NUMBER OF PATIENTS WITH PSORIATRIC ARTHRITIS (PSA) IN GERMANY UNTIL 2040: PROJECTION BASED ON DATA FROM 65 MILLION PEOPLE IN THE GERMAN STATUTORY HEALTH INSURANCE

P. Sewerin[1,2], S. Knippschild[3], S. Tulka[3], X. Baraliakos[1], R. Brinks[3]. [1]*Ruhr-Universtiy Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany;* [2]*Heinrich Heine University Düsseldorf, Department for Rheumatology, Düsseldorf, Germany;* [3]*Witten/Herdecke University, Chair for Medical Biometry and Epidemiology, Witten, Germany*

Background: Recently, we have reported an increase in the incidence and prevalence of patients with PsA in Germany based on claim data from 65 million people in statutory health insurance during 2009 to 2012 [1].
Objectives: Population-based estimation of long-term projection for incidence and prevalence of patients with diagnosis of PsA until the year 2040.
Methods: Based on prevalence and incidence of PsA, the number of men and women diagnosed with PsA until 2040 is projected using the illness-death model [2]. The mortality and age distribution of the general population is taken from the official population forecasts of the German Federal Statistical Office. Mortality of patients with PsA was considered by using estimates of the mortality rate ratios [3]. Percent change in projected case numbers refer to 2012 (base year).
Results: Starting from 2012, three scenarios about the incidence of PsA after 2012 were found (Graph 1): (A) increase of 5% per year as observed in [1], (B) no trend in incidence and (C) decrease of a similar 5% per year due to a theoretically anticipated early treatment effect. In scenario C, the number of men and women peaks at about 2028 and decreases slightly afterwards. The graph shows the projected numbers of men (left panel) and women (right) with PsA until 2040 in the three incidence scenarios. The projected numbers and the percent changes are given in the Table 1.
Conclusion: Different scenario may be considered based on recent population data for the incidence course of PsA until 2040. The most optimistic scenario showed a trend of stabilization of incidence including the anticipated population mortality rates. Thus, it is likely that substantially more medical resources for treating patients with PsA are necessary in the next two decades, whereby approaches to the potential prevention of PsA, for example by very early treatment of psoriasis patients, should be further pursued.

NEUROPATHIC PAIN IN PSORIATIC ARTHRITIS: ANALYSIS OF POPULATIONS TREATED WITH ANTI TNF AND ANTI IL17

V. Marino[1], I. Pantano[2], D. Mauro[2], F. Ciccia[2], R. Tirri[2]. [1]*University of Campania "Luigi Vanvitelli", Precision Medicine, Naples, Italy;* [2]*University of Campania "Luigi Vanvitelli", Precision Medicine, Naples, Italy*

Background: Psoriatic arthritis (PsA) is a disease characterized by chronic pain and it is often associated with the presence of fibromyalgia (FMS) with an estimated prevalence of 18%. Several studies demonstrated the central role of neuropathic pain in FMS. However, patients with inflammatory diseases such as PsA frequently complain of complex pain symptoms, with neuropathic characteristics. Therefore, in PsA we can recognize both an inflammatory pain and a neuropathic pain that can be exacerbated both by the concomitant fibromyalgia or depending only on the PsA itself. In fact, In the context of PsA, the presence of neuropathic pain features has been documented in 28% of patients. This could be a reason why the low remission rate in these patients. Finally, Studies on murin models revealed a possible role of IL17, key cytokine of PsA pathogenesis, in mechanism of neuropathic pain.
Objectives: To evaluate the role of anti-TNF and antiIL-17 in neuropathic pain in PsA patients treated with the first biological drug (bDMARDS).
Methods: A cross-sectional evaluation was conducted on 38 PsA patients classified by Classification criteria for Psoriatic Arthritis (CASPAR), referred to the PsA outpatient clinic of "University of Campania Luigi Vanvitelli". Thirty patients were treated with anti-TNF (mean age 53 years, 17F, 13M), 8 were treated with anti-IL17 (mean age 50 years, 5F, 3M), for almost 6 months. For each patient, an assessment of disease activity using DAPSA and physical function was carried out. The presence of comorbid fibromyalgia syndrome (FMS) was evaluated according to ACR 2016 criteria. We investigated neuropathic pain features through the PainDETECT Questionnaire (PDQ).
Results: Nine patients treated with anti TNF were in DAPSA remission; 18 patients had low disease activity, 3 had High disease activity, FMS was detected in 11 of 30 patients, no one in DAPSA remission for PsA. Characteristics of neuropathic pain (PDQ ≥ 19) were found in 13 (43.3%) patients overall; unlikely neuropathic pain (PDQ < 12) in 16 (53.3%) patients. In the first group 7 patients had FMS, in the second group 3 had FMS. So, our analysis revealed the presence of neuropathic pain in 6 patients (54,5%) with PsA treated with antiTNF with no FMS; all of them were in low disease activity. The same analysis was conducted on anti IL17 treated population: 4 patients were in DAPSA remission, 2 patients in low disease activity, 2 patients in high, disease activity. FMS was diagnosed in 3 patients, 1 of them was in DAPSA remission for PsA. PDQ>19 was found only in 1 patient, who had FMS in comorbidity; the others had no neuropathic pain. So, we had no PsA patient treated with antiIL17, that manifested symptoms of neuropathic pain.
Conclusion: The contribute of IL-17 in developing of neuropathic pain suggests the possible role of anti IL17 as therapy; our results support this tesis suggesting a possible role of anti IL17 in treatment of neuropathic pain. A limit to our work is given by the low sample size for which further studies are necessary to confirm this data.

IMPROVEMENT IN CLINICAL DISEASE ACTIVITY AND NO DETERIORATION IN QUALITY OF LIFE IN PSORIATIC ARTHRITIS PATIENTS FOLLOWED FOR 5 YEARS IN A NORWEGIAN OUTPATIENT CLINIC.

M. Wilk[1], S. Brådland[2], B. Michelsen[2], M. Korkosz[1,3], G. Haugeberg[2,4]. [1]*University Hospital, Division of Rheumatology and Immunology, Cracow, Poland;* [2]*Sørlandet Hospital, Department of Medicine, Division of Rheumatology, Kristiansand, Norway;* [3]*Jagiellonian University Medical College, Department of Rheumatology, Cracow, Poland;* [4]*5NTNU, Norwegian University*

of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway

Background: Recent years of progress in conventional and biologic disease-modifying anti-rheumatic drugs development and improved treatment strategies (treat to target) have yield in improved outcome in psoriatic arthritis (PsA) patients. [1,2]. Still, despite modern treatment and clinical monitoring methods, we might miss dimensions of disease burden outside our main focus including quality of life (QoL), which are of high importance from patients' perspective.
Objectives: Main objective of this study was to explore how clinical aspects of disease activity and QoL measures will change in PsA patients in an ordinary outpatient clinic in Norway, followed for 5 years, in the biological treatment era.
Methods: PsA patients fulfilling the CASPAR criteria visiting an outpatient clinic in Norway between January 2013 and February 2020 were consecutively included in the study. Data collection included variables for demographics, treatment, laboratory assessment of ESR and CRP, joint counts, disease activity score in psoriatic arthritis (DAPSA), global assessments – patient's (PGA) and investigator's (IGA), reported joint and global pain, patient reported outcomes (PROMs) regarding different aspects of quality of life (QoL), (MHAQ, RAID, QoL15D and reported fatigue level). Patients were analyzed at baseline and after 5-year follow-up period. Statistics included paired sample t test and McNemar test.
Results: Among 140 PsA patients included at baseline, 114 (81.4%) were re-examined after 5 years. Mean age at baseline was 52 years (95%CI 50.3-53.7) and percentage of women was 50.7%. Proportion of patients treated with biologics increased from 32.9% to 39.5%, but the difference wasn't statistically significant. During the 5 year follow up period most clinical disease activity measures decreased and QoL was maintained (Table 1).

Table 1. Demographic data, clinical activity measures and patient reported outcomes regarding quality of life in PsA patients followed for 5 years. Values are mean (95CI) or number (%).

	Baseline (140)	5-years follow up (114)	p
Age (years)	52.0 (50.3, 53.7)	56.3 (54.4, 58.3)	
Women	71 (50.7%)	56 (49.1%)	
Exercise >1h week	62 (44.3%)	59 (51.8%)	0.28
BMI (kg/m2)	28.4 (27.5, 29.2)	28.2 (27.3, 29.1)	0.89
Current smoker	24 (17.1%)	17 (14.9%)	0.90
Current bDMARD treatment	46 (32.9%)	45 (39.5%)	0.65
DAPSA	18.6 (16.2, 21.0)	12.8 (10.8, 14.8)	<0.01
TJC68	4.1 (3.2, 5.0)	1.8 (1.3, 2.4)	<0.01
SJC66	0.7 (0.5, 0.9)	0.3 (0.2, 0.4)	<0.01
ESR	15.9 (13.9, 18.0)	10.7 (7.8, 13.5)	<0.01
CRP	4.9 (3.5, 6.3)	5.3 (2.5, 8.2)	0.41
IGA (VAS 0-100)	4.1 (3.2, 5.0)	1.8 (1.3, 2.4)	<0.01
PGA (VAS 0-100)	36.6 (32.5, 40.8)	29.3 (25.0, 33.6)	0.12
Global pain (VAS 0-100)	35.1 (31.2, 39.0)	28.9 (24.4, 33.5)	0.42
Joint pain (VAS 0-100)	33.8 (29.9, 37.8)	27.5 (23.2, 31.9)	0.31
MHAQ (0-3)	0.4 (0.4, 0.5)	0.3 (0.3, 0.4)	0.72
RAID (0-10)	3.5 (3.1, 3.9)	3.2 (2.9, 3.6)	0.41
QoL15D (15-75)	24.2 (23.1, 25.2)	22.7 (21.6, 23.9)	0.85
Fatigue (VAS 0-100)	47.8 (41.5, 54.2)	39.1 (32.8, 45.4)	0.16

Conclusion: In our cohort of PsA patients after 5 years follow up disease activity was reduced and QoL maintained. Our data adds to the evidence that the burden of disease in PsA patients has decreased in the biologic treatment era however is still significant. Further improvement in pharmacological and non-pharmacological treatments in PsA patients is still needed.

A NEW SCREENING TOOL FOR PSORIATIC ARTHRITIS IN PSORIASIS PATIENTS: TURPAS

G. Ayan[1], G. Hatemi[2], G. Can[3], M. Bektaş[4], A. Ozdede[5], N. Akdogan[6], B. Yalici-Armagan[6], E. Oksum Solak[7], S. Yazici[8], E. Ozsoy Adisen[9], N. Atakan[6], E. Bulbul Baskan[8], M. Borlu[7], B. Engin[10], V. Hamuryudan[2], M. Inanc[4], S. Kiraz[1], F. Onen[3], S. Ugurlu[2], S. Yayli[11], U. Kalyoncu[1]. *[1]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine Division of Rheumatology, İstanbul, Turkey; [3]Dokuz Eylul University, Medical Faculty, Department of Internal Medicine Division of Rheumatology, Izmir, Turkey; [4]Istanbul University Istanbul Medical Faculty, Department of Internal Medicine Division of Rheumatology, İstanbul, Turkey; [5]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine Division of Rheumatology, İstanbul, Turkey; [6]Hacettepe University Medical Faculty, Department of Dermatology, Ankara, Turkey; [7]Erciyes University Medical Faculty, Department of Dermatology, Kayseri, Turkey; [8]Uludag University Medical Faculty, Department of Dermatology, Bursa, Turkey; [9]Gazi University Gazi Medical Faculty, Department of Dermatology, Ankara, Turkey; [10]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, İstanbul, Turkey; [11]Koc University, Department of Dermatology, İstanbul, Turkey*

Background: Psoriatic arthritis (PsA) is a heterogenous disease with different disease manifestations. Several tools have been developed for screening of PsA in patients with psoriasis with variable performances. An optimal screening tool for PsA is still an unmet need.
Objectives: We aimed to develop a new screening tool in Turkish which could detect different domains involved.
Methods: A core group was determined including 11 rheumatologists/10 dermatologist and a systematic literature review on PubMed until 15 August 2020 using the keyword 'psoriatic arthritis` was performed. The review revealed tools named PEST, PASE, EARP, STRIPP, SIPAS, SIPAT, TOPAS-II, GEPARD, PASQ, CONTEST, A novel, short, and simple screening questionnaire. Each item of those tools were included in the Delphi set. After the 3 rounds of Delphi, a new set of screening questionss was developed.
Results: Overall 85 items were inquired, including questions on joint, dactylitis, enthesitis, back, skin-nail domains as well as morning stiffness, function, treatment and others for the fırst round of Delphi. Seventeen experts (9 dermatologists/ 8 rheumatologists from the core group) and fifteen patients (Female/Male= 9/6) answered the Delphi (mean (SD) age of 39.3 (10.9) participated to the first round. The involvemet types were peripheral (73.4%), axial (40%), entheseal (33.4) and dactylitis was present in 14% of the patients. As a result of this first evaluation, 44 out of 85 questions were selected and carried to second round The distribution of these questions was as follows; joint question n=13, skin and nail involvement n=6, dactylitis n=5, morning stiffness n=5, axial n=3, enthesitis n=2, general questions n=5. These questions were sent to the members through rheumatology and dermatology societies. In total, 85 rheumatology specialists

Table 1. The new screening tool

Domain	Turkish version	English version
Joint	El/ayak parmaklarınızda ya da herhangi bir ekleminizde hiç şişlik veya ağrı oldu mu?	Have you ever had swelling or pain in your fingers/toes or any of your joints?
Dactylitis	Resimde gösterildiği gibi el veya ayak parmağınızda sosis şeklinde şişlik oldu mu?	Have you had a sausage-shaped swelling on your fingers or toes as shown in the picture?
Enthesitis	Topuk ağrınız olur mu?	Do you have heel pain?
Axial involvement and morning stiffness	Belinizde, sırtınızda veya boynunuzda istirahatle artan, özellikle sabaha karşı kötüleşen veya sabahları hareketinizi kısıtlayan ağrınız olur mu?	Do you have pain in your lower back, back, or neck that increases with rest, worsens especially in the morning, or restricts your movement in the morning?
Drug use	Eklem şikayetleriniz için zaman zaman ilaç kullanır mısınız?	Do you take medication for your joint complaints from time to time?
History of rheumatic disease	Size daha önce iltihaplı romatizma tanısı konuldu mu?	Have you ever been diagnosed with a rheumatic disease before?

and 48 dermatology specialists answered the questions in the second round. At the second tour, the number of questions was reduced from 44 to 22. The distribution of the questions was as follows; Skin and nail involvement n=5, dactylitis n=3, joint question n=2, axial involvement n=2, morning stiffness n=2, axial involvement and morning stiffness n=2, enthesitis n=1, general questions n=5. A consensus meeting was held to discuss 22 questions determined at the end of the second round within the initial core group. Each question was handled one by one, some of the questions were combined, if necessary, adapted to Turkish. The tool was given its final form. The final version of the questionnaire consists of 6 questions. (Table 1).

Conclusion: A new screening tool targeting different domains in Psoriatic disease was developed in Turkish. While cultural differences play an important role in screening, we believe that the first tool developed in Turkish will be helpful in clinical practice and research settings. Further assessments will be done to understand its validity and reliability within a large cohort of psoriatic patients.

AB0939 PSORIATIC ARTHRITIS RELATED FATIGUE: WHAT IS THE MAGNITUDE OF THIS PROBLEM AND WHAT ARE THE CORRELATED FACTORS? A CROSS-SECTIONAL STUDY.

A. Martins[1,2], D. Santos Oliveira[1,2,3], F. R. Martins[4], B. Samões[5], R. Nicolau[6], F. Oliveira Pinheiro[1,2], M. Rato[1,2], S. Pimenta[1,2], M. Bernardes[1,2], L. Costa[1]. *[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal; [3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; [4]Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal; [5]Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology Department, Vila Nova de Gaia, Portugal; [6]Centro Hospitalar Tondela-Viseu, Rheumatology Department, Viseu, Portugal*

Background: Fatigue is a common constitutional feature and has a significant impact on *quality of life* in patients with chronic inflammatory rheumatic diseases, such as psoriatic arthritis (PsA). It is a complex phenomenon and its pathogenesis remains unclear. Despite being a common symptom, it is largely ignored and rarely assessed in clinical practice.

Objectives: This study aims to evaluate the incidence and severity of fatigue in PsA patients under biological agents and to assess the influence of several clinical and demographic features on PsA related fatigue.

Methods: We conducted a cross-sectional study including patients with PsA, according to CASPAR criteria, treated with biological agents, from our University Hospital and registered in the national database (reuma.pt). Fatigue was assessed by a 13-item self-administered questionnaire (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F]). Data collected and analyzed included: demographic data, disease activity data, functional status, comorbidities and therapies. Student's t-test, ANOVA and Pearson's correlation were performed to compare data, as appropriate. A p-value <0.05 was considered statistically significant.

Results: 60 PsA patients were included, 61.7% were males, with a mean age at diagnosis of 38.1±10.5 years and a median disease duration of 13.0 (8.75-19.25) years. Most of the included patients had a predominant polyarticular pattern (n=33, 55.0%). The mean FACIT-F score was 34.48±11.61. No differences were found in the FACIT-F score according to gender, *pattern* of *joint involvement*, presence or absence of cutaneous involvement, nail dystrophy and/ or dactylitis. Patients with depression and enthesitis exhibited a lower FACIT-F score (p=0.017 and p=0.007, respectively). Patients treated with tofacitinib had a lower FACIT-F score than patients treated with adalimumab (p=0.025). No differences were found among the other biological agents. Patients in remission (according to EULAR response criteria) had a higher FACIT-T score than patients with moderate disease activity (p=0.032). In patients with a predominant axial involvement, inactive disease (according to ASDAS) was associated with a higher FACIT-T score, when compared to very high disease activity (p=0.02). Also, patients with moderate disease activity had a higher FACIT-T score than patients with very high (p=0.003) and high (p=0.008) disease activity.

FACIT-F showed a significant correlation with disease activity scores as BASDAI (r=-0.546, p<0.001), DAS 28 CRP (r=-0.506, p<0.001), CDAI (r=-0.672, p<0.001), SDAI (r=-0.641, p<0.001) and ASDAS CRP (r=-0.500, p<0.001). FACIT-F was also correlated with BASFI (r=-0.598, p<0.001), HAQ (r=-0.701, p<0.001), BASMI (r=-0.431, p<0.001) and MASES (r=-0.401, p<0.001). The authors found strong correlations between FACIT-F and HADS domains (Depression and Anxiety domains; r=-0.850, p<0.001 and r=-0.748, p<0.001, respectively). A strong correlation was also found between the FACIT-F and the 8 domains of health of the SF36 (p<0.001).

Conclusion: Fatigue was a common symptom in our sample of PsA patients and, its magnitude was closely related with disease activity, physical function, depression and anxiety status, indicating its multifactorial nature. We can speculate that achieving disease remission could significantly alleviate the fatigue intensity and vice versa. As recommended by EULAR/ACR task force in 2008, fatigue should be measured in clinical practice and should be part of the multidisciplinary approach, in addition to controlling disease activity.

AB0940 IS PSORIATIC ARTHRITIS REALLY SERONEGATIVE?

G. Ayan[1], N. E. Gezerer[2], E. Bilgin[1], G. K. Yardımcı[1], E. C. Bolek[1], B. Farisogullari[1], E. Duran[1], Z. Özsoy[1], G. Sandal Uzun[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdogan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. *[1]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; [2]Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey*

Background: Psoriatic Arthritis (PsA) is a heterogeneous disease classified as a seronegative group of inflammatory arthritis.

Objectives: Our aim was to understand the real-life seropositivity rates for commonly used autoantibodies in rheumatology practice in a cohort of PsA patients treated with biologic agents.

Methods: PsA patients from the Hacettepe University biological database (HUR-BIO) were assessed for the anti-nuclear antibody (ANA), rheumatoid factor (RF), and anti-cyclic citrullinated peptide (CCP) before and after the initiation of biologic agents. Demographic characteristics, the interval between the test and biologic initiation, and the rates of seropositivity for individual tests, autoantibody titers, and subtypes for ANA were determined.

Results: From 520 PsA patients registered, results of 419 patients with at least one autoantibody tested either before or after biologic treatment is presented in Table 1. From the patients tested, 69% of them had at least one autoantibody positive and 30.8 % of them were triple negative before the biologic treatment. The rates reached to 78.7% of seropositivity for at least

Table 1. Demographics and ANA, RF, Anti-CCP test results of patients before and after biologic treatment

	ANA		RF		Anti-CCP	
bDMARDs initiation	Before	After	Before	After	Before	After
Number of patients	104	132	310	278	144	97
Age	43.5 (12.7)	46.7 (11.6)	43.3 (12.5)	47.9 (11.9)	44.3 (12)	48.6 (12.1)

bDMARD: Biologic Disease Modifying Anti-Rheumatic Drugs, ANA: Anti-nuclear antibody, RF: Rheumatoid factor, Anti-CCP: Anti- Cyclic citrullinated peptide, F:Female, M:Male, IQR: Interquartile range, IU/ml: International units per milliliter, N/A: Not available *Subtype is not given for one patient in patients with positive ANA after biologic treatment

one autoantibody and 21.2 %triple negativity after treatment. ANA showed the highest rates of seropositivity among autoantibodies with a rate of 40% before and 55.3 % after biologic treatment. Concomitant seropositivity for RF and CCP autoantibodies showed rates of 2.8% and 6.3% before and after treatment, respectively. The most common subtype was AC4-5 before and AC1-4-5 after biologic agent treatment. ANA was tested in 31 patients both before and after biologic treatment showing 6 negative patients became positive after treatment and from 12 positive patients at the baseline 6 of them became negative (p=0.452). The most common biologic agents used in patients with ANA tested after treatment, were adalimumab (ADA) (42.4%), etanercept (ETN) (18.9%), and infliximab (IFX) (18.9%). The only difference was observed in IFX treated patients (n=25) with significantly higher rates of IFX usage in ANA-positive patients (p=0.001).

Conclusion: Synovial lymphoid neogenesis rates in PsA are similar to the frequency seen in rheumatoid arthritis (1). Nevertheless, PsA is classified under the group of "seronegative diseases". On the other hand, current reports have started to define specific autoantibodies particularly in psoriasis patients (2). The real-life experience in serology results of PsA patients showed that only 20-30 % of the patients were seronegative for all three tests commonly used in practice.

AB0941

DISCRIMINATION OF ENTHESIC INFLAMMATORY INVOLVEMENT IN PATIENTS WITH SPONDYLOARTHRITIS THROUGH THE USE OF COMPUTER ANALYSIS OF STATIC ULTRASOUND IMAGES

C. Guillén-Astete[1], Á. Andreu-Suárez[1], M. Tortosa-Cabañas[1], M. Martinez Aznar[2]. [1]*University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain;* [2]*Universidad Europea de Madrid, Faculty of Biological Sciences, Madrid, Spain*

Background: One of the weaknesses of the ultrasound study of the entheses is the absence of a universal, recognized and replicable ordinal evaluation scale that allows quantifying or semi-quantifying the degree of involvement of these structures.

Objectives: To analyze computer analysis of static images of patients with inflammatory enthesopathies differentiation capacity.

To determine its ability to discriminate between an affected and a healthy contralateral enthesis in the same individual.

Methods: Static images of the Achilles and epicondylar entheses of patients who consulted regarding enthesis pain associated with spondyloarthritis (ASAS/CASPAR criteria) were analyzed. We picked patients between 2016 and 2020. Images were obtained by the same observer under clinical practice routine circumstances and with the same ultrasound equipment (Logiq 8e, General Electric, USA). The same settings for each of the two enthesic examinations were used. Image analysis was performed using the ImageJ 1.53e program (Wayne Rasband & contributors – NIH, USA). Imaging records with contralateral studies in patients with recently diagnosed asymmetric enthesopathies (before the start of treatment) were selected. A repository of images from healthy controls, matched by age and sex of the patients, was used as control.

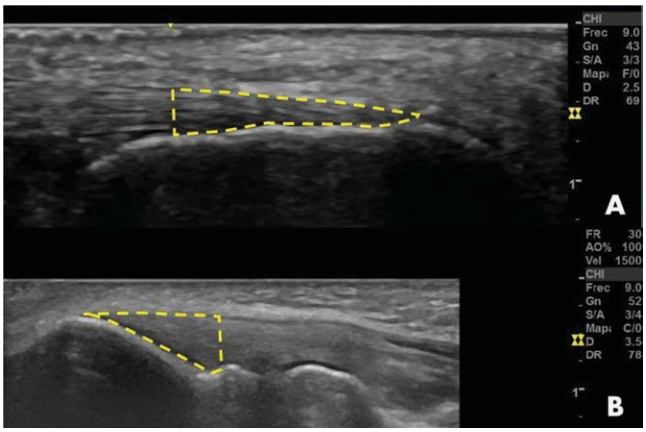

Figure 1. Scheme to obtain the analysis area of the Achilles (A) and epicondylar enthesis (B). The enthesic area was considered from the most distal point of the enthesis to the point of emergence or separation of the tendon from the cortex. Case A corresponds to a healthy control. Case B corresponds to a patient with psoriatic arthritis and severe epicondylar pain.

We compared the mean gray intensity (MGI), its dispersion (DGI) and the mode (MoGI) of the studied entheses. Figure 1 explains how to acquire the image for the study of both entheses.

Results: We included image records of 9 patients with axial spondyloarthritis (34.1 ±9.5 years, 7 males) and 10 with psoriatic arthritis (34.0 ±5.7 years, 8 males) with asymmetric involvement of 15 Achilles and 10 epicondylar entheses (LEI/MASES/ SPARCC). The distribution of the MGI, DGI, and MoGI variables was normal for both enthesis, contralateral patient controls and healthy subjects controls. In the records with Achilles involvement, the MGI on the affected side was 76.69 ±25.14, the DGI 24 ±3.48, and the MoGI 76.6 ±30.1. In the non-painful Achilles enthesis, the measurements were 83.99 ±27.29, 22.72 ±3.14 and 78.7 ±32.5, respectively. Statistically significant differences were detected in all pairwise comparisons (t -9.522, P=.000; t=3.393, P=.004; and t=-2.247, P=.041, respectively). In the epicondylar involvement records, the MGI on the affected side was 75.3 ±14.71, the DGI 25.93 ±2.52, and the MoGI 72.7 ±15.4. In the non-painful Achilles enthesis the measurements were 82.57 ±16.06, 25.7 ±2.99 and 74.9 ±16.5, respectively. Statistically significant differences between MGI and MoGI were identified (t=-9.849, P=.000; and t=-2.752, P=.022, respectively). The MIN ratio of the affected side and healthy side among patients was 1.18 ±0.047 while the MIN ratio between the dominant and non-dominant sides of the healthy athletes was 0.91 ±0.022 (t=25.81, P=.000).

Conclusion: Computer analysis of entheses static images correctly discriminates symptomatic from non-symptomatic entheses in early ultrasound studies. Even in non-symptomatic entheses, it detects differences compared to healthy subjects. This discriminatory capacity could be useful in updating ultrasound enthesis count indices. It may also be interesting as a criterion for evaluating changes over time. As a weakness, it is worth highlighting the potential confounding effect that enthesophytoses could have in this type of analysis if specific demarcations of the area studied are not made.

Psoriatic arthritis - clinical aspects (other than treatment)

AB0942 INVOLVEMENT OF THE FOOT IN PSORIATIC ARTHRITIS. A REVIEW OF 55 CASES.

F. E. Bennani[1], M. M. Pamela Chardene[1], A. Mougui[1], I. El Bouchti[1].
[1]*CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, RHEUMATOLOGY, Marrakech, Morocco*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory rheumatic disease belonging to the spondyloarthritis family with which it shares many clinical and radiographic features. The involvement of the feet with an asymmetric distribution of arthritis is very specific to Psoriasis.
Objectives: The objective of our study is to determine the frequency of foot involvement in a population of psoriatic arthritis by detailing the clinico-radiological aspect of the foot.
Methods: Retrospective descriptive study carried out on the files of patients hospitalized for psoriatic arthritis over a period of 9 years from January 2013 to December 2021. For each file, we collected epidemiological, clinical and radiological data.
Results: 55 patients were included: 41 women (74.5%) and 14 men (25.5%). The mean age was 48.81 ±17.08 years [20-85 years]. Personal and family history of skin psoriasis was noted in twenty and one patients, respectively. The average duration of evolution was about 5.5 years. Inflammatory talalgia was noted in 34 patients (61.8%) and forefoot involvement was found in 13 cases (23.6%). Sausage toe was noted in three cases (5.5%). None of the patients had Bauer's toe or psoriatic onychopachydermoperiostitis of the great toe. The radiographic workup showed calcaneitis in 34.5% (n=30), osteoperiostitis of the great toe in 6 patients (10.9%). According to the radiological criteria fingers-toes or (CRDO), 3 patients had juxta articular periostitis (5.5%), two cases of phalangeal tuft resorption (3.6%) and one case of osteolysis of an interphalangeal joint (1.8%).
Conclusion: In our context, the involvement of the foot during psoriatic arthritis is dominated clinically and radiologically by the involvement of the hindfoot. The importance of the classification criteria for Psoriasis cannot be undermind, and aim is improving their sensitivity and specificity.

AB0943 ASSOCIATION BETWEEN PULSE PRESSURE AND ATHEROSCLEROSIS IN PSORIATIC ARTHRITIS PATIENTS

A. N. Garza-Cisneros[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], M. A. Balderas-Palacios[1], A. Garcia-Heredia[2], N. Guajardo-Jauregui[1], A. B. Rodriguez-Romero[1], A. Cárdenas[1], D. E. Flores Alvarado[1]. [1]*Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico;* [2]*Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Cardiology, Monterrey, Mexico*

Background: Psoriatic arthritis (PsA) is associated with an increased prevalence of cardiovascular events due to accelerated atherosclerosis that seems to depend on traditional and non-traditional risk factors(1). There is a positive correlation between pulse pressure (PP) and the progression of atherosclerosis in general population (2). Currently, there are no studies linking PP as an independent risk factor of atherosclerosis in PsA patients.
Objectives: To compare PP between PsA patients with and without carotid plaque (CP).
Methods: This was a cross-sectional study that included patients aged 40 to 75 years with PsA diagnosis according to the 2006 CASPAR criteria. A carotid ultrasound was performed in all patients, and they were divided into two groups, 27 patients with the presence of CP and 27 patients without CP matched by age, gender, and comorbidities. Blood pressure and PP was measured according to current guidelines. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with Chi-square test for qualitative variables and Student´s t test for quantitative variables. A p value <0.05 was considered statistically significant.
Results: There were no differences regarding demographic characteristics between groups. When comparing the arterial measures, a statistically significant difference was found in the PP, which was higher in patients with CP (48.66 ± 12.04 mmHg vs 41.51 ± 9.10 mmHg, p=0.017) (Table 1). A binary logistic regression was performed, and we found that PP was the only independent factor for the presence of CP in patients with PsA, OR 6.638 (95% CI 0.453- 12.823, *p*=0.036).

Table 1. Demographic characteristics of the patients.

Characteristics	PsA patients with CP (n=27)	PsA patients without CP (n=27)	*P* Value
Age, mean ± SD	51.55±8.24	50.74±8.68	NS
Female gender, n (%)	16 (59.25)	15 (55.55)	NS
Obesity, n (%)	16 (59.25)	17 (62.96)	NS
T2DM, n (%)	20 (74.07)	23 (85.18)	NS
Hypertension, n (%)	19 (70.37)	22 (81.48)	NS
Dyslipidemia, n (%)	12 (44.44)	17 (62.96)	NS
Active smoking, n (%)	17 (62.96)	16 (59.25)	NS
Methotrexate, n (%)	9 (33.33)	11 (40.74)	NS
Glucocorticoid, n (%)	23 (85.18)	22 (81.48)	NS
bDMARD, n (%)	14 (51.85)	18 (66.66)	NS
SAP, mean ± SD	132.44±14.40	123.44±13.80	**0.023**
DAP, mean ± SD	83.77±10.71	81.92±10.95	NS
PP, mean ± SD	48.66±12.04	41.51±9.10	**0.017**

PsA, psoriatic arthritis; NS, non-significant; T2DM, type 2 diabetes mellitus; bDMARD, biologic disease-modifying anti-rheumatic drugs; SAP, systolic arterial pressure; DAP, diastolic arterial pressure; PP, pulse pressure.

Conclusion: PsA patients with CP presented higher measures of PP compared with PsA patients without CP. This suggests that PP could be related with an increased risk of subclinical atherosclerosis in PsA patients. It is recommended to consider PP as an important parameter when evaluating cardiovascular risk in PsA patients.

AB0944 HIGHER PREVALENCE OF PULSE PRESSURE IN PSORIATIC ARTHRITIS PATIENTS

A. N. Garza-Cisneros[1], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], N. Guajardo-Jauregui[1], A. B. Rodriguez-Romero[1], M. A. Balderas-Palacios[1], A. Garcia-Heredia[2], A. Cárdenas[1], D. E. Flores Alvarado[1]. [1]*Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico;* [2]*Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Cardiology, Monterrey, Mexico*

Background: There is an increased risk of cardiovascular diseases in patients with psoriatic arthritis (PsA) compared with the general population due to higher prevalence of cardiovascular risk (CVR) factors (1). Pulse pressure (PP) is an independent risk factor for cardiovascular morbidity and mortality (2). Currently, there are no studies about PP in PsA patients.
Objectives: To compare PP between PsA patients and healthy controls.
Methods: This was a cross-sectional, observational, and comparative study. A total of 74 PsA patients aged 40-75 years old, who fulfilled the 2006 CASPAR criteria were recruited and matched to 74 controls by age (±5 years), gender and comorbidities. Patients with history of a previous cardiovascular event or pregnancy were excluded from this study. Blood pressure and PP was measured according to current guidelines. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with Chi-square test for qualitative variables and Student´s t test and Mann-Whitney's U test for quantitative variables. A p value <0.05 was considered statistically significant.
Results: There were no differences regarding demographic characteristics between groups. When comparing the arterial measures, a statistically significant difference was found in the PP, which was higher in the PsA group [45.00 mmHg (40.00-56.50) vs 42.50 mmHg (38.00-50.00), p=0.024], and in the systolic

arterial pressure, higher in PsA patients (131.06 ± 18.27 mmHg vs 123.02 ± 14.27 mmHg, p=0.003) (Table 1).

Table 1. Demographic characteristics of the patients.

Characteristics	PsA patients (n=74)	Controls (n=74)	*P* Value
Age, mean ± SD	55.08±7.61	54.94±7.45	NS
Female gender, n (%)	41 (55.40)	41 (55.40)	NS
Obesity, n (%)	47 (63.51)	48 (64.86)	NS
T2DM, n (%)	58 (78.37)	56 (75.67)	NS
Hypertension, n (%)	48 (64.86)	44 (59.45)	NS
Dyslipidemia, n (%)	44 (59.45)	46 (62.16)	NS
Active smoking, n (%)	49 (66.21)	53 (71.62)	NS
SAP, mean ± SD	131.06±18.27	123.02±14.27	**0.003**
DAP, mean ± SD	81.06±11.12	79.13±9.69	NS
PP, median (p25-p75)	45.00 (40.00-56.50)	42.50 (38.00-50.00)	**0.024**

PsA, psoriatic arthritis; NS, non-significant; T2DM, type 2 diabetes mellitus; SAP, systolic arterial pressure; DAP, diastolic arterial pressure; PP, pulse pressure.

Conclusion: PsA patients presented higher measures of PP compared to healthy controls. This suggests that PsA patients could have a higher risk of cardiovascular disease. It is recommended to consider PP as an important parameter when evaluating CVR in PsA patients. Further studies are necessary to validate these results.

AB0945 SPECIAL FEATURES OF THE LIPID PROFILE IN PATIENTS WITH THE INFLAMMATORY ARTHROPATHIES

S. Spitsina[1,2], E. Mozgovaya[1], A. Trofimenko[1], S. Bedina[1], M. Mamus[1]. *[1]Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky", Clinical Biochemical Laboratory, Volgograd, Russian Federation; [2]Federal State Budgetary Educational Institution of Higher Education "Volgograd State Medical University" of the Ministry of Healthcare of the Russian Federation, Department of hospital therapy, Volgograd, Russian Federation*

Background: The main cause of death in patients with the inflammatory arthropathies is involvement of the cardiovascular system, and primarily atherosclerotic lesion with its complications. Initiation and progression of these arthropathies are underlied with similar immune and inflammatory mechanisms and associated with highly atherogenic changes of blood lipoproteins.

Objectives: Identification of particular qualities of the lipid profile in rheumatoid (RA) and psoriatic (PsA) arthritis, ankylosing spondylitis (AS) and their relationship with essential predisposing factors.

Methods: We enrolled 20 patients with RA, 15 with PsA, and 15 with AS, receiving basic anti-inflammatory therapy with methotrexate 10 to 20 mg per week for 6 months, in combination with various non-steroidal anti-inflammatory drugs. These diagnoses were verified according to the ACR/EULAR 2010, CASPAR 2006, ASAS 2009 criteria, respectively. The single exclusion criterion was the presence of a concomitant disease that could affect lipid metabolism. Total cholesterol (TC), HDL cholesterol, and triglycerides (TG) were measured in the plasma samples of all the patients, LDL cholesterol was calculated using Friedewald's formula: TC – (HDL + (TG/2.2)). The atherogenic index was taken as (TC – HDL)/HDL. Results were expressed as arithmetic means ± standard deviations. Differences were considered significant when $p<0.05$.

Results: The age of all patients ranged from 30 to 67 years, disease duration range was 1.5 to 12 years. All the patients with chronic arthritis had moderate or high disease activity grades. In the subgroup of RA patients average TC value was 5.63±1.6 mmol/l, HDL – 1.09±0.2 mmol/l, LDL – 3.74±1.16 mmol/l. Increased TC levels were detected in 80% of cases, TG - in 40%, LDL - in 80%, and decreased HDL - in 60% patients. There were strong relationships of TC with age, menopause, or overweight. The duration of RA also positively correlated with TC ($r=0.189$, $p<0.05$) and LDL ($r=0.159$, $p<0.05$). RA (C-reactive protein level) activity was negatively associated with HDL ($r=-0.169$, $p<0.05$). 80% of PsA patients had increased TC levels, but TG or HDL levels were within reference intervals. Mean TC in this subgroup was 6.04±1.55 mmol/l. TC values of PsA patients also positively correlated with age, BMI, and duration of PsA. There was an increase in TC, LDL, and the atherogenic coefficient in AS patients. Mean values of TC, TG, LDL, and HDL in this subgroup were 5.65±0.28, 1.28±0.12, 3.86±0.23 and 1.09±0.06 mmol/l, respectively.

Conclusion: Lipid disorders in patients with chronic inflammatory joint diseases may be a source of increased risk of early atherosclerosis and the cardiovascular events. Increased TC and LDL were most pronounced changes in lipid profiles of RA, PsA and AS patients. All these markers were revealed to be associated with both common cardiovascular (age, increased BMI) and the disease-associated factors (arthritis duration, activity of the underlying disease).

AB0946 PELVIS RADIOGRAPHY FINDINGS AND PROGRESSION RATES IN PATIENTS WITH PSORIATIC ARTHRITIS UNDER BIOLOGIC TREATMENT

G. Ayan[1], A. Sadic[2,3], L. Kılıç[1], U. Kalyoncu[1]. *[1]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; [1]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; [3]Hacettepe University Medical Faculty, Department of Internal Medicine, ankara, Turkey*

Background: Psoriatic arthritis (PsA) is a heterogenous disease that can present with various musculokeletal manifestations. Several studies have assessed the rate of sacroileitis in PsA population, however data on the involvement of other pelvic structures that may cause symptoms, such as major entheseal or hip involvevement, and progression rates during follow-up is scarce.

Objectives: This study aimed to understand overall pelvis radiography findings and progression rates during follow-up in a cohort of patients with PsA under biologic treatment.

Methods: PsA patients from the Hacettepe University biological database (HUR-BIO), were retreospectively analyzed for their pelvis radiographs. All radiographs for individual patient were consecutively scored. Modified New York (mNY) criteria was used to assess sacroileitis and ischium/ iliac wing/ greater-lesser trochanteric enthesopathy and symphysis pubis osteitis assessments were done using a grade 0, no changes, 1, minimal changes and grade 2 and more counted as significant changes (1). Hip involvement was scored using BASRI-hip score and data on prosthesis were noted (2). All of the assessments were done by an experienced rheumatologis (UK) and in cases with suspicion, another experienced rheumatologist reviewed the cases (LK) and a consensus was reached.

Results: Overall 273 patients (69.6% of females) with the mean (SD) age at the time of first radiography 43.3 (12) years were included. At their initial radiographic assessment, the median (IQR) PsA duration was 2 (7) years. Baseline radiographs showed 10 (%3.7) of the patients had transitional vertebra and 137 (50.2%) patients had sacroiletis according to mNY criteria. From patients without sacroileitis (n=136), 67 patients had following radiographs. After a mean (SD) 47.1 (37) months, 16 (23.8%) of them progressed to sacroiletitis according to mNY criteria. Regarding the major enthesopathies, Regarding significant changes, 26.8 % of the patients had ischium enthesopathy, 19.3% of the patients ad symphysis pubis involvement and 13.2% of the patients had iliac

Table 1. Distribution of major entheseal involvement and BASRI-hip socres and progression rates

*Defined as one unit increase in the grade

wing enthesopathy. Trochantor major enthesopathy rates were 2.4% and 1.4 % at right and left sites respectively. Only one patient had trochanter minor enthesitis on the left site (Table 1). Prosthesis requirement was observed in 4 hip joints and 4 hip joints had prosthesis. There was no correlation between meeting mNY criteria and having iliac, ischium, and pubis involvement ≥ 2. On the other hand, patients with when there is ischium enthesopathy ≥2 (17/46 (36.9%) vs 18/96 (18.7%), p=0.013) or iliac wing enthesopathy ≥2 above (10/18 (55.5%) vs. 26/129 (20.1%), p=0.001), any syndesmophyte in the spine is more commonly seen.

Conclusion: Half of the patients with PsA requiring advanced treatment modalities, had sacroileitis in a median 2 years of disease duration and the rest may progress to sacroileitis during the follow-up period. Major enthesopathy involvement was also seen in more than half of the patients. Ischium, iliac wing enthesopathies and spinal syndesmophytes may be all a part of the osteoproliferative process. Further assessment is needed to correlate those radiographic changes to clinical symptoms.

AB0947 CORRELATION BETWEEN ENTHESITIS AND CLINICAL PHENOTYPE PSORIASIS, NAIL PSORIASIS AND DURATION PSORIASIS IN PATIENTS WITH PSORIATIC ARTHRITIS

L. Vorobyova[1], T. Korotaeva[1], E. Loginova[1], E. Gubar[1], Y. Korsakova[1], M. Chamurlieva[1], E. Nasonov[2], A. Lila[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Psoriatic arthritis (PsA) is a disease with multidimentional manifestations in patients who have psoriasis (PsO). Enthesitis is an important component of PsA and may be a primary pathological feature driving other manifestations of the disease. [1] Psoriasis and psoriatic nail dystrophy are also important predictors of PsA. Skin and joint disease may indeed arise from the same underlying process at the same time, with patients developing similar inflammatory lesions in the skin and entheses, while the speed of detection of these lesions is different and allows skin changes to be detected earlier. [2]

Objectives: to evaluate correlation between enthesitis and clinical phenotype psoriasis, nail psoriasis and duration psoriasis in patients with psoriatic arthritis.

Methods: 187 (M/F=97 (50.2%)/90(48.8%) PsA pts fulfilling the CASPAR criteria were included. Mean age 45.6±11.7 years (yrs), DAPSA 21.05±21.03, median (Me) PsA duration 88 [16;421] mo. All pts underwent standard clinical examinations. Analysis were performed in 2 groups: enthesitis positive (42.3%) and enthesitis negative (57.7%), for assess enthesitis in PsA pts used Leeds Enthesitis Index (LEI), modified LEI (LEI and plantar fascia), Maastricht Ankylosing Spondylitis Enthesitis Score (MASES).

Results: When 79 (42.3%) pts with enthesitis and 108 pts (57.7%) without enthesitis were compared. In pts with enthesitis had more duration PsO – 275,6±153,4 vs 227,4±139,5, p=0,03. The duration of PsA, both groups were comparable (p=0,9). Also in pts with enthesitis had more nail PsO - 66,6% vs 45% (p=0,005). BSA in both group were comparable, but in pts with enthesitis had more inverse PsO – 6,94% vs 3%, gluttate PsO – 4% in pts without enthesitis with phenotype PsO did not have, and combination plaque and inverse PsO – 51,3% vs 31% (p=0,0056). Moreover, significant but weak positive correlations between the LEI score and duration PsO and nail PsO. Assessment of the correlation modified LEI score and MASES score showed significant positive correlations with duration PsO, nail PsO and phenotype PsO. (Table 1).

Table 1. Correlation between LEI, modified LEI, MASES and parameters PsO.

Parameters	LEI		Modified LEI		MASES	
	r	p	r	p	r	p
Duration psoriasis	0,3	0,001	0,3	0,01	0,34	0,03
BSA	0,05	0,4	0,06	0,4	0,07	0,3
Nail psoriasis	0,3	0,001	0,35	<0,0001	0,32	0,01
Phenotype psoriasis						
Plaque psoriasis	-	-	0,53	0,001	0,61	0,001
Plaque+inverse psoriasis	-	-	0,65	0,001	0,62	0,001
Inverse psoriasis	-	-	0,70	0,02	0,66	0,03
Gluttate psoriasis	-	-	0,63	0,001	0,63	0,001

Conclusion: In our cohort PsA pts reported that with enthesitis is associated with duration PsO, nail psoriasis and phenotype PsO. These finding should be considered in the turn of improved screening, earlier diagnosis, timely treatment initiation and, eventually, should improve overall disease outcomes.

AB0948 OSTEOPOROTIC SCREENING AND PREVALENCE OF SEVERE OSTEOPOROTIC FRACTURES IN A POPULATION OF PSORIATIC ARTHRITIS INITIATING A BIOLOGIC TREATMENT

M. Laffaire[1], M. Caroline[1], E. Allado[2], E. Bauer[1], I. Chary Valckenaere[1], D. Loeuille[1]. *[1]University Hospital, Rheumatology, Nancy, France; [2]University Hospital, Center of Sports Medicine and Adapted Physical Activity, Nancy, France*

Background: Osteoporosis is a common complication of Rheumatic diseases. The association between osteoporosis and rheumatoid arthritis is clearly demonstrated while this association is still debated as well as for the screening of osteoporosis by Dual-Energy X-Ray Absorptiometry (DEXA) or to demonstrate an increased risk of fracture on radiography in a population of Psoriatic Arthritis (PsA). The prevalence of fragility fractures reported on medical reports ranged between 12% and 40% in PsA patients. Only a few studies evaluated the prevalence of vertebral fracture (VF) on spine radiographs. To our knowledge no study has evaluated the contribution of radiographic or CT assessment of the spine on the prevalence of fragility fracture reported in medical records.

Objectives: To determine Psoriatic Arthritis patient's characteristics screened for osteoporosis by DEXA in a population initiating a biologic treatment (bDMARD) and to estimate the prevalence of severe osteoporotic fractures on medical reports and after imaging modalities scoring (X-ray or CT-scan).

Methods: Patients with psoriasis should satisfy the CASPAR or ASAS criteria and have been screened during their follow up for a bDMARD. Osteoporotic screening was defined by a BMD testing (DEXA). Vertebral fractures were scored according to Genant's method on spine X-ray or sagittal CT-scan images. Clinical and demographic data and the presence of previous severe osteoporotic fracture reported in the medical records were collected.

Results: On 417 PsA patients screened for bDMARDs during 2008-2019, 89 patients (21.3%) were assessed for osteoporosis by DEXA. Increased age, female sex, menopause, previous severe fracture, disease duration, presence of inflammatory bowel disease, current and previous corticosteroid and bDMARDs uses were significantly associated with osteoporotic screening. On DEXA, 7 patients (7.9%) were classified as osteoporotic. The prevalence of severe osteoporotic fracture was 6.7% in medical reports and increased to 23.6% after scoring spine radiographies or TAP-CT images. In univariate analysis the presence of severe osteoporotic fractures was associated with age (p=0.013), scanographic bone attenuation coefficient (p=0.005) and Lumbar T-score (p=0.039).

Conclusion: Less than a quarter of PsA patients initiating a bDMARD is screened for osteoporosis. The prevalence of osteoporosis on DEXA and severe osteoporotic fractures on medical records are inferior to 10%. After systematic imaging evaluation, this prevalence increases at 23.6%.

AB0949 PSORIASIS IN SPECIAL LOCALIZATIONS IN PATIENTS WITH PSORIASIS VERSUS PATIENTS WITH PSORIATIC ARTHRITIS

A. Alvarez de Cienfuegos[1], L. Schneller-Pavelescu[2]. *[1]Hospital Vega-Baja, Rheumatology, Alicante, Spain; [2]Hospital Vega-Baja, Dermatology, Alicante, Spain*

Background: Psoriasis and psoriatic arthritis (PsA) are chronic immune-mediated diseases that primarily affect the skin and joints, respectively. A large proportion of patients with plaque psoriasis suffer from psoriatic lesions on the scalp, nails, palmoplantar area and genitals. These locations can also be soley or predominantly affected. Psoriasis in special localizations are often perceived as particularly stigmatizing and significantly reduce quality of life. Involvement of these body parts is associated with an increased risk of PsA.
Objectives: To provide a descriptive analysis of psoriasis in special localizations in patients with psoriasis versus patients with PsA.
Methods: This cross-sectional study was performed in Vega-Baja Hospital (Orihuela-Spain) from May2021 to December 2021. We prospectively enrolled 77 consecutive psoriasis patients and 76 consecutive patients affected by PsA and followed at the Vega-Baja Hospital (Orihuela-Spain). Sociodemographic data and clinical characteristics were analysed.
Results: One hundred and fifty-three patients were included (77 psoriasis patients and 76 patients affected by PsA). The registry variables used in this study are detailed in Table 1.

Table 1. Patients' data variables recorded

	Psoriasis	PsA	p-value
Sex, n (%)			
Male	35 (45.5)	31 (40.8)	0.625
Female	42 (54.5)	45 (59.2)	
Age (years), mean (SD)	50.27 (15.3)	53.83 (10.2)	0.094
Weight (kg), mean (SD)	86.1 (21.3)	78.8 (17.7)	**0.022**
Height (m), mean (SD)	1.66 (0.1)	1.65 (0.1)	0.76
BMI (kg/m2), mean (SD)	31.3 (7.6)	28.7 (5.5)	**0.017**
HTA, n (%)	20 (26.0)	19 (25.0)	0.89
DM, n (%)	12 (15.6)	14 (18.4)	0.64
DLP, n (%)	25 (32.5)	29 (38.2)	0.46
Metabolic syndrome, n (%)	36 (46.8)	42 (55.3)	0.29
Smoker, n (%)			
No	31 (40.3)	23 (30.3)	**0.012**
Yes	29 (37.7)	19 (25.0)	
Ex-smoker	17 (22.1)	34 (447)	
Psoriasis in special localizations, n (%)	67 (87.0)	74 (97.4)	**0.031**
Scalp	52 (67.5)	51 (67.1)	0.96
Genital	30 (39.0)	31 (40.8)	0.817
Palmoplantar	19 (24.7)	18 (23.7)	0.886
Nails	30 (39.0)	42 (55.3)	**0.043**

BMI, body mass index; DLP, dyslipidemia; DM, diabetes mellitus; HTA, hypertension; PsA, psoriatic arthritis.

There was a significant difference in weight and body mass index between the groups. PsA patients have more frequent psoriasis in special locations.
Conclusion: We have found that patients with PsA have more frequent psoriasis in special locations.

AB0950 DETECTION OF ASYMPTOMATIC ENTHESEAL INVOLVEMENT IN PATIENTS WITH PSORIASIS: A CASE-CONTROL ULTRASOUND STUDY

R. Ben Aissa[1], S. Boussaid[1], S. Rekik[1], S. Rahmouni[1], S. Jemmali[1], H. Ajlani[1], H. Srairi Sahli[1], M. Elleuch[1], A. Souissi[2], M. Mokni[2]. *[1]Rabta Hospital, Department of Rheumatology, Tunis, Tunisia; [2]Rabta Hospital, Department of Dermatology, Tunis, Tunisia*

Background: Enthesopathy is one of the major features of psoriatic arthritis (PsA). The clinical screening for enthesopathies and synovitis in patients with psoriasis is nonspecific during the subclinical phase. Ultrasonography (US) has already demonstrated its ability to study entheses and joints in early stages of PsA.
Objectives: To evaluate the prevalence of ultrasonographic subclinical synovitis and enthesopathies in psoriasis patients with no clinical evidence of PsA compared with controls.
Methods: A cross-sectional study conducted on 40 patients with psoriasis and 40 healthy sex- and age- matched controls. The Leeds Enthesitis Index (LEI) and Spondyloarthritis Research Consortium of Canada (SPARCC) were used to evaluate entheseal involvement. US examination of 18 joints (wrists, metacarpophalangeal, and proximal interphalangeal joints) was performed along with 22 entheseal sites (deep flexor of the fingers, lateral epincondyle, triceps, quadriceps, patellar and calcaneal tendons and plantar fascia). Inflammatory-score (thickening, hypoechogenocity, bursitis and Doppler signal) and damage-score (calcifications, enthesophytes and erosions) were calculated (0= absent, 1=present for each abnormality). A total-score was obtained by adding these two scores.
Results: The mean age of psoriatic patients 51,90±15,90 [19 -76] and the sex ratio of males to females was 3:2. US synovitis were more frequent in psoriatic patients 7/1040 (0,68%) than in controls 3/1040 (0,29%) but this was not significant (p= 0,420). Patients with psoriasis had more US enthesopathies 37 (92,5%) comparing to controls 16 (40%) (p < 0,001). The total number of enthesopathies was higher in the psoriatic group 184/880 (20,90%) comparing to controls 42/880 (4,78%) (p < 0,001). Entheses with more US abnormalities in the psoriasis group comparing to controls were deep flexor tendons of the fingers entheses (p<0,001), distal patellar tendon entheses (p<0,001) and calcaneal tendon entheses (p<0,001). LEI and SPARCC scores were positively correlated to higher number of US enthesopathies (p=0,046, p=0,006). SPARCC was positively correlated to inflammatory-score and damage-score (p=0,009, p=0,024). The mean C-reactive protein level was higher in psoriatic arthritis 5,77±10,10 mg/L than in controls 2,15±3,26mg/L (p=0,037).
Conclusion: Our results confirm that US enthesopathies and synovitis are more frequent in patients with psoriasis comparing to healthy population. The US screening for subclinical enthesopathies should be the object of longitudinal investigations to define its value in predicting the clinical onset of PsA.

AB0951 ENTHESEAL INVOLVEMENT IN HEALTHY SUBJECTS: WHAT CAN LOWER LIMB ULTRASONOGRAPHY TELL US?

S. Boussaid[1], R. Ben Aissa[1], S. Rekik[1], S. Jemmali[1], S. Rahmouni[1], H. Ajlani[1], H. Srairi Sahli[1], M. Elleuch[1]. *[1]Rabta Hospital, Department of Rheumatology, Tunis, Tunisia*

Background: Over the past few years, ultrasonography (US) has been a very useful tool in the detection of subclinical enthesopathy especially in spondyloarthritis patients. However, could US entheseal involvement detection by US in healthy subjects be predictive of evolution to an inflammatory rheumatic disease?
Objectives: To identify by US the prevalence of entheseal abnormalities at the lower limb of healthy subjects and associated risk factors.
Methods: US assessment was performed on 400 entheses of 40 healthy volunteer subjects along with clinical examination. Exclusion criteria: Enthesitis on the physical examination, personal of family history of inflammatory rheumatic disease and previous surgery or procedural interventions in the knees and/or ankles. Quadriceps, patellar and calcaneal tendons, and plantar fascia entheses were scanned. Depending on lesion type, inflammation (thickening, hypoechogenecity, bursitis and Doppler signal) and chronic damage (calcifications, enthesophytes and erosions) scores (0= absent, 1=present) were calculated per entheseal site and per participant. Total score was obtained by adding these two scores. Data about age, gender, body mass index (BMI) and physical activity according to the short form of the International Physical Activity Questionnaire score (IPAQ-SF) were collected.
Results: The mean age of participants was 52.3±14.83 [20-78] and the ratio of males to females was 3:2. Fourteen participants had US subclinical enthesopathy (35%). Among 400 scanned entheses, thickening was the most frequent

inflammatory lesion observed in 4 % (n=16) of the entheses, followed by hypoechogenecity (0.5 %, n=2). Enthesophytes were the most frequent chronic damage lesions detected in 1.25% (n=5) of the entheses followed by erosions (0.5%, n=2). The highest total US scores per entheseal site were observed at the calcaneal enthesis [mean (SD) 0.27(0.59)], followed by plantar fascia [0.18(0.50)] and distal patellar tendon origins [0.10 (0.37)]. Age was not associated to higher scores (total, inflammation, chronic damage; p=0.339, p=0.412, p=0.531). Female participants had higher inflammation scores than males (mean inflammation scores (SD) 0.69 (1.44) versus 0.39 (0.71), p=0.044). The BMI was correlated to higher inflammation score (p=0.020, r=0.368) but not to chronic damage nor to total scores (p=0.478, p=0.104). Intense physical activity was associated to higher chronic damage score comparing to moderate physical activity (mean chronic damage scores (SD) 0.30(0.67) versus 0.003(0.00), p=0.058) and to low physical activity (mean chronic damage scores (SD) 0.30(0.67) versus 0.0018(0.00), p=0.043). No association between physical activity and inflammation score had been observed.

Conclusion: Our study demonstrates that US changes within the enthesis are associated with higher BMI and physical activity. These results support the effect of biomechanical forces on the entheses that should be considered when differentiating by US pathological from healthy entheses.

AB0952 CHARACTERIZATION OF PATIENTS WITH PSORIATIC ARTHRITIS IN DERMATOLOGIC AND RHEUMATOLOGIC CARE: AN ANALYSIS OF TWO DISEASE REGISTRIES

L. Lindner[1], M. Augustin[2], L. Kühl[2], A. Weiß[1], S. J. Rustenbach[2], F. Behrens[3], M. Feuchtenberger[4], I. Schwarze[5], U. Mrowietz[6], D. Thaçi[7], K. Reich[2], A. Strangfeld[1], A. Regierer[1]. *[1]German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany; [2]University Medical Center Hamburg-Eppendorf, IVDP - Institute for Health Services Research in Dermatology and Nursing, Hamburg, Germany; [3]Goethe University, Rheumatology, Frankfurt, Germany; [4]Hospital Burghausen, Department of Internal Medicine II, Burghausen, Germany; [5]Rheumatologist, Rheumatology, Leipzig, Germany; [6]University Medical Center Schleswig-Holstein, Department of Dermatology, Venerology and Allergology, Kiel, Germany; [7]University Medical Center Schleswig-Holstein, Comprehensive Center for Inflammation Medicine, Lübeck, Germany*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease affecting the musculoskeletal system, skin and nails. Therapeutic management in Germany is usually provided by a dermatologist or rheumatologist.

Objectives: The aim is to characterize the socioeconomic and clinical patient profiles in dermatologic and rheumatologic settings.

Methods: Baseline data of patients with PsA from [1] the dermatological German Psoriasis Registry PsoBest (PB) and [2] the rheumatological German disease register RABBIT-SpA (RS) [2] were analyzed. For this purpose, comparable anamnestic and clinical variables collected in the period 10/2017 to 12/2020 were identified and descriptively analyzed. The analysis was carried out in each of the data-holding registers.

Results: 1066 RS patients and 704 PB patients were included in the analysis (Table 1). The proportion of women was higher in the rheumatology setting (RS) (60% vs. 49%). Disease duration of psoriasis was longer in the dermatology setting (PB). Cutaneous severity was higher in PB, including affected body surface area and nail psoriasis. However, more patients in RS had tender joints and swollen joints. The physician-reported global disease activity was higher in RS. The mean DLQI (Dermatology Life Quality Index) was higher in PB and the mean HAQ (Health Assessment Questionnaire) was higher in RS. Patient reported global disease activity and pain were lower in PB. Most of the patients received biologics at inclusion (RS: 71% and PB: 73%). In the dermatology setting IL23 inhibitors were used more frequently, whereas TNF inhibitors were used more frequently in the rheumatology setting.

Table 1. Baseline data of patients with PsA from the registers PsoBest and RABBIT-SpA included 10/2017 to 12/2020.

	RABBIT-SpA (Rheumatology setting)	PsoBest (Dermatology setting)
N	1066	704
Age, mean (SD)	51.9 (12.2)	51.7 (13.2)
Female, n (%)	637 (60)	346 (49)
Disease duration skin, mean (SD)	14.3 (13.9)	21.6 (16.0)
Body surface area, mean (SD)	8.5 (15.0)	20.8 (19.8)
Nail psoriasis, n (%)	434 (41)	407 (58)
Tender joints, n (%)	905 (85)	498 (71)
Swollen joints, n (%)	708 (67)	387 (55)
Physician reported disease activity, mean (SD)	5.2 (1.9)	4.6 (2.7)
DLQI, mean (SD)	5.6 (6.2)	12.2 (7.6)
HAQ, mean (SD)	0.9 (0.7)	0.7 (0.6)
Patient reported disease activity, mean (SD)	5.7 (2.4)	4.9 (2.9)
Patient reported pain, mean (SD)	5.5 (2.4)	5.2 (2.8)
bDMARD, n (%)	751 (71)	514 (73)
TNF, n (%)	346 (46)	117 (23)
IL17, n (%)	351 (47)	246 (48)
IL23, n (%)	54 (7)	151 (29)
tsDMARD, n (%)	109 (10)	47 (7)
csDMARD, n (%)	195 (18)	142 (20)

Conclusion: The clinical specialization of the treating physician was associated with a different treatment and clinical status of patients with PsA. Our analysis showed that patients in the rheumatology setting more frequently had joint affections and lower functional status, whereas skin severity was worse in the dermatology setting, indicating selection effects of health care access. We hypothesize out that these differences may be biased due to different diagnostic and therapeutic routines in the specialized health care settings. Psoriatic arthritis should be treated in a multidisciplinary approach to take into account all facets of this complex disease.

AB0953 LACK OF RACIAL DIVERSITY IN CLINICAL TRIALS OF PSORIATIC ARTHRITIS

N. Goel[1,2]. *[1]Duke University School of Medicine, Internal Medicine, Division of Rheumatology, Durham, NC, United States of America; [2]Abcuro, Inc, Newton, MA, United States of America*

Background: Participant diversity in clinical trials of therapeutics in rheumatology is important to understand how persons of different races and ethnicities might respond differently to therapeutics. Specifically, for psoriatic arthritis (PsA), although people of color (POC) have lower disease prevalence, prevalence still ranges from 0.04-0.19% in Blacks, 0.13-0.19% in Asians, and 0.09-0.30% in Hispanics versus 0.19-0.34% in Whites in the insured population of the US[1]. Literature on the diversity of PsA clinical trials remains limited, though data suggest that minorities are underrepresented in clinical trials[2]. This analysis aims to evaluate the diversity of participants in randomized clinical trials (RCTs) of US Food and Drug Administration approved targeted therapies for PsA.

Objectives: To evaluate the reporting of race and ethnicity in published RCTs of targeted therapeutics approved for the treatment of PsA in the US.

Methods: Targeted therapies approved for use in the treatment of PsA in the US were identified. Package inserts and ClinicalTrials.gov (CT.gov) were used to

identify the pivotal double blind, RCTs in PsA which supported the approval of the identified therapeutics in the US. The articles reporting the primary endpoint data were obtained. Race and ethnicity data were extracted from the published data. Countries in which the studies were conducted were identified from the publications or CT.gov. Descriptive analyses were performed.

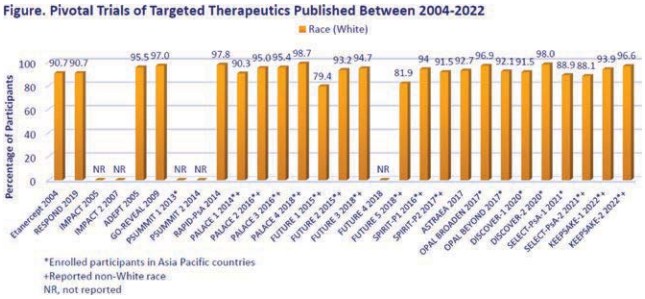
Results: Twenty-nine pivotal RCTs in PsA evaluating targeted therapeutics, published from 2002 – 2022, were identified; 24 reported race; non-White race was reported in only 13 (45%) (Table 1 and Figure 1). In the latter, people of Black race comprised <1% of the overall population in 12 RCTs and 2.7% in the remaining RCT. People of Asian race comprised 6.1% of the overall population reflecting <10% of the population in 11 studies and 11.3% and 19.0% in the remaining 2 studies. Overall, 19 (65.6%) trials recruited participants from Asia Pacific countries. Hispanic/Latinx ethnicity was not reported in any study. Studies published from 2017-2022 reported non-White race (n=7 of 15 [47%]) no more frequently than studies published from 2004-2016 (n=6 of 14 [43%]). Although the 13 RCTs reporting non-White race may not reflect unique individuals, the total number of people included across these RCTs was 7261, of which 48 (0.7%), 441 (6.1%), and 6598 (90.9%) were Black, Asian, and White, respectively.

Table 1. Race Reporting in Psoriatic Arthritis Pivotal Clinical Trials of Targeted Therapeutics

Race Reporting Status	Total Trials (N)	Trials which recruited in AP countries (n [% of N])	Total Participants (N)	White (n [% of N])	Black (n [% of N])	Asian (n [% of N])	Other* (n [% of N])
Not reported	5	1 (20.0)	1572	-	-	-	-
Non-White race reported	13	13 (44.8)	7261	6598 (90.9)	48 (0.7)	441 (6.1)	172 (2.4)
Non-White race not reported	11	5 (45.5)	6588	5803 (88.1)	-	-	-
Total (N)	29	19 (65.5)	15421	-	-	-	-

Abbreviations: AP, Asia Pacific; N and n, number.*Other also includes American Indian/Alaskan Native, mixed race, unknown raceNote: Numbers across rows may not add up to 0, and the total number of individuals reported in any one group may not be unique. Dashes reflect data not provided or able to be calculated.

Figure. Pivotal Trials of Targeted Therapeutics Published Between 2004-2022



Conclusion: Our data show under-reporting of race and ethnicity in publications of pivotal PsA RCTs, and no evidence of improved reporting over time. Whites were overrepresented in pivotal trials of PsA, especially when considering 72 and 62% of the US population was White in 2010 and 2020 (US Census data), respectively, and the reported prevalence of PsA by race in the insured population of the US[1]. Improved reporting of race/ethnicity and increased representation of racial/ethnic minorities in PsA RCTs are needed.

AB0954

CONCORDANCE BETWEEN DIFFERENT COMORBIDITIES SCORES IN PATIENTS WITH PSORIATIC ARTHRITIS

N. D. Popescu[1], A. Dima[1], I. A. Berza[1], G. M. State[1], F. Negoi[1], M. Panduru[2], M. Parvu[1]. *[1]Colentina Clinical Hospital, Department of Rheumatology, București, Romania; [2]Colentina Clinical Hospital, Department of Dermatology, Bucharest, Romania*

Background: Patients with psoriatic arthritis (PA) are more likely to suffer from other chronic medical conditions, associated comorbidities having significant impact upon both quality of life and survival. As disorders like the cardiovascular disease, metabolic syndrome, hepatic or renal pathologies were shown to be more prevalent in PA [1], assessment of comorbidities is important in these patients [2].

Objectives: To investigate the concordance of different comorbidities scores in patients with PA.

Methods: Prospective inclusion of patients diagnosed with PA according to the CASPAR (CIASsification criteria for Psoriatic ARthritis) criteria. Associated comorbidities were prospectively assessed using the Psoriatic arthritis comorbidity index (PsACI) with a cut-off of 8 points as previously defined [2]. Also, the following comorbidities scores were completed in all patients: Charlson comorbidity index (CCI), Rheumatoid Arthritis Comorbidity Index (RACI), Rheumatic Diseases comorbidity index (RDCI), Functional comorbidity index (FCI).

Results: A total of 56 patients were included: 27 (48.2%) were female, with a med (q1;q3) disease duration of 17.5 (12.7; 26.5) years for the cutaneous disease and 6.0 (4.0; 13.0) years for the articular one. At inclusion, the results of the comorbidities scores assessed were as follow: PsACI 3.2 (2.0; 6.5), CCI 1.0 (0.0; 2.0), RACI 3.5 (1.5; 6.5), RDCI 1.0 (0.0; 2.0), and FCI 2.0 (0.0; 2.0), respectively. According to PsACI, hypertension, hyperlipidemia, osteoarthritis, liver disease, and diabetes mellitus were the most frequent associated comorbidities in PA patients, in 53.6%, 44.6%, 41.1%, 37.5%, and 28.6% cases, respectively (see Table 1).

Table 1. Comorbidities according to the Psoriatic Arthritis Comorbidity Index

Parameter	n (%)	Parameter	n (%)
Diabetes mellitus	16 (28.6)	Cerebrovascular disease	1 (1.8)
Metabolic syndrome	8 (14.3)	Peripheral vascular disease	2 (3.6)
Ischemic heart disease	9 (16.1)	Osteoporosis	4 (7.1)
Myocardial infarction	1 (1.8)	Fracture	3 (5.4)
Hypertension	30 (53.6)	Fall	1 (1.8)
Hyperlipidemia	25 (44.6)	Liver disease	21 (37.5)
Arrhythmia	2 (3.6)	Renal disease	2 (3.6)
Depression	6 (10.7)	Pulmonary disease	6 (10.7)
Anxiety	10 (17.9)	Gastrointestinal tract	2 (3.6)
Endocrine	7 (12.5)	Osteoarthritis	23 (41.1)
Periodontitis	1 (1.8)	Fibromyalgia	3 (5.4)
Smoking	6 (10.7)	Amyloidosis	1 (1.8)
Infection	0 (0.0)	Eyes inflame/ uveitis	0 (0.0)
Vasculitis	0 (0.0)	Tumor	3 (5.4)

In bivariate analysis, we found significant correlations between the results of PsACI and those of the other comorbidities scores used: CCI (p<0.001, rho=0.668), RACI (p<0.001, rho=0.792), RDCI (p<0.001, rho=0.691), and FCI (p<0.001, rho=0.697), respectively. The ability of the comorbidities scores assessed to discriminate a PsACI high value is presented in Figure 1, AUC (95%CI): CCI 0.743 (0.601- 0.886) p=0.017, RACI 0.815 (0.634 - 0.996) p=0.002, RDCI 0.818 (0.657-0.980) p=0.002, and FCI 0.837 (0.725-0.948) p=0.001, respectively.

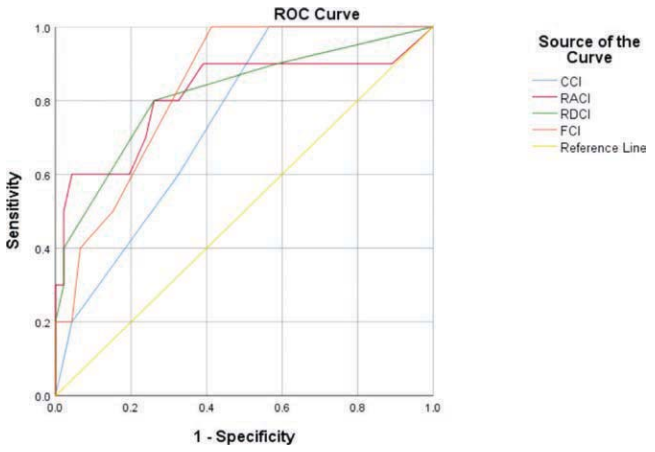

Figure 1. The Area Under the curve of the Receiver Operating Characteristic (AUROC) for high PsACI results (PsACI > 8)

Conclusion: The composite indexes offer the advantage of reducing all associated comorbidities as long with their severity into a single score. We herein

identified good correlations between the results of the comorbidities scores analyzed, PsACI, CCI, RDCI, RACI, and FCI, respectively.

AB0955 DISEASE ACTIVITY IMPACT OVER THE ANXIETY LEVEL IN PATIENTS WITH PSORIATIC ARTHRITIS

N. D. Popescu[1], A. Dima[1], I. A. Berza[1], G. M. State[1], F. Negoi[1], M. Panduru[2], M. Parvu[1]. *[1]Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania; [2]Colentina Clinical Hospital, Department of Dermatology, Bucharest, Romania*

Background: Psoriatic arthritis (PA) is a complex, systemic, chronic inflammatory condition with substantial multisystemic detrimental effects on patients' health status. In PA patients there was reported increased anxiety occurrence when compared to general population, even if specific predictors are not defined yet [1].

Objectives: To characterize disease-related predictors of anxiety in patients with PA.

Methods: Cross-sectional study with prospective, successive inclusion of patients fulfilling the CASPAR (CIASsification criteria for Psoriatic ARthritis) classification criteria for PA. Anxiety level was assessed using the General Anxiety Disorder-7 (GAD-7) with a cut-off of 10 points as previous defined [2]. Moreover, disease activity status for PA was defined using also validated scores, namely the Disease Activity Index for Psoriatic Arthritis (DAPSA), the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the Ankylosing Spondylitis Disease Activity Score (ASDAS), cutaneous involvement by the Psoriasis Area Severity Index (PASI), and comorbidities by Psoriatic arthritis comorbidity index (PsACI).

Results: 56 PA patients were included, 29 (51.8%) males, with mean±SD age at inclusion of 54.1±13.2years. Regarding the tools for disease activity assessment, the probability of impact over a high anxiety level as estimated by area under curve (AUC) was high (> 0.800) for BASDAI [AUC(95%CI) 0.859 (0.738-0.979)], especially in relation with the last 3 items about inflammation of other than neck, back or hip joints and morning stiffness (see Figure 1).

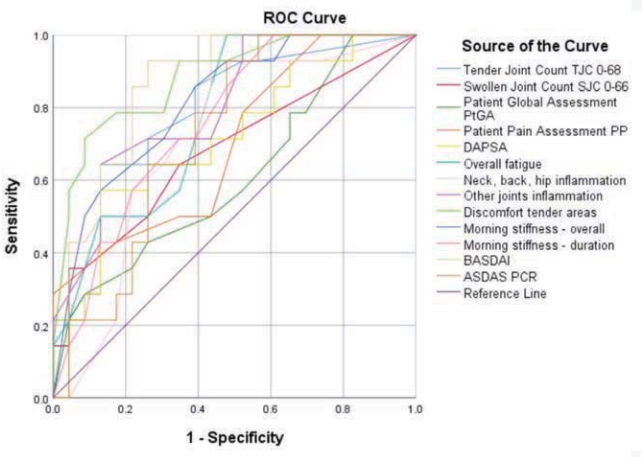

Figure 1. The Area Under the curve of the Receiver Operating Characteristic (AUROC) for high anxiety level (GAD-7 > 10)

In bivariate analysis, we found a significant difference regarding a higher anxiety level as assessed by GAD-7 for female gender (28.6% vs. 78.9%, p=0.001), concomitance of peripheral and axial articular involvement (25.7% vs. 52.6%, p=0.034), DAPSA (14.8 (7.1; 22.8) vs. 24.6 (12.2; 36.8), p=0.035), BASDAI (3.1 (1.3; 4.1) vs. 7.1 (5.0; 8.0), p<0.001), and ASDAS-CRP (2.5 (1.1; 3.7) vs. 3.5 (2.7; 4.0), p=0.038), but not for the other parameters search, namely age, smoking, alcohol intake, home settle (urban/ rural, living alone, kids), disease duration, HLA-B27 status, PASI, PsACI, Patient (PtGA) or Physician (PGA) Global Assessment, ongoing corticosteroid treatment, or inflammation status (ESR, CRP).In multivariate analysis, the PA disease-related predictor for increased anxiety was the auto-evaluation by BASDAI, OR (95%CI) 1.844 (1.198 - 2.839) (see Table 1).

Table 1. Independent predictors for anxiety in psoriatic arthritis patients

Parameter		95% CI		p-value
		lower	upper	
Gender, F/M (%F)	0.106	0.023	0.498	0.004
Articular axial and peripheric, Y/N (%Y)	0.289	0.055	1.503	0.140
DAPSA	1.017	0.973	1.063	0.460
BASDAI	1.844	1.198	2.839	0.005
ASDAS-CRP	1.312	0.877	1.964	0.186

Conclusion: Therefore, higher BASDAI results were associated with increased anxiety in PA and so such results should raise awareness about the need of search for associated anxiety disorders. On the contrary, the extension of the cutaneous involvement, the systemic inflammation level or the comorbidities degree were not identified as predictors for the anxiety occurrence.

AB0956 TO WHAT EXTEND IS NAIL ULTRASOUND DISCRIMINATIVE BETWEEN PSORIATIC ARTHRITIS AND HEALTHY SUBJECTS?

I. Mahmoud[1], S. Rahmouni[1], A. Ben Tekaya[1], S. Bouden[1], L. Rouached[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]. *[1]Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*

Background: Clinical physical examination can detect superficial nail changes in psoriatic patients. However, the nail matrix and bed are not accessible for clinical assessment. Recently, ultrasonography (US) has emerged as a useful tool to assess nail involvement in psoriatic arthritis (PsA) patients.

Objectives: To assess the discriminative utility of nail features detected by B-mode (BM) and color Doppler (CD) ultrasound (US) between patients with psoriatic arthritis (PsA) and healthy controls (HC).

Methods: This was a cross-sectional study including PsA patients and HC.

All patients and controls underwent an US assessment of the fingernails that included the study of morphological changes based on Wortsman's description [1]: focal hyperechoic involvement of the ventral plate without involvement of the dorsal plate (type I), loosening of the borders of the ventral plate (type II), appearance of wavy plates (type III) and loss of definition on both plates (type IV), blood flow disturbances and measurement of the thickness of nail bed (NBT), nail plate (TNP) and adjacent skin.

Results: A total of 536 nails were examined (PsA:326 nails, HC:210). Patients with PsA had significantly more morphological changes of the nails than healthy controls (23% vs 3.33%, p = 0.006). In PsA patients, the most frequently observed aspect was type III (47 nails, 14.4%), followed by type II (40 nails,12.3%) and type IV (38 nails, 11.6%). In HC, the only observed type was type (type II). US detected subclinical nail involvement in 37 healthy nails among PsA patients (11.34%). On the other hand, seven nails with clinical involvement did not demonstrate US changes: perionyxis (n=1), pitting (n=2), onycholyses (n=3), hemorrhage (n=1). The power Doppler signal of the nail bed and matrix was comparable between the groups (54% vs 61%, p= 0.603 and 41% vs 37.1%, p=0.432, respectively). NBT and skin thickness were higher in the HC group than the PsA group (1.90±0.22 mm vs 2.07±0.34 mm, p=0.047 and 2.25±0.69 vs 2.59±0.31 mm, p=0.002, respectively). While NPT was similar between the groups (0.38±0.09 vs 0.36±0.07mm, p=0.239).

Conclusion: Us detected morphological changes in clinically healthy fingernails in both PsA patients and healthy controls. However subclinical involvement was more common in PsA patients. Loosening of the borders of the ventral plate (type II) was the only aspect observed in HC. This would suggest that this type is not

a specific feature of psoriatic nail. With regards to nail plate thickness, the measurements were similar between PsA patients and HC as previously reported by Mondal et al [2].
However, unlike previous studies, we showed that the nail bed and skin thickness were significantly higher in healthy controls than PsA patients [3].

AB0957 LIMITED GENDER-RELATED DIFFERENCES CHARACTERIZE PSORIATIC ARTHRITIS: DATA FROM A MONOCENTRIC ANALYSIS OF 306 PATIENTS

N. Luciano[1], G. Roselli[1], L. Canziani[1], G. M. Guidelli[1], M. Caprioli[1], M. De Santis[1], A. Ceribelli[1], C. Selmi[1]. [1]*Humanitas Research Hospital - IRCCS, Rheumatology and Clinical Immunology, Rozzano, Italy*

Background: Psoriatic Arthritis (PsA) is characterised by a wide spectrum of clinical phenotypes which are ultimately driving therapeutic choices. The male-to-female ratio of the disease is approximately even but in the last decades some gender differences have been proposed in terms of clinical expression and therapeutic responses.
Objectives: The aim of this study is to confirm these differences in a real-life cohort of PsA patients.
Methods: A retrospective data collection has been conducted on a cohort of outpatients with PsA attending our Rheumatology Clinics at Humanitas Research Hospital between January 1st and December 31st 2021. All patients were ≥ 18 years old and fulfilled the CASPAR criteria for PsA. For each patient we obtained demographic, laboratory and clinical parameters and registered which domains (peripheral arthritis, axial PsA, skin and/or nail disease, enthesitis, dactylitis) have been involved in the course of the disease. We also collected data regarding any concomitant comorbidities and previous and current therapies. To investigate possible gender specific differences a cross-sectional univariate descriptive analysis was performed.
Results: Our cohort included 306 patients (169 - 55% - women) with PsA. The median age of disease onset was the same for men and women, also when separately considering skin (median 38 years) and articular presentation (median 48 years). No statistically significant differences were observed when comparing the two groups in terms of clinical phenotypes. In both groups peripheral arthritis was referred by the vast majority of patients (95% of women vs. 93% of men) and similar rates of axial involvement (34% in women vs. 37% in men). Considering current or previous therapies, we found a comparable use of non steroidal anti-inflammatory drugs (43% in both groups), systemic glucocorticoids (9% in men vs 10% in women), conventional synthetic DMARDs and biologic DMARDs and in each group the percentages of patients with a history of bDMARDs targeting TNFalfa, IL12-23 or IL17 failure (women vs men: 11%vs 11%, 9% vs 6% and 4% vs 5% respectively) were essentially the same. A higher proportion of women received apremilast (13% vs. 4% of men, P= 0.003). We also observed differences in terms of comorbidities: in our cohort women were more frequently affected by hypothyroidism (6/137 vs. 23/149 in men, P=0.006), fibromyalgia (2/137 vs 33/149, P<0.001) and neurologic disorders (13/137 vs. 41/149, P=0.001) compared to men.
Conclusion: Our cohort demonstrated limited gender-related differences in PsA course and therapeutic choices or duration, reporting only higher prevalence of hypothyroidism, fibromyalgia and neurologic disorders in women.

AB0958 THE RELATIONSHIP BETWEEN THE EXTENSOR TENDON ENTHESIS AND THE NAIL IN DISTAL INTERPHALANGEAL JOINT DISEASE IN PSORIATIC ARTHRITIS: ULTRASOUND STUDY

I. Mahmoud[1], S. Rahmouni[1], A. Ben Tekaya[1], S. Bouden[1], L. Rouached[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*

Background: It has been shown that there is an anatomical link between the distal interphalangeal joint (DIP) extensor tendon enthesitis and the nail changes in psoriatic arthritis (PsA) [1].
Objectives: To evaluate the relationship between nail involvement and enthesopathy at DIP level in PsA patients using ultrasonography (US).
Methods: We included patients with PsA. According to OMERACT, the following elemental lesions were dichotomously (presence/absence) evaluated on greyscale US assessment at extensor tendon insertion at distal phalanx of DIP joints: abnormally hypoechoic, enthesophytes, and erosions. We also measured the tendon thickness. Increased abnormal vascularization at entheseal level was also assessed using PD technique. We also performed an US assessment of the finger nails that included the study of morphological changes and measurement of the thickness of nail bed (NBT), nail plate (NPT) and adjacent skin (ST).
Results: We included 33 PsA patients (323 DIP). Eleven patients (34 %) presented psoriatic onychopathy (45 fingernails) with a mean NAPSI 7 (IQR (25,75)) [2 -18]. US study of the nails revealed dystrophy in 75 nails (23%). At patient level, the mean NPT, NBT and SK were 1.90±0.22, 0.38±0.09, and 2.33±0.62, respectively. None of the patients had clinical involvement of DIP. Using US, we examined 325 extensor tendon. The mean thickness of the tendon was 0.63mm ±0.1 mm. The tendon was abnormally hypoechoic in two fingers (0.61%). Erosions were present in 16 DIP (4.9%). We found enthesophytes in 82 DIP joints at insertion of extensor digitorum tendon (25.23%). We did not observe increased abnormal vascularization at entheseal level. At finger level, the extensor tendon thickness was higher in the presence of US nail dystrophy (0.70 mm vs 0.60, p=0.01). Erosions were more common in fingers with US nail involvement (14.6 % vs 1.9%, p=0.00). Osteophytes were present in 20% of fingers with US nail involvement and 26.3% of fingers without US nail involvement (p=0.166). The thickness of DIP digital extensor tendons was correlated with the NBT(r = 0.412, p = 0.00), the NPT (r = 0.310, p = 0.00), and the thickness of the adjacent skin (r = 0.509, p = 0.00).
Conclusion: The presence of US nail dystrophy was associated with thicker extensor tendon and more erosions. The thickness of the tendon was correlated with the thickness of the nail parts. This might be explained by the close relationship between nail and enthesis and supports the theory of the enthesis as an extended organ beyond the tendon bony attachment.

INIBIC, A Coruña, Spain*

Background: Patients with psoriatic arthritis (PsA) show an impact on the physical and psychological aspect of the disease and it can be measured with the PsA Impact of Disease (PsAID) questionnaire, and it is expected that the impact of the disease improves when the patient is in remission or low disease activity.
Objectives: To determine the rate of low impact of the disease in patients with PsA in daily clinical practice, and to evaluate its relationship with its axial activity.
Methods: A cross-sectional study was conducted in consecutive patients who met the CASPAR criteria, with positive clinical (DLI) and positive axial radiology, with or without peripheral involvement, and who were treated according to standard clinical practice (EULAR recommendations). Demographic, clinical, analytical data, HAQ index (0-3) and PsAID12 (0-10) were also collected. Patients were divided into 2 groups: those with a PsAID above 4 (high impact) or below 4 (low

impact). Continuous variables are shown as median (Q1-Q3) and categorical variables as percentages and frequencies. The analyzes were performed using SPSS23 software. Differences were considered statistically significant if $p < 0.05$.
Results: Of the 269 patients evaluated with PsA, 72 patients with axial involvement were included, 40 men (55.6%), with a median age of 54.1 years (45.0-62.0) and disease duration of 7 years (2-11). Obesity (BMI>29.99) affected 28.3% and serum CRP level was 0.45 mgr/dl (0.08-1.10). The treatments of the patients were: NSAIDs 43.1%, corticosteroids 21.6%, csDMARD 52.9% and biological therapy 51.9%. The BASDAI was 4.2 (2.0-6.2) and the ASDAS-PCR was 2.4 (1.5-3.2), with 39.6% being in low activity or remission. The median PsAID total score was 3.9 (1.6-5.4), evaluated in 61 patients. The patients who achieved a PsAID12 ≤4 was 63% (see Table 1), more men and with a lower CRP. In addition, the low impact measured by the PsAID12 was associated with a lower BASDAI and ASDAS-PCR.
Conclusion: Almost two thirds of patients with PsA with axial involvement in daily clinical practice had a low impact of the disease measured by PsAID12 and correlated with low activity in the BASDAI and ASDAS-PCR.

	PsAID≤4 n=39	PsAID>4 n=22	p

AB0960 ULTRASONOGRAPHIC ASSESSMENT OF DISTAL INTERPHALANGEAL JOINTS IN PSORIATIC ARTHRITIS

I. Mahmoud[1], S. Rahmouni[1], A. Ben Tekaya[1], S. Bouden[1], L. Rouached[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*

Background: Distal interphalangeal (DIP) joint involvement is frequent in Psoriatic arthritis (PsA). Ultraousnd (US) may help identify subclinal DIP arthritis.
Objectives: We aimed to assess by US the DIP joint involvement in PsA in comparison with healthy controls (HC).
Methods: This was a cross-sectional study including 33 PsA patients and 21 matched-healthy controls (HC). An US scan of all DIP joints was performed in order to look for erosions, synovitis (B-mode and doppler) and extensor tendon enthesopathy.
Results: We included 33 patients with PsA and 21 HC. There was no difference between the two groups regarding the age (51.2 ±12.5 vs 53±11.8 years, p=0.5), sex-ratio (0.65 vs 0.61, p=1), manual activity (p=1) and smoking status (23.8% vs 18%, p=0.433).On clinical examination,we did not find any tender nor swollen DIP joints in both groups. Eleven PsA patients (34 %) had psoriatic onychopathy (45 fingernails) with a mean NAPSI 7 (IQR (25,75)) [2 -18]. In the PsA group, a total of 323 DIP joints were examined by US, synovitis of the DIP joints was detected in ten DIP joints (3.1%) (right hand: seven, left hand:three), six of them had PD (right hand:four, left hand:two). Eosions were found in 16 DIP joints (4.95%) (right hand:seven, left hand: nine). Enthesophytes were seen in 82 DIP joints (25,2%). At patient level, six PsA patients had at least one US synovitis (18.1%), seven had at least one erosion (21.2%) and 22 had at least one DIP joint with enthesophytes (66.6%) Compared to HC, PsA patients had more synovitis (3.1% vs 0, p=0.001),more erosions (4.95% vs 0.4%, p=0,03), and more enthesophytes (25.2% vs, 17%, p=0,002) The was no difference between the two groups regarding the thickness of the extensor tendon (0.63 mm vs 0.61 mm, p=0.594).
In the PsA group, the patients with nail dystrophy had more osteophytes (24% vs 10%, p<0,001), more erosions (14.6% vs 1.96%, p=0.000), and more synovitis (6%, vs 1.9%, p=0.037).
Conclusion: Subclinical involvement of DIP joints is common in PsA patients, notably in the presence of nail dystrophy.

AB0961 UVEITIS IN PATIENTS WITH PSORIATIC ARTHRITIS

S. Monov[1], R. Shumnalieva[1], M. Sotirova[2], D. Monova[3]. [1]*Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria;* [2]*Medical Institute - MVR, Department of Ophthalmology, Sofia, Bulgaria;* [3]*Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*

Background: Psoriatic arthritis (PsA) is a common disease in Departments of rheumatology. PsA affects from 5 % to 30 % of patients with psoriasis. The arthritis associated with psoriasis follows different patterns, including oligoarticular disease, polyarticular disease, distal interphalangeal disease, arthritis mutilans and axial disease. The axial disease often overlaps with the other four groups. Psoriatic arthritis belongs to the group of spondyloarthropathies in which uveitis is an associated disease. The prevalence of uveitis among PsA patients is not well established.
Objectives: The aim of this study is to describe the clinical characteristics of uveitis related to psoriatic arthritis.
Methods: Uveitis is described as an inflammation of the tissues that comprise the uveal tract (i.e., iris, ciliary body, and choroid). It can be classified either according to the anatomic parts of uvea that are involved or according to its underlying etiological cause. Anterior uveitis involves the iris and/or the ciliary body, intermediate uveitis involves the vitreous humor, while posterior uveitis is characterized by inflammation of the uvea and the choroid. A retrospective database study was conducted on 164 (96 female, 68 male, mean age 52,36±16,14 years) adult PsA patients with ocular symptoms. Demographic variables, smoking status, socioeconomic status (SES), body mass index (BMI), presence of selected chronic comorbidities, and medication use, including conventional and biologic disease modifying anti-rheumatic drugs (c/b DMARD) were extracted. We collected data about psoriasis type, uveitis laterality, onset type, human leukocyte antigen types, visual acuity, ocular inflammation localization, anterior segment findings, funduscopy findings, complications, recurrence, intraocular pressure, visual acuity, comorbidities, and medical treatments and outcomes for uveitis and psoriasis, and medical treatments for uveitis and skin diseases. Descriptive statistics was applied as appropriate. Cox proportional hazard regression time dependent models were used to calculate the risk of uveitis given demographic variables, SES, smoking, selected comorbidities, and c/bDMARD. P values of ≤ 0.05 were considered statistically significant.
Results: This study included a broad spectrum of ocular inflammation associated with PsA. We found that conjunctivitis was the most common problem, affecting 53 patients (32,32 %). Iritis (anterior uveitis) was found in 10 (6,1%), episcleritis - in 3 (1,83 %) and keratoconjunctivitis sicca - in 5 (3,05 %) patients. 14 patients were with axial involvement, seven of them with anterior uveitis. Patients with PsA and uveitis were more often female (7), of a younger age (48,25±15,4 years). In our cohort of patients uveitis is bilateral in 7 patients, all cases had acute non-granulomatous anterior uveitis. Anterior uveitis is usually accompanied by pain and redness of the eye without vision loss, while intermediate (1 patients) and posterior (2 patients) uveitis are mainly associated with visual symptoms such as floaters or blind spots and may affect central vision. Patients with uveitis had a previous history of uveitis and were more often treated with cDMARDS, monoclonal anti-Tumor Necrosis Factor-a (antiTNF-a) agents and etanercept. No difference in uveitis occurrence was noted regarding demographic characteristics and comorbidities.
Conclusion: Uveitis, in particular, is being considered as a relatively rare but very serious ocular complication of psoriasis. Patients with psoriasis should be educated about the increased risk and manifestations of uveitis. An ophthalmological consultation is needed when patients present with eye symptoms.

AB0962 PSORIATIC ARTHRITIS WITH POSITIVE ACPA, WHICH FEATURES?

S. Ghazzali[1], I. EL Harch[2], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. [1]*University Hospital Hassan 2 of Fes, rheumathology, Fes, Morocco;* [2]*medical school of Fes, epidemiology, Fes, Morocco*

Background: Anti-cyclic citrullinated peptide antibodies (ACPA) have been detected in several patients with psoriatic arthritis (PsA). It is possible that these autoantibodies are associated with particular features of PsA.

Objectives: The objective of our study was to assess the frequency of anti-CCP antibody positivity in psoriatic arthritis, and to identify the factors associated with this positivity in PsA.
Methods: Observational cross-sectional study, carried out in the rheumatology department of the CHU Hassan II of FES between January 2012 and October 2021. Including 67 patients with RP fulfilling the CASPAR criteria. ACPA positivity threshold was >20Ui/ml.
Results: Our study included 67 patients, the mean age was 55.3 +/- 15 years, the sex ratio was 0.36 M/F, the mean disease duration was 6.61 +/- 9 years. ACPA were positive in 16.4% of cases (11 patients), and negative in 83.6% of cases (56 patients). In bivariate analysis, PsA with positive ACPA was more common in men (27.8% versus 12% p=0.049), PsA patients with positive ACPA presented less inflammatory back pain (14% versus 86%) (p=0.049), developed more frequently pulmonary complications (60%) (P=0.001, and presented more often a positive rheumatoid factor (32% versus 7%) (P=0.019). In multivariate analysis, male gender was significantly related to ACPA positivity (p=0.049, OR=22.702, IC=1.05-505). Likewise for lung involvement (p=0.010, OR=67.903, IC=2.6 -1709.8). Also, ACPA positivity during PsA was significantly related to that of rheumatoid factor (RF) (p=0.05 OR=61.375 IC=0.994-3789). In addition, no statistically significant difference was found between the two groups concerning the activity of the disease, the structural impact, the biological inflammatory syndrome and the use of biotherapy.
Conclusion: In our study, PsA is characterized by a low predominance of a positive ACPA form. This form with positive ACPA is found in our context to be more frequent among men, more often associated with positive RF, and is more complicated by pulmonary damage.

AB0963 FREQUENCY OF SEXUAL DYSFUNCTION IN PSORIATIC ARTHRITIS, SANTO DOMINGO, DOMINICAN REPUBLIC

J. Santana Peralta[1], A. Cornelio[1], D. Garcia[1], R. A. Alvarez Santana[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez Lorie[1], A. Feriz[1], R. Muñoz Louis[1]. [1]*Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Psoriatic arthritis (PsA) is an inflammatory joint disease that cause structural damage, disability, and an impairment of quality of life.[1]Sexual function is a neglected area of quality of life in patients with PsA, with a high prevalence of dissatisfaction.[2] It has been described that there is no relationship between the activity of the disease and the degree of joint dysfunction.[3] In 1 out of 5 patients consider that the disease negatively impacts their sexuality.[4] CSFQ-14 (Changes in Sexual Functioning Questionnaire), evaluates changes in sexual functioning due to an illness or treatment in 5 domains with a score range 14-70; cut-off point indicating sexual dysfunction -41 men and -47 women.[5]
Objectives: To evaluate the frequency and degree of sexual dysfunction in patients with psoriatic arthritis.
Methods: Prospective, observational, cross-sectional study. The patients of the outpatient clinic of the rheumatology service of the Padre Billini teaching hospital were interviewed during November 2021. Inclusion criteria: ≥18 years, PsA diagnosis according to CASPAR classification criteria 2006. Exclusion criteria: diagnosis of another autoimmune disease, depression, treatment with antidepressants. We analyzed the data in SPSS23 and used the Pearson correlation coefficient with a statistical significance p=<0.05 (rp) to relate the data.
Results: 58 met inclusion criteria. 63.8% (37) female, male 36.2% (21), mean age 54.8 + 11.75 y, mean diagnosis 7.9 y, married 55.2% (32), unmarried 39.7% (23), widowed 5.2% (3). Frequency of sexual dysfunction 39.7% (23), CSFQ-14 indicative of dysfunction in women 35.1% (23), men 47.6% (10). Female Domains: Pleasure dysfunction 35.1% (13), desire/interest 32.4% (12), desire/frequency 32.4% (12), arousal 24.3% (9), orgasm/completion 43.2% (16). Male Domains: Pleasure dysfunction 38.1% (8), desire/interest 47.6% (10), desire/frequency 33.3% (7), arousal 23.8% (5), orgasm/completion 42.9% (9). Correlation CSFQ-14/DAPSA28 domains: Pleasure dysfunction: DAPSA remission 19.2% (5), low 32.1% (9), moderate 50% (2). Desire/interest: DAPSA remission 34.6% (9), low 32.1% (9), moderate 100% (4). Desire/frequency: DAPSA remission 30.8% (8), low 37.5% (10), moderate 25% (1). Excitation: DAPSA remission 30.8% (8), low 17.9% (5), moderate 25% (1). Orgasm/completion: DAPSA remission 50% (13), low 37.5% (10), moderate 50% (2). r_p=. 042 p<0.05.
Conclusion: The study showed a modest frequency of global sexual dysfunction. In men it was superior. The orgasm/completion domain proved to be the most dysfunctional in both sexes. A statistically significant linear association of sexual dysfunction and disease activity was evident.

AB0964 PSORIATIC ARTHRITIS (PSA) WITH POSITIVE RHEUMATOID FACTOR (RF) VERSUS PSORIATIC ARTHRITIS WITH NEGATIVE RF

S. Ghazzali[1], I. EL Harch[2], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. [1]*University Hospital Hassan 2 of Fes, Rheumathology, Fes, Morocco;* [2]*University Hospital Hassan 2 of Fes, epidemiology, Fes, Morocco*

Background: Rheumatoid factor (RF) has been detected in several patients with psoriatic arthritis (PS). It is likely that its positivity is linked to a very specific clinical, biological and/or evolutionary profile of PsA.
Objectives: The objective of our study was to evaluate the frequency of positive rheumatoid factor during PsA, and to define the characteristics and factors related to this positivity.
Methods: Monocentric observational cross-sectional study including 84 patients with PsA, fulfilling the CASPAR criteria, and hospitalized in our rheumatology department in University Hospital Hassan II of Fez, on the period lying between January 2012 and October 2021. A threshold greater than 20Ui/ml of defines RF positivity.
Results: Our study included 84 patients, the average age was 57 +/- 13 years. The sex ratio was 0.35 M/F, the average duration of disease progression was 6 years +/- 8 years. 47.6% of patients had a positive RF (40 patients) while 52.4% of patients had a negative RF (44 patients). In bivariate analysis, PsA with positive RF had an earlier age of the disease onset (p=0.017), was more frequent in chronic smokers (p=0.045), and showed more enthesis damage (p=0.046). Also, patients with PsA and a positive RF had a higher biological inflammatory syndrome (p=0.013) in particular CRP (p=0.007), higher Basdai and DAPSA (p=0.021) (p=0.021) respectively In multivariate analysis, enthesis damage involvement was significantly linked to RF positivity (p=0.039, OR=3, IC=1.059-8.495), as was the biological inflammatory syndrome (p=0.010, OR=3.875, IC=1.382 -10.766).
Conclusion: In our study, PsA with positive RF is found to be earlier and more severe in comparison with PsA with negative RF, and more frequently adopts the peripheral enthesitic form.

AB0965 SERIAL SEROLOGY TESTING IN PATIENTS WITH PSORIATIC ARTHRITIS- SHOULD IT BE DONE?

S. Sundanum[1], D. Veale[1], C. Orr[1], L. O'neill[1], F. Young[1]. [1]*Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, University College Dublin, Rheumatology, Dublin, Ireland*

Background: The diagnosis of psoriatic arthritis (PsA) is largely based on clinical phenotype due to the heterogeneity of the presenting features, which can include synovio-entheseal disease, dactylitis, skin and nail disease, uveitis and axial involvement. (1) In contrast to rheumatoid arthritis (RA), PsA is a seronegative inflammatory arthropathy. Rheumatoid factor (RF) and Anti-CCP antibodies are usually absent in PsA, and if patients do have positive serological findings for RF or CCP, the titres tend to be low. (2) Seronegativity for RF has a significantly high discriminant value in the Classification Criteria for Psoriatic arthritis (CASPAR), such that a negative RF forms one of the five possible criteria; thus serological testing is often done once at the initial diagnostic appointment. (3) A previous study in the context of RA has shown that there is a tendency for

repeated serological testing with as much as 70% of patients having RF tested more than once.(4) Repeated testing amounts to additional expense and is rarely needed in PsA. The literature on the frequency of repeated serology testing in PsA patients is absent.

Objectives: To determine how often was serology for RF and anti-CCP antibodies repeated in a PsA cohort.

Methods: A cohort of consecutive patients attending the rheumatology clinic at our centre with a diagnosis of PsA were included. We reviewed the laboratory results of individual patients to determine how many times each patient had been tested for RF and anti-CCP antibodies.

Results: 118 patients with a diagnosis of PsA were included. 117 patients had RF antibody testing at least once and all 118 patients had a minimum of one anti-CCP antibody test. 59/117 (50.4%) patients had RF checked more than once and 28/117 (23.9%) had testing at least 3 times. 3 patients had an initial positive RF which was negative on subsequent testing. Anti-CCP antibody was checked on all 118 patients. 41/118 (34.7%) patients had anti-CCP checked more than once and 13/118 (11.0%) patients had testing at least 2 times. One patient had an initial equivocal anti-CCP antibody titre which was subsequently negative on repeat testing.

Conclusion: As opposed to RA, PsA has not been associated with the presence of circulating antibodies. The presence or absence of RF in PsA patients has for long been a subject of debate. (3) In cases of peripheral polyarticular PsA, which may be difficult to distinguish from RA, serological testing can be useful to identify RA. However, studies have found that RF can be present in 5-13% of PsA patients. (5) In the context of RA, serological conversion from negative to positive is infrequent and repeat testing is not recommended. (6) Over half of the patients in our PsA cohort had repeated RF testing. Certainly this is unlikely to be helpful or cost effective and serial serology measurements in PsA patients should be avoided.

AB0966

ARE CURRENT PATIENT REPORTED OUTCOMES TOOLS OPTIMIZED TO CAPTURE THE ENTIRE PATIENT EXPERIENCE?

P. J. Mease[1], V. Strand[2], D. Furst[3], E. Siegel[4], M. Mcilraith[5], M. E. Husni[6], M. C. Hay[7]. *[1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, Washington, United States of America; [2]Stanford, Rheumatology, Palo Alto, California, United States of America; [3]University of California Medical Center, Rheumatology, Los Angeles, California, United States of America; [4]Georgetown University School of Medicine, Rheumatology, Washington DC, United States of America; [5]MMc Consulting, Research, Dallas, Texas, United States of America; [6]Cleveland Clinic, Rheumatologic and Immunologic Disease, Cleveland, Ohio, United States of America; [7]Miami University, Anthropology, Oxford, Ohio, United States of America*

Background: Psoriatic Arthritis (PsA) affects multiple attributes of patient health; to assess treatment effectiveness a compilation of Patient Reported Outcomes (PRO) have been utilized. While useful, most of these were originally created for other diseases and only later validated or adapted for use in PsA. More recent efforts have focused on development of PsA specific PRO tools, with inclusion of patient input and relevance for use in both clinical research and clinical care (1).

Objectives: To subject a broad set of currently used PROs to patient assessment, giving insight into usefulness in the clinic and informing efforts for optimization of PsA PROs.

Methods: Four focus groups were conducted across three regionally-diverse areas in the United States from March 2016 to October 2016. Patients represented a range of disease history, symptoms, and severity. After trained facilitators encouraged open conversation about PsA, including symptoms, challenges and feelings about disease and treatment, patients reviewed 13 currently utilized PROs and rated relevance of these instruments to reporting their disease experiences on a 3 point scale of Relevant, Somewhat Relevant, and Irrelevant. Verbal discussion followed on the merits and challenges of each rated PRO

Results: PRO instruments ranged from overall global assessments to disease specific assessments (Table 1). The PROs received a variety of ratings, with Functional Assessment of Chronic Illness Therapy - Fatigue (FACIT-F) and Psoriatic Arthritis Impact of Disease (PsAID) judged as Very Relevant by the largest number of patients, followed by Health Assessment Questionnaire-Spondyloarthropathies (HAQ-S) and Pain VAS (Figure 1). Instruments receiving the most assessments of Not Really Relevant were Pt Global and PsA Quality of Life (PsAQOL). In the qualitative portion of the research, major patient critiques across PROs were the time frames listed on the questionnaires; some were too restrictive and disallowed reporting important recent disease activity. Preferences were for questions asked as '.since your last visit..' Multiple participants also agreed that a visual tool allowing patients to circle specific joints to indicate pain would be useful.

Table 1. Outcomes Instruments Assessed in the Study

Tool	Abbreviation	Time Period Queried
Patient Global	Pt GA	None Specified
Pain Visual Analog Scale	Pain VAS	In the past week
Health Assessment Questionnaire-Spondyloarthropathies	HAQ-S	Over the past week
Short Form - 36	SF-36	Different periods queried for different questions: Compared to a year ago; None Specified; Over the past 4 weeks
Functional Assessment of Chronic Illness Therapy - Fatigue	FACIT-F	Past 7 Days
EQ-5D and EQ Visual Analog Scale	EQ-5D-5L	Today
Psoriatic Arthritis Quality of Life	PsAQOL	None specified
Psoriatic Arthritis Impact of Disease	PsAID	During the last week
Dermatology Life Quality Index	DLQI	Over the last Week
Psoriasis Symptom Inventory	PSI	Last 7 days
Work Productivity and Activity Impairment: General Health	WPAI:GH	During the past 7 days
Work Productivity Survey - PsA	WPS-PsA	Last month
Beck Depression Inventory	BDI-II	During the past 2 weeks

Conclusion: Currently utilized PROs in PsA evaluating domains of fatigue, function, pain, and disease specific manifestations were all important regarding new therapeutic agents. However, some are more relevant than others to patients, most notably FACIT-F and PsAID, the latter being an important example of a patient-led and disease-specific development effort. Allowing reporting of items of concern without restrictive time periods is important to patients. These preferences and comments can be utilized to better understand the value of PROs in clinical settings to optimize patient-clinician communications.

Osteoarthritis

AB0967 IMPACT OF CARPAL TUNNEL SYNDROME ON SYMPTOMS AND STRUCTURAL SEVERITY OF HAND OSTEOARTHRITIS: RESULTS FROM THE DIGICOD COHORT.

H. J. Djossou[1], S. Tuffet[2], A. Rousseau[2], A. Latourte[3], J. D. Laredo[4], F. Berenbaum[1], J. Sellam[1]on behalf of DIGICOD. *[1]Hôpital Saint-Antoine, Paris, France, Service de Rhumatologie, Paris, France; [2]Hôpital Saint-Antoine, Paris, France, Service de Pharmacologie Clinique et Plateforme de Recherche Clinique de l'Est Parisien (URCEST, CRB, CRC), Paris, France; [3]Hôpital Lariboisière, Paris, France, Service de Rhumatologie, Paris, France; [4]Hôpital Lariboisière, Paris, France, Service de Radiologie, Paris, France*

Background: Carpal tunnel syndrome (CTS) and hand osteoarthritis (HOA) are common diseases that can coexist in the same patient. Only one recent study showed that CTS was associated with a significant decrease in strength and performance of the OA-affected hand [1]. This observation suggested that CTS-induced neuropathic disorders may have effects on the surrounding joints symptomatically supporting the role of nerve-joint axis in OA pain.
Objectives: Our work aimed to study the impact of CTS on the symptoms and structural severity of HOA in the DIGICOD (DIGItal Cohort Design) cohort.
Methods: DIGICOD is a single-center prospective hospital cohort which includes 426 patients over 35 years of age with symptomatic HOA [2]. Patients in our study were those in the DIGICOD cohort at inclusion for whom the dominant hand and laterality in case of CTS involvement were known. The analysis was based on the study of the dominant hand. We compared the demographic, clinical and radiographic characteristics (notably by the sum of the Kellgren Lawrence (KL) score) between patients with CTS and those without CTS. In case of comparison test, Chi-square or Fisher exact test were performed. Then, we investigated whether CTS was associated with grips strength, pinch strength and KL score by linear regression model and with number of joints painful pressure with negative-binomial model, after adjustment for age and sex.
Results: 417 patients including 39 with CTS were included in our study. Obesity and metabolic syndrome were more frequent in patients with CTS than in those without CTS (obesity: 29.7% vs 10.2%, p<0.01; metabolic syndrome: 51.4% vs 35.1%, p<0.05). The same was true for dysthyroidism (38.5% vs 18.5%, p<0.01) and thyroid hormone replacement therapy (30.8% vs 15.4%, p<0.05). At the level of the dominant hand, clinical signs of HOA (painful, swollen, or nodal joints), sum of Kellgren Lawrence (KL) score, number of joints with a KL score ≥ 2, and the presence of erosive HOA (defined by the presence of at least 1 erosive joint defined as phase "E" or "R" in the Verbruggen scoring) were comparable between HOA patients with and without CTS. After adjustment for age and sex, the presence of CTS in the dominant hand was not statistically associated with grip strength disturbances (measured with the Jamar dynamometer), pinch strength (thumb index finger pinch), number of joints painful to pressure, and KL score.
Conclusion: The risk factors for CTS in HOA are those known in the general population (hypothyroidism, obesity and metabolic syndrome). However, our study did not find any impact of CTS on the clinical signs and structural severity of HOA.

AB0968 ACUTE EFFECT OF A SINGLE BOUT OF BICYCLE ERGOMETRY EXERCISE ON AFFECT, MOOD AND PAIN IN INDIVIDUALS WITH KNEE OSTEOARTHRITIS

O. Idowu[1], O. Peter-Ogba[1], H. Fawole[1]. *[1]University of Benin, Physiotherapy, Benin-City, Nigeria*

Background: Exercise provokes psychological responses that results in an increase in positive affect and mood, and a reduction in negative affect in patients with musculoskeletal problems including knee osteoarthritis (KOA) (Hoffman and Hoffman, 2007; Ekkekakis and Petruzzello, 1999). However, there is no consensus on the optimum duration of exercise that will bring about such positive effects among individuals with KOA.
Objectives: The objective of this study was to compare the acute effects of 10- and 15- minute bicycle ergometry exercise on affect, mood and pain in patients with KOA.
Methods: A quasi-experimental study with a follow-up arm. Forty-six participants with KOA were randomly assigned to either a 10-minute bicycle ergometer (10BE) exercise group or a 15-minute bicycle ergometer (10BE) exercise group. Participants' affect, mood and pain were assessed at baseline, pre-exercise, immediately after the exercise, 10 minutes post-exercise, and 20 minutes post-exercise using the International Positive and Negative Affect Scale, Visual Analogue Mood Scale, and Visual Analogue Scale, respectively. Descriptive statistics, Friedman's ANOVA, Mann-Whitney-U and generalised estimating equation were used to analyse the data with P-value at 0.05.
Results: Participants' (94.23% females) age ranged from 40-79 years for the two groups. The mean age for 10BE and 15BE groups was 67.09±1.85 and 66.96±2.03 years, respectively. At baseline, the median scores for positive (19.00; interquartile range (IQR=18.00-20.00 vs. 20.00; IQR=18.00-21.00) and negative (8.00; IQR=7.00-11.00 vs. 9.00; 5.00-14.00) affect, mood (6.00; IQR= 3.00-8.00 vs. 7.00; IQR=4.75-8.00) and pain (5.00; IQR=5.00-8.00 vs. 5.50; IQR=5.00-7.00) were not significantly different between10BE and 15BE. Ten minutes of aerobic exercise significantly improved PA (*P*=0.001; Effect size (Es)=0.25)) and mood (*P*=0.001; Es=0.58), and reduced NA (*P*=0.001; Es=0.44) and pain (*P*=0.001; Es=0.73) of participants across the time points of the study. A 15-minute aerobic exercise also significantly improved PA (*P*=0.001; Es=0.25), mood (*P*=0.001; Es=0.45) and reduced NA (*P*=0.001; Es=0.49) and pain (*P*=0.001; Es=0.84) of participants across the time points of the study. There was no significant difference between groups and group-time interactions regarding effect of aerobic exercise on the outcomes (p>0.05).
Conclusion: Both 10- and 15-minutes single bouts of bicycle ergometry exercise had positive effects on affect and mood in individuals with KOA. Ten and 15- minutes single bout of bicycle ergometry exercise had comparable effects on affect and mood improvements in individuals with KOA.

AB0969 FACTORS INFLUENCING THE RESULT OF LOCAL INJECTION THERAPY WITH HYALURONIC ACID PREPARATIONS IN OSTEOARTHRITIS OF THE KNEE JOINT

V. Bialik[1], S. Makarov[1], E. Bialik[1], V. Nesterenko[1], M. Nurmukhametov[1], M. Makarov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rheumoorthopaedics and Rehabilitation, Moscow, Russian Federation*

Background: Local injection therapy (LIT) with hyaluronic acid (HA) preparations is one of the methods of conservative treatment of the knee joint osteoarthritis (KOA). However, the factors affecting the effectiveness of such treatment require clarification.
Objectives: to study the influence of age, body mass index (BMI), stage of KOA, the presence of deformity of the knee joint and enthesitis on the results of LIT with HA preparations in KOA.
Methods: from September 2017 to June 2019, intra-articular injections of HA were performed in 160 patients with primary and posttraumatic KOA stage I-III. For the analysis, the patients were divided into groups depending on the factor studied: by age into young - 36 (22.5%), middle age - 51 (31.3%), elderly - 61 (38.7%) and old age - 12 (7.5%); by BMI: on patients with normal values - 32 (20%), preobesity - 56 (35%), I - 43 (26.9%), II - 16 (10%) and III - 13 (8.1%) degrees of obesity; by stages of KOA: I - 37 (23.1%), II - 91 (56.8%), III - 32 (20.1%); by the presence of deformity: varus deformity <10° - 83 (51.8%), >10° - 23 (14.4%), valgus deformity - 22 (13.8%), no deformity - 32 (20%); and also depending on the presence (44 (27.5%)) or absence (116 (72.5%)) of enthesites. To assess the results, the pain intensity was determined using a visual analogue scale and the knee injury and osteoarthritis outcome score before treatment, 1, 3, and 6 months after the course of LIT.
Results: 1 month after the course of LIT, the best results were obtained in young patients (p=0.001), as well as stage I of KOA (p=0.0001) and normal BMI values

(p=0.034), the worst in elderly patients (p=0.006), at stage III of KOA (p=0.01), varus deformity >10° (p=0.006), obesity degree 3 (p=0.015) and the presence of concomitant enthesitis (p=0.003). 3 months after the course of LIT, the previously identified differences persisted, so the best results were again revealed in young people (p=0.0001), in stage I of KOA (p=0.0001), in the absence of deformity (p=0.002) and in normal BMI values (p=0.002), while lack of improvement or deterioration in elderly patients (p=0.001), in stage III KOA (p=0.0001), varus deformity >10° (p=0.001), obesity degree 3 (p=0.022) and the presence of concomitant enthesitis (p=0.001). 6 months after the course of LIT, the improvement remained as before in young patients (p=0.0001), as well as stage I of KOA (p=0.0001), in the absence of deformity (p=0.001) and with normal BMI values (p=0.0001). Lack of improvement or deterioration of knee joint function 6 months after the course of LIT was found in the elderly (p=0.03) and old age patients (p=0.06), in stage II (p=0.045) and III of KOA (p=0.007), varus deformity >10° (p=0.015), obesity degree 2 (p=0.025) and the presence of concomitant enthesitis (p=0.02).

Conclusion: The best LIT results with HA preparations can be obtained in young patients with normal BMI values, at the initial stage of KOA, in the absence of deformity and enthesitis. The elderly age of patients, the presence of stage III KOA, varus deformity of the knee joint >10°, BMI >40 kg/m^2, and the presence of enthesitis are associated with the lack of effect from intra-articular injections of HA preparations. Performing LIT with HA preparations in patients with stage II KOA and degree 2 obesity allows maintaining improvement for up to 6 months.

AB0970 WHAT IS THE EFFECT OF INTRA-ARTICULAR INJECTIONS OF GLUCOCORTICOIDS IN REAL CLINICAL PRACTICE?

V. Nesterenko[1], A. Karateev[2], M. Makarov[1], E. Bialik[1], S. Makarov[1], V. Bialik[1], M. Nurmukhametov[1], A. Roskidailo[1], N. Burikov[1], V. Kuznecov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rheumoorthopaedics and Rehabilitation, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Department of Inflammatory Joint Diseases, Moscow, Russian Federation*

Background: Intra-articular injections of glucocorticoids (IAI GC) are widely used in the complex therapy of rheumatic diseases (RD). However, there are relatively few modern data on their efficacy and safety in real clinical practice.

Objectives: To evaluate the effectiveness of IAI HA in RD in clinical practice.

Methods: The study group consisted of 290 patients with RD, mainly osteoarthritis (OA) and rheumatoid arthritis (RA) (69.0% of women, age 55.6 ± 12.6 years), who underwent IAI GC in the knee joint. The indications for IAI were determined by the attending physicians. The control consisted of 112 patients with OA (71.4% of women, age 59.3 ± 14.6 years), who underwent a course of IAI of hyaluronic acid (HA). The result of treatment was assessed after 2 weeks, 1 and 3 months. according to a telephone survey.

Results: After 2 weeks, 1 month. and 3 months. after IAI GC, the severity of pain during movement decreased (numerical rating scale, NRS 0-10, Me [25%; 75%]) from 6.0 [4.0; 8.0] to 1.0 [0; 2.0], 2.0 [1.0; 4.0] and 2.5 [1.0; 4.0], respectively (p <0.001). After 3 months. the number of patients with no / mild pain (<4 according to the NRS) was 63.8%, with a complete / almost complete absence of pain (≤1 by the NRS) - 30.3%. The effect of HSI HA was higher in RA than in OA: the dynamics of pain after 3 months. -4.0 [-2.0; -6.0] and -2.0 [-1.0; -5.0], p = 0.003. In OA, the effect of HAI HA and HA did not differ: the dynamics of pain after 3 months. was -2.0 [-1.0; -5.0] and -3.0 [-1.0; -5.0] p = 0.869. There were no serious adverse reactions in IAI.

Conclusion: IAI GC are an effective and fairly safe method of short-term treatment of synovitis in RD.

AB0971 RELATIONSHIP BETWEEN WALKING SPEED AND LOWER LIMB SKELETAL MUSCLE MASS IN PATIENTS WITH KNEE JOINT DISORDERS.

K. Inui[1,2], K. Mandai[1], S. Maeda[1], S. Masuda[1], S. Yamada[1], H. Ohashi[1], T. Ikawa[1]. *[1]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Orthopaedic Surgery, Osaka, Japan*

Background: Knee joint disorder is one of the factors causing frailty in the elderly, which is associated with a decrease in walking speed.

Objectives: We measured the walking speed of patients scheduled to undergo primary total knee arthroplasty (TKA) and examined factors correlated with walking speed.

Factor	Group	
disease (n)	osteoarthritis	78 (94%)
	rheumatoid arthritis	5 (6.0%)
body mass index (kg/m^2)		25.54 (4.11)
pain VAS on walking		37.08 (26.35)
total Knee Society Score		77.66 (27.85)
range of motion (degree)	flexion	119.46 (12.88)
	extension	-9.58 (6.59)
quadriceps power (N)		122.00 [53.00, 350.00]
waling speed (m/sec)		0.95 (0.33)
grip power (kg)		20.24 (6.97)
skeletal muscle mass index (kg/m^2)	appendicular	6.50 [4.92, 9.85]
	lower limb	5.06 [3.76, 7.56]
Frailty (n)	none	10 (12.5%)
	Pre-frail	41 (51.2%)
	frail	29 (36.2%)
Sarcopenia (n)	none	76 (92.7%)
	sarcopenia	4 (4.9%)
	severe sarcopenia	2 (2.4%)

mean (standard deviation); median [min max]

Methods: The patients with knee disorders scheduled to undergo knee arthroplasty at our hospital between July 2020 and May 2021 were included. They were assessed for basic attributes, clinical assessment including Kness Society Score (KSS), degree of pain on walking by visual analogue scale (VAS), range of motion (ROM), and also leg skeletal muscle mass index (SMI; whole-body mode DXA), quadriceps strength by dynamometer with written consent (UMIN ID: 000040940). And Japanese Cardiovascular Health Study criteria for frailty, and sarcopenia by Asian Working Group for Sarcopenia 2019 criteria were evaluated.

Results: Demographic data of 83 patients (65 women, mean age 74.9 years) included in this study was shown in Table 1. The distribution in frailty is 36.2% and that in sarcopenia is 7.3%. Most of the patients with frailty with knee disorder did not suffer from sarcopenia. A multivariate analysis was conducted with walking speed as the objective variable and the dependent variables as age, gender, pain VAS on walking, KSS, leg SMI, quadriceps strength, and ROM. The results showed that age and ROM in flexion were significantly and independently associated with walking speed (P=0.01, 0.03). Gender, pain VAS on walking, KSS, leg SMI, quadriceps strength, and ROM in extension were not significantly associated with walking speed (P=0.92, 0.11, 0.11, 0.52, 0.85, 0.52).

Conclusion: Among the patients with knee disorders immediately before arthroplasty, frailty was not caused by sarcopenia. Age was found to be the most correlated factor with walking speed, and walking speed became slower with age. In addition, poor flexion angle was also the factor for delayed walking speed, but it did not correlate with lower limb skeletal muscle mass or quadriceps strength. In this study pain on walking was not significant factor for walking speed, because it was observed in most of all cases.

AB0972 IMPACT OF OBESITY ON CLINICAL MANIFESTATIONS IN PATIENTS WITH OSTEOARTHRITIS OF THE KNEE

N. Zhuravleva[1], T. Smirnova[2], O. Sharapova[3,4], L. Gerasimova[5,6], L. Markelova[7]. *[1]Chuvash State University named after I. N. Ulyanov, Department of internal medicine, Cheboksary, Russian Federation; [2]Chuvash State University named after I. N. Ulyanov, Department of Obstetrics and Gynecology, Cheboksary, Russian Federation; [3]City clinical hospital of Vinogradov V.V., Head physician, Moscow, Russian Federation; [4]I.M. Sechenov First Moscow State Medical University, Department of Obstetrics and Gynecology, Moscow, Russian Federation; [5]City clinical hospital of Vinogradov V.V., The educational and methodical office, Moscow, Russian Federation; [6]Moscow State University of Food Production, Department of Obstetrics and Gynecology, Moscow, Russian Federation; [7]Institute for Advanced Medical Education, Department of therapy and family medicine, Cheboksary, Russian Federation*

Objectives: To determine the influence of obesity on clinical parameters in patients with knee osteoarthritis (OA) in comparison with patients with OA with normal body weight.

Methods: Overall 72 patients with OA were studied, 28 (39.8%) male and 44 (61.1%) female; mean age was 51.3±7.5 years and the duration of disease was 11.2±5,3 years. The diagnosis of OA was made according to the ACR criteria. Anthropometric data were assessed by height, body weight, waist and hip circumference, body mass index (BMI). Clinical and instrumental studies of OA revealed monoarthrosis in 2 (2.8%), oligoarthrosis in 32 (44.4%) and polyosteoarthrosis in 38 (52.8%) patients. Visual analogue scale (VAS) in centimetres (cm) was used to assess pain, Lequesne and WOMAC indices were determined. Synovitis was documented on the basis of an ultrasound examination of the joints.

Patients were divided into 2 groups according to BMI: BMI<24.9 kg/m^2, n=22 (no obesity); BMI>30kg/m^2, with signs of grade 1-2-3 obesity, n=50.
Results: OA patients with obesity had higher WOMAC and Lequesne index values than OA patients with normal weight (5.8±1.2 cm and 13.8±1.1 points versus 1.75±0.7 cm and 2.9±0.5 points, respectively, p<0.05). WOMAC parameters in overweight patients were significantly higher than in non-obese patients (31.2±5.9 vs. 9.7±2.7, respectively, p<0.05 for the above parameters). There was a direct correlation (p<0.05) between the severity of OA and increased BMI. Radiological changes of the joints in patients without obesity were stage I (60.6%) in 14 (60.6%), stage II in 7 (34.8%) and stage III in 1 (4.5%) patient. Grade I obesity was noted in 8 (16.0%), Grade II in 22 (44.0%), Grade III in 18 (36.0%), Grade IV in 2 (4.0%) patients. Inadequate joint function (NFS) grade I was in 16 (72.7%), II in 4 (18.2%), III in 2 (19.1%) patients with normal body weight, with NFS grade II (26 - 52%) and III (18-36%) predominating with obesity, grade I in 6 (12.0%). Synovitis was diagnosed in 37 (74.0%) with elevated BMI, significantly higher than in non-obese patients in 7 (31.8%). On the course: rapid progressive OA was seen more frequently in 11 obese patients (22. 0%) than in non-obese patients (4.5%); there was a direct correlation between the VAS pain index, Lequesne index and WOMAC index (r=0.5, p<0.05; r=0.4, p<0.05; r=0.45 p<0.05 respectively).
Conclusion: Overweight in patients with OA was associated with greater joint destruction and functional impairment of the joints, progressive course and pain syndrome, including secondary synovitis.

AB0973 LONG TERM EFFICACY OF INTRA-ARTICULAR VISCOSUPPLEMENTATION WITH HYALURONIC ACID IN HIP OSTEOARTHRITIS SECONDARY TO SYSTEMIC RHEUMATIC DISEASES: A PRELIMINARY EVALUATION

E. Cumbo[1,2], O. De Lucia[2], A. Murgo[2], C. Artusi[2], R. Cimaz[1,3], R. Caporali[1,2]. *[1]Università degli studi di Milano, Dipartimento di Scienze Cliniche e di Comunità, Milano, Italy; [2]Asst Pini-CTO, UOC Reumatologia Clinica, Milano, Italy; [3]Asst Pini-CTO, UOC Reumatologia Pediatrica, Milano, Italy*

Background: Few studies have assessed response to intra-articular HA viscosupplementation in patients affected by hip osteoarthirtis secondary to systemic rheumatic diseases (SOA). From in vitro studies we know that the synovial environment in these diseases presents different molecular characteristics in comparison to primary osteoarthritis (POA) in terms of pro-inflammatory activity and therefore in degradation of hyaluronic acid.
Objectives: To evaluate differences in efficacy and safety of treatment with US-guided intra-articular HA viscosupplementation between a cohort affected by POA and one affected by SOA, with regard to pain assessment and time to arthroplasty.
Methods: We conducted this observational retrospective study on consecutive patients treated with US-guided hip intra-articular injections with Hylan G-F 20 2 ml at the Rheumatology Unit of ASST-Pini-CTO (Milan, Italy) from 2013 to 2021. Joints with active synovitis detected by US examination weren't treated. VAS pain at baseline and at the end of October 2021 was registered as well as time to the event of hip arthroplasty and adverse reactions. Patients treated had hip pain at least 6 months before treatment and radiological OA assessed by standard hip X-rays no more than 6 months before baseline. Patients included in the SOA group had a diagnosis of rheumatic systemic disease, POA patients had osteoarthritis and any further rheumatological condition was ruled out. Additional clinical features recorded for the SOA patients were clinimetric assessment of disease activity according to SDAI for RA, clinical judgment for PMR, DAPSA for PsA, ASDAS for SpA and medical treatment at baseline.
Results: We included 55 primary OA patients and 16 systemic rheumatic diseases patients (5 JIA, 5 peripheral SpA, 2 PMR, 1 Axial-Spa, 1 PsA, 2 RA) who had received hip intra-articular HA injection with Hylan G-F 20 2 ml once a month for three consecutive months and then every six month. Mean duration of follow up was 51.1 (± 27.1) months. We observed significant longer treatment survival and lower VAS pain in POA patients at follow up (in absence of significant difference of VAS pain at baseline). In both cohorts we observed a reduction in VAS pain similar to that reported in literature: in the POA a mean reduction of 29.7 (95% CI 23.8-35.6), while in the SOA was noticed a mean reduction of 12.8 (95% CI 1.8-23.7) in absence of significant clinimetric variations over time. We observed higher incidence of local adverse reactions in SOA group (2 cases of post-injection synovitis in the SOA cohort only (12.5%), p 0.04).

	POA Hips (N=62)	SOA Hips (N=16)	p-value
Treatment duration, m	46.8±30.2	22.4±22.4	0.0038
HA injections, (N)	9.9±5.1	5.3±3.2	0.0011
3 or more HA injections, % (N)	85% (53)	81% (13)	0.70
Adverse reactions, % (N)	0	12.5% (2)	0.040
VAS Pain	3.25±1.73	4.3±1.4	0.029
Total Hip arthroplasty during follow up, % (N)	11.2 (7)	6.2 (1)	1.00
Time to arthroplasty, m	46.8±30.2	26	0.28

Conclusion: According to our results symptomatic hip SOA patients respond less and with a slightly higher degree of adverse reactions to intra-articular viscosupplementation when compared to POA patients, even if the incidence of these adverse events was similar to that observed in previous studies. We can infere that synovial pro-inflammatory enviroment in rheumatic systemic diseases can reduce efficacy of intra-articular viscosupplementation with hyaluronic acid.

Nasonova Research Institute of Rheumatology, Diagnostic Department, Moscow, Russian Federation*

Background: There are more evidence that diabetes mellitus (DM) aggravates the course of osteoarthritis (OA).
Objectives: At multicenter study to evaluate impact of DM as part of metabolic syndrome on course of knee OA.
Methods: The enrolled patients had knee OA based on ACR criteria with x-ray confirmation with stage I-III (Kellgren and Lawrence (K&L). Mean disease duration was 5 (2-10) years. Patients were evaluated by report form, using the anthropometric parameters, questionnaires, disease history and comorbidity, clinical examination data, assessment of knee joints pain, standard X-ray, ultrasound signs of OA, DXA three sites the L1-L4 lumbar spine, femoral neck, and total hip. All participants were signed an informed consent form.
Results: At prospective study were enrolled 253 women with mean age 58.3 ± 9.5 years (40-75) years, with knee OA. Compensated DM type 2 was diagnosed in 26 (10.3%) patients with knee OA. All patients with knee OA were divided into two groups:1st group was with DM and 2nd group without DM (Table 1). Patients with DM were older, had higher weight and BMI. In patients with DM was harder course of OA based on clinical and instrumental data: higher pain by WOMAC score; at X-ray were more frequent confirmed III stage (K&L) (OR=3.1, 95%CI 1.1-8.7, p= 0.01). At X-ray investigation narrow of medial joint space and at ultrasound thickness of the cartilage were also smaller at 1st group (p<0.05). Bone mineral density (BMD) in site total hip was also higher at DXA at 1st group. More often comorbidity at 1st group was hypertension (OR=3.5 (95%CI 1.2-10.6), p= 0.01), metabolic syndrome (MS) (OR=10.2 (95%CI 2.3-44), p=0.0002) and nonalcoholic steatohepatitis as part of MS (OR=33.9 (95%CI 3.22-356.8), p=0.003).

Table 1. Comparative characteristics of patients with OA with or without DM.

Parameters	1 group (n=26)	2 group (n=227)	p

I	10.5	32.8	
II	47.4	36.7	
III and more	41.2	9.4	
Nonalcoholic steatohepatitis, %	18.8	0.8	0.003

In the Spearman correlation analysis are confirmed positive associations between DM and more difficult and prolonged course of OA. We found out that higher WOMAC pain subscale (r=0.18), total hip BMD at DXA (r=0.25), smaller size of medial joint space (r=-0.24) and thickness of the cartilage at ultrasound (r= -0.13) are associated with DM (p<0.05 for all parameters). Positive relationships also are indicated with BMI (r=0.21), hypertension (r=0.15), MS (r=0.24), type, such as nonalcoholic steatohepatitis (r=0.26) and number of components of MS (r=0.39).

Conclusion: The patients with OA are high frequent comorbidity with DM (10.3%). Association OA and DM lead to severe OA and higher comorbidity.

AB0975 MINIMAL CLINICALLY IMPORTANT DIFFERENCE OF TOTAL KNEE ARTROPLASTY PATIENT-REPORTED OUTCOME MEASURES

K. S. Kacmaz[1], T. Ünver[2], B. Unver[2]. *[1]izmir katip celebi university, physical therapy and rehabilitation, izmir,Turkey; [2]dokuz eylul university, physical therapy and rehabilitation, izmir,Turkey*

Background: Total knee arthroplasty (TKA) is one of the commonest operations performed for end-stage osteoarthritis. Patient-reported outcome scales (PROMs) are optimal measures of the patient' aspects of their current condition and response to treatment. However, a statistically significant change does not always mean or create an effect that clinically meaningful. Clinicians can use a greater change than minimal clinically important difference (MCID) value as a meaningful change in patients with TKA [1]. Nevertheless, there are variations in MCID values in studies analyzing the same outcome measures or patient populations.

Objectives: The aim of this study is to create a global summary of literature of the MCID for PROMs for TKA.

Methods: A comprehensive literature search administered using PubMed database from their years of inception to January 2022. Original articles calculating MCID of PROMs for TKA were identified, and the full texts of these publications, as well as their bibliographies were reviewed. Keywords included "outcome scale," "TKA," and "MCID."

Results: This review examined 43 studies, in which 15 different outcome scales were administered to patients with TKA. MCIDs of the PROMs had distinct value or measurement process depending on the patients and clinical context. Distribution-based and anchor-based approaches were the most commonly used methods for calculating MCID. According to the analysis'; the WOMAC, KOOS, SF-12 and KSS were the most commonly used scales and there were so little research regarding the MCID of outcome instruments for TKA.

Conclusion: The reporting of outcomes in TKA were traditionally focused on implant survivorship and objective outcomes such as radiographic alignment, range of motion and, knee stability. However, patients and clinicans can have different perceptions of outcome, especially in the domains of subjective quality of life [2]. Therefore, it is recommended to use a combination of both objective and subjective measures to assess outcomes after TKA. In general, a wide range of MCID values was observed according to the scales. This can be due to the heterogenity in patient' clinical conditions recruited for the studies. Apart from the differences, MCIDs of the Oxford Knee Score and KOOS were lower than the WOMAC score therefore we can interpret that they are more sensitive as an outcome scale. However, the MCID values must be interpreted in light of all variables, including the participants which were administered to. Each method for determining MCID has advantages and disadvantages, and the best way to calculate an MCID is to combine the results of both methods. The MCID is not flawless in detecting a clinically significant change, as sensitivity and specificity play a role.

AB0976 DETERMINATION AND CHARACTERIZATION OF PATIENT SUBGROUPS WITH DIFFERENT PAIN PROGRESSION IN HAND OSTEOARTHRITIS

C. Van der Meulen[1], L. Van de Stadt[1], F. Rosendaal[2], J. Runhaar[3], M. Kloppenburg[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands; [3]Erasmus MC, Department of General Practice, Rotterdam, Netherlands*

Background: Hand pain is common in hand osteoarthritis (OA). Previous cohort studies reported stable average pain levels on the short to midterm. Subgroups with different pain trajectories have been found in knee OA. Similar subgroups of hand OA patients may exist. Knowledge of such subgroups in hand OA patients may help inform decisions for pain treatment.

Objectives: To determine and characterize subgroups with different hand pain trajectories over four years in hand OA patients.

Methods: Data from the ongoing HOSTAS (Hand OSTeoArthritis in Secondary care) cohort were used, collected from consecutive patients at the LUMC Rheumatology outpatient clinic with primary hand OA followed for four years. Hand pain measurements were collected annually starting at baseline with the AUSCAN pain questionnaire (range 0-20). Development of pain over time was modelled using latent class growth analysis (LCGA), dividing the cohort into subgroups based on differences in pain development. The optimal model was selected based on the AIC, BIC, entropy and likelihood ratio test for models with n vs n-1 classes. LCGA requires ≥2 measurements per case, so patients with less were excluded. Associations of LCGA classes with baseline demographics and factors associated with hand pain were analyzed using multinomial logistic regression.

Results: Of 538 participants, 484 completed the AUSCAN at ≥2 timepoints. Data of excluded patients were missing at random. Included and excluded patients were comparable. Of included participants 86% were women, mean (SD) age was 60.8 (8.5), 29% had erosive disease, median (IQR) symptom

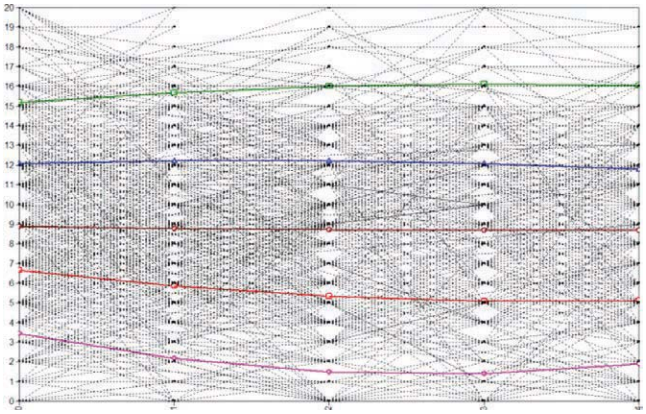

Figure 1. LCGA trajectories. *Trajectories of AUSCAN pain identified by latent class growth analysis.* Least pain to most pain, named class 1 (pink), class 2 (red), class 3 (brown), class 4 (blue) and class 5 (green).

duration was 5.2 (1.9-12.2), 91% fulfilled the ACR criteria for hand OA. Mean AUSCAN pain score was 9.3 (4.3). LCGA yielded five classes (Figure 1). Classes were characterized by different pain levels at baseline; mean level of pain remained stable over time. Classes with more pain were associated with more erosive disease, higher tender joint count, longer symptom duration, more comorbidities, worse AUSCAN function scores and worse SF-36 and HADS scores (Table 1).

Table 1. Multinomial logistic regression for associations with 5 LCGA classes

		OR (95% CI)			
Baseline	1 (N=37)	2 (N=104)	3 (N=171)	4 (N=131)	5 (N=41)
Erosive disease	1	1.20 (0.45-3.18)	1.48 (0.55-4.03)	1.23 (0.41-3.70)	1.21 (0.30-4.87)
Symptom duration, years;	1	1.05 (0.97-1.13)	1.09 (1.01-1.18)	1.13 (1.04-1.22)	1.12 (1.03-1.23)
KL sum score	1	1.01 (0.98-1.05)	1.01 (0.98-1.05)	1.02 (0.99-1.06)	1.03 (0.99-1.08)
Tender joint count	1	1.17 (0.98-1.39)	1.20 (1.00-1.44)	1.28 (1.07-1.54)	1.29 (1.06-1.57)
AUSCAN function	1	0.98 (0.90-1.08)	1.08 (0.99-1.18)	1.17 (1.06-1.30)	1.31 (1.13-1.51)
SF-36					
-PCS	1	0.95 (0.89-1.02)	0.90 (0.84-0.97)	0.84 (0.77-0.91)	0.81 (0.73-0.89)
-MCS	1	0.98 (0.90-1.06)	0.96 (0.89-1.04)	0.95 (0.87-1.03)	0.90 (0.82-0.99)
HADS					
-Depression	1	1.28 (0.91-1.82)	1.46 (1.02-2.09)	1.50 (1.04-2.16)	1.54 (1.04-2.28)
-Anxiety	1	1.09 (0.85-1.38)	1.19 (0.93-1.54)	1.19 (0.91-1.54)	1.24 (0.92-1.65)
No. Comorbidities	1	1.64 (0.77-3.47)	1.84 (0.86-3.90)	2.22 (1.01-4.88)	2.12 (0.89-5.06)

Multinomial logistic regression of variables associated with LCGA classes adjusted for baseline AUSCAN pain, age, sex and BMI. Class 1 = least pain, class 5 = most pain. SF-36 = Short Form-36. MCS = Mental component scale. PCS = Physical component scale. HADS = Hospital anxiety and depression scale. SF-36 scores are standardized on age, sex and nationality with mean 50 and SD 10.

Conclusion: Latent class growth analysis showed five subgroups with different pain trajectories in hand OA patients, with differing baseline pain and stable pain over time. These subgroups were associated with disease characteristics, number of comorbidities, psychological distress and health-related quality of life. This knowledge can help develop treatment for hand OA patients and inform them about the disease course.

AB0977 THE RELATIONSHIP OF OVERWEIGHT AND CONCOMITANT METABOLIC DISORDERS WITH THE FEATURES OF THE COURSE OF PRIMARY OSTEOARTHRITIS OF THE KNEE JOINTS

I. Bashkova[1,2], I. Madyanov[1,3], K. Misko[1]. *[1]Chuvash State University named after I.N. Ulyanov, Department of Hospital Therapy, Cheboksary, Russian Federation; [2]Federal Center of Traumatology, Orthopedics and Endoprosthesis, Consultative Polyclinic, Cheboksary, Russian Federation; [3]Republican Clinical Hospital, Department of Endocrinology, Cheboksary, Russian Federation*

Background: There are two theories of the relationship between osteoarthritis (OA) and obesity: biomechanical and metabolic.
Objectives: To study the prevalence of overweight and obesity and concomitant metabolic disorders in patients with OA and to assess their impact on the features of the course of primary OA of the knee joints.
Methods: Patients with primary OA with a lesion of the knee joints (n = 90, including 22 men) were examined. The age of the patients is 29-69 years, the duration of the disease is 1.5-20 years. The control group (n = 114, including 26 men) was formed by random sampling of the population from practically healthy people, it is representative by gender and age. Anthropometric examination, determination of lipid metabolism parameters, levels of dehydroepiandrosterone sulfate (DHEA-C) and cortisol in the blood, X-ray and arthrosonographic examination of joints were performed. The functional state of the knee joints was analyzed by the Lequesne gonarthrosis severity index and the WOMAC algofunctional index.
Results: Average Body Mass Index (BMI) in patients, OA was 28.6±5.8 kg/m^2 and was slightly higher than in the control group (27.6±4.5 kg/m^2, p>0.05). Overweight and obesity were detected, respectively, in 40.7% and 33.0% of patients with OA, and in 43.0% and 28.9% of the control group. An increase in BMI in patients with OA, despite the absence of a significant difference in age and duration of the disease, is accompanied by an increase in the total values of the WOMAC index (p=0.042) and Lequesne (p=0.038). According to arthrosonography, the increase in BMI is directly related to an increase in the size of osteophytes (r=+0.43, p=0.003) and inversely correlates with the width of the articular gap of the medial knee joints (r=-0.37, p=0.014). Knee synovitis was detected in 5 patients out of 24 people (20.8%) with normal body weight, in 11 patients out of 37 people (29.7%) who are overweight, and in 13 patients out of 30 people (43.3%) who are obese of varying severity (p>0.05). Synovitis of the knee joints in most cases was detected in patients with OA with an abdominal type of fat distribution. The negative influence of the abdominal type of fat distribution on the course of knee joint OA was revealed: positive correlations between waist circumference and the total Lequesne index (r=+0.443, p=0.027), and the radiological stage of OA (r=+0.467, p=0.019). In patients with OA with abdominal type of fat distribution, the severity of joint pain during exercise was 33.3% higher than in patients with gluteofemoral type (p<0.001), the total Lequesne and WOMAC indices were 27.2% (p=0.028) and 20.1% (p=0.041), respectively. In patients with OA, a significant increase in the blood content of cholesterol (HC) of low-density lipoproteins (LDL) was found (p=0.039) and a decrease in high-density lipoprotein (HDL) cholesterol (p=0.046). Disorders of lipid metabolism of atherogenic orientation were more pronounced in patients with III-IV radiological stages of gonarthrosis. In patients with OA who are overweight or obese, the serum DHEA-C content was lower than in patients with OA with normal body weight (2.31±0.98 mcg/ml vs 2.63±1.68 mcg/ml, p>0.05). As the radiological changes in the joints progress, there is a clear decrease in the concentration of DHEA-C. In women with OA, a significant relationship was found between waist circumference and the concentration of DHEA-C in the blood (r=-0.321, p=0.045). There was an increase in the concentration of cortisol in the blood of patients with OA. The inverse correlation relationship between the number of swollen joints with the blood content of DHEA-C (r=-0.269, p=0.012) and cortisol (r=-0.232, p=0.028) was revealed.
Conclusion: The mechanisms of the negative effect of overweight and obesity on the course of OA are lipid disorders (high concentrations of LDL cholesterol, low HDL cholesterol), hormonal changes (low DHEA-C, elevated cortisol levels) and the production of proinflammatory cytokines by adipose tissue.

AB0978 EFFECT OF ATORVASTATIN ON SKELETAL MUSCLES OF PATIENTS WITH KNEE OSTEOARTHRITIS: POST-HOC ANALYSIS OF A RANDOMISED CONTROLLED TRIAL

Y. Lim[1], F. Cicuttini[1], A. Wluka[1], G. Jones[2], C. Hill[3,4], A. Forbes[1], A. Tonkin[1], S. Berezovskaya[1], L. Tan[5], C. Ding[2,6], Y. Wang[1]. *[1]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; [2]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; [3]University of Adelaide, The Queen Elizabeth Hospital, South Australia, Australia; [4]University of Adelaide, Adelaide, Department of Medicine, South Australia, Australia; [5]The Alfred, Alfred Hospital, Melbourne, Australia; [6]Southern Medical University, Clinical Research Centre, Zhujiang Hospital, Guangdong, China*

Background: Statins are often discontinued due to muscle-related side effects. The effect of statin on skeletal muscles in populations with osteoarthritis is unknown.
Objectives: This study aims to examine the effect of atorvastatin on skeletal muscle biochemistry, strength, size and symptoms in patients with symptomatic knee osteoarthritis.
Methods: This is a post-hoc analysis of a multicentre randomised, double-blind, placebo-controlled trial over 2 years in which participants with knee osteoarthritis who met the American College of Rheumatology clinical criteria received atorvastatin 40mg daily (n=151) or placebo (n=153). Outcomes included levels of creatinine kinase (CK), aspartate transaminases (AST) and alanine transaminases (ALT) at baseline, 4 weeks, 6, 12 and 24 months; muscle strength measured by dynamometry at baseline, 12 and 24 months; vastus medialis cross-sectional area (CSA) on magnetic resonance imaging at baseline and 24 months; and self-reported myalgia during the trial.
Results: 304 participants [mean age 55.7 (SD 7.6) years, 55.6% female] were randomised. There were no significant differences in CK and AST levels between atorvastatin and placebo groups at 4 weeks (CK median 107 vs 110, p=0.76; AST 22 vs 21, p=0.14), 6 (CK 109 vs 101.5, p=0.37; AST 21 vs 20, p=0.45), 12 (CK 103 vs 103, p=0.93; AST 22 vs 21, p=0.99), and 24 (CK 103 vs 93.5, p=0.17; AST 22 vs 21, p=0.34) months. The atorvastatin group had higher ALT levels than the placebo group at 4 weeks [26 vs 21, p=0.0004] and 6 months [25 vs 22, p=0.007] but no between-group differences at 12 [24 vs 21, p=0.08] and 24 [24 vs 21, p=0.053] months. Muscle strength significantly increased in the atorvastatin group but not the placebo group over 24 months with no between-group differences [mean 8.5 (95% CI 2.6,14.4) vs 5.6 (-0.3,11.5), p=0.50]. Change in vastus medialis CSA over 24 months showed between-group differences favouring the atorvastatin group [+0.12 (-0.09,0.34) vs

-0.24 (-0.48,0.01), p=0.03] but of uncertain clinical significance. There was a trend for more myalgia in the atorvastatin group over 2 years (8/151 vs 2/153, p=0.06), mostly occurring within 6 months (7/151 vs 1/153, p=0.04). Of the 10 participants with myalgia, there was no relationship between the incidence of myalgia and CK levels.
Conclusion: In those with symptomatic knee osteoarthritis, despite a trend for more myalgia, there was no clear evidence of an adverse effect of atorvastatin on skeletal muscles, including those most relevant to knee joint health.

AB0979 RECOMMENDATIONS FOR WEIGHT MANAGEMENT IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW OF CLINICAL PRACTICE GUIDELINES

Y. Lim[1], J. Wong[1], S. M. Hussain[1], M. Estee[1], L. Zolio[2], M. Page[1], C. Harrison[3], A. Wluka[1], Y. Wang[1], F. Cicuttini[1]. *[1]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; [2]The Alfred, Alfred Hospital, Melbourne, Australia; [3]Monash University, Monash Centre for Health Research and Implementation, School of Public Health and Preventive Medicine, Melbourne, Australia*

Background: Weight loss interventions are often recommended to target overweight and obesity in the clinical practice guidelines (CPGs) for the management of osteoarthritis. This is despite evidence from meta-analyses of clinical trials that significant weight loss results in modest improvements in symptoms and minimal effects on disease progression[1,2]. There is evidence that weight gain is associated with increase in knee pain[3,4]. In countries such as USA, adults gain on average 0.5 to 1 kilogram per year from early to middle adulthood Preventing weight gain is easier to achieve and sustain than losing weight.
Objectives: Given that weight loss is accepted as fundamental to osteoarthritis management, we systematically reviewed the recommendations and approaches for weight management in all current osteoarthritis CPGs.
Methods: Nine databases were searched (1st January 2010 to 30th September 2021) to identify guidelines informing the non-pharmacological management of osteoarthritis. Three reviewers appraised guidelines according to the AGREE II instrument, and independently extracted data on their characteristics. One author extracted and summarised guideline recommendations on weight management. This systematic review is registered on PROSPERO (CRD42021274195).
Results: Fifteen CPGs from developed and developing countries were included. Weight loss was recommended for knee (12 of 13 guidelines) and hip (10 of 11 guidelines) but not hand osteoarthritis (0 of 4 guidelines). Combination approaches of diet and/or exercise were recommended for overweight or obese individuals (knee: 8 of 12; hip: 4 of 10), with 2 guidelines specifying ≥5% weight loss for knee and hip osteoarthritis. One of 15 guidelines specified strategies for weight loss and maintenance of lost weight. Two of 15 guidelines recommended controlling body weight for osteoarthritis, regardless of obesity status.
Conclusion: Most CPGs for knee and hip osteoarthritis include recommendations for weight loss in those with overweight or obesity as key to managing osteoarthritis, despite evidence of modest at best effect of weight loss on symptoms and no effect on joint structure[1,2]. Given obesity is a major risk factors for osteoarthritis, the prevention of weight gain may be more effective and practical in improving clinical outcomes for osteoarthritis, and hence should be considered as part of the key management in osteoarthritis.

Background: There is an unmet need for new treatments for hand osteoarthritis (OA). Symptomatic hand OA is more common in women and its incidence increases round the age of menopause. Pre-clinical, epidemiological and post hoc studies in Hormone Replacement Therapy (HRT) trials implicate estrogen deficiency as of likely importance in OA aetiopathogenesis. No clinical trials of HRT have been carried out in hand OA to date. The licensed HRT Duavive (conjugated estrogens + SERM bazedoxifene) was selected on its potential for efficacy and tolerability.
Objectives: We set out to determine the feasibility and acceptability of this form of HRT in post-menopausal women with hand OA, to generate proof of concept data and refine methods for a full study.
Methods: ISRCTN12196200. Females aged 40-65 yrs and 1-10yrs after final menstrual period with hand OA fulfilling ACR criteria and 2+ painful hand joints were recruited. Eligibility incorporated best practice for HRT prescription but did not require menopausal symptoms. Recruitment was at 3 sites in primary/secondary care, including directly from the community. Design was parallel group, double-blind 1:1 randomisation of Duavive or placebo, orally once daily for 24 weeks, then weaning for 4 weeks before stopping. Routes and rates of recruitment and the acceptability of randomisation, medication (compliance, retention), and proposed outcomes were measured, and the likelihood of unblinding. Measures related to hand pain and function, menopause symptoms and joint appearance. Patient and Public Involvement actively informed study rationale, design and materials. An end of study questionnaire and 2 participant focus groups provided further acceptability data.
Results: Recruitment was for 12/possible 18 months, interrupted due to COVID-19. Some study procedures were modified to allow reopening whilst collecting all primary outcomes. 434 enquiries/referrals were received, leading to 96 telephone pre-screens, of which 33 gave written informed consent and attended face to face screening. 28/33 screened (85%) were eligible and randomised. The highest number of randomisations was from study web presence (n=7) followed by SMS text from GP surgeries (n=5). Of 401 not proceeding, 250 (62%) were ineligible, most commonly due to contraindicated medication, followed by medical contraindication, whilst 55 (14%) decided not to take part, for reasons including not wanting to take a hormone-based drug or difficulty attending study visits. Retention and compliance were excellent. All 28 participants completed all study follow ups, with only 3 withdrawals from treatment due to AEs, 2 of these at week 24 and all in the placebo arm. There were no serious AEs. High levels of completeness of all study outcome measures were achieved. Bang's blinding index suggested that participants/investigators were well blinded. There were overall high/good levels of satisfaction with taking part in the study. 26/28 (92%) would recommend taking part to others with hand OA (irrespective of study arm). Many found the flexibility

offered by a combination of remote and face to face visits (due to the pandemic) attractive. Additional insights from focus groups were to include hand stiffness as well as pain measures but to reduce the overall number of questions.
Conclusion: Despite COVID-19 and a reduced recruitment period, this study recruited sufficient numbers to assess feasibility outcomes. Randomisation of eligible people and retention rates were high. A mixture of remote and face to face visits due to COVID-19 probably improved recruitment and retention and was supported by participants, who were generally satisfied with the study design and medication. The study provided useful insight and improvements that would be incorporated into a future study. Overall, this feasibility study showed that with clear messaging on eligibility and a defined recruitment strategy, recruitment and retention to a study testing this treatment is possible.

AB0981 DYNAMICS OF PAIN ACCORDING TO THE VAS SCALE, FUNCTIONAL ACTIVITY ACCORDING TO THE WOMAC INDEX AND QUALITY OF LIFE ACCORDING TO THE EQ-5D QUESTIONNAIRE IN ELDERLY AND SENILE PATIENTS WITH KNEE JOINT OSTEOARTHRITIS AFTER COVID-19

M. Letaeva[1], M. Koroleva[1], O. Malyshenko[1], J. Averkieva[1], T. Raskina[1].
[1]*Kemerovo State Medical University, Department of Propaedeutics of Internal Diseases, Kemerovo, Russian Federation*

Objectives: To evaluate the dynamics of pain on the VAS scale, functional activity according to the WOMAC index and quality of life according to the EQ-5D questionnaire in elderly and senile patients with knee joint osteoarthritis (OA) after COVID-19.
Methods: A total of 32 elderly and senile male patients with an established diagnosis of knee joint OA (according to the criteria of ACR, 1986) of stage II–III according to Kellgren–Lawrence, with pain ≥40 mm on a visual analog scale (VAS), who needed to take nonsteroidal anti-inflammatory drugs (NSAIDs), were included in the study. The median age of the patients included in this study was 72.6 (66.0; 79.3) years. All patients have been ill with COVID-19 for the last 6 months. Pain dynamics was assessed on the VAS scale, functional activity - on the WOMAC index, quality of life - on the EQ-5D questionnaire.
Results: When analyzing the clinical picture, it was found that the majority of patients - 22 people (68.8%) - had moderate COVID–19, 4 people (12.5%) – in mild form, 6 patients (18.7%) - in severe. The average duration of hospitalization was 14.0 (9.0; 17.0) days. The majority of patients were discharged with recovery - 30 people (93.75%), 2 people died (6.25%). The most frequent manifestations of postcovid syndrome in elderly and senile patients with OA: weakness – in 18 (56.2%) patients, arthralgia – in 17 (53.1%) and memory loss – in 14 (43.8%). There was a significant increase in the pain index on the VAS scale and the total WOMAC index after COVID-19. Pain on the VAS scale before COVID-19 was 45.9 (34.8; 72.4), after the disease - 60.9 (51.4; 68.5) ($p<0.001$); the total WOMAC index was 46.3 (38.5; 51.2) and 63.1 (48.9; 76.2), respectively ($p=0.007$). There were no differences in the need for NSAIDs before and after the disease. When filling out the EQ-5D questionnaire, all the interviewed patients indicated health problems to one degree or another. When calculating the quantitative index after COVID-19, there was a deterioration in the health index, but the changes were unreliable. The "health thermometer" also changed in a similar way.
Conclusion: COVID-19 in elderly and senile patients with OA occurred in a variant of moderate severity in 22 (68.8%), severe - in 6 (18.7%), mild - in 4 (12.5%). The most frequent manifestations of postcovid syndrome in elderly and senile patients with OA: weakness, arthralgia and memory loss. Negative dynamics of indicators of functional activity according to the WOMAC index and pain on the scale VAS after COVID-19 was registered.

AB0982 RISK OF OSTEOPORTIC FRACTURES IN POST-MENOPAUSE WOMEN WITH KNEE OSTEOARTHRITIS

O. Malyshenko[1], M. Letaeva[1], M. Koroleva[1], T. Raskina[1], J. Averkieva[1].
[1]*Kemerovo State Medical University, Department of Propaedeutics of Internal Diseases, Kemerovo, Russian Federation*

Background: Osteoporosis is an interdisciplinary problem, the medical and social significance of which is determined by its consequences: fractures of the vertebrae and bones of the peripheral skeleton.
Objectives: To estimate the 10-year probability of developing osteoporotic fractures in postmenopausal women with knee osteoarthritis (OA).
Methods: The study included 36 postmenopausal women (mean age 65.7±1.01 years). The main group consisted of 21 women with knee OA, the control group consisted of 15 women without OA. Bone mineral density (BMD) (g/cm2) and T-score (standard deviation, SD) of the femoral neck and lumbar spine (LI-LIV) were assessed by dual-energy X-ray absorptiometry (DXA) (Lunar Prodigy Primo, USA). The 10-year probability of developing major osteoporotic fractures (clinically significant vertebral fracture, distal forearm fracture, proximal femur fracture or shoulder fracture) and proximal femoral fracture was calculated using the FRAX calculator.
Results: Osteopenic syndrome in the study cohort was detected in 33 (91.7%) patients, including osteopenia in 18 (50.0%) women and osteoporosis in 15 (41.7%) women. Normal BMD was registered in 3 (8.3%) patients. In patients with knee OA osteopenic syndrome was registered in 19 (90.5%) patients: osteopenia - in 11 (52.4%), osteoporosis - in 8 (38.1%). In the control group, osteopenic syndrome was diagnosed in 13 (86.6%) people: osteopenia - in 6 (40.0%), osteoporosis - in 7 (46.7%). Normal BMD in both studied groups was determined only in 2 women (9.5% and 13.3%, respectively). There were no statistically significant differences in the structure of osteopenic syndrome among the studied groups ($p=0.961$). When analyzing the 10-year probability of developing major osteoporotic fractures, it was found that in women with OA of the knee, this probability was 12.4±0.91, in the control group it was 15.2±1.06 ($p=0.085$). The 10-year probability of a fracture of the proximal femur in women with knee OA was statistically significantly less than in the control group: 1.53(0.70;1.98) and 2.11(1.20;2.95), ($p =0.031$) respectively.
Conclusion: The overall incidence of osteopenic syndrome in the study cohort was 91.7%, with no statistically significant differences between the groups. The probability of developing a fracture of the proximal femur in women with knee OA was statistically significantly less than in the control group, while the risk of a 10-year fracture of the main localizations was comparable in the study groups.

AB0983 RESULTS OF A PROSPECTIVE 6-YEAR OBSERVATIONAL STUDY OF THE EFFICACY AND SAFETY OF A BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN SENILE PATIENTS WITH KNEE OSTEOARTHRITIS AND MULTIMORBIDITY

T. Raskina[1], J. Averkieva[1], M. Letaeva[1], O. Malyshenko[1], M. Koroleva[1].
[1]*Kemerovo State Medical University, Department of Propaedeutics of Internal Diseases, Kemerovo, Russian Federation*

Background: According to the updated ESCEO, 2019 guidelines for the management of the knee osteoarthritis (OA), SYSADOA, which includes bioactive concentrate small sea fish (BCSSF), is a mandatory component of OA therapy. There are few studies evaluating the efficacy and safety of BCSSF in elderly patients with knee OA and a high level of multimorbidity, which served as the basis for this work.
Objectives: To evaluate the efficacy and safety of BCSSF therapy in elderly patients (75–90 years old) with knee osteoarthritis (OA) and multimorbidity based on the results of a prospective 6-year follow-up.
Methods: The study included 38 elderly women with OA of the knee (according to the criteria of ACR, 1986) stage II-III according to Kellgren-Lawrence, with pain ≥40 mm on the visual analog scale (VAS), who needed non-steroidal anti-inflammatory drugs (NSAIDs). BCSSF was administered as 1 ml intramuscular injections 20 consecutive days with a 6-month interval (12 courses). The impact of comorbidity on long-term prognosis was assessed using the Charlson comorbidity index. The effectiveness of therapy was assessed by VAS and WOMAC index. All patients during V0, V4 (36 months), V5 (72 months) underwent radiography of the knee joint. The safety of therapy was monitored throughout the observation period. The duration of the study was 6 years, the number of visits (V) - 6: V0 - day 1 (inclusion in the study and initiation of therapy); V1 - 21st day of therapy, V2, V3, V4, V5 - 12, 24, 36 and 72 months after the start of treatment, respectively.
Results: The 29 (76.3%) patients completed the full course of BCSSF treatment. 9 (23.7%) patients withdrew from the study due to the inability to visit the treatment site (for reasons not related to the study). Elderly patients with OA of the knee showed a

high level of multimorbidity - an average of 5 comorbidities. The prognosis of 10-year mortality according to the Charlson index was 1–2 points (26%) in 2 (5.3%) patients, 3–4 points (52%) in 26 (68.4%) patients, ≥5 points (85 %) - in 10 (26.3%) respectively. There was a significant decrease in pain according to VAS (≥20%): by V1 - in 76.3%, by V2 - in 71.0%, by V3 - in 68.4%, by V4 - in 63.1% and V5 - in 55.2% of patients. There was a significant decrease in the total WOMAC index at all visits compared with baseline: V0 - 1125±135.0 mm, V1 - 647±229.0 mm, V2 - 642±224.0 mm, V3 - 594±216.0 mm, VB4 - 609±183.0 mm, V5 - 669±141.0 mm ($p \leq 0.001$ for all cases). The reduction in OA symptoms resulted in a significant reduction in the need for NSAIDs. By V1, 31.6% of patients refused to take NSAIDs, by V2 - 47.4%, by V3 - 44.7%, by V4 - 50.0% and by V5 - 44.7%. After 12 months of therapy, the number of days of taking NSAIDs significantly decreased to 5 (0; 10) days per month versus 14 (7; 15) days per month at the beginning of the study ($p = 0.005$). This rate remained relatively stable throughout the follow-up. X-ray progression of OA ≥1 stage according to Kellgren-Lawrence during BCSSF therapy after 36 months was recorded in 10.5% of patients, after 72 months - in 50.0%. During the entire period of observation, no serious adverse events were registered, including new cardiovascular accidents and allergic reactions.

Conclusion: The results of a 6-year prospective study demonstrate the high efficacy and safety of BCSSF in elderly patients with knee OA and high multimorbidity.

AB0984 CHANGES IN PLASMA VOLUME WHEN MEASURING BIOCHEMICAL MARKERS OF JOINT TISSUE TURNOVER IN RELATION TO ACUTE PHYSICAL ACTIVITY

J. Bjerre-Bastos[1,2], C. Sejersen[3], H. B. Nielsen[4], N. Secher[3], C. C. Kitchen[3], C. P. Miller[2], A. Mackey[1], A. R. Bihlet[2]. *[1]University of Copenhagen, X-Lab, Department of biomedical Sciences, Copenhagen, Denmark; [2]NBCD A/S, NBCD, Herlev, Denmark; [3]Rigshospitalet, Niels Secher Lab, Department of Anaestesiology, Copenhagen, Denmark; [4]Roskilde Hospital, Department of Anaestesiology, Roskilde, Denmark*

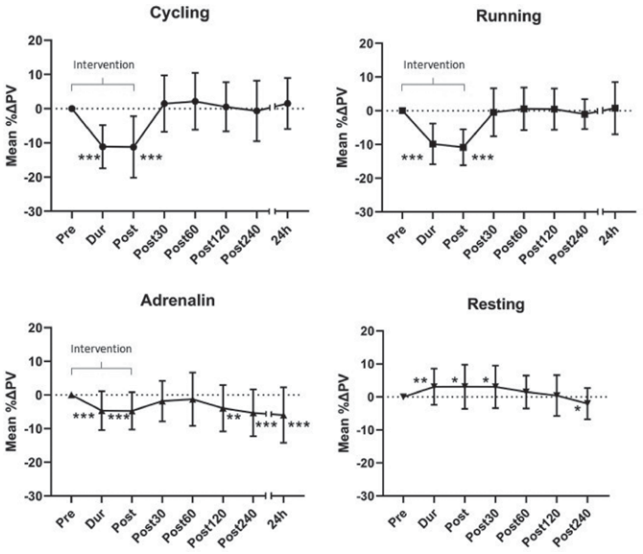
Background: Physical activity can induce acute changes in plasma volume (PV) and thereby influence concentration of plasma constituents, such as biochemical markers[1,2]. However, it remains undocumented to what extent PV changes occur during physical exercise in osteoarthritis (OA) patients.

Objectives: Investigating the direct course and magnitude of PV changes during and after weight-bearing (WB) and non-weight-bearing (NWB) exercise, adrenaline-induced cardiovascular stress and resting in an OA population.

Methods: Data originates from the EFEX-OA-02 study (Reg. no.: NCT04542668), which explored biomarker changes in knee OA patients during and after running, cycling, adrenaline infusion and resting on separate days. Blood samples were obtained before, during, at five time points after and again 24 hours post exercise/infusion. Hemoglobin (Hgb) and derived hematocrit (Hct) were measured at all time-points to monitor PV fluctuations. Main inclusion criteria: Cumulative Kellgren-Lawrence (KL) radiographic grade of the left and right knee of ≥ 2, 40-75 years of age, bodyweight 50-100 kg and BMI 18.5-35.0 kg/m^2. Active interventions consisted of 4x5-minute intervals each progressing from low intensity and peaking at ≥80% of the heart rate reserve (HRR). For the adrenaline infusion, 0.06 mg/kg of adrenalin was prepared in 50 mL saline and administered intravenously. At rest, blood samples were collected at time points similar to the other study interventions, however the 24-hour follow-up sample was omitted. Hgb was measured on a ABL800 FLEX blood gas analyzer and converted to Hct using the formula: Hct (%) = (0.0485 × ctHb (mmol/L) + 0.0083) × 100. Estimated PV change (% ΔPV) was calculated as: % $\Delta PV = [100 / (100 - Hct_{pre})] \times [100 (Hct_{pre} - Hct_{post}) / Hct_{post}]$, where: ΔPV % = Percentage change in PV: Hct_{pre} = Hct before exercise, Hct_{post} = Hct after exercise. A repeated measures linear mixed-model and 1-way ANOVA was used to assess PV changes and compare interventions, respectively.

Results: Forty subjects were included. Mean age was 60.4 years (Standard deviation (SD): 8.7), 16 (40%) were male, mean BMI was 27.0 kg/m^2 (SD: 3.5), and mean score in the nine item pain domain of the Knee Injury and Osteoarthritis Outcome Score (KOOS) at baseline was 67.5 (SD: 15.2) out of 100 (0 and 100 corresponding to max pain and no pain, respectively). Baseline Hgb was 9.05 mmol/L (SD: 0.68) and Hct was 44.7% (SD: 2.9%). All subjects were able to reach the defined peak cardiovascular intensity or higher during exercise, while reaching on average 70% (SD: 8.7%) of that during the adrenaline infusion.

Cycling, running and adrenaline infusion led to acute reductions in PV compared to rest: Cycling -14.3% (95%CI: -10.0 to -18.7%), running -13.9% (95%CI: -10.9 to -17.0%), adrenaline -7.8% (95%CI: -4.2 to -11.5%). The reductions in PV induced by both cycling and running were greater compared to adrenaline ($p<0.001$). There was no difference in PV changes after cycling vs. running ($p=0.99$). Thirty minutes after both modes of exercise, PV had returned to baseline. After completion of the adrenaline infusion, PV returned to baseline at 30-60 minutes, but was lower than baseline levels at 120 minutes by -3.9% (95%CI: -0.7 to -7.1%), at 240 minutes by -5.3% (95%CI: -2.1 to -8.6%), and at 24-hour by -5.9% (-2.0 to -9.9%). During seated rest, PV initially increased (3.1%, 95%CI: 0.7-5.4%) (Figure 1).



Conclusion: Moderate-high intensity running, cycling and cardiovascular stress led to rapid reductions in PV of knee OA patients. Adjustment for PV changes should be considered when measuring biochemical markers in relation to physical activity.

AB0985 PREDICTIVE VALUE OF ULTRASOUND IN HAND OSTEOARTHRITIS

S. Abdellaoui[1], S. Lefkir[1]. *[1]Issad Hassani Beni messous hospital, Rheumatology, Algiers, Algeria*

Background: Hand osteoarthritis (HOA) is a complex degenerative pathology with sometimes noisy joint manifestations that can mimic inflammatory rheumatism. The osteoarticular ultrasound, is a valuable addition to the clinical examination, remains little used for diagnosis and monitoring HOA.

Objectives: The objective of our study is to analyze the ultrasound characteristics of arthritic hands OA in order to know the lesions and to better correlate the clinical data with the sonographic results.

Methods: We performed an ultrasound study of 38 patients (76 osteoarthritis hands) suffering from finger osteoarthritis meeting the ACR criteria. SPSS.20 Software was performed to data analysis

Results: There were 38 patients: 84% women and 16% men, mean age was 61 years. 47.36% had had a manual profession, 39.47% had associated osteoporosis, 66% had reported the presence of finger nodules in the mother in family history. 60.52% of patients presented with Heberden's nodules, 34.21% with Bouchard nodules, 63.15%an adductus inch and 13.15% an inch in "M" deformation. Impairment of Metacarpo-phalangeal (MP), Proximal inter-phalangeal (PIP), Distal Inter-phalangeal (DIP) and Trapeziometacarpal (TM) were found respectively: clinically in 24%, 58%, 87% and 76% of cases, and in 8%, 37%, 74% and 92% after ultrasound examination. The impairment was more severe from side of the dominant hand in 39.47% of cases clinically vs 52.63% after an ultrasound analysis. Regarding "erosive" HOA, 36.84% of patients presented at least one clinical and / or sonographic criterion suggesting an erosive form. 7.89% of patients had rigidity, 13.15% erythema, 34.21% swelling and 60.52% paresthesia. According to ultrasound, 28.94% showed an erosion / reconstruction aspect. 26.31% of the patients had presented an effusion of the PIP, 47.36% an effusion of the DIP, grade 1 Doppler signal was found in 15.78% with a strong clinical correlation and positive ultrasound signs in 65,78% of cases, no synovitis was reported.

Conclusion: Hand osteoarthritis is a very heterogeneous disease, the added value of ultrasound appears to be of interest in the diagnosis and monitoring patients with this pathology.

AB0986 RISK OF SARCOPENIA IN THE WOMEN WITH OSTEOARTHRITIS

N. Grygorieva[1], N. Zaverukha[1], A. Musiienko[1], M. Bystrytska[1]. [1]*D. F. Chebotarev Institute of Gerontology, NAMS of Ukraine, Clinical Physiology&Pathology of Locomotor Apparatus, Kyiv, Ukraine*

Background: Recently, physicians all over the world have been focusing on the relationship between sarcopenia and osteoarthritis (OA) [1, 2]. This connection is considered from different positions: as coexisting conditions, sarcopenia as a risk factor for the progression of OA, or OA as a risk factor for sarcopenia.

Objectives: The aim of this study was to determine the risk of sarcopenia (according to the SARC-F Questionnaire) and the level of probable sarcopenia in Ukrainian women with (hip and knee) OA.

Methods: The study included 271 women aged 50-84 years old (mean age 65.6 ±8.0 years, mean height 162.2±5.6, mean body weight 76.7±14.2, mean BMI 29.1±5.1). All subjects were divided into 2 groups: the group of healthy women (group I, n=176), a group of patients with hip or knee osteoarthritis (OA) (group II, n=95). The risk of sarcopenia was determined by the SARC-F Questionnaire. The probable sarcopenia was determined due to muscles strength (handgrip strength using spring hand dynamometer ≤ 16(kg)) and physical performance (5-time chair stand test > 15 s), the fall risk – by Desmond Fall Risk Questionnaires and function – according to the assessment of IADL scale.

Results: In 20.3% of females without musculoskeletal pathology and in 34.7% of women with OA was detected high risk of sarcopenia. The probable sarcopenia was practically 2 times higher in patients with OA and was equal to 42.1% compared to 21.5% in healthy women. According to the Desmond Fall Risk Questionnaire, 27.5% of healthy subjects and 49.3% with OA had increased fall risk. Low function (according to the assessment of the IADL scale) was detected in 36.4% of females without pathology of the musculoskeletal system and in 57.2% of women with OA.

Conclusion: Our results demonstrated that the incidence of probable sarcopenia was 2 times higher in women with hip and knee OA, as well as the risk of sarcopenia – 34.7%, compared to healthy subjects – 20.3%. Also, the risk of falls and the need for outside help were higher in patients with hip and knee OA but their function (by IADL scale) was significantly lower.

AB0987 KNEE RESERVE: ULTRASONOGRAPHIC FEATURES OF KNEES IN PATIENTS WITH ASYMPTOMATIC KNEE OSTEOARTHRITIS

M. A. Mortada[1], Y. A. Amer[1]. [1]*Zagazig University, Rheumatology, Zagazig, Egypt*

Background: Symptoms of knee osteoarthritis (KOA) vary according to many factors mainly degree of KOA and degree of inflammatory features.The primary goal of treatment the patients with KOA is to maximize long-term health-related quality of life through control of symptoms. Understanding ultrasonographic characteristics of KOA in asymptomatic patients may help in management of knee osteoarthritis. Zagazig scale is a new validated and feasible tool for KOA assessment.

Objectives: To understand the ultrasonographic features of thepatients with asymptomatic knee osteoarthritis

Methods: Among 245 patients with knee OA diagnosed according to ACR criteria and recruited in a previous ultrasonographic study (1), data of patients with no or mild pain (VAS ≤ 2) was recorded and studied in a separate section. All patients were subjected to clinical assessment WOMAC scaleWestern Ontario and McMaster Universities Index of Osteoarthritis), global visual analogue scaleVAS, and functional assessment through the use of health assessment questionnaire-II (HAQ-II). Ultrasonographic assessment was conducted following ZAGAZIG scale comprising five domains: (1) Severity ofknee OA 6 grades (0-5) according to severity scale published by Mortadaet al 2016, (2) Effusion: 4 grades (0-3) no, mild moderate and severeeffusion respectively, (3) synovitis: 4 grades (0-3) using the combinedEULAR/OMERACT score of grey scale synovitis and Doppler activity, (4) Pes Anserine tendonitis /bursitis: 3 grades (0-2) normal, mild inflammation and severe inflammation (5) Baker cyst: 3 grades (0-2),grade0: normal no cyst, grade 1:small and simple cyst and grade 2: largeand/or complicated cyst. Each grade in all domains take one point in thescore with the total sore of all domains ranged from 0 to 15.

Results: At cut-off point of >5, total US score distinguishes between knee osteoarthritis patients with no or mild pain87.2% sensitivity and 87.2% specificity.

Table 1. Demonstrate demographic and ultrasonographic features of patients with KOA andVAS ≤ 2.

22 patients had no to mild pain according to Universal pain assessment, may have different combinations of wide range of degenerative changes (severity score (0-5) and inflammatory changes [effusion (0-3), synovitis (0-3), Pes Anserine (0-2) andBaker cyst (0-2)]but the total score of Zagazig scale ranged from 1 to 4. This may refer that patients can accommodate any combinations of degenerative and inflammatory changes with total score less than 5 on Zagazig scale with no or mild pain. Score less than 5 on Zagazig scale may consider as knee reserve in KOA.

Conclusion: The present study confirm that patients with KOA and asymptomatic or with mild pain may have awide range of degenerative changes and inflammatory changes. Score of less than 5on Zagazig scale are associated with no or mild pain. Score less than 5 may be considered as a marker of knee reserve in KOA.

