: We obtained 24 clusters which comprised between 362 and 1481 patients (among 3516 unique patients). These clusters were grouped into 5 groups according to most distinct characteristics at b/tsDMARD initiation: 1) ≥2 csDMARDs and prednisone use, 2) male sex, 3) seronegativity, female sex, and no prednisone use, 4) rather low disease burden, 5) seropositivity, female sex, and a rather high disease burden/duration.
Comparative effectiveness results among validation strata confirmed comparative effectiveness results observed among the 5 groups: Patients with ≥2 csDMARDs and prednisone at b/tsDMARD initiation, men, as well as patients with a lower disease burden responded better to tocilizumab than to adalimumab (HRs of reaching ≥20% reduction in DAS28-esr: 5.46, 95% CI [1.76-16.94], HR 8.44 [3.43-20.74], and HR 3.64 [2.04-6.49], respectively). Furthermore, seronegative women without use of prednisone at b/tsDMARD initiation as well as seropositive women with a higher disease burden and longer disease duration had a higher risk of non-response with golimumab (HRs of b/tsDMARD discontinuation: 2.36 [1.03-5.40] and HR 5.27 [2.10-13.21], respectively) than with adalimumab.
Conclusion: Our results suggest that RA patient groups identified by deep learning may respond differently to individual first-line b/tsDMARDs. Thus, our results can possibly support the decision on the best choice of first-time b/tsDMARD for certain RA patients, which is a step forward towards personalizing treatment. However, further research in other cohorts is needed to verify our results.

SAFETY OF B/TSDMARDS FOR RA AS USED IN CLINICAL PRACTICE - RESULTS FROM THE LAST DECADE OF THE ARTIS PROGRAM

T. Frisell[1], H. Bower[1], E. Baecklund[2], D. Di Giuseppe[1], B. Delcoigne[1], N. Feltelius[3], H. Forsblad-D'elia[4], E. Lindqvist[5,6], U. Lindström[4], J. Askling[1,7]on behalf of the ARTIS Study Group. [1]*Karolinska Institutet, Medicin Solna, Clinical Epidemiology Division, Stockholm, Sweden;* [2]*Uppsala University, Medical Sciences, Uppsala, Sweden;* [3]*Swedish Medical Products Agency, -, Uppsala, Sweden;* [4]*Sahlgrenska Academy, University of Gothenburg, Rheumatology and Inflammation Research, Gothenburg, Sweden;* [5]*Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden;* [6]*Skåne University Hospital, Department of Rheumatology, Lund, Sweden;* [7]*Karolinska University Hospital, Rheumatology, Stolckholm, Sweden*

Background: While the relative efficacy of treatments can be demonstrated in relatively small studies with limited follow-up, most safety concerns are infrequent, requiring longer follow-up and larger populations. This is recognized by the regulatory framework, where data from pivotal randomized controlled trials are usually considered sufficient for demonstrating efficacy and non-toxicity, but post-approval safety studies are required for many years to fully evaluate drug-associated risks. Though such regulatory safety-studies often focus on one drug (vs. all others), clinical decision-making requires data across all available treatment options. Long-standing longitudinal clinical registries, like the Anti-Rheumatic Therapies in Sweden (ARTIS) database, thus have a key role in assessing the relative safety of b/tsDMARDs, allowing simultaneous comparison of all drugs used in clinical practice, with consistent definitions of treatment cohorts, follow-up, and outcomes.
Objectives: To assess incidence rates of critical safety endpoints for individual b/tsDMARDs used to treat RA, updating previously published reports and including more recently introduced treatments.
Methods: Nationwide register-based cohort study including all RA patients in Sweden registered as starting any b/tsDMARD between Jan 1st 2010 and Dec 31st 2019, and followed until Dec 31st 2020. The incidence rates of selected outcomes, identified through national healthcare registers, were compared between individual b/tsDMARDs while adjusting for a range of potential confounders (covering demographics, RA-related characteristics and disease activity, and comorbidity) using Inverse Probability of Treatment Weighting. Probabilities were predicted by multinomial logistic regression, regressing all covariates on treatment status. Exposure time was counted from treatment start until stop (+90 days' lag time), censored at emigration and death.
Results: There were clear differences between patients starting individual b/tsDMARDs, in particular with TNF inhibitors more often used as a first line b/tsDMARD; sarilumab, baricitinib, and tofacitinib predominantly used later in the treatment course; rituximab used more often for older patients, and non-TNFi generally used more frequently for patients with higher disease activity or comorbidity. Expectedly, these differences translated into differences in the crude rate of safety endpoints. Several differences remained after confounder-adjustment (Table 1), including a higher rate of treatment discontinuation due to adverse events on baricitinib, tofacitinib, and sarilumab. Rituximab was associated with higher rates of several outcomes, but the confounder-adjustment markedly reduced risks and residual confounding likely explain part of the remaining increase. Baricitinib and tofacitinib were associated with higher rates of hospitalised herpes zoster, but not with similarly elevated rates of other serious infections. There were no clear differences in the rate of cardiovascular events or severe depression. Low number of events limit the comparison, in particular for sarilumab and tofacitinib.

Table 1. Weighted incidence rate per 1,000 person-years of selected safety outcomes.

DMARD	N	Discont. due to. adverse event	ACS	Stroke	Liver disease	Hosp. infection	Hosp. Herpes zoster	Hosp. depression	Any hosp.	All-cause mortality
ETA	8244	45	6.2	4.5	1.4	32	2.9	2.3	156	10.8
ADA	5069	46	5.9	5.6	1.1	36	3.5	1.5	166	9.5
INF	2832	50	8.2	5.8	3.1	43	3.2	2.0	197	12.7
CER	2072	54	6.4	7.0	2.5	34	3.6	1.7	172	11.0
GOL	1796	51	5.9	6.8	-	32	2.8	-	154	11.5
ABA	3254	56	7.3	4.7	1.9	36	2.3	1.6	172	13.9
RTX	3990	31	8.4	6.2	2.2	41	3.3	2.4	194	15.1
TCZ	2619	30	5.7	5.0	2.1	31	2.9	1.6	163	15.7
SAR	271	100	-	-	-	18	-	-	298	-
BARI	1665	69	3.0	4.2	1.4	37	8.8	2.6	173	16.7
TOFA	392	82	-	-	-	32	12.9	-	129	-

Note: Rates based on <5 events set to '-'

Conclusion: We found large differences in the rate of treatment discontinuations due to adverse events across b/tsDMARDs, which were not generally mirrored by corresponding differences in the rates for specific serious adverse events.

POS0638 RECOMMENDATIONS FOR COST-EFFECTIVE USE OF BIOLOGICAL AND TARGETED SYNTHETIC DMARDS IN INFLAMMATORY ARTHRITIS: RESULTS FROM AN INTERNATIONAL DELPHI STUDY

C. Van der Togt[1], B. Van den Bemt[2,3], D. Aletaha[4], R. Alten[5], K. Chatzidionysiou[6], J. Galloway[7], J. Isaacs[8], D. Mulleman[9], P. Verschueren[10], A. Vulto[11], P. Welsing[12], L. M. Verhoef[1], A. Den Broeder[1,13]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [2]Sint Maartenskliniek, Pharmacy, Ubbergen, Netherlands; [3]Radboud University Medical Center, Clinical Pharmacy, Nijmegen, Netherlands; [4]Medical University of Vienna, Rheumatology, Wien, Austria; [5]Schlosspark-Klinik Charlottenburg, Rheumatology, Berlin, Germany; [6]Nya Karolinska, Rheumatology, Solna, Sweden; [7]King's College London, Rheumatology, London, United Kingdom; [8]Newcastle University, Rheumatology, Newcastle, United Kingdom; [9]Université de Tours - Faculté de droit, économie et sciences sociales, Rheumatology, Tours, France; [10]UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium; [11]Erasmus University Rotterdam, Pharmacy, Rotterdam, Netherlands; [12]UMC Utrecht, Rheumatology, Utrecht, Netherlands; [13]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: Biological and targeted synthetic disease modifying antirheumatic drugs (b/tsDMARDs) are effective treatments for rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA), but associated with high costs. Therefore, various strategies for safe and cost-effective use of these drugs have been developed, such as tapering and biosimilar use. However, overarching recommendations on how clinicians or hospitals can use these strategies in clinical practice are absent.
Objectives: To develop evidence-based multidisciplinary recommendations on strategies for cost-effective use of b/tsDMARDs in the treatment of RA, PsA and SpA.
Methods: A task force was formed consisting of 13 experts in rheumatology, epidemiology and/or pharmacology from seven European countries. Relevant strategies for cost-effective use were collected and defined using one-to-one interviews with each task force member followed by group discussion. Next, a scoping review in PubMed and Embase was performed to summarize the evidence on each strategy, followed by a Delphi procedure and five online meetings, to form a set of overarching principles and recommendations. Levels of evidence and strengths of recommendations were determined in accordance with the 2018 EULAR additional guidance.[1] If consensus was reached on the formulation of the recommendation in the group meeting, voting on level of agreement was performed by every task force member separately using an online form. Level of agreement varied from 0 (completely disagree) to 10 (completely agree).
Results: Twelve strategies for cost-effective use of b/tsDMARDs were identified and four overarching principles were formulated (Table 1). For 10 strategies, there was enough evidence available to form one or multiple recommendation(s). In total, 20 recommendations were formulated, focussing on: the use of loading doses (2); the use of biosimilars where available (2); combining a csDMARD with a b/tsDMARD to maximise efficacy (3); the use of disease activity guided dose optimisation (4); the use of a drug formulary policy in clinical practice (1); considering using a lower dose where approved (2); improving medication adherence (1); non-medical drug switching within or between drug classes (1); therapeutic drug monitoring and other predictors for selecting or tapering a b/tsDMARD (2); and the use of different routes of administration of the same b/tsDMARD (2). The level of agreement for the recommendations varied between 7.9 (SD 1.2) and 9.8 (0.4).

Table 1. Overview of strategies (A) and overarching principles (B) for cost-effective use of b/tsDMARDs in RA, PsA and SpA

A.Strategies	
Avoid dose loading	Biosimilar/generic drug use
Combination therapy	Disease activity guided dose optimisation
Drug formulary policy	Drug wastage
Initial lower dose	Medication adherence
Nonmedical drug switching	Optimizing pharmacokinetic exposure
Response prediction	Route of administration
B.Overarching principles	
Cost-effectiveness considerations are an important aspect of treatment, and rheumatologists should have a leading role regarding this.	
Treat-to-target is the cornerstone of b/tsDMARD based treatment in RA, PsA and axSpA.	
Treatment choices must be based on shared decision making between the patient and the rheumatologist.	
Reimbursement policies should cover cost-effective use of pharmacological treatments, both on- and off-label, when they are evidence based and supported by (inter)national guidelines.	

Conclusion: These evidence-based recommendations provide caregivers in rheumatology with a consensus on strategies for cost-effective use of b/tsDMARDs in RA, PsA and SpA. Because high-quality evidence was limited, we were not able to formulate recommendations on all strategies.

POS0639 PHARMACOKINETIC BOOSTING TO ENABLE A ONCE-DAILY REDUCED DOSE OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

C. Van der Togt[1], L. M. Verhoef[1], B. Van den Bemt[2,3], N. Den Broeder[1], R. Ter Heine[3], A. Den Broeder[1,4]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [2]Sint Maartenskliniek, Pharmacy, Ubbergen, Netherlands; [3]Radboud University Medical Center, Clinical Pharmacy, Nijmegen, Netherlands; [4]Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands*

Background: Tofacitinib is an effective drug for rheumatoid arthritis (RA) and psoriatic arthritis (PsA). As tofacitinib is metabolized by the CYP3A4-enzyme, the manufacturer recommends to reduce the dose with 50% when combined with CYP3A4-inhibitors. This creates an opportunity to improve cost-effectiveness and patient experience by deliberately combining tofacitinib 5 mg once daily with a registered CYP3A4-inhibitor, cobicistat.
Objectives: Primary: pharmacokinetic (PK) bioequivalence of tofacitinib 5 mg and cobicistat 150 mg once daily (intervention) to tofacitinib 5 mg twice daily (control). Secondary: clinical efficacy (DAS28-CRP), safety, patient preference, and predictive modelling of long-term DAS28 and ACR20 response.
Methods: This open-label, cross-over, monocentre study (Sint Maartenskliniek, The Netherlands) included patients with RA or PsA, using tofacitinib 5mg twice daily for ≥ 14 days without co-medication affected by CYP3A4-inhibition. At the first sampling day, plasma samples of tofacitinib were collected pre-dose and 0.5, 1, 2, 3, 4, 6, 9 and 12 hours post-dose. Subsequently, patients switched treatment to tofacitinib 5 mg and cobicistat 150 mg once daily, and 2-6 weeks thereafter, another PK sampling was performed at the same timepoints and additionally at 24 hours post-dose. PK bioequivalence was defined as the 90% confidence interval of the average tofacitinib concentration ($C_{avg,ss}$) geometric mean ratio (GMR) falling between 80-125%. Secondary endpoints included efficacy (change in mean DAS28-CRP between sampling days), safety, and patient preference (7-point Likert scale at study end). Additionally, differences between both regimens in DAS28 and probability of ACR20 response were predicted using a validated PK/PD model.[1]
Results: Between September 2019 and March 2021, 27 participants were included. Twenty-five participants completed both PK measurements and were included in the primary analysis. The $C_{avg,ss}$ GMR was 84.8%, 90% CI 75.1% to 95.6%. The difference in absolute DAS28-CRP was 0.05 (95% CI -0.50 to 0.59, intervention to control). There were no significant or relevant

differences in adverse events between both regimens. Patient preference was 56% for intervention (Likert score 5-7), versus 18% for control (score 1-3). Median differences in predicted DAS28 and probability of ACR20 response were 0.03 (95% CI -0.16 to 0.22; intervention-control) and -0.01 (-0.07 to 0.05), respectively.

Conclusion: Due to slightly lower tofacitinib concentrations during combination therapy, pharmacokinetic bioequivalence could not formally be established. However, because of comparable short-term clinical efficacy and safety, a clear patient preference and no relevant differences in predicted DAS28 and ACR20-response at maximum efficacy, pharmacokinetic boosting seems an attractive strategy to improve cost-effectiveness of tofacitinib treatment.

Background: COMPACT is a non-interventional study evaluating the effectiveness and safety in patients (pts) with rheumatoid arthritis (RA), axial-spondyloarthritis (axSpA) or psoriatic arthritis (PsA) treated with GP2015 (an etanercept [ETN] biosimilar) in real-world conditions.

Objectives: We present the effectiveness and safety data from the final analysis of the COMPACT study for all patient groups.

Methods: Pts aged ≥18 years on treatment with GP2015 were enrolled. Baseline visit corresponded with date of study inclusion and not with date of GP2015 treatment start. Pts were categorised based on prior treatment status: pts on clinical remission or low disease activity under treatment with reference ETN or biosimilar ETN (initial ETN: [iETN]) and switched to GP2015 (Group A) or pts who received non-ETN targeted therapies and switched to GP2015 (Group B) or biologic-naïve pts who started GP2015 after conventional therapy failure (Group C) or DMARD-naïve pts with recent diagnosis of RA considered suitable for treatment initiation with a biologic and started on treatment with GP2015 (Group D). Effectiveness assessments included Disease Activity Score 28-joint count Erythrocyte Sedimentation Rate (DAS28-ESR) or Ankylosing Spondylitis Disease Activity Score (ASDAS) until Month 12 after enrolment (baseline) in the study.

Results: Of the 1466 pts enrolled, 572 were switched from iETN (Group A), 171 were switched from other targeted therapies (Group B), 713 were biologic-naïve (Group C), and 10 were RA DMARD-naïve (Group D). Comorbidities were more frequent in pts with RA (68.7%,) followed by pts with PsA (59.4%) and axSpA (52.1%). After 12 months of treatment with GP2015, pts with RA or PsA achieved comparable DAS28-ESR scores irrespective of whether they switched from iETN, or from other targeted therapies or were biologic-naïve. At Month 12, the mean ASDAS scores were comparable between the treatment groups in pts with axSpA (Table 1). Across all pt groups, no major differences were observed in the disease activity scores between baseline and Month 12 that may be explained by the ongoing GP2015 treatment at the time of enrolment for an observed average of 138 days. Overall, the proportion of patients with at least one adverse event (AE) and serious AE (SAE) was 47.6% and 7.7% in pts who were switched from iETN, 56.7% and 9.9% in pts switched from other targeted therapies, 56% and 8.7% in biologic-naïve pts, and 60% and 0% in DMARD-naïve pts. Rate of injection site reaction was low across the groups (Figure 1).

Table 1. Effectiveness outcomes in patients treated with GP2015

N, total number of patients in the treatment group; n, number of patients with available data at each time point, SD, standard deviation

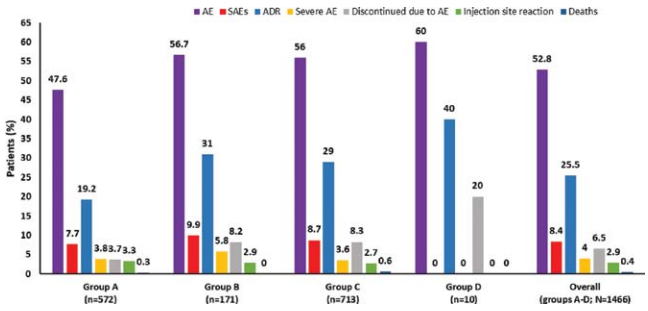

Figure 1. Overall safety outcomes in patients treated with GP2015Figure 1 represents the adverse events reported during GP2015 treatment.N, total number of patients in the treatment; n, number of patients in each treatment group

Conclusion: The results show comparable disease activity scores between pts who were switched from iETN, pts switched from other targeted therapies and biologic-naïve pts after 12 months of treatment with GP2015. No impact on the effectiveness of ETN was observed in pts with RA, axSpA or PsA who switched to GP2015. No new safety signals were reported.

POS0641 A RANDOMISED PHASE I PHARMACOKINETIC STUDY COMPARING HIGH-CONCENTRATION, LOW-VOLUME, AND CITRATE-FREE SB5 (40 MG/0.4 ML) WITH PRIOR SB5 FORMULATION, AND ADALIMUMAB BIOSIMILAR, IN HEALTHY MALE SUBJECTS

S. S. Ahn[1], M. Lee[1], Y. Baek[1], S. Lee[2]. *[1]Samsung Bioepis Co., Ltd., Product Evaluation Team, Incheon, Korea, Republic of (South Korea); [2]Samsung Bioepis Co., Ltd., Quality Evaluation Team, Incheon, Korea, Republic of (South Korea)*

Background: SB5, an adalimumab (ADL) biosimilar, was developed in a low-concentration (40 mg/0.8 mL, SB5-LC) aligned with the reference ADL product. Pharmacokinetics (PK) equivalence of SB5 and reference ADL was demonstrated in a Phase I study conducted in healthy subjects[1]. Equivalent efficacy and comparable safety between 40 mg/0.8 mL SB5 and 40 mg/0.8 mL reference ADL were demonstrated in a Phase III study conducted in patients with rheumatoid arthritis[2]. High-concentration, low-volume, citrate-free SB5 (40 mg/0.4 mL, SB5-HC) has been developed as a part of life cycle management in line with the reference ADL formulation.

Objectives: To compare the PK, safety, and tolerability of the newly developed SB5-HC (40 mg/0.4 mL) to prior SB5-LC (40 mg/0.8 mL) in healthy male subjects.

Methods: This study was a randomised, single-blind, two-arm, parallel group, single-dose study in healthy male subjects. Subjects were randomised in a ratio of 1:1 to receive a single dose of either SB5-HC or SB5-LC by subcutaneous injection on Day 1 and then observed for 57 days during which the PK, safety, and immunogenicity were evaluated. The serum concentration of ADL was measured using an enzyme-linked immunosorbent assay. The primary PK parameters were area under the concentration-time curve from time zero to infinity (AUC_{inf}) and maximum serum concentration (C_{max}). Equivalence for the primary PK parameters was to be concluded if the 90% confidence intervals (CIs) for the ratio of geometric least squares means (LSMeans) of the treatment groups compared were completely contained within the pre-defined equivalence margin of 0.80 to 1.25 using an analysis of variance.

Results: Of 188 randomised subjects, 187 subjects were analysed as PK Analysis Set (PKS) (n=93 in SB5-HC and n=94 in SB5-LC). One subject was excluded from the PKS in SB5-HC group (major protocol deviation for not being withdrawn in the event of confirmed COVID-19). The geometric LSMeans ratios for the comparison of SB5-HC and SB5-LC for AUC_{inf} and C_{max} were 0.920 and 0.984, respectively, and the corresponding 90% CIs were within the pre-defined equivalence margin of 0.80 to 1.25 (Table 1), indicating the two treatment groups are bioequivalent. There were no deaths, serious adverse events or discontinuation of the study due to treatment-emergent adverse events (TEAEs) during the study. The proportions of subjects who experienced TEAEs were comparable between the two treatment groups (44.7% in SB5-HC vs 51.1% in SB5-LC). The most frequent TEAEs were headache (10.6% in SB5-HC vs 12.8% in SB5-LC).

Table 1. Comparison of Primary PK Parameters between the Treatments

PK Parameter	Treatment	Geometric LSMean	Ratio	90% CI
AUC_{inf} (h·µg/mL)	SB5-HC	2616.1	0.920	0.8262; 1.0239
	SB5-LC	2844.3		
C_{max} (µg/mL)	SB5-HC	4.1	0.984	0.9126; 1.0604
	SB5-LC	4.1		

Conclusion: This study demonstrated PK equivalence between SB5-HC and SB5-LC in healthy subjects. Both SB5-HC and SB5-LC were generally well tolerated with similar safety profiles.

POS0642 THE PROBABILITY OF SUSTAINING RHEUMATOID ARTHRITIS REMISSION IN PATIENTS TAPERING TARGETED THERAPY USED AS MONOTHERAPY: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Meng[1], D. Rajesh[1], D. Jannat-Khah[1], O. Bruce[1], B. Jivanelli[2], V. Bykerk[1]. *[1]Hospital for Special Surgery, Rheumatology, New York, United States of America; [2]Hospital for Special Surgery Main Hospital, Kim Barrett Memorial Library, New York, United States of America*

Background: Up to 30% of RA patients receive monotherapy with biologic (b) DMARDs or JAK inhibitors (i), often due to intolerance of methotrexate (MTX). Monotherapy with IL-6i and JAK-i has been reported to be effective. The EULAR research agenda includes addressing the question of whether tapering of targeted therapy (bDMARDs and JAK-i) used as monotherapy (targeted monotherapy) is possible[1].

Objectives: To assess if it is feasible to taper (stop or reduce) targeted monotherapy with controlled RA using existing clinical trial data.

Methods: A systematic review of the literature (2014-2021), cited in Medline, Embase and the Cochrane Library, was performed. Meta-analyses were conducted using random effects models. Forest and funnel plots were created and heterogeneity calculated.

Results: Our search yielded 5762 citations. After de-duplication, screening of titles/abstracts and review of full text articles, we identified 5 studies comparing tapering of targeted monotherapy (TNF-i, tocilizumab (TCZ), abatacept (ABA) and baricitinib) to continuing therapy or other tapering regimens (Table 1). In our meta-analysis of data from 800 patients we observed a trend for lower odds of remission when tapering of targeted monotherapy vs comparator treatment regimen [pooled OR 0.72 (0.35, 1.48)]. In one study comparing stopping monotherapy to continuing MTX, we saw the lowest OR 0.55 (0.20, 1.48). In studies comparing two tapering regimens the pooled OR was higher 2.17 (1.13, 4.16). There was no heterogeneity in the studies which compared tapering to continuing therapy (I^2=0.0%, p=0.437) and moderate heterogeneity in the studies that tapered different treatments in both arms (I^2=53.7%, p=0.115). Trials using a gradual tapering strategy had a numerically higher odds of remission [OR 2.15 (0.94, 4.92); 3.61(1.85, 7.04)] compared to a trial implementing abrupt withdrawal [OR 1.19 (0.53, 2.68)]. There was a trend for higher remission outcomes in studies of early RA [pooled OR 1.71 (0.72, 4.05)] compared to established RA [pooled OR 1.12 (0.29, 4.27)] (Figure 1). Funnel plots indicate a paucity of studies, and perhaps publication bias.

Conclusion: There are no trials designed to compare tapering targeted monotherapy to continuing it, indicating a significant gap in knowledge in an area of increasing clinical relevance for our patients. There was insufficient evidence to demonstrate the significant effects of tapering targeted monotherapy in RA. Only one study out of 5 compared stopping targeted monotherapy to continuing therapy (MTX), and reported a low OR of remission. Three studies tapered therapy in both arms and one study performed a dose reduction. Our review suggests that stopping targeted monotherapy is unlikely to maintain disease control. More gradual tapering schemes, dose reduction and early treatment of disease may be associated with more successful tapering. More studies are needed to better inform our patients. Currently, we do not recommend stopping targeted monotherapy in RA.

POS0643

SUSTAINABILITY OF RESPONSE BETWEEN UPADACITINIB AND ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS THROUGH 3 YEARS FROM THE SELECT-COMPARE TRIAL

P. Nash[1], A. Kavanaugh[2], M. H. Buch[3], B. Combe[4], L. Bessette[5], I. H. Song[6], T. Shaw[7], Y. Song[6], J. Subotticki[6], R. M. Fleischmann[8]. *[1]School of Medicine, Griffith University, Brisbane, Australia; [2]University of California San Diego, Rheumatology, San Diego, United States of America; [3]University of Manchester & NIHR, Manchester Biomedical Research Centre, Manchester, United Kingdom; [4]Montpellier University, Rheumatology, Montpellier, France; [5]Université Laval, Centre Hospitalier de l'Université Laval, Laval, Canada; [6]AbbVie Inc., Immunology, North Chicago, United States of America; [7]AbbVie Inc., Immunology, Maidenhead, United Kingdom; [8]Univ of Texas Southwestern Med Center, Metroplex Clinical Research Center, Dallas, United States of America*

Background: The primary treatment target for patients with active rheumatoid arthritis (RA) is sustained clinical remission (REM) or low disease activity (LDA).[1,2] A greater proportion of patients with RA and inadequate response to methotrexate (MTX) receiving the JAK inhibitor, upadacitinib (UPA), achieved REM/LDA compared with adalimumab (ADA), both with background MTX, through 26 weeks in the phase 3, SELECT-COMPARE trial.[3]

Objectives: We assessed sustainability of response over 3 years in UPA-treated patients with RA.

Methods: SELECT-COMPARE included a 26-week, double-blind, placebo (PBO)-controlled period, a 48-week, double-blind active comparator-controlled period, and an ongoing long-term extension for up to 10 years. Patients on background MTX received UPA 15 mg once daily, PBO, or ADA 40 mg every other week. Patients who did not achieve at least 20% improvements in tender and swollen joint counts (Weeks 14-22) or LDA (CDAI ≤10 at Week 26) were rescued from UPA to ADA or PBO/ADA to UPA. This post hoc analysis evaluated clinical REM (CDAI ≤2.8; SDAI ≤3.3), LDA (CDAI ≤10; SDAI ≤11), and DAS28(CRP) <2.6/≤3.2 at first occurrence (prior to treatment switch [rescue]), as well as over 3 years following initial response in patients randomized to UPA or ADA. For those patients who achieved REM/LDA, Kaplan-Meier was used to define the time from when the response was first achieved to the earliest date at which the response was lost at two consecutive visits, discontinuation of study drug, or losing response at the time of rescue. The predictive ability of time to CDAI REM/LDA was assessed using Harrell's concordance (c)-index (range: 0 [all predictions wrong] to 1.0 [perfect predictive ability]. Non-responder imputation was used for missing data.

Results: Through 3 years, a significantly higher proportion of patients receiving UPA + MTX vs ADA + MTX achieved CDAI REM (47% vs 35%, $P = 0.001$) as well as CDAI LDA (70% vs 60%, $P = 0.001$). At 30 months after first occurrence of response, CDAI REM/LDA was sustained in 19%/42% of patients randomized to UPA and 10%/30% of patients randomized to ADA (Figure 1). Time to initial clinical response did not appear to be predictive of sustained disease control. The c-index for CDAI REM/LDA was 0.50/0.60 on UPA vs 0.49/0.56 on ADA. Through the last follow-up visit, 37%/58% of patients receiving UPA and 27%/48% on ADA remained in CDAI REM/LDA, respectively (Figure 2). Of patients who lost CDAI REM, 68% on UPA and 55% on ADA remained in LDA. Additionally, roughly similar proportions on UPA and ADA recaptured CDAI REM/LDA (UPA, 40%/17%; ADA, 48%/19%). Similar results were observed for REM/LDA based on SDAI and for DAS28(CRP) <2.6/≤3.2.

Conclusion: Among patients with inadequate response to MTX, a higher proportion receiving UPA + MTX achieved remission or LDA across disease activity measures vs ADA + MTX. UPA-treated patients demonstrated a consistently higher sustained response rate over 3 years compared to those receiving ADA. Furthermore, significant proportions of patients who lost response on either UPA or ADA were able to recapture remission or LDA.

Background: Crohn's disease (CD), Ulcerative Colitis (UC), Rheumatoid Arthritis (RA), Axial Spondyloarthritis (axSpA), Psoriatic Arthritis (PsA), and Psoriasis (PsO) are known as Chronic Inflammatory Diseases (CID). These CID's are prevalent diseases that share pathophysiological pathways, genetics, environmental factors and pharmacological therapies. Biologic disease-modifying drugs have revolutionised the treatment of CIDs but unfortunately up to 60% of the patients have no or only suboptimal response to the treatment. Aside pharmacologic treatment, many patients are interested in self-management strategies for their symptoms and often request dietary recommendations. However, sound evidence for such recommendations is lacking [1].

Objectives: To investigate if the treatment outcome of biological therapy (e.g. a TNF inhibitor) is associated with the habitual dietary intake of fibre and red/processed meat in patients with a CID [2].

Methods: In this prospective multicentre cohort study we consecutively enrolled 233 adult patients with a diagnosis of CD, UC, RA, axSpA, PsA or PsO for whom biologic therapy was planned. The Intention-to-Treat (ITT) population was defined as those with completed baseline food frequency questionnaires enabling stratification into a high fibre/low red and processed meat exposed group (HFLM) and an unexposed group (low fibre/high red and processed meat intake = LFHM). This was determined by the ratio of fibre to red/processed meat intake whereby HFLM constituted the upper tertile of the study sample and LFHM constituted the two lower tertiles of the study sample. The primary outcome was the proportion of patients with a clinical response to biologic therapy after 14-16 weeks of treatment. Based on the ITT population, differences between the dietary phenotypes in terms of the clinical response rate were analysed (while adjusting for the specific CID) in logistic regression models. **Trial registration** ClinicalTrials.gov NCT03173144.

Results: Of 193 patients included in the ITT population, we had outcome data on 176 (i.e. data from 17 patients were imputed): 114 (59%) had a clinical response to biologic therapy. In the HFLM group, 41 (64%) patients responded to treatment compared to 73 (56%) in the LFHM group, but the difference proved not to be statistically significant (Odds ratio, OR: 1.48, 95% confidence interval 0.72 to 3.05). For RA patients however, HFLM diet was associated with a clinical response in 82% compared to 28% in the LFHM group (OR: 9.84, 1.35 to 71.56). The same picture was seen for the 'As Observed' population (i.e. excluding the 17 patients without outcome data), see Figure 1. Changes in measures of health-related quality of life, physician's global assessment and C-reactive protein were comparable between groups and across conditions.

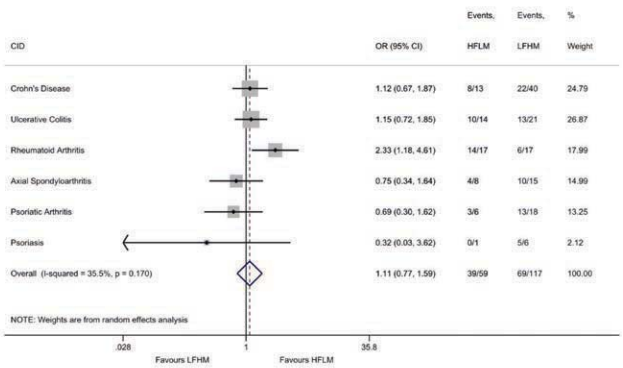

Figure 1. Meta-analysis (random effects model) of the included Chronic Inflammatory Diseases (CIDs) on the 'As Observed' population comparing clinical response to biologics in patients with a high intake of fibre and low intake of red/processed meat (HFLM) versus patients with a low intake of fibre and high intake of red/processed meat (LFHM). The horizontal lines represent the OR ± 95% CI. Event= clinical response according to the specified criteria for each CID.

Conclusion: Overall, habitual HFLM intake did not affect the clinical response to biological treatment across CIDs. However, a HFLM diet in RA patients might be associated with a better response following biological treatment.

POS0645 LONG-TERM SAFETY AND EFFICACY OF OLOKIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS – RESULT OF AN OPEN-LABEL EXTENSION STUDY, CREDO4

E. Feist[1], E. Nasonov[2], M. Luggen[3], S. Fatenejad[4], S. Grishin[5], M. Samsonov[5], R. M. Fleischmann[6]. *[1]Helios Clinic, Rheumatology, Vogelsang-Gommern, Germany; [2]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [3]University of Cincinnati College of Medicine, Division of Rheumatology, Allergy, and Immunology, Cincinnati, United States of America; [4]SFC Medica, LLC, Consultancy, Charlotte, NC, United States of America; [5]R-Pharm, Medical, Moscow, Russian Federation; [6]University of Texas Southwestern Medical Center, Research Center, Dallas, Texas, United States of America*

Background: Olokizumab (OKZ), an IL-6 ligand inhibitor, demonstrated significant improvements in signs and symptoms of RA vs placebo (PL) and non-inferiority to adalimumab (ADA) in doses of 64 mg every two weeks (q2w) or every 4 weeks (q4w).[1-3] Patients (pts) who completed core phase III studies, were enrolled in an open-label extension study (OLE) (ClinicalTrials.gov number, NCT03120949).
Objectives: To report long-term safety and efficacy results of OKZ in combination with MTX.
Methods: During the OLE study, pts continued OKZ 64 mg q2w or q4w, and those who were on PBO or ADA were randomized to OKZ 64 mg q2w or q4w. Adverse events (AE) were assessed through 82 weeks of the OLE treatment and an additional 20 weeks of safety follow-up. All AEs were analyzed using descriptive statistics. Efficacy assessments included proportions of pts who achieved ACR20/50/70 responses, SDAI ≤3.3, improvement in HAQ-DI ≥0.22, mean change in CDAI, and DAS-28-CRP using descriptive statistics.
Results: 2105 eligible pts were enrolled, 1709 (81.2%) pts completed the OLE treatment period and 394 (18.7%) pts discontinued treatment, mainly due to adverse events 180 (8.6%), due to subject decision 158 (7.5%) and due to lack of efficacy 9 (0.4%). Treatment emergent AE occurred in 1546 (73.5%) pts, the most common AE 809 pts (38.5%) were infections (Table 1). The most common AE leading to treatment discontinuation were infections (53 [2.5%]), investigations (43 [2.0%]) including 1% with ALT increase and blood and lymphatic system disorders (13 [0.6%]) including leuko- and lymphopenia (0.2%-0.1%). Serious AE were reported by 249 (11.8%) pts, serious infections - by 87 (4.1%) pts.

All cases, n (%)	OKZ 64 mg q2w (OLE), N=1061	OKZ 64 mg q4w (OLE), N=1043
Any AE	793 (74.7%)	753 (72.2%)
Any serious AE	120 (11.3%)	129 (12.4%)
Any AE leading to discontinuation of study drug	90 (8.5%)	87 (8.3%)
Any death	13 (1.2%)	13 (1.2%)
Any AE of special interest	611 (57.6%)	598 (57.3%)
Infections	398 (37.5%)	389 (37.3%)
Opportunistic infections	22 (2.1%)	19 (1.8%)
Malignancies	6 (0.6%)	9 (0.9%)
Basal cell carcinomas	1 (<0.1%)	2 (0.2%)
Hyperlipidemia	138 (13.0%)	120 (11.5%)
Systemic injection and hypersensitivity reactions	100 (9.4%)	99 (9.5%)
Anaphylactic reactions	0	0
Gastrointestinal perforation	2 (0.2%)	1 (<0.1%)
Neutro-, thrombocyte-, leukocyte-, pan-cytopenias	168 (15.8%)	146 (14.0%)
Potential hepatotoxicity (ALT >3 ULN)	63 (5.9%)	68 (6.5%)
Injection site reactions	34 (3.2%)	34 (3.3%)
Demyelination in peripheral or central nervous system	1 (<0.1%)	0
Autoimmune disorders	41 (3.9%)	48 (4.6%)
Serious infection	47 (4.4%)	40 (3.8%)
Any potential adjudicated major adverse cardiac events	7 (0.7%)	15 (1.4)

AE, adverse event; ALT, alanine aminotransferase; n, number of subjects; %, percentage of subjects calculated relative to the total number (N) of subjects in the population; ULN, upper limit normal

Deaths occurred in 1.2% of pts, equally distributed between the two groups with the most frequent reason being infections. Efficacy of OKZ was maintained throughout the OLE (Figure 1) and pts who switched from PBO or ADA showed the same level of improvement as those who were treated with OKZ in the core studies (data not shown).

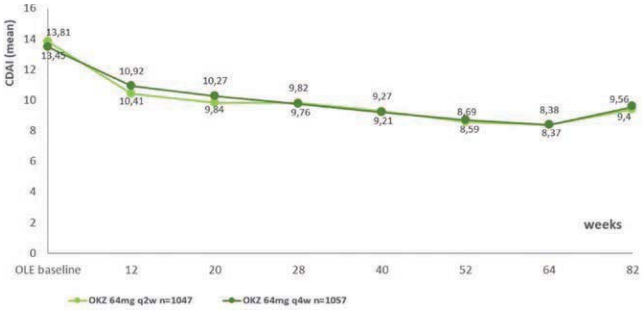

Figure 1. Mean CDAI over time (modified Intent-to-treat population). **Abbreviations**: CDAI, clinical disease activity index.

There were no apparent differences in safety and efficacy outcomes between OKZ arms, except incidence of major adverse cardiovascular events appeared slightly higher in q4w arm (Figure 1, Table 1).
Anti-drug antibodies occurred infrequently and neutralizing antibodies were rare.
Conclusion: OKZ was safe and well-tolerated that is consistent with the results of previously reported studies of OKZ and IL-6 inhibitors. Efficacy of OKZ was maintained through Wk 82 and discontinuation rates were low.

POS0646 NON-MEDICAL SWITCHING FROM TOCILIZUMAB TO SARILUMAB IN RHEUMATOID ARTHRITIS PATIENTS WITH LOW DISEASE ACTIVITY

N. Den Broeder[1,2], A. Den Broeder[1], L. M. Verhoef[1], F. Van den Hoogen[1], A. Van der Maas[1], B. Van den Bemt[1]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [2]Radboudumc, Radboud Institute for Health Sciences, Nijmegen, Netherlands*

Background: Tocilizumab (TCZ) and sarilumab (SRL) are IL6-receptor antagonists registered for the treatment of rheumatoid arthritis (RA). Data from extension of the ASCERTAIN trial showed that patients responding to blinded intravenous (IV) TCZ rarely experienced a loss of response when switching to open label SRL [1]. This within-class, between-drug switch has gained relevance given the recent pandemic-driven shortage of several bDMARDS including TCZ.
Objectives: To assess the efficacy and persistence of switching to sarilumab in RA patients responding well to tocilizumab.
Methods: SAARTOOS (SArilumab Actively Replacing TOcilizumab, an Open label Study) is an open, observational single arm study. RA patients doing well (DAS28-CRP<2.9 or <3.5 with clinical judgement of low disease activity) on a stable dose (>6 months) of TCZ were offered to switched to SRL in clinical care (because of lower injection frequency). Patients who switched and consented were followed for 6 months. SRL was prescribed at a dose of 200mg. The SRL dosing interval was determined by doubling patient's last TCZ dosing interval. All treatment decisions, including adjusting dose of or stopping SRL, were left to the treating physician. Co-primary outcomes were 1) the 90% confidence interval (CI) of DAS28-CRP change from baseline to month 6 compared to the non-inferiority

margin of 0.6 and 2) the 90% CI of the proportion of patients persisting with SRL at month 6, compared to a pre-specified minimum persistence of 70% at month 6. Secondary outcomes included the CDAI, proportion of patients experiencing DAS28-CRP based flare (and post-hoc the proportion of patients remaining on SRL at month 6 without flare), changes in co-medication, expectations both patient and physician on SRL efficacy and tolerability.

Results: Of 50 invited patients, 25 agreed to attempt a switch to SRL, of whom 23 patients switched and were included. Switching and therefore inclusion was halted at this point due to an observed increase in disease activity and lack of SRL persistence. One patient was lost to follow up immediately after inclusion, therefore 22 patients are included in analyses (Table 1).

Table 1. Baseline characteristics

Baseline characteristics	N=22
Age, mean (SD)	66 (11)
Female, n (%)	17 (77%)
Rheumatoid factor positive, n (%)	18 (82%)
Anti-CCP positive, n (%)	18 (82%)
Erosive disease, n (%)	14 (67%)
2010 ACR/EULAR classification criteria, n (%)	21 (95%)
DAS28-CRP, mean (SD)	1.9 (0.6)
CDAI, mean (SD) (n=15)	4.7 (3.1)
Disease duration, years, median (IQR)	20 (10-24)
Duration of tocilizumab use, years, median (IQR)	2.7 (2.1-7.3)
Tocilizumab dose, n (%)	
162mg per week	10 (45%)
162mg per 10 days	2 (9%)
162mg per 2 weeks	9 (41%)
162mg per 3 weeks	1 (5%)
Concomittant csDMARD use, n (%)	7 (32%)

DAS28-CRP changed significantly from baseline to month 6: mean 0.48 (90% CI: 0.1 to 0.9). 15 of 22 patients maintained SRL at month 6, leading to a persistence of 68% (90% CI: 51% to 82%). Both co-primary outcomes therefore failed to meet their non-inferiority criteria. DAS28-CRP change was driven by both objective and subjective components. Median (IQR) CDAI at month 6 was 7 (3-10). During the study, 8 (36%) patients experienced 1 or more DAS28-CRP based flare. Only 11 (50%) patients remained on SRL for 6 months without experiencing flare. Expectations of patients and physicians at baseline were positive, with no patients or physicians expecting worsening of either disease activity or adverse effects prior to switching. Patient preference after using SRL (n=20, 2 missings) was inconsistent, with 5 (25%) patients strongly preferring TCZ, and 5 (25%) patients somewhat or strongly preferring SRL. In terms of (co-)medication, 4 (18%) patients required additional corticosteroids (oral or intramuscular), 5 (23%) patients switched back to TCZ and 2 (9%) switched to baricitinib.

Conclusion: Non-medical switching from tocilizumab to sarilumab in patients doing well on tocilizumab is associated with a non-negligible risk of flare and non-persistence.

POS0647

DOES TNF INHIBITOR MOLECULAR STRUCTURE MATTER? ANALYSIS OF IMPACT OF BASELINE RHEUMATOID FACTOR TITERS ON DRUG LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Martínez-Feito[1], B. Hernández-Breijo[1], M. Novella-Navarro[2], A. Villalba[2], D. Peiteado[2], P. Nozal[1], D. Pascual-Salcedo[1], A. Balsa[2], C. Plasencia[2]. *[1]Institute for Health Research (IdiPAZ), Immuno-Rheumatology Research Group, Madrid, Spain; [2]La Paz University Hospital, Department of Rheumatology, Madrid, Spain*

Background: Elevated rheumatoid factor (RF) in patients with rheumatoid arthritis (RA) is associated with higher disease activity and increased risk for disease progression[1]. Recent publications indicate significantly lower efficacy of TNF inhibitors (TNFi) in RA patients with high RF levels compared with low/negative RF subgroup[2,3]. Fab therapy with Certolizumab pegol (CZP), a PEGylated, Fc-free monoclonal antibody (mAb), has shown comparable efficacy and consistent serum levels irrespective of baseline RF[4]. RF binds the Fc region of IgG1, the subtype used to engineer the majority of mAbs[5]. Formation of large immune complexes may likely explain the inceased clearance of mAbs in patients with high RF titers and reported reduced TNFi efficacy.

Table 1. Baseline characteristics.

Characteristics	Total (n=168)	IFX (n=90)	ADL (n=48)	CZP (n=32)	p value

*Median and interquartile range;**mean and standard deviation

Objectives: We aimed to evaluate in clinical practice whether RF levels in RA patients influence serum drug levels of 3 TNFi with different molecular structures.

Methods: We evaluated retrospectively a cohort of RA patients from La Paz University Hospital (RA-Paz Registry, 1999-2019) treated with Infliximab (IFX), Adalimumab

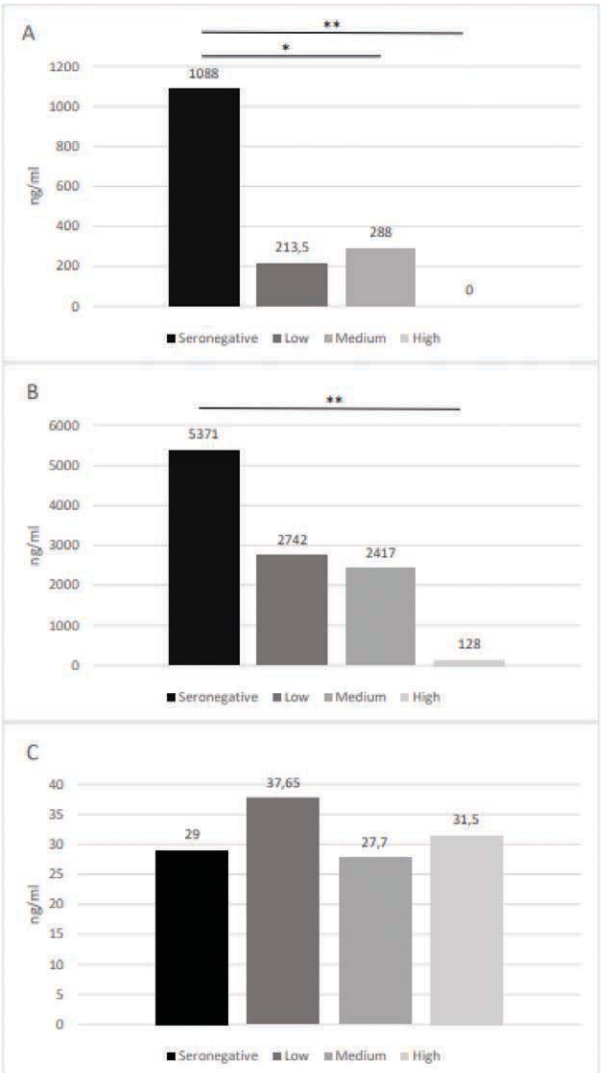

Fig. 1: Median drug levels (ng/ml) at 6 months by baseline RF titer. A: Infliximab; B: Adalimumab; C: Certolizumab pegol. *p<0.05; **p<0.01

(ADA) or CZP. Clinical and demographic data were collected at baseline (T0) and after 6 months (T6) of treatment. RF titers and serum drug levels were measured at T0 and T6 using nephelometry and ELISA respectively. Association between baseline RF titers and drug levels was assessed using non-parametric test (Mann-Whitney).

Results: 168 patients were evaluated: 90 received IFX, 48 ADA and 32 CZP. Characteristics at T0 are shown in Table 1. All patients had active disease at baseline and 76% were RF positive: ADA subgroup had lower percentage of positive RF than IFX and CZP subgroups. Patients were stratified into quartiles based on baseline RF titers: low (20-57 IU/ml), medium (57-380 IU/ml), high (>380 IU/ml) and seronegative (<20 IU/ml). Drug levels of IFX and ADA at T6 were significantly lower in those patients who had higher RF titers at T0 compared to seronegative. In contrast, CZP levels remained stable irrespectively of baseline RF titers, without significant differences among quartiles (Figure 1).

Conclusion: Higher baseline RF titers are associated with lower IFX and ADA levels at T6 in a cohort of RA patients. A concentration-response association has been clearly established for TNFi, and baseline RF levels appear to influence drug levels. Reduced immune complexes formation with CZP may result in a limited impact of baseline RF titers on drug levels.

SEX DIFFERENCES IN ADVERSE DRUG REACTIONS FROM BIOLOGICAL USE IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES

H. Gosselt[1], J. Van Lint[2], S. Tas[3], B. Van den Bemt[4,5], H. Vonkeman[6,7], F. Hoentjen[8], M. Nurmohamed[9], M. Van Doorn[10,11], N. Jessurun2. *[1]Netherlands Pharmacovigilance Center Lareb, Dutch Biologic Monitor,'s-Hertogenbosch, Netherlands; [1]Netherlands Pharmacovigilance Center Lareb, Dutch Biologic Monitor,'s-Hertogenbosch, Netherlands; [3]Amsterdam UMC, Location AMC, University of Amsterdam and Amsterdam Rheumatology & Immunology Center (ARC), Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands; [4]Sint Maartenskliniek, Department of Pharmacy, Ubbergen, Netherlands; [5]RadboudUMC, Department of Pharmacy, Nijmegen, Netherlands; [6]University of Twente, Department of Psychology, Health & Technology, Enschede, Netherlands; [7]Medisch Spectrum Twente, Department of Rheumatology & Clinical Immunology, Enschede, Netherlands; [8]University of Alberta, Division of Gastroenterology, Edmonton, Canada; [9]Reade, Amsterdam Rheumatology & Immunology Center (ARC), Amsterdam, Netherlands; [10]Erasmus MC, Department of Dermatology, Rotterdam, Netherlands; [11]Centre for Human Drug Research, -, Leiden, Netherlands*

Background: Women generally report more adverse drug reactions (ADRs) than men. Information on sex differences concerning the frequency and the nature of ADRs is still limited and sex differences are often not considered in research on ADRs. Consequently, no sex specific distinction is made when reporting results of ADR analyses or when providing information to patients.

Objectives: To examine sex differences in regard to the nature and frequency of reported ADRs in patients with immune-mediated inflammatory disease (IMIDs) treated with adalimumab or etanercept.

Methods: Patients with rheumatoid arthritis (RA), psoriatic arthritis or axial spondyloarthritis using etanercept or adalimumab, were included from the Dutch Biologic Monitor (DBM). Questionnaires concerning experienced ADRs were filled out bimonthly. ADRs were coded according to Medical Dictionary for Regulatory Activities (MedDRA) terminology. Sex specific ADRs (e.g. concerning menstruation) were excluded. MedDRA Preferred Terms (PTs) were analyzed to assess the nature and frequency of ADRs. Only PTs that were reported at least four times were analyzed. Discrepancies in the distribution of the nature of reported ADRs between male and female patients were assessed using Fisher Freeman Halton with Monte Carlo simulation. Subsequently, differences in frequencies at PT level were examined using Fisher's exact tests, corrected for multiple testing using Bonferroni correction.

Results: In total 748 consecutive patients were included of which the majority (59%) was female (Table 1). 362 participants (48%) reported at least one ADR during the study. Relatively more female patients (55%) reported at least one ADR compared to male patients (38%, p<0.001). In total 882 ADRs were reported comprising 264 distinct ADRs, of which the majority (74%) was reported by female patients. The ADR distribution differed significantly between male and female patients (p=0.025). 'Injection site pruritus' (p=0.004), 'injection site inflammation' (p=0.028), 'injection site hematoma' (p=0.017), 'injection site erythema' (p=0.026), 'hematoma' (p=0.011) and 'cystitis' (p=0.044) were reported relatively more often by female patients (Figure 1). These differences were no longer statistically significant upon correction for multiple testing.

Table 1. Demographics of included patients from the Dutch Biologic Monitor stratified on sex

Participants	Male	Female
N	304	444
Age, mean ± SD[a]	58.2 ± 11.9	56.6 ± 12.9
Indication[b], N(%)		
Bechterew's disease/axial SpA	71 (23.4)	39 (8.8)
Bechterew's disease/axial SpA and PsA	4 (1.3)	8 (1.8)
Bechterew's disease/axial SpA and RA	8 (2.6)	3 (0.7)
PsA	89 (29.3)	84 (18.9)
RA	132 (43.4)	310 (69.8)
bDMARDs, N(%)		
Adalimumab	138 (45.4)	199 (44.8)
Etanercept	159 (52.3)	232 (52.3)
Switched adalimumab/etanercept	7 (2.3)	13 (2.9)
Comedication, N(%)[c]		
Methotrexate	107 (35.2)	250 (56.3)
Corticosteroids	27 (8.9)	49 (11.0)
Thiopurines	3 (1.0)	10 (2.2)
Aminosalicylates	14 (4.6)	33 (7.4)

[a]Age was missing for 1 male and 1 female patient. [b]Patients could report multiple indications. 5 male and 14 female participants also reported other indications.[c]Reported comedication is from the moment of inclusion. Eleven patients (male=3, female=8) did not start with etanercept or adalimumab at the moment they were included. For these, comedication is from the moment they reported to be treated with adalimumab or etanercept for the first time.

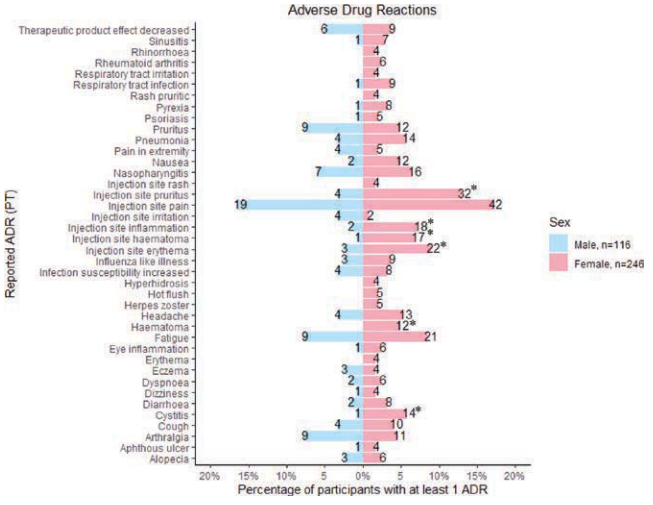

Figure 1. Top reported ADRsPercentages on the x-axis were calculated separately for sex, divided by the number of male or female patients with at least one ADR. *p-value<0.05.

Conclusion: Female patients reported relatively more ADRs than male patients. Also, the distribution of the nature of the ADRs significantly differed for male and female patients. In particular injection site reactions were reported relatively more often in female patients than in male patients. Therefore, sex differences in experiencing ADRs may exist and should be taken into consideration when investigating and reporting results on ADRs or when informing patients.

Background: Previously, 24-week results of phase III double-blind, placebo-controlled randomized clinical study (SOLAR) of levilimab in subjects with active rheumatoid arthritis (RA) proved a superiority of levilimab over placebo[1]. Here we present 1-year efficacy and safety data of the open-label period of the SOLAR study.
Objectives: To evaluate the efficacy and safety of levilimab in combination with methotrexate (MTX) in subjects with MTX resistant active RA.
Methods: The study was conducted at 21 clinical sites in Russia and Belarus. All randomized subjects had completed the study between November 2019 and October 2021. 154 adults, aged ≥ 18 years with confirmed diagnosis of RA[1] were randomly assigned (2:1) to receive either levilimab, 162 mg, SC (LVL QW) + MTX (n=102) or placebo (PBO) + MTX (n=52). After W24 of the study all subjects continued to receive open label levilimab +MTX. Subjects who had achieved DAS28-CRP ≤ 2.6 at W24 were switched to maintenance (Q2W) regimen of levilimab + MTX at W28: LVL QW/Q2W arm (n=27) and PBO/LVL Q2W arm (n=1). Those with DAS28-CRP > 2.6 at W28 continued with levilimab QW regimen + MTX: LVL QW/QW arm (n=75) and PBO/LVL QW arm (n=51). The efficacy analysis was done in a population of all randomized subjects (n=154). Those with missing data due to study discontinuation or rescue therapy prescription were considered non-responders. Otherwise, the analysis was performed on complete cases. Safety was assessed through monitoring of adverse events (AEs) in a population of those, who received at least one dose of LVL (n=152). Two subjects randomized to receive placebo were discontinued within first 24 weeks of the study, thus did not received any dose of levilimab and were excluded from safety analysis.
Results: Obviously, better response to the treatment was observed in LVL QW/Q2W arm as it was composed of those who had reached DAS28-CRP ≤ 2.6 at W24. At this time point 15/27 (55.6%) of them achieved ACR70; 23/27 (85.2%) achieved DAS28-CRP remission (< 2.6) and 7/27 (25.9%) achieved ACR/EULAR2011 remission of RA. After switching to LVL Q2W, rates of ACR70 and DAS28-CRP < 2.6 did not significantly changed until W52: 17/27 (63.0%) and 21/27 (77.8%), respectively, yet the proportion of subject with ACR/EULAR 2011 remission further increased and reached 12/27 (44.4%). LVL QW/QW arm was diminished by subjects who had achieved high response to treatment at W24 and composed LVL QW/Q2W arm. Thus, the ACR70, and remissions rate in this arm were close to zero at W24. However, continuation of LVL QW in those who had not achieved DAS28-CRP ≤ 2.6 at W24 induced ACR70 response in 37/75 (36.0%), DAS28-CRP remission in 35/75 (46.7%) and ACR/EULAR 2011 remission in 8/75 (10.7%) at W52. The most common adverse events (reported in ≥5% of subjects) were blood cholesterol increase (30.3%), ALT increase (23.0%), lymphocyte count decrease (17.1%), ANC decrease (16.4%). blood triglycerides increase (13.8%), bilirubin increase (11.2%), AST increase (9.9%), WBC decrease (9.9%), IGRA with M.tb antigen positive (7.2%) and injection site reactions (5.9%). No deaths were occurred.
Conclusion: Open label period confirmed the lasting efficacy and safety of levilimab in combination with MTX in subjects with MTX resistant active RA and suggested the possibility of switching to maintenance (Q2W) regimen of levilimab in those who achieved remission of RA at week 24.

POS0650 THE IMPACT OF OLD AGE ON THE PERSISTENCE AND SAFETY OF TREATMENT WITH BIOLOGIC AGENTS OR JAK INHIBITORS IN RHEUMATOID ARTHRITIS

R. Chakr[1], M. Bredemeier[1], A. Duarte[1], M. Pinheiro[1], B. Stadler[1], J. C. Macieira[1], R. Ranza[1], J. Miranda[1], V. Valim[1], G. Castro[1], M. Bertolo[1], M. D. F. Sauma[1], V. Fernandes[1], A. C. Medeiros-Ribeiro[1], R. Botelho[1], C. Brenol[1], H. M. Da Silveira De Carvalho[1], S. Studart[1], G. Da Rocha Castelar Pinheiro[1], L. Rocha Jr[1], I. Pereira[1], H. De Leon de Lima[1], M. Ohira Gazzeta[1], A. Kakehasi[1], P. Louzada Jr[1], A. L. S. Hayata[1], F. Pina[1], C. Lupo[1], L. Balarini[1], I. Silveira[1], S. Schowalski[1], D. Titton[1], A. Ranzolin[1], I. Laurindo[1], R. Xavier[1]on behalf of the BiobadaBrasil-SBR. *[1]Brazilian Society of Rheumatology, Register BiobadaBrasil, São Paulo, Brazil*

Background: The effect of age on persistence and safety of treatment with biologic disease modifying anti-rheumatic drugs (bDMARDs) in rheumatoid arthritis has been a subject to research interest. Two recently published studies did not observe significantly different survival of treatment with bDMARDs among older age (≥ 65 years) individuals (1,2); incidence of serious adverse events was higher in these patients (2).
Objectives: to evaluate association of the age with treatment survival and overall safety among patients receiving one or multiple courses of bDMARDs or targeted synthetic (ts-) DMARDs.

Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting their first bDMARD or tsDMARD (3). The present analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over one or multiple (up to six) courses of treatment necessarily involving a bDMARD or tsDMARD (latest date, Nov 19, 2019). Treatment course is defined as a period during which the medication scheme does not change, except for dose adjustments. Primary outcome was the incidence treatment interruption for any reason (except for pregnancy or disease remission), while interruption due to adverse events (AEs; including death) and due to inefficacy served as secondary outcomes. Incidence of serious adverse events (SAEs) also served as a secondary outcome. Extended (frailty) multivariate Cox proportional hazards models and negative binomial regression with generalized estimating equations (to calculate incidence rate ratios [IRRs]) were used for statistical analyses (both types of analyses including time-varying covariates over multiple courses of treatment).
Results: In total, 1316 patients (2335 treatment courses, 6508 patient-years [PY]) were enrolled. Of these, 160 patients (643 PY; 237 treatment courses) were ≥ 65 years old, mean age at starting treatment = 71 ± 5 yrs (84% female). Old age was not significantly associated with treatment interruption for any reason, but presented higher risk of interruption due to adverse events (after multivariate adjustment) and lower risk of stopping because of inefficacy (see Table 1). Older patients presented higher incidence of SAEs than younger ones (16.0 vs 8.4/100 PY, respectively; multivariate IRR: 2.06, 95% CI: 1.51 to 2.80, P<0.001). Among old patients, tocilizumab (HR: 2.73, 95% CI: 1.13 to 6.64, P=0.026), etanercept (2.13, 1.12 to 4.07, P=0.022), and infliximab (2.39, 1.19 to 4.79, P=0.014) presented higher risk of treatment termination as compared with adalimumab. In this subgroup (age ≥65 yrs), there was no significant difference in the risk of SAEs between different bDMARDs/tsDMARDs.

Table 1. Univariate and multivariate hazard ratios (HRs) of interruption of treatment course comparing older (≥65 years) versus younger patients (reference category). Results are HRs, 95% CIs, and P values.

Cause of interruption (n of events)	Crude analysis	Adjusted covariates*
Interruption - any reason (1321)	0.96 (0.75 to 1.23), P=0.760	1.09 (0.82 to 1.43), P=0.550
Interruption - adverse events (368)	1.33 (0.75 to 0.89), P=0.160	1.59 (1.07 to 2.35), P=0.020
Interruption - inefficacy (680)	0.56 (0.39 to 0.80), P=0.002	0.57 (0.38 to 0.87), P=0.009

* Age, baseline DAS28, disease duration, gender, smoking, RF or anti-CCP, previous malignancy, interstitial lung disease, diabetes, hypertension, hypercholesterolemia, renal failure, ischemic cardiomyopathy, COPD, heart failure, concomitant use of each cs-, b-, and tsDMARDs, corticosteroids, starting year, osteoporosis, hepatitis B,C, treatment sequence.

Conclusion: The overall risk of treatment interruption with biologic or targeted synthetic DMARDs is not higher in older patients. Higher risk of interruption due to AE was balanced by a lower risk of stopping treatment due to inefficacy. Older patients had a higher incidence of SAEs.

POS0651 IMPACT OF ADVERSE DRUG REACTIONS ON THE TREATMENT PATHWAYS OF EARLY RHEUMATOID ARTHRITIS PATIENTS

F. Poppelaars[1], J. Jansen[1], P. Ten Klooster[2], T. Coppes[3], K. Velthuis4, H. Vonkeman[5], N. Jessurun[1]. *[1]Netherlands Pharmacovigilance Centre Lareb, Research,'s-Hertogenbosch, Netherlands; [2]University of Twente, Department of Psychology, Health & Technology, Enschede, Netherlands; [3]Institute of Pharmaceutical Sciences, Division of Pharmacoepidemiology and Clinical Pharmacology, Utrecht, Netherlands; [1]Netherlands Pharmacovigilance Centre Lareb, Research,'s-Hertogenbosch, Netherlands; [5]Medisch spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands*

Background: Rheumatoid arthritis (RA) patients frequently pass through several medications in order to achieve and maintain acceptable disease control The clinical heterogeneity and variable course of the disease, plus the availability of multiple classes and subclasses of DMARDs may lead to very different and complex treatment sequencing in individual patients. Limited real-world data exists regarding treatment pathways among patients with RA. Adverse drug reactions (ADRs) belong to the stop reasons of medication, but the impact of ADRs on treatment pathways has not been quantified.
Objectives: To assess differences in treatment pathways between RA patients with and without adverse drug reactions (ADRs).
Methods: Single center retrospective observational study, using real-world data collected in the Dutch Rheumatoid Arthritis Monitoring (DREAM-RA) registry from Medisch Spectrum Twente (Enschede, the Netherlands). From all early RA patients enrolled between 16 July 2006 and 30 April 2020, the first four consecutive courses of treatment were assessed. Patients were selected from the DREAM early RA treat-to-target cohort I.[1] The use of corticosteroids per protocol was allowed but not considered as a DMARD treatment. Any alteration in (a combination of) medication was viewed as a separate treatment, and thus any addition, subtraction or change in medication was the start of a new treatment. If a patient was without continuous treatment for 90 days or more in between treatments, this was considered a temporary stop of treatment. Treatment pathways were stratified for occurrence of at least one 'ADR or 'No ADR'. Differences in duration of treatment, number of treatments, and the proportion of treatments with csDMARDs, bDMARDs and a combination of csDMARDs and bDMARDs between patients with and without ADRs are assessed.
Results: Treatment pathways of 372 RA patients (66.1% females) were assessed (Table 1). The average duration of treatment was shorter in patients that experienced at least one ADR (1.8 vs. 2.7 years, p<0.001), and the number of treatments was higher (3.5 vs. 2.5, p<0.001), than in those that experienced no ADR. Furthermore, there was a difference between these groups in the proportion of treatments with csDMARD(s), bDMARD(s) or a combination of the two (p<0.001). This was for the 'No ADR' group respectively 93%; 1%; 6%, and for the 'ADR' group respectively: 77%; 8%; 15%.

Table 1. Characteristics of patient with and without adverse drug reactions (ADRs) and treatment pathways

		All patients	Females	Males	Patients without ADRs	Patients with ADRs
Total, n (% of all patients)		372 (100.0)	246 (66.1)	126 (33.8)	285 (76.6)	87 (23.3)
Female, n (% of total)		246 (66.1)	N/A	N/A	183 (64.2)	63 (72.4)
Age at start of treatment in years, mean ±SD		57.8 ±14.0	57.3 ±14.3	59.0 ±13.2	58.4 ±14.4	56.0 ±12.3
Follow-up time in years, mean ±SD		6.7 ±3.7	6.8 ±3.6	6.6 ±3.9	6.9 ±3.8	6.2 ±3.4
Duration per treatment in years, mean ±SD		2.4 ±2.9	2.4 ±2.8	2.4 ±2.9	2.7 ±3.0	1.8 ±2.2*
Distribution of treatments:	**1**	113 (30.4)	72 (29.3)	41 (32.5)	104 (36.5)	8 (9.2)
number of patients that received 1, 2, 3 or 4 treatments, n (%)	**2**	25 (6.7)	18 (7.3)	7 (5.6)	20 (7.0)	5 (5.8)
	3	83 (22.3)	53 (21.5)	30 (23.8)	70 (24.6)	13 (14.9)*
	4 or more	151 (40.6)	103 (41.9)	48 (38.0)	91 (31.9)	61 (70.1)
Number of treatments, mean ±SD		2.7 ±1.3	2.8 ±1.3	2.7 ±1.3	2.5 ±1.3	3.5 ±1.0*
Number of patients stopped with treatment, n (% of total)		84 (22.6)	56 (22.8)	28 (22.2)	71 (24.9)	18 (20.7)

* p<0.001

Conclusion: Treatment pathways for patients with and without ADRs differ significantly. Patients that experience ADRs have shorter duration of treatments and have more consecutive treatments utilizing more bDMARDs.

POS0652 LONG-TERM EFFECTIVENESS OF ULTRA-LOW DOSES OF RITUXIMAB IN RHEUMATOID ARTHRITIS

N. Den Broeder[1,2], L. M. Verhoef[1], Y. A. De Man[3], M. R. Kok[4], R. M. Thurlings[5], W. Van der Weele[6], B. Van den Bemt[1], F. Van den Hoogen[1], A. Van der Maas[1], A. Den Broeder[1]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [2]Radboudumc, Radboud Institute for Health Sciences, Nijmegen, Netherlands; [3]Ziekenhuisgroep Twente (Hospital Group Twente), Rheumatology, Borne, Netherlands; [4]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; [5]Radboud University Medical Centre, Rheumatology, Nijmegen, Netherlands; [6]Reade, Rheumatology, Amsterdamn, Netherlands*

Background: The optimal rituximab (RTX) dose for the treatment of rheumatoid arthritis remains unclear. RTX treatment of 1000mg per 6 months and 2000mg per 6 months were shown to be similarly efficacious (1). The REDO trial showed comparable the 6-month efficacy of continued treatment with 500mg and 200mg compared to 1000mg, though formal non-inferiority could not be established (2).
Objectives: To assess the long-term effects of ultra-low dose RTX (1×500mg and 1×200mg) in RA patients previously responding well to conventional low dose RTX (1×1000mg).

Methods: Patients from the REDO trial were invited to participate in this study. Treatment decisions were left at the discretion of the rheumatologist and patient. Disease activity (DAS28-CRP), and medication use (b/tsDMARD, csDMARD, gluccocorticoids [GC]) were collected from start of the trial to censoring in April 2021. The primary outcome was disease activity, secondary outcomes were RTX persistence, RTX doses and intervals, and use of comedication. Disease activity was analyzed using a longitudinal mixed model with random intercepts to account for intra-patient correlations, in two ways: 1. By original randomization and stratification factors (RF/ACPA and csDMARD use). 2. By time-varying total RTX dose received in the year preceding each disease activity measurement, adjusted for current csDMARD or GC use, and RF/ACPA. The original DAS28-CRP non-inferiority (NI) margin of 0.6 was used.

Results: 118 out of 142 REDO patients were included in current analyses (Table 1) Reasons for exclusion were: continuing treatment elsewhere (n=3), no informed consent (n=9) and data yet to be collected in 2 study centers (n=12). Mean follow up was 3.2 years (total of 377 patient-years), with 7 patients switching to another b/tsDMARD (Figure 1) upon which they were censored from disease activity analyses.

Table 1. Patient characteristics by original randomization

	1000mg (n=24)	500mg (n=48)	200mg (n=46)
Age (years)	65 (9)	64 (11)	64 (12)
Female	15 (63%)	28 (58%)	34 (74%)
Meeting ACR1987 or ACRU/EULAR 2010 RA criteria	22 (92%)	47 (98%)	43 (93%)
Disease duration (years)	14 (9-24)	14 (7-21)	13 (8-20)
RF or ACPA positive	22 (92%)	44 (92%)	40 (87%)
Duration of rituximab use (years)	3.0 (1.6-5.5)	2.0 (1.0-5.5)	3.7 (2.0-5.7)
Concomitant csDMARD	17 (71%)	29 (60%)	27 (59%)
Previous number of b/tsDMARDs used	2 (2-2)	2 (1-3)	2 (1-2)
Previous number of csDMARDs used	3 (1-3)	2 (1-4)	3 (1-3)
Oral GC use at baseline	3 (13%)	8 (17%)	5 (11%)
Baseline DAS28-CRP	2.3 (0.9)	2.3 (0.9)	2.5 (1.1)

Data are n (%), mean (SD), or median (IQR).

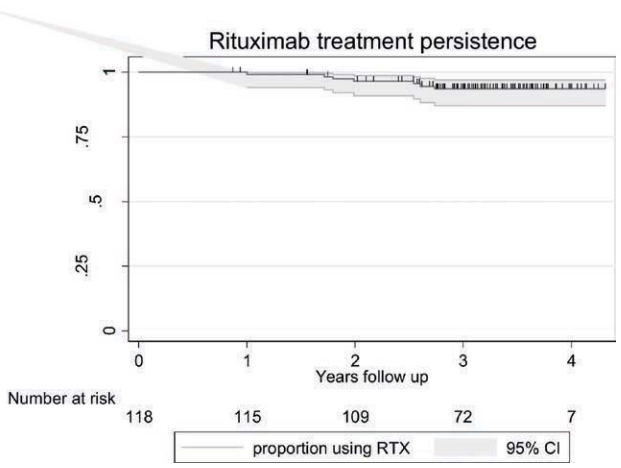

Figure 1. Rituximab treatment persistence during follow up.

Disease activity in both ultra-low dose groups was non-inferior to the 1000mg group, with a mean DAS28-CRP (95% CI) during follow-up of 2.2 (2.0-2.4) in the 1000mg group, 2.2 (2.1-2.4) in the 500mg group and 2.3 (2.2-2.5) in the 200mg group. Analyzed by received RTX dose, lower RTX dose was significantly associated with a higher DAS28-CRP: 0.15 (95% CI: 0.04-0.26) points higher per 1000mg more RTX. The upper limit for relevant RTX doses was below the prespecified NI margin, excluding a relevant effect of RTX dose on disease activity. Median (IQR) yearly RTX dose was 978mg (704mg-1425mg). Final RTX dose per infusion was 200mg in 37 patients (31%), 500mg in 47 (40%) and 1000mg in 34 (29%), with a median (IQR) final interval between infusions of 6.0 (5.7-6.5), 6.2 (6.0-7.4) and 6.4 (6.0-9.6) months respectively. The rate of GC injections was 0.38 (95% CI: 0.32-0.44) per patient-year and initiation rate of oral GC was 0.05 (0.03-0.08) per patient-year.

Conclusion: A majority of patients treated with ultra-low dose RTX remained on ultra-low doses for up to 4 years, while disease activity remained low and did not relevantly differ between RTX doses, either according to original randomization or by received dose. Switching to other b/tsDMARDS or use of GC was rarely required.

POS0653

CAN DOSAGE OF INFLIXIMAB BE ADJUSTED TO 8 WEEK INTERVALS WITHOUT LOSING EFFICACY IN ARTHRITIS PATIENTS ON MAINTENANCE THERAPY WITH MORE FREQUENT INFUSIONS?

E. Lindqvist[1], B. Månsson[1]. [1]*Lund University, Department of Clinical Sciences, Lund, Sweden*

Background: Infliximab is usually given every 8 weeks. To increase dosage, the dose can be increased or the interval between infusions shortened. To minimize patient visits and workload for the medical staff during the Corona pandemic, we intended to change all infliximab infusions to 8 week intervals. For patients with inflammatory bowel disease, a trough level of serum (s-) concentration of infliximab of 3-7 µg/ml is recommended. In Rheumatology the usefulness of assessing s-concentration is controversial. (1, 2)

Objectives: To evaluate if 8 week interval infliximab dosage, with retained weekly dose, can be used in arthritis patients, without worsening of disease activity or general health and study if s- concentration of infliximab is related to disease activity and general health.

Methods: All arthritis patients on stable infliximab treatment were evaluated at the time for infliximab infusion. Disease activity, DAS28-CRP, VAS pain, global, fatigue, doctors' global, HAQ, and ASDAS-CRP, BASFI for spondyloarthritis (SpA) patients were registered in the Swedish Rheumatology Quality registry (SRQ). Blood tests for CRP, ESR and s-concentration of infliximab were taken before infusion start. S-concentration was analysed at Karolinska Hospital, Solna, Sweden with an in-house ELISA. Antibodies were assessed if s-concentration was <0.5 µg/ml.

Patients with infusion intervals less than 8 weeks were recommended a switch to 8 week intervals with maintained weekly dose of infliximab. The new dose was given the same day and patients with changed doses were re-evaluated after 24 weeks. Paired samples T-test and Wilcoxon signed rank test for paired data were used for comparison of disease activity and general health after dosage change. Linear regression analyses were used to explore associations between s-concentration, disease activity and general health.

Results: Of 91 assessed patients, 66 with shorter intervals were recommended dosage change. The remaining 25 patients had infliximab every 8 weeks and served as controls. For baseline characteristics see Table 1. Dosage was changed in 58 patients and 90% (n=52) remained on 8 week intervals after 24 weeks, with a mean (SD) dose of infliximab of 5.3 (1.9) mg/kg. All assessed disease variables (DAS28-CRP, VAS pain, global, fatigue, Dr global, HAQ, ASDAS-CRP, BASFI, CRP and ESR) remained unchanged (p=0.051 (pain) – 0.83) (Figure 1 A, B) while S-concentration was lower (p<0.001) at follow up. S-concentration of infliximab did not relate to disease activity neither at baseline nor at follow up (p=0.15-0.24). (Figure 1 C, D)

Table 1. Patient characteristics at inclusion

Interval	4-7 w, n=66	8 w, n=25
Age, years	56 (15)	58 (14)
Female sex	42 (64%)	11 (44%)
Disease duration, years	20 (12)	20 (10)
Clinical diagnosis: RA/JIA+arthritis UNS	14 (21%)/ 5 (8%)	7 (28%)/2 (8%)
SpA/PsA	31 (47%)/16(24%)	10 (40%)/6 (24%)
S-concentration infliximab µg/ml	9.0 (4.6-14.0)	3.4 (1.1-5.1)
Antibodies against infliximab	2 (3%)	3 (12%)
ESR	24 (16-37)	24 (15-42)
CRP	1.3 (0.8-2.3)	1.1 (0.6-2.9)
DAS28-CRP	2.8 (1.1)	2.6 (1.2)
HAQ	1.0 (0.38-1.38)	0.38 (0.25-0.85)
Patients' VAS pain	23 (8-50)	20 (3-32)
Patient's VAS global health	31 (11-49)	15 (2-48)
Doctors' VAS global health	9 (6-11)	7 (2-12)
ASDAS-CRP	1.8 (0.7-2.5)	1.2 (0.6-1.5)
BASFI	3.3 (1.3-6.1)	1.4 (0.3-2.4)
Concomitant csDMARD	39 (59%)	16 (64%)
Glucocorticoids	12 (18%)	1 (4%)

Mean (SD), median (interquartile range (IQR)) or n (%). ASDAS-CRP and BASFI; 41 SpA patients.

Conclusion: Adjustment of infliximab dosage to every 8 weeks worked for a majority of the arthritis patients in this clinical setting without worsening of

disease activity or general health. S-concentration of infliximab did not relate to disease activity or general health.

POS0654 EFFECTIVENESS OF ABATACEPT IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS.

R. Redondo Rodriguez[1], F. Godoy-Navarrete[2], P. Morales-Garrido[3], M. Rojas-Giménez[4], C. M. Romero-Barco[5], N. Mena-Vázquez[1]. *[1]Instituto de Investigación Biomédica de Málaga (IBIMA), UGC de Reumatología, Hospital Regional Universitario de Málaga (HRUM), Málaga, Spain; [2]Hospital Universitario de Jaén, UGC de Reumatología, Jaén, Spain; [3]Hospital Universitario Clínico San Cecilio, UGC de Reumatología, Granada, Spain; [4]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), UGC de Reumatología, Hospital Universitario Reina Sofía de Córdoba, Córdoba, Spain; [5]Hospital Clínico Universitario Virgen de la Victoria, UGC de Reumatología, Málaga, Spain*

Background: Interstitial Lung Disease (ILD) is the most common lung involvement in rheumatoid arthritis (RA) and leads to increased morbidity and mortality. Some retrospective observational studies suggest that abatacept (ABT) could be effective and safety, although there are no clinical trials and prospectively collected data are scarce.

Objectives: To evaluate prospective the effectiveness and safety of ABT in patients with ILD associated RA (ILD-RA).

Methods: Design and Protocol: We performed a multicenter, prospective, observational study of patients with interstitial lung disease secondary to rheumatoid arthritis (ILD-RA) receiving ABT between 2015 and 2021. The patients were assessed using high-resolution computed tomography and lung function tests at the beginning of treatment (V0), at 12 months (V12), and at the end of follow-up in 2021 (fV). The study was approved by the Ethics Committee (Code 1719-N-15). **Main variable**: effectiveness of ABT according to evolution of ILD at the end of follow-up: (1) improvement (ie improvement of FVC ≥10% or DLCO ≥15% and no radiological progression), (2) no progression (stabilization or improvement in FVC ≤ 10% or DLCO <15% and no radiological progression), (3) progression (worsening of FVC >10% or DLCO >15% and radiological progression) or (4) death**. Other variables:** clinical and analytical characteristics, treatments and safety (infections, hospitalization and mortality). **Statistical analysis**: Cox regression analysis to identify factors associated with worsening of ILD-RA treated with ABT.

Results: Thirty-eight ILD-RA patients started ABT treatment during prospective follow-up. A total of 22/38 (57.9%) were men and the mean (SD) age was 66.1 (9.1) years. The mean (SD) evolution of ILD was 43.9 (30.0) months and the median (IQR) time with ABT was 17.0 (12.1-34.8) months. The baseline clinical-epidemiological characteristics and pulmonary progression of the patients are shown in Table 1. At the end of follow-up (fV) 28/38 (73.6%) had improvement/stabilization and 7/38 (18.4%) progressed and 3/38 (7.8%) of them died (COVID-19 pneumonia, respiratory infection and ILD progression, respectively). There were no significant differences in FVC (75.3 [8.7] vs 77.7 [14.6]; p=0.775) or in FEV1 (83.9 [10.7] vs 84.7 [13.2]; p=0.416) nor in the DLCO (61.0 [17.4] vs 60.7 [15.2]; p=0.789) at the end of follow-up. There was a greater numberwith improvement/stabilization among the patients who were in combination with Methotrexate compared to those who were in monotherapy (83.3% vs 39.1%; p=0.046). The baseline variables that were independently associated with progression-mortality of ILD-RA in fV were: baseline FVC (OR [95% CI], 0.895 [0.805-0.996]; p=0.042) and duration of ILD-RA (OR [95% CI], 1.204 [1.148-2.112; p=0.046]). Two patients discontinued ABT during follow-up due to insufficient joint and pulmonary response.