AB0988 FREQUENCY OF OSTEOPENIC SYNDROME AND LOW-ENERGY FRACTURES IN POSTMENOPAUSAL WOMEN WITH OSTEOARTHRITIS OF THE KNEE JOINT

E. Usova[1], T. Raskina[1], O. Malyshenko[1], M. Letaeva[1], M. Koroleva[1], J. Averkieva[1]. [1]*Federal State Educational Institution of Higher Education "Kemerovo State Medical University" Ministry of Health of the Russian Federation, Department of Internal Medicine Propaedeutics, Kemerovo, Russian Federation*

Background: The impact of knee osteoarthritis on the risk of low-energy fractures remains an open question in recent times. Some cohort studies show that OA of the knee joint is associated with increased risk of fractures [1-3]. Other studies do not support this link [4-5].
Objectives: to compare the incidence of osteopenic syndrome and low-energy fractures in postmenopausal women with osteoarthritis (OA) of the knee joint.
Methods: The study includes 98 women, of whom: 51 (median age 63.0 [59.3;69.8] years) are diagnosed with OA of the knee joint according to the ACR criteria (1991) and 47 without OA of the knee joint (median age 65.0[61.8;71.0] years). The bone mineral density (BMD) (g/cm2) and the T-criterion (standard deviation, CO) of the femur neck and lumbar spine (LI-LIV) were evaluated by the two-energy X-ray absorption (DXA) method (Lunar Prodigy Primo, USA). The DXA data of the femoral neck and the lumbar spine were interpreted using the following reference intervals: normal BMD - T-criterion -1 CO, osteopenia - T-criterion from -1 or less CO. Low-energy fractures were considered to have occurred with minimal trauma (falling from a height of own height to the same surface or an even smaller injury) and were found in the anamnesis.
Results: In the group of patients with OA of the knee joint, normal BMD was found to be statistically significantly more frequent than the control group (15.7% vs. 4.3%) p=0.033. It is shown that in women with OA of the knee joint, low-energy fractures were statistically less recorded than in the control group: in 29.4% and 51.0% of women respectively (p=0.002). The chances of having low-energy fractures in the group of patients with OA of the knee joint were statistically lower by a factor of 2.64 compared to the control group (OR = 0.378; 95%CI: 0.203 - 0.703).
Conclusion: The low frequency of low-energy fractures and the lower the chances of them in women with OA of the knee joint compared to the control group are probably associated with lower prevalence of the osteopenic syndrome among these patients.

AB0989 PLANTAR FASCIITIS IN PATIENTS WITH KNEE OSTEOARTHRITIS

S. Bouzid[1], S. Miladi[1], A. Fazaa[1], H. Bousaa[1], K. Ben Abdelghani[1], A. Laatar[1].
[1]*Mongi Slim Hospital, Rheumatology, La Marsa, Tunisia*

Background: Knee osteoarthritis (OA) is a highly prevalent disease, it shares with plantar fasciitis similar risk factors including aging, occupation, obesity, and inappropriate shoe wear. The association between knee OA and heel pain caused by plantar fasciitis has received limited attention to date.
Objectives: The aim of our study was to detect plantar fasciitis using ultrasound in patients with confirmed knee OA.
Methods: We conducted a cross-sectional study including 30 patients with symptomatic knee OA. Health status was evaluated using the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) index. The functional impairment of knee OA was determined by the Lequesne index. Ultrasound evaluation of heels was performed in all patients searching signs of plantar fasciitis (measure thickness, echogenicity, enthesopathy, calcification, erosion, doppler).
Results: The study included 30 patients. Mean age was 62.09 +/- 6.7 years. Patients reported lower back pain and heel pain in 67% (n=20) and 47% (n=14) respectively. Knee symptoms were evaluated by the WOMAC index: mean score for pain, stiffness, and physical function was 9.68 +/- 4.25, 4,18 +/- 7.55 and 27.27 +/- 16.39, respectively. Mean Lequesne index for the knee OA was 11,4 +/- 4,57. Physical examination revealed limited range of motion in knees in 33 % (n=10) with a genu flexum in two patients. Patella tap was positive in 20 % (n=6). Heel ultrasound revealed thickening of the plantar fascia in 50% (n=15). Other sonographic abnormalities found were loss of fibrillar structure in 26.7% (n=8), perifascial collections in 13.3% (n=4), calcifications in 16.7 % (n=5) and erosions in 33.3% (n=10). No correlation was found between health status attested by WOMAC index and the presence of plantar fasciitis.
Conclusion: Our study showed that half of our knee OA patients have plantar fasciitis confirmed with ultrasound. More studies with larger cohorts are needed to explain the correlation between the two lesions.

AB0990 CORRELATION OF CLINICAL PARAMETERS WITH URINARY COLLAGEN TYPE II C-TELOPEPTIDE AND KNEE CARTILAGE THICKNESS MEASURED WITH ULTRASOUND IN PATIENTS WITH KNEE OSTEOARTHRITIS

O. Iaremenko[1], D. Fedkov[1], M. Saifullina[1], K. Iaremenko[2]. [1]*Bogomolets National Medical University, Department of internal medicine №3, Kyiv, Ukraine;* [2]*Olexandrivska City Hospital, Central Laboratory Department, Kyiv, Ukraine*

Background: Although knee osteoarthritis (KOA) incidence is one of the highest among chronic diseases, no effective biomarkers are known for its management [1].
Objectives: To estimate the relationship between the sensitive marker of matrix metalloproteinase-dependent cartilage degradation - urinary collagen type II C-telopeptide (uCTX-II) levels, patient-reported outcomes (PRO), and knee cartilage thickness measured with ultrasound (US) in patients (pts) with KOA.
Methods: WOMAC questionnaire and Leken`s functional index, VAS pain by pts, knee joints US, uCTX-II levels (ng/ml; ELISA) were evaluated in 46 pts (71.7% female) with KOA, who haven`t received any medical treatment except paracetamol or NSAIDs the last 12 weeks. The mean age was 62.6±6.2, mean disease duration – 10.2±6.3 years; 63% and 27% of pts had Kellgren-Lawrence grade II and III, respectively. The knee cartilage thickness (mm) in three compartments (medial, middle, lateral) of the patellofemoral region was evaluated using a linear L50 sensor in standard sensor positions, frequency 5–12 MHz. Calculation of average thickness for each knee joint and both joints was performed. The Spearman correlation coefficient was utilized to detect the association of uCTX-II, PROs and knee cartilage thickness.
Results: The mean values (M±σ) of WOMAC and Leken`s indices were 39±13,65 and 12±4,18, respectively. The mean value of VAS pain by pts was 57.7±16.5. The mean concentration of uCTX-II was 0.18±0.12. The means of cartilage thickness were: 1.7±0.33 for the right, 1.7±0.36 for the left, and 1.7±0.31 for both knee joints. The mean value of both knee joints cartilage thickness had significant negative moderate correlation with Leken`s index (r=-0.354, p<0.01). Leken`s and WOMAC indices significantly correlated with each other (r=0.354, p<0.01). According to VAS following tertile groups were detected: 1 group: means interval less than 50 mm; 2 group: means interval 50-64 mm; 3 group: more than 64 mm. There were negative moderate correlations between cartilage thickness of the left knee joint and Leken`s index (r=-0.513, p=0.03) and WOMAC (r=-0.535, p=0.024) only in group 1. Also, pts were divided into three groups according to disease duration: 1 group: means interval less than 7 years; 2 group: means interval 7-10 years; 3 group: more than 10 years. There were negative correlations between uCTX-II and medial, middle compartments of left knee cartilage thickness (r=-0.474, p=0.03; r=-0.592, p<0.01, respectively). WOMAC negatively correlated with cartilage thickness of the left (r=-0.517, p=0.02) and right (r=-0.435, p=0.046) knee joints. Leken`s index negatively correlated with cartilage thickness of the left knee joint (r=-0.590, p<0.01). All correlations were moderate and found in group 2. There were negative moderate correlation between uCTX-II and the mean value of middle compartments of both knee joints cartilage thickness (r=-0.538, p=0.04) and positive moderate correlation between uCTX-II and Leken`s index (r=0.561, p=0.036) in men. There were no correlations between uCTX-II and cartilage thickness of each knee joint and both joints in all pts.
Conclusion: Cartilage thickness measured with US associated with PROs in KOA pts. At the same time, the association between uCTX-II and cartilage thickness was less pronounced, only in men and in pts with disease duration 7-10 years. In pts with VAS pain less than 50 mm and in the group of pts with 7-10 years disease duration - WOMAC and Leken`s indices negatively correlated with the thickness of the cartilage of the knee joints. In other cases, correlations didn`t represent the expected relationship between uCTX-II level and clinical, instrumental characteristics of KOA. This may be because the current level of uCTX-II characterizes only the state of cartilage metabolism at the time of examination of the patient and doesn`t show the cumulative results of previous anabolic/catabolic changes in articular cartilage.

DECREASE LEVEL OF PRO-INFLAMMATORY CYTOKINES ASSOCIATED WITH REDUCTION OF BODY WEIGHT IN PATIENTS WITH OSTEOARTHRITIS

L. Arefeva[1], L. Seewordova[1], G. Kravtsov[1], E. Papichev[1], Y. Akhverdyan[1], J. Polyakova[1], B. Zavodovsky[1]. [1]*Federal State Budgetary Institution «Zborovsky Research Institute of Clinical and Experimental Rheumatology», lab. methods of treatment and prevention of joint diseases, Volgograd, Russian Federation*

Background: Recently, much attention has been paid to the problems of comorbidity of rheumatic diseases. Patients with osteoarthritis (OA) have a high risk of developing cardiovascular disease (CVD) [1]. Common risk factors for them are metabolic disorders, overweight and an increase in the level of pro-inflammatory cytokines [2,3]. To study the effect of weight loss on leptin levels in patients with OA and metabolic syndrome.
Objectives: We examined 130 patients with OA and 45 practically healthy individuals aged 49.26±3.89 years. Average BMI = 30.49 kg/m^2. Cardiovascular pathology was revealed in 121 (93%) patients.
Methods: Serum leptin levels were determined by ELISA-test (DBC Inc., cat no. CAN-L-4260) before and after treatment.
Results: The average level of leptin in healthy men was 3.8±0.21 ng/ml (M±m); no increase in leptin level was detected in them. The level of normal leptin in men, defined as M±2d, ranged from 2.0 to 5.6 ng/ml. The average level of leptin in healthy women was 7.4±0.37 ng/ml (M±m). The level of normal leptin in women ranged from 3.7 to 11.1 ng/ml. An increase in leptin levels in healthy women was detected in 4% of cases (1 person). The level of leptin significantly correlated with the sex of patients (t=7.91, p<0.001). Elevated levels of leptin in patients with OA were found in 42 patients out of 130 (32.3%), which is significantly more common than in healthy individuals (p<0.001). Elevated leptin levels were also found in 33 out of 78 women with OA (42.3%), which is significantly more common than in healthy women (p<0.001). The average level of leptin in women with OA was 14.4±0.32 ng/ml, which is significantly higher than in healthy females (p<0.001). Elevated leptin levels were found in 9 out of 28 men with OA (21.4%), which is significantly more common than in healthy men (p<0.001). The level of leptin in men with OA was 6.2±0.25 ng/ml (p<0.001). In patients with elevated leptin levels, the following were more often detected: secondary synovitis, radiographic stage of OA - III-IV, functional insufficiency of joints II-III and disease duration of more than 5-10 years. A significant relationship was found between high levels of leptin and higher levels of C-reactive protein (t=2.31, p<0.05) and ESR (t=2.06, p<0.05), both in men and women. and in women with OA. We found that weight loss by more than 5 kilograms in 3 months improves the clinical condition of patients, lowering blood pressure, pulse rate, lowering leptin concentration (t=3.43, p<0.001), and reducing postprandial glycemia (t=2, 53, p<0.005), by increasing the concentration of stimulated C-peptide (t=5.00, p<0.001).
Conclusion: A high level of leptin is associated with a high atherogenic coefficient, the severity of the metabolic syndrome, and a severe course of osteoarthritis with secondary synovitis. Weight loss contributes to a decrease in leptin levels, a decrease in the manifestations of insulin resistance, stabilization of blood pressure and pulse rates, and an improvement in the clinical course of OA.

PROGNOSTIC FACTORS RELATED TO CLINICAL RESPONSE IN 197 PATIENTS WITH KNEE OSTEOARTHRITIS TREATED BY PLATELET RICH PLASMA (PRP)

C. Chopin[1], M. Geoffroy[1], C. Dorilleau[1], B. Loïs[1], A. Hittinger[1], I. Charlot[1], L. Kanagaratnam[2], J. H. Salmon[1]. [1]*CHU Reims - Hôpital Maison Blanche, Service de Rhumatologie, Reims, France;* [2]*CHU Reims - Hôpital Maison Blanche, Unité d'aide méthodologique, Reims, France*

Background: The European League Against Rheumatism (EULAR) [1] and the Osteoarthritis Research Society International (OARSI) [2] recommend a combination of non-pharmacological and pharmacological treatment in the management of knee osteoarthritis. New therapies have emerged such as Platelet Rich Plasma (PRP) injections. Many studies have shown the effectiveness of this treatment, and even its superiority over Hyaluronic Acid.
Objectives: The aim of this study was to determine the prognostic factors related to clinical response to PRP injections in knee osteoarthritis, in order to better select candidates for this therapy.
Methods: This was a single-center, prospective observational study including patients treated by PRP injections for knee osteoarthritis, from a university hospital. The PRP was leukocyte-poor, obtained by an ARTHREX kit, and was injected twice, at one-month intervals. They were assessed at 4 months (M4) and 7 months (M7) after the first injection. Pains on a Visual Analog Scale (VAS) and function with Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Knee injury and Osteoarthritis Outcome Score (KOOS) – Physical Function Shortform (KOOS-PS) were collected. Patients were then classified as responders if they met the OMERACT-OARSI criteria at M7. Univariate and multivariate analysis was performed to compare the two groups.
Results: Among 197 patients, 210 knees were treated. The mean age was 59.8±10.8 years, Body mass index (BMI) was 31.0±6.5. Patellofemoral osteoarthritis was found in 34.3% of the patients, the distribution according to Kellgren and Lawrence stages I, II, III, IV was 11.8%, 33.5%, 40.4% and 14.3% respectively. A majority of patients had failed viscosupplementation (62.4%). At 7 months, 43.8% were classified as responders. Total WOMAC was 49.4±16.1 at M0, 43.6±17.9 at M1, 31.1±19.0 at M4 and 31.9±19.8 at M7, with significant improvement at M4 and M7 versus baseline (p<0.0001). The VAS was 58.5±19.7, 51.6±21.7, 43.7±23.2 and 43.5±23.5 at M0, M1, M4 and M7 respectively (p<0.0001 at all 3 times versus baseline). Regarding treatment satisfaction, 70% of patients considered the treatment effective or very effective at M7. Physical therapy and a heel-buttock distance greater than 35 centimeters were the two criteria associated with a poorer response at M7 on multivariate analysis. The pain VAS at M7 appeared to be lower in patients whose osteoarthritis had been evolving for less than 24 months. Tolerance was good. There was an increase in joint effusions between M0 and M1 (17% vs. 41%, p<0.0001), but no increase in pain.
Conclusion: PRP treatment in knee osteoarthrisis appeared to be effective and well tolerated, and this response was not associated with the radiographic stage or the type of knee osteoarthritis. In accordance with the recommendations of a group of French experts, this treatment should be proposed in case of failure of drug and rehabilitation treatment, at the same level as hyaluronic acid injections.

INDICATORS OF BONE MINERAL DENSITY IN ELDERLY AND SENILE MALE PATIENTS WITH OSTEOARTHRITIS OF THE KNEE JOINT, DEPENDING ON THE STATE OF THE MUSCULAR APPARATUS

O. Malyshenko[1], M. Letaeva[1], T. Raskina[1], J. Averkieva[1], M. Koroleva[1]. [1]*Kemerovo State Medical University, Department of Propedeutics of Internal Medicine, Kemerovo, Russian Federation*

Objectives: To evaluate bone mineral density (BMD) indicators in elderly and senile male patients with osteoarthritis (OA) of the knee joint, depending on the state of the muscular apparatus.
Methods: The study included 32 patients with an established diagnosis of knee joint OA. The average age of patients was 68.7 (66.1; 70.3) years. The diagnosis of knee joint OA was established according to the diagnostic criteria of the American College of Rheumatology (ACR, 1991). For comparative analysis, all patients were divided into 3 groups depending on the state of the muscular apparatus (EWGSOP, 2010: muscle mass was assessed by multispiral computed tomography, muscle strength was measured using a wrist dynamometer, muscle function was examined using a battery of short tests): 1st – 9 patients without sarcopenia, 2nd - 11 patients with presarcopenia and 3rd - 12 patients with sarcopenia. BMD was assessed by two-energy X-ray absorptiometry in the neck and proximal femur as a whole and in the lumbar spine.
Results: Osteopenic syndrome in the study cohort was diagnosed in 23 (71.9%) patients: osteopenia - in 19 (59.4%) patients, osteoporosis – in 4 (12.5%). Normal BMD values were observed in 9 (28.1%) patients. Osteopenic syndrome was detected in patients with sarcopenia significantly more often than in patients without sarcopenia (p>0.05) and with presarcopenia (p=0.05). Thus, in the group of patients without sarcopenia, normal BMD indicators were noted in 6 (18.8%) patients, OPe – in 3 (9.4%), no cases of OP were detected. In patients with presarcopenia, normal BMD indicators were determined in 3 (9.4%) patients, OPe - in 8 (25%) patients, no cases of OP were also detected. In patients with sarcopenia, normal BMD indicators were not registered, OPS was detected in 12 (37.5%) patients, while OPe – in 8 (25.0%) and OP – in 4 (12.5%). BMD in patients with sarcopenia in the neck and proximal femur as a whole were statistically significantly lower than in patients without sarcopenia and with

presarcopenia (p<0.050). The BMD in the femoral neck in patients with sarcopenia was 0.908 [0.817; 0.977] g/cm2, which corresponds to -0.95 [-1.35; 0.425] CO according to the T-criterion, while in the groups of patients without sarcopenia and with presarcopenia, statistically significantly higher BMD values were recorded: 0.998 [0.935; 1.09] g/cm2 and 0.995 [0.94; 1.04] g/cm2 (p=0.009 and p=0.027), which corresponds to -0.30 [-0.80; 0.225] and -0.30 [-0.70; 0] CO according to the T-criterion (p= 0.013 and p=0.024), respectively. When comparing the BMD and T-test in the lumbar spine, there were no statistically significant differences in the studied groups of patients.

Conclusion: Sarcopenia is associated with low BMD in the neck and proximal femur in general in elderly and senile male patients with knee joint OA.

AB0994 EXPLORING KNEE OSTEOARTHRITIS PAIN TRAJECTORIES AND MOVEMENT-EVOKED PAIN CHANGES DURING A 24-WEEK OUTDOOR WALKING PROGRAM (WALK)

S. Drummen[1], S. Balogun[1,2], L. Scheepers[1], I. Munugoda[1], A. Lahham[3], K. Bennell[4], R. Hinman[4], M. Callisaya[1,5], G. Cai[1], P. Otahal[1], T. Winzenberg[1], Z. Wang[1], B. Antony[1], J. Martel-Pelletier[6], J. P. Pelletier[6], F. Abram[7], G. Jones[1], D. Aitken[1]. *[1]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; [2]Australian National University, College of Health & Medicine, Canberra, Australia; [3]Monash University, Respiratory Care group, Melbourne, Australia; [4]The University of Melbourne, Medicine, Dentistry and Health Sciences, Melbourne, Australia; [5]Monash University, Medicine, Nursing and Health Sciences, Melbourne, Australia; [6]University of Montreal, Hospital Research Centre (CRCHUM), Montréal, Canada; [7]Medical Imaging Research & Development, ArthroLab.Inc., Montreal, Canada*

Background: Exercise therapy is recommended as first line treatment for knee osteoarthritis (OA), but it remains to be sub-optimally applied (1). Movement-evoked pain is a potential barrier to exercise adherence, but recent evidence suggests that such pain can be improved by training (2). Walking programs are low-cost, easily adopted and can be performed outdoors which can minimize the risk of SARS-CoV-2 transmission when in a group (3).

Objectives: To explore the acute pain trajectories of individuals with knee OA during a 24-week outdoor walking intervention. In addition, to explore the effect of pain trajectories and/or baseline characteristics on retention and adherence.

Methods: Individuals with clinical knee OA and bone marrow lesions (BMLs) on magnetic resonance imaging (MRI) were asked to follow a 24-week walking program. Every week consisted of two one hour supervised group sessions at various outdoor locations and one unsupervised session. At the start and end of every supervised group walk, knee pain was self-reported by participants to their trainer using a numerical rating scale (NRS) (0-10). The difference between the NRS pain values was considered as an acute pain change evoked by that walk. At baseline, the most affected knee of each participant was assessed using the Visual Analogue Scale (VAS) pain, the Western Ontario and McMasters Universities Osteoarthritis Index (WOMAC) pain, stiffness and function, wellbeing (3 questionnaires) and the Osteoarthritis Research Society International (OARSI) recommended strength and performance measures.

Results: In total, N = 24 participants started the program of whom N = 7 (29%) withdrew. Pain at the start of each walk decreased from NRS 2.5 (SD 1.6) at the first walk (N = 24) to NRS 0.9 (SD 0.8) at the final walk (N = 17). This pain was estimated to decrease on NRS by -0.04 (95% CI -0.05 to -0.02) per supervised session, p < 0.001 during the first 12 weeks and -0.01 (95% CI -0.02 to -0.004), p = 0.004 during the second twelve weeks of the program. The number (%) of participants who experienced an acute increase in pain decreased from 11 (45.8%) at the first walk to 4 (23.5%) at the last walk. At baseline, non-adherent participants (<70% of group sessions) (N = 11) had lower physical performance scores, including the 30s Chair Stand Test (mean 10 (SD 1.7) stands versus mean 12.0 (SD 1.7) stands, p = 0.011), Fast Past Walk Test (1.23 (SD 0.14) meter per seconds (m/s) vs 1.50 (SD 0.20) m/s, p = 0.001), Six Minute Walk Test (418.8 (SD 75.9) m vs 529 (SD 72.6) m, p = 0.002), compared to adherent participants (N = 13). Non-adherent participants also had less severe self-reported symptoms including WOMAC stiffness (90.7 (SD 44.5) mm vs 121.5 (SD 17.0) mm, p = 0.031), compared to adherent participants. During the first two weeks of walking, acute increases in pain on average (mean ≥0.5 NRS) were reported by a greater number of non-adherent (N = 5 (45.5%)) than adherent participants (n = 4 (30.8%)).

Conclusion: This was an exploratory study and results need to be interpreted with caution due to the small sample size. The walking program resulted in clinically important improvements (MCIIs) (≥ 1 on NRS) (4) in start pain and acute pain changes. Improvements in start pain during the first 12-weeks were comparable to improvements measured in the NEMEX program (2) and may suggest that 12 weeks of exercise is sufficient to achieve MCIIs in pain. Improvements in acute changes in pain were smaller, which may have been related to a floor effect (5). Lower physical performance scores at baseline and more acute increases in pain during the first two weeks was associated with non-adherence. Participants with these characteristics may benefit from a lighter introduction to exercise.

Objectives: to outline specific biochemical and imaging features of metabolic phenotype of knee osteoarthritis (OA) in a multicenter prospective study.

Methods: 284 female patients with knee OA (according to the ACR criteria) aged 40-78 were included in this prospective multicenter study. OA radiologic stages in the study group varied from I to III (Kellgren & Lawrence) and all the patients signed an informed consent. Mean age was 58.5 ± 9.5 years, disease duration was 5 (2-10) years. BMI was 29.6 ± 5.6 kg/m^2, with hip (HC) – 109.3 ± 10.4 cm and waist circumference (WC) – 92.5 ± 12.5 cm. Physicians filled out individual case report forms, which included anthropometric information, history and physical assessment data. All patients performed lab tests, ultrasonography and x-ray of the knee, as well as proximal femur and lumbar spine DEXA.

Results: Metabolic phenotype was diagnosed in 52.4% of patients. Participants were then divided in two groups. Patients with metabolic phenotype of osteoarthritis were older (61 (57-68) vs 52 (43-58), respectively, p<0.0001), had higher BMI (31.6 (28.6-35.4) vs 26.4 (23.4-30.3), p<0.0001) and had more intense VAS knee pain while walking on flat surface (50 (40-60) vs 35 (10-50), p<0.0001). There were also statistically significant differences when we analyzed the imaging results (Table 1). Patients with metabolic phenotype of knee OA had higher chances of grade III K&L (OR=4.4, 95% CI 1.3-14.2, p=0.01) and more significant medial joint space narrowing, bigger tibial osteophytes; knee ultrasound revealed thinner cartilage and thicker synovium. DEXA showed higher total hip BMD. Patients with metabolic phenotype had higher levels of CRP, HbA1c, uric acid, cholesterol, LDL, triglycerides, ALT, AST, glucose, leptin and COMP.

Table 1. Comparison of patients depending on phenotype

Index	Metabolic phenotype (n=149)	No metabolic phenotype (n=135)	p
K&L radiologic grade			0.01
I grade	13.6%	56.7%	
II grade	62.7%	36.7%	
III grade	23.7%	6.6%	
Posterior lateral tibial cartilage, mm, Me	1.5 (1.4-1.8)	1.7 [1.6;1.8]	0.05
Posterior medial tibial cartilage, mm, Me	1.6 (1.3-1.8)	1.7 [1.6;1.8]	0.014
Medial knee joint space, mm, Me	2.6 (1-4.6)	3.6 [3;4.3]	0.023
Osteophytes of the medial tibial condyle, mm, Me	1 (1-2)	0 [0;0]	0.025
Osteophytes of the lateral tibial condyle, mm, Me	1 (1-2)	0[0;1]	0.042
Synovium thickness, mm, Me	3.1 (2.9-3.5)	2.9 (2.6-3.1)	0.02
Total hip BMD, (g/cm^2), mm, Me	0.95 (0.87-1.02)	0.87 (0.77-0.99)	0.03
CRP, mg/l, Me	2.8 (1.4-5.1)	1.1 (0.49-2.0)	0.0001
HbA1c, %, Me	5.7 (5.4-5.9)	5.2 (4.9-5.6)	0.0001
Uric acid, mcmol/l, Me	312 (268-391)	269.7 (233.9-324.5)	0.0002
Cholesterol, mmol/l, Me	6.4 (5.33-6.85)	5.4 (4.78-5.82)	0.002
LDL, mmol/l, Me	4 (3.38-4.59)	3.1 (2.6-3.89)	0.0009
Triglycerides, mmol/l, Me	1.6 (1.19-2.44)	1.1 (0.76-1.48)	<0.0001
ALT/AST, units/l, Me	21 (17.15-28.9)/ 20.6 (17.6-25)	15.9 (11.4-19.8)/ 18.1(14.9-21.6)	0.0006
Glucose, mmol/l, Me	5.6 (5.1-6,155)	5.2 (4.97-5.53)	0.001
Leptin, ng/ml, Me	35.6 (25.5-55.6)	20 (14.7-31)	<0.001
COMP, ng/ml, Me	1415 (1115-2100)	712.2 (484.5-1015)	<0.001
IL-6, pg/ml, Me	0.55 (0.25-0.8)	0.03 (0.01-0.4)	<0.005

Spearman correlation analysis showed positive correlations (p <0.05) between the metabolic phenotype and OA radiologic stage (r=0.44), size of tibial osteophytes (r=0.31), synovium thickness (r=0.28), hsCRP (r=0.44), HbA1c (r=0.45), cholesterol (r=0.29), LDL (0.3), triglycerides (r=0.36), uric acid (r=0.3), leptin (r=0.46), IL-6 (r=0.38), COMP (r=0.51). Negative correlations (p <0.05) were established with medial joint space (via X-ray): (r=-0.24) and cartilage thickness (via ultrasound) (r=-0.25).

Conclusion: Comprehensive examination of patients with the use of imaging and biochemical methods showed that metabolic phenotype of osteoarthritis is more severe (with correction for age taken into account). Patients with metabolic phenotype showed higher levels of hsCRP, leptin, IL-6, COMP, which possibly demonstrate a more active form of low-grade inflammation (the underlying mechanism of OA pathogenesis) and more significant cartilage damage

AB0996 THE POSSIBILITY OF LONG-TERM PAIN CONTROL IN PATIENTS WITH OSTEOARTHRITIS

E. Polishchuk[1], A. Karateev[1], A. Potapova[1], V. Amirdzhanova[1]. [1]*V.A.Nasonova Research Institute of Rheumatology, pain management, Moscow, Russian Federation*

Background: In some patients with osteoarthritis (OA), moderate or severe joint pain may persist for a long time and functional limitations may increase, which requires long-term administration of nonsteroidal anti-inflammatory drugs (NSAIDs).

Objectives: To evaluate the efficacy and safety of long-term use of NSAIDs in patients with OA in real clinical practice.

Methods: 611 patients with OA (knee or hip) were included in an open observational study. 64.5% were female, mean age 58.3±11.0years. All patients received aceclofenac at a dose of 200 mg / day. Pain at movement was determined on a 10-cm visual analog scale (VAS). The number of patients with severe pain (≥6 cm by VAS) and the number of patients with pain reduction ≥50% were evaluated. The assessment was carried out 2 weeks, 3, 6, 9 and 12 months after the start of therapy. Adverse events were noted at each visit.

Results: By 12 months of follow-up, 53.3% of patients had completed the study. The mean pain severity at baseline, after 2 weeks, 3, 6, 9 and 12 months was 6,5±1,2; 4,8±1,4; 3,2±1,4; 2,6±1,4; 2,2±1,1; 1,4±1,1 cm VAS (p<0.05). The number of patients with severe pain decreased from 77.8% to 24,9%, 2,9%, 2,3%, 0,9% and 0%. The number of patients with pain reduction ≥50% was 12,0%, 65,1%, 81,0%, 88,5% and 84.0%. Adverse events were observed in about 30% of patients, mainly mild or moderate dyspepsia (11.1%- 23.3%) and arterial hypertension (7.1% - 10.9%). No serious complications were recorded.

Conclusion: Taking into account the large number of drop-outs from the study (46.7%), approximately half of the patients can have long-term pain control with NSAIDs in real clinical practice. Aceclofenac is effective and well tolerated and can be used for long-term pain control in patients with OA.

AB0997 NEW EPIGENETIC PREDICTORS OF THE VARIOUS LOCALIZATIONS OSTEOARTHRITIS DEVELOPMENT

A. Tyurin[1], R. Khusainova[2]. [1]*Bashkir State Medical University, Internal Medicine, Ufa, Russian Federation;* [2]*Institute of Biochemistry and Genetics, Human molecular genetics, Ufa, Russian Federation*

Background: Osteoarthritis (OA) is one of the most common joint diseases, often causing persistent pain and immobilization [1]. The genetic contribution to OA varies from 40% to 65%, depending on the presence of the pathology in the immediate family, the location of the affected joint, sex, and ethnicity of the patients [2]. The study of miRNA target sites is a new promising direction in molecular diagnostics [3].

Objectives: The aim of our work was to study the microRNA binding sites of COL1A1, COL11A1, ADAMTS5, MMP1, MMP13, SOX9, GDF5, FGF2, FGFR1, FGFRL1 genes in patients with OA of different localization.

Methods: A total of 417 women (mean age 51.67±11.5) from Ufa (Republic of Bashkortostan, Russia) participated in the study between January 2013 and August 2017. The patients were examined to diagnose for osteoarthritis according to the criteria of the American College of Rheumatologists (1995) with X-ray confirmation. Overall, 356 women with OA were recruited and divided into 3 groups as follows: subgroup 1 included 84 women affected by generalized OA, subgroup 2 included 197 women affected by knee OA, subgroup 3 included 75 women affected by hip OA. For genotyping, RT-PCR analysis using KASP@ technology was used. Selection of the miRNA target loci was carried out using the database of the National Center for Biotechnological Information (https://www.ncbi.nlm.nih.gov), Ensemble Ge-nome-Browser (www.ensembl.org), and the base of polymorphisms of microRNA target sites (http: // compbio. uthsc.edu/miRSNP). As a calculation tool, Statistica v.6.2 (StatSoft) software packages were used. Considering the type I error caused by multiple testing, p values were adjusted by calculating the FDR value using the Benjamini-Hochberg method (https://tools.carbocation.com/FDR).

Results: The T allele of the rs9659030 (COL11A1) was associated with the generalized OA (p = 0.019; OR = 2.0; 95% CI 1.11 to 3.62), the TT genotype was associated with total patients (p = 0.026; OR = 1.59; 95% CI 1.05 to 2.42), generalized OA (p = 0.003; OR = 2.75; 95% CI 1.39 to 5.46) and OA of the hip (p = 0.016; OR = 2.3; 95% CI 1.14 to 4.36). With respect to rs229069 (ADAMTS5), a significant association was found between the C allele and the incidence of total OA (p = 0.018; OR = 1.43; 95% CI 1.06 to 1.93), as well as with the knee OA (p = 0.042; OR = 1.43; 95% CI 1.01 to 2.03) and hip OA (p = 0.026; OR = 2.039; 95% CI 1.08 to 3.85). The CC genotype was also found to be associated with total OA (p = 0.037; OR = 1.53; 95% CI 1.02 to 2.28) and hip OA (p = 0.026; OR = 2.039; 95% CI 1.08 to 3.85). The T allele of rs13317 (FGFR1) was strongly associated with the total OA (p = 0.001; OR = 1.67; 95% CI 1.2 to 2.3), knee OA (p = 0.003; OR = 1.74; 95% CI 1.19 to 2.55) and generalized OA (p = 0.044; OR = 1.67; 95% CI 1.01 to 2.75) After Benjamini-Hochberg correction, rs13317 remained statistically significant in the following groups: the T allele in control vs total patients (adjusted p*= 0.01) and in control vs OA of the knee (adjusted p* = 0.03). Neither the genotype nor the allele frequencies of rs1061347 (COL1A1), rs229077, rs9978597 (ADAMTS5), rs5854, rs470215 (MMP1), rs1042840 (MMP13), rs1042673 (SOX9), rs4647940 (FGFRL1) were significantly different between the affected individuals and normal controls.

Conclusion: The current study demonstrated an association between the T allele of rs13317 in FGFR1 and incidence of the total OA and knee OA in women from Volga-Ural region of Russia.

AB0998 DIET AND JOINT SYMPTOMS: A SURVEY OF MOROCCAN PATIENTS WITH OSTEOARTHRITIS

R. Bensaid[1], T. Fatima Zahrae[1], N. El Mansouri[1], A. Anass[1], I. Berrichi[1], B. Khadija[1], F. Abourazzak[1]. [1]*CHU Tangier, Rheumatology, Tangier, Morocco*

Background: The question of diet is frequently asked by patients with osteoarthritis. Beyond the effect of weight on the aggravation of their symptoms, patients

often ask whether certain foods, described as inflammatory or anti-inflammatory, can improve or worsen their disease.
Objectives: The objective of our study is to investigate whether Moroccan patients report a relationship between certain foods and their symptoms and also to study whether they adopt specific dietary behaviors in an effort to alleviate their symptoms.
Methods: This is a survey based on a questionnaire, that included any patient followed for osteoarthritis who presented to the rheumatology department.
The questionnaire consisted of 3 parts:
1) Socio-demographic data, co-morbidities, and information on osteoarthritis (location, duration of evolution, functional impact and treatments).
2) Beliefs and attitudes of patients regarding diet in relation to osteoarthritis.
3) A list of 24 foods for which patients were asked to indicate whether they aggravated, improved or left their joint symptoms unchanged.
Results: At this time we included 120 patients. The mean age was 57.1 ± 11.8, 88.3% of the patients were women, 41.2% had comorbidities, 62.5% were illiterate. The median duration of osteoarthritis was 4 years [2; 7]. 64.2% of the patients were followed for gonarthrosis, 25% for discarthrosis and 10.8% for digital osteoarthritis. The average BMI was 27.8 ± 5.2. 8.3% of the patients thought that diet influenced their osteoarthritis. 9.5% of the subjects stated that food had an effect on their symptoms, 9.2% of them reporting an improvement and 8.3% an aggravation. Fish (1.7%), garlic (1.7%), and olive oil (1.7%) were the foods most often cited as improving joint symptoms, while red meat (3.3%), and sweetened soft drinks (2.5%) were the most often cited as worsening symptoms. 6.7% of the patients had food avoidance behaviors, 10.8% adopted certain diets and 5.8% had tried fasting in order to relieve joint symptoms. In univariate and multivariate analysis, education level (OR: 0.165; 95% CI [0.046-0.592]; p=0.006) and experience with a food that improves symptoms (OR: 46.8; 95% CI [1.798-1222.5]; p=0.021) were associated with reporting that food influences OA symptoms.
Conclusion: Our study showed that associations between certain foods and worsening or improving joint symptoms were reported by a minority of patients and appeared to be mostly associated with patients' education level and experience of a food improving symptoms.

AB0999 OSTEOARTHRITIS. PHARMACOECONOMICS ASPECTS OF SYMPTOM-MODIFYING THERAPY IN REAL CLINICAL PRACTICE.

I. Krysanov[1,2,3], V. Krysanova[3,4], V. Ermakova[1,3,4], N. Shostak[5], N. Pravdyuk[5]. *[1]Institute of Clinical and Economic Assessment and Pharmacoeconomics",-, Mytishchi, Russian Federation; [2]Federal State Budgetary Educational Institution of Higher Education"A.I.Yevdokimov Moscow State University of Medicine and Dentistry"of the Ministry of Healthcare of the Russion Federation,-, Moscow, Russian Federation; [3]Moscow State University of Food Production, Medical Institute of Continuing Education, Moscow, Russian Federation; [4]FSAEI HE I.M. Sechenov First MSMU MOH Russia (Sechenov University),-, Moscow, Russian Federation; [5]Pirogov Russian National Research Medical University, Nesterov Department of Faculty Therapy, Moscow, Russian Federation*

Background: Treatment of osteoarthritis (OA) is a significant medical and social problem worldwide. Modern therapeutic approaches include a combination of pharmacological and non-pharmacological methods aimed at reducing pain, improving joint function, and preventing disease progression. A wide variety of symptomatic slow-acting drugs for osteoarthritis and their usage dictate the necessity for a clinical and economic analysis to select the most economically feasible treatment regimen for OA.
Objectives: To conduct a clinical and economic assessment of OA therapy using drugs of the SYSADOA group.
Methods: The search for publications for the period 2011-2022 on the clinical efficacy and safety of SYSADOA (bioactive concentrate of small marine fish containing chondroitin sulfate, amino acids, peptides, sodium, potassium, calcium, magnesium, iron, copper and zinc ions) was conducted using available sources (Medline, eLIBRARY.ru). The research selection methodology was in compliance with the PRISMA criteria(Preferred Reporting Items for Systematic reviews and Meta-analysis), 124 sources were analyzed. To collect data on the costs for managing patients in real clinical practice, a survey of 15 rheumatology experts was conducted with an assessment of the frequency and average duration of SYSADOA drugs usage. The direct medical costs paid from budgetary funds and/or funds of the compulsory medical insurance system related to the treatment of OA were assessed. Cost minimization analysis was carried out for 10 SYSADOA drugs; the average course cost of treatment was calculated according to the dosage regimens and duration of admission, as well as the cost of providing medical services.
Results: Analysis of the literature data showed that bioactive concentrate of small marine fish, produced by Biotehnos S.A. is a modern original SYSADOA for the initial therapy of knee joint OA with proven efficacy and safety. The estimated course cost of SYSADOA therapy ranges from 36.961 to 92 euros. The median exchange rate of all drugs in the sample was 50.2 euros; for SYSADOA drugs with oral administration - 85.82 euros; injectable drugs - 47.76 euros. The median amount of direct costs for injectable SYSADOA was 388,012 euros. Cost minimization analysis showed that the use of an alternating mode of administration of the drug (2 ml every other day intramuscularly - 10 injections) in patients with knee joint OA is the most cost-effective method for the treatment of OA and allows to reduce direct costs up to 64% per patient by reducing the number of medical services provided.
Conclusion: The analysis proved rationality of the established medical practice in prescribing of the injectable SYSADOA (bioactive concentrate of small marine fish was a leader among injectable SYSADOA according to HWC and IQVIA marketing analytical data for the period 2020-2021). Choosing the most economically feasible drug for the treatment of patients with OA will reduce the costs of the healthcare system and reduce the overall economic burden of OA.

AB1000 RELIABILITY AND VALIDITY OF THE CONE EVASION WALK TEST IN PATIENTS WITH TOTAL KNEE ARTHROPLASTY: A PILOT STUDY

K. S. Kacmaz[1], B. Unver[2], V. Karatosun[3]. *[1]izmir katip celebi university, physical therapy and rehabilitation, izmir, Turkey; [2]dokuz eylul university, physical therapy and rehabilitation, izmir, Turkey; [3]dokuz eylul university, orthopaedics and traumatology, izmir, Turkey*

Background: Total knee arthroplasty (TKA) is the gold-standard procedure for end-stage knee osteoarthritis, however, some residuel problems may still continue and cause a variety of dysfunctions, such as impaired strength, proprioception, gait, balance, postural instability, and, impaired ability to avoid obstacles while walking. Tripping over an obstacle is the most frequent cause of falls 1 and falls can limit daily activities and induce post-fall syndromes, such as dependence, loss of autonomy, immobilization, and depression 2. The Cone Evasion Walk test (CEW) to assess fall risk by the ability to evade obstacles, (ICF-code d455), which requires attentional, perceptual, and several neuromusculoskeletal and movement related functions 3. However, there is no study investigating the reliability and validity of the CEW in TKA patients.
Objectives: The aim of the study is to investigate the reliability and validity of the CEW in patients with TKA.
Methods: Twenty patients with TKA included in the study. The CEW, the Timed Up And Go Test (TUG) and the Hospital for Special Surgery (HSS) Knee Score administered to the patients. Patients rested between the tests for an hour.
Results: Mean age was 68.1 ± 2.59 years and the mean HSS Knee Score was 85.43± 3.47. The relative (ICC coefficient) and absolute (SEM and SRD95) reliability values were 0.98, 1.01, and 2.75 respectively. The Spearman correlation coefficient of the CEW with the TUG was 0.72.
Conclusion: Based on the current findings, the CEW has excellent reliability, high validity and responsiveness in evaluating dynamic balance and obstacle avoidance in patients with TKA. The minimal clinically important difference of CEW in TKA patients is 2.75 and it may be concluded that the fact that this value is low, indicates the sensitivity of the test. Therefore, the CEW can identify even small alterations in the functional status, can be reliably used for post-operative surveillance of TKA to observe patient results, and the usage of the CEW for assessing the fall risk and mobility in the community may be a better predictor of the patients' current condition.

AB1001 OSTEOARTHRITIS AND OBESITY: RELATIONSHIPS AND EFFICACY OF THERAPY.

E. Strebkova[1], L. Alekseeva[1,2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation;* [2]*Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation*

Background: Osteoarthritis (OA) is the most common joint disease. The most important factor not only in the development but also in the progression of OA is obesity. Higher incidence of OA in obese patients is associated with several factors. One of them is a large volume of fat mass, which increases the mechanical load on the joints. On the other hand, in obesity, hyperexpression of pro-inflammatory mediators (cytokines, adipokines) is observed, which negatively affect joint tissues, as well as provoke the development of low-level metabolic inflammation. Thus, the problem of OA and obesity is very relevant in modern rheumatology.
Objectives: To determine features of clinical manifestations of OA in obesity and evaluate the effectiveness of obesity therapy in OA.
Methods: The study included 73 patients (women) with knee OA (according to the ACR criteria) II-III X-ray stage by Kellgren-Lawrence: obese 50 (body mass index (BMI) > 30 kg/m2) and non-obese 23 (control group). Obese patients were divided into 2 groups: 1 group (n = 25) - received orlistat 120mg 3 times a day for 6 months in combination with non-medicamentous methods of controlling excess body weight and 2 group (n = 25), whose patients were recommended a diet and dosed exercise for 6 months. Monthly visits evaluated anthropometric measures, articular status, WOMAC. Initially and after 6 months, laboratory scores were evaluated in obese patients (determination of leptin, TNF-α, IL-6, CRP in peripheral blood).
Results: In patients with OA and obesity, a more severe course of OA is determined compared to the control group (Table 1).

Table 1. Comparative characteristics of obese and non-obese knee OA patients

Parameters	Obese patients (n = 50), BMI > 30 kg/m^2	Non-obese patients (n = 23), BMI < 30 kg/m^2	p
The mean age, y.o.,(M ± δ)	56.5 ± 5.86	58.69 ± 5.43	0,13
The mean age of OA onset, y.o., (M ± δ)	49.33 ± 6.14	55.17 ± 4.88	**< 0.001**
Average duration of OA, years, (M ± δ)	7.43 ± 3.93	3.52 ± 1.47	**< 0.001**
BMI of onset OA, kg/m^2, (M ± δ)	36.53 ± 4.35	25.8 ± 2.0	**< 0.001**
The mean body weight, kg, (M ± δ)	102.97 ± 14.57	70.87 ± 8.84	**< 0.001**
WOMAC pain, mm, (M ± δ)	227.9 ± 85.15	168.35 ± 49.17	**0.006**
WOMAC stiffness, mm, (M ± δ)	94.44 ± 49.4	71.52 ± 25.71	**0.039**
WOMAC functional insufficiency, mm, (M ± δ)	846.8 ± 337.57	692.69 ± 121.99	**0.037**
Total WOMAC, mm, (M ± δ)	1170.28 ± 437.85	932.61 ± 159.09	**0.014**

After 6 months of drug therapy of obesity in patients of group 1, a significant decrease in body weight by 10.07% ($p < 0.05$) was achieved. In patients of group 2, body weight decreased by 0.84% ($p > 0.05$). In patients of group 1, the indicators of the WOMAC index improved: pain decreased by 52.5% ($p < 0.05$), stiffness by 47.98% ($p < 0.05$), functional insufficiency by 51.55% ($p < 0.05$). In patients of group 2, there was also a decrease in the WOMAC index, however, these changes were worse than in patients with greater body weight loss. Analyzing laboratory data, in group 1 there was a significant decrease in the level of leptin ($p = 0.05$) and IL-6 ($p < 0.05$), in contrast to patients of group 2 ($p = 0.64$; $p = 1.0$, respectively). In the study of TNF-α, no significant changes in the two groups were determined. CRP level in 1 group of patients decreased by 23.74% ($p > 0.05$) compared to baseline data, in 2 group of CRP increased by 24.54% ($p > 0.05$). Correlation analysis revealed a direct relationship between a decrease in leptin level and a decrease in body weight ($r = 0.5$, $p = 0.02$) in patients with greater weight loss. Direct correlations of leptin reduction and WOMAC index decline (pain, stiffness, functional insufficiency, total WOMAC) ($r = 0.5$, $p = 0.01$; $r = 0.4$, $p = 0.04$; $r = 0.4$, $p = 0.03$; $r = 0.5$, $p = 0.01$, respectively).
Conclusion: The results of our study demonstrated a more severe clinical course of OA in obese patients. Drug therapy for obesity in patients with knee OA and obesity not only leads to a decrease in the presentation of clinical symptoms of OA, but also entails changes at the metabolic level: a decrease in leptin, IL-6 and CRP, which indicates a decrease in the intensity of metainflammation in obese patients. Thus, therapeutic interventions aimed at reducing body weight should be an integral part of knee OA therapy.

AB1002 CLASSIC VERSUS AQUATIC REHABILITATION IN GONARTHROSIS: WOMAC SCORE

R. Maaoui[1], M. Hfaidh[1], K. Ben Amor[1], N. Mouhli[1], H. Rahali[1], I. Ksibi[1], M. Slouma[2], L. Ben Ammar[2], L. Metoui[2], R. Dhahri[2], I. Gharsallah[2]. [1]*The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia;* [2]*The Military Hospital of Tunis, Rheumatology Departement, Tunis, Tunisia*

Background: Gonarthrosis is the most frequent and common condition of the lower limb, responsible for gonalgia, stiffness, leading sometimes to major functional impotence. The WOMAC with its three domains (pain, stiffness and function) is a valid index for the evaluation of lower limb osteoarthritis [1]. The management of gonarthrosis is multidisciplinary with rehabilitation as the mainstay. Currently, aquatic gymnastics is more and more prescribed in the management of this pathology.
Objectives: The objective of our work was to compare the contribution of aquatic rehabilitation to classical one in patients with gonarthrosis through the WOMAC score.
Methods: This is a prospective, comparative study conducted over a period of 15 months, between September 2016 and December 2017, including 120 patients recruited at the Physical Medicine and Functional Rehabilitation Department of The HMPIT, in whom the diagnosis of gonarthrosis was made according to the ACR criteria. The patients were randomly divided into 2 groups of 60 patients each. The first group, called G1, received a conventional rehabilitation program. The second group, called G2, received aquatic rehabilitation. Two evaluations were made, the first (T1) before the beginning of the rehabilitation and the second (T2) at the end of the eight weeks of treatment.
Results: The average age of the general population was 54.85 ± 9.5 years [40- 81 years]. The average age of G1 was 59.07 ± 10.2 years versus 50.63 ± 6.4 years for G2. Among the 120 patients, 28 were male (23%) and 92 were female(77%) There were 6 males and 54 females in group 1 versus 22 males and 38 females in group 2. Initially, the average WOMAC pain was 15.1 ± 3.9 in G1 and 12.3 ± 1.22 in G2. There was a statistically significant difference between the 2 groups ($p=0.01$). After rehabilitation, there was an improvement in the WOMAC pain score of 17% in G1 and 50% in G2 with a statistically significant difference between the 2 groups ($p<0.001$). The average WOMAC score for stiffness was initially 5.1 ± 2 in G1 and 3.2 ± 2 in G2 with no statistically significant difference between the 2 groups ($p=0.076$). After rehabilitation, an improvement of this score was noted in both groups, it was 19% in G1 and 50% in G2 with a statistically significant difference between the 2 groups ($p<0.001$). The average initial WOMAC function score was 42.32 ±15.7 in G1 and 33 ± 11 in G2 with a statistically significant difference between the 2 groups ($p=0.002$). After conventional rehabilitation, this score had improved by 10% and after hydrotherapy, the improvement was 46% with a statistically significant difference between the 2 groups ($p<0.001$).
Conclusion: These results were aligned with the literature and confirmed the effectiveness of functional treatment whether aquatic or classic with better outcome for aquatic rehabilitation. The best would be to combine the different methods according to the needs of the patient and their functional capacities in order to ensure a better adherence.

AB1003 EFFECTIVENESS OF CLASSIC VERSUS AQUATIC REHABILITATION IN GONARTHROSIS: LEQUESNE SCORE

R. Maaoui[1], K. Ben Amor[1], M. Hfaidh[1], N. Mouhli[1], H. Rahali[1], I. Ksibi[1], M. Slouma[2], L. Ben Ammar[2], L. Metoui[2], R. Dhahri[2], I. Gharsallah[2]. [1]*The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia;* [2]*The Military Hospital of Tunis, Rheumatology Departement, Tunis, Tunisia*

Background: Gonarthrosis is a benign knee condition, but it can become disabling if poorly managed. The evaluation of the functional impact of gonarthrosis is based on Lequesne's algofunctional index [1], thus judging the effectiveness or failure of the proposed treatment. Water gymnastics is increasingly prescribed in the management of this pathology.

Objectives: The main aim of our work was to compare the efficacy of aquatic gymnastics with conventional rehabilitation in patients with gonarthrosis using Lequesne's algofunctional index.
Methods: This is a prospective, comparative study conducted over a period of 15 months, between September 2016 december 2017, including 120 patients recruited at the outpatient clinic of the Physical Medicine and Functional Rehabilitation Department of The HMPIT, in whom the diagnosis of gonarthrosis was made according to the ACR criteria. The patients were randomly divided into 2 groups of 60 patients each. The first group, called G1, received a conventional rehabilitation program. The second group, called G2, received water gymnastics. Two evaluations were made, the first (T1) before the beginning of the rehabilitation and the second (T2) at the end of the eight weeks of treatment.
Results: The mean age of the general population was 54.85 ± 9.501 years [40-81 years]. The mean age of G1 was 59.07 ± 10.275 years versus 50.63 ± 6.425 years for G2. Thus, there was a female predominance with a sex ratio M/F of 0.11 in G1 and 0.57 in G2. Lequesne's algofunctional index was initially 11.46 ± 3.2 in G1 patients and 8.7 ± 1 in G2 patients with a statistically significant difference between the 2 groups (p<0.001). The discomfort according to the Lequesne algofunctional index was very important and unbearable in 69% of the cases in G1 against 41% of the cases in G2. The Lequesne index was ≥ 10 in 46 patients in G1 (i.e. 77%) versus 32 patients in G2 (i.e. 53%). After conventional rehabilitation, there was a 10% improvement in this index compared with a 28% improvement after water gymnastics with a statistically significant difference between the 2 groups (p<0.001).
Conclusion: The effectiveness of functional treatment whether aquatic or classic was well demonstrated by Lequesne's algofunctional index, with better result for aquatic rehabilitation. The best would be to combine the two according to the initial functional capacities of the patient to ensure his adherence to the rehabilitation program.

AB1004 CONTRIBUTION OF DRY REHABILITATION VERSUS BALNEOTHERAPY IN THE CONTROL OF PAIN TRIGGERS IN GONARTHROSIS

R. Maaoui[1], M. Hfaidh[1], G. Wechteti[1], N. Mouhli[1], H. Rahali[1], I. Ksibi[1], M. Slouma[2], L. Ben Ammar[2], L. Metoui[2], R. Dhahri[2], I. Gharsallah[2]. *[1]The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia; [2]The Military Hospital of Tunis, Rheumatology Departement, Tunis, Tunisia*

Background: Gonarthrosis is a very common condition and a real public health problem [1]. One of the pillars of its management is pain management. In addition to drug treatment, rehabilitation is part of the therapeutic arsenal.
Objectives: The main objective of our work was to compare the contribution of balneotherapy versus dry rehabilitation in the control of pain triggers.
Methods: We carried out a prospective, comparative study carried out over a period of 15 months, (September 2016- December 2017), in 120 patients recruited from the outpatient department of the Physical Medicine and Functional Rehabilitation Department of HMPIT in whom the diagnosis of knee osteoarthritis (KOA) was made according to the criteria of the ACR [2]. The patients were randomly divided into 2 groups of 60 patients each. The first group, called G1, received a standard rehabilitation program. The second group, called G2, received water gymnastics. Two evaluations were made, the first (T1) before the beginning of the rehabilitation and the second (T2) at the end of the eight weeks of treatment.
Results: The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of KOA was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). Pain was triggered by standing in 92% of cases in G1 versus 98% in G2 with a mean delay of 17.2 min for G1 and 20.1 min for G2. There was no statistically significant difference between the two groups (p=0.452). After rehabilitation, 22% of the patients in G1 and 43% in G2 noted an improvement in pain with a statistically significant difference between the 2 groups (p=0.001).Prolonged sitting in 62% of cases in G1 versus 38% in G2 with a mean delay of 6.2 min for G1 and 52.3 min for G2 awakened pain. There was a statistically significant difference between the two groups (p=0.02). After rehabilitation, 23% of the patients in G1 and 30% in G2 noted an improvement in pain with a statistically significant difference between the 2 groups (p=0.001). Pain was awakened by squatting in 93% of cases in G1 versus 97% of G2. There was no statistically significant difference between the 2 groups (p=0.554). After rehabilitation, 13% of the patients in G1 and 30% in G2 had noted a complete disappearance of pain with a statistically significant difference between the 2 groups (p=0.001). All patients in G1 and 92% of patients in G2 reported pain when climbing/descending stairs. There was no statistically significant difference between the 2 groups. An improvement in symptomatology was noted in both groups with disappearance of pain in 18% of G1 and 27% of G2. An adjustment on the parameters by which the 2 groups differed was made without impact on the results obtained.
Conclusion: Rehabilitation has an important role in the control of pain triggers by ensuring, in addition to analgesic means, good muscle balance, joint gain and good proprioception. Balneotherapy has proven to be more effective.

AB1005 EFFICACY AND SAFETY OF GARCINIA KOLA (CLUSIACEAE) IN KNEE OSTEOARTHRITIS: A PILOT STUDY

F. Kemta Lekpa[1,2], A. Happi Monthe[2], H. Namme Luma[2], S. P. Choukem[1], M. Ngandeu-Singwe[3]. *[1]University of Dschang, Faculty of Medecine and Pharmaceutical Sciences, Dschang, Cameroon; [2]Douala General Hospital, Internal Medicine, Douala, Cameroon; [3]University of Yaoundé I, Faculty of Medecine and Biomedical Sciences, Yaoundé, Cameroon*

Background: Administration of supplements to strengthen the joint cartilage matrix have become popular not only for pain relief but also for joint preservation. Reports have suggested anti-inflammatory and analgesic properties of *Garcinia kola* (GK) extracts in knee osteoarthritis (KOA)[1,2].
Objectives: To evaluate the non-inferiority of GK compared to Diclofenac in patients with KOA.
Methods: Randomized, double-blind, controlled trial (1:1) in outpatients aged 18 to 70 years followed at the Douala General Hospital, Cameroon for KOA with Kellgren-Lawrence grade ≥ 2. Patients with pain on the visual analog scale (VAS) > 5 and who had not taken non-steroidal anti-inflammatory drugs or corticosteroids in the previous 15 days were included. Paracetamol, tramadol, and codeine were accepted as analgesics. The trial was approved by the institutional ethics committee. Patients were divided into 2 groups: Garcinia kola (400 mg/12hours *per os*) and Diclofenac (50 mg/8hours *per os*). The primary endpoint was the per-protocol change in ultrasensitive CRP (CRP_{us}) measured at D0 and D15. Secondary endpoints were the decrease in VAS pain with clinical relevance if decrease ≥ 20%, and safety. Statistical significance was set at p<0.05.
Results: Forty-seven patients (33 women) were randomized (GK, n = 24 and Diclofenac, n = 23). There were no differences ($p > 0.05$) in sociodemographic, clinical, and radiographic characteristics between the two groups [Table 2]. Between D0 and D15, there was no difference in CRP_{us} variation between patients in the GK and Diclofenac groups ($p > 0.05$) [Table 2]. The same was true for pain VAS ($p > 0.05$), with an effect considered clinically relevant. Adverse events were mild to moderate in severity, including 2 cases of epigastralgia (Diclofenac) and 3 cases of increased libido (GK). No significant changes in seric level of liver transaminases, creatinine, and fasting blood sugar were observed.

Table 1. Main baseline patient characteristics

Variables	*Garcinia kola*, n = 24	Diclofenac, n = 23
Age, years	57 ± 12	58 ± 11
Female gender, n (%)	19 (79.1)	17 (73.9)
BMI, Kg/m2	27 ± 10	27 ± 12
Duration of osteoarthritis, years	4 ± 2	4 ± 1
Kellgren-Lawrence ≥ 2, n (%)	20 (83.3)	20 (86.9)
VAS pain, mm, mean	72 ± 17	70 ± 15
CRPus, mg/L	4.8 ± 0.7	4.2 ± 0.5

Table 2. Assessment of the evaluation criteria: CRP_{us} and VAS pain

	Garcinia kola (G.K)	Diclofenac
CRP_{us}*		
Day 0	4.8	4.2
Day 15	3.1	2.6
Variation, n (%)	-1.7 (35,4)	-1.6 (38,1)
p-Value	$p = 0.003$	$p < 0.001$
VAS pain**		
Day 0	72	70
Day 15	54	53
Variation, n (%)	-1.8 (25.0)	-1.7 (24.3)
p-Value	$p < 0.001$	$p < 0.001$

*GK *vs*. Diclofenac: $p > 0.05$; **GK *vs*. Diclofenac: $p > 0.05$

Conclusion: *Garcinia kola* (GK) was non-inferior to Diclofenac in reducing CRP_{us} and VAS pain in patients with KOA. The safety was good. GK would be a promising alternative to explore in the future management of osteoarthritis.

AB1006 IMPACT OF OSTEOARTHRITIS ON THE QUALITY OF LIFE IN PATIENTS WITH KNEE PAIN

A. Chaidou[1], K. Veliou[1], M. Gianniki[1], M. Migkos[1], F. Priftis[1], D. Giotis[2], N. Tsifetaki[1]. [1]*General Hospital of Ioannina, Rheumatology Department, Ioannina, Greece;* [2]*General Hospital of Ioannina, Orthopaedic Department, Ioannina, Greece*

Background: Knee osteoarthritis is a common disease which mainly concerns aged population and impairs the quality of life in all aspects. Apart from causing pain or other related biomechanical comorbidities, osteoarthritis might affect phychological and social aspects of life.

Objectives: The purpose of the study was to investigate the impact of knee osteoarthritis on the quality of life and whether certain factors are related to this impact.

Methods: In a cross-sectional study, performed in our Hospital from January 2016 to December 2016, 150 patients (127 females and 23 males) with a mean age of 61.8 ± 8.07 years were examined. The sample included outpatients of the Rheumatology Department diagnosed with osteoarthritis and patients displaying knee pain. Individuals who had undergone previous knee surgery, and those with other osteometabolic, rheumatic diseases or chronic degenerative disorders that could interfere with the quality of life, were excluded from the study. All participants, who gave their informed consent, answered the identification questionnaire and were interviewed with the Western Ontario and McMaster Universities Arthritis Index (WOMAC), The World Health Organization Quality of life (WHO QoL) questionnaire, the IPQ and the PHQ-9. All instruments used, were standardized in the Greek context.

Results: The effect of certain variables including patient associated characteristics, demographics, medical history, drug intake and symptomatology related to osteoarthritis, were evaluated with each of the WHO QoL measurements, the IPQ total score and the WOMAC scale. The regression analysis results demonstrated common significant correlations regarding the presence of injuries, the depression, the increased body mass index (BMI) and occasional crepitus. However, no significant difference was observed between patients with osteoarthritis and patients without osteoarthritis, concerning any of the examined parameters.

Conclusion: It was demonstrated that quality of life indices were related to agents that are not exclusively met in patients with osteoarthritis which implies that patients` quality of life does not depend on the specific diagnosis but on patient`s psychological aspect (depression), presence of pain (injury) and overall health status (BMI).

Osteoporosis

AB1007 CLINICAL SIGNIFICANCE OF SERUM CREATININE-TO-CYSTATIN C RATIO AS A SURROGATE MARKER FOR INCIDENT OSTEOPOROTIC FRACTURE

I. Yoshii[1], N. Sawada[2], T. Chijiwa[3]. [1]*Yoshii Hospital, Musculoskeletal Medicine, Shimanto-City, Japan;* [2]*Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan;* [3]*Kochi Memorial Hospital, Rheumatology, Kochi, Japan*

Background: In a previous article, we introduced a novel index of osteoporosis that represented as T-score ≤ -2.5, which constituted the combined criteria of age, serum creatinine-to-cystatin C ratio (Cr/CysC), and tartrate-resistant acid phosphatase-5b.

Objectives: We hypothesized that serum cystine C to creatine ratio (CysC/Cr), that is the reciprocal of Cr/CysC, might function as a predictive marker of incident osteoporotic fractures in elderly population and tested this hypothesis in a retrospective cohort study.

Methods: Subjects were 50 years of age or older who had their lumbar spine and femoral neck bone mineral density (BMD) measured by dual-energy X-ray absorptiometry, and simultaneously had their CysC/Cr measured. The dates of BMD and CysC/Cr measurements were set as baseline. The primary outcomes were incidental major osteoporotic fractures (MOF), including vertebral fractures, proximal femur fractures, proximal humerus fractures, and distal radius fractures. Follow-up was continued until the first fracture occurred, was terminated at death, was lost to follow-up, or was completed. In these patients, the relationship between baseline developmental MOF and variants was investigated using Cox regression analysis. The variants were candidate risk factors for MOF for positivity and negativity. After identifying risk factors using univariate models, multivariate model was undergone in order to relative higher risk in the factors. Receivers operating characteristic analyses (ROC) were conducted in order to determine cut-off index (COI) of these factors. Kaplan-Meier survival analysis was tested in order to determine hazard ratio for presenting these risk factors.

Results: A total of 175 patients, 38 men and 137 women, were included in the dataset. The mean age at baseline was 70.2 years, ranged from 50 to 98 years, and the mean follow-up was 30.4 months. Mean BMD at baseline was 0.734 and 0.659 g/cm^2 (T-score: -2.21 and -2.04) in lumbar spine and femoral neck, respectively, and mean CysC/Cr at baseline was 1.49. fall-ability, LSD, and pr-MOF, were present in, 59, 113, and 77, respectively. Administration of OPD, vitamin-D, GCS, and polypharmacy were present in 92, 170, 12, and 47, respectively (Table 1).

Table 1. Results of receiver operation characteristics and Kaplan-Meier survival analysis for each factor

Factor	cut-off index	area under the curve	p-value	Hazard ratio (95%CI)	p-value
CysC/Cr	> 1.345	0.614	< 0.01	6.32 (2.87 – 13.92)	< 0.01
LSD	present	0.626	< 0.01	3.60 (1.67 – 7.73)	< 0.05
Fall-ability	present	0.703	< 0.001	4.83 (2.16 – 10.21)	< 0.001
CKD	present	0.612	< 0.05	2.56 (1.06 – 6.20)	< 0.05
pr-MOF	present	0.685	< 0.001	4.81 (2.08 – 9.39)	< 0.001

In Cox regression analysis, the presence of prevalent MOF (pr-MOF), fall-ability, lifestyle-related diseases (LSD), chronic kidney diseases (CKD) ≥ Grade3a, and higher CysC/Cr had significant higher risk ratios with univariate models. In these, the presence of LSD and fall-ability had significant higher risk ratios with multivariate model. All the binary factors had COI as the presence of each event such with 0.626, 0.703, 0.612, and 0.685 of area under the curve for LSD, Fall-ability, CKD, and pr-MOF, respectively. CysC/Cr also had COI (1.345) with 0.614 of the area under the curve. In the Kaplan-Meier survival analysis, CysC/Cr > COI, Fall-ability, pr-MOF, LSD, CKD ≥ Grade 3 b was significantly higher in descending order of Hazard ratio (6.32, 4.83, 4.81, 3.60, 2.56, respectively) (Table 1).

Conclusion: These results suggest that CysC/Cr may be a predictor of MOF or a risk factor if it exceeds the COI. This value is the reciprocal of Cr/CysC, and if Cr/CysC reflects muscle mass, CysC/Cr is assumed to reflect low relative muscle mass. It is supposed that this is also affected by sex difference and age. There seems to be a correlation between MOF and CysC/Cr. Early measurement of CysC/Cr facilitates screening for fractures. As a result, it may be easier to implement fracture prevention programs such as drug interventions such as OPD and exercise habit guidance.

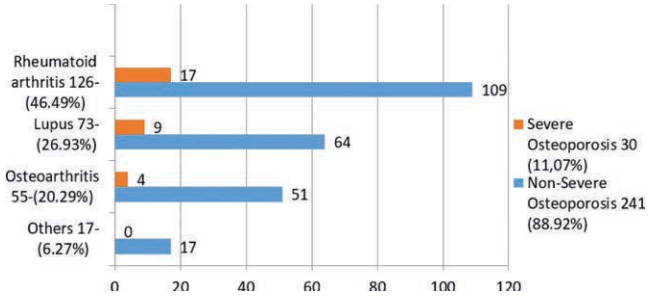
AB1008

CHARACTERIZATION OF THE RISK OF OSTEOPOROSIS IN A COHORT OF RHEUMATIC PATIENTS DURING 10 YEARS OF FOLLOW-UP.

L. Dulcey[1], J. Theran[2], D. Villamizar[3], E. Espinoza[2], R. Caltagirone[1], H. Gonzalez[4], J. Lopez[4], A. Quintero[5], R. Parales[2], M. Aguas[6]. *[1]Los Andes University, Internal Medicine, Bucaramanga, Colombia; [2]Bucaramanga University, Medicine, Bucaramanga, Colombia; [3]Industrial University of Bucaramanga, Medicine, Bucaramanga, Colombia; [4]Santander University, Medicine, Bucaramanga, Colombia; [5]Metropolitan University, Medicine, Bucaramanga, Colombia; [4]Santander University, Medicine, Bucaramanga, Colombia*

Background: Osteoporosis is the most common cause of fractures. The lifetime risk of fracture after age 50 is 40% for women and 13% for men.
Objectives: Patients with rheumatological diseases are at greater risk for the development of osteoporosis, either due to the natural history of their disease or due to the side effects of the medications used. We proposed to carry out this study.
Methods: Retrospective study aimed at determining the presence of risk factors in patients over 50 years of age who attend the Rheumatology service of a hospital in Venezuela during a follow-up from January 2010 to December 2020 in order to know these risk factors and thus generate strategies that allow better orienting the care of these patients.
Results: The main group of patients was constituted by the female gender and the ages between 50 and 65 years. The main rheumatological pathology was rheumatoid arthritis, followed by Lupus, Osteoarthritis in 3 place and finally in the last box other entities other than those indicated.



Graph 1. Prevalence of Osteoporosis due to rheumatological pathologies.

Conclusion: The 2 main risk factors for the development of osteoporosis were the use of steroids and obesity. The main type of osteoporosis of the 2 categories described was non-severe. The main group of rheumatological patients most associated with osteoporosis were those with rheumatoid arthritis. 12% of the patients with rheumatic disease and osteoporosis did not have appropriate therapy.

AB1009

EXERCISE IS ASSOCIATED WITH HIGHER BONE MINERAL DENSITY IN PATIENTS WITH POLYMYALGIA RHEUMATICA AND VASCULITIDES

A. Palmowski[1], E. Wiebe[1], S. Hermann[1], B. Muche[1], F. Buttgereit[1]. *[1]Charité - Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Exercise is an effective non-pharmaceutical intervention for osteoporosis (OP). However, it has not yet been explicitly validated whether it is associated with bone mineral density (BMD) in patients suffering from polymyalgia rheumatica (PMR) and vasculitides.

Objectives: To assess whether exercise is associated with BMD in PMR and vasculitis patients.
Methods: We evaluated baseline visits of patients enrolled in the monocentric, prospective "Rh-GIOP" cohort. Patients were included when having PMR or any kind of vasculitis. Simple and multiple linear regression models with minimum T-score (lumbar spine or hip, whichever was lowest) as the dependant variable were constructed. A dose-response analysis (frequency of exercise per week) was conducted in patients who were doing any kind of exercise. In multiple regression, we adjusted for potential confounders associated with minimum T-scores in an analysis of the overall cohort (*manuscript in preparation*): age, sex, menopause, body mass index, bisphosphonate use, denosumab use, current glucocorticoid dose, proton-pump inhibitor use, history of vertebral fractures, health assessment questionnaire scores, alkaline phosphatase levels, and gamma-glutamyltransferase levels. Multiple imputation by chained equations was used to handle missing data.
Results: 198 patients were included. The mean age was 68 ± 11 years, 68% were females, and the most common diseases were PMR (36%), giant cell arteritis (26%), and granulomatosis with polyangiitis (17%). The mean minimum T-score was -1.74 ± 0.9. Five patients had a disease duration of less than three months. In both unadjusted (Figure 1) and adjusted analysis, exercise was positively associated with minimum T-scores (unadjusted: $\beta = 0.36$; 97.5% CI 0.09 to 0.63; $p = 0.01$; adjusted: $\beta = 0.30$; 0.04 to 0.56; $p = 0.02$). In exercising patients, there was no association between frequency and minimum T-scores (p(ANOVA) = 0.66.
Conclusion: In PMR and vasculitis, exercise is positively associated with BMD. We adjusted for several covariates, including health assessment questionnaire scores, so it is unlikely that the association between exercise and BMD is only caused because generally healthier patients have a higher likelihood of exercising. However, we found no dose-response relationship by looking at exercise frequency. This is probably due to confounding caused by different kinds of exercises. E.g., weight-bearing exercise is thought to be more effective in elevating BMD. Furthermore, our analysis might have been underpowered (too few patients) to assess differences within the group of exercising patients. Our findings underpin the general advice given to most patients suffering from low bone mass or OP irrespective of their underlying disease, which is to start or to continue exercising within the scope of personal possibilities. Of note, this study is of cross-sectional nature and must be interpreted accordingly as residual confounding cannot be fully ruled out. We plan for the future longitudinal analyses.

AB1010 FACTORS ASSOCIATED WITH LONGITUDINAL BONE MINERAL DENSITY CHANGES IN RHEUMATOID ARTHRITIS

R. Ark[1,2], M. Bukhari[1,2]. *[1]Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom; [2]Lancaster University, School of Medicine, Bailrigg, United Kingdom*

Background: Rheumatoid Arthritis (RA) is a long-term inflammatory disorder affecting the joints. It is associated with osteoporosis, possibly linked to inflammation around affected joints and glucocorticoid medication. To our knowledge, longitudinal analysis of a UK based cohort of patients with RA has not been carried out. The impact of average tissue thickness on bone mineral density (BMD) has not been studied longitudinally in RA.

Objectives: This study aimed to identify factors that affect the rate of BMD change in patients with RA in a UK based cohort.

Methods: RA patients referred for multiple routine DEXA scans at the Royal Lancaster Infirmary from 2004-2019 were studied. Demographic and physical data such as age, sex, weight and height were collected. BMD in grams/centimetre2 and average tissue thickness were collected from DEXA images of the left and right hip (femoral neck and total femur), and the spine (L1-L4). BMD was modelled at the regions of the hip and spine using mixed-effects linear models. Age, sex, average tissue thickness and weight were used as explanatory variables.

Results: 1135 scans from 496 patients (80.4% female) with more than one scan were included, mean age was 64.1 (standard deviation 12.5). Fixed effect size and confidence intervals for each variable are shown in the Table 1. Female sex had a negative fixed effect at the hip but no significant effect on BMD change at the spine. Average tissue thickness had a significant positive fixed effect at all regions of the left and right hip, but no significant effect at the spine. Weight showed a significant positive fixed effect with BMD at the hip but no significant effect at the spine.

Conclusion: This study demonstrates that in RA patients, sex is associated with an increased rate of BMD loss at the hip but not at the spine. It also shows that weight and average tissue thickness are associated with lower BMD loss over time. This could be due to increased inflammation at the hip compared to the spine leading to osteoporosis. This study supports longitudinal data from other countries suggesting that factors associated with the rate of BMD change are different at the hip and the spine in RA (1). Average tissue thickness is associated with a reduced rate of BMD loss at the hip in RA patients, which is a novel finding. Average tissue thickness could be used in conjunction with other risk factors to help identify RA patients at risk of osteoporosis. This study may have been underpowered to detect changes at the spine. There may have been selection bias not all patients were routinely referred for repeat DEXA scans.

AB1011 FACTORS RELATED TO GLUCOCORTICOID-INDUCED OSTEOPOROSIS AND FRAGILITY FRACTURES IN YOUNG SUBJECTS.

H. Florez[1], J. L. Carrasco[2], M. Barberá[3], J. Hernández-Rodríguez[4], A. Muxi[5], S. Prieto-González[4], M. C. Cid[4], A. Monegal[1], N. Guañabens[1], P. Peris[1]. *[1]Hospital Clinic, University of Barcelona, Metabolic Bone Diseases Unit. Department of Rheumatology, Barcelona, Spain; [2]University of Barcelona, Biostatistics, Department of Basic Clinical Practice, Barcelona, Spain; [3]University of Barcelona,., Barcelona, Spain; [4]Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vasculitis Research Unit, Department of Autoimmune Diseases, Barcelona, Spain; [5]Hospital Clinic, University of Barcelona, Department of Nuclear Medicine, Barcelona, Spain*

Background: Glucocorticoid (GC) treatment is the most frequent cause of osteoporosis (OP) in young subjects. However, the factors related to the development of glucocorticoid-induced osteoporosis (GIOP) and fragility fractures (FF), and consequently, the therapeutic approach to GIOP in young populations is not well established.

Objectives: Analyze the prevalence of GIOP and FF in GC-treated patients and compare the risk factors related to their development according to age (< and ≥50 years).

Methods: 127 patients (62±18 years) receiving chronic GC treatment were included (≥5 mg/day of prednisone, >3 months). The clinical data collected included: dose and duration of GC treatment, disease activity, previous FF, anthropometric data, bone metabolism parameters (including bone turnover markers and the presence of hypogonadism), bone mineral density (by DXA; defining densitometric OP: T-score ≤-2.5 or Z-score ≤-2, depending on the age of the patient), trabecular bone score (by DXA), and vertebral fractures (X-ray). GIOP was defined as densitometric OP and/or FF. Results were compared between subjects < and ≥50 years old.

Results: The prevalence of GIOP was similar in both age groups: <50 (n=36) 44.4% vs. 46.1% ≥50 years (n=91). Five subjects <50 (13.8%) and 30 ≥50 years (33%) presented FF (p=0.05). Young subjects with FF tended to be >40 years, have a higher body mass index (BMI) (25.4 *vs.* 23.3, p=n.s.), and inflammatory disease activity (CRP 0.90 *vs.* 0.06mg/dL, p=0.06). When analyzing the differential risk factors related to FF depending on age, a higher body mass index (BMI) (29.63 *vs.* 26.95, p=0.048) and inflammatory disease activity (PCR -0.87 *vs.* -2.51 [log scale], p=0.03) were observed in young subjects, while low lumbar T-scores (-1.08 *vs.*-0.06 DE, p=0.003) and higher cumulative GC-doses (9.11 *vs.* 8.56 g, p=0.03) were differential factors in subjects over 50. Hypogonadism was a risk factor independent of age (OR 4.89; 95%CI 1.36-17.59), being associated with the presence of FF in both age groups.

Conclusion: More than 40% of the patients receiving GC developed GIOP, with a similar prevalence in both age groups (< and ≥50 years); however, FF are less common in young subjects. Hypogonadism is a determining risk factor for FF independent of age. In addition, young subjects with FF tend to be older, with a higher BMI and disease activity, and, thus, evaluation of these risk factors can improve the identification of subjects at increased risk of fracture.

AB1012 MANAGEMENT OF BREAST CANCER TREATMENT INDUCED BONE LOSS- RE-AUDIT

G. Ansari[1], A. Nandagudi[2], S. Pattapola[2]. *[1]Southend University Hospital Mid and South Essex NHS Foundation Trust, Rheumatology, Southend, United Kingdom; [2]Basildon University Hospital Mid and South Essex NHS Foundation Trust, Rheumatology, Basildon, United Kingdom*

Background: Breast cancer treatment therapies (aromatase inhibitors (AI)) are associated with early menopause and adverse effect on bone density. Identifying high-risk patients and managing them appropriately will help reduce their fracture risk.

Table 1

	Effect size estimate (95% confidence interval)		
Location	Sex	Weight	Average Tissue Thickness
Left femur	-0.104(-0.135,-0.074)*	0.004(0.004,0.005)*	0.022(0.018,0.025)*

L4	0.01(-0.035,0.054)	0(-0.001,0.001)	0.001(-0.003,0.005)

Objectives: We wanted to ascertain whether our management of breast cancer patients on aromatase inhibitors (AI) referred to osteoporosis clinic were as per guidelines. A consensus position statement from a UK expert group regarding breast cancer treatment induced bone loss, published with the support of the National Osteoporosis Society, the National Cancer Research Institute, Breast Cancer Study Group and the International Foundation.
The guideline recommend lifestyle advice for low risk patients; calcium plus vitamin D supplementation and lifestyle advice for medium risk; bisphosphonate, calcium plus vitamin D supplementation and lifestyle advice for high risk.
Methods: This is a re-audit cycle conducted for all patients referred to the osteoporosis clinic who were treated with aromatase inhibitors for breast cancer between 2016-2020. Patients were divided into two algorithms: Algorithm 1: women who had experienced premature menopause associated with ovarian suppression with or without AI. Algorithm 2: Postmenopausal women receiving treatment with an AI. T-scores were used to stratify patients in algorithm 1 into high risk (HR- T score <-2), medium risk (MR-T score -1 to -2) and low risk (LR- T score >-1). Algorithm 2 into high risk (HR-T score <-1) medium risk (MR -T score >-1).
Results:

Table 1. Showing the results of Audit 1 and Re-audit

	Audit 1		Re-audit	
Total Patients	54		72	
Data collected	2014-2016		2016-2020	
Gender	Female 100 (%)		Female 100 (%)	
Age in years	45-96		38-92	
Median age	77		68	
No of Osteoporotic patients	31		41	
No of Osteopenic patients	23		31	
Algorithm 1:	Total patients= 23	• 18 HR • 5MR • LR nil	Total patients = 20	• 19HR • 1 MR
Algorithm 2:	Total patients =31	• 31 HR • MR-nil • LR nil	Total patients =52	• 45HR • 5MR • 2LR
Drug therapy	45		63	
Bisphosphonates	21		49	
Denosumab	23		14	
Teriparatide	1		0	
Declined treatment	0		1	
Lifestyle/Vit D & Cal	9		6	
Lifestyle advice only	0		2	

Conclusion: Re-audit showed all patients were on AI and treated appropriately. As compare to audit 1, all high risk group patients were treated with drug therapy and bisphosphonate was the first line therapy as per guidelines. It was recommended that patients with risk of osteoporosis should be referred and treated according to their risk stratification. It is a collective responsibility of Breast surgeons, Geriatrician, Frailty team, Oncologist, Rheumatology and General Practitioners).All patients should have repeat bone density scan in 2 years' time after initial bisphosphonate therapy. The next audit cycle will be conducted in five years' time.

AB1013 SCHOOL FOR DOCTORS ON THE PROBLEM OF OSTEOPOROSIS - "START WITH YOURSELF".

Y. Polyakova[1], L. Seewordova[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation*

Background: Observing in practice the attitude of the medical community to the problem of OP, we decided to conduct a course of training lectures for doctors within the framework of the program "Start with yourself" on the basics of diagnosis and treatment of this disease. After the lecture material, the fracture risk was calculated using the FRAX (Fracture Risk Assessment Tool) in the audience before and after the two-energy X-ray absorptiometry (DXA). If necessary, additional examination and treatment were prescribed.
Objectives: To evaluate the frequency of decrease in bone mineral density in doctors, to raise awareness about the frequency of decrease in bone mineral density (BMD), to assess the attitude to therapy.
Methods: The risk of fractures according to FRAX was calculated for doctors of therapeutic specialties, DXA was performed at the Center for Osteoporosis of the A. B. Zborovsky Research Institute of KIER, Volgograd. Bone mineral density (BMD) was determined on the Lunar DPX (GE) apparatus.
Results: The average age of 59 trainees was 54 ± 10.55 (M±σ) years, 36 women were aged 50 years and older, 23 were under the age of 50, the average body mass index –BMI) was 26.51 ± 4.8 kg/m2. 47 (79.6%) of 59 showed a decrease in bone mineral density (BMD) below the norm (according to the T/Z criterion, according to age) in at least two positions. 15 (25.4%) of them showed a decrease in BMD according to the T criterion by -2.5 SD or lower, which corresponds to the diagnosis of "Osteoporosis". Of these 15 people, 9 had previously undergone DXA, were diagnosed with OP, and drug therapy was prescribed. Only 3 students are constantly taking medications. Another 6 people were previously treated, but for the last 2-3 years they have not been examined and have not taken anything. OP was detected for the first time in 6 listeners, for 2 listeners the diagnosis of OP was a complete surprise, 4 guessed about a possible decrease in BMD, but did not expect to detect such low indicators (T criterion -2.5 and -2.6 SD for the lowest values). Out of 5 students under 50 years of age with a decrease in BMD by the Z criterion of less than -2.0 SD, 4 had significant risk factors. No obvious risk factors were identified in 1 listener. The average values of TL1-L4 were -1.26 ± 1.06 SD [0.8 to -3.1], ZL1-L4 = -0.68 ± 0.9 [+1 to -2.7], the average values for TNeck were -1.14 ± 1.04 [1.5 to -2.7], Z Neck -0.26 ± 0.88 [1.9 to -1.7]. An additional result of the educational event was a change in the structure of patients referred to DXA. The proportion of patients with osteoporosis and osteopenia among the surveyed increased from 65% to 88% after a month after the schools.
Conclusion: As a result of the study, a high percentage of detection of a decrease in BMD in female doctors was found. Low compliance to treatment was found in doctors over 50 years of age, a positive attitude to preventive measures in younger doctors. Considering that we have just started the educational program, the first students sought to get examined for personal reasons, which probably overestimates the detectability of reduced BMD. At the same time, it should be noted that doctors with an existing history of low-traumatic fractures did not come for examination, citing high employment. It is necessary to further study the problem of the prevalence of BMD reduction among doctors, increase awareness of the problem of OP and the need for early preventive measures to prevent the development of OP. Conducting theoretical and practical classes in small groups based on the assessment of their own survey data makes it possible to increase the interest of practitioners in studying the problem of OP. The greatest interest on the part of listeners is caused by the DXA procedure itself with the decryption of protocols. When creating motivation for doctors' personal interest in maintaining personal bone health, the likelihood of a more attentive attitude of doctors to the prevalence of OP among the population increases.

AB1014 FRACTURES REDUCTION WITH OSTEOPOROTIC TREATMENTS IN PATIENTS OVER 75-YEAR-OLD: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Guillaumin[1], B. Poirson[1], A. Gerazime[2], M. Puyraveau[2], T. Tannou[1], F. Mauny[2], E. Toussirot[3]. [1]*University Hospital, Geriatrics, Besancon, France;* [2]*University Hospital, Biostatistics, Besancon, France;* [3]*INSERM CIC 1431, Rheumatology, Besancon, France*

Background: Osteoporosis consists in the reduction of bone mineral density and increased fracture risk. Age is a risk factor for osteoporosis. Although many treatments are available in osteoporosis, there is limited data regarding their efficacity in older people.
Objectives: We aimed to evaluate the efficacy of osteoporosis treatments in patients over 75 years old.
Methods: we reviewed all published studies in MEDLINE, COCHRANE and EMBASE including patients over 75-year-old treated by osteoporosis drugs and focused on vertebral fractures or hip fractures.
Results: we identified 4393 records for review. 4216 were excluded after title/abstract review. After full text review, 19 records were included in systematic review. Most of the studies showed a reduction of vertebral fracture with osteoporosis treatments but non-significant results were observed for hip fractures. Meta-analysis of 10 studies showed that osteoporosis treatments significantly reduced the occurrence of vertebral fractures at one (OR=3.67; 95%CI=2.50-5.38) and three years (OR=2.19; 95%CI= 1.44-3.34) as well as those of hip fractures at one (OR=2.14; 95%CI=1.09-4.22) and three years (OR=1.31, 95%IC=1.12-1.53).
Conclusion: osteoporotic treatments showed to be effective in the reduction of vertebral and hip fractures in older people. However, majority of data derived from *post hoc* and pre-planned analyses or observational studies.

AB1015

SUSTAINED SYNERGISTIC EFFECT ON BONE MINERAL DENSITY TREND WITH SHORT TERM COMBINATION OF TERIPARATIDE AND DENOSUMAB FOLLOWED BY DENOSUMAB ALONE IN POSTMENOPAUSAL WOMEN - A SINGLE INDIAN CENTRE EXPERIENCE.

A. K. Aggarwal[1], N. Aggarwal[2], H. Sharma[3]. [1]*institute of Rheumatology & Pain, Rheumatology, Ghaziabad, India;* [2]*institute of Rheumatology & Pain, Administration and Research, Ghaziabad, India;* [3]*Institute of Rheumatology & Pain, Pharmacy, Ghaziabad, India*

Background: Use of Teriparatide (PTH) with Denosumab (Dmab) have shown to have a synergistic effect on the bone mineral density (BMD) of both Hip and Spine[1] because Dmab completely inhibits the PTH induced bone resorption and does not interfere with the bone formation.
Objectives: Since PTH has a limited period of approved use, a short term (6 months) use of PTH in combination with Dmab followed by continued use of Dmab may show a sustained synergistic effect of the combination.
Methods: The BMD trends from real time data from a central dual-energy x-ray absorptiometry (DXA) at our centre in India was studied retrospectively to see if the effect was sustained. Women with postmenopausal osteoporosis who were treated with a combination of Dmab 60 mg via subcutaneous injection (sc) at 6 monthly interval along with PTH 20 mcg sc daily for the first 6 months (Combo), followed by Dmab alone for the next six months were inculded in the study group. Average BMD at L2, L3 and L4 (sp BMD), and Right and Left Hip (hip BMD) were studied from before treatment (a BMD), after the Combo treatment (b BMD) and after 6 months of the second injection of Dmab (c BMD). The mean percentage trend change between a-b BMD and b-c BMD were evaluated. Out of the patients treated with the protocol, 25 were randomly chosen for the retrospective analysis. The least significant change (LSC)[2] from a single centre DXA was used to validate the findings.
Results: The percentage change after the treatment for 6 months with the Combo was found to be 5.22% in the Spine (LSC= 2.6%)[2] and 4.13% in the hip (LSC=3.6%)[2]. The trend after use of Dmab alone was 5.39% in the spine and 2.93% in the hip showing sustained synergistic effect of the Combo for at least 6 months with the use of Dmab alone. The effect was more profound in the spine than the hip. A $p>0.05$ was considered statistically significant. Table 1 shows the percentage BMD changes.

Table 1. Percentage BMD changes

BMD trend (n=25)	sp BMD (LSC – 2.6%)	hip BMD (LSC – 3.6%)
a-b BMD	5.22%	4.13%
b-c BMD	5.39%	2.93%

sp BMD - Mean of L2,L3 & L4 Spine BMD, hip BMD - Mean of Right and Left Hip BMD, a-b BMD - Percent change in BMD from before treatment to 6 months of PTH & Dmab, b-c BMD -Percentage change in BMD form after 6 of Dmab & PTH to next 6 mths Dmab alone and LSC – Least significant change from a single DXA machine.

Conclusion: These findings suggest that a short term combination of Dmab and PTH for 6 months followed by Dmab alone shows sustained synergistic effect on the BMD trend which was more profound in the spine than the hip. This would help in judicious and cost effective utilisation of the limited period of PTH use.

AB1016

ROMOSOZUMAB AS A TREATMENT FOR OSTEOPOROSIS: PREDICTORS OF EFFICACY AT 12 MONTHS

Y. Hirano[1], Y. Ono[1]. [1]*Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan*

Background: Romosozumab (ROMO) is an antisclerostin antibody that is used in the treatment of severe osteoporosis (OP). In March 2019, ROMO was approved for use in Japan for treating severe OP in clinical practice, causing an increase in its prescription in our institute. Although efficacy data for ROMO have been presented in clinical trials, there is a lack of real-world data. In our experience, ROMO treatment results in significant bone mineral density (BMD) gain in some patients, but not all. Therefore, understanding the predictors that enhance the efficacy of ROMO treatments to achieve BMD gain is essential.
Objectives: This study investigated the efficacy of a 12-month ROMO treatment in patients with OP and explored the efficacy predictors of increased BMD.
Methods: Our study included 52 patients with OP, who were started on ROMO treatment between June 2019 and August 2020. The following information was collected: 1) baseline characteristics, 2) time-course of BMD (lumbar spine [LS] and total hip [TH]) and bone turnover markers (BTM; bone-specific alkaline phosphatase [BAP], type I procollagen-N-propeptide [P1NP], type I procollagen-N-propeptide[NTX], and tartrate-resistant acid phosphatase-5b [TRACP-5b]), 3) multiple regression analysis results following Spearman's correlation analysis of increased BMD values (%) at 12 months and BL characteristics, including BTM change (%) at one month, to investigate the efficacy predictors of ROMO.
Results: 1) The mean age of the participants was 72.9 years (48 female and four male). Of the 52 understudied patients, 78.8% had past insufficiency fractures, whereas 21.2% had been treated with concomitant prednisolone. Furthermore, 21 patients had primary OP, 20 had rheumatoid arthritis, nine had glucocorticoid-induced OP, and two had other conditions. Pretreatments for OP were bisphosphonate (33 patients), vitamin D (6), none (5), selective estrogen receptor modulator (4), and denosumab (3). 2) Both mean LS- and TH-BMD significantly increased in the patients for whom ROMO administration was continued for 12 months. The average percentage changes of LS- and TH-BMD were 7.1% and 1.6% at six months and 11.7% and 3.0% at 12 months, respectively (Figure 1). However, BAP and P1NP increased steeply at one month, followed by a gradual decrease. As observed, the average percentage changes of BAP and P1NP were +70.1% and +166.8% at one month, +50.3% and +91.7% at six months, and +24.4% and +41.5% at 12 months, respectively. The results also showed that TRACP-5b decreased from one to 12 months, with the average percentage changes being –22.9% at one month, –13.8% at six months, and –17.7% at 12 months. Moreover, NTX, a bone-resorptive marker, was slightly increased during ROMO treatment. 3) Multiple regression analysis results revealed that the baseline BAP and percentage calcium changes at 12 months were significant factors positively correlated with the percentage change of LS-BMD at 12 months. As observed, the baseline T-score of LS-BMD was a significant factor negatively correlated with the percentage change of LS-BMD at 12 months. The standardized partial regression coefficient values were +0.68, +0.26, and –0.40, respectively. Moreover, the multiple regression analysis results revealed no significant factor that was correlated with the percentage changes of TH-BMD at 12 months.

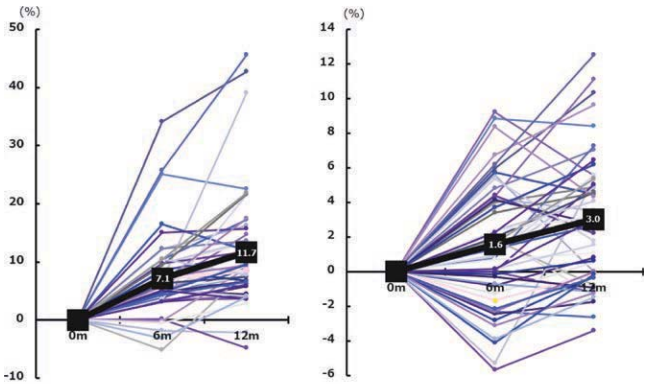

Figure: Time-course of % Change of Bone Mineral Density (Left: lumbar spine, Right: total hip)
Bold lines indicated averaged values. Thin lines indicated individual values of each patient.

Figure 1.

Conclusion: ROMO treatments rapidly increased BMD, especially LS-BMD, and changed BTM after one month. Baseline BAP were correlated with increased LS-BMD but not with TH-BMD. The factors correlated with increased BMD may differ between LS-BMD and TH-BMD.

RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY (REMS) AND DUAL-ENERGY X-RAYS ABSORPTIOMETRY FOR THE EVALUATION OF BONE MINERAL DENSITY IN A PERITONEAL DIALYSIS SETTING

A. Fassio[1], S. Andreola[2], D. Gatti[1], M. Gatti[1], G. Gambaro[2], M. Rossini[1], O. Viapiana[1], G. Zanetti[1], F. Pistillo[1], V. Messina[1], G. Adami[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy;* [2]*University of Verona, Nephrology Unit, Verona, Italy*

Background: Radiofrequency echographic multi-spectrometry (REMS) is a novel ultrasound-based technique that has shown good reliability in the assessment of bone mineral density (BMD).

Objectives: The aim of this study was to compare the performance of the REMS BMD assessment with dual-energy X-rays absorptiometry (DXA) in a cohort of patients affected by end-stage renal disease undergoing peritoneal dialysis (PD).
Methods: Consecutive patients referring to the PD clinic of our hospital were enrolled. Lumbar spine and proximal femur REMS scans were performed, and lumbar spine (anteroposterior and laterolateral) and proximal femur DXA scans were performed as well. Clinical data were extracted from medical records. The risk assessment outputs of two fracture risk algorithms (FRAX and DeFRA), calculated upon the worst BMD obtained from either technique were compared as well. Analysis of variance (ANOVA) with post hoc analysis (Bonferroni) and a two-sided Student's t-test were used to estimate the absolute differences between groups. Written informed consent was obtained from all participants included (protocol 1483 CESC).
Results: 41 total patients were enrolled (Table 1). No significant differences were documented between the BMD T-scores measured through DXA or REMS at the proximal femur. At the lumbar spine, the DXA laterolateral T-score was not significantly different from that of REMS, while the DXA anteroposterior T-score was significantly higher than both the anteroposterior DXA and the REMS measurements (Figure 1, panel A and B). When either DXA or REMS was adopted, no significant difference in the fracture risk estimate was found for both algorithms (Figure 1, panel C and D).

Table 1. anthropometrics, clinical and biochemical characteristics of the enrolled sample. CKD, chronic kidney disease; PTH, parathyroid hormone; ALP, alkaline phosphatase; IQR, interquartile range; VFA, vertebral fracture assessment.

Sample size (M)	41 (29)
Age (y)	
Median [IQR]	62 [52-73]
Height (cm)	
Median [IQR]	170 [165-176]
Body weight (Kg)	
Median [IQR]	74 [61-83]
Body mass index (Kg/m2)	
Median [IQR]	25 [22-27.8]
Disease duration – CKD (months)	
Median [IQR]	132 [48-140]
Dialysis duration (months)	
Median [IQR]	10 [3-24]
S-calcium (mg/dL)	
Median [IQR]	9.1 [8.6-9.4]
S-phosphorous (mg/dL)	
Median [IQR]	5.4 [4.6-6.4]
PTH (pg/mL)	
Median [IQR]	31.4 [22.8-46.8]
25OH Vitamin D (nmol/L)	
Median [IQR]	53 [36-72]
Patients with morphometric fractures (VFA)	15%
Patients with femoral fractures	2.4%
Total n° of morphometric fractures	12

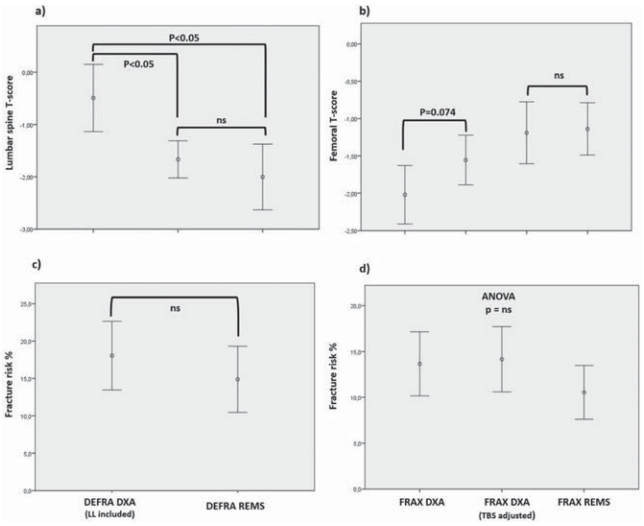

Figure 1. comparison of the mean T-scores (error bars represent 95%CI) measured with DXA and REMS at the lumbar spine (panel A), and at the femur (panel B). Comparison between the DeFRA DXA and REMS-derived outputs (panel C) and FRAX DXA and REMS-derived outputs (panel D) raw and after correction for TBS. DeFRA, FRAX-derived risk assessment tool; FRAX, Fracture Risk Assessment tool; AP, anteroposterior; LL, latero-lateral; TH, total hip; FN, femoral neck; TBS, trabecular bone score.

Conclusion: Our data showed a good agreement, in a real-life PD setting, between the DXA and REMS-derived BMDs and in the consequent fracture risk assessment obtained with the FRAX or DeFRA tools.

AB1018

RELATIONSHIP BETWEEN AORTIC CALCIFICATIONS AND DXA AND RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY (REMS) ACQUISITIONS

A. Fassio[1], S. Andreola[2], D. Gatti[1], M. Gatti[1], G. Gambaro[2], O. Viapiana[1], V. Messina[1], G. Zanetti[1], F. Pistillo[1], M. Rossini[1], G. Adami[1]. *[1]University of Verona, Rheumatology Unit, Verona, Italy; [2]University of Verona, Nephrology Unit, 37134, Italy*

Background: Data on the relationship between peritoneal dialysis (PD), BMD and aortic calcifications (AOC) are lacking.
Objectives: to study the relationship between the degree of AOC and DXA and Radiofrequency Echographic Multi-Spectrometry (REMS) acquisitions.
Methods: Consecutive patients referring to the PD our clinic were enrolled. Lumbar spine (LS) and proximal femur REMS scans were performed, and LS (anteroposterior and laterolateral) and proximal femur DXA scans were performed as well. The degree of AOC was assessed through the semiquantitative score described by Kauppila et al, and applied to the laterolateral LS DXA scans. To test for correlations between different variables, we used the Pearson's correlation for continuous variables and Spearman's rho for discrete variables. Multiple regression analysis was performed to adjust for age and body mass index (BMI) the correlation between BMD and the CKD duration. Written informed consent was obtained from all participants (protocol 1483CESC).
Results: 41 total patients were enrolled (29 males, 19 females). Median disease duration of CKD [IQR]: 132 months [48-140]. 15% had vertebral fractures at the DXA Vertebral Fracture Assessment (VFA). The median calcification score [IQR] was 2 [0-6] (min-max 0-20). We found a statistically significant positive correlation of moderate strength between the total calcification score and the difference between the DXA AP T-score and the DXA LL T-score at the LS (p<0.01, Spearman's rho = 0.402), Figure 1.

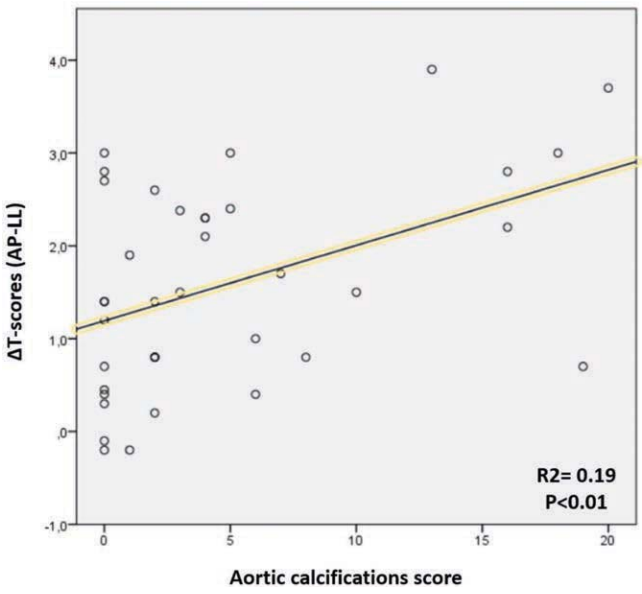

Figure 1. scatter plot reporting the relationship between the difference between the AP and LL T-scores and the aortic calcifications score.

After adjustment for confounders, we found a significant negative between the LS and femoral neck BMD measured through REMS and CKD duration (Table 1). The same correlation was not significant then BMD was assessed with DXA.

Table 1. multiple linear regression analysis for REMS T-score at each site after adjustment for age and BMI. BMI, body mass index; β, standardised coefficient.

REMS lumbar spine T-score		
	β	p
CKD duration (months)	-0.228	0.035
Age (years)	-0.511	<0.01
BMI (kg/m2)	0.566	<0.01
REMS femoral neck T-score		
	β	p
CKD duration (months)	-0.210	0.04
Age (years)	-0.612	<0.01
BMI (kg/m2)	0.484	<0.01
REMS total hip T-score		
	β	p
CKD duration (months)	-0.153	0.219
Age (years)	-0.523	<0.01
BMI (kg/m2)	0.560	<0.01

Conclusion: Our study confirmed that the overestimation of DXA BMD assessed with the anteroposterior scan is indeed influenced by AOC. Furthermore, our data suggest that REMS might be an interesting tool for the investigation of bone changes in CKD.

AB1019 THE EFFECTS OF THREE DIFFERENT VITAMIN D3 SUPPLEMENTATION REGIMENS IN DEFICIENT SUBJECTS ON INFLAMMATORY CYTOKINES – A RANDOMISED OPEN-LABEL PARALLEL GROUPS STUDY

A. Fassio[1], D. Gatti[1], M. Gatti[1], M. Rossini[1], E. Bertoldo[1], G. Adami[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: The effects of cholecalciferol supplementation on the regulation of inflammatory cytokines are still unclear.

Objectives: This is a preliminary analysis on exploratory outcomes the DIBA/11 RCT [1,2] and aimed to compare the effects on serum inflammatory cytokines of three different regimes of cholecalciferol supplementation in vitamin D-deficient subjects.

Methods: We evaluated, in healthy subjects affected by vitamin D deficiency (defined as 25OHD<20 ng/mL), 18 to 60 years of age, the efficacy of three different oral supplementation regimens: daily 10,000Iu administered for 8 weeks (group A), weekly 50,000Iu (group B) for 12 weeks and biweekly 100,000Iu (group C) for 12 weeks. Serum TNFα, interleukin-6 (IL6), interleukin-17 (IL17) and interleukin-10 (IL10) were dosed at baseline, Day 28, 53, 84 and 112. This study was approved by the institutional research committee (protocol identification: DIBA/11,EudraCT Number:2017-000194-36). Supported by Abiogen Pharma, Italy).

Results: A total of 75 subjects were randomized to receive one supplementation regimen. The descriptive of the sample at baseline and relative cytokines levels at the various observation points are reported in Table 1. The absolute changes of IL6, IL17 and IL10 are depicted in Figure 1. No significant differences were found among the three groups. TNFα was undetectable at baseline and at any time point.

Table 1. anthropometrics and laboratory parameters at baseline (mean values ± standard deviation)

Parameter	All patients (N=75)	Daily 10.000 Ui (N = 25)	Weekly 50.000 Ui (n = 25)	Biweekly 100.000 Ui (N = 25)	p-value (ANOVA)
M:F	31:44	12:13	7:18	12:13	NS
Age (years)	34.1 ± 10.2	30.2 ± 9.9	36.7 ± 8.7	35.4 ± 11.0	0.059
Body Weight (kg)	66.7 ± 12.4	65.8 ± 13.2	67.8 ± 10.8	66.6 ± 13.7	NS
BMI	23.1 ± 2.6	22.55 ± 2.7	23.8 ± 2.2	22.8 ± 2.7	NS
Baseline 25OHD (ng/mL)	13.5 ± 3.7	14.6 ± 3.9	12.8 ± 3	13.5 ± 4.1	NS
Baseline IL-6 (pg/mL)	1.3 ± 1.2	0.9 ± 0.6	1.4 ± 1.6	1.6 ± 1.3	NS
Baseline IL-17 (pg/mL)	0.4 ± 1.8	0.7 ± 3	0.2 ± 1.1	0.2 ± 0.7	NS
Baseline IL-10 (pg/mL)	0.9 ± 0.9	0.8 ± 0.7	1.2 ± 1.2	0.8 ± 0.7	NS

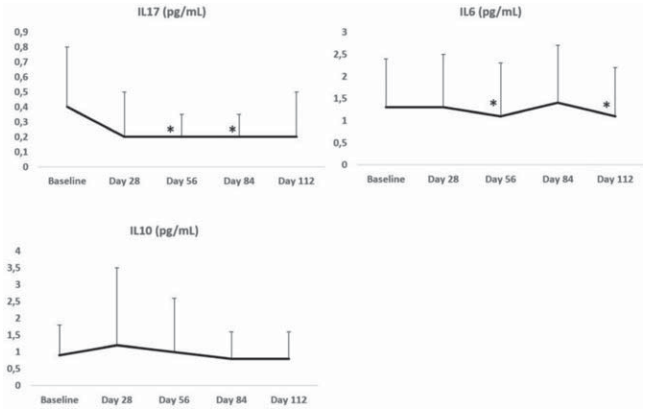

Figure 1. absolute changes of IL17, IL6 and IL10. *p<0.05 vs baseline.

Conclusion: In the overall cohort we found slight decreases in serum IL6 and IL17 serum levels. No differences were found among groups.

AB1020 OSTEOPOROSIS'S PARTICULARITIES IN BREAST CANCER PATIENTS UNDER AROMATASE-INHIBITORS

F. Idrissi Zaki[1], H. Tebaa[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology, Marrakech, Morocco*

Background: Breast cancer is the first female cancer, especially after menopause. In Morocco its prevalence is estimated at 35.8%. Its hormone-dependent aspect requires the use of hormone-modulating treatments, in particular aromatase-inhibitors responsible for hypogonadism, bone loss and osteoporosis (OP) with increased fracture risk.

Objectives: The aim of this study is to determine the epidemiological, clinical and densitometric profile of osteoporotic patients with breast cancer under aromatase-inhibitors and to evaluate the factors associated with bone gain in this population.

Methods: This is a descriptive and analytical retrospective study of 126 osteoporotic patients with breast cancer under aromatase-inhibitors, collected during a period of 4 years (2017 to 2021). Statistical data analysis was performed using SPSS version 20 software. The bivariate study was performed by ANOVA test.

Results: All the patients were treated for breast cancer and received systemic hormone-modulating anti-aromatase type therapy. All the patients had densitometric osteoporosis confirmed by a T score < or equal to –2.5, of which 31.7% had a T-score < or equal to -3.5. The average age was 62.29 (40–92) years. 1.6% had an osteoporosis family history and 0.8% had an osteoporosis's fracture family history, 77% had a personal history of fracture. 54.8% were overweight, 14.3% had a metastasis. 88.1% had insufficient vitamin D levels (<20 ng/L). 15.9% had high blood pressure. The average duration of anti-osteoporotic treatment was 2.31 years. 77% of patients were on Residronate, 8.7% on Zoledronate, and 14.3% on Alandronate. The study of bone gain involved patients who had an evaluation of osteodensitometry whithin 2 years, the average spine bone gain was 0.011 and 0.018 for femur bone gain. In bivariate analysis, they were a statistically significant association between the presence of a T-Score value <-3.5 and spine bone gain (p=0.035), the absence of metastasis with femur bone gain (p<0.0001), the absence of hypertension and femur bone gain (p=0.015), concerning the therapeutic means used there were an association between the use of zoledronic acid and spine bone gain (p =0.021).

Conclusion: Breast cancer patients under aromatase-inhibitors are particularly prone to osteoporosis, hence the interest of paying close attention to this population and intervening on the associated modifiable factors for better management.

AB1021 FACTORS ASSOCIATED WITH FRAGILITY FRACTURE IN PATIENTS WITH SYSTEMIC MASTOCYTOSIS: DATA FROM AN INCEPTION COHORT IN A SINGLE CENTRE

K. Carpio[1], F. Skrabski[2], I. Castrejon[1], A. Prieto Garcia[2], J. M. Alvaro-Gracia[1], T. González[1]. *[1]Hospital General Universitario Gregorio Marañon, Rheumatology Department, Madrid, Spain; [2]Hospital General Universitario Gregorio Marañon, Department of Alergology, Madrid, Spain*

Background: Systemic Mastocytosis (SM) is a very rare disease. Most common manifestations are skin related or anaphylaxis, however almost one third of patients may present with concomitant osteoporosis (OP) resulting in fragility fracture (FF) in around 5 -37% of patients affecting lumbar spine (LS) in young men. Alcohol consumption, high serum tryptase level, and low femoral T score have been described as risk factors but there are some discrepancies between studies. [1-2]

Objectives: Our primary objective was to identify factors associated with FF in patients with SM.

Methods: We analysed all consecutive patients attending a multidisciplinary clinic up to April 2021 with SM diagnosis according to the 2001 WHO criteria. We collected demographic data, general risk factors for OP, cutaneous, bone involvement and laboratory data as serum tryptase level. Bone involvement is defined as densitometric OP (T score ≤ - 2.5) or FF. Normally distributed variables are described as means (SD) and dichotomous variables as number and frequencies. Comparison between patients with and without FF is performed using t-test and Chi^2 when needed.

Results: Seventeen patients with SM are included in this preliminary analysis. Four patients (24%) presented a FF, all of them vertebral fractures identified by plain radiographies.Two men and two women presented FF, they were older versus patients without FF (Table 1), and without general risk factors for OP. All of them have a high basal serum tryptase and most of them presented other MS symptoms (cutaneous, anaphylaxia). FRAX tool was useful in only one patient to predict FF risk. The two men with FF diagnosis do not met criteria for densitometric OP, specific characteristics for these patients are presented in Table 2.

Table 2. Characteristics of Fragility Fracture in four patients with Systemic Mastocytosis.

Patient	Age	Gender	Localization of FF	Severity of Fracture	Time to fracture diagnosis
Patient 1	65	Male	D6,D8,D10,D11, L1	3 Mild 2 Moderate	2 years prior SM diagnosis
Patient 2	81	Female	D4,D8,D12, L1	1 Mild 3 Severe	2 years after SM diagnosis
Patient 3	65	Female	D4,D11	Unknown	2 years prior SM diagnosis
Patient 4	42	Male	D7,D8,D9,D11,D12, L1,L2,L3,L5	3 Mild 3 Moderate 3 Severe	At time of SM diagnosis

Conclusion: Twenty five percent of patients present FF (multiple, located in dorsal spine, and without densitometric diagnosis of OP). SM should always be considered in differential diagnosis in the presence of FF, especially in men with no OP or another risk factor associated.

AB1022 PLACE OF BONE MINERAL DENSITY MEASUREMENT IN THE DIAGNOSIS OF ASYMPTOMATIC VERTEBRAL FRACTURES

M. Brahem[1], O. Jomaa[1], R. Sarraj[1], S. Abdellatif[1], R. Ben Tekaya[1], H. Hachfi[1], Y. Mohamed[1]. *[1]Taher Sfar University Hospital, Rheumatology Department, Mahdia,Tunisia*

Background: Vertebral fracture (VF) is the most common fragility fracture. The majority of them are asymptomatic and only third of VFs are clinically recognized. Screening of osteoporosis may increase early detection of these fractures.

Objectives: to emphasize on the routine practice the lateral and frontal X-rays of dorso-lumbar spine each time that the diagnosis of osteoporosis has been made.

Methods: This is a cross-sectional study which includes patients followed for a well-defined rheumatological disease in the rheumatology department at TAHER SFAR University Hospital, Mahdia, Tunisia. All patients had a bone mineral density (BMD) measurement whenever there is an indication according to the HAS 2006 recommendation with a systematic radiography of the dorso-lumbar spine (face and profile incidences).

Results: Thirty seven female patients were enrolled, with a mean age of 59.8 ± 9.9 years. The average body mass index was 30.85 ± 5.7kg/m2 and 83.7% of them were overweight (BMI>25kg/m2). 86.5% of patients had a history of back pain and 16.2% of them had a family history of fracture of the femoral upper extremity. The reasons for performing BMD were dominated by corticosteroid therapy ≥7.5mg/d for more than 3 months and a history of vertebral fracture in 37.8% of cases each and treatment with anti-aromatases in 16.2% of cases .18 patients had a Spinal T-score ≥-2.5 DS. 12 patients had a spinal Tscore between -2.5 DS and -1 DS. 6 patients had a femoral Tscore ≥-2.5 DS and 12 had a femoral Tscore between -2.5 DS and -1DS. 19/37 patients (51.4% of cases) had osteoporosis. 9/19 (47.3%) had a vertebral fracture

Table 1

	Population (N = 17)	Without fragility fracture (N = 13)	With fragility fracture (N=4)	P
Male, n (%)	9 (53%)	7 (54%)	2 (50%)	0.89
Age at first symptoms, years, mean (SD)	37.6 (21.1)	33.0 (20.2)	58.1 (10.1)	0.05
Age at diagnosis, years, mean (SD)	47.7 (21.1)	38.8 (20.9)	59.7 (13.1)	0.08
Ever smoker, n (%)	6 (35%)	4 (30.8%)	2 (50%)	0.48
Alcohol, n (%)	2 (11.76%)	1 (7.69%)	1 (25%)	0.34
BMI, mean (SD)	26.5 (4.3)	25.3 (4.0)	30.6 (2.0)	0.02
BMI<19kg/m2, n (%)	1 (6%)	1 (7%)	0 (0%)	0.56
Cutaneous mastocytosis, n (%)	8 (47%)	5 (38.5%)	3 (75%)	0.20
Anaphylaxia, n (%)	8 (47%)	6 (46.1%)	2 (50%)	0.89
Digestive symptoms, n (%)	8 (47%)	7 (53.5%)	1 (25%)	0.31
Basal serum tryptase >11,4	12 (70.6%)	8 (61.5%)	4 (100%)	0.14
Basal serum tryptase, mean (SD)	20.20 (18.33)	10.68 (20.75)	22.85 (7.64)	0.75
General risk factors for OP present, n (%)	5 (29%)	5 (38.5%)	0 (100%)	0.14
Femoral T score, mean (SD)	-1.03 (1.22)	-3.82 (1.36)	-1.86 (1.23)	0.12
Lumbar T score, mean (SD)	-1.06 (1.57)	-5.27 (1.36)	-1.95 (2.08)	0.20
Femoral Z score, mean (SD)	-0.34 (1.05)	-1.79 (1.44)	-0.75 (0.65)	0.39
Lumbar Z score, mean (SD)	-0.30 (1.88)	-5,38 (1.57)	-0.67 (2.96)	0.66
FRAX global fracture, mean (SD)	2.27 (2.52)	2.34 (1.57)	6.83 (7.82)	0.11
FRAX hip fracture, mean (SD)	0.23 (1.01)	0.48 (0.27)	2.1 (1.92)	0.18

among which 12% were previously unknown and in women who were fully symptom-free. The vertebral fractures were mainly located at the dorsal-lumbar region: the L1 and T11 vertebrae were fractured in 3 patients and the T12 vertebrae in 3 patients.
Conclusion: Our study showed that nearly half of patients with BMD-objectified osteoporosis had a VF detected on standard X-rays, most of which were previously unknown. It is plausible to speculate the place of this method combining BMD with spinal X-rays in the diagnosis of asymptomatic VFs.

AB1023 CHARACTERISTICS OF PATIENTS REFERRED FOR FIRST BONE DENSITOMETRY TO A RHEUMATOLOGY FLS, WITH NORMAL RESULTS IN THE LUMBAR SPINE

J. Rosas[1], J. C. Cortés-Quiroz[2], C. Raya-Santos[3], C. Cano[4], A. Pons[4], M. Lorente Betoret[4], J. M. Senabre-Gallego[2], G. Santos Soler[4], J. A. Bernal[4], X. Barber[5], J. A. García-Gómez[6]on behalf of AIRE-MB. *[1]Hospital Marina Baixa, Rheumatology, 03570, Spain; [2]Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; [3]Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain; [2]Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; [5]Miguel Hernández University, CIO, Elche, Spain; [5]Miguel Hernández University, CIO, Elche, Spain*

Objectives: To analyze the characteristics of postmenopausal women referred for the first bone densitometry (BMD), with normal results in the lumbar spine.
Methods: Retrospective study of postmenopausal women, for a first BMD, at a rheumatology FLS, during February/2010-December/2021. General patient data (age, gender), osteoporosis (OP) risk factors were collected: age at menopause, parental hip fracture, body mass index (BMI), smoking and alcohol habit, drugs and potentially osteopenizing diseases, low-impact fractures in adulthood (fractures of osteoporotic origin included: vertebral, hip, humeral head and distal radius and pelvis), current treatment for OP and FRAX index.
Results: 2.930 postmenopausal women with normal lumbar BMD are included: 505 (17%) had suffered an OP fracture: mean age (SD): 63.2 years (8.5) and of menopause 48 years (10). Among the OP risk factors: early menopause: 818 (28%) women, active smoking: 521 (18%), alcohol > 3 units: 84 (2%), parents hip fracture: 310 (11%). Among osteopenizing diseases: rheumatoid arthritis/chronic arthritis: 112 (4%) patients, inflammatory bowel disease: 44 (2%), arteritis/polymyalgia rheumatica: 35 (1%) and the rest <1%. Among the osteopenizing drugs: omeprazole: 967 (33%) patients, thyroxine: 354 (12%), oral or inhaled corticosteroids: 261 (9%) and aromatase inhibitors: 168 (6%). 427 (15%) patients had had a previous OP fracture: distal radius: 188 (6%), vertebral: 146 (5%), humeral head: 46 (2%) and hip: 47 (2%). 808 (28%) patients were receiving treatment for OP: oral bisphosphonates: 518 (18%), SERM: 136 (5%), strontium ranelate: 75 (3%), denosumab: 51 (2%), teriparatide: 16 (0.7%) and zoledronate: 12 (0.5%) (Table 1).

Table 1. Characteristics of patients with normal lumbar spine BMD.

	TOTAL BMD LS Normal N: 2.930	Normal BMD LS WITH fracture N: 505 (17%)	Normal BMD LS WITHOUT fracture N: 2.425 (83%)	p
Age in BMD, years, mean (SD)	63,2	70.5 (7.78)	60.6 (26)	**0.0001**
Menopausal age, years, mean (SD)	48 (8.4)	45 (5.46)	48 (8.48)	**0.0001**
Early menopause, n (%)	814 (28)	171 (34)	643 (27)	**0.07**
BMI, kg/m^2, media (SD)	29,1 (10.3)	29.5 (17.03)	28,9 (10.3)	**0.44**
Active tobacco, n (%)	521 (18)	40 (8)	481 (20)	**0.06**
Alcohol ≥ 3 units, n (%)	84 (2)	10 (2)	74 (3)	0.85
Parent hip fracture, n (%)	310 (11)	60 (12)	250 (10)	0.65
Ostepenizing drug, n (%):	1.750	289 (57)	1.461 (60)	0.34
Omeprazole	967 (33)	178 (35)	789 (33)	0.60

Treatment, n (%):	808 (34)	226 (48)	582 (24)	**0.0001**
Oral bisphosphonate	518 (18)	127 (25)	391 (16)	
SERM	136 (5)	24 (5)	112 (5)	**0.02**
Strontium ranelate	75 (3)	20 (4)	55 (2)	1
Denosumab	51 (2)	31 (6)	20 (0.8)	0.35
Zoledronate	12 (0.5)	10 (2)	2 (<0.1)	0.84
Teriparatide	16 (0.7)	14 (3)	2 (<0.1)	0.84
BMD, mean Tscore (SD):				
Lumbar spine	0.89	0.04 (1.49)	0.05 (1.49)	0.89
Femoral neck	0.70	-1.3 (1.06)	-0.54 (1.06)	**0.0001**
Osteoporosis, n (%)	108 (4)	51 (10)	57 (2)	**0.07**
Osteopenia, n (%)	981 (33)	247 (49)	734 (30)	**0.0001**
Total hip	-0.31	-0.8 (1.12)	-0.17 (1.12)	**0,0001**
FRAX with BMD, mean (SD):				
Mean fracture	5.23	10.6 (5.79)	3.99 (5.78)	**0.0001**
Hip fracture	1.54	3.7 (3.58)	1.09 (3.58)	**0.0001**

The group with OP fractures, are significantly (Table 1): older (p<0.0001), with lower mean age of menopause (p<0.0001), receive more treatment (p<0.0001), especially oral bisphosphonates (p=0.02), have worse results in hip BMD (p<0.0001), with a higher percentage of osteopenia (50% vs 30%, p<0.0001) and worse result in FRAX of major fracture (p<0.0001) and of hip (p<0.001).
Conclusion: Among the patients referred to BMD, although the result of lumbar spine is normal, 17% have suffered an OP fracture, presenting this group: 1) Older age, 2) Osteopenia in hip BMD 50%, with high risk of fracture due to FRAX and they followed treatment for OP, especially oral bisphosphonates. 3) It is advisable to simultaneously perform BMD at the lumbar and hip levels, especially in older subjects

AB1024 SECONDARY PREVENTION OF VERTEBRAL FRACTURES SUSTAINED EFFICACY OVER TIME

J. E. Oller Rodríguez[1], E. Grau García[1], S. Leal Rodriguez[1], P. Muñoz Martinez[1], L. Mas Sanchez[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], C. Pávez Perales[1], M. De la Rubia Navarro[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], F. Ortiz-Sanjuán[1], E. Vicens Bernabeu[1], I. Cánovas Olmos[1], J. J. Fragío Gil[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], J. A. Román Ivorra[1]. *[1]La Fe University and Polytechnic Hospital, Rheumatology Department, València, Spain*

Background: Vertebral fractures entail a notorious social and health problem, and their presence is the greatest risk factor for the appearance of a new vertebral fracture. Despite the availability of different drugs for secondary prevention, there are few comparative studies in real clinical practice.
Objectives: Our aim is to evaluate the appearance of new vertebral fractures depending on the strategy chosen as secondary prevention.
Methods: We performed a retrospective descriptive study with patients who had suffered their first vertebral fracture between 2010 and 2018, in whom we checked the subsequent appearance of new vertebral fractures.
We selected only those patients who had completed a minimum of 18 months of secondary prevention with antiresorptive drugs, or a sequential scheme (anabolic treatment followed by at least 1 year with an antiresorptive drug). Those patients who had presented new fractures in the first 6 months of treatment were excluded. Finally, we adjusted efficacy by treatment time.
Results: A total of 452 patients were included, out of an initial baseline pool of 1184 patients. We found female predominance (83% of the total). The mean age of the first vertebral fracture was 69.2 years, with a mean latency to fracture of 51.4 months. A new vertebral fracture happened in 4.7% of these patients. The different secondary prevention strategies were classified according to the different therapeutic options, as we can see in Table 1.

Table 1.

Treatment	Patients (%)	New fractures (%)
Denosumab	205 (45.35%)	10 (4.87%)
Oral bisphosphonate	75 (16.59%)	5 (6.66%)
(alendronate, risedronate or ibandronate)		
Zoledronate	38 (8.41%)	3 (7.89%)
Teriparatide followed by Denosumab	94 (20.8%)	0 (0%)
Teriparatide followed by Oral bisphosphonate	36 (7.96%)	3 (8.33%)
Teriparatide followed by Zoledronate	4 (0.89%)	0 (0%)

No statistically significant differences between different treatments were observed, but we found a lower probability of a new fracture in patients treated with sequential treatment with teriparatide followed by denosumab. Finally, the Kapplan-Meier survival analysis showed a lower probability per year of new fractures in patients treated with teriparatide followed by denosumab, being this probability greater in patients treated with teriparatide followed by oral bisphosphonate.
Conclusion: A lower probability of refracture was observed in patients who received sequential treatment with teriparatide followed by denosumab.

AB1025 TRABECULAR BONE SCORE IN PATIENTS WITH AXIAL-SPONDYLOARTHRITIS

M. Daflaoui[1], H. Azzouzi[1], H. Boutaibi[1], F. Chennouf[1], I. Linda[1]. *[1]Mohamed I University, Rheumatology Department, Oujda, Morocco*

Background: In axial spondyloarthritis, the bone mineral density (BMD) is usually overestimated due to syndesmophytes. Hence, the trabecular bone score

(TBS) could be suggested as a complementary tool that provides additional information on bone microarchitecture (1).

Objectives: The aim of this study was to explore the trabecular bone score (TBS) association with disease parameters and vertebral fractures in axial spondyloarthritis.

Methods: We designed a cross-sectional study of patients with axial spondyloarthritis diagnosed according to the ASAS 2009 classification, recruited from December 1st, 2021. SA patients excluded were those with a history of cancer, hyperparathyroidism, hyperthyroidism, chronic kidney disease, cirrhosis, and those using osteoporosis and steroid drugs or having a body mass index (BMI) of more than 36kg/m ^{2}. BMD (of lumbar, hip, femoral neck, 33% distal radius of non-dominant hand) and TBS were measured with Dual-energy X-ray absorptiometry (DXA). Vertebral fractures (VF) were assessed by vertebral fracture assessment (VFA). They were defined as grade 2 or 3 according to Genant criteria. Clinical data and laboratory tests collected simultaneously with the DXA scan were analyzed. The associations between TBS and disease parameters: Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Metrology Index (BASMI), and the Modified stoke ankylosing spondylitis spinal score (mSASSS) were studied by correlations and multiple linear regressions using SPSS 20.

Results: Forty-three patients were included with a mean age of 36.42 ± 13.10 years and a mean disease duration of 12.88 ± 7.69 years. The mean TBS was 1.370 ± 0.098 and the mean lumbar BMD was 0.937 ± 0.210. The mean TBS was significantly lower in patients with comorbidities (high blood pressure and diabetes). TBS was also positively associated with lumbar BMD (r = 0.386; p = 0.011), hip BMD (r = 0.621; p < 0.001), but not forearm BMD (r = 0.276; p = 0.073). Moreover, TBS was negatively associated with age (r = - 0.525; p < 0.001), BMI (r = - 0.440; p = 0.001), and waist circumference (r = - 0.558; p < 0.001). TBS was also negatively correlated with the ASDAS score (r = - 0.378; p = 0.014), while there was no correlation with the BASDAI, BASMI, BASFI, and mSASSS. The association of TBS and ASDAS CRP was significant at adjustment on disease duration and mSASSS (p = 0.017; β = - 0.363; [- 0.056; - 0.006]). However, there was no association between TBS and VF.

Conclusion: In SA patients, TBS was negatively associated with disease activity score and positively associated with axial bone loss. This result may explain bone fragility in active spondyloarthritis. No clear association was found between TBS and VF in the present study.

AB1026 ASSOCIATION BETWEEN TRABECULAR BONE SCORE, 10-YEAR PROBABILITY RISK FOR FRACTURE, AND VERTEBRAL FRACTURES IN RHEUMATOID ARTHRITIS

H. Boutaibi[1], H. Azzouzi[1], F. Chennouf[1], I. Linda[1]. [1]*Mohamed I University, Rheumatology Department, Oujda, Morocco*

Background: Trabecular bone score (TBS) utility in vertebral fracture prediction is still questionable.

Objectives: To evaluate the association of trabecular bone score (TBS), the fracture risk assessment tool (FRAX), and TBS adjusted FRAX with prevalent vertebral fractures (VFs) in Rheumatoid Arthritis (RA).

Methods: This is a cross-sectional study of RA patients diagnosed according to ACR/EULAR 2010 criteria and recruited in our rheumatology department. Patients with an age under 40 or above 90, diabetes, thyroid disease, hyperparathyroidism, cancer, cirrhosis, renal clearance < 70 mL/min, and those using osteoporosis drugs or having a body mass index (BMI) of more than 36kg/m^2 were excluded. TBS, bone mineral density (BMD), and vertebral fracture assessment (VFA) were obtained using dual-energy X-ray absorptiometry (DXA). We used the FRAX tool to assess the 10-year probability of major osteoporotic fracture (MOF-FRAX) and hip fracture (HF-FRAX) with and without BMD. These parameters were further adjusted for TBS (FRAX/TBS-MOF and FRAX/TBS-HF). Prevalent VF was evaluated by two readers using VFA. We defined patients with prevalent VFs as patients who had moderate-to-severe degree VFs of the thoracic and lumbar spine (T4 to L4) according to Genant criteria. Osteoporosis was defined as a T-score < -2.5 in the lumbar spine, femoral neck, or 1/3 of the non-dominant forearm location. Clinical data, results of radiological and laboratory tests performed on the same day of the DXA scan were collected. Receiver operating characteristic curves were generated by SPSS.20 to study the predictability of each parameter for VF.

Results: Sixty-nine patients were enrolled, and 66.7% of them were menopausal. Their mean lumbar spine, hip, and forearm BMD were 0.817 ± 0.155, 0.681 ± 0.676, and 0.572 ± 0.119, respectively. The mean TBS was 1.328 ± 1.041. Thirty-nine patients (56.5 %) had osteoporosis. Nine patients (13%) had moderate to severe VFs with predominance at the thoracic spine (77.8%). There was a negative correlation between MOF-FRAX score and lumbar spine BMD (r = -0.473; p < 0.001), and also hip BMD (r = - 0.530; p < 0.001), while there was no correlation between MOF-FRAX score, HF-FRAX and TBS. The areas under curves were 0.824, 0.800, 0.792, and 0.443 for the FRAX-MOF score with BMD, FRAX-MOF score, FRAX-MOF score adjusted for TBS, and TBS, respectively.

Conclusion: In this study, MOF-FRAX score showed a better correlation with BMD than TBS. It was also superior to TBS and TBS adjusted FRAX in identifying prevalent VFs in RA patients.

AB1027 CLINICLAL EFFICACY OF SEQUENTIAL TREATMENT AFTER ROMOSOZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS FOR 18 MONTHS

Y. Kanayama[1]. [1]*Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan*

Background: Romosozumab (ROMO), a monoclonal antibody that binds sclerostin, increases bone formation and decreases bone resorption. And although it is a novel therapeutic agent for osteoporosis, which has shown high effects of increasing bone density and inhibiting fragile fracture in overseas clinical trials. However the clinical efficacy for rheumatoid arthritis complicated with osteoporosis (RA-OP) is unknown.

Objectives: To evaluate the clinical efficacy of ROMO for 12months and denosumab (DMB) 6months in patients with RA-OP for 18 months.

Methods: RA patients diagnosed according to the 2010 ACR/EULAR criteria. All patients met at least one of the following criteria were eligible; a bone mineral density T score of -2.5 or less at the lumber spine or total hip and either one or more moderate or severe vertebral fractures or two or more mild vertebral fractures. All patients were initiated ROMO from between April, 2019 and March, 2020. The total number of patients was 12 cases. The ROMO dose was 210mg at once every 1 months. After 12 months of ROMO, all cases were changed to DMB. In all cases native or activated vitamin D has been used. We reviewed the results for 12 months about the increase and decrease of bone mineral density (BMD) of lumbar spine(LS) and total hip(TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen(PINP) and tartrate-resistant acid phopshatate form 5b(TRACP-5b).

Results: he gender was all female. The mean age was 72.8 ± 7.0; disease duration was 17.7 ± 16.5 years; the body mass index was 19.4 ± 3.1 and the FRAX was 36.0 ± 14.9. Clinical findings related to RA-OP at baseline were as follows; CRP 1.25 ± 1.75; DAS28-CRP 3.45 ± 0.99; HAQ 1.56 ± 0.99 and, bone turnover markers and bone mineral density at baseline were as follows; P1NP 62.4 ± 36.2; TRACP-5b 485 ± 252; LS-BMD and T-score 0.79 ± 0.14 g/cm^2 and -2.82 ± 0.99 and TH-BMD 0.55 ± 0.07 g/cm^2 and -3.14 ± 0.53 g/cm^2. The rate of increased P1NP from baseline to 1, 3, 6, 12 and 18 months were each 116.3 ± 68.7% at 1 month, 135.0 ± 131.3% at 3 month, 126.1 ± 177.0% at 6 month, 83.7 ± 179.1% at 12 month and -45.1 ± 35.7% at 18 month and decreased TRAC-5b were -13.0 ± 91.4% at 1 month, 6.9 ± 38.8% at 3 month, 20.0 ± 63.4% at 6 month, 14.8 ± 64.5% at 12 month and -11.4 ± 95.9% at 18 month. The rate of increased LS-BMD from baseline to 6, 12 and 18 months were 10.8 ± 8.0%, 15.2 ± 9.5% and 18.9 ± 10.4% and TH-BMD were 4.1 ± 4.5%, 5.7 ± 6.3% and 8.4 ± 8.1% (Figure 1, 2).

Conclusion: Clinical efficacy of treatment with ROMO for 12months and DMB for 6months for RA-OP was extremely effective and has the high potential to be an important option in the treatment of RA-OP.

AB1028

REGRESSIVE BONE MINERAL DENSITY TRENDS SEEN WITH DELAY IN FOLLOW UP OF DENOSUMAB TREATMENT DUE TO THE PANDEMIC INDUCED LOCKDOWN - A SINGLE CENTRE INDIAN EXPERIENCE.

A. K. Aggarwal[1], N. Aggarwal[2], H. Sharma[3]. *[1]Institute of Rheumatology & Pain, Rheumatology, Ghaziabad, India; [2]Institute of Rheumatology & Pain, Administration and Research, Ghaziabad, India; [3]Institute of Rheumatology & Pain, Pharmacy, Ghaziabad, India*

Background: Denosumab (Dmab), a fully human monoclonal antibody that inhibits receptor activator of nuclear factor kappa-β ligand (RANKL), which selectively inhibits osteoclastogenesis can be used for a long period unlike the relatively short period with Teriparatide.[1-2] However the effects of Dmab can quickly regress if the treatment is delayed.[3]
Objectives: The pandemic led to multiple prolonged lockdowns since March 2020 to Jan 2022 in India. This resulted in follow up Dmab treatment delays. The retrospective study was aimed to look for the effect of the delays.
Methods: The bone mineral density (BMD) trends from the central dual-energy x-ray absorptiometry (DXA) at our centre were studied. The trends of patients under Dmab for one year and delay in follow up for 10 - 12 months for the forth dose were evaluated. 21 postmenopausal women who had been under treatment with Dmab 60 mg subcutaneous injection at 6 monthly interval for one year followed up with such delays. 6 were excluded because of history of sars-cov-2 infection and glucocorticoid use. In the study group of 15 (n=15), the mean BMD at L2, L3 & L4 (sp BMD) and Right and Left Hip (hip BMD) were studied from before treatment (a BMD), 6 months after 1st and at the time of 2nd injection (b BMD), 6 months of the 2nd and at the time of 3 rd injection of Dmab (c BMD), and that due to delay in follow up of 10-12 months (d BMD). The mean percentage trend change between a-b, b-c, and c-d BMDs was evaluated. The least significant change (LSC) [4] from a single centre DXA was used to validate the findings.
Results: The mean percentage change after the treatment for the 1st 6 months of Dmab (a-b BMD) was 4.08% and 3.60% and the second injection resulted in a further change (b-c BMD) of 5.98% and 4.52% in the sp BMD & hip BMD respectively. The delay in follow up of 10-12 months resulted in a change (c-d BMD) of -7.81% in the sp BMD and -2.96% in the hip BMD. The LSC from a single centre DXA is 2.6% and 3.6% for sp BMD and hip BMD respectively. A p>0.05 was considered statistically significant. Table 1 shows the BMD changes.

Table 1. Percentage BMD changes

BMD trend (n=15)	sp BMD (LSC – 2.6%)	hip BMD (LSC – 3.6%)
a-b BMD	4.08%	3.60%
b-c BMD	5.98%	4.52%
c-d BMD	-7.81%	-2.96%

sp BMD - Mean of L2,L3 & L4 Spine BMD, hip BMD - Mean of Right and Left Hip BMD, a-b BMD - Percent change in BMD from before to 6 months after Ist & at the time of 2nd Dmab, b-c BMD - Percentage change in BMD 6 months after 2nd & at the time of 3rd Dmab, c-d BMD - Percentage change in BMD after 3rd Dmab & follow up after delay of 10-12 months and LSC – Least significant change.

Conclusion: These findings suggest that regressive trend in BMD are seen when the treatment with Dmab is delayed even as early as 10 to 12 months. It was seen much faster in the spine compared to the hip. It is therefore advised that short term treatment with Dmab without follow up could lead to loss of all gains and may also worsen the osteoporosis.

CLINICAL AND RADIOLOGICAL OUTCOMES AFTER VERTEBROPLASTY AND KYPHOPLASTY FOR OSTEOPOROTIC VERTEBRAL FRACTURES

A. Ben Tekaya[1,2], E. Hannech[1,2], M. Bellil[2,3], M. Ben Salah[2,3]. *[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; [2]Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; [3]Orthopedic Department, Charles Nicolle Hospital, Tunis, Tunisia*

Background: Vertebral Fractures are among the most frequent osteoporotic fractures. Pain and spinal deformation cause loss of autonomy and predispose to a higher risk of morbidity and mortality. Vertebroplasty and Kyphoplasty are an efficient therapeutic alternative in the management of these fractures [1,2].
Objectives: The aim of our study was to evaluate functional and radiological outcomes of Vertebroplasty and Kyphoplasty for osteoporotic vertebral fractures.
Methods: It was a retrospective study including patients treated with Vertebroplasty or Kyphoplasty for osteoporotic vertebral fractures with no spinal cord injuries. Clinical, functional, and radiological data were collected. Pain assessment was evaluated by the Visual Analogue Scale (VAS) and the Denis pain scale. Oswestry Disability Index (ODI) was used to evaluate the functional impairment. The measurement of the vertebral height pre and postoperatively was assessed by the Beck's index on the spine lateral X-ray.
Results: There were 36 patients: 26 female and 10 male. The mean age was 65 years (41-74). The follow-up period was about 17 months. The thoracolumbar hinge was the most affected region (70%). Twenty two patients were treated by kyphoplasty and 14 by Vertebroplasty. The

mean VAS pain improved from 5.28 preoperatively to 2.92 postoperatively (delta VAS pain was 2.36, $p<10^{-3}$). The improvement in the VAS pain was by 3.42 ($p<10^{-3}$) in the last follow-up. There was no difference between the two technics regarding the pain improvement (p=0.06). On preoperatively, the mean Denis pain scale was 4. It was 2.19 after kyphoplastyand and 2.27 after Vertebroplasty with no significant difference between the two technics (p=0.6). The mean ODI at the last setback was fourteen: 95 % of patients had minimal to moderate disability, 5% had severe disability. There was no difference between Kyphoplasty and Vertebroplasty regarding the functional impairment (14.87 vs 12.36, p=0.5). Kyphosis on the level of the fractured vertebra improved from 16.8° preoperatively to 9.5° postoperatively with a significantly mean reduction of 7.3° ($p<10^{-3}$). Regional kyphosis improved from 12.1° to 7.4° with a significantly mean reduction of 4.3° ($p<10^{-3}$). Beck's index went up from 0.66 to 0.8 post-operatively (p<0.05). The improvement of kyphosis on the level of the fractured vertebra (angulair gain) was more important for the group treated with Kyphoplasty (8.45° vs 5.5, p=0.01). A significant association was found between the Beck's index losses with the ODI at the last setback (p=0.02). Complications were cement leakage in five patients without clinical symptoms. We had noted one anterior vascular leak without any clinical implication. Surgical site infection was noted in one case and was managed by medical treatment without any general complication.

Conclusion: Our study showed that Vertebroplasty and kyphoplasty were both effectively for the pain reduction and for restoration of autonomy in osteoporotic patients. They also allowed an improvement of the kyphosis necessary for an appropriate spinal static's.

PATIENT CARE AT THE FRACTURE LIAISON SERVICE REDUCE THE GAP IN THE TREATMENT OF OSTEOPOROSIS BETWEEN MEN AND WOMEN.

B. Hernández-Cruz[1], M. J. Miranda García[2], J. Barrera[3], F. J. Olmo Montes[2], M. A. Vázquez Gómez[4], M. Giner García[5], M. A. Colmenero Camacho[2], J. J. Pérez Venegas[6], M. J. Montoya García[5]on behalf of PAIDI Research Group CTS/211. *[1]Virgen Macarena University Hospital, Rheumatology, Seville, Spain; [2]Virgen Macarena University Hospital, Internal Medicine, Seville, Spain; [3]Virgen Macarena University Hospital, Internal Medicine, Seville, Spain; [4]University of Seville. Faculty of Medicine, Medicine, Seville, Spain; [5]University of Seville. Faculty of Medicine, Medicine, Seville, Spain; [1]Virgen Macarena University Hospital, Rheumatology, Seville, Spain*

Background: Osteoporosis (OP) between men and women is different,and the way it is treated also differs. In men, the gap in clinical care, especially diagnosis and treatment, is worse.

Objectives: To analyze the differences in the clinical characteristics of OP (demographics, comorbidities, diagnosis, and treatment) in an gold star Fracture Liaison Service (FLS).

Methods: Design: Observational, prospective, analytical study of usual clinical practice. All patients treated from an FLS from May 2018 to August 2021 were prospectively included. Of each patient, 160 clinical variables were introduced in a real time database, and they were followed for 2 years.

Results: 557 patients were analyzed, 472 (83%) women and 100 (17%) men. The main features are summarized in the table. In women the vertebral fracture predominated followed by the hip fracture, in men the hip followed by the vertebral ones. Men had higher rates of smoking and alcoholism. The frequency of secondary OP and exercise was different between sexes. Weight, height, and BMI were different, due to different body composition. The frequency of specific treatment for OP (bisphosphonate, denosumab, teripatide, SERM) before fracture was very low, lower in men. The most remarkable result was the low percentage of patients with OP receiving treatment before the FLS, and the differences between sex; 77 (16%) women versus 6 (6%) men had received it at some point in their lives, p=0.008. The probability of a man not receiving prior treatment was 2. 70 (95%CI 1.13- 7.81); p=0,008. After the FLS all the patients were treated. Treatment adherence in the first two years after the FLS was 84% in both sexes.

AB1031 PREVALENCE OF GLUCOCORTICOID INDUCED OSTEOPOROSIS IN AFRICAN ADULT PATIENTS WITH CHRONIC RHEUMATIC DISEASES. A SYSTEMATIC REVIEW AND META-ANALYSIS.

I. Hmamouchi[1,2], F. Paruk[3], S. A. A. Tabra[4], K. Maatallah[5], A. Bouziane[1,6], R. Abouqal[1,7], Y. El Miedany[8], A. EL Maghraoui[9], A. A. Kalla[10]. [1]*Mohammed V University Rabat, Laboratory of Biostatistics, Clinical Research and Epidemiology (LBRCE), Faculty of Medicine and Pharmacy, Rabat, Morocco;* [2]*Temara Hospital, Rheumatology Unit, Temara, Morocco;* [3]*University of Kwa-Zulu Natal, eThekwini, Department of Rheumatology, Inkosi Albert Luthuli Central Hospital, School of Clinical Medicine, College of Health Science, Durban, South Africa;* [4]*Tanta University, Lecturer of Rheumatology & Rehabilitation Department, Faculty of medicine, Tanta, Egypt;* [5]*University Tunis el Manar, Rheumatology Department, Kassab Orthopedics Institute, Faculty of Medicine of Tunis, Tunis, Tunisia;* [6]*Mohammed V University in Rabat, Department of Periodontology, Faculty of Dental Medicine, Rabat, Morocco;* [7]*Ibn Sina University Hospital, Acute Medical Unit, Rabat, Morocco;* [8]*Canterbury Christ Church University, Rheumatology Department, Canterbury, United Kingdom;* [9]*Mohammed V University Rabat, Private Medical Office, Rabat, Morocco;* [10]*University of Cape Town, Department of Medicine, Cape Town, South Africa*

Background: Glucocorticoid (GC) use is well established in the treatment of rheumatics diseases, particularly rheumatoid arthritis (RA). The use of low dose GC has been endorsed by EULAR recommendations for the management of rheumatic and musculoskeletal diseases even if in the context of SARS-CoV-2, but long-term use is generally discouraged.
Objectives: To estimate the prevalence of glucocorticosteroids induced osteoporosis (GIOP) on bone mineral density (BMD) in African adult patients with inflammatory rheumatic diseases.
Methods: For this systematic review and meta-analysis, PubMed, Google Scholar, Scopus and African index medicus were systematically searched up to December 2020 without language restrictions. We included studies as follows: population-based or hospital-based study, study with sufficient information to estimate the prevalence of GIOP and osteoporotic fractures in African patients with rheumatic disease. Searches were limited to peer-reviewed full text articles. A standardized data extraction form was used to collect information from eligible studies. A random-effects meta-analysis was conducted to obtain the pooled prevalence of GIOP in these studies. The meta-analysis was stratified by geographical region. The study is registered with PROSPERO, number CRD42021256252.
Results: Our search identified 8571 studies, of which 8 studies were included in the systematic review from only four African countries and 7 studies in the meta-analysis. The pooled prevalence of osteoporotic fractures in our study was 47.7% (95% CI 32.9–62.8) with 52.2% (95% CI 36.5-67.6) in North Africa and 15.4% (95% 1.9-45.4%) in South Africa (SA). There was no evidence of publication bias, although heterogeneity was high (p=0.018). There was no data from sub-Saharan Africa apart from the two studies from SA.
Conclusion: The overall prevalence of GIOP in African adult patients with inflammatory rheumatic diseases was high at 47.7% (95% CI 32.9–62.8). Meta-analysis calculation revealed patient geographic origin as possible confounding factors of the proportion outcomes and further studies are required.

AB1032 PREDICTORS OF INCREASING NUMBER OF FRACTURES IN A LARGE COHORT OF PATIENTS PRESENTING FOR DUAL-ENERGY X-RAY ABSORPTIOMETRY SCAN

Z. Sultan[1], M. Bukhari[1]. [1]*Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom*

Background: Osteoporosis has been described as a global epidemic(1), it is the most common disease affecting bones (2). Incidence of osteoporosis is estimated to double by 2034(2) and osteoporotic fractures are expected to cost the US healthcare system around $50 billion by 2040(1), this is more than that for either chronic lung disease, breast cancer, diabetes, or stroke (1). Thus, it is vital to define the risk factors and characteristics associated with fractures to aid early prophylaxis.
Objectives: 1.Identify risk factors and predictors associated with fractures.
Methods: 31546 patients presented to a district general hospital in North West England for dual energy X-ray absorptiometry scan between 1996 and 2017. Demographics, risk factors and incidence of fractures were recorded. This data was retrospectively analysed to identify patients who had sustained at least one fracture. Patients were divided into three groups – group 1 had one fracture, group 2 had two fractures and group 3 had three or more fractures. *STATA* was used for statistical analysis. One way ANOVA with a Tukey post-hoc test and chi-squared test were used to compare the three groups.
Results: 11839 patients were identified to have sustained at least one fracture, this included 9993 females and 1846 males (Table 1). Group 1 contained 9390, group 2 contained 2050 and group 3 contained 399 patients. A statistically significant increase in the proportion of females within in each group was observed as the number of fractures increased (chi squared=13.99, p=0.001). There was a significant reduction in average height, weight and BMI between the 3 fracture groups with an increasing number of fractures (f(2)=31.67, p=0.0000, f(2)=23.71, p=0.0000 and f(2)=8.14, p=0.0003 respectively). Group 3 had the oldest mean age and group 1 the youngest (f(2)=44.36, p=0.0000). A significant reduction in fat percentage of the spine was identified as number of fractures increased (f(2)=4.92, p=0.0073). A significant increase in the proportion of patients with a history of smoking and alcohol excess within each group was observed as number of fractures increased (chi squared=7.48, p=0.024 and chi squared = 23.12, p=0.000 respectively). Mean T score in the lumbar spine, total femur and femoral neck were significantly lower between the 3 fracture groups with increasing fractures (f(2)=60.54, p=0.0000, f(2)=156.44, p=0.0000 and f(2)=115.86, p=0.0000 respectively).

Table 1. No. of fractures vs patient characteristics.

Characteristic	1 Fracture	2 Fractures	≥3 Fractures
Mean height, cm (SD)	161.49 (8.33)	160.45 (8.45)	158.70 (8.73)
Mean weight, kg (SD)	70.77 (15.93)	69.70 (15.42)	65.51 (14.69)
Mean BMI, kg/m2 (SD)	27.09 (5.54)	27.01 (5.27)	25.96 (5.22)
Mean age (SD)	67.45 (11.85)	69.76 (11.76)	70.84 (11.62)
Mean spine fat, % (SD)	30.61 (10.92)	30.58 (10.52)	28.87 (11.36)
Mean lumbar spine T-score (SD)	-1.23 (1.60)	-1.55 (1.52)	-1.86 (1.47)
Mean total femur T-score (SD)	-1.28 (1.22)	-1.69 (1.15)	-2.07 (1.13)
Mean femoral neck T-score (SD)	-1.47 (1.10)	-1.80 (1.00)	-2.04 (0.97)
Proportion of females (%)	83.84	86.00	89.47
Proportion of pts with smoking history (%)	37.42	39.41	43.11
Proportion of pts with excess alcohol history (%)	7.96	9.90	13.78

Conclusion: Some important risk factors and characteristics in patients sustaining fractures have been identified. Increased height, weight and BMI are associated with sustaining fewer fractures. Increasing age is associated with having sustained more fractures, in line with what is expected with the reducing T-scores and the ageing process. A reduced spine fat percentage is associated with higher number of fractures suggesting that fat provides a protective effect to bone. Finally, a history of smoking and excess alcohol consumption are shown to be important risk factors in sustaining increasing numbers of fractures.

AB1033

RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) FOR THE ASSESSMENT OF FEMORAL BONE HEALTH IN A MALE POPULATION

F. A. Lombardi[1], P. Pisani[1], A. Natale[2], E. Casciaro[1], M. DI Paola[1], R. Franchini[1], M. Muratore[3], F. Conversano[1], S. Casciaro[1]. [1]*National Research Council, Institute of Clinical Physiology, Lecce, Italy;* [2]*Echolight Spa, R&D Department, Lecce, Italy;* [3]*ASL, Rheumatology, Lecce, Italy*

Background: Bone mass reaches the peak during the third decade of life. By this age, men reach an increased bone mass that starts declining in their fifties, however less rapidly than women after menopause. However, men and women lose bone mass at the same rate by age 65-70, becoming fragile and more likely to have fracture.

Objectives: This study aimed to evaluate the diagnostic accuracy in osteoporosis diagnosis of Radiofrequency Echographic Multi Spectrometry (REMS) technology applied on the proximal femur in an adult male population in comparison with the Dual-energy X-ray Absorptiometry (DXA).

Methods: A cohort of Caucasian males was enrolled in the study. Inclusion criteria were: age between 30 and 90 years, body mass index (BMI) less than 40 kg/m^2, no significant walking impairments and proximal femur DXA medical prescription. All the enrolled patients underwent proximal femur scans with both DXA and REMS. The agreement between REMS and DXA-measured BMD was expressed by Pearson correlation coefficient and Bland-Altman method. The classification into patients "with osteoporosis" or "without osteoporosis" was carried out considering the conventional threshold of T-score (-2.5) for both techniques independently. The accuracy was evaluated by the assessment of sensitivity and specificity considering the DXA outcome as reference [1].

Results: A total of 219 men were included in the analysis, with mean age of 55.5 (± 15.3) years. The Pearson correlation coefficient between REMS- and DXA-measured BMD values was r=0.94. At Bland-Altman analysis, Bias ± 1.96 Standard Deviation were -0.004 ± 0.04 g/cm^2. The REMS capability to discriminate osteoporotic patients from non-osteoporotic ones was very high: a sensitivity of 90.0% and specificity of 91.8% was detected.

Conclusion: REMS, applied to the proximal femur site, is a reliable technology for the diagnosis of osteoporosis also in men, thus confirming the diagnostic performance already observed in studies carried out in female populations [1, 2].

AB1034

FRACTURE RISK BY FRAX WITH AND WITHOUT BONE MINERAL DENSITY, COMPARISON OF FACTORS AFFECTING CONCORDANCE

A. Y. Lujano Negrete[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], M. C. Rodriguez-Ruiz[1], A. Aguilar-Leal[1], L. G. Espinosa Banuelos[1], A. Cárdenas[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: The Fracture Risk Assessment Tool (FRAX) estimates the 10-year probability of hip (FXC) and major osteoporotic (FXOM) fractures in patients aged 40 to 90 years using important clinical factors, such as bone mineral density (BMD), optional input variables. (1) There is convincing evidence that with or without the use of BMD it provides a well-validated instrument and may be useful in clinical practice for identifying patients at high risk of fracture and informing treatment decisions. (2)

Objectives: This study aims to determine the concordance between the treatment decision, calculated using FRAX scores with and without BMD, and to identify the risk factors associated with the discordance in patients with autoimmune rheumatic diseases.

Methods: A cross-sectional study was carried out in patients with autoimmune rheumatic diseases who had undergone osteoporosis detection (OP) using dual bone densitometry in the Rheumatology service of the University Hospital "Dr. José Eleuterio González" during the period August 2020 - August 2021. The FRAX questionnaire was applied to determine risk factors for OP and the results of the instrument with and without BMD were calculated, the patients were classified as low, intermediate, and high risk.

A Student's t-test, a Wilcoxon rank-sum test, and a Chi-square or Fisher's exact test were used to compare variables between groups and calculate P-values.

Results: A total of 88 patients were included. Based on FRAX questionnaire responses, 82 (93.18%) patients had at least one risk factor for OP. The FRAX result with or without densitometry resulted in a treatment decision in 48 (54.5%) and 28 (31.8%) patients, respectively. The results were concordant in 65 (73.9%) of the cases. It was found that patients with osteopenia due to BMD had a greater agreement between both measurements (93.3%, p 0.003) than patients with normal BMD (62.5% p 0.001). Likewise, patients with secondary osteoporosis had lower concordance than patients without this diagnosis (25% and 72.5%, respectively, p 0.006).

Conclusion: The results of FRAX with and without densitometry were mostly agreeable in predicting the need for treatment according to the 10-year probability of hip fracture, however, this concordance decreased in patients with a previous diagnosis of secondary osteoporosis, no significant difference was found between the risk factors for the concordant and discordant groups. More studies are required to determine the variables that cause a decrease in the concordance of the tests.

Table 1. Factors that affect the results between the discordant groups.

Variables	Concordant n=65	No concordant n=23	P value
Sex (%)			0.078
Men	8 (12.3%)	0 (0%)

Crystal diseases, metabolic bone diseases other than osteoporosis

AB1035 END STAGE RENAL DISEASE IN PATIENTS WITH GOUT AND CONTROLS, ETIOLOGICAL DIFFERENCES?

L. Höper[1], U. Lindström[1], H. Herlitz[2], M. Dehlin[1]. *[1]Sahlgrenska Academy at University of Gothenburg, Rheumatology and Inflammation Research, Gothenburg, Sweden; [2]Sahlgrenska Academy at University of Gothenburg, Molecular and Clinical Medicine/Nephrology, Gothenburg, Sweden*

Background: The association between gout and renal disease is well known. However, whether hyperuricemia causes renal disease, or if the association is explained by comorbidities, is still up for debate. Studies on the effects of urate and gout on chronic kidney disease (CKD) show conflicting results. There is a lack of data on the underlying causes of CKD in gout patients.
Objectives: To compare causes of end stage renal disease (ESRD) in patients with gout and population controls.
Methods: This is a population-based and register-based case-control study. Gout cases, aged 18 years or older, were identified by at least one visit to a physician either an in- or outpatient clinic with a registered ICD-10 code for gout (M10) in the Western Regional Healthcare Contact Register (VEGA), between January 1st 2001 through December 31st 2018. For each case five controls without gout were matched by sex, age, and county/place of residence at year of first diagnosis. Cases and controls were excluded if they prior to the first recorded ICD-10 code for gout, had a record of end stage renal disease, defined as codes for renal transplantation or dialysis either in VEGA or the Swedish Kidney Register (SNR). In this cohort, all cases and controls developing ESRD during the follow-up period (2001 to 2018) were identified, and the registered causes of ESRD were compared across the groups.
Results: In total, 48594 gout cases (mean age 68.4 years; 67% male), and their 150618 matched controls (mean age 63.3 years; 67% male) were included. Of the cases and controls, 529 (1.1%) and 128 (0.1%) developed ESRD, respectively. At the time-point of active uremia treatment start (as in start of dialysis or kidney transplantation), the cardiovascular comorbidity burden was higher for the gout patients (Table 1). There was no significant difference in the distribution of ESRD-causes between patients with gout and their controls (Figure 1).

Table 1. Baseline data

	Gout	Controls
Number (% of total)	529 (80.5)	128 (19.5)
Age at gout diagnosis, mean (median)	64.2 (65)	63.3 (65)
Age at ESRD, mean (median)	69.2 (72)	68.9 (71)
Male sex, n (%)	389 (73.5)	109 (85.2)
No renal failure at baseline, n (%)	239 (44.6)	77 (60.2)
Diabetes, n (%)	215 (40.6)	44 (34.4)
Hypertension, n (%)	473 (89.4)	110 (85.9)
Ischemic heart disease, n (%)*	206 (38.9)	26 (20.3)
Cerebrovascular disease, n (%)	89 (16.8)	15 (11.7)
Hematologic malignancy, n (%)	11 (2.1)	6 (4.7)
Dermatologic malignancy, n (%)	12 (2.3)	3 (2.3)
Other malignancy, n (%)	65 (12.3)	16 (12.5)

*p<0,001

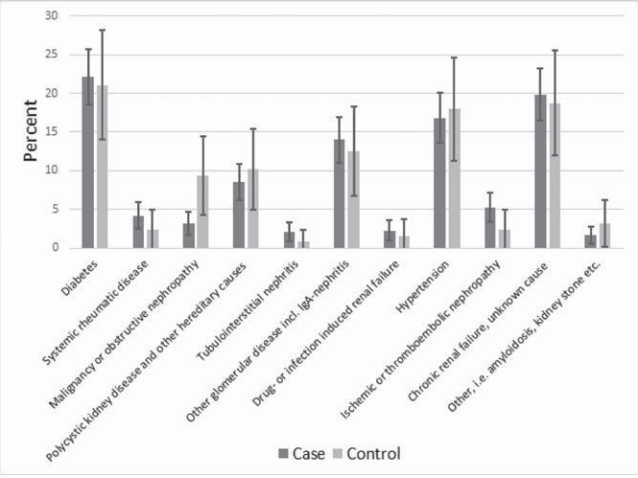

Figure 1.

Conclusion: In this study, including 48594 cases with gout, of which 529 developed ESRD, there was no apparent difference in the cause of ESRD compared to matched controls. This suggests similar pathophysiological mechanisms of ESRD development in patients with gout and the general population.

AB1036 IS HEMODIALYSIS ENOUGH TO CONTROL GOUT IN CHRONIC TERMINAL RENAL DEFICIENCY PATIENTS? A TEN YEARS RETROSPECTIVE STUDY

A. Hittinger[1], A. Steelandt[1], I. Kazes[2], P. Clavel[3], E. Canivet[3], P. Rieu[2], J. H. Salmon[1]. *[1]University Hospital of Reims, Rheumatology Unit, Reims, France; [2]University Hospital of Reims, Nephrology Unit, Reims, France; [3]Local Association for Home Dialysis Promotion (ARPDD), Dialysis Unit, Reims, France*

Background: Gout is the most common inflammatory rheumatism of industrials countries and chronic renal deficiency is one of the most usual risk factor(1). Uncontrolled gout can cause articular impairment but is also associated with a global and cardiovascular excess mortality, especially in dialysis population(2). International guidelines on gout management remain currently unclear for this particular population(3,4) and current literature data are contradictory on the effectiveness of hemodialysis alone in stemming gout flares.
Objectives: The objective of this study was to analyze the rate of gout flares, during 5 years on gouty patients who starts hemodialysis, treated or not by hypouricemic drugs.
Methods: We performed an observational, retrospective and multicentric study on gouty patients who started hemodialysis between 2005 and 2015 in two nephrology unit. We recorded demographic, clinical and therapeutic data at the start of hemodialysis and throughout 5 years of follow up. A gout flare was defined as presence of uric acid crystal in articular punction when it was performed, or clinical diagnosed as such with a colchicine prescription. The effectiveness of dialysis was measured by the KT/V ratio measured during gout flares and 3 times per year for each patient correlated with the serum uric acid level. According to the French legislation, no ethics committee approval was requested for such a retrospective survey. Survival analysis by Kaplan - Meier method and bivariate analysis have been performed to study gout flares and their association with clinical or biological factor.
Results: One hundred eighty two patients have been included, 98/182 (53, 8%) had long term hypouricemic treatment: 88/98 (89%) by allopurinol and 10/98 (11%) by febuxostat. Mean age at dialysis initiation was 68.6 years with a male/female sex ratio of 2.7:1. Sixty-four/182 patients (35.16%) presented at least one gout flare during the follow-up: 42 patients (65%) without hypouricemic treatment and 22 patients (45%) with hypouricemic treatment. Patients on hypouricemic treatment since hemodialysis beginning had significantly less gout flares compared to those without (p = 0.0009) **(graphic 1).** There was no significant KT/V ratios difference between the 2 populations at the time of gout flares. Hypouricemic treatment was a protective factor for the occurrence of gout attacks (HR: 0.42, 95% CI 0.25 – 0.71) (Table 1**).**

Table 1. Associated factor of gout flares after the beginning of hemodialysis on gouty patients

	HR	95% CI
Current or active smoking	0.92	0.46-1.86
Male	0.82	1.48-1.42
Caucasian ethnic	0.83	0.64-1.75
Hypouricemic treatment	**0.42**	**0.25-0.71**
High Blood Pressure	1.21	0.44-3.36
Obesity	0.84	0.47-1.51
Dyslipidemia	0.79	0.47-1.30
Diabetes	1.28	0.78-2.11
Cardiac failure	1.42	0.73-2.81

HR: Hazard Ratio; CI: Confidence interval

Conclusion: Therefore hypouricemic treatment at the initiation of hemodialysis seems to be a protective factor against gout flares, which may persist in dialysis patients. Prospectives studies should be performed to confirm these results for this particular gouty population.

AB1037 CRYSTAL DEPOSITS IN PRIMARY SYNOVIAL CHONDROMATOSIS

M. Bély[1], Á. Apáthy[2]. [1]*Hospital of the Order of the Brothers of Saint John of God in Budapest, Department of Pathology, Budapest, Hungary;* [2]*St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary*

Background: Primary synovial chondromatosis (**prSynCh**) is a metaplastic disorder of the synovial membrane, characterized by chondrocyte differentiation of synovial pluripotent stem cells, and chondroid tissue production. The **prSynCh** may be accompanied with amorphous calcium phosphate or carbonate deposition and bone formation, with or without true medullary spaces. The cause of stem cell differentiation is unknown; different irritative agents (infective, toxic, mechanic, etc.) are mentioned, but the condition may occur spontaneously as well [1, 2]. Crystal deposits as irritative agents of primary synovial chondromatosis due to a clinically latent metabolic disorder are not mentioned.
Objectives: The **aim** of this study was to determine the formal pathogenesis of synovial chondromatosis, and to detect crystal deposits in synovial membrane in order to explore the possible role of metabolic diseases in transformation of stem cells into chondrocytes, i.e., to demonstrate the metabolic origin of **prSynCh**.
Methods: Surgical specimens (synovial membranes of 14 knees, 4 hips and 2 elbows) of 20 patients (females 13. mean age of 50.17 years, range 40 – 74; males 7, mean age of 40.64 years, range 30 – 76years) with primary synovial chondromatosis were studied histologically. Cases of secondary synovial chondromatosis, i.e., due to osteoarthritis, rheumatoid arthritis, aseptic (avascular) bone necrosis, osteochondral traumatic injury, etc. were excluded. Serial sections (5 microns) of tissue samples were stained with **H-E**, **Alizarin red S** (specific for calcium), and **von Kossa**'s reaction (specific for phosphate and/or carbonate), and were compared with unstained sections according to **Bély** and **Apáthy** (2013). The non-staining technique is a very sensitive method to detect small crystals with weak birefringence viewed under polarized light [3-5].
Results: Chondromatosis (chondroid formation without osteoid or bone formation) was found in **8**, osteochondromatosis (chondroid with osteoid and bone formation) in **11**, and only bone formation in **1** of 20 patients. True medullary spaces accompanied bone formation in **8** of 12 cases. Different stages of chondroid and/or bone formation existed side by side in the same histologic section. In non-stained sections **HA** [$Ca_5(PO_4)_3(OH)$], **CPPD** [$Ca_2P_2O_7.2H_2O$] crystals, and/or unidentified crystal fragments were detected in all cases. Amorphous calcium phosphate and/or carbonate deposits were present in 12 of 20 patients.
Conclusion: The formal pathogenesis of primary synovial chondromatosis corresponded to the descriptions of the pertinent literature characterized by clean chondromatosis, mixed osteochondromatosis, and pure osteomatosis. We assume that the pre chondromatous phase of **prSynCh** starts with hydroxyapatite (**HA**) crystal deposition with or without calcium pyrophosphate dihydrate (**CPPD**) deposits, and the **prSynCh** may be regarded essentially a metabolic disease, like chondrocalcinosis or apatite rheumatism. The difference between these diseases is only in the prevalence and amount of **HA** and/or **CPPD** crystals, accompanied with or without amorphous calcium phosphate and/or carbonate deposits. In our opinion the chondrocalcinosis, apatite rheumatisms and **prSynCh** represent the same group of metabolic diseases.

AB1038 PEGLOTICASE URATE-LOWERING RESPONSE FOLLOWING COVID-RELATED GAP IN THERAPY: EXPERIENCES OF ONE RHEUMATOLOGIST

D. Mandel[1], P. Scott[1], B. Lamoreaux[2]. [1]*David R. Mandel, M.D. Rheumatology & Osteoporosis, Rheumatology, Mayfield Villiage, United States of America;* [2]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: When uncontrolled gout cannot be managed with oral urate-lowering therapies, pegloticase is one of the few remaining treatment options. Patients receiving infusion therapies experienced treatment interruptions due to the COVID-19 pandemic. As with other biologic therapies, patients can develop anti-drug antibodies (ADAs) against pegloticase, and longer infusion intervals can result in higher rates of pegloticase immunogenicity.[1] The literature suggests that co-administering an immunomodulator with pegloticase can markedly decrease the proportion of patients who develop ADAs,[2] increasing the proportion with sustained urate-lowering response.[3]
Objectives: This case series reports one rheumatologists' experience with a gap in pegloticase therapy during the COVID-19 pandemic.
Methods: Uncontrolled gout patients who underwent pegloticase treatment during 2019/2020 and had a gap in therapy of ≥28 days were identified. Patient, clinical, and treatment (number post-gap infusions, immunomodulation co-therapy) characteristics were retrospectively examined, along with urate-lowering response following therapy interruption. Patients who had a serum urate (SU) <6 mg/dL after the last post-gap pegloticase infusion were considered to have recaptured response.
Results: 7 patients (5 men, 64.3±13.5 years, pretherapy sUA: 7.76±2.47 mg/dL, 6 had tophi) were included with 2 remaining on therapy at data collection. Eleven gaps were noted with an average gap duration of 11.4±9.3 weeks (median: 9 weeks). For the last gap in therapy, patients received 13.9±7.0 infusions (range: 4-22) before the gap and 7.0±4.1 infusions (range: 2-14) after (Figure 1). Four patients (57%; Patients 1, 2, 5, 7) had recaptured urate-lowering at last pegloticase infusion, all of whom began immunomodulation (3 methotrexate, 1 mycophenolate mofetil/hydroxychloroquine) prior to resuming pegloticase. Of the 3 patients without response recapture, 2 initiated MTX after resuming pegloticase. 4 patients (57%) experienced ≥1 AE, including mild infusion reaction (n=1), acute gout flare (n=2), clinically meaningful decrease in eGFR (14.8 ml/min/1.73m^2, n=1), heart attack (n=1), and anemia (n=1).
Conclusion: These cases suggest that it may be possible to recapture urate-lowering response to pegloticase in some patients, particularly in the presence of immunomodulation. These preliminary findings are important to this vulnerable patient population, particularly during the COVID-19 pandemic. Further study is needed to confirm our findings.

AB1039 PATIENT REPORTED OUTCOMES AMONG PATIENTS RECEIVING TREATMENT FROM THE PEGLOTICASE PHASE 3 CLINICAL TRIALS FOR UNCONTROLLED GOUT

J. Sparks[1], K. Obermeyer[2], B. Lamoreaux[3]. [1]*Columbia University, Mailman School of Public Health, New York, United States of America;* [2]*Horizon Therapeutics plc, Biostatistics, Deerfield, United States of America;* [3]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Gout affects more than 9 million Americans,[1] with some suffering so severely that everyday life becomes painful and difficult.[2] Pegloticase is an infused uricase-based medicine that significantly reduces serum uric acid (sUA) levels in patients suffering from treatment-resistant gout,[3] but the direct effect of treatment on quality of life (QoL) by response status has not yet been reported.[4]

Objectives: To determine if the effect of pegloticase treatment on QoL and other patient-reported outcomes is significant compared to placebo, regardless of treatment response status.

Methods: This analysis utilized results from two parallel 6-month randomized phase 3 registrational clinical trials in which subjects were treated with 8 mg of pegloticase or placebo biweekly. Responders were those who maintained sUA levels <6 mg/dL for ≥80% of the time during Months 3 and 6 combined. Multiple QoL measurements were taken throughout the 6-month treatment period, including the Health Assessment Questionnaire (HAQ; Pain, Disability Index [DI], and Health), the 36-Item Short Form Health Survey Questionnaire (SF-36), and the number of swollen and/or tender joints. This analysis assessed the differences between three groups: treatment responders, treatment non-responders, and placebo-treated patients. The change from baseline to Week 25 in each assessment was analyzed using a mixed model for repeated measures adjusting for age, visit, presence of tophi at baseline, and the interaction between visit and group.

Results: A total of 36, 49, and 43 patients were included in the treatment responder, treatment non-responder, and placebo-treated groups, respectively. Significant differences in the change from baseline to Week 25 in HAQ-Pain, HAQ-DI, HAQ-Health, and SF-36 Physical Component Score (PCS) between treatment responders and placebo-treated patients were observed (all $P \leq 0.006$, Figure 1). The reduction in the number of swollen or tender joints was also significantly greater in treatment responders compared to placebo-treated patients ($P < 0.001$). Between treatment responders and treatment non-responders, there were no significant differences in the change from baseline in HAQ-Pain, HAQ-DI, HAQ-Health, and SF-36 PCS. Significant differences were observed between treatment non-responders and placebo-treated patients in the change in HAQ-Pain, HAQ-DI, HAQ-Health, and SF-36 PCS (all $P \leq 0.003$), as well as the number of swollen or tender joints ($P = 0.049$, Figure 1). The change in SF-36 Mental Component Score was not significantly different between any of the 3 groups examined.

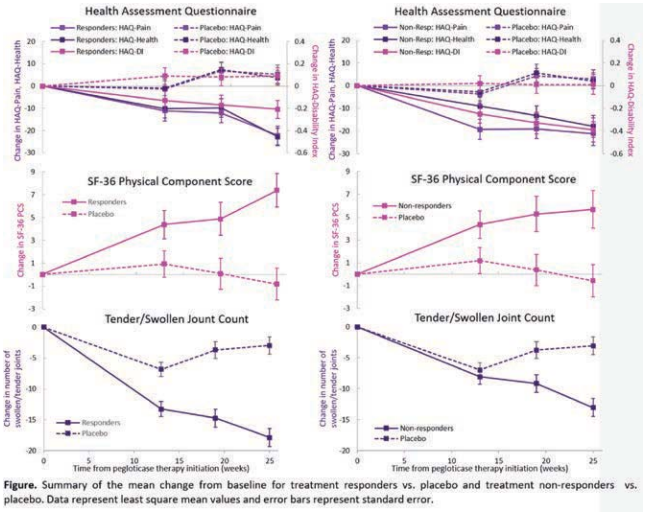

Figure. Summary of the mean change from baseline for treatment responders vs. placebo and treatment non-responders vs. placebo. Data represent least square mean values and error bars represent standard error.

Conclusion: In the Phase 3 registration trials of pegloticase used as monotherapy for uncontrolled gout, QoL parameters improved among pegloticase-treated patients regardless of response status.

AB1040 ASSOCIATION OF Q141K POLYMORPHISM OF ABCG2 GENE WITH THE EFFECTIVENESS OF URATE-LOWERING THERAPY IN PATIENTS WITH GOUT (PILOT STUDY)

M. Eliseev[1], M. Chikina[1], O. Sheliabina[1], E. Cheremushkina[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation*

Background: The effectiveness of allopurinol in pts with gout depends on genetic factors (GF) [1]. How GF works on probability of the target serum uric acid (sUA) level achievement is not studied.

Objectives: To study the opportunity of the target sUA level achievement in pts with gout while taking allopurinol or febuxostat, depending on the polymorphism (rs2231142) of the *ABCG2* gene.

Methods: The study included 82 pts with gout aged ≥18 yrs who did not take urate-lowering drugs (ULD) and had sUA level >360 μmol/l. Initially all patients were prescribed allopurinol 100 mg/day, than the dose was up-titrared to achieve the target sUA level (<360 μmol/l or <300 μmol/l in pts with chronic tophaceous gout). Maximum dosage was 900 mg/day; in pts with glomerular filtration rate (GFR) <60 ml/min/1.73 m^2 - 300 mg/day. Pts who did not achieve the target sUA level while using allopurinol were prescribed febuxostat 80 mg/day, which, if necessary, was increased to 120 mg/day. Each patient was followed up until the target sUA level was achieved. All pts underwent genotyping of the C>A (rs2231142) polymorphism of the *ABCG2* gene. During the study we compared: the probability of achieving the target sUA level, the average values of the sUA level decline, the average doses of ULD in pts with different genotypes (CC, CA, AA) of the *ABCG2* gene. Statistical analysis was carried out using the Statistica 12.0 software package, and descriptive statistics methods.

Results: The target sUA level was defined as <300 μmol/l in 45 (55%) of 82 pts, as <360 μmol/l in 37 (45%) pts. In 26 pts, the dose of allopurinol did not exceed 300 mg/day. In 28 (34%) pts on allopurinol therapy, the target level of sUA was achived. In 54 (66%) pts allopurinol was replaced with febuxostat, while in 22 (41%) of them, the level of sUA decreased and was below the target. The CC genotype of the *ABCG2* gene was found in 51 (62%) pts, the CA genotype in 30 (37%) pts, and the minor AA genotype in 1 (1%) pt. The opportunity of the target sUA level achievement during the allopurinol therapy in carriers of the

homozygous CC genotype and CA or AA genotypes did not differ: 17 (33%) and 11 (35%) cases, respectively. It turned out that CA and AA pts required a significantly higher dose of allopurinol (365±102 mg/day) than CC pts (290±85 mg/day), p=0.002. Of 54 pts treated with febuxostat who did not achieve the target sUA level, 30 (56%) pts had the CC genotype and 24 (44%) pts had the CA genotype. The opportunity of the target sUA level achievement was comparable (p=0.22).

Conclusion: The opportunity of achieving the target sUA level in pts with gout taking allopurinol is not associated with the C>A polymorphism of the *ABCG2* gene, but the presence of the CA and AA genotypes is associated with the need to prescribe large doses of allopurinol.

AB1041 REAL-WORLD REPORTING OF GOUT FLARES IN UNCONTROLLED GOUT PATIENTS CO-TREATED WITH PEGLOTICASE AND METHOTREXATE

J. Albert[1], L. Padnick-Silver[2], B. Lamoreaux[2]. [1]*Rheumatic Disease Center, Rheumatology, Milwaukee, United States of America;* [2]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Acute gout flares are a known result of urate-lowering in gout patients[1] and are the most common adverse event in patients treated with pegloticase.[2] Fortunately, the proportion of pegloticase-treated patients who experience flares and the number of flares/patient decrease over time.[3] Though well-studied in the clinical trial setting, little has been published on the rate of acute gout flares during pegloticase therapy in a real-world, rheumatology setting. This retrospective study examined one community practice's findings on gout flares in uncontrolled gout patients co-treated with pegloticase and methotrexate.

Objectives: This retrospective chart review examined acute gout flare occurrence and characteristics in patients undergoing pegloticase-methotrexate co-therapy. Patients with and without gout flares were also compared to investigate potential factors that may have influenced gout flare.

Methods: All patients who underwent pegloticase plus methotrexate co-therapy between January 2017 and March 2021 at a community rheumatology practice were included. Patient, treatment, and flare characteristics were extracted from the medical record and compiled into a de-identified data set.

Results: 29 patients treated with pegloticase and methotrexate (28 subcutaneous, 1 oral) were included. Mean patient age was 59.9±17.0 years and 79% were male. Gout duration was 11.7±10.8 years, pre-therapy serum uric acid (sUA) averaged 9.4±1.8 mg/dL, and 97% had visible tophi. Patients had received 12.8±14.3 pegloticase infusions over 25.1±9.7 weeks, with pre-infusion sUA<6 mg/dL in 27/29 patients (93%) at last pegloticase dosing. 23 gout flares were noted in 12 patients (41%, 1.9±1.8 flares/patient), 59% of which were noted as severe and 50% involved a single joint. Acute gout flare was most common in the first 4 weeks of therapy, with first flare occurring a mean of 3.4±2.1 weeks after first pegloticase infusion. Demographic and treatment characteristics were similar between flaring and non-flaring patients. However, patients with ≥1 flare were older (65.8±15.4 years vs. 55.6±17.8 years), more often obese (83% vs. 47%), and had an overall higher comorbidity burden.

Conclusion: This retrospective study of real-world pegloticase use suggests that gout flare rates may be lower in a real-world setting (41%) than that reported in clinical trials (76–86%[2,3]), which have different gout flare criteria. Consistent with clinical trials,[2,3] flare rate was highest during the first 4 weeks of pegloticase treatment, progressively decreasing over time. Interestingly, these data suggest that patients who experience gout flares on pegloticase may have more obesity and a higher comorbidity burden than those who do not experience flares. Further examination of gout flares during real-world pegloticase use is warranted.

AB1042 PEGLOTICASE USE IN RENAL TRANSPLANT RECIPIENTS WITH GOUT: AN INSURANCE CLAIMS STUDY

C. Shadur[1], B. Marder[2], C. Vesel[3], B. Lamoreaux[4]. [1]*Iowa Kidney Physicians, Nephrology, Des Moines, United States of America;* [2]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America;* [3]*Horizon Therapeutics plc, Data Science, Deerfield, United States of America;* [4]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Kidney transplant (KT) recipients have a high gout incidence due to reduced eGFR and medication use associated with hyperuricemia.[1] Oral urate-lowering therapies in KT patients are further limited by residual chronic kidney disease and potential drug-drug interactions. Pegloticase rapidly lowers serum urate in uncontrolled gout patients,[2-3] but efficacy for monotherapy is limited in ≥50% of treated patients by anti-drug antibodies that cause loss of urate-lowering effect and can lead to infusion reactions in some patients.[4-5] Anti-rejection medications are ubiquitously used after organ transplantation and are known to reduce the development of anti-drug antibodies,[6] but published data of pegloticase use in KT recipients is limited.

Objectives: This claims-based analysis examined real-world pegloticase use in KT patients to determine the number of administered infusions compared to non-transplanted patients.

Methods: Patients in the IQVIA database (2015-2020) who had ≥1 CPT or ICD9/10 code for KT and ≥1 pegloticase claim following KT were identified. Patients who returned to dialysis due to graft failure/rejection prior to pegloticase use were excluded. Patient characteristics and pegloticase therapy parameters were examined.

Results: 91 KT recipients with pegloticase use were identified. Of 85 patients with demographics, 81% were male, mean(±SD) age at first transplant was 55.0±10.7 years, and 67% had tophaceous gout. The most common comorbidities were hypertension (84%), hyperlipidemia (48%), anemia (46%), type 2 diabetes (40%), and heart failure (34%). First transplant and gout codes occurred 2.6±1.7 and 2.1±1.7 years, respectively, before first pegloticase claim. Among 67 patients with medication codes, immunosuppressive medications used <3 months before and/or during pegloticase included tacrolimus (51%), mycophenolate mofetil (49%), and/or cyclosporine (37%). Patients received 13±16 pegloticase infusions (median: 8 [Q1, Q3: 4, 15]), with 38% receiving ≥12 and 20% receiving ≥20 infusions.

Conclusion: This study showed a higher median number of pegloticase infusions than reported in prior claims-based studies of non-KT patients.[7] Real world data from KT patients support the hypothesis that transplant immunosuppression may allow more patients to receive a longer course of pegloticase therapy, presumably via anti-drug antibody attenuation. This is of particular importance for this vulnerable patient group that is at a high risk for developing uncontrolled gout.

AB1043 IDENTIFICATION OF UNUSUAL TOPHI ANTERIOR TO THE THYROID CARTILAGE USING DIFFERENT IMAGING METHODS

Y. Jiang[1], X. Wu[1], Z. Liao[1], J. Qi[1], J. Gu[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Inadequately treated gout patients could develop tophi. However, tophi could appear as atypical mass, leading to difficulty in differential diagnosis.

Objectives: The objectives of the study were to describe an unusual case with tophi anterior to the Thyroid Cartilage using different imaging methods.

Methods: Clinical information of the case was presented. Ultrasound, dual energy Computed Tomography (DECT) and CT scan were compared to describe the tophi.

Results: A 66-year-old man with a 30-year history of gout was admitted. He had received urate-lowering drugs intermittently over the past few years. Physical examination revealed multiple tophi on the hands, feet, and other auricular surfaces. Moreover, there was a subcutaneous mass above the thyroid cartilage (Figure 1A). Ultrasound revealed hyperechoic nodule anterior to the thyroid cartilage, 11*7cm in size, with uneven internal echo, no blood flow signal inside, and a close relationship between the barrier of the nodule and the thyroid cartilage (Figure 1B). DECT of the neck confirmed that the mass anterior to the thyroid cartilage were tophi (Figure 1C-D). A plain radiographic evaluation demonstrated

soft-tissue swellings and para-articular erosions involving hands (Figure 1E-F). The serum creatinine and uric acid levels were elevated as follows, creatinine, 562 µmol per liter (normal range, 31.8 to 116); and uric acid, 621 µmol per liter (normal range, 90 to 420).

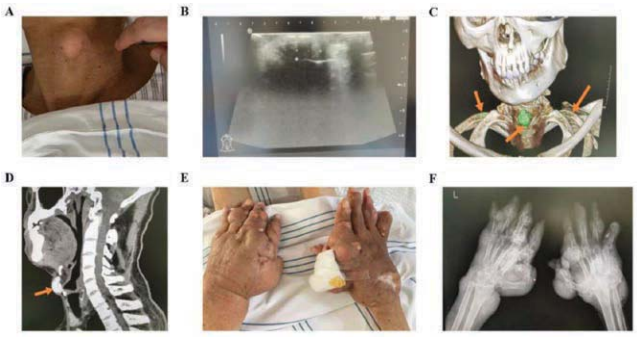

Figure 1. Tophi detected by different imaging methods. A.A picture of the mass anterior to the thyroid cartilage; B. A mass anterior to the thyroid cartilage detected by ultrasound; C. The mass anterior to the thyroid cartilage detected by dual energy CT; D. The mass anterior to the thyroid cartilage detected by CT scan; E. a picture of tophi in the hands; F. a plain radiograph of tophi in the hands.

Conclusion: DECT has more advantages over ultrasound and CT for detection of atypical tophi in gout patients.

AB1044 RISK FACTORS OF DIABETES MELLITUS IN PATIENTS WITH GOUT (RESULTS OF A PROSPECTIVE STUDY)

O. Sheliabina[1], M. Eliseev[1], S. Glukhova[2]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation; [2]VA Nasonova Research Institute of Rheumatology, Laboratory Axial Spondyloarthritis, Moscow, Russian Federation*

Background: It is assumed that the risk of developing diabetes mellitus (DM) is due not only to generally accepted risk factors (RF), but also to RF related to gout.
Objectives: To evaluate the influence of various RF for DM in pts with gout.
Methods: 444 pts aged ≥18 years with a crystal-verified diagnosis of gout without DM were included in the study. The average duration of observation was 5.66 [2.69; 7.4] yrs. To identify the RF associated with developing of DM in patients with gout, multivariate logistic regression was used. There were included: gender; DM in relatives; insufficient physical activity; unbalanced diet; age ≥45 yrs; ≥ 4 exacerbation of arthritis per yr; presence of tophi; BMI ≥ 30 kg/m^2; presence of hypertension; allopurinol, febuxostat, GC, diuretics, metformin or colchicine intake; GFR <60 ml/min/1.73 m^2; serum uric acid (sUA) level ≥420 µmol/l; UA ≥480 µmol/l. Statistica 12.0 package was used for statistical data processing.
Results: DM was developed in 108 (24.3%) pts. Pts who developed DM were older than those who did not develop (52.84±10.96 vs 49.72±11.95 respectively, p=0.02); they were more likely to have heredity for DM of the first and second kinship lines (49.1% vs 25.6% respectively, p=0.0001); they took antihypertensive drugs more often (73.1% vs 50.5%, p=0.0001), also diuretics (27.7% vs 14.8%, p =0.003) and GC (47.2% vs 36.4%, p=0.047). There were more pts with subcutaneous tophi (59.3% vs 29.9%, p=0.001), those who had ≥ 4 attacks of arthritis per yr (67.6% vs 31.6%, p=0.001), sUA ≥480 µmol/l (71.3% vs 50.8%, p=0.0002), sUA≥600 µmol/l (34.3% vs 11.8%, p=0.0002). According to a multivariable logistic regression, the risk of DM is increased in case of: ≥ 4 arthritis attacks per yr (odds ratio [OR] 5.231, 95% confidence interval [CI] 2.978-9.187, p=0.0001); presence of subcutaneous tophi (OR 2.609, 95% CI 1.500-4.537, p=0.001); sUA level ≥480 µmol/l (OR 2.261, 95% CI 1.022-5.004, p=0.144); hypertension (OR 2.577, 95% CI 1.348-4.926, p=0.004); taking diuretics (OR 2.353, 95% CI 1.193-4.64, p=0.014). The risk of developing DM was reduced by taking febuxostat (OR 0.309, 95% CI 0.113-0.844, p=0.022) and metformin (OR 0.49 (95% CI 0.21; 1.16), p=0.107).
Conclusion: The risk of developing DM in pts with gout is associated with the frequency of arthritis attacks, sUA level ≥480 µmol/l, hypertension and diuretics intake. Therapy with febuxostat or metformin is associated with descended risk of DM.

AB1045 QUALITY OF LIFE IN PATIENTS WITH GOUT TAKING URATE-LOWERING DRUGS, DEPENDING ON THE ACHIEVEMENT OF THE TARGET LEVEL OF SERUM URIC ACID

M. Chikina[1], O. Sheliabina[1], M. Eliseev[1]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation*

Background: Intake of urate-lowering drugs (ULD) leads to an improvement in the quality of life (QoL) in pts with gout. However, it is not clear to what extend the QoL is changed in pts who did not achieve the target level of serum uric acid (sUA).
Objectives: to evaluate the dynamics of the QoL in pts, taking ULD, who have achieved and have not achieved the target sUA level.
Methods: 98 pts with gout were included in the prospective study. The follow-up period was 24 months, allopurinol or febuxostat at doses sufficient to achieve the target sUA level (<360 µmol/l) were used. The maximum daily dose of allopurinol was 900 mg/day, febuxostat - 120 mg/day. Pts who did not achieve the target sUA level continued taking ULD at the maximum dosages. The values of the Qol in dynamics were calculated using the SF-36v2 questionnaire. The assessment of the QoL was carried out separately in pts who achieved and did not achieve the target level of sUA. The frequency of exacerbations of arthritis was also assessed. Statistica 12.0 package was used for statistical data processing.
Results: 69 of 98 (70%) pts achieved the target sUA level, wherein allopurinol was taken by 46 pts, febuxostat – 34 pts. Pts who achieved the target level of sUA after 6 mo. of ULD usage, demonstrated a significant improvement in the physical health (PH), including physical functioning (PF), role limitations due to physical functioning (RP), general health (GH), as well as vitality (VT) (p<0.05 for all). After 12 and 24 mo. improvement was achieved in RH, GH and PF (p<0.01), RP, bodily pain intensity (BP) and VT (p<0.05). General mental health (MH), role-emotional functioning (RE) and social functioning (SF) were unchanged throughout the study. Pts who did not achieve the target sUA level after 6 and 12 mo. significantly improved: PF, RP (p<0.05 for all). After 24 months, for all QoL parameters, the values did not differ from the initial ones. The frequency of arthritis exacerbation in pts who achieved the target sUA level decreased from 3.1±1.6 cases per year to 0.9±1.1 cases per year (p=0.0013); in those who did not achieve - from 3.1±1.9 cases per year to 2.4±1.6 cases per year (p=0.047).
Conclusion: : The QoL in gout pts who achieved target sUA level continues to improve during the first year of ULD intake. Even if the target sUA level is not achieved, the QoL of patients with gout treated with ULD remains stable for at least 2 years of therapy. This predetermines the need to use maximum daily doses of ULD, even if the target serum UA level is not achieved.

AB1046 EFFICACY OF FEBUXOSTAT IN PATIENTS WITH GOUT STRATIFIED BY BASELINE RENAL FUNCTION

M. Eliseev[1], O. Sheliabina[1], M. Chikina[1]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation*

Background: The opportunity of achievement of the target serum UA (sUA) level in pts with gout, stratified by renal function, is not studied.
Objectives: To compare the probability of the sUA level achievement during therapy with febuxostat in patients with gout, stratified according to renal function.
Methods: The prospective study included 136 pts aged ≥18 years with a crystal-verified diagnosis of gout and sUA level >360 µmol/L who had never taken febuxostat or other urate-lowering drugs (at least 2 weeks before the start of the study). All pts were prescribed febuxostat 80 mg/day; if the target sUA level (<360 µmol/l) was not achieved, the dose was increased to 120 mg/day. Prophylactic anti-inflammatory drugs (AIDs) were taken: colchicine in 59 (43.4%) pts, NSAIDs - 51 (37.58%) pts, GC - 12 (98.8%) pts. 14 (10.3%) pts did not take AIDs. Laboratory tests (serum levels of glucose, creatinine, UA) before and after 26 weeks of therapy were collected. GFR was calculated using CKD-EPI formula before and after therapy. The pts were initially divided into groups depending on the CKD stages according to the level of GFR (CKD-EPI): C1 – normal or high renal function (>90 ml/min/1.73 m^2), C2 – mildly decreased (60-89 ml/min/1.73 m^2), C3 - moderately decreased (30-59 ml/min/1.73 m^2), C4 – severely decreased (15-29 ml/min/1.73 m^2). The observation period covered at least 26 weeks, the primary end point was the achievement of the target sUA level. The dynamics of GFR was also assessed. Statistica 12.0 package was used for statistical data processing.
Results: It was found that 30 (22.12%) pts had CKD stage 0-1, 28 (66-20.6%) pts - C2, 62 (45.6%) pts – C3, 16 (11.8%) – C4. 98 (72.1%) pts received febuxostat 80 mg/day, 38 (27.9%) pts - 120 mg/day. Pts with CKD C4 were older than ones with CKD C2 (p=0.00001) and CKD C0-1 (p=0.002); had a longer duration

Table 1. Levels of UA, eGFR in patients with gout, stratified by the level of eGFR at baseline and after 26 weeks of febuxostat therapy.

Parameters	All patients, n=136	CKD C0-1, n=30	CKD C2, n=28	CKD C3, n=62	CKD C4, n=16
UA baseline, μmol/l	472,4±99,3	451,9±102,8	486,9±103,8	476,9±86,7	468,3±109,8
UA after 26 weeks, μmol/l	306,27±104,4	298,6±104,8*	282,2±95,8*	318,9±97,6*	313,5±106,9*
Δ UA, μmol/l	166±10,2	153,3±10,7	204,7±12,4	157,9±17,8	154,8±14,9
UA<360 μmol/l, n (%)	117 (84)	25 (83)	25 (89)	51 (82)	13 (81)
GFR baseline, ml/min/1.73 m^2	63,98±15,3	101,3±18,1	75,9±9,7	50,2±5,5	26,5±2,6
GFR after 26 weeks, ml/min/1.73 m^2	64,74±26,9	102,8±28,6*	76,7±9,3	50,9±6,9	27,3±4,9

* - p<0.05 between baseline and 26 weeks

of gout (p=0.003); they were more likely to have subcutaneous tophi than pts with CKD C2 (p=0.007). The frequency of diagnosing DM, hypertension, as well as the sUA level in the groups did not differ. The levels of sUA, GFR in patients with gout, stratified by the level of GFR at baseline and after 26 weeks of febuxostat therapy, are given below (Table 1). The target sUA level was achieved in 33 (87%) patients with DM (the probability did not depend on the initial GFR value). Achievement of target sUA level was registered in 84% of general sample: in 83% of pts with CKD C0-1, 89% - CKD C2, 82% - CKD C3, 81% of pts with CKD C4. Mean GFR values increased in all groups, but significant differences registered in patients with CKD C0-1 (p=0.002) only.

Conclusion: The ability to achieve the target sUA level while taking febuxostat in patients with gout does not depend on renal function, exceeding 80% in patients with CKD C4. The drug is well tolerated regardless of renal function.

AB1047 EFFECT OF THERAPY ON SUBCLINICAL CAROTID ATHEROSCLEROSIS IN PATIENTS WITH CALCIUM PYROPHOSPHATE DEPOSITION DISEASE (PILOT STUDY)

M. Eliseev[1], O. Sheliabina[1], M. Chikina[1], E. Markelova[2], I. Kirillova[3]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation; [2]MV Vladimirsky Moscow Regional Research Clinical Institute, Cardiology, Moscow, Russian Federation; [3]VA Nasonova Research Institute of Rheumatology, Specialized Medical Care, Moscow, Russian Federation*

Background: Supposedly, anti-inflammatory therapy in calcium pyrophosphate deposition disease (CPPD) pts may reduce the progression of atherosclerosis.

Objectives: Assessment of the dynamics of atherosclerosis development based on changes of carotid artery intima-media thickness (caIMT) in pts with CPPD receiving anti-inflammatory therapy (colchicine, methotrexate, hydroxychloroquine).

Methods: The prospective study included 26 pts aged ≥18 years with a crystal-verified diagnosis of CPPD and osteoarthritis (OA). Exclusion criteria were age >65 years, presence of cardiovascular disease, carotid artery (CA) atherosclerosis according to ultrasound results, high or very high SCORE (Systematic Coronary Risk Evaluation) index. The examination included anthropometric parameters, information about the affected joints and the time of onset of symptoms. Laboratory tests included determination of the following in blood serum: hs-CRP, lipid levels; SCORE index was calculated for all pts; CA Doppler ultrasonography (DU) was performed using the Esaote MyLab Twice ultrasound system (Italy). The manifestation of subclinical atherosclerosis was diagnosed in case of caIMT increase >0.9 mm. The criteria for the presence of an atherosclerotic plaque in the CA was a local caIMT increase of more than 50% compared to the surrounding areas or an caIMT increase >1.3 mm. CaIMT was measured at the first visit, then, pts with CPPD were administered methotrexate 15 mg/week or hydroxychloroquine 200 mg/day or colchicine 0.5 mg twice daily. Pts could take NSAIDs to relieve pain. After 26-28 weeks, a second examination was carried out. Statistica 12.0 package was used for statistical data processing.

Results: The baseline values of caIMT in pts with CPPD and OA did not differ. 22 pts with CPPD and 19 with OA were examined in dynamics. Baseline caIMT >0.9 mm was detected in 11 of 22 (50%) pts with CPPD and in 8 of 19 (42%) pts with OA (p=0.39). CaIMT >0.9 mm was associated with an increase in hs-CRP levels >0.2 mg/l in 8 pts with CPPD. 9 of 19 (47%) pts with OA demonstrated an increase in caIMT averages, the values in other pts remained unchanged. By the end of the study, 14 of 22 (64%) pts with CPPD had a decrease in the average values of caIMT, in 2 (9%) pts - an increase, in 6 pts the average values of caIMT did not change. 7 of 11 pts with CPPD showed normalization of caIMT, 5 of them (45.5%) had a decrease in serum hs-CRP <2 mg/l. A decrease in the number of pts with CPPD and caIMT >0.9 mm from 11 (42%) to 4 (18%) pts was found. At the same time, in 8 pts with CPPD the serum hs-CRP level significantly decreased: baseline 6.02 [0.69; 6.4] mg/l vs at the end of study period 1.71 [0.78; 2.25] mg/l, p=0.043. Pts with OA demonstrated the constant level: baseline 2.13[0.22; 2.8] mg/l vs at th end of study period 3.06 [0.39; 6.38] mg/l, p=0.627. A decrease in mean values of caIMT was noted in 5 of 6 (83%) pts took hydroxychloroquine, in 6 of 9 (67%) pts took colchicine, in 4 of 7 (57%) pts – methotrexate.

Conclusion: Therapy with colchicine, methotrexate and hydroxychloroquine in pts with CPPD leads to regression of early signs of atherosclerosis. This result can be achieved by suppressing chronic inflammation.

AB1048 ESTIMATED GLOMERULAR FILTRATION RATE CHANGES IN UNCONTROLLED GOUT PATIENTS CO-TREATED WITH PEGLOTICASE AND METHOTREXATE: A RETROSPECTIVE CASE SERIES

J. Albert[1], A. Broadwell[2], K. Masri[3], L. Padnick-Silver[4], B. Lamoreaux[4]. *[1]Rheumatic Disease Center, Rheumatology, Milwaukee, United States of America; [2]Rheumatology and Osteoporosis Specialists, Rheumatology, Shreveport, United States of America; [3]Bon Secours Rheumatology Center, Rheumatology, Richmond, United States of America; [4]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Gout patients are at increased risk for developing chronic kidney disease (CKD)[1] and hyperuricemia is an independent risk factor for CKD worsening,[2,3] particularly in women.[3] As a result, renal function is of concern in uncontrolled gout patients. Pegloticase, a recombinant PEGylated uricase, can rapidly decrease serum uric acid levels (sUA) in uncontrolled gout patients, but with pegloticase monotherapy <50% have sustained urate-lowering during Month 6 of treatment.[4] Pegloticase treatment response rate is markedly higher when immunomodulating therapies such as methotrexate (MTX) are co-administered,[5,6] but MTX use can be limited by renal impairment. Clinical trials excluded CKD patients, but real-world published cases of immunomodulation-pegloticase co-therapy have included patients with a pre-therapy eGFR <60 ml/min/1.73 m^2.

Objectives: This study examined pooled case data from prior studies, focusing on renal function changes during MTX-pegloticase co-treatment in patients with and without pre-therapy CKD.

Methods: This retrospective study examined deidentified case data collected for prior retrospective studies.[7-9] All patients who underwent MTX-pegloticase co-therapy were included and categorized as CKD (baseline eGFR <60 ml/min/1.73 m^2) or non-CKD (baseline eGFR ≥60 ml/min/1.73 m^2). sUA, renal function, blood cell counts, and liver function were closely monitored during therapy. Patient characteristics, pegloticase treatment parameters, proportion of treatment responders (≥12 infusions received and sUA <6 mg/dL at infusion 12 [ongoing patients with <12 infusions excluded]), renal function changes (eGFR, CKD stage), and adverse events were examined.

Results: 15 uncontrolled gout patients with CKD (9 stage 3a, 4 stage 3b, 2 stage 4; pre-therapy mean[±SD] eGFR: 43.2±11.3 ml/min/1.73 m^2, sUA: 8.5±2.2 mg/dL) and 27 without CKD (pre-therapy eGFR: 82.9±19.0 ml/min/1.73 m^2; sUA: 9.5±1.7 mg/dL) were included. Patient characteristics and comorbidity profiles were similar, but CKD patients were older (72.0±9.9 vs. 52.3±14.3 yrs) and more often female (33% vs. 7%). On average, MTX was initiated ~4 wks before pegloticase in both CKD status groups. MTX dose was lower in CKD patients (14.8±5.8 vs. 19.3±4.9 mg/wk). Pegloticase treatment was similar between groups (CKD: 14.7±8.1 infusions over 28.5±17.1 wks, non-CKD: 14.1±7.1 infusions over 27.9±15.1 wks), with similar urate-lowering response rate (92% vs. 86%). eGFR increased during therapy in 60% and 44% of CKD and non-CKD patients, respectively, with mean eGFR increase of 11.5±20.9 and 4.2±15.0 ml/min/1.73m^2, respectively. In the CKD group, CKD stage either improved or was stable in 13/15 patients (87%). The 2 patients with CKD progression both moved from stage 3a to 3b, and both stage 4 CKD patients had an eGFR increase, improving to stage 3a. In the non-CKD group, 3 patients developed stage 3 CKD (2 stage 3a, 1 stage 3b). 7/15 (47%) CKD and 13/27 (48%) non-CKD patients had ≥1 AE noted, with gout flare most reported (47% vs. 41%). A mild infusion reaction and pancytopenia occurred in 1 non-CKD patient each.

Conclusion: In this retrospective real-world review of a limited number of cases, MTX-pegloticase co-therapy resulted in sustained sUA lowering in uncontrolled gout patients with and without CKD. Close monitoring of renal function indicated stability or improvement during therapy in 86% of uncontrolled gout patients with CKD. Further study is needed to better understand therapy tolerance and treatment response rates of uncontrolled gout patients with CKD undergoing MTX-pegloticase co-therapy.

AB1049 PECULIARITIES AND COMPARISON OF 24-HOUR BLOOD PRESSURE MONITORING IN PATIENTS WITH GOUT AND OTHER FORMS OF ARTHRITIS

E. Mikhnevich[1], D. Homets[2], S. Lemiasheuskaja[3]. *[1]Belarusian State Medical University, Internal Diseases, Minsk, Belarus; [2]City Hospital Minsk, Rheumatology, Minsk, Belarus; [3]Belarusian State Medical University, Internal Diseases, Minsk, Belarus*

Background: The leading cause of death in patients with gout is cardiovascular diseases (CVD), with the mortality rate being higher as compared to that in the general population. Hypertension (HT) occurring early with gout is considered among other reasons. Current studies demonstrate a number of features of HT in gout (in contrast to patients with essential HT), which determine an unfavourable prognosis for gout.

Objectives: To compare the indicators of 24-hour blood pressure monitoring (24hBPM) in patients with gout and these in a group of patients with other forms of arthritis, as well as in the group of patients with essential HT.

Methods: The retrospective study included 162 patients hospitalized at the Rheumatology Department of the City Clinical Hospital № 11 (Minsk) from 2014 to 2021. The study group 1 (n=90) consisted of patients with gout (AKP, 1977). The comparison group 2 (n=39) included patients with other forms of arthritis different from gouty (rheumatoid arthritis – 25.6%, osteoarthritis – 60.7%, reactive arthritis – 13.7%); group 3 (n=33) – patients with essential HT. Patients from all groups were comparable in terms of gender and age (p>0.05). All patients underwent 24hBPM.

Results: In the study group, significantly higher average systolic blood pressure (SBP) (p˂0.05) and diastolic blood pressure (DBP) values were determined during night hours than in group 2 (p˂0.05). In the main group, there was also a higher time index of HT in SBP (p˂0.05) and DBP (p˂0.05) during the day and SBP during night hours (p˂0.01). The same group was characterized by a high DBP variability during the day (p˂0.01) and night hours (p˂0.01). In addition, in patients with gout, increased values (p˂0.01) and rate (p˂0.01) of the morning rise in DBP were more common. When compared to group 3, patients with gout had higher daytime SBP profiles (p˂0.01) and DBP (p˂0.01), nocturnal SBP profiles (p˂0.05), as well as high hypertensive time index (HTI) at the day (SBP, DBP, p˂0.01) and night hours (SBP, p˂0.01). The variability of BP in patients of the compared groups did not differ (p>0.05). When assessing the degree of nocturnal decline (DND) in all studied groups, impaired daily SBP and DBP profile was revealed. The proportion of patients with normal DND in SBP (dippers) in all three groups was comparable (p>0.05). In turn, the number of DBP dippers in the main group was less than in group 2 (x^2=6.66; p˂0.01). Thus, DND disorders according to DBP were more common (x^2=7.56; p˂0.01) in the study group. In the gout group, the following features were significantly more common than in group 2: obesity (x^2=15.3; OR=2.92; CI95% 2.30-3.70 p˂0.001), CKD with GFR<60 ml/min/1.73 m^2 (CKD-EPI) (x^2=4,93; OR=2.31; CI 95% 1.87-2.86; p˂0.05), and hyperuricemia (x^2=68.08; OR=41.7; CI 95%;23.2-74.4 p<0.001).

Conclusion: In patients with gout, 24hBPM parameters testify to a more severe course of HT than that in other forms of arthritis and essential HT. Contributing factors may include obesity, CKD with GFR<60 ml/min and hyperuricemia. All this requires more active strategy in the treatment of early detected HT in patients with gout and rational hypouricemic therapy already at the first gout attack in patients with concomitant HT.

AB1050 CHARACTERISTICS OF PATIENTS WITH COINCIDENT GOUT AND ADVANCED CHRONIC KIDNEY DISEASE

L. Stern[1], R. Johnson[2], P. Shakouri[3], A. Athavale[4], B. Lamoreaux[5], B. Marder[5], S. Mandayam[6]. *[1]Columbia University Irving Medical Center, Nephrology, New York, United States of America; [2]UCHealth University of Colorado Hospital, Division of Renal Diseases and Hypertension, Aurora, United States of America; [3]Advanced Kidney Care, Nephrology, Poughkeepsie, United States of America; [4]Trinity Life Sciences, Research, Waltham, United States of America; [5]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [6]The University of Texas MD Anderson Cancer Center, Nephrology, Houston, United States of America*

Background: Patients with chronic kidney disease (CKD) are at increased risk for developing gout[1] and vice versa.[2] Those with both gout and CKD present distinct challenges for patients and physicians because of the high prevalence of other comorbidities and restrictions on gout medication use, including non-steroidal anti-inflammatories[3,4] and some oral urate-lowering therapies (ULTs).[5] This unique patient population has not been well characterized using real-world data.

Objectives: This retrospective chart review study of patients with coincident gout and CKD was conducted to better understand patient characteristics and treatment patterns of this population. This study is unique in that patient data were obtained from nephrologists, allowing a glimpse of how they view gout and its management.

Methods: 111 nephrologists provided de-identified medical record data of their most-recently seen advanced (stage 3–5) CKD patients. Patients met study criteria for gout if any of the following were true: gout listed as a comorbidity, ULT use, or visible tophi or gout flares documented. A patient's gout was determined to be uncontrolled if they had serum uric acid >6 mg/dL in addition to ≥1 visible tophus, ≥2 gout flares in the past year, or gouty arthritis (≥1 tender or swollen joint). Characteristics of this unique population were examined, along with gout management patterns. Differences between patients with controlled and uncontrolled gout were also investigated using data from patients' most recent evaluation.

Results: 173 patients with stages 3-5 CKD and who met study criteria for gout were included. Mean age was 58.3±18.1 years and BMI averaged 32.0 ± 11.8 kg/m^2. A higher than expected proportion of patients were female (47%). The most common comorbidities were hypertension (85%), diabetes mellitus (47%), anemia of CKD (42%), CKD-mineral bone disorder (41%), ischemic heart disease (23%), and congestive heart failure (21%). Mean CKD duration was 4.1 ± 5.5 years, mean estimated glomerular filtration rate (eGFR) at most recent visit was 32.3 ± 13.9 ml/min/1.73 m^2, and 62% were using a ULT. 23 patients (13%) had uncontrolled gout (48% female, 63.1 ± 16.4 years, mean eGFR 32.0 ± 14.6 ml/min/1.73 m^2), all of whom had been prescribed a ULT. Compared with controlled gout patients, uncontrolled patients had higher rates of pulmonary hypertension (14% vs. 4%), gout-related chronic pain in the 12-months prior to data collection (63% vs. 42%), and joint involvement (joint swelling, tenderness, flexibility loss, and/or damage/lesions on x-ray; 26% vs. 9%). Colchicine was also used more frequently in uncontrolled gout patients (26% vs. 7%).

Conclusion: The coincident gout with advanced CKD population described here shows unique differences from the general gout population, including a high proportion of females (47%). Given that women have a lower likelihood of developing gout at the same serum uric acid level,[6] this finding was particularly surprising (general gout population: 67% male[7]). Importantly, nearly 40% of included patients were not utilizing a ULT, leaving them susceptible to developing the painful and debilitating sequalae of uncontrolled gout. Additionally, 41% of the study population had a CKD-related mineral bone disorder, indicating that patients with coincident gout and CKD may have bones that are more vulnerable to gout-related bone damage. Our study confirms a high prevalence of gout and its associated comorbidities in patients with advanced CKD and suggests another nephrology education opportunity to highlight the potential benefits of gout monitoring, earlier intervention, and management.

AB1051 CLINICAL OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION OF UNCONTROLLED GOUT PRIOR TO PEGLOTICASE THERAPY

R. Morlock[1], V. Divino[2], M. Dekoven[2], B. Lamoreaux[3], A. Powers[3], N. Barretto[3], R. Holt[3], S. Taylor[4]. *[1]CareChoices, Research, Ann Arbor, United States of America; [2]IQVIA, Health Economics & Outcomes Research, Falls Church, United States of America; [3]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [4]Horizon Therapeutics plc, Health Economics & Outcomes Research, Deerfield, United States of America*

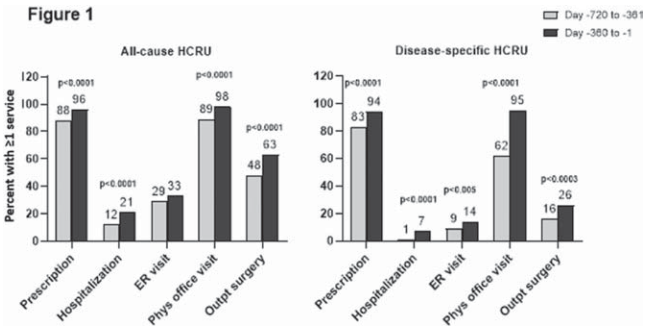
Background: By definition, uncontrolled gout (UG) cannot be managed with oral urate lowering therapies (ULTs) and is associated with substantial morbidity. UG, also known as refractory gout, results in escalated treatment and management. Recent American College of Rheumatology guidelines recommend treating gout to serum uric acid targets; if targets are not achieved or patients continue to have symptoms, pegloticase is recommended. There is a paucity of data documenting the clinical and economic burden of UG patients.
Objectives: Assess clinical outcomes and healthcare resource utilization (HCRU) of UG prior to pegloticase initiation.
Methods: A retrospective observational database analysis was conducted among patients initiating pegloticase between April 1, 2011 and August 31, 2020 using the PharMetrics Plus database. Eligible subjects had ≥1 pegloticase claim (first claim = index date) and continuous enrollment for 24 months prior to index. Relevant clinical and economic (HCRU) outcomes were evaluated over a 24-month pre-index period and compared between two different time intervals prior to index: time interval 1 (Day -720 to Day -361) and time interval 2 (Day -360 to Day -1). Assessment of comorbid disease burden included Charlson Comorbidity Index (CCI) and relevant health conditions. Dependent pairwise comparisons were conducted to compare clinical and economic outcomes between time intervals prior to pegloticase initiation. To assess statistical differences, paired t-tests (continuous variables) or McNemar's tests (categorical variables) were used.
Results: Of the 408 eligible subjects, most were male (88.5%), with an average age (SD) of 55.2 (11.3) years, 66.9% were between the ages of 45-64 years and 78.2% had a preferred provider organization (PPO) health plan. Most often (34.8% of patients), a rheumatologist was associated with initiation of pegloticase therapy, while primary care physicians accounted for 23.8% of initiations. Mean (SD) CCI score was 2.4 (2.4) with 37.3% of subjects having a CCI score of >3. Prevalence of relevant health conditions over the 24-month pre-index period included tophi (62.5%), urolithiasis (8.6%), chronic kidney disease (34.6%) and chronic pain/fibromyalgia (76.5%), all of which significantly increased from time interval 1 (Day -720 to Day -361) to time interval 2 (Day -360 to Day -1) prior to pegloticase initiation (Table 1). Of patients initiating pegloticase, 57.4% had 1 ULT (excluding probenecid), 11.3% had >2 ULT (excluding probenecid), and 10.3% UG patients had ≥1 probenecid claim over the 24-month pre-index period. Most patients (98.3%) had ≥1 physician office visit, 27.2% had ≥1 hospitalization and 45.3% had ≥1 emergency room (ER) visit over the 24-month pre-index period. HCRU significantly increased from time interval 1 to time interval 2, prior to pegloticase (Figure 1).

Table 1. Relevant Health Conditions and Disease-specific Health Care Resource Utilization (HCRU)

	Overall N= 408	Time Interval 1	Time Interval 2
Tophi	62.5%	15.4%	61.5%***
Urolithiasis	8.6%	4.2%	6.9%*
Chronic kidney disease	34.6%	22.5%	31.6%***
Cardiovascular disease	32.6%	21.3%	28.4%**
Type 2 diabetes mellitus	31.4%	23.3%	28.9%**
Hypertension	76.2%	58.1%	70.3%***
≥1 gout flare	87.7%	48.5%	83.8%***
Mean number of gout flare (SD)	3.5 (2.4)	1.0	2.1***
Gout-related medications	56%	39.5%	63.7%***
≥1 claim for colchicine			
≥1 claim for opioids	71%	52.9%	60.3%*
≥1 claim for oral corticosteroids	80%	50.2%	75.7%***
≥1 claim for injectable corticosteroids	64%	38.5%	53.7%***

†Time Interval 1: Day -720 to Day -361 prior to pegloticase initiation; ††Time Interval 2: Day -360 to Day -1 prior to pegloticase initiation***, p<0.0001; **, p<0.001; *, p<0.05

Figure 1



Conclusion: Overall, these data demonstrate the progressive nature of UG as confirmed by significant increases in gout-related conditions and healthcare resource utilization prior to pegloticase initiation. Further research is needed on healthcare resource utilization among patients with UG post-pegloticase use.

AB1052 ASSOCIATION BETWEEN BODY MASS INDEX AND HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH GOUT

I. Orlova[1], I. Vovk[2], M. Stanislavchuk[1]. *[1]National Pirogov Memorial Medical University, Vinnytsya, Ukraine, Department of Internal Medicine #1, Vinnytsya, Ukraine; [2]Municipal non-profit enterprise "Vinnytsya Regional Clinical Hospital n. a. M. I. Pyrogov, Vinnytsia Regional Council", Highly-specialized Clinical Center for Rheumatology, Osteoporosis and Biological Therapy, Vinnytsya, Ukraine*

Background: Gout is an inflammatory disease that may cause decreased function and health-related quality of life (HRQoL) [1]. In a few studies, it was demonstrated a negative relationship between body mass index (BMI) and HRQoL in individuals with gout; in the others, it was not confirmed.
Objectives: This study aimed to assess the BMI and quality of life in patients with gout and to value the association between these variables.
Methods: All 151 patients were male with mean age (M±SD) 52.4±9.2 years. Diagnosis of gout was based on the ACR/EULAR 2015 criteria [2]. Tophi was present in 51 (33.7%), and the median duration of gout was 7 years (25th to 75th interquartile range (IQR), 4 to 14.0). The mean uric acid in serum was (sUA) (M±SD) 477.2±120.5 μmol/l. HRQoL was evaluated by the SF-36 and calculated summary physical (PCS) and mental component (MCS) scores of the SF-36.
Results: About 67.5% of the surveyed patients had BMI > 30 kg/m2, while the average index was 31.9±3.4. The overall median SF-36 PCS score was 33.9 (IQR 28.8 to 38.4), and the overall median SF-36 MCS score was 41.1 (IQR 34.2 to 47.4). Among the eight subscales of SF-36, there was a correlation between BMI and role physical functioning (RP) r = -0.22 (p<0.01), general health (GH) r = -0.17 (p<0.05), but others were statistically not significant (P>0.05). Our analysis showed negative associations between BMI and physical and mental HRQoL. BMI correlated with PCS r = -0.19 (p<0.05) and MCS r = -0.17(p<0.05).
Conclusion: This analysis provides further evidence to support the injurious effects of obesity on different aspects of health patients with gout and underline the importance of weight loss.

AB1053 CARDIOVASCULAR RISKS AND MORTALITY IN KOREAN PATIENTS WITH GOUT

K. W. Moon[1] on behalf of ULTRA cohort group. *[1]Division of Rheumatology, Department of Internal Medicine, Kangwon National University School of Medicine, Chuncheon-si, Korea, Rep. of (South Korea)*

Background: Gout is associated with an increased risk of cardiovascular comorbidities and premature mortality. Many epidemiologic studies support an association between gout and increased risk of diverse cardiovascular diseases. There has been no study on cardiovascular risks and mortality in Korean patients with gout with large scale data. Therefore, we intended to investigate the risk of each specific cardiovascular disease and mortality in Korean patient with gout with the national insurance database. The purpose of this study is to investigate cardiovascular risks and mortality in Korean patient with gout.
Objectives: The purpose of this study is to investigate cardiovascular risks and mortality in Korean patient with gout.
Methods: Using Korean National Health Insurance Service data, we conducted a cohort study on gout patients. Gout patients were defined as those aged ≥ 20 years who were diagnosed as gout between 2009 and 2010, and control patients were matched with gout patients (1:1 ratio) after frequency matching for age, sex and index year. Primary outcomes were ischemic heart disease (IHD), acute myocardial infarction (AMI), congestive heart failure (CHF), cerebrovascular disease (CVD), cerebral infarction, cerebral hemorrhage, or transient ischemic attack (TIA). Secondary outcomes were all-cause mortality and cardiovascular mortality. We calculated hazard ratio (HR) in Cox regression, adjusting potential confounders.
Results: This study included 3,306 gout patients and an equal number of matched controls. Multivariate Cox regression analysis showed that gout patients showed increased risks of IHD (HR 1.860, 95% CI 1.446-2.392), AMI (HR 3.246, 95% CI 1.460-7.217), CVD (HR 1.552, 95% CI 1.177-2.036) after adjusting age, sex, laboratory findings, comorbidities, and medication (Table 1). However, statistical differences were not found in the risks of CHF, cerebral infarction, cerebral hemorrhage, TIA, all-cause mortality, and cardiovascular mortality.

Table 1. Multivariate Cox proportional HRs for cardiovascular risks of gout patients

Outcome	HR	95% CI	P-value
Ischemic heart disease	1.860	1.446-2.392	<0.001
Acute myocardial infarction	3.246	1.460-7.217	0.004
Congestive heart failure	1.399	0.853-2.295	0.183
Cerebrovascular disease	1.552	1.177-2.046	0.002
Cerebral infarction	1.061	0.687-1.637	0.790
Cerebral hemorrhage	0.779	0.283-2.145	0.629
Transient ischemic attack	1.233	0.651-2.336	0.521
All-cause mortality	1.199	0.737-1.952	0.465
Cardiovascular mortality	1.377	0.452-4.188	0.573

HR, hazard ratio; CI, confidence interval.

Conclusion: Our study showed that cardiovascular risks of Korean patients with gout were increased, especially IHD, AMI and CVD.

AB1054 FERRITIN LEVELS IN PATIENTS WITH GOUT AND COMORBID PATHOLOGY

G. Kuzmina[1], O. Lazarenko[1]. *[1]Dnipro State Medical University, Department of Therapy, Cardiology and Family Medicine Faculty of Postgraduate Education, Kryvyi Rih, Ukraine*

Background: Gouty arthritis is the most common type of inflammatory arthritis among the working-age population. In patients with gout, the following comorbidities are often recorded: hypertension, diabetes mellitus, and heart failure. The issue of the relationship between ferritin levels in patients with gout and comorbid pathology remains relevant, as well as establishing the nature of this relationship.
Objectives: The aim of this study was to determine the frequency of hyperferritinemia in patients with gout and comorbid hypertension.
Methods: 122 patients with hypertension, middle age of whom amounted to 56.0 (10.29) years, had been surveyed, 104 (85.2 %) men and 18 (14.8 %) women. All patients were divided into three groups: the main group – 72 patients with hypertension in combination with gout, comparison group – 50 patients with hypertension without gout, control group – 20 patients with gout. Standard clinical examination and laboratory evaluation including ferritin, uric acid levels were performed.
Results: The following ferritin values were determined in the main group 344.0 (196.5; 389.0) ng/ml, comparison group 130.9 (68.0; 143.3) ng/ml, control group 276.5 (257.0; 354.5). The ferritin level were significantly higher in the main group - 2.6 ($p < 0.01$) times than in the comparison group. The ferritin level were significantly higher in the control group - 2.1 ($p < 0.01$) times than in the comparison group. There is no significant difference the ferritin levels between main and control groups ($p > 0.05$), which indicates the important role of this marker in gout and requires further study of hyperferritinemia in gout and comorbid pathology.
Conclusion: The combination of hypertension with gout in patients was associated with a higher ferritin levels, which should be considered not only in the context of chronic inflammation, but as part of the disease with the possibility of further determining the cause and diagnostic value of hyperferritinemia in this category of patients.

AB1055 GENDER DIFFERENCES IN TAKING XANTHIOXIDASE INHIBITORS IN GOUT

M. Gromova[1], V. Tsurko[1]. *[1]Pirogov Russian National Research Medical University, Department of Faculty Therapy of the Medical Faculty, Moscow, Russian Federation*

Background: There is little evidence of a possible difference between men and women in response to urate-lowering therapy (ULT).
Objectives: To compare the clinical characteristics of the gout course and evaluate the differences in response to ULT with allopurinol and febuxostat in men and women.
Methods: The retrospective cohort study included 279 men and 83 women diagnosed with gout (ACR/EULAR, 2015). The comparative analysis of the clinical characteristics of gout and responses to taking xanthioxidase (XO) inhibitors in representatives of different genders was conducted. We compared the gender characteristics of obtaining a positive response to ULT, defined as achieving a target serum uric acid (sUA) level of <360 μmol/l within 6 months of treatment with allopurinol and febuxostat.
Results: By the age when gout manifistated women were older than men, the duration of their disease was shorter. Men showed a shorter duration of the first arthritis attack. Chronic arthritis was diagnosed in 56% of men and 35% of women ($p < 0,05$). The process involved the joints of the lower and upper extremities. More often the joints of the lower extremities were affected in men, and in the upper extremities in women. Tophus were detected in 35% of patients: 30,3% – men, 4,7% – women ($p < 0,05$). Allopurinol was prescribed to 216 men and 54 women, febuxostat – to 63 men and 29 women. After six months the proportion of women who achieved the target sUA was 57,5% and 65,8%, the proportion of men – 60,4% and 76,2% for allopurinol and febuxostat, respectively.
Conclusion: The clinical manifestations of gout in men and women differ. Due to the marked increase in the uric acid level, men develop more severe joint damage because of the tendency to chronicity. However, the study did not reveal gender differences in the response to XO inhibitors, which indicates that there is no need to choose therapy depending on the patient's gender.

AB1056 CHARACTERISTICS OF METABOLIC SYNDROME IN PATIENTS WITH GOUTY ARTHRITIS AND NON-ALCOHOLIC FATTY LIVER DISEASE

K. Zhigulina[1], S. Spitsina[1,2]. *[1]Federal State Budgetary Educational Institution of Higher Education "Volgograd State Medical University" of the Ministry of Healthcare of the Russian Federation, Department of Hospital Therapy, Volgograd, Russian Federation; [2]Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky", Clinical Biochemical Laboratory, Volgograd, Russian Federation*

Background: Gouty is an inflammatory and metabolic disease. Hyperuricemia can contribute to inflammation, hypertension and cardiovascular disease, adipogenesis and lipogenesis, impaired insulin and glucose metabolism, and liver disease. In turn, non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver disease worldwide; is closely associated with obesity, type 2 diabetes mellitus, dyslipidemia, and other metabolic risk factors included in the metabolic syndrome (MS). Problem of MS exists for many years, due to its extremely rapid spread in the world.
Objectives: To study the frequency and structure of MS in patients with gouty arthritis in combination with NAFLD, to identify the main traditional and disease-associated risk factors.
Methods: The study included 70 patients with gouty arthritis. The diagnosis was made based on the criteria of S. Wallace et al. All patients were examined with general clinical and biochemical blood tests (determination of uric acid, transaminases, glucose, glycosylated hemoglobin, insulin, lipid spectrum), physical examination (measurement of blood pressure, body mass index in kg/m2), calculation of the HOMA index. An ultrasound examination of the liver was performed as the instrumental diagnostic method.
Results: Among the surveyed, men and women accounted for 60% and 40%, respectively, with an average age of 52 years, with an average disease duration of 8.2±3.5 years. The debut of gouty arthritis was observed at 35.6 years. 25 patients had a family history of gouty arthritis. 64 patients had arterial hypertension. The patients were divided into two groups: the first group included 50 patients with primary gouty arthritis and signs of NAFLD (signs of steatosis in 64%, non-alcoholic steatohepatitis in 36%), the second group included 20 patients with gouty arthritis without signs of NAFLD. In group 1, 20 patients (40%) had arterial hypertension of the 1st degree, 30 (60%) patients of the 2nd degree. The uricemia level varied from 390.8 to 612.2 μmol/l. Dyslipidemia was diagnosed in 72% of patients (mainly type IIa and IIb). The average level of fasting glycemia was 7.8±3.0 mmol/l, and glycosylated hemoglobin was 7.0±1.5%. The average level of insulin in the blood serum of patients of the 1st group is 7.9 mIU/l, the 2nd group is 2.2 mIU/l, and the average HOMA index is 18.0. The body mass index ranged from 29.05 to 49.39 kg/m2 (70% were obese, the rest were overweight). All indicators of the metabolic syndrome in patients of the 1st group were significantly different from those of the 2nd group of patients (p<0.005).
Conclusion: Thus, a high prevalence of metabolic syndrome was revealed in patients with gouty arthritis and signs of NAFLD. In this group of patients, there are higher risks of developing insulin resistance and dyslipidemia, abdominal obesity and arterial hypertension, as well as hyperuricemia. All identified factors of the metabolic syndrome directly correlated with the duration of gouty arthritis.

AB1057 EFFICACY AND SAFETY OF LOW-DOSE RASBURICASE IN COMBINATION WITH CONVENTIONAL URATE-LOWERING THERAPY FOR REFRACTORY CHRONIC GOUTY ARTHRITIS: A PILOT STUDY IN

W. C. Zeng[1,2], Q. H. LI[1], A. J. Tang[1,2], H. G. LI[1], L. F. Chen[1], X. N. Wei[1], J. J. Liang[1], D. H. Zheng[1], L. Dai[1], Y. Q. Mo[1,2]. [1]*Sun Yat-sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China;* [2]*Shenshan Medical Center, Memorial Hospital of Sun Yat-Sen University, Department of Rheumatology, Shanwei, China*

Background: Recombinant uricase such as pegloticase are indicated for chronic gouty arthritis who have failed to achieve serum urate level <300μmol/L even though receiving conventional urate-lowering drugs. Rasburicase which is currently approved at a dosage of 0.2 mg/(kg.d) for 5 days for the prevention of tumor lysis syndrome in pediatric patients with hematological tumors, is the only available uricase in China at present.
Objectives: To evaluate the efficacy and safety of low-dose rasburicase in refractory chronic gouty arthritis.
Methods: We retrospectively collected data of 17 patients with refractory chronic gouty arthritis who were treated with rasburicase from January 2021 to September 2021 at Sun Yat-sen Memorial Hospital, Sun Yat-sen University. The refractory chronic gouty arthritis was defined as serum urate level was still more than 300μmol/L and dual-energy CT showed the volume of urate more than 10 cm^3, even though the allopurinol, febuxostat, and/or benzbromarone of the maximum tolerable amount were received for more than 3 months. Rasburicase was added every four weeks (week 0, week 4, and week 8) with a dosage of 1.5 mg/d for three consecutive days, on the basis of daily oral urate-lowering drugs of the maximum tolerable amount. The serum urate level was monitored. The primary outcome was the change in urate volume at week 12 compared to week 0 by dual-energy CT.
Results: ① Seventeen patients were recruited with 16 males (94%) and mean age 47±15 years old. The median gout course was 11 (6.5, 15) years with gout flares number 20 (11, 36) times in the previous year. At week 0 before the rasburicase add-on treatment, the mean serum urate was 652±94μmol/L and the median urate volume was 44 (21, 215) cm^3 (Table 1). ② Urate level after the rasburicase add-on treatment was significantly decreased than that before the treatment either at week 0, week 4, or week 8 (Figure 1A, all $p< 0.001$). The median reduction of serum urate were 565 (446, 621) at week 4, 214 (57, 373) at week 8, and 118 (21, 185) at week 12 (all $p<0.017$). Five cases (29%) showed serum urate lower than 300μmol/L at week 12. ③ The urate volume decreased at week 12 compared to week 0 in all patients (Figure 1B~D). The median volume of urate reduction was 24 (12, 60) cm^3 ($p<0.001$) and the median percentage of urate reduction 42% (25%, 66%). Urate reduction volume was positively correlated with baseline urate volume (r=0.890, $p<0.001$), while the percentage of urate reduction volume negatively correlated with baseline urate volume (r=-0.689, p=0.002). ④ Rasburicase was generally well tolerated. No gout attack occurred on the basis of intravenous methylprednisone 20mg before each rasburicase add-on treatment and oral colchicine 0.5mg/d to 1mg/d. No hypersensitive reaction occurred during the treatment. Phlebitis occurred in a patient (6%), while dizziness and nausea occurred in two patients (13%). One patient (6%) who was suffering chronic kidney disease of stage 3 developed acute kidney injury after rasburicase injection at week 0 and week 8, but the serum creatinine spontaneously returned to the baseline level during follow-up.

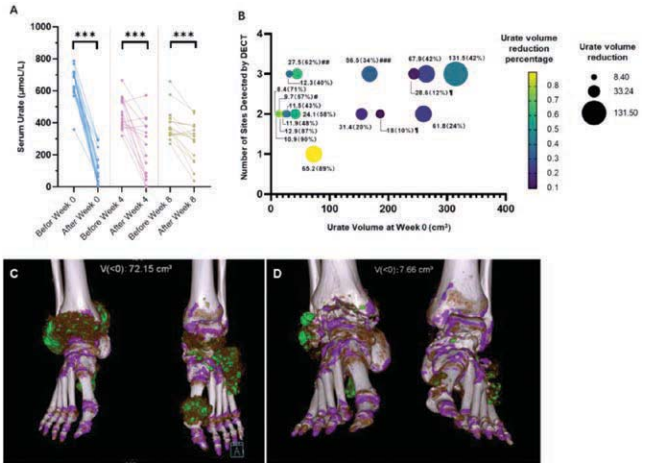

Figure 1. The serum urate and urate volume before and after rasburicase add-on treatment. A: Paired comparison of serum urate level before and after each time of rasburicase administration; B. Reduction value and percentage of urate volume at week 12 for each patient. C&D: Dual-energy CT (DECT) showed a dramatical reduction in urate volume from week 0 (C, urate volume: 72.15 cm3) to week 12 (D, urate volume: 7.66 cm3). ***: p< 0.001; #: Received rasburicase at week 0 only; ##&###: Received rasburicase 7.5mg at week 0.

Conclusion: This pilot study shows rasburicase is well tolerated in patients with refractory chronic gouty arthritis and may be a reasonable option to effectively lower the urate burden of these patients, although this is an off-label use. Further prospective randomized controlled studies to verify the efficacy and safety are needed.

AB1058 IS HYPERURICEMIA ASSOCIATED WITH TYPE 2 DIABETES DEGENERATIVE COMPLICATIONS?

F. Fhima[1], N. El Amri[1], D. Khalifa[1], A. Ben Abdelkrim[2], B. Ben Abdallah[2], S. Lataoui[1], K. Baccouche[1], E. Bouajina[1], K. Ach[2]. [1]*Farhat Hached Hospital, Rheumatology Department, Sousse, Tunisia;* [2]*Farhat Hached Hospital, Endocrinology and Diabetes Department, Sousse, Tunisia*

Background: Prevalence of hyperuricemia (HU) is constantly increasing around the world and HU is now identified as an independant cardiovascular risk factor.
Objectives: To determine the prevalence of HU in patients with type 2 diabetes (T2D) and to identify degenerative complications of T2D associated with HU.
Methods: A cross-sectional descriptive study was conducted in the rheumatology and endocrinology departments of Farhat Hached University Hospital of Tunisia over a period of 6 months. Patients diagnosed with T2D according to the 2021 guidelines of the American Diabetes Association were included. A cut-off of uric acid ≥ 360 μmol/L in females and ≥ 420 μmol/L in males was used to define HU.
Results: One hundred fifty-one patients were included. Sex ratio F/M was 1.4. The median of age was 61 years. The prevalence of HU was 17.2%. Only 6 % of patients had gout. Degenerative complications of T2D were encountered in 74.2% of cases. Diabetic neuropathy was the most common (51.7%) and was significantly associated with HU (p=0.049). Diabetic nephropathy was reported in 38.4% of patients and was also associated with HU (p= 0.008). HU was associated with renal failure (p < 0.01), microalbuminuria (<0.01), proteinuria (p=0.001) and history of ischemic stroke (p=0.048). Diabetic feet problems were reported in 15.9 % of patients and were associated with HU (p=0.008). Nevertheless,

diabetic retinopathy (39.7%), peripheral arteriopathy of lower limbs (27.2%) and myocardiopathy (15.2%) were not associated with HU.
Conclusion: HU is common in patients with T2D. Our study raises the question whether HU could be a risk factor for the development of degenerative complications in T2D patients. Screening for HU could be recommended in T2D patients for a holistic assessment of the disease.

AB1059 POSSIBILITIES OF COMBINED THERAPY FOR TREATMENT OF HYPERURICEMIA AND ARTICULAR SYNDROME EXACERBATIONS IN PATIENTS WITH GOUT

V. Tsurko[1], M. Gromova[1], O. Kisliak[1], N. Malysheva[1]. [1]*Pirogov Russian National Research Medical University (Pirogov Medical University), Department of Faculty Therapy of the Medical Faculty, Moscow, Russian Federation*

Background: Throughout the year 69 per cent of patients with gout experienced repeated exacerbations during therapy aimed at reducing urate levels. Prevention of arthritis exacerbations with low-dose NSAIDs should be done in the first 3-6 months of urate-reducing therapy.
Objectives: To assess the frequency of exacerbations and quality of life in patients with gout after a 12 weeks course of urate-reducing therapy with allopurinol in combination with the anti-inflammatory drug meloxicam for the prevention of gout exacerbations.
Methods: Physical examination, clinical blood, urine tests, biochemical blood tests, instrumental diagnostics were performed in all patients. Information about concomitant diseases was entered, drug therapy was recorded at the time of observation. Allopurinol was administered orally, once a day. Every 3 weeks under the control of serum uric acid levels (sUA), the allopurinol dosage was increased by 50 mg, up to 300 mg per day. The total daily dose of meloxicam administered in different dosage forms was 7.5-15 mg. After 3, 6, 9 and 12 weeks, the clinical effeciency of treatment was assessed using the EuroQol-5D-5L questionnaire, physical examination, joint pain dynamics at rest, during movement and palpation, as well as the Likert scale and visual analog scale (VAS) in mm. Factors such as the presence of anxiety or depression, self-care ability, normal daily activities of daily living were taken into account, as well as their rating of their level of satisfaction with the treatment on a scale of 1 to 5, where 1 is not an improvement but a deterioration and 5 is a very good result. Both the period of remission and the time before the onset of a recurrence of gouty arthritis were taken into account, as well as adverse events (AEs) were recorded.
Results: 143 patients with an established diagnosis of gout (ACR/EULAR, 2015) were examined at an outpatient appointment. Against the background of treatment with meloxicam 7.5 mg per day, more than two-thirds of the patients did not experience a worsening of the joint syndrome with an increase in the dose of allopurinol to 300 mg per day. By the 12th week of follow-up, it was found that the characteristic features of gouty arthritis significantly began to differ in improving mobility, self-care, habitual daily activities, reducing soreness, reducing anxiety and depression ($p < 0.05$). Moreover, the initial ESR and sUA levels were significantly different from the follow-up endpoint ($p < 0.05$), indicating a positive effect on the inflammatory process. A three-month course of combination therapy did not cause a significant increase in blood pressure or change in serum creatinine clearance in the patients. From the gastrointestinal tract there were no adverse events. 90.9% of patients assessed the treatment efficiency as very good. AEs in the form of an allergic skin rash were observed in one patient. But there was no need to interrupt the treatment, as the rash completely disappeared without consequences after completing the course of treatment with allopurinol and meloxicam.
Conclusion: A 12-week combination therapy with allopurinol, a urate-reducing drug, and meloxicam, an anti-inflammatory drug, prevents exacerbation of joint syndrome and improves quality of life in patients with gout.

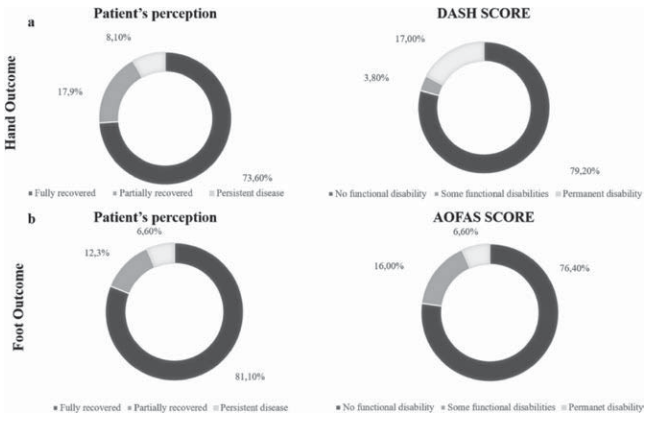
AB1060 LONG-TERM DISABILITY SECONDARY TO CRPS-1. RETROSPECTIVE MONOCENTRIC STUDY ON 106 CASES.

C. Crotti[1], F. Zucchi[1], M. Manara[1], R. Caporali[1,2], M. Varenna[1]. [1]*ASST Gaetano Pini-CTO, Department of Rheumatology, Milano, Italy;* [2]*University of Milan, Department of Clinical Sciences & Community Health, Milan, Italy*

Background: Complex regional pain syndrome type-1 (CRPS-1) is a severely disabling pain syndrome characterized by sensory and vasomotor disturbance, swelling, and functional impairment. Persistence of signs and symptoms has been observed in up to 64% of cases until 5.8 yrs after the onset of manifestations. Long-term disability, such as irreversible functional limitation, has been reported in up to 28% of cases with severe consequences on workability. No scores are validated to evaluate residual disability. Bisphosphonates have the best efficacy profile, compared with other therapeutic approaches, but data on long-term effectiveness are lacking.
Objectives: To retrospectively evaluate long-term residual disability in patients with CRPS-1 of hand or foot after treatment with IV Neridronate (IVNer). To identify predictors of residual disability. To quantify disease outcomes, such as patient's subjective perception and residual pain. To assess long-term safety profile.
Methods: We retrospectively collected data of patients affected by CRPS-1, treated with IVNer, referred to a tertiary Rheumatology Centre between Feb 2013 and Dec 2020. Visual analogue scale (VAS) and McGill Questionnaire (McGQ) were used for pain assessment. Disabilities of the Arm, Shoulder and Hand (DASH) and American Orthopaedic Foot and Ankle Society's (AOFAS) ankle-hindfoot scale for hand and foot involvement, respectively, were administered to explore disability through a phone survey. This kind of investigation was preferred for Covid pandemic.
Results: 106 patients with definite diagnosis of CRPS-1 were included, mean age±standard deviation 55.6±13 yrs, 67% females, mean follow up duration 56.3 months (range 14-94), 46.2% with hand involvement. The mean VAS score before treatment onset was 55.8±23.4mm, while the McGQ was 12.9±6.7 in the sensory domain, 4.9±3.3 in the affective domain and 17.8±9.2 on the total score. Based on the patient's subjective perception and the proposed semi-quantitative scale, 77.4% described themselves as fully recovered (FR), 15% partially recovered (PR), and 7.6% with persistent disease (PD). Comparison between baseline and follow-up VAS shows a significant reduction (55.8±23.4 vs 15.1±26.4, $p<0.00001$). Pain assessment by McGQ showed a significant improvement in global score (baseline vs follow-up 17.8±9.2 vs 3.9±7.8, $p<0.00001$), sensory (12.9±6.7 vs 2.7±5.7, $p<0.00001$) and affective (4.9±3.3 vs 1.2±2.3, $p<0.00001$) domains. According to DASH score, 79.2% of the patients were FR, 3.8% had some difficulties, but with overall preserved use of the upper limb, and 17.0% had permanent functional disability. According to AOFAS ankle-hindfoot scale 76.4% of patients were FR, 16.0% had partial recovery, and 7.6% had severe functional impairment. Percentages of DASH and AOFAS scores showed a complete accordance with patients' subjective perception (Figure 1a and b). The only predictor of long-term functional impairment for CRPS-1 in the hand was a delayed treatment compared to symptoms onset ($p=0.02$). No predictors were found for foot localization. No patients reported the occurrence of osteonecrosis of the jaw or atraumatic fractures/atypical fracture features.

Figure 1.



Conclusion: IVNer maintained a good long-term effectiveness and safety profile in the treatment of CRPS-1. The effectiveness of IVNer is maintained on both pain symptoms and function, in terms of reductions in the VAS, McGQ and in hand and foot disability scores.

AB1061 THE ROLE OF PROSTAGLANDIN E2 IN HYPERTROPHIC OSTEOARTHROPATHY AND/OR CLUBBING OF DIFFERENT CAUSES.

K. Cajiao[1], H. Florez[1], A. Monegal[1], N. Guañabens[1], P. Peris[1]. [1]*Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain*

Background: Hypertrophic osteoarthropathy (HOA) is characterized by several clinical findings, including arthralgia/arthritis, periostosis, and digital clubbing. It can occur as a congenital condition called pachydermoperiostosis, and more commonly, as a secondary manifestation of pulmonary or extrapulmonary diseases or malignancy. Genomic studies support the role of prostaglandin E2 (PGE2) in the pathogenesis of primary HOA, with mutations in the 15-hydroxyprostaglandin dehydrogenase encoding gene resulting in increased PGE2 levels.
Objectives: To analyse the clinical characteristics, comorbidities, and the potential role of PGE2 in primary and secondary forms of HOA and/or clubbing and also evaluate the clinical evolution of these patients.
Methods: Eighteen patients (10 men/8 women) aged 15 to 78 years (49,9 ± 15,6) diagnosed with clubbing and/or HOA were attended in our Rheumatology Department over an 11-year period. We reviewed the clinical characteristics of the patients, including associated comorbidities, image findings, bone turnover markers (BTM), and serum and urinary levels of PGE2, among others. Additionally, we evaluated the treatment and the clinical evolution of these subjects.
Results: Most patients presented associated clinical conditions for HOA and/or clubbing, with only one, the youngest (15 years old), having primary HOA (pachydermoperiostosis). Pulmonary disorders were the most frequent associated conditions, with interstitial lung disease (4 cases), COPD (3 cases), and lung cancer (4 cases) being the most frequent, followed by liver diseases including primary biliary cirrhosis (1 patient), liver cirrhosis (2 patients) and chronic hepatitis C virus (2 patients). All the subjects evaluated (15/18) presented increased urinary PGE2 levels (the highest being observed in primary HOA), with most also presenting increased serum PGE2 values. BTM were evaluated in most subjects (17/18) showing increased values in most (11/17), particularly in PINP and CTx. 4 patients were treated with selective inhibitors of cyclooxygenase-2 (COX-2) presenting, when evaluated, a small decrease in urinary PGE2 titers and partly improving their symptoms, which clearly improved after treating the associated cause when possible.
Conclusion: In the present series, all subjects with primary or secondary HOA and/or clubbing presented markedly increased PGE2values, particularly in urine, supporting the role of this agent in the etiopathogenesis of this disorder. Pulmonary disorders, including malignancy and liver diseases, constituted the most frequent associated conditions. The use of COX-2 seems to be an effective symptomatic therapeutic approach in this entity.

AB1062 EVALUATION OF THE EFFECTIVENESS OF GOUT THERAPY IN OUTPATIENT PRACTICE

A. Sarapulova[1], O. Teplyakova[2]. [1]*USMU, Outpatient Therapy, Yekaterinburg, Russian Federation;* [1]*USMU, Outpatient Therapy, Yekaterinburg, Russian Federation*

Background: gout is a socially significant pathology, as it affects men of working age and is associated with the development of cardiovascular diseases. Meanwhile, according to studies, most patients with gout do not reach the target values of uric acid (UA).
Objectives: to evaluate the effectiveness of gout therapy in real clinical practice and to identify factors that improve this indicator.
Methods: The study included patients with an established diagnosis of gout (according to ACR/EULAR criteria). Depending on the stage of the disease, patients were prescribed symptomatic anti-inflammatory therapy, and urate-lowering therapy (UST) - allopurinol or febuxostat - to reduce the level of UA. The dosage of allopurinol in the first 2 months of admission was 300 mg / day and then adjusted depending on the level of UA, the dosage of febuxostat was 80 mg, adjusted to 120 mg if necessary. To prevent exacerbation, all patients were prescribed colchicine 0.5-1.0 mg/day for up to 6 months. After 2 and 6 months of therapy, the effectiveness of it was assessed. All patients had a conversation about the correction of risk factors (diet, alcohol intake) and recommendation to watch online educational school for patients with gout.
Results: the average age of 60 patients included in the study was 46.9±9.9 years, the duration of the disease was 8.5±3.4 years, of which 96.7% were men. The mean number of exacerbation per year prior to therapy was 7.8±3.5. After 6 months of therapy, 46.7% of patients noted the absence of gout attacks, the rest - a decrease in the duration of attacks (from 10.4 to 1.6 days on average) and their intensity (the average pain during an attack on the VAS scale decreased from 7.8 points up to 3.9). The average level of UA decreased over 2 months from 541.3±146.8 to 387.4±146.9 μmol/l, and after six months of admission it was 299.6±56.5 μmol/l. The creatinine level did not change significantly and amounted to 104.7±34.9 μmol/l before therapy and 97.5±26.7 μmol/l after 6 months. None of the patients discontinued therapy due to intolerance; one of the patients experienced a slight leukopenia while taking febuxostat, which did not lead to discontinuation of the drug. It should be noted that the majority of the subjects - 56.7% - had previously consulted a rheumatologist, but most of them did not receive permanent therapy. Patients highlighted qualitative information and the effect of treatment as the most important reasons for continuing therapy.
Conclusion: This study proves that achieving the target level of UA is possible in most patients with gout, leads to a significant reduction in the number of attacks and their severity, requires educational work and patient monitoring. It is important that this work is part of a planned 2-year follow-up of patients with gout in order to determine the long-term effectiveness of therapy.

AB1063 POSSIBILITIES OF RENOPROTECTION IN PATIENTS WITH CHRONIC KIDNEY DISEASE AND HYPERURICEMIA

L. Khimion[1], I. Naishtetik[2], O. Burianov[3], S. Rotova[4], S. Smiyan[5], S. Danyliuk[1], V. Trofanchuk[6]. [1]*Shupyk National Healthcare University of Ukraine, Family Medicine, Kyiv, Ukraine;* [2]*Clinic of Modern Rheumatology, Rheumatology, Kyiv, Ukraine;* [3]*Bogomolets National Medical University, Traumatology and Orthopedics, Kyiv, Ukraine;* [4]*Shupyk National Healthcare University of Ukraine, Nephrology and Renal replacement Therapy, Kyiv, Ukraine;* [5]*I. Horbachevsky Ternopil National Medical University, Internal Diseases #2, Ternopil, Ukraine;* [6]*KNP KOR Kyiv Regional Clinical Hospital, Highl Specialized Therapeutic Department, Kyiv, Ukraine*

Background: the number of patients with progressive chronic kidney disease (CKD) and the costs of their treatment is constantly increasing. Possibly, control of serum uric acid (sUA) levels with urate lowering therapy (ULT) drugs can slow the progression of kidney function deterioration.
Objectives: to determine the efficacy and safety of allopurinol and febuxostat in treatment of patients with CKD to reduce the level of sUA and to analyze the effect of such treatment on glomerular filtration rate (GFR).
Methods: the study included 45 patients with CKD (stages 3b-5). Patients with recent acute kidney injury, acute glomerulonephritis, advanced heart failure, with kidney transplant, other severe/decompensated diseases; contraindications to the use of allopurinol/febuxostat – were not included. The target level of sUA for patients with pre-dialysis stages of CKD was set at 300 μmol/l, for patients on hemodialysis target was not set. All patients underwent a comprehensive clinical and laboratory examination, laboratory tests (full blood count, creatinine, sUA, ALT, AST, GFR calculation (CKD- EPI). All patients were divided into one of the study groups for the treatment of HU: Group I (28 patients, 61,3±3,2 y.o., CKD3b-12, CKD4-10, on hemodialysis-6 patients) received febuxostat (40-120 mg/day), Group II (24 patients, 60,7±4,1y.o., CKD3b-9, CKD4-10, on hemodialysis -5 patients) took allopurinol (50-300 mg/day – for patients with pre-dialysis CKD and up to 800 mg/day - for patients on hemodialysis). Clinical and laboratory examination was repeated after 1, 3 and 6 months; sUA levels were determined with individual frequency, with correction of of ULT drugs doses, taking into account GFR (for allopurinol).
Results: The majority of participants showed a significant decrease in the level of sUA under the influence of ULT drugs, however, the achievement of the target level of sUA was significantly more often registered in Group I: after 1 month – in 45.5% (in group II – in 15.9%, p<0.001); after 3 months - in 67.5% (in group II - 21.2% p<0.01); after 6 months, these figures were 90% and 37.1%, respectively (p<0.01). The achievement of sUA levels of less than 300 μmol/l was accompanied by significant positive GFR dynamics in most patients (in 90% of patients, GFR increased compared with the baseline, on average - in group I - by 3.1±0.51 ml/min, while in group II there was a gradual progression of GFR deterioration - in 31.8% of patients. During the study period, no serious adverse events (AE) were noted in study patients, mild and moderate adverse events (totally - 8 events) were registered in 5 patients (2 patients took febuxostat and 3 - allopurinol). Development of AEs did not lead to the discontinuation in study participation in any cases, but made impossible to increase the dose of allopurinol in 3 patients.
Conclusion: In patients with pre-dialysis stages of CKD, the use of febuxostat is accompanied by stabilization or increase in GFR. Use of febuxostat in patients with CKD stage 3b-4 and in patients on hemodialysis is safe and more effective for target sUA level achievement than the use of allopurinol.

AB1064 **HYPERURICEMIA IN PATIENTS WITH PRIMARY HYPERTENSION: PREVALENCE AND ASSOCIATED FACTORS**

N. El Amri[1], F. Fhima[1], D. Khalifa[1], A. Ben Abdelkrim[2], B. Ben Abdallah[2], S. Lataoui[1], K. Baccouche[1], E. Bouajina[1], K. Ach[2]. *[1]Farhat Hached Hospital, Rheumatology department, Sousse, Tunisia; [2]Farhat Hached Hospital, Endocrinology and Diabetes Department, Sousse, Tunisia*

Background: Hypertension and hyperuricemia (HU) are both cardivascular risk factors. HU is frequently associated with hypertension even without the use of treatments that potentially cause elevations of uric acid levels.
Objectives: To determine the prevalence of HU in patients diagnosed with primary hypertension and its associated factors.
Methods: A cross-sectional study was conducted in the rheumatology and endocrinology departments of Farhat Hached Hospital of Tunisia over a period of 6 months. Patients diagnosed with primary hypertension were included. HU was defined by uric acid levels ≥ 360 µmol/L in women and ≥ 420 µmol/L in men.
Results: One hundred patients were included. Study population was mainly made of women (65%). The median of age was 63 years [min:34, max:89]. The prevalence of HU was 26%. HU was more common in women (19%) compared to men (7%) without statistical significance (p= 0.315). The median values of systolic and diastolic blood pressure values were 140 mmHg and 80 mmhg, respectively. Elevated diastolic blood pressure was associated with HU (p=0.043). All patients presented other comorbidities. Type 2 diabetes was the most common one (83%) followed by obesity (56.7%). Forty three percent of patients had dyslipidema, 21% renal failure, 16.9% proteinuria, 9% gout, 8% hypothyroidism and 30% osteoarthritis. HU was significantly associated with hypothyroidism (p=0.027), renal failure (p= 0.000), obesity (p=0.038) and proteinuria (p=0.02). HU was not associated with disturbance of lipid and glycemic status. High uric acid levels were associated with the use of thiazide diuretics (p= 0.048) and ACE inhibitors (p= 0.037). Nonetheless, no association was found with the use of low dose aspirin (p= 0.412) nor other antihypertensive treatments.
Conclusion: Prevalence of HU is high in patients diagnosed with primary hypertension and is associated with hypothyroidism, obesity, renal failure, proteinuria and diastolic hypertension. HU is also associated with the use of thiazide diuretics and ACE inhibitors.

AB1065 **EARLIER ONSET OF ARTERIAL HYPERTENSION IS A RISK FACTORS FOR SEVERE COURSES OF GOUT**

E. Markelova[1], E. Ilinykh[2], D. Karateev[1], E. Luchikhina[1]. *[1]M.F. Vladimirsky Research Clinical Institute of the Moscow Region, Rheumatology Department, 61/2, Shchepkina Street, Moscow, 129110, Russian Federation; [2]V.A Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Rheumatology Department, Moscow, Russian Federation*

Background: Comorbidities cardiovascular disease such as arterial hypertension (AH) are common in people with gout and complicate its management and disease outcomes.
Objectives: Our purpose was to evaluate the effect of AH on the severity of gout.
Methods: We included data of 286 male patients with gout: median (Me) age 51.2 [interquartile range (IR) 42.8;59.4] years (ys), disease duration – Me 6.2 [IR 3.8;12.1] ys, number of joints involved during disease course – Me 7 [IR 4;12], subcutaneous tophi – in 35% pts, intraosseous tophi – in 44% pts. All pts underwent standard clinical examination. AH was defined using by 2018 ESC/ESH Guidelines for the management of arterial hypertension criteria: elevated blood pressure (BP) (systolic BP≥140 or diastolic BP≥90 mm Hg or treatment for hypertension).
Results: AH was found in 244 out of the 286 pts (85 %). AH was diagnosed before gout in 129 (52.9%) pts, and after gout - in 115 (47.1%) pts. The 1st degree of AH was found in 27 (11%), the 2nd degree – in 62 (25%), the 3rd degree – in 155 (64%) pts. AH developed at a younger age in patients with 3rd degree AH compared to patients with 2nd and 3rd degree AH, but did not reach statistical significance. Patients with 3rd degree of AH had longer gout and AH duration compared to patients with 1st and 2nd degree of AH. They had higher prevalence of subcutaneous and intraosseous tofuses, nephrolithiasis compared with the 1st and 2nd degree of AH, p<0.05 (Table 1).

Table 1.

Parameters	Grade 1 hypertension	Grade 2 hypertension	Grade 3 hypertension
Age of gout onset,ys	41.6[34.4; 53.5]	39.6[35.6; 48.0]•	44.1[36.9; 52.6]
Age of AH onset,ys	44.9[37.4; 55.4]	43.6[36.9; 49.9]	40.4[29.9; 49.9]
Gout duration,ys	3.8[1.6; 5.8]	5.6[3.8; 13.5]	8.0[4.8; 14.6]*
AH duration,ys	0.1[0; 2.0]	3.3[0.2; 9.8]	11.3[4.7; 22.8]*
Number of joints involved,n	4.0[2.0; 6.0]	7.0[4.0; 10.0]	9,0[5,0; 14.0]*
Subcutaneous tophi,%	4(14.8%)	16(26%)	69(44.5%)*
Intraosseous tophi,%	5(18.5%)	29(47%)	83(53.5%)*
Nephrolithiasis,%	16(59%)	34(55%)	124(80%)*

Data are presented in median values and IR (unless otherwise noted), •p<0,05 reliability of differences for trend, *p<0,05 compared vs group 3 (Mann -Whitney).

AH preceded the development of gout in 26% pts with 1st degree of AH, in 42% pts with 2nd degree of AH, in 62% pts with 3rd degree of AH.
Conclusion: Hypertension preceded the development of gout in 62% patients with 3rd degree of AH. They had a more severe course of gout compared to patients with 1st and 2nd degree of AH. It can be assumed that an earlier onset of AH is a risk factor for severe courses of gout.

AB1066 **TREATMENT OF ACUTE CALCIUM DEPOSITS IN HAND AND WRIST WITH ANAKINRA**

A. Durdzińska Timóteo[1], A. Dumusc[2], S. Durand[1]. *[1]Lausanne University Hospital, Plastic and Hand Surgery, Lausanne, Switzerland; [2]Lausanne University Hospital, Rheumatology, Lausanne, Switzerland*

Background: Acute calcium deposits (ACD) of hydroxyapatite in hand and wrist are a rare cause of acute pain due to crystal-induced soft tissue inflammation. There are no standard management guidelines for this condition, which is frequently treated with non-steroid anti-inflammatory drugs or steroid infiltrations with variable efficacy, some patients presenting symptoms for several months[1]. Anakinra, an interleukin-1 receptor antagonist, showed non-inferiority compared to usual care in the treatment of acute gout arthritis in a randomized controlled study[2] and demonstrated effectiveness in comorbid patients with recurrent crystal-related arthritis. Due to our local experience with anakinra to treat calcific periarthritis[3], we started using anakinra in the treatment of selected patients with ACD in hand and wrist with severe pain.
Objectives: To report our experience with anakinra to treat ACD in hand and wrist in terms of efficacy and safety.
Methods: We retrospectively included all patients treated with anakinra for ACD in hand or wrist in our department in 2020. We extracted data on treatment duration, pain, range of motion, skin erythema, hypervascularization, oedema and X-ray findings when available.
Results: Ten patients (mean age 45, SD 11) were treated for ACD in hand or wrist with anakinra 100 mg per day for a mean duration of 2.7 days. We observed a fast and significant improvement of pain at rest on a 0-10 VAS scale (mean pain reduction at day 2 (SD): -3.9 (2.8), p=0.01). All patients were free of pain at rest after day 6 and at motion after day 21. Range of motion significantly improved at day 2 (+41° (24), mean (SD), p=0.03). We observed local erythema and oedema improvement from day 2 and a decrease in skin temperature from day 3. Calcifications decreased in size or disappeared in the majority of the patients. We did not observe any adverse events. Patients did not report recurrence after phone contact, 12 months after treatment.
Conclusion: Anakinra was associated with a significant clinical improvement after only two days of treatment of ACD in hand or wrist and may be considered to treat patients with this condition, especially those with contraindication to NSAIDs or glucocorticoids. Further controlled studies are needed to confirm our observations.

AB1067 ASYMPTOMATIC HYPERURICEMIA AND ASSOCIATED FACTORS IN MALE PATIENTS VISITED HANOI MEDICAL UNIVERSITY HOSPITAL

T. Phạm[1], H. T. Pham[1], T. H. Pham[1], G. Trần[1], T. Nguyễn[1], T. Đỗ[1]. *[1]Hanoi Medical University Hospital, Rheumatology Unit - Internal Medicine Department, Hanoi, Vietnam*

Background: Asymptomatic hyperuricemia prevalence in Vietnamese men has rose over the past several years. This leads to gout and increase cardiovascular risk.
Objectives: To assess the prevalence of asymptomatic hyperuricemia and associated factors in male patients who had medical check-ups in Hanoi Medical University Hospital.
Methods: All asymptomatic hyperuricemia male patients over 18 years old, had medical check-ups in outpatient clinics from January 2020 to May 2021. Exclude criteria included patients having medicine which affected serum uric acid (allopurinol, probenecid, sulfinpyrazone, salicylate, phenylbutazone, ascorbic acid, ethambutol, pyrazinamide, ect.), had acute diseases, diabetes type 1, chronic kidney disease and malignancies. All patients were tested for serum uric acid, total Cholesterol, Triglyceride, HDL-C, LDL-C and fasting serum glucose using Roche Cobas 6000 analyzer. Age, body mass index, alcohol consuming, physical activities and comorbidities were identified.
Results: 798 male patients over 18 years old were included in the study. Mean age was 39.5 ± 11.2, overweight and obesity rate was 31.5% and 29.8%, respectively. 41.4% patients had hyperuricemia with mean serum uric acid was 405.2 ± 81.2 µmol/l (highest was 820 µmol/l). We found that the factors associated to hyperuricemia in men were: the presence of hypertension (OR 1.64, 95% CI 1.1 -2.34), dyslipidemia (OR 2.37, 95% CI 1.73-3.24) and alcohol consuming (OR 2.16, 95% CI 1.6-2.8). We did not find association between smoking, physical activities, impaired glucose tolerance with hyperuricemia.
Conclusion: Alcohol consuming, dyslipidemia and hypertension were associated with higher risk of incident asymptomatic hyperuricemia in Vietnamese men.

AB1068 HIGH FREQUENCY OF STRUCTURAL DAMAGE IN THE LOWER SPINE OF PATIENTS WITH CHONDROCALCINOSIS

K. Klavdianou[1,2], J. Kasfeld[1], M. Fruth[3], S. Tsiami[1], J. Braun[1], P. Sewerin[1], D. Kiefer[1], X. Baraliakos[1]. *[1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany; [2]'Asklepieion' General Hospital, Department of Rheumatology, Voula, Athens, Greece; [3]Blikk, Radiologie, Herne, Germany*

Background: Calcium pyrophosphate dihydrate crystal deposition disease (CPPD, chondrocalcinosis) is known to affect fibrocartilaginous tissue in the large and smaller peripheral joints. The affection of similar structures in the axial skeleton is unclear.
Objectives: To assess the frequency and severity of structural changes in the lower spine in patients with established CPPD in comparison to degenerative disc disease (DDD).
Methods: In a retrospective study, patients with CPPD or DDD as a main diagnosis with available spinal conventional radiographs (CR) performed during 2014 – 2020 were included. Definite other inflammatory conditions affecting the spine were excluded. The CR segments T7/8-L5/S1 were evaluated for the occurrence of disc calcification, intradiscal vacuum phenomenon, disc height (normal, narrowing, complete loss), endplate erosion, osteophytes and spondylolisthesis. When lumbar spine MRIs of the same time point were available, discovertebral units were evaluated for the occurrence of vacuum phenomena, endplate erosion, Modic changes and disc dehydration (Pfirrmann). Follow up CR were assessed if available. All available images were evaluated by 2 independent readers and discrepancies were solved by consensus.
Results: CR of 140 patients (1.171 discovertebral units) with CPPD and 99 DDD (803 discovertebral units) were evaluated (mean age 74.4±9.9 and 71±6.2, 20% vs. 20.2% males, respectively). MRIs of the spine were available from 48 CPPD and 44 DDD patients. Vacuum phenomena, disc calcification, osteophytes and erosion were significantly more frequently seen in patients with CPPD compared to DDD (Table 1) with no differences between the thoracic and the lumbar spine. Follow-up CR were available for 29 patients with CPPD and 46 DDD. Both groups presented statistically significant progression of endplate erosions and osteophytes (p 0.001 - 0.02 for both groups). Notably, even though CR follow-up times in the CPPD group were, compared to DDD (median (IQR) 1.9 (2.4) *vs* 3.0 (3.1) years, p=0.033, respectively), shorter, radiographic progression was noted more frequently in CPPD vs. DDD for erosive changes (6.8% vs. 0.6%, p=0.018) and disc calcification (5.8% vs. 0.6%, p=0.007), respectively. When comparing MRIs, a higher number of discovertebral units was affected by vacuum phenomena (34 *vs* 13, p=0.04) and endplate erosions (L4/5 (45.5% *vs* 24.4%, p=0.04), L5/S1(40.4% *vs* 19.5%, p=0.03) in patients with CPPD vs. DDD, respectively.

Table 1. Frequency of affected discovertebral units on conventional radiographs

	CPPD	DDD	p
Vacuum phenomenon	156 (13.3%)	44 (5.5%)	<0.001
Disc calcification	193 (16.5%)	42 (5.2%)	<0.001
Endplate erosion	159 (13.6%)	26 (3.2%)	<0.001
Osteophytes	861 (73.5%)	480 (59.8%)	<0.001
Spondylolisthesis	126 (10.8%)	69 (8.6%)	0.264

CPPD: calcium pyrophosphate dihydrate crystal deposition disease DDD: degenerative disc disease

Conclusion: Patients with chondrocalcinosis showed more severe and progressive degenerative findings in the lower spine as assessed by both, CR and MRI, even more in comparison to established DDD. This data shows that disease manifestations of CPPD in the axial skeleton are clinically relevant.

AB1069 URIC ACID LEVELS IN RELATION TO FASTING BLOOD GLUCOSE AND HBA1C

F. Fhima[1], N. El Amri[1], D. Khalifa[1], A. Ben Abdelkrim[2], S. Lataoui[1], B. Ben Abdallah[2], K. Baccouche[1], E. Bouajina[1], K. Ach[2]. *[1]Farhat Hached Hospital, Rheumatology Department, Sousse, Tunisia; [2]Farhat Hached Hospital, Endocrinology and Diabetes Department, Sousse, Tunisia*

Background: Hyperuricemia is reported to be a risk factor for the development of type 2 diabetes (T2D) and prediabetes.
Objectives: To determine the prevalence of HU and gout in T2D and prediabetes and to study the relationship between HU, gout, T2D and prediabetes.
Methods: A cross-sectional study was conducted beween January 2021 and June 2021 in the Rheumatology and endocrinology departments of Farhat Hached Hospital. Patients who fulfilled the diagnosis of diabetes or prediabetes according to the American Diabetes Association guidelines of 2021 were included. Uric acid levels were also assessed and HU was defined as uric acid levels ≥ 360 µmol/l in women and ≥ 420 µmol/l in men. Diagnosis of gout was based on the ACR/EULAR 2015 classification.
Results: One hundred fifty-one patients having T2D and 46 prediabetic patients were included. The mean of age in both groups was 61 and 54 years respectively. Prevalence of HU was 26.1% in prediabetic while it was 17.2% in the group of T2D with no statistical relevance (p=0.182). No difference related to gender was observed in both groups. The prevalence of gout was higher in the prediabetes group (15.2%) compared to the T2DM group (6%) but without significant difference (p=0.062). Uric acid levels were remarkably higher in prediabetic patients (mean=324,3 µmol/l) compared to patients having T2D (median=278 µmol/l) with a significant statistical difference (p=0.022). No association was identified between HU, fasting blood glucose and HbA1C in the two groups. However, uric acid levels are inversely proportional to fasting blood glucose (p=0,001) and HBA1C (p=0.001) in all patients.
Conclusion: Individuals with moderately elevated HbA1c and fasting glucose levels (prediabetes) may be at a higher risk of HU, whereas individuals with diabetes or elevated HbA1c levels may have a normal uricemia. This could be explained by the GLUT-9 transporter regulation in the renal proximal tubule that blocks the absorption of uric acid when glycosuria is present.

Infection-related rheumatic diseases

AB1070 INFECTIOUS SACROILIITIS: A RARE ENTITY IN RHEUMATOLOGY!

S. Rekik[1], O. Hamdi[1], S. Bousaid[1], S. Rahmouni[1], S. Jemmali[1], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta hospital, Rheumatology, Tunisia, Tunisia*

Background: Infectious sacroiliitis (ISI) is a rare disease, with misleading clinical symptoms that often delay the diagnosis.
Objectives: The aim of this study was to describe the clinical, microbiological, therapeutic and radiological characteristics of ISI.
Methods: This descriptive, retrospective study included all ISI patients that were hospitalized in our rheumatology department over an 11-year period [2010 - 2021].
Results: Overall, 25 cases of ISI were identified, comprising 15 men (60%) and 10 women (40%), with a mean age of 48.7±10.5 years [21-67]. ISI was caused by pyogenic microorganisms in 12 cases (70.5%), mycobacterium tuberculosis in 7 cases (41.2%), and brucella spp in 6 cases (35.3%). The mean symptoms duration in pyogenic, brucellar and tuberculous ISI was 42 days, 67 days, and 255 days, respectively. The onset was brutal in 88% of pyogenic ISI, while it was progressive in 68% of brucellar ISI and in all cases of tuberculous ISI. Lumbogluteal pain was the most common symptom (80%). The involvement of the sacroiliac joint was always unilateral, and inflammatory in 92% of cases. The other most common symptoms included: fever (80%), impotence (68%), and lumbago (52%). An infectious source was found in 17 patients: 41.2% pulmonary (tuberculosis, n=7), 29.4% urinary, 17.6% gynecological (postpartum, n=3), and 11.7% septicemic (n=2). Fifteen patients (60%) had a biological inflammatory syndrome. Leukocytosis was found in 11 cases (64.7%). Pelvic x-ray showed a narrowing of the sacroiliac joints in 52% of cases. CT of the sacroiliac joints showed erosions in 60% of cases. Sacroiliac MRI showed erosions (45%), joint effusion (32%), and psoas abscess (14%). A second infectious site was found in 20% of cases: psoas abscess (n=2), and a collection of the soft tissues facing the joint (n=1). A pathogenic agent was isolated by means of blood culture (48%; staphylococcus aureus 56%, streptococcus 28%, and staphylococcus with negative coagulase 16%), articular biopsy (40%), cytobacteriological examination of urine (20%), Wright serology (20%), and Tuberculin skin test (6.2%). All patients received germ-adapted antibiotics. No patients have had surgical treatment. Evolution was favorable in most cases (n=11). Four patients complained of residual pain in the sacroiliac region. None of the patients relapsed.
Conclusion: Although IS is rare, it remains an emergency diagnosis. A rigorous physical examination is essential in order to detect this infection early. Antibiotics often lead to clinical improvement, making thus the need for surgery exceptional.

AB1071 INFECTIONS IN RHEUMATOLOGIC PATIENTS IN A LATIN AMERICAN HOSPITAL, A 10-YEAR COHORT STUDY.

L. Dulcey[1], J. Theran[2], R. Caltagirone[1], H. Moreno[1], J. Pineda[1], R. Parales[2], M. Aguas[3]. [1]*Los Andes University, Internal Medicine, Bucaramanga, Colombia;* [2]*Bucaramanga University, Medicine, Bucaramanga, Colombia;* [3]*Santander University, Medicine, Bucaramanga, Colombia*

Background: Infections have been indicated to be the cause and / or consequence of the calving and decompensation of some Connective Tissue Diseases and, in principle, both the immunological disorder and the immunosuppressive action of medications contribute to this.
Objectives: To describe the frequency of infections associated with the various rheumatological pathologies in patients admitted to hospitalization and to know their associated factors.
Methods: A descriptive study was carried out in which 3328 medical records belonging to the patients of the Rheumatology service were reviewed during a follow-up period from January 2010 to December 2020, measures of central tendency such as mean, mode, median and applied the Chi square test to appreciate statistical value between the various variables to be correlated.
Results: Most of the patients were female. The main rheumatological pathology was Rheumatoid Arthritis, followed by Systemic Lupus Erythematosus, Osteoarthritis in 3 place and finally in the last box other entities other than those indicated. The main infectious were those of the urinary tract, in the second instance those of skin and soft tissues, in third place the respiratory ones and lastly those not included in the previous categories. The 2 main therapies related to infections were the use of steroids followed by biological therapy (p 0.001).

Table 1. Medications received, categories of infections and reason for hospitalization presented by patients in frequencies and percentages.

	Reumathoid Arthritis	Lupus	Osteoarthritis	others
	n=1 296 (43,9%)	n=347 (11,7%)	n=259 (8,7%)	n= 1 045 (35,4%)
Treatments				
Corticosteroids	829 (64)	220 (63,4)	165 (63,8)	545 (52,2%)
Non-steroidal immunomodulator	184 (14,2)	71 (20,6)	57 (22,2)	312 (29%)
TNF Inhibitors.	195 (15)	0 (0)	0 (0)	130 (12,5%)
No treatment	88 (6,7)	56 (16)	37 (14)	58 (6,4%)
Infections				
Urinary	773 (59,6)	215 (62)	165 (63,6)	648 (62,1%)
Skin	257 (19,8)	71 (20,6)	47 (18,3)	210 (20,1%)
Pneumonia	162 (12,5)	38 (10,8)	30 (11,5)	103 (9,8%)
Others	104 (8,1)	23 (6,5)	17 (6,6)	84 (8%)
Hospitalized				
Variable	Total Hospitalized (n_216)	Total Hospitalized (n_347)	Total Hospitalized (n_24)	Total (n_79)
Not infectious	71 (32,87%)	39 (11,2%)	3 (12,2%)	11 (13,8%)
Infections	145 (67,12%)	308 (88,8%)	21 (87,8%)	68 (86,2%)

Conclusion: In the present study it was found that infections were the main cause of decompensation and hospitalization in these patients. Infection is the cause of significant morbidity and mortality in rheumatology patients. Conclusions: Based on the observations obtained in the present study, it is recommended that the risks for the development of infections in rheumatology patients be evaluated through stratification systems and thus generate strategies that reduce their frequency.

AB1072 HERPES ZOSTER IN INDIVIDUALS WITH AUTOIMMUNE DISEASES AND RECOMBINANT HERPES ZOSTER VACCINE AS A PREVENTATIVE STRATEGY

K. Winthrop[1], F. A. Farraye[2], K. M. Sullivan[3], D. O. Willer[4], P. Vink[5], F. Tavares-Da-Silva[6]. [1]*Oregon Health and Science University, Portland, OR, United States of America;* [2]*Inflammatory Bowel Disease Center, Division of Gastroenterology and Hepatology, Mayo Clinic, Jacksonville, FL, United States of America;* [3]*Duke University Medical Center, Durham, NC, United States of America;* [4]*GSK Vaccines, Mississauga, ON, Canada;* [5]*GSK*

Vaccines, Rockville, MD, United States of America; [6]GSK Vaccines, Wavre, Belgium

Background: Individuals with autoimmune diseases (AIDs) are particularly vulnerable to herpes zoster (HZ) and its related complications. Although the live attenuated HZ vaccine is contraindicated in many of these individuals, the two-dose non-live recombinant zoster vaccine (RZV) can be used in immunosuppressed individuals. Based on accumulating data from RZV studies within specific immunosuppressive conditions, recently updated guidelines recommend RZV not only in immunocompetent adults aged ≥50 years, but also in adults aged ≥18 years (EU)/≥19 years (USA) at risk of HZ due to immunodeficiency or immunosuppression.[1–3]

Objectives: To evaluate the burden of HZ in individuals with AIDs and the use of RZV as a preventative strategy.

Methods: We reviewed PubMed for available data on HZ incidence, summarised RZV data (effectiveness and safety) and the current recommendations for RZV in individuals with AIDs. The latest search was conducted in September 2021.

Results: HZ incidence in the general population is 4–7/1000 person-years (increases with age) and 8–15/1000 person-years in individuals with AIDs. Common immunosuppressive and immunomodulatory therapies can predispose individuals to HZ, as shown by large meta-analyses of interventional and observational studies. No published randomised controlled trial data of RZV in AID populations were found in our search. In two retrospective cohort studies in patients with inflammatory bowel disease (IBD), [4,5] RZV demonstrated high vaccine effectiveness (OR 0.64; 95% CI 0.44, 0.77).[4] In a real-world observational study investigating RZV in beneficiaries of the Medicare national health insurance program in the USA, individuals with AIDs achieved vaccine effectiveness of 68.0% (95% CI 62.3%, 72.8%), which was similar to the overall population (70.1% [95% CI 68.6%, 71.5%]).[6] In two single-centre, retrospective studies of RZV in individuals with AIDs, including rheumatoid arthritis (RA), adverse events after the first RZV dose were mild[7,8]. Disease flares were uncommon, mild and self-limiting, although a flare at the first RZV dose was significantly associated with an increased risk of a flare at the second dose (hazard ratio 3.9; P=0.0015)[7]. In addition, glucocorticoid use during vaccination was significantly associated with flares (odds ratio [OR] 2.31; P=0.004; Lenfant, 2021)[7]. In a study of individuals with IBD, receiving ≥1 RZV dose was associated with a low flare rate[9]. Current RZV guidelines vary by country and will be revised as new data emerge. Ongoing studies include phase 4 studies of individuals with RA and IBD receiving immunotherapies, and a study investigating the immunogenicity and safety of RZV in individuals with stable systemic lupus erythematosus.

Conclusion: Individuals with AIDs are at increased risk of HZ and its related complications, which may be due to either or both of their underlying condition and the treatment(s) they are receiving. The developing collective scientific evidence from the published literature on RZV in individuals with AIDs demonstrates a favourable benefit:risk profile for RZV in this population which contributed to the recent USA ACIP recommendation. Further studies are warranted to evaluate potential effects of individual conditions and immunotherapies on vaccine efficacy and methods to optimise vaccine use.

AB1073 HIGH INCIDENCE OF VIRUSES INFECTION IN CONNECTIVE TISSUE DISEASES PATIENTS

R. Su[1], B. C. LI[1], H. Yan[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University,Taiyuan, Department of Rheumatology,Taiyuan, China*

Background: Connective tissue diseases (CTDs) are a group of diseases with a variety of clinical manifestations. The main drug was glucocorticoids and immunosuppressive drugs, but the results are not satisfactory and the side effects are obvious, increased the incidence of infection, especially opportunistic infections. Infections becomes important causes of morbidity and mortality in CTD patients.

Objectives: To evaluate the incidence of infection in CTD patients who were clinically considered for co-infection by a combination of metagenomic next-generation sequencing (mNGS) and conventional diagnostic testing methods.

Methods: We analyzed 126 connective tissue diseases (CTD)patients with suspected infections admitted to The Second Hospital of Shanxi Medical University. All patients with CTD were diagnosed according to relevant diagnostic criteria, including 34 systemic lupus erythematosus (SLE), 24 dermatomyositis and polymyositis (DM/PM), 19 rheumatoid arthritis (RA), 10 undifferentiated connective tissue disease(UCTD),16 Sjogren syndrome (SS), 5 mixed connective tissue disease (MCTD), 5 ANCA associated systemtc vasculitis (AAV), 5 adult onset Stillystemtc isease disease(tic criteria, including 34nfections admitted to The Second Hospital of Shanxi (TA), 1 systemic sclerosis (SSC), 1retroperitoneal fibrosis (RPF). All enrolled patients were tested for conventional diagnostic testing methods(CDT) and mNGS.

Results: Among the 126 patients with CTD who were clinically considered for co-infection, 31 patients were negative for mNGS, and pathogens were detected in 99 of them. In our results, the mNGS and CDT were both positive for pathogens detection in 28 individuals.Of both positive individuals, 2 cases were perfect matches,12 cases were partly matched, 14 cases were totally mismatched. A total of 23 cases were negative for both mNGS and CDT. 70 cases were positive for mNGS only.There were only 5 cases positive for pathogens detection by CDT only. In addition, the results of mNGS showed that 131 patients were virus-positive(54%), 78 patients were prokaryotes-positive (37%) inculding bacteria, mycoplasma and 14 patients were eukaryotes-positive (9%). Of course, someones have mixed infections among these patinets some of these patients, with two or more pathogens. In the mixed infection, 5 cases have no viruses infection, 38 cases with virus infection, including 20 cases of bacteria and viruses infection, 4 cases of bacteria,fungi and viruses infection, 9 cases of viruses mixed infection, 1 case of bacteria,viruses,fungi and mycoplasma infection, 1 case of bacteria,viruses and mycoplasma infection, 1 case of viruses and mycoplasma infection, 1 case of viruses and fungi infection. According to the results, viruses were the most common pathogens identified, followed by prokaryotes and eukaryotes. It is noteworthy that the incidence of Human gammaherpesvirus 4(EBV), Human betaherpesvirus 5(CMV) and Human alphaherpesvirus 1 are more common in virus-positive. The most frequently detected prokaryotes were Acinetobacter baumannii, Mycobacterium tuberculosis complex, followed by Staphylococcus aureus, Prevotella melaninogenica,Staphylococcus homini and Helicobacter pylori. The major pathogens were Pneumocystis jirovecii and Candida albicans among eukaryotes-positive individuals.

Conclusion: As a complementary approach to conventional methods, mNGS could help improving the identification of infection in CTD patients.The incidence of viral infection is high in patients with connective tissue disease and close attention should be paid to it in clinical works.

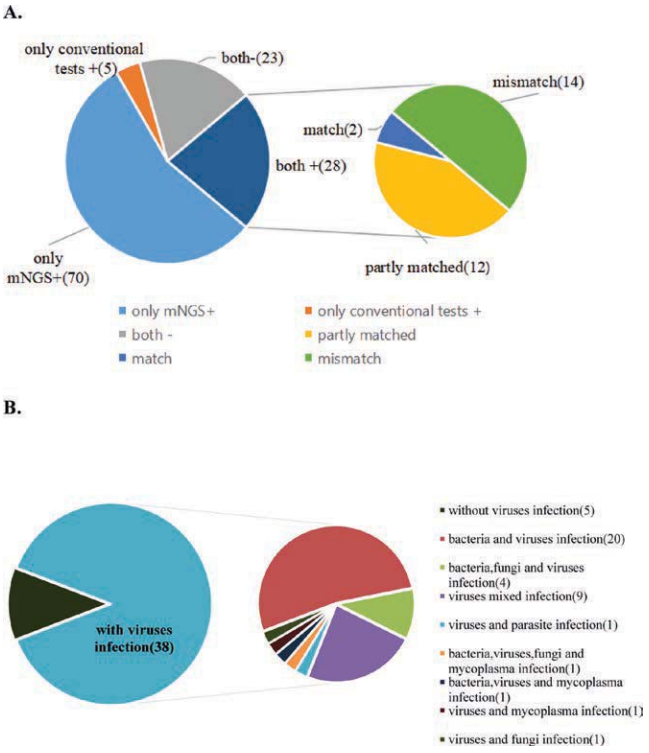

Figure 1. A. Comparison of test results between mNGS and conventional diagnostic testing methods(CDT) in CTD patients. B. The classification of mixed infections with or without viruses infection detected by mNGS and conventional diagnostic testing methods(CDT).

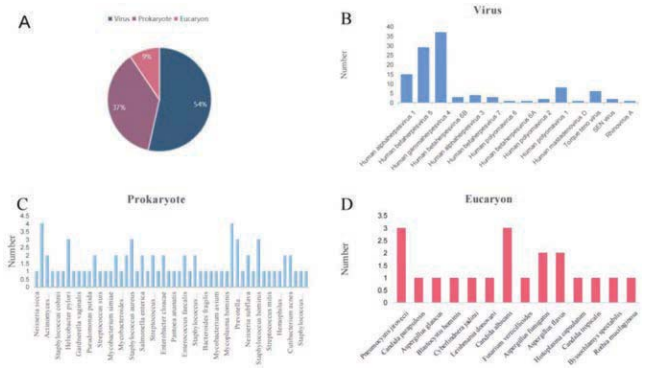

Figure 2. Distribution of pathogens detected by mNGS. A. Type distribution of pathogens identified by mNGS. Species distribution of viruses of B.viruses, C.Prokayote, D. Eucayon detected by mNGS.

AB1074

FATAL BUT PREVENTABLE - SINGLE CENTRE SERIES OF 6 CASES OF PNEUMOCYSTIS JIROVECII PNEUMONIA (PJP) IN PATIENTS WITH AUTO-IMMUNE INFLAMMATORY RHEUMATIC DISEASE (AIIRD) IN ONE YEAR.

A. Escudero Siosi[1], M. Andersson[2], C. Woodrow[3], S. Dubey[1]. *[1]Oxford University Hospitals NHS Foundation Trust, Rheumatology, Oxford, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Infectious Diseases and Microbiology, Oxford, United Kingdom; [3]Oxford University Hospitals NHS Foundation Trust, Infection Disease & General Medicine, Oxford, United Kingdom*

Background: Pneumocystis jirovecii pneumonia (PJP) is an uncommon but frequently fatal fungal infection, which can affect patients with rheumatic diseases treated with immunosuppressants or high doses of steroids. There are no clear guidelines on when to prescribe primary prophylaxis and available agreements differ depending on the disease or immunosuppressant.
Objectives: To raise awareness about this preventable infection and to highlight the urgent need to create a tailored probability scoring, before starting any immunosuppression so that the risk benefit of prophylaxis can be objectively assessed.
Methods: This is a retrospective case series of six patients who developed definite or probable PJP known to the Rheumatology Department at Oxford University Hospitals NHS FT since the beginning of 2021. These patients were identified through the microbiology and infectious disease teams, and notes were reviewed to collate data regarding the clinical characteristics. Of these, five were being treated for large vessels vasculitis (LVV) whilst the other one had seropositive rheumatoid arthritis (RA). The diagnosis of PJP was made on clinical picture, laboratory results, bronchoscopy and CT findings.
Results: In this series, the median age was 78 years (range 55-93) with equal gender distribution. In three LVV patients, the diagnosis was confirmed on ultrasound, one had a positive PET-CT whilst the other case had a high probability clinical diagnosis. Comorbidities included chronic kidney disease and hypertension in three patients, diabetes, or previous underlying malignancy in other two. Smoking history was present in four patients, while five patients had lymphopenia with counts <1x10^9/L. Four of the six cases were on combined therapy with disease modifying anti-rheumatic therapy drugs (DMARDs) and prednisolone, only one was exclusively on prednisolone and the patient with RA was on Methotrexate and Humira. The chronology of the infection was variable, still most of the patients developed PJP infection during the first three months of starting either a biologic or corticosteroids. The median steroids dose by the time of PJP infection was 30 mg and unfortunately three of the patients died. None of the patients who developed PJP had been given antibiotic prophylaxis prior to infection. Some proposed scoring systems for serious infection risk in patients with AIIRD exist, however they focused on RA or biologics use rather than patients with vasculitis or connective tissue disorders who might be on high dose corticosteroids. Additionally, PJP prophylaxis is not recommended in any of the current guidelines for LVV management (BSR, EULAR, ACR). Cochrane review suggests reduction of risk by 85% in patients given prophylaxis.
Conclusion: Pneumocystis Jirovecii pneumonia (PJP) prophylaxis is not current practice for patients with large vessel vasculitis. Consideration needs to be given to PJP prophylaxis for patients on high dose steroids for a prolonged period, particularly in the presence of other risk factors. More data will be needed to help establish guidelines on PJP primary prophylaxis.

KNEE ARTHRITIS BY PARACOCCIDIOIDES BRASILIENSIS IN A LONG-STANDING RHEUMATOID ARTHRITIS PATIENT

M. Barguil Macedo[1], C. Gama[1], I. P. D. B. Antonelli[1], F. H. C. De Souza[1], A. C. Medeiros Ribeiro[1]. [1]*Clinics Hospital of the University of São Paulo - HCFMUSP, Division of Rheumatology, São Paulo, Brazil*

Background: Arthritis by *Paracoccidioides brasiliensis* is a remarkably unusual etiology of infectious joint disease. While osseous lesions can be present in systemic disease, intra-articular-restricted disease without typical lung or lymph node involvement is mostly anecdotal[1,2].
Objectives: We hereby describe a case of this fungal arthritis in a patient with rheumatoid arthritis (RA) without significant immunosuppression.
Methods: Patient records review. Written informed consent was obtained.
Results: A 65-year-old female Brazilian patient with a 35-year history of seropositive RA complained of a painful knee edema for the last three weeks. Skin surrounding the joint was erythematous, warm, and tender to the touch, which initially raised the suspicion of cellulitis. She had already received a 10-day course of amoxicillin-clavulanate, with no improvement. C-reactive protein was 17.8 mg/L, rest of blood chemistry panel was within reference range. Point-of-care ultrasound revealed joint effusion, and a diagnostic arthrocentesis was performed. Synovial fluid was slightly turbid, with 10,100 cells per mm^3, of which 80% were lymphocytes. Cultures for bacteria and mycobacteria yielded negative results, but culture for fungi detected growth of *P. brasiliensis*. The patient had been solely on prednisone 5 mg once daily for the last year, given that, due to covid-19 pandemics, she lost regular follow-up and abandoned treatment with immunosuppressants. Aside from mild RA-related interstitial lung disease, she had no other comorbidity. She denied local trauma to the knee, which made hematogenous dissemination of the fungi the most probable source. Comprehensive work-up to search for organic involvement of paracoccidioidomycosis, including chest computed tomography and transthoracic echocardiogram, did not evidence any visceral compromise. Voriconazole 200mg t.i.d. was started, with good response. Three months after the beginning of the azole, tofacitinib was started for moderate RA disease activity, which also responded satisfactorily. Repeat arthrocentesis and synovial biopsy were performed eight months after the start of antifungal treatment, the former being normal (770 cells per mm^3, negative cultures), and the later only demonstrating non-specific chronic synovitis with fibrosis.
Conclusion: We reported an exceedingly rare presentation of *P. brasiliensis* infection with exclusive joint involvement.

IS THERE AN ADDITIONAL IMPACT OF STIMULATING CD8+ LYMPHOCYTES TO DETECT LATENT TUBERCULOSIS IN PATIENTS WITH RHEUMATIC DISEASES?

Z. Özsoy[1], A. Özdemir[2], M. Ekici[1], A. Eken[3], F. Çakmak[3], E. Bilgin[1], L. Kılıç[1], A. İ. Ertenli[1], Z. Sarıbaş[2], O. Karadag[1], B. Şener[2]. [1]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey;* [2]*Hacettepe University, Faculty of Medicine, Department Of Medical Microbiology, Ankara, Turkey;* [3]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*

Background: Purified protein derivative skin test (PPD) or interferon gamma release assays (IGRAs) are used as diagnostic tools to detect latent tuberculosis. QuantiFERON-TB Gold Plus (QFT-Plus) is a new test that detects latent tuberculosis. Antigens of *Mycobacterium tuberculosis* (ESAT-6 and CFP-10) are used. The test contains two tubes: TB1 and TB2. TB1 tube contains peptides of these antigens that induce CD4+T cell response while TB2 tube contains peptides designed to stimulate both CD4+ and CD8+ T cells. The amount of interferon gamma releases from those cells are determined by ELISA method. In patients with recent exposure to tuberculosis, there is an increased amount of CD8+ expression in comparison to patients with past exposure to tuberculosis.
Objectives: To investigate the additional impact of stimulating CD8+ lymphocytes with QFT-Plus test in order to detect latent tuberculosis in patients with inflammatory rheumatic diseases.
Methods: Hacettepe University Rheumatology Biologic Registry Database (HURBIO) database was used in this study. QFT-Plus test of patients with rheumatoid arthritis (RA) and spondyloarthritis (SPA) between January 2018 and March 2021 during work up before biologic/targeted therapy were analysed, retrospectively. Positivity of any of tubes has been reported as QFT (+). The impact of each tube on QFT positivity is analysed.
Results: 1480 patients (946 (64%) SPA, 534 (36%) RA) were enrolled. 957 patients were women. The median age was 45 (min-max:18-82). Totally 12.2% of patients had been reported as QFT(+). In 6% of QFT (+) patients only TB2 tube is positive (Table 1).

Table 1. The impact of each tube on QFT-Plus positivity

		QFT-Plus test (n=1480)	
Negative			86.2%
Indeterminate			1.5%
Positive	Only TB1 tube positivity	8% of positively reported patients	12.2% of all patients
	Only TB2 tube positivity	6% of positively reported patients	
	TB1 and TB2 positivity	86% of positively reported patients	

Conclusion: Disease inflammatory cascades along with ongoing usage of immunosuppressive agents could affect results of QFT-plus assay in rheumatic diseases. TB2 tubes stimulating CD8(+) T lymphocytes have additional impact in detecting latent TB infection in patients with RA and SpA.

AB1077

INFECTIOUS SPONDYLODISCITIS IN ELDERLY: IS IT MORE SEVERE DISEASE?

S. Rekik[1], Z. Zeineb[1], S. Boussaid[1], S. Jemmali[1], S. Rahmouni[1,1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1,1]. [1]*Rabta University Hospital, Rheumatology, Tunis, Tunisia*

Background: Spondylodiscitis is a chameleon among infectious diseases due to the lack of specific symptoms. In older patients, there are often difficulties in diagnosis and management.
Objectives: This retrospective study aimed to assess the characteristics of infectious spondylodiscitis in patients over 65 years of age.
Methods: This retrospective, monocentric study included patients aged over 65 years olds hospitalized in our department of rheumatology for spondylodiscitis.
Results: A total of 20 consecutive patients (10 males, 10 females) aged over 65 years were analyzed. The mean age of patients was 74 years (65-85). The most common comorbidities included diabetes (20%), chronic renal failure (5%). A history of nodal tuberculosis (10%), a tuberculosis contagion (30%), and raw milk ingestion (15%) were reported. The average delay for diagnosis was 10 months. The most common symptom was axial back pain (100% patients), then worsening health status (34%), and one patient had a significant neurological deficit. C-reactive protein was elevated in 95%. The most common involvement was in the lumbar vertebrae (13 patients, 65%), followed by thoracic and cervical level disease respectively in 3 patients (15%) and 2 patients (10%). Two patients (10%) had a multifocal spondylodiscitis. All patients underwent an MRI exam that confirmed the diagnosis. A percutaneous spine biopsy was performed in 80%. Pyogenic spondylodiscitis was the most common etiology (50%), followed by tuberculosis (35%) and brucellosis (15%). Antibiotic therapy was indicated to all patients with spinal immobilization in 65% of cases. Two patients underwent percutaneous drainage of paravertebral abscesses. The outcome was favorable in almost all cases until 12 months of following-up after completion of treatment. One patient died of septic shock and multi-visceral failure.

Conclusion: Elderly patients with infectious spondylodiscitis have fewer clinical symptoms leading to a delayed presentation. Increasing morbidity and mortality make rigorous monitoring necessary.

AB1078 SPECTRUM OF INFECTIONS DURING RHEUMATOID ARTHRITIS

S. Rekik[1], S. Boussaid[1], H. Tbini[1], S. Rahmouni[1], S. Jemmali[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia*

Background: Immunosuppression during rheumatoid arthritis (RA) induced by the disease but especially immunomodulatory treatments, is responsible for an increased frequency of infections in these patients.
Objectives: The purpose of this study is to assess the incidence of infections during RA and to determine their nature and management.
Methods: A retrospective study over a period of 10 years, including 150 patients with RA. We identified 33 patients who had at least one infectious episode during their follow-up.
Results: There were 19 women and 14 men. The mean age was 51 years old [39-63]. RA was immunopositive and erosive in all cases. The average disease duration was 8 years. A comorbidity was associated with RA in 14 patients (42%): diabetes in 7 cases, hypertension in 3 cases, ethylism in 2 cases and history of pulmonary tuberculosis in 2 cases. As an extra-articular manifestation, 15% of patients had Sjogren's syndrome and 18% had pulmonary interstitial fibrosis (3 cases) or pulmonary nodules (3 cases). The most prescribed DMARDs was Methotrexate, prescribed in monotherapy at the average dose of 17.5 mg/week [10-25mg] in 18 cases. The other patients received Methotrexate associated to Hydroxychloroquine in 4 cases, Sulfasalazine in 3 cases and biotherapy in 8 cases. Corticosteroid therapy at an average dose of 7.5 to 15 mg/day was received in 16 cases (48.5%). All infections noted in our population were community acquired. Urinary tract infection was the most common infection noted in 15 cases: pyelonephritis in 3 cases and cystitis in 12 cases. Other infection sites were ENT in 4 cases, bronchopulmonary in 6 cases including 2 cases of tuberculous infection and viral hepatitis (B and C) in 4 cases. Osteo-articular infections were noted in 3 cases: one cervical spondylodiscitis and two septic arthritis. Finally, one case of RA treated with rituximab was complicated by staphylococcal sepsis. Germs causing these infections were identified in 14 cases (42%).
Conclusion: The risk of infections is increased during RA, this is due to lymphocyte and autoimmune abnormalities but also to treatments and comorbidities that predispose to the emergence of infectious agents.

DOI: 10.1136/annrheumdis-2022-eular.4816

AB1079 INFECTIOUS SACROILIITIS ACCORDING TO THE GERM: ABOUT 42 CASES

S. Rekik[1], S. Boussaid[1], H. Tbini[1], S. Jemmali[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia*

Background: Infectious sacroiliitis is a rare rheumatological emergency. Its semiology is misleading due to the deep location of the joint. The responsible germs play an important role in its semiology.
Objectives: The objective of this work was to identify the germs responsible for infectious sacroiliitis and their effect in the sacroiliac joint.
Methods: We conducted a retrospective study, including 42 patients hospitalized for infectious sacroiliitis over a period from 2000 to 2020. Demographic, clinical, biological and radiographic data were collected.
Results: A total of 42 Patients were enrolled (11 men and 31 women). The mean age was 36,7 years [29-76]. Low back pain with difficulty walking were the most common manifestations (88%). The inflammatory syndrome was present in 70% of cases. Standard radiographs showed loss of cortical margins with erosion of the sacroiliac joints in 34 cases and were normal for the rest of the patients. MRI and CT scan were performed to confirm the diagnosis in 28 and 13 cases respectively. A puncture guided by ultrasound or scanner was performed in 24 patients. In the cases of absence of germ on the conventional examinations, we performed a sacroiliac biopsy and histological examinations. Pyogenic germs were responsible for 46% of infectious sacroiliitis: Staphylococcus Aureus in 11 cases (28%), Escherichia Coli in 7 cases (16 %) and Streptococcus in one case (2%). Tuberculosis and Brucella were responsible for 38% and 7% of the cases respectively. A subcutaneous abscess was associated with tuberculous sacroiliitis in 4 patients. The outcome was favorable in 36 cases (86%) under appropriate antibiotic therapy. Eight patients presented a treatment-related complication. Progression to multifocal bone tuberculosis and chronic brucellosis was noted in one case each. In 3 cases, rapid ankylosis was found on radiological control. Unfortunately, one patient died from septic shock.
Conclusion: Common germs are most responsible for infectious sacroiliitis and seem to have the best prognosis. Tuberculosis is responsible for various complications and its treatment has a high iatrogenic risk. Chronicity is the most feared development, mainly during Brucella sacroiliitis and would be related to a loss of antibiotic efficacy.

AB1080 BRUCELLAR SPONDYLODISCITIS: EPIDEMIOLOGICAL, CLINICAL AND BIOLOGICAL ASPECTS

S. Rekik[1], S. Boussaid[1], H. Tbini[1], S. Jemmali[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia*

Background: Brucellosis is a systemic infection characterized by significant clinical polymorphism and non-specific manifestations. The spine is a common location for brucellosis.
Objectives: The aim of this study was to describe the epidemiological, clinical and biological characteristics of brucellar spondylodiscitis.
Methods: A retrospective study over a period of 15 years, including 18 patients diagnosed with brucellar spondylodiscitis on clinical, biological and/or imaging data.
Results: Eighteen cases were collected (13 men and 5 woman). The mean age was 52 years [19-76]. The main symptom was unifocal or diffuse spinal pain associated or not with radiculalgia. Inflammatory pain was reported in 12 cases. Thirteen patients consumed raw milk, eleven had contact with farm animals or professional exposure. The average duration of symptoms was 5.7 months [0.5-12], the disease had a progressive onset in 13 patients. The general signs were frequent: deterioration of general condition (13 cases), fever (12 cases) and night sweats (6 cases). All patients had a biological inflammatory syndrome. Wright's serology, performed in 17 patients, was positive in 15 cases. The Rose Bengal test was positive in 13 of the 15 patients tested. Diagnosis by indirect immunofluorescence, performed in 11 patients, was positive in nine cases. However, the blood cultures, carried out in 13 patients and the disco-vertebral biopsy, carried out in 9 patients, did not find the causal agent.
Conclusion: The diagnosis of brucellar spondylodiscitis must be based on epidemiological, clinical arguments and biological examinations. Immunological examinations, however, seem to be more contributory and should be performed in case of diagnostic doubt and negative bacteriological investigation.

COVID-19

AB1081 FLARES OF RHEUMATOID ARTHRITIS FOLLOWING CORONAVIRUS VACCINATION

R. Hayward[1], Z. Farah[1]. [1]*Northwick Park Hospital, Rheumatology Department, Harrow, United Kingdom*

Background: With the emergence of the Coronavirus vaccine and the clear and important role it provides in maintaining the health of individuals and the population (1), it is important that our patients receive or are recommended the vaccine. We here document a case series of patients who have long-term quiescent rheumatoid arthritis who then experienced a flare of disease activity after receiving a vaccine. This information is important to understand as it allows informed discussions regarding the side effect profile of the vaccine and also the influence this may have on the patient's disease control and future management options.

Objectives: To understand the changes to control of rheumatoid arthritis in those experiencing a flare of disease after receiving the coronavirus vaccine.

Methods: Patients were reviewed in clinic as part of standard care. Individuals with Rheumatoid Arthritis who had experienced a flare defined as a self-reported disease activity score of >5.1 in otherwise stable disease were noted and their response to treatment reviewed. This was a review of usual clinical practice and did not alter the treatment undertaken or monitoring of the patent. Information obtained was through the consultation with a rheumatologist and the data was collected retrospectively through review of clinical notes and clinic letters.

Results: The table below outlines the patient details and treatment responses. All flares occurred within two weeks of receiving the vaccine. Of the patients who flared, two required short term steroid treatment; three an increase in the usual medications and one who had been in disease remission to re-start previous therapy. More patients in the Pfizer vaccine group required an escalation of usual care compared to the AstraZeneca vaccine group.

Table 1

Antibody status	Vaccine brand	Time since diagnosis	Time since last flare	Flare after 1st or 2nd dose	Usual treatment	Flare management
Seropositive, anti-CCP positive	AstraZeneca	13 years	3 years	1st	Etanercept, Methotrexate	Intramuscular Methylprednisolone
Seropositive, anti-CCP positive	AstraZeneca	11 years	4 years	1st	Etanercept, Sulfasalazine	Intramuscular Methylprednisolone, local joint injection
Seronegative, anti-CCP negative	AstraZenica	13 years	2 years	1st	Methotrexate	Increase methotrexate dose
Seronegative, anti-CCP positive	Pfizer	23 years	11 years	1st	Infliximab	Local joint injection, reduce interval of infusions
Seronegative, anti-CCP positive	Pfizer	7 years	3 years	2nd	Sulfasalazine, hydroxychloroquine	Increase Sulfasalazine dose
Seropositive, anti-CCP positive	Pfizer	7 years	4 years	2nd	nil	Re-start methotrexate, hydroxychloroquine

Conclusion: We report 6 cases of rheumatoid arthritis flare soon after receipt of the coronavirus vaccine. In all, disease control was returned with minimal changes to treatment, 42% of those requiring either no treatment or an intramuscular steroid injection alone. Therefore, we recommend that clinicians should counsel patients of this potential effect, but continue to advocate the vaccine, as the risk of complications to their underlying arthritis is very low and seemingly easily treatable.

AB1082 FREQUENCY AND SEVERITY OF COVID-19 IN PATIENTS WITH VARIOUS RHEUMATIC DISEASES TREATED REGULARLY WITH COLCHICINE OR HYDROXYCHLOROQUINE

M. Oztas[1], M. Bektaş[2], I. Karacan[3], N. Aliyeva[2], A. Dag[1], S. Aghamuradov[2], S. B. Cevirgen[1], S. Sarı[2], M. Bolayirli[4], G. Can[5], G. Hatemi[1], E. Seyahi[1], H. Ozdogan[1], A. Gul[2], S. Ugurlu[1]. [1]*Turkey, Istanbul University-Cerrahpasa, Department of Medicine,Division of Rheumatology, Istanbul,Turkey;* [2]*Istanbul University, Department of Medicine, Division of Rheumatology, Istanbul,Turkey;* [3]*Istanbul Medeniyet University, Department of Molecular Biology and Genetics, Istanbul,Turkey;* [4]*Istanbul University-Cerrahpasa, Department of Biochemistry, Istanbul,Turkey;* [5]*Istanbul University-Cerrahpasa, Department of Public Health, Istanbul, Turkey*

Background: Several anti-inflammatory drugs which were targeted different mechanisms and investigated for both prevention and treatment for COVID-19.

Objectives: The current study aimed to investigate whether patients regularly using colchicine or hydroxychloroquine (HCQ) have an advantage of protection from COVID-19 or developing less severe disease.

Methods: Patients who were taking colchicine or HCQ regularly for a rheumatic disease including Familial Mediterranean Fever, Behçet's syndrome, Systemic Lupus Erythematosus, Rheumatoid Arthritis and Sjogren's syndrome as well as their healthy household contacts as the control group were included into the study. The clinical data regarding COVID-19 were collected using a standard form, and serum samples were analyzed for anti-SARS-COV-2 nucleocapsid IgG. Patients treated with any biologic or immunosuppressive treatments were not included into the study.

Results: A total of 635 regular colchicine users with their 643 household contacts and 317 regular HCQ users with their 333 household contacts were analyzed. Anti-SARS-Cov2 IgG was positive in 43 (6.8%) regular colchicine users and 35 (5.4%) household contacts (OR=1.3; 95% CI:0.8-2; p=0.3) (Table 1). COVID-19 related symptoms were described by 29 (67.4%) of the patients and 17 (48.6%) household contacts (OR=2.2; 95% CI:0.9-5.5; p=0.09), and hospital admission was observed in five (11.6%) and one (2.9%) of these subjects (OR=4.5; 95% CI:0.5-40.2; p=0.1), respectively (Figure 1). Seropositive subjects were observed in 22 (6.9%) regular HCQ users and 24 (7.2%) household contacts (OR=1.1; CI:0.6-1.9; p=0.8) (Table 1). COVID-19-related symptoms occurred in 16 (72.7%) of the 22 patients and 12 (50%) of 24 household contacts (OR=2.7; 95% CI:0.8-9.1; p=0.1). Three patients (13.6%) were admitted to hospital, while one household contact (4.2%) was hospitalized (OR=3.6; 95% CI:0.3-37.8; p=0.2) (Figure 1). Disease-specific analyses disclosed that there was no significant difference in terms of COVID-19 frequency and severity between a particular disease subset and household contacts (Table 1). Univariate logistic regression analysis showed no effect of age and gender on the SARS-CoV-2 seroprevalence rate among regular colchicine or HCQ users and household contacts (p=0.2 and p=0.7, respectively for colchicine users versus contacts, p=0.7 and p=0.3, respectively for HCQ users versus contacts).

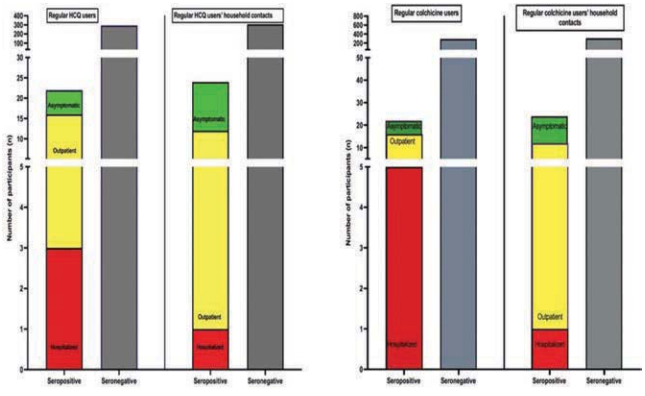

Figure 1. Severity of COVID-19 in regular colchicine or HCQ users and these patients' household contacts

Table 1. Disease specific outcomes of the entire cohort

Variable	FMF (n=373)	FMF HHC* (n=386)	P	Behcet Patients (n=262)	Behcet HHC (N=257)	P	SLE Patients (N=197)	SLE HH (n=221)	p	RA Patients (n=79)	RA HH (n=73)	P	Sjögren patients (N=41)	Sjögren HH (N=39)	p

AB1083 MUSCULOSKELETAL MANIFESTATIONS AND POSTCOVID SYNDROME IN HOSPITALIZED PATIENTS INFECTED WITH COVID-19

Ö. Küçülmez[1], G. Gençtoy[2]. *[1]Baskent University Alanya Education and Research Hospital, Physical Medicine and Rehabilitation, Antalya, Turkey; [2]Baskent University Alanya Education and Research Hospital, Nephrology, Antalya, Turkey*

Background: Covid-19 may cause musculoskeletal manifestations or postcovid syndrome (1-3). Molecular mimicry, precursor activation, continue immune activation are held responsible for the development of autoimmunity (4). It has been suggested that SARSCoV-2 infection can cause blockage of lymph vessels since the virüs can infect lymph endothelial cells branching tot he nasal cavity and may cause postcovid syndrome (5).

Objectives: The aim of this study was to characterise the prevalence of musculoskeletal complaints, postcovid syndrome in hospitalized COVID-19 patients and relationship between clinical features and labaratory parameters.

Methods: A single-centre retrospective cohort study was conducted of patients at Baskent University between March 1 and December 31, 2020. The study protocol was approved by the Ethics Committee. Hospitalized patients aged above 18 years, diagnosed with COVID-19 via RT-PCR are included the study. Pregnant patients, those with severe end-stage disease or with missing documentation were excluded. Data were obtained from electronic health records. Information was collected about patient demographics, history and duration of complaints, history of postcovid syndrome, fever or anosmia, respiratory problems, length of stay, history of intensive care and COVID- 19-related biochemical parameters and rheumatologic tests. The corelation between musculoskeletal manifestations, postcovid syndrome and clinical and labaratory parameters were observed. P value<0,05 was considered statistically significiant.

Results: Totaly 109 patiensts included to the study. %39,45 of patients were female (n=66), %60,55 of patients were male (n=43). %34,86 (n=38)of patiens complained about athralgia, %1.83 (n=2) had arthritis and %41,28 (n=45) described fatigue. Postcovid syndrome was determined in %32.11 (n=35) of patients. Positive otoantibody was determined in one patient and arthritis due to paraneoplastic syndrome was detected in a case. There was significiant corelation between fever, length of stay and control CRP (p<0,05). There was significiant corelation between basal CRP and control CRP, length of stay, history of intensive care, oxygen support (p<0,05). There was significiant corelation between postcovid syndrome and arthritis, arthralgia, fatigue (p<0.05) but there was no corelation between postcovid syndrome and basal or control CRP, fever, anosmia, length of stay, intenssive care or oxygen support (p>0.05).

Conclusion: As there was no corelation between musculoskeletal manifestations, postcovid syndrome and labaratory and clinical findings. There should be further studies for understanding mechanisms of musculoskeletal manifestations and postcovid syndrome in SARSCoV-2 infection.

AB1085 COVID-19 VACCINATION INTENTION AMONG TUNISIAN HEALTH CARE WORKERS

O. Hamdi[1], M. Boudokhane[2], Z. Teyeb[2], I. Abdelaali[2], T. Jomni[2], S. Belakhal[2], M. H. Dogui[2]. *[1]La Rabta Hospital, Rheumatology, Tunis, Tunisia; [2]FSI hospital, Internal Medicine, Tunis, Tunisia*

Background: Health care workers (HCW) are the soldiers in the forefront of the fight against the coronavirus (COVID-19) pandemic. It is therefore a priority target group in the COVID-19 vaccination process.

Objectives: Our purpose was to assess the COVID-19 vaccination intentions of Tunisian HCW and the reason for fear in case of hesitancy.

Methods: We conducted an anonymous online questionnaire in the months of May and June 2021among HCW via social networks. The data collected included demographic characteristics, vaccination intentions, and reasons of hesitancy.

Results: Five- hundred HCW were included in the study. Participants were divided as follows: 74% doctors (15% seniors, 37% juniors, 22% interns), and 26% nurses. The mean age was 34 ± 5 years [24 – 58]. Seventy-three percent of participants were female. A history of chronic illness was noted 150 HCW (30%). A psychiatric disease was noted in 105 participants (21%): anxiety disorder (62%), depression (33%), and bipolar disorder (5%). A treatment was prescribed in 63% of cases: anxiolytics (84.2%), antidepressants (16.6%), and neuroleptics (10%). Psychotherapy was prescribed in 47% of cases. A personal and family history of COVID-19 infection was noted in 50.4 and 55% of cases, respectively. The infection was mild in 91.2% of cases. Four-hundred and five HCW (81%) had the intention to get vaccinated against COVID-19. Twenty participants (4%) refused the vaccine, and 75 (15%) were still hesitant. Vaccination hesitancy was linked to concerns about the safety of a rapidly-developed vaccine in 92% of cases: adverse reactions (95.8%), tolerance (75%), and efficacy (25%). Sixteen percent of hesitant respondents expressed

concerns about the involvement of policy in vaccine development. Vaccines to avoid according to participants were: Astra Zeneca (62%), Synovac (26%), Sputnik (8%), and Pfizer (4%).
Conclusion: The intention to be vaccinated against COVID-19 reached 81% among Tunisian HCW. Acceptance of the vaccine, even among medically informed individuals, is based on a personal perception of the risks and benefits of vaccine safety. Hence the need for campaigns targeting both the general population and the HCW.

AB1086 VACCINE HESITANCY AGAINST COVID-19 VACCINES IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES AND EFFECT OF SPECIALIST COUNSELLING ON VACCINE HESITANT PATIENTS WILLINGNESS TO TAKE VACCINE

K. Kunalchandwar@gmail.Com[1], K. Kishor[1], J. Dixit[1], P. Dogga[1], D. Ekbote[1], P. Kumar[1], U. Dhakad[1]. *[1]King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Vaccination is one of the most significant public health achievements; however, the success has been marred with vaccine hesitancy. The reasons for vaccine hesitancy are neither singular nor straightforward and arise from a complex interplay between scientific, religious and political beliefs. This study aims to understand the possible reasons for vaccine hesitancy in patients with autoimmune rheumatic diseases and the effectiveness of Specialist counselling on vaccine-hesitant patients willingness to take the vaccine.
Objectives: 1. To assess causes of Vaccine hesitancy against COVID-19 vaccines in patients with autoimmune rheumatic diseases.
2. To study the effect of specialist counselling on vaccine-hesitant patients willingness to take vaccine.
Methods: Study design: We conducted an observational survey-based in person cross-sectional study. Patients attending a tertiary care hospital's outpatient department were asked about their vaccination status. Those unvaccinated were asked reasons for vaccine hesitancy The vaccine-hesitant patients were counselled by the treating rheumatologist and asked regarding their willingness to take the vaccine after the counselling. The patient responses were recorded. Sample: Convenience sampling was used, so the sample size was not calculated. Inclusion and exclusion criteria: All adults(>18yrs) with AIRD coming to the rheumatology OPD. Those vaccinated, recently infected(within 6 weeks), and non-AIRD patients were excluded. Data collection: The questionnaire included patients' demographic details, Diagnosis, medication details, and response to the reason for vaccine hesitancy. Statistical analysis: Descriptive statistics were performed by calculating measures of central tendency for quantitative variables and using counts and percentages for qualitative and nominal variables.
Results: A total of 322 patients participated in the study with a mean age of 40 years(18-76), with 73%(234) females and 27%(88) males. Most patients had Rheumatoid Arthritis(40%) followed by SPA (27%), SLE(13%) and others and may were on immunosuppressive medications(95%). A significant proportion of patients(60%) had more than one reason for vaccine hesitancy. Almost 60% of the respondents feared their disease might flare post-vaccination, while almost half(44.4%) were hesitant to take the vaccine due to the fear of vaccine side effects and more than one third (35%) feared vaccine may not be effective on them as they were on immunosuppressive medications. Other major causes of vaccine hesitancy were the inability to get a chance to get vaccinated (18%), doubts about vaccine efficacy (15%), and fear of injections (10%).Most patients(91%) were willing to take the vaccine after specialist counselling and only 28 of the 322 (9%) were unwilling even after specialist counselling.
Conclusion: Vaccine hesitancy can be multifactorial. Major reasons for vaccine hesitancy in patients with autoimmune rheumatic diseases were fear of flare of disease post-vaccination, fear of vaccine side effects and doubts whether the vaccine would work in patients taking immunosuppressive medications. Most patients were willing to take vaccine after counselling by a rheumatologist.

AB1087 COVID-19 IN PATIENTS WITH ANCA ASSOCIATED VASCULITIS

A. Hočevar[1,2], B. Burja[1], M. Tomsic[1,2], Z. Rotar[1,2]. *[1]University Medical Centre Ljubljana, Department of Rheumatology, LJUBLJANA, Slovenia; [2]Medical Faculty, University of Ljubljana, Internal Medicine, LJUBLJANA, Slovenia*

Background: In patients with ANCA associated vasculitis (AAV) a higher mortality rate due to COVID-19 has been observed compared to general population[1].
Objectives: We aimed to evaluate the frequency and severity of COVID-19 in a well-defined AAV cohort.
Methods: Medical records of AAV cases diagnosed at our secondary/tertiary rheumatology center between January 2010 and February 2020 and followed during the COVID-19 pandemic between March 2020 and November 2021 were analyzed.
Results: During the 122-month period, AAV was newly diagnosed in 117 patients. Fifteen patients died before the beginning of COVID-19 pandemic. Of the remaining 102 patients (68.8% females, 42 (41.2%) GPA; 32 (31.4%) MPA; 19 (18.6%) EGPA and 8 (7.8%) not further clinically subclassified AAV), SARS-CoV-2 infection was documented by PCR test in 11 (10.8%) patients (9 (81.8%) females; mean (SD) patient age at COVID-19 65.3 (±20.4) years; 7 GPA and 4 MPA). Five patients had mild COVID-19 symptomatically treated at home, and 6 patients had severe infection. Clinical features of COVID-19 are presented in Table 1. Three patients (27.3%) died due to COVID-19. There were 5 additional deaths of AAV patients during pandemic period, all these related to cancer progression. At the time of diagnosed COVID-19, AAV was in remission in 10 patients and relapsed 2 months prior in one patient. All patients except one were receiving immunomodulatory treatment (steroids only 2; DMARDs only 4; steroids + DMARDs 4). Of the 97 patients eligible for vaccination against COVID-19 (5 AAV patients died before vaccines against SARS-CoV-2 were available), 79 (81.4%) received by the end of November 2021 at least one dose, including 2 patients that later developed COVID-19 (both fully vaccinated; 2.5% breakthrough rate).

Table 1. Presentation of COVID-19 in AAV patients

Characteristics (11 patients)	No.	Characteristics (11 patients)	No.
COVID duration (days)	18(±9)	Respiratory insufficiency	4
Fever	6	Chest pain	5
Headache	6	Abdominal pain	1
Rhinitis	2	Diarrhoea	1
Smell loss	4	Malaise/fatigue	7
Taste loss	4	Myalgia	4
Cough	6	Arthralgia	4
Dyspnoea	7		

Conclusion: Our study shows that COVID-19 heralds a poor prognosis in AAV, with over 50% patients having severe disease and 25% deaths.

Can[1], İ. Sari[1], M. Birlik[1], F. Onen[1]. *[1]Dokuz Eylul University, Faculty of Medicine, Rheumatology, Izmir, Turkey; [2]Demiroglu Bilim University, Faculty of Medicine, Rheumatology, Istanbul, Turkey; [3]Izmir Katip Celebi University, Rheumatology, Izmir, Turkey; [4]Gazi University, Faculty of Medicine, Rheumatology, Ankara, Turkey; [5]Selcuk University, Faculty of Medicine, Rheumatology, Konya, Turkey; [6]Bursa Uludag University, Faculty of Medicine, Rheumatology, Bursa, Turkey; [7]Kahramanmaras Sutcu Imam University, Faculty of Medicine, Rheumatology, kahramanmaraş, Turkey; [8]Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey; [9]Firat University, Faculty of Medicine, Rheumatology, Elazığ, Turkey; [10]Ankara City Hospital, Rheumatology, Ankara, Turkey*

Background: Considering the concerns regarding COVID-19 vaccine safety among patients with rheumatic diseases due to a lack of data, an urgent need for studies evaluating safety profiles of vaccines emerged.
Objectives: Vaccination against the coronavirus disease-2019 (COVID-19) started in March 2021 in the group using biological therapy in our country. In this study, post-vaccine real-life data of patients with spondyloarthritis (SpA) followed up with biological therapy were analyzed.
Methods: Adult patients diagnosed with SpA who were followed up under biological therapy and vaccinated by CoronaVac inactive SARS-CoV-2 orBNT162b2 messenger RNA (mRNA) COVID-19 (Pfizer-BioNTech) vaccine were included in our observational, multicenter, prospective study.
Results: A total of 287 patients (58.2% male; mean age: 47) were included in the study. 202 (%70,4) of patients were being followed up with the diagnosis of AS, 40 (%13,9) of them with PsA, 32 (%11,1) of them with nr-axSpA, 11 (%3,8) of them with enteropathic arthritis, and 2 (%0,7) of them with uSpA. The

most common comorbidities were found to be HT (n:65; 22.6%) and DM (n:38; 13.2%). While 221 (77%) of the patients were receiving biological therapy alone, 27 (9.4%) patients were using methotrexate, 25 (8.7%) patients were using sulfasalazine, and 12 (4.2%) patients were using leflunomide. The median duration of biological therapy was 40 weeks (19-75 IQR). The most commonly used treatment was infliximab (26.8%), adalimumab (23.3%) was the second (Table 1). It was determined that 207 (72.1%) of the patients preferred inactivated virus vaccine, while 80 (27.9%) preferred mRNA vaccine. When the time between the biological treatment and the day of vaccination is examined, detected median time between biological treatment and the first dose of vaccination is 11.5 days (5-19 IQR), between the first dose of vaccination and biological treatment is 14 days (7-21 IQR), between treatment and the second dose of vaccine is 14 days (5-23.5 IQR), and between the second dose of vaccine and the next biological treatment is 12.5 days (7-15 IQR). While 25 (8.7%) of the patients had COVID-19 infection before vaccination, 7 (2.4%) patients were found to have COVID-19 after vaccination (p<0.001). While two of the patients who had COVID-19 infection in the pre-vaccination period required hospitalization, none of the patients who had COVID-19 in the post-vaccination period required hospitalization. The rate of patients who developed side effects after the first dose of the vaccine was 20.6%. The side effects seen, respectively, were detected as pain-redness at the injection site (16%), fatigue (11.8%), headache (8.4%), muscle-joint pain (7.3%) and fever (5.6%). The rate of patients reporting side effects after the second dose of the vaccine was 17.1%. The incidence of side effects after mRNA vaccine was found to be statistically significant compared to inactivated virus vaccine in terms of both doses (p=0.011, p<0.001). Major side effects such as myocarditis, anaphylaxis-angioedema, myocardial infarction, and thrombosis were not observed in any of the patients included in the study. There was no evidence of disease activation in the median follow-up of 209 days (145-280 IQR) after vaccination.

Conclusion: During the follow-up of the patients during the study, no major vaccine-related side effects, post-vaccine disease activation and the need for treatment change were not detected. In order to more accurately evaluate the efficacy of the vaccination program in the patient population using biologic agents, larger-scale studies including unvaccinated individuals are needed.

AB1089 PSYCHOSOCIAL IMPACTS OF THE COVID-19 PANDEMIC ON ETHIOPIAN AND CANADIAN RHEUMATOLOGY PATIENTS

C. Hitchon[1], D. Dacosta[2], B. Abdissa Adugna[3], S. Bernatsky[2], I. Colmegna[2], B. Demelash[3], P. Fortin[4], M. Meltzer[5], A. Mendel[2], R. Scuccimarri[2], A. Melkie[3]. *[1]University of Manitoba, Internal Medicine, Winnipeg, Canada; [2]McGill, Medicine, Montreal, Canada; [3]Addis Ababa University, Medicine, Addis Ababa, Ethiopia; [4]University Laval, Medicine, Quebec, Canada; [5]Jefferson University, Medicine, Philadelphia, United States of America*

Background: The Coronavirus-2019 (COVID-19) pandemic increased psychosocial distress in the general population and in patients with rheumatic disease. Limited data exists on the impact of COVID-19 in rheumatology patients living in Africa.

Objectives: To describe COVID-19 related illness and psychosocial impact in Ethiopian (ET) rheumatology patients attending the only public rheumatology clinic in Ethiopia (Tikur Anbessa Specialized Hospital (TAH) in Addis Ababa). To compare findings in ET with findings in Canadian (CA) rheumatology patients.

Methods: Between May 1 and Oct 31 2021, 130 patients attending the TAH rheumatology clinic answered questions related to COVID-19 infection, symptoms and testing, and psychosocial impacts of the COVID-19 pandemic. We assessed depression (Patient Health Questionnaire- 9), anxiety (General Anxiety Disorder-7; GAD7), COVID-19 stress factors and coping measures, Resilience (Brief Resilience Scale-BRS) and medication compliance (Morisky medication adherence scale – 4 item; MAS4). Rheumatic disease severity was assessed with the Routine Assessment of Patient Index Data-3 (RAPID-3). Questionnaires were translated to Amharic. Descriptive statistics are reported [mean (standard deviation), median (25%, 75%) number and percent.)] and compared to data of 97 CA patients with rheumatoid arthritis (RA) and lupus patients from Quebec[1].

Results: ET patients were mainly female (71%) with a mean (SD) age of 47 (16), and resided in the capital city (Addis Ababa) (72%). Half had RA or lupus. A quarter of patients had moderate to severe rheumatic disease severity desite good medication adherence [MAS4 score of 3(2,4)]. Most (89%) reported no COVID-19 symptoms since the beginning of the pandemic, were not tested for COVID-19 and reported few risk factors for COVID-19 exposure. Eight (6%) ETs were diagnosed with COVID-19; 2 required hospitalization. Diagnosed patients reported a median of 2 COVID-19 symptoms (range 0-8; mainly cough, fever and malaise). Within the entire cohort, depression (PHQ9= 10 or above) and anxiety (GAD7=10 or above) were more frequent in ETs than CAs (depression 30% vs 3%; anxiety 16% vs 1%) yet nearly half (47%) of ETs had normal or high resilience levels. The most common COVID-19 stressors were risk of contracting COVID illness personally [ETs vs CAs risk ratio(95% confidence limits- CL); 0.67 (0.5, 0.99)] or of loved one [0.56 (0.36, 0.86)]. More ETs reported COVID-19 related stress related to difficulty obtaining food, medicine or other essentials [1.74, (1.00-3.0)], and getting needed supports [1.97 (1.03, 3.77)] (Table 1). CAs and ETs used similar levels of problem solving [median (25%,75%) CA 3.3 (2.8, 3.3), ET 3.5 (3.0, 3.7)] and emotion-focus [CA 2.5 (2.2, 3.1); ET 3.3 (2.8, 3.7)] coping strategies.

Table 1. COVID-19 related stressors reported by Ethiopian and Canadian rheumatology patients

Common stressors from the coronavirus pandemic reported as severe †	ET % reported	CA % reported	RR (95% CI) ET vs CA
Getting sick	28	41	0.67 (0.5, 0.99)
Having a loved one who becomes ill	23	41	0.56 (0.36, 0.86)
Difficulty getting food, medicine and other essentials	29	16	1.74 (1.0-3.0)
Difficulty getting support or help	24	12	1.97 (1.03-3.77)
Postponement or cancellation of tests	8	20	0.42 (0.18, 0.95)
Losing a job or experiencing a drop in income	19	10	0.185 (0.90, 3.81)
Having more responsibilities at home	21	20	1.06 (0.59, 1.87)
Having to work in a place likely to expose you to the coronavirus	20	27	0.73 (0.42, 1.24)
Postponement or cancellation of medical visits	19	15	1.2 (0.63, 2.28)
Changes in treatments	7	15	0.43 (0.17, 1.06)

†Severe stress = score 2 (moderately) to 5 (extremely)

Conclusion: During the COVID-19 pandemic, depression was more common in ETs compared to CAs with rheumatic disease. COVID-19-related stressors due to insecurity in obtaining the basic essentials and support were more pronounced in ETs. Differences between ETs and CA in these stressors may reflect local public health and economic supports. There were no differences in coping strategies.

AB1090 IMPACT OF THE COVID19 PANDEMIC ON THE SOCIAL BEHAVIOR OF PATIENTS WITH RHEUMATIC DISEASES

L. Cano Garcia[1], S. Manrique Arija[1], M. Vera Rodríguez[2], R. Redondo[1], C. M. Romero-Barco[3], N. Mena-Vázquez[1]. *[1]Instituto de Investigación Biomédica de Málaga (IBIMA); Hospital Regional Universitario de Málaga, UGC de Reumatología, Málaga, Spain; [2]Universidad de Málaga, Medicine, Málaga, Spain; [3]Instituto de Investigación biomédica de Málaga (IBIMA); Hospital Universitario Virgen de la Victoria., UGC de Reumatología, Málaga, Spain*

Background: Depression in rheumatic diseases negatively influences the support network and the perception of company of these patients (1).

Objectives: To describe how the COVID-19 pandemic affects the social activitiesn patients with chronic rheumatic diseases such as Rheumatoid arthritis (RA), Systemic Lupus Erithematosus (SLE) and Spondyloarthritis (SpA).

Methods: Design: Observational, longitudinal study of a series of patients. Patients: RA (ACR/EULAR 2010 classification), SpA (ASAS/EULAR 2010 criteria), and SLE (ACR 1997 criteria) patients, age ≥ 18 years. Questionaries for the evaluation of participation in social activities is the Patient Reported Outcomes Measurement Information Systems (PROMIS) v2.0 Short-Form (8 items, PROMIS-APS) at baseline (OCT to DEC 2019) and after 18 months of pandemic (SEP to DEC 2021) were performed. Variables evaluated were: social activities in terms of various factors, such as satisfaction with social roles mobility, depression, companiony social isolation, emotional support, instrumental support, support via information and ability to participate in social activities. All the variables were evaluated using the PROMIS questionnaire with quantitative scores. We also recorded demographic, clinical, and comorbidity data. Statistical analysis: Multivariate Linear Regression (Dependent variable: PROMIS ability to participate in social activities 18 months COVID19) was performed.

Results: We recruited 91 patients, 31 (34.1%) RA, 30 (33%) SpA y 30 (33%) SLE. The 3 groups were well balanced in terms of clinical-epidemiological characteristics, except that patients with SLE were younger (mean 45 years) than patients with RA (53 years) and SpA (55 years) (p = 0.004) and because most of the patients with RA and SLE were women (97%) compared to those with SpA (60%) (p <0.001). There was a worsening after 18 months of the COVID19 pandemic in the mean scores of the PROMIS for: satisfaction of the social role (26.9 ± 8.7 vs 25.3 ± 8.4; 0.046), depression (14.7 ± 7, 6 vs 16.1 ± 8.4; p = 0.044) and for the ability to participate in social activities (27.7 ± 7.2 *vs* 26.1 ± 6.8; *p* = 0.020). By diagnoses, the ability to participate in social activities was very similarbetween the different groups except for worse mobility in patients with RA and SpA compared to SLE, both at baseline and at 18 months of the pandemic. SLE patients worsened more after 18 months of the COVID19 pandemic in social role satisfaction, depression, instrumental support and ability to participate in social activities. In the multivariate analysis, the ability to participate in social activities at 18 months of the COVID19 pandemic was inversely associated with the diagnosis of SLE compared to the rest (ß [95% CI], -2.60 [-4.62 - 0.58]; p = 0.012) and depression (ß [95% CI], -0.23 [-0.39, -0.08]; p = 0.004); and directly with social role satisfaction (ß [95% CI], 0.18 [0.10-0.35]; p = 0.031), mobility (ß [95% CI], 0.13 [0.07-0.20]; p = 0.001) and company (ß [95% CI], 0.32 [0.11-0.60]; p = 0.023).

Conclusion: At baseline evaluation, social activities were affected by the impact of rheumatic disease. After 18 months of the pandemic-COVID19, patients with RA and SPA remain stable but SLE patients significantly worsened their social role and depression.

AB1091 THE IMPACT OF COVID-19 PANDEMIC ON DISEASE MONITORING AND MONITORING FOR ADVERSE CLINICAL OUTCOMES IN THOSE ON BIOLOGIC THERAPY.

B. Preece[1], E. Thomas[1]. *[1]Royal Gwent Hospital, Rheumatology, South Wales, United Kingdom*

Background: The coronavirus pandemic, is an ongoing global pandemic of coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome coronavirus 2.[1] The pandemic has posed major challenges to the National Health Service, with implications for patients with rheumatological diseases. [2] In order to try and prevent transmission of the virus, the delivery of patient care has adapted, involving more telephone and virtual review of patients. The British Society of Rheumatology (BSR) has highlighted the importance of adopting a 'treat-to-target' [3] approach in managing these patients to facilitate early treatment escalation in the presence of active disease. Close monitoring of disease is an integral approach to managing these patients. Disruption to previous patterns of care and disease monitoring of biologic patients theoretically may increase the risk of disease flare and adverse clinical outcomes. [4]

Objectives: The BSR recommends all patients receiving biologic therapy should be reviewed for drug safety every 6 months. It recommends that patients prescribed a biologic should have monitoring blood tests every 3–6 months.[3, 5] The BSR has published mitigating guidance outlined within the COVID-19 rapid guideline.[5] This suggests it's safe to increase time intervals between blood tests for drug monitoring, particularly if 3-monthly blood tests have been stable for over 2 years. Our aims are to evaluate whether altering our delivery of care has impacted on the 'treat-to-target' approach and the frequency of blood monitoring in those on biologic therapy, despite the challenges of an ongoing global pandemic.

Methods: Over a period of 1 month a total of 51 patients receiving biologic therapy case notes were reviewed. Data was collected relating to underlying diagnosis, choice of biologic, whether a disease activity score was performed, method of consult and compliance with drug monitoring.

Results: Of the 51 patients 24 patients were receiving adalimumab, 20 baricitinib, 2 filgotinib, 2 upadacitinib and 3 on entarcept. Diagnoses ranged from 33 patients with rheumatoid arthritis, 7 psoriatic arthritis, 5 ankylosing spondylitis, 5 spondyloarthropathy and 1 enteropathic arthritis. Disease activity scores were documented in the majority of patients (75%). In those where disease activity scores were not documented, 11 had rheumatoid arthritis and the remaining 2 psoriatic arthritis. The majority of the patients who didn't have disease activity scores documented were reviewed via telephone consult (84%). All patients had undergone adequate blood monitoring with 100% compliance with blood tests performed within 6 months.

Conclusion: The COVID-19 pandemic has presented an extraordinary necessity for change in how we manage patients suffering from rheumatic disease. The impact of this global pandemic will be long-lasting and thorough analysis of patient outcomes is needed. However, this period presents an exciting opportunity to embrace new ways of working, which may improve efficiency and efficacy of patient care.

AB1092 INFLAMMATORY ARTHRITIDES IN POST-COVID-19 PATIENTS: AN ALBANIAN EXPERIENCE.

A. Pecani[1], J. Tula[2], L. Karaulli[3], A. Islamaj[3], S. Bala[4]on behalf of SUSHN 21. *[1]Rheumatology Unit, Department of Internal Medicine, University Hospital Centre "Shefqet Ndroqi", Tirana, Albania; [2]Rheumatology Unit, Department of Internal Medicine, University Hospital Centre "Shefqet Ndroqi", Tirana, Albania; [3]Pulmonology Clinic, Department of Pulmonology, University Hospital Centre " Shefqet Ndroqi", Tirana, Albania; [4]University Hospital Centre "Shefqet Ndroqi", Department of Pulmonology, Tirana, Albania*

Background: COVID-19 is a disease caused by the new pathogen SARS-CoV2 (severe acute respiratory syndrome coronavirus 2) typically presenting with pneumonia but also other systemic manifestation has been reported worldwide [1]. Different reports have described the appearance of inflammatory arthritis (IA) after resolution of acute infection from COVID-19 [2].

Objectives: To observe the frequency of Inflammatory Arthritis in an Albanian cohort of post-COVID-19 patients.

Methods: Post-Covid-19 patients, having two consecutive negative PCR (real-time reverse transcription polymerase chain reaction), discharged from the Pulmonology Department (January – July 2021) were invited to enter in a 6 (six) month multidisciplinary observational study. Data regarding post-COVID-19 inflammatory arthritis are presented in this study. Descriptive statistical analysis was used to express data.

Results: From 154 post-COVID-19 patients (F/M = 62/92) enrolled, 14 (9.09%) patients didn't follow regularly the dedicated ambulatory thus were excluded from this study. Considering the remaining 140 patients (F/M = 58/82), only 21 (15%) patients were diagnosed with IA where the most common were, respectively: Reactive Arthritis (ReA) 11 (52.3%) patients; Rheumatoid Arthritis (RA) 4 (19.09%) patients; Ankylosing Spondylitis (AS) 3 (14.2%) patients; Gout Arthritis (GA) 3 (14.2%) patients. All rheumatic conditions were more frequent in male than in female post-COVID-19 patients. Data summarized in Table 1. All patients that developed a post COVID-19 IA, had fever during the period of SARS-CoV2 infection. Arthralgia was a typical symptom that have been reported by patients that have developed RA and AS. All RA post-Covid-19 patients reported having had even symptoms like cough, dispnea and fatigue. None of the AS patients neither GA reported symptoms of dysguesia or anosmia. Only 9% of ReA patients reported having had abdominal pain during acute infection with SARS-Cov2. Data summarized in Figure 1.

Table 1.

Inflammatory Arthritis	Patients (N, %)	Age (mean ± SD)	Male (N, %)	Days after COVID-19 (mean ± SD)
ReA	11 (52.3)	48.2 ± 12.5	7 (63.6)	15.8 ± 9.9
RA	4 (19,09)	55.7 ± 8.7	2 (50)	32.3 ± 11.3
AS	3 (14.2)	50.5 ± 9.7	2 (14.2)	18.8 ± 5.5
GA	3 (14.2)	55.3 ± 1.2	3 (100)	10.6 ± 0.9

Conclusion: IA is another manifestation that follows acute infection from COVID-19. In this regard increased awareness and further investigations are needed

in order to better understand weather SARS-Cov2 infection can accelerate the development of a rheumatic autoimmune disease.

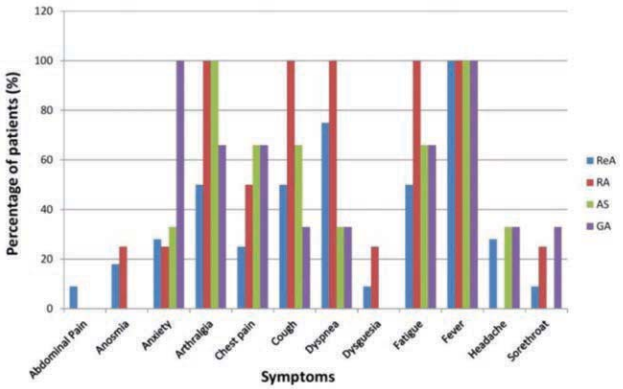

Figure 1. Most frequent symptoms during infection period for each post-COVID - IA.

AB1093 SAFETY OF COVID-19 VACCINES IN PATIENTS WITH RHEUMATOID ARTHRITIS (PRELIMINARY DATA).

A. Kulikov[1], N. Muravyeva[1], B. Belov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinoprophylaxis, Moscow, Russian Federation*

Background: Patients with rheumatoid arthritis (RA) are at high risk of developing COVID-19. Vaccination should be an effective method of preventing this disease. However, vaccination may be unsafe in RA patients. At present, data on the safety of vaccines against COVID-19 in RA patients are few and relate to foreign vaccines that are not licensed in Russia.

Objectives: To study the safety of COVID-19 vaccines in patients with RA in real clinical practice.

Methods: The study included 131 RA patients (120 women, 11 men, age 53.8±13.9 years, duration of disease 11.5±9.2 years) - the main group and 121 people without any immuno-inflammatory rheumatic diseases (87 women, 34 men, age 39.8±14.2 years) - the control group. 103 patients received disease-modifying antirheumatic drugs (54 - methotrexate, 30 - leflunomide, 10 - hydroxychloroquine, 8 - sulfasalazine, 1 - mofetil mycophenolate), 68 - biological drugs (58 - rituximab, 5 – TNF-α inhibitors, 4 - abatacept, 1 - tocilizumab), 64 - glucocorticoids, 10 - did not receive therapy. In the main group, 92 patients were vaccinated with Gam-COVID-Vac (Sputnik V), 21 with Sputnik Light, 16 with CoviVac, 2 with EpiVacCorona (110 patients received two components of the vaccine). In the control group, 91 were vaccinated with Sputnik V, 16 with CoviVac, 6 with BNT162b2, 5 with Sputnik Light, 2 with EpiVacCorona, 1 with mRNA-1273 (114 participants received two components of the vaccine). All participants were interviewed by a research doctor with a unified questionnaire, additional information was obtained from medical documentation.

Results: Local and systemic adverse events (AEs) were observed both in the main group and in the control group. After the introduction of the first component of the vaccine, local AEs (pain/hyperemia/edema) were noted in 12.2% of RA patients and in 10.7% of the control group, after the introduction of the second component of the vaccine - in 9.1% and 11.4% of respondents, respectively (in both groups p>0.05). There was a significant difference between the main group and the control group in the frequency of pain at the injection site without restriction of movements both after the first (24.4% and 40.5%, p=0.007) and after the second component (18.2% and 31.6%, p=0.021). The most frequent systemic AEs were weakness, fever, muscle or joint pain, headache, chills, which were observed in both groups after administration of both the first and second components of the vaccine. There was a significant difference between the main group and the control group in the frequency of fever (16.8% and 39.7%, p<0.001), weakness (26.0% and 38.8%, p=0.029), muscle and joint pain (9.2% and 25.6%, p<0.001) after administration of the first (but not the second) component of the vaccine. A significant difference was revealed between the main group and the control group in the number of patients with local and systemic AEs both after the introduction of the first component of the vaccine (19.1% and 43%, p<0.001) and after the second (15.5% and 30.7%, p=0.007). After administration of the two components of the vaccine, a higher number of patients without any AEs were detected in the main group compared to the control group (32.7% and 18.4%, p=0.014). Exacerbation of RA and the emergence of new autoimmune phenomena in main group are not marked.

Conclusion: According to preliminary data, the tolerance of vaccines against COVID-19 in RA patients is satisfactory. Further studies are needed to study the safety, immunogenicity and clinical efficacy of immunization against COVID-19 in patients of this cohort.

Farfan[4], G. Berbotto[4], G. Pons-Estel[1], E. E. Schneeberger[2]on behalf of SAR-CoVAC Registry. *[1]Argentine Society of Rheumatology, Research Unit - SAR-CoVAC Registry, CABA, Argentina; [2]Psychophysical Rehabilitation Institute, Rheumatology, CABA, Argentina; [3]Argentine Society of Psoriasis, Argentine Society of Psoriasis, CABA, Argentina; [4]On behalf of SAR-CoVAC Registry, Argentine Society of Rheumatology - Research Unit, CABA, Argentina*

Background: Currently there is little information on the efficacy and safety of SARS-CoV-2 vaccination in patients with immune-mediated diseases and/or under immunosuppressive treatment in our country, where different types of vaccines and mix regimens are used. For this reason, the Argentine Society of Rheumatology (SAR) with the Argentine Society of Psoriasis (SOARPSO) set out to develop a national register of patients with rheumatic and immune-mediated inflammatory diseases (IMIDs) who have received a SARS-CoV-2 vaccine in order to assess their efficacy and safety in this population.

Objectives: To assess SARS-CoV-2 vaccine efficacy and safety in patients with rheumatic and IMIDs.

Methods: SAR-CoVAC is a national, multicenter and observational registry. Adult patients with a diagnosis of rheumatic or IMIDs who have been vaccinated for SARS-CoV-2 were consecutively included between June 1st and September 17th, 2021. Sociodemographic data, comorbidities, underlying rheumatic or IMIDs, treatments received and their modification prior to vaccination and history of SARS-CoV-2 infection were recorded. In addition, the date and place of vaccination, type of vaccine applied, scheme and indication will be registered. Finally, adverse events (AE), as well as SARS-CoV-2 infection after the application of the vaccine were documented

Results: A total of 1234 patients were included, 79% were female, with a mean age of 57.8 (SD 14.1) years. The most frequent diseases were rheumatoid arthritis (41.2%), osteoarthritis (14.5%), psoriasis (12.7%) and spondyloarthritis (12.3%). Most of them were in remission (28.5%) and low disease activity (41.4%). At the time of vaccination, 21% were receiving glucocorticoid treatment, 35.7% methotrexate, 29.7% biological (b) Disease Modifying Anti-Rheumatic Drugs (DMARDs) and 5.4% JAK inhibitors. Before vaccine application 16.9% had had a SARS-CoV-2 infection. Regarding the first dose of the vaccine, the most of the patients (51.1%) received Gam-COVID-Vac, followed by ChAdOx1 nCoV-19 (32.8%) and BBIBP-CorV (14.5%). In a lesser proportion, BNT162b2 (0.6%), Ad26.COV2.S (0.2%) and CoronaVac (0.2%) vaccines were used. Almost half of them (48.8%) completed the scheme, 12.5% were mix regimenes, the most frequent being Gam-COVID-Vac / mRNA-1273. The median time between doses was 51days (IQR 53). More than a quarter (25.9%) of the patients reported at least one AE after the first dose and 15.9% after the second. The flu-like syndrome and local hypersensitivity were the most frequent manifestations. There was one case of mild anaphylaxis. No patient was hospitalized. Altogether, the incidence of AE was 246.5 events/1000 doses. BBIBP-CorV presented significantly lower incidence of AE in comparison with the other types of vaccines. (118.5 events/1000 doses, p<0.002 in all cases) Regarding efficacy, 63 events of SARS-CoV-2 infection were reported after vaccination, 19% occurred before 14 days post-vaccination, 57.1% after the first dose (>14 days) and 23.8%

after the second. In most cases (85.9%) the infection was asymptomatic or had an outpatient course and 2 died due to COVID-19.
Conclusion: In this national cohort of patients with rheumatic and IMIDs vaccinated for SARS-CoV-2, the most widely used vaccines were Gam-COVID-Vac and ChAdOx1 nCoV-19, approximately half completed the schedule and in most cases homologously. A quarter of the patients presented some AE, while 5.1% presented SARS-CoV-2 infection after vaccination, in most cases mild.

AB1095 POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME IN A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS AFTER COVID-19 VACCINATION: A CASE REPORT

D. Abdel Mohsen[1], R. A. Elziaty[1], A. A. Abdalkader[1]. [1]*Ain Shams University, Internal Medicine Department, Division of Rheumatology, Cairo, Egypt*

Background: The COVID-19 pandemic has infected millions of people around the world and there has been a new surge of virulent strains in many parts of the world[2]. Patients with Systemic Lupus Erythematosus (SLE) were reported to be at higher risk of SARS-CoV-2 infection and worse outcomes from COVID-19, possibly due to their intrinsic immune dysfunction, demographics, disease activity, medications, associated organ damage, comorbidities and as such, have been among the first to receive the vaccines [3]. The most common reason for vaccine refusal in patients with SLE is fear of SLE disease flare. Additionally, SARS-CoV-2 mRNA vaccines could potentially induce interferon production, associated with increased SLE disease activity[1].
Objectives: we report a case of SLE presented with lupus flare after receiving the 1st dose of phizer vaccine.
Methods: A 30-year-old female patient, kown case of SLE since 2011 well controlled on low dose steroids, hydroxychloroquine and azathioprine. Upon receiving her 1st shot of Pfizer-BioNTech COVID-19 Vaccine, she developed high grade fever associated with generalized tender papulovesicular skin eruption mainly on the back of the trunk and the outer surface of both thighs, then she developed generalized tonic-clonic convulsions and transferred for Intensive Care Unit (ICU), intubated, mechanically ventilated and received intravenous anti-epileptic medications. During her admission, Cerebrospinal fluid (CSF) examination and Magnetic Resonance Imaging (MRI) brain were done.she regained her consciousness, extubated after 48 hours.
Results: The initial laboratory invwstigations revealed COVID19-PCR: negative,ESR: 35 mm/hr,CRP: 78,C3: 70 mg/dL (90 – 180) and C4: 8 mg/dL (10 – 40). CSF examination revealed proteins: 116.9 mg/dL (15 – 45),glucose: 46.3 mg/dL (50-60% of serum),LDH: 49.1 U/L (10% of serum) and no cells.Emergency MRI brain was performed revealed multiple bilateral symmetrical mainly cortical and subcortical abnormal signal with cortical swelling are seen mainly involving both occipito-temporo-parietal lobes with patchy enhancement of left cerebellar hemisphere, cerebellar vermis, both thalami, medulla and pons,Picture suggestive of Posterior Reversible Encephalopathy Syndrome (PRES).Accordingly the patient received received pulse steroid therapy for 3 days under cover of oral acyclovir.She also received levetiracetam and Oxcarbazepine.the condition markedly improved and discharged from the hospital for follow up after one month.
Conclusion: 1)The mRNA COVID Vaccine may rarely cause CNS affection, or even SLE flare so, SLE patients must be well controlled before giving the Vaccine. 2) SLE patients must be monitored closely by clinical examination and laboratory investigations after taking mRNA COVID Vaccine.

AB1096 THE INFLUENCE OF THE BEHAVIORAL RESTRICTION OF COVID-19 PANDEMIC FOR THE FRAILTY OF PATIENTS WITH RHEUMATOID ARTHRITIS

M. Tada[1], Y. Yamada[2], K. Mandai[3], Y. Matsumoto[4], N. Hidaka[1]. [1]*Osaka City Generall Hospital, Orthopaedic Surgery, Osaka, Japan;* [2]*Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan;* [3]*Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan;* [4]*Osaka City University Graduate School of Human Life Science, Medical Nutrition, Osaka, Japan*

Background: We previously reported the prevalence of frailty and relation of disease activity at patients with rheumatoid arthritis (RA)[1]. The behavioral restriction of COVID-19 pandemic influenced for the lifestyle of people included patients with RA.
Objectives: The relationship between the behavioral restriction of COVID-19 pandemic and frailty was investigated.
Methods: We used the date from prospective observational study (CHIKARA study: UMIN000023744). 70 from 100 patients with RA were followed-up and evaluated the frailty and subcategories (social, physical, mental, nutrition, and cognitive) by frailty checklist. The prevalence of frailty and the change of exercise and daily life activities by visual analog scale were investigated at pre- and post-behavioral restriction. The correlation of frailty and change of amount of exercise and daily life activity examined by univariate analysis.
Results: Mean age was 69.7 years (women n=57, men n=13). The prevalence of frailty at post-behavioral restriction increased compared that at pre-behavioral restriction (post:35.8% vs pre:30.0%). Especially, cognitive and total score at post-behavioral restriction increased significantly. The rate of decrease of exercise by <25%, 26~50%, and 51%< were 70%, 21%, and 9%, respectively (mean:20% decrease). Whereas, the rate of decrease of daily life activities by <25%, 26~50%, and 51%< were 37%, 27%, and 36%, respectively (mean:44% decrease). The change of exercise was significantly negatively correlated with the change of nutrition (R=-0.245, P=0.041) at Table 1. There was no correlation between the change of daily life activities and subcategories.

Table 1. Univariate analysis of the changes in daily living activities or exercise and those in frailty and subcategories

	Change of daily living activities		Change of exercise	
	R value	P value	R value	P value
Δ Social	0.099	0.417	-0.006	0.962
Δ Physical	0.182	0.130	-0.005	0.965
Δ Mental	-0.200	0.097	-0.234	0.051
Δ Nutrition	-0.204	0.091	-0.245	0.041
Δ Cognitive	-0.087	0.476	-0.034	0.778
Δ Total	-0.091	0.454	-0.178	0.140

Δ, change from pre- to post-behavioral restriction. Analyzed by Spearman's rank correlation coefficient

Conclusion: The exercise slightly decreased and the daily life activities decreased almost 50% by the behavioral restriction of COVID-19 pandemic. The prevalence of frailty increased 5.8%, and cognitive and total score were significantly high at post-behavioral restriction of COVID-19 pandemic. The decrease of exercise correlated with the worse of nutrition.

AB1097 FEATURES OF THE COURSE AND CLINICAL AND DEMOGRAPHIC CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO UNDERWENT COVID-19

E. Aronova[1], G. Gridneva[1], B. Belov[1]. [1]*V.A.Nasonova Research Institute of Rheumatology, Department of Comorbid Infections and Vaccine Prevention, Moscow, Russian Federation*

Background: COVID-19 remains a serious problem almost two years later, despite the ongoing active search for effective tools to control it. To date, it is known that COVID-19 not only proceeds as an acute respiratory illness, but also leads to a systemic inflammatory response and hypercoagulability through activation of both the innate and adaptive immune systems. Patients with rheumatic and musculoskeletal diseases appear to be more vulnerable to the development of severe forms of COVID-19 due to the impaired immune response associated with RMD. In addition, immunosuppressants prescribed to control RMD increase the risk of infections. And finally, RMD is often combined with comorbid conditions from the group of risk factors for severe forms of COVID-19 such as arterial hypertension, diabetes mellitus and obesity.
Objectives: to characterize the features of the course of COVID-19 in patients with rheumatoid arthritis.
Methods: We studied the material of questionnaires filled out by patients of the hospital of the V.A. Nasonova Research Institute of Rheumatology who underwent COVID-19, verified by RT-PCR to SARS-CoV-2 RNA, for the period from 05/15/2020 to 12/15/2021. The information was supplemented with data from discharge reports after inpatient treatment of COVID-19. Statistica software (version 12) was used for statistical processing. The results of the correlation analysis were considered reliable at $p \leq 0.05$.