Table 1. Characteristics of patients with ILD-RA treated with Abatacept.

Variable	ILD-RA n=38
Baseline clinical-epidemiological characteristics	
Sex, man, n (%)	22 (57.9)
Age in years, mean (SD)	66.1 (9.1)
Race, caucasian, n (%)	38 (100.0)
Smoking history	
No smoker, n (%)	23 (60.5)
Smoker, n (%)	15 (39.5)
Time of evolution RA, months, median (IQR)	139.1 (68.1-218.7)
RF, n (%)	36 (94.7)
Anti-CCP, n (%)	32 (84.2)
ANA, n (%)	8 (22.9)
Radiological pattern	
UPI, n (%)	26 (68.0)
NSIP, n (%)	12 (32.0)
Treatment	
DMARDs, n (%)	33 (86.8)
Methotrexate, n (%)	19 (50.0)
Leflunomide n (%)	11 (22.9)
Sulfasalazine, n (%)	2 (5.3)
Hydroxychloroquine, n (%)	6 (15.7)
Immunosuppressants, n (%)	11 (297)
Antifibrotic, n (%)	1 (2.6)
Corticosteroids, n (%)	32 (84.2)
Corticosteroids, median (IQR)	5.0 (2.5-10.0)
Pulmonary progression (fv)	
Improvement-Stabilization, n (%)	22 (73.6)
Progression-Mortality, n (%)	10 (26.4)

Conclusion: More than half of the patients with ILD-RA treated with ABT manage to stabilize or improve their lung disease after a median follow-up of 17 months. Patients who worsen or die have lower baseline FVC values and ILD-RA with a longer evolution time.

Background: Advances in rheumatology and new therapeutic options have certainly impacted patient survival, changing the age range, from youth to seniors. The differences between the age groups could influence the evolution of the disease and the adverse events (AEs) related to the treatments. There are few real-world data on the safety and efficacy of treatments in different age groups.
Objectives: To evaluate the frequency of AEs and the survival of treatments according to the age in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS).
Methods: Retrospective, observational, multicenter study of real-life data of patients included in the BIOBADASAR 3.0 registry; exposed and not exposed to original biological treatments (b-DMARDs), biosimilars, targeted synthetic drugs (ts-DMARDs). The unexposed group received treatment with conventional disease-modifying drugs (cDMARDs). A Kaplan-Meier and Log Rank Test analysis was performed to study AEs-free survival and treatment in different age groups (young people <25; young adults 25-34; mature adults 34-65; old adults >65). Factors related to treatment survival were evaluated using Cox regression models.
Results: 5,297 patients were included, 80.3% female, mean age 43.7 years (SD 15.6) and median disease progression 14.3 [IQR 11.5]. RA 4658 (87.9%); APs 490 (9.25%) and EA 149 (2.8%). The main reason for treatment discontinuation was ineffectiveness, in 624 patients in the exposed group and in 53 (2.5%) patients in control group, followed by the presence of AEs in 352 (11.2%) and 83 (3.9%), respectively (p=0.001). A mean Charlson Score of 0.268 (SD 0.6) in the exposed group and 0.306 (SD 0.7) in the control group (p=0.095). Median EAs-free survival in the exposed group was 12.5 years [IQR 16.6] while in controls was 28 years [IQR 11], p<0.0001. Median AEs-free survival was 12 years (IQR 11) in young people, 11.5 years [IQR: 4.9] in young adults, 10 years [IQR: 3.25] in mature adults and 7.6 years [IQR: 6] in old adults with a difference statistically significant (p>0.017). The exposed group presented a median treatment survival in years of 11.25 years [IQR: 10] in young people; 12.5 years [IQR: 4.7] in young adults, 7.5 years [IQR: 12.1] in mature adults and 4.5 years [IQR: 1.14] in old adults (p>0.0001). Considering only the first line of treatment, a median survival of 11.5 years [IQR: 10] was evidenced in the age group <25; 12 years [IQR: 2.6] between 25-34 years old, 10 years [IQR: 12] in the group between 34-65 years old and 5.5 years [IQR: 1.14] in the group > 65 years old (p>0.004). (Figure 1). Considering the second line of treatment, the differences between the groups were not statistically significant (p=0.57). In the multivariate regression model for patients with RA, the factors with the greatest impact on treatment survival were female sex (HR 1.3, 95% CI 1.2-1.4), old age (HR 1.01, 95% CI 1.008-1.01), treatment with steroids (HR 1.19, 95% CI1.1-1.2) and longer disease duration (HR 1.01, 95% CI1.01 – 1.02).
Conclusion: In the present study we were able to demonstrate a greater occurrence of AEs in old adults and mature adults compared to young people and young adults. Conversely, survival for b-DMARDs and ts-DMARDs were greater in youth and young adults. In patients with RA, female sex, corticosteroid therapy, old aged and longer disease duration were associated with treatment discontinuation.

POS0656 FRAILTY AND RISK OF ADVERSE OUTCOMES IN BIOLOGIC OR TARGETED-SYNTHETIC DMARD TREATED PATIENTS WITH RHEUMATOID ARTHRITIS

N. Singh[1], L. Gold[2], K. Wysham[3], J. Andrews[1], A. O'hare[3], U. Makris[4], J. Lee[5], M. George[6], B. England[7], J. Baker[6], J. Jarvik[2], P. Heagerty[8], S. Singh[9]. *[1]University of Washington, Medicine, Seattle, United States of America; [2]University of Washington, Radiology, Seattle, United States of America; [3]VA Puget Sound, Medicine, Seattle, United States of America; [4]UT Southwestern Medical Center, Medicine, Dallas, United States of America; [5]University of Michigan, Medicine, Ann Arbor, United States of America; [6]University of Pennsylvania, Medicine, Philadelphia, United States of America; [7]University of Nebraska Medical Center, Medicine, Nebraska, United States of America; [8]University of Washington, Biostatiistics, Seattle, United States of America; [9]University of California San Diego, Medicine, San Diego, United States of America*

Background: Recently, it has been recognized that frailty and pre-frailty are common in patients with rheumatoid arthritis (RA) [1]. Whether frailty status portends an increased risk of adverse outcomes in patients with RA on biologic or targeted synthetic disease modifying anti-rheumatic drugs (b- or tsDMARDs) remains unknown.
Objectives: To evaluate the association between frailty and adverse outcomes in patients with RA exposed to b- or tsDMARDs.
Methods: Using the IBM/Watson MarketScan Commercial Claims and Encounters Databases, we identified all patients with RA who filled new prescriptions (or received infusions) for TNFα antagonists (TNFi), non-TNFi biologics (rituximab, abatacept, tocilizumab) or Janus Kinase inhibitors (JAKi) between 2008-2019. We used a 1-year lookback period without the use of these drugs to identify new users. The date of the first prescription within these three drug categories was the index date. Patients' frailty risk score was calculated using the Claims-Based Frailty Index (CFI) [2], which estimates a deficit-accumulation frailty index using International Classification of Diseases codes, Current Procedural Terminology codes, and Healthcare Common Procedure Coding System codes in administrative claims data in the 1-year baseline period. The index ranges from 0 (not at all frail) to 1 (severely frail). The primary outcome was time to serious infections (those requiring hospitalization); secondary outcomes: any infection (outpatient or inpatient encounters) and all-cause hospitalizations. Patients were followed until 1) outcome occurrence; 2) disenrollment; 3) >90 days elapsed (or >180 days for rituximab) without further fills of the first drug categories; 4) they filled/received infusions of b-/tsDMARDs from a different drug category; or 5) 2 years after index. Cox proportional hazards adjusting for demographics, calendar year, serious and/or opportunistic infections in the 12-months prior to index were used to estimate the adjusted hazard ratios (aHR) and 95% confidence intervals (CIs) for each outcome. In separate model, we additionally adjusted for comorbidity burden, and health care utilization (HCU).
Results: A total of 62,246 patients with RA met our inclusion criteria of whom 50,910 (82%) started TNFi as their first biologic, 9525 (15%) non-TNFi biologics, and 1811 (3%) JAKi. Among these, 3928 (6%) were considered frail. In multivariable analyses, frail patients had higher risk of serious infections compared to non-frail patients (aHR 2.37, 95% CI 2.05-2.74) which decreased to aHR 1.34, 95% CI 1.13-1.58 (Table 1) after adjusting for comorbidity burden and the HCU. Similarly, frailty was associated with increased risk of any infection (aHR 1.18, 95% CI 1.11-1.25), and all-cause hospitalizations (aHR 1.34, 95% CI 1.21-1.49) relative to non-frail individuals.

Table 1. Multivariable models evaluating the association between frailty status and inpatient infections as the outcome

Variable	#Hazard Ratio (95% Confidence Interval)	@Hazard Ratio (95% Confidence Interval)
Frail	**2.37 (2.05, 2.74)**	**1.34 (1.13, 1.58)**

#Model adjusts for age, sex, major infection requiring inpatient admission in 12 months prior, concomitant baseline drugs such as csDMARDs, glucocorticoids, NSAIDs and opioids@ Model additionally adjusts for Charlson comorbidy score and healthcare utilization

Conclusion: Frailty is an important predictor for the risk of adverse outcomes among patients with RA treated with b- or tsDMARDs. Our findings underscore the need for considering this parameter in patient evaluations (even among younger patients) in the clinic.

POS0657 SURVIVAL OF BARICITINIB VS ANTI-TNF AS THE FIRST BIOLOGICAL DRUG IN PATIENTS WITH RHEUMATOID ARTHRITIS, IN CLINICAL PRACTICE: RESULTS OF A LOCAL REGISTRY

J. Rosas[1], A. Pons[1], X. Barber[2], J. M. Senabre-Gallego[1], G. Santos Soler[3], E. Soler-Giner[4,4], J. A. Bernal[3], A. Raga[4], C. Raya-Santos[1], J. C. Cortés-Quiroz[1], M. Lorente Betoret[1], J. A. García-Gómez[2]on behalf of AIRE-MB. *[1]Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain; [2]Universidad Miguel Hernández de Elche, CIO, Elche, Spain; [3]Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; [4]Hospital Marina Baixa, Pharmacy, 03570, Spain*

Objectives: To evaluate survival in the first 4 years of treatment with Baricitinib (BARI) vs anti-TNF (TNFi), as the first biological drug (BIO-1), in patients with rheumatoid arthritis (RA).
Methods: Retrospective study of patients with RA, treated with the first BIO-1, with BARI or TNFi, from September-2017 to December-2021. General data (current age, at diagnosis of RA and at the start of BIO-1) were collected; RA: evolution time, RF, ACPA; type of BIO-1: dose received, time in treatment, reason for withdrawal. Univariate analysis of drug survival was performed using Kaplan-Meyer curves and the Long Rank test to differentiate by groups. For the multivariate study, Cox regression with proportional hazards.
Results: The study includes 96 patients with RA, who have started treatment for > 1 month with BIO-1: BARI (n: 63/66% patients) or TNFi (33/34% patients): women: 82 (96%), current mean age (SD): 62 (1) years, at diagnosis: 51 (1) years and at the start of BIO-1: 59 (1) years. 36 (37%) patients are ≥65 years old, the mean time

in AR is 7.6 years and the time in BIO-1: 1.34 (2.2) years. BIO-1 was withdrawn in 34 (40%) patients: Inefficacy: 17 (18%) patients, Complications: 14 (15%) [Cardiovascular/thrombosis: 2 (2%), rash: 2 (2%), infection-neoplasia-immunogenicity: 1 (1%) patient in each], loss to follow-up: 5 (5%) and others: 2 (2%). When comparing the BARI vs. TNFI group, no differences were detected between the general data, the percentage of patients >65 years of age, or the mean time in treatment or the reasons for drug withdrawal (Table 1). However, survival in the BARI group was significantly superior to TNFi throughout the period (p=0.04; HR: 0.47, 95% CI: 0.24-0.91, p=0.026) (Figure 1A).

Table 1. Characteristics of patients who receive Baricitinib (BARI) or anti-TNF as first BIO-1 (TNFi).

	All N: 96	BARI N: 63 (66%)	TNFi N: 33 (34%)	P
Female, n (%)	82 (85%)	56 (89)	26 (79)	0.2
Current age, mean (SD)	62 (4.2)	63 (6)	59 (11)	**0.057**
Age at diagnosis RA, mean (SD)	51 (4.9)	52.5 (7.8)	48.6 (15.5)	0.17
Age at start of BIO-1, mean (SD)	59 (2.1)	60 (4.9)	55.9 (9.9)	0.23
≥ 65 years, n (%)	36 (37)	27 (43)	9 (27)	0.39
RF positive, n (%)	77 (80)	54 (86)	23 (70)	0.1
ACPA positive, n (%)	74 (77)	50 (79)	24 (73)	0.56
Average time in BIO-1, years (DE)	1.34 (2.2)	1.85 (0.5)	1.32 (2.4)	0.21
BARI 2 mg, n (%)	-	23 (36)	-	-
Withdrawal of BIO-1, n (%):	38 (40)	20 (32)	18 (55)	0.15
- Complication	14 (15)	7 (13)	7 (21)	-
- Loss of efficacy	17 (18)	8 (13)	9 (27)	-
- Loss of follow up	5 (5)	5 (8)	-	-
- Other	2 (2)	-	2 (6)	-

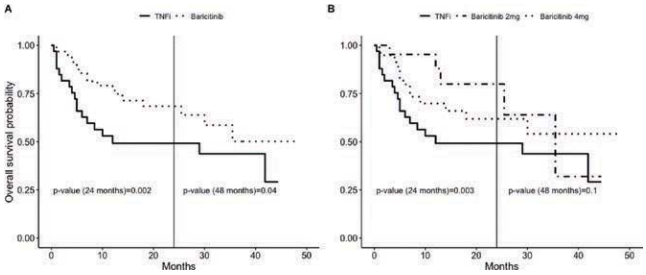

Figure 1. Survival probability in patients with rheumatoid arthritis who receive the first BIO-1. **A**. Between TNFi drug vs Baricitinib. **B**. Between TNFi vs Baricitinib 2 mg or 4 mg.

In patients <65 years, the greatest survival of BARI is maintained (p=0.05), being significant in the first 24 months of treatment (p=0.02). In patients ≥65 years, significance was not reached throughout the overall period (p=0.5) and in the first 24 months of treatment (p=0.06). When comparing the BARI 2 mg (n: 23/36%) and 4 mg (n: 40/64%) groups, the 2 mg group is significantly older at RA diagnosis (73 [SD: 2] years vs 56 [SD: 3] years; p<0.0001) and at the start of BIO-1 (72 [SD: 1.4] years vs 54 [SD: 2.8] years; p<0.0001). However, survival in the BARI 2 mg group was significantly higher in the first 24 months (p=0.003;) (Figure 1B): BARI 2 mg HR: 0.14, 95% CI; 0.04-0.56, p=0.005, HR BARI 4 mg: 0.44 (95% CI; 0.20-0.96, p=0.038).

Conclusion: 1. Survival of BARI is superior to TNFi during the first 4 years of treatment, especially during the first 24 months of treatment. 2. There are no differences between the cause that causes drug withdrawal. 3. The use of the 2 mg dose of BARI predominates in patients older than 65 years, with survival being greater than TNFi, especially in the first 24 months of treatment.

POS0658 TUMOR NECROSIS FACTOR BLOCKERS INDUCED SARCOIDOSIS: DESCRIPTION OF 31 CASES FROM THE FRENCH PHARMACOVIGILANCE DATABASE

M. Trenec[1], B. Chretien[2], N. M. Silva[1], C. Dolladille[2], J. Alexandre[2], A. Dumont[1], A. Nguyen[1], H. De Boysson[1], A. Aouba[1], S. Deshayes[1]. *[1]University of Caen Normandie Hospital Center, Internal Medicine, Caen, France; [2]University of Caen Normandie Hospital Center, Pharmacology, Caen, France*

Background: Development of Tumor Necrosis Factor blockers (TNFb) whose drug class has several mechanistic and pharmacologic sub-classes, have improved the management of autoimmune and inflammatory diseases, including sarcoidosis. With their increasing use, paradoxical reactions are described and one of the most frequent is sarcoidosis. However, the description of TNFb-induced sarcoidosis (TIS) remains poor, because reported in few and only short case-series.

Objectives: We aimed to better describe the clinical spectrum of TIS, and the differential involvement of TNFb sub-classes.

Methods: French pharmacovigilance database was used to collect data on TIS, excluding patients with previous idiopathic sarcoidosis. Statistical analyses were performed using the Mann-Whitney test for quantitative data and Fisher test for qualitative data. A p value < 0.05 was considered statistically significant.

Results: Data were obtained from 2002 to 2019 for infliximab, adalimumab, golimumab, certolizumab and etanercept. Thirty-one TIS patients were collected from the database, including 12 women (38.7%). In most cases, TNFb was introduced for ankylosing spondylitis (58%), psoriasis (19.3%) or rheumatoid arthritis (16.1%). Median age at TIS occurrence was 54 [43.5; 61.5] years, with a median time to onset of 24 [6.0; 72.0] months. The most frequent involved TNFb was etanercept (n=21, 67.8%). The two mains clinical TIS manifestations were lymph node (n=27, 87.1%) and lung involvement (n=16, 51.6%). The culprit drug was discontinued in 26 (84%) patients, and a double-barreled inflammatory gun to control both initial and induced disorders was proposed in 19 of them (90.5 %), mostly glucocorticoids (n=13, 68.4%) alone or combined with methotrexate (n=3, 15,8%). Among the 14 patients with the available data, the TIS had completely resolved in 11 (78.6%); for all these lasts, the TNFb was discontinued. No significant differences were observed between the TNFb sub-classes of monoclonal antibodies or fusion proteins, regarding clinical presentation, median time to onset or outcome.

Conclusion: This second largest case-series shows that TIS are mostly encountered with etanercept, but without any difference in clinical or prognostic implications with the other TNFb-subclasses.

POS0659 LONG-TERM DYNAMICS OF ANTIBODY RESPONSE TO ADALIMUMAB DETECTED WITH A DRUG TOLERANT ASSAY

S. Atiqi[1], M. Leeuw[1], F. Hooijberg[1], L. Boekel[1], F. Loeff[2], K. Bloem[2,3], C. Krieckaert[1], A. De Vries[3], M. Nurmohamed[1], T. Rispens[2], G. J. Wolbink[1,2]. *[1]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology, Amsterdam, Netherlands; [2]Sanquin Research and Landsteiner Laboratory Academic Medical Centre, Department of Immunopathology, Amsterdam, Netherlands; [3]Sanquin Diagnostic Services, Biologics Laboratory, Amstedam, Netherlands*

Background: Immunogenicity of adalimumab (ADL) has been the subject of extensive research, with the primary focus on its incidence, antibody titers and effects on clinical outcome. However, the temporal evolution of antibodies, i.e. dynamic and variation in titers, time point of emergent and persistence or transience of the response, remains under elucidated. To investigate this further, it is essential to collect samples at regular intervals and over a longer period of time. Also, a drug tolerant assay should be used to conquer with the phenomenon of drug interference (1).

Objectives: To evaluate the temporal evolution and to distinguish dynamic patterns of antibody response. Secondly, to assess the clinical impact and factors influencing these dynamic patterns.

Methods: ADA and adalimumab concentration were measured in sera of 511 consecutive ADL treated rheumatoid arthritis patients. Serum samples were drawn at week 0, 4, 16, 28, 52, 78 and 104. ADA were measured with a drug tolerant assay (Acid dissociation RadioImmunoAssay). Logistic regression analysis was carried out. Benjamini-Hochberg was used to correct for multiple testing.

Results: Baseline characteristics are depicted in Table 1. Fifty-nine percent of patients (n=300) developed ADA. Based on visual observations patients were

clustered in 9 groups, taking the next features in to account (Figure 1); the presence or absence of ADA, the height of ADA titers (higher or lower than 100AU/mL), emergent (early vs. late; cutoff week 28) and its persistence. Based on these features 397 (77%) patients were assigned to one of the groups. Due to missing data at crucial time points the remainder of patients were excluded. In the 'High early' and High early LTF' group was the rate of MTX use (adjusted odds ratio (AOR) 0.033 [95%CI 0.01-0.09] P<0.0001 respectively 0.79 [95%CI 0.03-0.22] P <0.0001), adalimumab concentration above 5mg/L (AOR 0.022[95%CI 0.01-0.08] P<0.001 respectively 0.026 [95%CI 0.01-0.09] P<0.001) and low disease activity (DAS28 <3.2) at week 52 (AOR 0.191[95%CI 0.07-0.56] P<0.002 respectively 0.102 [95%CI 0.03-0.31] P<0.001) significantly lower, compared to the negative group. Furthermore, the failure rate was in both groups significantly higher (AOR 9.19 [95%CI 3.7-22.87] P<0.0001 respectively 23.94 [95%CI 8.13-70.53] P<0.0001). In contrast to forgoing studies, our data does not show any differences in clinical outcomes between groups with persistent and transient ADA response.

Table 1. Baseline characteristics

Totaal N=511	
Follow-up	
Median weeks (IQR)	78 (28-104)
Demographics	
Age mean SD	53,7; ± 12,5
Female No (%)	409 (79.8)
Disease status	
Disease duration years median (IQR)	6,7 (3-13)
IgM rheumatoid factor + (%)	327 (68.2)
Anti-citrullinated protein antibody + (%)	315 (73.2)
Erosive (%)	296 (61.6)
DAS28-score mean SD	4.5 ± 1.5
Medication	
Methotrexate use no (%)	378 (73)

Conclusion: The majority of patients have an immune response to ADL. Based on ADA concentration, time point of emergence and its persistence, certain patterns of ADA response can be distinguished. Only high ADA concentration at early time points, causing low ADL concentration, are associated with unfavorable clinical effects. All the remaining distinctive patterns does not have any association with clinical outcomes. This suggests a regulated immune response in the majority of patients.

Background: The use of biological and targeted synthetic drugs has changed the outcomes of rheumatic diseases. The information on efficacy and safety provided by randomized controlled clinical trials does not always reflect the conditions of patients in real life. Data obtained from prospective registries, over extended periods and with real-world evidence, is a great contribution to the pharmacovigilance of these drugs.

Objectives: The aim of this study is to describe adverse events (AE) and survival of treatments of patients included in the Argentine Registry of Adverse Events of Biological Therapies and Target Synthetic Drugs (BIOBADASAR 3.0).

Methods: Observational, prospective and multicenter study of ten years of follow-up in patients with rheumatic diseases treated with original biological drugs, biosimilars or original and generic targeted synthetic therapies in Argentine. Those patients who received biological therapies were considered exposed while non-exposed patients represent the control group. All patients were evaluated at least once a year and whenever they experienced an AE or a change in treatment. Survival of treatments was evaluated by Kaplan Meier curves and the comparison between them was made by Log Rank Test analysis.

Results: A total of 6010 patients were included and 8810 treatment periods from 56 centers. 79.7% were female, mean age of 43.7 (SD 15.6) years. The most frequently reported rheumatological disease was rheumatoid arthritis (RA) (77.5%), followed by psoriatic arthritis (PsA) (8.2%), systemic lupus erythematosus (SLE) (3.1%), juvenile idiopathic arthritis (JIA) (2.6%) and ankylosing spondylitis (AS) (2.5%). The b-DMARD use frequencies were etanercept in 32.2%, followed by adalimumab in 18.7%, abatacept in 9.7%, certolizumab pegol in 8.7%, tofacitinib in 7.9%, rituximab in 7.3% and tocilizumab in 5.5%. The frequency of AE was 11.7% in the exposed group and 4.9% in controls (p=0.001). Infections were present in 41% in the exposed group vs 34% in controls (p<0.001). AE-free survival was 23 years [IQR: 18.2] in controls vs 10 years [IQR: 8.8]) in the exposed group p<0.0001). In the multivariate regression model, age (HR: 1.005, 95% CI 1.001-1.009) and corticosteroid treatment (HR:

1.18, 95% CI 1.05-1.34) were associated with a higher risk of AE in exposed patients. Treatment survival was 15 years [IQR: 28] in unexposed group vs 4.7 years [IQR: 10] in exposed patients (p<0.0001). In the multivariate analysis, female sex (HR 1.1, 95% CI 1.09-1.2), older age (HR 1.0, 95% CI: 1.010-1.014), corticosteroid treatment (HR 1.16, 95% CI 1.09-1.2), the diagnosis of systemic lupus erythematosus (HR1.547, CI95%1.3-1.8) and disease duration (HR1.01, CI95%1.008-1.015) were associated with a higher risk of treatment discontinuation while the diagnosis of rheumatoid arthritis (HR 0.83 CI95% 0.75-0.93) was associated with a lower risk of suspension.

Conclusion: We found that the use of steroids and elderly patients are still being associated with a higher risk of presenting an AE and treatment discontinuing. This could be related to the fact that the use of steroids is frequently associated with active disease or severe conditions. Exposed patients have a lower AE-free survival and a lower treatment survival. This could be since unexposed patients have a longer follow-up time and a longer duration of their disease. This data from real-world Latin American patients of ten years of follow-up are extremely useful for monitoring and pharmacovigilance of biological therapies in patients with rheumatic diseases.

POS0661 MAJOR COST SAVINGS ASSOCIATED WITH BIOLOGIC DOSE REDUCTION IN PATIENTS WITH INFLAMMATORY ARTHRITIS

A. Rehman[1], S. Tariq[1], J. Kumar[1], L. Martin[1], C. Bannon[1], T. Duffy[1], E. Murphy[1], J. Stack[2], M. Barry[1], C. L. Murphy[1]. *[1]Connolly Hospital Blanchardstown, Rheumatology, Dublin, Ireland; [2]Mater Hospital, Rheumatology, Dublin, Ireland*

Background: Anti-TNF drugs have dramatically improved the management of inflammatory arthritis (IA). Although the introduction of biosimilars have reduced the cost, chronic use of biologic agents has a high impact on healthcare expenditure. This study evaluated the cost effectiveness of a dose reduction strategy for the most commonly used anti- TNF drugs over a period of 10 years in patients with IA in remission.

Objectives: The purpose of this study was to explore whether patients with Inflammatory Arthritis (IA) (Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Ankylosing Spondylitis (AS) would remain in remission after 10 year period, following a reduction in biologic dosing frequency and to calculate the cost savings associated with dose reduction.

Methods: This prospective, non-blinded, non-randomised study was commenced in 2010. Patients with IA, Rheumatoid arthritis (RA),ankylosing spondylitis (AS) and Psoriatic arthritis (PsA) who were in remission as defined by disease activity indices (DAS28<2.6, BASDAI<4), and were offered Anti TNF dose reduction. Patients on etanercept were reduced from 50mg weekly to fortnightly, adalimumab 40mg once monthly instead of fortnightly. Patients were assessed for disease activity at 1, 4 and 10 years following reduction in dosing frequency.Cost saving was calculated by deducting the total annual cost of the biologic agent used over 10 years compared with the cost if the dosing interval had not changed.

Results: Seventy nine patients with inflammatory arthritis in remission were recruited. 57% had rheumatoid arthritis (n=45), 13% psoriatic arthritis (n=10) and 30% ankylosing spondylitis (n=24). 57% (n=45) were taking etanercept and 43% (n=34) adalimumab. The percentage of patients who maintained dose reduction at 10 years was 9% (n=7). Of the total 48 patients who were successfully dose reduced at year 1 (n=42), (69%, n=29) were able to maintain the dose reduction up to 4 years and 9% (n=7) maintained this dose reduction up to year 10. The estimated cost saving was €4,928 per patient per year. Estimated cost savings for 7 patients on reduced dose was €344,952.88 over 10 years.

Conclusion: Anti TNF dose reduction strategy in patients with IA results in substantial cost savings. Implementation of a dose reduction strategy while monitoring of disease activity reduces the financial impact of the use of biologic therapies. Further studies should be done to identify which patients are more likely to remain in remission while on dose reduction.

POS0662 BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS PRESCRIPTION OVER TIME IN A COHORT OF EARLY RHEUMATOID ARTHRITIS PATIENTS

A. L. Fedele[1], F. Melpignano[1], D. Bruno[1], R. La Ferrara[1], M. A. D'agostino[1]. *[1]Division of Rheumatology-Catholic University of the Sacred Heart, Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze Mediche e Chirurgiche, Rome, Italy*

Background: According to 2019 updated EULAR recommendations, therapy of Early Rheumatoid Arthritis (ERA) with biological disease-modifying antirheumatic drugs(bDMARDs) is adviced in presence of poor prognostic factors,i.e. persistently moderate/high disease activity, high acute phase reactants, high swollen joint count, autoantibody positivity, presence of early erosions, failure of two/more conventional synthetic DMARD.

Objectives: To evaluate over time prevalence of bDMARD therapy and factors associated to rapid initiation in our EA Clinic (EAC), comparing two different periods: from 2004 to 2012 and from 2012 to 2020. The last two years were not considered because of the adverse influence of COVID19 pandemia on early access to EAC and on timely scheduled visits.

Methods: A total of 281 ERA patients with less than 12 months of disease duration (53.9 years mean age, 75% female, 77% seropositive), followed according to the treat-to-target (T2T) strategy, were enrolled in the study. At baseline, and every three months, the ACR/EULAR core data set variables were recorded. At baseline and every year, hand and foot radiographs were examined according to modified Total Sharp score (mTSS). At each visit, clinical improvement and remission were evaluated according to EULAR criteria. The achievement of Comprehensive Disease Control (CDC) (28-joint Disease Activity Score using C reactive protein <2.6, Health Assessment Questionnaire <0.5 and change from baseline in mTSS ≤0.5) was assessed every year.

Results: We examined 164 patients from 2004 to 2012 and 117 subjects from 2012 to 2020. In the first group 72 patients (43.9%) initiated bDMARDs during the 8-year FU, with a mean delay of 41.8 months. In the second group 37 patients (31.6%) started biotechnological drugs over time, with a mean delay of 50.4 months.
Analyzing the period from 2004 to 2012, ERA patients starting bDMARDs were younger (*p<0.0001*), had longer disease duration (*p=0.02*) and higher body mass index (BMI) (*p=0.01*) compared to subjects not undergoing to biological therapy. Moreover, ERA patients in bDMARDs were in higher percentage anti-citrullinated peptide antibody (ACPA) positive (80.6%) and reached to a lesser extent CDC at 12months of FU (26.1%) compared to patients that didn't initiate bDMARDs (60.9% ACPA positive, *p=0.01*; 63% achieving CDC, *p<0.0001*, respectively). Examining the period from 2012 to 2020, bDMARD-treated ERA patients were younger (p=0.06),in higher percentage ACPA positive (81.1%) and erosive at baseline (35.1%) compared to patients that didn't initiate bDMARDs (64% ACPA positive, *p=0.02*; 17.5% erosive, *p=0.04*, respectively). As previously, patients in bDMARD reached to a lesser extent CDC at 12 month of FU (35.1%) compared to subjects not undergoing to biological therapy (55% achieving CDC, *p=0.05*). On multivariate analysis, ACPA positivity was associated with initiation of bDMARD in both patient groups *(p=0.02)*, whereas older age at onset and reaching CDC at 12 month were inversely associated (*p=0.001*; *p<0.0001*, respectively).

Conclusion: Despite the widest choice of bDMARDs currently available in the last 8 years, we did not observe an increase in the prescription of these drugs from 2012 to 2020. As in other ERA cohorts, bDMARD initiation is associated to poor prognostic factors, in particular ACPA positivity, presence of erosions at baseline and not achieving CDC at 12 months of FU. In the last 8 years, the decreased influence of disease duration at onset and of BMI could be a consequence of the improvement in strategies of early referral and control of modifiable risk factors.

Rheumatoid arthritis - non biologic treatment and small molecules

POS0663 THE USE OF EXPOSURE-ADJUSTED EVENT RATES VERSUS EXPOSURE-ADJUSTED INCIDENCE RATES IN ADVERSE EVENT REPORTING: INSIGHTS FROM FILGOTINIB INTEGRATED SAFETY DATA IN RHEUMATOID ARTHRITIS

P. Durez[1], E. Feist[2], R. Blanco[3], V. Rajendran[4], N. Verbruggen[5], K. Van Beneden[6], J. Galloway[7]. *[1]Institute de Recherche Expérimentale et Clinique (IREC), Cliniques Universitaires Saint-Luc - Université Catholique de Louvain, Rheumatology, Brussels, Belgium; [2]Helios Clinic Vogelsang-Gommern, Cooperation Partner of the Otto von Guericke University Magdeburg, Department of Rheumatology, Magdeburg, Germany; [3]Hospital Universitario Marqués de Valdecilla, Rheumatology Division, Santander, Spain; [4]Galapagos NV, Clinical Development, Mechelen, Belgium; [5]Galapagos NV, Biostatistics, Mechelen, Belgium; [6]Galapagos NV, Medical Affairs, Mechelen, Belgium; [7]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*

Background: Reporting of treatment-emergent adverse events (TEAEs) in rheumatoid arthritis (RA) clinical trials can be summarized as exposure-adjusted incidence rates (EAIRs) or exposure-adjusted event rates (EAERs). Censored EAIR (EAIR), weighing exposure up to a patient's first event, is commonly reported; uncensored EAIR (EAIRu), using total exposure time for all patients, can also be used. For EAIR, exposure time can vary by event. In contrast to EAIR(u), the total number of events are used to calculate EAER. The three methods account for different exposures and/or multiple events, which can impact the outcome evaluation. Studies of filgotinib (FIL) in RA[1] report safety data as EAIR/100 patient-years of exposure (PYE) for TEAEs, which is uncensored.

Objectives: To describe the outcome of long-term FIL integrated safety data in RA by applying different statistical methodologies: EAER, EAIRu and EAIR.

Methods: Integrated FIL safety data from seven clinical trials were assessed[1]. Predefined adverse events of special interest (AESI) included serious infections (any), herpes zoster (HZ), major adverse cardiac events (MACE), malignancies (excluding nonmelanoma skin cancer [NMSC]), NMSC and venous thromboembolism (VTE). The number of patients with an event, number of events, EAER, EAIRu and EAIR were summarized. The data extraction date was January 2021 for the DARWIN 3 (NCT02065700) long-term extension (LTE) and November 2020 for the FINCH 4 (NCT03025308) LTE.

Results: In total, 3691 patients received ≥1 FIL dose for 8085 PYE. In this population, 176 serious infections were reported in 137 patients, 125 HZ events were reported in 112 patients, 39 MACE were reported in 33 patients, 20 cases of VTE were reported in 15 patients, 60 malignancies excluding NMSC were reported in 49 patients and 21 cases of NMSC were reported in 20 patients. Within each treatment arm (FIL 200 mg [FIL200], FIL 100 mg [FIL100] or combined FIL), rates for most AESI were similar when reported as EAER, EAIRu or EAIR (Table 1). For serious infections, EAER was higher than EAIRu or EAIR. The total exposure time to first event (censored PYE) was high and comparable to total exposure (PYE) (>2700 years and >5100 years for the total populations in the FIL100 and FIL200 groups, respectively).

Table 1. Exposure-adjusted event and incidence rates for AESI

		FIL200	FIL100	FIL combined
Number of patients/PYE		2267/5302.5	1647/2782.6	3691/8085.1
Serious infections	**EAER**	1.9 (1.5, 2.4)	3.2 (2.2, 4.5)	2.0 (1.7, 2.4)
	EAIRu	1.5 (1.1, 1.9)	2.7 (1.9, 3.9)	1.6 (1.3, 2.0)
	EAIR	1.5 (1.2, 1.9)	2.8 (1.9, 4.0)	1.7 (1.4, 2.0)
HZ	**EAER**	1.6 (1.3, 2.1)	1.3 (0.9, 1.8)	1.5 (1.2, 1.8)
	EAIRu	1.5 (1.2, 2.0)	1.1 (0.8, 1.5)	1.4 (1.1, 1.7)
	EAIR	1.6 (1.2, 2.0)	1.1 (0.8, 1.6)	1.4 (1.1, 1.7)
MACE	**EAER**	0.3 (0.2, 0.5)	0.6 (0.4, 1.0)	0.4 (0.3, 0.6)
	EAIRu	0.3 (0.2, 0.5)	0.5 (0.3, 0.8)	0.4 (0.2, 0.6)
	EAIR	0.3 (0.2, 0.5)	0.5 (0.3, 0.9)	0.4 (0.2, 0.6)
VTE	**EAER**	0.3 (0.2, 0.5)	0.1 (0.1, 0.4)	0.2 (0.2, 0.4)
	EAIRu	0.2 (0.1, 0.4)	0.1 (0.1, 0.4)	0.2 (0.1, 0.3)
	EAIR	0.2 (0.1, 0.4)	0.1 (0.1, 0.4)	0.2 (0.1, 0.3)
Malignancies excluding NMSC	**EAER**	0.8 (0.5, 1.1)	0.8 (0.5, 1.2)	0.7 (0.2, 2.8)
	EAIRu	0.6 (0.4, 0.9)	0.6 (0.4, 1.0)	0.6 (0.4, 0.8)
	EAIR	0.6 (0.4, 0.9)	0.6 (0.4, 1.0)	0.6 (0.4, 0.8)
NMSC	**EAER**	0.3 (0.2, 0.5)	0.2 (0.1, 0.5)	0.3 (0.2, 0.4)
	EAIRu	0.3 (0.2, 0.5)	0.2 (0.1, 0.4)	0.2 (0.2, 0.4)
	EAIR	0.3 (0.2, 0.5)	0.2 (0.1, 0.4)	0.2 (0.2, 0.4)

Data are rate (95% CI) unless otherwise stated.

Conclusion: These data confirm that using different methods to analyze FIL safety data (EAER, EAIRu, EAIR) does not result in different safety outcomes, reinforcing the previously reported FIL safety profile in patients with RA. As the AESI reported in the long-term safety database with FIL are rare, patients commonly have long exposure times before experiencing an event, which are often associated with end of treatment. As such, EAIRu, EAIR and EAER are similar.

POS0664 RADIOGRAPHIC CHANGE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ESTIMATED BASELINE YEARLY PROGRESSION ≥5 OR <5: POST HOC ANALYSIS OF TWO PHASE 3 TRIALS OF FILGOTINIB

Y. Tanaka[1], T. Atsumi[2], D. Aletaha[3], R. B. M. Landewé[4], B. Bartok[5], A. Pechonkina[6], Z. Yin[7], L. Han[7], K. Emoto[8], S. Kano[8], V. Rajendran[9], T. Takeuchi[10]. *[1]University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; [2]Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Hokkaido, Japan; [3]Medical University of Vienna, Division of Rheumatology. Department of Medicine, Wien, Austria; [4]Amsterdam Rheumatology & Clinical Immunology Center (amC) & Zuyderland MC, Clinical Immunology and Rheumatology, Heerlen, Netherlands; [5]Gilead Sciences, Inc., Department of Clinical Research, Foster City, United States of America; [6]Gilead Sciences, Inc., Department of Clinical Research, Foster City, United States of America; [7]Gilead Sciences, Inc., Biostatistics, Foster City, United States of America; [8]Gilead Sciences K.K., Medical Affairs, Tokyo, Japan; [9]Galapagos BV, Inflammatory Diseases, Mechelen, Belgium; [10]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: In some patients (pts) with rheumatoid arthritis (RA), especially those with joint damage early in the disease, first-line methotrexate (MTX) treatment may not suffice to prevent further rapid radiographic progression (RRP).[1] In FINCH 1 (NCT02889796), filgotinib 200 mg (FIL200) and 100 mg (FIL100) reduced change in modified total Sharp score (mTSS) vs placebo (PBO) in pts with RA and inadequate response to MTX (MTX-IR).[2] In FINCH 3 (NCT02886728), FIL200 and FIL100 reduced change in mTSS vs MTX monotherapy (MTX mono) in MTX-naïve pts.[3]

Objectives: To evaluate, via post hoc analysis of 2 trials, filgotinib's effects on radiographic progression vs MTX mono in pts with estimated baseline (BL) yearly progression ≥5 or <5 mTSS units/year.

Methods: The double-blind 52-week (W) FINCH 1 study randomised MTX-IR pts with moderate–severe active RA to FIL200 or FIL100, subcutaneous adalimumab (ADA) 40 mg, or PBO; at W24, PBO pts were rerandomised blinded to FIL200 or FIL100; all took stable background MTX.[2] In FINCH 3, MTX-naïve pts were randomised, blinded, to FIL200 + MTX, FIL100 + MTX, FIL200 alone, or MTX mono for up to W52.[3] This analysis examined subgroups by estimated BL yearly progression (BL mTSS/duration in years of RA diagnosis), based on ≥5 or <5 mTSS units/year,[4] a threshold commonly used to define RRP. We assessed effects of filgotinib vs ADA or PBO in mTSS change from BL (CFB) at W24/W52 (using a mixed model for repeated measures) and percentages with no W24 progression (mTSS change ≤0, ≤0.5, ≤smallest detectable change [SDC], using Fisher's exact test).

Results: At BL, 558/1755 MTX-IR and 787/1249 MTX-naïve pts had BL estimated yearly progression ≥5. Median mTSS in pts with BL yearly progression ≥5 and <5 was 53.25 vs 5.00 respectively in the MTX-IR trial and 6.00 vs 2.50 in the MTX-naïve trial. At W24, the mTSS CFB in pts with BL yearly progression ≥5 and <5 was 0.84 and 0.22 in MTX-IR pts taking PBO + MTX, and 0.67 and 0.25 in MTX-naïve pts taking MTX mono. At W52, in pts with BL yearly progression ≥5, FIL200 + MTX reduced mTSS change vs PBO + MTX in the MTX-IR trial and vs MTX mono in the MTX-naïve trial (Figure 1). At W24, among pts with estimated BL yearly progression ≥5, FIL200 + MTX increased odds of no

Table 1. Ratio of no radiographic progression at W24

MTX-IR ORs are FIL vs PBO + MTX; MTX-naïve are FIL vs MTX. *Nominal *P*<.05. †Not applicable.ADA, adalimumab; FIL, filgotinib; IR, inadequate response; mTSS, modified total Sharp score; MTX, methotrexate; OR, odds ratio; SDC, smallest detectable change; W, week.

progression (≤0.5 or ≤0) vs PBO + MTX in MTX-IR pts and vs MTX mono in MTX-naïve pts (Table 1).

Conclusion: These data suggest filgotinib's inhibition of radiographic progression was numerically greater than MTX monotherapy in RA pts with high estimated BL yearly progression. In those with a more moderate estimated rate of progression, filgotinib suppressed progression comparably to ADA and/or MTX.

POS0665 DEVELOPMENT OF A BIOCHEMICAL TOFACITINIB ADHERENCE ASSAY IN RHEUMATOID ARTHRITIS: THE ORAL ADHERE STUDY

S. Church[1], K. Hyrich[2], K. Ogungbenro[3], R. Unwin[4], A. Barton[5,6], J. Bluett[5,6].
[1]Division of Cardiovascular Sciences, School of Medical Sciences, Faculty of Biology Medicine and Health, The University of Manchester, Core Technology Facility, Grafton Street, Manchester, United Kingdom; [2]Centre for Epidemiology Versus Arthritis, The University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom; [3]Centre for Applied Pharmacokinetic Research, Division of Pharmacy and Optometry, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom; [4]Stoller Biomarker Discovery Centre and Division of Cancer Sciences, School of Medical Sciences, Faculty of Biology Medicine and Health, The University of Manchester, CityLabs 1.0 (3rd Floor), Nelson Street, Manchester, United Kingdom; [5]NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; [6]Versus Arthritis Centre for Genetics and Genomics, Centre for Musculoskeletal Research, The University of Manchester, Manchester, United Kingdom

Background: Tofacitinib is a potent inhibitor of the JAK1/JAK3 tyrosine kinases effective in the treatment of rheumatoid arthritis (RA). Unlike biologic DMARDs, tofacitinib is administered orally. Oral administration offers a major benefit to patients, removing the risk of injection site reactions and previous research has shown that patients prefer an oral DMARD which may affect patient's adherence (1). Non-adherence is a health behaviour that results in reduced response and increased healthcare costs but can be challenging to accurately measure. Direct tofacitinib measurement may be an accurate measure of adherence that could, in the future, be used in a clinical setting as part of a behaviour change intervention. Tofacitinib can be measured using High Performance Liquid Chromatography Selected Reaction Monitoring Mass Spectrometry (HPLC-SRM-MS). Previous tofacitinib studies have demonstrated an assay sensitivity of 0.1ng/ml may be sufficient for the detection of adherence following 5mg twice daily administration (2).

Objectives: The aim of this study is to develop a HPLC-SRM-MS assay to measure biochemical tofacitinib adherence in patients with RA.

Methods: Human serum for method development was obtained from volunteers recruited to the collection of blood and urine samples from volunteers for the development of analytical methods study (UREC 12346) and the National Repository Study (REC 99/8/84) following informed consent. Samples were spiked with Tofacitinib/Tofacitinib-d3 and subjected to protein precipitation. LC-MS/MS analysis was performed on a TSQ Vantage triple quadrupole mass spectrometer coupled with an Accela UHPLC system (Thermo Fisher Scientific, USA). Validation of the assay was tested as adapted from European Medicines Agency guidelines on Bioanalytical Validation. Specifically, the lower limit of quantification (LLOQ), carryover, accuracy, linearity, precision, recovery and stability of the assay was determined.

To investigate the ability of the assay to detect adherence, serum samples (n=10) of patients prescribed tofacitinib from the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS) were analysed (REC reference: 04/Q1403/37). Participants self-reported date and time of tofacitinib ingestion prior to venepuncture. Samples were analysed in triplicate.

Results: The assay demonstrated a tofacitinib LLOQ of 0.1ng/ml, carryover of sample following injection of a 1000 ng/ml tofacitinib was <1%, linearity of r2=0.998, within run accuracy was between 81-85% at LLOQ and between 91-107% at all other levels. Between run accuracy was within 14.9% at LLOQ and within 0.2-5.1% of the nominal concentration at all other levels. Samples of tofacitinib spiked in whole blood and left at room temperature for seven days were within 0.98-10.25% of serum samples spiked on the day of analysis for all concentrations. To demonstrate the potential of the assay to determine adherence, all 10 BRAGGSS samples revealed tofacitinib levels above 0.1ng/ml with CV<15% (Table 1).

Table 1.

Sample ID	Time difference between self-reported tofacitinib ingestion and blood sample (hours)	Mean Tofacitanib (ng/ml, n=3)	CV (%)
49	7.0	26.43	2.82
40	2.8	100.55	5.51
70	3.6	73.23	2.27
68	1.5	150.37	8.09
20	1.5	137.46	9.09
30	1.8	117.85	14.97
33	1.4	90.89	1.18
79	5.4	217.47	11.40
17	2.8	108.43	7.43
37	2.5	335.04	3.48

Conclusion: A novel tofacitinib LC-MS/MS assay has been developed. The ability of the assay to measure biochemical adherence has been explored. Further research to establish the sensitivity of the assay and the ability of the assay to detect non-adherence are required.

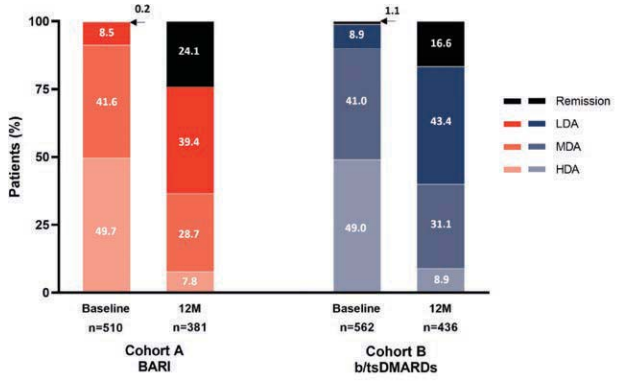
Background: Baricitinib (BARI), an oral selective JAK 1/2 inhibitor, is approved for treating adults with moderate to severe active rheumatoid arthritis (RA). RA-BE-REAL is a 3-year, multinational, prospective, observational study of adult patients with RA evaluating time to discontinuation of initial RA treatment for all causes (excluding sustained clinical response) over 24 months (M).

Objectives: This analysis reports time to discontinuation in the European (France, Germany, Italy, Spain, UK) subgroup, treated with either BARI, biologic (b) disease-modifying anti-rheumatic drugs (DMARDs) or any other targeted synthetic (ts)DMARDs, as well as, the effectiveness of RA treatment, at 12M.

Methods: In the two cohorts, patients were initiated with BARI 2-mg or 4-mg (cohort A), or any bDMARD or tsDMARD (b/tsDMARDs; cohort B). Treatment initiation and changes are at the discretion of the patient or physician. Response rates for remission, low disease activity (LDA), moderate disease activity (MDA) or high disease activity (HDA) were determined using the Clinical Disease Activity Index (CDAI) at 12M. Quality of life using the EQ-5D-5L and patient reported outcome (PRO) measures for pain (pain visual analogue scale; VAS) and physical functioning (Health Assessment Questionnaire Disability Index; HAQ-DI) were also assessed at 12M. This pre-specified interim analysis reports descriptive 12M data using summary statistics, without any inferential testing.

Results: This analysis involved 1073 adult RA patients with a mean age (standard deviation; SD) of 59.1 (13.2) (cohort A) and 57.0 (13.9) yrs (cohort B), respectively, and a mean disease duration (SD) of 10.0 (9.1) (cohort A) and 8.9 (9.6) yrs (cohort B), respectively. At baseline, 50.9% of patients in cohort A and 31.2% in cohort B initiated treatment as a monotherapy. At 12M, 26.7% of patients in cohort A and 44.1% of patients in cohort B had discontinued treatment. The most common reason for discontinuation in both cohorts was primary non-response. At 12M, 24.1% of patients in cohort A and 16.6% in cohort B achieved CDAI remission (Figure 1). The mean CDAI reduction was -14.5 and -12.0, respectively in cohorts A and B. Mean reductions from baseline in physician global assessment (PhGA) and in patient global assessment (PGA) were -3.4 and -2.5, respectively in cohort A and -3.0 and -2.1, respectively in cohort B. Improvements from baseline in EQ-5D-5L, HAQ-DI, and pain (VAS) were reported in both cohorts at 12M. The mean pain (VAS) reduction from baseline was -24.6 and -19.3 in cohort A and cohort B, respectively.



Footnote: Values are presented as percent of each cohort at each timepoint.

BARI; Baricitinib, b/tsDMARDs; biologic or any other targeted synthetic disease-modifying anti-rheumatic drugs, M; months, LDA; low disease activity, MDA; moderate disease activity, HDA; high disease activity.

Figure 1. Percentage of pts in cohorts A and B achieving remission and LDA at 12M

Conclusion: The majority of BARI-treated patients were in remission or had low disease activity and continued treatment at 12M.

Table 1. Disease activity and patient reported outcomes at baseline and 12M

	Cohort A Baricitinib			Cohort B b/tsDMARDs		
	Baseline	12M	CFB	Baseline	12M	CFB
CDAI	24.0 (11.7)	9.1 (8.2)	-14.5 (12.4)	23.8 (12.4)	10.7 (9.8)	-12.0 (12.6)

POS0667 CHARACTERIZING NON-RESPONSE TO METHOTREXATE MONOTHERAPY AMONG RHEUMATOID ARTHRITIS PATIENTS IN A LARGE REAL-WORLD LONGITUDINAL COHORT

Z. Icten[1], K. Starzyk[2], M. Friedman[3], J. Menzin[4]. *[1]Panalgo, Data Science Solutions, Boston, United States of America; [2]OM1, Real World Evidence, Boston, United States of America; [3]Panalgo, Medical Affairs, Boston, United States of America; [4]Panalgo, Executive Chairman, Boston, United States of America*

Background: Methotrexate (MTX) monotherapy is the first choice among disease-modifying drugs (DMARDs) for most moderate-to-severe rheumatoid arthritis (RA) patients, consistent with treatment guidelines.[1] However, response to, and tolerability of, MTX varies among patients.[2] Understanding the proportion of patients with MTX non-response in a real-world setting and identifying its predictors could enable earlier access to alternative or additional medications and improve management of disease progression.

Objectives: The objectives of this study were, using data from a large, geographically representative US cohort of RA patients, to describe the pattern of non-response among patients initiating MTX monotherapy and to identify predictors of non-response to MTX.

Methods: The OM1 RA Registry (OM1, Inc; Boston, MA) follows more than 210,000 RA patients in the US managed by rheumatologists longitudinally with deep clinical data, including laboratory, patient-reported and disease activity information, and linked administrative claims starting from 2013. In this retrospective observational study, patients aged ≥ 18 years initiating MTX between 01 January 2014 and 01 August 2020 without previous bDMARD/tsDMARD utilization were identified. The first MTX date was the index date, with ≥1 Clinical Disease Activity Index (CDAI) measurement and ≥2 all-cause healthcare encounters required in the preceding 12 months (baseline). Patients initiating a bDMARD/tsDMARD within 30 days of the index date or with a history of other conditions where the same bDMARD/tsDMARDs are indicated were excluded. MTX non-response was defined as failing to attain remission or low disease activity (i.e., CDAI >10) within 4 to 8 months and/or the initiation of a bDMARD/tsDMARD within 8 months following the index date (with or without continuing MTX; non-response could include patients discontinuing MTX due to tolerability). Baseline characteristics were summarized with descriptive statistics. Multivariate logistic regression with age, gender, region, race, payor, year of index, the most recent CDAI and body mass index (BMI) measurements from the baseline, and Charlson comorbidity index (CCI) was used to investigate risk factors of non-response. *P* value was considered significant if <0.01.

Results: Among 6,648 eligible RA patients, 3,748 (56.4%) were classified as non-responders. Baseline charactesistics are summarized in Table 1. Being female (OR=1.3), increasing baseline CDAI (OR: Low activity=1.9, moderate activity=8.1, high activity=13.0) and higher BMI (OR=1.01) were significantly associated with non-response. Being older was found protective of non-response (OR=0.98). The C-statistic was 0.74.

Table 1. Baseline Characteristics Overall and by Response Status

Statistic	Overall	Responders	Non-responders
Age	61.6 (13.3)	63.9 (13.0)	59.8 (13.3)
Female	5,059 (76.1%)	2,096 (72.3%)	2,963 (79.1%)
Region			
MIDWEST	905 (13.6%)	366 (12.6%)	539 (14.4%)
NORTHEAST	1,115 (16.7%)	520 (17.9%)	595 (15.9%)
SOUTH	4,063 (61.1%)	1,759 (60.7%)	2,304 (61.5%)
WEST	565 (8.5%)	255 (8.8%)	310 (8.3%)
Race			
BLACK	597 (9.0%)	243 (8.4%)	354 (9.5%)
WHITE	4,305 (64.8%)	1,935 (66.7%)	2,370 (63.2%)
OTHER	166 (2.5%)	73 (2.5%)	93 (2.5%)
UNKNOWN	1,580 (23.8%)	649 (22.4%)	931 (24.8%)
Payor			
COMMERCIAL	3,768 (56.7%)	1,516 (52.3%)	2,252 (60.1%)
MEDICARE	2,590 (39.0%)	1,273 (43.9%)	1,317 (35.1%)
MEDICAID	290 (4.4%)	111 (3.8%)	179 (4.8%)
CDAI	15.6 (10.4)	11.3 (9.5)	18.9 (9.8)
CCI	1.4 (1.1)	1.4 (1.1)	1.4 (1.1)
BMI	30.4 (7.1)	29.7 (6.8)	30.9 (7.3)

Conclusion: We found that over half of patients qualified as MTX non-responders at approximately 6 months. Significant predictors of non-response were younger age, female gender, higher CDAI score and BMI. Maximizing improvement as quickly as possible and deploying more tailored escalation of care may be aided by identifying RA patients at higher risk of early MTX treatment failure.

POS0668 THE EFFICACY OF TOFACITINIB ON CLINICAL DYNAMIC AND CONCENTRATION OF CYTOKINES IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Lapkina[1], A. Baranov[1], N. Levshin[1], N. Abaitova[1], A. Avdeeva[2], E. Leontieva[1], A. Artyuhov[3], E. Nasonov[2,4]. *[1]Yaroslavl State Medical University, Outpatient, Yaroslavl, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology of Rheumatic Diseases, Moskow, Russian Federation; [3]N.I. Pirogov Russian National Research Medical University, Institute of Translational Medicine, Department of Regenerative Medicine, Moskow, Russian Federation; [4]I.M. Sechenov First Moscow State Medical University, Rheumatology, Moskow, Russian Federation*

Background: Pathogenesis of RA includes numerous interactions of genetic and acquired defects in normal immunoregulation, one is disbalance of pro- and anti-inflammatory cytokines production. Basic treatment conception in RA is «treat-to-target», including biological agents and Janus kinase (JAK) inhibitors. Tofacitinib is one of the first JAK-inhibitors in clinical practice, but data on its influence on cytokine profile during course of treatment are still limited.

Objectives: To study the dynamics of clinical signs, laboratory parameters of inflammatory activity and cytokines profile in RA patients treated with tofacitinib.

Methods: A total of 10 adults with valid diagnosis of RA (ACR/EULAR, 2010) and high disease activity (DAS28 5,88 [5,53; 5,94], CDAI 33.0 [29.0; 36.0], SDAI 33.72 [30.75; 36.85] score) were enrolled to the study. Mean age was 51,0 [48,0; 62,0] years, median disease duration 7.0 [3,0;20.0] years. All patients received TOFA 5 mg bid, methotrexate, non-steroidal anti-inflammatory drugs. There were 3 control points: before treatment, 3 and 6 months of tofacitinib treatment. Concentration of IL-1β, IL-4, IL-6, TNF-α, INF-γ, IL-10, IL-17A, IL-17F, IL-21, IL-22, IL-23, IL-25, IL-31, IL-33, sCD40L were studied using multiplex technology (BioPlexTM 200 System, BIO-RAD, USA).

Results: Significant decrease in RA activity was marked after 3 and 6 months of treatment with tofacitinib - DAS28 of 4.55 [3.47; 5.16], 3.92 [3.80; 4.60]; CDAI 16.5 [11.0; 23.0], 18.0 [15.0; 19.0]; SDAI 16.6 [11.23; 23.06], 18.07 [15.06; 19.10]; ESR 19.0 [11.0; 26.0], 7.0 [4.0; 18.0]; CRB 0.56 [0.50; 1.99], 0.71 [0.51; 1.1], respectively. IL-6 levels decreased after 3 and 6 months of therapy ($p<0.05$). The concentration of IFN-γ significantly decreased after 3 months ($p<0.05$) but remained unchanged thereafter. Concentrations of IL-25 and IL-31 decreased after 3 months ($p<0.05$), and by the 6th month of treatment there was an increase, but not reaching the initial values. The results of the study are shown in Table 1

Table 1. Levels of cytokines in RA patients receiving tofacitinib, pg/ml, Me [25;75 percentile].

Cytokine	Initial	After 3 months of tofacitinib treatment	After 6 months of tofacitinib treatment
IL-1β	0,07 [0,03;0,13]	0,05 [0,03;0,08]	0,08 [0,06;0,11]
IL-4	4,28 [3,32;10,42]	3,96 [2,49;13,25]	7,03 [3,69;13,46]
IL-6	3,43 [2,44;11,02]	2,28 [1,62;3,85]*	1,55 [1,33;2,07]*
TNF-α	1,35 [0,68;2,41]	1,11 [0,68;1,76]	0,95 [0,49;1,57]
IFN-γ	2,05 [1,48;3,19]	0,99 [0,49;2,05]*	0,99 [0,49;2,62]*
IL-10	2,96 [1,20;2,56]	2,10 [1,50;3,04]	2,41 [1,80; 3,99]
IL-17A	1,57 [0,42;2,17]	1,20 [0,71;1,72]	1,27 [0,85;1,27]
IL-17F	2,49 [1,25;12,38]	1,56 [0,0;3,30]	2,49 [1,87;5,97]
IL-21	4,74 [1,19;49,36]	2,07 [0,0;5,93]	4,75 [4,75;10,46]
IL-22	2,76 [0,63;4,10]	1,18 [0,94;2,21]	2,21 [0,32;3,94]
IL-23	13,54 [7,34;46,27]	10,26 [4,41;19,74]	13,90 [8,80;20,46]
ИЛ-25	1,11 [0,32;2,18]	0,31 [0,0;1,25]*	0,42 [0,21;1,4]*
IL-31	6,95 [3,85;17,72]	3,00 [1,50;3,85]*	5,09 [3,85;6,33]*
IL-33	13,66 [8,72;38,48]	8,10 [3,90;22,37]	14,07 [9,96;26,09]
sCD40L	72,77 [8,90;201,18]	15,31 [4,29;34,80]	40,17 [26,53;68,55]

*p<0,05 (comparing with initial concentration)

Conclusion: The data obtained indicate the efficacy of tofacitinib in patients with RA, including decreasing of disease activity and concentrations of clue pro-inflammatory cytokines. Further studies are needed to investigate pathogenic role of cytokine-mediated inflammation in RA and the efficacy of targeted oral medications on the course of the disease.

Disclosure of Interests: None declared

POS0669

TAPERING SUBCUTANEOUS METHOTREXATE CAUSES MORE DISEASE FLARES COMPARED TO ORAL ADMINISTRATION IN ESTABLISHED RHEUMATOID ARTHRITIS PATIENTS.

A. Looijen[1], E. Van Mulligen[1,2], A. Van der Helm-van Mil[1,2], P. De Jong[1].
[1]Erasmus Medical Center, Department of Rheumatology, Rotterdam, Netherlands; [2]Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands

Background: Thanks to improved treatment strategies, disease remission in rheumatoid arthritis(RA) patients has become more common. Therefore, current guidelines recommend to consider tapering DMARDs, including methotrexate(MTX), in patients who are in sustained remission. Previous research has shown that subcutaneous methotrexate(MTXsc) has a better bioavailability, efficacy and tolerability in active RA than oral MTX[1]. However, these advantages might be a disadvantage when tapering of MTXsc is considered.
Objectives: To compare the 1-year cumulative flare rates between established RA patients who taper subcutaneous and oral MTX.
Methods: Data from the TApering strategies in Rheumatoid Arthritis(TARA) trial were used[2]. In this trial, established RA patients with a well-controlled disease, defined as Disease Activity Score(DAS)≤2.4 and swollen joint count(SJC)≤1, using ≥1 csDMARD and TNF-inhibitor(TNFi) were included. Participants were randomized into two groups which gradually tapered their csDMARD first followed by the TNFi, or vice versa. The csDMARD was tapered by reducing the dosage by a half at baseline, by a quarter at 3 months and was stopped at 6 months. Patients who tapered MTX were included in this analysis. If a disease flare(DAS>2.4 or SJC>1) occurred, the last effective therapy was restarted and intensified every 3 months, until DAS≤2.4 and SJC≤1. Following an intention-to-treat principle, flare rates were compared between patients who tapered subcutaneous and oral MTX, using a chi-square test. Two sensitivity analyses were performed were we 1) only included patients with a complete follow-up; and 2) assumed that patients developed a flare at the moment of drop-out.
Results: A total of 71 and 17 patients respectively used oral and subcutaneous MTX. The median disease duration was 5.9 years and 70% was female. The median MTX dosage for both administration routes was 20 milligrams per week. After 12 months, 53% of patients who tapered MTXsc developed a flare compared to 27% who tapered oral MTX (OR 3.1(1.0-9.1, 95%CI), p=0.037)(Figure 1). Respectively 68% and 67% of the patients who developed a flare and were using oral and subcutaneous MTX had a well-controlled disease 3 months after restarting their treatment(p=0.93). Both sensitivity analyses showed similar results.

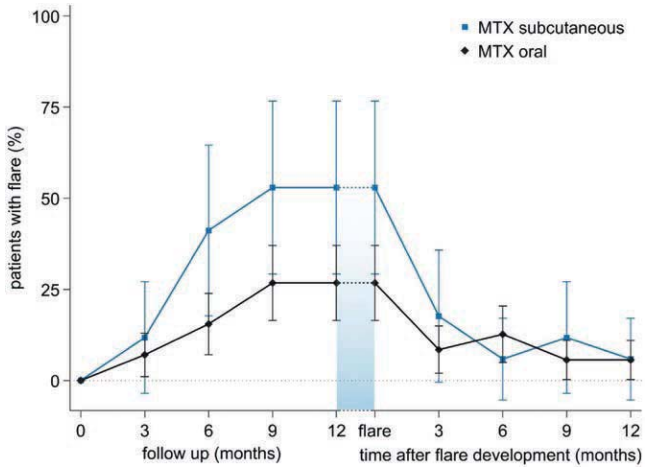

Figure 1. Flare development and resolution over time for different administration routes of methotrexate.*The first part on the X-axis illustrates the cumulative % of patients that develop a disease flare during follow up, the second part illustrates the cumulative % of patients that still has active disease (DAS>2.4 +/ SJC44>1) from point of flare development and after restarting the last effective treatment.Abbreviations: DAS, Disease Activity Score; MTX, methotrexate; SJC44, swollen joint count measured in 44 joints.*

Conclusion: Patients who tapered MTXsc have a higher chance at developing a disease flare compared to those who tapered oral MTX. This could be explained by a higher efficacy of MTXsc when similar dosages are used[1]. Alternatively, the better tolerability of MTXsc, especially regarding gastro-intestinal side effects[1], may lead to a difference in adherence. When deciding to taper MTX, the administration route should be taken into account. Because of the increased risk of flare after tapering MTXsc, these patients could be monitored more closely than those tapering oral MTX.

EVALUATION OF UPADACITINIB IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO FIRST-GENERATION JANUS KINASE INHIBITORS

M. Kamiya[1], S. Mori[1], K. Yamazaki[1], D. Togawa[1]. *[1]Nara Hospital, Kindai University, Department of Orthopaedics and Rheumatology, Ikoma-city, Japan*

Background: Janus kinase inhibitors (JAKi) are effective in the treatment of patients with difficult-to-treat rheumatoid arthritis (D2T RA), regardless of previous use of biological disease-modifying antirheumatic drugs (bDMARDs), and receive equal billing with biological therapies in the latest version of the EULAR recommendations for treatment of RA[1]. However, as with bDMARDs, cases of discontinuation due to intolerance or inadequate response have been observed in patients treated with the so-called first-generation JAKi, leading to the development of a new generation of JAKi that aims to maximize efficacy and improve safety by enhancing kinase selectivity. The results of randomized controlled trials and meta-analyses suggest that the efficacy and safety of Upadacitinib (UPA) treatment are favorable. Although there have been no head-to-head trials between JAKi, a matched-adjusted indirect comparative study has shown a difference in efficacy between JAKi[2], suggesting that the new generation of JAKi may be effective in rheumatoid arthritis patients with intolerance or inadequate response to first-generation JAKi. It is already apparent that a clear need exists for a JAK-IR trial to give guidance in those difficult patients who are JAKi non-responders[3].
Objectives: To evaluate real world efficacy of a second-generation JAK1-selective JAKi UPA in single-center cohort of RA patients who had discontinued first-generation JAKi.
Methods: Patients with RA who had discontinued tofacitinib and/or baricitinib due to inadequate response or intolerance, regardless of whether they had used bDMARDs or not, were eligible for the study if they had received UPA by October 2021 and had been followed up for at least 12 weeks. Endpoints were Kaplan-Meier survival rate with inadequate response or intolerance as reasons for discontinuation, various disease activity assessments (DAS28-ESR, SDAI, CDAI, etc.), and patient reported outcomes (visual analogue scales (VASs) such as pain and stiffness, HAQ-DI, FACIT-Fatigue Scale, etc.) at 12 weeks. In addition, the reasons for discontinuation were investigated.
Results: Fifty-one patients were included in the study, all of whom had D2T RA and had used at least one bDMARD as well as JAKi. The mean (median) age was 72.7 (77) years, disease duration 18.0 (17) years, number of bDMARDs used 3.34 (3), number of JAKi used 1.3(1), 5 patients with methotrexate, 6 patients with prednisolone, and DAS28-ESR 3.83 (3.9). At 12 weeks, the overall survival rate was 94% (94.6% in 37 cases used as 2nd JAKi and 92.9% in 14 cases used as 3rd JAKi). For reference, there was no significant difference from the 100% of the 15 cases used as the 1st JAKi (P=0.49). DAS28-ESR <3.2 and <2.6 were achieved in 60.8% and 29.4%, VASs for pain and stiffness decreased by a mean of 12.9 mm (9 mm) and 12.1 mm (7 mm), respectively, and FACIT-Fatigue scale improved by a mean of 3.0 (1). The reasons for discontinuation in the three patients were inadequate efficacy in two and leg cramps due to venous thromboembolism in one.
Conclusion: UPA is more selective for JAK1 than first generation JAKi, and is expected to reduce adverse reactions caused by inhibition of JAK family members other than JAK1. The present study suggests that UPA is effective and well tolerated, regardless of the number and type of first-generation JAKi used in the past, albeit for a short period of time. Limitations include the small number of cases and the short time frame for discussing adverse reactions.

IMPACT OF RACE ON THE EFFICACY AND SAFETY OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: A POST HOC ANALYSIS OF PHASE 2, 3 AND 3B/4 CLINICAL TRIALS

G. C. Wright[1], E. Mysler[2], Y. H. Chen[3], C. Kinch[4], A. Yndestad[5], K. Kwok[6], M. J. Cadatal[7], R. Germino[6], A. Ogdie[8]. *[1]Association of Women in Rheumatology, Grace C Wright MD PC, New York, NY, United States of America; [2]Organización Médica de Investigación, Department of Rheumatology, Buenos Aires, Argentina; [3]Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China; [4]Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada; [5]Pfizer Inc, Inflammation and Immunology, Oslo, Norway; [6]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America; [7]Pfizer Inc, Inflammation and Immunology, Manila, Philippines; [8]Perelman School of Medicine at the University of Pennsylvania, Department of Medicine, Philadelphia, PA, United States of America*

Background: While racial disparities in clinical outcomes for rheumatoid arthritis (RA) patients (pts) have been described,[1] there is a paucity of data on racial differences in response to advanced therapies.

Objectives: To evaluate impact of self-reported race on tofacitinib efficacy/safety in RA pts.

Methods: This post hoc analysis used pooled data from 8 Phase (P)2, 6 P3 and 1 P3b/4 randomised controlled trials (RCTs) of RA pts treated with tofacitinib 5 or 10 mg twice daily (BID), adalimumab (ADA; 40 mg once every 2 weeks) or placebo (PBO), stratified by self-reported pt race (White, Black, Asian, Other) at baseline (BL). Efficacy outcomes (Month [M]3): ACR20/50/70 and CDAI/DAS28-4(ESR) low disease activity (LDA; scores ≤10 and ≤3.2, respectively) rates, and least squares (LS) mean change from BL (Δ) in DAS28-4(ESR) and HAQ-DI. Incidence rates (IRs; unique pts with events/100 pt-yrs) were estimated for adverse events (AEs) and serious AEs.

Results: 6355 pts were included (White, n=4145; Black, n=213; Asian, n=1348; Other, n=649). BL characteristics were generally similar across treatment/racial groups, excepting higher prior bDMARD exposure rates in White/Black vs Asian/Other pts. Across treatments, White, Black, Asian and Other pts most commonly enrolled from Europe (40.9%), North America (68.1%), East/South Asia (97.9%) and Latin America (80.6%), respectively; most Other pts self-reported as Hispanic and/or Latino (52.4%), followed by mixed race (36.8%) and unspecified (4.6%). At M3, ACR50 rates were higher in Other vs White pts with tofacitinib, similar across racial groups with ADA, and numerically higher in Black vs White/Asian/Other pts with PBO (Figure 1); broadly similar trends were seen with ACR20/70 and CDAI LDA rates (data not shown [DNS]). DAS28-4(ESR) LDA rates, and LS mean ΔDAS28-4(ESR) and ΔHAQ-DI were generally comparable across racial groups with active treatment, and numerically higher in Black vs White/Asian/Other pts with PBO (DNS). Across efficacy outcomes, PBO-adjusted response rates and improvements generally supported the trends observed with active treatments (Figure 1; DNS). Safety outcomes were broadly similar across treatment arms, with some higher IRs for AEs observed with Black/Other vs White/Asian pts (Table 1). Results should be interpreted with caution due to low pt numbers in some groups and the heterogenous nature of the Other pts group.

Conclusion: Across racial groups, tofacitinib efficacy/safety was consistent with previous tofacitinib RA clinical programme findings. Some racial differences in clinical outcomes were observed, which may reflect regional practice norms or demographic differences. Future analyses should focus on the impact of socioeconomic, cultural, genetic or practice-based differences that may underpin these results.

ASSESSMENT OF THE DRUG-DRUG INTERACTION POTENTIAL OF BRANEBRUTINIB (BMS-986195), A HIGHLY POTENT AND SELECTIVE IRREVERSIBLE COVALENT INHIBITOR OF BRUTON'S TYROSINE KINASE, IN HEALTHY PARTICIPANTS

A. Fura[1], I. Girgis[2], M. Nowak[3], L. Carayannopoulos[4], D. Grasela[5], W. LI[6], B. Murthy[2], U. Aras[1]. *[1]Bristol Myers Squibb, Clinical Pharmacology and Pharmacometrics, Princeton, United States of America; [2]Bristol Myers Squibb, Research & Early Development, Princeton, United States of America; [3]Bristol Myers Squibb, Immunology and Fibrosis, Princeton, United States of America; [4]Bristol Myers Squibb, Early Clinical Development, Princeton, United States of America; [5]Bristol Myers Squibb, Early Development Program Leadership, Princeton, United States of America; [6]Bristol Myers Squibb, Drug Metabolism and Pharmacokinetics, Princeton, United States of America*

Background: Branebrutinib (BMS-986195) is a highly potent and selective irreversible small-molecule covalent inhibitor of Bruton's tyrosine kinase (BTK),[1] a non-receptor tyrosine kinase involved in the pathophysiology of immune-mediated diseases. Branebrutinib has the potential to be best in its class, as it achieves ~100% BTK occupancy in humans, sustained over a 24-hour dosing interval at low doses (≤ 10 mg once daily [QD]) despite its short half-life (≤ 2 hours),2 and demonstrates potent efficacy in murine models of immune-mediated diseases.1 Branebrutinib is under clinical study in multiple autoimmune inflammatory disorders such as RA, systemic lupus erythematosus, primary Sjögren's syndrome, and atopic dermatitis. In vitro drug-drug interaction (DDI) studies with branebrutinib predicted pharmacokinetic DDI potential with substrates of cytochrome P450 (CYP)3A4 and the breast cancer resistant protein drug transporter.
Objectives: To assess the DDI potential of branebrutinib when co-administered with potential concomitant medications and probe substrates of major drug-metabolizing enzymes (DMEs) and drug transporters.
Methods: DDI risk with branebrutinib was assessed in 3 single-sequence, cross-over clinical studies in healthy participants. In the first 2-part study, MTX was administered alone or with steady-state (SS) branebrutinib (10 mg QD) in part 1; in part 2, caffeine, montelukast, flurbiprofen, omeprazole, midazolam, digoxin, and pravastatin were taken with or without SS branebrutinib (9 mg QD). In the second study, rosuvastatin was taken alone or with SS branebrutinib (9 mg QD). In cycle 1 of the third study, the oral contraceptive (OC) loestrin (1.5 mg norethindrone/30 µg ethinyl estradiol) was taken alone; in cycle 2, SS branebrutinib (9 mg QD) was taken alone or with the OC.
Results: Weak DDI with montelukast (CYP2C8) was observed, leading to a mild increase in montelukast exposure (max concentration [C_{max}], 56%; area under the curve [AUC], 27%). A mild increase in digoxin exposure (P-glycoprotein [P-gp] substrates; C_{max}, 57%; AUC, 21%) was also observed. There was no potential DDI with MTX (Table 1). No other clinically relevant DDIs with branebrutinib were observed. No serious AEs or other significant AEs occurred during these studies. All AEs were mild to moderate in intensity.

Table 1. Results from clinical DDI studies of branebrutinib

		Adjusted geometric mean ratios with (test) and without (reference) branebrutinib	
Concomitant medication or probe substrate	DME or drug transporter tested	C_{max} ratio (90% CI)	AUC ratio (90% CI)
Digoxin (0.25 mg)	P-gp	1.57 (1.36–1.80)	1.21 (1.11–1.32)
MTX (7.5 mg)	BCRP, OATP1B1, OATP1B3, OAT1, OAT3, MRP2, MRP4	1.00 (0.92–1.09)	0.94 (0.90–0.99)
Pravastatin (40 mg)	OATP1B1, OATP1B3	1.25 (1.00–1.57)	1.06 (0.90–1.25)
Rosuvastatin (10 mg)	BCRP, OATP1B1, OATP1B3	0.81 (0.71–0.93)	0.96 (0.88–1.04)
Montelukast (10 mg)	CYP2C8	1.56 (1.24–1.95)	1.27 (1.10–1.47)
Caffeine (200 mg)	CYP1A2	0.98 (0.94–1.01)	1.16 (1.08–1.24)
Flurbiprofen (50 mg)	CYP2C9	1.06 (0.97–1.16)	1.12 (1.09–1.15)
Omeprazole (50 mg)	CYP2C19	1.05 (0.85–1.30)	0.97 (0.84–1.13)
Midazolam (5 mg)	CYP3A4	0.95 (0.82–1.11)	1.00 (0.84–1.19)
Ethinyl estradiol (30 µg)	CYP3A, CYP2C9, UGAT1A1, SULT1E1	1.16 (1.09–1.23)	1.17 (1.12–1.22)
Norethindrone (1.5 mg)	CYP3A4, CYP2C19	1.10 (1.04–1.15)	1.06 (1.01–1.12)

BCRP, breast cancer resistant protein; MRP, multidrug resistance-associated protein; OAT, organic anion transporting polypeptide; SULT, estrogen sulfotransferase; UGAT, uridine diphosphate glucuronosyltransferase.

Conclusion: In all 3 studies, co-administration of SS branebrutinib was generally well tolerated. The only potentially significant DDIs with substrates of major DMEs or transporters were mild increases in montelukast (CYP2C8) and digoxin (P-gp) exposures.

POS0673

ENDOTHELIAL INFLAMMATION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB

M. DeLaVega[1], C. Peon[1], G. Rodriguez[1], F. Benavidez[1], A. Benitez[1], M. J. Gamba[1], M. Eleta[2], A. Riopedre[1]. *[1]CEIM Investigaciones Médicas, Rheumatology, Buenos Aires, Argentina; [2]Imaxe, Radiology, Buenos Aires, Argentina*

Background: Systemic inflammation in rheumatoid arthritis (RA) seems to accelerate atherosclerosis process and increased cardiovascular (CV) events. An adequate joint inflammation control is correlated with endothelial inflammation (EI) improvement. 18F-fluorodeoxyglucose positron emission tomography with computed tomography (FDG PET/CT) has been shown as a non-invasive, sensitive, and specific tool to show EI. Maximum standardized uptake value (SUV(max)) greater than 1,6 has been correlated with vascular and joint inflammation. Tofacitinib is a Jak inhibitor (JaKi) approved for RA that improves activity and function. The aim of this study is to evaluate the EI outcome by FDG-PET in RA patients treated with tofacitinib.
Objectives: To assess the EI by FDG-PET/CT in RA patients at baseline and after 12 weeks of tofacitinib treatment initiation. To correlate the vascular findings with disease activity, lipid profile and carotid atherosclerosis by echo Doppler.
Methods: Prospective, observational study. Inclusion criteria: RA (ACR 2010) patients >18 years old, with high activity score (DAS 28 >3,2) and with biologics or synthetic Dmards requirement by Treat to Target strategy and who tofacitinib was prescribed. Exclusion Criteria: Biologics or Jaki previous use or major CV history known. A baseline Visit evaluating disease activity (DAS 28 and CDAI), functional status by Health Assessment Questionary (HAQ), CV and smoking history, treatments and lipid lab assessment was performed. EI was measured by PET-FDG/CT, showing the SUVmax and target-to-background ratio (TBR) in: right primitive carotid, left primitive carotid, ascendent aorta, descendent aorta and abdominal aorta. Carotid echo Doppler for showing plaque presence was done. During baseline visit tofacitinib was started. After 12 weeks the initial parameters were re-evaluated.
Results: Consecutively, 30 patients were included. Mean age 57 yo (21-79). Female 70%. Mean disease duration 8,3 years (1-40), mean Body mass index (BMI) 24,5. Clinical history: Hypertension 27%, smoking 6,6%, methotrexate treatment 46,6%, methotrexate plus leflunomide 50%, corticosteroids 7,6% (mean dosis 7,6 mg/day).
Mean values of DAS 28, CDAI and HAQ were 5.21, 26,6 y 1,56 in baseline and 3,04, 8,80 y 1,09 in the final visit respectively (p:< 0,001 in all comparations) showing statistical significance activity improvement. Echo doppler showed Carotid plaque in 40% of patients without change between visits. Mean cholesterol levels were 188,5 y 207,53 mg/dl in baseline and final visit respectively (p: 0,0039), showing statistical significance. Endothelial uptake by PET-FDG in the 5 areas measured, considering baseline and final visit was: Right Primitive Carotid: SUV Max 2,03 and 1,93 (p: 0,32) and TRB Max 0,94 and 0,85 (p:1,0); Left Primitive Carotid Suv Max 2,07 and 1,94 (p:1,0) and TRB Max 0,92 and 0,90 (p:0,57); Ascendent Aorta SUV Max 2,63 and 2,57 (p:1,0) and TRB Max 1,18 and 1,15 (p:1,0); Descendent Aorta SUV Max 2,77 and 2,57 (p:0,26) and TRB Max 1,27 and 1,17 (p:0,26) and Abdominal Aorta SUV Max 2,59 and 2,43 (p:0,85) and TRB Max 1,15 y 1,11 (p:0,32). None of the endothelial uptake comparisons showed a significant difference between baseline and final visit after 12 weeks.
Conclusion: This work shows that, despite the significant improvement in joint activity and function values, there was no modification in EI measured by FDG-PET during tofacitinib treatment along 12 weeks. It is noteworthy that all patients initially presented high inflammatory endothelial uptake values, which reinforces the hypothesis of vascular compromise associated with active joint disease. Studies with more observation time and evaluating the role of different treatments related to endothelium will be of clinical utility in the future.