Results: The study included 32 adult (over 18 years old) patients (29 women, 90%) with a reliable diagnosis of rheumatoid arthritis (ACR / EULAR). The average age of patients is 50.75 ± 16.48 years. In the study group, 29 (90.6%) patients never smoked, 2 smoked in the past and 1 was an active smoker. The duration of the course of RA (median) was 8 [4; 14.5] years. The most common comorbidities were diseases of the cardiovascular system (in 20 patients), diseases of the gastrointestinal tract (in 7 patients), diabetes (in 4 patients) and obesity (in 5 patients). The median number of comorbid diseases was 1 [0; 3]. At the time of the development of COVID-19, the severity of RA symptoms, assessed by the VAS, was 4.78 ± 3.06. As antirheumatic therapy, 10 (31.25%) patients took glucocorticoids at an average dose of 5 ± 3.9 mg / day. (prednisolone equivalent), 22 (68.75%) - DMARDs. 19 patients received bDMARDs, incl. 12 - rituximab (37.5%, of which 7 received the last infusion within 6 months or less before the first symptoms of COVID-19 appeared). Among the clinical manifestations of COVID-19, weakness was most often noted, fatigue - in 29 (90.6%), fever - in 23 (71.9%), anosmia - in 20 (62.5%), dysgeusia - in 19 (59.4%), increased arthralgia - in 17 (53.1%), shortness of breath during exercise - in 16 (50%), cough - in 15 (46.9%). There was a significant positive correlation between increased arthralgia during COVID-19 and RA activity. On average (median), each patient reported 13.5 [9.75; 19.25] symptoms associated with COVID-19. There was no significant correlation between the number of COVID-19 symptoms and RA activity. During COVID-19, CT scan was performed in 19 patients: CT-0 - in 1 patient (5.3%), CT-1 - in 9 (47.4%), CT-2 - in 5 (26.3%), CT-3 - in 3 (15.7%), CT-4 - in 1 (5.3%). There was no correlation between the CT stage and RA activity. 12 patients (37.5%) were hospitalized, of which 8 needed oxygen support. Rituximab treatment was not associated with hospitalization rates. Complications were reported in 4 cases (12.5%): venous thrombosis in 2 patients and acute respiratory failure in 2 more patients.
Conclusion: 37.5% of COVID-19 patients in the study group required inpatient treatment. In 12.5% - COVID-19 proceeded with complications. The number of symptoms associated with COVID-19 did not correlate with RA activity. However, patients with higher RA activity more often noted increased arthralgia.

AB1098 DEVELOPMENT OF INFLAMMATORY MYOPATHY AFTER COVID-19

I. Menshikova[1], A. Shilina[1], N. Nikolaeva[1]. [1]*I.M.Sechenov First Moscow State Medical University (Sechenov University), Rheumatology, Moscow, Russian Federation*

Background: It has been more than a year and a half since the WHO announced a pandemic of a new coronavirus infection caused by SARS-CoV-2. The virus belongs to the respiratory group, but it it can damage various organs and tissues of the body. COVID-19 infection is characterized by pathological activation of immunity, violated synthesis of pro-inflammatory, immunoregulatory, anti-inflammatory cytokines, such as interleukins-1 and -6, tumor necrosis factor α and others. These features contribute to the development of rheumatic diseases and syndromes in people who have had COVID-19. Cellular and humoral immune responses are also of primary importance in the pathogenesis of inflammatory myopathies.
Objectives: Description of a case of severe dermatomyositis after COVID-19.
Methods: The 34-year-old female patient complained of pain and weakness in the proximal muscles of the upper and lower extremities, difficulty swallowing solid and liquid food, rash on the face, neck, chest and arms. In August 2020 she had a mild case of COVID-19. A month later, flaky erythematous papules like Gottron's sign appeared on the extensor surfaces of the metacarpophalangeal joints and proximal interphalangeal joints of the hands. Six months later, sore throats, hoarseness of voice, belching of air, choking on solid food and episodes of subfebrility joined. Reflux esophagitis, duodenitis was detected by fibrogastroduodenoscopy. After 9 months, there were muscle pains and muscle weakness, erythema on the face, neck and chest, the patient lost 11 kg. She was hospitalized in the rheumatology department with suspected dermatomyositis.
Results: On objective examination: proximal myopathy, erythematous rashes on the face, neck, chest, Gottron's erythema on the hands. In the analyses: clinical analysis of blood and urine without pathology, ANA 1:1280, creatinkinase 5370 IU/l, with an increase in dynamics up to 9260 IU/l, CRP 0.03 mg /dl, LDH 1023 IU/l, rheumatoid factor and anti-ds DNA were negative. Nasal regurgitation was detected during radiography of the pharynx with contrast. Instrumental examination revealed no signs of a tumor process. Fibrogastroduodenoscopy - superficial reflux-esophagitis, duodenitis, Chest CT - interstitial pneumonitis, abdominal ultrasound without pathology, ECG - sinus rhythm, normal EOS position, accelerated A-V conduction, echocardiography - minor separation of pericardial leaves (up to 5 mm), colonoscopy - dolichosigma. The patient was diagnosed with idiopathic dermatomyositis of high activity. Because of progressive myopathy and increasing dysphagia, pulse therapy with methylprednisolone500 mg for 3 days and rituximab 1000 mg was performed. She also received metipred 48 mg per day orally, methotrexate 15 mg per week subcutaneously and folic acid 5 mg per week. Against the background of therapy, positive dynamics was noted: swallowing normalized, the severity of myopathy decreased, after 10 days CKdecreased to 2049 IU/l. After 6 months during the control examination: there are no skin rashes, muscle strength is restored, CK 300 IU/l. The dose of methylprednisolone is reduced to 10 mg per day, the patient continues injections of methotrexate 15 mg per week.
Conclusion: COVID-19 may be a trigger for the development of inflammatory myopathy. In this clinical case there are features of the course and therapy of inflammatory myopathies in patients after coronavirus infection.

AB1099 CORONAVIRUS INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (CASE SERIES).

I. Menshikova[1], A. Shilina[1], Y. Pak[1], I. Kolosova[1]. [1]*I.M.Sechenov First Moscow State Medical University (Sechenov University), Rheumatology, Moscow, Russian Federation*

Background: SARS -CoV 2 infection (Covid -19) has a wide range of Clinical and laboratpry symptoms typical for rheumatic diseases, in particular systemic lupus erythematosus (SLE).
Objectives: Analysis of the course of Covid-19 in patients with SLE and the influence of antirheumatic drugs on its outcomes.
Methods: A retrospective analysis of 12 patients with SLE previously observed in the rheumatology department and had Covid-19 in 2020-2021. Average age of patients (83% women) is 41 years (24-59 years old), duration of SLE - 11 years (3-25 years). 10 patients had low SLE activity, 1 - moderate, 1 - high. In anamnesis 8 patients had hematological disorders, 4 - secondary antiphospholipid syndrome (APS) with thrombosis, 3 - cerebrovasculitis, 5 - lung damage, 3 - lupus nephritis. All patients were treated with glucocorticosteroids (GCs) (the average dose 2 1/4 tablets per day), 10 (66,7%) - with hydroxychloroquine (HCQ), 4 (33,3%) – with immunosuppressants: 2 - mycophenolate mofetil, 1 - methotrexate, 1 – cyclophosphamide. 3 (25%) patients received rituximab (RTM) 2-3 months before the onset of COVID-19. 9 (75%) patients received outpatient treatment, 5 of them had a mild infection (3 - without lung damage, 2 - with lung damage - CT 1), 4 - had a moderate course, 3 (25%) - were admitted to the hospital,1 - to the intensive care unit.
Results: Patients were divided into 3 groups for SLE therapy. The first group (6 patients) was treated with GCs (average dose of 1 1/2 tab.) and HCQ (200-400 mg). All of them had mild to moderate course of infection without complications. Exacerbation of SLE was noted in 3 (50%) patients: 2 had capillarities, psycho-emotional lability, deterioration of laboratory parameters, 1 (with secondary APS) developed deep vein thrombosis of the legs and an exacerbation of lupus nephritis a month after. The second group (3 patients) received GCs (average dose 2 1/4 tab.) and immunosuppressants. In 2 patients the course of Covid-19 was mild, in 1 - moderate. Exacerbation of SLE was noted in 2 patients: 1 had headaches, high titers of ANA and anti-DNA, 2nd - a severe exacerbation (hematological disorders, lupus nephritis with impaired renal function). The third group (3 patients) received GCS (average dose 5 tab.) and rituximab. 2 patients received RTM for 2 years, the last infusion was carried out for 3 months before the onset of an infection. Their course of Covid-19 was moderate with CT-2 lung damage and mild respiratory failure. There were no exacerbations of SLE after recovery. The 3rd patient initially had a high activity of SLE with nephrotic syndrome, arterial hypertension, batterfly rash, arthritis, fever, which required high doses of GCs and 2 rituximab infusions of 500 and 1000 mg. A month later, a severe COVID-19 developed with 70% lung damage, severe respiratory failure (SpO2 - 80%), and cytokine storm syndrome. He was treated with GCS, anticoagulants, tocilizumab, immunoglobulin, followed by recovery. Mild and moderate course of COVID-19 was observed in 92% of patients with SLE, in 8% - severe. Exacerbation of SLE after infection occurred in 41% of cases with no lethal outcomes.
Conclusion: Patients with low activity SLE on small doses of GCs and HCQ tolerate COVID-19 relatively easily. The high activity of SLE and the use of rituximab contribute to the severe course of COVID-19 with damage to the lungs and respiratory failure, so the use of anti-B-cell therapy during a pandemic is undesirable. The effect of immunosuppressants is controversal. Exacerbation of SLE after COVID-19 in 41% of all patients requires monitoring of laboratory parameters and observation by a rheumatologist for at least six months after recovery from infection.

AB1100 COVID-19 VACCINATION IN A REAL-LIFE SETTING OF A RHEUMATOLOGICAL OUTPATIENT CENTER

S. G. Werner[1], L. Moll[1], A. Uhlenberg-Moll[1], S. Mettler[1], H. E. Langer[1]. [1]*RHIO (Rheumatology, Immunology, Osteology) Düsseldorf, RHIO Research Institute, Düsseldorf, Germany*

Background: Since approvement of the first vaccines against COVID-19 in European in 12/2020, a large vaccination (VAC) campaign was started. Patients with inflammatory diseases (ID) were graded as higher risk. Many of our patients used the possibility and got vaccinated. Until know, there is few knowledge about the efficacy and safety of VAC in patients with ID. There are some reports of less VAC response in patients with ID (1). Many antibody (AB) studies are ongoing but monitoring of AB status is not recommended by official recommendations (1,2). Nevertheless, AB testing is commonly used in daily care in outpatient centers (OC).
Objectives: To evaluate in a real life setting of a single rheumatological OC how many patients have been vaccinated against COVID-19, how many of these did not develop AB and search for possible explanations.
Methods: All consecutive patients of the routine follow up visits from 03/2021 to 12/2021 were retrospectively evaluated if VAC and an AB testing (e.g. ELISA-tests) was done ≥4 weeks after the 2nd VAC was documented. All AB tests were classified for AB levels (Ratio <0,8 negative, >0,8 Ratio < 4,5 low to moderate, Ratio ≥ 4,5 high level). The group of patients without AB was specified.
Results: N=1206 persons were questioned. N=23/1206 (1.9%) patients refused a VAC. N=1183/1206 (98.1%) have got a VAC. N=984/1183 (83.2%) were had an ID, n=199/1183 (16.8%) were healthy persons (HP). In n=608/1138 (51%) an AB status after ≥4 weeks after VAC was available. N=14/608 (20%) HP developed all but one high AB levels. 1 HP had a low to moderate AB level. In n=595/1183 (50%) patients with ID an AB status was available. N=438/595 (74%) patients developed high AB levels, n=126/595 (21%) low to moderate, n=30/595 (5%) had no AB. Mean age in the group without any AB was 69years (range 38-95). N=27/30 (90%) patients received ≥1 DMARD (disease modifying antirheumatic drug), n=3/30 patients were not treated with DMARD, n=2/3 of these patients received Prednisolone (P) instead. N=4/30 received Rituximab (RTX), n=1/30 Abatacept (ABA), n=1/30 MMF (3g), n=1/30 Azathioprine in combination with high P (55mg), n=15(50%) MTX alone or in combination, n=24/30(80%) P (range mg 1-55, mean 5,7). One 52y old patient without any AB did receive nether a DMARD nor P. N=3/30 patients got both vaccinations with Vaxzevira (V), n=25/30 (83,3%) Comirnaty (C), n=1/30 Spikevax, n=1/30 first V, second C. 1 patient, treated with ABA has been vaccinated with 2 doses of C. A AB testing 4 months later did not reveal any antibodies. This patient came down with COVID-19 5 months after complete VAC and died.
Conclusion: There is very high number of VAC (98,1%) in a real life setting of a rheumatological OC. Many patients (95%) developed low to high AB levels after 2 VAC, independently which agent was used. Otherwise, we must be aware of the small group of patients (5%) without developing any AB. Unfortunately, our group was too small to find significant risk factors (RF). But RF seems to be the age, therapy with RTX, ABA and P. This is in line with reported RF in clinical studies (1). Furthermore, we see lower levels in elderly patients who get vaccinated with C. This could be biased by the fact that, in the first months of the VAC campaign, C was used in patients with higher age and the 2nd C-VAC was given 3 weeks after 1st VAC. Retrospectively, this interval seems to be too short. Thus now, the 2nd VAC is given 4-6 weeks after 1st VAC. In conclusion it is still unclear, which levels of AB make VAC effective and which patients will develop AB levels. AB levels should be evaluated to pick out patients with VAC gap, since the high risk of fatal course of COVID-19-disease. The booster campaign and 3rd VAC will change the current state again, therefore revaluation will be necessary.

AB1101

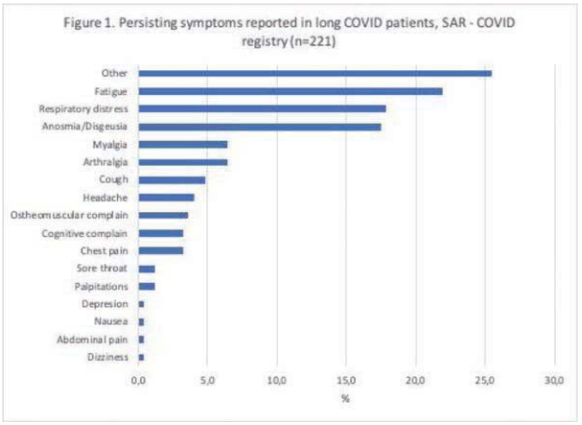
PREVALENCE OF LONG COVID IN RHEUMATIC DISEASE PATIENTS: ANALYSIS OF SAR COVID REGISTRY

C. A. Gonzalez Gomez[1], M. Cosatti[1], V. V. Castro Coello[2], M. Haye[2], Y. Tissera[2], A. A. Reyes[2], J. A. Albiero[2], S. Ornella[2], P. Alba[2], C. Gobbi[2], M. J. Gamba[2], I. E. Exeni[2], A. Cusa[2], J. Gallino Yanzi[2], V. I. Bellomio[2], G. Gomez[2], D. Zelaya[2], L. Takashima[2], L. Carlevaris[2], M. D. L. A. Correa[2], R. Rojas Tessel[2], M. García[2], N. German[2], A. L. Mercé[2], A. Bertoli[2], S. E. Aguero[2], M. E. Calvo[2], V. Martire[2], M. Mauri[2], M. L. Martin[2], E. Picco[2], D. Castrillon Bustamante[2], L. Ibañez Zurlo[2], M. N. Tamborenea[2], G. C. Subils[2], D. L. Vasquez[2], S. Soares de Souza[2], N. Herscovich[2], L. Raiti[2], V. Cosentino[2], F. Rodriguez[2], C. Ledesma[2], M. P. Diaz[2], M. L. Mamani Ortega[2], M. S. Castaño[2], G. Gómez[2], K. Roberts[2], R. Quintana[2], C. A. Isnardi[2], G. Pons-Estel[2], C. Pisoni[1]. [1]*CEMIC, Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno, Rheumatology Section, Ciudad de Buenos Aires, Argentina*; [2]*on behalf of SAR COVID Registry, SAR Research Unit, Ciudad de Buenos Aires, Argentina*

Background: Persistent symptoms after acute COVID have been described previously. Main symptoms reported are fatigue, arthralgias, myalgias and mental sickness. Definition and methods vary widely.[1]
Objectives: To asses prevalence and related factors to long COVID in a retrospective cohort of patients with rheumatic diseases from Argentina.
Methods: A total of 1915 patients were registered from August 18th, 2020 to July 29th, 2021. Patients > 18 years old, with rheumatic disease and confirmed infection by SARS-CoV-2 (antigen or RT-PCR) were included. Those dead, with unknown outcome, wrong date or missing data were excluded. Demographic data, comorbidities, rheumatic disease, and characteristics of SARS-CoV-2 infection were recorded. Long COVID was defined according to NICE guidelines (persistent symptoms for more than 4 weeks, without alternative diagnosis). Long COVID symptoms were defined by rheumatologist. Severity of infection was classified according to WHO ordinal scale. We used descriptive statistics, univariate model (Student's test, chi square test, ANOVA) and multivariate logistic regression analysis.
Results: 230 (12%) had long COVID. Median age was 51 (IQR 40-61]) years, 82% were females, 51% were not caucasian. Median of education was 13.3 years (IQR 12 – 16), 79 % had private health insurance and 55 % were employed. Nearly half (n=762, 46%) had comorbidities, the most prevalent was hypertension (n=396, 24%). The most frequent rheumatic diseases were rheumatoid arthritis (n=719, 42%) and systemic lupus erythematosus (n=280, 16 %). Most were in low activity/remission (79%), used Conventional DMARD (n=773 patients, 45%) and steroids (n=588, 34%) at low dose (n=415, 71%). Main laboratory findings were abnormal D-dimer (n=94, 28%) and leukopenia (n=93, 26%). Most patients had a WHO ordinal scale < 5 (n=1472, 86%). Median of hospitalization at intensive care unit (ICU) was 8 days [IQR 5, 13]. Treatment for SARS-CoV-2 infection (steroids, anticoagulation, azithromycin, convalescent plasma) was used in 461 (27%) patients. Most of long COVID (n= 152, 69%) reported 1 symptom, the most frequent was fatigue (n= 55, 22%). Figure 1. Univariate analysis is presented in Table 1. In multivariate logistic regression analysis non-caucasian ethnicity OR 1.44 (1.07-1.95), years of education OR 1.05 (1-1.09), treatment with cyclophosphamide OR 11.35 (1.56-112.97), symptoms of COVID – 19 OR 13.26 (2.75-242.08), severity scale WHO ≥ 5 OR 2.46 (1.68-3.57), and ICU hospitalization days OR 1.09 (1.05-1.14) were factors associated to long COVID.

Table 1. Univariate analysis of long COVID syndrome in SAR – COVID registry

Variable	Acute COVID n=1486	Long COVID n=221	P value
Age, years, median [IQR]	**51 [40, 60]**	**54 [42, 62]**	**0.032**
Caucasian, n (%)	744 (48)	132 (53)	0.227
Female sex, n (%)	1242 (80)	215 (86)	0.066
Education, years, median [IQR]	12 [10, 17]	13 [12, 16]	-
Private health insurance, n (%)	1161 (79)	181 (82)	0.325
Smoking, n (%)	381 (25)	71 (29)	0.224
Comorbidities, n (%)	650 (45)	108 (52)	0.066
Dyslipidemia, n (%)	**173 (12)**	**39 (19)**	**0.008**
Hypertension, n (%)	**332 (23)**	**60 (29)**	**0.053**
Low activity/remission disease, n (%)	1140 (80)	179 (77)	1
Rheumatoid arthritis, n (%)	623 (42)	96 (42)	1
Systemic lupus erythematosus, n (%)	243 (16)	37 (16)	0.996
DMARD, n (%)	664 (45)	109 (47)	0.486
Cyclophosphamide, n (%)	**3 (0.2)**	**3 (1)**	**0.035**
Rituximab, n (%)	**19 (1)**	**9 (34)**	**0.008**
Lymphocyte <1.500 / mm3, n (%)	**66 (23)**	**19 (30)**	**0.011**
Ferritin > 2000 ng/ml, n (%)	**32 (11)**	**16 (25)**	**0.011**
ICU hospitalization, days, median [IQR]	**7 [4, 10]**	**10 [8, 24]**	**<0.001**
Treatment for COVID-19, n (%)	**394 (27)**	**91 (41)**	**<0.001**



Conclusion: Prevalence of long COVID was 12%. Non-caucasian ethnicity, higher education, treatment with cyclophosphamide, symptoms of COVID – 19, severe disease and ICU hospitalization days were related to long COVID.

AB1102 A RARE CASE OF ACUTE INFLAMMATORY DEMYELINATING POLYRADICULOPATHY FOLLOWING THE SECOND DOSE OF PFIZER COVID-19 VACCINE

V. Courant[1], M. Silva[1], S. Grewal[1]. [1]*Mount Sinai Morningside, Internal Medicine, New York, United States of America*

Background: We present a case of a 36 year-old female who developed Acute Immune-mediated Demyelinating Polyneuropathy (AIDP) after receiving the second dose of Pfizer COVID-19 vaccine.

Objectives: To report a rare auto-immune complication of COIVD-19 vaccination. To educate and inform physicians about the approach to diagnosing AIDP and narrowing down its etiology.

Methods: Case report and literature review

Results: A 36 year-old female with no significant past medical history presented to the hospital with progressive bilateral paresthesia. She started to experience numbness and tingling sensation in her extremities 1 week after receiving the second dose of Pfizer COVID-19 vaccine. Following 5 days of symptoms onset, she was no longer able to hold onto objects and experienced difficulty ambulating without assistance. Physical exam was notable for decreased distal sensation to touch and pain in all 4 limbs, otherwise, the rest of her neurological and musculoskeletal evaluation was normal. MRI-head showed small scattered foci of increased FLAIR signal in the white matter, suggesting an underlying inflammatory process. Electromyography (EMG) was performed and showed evidence of acute diffuse sensorimotor neuropathy with mixed axonal and demyelinating features. These results along with the clinical features allowed us to diagnose our patient with Acute Immune-mediated Demyelinating Polyneuropathy (AIDP). Extensive autoimmune workup, including anti-GM1, GD1b, Gq1b, ANA, DS-DNA, RF, CCP, and C/P ANCA, were unremarkable. She had positive anti-Ro atb but did not have any clinical or physical features that would suggest Sjogren's Syndrome. Vitamin levels (B12, folate, thiamine) were found to be normal. Infectious workup of serum and CSF which included hepatitis serologies, Campylobacter jejuni serology, Lyme atb, CMV atb, EBV atb were all negative. The possible etiology of her disease was attributed to Pfizer COVID-19 vaccine given the temporal correlation. She was subsequently treated with 6 cycles of IVIG which resulted in moderate symptomatic improvement.

Conclusion: AIDP is an autoimmune-guided inflammatory neuropathy which result in axonal degeneration of myelinated nerves [1]. In some extremely rare cases, molecular mimicry following vaccination may lead to this disease [1]. There have been reports of AIDP linked to Johnson & Johnson and AstraZeneca COVID-19 vaccines [2]. Recently, a few cases have also been observed with Pfizer COVID-19 vaccine [2-3]. Interestingly, the majority of these cases occurred after the first dose of the vaccine, making our case even more peculiar [2]. We report this case as physicians should be made aware that AIDP is a potential complication of COVID-19 vaccination. Given the extreme rarity of these cases, it is also important to note that more common infectious and autoimmune etiology of AIDP should be investigated before attributing any potential causal relationship to COVID-19 vaccines.

AB1103 THE EFFECT OF COVID-19 PANDEMIC IN A LARGE SERIES OF PATIENTS WITH TAKAYASU ARTERITIS

A. Karakas[1], T. Yuce Inel[1], F. Onen[1], İ. Sari[1]. [1]*Dokuz Eylul University Faculty of Medicine, Rheumatology, Izmir, Turkey*

Background: Patients with inflammatory rheumatic diseases faced several challenges during the COVID-19 pandemic. Uncertainties such as the lack of evidence regarding the use of immunosuppressive (IS) therapies and deferred patient care because of limited health resources impacted negatively on many aspects of treatment decisions and routine follow-up of the patients (1).

Objectives: We aimed to investigate the prevalence and severity of SARS-CoV-2 infection, the impact of the pandemic on delays in routine clinical follow-up, changes in IS treatment, and COVID-19 vaccination status of patients with Takayasu arteritis (TAK).

Methods: The study was performed between July and September 2021. TAK patients who registered in our database were investigated with regards to the COVID-19 infection and vaccination status, delays in routine clinical visits, changes in their IS treatments, and flares during the pandemic. Physical examination, laboratory tests, and imaging of the patients were performed and ITAS2010 scores were calculated.

Results: There were 56 adult TAK patients (87.5% female and median age 47 years). 44 (78.6%) patients experienced a delay with routine follow-up visits to their physicians and about 20% of patients stopped their antirheumatic treatments without consulting their physicians. Compared to the pre-COVID-19 pandemic, 16 (28.5%) patients were flared. 13 (23.2%) patients had a mild COVID-19 infection. Pneumonia was reported in five patients, two of them required hospitalization, and all patients recovered completely. In the total group, about 90% of the patients had received the COVID-19 vaccine (Table 1).

Table 1. Effects of COVID-19 pandemic on patients with Takayasu arteritis

Patients with a delay regarding to the routine follow-up visits, n (%)	44 (78.6)
Average delay in routine follow-up visits since the beginning of COVID-19 pandemic (months), median, Q1-Q3	3.5 (2.25-9)
Patients who don't receive their treatment regularly due to COVID-19 concern, n (%)	11 (19.6)
Disease relapse compared to the pre-pandemic time, n (%)	16 (28.6)
Progression in acute phase reactants, n (%)	14 (25)
Progression in vascular involvement (according to MR angiography or Doppler ultrasound findings) n (%)	15 (26.8)
Patients diagnosed with COVID-19 disease, n (%), pre-vaccination / post-vaccination	13 (23.2), 8/5
Vaccination status, n (%)	50 (90.9)

Continuous data is presented with median (interquartile range, Q1-Q3) values and categorical data are presented as counts (n) and percentages (%)

Conclusion: COVID-19 disease in TAK patients were in mild severity and IS therapy seem not affecting the COVID-19 course. A substantial number of patients who stopped their medications flared and its long-term consequences need to be assessed by large-scale studies. New approaches are required to maximize healthcare access for patients who have chronic diseases during pandemic.

AB1104 CHARACTERISTICS OF POST-COVID SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Aronova[1], G. Gridneva[1], B. Belov[1]. [1]*VA Nasonova Research Institute of Rheumatology, Department of Comorbid Infections and Vaccine Prevention, Moscow, Russian Federation*

Background: Almost two years after the start of the pandemic, it has become clear that the severity of COVID-19 is not limited to the manifestations of the acute phase of SARS-CoV-2 infection. The so-called post-covid syndrome (PCS) can

occur even in patients who have experienced mild or moderate COVID-19 and includes long-term symptoms that may be associated with residual inflammation, organ damage, non-specific effects of hospitalization or prolonged ventilation, social isolation, or comorbid diseases. In October 2021, the WHO defined PCS as a condition that occurs in individuals with a history of probable or confirmed infection with the SARS-CoV-2 virus, usually within 3 months of the onset of COVID-19, and is characterized by the presence of symptoms for at least 2 months, as well as the impossibility of explaining them with an alternative diagnosis.

Objectives: To conduct a comparative assessment of clinical and demographic indicators in groups of patients with rheumatoid arthritis who underwent COVID-19, with and without PCS.

Methods: The material of the questionnaires filled in by patients of the V.A. Nasonova Research Institute of Rheumatology, who underwent COVID-19, verified by RT-PCR for SARS-CoV-2 RNA. The information was supplemented with data from discharge records after inpatient treatment for COVID-19. Statistica program (version 12) was used for statistical processing. The results of correlation analysis were considered significant at $p<0.05$.

Results: The study included 23 adult patients (over 18 years of age) with a reliable diagnosis of rheumatoid arthritis (ACR/EULAR). Of these, 11 (47.8%) patients noted the development of PCS (Group 1), and 12 patients underwent COVID-19 without consequences (Group 2). Both groups were represented predominantly by women (90.9% and 91.7%, respectively). The average age in both groups did not differ significantly and amounted to 56.73±14.79 years in group 1, and 48.17±19.59 years in group 2. The median number of comorbid diseases was 2 [1;4] in group 1 and 0.5 [0;2.5] in group 2. PCS was presented by the following symptoms: weakness, increased fatigue - in 6 patients, problems with attention, concentration - in 7, memory impairment - in 6, sleep disturbances - in 7, increased pain in the joints - in 7, shortness of breath during exercise - in 6, fluctuations in blood pressure - in 5, tachycardia - in 4. On average (median), each patient noted 10 [6.5;12] symptoms of PCS at a time. When assessing the number of symptoms in the infectious phase, in group 1, patients reported 20 [16;23], and in group 2, 10 [7;12] symptoms of COVID-19. At the time of development of COVID-19, the severity of RA symptoms, assessed by VAS, was 5.64±3.26 in group 1 and 4.75±2.99 in group 2. In group 1, 5 (45.5%) patients needed hospitalization, 3 of them needed oxygen support. In group 2, 4 (33.3%) patients were hospitalized, two of them needed oxygen support. 3 patients in group 1 suffered COVID-19 again on average 9.33±2.52 months after the first illness. One of them has been vaccinated. All patients in this group were treated as outpatients, while the first case of COVID-19 required one hospitalization and oxygen support. Statistical assessment of significant differences ($p<0.05$) between groups in terms of sex, age, number of comorbid diseases, number of COVID-19 symptoms in the infectious phase, severity of RA symptoms, and hospitalization rate was not revealed.

Conclusion: Even though when assessing the socio-demographic characteristics, no statistically significant differences were found between the study groups, the average age, the number of comorbid diseases, and the severity of RA symptoms at the time of COVID-19 were higher in the group of patients with RA and PCS. Patients with PCS reported higher rates of hospitalizations and more severe COVID-19. There were also repeated cases of COVID-19 in this group. It is necessary to continue the study on a larger cohort.

AB1105 PSEUDOPERNIOSIS AS A Llate MANIFESTATION AFTER SARS2-COD19 INFECTION. A PURPOSE OF A SERIES OF 19 CASES

F. J. Navarro Blasco[1]. [1]*Hospital General Universitario de Elche, Rheumatology, Elche, Spain*

Background: In winter, you can usually see a picture of Perniosis and / or chilblains. Painful, often itchy, red-to-purple lesions that affect the acrid surfaces of the fingers and toes after contact with the cold, resembling vasculitis, characterize them. Chilblains can be idiopathic and self-limiting or associated with systemic diseases. The diagnosis is usually clinical, but in some circumstances, analytical and microscopic studies of a biopsy sample may be necessary. We present a series of 19 consecutive cases of Pseudoperniosis associated with probable past INFECTION by SARS-CoV-2.

Methods: During the winter 2020-21, an unexpected number of cases referred as "acute arthritis/vasculitis" have been received in our rheumatology section and associated consultations. In the pathochrony of patients, exposure to cold was referred to as the main triggering factor. Initially qualified as PERNIOSIS. Given the appearance in the current situation of Pandemic by covid-19, we began to request the serology SARS2-COVID19 IgG / IgM. Appreciating an approximate rate of 70% of IgG+ positivity in which it was performed.

Results: Characteristics of the clinical data collected evolutionarily in the 19 patients: These are preferably young people, without any other pathology, although there are also people of all ages, with a clinical picture of edema of soft parts preferably of the hands, but also in the feet, with pain and some hemorrhage infusions, including ulcerations in the areas of the knuckles or pressure (PHOTO1-2-3). Despite the overwhelming nature of the picture, they do not associate any other symptoms and the analyses are normal, including acute phase reactants (ESR and PCR), and serological markers of autoimmune disease. Approximately 1/4 of them reported having passed clinical compatible with the covid19 infection and / or having been isolated with some minor symptom, but they had not been performed PCR. The others did not report any symptoms associated with COD19 infection. From the initial diagnosis, about 40 days passed on average. Many of them were being treated with corticosteroids/NSAIDs without improvement. In the ultrasounds performed, only edema of periarticular and paratendinous tissue is appreciated, such as that which can occur after a momentary ischemic picture. All evolved favorably avoiding cold (probable triggering factor), and with antiplatelet agent (infant aspirin).

Conclusion: This picture of Pseudoperniosis lacks the typical pruritus of perniosis and the main problem is pain along with edema of the tissues of the hand that leads to make it impossible to use. Similarly, asymmetric lesions similar to perniosis were observed in patients who presented skin manifestations of SARS-CoV-2 infection in a study conducted in Spain (1). We are following these patients to assess if there is any relationship with any other factor that facilitates this unusual incidence, and at the same time indicate the transience of the clinical picture that evolves favorably in a few weeks.

AB1106 HOW HAS THE COVID-19 PANDEMIC AFFECTED OUR RHEUMATOLOGY PATIENTS USING BIOLOGICAL/ TARGETED DMARDS?

S. Gulle[1], Y. Erez[1], A. Karakas[1], T. Yüce İnel[1], S. B. Kocaer[1], T. Demirci Yıldırım[1], G. Can[1], İ. Sari[1], M. Birlik[1], F. Onen[1]. [1]*Dokuz Eylul University School of Medicine, Rheumatology, Izmir, Turkey*

Background: Bioinformatics data, which are becoming more detailed day by day, show that male gender, advanced age, smoking, and comorbidities are associated with poor outcome of COVID-19. However, it is well known that the active disease state that may occur as a result of discontinuing the drugs also increases the susceptibility to infection.

Objectives: It was aimed to investigate the effects of the COVID-19 pandemic on the course and treatment of rheumatic disease in patients with inflammatory rheumatic musculoskeletal disease (iRMD) using biological or targeted synthetic DMARDs (b/tsDMARDs).

Methods: The study was carried out in two stages: while investigating the delay of b/tsDMARD treatment in the first 3 months of the pandemic with the fear of infected by SARS-Cov-2 in the first stage, in the second stage, it was investigated whether all patients who decided to continue treatment after interruption in the 12-month period.

Results: A total of 521 patients were included in the study. It was seen that the iRMD diagnosis were listed as SpA (54.3%), RA (25.7%), PsA (8.4%), vasculitis (6.1%), and others (5.4%). The overall 12-month drug retention rate was 92.3%. Concurrent use of hydroxychloroquine (HCQ) (HR=1.49), iv bDMARD use (HR=1.34), and a history of discontinuation of drug in the first 3 months of the pandemic (HR=1.19) were determined as factors that reduced 12-month drug retention rates. During a total of 12 months, 34 (6.5%) of patients had COVID-19. COVID-19 was severe in 7 patients and 5 of these patients died.The use of GC (HR=3.81) and having a diagnosis of ILD/COPD (HR=4.96) were found to increase the risk of infected by SARS-CoV-2.

Table 1. Comparison of demographic and clinical characteristics of patients with COVID-19

	COVID-19 (-) (n=487)	COVID-19 (+) (n=34)	
Demographics	**Median (Min./Max.)**	**Median (Min./Max.)**	**P**
Age	48 (18-86)	48 (18-82)	0.615
Disease Duration	130 (22-478)	144 (48-519)	0.573
b/ts DMARD Duration	45 (12-192)	26 (14-170)	0.253
GC dose, mg	4 (1-16)	4 (2-16)	0.863
	n (%)	**n (%)**	
Gender, F	259	19	0.909
COVID-19 diagnosis and outcome			
Hospitalization	–	**11 (32.3)**	–
Mortality	–	**5 (14.7)**	–
Active disease (anytime during the pandemic)	82 (16.4)	9 (26.5)	0.246
ILD and/or COPD	14 (2.9)	**4 (8.9)**	**0.002**
	n (%)	**n (%)**	
b/tsDMARD type			**0.049**
TNFi	**382 (78.4)**	15 (44.1)	0.243
Tocilizumab	19 (3.9)	2 (5.9)	0.684
Abatacept	13 (2.7)	1 (2.9)	0.886
Rituximab	9 (1.8)	**6 (17.6)**	**0.001**
GC	83 (17.0)	**17 (50.1)**	**0.001**

Conclusion: The results of this study with a long follow-up period suggest that the retention rates of b/tsDMARD treatment increased with good communication with iRMD patients during the COVID-19 pandemic.

AB1107 COVID-19 INFECTION MAY BE TRIGGER FOR DEVELOPMENT OF IMMUNE-MEDIATED DISEASES (IMDS)

N. Manukyan[1], V. Vardanyan[1], K. Ginosyan[1], A. Sargsyan[2], S. Mardoyan[1].
[1]*Yerevan State Medical University, Rheumatology, Yerevan, Armenia*;
[2]*"Mikayelyan" University Hospital, Rheumatology, Yerevan, Armenia*

Background: As considerable evidence indicates viruses play an important role in the pathogenesis of inflammatory rheumatic diseases as environmental factors. The most prominent pathogenic viruses which have been proposed in the triggering and initiation of autoimmune diseases include Parvovirus B19, Epstein-Barr-virus (EBV), Cytomegalovirus (CMV), Herpes virus-6, HTLV-1, Hepatitis A and C virus, and Rubella virus[1]. It is possible that COVID-19 infection is also a trigger. Because SARS-CoV-2 infection can break immune tolerance and trigger autoimmune responses, it is also likely to induce clinical autoimmunity[2].

Objectives: Find out a possible association between Covid-19 infection and development of IMDs.

Methods: We analyzed data of 21 patients (Male 4 /19 %/, female 17 /81%/, mean age 45.5 ± 13,9 years), who were admitted to Rheumatology department of "Mikayelyan" University Hospital after Covid -19 infection with newly diagnosed IMDs from June till December 2021. All of included had never had such kind of disorder before. EULAR/ACR criteria were used for diagnosis and assessment of disease activity.

Results: After SARS-CoV-2 infection some patients presented with preserved fever, high levels of CRP and ESR, had rash and arthritis. Particularly, 3 (14.3%) developed systemic lupus erythematosus, 3(14.3%) – antiphospholipid syndrome, 4 (19%) – rheumatoid arthritis, 2(9.5%) - spondyloarthritis, 3 (14.3%) - sarcoidosis, 4 (19%) - erythema nodosum, 1 (4.8%) - small-vessel vasculitis, 1 (4.8%) - undifferentiated arthritis, and 1(4.8%) - Tietze syndrome. 11 (52.4%) experienced severe course of Covid-19 with pneumonia and respiratory failure, in 10 (47.6%) patients the course of disease was mild. We've found a significant association between severe course of Covid-19 and development of erythema nodosum. ($p < 0.05$). Also an association between female gender and severe course of Covid-19 was determined ($p<0,05$).

Conclusion: In acute progression of the COVID-19 along with development of antiviral immunity, a dysregulated response of immune system may occur, represented by the marked cytokine release syndrome, macrophage activation, and systemic hyperinflammation.[3] We analyzed the data of patients who didn't have any typical symptom of rheumatic diseases before coronavirus infection, therefor, on our opinion, virus played an important role to induce clinical autoimmunity and autoinflammation and subsequently – IMDs. Possibly, Covid-19 infection may be included in the group of trigger viruses for

AB1108 IMPACT OF THE FIRST WAVE OF THE COVID 19 PANDEMIC ON HEALTHCARE ACCESSIBILITY, DISEASE BEHAVIOUR, ANXIETY, AND PHYSICAL ACTIVITY IN RHEUMATIC DISEASE PATIENTS: AN ONLINE SURVEY AND POTENTIAL SOLUTIONS

S. Yadav[1], R. Samant[1]. [1]*P. D. Hinduja National Hospital & Medical Research Centre, Rheumatology, Mumbai, India*

Background: Coronavirus Disease (covid 19) negatively impacted psychosocial health, health care accessibility and exercise regimen but problem's scope and potential solutions remain elusive. We conducted a patient based online survey to understand these impacts and discussed potential solutions.

Objectives: Assess impact of Covid 19 on rheumatological disease status, accessibility to health care, patient anxiety and behavior and continuation of physical activity during pandemic.

Methods: Google form (18-question) based questionnaire was sent via SMS/WhatsApp in Aug 2020, at height of first pandemic and responses were collected over next month.

Results: Only 339 /2700 patients (12.5 %) responded to the survey. Other authors (1)(2) have observed a similar low response rate to online surveys. We recognise questionnaires with fewer questions tend to generate more responses, which should be considered critical in constructing future health-related surveys. Patients' global assessment of their disease score was 7/10, with 0 representing the worst disease status and10 representing best disease status, also 1/3 patients not felt need for rheumatological consultation during six months (March 2020- Aug 2020) of lockdown. These may imply adequate rheumatic disease control over long periods and during subsequent waves of pandemic, rheumatology patients can be shielded by avoiding non-urgent hospital follow up visits. Significant number of patients (20%) were unable to contact their rheumatologist, implying a significant impact of covid 19 and lockdown on rheumatology care, as suggested by other authors (1). As expected, there was switch to tele consultancy mode of communication, with 22 per cent of patients already using it within 3 months of its introduction, which appears to be a good indicator of future adaptability and feasibility of teleconsultation. Identifying specific profile of patients during physical consultation who can be easily managed via teleconsultation, may reduce unnecessary hospital visits while also improving healthcare delivery. 1/3 of our patients had anxiety about disease flare, and 41 %were concerned about increased risk of covid 19 infection as they were on immunosuppressive medications as noted by other authors (3). Improving access to health care and increasing public awareness could help alleviate this anxiety. Reaching out to isolated rheumatology patients through SMS / educational video may improve the sense of health security. Contrary to our expectations, overall medication adherence was reasonable, likely due to be management of supply chains by local authorities .15% completely stopped exercising and 25% reduced their exercise regimen by 50%. Shifting to home-based exercise, educational videos on physical therapy and online teleconsultation with physiotherapists could overall have positive impact.

Conclusion: Covid 19 has significantly impacted rheumatological patients in terms of increased anxiety, decreased healthcare accessibility and decreased exercise and physical activities. Modifications in teleconsultation methodology are needed in the future. Patients' anxiety can be alleviated by educating them through digital and social media platforms and enrolling them in online patient support groups.

AB1109 EVALUATION OF THE POTENTIAL INDUCTION OF AUTOANTIBODIES AFTER THE ANTI-SARS-COV2-VACCINATION IN A COHORT OF PATIENTS WITH TRIPLE POSITIVITY FOR ANTIPHOSPHOLIPID ANTIBODIES

P. Semeraro[1], S. Bertocchi[1], S. Piantoni[1], L. Andreoli[1], F. Franceschini[1], E. Garrafa[2], A. Tincani[1]. [1]*University of Brescia - ASST Spedali Civili di Brescia, Clinical and Experimental Sciences, Brescia, Italy*; [2]*University of Brescia - ASST Spedali Civili di Brescia, Molecular and Translational Medicine, Brescia, Italy*

Background: Anti-SARS-CoV2 vaccines showed a good efficacy in prevention of severe COVID-19[1]. Their potential in induction of autoantibodies (abs) has not been well established[1]. One recent study demonstrated an increase of abs' titre after anti-SARS-CoV2 vaccination only in patients with already pre-existing positivity[2].

Objectives: To evaluate the potential induction of abs after anti-SARS-CoV2 vaccination in a triple positive antiphospholipid antibodies (aPL) cohort.

Methods: 18 subjects were enrolled [M/F= 17/1; median age=52 years; 5 Primary Antiphospholipid Syndrome (PAPS), 5 Systemic Lupus Erythematosus

Table 1. Autoantibodies' titre pre (T0) and post (T1) anti-SARS-CoV2 vaccination.

Autoantibodies	Level at T0	Level at T1	p-value*	Patients positive at T0	Patients positive at T1	p-value°
Anti-dsDNA (n.v. <27 IU/ml)	28.7 (21.8-64.5)	25.8 (15.9-68.5)	0.163	7/18 (38.9%)	6/18 (33.3%)	0.729

aβ2GPI IgG (n.v. <20 IU/ml)	9.3 (9.3-128.1)	19.4 (9.3-126.9)	0.844	8/18 (44.4%)	9/18 (50%)	0.738
aβ2GPI IgM (n.v. <20 CU)	16.9 (3.6-51.3)	6.8 (1.5-23.1)	**0.041**	7/18 (38.9%)	5/18 (27.8%)	0.480
aβ2GPI IgM (n.v. <20 IU/ml)	19.8 (11.1-78.8)	9.9 (9.3-52.4)	0.109	8/18 (44.4%)	7/18 (38.9)	0.735
aβ2GPI IgA (n.v. <20 IU/ml)	20.8 (9.3-39.9)	9.3 (9.3-37.8)	0.080	10/18 (55.6%)	7/18 (38.9%)	0.317

Antiphospholipid antibodies were determined with chemiluminescence (CU) and home-made ELISA (IU/ml) methods of detection. Pre and post-vaccine values are expressed as median (IQR). In bold, statistically significant comparisons. *Wilcoxon signed-rank test for paired variables was applied. °Chi-square test or Fisher's exact test were applied. dsDNA=double-stranded DNA; aCL: anti-cardiolipin; aβ2GPI: anti-beta2-glycoprotein I; n.v.: normal value.

(SLE) with associated APS and 8 aPL carriers (1 Behçet Disease, 1 SLE, 4 Undifferentiated Connective Tissue Disease, 2 with no diagnosis of systemic autoimmune disease)]. Serum samples were collected before the first (T0) and at least one month after the second administration (T1) of the anti-SARS-CoV2 vaccine (16 BNT162b2, 1 mRNA-1273, 1 Gam-COVID-Vac). A wide panel of abs were evaluated through routinely methods.

Results: None developed any additional sign of autoimmune diseases upon vaccination. Patients majority did not display any new autoantibody positivity (Table 1). Changes were observed in 3 patients: 1) one aPL carrier patient who was antinuclear antibodies (ANA) negative at T0 was found to be ANA positive at T1 [negative anti-double stranded DNA and anti-extractable nuclear antigen (ENA)]; this patient was actually ANA positive in her clinical history; 2) one aPL carrier patient affected by SLE, who was IgM and IgG aCL and IgG aB2GPI positive at T0, turned positive for IgM and IgA aB2GPI; 3) one aPL carrier patient affected by Behçet Disease, who was positive for IgM aCL and for IgM aB2GPI at T0, turned positive for IgA aCL and IgA aB2GPI. All emerging aPL were low titre. None of the patients displayed raising aPL titres from low to medium-high.

Conclusion: Anti-SARS-CoV2 vaccination did not induce any clinical signs of autoimmunity in a cohort of patients with triple aPL positivity. Serology for autoantibodies remained stable in the majority of patients. Few patients experienced the emergence of low titre aPL, possibly as an expected inter-assay variation rather than an evolving "serological flare".

AB1110 **COVID19 IN SPONDYLOARTHRITIS PATIENTS UNDER BDMARD – A COMPREHENSIVE ASSESSMENT**

F. R. Martins[1], A. Martins[2], D. Santos Oliveira[2,3], B. Samões[4], R. Nicolau[5], F. Oliveira Pinheiro[2], M. Rato[2], M. Bernardes[2,6], L. Costa[2]. *[1]University Hospital Center of Algarve, Faro, Rheumatology, Faro, Portugal*; *[2]São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; *[3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[4]Centro Hospitalar de Vila Nova de Gaia, Rheumatology, Vila Nova de Gaia, Portugal*; *[5]Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal*; *[6]Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal*

Background: SARS-Cov-2 infection had a major impact on patients with inflammatory rheumatic diseases. Spondyloarthritis (SpA) patients were one of the most affected groups of these patients.

Objectives: To assess the impact of Covid19 in spondyloarthritis patients under biological disease modifying anti-rheumatic drugs (bDMARDs).

Methods: A retrospective observational study was conducted using registry data of patients with SpA under bDMARD therapy, followed at a tertiary level hospital, that have been diagnosed with COVID19 from March 2019 to December 2021. At least one evaluation previous (t0) and two evaluations after SARS-CoV-2 infection (t1, t2) were included in our analysis. Sociodemographic, clinical, disease activity, therapeutic response, function and general health status data were collected. Statistical analysis (significance at $p < 0.05$) was performed using paired T-test, Wilcoxon test and McNemar tests for paired samples. Linear and logistic regression models were performed to assess direction and strength of association

Results: Thirty-two patients with SpA under bDMARD had COVID19, mostly women (20, 62.5%), with a disease course time averaged 18.65 (± 9.69) years, mainly with axial involvement (19, 59.4%) and positive for HLA-B27 antigen (11, 64.7%). The majority were under TNF inhibitors (30, 93.75%), with golimumab being the most common (9, 28.1%), and with a median bDMARD persistence of 2.63 (5.09) years. Seven (21.9%) were under a cDMARD, 3 (9.4%) under NSAID and 18 (56.3%) under corticosteroids. Three (9.4%) were already vaccinated against SARS-CoV-2, 2 (66.6%) with the mRNA-1273 vaccine, presenting a medium time since inoculation of 240 (± 234.01) days. Arterial hypertension was the most common comorbidity (5, 15.6%) and one patient (3.1%) had a previous diagnosis of type 2 diabetes. Most were never-smokers (17, 53.1%) and never-drinkers (29, 90.6%). The average age at infection was 40.97 (± 6.15) years and the most common symptom was cough (22, 68.8%), followed by headache (20, 62.5%) and myalgia (19, 59.4%). Event tree analysis didn't show association with SpA subtype, education level, work status, tobacco or alcohol consumption. Only one patient needed hospital admission but without needing of oxygen, therapy, ventilator or ECMO. Only one patient had an overlaid bacterial infection and no thromboembolic complications were observed. Two patients needed specific SARS CoV-2 infection treatment, one with hydroxychloroquine and another with azithromycin. Twelve (37.5%) patients suspended bDMARD at the time of infection, with only 2 (6.3%) maintaining suspension at the time of the first post-infection visit. When comparing clinical variables, higher disease activity was seen at t1 only for BASDAI mean values, without statistical significance. Higher all domains VAS scores were also observed at t1, but not at t2, also without statistical significance; moreover, physical function didn't change significantly. No differences were observed according to gender or SpA subtype, nor with the use of cDMARDs, NSAIDs or corticosteroids. The only statistically significant difference concerned MASES score between t0 and t1 (1 ± 4 vs. 2 ± 6, p=0.04), but not between t0 and t2. Higher baseline tender joint score ($p < 0.01$) and higher baseline LEI (p=0.03) negatively correlated with MASES score variation. Several baseline variables correlated positively with MASES at t1, including female gender ($p < 0.01$), corticosteroid use (p = 0.04), BASDAI ($p < 0.01$), ASDAS-ESR ($p < 0.01$), ASDAS-CRP ($p < 0.01$), DAS28 ($p < 0.01$), SPARCC (p = 0.04), physician VAS (p = 0.03) and total spine VAS (p = 0.01). Working status varied significantly after SARS-Cov-2 infection (at least part-time - 29, 90.6% vs. 22, 68.8%, p= 0.016).

Conclusion: SpA patients on bDMARD had a mild course of SARS-CoV-2 infection, with slight changes in enthesitis score in the short term, the latter particularly in those with higher disease activity in the pre-infection period. Long-term effects on work status could represent confounding factors related to the economic constraints of the pandemic.

AB1111

NO INCREASED RISK OF ADVERSE EVENTS OF THE WHO-VALIDATED COVID-19 VACCINES IN PATIENTS WITH RHEUMATIC DISEASES TREATED WITH BIOLOGICS

M. Yasmine[1], W. Triki[1], H. Ferjani[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: The COVID-19 pandemic is a major concern for the management of patients with rheumatic diseases (RD). Indeed, an increasing risk of coronavirus infection has been demonstrated in these patients, explained on the one hand by the chronic inflammation and on the other hand by the immuno-modulating treatments used [1]. In this context, vaccination represent an efficient mean to prevent infections and should be included in the management of these patients.

Objectives: The objective of our study was to determine the peculiarity of vaccination against SARS-COV2 in patients with RD treated with biologic therapies.

Methods: We conducted a cross-sectional study during August 2021, including patients with RD: rheumatoid arthritis (RA) and spondyloarthritis (SpA). Sociodemographic data as well as disease characteristics were recorded. Patients were asked to answer a self-questionnaire about SARS-COV2 vaccination: modalities, time between doses, type of vaccine, adverse events, and time to biologic injection. We compared these results between the two groups: group 1 patients on biologics and patients on conventional disease-modifying antirheumatic drugs (DMARDs). A significance level was set for p<0.05.

Results: The study included 102 patients with RD: RA (65.3%) and SpA (34.7%). The mean age was 52.4 ± 13 years [19-77]. There was a female predominance (71 women and 31 men) with a gender ratio of 0.4. The mean duration of disease progression was 7.8 ± 5 years [1-35]. Fifteen percent of patients were on corticosteroids with a mean dose of 6.7 mg [2-20] of prednisone equivalent. A CsDMARD was prescribed alone in 36.3% of cases and combined with a biologic in 18% of cases. SARS-COV2 infection was found in 27.3% of cases, of which 19% had a severe form. Sixty percent of patients received the SARS-COV2 vaccine, and 25% of them received only the first dose. The mean time between the two injections was 27 ± 7.6 days [23-67 days]. The most common type of vaccine was Pfizer (54.4%), Moderna (5.5%), followed by AstraZeneca (20%), Sinovac (16.4%), Johnson (1.8%) and Sputnik (1.8%). Three patients deferred their biotherapy injection by one week. Only one patient discontinued methotrexate therapy for one month. Sixteen patients reported adverse events such as injection site pain (62.5%), disease flare (12.5%) and fatigue and fever (25%). Patients receiving biologics were not at greater risk of SARS-COV2 infection (p=0.076) or hospitalization (p=0.131) compared to patients receiving conventional therapy. Similarly, patients on conventional therapy did not report more adverse events (p=0.678). The vaccination rate was significantly higher in patients on biologics compared to patients on CsDMARD: 72% versus 43%, p=0.004.

Conclusion: Our work demonstrated that patients treated with biologics adhered to vaccination and did not have more SARS-COV2 infections or adverse events compared to patients on conventional treatment.

AB1112

SARS-COV-2 INFECTION AND IT VACCINATION IN AUTOINMUNE DISEASE-ASSOCIATED INTERSTICIAL LUNG DISEASE

A. Garcia Studer[1], M. Rojas-Giménez[2], M. Velloso Feijoo[3], C. M. Romero-Barco[4], F. Godoy-Navarrete[5], N. Mena-Vázquez[1]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA), UGC de Reumatología, Hospital Regional Universitario de Málaga (HRUM), Malaga, Spain*; [2]*Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), UGC de Reumatología, Hospital Universitario Reina Sofía de Córdoba, Córdoba, Spain*; [3]*Hospital Universitario Virgen de Valme, Servicio de Reumatología, Sevilla, Spain*; [4]*Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Universitario Virgen de la Victoria, Málaga, Spain*; [5]*Hospital Universitario de Jaén, Servicio de Reumatología, Jaén, Spain*

Background: Intersticial lung disease (ILD) is a common condition in patients with systemic autoinmune diseases (SAI) that is characterized by increased morbility and mortality. Coronavirus disease 2019 (COVID-19), caused by SARS-CoV-2, has posed huge challenges worldwide and previous studies suggest that ILD patients experience a more severe clinical course.

Objectives: To analyze COVID-19 infection effects in patients with ILD associated systemic autoinmune disease (ILD-SAI) and to describe their vaccination status.

Methods: Design We performed a multicenter, retrospective, observational study from 6 teaching hospitals in Andalusia, Spain. **Study protocol** We included ILD-SAI patients: rheumatoid arthritis (RA), systemic sclerosis (SS) and inflammatory myopathies (IM), assisted in reumatology consultations in 2021. **Variables** COVID-19 infection was the main variable that we collected and it was confirmed by a positive result on a PCR test. Secondary variables: (1) COVID-19 severity defined as hospitalization or death; (2) vaccination status; (3) temporary relationship between infection and vaccination. Other variables included: clinical, epidemiological characteristics, treatments received, type of ILD (UIP/NSIP), pulmonary function testing and high-resolution computed tomography. **Statistic analysis** Two multivariable logistic regression analysis to indentify the "COVID-19" and "severe COVID-19" associated factors.

Results: We included 176 ILD-SAI, of whom: 105 (59.7%) had RA, 49 (27.8%) had SS and 22 (12.54%) had IM. The main baseline characteristics for the oversall simple and te 3 subgroups are shown in Table 1.

Table 1. Clinical and epidemiological characteristics of 171 ILD-SAI patients.

Variable	Rheumatoid artritis n=105	Systemic sclerosis n=49	Inflammatory myopathies n=22	p-value
Sex, women, n (%)	58 (55.2)	42 (85.7)	17 (77.3)	<0.001
Age in years, mean (SD)	67.9 (9.6)	60.9 (12.5)	55.7 (18.9)	<0.001
SAI evolution time, month, median (IQR)	46.2 (25.4-79.0)	67.1 (52.2-88.2)	39.1 (25.1-72.5)	0.010
Radiological patterns				<0.001
UIP, n (%)	66 (62.9)	8 (16.3)	1 (4.5)	
NSIP n (%)	32 (30.5)	39 (79.6)	20 (90.9)	
Last PFT				
FVC, mean (SD)	70.7 (19.9)	71.3 (21.4)	73.1 (16.6)	0.471
FEV1, mean (SD)	71.2 (19.3)	72.2 (17.3)	74.4 (17.9)	0.345
SB-DLCO, mean (DS)	54.3 (16.5)	52.4 (15.9)	60.8 (15.2)	0.140
Treatment				
sDMARD, n (%)	88 (86.3)	10 (20.4)	11 (50.0)	<0.001
Biologic DMARD, n (%)	47 (46.1)	14 (28.6)	6 (27.3)	0.590
Immunosuppressants, n (%)	37 (36.3)	33 (67.3)	17 (77.3)	<0.001
Corticosteroid, n (%)	72 (71.3)	24 (49.0)	18 (81.8)	0.007
COVID-19				
COVID-19 infection, n (%)	14 (13.3)	4 (8.2)	4 (18.2)	0.460
Severe COVID-19 infection, n (%)	7 (50.0)	0 (0.0)	0 (0.0)	0.085
Complete COVID-19 vaccination, n (%)	94 (89.5)	47 (95.9)	22 (100.0)	0.135

We recorded 22/179 (12.5%) SARS-CoV-2 infections, 7/22 (31.8%) of them were severe and 3/7 (42.85%) died. As to the vaccination, 163/176 (92.6%) patients received the complete dosis. Among those correctly vaccinated 18/163 (11%) had the SARS-CoV-2 infection, 4/18 (22.2%) after the vaccinated date and 14/18 (77.7%) when they still dint´t have the complete vaccination. From the 13 not vaccinated patients, 4/13 (30.7%) had COVID-19. As to frequency, COVID-19 severity and vaccination, there were no difference between subgroups of CTD-ILD patients. The risk factors associated with the COVID-19 infection were the last FVC (OR [CI 95%], 0.971 [0.944-0.998]; p=0.048), the vaccination (OR [CI 95%], 0.185 [0.049-0.691]; p=0.012) and the Rituximab treatment(OR [CI 95%], 3.172 [1.028-6.785]; p=0.045). Moreover, the only variable associated independently with the severe COVID-19 was the protective effect of vaccination (OR [CI 95%], 0.020 [0.003-0.119]; p<0.001).

Conclusion: A total of 12.5% ILD-SAI patients were COVID-19 infected, most of them without the complete vaccine. Rituximab and a deterioration of FVC were risk factors for the COVID-19 wehreas the vaccination was a protective factor for the mild and severe infection.

AB1113

THE IMPACT OF SARS-COV-2 INFECTION ON DISEASE ACTIVITY AND CLINICAL RESPONSE TO BIOLOGICAL DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Samões[1], A. Martins[2], D. Santos Oliveira[2], F. R. Martins[3], R. Nicolau[4], M. Rato[2], F. Oliveira Pinheiro[2], M. Bernardes[2], L. Costa[2]. [1]*Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology Department, Vila Nova*

de Gaia, Portugal; [2]*São João Universitary Hospital Center, Rheumatology Department, Porto, Portugal*; [3]*University Hospital Center of Algarve, Faro, Rheumatology Department, Faro, Portugal*; [4]*Centro Hospitalar Tondela - Viseu, Epe, Rheumatology Department, Viseu, Portugal*

Background: Infections are a known trigger for Rheumatoid Arthritis (RA) flares.[1] It is still unclear whether SARS-Cov-2 infection affects RA disease activity and the clinical response to biological disease-modifying antirheumatic drugs (bDMARDs).
Objectives: To evaluate the effect of SARS-Cov-2 infection on disease activity and bDMARD responses in patients with RA.
Methods: A retrospective study was carried out in a cohort of RA patients treated with bDMARDs from a tertiary hospital centre. Demographic and clinical data, including occurrence of SARS-Cov-2 infection, were obtained through medical records. Disease activity (DAS28, DAS28-CRP, CDAI and SDAI) and ACR and EULAR bDMARD responses were evaluated at four time points: baseline (t1 - last evaluation before Covid-19 pandemic), before (t2) and after (t3) SARS-Cov-2 infection and at the end of follow-up (t4 - last appointment of 2021). In patients with no record of SARS-Cov-2 infection the middle evaluations were obtained from two random consecutive appointments during Covid-19 pandemic. Statistical analysis (significance at $p<0.05$) was performed using paired t-test, Wilcoxon and McNemar tests for paired samples and unpaired t-test, Mann-Whitney, Fisher and χ^2 tests for independent samples according to the type of variable and the presence of normal distribution.
Results: Of the 237 patients included, most of them was women [n = 195 (82.3%)], with a mean age of 59.6 ± 10.1 years old and a median [min, max] disease duration of 18 [2, 50] years. The majority presented rheumatoid factor (RF) and/or anti-citrullinated protein antibodies (ACPA) positivity [n = 204 (87.9%)] and radiographic erosions [n = 119 (72.6%)]. The prevalence of SARS-Cov-2 infection was 11.4% (n=27). Mean disease activity was lower after SARS-Cov-2 infection compared to the previous evaluation on all scores used; however, this difference was not statistically significant. Nevertheless, when compared to the mean disease activity at the end of follow-up, there were statistically significant differences in DAS28-CRP (t2 3.2±1.0 vs. t4 2.8±1.1, p=0.017) and CDAI (t2 11.1±8.1 vs. t4 8.7±6.2, p=0.05) scores. The relative number of patients with no ACR or EULAR bDMARD responses before SARS-Cov-2 infection wasn't different from post infection and at the end of follow-up. At baseline, the infected and uninfected groups were similar regarding gender, age, RF and/or ACPA positivity, erosive disease, disease and biologic treatment durations, baseline disease activity and ACR and EULAR response. The variation in disease activity and the relative number of patients with worsening or improving EULAR and ACR bDMARD responses between t2 and t3 were not significantly different in the two groups, as well as between t2 and t4. The prevalence of patients who switched to another bDMARD was significantly higher in the group of patients who had Covid-19 [n=4 (14.8%) vs. 9 (4.3%), p=0.047]. The main reason for switching was the ineffectiveness of the therapy (n=11).
Conclusion: No worsening of disease activity or ACR and EULAR bDMARD responses was found after SARS-Cov-2 infection in RA patients under bDMARD. However, the later can be explained by the small sample size. Indeed, these patients exhibited a higher rate of switch due to ineffectiveness of therapy, suggesting a negative impact of SARS-Cov2 infection on the disease course.

AB1114

VACCINATION OF PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: AN ANALYSIS OF BARRIERS AND FACILITATORS IN A PROSPECTIVE COHORT

I. Andreica[1], I. Roman[1], X. Baraliakos[1], J. Braun[1], U. Kiltz[1]. [1]*Rheumazentrum Ruhrgebiet and Ruhr-Universität Bochum, Rheumatology, Herne, Germany*

Background: Patients (pts.) with chronic inflammatory rheumatic diseases (CIRD) are often not adequately protected against infectious diseases. As shown in an earlier study, less than 50% of CIRD pts. were vaccinated against pneumococci and influenza before the SARS-CoV2 pandemic started [1]. High vaccination rates are critical to achieve herd immunity. Knowledge on barriers and facilitators of vaccine uptake in CIRD pts. is limited.
Objectives: The aim of this study was to characterize barriers and facilitators towards vaccines in general and specifically against pneumococci, influenza and SARS-CoV-2 in adult CIRD pts.
Methods: In early 2021, consecutive CIRD pts. completed a structured questionnaire including knowledge on vaccination, attitudes, and perceived barriers and facilitators towards vaccination. A total of 12 facilitators and 11 barriers towards vaccination was assessed in general, and specifically for vaccination against pneumococci, influenza and SARS-CoV2. The Likert scales had 4 response options, ranging from 1 (completely disagree) to 4 (completely agree). Patient and disease characteristics, their vaccination history and attitudes towards vaccination against SARS-CoV-2 were assessed.
Results: Of 514 prospectively recruited pts., 441 responded (85.8%) to the questionnaire (table 1). Self-reported vaccine uptake was 48.8% against pneumococci and 66.2% against seasonal influenza. The majority (82.2%) was willing to be vaccinated against SARS-CoV-2. The majority (≥70%) had decent knowledge about vaccination, and only <10% doubted its effectiveness. The level of knowledge did not differ between the studied 3 vaccinations. Pts. were more likely to rate statements about facilitators favorably compared to statements about barriers. Facilitators for SARS-CoV-2 vaccination did not different from vaccination in general (Figure 1). Societal and organizational facilitators such as public vaccine campaigns or protection for high-risk pts. were more commonly named compared to inter- or intrapersonal facilitators. Protection of high-risk pts. was by far the most frequently cited facilitator. Most pts. indicated that they were likely to receive a vaccine if their health care professional would recommend it – without preference for GP or rheumatologist. The frequency of barriers was much lower compared to facilitators and more barriers towards SARS-CoV-2 vaccination were reported in comparison to vaccination in general or pneumococci and influenza, respectively. However, pts. frequently cited intrapersonal issues as barriers against vaccination. Importantly, the major barrier was an inadequate risk perception between the severity of COVID-19 and the potential adverse events of the vaccine.

Table 1. Patient and disease characteristics

Age, y	54.1 (12.6)
Women, No. (%)	272 (61.7)

variables as mean (SD)

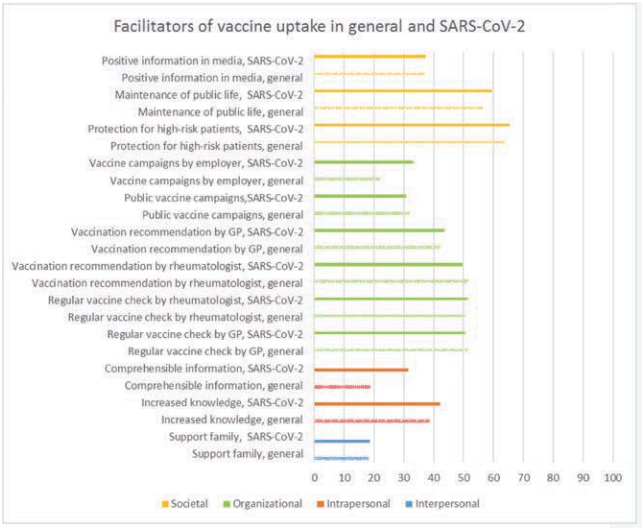

Figure 1. Facilitators of vaccine uptake in general and for SARS-CoV-2

Conclusion: A relatively high number of pts. was vaccinated against pneumococci and influenza, – a probable campaign success during the last years. In addition, more than 80% of pts. were willing to be vaccinated against SARS-CoV2. Facilitators were of greater significance than barriers in this scenario. The high number of societal and organizational facilitators enables the implementation of effective strategies to increase future vaccination rates.

AB1115 COVID-19 VACCINE HESITANCY AMONG RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGICS

E. Hannech[1,2], S. Boussaid[1,2], S. Rekik[1,2], S. Jemmali[1,2], S. Rahmouni[1,2], H. Ajlani[1], H. Sahli[1,2], M. Elleuch[1,2]. *[1]Rheumatology Department, La Rabta Hospital,Tunis,Tunisia*; *[2]Faculty of medicine of Tunis, University Tunis El Manar, Tunis,Tunisia*

Background: Vaccine hesitancy is defined by the OMS as "a delay in acceptance or refusal of vaccines despite availability of vaccination services" [1], and it is considered as one of threats to global health. This hesitancy emerges around Covid-19 vaccination. Patients on biologic Disease-Modifying Anti-Rheumatic Drug (bDMARD) are vulnerable to Covid-19 infection and their perception to vaccination is unknown.
Objectives: The aim of our study was to identify Covid-19 vaccine hesitancy among rheumatoid arthritis (RA) patient on bDMARD.
Methods: We conducted a monocentric, cross-sectional study, including patients with RA who met the ACR/EULAR 2010 criteria. All patients were on bDMARD with or without conventional synthetic (Cs) DMARD for at least 3 months. Disease activity was assessed using the Disease Activity Score (DAS) 28 (CRP) and the functional impairment using the Health Assessment Questionnaire (HAQ). A structured interview was done using a prepared questionnaire evaluating their vaccine hesitancy behavior.
Results: We enrolled 60 patients: 10 male (16.7%) and 50 females (83.3%). Their average age was 58.16±9.04 years [34-80]. For the education level; 38.5% of patients were illiterate, 34.6% had primary education, 23.1% had secondary education, and 3.8% have a university degree. Forty-four patients (73.3%) had no occupation, 13 patients (21.7%) were employed, and 5% were retired. The majority of patients lived in urban areas (85%) and 98.2% with their families. The average duration of RA was 15.23±8.92 years [2-39]. The average DAS28 (CRP) and the average HAQ were 4.05±1.22 [1.5-7.2] and 0.7±0.4 [0-2.4], respectively. Fifteen patients (25%) had a high disease activity and seven (11.7%) were in remission. When asking patients about their Covid19 infection and vaccination status; 15% had caught the virus and 61.7% have already received the vaccine. One third (35.6%) believed that they had enough information about vaccination. Their main sources were their family, friends, and the media. More than half of the asked patients (68.3%) reported vaccine hesitancy. Reasons of vaccine hesitancy were divided into three categories: lack of confidence (66.7%, p<0.005) (63.3% fear related to side effects, 10% conspiracy theory, 6.7% lack of confidence in the provider), complacency problem (16.7%, p=0.01) and lack of convenience (8.6%). There was no association between vaccine hesitancy and sociodemographic data. The existence of comorbidities had no influence on vaccine hesitancy (p=0.4). This hesitancy was not associated with DAS28 (CRP) (p=0.6) and with HAQ (p=0.7). Patients with moderate to high disease activity were more likely to deny the usefulness of Covid-19 vaccination (p=0.09). Regarding to the therapeutic data, there was no association between corticotherapy and vaccine hesitancy (p=0.1). There was no influence on the type of the current bDMARD (p=0.3) or of the rate of administration (p=0.4). The route of administration was associated with hesitation (53.65% intravenous vs 46.34% subcutaneous, p=0.04).
Conclusion: Our study showed that Covid-19 vaccination coverage among RA patients on bDMARDs was not optimal with a high percentage of hesitancy. The reasons are complex and they may be related to a lack of awareness. Rheumatologists should play a key role in the vaccine company.

AB1116 RESULTS OF PRESCRIBING BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS AND JANUS KINASE INHIBITORS FOR RHEUMATOID ARTHRITIS DURING THE COVID-19 PANDEMIC: DATA FROM A TELEPHONE SURVEY OF 254 PATIENTS.

A. Potapova[1], A. Karateev[1], E. Pogozheva[1], E. Matianova[1], A. Bobkova[1], A. Semashko[1], E. Filatova[1], V. Amirdzhanova[1], E. Zotkin[1], A. Lila[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Prescribing biologic disease-modifying antirheumatic drugs (bDMARDs) and Janus kinase (JAK) inhibitors during the global pandemic of coronavirus disease 2019 (COVID-19) requires a balanced approach and rigorous monitoring of patients' condition.
Objectives: To evaluate the effect of bDMARDs and JAK inhibitors on the condition of patients with rheumatoid arthritis (RA), taking into account the outcomes assessed by the patients themselves, as well as the incidence of COVID-19 in these patients.
Methods: A telephone survey was conducted of 254 patients with RA (age 49.8 ± 13.7 years, 83.5% women, RF + 64.4%, DAS28 5.4 ± 1.6), who in the period from January 2020 to June 2021 by decision of the medical commission of the V.A. Nasonova Research institute was first prescribed bDMARDs or JAK inhibitors: rituximab (RTX) - 148 (58.3%), TNF-a inhibitors - 57 (22.4%), JAK inhibitors - 20 (7.9%), IL 6 inhibitors - 17 (6 .7%), abatacept - 12 (4.7%).
Results: At the time of the survey, 204 (80.3%) patients continued to take the prescribed drugs. The main cause discontinuation of treatment was for non-medical reasons. Synthetic DMARDs (mainly methotrexate and leflunomide) were received by 68.0%, glucocorticoids - 45.3%, non-steroidal anti-inflammatory drugs - 44.5% of respondents. Among the patients who took bDMARDs or JAK inhibitors, 68.1% noted the "state of symptoms acceptable to the patient", the absence of frequent joint pain - 65.3%, increased fatigue - 14.3%. The incidence of COVID-19 and hospitalization associated with this disease didn't differ between individuals who continued and discontinued the use of bDMARDs or JAK inhibitors: 41.2% and 44.6; 13.7% and 14.0% respectively, p=0.80884. There was no significant difference in the incidence of COVID-19 and hospitalization associated with this disease in patients taking various biologics or JAK inhibitors.
Conclusion: Despite the COVID-19 pandemic, rituximab remains one of the most popular bDMARD. About a third of patients receiving bDMARDs and JAK inhibitors aren't satisfied with their condition. More than 40% of patients treated with these drugs experienced COVID-19, and 14.0% required hospitalization.

AB1117 THE IMPACT OF THE COVID-19 PANDEMIC ON HEALTH AND LIFESTYLE IN INDIVIDUALS WITH KNEE PAIN, A HALLOA STUDY

E. Sunesson[1], C. Sylwander[1,2], E. Haglund[1,3,4], M. Andersson[1,3], I. Larsson[1,2,3]. *[1]Spenshult Research and Development Centre, Halmstad, Sweden*; *[2]Halmstad University, School of Health and Welfare, Halmstad, Sweden*; *[3]Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; *[4]Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden*

Background: Covid-19 has affected everyday life, health and lifestyle among the general population and vulnerable groups. Individuals with knee pain are recommended an active lifestyle to reveal pain but find it difficult to maintain health and lifestyle compared to the general population due to the cause of chronic pain, impaired physical function and a diminishes quality of life. This adds to the importance of exploring how to preserve health and lifestyle among individuals with knee pain during the pandemic.
Objectives: The aim of this study was to explore the impact of the covid-19 pandemic on the health and lifestyle in individuals with knee pain.
Methods: Nineteen participants with current knee pain, and with no earlier diagnosed radiographic osteoarthritis, and no rheumatologic disorder or cruciate ligament injury, were recruited from The Halland Osteoarthritis (HALLOA) Cohort Study, twelve female and seven males, between 41-62 (median 51) years of age. Data were collected through individual interviews with open-ended questions: "What impact have you experienced with your health and lifestyle during covid-19?", and "What activities or strategies have you changed to maintain your health and lifestyle during covid-19? ". Qualitative content analysis was used, where two categories and five sub-categories emerged (Table 1).

Table 1. Categories, and sub-categories exploring the impact of the covid-19 pandemic on health and lifestyle in individuals with knee pain

Categories	Sub-categories
Adjusting behaviours due to covid-19	Spending time at home Becoming digitally Spending time outdoors
Valuing life due to covid-19	Having a positive outlook on life Sharing responsibility

Results: The result from this study explored how behaviour and attitude towards valuing life have been adjusted to maintain health and lifestyle among individuals with knee pain during covid-19. The category adjusted behaviours emerged with the sub-categories: spending more time at home, becoming digitally, and spending more time outdoors. These sub-categories determine how a more reclusive behaviour have appeared due to the pandemic, where digital platforms and outdoor activities have facilitated companionship and togetherness when feelings of loneliness and isolation were present. The category valuing life emerged with the sub-categories: having a positive outlook of life and sharing responsibility. These sub-categories establish the importance of trying to be grateful for maintaining health and lifestyle and trying to be solution-oriented to find the best possible outcomes to continue with everyday life, despite the pandemic. While having a responsibility towards others arose as a facility to manage to keep social distance during the pandemic.
Conclusion: In conclusion, the behaviour was adjusted to continue with everyday life and maintain health and lifestyle among individuals with knee pain during covid-19. Valuing life was also considered important to maintain health and lifestyle as well as supporting others maintain their health and lifestyle. The result may in the future contribute to alternative ways of maintaining health and lifestyle in different vulnerable groups and may be used in situations other than the pandemic.

AB1118 INVESTIGATION OF THE EFFECT OF THE HISTORY OF COVID-19 ON COGNITIVE LEVEL, PAIN CATASTROPHIZATION, AND PHYSICAL ACTIVITY LEVEL IN INDIVIDUALS WITH CHRONIC LOW BACK AND NECK PAIN

A. Asliyüce[1], O. Ulger[2]. [1]*Ankara, Physical Therapy and Rehabilitation, Ankara, Turkey*; [2]*Hacettepe University, Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: Low back and neck pain is one of the most common health problems in society and one of the top reasons for admission to the hospital (1). Studies show that the level of physical activity decreases in individuals with chronic pain, and the cognitive level and quality of life are negatively affected (2). There are studies examining the effects of the Covid-19 pandemic process on the level of physical activity and cognitive level in various groups. However, the number of studies on how the history of Covid-19 affects individuals with low back and neck pain is limited.
Objectives: The aim of this study is to examine the effect of Covid-19 history on cognitive level, pain catastrophe and physical activity level in individuals with chronic low back and neck pain in individuals.
Methods: A total of 25 individuals with chronic pain, including 16 with low back pain and 9 with neck pain, were included in the study. Demographic data such as age, gender and body mass index (BMI) were obtained from all individuals. The education levels of the individuals were recorded. Cognitive level was assessed by the Montreal Cognitive Assessment (MoCA)[3], pain severity was assessed by the Visual Analog Scale (VAS), pain catastrophization was assessed by the Pain Catastrophizing Scale (PCS)[4], and physical activity level was assessed by the International Physical Activity Questionnaire-Short Form (IPAQ- SF)[5].
Results:
Table 1.

		WITH A HISTORY OF COVID-19		WITHOUT A HISTORY OF COVID-19	
n(%)		7(28%)		18(72%)	
		FEMALE	MALE	FEMALE	MALE
Gender (%)		57	43	87	13
		X±SD		**X±SD**	
Age (year)		33.14±14.58		46.06±13.26	
BMI (kg/m$^{2)}$		22.38± 4.52		28.98 ±18.85	
Education level					
Primary school n (%)		0 (0%)		3 (16.7%)	
Secondary school n (%)		1 (14.3%)		7 (38.9%)	
High school n (%)		1(14.3%)		6 (33.2%)	
Bachelor's degree n (%)		5 (71.4%)		2 (11.2%)	
Education Level	**p**	**Median (IQR)**		**Median (IQR)**	
	0.01*	4 (4-5)		2 (2-3)	
Moca	**0.014***	30 (27-30)		25 (19.75-28.5)	
VAS	0.313	6 (4-8)		5 (2-7)	
PSC	0.671	13 (5-32)		13 (9.75-22.75)	
IPAQ-SF	0.326	924 (297-3684)		981.5 (577.5-3312)	

Demographic data, VAS, MoCA, PCS, and IPAQ-SF scores are given in Table 1. 7 of the participants had history of Covid-19, 18 did not. The MoCA scores and education levels of individuals with Covid-19 were higher than individuals without history of Covid-19 ($p<0.05$). There was no difference in physical activity, pain and pain catastrophization levels between the 2 groups ($p> 0.05$).
Conclusion: Surprisingly, individuals who had a history of Covid-19 had higher cognitive levels than individuals without a history of Covid-19. In addition, there was no difference between physical activity and pain catastrophization levels. This may be due to the higher education level of individuals with a history of Covid-19. There is a need for further studies in which education levels are similar, and hospitalization and the Covid-19 positivity process are examined in more detail.

AB1119 GLUCOCORTICOIDS' TREATMENT IMPAIRS THE MEDIUM-TERM IMMUNOGENIC RESPONSE TO SARS-COV-2 MRNA VACCINES IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS.

S. Garcia-Cirera[1], J. Calvet[1], A. Berenguer-Llergo[2], E. Pradenas[3], M. Llop Vilaltella[1], C. Galisteo[1], J. Blanco[3], J. Gratacos Masmitjà[1]. [1]*Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí (I3PT), Rheumatology Department, Sabadell, Spain*; [2]*Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí (I3PT), Biostatistics and Bioinformatics Rheumatoloy, Sabadell, Spain*; [3]*IrsiCaixa AIDS Research Institute, Germans Trias i Pujol Research Institute (IGTP), IrsiCaixa AIDS Research Institute, Badalona, Spain*

Background: Patients with rheumatic diseases are at an increased risk for community infections (1,2). There still exists lack of data regarding SARS-CoV-2 vaccines' efficacy in vulnerable collectives with a compromised immune system, either due to a chronic pathology or to therapies targeting an autoimmune disease (3).
Objectives: To evaluate neutralizing antibodies (nAB) to SARS-CoV-2 vaccine after 3 to 5 months from administration in Systemic Lupus Erythematosus (SLE) patients, as a surrogate of sustained-immunological response.
Methods: This cross-sectional study compared nAB titre of 39 SLE patients and 37 Healthy individuals with no previous SARS-CoV-2 infection, who had all received two doses of a mRNA SARS-CoV-2 vaccine within the last 3 to 6 months. SLE patients included 10 Not-treated subjects, 10 patients with Hydroxychloroquine (First-Line), 10 subjects with immunosuppressive drugs (Second-Line) and 9 patients under biological treatment (Third-Line). Glucocorticoids were permitted in all patient groups. Neutralization assay were used to determine nAB titre according previously validated protocol (4).
Results: Neutralizing antibody titres were assessed for a total of 76 serum samples from 39 (51%) Lupus patients and 37 (49%) healthy Controls. Healthy individuals showed the highest levels of nAB (1638.0 titre median), which were like not treated SLE subjects (1361.5 titre median). Treated patients presented substantially lower nAB titres compared to Healthy subjects: a 73% decrease for First-Line patients (p-value = 0.0135), 56% for patients received a Second-Line treatment (p-value = 0.2218) and 72% for Third-Line treated patients (p-value = 0.0104). A multivariate analysis pointed to Glucocorticoids as the most associated factor with declining nAB levels (75% decrease, p-value = 0.0037), and the one explaining, to a large extent, the lower acquired response in treated SLE patients. Furthermore, a significant reduction in nAB titres was observed for patients treated with Rituximab compared to Healthy subjects (89% decrease, p-value= 0.0008) (Figure 1).

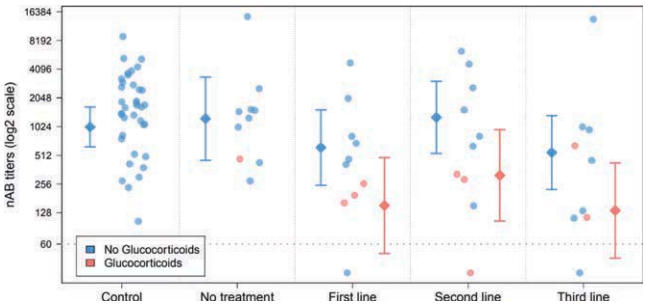

Figure 1. Neutralizing antibody (nAB) titre after SARS-CoV-2 vaccination in Healthy individuals (Controls) and Systemic Lupus Erythematosus (SLE) patients under different therapy regimes. Estimations are derived from a linear model in which sex, age, time from vaccination, vaccine type and corticoids therapy were included as covariates for statistical control.

Conclusion: Medium-term response of SLE patients to SARS-CoV-2 vaccination, as measured by the titre of nABs, may be compromised by Glucocorticoids and Rituximab users. This reduced response likely translates into a higher probability of COVID-19 infection These findings might help to inform recommendations in vaccination protocols for SLE patients.

Background: The COVID-19 pandemic has raised concerns about its psychological effects. Sleep disturbances, anxiety and/or depressive symptoms, post-traumatic stress symptoms have been reported in general population. Patients with chronic rheumatism, systemic autoimmune disease or auto-inflammatory disease, due to immunosuppression, are at risk of severe forms of infection. Currently, there is little information on psychological impact of the pandemic on the mental health of these more vulnerable patients.

Objectives: To compare psychological assessment between patients with chronic rheumatic, autoimmune and/or autoinflammatory diseases who presented with COVID-19 infection between March and September 2020, first wave of French pandemic, and patients with same diseases who did not presented with infection to date.

Methods: The MentCOVRMD study was a multicenter descriptive study. Cases were patients with chronic rheumatic, autoimmune and/or autoinflammatory diseases from the French RMD cohort who presented COVID-19 infection between March and September 2020. Controls were patients with same diseases who did not develop infection. The study is registered in Clinical Trials under number 2020-A02058-31. For participants, following criteria were collected: demographics (age, gender, smoking status); psychological assessment questionnaires: Insomnia Severity Index (ISI); Post-traumatic stress disorder (PTSD) checklist; Patient Health Questionnaire (PHQ9) Depression; Generalized Anxiety Disorder (GAD7) Anxiety; Patient Health Questionnaire-15 (PHQ-15) and Somatic Symptom Disorder (SSD)-12.

Results: Between February and December 2021, 60 cases (46 (76.7%) women), median age 52.0 (39.0; 63.0) were included, of which 15 (25%) had been hospitalized during infection, and 169 controls (148 (87.6%) women), median age of 52.0 (38.0; 63.0). There were more smokers in the group of cases 12 (20%) than controls 14 (9.1%) (p=0.028) as well as more cases on ARA2 treatment (8 (13.3%)) than controls (7 (4.5%)) (p=0.035) with no statistically significant difference in others comorbidities or treatments. There was no statistically difference concerning the ISI scores between cases (11.83 ± 7.31) of which 60% had sleep disorders and controls (11.64 ± 6.82) of which 70.4% had sleep disorders. There was no statistically significant difference in PTSD scores of 15.5 (5.0 to 28.0) for cases and 18.0 (8.0 to 35.0) for controls, of which respectively 12 (20%) had values indicating possible PTSD for cases and 50 (29.6%) for controls. There was no statistically significant difference in PHQ-9 scores (5.5 (1.5 to 11.0)) of which 50% had depressive symptoms and controls (6.0 (2.0 to 11.0)) of which 54.5% had symptoms. There was no statistically significant difference in GAD-7 scores (3.5 (0.0 to 8.0)) of which 40% had anxiety symptoms and controls (4.0 (0.0 to 8.0)) of which 43.2% had symptoms. There was no statistically significant difference in PHQ-15 scores (11.4 ± 6.7), 85% of whom reported presence of symptoms, and controls (10.9 ± 6.2), 82.3% of whom reported symptoms. There was no statistically significant difference in SSD scores between cases (17.7 ± 10.9) and controls (18.4 ± 10.9). There was a statistically significant difference in reported VAS scores of pain related to inflammatory rheumatism in cases with a median of 4.5 (3.0 to 6. 0) compared to controls with a median of 4.0 (1.0 to 6.0) (p=0.011). There was no statistically significant difference in any of the psychological assessment scores between the inpatient and outpatient COVID cases.

Conclusion: There was no statistically significant difference between COVID cases and controls in the evaluation of these psychological parameters. Prevalence of all these variables were high in the whole study population, testifying to the need to manage these psychological aspects for patients with chronic rheumatisms, autoimmune and/or autoinflammatory diseases.

Background: The COVID-19 pandemic has generated uncertainties and concerns along with expectations and hopes that may be of relevance to patients with rheumatic diseases.
Objectives: The aim of this study is to assess changes in the fears and hopes of patients with rheumatic diseases throughout the two phases of REUMAVID.
Methods: REUMAVID is an international cross-sectional study collecting data through an online survey in seven European countries led by the Health & Territory Research group of the University of Seville, together with a multidisciplinary team including patient representatives, rheumatologists, and health researchers. Data were collected in two phases: Phase 1 (P1) between April-July 2020 and Phase 2 (P2) between February-April 2021. Demographics, health behaviours, employment status, access to healthcare services, disease characteristics, WHO-5 Well-Being Index and Hospital Anxiety and Depression Scale (HADS). Participants rated a series of fears (infection, medication consequences, lack of medication, impact on healthcare, lost job, civil disorder) on a scale from zero ("no concern at all") to five ("extremely concerned") and hopes (treatment/vaccine availability, going outside, travel, economic situation, treatment continuation, health status) on a scale from zero ("no hopeful at all") to five ("extremely hopeful"). Descriptive analysis and Mann-Whitney test were used to explore fears and hopes in both phases of REUMAVID.
Results: A total of 3,802 participants were recruited across both phases in REUMAVID with comparable demographic characteristics: mean age 52.6 (P1) vs. 55.0 years (P2), 80.2% female (P1) vs. 83.7% (P2), 69.6% married (P1) vs. 68.3% (P2), and 48.6% university educated (P1) vs. 47.8% (P2). Most prevalent RMD was axial spondyloarthritis in P1 (37.2%), and rheumatoid arthritis in P2 (53.1%). In P1 and P2 the major concern was the impact on healthcare in the future (3.1 and 3.2 out of 5, p=0.051). Compared to P1, patients in P2 had less fears about RMD medications not reaching the country (2.4 vs. 1.9, p<0.001), civil disorders (2.0 vs. 1.8, p=0.001), or losing their jobs (1.4 vs. 1.5, p=0.003). Comparing hopes with P1, patients in P2 had greater hopes about availability of treatments or vaccines suitable for COVID-19 (3.2 vs. 3.9, p<0.001), to be able to go out as before the pandemic (3.1 vs. 3.5, p<0.001), to be able to travel as before the pandemic (2.8 vs. 3.3, p<0.001), maintain and even improve the current economic situation after the pandemic (2.6 vs. 3.0, p<0.001), and to be able to continue their treatment as usual (3.8 vs. 3.8, p=0.049; Table 1)

Table 1. Bivariate analysis of patients' fears and hopes in both phases of REUMAVID (N= 3,802, unless specify)

	Mean ± SD		
	First Phase n= 1,800	Second phase n= 2,002	P-value

Don't get infected with COVID-19 and continue in the same health, n= 3,280	3.5 ± 1.5	3.5 ± 1.5	0.696
Travel as before the COVID-19 pandemic, n= 3,311	2.8 ± 1.6	3.3 ± 1.5	**<0.001***
Maintain or improve economic situation after the COVID-19 pandemic, n= 3,310	2.6 ± 1.7	3.0 ± 1.7	**<0.001***

Conclusion: During the first phase of REUMAVID at the beginning of the pandemic, patients with RMDs were more fearful and less hopeful compared to the second phase. These fears were notable in terms of lack of medication for their RMD, while during the second phase, patients were hopeful of a treatment or vaccine against COVID-19, and of being able to go out and travel as before.

AB1122

HAVE TREATMENTS FOR AUTOIMMUNE DISEASES WORSENED THE PROGNOSIS OF COVID-19 INFECTION?

A. I. Rebollo Giménez[1], M. González Peñas[2], J. Seoane Romero[2], L. Martín de la Sierra López[2], L. Jiménez Rodríguez[2], D. Castro-Corredor[2], J. Anino-Fernández[2], D. Bellido Pastrana[3], J. L. Cuadra Díaz[2]. *[1]Istituto Giannina Gaslini, Pediatric and Rheumatology Clinic, Genoa, Italy*; *[2]Ciudad Real University General Hospital, Rheumatology, Ciudad Real, Spain*; *[3]Ciudad Real University General Hospital, Internal Medicine, Ciudad Real, Spain*

Background: According to the literature patients with autoimmune diseases (AID) have a high risk of develop serious infections due to the use of immunosuppressive treatment. In published clinical trials neither the risk nor the severity of COVID-19 infection in patients with AID seem to be higher than in the general population.
Objectives: The objective of our study is to analyse the clinical course in patients with AID undergoing immunosuppressive treatments and infected by COVID-19.
Methods: Patients were included after reviewing four rheumatology outpatient clinics from Ciudad Real University General Hospital between November 2020 and February 2021. The inclusion criteria were being older than 18 years and being positive for COVID-19 by epidemiological (positive molecular and/or antigen test) or clinical criteria (symptoms compatible between March and May 2020). We collected demographic data, cardiovascular comorbidities, AID, treatment with synthetic or biological DMARDs, immunomodulators or glucocorticoids; and progression of infection COVID-19.
Results: We found a total of 210 patients that had suffered from SARS-COV2 of which 95 patients were affected by AID. The most prevalent pathology in our sample was spondylarthritis followed by arthritis rheumatoid and systemic lupus erythematosus of which 81.82%, 100% and one 92.86% respectively were receiving treatment to control the disease. Among the 95 patients suffering from COVID and AID a small number of patients did not follow any immunosuppressive treatment regimen (n=25) but most of our patients were undergoing immunosuppressors (n=70); the most used drugs were prednisone and methotrexate. No statistically significant differences were found between the treated versus untreated group in the studied variables, being similar the results relative to mean age, sex, presence of cardiovascular risk factors, absence of symptoms, number of admissions to hospital ward or in Intensive Care Unit, or complications during COVID-19 infection (Table 1).

Table 1. Baseline characteristics of patient with AID undergoing or not immunosuppressors.

	Treated	Untreated	p
	n=70 (73,68%)	n=25 (26,32%)	
Medium age (SD)	51,74 (+/- 2,18)	55,74 (+/-3,36)	0,467
Female sex, n (%)	49 (70%)	17 (68%)	0,852
HTA, n (%)	22 (31,4%)	5 (20%)	0,277
DM, n (%)	8 (11,4%)	2 (8%)	0,632
DL, n (%)	13 (18,6%)	1 (4%)	0,078
Tobacco, n (%)	7 (10%)	3 (12%)	0,78
Asymptomatic, n (%)	13 (18,6%)	4 (16%)	0,773
Admitted, n (%)	11 (15,7%)	5 (20%)	0,623
ICU, n (%)	2 (2,9%)	0 (0%)	0,393
ARDS, n (%)	7 (10%)	2 (8%)	0,769
Overinfection, n (%)	4 (5,7%)	0 (0%)	0,222
Thrombosis, n (%)	1 (1,4%)	0(0%)	0,548
Death, n (%)	6 (8,6%)	2 (8%)	0,930

SD, standard deviation; n, absolute numbers; %, percentages; p, p-value; AID, autoimmune diseases; HTA, arterial hypertension; DM, diabetes mellitus; DL, dyslipidaemia; ICU: intensive care unit; ARDS: Acute respiratory distress syndrome

Conclusion: Patients treated with synthetic or biologicals DMARDs, immunomodulators or glucocorticoids do not seem have a higher rate of death or hospital admission respect to patients diagnosed of AID without such treatments.

AB1123 EFFICACY AND SAFETY OF SARS-COV-2 THIRD VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO DID NOT RESPOND AFTER PRIMARY TWO-DOSE REGIMEN

C. A. Isnardi[1,2], O. L. Cerda[2], E. E. Schneeberger[2], M. Landi[1,3], C. Calle Montoro[3], M. A. Alfaro[2], B. Roldan[2], A. B. Gómez Vara[2], P. Giorgis[2], R. A. Ezquer[2], M. G. Crespo Rocha[2], C. Reyes Gómez[2], M. D. L. A. Correa[2], M. Rosemffet[2], V. Carrizo Abarza[2], S. Catalan Pellet[3], M. Perandones[2], C. Reimundes[3], L. Cruces[4,5], L. Yesica[4,5], G. Turk[4,5], F. Quiroga[4,5], N. Laufer[4,5], R. Quintana[1], M. Delavega[6], P. Maid[3], G. Pons-Estel[1], G. Citera[2]. [1]*Argentine Society of Rheumatology, Research Unit, CABA, Argentina*; [2]*Psychophysical Rehabilitation Institute, Rheumatology, CABA, Argentina*; [3]*Hospital Universitario Austral, Rheumatology, Buenos Aires, Argentina*; [4]*CONICET – Universidad de Buenos Aires, Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS)., CABA, Argentina*; [5]*Universidad de Buenos Aires., Facultad de Medicina., CABA, Argentina*; [6]*Argentine Society of Rheumatology, Argentine Society of Rheumatology, CABA, Argentina*

Background: Vaccination for COVID-19 is an essential tool to fight the pandemic. Evidence suggests that patients with immune mediated inflammatory diseases (IMIDs) have less response. The application of a booster shot is a strategy that has been implemented in this population, however there is scarce information about its efficacy.

Objectives: To assess the humoral and cellular immune response after a third dose of SARS-CoV-2 vaccine in patients with rheumatoid arthritis (RA) with undetectable antibodies titles after primary regimen of two doses.

Methods: Observational study. Patients with RA (ACR/EULAR 2010 criteria) from two rheumatology centers, ≥18 years old, with no seroconversion after two doses of SARS-CoV-2 vaccine, who received a third dose of either mRNA or vector-based vaccines (BNT162b2 or ChAdOx1 nCoV-19) were included. Anti-SARS-CoV-2 IgG antibodies, neutralising activity and T cell responses were assessed between 21 and 40 days after the third dose. Sociodemographic data, comorbidities, treatment, vaccine applied and the presence of adverse events (AE) were recorded. Statistical analysis: descriptive analysis. Chi^2 or Fischer test and T test.

Results: A total of 21 non-responder patients were included, all of them females with a mean age of 63.7 years (SD 11,6) and mean disease duration of 15.8 years (SD 8). Most of them (81%) reported comorbidities, being the most frequent arterial hypertension, obesity and dyslipidemia. At vaccination time, 6 (28.6%) were receiving glucocorticoids, 3 of them ≥10 mg/day, 17 c-DMARDs (methotrexate 57.1%) and 18 (85.1%) b-DMARDs, 6 abatacept (ABT) and 4 rituximab (RTX). Regarding the primary vaccination regimen, 13 (61.9%) received two doses of BBIBP-CorV, 3 (14.3%) Gam-COVID-Vac, 3 (14.3%) ChAdOx1 nCoV-19 and 2 (9.5%) a mix regimen of Gam-COVID-Vac/mRNA-1273. The majority (95.2%) received BNT162b2 vaccine and only one of them ChAdOx1 nCoV-19, with a mean time between the second and third dose of 151,4 days (SD 46,4). After the third dose, 90.5% of the patients presented detectable anti-SARS-CoV-2 IgG and 76.2% presented neutralizing activity. The median of neutralizing antibodies titers was 1/12 (IQR 1/7-1/48). Both patients who did not present detectable antibodies were obese, recieved BBIBP-CorV during the primary regimen and BNT162b2 as the third dose, one of them was taking methotrexate and ABT and the other one RTX. Compared to other treatments, ABT and RTX was associated with no neutralizing activity in 4 (80%) patients and lower titers of neutralizing antibodies [median 1/3 (IQR 0-1/20) vs median 1/8 (IQR 1/4-1/128), p=0.197]. A T-cell response was present in 41.2% of all patients after the second dose, increasing to 75% after the third dose. The use of ABT was associated with a lower frequency of T-cell response (80% vs 20%, p=0.014). Sixteen (76.1%) patients reported at least one AE, 66.7% injection site reaction and 25% flu-like syndrome.

Conclusion: In this RA cohort who failed to seroconvert after two doses of SARS-CoV-2 vaccine, 90.5% presented detectable anti-SARS-CoV-2 IgG and 75% T-cell responce after a third dose. The use of ABT was associated with a lower frequency of T-cell response. This data highlights the importance of a third vaccine in this group of patients.

AB1124 IMPACT OF COVID-19 ON PATIENTS WITH RHEUMATIC DISEASES IN A SECOND LEVEL HOSPITAL

S. García-Díaz[1], D. Roig-Vilaseca[1], M. Vacas-Moreira[2], D. Cerda[1], P. Estrada Alarcón[1], V. A. Navarro Angeles[1], O. A. Camacho[1], S. Heredia[1], D. Reina[1]. [1]*Complex Hospitalari Moises Broggi, Rheumatology, Barcelona, Spain*; [2]*Complex Hospitalari Moises Broggi, Psychology, Barcelona, Spain*

Background: Covid-19 has generated a change in society and in people's daily lives. Patients with rheumatic diseases have suffered physically and mentally, both due to mobility restrictions and to the impact on personal, family, work and social life that COVID-19 has brought [1-4].

Objectives: To examine the impact of the pandemic COVID-19 on patients with rheumatic diseases.

Methods: Cross-sectional descriptive study in patients with rheumatic diseases. Data collection was done through an online questionnaire to assess the impact of COVID-19, adapted for this purpose and made up of 5 scales of the 9 of the Coronavirus Psychological Impact Questionnaire [3]. This instrument is divided into two parts: 1) sociodemographic variables and 2) Experience with Coronavirus(ECOVI); Preventive Behaviour Use(UCP); Fear against coronavirus Scale(EMC); Interference with the coronavirus Scale(EIC) and positive psychological aspects(EEPA). This questionnaire was accessed through a QR code (provided to all patients both in consultations and in the day hospital) by the rheumatology team for two weeks between November-December 2021. In addition, this code was sent by the nurse via WhatsApp to all patients registered in our database. Statistical analysis: SPSS 24.0 and Pearson Chi-square, T-Student and ANOVA tests.

Results: n=362 online surveys; 72% women with a mean age of 63 years ± 14.21 (22-70 years). The most frequent rheumatic diseases were Rheumatoid Arthritis (50%) and Spondyloarthritis (31%). 83.2% had only one rheumatic disease (mean 1.26 ± 0.66) and 90% self-completed survey. In experience with the Coronavirus (ECOVI), 89% patients had not had symptoms or confirmed diagnosis of coronavirus, 98% were not hospitalized, 91% had confidence in our health system; Regarding the Use of Preventive Behaviors (UCP), 98% used a mask outside the house and 78.5% kept a safe distance; In relation to the most common fears associated with the Coronavirus (EMC), 40% were a little afraid of getting infected (34% quite a bit) and 50% were almost nothing afraid of losing their job; Regarding the interference that the coronavirus has caused in these patients (EIC), 73% had not had serious work problems and 74% had not had difficulties in their studies. In reference to the positive psychological aspects (EEPA), 48% had discovered new hobbies, 19% had become more religious,83% had learned to value personal relationships more. It was significant that women were more afraid of infecting themselves or a loved one or family member and/or dying from coronavirus than men (p=0.02; p=0.011 and p=0.002 respectively). Regarding age, younger patients (45y) were more concerned that they could lose their job compared to older patients (61y), p=0.

Conclusion: The COVID-19 disease has impacted patients with rheumatic diseases. In our sample, women have been more concerned about being infected and dying themselves and their closest relatives/friends, and younger people more concerned about job loss and economic income than older people. It has to be considered that the majority of this population has not been hospitalized or diagnosed with COVID-19 and also has great confidence in our health care system. More studies are necessary to examine the impact of the COVID-19 after the 6th wave of the pandemic.

AB1125 SAFETY OF BIOLOGIC-DMARDS DURING COVID-19 OUTBREAK: FOLLOW-UP STUDY IN 1051 RHEUMATIC PATIENTS OVER THE FIRST TWO WAVES.

A. Sonaglia[1], R. Comoretto[2], E. Pasut[3], G. Del Frate[1], D. Colatutto[1], A. Zabotti[1], S. De Vita[1], L. Quartuccio[1]. [1]*Division of Rheumatology, Department of Medicine, Udine, Italy*; [2]*Zeta Research srl, Zeta Research srl, Udine, Italy*; [3]*Service of Hospital Pharmacy, Hospital Pharmacy, Udine, Italy*

Background: A novel viral infection known as COVID-19 (Coronavirus-19 disease) spread up in Wuhan (China) in December 2019, but rapidly diffused worldwide and nowadays it remains an international health problem. Because of its impact on immunologic system, immunomodulating therapies have been studied as possible treatments for severe cases of COVID-19. In that context, patients affected by from rheumatic musculoskeletal disorders (RMD) under disease modifying anti-rheumatic drugs (DMARDs) have been observed in several studies to evaluate the impact of COVID-19 on these subjects, well known to be at higher risk of infection.
Objectives: The primary objective of this study is to assess prevalence and severity of COVID-19 in patients with RMD under treatment with biologic (b-DMARDs) or targeted synthetic (ts-DMARDs) DMARDs, before the vaccination campaign. The second aim is to compare those data with that in general population of the same Area (Province of Udine, Friuli Venezia Giulia Region, Italy,).
Methods: A cohort of RMD patients treated with b-DMARDs or ts-DMARDs was observed from September 2019 to November 2020. Both pandemic waves have been considered, until the start of vaccination (since current variants can overcome vaccine protection), between February 2020 and April 2020 (first wave) and between September 2020 and November 2020 (second one).
Results: Among 1051 RMD patients treated with b- or ts-DMARDs COVID-19 prevalence was 3.5% (37 cases) without significant differences compared to general population of the same Region (Table 1). Infected patients were 18 men and 19 women, with a median age of 60 years (IQR 49-68). Notably, the infection rate of RMD patients was significantly lower compared to the general population of the same province, particularly during the second wave (p<0.001, Table 1). Almost all patients reported fever (70%). Gastro-intestinal symptoms (nausea, vomit and diarrhoea) have been recorded in 10 subjects (27%) and resulted significantly associated with longer swab positivity (p<0.05) (Figure 1). Only a small percentage of patients with COVID-19 infection was receiving corticosteroids (8%), and the doses were low (3.5 or 5 mg per day of prednisone equivalents). The most used b-DMARDs were anti-TNFs (24/37, 65%), while just 4/37 (11%) employed JAK inhibitors. A small percentage of patients (6/37, 16%) continued ongoing treatment, with no worsened outcomes, while none preventively suspended the immunosuppressant. The course of infection was generally benign with a mortality rate of 2.6% (1 patient, with several risk factors) and only 9 patients needed to be hospitalized (24%). After COVID-19 infection, 12 subjects (32%) had RMD flare and 5 of them subsequently needed to change the immunosuppressive drug.

Table 1. Cases and proportion of COVID-19 among different populations. *p<0.001, patients vs province population; °p<0.05 patients vs province population.

	Cases (proportions)		
Periods	**RMD patients**	**Province population**	**Region population**
Overall wave	37 (0.0352)*	14437 (0.1441)	32970 (0.0273)
First wave	5 (0.0048)°	1190 (0.0119)	3769 (0.0031)
Second wave	32 (0.0304)*	13247 (0.1322)	29201 (0.0242)

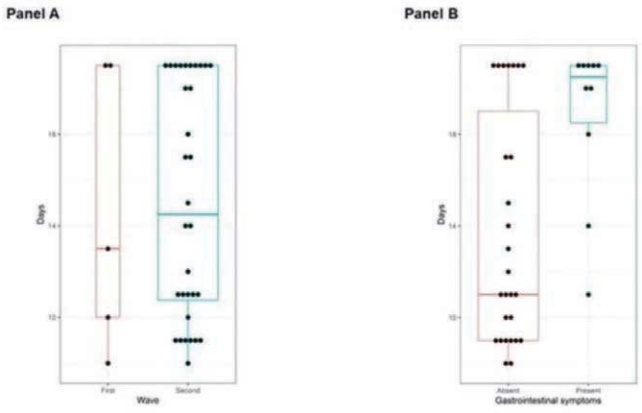

Figure 1.

Conclusion: The prevalence of COVID-19 in RMD patients has been confirmed low in both waves and it could be partially explained by the great awareness about preventive strategies by the patients. The benign course of COVID-19 in our patients may be linked to the very low amount of chronic corticosteroids used and the possible protective effect of anti-TNF agents, which were the main class of biologics herein employed. Gastro-intestinal symptoms might be a predictor of viral persistence in immunosuppressed patients. This finding could be useful to identify earlier COVID-19 carriers with uncommon symptoms (without respiratory manifestations), eventually eligible for antiviral drugs.

AB1126 CHARACTERISTICS AND OUTCOMES OF COVID-19 IN PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES: EXPERIENCE FROM A TERTIARY RHEUMATOLOGY CENTER IN MALAYSIA

S. Selvananda[1], S. L. Kan[1]. [1]*Penang General Hospital, Rheumatology Unit, Department of Internal Medicine, George Town, Malaysia*

Background: South East Asia was one of the first regions affected by the SARS-CoV-2 virus causing COVID-19 however data on the impact of COVID-19 infection in patients with systemic rheumatic diseases (SRD) in South East Asia remains scarce.
Objectives: To evaluate basic demographics, clinical features and outcomes of COVID-19 infection in patients with SRD from a tertiary rheumatology centre in West Malaysia.
Methods: A retrospective observational study of 77 patients with SRD diagnosed with COVID-19 between 1st December 2020 to the 31st of December 2021 was performed. Demographic details, type of SRD, number and type of disease-modifying antirheumatic drugs (DMARD), dose of glucocorticoid, comorbidities, SARS-CoV-2 vaccine (type and number of doses) hospitalisation, oxygen requirement, type of COVID-19 related complication and death were recorded.
Results: A total of 55 (71%) patients were hospitalised and 9 (12%) died. Mean age at time of COVID-19 diagnosis was 51 ± 14. Amongst these patients, 32 (42%) were Chinese, 30 (39%) Malays and 15 (19%) Indians. Majority of these patients had inflammatory arthritis (58%) which included rheumatoid arthritis and seronegative spondyloarthropathy. The most common DMARDs used was methotrexate (51%), hydroxychloroquine (46%), sulfasalazine (22%), leflunomide (13%), azathioprine and mycophenolate mofetil (5% each). Two patients were on Janus Kinase (JAK) inhibitors and 3 on biologic DMARDS (tumour necrosis factor inhibitor, IL-6 inhibitors and IL-17 inhibitors). There were 38 patients (49%) vaccinated with two doses of SARS-CoV-2 vaccine (Pfizer n=29, CoronoVac n=7 and AstraZeneca n=2) prior to admission and amongst those unvaccinated, 15 (20%) contracted COVID-19 before the vaccine was released in Malaysia. Among hospitalised patients, those more than 60 years and those with more than one comorbid had a higher chance of admission (n= 21, 88%; p=0.036 and n=28, 88%; p=0.001) and death (n=8, 33%; p<0.001 and n=7, 22%; p<0.001). Comorbidities associated with higher risk of hospitalisation was diabetes mellitus (85%, p=0.06), hypertension (92%, p<0.001) and coronary artery disease (100%, p=0.03) and those associated with death was obesity (33%, p=0.01) and hypertension (22%, p=0.007). Use of conventional DMARD, JAK, biologics and glucocorticoid were not associated with hospitalisation or morbidity. However, we found that patients who developed acute respiratory distress syndrome secondary to COVID-19 were mostly on sulfasalazine compared to other DMARDS (35%, p=0.01).

Conclusion: In our multiethnic cohort of patients with SRD we found that age and multiple comorbidities such as diabetes mellitus, hypertension, obesity and coronary artery disease were associated with hospitalisation and morbidity. Disease activity and glucocorticoid use which have been shown to be associated with morbidity [1] was not seen in our cohort. The association between sulfasalazine and poor outcomes have been reported [2] however further studies are still needed to investigate the causal relationship between the two.

AB1127 ANTIOSTEOPOROTIC TREATMENT AND COVID-19 RISK: IS THERE AN ASSOCIATION?

N. Grygorieva[1], M. Bystrytska[1], N. Zaverukha[1], A. Musiienko[1]. [1]*D. F. Chebotarev Institute of Gerontology, NAMS of Ukraine, Clinical Physiology&Pathology of Locomotor Apparatus, Kyiv, Ukraine*

Background: Nowadays, the COVID-19 and its complications are considered an important medical issue with aggravated medico-social outcomes, both at the worldwide scale, and in terms of various individual countries. Despite the recent ASBMR, AACE, Endocrine Society, ECTS and NOF recommendations according to osteoporosis management in the era of COVID-19 the influence of antiosteoporotic drugs on disease incidence and severity continue to be studied [1, 2].

Objectives: The purpose of this study was to assess the COVID-19 risk for the patients receiving the parenteral bisphosphonate or Denosumab treatment, and the severity of its course in the systemic osteoporosis patients.

Methods: We performed the phone survey and studied the results of 195 patients (92 % women; mean age – 62.7±10.8 years, height – 161.0±8.0 cm, body weight – 68.9±12.3 kg) with systemic osteoporosis depending on the current use of parenteral antiresorptive drugs (Zoledronic acid, Ibandronic acid, or Denosumab, n=125) and compared the results with patients with osteoporosis who did not use any antiosteoporotic drugs previously (n=70). The mean duration of antiosteoporotic treatment did not vary across the groups, accounting for 15 [9-27] months. Prior to the beginning of the antiosteoporotic therapy, all the patients had a confirmed diagnosis of osteoporosis at the Ukrainian scientific-medical Center of osteoporosis.

Results: We did not reveal any significant differences in the COVID-19 frequency and severity depending on the presence and type of parenteral antiosteoporotic therapy. Additionally, there were no differences depending on patients' age of sex, obesity presence, and other osteoporosis risk factors. The risk of COVID-19 in the patients with systemic osteoporosis did not differ depending on antiresorptive drug use, amounting (Odd Ratio (OR) 95 % CI) to 1.1 (0.6-2.0), or on the use of the definite antiosteoporotic drug (for the Zoledronic acid - 0.9 (0.4-2.0), the Ibandronic acid - 1.1 (0.5-2.3), and for the Denosumab - 1.6 (0.5-5.2).

Conclusion: Our study did not reveal any significant differences in the COVID-19 frequency and severity depending on the presence and type of parenteral antiosteoporotic therapy. We conclude that parenteral antiosteoporotic drugs (Zoledronic acid, Ibandronic acid, or Denosumab) do not have an influence on COVID-19 frequency and severity and can be recommended for the continuation of treatment of patients with osteoporosis.

AB1128 MAINTENANCE THERAPY FOR PATIENTS WITH RHEUMATIC DISEASES DURING THE COVID-19

D. Ben Nessib[1], M. Yasmine[1], H. Ferjani[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of orthopedics, Rheumatology, Tunis, Tunisia*

Background: The Covid-19 pandemic has been raging for more than a year in a pandemic mode. Since then, many questions have been raised regarding the management of patients with rheumatic diseases (RD). In this context, the maintenance therapy of conventional, biologic and targeted synthetic disease-modifying antirheumatic drugs (Cs DMARDs, bDMARDs and tsDMARDs respectively) during the Covid-19 infection remains a subject of debate given their immunosuppressive effects as well as their potential generation of lung fibrosis. While the EULAR 2020 guidelines emphasize that discontinuation or maintenance should be discussed on a case-by-case basis, the ACR guidelines advocate discontinuation of all therapies except for the anti-interleukin-6 [1,2].

Objectives: The objective of our work was to report our real-life experience of therapeutic maintenance during the covid-19 pandemic.

Methods: We conducted a cross-sectional study of patients with RD: rheumatoid arthritis (RA) and spondyloarthritis (SpA) recruited from the rheumatology department of the Kassab Institute of Orthopedics. All the patients were asked to complete a questionnaire about their disease management in the era of the Covid-19. The questionnaire included sociodemographic data, treatment modalities, as well as data related to the infection with the Covid-19 (severe forms defined by the need for oxygen therapy or hospitalization), and changes in treatment during the infection.

Results: The study included 102 patients with RA (65.3%) and SpA (34.7%). The mean age was 52.4 ± 13 [19-77] years. There was a female predominance with a sex ratio of 0.4. The mean duration of the disease was 7.8 ± 5 years [1-35]. Fifteen percent of patients were on corticosteroids with a mean dose of 6.7±4.5 mg/L [2-20] of prednisone equivalent. A CsDMARD was prescribed alone in 36.3% of cases and combined with a biologic in 18% of cases. A Covid-19 infection was occurred at least once in 25.5% of cases, of which 19.2% had a severe form (hospitalization (15.4%), oxygen therapy (19.2%)). No deaths were observed. The treatments received during the covid-19 infection were: corticosteroids (n=5), heparin therapy (n=6) and antibiotic therapy (n=10). No patient tapered treatment dosage of DMARDs but discontinuation was reported by 4 patients with a mean time between discontinuation and resumption of 2.1 ± 2 months [0.5-5 months]. The cessation of the treatment was dictated by the treating physician in 2 cases and involved csDMARD in 3 cases (Methotrexate (n=2), Leflunomide (n=1)) and biologics in only one patient. There were no cases of clinical pulmonary worsening upon resumption of the treatments. We found no statistically significant association between severe forms of the infection and the type of RD (p=0.925), as well as the presence of comorbidities (p=0.825). Similarly, the presence of severe forms was not associated with the use of long-term NSAIDs (p=0.29), corticosteroids (p=0.85), or biological treatment (p=0.7). However, maintenance therapy was significantly associated with a lower risk of severe forms (p=0.013).

Conclusion: Our work showed that the maintenance of conventional treatment during Covid-19 infection was associated with a lower risk of severe forms. Our results, along with those of other studies in the literature, support the maintenance of antirheumatic treatments.

AB1129 SAFETY OF VACCINES AGAINST COVID-19 IN PATIENTS WITH SPONDYLOARTHRITIS (PRELIMINARY DATA).

A. Kulikov[1], N. Muravyeva[1], B. Belov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinoprophylaxis, Moscow, Russian Federation*

Background: Patients with spondyloarthritis (SpA) probably have a high incidence of COVID-19. Vaccination remains one of the most effective methods of preventing infectious diseases. However, data on the safety of vaccines against COVID-19 in patients with SpA are few and relate to foreign vaccines that are not licensed in Russia.

Objectives: To study the safety of COVID-19 vaccines in patients with SpA in real clinical practice.

Methods: The study included 47 SpA patients (25 - ankylosing spondylitis, 13 - psoriatic arthritis, 9 - undifferentiated SpA, 19 women, 28 men, age 42.3±11.6 years, duration of the disease 11.8±9.2 years) - the main group and 97 people without any immuno-inflammatory rheumatic diseases (67 women, 30 men, age 43.7±13.1 years) - the control group. 20 patients received disease-modifying antirheumatic drugs (12 - methotrexate, 8 - sulfasalazine), 10 - biological drugs (8 – TNF-α inhibitors, 2 - IL-17 inhibitors), 6 - glucocorticoids, 1 - tofacitinib, 12 - only nonsteroidal anti-inflammatory drugs, 8 - did not receive therapy. In the main group, 40 patients were vaccinated with Gam-COVID-Vac (Sputnik V), 3 – CoviVac and Sputnik Light, 1 – EpiVacCorona (both components of the vaccine were received by 44 patients). In the control group 69 were vaccinated with Sputnik V, 15 - CoviVac, 5 - Sputnik Light and BNT162b2, 2 - EpiVacCorona, 1 - mRNA-1273. (91 participants received both components of the vaccine). All participants

were interviewed by a research doctor with a unified questionnaire, additional information was obtained from medical documentation.

Results: The data obtained are reflected in the Table 1. Local adverse events (AEs) occurred relatively less frequently in patients with SpA than in the control group. After the introduction of the first component of the vaccine, there was a significant increase in the frequency of pain without restriction of movement and edema/hyperemia in the control group (p<0.001 and p=0.049, respectively), while after the introduction of the second component, a significant difference was registered only for the first indicated symptom (p<0.001). The most frequent systemic AEs were weakness, fever, arthralgia or myalgia, headache, and chills, which were significantly less common (p=0.008) in the main group after immunization with the first component. The proportion of SpA patients without any reactions was significantly higher after the introduction of the first component of the vaccine (59.6% and 29.9%, p<0.001), while after immunity with the second component there were no differences (59.1% and 44.0%, p>0.05). After complete immunization, the percentage of patients without any AEs was significantly higher in the main group than in the control (50.0% and 17.6%, p<0.001). There was no exacerbation of SpA or development of new autoimmune phenomena in the main group after full vaccination.

Table 1. The frequency of AEs in SpA patients and in control

	The first component					The second component				
	SpA, n=47		Control, n=97			SpA, n=44		Control, n=91		
	n	%	n	%	p	n	%	n	%	p
Local AEs										
Pain w/r movement*	2	4.3	38	39.2	<0.001	2	4.5	32	35.2	<0.001
Pain w/r movement**	5	10.6	10	10.3	>0.05	4	9.1	4	4.4	>0.05
Edema or hyperemia	1	2.1	14	14.4	0.049	3	6.8	13	14.3	>0.05
Systemic AEs										
Weakness	13	27.7	36	37.1	>0.05	11	25.0	23	25.3	>0.05
Temperature >37.0ºC	13	27.7	33	34.0	>0.05	9	20.5	21	23.1	>0.05
Myalgia/Arthralgia	6	12.8	22	22.7	>0.05	6	13.6	14	15.4	>0.05
Headache	5	10.6	11	11.3	>0.05	6	13.6	6	6.6	>0.05
Chills	1	2.1	20	20.6	0.008	3	6.8	5	5.5	>0.05
Nausea/vomiting	1	2.1	2	2.1	>0.05	0	0	1	1.1	-
Other	1	2.1	10	10.3	>0.05	0	0	4	4.4	-

Notes: * - pain at the injection site **without** restriction of limb movement, ** - pain at the injection site **with** restriction of limb movement

Conclusion: According to preliminary data, the tolerability of vaccines against COVID-19 in patients with SpA is satisfactory. Further studies with an increased sample are needed to study the safety, immunogenicity and clinical efficacy of immunization against COVID-19 in patients of this cohort.

AB1130 A REDUCTION IN NEW REFERRALS FOR RHEUMATOID ARTHRITIS, OSTEOARTHRITIS AND CRYSTAL ARTHRITIS COMPARED TO GCA DURING COVID19 PANDEMIC

M. Tormo-Ratera[1], M. Mirza[2], R. Luqmani[2]. [1]*Hospital Universitari de Bellvitge, Rheumatology, L'Hospitalet de Llobregat, Spain*; [2]*Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom*

Background: The COVID-19 pandemic has had profound effects on the Rheumatology department; we wanted to see if consequently referrals for Rheumatoid arthritis (RA), Crystal Arthritis (CA), Osteoarthritis (OA) and Giant cell arteritis (GCA) were affected. A greater understanding of the impact may enable adequate number of clinics and resources to be made available where needed.

Objectives: To evaluate the impact of COVID-19 pandemic on volume of new referrals to the Rheumatology department for RA, CA, OA and GCA.

Methods: A retrospective analysis of data was conducted from the period of January 2016 to December 2021. The Rheumatology department database was closely analysed and information about new referrals for GCA, RA, OA and CA were evaluated. Statistical analysis was conducted using t-test to compare the mean value pre and during the COVID19 outbreak (2020).

Results: From 2016 to 2021 a total number of 9998 new patients were referred to the Rheumatology department. There were 2768 new referrals for GCA (15%), RA (34%), OA (40%) and CA (11%) made during this period. In 2020, there was a significant decrease in OA, RA and CA referrals (p value 0.000004, 0.00017, 0.0042 respectively) but an insignificant decrease in GCA referrals (p value 0.243).

	Number of referrals		
Diagnoses	**Mean nº 2016-2019**	**2020**	**p value**
GCA	79.75 (14%)	63 (33%)	0.24334236
RA	204 (36%)	55 (28%)	0.000175427
OA	219.7 (39%)	59 (30%)	4.26975E-06
CA	64.5(11%)	18 (9%)	0.004278881
	100%	100%	

Conclusion: During COVID19 pandemic in 2020 there was a significant reduction in the number of new referrals for RA, OA, and CA in contrast to GCA where the referrals have been constant. This may be due to the detrimental consequences of untreated GCA with regards to risk of sight loss. However, with less RA referrals, this may result in a delayed diagnosis with an impact on the disease course.

Background: Patients with autoimmune/inflammatory rheumatic diseases (AIRD) were suspected to be an at-risk population of severe COVID-19. However, whether this higher risk is linked to the disease or to its treatment is difficult to determine.

Objectives: To identify, among AIRD patients, factors associated with occurrence of moderate-to-severe COVID19 infection and to evaluate if having an AIRD was associated with an increased risk of severe form of COVID19 infection (defined by hospitalization in ICU or death), compared to general population.

Methods: Data source: The "Entrepôt des Données de Santé (EDS)" collect data from electronic health records of all patients hospitalized or followed in the AP-HP (39 hospitals in Paris area, France). The French RMD COVID19 cohort is a national multi-center cohort that included patients with confirmed AIRD and diagnosed with COVID-19. All AIRD patients diagnosed with COVID-19 before September 2020 from both cohorts were included.

-We Identified factors associated with severe COVID-19 was made in a combined analysis of the 2 cohorts.

-Then, we compared COVID-19 infection severity in the EDS-COVID database in AIRD patients and controls, by a propensity score (PS)-matched case-control (1:4) study

Results: Among 1213 patients (334 in EDS and 879 in RMD cohort), 195 (16.1%) experienced a severe COVID19. In multivariate analysis, greater age, history of interstitial lung disease, arterial hypertension, obesity, sarcoidosis, vasculitis, auto-inflammatory disease and treatment with corticosteroids or rituximab were associated with severe COVID-19 (Table 1).

Table 1. AIRD patient's characteristics associated with severity of COVID-19

	Patients with mild or moderate infection	Patients with severe infection	OR ajustés	
	(N = 1018)	(N = 195)	95%CI	p-value
Patients characteristics				
Age	55.9 (16.7%)	70.3 (14.3%)	1.05 [1.03;1.07]	<0.001
Gender: Female	695 (68.3%)	105 (54.1%)	0.59 [0.38;0.94]	0.025
Interstitial pneumonia	38 (3.7%)	20 (10.3%)	2.94 [1.34;6.34]	0.008
Obesity	143 (17.8%)	38 (27.7%)	2.09 [1.26;3.43]	0.004
Hypertension	268 (26.3%)	114 (58.5%)	1.81 [1.13;2.89]	0.013
Underlying Disease:				
Chronic inflammatory arthritis	618 (60.8%)	72 (36.9%)	Ref.	
Auto-inflammatory disease	29 (2.9%)	5 (2.6%)	3.91 [1.2;11.32]	0.025
Other	29 (2.9%)	4 (2.1%)	0.35 [0.06;1.41]	0.15
Connectivitis	190 (18.7%)	34 (17.4%)	1.13 [0.62;2.01]	0.69
Sarcoidosis	40 (3.9%)	24 (12.3%)	5.19 [2.15;12.3]	<0.001
Vasculitis	111 (10.9%)	56 (28.7%)	1.8 [1.02;3.16]	0.044
Treatments				
Corticosteroid	318 (31.2%)	117 (60.0%)	2.47 [1.58;3.87]	<0.001
Leflunomide	44 (4.3%)	2 (1.0%)	0.13 [0;0.97]	0.045
Rituximab	37 (3.7%)	22 (11.5%)	4.05 [1.96;8.27]	<0.001
Not significant in multivariate analysis	COPD, Asthma, Coronary heart diseases, stroke, diabetes, smoking, cancer, non-steroidal anti-inflammatory drugs, colchicine, hydroxychloroquine, methotrexate, salazopyrine, mycophenolate mofetil, azathioprine, intravenous immunoglobulins, anti-TNFα, anti-IL1, -IL6, -IL17, Abatacept, JAK inhibitor			

Among 35741 COVID-19 patients in EDS, 316 with AIRD were compared to 1264 PS-matched controls. Severe form occurred in 118 (37,3%) AIRD cases and 384 (30.4%) controls (Adjusted OR (aOR) for severe form= 1.43 [1.1;1.9], p=0,01). In analysis restricted to rheumatoid arthritis (RA) and spondylarthritis (SpA), no increased risk of severe form (aOR=1.11 [0.68;1.81]) form or death (aOR=1.00 [0.55;1.81]) was observed.

Conclusion: In this multicenter study we confirmed that AIRD patients treated with rituximab or corticosteroids were at increased risk of severe COVID-19, as were those with vasculitis, auto-inflammatory disease, and sarcoidosis. Also, when compared to controls from the same cohort of hospitalized patients, AIRD patients had, overall, an increased risk of severe COVID-19, increased risk not observed in an analysis restricted to patients with RA or SpA.

AB1132 FEATURES OF THE COURSE OF COVID-19 IN ELDERLY PATIENTS WITH IMMUNO-INFLAMMATORY RHEUMATIC DISEASES (PRELIMINARY DATA).

N. Muravyeva[1], B. Belov[1], A. Kulikov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinoprophylaxis, Moscow, Russian Federation*

Background: It is assumed that patients with immuno-inflammatory rheumatic diseases (IIRDs) in old age are susceptible to a more severe course of COVID-19 both due immunological disorders (autoimmune disease and its activity, immunosuppressive therapy, immunosenescence leading to systemic subclinical chronic inflammation with increased secretion of IL-6, IL-1, IL-18, TNF-α) and due to the presence of comorbid pathology. There are no Russian data on the course of COVID-19 in elderly patients with IIRDs.

Objectives: To study the features of the course of COVID-19 in elderly patients with IIRDs.

Methods: The study included 93 patients with IIRDs: 72 women, 21 men, average age 67.5±6.1 years. Of them, 62 patients suffered from rheumatoid arthritis, 9 - systemic sclerosis, 5 - ankylosing spondylitis, 4 - Sjogren's disease, 4 - systemic vasculitis, 3 - psoriatic arthritis, 2 - osteoarthritis, 1 - systemic lupus erythematosus, 1 - polymyositis, 1 - rheumatic polymyalgia, 1 - gout. At the moment of COVID-19, 10 patients had high activity of IIRDs, 26 - moderate, 40 - low, 17 - remission. 69 patients were treated with disease-modifying antirheumatic drugs-DMARDs (40 - methotrexate, 12 - leflunomide, 8 - sulfasalazine, 7 - hydroxychloroquine), 45 - glucocorticoids (34 - low doses, 11 - medium or high doses). 36 patients received biologic or target DMARDs: 24 - rituximab (the interval from the last administration to the development of COVID-19 symptoms averaged 7 months), 4 – TNF-α inhibitors, 3 - abatacept, 2 - secukinumab, 1 - tofacitinib, 1 - baricitinib, 1 - ustekinumab. Comorbidities included hypertension (n=74), coronary artery disease (n=27), obesity (n=17), diabetes mellitus (n=8), bronchial asthma (n=5), chronic obstructive pulmonary disease (n=4), chronic kidney disease (n=3). The patients were interviewed by a research doctor, additional information was obtained from medical documentation.

Results: The most common symptoms of COVID-19 were fever - 67.7%, weakness/drowsiness - 53.7%, cough - 48.4%, as well as anosmia and dyspnea - 35.5% each, headache - 20.4%, body aches - 16.1%, congestion nose - 8.6%, chest pain - 7.5%, dysgeusia - 5.4%, diarrhea/vomiting - 3.2%. According to CT chest scan, 8 patients had 0% of lung damage, 31 - 25%, 32 - 50%, 12 - 75%, in other cases the study was not carried out (n=9) or data are not available (n=1). In 2 patients the course of COVID-19 was complicated by bacterial pneumonia, in 1 - bacterial-fungal. An asymptomatic course was noted only in 2 patients (PCR+/IgM +, CT 0, close contact with a confirmed case of COVID-19). Recovery was noted in 90 patients, fatal outcome - in 3. Exacerbation of IIRDs after COVID-19 was noted in 48.4% of patients, which required intensifying antirheumatic therapy.

Conclusion: Preliminary data indicate that COVID-19 is characterized by moderate and severe course in elderly patients with IIRDs. Further studies are required to identify risk factors for severe course and complications in order to provide timely qualified care.

AB1133 MUSCULOSKELETAL MANIFESTATIONS AMONG PATIENTS WITH COVID-19 INFECTION

S. Tharwat[1], N. M. Shabana[2], M. K. Nassar[3]. [1]*Faculty of Medicine, Mansoura University, Mansoura, Egypt, Rheumatology & Immunology Unit, Department of Internal Medicine, Mansoura, Egypt*; [2]*Mansoura Manchester Programme for Medical Education, Faculty of Medicine, Mansoura University, Mansoura, Internal Medicine,Rheumatology & Immunology, Mansoura, Egypt*; [3]*Faculty of Medicine, Mansoura University, Mansoura, Egypt, Mansoura University Nephrology and Dialysis Unit, Internal Medicine Department, Mansoura, Egypt*

Background: Coronavirus disease-2019 (COVID-19) is declared as a global pandemic [1]. It is caused by a novel coronavirus with structural similarities to the virus that causes severe acute respiratory syndrome (SARS) [2].While the pulmonary consequences have received a lot of attention, the impact of the disease extends far beyond the respiratory system and affects other organs of the body such as heart,kidney or liver [3]. Although different musculoskeletal (MSK) manifestations have been linked to COVID-19 infection, a systematic approach to outline these manifestations is still lacking [4].

Objectives: The aim of this study was to determine the prevalence, distribution and determinants of MSK manifestations in patients with COVID-19 infection.

Methods: Patients with a history of confirmed COVID-19 infection were asked to answer a web-based survey. The survey consisted of multiple questions centered around demographic, clinical and COVID-19 infection data in addition to MSK discomfort form based on the Nordic MSK Questionnaire. The inclusion criteria included age of ≥18 years. Patients who had malignancies or any chronic rheumatic, MSK, neurological disease were excluded.

Results: There was a total of 110 participants, mostly females (72.7%), with mean age 37.7 years, only 9 (8.2%) were current smokers while 31 (28.2%) had associated comorbid conditions. Headache (75.5%), loss of smell (61.8%) and fever were the most main COVID-19 presenting symptoms. The MSK manifestations reported during or shortly after COVID-19 infection were myalgia (95.5%), arthralgia (81.8%) and facial muscle pain (7.3%). The severity of COVID-19 related arthralgia ranged from mild (18.2%), moderate (32.7%), severe (23.6%) and very severe (7.3%). The most affected part was low back (60%), neck (33.3%), and upper back (30%) (Figure 1). MSK manifestations were significantly associated with shortness of breath (p=0.004), fever (p=0.004), loss of taste (p<0.001), diarrhea (p=0.018), fatigue (p<0.001), higher severity of COVID-19 infection (p<0.001), and longer duration of COVID-19 symptoms (from the first day until symptoms resolved) (p<0.001).

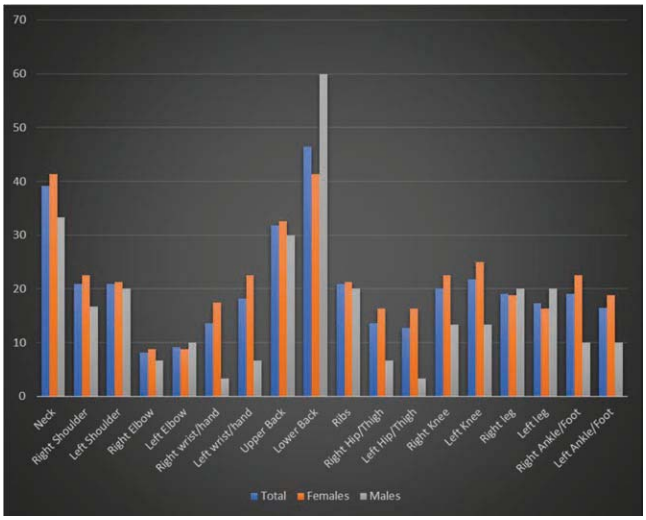

Figure 1. Distribution of MSK manifestations (ache, pain, discomfort, numbness) associated with COVID-19 infection

Conclusion: MSK manifestations are prevalent among patients with COVID-19 infection. They are usually associated with more severe COVID-19 infection and longer disease duration.

AB1134 BIBLIOMETRIC NETWORK ANALYSIS ON TOCILIZUMAB TREATMENT FOR COVID-19 PATIENTS

L. Cascella[1], F. Monaco[2], D. Nocerino[2], A. Infernuso[2], V. Cascella[3], F. Del Prato[2], S. Cascella[4], M. Cascella[2]on behalf of Study Group on AI in medicine. *[1]School of Medicine. University Federico II. Naples, Italy, Medicine, Naples, Italy*; *[2]Istituto Nazionale Tumori, IRCCS Fondazione G. Pascale, Division of Anesthesia and Pain Medicine, Naples, Italy*; *[3]School of Medicine. University of Pavia, Medicine, Pavia, Italy*; *[4]Istituto Nazionale Tumori, IRCCS Fondazione G. Pascale, Scientific Directorate, Naples, Italy*

Background: Tocilizumab is a humanized monoclonal antibody. It provokes inhibition of the proinflammatory signals by binding to IL-6 receptors [1]. Due to these properties, it is used in inflammatory arthritis conditions and in cytokine release syndromes [2]. Notably, given its ability to intercept proinflammatory cascades, tocilizumab is an important option for patients with critical forms of COVID-19 [3]. Nevertheless, several aspects about the use of tocilizumab in this clinical setting should be better explained [4].

Objectives: This bibliometric analysis is aimed at dissecting the developed research in the subject. It could provide useful findings for predicting the direction of future studies, implementing corrective measures, and enhancing research networks.

Methods: The global literature on tocilizumab treatment for COVID-19 was scanned in the Web of Science (WOS) online database. The search terms applied to identify the closest matching articles included "tocilizumab" and "COVID-19". All data were acquired on January 29, 2022. The information for the documents that met the requirements were extracted. The source was Journal Citation Reports™ 2020 (Clarivate Analytics). The literature analysis and knowledge visualization software tool VOSviewer (version 1.6.17) was used to analyze the co-occurrence of keywords (interconnection), co-citation (bibliographic coupling), co-citation analysis for sources, and countries, and analysis of the most productive organizations and networks.

Results: A total of 1019 articles on tocilizumab treatment for COVID-19 patients were published from 2020 to January 2022, in WOS. Of those: 462 in 2020, 546 in 2021, 11 on January 29, 2022. About article types, 697 were research articles, 322 reviews. The analysis of keywords provided by authors showed that of 50 keywords, 17 met the threshold (interconnection 2). The most frequent keywords were EFFICACY, and OFF-LABEL USE (Figure 1)

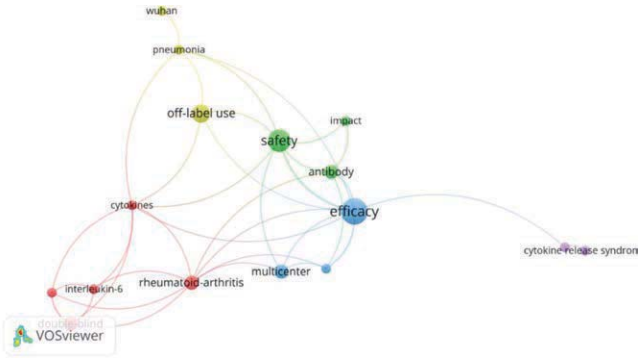

Figure 1. Co-occurrence of keywords

For the co-citation study, we used cited sources (journals) as unit (minimum numbers of citations of a source 1, maximum 3). Of 45 sources, 27 met the threshold. For each source, the total strength of the co-citation links with other sources was rated. The minimum number of documents per country was 2. Thus, 23 countries met the threshold. The largest number of partnerships regarded the US, and Italy. The analysis of affiliations was conducted by considering the cut-off 1 and 5 as the minimum and maximum number of documents. Out of 151 organizations, 94 met the threshold.

Conclusion: This bibliometric network analysis on tocilizumab treatment for COVID-19 patients can be useful for planning future research. It highlights the strength of representative scholars and core research teams. Additional networks should be built, and high-value clinical studies are needed.

AB1135 RESPONSE TO SARS-COV-2 VACCINATION IN SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASE DEPENDS ON IMMUNOSUPPRESSIVE REGIMEN: A MATCHED, PROSPECTIVE COHORT STUDY

P. Mandl[1], S. Tobudic[2], H. Haslacher[3], D. Mrak[1], T. Nothnagl[4], T. Perkmann[3], H. Radner[1], J. Sautner[4], E. Simader[1], F. Winkler[2], H. Burgmann[2], D. Aletaha[1], S. Winkler[2], S. Blüml[1]. *[1]Medical University of Vienna, Division of Rheumatology, Vienna, Austria*; *[2]Medical University of Vienna, Division of Infectious Diseases and Tropical Medicine, Vienna, Austria*; *[3]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*; *[4]Korneuburg-Stockerau Hospital, Lower Austrian Centre for Rheumatology, Second Medical Department, Stockerau, Austria*

Background: Vaccination efficiency has been demonstrated to be reduced in patients with systemic autoimmune rheumatic disease (SARD) compared with the general population.

Objectives: To assess the humoral response to mRNA vaccine in patients with (SARD) and the effect of immunosuppressive medication in a matched cohort study.

Methods: Patients with SARD were enrolled and matched 1:1 for gender and age with healthy control subjects (HC). Differences in the humoral response to two doses of mRNA vaccine BNT162b2 in terms of seroconversion rate and SARS-COV-2 antibody titer between the two groups and impact of treatment within SARD patients was assessed using Fisher's exact test, Student's t-test, Mann-Whitney test and Kruskal-Wallis test, adjusting for multiple testing.

Results: We enrolled 82 patients with SARD and 82 matched HC (Table 1). Among patients the seroconversion rate was significantly lower after the 1st dose (65% compared to 100% in HC, p<0.0001) but levelled up after the 2nd dose (94% vs. 100%). While the difference in seroconversion rate was independent of treatment regime (no disease modifying anti-rheumatic drug (DMARD), DMARD monotherapy, DMARD combination therapy), the seroconversion rate of SARD patients on mono- or combination DMARD therapy was also significantly lower as compared to those receiving no DMARD therapy (56% for monotherapy and 57% for combination therapy compared to 77% for no DMARD therapy, p=0.002 and p=0.004 respectively; Figure 1A). Seroconversion rate after the 2nd dose was significantly

lower for patients on combination DMARD therapy compared to all other groups (81% compared to 95% for monotherapy, and 100% for both no DMARD therapy and HC respectively, all p<0.0001); also antibody titers after the 2nd dose were lower when comparing patients on combination DMARD therapy to all other groups (49 binding antibody units (BAU)/ml versus 1673 BAU/ml in HC, p<0.0001; 2500 BAU/ml in those on no DMARD therapy, p<0.0001; and 687 BAU/ml in those on DMARD monotherapy, p=0.0072; Figure 1B). Considering effects of individual compounds, mycophenolate mofetil in mono- or combination therapy led to lower antibody titers after the 2nd dose as compared to HC or patients receiving no DMARDs (2 BAU/ml versus 1673 BAU/ml and 2500 BAU/ml respectively, both p<0.0001).

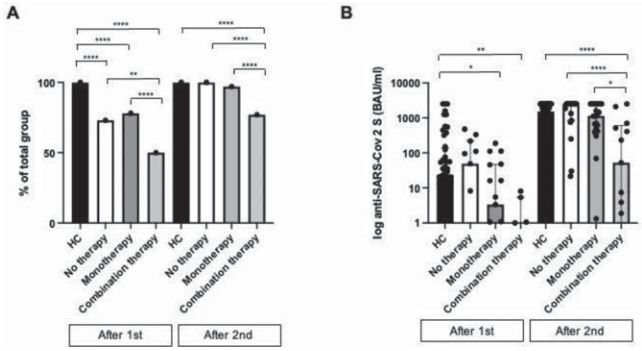

Figure 1. Seroconversion rate (A) and anti-SARS-Cov 2 S antibody levels (B) after the 1st and 2nd vaccination between the healthy control (HC) group and patients according to therapy

Table 1. Study subject characteristics

	SARD (n=82)	HC (n=82)

AB1136 **PREVALENCE OF COVID-19 IN SYSTEMIC LUPUS ERYTHEMATOSUS: A META-ANALYSIS**

J. Wang[1,2], S. X. Zhang[2,3,4], X. Y. Yin[2,5], B. R. Zhao[2,5], Y. R. Shi[1,2], J. Y. Meng[2,5], Q. Y. Su[2,3,4], X. F. LI[3], C. Wang[3]. *[1]Shanxi Medical University, Key laboratory of Cellular Physiology at Shanxi Medical University,Taiyuan,Shanxi, China*; *[2]Shanxi Medical University,Academy of Microbial Ecology,Taiyuan,Shanxi, China*; *[3]The Second Hospital of Shanxi Medical University, Department of Rheumatology,Taiyuan,Shanxi, China*; *[4]Shanxi Medical University, Key laboratory of Cellular Physiology at Shanxi Medical University,Taiyuan,Shanxi, China*; *[5]Shanxi Medical University, Key laboratory of Cellular Physiology at Shanxi Medical University,Taiyuan,Shanxi, China*

Background: Novel Coronavirus pneumonia 2019 (COVID-19) is a systemic infectious disease with prominent involvement of the respiratory tract, due to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)[1]. Systemic lupus erythematosus is charcterized by an aberrant immune response with the presence of circulating autoantibodies, lymphopenia, and proinflammatory[2]. They are immune-compromised and vulnerable to infections with immune-suppressants treatment. However, data regarding the impact of COVID-19 pandemic in patients with SLE and drug use were relatively scarce.

Objectives: The prevalence of COVID-19 in SLE patients was estimated by means of meta-analysis, and the effect of the use of anti-rheumatic drugs on the clinical outcome of SLE patients with COVID-19 was investigated.

Methods: Cross-sectional investigations and case series on SLE and COVID-19 published by CBM, CNKI, China Science and Technology Journal Database, Wan Fang Data, PubMed, Embase, Web of Science, Cochrane Library and Medline from its establishment to November 10, 2021 were searched. Random effects model was used to pool data. Heterogeneity and risk of bias was examined with I-squared index (I^2) statistic. Inconsistency was evaluated by using the I^2. Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

Results: A total of 14 studies comprising 5365 patients were identified (Table 1). Overall prevalence of COVID-19 in SLE patients was 1.5% (95%CI: 1.2%-1.8%). Eight of the studies included patients who used hydroxychloroquine as part of their treatment regimen, with 29.8% (95%CI: 25.8%-33.8%) hospitalization rates and 14.6% (95%CI: 11.5%-17.8%) adverse outcome rates. Among patients treated with hydroxychloroquine throughout the course of disease, the prevalence was 0.7% (95%CI: 0.4%-1.0%, Figure 1).

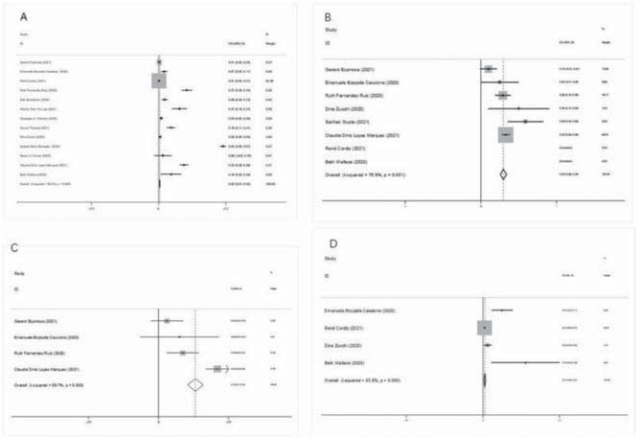

Figure 1. A:Forest map of a meta-analysis of COVID-19 prevalence in SLE patients.B: Forest map of a meta-analysis of hospitalization rates among patients treated with hydroxychloroquine.C:Forest map of meta-analysis of the rate of adverse outcomes in patients using hydroxychloroquine as part of a treatment regimen.D:Forest map of a meta-analysis of the prevalence of patients treated with hydroxychloroquine throughout the course.

Conclusion: Patients with SLE had a higher risk of COVID-19. Hydroxychloroquine might benefit to reduce the overall hospitalization rate and prevalence rate of COVID-19, and alleviate inflammatory damage in the chronic stage of viral infection by inhibiting over activation of the immune system.

USE OF TOCILIZUMAB IN CRITICALLY ILL SARS-COV-2 PATIENTS CARE- PROGNOSTIC FACTORS OF TREATMENT EFFECTIVENESS AND TREATMENT RESULTS

Z. Kardos[1,2], M. Szabó[3], Z. Baráth[1], Á. Miksi[1], Á. Kozma[3], G. A. József[3], Z. Szekanecz[4]. *[1]Borsod County Teaching Hospital, Rheumatology, Miskolc, Hungary*; *[2]University of Miskolc, Medical Faculty, Miskolc, Hungary*; *[3]Borsod County Teaching Hospital, Pharmacy, Miskolc, Hungary*; *[4]University of Debrecen, Rheumatology, Debrecen, Hungary*

Background: The treatment of COVID-19 caused by SARS-CoV-2 posed serious challenges to health care systems. In 8-10% of patients with severe COVID-19 have a cytokine storm syndrome, highlighting the importance of host immune response in pathogenesis.

Objectives: Our aim was to evaluate the effect of tocilizumab treatment in COVID-19 patients with severe cytokine storm who were refractory to standard of care therapy. To determine the prognostic factors that indicate the success of treatment in these patients.

Methods: Fifty-three patients were treated with tocilizumab during waves 2 and 3 of the pandemic due to a cytokine storm associated with SARS-CoV-2 infection. All patients underwent physical examination, saturation monitoring, laboratory examination, blood gas analysis and chest CT examination. Deteriorating clinical status, elevated IL-6 and other acute phase protein levels observed in patients treated with standard therapy suggest cytokine storm syndrome. The treatment of these patients was supplemented with 8 mg/kg (max. 800 mg) tocilizumab (1 or 2 times within 24 hours). We assessed the clinical and laboratory response of these patients to IL-6-R inhibitor therapy, the need for ventilation, the need for intensive care and mortality.

Results: Immunological consultations were performed in 31 patients, of whom 21 (68%) were successfully treated. Eleven patients of them (22%) died. In the 22 non-consulted patients, this rate was reversed: 7 (22%) were successful and 15 (68%) were treatment failures. The success of the treatment was mainly influenced by the well-established indication, the recognition of contraindications, and the condition that did not require invasive ventilation method. The 29 tocilizumab therapies initiated in the non-intensive care unit avoided intensive care unit treatment in 18 patients. Eleven patients were admitted to the intensive care unit, but 7 patients required temporary respiratory support and recovered, 4 patients required invasive mechanical ventilation and later died (14%). In contrast, 24 treatments initiated in the intensive care unit saved the lives of only 3 patients, and 21 patients were lost (87.5%). The effectiveness of treatment was not affected by age, with survival rates of 40%, 44%, 57% and 55% for the 40-49, 50-59, 60-69, 70-79 age groups, respectively. Interestingly, the extent of lung involvement also did not show a significant difference. Although it was a prerequisite for initiating tocilizumab treatment to have fresh alveolitis on the CT image of the chest.

Conclusion: Use of tocilizumab is most effective in patients with COVID-19 who have high levels of inflammatory activity and IL-6, who are at an early stage of lung involvement and who do not respond to high-dose corticosteroid therapy, who have no bacterial superinfection and require not invasive mechanical ventilation. It is also important that specialist who has immunological approach and routine with biological treatment be also involved in the care of patients with severe COVID-19 disease.

AB1138

SAFETY OF SARS - COV- 2 VACCINES IN PATIENTS WITH AUTOIMMUNE DISEASES

S. Monov[1], R. Shumnalieva[1], D. Monova[2]. *[1]Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria*; *[2]Medical University - Sofia, Medical Institute, Department of Internal Medicine, Sofia, Bulgaria*

Background: Patients (pts) with autoimmune diseases are at higher risk of infections, including those by SARS-COV-2. There is no general agreement regarding priority criteria for anti-COVID vaccine access for pts with autoimmune rheumatic diseases (ARD). Few studies have addressed the issue of anti-COVID vaccination in these pts, but many are available on the safety, immunogenicity, efficacy, and possible contraindications of traditional vaccines in pts with ARD. These studies may represent the basis on which to recommend the anti-COVID-19 vaccines.

Objectives: Patients (pts) with autoimmune diseases are at higher risk of infections, including those by SARS-COV-2. There is no general agreement regarding priority criteria for anti-COVID vaccine access for pts with autoimmune rheumatic diseases (ARD). Few studies have addressed the issue of anti-COVID vaccination in these pts, but many are available on the safety, immunogenicity, efficacy, and possible contraindications of traditional vaccines in pts with ARD. These studies may represent the basis on which to recommend the anti-COVID-19 vaccines.

Methods: A telephone survey investigating the AE of SARS-CoV-2 vaccinations on pts with systemic lupus erythematosus, systemic sclerosis, inflammatory arthritis (rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis), idiopathic inflammatory myopathies, ANCA-associated vasculitis was administered. Data extraction included diagnosis, disease activity status, demographics, disease duration, therapy, comorbidities, and laboratory tests. Vaccinated participants are asked to report whether they experienced any local or systemic AE following vaccination, and if so, to report on the severity and duration of the AE. Mild AE were defined as unpleasant reactions that did not limit daily activities, moderate AE as those that limited daily activities, and severe AE - required medical attention. Serious AE were defined as reactions that resulted in hospital admission.

Results: ChAdOx1 nCoV-19 and BNT162b2 are the most common vaccines in our pts. 98 (39,84 %) of 246 pts received the BNT162b2 vaccine, 95 (38,62 %) - ChAdOx1 nCoV-19 vaccine, 47 (19,10%) - CX-024414 and 6 (2,44 %) were vaccinated with Ad26.COV2-S. 127 (51,63%) pts had at least one mild AE and 51 (20,73 %) pts reported moderate AE. Severe AE were rare - 4 (1,63 %) pts and no serious AE were reported. The most commonly reported AE is pain (40,24 %), redness (30,49 %), swelling (18,7 %) at the injection site, which was consistent across all vaccines for both first and second doses. Systemic AE occurred in 104 (43,27 %) pts, most frequently fatigue (29,67 %), headache (27,13 %) and muscle ache (24,39 %). The symptoms started mostly during the first day post-vaccination and lasted for no more than two days. Joint complaints were reported in 8,94 %, but only a small proportion of pts (2,84 %) reported a deterioration of their autoimmune disease up to 3 months after COVID-19 vaccination. Age was a significant effect modifier in the association between autoimmune status and the risk of moderate or severe AE. Vaccination with ChAdOx1 nCoV-19, female sex, age between 35 - 50 years were independently associated with an increased likelihood of reporting any AE. The current results

support the safety of different COVID-19 vaccines in pts with ARD. This information can help fight vaccine hesitancy in this population.
Conclusion: Our data indicated that COVID-19 vaccines are well tolerated by pts with ARD. We did not observe any serious AE, but the number of pts included in our study is too low to draw conclusions about rare serious events. Additionally, our data suggest that COVID-19 vaccinations do not seem to trigger autoimmune disease flares, which is in accordance with data from previous small studies that assessed consequences of vaccines in pts with ARD.

AB1139 SARS-COV2- INFECTION AFTER VACCINATION AGAINST COVID-19 IN PATIENTS WITH RHEUMATIC DISORDERS IN A REAL LIFE SETTING OF A RHEUMATOLOGICAL OUTPATIENT CENTER

S. G. Werner[1], L. Moll[1], A. Uhlenberg-Moll[1], S. Mettler[1], H. E. Langer[1]. [1]*RHIO (Rheumatology, Immunology, Osteology) Düsseldorf, RHIO Research Institute, Düsseldorf, Germany*

Background: Coronavirus SARS-CoV-2 and its associated disease COVID-19 have become a worldwide pandemic since its first case in 12/2019. Since approvement of the first vaccines against COVID-19 in Europe in 12/2020 a large vaccination campaign was started. Our patients with inflammatory diseases (ID) were graded as higher risk, thus an early vaccination was possible. Many of our patients used the possibility and got vaccinated. Until now, there is few knowledge about the efficacy and safety of vaccination in patients with rheumatic disorders. There are some reports of less vaccination response in patients with ID (1). First reports of those patients with rheumatological disorder and infection with SARS-CoV2 are available (1,2). Nevertheless, there is few knowledge about SARS-CoV2-infection in patients with ID after vaccination against COVID-19, yet.
Objectives: The aim of our study was to evaluate, how many patients got infected with SARS-CoV2 after vaccination against COVID-19 and the course of the disease.
Methods: All consecutive patients of the routine follow up visits from 07/2021 to 01/2022 in our rheumatological outpatient center were questioned for SARS-CoV2-infection. In case of infection, they were questioned for vaccination status and the course of the disease.
Results: N=1206 patients could be evaluated. N=1183/1206 (98.1%) vaccinations were documented. N=12/1183 (1%) patients got infected with SARS-CoV2 after at least 2 doses of vaccination against COVID-19. N=1/12 (8.3%) patient got infected after 3 doses of vaccination. N=3/12 (25%) received 2 doses Vaxzevira (AstraZeneca), n=2/12 (16,7) patients 1st dose Vaxzevira, 2nd dose Comirnaty (Biontech), n=7 /58.3%) patients two doses Comirnaty. In n=8/12 (66.7%) patients antibody levels were available. N=7/8 (87,5%) patients developed high antibody levels after 2 vaccinations. N=1/8 (21,5%) patient developed any antibodies against SARS-CoV2 after 2 doses of Comirnaty, measured ≥4 months after 2nd vaccination dose. This patient was treated with Abatacept. This patient came down with COVID-19 5 months after complete vaccination and died after long-standing highly intensive care. All other patients developed a mild to moderate course of COVID-19, without need of hospitalizing.
Conclusion: There is a very high number of patients (98,1%), who got vaccinated in a real life setting of our rheumatological outpatient center. We have seen only a low number of SARS-CoV2-infections (1%). Most patients developed high antibody levels after vaccination and fortunately had a mild to moderate course of COVID-19 in case of SARS-CoV2-infection, independently from the different vaccination agents. Nevertheless, 1 patient came down with COVID-19 5 months after complete vaccination and died after long-standing highly intensive care. This patient did not develop any antibodies after vaccination. In conclusion, vaccination seems to be effective in patients with rheumatological disorders. However, we must be aware of the small group of patients without antibody development, since they are at risk to have a fatal course. Yet, antibody testing is not recommended in routine clinical care by official recommendations, largely because it is still unknown which level of antibodies predicts protection (3). The booster campaign and 3rd vaccinations will change the current state again, but a revaluation and further studies will be necessary.

AB1140 IMPACT OF COVID-19 NEWS SOURCES ON RHEUMATOID ARTHRITIS PATIENTS' LIFESTYLE AND THEIR DISEASE ACTIVITY FROM NINJA 2020 COHORT STUDY

A. Ihata[1], T. Matsui[2], S. Tohma[3]on behalf of NinJa registry. [1]*National Hospital Organization Yokohama Medical Center, Department of Rheumatology, Yokohama, Japan*; [2]*National Hospital Organization Sagamihara National Hospital, Department of Rheumatology, Sagamihara, Japan*; [3]*National Hospital Organization Tokyo National Hospital, Department of Rheumatology, Kiyose, Japan*

Background: One of the problems with the COVID-19 epidemic is infodemic. Insufficient and inaccurate information can be confusing and hinder treatment. In Japan, tabloid TV show might be an easily accessible source of information, but its reliability is low and it has a harmful effect on patients' mental status and lifestyle. There are no reports to examine what is the source of COVID-19 news for patients with rheumatoid arthritis and how these information affect patients' daily lives and disease activity. By using NinJa, Japanese largest database of rheumatoid arthritis, it may be possible to examine them in detail.
Objectives: To investigate the impact of the COVID—19 news sources on rheumatoid arthritis patients' lifestyle and their disease activity using NinJa 2020 cohort study.
Methods: At the timing of collection of patients' data of NinJa2020, questionnaire about their lifestyle and news source of COVID-19 was given. Questionnaire includes questions about frequency of scheduled visit, going out and exercise, weakness and news source.
Results: 6677 patients out of 15553 patients answered questionnaire. Most patients did not change the interval of scheduled visit. The frequency of hospital visits was "unchanged" in 85.8%, "longer" in 13.6%, and "shortened" in 0.6%. The chances of going out were "unchanged" at 14.4%, "significantly decreased" at 57.5%, "slightly decreased" at 27.8%, and "increased" at 0.3%. 42.6% answered that the amount of exercise did not change, 30.2% answered that it decreased considerably, 26.1% answered that it decreased a little, and 1.1% answered that it increased. Regarding muscular strength and physical strength, 46.0% answered "no change", 19.9% answered "significantly dropped", 33.5% answered "slightly dropped", and 0.6% answered "increased". The media used as information sources are "newspaper (86.4%)", "tabloid show (54.5%)", "family, acquaintances and friends (43.7%)", and "official web of Ministry of Health, Labor and Welfare and academic societies (9.4. %)". Respondents often referred to multiple media and 30.6% of them listed three sources (Figure 1). There was a positive correlation between the decrease in frequency of going out and the number of information sources, and a negative correlation between age and the number of information sources. We also found a negative correlation with age for muscle weakness. No correlation was found between the number of information sources and SDAI, CDAI, HAQ-DI, EQ-5D, HADS (A), HADS (D).

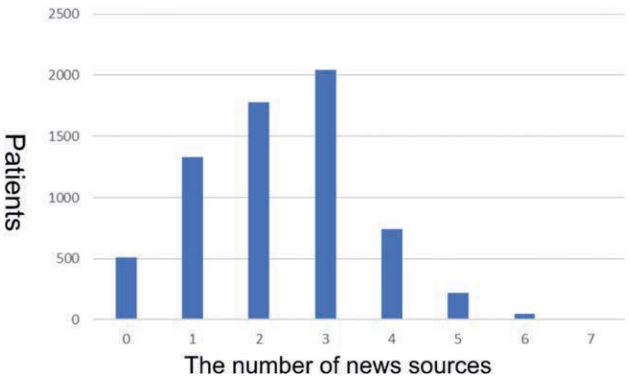

Figure 1.

Conclusion: The more sources of information, the less chance of going out. About 80% of the patients refrained from going out, the opportunity for exercise decreased in more than 50% of the patients, and the decrease in physical fitness was also noticed in nearly 50% of the patients. Newspapers, tabloid shows, and acquaintances were the most common sources of medical information, and relatively few patients used official sources. He provision of accurate information about COVID-19 was important to avoid infodemic. From this questionnaire, more practical information delivery system was required in Japan.

AB1141 **THE PATTERN OF POST COVID-19 REACTIVE ARTHRITIS**

N. Varghese[1], V. Salaru[2], V. Sadovici-Bobeica[1]. [1]*Nicolae Testemiţanu State University of Medicine and Pharmacy, Internal Medicine, Chişinău, Moldova, Republic of*; [2]*Nicolae Testemiţanu State University of Medicine and Pharmacy, Family Medicine, Chişinău, Moldova, Republic of*

Background: According to the recent medical literature, COVID-19 disease can lead to a constellation of clinical syndromes lasting well beyond the first 30 days of infection. The most common post COVID sequalae includes pulmonary, nervous system and neurocognitive, mental, metabolic, cardiovascular, gastrointestinal and several other clinical manifestations. Regarding joint involvement and particularly reactive arthritis (ReA), literature data is limited and describes case reports or series of cases of patients diagnosed with this condition following COVID-19 disease.
Objectives: To describe the pattern and the management of post-COVID reactive arthritis.
Methods: We have conducted a descriptive study of consecutive adult patients who presented to rheumatology outpatient clinic for joint or peri-articular pain/swelling/stiffness and received a diagnosis of post-COVID 19 reactive arthritis, by excluding other types of rheumatological conditions. The assessed clinical variables were: visual analogue scale (VAS) pain, swollen joint count (SJC), tender joint count (TJC), duration of morning stiffness, presence of enthesitis/tendinitis and axial involvement. Biochemistry and serology was performed: rheumatoid factor, ACPA, ANA, HLA B27, antiChlamydia Trachomatis, Ureaplasma Urealyticum and Mycoplasma Hominis Ab, anti HBs and HBc Ab, and anti HCV. COVID-19 disease prior to diagnosis of ReA was confirmed by PCR test.
Results: In the study were included 16 patients with confirmed post COVID-19 ReA. The mean age of the study group was 43.5±10.8 (range 21-60), the female: male ratio was 4:1 and the duration of joint symptoms was 10.4±11.8 (range 1-42) weeks. The severity of COVID-19 disease was mild in 68.7% cases, moderate in 18.7% and severe in only 6.2% of the cases. The duration between COVID-19 diagnosis and ReA varied between cases, with a mean value of 4.3±4.2 (range 1-12) weeks. In 43.7% of the cases patients had peripheral joint involvement (synovitis), in 37.5% - periarticular involvement (enthesitis), 6.25% - isolate axial involvement (sacroiliac joints), 6.25% enthesitis and axial involvement (cervical spine) and 6.25% synovitis and enthesitis. In patients with peripheral joint pattern, the distribution of pain was symmetric (71.4%). The pattern of synovitis was determined by a TJC of 6.25±5.2 (range 1-16) joints and SJC 1.6±2.4 (range 0-7) joints. Both TJC and SJC correlated positively with the duration of morning stiffness (r=0.9 and r=0.6), but did not correlate with the VAS pain scale. In most of the cases synovitis affected the hand (wrist, MCP and PIP) 62.5% and the knee, feet and ankles – 50%. Two patients presented with monoarthritis, 1 with oligoarthritis and 5 with polyarthritis, in the majority of cases, involvement being symmetric (75%). Periarticular pattern was determined by enthesitis, affecting the elbow and shoulder (50%), costo-sternal enthesitis (25%) and trochanteritis (25%). From the entire study group, 31.2% had elevated serum inflammatory markers (ESR and/or CRP). Patients responded well to NSAIDs alone in 68.7% cases, local (intra-articular or peri-articular infiltrations) or and systemic corticoids (5 mg Prednisolone equivalent) were administered in 5.3% and 12.5% cases respectively, in 12.5% cases (two patients) Methotrexate was administered.
Conclusion: Reactive arthritis represents a post COVID-19 sequelae. The time of onset of ReA varied between 1 and 12 weeks after COVID-19 diagnosis. The clinical pattern of the disease was expressed by joint or periarticular involvement, mainly affecting the hand, feet and knee symmetrically. Cases of axial manifestations were less common. Most of the patients responded well to NSAIDs, only in a few particular cases, low doses of corticoids and/or Methotrexate were recommended.

AB1142 **EFFECTS OF SULFASALAZINE USED IN AXIAL SPONDYLOARTHRITIS ON COVID-19 OUTCOMES: REAL-LIFE DATA FROM A SINGLE CENTER**

B. Armagan[1], E. Atalar[1], S. C. Güven[1], B. Özdemir[1], H. E. Konak[1], P. Akyüz Dağlı[1], A. Erden[1], K. Gok[1], Y. Maraş[2], I. Dogan[3], O. Küçükşahin[3], S. Erten[3], A. Omma[2]. [1]*Ankara City Hospital, Rheumatology Clinic, Ankara, Turkey*; [2]*University of Health Sciences, Ankara City Hospital, Rheumatology, Ankara, Turkey*; [3]*Ankara Yıldırım Beyazıt University, Department of Internal Medicine, Rheumatology, Ankara, Turkey*

Background: Compared to biologic-agents, little is known about effects of sulfasalazine used for axial spondyloarthritis(AxSpA) on COVID-19 outcomes.
Objectives: So, we aimed to understand the impact of sulfasalazine on COVID-19 in AxSpA patients.
Methods: This was a retrospective study from a single center which included 2344 AxSpA patients. We analyzed 219 of 406 confirmed COVID-19 patients from March 2020 to July 2021. The primary outcome was COVID-19 severity in terms of COVID-19 pneumonia, hospitalization rate and length of hospitalization. Analyses were stratified according to use of sulfasalazine and/or biologic-agents.
Results: Most of the patients were male(59%) with a mean age of 45.0 years. Peripheral arthritis was present in 35% and uveitis in 15%. In total, sulfasalazine was used in 42% and biologic-agent in 42%. COVID-19 pneumonia detected in 16%, hospitalization required in 14% and median(IQR) duration of hospitalization was 10(8) days. Two patients died due to COVID-19. The sulfasalazine users had higher age, more frequent COVID-19 pneumonia, hospitalization and longer hospitalization. After biologic-agent users were excluded, the sulfasalazine group had again longer hospitalization. When patients regrouped as sulfasalazine monotherapy, sulfasalazine+biologic and biologic monotherapy, in pairwise comparisons, sulfasalazine monotherapy group had a higher frequency of COVID-19 pneumonia than biologic monotherapy group(p=0.008).
Conclusion: Although sulfasalazine seemed to be related with increased rates of COVID-19 pneumonia and hospitalization, this impact diminished after exclusion of biologic-agent users. Sulfasalazine monotherapy and sulfasalazine+biologic therapy might be associated with development of COVID-19 pneumonia, compared to biologic monotherapy. Our results imply sulfasalazine may be related with worse disease course AxSpA patients with COVID-19.

AB1143 **MUSCULOSKELETAL PAIN AS A PART OF THE RHEUMATIC SPECTRUM IN COVID-19**

S. Bogdanova-Petrova[1], T. Georgiev[1], S. Dimitrov[1], S. Hristova[2], T. Shivacheva[1]. [1]*Medical University - Varna, First Department of Internal Medicine, Varna, Bulgaria*; [2]*Medical University - Varna, Department of General Medicine, Varna, Bulgaria*

Background: Since the outbreak of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), responsible for the coronavirus disease 2019 (COVID-19) (1), our understanding of the underlying pathophysiology is constantly evolving in order to explain the wide range of heterogenic clinical manifestations (2). Nevertheless, limited data are available for the severity and multifactorial causality of musculoskeletal pain in COVID-19 patients (3).
Objectives: This study aimed to evaluate the prevalence and intensity of rheumatic pain symptoms – arthralgia and myalgia and their association with anxiety and depression in a cohort of COVID-19 patients, hospitalized at the COVID-19 rheumatology department of the University Hospital St. Marina, Varna, Bulgaria.
Methods: In the present single-center cohort study, a prospective analysis was performed among COVID-19 patients who were hospitalized from 1 Oct 2021 to 20 Jan 2022 and self-reported for new-onset of musculoskeletal pain. All 226 patients (age 26 - 91 years) were treated for moderate or severe SARS-CoV-2 infection confirmed by laboratory tests, including positive antigen test or polymerase chain reaction (PCR) test, and imaging modality. Detailed disease history and clinical examination were carried out by a fully certified rheumatologist. All patients who reported new-onset of musculoskeletal pain during the acute phase of the infection, participated on a voluntary basis in a questionnaire survey, by completed Zung self-rating anxiety scale (SAS), Zung self-rating depression scale (SDS) and visual analogue scale (VAS) for arthralgia and myalgia. The questionnaire form also elicited information on sociodemographic characteristics of the patients. In all patients, inflammation and thrombotic biomarkers were assessed. The level of significance was set to 0.05.
Results: Among all 226 COVID-19 patients with musculoskeletal pain, 46.5% (n =105) were women and 53.5% (n = 121), were men. Mean age was 65.6 years. We found a significant correlation of depression and anxiety scales scores with pain intensity (both arthralgia and myalgia), all < 0.001. A multiple regression analysis found that SDS and SAS accounted for significant variance in the prediction of muscle pain ($\beta = 0.441$, $p < 0.001$; $\beta = 0.293$, $p = 0.003$, respectively) while SDS significantly predicted joint pain ($\beta = 0.341$, $p = 0.043$). On the other hand, musculoskeletal pain does not correlate with any of inflammation and thrombotic biomarkers assessed in SARS-CoV-2 patients ($p > 0.05$).
Conclusion: Rheumatic pain manifestations are part of the heterogeneous spectrum of COVID-19 disease. The pain intensity is significantly associated with

anxiety and depression symptoms and does not correlate with inflammation and thrombotic biomarkers.

AB1144 COGNITIVE AND PSYCHOSOCIAL OUTCOME IN CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME FOLLOWING SARS-COV-2 INFECTION

D. Gosar[1], M. Zajc Avramovič[2], N. Emersic[2], M. Šušterič[3], M. M. Šömen[3], D. Osredkar[1], T. Avcin[2]. [1]*University Medical Center Ljubljana, University Children's Hospital, Department of Child, Adolescent and Developmental Neurology, Ljubljana, Slovenia*; [2]*University Medical Center Ljubljana, University Children's Hospital, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia*; [3]*University of Ljubljana, Department of Psychology, Ljubljana, Slovenia*

Background: Despite the low rate of neurological deficits following the SARS-COV-2 infection in the pediatric population, children and adolescents who develop multisystem inflammatory syndrome (MIS-C) after being infected with SARS-COV-2 are at a higher risk for neurological abnormalities and brain injury, increasing the risk of adverse cognitive and psychiatric outcome.

Objectives: Given the increased risk of central nervous system impairment we chose to conduct a prospective study looking at the cognitive and psychosocial outcome of patients with MIS-C.

Methods: Our study included 27 of the 29 patients between 2 to 18 years of age (M = 11.1, SD = 4.4) who were treated for MIS-C from the onset of the SARS-COV-2 pandemic until the beginning of May 2021 at the only tertiary care pediatric immunology center in Slovenia. We assessed these patients 6 months after diagnosis using the age-appropriate Wechsler intelligence scales and a battery of neuropsychological test measuring attention, executive function, memory and fine motor skills. We also asked parents to report on patients' psychosocial outcome using the Achenbach Child Behavior Checklist.

Results: By using Bayesian statistics to take into account parental education and any potential pre-morbid learning difficulties we found no evidence of impairment on measures of intelligence. However, the posterior distribution of scores on neuropsychological measures indicated that a significant proportion of patients scored 1SD bellow expected levels on measures of attention (31%), executive function (28%) and visual memory (35%). Increased symptoms of depression, anxiety and attention difficulties were also reported by parents, although their extent did not rise to a clinically significant level.

Conclusion: The findings from our cohort suggest that the cognitive and psychosocial outcome of patients with MIS-C is generally favorable, although up to 35% may experience specific neuropsychological deficits more than 6 months after diagnosis. The most commonly impaired cognitive domains seem to be attention, executive function and visual memory.

AB1145 EVALUATION OF THE HUMORAL IMMUNE RESPONSE SECONDARY TO VACCINATION AGAINST SARS-COV2 IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES

P. M. Corbalán[1], M. Pera[1], G. V. Espasa[1], M. L. Leguizamón[1], A. L. Barbaglia[1], L. Gonzalez Lucero[1], H. R. Sueldo[1], M. C. Bertolaccini[1], R. N. Chehin[2], R. H. Tomas-Grau[2], D. Ploper[2], E. Vera Pinguitore[2], B. Socías[2], C. L. Ávila[2], S. I. Cazorla[3], C. Maldonado Galdeano[3], V. I. Bellomio[1]. [1]*Hospital Ángel C. Padilla, Rheumatology Unit, San Miguel de Tucumán, Tucumán, Argentina*; [2]*IMMCA (CONICET - UNT - SIPROSA), Instituto de Investigación en Medicina Molecular y Celular Aplicada, San Miguel de Tucumán, Tucumán, Argentina*; [3]*CERELA (CONICET), Centro de Referencia para Lactobacilos, San Miguel de Tucumán, Tucumán, Argentina*

Background: Several trials have reported lower seroconversion rates in patients with autoimmune rheumatic diseases than in healthy patients. In Argentina, the vaccines that were available during the development of this study were: Sputnik V (Gam-COVID-Vac), AstraZeneca (ChAdOx1 nCov-19), Sinopharm (BBIBP-CorV) and Moderna (mRNA-1273). Limited information is available about vaccines against SARS-CoV2 with inactivated virus or viral vector in autoimmune patients.

Objectives: To evaluate the humoral immune response to vaccines against SARS-CoV2 in patients with autoimmune rheumatic diseases; to compare the humoral response among patients with Systemic Lupus Erythematosus (SLE) and other autoimmune diseases and to analyse the variables associated.

Methods: We included patients with autoimmune rheumatic diseases (Rheumatology Unit of Padilla Hospital, Tucumán, Argentina), who received vaccination against SARS-CoV2 from June 2021. Sociodemographic, comorbidities, related to rheumatic disease, vaccination and SARS-CoV2 infection were the variables recorded. To evaluate the humoral immune response, the neutralizing anti-S-RBD IgG antibody titres were determined by ELISA "In House" test with a cut-off titre of 200 (IMMCA). The times established for the serological determinations were: T0 or baseline: 1st vaccine dose, T1: 14 ± 2 days after the 1st dose, T2: 2nd dose, T3: 21- 45 days after the 2nd dose, T4: 30 days after the 3rd dose, T5: 6 months and T6: 12 months after the 3rd dose.

Results: 66 patients were included, 91% women and 92.4% Amerindians. The mean age was 40.7 ± 11.4 years; 53% with SLE, 15.2% Rheumatoid Arthritis, 7.6% Systemic Sclerosis, 7.6% Juvenile Idiopathic Arthritis, 7.6% Systemic Vasculitis and 9% other diagnoses; mean disease duration was 12.05 ± 7.5 years; 63.6% had at least one comorbidity (57% HBP, 31% overweight or obesity). At baseline, the treatments received were: corticosteroids (37.9%, prednisone mean dose 4.12 ± 8 mg/day), cDMARDs (75.7%), bDMARDs (18.2%): Rituximab (58.3%) and anti TNF (25%). Sixteen patients (24.2%) had previous COVID19 (75% mild symptoms). The vaccines applied were: AstraZeneca 38.2%, Sinopharm 31.7%, Sputnik V 19%, and combined schedule Sputnik V/ Moderna in 11%. At baseline, 28.8% had detectable anti-S-RBD IgG antibodies. This frequency increased to 48.4% at 1st dose and 70.2% at 2nd dose. The variables that were associated with lower seroconversion rates and lower antibody titre were vaccination with Sinopharm (p 0.028) and treatment with bDMARDs (p 0.02), none of the 5 patients with Rituximab showed seroconversion. There were no significant differences in the levels of anti-S-RBD IgG antibodies between patients with SLE and the other rheumatic diseases. Patients who had SARS-CoV2 infection prior to vaccination had higher antibody titres in both T1 (p 0.006) and T2 (p 0.002) but after the two doses this difference was not significant (p 0.67). In the regression analysis, the variables that were independently associated with seroconversion were the type of vaccine applied at the 1st dose and the hypertensive disease. The chance of responding to vaccination was 13 and 9 times higher for those who received Sputnik V (OR 12.78; 95% CI 1.46 - 315.9) or AstraZeneca (OR 8.61; 95% CI 1.63 - 72.5) respectively, than Sinopharm in the 1st dose. The chance of being a responder was 88% lower for hypertensive patients (OR 0.12; 95% CI 0.02 - 0.58).

Conclusion: In this preliminary analysis, a seroconversion rate of 70.2% was associated with two-dose vaccination for SARS-CoV2 in patients with autoimmune rheumatic diseases. There were no differences in the serological response between patients with SLE and other rheumatic diseases. The humoral immune response was lower in patients with bDMARDs and null in those who received Rituximab. Seroconversion and antibody titres levels were associated with the type of vaccine applied, being Sinopharm who presented the lowest response. The follow-up will provide more knowledge about the behaviour of the humoral response in our patients.

AB1146 SARS-COV-2 VIRAL LOAD IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASE, A RETROSPECTIVE COMPARATIVE STUDY

O. Alsaed[1], Y. A. Y. Alrimawi[1], R. Saleh[1], M. Chaponda[2], P. Coyle[3], K. Becetti[1], H. Ashour[1], E. Elsayed[1], M. Hamed[1], F. Alam[1], B. Awadh[1], M. Hammoudeh[1], S. Al Emadi[1]. [1]*Hamad Medical Corporation, Medicine/Rheumatology, Doha, Qatar*; [2]*Hamad Medical Corporation, Medicine/Infectious disease, Doha, Qatar*; [3]*Hamad Medical Corporation, Laboratory Medicine and Pathology, Doha, Qatar*

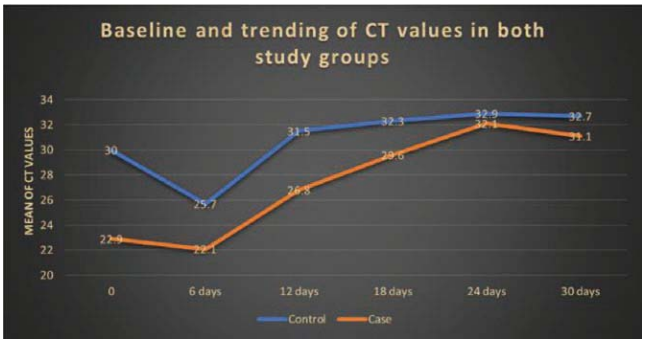
Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) viral load and its impact on disease outcome in patients with autoimmune rheumatic disease (ARD) are lacking. Also, whether patients with ARD receiving immunomodulators have different viral loads compared to the general population is unknown.

Objectives: To compare the viral load of SARS-CoV-2 and its trending between patients without and with ARD.

Methods: Retrospectively, patients with ARD infected with SARS-CoV-2 were matched by age and sex at a ratio of 1:2 to patients without ARD and not receiving immunosuppression or immunomodulator drugs. Viral load was determined by the cycle threshold (CT) value measured by a number of platforms: (a) Automated Platforms - the Roche Cobas 6800 system using the Cobas SARS-CoV-2 Test targeting the E and orf1a/b genes (Roche, Switzerland) and the Xpert Xpress SARS-CoV-2 targeting the E and N genes (Cepheid, USA); (b) Manual platforms - EZ1 (QIAGEN, USA), QIAsymphony (QIAGEN, USA), and Bioneer ExiPrepTM 96 Virus DNA/RNA kits Catalogue No K4614 (Bioneer, South Korea) extraction with thermal cycling using TaqPath™ PCR COVID-19 Combo Kit targeting the N, S and orf1a/b genes (Thermo Fisher Scientific, USA) on ABI 7500 thermal cyclers. Independent samples t-test was used to compare the mean CT values of the study groups at baseline and at 5 subsequent intervals (1 – 5.9, 6 – 11.9, 12 – 17.9, 18 – 23.9 and 24 – 30 days).
Results: Mean age (SD) of 197 cases and 420 controls were 45.2 (11.8) and 44.1 (12.3) years, respectively. Females were predominant in both groups 60% vs. 52%, P=0.053. The most common ARD was rheumatoid arthritis in 82 cases (41.6%), followed by spondyloarthropathy in 33 (16.8%) and systemic lupus erythematosus in 31 (15.7%). Of the cases, 67% were on conventional synthetic disease modifying anti-rheumatic drugs (DMARDs), 15.2% on biological DMARDs and 4.6% patients were on rituximab. The mean CT values was significantly lower in the ARD group at baseline and persisted till day 24.

Table 1. demographic characteristics and comparison of the mean CT values in the study groups at baseline and at different intervals with the corresponding OR (95% CI)

	Case (N=197)	Control (N=420)	OR (95% CI)
Mean (SD) age, years	45.2 (11.8)	44.1 (12.3)	1.008 (0.994–1.022)
Sex, female N (%)	120 (60.9%)	221 (52.6)	0.713 (0.505–1.006)
Mean (SD) CT values at Baseline	22.9 (5.5)	30 (5.2)	**0.799 (0.745–0.858)**
1 – 5.9 days	22.1 (4.6)	25.7 (6.3)	**0.901 (0.842–0.963)**
6 – 11.9 days	26.9 (4.9)	31.5 (3.9)	**0.802 (0.724–0.888)**
12 – 17.9 days	29.6 (4.1)	32.3 (3.2)	**0.827 (0.743–0.921)**
18 – 23.9 days	32.1 (4)	32.9 (2.5)	0.903 (0.728–1.119)
24 – 30 days	31.2 (1.2)	32.7 (2.6)	0.824 (0.589–1.151)



Conclusion: Compared to patients without ARD, the viral load of SARS-CoV-2 in patients with ARD is significantly higher at baseline testing and persists till day 24. This finding may indicate that patients with ARD are at higher risk of severe SARS-CoV-2 infection and prolonged potential transmission. Clinical outcome correlation is needed.

AB1147

COVID 19 INFECTION IN PATIENTS WITH RHEUMATIC IMMUNE-MEDIATED DISEASES IN A SINGLE UNIVERSITY HOSPITAL. MATCHED CASE-CONTROL STUDY.

D. Martínez-López[1], D. Prieto-Peña[2], F. Benavides-Villanueva[2], L. Sanchez-Bilbao[2], C. Corrales-Selaya[2], A. Herrero-Morant[2], C. Álvarez-Reguera[2], M. Trigueros-Vazquez[2], R. Wallman[3], M. A. González-Gay[2], R. Blanco[2].
[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain; *[2]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain*; *[3]Servicio Cántabro de Salud, Epidemiology, Santander, Spain*

Background: COVID19 may present different degrees of severity. It is generally thought that viral infections in patients with rheumatic inflammatory diseases (R-IMID) or receiving immunosuppressive treatment tend to present more severe disease. However, data comparing the severity of the disease between R-IMID and the general population are scarce.
Objectives: To assess the predisposing factors, clinical-analytical features and severity of COVID-19 infection in R-IMID compare to patients without R-IMID.
Methods: Case-control study in a single University Hospital. We included all consecutive patients with a diagnosis of a R-IMID and a positive test for COVID-19 up to March 31st, 2021. A total of 274 controls were selected for each case, and matched by sex, age (± 5 years), and without previous diagnosis of R-IMID or use of immunosuppresive therapy. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2. COVID-19 case severity was divided into mild, moderate, severe and critical according to the United States National Institute of Health (NIH) COVID-19 guidelines **(1).** Mild/moderate COVID19 was compared with critical.
Results: We included 274 patients (185 women/89 men), mean age 59.1 18 years. More frequent R-IMID were: Rheumatoid arthritis (RA) (n=87, 31.8%), Axial spondyloarthritis/ Psoriatic arthritis (SpA/PsA) (n=90, 32.8%), Polymyalgia Rheumatica (PMR) (n=22, 8%) and Systemic Lupus Erythematosus (SLE) (n=22, 8%) We also included 274 age and matched controls. Main characteristics of patients with R-IMID and controls are shown in **Table 1**.

Table 1. Main clinical and analytical features of patients with R-IMID and matched controls

	R-IMID patients (n=274)	Controls (n=274)	P
Age	59.1±18	58.8±17.3	0.842
Sex F/M, n, (%)	185/89 (67.5/32.5)	185/89 (67.5/32.5)	1
Comorbidities (n,%)			
Hypertension	119 (43.4)	84 (30.7)	**0.0026***
Dyslipidemia	119 (43.4)	79 (28.8)	**0.0005***
Diabetes mellitus	36 (13.1)	37 (13.5)	1
Pulmonary disease	29 (10.6)	32 (11.7)	0.79
Cardiovascular disease	45 (16.4)	33 (12)	0.18
Severity of the disease (n, %)			
Mild	209 (76.3)	204 (74.5)	0.69
Moderate	35 (12.8)	47 (17.2)	0.19
Severe	9 (3.3)	14 (5.1)	0.39
Critical	21 (7.7)	9 (3.3)	**0.04***
Deaths	17 (6.2)	7 (2.6)	**0.0076***
Analytical values, median [25-75th IQR]			
CRP	4.7 [2-9.3]	3.9 [1-7.3]	0.176
Lymphocytes (x103 /µL)	1 [0.6-1.5]	1.1 [0.8-2.5]	0.711
Platelets (x103 /µL)	179 [141-237]	174 [155-211]	0.722
D-Dimer (ng/mL)	999 [342-1417]	548 [336-997]	**0.032***

CRP: C-reactive protein.

Concerning comorbidities, hypertension and dyslipidemia were more frequent in patients with R-IMID (p< 0.05). COVID-19 symptoms' distribution is shown in Figure 1.

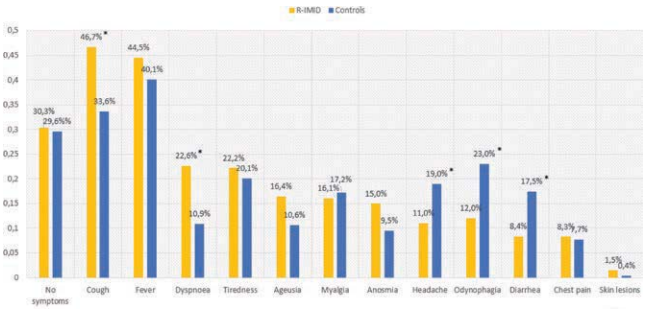

Figure 1. Symptoms in R-IMID patients and matched controls

*: p < 0.05

Cough and dyspnoea were more frequent and headache, odynophagia and diarrhea were less frequent in the R-IMID group. The only analytical difference was D-Dimer that was significantly higher in patients with R-IMID. Although most of the cases were mild, critical cases and deaths were more frequent in R-IMID (p <0.05).
Conclusion: Most of the patients present a mild COVID-19. However, a more severe syndrome was observed in R-IMID

AB1148 POST COVID-19 RHEUMATIC AND MUSCULOSKELETAL DISEASES

N. Varghese[1], N. Loghin-Oprea[1], V. Sadovici-Bobeica[1]. *[1]Nicolae Testemițanu State University of Medicine and Pharmacy, Internal Medicine, Chișinău, Moldova, Republic of*

Background: Recent data suggests that SARS-Cov-2 can alter self-tolerance and trigger autoimmune responses through cross-reactivity with host cells; therefore it can lead to late autoimmune and inflammatory manifestations. With regard to rheumatic and musculoskeletal diseases (RMDs), medical literature displays sporadic case reports describing a variety of conditions diagnosed after COVID-19, but it remains still unclear what are the most common problems in patients presenting to rheumatology clinic following COVID-19 disease.
Objectives: To describe the pattern of post-COVID-19 RMDs in a consecutive group of patients from rheumatology outpatient clinic.
Methods: We have performed an observational descriptive study of a group of adult patients who received a new diagnosis of RMD within a timeframe of 12 weeks after the confirmation of COVID-19. Data was collected based on clinical presentation, paraclinical pattern and radiological examinations.
Results: The study included 23 patients who were consulted in rheumatology outpatient clinic and had post COVID-19 new onset joint, periarticular, bone or inflammatory syndrome manifestations. The general characteristics of the study group were as follows: mean age 45.5±11.3 (range 21-63) years and female to male ratio of 1.8:1. The majority of subjects consulted for joint symptoms (91.4%), in other cases reason for consultation was persistent low grade fever and fatigue (4.3%) and skin rash with dyspnea (4.3%). The mean duration of symptoms was 9.8±10.5 (range 1-42) weeks, and the time of onset after COVID-19 diagnosis was 4.9±4.1 (range 0-12) weeks. Concerning COVID-19 severity, it was established that in 60.9% it was mild, 17.4 % - moderate and 21.7% - severe. After clinical and paraclinical examination, the following diseases were diagnosed: ReA, lupus like syndromes, avascular necrosis, new onset RA and new onset PsA. In 69.7% of patients were diagnosed with ReA, the clinical pattern being joint or periarticular involvement of the hand, knee and feet. In 13.0% cases patients had multisystemic involvement (myocarditis, pericarditis, skin rash, inflammatory arthritis and/or low grade fever) and positive ANA and or dsDNA Ab, these cases were diagnosed as lupus like syndromes and followed a severe form of COVID-19. In 8.7% of patients who presented with non-inflammatory hip pain, avascular necrosis was diagnosed, in both cases femoral head being the affected part. No be noted that patients with avascular necrosis had a severe form of COVID-19 disease and joint pain started later after COVID-19 diagnosis (10-12 weeks). In 4.3% of cases each, new onset RA and PsA were identified.
Conclusion: In the present study we have found that COVID-19 can be followed by a variety of RMDs. The most common symptom of patients presenting with RMD was joint pain. The most common disease was post-COVID ReA (69.7%). Avascular necrosis (8.7%) and lupus like syndromes (13.0%) were found in patients who experienced a severe form of COVID-19. More rarely, patients had new onset of rheumatoid arthritis (4.3%) or psoriatic arthritis (4.3%). Our findings suggest that during the COVID-19 recovery period patients might experience onset of RDMs; therefore, in the presence of joint symptoms or other manifestations suggesting an autoimmune disease, patients should be referred to a rheumatologist for careful clinical examination.

AB1149 EVALUATION OF THE EFFICACY AND SAFETY OF THE SARS-COV-2 VACCINE IN PATIENTS WITH CHRONIC INFLAMMATORY DISEASES TREATED WITH BIOLOGICAL THERAPY.

J. Calvo Gutierrez[1], C. López-Medina[1], M. C. Ábalos-Aguilera[1], A. B. Pérez Jiménez[2], D. Ruíz-Vilchez[1], F. U. Pilar[1], R. Ortega Castro[1], A. Escudero Contreras[1], E. Collantes Estevez[1]. *[1]Reina Sofia University Hospital; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC); Córdoba University (UCO)., Rheumatology Departmen, Córdoba, Spain; [2]Reina Sofia University Hospital; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC); Córdoba University (UCO)., Microbiology Departmen, Córdoba, Spain*

Background: In the current situation of the SARS-CoV-2 pandemic, the Spanish Society of Rheumatology recommends vaccination of patients with chronic inflammatory diseases (CID) under treatment with biological DMARDs (bDMARDs). However, the data regarding the generation of protective antibody titers after mRNA vaccines in patients with CID is limited.
Objectives: To determine the seroconversion rate and safety after the SARS-CoV-2 vaccine in patients with CID under treatment with bDMARDs
Methods: Cross-sectional observational study of 81 patients with CID from the HURS in Córdoba, who have received full vaccination for SARS-CoV-2 (without having previously suffered from COVID-19 disease) according to national guidelines. A determination of specific IgG-type antibodies against the trimeric spike protein of SARS-CoV2 was performed on all of them. The chemiluminescence technique with the kit was used in serum samples taken 4-5 weeks after administration of the second dose of the vaccine. Information about sociodemographic characteristics, disease, type of bDMARDs, concomitant treatments and adverse effects after the second dose of the vaccine were collected in each patient.
Results: 81 patients were included (mean age 59.5, 72.8% females). 50.6% of patients had RA, 17.3% SpA, 11% PsoA and 18.5% other CID. 23.5% were under treatment with Rituximab, 38.8% antiTNF, 13.6% Tocilizumab, 9.9% abatacept, 5% anti-JAK and 14.2% under other treatments. Anti-SARS-CoV-2 antibodies and neutralizing activity were detected in 80% of study participants. Rituximab treatment was significantly associated with negative seroconversion in comparison with patients under antiTNF treatment (OR 84.0 (95%CI 12.9-1709.2)). No interaction was found between the bDMARDs treatment and the type of vaccine with regard to the seroconversion, nor between bDMARDs and concomitant synthetic DMARD. When we evaluated IgG titers against the spike protein of SARS-CoV2, we found that patients under treatment with Rituximab showed the lowest titers levels in comparison with patients with other treatments (Figure 1, Table 1). In addition, patients who received AstraZeneca vaccine developed lower titers of antibodies in comparison with patients who received Pfizer (Table 1).

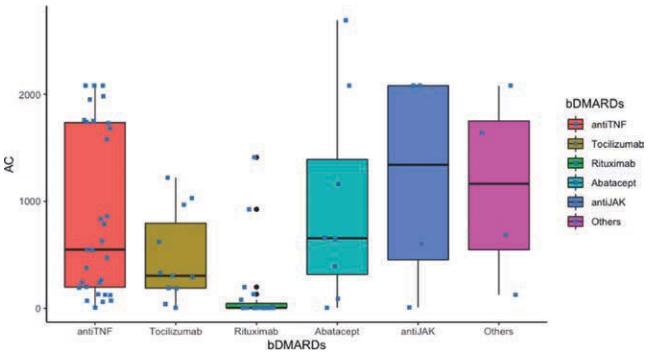

Figure 1. IgG titers against the spike protein of SARS-CoV2 with regard to the bDMARD

Table 1. Linear regressions to evaluate the IgG titers and their association with the bDMARD and the type of vaccine.

	Beta Coefficient (95% CI) IgG titers	p-value
bDMARD	Reference	
- Anti-TNF	-405.6 (-893.7 to 82.4)	
- Anti-IL6	-728.7 (-1133.8 to -323.5)	0.102
- Rituximab	88.7 (-462.8 to 640.1)	**<0.001**
- Abatacept	315.6 (-423.2 to 1054.4)	0.749
- Anti-JAK	256.3 (-482.5 to 995.1)	0.397
- Otros		0.491
Vaccine		
- Pfizer	Reference	
- AstraZeneca	-408.6 (-804.6 to-12.6)	**0.043**
- Janssen	- 783.4 (-1662.1 to 95.3)	0.08
- Moderna	130.6 (-407.5 to 668.7)	0.63
Methotrexate* bDMARD	27.3 (-215.3 to 269.9)	0.823
Leflunomide* bDMARD	208.0 (-188.9 to 604.9)	0.300
Corticosteroides* bDMARD	32.9 (-259.4 to 325.2)	0.823
Vaccine* bDMARD	4.2 (-106.1 to114.6)	0.939

Interestingly, among patients with antiTNF treatment, AstraZeneca was associated with lower IgG titers in comparison with Pfizer and Moderna [405.9 (553.0) vs. 1084.1 (791.2) vs. 1264.0 (1012.6), p=0.016, respectively]. No differences between vaccines were found in patients with the other type of bDMARDs.
Only 18.9% presented mild adverse effects. No serious adverse effects were observed and no patient experienced a disease flare after vaccination.
Conclusion: Our results show that SARS-CoV-2 mRNA vaccines produce seroconversion in most patients with CID, except in the case of patients with rituximab. No severe adverse effects or CID reactivation were found. Despite the small number of patients included, this study suggests the need for revaccination in the group of patients treated with rituximab or vaccinated with Astrazeneca.

AB1150 IMMUNOGENICITY AND SAFETY OF THE CORONOVAC AND BNT162B2 COVID-19 VACCINE IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES AND HEALTHY ADULTS: COMPARISON OF DIFFERENT VACCINES

S. Batıbay[1], R. Koçak Ulucaköy[2], Z. Günendi[1], I. Fidan[3], G. Bozdayı[3], F. N. Göğüş[4]. *[1]Gazi University, Rheumatology, Ankara, Turkey*; *[2]Hatay Training and Research Hospital, Rheumatology, Hatay, Turkey*; *[3]Gazi University, Medical Microbiology, Ankara, Turkey*; *[4]Gazi University, Rheumatology, Ankara, Turkey*

Background: Having an autoimmune disease was an exclusion criterion in the efficacy and safety phase studies of vaccines against Covid-19 (1-2). In Turkey vaccination first started with the inactivated CoronaVac, then with the mRNA BNT162b2 vaccine. Although there are studies on vaccine efficacy and safety in adults with inflammatory rheumatic disease (IRD), there are still many unknowns (3-4).
Objectives: Primary outcome of this study is to determine the seroconversion (SC) rate after CoronaVac and BNT162b2 vaccines in adults with IRD and to compare it with a healthy control group. Secondary outcomes are to evaluate whether there are efficacy differences in the two vaccine types, and to investigate the effects of the biologic agent used in the patient group on the vaccine immunogenicity.
Methods: This prospective observational single center study was conducted at the Gazi University Hospital. Patients who were followed up in our outpatient clinic with IRD and who received two doses of either CoronaVac or BNT162b2 vaccines were included. Subjects with two doses one of these vaccine without IRD were included in the healthy control group. Patients who had Covid-19 infection before or during vaccination were excluded. The demographic characters were recorded. The interval between the two doses was 4 weeks. The blood samples of the patient and control groups were taken a minimum of two and a maximum of 12 weeks after the second dose. Anti-S antibodies against SARS-CoV-2 spike proteins were evaluated with the IgG Abbott kit, and a value above 50 arbitrary unit/ml was considered as positive SC. The neutralizing antibody titers were evaluated with the DIA.PRO kit, and cut-off value was above 1 Co/S.
Results: The SC rate was slightly lower among patients with IRD versus controls (84% vs 97%, p:0.002). The SC rate was 100% in all participants who received BNT162b2 both in the patient and control group. The IgG antibody level after CoronaVac was significantly lower than that of BNT162b2 vaccine (p:0.031) in both patient and healthy controls (p:0.001). Among patients with IRD, those on rituximab (RTX)(12/81, %14.8) had significantly less SC rate (5/12, 41.7%) compared to patients on other biologicals (63/69, 91.3%) (p<0.001).
Conclusion: This study showed that all patients with BNT162b2 vaccine developed immunogenicity in patients with IRD, while there was a decreased antibody response with CoronaVac vaccine compared to the healthy control group. In particular, the use of RTX significantly reduces the SC rate.

AB1151 DOES PREDNISONE AFFECT COVID19 VACCINE T CELL RESPONSE? A STUDY OF VACCINE RESPONSE IN PATIENTS WITH IMMUNE SYSTEM DISEASES

L. Sailler[1], A. Blancher[2], F. Abravanel[3], J. Izopet[4], C. Bost[5], E. Treiner[6], N. Congy[7], Y. Renaudineau[3,7]. *[1]CHU Toulouse, University Toulouse III, Internal Medicine, TOULOUSE, France*; *[2]Immunology Department Laboratory, Institut Fédératif de Biologie, University Toulouse Hospital, Toulouse, France*; *[3]INFINITy, Toulouse Institute for Infectious and Inflammatory Diseases, INSERM U1291, CNRS U5051, TOULOUSE, France*; *[4]Virology Department Laboratory, Institut Fédératif de Biologie, INSERM U1291, CNRS U5051, University Toulouse III, Toulouse, France*; *[5]2.Immunology Department Laboratory, Institut Fédératif de Biologie, University Toulouse Hospital, 3.INFINITy, Toulouse Institute for Infectious and Inflammatory Diseases, INSERM U1291, CNRS U5051, Toulouse, France*; *[6]Immunology Department Laboratory, Institut Fédératif de Biologie, University Toulouse Hospital, 3.INFINITy, Toulouse Institute for Infectious and Inflammatory Diseases, INSERM U1291, CNRS U5051, Toulouse, France*; *[7]Immunology Department Laboratory, Institut Fédératif de Biologie, University Toulouse Hospital, Toulouse, France*

Background: A whole blood interferon gamma release assay (IGRA) based on the stimulation of SARS-Cov2-specific memory T cells using purified and full-lenght Spike and Nucleocapsid recombinant proteins was developed, together with anti-Spike antibody detection.
Objectives: To study COVID19 vaccine cellular and humoral responses in patients with immune system diseases (ISD) and healthy controls.
Methods: Non-vaccinated healthy individuals (n=103), SARS-Cov-2 infected individuals (n=9), and 104 samples from individuals having received COVID19 vaccine including 28 non-sars-cov2 infected patients with ISD diseases were included. Preliminary experiments were initiated using different platforms (ELISpot, IGRA, recombinant proteins or peptides) in order to evaluate Spike T cell

response in volunteers vaccinated with BNT162b2 showing a S2>S1 poly-epitopic response.

Results: Twenty-eight patients (25 women, 3 men; mean age 59.1(±17,8)) with various ISD were investigated. These patients suffered from lupus (n=14), vasculitis (n=4), myositis (n=2), sarcoidosis (n=2), primary immunodeficiency (n=3), Sjögren's syndrome (n=2) and pericarditis (n=1). Three patients had received 4 doses, 16 three doses, and 8 two doses of vaccine (Pfizer: n=25; Moderna n=1, Astra-Zeneca n=1). One patient refused the vaccination. The tests were performed 86.7 (±60.5) days after last vaccine dose. Ten patients were on prednisone (mean dose: 11,8 mg, median 7.5 mg, range: 5-40). Among those patients, 6 had only prednisone, 1 was also treated with belimumab, 3 with methotrexate (MTX) and 1 with azathioprine (AZA). Following COVID19 vaccination, humoral (100% in healthy vs 84.6% in ISD patients) and IGRA-Spike T cell (96% in healthy vs 59.7% in AI patients) responses took place with lower response reported among the ISD disease group (Figure 1). Humoral and cellular COVID19 vaccine responses significantly decrease after 100 days post vaccine.

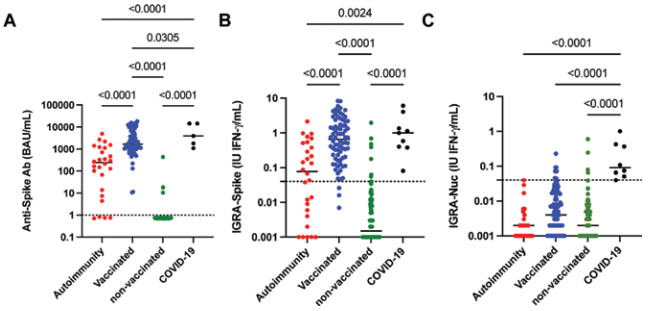

Figure 1. SARS-Cov2 humoral and T cell responses in non-vaccinated healthy individuals (n=103), SARS-Cov-2 infected individuals (n=9), and 104 samples from individuals having received COVID19 vaccine including 28 non-Sars-cov2 infected patients with ISD diseases. A- Anti-SARS-Cov2 Spike total IgM/IgG/IgA antibody (Ab) titers (BAU/mL) tested by ELISA. B- Whole blood IFN-γ release assay (IGRA) response to the full-length Spike recombinant protein (IGRA-Spike). C- Whole blood IGRA response to the nucleocapsid recombinant protein (IGRA-Nuc). Positivity cut-off (dot line) p values <0.05 are indicated when significant (ANOVA).

5/5 vaccinated patients on CS alone, 2/5 vaccinated patients on corticosteroids with MTX/AZA/Belimumab and 3/17 other vaccinated patients (all being primary immunodeficiency patients) had no cellular response. Humoral and T cell responses were independent from sex and age.

Conclusion: Altogether, this ongoing study confirms the utility of the IGRA-Spike/-nucleocapsid assay coupled with serology in COVID19 vaccinated individuals and in particular in ISD patients treated with steroids, who may be at risk when the humoral protection decreases.

AB1152 COVID-19 MRNA VACCINE BOOSTER IN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES

C. Cardelli[1,2], T. Caruso[1,3], C. Tani[2], F. Pratesi[1,3], R. Talarico[2], F. DI Cianni[1,2], N. Italiano[1,2], E. Laurino[1,2], M. Moretti[1,2], G. Cascarano[1,2], M. Diomedi[1,2], L. Gualtieri[1,2], R. D'urzo[2], P. Migliorini[1,3], M. Mosca[1,2]. [1]*University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy*; [2]*Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy*; [3]*Azienda Ospedaliero-Universitaria Pisana, Immunoallergology Unit, Pisa, Italy*

Background: Patients with systemic autoimmune diseases (SADs) are often treated with drugs that interfere with the immune system and previous data showed a reduced seroconversion rate after anti-SARS-CoV2 vaccine in these subjects compared to healthy controls[1]. Administration of a booster dose of the vaccine could be particularly important in these patients, but data available to date are still scarce.

Objectives: To evaluate the antibody response to the booster dose of mRNA SARS-CoV2 vaccine in patients with SADs and to compare it to the response after completion of the first vaccination course. Secondly, to find possible correlations between a low antibody titre and patients' clinical features, with special regard to ongoing immunosuppressive therapies.

Methods: Consecutive patients with an established diagnosis of SADs undergoing SARS-CoV2 vaccine were prospectively enrolled from January 2021; among them, we selected the patients who received the third vaccination dose between September and December 2021. Demographic and clinical data were collected at enrolment (sex, age, diagnosis, disease duration, ongoing therapies, previous SARS-CoV2 infection, presence of hypogammaglobulinemia); the last three elements were reassessed at each follow-up visit. Blood samples were collected 4 weeks both after the second (W4a) and the third (W4b) dose of the vaccine; a minority of patients was also tested 12 weeks after the second dose (W12). IgG antibodies to SARS-CoV2 receptor-binding domain (RBD) and neutralizing antibodies inhibiting the interaction between RBD and angiotensin converting enzyme 2 were evaluated. IgG anti-RBD were detected by solid phase assay on plates coated with recombinant RBD, while neutralising antibodies by using the kit SPIA (Spike Protein Inhibition Assay). Cut-off values were defined as the 97.5th percentile of a pre-vaccine healthy population. Statistical analysis was performed using IBM SPSS Statistics 20 and GraphPad Prism statistical packages. P values <0.05 were considered significant.

Results: Forty-five patients (95.6% female; mean age ±SD 55.6±14.1 years; mean disease duration 12.9±10.6 years) were enrolled. Diagnosis was in most cases connective tissue disease (31/45, 68.9%), followed by inflammatory arthritis (11/45, 24.4%) and systemic vasculitis (3/45, 6.7%). Two patients (4.4%) had a previous SARS-CoV2 infection and three had hypogammaglobulinemia (6.7%). At the time of the second dose, 18/45 patients were treated with glucocorticoids (GCs) [mean daily 6-methylprednisolone (6MP) dose 3.9 mg (min. 2, max. 14)], 17/45 with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) and 12/45 with biologic DMARDs (bDMARDs). At the third dose administration, 19/45 patients were treated with GCs [mean daily 6MP dose 4.1 mg (min. 1.5, max. 10)], 18/45 with csDMARDs and 13/45 with bDMARDs. Anti-RBD IgG were positive in 42/45 patients (93.3%) at W4a, in 16/18 (88.9%) at W12 and in 42/45 (93.3%) at W4b. Neutralizing antibodies were present in 38/45 patients (84.4%) at W4a, in 14/18 (77.8%) at W12 and in 42/45 (93.3%) at W4b. Both anti-RBD IgG titers and neutralizing antibody titers significantly increased after the third dose if compared to W4a (p<0.0001 both) (Figure 1). Interestingly, of the 7 patients who had not developed an adequate neutralizing antibody response after the first vaccination course, 5 mounted an adequate titer after the booster. Two non-responder patients were both on combination therapy (one with low dose of GCs plus mycophenolate mofetil, the other with methotrexate and infliximab).

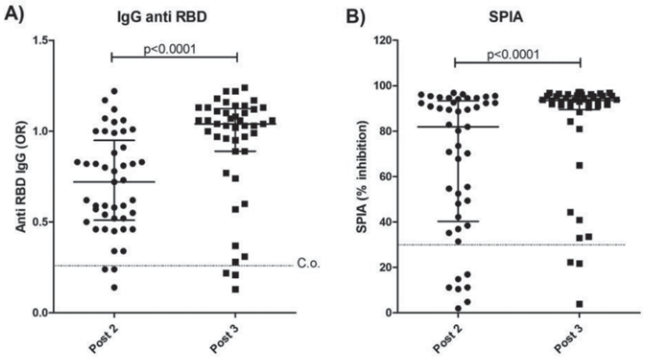

Fig. 1: levels (A) and neutralizing ability (B) of anti-RBD antibodies.

Conclusion: Our data suggest that in patients with SADs there is a decline in the antibody titers developed after COVID-19 vaccination, however the booster dose is effective in restoring an adequate antibody titre. These data consolidate the importance of a booster dose of COVID-19 vaccination in patients with SADs to aid in the generation of an immune response.

AB1153 HYPEREOSINOPHILIC SYNDROME FOLLOWING THE BNT162B2 (BIONTECH / PFIZER) VACCINATION

A. Hoxha[1], T. Tomaselli[1], G. Minicuci[2], G. Scanelli[1], D. Zardo[3], L. Naldi[4]. [1]*San Bortolo Hospital, Internal Medicine Unit, Department of Medicine, Vicenza, Italy*; [2]*San Bortolo Hospital, Department of Neurosciences, Vicenza, Italy*; [3]*San Bortolo Hospital, Department of Pathology, Vicenza, Italy*; [4]*San Bortolo Hospital, Department of Dermatology, Vicenza, Italy*

Background: Some reports of small vessel vasculitis following nSARS-CoV2 vaccination are reported in the literature (1, 2).

Objectives: We purpose to report the case of small-medium vessel vasculitis after BNT162b2 (BioNTech/Pfizer) vaccination.

Methods: We present the case of a 48 years old man with an unremarkable history who underwent BNT162b2 vaccination.
Results: Five days after the first shot of BNT162b2 vaccine, the patient refer the onset of left inguinal adenopathy, and erythematous dermatitis of the trunk. Ultrasound of the groin found increase bilateral inguinal lymph nodes with reactive characters. Contextually, erythematous, itchy and painful nodular lesions appear in the lower and upper limbs as well as acrocyanosis and paresthesia in the right hand and foot. The tests performed showed thrombocytopenia and eosinophilia. While, CRP, search for fecal parasites, pANCA, cANCA, ANA, RAST test, serum tryptase were all absent. Haematological evaluation, bone marrow biopsy, karyotype and molecular biology (FIP1L1/PDGFRa), were performed, all results negative. The patient was admitted in Internal Medicine ward for worsening of skin lesions and of acrocyanosis with gangrenous lesions at the tips of the fourth finger of the right hand. An angio-CT showed an occlusion of the right ulnar artery. At electromyography an axonal sensory neuropathy was found. The skin biopsy showed fibrinoid necrosis of venules of the superficial vascular plexus associated with numerous eosinophils, lymphocytes and karyorrhetic debris (Figure 1). High-resolution CT scan described diffuse minimal accentuation of the interstitial texture with micronodular aspects and some ground glass appearance. The diagnosis of hypereosinophilic syndrome was made. Therapy with Methylprednisolone 500 mg/daily for 3 days then Prednisone 1 mg/ kg daily in association with IL-5 inhibitor (mepolizumab) with good clinical response, in addition to anticoagulation with warfarin was started.

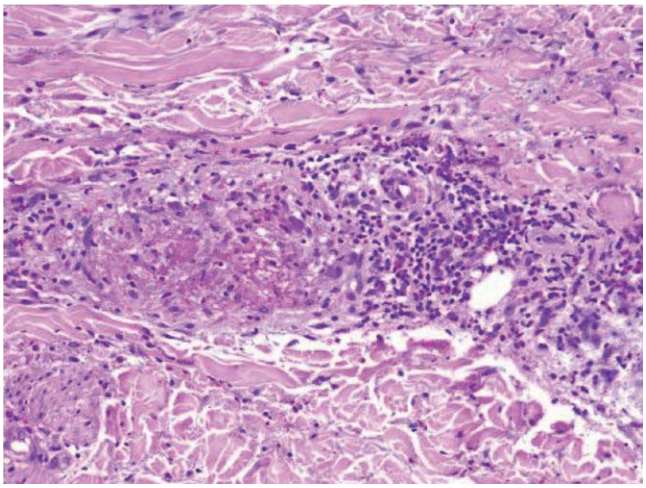

Figure 1.

Conclusion: To our knowledge this might be the first case of (HES) following COVID vaccine. As our experience, due to the short commercialization of antinSARs-CoV2 vaccines, is limited further studies are needed to explore the possible effect on small-medium vessels.

AB1154 HUMORAL AND CELLULAR RESPONSE TO A THIRD BOOSTER DOSE SARS-COV- 2 VACCINATION IN PATIENTS WITH AUTOIMMUNE DISEASE: A CASE SERIES

T. Dimitroulas[1], A. Tychala[2], K. Defteraiou[1], E. Katsimpourlia[3], E. Sidiropoulou[2], M. Papachristou[4], A. Fylaktou[4], L. Skoura[2]. *[1]Aristotle University of Thessaloniki, 4th Department of Internal Medicine, Hippokration general Hospital, Thessaloniki, Greece*; *[2]Aristotle University of Thessaloniki, Department of Microbiology, Ahepa University Hospital, Thessaloniki, Greece*; *[3]Papanikolaou General Hospital, Department of Immunology, Thessaloniki, Greece*; *[4]Hippokratio General Hospital of Thessaloniki, Immunology Departments, National Peripheral Histocompatibility Center, Thessaloniki, Greece*

Background: Patients with systemic rheumatic diseases (SRD) are at increased risk for viral infections and successful vaccination is crucial to combat COVID-19 pandemic in this population. However, reduced antibody responses have been described in a proportion of SRD individuals on immunosuppressant agents including mycophenolate (MMF).
Objectives: We aimed to assess humoral and cellular response of SRD patients who received a booster SARS-CoV- 2 vaccination.
Methods: Twenty patients without history of COVID-19 infection (11 men, median age 58 years (range:38-74), 12 on treatment with MMF (2gr daily) due to systemic sclerosis (n= 6), inflammatory myositis (n=4) and systemic lupus erythematosus (n=2) and 8 on tumor necrosis factor-alpha inhibitors (anti-TNF) due to spondyloarthritis (n=5), rheumatoid arthritis (n=2) and Bechet disease (n=1) were included. All were on monotherapy with anti-TNF except patient with Bechet. Patients on MMF discontinued treatment for 1 week after the booster dose whistle no treatment modification was implemented in anti-TNF group. Serological response to vaccination was assessed using the Abbott SARS-CoV-2 IgG II Quant assay. Cellular immunity was estimated via interferon-γ produced by CD4+ and CD8+ T-lymphocytes in response to a SARS-CoV-2 peptide cocktail, with the SARS-CoV-2 ELISA Kit.
Results: Nineteen patients (95%) demonstrated positive serological response following booster vaccine dose (Table 1). Only one female patient in MMF group failed to develop adequate levels of antibodies. The median antibody titers of patients under MMF and anti-TNF was 647.90 BAU/mL (range: 0.71-4795.32 BAU/mL) and 542.98 BAU/mL (range: 4.32-1391.33 BAU/mL) respectively. No statistically significant difference was found between the two groups. Regarding cellular immunity a T-cell response was present in all patients on monotherapy with anti-TNF but only in 7/12 under MMF including the one with negative humoral response.
Conclusion: We report sufficient immunogenicity following a third booster vaccine in patients with RSD on immunossupresive medications coupled by a strong cellular immune response particularly in patients on anti-TNF monotherapy. Perrivaccination management of immunosuppressive therapy represents an important parameter of vaccine administration in patients with RSD.

AB1155 PAUSING METHOTREXATE IMPROVES IMMUNOGENICITY OF COVID-19 VACCINATION IN PATIENTS WITH RHEUMATIC DISEASES

A. N. Arumahandi de Silva[1], L. M. Frommert[2], F. Albach[2], J. Klotsche[3], V. Scholz[2], A. Ten Hagen[2], L. M. Jeworowski[4], T. Schwarz[4], J. Zernicke[2], V. M. Corman[4], C. Drosten[4], G. R. Burmester[2], R. Biesen[2]. *[1]Charité University Hospital, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[2]Charité University Hospital, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[3]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), Berlin, Germany*; *[4]Charité University Hospital, Institute of Virology, Berlin, Germany*

Background: Several research groups have recently described a reduced vaccination response to COVID-19 vaccination under methotrexate (MTX) (1,2). The increase in humoral immune response when pausing MTX two weeks after vaccination has already been described for influenza vaccination (3). However, data regarding MTX-hold during COVID-19 vaccination are still lacking.
Objectives: To study the effect of MTX and its discontinuation on the humoral immune response after COVID-19 vaccination in patients with autoimmune rheumatic diseases (AIRD).
Methods: In this retrospective study, neutralising SARS-CoV-2 antibodies were measured after second vaccination in 64 rheumatic patients on methotrexate therapy, 31 of whom temporarily paused medication without a fixed regimen. The control group consisted of 21 AIRD patients without immunosuppressive medication.
Results: MTX patients showed a significantly lower mean antibody response compared to AIRD patients without immunosuppressive therapy (71.8 % vs 92.4 %, $p<0.001$). For patients taking MTX, age correlated negatively with immune response ($r=-0.49$; $p<0.001$). All nine patients with antibody levels below the cut-off were older than 60 years. Patients who held MTX during at least one vaccination showed significantly higher mean neutralising antibody levels after second vaccination, compared to patients who continued MTX therapy during both vaccinations (83.1 % vs 61.2 %, $p=0.001$). This effect was particularly pronounced in patients older than 60 years (80.8 % vs 51.9 %, $p=0.001$). The impact of the time

period after vaccination was greater than of the time before vaccination with the critical cut-off being 10 days.

Conclusion: MTX reduces the immunogenicity of SARS-CoV-2 vaccination in an age-dependent manner. Our data further suggest that holding MTX for at least 10 days after vaccination significantly improves the antibody response in patients over 60 years of age.

AB1156 COVID19 CLINICAL COURSE AND OUTCOMES IN PATIENTS WITH RHEUMATIC DISEASES: DATA FROM SINGLE INPATIENT CLINIC

A. Babaeva[1], E. Kalinina[1], K. Solodenkova[2]. *[1]Volgograd State Medical University, Department of Faculty Therapy, Volgograd, Russian Federation*; *[2]I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Outpatient Therapy of the N.V. Sklifosovsky Institute of Clinical Medicine, Moscow, Russian Federation*

Background: Considerations regarding clinical manifestations and outcomes of COVID19 in patients (pts) with autoimmune rheumatic diseases (ARD) still remain ambiguous.

Objectives: This study aims to assess the clinical course of moderate and sever COVID19 and its outcomes in hospitalized pts with ARD in comparing with osteoarthritis (OA) pts.

Methods: We have analyzed clinical picture and outcomes of COVID19 in 84 pts with RD admitted to inpatient clinic. 36 ARD pts and 48 OA pts were observed during whole period of hospitalization. Clinical, laboratory and instrumental data characteristic of COVID19 were monitored in both groups. The following COVID19 outcomes: ICU admission, mechanical or non-invasive ventilation and death were registered. The impact of concomitant diseases and antirheumatic therapy on adverse outcome was taken into account.

Results: The ARD group preferably consisted of SLE pts (10 pts - 27.78%), RA pts (12 pts - 33.33 %), and systemic vasculitis – SV (12 pts - 33.33%), there were only 2 pts with psoriatic arthritis -PsA (5.56%). In OA group there were 23 pts with knee lesion, 14 pts with hip lesion and 11 pts with both. The structure of ARD and OA groups were similar on demography and associated conditions (CVD, T2DM, obesity). Severe coronovirus pneumonia (CT≥3) was diagnosed in 27.78% pts from ARD group and 35.42% pts from OA group ($p>0.05$, χ^2-criterion). Prevalence of leucopenia, elevated CRP and ferritin in compared groups was comparable, but lymphopenia and elevated IL6 levels>1000 pg/ml were detected oftener in ARD group (77.78% vs 41.46%, $p< 0.05$; 44.44% vs 18.75%, $p<0.05$ respectively). There were no significant differences in mean indexes of WBC (6.55±2.41 vs 6.93±1.84, $p>0.05$), CRP (69.48±9.32 vs 62.19±7.35, $p>0.05$), ferritin (471.03±26.18 vs 428.14±19.02, $p>0.05$). However ICU admission and non-invasive ventilation was oftener in ARD group than in OA group: 38.89% vs 18.75% ($p<0.05$ χ^2-criterion). Fatal outcome was registered in 3 pts (8.33%) from ARD group (SLE -2, ANCA-vasculitis-1) and in 3 pts (6.25%) with concomitant CVD, T2DM and/or obesity from OA group. All deceased pts from ARD group had been treated with GC≥ 8mg, csDMARD and biological agents (rituximab in 2 cases).

Conclusion: The severity of COVID19 clinical course in general was identical in pts with ARD and in OA pts. At the same time lymphopenia and significantly elevated IL6 levels were detected in ARD group oftener than in OA group. Despite the comparable mortality rate in observed groups, more pts from ARD even without concomitant conditions required ICU admission and non-invasive ventilation. Deceased pts with ARD received moderate dose of GC, conventional and biological DMARDs, preferentially rituximab. In OA mortality from COVID19 was associated with CVD and/or metabolic disorders.

AB1157 CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATIC DISEASES AFTER COVID-19 IN THE REPUBLIC OF TATARSTAN

S. Lapshina[1], N. Shamsutdinova[2], V. Mukhamadieva[1], R. Abdrakipov[3], E. Sukhorukova[4], A. Sagitova[1], A. Zakirova[1], L. Krasnova[1], D. Abdulganieva[1]. *[1]Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*; *[2]Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*; *[3]Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation*; *[4]Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation*

Background: The management of patients with rheumatic diseases (RD) who have undergone a new coronovirus infection (NCI) is an urgent and significant problem.

Objectives: To study the course of the NCI and its influence on the course of RD in the Republic of Tatarstan.

Methods: From June 2020 to January 2022, 159 cases of NCI with a confirmed SarsCoV2 PCR result and/or X-ray computed tomography (CT) of the lungs in patients with RD were analyzed. The study included 104 patients with RA, 36 patients with AS, 18 patients with PsA. RD activity before NCI was low in 56 (35.2%) patients, moderate in 91 (57.3%), and high in 12 (7.5%) patients. Distribution by gender: 113 (71.0%) females, 46 (28.9%) males, mean age 58 [46; 64]. 56 patients (49.5%) were hospitalized, the average age of those hospitalized was 61 [49; 67] year. The average duration of RD at the time of NCI was 11 [7; 16.75] years. The results of clinical and laboratory examinations were evaluated before and 1-3 months after the NCI.

Results: Manifestations of infection in patients with RD in terms of frequency and severity were comparable to the course of NCI in the population: intoxication with fever above 38C, respiratory symptoms, ageusia, anosmia, pneumonia. 27.1% (43) of patients had asymptomatic or mild course of COVID-19, 64.1% (102) had moderate course, 8.8% (14) of patients - severe NCI. Lung involvement was detected in 116 (72.9%) patients. Patients received NCI therapy according to national guidelines. The outcome of COVID-19 in 154 (96.9%) patients was recovery, in 5 (3.1%) patients it was fatal, 3 of them were on rituximab therapy. A total of 8 patients received rituximab. After undergoing NCI, 26 (16.4%) patients did not develop an increase in activity, in 76 (47.7%) patients RD corresponded to a moderate degree of activity. In 57 (35.9%) patients RD activity became high, 3 months after the NCI, a significant ($p<0.05$) increase in the activity of the main RD was observed due to clinical and laboratory (C-reactive protein) parameters, which required intensification of antirheumatic therapy.

Conclusion: The prevalence and course of COVID-19 in patients with RD did not generally differ from those in the population. The most unfavorable course of NCI in terms of life prognosis was observed in patients receiving rituximab for underlying RD. The COVID-19 contributes to an increase in the activity of the main RD.

AB1158 CLINICAL CHARACTERISTICS OF POST-COVID SYNDROME IN PATIENTS WITH RHEUMATIC DISEASES IN THE REPUBLIC OF TATARSTAN

N. Shamsutdinova[1], S. Lapshina[1], V. Mukhamadieva[1], R. Abdrakipov[2], E. Sukhorukova[2], L. Kupkenova[3], D. Abdulganieva[4]. *[1]Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*; *[2]Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation*; *[3]Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*; *[4]Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*

Background: The management of patients with rheumatic diseases (RD) after a new coronavirus infection (NCI) is an urgent and significant problem.

Objectives: To study post-COVID manifestations in patients with RD in the Republic of Tatarstan.

Methods: From June 2020 to January 2022, 154 cases of NCI with confirmed SarsCoV2 PCR and/or X-ray computed tomography (CT) of the lungs in patients with

RD were followed up. The study included 100 patients with RA, 36 patients with AS, 18 patients with PsA. RD activity before NCI was low in 56 (36.4%) patients, moderate in 90 (58.4%) patients, and high in 8 (5.2%) patients. Among the patients, 110 (71.5%) were female, 44 (28.5%) were male, the average age was 58 [46; 64]. 28% (43) of patients had asymptomatic or mild NCI, 66.2% (102) had moderate NCI, and 5.8% (9) of people had severe NCI. Bilateral polysegmental pneumonia was detected in 111 (72.0%) patients. The results of clinical and laboratory examinations for RD were assessed before and 3 and 6 months after NCI. Patients underwent an in-depth survey 3 and 6 months after undergoing NCI for the presence of various symptoms, including manifestations of asthenia. Additionally, the severity of depression and anxiety was assessed using the Hospital Anxiety and Depression Scale (HADS) and the Hamilton Scale.

Results: 90.3% of patients noted the persistence or appearance of symptoms after undergoing NCI, and all of them had a combination of at least 3 different groups of symptoms. The most common asthenic manifestations were in the form of a decrease in the quality of life and working capacity in 85% of patients: significant in 47.9% of people, insignificant - in 38.7% of people. The second most frequent was the intensification/appearance of pain in the joints - 80.5% of the respondents. Strengthening/appearance of muscle pain and/or headache and/or dysautonomia occurred in 47.4%. The appearance/intensification of shortness of breath and a decrease in exercise tolerance were noted by 30.5% of the respondents, while there was no connection with the severity of NCI, and half of the patients had a mild course of COVID 19. The appearance/intensification of chest pain and/or palpitations was noted by 20.8% of people. After 3 months, a decrease in the quality of life, manifestations of depression and anxiety were revealed: 32.2% of people had a mild depressive disorder of moderate severity, 22.3% had clinically expressed anxiety and depression. Six months after the NCI, no abnormalities were detected on the Hamilton scale, and subclinically expressed anxiety/depression on the HADS scale.

Conclusion: In most patients with RD, post-covid manifestations persist, primarily due to general constitutional, articular and cognitive symptoms. Manifestations of NCI itself in the form of respiratory and cardiovascular manifestations persist in less than a third of patients.

AB1159 HYDROXYCHLOROQUINE SHORTAGE AND ITS RELATION TO ANXIETY LEVEL AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS DURING COVID-19 PANDEMIC

M. H. Abu-Zaid[1], H. Eitta[2], A. Moshrif[3], D. Abdeldaim[4], N. EL Ghobashy[5]. *[1]Tanta University, Rheumatology, Tanta, Egypt*; *[2]Al-Azhar University, Rheumatology, Cairo, Egypt*; *[3]Al-Azhar University, Rheumatology, Assiut, Egypt*; *[4]Tanta University, public health, Tanta, Egypt*; *[5]Cairo Universityr, Rheumatology, Cairo, Egypt*

Background: Concerns of hydroxychloroquine (HCQ) shortage for patients with rheumatic diseases are growing during the era of COVID-19 pandemic as it was assigned in some treatment protocols. Its nonavailability may impact the disease management especially in patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA).

Objectives: To evaluate the shortage of HCQ in patients with RA and SLE and its impact on patients anxiety and disease activity.

Methods: 219 RA patients (according to 2010 ACR/EULAR criteria) and 200 SLE patients (according to 2012 SLICC criteria) were recruited in the study. Demographic and clinical features of the patients together with the current disease activity parameters (CDAI and SELENA/SLEADI) were prospectively collected. previous disease activity measures were collected from the patients records before hydroxychloroquine shortage. Patient's anxiety was measured using Hamilton anxiety rating scale.

Results: A total of 419 patients divided into two groups, Group (1); 219 RA patients with mean age 45.6±9.6 years, disease duration 45.5±32.8 months with female predominance (63 %). Group (2): 200 SLE patients with mean age 33.8±7.9 years, disease duration 61.2±39.2 months with female predominance (84%). 168 (76.7%) of the RA patients and 128 (64%) of SLE patients reduced or stopped the dose of HCQ due to unavailability. Despite HCQ shortage, there was no significant change in disease activity in RA or SLE patients (P=0.063 and 0.064 respectively). All participants suffered from different levels of anxiety which was positively correlated with HCQ shortage (p= 0.001 and 0.005 for RA and SLE respectively).

Conclusion: COVID 19 pandemic caused hydroxychloroquine shortage in the majority of patients with RA and SLE with no significant impact on their disease activity. Anxiety was found correlating to HCQ shortage in both diseases more significantly in SLE patients.

AB1160 IMPACT OF COVID-19 TREATMENTS ON PERIPHERAL CAPILLARY DENSITY EVALUATED BY NAILFOLD VIDEOCAPILLAROSCOPY

E. Gotelli[1], A. Sulli[1], P. F. Bica[1], I. Schiavetti[2], T. Aloe'[3], M. Grosso[3], E. Barisione[3], C. Pizzorni[1], S. Paolino[1], V. Smith[4,5,6], M. Cutolo[1]. *[1]University of Genova, IRCCS San Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, Genova, Italy*; *[2]University of Genova, Department of Health Sciences, Genova, Italy*; *[3]IRCCS San Martino Polyclinic Hospital, Interventional Pneumology Unit, Genova, Italy*; *[4]Ghent University Hospital, Department of Rheumatology, Ghent, Belgium*; *[5]Ghent University Hospital, Department of Internal Medicine, Ghent, Belgium*; *[6]VIB Inflammation Research Center, Unit for Molecular Immunology and Inflammation, Ghent, Belgium*

Background: Human SARS-CoV-2 infection can induce a wide spectrum of organ dysfunctions, including microvascular impairment [1]. S_1 subunit of viral receptor-binding domain binds to the angiotensin-converting enzyme 2 receptor on endothelium and S_2 subunit allows the virus to enter endothelial cells. The resulting breakdown of barrier integrity drives a cascade of inflammatory and thrombotic events, that aggravate the course of COVID-19 together with other risk factors [2-4]. Up to date, a lower capillary density has been reported in several distinct body districts, using sublingual video microscopy, ocular optical coherence tomography angiography, skin functional laser Doppler perfusion imaging and nailfold videocapillaroscopy (NVC) [5-8]. NVC examination has been performed in adult COVID-19 patients, however, without a control group [8].

Objectives: To confirm the statistical significance of the reduction in capillary density per linear millimeter evaluated by NVC in comparison with primary Raynaud's phenomenon (PRP) patients and control subjects (CNT) and to evaluate the impact of an aggressive therapy against COVID-19 on the sparing in the number of capillaries.

Methods: Sixty-one COVID-19 survivors, thirty-one PRP patients and thirty CNT age and sex-matched underwent NVC analysis. Demographic and clinical data of COVID-19 survivors were collected with special regard to concomitant therapies, that included antivirals, antibiotics, anticoagulants and anti-inflammatory/immunomodulant drugs (glucocorticoids, hydroxychloroquine, IL-6 receptor antagonist). COVID-19 survivors were divided in two subgroups according to the severity of the active infection: thirty-four survivors with past mild-moderate disease (either unneedy for oxygen supplementation or need for Venturi mask) and twenty-seven survivors with past severe disease (need for Continuous Positive Airways Pressure and/or mechanical ventilation). The same Rheumatologist performed NVC evaluations in all patients and controls, using an optical probe, equipped with a 200x magnification lens and connected to a picture analysis software (Videocap, DS Medica, Milan, Italy). Absolute capillary number per linear millimeter was counted.

Results: COVID-19 survivors underwent NVC examination after a mean period of 126±53 days from the disease onset. Multivariate analysis showed differences in absolute capillary number per linear millimeter ($p<0.001$) after adjusting for age, sex, body mass index, comorbidities and concomitant drugs. The mean (± standard deviation) absolute nailfold capillary number per linear millimeter was significantly lower in severe (8.2±1.15) and mild-moderate (8.4±0.75) COVID-19 survivors than in both PRP (8.7±0.68) and CNT subjects (9.3±0.53) ($p<0.001$). The analysis of the impact of treatments on capillary density in the severe COVID-19 patients showed a positive trend (preservation of the capillary number) with antivirals (no: 7.8±1.53; yes: 8.5±0.64; p=0.35) and anti-IL-6 receptor antagonist administration (no: 7.8±1.36; yes: 8.6±0.74; p=0.16), while none of the other drugs was shown to be effective (glucocorticoids p = 0.46; antibiotics = 0.52; anticoagulants not evaluable as they were used in all COVID-19 patients).

Conclusion: SARS-CoV-2 infection seems associated to a significant capillary loss as distinctive NVC feature and data concerning the comparison of capillary density pre COVID-19 and post COVID-19 are desirable to reinforce this observation. The positive trend in saving the number of capillaries induced by aggressive anti-inflammatory therapies in COVID-19 survivors needs larger cohorts of patients.

AB1161 COVID-19 IN MY RA CLINIC: DATA FROM QUESTIONNAIRE, VACCINATION, INFECTION AND FLARES FROM THE RA LOUVAIN BRUSSELS COHORT

V. Pirson[1], T. Sokolova[1], X. Theunssens[1], L. Bricman[1], E. Sapart[1], S. DE Montjoye[1], S. Dierckx[2], A. Avramovska[1], P. Durez[1]. [1]*Cliniques Universitaires Saint-Luc – Université Catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium*; [2]*CHU Mont-Godinne, Rheumatology, Mont Godinne, Belgium*

Background: Over 5 million deaths from the COVID-19 disease have been reported in the world. Patients (pts) living with rheumatoid arthritis (RA) affecting the immune system or under immunosuppressive agent are considered as a high risk population for a SARS-CoV-2 infection. Since no antiviral treatment is available, the vaccination is a major option.
Objectives: The aim of this study is to evaluate in our RA cohort a questionnaire about the COVID-19 vaccination willingness, to analyse the vaccination rate, the number of COVID infection, the RA flares and the side effects.
Methods: We included pts with RA from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 classification criteria. A simple and standard questionnaire about the vaccine willingness was distributed in 2020 before the vaccination. From January to December 21, the rate of vaccination was calculated. The number of Covid infections, RA flares, therapy switches and side effects were also collected. All patient and RA characteristics were analyzed.
Results: 605 eligible RA pts were included. The average age of the population is 58.21 years. 72% of the patients are women. 21% are smokers and 65% are positive for anti-citrullinated protein antibody (ACPA) with a mean DAS28-CRP of 2.39 and a mean HAQ of 0.821. In 2020, 460 pts filled the questionnaire and 61% indicated they would receive the vaccine as soon as it is available. For the 179 pts (39%) who decline, the reasons for not having vaccine were no trust in the vaccine at this time (53%), fear of side effects (28%), opposition to vaccine (4%), previous SARS-CoV-2 infection (2%) and unknown (5%). Pts under the age of 50, women, low education grade, smokers, presence of RF/ACPA and treatment with a bioDMARD were less willing to receive the vaccine. In 2021, 538 pts were vaccinated and only 67 pts (11.1%) not. The majority received a mRNA vaccine (81.8%). 72 and 21 pts developed a SARS-CoV-2 infection before and after the vaccination, respectively. Among them, 5 were admitted to intensive care unit leading to 4 deaths. Only, 7 RA flares were observed and 17 pts switched the therapy. 101 adverse events were reported. All of them were mild and transient except 2 cases with pulmonary embolism and one case with Herpes Zooster infection.
Conclusion: The SARS-COV-2 global pandemic is responsible of many medical dramas. In our RA cohort, we observed first hesitation followed by a high rate of vaccination. The safety was reassuring with a minimal number of RA flares and serious adverse events including only 4 deaths.

AB1162 THE LINK BETWEEN INFLAMMATION AND THROMBOSIS: CLINICAL AND IMMUNOHISTOCHEMICAL CHARACTERIZATION OF PULMONARY ARTERIAL THROMBOSIS IN COVID-19 PATIENTS

L. Quartuccio[1], A. Sonaglia[1], L. Casarotto[2], D. Mcgonagle[3], C. DI Loreto[2], E. Pegolo[2]. [1]*Division of Rheumatology, Department of Medicine, Udine, Italy*; [2]*Institute of Anatomic Pathology, Department of Medicine, Udine, Italy*; [3]*Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), National Institute for Health Research (NIHR), Leeds Biomedical Research Centre (BRC), Leeds, United Kingdom*

Background: Coronavirus-19 disease (COVID-19) has been responsible, to date, for more than 5 million of deaths. Immunothrombosis may be a major factor contributing to mortality in COVID-19 and pulmonary arterial tree involvement that mimics multiple pulmonary embolism could be a major contributor to disease course. Immunomodulatory drugs are of some benefit but mechanism not completely clear. We investigated pulmonary arterial tree clots to better appreciate their immunothrombotic nature, in contrast to the pathological characteristics of non-inflammatory thrombi (1).
Objectives: The primary objective was to study in depth the arterial thrombosis in COVID-19, by characterizing the immunohistochemical nature of thrombi, performing macroscopic and microscopic analyses, and by comparing clinical, laboratory and anatomical-pathological data of these patients with other patients died for COVID-19 but without evidence of pulmonary arterial thrombosis.
Methods: Autopsies were performed in patients (cases) who died for COVID-19 with evidence of pulmonary arterial thrombosis at autopsy finding but without pathological signs of bronchopneumonia or peripheral venous thrombosis. COVID-19 positive patients without pulmonary arterial thrombosis were selected as control group. Hematoxylin and eosin stained slides were reviewed choosing those with visible pulmonary thrombi. Further histochemical and immunohistochemical staining were performed in selected paraffin blocks. Each component of the thrombus was evaluated with the software application QuPath in terms of fibrin, red blood cells, platelets and immune cells percentage after scanning the slides with Aperio System. Laboratory tests were recorded at 2 points: at hospital admission and at Intensive Care Unit transfer.
Results: We included 13 patients (cases) and 14 controls, matched for age, gender and time from diagnosis to death. Twenty arterial thrombi were studied. By immunohistochemistry, arterial thrombi were composed by white blood cells (WBC) [median, IQR range: 10% (5-12.25)], mainly neutrophils [58% (35.2-64.5)], red blood cells [12%, (6-34.25)], fibrin [19% (14.5-42.25)], platelets [39%, (31.75-48)] (Figure 1). Three cases had a history of previous thrombosis. All cases had received anticoagulant treatment during hospitalization, low molecular weight heparin in 12/13 (therapeutic regimen in 4/12, prophylactic in 8/12) while 1/13 continued oral anticoagulants for comorbidity. By comparing laboratory findings between cases and controls, cases showed significantly higher levels of platelet count [median, IQR range: 195000/mmc (157750-274500) vs 143500 (113000-175250), p=0.011], LDH [854 U/l (731-1315) vs 539 (391.5-660), p=0.003)] at hospital admission, and D-dimer at ICU transfer [25072 FEU (6951-50531) vs 1024 (620-5501), p=0.003)].

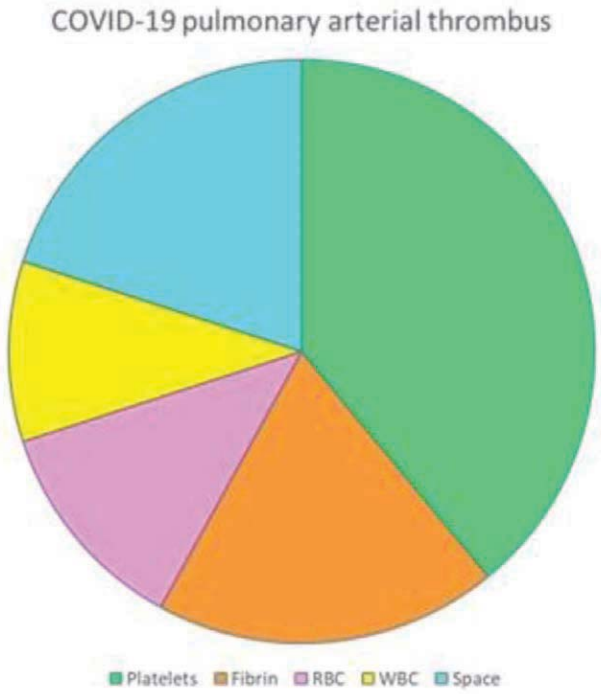

Figure 1.

Conclusion: Pulmonary arterial thrombosis in COVID-19 is a type of immune-mediated inflammatory thrombosis, since the amount of WBC is 6-times more than normal value seen in non-inflammatory thrombi. Some markers of inflammation, necrosis and coagulation are much more increased in this subset of patients. Chest CT angiography rather than simple CT scan at hospital admission could be more useful in this setting, and treatments with antiplatelet agents or anticoagulants, eventually in combination with immunotherapy, might positively affect the outcome.

AB1163 ATTITUDES AND HESITANCY IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES TOWARDS SARS-COV-2 VACCINATION: A SINGLE-CENTER STUDY FROM BULGARIA

T. Georgiev[1,2], R. Moraliyska[2], S. Bogdanova-Petrova[1,2], G. Gerganov[2,3], P. Kabakchieva[4,5], S. Dimitrov[1,2], S. Hristova[2,6], T. Shivacheva[1,2]. [1]*Medical University - Varna, First Department of Internal Medicine, Varna, Bulgaria*;

[2]*University Hospital St. Marina, Rheumatology Department, Varna, Bulgaria*; [3]*Medical University - Varna, Propedeutics of Internal Medicine, Varna, Bulgaria*; [4]*Multiprofile Hospital for Active Treatment – Varna, Military Medical Academy – Sofia, Clinic of Internal Medicine, Varna, Bulgaria*; [5]*Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*; [6]*Medical University - Varna, Department of General Medicine, Varna, Bulgaria*

Background: Bulgaria is among the countries with the lowest vaccination rate of adult population in Europe. The presence of autoimmune rheumatic disease could further contribute to vaccine hesitancy and skepticism and influence patients' attitudes towards vaccination [1, 2]. However, little is still known about the willingness and particular causes of hesitancy in patients with inflammatory joint diseases in the skeptical part of adult population across Europe.
Objectives: Our goal was to assess the rate of SARS-CoV-2 vaccination among patients with immune-mediated rheumatic joint diseases receiving biological and targeted synthetic disease-modifying antirheumatic drugs (DMARDs) and to determine the modifiable predictors of vaccination hesitancy.
Methods: Patients with rheumatoid arthritis, psoriatic arthritis, or ankylosing spondylitis undergoing biological or targeted synthetic DMARDs therapy were consecutively selected and included in this single-center cross-sectional study. Excluding criteria in patients were psychiatric or neurological disease preventing understanding or responding to the questions, being illiterate, or not willing to participate in the study. Various demographic, anthropometric, and clinical data were collected. Disease activity was determined using DAS28-CRP for rheumatoid arthritis and peripheral psoriatic arthritis and ASDAS for ankylosing spondylitis and psoriatic spondylitis. All patients were given a questionnaire assessing their vaccination status, hesitancy, and attitude towards vaccination. Binary logistic regression analysis was used to analyze the relationship between self-reported modifiable parameters and vaccination status for SARS-CoV-2.
Results: Two hundred and one participants were eligible for participating in the study with mean age and BMI of 54.6 years and 28.2, respectively. Of these, 40.3% were women; 30.3% had rheumatoid arthritis, 17.9% - psoriatic arthritis, and 51.7% - ankylosing spondylitis. 29.4 % of all participants had already survived a COVID-19 infection with a mean time of 8.4 months since the COVID-19 onset. Only slightly above 1/3 (35.8%) of the study group was fully vaccinated and the majority of them were vaccinated with BNT162b2 (68.1%). Among the modifiable factors, we identified preceding discussion with a rheumatologist, hesitancy due to autoimmune disease presence and (un)awareness of vaccine safety and efficacy as significant predictors of vaccination status
Conclusion: Our data suggest that there are still possibilities to influence rheumatic patients on their decision to vaccinate against SARS-CoV-2 in Bulgaria. Raising the awareness of the safety and efficacy of the SARS-CoV-2 vaccines and spending more time on the education of patients with rheumatic diseases may positively affect their attitude towards vaccination.

AB1164 EFFICACY AND TOLERABILITY OF THE VACCINE AGAINST SARS- COV-2 IN PATIENTS WITH SJOGREN'S SYNDROME RECEIVING VARIOUS TYPES OF THERAPY.

A. Torgashina[1], E. Sokol[1], B. Chalcev[1], J. Khvan[1], M. Kireeva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Didease and Sjogren`s Syndrome, Moscow, Russian Federation*

Background: there are some concerns among patients (pts) with rheumatic diseases regarding the tolerability and efficacy of SARS-CoV-2 vaccination. The impact effect of vaccination on the course of Sjogren`s syndrome (SjS) is not entirely clear.
Objectives: to evaluate the efficacy and tolerability of the heterologous recombinant adenovirus (rAd)-based vaccine Sputnik in pts with SjS receiving various types of therapy.
Methods: single center observational retrospective study. Diagnosis of SjS was based on ACR/EULAR 2016 criteria. Rituximab (RTM) was administered in two 1000 mg infusions 14 days apart for the 1 st course, then 500 mg every 6 months.
Results: 70 pts with a definite diagnosis of SjS were included in the study. Four out of 70 were women. The mean age was 52.5±14.6 years, the average duration of the SjS was 72 (36-120) months. Three pts had concomitant RA, 3 pts - SLE, 2 pts - Systemic sclerosis. Extraglandular manifestations of SjS were detected in 35 cases. Five pts received single-dose rAd26 vector-based COVID-19 vaccine "Sputnik Light", other 65 pts received 2 doses of Gam-COVID-Vac (Sputnik V). Eighteen pts did not receive any immunosuppressive therapy and were vaccinated before RTM therapy. One patient of them just diagnosed with lymphoma, 8 pts had extraglandular manifestations of the SjS (hypergammaglobulinemic purpura, cryoglobulinemic vasculitis with polyneuropathy, interstitial lung disease). 20 pts at the time of vaccination received various immunosuppressive drugs: 1 – cyclophosphamide (CYC), 1 – leflunomide, 1 – Azathioprine, 3 – methotrexate, 2 - mycophenolate mofetil (MMF), 10 – hydroxychloroquine, 13 - low doses of methylprednisolone. Thirty-two pts received anti B-cells therapy with RTM. The duration of RTM therapy before vaccination was 18 (12-36) months, the period of time between the last injection of the RTM and the vaccine was on average 6 (5-8) months. B-cells level was determined in 18 pts immediately before vaccination and it was normal only in 10 pts. The level of neutralizing antibodies after vaccination was monitored in 44 pts. The level of IgG antibodies against SARS-CoV-2 was positive in 15 of 22 pts who did not receive RTM and in 10 of 22 pts who received the RTM ($p>0.05$). Neutralizing antibodies did not develop in 4 pts despite complete recovery of B cells. It is important that none of the vaccinated pts was infected COVID-19 within at least 6 months after vaccination. Various types of adverse reactions were observed in 8 pts. The most common was flu-like syndrome. In one case this syndrome required the prescription of dexamethasone. In 3 cases disease exacerbation occurred after vaccination. These pts had extraglandular manifestations of SjS and received immunosuppressants (CYC, MMF or RTM), 2 of them required treatment intensification, in one case the exacerbation was self-limiting.
Conclusion: vaccination against SARS-CoV-2 infection was well tolerated by pts with SjS even in the absence of immunosuppressive therapy. In most cases, there were no exacerbation of the SjS and pts could continue immunosuppressive therapy without becoming infected COVID-19.

AB1165 THE ROLE OF MOLECULAR MIMICRY IN SARS-COV-2 RELATED AUTOIMMUNE RHEUMATIC DISEASES

C. Liaskos[1], E. Patrikiou[1], L. Komorowski[2], C. Tsigalou[3], A. Tsirogianni[4], L. Sakkas[1], D. Bogdanos[1]. [1]*Faculty of Medicine, University of Thessaly University General Hospital of Larissa, Department of Rheumatology and Clinical Immunology, Larissa, Greece*; [2]*AG Euroimmun, Immunology Experimental of Institut, Lübeck, Greece*; [3]*Democritus University of Thrace, Alexandroupolis, Greece, Laboratory of Microbiology, Alexandroupolis, Greece*; [4]*Evangelismos General Hospital, Athens, Greece, Department of Immunology-Histocompatibility, Athens, Greece*

Background: Several studies suggested that SARS-CoV-2 infection may induce autoantibodies related to autoimmune rheumatic diseases (ARD).
Objectives: To determine whether polyclonal antibodies from SARS-CoV-2 uninfected patients with ARDs cross-react with SARS-CoV-2 and vice versa.
Methods: 90 sera positive at high-titres for 23 common autoantibodies (all sera stored before 2018), were tested for reactivity against proteins of SARS-CoV-2 (spike protein S1, nucleocapsid NC etc) by ELISA and CMIA. Vice versa, 10 monoclonal antibodies against S1 protein (most of them against RBD) were tested for autoantibody reactivity by indirect immunofluorescence, ELISA, immunoblot and dot/line immunoassays coated with different antigens. Ten post-COVID sera with high titers of anti-Spike abs were tested by ELISAs for reactivity against various autoantigens related to ARDs.
Results: 88 out of 90 samples (%), were totally unreactive to SARS-CoV-2 proteins; 2 sera, one anti-CCP and one anti-CENP reacted against S protein. All sera tested negative for neutralized abs against SARS-CoV-2. None of 10 sera from SARS-CoV-2 infected patients reacted with different autoantigens by molecular assays. None of the 10 monoclonal abs against S1 protein reacted with 23 different self-antigens. On HEp2 cells as substrate for IIF, 3 of the 10 monoclonal abs gave a low-titre coarse speckled pattern. No reactivity was found by IIFL using tissue substrates.
Conclusion: Our data do not suggest a dominant role for molecular mimicry and immunological cross reactivity as a trigger of autoantibodies related to ARDs.

Background: Since the development of COVID 19 vaccines, more than 300 million people have been immunized worldwide. Soon after vaccinations were initiated, reports on cases of myocarditis following the second vaccine dose have emerged.
Objectives: This study aims to report our experience with nine patients with post COVID-19 vaccine myocarditis, and to compare them to a cohort of patients who presented with paediatric inflammatory multisystem syndrome (PIMS / PIMS-TS) post COVID 19 infection.
Methods: We collected all reported cases of patients who developed myocarditis following COVID 19 vaccination (Pfizer mRNA BNT162b2), from all pediatric rheumatology centers in Israel, and compared them to the cohort of patients previously diagnosed with PIMS.
Results: Nine patients with myocarditis post-vaccination were identified and compared to 78 patients diagnosed with PIMS. All patients with post-vaccination myocarditis were males who developed symptoms following their second dose of the vaccine. Patients with myocarditis post-vaccination had a shorter duration of stay at the hospital (4.4±1.9 vs. 8.7±4.7 days), less myocardial dysfunction (11.1% vs. 61.5%), and all had excellent outcomes as compared to chronic changes among 9.2% of patients with PIMS.
Conclusion: The clinical course of vaccine-associated myocarditis appears favorable, with resolution of symptoms in all the patients in our cohort. The risk–benefit decision for vaccination remains highly favorable, given the potential morbidity of patients with COVID-19, especially those with PIMS.

AB1167 THE USE OF ORAL AMINO-BISPHOSPHONATES AND CORONAVIRUS DISEASE 2019 (COVID-19) OUTCOMES

F. Pistillo[1], M. Rossini[1], A. Fassio[1], C. Benini[1], D. Gatti[1], G. Adami[1]. [1]*University of Verona, Rheumatology Unit, Department of Medicine, Verona, Italy*

Background: The determinants of the susceptibility to SARS-CoV-2 infection and severe Coronavirus Disease 19 (COVID-19) manifestations are yet not fully understood. Amino-bisphosphonates (N-BPs) have anti-inflammatory properties and have been shown to reduce the incidence of lower respiratory infections, cardiovascular events and cancer.
Objectives: We conducted a population-based retrospective observational case control study with the primary objective of determining if oral N-BPs treatment can play a role in thesusceptibility to the development of severe COVID-19.
Methods: Administrative ICD-9-CM and ATC data, representative of Italian population (9% sample of the overallpopulation), were analyzed. Oral N-BPs (mainly alendronate and risedronate) were included in the analysis. Patients treated with bisphosphonates (cases) were randomly matched (1:1 ratio) for age, sex and for other clinically relevant variables (presence of treatments other than bisphosphonates and hospitalizations) with all the health-assisted population without this treatment (controls).
Results: Incidence of Covid-19 hospitalization was 12.32 [95%CI 9.61-15.04] and 11.55 [95%CI 8.91-14.20], of ICU utilization due to COVID-19 was 1.25 [95%CI 0.38-2.11] and 1.42 [95%CI 0.49-2.36] and of all-cause death was4.06 [95%CI 2.50-5.61] and 3.96 [95%CI 2.41-5.51] for oral N-BPs users and non-users, respectively (Figure 1A). Figure 1B Incidence and 95% CI of COVID-19 related events in N-BPs treated and untreated subjects with anti-osteoporotic drugs and without corticosteroids. C. Incidence and 95% CI of COVID-19 related events in N-BPs treated and untreated without previous vertebral or hip fragility fractures. D. Incidence of COVID-19related events in bisphosphonates treated and untreated patients without previous vertebral or hip fracture without corticosteroid prescriptions.
Conclusion: In conclusion, we found that the incidence of COVID-19 hospitalization, intensive care unit (ICU) utilization and COVID-19 potentially related mortality were similar in N-BPs treated and non-treated subjects. Similar results were found in N-BPs versus other anti-osteoporotic drugs. We provided real-life data on the safety of oral N-BPs in terms of severe COVID-19 risk on a population-based cohort. Our results strongly support national and international guidelines that advocate against the discontinuation of oral bisphosphonates only for the fear of COVID-19.

AB1168 CLINICAL AND SEROLOGICAL EVOLUTION OF RHEUMATIC PATIENTS INFECTED BY SARS-COV-2

M. De la Rubia Navarro[1], J. Ivorra Cortés[1], E. Grau García[1], L. Gonzalez Puig[1], R. Negueroles Albuixech[1], I. Martínez Cordellat[1], F. Ortiz-Sanjuán[1], J. J. Fragío Gil[1], J. E. Oller Rodríguez[1], E. Vicens Bernabeu[1], C. Pávez Perales[1], S. Leal Rodriguez[1], L. Mas Sanchez[1], P. Muñoz[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], I. Cánovas Olmos[1], C. Nájera Herranz[1], J. A. Román Ivorra[1]. [1]*Hospital Universitario La Fe, Reumatología, Valencia, Spain*

Background: SARS-CoV-2 infection is a public health problem due to its high contagiousness and mortality. Spectrum of symptoms ranges from no symptoms to interstitial pneumonia. Patients with rheumatic disease present an increased infectious risk, especially those treated with immunosuppressants or biologic therapy. Since the beginning of the pandemic, risk of contagion and development of complications in these patients has been questioned.
Objectives: To describe hospitalization prevalence, seroconversion, and symptoms in patients under follow-up by the rheumatology department of a tertiary hospital.
Methods: Observational, cross-sectional study conducted by phone interview including patients with different diagnosis of rhematic diseases. Data about symptoms, hospital admission, serology by ELISA (when >15 days of evolution), diagnosis and baseline treatment, from March 2020 to February 2021 were collected.
Results: Eighty-six patients with different rheumatic diseases and positive COVID-19 PCR were included (82.35% women) in Table 1. Mean age was 49.30 years (16.16). The 48.71% received biological therapy, JAK inhibitors or apremilast, with a median of 3.11 years (Q1 1,08; Q3 3,17). Secukinumab was the biological therapy most often used (24,32%), followed by Tocilizumab (13,51%). The 34,18% received DMARDs or immunosuppressors, with a median of 5.09 years (Q1 12,25; Q3 11.09). The most frequent symptoms were asthenia (72.15%), headache (66.23%) and cough (59.49%). Nine patients (11.25%) were admitted to hospital, eight of them (10%) for pneumonia. Three of them were admitted to intensive care and one died.

Table 1.

Diagnosis	Number (%)
Rheumatoid arthritis	24%

Dermatomyositis	1%
Cutaneous panarteritis	1%

Seroconversion occurred in 53.25%. low IgG titers were present in 2.94% and IgM persisted positive in 56.25% of this group. In 6.45% the result was indeterminate.
Conclusion: Hospitalization and mortality rate obtained was low and the most frequent symptoms were mild. Seroconversion occurred in more than 50% of patients and the result of 6.45% was indeterminate. It's important to highlight that since March 2020 to May 2020 IgG positive prevalence was 25%, while since September 2021 to February 2021, this prevalence increased until 57,45%. This difference is due to a modification of autoantibody detection technique since summer 2020.

AB1169 IMMUNOMODULATORY EFFECTS OF SARS-COV-2 VACCINATION: INCREASE OF REGULATORY T CELLS AFTER MRNA VACCINE

F. La Gualana[1], F. Villani[1], G. Cusano[1], L. Gragnani[2], L. Stefanini[1], S. Santini[3], S. Basili[1], M. Casato[1], M. Fiorilli[1], M. Visentini[1]. [1]*Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy*; [2]*University of Florence, Department of Experimental and Clinical Medicine, Rome, Italy*; [3]*Catholic University School of Medicine, Department of Basic, Clinical, Intensive and Perioperative Biotechnological Sciences, Rome, Italy*

Background: Besides the ability to induce antigen-specific responses, vaccines can be endowed with immunomodulatory properties including the capacity to induce or downregulate regulatory T cells (Treg) that suppress adaptative and autoreactive immune responses (1).
Objectives: We asked if an anti-SARS-CoV-2 mRNA vaccine could also induce an accumulation of Treg cells in patients with mixed cryoglobulinemia vasculitis (MCV), who have a deficiency of Treg cells (2) and in healthy individuals. We also investigated immunologic variables possibly associated with a low immunogenicity of SARS-CoV-2 mRNA vaccine in patients with MCV (3).
Methods: We analyzed peripheral blood lymphocyte subpopulations and anti-SARS-CoV-2 serological response in 24 patients with MCV and 9 Healthy donors (HD) before and after 2 weeks after the second dose of the Pfizer/BioNTech vaccine.
Results: Among MCV patients we found 15 serological responders and 9 non-responders. All 5 seronegative patients treated recently with rituximab had <5 B cells/μL, whereas the absolute B cell count was increased in 2 of 4 untreated patients due to monoclonal B cell lymphocytosis, with monoclonal cells representing more than 90% of B cells, associated with non-Hodgkin lymphoma. The percentage of pathologic $CD21^{low}$ B cells was significantly increased in seronegative patients. Before receiving the Pfizer/BioNTech vaccine, patients with MCV had a significantly reduced frequency of Treg cells among $CD4^+$ T cells compared to HD. After the second dose of the vaccine, there was in MCV patients a significant increase in the percent and absolute count of Treg among CD4+ T cells Concerning the pre-vaccination distribution of T cells subpopulations, including the percentages and absolute counts of total $CD3^+$, $CD4^+$, $CD8^+$, HLA-DR^+ activated, Treg or $CD56^+$ natural killer T cells, we could not reveal any pattern significantly associated with lack of serological response to vaccine.
Conclusion: Our findings show that lack of immunoreactivity in patients with MCV may be associated with expansion of pathologic B cells and that anti-SARS-CoV2 mRNA vaccine may induce an increase of Treg cells.

AB1170 IMPACT IN PRENATAL EVALUATION OF PREGNANT WOMEN WITH RHEUMATIC DISEASES BY THE SARS-COV2 PANDEMIC

A. Y. Lujano Negrete[1], M. E. Corral Trujillo[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], A. Aguilar-Leal[1], M. C. Rodriguez-Ruiz[1], L. G. Espinosa Banuelos[1], A. Cárdenas[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: Due to the SARS-CoV-2 pandemic, an increase in stress, anxiety, and depression has been seen, as well as greater use of substances and a decrease in prenatal care in pregnant women. (1) Women of childbearing age with autoimmune rheumatic diseases (ARDs) experience greater psychological stress, which can negatively influence behavior. (2)
Objectives: This study aims to compare changes in prenatal laboratory and ultrasound tests by trimester, as well as the detection of anxiety and depression in pregnant women with ARDs due to the SARS CoV-2 pandemic.
Methods: This study was carried out on pregnant patients with ARDs from the Pregnancy and Rheumatic Diseases clinic of the rheumatology department of the University Hospital "Dr. José Eleuterio González" during the period from February 2018 to August 2021. Two standardized evaluations of anxiety and depression were carried out using the Inventory of Trait and State Anxiety (IDARE) and the Edinburgh Postpartum Depression Scale (EPDS) respectively in the third trimester of pregnancy. Maternal report of alcohol consumption during any trimester of pregnancy, as well as adherence to routine laboratory studies such as structural ultrasound and gestational diabetes screening, was addressed. Positive COVID-19 nasopharynx PCR results were evaluated during pregnancy beginning in the pandemic period (March 2020). The pre-pandemic recruited group was compared with the pandemic group. The comparison of the groups was carried out using the Chi-Square and Fisher tests. A significant value of $p < 0.05$ was considered. Statistical analysis was performed using the IBM SPSS v.25 program.
Results: 50 pregnant patients with ARDs were recruited, of which 24 were included in the pre-pandemic group and 26 in the pandemic group. Compared with the pre-pandemic group, pregnant women recruited during the pandemic had a statistically significant higher positivity for state anxiety (p=0.023), likewise trait anxiety, depression, and suicidal ideation were detected more frequently, but the difference was not statistically significant, a higher rate of adherence to laboratory and cabinet studies was found, being significant for laboratories performed in the 1st and 2nd trimesters (0.005 and 0.025 respectively). See Table 1.

Table 1. Characteristics of pregnant women with autoimmune rheumatic diseases before and during the SARS-CoV-2 pandemic.

Measure	Before pandemic n=24	During pandemic Covid Negative n=22	During pandemic Covid Positive n=4	P value[a]
EPDS Positive depression detection (≥10)	**16.7%**	**36.4%**	**50%**	**.197**
suicidal ideation	**16.7%**	**0%**	**25%**	**.099**
IDARE Positive state anxiety detection (>45)	**12.5%**	**27.3%**	**75%**	**.023**
IDARE Positive trait anxiety detection (>45)	**8.3%**	**13.6%**	**50%**	**.204**
Any alcohol consumption during pregnancy	**20.8%**	**4.5%**	**0%**	**.176**
Structural Ultrasound – Mid-Pregnancy	**66.7%**	**95.5%**	**100%**	**.025**
Gestational diabetes screening	**75%**	**86.4%**	**100%**	**.376**
Laboratories				
First trimester	**20.8%**	**50%**	**0%**	**0.005**
Second quarter	**45.8%**	**77.3%**	**100%**	**0.025**
Third trimester	**58.3%**	**81.8%**	**75%**	**0.216**

IDARE= State and Trait Anxiety Inventory, EPDS= Edinburgh Postpartum Depression Scale.A Chi-square test for categorical variables or Fisher's exact test where the expected cell n

Conclusion: A higher frequency of positivity for state anxiety was demonstrated in pregnant women with ARDs recruited during the pandemic, as well as higher trait anxiety, depression, and suicidal ideation, although this increase was not statistically significant. On the other hand, concern about the pandemic and health status could positively influence better adherence to screening and routine studies during pregnancy.

AB1171 **PERSISTENT POST-DISCHARGE SYMPTOMS AFTER COVID-19 IN RHEUMATIC AND MUSCULOSKELETAL DISEASES**

I. Perez-Sancristobal[1], L. León[1,2], M. P. Álvarez Hernandez[1], A. Madrid García[1], L. Lopez Pedraza[1], J. I. Colomer[1], S. Lerma Lara[3], P. Lois[1], A. Mucientes[1], L. Rodriguez Rodriguez[1], B. Fernandez[1], L. Abasolo[1]. *[1]Hospital Clinico San Carlos, Rheumatology Deparment, Madrid, Spain*; *[2]Universidad Camilo Jose Cela, Health Sciences Faculty., Madrid, Spain*; *[3]Centro Superior de Estudios Universitarios La Salle, Health Sciences Faculty., Madrid, Spain*

Background: The COVID-19 pandemic continues worldwide and has had a strong impact on public health. As the pandemic evolves, efforts have been intensified to identify persistent symptoms associated with the infection once resolved have intensified.

Objectives: We aimed to describe persistent symptoms and sequelae in patients with rheumatic and musculoskeletal diseases (RMD) after admission due to Covid-19. We also compared the role of autoimmune rheumatic diseases (ARD) with that of non–autoimmune rheumatic and musculoskeletal diseases (NARD) in persistent symptoms and sequelae.

Methods: We performed an observational study of patients with RMD who attended a rheumatology outpatient clinic in Madrid and required admission to hospital due to Covid-19 (1st March-30th May 2020) and survived. The study began at discharge and ran until 1st October 2020. The main outcomes were persistence of symptoms and sequelae related to Covid19. The independent variable was the RMD group (ARD and NARD). The covariates were sociodemographic data, clinical findings, and treatment. We ran a multivariate logistic regression model to assess the risk of the main outcomes by RMD group.

Results: We included 105 patients, of whom 51.5% had ARD and 68.57% reported at least 1 persistent symptom. The most frequent were dyspnea, fatigue, and chest pain. Sequelae were recorded in 31 patients. These included lung damage in 10.4% of patients, lymphopenia in 10%, central retinal vein occlusion (1 patient), and optic neuritis (1 patient). Two patients died. Eleven patients required readmission owing to Covid-19 problems (16.7% ARD vs 3.9% NARD; p=0.053). No statistically significant differences were found between RMD groups in the final models.

Conclusion: Many RMD patients have persistent symptoms, as in other populations. Lung damage is the most frequent sequela. Compared to NARD patients, ARD patients do not seem to differ in terms of persistent symptoms or sequelae, although ARD patients might generate more readmissions due to Covid-19.

AB1172 **POSTER: SARS-COV 2 INFECTION AND ANTI TNF THERAPY IN RHEUMATOID ARTHRITIS PATIENTS**

D. Anghel[1], O. G. Petrache[2], C. Jurcut[3], A. Mihai[3], M. M. Negru[4], A. Ghiațău[5]. *[1]Central Military Emergency University Hospital "Dr. Carol Davila", Department of Internal Medicine, Bucharest, Romania*; *[2]Central Military Emergency University Hospital "Dr. Carol Davila", Department of Internal Medicine, Bucharest,*; *[3]Central Military Emergency University Hospital "Dr. Carol Davila", Department of Internal Medicine, Bucharest, Romania*; *[4]"Sfânta Maria" Hospital, Department of Rheumatology, Bucharest, Romania*; *[5]Central Military Emergency University Hospital "Dr. Carol Davila", Department of Internal Medicine, Bucharest, Romania*

Background: High levels of tumor necrosis factor (TNF), a key proinflammatory cytokine, is associated with SARS-CoV-2 infection. In rheumatoid arthritis patients with SARS-CoV-2 infection, anti TNF therapy reduces not only TNF but other cytokines responsible for high morbidity and mortality. The severe systemic inflammation in COVID-19 causes respiratory symptoms, fever, fatigue, neurological and gastrointestinal manifestations.

Objectives: We followed the evolution of SARS-CoV-2 infection in rheumatoid arthritis patients who received anti TNF blockers.

Methods: Our study included 95 rheumatoid arthritis patients who were diagnosed with SARS CoV-2 infection through a positive RT-PCR-SARS-CoV2 test. 21 patients were men and 74 were women. Mean age was 58 ±11,5. 24 patients received monotheraphy with anti TNF blockers (Adalimumab/ Infliximab), 48 received TNF blockers in combination with Methotrexate (10 mg per week) and 23 received TNF blockers in combination with Leflunomide (20 mg per day).

We followed serum ferritin, C reactive protein and D-dimer in all patients. 59 patients were vaccinated with two doses of Pfizer-BioNtech (64.1 %).

The study group was analyzed from 30th December 2021 to 1st of January 2022. From 95 patients, 35 (36,8%) were hospitalized and 60 received ambulatory care.

Results: Our patients with COVID-19 presented with asimptomatic forms, forms with mild symptoms and complicated forms that required hospitalization. No patients had died. Milder forms were associated with the use of TNF blockers and Methotrexate and patients with monotherapy – TNF blockers. They presented with mild symptoms (fever, arthralgia, odynophagia, dysgeusia/ageusia, anosmia). Hospitalization rate in patients who received monotheraphy with TNF blockers was 29,1%, 31,2% in patients who received TNF blockers and Methotrexate and 56,5% in patients with TNF blockers and Leflunomide (69,3%). Factors associated with higher odds of hospitalization included older age (p=0,001), active disease (p=0,02), obesity (p=0,005), pulmonary chronic disease (p=0,02), diabetes (p=0,001) and concomitent dose of Leflunomide (p=0,0006). Female sex was associated with milder forms of the disease. Patients with high levels of D-dimer had a higher odd of hospitalization (p<0,001). Strong positive correlation was observed between elevated D-dimers and hospitalization odds.

Conclusion: TNF blockers in monotheraphy or associated with Methotrexate were correlated with lower odds of hospitalization and milder forms of COVID-19. No significant difference of hospitalization odd was observed between vaccinated and unvaccinated patients.

AB1173 **INCIDENT CASES OF COVID-19 AND VACCINATION ADHERENCE IN A MULTICENTRIC COHORT OF INFLAMMATORY ARTHRITIS IN BRAZIL**

S. M M de Souza[1], A. C. Medeiros-Ribeiro[1], M. Bredemeier[1], A. Duarte[1], M. Pinheiro[1], B. Stadler[1], J. C. Macieira[1], R. Ranza[1], J. Miranda[1], V. Valim[1], G. Castro[1], M. Bertolo[1], M. D. F. Sauma[1], V. Fernandes[1], R. Botelho[1], C. Brenol[1], H. M. Da Silveira DE Carvalho[1], S. Studart[1], G. Da Rocha Castelar Pinheiro[1], L. Rocha[1], H. De Leon de Lima[1], I. Pereira[1], M. Ohira Gazzeta[1], A. Kakehasi[1], P. Louzada Jr[1], A. L. S. Hayata[1], F. Pina[1], M. Alves Ferreira[1], L. Balarini[1], I. G. Silveira[1], S. Kowalski[1], D. Titton[1], R. Mendonça Da Silva Chakr[1], A. Ranzolin[1], I. Laurindo[1], R. Xavier[1]on behalf of BiobadaBrasil. *[1]Brazilian Society of Rheumatology, Register BiobadaBrasil, São Paulo, Brazil*

Background: The SARS-CoV-2 virus has caused a worldwide health crisis. Patients with inflammatory arthritis are at higher risk of hospitalization and death by COVID-19 due to comorbidities or immunosuppressive treatments. Vaccination is one the most important strategies to control the pandemic.

Objectives: To evaluate the incident cases of SARS-CoV-2 infection in a multicentric cohort of inflammatory arthritis in Brazil.

Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting their first bDMARD or tsDMARD (1). The present analysis is a retrospective evaluation of adult patients with inflammatory arthritis (rheumatoid arthritis – RA, spondylarthritis -SpA and psoriatic arthritis-PsA) that were alive since the beginning of the COVID-19 pandemics in Brazil in February 2020. We evaluated the incidence and severity of COVID-19 infection and the adherence to anti- SARS-CoV-2 vaccines schedules, up to January 2022.

Results: A total of 300 patients were interviewed and 69 (23.0%) reported confirmed anti-SARS-CoV infection and 5 (1.7%) had a second infection. Among known infected patients, 18.8% need hospitalization and oxygen support, 7.2% were admitted at ICU, and 5.8% died. After COVID-19 infection, 31.8% reported worsening of disease activity but only 6.1% had modification in medication due to disease activity. Distribution of cases followed the pattern of waves observed in Brazil (Figure 1). Regarding vaccination, 285 (95%) reported to have received at least one dose of any anti-SARS-CoV-2 vaccine: 43% received the first with the adenovirus ChAdOx1 nCoV-19 (AstraZeneca) adenovirus vaccine, 32% received the Sinovac-CoronaVac inactivated vaccine, 22% received the BNT162b2 (Pfizer-BioNtech) mRNA vaccine and 3% received the BNT162b2 (Pfizer-BioNtech) adenovirus vaccine. Almost all (98.1%) of these patients had already received the second dose of vaccine and after the first and second vaccine doses, 6% and 4% of patients, respectively, reported worsening of articular disease activity, while, after the third dose, no patient reported disease activity worsening.

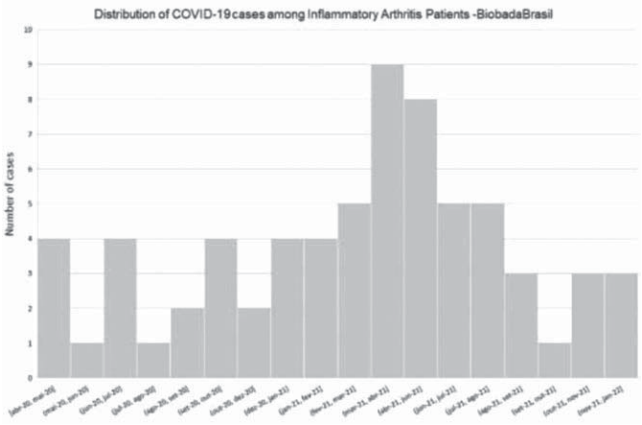

Figure 1.

Conclusion: During the pandemics, patients with inflammatory arthritis had a pattern of distribution of cases very similar to general population. Adherence to vaccination is high and well tolerated.

AB1174 ADVERSE EVENTS AFTER TWO DOSES OF BNT162B2 ANTI-SARS-COV-2 VACCINE IN PATIENTS WITH RHEUMATIC MUSCULOSKELETAL DISEASES: RESULTS FROM A SINGLE CENTER ITALIAN STUDY

A. Ciancio[1], D. Mauro[1], C. DI Vico[1], G. Rozza[1], M. D. Pasquale[1], I. Pantano[1], F. Ciccia[1]. [1]*University of Campania "Luigi Vanvitelli", Napoli, Italy, Rheumatology, Naples, Italy*

Background: Vaccination against COVID19 is the most important prevention tool against the current pandemic. However, since the approval of anti-COVID19 mRNA vaccines by EMA, safety and tolerability in patients with rheumatic musculoskeletal diseases has always been a much-discussed topic, given their novel, unprecedented mechanism of action and the concern for potential disease flares.

Objectives: To assess the safety and type of adverse events after two doses of BNT162b2 anti-SARS-CoV-2 vaccine in patients affected by rheumatologic diseases.

Methods: 241 patients who received two doses of BNT162b2 were invited to take part to a follow-up live visit 2 months after completion of the primary vaccination cycle. Data regarding age, sex, diagnosis, treatment and adverse events after vaccination were collected for each patient during the visit. Pearson chi-square and Fisher exact tests were used to compare the distribution of each type of adverse event between male and female and among Rheumatoid Arthritis, Spondyloarthritis and Connective Tissue Disease patients.

Results: Mean age of recruited patients was 57 years (IQR 49-65) and F:M ratio was 2.49:1 (172 F/69 M). Number and percentage of individuals for each disease category were represented as follows: Rheumatoid Arthritis 87 (36,10%), Spondyloarthritides 72 (29,88%), Connective Tissue Diseases 65 (26,97%), Autoinflammatory Diseases 4 (1,66%), Vasculitides 13 (5,39%). 42 subjects (17,42%) reported no adverse events, whereas local reactions such as pain and swelling at injection site were the most commonly reported side effect, (154 subjects, 63,9%, Table 1). Constitutional symptoms, comprising fatigue, muscle and joint pain, fever, chills and headache, were described in 54,77% of the interviews (132 subjects, Table 1). No patient experienced severe allergic reactions after vaccination. Statistical comparison among disease categories showed no differences in the distribution of adverse events. When analysing for sex, joint pain appeared to be reported significantly more frequently in male patients (p=0.002), while chills were more present in female patients (p=0.033). None of the interviewed subjects reported any sign or symptom relatable to disease flares.

Table 1

	All pts n (%)	Female n (%)	Male n (%)	RA n (%)	SpA n (%)	CTD n (%)
	241	172	69	87	72	65

AB1175 EFFECTS OF THE COVID-19 DISEASE ON AXIAL SPONDYLOARTHRITIS DISEASE FLARE

B. Armagan[1], E. Atalar[1], B. Özdemir[1], Ö. Karakaş[1], E. Kayacan Erdogan[1], S. C. Güven[1], I. Dogan[2], O. Küçükşahin[2], A. Erden[2]. [1]*Ankara City Hospital, Rheumatology, Ankara, Turkey*; [2]*Ankara Yıldırım Beyazıt University, Ankara City Hospital, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Rheumatological disease flares may be seen after many infections. However, our knowledge for the post-COVID axial spondyloarthritis (SpA) flares and its related factors is limited.

Objectives: We aimed to evaluate disease activity and factors that may be associated with disease activity in axial SpA patients in post-COVID period.

Methods: We retrospectively assessed the axial SpA patients who have had COVID-19 disease confirmed by a positive SARS-CoV-2 polymerized chain reaction (PCR) test result. Demographics, comorbid diseases, active medical treatments for SpA and information regarding COVID-19 clinical courses were collected from medical records. PCR positive patients were reached via telephone and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scored for pre- and post-COVID SpA symptoms. An increase of ≥2 points in the BASDAI score was defined as flare, and SpA groups with and without flare were compared. Factors predicting SpA flare were also analyzed by the logistic regression analysis.

Results: A total of 48 axial SpA patients were included in our study, 65% of them male and the mean±SD age was 42.3±8.6 years. Post-COVID SpA flare was seen in 38% patients. Demographic, clinical, medical features of the SpA patients and COVID-19 disease severity were similar between Flare and No flare groups. In comparison of the COVID-19 symptoms, although most of the

COVID-19 related symptoms were similar between two groups, the frequency of the back pain and diarrhea were higher in the Flare group than No flare group. But in multivariate analysis, only history of the inflammatory bowel disease had an increased risk for post-COVID SpA flare (Table 1).

Table 1. Results from adjusted logistic regression model of the spondyloarthritis flare

Variables	Enter Method			Backward:Conditional Method		
	OR	95% CI	p	OR	95% CI	p
Smoking	0.125	0.013-1.233	0.075			
Multimorbidity	0.244	0.047-1.256	0.091			
Inflammatory bowel disease	33.221	1.236-892.720	0.037	34.382	1.571-752.462	0.025
Fever	1.582	0.334-7.486	0.563			
Arthralgia	3.438	0.233-50.630	0.368			
Back pain	1.054	0.080-13.895	0.968			

OR: Odds ratio, CI: Confidence Interval

Conclusion: The presence of inflammatory bowel disease statistically significant related post-COVID SpA flares. In addition, diarrhea and back pain symptoms in COVID-19 disease may be stimulating factors for SpA flares but we found no effect of rheumatological therapies.

AB1176 DOES VACCINATION AND VARIANTS AFFECT THE COURSE OF THE COVID-19 IN INFLAMMATORY RHEUMATIC DISEASE?

S. Çelik[1], M. E. Kutu[1], B. Karadeniz[1], M. Soy[2]. *[1]Bakirkoy Dr Sadi Konuk Educational and Research Hospital, Rheumatology, Istanbul, Turkey*; *[2]Altinbas University Medicine Faculty, Rheumatology, Istanbul, Turkey*

Background: Although there have been expansion of knowledge about the course of COVID-19 in rheumatologic diseases, it still remains unclear the effect of vaccination status and variants on the disease course.

Objectives: We aimed to investigate the general clinical characteristics of our patients with inflammatory rheumatic disease (IRD) who had COVID-19 disease, their vaccination status and the time periods in which different variants were dominant during the disease.

Methods: During the routine follow-up of our patient's with IRD, whether the patients had COVID-19 disease, when they were vaccinated (Pfizer/Biontech or Sinovac in our Country) and main clinical characteristics and their comorbid diseases were recorded. The last patient was included in the study on January 25, 2022. They were divided into those who received insufficient or no vaccine and those who received a full dose of vaccine. The patients were divided into 3 groups according to the period they had the disease: Those who had the disease between March 2020 and June 2021accepted as "1st period patietns", the period when the Alpha and Beta variants, the initial forms of the disease, were dominant variants in populations; those who had the disease between July 2021 and November 2021, when the Delta variant dominated the World and in our country accepted as "2nd period patients"; and those who had the disease in December 2021 and later, when the Omicron variant was dominant throughout the world and in our country, was accepted as " 3rd period" patients.

Results: Total 463 (294 woman) IRD patients enrolled to the study. Distrubution of these patients included Behcet's syndrome:15; familial mediterranean fever: 57, rheumatoid arthritis:134, Sjogren's syndrome:24, systemic lupus erythematosus:26, Spondyloarthritis:141, necrotising vasculitis:6 and Others:50 cases. Mean age of patients were 46±13,2 (18-83) years. 354 (77%) of our patients got sick in the 1st period, 80 (17%) in the 2nd period and 28 (6%) in the 3rd period. When patients were compared in terms of their clinical complaints in these periods, dyspnea was significantly higher in patients in the 1st period (1st. period 36% vs 3rd period 18%; p:0.039), but there was no difference between other complaints including lung involvement and the frequency of hospitalization (p>0.05). 53% of patients had received at least 2 doses of mRNA vaccine. 84% of the patient has had COVID19 before full vaccination with any valid vaccine. When the patients who were full vaccinated and those who were not vaccinated or inadequately vaccinated at the time of illness were compared in terms of clinical features, lung involvement frequency and hospitalization frequency, no difference was found between them. (p>0.05, for all). However, hospitalization and lung involvement were less in those who received a booster dose of any valid vaccine (p: 0.03). While the average hospitalization rate was 17% for all groups, this rate was 50% for necrotizing vasculitis and was significantly higher (p:0,005). The probability of lung involvement and hospitalization were found to be significantly higher in patients using prednisolone 5mg (or equivalents) or more; (p:0.008 and p:0.000, respectively). Pulmonary involvement was significantly higher among patients receiving sulphasalasine (p:0.008). Among the patients on Rituximab, the probability of hospitalization was higher than those who did not (p: 0.01). There was no statistical difference in terms of hospitalization and pulmonary involvement between patients who took other drugs (p>0.05, for all). A total of 5 cases died, including 2 GPA, 1 EGPA, 1 RA and 1 FMF patients. Only 8 patients had a second history of COVID19.

Conclusion: The frequency of COVID-19 among IRD cases seems to decrease over time. Full vaccination seems effective for the prevention of COVID-19. It should be recommended that IRD patients have the full dose of vaccines and boosters. The risk of lung involvement and hospitalization increases in patients using certain drugs, such as corticosteroids, sulphasalasine and rituximab. These patients should be followed more closely.

AB1177 SEXUALITY, FAMILY PLANNING AND MENTAL HEALTH AMONG REPRODUCTIVE-AGE WOMEN WITH RHEUMATIC DISEASE DURING THE COVID-19 PANDEMIC

A. Puchner[1], N. Rosenberg[1,2], N. Valenta[1,2], V. Ritschl[3], T. Stamm[3], P. Mandl[1], D. Aletaha[1], K. Rosta[2]. *[1]Medical University of Vienna, Rheumatology, Wien, Austria*; *[2]Medical University of Vienna, Obstetrics and Gynecology, Wien, Austria*; *[3]Medical University of Vienna, Section for Outcomes Research CeMSIIS - Center for Medical Statistics, Informatics, and Intelligent Systems, Wien, Austria*

Background: Women with rheumatic disease are more likely to suffer from sexual dysfunction, infertility, depression, and anxiety. The pandemic may have affected these constraints.

Objectives: To investigate the effect of the Covid-19 pandemic on sexuality, family planning and mental health in a sample of women with rheumatic disease.

Methods: Women aged 18-50 with a rheumatic disease and women in an age-matched healthy control group received questionnaires featuring: 1) demographic information, sexual frequency, family planning; 2) the Female Sexual Function Index (FSFI); 3) the Depression, Anxiety and Stress Scale (DASS-21); and 4) the Coronavirus Anxiety Scale (CAS). Recruitment took place 3/21-12/21. Patients with rheumatic conditions were recruited at the Vienna University Clinic (AKH) and the control group through social media. Parameters were compared between the patients and the healthy control group, and with data on sexuality from women with rheumatic disease from 2019.

Results: A preliminary analysis was conducted with 83 patients with rheumatic disease and 124 healthy controls. The rheumatic disease group exhibited lower levels of stress (6.46 vs. 8.36 p<0.01) and Coronavirus Anxiety (6.27 vs 7.50 p<0.01) than the control group and was less likely to report that the pandemic led to a reduction of their sexual frequency (p<0.01). The control group cited "stress" frequently the decrease of sexual frequency. The FSFI analysis revealed that patients with rheumatic disease experienced higher levels of pain (p<0.001) during sex than the control group but were more satisfied with their relationships (p<0.05). In comparison to 58 patients with rheumatic conditions, whose data was collected in 2019, the 2021 cohort reported reduced FSFI values in the domains of desire (p<0.01), arousal (p<0.05), lubrication (p<0.05), and orgasms (p<0.01).

Conclusion: Consistent with research on female sexuality during the pandemic among healthy women, we found that patients with rheumatic conditions reported lower FSFI values in 2021, in comparison to 2019. Our finding that the pandemic had less impact on the patient group than a healthy control group, is consistent with research on MS and IBD patients, who showed surprising resilience in the face of the Covid-19 pandemic.

AB1178 THE COMPARISON OF EXECUTIVE FUNCTIONS OF RECOVERED COVID-19 PATIENTS WITH HEALTHY CONTROLS

C. Cakir[1], Y. Ulus[2], A. Bilgici[2]. *[1]Ministry of Health, Atakum İlçe Sağlık Müdürlüğü, Samsun, Turkey*; *[2]Ondokuz Mayıs University - Faculty of Medicine, Phyisical Medicine and Rehabilitation, Samsun, Turkey*

Background: The epidemiological and clinical features of COVID-19 patients are currently well characterized. However the subacute and long-term effects of COVID-19 are not clear. Cognitive disturbance is one of the residual effects of COVID-19 infection besides fatigue, dyspnea, chest pain, arthralgia, and decline in quality of life. It has been stated that patients with COVID-19 may have cognitive dysfunction, but it still remains unknown whether the COVID-19 infection is associated with cognitive impairment.

Objectives: The aims of this study were to compare the executive functions of recovered COVID-19 patients with healthy controls, and to evaluate the relation of the executive functions with sleep quality, emotional status, disease severity, and post COVID-19 duration in these patients.
Methods: Twenty-five patients aged 18-60 with a previous diagnosis of COVID-19 infection and 25 gender-age matched healthy individuals as a control group participated this study. The executive functions of participants were evaluated by the Wisconsin Card Sorting Task (WCST), Stroop Test-TBAG Form, and N-back test. Data on sleep quality by Pittsburgh Sleep Quality-Index (PSQI), depression by Beck Depression-Inventory (BDI), anxiety by Worry and Anxiety Questionnaire were collected in all participants. In patients, disease severity, COVID symptoms, and post-covid duration were noted. Data were analyzed by SPSS using Kolmogorov Smirnov test, chi-square test, Student-t test, and Pearson correlation analysis.
Results: In terms of WCST; patients' number of trials administered, total errors, and nonperseverative-errors scores were statistically higher; categories achieved and percentage of conceptual-level responses scores were statistically lower than controls ($p<0.05$). Patients' N-back test scores were statistically lower than controls ($p=0.012$). BDI, PSQI total, sleep quality, sleep latency, duration of sleep scores were significantly different in patients and controls ($p<0.05$). Patients were divided into three groups according to the severity of the disease and there was no significant difference between the three groups in terms of WCST, Stroop test, and N-back test ($p>0.05$). There were negative correlations between WCST-total errors and duration of sleep, WCST-number of trials administered and sleep efficiency, Stroop-number of errors and total PSQI scores. No correlation was found between the executive functions and emotional status of the patients ($p>0.05$).
Conclusion: According to the results of this study, executive functions may be effected in the patients recovered from COVID-19. After COVID-19 infection patients may have sleep problems, and executive dysfunctions may be correlated with sleep disorders in these patients. Since the executive functions were not associated with clinical findings of COVID-19 infection in this study, we suggest that it is not predicted in which patients executive functions will be impaired. Regardless of the COVID-19 infection severity, executive functions should be considered in the follow-up of these patients.

AB1179 CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO UNDERWENT COVID-19 IN THE REPUBLIC OF TATARSTAN

N. Shamsutdinova[1], S. Lapshina[1], V. Mukhamadieva[1], A. Sagitova[2], A. Zakirova[3], L. Krasnova[3], D. Abdulganieva[1], R. Abdrakipov[4], E. Sukhorukova[4]. *[1]Kazan State Medical UniversIty, Hospital Therapy, Kazan, Russian Federation*; *[2]Kazan State Medical UniversIty, Student, Kazan, Russian Federation*; *[3]Kazan State Medical UniversIty, student, Kazan, Russian Federation*; *[4]Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation*

Background: The management of patients with rheumatoid arthritis (RA) and novel coronavirus infection (NCI) is a significant problem due to the insufficient evidence base on this topic.
Objectives: To study the features of the transferred NCI in patients with RA and its influence on the course of RA.
Methods: From March 2020 to January 2022, 105 patients with RA who underwent NCI with a confirmed SarsCoV2 PCR result and/or X-ray computed tomography (CT) of the lungs were followed up. The age of the patients was 62 [55; 68] years, among them females - 84.7% (89 patients). The duration of RA at the time of NCI was 11 [6.5; 17.5] years. RA activity before NCI was low in 14 (13.3%) patients, moderate in 70 (66.6%), and high in 21 (20%) patients. The results of clinical and laboratory examinations were evaluated during the COVID-19, 1 and 3 months after it.
Results: The symptoms of NCI in patients with RA were comparable in frequency and severity to the course of infection in the population. 30 (28.6%) patients had a mild course of COVID-19, 74 (70.5%) had a moderate course, and 1 had a severe course. Bilateral polysegmental pneumonia was detected in 75 (71.4%) patients. The outcome of COVID-19 in all patients is recovery. Analysis of the course of RA showed a significant increase in activity 1 and 3 months after NCI: DAS28 from baseline to COVID-19 3.59±1.13 to 4.87±1.27 points after 3 months, respectively. Of the total number of recovered patients, 38.0% of patients showed an increase in activity due to clinical and laboratory parameters. 90.4% of patients noted the persistence or appearance of symptoms after undergoing NCI after 3 months, 45.7% had a combination of more than 3 different symptoms. The most common manifestations of asthenia in the form of a decrease in the quality of life (QOL) and working capacity. in 90.4% of patients: significant in 58.0% of people, insignificant in 32.4% of people. There was no significant correlation between RA activity and NCI severity. The second most frequent was the increase/appearance of pain in the joints - in 86.6% of respondents: significant in 72.3%, insignificant - 14.2%. Strengthening/appearance of muscle pain and/or headache and/or dysautonomia occurred in 44.7%. Appearance/intensification of shortness of breath and a decrease in exercise tolerance were noted by 36.1% of respondents: significant in 19.0% of people, insignificant in 17.1% of people. Among them, 64.8% (24) people with moderate severity, 35.2% (13) people with asymptomatic or mild NCI. Appearance/intensification of chest pain and/or palpitations was noted by 44.7% of people.
Conclusion: The prevalence and course of COVID-19 in patients with RA did not differ from that in the general population. However, coronavirus infection has led to an increase in pain and an increase in RA activity, a long-term persistence of post-COVID manifestations in the form of musculoskeletal pain and asthenic symptoms with a deterioration in the quality of life. There was no significant correlation between RA activity and NCI severity. At the same time, specific respiratory symptoms occurred only in a third of patients.

AB1180 COVID-19 HAD DISPROPORTIONATE IMPACTS ON RA SYMPTOMS AND FUNCTION BY SEX AND AGE: RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT (CATCH)

S. J. Bartlett[1], O. Schieir[2], M. F. Valois[2], D. Tin[3], E. Keystone[4], L. Bessette[5], J. Pope[6], G. Boire[7], G. Hazlewood[8], C. Hitchon[9], C. Thorne[3], V. Bykerk[10]on behalf of on behalf of CATCH Investigators. *[1]McGill University & McGill University Health Centre, Clinical Epidemiology & Rheumatology, Montreal, Canada*; *[2]McGill University, Clinical Epidemiology, Montreal, Canada*; *[3]The Arthritis Program Research Group, Rheumatology, Newmarket, Canada*; *[4]RheumKey, Rheumatology,Toronto, Canada*; *[5]University of Laval, Rheumatology, Quebec City, Canada*; *[6]Western University, Rheumatology, London, Canada*; *[7]University of Sherbrooke, Rheumatology, Sherbrooke, Canada*; *[8]University of Calgary, Rheumatology, Calgary, Canada*; *[9]University of Manitoba, Rheumatology, Winnipeg, Canada*; *[10]Hospital for Special Surgery, Rheumatology, New York, United States of America*

Background: During the COVID-19 pandemic, Canadians with RA faced considerable uncertainty due to greater risk of infection, hospitalization, changing access to RA medications, and very limited access to in-person RA care. Further, to reduce transmission of the virus and COVID-related hospitalizations, stringent mitigation measures were implemented across the country to greatly reduce social contacts including curfews, limits on private gatherings and business closures. Little is known about the impact of the COVID-19 pandemic and associated mitigation efforts in RA. We hypothesized that women and younger adults with RA would report greater impairments in HRQL.
Objectives: To compare changes in HRQL prior-to and during the COVID-19 pandemic by sex and age groups in real-world RA patients seen in routine practice settings.
Methods: Data were from patients in the Canadian Early Arthritis Cohort (CATCH) who completed a study visit in the year prior to the COVID-19 pandemic (Mar 2019 through Feb 2020) and a repeat assessment during the pandemic period (Mar 2020 – Jan 2022). RA disease activity was assessed using the RA Flare Questionnaire, a validated patient-reported measure of current RA disease symptoms (pain, stiffness, fatigue) and function (physical, participation). An RA-FQ score ≥ 20 was used to classify RA symptoms consistent with an RA inflammatory flare. HRQL was assessed using PROMIS-29 Adult Profiles. We compared changes in mean Physical (PHS) and Mental Health (MHS) scores, and the proportion of patients with impairments in each domain (i.e., scores ≥ 55 for pain interference, fatigue, anxiety, depression, and sleep and ≤45 for physical function and participation) before and during the COVID-19 pandemic across sex and age groups (<40, 40-64, ≥65 years).
Results: The 938 CATCH participants in the analytic sample with data available at both time periods had a mean (SD) age of 60 (13) and RA symptom duration of 5.8 (3.7) years; 72% were women, 88% were white, and 64% reported >high school education. Most (80%) were in CDAI REM/LDA at the most recent visit prior to start of pandemic. The proportion of patients with RA-FQ ≥20 were similar at both time periods. While physical and emotional RA symptom impacts

remained stable in men prior to and during the COVID-19 pandemic, women reported significant increases in anxiety and depression during the pandemic period. Younger RA patients <40 reported increases in depression, and older RA patients (65+) reported increases in anxiety and greater impacts on participation.
Conclusion: Our results illustrate that while the proportions of patients with high inflammatory disease activity were similar prior to and during the COVID-19 pandemic, we observed disproportionate impacts on HRQL by sex and age with a higher proportion of women, adults <40, and those ≥65 years of age experiencing greater impairments in several HRQL domains.

Table 1.

	Women (N = 673)		Men (N=265)		Age <40 (N=84)		Age 45-64 (N=492)		Age 65+ (N= 362)

AB1181 THE BURDEN OF POST-SARS-COV2 VACCINE COMPLICATIONS AND NEWLY DIAGNOSED IMMUNE-MEDIATED INFLAMMATORY DISEASES

F. Carubbi[1], A. Alunno[1], J. Santilli[1], J. Cipollone[1], C. Martini[1], V. Moronti[1], P. Sipari[1], C. Ferri[1]. [1]*Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*

Background: Local and systemic reactions have been observed after all vaccines for SARS-CoV-2 but in the majority of cases, symptoms are mild and self-limiting. However, evidence on more severe clinical scenarios, requiring admission to hospital or referral to outpatient clinics after the administration of SARS-CoV-2 vaccines has accrued. This also includes newly diagnosed diseases, such as cardiovascular and immune-mediated inflammatory diseases (IMID).
Objectives: We aimed at quantifying the burden of post-vaccine hospital admissions/referrals and of newly diagnosed IMID.
Methods: Clinical records of patients referred to our Internal Medicine institution (both inpatients and outpatients) between February and June 2021 were retrospectively assessed. Subjects having received one or more doses of any of the EMA-approved SARS-CoV-2 vaccines within the previous 30 days were included. Subjects with a previous diagnosis of IMID were excluded.
Results: Our cohort included 99 patients, 45 females and 54 males, with a mean age of 64 years and a median of 3 comorbities (range 0-7). Eighty-eight patients (89%) required admission to the Internal Medicine ward while 11 were referred to the outpatient clinic. 68 (69%) of patients received the vaccine BNT162b2, 16 (16%) the ChAdOx1 nCoV-19, 9 (9%) the mRNA-1273 and 6 (6%) the Ad26.COV2.S. Twenty-seven (27%) subjects developed symptoms after the first vaccine dose with a mean latency of 2 days (median=0 indicating symptom onset on the day of the vaccine administration). Twenty-four (24%) subjects developed symptoms after the second dose with a mean latency of 4 days (median 1 day). All the other subjects did not develop symptoms within the week after the vaccine and were admitted for reasons apparently unrelated to vaccine administration. The number of presenting complaints ranged between 1 and 4 with 87% of subjects presenting with 1 or two coexisting complaints. Gastrointestinal manifestations were the most frequent being the presenting complaint in 31 (31%) of patients followed by severe fatigue/appetite loss in 19 (19%) of subjects, fever in 18 (18.2%) and neurological manifestation in 16 (16%) of subjects. A temporal and causal association with the SARS-CoV-2 vaccine was identified since all other known causes for these manifestations were ruled out. No in-hospital deaths were observed and 19 (19%) patients were diagnosed with a new onset IMID (Table 1). The clinical picture of these subjects was not significantly different from that of patients without a confirmed IMID and neither were demographic features. No association with the type of vaccine was observed.

Table 1. Immune-mediated inflammatory diseases diagnosed after SARS-CoV2 vaccination (N=19)

Disease	Number of patients
Rheumatoid arthritis	5
Psoriatic arthritis	2
IgA vasculitis	2
Spondyloarthritis	1
Giant cell arteritis	1
Polymyalgia rheumatica	1
Gout	1
Primary biliary cholangitis	1
Antiphospholipid syndrome	1
Graves' disease	1
Ulcerative colitis	1
Autoimmune thrombocytopenia	1
Leukocytoclastic vasculitis	1

Conclusion: Our data show that post-vaccine newly diagnosed IMID may represent a challenge in clinical practice and it seems that no demographic or clinical feature is able to predict their onset. A multidisciplinary cooperation and registry data are needed in order to reliably estimate and define the impact of SARS-CoV-2 vaccinations on new onset IMID.

AB1182 SPECIALIZED PRO-RESOLVING MEDIATORS (SPMS) AND INFLAMMATORY NETWORKS IN PATIENTS AFFECTED BY ADULT ONSET STILL'S DISEASE (AOSD) AND COVID-19

L. Navarini[1,2], M. Vomero[2], O. Berardiucrti[1,2], D. Currado[1], A. Marino[1], A. Biaggi[1], S. Di Donato[1], F. Ursini[3,4], P. Ruscitti[5], R. Meliconi[3,4], P. Cipriani[5], A. Iagnocco[6], A. Afeltra[1,2], R. Giacomelli[1,2]on behalf of AOSD-GIRRCS Group. [1]*Campus Bio-Medico University of Rome, Rheumatology, Immunology, and Clinical Medicine, Rome, Italy*; [2]*Fondazione Policlinico Universitario Campus Bio-Medico, Immunorheumatology, Rome, Italy*; [3]*IRCCS Istituto Ortopedico Rizzoli, Rheumatology Unit, Bologna, Italy*; [4]*Alma Mater Studiorum University of Bologna, Department of Biomedical and Neuromotor Sciences (DIBINEM), Bologna, Italy*; [5]*Università degli studi Dell'Aquila, Department of Biotechnological and Applied Clinical Sciences, Rheumatology Unit, L'Aquila, Italy*; [6]*Università Degli Studi Di Torino, Academic Rheumatology Centre, MFRU, Dipartimento Scienze Cliniche E Biologiche, Torino, Italy*

Background: Uncontrolled systemic inflammation characterizes COVID-19 and autoinflammatory diseases such as adult-onset Still's disease (AOSD). Biosynthesis of pro-resolving mediators (SPMs), i.e. lipoxins (LX), resolvins (Rv), protectins (PD), and maresins (MaR), ensures inflammation shutdown and tissue repair, limiting neutrophils recruitment and stimulating macrophages to remove apoptotic cells. Among protectins, reduction of PD1 was found in the lungs of mice infected with the H5N1 influenza virus and experimental treatment with PD1 resulted in increased animals' survival (Morita M et al 2013).
Objectives: We investigated the effects of SPMs in pathogenesis and clinical evolution of AOSD and compared these data with mild and severe COVID-19. Finally, we analyzed the potential role of PD1 in modulating the inflammatory response of macrophages obtained from AOSD patients, COVID-19 patients and healthy donors (HDs).
Methods: 21 patients hospitalized for COVID-19 (10 ICU and 11 hospitalized in medical clinical unit) and 13 patients with AOSD were enrolled. Plasma PD1 levels from patients and controls were analyzed by ELISA, and monocytes-derived macrophages were polarized into M1 and M2 phenotype. We analyzed the effect of PD-1 on macrophages differentiation. At 10 days, macrophages were analyzed for surface expression of subtypes markers by flow cytometry. Cytokines production was measured in supernatants by Bio-Plex Assays. Peripheral blood mononuclear cells (PBMCS) from 3 AOSD patients, 2 COVID-19 patients and 3 HDs were obtained. Next-generation deep sequencing was then performed to identify the differences in PBMCs transcripts profiles.
Results: AOSD patients with systemic scored (SS) ≥1 showed an increase of PD1 levels compared to AOSD patients with lower systemic score (p=0.04) (Figure 1A). Similarly, plasma levels of PD1 were increased in COVID-19 patients independently from their clinical subsets, compared to HDs (p=0.02). I*n vitro* treatment with PD1 of monocytes-derived macrophages from AOSD and COVID-19 patients induced a significant increase of M2 polarization vs control (p<0.05) (Figure 1B). Furthermore, a significant release of IL-10 and

CCL4 from M2 macrophages was observed when compared to control (p<0.05) (Figure 1C). In the transcriptomes from 3 AOSD patients (2 mild and 1 severe), 2 COVID-19 patients (1 mild and 1 ICU) and 2 HDs, we observed that genes involved in inflammation, lipid catabolism and monocytes activation were specifically dysregulated in AOSD and COVID-19 patients when compared to HDs. Among them *pla2g15, pla2g12a, pla2g2d,* involved in mobilization of SPMs precursors, were significant upregulated in patients compared to HDs (p<.01, |log2FoldChange|>1.2) (Figure 1D). The largest part of the genes involved in inflammation, lipid catabolism, and monocytes activation are less expressed in AOSD patients when compared to COVID19 patients, as reported in Table 1.

Table 1.

Gene symbol	Log2 fold change	p	Adjusted p	Counts COVID19	Counts AOSD

RNASE4	2.48	0.0001	0.0092	86.66	15.42

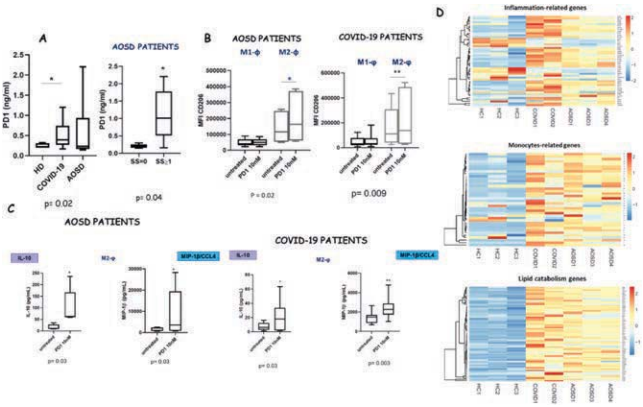

Figure 1.

Conclusion: The counterbalance by SPMs during inflammation is still a largely unexplored pathway. Our study suggests that an imbalance of SPMs in autoinflammatory diseases as well as COVID-19. The modulation of SPMs as observed in our experiments, might represent a new possible therapeutic strategy during AOSD and COVID-19.

AB1183 COVID-19 VACCINE: HESITANCY, ACCEPTANCE AND TOLERANCE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

M. Ghali[1], F. Fhima[1], M. Ardhaoui[1], N. Ben Chekaya[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba hospital, Rheumatology, Monastir,Tunisia*

Background: Patients with rheumatoid arthritis (RA) are considered a high-risk population to develop severe COVID-19 [1] and therefore vaccination is strongly recommended. Previous reports have shown a high hesitancy rate to receive a COVID-19 vaccine among RA.

Objectives: This study aimed to evaluate the attitude of patients with RA to vaccination against SARS-CoV-2, explore the factors which may influence it, and assess adverse events of SARS-CoV-2 vaccines.

Methods: This is a cross-sectional study including 106 patients with RA diagnosed according to the ACR/EULAR 2010 classification criteria and followed in the Rheumatology Department, over a period of 10 months from March to December 2021.Demographic and disease parameters were collected: age, gender, educational status, disease duration, erythrocyte sedimentation rate (ESR), disease activity score (DAS28), and treatments being used. All patients responded to a questionnaire on their perceptions and concerns about the covid-19 vaccine, and the adverse effects for those who got vaccinated.

Results: Among the 106 patients, 90 (84,9%) were females and 16 (15,1%) were males. The mean age was 54 ±13 years old [23-77]. Sixty-four percent were from urban areas and 36 % were from rural areas. Thirty-three percent of patients were illiterate. The mean disease duration was 9.54 ±5.76 years [2-22]. The mean DAS28 ESR was 3,88 ±1.34 [1.2-7.58]. All of our patients were taking conventional synthetic DMARDs. Seventeen percent of patients were on biological DMARDs. The majority of the patients (90%) reported that they respected the preventive measures. Twenty-two percent of patients had stopped their treatment because they were afraid of the covid-19. Twenty-eight patients had contracted the SARS- CoV-2. Seventeen percent of the patients reported that they didn't get vaccinated against covid-19. The reasons given by these patients were: presumed adverse events (53,3%), presumed inefficiency (25%), no recommendation from their doctor (46,7%), fear that the vaccine would make RA worse (64,7%). For the vaccinated patients, the vaccines administered were: 63,6 % Pfizer BioNTech, 6,8% Oxford/AstraZeneca, 5,7% Moderna, 4,5% Janssen/Johnson & Johnson, 2,3% Sinovac-CoronaVac and 17% unspecified. The majority of the patients (72,7 %) received two doses,14,8 % one dose and 12,5% 3 doses. After vaccination, 73,9% of patients reported adverse events, such as pain at the site of injection (88,1%), fatigue (35,8%), headache (14,9%), fever (13,4%) and muscle/joint pains (4,5%). Only 1 patient had experienced rheumatic disease flare. Hesitancy about the COVID-19 vaccination was associated with low intellectual level (p=0.004) and rural origin (p=0.001).RA disease duration, DAS28-ESR, and treatments have no influence on the attitude of patients towards COVID-19 Vaccination (p > 0,05).

Conclusion: The acceptance of COVID-19 vaccination by RA patients in our study is quite promising. The majority of patients tolerated their vaccination well, with rare RA flares up. These results should reassure rheumatologists and patients. Education and outreach efforts need to be continued, especially for illiterate people and those who live in rural areas.

AB1184 SAFETY PROFILE OF SARS COV-2 VACCINES IN PATIENTS WITH CONNECTIVE TISSUE DISEASE, VASCULITIS AND POLYMYALGIA RHEUMATICA. BI-CENTRIC STUDY.

G. Busto[1], D. Cici[1], V. Rella[1], C. Rotondo[1], M. Fornaro[2], R. Colia[1], A. Corrado[1], F. Iannone[2], F. P. Cantatore[1]. [1]*UOC di Reumatologia Universitaria, Dipartimento di Scienze Mediche e Chirurgiche, Foggia, Italy*; [2]*Reumatologia Universitaria, Bari, Dipartimento dell'Emergenza e dei Trapianti di Organi, Bari, Italy*

Background: In recent times, safety and potential adverse effects (AEs) of Sars-CoV-2 vaccines have gained great relevance and have been a central topic in scientific discussion.

Objectives: The aim of this study was to evaluate the incidence of AEs after Sars-CoV-2 vaccine administration in patients affected by Connective Tissue Disease, Vasculitis or Polymyalgia Rheumatica. Moreover, we assessed patients' adherence to the American College of Rheumatology (ACR)[1] or Italian Rheumatology Society (SIR)[2] recommendations.
Methods: 139 patients affected by Connective Tissue Disease, Vasculitis or Polymyalgia Rheumatica were enrolled at the Rheumatology Units of University Hospitals of Bari and Foggia. All patients were given a questionnaire to evaluate vaccine type and dose number, AEs, potential pre-vaccine prophylaxis, immunosuppressive therapy and its possible suspension according to the clinical guidance summary proposed by ACR or SIR.
Results: Among the 139 enrolled patients (120 females and 19 males, mean age 54 ± 14,7 year, mean disease duration 8,6 ± 7,4 years), 31 subjects (19%) received anti Sars-CoV-2 vaccination. 5 patients received the AstraZeneca COVID-19 vaccine, 23 the BioNTech-Pfizer COVID-19 vaccine and 3 the Moderna vaccine. Only 48% of subjects received two doses. 42% of patients reported non-severe AEs after the first dose of vaccine, specifically 45% of patients who received the BioNTech-Pfizer COVID-19 vaccine, 40% of those who were administered the AstraZeneca vaccine and 33% of those who received the Moderna vaccine. Most frequent AEs were site injection pain (19%), fatigue (13%), headache (13%), myalgia (6%), fever (6%), nausea (3%), rheumatic disease flare (3%) (the latest was reported only among the Polymyalgia Rheumatica patients). Considering the different diseases, the highest trend of AEs was observed in Polymialgya Rheumatica (66%), Systemic Sclerosis (57%), Sjogren Syndrome (40%) and undifferentiated connective tissue disease (23%) patients. 30% of patients who received the second vaccine dose reported AEs. All of them were administered the BioNTech-Pfizer COVID-19 vaccine. Most reported AEs after the second vaccine dose were site injection pain (6%), headache (3%), myalgia (6%), fever (6%). The highest trend of AEs was observed in undifferentiated connective tissue disease (60%) and Sjogren Syndrome (33%) patients. Only 13 % of subjects who reported AEs after the first vaccine administration, reported AEs also after the second dose. Only 9,7% of patients did not comply with the COVID-19 vaccine clinical guidance prosed by ACR or SIR regarding immunosuppressive treatment management before and after immunization.
Conclusion: Patients enrolled in this study developed mild AEs. Only among Polymyalgia Rheumatica patients were described disease flares and higher trend of AEs. Although patients affected by Systemic Lupus Erythematosus, Antiphospholipid Syndrome and Vasculitis were enrolled, none of them reported severe AEs, included the extensively discussed post-vaccine thrombosis. We found no significant dissimilarity of AEs relating to different types of vaccine and good patient compliance to physician recommendations about treatment management.

AB1185 PATIENT-REPORTED EXPERIENCE IN IMMUNE MEDIATED INFLAMMATORY DISEASES (IMID) IN THECONTEXT OF THE COVID-19 PANDEMIC: ACCESSIBILITY AND CONTINUITY OF CARE.

J. P. Baldivieso[1], E. Ramirez[2], M. Uriarte-Ecenarro[1], C. Valero[1], E. Velasco[1], I. Llorente[1], A. Morell[2], O. Solas[3], R. Garcia-Vicuna[1]. [1]*Hospital Universitario de La Princesa, IIS-Princesa, Rheumatology, Madrid, Spain*; [2]*Hospital de La Princesa, IIS-Princesa, Hospital Pharmacy, Madrid, Spain*; [3]*Hospital Universitario de La Princesa, IIS-Princesa, Senior Consultant Public Health & Policies, Madrid, Spain*

Background: The lockdown and mobility restrictions in early COVID19 pandemic had a great impact in chronic patient care due to limited access and scheduled visits. In our hospital, coordinated non-pharmacological interventions (NPI) were designed in Rheumatology and Pharmacy services to maintain the accessibility and continuity of care for patients with IMID.
Objectives: To evaluate the patient reported experience (PRE), health status and quality of life in Rheumatology outpatient IMID subjects since March 14, 2020 when lockdown was imposed and during subsequent restrictions, related to the healthcare team and medications accessibility, and continuity of care.
Methods: Observational study, using a patient survey. Adult patients attending the rheumatology outpatient clinic between Nov 2, 2020 to Feb 13, 2021, with rheumatoid arthritis (RA), psoriatic arthritis (PsA), spondylarthritis (SpA) or systemic autoimmune diseases (SAD), with at least 1 year from diagnosis and 1 month of treatment with conventional synthetic (cs) targeted synthetic (ts) or biological (b) disease modifying antirheumatic drugs (DMARD). Face to face or phone interviews were conducted using an ad hoc designed questionnaire that included COVID19 related questions, the 11 IEXPAC scale items (5 point Likert scale ranging from never to always) (www.iexpac.org), and 4 items (5 points, very good to very bad) of the global scale PROMIS 10 (Patient-Reported Outcomes, PRO). All questions refer to the patient's experience during the 6 months prior to data collection.
Results: From 174 screening patients, 158 completed the survey, mainly woman (66.5%) with a median age of 60 (IQR 47-69,3) years. The most frequent diagnosis was RA (43%) followed by ESAP (35%), EAS (22%) and PsA (13%). 46.8% of the patients have been prescribed b or ts DMARD and 53.2% sc DMARD, 32.9% in combination. From 158, 39 persons requested healthcare for COVID-19 related symptoms and diagnosis was confirmed in 17 (10,8%). Just 2 patients required hospital admission. Clinical control and continuity of care for COVID19+ patients were carried out from their primary care center and by phone consultation. Some key results of the survey are displayed in Table 1.

Table 1. PRO and Patients' perception during COVID19 lockdown and restrictions.

During confinement and restrictions due to covid-19, in the last 6 months …	Responses (%) N= 158
Your degree of concern about the COVID19 crisis is.	High + Quite high (86.7)
PRO (PROMIS 10)	
How good was your health …?	Very good (11.4), Good: (43.7)
and your emotional/mental health, including mood and ability to think?	Very good (10.1) Good (41.1)
your quality of life was.	Very good (8.25) Good (49,4)
Your satisfaction in performing daily tasks (home, work, family) was.	Very good (7.8) Good (55.1)
Accessibility to care and medications	
I could contact my rheumatologist whenever I needed (email, phone).	Always (79.9)
My rheumatologist changed my face-to-face visit for a phone call	Yes (53)
I received my medication at home from the hospital pharmacy	Yes (16)
I picked up my medication from the hospital pharmacy, without incident.	Yes (21)
I maintained the prescribed dose medication…	Always + almost always (96,2)
At some point I modify a medication by my own decision	Yes (6)
My doctor changed the dose or route of administration	Yes (7)
Your satisfaction with the care provided from all professionals in the team was	Very + Quite satisfied (75)
PREMS (IEXPAC)	
Item 2. The professionals … are coordinated to offer me good healthcare	Always (34.18)
Item 8. They make sure that I take my medication correctly	Always (73.42)
Item 9. They worry about my welfare	Always (74.68)

Conclusion: Lessons have learned during the COVID19 lockdown and restrictions by assessing patients' health status and patients-reported experience. Coordinated NPI such as medication monitoring and home delivery, appointment reorganization and protocolized phone visits can result in a good patient perception and medication adherence whilst receiving care in a challenging situation.

AB1186 ACUTE PERICARDITIS IN TIMES OF COVID

C. Azabal Perez[1], C. Ramos Giráldez[1], R. P. Álvaro[1], R. Martínez[1], M. Velloso Feijoo[1], J. L. Marenco[1]. [1]*Valme University Hospital, Rheumatology department, Seville, Spain*

Background: The most common etiology of acute pericarditis is usually infectious, especially viral. When its cause is inflammatory (up to 7% of cases), it can be presented as an isolated process or be a clinical manifestation in the context of multiple systemic autoimmune diseases (SAD), therefore it is necessary to make a broad differential diagnosis. Nowadays, an increased incidence has been described in relation to SARS-CoV-2 infection, and especially in global vaccination against this one. This represents a clinical challenge when we have to identify the cause of this pathology with a not insignificant comorbidity.

Table 1.

	Age	Sex	Underlying rheumatological disease	Previous treatment	Treatment performed	Pericardial effusion	Evolution
Case1	23	Male	Seronegative oligoarthritis and vasculitis	Hydroxychloroquine	Colchicine Steroids Azathioprine Anakinra	Moderate	Resolution
Case2	48	Woman	No	No	Colchicine Steroids Hydroxychloroquine	No	Resolution
Case3	68	Woman	Seropositive RA and Sjögren syndrome	Leflunomide Rituximab	Steroids Hydroxychloroquine Leflunomide Tocilizumab	Mild	Resolution
Case4	47	Woman	No	No	Colchicine Steroids Hydroxychloroquine	Moderate	Resolution
Case5	27	Male	No	No	Colchicine Steroids	Severe	Resolution
Case6	61	Woman	lcSSc	D-penicillamine	Steroids Azathioprine	Severe	Resolution
Case7	68	Woman	SLE	Steroids	Steroids Azathioprine Rituximab	No	Resolution
Case8	71	Male	ANA+ polyarthritis	Steroids	Steroids Hydroxychloroquine	No	Resolution

Objectives: To describe the characteristics of a series of patients with acute pericarditis and its association with SAD.

Methods: Retrospective and descriptive observational study. Digitalised records of patients with acute pericarditis evaluated in the Rheumatology unit of a tertiary hospital in Seville during 2021 were reviewed. Demographic, epidemiological, clinical and therapeutic variables were analysed.

Results: Eight cases of acute pericarditis were detected. The average age of the patients was 51.50 ± 18.601 years. 62.5% were women. 50% had previous rheumatological pathology: two rheumatoid arthritis (RA), one systemic lupus erythematosus (SLE) and one limited systemic sclerosis (LSS); with an average disease duration of 8.63 ± 2.387 months. Of these, 3 were on treatment with steroids and DMARDs (leflunomide or hydroxychloroquine) and 1 had previously received rituximab. Pericardial effusion was moderate in 50% of cases, severe in 33.3% and mild in 16.7%. One patient had cardiac tamponade. Five patients had pleural effusion, which was moderate in 80%, and in one case associated with pneumonia. As complications, one patient developed heart failure and the patient with ESL was diagnosed with pulmonary arterial hypertension. Two patients had previous COVID19 and 7 were vaccinated against Sars-CoV2. Treatment was colchicine in 57.15% of cases, steroids in 85.7%, DMARDsc in 85.8% (3 hydroxychloroquine and 3 azathioprine) and DMARDsb in 42.9% (1 anakinra, 1 tocilizumab and 1 rituximab). Pericarditis resolved in all patients. Table 1.

Conclusion: In the previous year, an increase in consultations from other departments for acute pericarditis with suspected inflammatory origin was observed. The possibility of a correlation with COVID19 or vaccination against COVID was initially considered, but it could not be demonstrated, since vaccination was later in vaccinated patients, and in those who had been infected, the time interval until the development of pericarditis was too long for it in order to be attributed to COVID19. Finally, in 5 of the 8 patients, pericarditis was related to SAD, in particular with the rheumatic pathologies most associated with this clinical manifestation (RA and SLE). Therefore, in the middle of the COVID pandemic, in addition to considering COVID19 or its vaccine in the differential diagnosis of acute pericarditis, we must not forget to include SAD in this diagnosis.

AB1187

AUTOIMMUNITY PROFILE AND LUNG INVOLVEMENT IN ITALIAN PATIENTS WITH DERMATOMYOSITIS DURING COVID-19 PANDEMIA

P. Triggianese[1], A. D'antonio[1], E. Cela[1], B. Kroegler[1], S. Modica[1], M. Ferraioli[1], P. Conigliaro[1], E. Greco[1], A. Bergamini[1], M. S. Chimenti[1]. [1]*Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", University of Rome Tor Vergata, Rome, Italy*

Background: Dermatomyositis (DM) is a rare idiopathic inflammatory myopathy that can present with a variable spectrum of cutaneous and systemic manifestations[1]. Correlations between myositis-specific autoantibodies (MSAs) and disease phenotype have been documented in DM in particular in association with the development of interstitial lung disease (ILD). Ongoing studies focus on the potential role of MSAs in similarities of the pathophysiological mechanisms of COVID-19 associated ILD and that related to DM suggesting an intriguing cross talk between autoimmunity and COVID-19[2].

Objectives: To explore clinical patterns including ILD and MSAs profile in DM patients from a population-based single-center study carried out in a Tertiary Referral Rheumatologic Clinic. SARS-CoV-2 infections and vaccination were also analysed.

Methods: We enrolled patients affected by DM classified according to 2017 EULAR/ACR criteria[1] with a disease onset at ≥18 years referring to the Rheumatologic Clinic of Tor Vergata University Hospital in Rome (Italy). Clinical data were collected from medical records: gender, age of onset of symptoms and diagnosis, clinical features, auto-antibodies patterns (ANA, MSAs including anti-tRNA synthetase, -Jo1, -PL7, -EJ, - MDA5, -NXP2, SAE, Mi2, and myositis-associated antibodies comprising anti-PM/Scl, -Ro-52, -Ku, U1RNP), pattern of lung abnormalities at thoracic CT scans, and treatments. The prevalence of SARS-CoV-2 infection and vaccination profile were also investigated.

Results: Among eligible cases (n=30), patients who completed the study (n=19) included almost entirely women (F=73.7%). The median age at disease onset was 57.4±12.4 yrs while the mean diagnostic delay resulted as 12±10 months. Skin manifestations and myalgia were the prevalent symptoms (79% and 63%, respectively) whereas dyspnea and cough occurred in a third of the cohort at DM onset. Besides the skin involvement, the decrease in pulmonary function was the main clinical manifestation at the first rheumatological referral (52.6% of cases) followed by joint pain (36.8%) and cardiovascular events (10.6%). ANA titer≥1:160 occurred in 79% of patients. All patients showed MSAs positivity with a similar distribution: a single case of double positivity was registered in a man with anti-MDA5 and -NXP2. The most common CT findings were ground-glass opacity and parenchymal band in a third of patients (32%). The entire cohort had undergone cycles of steroids from the onset of DM and during the follow-up, according to disease severity. The main used therapies were methotrexate (47%), intravenous immunoglobulin (42%) and mofetil micofenolate (31.6%). None of patients had SARS-CoV-2 infection (until December 2021). The 63% of the cohort received at least one dose of the anti- SARS-CoV-2 mRNA vaccine (BNT162b2), of which 10% had completed with the booster dose. No adverse reactions or post-vaccination DM flare were registered. A third of the cohort had not been vaccinated due to concomitant disease activity or therapies. No cases of post-COVID19 new-onset DM were diagnosed.

Conclusion: Our preliminary findings support the relevant impact of lung involvement in DM. The availability of MSAs can help to stratify patients with

DM for outcome and risk of potential disease complications. The impact of MSAs on ILD associated or not to COVID-19 deserve further investigations in a larger DM cohort and for a longer post-COVID-19 pandemia follow-up time.

AB1188 SARS-COV-2 VACCINATION WILLINGNESS AND PREDICTORS IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES (CIRD) AND WITHOUT CIRD

I. Andreica[1], I. Roman[1], X. Baraliakos[1], U. Kiltz[1], J. Braun[1]. [1]*Rheumazentrum Ruhrgebiet, Ruhr-University, Rheumatology, Herne, Germany*

Background: Recent surveys in chronic inflammatory rheumatic diseases (CIRD) showed a high degree of vaccine hesitancy. Current knowledge about patients' attitudes towards vaccination against SARS-CoV-2 is limited.

Objectives: To assess the willingness of CIRD patients to be vaccinated against SARS-CoV-2 and to identify influencing factors compared to non-CIRD patients.

Methods: In this cross-sectional study, two cohorts of consecutively in parallel recruited patients with and without CIRD presenting to our tertiary hospital answered questions of a structured interview to assess vaccination willingness to SARS-CoV-2, experience with SARS-CoV2 in their environment and their personal history of infections and vaccinations. Vaccination willingness was assessed by a numerical rating scale (0: fully disagree; 10: fully agree). Arbitrarily defined cut-offs were used to define definite (score ≥7) and probable willingness (scores of 5 or 6) to be vaccinated. Statistical analyses were performed with appropriate tests such as Kendall-tau b.

Results: A total of 514 CIRD and 100 non-CIRD patients, mean age 54.7±12.8 and 55.6±9.8 years, were included. Definite and probable willingness to be vaccinated against SARS-CoV-2 was declared by 79.6% and 90.7% vs. 76.0% and 85.0% of CIRD and non-CIRD patients, respectively. Only 60% of CIRD patients believed that the vaccines against SARS-CoV-2 were safe, and 42% indicated to be afraid of side effects. Vaccination willingness correlated significantly with the degree of education, age, identification with a risk group for COVID-19 disease, hypertension, and the degree of information about preventable diseases. There was no correlation with the history of infections or with immunosuppressive therapy.

Conclusion: Although our results show a high willingness for vaccination against SARS-CoV-2 in both groups, there was quite some uncertainty regarding the safety and efficacy of the vaccines. Since major influencing factors were education and information about SARS-CoV-2 and COVID-19, patient education should be immediately improved.

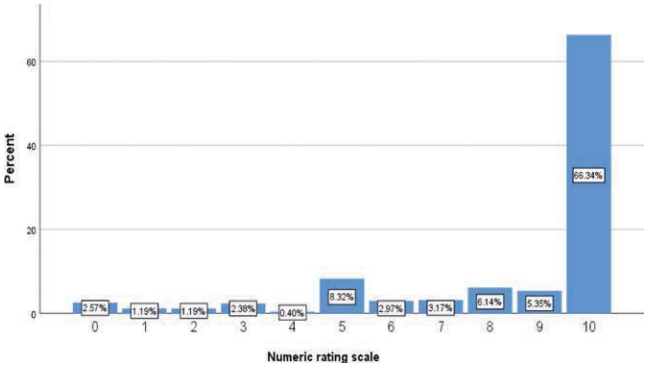

Figure 1. Vaccination willingness of CIRD patients

AB1189 THE RISK OF FLARE UP FOLLOWING NSARS-COV2 VACCINE IN INFLAMMATORY ARTHRITIS

F. Frizzera[1], F. Pettorossi[1], P. De Sandre[1], G. Scanelli[1], A. Hoxha[1]. [1]*San Bortolo Hospital, Internal Medicine Unit, Department of Medicine, Vicenza, Italy*

Background: As autoimmune phenomena following anti-nSARS-CoV2 vaccine was reported in the healthy population, there is increasing concern in patients with inflammatory joint diseases regarding possible side effects and disease flare-ups.

Objectives: We set out to evaluate the possible risk of disease exacerbation and the predisposing risk factors for the flare up.

Methods: This is a single center prospective cohort study, enrolling patients attending Arthritis Clinic at San Bortolo Hospital, during a follow-up of 12 months. All patients, after obtaining informed consent, answered a 24-item questionnaire including information about nSARS-CoV2 infection, vaccination, disease activity, ongoing treatment, vaccine side effects, disease flare up and need to change therapy.

Results: A total of 109 patients, 60 (55.1%) females and 49 (44.9%) males with a mean age of 60.1 years ±12.6 SD were enrolled. Forty-three (39.5%) were affected by rheumatoid arthritis, 43 (39.5%) from psoriatic arthritis and 23 from anchylosing spondylitis. There were 19 (17.43%) nSARS-CoV2 infection, of them 3 (15.8%) need hospitalization. Ninety-five (87.2%) receive at least one shot of nSARS-CoV2 vaccine, of these 78 (82.1%) got three shots of vaccine. Vaccine-related side effects were reported in 36 (37.9%), of these 15 (41.7%) have fever, 14 (38.8%) arthralgia and 29 (80.5%) fatigue. No patients required

medical attention. Twenty (21.05%) of patients who receive at least one vaccine shot experienced a flare up. Nine (45%) need to change therapy. The risk of flare up was significantly associated with low disease activity/active disease in the last 12 months, p=0.009; OD 4.0; 95% CI: 1.5-11.3.

Conclusion: Overall, the nSARS-CoV2 vaccine is well tolerated in patients with inflammatory arthritis. The risk of disease flare is associated with active disease within the past 12 months. According to our results, the patients affected by inflammatory arthritis in sustained remission have no reason to hesitate to get the nSARS-CoV2 vaccination.

AB1190 SOURCES OF INFORMATION ABOUT SARS-COV-2 USED BY PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES (CIRD)

I. Andreica[1], I. Roman[1], X. Baraliakos[1], U. Kiltz[1], J. Braun[1]. [1]*Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Rheumatology, Herne, Germany*

Background: Patients with chronic inflammatory rheumatic diseases (CIRD) may be at increased risk of Corona Virus Disease 2019 (COVID-19).[1] The quality of information obtained plays a crucial role for patients' decision to be vaccinated. Knowing patients' needs for information and which sources are used is important for the management of CIRD patients by rheumatologists and other physicians.

Objectives: To identify main sources of information on SARS-CoV-2 used by patients with CIRD and to analyze their influence on opinions and willingness to be vaccinated.

Methods: CIRD patients presenting to our tertiary rheumatology hospital were, after informed consent, consecutively included in the study once the vaccination campaign in Germany had started, to fill out a questionnaire. Next to sociodemographic and disease-specific data, vaccination willingness and knowledge regarding SARS-CoV-2 were assessed. Furthermore, patients' sources of information and their concerns about accuracy of information were evaluated. A numerical rating scale (NRS) ranging from 0 (completely disagree) to 10 (completely agree) was used. Values between ≥7 were taken as positive answer. Nonparametric tests and multivariate linear regression analyses were performed.

Results: In early 2021, a total of 514 patients were interviewed (Table 1). The majority (63.9 %) reported to be well-informed (NRS ≥7), whereas 18% had doubts regarding information on SARS-CoV-2. The most often used source of information was television, and only 8.6% reported to have been informed by a rheumatologist (Figure 1). About 20% of patients were no longer interested in receiving any information on SARS-CoV-2 through media. Information from rheumatologists, general practitioners, public health authorities or health related web sites did not reach 30.5% of patients. Of interest, 16% of subjectively well-informed patients were hesitant towards vaccination. As many as 43.6% of patients with doubts regarding information about SARS-CoV-2 indicated that they were not willing to be vaccinated. No source of information showed a strong correlation with SARS-CoV-2 vaccination willingness or with knowledge on SARS-CoV-2. Weak positive correlations were found between age and education level on the one hand and information sources about SARS-CoV-2 on the other hand. A weak negative correlation was found between doubts about information and health authorities, whereas positive correlations were found with social networks, friends and family.

Table 1. Sociodemographic and disease characteristics

Age (years)	54.7 ± 12.8
Women, No.* (%)	315 (61.3%)
Educational level, No.* (%)	
< 8 years	50 (10.4 %)
8-12 years	275 (57.4 %)
>12 years	154 (32.2 %)
Occupation, No.* (%)	
Full time	198 (38.5 %)
Pensioner	157 (30.5 %)
Part-time	80 (15.6 %)
Housewife/husband	37 (7.2 %)

no DMARDs	18 (3.5 %)

*Number of patients

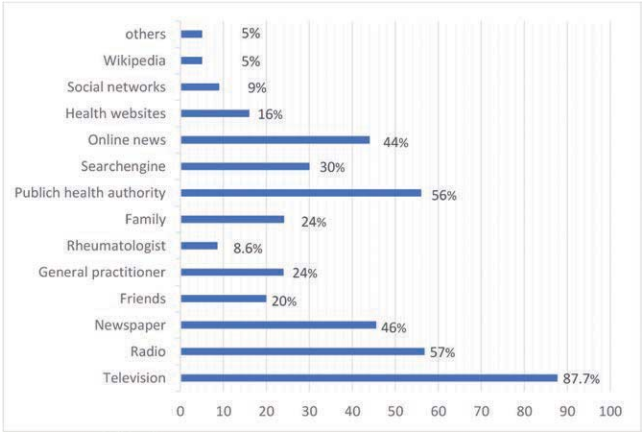

Figure 1. Sources of information of CIRD patients about SARS-CoV-2

Conclusion: Most CIRD patients think that they are well-informed about SARS-CoV-2. However, their information rarely comes from expert-based sources and rarely from rheumatologists. Thus, there is an unmet need for CIRD patients to receive appropriate and comprehensive information about SARS-CoV-2, its influence on rheumatic diseases, and about vaccination of patients with CIRD.

AB1191 SAFETY PROFILE OF COVID VACCINES IN ARTHRITIS PATIENTS. A TWO-CENTERS STUDY.

V. Rella[1], G. Busto[1], C. Rotondo[1], M. Fornaro[2], R. Colia[1], A. Corrado[1], F. Iannone[2], F. P. Cantatore[1]. [1]*Ospedali Riuniti di Foggia, Rheumatology Unit, Department of Medical and Surgical Sciences, Foggia, Italy*; [2]*Policlinico, Bari, Rheumatology Unit, Department of Emergency and Organ Transplantations, Bari, Italy*

Background: Coronavirus 19 disease (COVID-19) represents the most important pandemic of the last century. Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) infection has produced more than 170 million cases and more than 3 million deaths. Due to the easy spread of the infection and the possibility of serious clinical manifestations, the role of anti-COVID 19 vaccination is essential. Vaccines with different mechanisms of action have been developed: mRNA-based, such as Biontech-Pfizer and Moderna, and viral vectored, such as AstraZeneca and Janssen. Despite possible adverse events, benefits afforded by these vaccines significantly outweigh potential risks associated with their administration in the general population.

Objectives: This study aimed to evaluate incidence and severity of adverse events (AEs), secondary to vaccination, in patients with Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Spondyloarthritis (SpA), immune-mediated diseases treated with immunomodulating drugs, by administering a questionnaire.

Methods: 294 patients (201 f and 93 m) were enrolled with a diagnosis of arthritis (RA 28%, PsA 43%, SpA 28%).

Results: Of the 294 enrolled patients, 107 underwent COVID vaccination, 73% with Biontech-Pfizer vaccine, 20% Astrazeneca and 6% Moderna. 50% of patients completed the entire vaccination cycle. 46% of patients presented AEs after the first dose of vaccine (45% of vaccinated with Biontech-Pfizer; 48% of vaccinated with Astrazeneca, 33% of vaccinated with Moderna). The most frequently observed AEs are: pain at the injection site (17%), fever (13%), headache (12%), myalgia (12%), fatigue (7.5%). Only 2.9% of patients had arthritis flares. The greatest trend of AEs was observed in patients with PsA (48%), and RA (26%). 32% of patients receiving the second dose of vaccine presented AEs (40% Moderna, 32% Biontech-Pfizer). The most frequently observed AEs after the second dose are: pain at the injection site (4.7%), fever (9%), headache (2.8%), myalgia (6%). No patient had arthritis flare after the second dose. The greatest trend of AEs was observed in patients with SpA (66%). Only 11% of patients presented AEs after the administration of both doses. Thirteen percent of patients did not follow the clinician's recommendations for immunomodulatory drug management, provided as per ACR or SIR recommendations.

Conclusion: The incidence of adverse events in arthritis patients was in line with that of the general population, without presenting serious manifestations, such as thrombosis, and without indicating a preference on the type of vaccine.

AB1192 SARS-COV-2 VACCINE IN SPONDYLOARTHRITIS PATIENTS: OVERALL MODERATE/ HIGH IMMUNOGENICITY IMPAIRED BY IMMUNOSUPPRESSANTS AND BIOLOGICAL THERAPY

C. Saad[1], M. Rodrigues Silva[2], P. Degrava Sampaio-Barros[2], J. Moraes[2], C. Goldenstein-Schainberg[2], N. Aikawa[2], E. Neves[2], S. Pasoto[2], T. Pedrosa[2], R. Kenji Aoyama[2], C. Scognamiglio Renner Araujo[2], C. Silva[3], A. C. Medeiros Ribeiro[2], E. Bonfa[2]. [1]*Faculdade de Medicina da Universidade de São Paulo, Rheumatology, São Paulo, Brazil*; [2]*Faculdade de Medicina da Universidade de São Paulo, Rheumatology, São Paulo, Brazil*; [3]*Faculdade de Medicina da Universidade de São Paulo, Infectious Diseases, São Paulo, Brazil*

Background: We recently reported an attenuate immunogenicity in patients with autoimmune rheumatic diseases. However, the effect of spondyloarthritis (SpA) and its treatment on COVID-19 vaccine immunogenicity remains to be determined for this group of patients. We therefore aimed to evaluate humoral immune responses to inactivated SARS-CoV-2 vaccine (CoronaVac) in patients with SpA (axial spondyloarthritis and psoriatic arthritis) taking DMARDs and commonly used targeted biological therapies, compared with a control group(CG).
Objectives: Evaluate immunogenicity and safety of CORONAVAC (Sninovac, Beijing) in Spondyloarthritis (SpA) patients.
Methods: Prospective observational cohort patients diagnosed with 194 SpA and 183 CG were vaccinated with CoronaVac in two doses with a 28-days interval. 194 patients completed the study and could be paired with CG for immunogenicity analysis. Blood samples were collected in the days 0, 28 and 69 (D69) to evaluate anti-SARS-CoV-2 IgG seroconversion(SC) and presence of neutralizing antibodies (NAb) in participants with negative IgG and NAb at baseline.
Results: Patients and GC were comparable regarding age (p=0.93) and sex (p=1.00). Immunogenicity at D69 showed a moderate/high SC (80.2% vs. 95.7%, p<0.0001) and Nab positivity (61.6% vs. 82.7%, p<0.0001) in SpA but lower than CG. Factors associated with lower immunogenicity were older age (56.8 vs. 51.4;p=0.03318) and higher frequencies of prednisone (25.7% vs 4.2%; p=0.0004), methotrexate (51.4% vs 40.1%, p=0.0016) and TNF inhibitor (TNFi) (62.9% vs 34.5%, p=0.0035). Likewise, prednisone (17.6% vs. 2.8%, p=0.0013) and TNFi (50% vs 33.9%; p=0.0408) were associated with diminished NAb positivity. Sulfasalazine was associated with higher SC rates (8.6% vs. 26.8%, p=0.0246) and NAb positivity (13.2% vs. 29.4%, p=0.0168). The multivariate analysis revealed that older age (p=0.037), prednisone (p=0.001), TNFi (p=0.016), and methotrexate(p=0.017) were independently associated with lower SC while prednisone (p=0.006) and TNFi (p=0.027) were also associated with reduced NAb response.
Conclusion: Our finding of an excellent safety and moderate/high SC rate in SpA supports the recommendation of CoronaVac vaccination. The impaired immune response in the minority of patients under immunosuppressive and biological therapy requires novel strategies to enhance antibody response in this subgroup of patients.

AB1193 THE COURSE OF COVID-19 INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING VARIOUS BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

R. Samigullina[1], A. Dadalova[1], E. Vasilenko[1], V. Mazurov[1]. [1]*North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care Named After E.E.Eichwald, St. Petersburg, Russian Federation*

Background: With the ongoing COVID-19 pandemic, the safety of biologic disease-modifying antirheumatic drugs in patients with rheumatic disease remains an important issue.
Objectives: to assess the course of COVID-19 infection in patients with rheumatoid arthritis receiving various biological disease-modifying antirheumatic drugs.
Methods: An analysis was made of the course of COVID-19 in patients with rheumatic diseases who were under observation at the North-Western State Medical University. I.I. Mechnikov in the period from March 2020 to November 2021. During this period, 198 (14.04%) cases of COVID-19 were registered out of 1389 patients included in the registries of the anticytokine therapy center. Among patients with rheumatoid arthritis who recovered from COVID-19 infection, 105 cases were registered, of which 53 patients received outpatient treatment, and 52 patients received inpatient treatment. In 76% of cases, patients received biological DMARDs in combination with synthetic DMARDs.
Results: Exacerbation of the articular syndrome was observed only in 12 (11.4%) patients with RA during COVID-19. The low percentage of exacerbations in patients with RD on the background of COVID-19 was probably associated with the use of dexamethasone at a dose of 16-32 mg, which has the ability to reduce the activity of the immune-inflammatory process in rheumatic diseases. This statement is confirmed by the fact that out of 52 patients with RA who were hospitalized for COVID-19, 16 patients (30.8%) received dexamethasone intramuscularly or intravenously, and 8 patients (15.4%) continued oral administration of this drug.

Table 1. The course of COVID-19 infection in RA patients treated with various biological DMARDs.

Severity and outcomes of COVID-19	All patients (n=105) N (%)	Abatacept (n=11) N (%)	Rituximab (n=56) N (%)	IL-6 inhibitors (n=9) N (%)	TNF-alpha inhibitors n=15 N (%)	JAK inhibitors n=17 N (%)
No hospitalization required	53 (50,5)	3 (27,3)	19 (33,9)	8 (88,9)	12 (80)	11 (64,7)
Hospitalization without oxygen support	31 (29,5)	5 (45,5)	18 (32,1)	1 (11,1)	3 (20)	4 (23,5)
Hospitalization with oxygenation or mechanical ventilation	24 (22,8)	3 (27,3)	19 (33,9)	0	0	2 (11,8)
Death	5 (4,8)	1 (9,1)	4 (7,1)	0	0	0

Conclusion: The use of rituximab was associated with a more severe course of COVID-19, which required hospitalization in 66% of cases, compared with the group of patients treated with TNF-α inhibitors, in which hospital treatment was carried out only in 20% of cases. The introduction of blockers of co-stimulation of T-cells, IL-6 inhibitors, targeted synthetic drugs did not affect the severity of COVID-19.

Pain in rheumatic diseases, including fibromyalgia_

AB1194 PREVALENCE OF FIBROMYALGIA IN THE RHEUMATOLOGY OPDS DURING COVID19 LOCKDOWN: A CROSS-SECTIONAL STUDY

A. Abogamal[1,2], G. Harifi[3], I. Gamal[4], A. Alansari[5], A. Azaam[6], A. Massri[7]. *[1]Al-Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt; [2]Dr. Suliman Alhabib Hospital, Rheumatology, DUBAI, United Arab Emirates; [3]Mediclinic Parkview Hospital, Rheumatology, Dubai, United Arab Emirates; [4]Dr Sulaiman Al Habib Hospital in Dubai, Rheumatology, Dubai, United Arab Emirates; [5]Mediclinic Airport Road Hospital, Rheumatology, Abu Dhabi, United Arab Emirates; [6]Al Azhar Faculty of Medicine, Rheumatology, CAIRO, Egypt; [7]French Medical Center - Sharjah, Rheumatology, Sharjah, United Arab Emirates*

Background: In the challenging times of Covid 19, anxiety increased among the general population. Fibromyalgia patients are more at risk of developing anxiety in these difficult times. This might result in more frequent visits to the rheumatology clinics with an exacerbation of their chronic pain syndrome.
Objectives: The main objective of this study is to compare the prevalence of FM in the rheumatology outpatients' clinics during the Covid 19 lockdown period (2020) and during the same period in the previous year (2019).
Methods: A cross-sectional study is conducted through 5 rheumatology clinics located in the 3 biggest emirates of the country (3 in Dubai, 1 in Abu Dhabi and 1 in Sharjah) to detect the number and charachteristics of fibromyalgia from March 15 to May 15th2019, and March 15 to May 15th2020.
Results: Total number of patients seen from march to May 2019 was 3480 out of them 55 were fibromyalgia patients with frequency 0.0158%. While from march to May 2020 total number of patients seen were 1355 out of them 66 were fibromyalgia patients with frequency 0.0487%. Figure 1

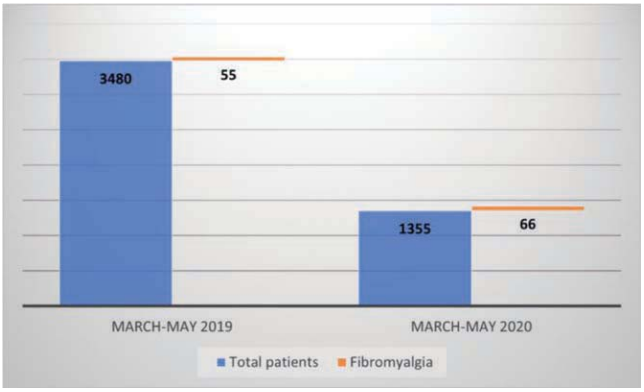

Figure 1. Total and fibromyalgia patients in March-May 2019 and March-May 2020

Descriptive analysis of fibromyalgia patients seen in the lockdown time March to May 2020 shows that; gender was 64 females 97%, 2 males 3%, profession 36 unemployed 54.5%, 28 white collar 42.4%, 2 blue collar 3%, Age minimum was 25 years, maximum 77 years, with mean 48.3±13 years. Table 1

Table 1. Descriptive analysis of the fibromyalgia paients

Gender *(Frequency)*	*Female*	64 (97%)
	Male	2 (3%)
Profession *(Frequency)*	*unemployed*	36 (54.5%)
	White collar	28 (42.4)
	Blue collar	2 (3%)
Fibromyalgia severity *(Mean±SD)*	*Tender Points*	15.7±3
	Pain	6.5±2.1
Fibromyalgia associates *(Frequency)*	*Headache*	32 (48.5%)
	Sleep Disturbance	47 (71.2%)
	Fatigue	65 (98.5%)
	IBS	26 (39.4%)
	Anxiety	43 (65.2%)
	Depression	37 (56.1%)

Tender points were 15.7±3, VAS for pain 6.5±2.1, sleep disturbance was present in 47 patients 71.2%, fatigue 65 patients 98.5%, irritable bowel syndrome in 26 patients 39.4%, headache in 32 patients 48.5%, anxiety in 43 patients 65.2%, and Depression in 37 patients 56.1 %. Comparing frequencies of fibromyalgia between March to May 2019 and 2020 shows a significantly higher frequency of fibromyalgia in March to May 2020, 3.1-fold more than 2019.

Conclusion: The prevalence of patients with fibromyalgia seen in the Rheumatology clinics significantly increased during the lockdown time in comparison to the same period of 2019.

AB1195 FIBROMYALGIA AND SOCIODEMOGRAPHIC FACTORS: DATA FROM THE ITALIAN FIBROMYALGIA REGISTRY

F. Atzeni[1], A. Alciati[2], M. DI Carlo[3], S. Farah[3], P. Sarzi-Puttini[4], F. Salaffi[3]on behalf of SIR Italian Register for Fibromyalgia. *[1]Rheumatology Unit, University of Messina, Department of Experimental and Internal Medicine, Messina, Italy; [2]Hermanas Hospitalarias, Villa San Benedetto Menni Hospital, Albese con Cassano, Humanitas Clinical and Research Center, Department of Clinical Neurosciences, Milano, Italy; [3]University Polytechnic of Marche, Rheumatological Clinic, Department of Clinical and Molecular Science, Jesi, Ancona, Italy; [4]ASST Fatebenefratelli-Sacco, Rheumatology Unit, Internal Medicine Department, Milan, Italy*

Background: Fibromyalgia (FM) is a chronic musculoskeletal pain syndrome of unknown etiopathogenesis. Its development and maintenance are related to a complex interplay of biological, psychological, and contextual factors. Among the contextual factors, sociodemographic aspects are poorly elucidated.
Objectives: This study aimed to evaluate the relationships between sociodemographic/clinical factors and symptom severity measures using a web-based registry of patients with FM.
Methods: The study included adult patients recruited between November 2018 and April 2019 at 19 Italian rheumatology centers. All the patients underwent a complete physical examination and those laboratory tests specified in the revised European League Against Rheumatism (EULAR) recommendations for the management of FM. The inclusion criteria were (a) age from 18 to 80 years and (b) diagnosis of FM based on the 2010/2011 criteria of the American College of Rheumatology (ACR), made by a rheumatologist with at least 10 years of experience. All patients were asked to complete a package of questionnaires about their sociodemographic data (age, sex, marital status, education and BMI), disease-related variables, their quality of life, and the type(s) of pharmacological and non-pharmacological treatments currently received. The data and measures were electronically entered into the web-based Italian Fibromyalgia Registry (IFR) by physicians working at those 19 Italian rheumatology centers. Two disease-specific questionnaires were used for the clinical evaluation in this study: the Revised Fibromyalgia Impact Questionnaire (FIQR) and the Polysymptomatic Distress Scale (PDS).
Results: Data relating to 3,221 patients (3001 women and 220 men) was collected. The ANOVA showed significant difference in mean FIQR scores when the five marital conditions (cohabiter, married, separated/divorced, single, widowed) were compared (F 3.321, p <0.01). While males and females were found to have comparable FIQR scores, the interaction between gender and marital status indicated that separated/divorced males have higher FIQR scores (F 5,684, p = 0,617) (Figure 1). The multiple regression analysis demonstrated that patients who reported lower educational level experienced more severe FM symptoms, as scored with FIQR (p <0.0001).
Conclusion: Our results indicated that being male and separated/divorced is associated to higher severity of FM symptoms, as rated with FIQR. Furthermore, a relationship between educational level and FIQR scores has been detected. This study supports the importance of collecting simple SES measures to identify environmental risk factors for FM severity.

AB1196 INFLUENCE OF NEUROPATHIC PAIN ON THE FUNCTIONAL STATUS OF ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

E. Sapozhnikova[1], M. Sapozhnikov[2], E. Guryanova[3], N. Alekseeva[4]. *[1]Second City Hospital of the Ministry of Health of the Chuvash Republic, X-ray Department, Cheboksary, Russian Federation*; *[2]I. N. Ulianov Chuvash State University, Department propedeutics of Internal Diseases, Cheboksary, Russian Federation*; *[3]I. N. Ulianov Chuvash State University, Department Internal Diseases, Cheboksary, Russian Federation*; *[4]I. N. Ulianov Chuvash State University, Department of Normal and Pathological Physiology, Cheboksary, Russian Federation*

Objectives: The aim of the study was to study the influence of neuropathic pain on functional status in elderly patients with rheumatoid arthritis (RA) with moderate disease activity.

Methods: Methods. The study included 115 geriatric patients who were divided into two groups. Group G1 included 80 patients (mean age 76.9 ± 9.6 years) with neuropathic pain, group G2 - 35 persons of comparable age (77.1 ± 8.6 years) without signs of neuropathic pain. Neuropathic pain was identified using the DN4 questionnaire. The RA activity in patients of both groups did not differ statistically significantly. All patients underwent a comprehensive geriatric assessment (CGA) to determine the functional status and diagnose geriatric syndromes [1]. All patients received basic anti-inflammatory drugs. Patients G1 and G2 were compared in terms of the following parameters, such as pain intensity according to a visual analogue scale (VAS, 0-100 mm), Rivermead Mobility Index (0-15), functional disorders according to International Classification of Function (ICF) (0-4), signs of anxiety and depression (HADS).

Results: According to the CGA data, senile asthenia syndrome was detected in 32 (40.2%) patients with neuropathic pain and in 10 (28.6%) patients without neuropathic pain (p = 0.035). The average number of geriatric syndromes in G1 was 6.06 ± 1.03, in group B - 4.5 ± 1.0 (p <0.05). Patients with G1 showed higher indices of pain severity according to VAS than in patients of the control group: 68.2 ± 10.1 and 52.1 ± 4.1 mm, respectively (p <0.001). In G1, patients had a significant decrease in mobility, in the domain «Activity and participation» in the ICF categories d450 (walking), d 540 (dressing), the indicator of dysfunction was 2.9 ± 0.3 versus 2.2 ± 0.2 (p = 0.049), there were more symptoms of anxiety and depression 56.5% and 35.2% (HADS ≥7; p <0.001), respectively.

Conclusion: Elderly patients with chronic neuropathic pain have higher signs of senile asthenia and decreased mobility and physical functioning in daily life. It is necessary to include the help of a psychologist and occupational therapist in planning the most effective comprehensive strategies for the treatment and prevention of exacerbations of neuropathic pain.

AB1197 ANTIDEPRESSANTS TREATMENT AND SEVERITY OF PAIN IN RHEUMATOID ARTHRITIS PATIENTS WITH ANXIETY AND DEPRESSIVE DISORDERS

A. Abramkin[1], T. Lisitsyna[1], D. Veltishchev[2], O. Seravina[2], O. Kovalevskaya[2], S. Glukhova[2], E. Nasonov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, thromboinflammation, Moscow, Russian Federation*; *[2]Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Stress Disorders, Moscow, Russian Federation*

Background: Anxiety and depressive disorders (ADD) significantly affect disease activity and pain modulation in rheumatoid arthritis (RA) patients. Psychopharmacotherapy (PPT) of ADD attempts to improve RA disease activity and manage pain in RA patients.

Objectives: To determine factors associated with intensive pain syndrome in antidepressants-treated RA-patients at five years endpoint.

Methods: 128 RA-patients (pts) were enrolled, 86% were women with a mean age of 47,4±11,3 (M±SD) yrs. All patients met the full ACR/EULAR 2010 criteria for RA. Disease activity was assessed using DAS28, pain severity – using Brief Pain Inventory scale (BPI). Severe Pain was defined as BPI Worst Pain Score (BPImax) from 7 to 10. 69,4% RA-pts were already taking prednisone (9 [5; 10] mg/day (Me (25%; 75%)), 84,4% - cDMARDs, 7,8% - bDMARDs (anti-TNF-α – 6,3%, rituximab – 1,6%). Biologics treatment duration varied from 1 to 6 years, antidepressants – from 6 to 96 weeks. ADD were diagnosed by psychiatrist in 123 (96,1%) of RA-pts in accordance with ICD-10 in semi-structured interview. Severity of depression and anxiety was evaluated with Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A). RA-pts with ADD were divided into the following treatment groups: 1 – cDMARDs (n=39), 2 – cDMARDs + PPT (sertraline or mianserine) (n=43), 3 – cDMARDs + bDMARDs (n=32), 4 – cDMARDs + bDMARDs + PPT (sertraline or mianserine) (n=9). Baseline BPImax by groups was as follows: 4,82±2,1, 5,85±2,06, 5,5±2,1, 7,57±2,17, respectively (p1-4<0,001; p2-4=0,048; p3-4=0,013). Multivariate logistic regression was used to determine predictors of severe pain.