Szekanecz[13]. *[1]University of California, Division of Rheumatology, Department of Medicine, Los Angeles, CA, United States of America; [2]University of Manchester and NIHR Manchester Biomedical Research Centre, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; [3]Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Université de Paris, Department of Rheumatology, Paris, France; [4]PRES Sorbonne Paris-Cité, INSERM (U1153): Clinical Epidemiology and Biostatistics, Paris, France; [5]Brigham and Women's Hospital and Harvard Medical School, Department of Cardiovascular Medicine, Boston, MA, United States of America; [6]Columbia University Vagelos College of Physicians and Surgeons, Division of Rheumatology, New York, NY, United States of America; [7]Mayo Clinic, Division of Rheumatology, Rochester, MN, United States of America; [8]University of North Carolina at Chapel Hill, Department of Biostatistics, Chapel Hill, NC, United States of America; [9]Pfizer Ltd, Inflammation and Immunology, Tadworth, Surrey, United Kingdom; [10]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America; [11]Pfizer SLU, Inflammation and Immunology, Madrid, Spain; [12]Pfizer Inc, Inflammation and Immunology, Oslo, Norway; [13]University of Debrecen, Division of Rheumatology, Faculty of Medicine, Debrecen, Hungary*

Background: ORAL Surveillance (NCT02092467) was a post-approval safety study of tofacitinib vs TNF inhibitors (TNFi) in rheumatoid arthritis (RA) patients (pts) aged ≥50 yrs with ≥1 additional cardiovascular (CV) risk factor and an inadequate response to methotrexate (MTX).

Objectives: To identify independent risk factors for major adverse CV events (MACE) in ORAL Surveillance.

Methods: Pts on stable MTX were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (adalimumab 40 mg every 2 weeks or etanercept 50 mg once weekly). Incidence rates (IRs; pts with first events/100 pt-yrs) and hazard ratios (HRs; tofacitinib vs TNFi) were assessed for adjudicated MACE (total/fatal/non-fatal), sudden cardiac death, and total/fatal/non-fatal myocardial infarction (MI) and stroke. Post hoc univariate Cox model analyses identified potentially independent baseline (BL) risk factors for MACE across treatments; those with p<0.10 were entered into a multivariate Cox model using backward selection (p<0.10 stay criteria). MACE HRs were produced for subgroups for BL risk factors with p<0.05 in the final multivariate Cox model.

Results: 4362 pts were included (tofacitinib 5 mg BID, n=1455; tofacitinib 10 mg BID, n=1456; TNFi, n=1451). IRs for total/fatal/non-fatal MACE, sudden cardiac death, and total/non-fatal MI were higher with tofacitinib vs TNFi (Table 1). Fatal MI and stroke (including fatal/non-fatal events) IRs were similar across treatments (Table 1). Total MACE and MI IRs and risk were higher with tofacitinib vs TNFi (HRs >1) and higher for non-fatal MI for tofacitinib 5 mg BID (Table 1). Current smoking, aspirin use, history of chronic lung disease, history of diabetes, male sex and older age were BL risk factors for MACE. While MACE risk was generally higher with tofacitinib vs TNFi across all BL risk factors, increased risk was clearest in current/past smokers (vs never smoked) and aspirin users (vs non-users) (Figure 1). When age and smoking status were considered in combination, pts aged ≥65 yrs or who had ever smoked had a particularly elevated MACE risk vs never smokers aged ≥50–<65 yrs (Figure 1).

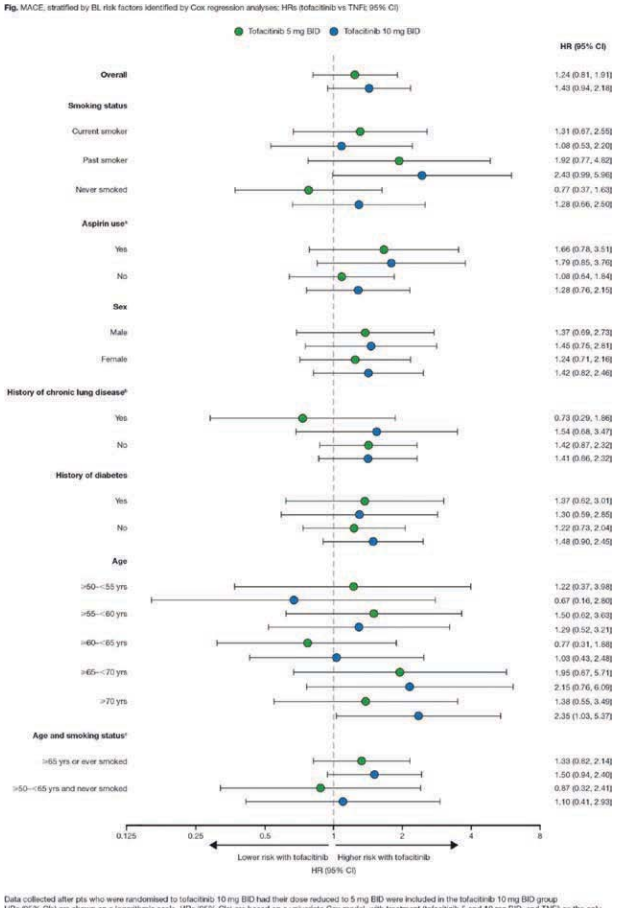

Table 1. MACE, MI and stroke IRs (pts with first events/100 pt-yrs; 95% CI) and HRs (tofacitinib vs TNFi; 95% CI)

	Tofacitinib 5 mg BID (N=1455)			Tofacitinib 10 mg BID (N=1456)			TNFi (N=1451)	
	n	IR (95% CI)	HR (95% CI)	n	IR (95% CI)	HR (95% CI)	n	IR (95% CI)
MACE	47	0.91 (0.67, 1.21)	1.24 (0.81, 1.91)	51	1.05 (0.78, 1.38)	1.43 (0.94, 2.18)	37	0.73 (0.52, 1.01)
Fatal MACE	14	0.27 (0.15, 0.45)	1.14 (0.53, 2.47)	19	0.39 (0.23, 0.60)	1.63 (0.79, 3.36)	12	0.24 (0.12, 0.41)
Non-fatal MACE	33	0.64 (0.44, 0.90)	1.29 (0.77, 2.17)	32	0.66 (0.45, 0.93)	1.33 (0.79, 2.24)	25	0.50 (0.32, 0.73)

MI	19	0.37 (0.22, 0.57)	1.69 (0.80, 3.55)	19	0.39 (0.23, 0.61)	1.80 (0.85, 3.77)	11	0.22 (0.11, 0.39)
Fatal MI	0	0 (0.00, 0.07)	NI	3	0.06 (0.01, 0.18)	1.03 (0.21, 5.11)	3	0.06 (0.01, 0.17)
Non-fatal MI	19	0.37 (0.22, 0.57)	2.32 (1.02, 5.30)[a]	16	0.33 (0.19, 0.53)	2.08 (0.89, 4.86)	8	0.16 (0.07, 0.31)
Stroke	18	0.35 (0.21, 0.55)	1.03 (0.53, 2.00)	18	0.37 (0.22, 0.58)	1.10 (0.57, 2.13)	17	0.34 (0.20, 0.54)
Fatal stroke	4	0.08 (0.02, 0.20)	NI	2	0.04 (0.00, 0.15)	NI	0	0.00 (0.00, 0.07)
Non-fatal stroke	14	0.27 (0.15, 0.45)	0.80 (0.40, 1.63)	16	0.33 (0.19, 0.53)	0.97 (0.49, 1.93)	17	0.34 (0.20, 0.54)

[a]HR 95% CI excludes 1. Data collected after pts who were randomised to tofacitinib 10 mg BID had their dose reduced to 5 mg. BID were included in the tofacitinib 10 mg BID group. HRs (95% CI) were not informative when one of the treatments in the comparison had 0 events. Risk period was defined as time from first dose to last dose +60 days or to the last contact date, whichever was earlier. CI, confidence interval; NI, non-informative

Conclusion: MACE IRs and risk were higher with tofacitinib vs TNFi in ORAL Surveillance. BL risk factor findings could aid identification of RA pts with potentially highest risk for MACE, with a view to informing treatment decisions.

POS0675 IMPACT OF PAST USE OF DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ON JAK INHIBITOR TREATMENT FOR RHEUMATOID ARTHRITIS - DATA FROM THE FUKUI ISHIKAWA TOYAMA DATABASE OF RHEUMATOID ARTHRITIS

M. Konishi[1], I. Mizushima[1], M. Kawano[1], T. Murayama[2], S. Nakazaki[2], K. Shinoda[3], T. Kido[3], Y. Katsuki[4], H. Fujinaga[5], T. Watanabe[5], H. Motomura[6], I. Matsushita[7]. [1]*Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan;* [2]*Jouhoku Hospital, Department of Rheumatology, Kanazawa, Japan;* [3]*Toyama University Hospital, Department of Rheumatology, Toyama, Japan;* [4]*Yawata Medical Center, Department of Orthopedic Surgery, Komatsu, Japan;* [5]*Toyama Prefectural Central Hospital, Rheumatoid and Japanese-Chinese Clinical Department, Toyama, Japan;* [6]*Takaoka Rheumatism Orthopedic Surgery Clinic, Department of Orthopedic Surgery, Takaoka, Japan;* [7]*Kanazawa Medical University Hospital, Department of Rehabilitation Medicine, Uchinada, Japan*

Background: Currently, five types of Janus kinase inhibitors (JAKis) are used for rheumatoid arthritis (RA) treatment. The number of cases in which multiple JAKis have been prescribed is increasing. However, the real-world efficacy and safety of JAKis and related factors require further evaluation.
Objectives: The primary objective of this study was to elucidate the impact of past use of disease-modifying anti-rheumatic drugs on RA treatment using JAKis. The secondary objective was to investigate the safety profiles of these agents in a real-world setting.
Methods: Of the 303 JAKi-treated patients in the Fukui Ishikawa Toyama Database of RA included in this study, 30 had switched from one JAKi to another (JJ group), 214 switched from a biologic agent to a JAKi (BJ group), and 47 were naïve to either biologics or JAKis (NJ group). We compared baseline factors, treatment response, and JAKi continuation rates among the three groups. Factors related to JAKi discontinuation were assessed using Cox regression analysis. Furthermore, we investigated adverse events and reported them using exposure-adjusted incidence rates (EAIR; incidence rates per 100 patient-years).
Results: Data from the 303 cases were analyzed (mean age = 63.6 years; female, 82%; mean RA duration, 176 months). Of the 303 patients, 118, 106, 50, and 29 were treated with tofacitinib, baricitinib, peficitinib, and upadacitinib, respectively, on initial observation. Rate of concomitant use with methotrexate and prednisolone was 52% and 49%, respectively.
Regarding efficacy, no significant differences were observed among the three groups in terms of treatment response and JAKi continuation rates, except for the 6-month treatment response between the JJ and NJ groups. Cox regression analysis of the 303 cases revealed that only past use of JAKis during the disease history was significantly associated with JAKi discontinuation. The Kaplan–Meier method showed that patients who previously used JAKis had significantly shorter median JAKi treatment duration than those without such a history (20.9 vs. 54.7 months; p = 0.012). Treatment response was significantly poor in patients who had previously used JAKis, especially 6 months after treatment initiation. In terms of safety, the total exposure period for the 303 cases was 495 person-years, and the total number of adverse events was 161 (EAIR, 32.5). There were 12 cases (EAIR, 2.5) of serious infections, 23 cases (EAIR, 5.1) of herpes zoster, 7 cases (EAIR, 1.4) of malignant tumors, and 4 cases (EAIR, 0.8) of MACE. Adverse events led to JAKi discontinuation in 34 patients (EAIR, 6.9); the main causes of adverse events leading to treatment discontinuation were infectious diseases in 10 cases (EAIR, 2) and neoplasms in 4 cases (EAIR, 0.8). Within 1 year of initiating JAKi therapy, 21 patients discontinued treatment owing to adverse events, which accounted for 27% of the reasons for treatment discontinuation. We also investigated cases of JAKi dose reduction, observed in 42 of the 303 cases. Among them, 10 patients required a re-increase in the JAKi dose, and 13 patients (56.5%) were able to maintain the reduced dose for more than 1 year. The remaining 19 patients were excluded from the analysis because the treatment duration at the lower dose had not exceeded 1 year at the time of data extraction. No difference in disease activity at the time of dose reduction was observed between those who maintained the new dose and those who did not (mean DAS28-CRP: 1.48 ± 0.26 vs. 1.89 ± 0.62).
Conclusion: Past use of JAKis may contribute to decreased response and continuation rates for JAKi treatment. In this study, conducted in Japan, development of herpes zoster was found to the most frequent adverse event among the priority survey items.

Background: Filgotinib (FIL) is a Janus kinase 1 preferential inhibitor for the treatment of moderate to severe rheumatoid arthritis (RA)[1]. The recommended dose for adults with RA is 200 mg (FIL200); however, a starting dose of 100 mg (FIL100) is recommended for those aged ≥75 years (y) in view of limited clinical experience[1]. An important consideration is the generally higher incidence of adverse events (AEs) in the elderly due to comorbidities.
Objectives: To evaluate the efficacy and safety of FIL100 and FIL200 in patients with RA aged ≥75 y.
Methods: FINCH 4 (NCT03025308) is an ongoing phase 3 open-label LTE study of FIL100 and FIL200 for RA. Eligible patients completed a prior phase 3 randomized double-blind study of FIL lasting 52 weeks (FINCH 1 or 3) or 24 weeks (FINCH 2). In this *post hoc* analysis, safety and efficacy were assessed in patients aged <75 and ≥75 y in FINCH 4. Efficacy measures were American College of Rheumatology (ACR)20/50/70 responses, clinical disease activity index (CDAI) ≤10/≤2.8, disease activity score (DAS)28 <2.6/≤3.2 and health assessment questionnaire-disability index (HAQ-DI).
Results: At LTE Week 48, 52% and 44% of patients aged <75 and ≥75 y, respectively, were on methotrexate. In both age groups, response rates for key efficacy measures at LTE Week 48 were generally maintained from LTE baseline (Figure 1) in patients with and without prior FIL exposure in FINCH 1–3, and were numerically higher with FIL200 vs FIL100. Mean change from baseline in

HAQ-DI with FIL200 and FIL100 was 0.61 and 0.74 in those aged <75 y and 1.04 and 0.98 in those aged ≥75 y, respectively.

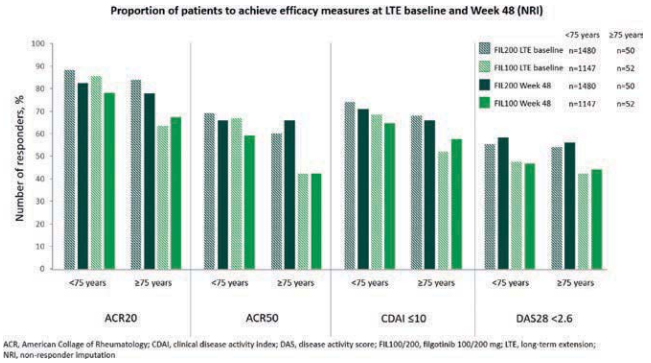

Figure 1.

The exposure-adjusted incidence rate (EAIR) of serious AEs and AEs of special interest (AESI) was generally higher in patients aged ≥75 y than <75 y. In those aged ≥75 y, the EAIR of AEs leading to premature study discontinuation, treatment-emergent AEs (TEAEs), and serious TEAEs was higher with FIL200 vs FIL100; the incidence of major adverse cardiovascular events, venous thrombotic and embolic events, serious infections, herpes zoster and malignancies was low in both dose groups (Table 1). Three patients died, all from the FIL200 group; each had a medical history relevant to the cause of death.

Table 1. Exposure-adjusted incidence rate (95% CI) of AEs at Week 48 as events per 100 years of exposure

	FIL200		FIL100	
Age, years	<75	≥75	<75	≥75
	n=1469	n=61	n=1136	n=63
	(PYE 2253.9)	(PYE 92.2)	(PYE 1753.7)	(PYE 98.4)
With prior FIL exposure, n (%)	1142 (77.7)	53 (86.9)	830 (73.1)	33 (52.4)
TEAE	48.3 (45.5, 51.3)	55.3 (42.1, 72.8)	48.7 (45.5, 52.1)	42.7 (31.6, 57.8)
Serious TEAE	6.8 (5.8, 8.0)	17.4 (10.6, 28.3)	7.4 (6.2, 8.7)	14.2 (8.4, 24.0)
AE leading to premature study discontinuation	2.9 (2.3, 3.7)	9.8 (5.1, 18.8)	3.9 (3.1, 5.0)	4.1 (1.5, 10.8)
AE leading to death	0.5 (0.3, 0.9)	3.3 (0.7, 9.5)*	0.3 (0.2, 0.8)	0.0 (0.0, 3.8)
Infections	28.8 (26.6, 31.1)	29.3 (20.1, 42.7)	27.4 (25.0, 29.9)	26.4 (18.0, 38.8)
Serious infections	1.6 (1.2, 2.2)	2.2 (0.5, 8.7)	1.7 (1.1, 2.4)	3.1 (1.0, 9.5)
Herpes zoster	1.6 (1.2, 2.3)	2.2 (0.5, 8.7)	1.0 (0.6, 1.6)	3.1 (1.0, 9.5)
Adjudicated major adverse cardiovascular event	0.4 (0.2, 0.7)	2.2 (0.5, 8.7)	0.5 (0.2, 0.9)	1.0 (0.1, 7.2)
Venous thrombotic and embolic events	0.3 (0.1, 0.6)	2.2 (0.5, 8.7)	0.2 (0.1, 0.5)	1.0 (0.1, 7.2)
Malignancy excluding NMSC	0.7 (0.4, 1.2)	4.3 (1.6, 11.6)	0.7 (0.4, 1.2)	3.1 (1.0, 9.5)
NMSC	0.4 (0.2, 0.8)	1.1 (0.0, 6.0)	0.2 (0.1, 0.6)	0.0 (0.0, 3.8)

*Cause of death: esophageal carcinoma; cardiovascular; unknown. FIL(100/200), filgotinib (100/200 mg); NMSC, nonmelanoma skin cancer; PYE, patient years of exposure; (TE)AE, (treatment-emergent) adverse event

Conclusion: In the ≥75 y group, response rates for key efficacy measures remained stable to Week 48 and were generally higher with FIL200 vs FIL100. The incidence of serious AEs and AESI was higher in those aged ≥75 than <75 y. Patient numbers/exposure time may have been insufficient to show potential between-group differences in safety/efficacy outcomes.

POS0677 CONSISTENCY IN TIME TO RESPONSE WITH UPADACITINIB AS MONOTHERAPY OR COMBINATION THERAPY AND ACROSS PATIENT POPULATIONS WITH RHEUMATOID ARTHRITIS

A. Rubbert-Roth[1], B. Combe[2], Z. Szekanecz[3], S. Hall[4], B. Haraoui[5], S. Attar[6], A. K. H. Ekwall[7], Y. Song[8], T. Shaw[9], O. Nagy[8], R. Xavier[10]. *[1]Cantonal Hospital St. Gallen, Rheumatology, St. Gallen, Switzerland; [2]Montpellier University, Rheumatology, Montpellier, France; [3]University of Debrecen, Rheumatology, Debrecen, Hungary; [4]Monash University, Rheumatology, Melbourne, Australia; [5]Institut de Rhumatologie de Montréal, Rheumatology, Montreal, Canada; [6]King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia; [7]University of Gothenburg, Rheumatology, Gothenburg, Sweden; [8]AbbVie Inc., Immunology, North Chicago, United States of America; [9]AbbVie Ltd., Immunology, Maidenhead, United Kingdom; [10]Universidade Federal do Rio Grande do Sul, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

Background: Upadacitinib (UPA) has demonstrated efficacy in patients with moderate-to-severe rheumatoid arthritis (RA) across various patient populations.[1–4]

Objectives: This post hoc analysis aimed to evaluate the consistency in time to achieving meaningful clinical response with UPA 15 mg + conventional synthetic (cs) DMARDs in biologic (b) DMARD-inadequate responder (IR) versus csDMARD-IR patients with RA as well as with UPA 15 mg monotherapy versus UPA 15 mg + csDMARDs in csDMARD-IR patients.

Methods: Patients originally randomized to UPA 15 mg once daily from four Phase 3 trials were included in this analysis: SELECT-BEYOND[1] and SELECT-CHOICE[2] (UPA 15 mg + csDMARDs in bDMARD-IR patients), SELECT-NEXT[3] (UPA 15 mg + csDMARDs in csDMARD-IR patients), and SELECT-MONOTHERAPY[4] (UPA 15 mg monotherapy in methotrexate-IR patients). Time to response was estimated using the Kaplan–Meier method for clinical outcomes over 24 weeks (26 weeks in SELECT-MONOTHERAPY). Clinical outcomes included achievement of 28-joint Disease Activity Score with C-reactive protein (DAS28[CRP]) ≤3.2; low disease activity (LDA) defined as Clinical Disease Activity Index (CDAI) ≤10 and Simple Disease Activity Index (SDAI) ≤11; and 50% improvement in American College of Rheumatology (ACR) core components and morning stiffness (MS) duration/severity. Data presented were as observed.

Results: Overall, 905 patients were included (SELECT-BEYOND: n=164; SELECT-CHOICE: n=303; SELECT-NEXT: n=221; SELECT-MONOTHERAPY: n=217). csDMARD-IR patients had a mean disease duration of 7.3 (SELECT-NEXT) or 7.5 years (SELECT-MONOTHERAPY); bDMARD-IR patients had a mean disease duration of 12.4 years, with a more refractory population (≥3 prior bDMARDs) in SELECT-BEYOND (23%) than SELECT-CHOICE (10%). In general, the median time to DAS28(CRP) ≤3.2, CDAI LDA, 50% improvement in ACR core components, and 50% improvement in MS duration/severity were consistent across the studies in bDMARD-IR and csDMARD-IR patients. For SELECT-BEYOND, SELECT-CHOICE, SELECT-NEXT, and SELECT-MONOTHERAPY, the median (95% CI) time to achieve DAS28(CRP) ≤3.2 was 12 (12, 16), 12 (8, 12), 12 (8, 12), and 14 (8, 14) weeks, respectively (Figure 1), and the median time to achieve CDAI LDA was 20 (12, 24), 16 (12, 16), 16 (12, 16), and 20 (14, 20) weeks, respectively (Figure 2). A longer median (95% CI) time to achieve SDAI LDA was observed with UPA monotherapy (20 [14, 20] weeks) versus UPA + csDMARDs (12 [12, 16] weeks) in csDMARD-IR patients. Among bDMARD-IR patients, the median (95% CI) time to 50% improvement in pain was longer in SELECT-BEYOND versus SELECT-CHOICE (16 [12, 20] versus 8 [8, 12] weeks).

Conclusion: In diverse patient populations with RA, patients treated with UPA 15 mg, as monotherapy or with csDMARDs, generally demonstrated consistent

time to achieving DAS28(CRP) ≤3.2, CDAI LDA, and 50% improvement in clinical outcomes.

CLINICAL OUTCOMES OF METHOTREXATE (MTX)-NAIVE RHEUMATOID ARTHRITIS (RA) PATIENTS (PTS) ON FILGOTINIB (FIL) LONG-TERM EXTENSION (LTE) TRIAL INITIALLY ON FIL OR MTX DURING THE PHASE 3 PARENT STUDY (PS)

D. Aletaha[1], R. Westhovens[2], T. Atsumi[3], Y. Tan[4], A. Pechonkina[4], Q. Gong[5], V. Rajendran[6], S. Strengholt[7], G. R. Burmester[8]. *[1]Medical University of Vienna, Division of Rheumatology, Vienna, Austria; [2]University Hospitals KU Leuven, Rheumatology Department, Leuven, Belgium; [3]Hokkaido University, Department of Rheumatology, Hokkaido, Japan; [4]Gilead Sciences, Inc., Clinical Development, Foster City, United States of America; [5]Gilead Sciences, Inc., Biostatistics, Foster City, United States of America; [6]Galapagos NV, Clinical Development, Mechelen, Belgium; [7]Galapagos BV, Medical Affairs, Leiden, Netherlands; [8]Charité University Hospital Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: The preferential Janus kinase-1 inhibitor FIL is approved for treatment of moderate to severe active RA in Europe and Japan.

Objectives: In this post hoc, exploratory analysis, efficacy and safety of long-term treatment with FIL (± MTX) were assessed in MTX-naïve pts treated with FIL or MTX in the Phase 3 PS (NCT02886728).[1]

Methods: Pts received FIL 200 mg (FIL200)+MTX, FIL 100 mg (FIL100)+MTX, FIL200 alone, or MTX alone up to 52W in PS.[1] Those completing PS on study drug could enter LTE (NCT03025308; data cutoff: June 1, 2020). MTX completers were rerandomized, blinded, to FIL200 or FIL100; pts on FIL in PS remained on the same dose in LTE. MTX was washed out for 4W at LTE baseline (BL); pts could (re)start MTX and/or other conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) ≥4W after LTE first dosing.[1] Efficacy data to LTE W48 and safety data are reported.

Results: As of June 1, 2020, 439/492 (89%) and 144/169 (85%) pts who entered LTE from PS FIL200 and PS FIL100 groups, respectively, remained on LTE study treatment; of those rerandomized from MTX, 131/148 (89%) FIL200 and 133/151 (88%) FIL100 pts remained on study treatment. LTE BL characteristics were similar between FIL200 and FIL100 groups. After MTX washout, 17% of FIL200 and 23% of FIL100 pts (re)started MTX (at clinical judgment). ACR20/50/70 response rates among pts from PS FIL arms decreased modestly from LTE BL to W12 then stabilized. Among pts who switched from PS MTX to LTE FIL, response rates remained stable or improved to approach those of PS FIL pts by W48 (Figure 1). Similar trends were seen in DAS28(CRP) and CDAI. Treatment-emergent adverse events (TEAEs), Grade ≥3 AEs, serious AEs, and infections were largely comparable across groups and did not increase after MTX to FIL switch. There were 6 deaths, all among PS FIL200 pts (Table 1).

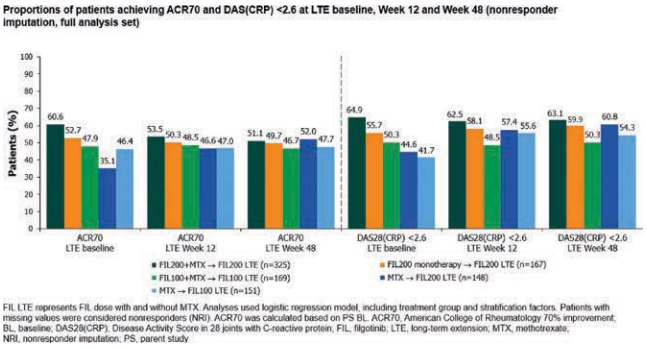

Figure 1.

Conclusion: Overall, response rates improved from LTE BL to W48 for pts switched from PS MTX to FIL and decreased modestly for PS FIL pts. Rates of AEs of special interest were generally low and tended to be higher in pts maintained on FIL from PS. Safety findings in this subpopulation were comparable with the PS through W52[1] and with a 7-trial integrated safety analysis.[2] Limitations: the LTE was not formally randomized at BL, the groups were of unequal size, and the switch from MTX to FIL for LTE was by design rather than based on disease activity.

CLINICAL OUTCOMES UP TO WEEK (W) 48 IN THE ONGOING FILGOTINIB (FIL) LONG-TERM EXTENSION (LTE) TRIAL OF RHEUMATOID ARTHRITIS (RA) PATIENTS (PTS) WITH INADEQUATE RESPONSE (IR) TO METHOTREXATE (MTX) INITIALLY TREATED WITH FIL OR ADALIMUMAB (ADA) DURING THE PHASE 3 PARENT STUDY (PS)

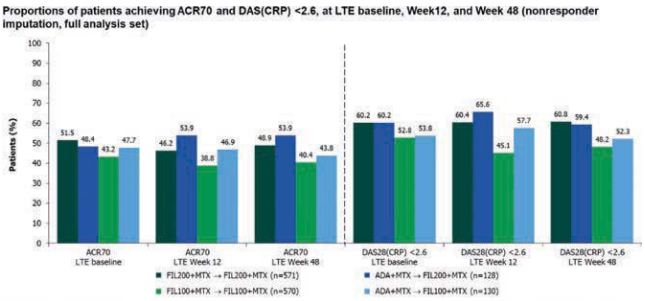
B. Combe[1], Y. Tanaka[2], P. Emery[3], A. Pechonkina[4], A. Kuo[4], Q. Gong[5], K. Van Beneden[6], V. Rajendran[7], H. Schulze-Koops[8]. *[1]University of Montpellier, Rheumatology Department, Montpellier, France; [2]University of Occupational and Environmental Health,The First Department of Internal Medicine, Fukuoka, Japan; [3]University of Leeds, Leeds NIHR Biomedical Research Centre, LIRMM, Leeds, United Kingdom; [4]Gilead Sciences, Inc., Clinical Development, Foster City, United States of America; [5]Gilead Sciences, Inc., Biostatistics, Foster City, United States of America; [6]Galapagos NV, Medical Affairs, Mechelen, Belgium; [7]Galapagos NV, Clinical Development, Mechelen, Belgium; [8]Ludwig-Maximilians-University, Division of Rheumatology and Clinical Immunology, Department of Medicine IV, Munich, Germany*

Background: The preferential Janus kinase-1 inhibitor FIL is approved for treatment of moderate to severe active RA in Europe and Japan.

Objectives: Efficacy and safety of FIL were assessed in pts with IR to MTX who completed a Phase 3 trial (NCT02889796)[1] and enrolled in an LTE (NCT03025308).

Methods: Pts completing the PS[1] on study drug were eligible to enter the LTE (data cutoff: June 1, 2020). Median exposure: 2.2 years (y). Efficacy data to W48 are reported for 4 treatment groups (all with background MTX): pts receiving FIL 200 mg (FIL200) or FIL 100 mg (FIL100) in the PS and continuing their dose in LTE (FIL200/FIL200, FIL100/FIL100) and ADA pts rerandomized, double blind, to FIL200 or FIL100 for LTE (ADA/FIL200, ADA/FIL100); safety data are reported.

Results: As of June 1, 2020, 522/571 (91%) FIL200/FIL200, 502/570 (88%) FIL100/FIL100, 118/128 (92%) ADA/FIL200, and 115/130 (89%) ADA/FIL100 pts remained on study drug. LTE baseline disease characteristics were similar between groups: mean duration of RA approximately 8.7 y; DAS28(CRP) 2.55, and mean concurrent MTX dosage was 15.0 mg/week. Proportions of pts achieving ACR20/50/70, DAS28(CRP) ≤3.2, <2.6, and CDAI ≤10, ≤2.8 were generally maintained in all LTE groups through W48 (Figure 1). Numerically greater proportions of pts met response criteria at W48 in the FIL200 groups vs FIL100, regardless of PS treatment. Treatment-emergent AEs (TEAE), serious AEs, and AEs Grade ≥3 were largely comparable between groups and lowest in ADA/FIL100. There were 10 deaths (Table 1). Exposure-adjusted incidence rates (EAIRs)/100 pt-y of exposure for deaths were lower for FIL/FIL vs ADA/FIL.



FIL200+MTX and FIL100+MTX groups included patients who were initially on placebo but later were rerandomized at W24 to FIL200+MTX or FIL100+MTX to W52. Analyses used the logistic regression model, including treatment group and stratification factors; no formal comparison of efficacy outcomes was performed. ACR70 was calculated based on PS BL. ACR70, American College of Rheumatology 70% improvement; ADA, adalimumab; BL, baseline; DAS28(CRP), Disease Activity Score in 28 joints with C-reactive protein; FIL, filgotinib; MTX, methotrexate; PS, parent study; W, week

Figure 1.

Conclusion: During the LTE through W48, response rates generally were maintained for FIL/FIL and ADA/FIL pts. Though there were differences between LTE groups, safety was largely comparable and consistent with PS observations[1] and previously reported results from 7 trials[2]: rates of AEs of special interest were low; all confidence intervals were overlapping. Limitation: the LTE was not formally randomized for comparison between FIL/FIL and ADA/FIL treatment groups, the groups were of unequal size, and the switch from ADA to FIL for LTE was by design, rather than based on disease activity.

PHYSICIANS' REASONS FOR PRESCRIBING JANUS KINASE INHIBITORS (JAKI) IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA), AND ASSOCIATED ALIGNMENT BETWEEN PHYSICIANS AND PATIENTS IN A REAL-WORLD CLINICAL SETTING

P. C. Taylor[1], B. Fautrel[2], Y. Piette[3], S. Romero-Yuste[4], J. Broen[5], M. Welcker[6], E. Holdsworth[7], M. Zignani[8], K. Van Beneden[8], R. Caporali[9], R. Alten[10].

Background: Shared decision making, a cornerstone of RA management[1], allows physicians and their patients to make informed decisions about their treatment goals and choice of care. As new treatments become available, it is important to understand rheumatologists' reasons for choosing JAKi.
Objectives: This survey evaluated rheumatologists' clinical and patient centric reasons for choosing JAKi, in addition to exploring alignment between rheumatologists and RA patients in terms of treatment choice and satisfaction.
Methods: The Adelphi RA Disease Specific Programme™[2] is a large, multinational, point-in-time survey conducted amongst rheumatologists and their consulting patients with RA in Europe (Belgium, France, Germany, Italy, Spain, UK) between January and October 2020. Physicians completed record forms for up to 10 consecutive RA patients, collecting demographic, clinical and treatment data, and reasons for current treatment choice. Patients were invited to complete a patient questionnaire to assess their satisfaction with ongoing treatment (5-point scale), and perceptions of shared decision making for the current treatment.
Results: 316 rheumatologists provided data for 3121 patients, of whom 1130 (36.2%) completed patient reported questionnaires. Overall, 67% were female, mean age was 53 years (SD 14), 23% had moderate-high disease activity score (DAS28: >3.2). 68% of patients were currently receiving either a biologic or targeted synthetic disease-modifying antirheumatic drug (DMARD; defined here as advanced therapy, AT), 72% were on first line AT. Overall, physicians and their patients were aligned that a conversation took place about a treatment decision (n=855, 79% net alignment), and this was a shared treatment decision (n=814, 75% net alignment). 15% of patients not taking an AT were reported to have a clinical condition warranting one; reasons for not taking AT included patients' concerns about infection (24%), conventional synthetic DMARDs were tolerable and safe in the patient (18%), and patient dislike of infusions/injections (17%). Of 2143 patients receiving AT, 19% were prescribed JAKi; 57% as monotherapy, 43% as combination therapy. For physician stated reasons for choice of JAKi, factors were driven by both perceptions of clinical efficacy and onset of action, as well as factors relating to patient acceptability such as method of delivery and ease of use (Table 1). With respect to JAKi treatment (n=135 patient-physician pairs), 62% of physicians and their patients were aligned on satisfaction, however 30% of patients reported less satisfaction than their consulting physician (Figure 1).

Table 1. Physician stated clinical and patient centric reasons for prescribing a JAKi in their patients with RA (data are percentage of patients; n=397)

Reasons for prescribing JAKi	Patients (%)
Top 5 clinical reasons	
Strong overall efficacy	74
Fast onset of action	49
Inhibition of disease progression	42
Strong efficacy as monotherapy	39
Achievement of clinical remission	37
Top 5 patient centric reasons	
Acceptability of method of delivery for the patient	39
Enabling patient to perform everyday tasks/activities	36
Ease of product use (for the patient)	33
Improvement or maintenance of quality of life	30
Improving patient's mood/state of mind	14

Conclusion: Communicating the choice of pharmacological therapy to patients with RA has become increasingly complex for physicians with expansion of approved treatments. In this subgroup of patients on JAKi, the drug attributes considered as reasons for prescribing were driven by clinical factors as well as by patient centric attributes. Although communications between patients and physicians were largely aligned, better understanding of patient expectations might serve to improve messaging about treatment options and resulting satisfaction.

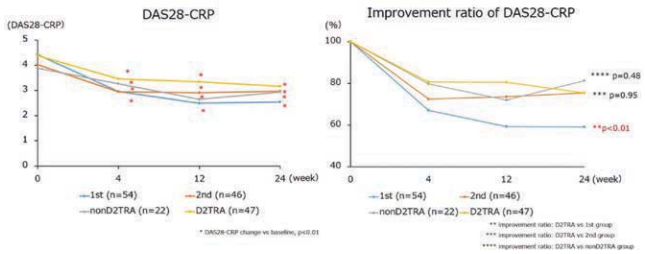
POS0681 DRUG RETENTION RATE AND EFFECTIVENESS OF JAK INHIBITOR IN PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

S. Anno[1,2,3], T. Okano[1], K. Mandai[4], K. Orita[3], Y. Yamada[1], K. Mamoto[1], T. Iida[5,6], M. Tada[7], K. Inui[4], T. Koike[8,9], H. Nakamura[1]. *[1]Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan; [2]Osaka Social Medical Center, Orthopaedic Surgery, Osaka, Japan; [3]Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; [4]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan; [5]Koryokai Hospital, Orthopaedic Surgery, Osaka, Japan; [6]Takahiro Clinic, Orthopaedic Surgery, Nishinomiya, Japan; [7]Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan; [8]Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; [9]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan*

Background: Recently, the disease activity of rheumatoid arthritis (RA) was improved due to the 'treat-to-target' strategy. However, some patients remain various symptoms despite recommended treatment was performed. Then, the term of 'difficult-to-treat RA (D2TRA)' is widely recognized. Janus kinase inhibitor (JAKi) might be effective for D2TRA patients, because JAKi can simultaneously block the function of multiple cytokines.
Objectives: The aim of this study was to evaluate drug retention rate and effectiveness of JAKi in patients with D2TRA.
Methods: This study included 220 RA patients (tofacitinib 101, baricitinib 83, upadacitinib 20, peficitinib 14, filgotinib 2) treated with JAKi. Sixty-two patients were treated as first line bDMARDs/JAKi (1st group), 57 patients were treated as second line bDMARDs/ JAKi (2nd group), 101 patients were treated as third and more bDMARDs/ JAKi. In these 101 patients, 25 patients did not met D2TRA criteria (non-D2TRA group) and 76 patients met D2TRA criteria (D2TRA group). Drug retention rate and effectiveness of JAKi were evaluated during 24 weeks in each group.
Results: Usage rate of methotrexate was lower and dosage of glucocorticoid was higher in D2TRA group than in other groups (Table 1). Drug retention rate at 24 weeks was 87.1% (54/62) in 1st group, 80.1% (46/57) in 2nd group, 88% (22/25) in non-D2TRA group, 61.8% (47/76) in D2TRA group. Drug retention rate was lower in D2TRA group compared to 1st group, 2nd group and non-DT2RA group (p<0.01, p=0.03, p=0.01). DAS28-CRP was 4.4, 4.0, 3.9, 4.4 at baseline, 3.0, 3.0, 3.3, 3.5 at 4 weeks, 2.5, 2.9, 2.7, 3.3 at 12 weeks, 2.5, 3.0, 2.9, 3.2 at 24 weeks in 1st group, 2nd group, non-D2TRA group and D2TRA group, respectively. Improvement ratio of DAS28-CRP was 32.9, 27.6, 20.4, 19.3 % at 4 weeks, 40.8, 26.5, 28.1, 19.5 % at 12 weeks, 40.8, 24.6, 18.7, 24.7 % at 24 weeks. DAS28-CRP was improved in all groups. Altough 1st group showed higher improvement ratio of DAS28-CRP at 24 weeks compared to 2nd group, non-DT2RA group and D2TRA group (p<0.01, p<0.01, p<0.01), there was no differences between DT2RA group and 2nd group or non-D2TRA group (p=0.95, p=0.48). SDAI was 22.9, 19.9, 18.3, 23.9 at baseline, 11.8, 11.9, 13.3, 14.4 at 4 weeks, 7.9, 11.3, 8.4, 13.3 at 12 weeks, 8.5, 11.5, 9.7, 12.6 at 24 weeks. CDAI was 21.3, 18.8, 17.6, 21.8 at baseline, 11.3, 11.2, 12.5, 13.9 at 4 weeks, 7.5, 10.9, 8.0, 12.3 at 12 weeks, 8.1, 10.7, 8.6, 12.1 at 24 weeks. HAQ was 1.15, 0.99, 0.89, 1.39 at baseline, 0.84, 0.76, 0.93, 1.22 at 4 weeks, 0.79, 0.84, 0.77, 1.17 at 12 weeks, 0.76, 0.79, 0.76, 1.14 at 24 weeks. Improvement rate of HAQ at 24 weeks were 44.3%, 23.9%, 21.2%, 8.1%.

figure



Conclusion: Drug retention rate of JAKi in treatment of D2TRA group were lower than that of 1st group, 2nd group, and non-D2TRA group. Clinical efficacy of JAKi in D2TRA group were not significantly different to 2nd group and non-D2TRA group. However, HAQ improvement was weak in D2TRA group.

POS0682 LONG-TERM EFFICACY OF BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH INADEQUATE RESPONSE TO BDMARDS: RESULTS FROM RA-BEYOND FOLLOWING 6.9 YEARS OF TREATMENT

R. Caporali[1], D. Aletaha[2], R. Sanmartí[3], T. Takeuchi[4], D. Mo[5], E. Haladyj[5], L. Zaremba-Pechmann[6], P. C. Taylor[7]. *[1]University of Milan, Department of Clinical Sciences & Community Health, Milan, Italy; [2]Medical University of Vienna, Department of Medicine III, Vienna, Austria; [3]Hospital Clínic de Barcelona and IDIBAPS, Rheumatology Department, Barcelona, Spain; [4]Keio University School of Medicine, Division of Rheumatology, Tokyo, Japan; [5]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America; [6]HaaPACS GmbH, HaaPACS GmbH, Schriesheim, Germany; [7]University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Baricitinib (BARI), an oral selective Janus kinase 1/2 inhibitor, is approved for treatment of adults with moderately-to-severely active rheumatoid arthritis (RA). BARI demonstrated efficacy in patients (pts) with RA who have inadequate response to biologic disease-modifying antirheumatic drugs (bDMARD-IR) in a 24-week (wk) phase 3 study, RA-BEACON.[1] BARI efficacy was evaluated up to 3 years (yrs) of treatment in a long-term extension (LTE) study, RA-BEYOND.[2]
Objectives: Disclose long-term efficacy of BARI 4 mg and 2 mg in bDMARD-IR pts in the completed study RA-BEYOND.
Methods: In RA-BEACON, pts were randomized 1:1:1 to BARI 4 mg, 2 mg, or PBO; pts with no response could be rescued after wk 16. Completers to wk 24 could enter with BARI 4 or 2mg RA-BEYOND for up to 360 wks (6.9 yrs). LTE data were analysed by treatment assigned at baseline in RA-BEACON as observed up to time of stepdown (if applicable), study discontinuation, or study completion, whichever occurred earlier. Efficacy response rates (RR) were assessed as proportions of pts with observed data up to wk 360 for low-disease activity (LDA) (SDAI ≤ 11, DAS28-hsCRP ≤ 3.2, CDAI ≤ 10), remission (REM) (SDAI ≤ 3.3, DAS28-hsCRP < 2.6, CDAI ≤ 2.8, Boolean), and physical functioning (HAQ-DI ≤ 0.5). No formal statistical comparisons were conducted.
Results: 156, 152, and 140 pts entered the LTE (4 mg, 2 mg, and PBO, respectively). Pts in BARI 4 and 2 mg arms had higher LDA and REM RR vs PBO at LTE

Table 1. Efficacy outcomes in RA-BEYOND

	BARI 4 mg	27/19 (70.4)	27/20 (74.1)	27/20 (74.1)	27/7 (25.9)	27/7 (25.9)	27/15 (55.6)	27/4 (14.8)	27/7 (25.9)

N: Number of pts with observed data; n: Number of pts with response. [a]Number of wks from randomisation. [b]Treatment groups as assigned at randomisation.

entry (wk 24) (Table 1). PBO-treated pts achieved comparable RR to pts in the BARI 4 mg arm by wk 48 (24 wks after switch to BARI 4 mg) and up to wk 360. Of pts enrolled to RA-BEYOND, approx. 50% in BARI 4 mg, 65% in 2 mg and 61% in PBO remained active at wk 156; 17%, 26% and 26% at wk 360, respectively. SDAI LDA RR were 47%/70% and 61%/74% for pts treated with BARI 4 mg and 2 mg, at wk 156 (yr 3)/ 360 (yr 6.9), respectively; SDAI REM RR were 15%/26% and 26%/26% for BARI 4 mg and 2 mg, at wk 156/360, respectively (Table 1). SDAI and CDAI had comparable RR. DAS-28CRP LDA RR were similar to SDAI and CDAI, while REM RR were about twice those of SDAI and CDAI. HAQ-DI ≤ 0.5 RR was 15%/26% (BARI 4 mg), 21%/15% (BARI 2mg), and 9%/3% (PBO) at 3/6.9 yrs.

Conclusion: In observed data, BARI maintained efficacy and normative physical function bDMARD-IR population up to 6.9 yrs (360 wks).

POS0683

EFFICACY AND SAFETY OF UPADACITINIB IN TNFI-IR PATIENTS WITH RHEUMATOID ARTHRITIS FROM THREE PHASE 3 CLINICAL TRIALS

R. M. Fleischmann[1,2], L. Bessette[3], J. Sparks[4,5], S. Hall[6], M. Jain[7], A. Kakehasi[8], Y. Song[9], S. Meerwein[10], R. Demasi[9], J. Subotticki[9], A. Rubbert-Roth[11]. *[1]Metroplex Clinical Research Center, Department of Medicine, Dallas, Texas, United States of America; [2]University of Texas Southwestern Medical Center, Department of Medicine, Dallas, Texas, United States of America; [3]Laval University, Rheumatology, Quebec City, Quebec, Canada; [4]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, Massachusetts, United States of America; [5]Harvard Medical School, Division of Rheumatology, Inflammation, and Immunity, Boston, Massachusetts, United States of America; [6]Monash University and Emeritus Research, Rheumatology, Melbourne, Australia; [7]Great Lakes Clinical Trials, Rheumatology, Chicago, Illinois, United States of America; [8]Federal University of Minas Gerais, Hospital das Clínicas, Belo Horizonte, Brazil; [9]AbbVie Inc, Immunology, North Chicago, Illinois, United States of America; [10]AbbVie Deutschland GmbH & Co. KG, Immunology, Ludwigshafen, Germany; [11]Cantonal Clinic St. Gallen, Division of Rheumatology, St. Gallen, Switzerland*

Background: For patients with RA who are refractory to biologic DMARDs (bDMARDs), such as tumor necrosis factor inhibitors (TNFis), optimal disease control is less likely to be achieved with subsequent therapy.[1] In line with recommendations from EULAR and ACR, switching to a treatment with a different mechanism of action is appropriate for these patients.

Objectives: To describe the efficacy and safety of upadacitinib (UPA) 15 mg once daily in patients with RA and an inadequate response or intolerance to TNFis (TNFi-IR).

Methods: A post hoc subgroup analysis was conducted in TNFi-IR patients who were treated with UPA 15 mg once daily in three Phase 3 clinical trials: SELECT-BEYOND,[2] -CHOICE,[3] and -COMPARE.[4] For COMPARE, only patients treated with adalimumab and switched to UPA as rescue therapy were included. ≥20/50/70% improvement in ACR criteria, DAS28(CRP), CDAI, and SDAI, as well as change from baseline in HAQ-DI and other patient-reported outcomes (PROs) were reported through 24 weeks. Non-responder imputation was used for all missing categorical outcomes; as observed (COMPARE) or multiple imputation (CHOICE, BEYOND) were used for missing continuous outcomes. Pooled safety results were presented as exposure-adjusted event rates (EAERs) with a cut-off of June 30, 2021.

Results: 568 TNFi-IR patients were included: 146 from BEYOND, 263 from CHOICE, and 159 from COMPARE. Mean duration since RA diagnosis was longer for BEYOND and CHOICE versus COMPARE; cardiovascular (CV) risk factors were common among this refractory population (Table 1). ACR20/50/70 and disease activity outcomes observed in the TNFi-IR population were generally consistent with the overall BEYOND[2] and CHOICE[3] bDMARD-IR populations, and consistent across the three studies in the TNFi-IR subgroups (Figure 1). Improvements in PROs including HAQ-DI, fatigue, pain, and morning stiffness over 24 weeks were observed (data not shown). Pooled safety results reporting 1574.8 patient-years (PY) of exposure in the TNFi-IR subgroup showed similar results to the overall BEYOND[2] and CHOICE[3] bDMARD-IR study populations, with EAERs of 3.1 events/100 PY for herpes zoster and 0.8 events/100 PY for adjudicated major adverse CV events, adjudicated venous thromboembolism (VTE), and malignancy excluding non-melanoma skin cancer. The EAER of any AE leading to death was 1.4 events/100 PY.

Table 1. Baseline characteristics of TNFi-IR patients treated with UPA 15 mg

n (%), unless specified	SELECT-BEYOND (n=146)	SELECT-CHOICE (n=263)	SELECT-COMPARE (ADA → UPA) (n=159)
Female	122 (83.6)	219 (83.3)	133 (83.6)
Mean (SD) age, years	56.6 (11.0)	55.5 (11.1)	53.9 (10.6)
Mean (SD) duration of RA diagnosis, years	13.2 (9.5)	12.5 (9.4)	8.2 (8.5)
Concomitant csDMARDs			
MTX alone	100 (70.4)	195 (74.1)	159 (100.0)
MTX and other csDMARDs	20 (14.1)	25 (9.5)	0
csDMARDs other than MTX	22 (15.5)	38 (14.4)	0
Concomitant oral steroids	73 (50.0)	140 (53.2)	98 (61.6)
1 prior bDMARD	68 (46.6)	172 (65.4)	142 (89.3)
2 prior bDMARDs	40 (27.4)	62 (23.6)	17 (10.7)[a]
≥3 prior bDMARDs	38 (26.0)	29 (11.0)	0
Failed ≥1 prior TNFi due to lack of efficacy[b]	131 (89.7)	223 (84.8)	159 (100.0)
History of VTE / CV event	3 (2.1) / 28 (19.2)	6 (2.3) / 20 (7.6)	4 (2.5) / 14 (8.8)
CV risk factors			
Hypertension	72 (49.3)	109 (41.4)	68 (42.8)
Diabetes mellitus	22 (15.1)	34 (12.9)	17 (10.7)
Smoking (current former past)	68 (46.6)	109 (41.5)	55 (34.6)
Elevated LDL-C (≥3.36 mmol/L)	38 (26.0)	52 (20.0)	48 (30.2)
Low HDL-C (≤1.55 mmol/L)	80 (54.8)	171 (65.0)	88 (55.3)

[a]These patients received one bDMARD before entry into SELECT-COMPARE.[b]Remaining patients were intolerant to ≥1 prior TNFi.

Conclusion: In this post hoc subgroup analysis, TNFi-IR patients treated with UPA 15 mg achieved clinically meaningful efficacy responses over 24 weeks, with safety consistent with the overall bDMARD-IR patient population in the Phase 3 program.

POS0684

IS UPADACITINIB CAPABLE OF IMPROVING PATIENT-REPORTED OUTCOMES OF RHEUMATOID ARTHRITIS IN A REAL-WORLD SETTING? RESULTS FROM THE POST-MARKETING OBSERVATIONAL UPWARDS STUDY

T. Witte[1], U. Kiltz[2], F. Haas[3], E. Riechers[1], U. Prothmann[4], D. Adolf[5], C. Holland[6], A. Roessler[6], K. Famulla[7], K. Götz[7], K. Krueger[8]. *[1]Hannover Medical School, Department for Rheumatology and Immunology, Hannover, Germany; [2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [3]Internistisch-Rheumatologische Facharztpraxis, Rheumatology, Tübingen, Germany; [4]Knappschaftsklinikum Saar, Rheumatology, Püttlingen, Germany; [5]StatConsult GmbH, Statistics, Magdeburg, Germany; [6]AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany; [7]AbbVie Germany GmbH & Co. KG, Immunology, Wiesbaden, Germany; [8]Praxiszentrum St. Bonifatius, Rheumatology, München, Germany*

Background: The efficacy of Upadacitinib (UPA), a selective Janus kinase inhibitor, has been evaluated in the SELECT clinical program [1-6]. In addition, recent results from the non-interventional UPwArds study further confirmed UPAs clinical effectiveness regarding standard disease activity scores for rheumatoid arthritis (RA) in a real-world setting [7]. However, patient-reported outcomes (PROs) as another cornerstone of clinical decision making yet remain to be addressed in the context of a post-marketing setting. This interim analysis, conducted after 250 patients had completed the 6-month follow-up visit, aims to fill this gap.

Objectives: To evaluate the change of selected PROs over 6 months in patients treated with UPA in a real-world data environment.

Methods: UPwArds is a prospective, open-label, multicenter, non-interventional, post-marketing study including adult patients with moderate-to-severe RA (swollen joint count [SJC28] ≥ 3 and inadequate response or intolerance to at least one previous disease-modifying antirheumatic drug). According to the German label, patients were treated with UPA 15 mg once daily, as monotherapy or in combination with methotrexate. For this analysis, the following PROs were included: 0-10 numerical rating scales (NRS) for pain and fatigue, the Health Assessment Questionnaire Disability Index (HAQ-DI), the duration and severity of morning stiffness, the Patient Health Questionnaire 9 (PHQ-9), and the Rheumatoid Arthritis Impact of Disease Questionnaire (RAID). Changes from baseline were evaluated for follow-up periods of 1 month, 3 months, and 6 months. Results are presented for the total sample using descriptive measures reflecting sample size (N), average values (standard deviation) for each assessment and average change scores (standard deviation) for follow-up visits. All data were analyzed as observed, with no imputation of missing data.

Results: 483 patients (369 female, 114 male) were included in the study, with available baseline PRO information for 481 patients. 6-months follow-up data were yet available from 279 patients The baseline average age and disease duration were 58.0 (12.3) years and 9.0 (8.0) years, respectively, whereas the mean initial DAS28-CRP was 4.6 (1.0). At baseline, 60.8% of enrolled patients had previously been treated with biologic or targeted synthetic disease-modifying antirheumatic drugs. Overall, PRO scores improved from baseline throughout month 6 with a considerable amelioration at month 3, which was maintained at month 6. Responses were rapid, with improvement already evident at month 1 (Table 1). The NRS pain as a crucial PRO in RA confirmed the previously described pattern of results seen for most of the other PROs (Figure 1).

Table 1. Baseline scores and average changes from baseline scores

	N	Baseline scores (SD)	N	Change from baseline - month 1 (SD)	N	Change from baseline - month 3 (SD)	N	Change from baseline - month 6 (SD)
Pain (NRS)	481	6.2 (2.2)	393	-2.2 (2.3)	392	-2.5 (2.5)	258	-2.4 (2.4)
Fatigue (NRS)	481	5.5 (2.6)	393	-1.4 (2.3)	393	-1.6 (2.4)	259	-1.5 (2.3)
HAQ-DI	471	1.3 (0.6)	380	-0.2 (0.3)	376	-0.2 (0.4)	253	-0.2 (0.4)
Morning stiffness (duration, minutes)	439	68.9 (63.9)	313	-25.0 (55.3)	296	-29.6 (54.9)	179	-31.6 (51.7)
Morning stiffness (severity)	478	5.2 (2.7)	386	-1.8 (2.3)	393	-2.2 (2.6)	258	-2.2 (2.9)
PHQ-9	477	8.7 (5.2)	383	-1.9 (3.9)	381	-2.3 (4.0)	255	-2.2 (3.8)
RAID	481	5.6 (2.0)	393	-1.7 (1.8)	392	-2.0 (2.0)	258	-1.9 (1.9)

Conclusion: This interim analysis confirmed a meaningful improvement regarding included PROs that cover various RA-related symptoms, depressiveness and the impact of symptoms of RA on daily life.

POS0685 LONG-TERM SAFETY AND EFFICACY OF UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: FINAL RESULTS FROM THE BALANCE-EXTEND OPEN-LABEL EXTENSION STUDY

A. Kivitz[1], A. F. Wells[2], J. Ignacio Vargas[3], H. S. B. Baraf[4,5], M. Rischmueller[6,7,8], J. Klaff[9], N. Khan[9], Y. Li[9], K. Carter[9], A. Friedman[9], P. Durez[10]. *[1]Altoona Center for Clinical Research, Altoona Arthritis & Osteoporosis Center, Duncansville, Pennsylvania, United States of America; [2]Aurora Rheumatology and Immunotherapy Center, Department of Rheumatology, Franklin, Wisconsin, United States of America; [3]Quantum Research, Medicine, Puerto Varas, Los Lagos, Chile; [4]The Center for Rheumatology and Bone Research, Rheumatology, Wheaton, Maryland, United States of America; [5]The George Washington University, Rheumatology, Washington, DC, United States of America; [6]The Queen Elizabeth Hospital, Rheumatology Department, Woodville South, Australia; [7]Basil Hetzel Institute, Rheumatology Research Group, Woodville South, Australia; [8]University of Adelaide, Adelaide Medical School, Rheumatology, Adelaide, Australia; [9]AbbVie, Inc, Immunology, North Chicago, Illinois, United States of America; [10]UCLouvain Saint-Luc, Institut de Recherche Expérimentale et Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Background: Upadacitinib (UPA) was previously evaluated in two Phase 2, randomized, controlled trials (RCTs) in patients (pts) with rheumatoid arthritis (RA) and inadequate response to tumor necrosis factor inhibitors (BALANCE-1) or methotrexate (BALANCE-2).

Objectives: To assess the final safety and efficacy of UPA in BALANCE-EXTEND, a 312-week open-label extension (OLE) enrolling pts who completed either BALANCE-1 or BALANCE-2.

Methods: All pts initially received UPA 6 mg twice daily (BID). Increase to 12 mg BID was required for pts with <20% improvement in swollen or tender joint counts (S/TJC) at Week 6 or 12, and permitted for those not achieving Clinical Disease Activity Index (CDAI) low disease activity (LDA). Pts with <20% improvement in SJC or TJC 6 weeks after escalation, or at any two consecutive visits, discontinued. Return to 6 mg BID was permitted for safety or tolerability reasons. After January 2017, the 6 and 12 mg BID doses were replaced by 15 and 30 mg once-daily (QD) extended-release equivalents. As-observed efficacy data are shown at Week 312 for three subgroups: pts who received 6 mg BID/15 mg QD throughout ("Never titrated"), those titrated up to 12 mg BID/30 mg QD for efficacy ("Titrated up"), and those titrated up to 12 BID/30 mg QD and then back to 6 mg BID/15 mg QD due to safety concerns ("Titrated up and down"). Exposure-adjusted adverse events (EAERs) per 100 patient-years (PY) of exposure were summarized from OLE Day 1 in all pts who received UPA (Any UPA).

Results: Overall, 493 pts entered the OLE, receiving UPA for ≤6.2 years (Never titrated, n=306; Titrated up, n=149; Titrated up and down, n=38), and 270 pts (54.8%) discontinued, mostly due to withdrawal of consent (16.8%; n=83) or AEs (14.6%; n=72). Mean (standard deviation) duration of UPA exposure was 3.8 (2.4) years (range <1–6.2 years); cumulative exposure was 1863 PY. The AE profile in pts receiving UPA 15 mg was generally similar to the Any UPA population, and to that observed in the Phase 3 UPA 15 mg clinical trial population (Table 1). Efficacy was maintained to Week 312, with 84.5% and 86.6% of pts in the Never titrated group achieving DAS28-CRP ≤3.2 and CDAI LDA, respectively (Figure 1).

Table 1. Summary of AEs in pts who received UPA 6 mg BID/15 mg QD in the OLE and in the UPA 15 mg Phase 3 study program

	BALANCE-EXTEND (UPA 6 mg BID/15 mg QD)	UPA 15 mg – Phase 3 program[b]
	Events/100 PY (95 CI)[a]	Events/100 PY (95% CI)[a]
	N=493, PY=1277	N=3209, PY=9079
Any AE	138.4 (132.0, 145.0)	205.5 (202.5, 208.5)
Any SAE	7.9 (6.4, 9.6)	12.4 (11.7, 13.2)
AE leading to discontinuation	4.2 (3.2, 5.5)	4.9 (4.4, 5.3)
Death	0.4 (0.1, 0.9)	0.5 (0.4, 0.7)[c]
Infection	49.2 (45.5, 53.2)	63.9 (62.3, 65.6)
Serious infection	1.4 (0.8, 2.2)	2.8 (2.4, 3.1)
Opportunistic infection	0.2 (0.0, 0.6)	0.3 (0.2, 0.4)
Herpes zoster	2.0 (1.3, 3.0)	3.0 (2.6, 3.3)
Anemia	1.1 (0.6, 1.8)	3.0 (2.7, 3.4)
Neutropenia	1.3 (0.8, 2.1)	2.1 (1.8, 2.5)
Lymphopenia	1.7 (1.1, 2.6)	1.7 (1.4, 1.9)
Gastrointestinal perforation	0	<0.1 (0.0, 0.1)
Any malignancy	1.2 (0.7, 1.9)	1.1 (0.9, 1.4)
Non-melanoma skin cancer (NMSC)	0.4 (0.1, 0.9)	0.4 (0.3, 0.5)
Excluding NMSC	0.8 (0.4, 1.4)	0.7 (0.6, 0.9)
Creatinine phosphokinase elevation	3.4 (2.5, 4.6)	4.4 (4.0, 4.9)
Hepatic disorder	4.1 (3.0, 5.3)	10.2 (9.5, 10.8)
Venous thromboembolism	0.5 (0.2, 1.0)	0.4 (0.3, 0.6)
Major adverse cardiovascular event	0.5 (0.2, 1.0)	0.4 (0.3, 0.5)

[a]Multiple events occurring in the same pts are counted in the calculation of events/100 PY. [b]Cut-off, June 30, 2021. [c]Based on 9080 PY.

Conclusion: In this OLE, UPA treatment over ~312 weeks showed sustained long-term efficacy in pts with RA who had completed Phase 2 RCTs. Overall safety results showed that UPA was well tolerated over time; the types and frequencies of AEs were consistent with those in pts with similar populations of moderately to severely active RA receiving Janus kinase inhibitors.

Figure. Summary of disease activity measures at Week 312 in pts who entered the OLE (observed data)

POS0686

EFFECTIVENESS OF UPADACITINIB IN THE TREATMENT OF RHEUMATOID ARTHRITIS: ANALYSIS OF 6-MONTH REAL-WORLD DATA FROM THE UNITED RHEUMATOLOGY NORMALIZED INTEGRATED COMMUNITY EVIDENCE (UR-NICETM) DATABASE

A. Gibofsky[1], M. E. Pearson[2], A. Concoff[3], A. Shmagel[4], P. Zueger[4], Y. Song[4], L. Smith[4], G. C. Wright[5]. *[1]Weill Cornell Medical College, Hospital for Special Surgery, New York, New York, United States of America; [2]West Suburban Center For Arthritis, Rheumatology, Brookfield, Wisconsin, United States of America; [3]United Rheumatology, Rheumatology, Hauppauge, New York, United States of America; [4]AbbVie Inc., Immunology, North Chicago, Illinois, United States of America; [5]Association of Women in Rheumatology, Rheumatology, New York, New York, United States of America*

Background: The efficacy of upadacitinib (UPA), an oral Janus kinase inhibitor (JAKi), in the treatment of rheumatoid arthritis (RA) has been demonstrated in the phase 3 SELECT clinical trial program.[1–6] However, few real-world data have been reported to date.

Objectives: To assess the 6-month effectiveness of UPA in patients (pts) with RA initiating UPA treatment in clinical practice.

Methods: This observational study included US-based pts from the United Rheumatology Normalized Integrated Community Evidence (UR-NICE) database who initiated UPA 15 mg once daily from Aug 2019 to the data cut-off in Nov 2021. Pts with ≥6 months of baseline (BL) data before UPA initiation, and with Clinical Disease Activity Index (CDAI) score recorded at BL and 6 months (±45 days) after initiation, were included in the analysis. Effectiveness measures included CDAI score, Routine Assessment of Patient Index Data 3 (RAPID3), and Disease Activity Score in 28 joints based on C-reactive protein (DAS28-CRP); patient-reported outcomes (PROs) including Health Assessment Questionnaire-Disability Index (HAQ-DI), Pain, and Patient's Global Assessment of Disease Activity (PtGA); and Physician's Global Assessment of Disease Activity (PhGA). Subgroup analyses were conducted by prior tumor necrosis factor inhibitor (TNFi) and tofacitinib (TOFA) treatment history.

Results: 363 pts were included in the analysis and most were female (80.2%) (Table 1). 140 (39%) received UPA monotherapy and 223 (61%) received UPA plus conventional synthetic (cs) disease-modifying antirheumatic drugs (DMARDs). 83% of pts received prior csDMARDs, 72% prior biologics (TNFi 55%), and 41% JAKis (TOFA 39%). Overall, 46% (166/363), 23% (57/245), and 55% (95/173) of pts achieved LDA by CDAI, RAPID3, and DAS28-CRP, respectively, and 14% (51/363), 16% (39/245), and 36% (62/173) of pts achieved remission (REM) by CDAI, RAPID3, and DAS28-CRP, respectively. Results were similar regardless of prior TNFi or TOFA exposure (Figure 1). Improvements from BL were seen in PhGA and all PROs in the total population and all subgroups.

Table 1. Demographic and baseline characteristics

Parameter, n (%)	Full analysis set		Prior TNFi		Prior TOFA	
	(N=363)		(n=199)		(n=143)	
Female	291 (80.2)		156 (78.4)		119 (83.2)	
Age, years						
<40	22 (6.1)		11 (5.5)		8 (5.6)	
40–<65	240 (66.1)		132 (66.3)		94 (65.7)	
≥65	101 (27.8)		56 (28.1)		41 (28.7)	
Oral steroid use	185 (51.0)		103 (51.8)		83 (58.0)	
Parameter, mean (SD)	**N**	**Mean (SD)**	**n**	**Mean (SD)**	**n**	**Mean (SD)**
Duration of RA, years	276	4.5 (3.1)	162	5.1 (3.0)	113	5.1 (2.9)
Body mass index, kg/m^2	321	30.0 (6.9)	175	29.9 (6.6)	125	29.2 (6.7)
Oral steroid dose (prednisone equivalent), mg/day	154	7.9 (6.9)	87	7.8 (6.5)	70	7.6 (6.1)
Methotrexate dose, mg/week	119	18.3 (4.9)	74	17.8 (5.2)	37	18.2 (4.7)
C-reactive protein, mg/L	228	9.6 (16.2)	132	9.4 (15.0)	90	11.3 (17.9)
CDAI	363	21.2 (12.8)	199	22.1 (13.0)	143	21.7 (13.3)
RAPID3	268	4.7 (2.1)	141	4.7 (2.2)	100	4.9 (2.1)
DAS28-CRP	228	3.9 (1.3)	132	4.0 (1.4)	90	4.2 (1.3)
HAQ-DI[a]	273	2.6 (2.1)	148	2.8 (2.2)	106	3.0 (2.2)
Pain[b]	338	59.6 (26.6)	186	58.4 (27.2)	131	61.3 (25.1)
PtGA[b]	363	54.1 (25.6)	199	54.7 (26.9)	143	55.9 (25.2)
PhGA[b]	363	41.3 (26.0)	199	41.2 (24.8)	143	40.7 (26.8)

[a]0–10 visual analog scale. [b]0–100 visual analog scale. SD, standard deviation.

Conclusion: In this study, almost half (46%) of pts treated with UPA achieved CDAI LDA at 6 months and 14% achieved CDAI REM. Improvements in all PROs and PhGA were observed. Effectiveness of UPA was not impacted by prior TNFi or TOFA exposure, supporting UPA as an effective treatment option in clinical practice, including in pts with prior exposure to advanced therapy.

POS0687

INHIBITION OF BONE EROSION, DETERMINED BY HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY (HR-PQCT), IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING A CONVENTIONAL SYNTHETIC DMARD (CSDMARD) PLUS DENOSUMAB VS CSDMARD THERAPY ALONE: RESULTS OF AN OPEN-LABEL, RANDOMIZED, PARALLEL-GROUP STUDY

N. Iwamoto[1], K. Chiba[2], S. Sato[3], K. Shiraishi[2], K. Watanabe[2], N. Ohki[4], A. Okada[5], T. Koga[1], M. Kobayashi[6], K. Saito[6], N. Okubo[7], A. Kawakami[1].
[1]Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; [2]Nagasaki University Graduate School of Biomedical Sciences, Department of Orthopedic Surgery, Nagasaki, Japan; [3]Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan; [4]Nagasaki University Graduate School of Biomedical Sciences, Department of Radiological Sciences, Nagasaki, Japan; [5]Japanese Red Cross Nagasaki Genbaku Hospital, Department of Rheumatology, Nagasaki, Japan; [6]Daiichi Sankyo Co., Ltd., Primary Medical Science Department, Medical Affairs Division, Tokyo, Japan; [7]Daiichi Sankyo Co., Ltd., Data Intelligence Department, Digital Transformation Management Division, Tokyo, Japan

Background: Denosumab, a human IgG2 monoclonal antibody with high affinity for RANKL, is approved for treatment of bone erosion (ER) in patients with RA, based on the results of clinical trials. However, its effectiveness in combination with conventional therapy in RA patients has not been fully investigated in clinical practice.
Objectives: This exploratory study aimed to compare, in patients receiving conventional synthetic disease-modifying anti-rheumatic drugs (csDMARD) for treatment of RA, the effectiveness of combined use of csDMARD and denosumab vs csDMARD alone, in terms of inhibition of ER determined by HR-pQCT.
Methods: Detail protocol of this open-label, randomized, parallel-group study has been published previously.[1] RA patients with moderate or low disease activity and progressive ER were eligible, and were randomly assigned to receive denosumab in addition to the csDMARD (denosumab) group or to continued use of the csDMARD alone (csDMARD) group. Denosumab was administered every 6 months during the 12-month study period. The primary endpoint was change in ER-depth at the second and third metacarpal bones, determined by HR-pQCT at month 6. For the primary endpoint, a linear mixed effect model analysis was performed using treatment group, sex, anti-cyclic citrullinated peptide (CCP) antibody (positive vs negative), and baseline disease activity (DAS28-ESR) as fixed effects, patients as random effects, and baseline values as covariates. For extension data, measurement time-point and the interaction between treatment group and measurement time-point was further added as fixed effects. The adverse events (AEs) were recorded.
Results: A total of 46 patients were randomized to denosumab and csDMARD groups (both N=23), and baseline characteristics were similar between both groups. Although the difference was not significant, the estimate mean (95%CI) change of ER-depth at month 6 from baseline as the primary endpoint was –0.57 (–1.52, 0.39) in the denosumab group vs –0.22 (–0.97, 0.53) in the csDMARD group, respectively. At months 6 and 12, ER-depth, -width, and -volume (extension data) were numerically lower in the denosumab group than in the csDMARD group (Table 1). Compared with patients in the csDMARD group, those in the denosumab group had significantly higher volumetric bone mineral density (vBMD) at month 12. AEs were reported in 12 (52.2%) and 13 (56.5%) of patients in the denosumab and csDMARD groups, respectively. The most common AEs of denosumab groups was hypocalcemia (reported in 4), and all the events were causally related with denosumab. Serious AEs were reported in 1 (4.3%) and 2 (8.7%) of patients in the denosumab and csDMARD groups, and which were not related to treatment drug.

Table 1. ER and microstructure in denosumab group vs csDMARD group

	Month	Denosumab group (n=21)		csDMARDs group (n=22)		Difference (Denosumab- csDMARDs)
		n1	Estimate Means [95%CI]	n1	Estimate Means [95%CI]	Estimate Means [95%CI]
ER-depth	6	17	–0.46 [–1.31, 0.39]	25	–0.20 [–0.89, 0.49]	–0.27 [–0.86, 0.32]
	12	17	–0.56 [–1.41, 0.29]	22	–0.20 [–0.90, 0.49]	–0.35 [–0.95, 0.24]
ER-width	6	17	–0.26 [–1.10, 0.57]	25	–0.06 [–0.73, 0.61]	–0.20 [–0.81, 0.40]
	12	17	–0.27 [–1.10, 0.56]	22	–0.03 [–0.70, 0.64]	–0.24 [–0.85, 0.38]
ER-volume	6	16	–6.21 [–23.89, 11.46]	24	–1.71 [–16.07, 12.66]	–4.51 [–16.67, 7.65]
	12	17	–6.25 [–23.94, 11.44]	21	–3.18 [–17.56, 11.20]	–3.07 [–15.32, 9.17]
vBMD	6	42	6.41 [2.78, 10.03]	44	2.46 [–1.33, 6.24]	3.95 [–0.05, 7.94]
	12	38	9.20 [5.46, 12.95]	42	3.66 [–0.15, 7.46]	5.55 [1.46, 9.63]*

These were extension data.This is the efficacy analysis set which excluded 3 patients from the full analysis set.*; p<0.01n, number of patients; n1, number of measurement points

Conclusion: Our results suggest that adding denosumab to csDMARD therapy may help prevent ER, promote ER repair, and improve bone microstructure.

POS0688 PHASE 2A STUDY IN PATIENTS WITH MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO MTX AND/OR ANTI-TNFA THERAPEUTICS SHOWS THAT ORAL ABX464 50 MG ONCE DAILY IS SAFE, WELL TOLERATED AND SHOWS PROMISING EFFICACY RESULTS

C. Daien[1], M. Krogulec[2], P. Gineste[3], J. M. Steens[4], L. Desroys Du Roure[5], S. Biguenet[6], D. Scherrer[6], J. Santo[6], H. Ehrlich[5], P. Durez[7]. *[1]Montpellier University, CHU de Montpellier, Inserm U1046, CNRS UMR 9214, Montpellier, France; [2]NZOZ Lecznica, MAK-MED S.C, Nadarzyn, Poland; [3]Abivax, Clinical Operations, Paris, France; [4]Medical Consultant, Brussels, Belgium; [5]Abivax, Paris, France; [6]Abivax, Montpellier, France; [7]Cliniques Universitaires Saint-Luc, Service de Rhumatologie, Brussels, Belgium*

Background: ABX464 upregulates the expression of the anti-inflammatory microRNA miR-124 and is a first-in-class drug candidate as an oral treatment for moderate-to-severe Rheumatoid Arthritis (RA).
Objectives: This phase 2a randomized, double blind, placebo controlled, parallel group 12-week study evaluated the safety and preliminary efficacy of ABX464 (50 and 100 mg q.d.), in combination with methotrexate (MTX) in 60 patients (1:1:1 ratio) with moderate-to-severe active RA who have inadequate response to MTX or/and to an anti-TNFα therapy. Patients who completed the 12-week induction phase could roll over into a 52-week open-label maintenance study to evaluate the long-term safety and efficacy of 50 mg q.d oral ABX464 in RA.
Methods: The primary end point was the safety of ABX464; efficacy endpoints included the proportion of patients achieving ACR20/50/70 responses, disease activity scores (DAS28, SDAI, CDAI), EULAR response, DAS28 low disease activity (DAS28-CRP ≤ 3.2) or remission. Blood samples from patients were used to measure the expression of miR-124 and the relative concentrations of cytokines (baseline and week 8).
Results: Patients baseline characteristics were well balanced in terms of disease severity and demographics (mean ± SD DAS28-CRP: 5.43 ± 0.78; RA duration: 6.43 ± 7.43 years). ABX464 50 mg was safe and well tolerated. Two serious adverse events (SAEs) were reported (one on placebo group and one on ABX464 100 mg). Eleven patients were withdrawn for AEs (9 patients on 100 mg, 1 on 50 mg and 1 on placebo). An increased incidence of largely mild-to-moderate gastrointestinal AEs in the 100 mg treatment group led to a higher drop-out rate of patients. The nature of these AEs was consistent with what has been observed in more than 1023 subjects who have so far been treated in other clinical trials with ABX464 across different indications. No cases of opportunistic infection, no malignancies and no death were reported. Although the sample size of this proof-of-concept study was not powered to show efficacy, multiple early efficacy endpoints showed signs of promise with the ABX464 50 mg daily dose. Compared to placebo, ABX464 50 mg showed significantly higher proportions of patients achieving ACR20 and ACR50 responses at week 12 in the per protocol population (PP). DAS28-CRP and DAS28-ESR decreased significantly (Intent-to-Treat Population, ITT) and rates of categorical DAS28-CRP response (PP) or CDAI remission (ITT) increased significantly on ABX464 at week 12 (Table 1). Compared to placebo, a significant upregulation of miR-124 expression and a decrease in IL-6 blood levels were observed for every patient dosed with ABX464. 40 patients enrolled in the ongoing open-label maintenance study with ABX464 50 mg q.d. At week 52, the drop-out rate of patients was 44 % (17/39), including 7 drop-outs due to AE (18 %). Preliminary maintenance efficacy data, defined as Low Disease Activity, were obtained from 22 patients who reached 52 weeks of treatment: 44 % patients achieved LDA according to ITT.
Conclusion: Efficacy and safety findings of the first-in-class drug candidate ABX464 warrant further exploration at 50 mg q.d. or less as an oral treatment for RA patients.

POS0689 GENICULAR NERVE BLOCK IN JUVENILE IDIOPATHIC ARTHRITIS: A RANDOMIZED CLINICAL TRIAL

A. Radwan[1], H. Eitta[2], A. Elsaman[1]. *[1]Sohag University Hospital, Rheumatology and Rehabilitation, Sohag, Egypt; [2]Alazhar University, Rheumatology and Rehabilitation, Cairo, Egypt*

Background: Genicular nerve block (GNB) showed promising results in improving pain, function, and inflammation in adults with rheumatoid arthritis suffering from persistent knee arthritis (1).
Objectives: This study aimed at testing the effect of GNB in juvenile idiopathic arthritis (JIA) patients with unilateral persistent knee arthritis on pain, function, range of motion, and inflammation parameters.
Methods: N=104 JIA patients diagnosed according to the ILAR criteria with persistent unilateral knee arthritis. They were assigned randomly into two groups; group I received nerve block, group II received intra-articular triamcinolone. Visual analogue scale, SOLAR scoring system, and Lysholm scores were assessed at 0, 2, and 12 weeks intervals. Tenderness and swelling were evaluated by a semi-quantitative score at the same intervals.
Results: VAS, tenderness, swelling, and SLOAR scores were significantly decreased after 2 weeks of interventions in both groups, but this reduction was greater in GNB group regarding VAS and tenderness, while was greater in steroid group regarding SOLAR and swelling. At 12 weeks, all these outcome measures revealed better values in GNB group in comparison to steroid group, but this was significant only for VAS. Moreover, Lysholm score was significantly increased in both groups at 2 and 12 weeks intervals with higher values in steroid group versus GNB group at 2 weeks.
Conclusion: Nerve block was able to control pain, improve function and inflammation outcome measures of the knee joint in JIA patients. Although steroid achieved better results after 2 weeks, GNB achieved a better long-term improvement after 12 weeks.

POS0690 SYSTEMATIC LITERATURE REVIEW: WHICH ROUTE AND DOSE OF CORTICOSTEROID IS MOST EFFECTIVE IN INDUCING REMISSION IN EARLY RHEUMATOID ARTHRITIS?

L. Parker[1], N. Gullick[1,2]. [1]*University of Warwick, Warwick Medical School, Coventry, United Kingdom;* [2]*University Hospital Coventry & Warwickshire, Rheumatology, Coventry, United Kingdom*

Background: Current NICE guidance for rheumatoid arthritis (RA) states that glucocorticoids may be used for bridging therapy and to rapidly decrease inflammation in acute flares[1]. However, a recommended route and dosage is not specified, and variation has been observed between individual departments as to whether or not steroids are administered[2]. Glucocorticoids are associated with adverse events that can be severe, leading to a strong recommendation by the American College of Rheumatology to avoid long term use[3]. It is therefore important to ascertain the efficacy of available routes and dosages of glucocorticoids to weigh against these risks.
Objectives: This review aimed to ascertain the optimum route and dose of corticosteroid for adults with early RA.
Methods: Papers included were full text, English language, randomised controlled trials that fulfilled the PICO criteria. The population was defined as adults with early RA with onset <2 years, the intervention corticosteroids of any route or dose, the comparator conventional DMARDs or placebo, and the primary outcome remission. Functional improvement and X ray progression were considered as secondary outcomes. MEDLINE, Embase, Web of Science and Cochrane Central were searched. Screening of results and extracted data was carried out by both reviewers. During data extraction, outcomes were rounded to timepoints of 3, 6 and 12 months, and steroid doses were stratified into low (up to 10mg/day prednisolone or equivalent), medium (15-30mg) and high (>30mg). Meta-analyses were carried out in RevMan 5.4 when 3 or more studies measured the same outcome at the same dose and route. A funnel plot was generated to check for publication bias.
Results: Three papers measured DAS28 remission rate at 1 year, comparing DMARDs only to DMARDs plus low dose oral steroids. The Forest plot for this meta-analysis is shown in Figure 1. As I^2 = 0%, a fixed effect method was used. This shows an odds ratio (OR) of 1.73 (95% CI 1.25, 2.39) favouring low dose steroids in addition to DMARDs. Meta-analyses were also possible for HAQ at 1 year, and mean DAS28 at 1 year, comparing DMARDs alone to DMARDs plus low dose steroids. Both analyses favoured steroids; for HAQ scores the standardised mean difference (SMD) was -0.69 (95% CI -1.66, 0.29), and for DAS28 the SMD was -0.36 (95% CI -0.58, -0.15). At 3 and 6 months there was a lack of available data for meta-analyses.

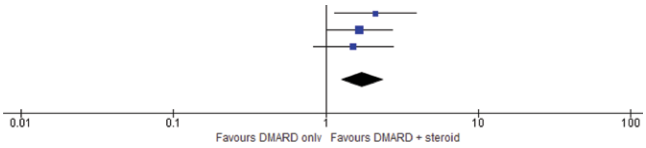

Figure 1. Forest plot showing the OR of DAS28 remission with low dose steroids and conventional DMARDs vs DMARDs only

Conclusion: At 1 year, remission and improvement in function appear more likely if low dose steroids are used. Due to a lack of available data, non-oral routes, higher doses and X ray progression could not be analysed. Studies were not designed to detect differences in adverse events. This highlights the need for further clinical research into steroid efficacy in early RA, as the meta-analyses suggest that glucocorticoids may be more effective in inducing remission in early disease than conventional DMARDs alone.

Background: There is increasing recognition of the complementary role for real-world evidence (RWE) in health care and regulatory decision-making (1). However, careful analysis is required when drugs are compared using observational data to account for differences between treatment groups. Electronic medical records (EMR) are an important source of real-world data (RWD), but outcomes are often recorded incompletely. We emulated a target trial of adalimumab (ADA) versus tofacitinib (TOF) in patients with rheumatoid arthritis (RA) using the OPAL dataset to illustrate the application of methodologies to address the challenges of non-random treatment assignment and incomplete data. The OPAL dataset is derived from EMR of 112 community-based rheumatologists around Australia, where practitioners have discretion to prescribe whichever b/tsDMARD they consider most clinically appropriate.
Objectives: To estimate the average treatment effect (ATE) of TOF compared to ADA at 3 and 9 months, defined as the difference in mean disease activity score (DAS28CRP), in patients with RA who are new users of a b/tsDMARD. This is equivalent to aiming to estimate the intention-to-treat effect in a randomised controlled trial.
Methods: OPAL patients diagnosed with RA were included if they initiated ADA or TOF between 1 October 2015 and 1 April 2021, were new b/tsDMARD users (no prior recorded b/tsDMARD, at least 6 months of prior csDMARD treatment), and had at least 1 component of DAS28CRP recorded at baseline or during follow-up. Data were also extracted on baseline characteristics. Baseline characteristics were DAS28CRP, patient demographics, regional location, disease duration, prescriber characteristics (including gender, experience), prior recorded comorbidities, and prior and concomitant treatment with csDMARDs and oral corticosteroids. We used random forest multiple imputation to impute missing baseline and follow-up DAS28CRP components (2). Stable balancing weights (SBW) were then used to balance the treatment groups in terms of their

baseline characteristics, including DAS28CRP (3). For each imputed dataset, the ATE at 3 months was estimated as the difference between the mean outcome in the two treatment groups after balancing (i.e. weighting) the sample, and then these estimates were averaged across the 10 imputed datasets. The ATE at 9 months was estimated similarly. The whole procedure was subsequently performed in 1000 bootstrap samples to estimate a 95% confidence interval (CI) for the ATEs using the percentile method (4).

Results: 842 patients were identified including n=569 treated with ADA and n=273 treated with TOF. After applying the SBW, the maximum difference between the mean of each baseline characteristic in the ADA and TOF groups was less than 0.03% of the corresponding standard deviation in the whole sample, indicating reasonable balance was achieved in this complex dataset. After weighting, mean DAS28CRP reduced from 5.3 at baseline (both ADA and TOF groups) to 2.6 and 2.3 at 3 and 9 months for ADA, and 2.4 and 2.3 at 3 and 9 months for TOF. The estimated ATE was -0.22 (95% CI -0.36, -0.03; p=0.02) at 3 months, indicating a modest but significant reduction in disease activity for patients on TOF. The estimated ATE was -0.03 (95% CI -0.19, 0.1; p=0.56) at 9 months, indicating no difference between groups.

Conclusion: DAS28CRP was significantly lower at 3 months for patients treated with TOF compared to ADA. However, 3 months of treatment with either drug led to substantive average reductions in mean DAS28CRP, consistent with remission. There was no difference between drugs at 9 months. Future work will estimate a per-protocol effect.

POS0692

RHEUMATOID ARTHRITIS PATIENTS WHO SWITCHED TREATMENT FROM ADALIMUMAB TO UPADACITINIB DEMONSTRATE A ROBUST REDUCTION OF INFLAMMATION-RELATED BIOMARKERS: PROTEOMICS ANALYSIS FROM THE SELECT-COMPARE PHASE 3 STUDY

T. Sornasse[1], F. Cai[1], H. Camp[2], I. H. Song[2], I. Mcinnes[3]. [1]*AbbVie, Precision Medicine Immunology, South San Francisco, United States of America;* [2]*AbbVie, Immunology Clinical Development, North Chicago, United States of America;* [3]*University of Glasgow, Institute of Infection, Immunity & Inflammation, Glasgow, United Kingdom*

Background: Upadacitinib 15 mg QD (UPA), an oral JAK inhibitor, showed greater efficacy compared to adalimumab (ADA) in patients (pts) with active rheumatoid arthritis (RA) on background MTX at wk 12 of the SELECT-COMPARE phase 3 study[1]. A subset of pts switched treatment (ADA to UPA [23.5%] and UPA to ADA [19.2%]) due to non-response (NR) to the initial therapy. A higher proportion of pts rescued from ADA to UPA achieved CDAI ≤10 (LDA) post-switch (47%) vs pts rescued from UPA to ADA through 24 wks (36%)[2].

Objectives: To explore the biological mechanisms associated with the differential clinical response in RA pts who switched treatment due to NR to initial ADA or UPA therapy in comparison to pts who continued treatment based on response (R) to the initial therapy.

Methods: We included a random subset of pts (100 pts each from the originally randomized treatment groups [UPA, n=651; ADA, n=327]). NR was defined as <20% improvement in TJC or SJC at wks 14–24 compared to baseline (BL) and R as achieving these improvements. The levels of 181 inflammation-related protein biomarkers (BM) were analyzed using the Olink platform at BL, wks 2, 8, and 26. Contrasts between relative BM levels were assessed using a repeated measure mixed linear model, and correlations between BM levels and DAS28-CRP were computed using Pearson's method.

Results: In this patient subset, 40% of ADA NR who switched to UPA achieved CDAI LDA at wk 26 vs 17% of UPA NR who switched to ADA. Proteomics analysis identified 42 BMs that showed significant differential modulation between R and NR prior to switch (BL to wk 8) or after switch (wks 8–26) (Table 1). Ten BMs (CCL7, CCL8, CHI3L1, CSF1, IL6, MMP1, SLAMF1, TNFRSF9, TNFSF14, and VEGFA) were differentially modulated between ADA R and NR and were significantly decreased after switching to UPA (wk 26). The levels of these 10 BMs were similar between UPA R and NR through wk 8, except for CHI3L1, and MMP1, SLAMF1, and TNFSF14 increased after switching to ADA (wk 26). Another group of 13 BMs (CCL13, CCL19, CCL23, FGF21, IL18, IL10RA, IL18BP, IL1R1, IL2RA, MMP3, TNFSF11, TNFSF13B, TNFRSF1A) had similar levels between ADA R and NR through wk 8 and were significantly decreased after switching to UPA (wk 26). The levels of these 13 BMs were similar between UPA R and NR, except for FGF21, and the levels of CCL13, CCL19, CCL23, IL10RA, IL1R1, IL2RA, and TNFSF11 increased after switching to ADA (wk 26). Notably, the BL levels of CCL7, CCL23, CHI3L1, CSF1, IL2RA, IL6, MMP1, MMP3, and VEGFA were correlated with DAS28-CRP at BL, suggesting a potential relationship of these BMs in the pathobiology of RA. Among the remaining BMs, the levels of CCL3, CCL4, CX3CL1, EPCAM, and FLT3LG were similar between UPA R and NR and decreased after switching to ADA (wk 26).

Conclusion: We propose that switching to UPA from ADA NR leads to more favorable clinical improvement that is paralleled by a more profound immune modulation than switching to ADA from UPA NR, consistent with the broader mechanistic inhibition achieved by JAK-associated signaling pathway inhibition compared with discrete TNF-signaling inhibition.

IMPACT OF UPADACITINIB VERSUS ABATACEPT ON INDIVIDUAL DISEASE OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSES TO BIOLOGIC DMARDS

R. Van Vollenhoven[1], A. Rubbert-Roth[2], S. Hall[3], R. Xavier[4], A. Shmagel[5], Y. Song[5], S. Anyanwu[5], V. Strand[6]. *[1]Amsterdam Rheumatology and Immunology Center, Rheumatology and Immunology, Amsterdam, Netherlands; [2]Cantonal Clinic St. Gallen, Division of Rheumatology, St. Gallen, Switzerland; [3]Emeritus Research and Monash University, Rheumatology, Melbourne, Australia; [4]Hospital de Clínicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Departamento de Reumatologia, Porto Alegre, Brazil; [5]AbbVie Inc., Immunology, North Chicago, United States of America; [6]Stanford University, Division of Immunology and Rheumatology, Palo Alto, United States of America*

Background: The phase 3 SELECT-CHOICE trial of patients with rheumatoid arthritis (RA) and prior inadequate response to biologic DMARD(s) (bDMARD-IR) demonstrated superiority of the JAK inhibitor upadacitinib (UPA) vs abatacept (ABA) in the mean change from baseline (BL) in DAS28(CRP) and in the proportion achieving DAS28(CRP) <2.6 at week (wk) 12, with higher incidence of serious adverse events reported in the UPA treatment group.

Objectives: To evaluate the impact of UPA vs ABA on individual components of composite measures of disease activity in SELECT-CHOICE.

Methods: In SELECT-CHOICE, a double-blind phase 3 trial, bDMARD-IR patients were randomly assigned to UPA 15 mg once daily or ABA, each with background conventional synthetic DMARDs, for 24 wks. For this post hoc analysis, the proportions of patients achieving improvement from BL through wk 24 in ACR core variables (including SJC, TJC, Patient Global Assessment [PtGA], Physician Global Assessment [PhGA], pain, HAQ-DI, and hsCRP) and Boolean remission criteria were evaluated. Differences in the cumulative distributions of CDAI, DAS28(hsCRP), SDAI, and ACR-n (the lowest of percent change in TJC, percent change in SJC, or median of the other 5 ACR components) were determined using the Kolmogorov-Smirnov test and are reported as observed. For all other variables, non-responder imputation was applied for missing data. Nominal *P* values are provided throughout.

Results: A total of 616 bDMARD-IR patients with moderate to severe RA were randomized in SELECT-CHOICE (UPA 15 mg, n=303; ABA, n=309). BL demographic and disease characteristics were generally comparable between treatment groups, with a mean disease duration of approximately 12 years and mean CDAI of 39.6. At wk 12, more patients receiving UPA vs ABA achieved ≥50% improvements from BL in TJC68, PtGA, and hsCRP, with comparable proportions observed between UPA and ABA for the remaining ACR components (Figure 1). At wk 24, similar proportions of patients receiving UPA and ABA achieved ≥50% improvements in all but the hsCRP component. Overall, 15% and 26% of patients on UPA compared with 6% and 15% on ABA demonstrated ≥50% improvements across all ACR components at wks 12 and 24, respectively. At wks 12 and 24, Boolean remission was achieved by 6% and 14% of patients on UPA vs 2% and 10% of patients on ABA, respectively; the proportion of patients in both treatment groups achieving the individual Boolean components were also reported (Table 1). While comparable at BL, cumulative distributions of CDAI, SDAI, DAS28(hsCRP), and ACR-n were improved on UPA vs ABA at wk 12 (all nominal *P* <0.05); differences persisted for most measures at wk 24.

Table 1. Proportions of Patients Achieving Boolean Remission and Its Components at Week 12 and 24 (NRI)

	Week 12		Week 24	
	UPA 15 mg	ABA	UPA 15 mg	ABA
n (%)	(N=303)	(N=309)	(N=303)	(N=309)
Boolean Remission	19 (6)***	5 (2)	42 (14)*	30 (10)
PtGA ≤10	54 (18)***	29 (9)	80 (26)*	66 (21)
TJC ≤1	89 (29)***	64 (21)	134 (44)*	115 (37)
SJC ≤1	127 (42)**	106 (34)	169 (56)*	152 (49)
hsCRP ≤1 mg/dL	257 (85)***	209 (68)	244 (81)***	199 (64)

Nominal ***P <.001, **P <.01, *P <.05 for UPA vs ABA. ABA, abatacept; PtGA, Patient's Global Assessment of disease severity; UPA, upadacitinib.

Conclusion: In this post hoc analysis of bDMARD-IR RA patients, improvements in components of disease measures were reported for both UPA and ABA through 24 weeks, with numeric differences noted for several components. Nominally higher attainment of Boolean remission and its components were observed for UPA over ABA.

POS0694

WHAT TREATMENT GIVES THE BEST CLINICAL RESPONSE AFTER CESSATION OF JAKI THERAPY IN PATIENTS WITH RA? DATA OF THE TARDIS-RA REGISTRY, A NATIONWIDE BELGIAN BIOLOGIC REGISTRY

D. De Cock[1], P. Durez[2,3], V. Badot[4], R. Westhovens[1,5], P. Verschueren[1,5]on behalf of the TARDIS Working Group. *[1]KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium; [2]Université Catholique de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Louvain La Neuve, Belgium; [3]Cliniques Universitaires Saint-Luc, Division of Rheumatology, Louvain La Neuve, Belgium; [4]CHU-UVC Brugmann, Division of Rheumatology, Leuven, Belgium; [5]University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium*

Background: JAKi represent a new important class in Rheumatoid Arthritis (RA) treatment options. It is unknown which specific bDMARD or mode of action should be selected after stopping a JAKi.

Objectives: To study if clinical response differs between advanced therapies that are initiated after stopping a JAKi.
Methods: Patients were included from the electronic platform "Tool for Administrative Reimbursement Drug Information Sharing" (TARDIS). Data from all Belgian RA patients on biologic and targeted therapy are collected here for drug reimbursement. Patients were selected for this analysis if they had stopped JAKi therapy and initiated a subsequent therapy. Patients were grouped by TNFi, T/B cell therapy, IL6i or JAKi therapy. The DAS28 response and proportion of patients in remission at the first follow-up (between 3 and 6 months) were compared between groups. Remission was defined as DAS28<2.6. Analyses were repeated in patients who were prescribed the stopped JAKi as first-line or as subsequent line therapy. Data were compared via χ^2, Anova and t-tests.
Results: In total, 1238 patients who had stopped JAKi therapy were included. TNFi, T/B cell therapy, IL6i or JAKi therapy was initiated in 36% (441/1238), 19% (233/1238), 18% (227/1238) and 27% (337/1238) respectively. Most baseline demographic and clinical characteristics differed between groups (Table 1).

Table 1.

	TNFi	B/T cell	IL6i	JAKi	p-value
Number	441 (36%)	233 (19%)	227 (18%)	337 (27%)	
Age (years)	**55 ± 14**	**57 ± 13**	**55 ± 14**	**59 ± 12**	**<0.001**
Gender (women)	323 (73%)	177 (76%)	186 (82%)	257 (76%)	0.100
Weight (kg)	74 ± 15	79 ± 17	75 ± 15	75 ± 15	0.111
Disease duration (years)	**9 ± 8**	**10 ± 9**	**11 ± 9**	**11 ± 9**	**0.002**
HAQ (0-3)	1.6 ± 0.7	1.8 ± 0.6	1.5 ± 0.7	1.5 ± 0.8	0.353
PGA (0-100)	**65 ± 20**	**68 ± 21**	**67 ± 21**	**57 ± 24**	**<0.001**
CRP (mg/l)	**10 ± 16**	**14 ± 20**	**16 ± 28**	**11 ± 17**	**0.003**
ESR (mm/h)	22 ± 21	24 ± 19	27 ± 21	25 ± 22	0.117
TJC28	**8 ± 6**	**8 ± 6**	**9 ± 6**	**7 ± 6**	**0.001**
SJC28	**5 ± 4**	**6 ± 5**	**6 ± 4**	**5 ± 5**	**0.006**
DAS28	**4.7 ± 1.1**	**4.8 ± 1.1**	**4.9 ± 1.2**	**4.4 ± 1.3**	**<0.001**
2nd line of therapy after initial JAKi therapy	**211 (48%)**	**56 (24%)**	**52 (23%)**	**112 (33%)**	**<0.001**

Numbers given are mean ± SD or number, proportion. TNFi = tumour necrosis factor inhibitor, ts= targeted synthetic, HAQ= health assessment questionnaire, PGA= Patient Global assessment; CRP= C-reactive protein; ESR= erythrocyte sedimentation rate; TJC= tender joint count; SJC= Swollen joint Count; DAS28 = disease activity score based on the 28joints

The clinical response could be studied in 577 patients. Patients on rituximab were excluded as these were retreated on flare, following Belgian reimbursement criteria. TNFi, Tcell therapy, IL6i or JAKi therapy was initiated in 37% (211/577), 13% (76/577), 18% (102/577) and 33% (188/577) of these patients respectively. DAS28 decreased on average with 1.7 ± 1.5, 1.6 ± 1.4, 2.4 ± 1.6* and 1.3 ± 1.6 for patients on TNFi, T cell therapy, IL6i or JAKi therapy respectively (*p<0.001). Remission was reached in 42%, 41%, 56%* and 39% for patients on TNFi, T cell therapy, IL6i or JAKi therapy respectively (*p=0.045).
Before switching, JAKi therapy was the first advanced therapy in 35% (204/577). In this "naïve" subgroup, DAS28 decreased on average with 1.9 ± 1.5, 1.9 ± 1.3, 2.4 ± 1.8 and 1.0 ± 1.7* for patients on TNFi, Tcell therapy, IL6i or JAKi therapy respectively (*p=0.001). Remission was reached in 44%, 48%, 58% and 35% for patients on TNFi, Tcell therapy, IL6i or JAKi therapy respectively (p=0.279).
In the "experienced" subgroup, who started JAKi therapy as subsequent line therapy in 65% (373/577), DAS28 decreased on average with 1.5 ± 1.6, 1.5 ± 1.4, 2.3 ± 1.6* and 1.4 ± 1.6 for patients on TNFi, Tcell therapy, IL6i or JAKi therapy respectively (*p<0.001). Remission was reached in 40%, 38%, 55% and 41% for patients on TNFi, Tcell therapy, IL6i or JAKi therapy respectively (p=0.118).
Conclusion: Our results show clearly that IL6 inhibitors have a better clinical response after JAKi cessation compared to other mode of actions, including other JAKi. However, considerable baseline differences existed, that could influence our results.

POS0695 EFFECT OF METHOTREXATE AND FOLIC ACID CO-ADMINISTRATION IN ARTHRITIS

E. Dalix[1], M. Maalouf[1], S. Peyroche[1], A. Vanden-Bossche[1], C. A. Arthaud[1], S. Hodin[1], H. Marotte[1,2], R. Müller[3,4]. *[1]INSERM, U1059-SAINBIOSE, University of Lyon, Saint-Etienne, France; [2]University Hospital of Saint-Etienne, Rheumatology, Saint-Etienne, France; [3]Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, Ludwig-Maximilians-University Munich, Munich, Germany; [4]Rheumazentrum Ostschweiz, Rheumatology, St. Gallen, Switzerland*

Background: Methotrexate (MTX) is the recommended first-line treatment for rheumatoid arthritis. Adjuvant-induced arthritis (AIA) rat is a robust model with a high prevalence of arthritis used to investigate arthritis. MTX reduces inflammation, but associated with adverse events, such as gastrointestinal, hepatic, and hematology toxicity (1). To reduce these side effects, folic acid (FA) is administrated at distance to MTX with no defined recommendation for its dosing (5-25mg/week) or time point of administration (2) (1-3 days after MTX application). Whether the complicated therapeutic regimen with MTX once a week and FA at another time point affects compliance is an open question. MTX is metabolized in polyglutamates derivates (MTX-PG), which is a biomarker of MTX efficacy as its half-life (1-4 weeks) is longer than MTX (4h) (3).
Objectives: The aim of this study was to assess efficacy and tolerance of co-administration of MTX and FA compared to MTX with FA applied one day after MTX in the AIA.
Methods: Female Lewis rat were randomly divided in three groups and received an injection of Mycobacterium butyricum defining day (D) 0 to induce arthritis. An historic AIA group was used as control. Treatment began on D9, one day before arthritis onset in this model. The first group rats were treated with MTX only (n=13), the second group received MTX and FA at the same day (n=14), and the third group received FA one day after MTX administration (n=14). MTX was administrated intraperitoneally (IP) at 1 mg/kg every 3 days (4) and FA was delivered IP at 0.17 mg/kg. Arthritic index (AI) and ankle circumference (AC) were monitored to assess arthritis. Microcomputed tomography of the ankle was performed to assess bone loss. Moreover, complete blood count, transaminases, and MTX-PG were assessed.
Results: Arthritis developed at D10 in all groups. AI and AC were similar in MTX groups at the various time points. At D17, arthritis severity was lower in MTX groups (AI (mean and standard deviation): 1.4 ± 1.6; AC: 35 ± 7 mm) compared to AIA historical group (AI: 3.3 ± 0.6; AC: 42 ± 4 mm). Bone erosion and bone loss parameters were similar in all groups. Cortical porosity was around 0.40% ± 0.15 and bone volume / total volume was around 0.22% ± 0.13. MTX-PG1 was found at similar levels in MTX groups and correlated negatively with AI in MTX alone or MTX and FA at the same day groups ($p<0.05$ and $p<0.01$, respectively). Finally, white and red blood cells, platelets, hemoglobin, mean corpuscular volume, transaminases, and creatinine were found at a similar level in MTX groups.
Conclusion: Co-administration of MTX with FA on the same day is effective compared to FA application one day after MTX. MTX metabolism was not affected, as demonstrated by the MTX-PG concentrations. The biological tolerance between the protocols was comparable. Thus, co-administration of MTX and FA seems to be possible and may be more convenient to the patients and improve compliance at the end.

POS0696 DOES PREDNISONE USE DURING PREGNANCY IN WOMEN WITH RHEUMATOID ARTHRITIS INDUCE INSULIN RESISTANCE IN THE OFFSPRING?

F. D. O. De Steewninkel[1], R. Dolhain[1], J. Hazes[1], A. C. Hokken-Koelega[2]on behalf of PARA. *[1]Erasmus University Medical Centre, Rheumatology, Rotterdam, Netherlands; [2]Erasmus University Medical Centre, Sophia Children's Hospital, Department of Paediatrics, Subdivision of Endocrinology, Rotterdam, Netherlands*

Background: The use of long-term corticosteroids during pregnancy has been growing over the past decades[1]. Corticosteroids can be given when an auto-inflammatory disease like rheumatoid arthritis (RA) is too active. Several studies have shown that long-term corticosteroids use in pregnancy is associated with maternal and fetal adverse outcomes, like preeclampsia, shorter gestational age, lower birth weight and rapid catch-up growth [1-3]. These last two outcomes could influence the insulin resistance later in life[4].

Objectives: Does prednisone use in pregnant women with RA induces insulin resistance in the offspring?
Methods: 103 children were included after their mother had participated in a prospective cohort study on RA and pregnancy. 42 children were *in utero* exposed to prednisone and 61 were non-exposed. To assess insulin resistance, we measured Homeostasis Model of Assessment Insulin Resistance (HOMA-IR), serum adiponectin and lipid levels, corrected for body fat distribution.
Results: There was no difference in mean HOMA-IR (SD) between the children who were prednisone-exposed *in utero* (1.10 (0.84)) and those non-exposed (1.09 (0.49)). No difference was found in mean adiponectin (SD) level, 16.45 (4.06) µg/mL and 15.40 (3.59) µg/mL, respectively. Also no difference was found in body fat distribution or lipids such as total cholesterol, fasting triglyceride or high-density lipoprotein.
Conclusion: Children who are prednisone-exposed *in utero* have no increased risk for insulin resistance at the age of approximately 7-years. This findings are reassuring, but further research has to be performed to evaluate if prednisone-exposure *in utero* has no other negative effects on the long-term and if insulin resistance remains absent in the future.

POS0697 OPHTHALMOLOGICAL ADVERSE EVENTS UNDER JAK: CASE ANALYSIS OF THE EUROPEAN PHARMACOVIGILANCE DATABASE

S. Hecquet[1,2], M. B. Rabier[3], M. Lepelley[4], M. Chouk[1], F. Verhoeven[1,2], C. Prati[1,2], D. Wendling[1,5]. *[1]Centre Hospitalier Régional Universitaire de Besançon, Rheumatology, Besançon, France; [2]University of Franche-Comté, UR 4267 PEPITE, Besançon, France; [3]Centre Hospitalier Régional Universitaire de Besançon, Pharmacovigilance, Besançon, France; [4]Centre Hospitalier Universitaire de Grenoble, Pharmacovigilance, La Tronche, France; [5]University of Franche-Comté, UR 4266 EPILAB, Besançon, France*

Background: Ophthalmological manifestations in rheumatic diseases include dry syndrome, scleritis, episcleritis, uveitis and peripheral ulcerative keratitis (PUK). Among the target therapies, JAK inhibitors (JAKinhib) are the most recent to have been approved in rheumatic diseases, rheumatoid arthritis (RA) and spondyloarthritis (SpA), but also in other indications such as inflammatory bowel disease.
Objectives: The aim of this work is to describe and characterise ophthalmological events in patients exposed to JAKinhib based on European pharmacovigilance (PV) data.
Methods: The ophthalmological manifestations that appeared under JAK inhib were extracted from the European PV database (April 2020), EUDRAVIGILANCE following a request addressed to the National Drug Safety Agency carried out according to the following MedDRA classification "SOC eye disorders and BARICITINIB" and "SOC eye disorders and TOFACITINIB".
Results: A total of 1411 patients with ophthalmological adverse events (AEs) were identified with JAKinhib. 103 with BARICITINIB (81 women, mean age 59.7 years), 1308 with TOFACITINIB (1116 women, mean age 64.7 years). Among these AEs, 58% were reported by medical and paramedical staff and 42% were reported by patients. JAKinhib was initiated mainly in patients with RA (1070 patients), SpA (26 patients) and ulcerative colitis (UC) (27 patients). Of the reported AEs, 10% were inflammatory disorders of the anterior or posterior segments of the eye [51 uveitis (40 RA, 1 SpA, 1 RCUH, 1AJI, 8 undetermined (n.d.)), 49 corneal ulcerations (38 RA, 2 RCHU, 9 n.d.), 28 scleritis (20 RA, 8 n.d.), 13 keratitis (8 RA, 1 SpA, 1 Crohn's, 3 n.d.)]. Visual loss and complete loss of vision were also reported in 200 patients. Finally, retinal detachment, retinal vascular thrombosis, cataracts and unspecified ophthalmological AEs were observed in 27, 25, 329 and 185 patients respectively. The mean time to onset of inflammatory ophthalmological events was 258 days after initiation of treatment (Table 1).

Table 1. Ophthalmological adverse events with JAK inhibitors

	BARICITINIB	TOFACITINIB	
	n=103	n=1308	Mean delay (in days)
Inflammatory involvement	2 (2)	26 (2)	190±197
Scléritis, n (%)	8 (8)	41 (3)	321±405
Corneal ulcération, n (%)	1 (1)	50 (4)	292±296
Uvéitis, n (%)	2 (2)	11 (1)	172±244
Kératitis			
Decreased visual acuity, n (%)	10 (10)	118 (9)	165±193
Visual loss, n (%)	0	72 (5)	74±83
Red eyes, n (%)	14 (14)	51 (4)	80±149
Dry eyes, n (%)	15 (15)	136 (10)	166±454
Photophobia, n (%)	3 (3)	14 (1)	272±519
Retinal detachment, n (%)	1 (1)	26 (2)	461±360
Retinal vascular thrombosis, n (%)	3 (3)	22 (2)	367±490
Retinal haemorrhage, n (%)	2 (2)	19 (1)	168±199
Cataract, n (%)	9 (9)	320 (24)	
Glaucoma, n (%)	0	77 (6)	432±360
Age related macular degeneration (%)	0	34 (3)	351±549
Unspecified ophthalmological AEs	8 (8)	177 (14)	126±184

Conclusion: Ophthalmological manifestations under JAK inhib seem rare but not exceptional. The rheumatologist must be made aware of them in order to discuss the potential imputability of the treatment and to report these manifestations to the pharmacovigilance structures. A detailed history, exclusion of infections and histopathological evaluation of the lesions are recommended to ensure that a differential diagnosis is not ignored. Topical treatments, and if necessary, discontinuation of the drug and switching to another targeted therapy may be considered. Discontinuation of JAKinhib appears to be warranted pending ophthalmologic advice.

POS0698 CHANGES IN RA PATIENT PROFILE AT INITIATION OF FIRST TARGETED THERAPY OVER A FIVE-YEAR PERIOD: ANALYSIS OF THE STRATEGE 1 AND STRATEGE 2 STUDIES.

C. Gaujoux-Viala[1], E. Dernis[2], E. Senbel[3], H. Herman-Demars[4], A. Courbeyrette[4], R. M. Flipo[5]. *[1]IDESP, Université Montpellier, INSERM, Department of Rheumatology, CHU Nîmes, Nîmes, France; [2]Le Mans Central Hospital, Rheumatology Department, Le Mans, France; [3]Cabinet de Rhumatologie, NA, Marseille, France; [4]Nordic Pharma France, Medical Department, PARIS, France; [5]Centre Hospitalier Universitaire de France, Université de Lille, Lille, France*

Background: The objective of the STRATEGE2 study (inclusion period: Feb. 2019-Dec. 2020) is to describe the therapeutic strategy in rheumatoid arthritis (RA) patients treated with methotrexate (MTX) for at least 3 months, not having received targeted biological (bDMARD) or synthetic (tsDMARD) therapy and who are candidates for initiation of first b/tsDMARD therapy due to RA activity.
The STRATEGE1 study [1] (conducted between 2014 and 2015) described the therapeutic strategies introduced for RA patients with an inadequate response to MTX monotherapy.
Objectives: We aim to compare the profiles of patients included in these two studies at first prescription of b/tsDMARD therapy, in order to evaluate changes in rheumatologist practices over this five-year period.
Methods: STRATEGE1 and 2 are two French multicentre, prospective, longitudinal, observational studies including patients with confirmed RA (ACR 1987 or ACR/EULAR 2010). Our aim is to compare baseline data. Only data from the sub-group of patients initiating b/tsDMARD therapy are presented for STRATEGE1. Qualitative variables are compared by Fisher's exact test and quantitative variables by t-test.
Results: In STRATEGE1 (2014-2015), 117 out of 854 patients initiated a b/tsDMARD therapy. In STRATEGE2 (2019-2020), 230 patients were included, with 180 in the analysis population.

Table 1.

At baseline (before b/tsDMARD initiation)	STRATEGE1 (N=117)	STRATEGE2 (N=180)	p
Mean age (years)	52.6 ±12.5	56.4 ±13.6	0.0158
RA duration (years)	6.5 ±7.1	5.6 ±7.2	NS
Radiological signs	50.0%	48.0%	NS
Average MTX initiation (years)	4.6 ±4.3	4.3 ±5.3	NS
MTX per os	44.0%	28.9%	0.0088
→ mean dosage (mg/week)	16.2 ±3.6	16.0 ±4.1	NS
MTX subcutaneous	52.6%	70.6%	0.003
→ mean dosage (mg/week)	18.5 ±3.2	19.9 ±3.9	NS
→ Patients self-administration	53.8%	75.8%	0.0001
Corticosteroid therapy	53%	50.6%	NS
→ mean dosage (mg/day)	8.1 ±4.1	9.5 ±5.8	NS
Mean DAS28	4.6 ± .1	4.3 ±1.2	0.0074
Mean HAQ	1.4 ±0.9	1.0 ±0.7	<0.0001

The baseline visits involved initiation of b/tsDMARD therapy with 100% *vs.* 88.9% bDMARD (anti-TNF: 78.8% *vs.* 58.3%; anti-IL6: 6.7% *vs.* 12.8%; CTLA4 Ig: 11.5% *vs.* 16.7%; anti-CD20: 2.9% *vs.* 1.1%) and 0% *vs.* 11.1% tsDMARD. Therapeutic decisions concerning MTX were (STRATEGE 1 vs STRATEGE 2): identical regimen maintained (pharmaceutical form + dosage): 69.2% *vs.* 76.1%; discontinuation: 4.3% *vs.* 2.2%; adjustment: 26.7% *vs.* 21.7% [with dose reduction: 18.2% *vs.* 93.5% and/or change in pharmaceutical form (p.o. to SC): 54.5% *vs.* 0%].
Main reasons for adjusting treatment were (STRATEGE 1 vs STRATEGE 2): active RA: 86.1% *vs.* 77.8%; RA not in remission: 3.5% *vs.* 21.1%; exacerbation based on clinical/laboratory parameters: 42.6% *vs.* 10%.
Conclusion: Over the five-year period, these results suggest a change in practices for RA patients with an inadequate response to MTX and initiating their first targeted therapy: now with earlier recourse to first targeted therapy, for less active RA, and more pronounced investigation of remission.

POS0699

SIMILAR EFFICACY AND DRUG SURVIVAL RATES OF BARICITINIB MONOTHERAPY AND BARICITINIB/METHOTREXATE COMBINATION THERAPY IN REAL-LIFE TREATMENT OF RHEUMATOID ARTHRITIS - RESULTS FROM A PROSPECTIVE COHORT OF BARICITINIB-TREATED PATIENTS

S. Bayat[1,2], K. Tascilar[1,2], D. Bohr[1,2], D. Simon[1,2], G. Krönke[1,2], F. Hartmann[1,2], J. Knitza[1,2], G. Schett[1,2], A. Kleyer[1,2]. *[1]Rheumatology and Immunology, Department of Internal Medicine 3, Erlangen, Germany; [2]Friedrich-Alexander-Universität Erlangen-Nürnberg and University Hospital Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany*

Background: In clinical trials, baricitinib (BARI), in combination with methotrexate (MTX), demonstrated efficacy in patients with rheumatoid arthritis (RA) who have not responded adequately to conventional (cs)or biologic (b) DMARDs [1]. Since MTX is often not tolerated very well [2], BARI monotherapy may be preferable over BARI/MTX combination in some patients with RA. Therefore, real-life data on BARI mono- vs. combination therapy are needed to support such decisions.
Objectives: The aim of our study was to evaluate the efficacy of BARI as mono- or combination therapy in a prospective, open label cohort of RA patients failing previous cs/bDMARD therapy.
Methods: Patients with active RA (DAS28-ESR >3.2), fulfilling the ACR/EULAR 2010 classification criteria and failing previous cs/bDMARD therapy were included. All patients received BARI either as monotherapy or in combination with MTX based on the judgement of the treating physician. Demographics, medical history, disease activity parameters such as 66/68 TJC/SJC, composite scores such as DAS28-ESR, HAQ-DI, as well as medication were prospectively recorded every 3 months according to a pre-defined protocol. Informed consent and ethics approval (19_18 B) were obtained. To evaluate clinical efficacy, DA28 ESR responses was recorded at respective visit dates (until week 96). We estimated least-square mean DAS-28 scores over time using linear mixed effects models including time-group interactions. Kaplan-Meier method was used to estimate baricitinib survival and probability of remission over time.
Results: 139 patients (98 women/41 men; aged 58.4 (12.8) years; mean disease duration of 9.7 years) were included between 4/2017-10/2021. Of these, 46 patients received a combination of BARI with MTX (BARI/MTX) and 93 patients BARI monotherapy. Baseline demographic and disease-specific characteristic were comparable between BARI/MTX and BARI patients (Table 1). Median follow up was 53.1 weeks (IQR 23.0-109.3). Decrease in DAS28-ESR showed a similar dynamics in BARI/MTX (baseline DAS28-ESR: 4.2+/-1.3; 48 weeks: 2.9 (95%CI 2.6 to 3.2)) and BARI (4.3+/-1.3; 48 weeks: 3.0 (95%CI 2.8 to 3.3)) with numerical but no significant differences (Figure 1a). 62% (95%CI 40 to 76%) patients in the BARI/MTX group and 51% (95%CI: 37 to 61%) patients in the BARI attained DAS28ESR remission after 48 weeks. Drug survival was comparable among BARI/MTX and BARI patients. (69 vs.67% at 1 year and 62 vs 56% at 2 years) (Figure 1b).
Conclusion: These data show that BARI monotherapy is efficacious in real life treatment in RA patients with insufficient response to MTX. Clinical efficacy and drug survival is comparable between BARI monotherapy and BARI/MTX combo in a real-life setting.

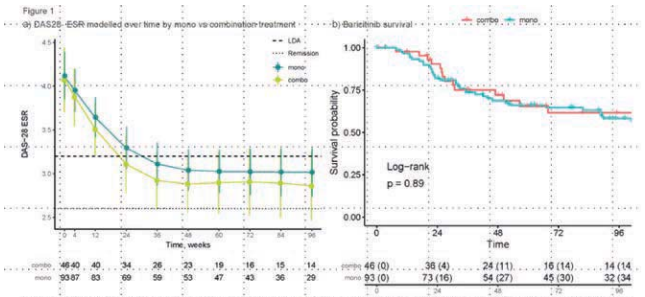

Figure 1a) shows DAS28 ESR values (SD) over time for each group including the number of patients. For example, at week 48, 47 patients in the combination group and 26 patients in the monotherapy group were still on baricitinib. At week 48 mean DAS28 ESR values for monotherapy were: 3.17 (2.95 to 3.40) compared to 2.73 (2.42 to 3.94) for combination therapy with no statistic difference. This was maintained until week 96. Figure 1b displays survival probability curve for baricitinib treatment in this cohort with respect to mono vs combination therapy

Table 1			All	combo	mono
N			139	46	93
Age		Mean (SD)	58.4 (12.8)	56.2 (14.1)	59.5 (12.0)
Sex	Female	N(%)	98 (70.5)	28 (60.9)	70 (75.3)
	Male	N(%)	41 (29.5)	18 (39.1)	23 (24.7)
CCP-AB Status	negativ	N(%)	45 (32.4)	17 (37.0)	28 (30.1)
	positiv	N(%)	94 (67.6)	29 (63.0)	65 (69.9)
Disease duration (y)		Mean (SD)	9.7 (8.5)	9.7 (7.5)	9.6 (9.1)
		Median (IQR)	6.9 (3.5-13.8)	7.5 (4.4-13.8)	6.2 (3.0-13.8)
Follow up (y)		Mean (SD)	68.9 (53.6)	61.5 (48.9)	72.5 (55.6)
		Median (IQR)	53.1 (23.0-109.3)	47.6 (21.0-112.4)	62.3 (23.1-105.0)
DAS-28 ESR		Mean (SD)	4.3 (1.3)	4.2 (1.3)	4.3 (1.3)
HAQ		Mean (SD)	1.1 (0.7)	1.1 (0.6)	1.2 (0.7)

Table1: Demographics, DAS28 ESR, Antibody Status, Follow up time, HAQ are shown for all patients as well as for the monotherapy and combination therapy arm: statistically no significant difference between the groups.

Background: It is recommended that vaccinations should be performed prior to start methotrexate (MTX) knowing that delaying initiation of background therapy may have an impact on the progression of RA.
Objectives: To access the impact of delaying initiation of MTX by 1 month on the outcome of RA at 1 year.
Methods: The VACIMRA study is a prospective, randomized, parallel-group, multicenter trial comparing the vaccine protection obtained in patients with rheumatoid arthritis according to the 1-month delay between anti-pneumococcal vaccine PCV13

DAS 28-ESR evolution during 1 year of follow-up

and methotrexate initiation in one arm, versus immediate introduction of MTX following vaccination in the other arm. We analyzed disease activity based on DAS28-ESR at baseline (M0), 1, 2, 3, 6 and 12 months between the 2 groups. For structural progression, we performed a radiographic analysis of 79 RA patients included in the Montpellier center at baseline, 6 and 12 months. This analysis was performed by the same physician two times, blinded to the patient's group. Structural damage progression at 6 months and 1 year was assessed according to van-der-Heijde-modified Sharp score (vSHS) on radiographs performed at inclusion, at 6 and 12 months of follow-up. Comparisons of the means of activity scores and radiographic scores were made with the non-parametric Wilcoxon-Mann-Whitney test.

Results: Of the 276 patients randomized, 261 could be analyzed (131 in the IMMEDIATE group and 130 in the DELAY group). At inclusion, there were no significant differences in demographic, disease activity (DAS28-ESR), biological and radiographic characteristics between the 2 groups (Table 1).

There was a significant difference in the means of DAS28-ESR at 1 month between the DELAY and IMMEDIAT groups (3.96 ± 1.46 vs 3.41 ± 1.33; p<0.001, respectively). There was no significant difference in the means of DAS28-ESR between the 2 groups at 3 months (3.19± 1.46 in the 2 groups p<0.91), at 6 months (3.11 ± 1.42 vs 3.24 ± 1.43; p=0.46, respectively) and at 12 months (2.96 ± 1.34 vs 2.98 ± 1.26p=0.89) (Graphic). Similarly, there was no significant difference in mean radiographic scores at 6 months (2.00 ± 4.41 vs. 1.80 ± 4.03 p=0.81) or at 12 months (2.23 ± 4.86 vs. 2.00 ± 4.07 p=0.93).

There was no significant variation between radiographic scores at 6 months compared to baseline in either group (mean difference 0.21 ± 0.52 vs. 0.36 ± 1.01, p=0.90) nor at 12 months compared to baseline (mean difference 0.40 ± 1.06 vs. 0.62 ± 1.58, p=0.85).

Conclusion: In patients with rheumatoid arthritis, initiation of methotrexate 1 month after PCV13 vaccination has no significant impact on RA activity and structural outcome at 1 year. Performing vaccinations 1 month before starting MTX can be proposed without significant impact on RA outcome at 1 year.

POS0701

LONG-TERM EFFICACY OF BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAVE HAD INADEQUATE RESPONSE TO CSDMARDS: RESULTS FROM RA-BEYOND UP TO 7 YEARS OF TREATMENT

R. Caporali[1], D. Aletaha[2], R. Sanmartí[3], T. Takeuchi[4], D. Mo[5], E. Haladyj[5], L. Zaremba-Pechmann[6], P. C. Taylor[7]. [1]*University of Milan, Department of Clinical Sciences & Community Health, Milan, Italy;* [2]*Medical University of Vienna, Department of Medicine III, Vienna, Austria;* [3]*Hospital Clínic de Barcelona and IDIBAPS, Rheumatology Department, Barcelona, Spain;* [4]*Keio University School of Medicine, Division of Rheumatology, Tokyo, Japan;* [5]*Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America;* [6]*HaaPACS GmbH, HaaPACS GmbH, Schriesheim, Germany;* [7]*University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Baricitinib (BARI), an oral selective Janus kinase 1/2 inhibitor, has demonstrated efficacy in patients (pts) with rheumatoid arthritis (RA) for up to 3 years (yrs) in a long-term extension (LTE) study RA-BEYOND.[1]

Objectives: Disclose efficacy of BARI in csDMARD-IR pts in the completed LTE study (up to 7 yrs).

Methods: In RA-BUILD, csDMARD-IR pts were randomized 1:1:1 to BARI 4 mg, 2 mg, or placebo (PBO). Completers to week (wk) 24 could enter the LTE and received BARI 4 or 2 mg. In RA-BEAM, MTX-IR pts were randomized 1:1:1 to BARI 4 mg, adalimumab (ADA) 40 mg, or PBO. Completers to wk 52 received BARI 4 mg in the LTE. Pts with no response could be rescued after wk 16 in both studies. Data were analysed by treatment assigned at baseline in originating studies as observed up to time of stepdown (if applicable), study discontinuation or completion, whichever occurred earlier. Efficacy response rates (RR) were assessed as proportions of pts with observed data up to yr 7 (wk 364) for low-disease activity (LDA) (SDAI ≤ 11, DAS28-hsCRP ≤ 3.2, CDAI ≤ 10), remission (REM) (SDAI ≤ 3.3, DAS28-hsCRP < 2.6, CDAI ≤ 2.8, Boolean), and physical function (HAQ-DI ≤ 0.5). No formal statistical comparisons were conducted.

Results: Approximately 56%/25% of pts in BARI 4 mg, 80%/31% in BARI 2 mg, and 60%/25% in PBO from RA-BUILD remained active at yr 3/7; 59%/17% of pts in ADA, 54%/16% in BARI 4 mg, and 67%/14% in PBO from RA-BEAM remained active at year 3/7. SDAI and CDAI had comparable RR for LDA and REM (Table 1). DAS-28CRP LDA RR were similar to SDAI and CDAI, while REM RR were about twice those of SDAI and CDAI (Table 1). HAQ-DI ≤ 0.5 RR was achieved by 25-30% of BARI-treated pts from both trials and maintained to the end of LTE.

Conclusion: In observed data, BARI demonstrated maintained efficacy in treatment and maintenance of physical function of a csDMARDs-IR RA pt population up to 7 yrs.

POS0702

ANTI-RHEUMATIC TREATMENT ALTERS PFKFB3 EXPRESSION, KEY OF GLYCOLYSIS, IN CD14+ MONOCYTES OF RA PATIENTS, WHICH CONTRIBUTES TO DISSIMILARITIES OF THE IFNG-SIGNATURE

M. Erlandsson[1,2], E. Malmhäll-Bah[1], K. M. Andersson[1], S. Töyrä Silfverswärd[1], R. Pullerits[1,2], M. I. Bokarewa[1,2]on behalf of Bokarewa. *[1]Gothenburg University, Rheumatology and Inflammation Research, Göteborg, Sweden; [2]Sahlgrenska Academy, Rheumatology clinic, Gothenburg, Sweden*

Background: Interferon-gamma (IFNαnterferon-gamma (IFNRheumatology clinic, Gothenburg, Swedenh, Göteborg, Swedenmonocytes of RA patients, which contributes to dissimilarities of the IFNg-signature Peter C. Taylor Consultant of: AbbVie, Biogen, Eli Lilly and Company, Fresenius, Galapagos, mulation is energy consuming and often demands metabolic adaptation of a cell by switching glucose metabolism from the tricarboxylic acid cycle (TCA) to the pentose phosphate pathway (PPP) alternative of glycolysis that dramatically increases glucose intake. Fructose-2,6-biphosphatase 3 (coded by *PFKFB3*) has been identified as the rate-limiting regulator of glucose metabolism suppressed in leukocytes of RA patients (2).

Objectives: To study effect of anti-rheumatic treatment on the cellular energy metabolism of $CD14^+$ mononuclear cells and its connection to the phenotype and IFNαmononuclear.

Methods: $CD14^+$ cells were sorted from the peripheral blood of the randomly recruited 60 RA patients (mean age 59.6y, DD 13.8y). The cells were LPS activated for 2h and submitted to RNA sequencing (RNAseq, IluminaNextseq). The patients were divided by actual DMARD treatment into those who had no DMARDs (n=8), methotrexate (MTX) only (n=15), biologics (MTX+aTNF n=12, MTX+RTX n=4) and JAK-inhibitors (JAKi, n=24). Differentially expressed gene (DEG) analysis between the groups was performed in R-studio, Bioconductor package, DESeq2. Reported IFN signatures (1) were combined in a set of 51 IFN signature genes (ISG) and analyzed in relation to the transcriptomic profile behind the cellular energy metabolism and DMARD treatment.

Results: MTX and JAKi but not biologics make a significant and opposing contribution of the transcriptomic of energy metabolism in $CD14^+$ cells. MTX-treated patients had significantly higher levels of the rate-limiting enzyme of glycolysis *PFKFB3* and *PGAM1* compared to those with no DMARDS, which normalized aerobic glycolysis by increasing expression of the pyruvate dehydrogenase complex proteins *PDHA1*, *PHDX* and *PDK3* linking glycolysis with TCA and decreasing PPP enzymes *PGLS*, *RPIA* and *TKT*. In contrast, *PFKFB3* was suppressed in patients treated with JAK-inhibitors compared to those treated with MTX (cor. p=1.32e-8), which significantly activated glycolysis downstream of PFKFB3 and shunting metabolism to PPP inducing expression of *G6PD* (cor.p=5.0e-92) and *PGLS* (cor.p=3.1e-46) and increased the major glucose transporter *SLC2A1* (cor. p=1.11e-24). These differences in glucose metabolism were linked to divergent phenotype of $CD14^+$ cells being short-lived $CD14^{int}CD11c^{hi}$ cells and IL6 producing in MTX-treated patients and long-lived mature $CD14^{hi}CD11b^{hi}CX3CR1^{hi}$ cells and IFNαcells and IFN producing in MTX-treated pa^+ cells of JAKi-treated patients expressed low levels of *STAT1* and ISGs compared to MTX-treated patients.

Conclusion: DMARD treatment har divergent effect on glycolysis of $CD14^+$ cells, acting through PFKFB3. This has significant impact on the phenotype of $CD14^+$ cells and inflammatory ability.

Background: Considering the highest adverse events risk (predominantly infectious disease and osteoporosis) of glucocorticoids (GCs), EULAR recommended a short-term use of GCs with rapid tapering as soon as clinically feasible in rheumatoid arthritis (RA) patients. Although a prednisone dose less than or equal to 7,5 mg/die is considered more safety, the complete discontinuation of the GCs would be desirable. Few data are available on real tapering or withdrawal of GCs in RA patients treated with DMARDs both in clinical trial and registry study.

Objectives: To evaluate the steroid tapering rate and the discontinuation of GCs in RA patients treated with biological-DMARDs (b-DMARDs) or target synthetic DMARDs (ts-DMARDs) in different treatment lines.

Methods: We revised retrospectively 1616 clinical records of RA patients who started b/ts-DMARDs between December 2017 and June 2021. We recruited 420 RA patients who were stably treated for at least 6 months with b/ts-DMARDs with or without cs-DMARDs and were taken GCs at baseline visit. The evaluations of GCs discontinuation time were realized by Kaplan-Meier estimate, followed by log-rank (Mentel-Cox) test for the comparison among different b/ts-DMARDs groups. Statistical significance was set at $p \leqslant 0.05$.

Results: RA patients treated with different b/ts-DMARDs were comparable for disease duration (anti TNF-alpha: 76 weeks ± 64; JAK-I: 121 weeks ± 122; anti-IL6: 78 weeks ± 70; abatacept: 111 weeks ± 121), disease activity (DAS 28 ESR: anti TNF alpha: 3,9 ± 1,3; JAK-I: 4,1 ± 1; anti IL-6: 4 ± 1,3; abatacept: 4 ± 1,2; p=0,958), and GCs dose (anti TNF alpha: 5,7 mg ± 7,5; JAK-I 5,5 mg ± 2,5; anti IL-6 5,7 mg ± 4,1; abatacept 5,6 mg ± 2,5; p=0,879) at baseline visit. 158 RA patients started for the first-time b/ts-DMARDs, 83 patients started 2^{nd} line of b/ts-DMARDs, 66 patients started 3^{rd} line b/ts-DMARDs and 113 patients were failure to more than 3 b/ts-DMARDs.

Considering RA patients who started b/ts-DMARDs for the first time, the groups treated with anti-IL6 or JAK-I showed a shorter discontinuation time than those treated with anti TNF-alpha or Abatacept (respectively 22 weeks ± 0,7, 22,6 weeks ± 0,7, 23,8 weeks ± 0,1, 23,1 weeks ± 0,4; p=0,046). As regards the steroid sparing in 6^{th} month of follow-up, the rates of GCs dose spared than the staring GCs dose were higher in JAK-I (44%) and anti-IL 6 (42%) compared to abatacept (30%) and anti-TNF alpha (33%).

Considering the group of RA patients treated in 2^{nd} or other lines of b/ts-DMARDs, no differences were found among various treatments in GCs discontinuation time.

Conclusion: In clinical practice GCs are useful therapeutic tools to reach as rapidly as possible low disease activity in RA patients; but the possible adverse effects of long-term GCs treatment limit their use. The introduction of biotechnological drugs has significantly improved clinical management of RA patients, achieving the aim of

rapid GCs discontinuation or their dose reduction. In particular, the mechanisms of action of anti-IL6 and JAK-I seems perform more quickly on steroid discontinuation than anti TNF alpha or abatacept, above all in 1st line of b/ts-DMARDs in RA patients.

POS0704

EFFICACY AND SAFETY OF FILGOTINIB IN PATIENTS WITH INADEQUATE RESPONSE TO METHOTREXATE, WITH 4 OR <4 POOR PROGNOSTIC FACTORS: A POST HOC ANALYSIS OF THE FINCH 1 STUDY

B. Combe[1], Y. Tanaka[2], M. H. Buch[3], G. R. Burmester[4], B. Bartok[5], A. Pechonkina[5], L. Han[6], K. Emoto[7], S. Kano[7], T. Hendrikx[8], D. Aletaha[9]. *[1]University of Montpellier, Department of Rheumatology, Montpellier, France; [2]University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; [3]University of Manchester, Centre for Musculoskeletal Research, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; [4]Charité University Hospital Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [5]Gilead Sciences, Inc., Clinical Research Department, Foster City, United States of America; [6]Gilead Sciences, Inc., Biostatistics, Foster City, United States of America; [7]Gilead Sciences K.K., Medical Affairs, Tokyo, Japan; [8]Galapagos BV, Medical Affairs, Leiden, Netherlands; [9]Medical University of Vienna, Division of Rheumatology, Wien, Austria*

Background: Patients (pts) with rheumatoid arthritis (RA) and poor prognostic factors[1] (PPF) are at risk for progression without adequate treatment. Filgotinib (FIL) is a once daily Janus kinase 1 preferential inhibitor. In FINCH 1 (NCT02889796), FIL 200 mg (FIL200) was effective vs placebo (PBO) and non-inferior to adalimumab (ADA) in pts with RA and inadequate response to methotrexate (MTX-IR); FIL200 and FIL 100 mg (FIL100) were well tolerated.[2]
Objectives: This post hoc, exploratory analysis examined efficacy and safety of FIL in MTX-IR pts with 4 or <4 PPF.
Methods: The FINCH 1 52-week (W), double-blind trial randomised MTX-IR pts with moderate–severe RA to FIL200 or FIL100, ADA, or PBO; all received background MTX. PBO pts were rerandomised, blinded, at W24 to FIL200 or FIL100. We examined pts with 4 PPF at baseline (BL): erosions on X-ray, seropositivity for rheumatoid factor or anticyclic citrullinated peptide, high-sensitivity C-reactive protein (hsCRP) ≥6 mg/L, and disease activity score in 28 joints with CRP (DAS28[CRP]) >5.1, along with those with <4 PPF. Efficacy included DAS28(CRP) <2.6 and modified Total Sharp Score (mTSS) change from baseline (CFB). Fisher's exact test was used for DAS28(CRP); the mixed-effects model was used to generate least squares mean mTSS CFB. *P* values were nominal, not adjusted for multiplicity.
Results: At BL, of 1755 randomized, treated pts, 687 had 4 PPF, and 1068 had <4 PPF. Among pts with <4PPF, 804 [75%] had erosions, 810 [76%] were seropositive, 377 [35%] had hsCRP ≥6 mg/L, 638 [60%] had DAS28[CRP] >5.1). Pts with 4 vs <4 PPF were aged 53 vs 52 years, had RA duration 8.3 vs 7.4 years, DAS28(CRP) 6.3 vs 5.4, and SDAI 45.6 vs 37.7. In pts with 4 or <4 PPF, higher proportions receiving FIL200 or FIL100 achieved DAS28(CRP) <2.6 at W12 vs PBO (nominal *P* <.001); proportions with DAS28(CRP) <2.6 increased with FIL200, FIL100, or ADA at W52 (Figure 1). DAS28(CRP) responses for FIL200 at W52 were similar in 4 vs <4 PPF pts; FIL100 and ADA responses were numerically higher in <4 vs 4 PPF pts. At W24, mTSS CFB in pts with 4 PPF was 0.21, 0.23, 0.30, and 0.66 for FIL200, FIL100, ADA, and PBO (*P* <.05 for FIL200 and FIL100 vs PBO); corresponding changes in <4 PPF pts were 0.08, 0.10, 0.11, and 0.24 (*P* >.05). At W52, mTSS CFB in 4 PPF pts was 0.29, 0.84, and 0.80 for FIL200, FIL100, and ADA, respectively, and 0.14, 0.25, and 0.53 in <4 PPF pts. Rates of adverse events (AEs), including AEs of interest, were comparable for pts with 4 PPF and <4 PPF for all treatment arms (Table 1).
Conclusion: In high-risk (4 PPF) pts with MTX-IR RA, FIL200 and FIL100 showed similar reductions in disease activity vs PBO at W12 as in pts with <4 PPF; mTSS in FIL200 pts changed little from W24 to W52. Tolerability was comparable across treatment arms, regardless of presence of 4 or <4 PPF.

POS0705 DILEMMA OF BELIMUMAB THERAPY (DIS) CONTINUATION DURING PREGNANCY: RESULTS OF A RETROSPECTIVE STUDY IN EUDRAVIGILANCE

N. Ghalandari[1], H. J. M. J. Crijns[2], R. Dolhain[1], J. Hazes[1], E. Van Puijenbroek[3]. *[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands; [2]CBG-MEB, Pharmacovigilance, Utrecht, Netherlands; [3]Lareb, Pharmacovigilance, 's Hertochenbosch, Netherlands*

Background: Active systemic lupus erythematosus (SLE) and nephritis due to SLE contribute to poor pregnancy outcomes. (1, 2) A meta-analysis has shown a relative risk of 1.51 for miscarriage in SLE patients compared to women without SLE. (3) The risk is even higher if the disease is active during pregnancy (around 3-fold increase in pregnancy loss). (4) Corticosteroids, azathioprine, hydroxychloroquine, ciclosporine and tacrolimus are considered safe treatments. (5) However, these treatment options may still not be sufficient in patients poorly responsive to conventional therapies or patients who suffer from nephritis. (6) The only biologic authorized for SLE up to this date, belimumab, is currently not recommended for use during pregnancy due to lack of data. Provided that the health of the child begins with the health of the mother, pregnant patients, face the dilemma of cessation or continuation of belimumab. If belimumab is stopped there will be a risk of SLE flare and its consequences for mother and foetus. Continuation is also not optimal because the lack of knowledge on safety for use during pregnancy.

Objectives: To compare the reported foetal outcomes in SLE patients who stopped scheduled belimumab within the first trimester (group A) and who continued scheduled belimumab during the first trimester or thereafter (group B).

Methods: All belimumab-exposed pregnancy-related reports, were extracted from the EudraVigilance (EV) database until March 11th 2021. After case review, repeated cases, uninformative reports, non-medical elective abortions and foetal chromosomal abnormalities were excluded. Included pregnancies were divided into two groups (group A and B, as described above). Foetal outcomes were divided into live birth or foetal death (due to miscarriage or still birth) and were compared between both groups. Furthermore, neonatal outcomes, such as reporting rates of pre-term birth, low birth weight and major congenital malformations (CMs) were compared.

Results: No statistical difference in foetal death was observed between group A and B (reporting rates: 46.4% and 52.4%, respectively; p-value>0.05). Occurrence of major CMs, pre-term birth and low birth weight was higher - though not statistically different- in group A (Table 1).

Table 1. Neonatal characteristics of live born children (including twin pregnancies)

Live births	Stopped (group A); (n=37)	Continued (group B); (n =10)	Total; (n=47)
Gestational age at birth, median (IQR), weeks	37.1 (35.5, 40.0)	38.2 (36.4, 39.1)	**37.6 (36.0, 39.4)**
Weight, median (IQR), grams	2749 (2268, 3200)	2975 (2700, 3175)	**2835 (2406-3175)**
Preterm birth*; n (%)	16 (43.2)	4 (40.0)	**20 (42.5)**
Low birth weight*; n (%)	9 (24.3)	0 (0.0)	**9 (19.4)**

Conclusion: Based on our data belimumab continuation during first trimester or thereafter does not result in higher reporting of foetal death. Therefore, continuation might be even preferable if the pregnancy is already exposed to belimumab. Since the analysis is based on spontaneous reports / retrospective data, additional studies are needed to confirm the results.

POS0706 LONG-TERM HYDROXYCHLOROQUINE TREATMENT IMPROVES ESSPRI AND ESSDAI IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

N. Hashimoto[1], T. Nakazawa[2], T. Iwasaki[3], T. Hashimoto[1]. *[1]Hashimoto Rheumatology Clinic, Department of Rheumatology, Osaka, Japan; [2]Osaka Saiseikai Nakatsu Hospital, Department of Rheumatology, Osaka, Japan; [3]Keiseikai Medical Corporation, Department of Internal Medicine, Higashiosaka, Japan*

Background: Primary Sjögren's syndrome (pSS) is a chronic, systemic autoimmune disease typically affecting the salivary and lacrimal glands and producing symptoms of dry mouth, dry eyes, fatigue and pain. Hydroxychloroquine (HCQ) have been shown to have various immunomodulatory and immunosuppressive effects, and currently have established roles in the management of rheumatoid arthritis and systemic lupus erythematosus (SLE). However, the use of HCQ in pSS is based in expert recommendations and in few studies with a low level of evidence. There are very few publications assessing HCQ use in a double-blind, randomized, and placebo-controlled studies. In Japan, HCQ is indicated for patients with SLE and cutaneous lupus erythematosus (CLE) and is off-label use for pSS patients without CLE. Recently, ESSPRI and ESSDAI have been developed by the European League Against Rheumatism (EULAR) SS study group as standardized outcome tools for measuring patients' reported symptoms and disease-specific activity. ESSDAI and ESSPRI have been proven to be valid and reliable, they have been used to select patients or as the primary or secondary outcome measures in clinical trials.

Objectives: The aim of this study was to examine the efficacy of HCQ in pSS at 8 and 52 weeks after treatment evaluated by ESSPRI and ESSDAI.

Methods: Twenty-six pSS patients (26 female, mean age 51.6 ± 13.6 years) with CLE who fulfilled the ACR/EULAR classification criteria for SS and/or the Japanese Ministry of Health and Welfare criteria for SS were studied. The clinical indexes were evaluated by ESSDAI, ESSPRI, IgG and CH50 before and after HCQ treatment at 8 and 52weeks. ESSPRI components were calculated individually and as a single factor composed of the mean of the three components (pain, fatigue, and dryness: VAS 0-10). ESSDAI (0–123) proposes the evaluation of 12 domains or organ systems (constitutional, lymphadenopathy, glandular, articular, cutaneous, pulmonary, renal, peripheral nervous system, central nervous system, muscular, hematological and biology).

Results: ESSPRI and component of fatigue and pain were significantly lower at 8 and 52 weeks after treatment than HCQ pre-treatment (ESSPRI: 4.14±1.45 vs 3.38±1.57, 3.34±1.56, p=0.005, p=0.045, fatigue: 4.68±2.12 vs 3.68±1.96, 3.58±1.87, p=0.010, p=0.036, pain: 3.32±1.94 vs 2.09±1.60, 1.79±1.51, p=0.0043, p=0.0014). However, there was no significant difference in dryness component between HCQ pre-treatment and 8 and 52 weeks after treatment (4.41 ± 2.09 vs 4.32 ± 2.06, 4.21 ± 2.39, p = 0.71, p = 0.94), and the amount of saliva produced by the gum test also showed no significant difference between pre-HCQ treatment and 52 weeks after treatment (8.21 ± 6.72 vs 8.24 ± 6.79 mL / 10 minutes, p = 0.45). There was also a significant decrease in ESSDAI and constitutional, articular, cutaneous and biological domain at 52 weeks after treatment compared to HCQ pre-treatment (ESSDAI: 9.68±6.14 vs 4.74±6.43, p=0.0004; constitutional: 1.41±1.50 vs 0.63±1.26, p=0.034, articular: 1.00±1.02 vs 0.21±0.63, p=0.0027, cutaneous: 2.86±3.27 vs 1.11±2.49, p=0.010, biological: 1.14±0.83 vs 0.79±0.86, p=0.014). An improvement of at least 1 point or 15% in ESSPRI and at least 3 points in ESSDAI compared to HCQ pr-treatment were observed in 63.6% and 31.8% at 8 weeks and 73.7% and 68.4% at 52 weeks after treatment. In addition, IgG was significantly decreased at 52 weeks after treatment compared to HCQ pre-treatment (1934 ± 613 vs 1714 ± 564 mg / dL, p=0.0005).

Conclusion: HCQ treatment improved pain such as arthritis, fatigue, constitutional and cutaneous manifestations, but was not effective for salivary function and dryness. HCQ treatment was useful in improving ESSPRI and ESSDAI, and long-term treatment increased the number of effective cases from 8 weeks to 52 weeks.

Background: The goal of targeted treatment in patients with Systemic Lupus Erythematosus (SLE) is to achieve clinical remission or low disease activity, with the best quality of life, low damage rates and better survival [1-4]. RELESSAR is a multicenter, cross-sectional study registry of ≥18 years SLE (ACR 97) patients [5].
Objectives: To describe demographic, clinical characteristics and treatments in SLE patients according to disease activity state. To evaluate the proportion of SLE and refractory SLE patients that are potentially candidates for Belimumab treatment (Active SLE despite standard treatment including increased acDNA autoantibodies and low complement).
Methods: We evaluated demographic and clinical data, treatments, score of damage (SLICC), activity (SLEDAI) and comorbidity (Charlson), hospital admissions and severe infections. The patients were compared according to disease activity: remission (SLEDAI = 0 and without corticosteroids), low disease activity (LDA, SLEDAI> 0 and ≤4 and without corticosteroids) and non-optimal control (SLEDAI> 4 and any dose of corticosteroids). Refractory SLE was defined according to Rituximab (RTX) use, non-response to cyclophosphamide or two or more immunosuppressant or splenectomized patients. Potential use of Belimumab according approved prescription in Argentina was analyzed.
Results: Overall, 1277 patients were analyzed: 299 (23.4%) were in remission, 162 (12.7%) in LDA and 816 (63.9%) with non-optimal control of the disease. Patients in non-optimal control group were younger, less frequently female and they showed less time of disease and lower socioeconomic status (p < 0.001). They were also more prevalent mestizos (p= 0.004), had higher SLEDAI and SLICC indexes (p <0.001) and higher use of immunosuppressant therapy (p <0.001). There was no difference regarding biologic treatment (RTX p= 0.547 and Belimumab p= 0.08). This group had higher proportion of hospital admissions and severe infections (p<0.001, respectively). Two hundred and one SLE patients fulfilled the use of Belimumab prescription criteria but only 45/201 patients (22,3%) received it in the last visit. Malar rash was the only clinical variable associated with the use of Belimumab (72.7% vs 29.8% p= 0.005). Seventy-six patients classified as refractory SLE (15.7%) and 56/76 (75.7%) never received Belimumab. Patients on Belimumab therapy were associated to treatment with lower doses of corticoids (p= 0.018) and lower rate of hospital admission caused by SLE flare (p= 0.027).
Conclusion: A high percentage of patients had uncontrolled disease upon entry into the registry and were potential candidates for treatment with Belimumab. The patients who received biologic treatment showed the benefit of requiring fewer doses of corticosteroids and having a lower rate of hospitalizations.

POS0708 EVALUATING THE HYPERSENSITIVITY PROFILE OF ANIFROLUMAB AND THE NEED FOR PREINFUSION PROPHYLACTIC TREATMENT IN PATIENTS WITH SLE

K. C. Kalunian[1], Y. Tanaka[2], I. Hupka[3], L. J. Zhang[4], M. Shroff[5], S. Werther[6], G. Abreu[6], C. Lindholm[6], R. Tummala[4]. *[1]University of California, San Diego, Division of Rheumatology, Allergy and Immunology, La Jolla, CA, United States of America; [2]University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; [3]AstraZeneca, BioPharmaceuticals R&D, Warsaw, Poland; [4]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America; [5]AstraZeneca, BioPharmaceuticals R&D, Waltham, MA, United States of America; [6]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*

Background: Anifrolumab, a human monoclonal antibody (mAb), is approved in Canada, Japan, and the United States for the treatment of patients with systemic lupus erythematosus (SLE) based on results from the phase 2b MUSE and the phase 3 TULIP-1/-2 trials.[1–3] Anaphylactic reactions (ARs), hypersensitivity reactions (HSRs), and infusion-related reactions (IRRs) are risks of mAb infusions, so physicians prescribing anifrolumab may wish to understand the hypersensitivity profile and whether prophylactic pretreatments are required to mitigate HSR/IRRs.
Objectives: To evaluate the hypersensitivity profile of anifrolumab and the need for pretreatment.
Methods: Pooled data were analyzed from patients with moderate to severe SLE despite standard therapy who received intravenous infusions (every 4 weeks, 48 weeks) of anifrolumab or placebo in the randomized, 52-week MUSE (NCT01438489),[1] TULIP-1 (NCT02446912),[2] and TULIP-2 (NCT02446899)[3] trials. An AR (analyzed in the anifrolumab 150/300/1000 mg and placebo groups) was defined as acute illness onset within minutes to several hours of infusion with involvement of skin and/or mucosal tissue, and/or respiratory compromise, and/or reduced blood pressure, and/or persistent gastrointestinal symptoms. HSRs and IRRs were analyzed in the anifrolumab 300 mg group (as this is the approved dose) and the placebo group. An HSR was defined as acute illness onset with involvement of skin and/or mucosal tissue during infusion (not meeting the AR definition); IRR was defined as any other reaction occurring during/within 24 hours of infusion. Patients did not receive pretreatment unless they had experienced a previous IRR/HSR in the program. Pretreatment was assumed if a patient received prophylactic antihistamine, corticosteroid, non-steroidal anti-inflammatory drug, and/or dopamine antagonist 1 day before/on the day of infusion.
Results: Of patients who received anifrolumab 300 mg (n=459), anifrolumab 1000 mg (n=105), or placebo (n=466), none experienced ARs; 1 patient who received anifrolumab 150 mg (n=93) experienced an AR. HSRs occurred in 3% (n=12) of anifrolumab 300 mg-treated patients (of whom 4 had a history of

HSRs) vs 1% (n=3) in the placebo group. IRRs occurred in 9% (n=43) of anifrolumab-treated patients vs 7% (n=33) in the placebo group. All HSRs and IRRs were mild/moderate in intensity. There were no discontinuations due to HSRs or IRRs in the anifrolumab group, while there were 2 in the placebo group (HSR: n=1; IRR: n=1). In the anifrolumab 300 mg and placebo groups, more patients experienced HSR/IRRs with the initial (1–6) vs later infusions (Figure 1). In the anifrolumab group, the median (median absolute deviation) time to first HSR or IRR was 30.5 (29.5) days or 27.0 (26.0) days, respectively. Of the 12 anifrolumab-treated patients with ≥1 HSR, 3 received subsequent pretreatment, and none had any HSR after the use of pretreatment. Of the 43 anifrolumab-treated patients with ≥1 IRR, 2 received pretreatment, of whom 1 had an IRR after pretreatment and anifrolumab dosage remained unchanged.

Conclusion: Following anifrolumab infusion, ARs were uncommon, and few (3%) patients experienced HSRs. HSRs and IRRs with the approved anifrolumab 300 mg dose were mild to moderate, occurred early in treatment, did not lead to discontinuation, and only rarely required pretreatment. Our data support a safe and manageable hypersensitivity profile for anifrolumab.

POS0709

SUSTAINED BICLA AND BILAG ORGAN DOMAIN RESPONSES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) RECEIVING ANIFROLUMAB IN TWO PHASE 3 TRIALS

R. Van Vollenhoven[1], R. Furie[2], E. F. Morand[3], R. Tummala[4], E. Maho[5], C. Lindholm[6]. *[1]University of Amsterdam, Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, NY, United States of America; [3]Monash University, Faculty of Medicine, Nursing & Health Sciences, School of Clinical Sciences, Melbourne, VIC, Australia; [4]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America; [5]AstraZeneca, BioPharmaceuticals R&D, Cambridge, United Kingdom; [6]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*

Background: Incomplete SLE disease control is associated with progressive organ damage, poor quality of life, and increased mortality.[1–3] Sustained reduction in overall disease activity is therefore an important treatment goal.

Objectives: To investigate sustained British Isles Lupus Assessment Group 2004–based Composite Lupus Assessment (BICLA) response and British Isles Lupus Assessment Group (BILAG) responses by organ domain in pooled data from the TULIP-1 and TULIP-2 trials of the type I interferon receptor monoclonal antibody, anifrolumab, in patients with SLE.[4,5]

Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) were phase 3, randomized, placebo-controlled, 52-week trials of intravenous anifrolumab administered every 4 weeks for 48 weeks in eligible patients with moderate to severe SLE who were receiving standard therapy.[4,5] Sustained BICLA and BILAG response rates, measured as the number of consecutive patient visits with BICLA or BILAG domain responses, respectively, from Week 4 to Week 52 were compared between the anifrolumab vs placebo groups. BILAG-2004 response was defined as a reduction from A (severe disease) at baseline to B (moderate), C (mild), or D (no current disease) or reduction from B at baseline to C or D.[6]

Results: In total, 360 patients received anifrolumab 300 mg and 366 patients received placebo in the TULIP-1 and TULIP-2 trials. Analysis of pooled TULIP data revealed that more patients who received anifrolumab had sustained BICLA responses compared with placebo (Table 1). The proportions of patients who had BICLA responses sustained for ≥3, ≥6, ≥9, and 12 months inclusive of Week 52 were 33.6%, 27.2%, 16.4%, and 9.2% in the anifrolumab group, and 20.5%, 15.0%, 8.5%, and 1.9% in the placebo group, respectively. The most commonly affected organ domains were musculoskeletal (645/726 patients) and mucocutaneous (627/726 patients) (Figure 1). More patients receiving anifrolumab had BILAG responses for 12 months compared with placebo in these two domains (musculoskeletal: 19.9% vs 13.1%; mucocutaneous: 17.1% vs 7.1%); analyses of all other organ domains were limited by small sample sizes.

Table 1. Number of Patients With Consecutive Visits of Sustained BICLA Response Up to and Including Week 52 in Pooled TULIP-1 and TULIP-2 Trials

n (%)	Anifrolumab 300 mg (n=360)	Placebo (n=366)
≥3 months (≥5 visits, Week 36–52)	121 (33.6)	75 (20.5)
≥6 months (≥8 visits, Week 24–52)	98 (27.2)	55 (15.0)
≥9 months (11 visits, Week 12–52)	59 (16.4)	31 (8.5)
12 months (13 visits, Week 4–52)	33 (9.2)	7 (1.9)

BICLA, British Isles Lupus Assessment Group–based Composite Lupus Assessment.

Conclusion: In two phase 3 studies, more anifrolumab-treated patients achieved sustained BICLA and BILAG responses compared with placebo. In the frequently affected musculoskeletal and mucocutaneous domains, sustained treatment benefit of anifrolumab over placebo was observed. These data support the durable clinical benefit of anifrolumab treatment in patients with moderate to severe SLE who are receiving standard therapy.

POS0710 INTERSTITIAL LUNG DISEASE IN PRIMARY SJÖGREN'S SYNDROME: CLINICAL AND LABORATORY FEATURES, EFFECTIVENESS OF RITUXIMAB THERAPY.

B. Chalcev[1], A. Torgashina[1], E. Sokol[1], J. Khvan[1]on behalf of the Department of Rare Rheumatic Diseases and Sjogren's Syndrome. *[1]V.A. Nasonova Research, Laboratory of Rare Rheumatic Diseases and Primary Sjögren's Syndrome, Moscow, Russian Federation*

Background: Interstitial lung disease (ILD) often occurs in primary Sjogren's syndrome (pSS) and reduces the survival of patients [1, 2]. Diagnosis and therapy in pSS-ILD are not standardized.
Objectives: To evaluate clinical characteristics of pSS-ILD and efficacy of rituximab therapy in this group of patients.
Methods: We conducted retrospective study which included 19 pSS-ILD patients. pSS was diagnosed based on the ACR 2012 or ACR/EULAR 2016 criteria. Diagnosis and dynamic assessment of ILD was carried out on the basis of high-resolution computed tomography (HRCT) and pulmonary function tests (PFT). The median age of pSS debut was 49 years (7-72 years), the median age of ILD debut – 57 years (29-75 years). All 19 patients received rituximab: 10 as a monotherapy, 6 in combination with cyclophosphamide, 3 in combination with mycophenolate mofetil. The median follow-up duration was 24 months (3-108 months).
Results: In 5 of 19 patients (26%), ILD was the first manifestation of pSS, while 14 patients (74%) developed ILD after an average of 9 years of disease course in the absence of therapy or taking low doses of glucocorticoids and hydroxychloroquine. The most common patterns of ILD were nonspecific interstitial pneumonia (52,6%) and lymphocytic interstitial pneumonia (26,3%), while organizing pneumonia and usual interstitial pneumonia were significantly less common (10,5% respectively). Both patients with organizing pneumonia were diagnosed with pulmonary lymphoma (also they had persistent salivary gland enlargement, lymphadenopathy and paraproteinemia). When analyzing clinical and laboratory features, we did not identify any predictors of ILD in pSS (Table 1). Rituximab therapy was effective in 16 of 19 patients (84,2%) based on stabilization or improvement in HRCT and PFT. The therapy was ineffective in 3 patients (15,8%), one of whom (patient with pulmonary lymphoma) died from an acute exacerbation of ILD.

Table 1. Clinical and laboratory features of pSS-ILD patients (N=19).

Sign	Frequency, %
Asymptomatic course of ILD	36,8
ANA+	100
AntiRo+	73,7
AntiLa+	47,4
RF IgM +	55
High CRP	28
High ESR	33
Hypocomplementemia	37,5
Hypergammaglobulinemia	44
High IgG	39
mIg	36
Cryoglobulinemia	18
Severe xerostomia, xerophthalmia	44
Focus score>4	44
Vasculitis	26
Lymphoma	31,6

Conclusion: Considering asymptomatic cases and the absence of pSS-ILD predictors, all patients with pSS at the onset of the disease and in the dynamics should undergo HRCT and PFT for the purpose of ILD early diagnosis. In the present study, rituximab therapy was highly effective in pSS-ILD, further prospective studies are needed to confirm these data. In patients with pSS-ILD, vigilance for pulmonary lymphoma is necessary, especially in the presence of persistent salivary gland enlargement, lymphadenopathy, paraproteinemia, pattern of organizing pneumonia and a lack of response to rituximab and cyclophosphamide therapy.

Background: The low prevalence of systemic autoimmune diseases and the diversity of their clinical manifestations make complex to conduct randomised clinical trials to assess the potential efficacy of targeted treatments.
Objectives: To assess the tolerance and efficacy of targeted therapies prescribed off-label in refractory autoimmune diseases.
Methods: The TATA registry (*TArgeted Therapy in Autoimmune Diseases)* is a prospective, observational, national and independent cohort follow-up. The inclusion criteria in the registry are as follows: age > 18 years; rare systemic autoimmune disease (systemic lupus erythematosus, Sjögren's syndrome, systemic scleroderma, inflammatory myopathy, vasculitis) or other refractory rheumatism treated with off-label drugs started after 1st January 2019.
Results: Hundred (100) patients (79 females) were enrolled. The median age was 52.5 years [49;56], the median disease duration before enrolment was 5

years [3;7]. The targeted therapies at enrolment were as follows: JAK/STAT inhibitors (44%), anti-IL6R (22%), anti-IL12/23, anti-IL23 and anti-IL17 (9%), anti-BAFF (5%), abatacept (5%), other targeted treatments (9%), and combination of targeted treatments (6%). 73% of patients were receiving corticosteroid therapy at enrolment (median dose 10 mg/day). The current median follow-up time is 9 months [8;10]. Safety: 11 serious infections (incidence rate of 14.8 /100 patient-years) and 1 cancer (1.3 cancers/100 patient-years) were observed. Two patients died from severe COVID-19 (2.7 deaths/100 patient-years). Efficacy: The targeted treatment was considered effective by the clinician in 56% of patients and allowed in responders a median reduction of oral corticosteroids of 15 [9-21] mg/day.

Conclusion: These initial results of the TATA registry confirm the diversity of targeted treatments prescribed off-label in refractory autoimmune diseases and their corticosteroid-sparing effect when effective. Tolerance was acceptable in these refractory patients with a long history of treatment with immunosuppressive drugs.

Background: Belimumab (BEL) is an approved systemic lupus erythematosus (SLE) treatment. Despite BEL clinical studies demonstrating a favourable benefit–risk profile, varying incidence rates of mortality and adverse events of special interest, including malignancies, require further evaluation.
Objectives: To assess long-term safety following BEL therapy.
Methods: This was a Year (Yr)-4 post-treatment follow-up of the Phase 4, double-blind, placebo (PBO)-controlled Belimumab Assessment of Safety in SLE (BASE) study (GSK Study BEL115467; NCT01705977).[1] Overall, 4003 adults with active, autoantibody-positive SLE received BEL (10 mg/kg IV) or PBO, plus standard therapy (ST), for 48 weeks. Patients (pts) then entered a Yr 2–5 follow-up period in which they received physician-directed ST. All pts were contacted annually by telephone, including pts who discontinued treatment. Mortality and new malignancies (including nonmelanoma skin cancer) were the endpoints collected, and rates summarised. We present Yr-4 follow-up data by Yr-1 treatment received.
Results: Baseline characteristics for the Yr-4 follow-up population (N=3204) were similar to the Yr-1 double-blind study population (N=4003). By the Yr-4 follow-up, cumulatively 12.7% and 11.0% of pts in the BEL and PBO Yr-1 groups had received BEL as part of physician-directed care, respectively (data not shown). As shown in the Table 1, cumulative follow-up adjusted mortality rates were lower in the BEL vs PBO Yr-1 treatment group for Yrs 2 to 4. Cumulative follow-up adjusted new primary malignancy rates were lower in the BEL vs PBO Yr-1 treatment group for Yrs 2 and 3, but similar in Yr 4.
Conclusion: Post-treatment Yr-4 follow-up results in BASE, the largest double-blind trial in pts with SLE to date, support the safety of BEL therapy, with no new BEL safety concerns identified in this analysis.