Results: At five-years follow-up pain severity was assessed in 74 out of a total of 83 patient. By univariate logistic regression, baseline age, HAQ, CRP, DAS28 and BPImax, presence of extraarticular manifestations, cardiovascular diseases, cognitive impairments and schizotypal personality disorder, lower HADS for anxiety, no remission of anxiety or depression at five years and no history of glucocorticoids usage were significantly (p≤0,3) associated with severe pain at five-years follow-up (Table 1). These variables were subjected to multivariate stepwise logistic regression. Only extraarticular manifestations at baseline (OR 4,01 (95%CI 0,96 – 16,77), p=0,057), no history of glucocorticoids usage (OR 0,15 (95%CI 0,04 – 0,56), p=0,005) and nonremission of anxiety and depressive symptoms at 5-yrs (OR 0,11 (95%CI 0,019 – 0,668), p=0,016) were independently associated with severe pain at 5-years follow-up (R2=0,406, sensitivity 38,5%, specificity 92,7%).

Table 1. Factors associated with severe pain at 5 years (univariate logistic regression).

Factor	p	OR	95%CI	
			low	up
Baseline age	,129	1,047	,987	1,112
Baseline HAQ	,056	2,155	,981	4,734
Baseline DAS28	,075	1,361	,969	1,911
Baseline CRP	,151	1,011	,996	1,026
Baseline BPImax	,083	1,269	,970	1,662
Extraarticular manifestations at baseline (yes/no)	,027	4,278	1,179	15,517
Cardiovascular diseases at baseline (yes/no)	,259	2,111	,577	7,718
Cognitive impairments at baseline (yes/no)	,218	2,758	,549	13,860
Schizotypal personality disorder	,085	3,733	,834	16,715
HADS anxiety	,259	,904	,758	1,077
Anxiety and depressive symptoms remission at 5-yrs endpoint	,102	,313	,077	1,261
History of glucocorticoids usage (yes/no)	,025	,234	,066	,833

Conclusion: RA patients with severe pain should be routinely screened for anxiety and depression, and in patients with probable ADD consultation with a psychiatrist and prescription of antidepressants should be considered.

AB1198 PREVALENCE AND PSYCHOPATHOLOGICAL CHARACTERISTICS OF ANXIETY AND DEPRESSIVE SYMPTOMS IN FIBROMYALGIA PATIENTS

V. Marino[1], A. Pasca[2], F. Galante[2], M. Fabrazzo[2], E. L. DI Caprio[2], F. Riccio[1], S. Fasano[1], F. Ciccia[1], R. Tirri[1]. [1]*University of Campania "Luigi Vanvitelli", Precision Medicine, Naples, Italy*; [2]*University of Campania "Luigi Vanvitelli", Mental and Physical Health and Preventive Medicine, Naples, Italy*

Background: Several studies reported higher depression and anxiety rates in fibromyalgia (FM) patients compared to the general population. Furthermore, dysfunctional coping strategies have been pointed to as intrinsic parts of the pathogenesis of FM.
Objectives: Our study aimed to verify the prevalence of anxiety and depressive symptoms and explore their correlation with physical symptoms as fatigue, sleep, and widespread pain in a cohort of patients diagnosed with FM. We also aimed to determine whether dysfunctional coping strategies might increase the depression and anxiety burden, besides worsening the core symptoms of FM.
Methods: We analyzed a cohort of 105 patients (median age of 53 years 6 M, 99 F) with a diagnosis of FM according to the ACR 2016 criteria. The participants were consecutively recruited from the Fibromyalgia clinic of the University of Campania "Luigi Vanvitelli". All patients underwent a psychiatric evaluation. We assessed widespread pain by the Widespread Pain Index (WPI) and the presence of fatigue by the Symptom Severity score (SS). Sleep disorders were investigated through Pittsburgh Sleep Quality Index (PSQI). We analyzed mental alterations by Hamilton Depression and Anxiety Rating Scales (HAM-D, HAM-A), and coping strategies by Coping Orientation to Problems Experienced (COPE) Inventory.
The Statistical Package for Social Sciences (SPSS) 22.0 was used; the level of significance was set at $p < 0.05$.
Results: All patients showed fatigue and widespread pain (100%); sleep disturbances were found in 90.5% of patients and overlapped with all sleep phases. The prevalence of anxiety associated with depression was 75.2%. We found isolated anxiety in 14.3% and isolated depression in 4.8% of patients. We further evidenced a different degree of depression: mild (50.7%), moderate (24.3%), and severe (6.5%). All patients showed depressed mood only if questioned (low tendency to spontaneous verbalization). COPE analysis showed no significant differences in the use of the three coping strategies (Problem-focused, emotion-focused, avoidance-focused). Pearson's correlation analysis highlighted a negative relationship between problem-focused strategies and the severity of anxiety ($r = -0.31$, $p = .001$) and depression ($r = -0.32$, $p = .001$). Our analysis also highlighted a positive correlation between fatigue, sleep disturbances, widespread pain, and both anxiety and depression. The analysis of the characteristics of anxiety and depressive symptoms showed a scarce tendency to spontaneous verbalization of depressed mood and ideas of guilt, mostly limited to family relationships, and a sense of ineffectiveness conditioned by the physical symptoms of the disease. Most patients showed psychomotor agitation, psychic and somatic anxiety, poor insight. The analysis of coping strategies adopted showed a negative correlation between problem-focused strategies and anxiety-depressive symptoms, suggesting that such strategies are less frequent in FM patients with comorbid anxiety and depressive symptoms.
Conclusion: Our study confirms the high prevalence of anxiety and depressive symptoms in FM patients. A positive correlation between the pivotal symptoms and anxiety and depressive symptoms may suggest, without implying a cause-and-effect relationship, that psychiatric intervention should be considered along with rheumatologic treatment, to improve both physical symptoms and quality of life. Potentiating problem-focused coping strategies may represent a target to improve anxiety and depressive symptoms.

AB1199 THE ROLE OF THORACOLUMBAR FASCIA ULTRASOUND IN LOW BACK PAIN - IMPLICATION FOR GUIDED DRY NEEDLING

R. Bubnov[1], L. Kalika[2]. [1]*Clinical Hospital `Pheophania`, Ultrasound, Kyiv, Ukraine*; [2]*drlevkalika@gmail.com, Rehab, New York, United States of America*

Background: Dry needling under ultrasound guidance (DN-US) is a crucial therapeutic for treatment myofascial pain [1], restore muscle function and motion [2], is among priotized methods for treatment low back pain (LBP), can be effective in rheumatic diseases. The definition `myo-fascial` calls for searching trigger points (TrPs) in fascia to improve the treatment effectiveness [3]. Ultrasound examination and guided dry needling can help understanding the role of the thoracolumbar fascia (TLF), its layers function and role in development of low back pain.
Objectives: Aim was to evaluate the relevance of fascial ultrasound and guided dry needling in low back pain in particular for thoracolumbar fascia (TLF).
Methods: We included 32 patients (20 females, 21-63 years old) with myofascial low back pain, postural imbalance; did DN-US protocol according to R. Bubnov [1]: muscle TrPs were identified, fine (28G) steel needle DN-US was applied. Additionally considered fascial structures for detecting areas of abnormalities (hypervascularity, heterogeinity, hypomotility, adhesions) aka `trigger points`. We did separate re-evaluating after stage of fascia and muscle needling.
Results: In all patients movement restored and pain decreased after muscles DN; in 24 patients additionally we detected changes in the major fascial points as follows: TLF, its layers (thickness increased up to 5-10 mm, local and diffuse calcification), sacroiliac joint (SIJ); and did successful DN-US to affected areas (increased thickness and stiffness according to SWE). During procedure we revealed places of stiff areas in fascia (TrPs), did precise dry needling to place the top of needle in the affected area in fascia. The strong `needle grasp`, low level of sensation during needling, local twitch response was not seen in fascia. TFL TrPs were associated with quadratus lumborum muscle. We noted fair improvement of motion in lumbar level after TFL needling alone, decreased hyperechoic lamina to 2-4 mm after DN. We detected higher rates of motility, improvement postural balance and pain decrease, fewer sessions needed in patients after extensive protocol.
Conclusion: Fascia dry needling is accessible and effective method for myo-fascial low back pain treatment, can provide additional mechanical benefit and help to maintain treatment effect. Affected fascia can be considered as relevant TrPs, specific ultrasound symptoms should be validated.

AB1200 THE IMPACT OF THE PRESENCE OF FIBROMYALGIA ON ILLNESS PERCEPTIONS AND COPING STRATEGIES IN HIV INFECTED PATIENTS: PRELIMINARY STUDY

Y. Ulus[1], O. Acar Cakan[2], M. A. Karacesme[1], A. Bilgici[1], A. Deveci[3], H. C. Bilek[3]. [1]*Ondokuz Mayıs University - Faculty of Medicine, Physical Medicine and Rehabilitation, Samsun, Turkey*; [2]*Samsun State Hospital, Physical Medicine and Rehabilitation, Samsun, Turkey*; [3]*Ondokuz Mayıs University - Faculty of Medicine, Clinical Microbiology and Infectious Diseases, Samsun, Turkey*

Background: Coexisting fibromyalgia syndrome (FMS) to the chronic diseases and its negative impact on global health status in these diseases has been identified. Recent treatment strategies have changed HIV from a terminal disease to a chronic condition that requires great effort because of regular treatment and periodic medical screenings. The prevalence of fibromyalgia has been reported in HIV patients as 1-17%. It was reported that greater illness perceptions are associated with dysfunctional coping strategies in HIV patients with detectable or high viral load. There are no data on illness perceptions and coping strategies in HIV patients with FMS.
Objectives: The aim of this study was to evaluate the impact of the presence of fibromyalgia on illness perceptions and coping strategies in HIV infected patients.
Methods: Data about illness perceptions by The Brief Illness Perception Questionnaire (Brief-IPQ) and coping strategies by the COPE questionnaire were collected from 79 HIV patients. FMS was determined according to 2010 American College of Rheumatology criteria. CD4+ cell counts, viral load, and disease

duration were also noted. Kolmogorov Smirnov test, chi-square test, Mann Whitney-*U* test, Spearman correlation analysis, and Univariate analysis of variance were used for statistical analyses.

Results: Patients were aged between 22 and 77 years, with a mean age of 44.63±10.7 years. Thirteen patients (16.5%) were diagnosed with FMS and of those 4 (30.8%) were women. Cognitive illness representations and emotional representations scores were higher in HIV patients with FMS than those without FMS ($p<0.05$). Disease duration, HIV-progression biomarkers (CD4+ and viral load), COPE questionnaire scores, and illness comprehensibility sub scores of Brief-IPQ were not different between the HIV patients with and without FMS ($p>0.05$). The significant effect of the presence of FMS on cognitive illness representations ($p<0.001$) and emotional representations ($p<0.05$) was found by univariate analysis of variance in patients with HIV.

Conclusion: According to the preliminary results of this study, FMS was detected 16.3% of 79 HIV patients and coexisting FMS was associated with increased cognitive and emotional representations in patients with HIV. Coping strategies were not affected by the comorbid FMS. The presence of FMS may adversely affect perceptions of the disease in HIV infected patients. Since the patients' beliefs about their illness have great importance in the patients' health outcomes and the understanding of the disease, physicians should be aware of the possibility of concomitant FMS in patients with HIV.

AB1201

PAIN DESCRIPTORS AND DETERMINANTS OF PAIN SENSITIVITY IN KNEE OSTEOARTHRITIS: A COMMUNITY-BASED CROSS-SECTIONAL STUDY

J. E. Vriezekolk[1], Y. A. S. Peters[2], M. A. H. Steegers[3,4], E. Blaney Davidson[5], C. Van den Ende[1]. *[1]Sint Maartenskliniek, Rheumatology Research, Nijmegen, Netherlands*; *[2]Sint Maartenskliniek, Rheumatology Research, Nijmegen, Netherlands*; *[3]Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands*; *[4]Radboud University Medical Center, Anesthesiology, Nijmegen, Netherlands*; *[5]Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands*

Background: The phenomenon of heightened pain sensitivity is implicated in the pain experiences of people with OA[1]. Limited research show that pain sensitivity is associated with poor health and treatment outcomes. However, epidemiological research investigating the extent and determinants of pain sensitivity in OA is scarce. In addition, the quality of pain is poorly described. Both the assessment of quality of pain and pain sensitivity can be important to inform clinical decision-making and treatment.

Objectives: To explore pain characteristics in individuals with knee osteoarthritis (KOA), to compare pain sensitivity across individuals with KOA, chronic back pain (CBP) and pain-free individuals (NP), and to examine the relationship between clinical and pain characteristics with pain sensitivity in KOA.

Methods: Cross-sectional, community-based online survey. Two datasets were combined comprising Dutch individuals of ≥ 40 years of age, experiencing chronic knee pain (KOA, N=445; dataset 1), chronic back pain (CLP, N=504; dataset 2), or no pain (NP, N=256; dataset 2). Demographic and clinical characteristics, global health, physical activity/exercise, and pain characteristics including intensity, spreading, duration, quality (SF-MPQ), and sensitivity (PSQ) were assessed. Differences between (sub)groups were examined using analyses of variance or Chi-square tests. Regression analyses were performed to examine determinants of pain sensitivity in the KOA group.

Results: Quality of pain was most commonly described as aching, tender, and tiring-exhausting in the KOA group (Figure 1). Overall, the KOA group had higher levels of pain sensitivity compared to NP group, but lower levels than the CBP group (Table 1). Univariately, pain intensity, its temporality and spreading, global health, doing exercise, and having comorbidities were weakly related to pain sensitivity (standardized beta's: 0.12-0.27). Symptom duration was not related to pain sensitivity. Older age, higher levels of continuous pain, lower levels of global health, and doing exercise uniquely contributed, albeit modest, to pain sensitivity ($P<0.05$).

Table 1. Mean (SD) pain sensitivity scores across three groups

	KOA	CBP	NP	KOA vs CBP¥		KOA vs NP¥	
	N=445	N=504	N=256	Difference#	95% CI	Difference#	95% CI
PSQ-total, mean (SD)	4.4 (1.5)	4.7 (1.8)	3.6 (1.4)	-0.23	-0.49, 0.03	0.68	0.36, 1.01
PSQ-minor, mean (SD)	3.2 (1.6)	3.7 (2.0)	2.4 (1.3)	-0.32	-0.60, -0.05	0.70	0.36, 1.05

Abbreviations: PSQ=Pain Sensitivity Questionnaire, KOA=Knee OA pain group, CBP=Chronic Back Pain group, NP=Non-pain group. ¥CBP: N = 487, NP: N=242. #Mean differences adjusted for sex and age.

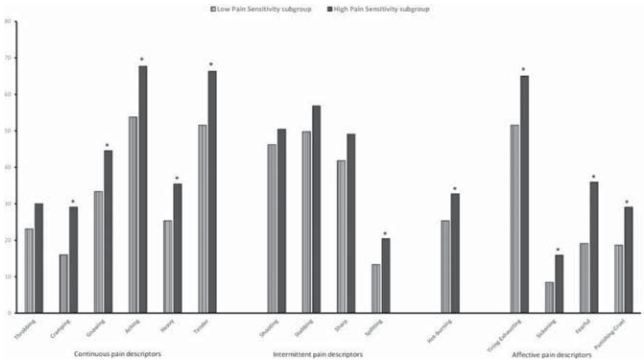

Figure 1. Percentage of individuals with self-reported knee OA who rated pain descriptors as moderate to severeNote: Subgroups based on median split total score Pain Sensitivity Questionnaire. *P<0.05

Conclusion: Continuous pain such as aching and tenderness in combination with decreased physical activity may be indicative for individuals at risk for widespread pain and, ultimately, poor treatment outcomes.

AB1202

ASSESSMENT OF PAIN THRESHOLDS TO VERIFY CENTRAL SENSITIZATION IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS OF THE KNEE

E. Filatova[1]. *[1]VA Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Central sensitization in patients with rheumatoid arthritis, osteoarthritis of the knees increases the risk of comorbid disorders, the most frequent of which are depression, cognitive impairment and insomnia. Verification and timely diagnosis of central sensitization will help to improve pain control in rheumatic diseases. (1,2)

Objectives: to study pressure pain thresholds in patients with rheumatoid arthritis (RA) and osteoarthritis of the knee (OAk) with chronic pain.

Methods: All patients had pain intensity scores according to the VAS scale, neuropathic/nocytoplastic pain severity according to the DN4 and Pain DETET questionnaires, central sensitization severity was assessed using the CSI scale. To verify the presence of central sensitization instrumentally and to confirm the presence of secondary hyperalgesia detected clinically, algometry was performed in 42 female patients with OAk and 42 patients with RA. A comparison group of 42 healthy volunteers comparable in gender and age with the patients was also selected. Using a Wagner FDK20 algometer, pressure pain thresholds for OAk in the knee joints were studied (4 points: 1st point located 2.5 cm medial to the patella, 2nd point in the center of the patella, 3rd 2.5 cm distal to the patella, 4th in the goosefoot area) and m. Trapezius (5th reference point) in all patients with OAC and controls. In the group with RA, pain thresholds were studied at 4 points: 1st - nail bed of the 1st finger, 2nd - wrist (above the extensor tendon retention), 3rd - 2.5 cm lateral to the kneecap and 4th m. trapezius (reference point) in all patients and controls.

Results: The mean age of patients with RA and OAk was 53.0 [41.0;61.0] and 61.0[57.0;63.0] years, with disease duration at the time of study of 9.0 [4.0;13.0] and 13.0[7.0;15.0] years, respectively. The DN4 questionnaire scores were 2.0 [1.0;4.0] for RA and 5.0[5.0;6.0] for OAk, and the Pain DETECT scores were

9.0[4.0;15.0] for RA and 17.0[14.0;19.0] for OAk. Pain intensity on VAS in patients was 60.0[40.0;70.0] for RA and 70.0[60.0;80.0] for OAk.
The results of algometry are shown in Figure 1.

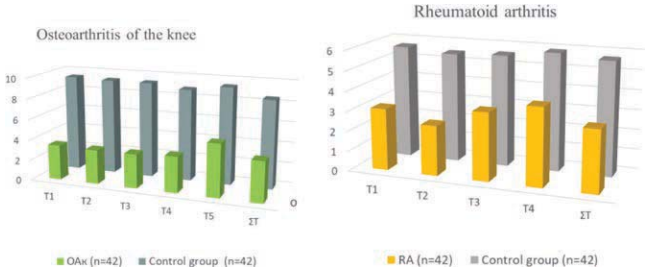

Figure 1.

Lower pain thresholds in patients with RA and OAk were noted not only in the area of the affected joints, but also in the distant reference point, indicating the presence of secondary hyperalgesia in these patients, which is a neurophysiological sign of central sensitization. A significant decrease in the pain threshold index was also noted in patients with central sensitization compared to those in the control groups.
Conclusion: The study of pain thresholds is one of the tools for verification of CS in patients with RA and OAk, but requires further study.

AB1203 DAS28 (DISEASE ACTIVITY SCORE) ELEVATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) WHO HAVE COMORBID FIBROMYALGIA ARE EXPLAINED BY ELEVATED TENDER JOINT COUNTS AS MUCH AS BY ELEVATED PATIENT GLOBAL ASSESSMENT

S. Kannayiram[1], K. Schroeder[2], N. Goodson[3], T. Pincus[2]. [1]*John H. Stroger, Jr. Hospital of Cook County, Internal Medicine, Chicago, United States of America*; [2]*Rush University Medical Center, School of Medicine, Chicago, United States of America*; [3]*University Hospital Aintree, Rheumatology, Liverpool, United Kingdom*

Background: DAS28 (disease activity score 28) is elevated in the 20-30% of patients with rheumatoid arthritis (RA) who have comorbid fibromyalgia (FM), largely on the basis of tender joint count (TJC) and patient global assessment (PATGL) [rather than swollen joint count (SJC) or erythrocyte sedimentation rate (ESR)].[1] High DAS28 in the absence of clinical inflammatory activity may suggest inappropriate treatment escalation and/or changes in a treat-to-target approach. Some reports suggest removal of PATGL from criteria for remission[2].
Objectives: We analyzed the 4 DAS28-ESR component measures in reports of FM+ or FM- RA patients, to recognize the possible contribution of each to elevated DAS28 in patients with FM.
Methods: We reviewed reports from a meta-analysis of elevated DAS28 in RA patients with comorbid FM,[1] and conducted a PubMed search for further reports of DAS28-ESR in FM+ or FM- RA patients in routine care. We analyzed reports that presented the 4 individual DAS-28-ESR components in FM+ vs FM- RA patients, calculated overall medians of published mean or median results, and calculated ratios of each component measure in FM+ and FM- patients.
Results: Eleven reports were identified. Mean disease duration was 5-12.8 years. Median DAS28-ESR of means/medians in FM+ RA patients was 5.3, and >5.1 in 9 of 11 studies, suggesting high disease activity (moderate in 2 studies) (Table 1). By contrast, median DAS28-ESR of means/medians in FM- RA patients was 4.1, moderate (3.2–5.1) in all 11 studies (Table 1). Medians of individual DAS28-ESR components were 28.5 vs 26 for ESR, 3.25 vs 3 for SJC, 12.3 vs 5.5 for TJC, and 62.7 vs 40 for PATGL in FM+ vs FM- RA patients, respectively. Ratios of DAS28 components in FM +/FM - patients were 2.7 for TJC, 1.6 for PATGL, 1.1 for ESR, and 1.0 for SJC.
Conclusion: Mean DAS28-ESR indicated high vs moderate disease activity in 9 of 11 FM+ RA patient groups vs all 11 FM- RA groups, respectively. Among the 4 DAS28 component measures, TJC differed most in FM+ vs FM- RA patients followed by PATGL, while SJC and ESR were similar in both groups. The impact of TJC likely is underestimated as the DAS28 formula weights TJC twice as SJC. Elevated DAS28 in the absence of inflammation in RA FM+ patients may result as much or more from TJC as from PATGL.

AB1204 MUSCULOSKELETAL MANIFESTATIONS IN PATIENTS WITH ENDOCRINE DISORDERS IN AN AMAZON OUTPATIENT CLINIC

T. Quereza e Silva Faria[1], S. Ribeiro[1], G. Araújo[1], J. Simão[1], A. Vieira[1], L. Praciano[1], A. P. Narciso Resk Maklouf[1]. [1]*UFAM - Faculty of Medicine, Medical clinic, Manaus, Brazil*

Background: Chronic pain is frequently associated with these conditions and is an important cause of care in the health service. This pain is among the main manifestations of the musculoskeletal system, and 40% of individuals can manifest this type of pain at some point in their lives. That is why it is important to have doctors prepared to make an adequate approach to the symptomatology and especially to the underlying diseases. Rheumatic manifestations are part of the manifestation of systemic diseases, in which include diseases of the endocrine

* All values were reported means other than medians noted by asterisk (*).

system, which can mimic rheumatic conditions. Despite the ignorance of some, endocrine diseases are underlying diseases linked to musculoskeletal manifestations. Thus, secondary arthropathies of non-rheumatologic origin or osteoarticular complaints that simulate or show rheumatic diseases can be found in patients with endocrine diseases during their evolution or in the initial phase along with other systemic symptoms. Based on this concept, we carried out the follow-up and evaluation of musculoskeletal manifestations presented by patients with endocrine disorders in a tertiary health service.

Objectives: The aim of this study is to characterize the musculoskeletal manifestations in patients with endocrine diseases: type 1 and type 2 Diabetes Mellitus; hypothyroidism; hyperthyroidism and pituitary diseases and to clinically classify the patients based on physical examination and imaging findings.

Methods: A cross-sectional and descriptive study, where clinical screening was performed at the endocrinology outpatient clinic, in which patients with musculoskeletal complaints were identified. These patients were referred for evaluation with a rheumatologist with clinical, laboratory and imaging investigation for the diagnosis of rheumatic disease. A questionnaire with epidemiological and clinical data was applied.

Results: To date, 466 patients diagnosed with endocrine diseases have been interviewed, 53.4 ± 14.7 years old, 371 (79.6%) were female and 95 (20.4%) were male. Of the patients interviewed, 326 (70.1%) reported musculoskeletal pain. In relation to endocrine diseases, the most frequent one was type 2 DM with 212 patients (45.5%), and 77.25% of these people have chronic musculoskeletal pain, most of them 5 to 7 times a week, showing an intrinsic character of this disease with pain complaints from a great part of this population. The prevalence of 27.3% of hypothyroidism, 10.7% of DM type 1, 7.1% of hyperthyroidism, and less expressive amounts of other endocrine diseases such as acromegaly (1.7%), giantism (0.4%), and the like were also identified. About 59.6% of those who have pains are not followed up in the rheumatology service, 41.3% of these have already indicated these pains to their endocrinologist, however they did not have their complaint properly signaled. Of those interviewed, 94 (37.5%) take antihypertensives and 32.7% oral anti-diabetics. The most commonly found diagnoses in rheumatic diseases: Rheumatoid Arthritis (39%); Osteoarthritis 22.9% and Fibromyalgia 20%; Osteoporosis 19%, Tendinitis calcaria, Psoriatic Arthritis and GOTA with 5.7%. The main joints affected were: Hands (54.4%); Knees (45.3%) and feet (41.8%).

Conclusion: Our research with pre liminal results has demonstrated the mutuality between endocrine diseases and musculoskeletal manifestations and, therefore, that rheumatologic diagnoses are increasingly frequent in this population. The high prevalence of these symptoms secondary to endocrine diseases raises serious questions to improve the quality of life of these patients, and also to increase the number of investigations in this field, because the pathophysiological mechanisms of this association are not well elucidated and, from there, to expand this information to professionals who may not be aware of this relationship.

MEDICAL AND PSYCHOLOGICAL COMORBIDITIES IN FIBROMYALGIA: A CROSS SECTIONAL STUDY

K. N. Thomas[1], A. Lawrence[1]. [1]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Psychological disorders are commonly observed in fibromyalgia (FMS). Medical comorbidities are less well characterised in FMS. We sought to assess the prevalence of these disorders in an observational cohort of patients in a tertiary hospital in North India.

Objectives: The prevalence of medical and psychological comorbidities in FMS and the prevalence of these disorders in FMS subgroups classified according to different ACR classification criteria were assessed.

Methods: Patients satisfying either the 1990 ACR or the 2016 ACR Fibromyalgia criteria were included in a cross-sectional study between October'19 and December'21. All patients were assessed for prevalence of chronic fatigue syndrome (CFS), post-traumatic stress syndrome (PTSD), restless leg syndrome (RLS) and medical comorbidities including obesity, obstructive sleep apnoea, anemia, diabetes mellitus, hypertension and hypothyroidism.

Results: A total of 98 patients of median age 39 years (34 – 47) were included, of which 9 met only the 1990 ACR criteria (100% females), 30 met only 2016 ACR criteria (86% females) and 59 met both criteria (89% females). Widespread Pain index was significantly higher in the 1990+2016 group compared to subgroups which met only either of the criteria. Hypothyroidism (subclinical or clinical) was similarly higher in the 1990+2016 subgroup. At least one psychological comorbidity was seen in 41%, with CFS present in 30% and PTSD in 14%. The median systolic blood pressure was in the hypertensive range (146 mm Hg) in the 1990-only group, with hypertension being present in 1/3rd of the total cohort. Obesity was present in 59% and Diabetes in 11%. Iron deficiency anemia was seen in 20%.

Table 1. Prevalence of comorbidities in different subgroups of Fibromyalgia

Clinical features	FMS Cohort (N-98)	ACR 1990 (N-9)	ACR 1990+2016 (N-59)	ACR 2016 (N-30)	p-value
F:M	**88:10**	9:0	53:6	26:4	0.6
Age (years)	**39 (34 – 47)**	38 (32 – 46)	38 (34 – 45)	44 (35 – 50)	0.2
Duration of symptoms (months)	**48 (24 – 84)**	48 (36 – 84)	48 (24 – 78)	60 (27 – 84)	0.6
WPI	**15 (12 – 17)**	14 (8 – 15)	16 (14 – 18)	13 (10 – 16)	0.001

University of Pavia, Medicine, Naples, Italy*; *[4]Istituto Nazionale Tumori, IRCCS Fondazione G. Pascale, Scientific Directorate, Naples, Italy*; *[5]Ospedale Cardarelli, Transplant Unit, Napoli, Italy*

Background: In 1985, Yunus and Masi described the juvenile primary fibromyalgia syndrome (JPFS). It is a chronic musculoskeletal pain syndrome that affects children and adolescents [2] with an estimated prevalence that varies from 1.2 to 6.2% [3]. Clinical features are widespread persistent pain, sleep disturbance, fatigue, and the presence of multiple discrete tender points on physical examination. Notably, this syndrome can impact the quality of life status and psychosocial development of children and adolescents [4]. Despite a lot of research being conducted, several aspects on etiology and pathogenesis, clinical characteristics, and evaluation, as well as therapy should be better explained.
Objectives: This bibliometric analysis is aimed at dissecting the developed research in the subject. It could provide helpful findings for predicting the direction of future studies, implementing corrective measures, and improving research networks.
Methods: The global literature on JPFS was scanned in the Web of Science (WOS) online database. The search string applied to identify the closest matching articles was "Juvenile primary Fibromyalgia Syndrome (all field)".All data were acquired on January 30, 2022. The information for the documents that met the requirements were extracted. The source was Journal Citation Reports™ 2020 (Clarivate Analytics). The literature analysis and knowledge visualization software tool VOSviewer (version 1.6.17) was used to analyze the co-occurrence of keywords (interconnection), co-citation (bibliographic coupling), co-citation analysis for sources, and countries, and analysis of the most productive organizations and networks.
Results: A total of 66 articles on JPFS were published from 1985 to January 2022, in WOS (n=24; median 2). About article types, 38 were research articles, 16 reviews, 8 meeting abstracts, 2 letters, 1 book chapters, 1 correction, 1 proceeding papers.
The analysis of keywords provided by authors showed that of 235 keywords, 38 met the threshold (interconnection 3). The most frequent keywords were Children (n=14); Adolescent (n=13), and Functional disability (n=10) (Figure 1)

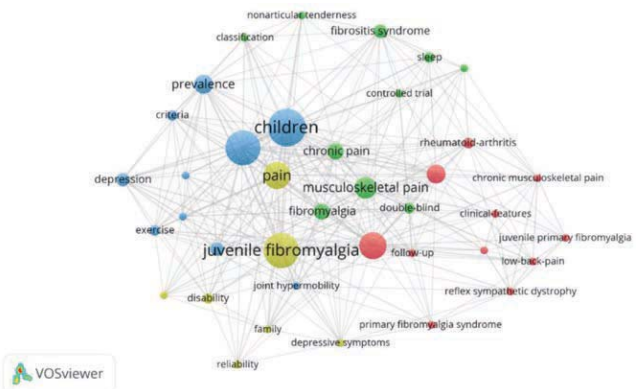

Figure 1. Co-occurrence of keywords

For the co-citation study, we used cited sources (journals) as unit (minimum numbers of citations of a source 15). Of 563 sources, 23 met the threshold. For each source, the total strength of the co-citation links with other sources was rated. The JOURNAL OF RHEUMATOLOGY (IF 4.66; Q2) obtained 22 links and 173 citations.
Most documents came fro the US (n=40; links=5), and Israel.
The analysis of affiliations was conducted by considering the cut-off 2 as the minimum number of documents of an organization. Out of 59 organizations, 23 met the threshold. The University of Cincinnati produced a total length strength of 3675 (11 documents).

Conclusion: This bibliometric network analysis on JPFS can be helpful for planning future research. It highlights the strength of representative scietists and core research teams. Research networks should be built, and high-value investigations are warranted.

Background: Glucocorticoids (GC) are the therapeutic mainstay in polymyalgia rheumatica (PMR). However, their adverse effects are of particular concern in elderly patients. Relapses and long-term GC dependency are common.
Objectives: Assess the risk factors for higher relapse rate and/or prolonged glucocorticoid therapy in 185 PMR patients from Argentina.
Methods: A multicenter observational study of PMR patients diagnosed according to the Chuang criteria seen at the outpatient clinics at 12 public or private rheumatology units from Argentina between 2006 and 2021 was performed. Patients were followed until permanent remission, lost to follow up, or a maximum of 2 years after diagnosis. Relapse was defined as an exacerbation of PMR symptoms requiring an adjustment of GC dose (≥ 4 mg) occurring at least 1 month after diagnosis. Time to relapse was modeled using the Kaplan-Meier method. Cox regression models were used to evaluate predictors of time to first and subsequent relapses.
Results: A total of 185 patients were included (69.1% female) with a median age of 71 years (IQR 65-78 years). The median follow-up time was 17.1 months (IQR 6.8-34.7) and the incidence of relapses was 1.2 per 100 persons/month. The median time to relapse was 70.5 months (25th percentile = 14 months). Pain and/or stiffness in shoulder girdle and pelvic girdle together more common (p = 0.02) in the clinical presentation of patients who relapsed. In univariate analysis, PMR patients with a previous history of dyslipidemia had a lower risk of relapse (HR = 0.55, 95% CI = 0.33-0.94, p = 0.03). Laboratory at time of diagnosis showed that an ESR > 50 mm was found as a risk factor for relapse (HR = 2.50, 95% CI = 1.23-5.10, p = 0.011). Regarding therapy, meprednisone (HR = 2.38, 95% CI = 1.31-4.31, p = 0.004) and high dose GC (HR = 2.35, 95% CI = 1.42-3.87, p = 0.001) had higher risk of relapse. In multivariate analysis, only meprednisone (HR = 2.59, 95% CI = 1.28-5.23, p = 0.008) and high dose of GC (HR = 2.41, 95% CI = 1.19-4.89, p = 0.014) remained the only risk factors for relapse.
Conclusion: A lower relapse rate than that reported in the literature was observed. Meprednisone and high dose of GC are significant predictors of future relapses. Our results suggest that efforts should be made to minimize initial GC dose and avoid the use of meprednisone as GC of first choice in order to prevent disease relapses.

AB1208

FREQUENCY OF MUSCULOSKELETAL AND OTHER EXTRA-INTESTINAL SYMPTOMS IN PATIENTS WITH CELIAC DISEASE

A. Pilipenko[1], V. Mazurov[1], I. Gaydukova[1]. [1]*North-Western State Medical University Named After I. I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E. Eikhvald North-Western Medical University. I.I. Mechnikov., Saint-Petersburg, Russian Federation*

Background: Celiac disease (CD) is one of the most common gastrointestinal tract diseases, in adults and children. Prevalence of CD is 1-3% [2]. The most common symptoms of CD are gastrointestinal symptoms. At the same time, celiac disease may manifest with extraintestinal symptoms, including the musculoskeletal, nervous, reproductive system, and skin, especially when it debuts at a late age [1,2]. However, data about musculoskeletal manifestations of CD are limited.

Objectives: To show the frequency of musculoskeletal complaints and their peculiarities in patients with CD.

Methods: Data from 94 patients with diagnosed by gastroenterologist celiac disease were collected with the on-lain survey. All the patients were positive in CD-related immunological and genetic tests and had biopsy established CD.

Results: The average age of respondents is 37,52 ± 11,2 years, women 79 (84,1%), men 15 (15,9%). Among 94 respondents 0.1% do not follow a gluten-free diet, 10.6% <1 year, 25.5% from 1 to 3 years, 11.7% – 4-5 years, 28.7% are on a gluten-free diet >5 years, 14.9% – 10-15 years, 8.5% > 15 years. Gastrointestinal symptoms have started at the age < 10 years old in 59.6% of patients, in 4.2% in 11-16 years old, 13.8% at the age 17-25 years old, 12.8% at the age 26-40 years old, 9.6% had late CD onset (>40 years old).

Extraintestinal symptoms such as drowsiness were noted by 46.8 %, headaches by 40.4%, weakness by 59.6%, irritability by 57.4% of respondents. Lack of coordination was noticed in 18.1% of cases, dizziness in 22.3%, 57.4% have numbness, decreased sensitivity, and tingling feeling in the limbs. Joint pain had 54.3% of the patients with CD (Figure 1).

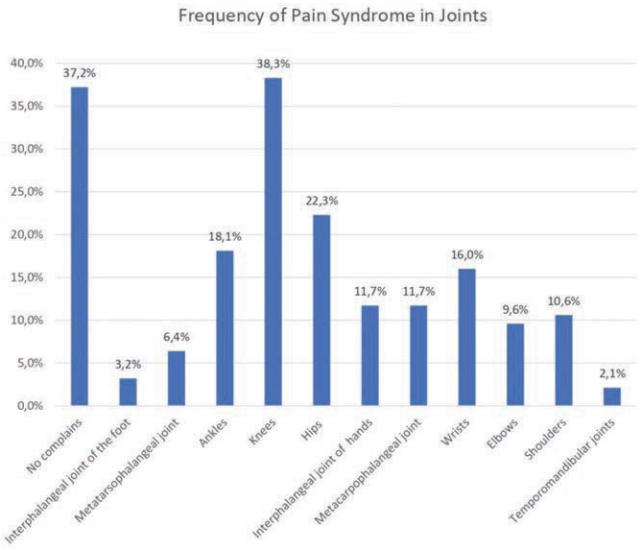

Figure 1. Frequency of pain in different joints

The maximal intensity of pain was noticed in the morning (8.5%) or late night (13.8%) times and fulfilled inflammatory pain criteria (ASAS). In 17% was noticed interrelation between gluten-free diet violation and the appearance of joint pain. In 26.6% was noticed signs of enthesitis. Weakness of arms was noticed by 39.4% of respondents. Non-steroidal anti-inflammatory drugs (NSAIDs) were started by 35.1% of patients, without any improvement in 66% of cases.

Conclusion: Patients' surveys showed that musculoskeletal symptoms in patients with celiac disease are not a rare problem and they are comparable with the frequency of neurological symptoms. Additional research is necessary for a better understanding of the nature of musculoskeletal involvement in celiac disease.

MECHANISTIC FACTORS CONTRIBUTING TO PAIN AND FATIGUE IN FIBROMYALGIA AND ME/CFS: AUTONOMIC AND INFLAMMATORY INSIGHTS FROM AN EXPERIMENTAL MEDICINE STUDY

J. Eccles[1,2], C. Thompson[3,4], B. Thompson[1], M. Amato[1], K. Themelis[1,5], H. Critchley[1], N. Harrison[1,6], K. Davies[4]. [1]*Brighton & Sussex Medical School, Neuroscience, Falmer, United Kingdom*; [2]*University Hospitals Sussex NHS Foundation Trust, CIRU, Brighton, United Kingdom*; [3]*University Hospitals Sussex NHS Foundation Trust, Rheumatology, Brighton, United Kingdom*; [4]*Brighton & Sussex Medical School, Clinical and Experimental Medicine, Falmer, United Kingdom*; [5]*University of Warwick, Psychology, Coventry, United Kingdom*; [6]*University of Cardiff, CUBRIC, Cardiff, United Kingdom*

Background: Fibromyalgia and ME/CFS are multifaceted conditions with overlapping symptoms(1); the pathoaetiological mechanisms are complex and debated(2), however there is a strong association with features of hereditary disorders of connective tissue (hypermobility) and autonomic and inflammatory abnormalities (1,2).

Objectives: To determine potential autonomic and inflammatory mechanisms of pain and fatigue in fibromyalgia and ME/CFS

Methods: After excluding participants with WCC higher than 10 (suggesting acute infection) baseline markers of inflammation (CRP and ESR) were available for 60 patients with confirmed diagnoses of Fibromyalgia and/ or ME/CFS and 23 matched controls. Participants then underwent full research diagnostic evaluation including a hypermobility assessment(1) and autonomic challenge (60 degree head up tilt, ISRCTN78820481). Subjective pain and fatigue were assessed before and after challenge (VAS). Linear regression models were used to explore predictors, with adjustment for confounders as appropriate. Mediation analyses (looking for mechanistic effects) were conducted according to the method of Hayes (3) and mediation considered significant if bootstrapped confidence intervals of the estimated indirect effect did not cross zero. In these mediation analyses predictor variable was group membership (patient or control), outcome variable was change in 1)pain and 2)fatigue induced by challenge and mediatiors 1)no of connective tissue features in hypermobility diagnostic criteria endorsed by participant; 2)baseline inflammatory markers.

Results: ESR and CRP were significantly higher in patients rather than controls, even after correcting for BMI, age and sex (B=5.15, t=2.05, p=0.044; B=1.77, t=2.15, p=0.044 respectively). Adjusted ESR and CRP correlated with both subjective fatigue (B=0.44, t=2.09, p=0.04; B=1.63, t=2.60, p=0.011) and pain severity (B=0.13, t=2.51, p=0.014; B=0.45, t=3.01, p=0.004) at baseline. Autonomic challenge amplified pain (B=14.20, t=2.87, p=0.005) and fatigue (B=31.48, t=5.95, p=<0.001) in patients to a significantly greater degree than controls, controlling for baseline levels. Baseline ESR and CRP also predicted challenge-induced increase in fatigue (B=0.78, t=370, p=<0.001; B=1.91, t=3.36, p=<0.001) and ESR challenge-induced increases in pain (B=0.46, t=2.35, p=0.021).

Mediation analysis demonstrated that number of connective tissue features expressed in hypermobility criteria mediated the degree to which subjective pain was increased by the autonomic challenge (Bootstraped 95% CI of indirect effect do not cross zero, 0.1572 – 6.8171). ESR mediated the degree to which subjective fatigue was increased by the autonomic challenge (Bootstraped 95% CI of indirect effect do not cross zero,0.7541 – 7.3888).

Conclusion: To our knowledge this is the first study to directly explore autonomic and inflammatory mechanisms of pain and fatigue in a combined population of Fibromyalgia and ME/CFS. This study this adds to the evidence-base of baseline inflammatory abnormalities in fibromyalgia and ME/CFS. It highlights their potential role in predicting symptom severity and their potential mechanistic role in autonomic induced pain and fatigue, suggesting future treatment strategies.

FIBROMYALGIA AND BODY MASS COMPOSITION IN POST-MENOPAUSAL WOMEN: PRELIMINARY RESULTS FROM A CROSS-SECTIONAL MONOCENTRIC STUDY

E. Hysa[1], S. Paolino[1], R. Mascaro[1], A. Casabella[1], L. Carmisciano[2], E. Gotelli[1], C. Pizzorni[1], A. Sulli[1], V. Smith[3], M. Cutolo[1]. *[1]Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Italy – IRCCS Rheumatology Unit San Martino Polyclinic, Genoa, Italy, Genova, Italy*; *[2]Section of Biostatistics, University of Genova, Genova, Italy., Department of Health Sciences (DISSAL), 16132, Italy*; *[3]Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Corneel Heymanslaan 10, 9000 Ghent, Belgium, Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium*

Background: Fibromyalgia (FM) is characterized by chronic musculoskeletal widespread pain, fatigue, sleep disturbances and functional symptoms.
Objectives: Our study aimed to determine if FM could affect body composition of post-menopausal women and to investigated potential correlations between disease severity and body mass variables.
Methods: Thirty post-menopausal FM female patients (median age 58 years, BMI = 25.8) were diagnosed according to either ACR 1990 fibromyalgia classification criteria or ACR 2010 preliminary diagnostic criteria. They underwent Dual-energy X-ray absorptiometry (DEXA) for clinical purposes (i.e. screening for osteoporosis). The parameters analyzed by a dedicated software (GE Lunar, USA) were the spine and femoral bone mineral density (BMD), the total lean mass and the total body fat (TBF), quantitative variables of bone, muscle and fat composition. Additionally, qualitative analysis of the bone was indexed by the trabecular bone score (TBS). All the variables were compared with the parameters of 30 healthy controls (median age 59 years, BMI = 24.4) matched for sex and age. For each patient, data on disease duration, comorbidities, current treatment and disease severity self-reported scores were collected. The last ones derived from the Italian Fibromyalgia Impact Questionnaire Revised (FIQ-R) version that each patient independently compiled before the medical visit: widespread pain index (WPI), symptom severity scale (SSS), polysymptomatic distress scale (PDS), modified fibromyalgia assessment status (modFAS) and the FIQ-R total score.
Results: The clinical features of the FM patients included in our cohort are reported in Table 1. No statistically significant differences were observed between femoral/spine BMD, TBS and muscle mass between patients and controls (p = 0.3, p = 0.06, p = 0.16, p = 0.8 respectively). Conversely, both total and central body fat were significantly higher in patients compared with healthy controls (29.4 kg vs 25.2 kg, 15.7 kg vs 13.2 kg, p = 0.006 and p = 0.01 respectively). No significant correlations were observed between body mass composition indexes with scores of disease severity. Body mass composition variables did not statistically differ when patients were sub-analyzed according to pharmacological treatment and comorbidities.

Table 1. Clinical features of FM patients included in present cohort (please see text for explanations of terminology)

	Patients, N = 30
Age (range)	58.0 [53.8, 69.2]
BMI (range)	25.8 [23.0, 28.4]
Disease duration (years), Median [IQR]	4.5 [2.2, 9.2]
ModFAS, Median [IQR]	24.5 [20.0, 29.2]
PDS, Median [IQR]	17.5 [16.0, 23.2]
SSS, Median [IQR]	8.0 [6.0, 9.0]
WPI, Median [IQR]	12.0 [7.8, 15.0]
FIQ-R, Median [IQR]	57.9 [32.4, 68.8]
Current pharmacological treatment	
Cyclobenzaprine N (%)	24 (80)
Fluoxetine N (%)	5 (16.6)
Duloxetine N (%)	4 (13.3)
Gabapentinoids N (%)	2 (6.6)
Tizanidine N (%)	2 (6.6)
Benzodiazepines N (%)	2 (6.6)
Cannabinoids N (%)	3 (10)
Nson-pharmacological treatment	
Aerobic physical activity N (%)	5 (16)
Comorbidities	
Hypertension N (%)	10 (33.3)
Diabetes N (%)	3 (10)
Osteoarthritis N (%)	10 (33.3)
Anxiety/depression N (%)	3 (10)
Psoriasis N (%)	3 (10)

Conclusion: Our preliminary results suggest that FM seems not associated with impaired bone mass and bone quality in post-menopausal women compared to matched healthy controls, in line with the majority of literature evidences [1]. However, total and central adipose tissue mass resulted higher in this cohort of FM patients compared with controls but not correlate with disease severity. This might be due to a disease-induced sedentary lifestyle and might reinforce the concept that physical activity represents the best preventive method of overweight and obesity, one of most reported comorbidities for FM patients[2].

AB1211

DOES BODY MASS INDEX AND METABOLIC SYNDROME IMPACT ON FIBROMYALGIA?

G. Tramontano[1,2], V. Tomatis[1], M. Gilio[3], A. Giusti[1,2], F. Giarracca[2], R. Gallo[2], L. Bandi[2], G. Bianchi[2]. *[1]Rheumatology Unit, Department of Medical Specialties, Regional Health Trust 3, Genoa, Italy*; *[2]Metabolic Bone Diseases Unit and Fracture Liaison Service, Department of Medical Specialties, Regional Health Trust 3, Genoa, Italy*; *[3]Infectious Disease Unit, Infection Disease Unit - San Carlo Hospital, Potenza, Italy*

Background: Fibromyalgia (FBM), obesity and the metabolic syndrome (MTB) are common conditions with significant impact on health and quality of life, producing relevant economic burden for healthcare systems. Although obesity represents a negative prognostic factor for FBM, the relation between body mass index (BMI) or MTB and FBM severity is still unclear.
Objectives: The aim of our ongoing study was to evaluate the relationship between BMI or prevalent MTB and FBM severity, estimated with 3 different severity scores.
Methods: We included the first 100 women presenting with FBM, defined according to the ACR2016 diagnostic criteria, consecutively evaluated during the period of 1 year in 2 Clinic in Italy. On enrolment were assessed/recorded demographic, clinical and pharmacological characteristics, weight, height, physical activity, tenderness, pain and symptoms. The following scores were calculated: tender points count (TP), Widespread Pain Index (WPI), Polysymptomatic Distress Scale (PDS), Fibromyalgia Impact Questionnaire (FIQ) and modified Fibromyalgia Assessment Status (mFAS). BMI was calculated, and the presence of MTB was evaluated according to current definition. Patients were categorized as presenting with severe disease or moderate/mild disease according to recent definition validated in an Italian population. The prevalence of MTB and the mean ± standard deviation (SD) BMI in subgroups defined according to severity were estimated.
Results: Mean age ±SD was 57.5±12.7 years, mean BMI ±SD was 25.3±5.1, and 9.5% presented with MTB. FBM severity (mean±SD) calculated by PDS, FIQ and mFAS was respectively 25.3±9.3, 63.2±23.1, and 30.1±7.7. Patients with the highest FBM severity according to PDS (>25) were less likely to present with MTB (2.4%) compared to those with a PDS of 0-25 (20.0%, P=.026), with an adjusted (age and BMI) OR (95%CI) for presenting with MTB in patients with less severe FBM of 8.2 (0.962-69.925, P=.054). Similar results were found when the specific conditions characterizing the MTB were considered separately, except for excessive body fat around the waist (not related to severity). The BMI ±SD was comparable between patients with severe disease (25.8±5.8) according to PDS and those with less severe FBM (24.8±4.4, P=.388), with no correlation between BMI and PDS (Rho: 0.083, P=.454). Considering all other characteristics of the two groups defined according to PDS categories (PDS >25 versus PDS 0-25) a significant difference was found in mean age ±SD, greater in patients with less severe FBM (60.2±13.2) compared to those with highest FBM severity (54.8±11.6, P=.046). Similar but less significant findings were found also with FIQ and mFAS. The prevalence of MTB according to the FIQ was 7.3% for highest severity versus 14.3% for less severe FBM (P=.200), with a comparable BMI ±SD between the two groups (respectively 26.2±6.1 versus 24.4±3.7, P=.125). Corresponding figures for MTB or BMI and FBM severity according to the mFAS were respectively: prevalence of MTB in highest severity 3.0% versus 16.3% in the less severe FBM (P=.078); mean ±SD BMI in highest severity 26.4±6.2 versus 24.6±4.2 in less severe patients (P=.121).
Conclusion: The preliminary results of our ongoing analysis demonstrated a slightly inverse relationship between FBM severity and the prevalence of MTB, trending to significance, while no relationship was found between severity and BMI.

AB1212 GENDER DIFFERENCES IN FIBROMYALGIA PATIENTS IN VIEW OF THE 1990, 2011, AND 2016 ACR CRITERIA

A. Moshrif[1], M. Z. Shoaeir[1], A. S. Abbas[1], T. M. Abdel-Aziz[1], W. Gouda[1]. [1]*Al Azhar University, Rheumatology, Assiut, Egypt*

Background: Fibromyalgia (FM) is a common rheumatic illness distinguished by chronic pain, headache, fatigue, cognitive problems, and functional disability. However, the differences between men and women have not yet been comprehensively studied, especially after the development of the last 2016 American College of Rheumatology (ACR) criteria.
Objectives: The aim of this study was to evaluate the gender differences in symptom characteristics, cognitive dysfunction, and disease severity in Egyptian FM patients considering both the ACR 1990, 2011, and the last 2016 ACR diagnostic criteria
Methods: In this cross-sectional study, 352 individuals with fibromyalgia were interviewed from January 1, 2020, to June 1, 2021. In addition to the number of tender points (TPC), data was collected on age, gender, body mass index (BMI), marital status, disease onset, duration, and diagnostic delay. The Widespread Pain Index (WPI), the Symptom Severity Scale (SSS), fatigue, cognitive dysfunction, sleep disturbance, awakening unrefreshed, headache, abdominal pain, and depression were evaluated and scored according to 2010 and 2016 ACR criteria. The questionnaire includes a visual analog scale (VAS) for pain, fatigue, stiffness, anxiety, and depression. Total score ranges were calculated with total score ranges between 0 and 80 (without job items), where higher scores indicated a greater negative impact and/or severity of symptoms. The Polysymptomatic distress scale (PDS) has been calculated by the summation of the SSS with the WPI. The Revised FM impact questionnaire (FIQR) has also been evaluated.
Results: The study shows that females have a significantly higher prevalence of fatigue, cognitive dysfunction, sleep disturbance, headache, and abdominal pain ($p < 0.05$). Also, females showed significantly higher scores than males regarding WPI, SSS, and mean TPC ($p = 0.004$, 0.027, and 0.001, respectively). While there was no difference regarding the FIQR ($p=0.93$), PDS was significantly higher in women ($p= 0.001$).
Conclusion: Female patients with FM had greater disease severity scores, symptomatology, and number of tender points. Whatever the criteria applied, the prevalence and intensity of the disease features are higher in females, which may underestimate the disease in male patients.

AB1213 EFFECTIVENESS OF A ONE-WEEK INPATIENT MULTIMODAL PAIN TREATMENT PROGRAM FOR PATIENTS WITH RHEUMATOLOGIC DISEASES AND MUSCULOSKELETAL PAIN – A SINGLE CENTER OBSERVATIONAL STUDY

I. Pirker[1], A. Rubbert-Roth[1], C. Haller[1], F. Mayr[1], J. Von Kempis[1]. [1]*Kantonsspital St.Gallen, Division of Rheumatology and Immunology, Department of Internal Medicine, St. Gallen, Switzerland*

Background: Multimodal rheumatologic complex treatment (MRCT) is a treatment concept for patients with rheumatologic diseases requiring acute inpatient care suffering from exacerbated pain and/or functional impairment. A rheumatologist directs the treatment program including multimodal assessments and treatment from three of the following: ergotherapy, physiotherapy, pain medicine and cognitive behavioural treatment. Most studies evaluated data from a two-week inpatient MRCT program.[1] Available data on the effectiveness of a one-week inpatient multimodal treatment program are scarce. However, whether a shorter program might also be effective has not been studied so far.
Objectives: To evaluate the effectiveness of a one-week inpatient multimodal and interprofessional treatment program on musculoskeletal pain and function of patients with rheumatologic disorders.
Methods: 59 consecutive patients were entered into a program of multimodal treatment courses (MRCT) from January 2021 until December 2021. All patients completed a total of 11 hours of therapy in one week. Two patients were excluded for evaluation (one patient acquired COVID 19 during hospitalization and one patient was excluded due to missing data).
Pain was assessed via visual analogue scale (VAS) and functional impairment via the "Funktionsfragebogen Hanover (FFbH)" and the "Health Assessment Questionnaire (HAQ)" at admission, at discharge and at 12 weeks of follow up. Paired t-test analyses for all treatment episodes were performed.
Results: The mean treatment duration (days, ±SD) was 8.1 ± 0.8. Mean age (years, ±SD) of the 57 patients treated in the MRCT program was 57.2 ± 12.5, with 72% female and 28% male patients. Of all patients, 40% had an underlying inflammatory disorder, 60% a non - inflammatory rheumatic disease. 23% of all patients had "back pain", 14% "spondyloarthritis" and 11% "rheumatoid arthritis". Overall, VAS (pain) mean at admission was 6.9 ± 1.0 (SD), HAQ mean 0.57 ± 0.23 (SD) and FFbH mean 81.44 ± 7.95 (SD), respectively. Significant improvements in VAS, HAQ and FFbH were demonstrated at discharge (day 8), with a mean improvement of VAS of -2.86 (95% CI: -3.07 to -2.64, P value: <0.0001), a mean improvement of HAQ of -0.24 (95% CI: -0.28 to -0.20, P value: <0.0001) and a mean improvement of FFbH of 5.38 (95% CI: 3.78 to 6.98, P value: <0.0001). Follow up assessment at week 12 was recorded in 22 patients (39%) with a significant mean improvement in VAS of -2.23 (95% CI: -2.98 to -1.48), P value < 0.0001) (Table 1 and Figure 1).

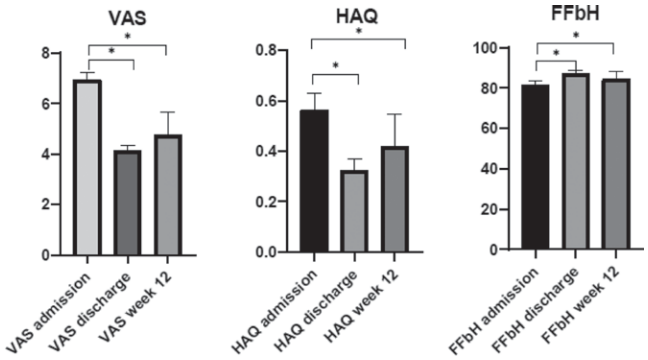

Figure 1.

Table 1.

VAS mean difference admission/discharge	**-2.86 (95% CI: -3.07 to -2.64, P value: <0.0001), n= 55**
HAQ mean difference admission/discharge	**-0.24 (95% CI: -0.28 to -0.20, P value: <0.0001), n= 57**
FFbH mean difference admission/discharge	**5.38 (95% CI: 3.78 to 6.98, P value: <0.0001), n= 56**
VAS mean difference admission/12 weeks follow up	**-2.23 (95% CI: -2.98 to -1.48, P value: <0.0001), n= 22**
HAQ mean difference admission/ 12 weeks follow up	**-0.16 (95% CI: -0.29 to -0.04, P value: 0.01), n= 22**
FFbH mean difference admission/12 weeks follow up	**3.96 (95% CI: 1.18 to 6.74, P value: 0.01), n= 22**

Conclusion: Significant improvement of pain and function was demonstrated at discharge and at week 12 in patients with rheumatologic diseases and musculoskeletal pain completing a one-week inpatient multimodal interprofessional treatment program. A multimodal therapeutic approach may provide an effective treatment strategy superior to unimodal standard management.

AB1214 VITAMIN D SUPPLEMENTATION IN FIBROMYALGIA: A SYSTEMATIC REVIEW

H. Sousa[1], A. S. Pinto[2], J. F. Ferreira[1,2]. [1]*Science of Heath Faculty Beira Interior University, Rheumatology, Covilhã, Portugal*; [2]*Unit Local Health of Guarda, Rheumatology, Guarda, Portugal*

Background: Fibromyalgia (FM) is a chronic disease characterized by diffuse pain associated with high levels of fatigue whose intensity is very variable. Similar symptoms are found in patients with low levels of vitamin D, a vitamin that behaves like a hormone with multiple receptors spread in several tissues. Although its role in the pathophysiology of FM remains unclear many studies point to a correlation between vitamin D deficiency and FM symptoms severity. (1)

Objectives: Conduct a systematic review of the literature to determine the value of vitamin D supplementation in fibromyalgia.
Methods: Medline, EMBASE, and Cochrane databases were searched, from January 2000 to January 2022, using the descriptors "Fibromyalgia", "Fatigue" and "Vitamin D." Randomized and clinical control trials including FM patients in whom supplementation of vitamin D was made were selected. Data comprised sociodemographic description, diagnosis criteria, fibromyalgia symptoms, Fibromyalgia Impact Questionnaire (FIQ), short-form 36 (SF36), and vitamin D supplementation protocol was collected.
Results: Of the initial 2480 articles, 4 were eligible for final analysis. One did not observe any significant improvement in FIQ scores with vitamin D supplementation. The remaining three observed significant improvements in SF-36 and FIQ scores but to different extents. One only demonstrated improvements in specific components of the SF-36, also demonstrating improvements concerning morning fatigue. Another demonstrates improvements in all SF-36parameters, except for pain level. Lastly, other observed improvements in the scores of both FIQ and SF-36 scales.
Conclusion: Our review shows conflicting results regarding the role of using vitamin D supplementation in the quality of life of patients with FM(S). These results can be explained by different supplementations protocols and also different baseline levels of vitamin D for which it was decided to supplement. Nevertheless, vitamin D supplementation appears to have a benefit in fatigue and quality of life in FM patients. Larger studies, which last longer and have a more uniform supplementation protocol, are needed to confirm the results of this review.

AB1215 A COMPARATIVE ANALYSIS OF RADIOLOGICAL FINDING BETWEEN TUBERCULOUS, BRUCELLAR AND PYOGENIC SPONDYLODISCITIS

N. Ben Chekaya[1], F. Fhima[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], M. Jguirim[1], N. Bergaoui[1]. [1]*fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia*

Background: Infection spondylodiscitis (IS) is a serious infectious disease which involves intervertebral disc and its adjacent vertebral bodies but later may also extend into the the adjacent neural structures. The clinical picture of IS is rather non specific but there are significant radiological differences that permit a presumptive aetiological diagnosis and orient the initial empirical treatment.
Objectives: This study aimed to compare the radiological features of of tuberculous (TS), brucellar (BS) and pyogenic spondylodiscitis (PS).
Methods: A retrospective monocentric study involving 70 cases of infectious spondylodiscitis admitted between January 2009 and August 2019 at our rheumatology department. Clinical, laboratory and radiological data of the patients were collected.
Results: Of these 70 patients, 18 (25.7%) had TS, 8 (11.4%) BS and 44(62.9%) PS. There were 37 women (52.9%) and 33 men (47.1%). The age of the patients ranged from 12 to 82 years, with a mean of (SD±) 54± 15,23 years. Standard X-rays showed abnormalities suggestive of spondylodiscitis in 78.6% of cases. A great majority of the patients had involvement at only one vertebrae level (70%). The most frequently affected level, were the thoracic (33.3%), the lombosacral (100%) and the lombar (38.6%) segment in the TS, BS and PS respectively. In BS the lombosacral segment was significantly the most frequently affected level (p<0.0037). Computed tomography was performed in 52.9% of cases and showed that the epidural and paravertebral abscess were characteristic of tuberculous involvement (p=0.013 and 0.05). Magnetic resonnance imaging was performed in 63% of cases. The intervertebral disc narrowing was observed in 87.3% of patients. Paravertebral or epidural masses were present respectively in 53.5% and 86.7% of TS, versus 14.3% and 71.4% of BS, and 46.3% and 80.5% of PS, there were no significant differences between the groups.The enhancement was rather heterogeneous in the SDT and homogeneous in the two other groups, but these differences were not statistically significant.
Conclusion: There are significant radiological differences between TS, BS and PS. A better understanding of typical and atypical manifestations on imaging can be an excellent diagnostic tool for every attending physician.

AB1216 TUBERCULOUS, BRUCELLAR AND PYOGENIC SPONDYLODISCITIS: A DESCRIPTIVE AND COMPARATIVE STUDY OF 70 CASES

N. Ben Chekaya[1], F. Fhima[1], M. Ghali[1], A. Ben Salem[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], M. Jguirim[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia*

Background: Infection spondylodiscitis is a serious infectious disease which involves intervertebral disc and its adjacent vertebral bodies but later may also extend into the the adjacent neural structures. Early diagnosis and identifing the causative agent seem critical in term of prognosis.
Objectives: To describe and to compare the clinical, biological and radiological features of tuberculous (TS), brucellar (BS) and pyogenic spondylodiscitis (PS).
Methods: A retrospective monocentric study involving 70 cases of infectious spondylodiscitis admitted between January 2009 and August 2019 at our rheumatology department. Clinical, laboratory and radiological data of the patients were collected.
Results: Of these 70 patients, 18 (25.7%) had TS, 8 (11.4%) BS and 44(62.9%) PS. There were 37 women (52.9%) and 33 men (47.1%). The age of the patients ranged from 12 to 82 years, with a mean of (SD±) 54± 15,23 years. The patients with TS were younger than those with PS (p=0.0016). Of our cases, 67.1% had comorbid chronic diseases such as predominantly renal failure and diabetes. The median diagnostic delay (MDD) in our series was 120,180 and 30 days for TS, BS and PS respectively (p=0.004).All of the patients included in this study suffered from pain, 30 of these had fever and 19 had night sweats. Radiculalgia was found in 50% of cases and 8.6% of them had a neurological deficit. There were no significant differences those clinical features between the groups. In view of laboratory findings, increased erytrocyte sedimentation rate (ESR) was detected in 82.9%, C-reactive protein(CRP) positivity in 84.3% and hyperleukocytosis in 33.3% of patients. ESR and CRP levels were significantly higher in PS patients when compared with TS cases (p=0.005; P=0.006, respectively). Standard X-rays showed abnormalities suggestive of spondylodiscitis in 78.6% of cases. Computed tomography and Spinal magnetic resonance imaging were performed respectively in 52.9% and 63% of cases and were pathological in all cases. A great majority of the patients had involvement at only one vertebrae level (70%). The most frequently affected level, were the thoracic (33.3%), the lombosacral (100%) and the lombar (38.6%) segment in the TS, BS and PS respectively. In BS the lombosacral segment was significantly the most frequently affected level (p<0.0037). The intervertebral disc narrowing was observed in 87.3% of patients. Paravertebral or epidural masses were present respectively in 53.5% and 86.7% of TS, versus 14.3% and 71.4% of BS, and 46.3% and 80.5% of PS, there were no significant differences between the groups.
Conclusion: There are significant clinical, biological and radiological differences between TS, BS and PS. The presence of back pain, fever, moderate elevation of inflammatory markers with thoracic radiological involvement was suggestive of tuberculous spinal infection.

AB1217 CHRONIC LOW BACK PAIN AND MUSCULAR HYDATIDOSIS: THE TREE THAT HIDES THE FOREST

R. Ben Aissa[1], M. A. Khlif[2], S. Boussaid[1], H. Eleuch[2], K. Zitouna[2], M. Barsaoui[2]. [1]*Rabta Hospital, Department of Rheumatology, Tunis, Tunisia*; [2]*Rabta Hospital, Department of Orthopedic Surgery, Tunis, Tunisia*

Background: Hydatid cyst disease is a zoonosis caused by *Echinococcus granulosus*. The parasite implants most commonly in the liver and lung. Musculoskeletal involvement is rare.
Objectives: To describe clinical and imaging presentation of spinal and muscular hydatidosis.
Methods: We report two cases of chronic low back pain caused by hydatid cyst.
Results: Case 1: A 36-year-old woman living in a rural area presented with a three-years history of lumbar back pain complicated with right-sided sciatica and intermittent episodes of urinary retention. The pain was gradually worsening and resisting conventional analgesics and physiotherapy. On physical examination, she had tenderness of the lumbar back and left sacroiliac joint with limited mobility. Biological findings were normal and X-ray features showed osteolytic lesions of L5 left side. The magnetic resonance imaging (MRI) results revealed septated multilocular hydatic cysts with high signal intensity in T2-weighted images and low signal intensity in T1-weighted images along L5 and the sacrum left side. Serological test for hydatid disease was positive. The treatment was wide surgical resection combined with Albendazole (400 mg/day) for one year postoperatively. Case 2: A 62-year-old woman presented with a one-year history of lumbar back pain with gait instability and right flank swelling. Biological findings and X-ray features were normal. The patient first was explored by uro-CT to assess for nephrolithiasis and it revealed retro and sub-peritoneal two multilocular hydatic

cysts (60x80mm, 36x35mm) along right iliopsoas and adductor muscles. MRI showed same cystes described on the CT (Figure 1). No other localizations were detected. The diagnosis of hydatidosis was confirmed perioperatively after visualization of the cyst. Wide resection was performed but signs of recurrence were detected by MRI at the 3-month follow-up.

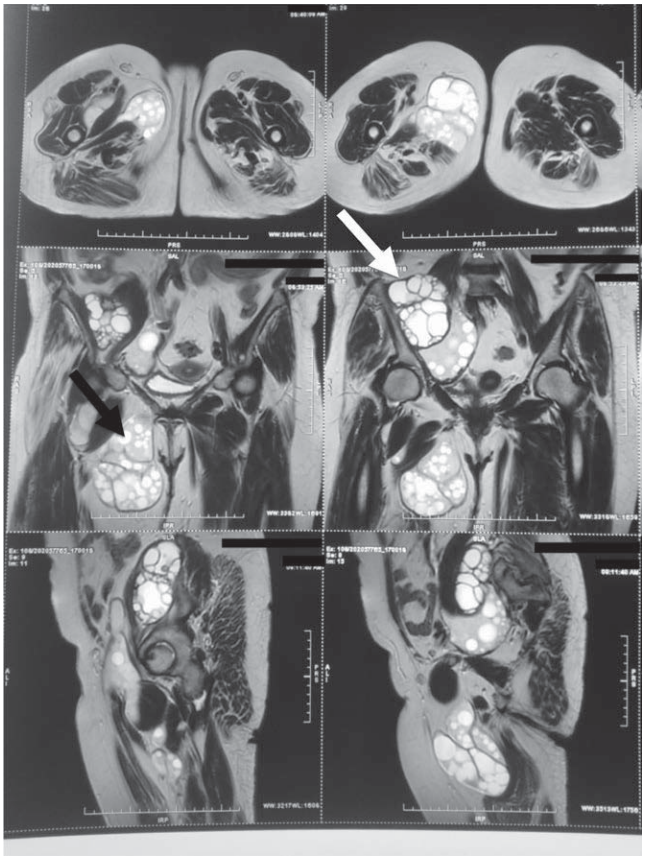

Figure 1. MRI showing two multilocular cysts along right iliopsoas (white arrow) and adductor muscles (black arrow).

Conclusion: In endemic areas, bone and muscle involvement from echinococcosis should be considered during clinical investigation of chronic lumbar pain.

AB1218 AURICULOTHERAPY AS A TREATMENT FOR CHRONIC NECK PAIN: AN INTERVENTIONAL COMPARATIVE STUDY

O. Saidane[1], W. Lahmar[1], F. Saadi[1], A. Ben Tekaya[1], S. Bouden[1], R. Leila[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicolles Teaching Hospital, Rheumatology, Tunis, Tunisia*

Background: Data indicates promising benefits of auriculotherapy (AT) in pain management of several pathologies. Common cervical pain (CCP) is recurrent plaint often resistant to standard treatment. And use of auriculotherapy as a therapeutic solution in neck pain has not been well explored.
Objectives: The aim of our study is to evaluate efficacy of a single session of AT in the management of CCP's pain and disability.
Methods: We conducted an interventional comparative study. Fifty patients with CCP consulting were divided in two group of 25: group A underwent a session of AT, group P had a placebo treatment using a detuned ultrasound machine. Evaluation of the patients was performed before, and right after the intervention. The Neck and Pain Disability Scale (NPDS) questionnaire. It includes 3 areas: F1 for functional disability, F2 for movement-induced pain and F3 for pain in static position.
Results: We enrolled 32 women and 18 men with an average age of 47. Epidemiological, clinical and radiographic features were comparable for both groups, except for the standard of living and the consumption of analgesics, which were significantly higher in the group A (p=0.027and p<0.001, respectively). Initially, NPDS total score and F1, F2, F3 sub scores were comparable in both groups.
After the intervention, all scores had decreased significantly. In the A group: NPDS total went from 34.3 to 22.9 (p<0.001), F1 went from 9.5 to 6.2 (p<0.001), F2 went from 16.5 to 11.9 (p<0.001), F3 from 8 to 5.4 (p<0.001). In the P group: NPDS total decreased from 28.9 to 26 (p=0.001), F1 from 6.3 to 5.7 (p= 0.001), F2 going from 14.4 to 13.3 (p =0.013), F3 went from 8 to 7.3 (p=0.006).
When we compared the scores after the intervention, the improvement was statistically higher in the A group for all scores (p<0.001 for total, F1 and F2, and p=0.002 for F3 sub score).
Conclusion: Our study revealed that a single session of auriculotherapy is effective on short term in the treatment of pain and disability related to CCP. This alternative technique may gain its place in the therapeutic management protocol to overcome disability of chronic neck pain.

AB1219 ASSOCIATION OF CAROTID ATHEROSCLEROSIS WITH SARCOPENIA IN MALE PATIENTS WITH CORONARY ARTERY DISEASE

M. Letaeva[1], O. Malyshenko[1], M. Koroleva[1], J. Averkieva[1], T. Raskina[1]. [1]*Kemerovo State Medical University, Department of Propedeutics of Internal Medicine, Kemerovo, Russian Federation*

Objectives: To investigate the association between sarcopenia and carotid atherosclerosis in male patients with coronary artery disease (CAD).
Methods: Here we enrolled 79 male patients with CAD verified by coronary angiography (median age = 63 (57; 66) years). Sarcopenia was diagnosed according to the recommendations of the European Working Group on Sarcopenia in Older People (EWGSOP, 2010) by examining muscle strength, muscle mass, and muscle function. Severity of carotid atherosclerosis was assessed by color duplex scanning by measuring intima-media thickness and percent stenosis. Patients were then divided into those without sarcopenia (n = 31), with pre-sarcopenia (n = 21), and sarcopenia (n = 27).
Results: Patients with sarcopenia had significantly higher intima-media thickness than those without sarcopenia (p = 0.005). Multiple carotid plaques and > 50% stenosis were significantly more frequent in patients with sarcopenia compared with those with pre-sarcopenia (48.15% versus 9.50%, p = 0.015) and without sarcopenia (48.15 % versus 12.90%, p = 0.013). Severity of carotid atherosclerosis negatively correlated with musculoskeletal index (r = -0.227, p = 0.047).
Conclusion: Severe carotid atherosclerosis was associated with a decrease in muscle mass, suggesting a link between atherosclerosis and sarcopenia and potentially elevated risk of adverse outcomes in patients with a sarcopenia comorbidity.

AB1220 CHARACTERISTICS OF INFECTIOUS SPONDYLODISCITIS IN ELDERLY

I. Mahmoud[1], M. Aouini[1], A. Ben Tekaya[1], S. Bouden[1], R. Leila[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*

Background: Infectious spondylodiscitis is a rare but growing disease. It is a serious infection that can compromise both the functional and vital prognosis especially on elderly subjects.
Objectives: The purpose of this study was to compare the clinical, bacteriological and evolutionary characteristics of elderly patients admitted for management of infectious spondylodiscitis with a case-control group of young subjects.
Methods: Retrospective, descriptive study carried out in the rheumatology department of the Charles Nicolle Hospital from 2010 to 2019. Adult patients hospitalized for infectious spondylodiscitis were included. Clinical, bacteriological and evolutionary data were analysed and comparing those over 65 years of age with young case-control subjects.
Results: Of the 78 patients included, 33 patients belonged to the elderly group and 45 to the control group. The duration of evolution was shorter for the control group (123 vs. 181 months for the elderly; p=0,71). The progressive mode of onset characterised the elderly group (P<0.05). Spinal pain was constant. Neurological abnormalities, night sweats, and altered general condition were more present in the elderly (p<0.05). Spinal stiffness was more present in the control group (p<0.05). There was no difference between the two groups in terms of the presence of fever and radiculalgia. Spinal biopsy was performed in 72% of the elderly subjects and in 80% of the control group. The most common germ in the elderly group was tuberculosis and brucellosis in the control group (p<0.05). A favorable evolution was noted in 75% of the cases in the control group compared to 66% of the elderly subjects (p<0.05). Neurological complications and mortality were more common in the elderly (p<0.05).
Conclusion: Infectious spondylodiscitis on elderly is characterised by an insidious onset, a confusing clinical picture and a more severe presentation than young people with significant complications and mortality.

AB1221

START BACK TOOL RISK SCORE: WHAT GUIDANCE TO GIVE IN A MILITARY LOW BACK PAIN POPULATION?

R. Dhahri[1], W. Lahmar[1], O. Dhrif[2], M. Slouma[1], L. Metoui[1], I. Gharsallah[1], K. Amri[3], Y. Mallat[3], L. Nouisri[3]. [1]*Military Teaching Hospital, Rheumatology, Tunis, Tunisia*; [2]*University of Tunis El Manar, Internal Medecine, Tunis, Tunisia*; [3]*Military Teaching Hospital, Orthopedics, Tunis, Tunisia*

Background: The Keele start back Tool (SBT) is a 9-item self-reported questionnaire validated to identify individuals with non-specific low back pain (LBP) who have prognostic factors for persistent disabling pain. Thus, it is a useful component of stratified care, where patients' prognostic subgroups are matched with appropriate treatment.
Objectives: The aim of our study was to report the prevalence of SBT-calculated risk for back pain disability in Tunisian military patients.
Methods: It was a cross sectional study. The SBT questionnaire was administered to patients > 18 years presenting with common low back pain in outpatient Military teaching hospital in Tunis, Tunisia (from January to Mars 2021). The normality of data distribution was checked by the Kolmogorov-Smirnov test. Quantitative variables were presented as mean ± standard deviation (SD) or median (interquartile range), as appropriate. The categorical variables were expressed as percentages.
Results: Out of 114 participants; the mean age at diagnosis was 79 +/- 12 years old, sex ratio was equal to 1, the median of symptom duration was 22 (6-36) months, 83 (72.8%) were employed, 54 (47.4%) were on active military duty. Comorbidities reported in our patients were distributed as followed: 52 (45.6%) cases of overweight, 21 (18.4%) cases of obesity, 17 (14.9%) had hypertension, 13 (11.4%) suffered from type 2 diabetes, 10 (8.8%) had dyslipidemia, 6 (5.3%) cases of hypothyroidism and 3 (2.6%) cases of auto-immune diseases. Seventy (61.4%) participants reported anxious thoughts, 75 (65.8%) patients expressed avoidance beliefs, 59 (51.8%) patients mentioned catastrophizing thoughts and 50 (43.9%) were dealing with low mood. Mean SBT psychological score was at 2.68 +/-1.5. Patients reported a mean SBT score of 5.31+/-2.1 with the following risk stratification: 27 (23.7%) scored low-risk, 47 (41.2%) medium risk, and 40 (35.1%) high-risk.
Conclusion: This is the first study to report the prevalence of SBT-designated risk subgroups among Tunisian population. Medium or high-risk scores for back pain disability were more prevalent the surveyed sample. Also, rates of low mood and anxious thoughts indicate a need for future research to explore psychosocial factors in non-specific low back pain.

AB1222

POSITIVE DIAGNOSIS OF TUBERCULOUS SPONDYLODISCITIS: CT-GUIDED PERCUTANEOUS BIOPSY OF SPINAL LESIONS VERSUS CLINICAL, BIOLOGICAL AND IMAGING ARGUMENTS

M. Mrabet[1], S. Boussaid[1], S. B. Troudi[1], S. Rekik[1], S. Jemmali[1], S. Rahmouni[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: Tuberculosis is still endemic in Tunisia. Although pulmonary localization is the most common, other localizations, including osteo-articular involvement, are increasingly diagnosed. Spinal or «Pott's Disease» is the most common expression. A bundle of clinical, paraclinical and evolutionary arguments or a disco-vertebral biopsy puncture (DVBP) contribute to the positive diagnosis.
Objectives: Our aim was to assess the real contribution of DVBP compared to clinical-biological and imaging arguments for the diagnosis of tuberculous spondylodiscitis (SPDT).
Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from files of patients hospitalized in the past 20 years (2000-2020) who have been diagnosed with SPDT.
Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age of the population was 55.21 years ± 17.79 [19-91]. Diagnosis SPDT was retained based on the results of the DVBP in 15 patients (28.8%); and it was strongly suspected in front of the presence of clinico-biological and imaging arguments in 37 patients (71.2%). Among the clinical arguments suggestive of SPDT were: progressive onset of symptoms in 47 patients (90.4%), segmental spinal stiffness in 37 patients (71.2%), spinal pain with general signs of tuberculosis such as impaired general condition, fever, night sweats and weight loss in 32 patients (61.5%). Lumbar spine involvement was the most common in tuberculous SPD (57.7%). A biological inflammatory syndrome has been objectified in 38 patients (73.1%). Imaging was contributive to positive diagnosis using standard X-rays, computed tomography and magnetic resonance imaging (MRI). Disc pinch, erosion of vertebral plateaus and vertebral collapse were the major signs. Once the diagnosis was retained for these patients, the first week noted a most significant clinical improvement (56.8%) in patients diagnosed with a range of suggestive arguments (p = 0.002). During the second week, clinical improvement was most marked in patients diagnosed with suggestive clinical and paraclinical arguments (70.3%) but with no statistically significant difference (p = 0.1). The improvement was statistically greater during the fourth week (66.7%) and the third month (60%) in patients diagnosed with histological examination (p < 0.001).

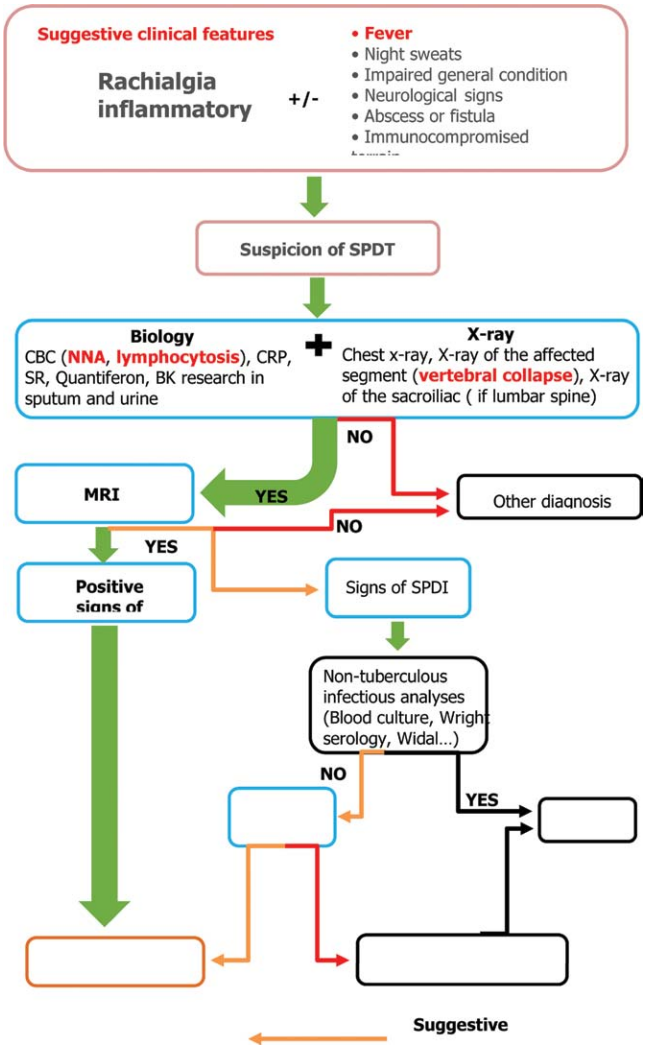

Figure 1. *SPDT Diagnostic Strategy*SPDT= Tuberculous spondylodiscitis, CBC= Cell blood count, NNA= Normochromic normocytic anemia, CRP= C reactive protein, SR= Sedimentation rate, BK= koch's bacillus, SPDI= infectious spondylodiscitis, SPDNT= Non-tuberculous spondylodiscitis

Conclusion: Tuberculous spondylodiscitis is a frequent condition that needs to be treated rapidly. A range of highly suggestive clinical, paraclinical and evolutionary arguments contribute in the majority of cases to the positive diagnosis with a comparative clinical evolution to that of the DVBP which remains an invasive exam with variable sensitivity depending on studies.

AB1223

ACTIVE MILITARY ARE AT HIGHER RISK OF CHRONICITY IN LOW BACK PAIN: A CROSS SECTIONAL COMPARATIVE STUDY

W. Lahmar[1], R. Dhahri[1], O. Dhrif[1], M. Slouma[1], L. Metoui[1], I. Gharsallah[1], K. Amri[2], Y. Mallat[2], L. Nouisri[2]. [1]*Military Teaching Hospital, Rheumatology, Tunis, Tunisia*; [2]*Military Teaching Hospital, Orthopedics, Tunis, Tunisia*

Background: The incidence of low back pain (LBP) was 40.5 per 1,000 person-years in active military population and thus was comparable to the general population. Other than pain and disability, chronicity of LBP has a significant impact on work through the high rates of resulting sick leave. The Start Back

Tool (SBT) questionnaire is a well-known tool used to detect patients with prognostic factors for persistent and disabling back pain. The risk of chronicity in individuals on active military duty suffering from acute back pain is yet to be explored.

Objectives: The aim of our study was to assess the risk of chronicity in active Tunisian military population compared to non-military controls using the SBT questionnaire.

Methods: Cross sectional study in which we enrolled adult patients suffering from acute back pain, who consulted the outpatient department of rheumatology in the military hospital of Tunis from January 2021 to Mars 2021. All patients had a standardized clinical examination. They completed the SBT questionnaire in the validated Arabic language version. Patients were stratified in two groups, active military group (AMG) and non-military group (NMG). Categorical variables were compared with the $\chi 2$ -test. Comparisons of the differences of continuous variables were performed by Student's T-test.

Results: We included 54 patients in the active military group and 60 patients in the non-military group, epidemiologic characteristics were distributed respectively as followed: mean age was at 43+/-8 versus 53+/-13 years old (p<0.001), sex ratios (F/H) were 0.23 versus 3.62 (p<0.001), 54% versus 73% (p=0.033) of patients were overweight or obese, 4% versus 18% (p=0.014) of patients had type 2 diabetes, 4% versus 13% (p=0.099) of patients had dyslipidaemia while 9% versus 20% (p=0.108) of patients had hypertension. Active military group patients had significantly higher proportions of high risk SBT scores than non-military patients 50% versus 22% (2.27 risk ratio 95% CI 1.47 to 3.08; p=0.002), with total mean of scores significantly higher in the active military group 5.81 (95% CI 5.33 to 6.29) versus 4.85 (95% CI 4.43 to 5.27), p=0.014. Active military group patients scored significantly higher on the psychological SBT sub-score with a mean of 3.02 (95% CI 2.8 to 3.24) versus 2.38 (95% CI 2.07 to 2.7) p=0.032, they were more susceptible to express low mood 53% versus 35% (1.51 risk ratio 95%CI 1.13 to 1.89; p=0.044). There was no significant difference in expressed anxiety 69% versus 55% (p=0.139), catastrophizing thoughts 57% versus 47% (p=0.252) and avoidance beliefs 72% versus 60% (p=0.170) though all of these parameters were more prevalent in the active military group.

Conclusion: Though NMG patients had more classic low back pain risk factors such as age and obesity, this did not prevent the AMG to show higher trends toward chronicity via SBT scores. This is to our knowledge the first study to assess the high risk of persistent disabling back pain using the SBT in a Tunisian military population. The implementation of risk stratification for patients with low back pain in routine military health may improve physical function and time off work, sickness certification rates and reductions in healthcare costs compared to usual non-stratified care.

AB1224 NON-CONTIGUOUS MULTIFOCAL SPONDYLODISCITIS: A RETROSPECTIVE OBSERVATIONAL STUDY

S. Rekik[1], S. Boussaid[1], Z. Zeineb[1], S. Jemmali[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta University Hospital, Rheumatology, Tunis, Tunisia*

Background: Non-contiguous multifocal spondylodiscitis (mSpD) is a serious infection. Although literature data highlight the opportunity to miss a non-contiguous spondylodiscitis (SpD), recommendations for which cases an MRI of the entire spine should be performed are missing.

Objectives: The aim of the study was to assess the clinical features of mSpD to reveal risk factors underlining the need for screening a multifocal spine involvement

Methods: We retrospectively evaluated the data of patients with confirmed non-contiguous multifocal spondylodiscitis

Results: Twelve patients suffered from mSpD were included (6 males, 6 females). The mean age was 60 years. Four patients had underlying chronic comorbidity, Diabetes (n=3), hepatitis C virus (n=1). Most patients had spine pain (11 patients,), radiculalgia in one patient, neurologic deficit (3 patients), worsening health status (7 patients). Symptoms onset was acute (n=1) or sub-acute (n=3) or long term (n=8) before admission. The mean duration between the diagnosis and the onset on symptoms was 9,6 months. Tubercular spondylodiscitis was the most detected etiology (n=8), confirmed by histological analysis (n=3) then brucellar, confirmed by serlology lab test, and pyogenic SpD in two patients each. Non-contiguous multi-level involvement in the lumbar, thoracic, and cervical spine was detected in one patient for each region. Seven patients suffered from a lumbar and thoracic spine involvement and SpD occurs in the three regions in two patients. Elevated inflammatory biomarkers (CRP and ESR) were present in all cases. Entire spine MRI was performed for almost all patients, confirmed the diagnosis, showed para-vertebral abscess (n=3), epidural inflammation (n=6), and spinal cord compression (n=3). The majority of cases showed a favorable evolution with appropriate antibiotic therapy. One patient maintain a neurologic deficit, and one suffered from a severe degree of pain. Surgical approach was not indicated.

Conclusion: In our study, mSpD did not appear to be associated with a particular pattern. Tuberculosis was the dominant etiology. That suggests, an MRI of the entire spinal column should be performed for each patient with suspicious SpD, especially when tuberculosis is evocated

AB1225 TUBERCULOUS SPONDYLODISCITIS: DIAGNOSTIC DELAY AND OUTCOMES

M. Mrabet[1], S. Boussaid[1], T. Abdelkefi[1], S. Rekik[1], S. Rahmouni[1], S. Jemmali[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: Tuberculous spondylodiscitis (SPDT) is a serious clinical condition that must be treated promptly. Despite the actual availability of more effective diagnostic tools, early diagnosis of SPDT remains difficult and a high index of suspicion is needed due to the chronic nature of the disease and its insidious and variable clinical presentation.

Objectives: Our aim was to study the correlation between the diagnostic delay of SPDT and its outcomes.

Methods: We conduct a monocentric retrospective and descriptive study in a rheumatology department. Data were collected from observations of patients hospitalized in the past 20 years (2001-2021) who have been diagnosed with SPDT. An early diagnosis is defined by a diagnosis within the first six months versus a late diagnosis that is retained after 6 months of symptoms.

Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age of the population was 55.21±17.79 years [19-91]. Late diagnosis was more common: 41 patients (78.8%) versus 11 patients (21.2%) diagnosed early. Complications were more frequent (61%) in patients diagnosed late, but with no statistically significant difference (p=0.1). Disease-related complications, such as spinal compression, spinal deformation and recurrence of the disease, was statistically higher (45.5%) in early diagnosed patients (p < 0.001). Drug complications, such as disruption of liver balance, hyperuricemia and major intolerance to anti-tuberculosis, were more frequent (36.6%) in patients diagnosed late (p = 0).

Conclusion: Despite highly sensitive imaging techniques, the diagnosis of tuberculous spondylodiscitis is often late, which may lead to severe deformity and early or late neurological complications.

AB1226 AUTOLOGOUS MOSAIC OSTEOCHONDROPLASTY IN THE TREATMENT OF TALAR OSTEOCHONDRAL DEFECTS

T. Omelchenko[1], O. Burianov[1], A. Liabakh[2], E. Levitskyi[1], O. Turchin[2]. [1]*Bogomolets National Medical University, Traumatology & Orthopaedics, Kyiv, Ukraine*; [2]*State Institute "The Institute of Traumatology and Orthopedics of Ukraine", The Clinic for Foot Pathologies and Complex Prosthetic Treatment, Kyiv, Ukraine*

Background: Osteochondral defects of the talus (ODT) is a relatively rare, mostly traumatic pathology, in 6.5 % of cases complicate the course of inversion and eversion injuries of the foot and ankle [1].

Objectives: To conduct a clinical analysis of the effectiveness of autologous mosaic osteochondroplasty in the treatment of patients with osteochondral defects of the talus on the basis of determining the dynamics of pain and restoring the amplitude of ankle movements.

Methods: The study included 34 patients with post-traumatic osteochondral defects of the talus (27 men, 7 women, mean age 24.8 ± 2.1 years) who underwent osteochondroplasty. The duration of painful clinical symptoms before osteochondroplasty ranged from 4 to 18 months. Functional treatment outcomes were assessed over a period of 12 to 36 months using the International Foot and Ankle Surgery Scale (AOFAS), pain dynamics were assessed using the Visual Analog Scale (VAS), and ankle movement recovery dynamics were determined.

Results: Osteochondral autologic grafts were removed from the lateral condyle of the ipsilateral femur. Defect sizes: square from 82 to 129 mm^2 (110,3 ± 0.8 mm^2), depth from 7 to 16 mm (12 ± 0,8 mm). Incorporation of the graft in the recipient bed occurred within 1,5 – 3 months. Long-term follow-up was 12 – 36 months (22,8 ± 3,8 months). The level of pain was decreased from 5,7 ± 0,3 before to 0,9 ± 0,3 after the operation (p < 0.001; paired t-test). Improving of foot function according to AOFAS scale (hindfoot section) was established from 64,9

± 1,4 to 95,9 ± 1,1 (p < 0.001; paired t-test). Extension increasing from 15,0 ± 0,9 to 18,4 ± 0,7 and flexion increasing from 22,9 ± 1,2 to 30,7 ± 1,1 was registered. There were no cases of implants failure or their instability neither the increasing of degenerative changes in the ankle joint.

Conclusion: Osteochondroplasty is the effective method of congruity restoration in cases of post-traumatic talus osteochondral defects, promotes a significant reduction in pain syndrome and an improvement in the function of the ankle. The unknown mechanism of the analgesic effect of osteochondroplasty requires further research.

AB1227 ATTITUDES AND BELIEFS ABOUT LOW BACK PAIN OF TUNISIAN PATIENTS: A KEY PREDICTOR OF RECOVERY

A. Fazaa[1], M. Ben Messaoud[1], S. Miladi[1], H. Boussaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim, Rheumatology, Tunis, Tunisia*

Background: Low back pain (LBP) is a common problem related with significant disability and psychosocial dysfunction. Unhelpful beliefs about it are associated with higher levels of pain and may cause a delay in recovery due to unsuitable behaviours. Therefore, studies targeting these beliefs are necessary to modulate messages delivered to the population in order to decrease the burden of LBP.

Objectives: The aim of the present study was to assess the attitudes and beliefs in the management of patients with LBP.

Methods: We applied a cross sectional study including Tunisian patients with LBP. The arabic version of Back Pain Attitudes Questionnaire (10-item Back-PAQ) was used to evaluate back beliefs as a clinical screening tool. We analysed patients' attitudes in 5 domains: vulnerability of the back (items 1 and 2), relationship between back pain and injury (items 3 and 4), activity participation during back pain (items 5 and 6), psychological influences on back pain (items 7 and 8), prognosis of back pain (items 9 and 10). For each item, the scale ranges from "False" to "True" which is the option that represents unhelpful beliefs for recovery. Intermediate labels are: "Possibly False", "Unsure", "Possibly True". Responses were scored from –2 ("True") to +2 ("False"). Unhelpful beliefs attract negative scores and vice versa.

Results: The questionnaire was completed by 32 participants (27 women and 5 men) with a mean age of 56.6 years [45-69]. The mean LBP's duration was 9.1 years [2-28]. The mean Body Mass Index (BMI) was 29.4 [25.5-46.8]. The mean Schober's Test and Fingertip-to-floor (FTF) were respectively 2.8 [1.5-4] and 13.2 [0-50]. The mean Visual Analogue Scale of pain (VAS pain) was estimated at 69 [40-100]. The mean Oswestry Disability Index (ODI) and Short form Health Survey (SF36) were 42.4 [28-66] and 48.3 [20-80] respectively. Unhelpful beliefs were widespread. The mean Back-PAQ-10 score was -4 [-13 -3]. Women had significantly a lower score compared to men (-4.1 [-13-2] versus -1.6 [-5-3]) (p=0.01). Vulnerability of the back had an average score of -2[-3-1]. The relationship between back pain and injury had a mean score of –2.4 [-4-0]. The activity participation during back pain had a mean score of -4 [-4-1]. The psychological influences and prognosis of back pain had an average score of -2[-3-0] and -1.6[-2-3] respectively.

Conclusion: The results of this survey reveal that Tunisian patients have high levels of negative beliefs about LBP. As beliefs and attitudes have been recognised as significant predictors of recovery from LBP, we should promote cognitive behavioural therapy aiming at coping with unhelpful beliefs.

AB1228 MEDICAL CARE CONSUMPTION BY TUNISIAN DOCTORS SUFFERING FROM LOW BACK PAIN

A. Fazaa[1], H. Boussaa[1], S. Miladi[1], K. Ouenniche[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim university hospital, Rheumatology, Tunis, Tunisia*

Background: Common low back pain (LBP) is a real public health problem. Indeed, LBP is associated with important socio-professional consequences and involves a raised cost for society due to absenteeism and medical consumption. Various studies show that it is also a major problem in workplace especially in hospitals.

Objectives: The aim of this study was to evaluate LBP medical consequences among doctors.

Methods: We performed a cross-sectional study including the medical staff of a Tunisian hospital. A standardized questionnaire was distributed to all departments and collected the following day. Doctors who had not responded to the questionnaire received two reminders before considering their exclusion. We defined two groups: Group 1 with acute LBP (<3 months) and Group 2 with chronic LBP (≥3 months). The following parameters were collected: consultation with a physician, self-medication, treatments used, hospitalization, use of imaging methods and objectified spinal abnormalities. A *p* value inferior to 0.05 was considered statistically significant.

Results: Of the 217 questionnaires distributed to physicians, 107 (49.3%) were completed. The participants were composed of 85 women and 22 men. The mean age was 31.8 ± 7.7 years [25-57]. The mean BMI was 23.2±3.7 kg/m^2 [16.6-36.7]. Consumption of tobacco and alcohol was noted in 16.7% and 20.4% of cases respectively. Five participants (4.6%) reported consumption of cannabinoids. Depression, anxiety and sleep disturbances were reported in 25.3%, 57.3% and 46.7% of cases respectively. Among the participants, 84.3% reported having had LBP at least once in their life, and 71.3% reported LBP in the past 12 months. The mean duration of low back pain was greater than 3 months in 11.9% of cases. The mean pain intensity was 4.4 ± 1.9 [2-10]. Twenty participants (26%) consulted a doctor. It was a rheumatologist in 13 cases, an orthopedist in 7 cases, a neurosurgeon in 1 case and a family doctor in 1 case. More than half of the participants (57.5%) self-medicated. Standard radiography was performed in 18 cases, computed tomography (CT) in 5 cases and magnetic resonance imaging (MRI) in 8 cases. The following abnormalities were objectified: degenerative disc disease (13.6%), herniated disc (22.7%) and posterior inter-apophyseal osteoarthritis (9%). Medication use was noted in 56 cases (72.7%), functional rehabilitation in 9 cases (11.7%), back support belt in 3 cases (3.9%), epidural corticosteroid injection in 1 case (1.3%), thermal treatment in 1 case (1.3%), and surgery in 1 case (1.3%). Three doctors required hospitalization ranging from 2 to 15 days. Medical care consumption was significantly more important in patients with chronic LBP: functional rehabilitation (6,8% in group 1 vs 50% in group 2, p<0.001), back support belt (1,6% vs 20%, p=0.046), epidural corticosteroid injection (0% vs 10%, p=0.035), thermal treatment (0% vs 10%, p=0.035), surgery (0% vs 10%, p=0.035) and hospitalization (0% vs 30%, p<0.001).

Conclusion: Medical care consumption was important among LBP and chronic LBP sufferers. Thus, a prevention strategy must be established in hospitals in order to reduce the socio-economic cost of LBP among caregivers.

AB1229 FRÉQUENCE ET ÉTIOLOGIES DES LOMBOSCIATIQUES SECONDAIRES: EXPÉRIENCE D'UN SERVICE DE RHUMATOLOGIE

Z. Sfar[1], M. Brahem[2], H. Hachfi[1], Y. Mohamed[3]on behalf of service de Rhumatology-Mahdia. [1]*Mahdia, Service de Rhumatology, Mahdia, Tunisia*; [2]*Hopital Taher Sfar, Service de Rhumatology, Mahdia, Tunisia*; [3]*Mahdia-Hopital Taher Sfar, Service de Rhumatology, Mahdia, Tunisia*

Background: Secondary lumbosciatica (LS) is a rare clinical situation, but which must be eliminated in the event of any radiculopathy for better therapeutic management.

Objectives: The objective of our study was to determine the frequency and etiologies of secondary LS among patients hospitalized in the rheumatology department for exploration of lumbosciatica.

Methods: This is a retrospective, single-center study including patients hospitalized in the Rheumatology department of the Taher Sfar hospital in Mahdia for treatment of lumbosciatica, during the period between January 2014 and November 2021.

Results: We included in this study 357 patients hospitalized in our department for exploration of LS. After an etiological assessment, we retained the diagnosis of secondary LS in only 11 patients among our study population, ie 3.1% of cases. Among them, 8 patients were men (72.72%) and the other 3 were women (27.27%) with a sex ratio (M / F) of 2.66. The average age was 65 years with extremes between 55 and 88 years. The mean duration of symptomatology evolution was 6 months with extremes ranging from 15 days to 02 years. The mean pain VAS was 6.8 [2-8], and the majority (81.81% of cases) had inflammatory sciatica. 36.36% of patients (4 cases) had an L5 path, one patient had S1 irradiation and 54.54% (6 cases) had a truncated LS The general deterioration with weight loss was noted in 5 patients (45, 45% of cases) and vesico-sphincteric disorders in 2 patients (18.18%). Physical examination revealed spinal syndrome in 63.63% of cases (7 patients), radicular syndrome in 45.45% of cases (5 patients) and neurological signs of cauda equina syndrome in two patients (18, 18% of cases). Biologically, 81.81% of

patients (9cas) had a biological inflammatory syndrome, 36.36% (4cas) had impaired protein electrophoresis (hypo-gamma peak) and 27.27% (3cas) had hypercalcemia. Recourse to CT or lumbar MRI made it possible to objectify tumor bone lesions in 72.72% (8 cases) of patients, of which 3 cases (37.5%) were of prostatic origin, 2 cases (18,18 %) multiple myeloma, one case of small cell carcinoma, one case of squamous cell carcinoma and one case of bladder tumor. For the other three patients (27.27% of cases), LS was caused by infectious spondylodiscitis in the lumbar stages.

Conclusion: As evidenced by our study, secondary sciatica is a very rare clinical situation, more encountered in the elderly with often an alteration of the general condition. But in front of its seriousness and its functional repercussions, arises the need to eliminate it systematically whatever the ground before starting the treatment.

AB1230 EVALUATION OF THE STRUCTURAL MODIFICATION OF THE SUPRASPINATUS TENDON BY COMPUTER ANALYSIS OF ULTRASOUND IMAGES THROUGHOUT THE EVOLUTION OF TENDINOSIS.

M. Tortosa-Cabañas[1], C. Guillén-Astete[1], Á. Andreu-Suárez[1]. [1]*Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: In subacromial pain syndrome, the supraspinatus tendon is the most frequently injured. Supraspinatus tendinosis is a structural lesion of the tendon stroma whose ultrasound diagnosis depends largely on the observer. Due to this, the follow-up is mainly clinical, based on ordinal scales of pain or mobility. The computer analysis of the image has been recently integrated into the musculoskeletal pathology, but the evidence in ultrasound is very limited.

Objectives: To evaluate the computer analysis of the ultrasound image of the supraspinatus tendon at diagnosis and during evolution depending on the treatment administered.

Methods: A retrospective study was carried out based on the ultrasound records of patients diagnosed with supraspinatus tendinosis between 2014 and 2020. All images were obtained with the same ultrasound equipment. The records had to fulfill the following characteristics: (i) Absence of direct or indirect ultrasound signs of fibrillar continuity solution, (ii) absence of calcifying lesions and (iii) availability of an ultrasound study 5-7 months after diagnosis with the same frequency, gain, and depth parameters for each case. The ultrasound images showing tendinosis were analyzed using the ImageJ 1.53e program. The means and modes of the grayscale signal intensities were determined in longitudinal and transverse projection for each image. For the statistical analysis, paired before-after comparisons based on the normal distribution were used, grouping the patients according to the injured tendon area (lateral, central, medial) and the treatment administered. To determine the weight of the variables analyzed in the probability of resolution, a forward modeled binary logistic regression was performed using the Wald method.

Results: Records of 35 patients were included: 10 treated with immobilization, 12 with corticosteroid injections and 13 with physical therapy. Table 1 summarizes the demographic and clinical characteristics of the population. The changes observed in the mean gray intensity in the longitudinal projection of the tendon did not correlate with the fact that the patients were discharged (0.006 SD 10.47) or not (2.231 SD 7.8835) after the second evaluation (t=-0.708, P=.484). In contrast, the gradient of the mean gray intensity in the transverse projection of the tendon showed significant differences between patients discharged (9.268 SD 3.752) or not (-0.2054 SD 5.26), (t=6.162, P=.000). On the other hand, in the group of patients discharged, a greater reduction was observed in the dispersion of the mean gray intensities (-11.08 SD 5.843) compared to the group that was not discharged (1.178 SD 1.859), (t=-8.458, P=.000). In the multivariate logistic regression analysis, only the final dispersion of gray intensity was associated with the discharge condition with Coef. B=-0.096, P=.027, HR 0.908 (95% CI: 0.834-0.989).

Conclusion: Computer analysis of ultrasound images of the supraspinatus tendon in patients with pure structural tendinosis distinguishes a favorable clinical course only in the study of the cross-sectional projection, probably due to the more flattened shape of the tendon. Clinical resolution, understood as medical discharge after the second evaluation, is associated with an increase in the mean intensity of grays but especially with a reduction in the dispersion of grays.

AB1231 ULTRASOUND-GUIDED INJECTION OF LOW MOLECULAR WEIGHT HYALURONIC ACID VERSUS STEROID FOR INFLAMMATORY AND DEGENERATIVE SACROILIITIS: A RANDOMIZED CONTROLLED TRIAL

K. Hosny[1], M. I. Abdelkareem[1], A. Moshrif[1]. [1]*Al-Azhar University, Rheumatology, Assiut, Egypt*

Background: Sacroiliitis may be degenerative (DSI) or inflammatory (ISI) and the latter is one of the clinical features of spondyloarthropathies.

Objectives: To determine the effect of hyaluronic acid versus corticosteroid injection for chronic sacroiliac joint arthropathy.

Methods: forty patients with sacroiliitis either degenerative (DSI: 20 patients) or inflammatory (ISI: 20 patients) based on the New York criteria. Each group was allocated into 2 subgroups; 10 patients received 2ml Betamethasone dipropionate plus 2 ml lidocaine 2% (A) and 10 patients received 2 ml hyaluronic acid plus 2 ml lidocaine 2% (B). All sacroiliac joint injections were done under ultrasonographic guidance using a 22-gauge needle. Visual analogue scale was used for pain assessment at base line, 1, 2 and 4 week post injection.

Results: there was no significant difference between main groups (ISI & DSI) regarding VAS score before injection, 1, 2 and 4 weeks after injection while there was a significant difference between subgroups A&B in ISI group at 2 and 4 weeks (P= 0.012 and 0.008 respectively). Also, there was a significant difference between subgroups A & B in DSI group at 1, 2 and 4 weeks after injection (P= 0.04, 0.006, and 0.005 respectively). There was a high significant difference before and after injection in the main groups and all subgroups. However, there was no significant difference between the subgroups of ISI and DSI.

Conclusion: both steroid and hyaluronic acid were effective in relieving pain in treatment of inflammatory and degenerative sacroiliitis but steroid was more efficacious than the hyaluronic acid.

AB1232 RELATIONSHIP BETWEEN NEW BIOMARKER (IL18 AND IFN GAMMA) WITH DISEASE ACTIVITY SCORES (DAS71 ESR AND DAS71 CRP) IN JUVENILE IDIOPATHIC ARTHRITIS (JIA)

M. Besar[1], A. Abd El Salam[1]on behalf of prof. Dr. Dina Abd El Halim Shahin Professor of Internal Medicine (Rheumatology& Immunology Unit) Faculty of Medicine, Mansoura University. [1]*Faculty of Medicine, Mansoura University, Rheumatology, Immunology, Internal Medicine, Mansoura, Egypt*

Background: Juvenile idiopathic arthritis (JIA) is a chronic inflammatory condition lasting ≥6 weeks in children ≤ 16-year-old and characterized by pro-inflammatory cytokines (IL1B, IL6, IL18, and IFN- gamma) as a key cytokine in inflammation. The pathogenesis of JIA are still poorly understood and different theories are implicated. Different disease activity scores aimed at guiding the treatment strategies.

Objectives: Correlation between new biomarker (IL18 and IFN gamma) with disease activity scores (DAS71 ESR and DAS71 CRP) and how much these biomarkers change with treatment.

Methods: Prospective nonrandomized study carried on 45 child diagnosed as Juvenile Idiopathic Arthritis (JIA) fulfilling (ILAR)1997 where assessment of the level of IL18, IFN gamma and IL18, IFN-gamma decrement with correlation to disease activity (Juvenile Arthritis Disease Activity Score (JADAS)) and their role as prognostic markers.

Results:

- Serum IL18 and IFN gamma show significant decrease with the end of the study (Figure 1).
- The disease activity (JDAS71 ESR), (JDAS71 CRP) has decreased significantly with the end of the study (Table 1).
- Serum IL18 show negative correlation with ESR, CRP, JDAS71ESR, JDAS-71CRP and IFN gamma level.
- Poor response groups show higher level of ESR, JDAS71ESR and IL18 than good response groups. IL18 and IFN-gamma decrement level was statistically significant higher in good response than poor response.

Conclusion: IL18 and IFN-gamma cytokine and level of decrement are a useful biomarker in predicating the disease activity and response to therapy.

AB1233 CHARACTERISTICS OF PEDIATRIC MPO AND PR-3 ANCA ASSOCIATED VASCULITIS- SINGLE CENTER EXPERIENCE FROM CENTRAL CALIFORNIA

D. Singh[1], S. Sukesh[1]. [1]*Valley Children's Healthcare, Division of Rheumatology, Madera, United States of America*

Background: ANCA-associated vasculitides (AAV) are rare in childhood and characterized by necrotizing inflammation in small to medium sized vessels. Most of the available literature in children focuses on clinical subtypes Granulomatosis with Polyangiitis (GPA), Microscopic Polyangiitis (MPA), and Eosinophilic Granulomatosis with Polyangiitis (EGPA). Adult studies have demonstrated differences in clinical outcomes based on myeloperoxidase (MPO) and proteinase 3 (PR3) ANCA specificity (1). There is limited information about the characteristics of MPO- AAV and PR3-AAV in children.

Objectives: The objective of this study was to review the characteristics of MPO-AAV and PR3-AAV at a children's hospital in multi-ethnic Central California, United States.

Methods: We performed a retrospective case review of patients less than 18 years of age diagnosed with AAV at a tertiary care children's hospital in Central California in United States from January 1, 2010 to March 31, 2021. Cases were identified from electronic health records using ICD-9 and ICD-10 codes for vasculitis. Records were reviewed for a diagnosis of AAV based on ACR/EULAR classification criteria. Demographic and clinical data including laboratory parameters including ANCA specificity, treatment, and outcomes were collected. Continuous data were expressed as a median and interquartile range, categorical data as frequency and percentages. Chi-square and Mann-Whitney U tests were used for statistical comparison as appropriate.

Results: Eighteen cases of pediatric AAV were identified, of which 10 (55.5%) patients had MPO-AAV and 8 (44.4%) had PR3-AAV. All patients who were MPO positive were diagnosed with MPA. Among PR3-AAV cohort, 7 patients were diagnosed with GPA and 1 patient received diagnosis of MPA. The median age at diagnosis was 12.6 years (IQR 10.1-15.4) in patients with MPO-AAV and 14.8 years (13.8-16.7) in children with PR3-AAV. In MPO-AAV cohort, 90% (n=9) were female, meanwhile 37.5% (n= 3) of patients diagnosed with PR3-AAV were female (p=0.02). Significantly higher proportion of patients diagnosed with MPO-AAV were from racial and ethnic minority groups (n=10, 100%) which included Hispanic (8), Asian (1) and other (1). In comparison, patients with PR3-AAV were predominantly white (n= 7, 87.5%; p <0.01). Median length of hospital stay was 19 days (IQR=12.8-41) in patients with MPO-AAV and 14 days (IQR=9.5-21.8) in patients with PR3-AAV. Rate of ICU admission was 60% in MPO-AAV cohort and 37.5% in PR-3 cohort, although this was not statistically significant. 50% (n=5) of patients in MPO-AAV cohort required dialysis and 25% (n=2) in PR3-AAV cohort. Peak creatinine was higher in MPO-AAV cohort (7.4, IQR 1-13.4 versus 2, IQR 0.7-3.7 mg/dL), although it did not reach statistical significance (p=0.1). PR3-AAV group had significantly higher levels of C-reactive protein (22.9, IQR=7.05-26.3) compared to MPO-AAV cohort (2.25, IQR=0.3-6.2; P=0.02). ENT involvement was more frequent in PR3-AAV cohort (87.5% versus 10%). All patients received treatment with high dose corticosteroids at diagnosis. Other immunosuppressive therapy included cyclophosphamide (40% in MPO-AAV cohort and 75% in PR-3 AAV cohort), rituximab (40% MPO-AAV cohort and 0% in PR-3 AAV cohort), cyclophosphamide and rituximab (10% in MPO-AAV cohort and 25% in PR-3 AAV cohort). Two deaths were reported in MPO-AAV cohort, related to Aspergillus pneumonia and pulmonary hemorrhage.

Conclusion: Our study reviews characteristics of pediatric MPO-AAV and PR3-AAV in the Central California of United States. We observed a more frequent diagnosis of MPO-AAV in racial/ethnic minority children. Limitations of our study include small sample size. This study highlights the need for further research to understand the impact of ethnicity and MPO and PR3 positivity on pediatric AAV presentation, disease activity and outcomes.

AB1234 RHEUMATIC MASKS OF ONCOLOGICAL DISEASES IN CHILDREN

N. Zhuravleva[1], T. Smirnova[2], O. Sharapova[3,4], L. Gerasimova[5,6], L. Markelova[7]. [1]*Chuvash State University named after I. N. Ulyanov, Department of Internal Medicine, Cheboksary, Russian Federation*; [2]*Chuvash State University Named After I. N. Ulyanov, Department of Obstetrics and Gynecology, Cheboksary, Russian Federation*; [3]*City Clinical Hospital of Vinogradov V.V., Head physician, Moscow, Russian Federation*; [4]*I.M. Sechenov First Moscow State Medical University, Department of Obstetrics and Gynecology, Moscow, Russian Federation*; [5]*City Clinical Hospital of Vinogradov V.V., The Educational and Methodical Office, Moscow, Russian Federation*; [6]*Moscow State University of Food Production, Department of Obstetrics and Gynecology, Moscow, Russian Federation*; [7]*Institute for Advanced Medical Education, Department of Therapy and Family Medicine, Cheboksary, Russian Federation*

Background: Early diagnosis of oncological pathology, which can occur under the guise of other diseases, including rheumatic diseases, is relevant.

Objectives: To analyze the features of the course of rheumatic masks of oncological diseases in children.

Methods: An analysis was made of the features of the course of oncological diseases in 15 children (5 girls and 10 boys) aged 3 to 15 years, hospitalized in the rheumatology department of the Republican Children's Clinical Hospital for the period from 2012 to 2021.

Results: The disease was manifested by fever in 11 of 15 patients. Complaints when contacting a rheumatologist: pain and limitation of movement in the joints (15/15), in the lumbar region (2/15), weakness (8/15), abdominal pain (3/15), vomiting (2/15), myalgia (3/15), hair loss (1/15), nosebleeds (1/15). On physical examination: peripheral lymphadenopathy (4/15), periorbital shadows, pallor (10/15), lupus-like erythema on the face (1/15), joint tenderness on palpation and movement (11/15), joint deformity (2/15). 15), spinal rigidity (3/15), hepatosplenomegaly (5/15). On laboratory examination: anemia (7/15), leukopenia (3/15), leukocytosis (4/15), thrombocytopenia (3/15), thrombocytosis (1/15), pancytopenia (1/15), hypoalbuminemia (2/15). 15), increase in ESR (11/15), CRP (11/15), LDH (4/15), AST, ALT (3/15). Established preliminary clinical diagnoses: juvenile rheumatoid arthritis (10/15), systemic lupus erythematosus (2/15), dermatomyositis (1/15), reactive arthropathy (1/15), fever of unknown origin (1/17). Appointed: NSAIDs (8/16), glucocorticoids (9/15), methotrexate (5/15), cyclophosphamide

(1/15). An oncological search was carried out. The following diagnoses were verified: stage 4 neuroblastoma (4/15), acute lymphoblastic leukemia (5/15), stage 4 B-large cell lymphosarcoma (1/15), stage 4 B-lymphoblastic lymphoma/leukemia (1/15), T-cell lymphoma (1/15), stage 3 glioma (1/15), malignant histiocytoma (1/15), brain tumor (1/15).

Conclusion: Oncological diseases in children can occur under the guise of rheumatic diseases. Immunosuppressants and glucocorticoids mask the true clinical picture of the neoplasm and prevent early diagnosis.

AB1235 MULTISYSTEM INFLAMMATORY DISEASE IN CHILDREN (MIS-C) IN SINGAPORE CHILDREN: ARE WE DIFFERENT?

L. Das[1], K. L. Teh[1], X. Gao[1], T. Arkachaisri[1,2]. *[1]KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore*; *[2]Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore*

Background: Multisystem Inflammatory Syndrome in Children (MISC) is a hyper-inflammatory state with similarities to Kawasaki Disease, 4 to 6 weeks after Covid-19 infection[1]. Literature describes a 11:1 Relative Risk for Asian children versus Caucasians[2]. Since the start of the pandemic, 17,699 children under 12 years were infected with Covid-19[3].

Objectives: To describe presentation and short term outcomes, for a cohort of children with MIS-C at the sole Children's Hospital in Singapore.

Methods: Demographic and clinical/lab data were collected from children diagnosed with MIS-C accrording to the WHO criteria[4] at KK Woman's and Children's Hospital, Singapore. Nonparametric descriptive statistics were used to describe and analyse data.

Results: Eleven patients were diagnosed with MIS-C between October 2021 and Jan 2022. Seven (64%) were male and 4 (36%) were Chinese, with median age at presentation was 8.08 years (IQR 4.54 - 9.79). All patients had positive COVID-19 serology at the time of diagnosis. Median duration of fever prior to diagnosis was 5 days (IQR 4 - 5); Nine (82%) had gastrointestinal symptoms and median number of Kawasaki Disease (KD) features were 2 (IQR 2 - 3.5); common manifestations were conjunctivitis (90%), red lips (55%) and rash (36%). Of note, 8 (70%) patients had KD type peeling on follow-up. No BCGitis was found during acute phase. Seven (64%) were admitted to higher dependency care.

Table 1, all patient received IVIG and IV steroids; 6 (55%) as pulse (30mg/kg/day) therapy. Patient 8, additionally received Anakinra. Median duration of admission was 6 days (IQR 5-13). One patient developed complications post therapy and was re-admitted to hospital for hematochezia. Treatment involved stopping Enoxaparin and Prednisone. Aspirin was resumed as soon as bleeding ceased. Laboratory characteristics and outcomes are denoted in Table 1. All patients had a monophasic course during the median of 10 weeks (IQR 8 - 11.5) of follow-up.

Conclusion: 1.Asian prevalence of MIS-C is not as high as that reported from the West. Similarities in presentation as to age and gender were noted.

2.Most of our MIS-c patients developed periungual peeling at follow up, similarly to Kawasaki Disease.

3.Different from our typical KD population, no BCG site inflammation was found.

Background: Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease with a prevalence of 3 in 1 000 000 children. Information on long-term development of organ involvement and clinical characteristics of jSSc patients in adulthood are lacking. It was believed that patients in adult cohorts may represent a survival biased population.

Objectives: To assess differences in clinical characteristics of jSSc-onset patients from the pediatric age group, with a mean disease duration of 3 years, compared to the adult age jSSc-onset group, with a mean disease duration of 18.5 years.

Methods: We extracted clinical data at time of inclusion into the cohorts from the Juvenile Scleroderma Inception Cohort (jSScC) and data from juvenile-onset adult SSc patients from the European Trials and Research Group (EUSTAR) cohort. We compared the clinical characteristics of the patients by descriptive statistics.

Table 1.

No	Age (yr)	GI symptoms	KD features	Hemoglobin (g/DL)	Absolute Lymphocyte (10x9/L)	Platelet (10x9/L)	CRP (mg/L)	D-Dimer (mg/L FEU)	Ferritin (ug/L)	Enoxaparin started	Peeling	Abnormal echo
1	10	YES	2	12.2	0.23	67	173.2	32	3179.1	YES	YES	YES
2	11	NO	2	14.8	1	166	94.9	2.51	350	NO	YES	YES
3	4.25	YES	2	10.4	1.02	241	134.6	6.05	277.2	YES	NO	YES
4	7.67	YES	5	11	0.41	102	250.6	9.32	3607.6	YES	YES	NO
5	8.58	YES	4	11.4	0.56	93	105.6	1.31	846.6	NO	YES	NO
6	4.58	YES	2	10.3	3.09	198	137.4	1.87	291	NO	NO	NO
7	9.58	YES	3	12.2	1.31	119	184	2.51	244.3	NO	YES	NO
8	4.5	YES	4	11.9	0.45	102	181.8	11.12	1798.4	YES	NO	YES
9	11	YES	1	10.1	1.23	59	74.2	4.53	1445.8	YES	YES	NO
10	3.42	NO	2	9.1	1.09	138	153.9	8.66	609.4	YES	YES	NO
11	8.08	YES	2	11.4	1.25	101	66.8	1.31	521.8	NO	YES	YES

Results: We extracted data of 187 jSSc patients from the jSScC and 236 patients from EUSTAR. The mean age at time of assessment was 13.4 years old in the jSScC and 32.4 years old in EUSTAR. The mean disease duration since first non-Raynaud was 3.0 years in jSScC and 18.5 years in the EUSTAR (Table 1). We found significant differences between the cohorts. There were more female patients in EUSTAR (87.7% versus 80.2%, p=0.04). More patients had diffuse subtype in jSScC (72.2% versus 40%, p<0.001). The modified Rodnan skin score (mRSS) was significantly higher in jSScC (14.2 versus 12.1, p=0.02). Active digital ulceration occurred more often in EUSTAR (26.6%, versus 17.8% p=0.01), but history of active ulceration was more frequent in jSScC (54.1% versus 43%, p<0.001). Mean DLCO was lower in jSScC (75.4 versus 86.3, p<0.001). Intestinal involvement was significantly more common in jSSc (33.2% versus 23.8%, p=0.04). Esophageal involvement was more common in EUSTAR (63.7% versus 33.7%, p<0.001). (Table 1).

Table 1. Clinical characteristics of juvenile onset SSc patients at time point of the inclusion into the juvenile scleroderma inception (jSScC) cohort and in the adult EUSTAR- cohort

	jSScC	EUSTAR Cohort	P value
Number of patients	187	236	0.04
Age in years, mean (SD)	13.4 (3.6)	32.4 (15.4)	
Female patients, n (%)	150 (80.2%)	207 (87.7%)	
jSSC Subtype, n (%)			
diffuse	135 (72.2%)	87 (38.1%)	<0.001
limited	52 (27.8%)	121 (53.3%)	
Age at Raynaud onset in years, mean (SD)	10.0 (3.9)	13.7 (9.1)	
Age at non-Raynaud onset in years, mean (SD)	10.3 (3.9)	11.7 (3.7)	
Duration since first Raynaud symptoms in years, mean (SD)	3.4 (2.7)	20.6 (15.9)	
Duration since first non-Raynaud symptoms in years, mean (SD)	3.0 (2.7)	18.5 (15.6)	
Raynaud´s, n (%)	170 (90.9%)	222 (94.9%)	
ANA positive, n (%)	166 (91.7%)	210 (92.9%)	0.99
Anti-Scl 70 positive, n (%)	62 (34.4%)	73 (33.3%)	0.68
Modified Rodnan Skin Score, mean (SD)	5%	*Data missing*	
Modified Rodnan Skin Score, mean (SD)	14.2 (11.7)	12.1 (14.5)	0.02
Digital ulceration, n (%)			
At the time of inclusion	33 (17.8)	21 (26.6%)	0.01
In the past history	100 (54.1%)	34 (43%)	<0.001
Telangiectasia	*62 (37.4%)*	*42 (53.2%)*	*0.04*
FVC, mean (SD)	84.1 (18.6)	84 (22.4)	0.96
DLCO, mean (SD)	75.4 (19.2)	86.3 (19.9)	<0.001
Arterial hypertension, n (%)	10 (5.4%)	20 (8.5%)	0.26
Renal crisis, n (%)	0	3 (1.3%)	0.26
Esophageal involvement, n (%)	63 (33.7%)	149 (63.7%)	<0.001
Intestinal involvement, n (%)	62 (33.2%)	56 (23.8%)	0.04
Articular involvement, n (%)	34 (18.3%)	27 (11.6%)	0.06
Muscular involvement, n (%)	31 (19.3%)	46 (19.8%)	0.45

Conclusion: Patients with jSSc-onset who are currently adult age (defined as >18 years of age) are less frequently male and from the diffuse subset, have lower mRSS, less digital ulcers and intestinal involvement. This might represent a combination of both survival bias and/or be explained by the longer observation time with less active disease (i.e. natural progression decreased mRSS over time). Further long-term observational studies with jSSc patients are required to address this issue.

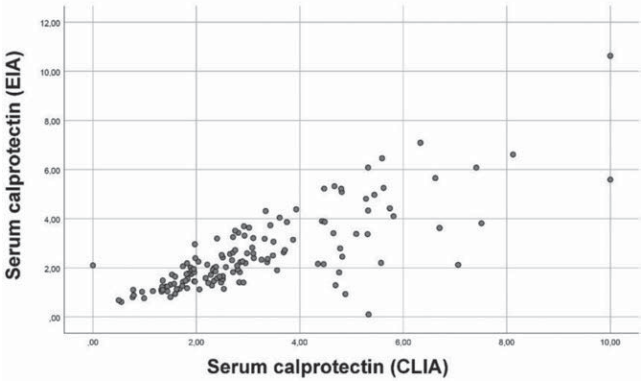
COMPARISON BETWEEN ENZYME IMMUNOASSAY AND CHEMILUMINESCENCE TO DETERMINE THE CONCENTRATION OF SERUM CALPROTECTIN AND ITS ASSOCIATION WITH CLINICAL VARIABLES IN PEDIATRIC RHEUMATOLOGY.

H. Codes-Mendez[1], B. Magallares[1], L. Martínez-Martínez[2], H. Park[1], D. Lobo Prat[1], L. Sainz Comas[1], I. Gich[3], Y. Alvaro[2], E. Molto[2], V. Calahorro[2], S. Boronat[4], H. Corominas[1]. *[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[2]Hospital de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Epidemiology, Barcelona, Spain*; *[4]Hospital de la Santa Creu i Sant Pau, Pediatrics, Barcelona, Spain*

Background: Serum calprotectin (SC) is an emerging biomarker in the measurement of inflammation. It can be determined by different techniques, such as enzyme immunoassay (EIA) or chemiluminescence (CLIA). However, there are no studies comparing whether there is a correlation between the two diagnostic methods in paediatric rheumatologic diseases.
Objectives: (i) To assess whether there are differences between serum calprotectin (SC) levels determined by EIA (Bühlmann) method and CLIA (QUANTA Flash) in pediatric age patients with systemic autoimmune rheumatic disease (SARD). (ii) To evaluate which clinical and analytical variables are associated with an increase of SC in each method.
Methods: Analytical cross-sectional study that included patients from a pediatric rheumatology specialized unit between 02/2017 and 05/2021. We included 41 patients with SARD who had at least one SC analysis determined by EIA in their routine controls (144 serum) and afterwards had SC determined again, this time using the CLIA method. The collected variables were sex, age, remission according to clinical judgment, swollen joint count according to physical examination (PE Count) and ultrasound (US Count), Juvenile Arthritis Disease Activity Score according to physical examination (PE JADAS-27) and ultrasound (US JADAS-27), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). As for the statistical analysis, intraclass correlation (ICC) and paired samples t-test were performed to compare the two methods. Univariate linear regression was performed to study the association between EIA, CLIA and both clinical and analytical variables.
Results: We included 41 patients, 50.1% were women with a mean age (± SD) of 13.1 (± 3.8) years. The details of their descriptive characteristics were: mean SC (EIA) of 3.1 (±1.8) µg/ml, mean SC (CLIA) of 2.5 (±1.6) µg/ml, mean CRP of 2.6 (± 6.5) mg/l, mean ESR of 10.1 (± 11) mm/h, and mean PE JADAS-27 of 2.8 (± 8). Most frequent diagnosis was oligoarticular juvenile idiopathic arthritis (JIA) (24.4%), followed by enthesitis-related (ERA) JIA (12.2%) and polyarticular JIA (12.2%), familial Mediterranean fever (FMF) (9.8%), psoriatic JIA (4.9%), systemic JIA (4.9%) and syndrome of periodic fever, aphtous stomatitis, pharyngitis, and cervical adenitis (PFAPA) (4.9%), vasculitis (4.8%), and undifferentiated JIA (2.4%). Clinical diagnosis was unspecific in 9.8% of the patients. In our sample, 66.7% were in clinical remission at the discretion of the specialist. A statistically significant Pearson's CCI of 0.77 (95%CI 0.70-0.83; p=0.00) was observed as a single measure between EIA and CLIA and with an average of 0.87 (95%CI=0.82-0.91; p=0.000). Figure 1 shows the dispersion of this correlation.

Figure 1. Dispersion diagram representing the correlation between EIA and CLIA.



On the other hand, we observed a statistically significant difference in the mean between both methods of 0.58 (95%CI=0.40-0.77; p=0.000), observing a greater difference in SC (EIA) > 4 µg/ml.
A significant association was observed between EIA and clinical remission, joint count, JADAS and CRP; and also between CLIA and clinical remission, JADAS and CRP. The analysis performed is shown in Table 1.

Table 1. Association between EIA and CLIA with clinical and analytical variables.

	Remission		PE Count		US Count		PE JADAS		US JADAS	
	b	**p**	**b**	**p**	**b**	**p**	**b**	**p**	**b**	**p**
SC(EIA)	0.43	**0.011**	0.14	**0.027**	0.08	**0.024**	0.09	**0.000**	0.06	**0.000**
SC(CLIA)	0.53	**0.000**	-0.00	0.945	0.31	0.320	0.05	**0.021**	0.04	**0.015**
	Sex		**Gender**			**ESR**		**CRP**		
	b	**p**	**b**	**p**		**b**	**p**	**b**	**p**	
SC(EIA)	0.00	0.997	0.05	0.207		0.00	0.487	0.05	**0.027**	
SC(CLIA)	-0.24	0.362	0.01	0.795		0.02	0.105	0.08	**0.000**	

b, regression coefficient; p, statistical significance.

Conclusion: There is a good correlation between EIA and CLIA methods to determine SC in pediatric patients with SARD. Significant differences were observed between both methods above the value of 4 µg/ml. This fact could be explained by methodological differences, since CLIA discriminates better at higher values than EIA.

An association was observed between both methods and variables of remission or disease activity.

AB1238 THE EFFECT OF DRUG THERAPY IN JUVENILE IDIOPATHIC ARTHRITIS ON THE LEVEL OF CYSTATIN C AS A MARKER OF RENAL DYSFUNCTION

S. Samsonenko[1], T. Borysova[1]. [1]*Dnipro State Medical University, Department of Pediatrics 2, Dnipro, Ukraine*

Background: Juvenile idiopathic arthritis (JIA) is a chronic disease requiring years of therapy with non-steroidal anti-inflammatory drugs (NSAIDs), immunosuppressant's, cytostatics, immunobiological agents. The aforementioned drugs, namely NSAIDs and cytostatics are potentially nephrotoxic [1]. The above drugs, namely NSAIDs and cytostatics, are potentially nephrotoxic. About 8% of children with JIA have kidney damage, which develops on average 5 years after the onset of the disease. It has been established that the main risk factor for the development of kidney damage is the long-term exposure to NSAIDs and methotrexate in children with active forms of JIA [2]. Early diagnosis of kidney damage will allow timely correction in the dosage of drugs and avoid their nephrotoxic effects [3].
Objectives: To determine the effect of drug therapy in children with JIA on eGFR by using the Cystatin C-based equation and the Hoek formula based on the serum cystatin C study.
Methods: 80 children with JIA participated in the study. The age of subjects was 10.4±4.41 (10.6-15.0) years. All children received methotrexate as a base drug. At the moment of examination 22 children received NSAIDs, 25 children received immunobiological preparations. Serum cystatin C content was determined by enzyme immunoassay. The Cystatin C-based equation 2012 and Hoek formulas were used to set the GFR by serum cystatin C levels.
Results: Non-steroidal anti-inflammatory drugs led to a decrease in GFR as found by both the Cystatin C-based equation 2012 and the Hoek formula. The incidence of GFR reduction in patients treated with NSAIDs using the Cystatin C-based equation 2012 was 100%, and using the Hoek formula was 81.8%.
The use of NSAIDs in children with JIA is a risk factor for the development of reduced GFR calculated by the Hoek formula. The incidence of reduced GFR in children with NSAID use was 54.5%, 6.7 times greater than in those without NSAIDs (OR = 12.9; CI: 3.76-44.25; p<0.001). There was a low chance of a Hoek formula decrease in GFR in children with JIA who received immunobiological therapy 9.1% vs 46.8% (OR = 0.11; CI: 0.03-0.42; p<0.001).
Conclusion: Use of NSAIDs in children with JIA was more often associated with a reduction in GFR: by Cystatin C - based equation 2012 in 100% of cases p<0.01, by Hoek in 81.8%, p<0.001. The average of GFR was significantly lower in children treated with NSAIDs than in children without NSAIDs. Immunobiological therapy had a positive effect on the GFR value. The frequency of a decrease in GFR was significantly lower in the children treated with immunobiological therapy compared with those without immunobiological therapy 9.1% vs 46.8% (OR = 0.11; CI: 0.03-0.42; p<0.001).

AB1239 PRIMARY SJÖGREN'S SYNDROME WITH JUVENILE ONSET: REPORT OF 15 CASES

M. Kaleda[1], I. Nikishina[1], S. Salugina[1], E. Fedorov[1], A. Shapovalenko[1], T. Pachkoria[1], S. Arsenyeva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: Primary Sjögren's syndrome (pSS) is a chronic and progressive multisystem autoimmune disease which rarely onset in children and adolescents. Diagnostic delay in large part of patients are common due to the non-specific and variable symptoms and the slow progression of disease.
Objectives: To analyse demographic data, specific extraglandular, salivary and ocular manifestations, laboratory parameters and therapy of pSS with juvenile onset.
Methods: Retrospective study of all patients (pts) with pSS in single center.
Results: pSS was verified in 15 pts (6.7% were boys), which amounted to 23.8% of all pts with SS in our pediatric rheumatologic department. The median age of pSS onset was 8.0 y.o. [IQR 7.0; 10.2]. The median of disease duration at the time of pSS verification was 2.75 years [2.2; 5.6]. All patients had systemic manifestations at onset: constitutional abnormalities – 33.3%, nonerosive polyarthritis – 64.3%, polyarthralgias – 26.7%, lymphadenopathy – 73.3%, cutaneous involvement – 53.3% (2 – xerosis, 2 - annular erythema, 1 - erythema nodosum, 2 – Raynaud phenomenon, 2 – nonspecific spotty rashes, 1 – hemorrhagic rash). At the time of diagnosis 7 pts (46.7%) had isolated involvement of salivary glands, 8 pts (53.3%) – combined with involvement of lacrimal glands. The decrease in salivary gland function was recorded in 80% of cases, hypolacrimia – in 46.7%, 1 patient had isolated hypolacrimia. Recurrent parotitis was present in 6 pts (40.0%). At time of diagnosis pulmonary involvement had 20.0% of pts, 1 patient had renal tubular acidosis. 8 pts (53.3%) had various hematological disorders: anemia – in 3 pts (20.0%), leukopenia – in 6 (40.0%). ANA Hep-2 were detected in 100% pts (in titer 1/640 – 4, 1/1280 – 7, 1/2560 – 3, 1/20480 - 1, with mixed patterns in all pts: speckled + homogeneous – 9 pts, speckled + homogeneous+cytoplasmic – 6 pts), anti-Ro - in 12 pts (80.0%), anti-La - in 8 pts (53.3%), RF+ - in 9 pts (60.0%). 6 pts (40.0%) had polyclonal hypergammaglobulinemia, max 42%. 2 pts (13.3%) had concomitant autoimmune non-rheumatic disease; 1 – cutaneous psoriasis, 1 - autoimmune thyroiditis. The treatment of each patient was justified by the main individual manifestations: 93.3% received glucocorticoids, 26.7% - methotrexate, 33.3% - hydroxychloroquine, 6.7% - mycophenolate mofetil. Treatment with biologics (B) was received by 13 (93.3%) pts (7 – rituximab (RTM), 6 – abatacept (ABA)) with a good response in 10 pts, including improvement in the function of the salivary and lacrimal glands in 7 pts. 1 patient received 2B - RTM and ABA sequentially due to the development of MAS 7 days after 1st RTM infusion. B was discontinued in 3 pts: 1 due to development of hemorrhagic vasculitis 2 days after the 1st RTM infusion, 1 – COVID-19 with lung involvement (CT 3-4) 2 weeks after the 1st RTM infusion, 1 – inefficiency of ABA during 15 months.
Conclusion: In our pediatric rheumatologic department pts with pSS made up less than a quarter of all pts with SS. The diagnosis was verified delayed in all pts, which can be explained by a wide range of nonspecific manifestations at the onset. However, the manifestations of SS that were present at the time of diagnosis were brought under control on the background of complex therapy, including the prescription of B, with a good efficacy and safety profile of therapy.

AB1240 PROSPECTIVE EVALUATION OF COGNITIVE FUNCTION IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

F. Ortiz-Márquez[1], C. Padilla-Leiva[2], P. Cabezudo-García[3], G. Diaz-Cordobes[1], L. Muñoz-Becerra[3], N. Mena-Vázquez[1]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, UGC de Reumatología, Málaga, Spain*; [2]*Universidad de Málaga, Departamento de Medicina, Málaga, Spain*; [3]*Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, UGC de Neurociencias, Málaga, Spain*

Objectives: Prospectively evaluate changes in the cognitive function of patients with juvenile idiopathic arthritis (JIA) and associated factors.
Methods: Design and protocol: We performed a prospective cohort study with JIA patients that participated in a previous cross-sectional study (2019) to evaluate cognitive function. After 24 months, the patients were administered the same test battery previously used through an established protocol, and data was collected from their clinical histories. The neuropsychological tests were corrected by a neurologist and neuropsychologist. Study population: Inclusion criteria: Patients aged ≥16 years with JIA classified according to the criteria of ILAR 2001. Patients with inflammatory or rheumatic diseases other than JIA, previous neurological disease not associated with the course of JIA, and patients with scores lower than the normal in the manual skill test were excluded. Outcomes: The main variable was cognitive impairment, defined as worsening of ≥2 scaled points after 24 months (V24) in any of the subtests used to evaluate each cognitive area in the Wechsler Adult Intelligence Scale (WAIS). The evaluated cognitive domains and their respective subtests were: Attention/concentration (Digit Span); verbal function (Vocabulary); visuospatial organization (Block Design); working memory (Letter-Number Sequencing); problem-solving (Similarities). Depression was evaluated by The Beck Depression Inventory-II (BDI-II): minimal (0-13), mild (14-19), moderate (20-28), and severe (29-63). Other variables: Clinical-epidemiological characteristics; treatments; and inflammatory activity evaluated as the C-reactive protein average (CRP) and JADAS-27 along the 2 years of follow-up. Statistical analysis: Descriptive analysis, followed by $\chi 2$ and paired T-test. Multivariate analysis to identify independent variables associated with impairment of cognitive function in JIA.

Results: Thirty patients with JIA were included. The clinical characteristics in V24 are shown in Table 1. Thirteen patients (43%) showed impairment in one or more cognitive functions. The most frequent impaired cognitive functions were verbal function (13.3%), visuospatial organization (13.3%) and problem solving (13.3%); followed by attention/concentration (10.0%) and working memory (6.7%). The variables independently associated with cognitive impairment were the mean CRP along the follow-up (OR [IC 95%], 1.510 [1.012-2.254]; p=0.044) and depression (OR [IC 95%], 1.358 [1.028-1.794]; p=0.031). This model would explain the 47% of the cognitive impairment in JIA (R2=0.470).

Table 1. Clinical, laboratory, and treatment characteristics of 30 patients with JIA

Variable	JIA n=30
Age in years, mean (SD)	2.4 (7.0)

Uveitis, n (%)	9 (30.0%)
Current synthetic DMARDs, n (%)	18 (60.0%)
Previous biologic DMARDs, n (%)	12 (40.0%)
Corticosteroid, n (%)	5 (16.6%)

BMI: Body Mass Index, JIA: Juvenile Idiopathic Arthritis, ANA: Antinuclear antibodies, CRP: C-Reactive Protein, DMARD: Disease-Modifying Antirheumatic Drugs.

Conclusion: Forty percent of the patients with JIA showed cognitive impairment after 24 months of follow-up. Cognitive impairment was associated with higher inflammatory activity and depression.

AB1241 BONA MINERAL DENSITY IN JUVENILE ONSET MIXED CONNECTIVE TISSUE DISEASE AFTER LONG-TERM DISEASE DURATION - A CASE-CONTROL STUDY

S. Opsahl Hetlevik[1], B. Flatø[2], K. Godang[3], J. Bollerslev[3], V. Lilleby[1]. [1]*Surgery, Inflammatory Medicine and Transplantation, Rheumatology, Oslo, Norway*; [2]*Surgery, Inflammatory Medicine and Transplantation, Department of Rheumatology, Oslo, Norway*; [3]*Medicine, Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo, Norway*

Background: Rheumatic diseases are associated with reduced bone mineral density (BMD) as measured by Dual Energy x-ray absorptiometry (DXA). Mixed connective tissue disease (MCTD) is a rare connective tissue disease, and about 25% of all cases have a pediatric presentation. One study implies that osteoporosis is common in postmenopausal women with MCTD (1), but data regarding BMD and osteopenia are lacking in younger patients with the disease.

Objectives: To assess the BMD in a cohort of juvenile mixed connective tissue disease (JMCTD) patients compared to a matched control group.

Methods: BMD was measured in a cohort of 52 JMCTD patients with mean age 28.2 years (SD 10.3) and mean disease duration 16.2 years (SD 10.3), and 52 controls matched for age and gender. Inclusion criteria were fulfilment of the Kasukawa- or the Alarcon-Segovia criteria and symptom debut before the age of 18 years.

Results: Patients and controls did not differ in age, body mass index, smoking habits, level of physical activity or vitamin D status (Table 1). Forty-four (85%) were female. Patients were shorter and had lower body weight compared to controls. None had had osteoporotic fractures. Patients over 20 years of age at examination had significantly lower BMD in the spine, femoral neck, proximal- and distal radius. Patients also had lower T-score compared to matched controls.

Table 1.

Variable	JMCTD patients (n=52)	Controls (n=52)	P value
BMI, kg/m^2	22.7 (3.5)	23.4 (3.0)	0.239
Height, cm	166.0 (7.5)	170.1 (8.5)	**0.016**
Weight, kg	63.0 (12.1)	68.1 (12.1)	**0.033**
Never smokers, n (%)	35 (67)	34 (65)	0.83
Moderate physical activity (hours/week), median (range)	2.0 (0-28)	1.2 (0-30.0)	0.278
Vitamin D*, nmol/l, median (range)	50.0 (27-106)	51.5 (23-115)	0.829
BMD, gm/cm^2			
Spine L2-L4	1.19 (0.13)	1.25 (0.10)	0.110
< 20 years (n = 14, 27%)	1.14 (0.21)	1.17 (0.11)	0.496
>20 years (n = 38, 73%)	1.19 (0.12)	1.26 (0.10)	**0.018**
Femoral neck	0.97 (0.12)	1.04 (0.09)	**0.006**
>20 years	0.97 (0.12)	1.04 (0.09)	**0.002**
Proximal radius	0.79 (0.12)	0.86 (0.09)	**0.007**
>20 years	0.79 (0.12)	0.86 (0.09)	**0.013**
Distal radius	0.40 (0.07)	0.50 (0.10)	**<0.001**
>20 years	0.41 (0.07)	0.51 (0.10)	**<0.001**
T-score >20 years			
Spine L2-L4, median (range)	-0.40 (-2.3 to 2.0)	0.29 (-1.4 to 1.8)	**0.006**
Femoral neck, median (range)	-0.50 (-2.2 to 2.1)	0.40 (-1.7 to 1.6)	**0.007**
Proximal radius, median (range)	-0.90 (-0.2 to 1.6)	-0.30 (-0.2 to 1.3)	**0.044**
Distal radius, median (range)	-1.0 (-3.0 to 1.3)	0.20 (-2.6 to 3.8)	**<0.001**

All values are mean (SD) unless otherwise stated

Conclusion: Bone mineral density was impaired in JMCTD patients after 16 years disease duration compared to matched controls.

AB1242 RETROSPECTIVE SINGLE CENTER STUDY OF BIOLOGICAL THERAPY IN CHILDREN WITH RHEUMATOID FACTOR-POSITIVE SUBTYPE OF JUVENILE IDIOPATHIC ARTHRITIS

M. Kaleda[1], I. Nikishina[1], E. Fedorov[1], S. Salugina[1], S. Arsenyeva[1], Z. Kolkhidova[1], A. Shapovalenko[1], T. Pachkoria[1], V. Matkava[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: Rheumatoid factor-positive subtype of juvenile idiopathic arthritis (RF+ JIA) is a relatively rare condition (5-7% of all cases of JIA), but is associated with a poor prognosis. For these patients (pts), it is extremely important to timely prescribe adequate therapy, including biologics (B), to prevent rapid progression and early disability.

Objectives: To analyze in retrospective study the rate of usage, efficacy and safety of B in pts with RF+ JIA.

Methods: Pts with RF+ JIA were identified from clinical database. Diagnosis of RF+ JIA was reviewed based on New Classification Criteria for JIA, PRINTO, 2019 [1]. Demographic and clinical data, therapy, efficacy and adverse effects observed under B were analysed.

Results: The diagnose RF+ JIA was verified in 81 pts (11,1% boys). The median age at onset of JIA was 12.0 y.o. (7.4; 14.0). The median age at time of diagnosis – 13.0 y.o. [9.3; 15]. In total, RF+ were detected in 93.8% of pts (median 71.4 IU/ml [IQR 28.8; 218.5]), anti-cyclic citrullinated peptide antibodies-positive (ACCP+) - in 70.4% of pts (median 164.9 EU/ml [97.4; 300]). 64.2% of pts had combination RF+ and ACCP+, 29.6% - only RF+, 6.2% - only ACCP+. The therapy included NSAIDs in 97.5% of pts, steroids – in 48.1%, DMARDs in all pts (methotrexate (MTX) alone – 80.2%, 2 DMARDs – 13.6%, 3 DMARDs consecutive – 6.2%), B - in 85.2 % of pts. 2 pts received JAK-inhibitors (1 - tofacitinib, 1 – baricitinib). The median of the number of active joints at start of B was 16 [10; 23]. The median of ESR was 26 [18;43] mm/h, CRP - 14.7 [5.3;31.8] mg/l. We observed extra-articular manifestations in 29.0% of pts: 24.6% - lymphadenopathy, 4.3% - rheumatoid lung disease, 2.9% - rheumatoid nodules, 4.3% - distal polyneuropathy. Secondary Sjögren's syndrome (SS) was diagnosed in 27.5% of pts. The experience of using B included from 1 to 4 prescriptions sequentially: 83.3% of pts received only 1 B, 20.3% - 2 B, 8.7% - 3 B, 4.3% - 4 B. B was started during the 1st year of disease in 82.7% of pts due to the rapid progression of the erosive process. As the 1st B used: abatacept (ABA) – 47.8%, etanercept (ETA) – 20.3%, adalimumab (ADA) – 10.1%, rituximab (RTM) – 7.2%, infliximab (INF) – 5.8%, tocilizumab (TCZ) – 4.3%, golimumab (GLM) – 1.4%, sarilumab – 2.9%. As the 2nd B used: 26.1% - RTM, 21.7% - ADA, 17.4% each - ETA and ABA, 13.0% - TCZ, 4.3% - GLM. As the 3d B used: 33.3 % each – TCZ and ADA, 22.2% - PTM, 11.1% - ETA. 3 pts received successively 4 B (ABA-ETA-ADA-TCZ, ABA-ETA-ADA-RTM, TCZ-ABA-ADA-RTM). Adverse events (AE) were observed in 24.6% of pts as recurrent uncomplicated upper respiratory tract infections being the most common. The reasons for substitution therapy were serious AE, subsequent loss of effect. The frequency of ACCP+ was not statistically different in groups with the effective use of only 1 B and, if necessary, replacement. In the presence of systemic manifestations, preference was given to TCZ or RTM, with secondary SS - RTM or ABA.

Conclusion: Most pts with RF+ JIA needs to require B in the first year of the disease. Application B has good efficacy and an acceptable safety profile. The presence of systemic manifestations/secondary SS influence on choice of B. Our data didn't reveal the effect of ACCP+ on preferred choice or frequency of replacement B.

AB1243 EFFICACY OF ABATACEPT IN THE TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED UVEITIS

P. Rodríguez González[1], D. Fernández Fernández[2], I. Gonzalez Fernandez[2], R. Dos-Santos[2], P. Castro-Santamaria[2], M. Sanchez-Wonenburger[2], J. L. Puga Guzmán[2], A. Mata[2], A. Souto Vilas[2], E. Perez-Pampín[2], A. Mera Varela[2].
[1]*Facultade de Medicina (USC), Medicine, Santiago de Compostela, Spain*; [2]*Santiago Clinic Hospital CHUS, Rheumatology, Santiago de Compostela, Spain*

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in pediatric age, uveitis IS the most frequent extra-articular complication (1). Uveitis, if not properly treated, can lead to potentially irreversible ocular complications such as blindness.
The treatment of uveitis associated with JIA (U-JIA) remains a challenge due to the aggressiveness of the disease and the frequency of complications.
Following the current guidelines for screening and treatment of uveitis, the use of topical and sistemic corticosteroids, Methotrexate, cyclosporine or some biological drugs such as Adalimumab constitute the mainstay of treatment in this manifestation.
In some refractory cases, the use of Abatacept has been reported
Objectives: To analyze the efficacy of Abatacept in the treatment of U-JIA from the data avaliable in the scientific literature.
Methods: We perform a systematic review of the scientific literature, following the PRISMA statement, using the following electronic databases: *Medline, Embase, Cochrane Library and Web of Science*.
Results: An overall of 89 bibliographic references fulfill the inclusion criteria. A total of 64 patients from 6 studies were followed for a mean time per patient of 11.5 months. The mean age of onset of JIA was 5.25 years, with a time of evolution of the disease of 7 and 11.85 years.
In all the series included, a high percentage of patients showed complications secondary to ocular inflammation (synechia, band keratopathy, cataracts, macular cystic edema and/or ocular hypertension) as well as visual deficits secondary to JIA-U.
All patients, fhave shown refractoriness to conventional DMARDs, as well as anti-TNF biological drugs.
In all the studies, the best correct visual activity (BCVA) is used as main outcome measure. Another outcome measures were used: number of uveitis flares, the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), or the number of cells present in the anterior eye chamber.
Four series of cases showed an improvement or stabilization of visual acuity after Abatacept treatment. Two studies provided variations in visual acuity that are not statistically significant.
Regarding the efficacy of Abatacept, we can observe improvement, in the most of the studies we observed a decrease in the severity of the ocular inflammation and/or its complete remission.
Due to the lack of comparable data, a meta-analysis could not be performed. However the data suggest a clear recovery of t JIA-U patients refractory to conventional treatment.
Conclusion: Abatacept is shown as a promising drug in the treatment of U-JIA, considering its efficacy in improving visual acuity, as well as in the control of flare-ups and the decrease in inflammatory eye symptoms. However, more studies are necessary to corroborate the efficacy of Abatacept

AB1244 TOTAL KNEE ARTHROPLASTY IN PATIENTS UNDER 21 YEARS OF AGE: A U.S. NATIONWIDE ANALYSIS

J. A. Gibbons[1], C. Kahlenberg[2], D. Jannat-Khah[1,3], S. Goodman[1,3], P. Sculco[2], M. Figgie[2], B. Mehta[1,3]. [1]*Hospital for Special Surgery Main Hospital, Medicine, New York, United States of America*; [2]*Hospital for Special Surgery Main Hospital, Surgery, New York, United States of America*; [3]*Weill Cornell Medicine, Medicine, New York, United States of America*

Background: Total knee arthroplasty (TKA) is a procedure rarely performed in patients under 21 years old. However, the number of patients <21 undergoing TKA in the United States (US) is unknown. In one of the largest US studies of an institutional arthroplasty registry, only 19 TKAs were performed in patients <21 out of ~30,000 primary TKAs over 34 years[1]. While a few national or multi-national studies have been performed outside the US, these studies have small cohorts (~100), making it difficult to determine the indications for TKA in this age group.
Objectives: We identified the number of patients <21 years of age who underwent TKA in a US nationwide dataset. Additionally, we determined the epidemiological characteristics of patients undergoing TKA, including their age, sex, race, indications for surgery, and in-hospital mortality.
Methods: We analyzed the Kids' Inpatient Database, which is a national weighted sample of all inpatient hospital admissions in the US in patients <21 years old from ~4,200 hospitals in 46 states. We included all admissions from 2000-2016 with a primary procedural code of TKA determined by ICD-9 and 10 codes. Descriptive statistics such as means and percentages, along with 95% confidence intervals were calculated using appropriate sample weights.
Results: The total number of TKAs performed in patients <21 years old from 2000 to 2016 was 1,331 (Table 1). The majority of TKAs performed (n=936; 70.3%) were for treatment of an oncologic disease. The most common diagnosis was malignant tumor (68.7%), followed by osteoarthritis (7.3%) and inflammatory arthritis or juvenile idiopathic arthritis (JIA) (7.0%) (Figure 1). Osteonecrosis accounted for 3.9% of cases, while mechanical complications accounted for 3.3%. Fewer than 2% of cases had an indication of either benign or uncertain tumor, infection, or trauma. The mean age was 14.8 years, and 48.4% of the cohort was female. A higher proportion of the non-tumor cohort was female (57.1%) than the tumor cohort (44.7%). 57.1% of patients in the overall cohort were White, and this proportion was smaller in the tumor group (53.8%) than the non-tumor group (64.9%). No patients died during the inpatient event. 87.8% of TKAs were performed in urban teaching hospitals.

Table 1. Characteristics of patients <21 undergoing TKA by diagnosis type

Variable	Overall N = 1331	Non-tumor N = 395	Tumor N = 936
Age, mean (95% CI)	14.8 (14.4, 15.2)	15.9 (14.7, 17.1)	14.3 (14.1, 14.6)
Sex: Female, % (95% CI)	48.4 (44.9, 51.9)	57.1 (49.1, 64.8)	44.7 (41.1, 48.3)
Race, % (95% CI)			
White	57.1 (52.3, 61.8)	64.9 (55.5, 73.3)	53.8 (48.4, 59.2)
Black	13.1 (10.1, 16.9)	16.9 (10.1, 27.2)	11.5 (8.7, 14.9)
Hispanic	19.7 (16.6, 23.3)	14.3 (9.9, 20.2)	22.0 (18.1, 26.6)
Asian or Pacific Islander	3.4 (2.1, 5.4)	**	4.6 (2.9, 7.4)
Native American	0.9 (0.4, 1.9)	**	**
Other	5.8 (4.1, 8.1)	2.9 (1.3, 6.4)	7.0 (4.8, 10.0)
Payor, % (95% CI)			
Medicare	1.4 (0.7, 2.9)	4.7 (2.2, 9.7)	—
Medicaid	31.1 (27.5, 35.0)	28.0 (21.0, 36.3)	32.4 (28.3, 36.7)
Private	57.8 (53.7, 61.7)	60.2 (52.1, 67.8)	56.7 (52.2, 61.1)
Self-pay	3.3 (2.3, 4.9)	**	4.2 (2.7, 6.2)
Other	6.1 (4.4, 8.3)	5.1 (3.0, 8.6)	6.6 (4.5, 9.4)
Admission type: elective, % (95% CI)	85.9 (81.1, 89.6)	81.6 (72.6, 88.2)	87.7 (82.2, 91.6)

N represents weighted estimateCI = Confidence Interval** Per HCUP guidelines, cell sizes ≤10 have been omitted to protect patient confidentiality

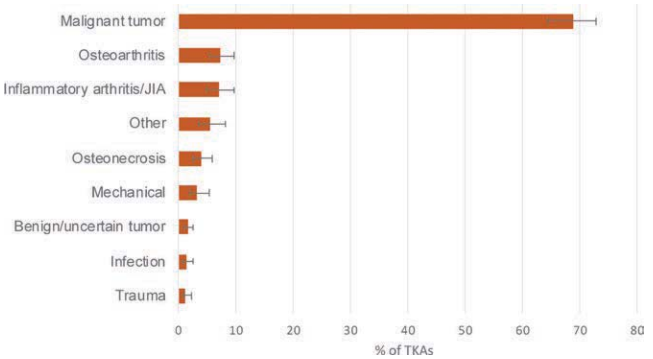

Figure 1. Most common primary diagnoses for TKA in patients <21 years oldThe most common primary diagnosis of 1,331 patients <21 undergoing TKA. Bars represent 95% Confidence Intervals. JIA = juvenile idiopathic arthritis.

Conclusion: TKA is a rarely-performed procedure for patients <21 years old in the US; it is mainly performed in urban teaching centers and has excellent in-hospital survival rates. 70.3% of these procedures are performed for tumors—the vast majority of which are malignant. Also, even with the advent of better treatment options for JIA and inflammatory arthritis, TKA is still performed frequently in this population indicating that better clinical management is needed.

AB1245 HOSPITAL ADMISSION RATES FOR JUVENILE IDIOPATHIC ARTHRITIS IN WESTERN AUSTRALIA HAVE NOT CHANGED FOLLOWING THE INTRODUCTION OF BIOLOGICAL DRUG THERAPY.

E. Kelty[1], E. Quintrell[1], P. Manners[2], D. Preen[1], J. Nossent[3,4]. [1]*The University of Western Australia, School of Population and Global Health, Perth, Australia*; [2]*University of Western Australia, Faculty of Health and Medical Sciences, Perth, Australia*; [3]*The University of Western Australia, Medical School, Rheumatology Section, Perth, Australia*; [4]*Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*

Background: Aggressive treatment with disease modifying drugs to reach early disease remission has become standard of care for juvenile idiopathic arthritis (JIA) in Australia this millennium (1,2).

Objectives: We examined whether this modern approach including the availability of subsidised TNF inhibitor treatment has led to a change in the rate of first hospitalisation for JIA patients in Western Australia (WA). Hospital data were also used to estimate a minimum prevalence of JIA in WA.

Methods: State-wide hospital data were used to identify patients aged 15 years and younger with a first hospitalisation for JIA between 1990 and 2012. Changes in the hospitalisation rate over time were examined using join-point regression. State-wide PBS prescription data on TNFi (available for JIA since 2004) were obtained from Services Australia and expressed as defined daily dose /1000/day (DDD).

Results: We identified 786 unique cases of JIA in WA hospital records. At the time of the index hospitalisation, patients were on average 7.6 (± 4.4) years of age and female patients made up the majority of cases (n=465, 59.2%). The overall rate for a first hospitalization for JIA was 7.9 (95%CI: 7.3, 8.4) per 100,000 children ≤15 years, and did not change significantly over the study period (annual percentage change (APC): 1.3, 95%CI -0.3, 2.8), although TNFi usage increased linearly and DDD reached 0.3 at the end of study. The hospital-based prevalence of JIA in 2012 reached 114.5/100.000 for girls (0.12%) and 52.9/100.000 for boys (0.05%).

Conclusion: The hospital based (i.e. minimum) prevalence of JIA in WA aligns with international data. Rates for a first hospitalization for JIA have not decreased during a time when early aggressive therapy became common practice and TNFi use for JIA reached 30/100.000. This unexpected finding requires further investigation.

AB1246 ANALYSIS OF 38 CYTOKINES PROFILE IN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Raupov[1,2], O. Kalinina[3], E. Zaikova[3], E. Kalashnikova[1], E. Suspitsin[4,5], M. Kostik[1,3]. [1]*Saint-Petersburg State Pediatric Medical University, Pediatrics, Saint-Petersburg, Russian Federation*; [2]*City Hospital №40, Medical Rehabilitation of Children, Saint-Petersburg, Russian Federation*; [3]*Almazov National Medical Research Centre, Laboratory of Autoimmune and Autoinflammatory Diseases, Saint-Petersburg, Russian Federation*; [4]*N.N.Petrov Institute of Oncology, Molecular diagnostics, Saint-Petersburg, Russian Federation*; [5]*Saint-Petersburg State Pediatric Medical University, Medical Genetics, Saint-Petersburg, Russian Federation*

Background: systemic lupus erythematosus (SLE) as "the disease of thousand faces" has multiple pathogenic mechanisms with disturbance in different parts of immune system. A variety of cytokines have been found as a biomarker of active disease and a candidate for targeting treatment [1].

Objectives: to analyze 38 cytokines profile in juvenile SLE (jSLE) and compare them with disease activity and clinical manifestations.

Methods: 29 patients with SLE under 18 years (3 boys, 26 girls, median age – 16.0 (13.0; 16.9) and 28 health control patients (14 boys, 14 girls, median age 16.0 (11.0; 17.0) were included in the study. Cytokine levels in the serum were measured by multiplex analysis using the MILLIPLEX MAP Human Cytokine/Chemokine/Growth Factor Panel A 41 plex kit (MilliporeSigma, USA) on the Luminex MAGPIX System (Luminex, USA).

Results: significant differences between jSLE patients and health control have observed in 10 cytokines (Table 1). Interestingly upregulation in jSLE compared to HC was found only in IP10 and IL1RA, while other cytokines were lower. MCP1 was associated with disease activity measured by SLEDAI (p=0.0073), while activity measured by ECLAM correlated with TGFa (p=0.049), MCP3 (p=0.025), IL-15 (0.038), IL-7 (p=0.002), IL-8 (0.043), MCP1 (p=0.014), MIP1b (p=0.014). Positive correlation was found between skin involvement and IL-6 (p=0.43), carditis and FLT-3L (p=0.018), IL1RA (p=0.03), IL-8 (p=0.019), TNFa (p=0.05), lung involvement and FLT3-3L (p=0.014), IL-15 (p=0.047), IL1RA (p=0.034), IL-5 (p=0.005), TNFa (p=0.004), myositis and TGFa (p=0.011), MCP3 (p=0.000), IL-13 (p=0.000), IL1a (p=0.000), IL-9 (p=0.000), IL1b (p=0.03), IL-4 (p=0.000) TNFb (p=0.000), anti-dsDNA levels and MDC (p=0.016), anemia and GRO (p=0.030), IL-1b (p=0.050), IL-3 (p=0.022). There's no correlation between nephritis, CNS involvement and cytokines levels.

Table 1.

Cytokines	jSLE (n=29)	HC (n=28)	p-value
EGF	28.4 (15.3-133.3)	122.0 (25.8-218.5)	0.032
TGFa	1.4 (0.0-2.6)	4.6 (3.2-7.7)	0.00001
IL-10	3.8 (2.8-8.7)	2.4 (2.0-3.6)	0.034
MDC	461.3 (297.8-663.3)	1042.5 (808.9-1277.5)	0.00000
sCD40L	945.6 (126.5-1322.0)	1991.5 (1275.0-2395.0)	0.00003
IL1RA	21.9 (12.3-38.7)	12.3 (8.6-19.4)	0.013
IL1b	0.9 (0.6-1.2)	1.0 (0.9-1.9)	0.010
IL4	17.3 (11.1-32.2)	35.2 (19.6-87.8)	0.003
IL5	1.0 (0.8-1.4)	1.6 (1.0-3.0)	0.038
IL8	9.1 (7.4-21.3)	30.1 (11.5-46.5)	0.010
IP10	310.9 (215.6-472.1)	118.0 (89.3-143.7)	0.000009

Conclusion: we identified differences in cytokines levels between jSLE patients and HC and found multiple correlation between manifestations and different cytokines levels. Most of them were in FLT-3L, MIP-1b, TNFa, IL1RA, IL-3, IL-5, IL-8, IL-15, MCP1 and MCP3.

AB1247 **ASSESSMENT OF ARTICULAR AND EXTRA-ARTICULAR DAMAGE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS**

A. Fazaa[1], N. Ben Salem[1], S. Miladi[1], H. Boussaa[1], L. Souabni[1], K. Ouenniche[1], S. Chekili[1], S. Kassab[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) affects patients' well-being and can lead to disability and long-term damage. Evaluating damage in patients can be beneficial to make therapeutic decisions and take rehabilitation measures.
Objectives: To assess articular and extra articular damage in patients with JIA by the use of the Juvenile Arthritis Damage Index (JADI)[1] and to identify variables that correlate with disease damage.
Methods: We conducted a cross-sectional study among patients with JIA who met the ILAR classification criteria and had a disease duration more than 12 months. Early clinical data was obtained from medical files. It included socio-demographic features, biological and radiological parameters, subtype of JIA, disease duration and ongoing treatments. Damage was assessed in the last clinical visit using articular and extra-articular damage index[1] (JADI-A and JADI-E).
Results: Thirty-two patients were enrolled in this study with a mean age of 23.8 ±11.6 years. Sex ratio was 0.6 (12 males and 20 females). The mean age of disease onset was 8.3 years [3-15], and the mean disease duration was 183.7 months [12-624]. At the last clinical examination, 71.9% of patients had joint damage with a mean JADI-A score of 5.09 ±5.4 and 40.6% of patients had extra-articular damage with a mean JADI-E score of 0.75±1.2. The most affected joints were: the elbows (43.8%), the hips (37.5%) and the wrists (25%). Extra articular damage was mainly: a growth failure (25%), osteoporosis (18.8%) and ocular damage (12.5%). Patients with polyarticular arthritis without rheumatoid factor had the highest JADI-A score with a mean of 7.83 while patients with systemic arthritis had the highest JADI-E score with a mean of 3. Mean JADI-A score was significantly different between patients who received corticosteroids and those who did not receive them (8.5 Versus 3.4, p=0.004). Damage scores correlated with disease duration (p<0.001 for JADI-A score and p=0.034 for JADI-E score). Damage scores were not significantly different between different classes of treatment (conventional dmards and biologic dmards).
Conclusion: Articular damage is frequent in patients with JIA. It is higher for patients on corticosteroids. Articular and extra articular damage correlate with disease duration, but they were not significantly different between classes of treatment.

AB1248 **CONTRIBUTION OF IMAGING IN THE DIAGNOSIS OF ATRAUMATIC HIP**

M. Yasmine[1], H. Ferjani[1], F. Taboubi[1], W. Triki[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: Joint pain of the hip in children and adolescents is one of the most frequent symptoms seen by pediatricians, orthopedists, and pediatric rheumatologists, with an annual incidence of 148.1/100 000 [1]. The identification of an etiology for atraumatic hip pain is challenging. Even though imaging findings are often various and nonspecific, they are necessary for an accurate diagnosis.
Objectives: The main goal of this study is to investigate the contribution of the different imaging techniques in the diagnosis of the hip main in children.
Methods: We conducted a retrospective study including children and adolescents with atraumatic hip pain recruited from the Kassab institute of orthopedics. Transcribed data included age, sex, and the etiology of the hip disease. We also recorded different imaging techniques performed for the diagnosis: plain radiography, ultrasound (US), Computed tomography (CT) as well as magnetic resonance imaging (MRI).
Results: The study included 81 patients. There was a male predominance (59.3% boys versus 40.7% girls) with a sex ratio of 1.45. The mean age at diagnosis was 9.9 years [1-16]. The mean disease duration was eight months [0.1-156]. Hip disorders were distributed as follows: Legg-Calvé-Perthes disease (n=3), epiphysiolysis of the femoral head (n=30), transient synovitis of the hip (n=7), septic hip (n=10), tumor (n=4), hip dislocation (n=8), hip dysplasia (n=4), juvenile idiopathic arthritis with coxitis (n=15). The hip X-ray was abnormal in 75.6% of cases. The hip US was performed in 34.2% of the patients and showed abnormalities in most of the cases (88.5%). US findings were as follows: joint effusion (n=26), synovial thickening (n=18), synovitis (n=12), and a positive power Doppler signal (n=7). Seven patients underwent pelvic CT scans. The main findings were joint effusion (n=2), synovial thickening (n=1), and hip dysplasia (n=4). MRI of the hip was carried out in 23 children and was contributive in 91.3% of the cases. The main findings were as follows: joint effusion (n=12), synovitis (n=10), bone marrow edema (n=8), synovial thickening (n=7), nidus (n=3) and tumoral process (n=1).
Conclusion: Our study showed that hip X-ray and US are the first-line imaging modalities in an atraumatic hip diagnosis. However, in other cases, further investigations may be needed to make an early diagnosis and avoid adverse sequelae.

AB1249 **IMPACT OF OVERWEIGHT AND OBESITY ON HIP INVOLVEMENT IN JUVENILE IDIOPATHIC ARTHRITIS**

H. Ferjani[1], M. Yasmine[1], H. Affes[2], K. Maatallah[1], W. Triki[1], D. Ben Nessib[1], D. Kaffel[1], M. Jenzri[2], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*; [2]*Kassab Institute of Orthopedics, Orthopediatrics, Tunis, Tunisia*

Background: The prevalence of obesity among children is on the rise, becoming a worldwide epidemic. The overweight is also associated with mechanical stress in the weight-bearing joint especially in the hip joint. Previous studies showed that increased Body mass index was a predicting factor of a poor outcomes [1].
Objectives: In this regard, we proposed to evaluate the effect of obesity on hip involvement in JIA patients.
Methods: We conducted a cross-sectional study including children with JIA according to the International League of Associations for Rheumatology (ILAR)). Transcribed data included age, sex and the characteristics of the disease (subtype of JIA, disease duration). Data on hip involvement was also collected. Weight and height of each patient was recorded. The body mass index (BMI) was calculated (Kg/m^2). We compared these parameters between two groups: G1: presence of coxitis and G2: absence of coxitis.
Results: The study included 62 patients with a male perdominance: sex ratio was 2.3. The mean age of onset of the disease was 11.4 years [3-16].The frequency of each JIA subset was at follows: polyarticular with rheumatoid factor (n=2), polyarticular without rheumatoid factor (n=4), systemic (n= 1), enthesitis-related arthritis (n=44), oligoarthritis (n=8), psoriatic arthritis (n=3). Hip involvement was reported in 71 % of cases and was bilateral in 81% of patients. The mean weight (Kg) and height (meter) was similar between the two groups (57.4 in G1 vs 53.6 in G2, p=0.486) and (1.61 in G1 vs 1.58 in G2, p=0.483) respectively. The prevalence of overweight patients was higher in G1 than G2 without reaching a statistically significant correlation (23% vs 12.5%, p=0.518). Similarly, there was no statistically significant correlation between the body mass index (Kg/m^2) and coxitis (22.2 vs 21, p=0.45). Moreover, a higher BMI was not associated with a limited range of motion as well as hip replacement (p=0.7, p=0.1 respectively).
Conclusion: Our study showed that BMI did not impact hip involvement in juvenile idiopathic arthritis patients. As obesity confers an additional health risk, addressing this co-morbidity should be a health priority in these patients.

AB1250 **TOFACITINIB IS A SAFE AND EFFECTIVE TREATMENT OPTION FOR JUVENILE IDIOPATHIC ARTHRITIS**

N. Prabu[1], V. Petciappan[2], G. Anand[1], S. Ram[1], A. Kumar[1]. [1]*Sakthi Rheumatology Centre Pvt. Ltd, Rheumatology, Coimbatore, India*; [2]*PSG Institute of Medical Sciences & Research, General Medicine, Coimbatore, India*

Background: The management of juvenile idiopathic arthritis(JIA) is often constrained by the limited number of oral drugs available. Whether JAK inhibitors would add a much needed therapeutic armamentarium in this regard needs to be explored.
Objectives: To assess the safety and efficacy of tofacitinib in juvenile idiopathic arthritis (JIA) patient who were prescribed during the period January 2021 to December 2021.
Methods: It's a retrospective study of JIA patients who were prescribed tofacitinib during the period Jan 21 to Dec 21 with minimum of 3 months' follow-up after prescribing tofacitinib. The demographics,details of medications,investigations parameters and any adverse events were noted.

Results: There were a total of 35 patients who were given tofacitinib during this period. Male is to female ratio is 25:10, mean age of 12.91(4.81) yrs., the mean disease duration was 58.6 months. Enthesitis related arthritis(ERA) was the commonest seen in 12, followed by oligo articular in 10, polyarticular in 7 and systemic onset in 6. In the ERA group 10 were HLA B27 +VE, of the oligo articular 6 were ANA +VE, in the polyarticular one was RF +ve. Out of the 35,14 were already on biologicals (tocilizumab and anti TNFs). Tofacitinib was stopped in 8 patients during this period, 5 as they achieved remission, 2 with no response and one because of itching and abdominal pain. There were no documented infections. There was significant reduction in the inflammatory markers (ESR, CRP), leucocyte count and platelet count.

	Before tofa	After tofa	p value
Methotrexate in mg (week) mean(stdev)	9.64(1.94)	8.88(3.34)	0.66
Steroid in mg mean (stdev)	3(2.35)	2.8(1.8)	0.91
Leucocyte count mean(stdev)	11242(1858)	7884(1471)	0.005
Platelet count in lakhs Mean(stdev)	4.51(0.48)	3.37(0.82)	0.017
ESR mm/1hr	57.75(17.25)	30.83(11.48)	0.009
CRP mg/L	25.36(10.9)	12.36(7.97)	0.05

Conclusion: Tofacitinib seems to be a promising drug in the management of JIA with good safety profile and efficacy.

AB1251 LATE ONSET PRIMARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN AN INDIAN ADOLESCENT BOY DURING A PEAK OF POST COVID-19 MULTISYSTEM INFLAMMATORY SYNDROME

D. B. Pandya[1]. [1]*Dev Paediatric Rheumatology & Immunology Center, Pediatric, RAJKOT, India*

Background: Familial Hemophagocytic lymphohistiocytosis (fHLH) categorized as FHL2 (*PRF1)*, FHL3 (*UNC13D)*, FHL4 (*STX11)*, and **FHL5 (*STXBP2)*** encoding for Perforin, Munc13-4, Syntaxin11, and Syntaxin binding protein 2, respectively. There is limited information available about the clinical and mutational spectrum of FHL patients in Indian population.

Objectives: To delineate clinical and laboratory features of late onset familial Hemophagocytic Lymphohistiocytosis.

Methods: A **12-years**-old well nourished sick looking boy, born to a non-consanguineous parents with normal birth, development and immunization history with uneventful past presented to us with 6 days history of high fever, cough, breathing difficulty and severe headache. He had occasional vomiting, abdominal pain, polyarthragia & chest pain from last 10 days. Mother also had given history of throat pain, backache & some non-specific papular rashes over face before the onset of fever. His vitals were normal. Examination revealed faint diffuse fixed erythematous rash all over the body, pallor, icterus and hepatosplenomegaly. Musculoskeletal examination was unremarkable. Lab evaluation revealed HB 8.9gm%, TLC 4700/cumm with neutrophils 40% and lymphocytes 56% with 8-9% activated lympocytes. Further evaluation showed low ESR 6mm/hr, fibrinogen 97mg% and albumin 2.2 gm% with elevated CRP 40mg/L, ferritin 2000ng/ml, LDH 658IU/L, SGPT 110IU/L, SGOT 221 IU/L, total bilirubin 6mg%, D-dimer 4355 ng:EFU/ml and Triglycerides 441mg%. His blood, urine, CSF and bone marrow cultures were sterile for endemic bacterial and viral infections in our area. **His EBV PCR, CoVID RT PCR and CoVID antibody (Total & IgG) test were negative**. His immunoglobulin leves were normal. HRCT Chest showed bilateral mild-moderate plural effusions, mild interstitial thickening in both the lower lobes, few fibrotic opacities & old areas of consolidation bilaterally. 2D echo showed mild pericardial effusion. Bone marrow examination showed Hypercellular marrow with iron depletion and occasional hemophagocytosis with CD8 T lymphocytes proliferation (55.2%) and double positive CD4 & CD8 (1.2%). He was initially commenced on supportive therapy, oxygen & intravenous antibiotics. In view of most probable non-infectious, non-malignant hemophagocytic lymphohistiocytosis, he was finally given intravenous immunoglobulin (2gm/kg) and intravenous pulse methylprednisolone (30mg/kg). He responded well to above regimen within 3 days. He was discharged with tapering steroids over few weeks. Clinical exome by NGS revealed Homozygous Mutation in **STXBP2 gene** Intron 14, c.1280-1G>C (3' Splice Site) His parents has been counselled for hematopoietic stem cell transplantation and their decision is still pending.

Results: We compared our patietnt with a reference to the largest Indian series of pediatric HLH[1].

Table 1.

	Snehal Shabrish et al*	Index Patient
Age > 4 years	56%	Yes
Male Sex	89%	Yes
Family History	20%	No
Consanguinity	57%	No
Fever	100%	Yes
Organomegaly	100%	Yes
Bicytopenia	78%	Yes
Hyperferritinemia	86%	Yes
Hemophagocytosis	100%	Yes
Hypertriglyceridemia	100%	Yes
Hypofibrinogenemia	40%	Yes
Splice Site Intronic Mutation	38%	Yes
Expired during presentation	55%	No
Remission under protocol and awaiting transplantation	22%	Yes

Conclusion: Primary HLH type 5 can present first time during childhood and adolescence. Any child presenting with unexplained HLH features should undergo genetic analysis irrespective of person's past and family history.

AB1252 RETROSPECTIVE SINGLE CENTER STUDY OF THE PREDICTIVE ROLE OF CERTAIN BIOMARKERS IN MACROPHAGE ACTIVATION SYNDROME RELATED TO SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

M. Kaleda[1], E. Fedorov[1], I. Nikishina[1], S. Salugina[1], V. Matkava[1], M. Cherkasova[2], E. Samarkina[3]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*

Background: Systemic juvenile idiopathic arthritis (sJIA) is a childhood arthritis with signs of autoinflammation and high risk of macrophage activation syndrome (MAS). Immunopathogenesis of sJIA is based on excessive activation of innate immunity, which is characterized by hyperproduction of pro-inflammatory cytokines - interleukin (IL)-1 and IL-18, which play a key role in induction of synthesis of other pro-inflammatory mediators. Macrophage activation mediates the evidence of hyperferritinemia, which stimulates a pathological immune response with the development of MAS. In clinical practice, the study of the cytokine profile and its comparison with the acute-phase inflammatory response markers in patients (pts) with sJIA can make possible assessment the nature of the course process and predict the possibility of MAS.

Objectives: To study distinctive features of some biomarkers in pts with sJA in relation with history of MAS.

Methods: Total IL-18, IP-10, IL1RA, IL1b, IL6, CRP and ferritin levels were determined in pts with sJIA and compared between between groups regarding to disease activity and history of MAS. Serum levels of cytokines, ferritin were measured using standard commercial enzyme-linked immuno-sorbent assay. CRP were estimated by commercial nephelometric method.

Results: A total of 39 pts were included to study, the ratio of boys and girls was 1:1.4. Median age of sJIA onset was 4.4 years [2.9; 6.5], age at the time of examination - 11.4 years [7.35; 13.5]. The pts were divided into 3 groups: group I - with MAS (8 pts), group II - with active sJIA without MAS (16 pts), group III - with inactive sJIA (15 pts). Total IL-18 levels were significantly higher in pts with MAS (group I) (median 6036.5 pg/ml [IQR 1932.5; 9160.3], and remained persistently elevated even in the majority of pts with inactive disease (group III) (median 1625.25 pg/ml [IQR 634.1; 2451.6]. CRP was higher in group I (CRP: median 60.6 mg/l [IQR 41.2; 109.4]), than in group II (CRP: median 15.65 mg/l; IQR 10.4; 38.4), without a statistically significant difference (p=0.5), but the level of ferritin was significantly higher in group I (median 893.25 ng/ml [IQR 253.9; 7725.25]), than in group II (median 62.1 ng/ml [IQR 19.8; 211.8], p=0.009). Generally, we observed positive correlation between CRP and ferritine (r=0.629, p<0.05), CRP and IL-18 (r=0.352, p<0.05), CRP and IL1RA (r=0.693, p<0.05); between ferritin and IL-18 (r=0.566, p<0.05), between ferritin and IL1RA (r=0.545, p<0.05). The strongest correlation was for ferritin and overall for groups I and II. We didn't observe significantly difference between IP-10, IL1b, IL6 between groups.

Conclusion: Serum levels of IL-18 were elevated in the majority of pts with sJIA regardless of activity, but were significantly higher in pts with active disease and, especially, in pts with MAS. Increased level of IL-18 may reflect increased disease activity or

development of MAS, that confirms the key role of IL-18 in sJIA and MAS. According to our data, in clinical practice the measure of serum level of ferritin more useful for early detecting MAS in pts with sJIA due to more stronger correlation between the levels of proinflammatory cytokines and ferritin, than between proinflammatory cytokines and CRP. We were unable to identify a statistically significant difference in the level of IL1RA in active sJIA and MAS, despite a significant correlation between the level of CRP and IL1RA, ferritin and IL1RA, which may be associated with small number of pts.

AB1253 DISEASE PERCEPTION ASSESSMENT IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS AND THEIR PARENTS.

A. Fazaa[1], S. Nouicer[1], S. Miladi[1], H. Boussaa[1], K. Ouenniche[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laater[1]. [1]*Mongi Slim, Rheumatology, Tunis, Tunisia*

Background: Juvenile Idiopathic Arthritis (JIA) has an impact on the quality of life of the patient and his family. Parent/patient reported outcomes have shown an increasing interest in the management of JIA because it reflects the perception of the disease course and the effectiveness of the therapeutic interventions.

Objectives: To determine the level of agreement between patients with JIA and their parents for the five quantitative items in Juvenile Arthritis Multidimensional Assessment Report (JAMAR) questionnaire.

Methods: We included children aged between 7 and 18 years old with AJI (ILAR criteria) and their parents. Demographic data and disease related parameters were collected. We asked both parent and child to complete the five quantitative items of JAMAR questionnaire. Were measured on a 21-numbered circle visual analogue scale (VAS) for pain (0 =no pain; 10 =very severe pain), disease activity (DA): (0 =no activity; 10 =maximum activity) and well-being (WB): (0 =very well; 10 =very poorly). Physical function was assessed by Juvenile Arthritis Functional Score (JAFS) [0-45] and health-related quality of life (HRQoL) [0-30] through the Physical Health (PhH) and Psychosocial Health (PsH) subscales. We calculated children and parents median scores for the five items. Intra class correlation coefficient ICC was used for analysis (ICC below 0.50: poor; between 0.50 and 0.75: moderate; between 0.75 and 0.90: good; above 0.90: excellent).

Results: A total of 21 patients/parent (12 girls and 9 boys) were included in the study. Forty percent belong to rural enviroment. Majority of patients were in secondary school (77%), 23% were in primary school. Seven patients had oligoarticular JIA, 13 had polyarticular JIA and one had systemic JIA. Median age at diagnosis was 11.4 ± 1.2 years [6-13]. Median age at disease onset was 9.5 ± 1.9 years [2-13]. Median disease duration was 4.3 years [0-7]. Median JADAS was 10 [8-18]. Uveitis was noted in 30% of cases. Comparison of parent proxy-reported and child self-reported data revealed a striking similarity for all items ($p<0.001$). The results of the five quantitative items of JAMAR questionnaire are represented in Table1. Good correlation was noted in JAFS, DA VAS, well-being VAS and HRQoL. Excellent correlation was noted in VAS pain.

Table 1. Assessement of quantitative items of Juvenile Arthritis Multidimensional Assessment Report by patients and parents.

Items	Patients	Parents	ICC
Mean pain VAS (0-10)	4.2 [4-6]	4.3[4-6]	0.97
Mean disease activity VAS (0-10)	4.1 [4-5]	4.2 [4-5]	0.81
Mean well-being VAS (0-10)	4.4 [4-6]	4.3 [4-5]	0.9
Mean Juvenile Arthritis Functional Score (JAFS)	10.0 [1-20]	10.2 [2-21]	0.81
Mean HRQoL score	14.1 [7-17]	14.8 [6-14]	0.88

ICC: Intraclass Correlation Coefficient; HRQoL: Health-Related Quality of Life; VAS: Visual Analogue Scale.

Conclusion: Our study showed high level of agreement between patients and parents. The JAMAR provides a promising approach to quantitative measurement in standard pediatric rheumatology care. Availability of this new instrument may enhance regular use of parent/patient questionnaires in routine practice and improve disease management.

AB1254 CHALLENGES FACED BY FAMILIES OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

W. Triki[1], A. Dghaies[1], H. Ferjani[1], R. Ben Aissa[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Institut Mohamed Kassab d'orthopédie, Rheumatology, Manouba, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common inflammatory rheumatism of childhood. Diagnostic and therapeutic approaches are difficult for families to sustain with significant psychological and social effect.

Objectives: The aim of this study is to understand the different challenges faced by families with children suffering from JIA.

Methods: Parents of children with JIA (according to the International League of Associations for Rheumatology (ILAR)) followed in rheumatology department were asked to complete a survey in order to screen the impact of their children's disease on their family life. Open-ended questions and directed questions were included. General demographic and clinical information (family history of chronic inflammatory disease, child's current age, diagnosis and type of JIA and, duration of disease progression) were also collected.

Results: The study included 24 children with a gender-ratio of 1. The mean age was 12.4 years old [4-16]. The mean duration disease was 4 years with extremes varying from 3 months to 13 years. The frequency of each JIA subset was at follows: polyarticular with rheumatoid factor (n= 2), polyarticular without rheumatoid factor (n=5), psoriatic arthritis (n= 1), enthesitis-related arthritis (n=10) and oligoarthritis (n= 6). Twenty-four parents completed the survey. The mother was the one who answered the questions in 83% of the cases. Other family members with a chronic rheumatic disease were reported in 40% of the families. Parents noted negative impact on their work in 50% of cases (40% missing time from work, 10% changing work schedule) and, significant parental stress, anxiety, and fatigue in 75% of the cases. In 33% of the cases, parents had difficulty getting the required medical care and attention for their child's illness because of financial issues and 37.5% of them were feeling anxiety regarding diagnosis uncertainty. Parents reported worry about their child's daily functioning and future in 75% of the cases. They noted psychological impact on the child itself in 58% of the cases and child missing school in 41% of the cases. The most common resources parents used for information were health care professionals in 54.2 % of the cases and 45.8% of them got additional information from online research.

Conclusion: Parents of children with JIA share common challenges due to their child's illness including a substantial impact on their work and personal wellness in addition to the psychosocial impact of the disease on the child. Support groups or educational sessions may be needed to provide guidance for these families to cope with disease.

AB1255 ASSESSMENT OF SLEEP DISTURBANCES IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

W. Triki[1], A. Dghaies[1], H. Ferjani[1], R. Ben Aissa[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Institut Mohamed Kassab d'orthopédie, Rheumatology, Manouba, Tunisia*

Background: Sleep problems are common among children with chronic illnesses such as Juvenile Idiopathic Arthritis (JIA), which is one of the most common rheumatic diseases in childhood. Sleep disturbances collectively refer to impairments in the ability to initiate or maintain sleep. They can be measured by parent or child self-report and by objective measures such as actigraphy and polysomnography.

Objectives: The aim of this study was to assess sleep disorders in children with JIA.

Methods: Parents of children suffering from JIA (according to the International League of Associations for Rheumatology (ILAR)), followed in rheumatology department were asked to complete a specific specialized scale for children (HIBOU) [1] to screen sleep disorders. This scale assesses five aspects of sleep: irregular schedule and daytime drowsiness, insomnia, moves in sleep, nose obstruction and ultra-vigilance. Parents were asked to answer 8 questions rated from 1 to 3 according to the frequency of the problem, 1: rarely, 2: 3 to 4 times a week and 3 if 5 to 7 times a week. If the sum is ≤ 9, only sleep hygiene is recommended. If the sum is between 10 and 15 the child requires regular supervision. If the sum is between 16 and 24, the child needs to be referred to a specialist. General demographic and clinical information (family history of chronic inflammatory disease, child's current age, diagnosis and type of JIA, duration of disease progression and activity of the disease) were also collected.

Results: Twenty-four children with a mean age of 12 years [4-16] were included in the study. The gender ratio was 1. The mean duration of the disease was 4 years with extremes from three months to thirteen years. The frequency of each JIA subset was as follows: polyarticular with rheumatoid factor (n= 2), polyarticular without rheumatoid factor (n=5), psoriatic arthritis (n= 1), enthesitis-related arthritis (n=10) and oligoarthritis (n= 6). Irregular sleep schedule and daytime drowsiness were reported at least 3 times a week by 58.3% of the children. Insomnia and inability to initiate sleep were reported in 29.3% of the children at least 3 times a week. Parents reported exaggerated moves during sleep in 50% of the cases and airway obstruction or snoring in 58.3% more than 3 times a week. Difficulties to maintain a good night of sleep more than three times a week were reported in 25% of cases. To sum up, 29.2% of the children had a score above 15 and needed to be referred to a specialist and 58.3% of them need a regular supervision of their sleep and may need to be referred to a specialist. Only three children had a score under 9 and don't have concerning sleep disorders according to this scale.

Conclusion: This study showed that sleep disorders are a common challenge in children and adolescents with JIA which could have a huge impact on their physical and psychosocial health-related quality of life. This study highlights the need for assessment of sleep disorders in JIA patients.

Background: Juvenile Idiopathic Arthritis (JIA) is the leading cause of chronic inflammatory rheumatic disease in children. It's classified into subtypes with different relative prevalences depending on geographical area (Oligarticular subtype predominates in Western Europe/North America. Enthesitis-related arthritis subtype predominates in Eastern Europe/Asia). To ensure continuity of care in adult rheumatology services, a systematic transition process is recommended. Various authors recommend that the process, of which pediatric and adult rheumatology teams should be part, begins around 14 years and ends around 18 years of age.
Objectives: We aim to study the age, relative prevalence and treatment profile in JIA subtypes at the beginning of the transitional care.
Methods: Descriptive and cross-sectional study of patients with JIA (according to ILAR criteria), diagnosed and treated in the pediatric rheumatology service and seen in the transitional care unit of the adult rheumatology service within the same tertiary hospital between January 2013 and December 2018. Demographic, clinical, analytical and treatment data were collected at the first visit to the transitional care unit.
Results: 72 patients were included (46 women) mean age at diagnosis of 9.5 ± 4.6y and mean of 11.3 ± 4.36y from diagnosis to the first visit at the transitional care unit. 27.7% were diagnosed with oligoarticular JIA, 20.8% with arthritis-enthesitis JIA, 19.4% with Rheumatoid Factor negative (RF-) polyarticular JIA, 11.1% with systemic JIA, x9.7% with undifferentiated JIA, 5.5% with Rheumatoid Factor positive (RF+) polyarticular JIA and 5.5% of psoriatic arthritis. The mean age at the first visit to the transitional care unit was 20.81 ± 2.96y (no differences between subtypes). Oral ulcers (20.8%), anterior uveitis (13.8%) and enthesitis (13.8%) were the most frequent extra-articular manifestations. 56.9% had antinuclear antibodies (ANA) titers >1/160 at some point in course of disease (Table 1). 43% were treated with methotrexate, 38% with biological therapies, 11.% with glucocorticoids (GC) and 22.% had no treatment.
Conclusion: The oligoarticular form was the most prevalent subtype of JIA, similar to previously published series from Western Europe. The first visit at the transition care unit occurred significantly later than recommended by various authors. The most frequent treatment was methotrexate. The use of biological therapies was high, with TNF alpha inhibitors being the most widely used, especially etanercept. The use of glucocorticoids was low. A non-negligible number of patients were treatment free.

AB1257 INVESTIGATING THE ASSOCIATIONS BETWEEN THE MAXIMAL RESPIRATORY PRESSURES AND CARDIORESPIRATORY FITNESS PARAMETERS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

D. C. Saraç[1], D. Bayraktar[1], D. Ozer Kaya[1], O. Altug-Gucenmez[2], D. Oskay[3].
[1]*Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey*; [2]*University of Health Sciences, Dr. Behçet Uz Pediatric Diseases and Surgery Training and Research Hospital, Department of Pediatric Rheumatology, Izmir, Turkey*; [3]*Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*

Background: The most prominent symptom of juvenile idiopathic arthritis (JIA) is joint involvement; however, the effect of the disease is not limited to the joints. Evidence suggests that cardiopulmonary fitness is affected in children with JIA compared to their healthy peers [1].
Objectives: This study aimed to investigate the associations between the maximal respiratory pressures and cardiorespiratory fitness parameters.
Methods: Seventeen children with JIA (mean age: 15.4±2.2 years, 11 male) who have been using biological agents for at least three months were included in the study. Maximal inspiratory pressure (MIP) and maximal expiratory pressure (MEP) were evaluated with a portable device (Cosmed Pony FX Desktop Spirometer, USA). The Quark Cardiopulmonary Exercise Test Treadmill System (COSMED, Rome, Italy) was employed to analyze cardiorespiratory fitness parameters by using expired gas collection and analysis.
Results: Significant moderate correlations were detected between MIP and maximum oxygen consumption ($VO_{2max)}$ values (r=0.519, p=0.033) and MEP and VO_{2max} values (r=0.507, p=0.038), (Table 1). No other significant correlations were observed between maximal respiratory pressures and other parameters.

Table 1. The associations between maximal respiratory pressures and cardiorespiratory fitness parameters

n:17	MIP (cmH_2O) (r)	*p*	MEP (cmH_2O) (r)	*P*
VO_{2max}(ml/kg/min)	0.519	**0.033***	0.507	**0.038***
METs (ml/kg/min)	0.276	0.283	0.298	0.246
HR (bpm)	0.285	0.268	0.184	0.479
VO2/HR	0.456	0.066	0.479	0.052
$PETCO_{2max}$ (mmHg)	0.416	0.097	0.358	0.158
$PETO_{2max}$ (mmHg)	-0.284	0.269	-0.158	0.544

***:** $p<0.05$, Pearson Correlation Coefficients**,** **VO_{2max}**: Maximum oxygen consumption, **ml:** milliliters**,** **kg**: kilograms, min: minute, **METs:** Metabolic equivalent **HR:** Heart rate, **bpm:** beats per minute, **VO_2/HR:** Oxygen consumption/heart rate, **$PETCO_2$**: Tidal partial pressure for carbon dioxide, **$PETO_2$**: Tidal partial pressure for oxygen.

Conclusion: The results of the study suggest that maximal respiratory pressures are associated with maximal oxygen consumption. Evaluating maximal respiratory pressures might be helpful when prescribing exercise programs for JIA patients with diminished cardiorespiratory fitness.

THE PREDICTED VERSUS MEASURED RESPIRATORY PRESSURES, PULMONARY FUNCTIONS, CARDIOPULMONARY FITNESS PARAMETERS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

D. C. Saraç[1], D. Bayraktar[1], D. Ozer Kaya[1], O. Altug-Gucenmez[2], D. Oskay[3]. [1]*Izmir Katip Çelebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İzmir, Turkey*; [2]*University of Health Sciences, Dr. Behçet Uz Pediatric Diseases and Surgery Training and Research Hospital, Department of Pediatric Rheumatology, Izmir, Turkey*; [3]*Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*

Background: Although musculoskeletal system-related symptoms are the most common problems in children with Juvenile Idiopathic Arthritis (JIA), cardiac and pulmonary manifestations are observed in more than half of these children. However, the available research on the extent of cardiorespiratory involvement is very limited [1].

Objectives: The aim of this study was to compare the predicted respiratory pressures, pulmonary functions, cardiopulmonary exercise test (CPET) values to objectively measured ones in children with JIA.

Methods: Twenty-two children with JIA (mean age: 15.5±2.3, 14 male) who were under biological agents for at least three months were included in the study. Maximal inspiratory pressure (MIP), maximal expiratory pressure (MEP), and pulmonary functions were measured by using a portable automated testing device (Cosmed Pony FX Desktop Spirometer, USA). Cardiorespiratory fitness parameters were measured with the Quark CPET Treadmill System (COSMED, Rome, Italy). The values calculated by the softwares of the Cosmed Pony FX Desktop Spirometer and Quark CPET Treadmill System according to the healthy children's normative data were used as predictive values.

Results: Within-group analyses demonstrated statistically significant differences between all measured and predicted parameters ($p<0.05$), (Table 1), except for MIP and forced vital capacity/forced expiratory volume values.

Table 1. The comparison of predicted versus measured respiratory pressures, pulmonary functions, cardiopulmonary fitness parameters

	Measured	Predicted	*p*
	(Mean±SD)	(Mean±SD)	
FVC (l)	3.82±0.92	4.20±1.04	**<0.001***
FEV_1 (l)	3.31±0.80	3.59±0.86	**0.004***
FEV_1/FVC (%)	86.13±7.74	83.91±0.41	0.179
MIP (cmH_2O)	101.90±37.45	104.31±21.92	0.686
MEP (cmH_2O)	95.13±47.84	134.36±30.22	**<0.001***
VO_{2max} (ml/kg/min)	2109.83±732.95	3159.94±745.87	**<0.001***
METs (ml/kg/min)	9.71±2.180	14.88±2.39	**<0.001***
HR (bpm)	187.88±20.28	205.0±2.37	**0.02***
VO_2/HR (ratio)	11.20	15.42±3.75	**<0.001***

***:** $p<0.05$, Student's t-test, **FVC:** Forced vital capacity, **FEV_1**: Forced expiratory volume, **FEV_1/FVC:** Forced expiration volume/forced vital capacity, **VO_{2max}**: Maximum oxygen consumption, **ml:** milliliters, **kg**: kilograms, **min:** minute, **METs:** Metabolic equivalent **HR:** Heart rate, **bpm:** beats per minute, **VO_2/HR:** Oxygen consumption/heart rate.

Conclusion: The present study's findings indicate that the respiratory pressures, pulmonary functions, and cardiopulmonary fitness parameters of the children with JIA are diminished compared to predicted values.

AB1259

THE NEUTROPHIL-TO-LYMPHOCYTE AND THE PLATELET-TO-LYMPHOCYTE RATIOS AS INFLAMMATORY MARKERS IN JUVENILE IDIOPATHIC ARTHRITIS

D. Ben Nessib[1], R. Ben Aissa[1], H. Ferjani[1], A. Dghaies[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Department of Rheumatology, Tunis, Tunisia*

Background: The neutrophil-to-lymphocyte ratio (NLR) and the platelet-to-lymphocyte ratio (PLR) have recently emerged as potential indicators of systemic inflammation in chronic rheumatic diseases such as polymyalgia rheumatica, rheumatoid arthritis, and spondyloarthritis.

Objectives: To investigate the value of NLR and PLR as inflammatory markers in juvenile idiopathic arthritis (JIA) and to explore possible associations with disease activity parameters.

Methods: We enrolled 29 patients with JIA according to International League of Associations for Rheumatology (ILAR) criteria. Tender joint count (TJC), swollen joint count (SJC) and laboratory tests were retrospectively collected from medical records. Disease activity was also assessed by the Juvenile Arthritis Disease Activity Score (JADAS). All data were checked for normality by the Kolmogorov-Smirnov test. The Spearman correlation was used for data analysis and *p* values less than 0.05 were considered statistically significant.

Results: A total of 54 consultations (29 at baseline and 25 at the last follow-up consultations) of 29 patients were included in our study. The mean age was 13.1±4.2 years [4-21] and the sex ratio of males to females was 1.07. JIA subtypes were: enthesis-related arthritis (n=12), polyarthritis (n=7), oligoarthritis (n=6), undifferentiated (n=3) and psoriatic arthritis (n=1). At baseline 51,73% of the patients were not under treatment, 34.49% were under non-steroidal anti-inflammatory drugs (NSAIDs) and 13.8% under methotrexate (MTX). At the last follow-up consultation 41.38% of the patients were under MTX, 34.49% under NSAIDS and 10.35% under Etanercept. At baseline, NLR1 was positively correlated with TJC1 (p=0.022, r=0.424) and SJC1 (p=0.014, r=0.453) but not with C-reactive protein CRP1 (p=0.512) neither erythrocyte sedimentation rate ESR1 (0.096) nor disease activity scores JADAS-CRP1 (p=0.063) and JADAS-ESR1 (p=0.091). PLR1 was positively correlated with SJC1 (p=0.004, r=0.521) and both disease activity scores JADAS-CRP1 (p=0.026, r=0.462) and JADAS-ESR1 (p=0.052, r=0.364). At the follow-up consultations only PLR2 was positively correlated to CRP2 (p=0.045, r=0.404). No correlation was noted between NLR2 and PLR2 and JADAS-CRP2 (p=0.281, p=0.063) and JADAS-ESR2 (p=0.324, p=0.082).

Conclusion: Our study suggests that NLR and PLR may be used as assessment tools of disease activity in patients with JIA. Further studies with larger sample sizes are needed to confirm these results and to explore the value of these ratios in the follow-up and the prognosis of JIA.

AB1260

SIGNIFICANCE OF WHOLE-BODY MRI IN CHILDREN WITH RHEUMATIC DISEASES

I. Nikishina[1], Z. Kolkhidova[1], L. Blank[2], T. Pachkoria[1], S. Arsenyeva[1], V. Matkava[1], A. Shapovalenko[1], M. Shalygina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Department of Radiation Diagnostics, Moscow, Russian Federation*

Background: Whole-body MRI (WB-MRI) has the potential to detect early or hidden signs of inflammation and seems to be more informative test than X-ray and ultrasound methods for bone and joints diseases. WB-MRI is important for identification of asymptomatic inflammation areas that are not available for clinical examination methods (sacroiliitis, TMJ). WB-MRI can become a tool for monitoring the progression of the disease and the efficacy of therapy. There is not enough data of knowledge about the role of WB-MRI in children with JIA.

Objectives: To evaluate the results of WB-MRI in children with rheumatic diseases (RD) in a single-center retrospective study.

Methods: 57 WB-MRI studies performed in children with RD in our center as a part of real-life diagnostic procedures.

Results: Among 57 children there are 22 boys and 35 girls, the average age is 13 years [11; 16]. 33 patients were examined once, 20 children twice after the initial course of therapy, two children underwent WB-MRI three times to evaluate the dynamics. It was most important to detect inflammatory lesions in multifocal non-bacterial osteomyelitis (mf-NBO). The structure of diagnosis and therapy before and after WB-MRI is present in Table 1.

Table 1. The effect of MRI on changes in the structure of diagnoses and approaches to therapy

	Before WB-MRI	After WB-MRI
Diagnosis:		
Juvenile idiopathic arthritis (JIA)	22	12
JIA+ mf-NBO	22	30
JIA+ mf-NBO +Psoriasis	5	8
JIA+ mf-NBO +FMF	1	1
JIA+ Psoriasis	2	0
JIA+IBD	1	1 (JIA+IBD+ mf-NBO)
Fibrodisplasia ossificans progressive (FOP) +JIA	1	1
Systemic JIA	1	1
Juvenile dermatomyositis (JDM)	1	1
Systemic lupus erythematosus (SLE)	1	1
SLE+ mf-NBO	0	1
Therapy:		
NSAIDs mono	17	12
DMARDs	26	29
Biologics: / bDMARDs:	12	27
anti-TNFα	10	21
Tofacitinib	1	5
Abatacept	1	1
Bisphosphonates	4	5
No current therapy	3	0

11 patients have multimorbidity (in addition to RD, one girl has Down syndrome). 5 pts had severe hypermobility syndrome patients making it difficult to identify inflammation due to the discrepancy between objective signs and the absence of limitation of joint mobility. 2 patients had multiple ankylosis. 7 patients underwent surgical interventions: 5 because of vertebral fracture, 2 because of osteomyelitis. The WB-MRI revealed: 48 polyarthritis signs, 33 osteitis, 3 osteonecrosis, 11 sacroiliitis, 1 sequestration, 1 epiphyseolysis, 1 initial signs of myositis. Surgical intervention was recommended to two patients after the diagnosis of WB-MRI (sequestration of the osteomyelitis focus and vertebral fracture).

Figure 1. WB-MRI 10-yrs old girl with JIA+ mf-NBO +Psoriasis. Than WB-MRI picture 4 months after the Etanercept administration. Positive dynamics in the sacroiliac joints, but the persistence of osteitis in the right radius, calcaneus, femur with the forming lytic destruction.

The principal significance and purpose of the performance of WB-MRI were disease control (continuation of therapy) - 22 (39%), the onset of DMARDs/bDMARDs – 17 (30%), the change of bDMARDs - 2 (3%), differential diagnosis – 16 (28%).
Conclusion: WB-MRI is useful for detecting asymptomatic and radiologically hidden lesions in JIA. Early diagnosis leading to appropriate treatment can prevent long-term structural damage to the joint. WB-MRI is a important tool for the diagnosis and diseases control in children with RD.

AB1261 THE ANALYSIS OF THE ONSET OF SYSTEMIC LUPUS ERYTHEMATOSUS IN PEDIATRIC POPULATION

R. Denisova[1], E. Alexeeva[1,2], T. Dvoryakovskaya[1,2], K. Isaeva[1], A. Chomakhidze[1], A. Mamutova[1], O. Lomakina[1], A. Fetisova[1], M. Gautier[1], K. Chibisova[1], I. Kriulin[1,2], E. Krekhova[1,2], I. Tsulukiya[1]. [1]*National Medical Research Center of Children's Health, Rheumatology, Moscow, Russian Federation*; [2]*Sechenov University, Pediatrics, Moscow, Russian Federation*

Background: Systemic lupus erythematosus (SLE) is characterized by multiple autoantibodies associated with a multisystem illness where any organ can be targeted. There are different classification criteria for SLE. Sensitivity and specificity of three criteria have been debated and may vary in different populations and clinical settings.
Objectives: We aim to evaluate the clinical and laboratory symptoms of the onset of systemic lupus erythematosus in pediatric population.
Methods: A total of 116 SLE patients (female –92, male-24) were included into the study. We analyzed the primary diagnosis, the time before identification the SLE, clinical and laboratory symptoms, their combination, and fulfilling the classification criteria of SLE. All data is presented as Me (IQR).
Results: The age of the onset of SLE was 13.3 (10.7, 15.2) years. 55/116 patients had other diagnosis before the verification of SLE, the time before the verification was 10 (5, 26) months. The loss of weigh was in 63(54%) of patients, fever – in 83(72%) (febrile – 57, subfebrile -26), adenopathy in 55(47%), malar rash – in 45(39%), discoid rash – in 19(16%), alopecia – in 19 (16%), photosensitivity – in 39(34%), oral ulcers – in 38 (33%), nazal ulcers – in 11(9.5%), arthritis – in 31(27%), pleuritis- in 18(16%), pericarditis- in 20(17%), renal disorder – in 52(47%), seizures- in 7(6%), psychosis – in 1(0.9%), myelitis – in 2(1.7%), peripheral neuropathy – in 3(2.6%), cranial neuropathy – in 2(1.7%), hemolytic anemia – in 59(51%), leukopenia- in 62(53%), thrombocytopenia- in 27(23%), ANA positivity – in 100(86%), anti-dsDNA antibody positivity – in 91(78%), antiphospholipid antibody positivity– in 27 (25%), direct Coombs' test- in 22(19%). SELENA–SLEDAI Score was 13 (9, 20): low activity- in 14(12%) patients, moderate activity- in 23(20%), high activity – in 42(36%), very high activity – in 37(32%).
96 (83%) patients met the eligibility criteria ELAR/ACR 2019, 112(97%) – ACR criteria modified in 1997, 106(91%) – SLICC in 2012.
Conclusion: In this cohort, although all three criteria have sufficient. Some SLE patients with a clinical diagnosis lacked sufficient number of criteria.

AB1262 PERFORMANCE OF JADAS-ESR AND JADAS-CRP IN THE ASSESSMENT OF DISEASE ACTIVITY IN TUNISIAN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

R. Ben Aissa[1], D. Ben Nessib[1], H. Ferjani[1], A. Dghaies[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Department of Rheumatology, Tunis, Tunisia*

Background: The Juvenile Arthritis Disease Activity Score (JADAS) is a feasible tool which consists of four items: tender (TJC) or swollen joint count (SJC), the physician and the patient's/parent's global assessment and the erythrocyte sedimentation rate (ESR). C-reactive protein (CRP) has also been suggested as an alternative inflammatory marker.
Objectives: To compare the performance of JADAS-ESR and JADAS-CRP in the evaluation of JIA activity.
Methods: Twenty nine patients who met the International League of Associations for Rheumatology (ILAR) criteria for JIA were enrolled in the study. Disease activity was assessed by the JADAS-ESR and JADAS-CRP scores at 54 consultations, 29 at baseline and 25 during the last follow-up consultation. Data of JIA subtypes, disease duration and treatment were retrospectively collected from medical records. All data were checked for normality by the Kolmogorov-Smirnov test. The Spearman correlation was used for data analysis and p values less than 0.05 were considered statistically significant.
Results: The mean age of our population was 13.1±4.2 years [4-21] and the sex ratio of males to females was 1.07. The mean disease duration was 4.69±3.26 years [0.3-13]. JIA subtypes were: enthesis-related arthritis (n=12), polyarthritis (n=7), oligoarthritis (n=6), undifferentiated (n=3) and psoriatic arthritis (n=1). At baseline most of our patients (51,73%) were not under treatment, 34.49% were under non-steroidal anti-inflammatory drugs (NSAIDs) and 13.8% under methotrexate (MTX). At the last follow-up consultation 41.38% of the patients were under MTX, 34.49% under NSAIDS and 10.35% under TNF inhibitor (Etanercept). At baseline JADAS-ESR1 was correlated to JADAS-CRP1 ($p<0.001$, $r=0.808$) in all AIJ subtypes. JADAS-ESR1 and JADAS-CRP1 were not correlated to ESR1 ($p=0.416$, $p=0.661$) nor to CRP1 ($p=0.376$, $p=0.058$). Both JADAS-ESR1 and JADAS-CRP1 were correlated to TJC1 ($p<0.0001$, $r=0.643$; $p=0.015$, $r=0.502$) and only JADAS-ESR1 was correlated to SJC1 ($p=0.012$, $r=0.461$). At the last follow-up consultation, correlations were observed between JADAS-ESR2 and JADAS-CRP2 ($p<0.001$, $r=0.992$) in all AIJ subtypes. JADAS-ESR2 and JADAS-CRP2 were both correlated to CRP2 ($p=0.015$, $p=0.003$) but not to SJC ($p=0.175$, $p=.119$), nor to ESR2 ($p=0.535$, $p=0.426$).
Conclusion: Our study suggests that both JADAS-ESR and JADAS-CRP correlate closely during the follow-up of JIA. JADAS-CRP could be recommended for assessing disease activity in JIA.

AB1263 CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS IN CHILDREN: A SINGLE CENTER 10-YEAR EXPERIENCE.

A. Nargizyan[1], S. Kurbanova[1], A. Glazyrina[1], E. Korobyants[1], V. Yusupova[1], A. Sologub[1], E. Zholobova[1,2]. [1]*Morozovskaya Children's City Clinical Hospital, Department of Rheumatology, Moscow, Russian Federation*; [2]*I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Rheumatology, Moskva, Russian Federation*

Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a chronic autoinflammatory disease that primarily affects the skeleton in the absence of an infectious etiology in children and adolescents. It is an orphan disease with many unclear aspects in terms of diagnosis, treatment and follow-up.
Objectives: To report demographic, clinical and laboratory characteristics of a single center cohort of CRMO patients in Morozovskaya Children's City Clinical Hospital in Moscow, Russia.
Methods: We retrospectively and prospectively reviewed clinical records of 33 CRMO patients diagnosed between 2011 and 2021 and admitted to Rheumatology Department of Morozovskaya Children's City Clinical Hospital.
Results: We identified 33 patients with CRMO. Twenty-five (75%) were female. Median age of symptoms onset was 9 [6;12] years. Median delay in diagnosis was 12 month. All patients had bone pain as an initial symptom; fever has been present in 12 patients (63%). Joints involvement was observed in 22 patients (67%) – 39%, 18%, 12%, and 3% of patients had ankle, hip, knee, and shoulder and wrist joints involvement, respectively. All patients had multifocal bone lesions, which were confirmed by radiological methods (CT scan, MRI, scintigraphy). Vertebrae (42.4%) and femur (48.5%) were the most commonly affected bones. One child had a skull lesion (os parietale). Eleven patients (33%) also had sacroiliitis. Other organs involvement was observed 7 patients presented with palmoplantar pustulosis and psoriasis. Histopathological examination has been performed in 24 (73%) patients to confirm the diagnosis. Mean ECR was 43 [28;80] mm/h and CRP – 27 [15;61] mg/L. Twenty-three (69,6%) patients had immunological activity.
Conclusion: From our experience, most of the patients had delay in diagnosis. Laboratory tests showed mild elevation of inflammatory parameters. Seven (21%) patients had psoriasis.

AB1264 CLINICAL, DEMOGRAPHIC CHARACTERISTICS AND TREATMENT RESPONSES OF PATIENTS WITH CRYOPYRIN-ASSOCIATED PERIODIC SYNDROME

Ş. Çağlayan[1], K. Ulu[1], T. Coşkuner[1], R. E. Yigit[1], G. Ozomay Baykal[1], F. Demir[1], M. Çakan[1], B. Sözeri[1]. *[1]University of Health Sciences, Umraniye Education and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey*

Background: Cryopyrin-associated periodic syndrome (CAPS) is a rare autoinflammatory disease that inherited autosomal dominantly. The disease occurs as a result of mutations in the NLRP3 gene, which encodes cryopyrin (1). It has three clinical presentations called familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS) and neonatal-onset multisystem inflammatory disorder (NOMID) or chronic infantile neurologic, cutaneous and articular (CINCA) syndrome (2). FCAS is the mildest form of this spectrum, characterized by cold-induced fever, urticarial rash, joint complaints, conjunctivitis, and systemic inflammation.
Objectives: In our study, we aimed to evaluate the clinical and demographic characteristics and treatment responses of CAPS patients.
Methods: We retrospectively enrolled 44 pediatric patients who were diagnosed with CAPS admitted to Umraniye Training and Research Hospital, Pediatric Rheumatology Clinic, Istanbul, Turkey, June 2016 - December 2021. Medical records were analyzed for clinical presentation, disease associations, physical examination, and laboratory findings.
Results: A total of 44 patients (41 FCAS, 3 MWS) were included in the study. Of the patients, 19 were girls and 25 were boys. The median age of the patients was 10.5 (1.4-20.6) years. The median age of onset of attack was 3 years (1 month-14.6 year), age at diagnosis was 7.9 years (13 months-18 years), and the follow-up period was 2.2 years (4 months-5.2 years). There were a history of consanguinity in 9 (20.4%) patients. Twelve (27.2%) patients had the autoinflammatory disease in their families. The most common clinical findings were fever (100%), joint pain (86.4%), and abdominal pain (79.5%). Afterward, rash (56.8%), myalgia (45.5%), conjunctivitis (31.8%), arthritis (31.8%), diarrhea (31.8%), chest pain (27.3%), headache (25%), and vomiting (22.7%) were other findings accompanying the attacks. Thirty-nine (88.6%) patients had mutations in the NLRP3 gene. No mutation was detected in five (11.4%) patients. The most common Q705K mutation was detected in 28 (71.4%) patients. Forty-two (95.4%) patients were started on colchicine treatment. Biological therapy was started in 9 (21.4%) patients whose attacks continued despite colchicine. Anakinra and canakinumab, which are anti-interleukin 1 agents, were used as biologic therapy. FCAS patients had an adequate response to standard doses of canakinumab therapy, while MWS patients required significantly higher doses of canakinumab therapy.
Conclusion: Although familial Mediterranean fever and PFAPA are the most frequent periodic fever syndromes in our country, CAPS should be included in the differential diagnosis in patients with recurrent fever complaints and accompanying urticaria-like rash and conjunctivitis. In our clinical experience, some FCAS patients show significant clinical benefits with colchicine treatment. We think that it would be beneficial to try colchicine treatment before starting biologic therapy in FCAS patients.

AB1265 BIOTECHNOLOGICAL AGENTS IN PEDIATRIC-ONSET SCLERITIS

A. Vitale[1], C. Gaggiano[1], V. Berlengiero[1], C. Fabiani[2], F. Ricci[3], G. Nascimbeni[3], V. Caggiano[1], G. M. Tosi[2], B. Frediani[1], M. Cattalini[3], L. Cantarini[1]. *[1]Rheumatology Unit, Department of Medical Sciences, Surgery, and Neurosciences, Siena, Italy; [2]Ophthalmology Unit, Department of Medical Sciences, Surgery, and Neurosciences, Siena, Italy; [3]Pediatric Clinic, University of Brescia and Spedali Civili di Brescia, Brescia, Italy*

Background: the term scleritis refers to the inflammation of the sclera, the white outer type I collagen tunic of the eye (1). It may be rarely found in pediatric patients, with the incidence of pediatric scleritis accounting for about 1.2% of all scleritis cases (2). An early diagnosis and an adequate treatment are mandatory to avoid irreversible ocular sequelae (3). In this regard, the experience of biotechnological agents in patients with pediatric scleritis is quite limited at current.
Objectives: To assess the effectiveness of biotechnological agents in terms of scleritis control and glucocorticoid dosage tapering in patients with pediatric-onset scleritis; b) to assess the safety of the biotechnological agents employed and their ability in avoiding new ocular disease complications.
Methods: patients with pediatric-onset scleritis resistant to the conventional therapy and treated with biotechnological agents were retrospectively enrolled and prospectively followed-up. Demographic, clinical, ophthalmologic and therapeutic data were collected. The endpoints of the study consisted in the description of the therapeutic details gathered at the start of the biotechnological agents compared to what was observed at the 6-month, 12-month and last follow-up visits.
Results: 5 patients (3 males; 2 females) treated with adalimumab, infliximab, abatacept secukinumab were consecutively enrolled. A remarkable clinical efficacy was observed in 5/5 cases during a 10-to-54 months follow-up period; complete and persistent suppression of ocular inflammation was pointed out in 2/2 patients with active disease at the start of the treatment, while a clinically relevant decrease of scleritis relapses was observed in 5/5 patients after the start of biotechnological treatment, compared to the past years of scleritis activity. In particular, the 5 patients suffered from a total number of 17 scleritis relapses during the 12 months preceding the start of the biologic treatment; the same patients suffered from 2 scleritis relapses within the first 12 months from the start of the treatment and 4 scleritis relapses during the entire follow-up period (median time of 28 months, interquartile range=118 months). These results were obtained despite the progressive and persistent glucocorticoid sparing effect, with a median daily dosage of prednisone or equivalent ranging from 15 (interquartile range =21.75) mg/day at the start of treatment to 2.5 (interquartile range =8.75) mg/day at the 3-month assessment, 2.5 (interquartile range=0) mg/day at 6 month visit, and 0.0 (interquartile range =2.5) mg/day at the last assessment. Regarding the safety profile, one out of five patients experienced an adverse event represented by oral candidiasis, presumably related to the concomitant use of glucocorticoids.
Conclusion: biotechnological agents have shown to be highly effective in controlling pediatric-onset scleritis, allowing a remarkable glucocorticoids sparing effect in patients previously resistant to conventional treatment and recalcitrant to a glucocorticoid-sparing approach. The safety profile was excellent.

AB1266 ANGIOTENSIN-CONVERTING ENZYME LEVEL IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

N. Shevchenko[1,2], T. Holovko[2,3], L. Bohmat[2,3], V. Nikonova[2]. *[1]V.N. Karazin Kharkiv National University, Department of Pediatrics No 2, Kharkiv, Ukraine; [2]SI Institute for Children and Adolescents Health Care of NAMS of Ukraine, Department of Rheumatology and Comorbid States, Kharkiv, Ukraine; [1]V.N. Karazin Kharkiv National University, Department of Pediatrics No 2, Kharkiv, Ukraine*

Background: One of the most common comorbid conditions accompanying rheumatoid arthritis is atherosclerosis and arterial hypertension. Previous studies have shown a change in the blood lipid spectrum with an increase in the atherogenic index in children with juvenile idiopathic arthritis. The next link in the development of this pathology is a change in the endothelial function of the vessels.
Objectives: To study the level of angiotensin-converting enzyme in children with JIA and establish its interdependence with the blood lipid spectrum of sick children.
Methods: The level of angiotensin-converting enzyme (ACE) was studied in 46 children (28 girls and 18 boys) from 11 to 17 years old by enzyme immunoassay as well as indicators of the lipid spectrum: low density lipoprotein cholesterol (LDL), very low-density lipoprotein cholesterol (VLDL) and atherogenic coefficient. The results obtained were compared with the data of children in the control group, which consisted of 34 people. Data were analyzed depending on patients' gender, age, and age of JIA onset, its variant, duration, activity, and presence of methotrexate (MTX).
Results: The results of the study are presented in the Table 1.

Table 1.

Lipid spectrum indicators	Children's groups	M+m	Me	Min	Max	p
LDL	JIA, n=46	2,33±0,09	2,18	0,97	4,31	0,001
	Control, n=34	2,5±0,09	2,55	1,39	4,13	
VLDL	JIA, n=46	0,36±0,09	0,35	0,13	1,1	0,001
	Control, n=34	0,14±0,01	0,13	0,06	0,27	
KA	JIA, n=46	2,04±0,09	1,83	0,82	3,5	0,4
	Control, n=34	2,03±0,09	2,02	0,83	3,8	
ACE	JIA, n=46	41,23±3,9	35,59	14,4	101,2	0,2
	Control, n=34	40,22±6,37	46,75	17,97	63,78	

There were no significant differences in the ACE level in children with JIA in comparison with the control group. Analysis of the data obtained did not reveal significant changes in the obtained ACE parameters depending on the gender and age of patients, JIA activity, and the presence of MTX in complex treatment. At the same time, a direct correlation of ACE values and low-density lipoprotein levels ($r=0.5$, $p<0.05$) was obtained, which confirms the relationship between the ACE level and the development of dyslipoproteinemia in children with JIA.
Conclusion: The obtained results illustrate the stages of development of atherogenic changes in children with JIA. Data were obtained that against the background of an increase in the level of VLDL and a decrease in LDL, the level of ACE remains preserved, which reflects the absence of changes in the endothelium. Research into these changes is ongoing.

AB1267 LONG-TERM SINGLE CENTER EXPERIENCE OF THE THERAPY WITH BIOLOGICS IN MULTIFOCAL NON-BACTERIAL OSTEOMYELITIS

I. Nikishina[1], S. Arsenyeva[1], V. Matkava[1], M. Kaleda[1], M. Shalygina[1], Z. Kolkhidova[1], T. Pachkoria[1], S. Salugina[1], D. Alexseev[1], O. Borodacheva[1], A. Shapovalenko[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Paediatric, Moscow, Russian Federation*

Background: Children and adolescents who suffered from the rare polygenic autoinflammatory disease such as multifocal non-bacterial osteomyelitis (NBO) can stay without specialized care for the long time. Currently we don't have standardized treatment for these patients. Administration of Biologics (B) established on opportunity to diagnose juvenile idiopathic arthritis (JIA) or juvenile ankylosing spondylitis (JAS) in relation to combination of bone lesions with arthritis and/or axial skeleton damage.
Objectives: To describe clinical/laboratory findings and therapy approaches in patients with NBO who was treated by BA.
Methods: We analyzed a single center retrospective nine-year study, which includes cohort of 56 patients (pts) with multifocal NBO. 22 pts of them were treated by different B (TNF-inhibitors mostly) in our pediatric department. Standard rheumatological assessment were included for all pts. X-ray, whole-body MRI and/or scintigraphy were done for revealing all localizations of bone lesion. Infection, oncology and other reasons of bone damage were excluded at the time of B administration.
Results: In total we identified 22 pts (10-boys; 12-girls) treated by B (TNF-inhibitors as first-line) among the whole group (n=56). The median age at the disease onset was 10 years (Me 10, range 1.3;16,5). Classifying diagnosis according to rheumatological nosology as JIA or JAS we were able for legal administration of targeted agents. 12 pts had JIA (7 girls), 10 pts had JAS (5 girls). JIA was presented by poly- (7 pts) and oligoarticular (5 pts) types. MRI evidence of axial involvement that was established on active erosive sacroiliitis with deep bone marrow edema had 15 pts (68%), on active spondylitis in thoracic spine – 3 pts, on erosive arthritis with partial ankyloses of facet joints of neck – 3 pts; multiple syndesmophytes had 1 girl. According to our findings, axial damage associated with NBO had developed much earlier (at 2 y.o. as minimum) than in case of «idiopathic» JAS. HLA-B27 positive was 11 pts, high levels of ANA had 5 pts (all of them HLA-B27 negative). Extraskeletal manifestations were observed in 8 pts (acne conglobate, uveitis, inflammatory bowel disease – one in each condition, psoriasis pustulosus – 5). High laboratory markers were revealed before biologics in 14 pts. Non-biological therapy was based on worldwide practice and included NSAIDs (all pts), methotrexate (10 pts), sulfasalazine (10 pts, in 9 pts it was withdrawal), bisphosphonates (2 pts), glucocorticoids (7 pts). Persistent arthritis, severe course of NBO, appearance of new bone lesions, refractory to treatment were determinant factors for administrate the TNF-inhibitors. Among first line of B etanercept (ETN) was used in 14 pts (63%), adalimumab (ADA) – in 5 pts (23%), golimumab – in 2 pts (9%), infliximab (IFX) – in 1 pts (4,5%). At the start of B the average age was 13.7 years (range 7.2-17.9); mean disease duration was 3,4 years (range 0.3-8.1). There were 4 cases of withdrawals: 1 for IFX (to ETN) due to development of skin involvement (chalazion,streptoderma), 3 for ETN. In 2 pts due to ineffi-cacy ETN was switched to ADA. Decreasing of disease activity was detected in the most of patients. Among them 2 pts developed the whole remission with resolving of active arthritis and bone marrow edema spots. Skin lesions (acne, psoriasis) were significantly improved. There weren't fixed adverse events during TNF-therapy except of the development of staphylococcus sepsis under ETN in a patient with rare genetic comorbidity (congenital indifference to pain). ETN was withdrawn immediately. The patient was treated for a long time by the surgery methods and antibiotics. A year later because of flares of arthritis JAK-inhibitors tofacitinib was administrated and marked improvement achieved.
Conclusion: Established on our experience, we can suggest that treatment with TNF-inhibitors is a good therapy approach for patients with high activity of NBO. It's expected that option of prescribing BA can prevent progression and bone destruction.

AB1268 CLINICAL ASPECT AND THERAPEUTIC MANAGEMENT OF SUBACUTE OSTEOMYELITIS IN CHILDREN

R. Dghaies[1], A. Dghaies[2], M. Jerbi[3], H. Ben Ghozlene[3], F. Abid[3]. *[1]University Hospital Center Hedi Chaker Sfax, Pediatric Surgery, Sfax, Tunisia*; *[2]University Hospital Center Hedi Chaker Sfax, Rheumatology, Sfax, Tunisia*; *[3]University Hospital Center Taher Sfar Mahdia, Traumatology-Orthopedic Department, Mahdia, Tunisia*

Background: Subacute osteomyelitis in children is a distinct entity encompassing primary localized osteomyelitis. It poses a diagnostic problem related to its few or no constitutional symptoms, misleading radiological manifestations and often a negative bacteriological investigations. The treatment remains very controversial.
Objectives: The aim of this study was to identify the main epidemiological, clinical, histological and evolutionary characteristics of this affection and to propose an adequate therapeutic attitude.
Methods: It was a retrospective longitudinal study, carried out over a period of 25 years from January 1995 to December 2019 in the orthopedic department of Taher Sfar Hospital,Mahdia, that included 37 cases of subacute osteomyelitis in children.
Results: The mean age of the patients was seven years nine months with a male predominance (sex ratio: 2.27). The average time to hospitalization was 41 days. A diagnostic delay was very likely because of delay in consultation which was related to clinical latency, reported in all cases. The imaging showed osteolysis in all cases, setting in long bones in 54% of cases and in 46% other cases in short and flat ones. The lesion was multiple in two different bones only in one case and was found in pure epiphyseal location in seven cases. The bacteriological investigation allowed the isolation of a germ only in eight cases. In all cases, it was a Staphylococcus aureus. Surgical treatment was performed in 21 cases (60% of patients). The outcome was favorable in 35 cases (95% of cases). An infectious awakening was noted in 2 cases.
Conclusion: Subacute osteomyelitis poses a diagnosis and therapeutic problem. Magnetic resonance imaging is a valuable examination. Surgical treatment combined with appropriate antibiotic therapy is indicated for any suspicious lesion. It can be useful in taking samples for diagnosis, improve distribution of the antibiotic in injury and accelerate healing radiation.

Other orphan diseases

AB1269 SHULMAN'S DISEASE OR EOSINOPHILIC FASCIITIS, A RARE FIBROSING DISORDER: A CASE REPORT TREATED WITH TOCILIZUMAB

A. Laria[1], A. M. Lurati[1], M. G. Marrazza[1], K. Re[1], D. Mazzocchi[1], P. Faggioli[2], A. Mazzone[2]. [1]*ASST Ovest Milanese, Fornaroli Hospital, Rheumatology, MIlan, Italy*; [2]*ASST OVEST Milanese Civil Hospital Legnano, Internal Medicine Unit, Legnano, Italy*

Background: Schulman eosinophilic fasciitis (EF) is a rare fibrosing disorder, typified by erythema, edema, and symmetric induration of the distal bilateral extremities (only proximal to the wrists and ankles) or/and trunk**(1).**The "groove sign" and/or a pseudocellulite appearance of the involved skin may be present**(1),** followed by joint contractures **(1).**Fascial biopsy is the gold standard for making a diagnosis.Systemic corticosteroids are first-line treatment**(2).**The use of c/bDMARDs is described in literature with clinical improvements**(2).**
Objectives: to evaluate efficacy of Tocilizumab in a patient affected by Shulman's disease
Methods: A 54-year-old woman went to our observation for appearance of abrupt-onset simmetric edema followed by induration of the bilateral extremities and trunk. She has been feverish for about 2 weeks associated with diffuse arthromyalgia. On rheumatological examination: non-liftable skin in folds on the bilateral arms and forearms and lower limbs; absence of frank synovitis or lymphoglandular swellings. The blood tests performed showed an increase in acute phase reactants. The ferritin and electrophoretic picture, complement and immunoglobulin dosage were normal. The blood count showed a marked absolute eosinophilia accompanied by modest monocytosis and modest platelet disease. There was a slight increase in LDH and in serum beta2microglobulin. Serology for viral infections and autoimmunity were negative. Screening for celiac disease was negative. Coprocultures, parasitology and the search for the fecal H. pylori antigen are negative. Excluded lymphadenopathy or hepatosplenomegaly to the total body computed tomography. Modest non-buffering pericardial effusion was reported in CT scan. Nailfold capillary changes were absent. Chronic inflammatory bowel diseases were excluded. A skin biopsy of the left forearm confirmed the clinical diagnosis of EF. In particular, it documented thickening of the fascia, site of an inflammatory process that included small lymphocytes, plasma cells, histiocytes and some eosinophils, distributed both diffusely and around blood vessels.The underlying muscle tissue and the supra-fascial skin were free from alterations. Secondary fasciitis was excluded by 18 fluorodeoxyglucose (FDG)-positron emission tomography; this showed a diffusely accumulation of the radiopharmaceutical in the muscles of the forearms and of both lower limbs, compatible with eosinophilic fasciitis and confirmed the pericardial effusion. Immunophenotypic analysis on peripheral blood excluded the presence of a monoclonal cell population. Diagnosis of primary eosinophilic fasciitis was made and therapy was started with methylprednisolone 1 g intravenously for 3 days followed by another 3 boluses of methylprednisolon of 500 mg iv. Given the poor response, it was decided to set up therapy with Methotrexate 15 mg up to a dose of 20 mg intramuscularly per week associated with prednisone 25 mg/day. The rheumatological re-evaluation at 3 months showed a worsening of the fibrosis and diffuse skin edema with an obligatory kyphosis of the spine and limitation in the patient's movements. Therefore it was decided to start off label infusion therapy with Tocilizumab 8 mg/kg/month.
Results: A complete resolution of the skin picture with disappearance of the pericardial effusion was documented 12 months after the start of the biological drug
Conclusion: There are currently no guidelines for the treatment of eosinophilic fasciitis. Tocilizumab has been shown to be effective when introduced in the early inflammatory stages of the disease, as in the case described.

AB1270 EFFICACY AND SAFETY OF THE OPTIMISATION OF BIOLOGICAL THERAPY IN NON-INFECTIOUS UVEITIS: SYSTEMATIC REVIEW

M. Salido Olivares[1], E. Loza[2]. [1]*Infanta Cristina University Hospital, Rheumatology, Parla, Spain*; [2]*Institute of Musculoskeletal Health (inMusc)., Rheumatology, Madrid, Spain*

Background: In other rheumatic diseases it is possible to optimize biological therapy, maintaining its effectiveness and without risk in its safety. But this aspect has not been studied in the field of non-infectious uveitis.
Objectives: In other rheumatic diseases it is possible to optimize biological therapy, maintaining its effectiveness and without risk in its safety. But this aspect has not been studied in the field of non-infectious uveitis.
Methods: A search strategy (Pubmed, Embase and Cochrane) was carried out on UNI up to Jan-22 with Mesh vocabulary and free text (human beings, English or Spanish). Review last 2 years of International Congresses Rheumat/Oft. We included meta-analyses, systematic reviews, clinical trials, prospective and retrospective longitudinal observational studies (OA). Secondary manual search and quality assessment with the Oxford scale by 2 independent researchers. The population included were UNI in ophthalmological remission after TB use. Articles with TB optimization strategies and whether there is a comparison with those that maintain the smPC dose are examined. The main measures being evaluated are efficacy and safety. Data are collected on eye activity, number of outbreaks, GC (glucorticoid) doses and adverse effects.
Results: 11 articles of low or moderate quality. They were mostly retrospective EO (n=7), and to a lesser extent prospective (n=4), and included 513 patients. With a variable follow-up from a minimum of 12 months, up to 17 years of evolution. There was a predominance of males, of average age of 36 years, the most represented disease was Bechet's disease. There was no homogeneous criterion when trying to optimize, since the minimum required time of remission maintained with TB, varied from 3 to 12 months. The use of FAME and GC was allowed. The intervention is described in 7 articles with Infliximab, 2 with Adalimumab and 2 with Etanercept. Other TB other than anti-TNF, have not performed optimization so they are not included in this systematic review. They included patients treated with DMARD and even with previous anti-TNF. Many articles did not have a comparison group. Studies suggest that after 3-6 months in remission, it could be a time to assess optimization. The remission maintained after discontinuation of the drug, is maintained from 7.5 months, up to 2 years. GC reduction and suspension up to 74% and even 40% FAME are described. But there are also relapses in 25-50%, but they are controlled in general with the increase in doses and in some cases with change of TB. There were no relevant security issues.
Conclusion: 1. Low quality of the evidence. 2. Great variability in patients, pathologies, definitions or outcome variables. 3. There is no consensus at the time of starting the optimization, the data suggest that after 3-6 months in remission it could be assessed. 4. Articles with a limited number of cases (some without a control group) or retrospective are included. There is great heterogeneity in the optimization and protocols used. But despite all this, these results suggest that optimization and/or suspension (in selected cases) can be carried out safely and planned for anti-TNF TB, with a low probability of short-term recurrences. 5. In case of reactivation of uveitis, it seems that it is usually controlled in most cases, using again the standard doses. 6. There were no relevant security issues. 7. More studies with homogeneous criteria and established protocols are needed to determine the duration of the ideal treatment and see if there are differences in the etiology of uveitis or TB used.

AB1271 PREVALENCE OF RHEUMATOLOGIC DISEASES IN PATIENTS PRESENTING WITH UVEITIS

E. Ozturk[1], T. Yuce Inel[2], M. Kaya[3], F. Onen[2], G. Can[2]. [1]*Dokuz Eylul University Faculty of Medicine, Internal Medicine, Izmir, Turkey*; [2]*Dokuz Eylul University Faculty of Medicine, Rheumatology, Izmir, Turkey*; [3]*Dokuz Eylul University Faculty of Medicine, Ophthalmology, Izmir, Turkey*

Background: Uveitis may occur in the course of systemic inflammatory rheumatic diseases, or it may be the first clinical presentation of these diseases.
Objectives: To determine the prevalence of systemic inflammatory rheumatic disease in patients whose initial clinical manifestation is non-infectious uveitis.
Methods: Adult patients diagnosed with non-infectious uveitis in Dokuz Eylul University Ophthalmology Department and referred to investigate the

etiology of rheumatological disease were included in the study. Demographic and clinical features, laboratory and imaging findings of the patients were examined.

Results: 106 patients diagnosed with uveitis (42.4% anterior uveitis, 2.8% intermediate uveitis, 19.8% posterior uveitis, 34.9% panuveitis) were included in the study. 52.8% of the patients were male and the mean age was 40.19±14.82 years. The mean age of uveitis attack was 38.7±15.02 years. 33% of the patients were diagnosed with rheumatologic disease (10 SpA, 17 Behçet's Disease, two vasculitis, two sarcoidosis, three undifferentiated connective tissue disease, one rheumatoid arthritis). SpA was diagnosed in 20% of patients presenting with anterior uveitis. Behçet's disease was detected in 27% of patients referred with panuveitis and in 33.3% of patients whose first clinical finding was posterior chamber involvement. Bilateral uveitis was detected in two-thirds of patients with posterior chamber affected, and it tends to recur more (p=0.014).

Conclusion: A rheumatological disease was detected in approximately one-third of the patients presenting with uveitis. Investigation of patients referred for uveitis in terms of systemic rheumatological diseases is very important as it may change the diagnosis and treatment process.

AB1272 FACTORS AFFECTING PATIENT-ACCEPTABLE SYMPTOM STATES IN FAMILIAL MEDITERRANEAN FEVER

D. Yildirim[1], R. C. Kardaş[1], B. Ozkiziltas[1], I. Vasi[1], M. A. Ozturk[1], S. Haznedaroglu[1], B. Goker[1], A. Tufan[1]. [1]*Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever, serositis, and musculoskeletal symptoms (1, 2). Arthritis is the most common musculoskeletal symptom of attacks and also included in diagnostic criteria of FMF (3). If it is specifically queried, myalgia may be detected in up to 20-25% of the patients with FMF. (4,5).

Objectives: In our study, we aim to assess the localization of attack-related myalgia and associated parameters in patients with FMF.

Methods: A total of 349 consecutive patients followed by FMF in our clinic were enrolled in the study and asked for attack-induced myalgia and if present, localization of muscle groups on the mannequin body parts diagram.

Attack frequency, duration, and disease activity were evaluated with the Auto-Inflammatory Diseases Activity Index (AIDAI) scoring system (6). Patients were also asked for work/study day loss during attacks and patient acceptable symptom state (PASS) status (7).

Results: 126 patients showed attack myalgia (36%); attack duration, frequency, severity were significantly higher in patients with attack-myalgia (p<0,005). Most common muscle groups were calves, lower back, and latissimus dorsi muscles in order. Myalgia was most commonly accompanied by arthritis (p<0,002). Patients with myalgia have a higher frequency of colchicine resistance and work/study day loss due to attacks.

Conclusion: Our results conclude that myalgia is an important domain of attacks and causes absenteeism and uncontrolled disease activity. Treatment of myalgia attacks may provide controlled disease act**iv**ity, and prevent absenteeism from work/school.

AB1273 MACROPHAGE ACTIVATION SYNDROME IN RHEUMATIC DISEASE: CLINICAL CHARACTERISTICS AND PROGNOSIS OF 20 PATIENTS

S. H. Nam[1], S. M. Ahn[2], J. S. Oh[3], S. Hong[2], C. K. Lee[2], B. Yoo[2], Y. G. Kim[2]. [1]*Uijeongbu Eulji Medical Center, Department of Internal medicine, Division of Rheumatology, Uijeongbu, Korea, Rep. of (South Korea)*; [2]*Asan Medical Center, Department of Internal medicine, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea)*; [3]*Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)*

Background: Macrophage activation syndrome (MAS) is a hyperinflammatory condition that is known to be secondary hemophagocytic lymphohistiocytosis (HLH) in patients with rheumatic disease.

Objectives: The aim of study was to evaluate the clinical manifestations and outcomes in patients with MAS with rheumatic disease.

Methods: We performed a retrospective study of 20 adult patients who were diagnosed with MAS from 2012 to 2020. MAS was classified according to the HLH-2004 criteria. Patients' information, including clinical features, laboratory findings, and treatment regimens, was collected, and the overall survival rate was estimated by the Kaplan–Meier method.

Results: Twenty patients (18 women, 35.6 ± 18.3 years) who met the HLH-2004 criteria also fulfilled the 2016 EULAR/ACR/PRINTO classification criteria for MAS, and HScore was higher than 169 (median, 238.5). Fourteen patients with systemic lupus erythematosus and 6 patients with adult-onset Still's disease were included. All patients were treated initially with corticosteroids, and 16 patients required additional immunosuppressants. The overall survival at 3 and 6 months was 75.2% and 64.3%. In survivors, renal impairment was less common (23.1% versus 42.9%, p = 0.007), the levels of AST (202.0 versus 72.0 IU/L, p = 0.006) and LDH (1144.0 versus 343.0IU/L, p = 0.001), and platelet count (90.0 versus 46.0 × 10^9/L, p = 0.016) were higher in compared to non-survivors. Nine patients had opportunistic infections, five of whom died during admission.

Conclusion: The mortality of patients with MAS remains high. Renal impairment, levels of AST and LDH, and platelet count might be associated with prognosis.

Table 1. Treatments and management characteristics of patients with MAS

No.	Age/sex	Disease	Disease duration (months)	1st Treatment (corticosteroids)	2nd Treatment	3rd Treatment	Combined infection	Alive/dead
1	19/F	SLE	1	1 mg/kg	IVIG + PP	TCZ, RTX	Bacteremia	Dead
2	20/M	SLE	0	1 mg/kg	-	-	-	Alive

AB1274 ADULT-ONSET STILL'S DISEASE IN WESTERN AUSTRALIA: EPIDEMIOLOGY, COMORBIDITY AND LONG-TERM OUTCOME.

J. Nossent[1,2], W. Raymond[2], H. Keen[2,3], D. Preen[4], C. Inderjeeth[1,4]on behalf of WARDER steering group. *[1]Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*; *[2]The University of Western Australia, Medical School, Rheumatology section, Crawley, Australia*; *[3]Fiona Stanley Hospital, Rheumatology, Murdoch, Australia*; *[4]The University of Western Australia, School of Population and Global Health, Crawley, Australia*

Background: Adult-onset Stills disease (AOSD) is a rare, potentially life-threatening autoinflammatory condition for which the reported prevalence shows regional variation and where comparative long-term outcome data are scarce (1).

Objectives: To investigate annual incidence and point prevalence of AOSD in Western Australia (WA) and compare long-term health-related outcomes between AOSD patients and hospital-based controls.

Methods: Population-based cohort study using longitudinally linked administrative health data from all hospitals in WA between 1999 and 2013. ASD patients (ICD-10-AM code M06.1) were matched to controls for age and gender. Rate and odds ratios (RR/OR) with 95% confidence intervals (CI) were used to compare ASD patients and controls for serious infections (SI), osteoporosis, joint replacement and the modified Charlson Comorbidity (mCCI).

Results: In total 52 patients had incident AOSD for an average period incidence of 0.22/100,000 and a point prevalence of 2.4 /100.000 (per 30/12/2013). Compared to controls, ASD patients (median age 41.5 years, 59.6% females) had higher odds of prior liver disease (OR 2.67, 95%CI: 1.31-5.45), fever (OR 54.1, 95%CI: 6.6-43), rash (OR 15.7, 95%CI: 4.08-60.8) and SI (OR 4.36, 95%CI: 2.11-22.8). During 49 months of follow up, crude mortality (11.5% vs 7.5%; p=0.34), survival at one and five years (p=0.78) and m-CCI score at last observation (median 2 vs 2) were similar for ASD patients and controls. However, the odds for subsequent joint replacement (in 7 patients; 13.5%) (OR 45.5, 95%CI: 4.57-93), osteoporosis (OR 31.3, 95%CI: 3.43-97) and SI (RR 5.68, 95%CI: 6.61-8.74) were significantly higher in ASD patients.

Conclusion: The epidemiology and demographics of AOSD in Western Australia fall within the internationally reported range. Compared to controls, AOSD patients presented higher rates of liver disease, rash and SI before disease onset. Mortality following AOSD was not increased for five years despite high rates of chronic arthritis requiring joint replacement, SI, and osteoporosis.

AB1275 SUGGESTED APPROACH TO UBA1 GENE MUTATION TESTING IN PATIENTS WITH SUSPECTED VEXAS SYNDROME

K. Pavelcova[1], B. Stiburkova[1,2,3], V. Balajková[1], M. Belickova[4], C. Salek[4,5], M. Vostry[4], H. Mann[1,2], J. Vencovský[1,2]. *[1]Institute of Rheumatology, Prague, Czech Republic*; *[2]First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*; *[3]First Faculty of Medicine, Charles University and General University Hospital, Department of Pediatrics and Inherited Metabolic Disorders, Prague, Czech Republic*; *[4]Institute of Hematology and Blood Transfusion, Prague, Czech Republic*; *[5]First Faculty of Medicine, Charles University, Institute of Clinical and Experimental Haematology, Prague, Czech Republic*

Background: VEXAS syndrome (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) is a recently identified autoinflammatory disease caused by *de novo* somatic mutations in the X-linked gene *UBA1* (1). This disease is clinically characterized by inflammatory symptoms and bone marrow failure (2).

Objectives: The aim of our study was to identify genetic variants associated with VEXAS syndrome and to design an algorithm for detection of *UBA1* gene mutations in patients with suspected VEXAS syndrome, which could be used for diagnosis.

Methods: We examined the UBA1 gene in 9 patients with clinically suspected VEXAS syndrome. We first focused on variants p.Met41Val, p.Met41Thr and p.Met41Leu with a known association with this disease (1). Samples of individual blood cell populations obtained by magnetic isolation were evaluated using RFLP, tetra-primer ARMS-PCR and Sanger sequencing. Subsequently, we analyzed the remaining exons of the *UBA1* gene by Sanger sequencing.

Results: Using the above described method we have identified the previously described variants p.Met41Thr in two and p.Met41Leu in another two patients. In one patient, we discovered a new mutation p.Gly477Ala (c.1430G>C) in exon 14 that has not yet been identified. The presence of these variants and their allelic forms (heterozygous / homozygous) varied between cell populations in individual patients.

Conclusion: The increasing number of reports suggests that VEXAS syndrome is not rare. In patients with clinical suspicion, typically UBA1 sequencing analysis of haematopoietic cells is performed in hot spot sites of p.Met41 in exon 3 only. Our results suggest that other variants, such as the newly identified p.Gly477Ala variant, may also be associated with clinical features of VEXAS syndrome. We propose that an extended analysis of all coding regions of the *UBA1* gene may uncover other mutations with putative functional consequences.

AB1276 EVALUATION OF DRUG-FREE REMISSION RATES IN IDIOPATHIC GRANULOMATOUS MASTITIS

M. N. Kaya[1], Ö. Kılıç[1], E. Tekgoz[1], S. Colak[1], M. Çınar[1], S. Yilmaz[1]. [1]*University of Health Sciences Turkey, Gülhane Training and Research Hospital, Rheumatology, Ankara, Turkey*

Background: Idiopathic granulomatous mastitis (IGM) is a rare inflammatory breast disease. There is no clear consensus on its treatment yet (1).
Objectives: The aim of the study was to evaluate the rates of drug-free remission of the patients with IGM in a period of three-year follow-up.
Methods: A total of 76 patients who were followed-up with biopsy proven IGM, between February 2011 and November 2021 in rheumatology outpatient clinic of Gulhane Training and Research Hospital, were evaluated retrospectively. To analyze long-term outcomes, 55 patients who were followed up for 3 years were included in the study. Data regarding the demographic and clinical characteristics of the patients were obtained from patients' files.
Results: The study included 55 female patients with a mean age of 36.8 ± 6.3 years. Forty-nine (89.1%) patients received immunosuppressive treatment, one (1.8%) patient received postoperative immunosuppressive treatment, 3 (5.4%) patients had immunosuppressive treatment due to recurrence after surgery, and 1 (1.8%) patient underwent only surgery. One (1.8%) patient had no treatment for IGM. Patients who received immunosuppressive drugs for initial treatment, 38 (69.1%) received methotrexate (MTX) and corticosteroids (CS), 7 (13.2%) received azathioprine (AZA) and CS, 3 (5.6%) received only CS and 1 (1.8%) received cyclosporine A (CsA) and CS. Four (7.2 %) patients had received MTX after surgery. At 3-year follow-up 54 (98.1%) patients were in drug-free remission. The median duration of drug-free remission in patients receiving MTX plus CS, CS, and azathioprine plus CS was 19.7, 32.9, and 14.7 months, respectively. One patient who received CsA plus CS was in drug-free remission for 28.3 months. The median duration of treatment with combination of CS and other immunosuppressives was 6.7 months. The median duration of immunosuppressive treatment was 15.8 months (Table 1). Recurrence was observed in 4 (80%) patients who did not receive immunosuppressive therapy after surgery. Three (75%) of these patients received MTX due to recurrence, and remission was achieved.

Table 1. Duration of immunosuppressive treatment and drug-free remission of the patients

Treatment	Duration of immunosuppressives, (n=53)	Duration of drug-free remission, (n=54)
Only corticosteroids (month)*	4.6 (2.9-5.8)	32.9 (32.4-33.4)
Methotrexate (month)*	19.7 (2.8-32.4)	19.7 (2.7-32.4)
Azathioprine (month)*	16.2 (11.0-30.1)	14.7 (8.8-22.9)
Cyclosporine (month)	7.6	28.3
Total (month)*	15.8 (2.9-34.3)	21.2 (2.7-36.6)

* Variables as median, (minimum - maximum)

Conclusion: Immunosuppressives provide a remarkably high sustained remission and maintain a longer drug-free remission in patients with IGM.

AB1277 POOR LONG-TERM OUTCOMES AND SUBSTANTIAL BURDEN OF COMORBIDITIES IN EUROPEAN PATIENTS WITH DERMATOMYOSITIS/POLYMYOSITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

J. Vencovský[1], K. Pisarczyk[2], R. Leff[3], E. Park[4], K. Palaniswamy[4], L. Long[3]. [1]*Institute of Rheumatology, Research Department, Prague, Czech Republic*; [2]*Maple Health Group, Market Access, Cracow, Poland*; [3]*Kezar Life Sciences, Clinical Development, South San Francisco, CA, United States of America*; [4]*Kezar Life Sciences, Medical Affairs, South San Francisco, CA, United States of America*

Background: Dermatomyositis (DM) and polymyositis (PM) are rare heterogenous systemic autoimmune disorders of the skin, muscles and other organs that may have a devastating impact on patients' lives. Despite various therapies used in clinical practice, a notable proportion of patients seem not to achieve sustainable remission. There is a need to better understand long-term outcomes and comorbidities in patients with DM/PM in Europe.
Objectives: To systematically review and summarize evidence on clinical burden of disease in patients with DM/PM in Europe.
Methods: A systematic literature review (SLR) was conducted in MEDLINE and Embase databases to identify studies in children and adults with DM/PM, published in the English language between 2011 and 2021. Primary studies enrolling 10 or more patients were included, irrespective of country or region. Each eligible article was independently reviewed by two reviewers. The title and study abstracts were reviewed to assess eligibility for full-text review. The current abstract summarizes SLR results on the long-term outcomes and comorbidities in patients with DM/PM in Europe.
Results: A total of 2,967 non-duplicated publications were retrieved from medical databases and analyzed against pre-defined study selection criteria. There were 2,574 records excluded at title and abstract screening. Remaining 393 records were analyzed in the full text with 208 papers considered relevant. Additional 21 papers were identified from searching reference list of relevant studies and conference proceedings. In total, 222 studies (229 publications) were included in data abstraction. Among 43 studies conducted across 14 European countries, 23 studies evaluated long-term outcomes of disease and burden of comorbidities. There were 14 longitudinal cohort studies, 7 cross-sectional analyses and 2 case-control studies. Only 29-44% of DM/PM adults achieved remission. Between 38% and 62% of adults with DM/PM required at least 3 different medications, suggesting inadequate response to initial and subsequent regimens. During a mean follow-up of 13.9 years, 69% patients with JDM had polycyclic or chronic disease characterized by periods of remission and recurrence or by permanently active disease for more than 2 years after diagnosis. A notable proportion of children (60.4%) showed evidence of damage in at least one body organ and 13-20% of patients had complications such as calcinosis, lipodystrophy, or muscle atrophy. Adults with DM/PM often suffered from interstitial lung disease (16-66%), serious infections leading to hospitalization or death (21-26.7%), and cardiovascular disorders (CVDs) (19-71%). Compared to age and gender matched controls without DM, patients with DM had 16-times higher risk of venous thromboembolism (HR=16.44, 95% CI: 7.54-35.86). Incidence of coronary heart disease, hemorrhagic stroke, or ischemic stroke during 10-year follow-up was approximately 1.5- to 2-times higher in DM/PM adults relative to general population. Multiple studies reported high rates of any malignancy in DM adults (7.5-33%) and in PM adults (8-11.7%). During approximately 24,000 patient-years of follow-up, adults with DM/PM had more than 4-times higher incidence of lung cancer compared to general population that also was one of the highest incidences among multiple other autoimmune diseases. Long-term prognosis in DM/PM was poor with 20-year survival below 70%. The most common causes of deaths were pulmonary-related, malignancies, and cardiac complications. Mortality due to lung cancer was more than 4-times higher than in general population (standardized mortality ratio=4.17, 95% CI: 3.03-5.60).
Conclusion: European patients with DM/PM suffer from substantial burden of comorbidities including serious infections, malignancies and CVDs that lead to poor long-term outcomes. A notable proportion of adult and juvenile patients do not achieve sustainable remission or experience relapse indicating high unmet need.

AB1278 INCIDENCE OF ENDOCRINE AND EXOCRINE INSUFFICIENCY IN PATIENTS WITH AUTOIMMUNE PANCREATITIS AT DIAGNOSIS AND AFTER TREATMENT

M. Lanzillotta[1], M. Tacelli[2], G. Capurso[2], L. Dagna[1], E. Della Torre[1]. [1]*San Raffaele Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, IRCCS San Raffaele Scientific Institute, Milan, Italy, Milan, Italy*; [2]*San Raffaele Scientific Institute, Pancreato-Biliary Endoscopy and Endosonography Division, Pancreas Translational and Clinical Research Center, IRCCS San Raffaele Scientific Institute, Milan, Italy;, Milan, Italy*

Background: Autoimmune pancreatitis (AIP) is a rare form of chronic pancreatitis that may lead to endocrine and exocrine insufficiency if left untreated. AIP clinically responds to glucocorticoids (GCs) therapy, but multiple GCs courses are often required to maintain remission with potential detrimental effects on glycaemic control. To date, data on pancreatic function in AIP are scanty and heterogeneous.
Objectives: We aimed to assess the rate of endocrine and of exocrine insufficiency at diagnosis and at follow up in patients with AIP as well as the impact of GC therapy on pancreatic function in the long term.

Methods: The MEDLINE, SCOPUS, and EMBASE databases were searched from inception to August 2021 to identify studies reporting data on endocrine and exocrine insufficiency in patients with type 1or type 2 AIP. Studies involving ≥ 3 patients were selected. In case of duplicated studies, the most recent or the one with the largest sample were included. The study was conducted in accordance with Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Pooled events were calculated using a random-effect model and expressed in terms of pooled prevalence rates.
Results: A total of 6522 AIP patients and sixty-two studies were included in the analysis. The pooled estimate rate for the overall prevalence of diabetes in AIP at baseline (combined type 1 and type 2 AIP) was 36.9% (95% CI 31.9-41.9, I^2 96.1%). The pooled estimate for the prevalence of diabetes was 44.3% (95%CI 39.1-49.4, I^2 91.9%) in type 1 AIP and 11.3% (95%CI 6.1-16.6, I^2 42.5%) in type 2 AIP ($p < 0.01$), respectively. The pooled prevalence rate of exocrine insufficiency was 45.2% (95%CI 32.9-57.4; I^2 97.4%). The pooled estimate rate of diabetes at follow-up was 44.2% (95%CI 26.1-62.4) in studies where GCs were given to 100% of patients and 41.8% (95%CI 30.6-52.9) in studies where GCs were given to less than 100% of patients. The pooled prevalence of pancreatic exocrine insufficiency was 36.2% (95%CI 20.4-52.0, I^2 96.4%).
Conclusion: A large proportion of patients with AIP displays concomitant exocrine and endocrine insufficiency at the time of diagnosis. The incidence of diabetes at the longest available follow up tends to increase in patients treated with GCs. Further long-term studies are warranted to assess the impact of GCs and immunosuppressive treatments on glycaemic control and on exocrine pancreatic function.

AB1279 POOR QUALITY OF LIFE AND REDUCED WORK PRODUCTIVITY IN EUROPEAN PATIENTS WITH DERMATOMYOSITIS AND POLYMYOSITIS: FINDINGS FROM A SYSTEMATIC LITERATURE REVIEW

J. Schmidt[1], K. Pisarczyk[2], R. Leff[3], K. Palaniswamy[4], E. Park[4], L. Long[3]. *[1]Immanuel Klinik Rüdersdorf University Hospital of the Brandenburg Medical School Theodor Fontane, Department of Neurology and Pain Treatment, Rüdersdorf bei Berlin, Germany*; *[2]Maple Health Group, Market Access, Cracow, Poland*; *[3]Kezar Life Sciences, Clinical Development, South San Francisco, United States of America*; *[4]Kezar Life Sciences, Medical Affairs, South San Francisco, CA, United States of America*

Background: Dermatomyositis (DM) and polymyositis (PM) are rare heterogenous systemic autoimmune disorders of the skin, muscles, and other organs with few effective treatment options available. They are described as devastating diseases but the full impact on patients' lives in Europe is not well understood.
Objectives: To systematically review and summarize evidence on humanistic burden of disease in patients with DM and PM in Europe to better understand patient-relevant aspects of disease and key domains of life impacted by DM and PM in the European setting.
Methods: A systematic literature review (SLR) was conducted in MEDLINE and Embase databases to identify studies in children and adults with DM and PM, published in the English language between Jan 1, 2011, and Apr 28, 2021. Only primary studies enrolling 10 or more patients were included, irrespective of country or region. Each eligible article was independently reviewed by two reviewers. The title and study abstracts were reviewed to assess eligibility for full-text review. The topics of interest were clinical, humanistic, and economic burden of disease, as well as current management and unmet needs in DM and PM. Information on geographic scope was extracted from the papers of included studies. The current abstract summarizes SLR results on humanistic burden of DM and PM in European patients.
Results: A total of 2,967 non-duplicated publications were retrieved from medical databases and analyzed against pre-defined study selection criteria. There were 2,574 records excluded at title and abstract screening. Remaining 393 records were analyzed in the full text with 208 papers considered relevant. Additional 21 papers were identified from searching reference list of relevant studies and conference proceedings. In total, 222 studies described in 229 publications were included in data abstraction. Among 43 studies conducted across 14 European countries, 12 studies evaluated health-related quality of life (HRQoL) and work productivity in patients with DM and PM. In 6 studies, patients received standard of care therapy. Six studies enrolled adults with DM and PM and 6 were conducted in patients with juvenile onset of DM. There were 6 cross-sectional analyses, 4 longitudinal cohort studies, 2 case-control studies, with sample size ranging from 11 to 246 patients. Adults with DM and PM had significantly worse HRQoL across multiple domains of 36-Item Short Form Survey (SF-36) compared to controls from general population, with a strong negative impact of muscle weakness on physical functioning. Patients reported high difficulties in performing leisure time activities, moving around and work as indicated by median scores of 4-5 points in a 7-point Myositis Activity Profile (MAP). Reduced grip force in DM and PM adults was significantly associated with worse performance in domestic activities in the MAP assessment ($p<0.05$). In women with DM and PM, poor grip force additionally impacted vitality and mental health as measured by SF-36 ($p<0.05$). There were no associations between grip force and any SF-36 domain in men. Approximately 60% of adult patients rated their ability to work as "poor" or "less good" according to the Work Ability Index, 68% of patients had more than one week of sick leave in the past year, and 20.8% of them were permanently not able to work for at least 2 years. Children and adolescents with DM had impaired physical and psychosocial functioning compared to healthy norms with 40% of individuals showing increased emotional distress requiring in-depth psychological assessment.
Conclusion: European patients with DM and PM experience a muscle weakness that has a detrimental impact on HRQoL, daily activities and ability to work. Similar disease impact on HRQoL was reported in patients in North America. These findings suggest a need for a novel therapy that will restore physical functioning in patients with DM and PM.

AB1280 IGG4 RELATED DISEASE WITH ATYPICAL SCALENE MUSCLES INVOLVEMENT

L. F. Valdés Corona[1], M. Arroyo[2], F. J. Zamarripa Molina[3], A. C. Chávez Alanis[4]. *[1]Hospital Angeles Lomas, Rheumatology, Mexico City, Mexico*; *[2]Hospital Angeles Lomas, Internal Medicine, Mexico City, Mexico*; *[3]Hospital Angeles Lomas, Ophtalmology, Mexico City, Mexico*; *[4]Hospital Angeles Lomas, Radiology, Mexico City, Mexico*

Background: IgG4 related disease is a chronic, immune-mediated, fibro-inflammatory condition that may affect nearly any organ, but most common presentations include salivary glands and lacrimal enlargement, orbital disease, pancreatitis, retroperitoneal fibrosis and tubulointerstitial nephritis. Even as IgG4-related disease is increasingly associated with head and neck manifestations, the involvement of scalene muscles hasn't been previously described.
Objectives: Describe an interesting case of IgG4 related disease presenting with scalene muscle and ocular manifestations.
Methods: Case report and clinical imaging
Results: 79-year-old female, with a history of Sjogren syndrome treated with hydroxychloroquine 200mg twice a week, presented with unilateral right blepharoptosis. Physical examination confirmed right eye ptosis, supraorbital soft tissue enlargement, diplopia and limited ocular movement. CT Scan revealed right and left orbit with diffuse enlargement of the right superior rectus, suggesting bilateral dacryoadenitis, and most important it described a pseudotumor of 5.7 cm x 3.2 cm x 6.2 cm infiltrating asymmetrically the lower portion of the left scalene muscle. Lacrimal biopsy and immunohistochemistry revealed IgG4 related disease (dense lymphocytic infiltrate, IgG4+:IgG+ ratio 53% and more than 10 cells/hpf). Serum IgG4 concentration 633 mg/dl (more than 5 times upper limit of normal). Pulmonary embolism was also detected. The patients received treatment with a tapering regime of oral prednisone and mycophenolate mofetil for long term immunosuppression, with adequate response and complete remission of symptoms.
Conclusion: The multiorgan involvement and recently recognized nature of IgG4 related disease, may cause confusion among physicians; leading to misdiagnosis, unnecessary procedures and delay in treatment. It requires a high degree of clinical suspicion to diagnose a IgG4 RD, when presenting with ocular involvement, and even more when it affects organs that are not usually associated with this condition, such as scalene muscles. The diagnosis is supported by pathognomonic histopathological findings, and even as treatment strategies are constantly evolving, glucocorticoids remain as first line treatment.
Whether this finding is related with those observed in the paravertebral band – like soft tissue in the thorax, has to be defined. Also interesting is that in this case, this pseudotumor is in the left side.

AB1281 PRESENTATION, TREATMENT AND PROGNOSIS OF SARCOIDOSIS IN A COHORT OF SPANISH PATIENTS

A. I. Rebollo Giménez[1], L. Sacristán-Bou[2], D. Bellido Pastrana[3], P. Mata Calderón[2], I. Domínguez Osorio[3], I. M. Ordóñez Dios[2], M. Orta Caamaño[2], C. Bujalance Cabrera[2], F. J. Lázaro Polo[2]. *[1]Istituto Giannina Gaslini, Pediatric and Rheumatology Clinic, Genoa, Italy*; *[2]Ciudad Real University General Hospital, Pneumology, Ciudad Real, Spain*; *[3]Ciudad Real University General Hospital, Internal Medicine, Ciudad Real, Spain*

Background: Sarcoidosis is usually a benign disease, but it is described that the lung is the most frequently affected organ and in some cases the disease can progress to pulmonary fibrosis. Systemic corticosteroids, immunosuppressants and/or monoclonal antibodies are used for its treatment. The mortality rate without treatment is 1% to 6%.
Objectives: To establish the frequency of appearance of the stages of radiological involvement in patients diagnosed with sarcoidosis at Ciudad Real University General Hospital (CRUGH) for 4 years, describe the treatment guidelines used and investigate the causes of death.
Methods: Retrospective descriptive study that includes patients treated at Pneumology, Rheumatology and Internal Medicine Services of CRUGH from January 2017 to January 2021. Sarcoidosis diagnosis has been established according to ATS/ERS/WASOG (1999) criteria: compatible clinical and radiological presentation, evidence of non-caseating granulomas and exclusion of other granulomatous disease. The variables have been collected in an anonymized database analyzed by SPSS program.
Results: We have included 47 patients, 24 men and 23 women, with 52.0 ± 14.3 years of age. All presented radiological pulmonary involvement and in 26 cases (55.3%) there were also extrapulmonary manifestations. The most frequent radiological pattern is stage II in 29 cases (67.7%, hilar adenopathies and pulmonary infiltrates); followed by stage I in 16 (34.1%, hilar adenopathies) and only 2 cases presented stage IV (4.2%, fibrosis). Currently, 20 patients (42.5%) are without treatment: 9 (19.1%) have not required it due to hyliomediastinal lymph node involvement without associated symptoms, and 11 (23.4%) achieve remission with oral glucocorticoids [OCG] at doses recommended in clinical guidelines. The other 27 (57.5%) receive these regimens: 10 (21.3%) OCG at usual doses; 11 (23.4%) OCG and conventional immunosuppressants -metrotexate 9 (19.1%), azathioprine 1 (2.1%) and cyclophosphamide 1 (2.1%)-; 3 (6.4%) OCG and antimalarials (hydroxychloroquine); 2 (4.2%) monotherapy with azathioprine; and 1 (2.1%) biological treatment with infliximab. Three patients died (6.4%): one aged 71 due to progression to pulmonary fibrosis (2.1%), another 2 due to pulmonary adenocarcinoma (47 years old) and due to adenocarcinoma of the rectum (81 years old).
Conclusion: The predominant radiological pattern in our cohort is stage II with hilar adenopathies and pulmonary infiltrates. The most used treatment is OCG, as monotherapy (44.7%) or combined (29.4%). The high frequency of cancer mortality stands out.

AB1282 OVARIAN RESERVE IN BEHCET'S DISEASE

Z. Alekberova[1], R. Goloeva[2], M. Cherkasova[2], A. Lila[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, advisory department, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Trobovinflammation Laboratory, Moscow, Russian Federation*

Background: Behcet's disease (BD) is a multisystemic disease of unknown cause. Anti-Mullerian hormone (AMH) is one of the key parameters for assessing reproductive function and ovarian reserve. The levels of AMH correlates with the residual follicular pool in women of reproductive age.
Objectives: To assess AMH levels in BD female patients of child-bearing potential, and analyze the relationship between AMH levels and disease severity, as well as relationship between serum AMH levels and different therapeutic regimens.
Methods: The study group included 45 women with BD (according to ISGBD 1990 and ICBD 2014) aged 20-40 years, and the control group icluded 15 age-matching healthy women. Pts' mean age was 31,3 [27;35] yrs, disease duration 6 [3;8] yrs. 17,8% pts had severe BD according to Ch.Zouboulis classification (due to generalized uveitis, retinal vasculitis and parenchymatous CNS lesions), 37,8% pts had a moderate disease, 44,4% pts had a mild disease with mainly dermal-mucous manifestations. AMH levels was measured using ELISA. AMH reference values ranged within 1.0-10.6 ng / ml. Values <1.0 were interpreted as a decreased ovarian reserve.
Results: The mean levels AMH was 2.5 ng/ml in BD pts, and 3.1 ng/ml in control group, showing no statistical difference. A decrease in ovarian reserve (AMH less than 1.0 ng/ml) was observed with the same frequency 18% in patient's vs. in control group 13%. In the analysis of AMH, depending on the severity of BD, a decrease in ovarian reserve was more often observed in patients with moderate and severe forms of BD.

Table 1. AMH and severe BD

severe	mild, n=20	moderate disease, n=17	severe, n= 8	p
AMH	2,7 [1,6-3,5]	2,5 [1,0-3,7]	1,9 [0,8;6,7]	ns
AMH >1 ng/ml, %	10	23	25	0,02

There are no correlations of levels AMH with treatment of BD.

A decrease in ovarian reserve was noted in two patients under 30 years old, one was 29 years old woman with "Neurobehcet" with two children, and the patient with BB+AS was not married, had no pregnancies, and received colchicine therapy for a long time. Two BD patients with low AMH had no pregnancies - unmarried, all other patients with reduced ovarian reserve had from 1 to 6 children. When analyzing the levels of AMH with the clinical picture and BD therapy, no correlations were found.

Conclusion: The average levels of AMH in women with BD and in the control group did not differ. A decrease in ovarian reserve (AMH less than 1.0 ng/ml) occurred with the same frequency in patients with BD and controls. A decrease in ovarian reserve was more often observed in patients with moderate and severe BD.

AB1283 HOW TO COUNSEL A WOMAN WITH BEHÇET'S DISEASE: RESULTS FROM A MONOCENTRIC COHORT OF WOMEN DIAGNOSED DURING CHILDBEARING AGE

M. Arbrile[1], M. Radin[1], D. Rossi[1], E. Menegatti[1], D. Roccatello[1], S. Sciascia[1]. [1]*University of Turin, Clinical and Biological Sciences, Turin, Italy*

Background: Patients with autoimmune diseases require appropriate pregnancy counceling, as their disease can negatively impact both maternal and fetal outcomes. In regards to Behçet's disease (BD), although commonly diagnosed during the childbearing age, only few studies focused on its impact on gestation, with contradictory results.

Objectives: We aimed to collect new data on BD and its impact on pregnancy by designing a single-center cohort study, reporting the pregnancy and maternal outcomes in BD patients attending the Multidisciplinary Centre for Immunopathology and Rare Diseases at Giovanni Bosco Hospital (Turin, Italy).

Methods: We retrospectively included 26 women diagnosed with BD followed at our center. Out of 26 patients, data from 33 pregnancies in 16 women were collected. Ten patients were never pregnant. Table 1 shows the demographical and clinical characteristics and the pregnancy outcomes of the enrolled patients.

Table 1. Clinical characteristics and pregnancy outcome of the Behçet's disease patients enrolled in the study.

	Patients (tot=31)
Nulliparous; n (%)	10/26 (38,46%)
Primigravida; n (%)	16/26 (61,54%)
Demographics	
Age at BD diagnosis; mean± S.D.	40,56±11,42
Age at first pregnancy; mean ± S:D.	24,86 ± 6,56
Clinical characteristics of BD	
Oral ulcers; n (%)	26/26 (100 %)
Genital ulcers; n (%)	21/26 (80,76%)
Folliculitis; n (%)	15/26 (57,69%)
Erythema nodosum; n (%)	6/26 (23,08%)
Ocular manifestations; n (%)	11/26 (42,31%)
HLA B-51+; n (%)	13/26 (50%)
Pregnancy outcome	
Rate of live births; n (%)	27/33 (81,81%)
Any complications; n (%)	12/33(36,36%)
Early miscarriage before 10 weeks of gestation; n (%)	6/33 (18,18%)
Gestational diabetes; n (%)	3/33 (9,09%)
Placental abruption; n (%)	2/33 (6,06%)
Vaginal bleeding before 20 weeks of gestation; n (%)	1/33 (3,03%)
Worsening of oral and genital ulcerations; n (%) *	2/ 11 (18%)

* This information was available only for 11/33 pregnancies.BD – Behçet's diseaseS.D – Standard deviation

Results: All included patients fulfilled the international criteria for BD (1), with a median age at the time of diagnosis of BD and first pregnancy of 40,56±11,42 and 24,86±6,86 respectively. The frequency of clinical manifestations was oral ulcers (100%), genital ulcers (80,76%), erythema nodosum (23,08%), folliculitis (57,69%), ocular manifestations (42,31%) and HLA B-51+ (50%), respectively. The overall rate of live births was 81,81% (27/33). Twelve women experienced pregnancy complications (36,36%), in particular we report one case of vaginal bleeding before 20 weeks of gestation, six miscarriages before the 10th week of gestation, three cases of gestational diabetes and two placental abruptions. Among the analyzed pregnancies, a worsening of oral and genital ulcerations was observed in the 18% of them, while in the remaining cases a subjective amelioration of aphtosis and other concurrent symptoms was reported by the patients. No systemic flare, worsening of ocular complications and VTE was reported during pregnancy and in the post-partum period.

Conclusion: The results of our study highlight an overall favorable rate of life births in BD women and a positive rate of disease remission in pregnancy. Currently, the studies focusing on pregnancy outcomes in BD are scarce, however it might be appropriate to give a specialized counseling to a BD woman planning for a pregnancy and follow these patients with a multidisciplinary approach.

AB1284 GENDER CHARACTERISTICS OF IDIOPATHIC LOBULAR PANNICULITIS

O. Egorova[1], G. Tarasova[1], A. Datsina[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation*; [2]*Pirogov Russian National Research Medical University, Ministry of Health of Russia, Pirogov Russian National Research Medical University, Ministry of Health of Russia, Moscow, Russian Federation*

Background: Idiopathic lobular panniculitis (ILP) (Weber-Christian disease) is the least studied disease from the group of "systemic lesions of the connective tissue" and is characterized by a multifaceted lesion of the subcutaneous adipose tissue (SAT) of organs.

Objectives: to compare the incidence of clinical and laboratory manifestations of ILP in patients of different sexes in the Russian cohort.

Methods: We examined 67 patients (9 men and 58 women) aged 20 to 76 years with an average duration of the disease 78.91 months [48; 540] with a verified diagnosis of ILP, who were observed at the V.A. Nasonova Research Institute of Rheumatology in 2010-2021. In addition to general clinical examination, determination of the titer of α-1 antitrypsin, liver fractions, amylase, lipase, trypsin, ferritin, creatine phosphokinase, leptin, TNF-α, computed tomography of the chest and pathomorphological studies of induration were carried out.

Results: The peak of the disease in men (55.55%) was detected at 35–45 years old, while in women (38.5%) from 50 to 60 years old. In 55.2% of women, two periods of the development of the disease were identified – from 16 to 25 in 12 patients (32.4%) and from 46 to 60 in 25 patients (67.5%). When analyzing the demographic indicators in patients with ILP, 86.3% were residents of the European part of Russia, no gender differences were found. In 3 men (33.3%) and 22 women (37.9%), ILP was diagnosed within a year. With the disease duration of 1 to 5 years, the diagnosis was confirmed in 44.4% of men and in every third woman. The duration of more than 5 years from the onset of the first symptom to the establishment of a reliable diagnosis of ILP in women was 32.7%, while in men – 11.1% ($p < 0.03$). The nodular form (Nf; 55.5%) and the mesenteric form (Mf; 33.3%) were observed somewhat more often in men than in women, with a tendency to a higher body temperature and a greater number of painful (according to VAS) indurations. In women, Nf was found in 43.1% of cases, plaque form and Mf – in 15.5% each. The infiltrative form (25.8%) was found only in women. Indurations were characterized by a subfebrile temperature, mainly with localization on the thighs (75.8%), upper limbs (51.7%) and trunk (43.1%). Later, in 31 patients (46.2%) (93.5% of them were women), a combination or transition from one form to another was detected, indicating a mixed nature of the disease. Body temperature indices in men were inversely correlated with the duration of the disease ($r = –0.73$; $p < 0.05$). In women, there was a significant association of an increase in body temperature with pain (according to VAS) of the nodes ($p < 0.05$), as well as with the form of the disease ($p < 0.03$). Average ESR data were higher in women (24.50 ± 15.99 mm/h). In men, a high level of CRP (46.2 ± 21.7 pg/ml) was significantly more often observed with Mf ($p < 0.0176$), which correlated with the concentration of TNF-α ($r = 0.72$; $p < 0.05$). Women had a 2.3 times higher leptin content than men ($r = 0.46$; $p < 0.05$). Pathomorphological examination of a biopsy of the skin and SAT confirmed lobular panniculitis (ILP) in all cases.

Conclusion: In the Russian cohort of patients, male gender is associated with a progressive course of the disease, which is the basis for prescribing immunosuppressive therapy for men with ILP at early stages of the disease.

BEHCET'S DISEASE IN RUSSIAN FEDERATION: GENDER RELATED CLINICAL FEATURES

T. Lisitsyna[1], Z. Alekberova[1], G. Davidova[2], T. Reshetnyak[3], E. Nasonov[4]. [1]*V.A. Nasonova Research Institute of Rheumatology,Thromboinflammation, Москва, Russian Federation*; [2]*Moscow Helmholtz Research Institute of Eye Diseases, Retinal Pathology, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology,Thromboinflammation, Moscow, Russian Federation*; [4]*V.A. Nasonova Research Institute of Rheumatology, Scientific Director of the Institute, Moscow, Russian Federation*

Background: In Behcet's Disease (BD) some major organs are more involved in men and have worse outcomes. Gender related clinical features of BD are different in various countries.
Objectives: to describe the gender related clinical features of Russian Federation's cohort of BD patient's.
Methods: This single center cohort study was carried out at the V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia from 1990 to 2021. 560 of BD patients (351 men (62,7%) and 209 (37,3%) women were consecutively enrolled in the study. All the patients met the ICBD (2014). The activity of the disease was determined using a Behcet's Disease Current Activity Form (BDCAF). Clinical features of the BD were compared according to the patient's gender.
Results: Female to male ratio was 1,0: 1,7. The majority of patients were natives of the North and South Caucasus (66,0%) and ethnic Russians (21,6%). Mean (M±SD) age of male and female did not differed at the study inclusion (32,4±9,65 vs 33,8±10,5 years) and at disease onset (22,1±9,67 vs 22,6±10,8 years). The most frequent clinical manifestations were oral and genital aphthosis, skin, ocular and joints involvements. Men had higher BD-activity score (BDCAF) (p<0,001), prevalence of skin (91,1% vs 79,4%, OR=1,57, 95% CI=0,95-2,58, p<0,001), ocular (68,4% vs 48,8%, OR=1,38, 95% CI=0,96-1,96, p<0,001), vascular (venous and arterial thrombosis) involvement (21,4% vs 11,5%, OR=1,26, 95% CI=0,77-2,07, p=0,002), pathergy test (33,3% vs 22,9%, OR=1,19, 95% CI=0,80-1,77, p=0,004) and HLA-B51 (65,0% vs 40,6%, OR=1,53, 95% CI=1,02-2,29, p<0,001) positivity. Male and female did not differ in prevalence of oral and genital aphthosis, joint, neurological, gastrointestinal manifestations (Table 1).

Table 1. BD manifestations in the Russian Federation depending on gender

Characteristics, M±SD; n (%)	Male, n=351	Female, n=209	p
Mean age, yrs	32,4±9,65	33,8±10,5	n/s
Mean age at disease onset, yrs	22,1±9,67	22,6±10,8	n/s
BDCAF, point	7,43±2,23	6,62±2,11	<0,001
Oral aphthosis	338 (96,3%)	204 (97,6%)	n/s
Genital ulcers	245 (69,8%)	146 (69,8%)	n/s
Ocular involvement	240 (68,4%)	102 (48,8%)	<0,001
Skin involvement	320 (91,1%)	166 (79,4%)	<0,001
Positive pathergy test	117 (33,3%)	48 (22,9%)	0,005
Gastro-intestinal involvement	67 (19,1%)	37 (17,7%)	n/s
Neurological involvement	52 (14,8%)	21 (10,0%)	n/s
Vascular involvement	75 (21,4%)	24 (11,5%)	0,002
Joints involvement	230 (65,5%)	137 (65,6%)	n/s
HLA-B5(51) positivity	158 from 243 (65,0%)	71 from 175 (40,6%)	<0,001

Conclusion: Russian Federation's cohort of BD patients did not differ in clinical characteristics from other world regions. Ocular, skin, vascular lesions, positive pathergy test and HLA-B51 positivity are more frequent in men than in women.

BEHCET'S DISEASE IN RUSSIAN FEDERATION: ETHNICITY RELATED CLINICAL FEATURES

T. Lisitsyna[1], Z. Alekberova[1], G. Davidova[2], T. Reshetnyak[1], E. Nasonov[3]. [1]*V.A. Nasonova Research Institute of Rheumatology,Thromboinflammation, Moscow, Russian Federation*; [2]*Moscow Helmholtz Research Institute of Eye Diseases, Retinal Pathology, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Scientific Director of the Institute, Moscow, Russian Federation*

Background: clinical manifestations of Behcet's Disease (BD) determine the prognosis and differ in patients of different ethnicity.
Objectives: to describe the ethnicity related clinical features of Russian Federation's cohort of BD patient's.
Methods: This single center cohort study was carried out at the V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia from 1990 to 2021. 560 of BD patients (351 men (62,7%) and 209 (37,3%) women) were consecutively enrolled in the study. All the patients met the ICBD criteria (2014). The activity of the disease was determined using a Behcet's Disease Current Activity Form (BDCAF). Clinical features of the BD were compared according to the patient's ethnicities.
Results: The majority of patients were natives of the North and South Caucasus (370 (66,0%)) and ethnic Russians (121 (21,6%)), 48 (8,57%) - natives of Central Asia, 12 (2,14%) – Ukrainians/ Moldovans, 6 (1,07%) – Yakuts/ Evenks and 3 (0,53%) - Jews. Mean age of Caucasus and Russians patients did not differ; the Russian were significantly older than Central Asia patients. Patients of different ethnicities did not differ in the BDCAF score. The most frequent clinical manifestations were oral aphthosis and skin involvements for all groups. Joints involvement occurred with a similar frequency in all groups. Genital ulcers were significantly more common in Russians and Caucasus compared to Central Asia patients. Ocular and vascular involvement was more typical for the Central Asia and the Caucasus natives. Gastrointestinal and neurological manifestations were more common for Russians. HLA-B51 positivity was less frequent in the Russians (Table 1).

Table 1. BD manifestations in the Russian Federation depending on ethnicity

Characteristics,	North and South Caucasus, n=370	Russians, n=121	Central Asia, n=48	p
M±SD; n (%)	1	2	3	
Mean age, yrs	32,7±9,74	34,5±11,0	29,9±9,15	P_{2-3}=0,012
Mean age at disease onset, yrs	22,5±9,74	22,8±11,5	18,5±8,98	p_{1-3}=0,011 p_{2-3}=0,027
BDCAF, point	7,27±2,34	6,90±1,85	6,93±1,98	n/s
Oral aphthosis	360 (97,3%)	117 (96,7%)	46 (95,8%)	n/s
Genital ulcers	263 (71,0%)	88 (72,7%)	26 (54,2%)	P_{1-3}=0,015; P_{2-3}=0,017
Skin involvement	324 (87,6%)	101 (83,5%)	40 (83,3%)	n/s
Positive pathergy test	99 (26,7%)	45 (37,2%)	16 (33,3%)	p_{1-2}=0,020
Ocular involvement	232 (62,7%)	58 (47,9%)	34 (70,8%)	p_{1-2}=0,003, p_{2-3}=0,005
Gastrointestinal involvement	59 (15,9%)	33 (27,3%)	7 (14,6%)	p_{1-2}=0,005
Neurological involvement	44 (11,9%)	21 (17,3%)	3 (6,3%)	P_{2-3}=0,046
Vascular involvement	72 (19,5%)	18 (14,8%)	10 (20,8%)	n/s
Joints involvement	246 (66,5%)	83 (68,6%)	27 (56,2%)	n/s
HLA-B5(51) positivity	179 from 251 (71,3%)	28 from 79 (35,4%)	20 from 36 (55,5%)	P_{1-2}<0,001, P_{1-3}=0,044, P_{2-3}=0,034

Conclusion: Behcet's disease is most often detected in natives of the North and South Caucasus, Russians and natives of Central Asia in the Russian Federation's cohort. Differences in the frequency of various clinical manifestations depending on the ethnicity of patients were revealed.

DESIGN OF A GLOBAL PHASE 2/3 RANDOMIZED, PLACEBO-CONTROLLED TRIAL EVALUATING THE EFFICACY AND SAFETY OF RAVULIZUMAB IN ADULTS WITH DERMATOMYOSITIS

L. Cavagna[1], R. Aggarwal[2], N. Iikuni[3], S. Rakhade[3]. [1]*University of Pavia, Department of Rheumatology, IRCCS Policlinico S. Matteo Foundation, Pavia, Italy*; [2]*University of Pittsburgh Medical School, Division of Rheumatology, Pittsburgh, United States of America*; [3]*Alexion, AstraZeneca Rare Disease, Boston, United States of America*

Background: Dermatomyositis (DM) is a rare and life-altering chronic immune-mediated disease characterized by distinct skin rash and/or progressive muscle weakness and other systemic manifestations. Many patients are refractory and/or experience serious adverse effects when treated with currently prescribed medications, including high-dose systemic steroids and immunosuppressive therapies[1-3], which are often prescribed off-label. Therefore, there is a need for new DM treatment options that offer more favorable risk-benefit profiles. The classical complement pathway is implicated in DM pathophysiology, including a close correlation between endothelial deposition of the C5b-9 membrane attack complex (MAC) and organ damage.[4] Treatment with the long-acting anti-C5 monoclonal antibody ravulizumab is associated with immediate, complete, and sustained inhibition of the complement protein C5, which prevents its cleavage to form MAC, and it has proven to be a safe and effective therapeutic approach for multiple complement-mediated diseases.[5]
Objectives: Given the continued unmet need in DM and the evidence implicating the terminal complement pathway in the disease pathophysiology, a global, multi-center double-blind, randomized, placebo-controlled Phase 2 (Part A)/Phase 3 (Part B) trial was designed to evaluate the efficacy and safety of the C5 inhibitor ravulizumab compared with placebo in adults with DM (ALXN1210-DM-310; NCT04999020; EudraCT2021-001200-15).
Methods: A total of 180 adult patients with DM[6] who have active disease with muscle weakness and inadequate responses or intolerances to two or more DM treatments including glucocorticoids will be randomized to receive either intravenous

ravulizumab or placebo, delivered as loading dose followed by maintenance administration once every eight weeks. Different patients will be enrolled in Parts A and B, which each consist of a screening period, a randomized, controlled period (Part A; 26 weeks; Part B: 50 weeks), and an open-label extension period. The primary endpoints are the proportion of patients with a minimal improvement from baseline on the ACR/EULAR Myositis Response Criteria Total Improvement Score (TIS20) at 26 weeks (Part A) and 50 weeks (Part B). In addition, a wide range of key secondary and exploratory outcome measures will be evaluated, including the mean change from baseline in the Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) activity score and a novel participant-reported outcome measure, the Dermatomyositis-Disease Symptoms Questionnaire (DM-DSQ). Safety will be assessed by analyzing the incidence of treatment-related adverse events (TEAEs), including those classified as serious and/or leading to intervention discontinuation.

Results: The ALXN1210-DM-310 trial is currently enrolling patients.

Conclusion: ALXN1210-DM-310 is the first global, multi-center, randomized, placebo-controlled Phase 2/3 interventional trial designed to evaluate the safety and efficacy of a C5 inhibitor in adult patients with DM who continue to have active disease despite treatment with standard medications.

AB1288 FIRST USE OF ETORICOXIB FOR LOBULAR PANNICULITIS

B. Belov[1], O. Egorova[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinal Prevention, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation*

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) are the primary means of controlling chronic pain in many rheumatic diseases and, in particular, in lobular panniculitis (LPn).

Objectives: to evaluate a possibility of effective and safe control of patients with LPn during long-term use of NSAIDs in clinical practice.

Methods: We studied 21 patients (15 women and 6 men, average age 41.2±9.3 years) with LPn who were treated with etoricoxib in a dose of 60 mg/day. Patients' condition was assessed at the time of prescription, after 2 and 4 weeks of therapy, and 4 weeks after discontinuation of treatment (8 weeks from baseline). Localization, prevalence, color and number of affected skin areas and subcutaneous fat were determined during clinical examination. Pain intensity in motion was evaluated by 10-cm Visual Analog Scale (VAS), as well as general health score (GHS) on a 10-cm VAS, pain intensity on the Likert Verbal Rating Scale (VRS) (0-4), number of patients with pain reduction ≥50% from baseline, and patients' assessment of therapy outcome on the Likert VRS (1-5). Adverse reactions (ARs) were evaluated at each visit. General clinical examination included standard diagnostic methods.

Results: In 90% of cases, the affected areas of skin and subcutaneous fat were located on the tibia, mainly on the anterior and medial surface, in 33% – on the hips, in 24% – on the upper extremities, and in 5% – on the torso. Symmetrical rashes occurred in 62% of patients. In 48% of patients the nodes merged into a conglomerate. The fact that more than 50% of the lower leg surface (67%) was affected was directly associated with the number of nodules ($p < 0.001$; $r = 0.60$) and C-reactive protein level ($p = 0.006$; $r = 0.38$). There was a direct correlation between the number of nodules and the duration of LPn ($p = 0.04$; $r = 0.20$) and their tendency to merging ($p < 0.001$; $r = 0.39$). Signs of joint involvement were detected in 14 patients (67%), with predominant involvement of the ankle (67%) and knee (38%) joints. In 29% of the patients, the affected joints were asymmetrical. All patients took Etorax for 4 weeks. Mean pain severity (according to VAS) at baseline, after 2, 4 and 8 weeks was 6.5±1.2; 4.8±1.4; 2.6±1.4; 2.2±1.1 cm (significant difference from baseline in all points, $p<0.05$). Similarly, there was a statistically significant difference in VAS values. The number of patients with moderate/severe pain (Likert scale) decreased from 77.8% to 24.9%, 2.9%, and 2.3%. The number of patients with pain reduction ≥50% from baseline were 12.0%, 65.1%, 81.0%, and 78.5%. A good or excellent rating of the treatment results after 2 weeks was demonstrated by 57.1% and after 4 weeks by 76.1% of patients. ARs were registered in approximately 14.2% of patients, mostly mild dyspepsia (in 5%) and arterial hypertension (in 10%). No severe ARs were reported

Conclusion: Etoricoxib is effective and relatively safe for long-term control of chronic pain in LPn.

AB1289 STUDY DESIGN OF A PHASE 2/3 RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY TO ASSESS THE EFFICACY AND SAFETY OF NIPOCALIMAB, AN FCRN ANTAGONIST, IN WARM AUTOIMMUNE HEMOLYTIC ANEMIA (WAIHA)

I. Murakhovskaya[1], B. Fattizzo[2], D. Cueto[3,4], M. H. Jouvin[3]. [1]*Albert Einstein College of Medicine/Montefiore Medical Center, Department of Hematology and Oncology, Bronx, NY, United States of America*; [2]*Fondazione IRCCS Ca'Granda Ospedale Maggiore Plicilinico, Haematology Unit, Milan, Italy*; [3]*Momenta Pharmaceuticals, Inc, Clinical Development Operations, Cambridge, MA, United States of America*; [4]*Janssen Global Services, LLC, Global Clinical Development Operations, Cambridge, MA, United States of America*

Background: Warm autoimmune hemolytic anemia (wAIHA) is characterized by the destruction of red blood cells (RBCs) by pathogenic autoantibodies which bind to RBCs and lead to their clearance in the spleen and liver. Patients with wAIHA can experience acute worsening of anemia, which can be a medical emergency, and have an increased risk of thromboembolic events and premature death. Nipocalimab is a fully human, aglycosylated, effectorless IgG1 monoclonal antibody that targets the IgG binding site on the neonatal Fc receptor (FcRn) with high affinity. FcRn, which is expressed in endothelial cells, is responsible for recycling IgG into the circulation and for the relatively long half-life of IgG antibodies compared to other Igs. It is expected that nipocalimab, by inhibiting IgG binding to FcRn, will prevent IgG recycling and lower pathogenic IgG autoantibodies that cause many autoimmune diseases including warm autoimmune hemolytic anemia (wAIHA). Nipocalimab has been studied in multiple phase 1 studies in healthy subjects and in a recently completed phase 2 study in subjects with Generalized Myasthenia Gravis (gMG). In the gMG phase 2 study, nipocalimab was well tolerated at doses from 5 mg/kg every 4 weeks to 60 mg/kg every 2 weeks. Treatment with nipocalimab was associated with rapid and durable total serum IgG and pathogenic IgG autoantibody reduction and meaningful clinical response. A statistically significant relationship between IgG autoantibody reduction and clinical benefit was observed. This study provided proof-of-concept evidence that lowering pathogenic IgG autoantibodies can ameliorate the autoimmune condition these antibodies cause.

Objectives: To share the rationale and study design for an adaptive, phase 2/3 multicenter, randomized, double-blind, placebo-controlled study in patients with wAIHA whose aim is to evaluate the efficacy, safety, tolerability, PK, and PD of nipocalimab compared with placebo[1].

Methods: Male or female patients ≥18 years of age who have been diagnosed with primary or secondary wAIHA and have not experienced a sufficient response or have not tolerated currently available treatments will be included in the study. Patients with cold antibody AIHA, cold agglutinin syndrome, mixed type (i.e., warm and cold) AIHA, or paroxysmal cold hemoglobinuria will be excluded. Patients will be randomized 1:1:1 to receive nipocalimab at two different dose schedules or placebo. Following completion of 24 weeks of double-blind treatment, patients may enter an open-label extension period to receive nipocalimab.

Results: The following endpoints will be analyzed:

Primary endpoint: Percentage of participants achieving durable response of improvement in hemoglobin (Hgb).

Main secondary endpoints: Change from baseline in the total score from the Functional Assessment of Chronic Illness Therapy-Fatigue Scale at the end of the double-blind period. Number of participants who attain normal lactate dehydrogenase, normal haptoglobin, and normal indirect bilirubin levels at a minimum of 3 consecutive visits after baseline.

Conclusion: A phase 2 study investigating nipocalimab in patients with gMG provided proof of concept for a phase 2/3 interventional study with nipocalimab in patients with wAIHA. This phase 2/3 study is currently enrolling in the USA and Europe.

AB1290 SOMETIMES IT IS ALL IN THE HEART; CARDIAC INVOLVEMENT IN BEHCET'S SYNDROME

R. Yildirim[1], M. Dinler[1], N. S. Yasar Bilge[1], T. Kaşifoğlu[1]. [1]*Osmangazi University School of Medicine, Rheumatology, Eskişehir, Turkey*

Background: Cardiac involvement is an uncommonly seen but might be a fatal clinical manifestation of Behcet's syndrome (BS), if not recognized early and treated aggressively.
Objectives: Our aim was to retrospectively evaluate the characteristics of cardiac involvement in Behcet's syndrome and investigate possible risk factors.
Methods: 800 patients with BS diagnosis according to International Study Group for Behcet's Disease (ISG) criterias in our center were screened. 14 patients with cardiac involvement were included in this study.
Results: All the patients were male with positive smoking history. The age at the onset cardiac involvement was 32.5 ± 7.8 years. In 3 patients, diagnosis of BS was made simultaneously with cardiac involvement. Types of cardiac involvement were as following; intracardiac thrombosis (ICT) in 8, right coronary artery aneurysm in 2, and myocardial infarction in 4 patients. The majority of ICT was seen in right ventricle followed by right atrium (75% vs 25%). Deep vein thrombosis (DVT) was the most common accompanying other vascular involvement (57%).Thrombophilic factors were studied in 8 patients, whom only 2 cases were found positive for heterozygous factor V Leiden mutation. Cyclophosphamide was the most common used immunosuppressive agent and anticoagulation was used in 9 patients (Table 1).

Table 1. Characteristics of cardiac involvement in BS patients

Male/female, (n), (%)	14 (100%)
Diagnosis age, years (Mean ± SD)	30 ± 7
Age of cardiac involvement, years, (Mean ± SD)	32.5 ±7.8
Smoking history, (n), (%)	14 (100%)
Other vascular involvement, (n), (%)	12 (85%)
-Deep vein thrombosis, (n)	8
-Pulmonary involvement, (n)	4
-Peripheral artery aneurysm, (n)	1
Cardiac involvement patterns	
-ICT, (n), (%)	
• RV	6
• RA	2
-CAA, (n), (%)	2(14.3%)
-AMI, (n), (%)	4(28.6%)
Immunosuppression, (n)	
-Steroid	14
-CYC	9
-AZA	3
-IFN	1
Anticoagulation, (n)	9

ICT; intracardiac thrombosis, RV; right ventricle, RA; right atrium, CAA; coronary artery aneurysm, AMI; acute myocardial infarction, CYC; cyclophopshamide, AZA; azathioprine, IFN; interferon

Conclusion: Most common type of cardiac involvement is pericarditis, whereas intracardiac thrombosis has its unique characteristics (1). Male gender and smoking seems to be major significant risk factors.

AB1291 AGE OF ONSET AND DIAGNOSTIC DELAY IN PATIENTS WITH MONOGENIC AUTOINFLAMMATORY DISEASES AND SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS - DATA FROM THE FEDERAL CENTER IN RUSSIAN FEDERATION

S. Salugina[1], M. Kaleda[1], E. Fedorov[1]. [1]*V.A.Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: Autoinflammatory diseases (AIDS) are a group of rare monogenic and multifactorial diseases manifested by systemic inflammation, organ disorders, the development of complications, primarily amyloidosis, and possible death without timely targeted therapy. Rapid diagnosis contributes to the early appointment of treatment, prevention of the development of organ damage and improvement of prognosis in such patients.
Objectives: To establish the age of the onset and the duration of the delay of diagnosis in patients (pts) with monogenic AIDS (m AIDS) and systemic juvenile idiopathic arthritis (sJIA) according to the Federal Rheumatology Center.
Methods: 273 pts were included in the study for the period from 2007 to 2021, 158 of them with mAIDS: FMF - 75, CAPS - 50, TRAPS - 28, HIDS/MKD - 5; 115 pts with sJIA.
Results: The age of pts with mAIDS ranged from 6 months to 65 y.o. (120 children and 38 adults), among pts with sJIA there were only children aged 12 months to 17 y.o. Most of the pts with CAPS, TRAPS, HIDS/MKD were female (62.4%), as with sJIA (57.4%). FMF was more often affected by male persons (56.6%). The age of the onset of mAIDS ranged from 0 to 53 y.o., sJIA - from 4 months to 15 y.o., was the smallest in pts with CAPS and HIDS/MKD. 33.5% pts with mAIDS had the onset of the disease from birth or within the first year of life, more often with CAPS and HIDS /MKD, in the first decade of life in half of the pts (52.5%), more often in FMF and TRAPS, from 10 to 18 years - 8.2%, in adulthood - 5.7%. In pts with sJIA, the onset of the disease was mainly in the first 5 years of life – 69 (60%), from 5-10 years – 38 (33%), rarely in the first year of life and after 10 years of age (6.95%). The duration of the disease at the time of diagnosis ranged from 1 month to 48 years in FMF pts, from 1 month to 46 years with CAPS, from 3 months to 59 years with TRAPS, from 3.5 to 16.5 years with HIDS/MKD, from 3 weeks to 7.8 years with sJIA. Within 1 year the diagnosis was established in 15.2% of children with mAIDS, in 12.2% with sJIA, in the first 5 years of the disease in 35.4% and 15.6% respectively. The delay in diagnosis for more than 5 and 10 years was observed in 24.1% and 25.9% of pts with mAIDS, practically did not occur in sJIA. The least delay in diagnosis was noted in pts with FMF.
Conclusion: Most of the pts with mAIDS had the onset of the disease in the first 5-10 years of life, an earlier age of onset was noted in pts with CAPS and HIDS/MKD. To date, the delay in diagnosis in pts with mAIDS remains very long and reaches decades, especially with CAPS, TRAPS and HIDS/MKD. In pts with sJIA, the diagnosis was established faster, according our opinion a later diagnosis is associated with a polycyclic course of the disease. Earlier diagnosis and the appointment of targeted therapy are needed, which will help to avoid complications, improve the prognosis and quality of life of pts.

AB1292 CHARACTERISTICS OF UVEITIS IN BEHCET'S SYNDROME; A RETROSPECTIVE ANALYSIS OF 109 PATIENTS

R. Yildirim[1], M. Dinler[1], N. S. Yasar Bilge[1], T. Kaşifoğlu[1]. [1]*Osmangazi University School of Medicine, Rheumatology, Eskişehir, Turkey*

Background: Uveitis is still an important cause of morbidity leading to vision loss in Behcet's syndrome (BS).
Objectives: Our aim in this study was to retrospectively evaluate characteristics of uveitis, long term complications, and its association with the other components of BS.
Methods: 800 patients with BS diagnosis according to International Study Group for Behcet's Disease (ISG) criterias in our center were screened and among those, data of 109 patients with BS-related uveitis were included in this study.
Results: The overall prevalence of uveitis was found 13% among all BS population. Majority of BS-related uveitis were male (65,1%/34,9%). Mean age for BS diagnosis and onset of uveitis were found 28 ± 8,48 and 27 ± 8,42 years. In this group, uveitis developed before BS diagnosis in 33% of patients,

Table 1.

	FMF	CAPS	TRAPS	HIDS/MKD	sJIA
Age (me, IQR) y	10,5[6,0;15,4]	13[7,0;31,5]	9,0[7,9;14,5]	9,0[5,0;17]	4,5[2,8;7,6]
Age of onset	3[1,5;5]	1,0[0,15;7,0]	4,0[1,0;7,1]	0,5[0,4;1,5]	4,2[2,1;6,75]
(me, IQR), y	18 (24%)	24(48%)	8 (28,6%)	3 (60%)	8 (6,95%)
≤1y	46 (61,3%)	18 (36%)	17 (60,7%)	2 (40%)	99 (86,1%)
>1-10y	7 (9,3%)	5 (10%)	1 (3,6%)	-	8 (6,95%)
>10-18y	4 (5,3%)	3 (6%)	2 (7,1%)	-	-
>18y					
Delayed diagnosis (me, IQR), y	10,5[6,0;15,4]	13[7,0;31,5]	9,0[7,9;14,5]	9,0[5,0;17]	0,25[0,1;0,5]
≤1y	11 (14,7%)	9 (18%)	4 (14,3%)	-	14 (12,2%)
>1-5y	30 (40%)	12 (24%)	12 (42,9%)	2 (40%)	18 (15,6%)
>5-10y	20 (26,7%)	11 (22%)	6 (21,4%)	1 (20%)	1 (0,9%)
>10y	13 (17,3%)	18 (36%)	8 (28,6%)	2 (40%)	-

whereas 44% were diagnosed at onset of uveitis.The frequency of this population was estimated 6% among all BS patients,. Characteristics of uveitis were as following; unilateral (45/99), bilateral (54/99), anterior (12), posterior (30), panuveitis (30), retinal vasculitis (9) and not defined (9). 25 patients experienced only one attack, whereas more than one attack was seen in 45 patients during follow up. 74 patients whose complications data was available, cataract, maculopathy, glaucoma, and optic atrophy developed in 10, 7, 6 and 3 patients, respectively. Vision loss was seen in 8 patients as partial, in 28 as total (Table 1).

Table 1. Characteristics of uveitis, complications and other components of BS patients

Male/female, (n), (%)	71/28 (%65,1/%34,9)
Age at diagnosis, years (Mean± SD)	28 ±8,48
Age at uveitis, years (Mean± SD)	27 ±8,42
Uveitis-Behcet's diagnosis relationship, (n)	109
-Before, (n), (%)	36 (%33)
-At the time of, (n), (%)	48 (%44)
-After, (n), (%)	25 (%23)
Characteristics of uveitis, (n)	99/109
-Unilateral/Bilateral	45/54
-Anterior	12
-Posterior	30

-Retinal vasculitis	9
Complications, (n)	26/74
-Maculopathy	7
-Glaucoma	6
-Cataract	10
-Optic atrophy	5
-Vision loss (partial/total)	8/28

BS; Behcet's syndrome

Conclusion: Male gender and onset at young age are important risk factors for uveitis development. Uveitis is seen as a critical component for diagnosis. Complications, despite declining in the era of biologics use, are still a major concern. Retrospective design and missing data are limitations of this study.

AB1293 INTRATHECAL INJECTION OF METHOTREXATE COMBINED WITH DEXAMETHASONE FOR COGAN SYNDROME WITH NEUROLOGICAL INVOLVEMENT: A CASE REPORT

J. Hu[1], H. Du[1], J. Su[1], R. Wu[1], J. Zhu[1], T. Wu[1]. [1]*Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Department of Rheumatology and Immunology, Chengdu, China*

Background: Cogan syndrome (CS) is a rare autoimmune disease, mainly occurring among young people, with an incidence rate of <0.11/100000 (100000). CS is mainly characterized by interstitial keratitis, visual loss associated with cochlear vestibular involvement and Meniere type vertigo. It usually involves all systems of the body, and about 10% to 13% of cases have nervous system involvement. Fewer than 400 cases have been reported worldwide (*1*). Glucocorticoid is mainly used in acute attack as the basis of treatment, the effect was not satisfactory(*2*). Here, we report a case of CS with nerve injury as the main manifestation, which was successfully treated by intrathecal injection of methotrexate combined with dexamethasone.

Objectives: CS often involves multiple systems throughout the body and has a poor clinical prognosis. From a review of our patient's treatment experience, intrathecal methotrexate combined with dexamethasone may be an effective treatment modality for CNS involvement in patients with refractory recurrent Cogan syndrome.

Methods: The clinical manifestation, laboratory test, treatment, and outcome were described.

Results: A 31-year-old man presented with recurrent bimanual joint pain for 2 years, after which the patient developed interstitial keratitis, hearing loss and was diagnosed with CS. The patient received treatment with glucocorticoid, cyclophosphamide, methotrexate, tacrolimus, leflunomide, mycophenolate mofetil, hydroxychloroquine, adalimumab. The joint pain was improved, but the headache, dizziness, tinnitus and hearing impairment were significantly aggravated, and syncope occurred. Cerebrospinal fluid examination for lumbar puncture on admission of the patient showed CSF pressure > 185 mmH_2O, CSF microprotein 1.10 g/l, and CSF nucleated cell count 120x10^6 /L. At the beginning, we successively treated the patient with methylprednisolone (40 mg, QD), gamma globulin (10 g, QD), methotrexate (20 mg, QW) and cyclophosphamide (100 mg, QOD), but the effect was not satisfactory. After excluding infection, we treated this patient with intrathecal methotrexate 10 mg combined with dexamethasone 10 mg, and the patient's symptoms of dizziness, headache, and tinnitus improved significantly, and his hearing did not decline significantly any more. The patient received a total of seven intrathecal injections (cumulative methotrexate 60 mg + dexamethasone 65 mg) during the subsequent 6 months. His dizziness, headache, tinnitus and other neurological symptoms improved significantly, no further syncope, fever. CSF protein quantification and the number of CSF nucleated cells decreased significantly.

Conclusion: CS patients are often accompanied by multisystem injuries, so it is essential to correctly identify CS and provide appropriate treatment as soon as possible. For patients with neurological involvement who do not respond to treatment with glucocorticoids and immunosuppression, intrathecal methotrexate combined with dexamethasone may be considered as a treatment option for CS in the future.

AB1294 CO-OCCURRENCE OF IGG4 RELATED DISEASE AND OTHER SYSTEMIC IMMUNO-MEDIATED DISORDERS.

V. Batani[1,2], M. Lanzillotta[1], F. Chiabrando[1], G. Mancuso[1], J. Mahajne[1], L. I. Belli[1], L. Dagna[1], E. Della Torre[1]. [1]*Vita-Salute San Raffaele University, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy*; [2]*University of Verona, Medicine - Unit of Immunology, Verona, Italy*

Background: IgG4-related disease (IgG4RD) is a fibroinflammatory disease with unique clinical and pathophysiological features. According to the recently released Classification Criteria, the presence of other concomitant immunological disorders (OID) represents an exclusion criterion for the classification of IgG4RD (1). Rigorous application of the Classification Criteria, however, can lead to misdiagnosis because our increasing appraisal of IgG4RD indicates that this condition may coexists with OID (2).

Objectives: To describe IgG4RD presentation in the context of OID.

Methods: IgG4RD was diagnosed based on definitive histological findings. OID were diagnosed based on specific classification/diagnostic criteria.

Results: In six out of 234 (3%) patients IgG4RD occurred in accompaniment with OID, including two patients with sarcoidosis (33%), two with granulomatosis with polyangiitis (33%) one with eosinophilic granulomatosis with polyangiitis (16%) and one with Takayasu arteritis (16%). In three cases IgG4RD preceded OID (Table 1).

Conclusion: Our data demonstrate that IgG4RD can occur in overlap with OID, especially granulomatous diseases. Further research is needed to define whether this clinical scenario is associated with different pathological bases and long-term outcomes.

TREATMENT OUTCOMES OF ADULT-ONSET STILL'S DISEASE PATIENTS WITH BIOLOGICAL THERAPY

Y. Erez[1], T. Demirci Yildirim[2], M. Birlik[2], G. Can[2], F. Onen[2], İ. Sari[2]. *[1]Dokuz Eylul University School of Medicine, Division of Rheumatology, İzmir, Turkey*; *[1]Dokuz Eylul University School of Medicine, Division of Rheumatology, İzmir, Turkey*

Background: Adult-onset Still's disease (AOSD) is a rare systemic inflammatory disorder with heterogeneous distrubition (1). Due to rarity of AOSD and limited controlled study about efficacy of biologic treatment in AOSD, management of refractory AOSD patients poses several challenges.

Objectives: The aim of this study to investigate clinical characteristics and treatment outcomes of AOSD patients who receive biological therapy.

Methods: Patients were identified who met Yamaguchi classification criteria between January 2010 and December 2021 from our database. AOSD patients treated with biologic treatment were included in this study. Demographic data, clinical features and treatment characteristics were recorded.

Results: 49 AOSD patients were identified from database. 9 AOSD patients with biologic therapy (7 female, mean age 42.3±19) were included in this study. Mean age at diagnosis was 31.5± 16.7 and mean follow-up period was 9.3± 5.5 years. Median drug retention duration was found 95 (5-150) months. It was established that all patients used high dose steroid at diagnosis and 3 (33.3%) out of them received pulse steroid therapy. Initial therapy was methotrexate for all patients and leflunomid was used secondly as monotherapy or combination therapy after methotrexate inefficacy. It was observed that indication for biologic therapy was arthritis and systemic inflammatuar symptoms in 5 patients. 4 patients was initiated biologic therapy for refractory arthritis without systemic inflammation findings. First biologic agents were tocilizumab and etanercept in 3 patients, infliximab and anakinra in 2 patients. It was shown that biological therapy was switched in 3 patients due to inefficacy and 2 patients because of side effects. Allergic reaction developed in 2 patients treated with infliximab and infliximab switched to adalimumab and etanercept. Biological therapy was discontinued in 2 patients due to remission, and patients remained in remission after cessation of biological agent. None of patients had serious infection. Hemophagocytic syndrome was developed in only one patient during disease course.

Conclusion: According to our cohort, one of five AOSD patients received biological therapy during follow-up. Our results revealed that the need for biologic therapy during the course of the disease is not uncommon in AOSD, and that biologic therapy is essential for maintaining remission in resistant patients.

LONG-TERM EXPERIENCE OF THE THERAPY WITH INTERLEUKIN-1 INHIBITORS IN MONOGENIC AUTOINFLAMMATORY SYNDROMES AND SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN REAL-LIFE PRACTICE OF RHEUMATOLOGISTS IN SINGLE FEDERAL CENTER

S. Salugina[1], M. Kaleda[1], E. Fedorov[1], I. Nikishina[1], A. Torgashina[2]. *[1]V.A.Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; *[2]V.A.Nasonova Research Institute of Rheumatology, Laboratory of Intensive Therapy Methods, Moscow, Russian Federation*

Background: Autoinflammatory diseases (AIDs) are a heterogeneous group of rare genetically determined conditions. Biologics (B) are used, especially inhibitors of interleukin 1 (iIL-1), in the treatment of the most common monogenic AIDs (mAID) – FMF, TRAPS, HIDS/MKD, CAPS. IIL-1 has shown high efficiency and led to significant progress in the treatment of these patients (pts). Currently, iIL1 are the first-line drugs for mAIDs therapy, primarily CAPS. In pts with systemic juvenile idiopathic arthritis (sJIA) IL-1 inhibitors are also successfully used in the first or second line of therapy along with IL-6 inhibitors.

Objectives: To evaluate in the real clinical practice the frequency of prescribing, efficacy and safety of IL-1 therapy in pts with mAIDS and sJIA according to the Federal Rheumatology Center.
Methods: A retrospective study from 2013 to 2021 included 66 pts who were prescribed iIL-1. Among them 45 pts with mAIDS: FMF - 8, CAPS - 25, TRAPS - 10, HIDS/MKD – 2, 21 pts had sJIA. Canakinumab (CAN) was administered subcutaneously at the dose of 2-5mg/ kg or 150mg every 4-8 weeks, anakinra (ANA) - subcutaneously at the dose of 1-5mg/ kg or 100mg daily.
Results: Among pts with mAIDS 45 received iIL-1. The age of pts ranged from 1.5 to 44 years, the median (Me) age was 9.5[6.9;17] years. Female pts predominated (60%). The median age at onset was 0.5 [0;4] years (0 - 35 y). The median duration of the disease was 7.5 [3.9;15.1] years (3 months to 44 years). 35 pts received CAN, 10 - ANA. Both drugs showed significant positive dynamics with a complete response in 40 (88.9%), a partial response in 5 (11.1%), mainly due to serious neurological and cognitive impairments in 2 pts with CINCA/NOMID, sensorineural hearing loss in 3 adult pts with MWS, as well as amyloidosis in 1. In 7 pts with CAPS who received ANA as first biologic treatment, after achieving a reliable positive response, switching to CAN was performed while maintaining full efficacy. It was possible to discontinue the glucocorticoids (GC) in all pts. In 2 pts with CINCA/NOMID (1), MWS (1) due to insufficient efficiency the interval between injections of CAN was reduced from 8 to 4 weeks. The duration of use of CAN in pts with mAIDS ranged from 6 months to 12 years, ANA – 2 months to 12 years, 13 pts (28.9%) have been receiving therapy for 5 years or more. The age of pts with sJIA ranged from 3 to 17 years, Me 8,15 [5,3; 12,7] years. The age of the onset varied from 4 months to 12 years, Me 3,1 [1,8; 5,7] years. Female pts predominated (61,9%). 20 pts received CAN (18 after secondary inefficiency/infusion reaction of tocilizumab (TCZ), 2 had previous experience of 3 B: TCZ-etanercept-adalimumab, TCZ-abatacept-adalimumab). 1 patient received ANA. The duration of CAN treatment was from 5 months to 4.5 years. Among pts with sJIA who received CAN, secondary inefficiency with discontinuation was observed in 6 (28,6%) (10-25 months after treatment initiation), and in 1patient who received anakinra for 8 months. The tolerability of therapy was generally good. We have not observed any SAE in the treatment of iIL-1. All pts are continue taking medications.
Conclusion: Among the B iIL-1 are used in most pts with mAIDS, these are currently first-line drugs, especially for CAPS and TRAPS. They have high efficiency and good tolerance for long-term use. While among pts with sJIA there is a high frequency of secondary inefficiency and discontinuation, which, however, may be due to the late timing of iIL-1 treatment initiation. As a test of administration, and base on the concept of window of opportunity in treatment sJIA pts it is possible to use short-acting iIL-1 (ANA) with switch to CAN as a drug with a prolonged duration of action.

AB1297 EVALUATION OF POSSIBLE RISK FACTOR OF PULMONARY EMBOLISM IN SARCOIDOSIS PATIENTS

B. Ruaro[1], P. Confalonieri[1], C. Torregiani[2], S. Pichierri[2], M. Confalonieri[1], F. Salton[1]. [1]*Department of Pulmonology, University of Trieste, Trieste, Italy*; [2]*Department of Pulmonology, University Hospital of Cattinara, Trieste, Italy*

Background: Some studies reported a correlation between sarcoidosis and an increased risk of pulmonary embolism (PE) [1,2].
Objectives: To assess possible risk factors of PE in sarcoidosis patients.
Methods: We enrolled 260 sarcoidosis patients (170 females and 90 males; mean age at diagnosis 46 ± 9), after giving written informed consent. We perform clinical evaluations, laboratory tests and radiology features.
Results: Our study population included 20 sarcoidosis patients with PE (14 females and 6 males; mean age at diagnosis 45 ± 10), diagnosed by lung scintigraphy and 240 sarcoidosis patients without PE (170 females and 70 males; mean age at diagnosis 46 ± 11). There was a significant increase of the presence of antiphospholipid antibodies in the sarcoidosis group with pulmonary embolism (55%) than in group without PE (9%) (p-value<0.01). There was no statistically significant difference between the two groups on smoking habit, obesity, treatments and hereditary thrombophilia frequency (p > 0.05, respectively).
Conclusion: This study demonstrated an increased of antiphospholipid antibodies positivity in sarcoidosis patients with pulmonary embolism. Furthermore, we propose screening for these antibodies
in all sarcoidosis patients.

AB1298 AL-AMYLOIDOSIS MIMICKING IGG4-RELATED DISEASE

B. Chalcev[1], A. Torgashina[1], E. Sokol[1], J. Khvan[1]on behalf of Laboratory of Rare Rheumatic Diseases and Primary Sjögren's Syndrome. [1]*V.A. Nasonova Research, Laboratory of Rare Rheumatic Diseases and Primary Sjögren's Syndrome, Moscow, Russian Federation*

Background: Hematological diseases such as multiple myeloma (MM) and POEMS-syndrome can be accompanied by high serum IgG4 level and thus mimic an IgG4-related disease (IgG4-RD) [1, 2]. However, there are no descriptions of AL-amyloidosis with increased secretion of IgG4 in the literature.
Objectives: to present a clinical case of AL-amyloidosis mimicking IgG4-RD.
Methods: At the age of 42, patient S. developed nasal congestion, and 2 years later bilateral symmetrical swelling of submandibular salivary glands developed. Chest CT scan revealed hydrothorax and pericarditis, interstitial changes in both lungs and intrathoracic lymphadenopathy. According to blood tests, ANF, RF and CRP were within normal values, an increase in the serum IgG4 (32.9 g/l) and IgG (34.1 g/l) levels was detected, and the patient was admitted to our clinic with suspicion of IgG4-RD.
Results: On examination, we noticed a symmetrical enlargement of submandibular salivary glands and macroglossia. The patient also complained of tingling in the fingers, we performed electroneuromyography and revealed bilateral carpal tunnel syndrome. According to the immunofixation of blood and urine proteins, IgG-lambda paraproteinemia (18,3 g/l) and a trace amount of Bence-Jones-lambda protein in the urine were detected. AL-amyloidosis was suspected and a biopsy of the submandibular salivary gland was performed, followed by Congo red staining and darkfield microscopy that confirmed amyloidosis (Figure 1). There were no signs of IgG4-RD (storiform fibrosis or obliterative phlebitis) in the biopsy specimens. Echocardiography revealed thickening of the interventricular septum and hypertrophy of the ventricular myocardium. MM and other malignancies were excluded on the basis of bone marrow trephine biopsy and PET-CT (also revealed severe hepatomegaly). The diagnosis of IgG4-secreting AL-amyloidosis affecting salivary glands, tongue, heart, lungs, liver, nervous system was made and polychemotherapy was started, the patient's further life remained unknown.

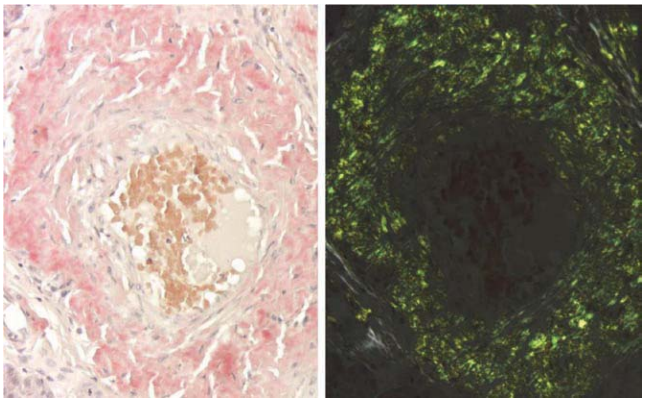

Figure 1. Congo red staining and darkfield microscopy demonstrating amyloid deposits.

Conclusion: AL-amyloidosis can be accompanied by high serum IgG4 level and mimic IgG4-RD. The serum level of IgG4 should not be used as a criterion for IgG4-RD, and in all cases of suspected IgG4-RD the diagnosis should be confirmed morphologically.

AB1299 DIFFERENCES IN THE CLINICAL SPECTRUM OF HAPLOINSUFFICIENCY OF A20 (HA20) CASES DIAGNOSED DURING ADULTHOOD

S. Amikishiyev[1], N. Aliyeva[1], M. Bektas[1], N. Koca[1], L. Soltanova[2], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], A. Gül[1]on behalf of The Team of Istanbul Faculty of Medicine, Istanbul University. [1]*Istanbul Faculty of Medicine, Istanbul University, Division of Rheumatology, Istanbul, Turkey*; [2]*Istanbul Faculty of Medicine, Istanbul University, Department of Internal Medicine, Istanbul, Turkey*

Background: Haploinsufficiency of A20 (HA20) is a monogenic autoinflammatory disease caused by heterozygous loss-of-function mutations in *TNFAIP3* gene and characterized by Behçet disease (BD)-like manifestations such as mucocutaneous, articular, gastrointestinal, ocular symptoms as well as recurrent fever, elevated acute-phase reactants during relapses; and it usually starts during early childhood. Autoimmunity is another component of HA20 with autoantibodies and variable clinical features resembling systemic lupus erythematosus (SLE) and other autoimmune diseases.
Objectives: We herein present three cases of HA20 with different clinical features and diagnosed during adulthood.
Methods: We used the Ion Torrent platform for deep sequencing.
Results: Case 1: A 51-year old woman diagnosed with BD because of oral and genital aphthous ulcers, arthralgias, erythema nodosum, and pathergy positivity starting from age of 40 in 2012. She developed sudden vision loss (diagnosed with bilateral optic neuropathy), sixth nerve palsy, and entrapment neuropathies in the lower limbs in 2014; and she had flares of neurologic findings between 2014-2020. The only laboratory abnormality was elevated acute-phase reactants, and no pathologic finding was reported for cranial MRI. Pathological examination of sural nerve biopsy revealed chronic inflammatory demyelinating polyneuropathy (CIDP). She received adalimumab and then tofacitinib, and her treatment was switched to certolizumab and IVIG (30 g/6 weeks) in 2020. At the last visit, she was asymptomatic with normal acute phase response, and her examination revealed normal eye movements.
Case 2: A 33-year old woman was followed for 12 years with the diagnosis of SLE, based on fever, photosensitivity, alopecia, polyarthritis, serositis, positive anti-nuclear antibody (ANA) at a titer of 1:1280 with a homogeneous pattern, positive anti-dsDNA, anti-Sm, anti-Sm/RNP, and lupus anticoagulant test, and leukopenia, lymphopenia, hypocomplementemia in 2008. She developed shrinking lung syndrome and Jaccoud arthropathy during the disease course. She received several drugs including corticosteroids, hydroxychloroquine, cyclophosphamide, mycophenolate mofetil, belimumab, rituximab, tocilizumab, abatacept, tofacitinib because of fever, arthritis, skin rash, increased acute-phase reactants, pancytopenia, anti-dsDNA positivity. Her fever, red arthritis attacks with high CRP values did not respond, and after the genetic diagnosis of HA20, anakinra was added to treatment. Due to the high dose anakinra requirement, her treatment was switched to canakinumab (150 mg/2 week), and at the last visit, her attacks were significantly reduced.
Case 3: A 44-year old woman was evaluated because of recurrent prolonged >38°C fever attacks (2 days-2 weeks duration), arthritis of the elbow, wrist, knee joints, and high acute phase reactant in 2004. She did not have a history of recurrent oral and genital aphthous ulcers, intermittent periorbital edema, rash, any ocular symptoms, or sensorineural hearing loss. ANA, RF, anti-CCP, and MEFV gene mutation were negative on admission. PET-CT demonstrated FDG uptake in the wall of the ascending aorta, aortic arch, and descending aorta in 2011. She had used colchicine in 2004, etanercept between 2009 and 2010, anakinra in 2011, tocilizumab in 2012, and canakinumab in 2013. She repeatedly received IV methylprednisolone pulse therapy, but she experienced a relapse of fever when she reduced the dose of methylprednisolone to <8 mg/day. Her knee arthritis did not respond to adalimumab, and she is currently on infliximab treatment since 2019 with a Daily methylprednisolone dose of 8-12 mg.
Conclusion: HA20 can be diagnosed even in adult patients, and the clinical picture of presented cases suggests that monogenic autoinflammatory disorders including HA20 should be suspected in any patient with flares of described manifestations along with strong acute phase response even in adults. Response to corticosteroids and targeted treatments may also be variable.

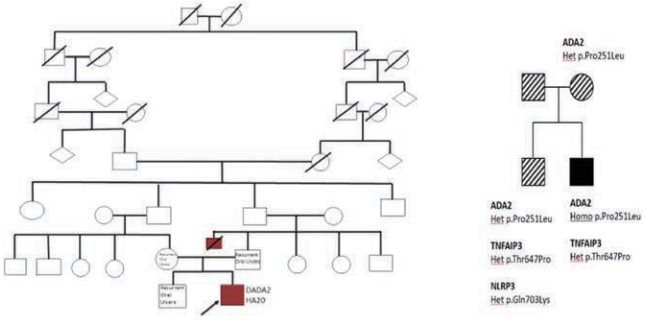
AB1300 AA AMYLOIDOSIS IN A PATIENT WITH MUTATIONS IN BOTH ADA2 AND A20 GENES

S. Amikishiyev[1], B. Ince[1], M. Bektas[1], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], A. Gül[1]on behalf of The Team of Istanbul Faculty of Medicine, Istanbul University. [1]*Istanbul Faculty of Medicine, Istanbul University, Division of Rheumatology, Istanbul, Turkey*

Background: Adenosine Deaminase 2 Deficiency (DADA2) and Haploinsufficiency of A20 (HA20) are two recently described monogenic autoinflammatory diseases (AID). The uncontrolled inflammatory response has been associated with an increased risk of AA amyloidosis in other AID, but there are only two reported patients with DADA2-related amyloidosis so far.[1,2]
Objectives: We herein report a patient with AA amyloidosis and AID associated with both DADA2 and HA20.
Methods: We used the Ion Torrent platform for deep sequencing.
Results: Case: A 20-year-old male patient born to consanguineous parents (Figure 1), was admitted to our hospital with fever and abdominal pain in June 2014. Peritonitis, hepatomegaly, and a palpable non-tender mass in the right axillary cavity were detected in physical examination, and his laboratory investigations revealed neutrophilic leukocytosis, high acute phase reactants (APR), and nephrotic range proteinuria. CT angiography showed multiple thrombotic microaneurysms in celiac, splenic, superior, and inferior mesenteric and bilateral renal arteries; and MRI documented an additional aneurysm in anterior communicating artery. No finding was detected in hepatitis serology. He had been diagnosed with polyarteritis nodosa, and prednisolone and azathioprine were started. Renal histopathology confirmed the AA amyloidosis. Genetic analysis revealed no pathogenic *MEFV* variant. Colchicine and anakinra 100 mg/day were added to his treatment. He experienced 1-2 abdominal episodes annually between 2014-2019, and APR were normal between attacks. In March 2019, he was admitted to the hospital because of abdominal pain, high APR, and iron deficiency anemia. No gross pathology was observed in endoscopic examination of gastrointestinal tract, but histopathological investigation of the gastric mucosa and terminal ileum showed AA amyloidosis. Multiple aneurysms were detected in renal arteries with angiography. Deep sequencing of the targeted genes revealed homozygous p.Pro251Leu in ADA2 gene and heterozygous p.Thr647Pro in TNFAIP3 gene encoding A20, confirming the molecular diagnosis of DADA2 and HA20. The patient described oral recurrent aphthous ulcers starting from his childhood, but he had no uveitis or genital ulcers. His mother and brother also had recurrent oral aphthous ulcers. Genetic analyses showed heterozygous p.Pro251Leu variant in ADA2 gene in his mother, and heterozygous p.Gln703Lys variant in NLRP3 gene as well as heterozygous p.Thr647Pro TNFAIP3 variant and heterozygous p.Pro251Leu ADA2 in his brother. An improvement in his findings was observed within 2 weeks after switching his anakinra to adalimumab 40 mg every other week. At his last visit in February 2021, the patient had no complaints with normal APR, and urinalysis analysis showed 200 mg/day proteinuria, which was regressed from 3 g/day.
Conclusion: This is the first case of AA amyloidosis associated with ADA2 and TNFAIP3 (A20) variants. ADA2 p.Pro251Leu variant has previously been validated as likely pathogenic, and our patient's clinical findings were mainly compatible with DADA2. On the other hand, TNFAIP3 gene p.Thr647Pro mutation has been reported as

Figure1: Pedigree of family and results of genetic analyses



variant of unknown significance, but it may have contributed to the DADA2 associated increased risk of amyloidosis. A better response of proteinuria to adalimumab treatment indicates superiority of anti-TNFs in DADA2 patients compared to anti-IL-1 drugs.

AB1301 DETERMINING THE RELATIONSHIP BETWEEN SERUM INTERLEUKIN 33 LEVELS AND CLINICAL FEATURES OF THE DISEASE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

A. Demirezen[1], A. Avanoglu Guler[2], H. Karadeniz[2], D. Yildirim[2], H. Küçük[2], M. Kavutcu[3], M. A. Ozturk[2], A. Tufan[2]. [1]*Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey*; [2]*Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*; [3]*Gazi University Faculty of Medicine, Biochemistry, Ankara, Turkey*

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent fever, serositis, arthritis and erysipelas-like erythema caused by mutations over activating caspase-1. As Interleukin (IL)-1 beta, IL-33 is a nuclear cytokine from IL-1 family which is activated by caspase-1. IL-33 is known to take part in pathogenesis of several rheumatic diseases.
Objectives: The aim of this research is determining the relationship between serum IL-33 levels and clinical features of the disease in patients with FMF disease.
Methods: The research involved 54 FMF patients and 29 healthy volunteers. Serum IL-33 levels were evaluated in both patients and healthy individuals, and its relationship between clinical and laboratory features of FMF.
Results: 28 out of 54 patients (%51.8) had favorable response to colchicine while 26 patients (%48.2) had colchicine resistant disease. FMF patients had lower IL-33 levels compared to healthy control group (p= 0.06). There were no difference between colchicine responsive and resistant patients (p=0.12) and no association was found between clinical features and serum IL-33 levels. Additionally, IL-33 did not correlated with C-reactive protein and disease activity assessed by autoinflammatory disease activity index.
Conclusion: No association was found between serum IL-33 levels and FMF disease features and laboratory findings. This may be due to the small size of our patient group, the involvement of IL-33 in tissue homeostasis as well as inflammation, and the use of higher doses of colchicine in the resistant disease group than in the remission group. Additional research is needed to determine IL-33's role in FMF pathogenesis and its relationship with clinical and laboratory features.

AB1302 EVALUATING THE CLINICAL UTILITY OF PATIENT ACCEPTABLE SYMPTOM STATE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

A. Demirezen[1], A. Avanoglu Guler[2], H. Karadeniz[2], D. Yildirim[2], H. Küçük[2], M. A. Ozturk[2], A. Tufan[2]. [1]*Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey*; [2]*Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever, serositis, arthritis and erysipelas-like erythema. Patient acceptable symptom state (PASS) is a disease evaluation method to assess disease activity with a simple question especially in rheumatic diseases.
Objectives: We aimed to investigate clinical utility of PASS in FMF patients.
Methods: The research involved 54 FMF patients. Patient acceptable symptom state was applied to all patients in the study. The answers to PASS were compared with the patients clinical and laboratory features.
Results: 28 out of 54 patients (51.8%) were colchicine responsive whereas, 26 patients (48.2%) had colchicine resistant disease. The number of patients who answered yes to PASS (I'm happy with my current disease condition) was 32 (59%), while answered no (I need further treatment options) was 22 (41%). Considering the disease severity assessed with International severity scoring FMF (ISSF) of those who answered yes, 22 (68%) patients had mild disease, 10 patients had moderate (32%) disease, and there was no patient with severe disease in this group. Among those who answered no, 3 (14%) had mild disease, 14 (63%) had moderate disease, and 5 (23%) had severe disease (p <0.001). When the CRP levels of the patients were compared, the median CRP value of those who answered yes was found to be 4.45 mg/L, and the median value of CRP for those who answered no was 11.25 mg/L (p= 0.04).
Sensitivity and specificity of PASS for detecting patients in remission was 78% and 61% respectively. Moreover, PASS had a positive and negative predictive value of %68 and %72 respectively, for determining patients in remission. If cut off level of CRP was chosen as 6.5 mg/L for answering "yes" to PASS, sensitivity of test has been found to be 62.5% while the specificity is 59.1%. On the other hand, if cut off level of CRP is selected as 9.35 mg/L; sensitivity and specificity of the test was found as 75% and 72.7% respectively (p=0.045).
Conclusion: Patient acceptable symptom state is found beneficial in evulation these patients simply and swiftly especially in terms of distinguishing severe FMF disease. In FMF, laboratory remission is as important as clinical remission, therefore, PASS by alone, is not sufficient for making treatment decisions and should be supported by inflammatory markers.

AB1303 VACCINATION PRACTICES OF ADULT FAMILIAL MEDITERRANEAN FEVER PATIENTS IN TURKEY.

N. Şen[1], R. Mercan[2], Ö. Volkan[1], E. Bayar[3], S. Yilmaz-Oner[1], M. E. Tezcan[1]. [1]*Kartal Dr. Lütfi Kırdar Şehir Hastanesi, Rheumatology, Istanbul, Turkey*; [2]*Tekirdağ Namık Kemal Üniversitesi, Rheumatology, Tekirdağ, Turkey*; [3]*Sivas Devlet Hastanesi, Internal Medicine, Sivas, Turkey*

Background: Vaccines are the safest and most effective method to prevent invasive and life-threatening infections. Vaccines against influenza, pneumococcal disease, herpes zoster, and human papillomavirus are the main recommended vaccines for adults. In addition, rheumatology patients are advised to receive adult vaccinations according to the vaccines available in their country and local guidelines. In Turkey, both influenza and pneumococcal disease vaccines are commercially available. In addition, these vaccines are strongly recommended for rheumatology patients in local guidelines. Although familial Mediterranean fever (FMF) is one of the most common rheumatological diseases in Turkey, it is often neglected in vaccination recommendations.
Objectives: In this study, we surveyed the vaccination practice against influenza or pneumococcal diseases of adult FMF patients in our cohort. In addition, we evaluated the factors related to favorable vaccination practice.
Methods: We included 360 FMF patients over 18 years of age. All patients fulfilled the Tel-Hashomer criteria for FMF. We asked them if they had ever been vaccinated against pneumococcal or influenza, and how often they received them. In addition, we dichotomised patients in terms of vaccinated against at least one of influenza or pneumococcal diseases. We then compared the groups for demographic (age gender and comorbidities) and disease related characteristics (disease duration, disease activity calculated by ISSF and colchicine dose). We used qi-square test to compare categorial variables and Mann-Whitney U test to compare continuous variables. P<0.05 was accepted as significant.
Results: Of 360 FMF patients, 238 (66.1%) were female. The mean age of the patients was 34.5±10.7 years. Disease duration of the patients was 9.38±0.7 years. In addition, the mean ISSF score of the patients was 1.83±1.5. The mean dose of colchicine received by the patient was 1.23 ± 0.47 mg. Only 54 (15.0%) of the patients had at least one comorbidity. In our cohort, 22 (6.1%) patients were vaccinated against influenza or pneumococcal disease. Only 18 (5.0%) of the patients have been vaccinated against influenza at least once so far. Half of these patients (9/18) were vaccinated against influenza each year. In addition, 8/360 (2.2%) patients were fully vaccinated against pneumococcal diseases. Here, six of them received the pneumococcal vaccine after the start of the COVID-19 outbreak. There was no statistically significant difference between the groups in terms of demographic and disease related characteristics.
Conclusion: We found that vaccination practice of FMF patients in our cohort was unsatisfactory. Few patients follow adult vaccination recommendations. In addition, clinicians should be concerned about the importance of vaccination and guide their patients to get the adult vaccines available in their country.

AB1304 COMPARISON OF CHARACTERISTICS OF PATIENTS WITH IDIOPATHIC GRANULOMATOSIS MASTITIS IN REMISSION AND NON-REMISSION: RESULTS FROM A TERTIARY REFERRAL CENTRE

B. Farisogullari[1], B. Usta[2], E. Ersal Deregözü[2], G. K. Yardımcı[1], Ö. Cennet[3], K. Kösemehmetoğlu[4], A. Konan[3], U. Kalyoncu[1]. *[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*; *[3]Hacettepe University, Faculty of Medicine, Department of General Surgery, Ankara, Turkey*; *[4]Hacettepe University, Faculty of Medicine, Department of Pathology, Ankara, Turkey*

Background: Idiopathic granulomatous mastitis (IGM) is an uncommon, benign, chronic inflammatory disease of the breast of unknown etiology. Although an ideal treatment regimen is controversial in IGM, the ultimate goal is remission.
Objectives: To compare the clinical, radiological, laboratory and treatment features of patients in remission and non-remission, and assess predictor factors of remission.
Methods: The data of patients who were histopathological diagnosed with IGM between 2010 and 2020 were evaluated retrospectively. The patients were divided into 2 groups as those in complete remission and non-remission. Complete improvement in clinical and physical examination with medical and/or surgical intervention findings at 2 consecutive visits was defined as complete remission. Patients who were not in complete remission including partial remission and refractory to treatment, were defined as non-remission group.
Results: In this study, there were a total of 103 patients with a diagnosis of IGM followed-up in the rheumatology clinic. Of these, 39 (38%) were in remission and 64 (62%) were non-remission. Age, age at symptom onset, comorbidity, pregnancy (ever), disease localization, clinical signs and symptoms, imaging classification, and baseline acute phase reactants and autoimmune markers were similar in the remission and non-remission groups. The use of antibiotics and azathioprine was significantly higher in the remission group than in the non-remission group. However, there was no difference between the groups in terms of breast surgery, use of corticosteroids and methotrexate (Table 1). In the univariable analysis, antibiotic use [OR: 2.55 (95% CI 1.07-6.11)] was found to be a predictor factor of remission.
Conclusion: Patients with in remission did not have the distinctive baseline demographic, clinical, laboratory and radiological features that distinguish them from patients with in non-remission. Patients in remission used more antibiotics and azathioprine. Antibiotic use seems to be associated with remission in univariable analysis. However, further studies are needed to evaluate the factors associated with remission in IGM.

AB1305 A SYSTEMATIC REVIEW OF AA AMYLOIDOSIS AMONG PATIENTS WITH BEHÇET'S SYNDROME

G. Karatemiz[1,2], S. N. Esatoglu[1,2], M. Gurcan[3], Y. Ozguler[1,2], S. Yurdakul[1,2], V. Hamuryudan[1,2], I. Fresko[1,2], M. Melikoglu[1,2], E. Seyahi[1,2], S. Ugurlu[1,2], H. Ozdogan[1,2], H. Yazici[1,2], G. Hatemi[1,2]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul, Turkey*; *[3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*

Background: Data on patients with Behçet's syndrome (BS) complicated with AA amyloidosis is limited to case reports or case series with a small number of patients.
Objectives: In this study, we aimed to perform a systematic review (SR) of published reports on BS patients with AA amyloidosis.
Methods: PubMed and EMBASE were searched with the keywords "Behcet* AND amyloidosis", without date and language restriction, until May 2020. Two independent reviewers (SNE, GK) performed title/abstract and full text screening and data extraction. A third reviewer (GH) made the final decision in case of disagreement between the two reviewers. Studies that reported patients who were reported by authors as having BS and AA amyloidosis were included. The risk of bias assessment was done using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) tool.
Results: The systematic literature search yielded 760 articles of which 703 were excluded after title and abstract review. After full-text review, we further excluded 15 duplicate articles and 1 article was added after handsearching the reference lists of the full texts. Finally, we included 43 articles reporting 96 cases. Among these articles, 38 were case reports and 5 were case series reporting between 6 and 14 patients. All patients but 8 were reported from Mediterranean countries.

Table 1. Characteristics of patients in remission and non-remission

Results are given as mean ± SD or median (IQR).
ANA: Antinuclear antibody; anti-CCP: Anti-cyclic citrullinated peptides; BI-RADS: Breast imaging-reporting and data system; RF: Rheumatoid factor

The quality of all articles according to GRADE was very low due to the lack of a control group.

The main features of the patients were male predominance (81/96, 84%), a high frequency of major organ involvement (62/80, 77.5%) especially vascular involvement (60%), a low frequency of comorbidities predisposing to AA amyloidosis (11/96, 11.5%), and a very low frequency of gastrointestinal involvement (3/72, 4%). All but 8 patients were diagnosed with BS and AA amyloidosis simultaneously. The most common presentation was nephrotic syndrome (60/81, 74%). Presenting symptoms other than proteinuria were diarrhea (n=2), acute renal failure (n=2), upper gastrointestinal bleeding (n=1), end stage renal disease (ESRD) (n=1), cardiac symptoms due to cor pulmonale (n=1), and hypertension (n=1). Renal biopsy (72%) and rectal biopsy (17%) were the most commonly used procedures to diagnose AA amyloidosis.

After diagnosing AA amyloidosis, colchicine was initiated in 58 patients, cyclophosphamide in 16, and biologics in 3 (1 anakinra and 2 tocilizumab). In the 67 patients with available data on follow-up, 43% of the patients were followed-up for ≤1 year and median follow-up duration was 20 months (IQR: 4-48). Among the 64 patients with available data, 30 (47%) had developed ESRD. Among the 72 patients with available data on survival status, 30 patients (42%) had died. Ten patients (33%) had died within 6 months, 15 had died after a median follow-up of 48 months (IQR: 24-150), and follow-up duration was not available in the remaining 5 patients including 3 patients whose diagnoses were made by autopsy. Reasons for death were infection (n=7), ESRD (n=6), intractable diarrhea (n=3), pulmonary embolism (n=1), cor pulmonale (n=1), hemorrhage due to pulmonary artery aneurysm (n=1), liver cirrhosis (n=1), gastric cancer (n=1), subarachnoid hemorrhage (n=1), and not reported (n=8).

Conclusion: Male gender and major organ involvement, especially vascular involvement, appear to be risk factors for the development of AA amyloidosis in BS patients. While BS patients complicated with AA amyloidosis have been reported rarely, it is a fatal complication of BS. One third of the patients had died within 6 months after AA amyloidosis diagnosis.

AB1306 AA AMYLOIDOSIS IN CHRONIC RHEUMATIC DISEASES: ABOUT 20 CASES

M. Ardhaoui[1], J. Mahbouba[1], M. Ghali[1], F. Fhima[1], N. Ben Chekaya[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology, Monastir,Tunisia*

Background: Secondary AA amyloidosis is a complication of certain uncontrolled chronic inflammatory rheumatic diseases. The diagnosis of AA amyloidosis is anatomo-pathological based on the detection of amyloid deposits within a biopsy specimen.

Objectives: The aim of this study is to determine the clinical, biological, therapeutic and evolutionary aspects of amyloidosis during these diseases.

Methods: This is a retrospective descriptive study conducted in the rheumatology department in Monastir, Tunisia, including patients followed for chronic inflammatory rheumatism complicated by AA amyloidosis.

Results: Our study included 20 patients (13 women and 7 men). Their mean age at the time of diagnosis of amyloidosis was 55.4 years [18-76]. The rheumatic diseases were: Rheumatoid Arthritis (RA) in 13 cases (65%), Ankylosing Spondylitis in 3 cases (15 %), Behçet's disease in 2 cases and Juvenile idiopathic arthritis in its systemic form in 2 cases (10% for both). Amyloidosis occurred after a mean duration of rheumatic disease of 11.5 years [3-27]. The mean sedimentation rate at diagnosis of amyloidosis was 100.5 mm per hour [21-131]. The mean C-reactive protein at diagnosis was 38.35 mg/L [1.4-135]. Inaugural manifestations of amyloidosis were: edema of lower limbs in 8 cases, nephrotic syndrome in 7 cases, renal failure in 4 cases and an abdominal clinical presentation (diarrhea and abdominal pain) associated with proteinuria in 2 cases. Proteinuria was constant, with a mean level of 7.5 g/24 h [3.5-20]. It was isolated in 5 cases. Amyloidosis was subclinical in 2 cases and was discovered by an abdominal fat biopsy performed during a research protocol. The diagnosis was confirmed by: renal biopsy (n=9), rectal biopsy (n=5), salivary gland biopsy (n=4) and abdominal fat biopsy (n=2). Amyloidosis extension was assessed for 50% of our patients. Cardiac involvement was the most frequent, revealed in 5 patients. Concentric left ventricular hypertrophy was found in 4 patients. Pulmonary arterial hypertension and pericardial effusion were found in 1 case. Hepatic involvement was detected in 2 cases in the form of hepatomegaly without disturbance of liver function tests. Adrenal gland involvement was detected in 1 case with homogeneous hypertrophy of the adrenal glands associated with adrenal dysfunction. Only 1 patient had peripheral nerve damage in the form of bilateral carpal tunnel syndrome. Concerning the treatment; 12 patients received Colchicine. Chloraminophen was tried for 4 patients with amyloidosis secondary to RA and Azathioprine for one patient with RA. The evolution was unfavorable in 6 cases marked by death within a mean time of 3.4 years.

Conclusion: Although its prevalence is decreasing, owing to therapeutic progress in chronic rheumatic diseases, AA amyloidosis remains a not exceptional complication. It has a poor prognosis, particularly because of renal disease and cardiac involvement.

AB1307 RHEUMATIC SYNDROMES INDUCED BY ONCOLOGIC AND HEMATOLOGIC TARGETED THERAPIES

J. A. Gómez-Puerta[1], M. Tormo-Ratera[2], A. Ponce Fernandez[1], L. Farran[2], B. Frade-Sosa[1], J. C. Sarmiento Monroy[1], J. Narváez[2]. [1]*Hospital Clinic de Barcelona, Rheumatology, Barcelona, Spain*; [2]*Hospital de Bellvitge, Rheumatology, L' Hospitalet de Llobregat, Barcelona, Spain*

Background: Targeted therapy has gradually become the first-line clinical therapy for solid tumors and hematologic disorders (1). Immune related adverse side effects (irAE) due to checkpoint inhibitors are well recognized side effects in patients with underlying oncologic disorders; however, information regarding rheumatic side effects due to several targeted therapies are rarely reported.

Objectives: Our aim was to describe the main rheumatic syndromes induced by targeted therapies.

Methods: This observational study included patients from 2 referral University centers in Barcelona. We included patients referred from Oncology and Hematology departments visited from January 2017 to January 2022 at Hospital Clinic and Hospital de Bellvitge, Barcelona, Spain.

Results: Fifteen patients were included (Female 60%), with a mean age 63.3± 10.8 years. Nine patients had hematological disorders and 8 solid tumors. Main diagnosis included Multiple Myeloma in 3 (20%) patients, Non-Hodgkin Lymphoma 2 (13%), Acute Myeloid Leukemia 2 (13%), Melanoma 2 (13%), Colon carcinoma 1 (6.7%), Breast carcinoma 1 (6.7%), Glioblastoma multiforme 1 (6.7%), Chronic lymphatic leukemia 1 (6.7%), Renal cell carcinoma 1 (6.7%) and Sésary Syndrome in 1 (6.7%) patient. Targeted therapies included MAP kinases in 4 (26.7%) patients, Anti CD-38 in 3 (20%), Anti BRAF in 2 (13.3%), and anti STAT-3, anti VEGF, BTK inhibitor, anti CCR4, Isocitrate dehydrogenase 2 inhibitor and Halichondrin B analoge in 1 (6.7%) patient each. Treatment was administrated as monotherapy in 9 (60%) and as combined therapy in 6 (40%). Mean time from the initiation of targeted therapies and rheumatic syndrome onset was 5.0 ± 3.8 months. Main rheumatic syndrome were: Polymyalgia rheumatica (PMR) in 4 (26%) patients, Raynaud's phenomenon in 2 (13%), Tenosynovitis in 2 (13%), RA-like 2 (13%), cutaneous vasculitis, amyopathic dermatomyositis, oligoarthritis, spondyloarthropathy-like and non-inflammatory arthralgias in 1 (6.7%) case each. Main clinical characteristics are summarized in Table 1. In 8 (53%) cases, targeted therapies were stopped due side effects. Rheumatic syndrome were treated with, glucocorticoids (GC) 12 (80%), calcium antagonist 2 (13%), Hydroxychloroquine in 2 (13%), Methotrexate in 1 (6.7%), Sulfasalazine in 1 (6.7%) and NSAID in 1 (6.7%) patient. Mean follow-up were 15.4± 20 months. Most of the patients remain alive (86%). According oncologic prognosis, 4 (26%) had complete response, 6 (40%) had partial response and 5 (33%) had disease progression. At the time of the last visit, 6 (40%) patients remain on GC (mean dose 6.7 ± 4.7 mg/d) and 4 (26%) patients on DMARD therapy.

Conclusion: In this heterogeneous group of patients treated with targeted therapies, we described a variety of induced rheumatic syndromes including PMR, arthritis, and even vasculitis or dermatomyositis. An important proportion of patients stopped the treatment due to side effects and some of them required sustained treatment including GC and DMARD.

AB1308

MYCOPHENOLATE FOR THE TREATMENT OF EYE INVOLVEMENT IN PATIENTS WITH BEHÇET'S SYNDROME

D. Ucar[1,2], Y. Ozyazgan[1,2], S. N. Esatoglu[2,3], E. Cerme[4], V. Hamuryudan[2,3], M. Melikoglu[2,3], I. Fresko[3], S. Yurdakul[2,3], H. Yazici[2,3], G. Hatemi[2,3]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul, Turkey*; [3]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [4]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*

Background: Experience with mycophenolate in uveitis associated with Behçet's syndrome (BS) is limited.

Objectives: We aimed to report the efficacy and safety of mycophenolate mofetil (MMF) and mycophenolate sodium (MPA) in the treatment of BS uveitis.

Methods: All patients with panuveitis or posterior uveitis who used mycophenolate for eye involvement between 2016 and 2018 were included. Patient charts were reviewed and data on demographic features, previous immunosuppressives, concomitant therapies, ocular attacks and outcome, and adverse events were extracted. Follow up was ended on October 2021.

Results: We included 12 BS patients (M/W: 8/4, mean age: 35±7 years) treated with mycophenolate during a mean follow-up of 42±19 months (Table 1). All but 3 patients had bilateral eye involvement. IFX and INF-α had been discontinued due to adverse events in all patients, AZA in 10/12, and Cy-A in 7/10. Seven patients were prescribed mycophenolate for remission induction. One of these patients had had his first uveitis attack while on AZA treatment due to gastrointestinal involvement. The remaining 6 patients were using other immunosuppressives and experienced relapses that led to mycophenolate use. MMF was added to a biologic agent in 2 patients (IFX and ADA) and was initiated in combination with IFX in 1 patient. These 3 patients did not experience further ocular attacks and IFX was stopped due to remission in 1 patient. In the fourth patient, MMF was switched to MPA due to numbness in hands and feet and MPA was stopped due to arthralgia. This patient did not experience ocular attacks during 5 months of MPA therapy. The remaining 3 patients had further uveitis attacks without decrease in visual acuity 2, 6, and 12 months after MMF initiation, and IFX was added in 2 patients, and ADA in 1 patient. Two of these patients were switched to INF-α due to uveitis relapses. MMF was switched to MPA for diarrhea in 1 patient. Five patients had received MMF for maintenance. One of these was using IFX when MMF was started and these 2 agents were used together. This patient discontinued MMF due to remission 17 months after MMF initiation and is still on IFX monotherapy. The second patient is still on MMF for 39 months without further ocular attacks. ADA, IFX and Cy-A were added in the remaining 3 patients due to ocular attacks 2, 5 and 31 months after MMF initiation. One of these 3 patients stopped IFX and MMF due to remission and is off treatment for 2 years.

Conclusion: Mycophenolate may be an alternative treatment modality in addition to biologics for patients with eye involvement who are intolerant to conventional therapies. Further data is needed to show whether it would be effective when used alone.

ANALYSIS OF A MONOCENTRIC COHORT OF IGG4-RELATED DISEASE PATIENTS: GREATER REDUCTION OF THE RESPONDER INDEX IN PHARMACOLOGICALLY-TREATED PATIENTS AS COMPARED TO UNTREATED ONES

S. Bertocchi[1,2], F. Regola[1,2], C. Nalli[1], L. Andreoli[1,2], F. Franceschini[1,2]. *[1]Spedali Civili di Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; *[2]University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: IgG4-related disease (IgG4-RD) is a systemic disease characterized by lymphoplasmocellular infiltration and storiform fibrosis. Pancreas, biliary tract, lacrimal and salivary glands, lymph nodes and retroperitoneum are frequently involved, although the clinical presentation may vary [1].
Objectives: The aim of this study is to retrospectively describe the clinical manifestations of a monocentric cohort of patients with IgG4-RD and analyze their clinical course by applying the validated IgG4-Related Disease Responder Index (RI) [2].
Methods: We enrolled 22 IgG4-RD patients classified with 2011 diagnostic criteria [3] and/or 2019 classification criteria [4].
Results: 22 IgG4-RD patients (M/F=3.4/1), mostly Caucasian (91%), were diagnosed at a mean age of 59 years (44-74) with a median IgG4 concentration at diagnosis of 239 mg/dl (IQR 106-391 mg/dL). 14/22 (64%) patients fulfilled the 2011 classification criteria, while 8/22 (36%) were classified as possible (2), probable (5) or definitive (1) according to the diagnostic criteria of 2011. Organ involvement at diagnosis (T0) is described in Table 1. The organs most involved were lymph nodes, salivary glands and retroperitoneum. Patients were followed for a median of 49 months (IQR 16-88). Three patients were lost to follow-up. One patient died for pneumonia 96 months after diagnosis. During the follow-up 5 (23%) patients didn't receive specific treatment, 1 (5%) was treated surgically, 6 (27%) with steroid only, 10 (45%) with steroid and immunosuppressants (with methotrexate and/or rituximab, tocilizumab, mycophenolate, cyclosporine, hydroxychloroquine, azathioprine) and/or surgical resection. A statistically significant reduction in RI between T0 and last follow-up (TLF) was observed in all the patients [from 6 (3-6) to 3 (1-4) p=0.010]. A significant reduction was also observed in the group of pharmacologically treated patients [from 6 (3-6) to 3 (1-4) p=0.035] but not in the group of patients without drug treatment (p = 0.174).