POS0713 BIIB059 EFFICACY IN PARTICIPANTS WITH ACTIVE CUTANEOUS LUPUS ERYTHEMATOSUS (CLE): SUBGROUP ANALYSIS OF PARTICIPANTS ACHIEVING CLEAR/ALMOST CLEAR DISEASE ACTIVITY FROM PART B OF THE TWO-PART PHASE 2 LILAC STUDY

V. Werth[1], R. Furie[2], F. Nyberg[3], X. Huang[4], C. Barbey[5], C. Musselli[6], N. Franchimont[7]. *[1]University of Pennsylvania and Corporal Michael J. Crescenz VAMC, Department of Dermatology, Philadelphia, United States of America; [2]Northwell Health, Division of Rheumatology, Great Neck, United States of America; [3]Karolinska University Hospital, Department of Dermatology, Stockholm, Sweden; [4]Biogen, Biostatistics, Cambridge, United States of America; [5]Biogen, Multiple Sclerosis and Immunology Development Unit, Baar, Switzerland; [6]Biogen, Clinical Development Immunology, Cambridge, United States of America; [7]Biogen, Multiple Sclerosis and Immunology Development Unit, Cambridge, United States of America*

Background: CLE is an autoimmune disease that occurs with or without systemic manifestations. The chronic manifestations of CLE often have a lasting negative impact on a patient's quality of life.[1,2] Clearance of skin activity is the most desirable outcome for a targeted treatment in patients with CLE; however, it is a challenging target to achieve. Activation of both the innate and adaptive immune systems leads to the typical inflammatory histopathological characteristics of CLE and its clinical manifestations.[3] BIIB059 is a humanized monoclonal antibody that engages blood dendritic cell antigen 2 (BDCA2), a receptor on plasmacytoid dendritic cells, inhibiting production of Type I interferons and other chemokines/cytokines.[4] The randomized Phase 2 LILAC study (NCT02847598) met its primary endpoint in CLE (Part B), demonstrating a dose response in the percent change in Cutaneous Lupus Erythematosus Disease Area and Severity Index – Activity (CLASI-A) from baseline (BL) to Week 16 for BIIB059 vs placebo (PBO).[5]
Objectives: To determine the proportions of participants achieving a clear or almost clear skin status as defined by the attainment of CLASI-A scores of 0–1 or 0–3 at Week 16.
Methods: In Part B, adults with histologically confirmed active CLE with or without systemic manifestations and adjudicated BL CLASI-A ≥8 received BIIB059 (50, 150, or 450 mg) or PBO subcutaneously Q4W through Week 12, with an additional loading dose at Week 2. CLASI-A was assessed at each dosing visit and at Week 16. The proportions of participants achieving CLASI-A scores of 0–1 (prespecified analysis) or 0–3 (ad-hoc analysis) and mean absolute CLASI-A score changes at Week 16 were determined.
Results: At BL, mean (standard deviation [SD]) CLASI-A scores were 16.6 (8.8) and 16.5 (8.5) for the pooled BIIB059 and PBO groups, respectively. At Week 16, more participants in the BIIB059 50, 150, and 450 mg treatment groups achieved CLASI-A scores of 0–1 and 0–3 vs those in the PBO group (Table 1). In participants achieving CLASI-A scores of 0–1, mean (SD) absolute CLASI-A scores decreased by 11.0 (SD not applicable), 19.6 (11.1), and 16.4 (11.5) points from BL at Week 16 in the 50, 150, and 450 mg treatment groups, respectively; in participants achieving CLASI-A scores of 0–3, CLASI-A scores decreased by 8.8 (2.7), 15.4 (10.3), and 13.2 (9.5) points from BL at Week 16 in the 50, 150, and 450 mg treatment groups, respectively, vs 8.3 (2.5) points in the PBO group. Among the 11 participants who achieved CLASI-A scores of 0–1, six had CLASI-A scores of 0 (representing a 100% resolution of skin disease) with a decrease in CLASI-A score ranging from 11 to 30 points.

Table 1. Proportion of pts who achieved CLASI-A scores of 0–1 and 0–3

		BIIB059		
	PBO	50 mg	150 mg	450 mg
	(n=33)	(n=26)	(n=25)	(n=48)
Number of pts achieving CLASI-A score of 0–1 at Week 16 (%)	0/32 (0)	1/26 (3.9)	5/25 (20.0)	5/43 (11.6)
Number of pts achieving CLASI-A score of 0–3 at Week 16 (%)	3/32 (9.4)	5/26 (19.2)	8/25 (32.0)	9/43 (20.9)

Pts considered as treatment failures or who discontinued treatment were classified as non-responders at visits post treatment failure or treatment discontinuation. Pts who completed treatment but had a missing score at any primary timepoint are classified as non-responders for that timepoint.

Conclusion: After 16 weeks of treatment, greater proportions of participants with active CLE treated with BIIB059 vs PBO achieved a clear or almost clear skin status, defined as CLASI-A score of 0–1 or 0–3, further supporting the efficacy of BIIB059 in CLE.

POOLED SAFETY ANALYSIS OF BARICITINIB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM THREE RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, CLINICAL TRIALS

T. Dörner[1], Y. Tanaka[2], M. Mosca[3], I. N. Bruce[4], M. Cardiel[5], E. F. Morand[6], M. A. Petri[7], M. Silk[8], C. Dickson[8], G. Meszaros[8], M. Issa[8], L. Zhang[8], D. J. Wallace[9]. *[1]Charite Universitätsmedizin, Medicine/Rheumatology and Clinical Immunology, Berlin, Germany; [2]University of Occupational and Environmental Health, First Department of Internal Medicine, Kitakyushu, Japan; [3]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [4]University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; [5]Centro de Investigación Clínica de Morelia, Clinical Research, Michoacán, Mexico; [6]Monash University, Centre for Inflammatory Disease, Melbourne, Australia; [7]Johns Hopkins University, Division of Rheumatology, Baltimore, United States of America; [8]Eli Lilly and Company, N/A, Indianapolis, United States of America; [9]Cedars-Sinai Medical Center/ University California, Division of Rheumatology, Allergy and Immunology, Los Angeles, United States of America*

Background: Baricitinib (BARI), an oral selective inhibitor of Janus kinase 1 and 2 approved for the treatment of rheumatoid arthritis and atopic dermatitis, has been evaluated in clinical studies in patients with systemic lupus erythematosus (SLE).
Objectives: To assess the safety profile of BARI in patients with SLE.
Methods: Patients with SLE receiving stable background therapy were randomised 1:1:1 to BARI 2-mg, 4-mg, or placebo (PBO) once daily in one 24-week, phase 2 (NCT02708095) and two 52-week, phase 3, PBO controlled studies (NCT03616912 and NCT03616964).
Results: A total of 1,849 patients were included in this pooled analysis, representing 1,463.5 patient years of exposure (PYE). The incidence rates per 100 PYR at risk (IR/100 PYR) for serious adverse events (SAEs) were 9.5, 14.7, and 14.1 respectively for PBO, BARI 2-mg, and BARI 4-mg. There were no clinically meaningful differences between treatment groups for discontinuations due to AEs or death (Table 1).

Table 1. Overview of safety measures of baricitinib in patients with SLE

	PBO	BARI 2-mg	BARI 4-mg	Pooled-BARI

	488.0	494.1	481.4	975.5
	[0.4; 0.0, 1.5]	[0.6; 0.1, 1.8]	[0.4; 0.1, 1.5]	[0.5; 0.2, 1.2]
NMSC	2 (0.3)	0	0	0*
	486.7	494.0	481.4	975.4
	[0.4; 0.0, 1.5]	[0.0; NA, 0.7]	[0.0; NA, 0.8]	[0.0; NA, 0.4]

Data are n (%) patients PYR [IR; 95% CI]. #Phase 2 study data not included. AE=adverse event; CI=confidence interval; MACE=major adverse cardiac event; NMSC=non-melanoma skin cancers; VTE=venous thrombotic event (includes deep vein thrombosis and pulmonary embolism); IR=incidence rate (100 times the number of patients reporting an adverse event divided by the event-specific exposure to treatment); N=number of patients in the analysis population; n=number of patients in the specified category; PYE=patient-year of exposure; PYR=patient years at risk; SAE=serious adverse event. *p≤0.05 vs placebo.

The IR/100 PYR for serious infections were 2.5, 4.5, and 5.9 respectively for PBO, BARI 2-mg, and BARI 4-mg. The risk of Herpes Zoster was higher in BARI 4-mg (4.7%) vs PBO (2.9%) (Table 1).
The IR/100 PYR for positively adjudicated venous thrombotic events (VTEs) were 1.4, 0.7, and 0.2 respectively for PBO, BARI 2-mg, and BARI 4-mg. The IR/100 PYR for positively adjudicated major adverse cardiac event (MACE) was numerically higher in BARI 2-mg (0.2) and BARI 4-mg (0.7) vs PBO (0.0), however the pooled-BARI IR/PYR (0.5) was within the range of background disease (1). No increased risk for malignancies was observed.
Conclusion: The safety profile of BARI in SLE patients was consistent with the known BARI safety profile. There was no increased risk of VTE in BARI treatment groups.

TREATMENT OF SLE PATIENTS WITH ZETOMIPZOMIB (KZR-616), A SELECTIVE INHIBITOR OF THE IMMUNOPROTEASOME, RESULTS IN CIRCULATING GENE EXPRESSION, PROTEIN LEVEL, AND IMMUNE CELL PHENOTYPIC CHANGES WITH POTENTIAL CORRELATIONS TO CLINICAL RESPONSE

A. Fan[1], B. Tuch[1], T. Muchamuel[2], J. Anderl[1], R. Leff[3], N. Henig[3], C. Kirk[4]. *[1]Kezar Life Sciences, Biology and Translational Research, South San Francisco, United States of America; [2]Kezar Life Sciences, Pharmacology and Toxicology, South San Francisco, United States of America; [3]Kezar Life Sciences, Clinical, South San Francisco, United States of America; [4]Kezar Life Sciences, Research, South San Francisco, United States of America*

Background: Systemic lupus erythematosus (SLE), a severe multiorgan autoimmune disease, involves dysfunction of multiple immune system components. In preclinical studies, KZR-616, a first-in-class small molecule selective inhibitor of the immunoproteasome, demonstrated pleiotropic immunomodulatory functions encompassing both innate and adaptive immune pathways[1,2]. In the recently completed MISSION Phase 1b trial in SLE patients (pts), KZR-616 exhibited encouraging safety, tolerability, and clinical improvements[3]. Preliminary biomarker analysis of the first two cohorts was previously reported[4]. Here, we present complete biomarker results from all cohorts in this study.
Objectives: 1) To characterize biomarker changes (gene expression, circulating protein levels and immune cell phenotypes) following KZR-616 treatment. 2) To evaluate correlations between biomarker changes and treatment response to KZR-616.
Methods: The open-label Phase 1b MISSION Trial (NCT 03393013) was a 25-week trial of KZR- 616 administered subcutaneously once weekly at doses ranging from 30-75 mg for 13 weeks (W) with a 12 W follow-up. Forty-seven SLE pts with and without nephritis were enrolled with 35 completing all 25 W of study. Clinical response definitions at W13 or later were defined as either a >4 reduction of SLEDAI-2K or >50% drop in swollen joint counts (SJC) (baseline SJC>2). Biomarker samples included whole

blood in RNA tubes (31 pts), cryopreserved PBMCs (15 pts), plasma (35 pts) and urine (2 pts). Whole blood RNA sequencing was performed using Illumina TruSeq. Differential expression was modelled using DESeq2. Fast pre-ranked gene set enrichment analysis (GSEA) was performed with gene sets derived from published literature. Cryopreserved PBMCs were analysed by flow cytometry to profile immune cell subtypes. Plasma protein was measured by Meso Scale Discovery (MSD) kits. Healthy volunteer (HV, N=12) samples were used to establish potential disease-related biomarker changes in patients at baseline (BL).

Results: Many gene modules were found to be altered at BL in SLE pts, relative to HV, including those representing interferon (IFN) response and B/plasma cells and changes were consistent with our prior report[4]. Comparisons of SLEDAI-2K responders (R) versus non-responders (NR) revealed enrichment of 193 gene modules (57 down and 136 up-regulated, p_{adj}<0.1) at BL and 190 modules (105 down and 85 up) 4 weeks after treatment (W17). Expression of a 4-gene IFN module was enriched in SLEDAI-2K R vs NR at BL; expression of this module trended downward at W17 in R, whereas it increased over time in NR at W 5. Reduced numbers of circulating class-switched memory B cells and IgG-producing plasma cells were observed at W17 and/or W25. Plasma levels of BAFF were consistently increased at W5 but returned to BL levels by W17. Plasma levels of CD169/ SIGLEC-1, a monocyte activation marker, were higher at BL in SJC R vs. NR and were reduced after treatment in both groups. Two pts with active proliferative nephritis were enrolled into this study and both showed a reduction in levels of urine CD163 (uCD163), while plasma levels of this marker were stable.

Conclusion: Our integrative analysis indicates that KZR-616 elicits a potent effect on multiple immune pathways in SLE patients. Potential new biomarkers (gene, gene module, circulating protein) that may be useful for prediction of patient response were identified. Future biomarker studies in placebo-controlled trials may further our understanding of KZR-616 mechanism of action, patient selection and prediction of patient responses.

POS0716 EFFICACY AND SAFETY OF LOW-DOSE IL-2 IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Q. Y. Su[1,2,3], J. Luo[1,2,3], J. K. Di[2,3], X. Y. Yin[2,3], D. N. Xu[2,3], X. Li[1,2,3], C. Wang[1,2,3], S. X. Zhang[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; [3]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by disturbances of regulatory and effector $CD4^+$T cells, which were regulated by interleukin (IL)-2[1,2].

Objectives: The aim of this study was to systematically evaluate the efficacy and safety of low-dose IL-2 therapy in SLE treatment.

Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM and Technology Journal Database were performed. Original case reports, case series, observational studies and clinical trials reporting the efficacy or safety data on SLE patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I^2 and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

Results: A total of 7 studies comprising 327 patients were identified (Table 1). After the low-dose IL-2 treatment, 54.8% Lupus nephritis patient had distinct clinical remission. The SRI-4 response rates were 0.816 (95%CI 0.730-0.901) and the SELENA-SLEDAI scores were significantly decreased [SMD=-2.504, 95%CI (-4.089,-0.919), P=0.002]. Injection site reaction and fever, which were common side effects for IL-2, occurred in 33.1% and 14.4% of patients, None serious adverse events were reported among all these studies. Besides, the proportions of $CD4^+$T cells and Tregs were significantly increased after IL-2 injection [SMD=0.600, 95%CI (0.108,1.093), P=0.017; SMD=1.168, 95%CI (0.429,1.908), P=0.002], while there were no statistical differences in the proportions of $CD8^+$T cells, Th17 cells, Th1 cells and Th2 cells between before and after IL-2 treatment (P>0.05)(Figure 1).

Conclusion: Low-dose IL-2 was promising and well-tolerated in the treatment of SLE, which could promotes the proliferation and functional recovery of Tregs.

POS0717

ASSOCIATION BETWEEN CUMULATED HYDROXYCHLOROQUINE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND DEVELOPMENT OF CARDIAC CONDUCTION ALTERATIONS: A MULTIPLE LOGISTIC REGRESSION ANALYSIS

A. Herrero-Morant[1], J. Zubiaur-Zamacola[1], A. Margarida-de Castro[1], R. Pérez-Barquín[1], M. Á. González-Gay[1], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology and Cardiology, Santander, Spain*

Background: Hydroxychloroquine (HCQ) is a widely used drug in Systemic Lupus Erythematosus (SLE). It may cause cardiac alterations which includes short term arrhythmic events (via QT interval prolongation) and medium-late term dose dependent cardiomyopathy[1]. The few research articles published on the medium-late term effects of HCQ in cardiac conduction disorder do not show relevant alterations[2-3].
Objectives: To assess the effect of HCQ in cardiac conduction in a consecutive SLE population.
Methods: Observational, single University hospital study of all consecutive SLE patients with an electrocardiogram (EKG) at HCQ onset and at least one EKG in follow-up, with a period of at least 3 months on HCQ treatment was performed. We assessed conduction alteration (CA) by EKG, defined as atrio-ventricular block, bundle branch block or QT interval prolongation. The EKGs were gathered from the clinical history and interpreted at the beginning of the treatment and during the 15.2 years (CI95% 13.24-17.16) follow-up period. We defined cumulated HCQ (cHCQ) as the multiple of the mean annual dose of the sample. A Multiple logistic regression model, adjusted by different variables according to statistical significance and clinical relevance, was performed.
Results: We studied 109 (96 women/13 men) SLE patients with a mean (±SD) age of 61 ±. 2.78 years. A statistically significant association was observed between the cHCQ, and the development of CA [OR 1.1 CI95% 1.02-1.9; p = 0.011] (Table 1 **&** Figure 1). A total of 8 covariates were included. Among them, those that had the greatest influence on the development of the primary event were previous CA [OR 4.15 CI95% 6.39-624.54; p <0.01]; valvular heart disease [OR 7.15 CI95% 1.31-38.91; p = 0.023] and age [OR 1.07 95% CI 1.0-1.14; p = 0.04].

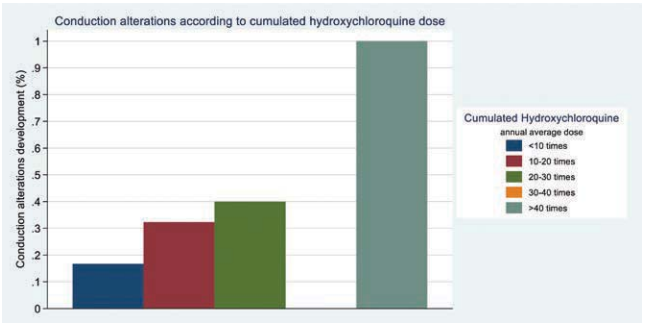

Figure 1. Cardiac conduction alterations development according to cumulated Hydroxychloroquine dose.

Conclusion: According to our study, it seems to be an association between the cHCQ and development of CA regardless of other variables evaluated. Wider longitudinal studies are required with a protocolized EKG performance in successive visits to further analyze this association.

anti-thrombosis treatment. Currently there is an extreme paucity of effective and safe drugs for long-term management of TP in primary APS patients.
Objectives: We aimed to explore the efficacy and safety of sirolimus monotherapy.
Methods: In this real-world study, we included 7 consecutive patients with primary APS who received sirolimus monotherapy for TP. Oral sirolimus was initiated at a dose of 1-2 mg once daily and then adjusted primarily based on clinical efficacy and tolerance, with consideration of sirolimus trough concentration of ≤15 ng/ml.
Results: Of included patients, the median age was 58 years with median disease course of 1.5 years and 4 patients were treatment-naïve. All patients completed 6 months of sirolimus therapy with median follow-up of 6 months (range: 6-15). All patients received sirolimus monotherapy for TP during entire follow-up, without adding any additional agents. Overall, platelet count exhibited substantially increasing trend after sirolimus administration during the first six months ($p<0.001$) and being stable later. Specifically, median platelet count was significantly increased from 59×10^9/L before sirolimus to 90×10^9/L at month 1 ($p=0.028$), 131×10^9/L at 3 months ($p=0.028$) and 178×10^9/L at 6 months ($P=0.018$). Overall and complete response were respectively achieved in 6 (85.7%) and 5 (71.4%) patients at month 6. Importantly, overall response was achieved in all 4 treatment-naïve patients. Additionally, there was different extents of decline in the titers of antiphospholipid antibodies after sirolimus treatment. Regrading safety, only one patient experienced elevated cholesterol level with recovery after atorvastatin treatment.
Conclusion: Sirolimus monotherapy confers good efficacy and tolerance for TP in primary APS patients, and therefore may be considered as a first-line therapy.

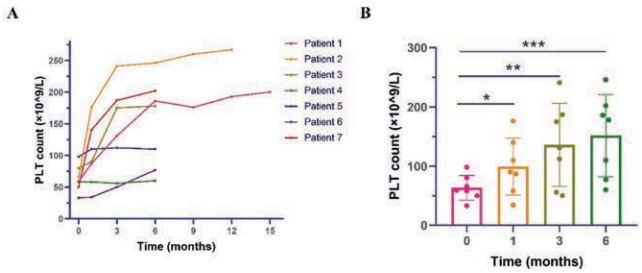

Figure 1. Changes in platelets levels after sirolimus therapy in primary antiphospholipid syndrome patients with thrombocytopenia, (A) platelet count of individual patient during the whole follow-up, (B) Median platelet count of included patients during the first six months.

POS0719 **RAPID EFFICACY OF ANIFROLUMAB IN MULTIPLE SUBTYPES OF RECALCITRANT CUTANEOUS LUPUS PARALLELS DISCRETE CHANGES IN TRANSCRIPTOMIC AND CELLULAR BIOMARKERS.**

L. M. Carter[1,2], Z. Wigston[1], P. Laws[2], E. Vital[1,2]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom;* [2]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Cutaneous lupus eyrthematosus (CLE) is frequently refractory to immunosuppressive therapies including B-cell depletion, but this varies by morphology with the chronic discoid (DLE) subtype being particularly resistant. Local production and response to type-I interferon (IFN-I) is implicated in all subtypes of CLE. Therapeutic blockade of the IFN-I receptor with anifrolumab has direct effects on IFN-I signaling, and subsequent more widespread effects on other immune functions regulated by IFN-I[1]. Response to anifrolumab by lesion subtype have not been described, and it is unclear which effects of IFN-blockade are responsible for cutaneous response. We hypothesise that the efficacy of anifrolumab will differ dependent on the relative contribution of direct IFN-I effects vs. the downstream immunostimulatory effects of IFN-I on other immune functions.
Objectives: To evaluate the effect of anifrolumab on (i) rituximab-refractory CLE; (ii) on DLE; (iii) to compare clinical responses with IFN-specific biomarkers and transcriptomic evaluation of broader immune responses; (iv) to compare early and late immunophenotypic and clinical responses.
Methods: SLE patients with active recalcitrant CLE were treated with anifrolumab 300 mg IV every 4 weeks and evaluated using the cutaneous lupus erythematosus disease area and severity index (CLASI) and dermatology life quality index (DLQI). Fluorescence intensity of tetherin (CD317), a cell surface interferon biomarker, was evaluated on major cell subsets by multiparameter flow cytometry of peripheral blood mononuclear cells (PBMCs). Previously validated IFN-Scores-A and B [2], in addition to gene expression scores annotated to inflammation, myeloid lineage and plasmablasts modules [3], were measured in PBMCs using customised Taqman array at baseline, 1 month and 3 months into treatment.
Results: 8 patients (DLE n=5, chillblain / nodular vasculitis n=2, subacute CLE n=1) have enrolled to date. One month clinical and biomarker data are now available for 5. Median number of previously failed standard therapies is 6, including rituximab in 6/8 patients, belimumab in 3/8 and thalidomide in 4/8. Four patients required long-term oral prednisolone >10 mg daily. Median baseline CLASI activity score was 16 and DLQI was 16/30. Rapid clinical responses were evident at 1 month in 4/5 patients, being greatest in magnitude in patients with SCLE and DLE compared with chillblain lesions. Median fall in CLASI activity score at 1 month was 6 points with a median percentage change from baseline of 31%. In all patients, a rapid and marked suppression of IFN-Score-A (mean difference 2.92, $p<0.01$) and plasmablast tetherin ($p=0.01$), was evident by 1 month. Small and variable downward trends were observed in inflammation- and IFN-Score-B ($p=0.06$), myeloid ($p=0.27$) and plasmablast ($p=0.15$) -annotated gene expression scores. Major cell population numbers were proportionally unaltered in flow cytometry.
Conclusion: These preliminary results suggest that anifrolumab: (i) may be effective in rituximab-resistant CLE, (ii) is effective in DLE; (iii) rapidly suppresses IFN-I response, but with lesser effects on non-IFN immune biomarkers and (iv) early direct effects on IFN-I are associated with rapid clinical response.

POS0720 **LOW-DOSE GLUCOCORTICOIDS WITHDRAWN IN SYSTEMIC LUPUS ERYTHEMATOSUS: A DESIRABLE AND ATTAINABLE GOAL**

L. Ji[1], D. Gao[1], Y. Hao[1], Z. Zhang[1]. [1]*Peking University First Hospital, Rheumatology, Beijing, China*

Background: Prolonged use of GC may cause irreversible organ damage, leading to impaired quality of life and even increased mortality. However, many physicians are worried about severe flares after GC withdrawal in daily practice.
Objectives: To assess the risk of flare in systemic lupus erythematosus (SLE) patients after low dose glucocorticoids (GC) discontinuation and evaluate the risk factors of flare.
Methods: SLE patients who ever discontinued GC were identified from PKUFHS cohort. The disease flare profile after GC discontinuation were analyzed. Flare rate was analyzed using Kaplan-Meier analysis. COX regression was used to determine the effect of variables on SLE flare. A prognostic nomogram using Cox proportional hazards regression modeling were developed.
Results: 132 SLE patients were eligible for the final analysis. They were followed up for a median (IQR) period of 21.8 (9.01, 36.7) months. The cumulative probability of flare after GC discontinuation was 8.3 % at 6 months, 16.8% at year 1 and 27.5% at year 2 (Figure 1A). In multivariate COX analysis, hypocomplementemia and serologically active clinically quiescent (SACQ) were independent risk factors of flare [HR 2.53, 95% CI (1.32, 4.88); HR 3.17, 95% CI (1.44, 6.97), respectively]. Age ≥ 40y at GC withdrawal and hydroxychloroquine usage were independent protective factors of flare [HR 0.53, 95% CI (0.29, 0.99); HR 0.32, 95% CI (0.17, 0.62), respectively] (Table 1). The protective effect of hydroxychloroquine was dosage related. From the prospective of different tapering strategies embodied as duration from prednisone 5mg/d to complete discontinuation, slower tapering strategy (12-24 months) significantly reduced the risk of flare compared to faster tapering strategy (< 3 months) [HR 0.30, 95% CI (0.11, 0.82), p=0.019]. The prognostic nomogram including aforementioned factors effectively predicted 1- and 2-year probability of flare-free (Figure 1B).

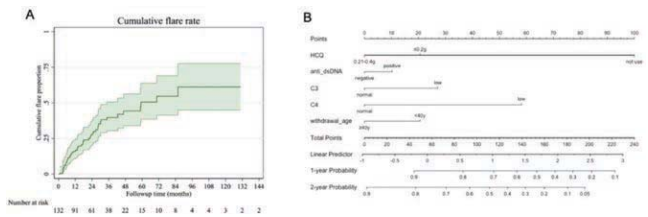

Figure 1.

Conclusion: Low-dose GC is feasibly discontinued with infrequent flare in real-life setting. SACQ and younger age are potential risk factors of SLE flare,

Table 1. Predictors of flare by univariate and multivariate COX analysis.

			Multivariate		Multivariate	
	Univariate	**p**	**Model 1**	**p**	**Model 2**	**p**
age≥40y at GC withdrawal	0.59 (0.33,1.07)	0.084	0.53 (0.29, 0.99)	0.049	0.63 (0.33, 1.18)	0.147
Age at onset ≥18y	2.03 (0.62, 6.66)	0.244	2.75 (0.77, 9.85)	0.121	2.88 (0.81, 10.2)	0.103
Remission duration≥60 months since the last flare	0.66 (0.35, 1.27)	0.217	0.81 (0.41, 1.57)	0.526	0.73 (0.38, 1.41)	0.346
history of thrombocytopenia	1.73 (0.94, 3.18)	0.077	1.36 (0.70, 2.65)	0.359	1.45 (0.74, 2.83)	0.278
history of lupus nephritis	0.86 (0.47, 1.55)	0.610	/	/	/	/
Hypocomplementemia	1.97 (1.06, 3.66)	0.031	2.53 (1.32, 4.88)	0.005	/	/
anti-dsDNA positive	1.25 (0.70, 2.23)	0.456	/	/	/	/
SACQ (both)	2.91 (1.38, 6.15)	0.005	/	/	3.17 (1.44, 6.97)	0.004
SACQ (or)	1.29 (0.73, 2.30)	0.380	/	/	/	/
Hydroxychloroquine or not	0.29 (0.16, 0.53)	<0.001	0.29 (0.15, 0.56)	<0.001	0.32 (0.17, 0.62)	0.001
Immunosuppressant or not	0.77 (0.40, 1.48)	0.426	/	/	/	/

There was strong collinearity between hypocomplementemia and SACQ, so the two parameters were separated into two models. SACQ (both): anti-dsDNA positive and hypocomplementemia; SACQ (or): anti-dsDNA positive or hypocomplementemia; GC: glucocorticoids. Data were shown as HR (95% CI).

while hydroxychloroquine usage and slow GC tapering to withdrawal can reduce relapse. The visualized model we developed may help to predict risk of flare among SLE patients who discontinued GC.

Background: Antiphospholipid Syndrome (APS) is a rare autoimmune disease characterized by thrombotic events and/or pregnancy morbidities in the presence of confirmed positivity for antiphospholipid antibodies (aPL). Complement was demonstrated to be involved in aPL-related pregnancy loss in animal models and several groups investigated the significance of complement levels in human disease. C3 and C4 serum levels were assessed in several cohorts of pregnant patients with APS and/or aPL positivity in order to relate complement consumption with adverse pregnancy outcome (APO). According to some authors, hydroxychloroquine (HCQ) can control the activation of the complement system, improve pregnancy outcome and reduce aPL title.
Objectives: This study was designed to verify the effect of HCQ in addition to low dose aspirin (LDA) + low molecular weight heparin (LMWH) treatment in a multicenter cohort of primary APS (PAPS) and aPL carriers pregnant women and the possible correlation with preconception serum C3/C4 levels.
Methods: Medical records of pregnant women with confirmed positivity for aPL antibodies attending twelve referral centers from January 2010 to December 2020 were retrospectively evaluated. We considered as aPL-related APO: spontaneous abortions (<10 weeks of gestation), fetal loss (≥10 weeks of gestation), neonatal death (death of a formed fetus alive at birth in the first 28 days of life), preterm delivery before 37 weeks of gestation, preeclampsia, eclampsia or HELLP syndrome (hemolysis, elevated liver enzymes, and low platelet).
Results: We have analyzed 164 singleton PAPS/aPL carrier pregnancies (22 aPL carriers - 13%) in 128 patients: all were treated with combination therapy (LDA+LMWH), and in 30 HCQ was added. 58 pregnancies (43%) had low levels of preconception C3/C4. A triple aPL positivity was observed in 54 pregnancies, 14 of them were treated with combination therapy + HCQ. When considering the whole cohort, the addition of HCQ had not significantly improved the gestational outcome. Further stratification was performed on the basis of complement consumption. In the group of patients with preconception low C3/C4 levels the addition of HCQ had not significantly improved pregnancy outcome. We have lastly evaluated 40 pregnancies with a high-risk profile (triple aPL positivity and complement consumption), in which we have found that HCQ significantly improved gestational outcome (p=0.018, Table 1).
This observation could not be confirmed in patients with single or double aPL positivity.
Conclusion: The study shows that administering HCQ in addition to combination therapy can improve gestational outcome in aPL/PAPS high-risk patients. This observation confirms that HCQ exerts a beneficial effect on aPL pregnancies by complement inhibition as it was shown in animal models. In addition, our results provide the clinicians a useful tool to implement conventional treatment in patients at high risk of pregnancy complication or loss.

Background: The detection of somatic mutations in genes of myeloid cells in asymptomatic patients - defining clonal hematopoiesis of indeterminate potential (CHIP) - predisposes to cardiovascular events (CVE) in the general population.
Objectives: We aimed to determine whether CHIP was associated with CVE in SLE patients.
Methods: The study is an ancillary study of the randomized, double-blind, placebo-controlled, multicenter trial PLUS study conducted from June 2007 through August 2010 at 37 centers in France involving 573 SLE patients. The search for somatic mutations by high-throughput sequencing of 53 genes involved in clonal hematopoiesis was performed on genomic DNA collected at PLUS inclusion. The CHIP prevalence was assessed in SLE and in a retrospective cohort of 479 patients free of hematological malignancy. The primary outcome was the incident CVE in SLE.
Results: Screening for CHIP was performed in 438 SLE patients (38 [29-47] years, 91·8% female). Overall, 63 somatic mutations were identified in 47 patients defining a CHIP prevalence of 10·7% in SLE. Most SLE patients (78·7%) carried a single mutation. Most variants (62·5%) were located in the *DNMT3A* gene. CHIP was associated with age, age at SLE diagnosis and a lower frequency of antiphospholipid antibodies. CHIP occurred more than 20-years earlier (p<0·00001) in SLE than in controls. The detection of CHIP at inclusion was not associated with the occurrence of CVE during follow up (HR= 0·42 (0·06 – 3·21), p=0·406).
Conclusion: The prevalence of CHIP is high in SLE with respect to age but was not associated with incident CVE.

POS0723 DIETARY HABITS AND THE IMPACT ON CLINICAL FEATURES IN PRIMARY SJOGREN'S SYNDROME

A. Alunno[1], F. Carubbi[1], F. M. Mariani[1], M. Rossi[1], P. Sipari[1], D. Grassi[1], C. Ferri[1]. [1]*Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*

Background: In recent years, increasing evidence on the role of diet on chronic conditions, including cardiovascular diseases (CV) and rheumatic and musculoskeletal diseases (RMDs) has accrued. Most studies exploring the possible role of nutrients and dietary patterns on both the risk to develop RMDs in the general population and the natural history of the disease in patients with established RMDs pertain to rheumatoid arthritis. Data in patients with established primary Sjogren's syndrome (pSS) is lacking.
Objectives: To explore dietary habits and their relationship with metabolic and inflammatory features in a cohort of patients with established pSS.
Methods: Consecutive patients with pSS were recruited and dietary habits over the previous 12 months were explored. Adherence to the Mediterranean Diet was assessed with the 14-item PREvencion con DIeta MEDiterranea' (PREDIMED) tool and the 28-item Mediterranean Lifestyle (MEDLIFE) index. Adherence to the Dietary Approaches to Stop Hypertension (DASH) was estimated using a score based on 8 food items. Tea/herbal tea and coffee intake were also explored and clinical/serological records were retrospectively collected.
Results: We enrolled 105 patients with pSS (95% females) with a mean age of 59 years. According to the PREDIMED score 32 (31%) patients had a good adherence to the Mediterranean Diet, 64 (61%) a medium adherence and only 9 (8%) a poor adherence. According to the DASH score, 74 (71%) patients had low adherence and 31 (29%) had high adherence. When dividing patients according to the extent of adherence to either of the dietary patterns and correlating the diet adherence scores to disease specific variables some associations emerged. The PREDIMED score was inversely correlated with disease activity, as measured by the EULAR Sjögren's syndrome disease activity index (ESSDAI) (Spearman's rho=-0.27, p= 0.009) and ClinESSDAI (Spearman's rho=-0.26, p=0.01) revealing that a higher adherence to the Mediterranean Diet was associated with lower disease activity. With regard to the MEDLIFE, the total of blocks 1 and 2, that are related to Mediterranean foods and dietary habits, did not correlate with the total of block 3 (related to other healthy habits such as physical activity), meaning that the patients adhering the most to the Mediterranean Diet not necessarily had an overall healthy lifestyle. Adherence to DASH was not associated with disease activity. With regard to individual nutrients, fish consumption was associated with a lower prevalence of hypertension as observed in the general population. Higher intake of red meat was associated with higher values of self-reported pain (Spearman's rho=-0.3; p=0.01) while high wholegrain intake was associated with a lower number of coexisting CV risk factors (OR=0.7; 95% CI=0.52-0.97; p=0.03).
Conclusion: Adherence to the Mediterranean Diet, with particular attention to high intake of fish and wholegrains and low intake of red meat, may be beneficial on various domains in pSS, such as the CV system and the inflammatory environment, and as such should be recommended to patients with this disease.

POS0724 RISK FACTORS FOR CORONARY ARTERY DISEASE IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTI-CENTER, RETROSPECTIVE, COHORT STUDY

W. Ci[1], J. Zhao[2], Y. Wang[3], L. Pan[1], M. Li[2]on behalf of the Beijing Systemic Lupus Erythematosus Co-Operated Group. [1]*Beijing Anzhen Hospital, Capital Medical University, Department of Rheumatology and Immunology, Beijing, China;* [2]*Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing, China;* [3]*Beijing Shijitan Hospital, Capital Medical University, Department of Rheumatology and Immunology, Beijing, China*

Background: Coronary artery disease (CAD) not only has an increased prevalence but also is a major cause of premature mortality in systemic lupus erythematosus (SLE) [1, 2]. However, information is limited regarding the risk factors for CAD in Chinese patients with SLE.
Objectives: To assess the risk factors for CAD in Chinese patients with SLE.
Methods: This multi-center, retrospective, cohort study included 3778 consecutive SLE patients, with CAD (CAD group) or without a medical history of CAD (control group). CAD was defined as a coronary stenosis ≥50% in any major epicardial coronary vessel detected by coronary angiography or a history of myocardial infarction confirmed by medical records. General parameters, clinical features, laboratory tests and medical therapies were compared between groups, and the risk factors for CAD in SLE were analyzed by logistic regression analysis.
Results: The age at baseline was older, male ratio was higher and body mass index was greater in CAD group (all *P*<0.001). Traditional CAD risk factors including diabetes mellitus, hypertension, dyslipidemia, family history of CAD and smoking were more common in CAD group (all *P*<0.001) (Figure 1). SLE Disease Activity Index 2000 was greater (*P*=0.012), hyperuricemia and elevated C-reactive protein (CRP) were more prevalent (both *P*<0.001), and an increased corticosteroids' usage (*P*=0.018) was detected in CAD group (Table 1). Binary logistic regression analysis showed hyperuricemia (odds ratio: 3.082, 95% confidence interval: 1.283-7.403; *P*=0.012) and CRP (odds ratio: 7.248, 95% confidence interval: 2.931-17.925; *P*<0.001) were independent risk factors for CAD in SLE patients.

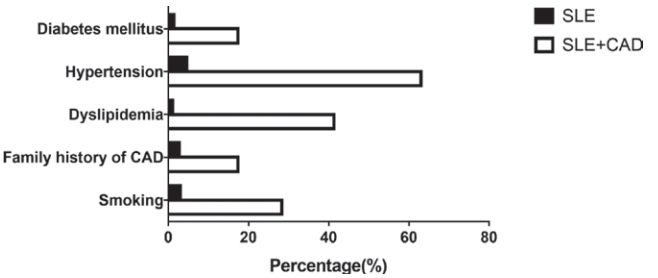

Figure 1. Comparison of traditional risk factors in SLE patients between CAD group and control group. Abbreviations: CAD, coronary artery disease; SLE, systemic lupus erythematosus. All *P*<0.001.

Table 1. Comparison of clinical features in SLE patients between CAD group and control group.

Parameters	Control group (n=3732)	CAD group (n=46)	*P*
Age at baseline [years, median (P25, P75)]	35.00 (29.00, 45.00)	59.50 (50.25, 67.75)	***<0.001***
Male, n (%)	296 (7.94)	11 (23.91)	***<0.001***
Disease duration [years, median (P25, P75)]	8.00 (4.00, 12.00)	10.00 (4.00, 19.00)	0.173
Body mass index [kg/m^2, median (P25, P75)]	21.77 (19.63, 24.16)	23.50 (22.09, 25.36)	***<0.001***
Renal disorder, n (%)	1737 (46.57)	9 (19.57)	***<0.001***
Neurologic disorder, n (%)	595 (15.95)	3 (6.52)	0.082
Thrombocytopenia, n (%)	859 (23.03)	8 (17.39)	0.366
SLEDAI-2K [median (P25, P75)]	3.00 (0.00, 8.00)	5.50 (1.50, 14.00)	***0.012***
Elevated creatinine, n (%)	295 (7.91)	10 (21.74)	***0.002***
Hyperuricemia, n (%)	209 (5.60)	16 (34.78)	***<0.001***
Elevated ESR, n (%)	951 (25.5)	22 (47.83)	***0.001***
Elevated CRP, n (%)	210 (5.63)	15 (32.61)	***<0.001***
Positive aPL, n (%)	734 (19.68)	11 (23.91)	0.474
Corticosteroids, n (%)	2752 (73.78)	41 (89.13)	***0.018***
Immunosuppressants, n (%)	2950(79.09)	37 (80.43)	0.823

Abbreviations: aPL, antiphospholipid antibody; CAD, coronary artery disease; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; SLE, systemic lupus erythematosus; SLEDAI-2K, SLE Disease Activity Index 2000. *P* <0.05 are shown as italics and bold.

Conclusion: Hyperuricemia and CRP are independent risk factors for CAD in SLE patients. This study highlights the association between hyperuricemia, CRP and CAD burden in SLE, and might provide a modifiable perspective on improving SLE outcomes.

POS0725 VALIDATION OF SJÖGREN'S SYNDROME SCREENING QUESTIONNAIRE (SSSQ) IN A COHORT OF PATIENTS WITH SICCA SYMPTOMS

K. Perdan-Pirkmajer[1,2], K. Fortuna[3], Z. Teršek[3], J. Kramarič[1], A. Hocevar[1,2]. *[1]University Medical Centre Ljubljana, Rheumatology, Ljubljana, Slovenia; [2]University of Ljubljana, Faculty of Medicine, Department of Internal Medicine, Ljubljana, Slovenia; [3]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia*

Background: ACR/EULAR 2016 classification criteria for Sjögren disease (SS) [1] use 5 standard questions on ocular and oral sicca symptoms as an entrance criteria. However, these questions do not differentiate between SS and non-SS sicca etiology. Recently, a new 5-item Sjögren's Syndrome Screening Questionnaire based on SICCA study data was designed for the use in clinical practice, better differentiating SS from non-SS sicca patienents.[2]

Objectives: We aimed to validate the SSSQ in our population with sicca symptoms.

Methods: Our study cohort represented 535 patients referred to UMC Ljubljana during the 3-year period Jan/2016 to Dec/2019 with suspected SS. All subjects underwent at that time a standardized SS diagnostic procedure, including 5 standard sicca questions, Schirmer test, Rose Bengal test, unstimulated salivary flow test, salivary gland ultrasound, immunoserological and lip biopsy. In Sep - Oct 2021 all subjects were contacted by phone to fulfil the new SSSQ (5 questions resulting in 0-11 points: cut-off for SS ≥7 points). The performance of SSSQ recognizing SS was assessed using ACR/EULAR 2016 classification criteria as gold standard test for SS diagnosis.

Results: 415 out of 525 subjects agreed to participate in the study (384 (92.5%) females, mean (SD) age 57.6(13.8)), the rests either declined (21), died (2) or could not be reached (97). Based on the ACR/EULAR 2016 criteria SS was diagnosed in 127 (30.6%) and excluded in 288 subjects. 376/415 (90.6%) subjects responded positively on 5 standard sicca questions (110 with and 266 without SS). In the new SSSQ 129 (31.1%) subjects (54 with and 75 without SS) responded positively (reached ≥7 points). The performance of SSSQ recognizing SS is presented in Table 1.

Table 1. Diagnostic accuracy of SSSQ (Sjögren's Syndrome Screening Questionnaire) and ACR/EULAR 2016 sicca questions in our cohort. PLR Positive Likelihood Ratio; NLR Negative Likelihood Ratio; PPV Positive Predictive Value; NPV Negative Predictive Value;

Statistics	SSSQ	Standard sicca questionairre
	Value (95% CI)	Value (95%CI)
Sensitivity	42.5% (33.8 to 51.6%)	86.6% (79.4 to 92.0%)
Specificity	73.7% (68.5 to 78.9%)	7.6% (4.9 to 11.3%)
PLR	1.4 (1.2 to 2.2)	0.9 (0.9 to 1.0)
NLR	0.8 (0.7 to 0.9)	1.8 (1.0 to 3.2)
PPV	41.9% (35.2 to 48.8%)	29.3% (27.7 to 30.9%)
NPV	74.5% (71.2 to 77.5%)	56.4% (41.6 to 70.2%)
Accuracy	64.3% (59.5 to 69.0%)	31.8% (27.4 to 36.5%)
AUC	0.58 (0.52-0.64)	0.52 (0.46-0.57)

Conclusion: SSSQ showed higher specificity and better diagnostic accuracy compared to current standard questionnaire in a cohort of sicca patients.

Medina-Rivera[1]. *[1]Coordinación de la Investigación Científica, UNAM, Laboratorio Internacional de Investigación sobre el Genoma Humano, Querétaro, Mexico; [2]Salvador Zubirán National Institute of Health Sciences and Nutrition, Department of Immunology and Rheumatology, Ciudad de México, Mexico; [3]Facultad de Psicología UNAM, Laboratorio de Neurogenómica Cognitiva, Ciudad de México, Mexico; [4]Red Mexicana de Bioinformática, NA, Cuenavaca, Morelos, Mexico; [5]Universidad de Monterrey, Programa de Médico Cirujano y Partero, Monterrey, Mexico; [6]UNAM Institute of Neurobiology, Departamento de Neurobiología Conductual y Cognitiva, Querétaro, Mexico; [7]Universidad Autónoma de Durango, Escuela de Medicina, Querétaro, Mexico; [8]Private Practice, NA, Cuernavaca, Morelos, Mexico; [9]Hospital General Regional IMSS II, Reumatología, Santiago de Querétaro, Mexico; [10]IMSS Hospital General Regional No. 1 Querétaro, Medicina Interna, Santiago de Querétaro, Mexico; [11]QIMR Berghofer Medical Research Institute, Genetic Epidemiology, Brisbane, QLD, Australia; [12]Rheumatology Practice, NA, Cuernavaca, Morelos, Mexico*

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease, characterized by a wide variety of clinical manifestations, as well as continuous relapses and exacerbation of symptoms. This complex panorama complicates an early and proper diagnosis, treatment, and follow-up of the people with SLE and therefore has a significant impact on their health-related quality of life (HRQoL). Although the importance of assessing HRQoL in SLE has become evident in recent years, in Mexico there is no epidemiological surveillance system nor national registry that conveys this information.

Objectives: To evaluate health related quality of life (HRQoL) in Mexican individuals with SLE using the data from the Mexican Register of Lupus (Lupus RGMX).

Methods: The Mexican Lupus Registry (Lupus RGMX) is an ongoing online register. This cohort includes sociodemographic and clinical data of Mexican individuals with SLE. In this study we assessed and compared HRQoL in patients with SLE and a matched control group of Mexican individuals without SLE diagnosis. We estimated QoL using the World Health Organization Quality of Life (WHOQOL-bref) and Short Form-36 (SF36) questionnaires. For both WHOQOL-bref and SF36, higher scores mean better HRQoL. Statistical analysis was performed using R 4.1.2 (R Core Team, 2021).

Results: A total of 631 SLE and 272 control registers were analyzed (Table 1). Significant lower scores on HRQoL were observed on participants with SLE for both SF36 and WHOQOL-bref questionnaires, compared with the matched control group. All score components were lower in SLE individuals. Physical role functioning, bodily pain and general health exhibited the lowest scores among

the SF36 factors, whereas physical factor was the lowest for WHOQOL-bref (Table 1).

Table 1. SF36 and WHOQOL-bref median scores (25-75 IQR) of SLE participants and controls.

	Controls	SLE	*p-value*
	(n=272)	(n=631)	
Female sex n (%)#	211 (77.6%)	596 (94.4%)	<0.001
Age*	28 (24-35)	35 (28-43)	<0.001
*SF36 (max 100 points per function) **			
Physical functioning	100 (95-100)	65 (45-85)	<0.001
Physical role functioning	100 (100-100)	25 (0-100)	<0.001
Bodily pain	84 (61-100)	31 (22-52)	<0.001
General health	77 (62-100)	35 (20-47)	<0.001
Vitality	65 (50-100)	40 (25-55)	<0.001
Social functioning	100 (62.5-100)	50 (37.5-75)	<0.001
Emotional role functioning	100 (66.7-100)	66.7 (0-100)	<0.001
Mental health	76 (60-100)	56 (42-74)	<0.001
*WHOQOL-bref (max 20 points per function) **			
Physical	16.6 (14.8-17.7)	11.4 (9.1-13.1)	<0.001
Psychological	15.3 (13.3-19.3)	12.7 (10.7-14.7)	<0.001
Social relations	14.7 (12-16)	12 (9.3-14.7)	<0.001
Environmental	15.5 (14-17)	13 (11-15)	<0.001

Chi-square test, *U Mann-Whitney test

Conclusion: In Mexican people with SLE, a significant decrease in HRQoL was detected compared with controls. The implementation of a national register in Mexico (Lupus RGMX) will provide additional psychosocial and clinical information to deepen our knowledge of this disease.

POS0727 IMPACT OF AIR POLLUTANTS ON DISEASE ACTIVITY AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN MALAYSIA

J. H. Jaafar[1], S. S. Shaharir[1], S. Rajalingham[1], R. Mohd[1], M. T. Latif[2]. *[1]Universiti Kebangsaan Malaysia Medical Centre (UKMMC), Internal Medicine, Kuala Lumpur, Malaysia; [2]Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Department of Earth Sciences and Environment, Bandar Baru Bangi, Malaysia*

Background: Systemic Lupus erythematous (SLE) is an autoimmune disease with a wide spectrum of clinical manifestations and characterized by remission and flares. Recent epidemiological studies postulated that air pollution confers an increased risk of flare in various autoimmune diseases. Haze is a common phenomenon afflicting Southeast Asia (SEA), including Malaysia, and has occurred almost every year within the last few decades.

Objectives: This study was aimed to determine the correlation and association between SLE disease activity with exposure to inhaled Particulate Matter (PM_{10}) and Nitrogen Dioxide ($NO_{2)}$.

Methods: SLE patients who attended rheumatology and nephrology clinic in University Kebangsaan Malaysia Medical Centre (UKMMC) from June 2019 until March 2020 were recruited. Their medical records were reviewed for retrospective assessments of the disease activity using the Modified-SLE Disease Activity Index (M-SLEDAI) and The British Isles Lupus Assessment Group (BILAG 2004) index from January 2015 until September 2019. Clinic visits with presence of infection or recent change of immunosuppressive treatment of ≤ 3 months were excluded. The average of daily concentrations of inhaled PM_{10} ($\mu g/m^3$), and NO_2 (ppb) were evaluated within 30 days preceding the clinic visits, and the data was obtained from Department of Environment (DOE) Malaysia. Comparison of the means was performed by Student's t-test; and the correlations between PM_{10}, and NO_2 were determined by Pearson's correlation coefficient. The associations between the effect of daily pollutant concentrations on M-SLEDAI and BILAG 2004 scores were analyzed using the generalized estimating equation (GEE) model, while considering fixed effects for repeated measures.

Results: A total of 46 patients were recruited with 603 clinic visits were recorded. A significantly higher NO_2 level was found in active disease patients with M-SLEDAI score of ≥ 4 (33.09 ± 9.15 vs 31.09 ± 9.79, p=0.32), and presence of BILAG B and/or A (score ≥ 8), 35.03± 2.97 vs 31.1 ± 9.8, p= 0.003). There were positive correlations between M-SLEDAI scores (r_s 0.128, p=0.002) and BILAG scores with NO_2, (r_s 0.142, p<0.001). In the GEE analysis, significant correlations were found between M-SLEDAI score [OR 1.27 (95% C.I: 1.06-1.53), p=0.01] and BILAG score with NO_2 [OR 1.47 (95% C.I: 1.15-2.1.88), p=0.002].

Conclusion: Our study suggests that air pollutant NO_2 exposure 30 days prior to clinic visit is associated with high disease activity among patients with SLE in Malaysia. Further prospective study is warranted to confirm this finding.

Yajima[3]on behalf of the TRUMP2-SLE Project. *[1]Kochi Medical School, Department of Clinical Epidemiology, Nankoku, Japan; [2]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan; [3]Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; [4]School of Medicine, University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; [5]Yokohama City University Graduate School of Medicine, Department of Stem Cell and Immune Regulation, Yokohama, Japan; [6]Shinshu University School of Medicine, Department of Medicine (Neurology and Rheumatology), Matsumoto, Japan; [7]Fukushima Medical University, Department of Clinical Epidemiology, Graduate School of Medicine, Fukushima, Japan; [8]Fukushima Medical University Hospital, Department of Innovative Research and Education for Clinicians and Trainees (DiRECT), Fukushima, Japan*

Background: In clinical practice for systemic lupus erythematosus (SLE), the concept of "treat to target" has been introduced with an established goal of reducing glucocorticoid dose as much as possible while controlling disease activity. Although it has been shown that various personality characteristics of patients with SLE affect their disease activity and damage, it is not clear whether the personality characteristics of attending physicians affect the outcomes of patients with SLE. Grit is a personality trait characterized by perseverance and passion for achieving long-term goals.

Objectives: This study aims to evaluate the relationship between attending physicians' grit personality characteristics and treatment goal achievements in patients with SLE.

Methods: A cross-sectional study was conducted on 386 patients with SLE in five referral hospitals in Japan. The main exposure was the "perseverance" and "consistency" (scores 1-5) of the attending physicians, as measured by the Short Grit Scale, and the primary outcome was the achievement of the Lupus Low Disease Activity Score (LLDAS). Considering the clustering of achievement of LLDAS by each attending physician, the association between attending physician's personality and LLDAS was analyzed by logistic regression with cluster robust variance estimation. Odds ratios to assess the relationship between perseverance and consistency and LLDAS were estimated with adjustment for confounders (age, sex, disease duration, hydroxychloroquine use, immunosuppressant use, and Systemic Lupus International Collaborating Clinics-Damage Index). We used multiple imputation to handle the uncertainty caused by missing values of potential confounders on the assumption of missing at random.

Results: The median age of the patients was 45 years (interquartile range[IQR],36-56), 88% were female, and the median disease duration was 152 months(IQR, 80-240). Thirty-seven doctors were in charge of the patients (1-79 patients/each doctor). The median age of the attending physicians was 40 years (IQR, 35-43), and 19% were female. The median perseverance and consistency scores of attending physicians were 3.1 (IQR, 3.0-3.5) and 3.3 (IQR, 2.8-3.8), respectively. Of the enrolled patients, 154 (40%) had achieved LLDAS. The attending physicians with a lower consistency score of <3 were more frequent in the patients who achieved LLDAS (40% vs. 29%, p=0.026). The lower consistency score of attending physicians was still related to LLDAS independently (adjusted odds ratio 1.63, 95% confidential interval 1.17-2.27). There was no association between the achievement of LLDAS and perseverance.
Conclusion: The grit personality characteristics of the attending physician may affect the achievement of treatment goals in patients with SLE.

POS0729 FOOT DISORDERS ASSOCIATED WITH JACCOUD'S ARTHROPATHY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A DESCRIPTIVE STUDY.

L. Cano Garcia[1], J. García-Campos[2], A. Garcia Studer[1], F. Ortiz-Márquez[1], G. Diaz-Cordobes[1], J. Marco-Lledó[3]. *[1]Instituto de Investigación Biomédica de Málaga (IBIMA); Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain; [2]Universidad Miguel Hernández, Ciencias del Comportamiento y la Salud, Alicante, Spain; [3]Universidad Miguel Hernández; Instituto de Investigación Sanitaria y Biomédica de Alicante, Ciencias del Comportamiento y la Salud, Alicante, Spain*

Background: Systemic lupus erythematosus (SLE) is a chronic disease of autoimmune origin mediated by autoantibodies, affecting various organs[12]. 95% of patients with SLE develop musculoskeletal involvement[1], most of the time as arthralgia or non-erosive arthritis, mainly affecting the hands and knees. A subgroup of patients with lupus that is seen with increasing frequency, late develops a deforming arthropathy as a result of the laxity of ligaments and peritendinous apparatus that produces a joint subluxation. The foot is a highly affected structure that may initially go unnoticed, but it leads to significant disability.
Objectives: To know the prevalence of foot problems in a sample of patients with SLE.
Methods: A cross-sectional study design. Forty-seven subjects with a diagnosis of SLE were consecutively recruited in a Rheumatology Unit between March and May 2021. The inclusion criteria were: patients with a diagnosis of SLE according to the EULAR / ACR 2019 criteria, with at least one year of evolution and age equal to or greater than 18 years. A Rheumatology nurse collected information on socio-demographic data and the characteristics of the feet regarding the musculoskeletal system, skin, appendages, circulatory system and nervous system using a pre-designed questionnaire. The study was approved by the Ethics Committee, following the recommendations of the Declaration of Helsinki and the legal regulations in force in our country regarding clinical research and the current Good Clinical Practice standards. All participants were informed of the objectives and methods of the study and signed the informed consent. Descriptive statistical analysis.
Results: 47 subjects participated (93.6% women) with a mean age (SD) of 49.2 (10.8) years (range 23-66 years). Thirty-five (74.5%) patients presented a low internal longitudinal arch in one or both feet, 19 (40%) Hallux Abductus Valgus (HAV) and 30 (63.8%) presented alterations in the other toes. Seventeen (36.2%) patients had pain in the hindfoot, 16 (34.0%) in the midfoot, 17 (36.2%) in the forefoot, and 14 (29.8%) in the toes. Stiffness in the feet appeared in 8 (17%) while joint swelling appeared in only one (2.1%). On the skin and appendages: 10 (21.3%) showed nail lesions and 39 (80.3%) presented some dermal lesion of the hyperkeratosis type due to friction or poor support. In the circulatory system there were no findings. Two (4.3%) patients had less bilateral sensitivity in the examination of the nervous system in the feet.
Conclusion: The most prevalent foot problems affect the musculoskeletal system and are related to Jaccoud arthropathy, especially the sinking of the internal longitudinal arch. Hyperkeratosis associated with poor foot support were also very prevalent.

POS0730 A BETTER SELF-EFFICACY IS PREDICTIVE OF BETTER HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS. DATA FROM A LATIN AMERICAN MESTIZO COHORT

M. F. Ugarte-Gil[1,2], R. V. Gamboa Cárdenas[1,2], C. Reategui Sokolova[2,3], V. Pimentel-Quiroz[1,2], M. Medina Chinchon[2], C. Elera-Fitzcarrald[1,2], Z. Rodriguez Bellido[2,4], C. Pastor Asurza[2,4], R. Perich Campos[2,4], G. S. Alarcon[5,6]. *[1]Universidad Científica del Sur, Grupo Peruano de Estudio de Enfermedades Autoinmunes Sistémicas, Lima, Peru; [2]Hospital Nacional Guillermo Almenara Irigoyen, EsSalud, Rheumatology, Lima, Peru; [3]Universidad San Ignacio de Loyola, Unidad de Investigación para la Generación y Síntesis de Evidencias en Salud, Lima, Peru; [4]Universidad Nacional Mayor de San Marcos, School of Medicine, Lima, Peru; [5]The University of Alabama at Birmingham, Birmingham, School of Medicine, Alabama, United States of America; [6]Universidad Peruana Cayetano Heredia, School of Medicine, Lima, Peru*

Background: Systemic lupus erythematosus (SLE) patients have a worse health-related quality of life (HRQoL) than the general population. This seems to be related to patients characteristics like age, poverty, behavioral issues rather than to disease activity or damage. Self-efficacy is defined as individual's confidence on performing a task and could impact on patient-reported outcomes.
Objectives: To determine the possible predictive value of self-efficacy on HRQoL in SLE patients.
Methods: SLE patients from a single-center prevalent cohort were included. Self-efficacy was ascertained with six instruments of the Patient-Reported Outcomes Measurement Information System (PROMIS) Self-efficacy for Managing Chronic Conditions. Instruments included were general self-efficacy, and self-efficacy for managing emotions, managing symptoms, managing daily activities, managing social interactions and managing medications and treatments. For PROMIS instruments, a score of 50 is the average for a clinical population (people with a chronic condition), a higher score indicates that the respondent has greater self-efficacy. HRQoL was ascertained with the physical and mental component summary (PCS and MCS) measures of the Short-Form 36 (SF-36). Generalized estimating equations were performed, using as outcome the PCS or MCS in the subsequent visit, and the self-efficacy instrument in the previous visit; multivariable models were adjusted for possible confounders (age at diagnosis, gender, socioeconomic status, SLEDAI-2K, SLICC/ACR damage index, disease duration at baseline, prednisone daily dose, antimalarial and immunosuppressive drugs use and PCS or MCS in the previous visit). All the confounders were measured in the same visit than the self-efficacy instrument.
Results: Two-hundred and nine patients for a total of 564 visits were included; 194 (92.8%) patients were women, mean age at diagnosis was 36.4 (14.0) years and disease duration at baseline was 6.5 (6.0) years. At baseline, PCS was 55.0 (22.3) and MCS was 53.9 (20.4). At baseline, mean general self-efficacy was 47.2 (10.4), self-efficacy for managing emotions was 44.6 (8.0), for managing symptoms was 47.7 (8.2), for managing daily activities was 45.5 (7.5) for managing social interactions was 42.9 (7.9) and for managing medications and treatment was 43.9 (7.0). In the multivariable models a better PCS was predicted by a better general self-efficacy, and self-efficacy for managing symptoms, managing social interactions and managing medications and treatments and a better MCS was predicted by a better self-efficacy for managing symptoms, managing daily activities, managing social interactions and managing medications and treatments. These data are depicted in Table 1.
Conclusion: A better self-efficacy is predictive of a subsequent better HRQoL, even after adjustment for possible confounders. These results should encourage clinicians to develop strategies to improve self-efficacy in SLE patients.

ASSOCIATION OF PATIENT-REPORTED OUTCOMES WITH TYPE I INTERFERON GENE SIGNATURE FROM THE INTERNATIONAL SYSTEMIC LUPUS ERYTHEMATOSUS PROSPECTIVE OBSERVATIONAL COHORT STUDY (SPOCS)

M. Aringer[1], L. Arnaud[2], C. Peschken[3], R. Furie[4], E. F. Morand[5], C. Seo[6], E. Rapsomaniki[7], J. Hedberg[8], J. Knagenhjelm[9], T. Grünfeld Eén[8], B. Desta[10], R. Tummala[11], A. Sorrentino[7], H. Stirnadel-Farrant[7]. *[1]University Medical Center and Faculty of Medicine TU Dresden, Division of Rheumatology, Department of Medicine III, Dresden, Germany; [2]Hôpital de Hautepierre, Department of Rheumatology, National Reference Centre for Rare Auto-Immune Diseases, Strasbourg, France; [3]University of Manitoba, Max Rady College of Medicine, Rady Faculty of Health Sciences, Winnipeg, Canada; [4]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, NY, United States of America; [5]Monash University, Faculty of Medicine, Nursing & Health Sciences, School of Clinical Sciences, Melbourne, VIC, Australia; [6]AstraZeneca, BioPharmaceuticals Medical, Gaithersburg, MD, United States of America; [7]AstraZeneca, BioPharmaceuticals Medical, Cambridge, United Kingdom; [8]AstraZeneca, BioPharmaceuticals Medical, Gothenburg, Sweden; [9]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden; [10]AstraZeneca, BioPharmaceuticals Business Unit, Gaithersburg, MD, United States of America; [11]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America*

Background: The aim of the Systemic Lupus Erythematosus Prospective Observational Cohort Study (SPOCS) is to examine the disease course of patients with systemic lupus erythematosus (SLE) in relation to their type I interferon gene signature (IFNGS) status.[1] IFNGS has been associated with SLE disease activity.[2]
Objectives: To identify associations between IFNGS status and patient-reported outcomes (PROs) among patients receiving clinical care while enrolled in SPOCS.
Methods: This noninterventional, international, prospective, observational cohort study included adult patients (≥18 years) with moderate to severe SLE receiving standard therapy. Short Form 36 Health Survey version 2 (SF-36; 0–100), Lupus Quality of Life (LupusQoL; 0–100) and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F; 0–52) were assessed at baseline, 6 months, and 12 months. Higher scores indicate better outcomes. Analyses were stratified by high or low IFNGS status (4-gene test) at baseline.
Results: Of 827 patients, mean (standard deviation [SD]) age was 45.1 (14.0) years, 771 (93%) were female, 525 (63%) were IFNGS high, and 219 (26%) were IFNGS low. IFNGS-high patients were younger than IFNGS-low (mean [SD] 43.0 [13.7] vs 50.7 [12.9] years), had fewer comorbidities (83% vs 91%) and similar baseline disease activity (mean [SD]: SLE Disease Activity Index 2000, 9.8 [4.3] vs 9.2 [5.2]; Physician's Global Assessment, both 1.5 [0.6]). At baseline, there were some differences in PROs between IFNGS-high and -low patients. At Month 12, changes in most domains did not meet the minimal clinically important difference (MCID). Slight improvement was observed only in selected domains in the IFNGS-high group. This group was younger and had fewer comorbidities at baseline. (Table 1, Figure 1).
Conclusion: In this cohort study, patients with moderate to severe SLE had poor health status, health-related quality of life, and fatigue. A clinically meaningful change was not met in most PROs, suggesting patients continue to have a high need for improved treatment options.

POS0732 CLINICAL, HISTOLOGICAL, AND SEROLOGICAL FEATURES ASSOCIATED WITH SALIVARY GLAND ULTRASOUND IN PRIMARY SJÖGREN'S SYNDROME

M. I. González-Nieto[1], A. Portella Alegre[2], M. Planes-Conangla[2], S. Bujan Rivas[1], X. Serres-Créixams[2], R. Solans-Laqué[1]. *[1]Hospital Universitari Vall d'Hebron, Internal Medicine, Barcelona, Spain; [2]Hospital Universitari Vall d'Hebron, Radiology, Barcelona, Spain*

Background: Salivary gland ultrasound (SGUS) is a simple and non-invasive procedure that is readily available and supplies important information on the major salivary glands. Several recent studies have assessed SGUS as a tool for diagnosing primary Sjögren's syndrome (pSS), and have reported its association with different features in pSS.

Objectives: To investigate the association of SGUS findings with clinical, histological, and serologic features of pSS in our cohort. In addition, we include monospecific antibody determination to Ro60 or Ro52.

Methods: Patients with pSS were determined according to the American-European Consensus Group (AECG) criteria for pSS. A total of 53 of these pSS patients underwent SGUS evaluation. We considered SGUS score based on parenchymal homogeneity, presence of hypoechogenic areas, and clearness of posterior glandular border of salivary glands. The score of the highest graded gland was considered and a score ≥2 was defined as a positive SGUS, according to OMERACT US-SG scoring [1]. Patients were classified into two groups according to positive vs. negative SGUS. Demographic, clinical, histopathological, and laboratorial data were collected and compared between the groups. Categorical variables were compared using the Chi-square test or Fisher's exact test when the conditions for Chi-square test were not met, and continuous variables were compared using Student's t-test with Welch's correction. p-values <0.05 were considered significant.

Results: Study participants were predominantly women (98%) and had a mean age of 60.2 years. SGUS was positive in 32 (63%) pSS patients, they were all women and had a mean age of 59 years. Positive SGUS was associated with objective evidence of ocular involvement (defined as a positive result for at least one of the ocular tests, p<0.001), time of evolution of xerophthalmia at diagnosis (mean 5.8 years vs. 2.2 years, p=0.037), pathological result of the labial salivary gland biopsy when it was performed (p<0.001), and the presence in the serum of both antiRo60 and antiRo52 antibodies (p=0.004), antiLa antibody (p=0.008) and ANA titer ≥1:320 (p<0.001). No significant differences were found between positive SGUS and negative SGUS patients regarding the presence of xerophthalmia nor xerostomia, time of evolution of xerostomia at diagnosis, episodes of parotid inflammation, abnormal salivary scintigraphy, nor the presence in the serum of monospecific antiRo52 nor antiRo60 in the absence of each other, nor positive rheumatoid factor.

Conclusion: Positive SGUS was associated in pSS patients with objective evidence of pathological ocular function, histopathology of minor salivary glands, and serology of pSS, specifically the presence of both antiRo52 and antiRo60 antibodies. In our cohort, no significant association was found regarding xerostomia, episodes of parotid inflammation, nor objective evidence of oral involvement. Thus, SGUS could be a useful tool to establish objective salivary gland involvement, independently of oral symptoms and other oral tests.

POS0733 DISCORDANCE BETWEEN PATIENT GLOBAL ASSESSMENT AND PHYSICIAN GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN THE MODERATE TO SEVERE SYSTEMIC LUPUS ERYTHEMATOSUS PROSPECTIVE OBSERVATIONAL COHORT STUDY (SPOCS)

L. Arnaud[1], R. Furie[2], E. F. Morand[3], C. Peschken[4], M. Aringer[5], E. Rapsomaniki[6], J. Hedberg[7], J. Knagenhjelm[8], C. Seo[9], T. Grünfeld Eén[7], B. Desta[10], A. Sorrentino[6], R. Tummala[11], H. Stirnadel-Farrant[6]. *[1]Hôpital de Hautepierre, Department of Rheumatology, National Reference Centre for Rare Auto-Immunes Diseases, Strasbourg, France; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, NY, United States of America; [3]Monash University, Faculty of Medicine, Nursing & Health Sciences, School of Clinical Sciences, Melbourne, VIC, Australia; [4]University of Manitoba, Max Rady College of Medicine, Rady Faculty of Health Sciences, Winnipeg, Canada; [5]University Medical Center and Faculty of Medicine TU Dresden, Division of Rheumatology, Department of Medicine III, Dresden, Germany; [6]AstraZeneca, BioPharmaceuticals Medical, Cambridge, United Kingdom; [7]AstraZeneca, BioPharmaceuticals Medical, Gothenburg, Sweden; [8]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden; [9]AstraZeneca, BioPharmaceuticals Medical, Gaithersburg, MD, United States of America; [10]AstraZeneca, BioPharmaceuticals Business Unit, Gaithersburg, MD, United States of America; [11]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America*

Background: Emphasis in clinical research and care has been placed on the need to include evaluations that reflect the perspectives of both patients and physicians.

Objectives: The goal of this study was to analyze patient and physician assessments and to determine characteristics associated with concordance and discordance of these assessments.

Methods: Baseline data of patients with moderate to severe SLE enrolled in the Systemic Lupus Erythematosus Prospective Observational Cohort Study (SPOCS)[1] were analyzed. Physician's Global Assessment (PGA) representing disease activity during the 4-week interval prior to baseline and Patient Global Assessment (PtGA) representing the impact of disease during a 1-month interval prior to baseline were independently scored on visual analogue scales (PGA 0-3; PtGA 0-100). Spearman's rank (rho) was calculated to assess their correlation. A difference between PGA and PtGA scores ≥25 points defined discordance (after rescaling PGA to 0–100).[2] Baseline characteristics associated with concordance and discordance were assessed.

Results: 827 patients were included in this analysis. At baseline, the mean PGA score was 1.5 (SD 0.6, n=824), and the mean PtGA score was 51.1 (SD 25.5, n=790). The correlation between PGA and PtGA was low (rho=0.19, *P*<0.001, n=787) (Figure 1). PGA and PtGA scores were discordant in 301 (38%) of patients. Among those patients exceeding the threshold defining discordance, 152 (19%) had higher PGA scores than PtGA scores, and 149 (19%) had higher PtGA scores than PGA scores. The subgroup of PGA-higher discordant patients had higher mean SLEDAI-2K scores, greater serological activity, and more frequent type 1 interferon gene signature positivity, whereas PtGA-higher discordant patients were more likely to be using analgesics and/or anti-depressants, had higher mean BMI and were less likely to be employed (Table 1).

Table 1. Characteristics associated with PGA and PtGA scores*a*

	Concordant (N=486)	PGA higher (N=152)	PtGA higher (N=149)	P-value-1[b]	P-value-2[b]
Age, years	45.5 (13.7)	42.7 (14.4)	46.4 (14.0)	0.022	0.043

Positive ANA/anti-dsDNA	436 (90%)	143 (94%)	127 (85%)	0.012	0.041
Low Complement (C3 or C4)	132 (46%)	58 (60%)	41 (43%)	0.014	0.026
High IFNGS	313 (71%)	101 (78%)	89 (64%)	0.014	0.049
≥1 mild flare	115 (24%)	20 (13%)	45 (30%)	<0.001	0.001
≥1 moderate flare	88 (18%)	37 (24%)	23 (16%)	0.057	0.120
≥1 severe flare	39 (8%)	11 (7%)	15 (10%)	0.372	0.628
OCS daily dose				0.052	0.129
No OCS	214 (44%)	57 (38%)	62 (42%)		
>0–7.5 mg	139 (29%)	38 (25%)	52 (35%)		
>7.5–15 mg	75 (15%)	37 (25%)	18 (12%)		
>15 mg	57 (12%)	19 (13%)	17 (11%)		
Immunosuppressants	271 (56%)	80 (53%)	75 (50%)	0.690	0.467
Biologics	106 (22%)	25 (16%)	19 (13%)	0.364	0.032
Analgesics	152 (31%)	22 (14%)	46 (31%)	<0.001	<0.001
Antidepressants	123 (25%)	31 (20%)	52 (35%)	0.005	0.013

[a]Mean (SD) for continuous, n (%) for nominal variables. Missing data was <10% of patients for the variables displayed. Denominators exclude missing data. [b]*P*-value-1 compares PGA higher vs PtGA higher. *P*-value-2 compares all 3 groups. Based on the chi-squared test for categorical variables and t-test or ANOVA for continuous variables.IFNGS, type 1 interferon gene signature; OCS, oral corticosteroid; PGA, physician global assessment; PtGA, patient global assessment

Conclusion: Low correlation between PGA and PtGA suggests both should be used to acquire a broad perspective of the impact of disease on the overall health of patients. Different baseline characteristics were associated with the PGA-higher compared to the PtGA-higher discordant subgroups.

Nakajima[11], A. Murashima[3]. *[1]Showa University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; [2]Kyoto University, Department of Healthcare Epidemiology, School of Public Health in the Graduate School of Medicine, Kyoto, Japan; [3]National Center for Child Health and Development, Division of Maternal medicine, Center of Maternal-Fetal, Neonatal and Reproductive Medicine, Tokyo, Japan; [4]The University of Tokyo, Department of Allergy and Rheumatology, Graduate School of Medicine, Tokyo, Japan; [5]Kitasato University, Department of Rheumatology and Infections Diseases, Sagamihara, Japan; [6]Juntendo University School of Medicine, Department of Internal Medicine and Rheumatology, Tokyo, Japan; [7]Tokyo Women's Medical University Hospital, Department of Pediatric Rheumatology, Institute of Rheumatology, Tokyo, Japan; [8]Kanazawa University, Department of Nephrology and Laboratory Medicine, Kanazawa, Japan; [9]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; [10]University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyusyu, Japan; [11]Mie University Graduate School of Medicine, Division of Rheumatology, Tsu, Japan*

Background: The risk of pregnancy complications, such as gestational hypertension is high in pregnancies with SLE. In addition, the risk of flare is elevated if pregnancy occurs during the high disease activity. The EULAR recommendation provides a checklist for preconception counseling, in which patients with SLE desiring pregnancy were required the condition that the disease activity prior to pregnancy should be stable for 6-12 months in terms of serological activity (1). However, it does not provide specific criteria for serological activity so that physicians should evaluate the risk of pregnancy in each case by their clinical intuitions.

Objectives: In order to uncover the present clinical situation for the acceptability of pregnancy in patients with SLE, we performed questionnaire survey to physicians regarding to the degree of serological activity.

Methods: This cross-sectional study was performed to physicians registered with the Japanese College of Rheumatology from December 2020 to January 2021 using the online survey. The questionnaire asked about the characteristics of physicians, facilities and the permission of pregnancies with SLE using vignette scenarios. In this study, data from vignettes of women visiting a regular outpatient clinic were used. The vignettes varied in age (28 or 35 years), duration of stable disease and serological activity. Analysis methods were descriptive statistics, chi-square test. generalized estimating equations (GEE) was performed to investigate the relationship between the determining permission for pregnancy and the scenario patient's characteristics (age, period of stable disease, titer of anti ds-DNA antibody)

Results: The questionnaire was distributed to 4946 physicians, and 463 responded. Completion rate (ratio agreed to participate/finished survey) of survey was 91.1%. The median age of physicians was 46 (interquartile range (IQR) 2-10). The specialty was rheumatology (84.9%), other internal medicine (8%), and pediatrics (5.6%). There were no significant differences in patient's age about the acceptability of pregnancy (coeffficianet -0.02, 95% CI -0.17 -0.01, p=0.42). Case who had been stable for 6 months were more tolerant of pregnancy than case who had been stable for 3 months (coeffficianet 0.12, 95% CI 0.09-0.15, P<0.001) Pregnancy was not allowed in case with mild or high serological activity (mild: coefficient -0.49, 95% CI -0.29- -0.22, p <0.001, high: -0.64, 95% CI -0.65 - -0.61, p <0.001). In contrast, as many as 92 (19.2%) physicians tolerated pregnancy even in the presence of residual high anti ds-DNA antibody titers. Female physicians are significantly more cautious about pregnancy than male when patients have a serologically high activity (12% vs 37.5%, p<0.001). There were no significant differences in specialty status or clinical experience.

Conclusion: We found that even mild serological activity alone had a significant negative effect on the physician's decision to allow pregnancy. We conclude that current physicians make cautious decisions about pregnancies of patients with SLE following the recommendation. On the other hand, an additional investigation should be performed about the results of pregnancies in patients with serological abnormalities, since there are some physicians who thought that pregnancy may be acceptable for patients with only serological abnormalities if the clinical symptoms are stable.

POS0735

EFFECT OF OSTEOPOROSIS ON MAJOR ADVERSE CARDIOVASCULAR EVENTS (MACES) AND MORTALITY IN SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL STUDY

C. C. Mok[1], K. L. Chan2, L. Y. Ho[1], C. H. To[3]. [1]*Tuen Mun Hospital, Medicine, Hong Kong, China;* [1]*Tuen Mun Hospital, Medicine, Hong Kong, China;* [3]*Pok Oi Hospital, Medicine, Hong Kong, China*

Objectives: To study the effect of osteoporosis on major adverse cardiovascular events (MACEs) and mortality in a longitudinal cohort of patients with systemic lupus erythematosus (SLE).
Methods: Patients who fulfilled ≥4 1997 ACR criteria for SLE and participated in a cross-sectional study on osteoporosis in the year 2011 were studied. All patients had a dual energy x-ray absorptiometry (DXA) scan (Delphi densitometer; Hologic, Bedford, USA) performed between the years 2004-2008 and were followed in the rheumatology clinics by the same team of physicians. The incidence of new MACEs, which were defined as ischemic vascular events (acute coronary syndrome, stroke, peripheral vascular disease) documented by imaging and angiographic studies, was evaluated. Patients were stratified into 2 groups according to the presence of osteoporosis at baseline, which was defined as a DXA T score of <-2.5 or Z score <-2.0 at the hip, femoral neck or lumbar spine, or having a past history of fragility fractures. The effect of osteoporosis on the development of MACEs and mortality was studied by Cox regression analysis, adjusted for demographic characteristics, traditional cardiovascular risk factors, antiphospholipid antibodies and the use of medications.
Results: 383 SLE patients were studied (age at DXA scan 40.5±13 years; 94% women; SLE duration 8.0±7.4 years). Osteoporosis at the hip, femoral neck or spine at baseline was present in 105 patients (13 with old fragility fractures) and 8 patients had osteopenia and past fragility fractures. The demographic characteristics, prevalence of traditional atherosclerotic risk factors and antiphospholipid (aPL) antibodies (lupus anticoagulant or moderate/high titers of IgG-anticardiolipin antibodies) were not significantly different between those with osteoporosis/fracture (N=113) and without (N=270). Patients with osteoporosis/fracture were more likely to be using glucocorticoids (79% vs 62%; p=0.002) and mycophenolate mofetil/azathioprine/calcineurin inhibitors (58% vs 48%; p=0.08) but less likely to be treated with hydroxychloroquine (40% vs 51%; p=0.051) at baseline. Over a follow-up of 153±41 months, 44 new MACEs (acute coronary syndrome [n=19]; ischemic stroke [n=19]; peripheral vascular disease with digital gangrene/amputation [n=6]) developed in 42 patients. The incidence of MACEs was significantly higher in patients with osteoporosis/fracture than those without (1.59 vs 0.63/100 patient-years; p=0.001). The cumulative risk of MACEs at 3, 5 and 10 years was 6.3%, 11.7%, 14.7%, and 0.4%, 1.9%, 4.7%, respectively, in the osteoporosis and non-osteoporosis groups (log rank test; p=0.002; univariate hazard ratio 2.58[1.40-4.74]; p=0.002). In a Cox regression model, osteoporosis/fracture remained an independent risk factor for the development of MACEs after adjustment for age, sex, LDL level, atherogenic index, diabetes mellitus, hypertension, past MACE, aPL antibodies, smoking, obesity and the use medications that included immunosuppressive drugs, aspirin/warfarin, statins, vitamin D and bisphosphonates (HR 2.41[1.25-4.67]; p=0.009). At last follow-up, 62(16%) patients succumbed (MACEs in 8 patients [vascular mortality], infective complications in 27 patients, cancer in 10 patients). Osteoporosis/fracture was associated with vascular mortality (HR 11.1[1.02-120]; p=0.048) but not with all-cause mortality (HR 1.55[0.89-2.68]; p=0.12) after adjustment for the same covariates in separate multivariate models.
Conclusion: Osteoporosis increases the risk of MACEs and vascular mortality in patients with SLE, which is not accounted by traditional vascular risk factors. Elevation of inflammatory cytokines in SLE that are common to bone metabolism and atherosclerotic vascular disease may be responsible.

POS0736

PREVALENCE AND RISK FACTORS OF FRAGILITY FRACTURES IN SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL STUDY OVER 12 YEARS

C. C. Mok[1], K. L. Chan[1], L. Y. Ho[1], C. H. To[2]. [1]*Tuen Mun Hospital, Medicine, Hong Kong, China;* [2]*Pok Oi Hospital, Medicine, Hong Kong, China*

Objectives: To study the prevalence and risk factors of fragility fractures in a longitudinal cohort of patients with systemic lupus erythematosus (SLE).
Methods: All patients who fulfilled ≥4 1997 ACR criteria for SLE and have been registered in our cohort database since 1990 were included. Symptomatic fragility fractures, defined as those that occurred with no preceding injury or after a low-energy impact, were identified from the SLE organ damage index (SDI) data and verified by record review. A longitudinal cohort of 383 SLE patients who participated in a cross-sectional study in 2011 and had a baseline dual energy x-ray absorptiometry (DEXA) scan performed was further analyzed for factors predicting new fragility fractures over time. These patients were stratified into 2 groups according to the presence of previous fragility fracture or osteoporosis at baseline, defined as a DEXA T score <-2.5 or Z score <-2.0 at the hip, femoral neck or lumbar spine. The cumulative incidence of new fractures was studied by Kaplan-Meier's analysis and risk factors were studied by Cox regression, adjusted for demographic characteristics, medications and other confounding factors.
Results: 1140 SLE patients were included (age of onset 34.7±14.4 years; 91.5% women). 102 fractures (hip [n=15]; vertebral [n=54]; limbs (non-hip) [n=14]; digital/rib [n=19]) developed in 91(8.0%) patients over a mean of 13.1 years. The prevalence of major osteoporotic and hip fractures was 0.56 and 0.10 per 100 patient-years, respectively. A cohort of 383 SLE patients were further analyzed (age at DEXA scan 40.5±13 years; 94% women). Osteoporosis was present in 105 patients (13 with past fractures) at baseline and 8 other patients had osteopenia but a history of fragility fractures. Patients with osteoporosis/previous fractures (N=113), compared to those without (N=270), were more likely to have SLE onset during childhood (<18 years), longer SLE duration and a higher prevalence of thrombocytopenia, hemolytic anemia or neuropsychiatric manifestations that required immunosuppressive therapies. Use of glucocorticoids (79% vs 62%; p=0.002) and mycophenolate mofetil (MMF)/azathioprine (AZA) (55% vs 42%; p=0.02), body mass index (BMI) ≤18kg/m2 (14% vs 7%; p=0.04) or menopause before the age of 45 years (14% vs 4%; p=0.001) were also more frequent in the osteoporosis/fracture group. However, no difference in the SLEDAI scores at time of DEXA scan was observed between the 2 groups (3.7±3.8 vs 4.1±3.3; p=0.26). Over a follow-up of 153±41 months, new symptomatic fragility fractures developed in 34(8.9%) patients (vertebral [n=19], hip [n=2], limbs (non-hip) [n=6], digital/rib [n=7]; incidence 0.69 per 100 patient-years). The cumulative risk of new fragility fractures at 3,5,10 and 15 years was 1.8%, 3.7%, 14.7%, 22.2%; and 1.5%, 1.9%, 3.9%, 6.7%, respectively, in the osteoporosis/previous fracture and non-osteoporosis groups (log rank test; p<0.001). Cox regression showed that older age (HR1.08[1.03-1.12]; p=0.001), osteoporosis/previous fracture (HR3.47[1.59-7.59]; p=0.002) and a family history of fracture (HR4.31[1.41-13.2]; p=0.01) at baseline were independently associated with the development of new fractures after adjustment for confounding factors. SLE duration, childhood onset disease, low BMI, chronic smoking, premature menopause, use of glucocorticoids, MMF, AZA or hydroxychloroquine, anti-Ro positivity, history of thrombocytopenia, hemolytic anemia and neuropsychiatric manifestations were not significant risk factors for new fractures. In those patients using glucocorticoids at baseline, there was no significant relationship between the daily dosage of prednisolone and new fractures.
Conclusion: In a longitudinal cohort of SLE followed for over 12 years, new fragility fracture developed in 8.9% of patients. Increasing age, osteoporosis, a personal or family history of fractures were major risk factors.

SICCA SYNDROME: A MULTIMODAL ASSESSEMENT TO CHARACTERIZE PATIENT COHORTS BEYOND SJÖGREN'S SYNDROME CLASSIFICATION CRITERIA

E. Kramer[1], T. Seeliger[2], T. Skripuletz[2], V. Gödecke[3], S. Beider[1], A. Jablonka[1], T. Witte[1], D. Ernst[1]. [1]*Medizinische Hochschule Hannover, Rheumatology and Immunology, Hannover, Germany;* [2]*Medizinische Hochschule Hannover, Neurology, Hannover, Germany;* [3]*Medizinische Hochschule Hannover, Centre of Rare Diseases, Hannover, Germany*

Background: Sicca syndrome represents a heterogeneous group of conditions, including Sjögren syndrome, causing xerophthalmia and xerostomia.
Objectives: This study characterizes in depth patients with Sicca syndrome and evaluates salivary gland ultrasound (SGUS) in this cohort.
Methods: Principal component analysis and hierarchical clustering of clinical parameters, including ESSPRI, ESSDAI and laboratory data were performed on all referrals for assessment of Sicca symptoms between October 2018 and March 2021. SGUS and labial gland biopsies were compared across groups.
Results: 583 patients were assessed. Objective dryness was confirmed in 73% of patients. Cluster analysis identified 3 groups with *post-hoc* analysis confirming distinct phenotypes: *Somatic Group* (283/583; 49%) with higher reported symptoms but limited objective dryness; *Dry Without Autoimmune Features* (DAF_{neg}, 206/532; 35%) and *Dry With Autoimmune Features* (DAF_{pos}, 94/532; 16%). DAF_{pos} patients had highest autoantibody titres (SSA 240 vs 3.6 vs 3.8; p<0.001), most extra-glandular manifestations (p<0.001) and highest median SGUS Score (DAF_{pos}: 8 [IQR 4-10] vs SG: 2 [1-4] vs DAF_{neg} 4 [2-5]; p< 0.001). No tangible correlation primary Sjögren syndrome criteria was observed.
Conclusion: SGUS score correlated with a subset of Sjögren syndrome patients, identified in the DAF_{pos} cluster. This study highlights heterogeneity within Sicca and indeed Sjögren syndrome, highlighting the need for further studies.

Table 1. Comparing and contrasting the clinical demographics and attributes of the entire cohort subdivided into the three groups identified through principal component analysis and subsequent hierarchical clustering. Results are shown as mean and interquartile range unless otherwise stated.

IMMUNOGENICITY AND SAFETY OF COVID-19 VACCINATION IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

G. M. Verstappen[1], L. De Wolff[1], S. Arends[1], H. M. Heiermann[1], Y. Van Sleen[1], A. Visser[1], J. H. Terpstra[1], D. Diavatopoulos[2,3], M. Van der Heiden[4], A. Vissink[5], D. Van Baarle[4,6], F. G. M. Kroese[1], H. Bootsma[1]. *[1]University of Groningen, University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]Radboud University Medical Centre Nijmegen, Radboud Centre for Infectious Diseases, Nijmegen, Netherlands; [3]Radboud University Medical Centre Nijmegen, Laboratory of Medical Immunology, Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands; [4]University of Groningen, University Medical Centre Groningen, Medical Microbiology and Infection Prevention, Nijmegen, Netherlands; [5]University of Groningen, University Medical Centre Groningen, Oral and Maxillofacial surgery, Groningen, Netherlands; [6]National Institute of Public Health and the Environment, Centre for Infectious Disease Control, Bilthoven, Netherlands*

Background: Patients with primary Sjögren's syndrome (pSS) worry about the effectiveness and safety of COVID-19 vaccination. pSS is characterized by B-cell hyperactivity, and previous influenza vaccination studies showed that pSS patients generate higher influenza-specific antibodies than healthy controls (HC).[1,2] Furthermore, influenza vaccination resulted in elevated auto-antibody levels.[1,2] Therefore, it is hypothesized that COVID-19 vaccination may also lead to a higher spike-specific antibody response.

Objectives: To evaluate humoral and cellular immune response and adverse events (AEs) after COVID-19 vaccination in pSS patients compared to HC, and disease activity following vaccination in pSS patients. Furthermore, to evaluate change in spike-specific antibody levels in saliva and anti-SSA levels in serum following vaccination.

Methods: In this prospective, longitudinal cohort study, pSS patients and HC were included in a 2:1 ratio. Participants received COVID-19 vaccinations following the Dutch vaccination programme. pSS patients did not use

immunomodulatory drugs, except hydroxychloroquine (HCQ). Anti-spike 1 (S1) receptor binding domain (RBD) IgG serum antibody levels were measured 28 days after complete vaccination. AEs were collected 7 days after vaccination. Change in disease activity following vaccination was measured with EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) and EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI). In a subgroup of participants, spike-specific T-cell response was measured 7 days after complete vaccination with IFN-γ ELIspot. Definition of a T-cell responder was ≥2-fold increase in spot-forming cell (SFC) counts from pre- to post-vaccination and SFC counts of ≥50/10^6 cells in the post-vaccination sample. Salivary anti-S1 and anti-RBD antibodies and serological anti-SSA antibodies were also measured in this subgroup in pre- and post-vaccination samples (28 days after complete vaccination).

Results: In total, 67 pSS patients and 33 HC were included. Of these, 47 (70%) and 14 (42%) received BNT162b2 (Pfizer-BioNtech), 13 (19%) and 5 (15%) received ChAdOx1 nCoV-19 (AstraZeneca), 6 (9%) and 8 (24%) received mRNA-1273 (Moderna), and 1 (1%) and 6 (18%) received Ad.26.COV2.S (Janssen), respectively. Overall, pSS patients were significantly older than HC, which was mainly due to the younger age in the Moderna and Janssen groups. All participants had positive anti-SARS-CoV-2 antibody levels (>2500 AU/ml) post-vaccination. No differences in anti-SARS-CoV-2 antibody levels were observed between pSS patients and HC, for any of the vaccine types (Figure 1). Percentage of spike-specific T-cell responders was comparable between pSS patients (20/24, 83%) and HC (4/5, 80%). Salivary anti-SARS-CoV-2 IgG antibodies, but not IgA, increased post-vaccination in pSS patients (n=26) and HC (n=9). Salivary anti-RBD IgG antibodies were significantly correlated with serum anti-RBD antibodies (r= 0.597, p<0.001).

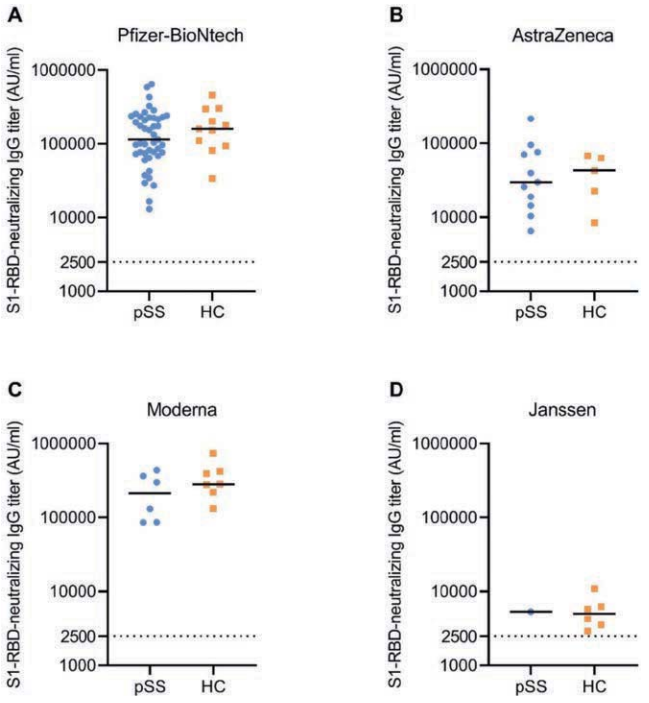

Figure 1. Anti-S1 RBD IgG antibody levels of participants who received **A)** Pfizer-BioNtech **B)** AstraZeneca **C)** Moderna or **D)** Janssen. Dashed line indicates positive level.

No serious AEs occurred. Frequencies of systemic AEs were comparable between pSS patients and HC (first vaccination: 34/67 (51%) vs. 16/33 (48%), p=0.83; second: 41/66 (62%) vs. 14/25 (56%), p=0.59). No significant worsening was observed in median ESSPRI (baseline: 6 (IQR 5-7), post-vaccination: 6 (4-7), p=0.16, n=64) and ESSDAI (baseline: 3 (IQR 1-4), post-vaccination: 2 (0-5), p=0.88, n=36). Furthermore, no increase in anti-Ro52 and anti-Ro60 antibody levels was seen (p=0.65 and p=0.58, respectively).

Conclusion: pSS patients had similar humoral and cellular immune responses as HC, providing evidence that COVID-19 vaccination is effective in pSS patients. AEs were also comparable, and no increase in disease activity was seen in pSS patients, indicating COVID-19 vaccination is safe in pSS patients.

THE RENAL ACTIVITY INDEX FOR LUPUS (RAIL) DIFFERENTIATES ACTIVE AND INACTIVE NEPHRITIS IN ADULT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

E. Cody[1], H. Brunner[2], B. Huang[3], T. Qiu[3], P. Devarajan[4], M. Ramaswamy[5], D. Sinibaldi[5], P. Z. Brohawn[5], J. Knagenhjelm[6], F. Jones[7], R. Tummala[5], C. Lindholm[6], W. White[5]. *[1]Cincinnati Children's Hospital Medical Center, Division of Pediatric Nephrology, Cincinnati, OH, United States of America; [2]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Pediatric Rheumatology Collaborative Study Group, Cincinnati, OH, United States of America; [3]Cincinnati Children's Hospital Medical Center, Division of Biostatistics and Epidemiology, Cincinnati, OH, United States of America; [4]Cincinnati Children's Hospital Medical Center, Division of Nephrology and Hypertension, Cincinnati, OH, United States of America; [5]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America; [6]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden; [7]AstraZeneca, BioPharmaceuticals R&D, Cambridge, United Kingdom*

Background: Lupus nephritis (LN) confers a poor prognosis, with lack of effective laboratory tests to diagnose and evaluate therapies. We have demonstrated that the RAIL score, based on a set of six urinary biomarkers (*NGAL, KIM-1, MCP-1,* adiponectin, hemopexin, ceruloplasmin) is sensitive and specific in adult patients with active LN, using renal biopsy as reference.[1,2] RAIL has been shown in the pediatric population to be effective in distinguishing inactive vs active LN with no effect from mycophenolate mofetil (MMF) treatment. A comparable study has not been conducted in an adult population.

Objectives: To assess the ability of RAIL to discriminate patients with active LN vs active non-renal SLE and to evaluate if RAIL performance varies by MMF treatment using urine samples from adult LN patients.

Methods: Urine samples were obtained at baseline in two clinical trials: a phase 2 study in adult patients with biopsy-proven active Class III and IV LN (NCT02547922) and a subset of patients from the phase 3 trial in adults with active non-renal SLE (NCT02446912) who had baseline renal BILAG scores C, D, or E. RAIL biomarkers were assayed using single-plex assays. Patient demographics and clinical characteristics were compared between studies. Wilcoxon rank sum test was performed comparing the urinary biomarkers between the two studies and RAIL score was then calculated. Receiver operating characteristic (ROC) analyses were conducted assessing the ability for RAIL scores to distinguish patients with renal activity and involvement.

Results: Comparison of the patient demographic, clinical characteristics, and biomarkers is in the Table 1. Wilcoxon rank sum test showed the six urinary biomarkers were significantly different between two groups of patients as demonstrated (Table 1). Each of the RAIL biomarker concentrations and the creatinine-adjusted median score were higher in the active LN group than the SLE group (P<0.001). ROC analyses including RAIL score showed an area under the ROC curve of 0.8 (Figure 1), with odds ratio of log-transformed RAIL 2.027 (95% CI [1.587, 2.589]). There were no significant interactions between RAIL and MMF. RAIL remained significant after adjusting for estimated glomerular filtration rate (eGFR), which was not statistically significant.

POS0740

IMPACT OF TIME TO REMISSION, FLARES AND EXPOSURE TO IMMUNOSUPPRESSIVES ON THE DEVELOPMENT OF ADVANCED CHRONIC KIDNEY DISEASE (STAGE IV OR WORSE) IN LUPUS NEPHRITIS

K. Tselios[1], D. D. Gladman[2,3], J. Su[2], M. B. Urowitz[2,3]. *[1]McMaster Lupus Clinic, Department of Medicine, Hamilton, Canada; [2]University Health Network, Schroeder Arthritis Institute, Toronto, Canada; [3]University of Toronto, Department of Medicine, Toronto, Canada*

Background: Lupus nephritis (LN) affects up to 40% of patients with SLE and leads to end stage kidney disease (ESKD) in 17-33% after 10 years. The prevalence of chronic kidney disease stage IV (estimated glomerular filtration rate, eGFR=15-29ml/min/1.73m^2) is not known; however, approximately two thirds of such patients will progress to ESKD after 6 years on average.[1]

Objectives: To determine the impact of time to remission and flares on the development of advanced CKD (stage IV or worse) in LN.

Methods: Patients with LN based on biopsy or abnormal proteinuria (>0.5g/day) with or without hematuria/pyuria/casts for two consecutive visits in the absence of other plausible explanation were retrieved from the Toronto Lupus Clinic database. Individuals with advanced CKD at baseline were excluded. All patients were followed for at least 5 years. The primary outcome was the development of advanced CKD (eGFR≦29ml/min/1.73m^2). Remission was defined as proteinuria<0.5g/24h, no active urinary sediment and serum creatinine of ≤120% of baseline. Flare was defined as any abnormal proteinuria (>0.5g/day) after remission. Death was treated as competing risk in survival analysis. Statistical analysis with SAS 9.4; $p<0.05$ was considered significant.

Results: Out of 418 eligible patients, 209 (50%) achieved remission within the first year from LN diagnosis, 102 (24.4%) within the 2nd and 3rd years, 70 (16.7%) after 3 years and 37 (8.9%) never achieved remission. Sixty-six patients (15.8%) developed advanced CKD after 9.5 years on average (37 with ESKD). At baseline, these patients had a higher SLICC/Damage Index (0.6±1.2 vs. 0.3±0.7, $p=0.003$), lower eGFR (73±38 vs. 94±33ml/min/1.73m^2, $p<0.001$), higher prevalence of hypertension (85% vs. 73%, $p=0.046$), proliferative nephritis (combined class III and IV, 66% vs. 47.8%, $p=0.017$) and more often treated with ACE inhibitors or angiotensin receptor blockers (35% vs. 22%, $p=0.02$). The other variables did not differ significantly. Remission rates, flares and exposure to immunosuppressives after remission are shown in Table 1.

Table 1. A. Time to remission, exposure to immunosuppressives and flares in all patients

VARIABLE	Advanced CKD (n=66)	No advanced CKD (n=352)	*p*
Years from LN to complete remission	3.0 ± 3.4	1.6 ± 2.1	<0.001
Years on Immunosuppressives from complete remission to outcome/last date (median)	2 (0-7)	4 (0-8)	0.008
Number of flares in first five years after LN			
0	12 (18.2%)	156 (44.3%)	<0.001
1	14 (21.2%)	79 (22.4%)	
2 or more	40 (60.6%)	117 (33.2%)	
B. Multivariate analysis for the outcome of advanced CKD (stage IV or worse)			
	HR	**95%CI**	***p***
Serum creatinine at baseline	1.02	1.01-1.02	<0.0001
Complete remission between 1-3 years (compared to remission within 1 year)	2.48	1.14-5.37	0.022
Complete remission after 3 years or no remission (compared to remission within 1 year)	2.99	1.41-6.34	0.004
Years on Immunosuppressives from complete remission to outcome/last date	0.89	0.83-0.95	<0.0001
One flare (compared to no flares)	2.68	1.05-6.86	0.04
Two or more flares (compared to no flares)	3.55	1.51-8.34	0.004

Patients who achieved remission within one year from diagnosis demonstrated better outcomes compared to all other groups ($p<0.0001$), Figure 1. Patients with complete remission between one and three years had similar outcomes for the first 10 years from diagnosis and deteriorated during the second decade of follow-up.

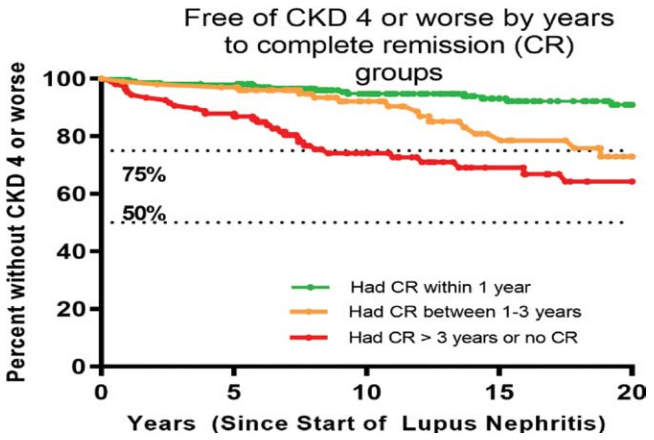

Figure 1.

Conclusion: Complete remission within the 1st year from LN diagnosis strongly protects against advanced CKD. Flares significantly affect prognosis. One flare was associated with 2.7-fold increased risk for advanced CKD (3.6-fold for 2 or more flares). Longer time on immunosuppressives after remission is associated with decreased risk for advanced CKD. Our findings emphasize the importance of early remission as well as flare prevention with prolonged immunosuppressive use to maximize renal survival in LN.

POS0741 REPORT FROM THE APS STUDY GROUP OF THE ITALIAN SOCIETY FOR RHEUMATOLOGY (SIR-APS) ON APL NEGATIVIZATION

S. G. Foddai[1], S. Sciascia[1], C. Alessandri[2], A. Alunno[3], L. Andreoli[4], A. Barinotti[1], A. Calligaro[5], V. Canti[6], F. Carubbi[7], I. Cecchi[1], C. Chighizola[8], F. Conti[2], G. Emmi[9], A. Fioravanti[10], F. Fischetti[11], F. Franceschini[4], M. Gerosa[8], A. Hoxha[5], M. Larosa[5], M. G. Lazzaroni[4], C. Nalli[4], G. Pazzola[12], M. Radin[1], B. Raffeiner[13], V. Ramoni[14], D. Roccatello[1], E. Rubini[1], G. Sebastiani[15], S. Truglia[2], M. L. Urban[9], A. Tincani[4]on behalf of SIR-APS. *[1]University of Turin, Clinical and Biological Sciences,Turin, Italy; [2]University of Rome, Lupus Clinic, Rome, Italy; [3]University of Perugia, Rheumatology Unit, Perugia, Italy; [4]University of Brescia, Unit of Rheumatology and Clinical Immunology, Brescia, Italy; [5]Rheumatology Unit, University of Padua, Padua, Italy; [6]University of Milan, IRCCS San Raffaele, Milan, Italy; [7]University of l'Aquila, Internal Medicine, Aquila, Italy; [8]University of Milan, Rheumatology Unit, Milan, Italy; [9]University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy; [10]University of Siena, Rheumatology Unit, Siena, Italy; [11]University of Trieste, Rheumatology Unit,Trieste, Italy; [12]University of Modena and Reggio Emilia, Rheumatology Unit, Modena, Italy; [13]Bolzano, Rheumatology Unit, Bolzano, Italy; [14]University of Pavia, Rheumatology Unit, Pavia, Italy; [15]University of Rome, San Camillo Forlanini, Rome, Italy*

Background: The rate of antiphospholipid antibodies (aPL)negativization in antiphospholipid syndrome (APS) patients is uncertain, but it is estimated to be as high as 8%. aPL disappearance seems to be more frequent in patients positive for one single aPL test and appears to be related with the immunosuppressant/immunomodulatory treatment undertaken by the patient. Currently, a consensus definition of aPL negativization is lacking, as well as international recommendations on how to approach treatment in patients with a persistent aPL negative seroconversion.

Objectives: The aim of our work was to evaluate the clinical approach and the level of consensus among experts from the APS Study Group of the Italian Society for Rheumatology (SIR-APS) in different clinical scenario addressing aPL negativization and its definition.

Methods: Experts of SIR-APS were contacted using a survey methodology.

Results: A structured survey was circulated among 30 experts.Up to 90% of the interviewed experts agreed on defining aPL negativization as the presence of two negative determinations, one year apart (90%).Almost ful lconsensus exist among experts in some clinical settings, including: a) the role of aPL negativitation in the management of a thrombotic event determined by concomitant presence of cardiovascular risk factors, both modifiable and not modifiable (90%): b) approach to young patients with triple aPL positivity who experienced pulmonary arterial thrombotic event and tested negative for aPL detection after five year of vitamin K antagonist (VKA) treatment (90%); c)the use of "*extra criteria*" aPL antibodies testing before pondering VKA suspension (93%).

Conclusion: Consensus is needed to support the management of patients with APS in areas where controlled data are missing. A substantial agreement exists among expert in defying aPL negativization as the presence of two negative determinations, one year apart. On the contrary, VKA suspension should be embraced with extreme caution when it comes to APS patients, particularly if they experienced arterial thrombotic events and/or tested positive for triple aPL. Nevertheless, VKA cessation might be considered when risk factors are carefully monitored/treated and the presence for "*extra criteria"* aPL is ruled out.

POS0742 DISCRIMINATIVE POWER OF SALIVARY GLAND ULTRASOUND IN RELATION TO ENDOTYPES IN SUSPECTED AND DEFINITE PRIMARY SJÖGREN'S SYNDROME

L. Deroo[1,2], H. Achten[1,2], K. De Boeck[1], E. Genbrugge[3], W. Bauters[3], D. Roels[4], I. Phlypo[5], F. Dochy[6], D. Creytens[7], D. Elewaut[1,2], I. Peene[1,8]. *[1]Ghent University Hospital, Rheumatology, Ghent, Belgium; [2]VIB-UGent, Center for Inflammation Research, Ghent, Belgium; [3]Ghent University Hospital, Radiology, Ghent, Belgium; [4]Ghent University Hospital, Ophthalmology, Ghent, Belgium; [5]Ghent University Hospital, Dentistry, Ghent, Belgium; [6]Ghent University Hospital, Head and Neck Surgery, Ghent, Belgium; [7]Ghent University Hospital, Pathology, Ghent, Belgium; [8]AZ Sint-Jan, Rheumatology, Bruges, Belgium*

Background: Primary Sjögren's Syndrome (pSS) is an auto-immune disease with characteristic complaints of oral and ocular dryness, typically affecting adult women. In addition, up to 30-40% of patients suffers from systemic manifestations and lymphoma risk is increased 15-20 fold. pSS is thus highly heterogenous both in presentation and pathophysiology. In an attempt to address this issue Tarn et al. applied cluster analysis based on patient reported outcomes assessing dryness, fatigue, pain and features of anxiety and depression, on a population of pSS patients. This resulted in four groups: low symptom burden (LSB), pain dominant with fatigue (PDF), dryness dominant with fatigue (DDF) and high symptom burden (HSB). These groups, referred to as endotypes, also seemed to have different biological profiles.(1)

Objectives: The aim of this study was to explore salivary gland ultrasound (SGUS) in relation to symptom-based endotypes in a cohort of patients with definite and suspected pSS.

Methods: Data from the Belgian Sjögren's Syndrome Transition Trial (BeSSTT) were used in which patients positive for at least one of the 2016 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) classification criteria, were enrolled. Patients were considered 'definite pSS' when fulfilling these criteria and 'suspected pSS' otherwise.

The Newcastle Sjögren's Stratification Tool, developed and provided by J. Tarn and colleagues, was applied to stratify the cohort into endotypes. Hocevar score (0-48) was used to assess SGUS abnormalities. Scores of at least 17 were considered positive.

Results: Stratification of the BeSSTT (n=241) cohort resulted in 4 endotypes, both in definite (n=141) and suspected pSS (n=100). The proportion of anti-SSA positive patients was high in definite pSS in all endotypes (91.9%; p=0.239). This proportion was significantly lower in suspected pSS patients in all endotypes

(27.6%; p=0.064) albeit that the difference was less pronounced in LSB (50.0%) and, to a lesser degree, in PDF (32.7%) endotypes.
SGUS scores were higher in definite than suspected pSS (22 (12-37) vs 10 (2-16); p<0.001) in all endotypes (Figure 1). In definite pSS, Hocevar scores were highest in DDF compared to other endotypes (35 (24-43); p<0.001) and SGUS had a very strong discriminating power in this endotype (PPV=94.1%, NPV=76.2%). Salivary gland function was poorest in the definite pSS DDF endotype.

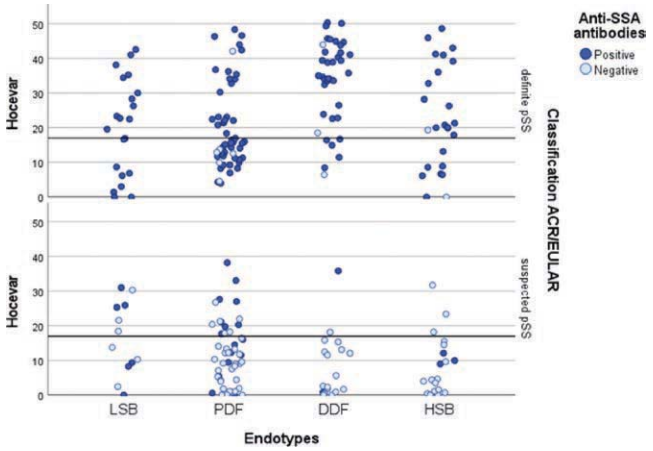

Figure 1. Scatter plot of Hocevar score (0-48) by endotype. The upper plot represents patients with definite and the lower with suspected pSS. The colour of the dots indicates presence or absence of anti-SSA antibodies. The horizontal line is drawn at a Hocevar score of 17 and represents cut-off for positive SGUS.

In the suspected pSS subgroup, Hocevar scores tended to be higher in the LSB endotype (17 (6-26); p=0.053) and were significantly higher in anti-SSA positive than negative patients (12 (6-26) vs 8 (1-14); p=0.017) (Figure 1). Of the 24 suspected pSS patients (24.0%) with a positive SGUS, 12 (50.0%) were anti-SSA positive. Anti-SSA positive suspected pSS patients with an aberrant SGUS were markedly younger than the rest of the BeSSTT cohort (mean±SD age of 36 ±15 years vs 52 ±14 years) suggesting they may represent an early at-risk population.
Conclusion: These results show prominent SGUS differences between endotypes in pSS, supporting its potential as biomarker. Hocevar scores are highest in patients with DDF endotypes, further suggesting a different biological profile. SGUS is a powerful tool to identify definite pSS patients from a group of patients with DDF endotypes who fulfil at least one of the ACR/EULAR classification criteria. In addition, a subset of young anti-SSA positive patients without overt dryness (LSB and PDF endotype) reveals high SGUS scores. We would thus propose SGUS in all anti-SSA positive patients, regardless of symptoms, to reveal this glandular involvement.

POS0743 CLINICAL CHARACTERISTICS AND BURDEN AMONG PATIENTS WITH SLE AND MUSCULOSKELETAL ORGAN INVOLVEMENT: RESULTS FROM A REAL-WORLD STUDY IN THE US

A. Vadhariya[1], J. Birt[1], J. Wu[1], K. Griffing[1], F. Bailey[2], J. Hetherington[2], E. Rottier[2], S. Barlow[2], K. Costenbader[3]. *[1]Eli Lilly & Co, Indianapolis, United States of America; [2]Adelphi Real World, Bollington, United Kingdom; [3]Brigham and Women's Hospital, Division of Rheumatology, Inflammation and Immunity, Boston, United States of America*

Background: Limited information exists concerning the clinical burden and unmet need of musculoskeletal (MSK) organ involvement among patients with SLE in clinical practice.
Objectives: To examine demographics, clinical status, treatment patterns, and patient-reported outcomes (PROs) among patients with SLE in clinical practices and assess the impact of MSK organ involvement.
Methods: Data were drawn from the Adelphi Real World Lupus IV (2021) Disease Specific Programme™, a point-in-time survey of 79 US physicians and their patients with SLE. Physicians completed questionnaires regarding patient demographics, clinical status, and treatment. The same patients were invited to complete questionnaires containing the EuroQoL 5-Dimensions (EQ-5D), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-Fatigue) and Work Productivity & Activity Impairment questionnaire (WPAI) PRO tools. Physicians stated their patients' organ involvement at the time of data collection (current), in the categories of musculoskeletal, mucocutaneous, renal, cardiorespiratory, constitutional, haematologic, ophthalmologic, gastrointestinal, respiratory, or other. Two mutually exclusive patient groups were analysed: A.MSK – Current physician assessed musculoskeletal organ involvement (+/- other organ/tissue involvement). B.Non-MSK – No current musculoskeletal organ involvement as assessed by the physician Bivariate analysis was conducted for numeric variables using t-tests; binary categorical variables using a Fisher's exact test; ordinal categorical variables using a Mann-Whitney test; and other categorical variables were compared using a chi-squared test.
Results: A total of 595 patients were included in this analysis: 64.7% MSK and 35.3% non-MSK. Mean[SD] patient age was 45.2[14.3] years, 83.2% were female, 53.3% were White/Caucasian, 27.9% were African American, and mean[SD] time diagnosed with any SLE was 5.3[6.2] years. Point-in-time assessment of clinical status, treatment patterns and patient-reported outcomes, revealed that those with MSK organ involvement assessed by their rheumatologist had higher overall SLE disease severity, more flares in the last 12 months, and slightly worse quality of life scores and work impairment.

Table 1. Point-in-time clinical status, treatment patterns and PROs among patients with SLE MSK organ involvement

		Total	MSK	Non-MSK	
		(n=595)	(n=385)	(n=210)	p value
Physician-Reported Patient Clinical Status & Treatment History					
Current SLE severity, n(%)	Mild	405 (68.1)	243 (63.1)	162 (77.1)	<0.001
	Moderate	169 (28.4)	128 (33.3)	41 (19.2)	
	Severe	21 (3.5)	14 (3.6)	7 (3.3)	
Current joint symptoms, n(%)	Joint tenderness	251 (42.2)	210 (54.6)	41 (19.5)	<0.001
	Joint stiffness	255 (42.9)	212 (55.1)	43 (20.5)	<0.001
	Joint swelling	135 (22.7)	111 (28.8)	24 (11.4)	<0.001
Mean [SD] Flares in the last 12 months		1.6 [1.7]	1.7 [1.8]	1.2 [1.3]	0.015
Currently prescribed, n(%)	Belimumab	113 (19.0)	79 (20.5)	34 (16.2)	0.198
	Immunosuppressant	164 (27.6)	105 (27.3)	59 (28.1)	0.830
	Corticosteroids	333 (56.0)	228 (59.2)	105 (50.0)	0.030
	Antimalarials	429 (72.1)	268 (69.6)	161 (76.7))	0.067
Mean [SD] years on current treatment		2.9 [3.6]	2.5 [3.0]	3.6 [4.4]	<0.001
Patient-Reported Outcomes					
Mean [SD] EQ5D-5L Utility score (0= death to 1= full health)		0.79 [0.20]	0.76 [0.22]	0.85 [0.16]	0.002
Mean [SD] FACIT-Fatigue score (0 worst fatigue to-52= no fatigue)		32.4 [12.0]	31.0 [11.5]	35.4 [12.6]	0.005
Mean [SD] WPAI, overall work impairment score(0= no impact to 100= completely impacted)		29.0 [21.0]	30.5 [18.6]	25.9 [25.2]	0.223

Conclusion: In this large sample of patients with SLE followed in clinical practices in the U.S., compared to those with little or no rheumatologist assessed MSK involvement, those with MSK involvement, had lower quality of life, with higher impact on their work productivity. These results highlight the heterogeneity of SLE and the impact of major MSK manifestations on quality of life in SLE.

POS0744 SYSTEMIC LUPUS ERYTHEMATOSUS WITH ACTIVE MUSCULOSKELETAL SYMPTOMS: PATIENT REPORTED SYMPTOM IMPACT, TREATMENT PATTERNS AND SATISFACTION WITH CURRENT THERAPY OPTIONS

D. L. Kamen[1], J. Birt[2], M. Hadi[3], E. Gibbons[3], D. Bushnell[4], R. Yu[4], L. Delbecque[5], K. Griffing[2], A. Askanase[6,6]. *[1]Medical University of South Carolina, Health, Charleston, United States of America; [2]Eli Lilly and*

Company, Global Patient Outcomes, Indianapolis, United States of America; [3]Pharmaceutical Product Development, Evidera, London, United Kingdom; [4]Pharmaceutical Product Development, Evidera, Bethesda, United States of America; [5]Eli Lilly & Company, Global Patient Outcomes, Brussels, Belgium; [6]Columbia University College of Physicians and Surgeons, Medical, New York, United States of America

Background: Musculoskeletal (MSK) symptoms affect 50-95% of patients with SLE over their disease course negatively impacting functioning, and quality of life (QoL).1 In SLE-UPDATE, a US, cross-sectional, non-interventional online survey of adults with SLE, over half of the participants reported active MSK symptoms, including pain or swelling in the joints (53%) and stiffness (57%).2 The present study evaluated the sub-group of participants with 'currently active' MSK symptoms.

Objectives: To describe the self-reported disease burden, treatment patterns, and satisfaction with therapies in patients with SLE, comparing those with versus without active MSK symptoms.

Methods: This secondary analysis of SLE-UPDATE survey data stratified participants into active or non-active MSK group. Participants currently experiencing pain or swelling and/or stiffness in their joints and had a Joint Pain NRS > 4 were in the "active MSK group". All remaining participants were in the "non-active MSK group". Analysis comprised descriptive statistics, mean (standard deviation [SD]) for continuous variables, and frequency (percentage [%]) for categorical variables. Two-sample t-test to compare mean scores and chi-squared testing to compare proportions were used.

Results: Of the survey participants, 285 were in the active MSK group and 215 in the non-active MSK group. The active MSK group was older (44.3 vs. 40.2 years, <0.001) and had a longer time since diagnosis (12.6 vs. 9.2 years, <0.001). More people in the MSK group had fibromyalgia (FM) (45 vs 12%, <0.0001), worse pain, fatigue, and QoL (Table 1) suggestive of Type 2 non-inflammatory SLE symptoms. Fewer in the MSK group were employed full-time (36.5 vs. 62.8%) and more were on permanent disability (27.0 vs. 6.5%). More participants in the active MSK group negatively assessed their general health (fair or poor) over the last month (53.4 vs. 20.4%). The active MSK group self-reported more "flares" over the prior 3 months; with 44.9 vs 41.9% reporting 1-3 flares, 15.1 vs 5.1% reporting 4-6 flares, and 8.1 vs 2.3% reporting > 7 flares.

Table 1. Patient Reported Outcomes

	Active MSK		Non-Active MSK	
	FM	Non-FM	FM	Non-FM
	N=129	N=156	N=26	N=189
Worst Pain NRS, Mean (SD)	6.5 (1.7)*		4.8 (2.6)	
	6.9 (1.6)*	6.2 (1.8)	4.0 (2.2)	4.9 (2.6)~
Worst Joint Pain NRS, Mean (SD)	6.7 (1.7)*		4.5 (2.6)	
	7.1 (1.6)*	6.5 (1.6)	3.5 (2.0)	4.6 (2.6)*
FACIT Fatigue Score, Mean (SD)	19.1 (10.8)*		28.1 (11.6)	
	15.4 (9.5)*	22.1 (10.9)	25.7 (13.8)	28.4 (11.3)~
LupusPRO HRQoL Score (SD)	48.9 (20.2)*		64.1 (23.0)	
	45.5 (18.1)*	51.7 (21.4)	63.0 (23.9)	64.3 (22.9)~

NRS: 0 (none)-10 (worst imaginable); FACIT Fatigue: 0-52, higher= less fatigue; LupusPRO: 0-100, higher= better QoL; *p < 0.05; ~ Not significant

The active MSK group used more anti-malarials (50.9 vs. 30.7%), immunosuppressants (37.2 vs. 26.5%), including methotrexate (12.6 vs 3.3%), narcotic analgesics (18.6 vs. 10.2%), and topicals for joint pain (30.5 vs. 10.2%). Interestingly, treatment goals of greatest importance in both groups were reduction in fatigue and pain, but pain reduction had higher importance in active MSK group (rated very important by 26.7 vs. 18.1%). Lower proportions in the active MSK group were satisfied with steroids (58.0 vs. 77.8% <0.01), immunosuppressants (65.1 vs. 80.7% <0.05), methotrexate (47.2 vs. 85.7% =0.061), and belimumab (80 vs. 95.5%=0.102).

Conclusion: Reduction of pain and fatigue was the main treatment goal of patients with SLE whether they had active or non-active MSK symptoms. Patients with active MSK symptoms had higher pain and fatigue, lower QoL, and less satisfaction with current therapies compared to SLE patients without active MSK symptoms, driven only in part by co-morbid FM. Findings from these analyses suggest there are unmet needs to better understand MSK manifestations, their overlap with Type 2 SLE symptoms, align patient/physician priorities, and improve therapies for MSK symptoms for patients with SLE.

POS0745 GUT DYSBIOSIS ASSOCIATED WITH PERIPHERAL LYMPHOCYTES AND CYTOKINES IN PATIENTS WITH SJÖGREN'S SYNDROME

S. Song[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], R. Zhao[2,3,3], T. Cheng[1,2,3], X. Li[1,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; [3]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*

Background: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by disorders of lymphocyte subpopulations with various cytokines and auto-antibodies[1]. Growing evidences suggest that gut microbiome dysbiosis may contribute to the development of pSS[2].

Objectives: To investigate the alterations to the gut microbiome and the correlation with peripheral lymphocytes and serum cytokines as well as inflammatory factors in pSS patients.

Methods: A total of 101 pSS patients and 101 age- and sex- matched healthy controls (HCs) were enrolled in this study from The Second Hospital of Shanxi Medical University (Taiyuan, Shanxi, China). Patients fulfilled the 2019 ACR/EULAR classification criteria. We conducted 16S rRNA gene sequencing using fecal microbiota samples and analyzed the peripheral lymphocyte subsets by flow cytometry. Serum cytokines, erythrocyte sedimentation rate (ESR), C-reaction protein (CRP), unstimulated and stimulated whole saliva (UWS and SWS) secretion rate was also collected, respectively. Sequence data were compiled and processed using Qiime2 and OTU-profiling tables were constructed. Correlations between different taxa and gut microbiome, as well as clinical variables, were calculated by Spearman's rank test.

Results: Patients with pSS exhibited a significant reduction in the richness and diversity of gut microbiota compared with those of HCs (Figure 1A-B, $p < 0.05$). Detailly, at the phylum level, pSS patients had a lower frequency of Firmicutes while higher Proteobacteria (Figure 1C, $p < 0.05$). Compared with HCs, 11 species of flora were discovered to be distinctly different at the genus level ($p < 0.05$). Patients presented fewer Faecalibacterium and Roseburia but more Lactobacillus (Figure 1D, $p < 0.05$). Lactobacillus negatively correlated with T cells (r=-0.407), CD8+T (r=-0.417) and Th2 (r=-0.323). There was a significant positive correlation between Faecalibacterium and IL-2(r=0.312), IFN-γ(r=0.338), TNF-α levels(r=0.322) (Figure 1E, $p < 0.05$). As for clinical disease measures, IL-6 increases were in line with ESR and CRP, while IL-2 levels inversely related to CRP. Additional UWS secretion rate and SWS secretion rate had negative correlation with ESR (Figure 1F, $p < 0.05$).

Conclusion: The structural disorder of gut microbiota was distinct in pSS which were associated with peripheral lymphocyte subsets and cytokines. Disorders of gut microbiota and immune systems may contribute to the occurrence and development of pSS.

POS0746

MEASUREMENT OF ANTI-SUPRABASIN ANTIBODIES, MULTIPLE CYTOKINES AND CHEMOKINES AS POTENTIAL PREDICTIVE BIOMARKERS FOR NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

T. Hoang[1], K. Ichinose[1], S. Morimoto[2], K. Furukawa[1], L. Le[3], A. Kawakami[1].
[1]Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; [2]Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan; [3]Nagasaki University, Graduate School of Engineering, Nagasaki, Japan

Background: The pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE) is multifactorial and involves diverse cytokines, autoantibodies and immune complexes inducing blood-brain barrier (BBB) dysfunction, neuroendocrine-immune imbalance, vascular occlusion, tissue, and neuronal damage. Several pro-inflammatory cytokines have been implicated in the pathogenesis of NPSLE [1]. Previously we have shown that the titer of anti-suprabasin (SBSN) antibodies in cerebrospinal fluid (CSF) of NPSLE patients was significantly higher than in SLE, MS and NPH groups [2]. However, distinguishing NPSLE from other neuropsychiatric conditions with different etiologies is challenging.
Objectives: This study determined the most critical serum biomarkers for the development of NPSLE as they may have clinical utility prior to the onset of neuropsychiatric symptoms.
Methods: We retrospectively analyzed 35 NPSLE patients, 34 SLE patients, 20 viral meningitis (VM) patients, and 16 relapsing-remitting multiple sclerosis (MS) patients. We measured anti-SBSN antibodies concentrations in serum by using Luciferase immunoprecipitation system (LIPS) assay. The serum concentrations of cytokines/chemokines were measured by using multiplex bead-based assay. All the clinical information and laboratory tests were collected at the time of admission.
Results: The Bayesian posterior mean and 95% HPDI of the cut-off of AI and its PPV and 1-NPV values were 5.26 (3.68;7.17), 0.87, (0.72; 1.0) and 0.44, (0.36; 0.5), respectively (Figure 1).

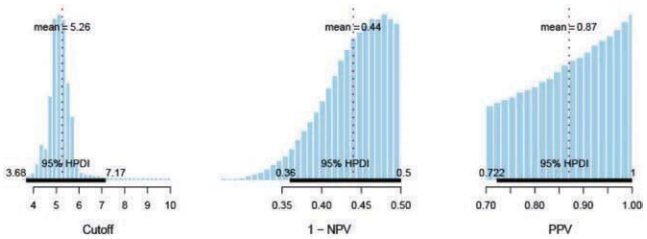

Figure 1. Summary of the posterior distribution of the cutoff of AI and its predictive value (1-NPV and PPV). The 95% HPDI is shown as the thick black horizontal line with the boundaries written above the line

Among analyzed biomarkers, VEGF had the highest sparsity-oriented important learning (SOIL) importance, followed by AI, sCD40L, IL-10, GRO, MDC, IL-8, IL-9, TNFα, MIP-1α (Figure 2).

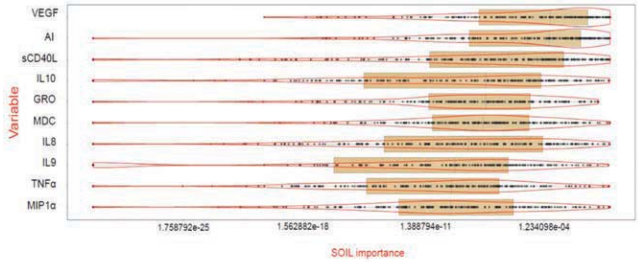

Figure 2. Top 10 biomarkers having highest SOIL importance in prediction of NPSLE. Abbreviations• AI: anti-SBSN antibody index• PPV: positive predictive• NPV: negative predictive value• SOIL: sparsity-oriented important learning• IL: interleukin•MIP: macrophage inflammatory protein• sCD40L: soluble CD40 ligand• MDC: macrophage-derived chemokine• VEGF: vascular endothelial growth factor• MDC: macrophage-derived chemokine• TNF: Tumor necrosis factor

Conclusion: Our data demonstrated the ranking of serum biomarkers for the prediction of NPSLE. The most essential biomarkers are VEGF, anti-SBSN antibodies, sCD40L, IL-10, GRO, MDC, IL-8, IL-9, TNFα, MIP-1α.

POS0747

ANTI-PHOSPHATIDYLSERINE/PROTHROMBIN ANTIBODIES AND VASCULAR EVENTS ASSOCIATE POSITIVELY WITH HLA-DRB1*13 AND NEGATIVELY WITH HLA-DRB1*03 IN SLE

S. Elbagir[1], L. M. Diaz-Gallo[2], G. Grosso[2], A. Zickert[2], I. Gunnarsson[2], M. Mahler[3], E. Svenungsson4, J. Rönnelid[1]. *[1]Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden; [2]Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden; [3]Werfen Autoimmunity, Research and Development, San Diego, United States of America; [2]Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*

Background: Anti-phosphatidylserine/prothrombin antibodies (anti-PS/PT) associate with thrombotic events (1). *HLA-DRB1* alleles contribute to the occurrence of conventional antiphospholipid antibodies (aPL), including anti-beta2glycoprotein-I (beta2GPI) and anti-cardiolipin (CL) (2).
Objectives: We investigated associations between anti-PS/PT and *HLA-DRB1* alleles and thrombosis in patients with SLE. Conventional aPL were included for comparison.
Methods: We included 341 consecutive Swedish SLE patients, with information on general cardiovascular risk factors, including blood lipids, lupus anticoagulant (LAC) and thrombotic events. Anti-PS/PT, anti-beta2GPI and anti-CL of IgA/G/M isotypes were quantified in parallel using particle-based multi-analyte technology. The 99th percentiles among 162 age- and sex-matched populations controls were used as cutoffs. *HLA-DRB1* typing was performed using sequence-specific primer PCR.

Results: Anti-PS/PT antibodies associated positively with *HLA-DRB1*13* (odds ratio [OR] 2.7, P=0.002), whereas anti-beta2GPI and anti-CL antibodies associated primarily with *HLA-DRB1*04* (OR 2.5, P=0.0005; Table 1). These associations remained after adjustment for other significant *HLA-DRB1* alleles identified in Table 1 (Figure 1a and b) also for LAC (Figure 1c), and also after adjustment for age and gender (not shown). *HLA-DRB1*13*, but not *DRB1*04*, remained as an independent risk factor for thrombosis after adjustment for significant HLA alleles (Figure 1d), and also after adjustment for cardiovascular risk factors in stepwise regression (not shown). Mediation analysis showed that 31.3% of the *HLA-DRB1*13*-related risk for thrombosis was mediated by anti-PS/PT positivity. *HLA-DRB1*03*, on the other hand, associated negatively with thrombotic events (Figure 1d) as well as with all aPL (Figure 1a-c). *HLA-DRB1*03* had thrombo-protective effect in aPL positive patients (Figure 1d). Additionally, *HLA-DRB1*03* positivity was associated with a favourable lipid profile regarding high-density lipoprotein (median 1.4 vs. 1.2 mmol/L, p=0.02) and triglycerides (median 0.9 vs 1.1 mmol/L, p=0.04); whereas no other *HLA-DRB1* alleles showed any associations to lipid levels.

Table 1. Frequency of individual HLA DRB1 and associations with antibody phenotypes. Odds ratios (OR) and confidence intervals (CI) for being antibody positive given a specific HLA allele and corresponding p values were calculated using Chi2 tests, with significant associations underlined.

HLA DRB1	*HLA-DRB1* n (%) total patients	Anti-PS/PT positive (any isotype) n=48	OR (95%CI); P	Anti-β_2GPI or anti-CL positive (any isotype) n=96	OR (95%CI); P
*01	41 (12.9%)	4 (8.3%)	0.6 (0.2-1.7); 0.3	11 (11.4%)	0.8 (0.4-1.7); 0.6

*04	94 (29.7%)	18 (37.5%)	1.6 (0.8-2.9); 0.2	41 (42.7%)	2.5 (1.5-4.1); 0.0005
*07	28 (8.9%)	6 (12.5%)	1.5 (0.6-4); 0.4	9 (9.4%)	1 (0.4-2.4); 0.9
*08	28 (8.9%)	6 (12.5%)	1.6 (0.6-4.3); 0.3	9 (9.4%)	1.2 (0.5-2.7); 0.7
*09	9 (2.8%)	1 (2.1%)	0.7 (0.1-5.5); 0.7	2 (2.1%)	0.6 (0.1-3.0); 0.5
*10	7 (2.2%)	0 (0)	NA	2 (2.1%)	0.9 (0.2-4.6); 0.9
*11	27 (8.5%)	6 (12.5%)	1.6 (0.6-4.3); 0.3	8 (8.3%)	0.9 (0.4-2.2); 0.8
*12	7 (2.2%)	0 (0)	NA	1 (1%)	0.4 (0.05-3.7); 0.4
*13	79 (25%)	21 (43.7%)	2.7 (1.4-5.2); 0.002	33 (34.3%)	2 (1.2-3.4%); 0.01
*14	6 (1.9%)	2 (4.2%)	3.7 (0.6-23); 0.1	2 (2.1%)	1.4 (0.2-8.9); 0.8
*15	118 (37.3%)	12 (48%)	0.5 (0.2-0.9); 0.045	27 (28.1%)	0.5 (0.3-0.9); 0.01
*16	8 (2.5%)	1 (2.1%)	0.8 (0.09-6.4); 0.8	4 (4.2%)	2.2 (0.5-9.2); 0.2

Conclusion: *HLA-DRB1*13* confers risk for both anti-PS/PT and thrombotic events in SLE. The association between *HLA-DRB1*13* and thrombosis is largely, but not entirely, mediated through anti-PS/PT. Due to the negative association of *HLA-DRB1*03* with aPL and the positive association with favourable lipid levels, *HLA-DRB1*03* seems to identify a subgroup of SLE patients with reduced vascular risk.

POS0748 COMPARISON BETWEEN PRIMARY SJÖGREN'S SYNDROME PATIENTS WITH AND WITHOUT DRYNESS

A. Kachaner[1], X. Mariette[2], F. Desmoulins[2], G. Nocturne[2], R. Seror[2]. [1]*Université de Paris, Internal Medicine, Paris, France;* [2]*Kremlin-Bicêtre, Rheumatology, Le Kremlin-Bicêtre, France*

Background: To date, no study has clinically focused on primary Sjögren's Syndrome (pSS) patients presenting without or with low level of dryness features.

Objectives: To describe pSS patients presenting no dryness or with low level of dryness and to compare them with pSS patients with dryness features to determine whether a specific clinical presentation can be identified in these patients.

Methods: All patients diagnosed with pSS according to AECG or ACR/EULAR criteria in our tertiary reference center were included. All patients were recruited between 1999 and 2020. Patient were considered without subjective dryness if the VAS for dry eyes or dry mouth was ≤ 30/100 and/or without objective dryness if having both normal Schirmer and salivary flow rate.

Results: Overall, 509 patients were included in the subjective dryness comparison group and 434 in the objective one (Table 1). Compared to patients with subjective dryness (n=456), patients without subjective dryness (n=53) were significantly younger (p=0,0025), were diagnosed earlier (p=0,0056), were more frequently anti-SSA positive (p=0,008), had lower levels of fatigue (p=0,0005). But no difference was observed regarding the level of disease activity or frequency of organ involvement. By contrast, patients reporting subjective dryness had more frequently chronic cough (p=0,022), with no more frequent objective lung involvement. Thus, the higher prevalence of chronic cough might be explained by dryness of the upper airways.

Table 1. Comparison of pSS patients with or without dryness

	No Subjective dryness n=53	Subjective dryness n=456	P value
Age, median (IQR)	49 (39-62)	58 (47-67)	0,0025**
Diagnostic delay, mean, years	4,32	6,27	0,0056**
ESSDAI, mean (SD)	3,55 (3,38)	3,22 (3,28)	0,52
MSGB# Chisolm score of 3 or 4, n (%)	36 (68)	362 (79)	0,08
Anti Ro/SSA, n (%)	44 (83)	292 (64)	0,008**
Chronic cough, n (%)	5 (9)	110 (24)	0,022*
VAS pain, median (IQR)	40 (4-70)	53 (23-77)	0,06
VAS fatigue, median (IQR)	47 (13-71)	65 (44-82)	0,0005***
	No Objective dryness n=108	Objective dryness n=326	
Age, median (IQR)	52 (41-60)	59 (47-67)	0,0026**
Diagnostic delay, mean, years	5,9	6,1	0,75
ESSDAI, mean (SD)	3,46	2,96	0,056
MSGB# Chisolm score of 3 or 4, n (%)	81 (75)	255 (78)	0,49
Anti Ro/SSA, n (%)	84 (78)	204 (62)	0,0042**
Arthralgia, n (%)	81 (75)	210 (64)	0,04*
VAS pain, median (IQR)	59,5 (32,5-80)	50 (20-73)	0,03*
VAS fatigue, median (IQR)	66 (44-83)	61 (39-80)	0,27
VAS eye dryness, median (IQR)	49 (17-71)	57 (25-80)	0,019*
VAS mouth dryness, median (IQR)	58 (34-75)	70 (48-88)	0,001**

MSGB: minor salivary gland biopsy

The patients without objective dryness (n=108) were also younger (p=0,0026), and had more frequently anti-SSA positive (p=0,0042). They also had a higher disease activity (mean ESSDAI: 3,46 versus 2,96, p=0,056). In this group of patients, the higher frequency of anti-SSA might be explained by the need of other criteria to fulfil diagnostic criteria, in the absence of abnormal Schirmer and salivary flow. Patients with objective dryness had more frequently arthralgia (p=0,04), a higher level of pain VAS (p=0,03) and subjective dryness VAS (p=0,019 for ocular and p=0,01 for oral) than patients without objective dryness.
Among the 108 patients with no objective dryness, only 17 had also had no subjective dryness (VAS <30mm).
P value corresponds to the comparison of the two strata with Student's t or Mann Whitney-U test
Conclusion: Among the patients with pSS, those without subjective or objective dryness features had a younger profile, shorter diagnosis delay which may result from a more acute onset, were more frequently anti-SSA positive. Those having no objective dryness also had more systemic disease, arthralgias and pain than patients with dryness features. Subjective dryness was associated with higher level of fatigue.

POS0749 ANTI-Β2GPI-DOMAIN 1 ANTIBODIES STRATIFY HIGH RISK OF EXTRA-CRITERIA MANIFESTATIONS IN A LARGE PROSPECTIVE CHINESE COHORT OF ANTIPHOSPHOLIPID SYNDROME

Y. Zhou[1], W. Qi[1], J. Zhao[1], M. Li[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Department of Rheumatology, Beijing, China*

Background: Anti-β2GPI-Domain 1 (β2GPI-D1) antibodies are potentially pathogenic in patients with antiphospholipid syndrome (APS), but their clinical associations and diagnostic value were unclear.
Objectives: To evaluate the clinical characteristics of APS patients with anti-β2GPI-D1 positivity, and its utility in diagnosing APS among SLE patients.
Methods: A total of 338 patients were included, of which 169 patients diagnosed with primary APS (PAPS group), 50 with APS secondary to SLE (SAPS group), 209 with SLE (SLE group). Serum anti-β2GPI-D1 IgG was measured using chemiluminescent immunoassay (Inova Company). Extra-criteria manifestations were analyzed, including thrombocytopenia, autoimmune hemolytic anemia, valvular lesions, APS nephropathy, and non-vascular neurological manifestations.
Results: Similar presence of anti-β2GPI-D1 IgG was seen among PAPS (32.80%) and SAPS (32.0%) patients, and 96.4% of those with positive anti-β2GPI-D1 IgG showed triple aPLs positivity. Anti-β2GPI-D1 IgG was significantly associated with recurrent thrombosis before APS diagnosis, microscopic thrombosis (p<0.05), but not with adverse pregnancy events (Figure 1). Notably, patients with extra-criteria manifestations, especially thrombocytopenia and APS nephropathy, showed significantly higher titers in anti-β2GPI-D1 IgG (p<0.05). After a median follow-up of twenty-five months, patients with anti-β2GPI-D1 IgG also showed a tendency of more extra-criteria events (3/55 vs 1/114, p=0.095), but not thrombotic events or adverse pregnancy events. Anti-β2GPI-D1 was positive among 8.13% of the SLE controls, and showed higher specificity (91.9%) in diagnosing SAPS among SLE patients as compared to classic aPLs.

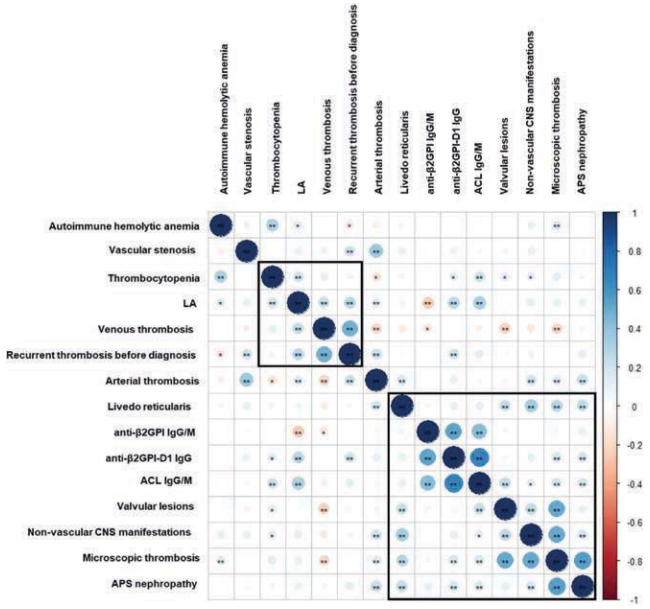

Figure 1.

Conclusion: Anti-β2GPI-D1 IgG had a stronger association with extra-criteria manifestations in APS patients compared to three classic APLs, which properly indicated its pathogenic role of microangiopathy.

SLE: systemic lupus erythematosus. [a]Evidence level (EL) of each study was based on Oxford Center for Evidence-Based Medicine 2011. [b]Quality (Q) of each study was based on the Newcastle-Ottawa Quality Assessment Scale case.

Second Hospital of Shanxi Medical University,Taiyuan, China; [2]Academy of Microbial Ecology, Shanxi Medical University,Taiyuan, China; [3]Key laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education,Taiyuan, China

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease which involves in multiple tissue and organ injury. Regulatory B cells (Bregs) are unique subpopulations of B cells with immune-regulating properties. Interestingly, different subsets of Bregs have distinct markers and phenotypes and participate in self immune regulation by different ways. However, the level of Bregs in SLE remains debated.
Objectives: This study aims to clarify the proportions of Bregs with special controversial cellular markers and Breg-related cytokines in SLE patients.
Methods: We explored the proportion of Bregs and Breg-related cytokines (IL-10) in SLE patients by searching literature through November 2021 from CBM, CNKI, China Science and Technology Journal Database, Wan Fang Data, PubMed, Embase, Web of Science, Cochrane Library and Medline. Random effects model was used to pool data. Heterogeneity and risk of bias was examined with I-squared index (I^2) statistic. Inconsistency was evaluated by using the I^2 and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).
Results: Total 14 case-control studies involving 489 PsA patients and 330 healthy controls (HCs) were included in this study (Table 1). No significant difference in the proportions of Bregs was evident between SLE patients and HCs [SMD=0.067, 95%CI (-0.924,1.059), P=0.894]. Because of a significant statistical heterogeneity observed [I^2=97.1%, p<0.001], we conducted sub-analyses based on individual definitions of Bregs. We found the proportions of $CD19^+CD24^{hi}CD38^{hi}$ Breg cells was significantly increased in SLE [SMD=0.902, 95%CI (0.157,1.647), P<0.001](Figure 1A). The level of serum IL-10 was increased in SLE compared to that of HCs [SMD=1.062, 95%CI (0.754,1.370), P<0.001] with no publication bias based on the Egger tests (t=0.91, P=0.366)(Figure 1B).

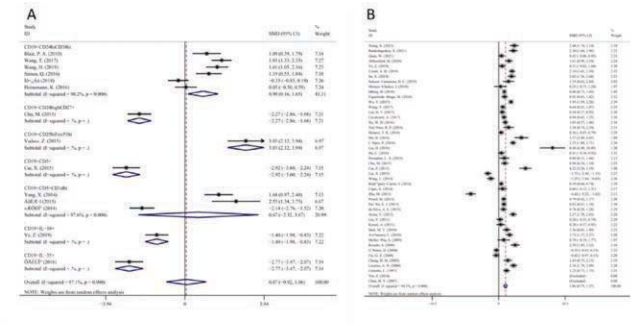

Figure 1: (A)Forest plot of the subgroup meta-analysis of individual definitions of peripheral Bregs proportions, between SLE and HCs. (B) Forrest plot of the levels of serum IL-10 between SLE and HCs.SLE, systemic lupus erythematosus; HCs, healthy controls.

Figure 1.

Conclusion: The levels of $CD19^+CD24^{hi}CD38^{hi}$ Bregs and IL-10 were significantly increased in SLE patients, suggesting that the abnormalities of Bregs numbers and function are the critical causes in the development of SLE.

POS0751 TEMPORAL TREND IN HOSPITALISATION FOR OPPORTUNISTIC INFECTIONS IN PATIENTS WITH CONNECTIVE TISSUE DISEASES.

J. Nossent[1,2], H. Keen[1,3], D. Preen[4], C. Inderjeeth[1,2]. *[1]The University of Western Australia, Medical School, Crawley, Australia; [2]Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia; [3]Fiona Stanley Hospital, Rheumatology, Murdoch, Australia; [4]The University of Western Australia, School Population and Global Health, Perth, Australia*

Background: Patients with autoimmune connective tissue disease (CTD) and systemic vasculitis (SV) often require aggressive immune-modulating therapy to prevent organ damage. This however increases the risk for common and uncommon infections.
Objectives: To compare the temporal rates and associated mortality of hospitalisation with opportunistic infections (OI) for CTD and SV patients in Western Australia between 1985 and 2015.
Methods: All patients hospitalized in Western Australia in the period 1985-2015 with ≥ 2 ICD based diagnostic codes for SLE (n=1432), other CTD (o-CTD; incl DM/PM, systemic sclerosis, Sjogren's syndrome; n=2161) and Systemic vasculitis (SV; n=1599) and a microbiologically confirmed OI (Mycobacterial, Fungal and viral infections) were included. Descriptive data are given as median (IQR) and frequency (%). Incidence rates per 1000 person years (IR) were calculated during 100.410 person years.
Results: OI occurred in 12.4 % of lupus, 11.5% of SV and 10.4% of o-CTD patients (p=0.72), but overall IR rates for OI were higher for lupus patients (9.87, CI 5 .49-15.76) than for SV (5.94, CI-2.81-10.24) and o-CTD patients (3.40, CI 1.62-7.23). However, whereas the IR for OI in lupus decreased over time, the IR increased for SV and o-CTD patients (Figure 1). Viral infections were the most frequent specific OI followed by tuberculosis and mycotic infections. Cryptococcal infections were observed in lupus patients only and the limited cases of pneumocystis occurred predominantly in SV patients with no cases observed after 2000 (Figure 2). In hospital mortality during OI admission was 11.5% for SV, 5.6 % for lupus and 3.5% for o-CTD patients (p=0.004).

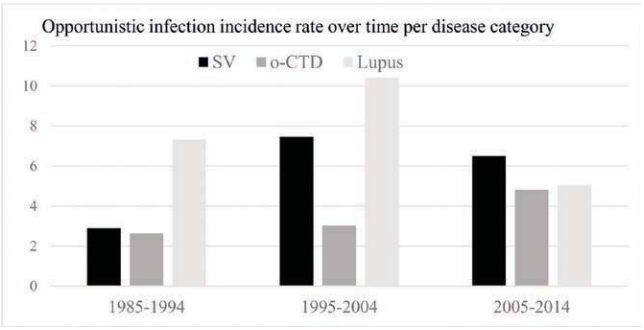

Figure 1.

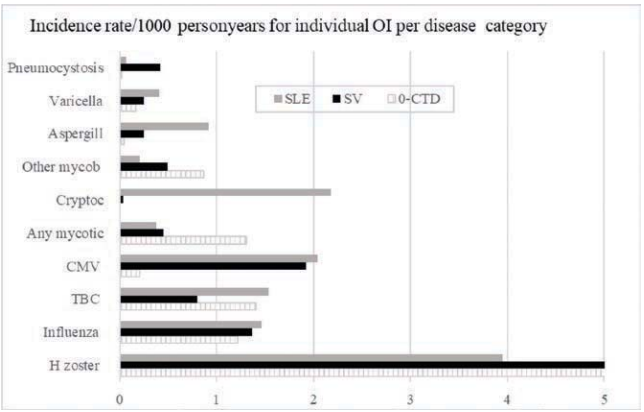

Figure 2.

Conclusion: Hospitalization rates for OI have decreased for lupus patients especially since 2005, whereas viral and mycotic OI rates have increased for both SV and o-CTD patients. Hospitalization for OI associated with significant case fatality in especially SV patients, indicating a need for increased prevention of OI.

POS0752 DISEASE FEATURES AT DIAGNOSIS AND CHANGES IN DISEASE COURSE SEVERITY AMONG PATIENTS WITH CHILDHOOD-ONSET COMPARED TO ADULT-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

A. Phillips-Beyer[1], Q. Li[2], M. E. Stokes[2], M. Pozzobon Da Silva[3]. *[1]Innovus Consulting Limited, London, United Kingdom; [2]Evidera, Waltham, United States of America; [3]Therapeutic Area Units, Idorsia Pharmaceuticals, Allschwil, Switzerland*

Background: Systemic lupus erythematosus (SLE) is characterised by a heterogeneous clinical presentation with alternating periods of remission and relapse. Disease severity is determined by the type and level of involvement of different organ systems. SLE can occur in childhood or later in life, and patients may present with differing levels of disease severity according to the age of onset. Changes in disease severity following treatment may also differ depending on age of onset. There are limited data that document these differences.
Objectives: To compare demographic and clinical characteristics including baseline disease severity and changes in severity over time between patients with childhood-onset and adult-onset SLE in the United States.
Methods: We identified patients aged 0–64 years and diagnosed with SLE during 2015–2019 using the IBM MarketScan claims databases. SLE severity was determined using a published algorithm, which combines elements of organ involvement and the use of SLE-related medications to assign patients to mild, moderate, and severe disease states.[1] Baseline disease severity was determined using a 90-day period following the initial SLE diagnosis. The index date was the day after this initial 90-day period. Baseline comoribidities were assessed during the 12 months prior to the index date. Disease severity was evaluated at 0 to <6 months, ≥6 to <12 months, and ≥12 to <24 months post-index. Patients were categorised according to the highest severity level identified during each period. Changes in severity vs. baseline were also measured during each evaluation period. For example, worsening severity was defined as a transition from a lower to higher disease severity state (e.g., moderate to severe). Analyses were conducted separately for cohorts with Commercial Health Insurance (CHI) and Medicaid. Within each cohort, patients with childhood-onset (≤17 years) were descriptively compared to those with adult-onset (≥18 years) SLE.
Results: Most enrolees were female (CHI: 90%, Medicaid: 92%). Mean age at index date was 14.0 vs. 43.4 years for childhood- and adult-onset groups, respectively. Baseline infections were more prevalent among children vs. adults in both CHI (41.4% vs. 30.1%) and Medicaid (45.3% vs. 39.3%) cohorts (Table 1). A higher proportion of children vs. adults had severe disease at baseline in the CHI (38.3% vs. 10.7%) and Medicaid (48.0% vs. 14.2%) cohorts. Overall, the largest decreases in SLE severity compared to baseline were observed during ≥6 to <12 months of follow-up. Children were more likely to experience a decrease in severity than adults. During ≥12 to <24 months, 19.9% of children in the Medicaid cohort had an increase in severity compared to baseline vs. only 12.3% of children in the CHI cohort.

Table 1. Profiles of patients with SLE

Characteristic %	Commercial Health Plan		Medicaid	
	0–17 years	18–64 years	0–17 years	18–64 years
	(N=290)	(N=10,622)	(N=298)	(N=3,143)
Age in years at index date, mean (SD)	14.2 (2.7)	44.6 (12.0)	13.7 (3.1)	39.2 (11.9)
Median (range)	15.0 (1–17)	48.0 (18–64)	15.0 (2–17)	39.0 (18–64)
Female	86.7%	90.1%	83.9%	93.1%
Baseline treatment				
Corticosteroids	77.6%	69.3%	84.6%	69.7%
Immunomodulators	42.4%	23.2%	55.0%	19.4%
Antimalarials	71.7%	60.5%	80.2%	49.1%
SLE severity change from baseline				
0–<6 months follow-up				
Increase	10.9%	20%	7.5%	21.7%
Decrease	20.9%	17.2%	25.9%	18.8%
≥6–<12 months follow-up				
Increase	11.6%	20.4%	9.2%	22.8%
Decrease	36.7%	19.9%	39.5%	22.7%
≥12–<24 months follow-up				
Increase	12.3%	30.1%	19.9%	33.2%
Decrease	33.3%	15.6%	38.0%	17.8%

SD, standard deviation.

Conclusion: Children with SLE present with greater severity of symptoms compared to adults and are more likely to experience an improvement following the initial treatment period.

POS0753 PROSPECTIVE EVALUATION OF HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN A MONOCENTRIC COHORT OF PATIENTS WITH LONGSTANDING SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

E. Elefante[1], C. Tani[1], V. Signorini[1], C. Stagnaro[1], D. Zucchi[1], F. Trentin[1], L. Carli[1], F. Ferro[1], M. Mosca[1]. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: The optimization of HRQoL in SLE patients is defined as one of the treatment goals in the 2019 EULAR recommendations[1] for the management of SLE. Most studies have examined HRQoL at one point in time, while the few longitudinal studies do not report a clear variation in Patient Reported Outcomes (PROs) with respect to changes in disease activity. It would be important to understand if, even in a real-life setting, the improvement of patients' HRQoL may represent an achievable target.
Objectives: the aim of this study was to analyze HRQoL over time in a monocentric cohort of patients with SLE and investigate which disease-related factors determine short-term variation of HRQoL in a real-life setting.
Methods: this is a longitudinal, prospective monocentric study which included consecutive adult outpatients with SLE (1997 ACR classification criteria), regularly followed at the Rheumatology Unit of Pisa. Patients were enrolled over a period of 2 years, before the pandemic outbreak, and had at least 2 assessments per year. For each patient, demographics, comorbidities, treatment, clinical and laboratory data were collected. Disease activity was evaluated with the SELENA-SLEDAI and organ damage with the SLICC/DI. We defined as a significant variation of disease activity, a difference of clinical SELENA-SLEDAI ≥ 4 points between 2 subsequent evaluations. At each visit, patients completed the following PROs: SF-36, FACIT-Fatigue and LIT.
Results: we enrolled 210 consecutive SLE patients, mainly female (93.8%) and of Caucasian ethnicity (97.1%), with a mean age at enrollment of 45.1±12.7 years and a median disease duration of 13 years (IQR 5-21). At baseline, the median SLEDAI of the cohort was 2 (IQR 0-4). The most frequent active disease manifestations were: articular (17.1%) and hematological (15.2%); 6.7% of patients had active renal disease. 47.14% had a SLICC-DI > 0 with a median SLICC-DI among them of 2 (IQR 1-3). 11.43% of patients had a concomitant fibromyalgia. Most patients were on Hydroxychloroquine (78.1%) and low dose glucocorticoid (55.2%), with a median daily dose of 2 mg (IQR 0-4) of prednisone equivalent; 41.4% were on conventional immunosuppressants and 11.9% on biologics, mainly belimumab. The median scores of PROs at enrollment are reported in Table 1. At baseline, fibromyalgia confirmed to have a significant negative impact on all PROs after adjustment for confounding factors (p<0.05). Each patient underwent two consecutive evaluations, with a median interval between them of 11.4 months. We observed a significant variation of disease activity in 36/210 patients (17.14%). Then, we compared the subgroup of patients with unchanged disease activity with that of patients who showed a significant variation of disease activity. We found that FACIT and LIT scores didn't change over time in both subgroups, whereas PCS (p<0.001) and MCS (p<0.01) scores of the SF-36 showed a significant variation in both groups, between the first and the second clinical assessment. However, in the subgroup of patients with a significant change of disease activity, the variation of PCS and MCS was not correlated with the variation of disease activity or ongoing treatment. In particular, patients with a significant improvement of HRQoL over time didn't have a corresponding significant reduction of the SLEDAI score or of the daily glucocorticoid dose.

Table 1. PROs scores at baseline.

PROs	Median scores at baseline
SF-36 PCS	58 (IQR 49.09- 68)
SF-36 MCS	57 (IQR 46.42-67)
FACIT	42 (IQR 32-46)
LIT	20 (IQR 7.5-40)

Conclusion: our findings seem to suggest that HRQoL over time in outpatients with longstanding SLE tends to be stable (maybe because patients are able to adapt to their illness) or varies unpredictably, maybe influenced by not disease-related factors. Further studies are needed to better understand which factors influence HRQoL over time and which questionnaires are more sensitive to catch its variation.

POS0754 PATIENT ACCEPTABLE SYMPTOM STATE (PASS) IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME IN DAILY CLINICAL PRACTICE

L. De Wolff[1], S. Arends[1], E. Mossel[1], G. S. Van Zuiden[1], J. F. Van Nimwegen[1], L. Olie[2], A. J. Stel[1], K. Delli[3], G. M. Verstappen[1], F. G. M. Kroese[1], A. Vissink[3], H. Bootsma[1]. *[1]University of Groningen, University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University of Groningen, University Medical Centre Groningen, Ophthalmology, Groningen, Netherlands; [3]University of Groningen, University Medical Centre Groningen, Oral and Maxillofacial Surgery, Groningen, Netherlands*

Background: Primary Sjögren's syndrome (pSS) has great impact on all aspects of patients' lives, not only physically, but also mentally, socially and financially.[1] Sicca symptoms are mainly treated with local treatment, but no systemic immunosuppressive treatment is registered yet for pSS, which may have significant consequences on whether patients find their symptom state acceptable (PASS). In a previous study, a cut-off for acceptable symptom state based on the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI, score <5) was developed for inclusion of patients with an unacceptable symptom state in clinical trials.[2]

Objectives: To explore the presence of PASS in a standard of care cohort of pSS patients and to compare patient characteristics and disease activity including ESSPRI between patients with and without PASS.

Methods: Consecutive outpatients with pSS from the REgistry of Sjögren Syndrome LongiTudinal (RESULT) cohort, who fulfilled the ACR/EULAR classification criteria and had available PASS data at baseline were included. Patient-reported outcomes were reported through questionnaires, which included the PASS ("Considering all the different ways your disease is affecting you, if you were to stay in this state for the next few months, do you consider your current state satisfactory?"; yes/no) and ESSPRI ("How severe has your dryness, fatigue and pain been during the last two weeks?"; scale 0-10). An acceptable ESSPRI symptom state has been defined as <5.[2] Systemic disease activity was assessed with EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI). Independent samples t-test, Mann-Whitney U test or Chi Square test were used to analyse differences between patients with or without PASS.

Results: Of 277 included pSS patients, 248 (90%) were female, median age was 54 years (IQR 43-64) and disease duration 5 years (2-11). 198 (71%) patients scored their symptom state as acceptable according to PASS. Patients with PASS were significantly older and had a longer disease duration compared to patients without PASS. Furthermore, patients with PASS had more often a low disease activity according to ESSDAI, and less often moderate disease activity (Table 1). The difference in ESSDAI activity was mainly observed in the articular and constitutional domains. ESSPRI was significantly lower in patients with PASS (median 5 vs. 7). No differences were seen in functional or laboratory parameters (Table 1). Of all included patients, only 86 (31%) patients had an acceptable symptom state according to the pre-defined cut-off point for ESSPRI (score <5). Sensitivity and specificity of this ESSPRI cut-off point for reaching PASS was 40% and 92%, respectively.

Table 1. Baseline characteristics of pSS patients with and without PASS

	PASS (n=198)	Without PASS (n=79)
Gender (female)	177 (89)	71 (90)
Age (years)	57 (44-65)*	49 (41-60)*
Disease duration (years)	6 (2-12)*	5 (2-8)*
ESSDAI (total)	4 (2-6) (n=191)	4 (2-9) (n=75)
<5	127 (66)*	38 (51)*
5-14	52 (27)*	32 (43)*
≥14	12 (6)	5 (7)
ESSPRI (total)	5 (4-7)**	7 (6-8)**
<5	80 (40)**	6 (8)**
Schirmer's test (mm)	4 (1-10) (n=179)	4 (1-10) (n=72)
Ocular staining score	2 (1-4) (n=190)	2 (0-4) (n=77)
Unstimulated whole salivary flow (ml/min)	0.05 (0.01-0.14) (n=187)	0.08 (0.01-0.19) (n=76)
Stimulated whole salivary flow (ml/min)	0.54 (0.15-0.99) (n=189)	0.58 (0.21-0.97) (n=76)
SSA positive	172/197 (87)	66/79 (84)
IgG (g/L)	14 (11-19) (n=196)	14 (10-19) (n=79)
Rheumatoid factor (IU/ml)	12 (3-39) (n=196)	16 (2-47) (n=78)

Data presented as median (IQR) or n (%)*Significant difference p<0.05***Significant difference p<0.001

Conclusion: The majority (71%) of pSS patients reported being in an acceptable symptom state according to the PASS question in our standard of care cohort in daily clinical practice, despite high ESSPRI scores (60% with score ≥5). Further analyses of influences of treatment in these patients will be conducted.

POS0755 SAFETY, TOLERABILITY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF A SINGLE ORALLY ADMINISTERED DOSE OF ENPATORAN IN A PHASE I STUDY OF HEALTHY JAPANESE AND CAUCASIAN PARTICIPANTS

S. Gopalakrishnan[1], A. Krebs-Brown[2], M. Nogueira Filho[1], Y. Kuroki[3], A. Bachmann[1], A. Becker[4], F. Schippers[5], M. Fluck[1], Ö. Yalkinoglu[1], L. Klopp-Schulze[1]. *[1]Merck Healthcare KGaA, Translational Medicine, Darmstadt, Germany; [2]Merck Healthcare KGaA, Global Biostatistics, Darmstadt, Germany; [3]Merck Biopharma Co. Ltd., an affiliate of Merck KGaA, Translational Medicine, Tokyo, Japan; [4]Merck Healthcare KGaA, Global Clinical Development, Darmstadt, Germany; [5]Merck Healthcare KGaA, Global Patient Safety, Darmstadt, Germany*

Background: Enpatoran, a novel, highly selective and potent dual toll-like receptor (TLR) 7 and TLR8 inhibitor, is in development for the treatment of autoimmune disorders including systemic and cutaneous lupus erythematosus. A first-in-human study in healthy participants has shown that enpatoran is well-tolerated and has a linear pharmacokinetic (PK) profile.

Objectives: To compare the PK parameters, safety, and tolerability of single ascending oral doses of enpatoran in a Phase I study in Japanese and Caucasian participants, and to explore a potential PK/pharmacodynamic (PD) relationship.

Methods: A single-centre, open-label, sequential dose group study enrolled healthy Japanese and Caucasian participants into three dose cohorts. Each Caucasian participant was matched by body weight (± 20%), height (± 15%) and sex to a Japanese participant. Participants received a single orally administered enpatoran dose of 100 mg, 200 mg, or 300 mg as a film-coated tablet under fasting conditions. PK parameters, (maximum plasma concentration [C_{max}]; area under the plasma concentration–time curve (AUC) from time 0 to infinity [$AUC_{0\text{-inf}}$]; AUC from time 0 to the last sampling time [$AUC_{0\text{-tlast}}$]) determined using noncompartmental analysis, were estimated post-dose from Day 1–3. Safety was assessed from Day -1 to 8. PK (exposure) between the two ethnic groups was compared using an analysis of covariance (ANCOVA) model including ethnic group, natural log-transformed dose, and ethnic group by natural log dose interaction. *Ex vivo* secretion of cytokines (PD) under stimulated (using the TLR7/8 agonist, R848) and unstimulated conditions, was assessed pre- and post-dose. A panel of cytokines was analysed by multiplex immunoassay; IL-6 was considered the primary PD biomarker.

Results: The study included 36 male participants (18 Japanese and 18 Caucasian) with a mean (± SD) age of 35.1 (± 10.8) years and mean (± SD) body mass index of 23.1 (± 2.1) kg/m^2. Each dose group included six Japanese and six Caucasian participants. The geometric mean enpatoran plasma exposure parameters (C_{max}, $AUC_{0\text{-inf}}$, and $AUC_{0\text{-tlast}}$) were consistent between the two ethnic groups for each dose level (Table 1) and indicated dose proportionality. ANCOVA modeling demonstrated comparable exposure between the two groups (geometric least square mean ratio [Japanese/Caucasian;90% CI] of C_{max}: 0.9409 [0.7855–1.1270]; $AUC_{0\text{-inf}}$: 0.8959 [0.7497–1.0704] and $AUC_{0\text{-tlast}}$: 0.8963 [0.7511–1.0695]). Treatment-emergent adverse events (TEAEs) were observed in six Japanese (n = 0, 100 mg; n = 3, 200 mg; n = 3, 300 mg) and four Caucasian (n = 1, 100 mg; n = 0, 200 mg; n = 3, 300 mg) participants. There we no serious TEAEs; most were mild and not dose dependent. Treatment-related TEAEs were mild diarrhoea, mild flatulence, and moderate headache. There were no deaths, withdrawals, or early terminations due to TEAEs. Administering enpatoran effectively reduced *ex vivo* stimulated cytokine

release, with maximal inhibition observed at 2 hours post-dose (IL-6: mean ≥99%). High inhibition levels were sustained through 24 hours in a dose-dependent manner (IL-6: mean ~76–97%). The pattern of cytokine release inhibition was consistent across doses and ethnic groups.

Table 1. PK parameters in Japanese and Caucasian participants at the three enpatoran dose levels

Parameter	100 mg		200 mg		300 mg	
	Japanese	Caucasian	Japanese	Caucasian	Japanese	Caucasian
	N = 6	N = 6	N = 6	N = 6	N = 6	N = 6
C_{max} (ng/mL)	139	175	260	245	486	490
$AUC_{0\text{-inf}}$ (h*ng/mL)	774	948	1910	1850	2840	3330
$AUC_{0\text{-tlast}}$ (h*ng/mL)	758	931	1880	1830	2810	3270

All values are Geometric mean.C_{max}, maximum plasma concentration $AUC_{0\text{-inf}}$, area under the plasma concentration–time curve (AUC) from time 0 to infinity; $AUC_{0\text{-tlast}}$, AUC from time 0 to the last sampling time.

Conclusion: There were no relevant ethnic differences in PK, PD, and safety between healthy Japanese and Caucasian participants across a range of single oral enpatoran doses, thus supporting the inclusion of Asian participants in future global Phase II studies.

POS0756 DETERMINANTS OF HEALTH-RELATED QUALITY OF LIFE (HR-QOL) ACROSS THE SPECTRUM OF SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES: RESULTS FROM THE LEAP COHORT

S. Dyball[1], J. Reynolds[2,3], A. Herrick[1,4,5], H. Chinoy[1,4,5], S. Haque[6], S. Naz[7], E. Bruce[8], I. N. Bruce[1,5,8], B. Parker[5,8]. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [2]University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, College of Medical and Dental Sciences, Birmingham, United Kingdom; [3]Sandwell and West Birmingham NHS Foundation Trust, Rheumatology Department, Birmingham, United Kingdom; [4]Salford Royal NHS Foundation Trust, Department of Rheumatology, Manchester, United Kingdom; [5]NIHR Biomedical Research Centre Manchester,The University of Manchester, Manchester, United Kingdom; [6]Manchester University NHS FT, Department of Rheumatology, Manchester, United Kingdom; [7]Pennine Acute Hospitals NHS Trust, Department of Rheumatology, Manchester, United Kingdom; [8]Manchester University NHS FT,The Kellgren Centre of Rheumatology, Manchester, United Kingdom*

Background: Poor health-related quality of life (HR-QoL) is recognised in patients with established connective tissue diseases (CTDs), however it is not clear how it affects patients with undifferentiated CTD (UCTD) which has traditionally been associated with a mild or more benign profile.

Objectives: To investigate HR-QoL in patients affected with a variety of CTDs (including UCTD) using the SF-36 questionnaire; and secondly, to review demographic and clinical factors predictive of a poor HR-QoL

Methods: The Lupus Extended Autoimmune Phenotype (LEAP) cohort is a multicentre prospective study of patients with a CTD. Rheumatologist diagnosis was used to classify patients into four groups: systemic lupus erythematosus (SLE), primary Sjögren's syndrome (pSS), UCTD, and (combined because of low numbers) those with an idiopathic inflammatory myopathy (IIM), systemic sclerosis (SSc) or overlap syndrome. The SF-36 quality of life questionnaire was completed at enrolment and includes eight domains: physical function (PF), role physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH) which range from 0 to 100, with higher scores reflecting better HR-QoL. Physical (PCS) and mental component score (MCS) were calculated for each group, with a score below 50 representing a worse HR-QoL compared to the general UK population. Predictors for poor HR-QoL was chosen a priori, then tested using linear regression adjusted for age, gender and ethnicity. All statistical analysis was performed using STATA v14, with results expressed as beta coefficients with 95% confidence intervals (95%CI).

Results: Data were collected from 309 patients (280 [90.6%] women, with a mean [SD] age of 48.9 [12.9] years) from three UK rheumatology centres. The majority of patients were Caucasian (n=235, 76.1%). By rheumatologist diagnosis, 115 (37.2%) had SLE, 56 (18.1%) pSS, 72 (23.3%) UCTD and 66 (21.4%) SSc, IIM or an overlap syndrome. Patients with UCTD, pSS and SSc/IIM spectrum disorders had a shorter median disease duration (3.8, 3.7 and 6.1 years respectively) compared with patients with those with SLE (11.0 years), p<0.001. Previous steroid and immunosuppressant use was highest in patients with SLE and SSc/IIM spectrum disorders (p<0.001). The most affected domains include VT, GH and BP (Figure 1), and the PCS is more impaired compared with the MCS, with similar scores across disease groups. Agnostic of disease group, factors associated with a lower PCS include increasing age (beta -0.15 [95%CI -0.26, -0.06], p=0.008), prednisolone use (-3.1 [-6.05, -0.19], p=0.037), c-reactive protein (-0.09 [-0.62, -0.10], p=0.007), fatigue (-2.00 [-3.79, -0.22], p=0.028), and sicca syndrome (-4.70 [-7.66, -1.74] p=0.002), and these remained significant in a multivariate model.

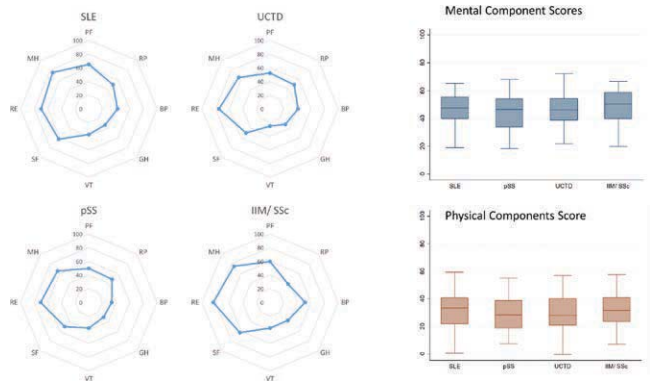

Figure 1. radar diagrams of eight SF-36 domains, and MCS and PCS boxplots. SLE; systemic lupus erythematosus; UCTD, undifferentiated CTD; pSS, primary Sjögren's syndrome; IIM, idiopathic inflammatory myopathy; SSc, systemic sclerosis; PF, physical function; RP, role physical; BP, bodily pain; GH, general health; VT, vitality; SF, social functioning; RE, role emotional; MH, mental health

Conclusion: Patients with UCTD exhibit similar impairment in physical components of HR-QoL compared with other established CTDs, despite perceived differences in disease severity. This study highlights sicca syndrome, fatigue, and steroid burden as key targets for improving HR-QoL in patients across the spectrum of CTDs.

POS0757

COVID-19 INFECTION AND RECOVERY AMONGST PATIENTS WITH MODERATE-TO-SEVERE LUPUS DURING THE PANDEMIC: RESULTS FROM THE BILAG-BIOLOGICS REGISTER (BILAG-BR)

S. Dyball[1], M. Rodziewicz[1], E. Sutton[1], B. Parker[2,3], I. N. Bruce[1,2,3]on behalf of BILAG-BR. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [2]NIHR Manchester Biomedical Research Unit, Centre for Musculoskeletal Research, Manchester, United Kingdom; [3]Manchester University Hospital, The Kellgren Centre for Rheumatology, Manchester, United Kingdom*

Background: Patients with systemic lupus erythematosus (SLE) are thought to be at greater risk of severe COVID-19 illness and associated complications due to a combination of inherent aberrant immune responses, immunosuppressive medications and co-morbidities.
Objectives: To review COVID-19 infections, hospitalisation and recovery in a real-world cohort of patients with moderate to severe SLE and high immunosuppressant use.
Methods: The British Isles Lupus Assessment Group Biologics Registry (BILAG-BR) is a national prospective registry of lupus patients from the UK (2010-21) requiring significant immunosuppressive therapies. Patients from the BILAG-BR were invited to complete a paper or online questionnaire which consisted of 17 questions to assess prior COVID-19 infection and their recovery during the COVID-19 pandemic. Questionnaires were completed between 9th Oct 2021 and 7th Jan 2022. Responses were linked with data collected in the BILAG-BR. Mortality data were collected from study centres and the Office of National Statistics from Dec 2019-Jan 2022.
Results: Data were collected from the first 202/1268 patients to respond. Patients were predominately female (186, 92.1%), had a median age of 51 (IQR 38-61) years and were from 37 UK centres. Previous therapy included rituximab (165, 81.7%), belimumab (33, 16.3%) and cyclophosphamide (54, 26.7%). In the past 12 months, over two thirds of patients (138, 68.3%) had received oral prednisolone (current median dose 5mg [IQR 5-8mg] daily), and almost a third had received parental steroids (60, 29.7%). Self-reported COVID-19 diagnosis occurred in 48 (23.8%) patients, of whom 20 reported a positive test. Eleven (55%) patients reported testing positive for COVID-19 after being vaccinated. Median reported recovery was 80% (IQR 60-100%), with subjective full recovery reported in 30% of patients (6/20) who had received a positive test. Of the 20 patients who tested positive for COVID-19, 5 were receiving belimumab, 1 tocilizumab, and in the prior 12 months, 2 had received cyclophosphamide and 4 rituximab. Of all respondents, three individuals were hospitalised with COVID-19, and one required an ICU admission. Of those hospitalised, two patients were unvaccinated prior to COVID-19 infection, and the other patient had received rituximab and cyclophosphamide prior to vaccination. Four/1387 patients registered in the BILAG-BR were confirmed to have died from COVID-19 since the beginning of the pandemic.
Conclusion: In this cohort of moderate-to-severe SLE patients there was a low incidence of COVID-19 infection. Despite this, full recovery from PCR or lateral flow test proven COVID-19 infection was seen in only a third of patients. This raises concerns over the potential risk of long COVID in patients with SLE and warrants further investigation.

POS0758

REDUCED CENTRAL NERVOUS SYSTEM DRIVE IN PRIMARY SJÖGREN'S SYNDROME IS ASSOCIATED WITH OBJECTIVE DECLINE IN MOTOR PERFORMANCE AND SELF-REPORTED FATIGUE

R. Prak[1], S. Arends[2], G. M. Verstappen[2], G. S. Van Zuiden[2], F. G. M. Kroese[2], H. Bootsma[2], I. Zijdewind[1]. *[1]University Medical Center Groningen, University of Groningen, Biomedical Sciences of Cells and Systems, Groningen, Netherlands; [2]University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Fatigue is a major complaint in primary Sjögren's syndrome (pSS). The importance of fatigue in pSS is demonstrated by its inclusion as one of the three domains of the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) as well as being the primary outcome measure of a large clinical trial.[1] To date, there is no effective treatment for fatigue and more fundamental studies are needed to identify potential targets for therapy. In a conceptual framework, fatigue is defined as a self-reported symptom derived from two attributes: performance fatigability and perceived fatigability (Figure 1).

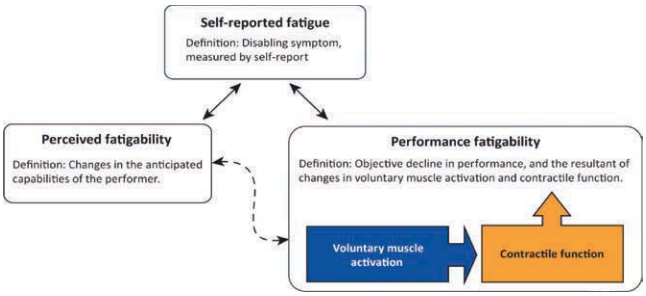

Figure 1. Conceptual framework (adapted from Enoka)[2]

Objectives: To acquire a better understanding of fatigue in pSS, we investigated objective measures of performance decline and evaluated the relation of self-reported fatigue with performance fatigability and factors modulating perceptions of fatigability.
Methods: 39 pSS patients and 27 healthy controls were included. To assess performance fatigability, force decline was measured during a sustained (124s) maximal voluntary contraction (MVC) with the index finger abductor muscle, and voluntary muscle activation was indexed using peripheral nerve stimulation superimposed on maximal voluntary contractions. Self-reported fatigue was quantified using the Fatigue Severity Scale (FSS) and Modified Fatigue Impact Scale (MFIS). Pain, depression, and anxiety were assessed using questionnaires and serological inflammatory markers were measured in serum as factors relating to perceived fatigability.
Results: Self-reported fatigue was significantly higher in pSS than controls (FSS: 4.8 vs. 2.3, $p<0.001$); 67% of patients and no controls reported significant fatigue (FSS>4). Mean voluntary muscle activation was reduced in pSS compared to controls (81.5% vs. 87.8%, $p=0.030$). Force decline during the sustained MVC did not differ between groups (60.6% vs. 63.1%, $p=0.246$). MFIS physical was positively associated with symptoms (ESSPRI pain: $\rho=0.51$, HADS depression: $\rho=0.45$ and HADS anxiety: $\rho=0.29$) and negatively associated with serological inflammatory markers (MxA: $\rho=-0.49$ and CXCL10: $\rho=-0.37$). Multivariable linear regression showed that force decline, pain and depression were associated with the MFIS physical domain in pSS (total explained variance of 47%). The inclusion of serological inflammatory markers did not help to explain more variance in this model.
Conclusion: This study demonstrates that performance fatigability in pSS was compromised by a reduced capacity of the central nervous system to drive the muscle. Furthermore, self-reported fatigue is a multifactorial symptom associated with both performance fatigability and perceived fatigability in patients with pSS.

POS0759

DOES LLDAS DEFINITION MATCH THE RHEUMATOLOGIST OPINION? THE FIRST VISIT EVALUATION OF A LONGITUDINAL SPANISH MULTICENTER STUDY TO ASSESS REASONS OF DISAGREEMENT.

I. Altabás González[1,2], I. Rua-Figueroa[3], N. Jiménez[2], F. Rubiño[3], C. Mouriño Rodríguez[1,2], I. Hernández[1], R. Menor-Almagro[4], E. Uriarte Isacelaya[5], E. Tomero Muriel[6], T. C. Pego-Reigosa[1,2]. *[1]Complejo Hospitalario Universitario de Vigo, Rheumatology, Vigo, Spain; [2]IRIDIS (Investigation in Rheumatology and Immune-Mediated Diseases) Group, Rheumatology, Vigo, Spain; [3]Hospital Universitario de Gran Canaria Dr. Negrín, Rheumatology,*

Las Palmas de Gran Canaria, Spain; [4]Hospital Universitario De Jerez, Rheumatology, Jerez de la Frontera, Spain; [5]Donostia Unibertsitate Ospitalea, Rheumatology, Donostia, Spain; [6]Hospital de La Princesa, Rheumatology, Madrid, Spain; [7]Hospital del Mar, Rheumatology, Barcelona, Spain; [8]University Hospital October 12, Rheumatology, Madrid, Spain; [9]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal

Background: Treat to Target strategies are necessary in Systemic Lupus Erythematosus (SLE). They are difficult to establish due to the heterogeneity of the disease. The current definitions of Lupus Low Disease Activity State (LLDAS) according to the Asia Pacific Lupus Collaboration (APLC) and remission according to Definition of Remission in SLE (DORIS) 2021 are difficult to achieve and maintain over time.
Objectives: To evaluate the concordance between the LLDAS and the clinical status according to the rheumatologist opinion and reasons of disagreement. To explore modifications in LLDAS definition that best fit with the expert´s opinion.
Methods: Prospective multicenter study of SLE patients (ACR 1997 Classification Criteria or clinical diagnosis by the physician) from seven Spanish Rheumatology Departments. Statistical analysis: descriptive cross-sectional (at the time of recruitment) analysis of the demographic and clinical characteristics, treatments; remission and LLDAS and the subjective evaluations of SLE activity by the rheumatologist. Analysis of the level of agreement between expert opinion and the definition of LLDAS and its modification were evaluated using Cohen's kappa.
Results: DEMOGRAPHIC, DISEASE CHARACTERISTICS AND TREATMENTS. Five hundred and eight were included (92% women; mean age (±SD): 50.4 years (±13.7)). Mean SLEDAI-2K (±SD) was 2.84 (±3.31). A total of 406 (79.9%) patients presented SLEDAI-2K≤4. A total of 317 (74.1%) patients were on antimalarial treatment. Two hundred and twenty-two (43.7%) patients were on some type of immunosuppressive or biological therapy. More than half of patients were not taking glucocorticoids (n=310, 61%). A total of 38 patients (7.5%) were taking doses of prednisone higher than 7.5mg/day.
REMISSION/LLDAS 267 (54.4%) patients were in remission and 304 (62.7%) patients were in LLDAS. According to the expert opinion of the rheumatologist, remission was the most frequent state considered (n=206, 41.6%); followed by low activity (n=153, 30.9%); serologically active (n=71, 14.3%); moderate activity (n=55, 11.1%) and high activity (n=10, 2%).
AGREEMENT Overall agreement between expert opinion and the definition of LLDAS was 71.4 % with a Cohen's kappa of 0.3. The majority of the cases (96.1%) that fulfilled the definition of LLDAS, were classified by the expert as remission, serologically active or low activity. Only 12 (3,9%) patients were classified by the expert as moderate or high activity. Of the patients that did not fulfill the definition of LLDAS, 126 out of 179 (70.4%) patients were classified by the expert as remission/low disease activity (Figure 1). The main reasons for discordance in the group that did not fulfill the definition of LLDAS were the presence of new clinical features compared to previous visit and a SLEDAI 2-K >4, in 74 (58.7%) and 59 (46.8%) patients, respectively. The LLDAS adjustment that meant a significant increase in the agreement was the exclusion of the comparative features with the previous visit, with an increase in the agreement to 82.6% (95% CI: 81.61-83.96%). The modification of prednisone to 5mg/daily dose, did not represent a significant change in agreement from the original definition.

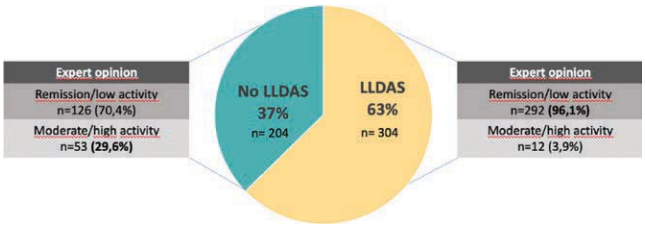

Figure 1. Comparison of LLDAS and expert opinion

Conclusion: At a given point in time, almost two thirds of SLE patients were in remission or in LLDAS. There is a good correlation between LLDAS and the physician's opinion, particularly for those patients who fulfill LLDAS definition. However, the agreement is not so good for patients who don't, these being excessively classified by the physician as remission or low activity. The main LLDAS items causing this disagreement were a SLEDAI-2K >4 and the appearance of different clinical manifestations from the previous evaluation. On the contrary, physician assessment by the PGA adequately fits the LLDAS definition. The modification of the LLDAS definition excluding the comparison with previous assessment increases the agreement with the expert opinion to 82.6%.

POS0760 HIGH LEVELS OF PROTEINS, CELL COUNTS, AND IL-6 IN CEREBROSPINAL FLUID IN PATIENTS WITH NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS ARE ASSOCIATED WITH DAMAGE ACCRUAL OF NON-NEUROPSYCHIATRIC DOMAINS AS WELL AS THAT OF NEUROPSYCHIATRIC DOMAINS

M. Edamoto[1], J. Kikuchi[1], H. Hanaoka[1], S. Saito[1], K. Hiramoto[1], Y. Kaneko[1].
[1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Neuropsychiatric systemic lupus erythematosus (NPSLE) is one of severe organ manifestations and directly associated with neuropsychiatric damages, such as cerebral vascular accident, cognitive impairment, or seizures. However, factors associated with damage accrual of neuropsychiatric and non-neuropsychiatric domains in NPSLE patients remain unknown.
Objectives: The aim of this study was to identify factors associated with damage accrual in patients with NPSLE.
Methods: We reviewed all patients with SLE who had attended our hospital between January 2010 to December 2020 retrospectively and identified those with NPSLE. We analyzed clinical characteristics and laboratory data including cerebrospinal fluid (CSF) in association with the Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) damage index (SDI) progression after the onset of NPSLE.
Results: 461 patients with SLE were reviewed. Among them, 37 (8.0%) were diagnosed with NPSLE. Thirty-six patients were included in the analysis after excluding one patient with insufficient information. Seventeen (47.2%) patients were diagnosed with NPSLE at the same time with SLE diagnosis and 19 patients were diagnosed at relapse. At NPSLE onset, the mean age was 33.7 years, 35 were female, and the mean SLEDAI-2K was 21.8. Eighteen (50.0%) patients had active lupus nephritis simultaneously at the onset of NPSLE. The most frequent NPSLE types according to the 1999 ACR classification were lupus headache in 10 patients, followed by cerebrovascular disease in 7, seizure disorders in 6, acute confusional state, psychosis and mononeuropathy in 3, and aseptic meningitis in 2. All patients were treated with glucocorticoids, and the mean initial dose of prednisolone was 52.3 mg/day with steroid pulse therapy in 19 patients. Thirty (83.3%) patients were treated with concomitant immunosuppressive treatments. During the observation period with the mean of 10.0 years, 17 (47.2%) patients developed at least one point of SDI. Among them, 9 patients (25.0%) had neuropsychiatric damage progression including cerebrovascular accident in 6, seizures requiring drug treatment for more than 6 months in 2, and cognitive impairment in 1. Non-neuropsychiatric damage was also increased such musculoskeletal in 5, ocular in 3, cardiovascular in 2, renal, gastrointestinal, premature gonadal failure, diabetes, and malignancy in each one case. Neither neuropsychiatric nor overall damage progression were associated with SLEDAI-2K, anti-cardiolipin antibodies positivity, abnormal electroencephalogram, abnormal single photon-emission computed tomography at NPSLE onset or kinds of immunosuppressive treatments. In 21 patients who underwent CSF examination, the high level of CSF IL-6 was associated with neuropsychiatric damage progression (p=0.032). Also, high levels of CSF protein (p=0.030), cell counts (p=0.007), and IL-6 (p=0.032) were associated with overall SDI progression.
Conclusion: CSF IL-6 concentrations are associated with neuropsychiatric damage progression, and high CSF protein, cell counts and IL-6 at onset in patients with NPSLE can predict overall damage accrual.

POS0761 TIME-DEPENDENT ANALYSES OF CLINICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS IDENTIFY PATIENTS AT HIGH RISK OF INCIDENT PROTEINURIA

M. Andersen[1], A. Stockmarr[2], H. Leffers[1], A. Troldborg[3], A. Voss[4], S. Kristensen[5], B. Deleuran[3], L. Dreyer[5], L. Johnsen[6], A. Colic[7], S. Jacobsen[1].

Aalborg, Denmark; [6]Copenhagen University Hospital Rigshospitalet, Center for Rhematology and Spine Diseases, Gentofte, Denmark; [7]Zealand University Hospital Køge, Department of Rheumatology, Køge, Denmark

Background: Nephritis (LN) in systemic lupus erythematosus (SLE) is still a major determinant of poor prognosis[1]. The vast majority of LN occurs in proximity to the SLE diagnosis[2]. Identification of individuals at high risk, especially early onset SLE, is therefore warranted. Inclusion of risk factors prior to the SLE diagnosis may thus be of importance to enable sufficient risk factor profiling. SLE-patients seem to cluster according to clinical and serological phenotypes suggesting distinct disease trajectories[3-5].
Objectives: To determine if incident proteinuria associated with the debut age of non-renal SLE characteristics.
Methods: Data of SLE patients from six Danish centers were obtained from the Danbio-database from 2017 – 2020. The occurrence and timing of proteinuria was compared with first time onset of any non-renal manifestations as defined by the 1997 American College of Rheumatology Classification Criteria. Cox-regression models were used to identify risk factors for incident proteinuria. Time from first occurring non-renal manifestation to incident proteinuria or censoring defined time at risk. Covariates were eliminated if p >0.01 in a 'backwards' manner. After the model reduction process p-values <0.05 were considered statistically significant.
Results: 586 SLE patients, mainly white (94%) women (88%), mean age at inclusion of 34.6 years (standard deviation, SD = 0.6 years) and observed for a mean of 14.9 years (SD =0.5 years), were recruited. The cumulative prevalence of proteinuria was 40%. Male gender hazard ratio, HR = 1.35 (range 0.77-2.35), p=0.009, lymphopenia HR = 1.77 (range 1.24-2.52), p=0.005 were associated with incident proteinuria. In contrast, patients with discoid rash had lower risk of incident proteinuria HR 0.42 (range 0.21-0.83), p=0.01. Male patients with lymphopenia had the highest risk of proteinuria with a one-, 5- and 10-year risk of proteinuria ranging from 9-27%, 34-75% and 51-89 %, depending on the age at presentation (debut at 20, 30, 40 or 50 years). The corresponding risk-profiles for women with lymphopenia were 3-9%, 8-34% and 12-58%, respectively, as illustrated in Figure 1.
Conclusion: The occurrences of lymphopenia and discoid rash were oppositely associated with risk of incident proteinuria and the risk effects varied according to gender and patient age at onset of these manifestations. Thus, the risk of proteinuria may not be constant but could vary according to presentation of non-renal manifestations that may call for a differentiated clinical follow-up. Based on these findings, we suggest that the debut age of known prognostic factors, even prior to the SLE diagnosis should be considered when designing prognostic statistical models.

POS0762 LONG-TERM RENAL OUTCOMES OF PATIENTS WITH NON-PROLIFERATIVE LUPUS NEPHRITIS

E. Kang[1], S. Hong[1], Y. G. Kim[1], C. K. Lee[1], J. S. Oh[1], B. Yoo[1], S. M. Ahn[1].
[1]Seoul, Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of (South Korea)

Background: Although proliferative (class III or IV) lupus nephritis (LN) is the most common finding in the classification of LN, pure membranous (class V) or mesangial (class I or II) LN can occur as a form of LN. Even though non-proliferative LN (class I, II, or V) is a less severe form with good outcomes, data on long-term renal prognosis are limited.
Objectives: This study investigated the long-term outcomes and prognostic factors in non-proliferative LN.

AZA	0.589	0.133-2.611	0.486			

[a] LN classifications were based on the International Society of Pathology/Renal Pathology Society (ISN/RPS) classification.[b] Medications maintained at least one year since Lupus Nephritis diagnosis.HR, hazard ratio; 95% CI, 95% confidence interval; SLEDAI, systemic lupus erythematosus disease activity index; eGFR, estimated glomerular filtration rate; LN, lupus nephritis; anti-dsDNA, anti-double strand DNA; C3/C4; complement 3/4; ACEi, angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor blocker; CNI, carcineurin inhibitor; MMF, mycophenolate mofetil; AZA, azathioprine.

Methods: We retrospectively reviewed the medical records of patients with systemic lupus erythematosus who were diagnosed with LN class I, II, V or II+IV by kidney biopsy between 1997 and 2021 at a tertiary referral center. Clinical and laboratory data were compared between patients with and without poor renal outcomes. Poor renal outcome was defined as an estimated glomerular filtration rate (eGFR) of < 60 mL/min/1.73 m2 or death due to renal cause. Univariate and multivariate analyses were performed with the Cox proportional hazard model to identify the factors associated with poor renal outcomes.

Results: We included 71 patients with non-proliferative LN (4: class I; 17: class II; 48: class V, 17; 2: class II+V). Median follow-up duration was 103 months (interquartile range 27–185) and the overall rate of poor renal outcomes at last follow-up was 29% (21/71), including end-stage renal disease (n=2) and renal death (n=1). Univariate analysis indicated that older age (HR 1.05; 95% CI: 1.00–1.09), low eGFR (HR 0.97; 95% CI: 0.95–0.99) and failure to reach complete remission at 6 months (HR 0.332; 95% CI: 0.12–0.92) were significantly associated with poor renal outcomes. Multivariate analysis revealed that low eGFR at 6 months (HR 0.97; 95% CI: 0.95–0.99) was significantly associated with poor renal outcomes.

Conclusion: Poor renal outcomes occurred in approximately 30% of patients with non-proliferative LN (class I, II or V) after long-term follow-up. Our findings suggest that more active management may be needed for non-proliferative LN, particularly in patients with low eGFR at 6 months.

POS0763

A MULTIMODAL MAGNETIC RESONANCE IMAGING STUDY OF COGNITIVE FUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS: A MACHINE LEARNING APPROACH

S. H. Tay[1], M. Stephenson[2], N. A. Allameen[3], S. Narayanan[4], B. Lee[5], A. Mak[2]. [1]*National University Hospital, Medicine, Singapore, Singapore;* [2]*National University of Singapore, Medicine, Singapore, Singapore;* [3]*Woodlands Health Campus, Medicine, Singapore, Singapore;* [4]*Institute of Molecular and Cell Biology (IMCB), JEC Lab, Singapore, Singapore;* [5]*Nanyang Technological University, Centre for Biomedical Informatics, Singapore, Singapore*

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disorder that can affect the central nervous system. Cognitive dysfuncion is the most common neuropsyhiatric event in SLE patients, yet it is also one of the hardest to diagnose.

Objectives: To investigate if multimodal imaging to assess anatomical magnetic resonance imaging (MRI) abnormalities in the brains of SLE patients can predict cognitive function.

Methods: Subjects underwent voxel-based morphometry (VBM), magnetization transfer imaging (MTI), and dynamic contrast-enhanced (DCE) MRI. Automated Neuropsychological Assessment Metrics (ANAM) was used to assess cognitive function in this cross-sectional study and the primary measure was the total throughput score (TTS). TTS is the total of the throughput scores for each of the 8 ANAM subtests: (i) code substitution learning (CSL); (ii) code substitution immediate (CSI); (iii) code substitution delayed (CSD); (iv) spatial processing (SP); (v) matching to sample (MSP); (vi) running memory continuous performance test (CPT); (vii) mathematical processing (MTH) and (viii) memory search (MS). Olfactory assessment was done using the University of Pennsylvania Smell Identification Test. We used a machine learning-based model (i.e. GLMnet) to predict TTS. Subjects with active SLE disease or above 40 years old were excluded.

Results: Thirty SLE patients [26 female, 32.0 (26.8-37.0) years] without clinically overt neuropsychiatric manifestations and 10 healthy controls (HCs) [9 females, 27.0 (23.0-31.5) years] were enrolled in this study. Both groups had comparable cognitive and olfactory functions. No significant differences were observed in VBM, MTR, olfactory blub and tract (OBT) volume in SLE patients compared to HCs. We observed increased blood-brain barrier (BBB) permeability parameters (Ktrans and PS) in several regions of SLE patients. DCE-MRI perfusion parameters such as perfusion (F) and vp but not permeability measures were associated with TTS. In particular, F right amygdala correlated with TTS in SLE patients (r = 0.636, FDR p < 0.05) (Table 1). Using GLMnet, we trained a multimodal MRI model comprising of VBM, MTR, DCE-MRI and OBT volume parameters to predict TTS in SLE patients (r = 0.998, p < 0.0005) (Figure 1).

F right parietal	0.376†	0.249	0.082	0.274	0.283	0.139	0.460†	0.255	0.311
F right parahippocampal gyrus	0.375†	0.353	0.119	0.302	0.341	0.241	0.353	0.208	0.273

† p < 0.05, ‡ p < 0.01, *FDR p < 0.05

Conclusion: These findings suggest that the BBB may be affected early in the course of cognitive dysfunction, even preceding detectable changes in other MRI sequences and machine learning algorithms can be used to predict TTS measures, even in asymptomatic SLE patients.

POS0764

CLINICAL AND LABORATORY FINDINGS IN PRIMARY SJOGREN'S SYNDROME PATIENTS WITHOUT SUBJECTIVE SICCA SYMPTOMS

V. Koulouri[1], L. Chatzis[1], C. Baldini[2], A. Goules[1], A. Tzioufas[1]. [1]*National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece;* [2]*University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: Sjogren's syndrome (SS) is a systemic autoimmune rheumatic disease characterized by symptoms of dryness. In fact, subjective manifestations of dry eyes or dry mouth are part of the inclusion criteria of the 2016 ACR-EULAR Classification Criteria for primary SS (pSS). However, some patients with SS diagnosis may present without subjective dryness, meeting the inclusion criteria based on the EULAR SS disease activity index (ESSDAI) questionnaire (1). Studies on non-dryness SS patients are missing.
Objectives: To describe the clinical phenotype of pSS patients who lack subjective dryness symptoms.
Methods: From 1738 consecutive pSS patients who fulfill the 2016 ACR-EULAR Classification Criteria for primary SS and were followed up in 4 centers from Greece and Italy (Universities of Athens, Pisa, Harokopio and Ioannina) (PAHI group), those without sicca symptoms were identified (non-Dryness Group) (1). Cumulative, clinical, laboratory, immunologic and histologic data were collected and compared with age, gender and disease duration-matched SS patients with both oral and eye dryness in 1:2 ratio (Dryness Group) (Table 1). Statistical analysis for categorical data was performed by Fisher exact test or $\chi 2$ square test accordingly and numerical data with Mann-Whitney test or t test.

Table 1. Comparison of clinical and laboratory features of pSS patients with (Dryness Group) and without sicca manifestations (Non-dryness Group)

Clinical and Laboratory features	Non-Dryness Group, %, n=38	Dryness Group, %, n=76	p-value
ANA positivity %	100	95.9	0.55
RF positivity %	58.3	64.3	0.7
Anti-Ro positivity %	100	90.8	0.09
Anti-La positivity %	54.1	50.7	0.89
Salivary gland biopsy positivity %	93.9	89.8	0.71
Focus score	2.12	2.19	0.97
Ocular tests positivity %	55.6	93.9	**<0.001**
Salivary gland enlargement %	26.3	30.3	0.83
Arthralgias %	52.6	56.6	0.84
Arthritis %	25.7	17.6	0.48
Raynaud's phenomenon %	23.7	27.6	0.82
Palpable purpura %	7.9	18.4	0.17
Lymphadenopathy %	22.6	20.3	0.99
Leukopenia %	20.7	26.1	0.76
Lymphopenia %	0	17.3	**0.049**
Neutropenia %	20.8	5.8	0.1
Thrombocytopenia %	13.8	3.1	0.07
Low C4 %	23.3	30.3	0.65
Cryoglobulinemia %	10.5	3.9	0.3
Lymphoma %	10.8	6.7	0.47

Results: Thirty-eight SS patients were found without sicca manifestations (2.19%). The most common presenting clinical manifestation of non-dryness pSS patients were arthralgias (47.4%), followed by parotid gland enlargement (23.6%), Raynaud's phenomenon (10.5%), generalized lymphadenopathy (10.5%), fatigue (10.5%), palpable purpura (5.3%) and pulmonary symptomatology of dry cough or exertional dyspnea (5.3%). Despite the lack of ocular dryness, non-dryness group had positive ocular tests but statistically lower compared to those with sicca symptoms (55.6% vs 93.9%, p<0.001), and displayed lymphopenia less frequently (0 vs 17.3%, p=0.049). No statistical differences were found in terms of salivary gland enlargement (SGE), focus score (FS), cryoglobulinemia and autoantibody profile between the 2 groups.
Conclusion: SS patients without subjective dryness are characterized by similar underlying immunopathologic processes as typical SS sicca patients.

POS0765 IS THERE ANY DIFFERENCE IN THE CLINICAL FEATURES AND OUTCOMES OF PROLIFERATIVE AND NON-PROLIFERATIVE FORMS OF LUPUS NEPHRITIS PROVEN BY BIOPSY?

E. Duran[1], T. Yıldırım[2], A. Taghiyeva[3], E. Bilgin[1], M. Arıcı[2], A. Saglam[4], S. Özen[5], M. Üner[4], Y. Erdem[2], U. Kalyoncu[1], A. I. Ertenli[1]. *[1]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; [2]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Nephrology, Ankara, Turkey; [3]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey; [4]Hacettepe University School of Medicine, Department of Department of Pathology, Ankara, Turkey; [5]Hacettepe University School of Medicine, Department of Pediatrics, Division of Rheumatology, Ankara, Turkey*

Background: Lupus nephritis (LN), which occurs in 60-70% of patients with systemic lupus erythematosus, is a major determinant of morbidity and mortality. There still are many uncertain aspects in clinical, pathological, and prognostic characteristics about LN.
Objectives: We aimed to compare clinical features, outcomes, and to define the predictive factors of complete renal response (CRR) in patients with proliferative and non-proliferative LN.
Methods: Patients with SLE followed between 2014 and 2020 at Hacettepe University Hospitals and who had a kidney biopsy were the subject of the study. One hundred and sixteen patients whose kidney biopsy reported as LN were evaluated retrospectively. Clinical features, laboratory values at the time of kidney biopsy, histopathological forms of LN, and renal response (complete or partial) were recorded. The predictive factors for CRR during the two-year follow-up after induction therapy were analyzed.
Results: Of 116 (93 females, 23 males) patients, 95 (81.9%) were in the proliferative (class III and IV) and 21 (18.1%) were in the non-proliferative group (class II and V). In the proliferative group, elevated basal creatinine, median daily proteinuria, anti-dsDNA positivity, low C3 and C4, the presence of active urinary sediment, and median renal SLE Disease Activity Index (SLEDAI) scores at the time of kidney biopsy were significantly higher than non-proliferative group. During the two-year follow-up after LN diagnosis, 70 patients achieved CRR and time-to-CRR was similar for the groups (p=0.64, log-rank). The Cox proportional hazards model showed that achieving CRR was associated with female gender [HR: 2.15 (1.19-3.89 95% CI), p=0.011], newly diagnosed SLE with renal biopsy [2.15 (1.26-3.67), p=0.005], hypertension [0.40 (0.27-0.94), p=0.032], eGFR increase [1.01 (1.00-1.01), p=0.046], and presence of active urinary sediment [0.46 (0.22-0.96), p=0.039].
Conclusion: Achieving CRR was similar in both the proliferative and non-proliferative LN patients although certain laboratory parameters differed at onset. Our results indicated the importance of kidney biopsy in the decision-making of treatment of SLE patients with renal involvement and that the defined factors associated with CRR achievement help to predict good renal response.

Table 1. Demographic, clinical characteristics, and outcomes of the patients with LN

POS0766 THE ROLE OF ANTIBODIES TO THE PHOSPHATIDYLSERINE/PROTHROMBIN COMPLEX IN THE DIAGNOSIS OF ANTIPHOSPHOLIPID SYNDROME

T. Reshetnyak[1,2], F. Cheldieva[1,2], M. Cherkasova[1], A. Lila[2,3], E. Nasonov[3].
[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]Federal State Budgetary Educational Institution of Further Professional Education «Russian Medical Academy of Continuous Professional Education» of the Ministry of Healthcare of the Russian Federation, Department of Rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology, Moscow, Russian Federation

Background: The study of other non-criteria antiphospholipid antibodies (aPL) may improve the stratification of patients with antiphospholipid syndrome (APS) and assist in the interpretation of conflicting results on aPL testing.
Objectives: To determine the significance of antibodies to the phosphatidylserine/prothrombin complex (anti-PS/PT) in patients with systemic lupus erythematosus (SLE) and APS.
Methods: The study included 190 patients who signed informed consent, aged 37,0 [29,0-44,0] years and disease duration 7,0 [2,0-15,0] years. Male/female ratio was 44 (23)/146 (77). 123 (64,7%) of 190 patients had reliable SLE and 55 (29%) had PAPS. The control group was left with 100 relatively healthy, age-matched individuals. Classical aPL (IgG/IgM-aCL, IgG/IgM-$\alpha\beta$2-GP1, LA) were meassured at two time points separated by at least 12 weeks in all patients included in this study. IgG/IgM anti-PS/PT was determined by enzyme immunoassay (ELISA) using a Tecan sunrise absorbance microplate spectrophotometer (Austria) with an AESKULISA Serin-Prothrombin-GM antibody reagent kit. IgG/IgM anti-PS/PT were measured in U/ml. Values >18 U/ml were considered positive. The range of measurements was: 1 to 300 U/ml.
Results: In 144 (76%) of 190 patients were revealed IgG anti-PS/PT, 55 (29%) - IgM anti-PS/PT, a combination of IgG anti-PS/PT and IgM anti-PS/PT was found in 53 (28%). IgG anti-PS/PT and IgM anti-PS were detected in 39 of the 70 (56%) remaining patients who were negative for criterion aPL. The median IgG anti-PS/PT was 101.2 U/ml [31,0-180,5] in patients with APS and was significantly higher than 23,7 [14,1-49,8] U/ml in patients without APS and controls. IgM anti-PS/PT levels in patients with and without APS were comparable. Thrombosis was significantly more common in patients with IgG anti-PS/PT: 95 (81,2%) of 117 patients with thrombosis compared with patients negative for IgG anti-PS/PT (22 (18,8%) of 46 patients) (χ2=4,85; P=0,03). Arterial, but not venous thrombosis, was associated with IgG anti-PS/PT positivity. IgG anti-PS/PT was detected in 53 (88,3%) of 60 patients with arterial thromboses, and in 7 (11,7%) of 46 patients of IgG anti-PS/PT negative. The incidence of thrombocytopenia in the SLE+APS patient group was associated with the presence of IgG anti-PS/PT, which was detected in 18 of 19 patients, versus 6 of 12 in SLE without aPL (P<0,007). In the other patient groups, the frequency of thrombocytopenia and IgG anti-PS/PT positivity was not statistically significant. The frequency of anti-PS/PT detection was independent of LA positivity. IgG and/or IgM anti-PS/PT were detected in 26 (87%) of 30 patients positive for LA and in 21 (78%) of 27 patients LA negative. (P<0,05). The sensitivity of anti-PS/PT IgG for APS was 85%, specificity - 64%, the sensitivity of anti-PS/PT IgM was lower - 35%, but higher specificity - 88%.
Conclusion: The frequency of anti-PS/PT detection in the examined patients was high: 76% had IgG anti-PS/PT, 29% - IgM anti-PS/PT and 28% - a combination of them. The levels of IgG anti-PS/PT were significantly higher in patients with APS compared to patients without APS and controls. IgM anti-PS/PT values in patients with and without APS were comparable but higher compared to controls. Thrombosis was associated with IgG anti-PS/PT positivity. Arterial thrombosis was significantly more frequent in patients with IgG anti-PS/PT (χ2=4,85; P=0,006). The sensitivity of IgG anti-PS/PT for APS was 85%, and specificity was 64%; IgM anti-PS/PT had a lower sensitivity of 35%, but a higher specificity of 88%.
The study was performed at the V.A. Nasonova Research Institute of Rheumatology within the framework of the fundamental topic FURS-2022-003.

POS0767 GLANDULAR INVOLVEMENT IN PRIMARY SJÖGREN SYNDROME PATIENTS WITH INTERSTITIAL LUNG DISEASE (ILD) ONSET: A SINGLE CENTER CROSS-SECTIONAL STUDY

G. La Rocca[1], F. Ferro[2], G. Fulvio[1], S. Fonzetti[1], G. Governato[1], V. Donati[1,3], M. Mosca[1,2], C. Baldini[1,2]. *[1]University of Pisa, Clinical and Experimental Medicine, Pisa, Italy, Rheumatology, Pisa, Italy; [2]Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy; [3]Azienda Opedaliero-Universitaria Pisana, Unit of Pathological Anatomy 2, Pisa, Italy*

Background: Primary Sjögren Syndrome (pSS) is an autoimmune exocrinopathy classically presenting with sicca symptoms. Nonetheless, disease onset with extraglandular manifestations, particularly interstitial lung disease (ILD), is increasingly reported and probably underestimated. However, studies investigating pSS patients presenting with ILD (pSS-ILD) are limited.
Objectives: Aim of this study was to better characterize the phenotype of pSS patients presenting with ILD in comparison to pSS patients with classical sicca-onset. We especially investigated whether the two groups differed in glandular involvement comparing functional, imaging and histologic findings, as well as patient reported outcome (PRO).
Methods: Consecutive newly diagnosed pSS patients, all fulfilling the ACR/EULAR 2016 criteria, were included in this cross-sectional study from September 2016 to October 2021. Clinical, serological and histological initial features where compared in pSS-ILD patients and in pSS patients without ILD involvement, diagnosed during the same time period. Presence of ILD at pSS diagnosis was defined based on clinical findings, imaging assessment and pulmonary function tests. In addition to functional tests, a minor salivary gland biopsy was performed in all cases, recording number of foci and GC-like structures and focus score (FS). Salivary glands ultrasonography (SGUS) was graded using the OMERACT semiquantitative scoring system (0-3) based on parenchyma inhomogeneity. PRO including ESSPRI, OHIP and OSSDI were collected. Extraglandular clinical features and biological abnormalities included in the ESSDAI were recorded. Data were presented as mean±SD, or percent frequency as appropriate. Intergroup comparisons were made using the t-test/Mann–Whitney test for continuous variables and Fisher's exact test for categorical variables.
Results: We included 178 newly diagnosed pSS patients (F:M=158:20). ILD was the first pSS manifestation in 11 (6%) cases, 8 F and 3 M, with a median time from ILD onset to pSS diagnosis of 2 ± 2 years. At HRCT, the following patterns were observed: NSIP (4/11), UIP (4/11), NSIP+OP (2/11) and LIP (1/11). Dyspnea on exertion or chronic cough were reported by 7/11 (63.6%) patients. In comparison to sicca-onset patients, pSS-ILD patients presented an older age at diagnosis (55±13 vs 70±7, p= 0.001) and a higher ESSDAI (3.9±4.7 vs 12.3±4.3, p=0.001) driven by the pulmonary domain. Regarding glandular involvement, pSS-ILD patients reported milder xeropthalmia (VAS 5.8±3.1 vs 2.8±3.5, p=0.002), and significative lower scores in OSDI (35.6±24.9 vs 15.3±22.9, p=0.04) and OHIP (4.8±4.4 vs 1.4±3.8, p=0.04), despite no significant differences observed between the two groups in ocular tests and unstimulated salivary flow rate. With respect to histology, no significant differences were found in number of foci and GC-like structures, and FS. Notably, there was a trend towards a different distribution of the SGUS OMERACT score in the two groups. Particularly, none of pSS-ILD patients presented OMERACT score 3 in parotid and submandibular glands, in contrast to 26/167 (15.5%) and 18/167 (10.8%) of classic sicca-onset pSS patients respectively. Finally, no significant differences were observed between the two groups with respect to non-pulmonary extraglandular manifestations, serologic features and other biological parameters.
Conclusion: ILD-onset pSS patients represent an atypical phenotypic subset, with less pronounced sialadenitis sonographic changes in salivary glands, and with sicca symptoms probably overshadowed by the respiratory disease.

POS0768

PRESENCE OF ANTI-RO/SSA AUTOANTIBODIES, HYPOCOMPLEMENTEMIA AND PHOTOSENSITIVITY INDICATE INDIVIDUALS WITH CONNECTIVE TISSUE DISEASE FEATURES WHO ARE AT INCREASED RISK FOR TRANSITION TO SYSTEMIC LUPUS ERYTHEMATOSUS

E. Emmanouilidou[1], C. Adamichou[1,2], M. Nikoloudaki[1], E. Kalogiannaki[1], A. Repa[1], N. Avgustidis[1], A. Eskitzis[1], N. Kougkas[1,2], P. Sidiropoulos[1,3], G. Bertsias[1,3]. *[1]University of Crete Medical School, Rheumatology, Clinical Immunology, Heraklion, Greece; [2]Hippokration Hospital, Rheumatology Clinic, Fourth Department of Internal Medicine, Thessaloniki, Greece; [3]Foundation for Research and Technology - Hellas (FORTH), Institute of Molecular Biology and Biotechnology (IMBB), Heraklion, Greece*

Background: Early or pre-clinical forms of lupus encompass a broad range of presentations, spanning from asymptomatic individuals with immunological abnormalities to individuals with autoantibodies and some features suggestive of SLE who do not yet meet the classification criteria. Research on this topic could reveal predictive and diagnostic biomarkers for individuals at-risk for progression to SLE.
Objectives: To examine the rate of transition from at-risk to classified (ACR 1997 criteria) SLE, and identify demographic and clinical predictors. To prospectively evaluate the sensitivity and accuracy of the newer classification criteria (SLICC 2012, EULAR/ACR 2019) and the SLE Risk Predictive Index (SLERPI)[1] in patients at-risk who progress or not to classified SLE.
Methods: This is a single-centre analysis of individuals at-risk for SLE as part of an ongoing multicentric inception cohort study aiming to identify clinical, environmental and molecular prognostic factors for SLE onset. Enrolled individuals: a) were 18–55 years old; b) had clinical and/or serological features suggestive of SLE; c) had no clinical diagnosis of SLE or other autoimmune rheumatic disease; and d) did not fulfill the ACR 1997 classification criteria. Prospective monitoring at 6-month intervals was performed to determine accrual of classification and non-classification features, and ascertain the disease status (at-risk/undifferentiated connective tissue disease, SLE, other connective tissue disease).
Results: A total 124 subjects were included, all Whites, 94.4% women, with an average (standard deviation) age 36 (11) years. At first assessment, individuals fulfilled 2.25 (0.72) ACR 1997 criteria with ANA being the most prevalent feature (75.8%) followed by low complement (43.5%), arthritis (37.9%), photosensitivity (28.2%), malar rash (23.4%), and non-scarring alopecia (18.5%). After a median follow-up of 16 months, 27 participants (21.8%) fulfilled the ACR 1997 criteria, of whom 8 (6.5%) developed moderate or severe SLE. Multivariable-adjusted logistic regression identified anti-Ro/SSA (odds ratio [OR] 6.93; 95% confidence interval [95% CI] 1.75–27.5, p=0.006), combined low C3 and low C4 (OR 4.82; 95% CI 1.42–16.3, p=0.012) and photosensitivity (OR 3.25; 95% CI 1.17–8.99, p=0.023) as independent predictors for transition to classified SLE. The sensitivity of SLICC 2012, EULAR/ACR 2019 and SLERPI (>7) at baseline for detecting individuals who progressed to SLE (ACR 1997) was 40.7%, 25.9% and 40.7%, respectively, with corresponding specificities of 83.5%, 88.7% and 79.4%.
Conclusion: Among individuals at-risk for SLE, about 20% may evolve into classified disease after a medium follow up of 16 months which is predominantly of mild severity. Presence of anti-Ro/SSA, hypocomplementemia, and photosensitivity indicate subjects who at increased risk for transition to SLE. Newer classification systems may capture as many as 40% of progressors with acceptable specificity.

POS0769

CANCER DEVELOPMENT IN PATIENTS HOSPITALISED WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL, POPULATION-LEVEL DATA LINKAGE STUDY

W. Raymond[1], D. Preen[2], H. Keen[1,3], C. Inderjeeth[1,4], J. Nossent[1,4]. *[1]The University of Western Australia, Medical School, Perth, Australia; [2]The University of Western Australia, School of Population & Global Health, Perth, Australia; [3]Fiona Stanley Hospital, Rheumatology, Perth, Australia; [4]Sir Charles Gairdner & Osborne Park Healthcare Group, Rheumatology, Perth, Australia*

Background: The association between systemic lupus erythematosus (SLE) and cancer risk is unclear.
Objectives: Describe the association between systemic lupus erythematosus (SLE) and the risk of cancer development and subsequent 5-year mortality in Western Australia (WA).
Methods: Population-level cohort study of SLE patients (n=2,111) and general population comparators (n=21,110) hospitalised between 1980–2014. SLE patients (identified by ICD-9-CM: 695.4, 710.0, and ICD-10-AM: L93.0, M32.0) were nearest matched (10:1) for age, sex, Aboriginality, and temporality. Follow-up was from timezero (index SLE hospitalisation) to cancer development, death or 31/12/2014. Using longitudinal linked health data, we determined the risk of cancer development and subsequent 5-year mortality between SLE patients and comparators with Cox proportional hazards regression models.
Results: SLE patients had similar multivariate-adjusted risk (aHR 1.03, 95%CI 0.93, 1.15; P=0.583) of cancer development. Cancer development risk was higher in SLE patients <40 years old (aHR 1.51), and from 1980-1999 (aHR 1.28). SLE patients had higher risk of developing cancer of the oropharynx (aHR 2.13); vulvo-vagina (aHR 3.22); skin (aHR 1.20), and, lymphatic and haematopoietic tissues (aHR 1.78), all P<0.05. SLE patients had reduced risk of breast cancer (aHR 0.64). After cancer development, SLE patients had increased risk of 5-year mortality (aHR 1.16, 95%CI 1.01, 1.33); highest in 40-49 years old (aHR 1.89), and in those with skin (aHR 1.65) or prostate cancer (aHR 4.74).
Conclusion: Hospitalised SLE patients had increased risk of multiple cancers, but a reduced risk of breast cancer. Following cancer development, SLE patients had increased risk of 5-year mortality. Together there is scope to improve cancer prevention and surveillance in SLE patients.

POS0770

INCREASED RISK OF FRACTURE, RECURRENT FRACTURE AND POST-FRACTURE MORTALITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A POPULATION-LEVEL, LINKED DATA STUDY

W. Raymond[1], C. Inderjeeth[1,2], D. Preen[3], H. Keen[1,4], J. Nossent[1,2]. *[1]The University of Western Australia, Medical School, Rheumatology Section, Perth, Australia; [2]Sir Charles Gairdner & Osborne Park Healthcare Group, Rheumatology, Perth, Australia; [3]The University of Western Australia, School of Population & Global Health, Perth, Australia; [4]Fiona Stanley Hospital, Rheumatology, Perth, Australia*

Background: Systemic lupus erythematosus (SLE) patients have higher fracture risk, driven by primary (chronic inflammation) and secondary (glucocorticoids treatment) osteoporosis. However, there is limited data on fracture recurrence and post-fracture mortality in this vulnerable population.
Objectives: To describe the association between systemic lupus erythematosus (SLE) and the risk of fracture(s), 5- and 10-year recurrent fracture(s), and 5-year post-fracture mortality, compared to hospital-based controls in Western Australia (WA) from 1980 - 2014.
Methods: Population-level cohort study of SLE patients (n=2,440, 28,002 person-years) and general population comparators (controls) (n=10,220; 161,392 person-years) identified within the Western Australia (WA) Rheumatic Disease Epidemiological Registry (WARDER). SLE patients 18-80 years old (identified by ICD-9-CM: 695.4, 710.0, ICD-10-AM: L93.0, M32.0) and controls were nearest matched (5:1) for age, sex, Aboriginality, and temporality. Follow-up was from timezero (index SLE hospitalisation) to fracture-related hospitalisation, death or 31/12/2014. Using longitudinal linked health data we determined the relative risk of (low impact) fracture-related hospitalisations (after excluding for traumatic and external factors, such as, falls from more than standing height and transport accidents), 5- and 10-year recurrent fractures, and 5-year post-fracture mortality between SLE patients and controls with multivariate Cox proportional hazards regression models from 1980-2014.
Results: Compared to general population controls, SLE patients had higher multivariate-adjusted risk (aHR 2.44, 95%CI 2.08, 2.87; P<0.01) of fractures during follow-up. SLE patients had higher fracture risk regardless of sex, Aboriginality, age group (highest in those <50 years of age), or study period (2000-2014: aHR 1.83, 95%CI 1.32, 2.55; P<0.01). SLE patients had higher risk of hand, wrist and forearm fractures (aHR 1.95), vertebral fractures (aHR 5.73), hip fractures (aHR 1.83), and lower limb, ankle and foot fractures (aHR 2.14). Similarly, SLE patients had higher risk of both 5- (aHR 2.89) and 10-year (aHR 3.00) fracture recurrence, which held across sub-group analyses and remained high in the most recent 2000-2014 period (aHR 2.84 and aHR 3.04, respectively). SLE patients had higher (aHR 1.56, 95%CI 1.16, 2.09; P<0.01) risk of 5-year post-fracture mortality, which held for female SLE patients (aHR 1.45), those ≥70 years-old (aHR 1.72), and remained in the 2000-2014 period (aHR 1.57).

Conclusion: SLE patients have an increased risk of fractures, 5- and 10-year recurrent fractures, and 5-year mortality post-fracture compared to controls from the general population. After adjustment for conventional risk factors, these associations remained unchanged in the most recent period (2000-2014). This study highlights the need for improved primary prevention of a first fracture event in SLE patients.

POS0771 ULTRA HIGH-FREQUENCY ULTRASOUND (UHFUS) OF MINOR LABIAL SALIVARY GLANDS (MLSGS): DIAGNOSTIC ACCURACY IN ANTI-RO/SSA POSITIVE AND ANTI-RO/SSA NEGATIVE PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME (PSS)

G. Fulvio[1], F. Ferro[1], R. Izzetti[2], S. Fonzetti[1], G. Governato[1], G. La Rocca[1], V. Donati[3], M. Mosca[1], C. Baldini[1]. *[1]University of Pisa, Rheumatology Unit, Clinical and Experimental Medicine, Pisa, Italy; [2]University of Pisa, Unit of Dentistry and Oral surgery, Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine, Pisa, Italy; [3]Unit of Pathological Anatomy 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

Background: Last-generation Ultra High-frequency ultrasound (UHFUS) transducers are highly sensitive tools for the study of tiny superficial structures such as minor labial salivary glands (MLSGs). Compared to conventional ultrasound, UHFUS operates with higher frequencies allowing for outstanding image resolution, up to 30 µm.

Objectives: To determine the diagnostic accuracy of MLSG UHFUS in primary Sjogren's syndrome (pSS) and to assess its contribution in anti-Ro/SSA positive and anti-Ro/SSA negative patients

Methods: Consecutive patients undergoing a MLSG biopsy for clinically suspected pSS were included in this cross-sectional study from January 2018 to October 2021. MLSG UHFUS was performed by using a 70 MHz probe, evaluating parenchymal inhomogeneity (score 0-3, similar to major salivary glands four-grade OMERACT scoring system). Patients' clinical, biological, and histological features were collected. Anti-Ro/SSA antibody specificity was determined by immunoblotting. Receiver operating characteristic (ROC) curves, optimal cut-off point, AUC (area under curve), sensitivity (SE), specificity (SP), positive (PPV) and negative predictive values (NPV) were identified.

Results: A total of 194 patients were enrolled. Out of them, 88 patients fulfilled the ACR/EULAR 2016 criteria for pSS and 74 were anti-Ro/SSA+ (69 pSS and 5 no-SS). The distribution of UHFUS grades was significantly different in patients with pSS than in no-SS subjects: grade 0: 0/88 (0) vs 17/106 (16%); grade 1: 28/88 (31.8%) vs 55/106 (51.9%); grade 2: 46/88 (52.3%) vs 31/106 (29.2%); grade 3: 14 (15.9%) vs 3(2.8%); p<0.0001. ROC curve analysis indicated that at the optimal cut-off value of 2, UHFUS identified pSS and no-SS patients with a SE=68.2%, a SP=67.9%, a PPV= 63.8%, and a NPV= 72% (AUC=0.722, 95%CI: 0.651-0.793) and can predict a FS≥1 at the MLSG biopsy with a SE =73%, a SP=63.4%, a PPV= 48.9% and a NPV = 83% (AUC= 0.732, 95% CI: 0.657-0.806). Subgroup analyses highlighted significant differences in UHFUS diagnostic accuracy between anti-Ro/SSA+ and anti-Ro/SSA- patients. Particularly, in the latter group UHFUS showed a higher diagnostic accuracy (AUC= 0.754, 95% CI: 0.641-0.867) with a NPV increased up to 93.3%; similarly, UHFUS showed a higher accuracy (AUC= 0.755, 95% CI: 0.650-0.860) in predicting a MLSG FS≥1 with a NPV raised up to 90.7%.

Conclusion: MLSG UHFUS score system presents a good SE and SP in distinguishing pSS from no-SS subjects. The diagnostic accuracy of MLSG UHFUS may be significantly enhanced when combined with anti-Ro/SSA antibodies status. If anti-SSA antibodies are negative and UHFUS grade is 0 or 1, the diagnosis of pSS is very improbable and MLSG biopsy could be avoided. Further studies are in progress to define the added value of UHFUS with respect to major salivary gland ultrasonography.

POS0772 HEPATIC STEATOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: PREVALENCE AND ASSOCIATION WITH DISEASE FEATURES

A. Barrera-Vargas[1], A. A. Baeza-Zapata[2], A. Fortanell-Meza[1], D. San Agustín-Morales[1], J. Merayo-Chalico[1], C. Moctezuma-Velázquez[2]. *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Immunology and Rheumatology, Mexico City, Mexico; [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Gastroenterology, Mexico City, Mexico*

Background: The spectrum of hepatic involvement in patients with systemic lupus erythematosus (SLE) is broad and multifactorial. Steatosis is a common finding in liver biopsies performed on these patients; however, there is no further evidence of its prevalence in this population. Early detection of steatosis is important to consider ideal management options, and transient elastography (Fibroscan) offers a non-invasive, fast, and easy tool that provides reliable diagnoses.

Objectives: To determine the prevalence of hepatic steatosis in patients with SLE by using the controlled attenuation parameter (CAP). We also aimed to describe factors associated with steatosis in lupus, such as metabolic syndrome criteria, treatment, and disease activity.

Methods: Between July and December 2021, we measured the degree of hepatic steatosis in patients who fulfilled the 2019 EULAR/ACR SLE classification criteria from a rheumatology outpatient clinic in a tertiary referral center in Mexico City, using the CAP obtained with Fibroscan. The cut-off value for considering hepatic steatosis was 275 dB/m. Fibroscan results, metabolic syndrome criteria, treatment, and SLE-associated variables were recorded. Variables were analyzed using Chi-squared, Fisher's exact, and Mann-Whitney U tests. We used logistic regression to compare variables associated with lupus activity and steatosis. A p value <0.05 was considered statistically significant.

Results: A total of 102 patients (83% female, mean age 39±14 years) with SLE were included. We identified 23 patients (22.5%) with hepatic steatosis. Patients with steatosis had a higher mean waist-to-hip ratio (WHR; 0.92 vs 0.85 cm p<0.001), and prevalence of overweight/obesity (82% vs 49% p=0.004) compared with patients without steatosis. Univariate analyses showed that steatosis was significantly associated with higher body mass index (BMI; OR 1.24 [95%CI 1.11-1.39], p<0.001), WHR (OR 1.13 [95%CI 1.03-1.23], p=0.006), serum glucose (OR 1.04, [95%CI 1.00-1.07], p=0.04), and paradoxically, higher C3 complement levels (OR 1.03 [95%CI 1.01-1.05], p=0.002). Additionally, hydroxychloroquine was found to be a protective factor (OR 0.34 [95%CI 0.12-0.98], p=0.047). There were no differences between patients with and without steatosis in terms of disease duration and types of activity. Also, no differences were found in the activity (SLEDAI-2K) and chronic damage (SLICC-DI) indices between groups. In the multivariate analysis, the only variables that remained significantly associated with steatosis were BMI (OR=1.23 [95%CI 1.05-1.43], p=0.007), and WHR (OR 1.15 [95%CI 1.03-1.28], p=0.01).

Table 1. UHFUS diagnostic accuracy in pSS (A) and for predicting a MLSG FS≥1 in all the cases and in anti-Ro/SSA negative patients. OCP, optimal cut-off value.

	SE	SP	PPV	NPV	AUC (95%CI)	OCP
pSS diagnosis (all pts)	60/88 (68.2%)	72/106 (67.9%)	60/94 (63.8%)	72/100 (72%)	0.722 (0.651-0.793)	2
FS≥1 prediction (all pts)	46/63 (73%)	83/131 (63.4%)	46/94 (48.9%)	83/100 (83%)	0.732 (0.657-0.806)	2
pSS diagnosis (SSA- pts)	14/19 (73.7%)	70/101 (63.9%)	14/45 (31.1%)	*70/75 (93.3%)*	0.754 (0.641-0.867)	2
FS≥1 prediction (SSA- pts)	17/24 (70.8%)	68/96 (70.8%)	17/45 (37.9%)	*68/75 (90.7%)*	0.755 (0.650-0.860)	2

Although it did not reach statistical significance, current use of hydroxychloroquine tended to be a protective factor for steatosis (OR=0.18 [95%CI 0.03-1.10], p=0.06).

Conclusion: The prevalence of hepatic steatosis in patients with SLE is similar to that of the general population. Metabolic risk factors were associated with a higher prevalence of steatosis in patients with lupus, contrary to other SLE disease features such as activity, treatment, and chronic damage. Interestingly, hydroxychloroquine use tended to be a protective factor for steatosis in these patients.

Table 1. Characteristics of SLE patients according to the presence of steatosis.

	All patients	Patients without steatosis	Patients with steatosis	
	(n=102)	(n=79)	(n=23)	P value
Age	37 (29-51)	38 (29-51)	34 (30-55)	0.8
Weight (kg)	66.5 (58-76.7)	63 (57-73)	77 (68-89)	**<0.001**
Body mass index (kg/m^2)	26.3 (22.9-29.9)	25 (22-29)	31 (26-33)	**<0.001**
Obesity	25 (24%)	13 (16%)	12 (52%)	**<0.001**
Waist-to-hip ratio	87.2 (81.3-92.2)	85.6 (80.2- 91.7)	92.2 (87.4-94.6)	**0.003**
Current use of hydroxychloroquine	85 (80%)	70 (84%)	15 (65%)	**0.04**
SLEDAI score	4 (2-6)	4 (2-6)	2 (1-6)	0.4
SLICC-DI score	1 (0-1)	1 (0-1)	1 (0-1)	0.8

POS0773 AUTOANTIBODIES IN A MULTI-INSTITUTIONAL INDIAN COHORT (INSPIRE) OF SLE PATIENTS: PREVALENCE, CLUSTER ANALYSIS AND PHENOTYPE ASSOCIATION

A. Aggarwal[1], R. Gupta[2], R. Chatterjee[1], V. Negi[3], B. K. Das[4], P. Ghosh[5], D. Danda[6], V. Shobha[7]on behalf of INSPIRE. *[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology & Rheumatology, Lucknow, India; [2]All India Institute of Medical Sciences, Rheumatology, New Delhi, India; [3]JIPMER, Clinical Immunology & Rheumatology, Puducherry, India; [4]SCB Medical College, Medicine, Cuttack, India; [5]IPGMER, Clinical Immunology & Rheumatology, Kolkata, India; [6]Christian Medical College, Clinical Immunology & Rheumatology, Vellore, India; [7]St. John's Medical College, Clinical Immunology & Rheumatology, Bengaluru, India*

Background: Systemic Lupus Erythematosus (SLE) is characterized by an array of autoantibodies. Different autoantibodies have been associated with different clinical features like anti-dsDNA antibodies with nephritis and anti-phospholipid antibodies with pregnancy loss. However, the prevalence of autoantibodies has been variable across different ethnic groups. Data on the Indian population is limited.

Objectives: To assess the prevalence of different autoantibodies in a multi-institutional cohort (INSPIRE) of Indian SLE patients and to test their association with various clinical features using cluster analysis

Methods: The patients (n=1053) enrolled in a multi-institutional cohort of Indian patients (Indian SLE inception cohort for Research [INSPIRE]) were included.[1] Antibodies were assayed using Immunoline (Euroimmune, Germany) 17 antigen kit. Anti-phospholipid antibodies (IgG and IgM anti-cardiolipin antibodies (ACLs), IgG anti-Beta 2 GpI antibodies) were measured using ELISA (Euroimmune). Lupus anticoagulant was available in a subset of patients. The prevalence data for autoantibodies were analyzed using an intensity of only ++ and above on Immunoline assay as significant. Univariate analysis by Chi-square test was done to identify associations between individual autoantibodies and their clusters with clinical manifestations.

Results: The clinical features were fever in 702, alopecia in 813, oral ulcers in 628, acute cutaneous lupus (ACLE) in 520, proteinuria in 400, pleural effusion in 181, thrombocytopenia in 250 and autoimmune hemolytic anemia in 137 patients. The prevalence of various autoantibodies by ELISA was anti-dsDNA antibodies in 70.2% (551/784), IgG Anti- beta-2 GpI in 4.47% (42/938), IgG ACL in 6.14% (61/992) and IgM ACL in 7.1% (54/760). Lupus anticoagulant was present in 13.9% (112/ 805). By Immunoline assay, the prevalence for anti-Ro 52, anti-Ro 60, anti-La and anti-Ribosomal P was 28.49%, 33.14%, 10.07% and 24.03% respectively (Table 1).

Table 1. Prevalence of different autoantibodies in the INSPIRE lupus cohort

S. No.	Autoantibody	Prevalence (%) (n=1053)
1.	dsDNA	28.11
2.	Nucleosomes	27.83
3.	Histones	24.88
4.	Ro_52_SSA	28.49
5.	Ro_60_SSA	33.14
6.	SSB-La	10.07
7.	Ribosomal P	24.03
8.	nRNP	36.75
9.	Sm	33.14
10.	Scl-70	3.23
11.	PM-Scl	0.38
12.	Jo-1	0.09
13.	CENP-B	0.38
14.	PCNA	1.33
15.	AMA-M2	2.28

Cluster analysis (Figure 1) revealed association (Odds ratio with 95% confidence interval) of Cluster 1 (antibodies against dsDNA, histones and nucleosomes) with arthritis (1.51 [1.18-1.94]), proliferative nephritis (3.05[2.08-4.48]) and pleural effusion (1.49[1.08-2.05]), cluster 2 (antibodies against Sm, nRNP, Ro52, Ro60 and Ribosomal P) with ACLE (1.3[1.02-1.65]) and non-proliferative nephritis (1.64[1.09-2.46]) and cluster 3 (antiphospholipid antibodies) with thrombocytopenia (3.34[1.57-7.11]).

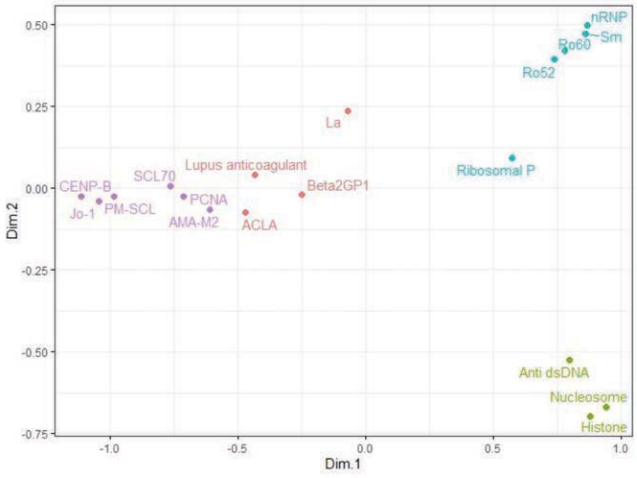

Figure 1. Cluster analysis of autoantibodies (Cluster 1: dsDNA, histone and nucleosome; cluster 2: Sm, nRNP, Ro52, Ro60 and Ribosomal P; cluster 3: cardiolipin, β2GP1 and La and lupus anticoagulant; cluster 4: Scl-70, Jo-1, PCNA, AMA-M2, PM-SCL and CENP-B)

Conclusion: The prevalence of anti-Sm antibody and Anti-Ribosomal P antibody is higher whereas that of anti-La antibody is lesser in the Indian SLE patients as compared to other cohorts of SLE patients with different ethnicities.[2] Cluster analysis reveals co-occurrence of different autoantibodies in our patients and their significant association with various clinical manifestations which suggests a possible pathogenic role of autoantibodies or a common genetic basis for it.

POS0774

ANTI-SM AUTOANTIBODIES IDENTIFY A PHENOTYPE OF SEVERE SLE WITH AN ASSOCIATED SERUM BIOMARKER PROFILE

A. Hoi[1,2], S. Toor[2], J. Monk[1], J. Chang[1], R. Koelmeyer[1], A. Papadaki[3], J. Peters[3], F. Vincent[1], J. Ooi[1], E. F. Morand[1,2]. [1]*Monash University, Medicine, Clayton, Australia;* [2]*Monash Health, Rheumatology, Clayton, Australia;* [3]*Imperial College London, Immunology and Inflammation, London, United Kingdom*

Background: Antibodies to Smith (Sm) have been described as one of the most specific autoantibodies for systemic lupus erythematosus (SLE). Other than its association with lupus nephritis, there is, however, limited understanding of its clinical significance[1,2].

Objectives: To describe clinical associations and serum protein profiles of anti-Sm positivity in SLE.

Methods: Patients fulfilling SLE classification criteria who were followed longitudinally in a prospective multicentre cohort were studied according to their baseline anti-Sm antibody status. Comparison between Sm+ and Sm- patients was made using descriptive statistics. Clinical associations of Sm positivity with patient disease characteristics were studied using logistic regression. In a subset, 211 serum analytes were measured using Quantibody, Luminex and ELISA assays. Associations between serum proteins and Sm positivity were studied using Least Absolute Shrinkage and Selection Operator (LASSO) penalised regression, adjusting for demographics (age, sex, ethnicity) and medication use

Results: 383 patients were studied with median (IQR) follow-up of 4.9 (2,9) years; 65 (17%) had positive anti-Sm antibodies. Sm+ patients were significantly more likely to be of non-European ancestry (OR 2.73, 95% CI 1.55-4.82, p<0.001), and to be positive for anti-dsDNA antibodies (OR 2.8, 95% CI 2.3-3.4, p<0.001), anti-RNP antibodies (OR 15.7, 95% CI 13.9-17.8, p<0.001), direct anti-globulin test (OR 2.36, 95% CI 2.07-2.7, p<0.001) and hypocomplementemia (OR 7.73, 95% CI 5.1-11.7, p<0.001). Sm+ patients were significantly more likely to have active disease during the observation period in a range of organ domains, including mucocutaneous, renal, vasculitis and fever. More Sm+ patients had episodes of High Disease Activity Status (HDAS, SLEDAI-2K ≧10)[3] (OR 3.07, 95% CI 1.70-5.54, p<0.001) and persistent active disease (time-adjusted mean SLEDAI-2K > 4) (OR 3.23. 95% CI 1.84-5.70, p<0.001). Conversely, fewer Sm+ patients attained LLDAS for ≥50% observed time (19.7% vs 41.8%, p=0.002). Sm+ patients were more likely to be treated with glucocorticoids, immunosuppressants, and rituximab. There was no significant difference in damage accrual between Sm + and Sm - patients. In serum protein analysis (n=197, 29 Sm+), LASSO modelling retained 3 proteins associated with Sm+ status, CXCL13, IL1RL1 and FLT1, along with Asian ethnicity and age. In analysis including pairwise interaction between predictors, 28 Sm+ associated proteins were identified, including CCL4, VCAM1, IL1RL1, Fcg R IIB/C, TDGF1, CEACAM1, TIMP1, BMP5, GDF15, and TNFRSF17.

Conclusion: Anti-Sm autoantibodies, present in 17% of SLE patients, were strongly associated with classical disease manifestations, more severe disease activity, and a specific serological and proteomic profile. These findings suggest anti-Sm+ SLE as a specific disease subset.

POS0775

COMBINED MODEL OF RENAL HISTOPATHOLOGY AND CLINICAL PARAMETERS BETTER PREDICT ONE YEAR RENAL OUTCOMES IN LUPUS NEPHRITIS: ANALYSIS OF 334 KIDNEY BIOPSIES

A. Gopal[1], C. Kavadichanda[1], D. Bairwa[1], S. Bh[2], M. M. Thabah[1], V. Negi[1,3]. [1]*Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Clinical Immunology, Puducherry, India;* [2]*Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Pathology, Puducherry, India;* [3]*AIIMS Bilaspur Himachal Pradesh, Director, Kothipura, India*

Background: Diagnosis of Lupus Nephritis (LN) is currently based on laboratory tests and renal histopathology. Role of histopathological features in determining long term outcomes is unclear.

Objectives: 1. To assess if clinical and biochemical parameters at baseline can identify renal histopathological class. 2. To assess the clinico-histopathological predictors of renal response.

Methods: This is a single centre retrospective study comprising 334 LN renal biopsies. Clinical and biochemical parameters at the time of biopsy were noted and their association with histopathological class, activity and chronicity scores (AS/CS) (ISN/RPS classification) were evaluated. Complete, partial or no response (CR, PR, NR) for renal outcome (EULAR/EDTA) at 1 year were assessed for 293 patients. Binary logistic regression was done to look for the predictors of NR.

Results: Class III/IV LN was seen in 240(71.8%). Hypertension was seen in (52.1%) of class III/IV and <25% each with class II, V and combined class(p<0.001). Class III/IV had lower eGFR [87.6(62.75-118.8)] (p<0.001) than the other classes. Nephrotic range proteinuria was seen in 32% of class V and 21% in class III/IV (p=0.004). Among class-III/IV, AS had weak correlation with baseline UPCR (r=0.31) and eGFR (r=-0.172) (p<0.01). CS had weak negative correlation with eGFR (r=-0.212, p<0.01). NR at 1 year was higher in males (OR-4.6,95%CI-1.9-10.8, p<0.001), those with abnormal serum creatinine (OR-3.3,95%:CI1.6-7.02, p-0.001), higher renal SLEDAI (p<0.05), higher AS, CS (p<0.001), interstitial inflammation and tubular atrophy(p<0.005) (Table 1). On binary logistic regression a combined clinico-histopathological model comprising of serum creatinine, UPCR, male sex and CS performed best in predicting NR (Figure 1).

Table 1. Comparison of baseline characteristics among those who attained any response (CR/PR) versus others at 1 year

Parameter	Any response Complete Response CR/PR (n=233)	Others (No response/rescue) (n=60)	OR (95% CI)	P value
Female/male, n (%)	221(94.8)/12(5.2)	48(80)/12(20)	**4.6(1.9-10.8)**	**0.001**

Interstitial inflammation, n (%)	86(36.9)	33(55)	**2.08(1.17-3.70)**	**0.003**
Interstitial fibrosis, n (%)	23(10.7)	9(15)		0.273
Tubular atrophy, n (%)	64(27.5)	27(45)		**0.003**
Blood vessel changes, n (%)	2(0.9)	1(1.7)		0.606
Fibrinoid necrosis	206(88.4)	50(83.3)		0.339
Other changes*				

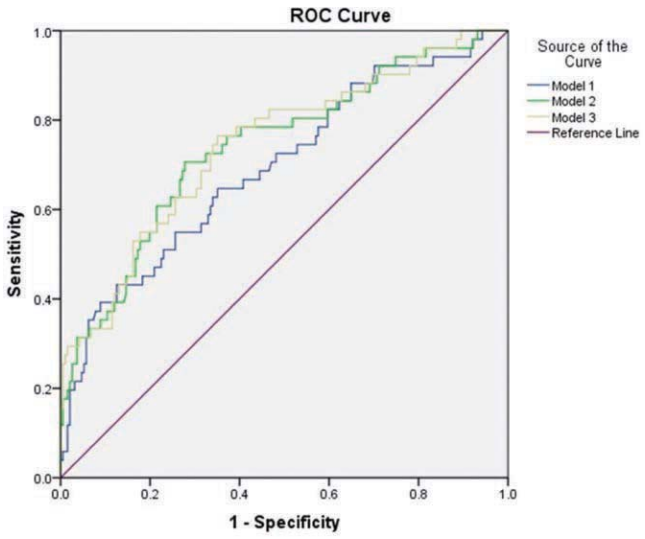

Figure 1. ROC curve and AUC for the three different modelsModel 1: Baseline serum creatinine, urine PCR, male sex; AUC – 0.694(0.609-0.779), p <0.001Model 2: Baseline serum creatinine, urine PCR, male sex, chronicity score; AUC – 0.740(0.660-0.820), p<0.001Model 3: Baseline serum creatinine, urine PCR, male sex, chronicity score, crescents, interstitial inflammation; AUC – 0.744(0.664-0.824), p<0.001

Conclusion: Clinical and biochemical parameters can predict the renal histological class to a fair extent but has limited value in predicting the activity and chronicity parameters. Since a combination of clinical and histopathology parameters are better in predicting renal outcomes, performing renal biopsies should be encouraged in LN.

POS0776 IMMUNOGENICITY AND SAFETY OF INACTIVATED AND MRNA COVID-19 VACCINES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

H. So[1], T. K. Li[1], V. Chan[1], L. S. Tam[1], P. K. Chan[2]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR);* [2]*The Chinese University of Hong Kong, Microbiology, Hong Kong, Hong Kong (SAR)*

Background: Vaccination against SAR-CoV-2 is a new campaign and believed to be the key to end the pandemic. Currently, there are two COVID-19 vaccines with different mechanism of action available in Hong Kong - they are the inactivated virus vaccine and the mRNA-based vaccine. Both vaccines have obtained approval for emergency use by the World Health Organization (WHO) and were widely deployed globally (1). A mass voluntary vaccination program for all Hong Kong residents has started in late February, 2021 (2). However, the efficacy and safety of COVID-19 vaccines in patients with SLE is uncertain due to a complex interplay of underlying autoimmunity and immunosuppressive therapies used.

Objectives: This study was to investigate the effects of both inactivated and mRNA COVID-19 vaccines in patients with SLE.

Methods: This was a prospective, single-centre, case-control study. Patients with SLE planning to receive COVID-19 vaccines were recruited and matched 1:1 with healthy controls. The immunogenicity of the COVID-19 vaccines was assessed by a surrogate neutralization assay at 28 days after the second dose. The main outcomes included the antibody response and adverse effects comparing SLE patients and controls. Predictors of responses in SLE patients were analyzed. The change of SLE disease activity was evaluated.

Results: Sixty-five SLE patients received 2 doses of COVID-19 vaccines (Comirnaty: 38; CoronaVac: 27) were recruited. Many of them were on systemic glucocorticoids (75.8%) and immunosuppressants (54.5%). At day 28 after the second dose of vaccines, 92.3% (Comirnaty: 100%; CoronaVac: 81.5%, p=0.01) had positive neutralizing antibody. However, compared to the age, gender, vaccine type matched controls, the level of neutralizing antibody was significantly lower (p<0.001) in patients with SLE (Figure 1). The self-reported side effects of the vaccines in lupus patients were common but mild, and were more frequent in the Comirnaty group. There was no significant change in lupus disease activity up to 28 days after vaccination. The independent predictors of neutralizing antibody level included the dosage of systemic glucocorticoids, use of mycophenolate and type of vaccines (Table 1).

Table 1. Multivariate linear regression analysis for neutralizing antibody activity

	Beta	95% confidence interval	P value
Age	-0.022	-0.425 – 0.381	0.914
Gender	8.16	25 (92.6)	0.296
SLEDAI-2k	-1.96	-4.22 – 0.31	0.088
Prednisolone dosage	-2.01	-3.66 - -0.37	**0.018**
Mycophenolate mofetil	-15.2	-24.4 - -6.0	**0.002**
Type of vaccines: Comirnaty	28.8	20.1 – 37.5	**<0.001**

Conclusion: COVID-19 vaccines produced satisfactory but impaired serological response in SLE patients compared to controls which was dependent on the immunosuppressive medications use and type of vaccines received. There was no new short-term safety signal noted. Booster dose is recommended.

Background: B cells play a central role in systemic lupus erythematosus (SLE) pathogenesis connecting innate with adaptative immunity.

Objectives: To investigate the peripheral blood B cell phenotype in a cohort of SLE patients with renal involvement (LN-SLE) in relation to disease activity and renal histological lesions compared to healthy controls.
Methods: One hundred LN-SLE patients with active renal involvement, 40 at disease onset (Early) and 60 in whom LN occurred after the disease onset (Long) were enrolled. Thirty-seven healthy controls were included. Clinical, laboratory and demographic data were collected at baseline and at 6 and 12 month of follow-up. Disease activity was recorded using SLEDAI-2K. Ultrasound-guided renal biopsy has been performed for the definition of the nephritic class according to the ISN/RPS classification. The memory B cells immunophenotyping (IgD/CD27 classification) was analyzed in peripheral blood through flow cytometry. To clarify the role of key molecules in the B cells activation, IL-6 and BAFF serum levels were assayed by Enzyme-linked immunosorbent assay (ELISA).
Results: According to the onset of renal symptoms, there were no differences in the distribution of the renal classes and in activity and chronicity indices in the two groups. A direct correlation was observed between chronicity index score and creatinine in the whole cohort (R=0.342;*p<0.01*) and in LN-SLE Early (R=0.528;*p=0.01*) and Long (R=0.337;*p=0.02*). The disease activity index was found to be significantly higher in anti-dsDNA positive than in negative ones (6.6±4.8 *vs* 2.8±3.5;*p=0.01*), and in patients with at least one antiphospholipid antibody-APL positivity (6.8±4.8 *vs* 5.1±4.8;*p=0.05*). Considering predictive biomarkers of the remission within 12 months, the presence of histological lesions (glomerulosclerosis and fibrocellular crescents) and the positivity for at least one of the APL antibodies were associated to the failure in achieving clinical remission, while baseline 24h-UP levels ≤2750mg were associated to remission achievement [OR:2.6(95%CIs:1.1-5.8)]. Studying the B cells subset, a lower percentage of $CD19^{pos}$ and unswitched memory ($IgD^{pos}CD27^{pos}$) in LN-SLE compared to controls (6.8±5.5% *vs* 10.5±3.5%;*p<0.01* and 11.1±12.0% *vs* 15.3±8.0%;*p<0.01,*respectively) was observed. In addition, we found higher levels of double-negative memory B cells ($IgD^{neg}CD27^{neg}$) and plasmablasts ($CD27^{pos}CD38^{pos}$) in LN-SLE than in controls [($CD27^{neg}IgD^{neg}$ 10.0±8.7% *vs* 4.1±1.9%;*p<0.01*)($CD27^{pos}CD38^{pos}$ 4.4±5.3% *vs* 1.0±0.5%;*p<0.01*)]. Furthermore, $CD19^{pos}$ and $IgD^{pos}CD27^{pos}$ negatively correlated with BAFF [(R=-0.327;*p=0.03* and R=-0.305;*p=0.04*) respectively] while a direct correlation was observed between $IgD^{neg}CD27^{neg}$ B cells and IL-6 serum levels (R=0.302;*p*<0.01). No correlation was found between B cells subsets and the disease activity parameters. Considering the remission status achievement within 12 months both LN-SLE groups had significantly lower frequencies of $IgD^{pos}CD27^{pos}$ than controls [(Remission:10.7±12.4% *vs* 15.3±8.0%;*p<0.01*) (No-Remission:9.8±9.5% *vs* 15.3±8.0%;*p<0.01*)] conversely had a significantly higher rate of $IgD^{neg}CD27^{neg}$ than controls [(Remission:11.5±10.0% *vs* 4.1±1.9%;*p<0.01*;NoRemission:9.6±6.7% *vs* 4.1±1.9%;*p<0.01*] and plasmablasts [(Remission 5.2±6.7% *vs* 1.0±0.5;*p=0.05;*NoRemission:4.1±3.4 *vs* 1.0±0.5;*p<0.01*)]
Conclusion: This study suggests that the active injury and chronic damage histological features of LN do not depend on the SLE duration *per se*, but could be associated to the failure in achieving clinical remission within 12 months. Furthermore, data on memory B cells immunophenotyping reveals a distinct B cells subset of SLE patients when compared to healthy controls, confirming an alteration of B cells subsets in SLE patients and strengthening the hypothesis of the pathogenetic role played by B lymphocytes in the course of LN.

POS0778 THE USEFULNESS OF ULTRASOUND-GUIDED CORE NEEDLE BIOPSY OF THE PAROTID GLAND FOR THE DIAGNOSIS OF PRIMARY SJÖGREN'S SYNDROME

A. Zabotti[1], I. Giovannini[1], V. Manfrè[1], M. Lorenzon[2], E. Pegolo[3], C. Dejaco[4,5], A. Hocevar[6], L. Quartuccio[1], S. De Vita[1]. *[1]Rheumatology Clinic, Azienda Sanitaria Universitaria Friuli Centrale c/o University of Udine, Udine, Italy; [2]Institute of Radiology, Azienda Sanitaria Universitaria Friuli Centrale c/o University of Udine, Udine, Italy; [3]Institute of Anatomic Pathology, Azienda Sanitaria Universitaria Friuli Centrale c/o University of Udine, Udine, Italy; [4]Department of Rheumatology, Hospital of Bruneck, Bruneck, Italy; [5]Division of Rheumatology and Immunology, Medical University Graz, Graz, Austria; [6]University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*

Background: Ultrasound-guided Core Needle Biopsy (US-guided CNB) of the parotid gland has proved to be a novel and safe technique for the diagnosis of lymphoma in Sjögren's Syndrome (pSS) patients with salivary gland enlargement.[1] The potential role of US-guided CNB for the diagnosis of pSS has been never reported, while only one group uses open surgical parotid biopsy to this end in pSS[2].
Objectives: To explore the value of US-guided CNB of the parotid gland as a diagnostic tool for pSS.
Methods: From September 2019 to June 2021, 22 patients with a clinical diagnosis of pSS underwent US-guided CNB of the parotid gland due to persistent (≥2 months) parotid swelling and suspected glandular lymphoma. In 21/22 (95.4%) patients, the tissue sampling was adequate for the histopathological diagnosis. No persistent complications were reported. For the aim of this study, 2/21 (9.5%) patients were excluded for a different final diagnosis (i.e., IgG4-RD and sarcoidosis), and 13/21 (61.9%) patients for a diagnosis of parotid gland lymphoma. Six out of 21 (28.5%) were finally included for the evaluation of US-guided CNB in the histopathological diagnosis of pSS. The following histopathological features related to pSS were studied: focus score (FS); presence of germinal centres (GCs); presence of lymphoepithelial lesions (LELs); and presence of Myo-/Lympho-epithelial sialadenitis (MESA/LESA).
Results: All 6 patients already satisfied the ACR/EULAR classification criteria for pSS and were females, with a mean age of 47.6 years (SD ±17.0) and a mean disease duration of 8.3 years (SD ±8.0). In all of them, specific findings of pSS were observed (Table 1). The FS could be calculated in 3/6 cases and was ≥1 in 2/3 cases, while in 3/6 cases it could be not calculated due to the evidence of MESA/LESA. GCs were found in 4/7 cases, while LELs were present in 3/7 cases (Table 1).

Table 1. Histopathological features in the parotid gland biopsy.

#Patient	Focus score	LELs	GCs	MESA/LESA
#1 NI	Not applicable	✗	✗	✓
#2 BM	≥1	✓	✓	✗
#3 CM	Not applicable	✓	✓	✓
#4 RC	<1	0	✓	✗
#5 FR	Not applicable	✓	✓	✓
#6 RV	≥1	✗	✗	✗

Conclusion: US-guided CNB of the parotid gland could represent a potential novel tool for the diagnosis of pSS patients. When parotid swelling is present, it may be more convenient than lip biopsy. In addition, CNB can be ultrasound-guided in specific glandular areas showing different sonographic appearances, consistent with different histopathology, leading the way for the role as diagnostic tool for pSS, and not only as improved lymphoma detection tool.
The next step is to evaluate US-guided CNB in pSS patients without glandular swelling, and to compare the results with labial biopsy.

POS0779 STANDARDIZED MORTALITY RATIO AND RISK FACTORS FOR DEATH IN SOUTHERN CHINESE PATIENTS WITH THE ANTIPHOSPHOLIPID SYNDROME (APS)

C. Lee[1], M. C. Leung[2], Y. K. Tang[3], C. Ho[4], M. C. Wan[5], S. Woo[5], M. L. Lee[6], K. H. Ng[7], H. So[8], M. Y. Lee[9], S. K. Y. Ying[10], M. H. Leung[11], P. Y. Wong[12], C. C. Mok[13]on behalf of the Hong Kong APS Registry. *[1]Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR); [2]United Christian Hospital, Medicine, Hong Kong, Hong Kong (SAR); [3]Kwong Wah Hospital, Medicine, Hong Kong, Hong*

Kong (SAR); [4]Queen Mary Hospital, Medicine, Hong Kong, Hong Kong (SAR); [5]Rutonjee Hospital, Medicine, Hong Kong, Hong Kong (SAR); [6]Yan Chai Hospital, Medicine, Hong Kong, Hong Kong (SAR); [7]Caritas Medical Center, Medicine, Hong Kong, Hong Kong (SAR); [8]Prince of Wales Hospital, Medicine, Hong Kong, Hong Kong (SAR); [9]Tai Po Hospital, Medicine, Hong Kong, Hong Kong (SAR); [10]Princess Margaret Hospital, Medicine, Hong Kong, Hong Kong (SAR); [11]Queen Elizabeth Hospital, Medicine, Hong Kong, Hong Kong (SAR); [12]Tseung Kwan O Hospital, Medicine, Hong Kong, Hong Kong (SAR); [13]Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)

Objectives: To report the mortality rate and risk factors for death in southern Chinese patients with the antiphospholipid syndrome (APS)

Methods: The HKAPS registry was established in early 2020 by the Hong Kong Society of Rheumatology to study the outcomes of Chinese patients with APS treated in public hospitals in Hong Kong. Patients aged ≥18 years were identified by the Hospital Authority Clinical Data retrieval system using the ICD-10 diagnostic code of APS. The medical history and APS diagnosis was verified by sub-investigators in different hospitals using the 2006 modified consensus criteria for the APS. Eligible patients were classified into definite APS or probable APS, which was further categorized into primary (without underlying rheumatic diseases) and secondary types. The treatment and outcome (recurrence and mortality) of the patients was studied by Kaplan-Meier analysis and risk factors for recurrence of thrombosis and mortality were studied by Cox regression.

Results: 428 APS patients were studied - 282 fulfilled the 2006 criteria for APS while 146 patients had probable APS (anti-phospholipid [aPL] antibodies positive once or with non-criteria manifestations). All were ethnic Chinese. The mean age at diagnosis was 44.1±15.6 years and the female to male ratio was 3.4:1. APS was primary in 211 patients and secondary to concomitant rheumatic diseases in 217 patients (SLE in 89.9%). 369(86.4%) patients had thromboembolic manifestations, 85(19.9%) had obstetric morbidities and 20(4.7%) had both. In patients with secondary APS, 23% thrombotic or obstetric manifestations occurred before diagnosis of the rheumatic diseases. Lupus anticoagulant (LAC), moderate/high titers of IgG anticardiolipin and anti-β2glycoprotein-1 antibodies was present in 326(76.1%), 242(56.5%) and 29(6.7%) patients, respectively. 137(32%) patients were double positive while 19(4.4%) patient was triple positive for these aPL antibodies. Among the thromboembolic manifestations, arterial thrombosis (n=201) was more common than venous thrombosis (n=186). The following treatment regimens were used: warfarin (63.6%), aspirin plus subcutaneous heparin (6.8%), aspirin plus warfarin (3%), aspirin alone (17.8%) and direct oral anticoagulant (DOAC) (2.8%). Bleeding complications developed in 77(18%) patients. After a mean follow-up of 8.0±14.1 years, recurrence of thromboembolic or obstetric complications occurred in 83(19.4%) and 14(3.3%) patients, respectively (1 patient had recurrence of both thrombosis and obstetric complications). Cox regression did not reveal any factors significantly associated with recurrence of thrombosis. A total of 67(15.7%) patients succumbed (median time to death 7.3 years). The causes of death were vascular in 29.9% (intracranial haemorrhage [35%], myocardial infarction [30%], limb ischemia [10%], ischemic stroke[10%], bowel ischemia[5%]) and non-vascular in 70.1% of patients (infection [59.6%], malignancy [10.6%], SLE activity [6.4%], pulmonary arterial hypertension [2.1%], organ failure [6.4%] and others). The cumulative risk of mortality over time was 6.4% at 5 years and 11.9% at 10 years. The age and sex adjusted standardized mortality ratio (SMR) of our APS patients relative to the general population was 18.2(14.2-23.0). In patients with thrombotic APS, mortality was associated with older age (≥60 years) (HR 2.57[1.34-4.95]) and the presence of LAC (HR 2.01[1.07-3.75]), adjusted for age, sex and vascular risk factors that included hypertension, diabetes mellitus, dyslipidaemia, smoking and atrial fibrillation.

Conclusion: APS in southern Chinese is relatively uncommon and most cases were associated with SLE. In contrast to the Caucasians, venous thrombosis related to APS is less frequent. Over 8 years, recurrence of thrombotic events is uncommon. The mortality of APS in our Chinese patients was increased, with older age and the presence of LAC being independent risk factors.

POS0780 MONOGENIC SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN NORTHERN ISRAEL

I. Spivak[1], T. Hershkovitz1[2], R. Zaid[2], K. Weiss[2], Y. Butbul Aviel[3]. *[1]Rambam Medical Center, Pediatrics B, Haifa, Israel; [2]Rambam Medical Center, Genetic Institute, Haifa, Israel; [3]Rambam Medical Center, Pediatric Rheumatology Unit, Haifa, Israel*

Background: Systemic Lupus erythematous (SLE) is a heterogenic clinical syndrome with a multifactorial etiology including diverse environmental, immunological and genetic causes and modifiers. Increasingly, utilizing next generation sequencing tools, monogenic forms of SLE have been identified.

Objectives: The aim of our study was to identify monogenic causes of SLE in the unique pediatric population of Northern Israel.

Methods: A retrospective and prospective study was carried out between 2010-2021 in a single tertiary pediatric medical center. Genetic testing including Whole exome sequencing (WES) was performed for select patients including family history of SLE, consanguinity and\or clinical findings suggestive of specific disorder.

Results: 75 children were diagnosed with SLE. 13/75 had one or more relatives with SLE, including a pedigree with 4 affected members. Mean age at presentation was 10.1±4.7. A monogenic disorder was identified in total of 7/75 of pedigrees. Four patients were diagnosed with Prolidase deficiency, one patient with *ADAR1* mutation related to Aicardi–Goutières syndrome and one pedegree with APC5 mutations. Candidate variants in genes related to immune system were identified in one proband and her father requiring further study. Additional WES results are pending

Conclusion: We detected monogenic causes of SLE in a select cohort of patient in Northern Israel. Identification of a genetic basis for disease has direct clinical implication for patients and families and can also enhance our understanding of the pathogenesis and disease mechanisms involved in the more common sporadic forms of SLE.

POS0781 RESIDUAL DISEASE ACTIVITY IN SLE: A REAL-LIFE CROSS-SECTIONAL STUDY IN THREE TERTIARY CENTRES TO EXPLORE THE ROOM FOR NOVEL THERAPIES

O. Gioti[1], M. Nikoloudaki2, K. Chavatza[3], E. Theotikos[1], A. Elezoglou[1], P. Sidiropoulos[2], G. Bertsias[2], D. Boumpas[3], A. Fanouriakis[4]. *[1]"Asklepieio" General Hospital, Department of Rheumatology, Athens, Greece; [2]University Hospital Heraklion, Rheumatology, Clinical Immunology and Allergy, Crete, Greece; [3]"Attikon" University Hospital, Rheumatology and Clinical Immunology, Athens, Greece; [4]"Laikon" General Hospital, 1st Department of Propaedeutic Internal Medicine, Athens, Greece*

Background: According to updated EULAR recommendations, the goal of treatment in systemic lupus erythematosus (SLE) should be remission or low disease activity in all organ systems, achieved with the least possible dose of glucocorticoids.[1] The proportion of patients achieving these two activity states under conventional therapies may vary between different patient cohorts and clinical settings.

Objectives: To assess the current disease activity state of SLE patients during their most recent visit in three tertiary centres experienced in the management of SLE.

Methods: In a cross-sectional study, patients were categorized as: 1) *Remission off-therapy*: SLE Disease Activity Index (SLEDAI)=0 without glucocorticoids (GC) or immunosuppressive drugs (IS), 2) *Remission on-therapy:* SLEDAI=0, GC ≤5mg/day prednisone (Pz) and/or IS (conventional and biologic, maintenance phase), 3) *Low disease activity (LDA)*: SLEDAI ≤4, Pz ≤7.5mg/day and/or IS (maintenance phase), 4) Active/Non-optimally controlled: SLEDAI >4 and/or Pz >7.5mg/day and/or IS (induction phase).[2] Hydroxychloroquine (HCQ) was allowed in all groups.

Results: A total of 332 patients were included [93.1% female, mean (SD) age 48.5 (14.7) years, median (IQR) disease duration 6.5 (12.4) years]. 81% (n=269) of patients were on HCQ and 69.6% (n=231) were receiving an additional IS at last visit. Regarding glucocorticoids (GC), almost half of our patients (48.2%, n=160) were not receiving any GC and of those receiving, only 7.8% (n=26) were receiving a Pz dose > 7.5 mg/day. Mean (SD) total and clinical SLEDAI were 3.7 (3.0) and 3.0 (2.9), respectively. At their most recent visit, 33.7% (n=112) of patients had no clinical activity (clinical SLEDAI=0) and 24.4% (n=81) had neither clinical nor serological activity (total SLEDAI=0). 31.6% and 49.1% of patients had a total SLEDAI-2K ≥6 and a clinical SLEDAI-2K ≥4, respectively (Table 1). Regarding disease activity states, 23.2% (n=77) of patients were in remission (off or on therapy), 36.7% (n=122) were in LDA, while 40.1% (n=133) were categorized as non-optimally controlled. In the latter group, a total SLEDAI > 4 was present in most of patients (79.2% vs. 21.9% for prednisone > 7.5 mg/day and 19.8% for IS at induction regimen). In patients with LDA or non-optimally controlled disease, activity was mainly driven by the mucocutaneous and musculoskeletal components of SLEDAI, along with serologic activity (Figure 1).

The latter was more common in LN patients. Overall, 83 patients (25.0%) in our cohort had evidence of serologic activity, of whom 31 (9.3% of total) had a clinical SLEDAI of 0.

Table 1. Distribution of patients based on total and clinical SLEDAI-2K score at most recent visit

Total SLEDAI		Clinical SLEDAI	
Score	Patients, n(%)	Score	Patients, n(%)
0	81(24.4)	0	112(33.7)
1-5	146(44)	1-3	57(17.2)
6-10	101(30.4)	4-8	154(46.5)
>10	4(1.2)	>8	9(2.7)

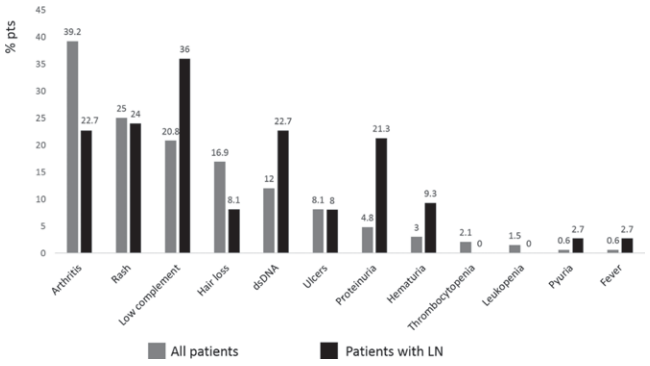

Figure 1. Components of SLEDAI-2K at most recent visit (total cohort of patients and patients with LN)

Conclusion: Although a significant proportion of our patients were on HCQ and additional IS, about 40% of them were not in optimal control. Yet, residual disease activity, based on SLEDAI-2K, was moderate, compared to relatively high mean baseline SLEDAI-2K of lupus trials. These data provide a pragmatic view of lupus patients, who could be potential candidates for novel treatments or inclusion in clinical trials.

POS0782 ULTRASONOGRAPHIC EVALUATION OF MAJOR SALIVARY GLANDS IN PRIMARY SJOGREN'S SYNDROME: COMPARISON OF THREE SCORING SYSTEMS AND ASSOCIATION WITH BIOPSY RESULTS.

C. Galisteo[1], S. Garcia-Cirera[1], S. Retamozo[1], M. Moreno[1], E. Casado[1], M. Rusiñol Gonzalez[1], J. Calvet[1], J. Gratacos-Masmitja[1]. *[1]ParcTaulí Hospital Universitari, Institutd'Investigació i Innovació ParcTaulí, Rheumatology, Sabadell, Spain*

Background: Salivary glands ultrasound is an imaging technique useful for primary Sjogren's syndrome (pSS) diagnosis. Nowadays, the use of ultrasound in diagnostic criteria is not clear. Different scoring systems have been published in recent years.

Objectives: This study aims to compare the reliability between three salivary glands ultrasound (SGUS) scores in a series of patients with pSS. Furthermore, we assessed the association of the three SGUS scores with minor salivary gland biopsy.

Methods: A cross-sectional study including 98 subjects fulfilling the ACR-EULAR 2017 classification criteria for pSS. All patients underwent an ultrasound of the salivary glands and a minor salivary gland biopsy requested as per clinical practice. An experienced Rheumatologist in SGUS evaluated systematically the previously acquired images. This Rheumatologist classified the images using three different scoring systems obtained from the grades of bilateral parotid and submandibular glands: De Vita (0-3), Salaffi (0-4) and Omeract (0-3). These three scores were performed in different days and blinded for the previous scores results. SGUS grade ≥ 2 was considered positive. Positive biopsy was deemed when focus score ≥1. We evaluated the agreement between the three scores and the individual scores with respect to the biopsy.

Results: This study included 98 patients with pSS. The distribution of the different grades according to the score system and the percentage of a positive SGUS are shown in Table 1. The reliability for a positive score for the three evaluated systems was almost perfect, with a Light's kappa of 0.95 [0.9-1] for the De Vita-Salaffi, 0.87 [0.77-0.97] for De Vita- Omeract and 0.83 [0.71-0.94] for Salaffi-Omeract. We observed a same degree of concordance when the individual parotid and submandibular scores were evaluated. There was only a fair agreement for positivity of SGUS and a positivebiopsy in all scoring systems, specifically De Vita (kappa = 0.27 [0.09-0.45]), Salaffi (kappa = 0.26 [0.06-0.45]) and Omeract (kappa = 0.22 [0.03-0.42]). This associations with a positive biopsy did not change in magnitude when individually evaluated parotid and submandibular glands.

Table 1. Distribution of the ultrasound grades and the percentage of positive biopsy in the different scoring systems evaluated.

	0	1	2	3	4	Positive score
Vita	23 (23.5%)	31 (31.6%)	26 (26.5%)	18 (18.4%)	0	44 (44.9%)
Salaffi	23 (23.5%)	29 (29.6%)	16 (16.3%)	23 (23.5%)	7 (7.1%)	46 (46.69%)
Omeract	27 (28.4%)	29 (30.5%)	23 (24.2%)	16 (16.8%)	0	39 (41.1%)

Conclusion: The three SGUS scores are reliable for the evaluation of the main salivary glands in pSS. There was only weak agreement for SGUS and biopsy, so these two techniques provides complementary information and currently, SGUS cannot replace the biopsy for diagnosis purposes.

POS0783 ASSOCIATION BETWEEN ENVIRONMENTAL FACTORS AND SALIVARY GLAND ULTRASOUND FINDINGS IN PATIENTS WITH SUSPECTED PRIMARY SJÖGREN SYNDROME

L. Barrio Nogal[1], M. Novella-Navarro[2], L. Sala-Icardo[1], A. Prada-Ojeda[1], C. Bohórquez[3], A. Pérez Gómez[3]. *[1]Hospital Universitario de Torrejón de Ardoz, Servicio de Reumatología, Madrid, Spain; [2]Hospital Universitario la Paz, Servicio de Reumatología, Madrid, Spain; [3]Hospital Universitario Príncipe de Asturias, Servicio de Reumatología, Madrid, Spain*

Background: The influence of environmental factors in primary Sjögren's syndrome (pSS) and their relationship with serological, histological and ultrasound findings remains still poorly understood. A possible protective effect of female sex hormones and smoking has been related to a lower focal lymphocytic sialadenitis on the minor salivary gland biopsy (MSGB), but the relationship between histological findings and other chemical, toxic or dietary factors remains scarce or controversial, and even more so the relationship between these factors with salivary gland ultrasound (SGUS) findings, an emerging tool in the diagnostic and management of pSS.

Objectives: To analyze the relationship between sociodemographic, clinical and environmental factors with pathologic SGUS findings in patients with suspected pSS.

Methods: 72 patients with clinical and/or analytical suspicion of pSS were consecutively recruited. SGUS was performed: pathological (grade ≥2 according to *Cornec et al* system) vs non-pathological. Final diagnosis of pSS was made according to AECG, ACR/EULAR criteria and MSGB. Sociodemographic, clinical, analytical, activity indexes (ESSPRI and ESSDAI), environmental factors, toxic and dietary habits were collected. Chi-square and Fisher tests were used to compare qualitative variables and T-student and U-Mann Whitney tests, for quantitative variables (statistical significance $p<0.05$). Defining pathologic vs non-pathologic US as the outcome variable, binomial logistic regression was performed for bivariate analysis, with calculation of Odds Ratio (OR) and 95% confidence interval (CI).

Results: 70.8% presented pathological SGUS, this percentage was significantly higher in patients with a definitive diagnosis of pSS (56.6% vs 26.6%; p=0.02). 97.2% were women with a mean age 57.3±11.8 years. Patients with pathological SGUS had in lower frequency a varied diet (64.2 vs 89.5; p=0.03), higher exposure to environmental toxics (71.1 vs 61.1; p=0.05), lower percentage of smokers (26.4 vs 52.6; p=0.03) and a lower mean age at menopause than patients with non-pathologic SGUS (47.3±3.9 vs 50.2±4.2; p=0.03). Significant differences were found in antiRo52 positivity and hypergammaglobulinemia. Bivariate analysis showed that menopause at younger age confers higher probability

of presenting pathologic SGUS (OR=1.2 CI95% 1.02-1.41) and smoking was protective against pathologic SGUS (OR=0.32 CI95% 0.11-0.95). Hypergammaglobulinemia (OR=8.80 CI95% 2.27-34.02) and antiRo52 (OR=3.89 CI95% 1.14-13.20) imply an increased risk of pathological findings on SGUS.

Conclusion: Pathologic SGUS was more frequent in patients with definitive diagnosis of pSS, antiRo52 antibodies and hypergammaglobulinemia. Late menopause and smoking were protective factors against pathologic SGUS, and a tendency for a varied diet and absence of exposure to environmental chemicals. SGUS could be the initial diagnostic test in patients with suspected pSS and positive antiRo who have less exposure to estrogens, tobacco and mediterranean diet and greater exposure to chemicals. For this reason, SGUS could be useful in identifying modifiable environmental risk factors to decrease the incidence and severity of this disease, for which effective therapy is still lacking.

POS0784 LOW COMPLEMENT LEVELS ARE ASSOCIATED WITH HIGHER MORTALITY IN HOSPITALIZED PATIENTS WITH POSITIVE ANTIPHOSPHOLIPID ANTIBODIES

E. Itelman[1], M. Perelman[1], D. Kent[1], N. Bibar[1], G. Segal[1], L. Negru[1], A. Dagan[2]. *[1]Sheba Medical Center, Internal Medicine Ward "T", Ramat Gan, Israel; [2]Wolfson Medical Center, Rheumatology Unit, Holon, Israel*

Background: Antiphospholipid Syndrome is an autoimmune disease characterized by increased risk for vascular thrombosis (arterial and/or venous) thrombosis and/or pregnancy morbidity in the presence of antiphospholipid antibodies. The mechanisms by which aPLs induce thrombosis are unclear; several have been suggested, among them complement activation.(1-2) The complement system is a system of enzymes and regulatory proteins of the innate immune system that play a crucial role in the inflammatory response to various pathogenic stimuli. The complement and coagulation pathways are interconnected, and expanding evidence indicates that complement may be activated in patients with antiphospholipid syndrome (3-5).

Objectives: Our study was intended to better characterize the complicated relations between antiphospholipid antibodies and complement activation among hospitalized patients with antiphospholipid syndrome and its impact on short- and long-term prognosis

Methods: A retrospective cohort studies. Clinical and prognostic data of hospitalized patients with antiphospholipid syndrome and a measurement of complement levels (C3 or C4) were obtained. Rates of long-term mortality, one-year mortality, deep vein thrombosis (DVT), and pulmonary emboli (PE) were compared between patients with low complement levels and patients with normal complement levels. Low complement was defined as C3 < 90 mg/dl or C4 < 10 mg/dl. A multivariate analysis was performed to control for Anticardiolipin levels, β_2 macroglobulin levels and RVVT ratio.

Results: Complete data was available for 6,599 patients, of which 712 (11%) had low complement levels. The median age of the cohort was 47.7, and most of the patients were females (56%). Patients with low complement levels had significantly higher mortality rates 30% vs. 18%, p < 0.001 for long-term mortality (Figure 1) and 15% vs. 5%, p < 0.001 for 1 year mortality when compared to patients with normal complement levels. DVT and PE rates were similar (4% vs 3.8%, P = 0.78 and 4% vs 2.4%, P = 0.13 respectively). Results of the multivariate analysis (Table 1) were consistent and showed that patients with low complement levels had 111% higher mortality rates (CI 1.52-2.90, P < 0.001).

Table 1. Multivariate Analysis for long term mortality

Multivariate Analysis		
	OR (CI)	p
Low Complement	2.11 [1.52, 2.90]	<0.001
Anticardiolipin IGG	1.00 [1.00, 1.01]	0.243
Anticardiolipin IGM	0.99 [0.98, 1.00]	0.084
β_2 IGM	1.01 [1.00, 1.01]	0.017
β_2 IGG	1.00 [0.99, 1.00]	0.663
RVVT Ratio	0.99 [0.63, 1.52]	0.954

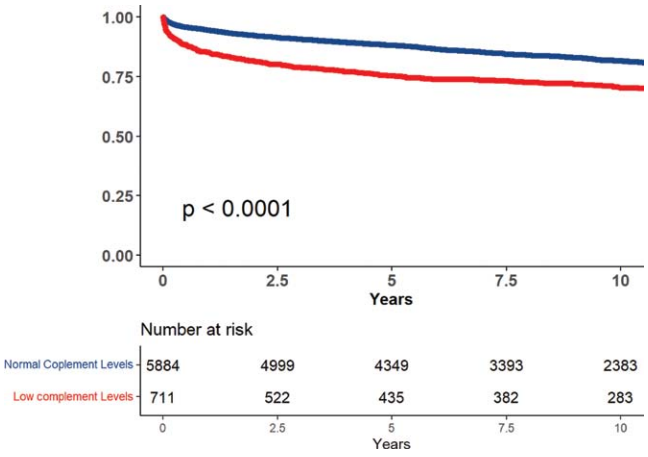

Figure 1. Cumulative 10-Year survival

Conclusion: In hospitalized patients with high aPLs, low complement levels are associated with significantly higher mortality rates. This finding is in correlation with recent literature, suggesting an important role for complement activation in APS.

POS0785 EXPRESSION OF MYXOVIRUS RESISTANCE PROTEIN A IN LUPUS NEPHRITIS

L. Liu[1], K. De Leeuw[1], G. Diercks[2], C. Stegeman[3], B. Doornbos- van der Meer[1], H. Van Goor[2], M. Heuvel[2], J. Westra[1]. *[1]University Medical Centre Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Centre Groningen, Department of Pathology, Groningen, Netherlands; [3]University Medical Centre Groningen, Department of Internal Medicine, Division of Nephrology, Groningen, Netherlands*

Background: Lupus nephritis (LN) is regarded as one of the most severe organ manifestations of systemic lupus erythematosus (SLE) [1]. It has been shown that type I interferons (IFN) are important cytokines in the pathogenesis of SLE and LN and could possibly serve as a histological marker for kidney lesions in LN [2]. However, the direct measurement of type I IFN protein in tissues has remained elusive. Myxovirus resistance protein A (MxA) which is upregulated by IFN-1, can easily be measured, and could be used as a potential biomarker. In addition, dendritic cells are main producers of IFN-1.

Objectives: To investigate the expression of MxA and CD303 which is a plasmacytoid dendritic cells (pDCs) specific marker [3] by immunohistochemical analysis of renal specimens obtained from LN patients and from patients with other types of nephritis.

Methods: LN was diagnosed based on the International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification. In total, 41 renal tissue samples were collected from lupus nephritis including all classes (I-V according to ISN/RPS classification), and compared to 70 biopsies from other forms of nephritis. MxA was detected by immunohistochemistry staining. Scoring of MxA staining was done semi-quantitative for separate structures in nephritis tissues with a range from 0 to 3+. Scoring was based on the intensity of the staining, in which '0' meant no expression; '1': weak expression; '2': moderate expression; and '3+': strong expression. The expression of CD303 was measured by counting the number of CD303 positive cells in the glomerulus or in the tubular interstitium.

Results: The MxA average scores of the total LN group were higher than control specimens especially in distal tubules (Figure 1). The MxA expression in LN

classes I, II, and V biopsies was mainly increased compared to tissues of patients with minimal change disease, mesangioproliferative nephritis, and membranous nephropathy (Figure 2a,2b,2d). However, MxA staining was comparable in LN classes III/IV compared to control groups (Figure 2c). The staining of CD303 showed that pDC are more present in tubular interstitium than in glomeruli. Furthermore, CD303-positive cells were highest in LN class IV, but overall numbers of pDCs were higher in controls groups compared to LN groups (Figure 3).

Conclusion: Our data indicate that MxA expression is higher in LN vs. other types of nephritis. These results suggest that MxA could be a potential additional histological marker to establish the diagnosis of lupus nephritis on the kidney biopsy. In contrast to the increased expression of MxA in LN, we found decreased numbers of pDCs. Therefore, it is important to investigate which other cells are the main producers of IFN-1 in further studies.

POS0786

IDENTIFYING INDIVIDUALS AT RISK FOR SJÖGREN'S SYNDROME – THE PRE-SJÖGREN SYNDROME TARGETED IMMUNOLOGY EVALUATION (PRESTIGE) STUDY

S. Zenz[1], L. Erlacher[1], E. Windisch[1], B. Dreo[1], P. Javorova[1], A. Lackner[1], M. D'orazio[1], J. Thiel[1], D. Cornec[2], M. Stradner[1]. [1]*Medical University of Graz, Department of Rheumatology and Immunology, Graz, Austria;* [2]*University of Brest, Department of Rheumatology, Brest, France*

Background: Primary Sjögren's Syndrome (pSS) is a chronic autoimmune disease. Symptoms range from sicca to systemic, potentially life-threatening organ damage. Little is known about the onset of the disease. Anti-Ro antibodies are described to develop years before the first symptoms. In addition, first degree relatives of pSS patients have an 11- to 19- fold increased risk of developing pSS themselves.

Objectives: To identify and follow-up individuals at risk for pSS in order to study symptoms and immune pathology before and at development of pSS.

Methods: In this ongoing long-term study individuals at risk for developing pSS but not fulfilling the ACR-EULAR classification criteria of pSS were included, defined as: 1.) Anti-SSA positive individuals (Anti-SSA$^+$) without any sicca symptoms or diagnosis of an underlying systemic autoimmune disease; 2.) First degree relatives of patients (relatives) with an established diagnosis of pSS and typical autoantibodies (ANA ≥ 1:160 and/or anti-SSA$^+$ and/or rheumatoid factor$^+$); 3.) Individuals with at least one feature of the ACR-EULAR classification criteria for pSS, but not fulfilling the criteria (incomplete). At baseline and at annual visits, demographic data, blood, saliva and urine samples were collected and stored. Salivary and lacrimal flow, salivary gland ultrasonography (SGUS), and patient-related outcome measures were analysed. A lip salivary gland biopsy was performed at baseline and upon development of symptoms suggestive of pSS. The primary endpoint was the development of definite pSS according to the ACR-EULAR classification criteria.

Results: After the first year of recruitment, 50 individuals (Anti-SSA$^+$ n=27, relatives n=21, incomplete n=2) were screened at baseline, of whom 28 were identified as individuals at risk for pSS and were included in the study. Twenty-two individuals were excluded from the study, most of whom were "relatives" with negative autoantibodies. Of these 28 individuals at risk, 89% were female (n=25), they had a median age of 53 years (IQR: 19) and 57% (n=16) had positive antinuclear antibodies. 86 percent were positive for anti-SSA and 14% were positive for anti-SSB. Decreased complement C3 and C4 were found in 18% and 4%, respectively. Serum IgG concentration was elevated in 29% of individuals. A reduction of lacrimal flow was found in 29% and stimulated whole salivary flow was reduced in 29%. The median of the ESSPRI was 1.6 (3.0). Eight-teen percent of the investigated individuals had a pathological ultrasound [Hocevar score median 4,5 (9,0)] and in 9% a focus score ≥ 1 [median 0.15 (0.57)] was found in the lip salivary gland biopsies. Four patients (14%) met the primary endpoint and were diagnosed with pSS within the first year.

Conclusion: The design of the PRESTIGE study allows us to follow individuals at risk for pSS and will help to unveil symptoms and immune pathology as pSS develops. We suggest to establish a larger international pre-pSS cohort to increase statistical power.

POS0787

THE EFFECT OF ANTI-RIBOSOMAL-P AND ANTI-NR2 ANTIBODIES ON FUNCTIONAL BRAIN MRI NETWORKS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH DEPRESSION AND BEHAVIORAL COGNITIVE DISORDERS.

E. Chessa[1], M. Piga[1], M. Porcu[2], E. Pintus[3], A. Perra[3], C. Serafini[1], A. Floris[1], M. Congia[1], M. M. Angioni[1], M. G. Carta[3], L. Saba[2], A. Mathieu[1], A. Cauli[1]. [1]*University and AOU Cagliari - Rheumatology Unit, Department of Medical Sciences and Public Health, Monserrato, Italy;* [2]*Azienda Ospedaliero Universitaria (A.O.U.), Department of Radiology, Cagliari, Italy;* [3]*University of Cagliari, Department of Health Sciences and Public Health, Cagliari, Italy*

Background: Cognitive dysfunction (CD) and mood disorders (MD) are among the most frequent neuropsychiatric (NP) events in Systemic Lupus Erythematosus (SLE), but their pathogenesis has not been clarified yet. Until now, an unquestionable correlation between the presence of specific autoantibodies, brain alterations and the presence of CDs and MDs in SLE is lacking.

Objectives: The primary aim of the study was to explore the effects of anti-NR2 (anti-DWEYS) and anti-ribosomal-P (anti-P) antibodies on CDs and MDs and their relation with functional brain connectivity in patients affected by SLE.

Methods: A cross-sectional study was conducted, between April 2019 and February 2020, including adult patients who fulfilled the ACR/EULAR 2019 SLE criteria. Demographics, ongoing medications, SLEDAI and SLICC/Damage Index were recorded. Serum level quantification for anti-P (normal values <18 U/ml) and anti-NR2 (normal values <0.5 OD) antibodies were performed using an ELISA. A battery of neuropsychological testing was interpreted by a neuropsychologist, exploring cognitive domains, depression and quality of life. A resting-state functional connectivity (rs-fc) MRI analysis was performed within 2 weeks since the neuropsychological status assessments. Two region

of interest to region of interest (ROI-to-ROI) analyses with the graph theory was performed.

Results: Thirty-three SLE patients (9% male) were enrolled, mean age 43.5 (+-14) years, and median disease duration of 10.4 years (IQR 2.9-25.4) (Table 1). Anti-P were positive (range 0-255 U/ml) in 6 patients (18.2%) and anti-DWEYS (range 0-1.8 OD) in 14 (42.4%). Nineteen out of 33 patients (57.6%) showed at least a cognitive test alteration, but no significant association with antibodies was found. Depression was found in 14 (42.4%) patients using the Center for Epidemiologic Studies Depression Scale (CES-D) as screening instrument. In multiple regression backward models, after correction for age, disease duration, SLEDAI and SDI, the CES-D showed an independent association with anti-P titre (β= 0.32 per U/ml; p=0.049) and prednisone daily dose (β=0.38 per mg/day; p=0.023). The rs-fc MRI analysis revealed a statistically significant association between the titre of anti-P and many altered properties of the brain ROIs (Figure 1), but no effects of PDN daily dose on specific cerebral networks.

Table 1. Demographic and clinical characteristics of the patients in total, Legend: PDN: Prednisone; LLDAS: Lupus Low Disease Activity State; OD: Optical density

Demographic and clinical characteristics of the participants	(N=33)
Age, years mean (DS)	43.5 (14.0)
Gender (M, %)	3 (9%)
Disease duration, months median (IQR)	124.4 (34.7-305)
SLEDAI-2k mediane (IQR)	4 (0-14)
Dose PDN mg/daily median (IQR)	6.4 (3.8-13.5)
LLDAS N, %	12 (36,4%)
SLICC-DI mediane (IQR)	0 (0-1)
Ongoing treatment	25 (75.8%)
Hydroxychloroquine	30 (90.9%)
Immunosuppressive	9 (27.3%)
Biologics	
Education less than 8 years	13 (39.4%)
Anti-Rib-P N, %	6 (18.2%)
Anti-Rib-P (U/ml) mean (DS)	10.9 (5.7-13.3)
Anti-DWEYS N, %	14 (42.4%)
Anti-DWEYS (OD) mean (DS)	0.4 (0.25-0.67)
Anti-phospholipids N, %	11 (33.3%)
anti-dsDNA N, %	18 (54.5%)
anti-dsDNA Titre mediane (IQR)	22.5 (2.9-74.5)

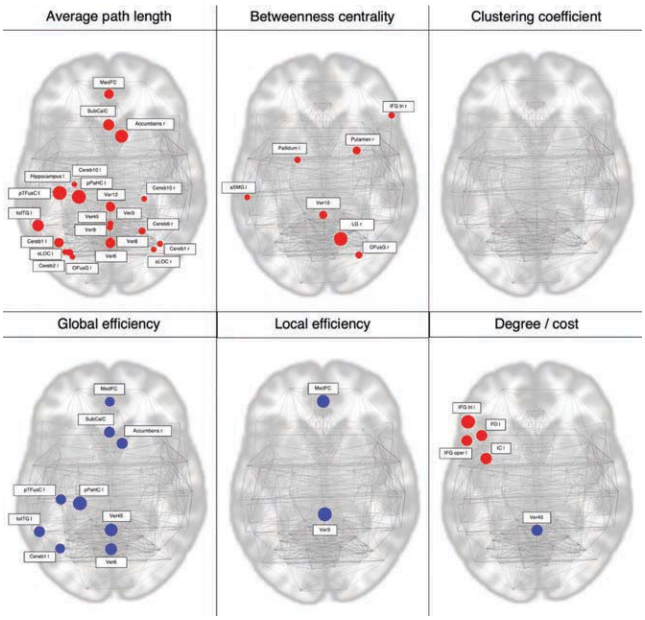

Figure 1. Results of rs-fc MR Analysis 1 (effects of Anti-rib-P titre) on cerebral networks. The regions with decreased and increased property are shown in blue and red nodes, respectively (p< 0.01). The node size represents the significance of the between-group differences in the nodal degree.

Conclusion: Anti-P antibodies are associated with depressive symptoms and changes of brain network properties in SLE patients, which add knowledge on their pathogenetic effect.

POS0788

DISTINCT CYTOKINE/CHEMOKINE PROFILE IN SJÖGREN'S SYNDROME IS ASSOCIATED WITH DISEASE ACTIVITY AND CLINICAL MANIFESTIONS

C. Perricone[1], R. Bursi[1], G. Cafaro[1], R. Ilenia[1], S. Calvacchi[1], E. Marcucci[1], S. Cipriani[1], O. Bistoni[1], R. Gerli[1], E. Bartoloni Bocci[1]. [1]*University of Perugia, Rheumatology, Department of Medicine and Surgery, Perugia, Italy*

Background: Sjögren's syndrome (SjS) is an autoimmune disease of unknown aetiology. Several cytokines, chemokines and collagenases have been implicated in the pathogenesis of the disease. Nonetheless, biomarkers of diagnosis, outcome and response to treatment are still lacking.

Objectives: We aimed at evaluating potentially pathogenic cytokines/chemokines in a monocentric cohort of SjS patients.

Methods: Sera were drawn from SjS patients classified according to 2016 ACR/EULAR criteria and 23 cytokines/chemokines (CCL2/MCP-1, IP-10/CXCL10, Flt3 Ligand, IFNa2, IL6, IL7, IL12, IL13, IL15, IL17A, TNFa, IL-1Ra, CXCL13, IL21, IL23, IL33, TSLP, IL-2RA, IL1RII, TNFRII, BAFF, CCL19/MIP-3B 66, MMP-8) were quantified using Luminex multiplex immunoassay (BioRad- BioPlex 200 System-Luminex-Map technology R&D Systems, USA) following the manufacturer's instructions and customized procedures. Data were acquired using Bioplex manager v 6.1. P value ≤ 0.05 was considered significant. Data were analyzed using GraphPad Prism V.8 (GraphPad Software, Inc.) software.

Results: Clinical and demographic features of 21 SjS patients are reported in Table 1. Our main findings were that several cytokines positively correlated with indexes of disease activity. Particularly, we observed a correlation between IL-2RA and ESSDAI (r=0.602, P=0.005) and between IL-12p40 and ESSPRI (r=0.674, P=0.016) (Figure 1). Levels of IL-17A seem to be influenced by age (r=0.622, P=0.039) and showed a trend towards a positive correlation with labial salivary gland biopsy focus score (r=0.942, P=0.058). The only patient with cryoglobulins was the male who showed levels of BAFF/BLyS >20x higher than the remaining 20 females (43.4 ng/ml vs 1.8±1.6 ng/ml).

Table 1.

	N	%
Sex	1M/20F	4.8/95.2
Age (years, mean±SD)	53.43±12.27	
disease duration (months, mean±SD)	30.29±10.47	
ESSDAI (mean±SD)	2.20±2.40	
ESSPRI (mean±SD)	4.18±2.12	
Global dryness VAS (0-10) (mean±SD)	5.00±2.32	
VAS fatigue (0-10) mean±SD)	4.00±2.39	
VAS pain (0-10) (mean± SD)	3.48±3.28	
Dry mouth	15	71.40
Dry eyes	17	81
Parotid Gland Swelling	4	19

Salivary Gland Biopsy Focus Score (Mean±SD)	1.99±1.45	
Hydroxychloroquine	5	23.8
Immunosuppressant	1	4.7

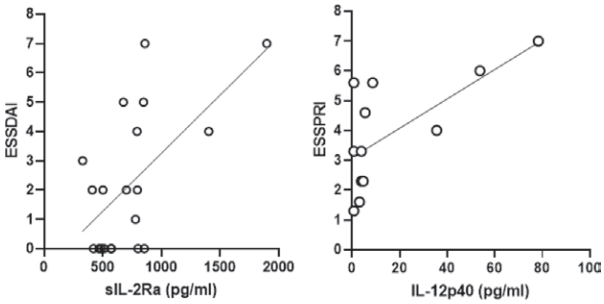

Figure 1.

Conclusion: For the first time we suggest the potential usefulness of IL-2RA as a marker of disease activity in SjS. Notably, IL2RA has been used as a marker to identify CD4+FoxP3+ regulatory T cells. So far, it is known that T follicular helper (Tfh) cell differentiation is inhibited by IL-2 while regulatory T cell differentiation and survival depend on it. Nonetheless, Wing et al. (1) described a CD25- subpopulation within human PD1+CXCR5+Foxp3+ Tfh cells preferentially located in germinal centers which is reduced by the presence of IL-2, possibly explaining the association with disease activity. IL-12p40 is known to have a pathogenic role in SjS (2) and we suggest that it may represent a complementary tool in the evaluation of patients' symptoms. The presence of high levels of IL-15 in SjS is not novel and associated with T cell migration and proliferation in germinal centers. Finally, the observation of very high BAFF/BLyS levels in the male with cryoglobulins will require further analysis.

POS0789 CLINICAL FEATURES OF SJÖGREN'S SYNDROME WITH AND WITHOUT NEUROLOGICAL INVOLVEMENT (NEURO-SJÖGREN)

T. Seeliger[1], E. Kramer[2], F. F. Konen[1], S. Beider[2], A. Jablonka[2], T. Witte[2], T. Skripuletz[1], D. Ernst[2]. *[1]Medizinische Hochschule Hannover, Neurology, Hannover, Germany; [2]Medizinische Hochschule Hannover, Rheumatology and Immunology, Hannover, Germany*

Background: Sjögren's Syndrome is well known for its characteristic sicca symptoms due to autoinflammatory destruction of the salivary and lacrymal glands, but neurological involvement is also common in this entity. Nevertheless, previously published smaller studies suggested distinct clinical features for Sjögren's syndrome with and without neurological involvement, such as a more balanced gender distribution and lower IgG levels in patients with Sjögren' syndrome and neurological involvement[1,2].

Objectives: We therefore aimed to systematically assess clinical features of patients with Sjögren's syndrome with and without neurological involvement, find relevant in-between group differences and hereby aid early detection of both patient groups in the clinical routine to facilitate further studies, potentially with new therapeutic approaches.

Methods: We retrospectively assessed patients with Sjögren's syndrome treated at the neurological and rheumatological/ immunological departement of our university hospital between 05/2014 and 09/2021 for available laboratory and clinical data. The displayed data represent preliminary results of this ongoing study.

Results: 405 patients, who fulfilled the current ACR/EULAR classification criteria for Sjögren's syndrome[3] were currently included in the study (median age 59years [IQR 50-70 years], median ESSDAI 10 [IQR 3-16]). 228 patients (56%) showed neurological involvement. They were significantly more often male (32% vs. 14%; p<0.001) and showed lower IgG serum levels (median 11 g/l [IQR 9-13 g/l] vs 12 g/l [IQR 10-16 g/l], p<0.01) in comparison to patients with Sjögren's syndrome but without neurological involvement. However, presence of objective xerostomia, objective xerophthalmia, SSA(Ro)-antibody-positivity or sialadenits grade 3 or 4 (Chisholm and Mason) on salivary gland biopsy did not differ between the two groups.

Conclusion: Preliminary analysis of this ongoing study supports the hypothesis, that patients with Sjögren's syndrome and neurological impairment might express a distinct clinical phenotype in comparison to patients with Sjögren's syndrome but without neurological involvement.

POS0790 18F-FLUORODEOXYGLUCOSE (FDG) PET-CT IMAGING OF SALIVARY GLANDS IN PRIMARY SJÖGREN'S SYNDROME AND ITS CORRELATION WITH ULTRASONOGRAPHIC SCORES AND SALIVARY FLOW RATE COMPARED TO HEALTHY CONTROLS

K. Abacar[1], T. N. Kıssa[2], K. Oksuzoglu[2], T. Ones[2], G. Mumcu[3], G. Bruyn[4], N. Inanc[1]. *[1]Marmara University School of Medicine, Rheumatology Department, Istanbul,Turkey; [2]Marmara University School of Medicine, Nuclear Medicine Department, Istanbul,Turkey; [3]Marmara University School of Health Sciences, Health Management, Istanbul,Turkey; [4]Reumakliniek Lelystad, Rheumatology, Lelystad, Netherlands*

Background: The use of salivary gland imaging modalities in patients with primary Sjögren's syndrome (pSS) has been increasing recently. The contribution of each imaging method in terms of diagnosis or disease activity differs from each other. Although ultrasound and MRI are the most commonly used imaging modalities, the role of PET-CT for diagnosing pSS and determining glandular and extraglandular involvement has largely been neglected.

Objectives: This study aimed to compare the sizes and metabolic activities of the major salivary glands in patients with pSS and healthy controls (HC). Correlation of the ^{18}F-FDG PET-CT uptake characteristics with ultrasound scores and salivary flow rates of the patients and HC was also determined.

Methods: 22 patients with pSS and 10 age/sex-matched HC were included in the study. The sizes and FDG uptakes of the parotid and submandibular glands of pSS patients and HC were assessed by PET-CT. The maximum standardized uptake value (SUVmax) was evaluated for FDG uptakes, and each patient's liver uptake and salivary gland uptake ratio were calculated. In addition, correlations of gland sizes and FDG uptakes in PET-CT with OMERACT and Hocevar ultrasound scores, stimulated and unstimulated SFR, ESSPRI dryness scores and disease durations of pSS patients were calculated by Spearman test.

Results: The mean age (SD) of the patients was 58.6 years (10.5) versus 58.6 years (19.1) of HC; the mean (SD) disease duration was 8.96 (8.77) years. ANA was positive in all patients, anti-SSA positivity was present in 82.6%, and 30.4% of patients experienced ≥1 parotid swelling episode. Compared to HCs, the mean size of both submandibular glands (p=0.006 for left and p=0.032 for right) and SUVmax of the left submandibular gland (p=0.044) were significantly smaller in patients with pSS. In pSS patients, both right and left parotid sizes were smaller and SUVmax uptake was greater than in HC; these differences however did not reach statistical significance. When the PET-CT involvement characteristics of the patients were compared with the salivary gland ultrasonography scores, there was a statistically significant negative correlation between the left parotid gland size in PET-CT and the ultrasonographic inhomogeneity of Hocevar score and OMERACT score. There was a statistically significant negative correlation between right parotid gland size measured on PET-CT with ultrasonographic inhomogeneity, hyperechoic foci, parenchymal echogenicity, Hocevar total score, and OMERACT score. No statistically significant correlation was found between SUVmax scores detected by PET-CT and ultrasound scores in both parotid glands and submandibular glands. A statistically significant positive correlation was found between the total gland size measured in PET-CT and the unstimulated salivary flow rate (p=0.038, r=0.604). There was a negative correlation between total gland size and ESSPRI dryness scores and symptom duration, which did not reach statistical significance.

Conclusion: PET-CT SUVmax measurements do not provide sufficient information for pSS-related involvement of the major salivary glands. Secondly, size measurement of the parotid glands by PET-CT is associated with OMERACT ultrasound scores, and also the sizes of both submandibular and parotid glands are smaller than HC.

POS0791 A NATIONWIDE STUDY OF OCULAR MANIFESTATIONS AMONG HOSPITALIZED PATIENTS WITH GIANT CELL ARTERITIS

P. Therkildsen[1,2], A. De Thurah[1,2], M. Faurschou[3], B. Baslund[3], I. Hansen[1,2], M. Nørgaard[2,4], B. Dalsgaard Nielsen[5], E. M. Hauge[1,2]. *[1]Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark; [2]Aarhus University, Department of Clinical Medicine, Aarhus C, Denmark; [3]Copenhagen University Hospital, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; [4]Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus N, Denmark; [5]Horsens Regional Hospital, Department of Internal Medicine, Horsens, Denmark*

Background: Ocular manifestations are common among patients with giant cell arteritis (GCA). Most feared is a permanent visual impairment reported in up to 15-20% of GCA patients[1]. Estimates of ocular manifestations vary significantly between studies, and large, nationwide studies are currently lacking. In GCA, visual impairment has been associated with high and low inflammatory markers[2]. Also, low-dose aspirin treatment has been associated with a reduced risk of visual impairment in patients with GCA[3], but the evidence remains sparse.
Objectives: To investigate the risk of ocular manifestations among hospitalized patients with GCA. Furthermore, to investigate the association between inflammatory marker levels and low-dose aspirin treatment with the risk of ocular manifestations.
Methods: A Danish, nationwide, register-based cohort study including 14,574 incident GCA patients diagnosed between 1996 and 2018, and 145,740 general population referents, matched on age, sex, and calendar time. Ocular manifestations were defined as retinal vascular occlusions, disorders of opticus, visual impairment, diplopia, and amaurosis fugax. We tabulated characteristics of the GCA and reference cohort at the time of diagnosis including ocular manifestations recorded within one year of the GCA diagnosis. Regression analyses for incident ocular manifestations were performed using a pseudo-observational approach with the index date defined as the date of the GCA diagnosis. Cumulative incidence proportions (CIPs) and relative risks (RRs) of incident ocular manifestations with 95% confidence intervals (CIs) were calculated with death as a competing risk.
Results: Within one year of the diagnosis, 1,026/14,574 (7%) of GCA patients were registered with ocular manifestations with 392/1,026 (38%) being prior to and 634/1,026 (62%) after the GCA diagnosis, and 744/1,026 (73%) were registered within one month of the diagnosis. A total of 336/1,026 (33%) were retinal vascular occlusions, 300/1,026 (29%) disorders of the opticus nerve, 177/1,026 (17%) visual impairment, 90/1,026 (9%) diplopia, and 123/1,026 (12%) amaurosis fugax. The CIP of ocular manifestations among GCA patients was 4.0% (95% CI: 3.6-4.3), 4.2% (95% CI: 3.9-4.6), and 4.6% (95% CI: 4.2-4.9) after 3, 6, and 12 months following the diagnosis with a 1-year RR of 28.0 (95% CI: 24.0-32.7) compared to the general population. Age above 70 years, male sex, and a positive temporal artery biopsy were associated with an increased 1-year RR of incident ocular manifestations. Neither treatment with low-dose aspirin nor baseline CRP nor ESR levels was related to the risk of ocular manifestations.
Conclusion: In GCA, most cases of ocular manifestations occur at the time of diagnosis with over one-third of cases occurring prior to the diagnosis, emphasizing the need for early recognition and treatment. Low-dose aspirin treatment was not associated with a reduced risk of ocular manifestations among patients with GCA.

POS0792 PULMONARY ARTERY INVOLVEMENT IN BEHCET'S DISEASE: SINGLE CENTER RESULTS

O. Ozdemir Isik[1], S. Şan[1], D. Temiz Karadağ[1], A. Yazici[1], A. Cefle[1]. *[1]Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey*

Background: Behcet's disease (BD) is a multisystem inflammatory vasculitis. Skin, mucosa, eye, vascular area, joint, gastrointestinal system and central nervous system involvement is observed.
Objectives: In this study, we aimed to present the data of patients with pulmonary artery involvement (PAI) followed up with the diagnosis of BD.
Methods: The clinical, demographic and laboratory data of 394 patients with the diagnosis of BD, who were followed up in our rheumatology outpatient clinic between 2000 and 2020, were evaluated retrospectively.
Results: Of the patients followed up with the diagnosis of BD, 44% were female and 56% were male. Oral aphthous ulcers were found in 96%, genital ulcers in 65%, papulopustular lesions in 33%, erythema nodosum in 38%, and pathergy positivity in 47% of the patients. PAI was detected in 3% (n:13) of the patients who were followed up with a diagnosis of BD. 69% of the patients who had PAI were male, and their mean diagnosis age was 27±9, disease duration was 10±4.7 years. Pulmonary artery aneurysm was observed in 62%, pulmonary artery thrombosis (PAT) was observed in 85%, and both conditions were observed in 46% of the patients. Oral aphthous ulcer were found in all patients, genital ulcers in 70%, papulopustular lesions in 23%, pathergy positivity in 39%, and erythema nodosum in 23%. One of the patients with PAI had hereditary thrombophilia and also lower extremity deep vein thrombosis (DVT). Cardiac involvement was in the form of intracardiac thrombus in patients with PAI. Patients with and without PAI were compared in terms of clinical findings. A significant difference was observed in terms of DVT in the lower extremity, venous and cardiac involvement. The relationship between PAI and these involvements was also shown in the regression analysis (Table 1).

Table 1. Comparison of data of patients with and without pulmonary artery involvement

	Pulmonary Artery Involvement (+)	Pulmonary Artery Involvement (-)		
N (%)	N=13	N=381	P	OR (%95 CI)*
Gender Female	4(30)	168(44)	0.341	
Male	13(70)	213(56)		
Family History	2(15)	46(12)	0.664	
Oral Aphthous Ulcer	13(100)	366(96)	1	
Genital Ulcer	9(70)	247(65)	1	
Papulopustular lesion	3(23)	126(33)	0.559	
Erythema Nodosum	3(23)	147(39)	0.385	
Pathergy positivity	5(39)	180(47)	0.738	
Uveitis	-	138(36)	NA	
Retinal Vasculitis	-	11(3)	NA	
Arthritis	1(8)	97(26)	0.200	
Venous Involvement	8(62)	68(18)	***0.001***	7.365(2.33-23.20)
Lower Extremity Deep Venous Thrombosis	6(46)	46(12)	***0.003***	6.24(2.01-19.38)
Peripheral Artery Aneurysm	-	5(1)	NA	
GIS involvement	-	17(5)	NA	
Cardiac involvement	3(23)	4(1)	***0.001***	38.27(5.57-143.25)
Cranial Involvement	-	24(6)	NA	

*Significant data in logistic regression analysis were presented, GIS: Gastrointestinal system

Cranial involvement was not detected in any of our patients with PAI. In subgroup analysis, a significant relationship was observed between PAT and intracardiac thrombus (p=0.001 OR:21.05 95%CI 3.4-130) and lower extremity DVT (p=0.001 OR: 8.79 95%CI 2.58-29.96).
Conclusion: PAI is rare but the most important involvement affecting mortality in BD patients. Recently, there has been an increase in the incidence of isolated PAT with the contribution of the developments in imaging methods.[1] PAI is associated with lower extremity DVT, cerebral venous thrombosis and intracardiac thrombus.[2] In our study, a significant correlation was found between PAI and the presence of venous involvement, lower extremity DVT and intracardiac thrombus.

POS0793 IMPROVED RELAPSE-FREE SURVIVAL WITH THE NORWICH PREDNISOLONE REGIMEN FOR GIANT CELL ARTERITIS

G. Ducker[1], K. Mills[1], C. Yong[1], C. Jones[2], C. Mukhtyar[1]on behalf of the Mukhtyar Vasculitis Working Group. *[1]Norfolk & Norwich University Hospital,*

Rheumatology, Norwich, United Kingdom; [2]Norfolk and Norwich University Hospital, Ophthalmology, Norwich, United Kingdom

Background: Glucocorticoid therapy is the mainstay treatment for GCA. There is no consensus on the dose of prednisolone to be used. Prednisolone regimens used in clinical trials have reported relapse rates of 66 to 92%. The long-term follow-up of Tocilizumab and prednisolone for 1-year showed a relapse rate of 74% at 2 years. The Norwich Regimen is a bespoke prednisolone plan with an initial dose of 1mg/kg of lean body mass. It delivers 164.64 mg/kg of lean body mass in a logarithmic taper over 100 weeks. It was devised to reduce the risk of relapse and allow patients to be in control of their prednisolone reduction.
Objectives: To document drug-free survival at 150 weeks of people with GCA treated with a bespoke prednisolone taper
Methods: All patients were diagnosed by biopsy, ultrasonography or PET scan and provided with a printed prednisolone plan at diagnosis. All individuals were assessed at approximately 3-6 monthly intervals in addition to suspected relapse, toxicity or other need for course correction. Relapses were confirmed objectively using a modification of the Kerr criteria. Relapse free survival was recorded at 100 weeks. Patients were given an open invite to contact us in the event of a suspected relapse after coming off prednisolone. A notes review was done to record events at 150 weeks.
Results: 150 consecutive people with objectively diagnosed GCA (mean age 74) since 10/01/2012 have completed 150 weeks since starting prednisolone. Drug-free, relapse-free survival at 100 weeks was met by 133/150 (89%). 7 individuals died and 20 relapsed. A further 5 died and 15 relapsed by week 150; 103/150 (69%) survivors were in prednisolone-free remission. Of the 12 deaths – 6 died of cancer, 1 subdural haemorrhage, 1 ischaemic bowel, 1 septicaemia, 1 general decline (aged 93). The cause of death was not available for 2 individuals who died in the community. The median time to relapse for the 35 individuals was 80 weeks (IQR 64,109).
Conclusion: We report the first results of a bespoke prednisolone taper to be used in real life. The Norwich Regimen for the treatment of GCA results in drug-free relapse-free survival of 89% at 100 weeks and 69% at 150 weeks, which is superior to all other reports published so far.

Background: Takayasu arteritis (TAK), a granulomatous large vessel vasculitis, mainly involves the aorta and its proximal branches and commonly occurs in young females. However, studies of pregnancy in women with TAK are sparse and limited, probably due to the rarity of the disease.
Objectives: The purpose of this study was to understand the status quo of medical treatments of the primary disease and outcomes of pregnancy in patients with TAK, and birth outcomes of the children in Japan.
Methods: Patients with TAK who conceived after the onset of the disease and were managed at medical facilities participating in the Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS) were retrospectively enrolled in this study. The following information was collected from patients who had a live-born baby: age at diagnosis of TAK, disease classification, age at delivery, treatments before and during pregnancy, complications during pregnancy, birth outcomes of the children, and changes in disease activity during pregnancy and after delivery.
Results: Fifty-one cases and 69 pregnancies from 19 ethics committee-approved centers were enrolled during the study period 2019–2021. Of these, 49 cases and 66 pregnancies (95.7%) resulted in delivery and live-born babies. The Numano classification of the 49 cases was as follows: type I, 11; type IIa, 15; type IIb,12; type III, 1; type IV, 1; type V, 9; with type IIa being the most common. The age of diagnosis was 22 years (13–37 years, year of diagnosis 1965–2017), the median age of the delivery of 66 pregnancies was 31 years (year of delivery 1969-2021), and the median duration of illness at delivery was nine years. There were 34 planned pregnancies (51.5%, including four pregnancies by artificial insemination/ovulation induction). Preconception therapy included prednisolone (PSL) in 51 pregnancies (77.3%, median dose 7.5 mg (range 4–30 mg)/day), immunosuppressive drugs in 18 pregnancies (27.3%, azathioprine 8, tacrolimus 7, methotrexate 4, cyclosporin A 1, and colchicine 1), biologics in 12 pregnancies (18.1%, infliximab 6, tocilizumab 5, and adalimumab 1), antihypertensive drugs in 5 pregnancies (7.6%). Surgical treatment had been performed before pregnancy in 6 cases (aortic root replacement 2, subclavian artery dilatation 1, subclavian artery bypass 1, subclavian artery stenting 1, and ascending aorta semicircular artery replacement 1). Medications used during the course of pregnancy included PSL in 48 pregnancies (72.7%, median dose 8 mg (range 4–30 mg)/day, increased in 13 pregnancies, decreased in 1 pregnancy), immunosuppressants in 13 pregnancies (19.7%, azathioprine 6, tacrolimus 6, and cyclosporin A 1), biologics 9 pregnancies (13.6%, infliximab 4, tocilizumab 4, and adalimumab 1). Immunosuppressants and biologics were discontinued in five and four pregnancies after conception. Complications during pregnancy were observed in 20 pregnancies (30.3%), with hypertension being the most common. Complications related to TAK or its treatment were severe infections in two pregnancies and aneurysm enlargement due to increased circulating plasma volume in one pregnancy. Aortic arch replacement was performed after delivery for the latter case. Relapse of TAK was observed in 4 pregnancies (6.1%) during pregnancy and in 8 pregnancies (12.1%) after delivery. One pregnancy resulted in restenosis of subclavian artery for which dilatation procedure was performed prior to the pregnancy. There were 13/66 (19.7%)

preterm infants and 17/59 (28.8%) low birth weight infants; all but one had a birth weight of more than 2,000 g and no had serious postnatal abnormalities. Forty-three (82.7%) of the 52 confirmed infants were breastfeed fully or mixed.
Conclusion: Most of the pregnancies in patients with TAK were successfully delivered while they had low disease activity at a dose of less than 10 mg/day of PSL. Relapse occurred during pregnancy and after delivery in some cases. The babies tended to have low birth weight, but 82.7% of them were breastfed without serious complications.

Background: Epidemiological information on Giant Cell Arteritis (GCA) comes mainly from the Scandinavian countries of northern Europe, which show a higher incidence than the countries of southern Europe. GCA clinical manifestations can be divided into cranial, extracranial, and general syndrome.
Objectives: In a large series of GCA from Spain, we studied **a)** the incidence of GCA, **b)** clinical manifestations, and **c)** comorbidities at the time of disease diagnosis.
Methods: ARTESER is a retrospective epidemiological observational study of GCA promoted by the Spanish Society of Rheumatology in which 26 hospitals participate. The inclusion criteria were: all new patients diagnosed with GCA by a) ACR criteria, b) positive diagnostic test (temporal artery biopsy, temporal artery ultrasound or other relevant imaging techniques) and/or c) investigator's clinical judgment. The patient recruitment period ranged from June 1, 2013 to March 29, 2019. The overall incidence of GCA per 100,000 people ≥50 years for the whole period and the mean annual incidence were evaluated. The clinical variables were collected by reviewing the patient's medical history.
Results: 1675 patients were included. The average annual incidence rate was 7.42 (95% CI: 6.57-8.27). All the cases were older than 50 years, and the age group with the highest annual incidence was that of 80 to 84 years, where it reached a value of 22.63 (95% CI: 22.04 -23.22). The mean annual incidence is higher in women than in men 10.07 (95% CI: 8.74-11.55) vs 4.81 (95% CI 3.84-5.93) (Table 1).

Table 1. General characteristics, comorbidities and clinical manifestations

Epidemiologic, demographic and diagnosis	Men	Women	Total
Gender, n (%)	497 (29.7)	1178 (70.3)	1675
Incidence annual rate (95% CI)	4.81 (3.84-5.93)	10.07 (8.74-11.55)	7.42 (6.57-8.27)
Age at diagnosis, years, mean (SD)	76.9 (8.3)	76.9 (8.0)	76.9 (8.1)
Diagnosis only by ACR Criteria	89 (17.91)	266 (22.58)	355 (21.19)
Diagnosis only with objective tests	73 (14.69)	140 (11.88)	213 (12.72)
Diagnosis ACR criteria + diagnosis objective tests	311 (62.58)	734 (62.31)	1045 (62.39)
Diagnosis by clinical judgment	24 (4.8)	38 (3.2)	62 (3.7)
Comorbidities at diagnosis			
Arterial hypertension, n (%)	330 (66.8)	749 (63.7)	1079 (64.6)
Dyslipidemia, n (%)	238 (48.3)	563 (47.9)	801 (48.0)
Cranial clinical manifestations			
New-onset headache, n (%)	382 (76.9)	955 (81.1)	1337 (79.9)
Visual Clinic, n (%)	194 (39.0)	411 (34.9)	605 (36.1)
Extracranial manifestations and general syndrome			
Polymyalgia rheumatica, n (%)	178 (35.8)	521 (44.3)	699 (41.8)
Asthenia, n (%)	239 (48.1)	634 (53.9)	873 (52.2)
Analysis at diagnosis			
Erythrocyte sedimentation rate mm/h, mean (SD)	72.3 (34.7)	77.4 (33.0)	75.9 (33.6)

The principal clinical characteristics of the population is shown in Table 1, the mean age at diagnosis was 76.9±8.1 years, 1178 (70.3%) were women. 1045 patients (62.39%) had ACR criteria and some positive objective test, 355 patients (21.9%) presented only ACR criteria and 213 (12.72%) only had a positive diagnostic test; 62 (3.7%) of the patients underwent diagnosis based on clinical judgment. The more frequent comorbidity was arterial hypertension (n=1079; 64.6%),

followed by dyslipidemia (n=801, 48%). The predominant cranial manifestation was headache (n= 1337; 79.9%) and 605 patients experienced visual symptoms (36.1%). Polymyalgia rheumatica (n=699; 41.8%) and asthenia (n=837; 52.2%) were the most frequent extracranial and general syndrome manifestation, respectively. Regarding laboratory parameters, the most characteristic data was the increase of ESR (75.9±33.6 mm/1st h).

Conclusion: The mean annual incidence of GCA in Spain, 7.42 (95% CI: 6.57-8.27), is lower than that of the Scandinavian countries. It is higher in people older than 80 years. More than 60% of the patients met the ACR criteria and had a positive diagnostic test. Cranial manifestations constituted the most clinical features. The most frequent clinical manifestations are cranial. Up to a third of patients had visual manifestations.

Background: Glucocorticoids (GC) are the mainstay therapy in Giant Cell Arteritis (GCA), initially at high doses (40-60 mg/day) followed by gradual glucocorticoid tapering. This treatment, especially in older patients, is associated with numerous adverse effects (AE). In addition, there are frequent relapses. Therefore, conventional synthetic immunosuppressants such as methotrexate (MTX), leflunomide, azathioprine, cyclophosphamide or mycophenolate, have been used with controversial results. Studies with biological immunosuppressants, such as TNFi have been ineffective; in contrast, tocilizumab (TCZ) has obtained positive results and was approved for the treatment of GCA.

Objectives: In the ARTESER study we describe **a)** treatment with GC, synthetic or biological immunosuppressants; **b)** AE of CG; and **c)** evolution.

Methods: ARTESER is a retrospective observational study sponsored by the Spanish Society of Rheumatology. 26 Spanish centers participated and all new patients diagnosed with GCA from June 1, 2013 to March 29, 2019 were included. Data on GC and immunosuppressants were collected at the beginning and during the follow-up of GCA patients. For the calculation of the cumulative dose of GC, an application was developed that, by including the periods of time, dose and type of GC received during follow-up, performs the automatic calculation in mg of prednisone.

Results: Of the 1675 patients included, GC treatment was adequately recorded in 1650 patients (Table 1). All received oral treatment, being prednisone the most frequently drug used (N=1602, 97.09%). In addition, 426 (25.82%) patients received at least one iv pulse of methylprednisolone, being the 1000 mg regimen the most frequent (n=217; 50.9%). The total mean duration of GC treatment was 22.65 months. The mean cumulative dose per patient at the end of follow-up was 8514.98 mg of prednisone.

Table 1. Corticosteroid treatment and immunosuppressive treatment

Patients taking oral corticosteroid	1650
Prednisone, n (%)	1602 (97.09)
Methylprednisolone, n (%)	164 (9.94)
Deflazacort, n (%)	64 (3.88)
Patients receiving intravenous corticosteroid, n (%)	426 (25.82)
Mean duration of steroid treatment, mean (SD)	22.65 (17.36)
Mean cumulative dose at the end of follow-up per patient, mg of prednisone, mean (SD)	8514.98 (6570.21)
Methotrexate at diagnosis*, n (%)	165 (9.9)
Leflunomide at diagnosis*, n (%)	2 (0.1)
Azathioprine at diagnosis*, n (%)	3 (0.2)
Cyclophosphamide at diagnosis*, n (%)	7 (0.4)
Mycophenolate at diagnosis*, n (%)	1 (0.1)
Tocilizumab at diagnosis*, n (%)	22 (1.3)
Methotrexate during follow-up, n (%)	532 (31.8)
Leflunomide during follow-up, n (%)	19 (1.2)
Azathioprine during follow-up, n (%)	26 (1.5)
Cyclophosphamide during follow-up, n (%)	10 (0.6)
Mycophenolate during follow-up, n (%)	10 (0.6)
Tocilizumab during follow-up, n (%)	153 (9.1)

The most widely used immunosuppressant was MTX both at diagnosis (n=165; 9.9%) and during follow-up (n=532; 31.8%), followed by TCZ, at diagnosis (22; 1.3%) and at follow-up (153; 9.1%). AE with GC were described in 393 patients (23.8%), highlighting serious infections (n=67; 10.03%) followed by diabetes mellitus (n=63; 9.43%), steroid myopathy (n=53; 7.9%), vertebral fractures (n=47; 7.04%), non-vertebral fractures (n=36; 5.39%), heart failure (n=36; 5.39%), arterial hypertension (n=34; 5.09%) and neuropsychiatric alterations (n=27; 4.04%). During the follow-up, 334 (19.9%) patients had relapses, 532 (31.8%) were hospitalized on some occasion, and 142 patients (8.48%) died. The main cause of death were infections (n=44; 30.99%), neoplasms (n=23; 16.2%), cardiovascular (n=15; 10.56%), and cerebrovascular (n=10; 7.04%).

Conclusion: The main treatment for GCA was oral GC, which were required for almost two years on average, in a quarter of patients associated with IV pulses. The cumulative steroid dose was high as well as the side effects. MTX was the most widely used immunosuppressant and TCZ was prescribed in 10%. Relapses and admissions at the hospital were relatively frequent.