Table 1. Organ involvement at diagnosis

Organ involvement T0	N. Patients (%)
Pancreas	2 (9)
Lymph nodes	14 (64)
Salivary glands	13 (59)
Lungs	1 (5)
Aorta and large blood vessels	4 (18)
Retroperitoneum, mediastinum, mesentery	6 (27)
Bile duct and liver	3 (14)
Kidneys	2 (9)
Pachymeninges	1 (5)
Orbits and lacrimal glands	3 (14)
Paranasal sinuses and / or nasal mucosa	5 (23)

Conclusion: In our cohort, patients were predominantly male with mean age at diagnosis of 59 years, consistent with literature data [1]. A statistically significant reduction in disease activity defined by reduction of RI was observed in patients who received immunosuppressive therapy. No significant reduction was observed in patients not pharmacologically treated.

JANUS KINASE INHIBITORS IN SEVERE AND REFRACTORY INFLAMMATORY OCULAR PATHOLOGY. CASES REPORTS AND LITERATURE REVIEW

L. Sanchez-Bilbao[1], V. Calvo-Río[1], J. L. Martín-Varillas[2], I. Torre-Salaberri[3], O. Maiz[4], E. Beltrán[5], J. L. Álvarez Vega[5], C. Álvarez-Reguera[1], R. Demetrio-Pablo[6], M. A. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; *[2]Hospital de Laredo, Rheumatology, Laredo, Spain*; *[3]Hospital de Basurto, Rheumatology, Bilbao, Spain*; *[4]Hospital Universitario de Donostia, Rheumatology, San Sebastián, Spain*; *[5]Hospital del Mar, Rheumatology, Barcelona, Spain*; *[6]Hospital Universitario Marqués de Valdecilla, Ophthalmology, Santander, Spain*

Background: Inflammatory ocular pathology (IOP) includes internal and external involvement. IOP may be severe ocular conditions refractory to conventional immunosuppressants and even biological therapy. Janus Kinase inhibitors (JAKINIB) had shown efficacy in refractory cases of different immune-mediated inflammatory diseases (IMID).
Objectives: In patients with refractory IOP treated with JAKINIB our aims were **a)** to assess the patients of Spanish referral centers, **b)** Literature review.
Methods: Multicenter study of 6 patients with refractory IOP treated with JAKINIB. For Literature review a search was conducted in PubMed, Embase and the Cochrane library from their inception to 1st January 2022, and conference proceedings from four major rheumatology conferences. In addition, a therapeutical approach of refractory IOP is proposed.
Results: We have identified 6 cases in five University Hospitals and 11 cases in the literature review. These 17 patients (14 women/ 3 men) (24 affected eyes), mean age 35.5±23.4 years had different refractory IOP (uveitis=11; scleritis= 3, PUK= 3). Most of IOP were associated with IMID (n=13, 76.5%). The main underlying IMID were juvenile idiopathic arthritis (n=5, 29.4%), rheumatoid arthritis (n=2, 11.8%) and spondyloarthritis (n=2; 11.8%) (Table 1**).**
Uveitis (n=11) followed by ocular surface pathology (n=6) were the most frequent subtypes of IOP. Patterns of uveitis were panuveitis (n=6), anterior uveitis (n=4; 2 of them with Cystoid macular edema) and posterior (n=1). Ocular surface pathology was due to scleritis (n=3) and PUK (n=3).
Besides systemic corticosteroids, before JAKINIB, conventional (n= 16; 94.1%) and biological immunosuppressive drugs (n=13; 76.5%) were required. The JAKINIB most widely used was tofacitinib (n= 10; 58.8%) followed by baricitinib (n=7; 41.2%). In only one patient with Blau Syndrome and uveitis, tofacitinib was switched to baricitinib due to severe lymphopenia.
After starting JAKINIB treatment, all patients presented clinical improvement, complete (n=15, 88.2%) or partial (n= 2; 11.8%).

Based on these data a therapeutical approach of refractory IOP was proposed (Figure 1**).**

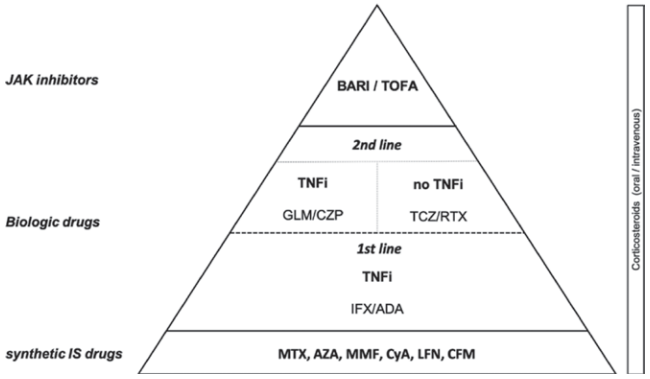

Figure 1. Therapeutical approach

Conclusion: JAKINIB may be an effective and safe therapy in IOP refractory to conventional or even biological immunosuppressive therapy.

AB1311

INCREASED RISK OF HEPATOTOXICITY WITH DMARDS IN PATIENTS WITH PREVIOUS LIVER TOXICITY WITH ISONIAZID. STUDY IN A SINGLE UNIVERSITY HOSPITAL

D. Martínez-López[1], J. Osorio-Chavez[2], V. Portilla[1], C. Álvarez-Reguera[1], A. Herrero-Morant[1], L. Sanchez-Bilbao[1], I. Gonzalez-Mazon[1], M. A. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain*; *[2]Hospital Universitario Marqués de Valdecilla, Pulmonology, Santander (SPAIN), Spain*

Background: Isoniazid (INH) is used to treat latent tuberculosis infection (LTBI), and hepatotoxicity is one of the most frequent adverse effect. Several Disease-modifying drugs (DMARDs) can also cause hepatotoxicity. Many patients with rheumatic immune mediated diseases (R-IMID) receive INH prior to DMARDs for prophylaxis of LTBI. This risk of hepatotoxicity with DMARDs after hepatotoxicity with INH is unknown.

Objectives: To assess the risk of hepatotoxicity with DMARDs in patients who have presented hepatotoxicity with INH.

Methods: Study of all consecutive R-IMID patients evaluated in the last five years (2016-2020) in a University Hospital, who presented hepatotoxicity after INH and later received DMARDs. We study if they also presented hepatotoxicity with DMARDs. Hepatotoxicity was defined as an elevation of liver enzymes (ALT and/or AST) upper the high limit after the introduction of the treatment.

Results: INH was used in 232 of 7218 patients with R-IMID. We finally included 64 patients (45 women; 70.3%; mean age 53.4±10.5 years), who had hepatotoxicity due to INH (Table 1).

Table 1. Main characteristics of 64 patients with rheumatic immune-mediated diseases (R-IMID) that presented hepatotoxicity after receiving isoniazid (INH).

Variables	Patients (n=64)
Age (years), mean ±SD	53.4±10.5
Sex (women), n (%)	45 (70.3)
R-IMID	
- SpA / PsA	36 (56.3%)
- RA	21 (32.8%)
- SSc	3 (4.7%)
- Conectivopathies	3 (4.7%)
- Other	2 (3.2%)
Liver enzyme elevation over baseline (INH)*	
- x2	64 (100)
- x3	22 (34.4)
- x4 or higher	13 (20.3)
csDMARDs	
- MTX	34 (53.1%)
- HCQ	15 (23.4)
- LFN	13 (20.3)
- SSZ	10 (15.6)
bDMARDs	47 (73.4%)
Targeted synthetic DMARDs (Jakinib)	8 (12.5)

ABA: Abatacept; AZA: Azathioprine, HCQ: Hydroxychloroquine; INH: Isoniazid; LFN: Leflunomide; MMF: Mycophenolate mofetil, MTX: Methotrexate; PsA: Psoriatic arthritis, RA: Rheumatoid arthritis, RTX: Rituximab; SpA: Axial spondyloarthritis; SSc: Systemic sclerosis; TCZ: Tocilizumab; TNFi: TNF inhibitors* Patients with higher liver enzyme elevation are included in the previous groups.

The most frequent R-IMIDs were rheumatoid arthritis, axial spondyloarthritis and psoriatic arthritis. Methotrexate (MTX) (n=34, 53.1%) and TNF inhibitors (n=27, 42.2%) were the conventional and biologic-DMARD more frequently used, respectively. Hepatotoxicity was higher with MTX (14 of 34, 41.2%), and lower with the other DMARDs (Figure 1). Hepatotoxicity was not observed with hydroxychloroquine, azathioprine, mycophenolate mofetil, secukinumab, abatacept or rituximab.

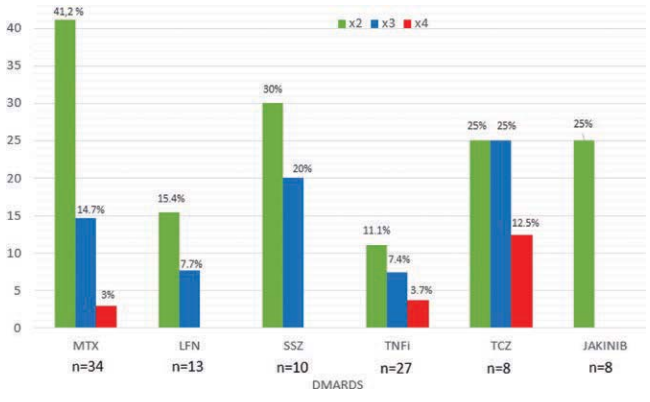

Figure 1. Hepatotoxicity with different DMARDs in 64 patients with previous hepatotoxicity with INH* Patients with higher liver enzyme elevation are included in the previous groups.

Conclusion: In patients with previous hepatotoxicity with INH, we observed an increased risk with different DMARDs, especially with MTX.

AB1312 HIGH PREVALENCE OF IRMD IN SARCOIDOSIS PATIENTS

S. Gulle[1], M. C. Ataca[2], G. Can[1], İ. Sari[1], M. Birlik[1], F. Onen[1]. [1]*Dokuz Eylul University School of Medicine, Rheumatology, Izmir, Turkey*; [2]*Dokuz Eylul University School of Medicine, Internal Medicine, Izmir, Turkey*

Background: Sarcoidosis is a chronic granulomatous disease that primarily affects the lungs and lymph nodes, and can affect any organ and system (1). The incidence of concomitant iRMD is increased in patients with sarcoidosis. Anti-nuclear antibody (ANA) test are frequently used markers for inflammatory rheumatic diseases (iRMDs) (2). The relationship of this association with ANA is not clear.

Objectives: We aimed to determine the frequency of ANA in sarcoidosis patients and its possible correlation with clinical and laboratory data, and also to reveal the severity of osteoporosis in patients with sarcoidosis.

Methods: Ninety sarcoidosis patients, who were followed up in rheumatology clinic were included in this study. ANA were determined with indirect immunofluorescent method and 1/160 titration was accepted as positive. Demographic, clinical, serological, and bone mineral densitometry (BMD) results of all patients were recorded. BMD results were obtained from the images taken before the last date or osteoporotic fracture of the patients.

Results: Average age of the 90 patients (79 females) with sarcoidosis was 57.5 (IQR: 51–66) years, and median disease duration was 7.6 (IQR: 4-19) years. 28 (31.1%) patients had a diagnosis of extrapulmonary sarcoidosis (Most commonly skin, n=20, 71.4%). 21 patients had BMD values consistent with osteoporosis, while 9 patients had osteoporotic fractures. In 18 (20%) patients, rheumatologic autoimmune disease combined with sarcoidosis was found. SpA was diagnosed in 6 patients, RA in 2 patients, Lofgren Syndrome in 2 patients, SjS in 2 patients, systemic sclerosis in 1 patient, and morphea in 1 patient. Other rheumatological diseases were found as uBDH, polymyositis, Gout, Behçet's Disease and FMF. ANA test was performed in a total of 83 patients. ANA positivity was found in 30 (36.1%) patients with sarcoidosis (1/100-1/320 in 12 patients; >1/320 in 18 patients). There was no significant relationship between ANA positivity and gender distribution, age, disease duration, development of extrapulmonary sarcoidosis, refractory disease status, and laboratory findings at the time of diagnosis. It was found that ANA positivity at diagnosis time for sarcoidosis increased the risk of developing iRMD 4.8 times in patients [HR: 4.8, CI 95% (1.455-15.833), p=0.009].

Conclusion: In sarcoidosis, ANA positivity is of great importance in the determination of accompanying iRMDs. It was found that ANA positivity at the time of diagnosis in sarcoidosis patients increased the risk of developing rheumatological autoimmune disease 4.8 fold. Since these patients receive long-term moderate-high-dose steroid-based treatments, they should be closely monitored and screened for osteoporosis.

AB1313 THE RATIONAL USE OF BIOLOGICS IN REFRACTORY IMMUNE-MEDIATED INFLAMMATORY DISEASES CONSORTIUM (RUBRIC) NATIONAL REGISTRY: RESULTS ON GLUCOCORTICOID USE AND WORK PRODUCTIVITY

A. Musters[1], M. Kleijn-de Graaf[1], S. Tas[1]. [1]*Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*

Background: Rare therapy-refractory immune-mediated inflammatory diseases (IMIDs) are increasingly treated with new targeted therapies such as biological (b) or targeted synthetic (ts) DMARDs. However, in the Dutch healthcare system these treatments are not reimbursed for off-label use unless there is sufficient evidence of efficacy. Currently, no official guidelines or treatment protocols exist for many of these rare diseases. To overcome this issue we set up a national registry to document off-label use of b/tsDMARDs in patients with rare therapy-refractory IMIDs and to document efficacy and safety of these therapies.

Objectives: To report results on glucocorticoid use and work productivity of patients with rare therapy-refractory IMIDs treated off-label with b/tsDMARDs.

Methods: Using the web-based RUBRIC registry patients with rare therapy-refractory IMIDs treated off-label with b/tsDMARDs were prospectively followed to document efficacy and safety. Physicians supplied data on disease activity (i.e. VAS physician and ESR/CRP) and concomitant medication, including glucocorticoid use. Patients filled out questionnaires on patient reported outcomes (PROs; i.e. HAQ, WPAI-GH, SF-36, PASS, EQ-5D) prior to starting off-label treatment and at regular intervals afterwards. Any potential serious adverse events were also recorded.

Results: Many different diagnosis-treatment combinations were recorded (i.e. undifferentiated vasculitis, TRAPS, Hyper-IgD syndrome, auto-inflammatory diseases treated with various b/tsDMARDs). Of the 82 patients currently followed in RUBRIC, for 61 patients multiple questionnaires over a time period of > 1 year were available for analysis. Glucocorticoid use was documented accurately in 55 patients. Analysis of glucocorticoid use demonstrated that the majority of patients (38/55; 69.1%) used glucocorticoids prior to off-label treatment and all patients remained at a stable dose (10/55; 18.2%) or could reduce the dose (23/55; 41.8%), whereas (5/55; 9.1%) could eventually even stop glucocorticoids completely. Of the patients that did not use glucocorticoids prior to off-label b/tsDMARD therapy, no glucocorticoids were initiated. Analysis of WPAI-GH over time revealed that off-label treatment resulted in a significant gain in work productivity in all working patients and 15% of patients who were not employed prior to initiating off-label treatment were able to resume work again, whereas none of the patients became unemployed during off-label treatment. No serious adverse events associated with off-label b/tsDMARD therapy were reported.

Conclusion: Off-label treatment of rare therapy-refractory IMIDs with b/tsDMARDs results in a clear beneficial effect as glucocorticoid use could be reduced or stopped in the majority of patients and a clear increase in work productivity/

employment was observed. Despite these positive outcomes, at present not enough patients per diagnosis-treatment combination have been included in the registry to draw definitive conclusions on efficacy and safety of specific off-label treatments or to formulate treatment recommendations for certain diseases. Consequently, it is important to continue the registry and include more patients or link various (inter)national registries to obtain sufficient data and promote evidence-based and effective use of biologics in rare therapy-refractory IMIDs. This may eventually also help to facilitate reimbursement of these therapies.

AB1314 JANUS KINASE INHIBITORS IN REFRACTORY AUTOINFLAMMATORY SYNDROMES. TWO CASE REPORTS AND LITERATURE REVIEW.

C. Álvarez-Reguera[1], D. Prieto-Peña[1], L. Sanchez-Bilbao[1], A. Herrero-Morant[1], D. Martínez-López[1], M. Á. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Autoinflammatory syndromes are characterized by dysregulation of innate immunity and recurrent episodes of fever, cutaneous and other. Janus Kinase inhibitors (JAKINIB) may inhibit innate and acquired immunity. They have been approved in several immune mediated diseases, but not in autoinflammatory syndromes.

Objectives: To assess the efficacy and safety of JAKINIB in refractory autoinflammatory syndromes.

Methods: Study of patients from a single University Hospital and Literature review of refractory autoinflammatory syndromes treated with JAKINIB.

Results: We have identified 2 cases in our hospital. One of them was a 25-year-old girl diagnosed with Blau syndrome refractory to different conventional and biological therapies. Tofacitinib (TOFA) had a good clinical response but was switched to Bariticitinib (BARI) due to severe lymphopenia. The 2nd patient was a 65-year-old man, diagnosed with an autoinflammatory syndrome (WDR1 mutation) and policytemia vera (positive JAK-2; V617F mutation). Based on the JAK2 mutation, BARI was started with complete improvement. In literature review, we found 59 patients (41 women/ 18 men), mean age 38.1±13 years. TOFA (n=23) was the most used JAKINIB, followed by BARI (n=20) and Ruxolitinib (RUXO) (n=16). After starting JAKINIB treatment, most patients presented clinical complete (n=45, 76.3%) or partial (n=11; 18.6%) improvement, only 3 (5.1%) did not respond. (Table 1)

Conclusion: JAKINIB may be an effective therapy in autoinflammatory syndromes refractory to conventional and/or biologic therapy.

AB1315 SARILUMAB IN PATIENTS WITH REFRACTORY GRAVES' ORBITOPATHY. EFFECTIVENESS AND SAFETY IN A SERIES OF CASES IN CLINICAL PRACTICE.

V. Moreira Navarrete[1], F. J. Toyos Sáenz de Miera[1], A. M. Garrido Hermosilla[2], P. Muñoz Reinoso[1], M. J. Madrigal Domínguez[1], J. J. Pérez Venegas[1]. [1]*Hospital Virgen Macarena, Rheumatology, Sevilla., Spain*; [2]*Hospital Virgen Macarena, Ophthalmology, Sevilla, Spain*

Background: Graves' orbitopathy (GO) is an autoimmune disease of the retroocular tissues that occurs in patients with Graves' disease. Tocilizumab (TCZ), an interleukin (IL)-6 inhibitor has been used in patients with glucocorticoid (GC)-resistant Graves' orbitopathy with good results. We have previously reported results obtained in 15 OG patients treated with TCZ where a decrease in mean CAS from 4.9 to 1.7 was observed. Sarilumab, another IL-6 inhibitor, is indicated for the treatment of rheumatoid arthritis and has been used in other pathologies as an off-label use, similar to TCZ, on the grounds that they share a common mechanism of action.

Objectives: To analyse the effectiveness of Sarilumab treatment in patients with GC-resistant OG in routine clinical practice.

Methods: A descriptive retrospective observational study of a series of patients with moderate-severe active OG on Sarilumab treatment was performed. Medical records of patients who had received at least 1 cycle of Sarilumab treatment were reviewed. Demographic and disease data were collected. Effectiveness was assessed by CAS (Clinical Activity Score) reduction before and at 3-6 months of treatment. A reduction of CAS≥ 2 points together with obtaining inactivity (CAS < 3) was considered a favourable response. The study was approved by Research Ethics Committee.

Results: In the rheumatology department of the Hospital Virgen Macarena, 25 patients were treated with IL-6 inhibitors, 20 with tocilizumab and 5 with Sarilumab. Five patients were included, 2 women and 3 men, with a mean age of 43 years. All but one had bilateral ocular involvement. 2 patients were active smokers, 1 ex-smoker and 2 non-smokers. Two patients were diabetic, none of them had retinopathy. The mean time of disease until their evaluation in Rheumatology was 3.5 years. All had been treated with antithyroid drugs, 1 with Radioiodine and one patient had undergone thyroidectomy. 100% of patients had an active moderate-severe orbitopathy, all had been treated with local measures, 3 with selenium and none had undergone rehabilitative surgery. Three patients had been on at least one course of intravenous steroids. Patients received Sarilumab at a dose of 200 mg subcutaneous injection every 15 days for a mean of 11 months (range 7-21 months), 100% in monotherapy. The mean initial CAS was 5/7 and the final CAS was 2.75/10. The CAS score was reduced by 3 points on average. 100% had a favourable response and achieved inactivity, also reducing the severity of the disease. Furthermore, there was an improvement in thyroid function parameters

and a reduction in antibody titters against TSH receptor and anti-thyroid peroxidase. All patients were continuing treatment except for one patient who had discontinued treatment due to clinical remission. No adverse events were recorded except for mild neutropenia in one patient, which did not require dose reduction. No patient required subsequent immunosuppressive treatment or surgery.

Conclusion: Sarilumab treatment in patients with moderate-severe active OG appears to be an effective and safe therapeutic alternative, clinically similar to that obtained with TCZ in our series. This is the first published series of Sarilumab use in OG patients.

AB1316 PREVALENCE, DIAGNOSTIC DELAY AND TREATMENT PROFILE OF PATIENTS WITH MONOGENIC AUTOINFLAMMATORY DISEASES IN AN ADULT RHEUMATOLOGY SERVICE OF A TERTIARY HOSPITAL.

C. Pávez Perales[1], E. Molina Rus[2], E. Grau García[1], M. De la Rubia Navarro[1], S. Leal Rodriguez[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], P. Muñoz Martinez[1], L. Mas Sanchez[1], J. Ivorra Cortés[1,2], J. E. Oller Rodríguez[1], J. J. Fragío Gil[1], R. González Mazarío[1], I. Cánovas Olmos[1], I. Martínez Cordellat[1], E. Vicens Bernabeu[1], F. Ortiz-Sanjuán[1], R. Negueroles Albuixech[1], L. Gonzalez Puig[1], C. Nájera Herranz[1], J. A. Román Ivorra[1,2]. *[1]La Fe University and Polytechnic Hospital, Rheumatology, València, Spain*; *[2]Universidad Católica de Valencia San Vicente Mártir, Medicina, València, Spain*

Background: Monogenic autoinflammatory diseases (MAISs) have a low prevalence and a delay in their diagnosis, with the risk of complications being AA amyloidosis the most serious. Biological therapy has been a fundamental pillar in improving the prognosis of these diseases, reducing said risk.

Objectives: We aim to study the prevalence, diagnostic delay and treatment profile of MAISs patients in an adult rheumatology service of a tertiary hospital.

Methods: Observational and retrospective study of patients with MAISs, excluding those without genetic test or negative genetic test, with a follow-up period of 17 years (2005-2021). Demographic, clinical and therapeutic variables were collected.

Results: 24 patients (50% men) were included with a mean age of 27,88 ± 11.57y. The prevalence of MAISs was 0.34%, from a total of 7,032 patients followed up in the Rheumatology service during 2020. Familial Mediterranean Fever (FMF) was the most frequent (70.83%). FMF, Tumor Necrosis Factor Receptor Associated Periodic Syndrome (TRAPS), and Hyperimmunoglobulin D Syndrome (HIDS) had a median age at symptom onset of 6, 8.5 and 2 years, a median diagnostic delay of 6, 8.75 and 11 years and a mean duration of the bouts of 4.47 (2.87), 12.25 (7.59) and 6 (2.65) days, respectively. The most frequent symptoms were: fever (79.17%), arthralgia/arthritis (79.17%) and abdominal pain (75%). During follow up 20.83% received glucocorticoids (GC) chronically (more than 3 months), 79.16% colchicine, 16.66% methotrexate and 41.66% biological therapies (Table 1). At the end of follow up 4.17% were receiving GC, 79.16% colchicine, 4.16% methotrexate and 33.33% biological therapies (Table 1). No AA amyloidosis or deaths were reported.

Table 1.

MAISs	Gender (men %)	Biological therapies prescribed during follow up (n)	Patients under biological therapies at the end of follow up (n)
FMF (n=17)	41.17%	Anakinra: 2 Canakinumab: 2 Etanercept: 1 Tocilizumab: 1	Anakinra: 3 Canakinumab: 2
TRAPS (n=4)	100%	Anakinra: 1 Canakinumab: 1 Etanercept: Tocilizumab:	Canakinumab: 1
HIDS (=3)	66.66%	Anakinra: 3 Canakinumab: 3 Etanercept. 1	Canakinumab: 2

Conclusion: MAISs prevalence was 0.34%. The diagnostic delay was of years, more than a decade for HIDS. Colchicine was widely used and well tolerated. Synthetic DMARDs had little role in treatment. Biological therapies were prescribed in a third of patients, anti IL-1 being the most used.

AB1317 SERUM INTERLEUKIN 37 LEVELS IN FAMILIAL MEDITERRANEAN FEVER PATIENTS AND ASSOCIATION WITH CLINICAL FEATURES

A. Fincan[1], M. Kavutcu[2], N. Atas[3], H. Babaoglu[3], R. Bilici Salman[3], H. Satış[3], D. Yildirim[3], M. A. Ozturk[3], H. Küçük[3], A. Tufan[3]. *[1]Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey*; *[2]Gazi University Faculty of Medicine, Biochemistry, Ankara, Turkey*; *[3]Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*

Background: Familial Mediterranean Fever (FMF) is the most common form of autoinflammatory diseases that is characterized by febrile episodes of serositis, arthritis and skin rash (1). Mutations in MEFV gene causes dysfunction of pyrin inflammasome, ultimately resulting in over-activation of Caspase-1 which is responsible for catalytic activation of interleukin (IL)-1 beta and gasdermin-D (2). IL-37 is also one of the IL-1 cytokines activated by caspase-1 acting as natural inhibitor of inflammation (3).

Objectives: IL-37 has pathogenetic roles for certain inflammatory diseases. We aimed to investigate serum IL-37 levels and its relationship with clinical and laboratory features of disease.

Methods: 58 adult patients diagnosed with FMF according to Tel Hashomer criteria were included. Thirty subjects were served as healthy control subjects. Demographic, genetic, clinical and laboratory features and treatment responses of patients were recorded. Twenty-nine patients were colchicine responsive whereas 29 were colchicine refractory. Serum IL-37 levels were measured by ELISA from blood samples obtained at attack free periods.

Results: Peritonitis was the most common attack type (81%) followed by fever (80%) and arthritis (67%). There was no difference between FMF patients and healthy subjects for their serum IL-37 levels. A negative correlation was found between IL-37 values and erythrocyte sedimentation rate in FMF patients (r: -0,31; p:0.015). IL -37 level was found to be significantly lower in patients who suffer from arthritis (median [IQR] 119 [396] ng/L vs 53 [164] ng/L, p= 0.03), myalgia (147 [364] ng/L vs 53 [84] ng/L, p= 0.05) or skin rash (102 [360] ng/L vs 54 [130] ng/L, p= 0.05) compared to those who did not have these attacks.

Conclusion: Although there was no difference in serum IL-37 levels between FMF patients and healthy subjects, IL-37 seem to be associated with musculoskeletal and skin attacks of FMF. Further research is needed to determine whether IL-37 have relationships with other features of FMF such as spondyloarthritis and febril myalgia.

AB1318 ULTRASOUND EVALUATION OF ACHILLES ENTHESIS AND GASTROCNEMIUS ARCHITECTURE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: PRELIMINARY RESULTS FROM A CROSS-SECTIONAL STUDY

N. Güven[1], S. C. Güven[2], A. Kahveci[1], P. Bora Karsli[1], Ş. Ataman[1]. *[1]Ankara University Medical School, Physical and Rehabilitation Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Ankara City Hospital, Clinic of Rheumatology, Ankara, Turkey*

Background: Exertional leg pain and Achilles enthesitis are two musculoskeletal manifestations which have been described in familial Mediterranean fever (FMF) patients. Muscle performance is related both with mass and architecture. Measurements of muscle thickness and pennation angle in muscles with pennate structure, such as gastrocnemius, are representative of muscle mass and architecture, both of which can easily be measured via musculoskeletal ultrasound.

Objectives: Aim of this study is to evaluate thickness and pennation angle of medial gastrocnemius via ultrasound to evaluate muscle structure in FMF patients in order to detect implications of altered muscle condition and search for any relations with exertional leg pain/Achilles enthesitis. To our best knowledge this is the first study on the subject.

Methods: Consecutive FMF patients meeting Tel-Hashomer criteria between the ages of 18-65 were enrolled. A control group was formed from healthy volunteers

with similar demographics. All ultrasound evaluations were performed by the same observer. Thickness and pennation angle of medial gastrocnemius was measured. Achilles tendon findings were scored according to OMERACT suggestions and total inflammation and structural damage scores recorded.

Results: A total of 40 FMF patients and 17 controls were enrolled. Clinical characteristics and ultrasound findings of subjects were presented in Table 1. All FMF patients were under colchicine treatment and 10% was also under anti-interleukin 1 treatment. Demographics were similar between groups. Right gastrocnemius pennation angle was significantly reduced in FMF group (degree, median(IQR): 20.8 (3.6) vs 22.7 (4.5), p=0.048). OMERACT ultrasound inflammation total scores were incresed on both sides in FMF group. When gastrocnemius and enthesis ultrasound findings were compared between FMF patients with and without exertional myalgia, no significant differences were observed. When FMF patients with and without enthesis findings in ultrasound examination were compared, again no significant differences in pennation angles and muscle thicknesses were observed.

Table 1. Clinical characteristics and ultrasound findings in subjects

	FMF group	Control group	
	N =40	N=17	p
Age, years, median (IQR)	42.8 (23.0)	38.0 (15.0)	0.447
Gender, female, number (%)	29 (72.5)	10 (58.8)	0.310
BMI, median (IQR)	24.6 (5.3)	24.8 (5.7)	0.485
Presence of exertional myalgia, number (%)	22 (55)		
Gastrocnemius thickness, mm, median (IQR)			
Right	19.7 (2.9)	20.7 (5.6)	0.303
Left	19.6 (2.7)	20.7 (4.6)	0.321
Gastrocnemius pennation angle, degrees, median (IQR)			
Right	20.8 (3.6)	22.7 (4.5)	**0.048**
Left	21.0 (3.3)	21.8 (4.7)	0.417
OMERACT ultrasound tissue damage total score, median (IQR)			
Right	2.0 (2.0)	2.0 (2.0)	0.659
Left	2.0 (2.0)	2.0 (2.0)	0.280
OMERACT ultrasound inflammation total score, median (IQR)			
Right	0 (2.0)	0 (0)	**0.005**
Left	0 (2.0)	0 (0)	**0.023**

Conclusion: Our preliminary results imply altered right gastrocnemius structure in FMF patients regardless of Achilles tendon involvement and exertional myalgia, which may imply altered muscle function. By increasing the number of subjects we plan to achieve more accurate results.

AB1319 MUSCULOSKELETAL IMMUNE-RELATED ADVERSE EVENTS IN PATIENTS WITH SOLID CANCER TREATED WITH CHECKPOINT INHIBITORS: A CASE SERIES

A. Koltakova[1], A. Lila[2], M. Cherkasova[3], A. Fedenko[4]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Systemic Sclerosis, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Tromboinflammation, Moscow, Russian Federation*; [4]*National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Department of Drug Treatment of Cancer, Moscow, Russian Federation*

Background: Immune-related adverse events (irAE) are common in cancer patients treated with checkpoint inhibitors. irAE can affect any organs and systems including musculoskeletal. The characteristics of immune-related musculoskeletal disorders (MD) still remain incomplete.

Objectives: to determine the characteristics of MD manifested during the treatment of solid cancer with check-point inhibitors in case series.

Methods: We identified 13 patients with inflammatory MD manifested during treatment with check-point inhibitors. Mean age of patients was 59±10 (ranged 43-74) years, 7 (54%) of them were female. Patients were treated with anti-PD-1 (77%) and anti-PD-L1 (33%) drugs (nivolumab [n=6], pembrolizumab [n=3], atezolizumab [n=3], prolgolimab [n=1]). Cancer types include melanoma (n=5), renal cell carcinoma (n=3), bladder cancer (n=2), non-small cell lung cancer (n=1), breast cancer (n=1), cervical cancer (n=1). 7 (54%) patients had another irAE also including thyroiditis (n=3), neuropathy (n=2), rash (n=1), sicca syndrome (n=1), hepatitis (n=1). The median time of musculoskeletal manifestation after the treatment`s onset was 20 [9-48] weeks.

Results: Musculoskeletal manifestations were performed by synovitis in 9 (69%) cases, tenosynovitis in 11 (85%), entesitis in 4 (31%), morning stiffness(>30min) in 4 (31%). The most commonly affected areas were knees (77%) shoulders (69%), hands (69%) and feets (46%). Bilateral involvement was in 9 (69%) cases. MD was transient in 2 cases and persistent in 11 (9 patients with inflammatory arthritis and 2 patients with periarthritis). Clinical characteristic of inflammatory arthritis was represented by tenosynovitis more than synovitis in 3 cases (2 patients with symmetrical inflammatory polyarthritis and severe tenosynovitis, 1 patient with RS3PE-syndrome). In 6 cases inflammatory arthritis was represented by synovitis primarily (3 patients with symmetrical polyarthritis, 2 patients with oligoarthritis, 1 patient with monoarthritis). Severity of MD was assessed according to Common Terminology Criteria for Adverse Events V5.0. Grade 1 was in 2 cases (15.5%), grade 2 in 9 (69%), grade 3 in 2 (15.5%). Laboratory findings include ESR ≥30 mm/h in 7/12 (58%) cases (the median of ESR was 34 [14-42] mm/h); CRP >5 mg/l in 7/10 (70%) cases (the median of CRP was 7.2 [4.6-12.9] mg/l). RF, ACPA were negative in all cases. ANA test was positive without any specificities in 7/10 (70%) cases in dilution 1:160 (n=2), 1:320 (n=3), 1:640 (n=2). Treatment of these conditions include NSAIDs (n=10), oral systemic corticosteroids (n=5), intra-articular corticosteroids (n=1), and csDMARDs (hydroxychloroquine [n=5] methotrexate [n=1]) as corticosteroid-sparing agents. 2 patients with polyarthritis and generalized tenosynovitis and 1 patient with symmetrical polyarthritis required treatment with ≤20 mg daily of prednisone. 2 patients with poly- and oligoarthritis were treated with 5-10 mg daily of prednisone. 5 patients with arthritis required long-term treatment with NSAIDs, corticosteroids and csDMARDs (the median of follow-up was 12 [3-12] months). 1 case of the inflammatory polyarthritis with severe tenosynovitis required to suspend the anticancer treatment with checkpoint inhibitor.

Conclusion: Our data demonstrated that the musculoskeletal irAE may be represented by heterogeneous manifestation and required long-term treatment. In rare cases musculoskeletal irAE can lead to suspension of the anticancer treatment with checkpoint inhibitors.

AB1320 JAK2 (V617F) MUTATION AND ASSOCIATION TO RHEUMATOLOGICAL DISEASES TREATMENT. STUDY OF 130 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL.

C. Álvarez-Reguera[1], L. Sanchez-Bilbao[1], S. Fernández López[2], A. Batlle-López[1], A. Herrero-Morant[1], D. Martínez-López[1], M. Á. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, Hematology, Santander, Spain*

Background: Janus Kinases (JAK) can promote cytokine production in immune and hematopoietic cells. The JAK-2 (V617F) mutation is the most frequently detected mutation in myeloproliferative neoplasms (MPN) which include essential thrombocythemia (ET), polycythemia vera (PV), primary myelofibrosis (PMF) and undifferenciated MPN. JAK-2 (V617F) mutation displays a pro-inflammatory phenotype that may be associated to a higher risk of immune mediated diseases (IMID).

Objectives: In a wide series of JAK2 (V617F) mutation, we assess the presence of a) IMID (rheumatic and non-rheumatic), b) treatment of rheumatic IMID.

Methods: We studied all the patients diagnosed with a positive JAK-2 (V16F) mutation in a single University Hospital from January 2004 to December 2019. JAK-2 (V16F) mutation was detected by using both peripheral blood and bone marrow samples. Associated IMID and treatment of rheumatic IMID were evaluated.

Results: We included 130 patients (73 men/57 women; mean age, 70.1±14.5 years). All of them were diagnosed of MPN; ET (n=64, 49.2%), PV 46 (35.4%), undifferentiated MPN (n=12, 9.2%) and PMF (n=8, 6.1%). In 10 of these 130 patients (7.7%) a rheumatic IMID was diagnosed: rheumatoid arthritis (RA) (n=4; 40%), polymyalgia rheumatica (PMR) (n=3; 30%), Sjögren syndrome (SS) (n=1; 10%), antiphospholipid syndrome (APS) (n=1; 10%) and autoinflammatory syndrome (WDR1 mutation) (n=1; 10%). Patients with RA, SS, PmR, and APS were clinically mild. RA patients were seronegative, non-erosive and without extraarticular involvement. Treatment and response are summarized in Table 1. All patients diagnosed with PMR were treated with glucocorticoids (prednisone 5 mg/12 hours), SS with hydroxychloroquine (HCQ) (200 mg/day), APS was anticoagulated with acenocumarol and one autoinflammatory syndrome was finally treated with baritinib (4 mg/day) after failure to anakinra (100 mg/day).

Conclusion: Except in autoinflammatory syndrome, most rheumatic IMID associated to JAK-2 (V16F) mutation are clinically mild, and treatment and response of patients seems similar or even better than those without this mutation.

Table 1. Treatment of 10 patients with rheumatic IMIDs and JAK-2 (V16F) mutation.

AB1321 THE DIAGNOSTIC DELAY IN PATIENTS WITH SCHNITZLER SYNDROME: A CASE SERIES

E. Borzova[1,2], S. Salugina[3], V. Rameev[4], V. Gorodetskiy[5], A. Torgashina[5]. [1]*I.M.Sechenov First Moscow State Medical University, Department of Dermatology, Moscow, Russian Federation*; [2]*Veltischev Research and Clinical Institute for Pediatrics of the Pirogov Russian National Research Medical University, Department of Clinical Genetics, Moscow, Russian Federation*; [3]*V.A.Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; [4]*I.M.Sechenov First Moscow State Medical University, E.M.Tareev Clinic of Internal, Occupational Diseases and Rheumatology, Moscow, Russian Federation*; [5]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of Intensive Therapy Methods, Moscow, Russian Federation*

Background: Schnitzler syndrome is a rare syndrome associated with recurrent whealing and monoclonal gammopathy. Since its first description in 1972 by the French dermatologist Prof. Liliane Schnitzler, around 500 cases have been described in Europe. The diagnostic delay in Schnitzler syndrome of 5 years was previously reported [Lipsker et al, 2001]. Despite a growing clinical experience [de Koning et al, 2014], Schnitzler syndrome presents a diagnostic challenge in clinical practice. The variation in the diagnostic delay in Europe is a subject of an ongoing systematic review by our multidisciplinary team.

Objectives: In this work, we would like to analyze a diagnostic delay in the patients with Schnitzler syndrome followed up at tertiary clinical and research setting.

Methods: We present the data from the patients with Schnitzler syndrome that have been under our care by a multidisciplinary team over a period from 2015 to 2021. All patients were analyzed for the age of disease onset and a diagnostic delay for Schnitzler syndrome.

Results: There are currently 14 patients with Schnitzler syndrome under our care. Of these, there were eight men and six women. The median age at the disease onset was 50.5 years, with the range from 25 to 79 years. The median diagnostic delay in our patient series was 3 years, ranging from 1 to 22 years. Noteworthy, in three patients the diagnostic delay for Schnitzler syndrome was over 5 years [6, 12 and 22 years]. Nine patients were treated with IL-1 inhibitors (iIL-1) (canakinumab and anakinra).

Conclusion: Our analysis suggest that the diagnostic delay remains considerable even 50 years after the initial description of this syndrome. Our data on the diagnostic delay in Schnitzler syndrome is in keeping with the clinical experience in most countries with over 5 published cases, including France, Germany, Spain, Portugal and Italy. An early recognition of Schnitzler syndrome is crucial for prompt treatment targeting IL-1. The rarity of this syndrome and a wide range of initial signs and symptoms in these patients delay the correct diagnosis and a start of the biological therapy in these patients. An increased awareness of Schnitzler syndrome may reduce the diagnostic delay in these patients. A multidisciplinary approach is essential for an early diagnosis of Schnitzler syndrome.

AB1322 APPENDICITIS STILL A MISDIAGNOSIS FOR FMF PATIENTS

S. N. Baspinar[1], A. Alkan[1], M. B. Yuzbasioglu[1], S. Yenigun[1], A. Y. Ayla[1], I. Durucan[1], M. Candan[1], A. Karabicek[1], C. Belli[1], T. Bayraktar[1], H. Ozdogan[1], S. Ugurlu[1]. [1]*Cerrahpaşa Tıp Fakültesi, Deparment of Internal Medicine Division of Rheumatology, Istanbul, Turkey*

Background: Familial Mediterranean Fever(FMF) is an autoinflammatory disease characterized by recurrent polyserositis attacks. Attacks typically consist of fever and/or abdominal pain and/or chest pain and/or arthritis. The disease is caused by mutations in the MEFV gene. Abdominal pain during the attacks is frequently misdiagnosed as acute abdomen and these patients go undersurgical intervention is not uncommon [1].

Objectives: Severe abdominal pain during FMF attacks is frequently misdiagnosed as acute abdomen and patients receive surgical intervention. In this study, we aim to compare the clinical and genetic characteristics of FMF patients with appendectomies to those without appendectomies.

Methods: We reviewed 176 patients with FMF who went under appendectomy. We randomly matched these patients with 176 FMF patients without appendectomy for comparison. We compared clinical manifestations, MEFV mutations, and treatment modalities.

Results: In this study, 176 patients with FMF went under appendectomy. Only 2 of these appendectomies were performed after FMF diagnosis. In the appendectomy group fever(84% vs 68%), abdominal pain(91% vs 79%), pathogenic exon 10 mutations(65% vs 59%), lower leg pain(0.5% vs 0%) and orchitis(0.5% vs 0%) were more common but only the abdominal pain and fever was statistically significant. In the control group chest pain(18% vs 19%), arthralgia(46% vs 53%), arthritis(29% vs 37%), anti IL-1 usage(3% vs 5%), amyloidosis (0% vs 3%) and erysipelas(1% vs 3%) were more common but none of them were statistically significant. Myalgia(3%) was the same in both groups[Table 1]. Median diagnostic delay was 8(IQR 2-15) years in the appendectomy group and 3.5(IQR1-10) years in the control group.

Table 1. Characteristics of the patients

	No Of Patients(%) Appendicitis	No Of Patients(%) Control Group	P value
Patients	176(100)	176(100)	
Fever	148(84)	120(68)	0.0007
Abdominal Pain	160(91)	139(79)	0.0029
Chest Pain	32(18)	33(19)	1
Arthralgia	81(46)	94(53)	0.20
Arthritis	51(29)	65(37)	0.12
Myalgia	5(3)	5(3)	1
Erysipelas	2(1)	5(3)	0.45
Lower Leg Pain	1(0.5)	0(0)	-
Orchitis	1(0.5)	0(0)	-
Anti IL-1 usage	6(3)	9(5)	0.6
Amyloidosis	0(0)	6(3)	-
Diagnostic Delay	8.5(IQR2-15) years	3.5(IQR1-10) years	0.0002
Pathogenic Exon 10 Mutations	114(65)	103(59)	0.27
Appendectomy Before FMF diagnosis	174(99)	0(0)	

Conclusion: Even after the discovery of colchicine and identification of the MEFV gene diagnosis of FMF remains a challenge. Previous studies reported a median diagnostic delay of 8.2-11 years. In these studies, 28%-32% of the patients went under abdominal surgical intervention before the diagnosis of the FMF[2,3]. The most common symptoms of FMF(fever and abdominal pain) are also the most common symptoms of acute abdomen. Thus distinguishing between FMF and acute abdomen in undiagnosed FMF patients represents an understated problem. These patients have a longer diagnostic delay[8(IQR 2-15) vs 3.5(IQR1-10) years], worse control of attacks, poorer quality of life. In our study, most of the appendectomies were unnecessary in the FMF patients. Thus we recommend investigating the patient for FMF if the evidence of the acute abdomen does not expand beyond the symptoms.

AB1323 THE MYSTERY OF FAMILIAL MEDITERRANEAN FEVER: IS THERE ANY FACTOR TRIGGERING THE ATTACKS?

S. N. Baspinar[1], I. Durucan[2], M. B. Yuzbasioglu[1], S. Yenigun[1], A. Y. Ayla[2], A. Alkan[2], T. Ayalti[2], F. Demirkol[2], B. Sahin[2], S. Alizade[2], H. Ozdogan[2],

S. Ugurlu[2]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Division of Rheumatology, Department of Internal Medicine, Istanbul, Turkey*

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent episodes of fever and serositis. Although it is known that the attack frequency differs among patients carrying different mutant genotypes [1], whether physical and environmental factors play a role in triggering attacks or whether they have an influence on timing of attacks remains to be elucidated.
Objectives: We aimed to identify different conditions causing flare-ups in FMF course and to investigate if there is a significant difference between patients carrying distinct mutations, regarding the distribution of the factors mentioned.
Methods: Two hundred patients were randomly selected among individuals who were routinely followed-up with FMF diagnosis in our centre. Individuals carrying only a variant of unknown significance or polymorphism such as R202Q, according to Infevers database, were excluded in order to gather a cohort consisting of patients with definite FMF. An inquiry was made based upon triggering factors determined by the patients themselves. The patients were classified into subgroups by their sex and mutation genotype. Since M694V variant is responsible for pronounced FMF course [2], we sorted the patients according to their status for M694V mutant allele. Group A included patients carrying M694V homozygously. Group B included patients carrying at least one M694V mutant allele whereas Group C consisted of patients who were non-M694V carriers. Chi-square test was performed to assess distribution of the trigger factors in terms of establishing its significance.
Results: Detailed distribution of trigger factors is shown in Table 1. 144 out of 200 patients described a culprit condition. Patients usually stated more than one factor, however some patients reported only one. The most-reported trigger factors by the cohort are summarized as following: 76 emotional stress (38%), 60 menstruation (30%), 40 cold exposure (20%), 34 fatigue (17%), 13 seasonal changes (6.5%). The distribution of trigger factors between Group A, B, and C were non-significant (p=0.88).

Table 1. The distribution of triggering factors in subgroups.

Group	Total (%)	Reported trigger factor (%)	Menstruation (%)	Emotional stress (%)	Cold exposure (%)	Fatigue (%)	Seasonal changes (%)	Others (%)
Female	123	97 (78.8)	60 (48.8)	47 (38.2)	24 (19.5)	19 (15.4)	7 (5.7)	6 (4.9)
Male	77	47 (61)	-	29 (37.7)	16 (20.8)	15 (19.5)	6 (7.8)	7 (9.1)
Group A	61	44 (72.1)	14 (23)	24 (39.3)	13 (21.3)	12 (19.7)	4 (6.6)	6 (9.8)
Group B	165	120 (72.7)	49 (29.7)	66 (40)	34 (20.6)	29 (17.6)	13 (7.9)	11 (6.6)
Group C	35	24 (68.6)	11 (31.4)	10 (28.6)	6 (17.1)	5 (14.3)	0	1 (2.8)

Group A: M694V homozygous patients, Group B: patients with at least one M694V allele, Group C: non-M694V carriers

Conclusion: We concluded that trigger factors did not vary between distinct mutant genotypes. Although emotional stress is the most reported trigger factor by the participants, one should bear in mind that emotional stress influences most chronic diseases negatively. We also observed that menstruation overtly triggers an FMF attack. Additionally, cold exposure should be considered as a notable trigger factor. It is still unclear what triggers an FMF attack in 28% of the patients, remains a mystery.

AB1324 DIFFERENCES IN PERIPHERAL BLOOD B-CELL SUBSETS IN PATIENTS WITH IGG4-RELATED DISEASE, PRIMARY SJOGREN'S SYNDROME AND HEALTHY DONORS

E. Sokol[1], A. Torgashina[1], B. Chalcev[1], J. Khvan[1], D. Tabakov[2], A. Aleksankin[2], M. Kireeva[3]. [1]*V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Diseases and Sjogren's Syndrome, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Educational and Methodical Department, Moscow, Russian Federation*

Background: The level of circulating plasmablasts has been proposed as a good marker for diagnosing and monitoring IgG4-related disease (IgG4-RD) independent of serum IgG4 level [1]. However elevated plasmablasts can be seen in other rheumatologic conditions.
Objectives: To compare B-cell subsets in peripheral blood of IgG4-RD, Sjogren's syndrome (SjS) patients (pts) and healthy controls.
Methods: Twelve pts with clinically active IgG4-RD (7F/5M, mean age 50,25 years (range 33-62), 20 active SjS pts (19F/1M, mean age 42 years (range 32-54 years); median disease duration 3 (2-10) years; ESSDAI score ≥5 in 6 pts,) and 20 healthy donors were included. SS was diagnosed based on the ACR-EULAR 2016 criteria. IgG4-RD was diagnosed according to comprehensive diagnostic criteria (H. Umehara, 2011). CD19+ B cells, memory B-cells (CD19+CD27+), non-switched memory B-cells (CD19+IgD+CD27+), switched memory B-cells (CD19+IgD-CD27+), naïve (CD19+IgD+CD27-), double negative (CD19+IgD-CD27-), transitional (CD19+IgD+CD10+CD38+) B-cells, plasmablasts (CD19+CD38+++IgD-CD27+), and plasma cells (CD19+CD38+) were analyzed by multicolor flow cytometry using cytometer Navios (Beckman Coulter, USA). The nonparametric Mann-Whitney test was used for statistical analysis. Data were shown as median (Me) with an interquartile range of 25 - 75 percentile. The differences were considered statistically significant when $p < 0.05$. Statistica 10 for Windows (StatSoft Inc., USA) package was used for statistical data processing.
Results: There were no significant differences in the number of all studied B-cell subsets between pts with IgG4-RD and with SjS. But absolute numbers of plasmablasts, memory B-cells cells and transitional B-cells in IgG4-RD were significantly higher than in healthy donors: 4.5[1;9.8] $x10^3$/µl vs. 0.2 [0.09;0.4] $x10^3$/µl; 41 [33.5;57.5] $x10^3$/µl vs. 2.5 [1;6.3]; 12 [6.5;21] $x10^3$/µl vs. 0.1 [0;0.23] $x10^3$/µl respectively, $p<0.05$ for all cases.

Table 1. Peripheral blood B-cell subsets in patients with SS and healthy donors.

B-cell subsets, Abs. $x10^3$/µl	IgG4-RD	SjS	HD	P<0.05
B lymphocyte	166 [109.3;251.3]	164.5 [109.3;236.3]	150 [95;200]	
plasmablasts	4.5 [1;9.8]	2 [1;3.5]	0.2 [0.09;0.4]	*
transitional B-cells	12 [6.5;21]	8.5 [4;32.5]	0.1 [0;0.23]	*
switched cells	24.5 [20;41.8]	18.5 [11;29.8]	20 [9.75;40]	
non-switched cells	16.5 [10.5;21]	7 [3.75;15.5]	10 [4.75;20]	
memory B-cells	41 [33.5;57.5]	26 [14.8;40.8]	2.5 [1;6.3]	*
naïve B-cells	122 [63.3;176.5]	107.5 [49.5;193.8]	100 [57.5;100]	
double negative	13.5 [8.8;17]	10.5 [5.3;22.3]	20 [9.75;22.5]	

HD healthy donors
* IgG4-RD and HD groups compared, $p<0.05$

Conclusion: Immunophenotyping showed disturbed homeostasis of the B-cells subpopulations in IgG4-RD pts with a significant increase in plasmablasts compared to HD, but there were no differences between IgG4-RD and SjS pts. Further research is needed to evaluate the diagnostic utility of circulating plasmablasts in IgG4-RD.

AB1325 DIAGNOSTIC DELAY IN FAMILIAL MEDITERRANEAN FEVER: IS IT STILL A PROBLEM?

M. B. Yuzbasioglu[1], A. Y. Ayla[1], I. Besiroglu[1], S. N. Baspinar[1], S. Yenigun[1], I. Durucan[1], A. Alkan[1], M. E. Gazioglu[1], M. F. Hiyamli[1], I. Sarac[1], H. Ozdogan[1], S. Ugurlu[1]. [1]*Istanbul University-Cerrahpasa, Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Familial Mediterranean fever (FMF) is a rare hereditary autoinflammatory disease with disease onset in childhood in most cases. Although autoinflammatory disease awareness is increasing among physicians, delayed diagnosis is still prevalent as a cause of greater morbidity[1].
Objectives: We aimed to study the characteristics of FMF patients diagnosed between 2000-2010 and 2011-2021 and to see if there was a difference in diagnostic delay.
Methods: We retrospectively evaluated the medical records of the FMF patients followed up in our rheumatology clinic that were diagnosed between 2000-2021 and split them into two groups according to the year they received their diagnosis. There were 1151 patients diagnosed between 2000-2010 (Group 1) and 821 patients diagnosed between 2011-2021 (Group 2). The data studied included gender, age of onset, diagnostic delay, attack characteristics, MEFV mutation, and family history.
Results: The median current age of patients in Group 1 is 37 years (IQR:30-46) and the median current age of the patients in Group 2 is 36 years (IQR:29-44). The female to male ratio was 1.57 in Group 1 and 1.75 in Group 2, with no significant difference between the groups. Group 2 had later disease onset ($p<0.001$) and later diagnosis ($p<0.001$) than Group 1 as shown in the Table 1. The proportion of patients with at least one M694V mutation was higher in Group 2 ($p<0.001$). The attack durations did not vary between the groups. There was no significant difference in the prevalence of abdominal pain, fever, arthritis, and arthralgia between

Group 1 and Group 2. Chest pain (p=0.005), myalgia (p<0.001), and erysipelas-like erythema (p=0.041) were more common in Group 2 than Group 1. Patients with positive family history were more frequent in Group 2 than Group 1 (p=0.046).

Table 1.

	Group 1 (2000-2010, n=1151)	Group 2 (2011-2021, n=821)	p
Female/Male, n	704/447	522/299	0.275
Age at onset, median (IQR) years	13 (7-21)	18 (12-26)	**<0.001**
Delay in diagnosis, median (IQR) years	4 (1-11)	5,5(2-15)	**<0.001**
Attack duration, median (IQR) years	3(2-4)	3(2-4)	0.325
Presence of at least one M694V mutation (%)	526(46%)	390(60%)	**<0.001**
Presence of abdominal pain in the initial attack (%)	936(81%)	669(81%)	0.926
Presence of fever in the initial attack (%)	855(74%)	592(72%)	0.281
Presence of chest pain in the initial attack (%)	218(19%)	199(24%)	**0.005**
Presence of arthritis in the initial attack (%)	330(29%)	215(26%)	0.224
Presence of arthralgia in the initial attack (%)	213(19%)	170(21%)	0.223
Presence of myalgia in the initial attack (%)	45(4%)	65(8%)	**<0.001**
Presence of erysipelas like erythema in the initial attack (%)	31(3%)	36(4%)	**0.041**
Presence of positive family history (%)	652(57%)	502(61%)	**0.046**

Conclusion: There was some increase in the diagnostic delay in 2011-2021 compared to 2000-2010. This may be partly due to the later onset of symptoms in patients diagnosed in 2011-2021, which could have led the physicians to consider other differential diagnoses. Nevertheless, diagnostic delay in FMF still seems a prevalent problem that should be addressed to prevent excess morbidity and mortality.

AB1326 EFFICACY AND SECURITY OF TNF-A INHIBITORS BIOSIMILARS IN NON INFECTIOUS UVEITIS

M. Gomez Vargas[1]. [1]*Hospital Universitario Virgen del Rocio, Rheumatology, Seville, Spain*

Background: Biological drugs have become established as an effective therapeutic alternative to non infectious uveitis refractory to the usual treatment. In that sense, expiry of patents for tumor necrosis factor (TNF-a inhibitors) has allowed the development of biosimilars such as Infliximab and Adalimumab; both originals with years of experience in such pathology but with barely no evidence in real life case series of its biosimilars.

Objectives: To analyze the effectiveness and security of biosimilars of Infliximab and Adalimumab used in uveitis in a third level hospital.

Methods: Descriptive study based on a retrospective cohort of 40 patients suffering of non infectious uveitis who have received biological treatment with Infliximab and Adalimumab collected over the last 20 years (2000-2021), taking into account the complete substitution of the original for the biosimilar in our hospital in February 2015 and March 2019, respectively. The number of outbreaks during both the years before and after the start of the biological therapy, as well as the number of outbreaks during the year following the switch from the original to the biosimilar, have been analyzed. In that regard, we have studied variables such as visual acuity, presence of macular edema, vitritis and retinal vasculitis, as well as the need for systemic corticosteroids treatment. We have registered minor and major side effects associated with the treatment and the cases that have required a change of drug.

Results: The average duration of the immunosuppressive therapy previous to the introduction of the biological therapy was 3,15 years with an average frequency of 2,25 outbreaks during the previous years of the start of the biological therapy. Subsequently, 30 patients received treatment with Adalimumab and 10 with Infliximab showing an average of 0,35+- 0,73 outbreaks during the following year of its start. The switch from the original drug to the biosimilar was subsequently performed in 27 patients (25 for Adalimumab and 2 for Infliximab) with an average of 0,2 +-0,5 and 0,12+-0,44 outbreaks during the 12 months following the switch. Most of them (87%) stayed with the concomitant immunosuppressive treatment, being the Methotrexate the most frequently used (55%). No major side effect has been registered during the biological therapy; however a 25% of the patients showed minor side effects, mostly infections. In 11 cases (27,5%) the biosimilar drug had to be switched, in 7 cases due to inefficiency and 4 to poor tolerance, all of them corresponding to Adalimumab biosimilar. In 5 of those cases the switch was back to the original biological therapy while in the 5 remaining it was to Infliximab biosimilar (4) and Tocilizumab. Two cases of suspension of Adalimumab biosimilar due to disease remission should be highlighted.

Conclusion: According to our experience, the use of biosimilars of Infliximab and Adalimumab in non infectious uveitis is safe. The switch to biosimilars could be considered a feasible therapeutic choice in regards to keeping its effectiveness in patients previously treated with the original drug, even though studies featuring longer follow-up time and more population would be needed.

AB1327 PREVALENCE OF IMMUNORELATED MUSCULOSKELETAL ADVERSE EFFECTS IN PATIENTS WITH LUNG CANCER OR MELANOMA TREATED WITH IMMUNO-CHECKPOINT INHIBITORS

L. Salvatierra Velasco[1], S. Sequero[1], J. Rubio Ubeda[1], D. Martinez Peñalver[1]. [1]*Hospital Universitario Clinico San Cecilio, Reumatología, Granada, Spain*

Background: mmunotherapy in the field of medical oncology, consisting of inhibiting key immune checkpoints, is revolutionising the way patients with these pathologies are treated, being mainly used in skin and lung tumours. These molecules are aimed at controlling T-cell activation by interacting with cytotoxic T-lymphocyte antigen 4 (CTLA-4) protein (Ipilimumab); by acting on the programmed cell death receptor (PD-1) (Pembrolizumad, Nivolumab); or by binding to programmed cell death ligand 1 (PDL-1) such as Atezolizumad or durvalumad. Despite the improvement in survival in the management of cancers with poor prognosis, this type of therapy is characterised by a series of side effects, including dermatological, gastrointestinal, endocrine, rheumatological and other effects. In this study, we focused mainly on rheumatological adverse effects, ranging from mechanical and/or inflammatory musculoskeletal involvement to dry syndrome, vasculitis, polymyalgia rheumatica, inflammatory myopathy, among others.

Aims: To assess the prevalence of immuno-related adverse effects (Eair) in cancer patients with lung cancer or melanoma treated with immunotherapy targeting check-ponits, such as anti-CTLA-4, anti-PD-1, anti-PDL-1.

Objectives: To assess the prevalence of immuno-related adverse effects (Eair) in cancer patients with lung cancer or melanoma treated with immunotherapy targeting check-ponits, such as anti-CTLA-4, anti-PD-1, anti-PDL-1.

Methods: Observational study of a series of 115 patients diagnosed with lung cancer or melanoma, in treatment with checkpoint inhibitors (nivolumab, pembrolixumab, durvalumab, atezolizumab), from 2016 to 2021 at the Hospital Universitario Clínico San Cecilio. Patients who developed some type of rheumatological symptomatology after the start of immunotherapy were included. The clinical history of these patients was reviewed to confirm or rule out these adverse effects. The following musculoskeletal Eair were included: arthralgias, arthritis, generalised musculoskeletal pain, myalgias, osteoporosis and/or osteopenia. In the Eair registry, the following entities were not included: polymyalgia rheumatica, vasculitis and myositis.

Results: Out of a total of 115 patients who received immunotherapy, with age, type of tumour and treatment received (Table 1); 24 developed non-specific arthromyalgia, low back pain and/or neck pain, with no previous history of interest, and clearly related to the immunotherapy treatment. Five of the patients developed active arthritis with visible swelling; only one of them had previous RA with treatment, the others had no PA of interest. Of the patients with rheumatological involvement, x had underlying PsA, x had a family history of immune-mediated disease. Of the total patients, 2 had a gout flare-up (one of them with a previous diagnosis).

Conclusion: The most frequent rheumatological adverse effects related to immunotherapy are non-specific arthromyalgias considered to be grade 1 or 2 in severity, for which patients do not require specific treatment or suspension of treatment doses. However, several of the patients did develop active arthritis, requiring corticosteroid treatment and in some cases, the suspension of at least one treatment session. In our study, there is no clear relationship between one immunosuppressive drug or another for the development of Eair.

Diagnostics and imaging procedures

AB1328 A FEASIBILITY STUDY ON A NOVEL COMBINED THERMAL IMAGING AND CLINICAL JOINT ASSESSMENT APPROACH USING ULTRASOUND DETECTED JOINT INFLAMMATION OUTCOMES IN RHEUMATOID ARTHRITIS

Y. K. Tan[1], C. Hong[1], H. LI[2], J. C. Allen Jr[3], J. Thumboo[1]. [1]*Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; [2]*Singapore General Hospital, Health Services Research Unit, Singapore, Singapore*; [3]*Duke-NUS Medical School, Centre for Quantitative Medicine, Singapore, Singapore*

Background: Thermal imaging (TI) is a portable, low cost imaging tool with high feasibility for use. Clinical joint assessment. Is routinely performed in rheumatoid arthritis (RA) patient care.
Objectives: To assess a combined TI and clinical joint assessment (CTCA) approach in comparison with TI alone using ultrasound (US) detected joint inflammation outcomes as a gold standard.
Methods: Bilateral (BL) hand and wrist (22 joint sites) were assessed in this cross-sectional study. For TI (performed in a draft free room with a controlled temperature of around 22°C), the adjusted maximum (Tmax), minimum (Tmin) and average (Tavg) temperatures were derived by subtracting a control temperature (lowest Tmin at the joints per subject) from the Tmax, Tmin and Tavg per joint. US power Doppler (PD) and greyscale (GS) joint inflammation were graded semi-quantitatively (0-3) using validated scoring methods. Joint swelling and tenderness were graded as yes = 1 or no = 0. To increase the relative weightage of CTCA-MAX, CTCA-MIN and CTCA-AVG on the CTCA scores, if the joint was swollen and/or tender, the adjusted Tmax, Tmin and Tavg at each joint were multiplied by a factor of 2; otherwise, they remained unchanged. Receiver operating characteristic (ROC) analysis assessed the performance of TI and CTCA in identifying joints with US PD score > 1 and GS score > 1. A parameter was selected as a univariate predictor if statistically significant (P < 0.05) with area under the ROC curve (AUC) ≥ 0.70.
Results: This study included 814 joints from 37 RA patients (mean disease duration, 30.9 months; mean DAS28, 4.43). For both TI and CTCA, out of the 22 joints sites, 3 joint sites were evaluated for PD score > 1 and 14 joint sites for GS score > 1; the remaining joint sites had AUC results unavailable due to small number of outcomes. For TI (Table 1), 3 joint sites had ≥ 1 predictive parameter for either PD score > 1 and/or GS score > 1 as follows: left (L) wrist and right (R) MCPJ 1, AUCs (0.813 to 0.897) for PD score > 1; L wrist and R MCPJs 1 and 3, AUCs (0.808 to 0.947) for GS score > 1. For CTCA (Table 1), 6 joint sites had ≥ 1 predictive parameter for either PD score > 1 and/or GS score > 1 as follows: BL wrists, AUCs (0.726 to 0.899) for PD score > 1; BL wrists, MCPJs 2 and 3, AUCs (0.739 to 0.931) for GS score > 1.

Table 1. Identifying joints with ultrasound PD score >1 & GS score >1

AB1329 INTERAPOPHYSEAL JOINTS INJECTION UNDER ULTRASOUND GUIDANCE AN ALTERNATIVE TO FLUOROSCOPY GUIDANCE

E. Touboul[1], S. Salomon-Goeb[1], V. Deprez[1], M. Boistelle[1], V. Goeb[1]. [1]*Chu Amiens-Picardy Site Nord, Rheumatology, Amiens, France*

Background: Ultrasound-guided injections are an alternative to evaluate, it eliminates the risk of ionizing radiation for both the patient and the practitioner as fluoroscopic procedures require a radiology technician, increase the overall support time and cost, decrease accessibility.
Objectives: The main objective of the study was to compare the short-term efficacy of posterior inter-apophyseal joint infiltrations under ultrasound versus scopic guidance.
Methods: Observational, retrospective, single-centre study. Patients benefited from posterior zygapophysial joints injection(s) under fluoroscopy or ultrasound and a follow-up consultation at one month.
Results: Data from 54 patients was collected. The evolution of VAS at 1 month was on average - 31.4cm (p <0.001) in the ultrasound group and - 31.3cm (p <0.001) in the fluoroscopy group with no statistically significant difference between the two groups (p =0.835). There were no injection-related complications in either group during the follow-up. The decrease in the consumption of NSAIDs was no statistically significant difference between both groups (p = 1.00). Statistically significant differences in procedure time were observed between groups with a longer time recorded for the ultrasound group (p = 0.007).
Conclusion: A corticosteroid injection of the posterior zygapophysial joints under ultrasound allows for a significant reduction in pain after one month with no difference found between the two techniques. Injection under ultrasound are a reliable, accessible and safe alternative.

AB1330 AUTOMATIC SUBPIXEL MEASUREMENT OF RADIOGRAPHIC FINGER JOINT SPACE NARROWING IN RHEUMATOID ARTHRITIS PATIENTS UNDER TOCILIZUMAB TREATMENT

T. Okino[1,2], Y. Ou[3], M. Ikebe[3], A. Furusaki[4], A. Sagawa[4], M. Kato[5], T. Atsumi[5], T. Kamishima[6]. [1]*Hokkaido University, Graduate School of Health Sciences, Sapporo, Japan*; [2]*Sapporo City General Hospital, Department of*

Radiological Technology, Sapporo, Japan; [3]*Hokkaido University, Research Center for Integrated Quantum Electronics, Sapporo, Japan*; [4]*Sagawa Akira Rheumatology Clinic, Sapporo, Japan*; [5]*Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Graduate School of Medicine and Faculty of Medicine, Sapporo, Japan*; [6]*Hokkaido University, Faculty of Health Sciences, Sapporo, Japan*

Background: The conventional scoring methods of radiographic joint space narrowing (JSN) in rheumatoid arthritis (RA) such as the Genant-modified Sharp score (GSS) are widely accepted but include subjective and time-consuming nature[1]. Therefore, we have developed an in-house software equipped with partial image phase-only correlation (PIPOC)[2] which can automatically quantify joint space width (JSW) change.
Objectives: The purpose of this study was to investigate whether the in-house software can predict the inhibitory effect of tocilizumab on joint destruction in a short period of time.
Methods: The study included 39 RA patients (35 female) who were treated with tocilizumab (Table 1). Radiological progression of the metacarpophalangeal and the proximal interphalangeal joints was evaluated according to the GSS at 0, 6, and 12 months. Automatic measurement was performed by the in-house software (Figure 1). We then validated in-house software in terms of accuracy in detecting the JSN.

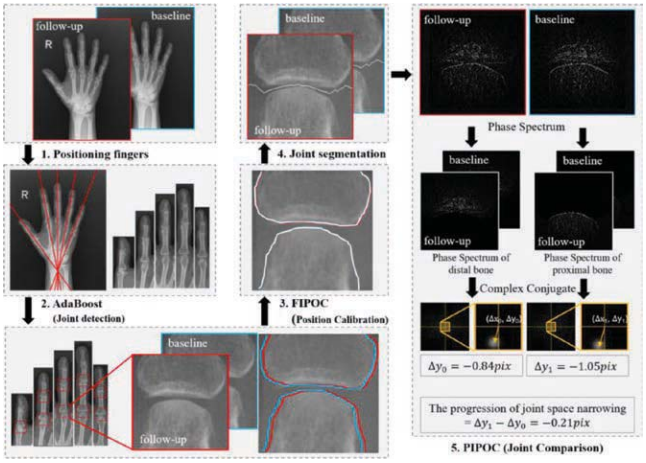

Figure 1. The algorithm flow of in-house software equipped with PIPOC

Table 1. Clinical characteristics of RA patients

variable	baseline	6 months	12 months
Total number of patients	39		
Sex, female/male	35/4		
Rheumatoid factor status, positive/negative	29/10		
Age, mean (SD) years	61.5 (14.6)		
Duration of disease, mean (SD) months	111.4 (85.0)		
Swollen joint count, mean (SD)	6.0 (4.7)	3.5 (3.5)	2.9 (4.0)
Tender joint count, mean (SD)	6.4 (3.5)	2.9 (2.2)	1.9 (2.0)
DAS28-ESR, mean (SD)	4.9 (1.2)	3.0 (1.1)	2.6 (1.0)
DAS28-CRP, mean (SD)	4.4 (1.1)	3.0 (0.9)	2.6 (0.8)

RA, rheumatoid arthritis; SD, standard deviation; DAS28, disease activity score with 28 joints; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein

Results: To ensure homogeneity of the subjects, we targeted the joints with GSS = 0 at baseline in the software analysis. The success rate of the in-house software for JSW measurement was 96.8% (449/464). Here, the GSS (+)/PIPOC (+) were defined as joints with JSN progression according to the GSS and the software analysis, respectively. Otherwise, joints were defined as the GSS (-)/PIPOC (-) namely non-progressive JSN. The 0–12-month GSS with the 0–6-month GSS (+) group was significantly more JSN progression than the 0–6-month GSS (-) group (Mann-Whitney U test, $p < 0.001$). Similarly, the 0–12-month PIPOC with the 0–6-month PIPOC (+) group was significantly more JSN progression than the 0–6-month PIPOC (-) group ($p < 0.001$). The 0–12-month JSW change of finger joints with the 0–12-month GSS (+) detected by the in-house software was significantly greater than the 0–12-month GSS (-) ($p = 0.02$).
Conclusion: Our in-house software equipped with PIPOC might be able to predict the subsequent joint destruction with 6 months observations.

AB1331 DIAGNOSTIC CAPABILITY OF ANESTHETIC INTRA-ARTICULAR INJECTIONS FOR FEMOROACETABULAR IMPINGEMENT

E. Campos Martins[1], D. Araujo Fernandes[1], G. Melo[1], F. De Souza Neves[2]. [1]*Federal University of Santa Catarina, Department of Surgery, Florianópolis - SC, Brazil*; [2]*Federal University of Santa Catarina, Internal Medicine Department, Florianópolis - SC, Brazil*

Background: Femoroacetabular impingement syndrome (FAIS) is a highly prevalent painful disorder that is considered a risk factor for hip osteoarthritis. Confirming that FAIS is the main cause of a pain is a hard task. There are patients who have the typical morphological alterations of FAIS, but are asymptomatic. FAIS morphologies can represent a major confounding factor in patients with undiagnosed rheumatic diseases. On the other hand, surgery can significantly improve quality of life of patients with FAIS. Anesthetic intra-articular injections might constitute viable alternatives for diagnosing FAIS.
Objectives: This systematic review aimed to answer the following question: "What is the diagnostic capability of anesthetic intra-articular hip injections for the assessment of FAIS?".
Methods: This study was conducted following the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) statement. Embase, CINAHL, LILACS, PubMed, SCOPUS, SPORTDiscuss, The Cochrane Library, and Web of Science databases were screened. All studies that assessed the diagnostic capability of anesthetic intra-articular hip injections for the assessment of FAIS were considered eligible. Study selection and data collection were performed by three independent reviewers. Risk of bias of the included studies was assessed through the QUADAS-2 tool.
Results: A total of 13 articles were selected for full-text reading, of which 5 were finally considered eligible and included for analysis [1-5]. A summary of the studies' descriptive characteristics can be found in the Table 1. Overall judgment was "at risk of bias" for all included studies (Figure 1). More detailed information regarding bias assessment at QUADAS-2 is available in the Figure 1. From 5 included studies, only 2 [2,5] indicated that anesthetic intra-articular injections can be useful as diagnostic tools for FAIS.
Figure 1.

Table 1.

Author	Mean Age	N (Female)	Injection Content	Injection Guidance	Time for pain assessment after injection (Way of assessment)	Threshold to consider FAIS diagnosis	Reference Standard	Findings
Kivlan	29.9 ± 10.4	72 (54)	Lidocaine + bupivacaine + triamcinolone	Fluoroscopy	2 hours (provocative activities)	Not established	Arthroscopy	No difference in pain relief after injection between individuals with and without FAIS (p=0.128)
Kraeutler	38.8 ± 14.2	161 (120)	Lidocaine + triamcinolone	Non-guided	10 minutes (physical tests and provocative activities)	>70% of pain relief after injection	Symptoms + physical tests + radiography	FAIS and dysplasia diagnosed in 76% of patients with >70% of pain relief after injection, and in 67% in patients presenting <70% (p=0.62)
Chinzei	36.7 ± 14.7	49 (27)	Lidocaine	Fluoroscopy	2 weeks (uninformed)	>50% of pain relief	Arthroscopy	No significant association between pain relief intensity after injection and the presence of FAIS (p>0.05)
Gao	36 (16-65)	78 (41)	Lidocaine + betamethasone	Ultrasound	10 minutes and 1 week (routine tasks)	> 50% of pain relief	Arthroscopy	Response to injection is 91.7% accurate for detecting FAIS
Perdikakis	33 (18-58)	34 (20)	Ropivacaine	Fluoroscopy	30 minutes (physical tests)	Uninformed	Arthroscopy	Response to injection presented 92% of PPV and 96,5% of accuracy for diagnosing FAIS, with NPV and sensitivity of 100%

Conclusion: Evidence regarding the diagnostic capability of anesthetic intra-articular hip injections for FAIS is sparse. In order to accurately answer our research question, future studies that use standardized and optimized protocols of injection and pain assessment after injection are still essential. Furthermore, the need to take into account the different biases surrounding diagnostic studies was highlighted in our study.

AB1332

INSIGHTS INTO DISEASE ACTIVITY SCORE IN 28 JOINTS (DAS28) AND ITS COMPONENTS FROM AN ULTRASOUND PERSPECTIVE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

J. Kow[1], G. H. Lim[2], Y. K. Tan[1]. [1]*Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; [2]*Singapore General Hospital, Health Services Research Unit, Singapore, Singapore*

Background: Disease Activity Score in 28 Joints (DAS28) is a composite disease activity score commonly used to evaluate disease activity in rheumatoid arthritis (RA). Musculoskeletal ultrasound (US) allows visualization and assessment of joint inflammation and structural damage in RA.
Objectives: The aim of this study is to gain insights into DAS28 and its components through studying their relationship with US detected joint inflammation and bone erosion (BE).
Methods: At each joint recess, US power Doppler (PD) and greyscale (GS) joint inflammation were semi-quantitatively (0 to 3) graded using validated scoring methods while BE was scored as present=1 or absent=0 based on Outcome Measures in Rheumatology (OMERACT) consensus definition of BE. At the patient level, Pearson's correlation coefficient was used to correlate US PD, GS and Erosion scores with the following clinical variables: DAS28 and its components (including the erythrocyte sedimentation rate (ESR) in mm/hr; swollen joint count (SJC) ranging from 0 to 28; tender joint count (TJC) ranging from 0 to 28; and patient's global assessment (PGA) of disease activity ranging from 0 to 100). Bonferroni correction was used to account for the above multiple testing. Among associations which were statistically significant, simple linear regression was used to describe the relationship between variables.
Results: A total of 2520 joints and 2800 joint recesses from 36 joint sites (bilateral proximal interphalangeal joints, thumb interphalangeal joints, metacarpophalangeal joints, metatarsophalangeal joints, wrists, elbows and ankles) were scanned in 70 adult RA patients (baseline characteristics: 81.4% female; 74.3% Chinese; mean (SD) DAS28 3.99 (1.25); mean (SD) disease duration 75.3 (61.2) months). All 70 patients underwent US joint inflammation assessment with a subset of 30 patients assessed for US BE. Table 1 summarizes the correlation results between the US and clinical variables. US PD scores were correlated with DAS28 (r=0.34, p=0.02) and SJC (r=0.33, p=0.03). US GS scores were correlated with DAS28 (r=0.42, P=0.002). US Erosion scores were correlated with SJC (r=0.69, P<0.001). Simple linear regression (see scatter plots in Figure 1) demonstrated a statistically significant relationship between the following variables: US PD score versus DAS28 (R^2=0.13, p=0.004); US PD score versus SJC (R^2=0.11, p=0.008); US GS score versus DAS28 (R^2=0.18, P<0.001); US Erosion score versus SJC (R^2=0.48, p<0.001).
Conclusion: Both DAS28 and SJC have significant correlation with US detected joint inflammation. However, among the clinical variables, only SJC appears to be associated with structural damage and has significant correlation with US detected BE. Therefore, it appears that the results from both DAS28 and SJC can be more reflective of the RA disease status when compared to DAS28 alone. The role(s) of both DAS28 and SJC versus DAS28 alone as patient outcome measures in RA need to be further explored.

AB1333 **ULTRASOUND FINDINGS IN NORMAL ANKLES – ULTRASOUND-MRI COMPARISON**

L. Enache[1,2], C. Popescu[1,2], C. Codreanu[1,2]. [1]*Carol Davila University of Medicine and Pharmacy, Rheumatology, Bucureşti, Romania*; [2]*Center for Rheumatic Diseases, Rheumatology, Bucureşti, Romania*

Background: Although in recent years efforts have been made to standardize the protocols of ultrasound acquisition for each anatomical region, as well as the definitions and quantification of pathological findings, there is still an unanswered question: what should an ankle joint look like in a healthy subject?
Objectives: The study aims to describe ultrasound changes in the ankles of healthy subjects and to compare the ultrasound method with MRI.
Methods: The study included healthy volunteering adults, without any ankle symptoms or local pathological medical history. The right ankle was examined clinically, by ultrasound (by the same expert, using a Esaote MyLabTwice with a 12-18 MHz linear probe, with standard definition of imaging findings [1-4]) and by MRI without contrast (by the same expert, using a 1.5 T GE Optima 450 WGEM machine, with standardized definitions of finding [5-7]).
Results: The study included 25 healthy subjects, with a median age of 54.6 ± 11.8 years, mostly women (84%). Ultrasound identified minimal synovial effusion (SE) in the tibiotalar joint (TTJ) in 20% of subjects (24% on MRI, overall agreement - OA=88%, k=0.65, sensitivity=66.7%, specificity=94.7%), in equal proportions between the anterior and posterior recess (12% on ultrasound and 16% on MRI). One subject had SE in both TTJ's recesses. Ultrasound minimal SE was also found in the subtalar joint in 36% of subjects (44% on MRI, OA=92%, k=0.83, sensitivity=81.8%, specificity=100%), only in the posterior recess (8% in the anterior recess on MRI, with 2 subjects having SE in both recesses). A minimal amount of SE in tendon sheets, only in the medial ankle compartment (flexor tendons, retro and infra-malleolar segments), was also found and quantified in ultrasound mode B as grade 1 tenosynovitis: 20% in tibialis posterior (48% on MRI, OA=72%, k=0.43, sensitivity=41.7%, specificity=100%, mean MRI thickness of 1.28±0.26mm – grade 1), 16% in flexor digitorum longus (32% on MRI, OA=76%, k=0.36, sensitivity=37.5%, specificity=94.1%, 2.70±2.39mm, of which 24% grade 1 and 8% grade 3) and 20% flexor hallucis longus tendons (32% on MRI, OA=88%, k=0.69, sensitivity=62.5%, specificity=100%, 1.38±0.69mm, of which 28% grade 1 and 4% grade 3). There were no cases of articular or tendon sheath synovial hypertrophy and no cases of intra- or peri-articular power Doppler signals.
Conclusion: Ultrasound has proven to be an accurate imaging method for ankle examination. Healthy subjects may exhibit minimal ankle intra- and peri-articular SE, especially in the posterior recess, respectively in the medial compartment of the ankle, which may imply that these findings should not be of clinical relevance in the diagnostic evaluation or monitoring of rheumatoid arthritis disease activity.

AB1334 **SCANOGRAPHIC EVALUATION OF BONE FRAGILITY 2 YEARS AFTER BARIATRIC SURGERY IN OBESE PATIENTS: AN OBSERVATIONAL STUDY**

M. Fauny[1], M. Halin[1], E. Allado[2], D. Quilliot[3], L. Brunaud[4], E. Albuisson[5], I. Chary Valckenaere[1], D. Loeuille[1]. [1]*University Hospital of Nancy, Rheumatology, Nancy, France*; [2]*University Hospital of Nancy, University Center of Sports Medicine and Adapted Physical Activity, Nancy, France*; [3]*University Hospital of Nancy, Department of Endocrinology Diabetology and Nutrition, Nancy, France*; [4]*University Hospital of Nancy, Department of Digestive, Hepato-Biliary and Endocrine Surgery, Nancy, France*; [5]*University Hospital of Nancy, Data Management et Statistiques, Nancy, France*

Background: Osteoporosis is a common disease whose prognosis can be seriously impacted by the development of fractures that lead to functional limitations and may even have life-threatening sequelae (1). CT is useful for diagnosing vertebral fracture (VF) and measuring the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC- L1). Obesity might be a protective factor against bone loss and osteoporosis (2). Nonetheless, epidemiological studies have reported an association between obesity and an increased risk of fragility fractures (3) and suggested that obesity may be a risk factor for fracture and decreased bone density (4,5). For bariatric surgery, the results are less controversial. According to many studies, malabsorptive procedures lead to a decrease in bone mineral density and sometimes an increased risk of fragility fractures (2,6,7,8). However, the kinetics of bone loss and its physiopathology are unclear.
Objectives: The primary objective was to evaluate bone fragility on computed tomography (CT) in obese patients before and 2 years after bariatric surgery. The secondary objectives were to identify risk factors for a decrease in the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1).
Methods: This descriptive study included obese patients who underwent bariatric surgery between January 2014 and December 2019 and CT before and two years (±6 months) after bariatric surgery. SBAC-L1 (in Hounsfield units (HU)) was measured on CT, and vertebral fracture (VF) was manually assessed. The SBAC-L1 fracture threshold was defined as below 145 HU.
Results: Among the 78 included patients, 85.9% were women, with a mean age of 48.5 years (±11.4); the mean body mass index (BMI) was 46.2 kg/m2 (±7) before surgery and 29.8 kg/m2 (±6.7) 2 years after surgery. There was a significant change in SBAC-L1 two years after surgery (p=0.037). In multivariate analysis, the risk factors for having an SBAC-L1 ≤ 145 HU 2 years after bariatric surgery in those with an SBAC-L1 > 145 HU before surgery were age and sex, with men and older patients having a higher risk (OR = 32.6, CI95% = [1.86-568.77], and OR = 0.85, CI95% = [0.74-0.98], respectively).
Conclusion: SBAC-L1 was significantly lower two years after bariatric surgery than before surgery. When the SBAC-L1 was over 145 HU before bariatric surgery, men sex and older patients were the risk factors for having an SBAC-L1 below the fracture threshold 2 years after surgery.

AB1335 **BONE MARROW EDEMA SCORE IN HAND X-RAY FILM BY AI DEEP LEARNING ASSOCIATE WITH MRI BONE EDEMA IN RHEUMATOID ARTHRITIS.**

K. Katayama[1], D. Pan[2], M. Oda[3], T. Okubo[4], K. Mori[5]. [1]*Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan*; [2]*Graduate School of Informative, Nagoya University, Information and Communications, Nagoya, China*; [3]*Graduate School of Informative, Nagoya University, Information and Communications, Nagoya, Japan*; [4]*Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan*; [5]*Graduate School of Informative, Information and Communications, Nagoya, Japan*

Background: Rapid radiographic progression (RRP) was reported to be one of clinical symptom in difficult to treat RA(D2T RA) (1). Eular recommendation for imaging showed BME is strong and independent prognostic factor for bone destruction(2). We reported bone marrow edema (BME) in MRI image was most associated with RRP compared with bone erosion, synovitis in Adalimumab add-on therapy in MTX-IR RA patients(3). To rescue RRP, early detection of BME is important although cost of MRI is expensive and hard to repeat.
Objectives: To investigate the score of BME in hand X ray film by deep learning between X ray film and MRI BME information can discriminate the differences between BME and non-BME images.
Methods: In this work, we use a neural network consisted of convolutional layers and fully connected layers to classify X-ray images (Figure 1) In this paper, the output is the socre of BME which ranges from 0 to1(threshold = 0.4). We also

used an interpretation technique called the Grad-CAM for visual explanations. Hand MRI (1.5T) were used.

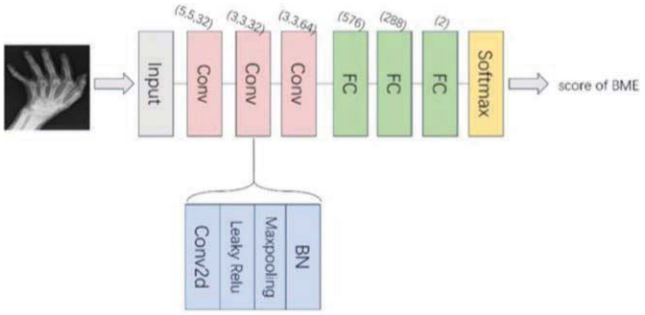

Figure 1. The convolutional neural network design. A red block "Conv" means a convolutional block. It contains a 2D convolution layer, a leaky relu activation function, a maxpooling layer and a batch normalization layer. The numbers above each "Conv" block are (kernal size, kernal size, kernal number). A green block "FC" is a fully connection layer. The number above it is (neuron number). After the last Softmax layer, the output becomes the probability of BME which ranges from 0 to 1.

Results: Regarding data split, 104 images including 79 non-BME images and 25 BME images are used as a hold-out test set. The rest of the images (473 images) are used as training data and validation data. Five fold cross-validation is used for these 473images. For each fold, there are about 378 images including 297 non-BME images and 81 BME images in the training set. There are about 95 images including 74 non-BME images and 21 BME images in the validation set. In order to fully utilize every image and unify the distribution of the training set and the validation set, the ratio of non-BME and BME is controlled to be the same which is about 3.66:1. The five folds showed similar performance on the hold-out test set. AUC is the area under the ROC curve. As the result, AUC which indicates the general performance of this model, ranged from 0.88 to 0.91. The average precision was 63% and the average recall rate was 87%. In this experiment, the initialization seed will greatly influence the final result. For example, AUC can be reduced to 0.73 from 0.89 because of a different initialization seed. It perhaps results from the shortage of data, which can easily make the neural network drop into a local minimum.We also utilized Grad-cam to visualize the result. The result of Grad-cam shows the importance of each part to the final prediction(Figure 2).

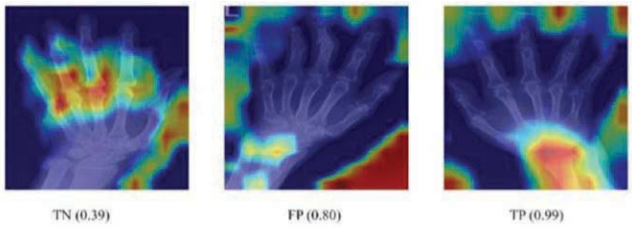

Figure 2. Result of Grad-cam. Numbers in the parenthesises are the possibilities of BME. The middle case is unexpected because red region is the surrounding of the hand. The left and right cases may indicate the evidence for prediction.

Conclusion: The preliminary result is much better than a random guess. According to this result, there should be a certain difference between BME and non-BME images. If it's the characteristic of BME that domains this difference, our classification algorithm will be feasible for BME. Our future work is to justify the evidence of the predictions and improve performance.

AB1336 EFFECTS OF MUSLIM PRAYER ON LOWER LIMB ENTHESIS ULTRASOUND

M. Slouma[1], S. Ben Dhia[1], C. S. Bellagha[1], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[2]. [1]*The Military Hospital of Tunis, Department of Rheumatology, Tunis, Tunisia*; [2]*The Military Hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia*

Background: Muslim prayer, also known as salat, includes a series of postures and movements, concomitant with a spiritual meditation and Quran recitations, performed at least 5 times a day by Muslim worshipers [1]. Each prayer includes a specific number of rakaa which consists of a single iteration of movements [2].
Objectives: We aim to assess the effects of the Muslim prayer movements on the lower limb entheses, using ultrasonography (US).
Methods: We performed a cross-sectional study including asymptomatic healthy individuals. Each subject was asked if they performed prayer (G1) or not (G0). People who performed prayer were asked about the age and year when they started praying, number of rakaa performed daily and duration of each rakaa. US of lower limb entheses was performed. We explored the entheses of quadricipital tendon (QT), proximal patellar tendon (PPT), distal patellar tendon (DPT), calcaneal tendon (CT), and plantar aponeurosis (PA) looking for thickening, hypoechogenicity, loss of fibrillar pattern, presence of doppler signal and structure damage lesions (calcifications, cortical irregularity, erosions and enthesophytes). The highest value of enthesis thickness of both sides was considered. Ultrasonographic enthesitis assessment tools were used: the Spanish Enthesitis Index (SEI) [3] and the Glasgow Ultrasound Enthesitis Scoring System (GUESS) [4]. Data analysis was performed using the IBM SPSS software version 26.
Results: A total number of 370 entheses was evaluated. There were 29 males (78%) and 8 females. The mean age was 44.73±12.7 years. Twenty-five subjects (68%) practice prayer. The mean prayer starting age of 28.58±13.345 years. The mean number of years since prayer was started of 20±16.32 years. The mean daily number of rakaa was 19.16±4.16. The mean total daily prayer duration was 35.28±65.58 minutes. The mean enthesis thickness was 5.98±0.72 mm (QT), 3.69±0.48 (PPT), 4.1±0.64 (DPT), 4.83±0.62 (CT) and 4.89±0.75 (PA). Structural damage lesions were found in 43.2% of subjects (QT), 8.1% (PPT), 13.5% (DPT), 64.9% (CT) and 21.6% (PA). Structure damage lesions of CT enthesis were significantly more frequently found in people who performed prayer (G0: 41.6%, G1: 76%, $\chi 2$=4.194, p=0.041). Furthermore, they are significantly more likely to have thickened PA enthesis (G0: 50%, G1: 84%, $\chi 2$=4.752, p=0.029). The mean SEI was 17.83 in G0 and 19.56 in G1, p=0.647. The mean GUESS was 18.29 in G0 and 19.34 in G1, p=0.781. A positive correlation was found between total daily duration of prayer and PPT enthesis thickness (r=0.575, p<10-3), DPT enthesis thickness (r=0.362, p=0.028), SEI (r=0.360, p=0.026) and GUESS (r=0.388, p=0.018). Thickness of PPT enthesis was also positively correlated to the number of years since prayer was started (r=0.036, p=0.026).
Conclusion: Our study showed that lower limb enthesis US abnormalities are frequent in asymptomatic and healthy subjects who perform Muslim prayer. This finding suggests that lower limb enthesis US should be carefully interpreted in these subjects.

AB1337 EFFECT OF CONTRAST MEDIA IN BONE MINERAL DENSITY MEASUREMENTS AND THE POTENTIALS FOR OPPORTUNISTIC OSTEOPOROSIS SCREENING USING QUANTITATIVE COMPUTED TOMOGRAPHY – A SYSTEMATIC LITERATURE REVIEW

A. Hjortdal[1], A. Cheneymann2, J. Therkildsen[2,3], E. M. Hauge[2,3], S. Winther[4], M. Böttcher[4]. [1]*Aarhus University Hospital, Dept. of Rheumatology, Aarhus, Denmark*; [1]*Aarhus University Hospital, Dept. of Rheumatology, Aarhus, Denmark*; [3]*Aarhus University Hospital, Dept. of Clinical Medicine, Aarhus, Denmark*; [4]*Gødstrup Regional Hospital, Department of Cardiology, Herning, Denmark*

Background: Quantitative computer tomography (QCT) has emerged as a screening tool for opportunistic measurements of volumetric bone mineral density (vBMD) from clinical CT scans, enabling early diagnosis of osteoporosis. However, intravenous contrast media administered during clinical CT examinations, calibration methods as well as different scan phases may influence vBMD and must be considered.[1] Calibration methods include synchronous and asynchronous CT phantoms as well as phantom-less internal calibration.
Objectives: To investigate the effect of intravenous contrast media on QCT-measured vBMD. Furthermore, to review the effects of different calibration methods and scan protocols on vBMD.
Methods: In this systematic literature review, two independent reviewers (AH and AC) conducted a blinded screening for articles involving human participants who had undergone a contrast and non-contrast CT scan to measure vBMD. A total of 1,981 studies, published between 01.01.2000 and 17.01.2021, were screened and 9 eligible studies were included. A meta-analysis was conducted and standard mean differences (SMD) with 95% confidence intervals (CI) were calculated and presented in a forest-plot. Quality of studies was rated by the preliminary ROBINS-E risk of bias tool.[2]
Results: In total, the 9 studies included 515 patients. On average the vBMD SMD changed 0.45 (95% CI: 0.24-0.67, *P < .0001)* from non-contrast to contrast-enhanced (CE) scans at the lumbar region (Figure 1). Phantom-based QCT had a SMD of 0.64 (95% CI: 0.33-0.94, *P < .0001*) and phantom-less QCT had a SMD of 0.20 (95% CI: -0.00-0.40, P = 0.05). Subgroup analyses showed a mean arterial phase vBMD SMD of 0.29 (95% CI: 0.12-0.45 P < .0008) and a venous phase vBMD of 0.56 (95% CI: 0.30-0.81, P < .0001). All studies were deemed to have moderate or serious risk of bias by the ROBINS-E tool.

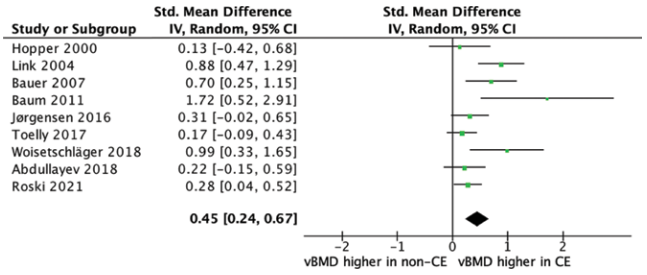

Figure 1. *Meta-analysis of standardized mean difference in lumbar spine vBMD (mg/cm^3) change from non-contrast enhanced (non-CE) CT scans and contrast enhanced (CE) CT scans.*

Conclusion: QCT-measured vBMD is higher in CE scans in both phantom-based and phantom-less scans compared to non-contrast CT. Our meta-analysis suggest that contrast has a larger impact on vBMD in phantombased vs. phantom-less and in venous phase scans vs. arterial phase scans, underlining not only the time-dependency but also the dependency of the calibration method. Arterial phase CT scans using internal calibration may be preferred when measuring vBMD in a clinical setting without an adjusting conversion factor. However, if CE scans are to be used in opportunistic vBMD screening, development of a universal calibration- and protocol specific conversion factor is of importance.

AB1338 CALPROTECTIN, A SENSITIVE MARKER OF INFLAMMATION, IS ROBUSTLY ASSESSED IN PLASMA FROM PATIENTS WITH ESTABLISHED RA BY USE OF DIFFERENT LABORATORY METHODS

H. B. Hammer[1,2], S. L. Pedersen[3], I. Gehring[4], L. Mathsson-Alm[5], J. Sexton[1], J. Askling[6]. [1]*Diakonhjemmet Hospital, Dept of Rheumatology, Oslo, Norway*; [2]*Faculty of Medicine, University of Oslo, Oslo, Norway*; [3]*Diakonhjemmet Hospital, Clinical Laboratory, Oslo, Norway*; [4]*Thermo Fisher Scientific,Thermo Fisher Scientific, Freiburg, Germany*; [5]*Thermo Fisher Scientific / Phadia AB, Thermo Fisher Scientific, Uppsala, Sweden*; [6]*Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden*

Background: Calprotectin (S100A8/S100A9, MRP8/MRP14) in plasma has been shown to be more sensitive than C-Reactive Protein (CRP) or Erythrocyte Sedimentation Rate (ESR) in reflecting inflammatory activity in patients with rheumatoid arthritis (RA).[1,2]
Objectives: The present objective was to explore the robustness of laboratory examination of calprotectin by comparing the results from assessments by use of two different methods.
Methods: Frozen plasma samples from a study of 177 patients with established RA initiating biologic disease modifying drugs were analysed for calprotectin levels at baseline and after 1, 2, 3, 6 and 12 months by use of either enzyme-linked immunosorbent assay (ELISA) or fluoroenzyme immunoassay (FEIA). The ELISA technique used kits from Calpro AS (Oslo, Norway) and the samples were assessed in a semi-automatic analysis machine Dynex DS2 (Dynex Technologies, Virginia, USA) at Diakonhjemmet hospital. The Calpro AS kits included all necessary buffers, cleansing solutions, enzyme substrate, standards, and controls (high and low calprotectin levels) and their protocol was used for the calprotectin assessments. The standards and controls were used as the mean of two measures, while all the patient samples were analysed as single measures. As a sub-study in NORA (a study exploring personalized medicine in RA by including several study cohorts from the Nordic countries), the same plasma samples were additionally assessed by FEIA. The FEIA technology used the EliA™ calprotectin 2 wells in a Research Use Only setting on the PhadiaTM 2500 instrument (Phadia AB, Uppsala, Sweden) with a 1:50 dilution. Spearman was used for correlation assessments. To explore differences across concentration levels the baseline calprotectin levels were divided into 3 groups based on results from the Calpro AS assay (normal levels; ≤ 910 µg/L; moderately elevated; 911-2000 µg/L, highly elevated; > 2000 µg/L).
Results: A total of 917 samples from the 177 patients (mean (SD) age 52.9 (13) years, disease duration 10 years (ranging from a few months to 46 years), 81% women, 78% anti-CCP IgG positive and 81% RF IgM positive) were included. The median of the correlation coefficients between the two methods at the six visits was 0.96 (range 0.91-0.97). Correlations were very high for normal levels (0.91) but somewhat lower for moderate and highly elevated levels (0.85 and 0.79, respectively). There were no significant differences between the associations depending on age, sex, or disease duration, nor on the anti-CCP IgG and RF IgM status of the patient.
Conclusion: The present study supports the robustness of calprotectin analyses, showing similar results across two different analytical methods, and that the concentrations were not influenced by demographic or immunological variables. Being a robust and more sensitive marker of inflammation than the commonly used CRP and ESR, calprotectin analyses should be available for assessments of RA patients in routine clinical care.

AB1339 MUSCLE ULTRASOUND FOR THE DIAGNOSIS OF SARCOPENIA IN RHEUMATOID ARTHRITIS (RA).

L. Cano Garcia[1], J. Vacas[2], C. Dominguez[3], D. Ruiz[4], J. M. Martín Martín[5], F. G. Jiménez-Núñez[1]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA); Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain*; [2]*Hospital Universitario Reina Sofía, Universidad de Córdoba, Rheumatology, Cordoba, Spain*; [3]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*; [4]*Hospital Universitario Reina Sofía, Instituto Maimónides de Investigación Biomédica (IMIBIC), Universidad de Córdoba, Rheumatology, Córdoba, Spain*; [5]*Hospital Universitario Nuestra Señora de la Candelaria, Rheumatology,Tenerife, Spain*

Background: Sarcopenia is a muscular disease characterized by a loss of muscle mass and function. The condition is associated with chronic diseases and

ageing and predicts disability, hospitalization and death (1). Due to chronicity and disability produced by RA, it is convenient to see the relationship with sarcopenia.

Objectives: To assess the diagnostic utility of ultrasound (US) for sarcopenia.

Methods: Cases: Outpatients, 65 years old or more, with RA (ACR/EULAR 2010 criteria) from the rheumatology clinics of 4 Spanish University Hospitals were randomly selected consecutively from rheumatology consultation since May 2021 to September 2021. Controls: Control subjects without rheumatoid disease were selected from family members or friends of the cases, paired by age, gender and social status from May to September 2021. Variable and measures: The main evaluated outcome was sarcopenia as defined in 2019 by the European Working Group on Sarcopenia in Older People (EWGSOP). Crossectional Ultrasounds (US) of the third proximal forearm were evaluated for the perpendicular distance (milimetres) between superficial surface of subcutaneous celular tissue and the deep surface close to the ulnae with two different measures (66% and 75%). Crossectional US images were also obtained of lower limbs, at an equidistant point between anterosuperior iliac spine and the upper border of the patella for measuring the distance between superficial surface of subcutaneous celular tissue and the deep interface of the femur with vastus medialis muscle with two different measures (50% and 75%). Handheld dynamometer was used to measure the strength in upper limbs. Body composition was evaluated using dual-energy X-ray densitometry.

Statistics: A descriptive analysis, chi square y T-student tests were done to compare the main characteristics and results between patients and controls. Correlations between forearm US and strength and between thigh US and total DEXA were calculated by Pearson's test.

Results: 76 patients and 76 controls were included in the study, 120 were women (78,9%), with media ± SD of age 74,7 ±6,98 of media and 32 (21,1%) were men, with age 70,1 ±3,78 of media. In comparation with controls, RA patients presented more frequency of sarcopenia (30 [19,53%] vs 6 [3,94%]; p=0,005) according to EWGSOP criteria. From the point of view of ultrasound, RA patients presented less muscle mass in cubital forearm and thigh. Control group presented larger size of muscle (Table 1).

Table 1. ***Results measirements case-control in milimeters***

	Control (m±ds)	RA (m±ds)	p-valor
Right forearm 66% ulnar	42,92±8	38,72±9,33	0,003
Left forearm 66% ulnar	41,17±8,97	37,93±9,27	0,03
Left forearm 75% cubital	38,74±7,7	35,18±8,5	0,008
Right Thigh 50% FR+VI	30,9±7,46	28,09±6,31	0,011
Right Thigh 50%VI	14,5±4,26	13,08±4,27	0,042
Right Thigh 50% FR	15,26±3,6	13,5±3,28	0,002
Right Thigh 50% area FR	588±181,29	481,49±140,56	0,001
Lefth Thigh 50% FR+VI	27,67±8,9	22,37±8,26	<0,001

Ultrasound measurements in forearm which showed a positive correlation with strength were: right forearm: 66% ulnar (r=0,364, p=0,001), 75% ulnar (r=0,365, p=0,001); left forearm: 66% ulnar (r=0,348, p=0,002), 75% ulnar (r=0,337, p=0,003). In the other hand, ultrasound measurements in thigh which showed a positive correlation with DXA were: right thigh 50% femoral rectus (FR)-vastus intermedius (VI) (r=0,255, p=0,003), 50% VI (r=0,256,p=0,003), 50% FR (r=0,265, p=0,002), 50% area FR (r=0,280, p=0,003), 75% FR-VI (r=0,357,p<0,001), 75% VI (r=0,382,p<0,001), 75% FR (r=0,240, R2=0,006), 75% area FR (r=0,218,p=0,023); Left thigh: 50% FR-VI (r=0,251, p=0,004), 50% VI (r=0,293,p=0,001), 50% FR (r=0,214, p=0,015), 75% FR-VI (r=0,347,p<0,001), 75% VI (r=0,342, p<0,001), 75% FR (r=0,295, p=0,001).

Conclusion: Muscle Ultrasound is a useful diagnostic tool to detect sarcopenia. It can be cost-efficient and faster when compared with DEXA and the results correlate consistently with the strength in forearm. Patients with rheumatoid arthritis are in high risk of suffering sarcopenia and US could be used to control the evolution of this condition.

AB1340 PREVALENCE OF THE WRISTS AND HANDS SYNOVITIS IN SUBGROUPS OF PATIENTS FOLLOWED FOR SYSTEMIC LUPUS ERYTHEMATOSUS.

N. Khaldoun[1], S. Haid[1], L. Soumia[2], L. Boulegheb[3], F. Rahal[1], I. Allam[4], R. Djidjik[4], N. Brahumi[1], A. Ladjouze-Rezig[1], F. Hanni[1]. *[1]Ben Aknoun Hospital, Rheumatology, Algiers, Algeria*; *[2]Faculty of Biological Sciences - USTHB. Algiers., Cytokine and NO synthase laboratory, Algiers, Algeria*; *[3]Ben Aknoun Hospital, Radiology, Algiers, Algeria*; *[4]Beni Messous Hospital, Immunology, Algiers, Algeria*

Background: Joint damage is one of the most common manifestations of SLE. Represented by the presence of arthralgia or arthritis, with or without deformities or erosions. Musculoskeletal ultrasound allows evaluation of the inflammatory joint damage for more targeted therapeutic approach.

Objectives: The aim of this study was to estimate the prevalence of the wrists and hands synovitis (WHS) in subgroups of patients with systemic lupus erythematosus (SLE) and to compare them with each other.

Methods: One hundred and sixty-nine patients with SLE were consecutively recruited in the rheumatology unit (consultation or hospitalization) of the Ben Aknoun hospital, Algiers-Algeria. Stratification into subgroups was carried out: non-deforming non-destructive patients (NDND), rhupus patients (if coexistence of lupus and rheumatoid arthritis criteria), patients with moderate deforming arthropathy (MDA) or Jaccoud arthropathy according to the score of the Spronk index. For each patient, demographic data, duration of SLE evolution and joint involvement were collected, a standard inflammatory biology report and screening for rheumatoid factor (RF) and anti-CCP (ACPA) were requested. A musculoskeletal ultrasound of the wrists, MCP and PIP (from the 2nd to the 5th rays) was performed with a search for synovitis and erosions, the ultrasound examination was preceded by the calculation of the SLEDAI score and the HAQ score.

Results: 169 patients were recruited: 135 NDND, 18 rhupus, 10 Jaccoud, 6 MDA, respective mean age of 38.38 ± 11.79, 39.39 ± 11.74, 41.10 ± 9.5, 47 ± 9.35 years. The mean duration of lupus was 8.23 ± 6.97, 12.33 ± 8.71, 13.10 ± 6.6 and 15 ± 5.93 years, respectively. The mean duration of joint involvement was 7.38 ± 6.920, 12.22 ± 8.84, 13.10 ± 6.6, 15 ± 5.93 years. The positive CRP was found respectively in 20%, 38.9%, 20%, and 16.7%. The frequency of WHS, RF, ACPA and erosions was significantly higher in the rhupus group compared to that of NDND (p <0.001). No difference in mean SLEDAI scores between subgroups. The mean HAQ score was higher in patients in the rhupus and Jaccoud groups compared to the mean score in patients in the NDND and MDA group (p <0.0001).

Conclusion: Our results confirm that rhupus patients have more inflammatory and erosive involvement than other lupus subgroups. It represents an overlap between rheumatoid arthritis and lupus more than a separate entity. We have also shown that deforming arthropathies without structural damage correspond to a late course in a group of patients initially non-deforming non-destructive.

AB1341 ASSESSMENT OF COMMON FEMORAL VEIN INTIMA-MEDIA THICKNESS BY ULTRASOUND IN BEHÇET'S DISEASE: COMPARATIVE STUDY OF PATIENTS WITH OR WITHOUT VASCULAR INVOLVEMENT IN A NATIONAL REFERRAL CENTER

D. Prieto-Peña[1,2], A. Del Peral Fanjul[2], B. Atienza-Mateo[1,2], V. Pulito-Cueto[2], M. A. González-Gay[1,2], R. Blanco[1,2]. *[1]Hospital Universitario Marqués de Valdecilla, Department of Rheumatology, Santander, Spain*; *[2]IDIVAL, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and Metabolic Bone Diseases of the Musculoskeletal System, IDIVAL, Santander, Spain*

Background: Vascular manifestations are frequent in Behçet's disease (BD). However, they have been less studied than other manifestations, such as uveitis [1]. Increased venous wall thickness assessed with ultrasound (US) has been reported in BD [2]. However, it remains unclear if US findings correlate with vascular involvement in BD.

Objectives: To assess vascular Doppler US findings in patients with BD with and without clinical vascular manifestations.

Methods: Observational study of unselected consecutive patients with BD assessed in a national referral center, from March 2021 to May 2021. All patients fulfilled the 2014 ICBD criteria [3]. They were evaluated sequentially with a scheduled clinic visit after signing an informed consent. Demographic and clinical variables were collected. Patients were considered to have vascular involvement

Table 1.

	Vascular manifestations (n=17)	Without vascular manifestations (n=25)	P value
Sex *(men)*, n (%)	10 (41.2)	13 (48)	0.663
Age *(years)*, mean ± SD	51.24±12.8	45.56±12.88	0.133
HLA B51 positive, n/tested cases	4/17	14/25	-
Evolution time (years) from diagnosis, mean ± SD	13.35 ± 10.45	13.04 ± 8.52	0.891

Neurological manifestations, n (%)	2 (11.8)	2 (8)	0.683
Ultrasound findings			
Femoral vein IMT (mm), median [IQR]	0.65 [0.45-0.82]	0.49 [0.39-0.55]	**0.028**

IMT: intima-media thickness. IQR: interquartile range.

if they had history of deep vein thrombosis, pulmonary thromboembolism, superficial thrombophlebitis, arterial thrombosis (peripheral arterial thrombosis, stroke, transient ischemic attack), aneurysms, acute myocardial infarction or Raynaud's disease. Wall thickness of bilateral common femoral vein was measured by assessing the intima-media thickness (IMT) with a high-resolution Doppler US [2]. Statistical analysis was performed with SPSS. Student´s t test or Mann-Whitney U test was used to compare continuous variables, and Chi-squared test or Fisher´s exact test for categorical variables, as appropriate.

Results: We evaluated 17 BD patients with vascular manifestations and 25 BD patients without vascular manifestations. Main clinical and demographic characteristic are described in Table 1. The vascular manifestations were deep vein thrombosis (n=4), superficial thrombophlebitis (n=1), arterial aneurysms (n=2), acute myocardial infarction (n=3), arterial thrombosis (n=1) and Raynaud's disease (n=10). The median [IQR] value of the common femoral vein IMT was significantly higher in patients with vascular manifestations (0.65 [0.45-0.82] vs 0.49 [0.39-0.55]; p= 0.028). A significant increase in vascular manifestations was observed in patients with arterial hypertension (p=0.003). HLA B51 presence was more frequent in patients with no vascular manifestations.

Conclusion: Patients with BD and vascular involvement present higher values of common femoral vein IMT. The assessment of venous wall thickness with Doppler US constitutes a useful technique to evaluate clinical vascular involvement in BD patients.

THE EVALUATION OF 18F-PET-CT USE IN RHEUMATOLOGY CLINICAL PRACTICE WITH DEMOGRAPHIC AND CLINICAL FINDINGS

M. C. Ataca[1], S. Gulle[2], Y. Erez[2], G. Can[2], E. Derebek[3], F. Onen[2]. *[1]Dokuz Eylul University Faculty of Medicine Hospital, Department of Internal Medicine, Izmir, Turkey*; *[2]Dokuz Eylul University Faculty of Medicine Hospital, Department of Rheumatology, Izmir, Turkey*; *[3]Dokuz Eylul University Faculty of Medicine Hospital, Department of Nucleer Medicine, Izmir, Turkey*

Background: There is an increasing number of studies in the literature on the use of 18 F-FDG-PET/CT in the diagnosis and treatment follow-up of inflammatory rheumatic and musculoskeletal diseases (iRMD) (1). PET/CT do have an important place in the diagnosis of large-vessel vasculitis (LVV), which shows increased involvement in the walls of large vessels (2).

Objectives: In this study, the aim was to evaluate the demographic, clinical, and laboratory characteristics, compatibility of PET/CT with other imaging methods, and the role of PET/CT in treatment follow-up of the patients who underwent PET/CT at the Rheumatology Clinic between 01.01.2010 and 31.12.2020.

Methods: The patients' age, gender, comorbidities, iRMD types, medications, PET/CT, and ages at the time of iRMD diagnosis were collected. In addition, the compatibility of PET/CT with other imaging methods (MR angiography, Doppler US, and CT angiography) was evaluated in vasculitis subgroups. Control PET/CT images of the patients were evaluated by comparing them with previous imaging findings.

Results: A total of 280 patients, 179 (63.9%) women, with a mean age of 58±15 years, underwent PET/CT in the rheumatology department. 202 (72.1%) patients had a diagnosis of iRMD before PET/CT. After PET/CT, 40 (48.2%) patients were diagnosed with a new iRMD, and 43 (41.8%) were diagnosed with a non-iRMD. No rheumatic disease was detected in 33 (11.8%) patients. iRMD diagnosed by PET/CT are respectively; LVV (n=11), IgG4-RD (n=10), sarcoidosis (n=9), and other (n=10). It was determined that 22 (26.5%) of newly diagnosed patients other than iRMD had malignancy [Bronchial (n=8), lymphoma (n=3), breast (n=3), other (n=8) cancer]. PET/CT revealed lymphadenopathy (LAP) in 119 of 165 patients who underwent the scan to exclude malignancy, and 22 of 91 patients who underwent PET/CT for rheumatologic diagnosis. LAP was found in 45% of those diagnosed with iRMD and 74.4% of those diagnosed with non-iRMD (p=0.002). PET/CT imaging was performed on 18 patients for follow-up. The treatment of 4 out of 18 patients with follow-up PET/CT and 76 out of 280 total patients was changed after imaging. In patients with a diagnosis of giant cell arteritis (GCA), the compatibility of PET/CT with MRA was 62.5%, while its agreement with CTA was 100%, and with Doppler US was 40%. In patients diagnosed with Takayasu's arteritis, the compatibility of PET/CT with MRA was 40%, while its compatibility with CTA was 50% and with Doppler USG was 38%.

Conclusion: PET/CT imaging was found to be an important adjunctive examination in the diagnosis and follow-up of sarcoidosis, LVV, and IgG4-RD in patients evaluated in the rheumatology clinic. It has been observed that it is often used in the diagnosis and follow-up of RA, SpA, and autoinflammatory diseases, to investigate the malignancies accompanying rheumatic diseases and to evaluate the characteristics of LAP. PET/CT findings provide significant benefits to the clinician in the early diagnosis of iRMDs and differentiation of malignant and/or infectious etiologies.

ON THE DEVELOPMENT OF NEW DISEASE ACTIVITY SCORES FOR REMOTE ASSESSMENT OF PATIENT WITH RHEUMATOID ARTHRITIS USING THERMOGRAPHY AND MACHINE LEARNING.

I. Morales-Ivorra[1,2], J. Narváez[3], C. Gómez Vaquero[3], J. M. Nolla[3], C. Moragues Pastor[3], D. Grados Canovas[1], J. A. Narvaez[4], M. A. Marin-López[2]. *[1]Hospital Universitari d'Igualada, Rheumatology, Igualada, Spain*; *[2]Singularity Biomed, R+D, Sant Cugat del Vallès, Spain*; *[3]Hospital Universitari de Bellvitge, Rheumatology, Hospitalet de Llobregat, Spain*; *[4]Hospital Universitari de Bellvitge, Radiodiagnosis, Hospitalet de Llobregat, Spain*

Background: Disease activity scores are used in the follow-up of patients with rheumatoid arthritis (RA). These scores include variables obtained through physical examination, such as the tender and swollen joint count. In telematic consultations it is not possible to determine these variables. Thermography is a safe and fast technique that measures heat through infrared imaging. Inflammation of the joints causes an increase in temperature and could therefore be detected by thermography. Machine learning methods are highly accurate in analyzing medical images, and could be used to analyze thermal images automatically. Thermography of hands, patient global health (PGH) and acute phase reactants could be combined to develop new activity scores that facilitate remote assessment of RA patients.
Objectives: To develop new disease activity scores based on the machine learning analysis of thermal images of the hands, PGH and acute phase reactants.
Methods: Multicenter observational study conducted in the rheumatology and radiology service of two hospitals. Patients with RA, psoriatic arthritis, undifferentiated arthritis and arthritis of hands secondary to other diseases that attended the follow-up visits were recruited. Companions of patients and healthcare professionals were also recruited as healthy subjects. In all cases, a thermographic image of the hands was taken using a Flir One Pro or a Thermal Expert TE-Q1 camera connected to a smartphone. Ultrasound (US) of both hands was performed. The degree of synovial hypertrophy (SH) and power doppler (PD) was assessed for each joint (score from 0 to 3). Machine learning was used to quantify joint inflammation from the thermal images using US (SH+PD) as ground truth. This score has been named ThermoJIS. RA patients whose thermal image was taken with the Thermal Expert TE-Q1 camera were used to evaluate the performance (test dataset). The other participants were used as training dataset. The PGH, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were also assessed in the test dataset. ThermoDAS (ThermoJIS + PGH), ThermoDAS-ESR (ThermoJIS + PGH + ESR) and ThermoDAS-CRP (ThermoJIS + PGH + CRP) activity scores were developed using a linear regression. The Spearman's correlation coefficient of ThermoJIS, ThermoDAS, ThermoDAS-ESR and ThermoDAS-CRP vs. SH, PD, PGH, ESR and CRP were used to characterize the new developed disease activity scores. The study was approved by the Clinical Ethics and Research Committee of both centers.
Results: The total number of recruited subjects were 616 (475 for the training and 141 for the testing dataset). The correlations obtained between the different activity scores (ThermoJIS, ThermoDAS, ThermoDAS-ESR and ThermoDAS-CRP) vs. SH, PD, PGH, ESR and CRP are shown in Table 1. All correlations are statistically significant.

Table 1. Spearman's correlations of the developed scores vs synovial hypertrophy (SH); vs power doppler (PD); vs patient global health (PGH); vs erythrocyte sedimentation rate (ESR) and vs C-reactive protein (CRP).

	SH	PD	PGH	ESR	CRP
ThermoJIS	0.42	0.43	0.18	0.16	0.12
ThermoDAS	0.50	0.53	0.87	0.16	0.19
ThermoDAS-ESR	0.54	0.53	0.79	0.49	0.33
ThermoDAS-CRP	0.60	0.60	0.77	0.49	0.54

Conclusion: ThermoJIS shows moderate correlation with US but weak correlation with PGH and acute phase reactants, suggesting that ThermoJIS is non-redundant with symptoms and laboratory assessment. Adding PGH and acute phase reactants to ThermoJIS improves all correlations, including correlation with US. These thermographic scores do not require a physical examination, opening an opportunity to facilitate remote consultations in RA patients.

THE ROLE OF ULTRASOUND CRITERIA IN PREDICTING THE OUTCOME OF EARLY UNDIFFERENTIATED ARTHRITIS OF THE SMALL JOINTS OF THE HAND

N. Aleksandrova[1], A. Aleksandrov[1,2], N. Nikitina[1], V. Aleksandrov[1,2]. *[1]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology Named After A.B. Zborovsky», Department of Functional Research Methods, Volgograd, Russian Federation*; *[2]Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation*

Background: Arthritis of peripheral joints is among the most frequent manifestations in the onset of rheumatic diseases. Determining its nosological identity and rational therapy at an early stage is a complex clinical problem.
Objectives: To evaluate the possibility of using hand ultrasound to predict the outcome of early undifferentiated arthritis (EUA).
Methods: Since 2018, patients with a first-time diagnosis of early undifferentiated arthritis were consecutively included into the study. The final group consisted of 102 patients (women, 71.6%; mean age 44.8±17.2 years old) who were prospectively observed at baseline, after 3 months, and after 1 year. Ultrasound examination (ultrasound) of the hand joints was performed according to a standard technique using a 5-12 MHz linear transducer on an Accuvix V10 ultrasound diagnostic system (Samsung Medison, South Korea). Ultrasound was performed twice with the following criteria: 1) synovium thickness, 2) blood flow in synovium by Doppler, 3) presence of hyperechogenic inclusions in synovium, 4) cortical bone contour, 5) signs of tendon inflammation (flexors and extensors of the fingers). Synovium thickness in the hand joints over 3 mm was interpreted as synovial thickening [1]; appearance of blood flow from the contour of the cortical bone of the joint with tree branching — as "pannus", single loci of blood flow by Doppler — as synovitis in hyperemia stage.
Results: During 12 months of follow-up, 47 patients (46.1%) were diagnosed with early rheumatoid arthritis (based on clinical diagnosis according to 2010 criteria and/or prescription of basal anti-inflammatory drugs); 16 (15.7%) had reactive arthritis associated with urogenital infection; 7 (6.9%) had gouty arthritis; 3 (2.9%) had psoriatic arthritis; 2 (1.9%) had systemic lupus erythematosus; 1 patient (0.9%) was found to have a renal malignancy; 26 (25.5%) had no change in EUA diagnosis. Retrospective analysis of the data showed that initially patients with rheumatoid arthritis (RA) in 46.8% (22/47) were determined to have a tree-like blood flow in the synovium of the joint from the cortical contour of the bone ("pannus"); in patients with reactive arthritis associated with urogenital infection, axial tendon lesions were found most frequently (43.8%; 7/16); in patients with gouty arthritis, changes in the triangular cartilage and hyperechogenic inclusions in the synovium were more common (42.9%; 3/7). During the initial examination of patients with EUA who were subsequently diagnosed with RA, the ultrasound picture of the hand joints in the overwhelming percentage of cases (83%; 39/47) was characterized by the presence of extensor tenosynovitis and/or synovial thickening with Doppler blood flow (against the background of symmetrical arthritis of the metacarpophalangeal joints). The sensitivity of detection of these criteria to the development of RA in patients with small joint EUA was 56% with a positive prognostic value of 69%. It has been previously demonstrated that in EUA the presence of subclinical inflammation of the major joints and high titers of antibodies to cyclic citrullinated peptide are strong predictors of RA development [2]. Probably, the combination of clinical and serological tests with the presented ultrasound data of small joints can also increase the accuracy of diagnosis of early RA in patients with EUA.
Conclusion: Detection of subclinical inflammation in the small joints of the hand and synovial thickening with Doppler blood flow in patients with EUA at baseline can help in the stratification of patients at high risk of developing RA.

PREDICTIVE MODEL FOR THE DIAGNOSIS OF PSORIATIC ARTHRITIS IN DERMATOLOGY REFERRALS ACCORDING TO PURE-4 SCALE

N. De la Torre Rubio[1], J. Campos Esteban[1], M. Pavía Pascual[1], M. Machattou[1], P. Navarro Palomo[1], O. Rusinovich[1], M. Fernandez Castro[1], H. Godoy[1], C. Barbadillo Mateos[1], C. Merino Argumánez[1], B. Garcia-Magallon[1], J. Sanz[1], L.

F. De Villa[1], J. L. Andréu Sánchez[1]. [1]*Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain*

Background: The rate of psoriatic arthritis progression is increased in those patients presenting with established disease greater than 2 years duration, so it is necessary to find tools that allow early diagnosis to prevent joint damage[1]. Prevalence of psoriatic arthritis varies according to the screening strategies used. The COMPAQ study compared four screening questionnaires for psoriatic arthritis (PEST, ToPAS, PASE and EARP), whose sensitivities ranged from 44 to 91%, with the EARP questionnaire showing the highest sensitivity[2]. A new, shorter questionnaire, PURE-4 scale, has been developed, with a sensitivity of 85.7%[3].
Objectives: To evaluate the usefulness of PURE-4 scale in real clinical practice conditions to identify patients with psoriatic arthritis in patients with psoriasis referred from a dermatology department to a rheumatology department.
Methods: Retrospective descriptive study of patients diagnosed with psoriasis who have been referred from the Dermatology Department in the last 12 months for suspected joint domain according to PURE-4 scale used by this department. The following variables were collected: age, sex, obesity, dyslipidaemia, smoking, family history of psoriasis, form of psoriasis (plaque, palmoplantar, scalp, nail), previous treatment (topical, methotrexate, other, none), PASI index, compliance with CASPAR criteria, rheumatological diagnosis (psoriatic arthritis yes/no), PURE-4 score, morning stiffness in hands, Achilles enthesitis, inflammatory low back pain and need for anti-inflammatory drugs for joint pain in the last 3 months. Descriptive statistics was performed and Chi-square test was used to compare the diagnosis of psoriatic arthritis with PURE-4 values (at the response threshold ≥ 1 it has a sensitivity of 85.7% and a specificity of 83.6%).
Results: In the last 12 months the Dermatology Department of our hospital made 33 referrals for suspected psoriatic arthritis in patients diagnosed with psoriasis. Mean age was 46.4 ± 12.4 years, 51.5 % were men. Fifty-one percent of the patients had a BMI ≥25, 30.3% had dyslipidaemia and 45.5% were smokers; 10% of the patients had family history of psoriasis. The most prevalent form of psoriasis was plaque (18%) followed by nail (6%), palmoplantar (3%), scalp (3%) and droplet (3%) involvement; 51.5% of patients were on topical treatment, 9% on methotrexate and 39.4% on biologic treatments; mean PASI was 6.2 ± 7.5. Seventy-five percent of the referred patients did not meet CASPAR criteria; 33.3% were diagnosed with psoriatic arthritis by the rheumatologist. Of the 33 patients, 4 (12.1%) scored 0 points on PURE-4 scale; 21 (63.6%) scored 1 point; and 8 (24.3%) scored 2 points. Once assessed by a rheumatologist, 75.5% had no morning stiffness in the hands, 93.9% had no Achilles enthesitis and 87.9% had no inflammatory low back pain; only 24.2% of patients had required NSAIDs in the previous 3 months for joint pain. Finally, the diagnosis of psoriatic arthritis was analyzed against the PURE-4 cut-off point (Table 1).

Table 1. ***Psoriatic arthritis diagnosis based on total score on PURE-4 scale***

PURE-4 Score	Chi-squared test	p value
≧ 1	0.25	0.61
= 1	0.10	0.74
= 2	0.69	0.41

Conclusion: PURE-4 scale with a score ≥ 1 does not seem to improve the diagnosis of arthritis in psoriatic patients. It would be necessary to implement other questionnaires that are more complete, but at the same time affordable, when carried out during the dermatology consultation in order to increase the sensitivity to refer or not to the rheumatologist.

AB1346 **ULTRASOUND ASSESSMENT OF SUB-CLINICAL HAND JOINT INFLAMMATION: A COMPARATIVE STUDY BETWEEN EARLY RHEUMATOID AND PSORIATIC ARTHRITIS**

F. Liu[1], Y. Xin[1], J. Zhu[1]. [1]*Peking University People' s Hospital, Department of Ultrasound, Beijing, China*

Background: Ultrasound (US) detected subclinical inflammation can be present in early psoriatic arthritis (PsA) and rheumatoid arthritis (RA), and also in patients fulfilling clinical remission criteria[1-2]. Numerous evidences support that the persistence of subclinical synovitis detected by US is associated with a high risk of disease progression [2-3].
Objectives: To evaluate sub-clinical inflammation of PsA and RA at the level of small joints of the hand and wrist by B-mode and Power Doppler US.
Methods: 30 patients of early PsA and 35 patients of early RA (no clinical evidence of hand joint involvement, PsA disease duration <2 years, and RA disease duration <1 year) were recruited. US [grey scale (GS) and power Doppler (PD)] was performed to assess synovitis, tenosynovitis, joint effusion, and bone erosion of bilateral wrists, metacarpophalangeal joints, proximal and distal interphalangeal joints, as well as the flexor tendons and extensor compartments.
Results: A total of 35 patients were included in the RA group, including 10 males and 25 females. A total of 30 patients were included in the PsA group, including 12 males and 18 females. There were no significant differences in gender composition, age, and duration of disease between the two groups (P>0.05) (Table 1). 19 (63.33%) PsA patients and 16 (45.71%) RA patients had sub-clinical hand joint synovitis. At the joint level, wrist joints were most commonly involved (23.08%), followed by MCP3 (15.38%) and DIP3 (13.46%) in PsA group. In RA group, wrist joints were most commonly involved (55.17%), followed by MCP3 (12.41%), and MCP2 (11.03%). Eight (26.67%) PsA patients and 16 (45.71%) RA patients were detected tenosynovitis. Tenosynovitis was most frequently presented at the extensor tendons in RA and at the flexor tendons in PsA patients (p<0.05). The two most commonly affected were the 4th and 1st extensor compartments in RA patients, and the flexor pollicis longus and flexor digitorum profundus in PsA patients. 81 (6.80%) joint recesses in the RA and 75 (7.35%) joint recesses in PsA were detected effusion. Joint effusion was most frequently detected at radiocarpal and midcarpal joints in RA (30.86%, 25.92%, respectively). Effusion in PsA was most commonly presented at the 3rd PIP joints (26.67%), followed by radiocarpal joints (24.00%). Bone erosions were uncommon, totally 2 (6.67%) PsA patients and 3 (8.57%) RA patients were detected bone erosions.

Table 1. Demographic characteristics of RA and PsA patients

	RA (n=35)	PsA (n=30)	*P*
Female, n(%)	25 (71.43%)	18 (60.00%)	0.33
Age, years, mean±SD	53.20±14.50	54.23±13.65	0.77
Disease duration, years, mean±SD	0.72±0.37	0.91±0.53	0.07

Conclusion: There are significant differences in the US findings of sub-clinical inflammation at the hand and wrist joints, such as the joint effusion and tenosynovitis, which may assist the identification between early RA and PsA. Simultaneously, it should be pointed out that there are some similarities in the joint involvement of sub-clinical synovitis between RA and PsA, physicians should take this into account in clinical work.

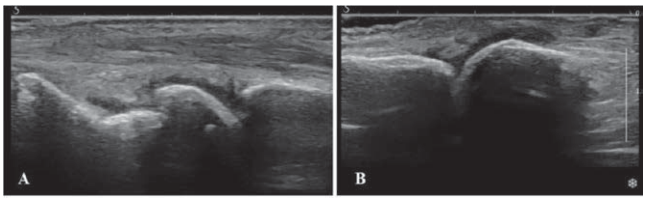

Figure 1. Gray scale ultrasound sagittal view shows synovitis at the wrist joint in an RA patient (A) and at MCP3 in a PsA patient.

Maria della Misericordia" c/o University of Udine, Udine, Italy*; [8]*Institute of Hygiene and Clinical Epidemiology, University Hospital "S. Maria della Misericordia" c/o University of Udine, Udine, Italy*

Background: Magnetic resonance enterography (MRE) is usually performed in patients with Crohn's disease (CD) for evaluating small bowel involvement. Inflammatory bowel disease (IBD) mainly affect the gastrointestinal tract, although patients may present extraintestinal manifestations (1). Musculoskeletal symptoms are the most frequent extraintestinal manifestation in IBD, especially in CD. Furthermore, sacroiliitis at imaging occurs in about 6-46% of CD patients and may correlate with axial spondyloarthritis (2,3).

Objectives: The primary aim of our study was to assess the prevalence of sacroiliitis in adult and pediatric patients affected by CD who performed MRE. We also evaluated the inter-rater agreement for MRE sacroiliitis and the association between sacroiliitis and patients' clinical data.

Methods: We included consecutive patients with CD diagnosis (4), who underwent an MRE in the period between December 2012 and May 2020. We excluded patients with a known diagnosis of SpA; patients with confirmed or suspected inflammatory back pain; and patients treated at the time of MRE with systemic Disease-Modifying Antirheumatic Drugs (DMARDs), which influence both bowel and joint disease (i.e., conventional DMARDs, and biologic DMARDs).

Two radiologists assessed the prevalence of sacroiliitis at MRE. We evaluated the inter-rater agreement for sacroiliitis and assessed the correlation between sacroiliitis and demographic, clinical, and endoscopic data.

Results: We retrospectively identified 100 adult and 30 pediatric patients. The prevalence of sacroiliitis at MRE was 20% in adults and 6.7% in pediatric patients. The inter-rater agreement for sacroiliitis was substantial (k=0.62, p<0.001) in the adults, and moderate (k=0.46, p=0.011) in the pediatric cohort. Age ≥50 years and the time between CD diagnosis and MRE (≥86.5 months) were significantly associated with sacroiliitis in adult patients (p=0.049 and p=0.038, respectively).

Conclusion: Asymptomatic sacroiliitis at MRE is a frequent and reliable abnormality in adult patients with CD, associated with age of the patients ≥ 50 years and CD duration. Detecting sacroiliitis at MRE in patients affected by CD may help the appropriate and early referral to the rheumatologist.

AB1348

COMPARISON OF SACROILIAC CT FINDINGS IN PATIENTS WITH AND WITHOUT PSORIATIC ARTHRITIS: RESULTS OF THE CASIPSA STUDY.

O. Fakih[1], A. Ramon[2], C. Prati[1,3], P. Ornetti[2], D. Wendling[1,4], F. Verhoeven[1,3]. [1]*CHU de Besançon, Rheumatology, Besançon, France*; [2]*CHU de Dijon, Rheumatology, Dijon, France*; [3]*UFR Santé, Université de Franche-Comté, EA 4267 'PEPITE', Besançon, France*; [4]*UFR Santé, Université de Franche-Comté, EA 4266 'EPILAB', Besançon, France*

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis associated with various rheumatological manifestations, such as arthritis or enthesitis, predominantly in the peripheral skeleton. However, the axial skeleton may be affected, as shown clinically or by conventional radiographs in up to 70% of patients with peripheral involvement. While there are studies comparing joint damage on standard radiography between patients with PsA and patients with ankylosing spondylitis [1], to our knowledge, no study has specifically evaluated the extent of structural lesions of the sacroiliac joints (SIJs) on computed tomography (CT) in patients with PsA compared with healthy controls.

Objectives: To describe SIJ CT characteristics in patients with PsA and compare them with those of age- and sex-matched controls.

Methods: An observational, retrospective study was performed using medical records from Besançon and Dijon University Hospital's rheumatology departments, which were screened to identify patients with PsA, according to the CASPAR criteria. A search was then carried out for patients in the hospitals' imaging archiving system to identify those who had undergone a CT which included the SIJs in their entirety. Non-inclusion criteria were the existence of pelvic bone lesions and a history of pelvic radiotherapy. Each patient was then matched with a control of the same age and sex, recruited through the hospital's imaging archiving system. For each individual, CT was interpreted by two independent readers using a score previously used by Diekhoff et al. [2], dividing each SIJ into 12 regions, for each of which joint space narrowing (JSN), erosions, and sclerosis are assessed. For this study, we also observed the existence of intra-articular gas and diffuse idiopathic skeletal hyperostosis (DISH) lesions for each region. Quantitative variables were compared using Student's t-test. Qualitative variables were compared using the Chi-2 test.

Results: 48 patients and 48 controls were included. Mean (SD) age was 54.76 ± 12.91 in the PsA group and 54.74 + 12.87 in the control group. 26 (54.18%) were male in both groups. In PsA patients, mean (SD) disease duration was 22.87 ± 14.95 years, 10 (43.48 %) were HLA-B27 positive, and 1 (2.86%) had a bamboo spine. CT findings are described in Table 1. The only lesion found significantly more frequently in PsA patients was erosion, which appeared to be preferentially located on the anterior and middle regions of the SIJs (Figure 1). A positive CT scan (significant joint space narrowing, erosion and/or sclerosis) was found in 15 (32.61%) of the patients with peripheral involvement and 6 (30.00%) of the patients with axial involvement.

Table 1. Sacro-iliac CT findings using a score modified from Diekhoff et al.

Finding	PsA Patients	Controls	p-value
Mean (SD) total score (range 0-264)	26.37 ± 29.12	14.47 ± 10.85	0.01
Global positivity, n (%)	16 (33.33 %)	10 (20.83 %)	0.17
Bilateral ankylosis, n (%)	5 (10.42 %)	0 (0.00 %)	0.02
Positive joint space score, n (%)	15 (31.25 %)	10 (20.83 %)	0.25
Positive erosion score, n (%)	9 (18.75 %)	1 (2.08 %)	0.008
Significant sclerosis, n (%)	11 (22.92 %)	12 (25.00 %)	0.81
Intra-articular gas, n (%)	29 (60.42 %)	35 (72.92 %)	0.19
DISH, n (%)	9 (18.75%)	11 (22.92 %)	0.62

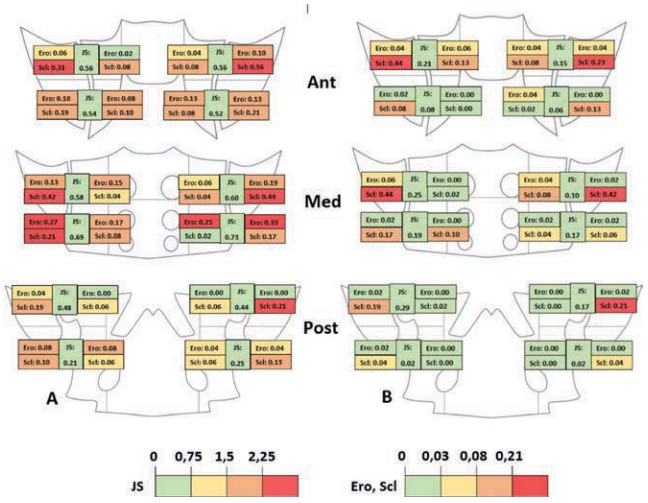

Figure 1. Mean scores by region on anterior, middle, and posterior slices (JS: joint space, Ero: erosions, Scl: sclerosis) in PsA patients (A) and controls (B).

Conclusion: The CT characteristics of SIJs from patients with PsA were similar to those of age- and sex-matched controls, but with a higher prevalence of erosions. Structural lesions of the SIJs were found in nearly one PsA patient out of three.

AB1349 CORRELATION OF CHRONIC INFLAMMATION MARKERS WITH ULTRASOUND SIGNS OF ATHEROSCLEROTIC HEART DISEASE AND BRACHIOCEPHALIC ARTERIES LESIONS IN RHEUMATOID ARTHRITIS

N. Aleksandrova[1], A. Aleksandrov[1,2], N. Nikitina[1], V. Aleksandrov[1,2]. *[1]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology Named After A.B. Zborovsky», Department of Functional Research Methods, Volgograd, Russian Federation*; *[2]Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation*

Background: Clinical and experimental data confirm the role of both systemic and arterial inflammation in potentiating atherosclerosis and increasing cardiovascular risk in patients with rheumatoid arthritis (RA) against the background of severe immunological disorders.

Objectives: To study the severity of ultrasound signs of atherosclerotic lesions of brachiocephalic arteries and heart valve apparatus in patients with rheumatoid arthritis (RA).

Methods: 57 patients with RA (50 women and 7 men; mean age 50,45±10,12 years old; mean duration of disease 9,2±6,8 years; DAS28 activity: low - 3,5%, medium - 86%, high - 10,5%) were examined. Laboratory examination included determination of serum IgG-RF, CRP, antibodies to cyclic citrullinated peptide (ACCP), antibodies to modified citrullinated vimentin (MCV), total antinuclear antibodies (ANA), and levels of proinflammatory cytokines (IL-1, IL-6, TNF-α, angiopoietin-like proteins types 2, 3, and 4 - ANGPTL 2, 3, 4) by enzyme immunoassay. Cardiac ultrasound examination was performed according to the traditional technique on an Accuvix V10 ultrasound diagnostic system (Samsung Medison, South Korea) equipped with a multifrequency microconvex transducer with a frequency of 2-4 MHz. All patients underwent duplex scanning of brachiocephalic arteries (BCA) with assessment of the severity of atherosclerotic changes (A0 - absence of BCA atherosclerosis, AI - isolated thickening of intima-media complex as a manifestation of non-stenotic BCA atherosclerosis, AII - presence of atherosclerotic plaques and artery stenosis as manifestation of stenotic BCA atherosclerosis). The following gradation was used to estimate the degree of cardiac valve calcification: 0 - no calcification, 1st degree - unexpressed calcification, 2nd degree - moderate calcification, 3rd degree - expressed calcification of cardiac valves.

Results: Signs of cardiovascular system lesions (pericarditis, heart valve lesions, cardiomyopathies, cardiac conduction pathway lesions, myocarditis, endocarditis, coronary arteritis etc.) were diagnosed in 28 (49,1%) RA patients. Heart valve dysfunction was manifested by mitral valve (MV) and/or aortic valve (AV) insufficiency in the majority of cases. In RA patients, ultrasound signs of cardiac valve calcification occurred in 40.4% (23/57) of cases; there was a high prevalence of aortic valve calcification of varying severity (19/23; 82.6%) and less detectable mitral valve calcification (12/23; 52.17%); patients with grade II-III cardiac valve calcification predominated (16/23; 69.6%); 5 patients (21.7%) had combined AV and MV lesions. In 25 (43.8%) patients with RA the signs of atherosclerosis of brachiocephalic arteries were determined: in 19 (33.3%) - non-stenotic (AI), in 6 (10.5%) - stenotic atherosclerosis (AII). No statistically significant correlations were found between changes of cardiac valve apparatus, BCA lesions and main clinical characteristics of RA (disease activity, erosions, RF and ACCP positivity). Increased levels of ANGPTL2 (χ2=4.6, p=0.032) were observed in the group of RA patients with cardiac valve lesions, and ANA (χ2=3.91, p=0.049) and elevated IL-6 (χ2=4.28, p=0.039) were detected more frequently in patients with signs of atherosclerotic lesions of BCA. The presence of autoimmune chronic inflammatory process is an independent sign of premature atherosclerosis development and causes the highest risk of atherosclerotic lesion of BCA and accelerates the processes of cardiac valve calcification in RA patients.

Conclusion: Regular echocardiography (with duplex scanning of BCA and heart valve examination) in RA patients can contribute to earlier identification of groups of patients possible requiring changes in therapeutic approaches to treatment and prevention of vascular accidents.

AB1350 CAN DIFFUSION-WEIGHTED MRI REPLACE INTRAVENOUS GADOLINIUM CONTRAST-ENHANCED MRI FOR ASSESSMENT OF SYNOVITIS?

J. Møllenbach Møller[1], K. L. Gandrup[1], M. Østergaard[2], D. Glinatsi[3], O. Madsen[4], K. Hørslev-Petersen[5,6], S. Møller-Bisgaard[7]. *[1]Copenhagen University Hospital Herlev - Gentofte, Radiology, Herlev, Denmark*; *[2]University Hospital of Copenhagen, Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; *[3]Skaraborg Hospital, Department of Rheumatology, Skövde, Denmark*; *[4]University Hospital of Copenhagen, Rigshospitalet, Gentofte, 5Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Gentoftet, Denmark*; *[5]Danish Hospital for Rheumatic Diseases, Department of Rheumatology, Sønderborg, Denmark*; *[6]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; *[7]University Hospital of Copenhagen, Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Gentofte, Denmark*

Background: In clinical trials of rheumatoid arthritis (RA) patients, intravenous gadolinium contrast injection is the gold standard method for MRI assessment of synovitis, e.g. by the OMERACT RA MRI Scoring method (RAMRIS). It has been shown that diffusion-weighted MRI (DW-MRI) allows visualization of synovitis[1].

Objectives: To establish a method for measuring MRI-derived apparent diffusion coefficient (ADC) from DW-MRI and to test its correlation with RAMRIS synovitis scoring.

Methods: MRI including diffusion-weighting of the dominant hand was performed in a cohort of RA patients in clinical remission (disease activity score in 28 joints-C-reactive protein [DAS28-CRP] <3.2 and no swollen joints). ADC measurements of the synovium were assessed in 7 areas (3 wrist joint areas and 4 metacarpophalangeal (MCP) joints), similar to the RAMRIS. Intra-observer agreement for the ADC reading was determined using the intraclass correlation coefficient (ICC). Spearman's rho (ρ) was calculated for the correlation of ADC with RAMRIS Synovitis. Differences in mean ADC between the individual RAMRIS synovitis grades were examined using ANOVA with Bonferroni correction for multiple tests.

Results: In 63 patients (67% females, age mean 61.0 years (range 36-78 years), disease duration 11.9 years, 0-59 years), DAS28-CRP 2.1 (1.6-3.0) the total RAMRIS synovitis was mean 5.8 (range 0-18). The mean ADC was 0.98x10-3 mm^2/s (0.11-2.80). Correlations between RAMRIS synovitis and ADC in the 7 joint areas and mean differences in ADC between RAMRIS synovitis grades are presented in the Table 1. When all 7 joints were pooled the mean ADC and RAMRIS synovitis were moderately positively correlated, ρ=0.49; p<0.01. Statistically significant differences (p<0.01) in mean ADC were observed between all RAMRIS synovitis grades (0 vs 1, 0 vs 2, etc) except for the difference between grade 2 and 3. Good intra-observer (ICC = 0.62 (95%CI 0.49-0.72)) was found.

Conclusion: ADC, determined from DWI-MRI, may be used to grade synovitis without the use of gadolinium contrast injection.

AB1351 FULL LONGITUDINAL NAILFOLD VIDEOCAPILLAROSCOPY ANALYSIS OF MICROVASCULAR CHANGES DURING NORMAL PREGNANCY

G. Pacini[1], C. Schenone[1], A. Pogna[1], A. Ferraiolo[2], S. Ferrero[2], C. Gustavino[2], L. Carmisciano[3], C. Pizzorni[1], S. Paolino[1], E. Gotelli[1], A. Sulli[1], V. Smith[4], M. Cutolo[1]. *[1]IRCCS San Martino Polyclinic Hospital, University of Genova, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Postgraduate School of Rheumatology, Department of Internal Medicine, Genova, Italy*; *[2]IRCCS San Martino Polyclinic Hospital, Unit of Obstetrics and Gynaecology, Genova, Italy*; *[3]University of Genova, Biostatistics Unit, Department of Health Sciences, Genova, Italy*; *[4]Ghent University Hospital, Department of Internal Medicine, Department of Rheumatology, Ghent, Belgium*

Background: During pregnancy profound physiologic changes are required to ensure fetal development and meet maternal needs. Microvascular remodelling is one major responsible for pregnancy haemodynamic adaptation, still it is not routinely evaluated in the obstetric field [1–2].
Objectives: To investigate the role of nailfold capillaroscopy (NCV) as a gold-standard and safe technique in detecting microvascular changes during normal pregnancy and to explore its possible application in clinical obstetric setting.
Methods: A population of 30 healthy pregnant women was longitudinally followed performing clinical assessment and NVC evaluation at each trimester and post-partum. Thirty non-pregnant age-matched healthy women having received at least two NVCs with a minimum 9 to 12-month interval were selected as controls. All NVC images were evaluated by a qualitative and semi-quantitative assessment using current standardised approach [3]. Statistical analyses were conducted to explore NVC parameters trend throughout gestation and its possible association with pregnancy course and clinical macrovascular parameters (i.e., systemic blood pressure, umbilical artery Doppler ultrasound).
Results: A progressive significant increase of capillary neoangiogenesis and a specular reduction in capillary dilations was observed during pregnancy ($p<0.05$). These statistically significant variations were not found in age-matched controls, who showed stable NVC parameters over a similar time frame ($p<0.05$). Not any significant association was found between NVC changes and pregnancy course, delivery outcome or macrovascular parameters.
Conclusion: This first comprehensive longitudinal NVC evaluation during normal pregnancy reports significant physiological microvascular variations throughout gestation, suggesting NVC as a safe and promising technique for further investigate and define patterns of microvascular changes in pregnant patients with rheumatic diseases.

AB1352 VALIDATING DIAGNOSTIC GCA ULTRASONOGRAPHY SKILLS AGAINST AN EXPERT SONOGRAPHER

F. Coath[1], C. Mukhtyar[2]. *[1]Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom*; *[2]Norfolk & Norwich University Hospital, Rheumatology, Norwich, United Kingdom*

Background: Ultrasonography has become the recommended first line investigation for suspected giant cell arteritis (GCA). However, it is still not yet widely available in the UK due to a paucity of skilled rheumatologists. Effective training programmes have been developed, but subsequent hands-on practice is needed to become truly proficient. There is no consensus on the logistics of gaining the 'appropriate' level of skill.
Objectives: This project demonstrates a potential mechanism for validation against an expert sonographer.
Methods: Over a 6-month period, 12 scans of patients referred with suspected GCA were sequentially performed by first a trainee (FC) and then an expert sonographer (CM) on the same day. FC had theoretical knowledge and supervised practical experience but had not scanned independently prior to this project. CM has performed >1000 scans. 6 vascular territories considered to be the core GCA US data set (common, frontal and parietal branches of the superficial temporal artery, and the 1st, 2nd and 3rd part of the axillary artery) were marked as either 'normal' or 'halo'. CM was blinded to FC's results. Inter-observer reliability was calculated for all vascular territories using Cohen's kappa.
Results: A total of 144 vascular territories were scanned in 12 patients. Table 1 details the inter-observer variation, with a near perfect level of agreement demonstrated, kappa=0.90 (95% CI 0.83 – 0.98).

Table 1. Matrix of inter-observer variation for all vascular territories in 12 patients, k=0.90 (95% CI 0.83 – 0.98)

	FC positive	FC negative	Total
CM positive	48	4	50
CM negative	2	90	92
Total	50	94	

Conclusion: This is the first study that demonstrates a mechanism for validation of ultrasonography skills which will allow GCA US to become a feasible reality in clinical practice. This project demonstrates that after acquiring supervised training, near perfect levels of agreement can be arrived between a trainee and expert.

AB1353 VESSEL AFFECTION AND THE INFLUENCE OF GLUCOCORTICOIDS ON 18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY IN GIANT CELL ARTERITIS

L. Malich[1], F. Gühne[2], T. Hoffmann[1], A. Malich[3], P. Oelzner[1], G. Wolf[1], M. Freesmeyer[2], A. Pfeil[1]. *[1]Jena University Hospital - Friedrich-Schiller-University Jena, Department of Internal Medicine III, Jena, Germany*; *[2]Jena University Hospital - Friedrich-Schiller-University Jena, Clinic of Nuclear Medicine, Jena, Germany*; *[3]Suedharz-Hospital Nordhausen, Institute of Diagnostic Radiology, Nordhausen, Germany*

Background: ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT) represents one of the standard imaging modalities in the detection of giant cell arteritis (GCA). Detailed data regarding the vessel involvement in GCA are not available.
Objectives: The aim of this study was to quantify arterial vessel involvement at the onset of GCA by ^{18}F-FDG PET/CT and to verify the influence of glucocorticoid treatment on the diagnostic performance of ^{18}F-FDG PET/CT.
Methods: This study included 60 patients (44 women and 16 men, mean age 72.8 ± 8.8 years) at the onset of GCA. All patients received a PET/CT. 44 patients were glucocorticoid naïve. 16 patient were treated with glucocorticoid (prednisone median dose 60 mg) 3.5 ± 4.4 days before the ^{18}F-FDG PET/CT was performed. All ^{18}F-FDG PET/CT scans were scored regarding the active inflammation of the large arteries.
Results: The most affected arteries were the aorta ascendens (72 %), followed by truncus brachiocephalicus (62 %), acrus aortae (60 %), aorta descendens (60 %), left and right arteria sublcavia (60 % and 58 %). The aorta and their outgoing arteries presented an involvement in 39 GCA patients (89 %). A singular affection of the aorta was shown in 9 patients (20 %). glucocorticoid naïve patients (89 %) showed affected arteries more frequently than glucocorticoid treated patients (38 %).
Conclusion: The study showed that the thoracic aorta (in particular aorta ascendens) is the most involved vascular segment in GCA. The use of glucocorticoids was associated with a marked decrease of vascular inflammation. Consequently,

the imaging of the thoracic aorta should be included in the diagnostic procedure of GCA. ^{18}F-FDG PET/CT should be performed without glucocorticoid treatment, if the clinical situation allowed this proceeding.

AB1354 ULTRASOUND JOINT EXAMINATION BY AN AUTOMATED SYSTEM VERSUS BY A RHEUMATOLOGIST – FROM A PATIENT PERSPECTIVE

B. A. Frederiksen[1], M. Schousboe[2], L. Terslev[3,4], N. Iversen[5], H. M. Lindegaard[6], T. R. Savarimuthu[2], S. A. Just[1]. [1]*Svendborg Hospital - Odense University Hospital, Department of Medicine, Section of Rheumatology, Svendborg, Denmark*; [2]*The Mærsk Mc-Kinney Møller Institute, University of Southern Denmark, Odense, Denmark*; [3]*Rigshospitalet Glostrup, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Glostrup, Denmark*; [4]*Copenhagen University, Department of Clinical Medicine, Faculty of Health and Medical Sciences, København, Denmark*; [5]*ROPCA, ROPCA Holding, Odense, Denmark*; [6]*Odense University Hospital, Department of Rheumatology, Odense, Denmark*

Background: The Arthritis Ultrasound Robot (ARTHUR) is an automated system for ultrasound scanning of the joints of both hands and wrists, with subsequent disease activity scoring using artificial intelligence.
Objectives: To describe the patients' perspective of being examined by ARTHUR, compared to an ultrasound examination by a rheumatologist. Further, to register any safety issues in the use of ARTHUR.
Methods: Twenty-five patients with rheumatoid arthritis (RA) had both hands and wrists examined by ultrasound, first by a rheumatologist subsequently by ARTHUR (see Figure 1 A, B and C). Patient-reported outcomes (PRO) were obtained after the examination by the rheumatologist and then again after the examination by ARTHUR. PROs regarding pain, discomfort and overall experience were collected. In addition, willingness to be scanned again by ARTHUR as part of future clinical follow-up was also collected. All ARTHUR examinations were observed for safety issues.

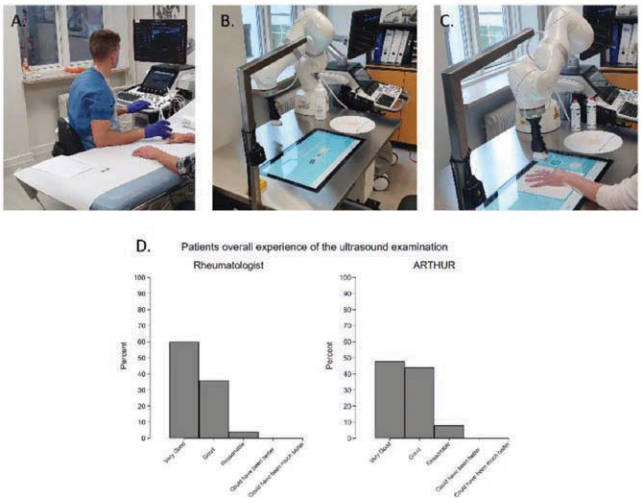

Figure 1. A. The rheumatologist is performing the ultrasound examination. B. The ARTHUR system used in this trial used a GE Logiq 10 ultrasound scanner. C. ARTHUR started ultrasound scanning a RA patient. The patient follows the instructions given on the touchscreen and by audio. D. Overall experience with ultrasound scanning by Rheumatologist and ARTHUR.

Results: For baseline characteristics of RA patients, see Table 1.

Table 1. Baseline Characteristics. CRP: C-reactive protein; DAS28CRP: Disease Activity Score in 28 joints combined with CRP value, RF: Rheumatoid factor antibody, CCP: cyclic citrullinated peptide antibodies.

Table 1	Patients
Patients, n	25
Age (SD)	63,7 (12,22)
Female, n (%)	17 (68 %)
Erosive disease, n (%)	10 (40%)
RF and/or CCP-positive, n (%)	17 (68%)
DAS28CRP (SD)	2.8 (1.2)

There was no difference in pain or discomfort between the examination by a rheumatologist and by ARTHUR (p=0.29 and p=0.20, respectively). The overall experience of an examination by ARTHUR (see Figure 1 D) was described as very good or good by 92% (n=23), with no difference compared to the examination by the rheumatologist (p=0.50). All (n=25) patients were willing to be examined by ARTHUR again, and 92% (n=23) would accept ARTHUR as a regular part of their RA clinical follow up. No safety issues were registered.
Conclusion: Joint ultrasound examination by ARTHUR was safe and well-received, with no difference in PRO components compared to ultrasound examination by a rheumatologist. Fully automated systems for joint disease activity assessment could be important in future strategies for RA management.

AB1355 NAILFOLD CAPILLAROSCOPY CHANGES IN PATIENTS WITH PSORIATIC ARTHRITIS AND RHEUMATOID ARTHRITIS

E. Molteni[1], G. Pellegrino[1], C. Castellani[1], D. M. Reza Beigi[1], F. Conti[1], R. Scrivo[1], V. Riccieri[1]. [1]*Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy*

Background: In psoriatic arthritis (PsA) and rheumatoid arthritis (RA) systemic inflammation is known to cause endothelial dysfunction[(1)]. Nailfold videocapillaroscopy (NVC) analyzes *in vivo* blood vessels, looking for alterations due to microvascular damage, and its application in these pathologies often highlights interesting abnormalities. PsA is characterized by lower mean capillary length and density and abnormal morphology, such as tight terminal convolutions. In RA typically elongated and dilated capillaries and prominent subpapillary plexus are described[(2, 3)]. Differences between RA and PsA NCV patterns are known but not well defined yet[(3)].
Objectives: Aim of our study was to evaluate the microvascular features circulation by NVC in patients affected by PsA and RA, looking for possible differences that may characterize the two diseases.
Methods: We recruited outpatients affected by PsA or RA classified according to standard criteria[(4, 5)] referring to the Rheumatology Unit at Sapienza University of Rome. Healthy controls (HCs) without known risk factors for nailfold capillary alterations[(6)] were also recruited. Patients and HCs underwent NVC with a 200x magnification lens. The following morphological parameters were considered: number of capillaries per square millimeter, alterations in length, dimension, morphology and distribution of the capillary; presence of ectatic loops, hemorrhages, flux abnormalities[(7, 8)]. A semi-quantitative rating scale was adopted to score these changes, according to previous studies[(9)]. The mean score for each subject was obtained by analyzing all fingers, except the thumbs. For the statistical analysis, Chi-square and Mann-Whitney tests were used. All tests were two-sided with a significance level set at p<0.05.
Results: We recruited 34 patients (20 with PsA and 14 with RA) and 30 HCs. For patients, the mean age was 61,7 years (SD 15,4), median disease duration was 184 months (SD 204) and males were 18 (53%). Active or past smokers were 11 (18%), 9 (15%) suffered from arterial hypertension and 2 (0.03%) from type 2 diabetes mellitus. Raynaud's phenomenon was present in 4 patients with PsA (20%) and 6 with RA (43%). The most frequent morphological changes were tortuous capillaries (90% in PsA and 100% in RA), single-crossing shape (90% and 86%) and bizarre capillaries (30% in both groups) while multiple crossing and ramified capillaries were present in 50% and 21 % RA patients only. With respect to HCs, we found significantly more frequent changes concerning morphology, ectatic loops, presence of hemorrhages and capillary plexus visibility in both PsA and RA patients. Moreover, patients with RA showed significantly more frequent abnormalities of the blood flow with respect to HCs. These results are shown in Table 1.

Table 1. Comparison of the main NVC changes in patients and HCs.

NVC Changes	HC	PsA		RA	
	N (%)	N (%)	P value vs HCs	N (%)	P value vs HCs
Morphology	3 (10%)	14 (70%)	**p<0.0001**	12 (86%)	**p<0.0001**
Ectatic loops	0 (0%)	11 (55%)	**p<0.0001**	8 (57%)	**p<0.0001**
Hemorrhages	2 (0.07%)	1 (5%)	**p<0.01**	6 (43%)	**p<0.0058**
Plexus	19 (63%)	10 (50%)	**p<0.02**	7 (50%)	**p<0.02**
Flux abnormalities	3 (10%)	6 (30%)	p>0.05	5 (36%)	**p<0.026**

The presence of hemorrhages was significantly higher in RA rather than in PsA patients (p<0.01). No significant differences were found in number, length, and distribution of capillaries between PsA/RA cases and HCs.

Conclusion: Our study confirms and completes the frame of NCV alterations in PsA and RA. We described for the first time alterations in the capillary morphology and the presence of hemorrhages in both groups of patients with respect to HCs. It remains to evaluate how these findings can reflect the microvascular environment of chronic arthritis.

AB1356 QUANTITATIVE ANALYSIS BY SODIUM AND PROTON BASED 3-TESLA MR IMAGING OF THE ACHILLES TENDON

A. Müller-Lutz[1], B. Kamp[1], L. Klein-Schmeink[1], S. Tsiami[2], M. Frenken[1], A. Nagel[3], X. Baraliakos[2], P. Sewerin[2,4]. *[1]Uniklinik Düsseldorf, Department for Radiology, Düsseldorf, Germany*; *[2]University Hospital Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany*; *[3]University Hospital Erlangen, Institute of Radiology, Erlangen, Germany*; *[4]Uniklinik Düsseldorf, Hiller-Research Unit, Düsseldorf, Germany*

Background: Decrease of proteoglycan is the initiating stage of post-inflammatory tissue degradation. Sodium MRI is promising great potential for identification and monitoring of proteoglycan changes in tendons and cartilage associated with inflammatory and degenerative musculoskeletal diseases, where the Achilles tendon is frequently affected.
Objectives: Proof-of-concept study to examine the usage of sodium MRI in quantifying sodium concentrations in the Achilles tendon in healthy volunteers.
Methods: Sodium (^{23}Na) MR imaging of the Achilles tendon together with established proton (^{1}H) MRI sequences were performed in 10 healthy volunteers (6 males, 4 females, age 29 ± 9 years) using a dual-tuned ^{23}Na/^{1}H surface coil (RAPID Biomedical GmbH, Würzburg-Rimpar, Germany). Imaging was performed using a 3D density adapted radial sequence [1] providing sufficient signal-to-noise ratio for sodium imaging. Reference tubes on the backside of the coil were used to enable assessment of sodium concentration from sodium signal-to-noise ratio maps. Sodium concentrations were determined for tendon insertion into calcaneus bone (INS), middle portion of the tendon (MID) and muscle-tendon junction (MTJ) and for the whole Achilles tendon. Statistical differences were analysed by Wilcoxon test.
Results: Sodium concentrations c [mM] of the Achilles tendon could be quantified in all 10 (exemplary selected volunteer is shown in Figure 1). Significantly higher sodium concentrations were obtained in INS compared to MID (p=0.002) and MTJ (p=0.002) and in MID compared to MTJ (p=0.037). The average sodium concentration of the whole Achilles tendon was 57.23±17.69 mM with only minor outliers in this healthy population.

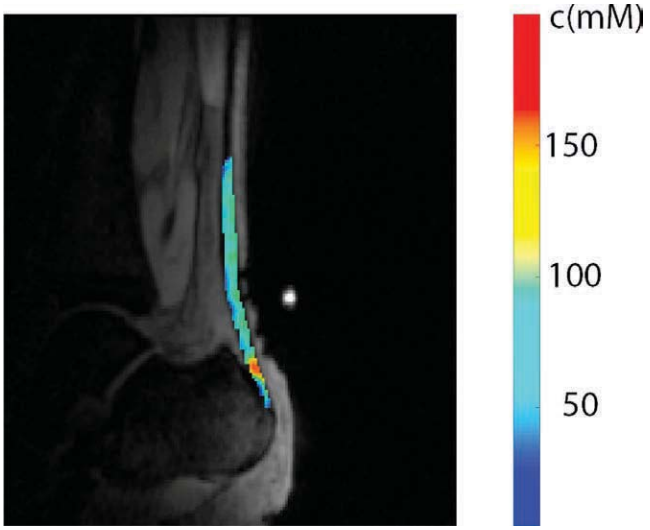

Figure 1. Sodium concentrations of the Achilles tendon. Highest sodium concentrations c(mM) were observed at the tendon insertion into calcaneus bone (INS), whereas lower concentrations were measured in the middle portion of the tendon (MID) and muscle-tendon junction (MTJ).

Conclusion: Performance of quantitative sodium imaging of the Achilles tendon in a high-field MRI machine is feasible for assessing sodium concentrations, a surrogate biomarker for proteoglycan content. Molecular MR studies investigating changes in the proteoglycan content of the Achilles tendon in patients with inflammatory and degenerative musculoskeletal diseases could support early diagnosis or therapy monitoring in the future.

AB1357 THE BEST CUT-OFF POINT FOR MEDIAN NERVE CROSS SECTIONAL AREA AT THE LEVEL OF PISIFORM BONE

A. Carones Esteves[1], P. Freitas[2], L. Brites[3], T. Santiago[1], M. Santiago[1], J. Rovisco[1], J. A. P. Da Silva[1]. *[1]Centro Hospitalar e Universitário de Coimbra, Serviço de Reumatologia, Coimbra, Portugal*; *[2]Hospital CUF Coimbra, Reumatologia, Coimbra, Portugal*; *[3]Hospital Santo André - Hospital Distrital de Leiria, Serviço de Reumatologia, Leiria, Portugal*

Background: Carpal tunnel syndrome (CTS) is a focal neuropathy caused by compression of the median nerve (MN) at the wrist. Electromyography (EMG) is the gold standard for the diagnosis of CTS. Currently, the ultrasound (US) is frequently used as an initial screening exam by measuring the cross-sectional area (CSA) of the MN. The cut-off point of the CSA at the pisiform bone level to define CTS remains controversial with previous studies reporting values between 6.5mm^2 and 15mm^2 (1).
Objectives: The aim of this study is to determine the best cut-off point of the CSA for the diagnosis of CTS.
Methods: Cross-sectional study at a Tertiary Rheumatology Department including patients aged ≥ 18 years with symptoms compatible with CTS. Sociodemographic and clinical data, visual analogue scale for pain (VAS), Boston Questionnaire (BQ), and the results of EMG and US performed in each patient were collected. The EMG was performed according to the standardized protocol (sensory conduction velocity, sensory amplitude, distal sensory and motor latency), and the patients were categorized in 4 groups: normal, mild, moderate, and severe. A rheumatologist with expertise in imaging performed all the US evaluations by means of a 6–18-MHz (Siemens ACUSON S 2000) linear array transducer. The largest CSA of the MN was measured at the level of the pisiform bone. Receiver operating characteristic (ROC) curve was used to determine optimal cut-off values of the CSA taking the EMG result as the gold-standard. One-way ANOVA test was used to compare CSA between the 4 EMG groups.
Results: Fifty patients were included, 90% were female, mean age was 52.1 ± 10.8 years and median duration of symptoms was 28.0 (IQR 23.0-31.0) months. The mean VAS was 4.2 ± 2.9. In the BQ there was a mean symptom severity score of 2.4 ± 0.6 and a mean functional status score of 2.0 ± 0.9. One-way ANOVA showed that mean CSA values were significantly different in the 4 groups of patients. The Ryan-Einot-Gabriel-Welsch post hoc analysis showed that only the mean CSA of patients with severe STC is different from the remaining groups defined by EMG results. The best cut-off point for CSA at the pisiforme bone level for CTS diagnosis was 6.6 mm^2 with a sensitivity and specificity of 92.9% and 75.0% (AUC=0.9, P<0.001). The positive and negative predictive values were 95.1% and 66.7%, respectively. For severe CTS diagnosis the best cut-off point for CSA was 12.3mm^2 with a sensitivity of 82.4% and a specificity of 72.7% (AUC=0.8, P<0.001). The positive and negative predictive values were 60.9% and 88.9%, respectively.
Conclusion: In our study we found that the best cut-off point of the CSA was 6.6mm^2 for distinguishing patients with/without CTS based on EMG alterations, with a high sensitivity and moderate specificity. This is a lower cut-off value than usually used in clinical practice and could be explained by small sample and the greater number of patients with mild and moderate STC on EMG.

AB1358

AN OLD METHOD FOR CURRENT CHALLENGES: SKIN TEST CONVERSION OF PURIFIED PROTEIN DERIVATIVE (PPD) IN RHEUMATOLOGICAL PATIENTS TREATED WITH ANTI-TNF-α

B. Abdala[1,2], A. Ringer[1], J. Ruffino[1], F. Martinez[1], M. C. Argento[1], S. Chulibert[1], D. Carbone[1], F. Lucci[1], A. Gatica[1], L. Cichillitti[1], M. Palatnik[1], M. N. Cortese[1], J. C. Crema[1], M. Lagrutta[3], B. Finucci Curi[2], A. Co[2], M. Abdala[1]. [1]*Rheumatology Unit, Hospital Provincial del Centenario, Rosario, Rosario, Argentina*; [2]*Internal Medicine Unit, Hospital Provincial de Rosario, Rosario, Rosario, Argentina*; [3]*Internal Medicine Unit, Hospital Provincial del Centenario, Rosario, Rosario, Argentina*

Background: Anti-TNF-α are a cornerstone for the treatment of multiple rheumatic diseases. They are associated with an increased risk of developing tuberculosis (TB), which is endemic in several countries and an important burden across the globe. Purified protein derivative (PPD) is one of the tests used to demonstrate a latent TB infection (LTBI). Screening is recommended for TB prior to the onset of anti-TNF-α and monitoring evaluating possible conversion of PPD during treatment, defined as the change from a negative (<5 mm) to positive result (≥5 mm). Identification and treatment of LTBI can reduce the risk of disease development by up to 90%. Currently the results of PPD conversion and its interpretation during anti-TNF-α treatment are variable and that is why we set out to know the frequency of conversion of PPD in this group of patients in our environment.
Objectives: To identify PPD conversion in patients with rheumatological diseases undergoing anti-TNF-α treatment.
Methods: A descriptive, analytical, observational, retrospective study was conducted from January 1, 2018 to January 1, 2022. Inclusion criteria: Patients >18 years old, diagnosed with rheumatological diseases and treated with anti-TNF-α for more than 3 consecutive months, with a negative PPD (<5 mm diameter) previous starting anti-TNF-α and a normal chest X-ray.
Results: 62 patients (age 45.8 ± 12.5 years), with rheumatological diseases (41 rheumatoid arthritis, 7 juvenile idiopathic arthritis, 5 ankylosing spondylitis, 4 psoriatic arthritis, 4 uveitis and 1 interstitial keratitis) under anti-TNF-α therapy (35 adalimumab, 18 certolizumab, 9 etanercept) were included. Concomitant use of immunomodulators (52 methotrexate, 23 leflunomide, 10 hidroxicloroquine, 3 sulfasalazine, 2 azathioprine and 1 mycophenolate mofetil) and glucocorticoids (33/62) was observed. The conversion of PPD took place in 4 patients (6.5%) (Table 1).
Conclusion: Considering the prevalence of TB in our country, this research showed a lower PPD conversion percentage compared to previous reports. Anti-TNF-α have radically changed the evolution of rheumatological diseases, considerably improving the patient's quality of life. With the increase in the accessibility of anti-TNF-α worldwide, new challenges have arisen regarding infectious diseases such as TB, which is endemic in some countries. PPD is a well known, cheap, sensitive and widely available method, suitable for LTBI diagnosis. Although sensitivity could be increased using, in addition, other LTBI detection methods such as IGRAs (interferon gamma release assays), they are usually unavailable in developing countries (1-3).

AB1359

DO LATERAL AND AP RADIOGRAPHS TELL DIFFERENT STORY IN PATIENTS WITH PSORIATIC ARTHRITIS?

G. Ayan[1], A. Sadic[2], L. Kılıç[1], U. Kalyoncu[1]. [1]*Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey*; [2]*Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey*

Background: The conventional radiography score that is frequently used in spondyloarthritis patients is mSSASS. This score was developed for Anylosing Spondylitis patients and is also frequently used in Psoriatic arthritis (PsA) (1). The mSSASS score takes into account lateral imaging of the lumbar and cervical radiographs. On the other hand, syndesmophytes can be detected on lumbar anterior-posterior (AP) radiographs, which may not be seen on lateral assessment.
Objectives: The aim of this study is to determine whether lumbar AP radiographs have an additional contribution to the evaluation of syndesmophytes in PsA patients.
Methods: Lumbar lateral radiographs and AP radiographs of 274 PsA patients receiving bDMARD therapy were evaluated. A total of 182 lateral lumbar radiographs and 144 AP radiographs were evaluated. On lateral lumbar radiographs each lumbar vertebral unit was evaluated between T12 lower and S1 upper ends. Areas between L1-L5 as AP, right-left, upper and lower vertebral units were evaluated. Syndesmophytes are classified as follows; corner and/or non-marginal syndesmophytes and bridging syndesmophytes. All of the assessments were done by an experienced rheumatologis (UK) and in cases with suspicion, another experienced rheumatologist reviewed the cases (LK) and a consensus was reached.
Results: 182 patients had lumbar radiographs with the mean (SD) age of 44.9 (12.7) years and the mean (SD) PsA duration of 4. 8(6.1) years at the time of the radiographs were taken. The rate of females was 70.3%. When the lateral lumbar radiographs were evaluated, 42/182 (23.1%) patients had at least one syndesmophyte. These 42 patients had a total of 80 syndesmophytes, 41 of which were bridging and 39 were corner syndesmophytes. The distribution of syndesmophytes is shown in the Table 1. The mean number of syndesmophytes in patients with at least one syndesmophyte on the lumbar lateral radiograph is 80/42 (1.9). In patients with at least one syndesmophyte, 14/42 (33.3%) patients had additional syndesmophytes not seen on lateral radiographs but on AP X-ray. Their distribution is as follows: L1 (4 patients), L2 (3 patients), L3 (2 patients), L4 (6 patients) and L5 (1 patient). In addition, 11 corner syndesmophytes and 5 bridging syndesmophytes were detected in the lumbar AP radiograph. When lumbar and AP radiographs are evaluated together, 44/182 (24.2%) patients have at least one syndesmophyte. When the lumbar lateral and AP radiographs are evaluated together, there are 96 syndesmophytes in 44 patients with syndesmophytes, 46 of which are bridging and 50 are corner syndesmophytes. Average number of syndesmophytes were 96 in 44 patients (2.2 per-patient).

Table 1. The distribution of syndesmophytes on lateral lumbar radiographs

Lateral Lumbar X-ray	Patients with syndesmophytes	Total syndesmophyte count n(%)	Number of bridging syndesmophyte	Number of corner syndesmophyte
	N (%)		n(%)	n(%)
L1 lower-L2 upper border	14	29	16	13
L2 lower-L3 upper border	14	21	12	9
L3 lower-L4 upper border	15	21	10	11
L4 lower-L5 upper border	4	6	2	4
L5 lower-S1 upper border	2	3	1	2

Conclusion: AP radiographs are not taken into account in conventional radiograph scores accepted as mSSASS. PsA patients have syndesmophytes in approximately one-quarter of patients on lateral radiograph, with an average syndesmophyte number of about 2. On the other hand, when AP radiographs are evaluated, new syndesmophytes that are not seen on lateral radiographs are seen in one-third of patients with at least one syndesmophyte. Although it does not cause a significant change in the number of patients with syndesmophytes, it should be kept in mind that the use of AP radiographs in PsA patients may cause an increase in the total score. Whether there is a difference between PsA and SpA patients should be investigated in further studies.

AB1360 DISTRIBUTION OF INFLAMMATORY/DEGENERATIVE/ AMBIGUOUS LESIONS ON CONVENTIONAL LUMBAR LATERAL RADIOGRAPHS IN PSORIATIC ARTHRITIS PATIENTS

G. Ayan[1], A. Sadic[2], L. Kılıç[1], U. Kalyoncu[1]. [1]*Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey*; [2]*Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey*

Background: Psoriatic arthritis (PsA) patients are relatively older than spondyloarthritis patients, and accordingly, degenerative changes on spine are more frequent and confusing.
Objectives: The aim of this study is to determine the distribution, relation of different type of lesions on the lumbar spine in PsA patients receiving bDMARD therapy.
Methods: 182/274 (66.4%) patients had lateral lumbar radiographs. Two and three lumbar radiographs were present in 53 (19.3%) 14 (5.1%) patients respectively. The upper and lower regions of each vertebra were evaluated between T12, S1 (total of 2184 regions). Lesions were determined as osteophyte (O) (grade 0-3), vertebral corner erosion, sclerosis, squaring, corner syndesmophyte (SP), bridging SP. While osteophyte was determined according to the degenerative character of new bone formations, the definition of SP was made according to mSSASS. Lesions that the clear distinction of cannot be made were defined as ambigious. For patients with follow-up radiographs, the change of lesions defined as ambigious was also recorded. All of the assessments were done by an experienced rheumatologis (UK) and in cases with suspicion, another experienced rheumatologist reviewed the cases (LK) and a consensus was reached.
Results: The mean (SD) age of 182 PsA (69.2% female) patients was 47.6 (12.7), the age at diagnosis of PsA was 39.7 (12.7). Of the patients, 112 (61.5%) met the criteria for mNY. There was at least one abnormality in 111 (61.0%) patients with lumbar spine radiograph. O was the most frequently detected lesions (42.3%), with 18.1% of patients having O grade 2 and above. While SP was present in 24.2% of all patients, ambigious lesions were detected in 13 (4.7%) patients. While O were most frequently grouped between L2 upper and L4 upper regions, SPs were distributed in a similar ratio between L4 upper and T12 lower regions. Ambigious lesions were anywhere between T12 sub-L5. Patients with ambigious lesions were older (55.7 (9.8) vs 47.0 (12.7), p=0.017), lumbar mSSASS score was higher (5.4 (8.1) vs 1.6 (3.8), p=0.002) corner SPs (46.1% vs. %) 17.7, p=0.013) and bridging SPs (30.7% vs 7.7%, p=0.006) were more common, while no difference was found in terms of O grade 2 (23.1% vs 17.7%, p=0.63). Changes were observed in 5 ambigious lesions in patients with follow-up lumbar radiography, 4 of them transformed into corner SP at follow-up, and one was evaluated as osteophyte grade 2.
Conclusion: Approximately one-fifth of patients presenting with significant degenerative new bone formation and SP was found in one fourth. In approximately 5% of all patients, lesions in the lumbar vertebrae could not be differentiated. The frequency of SPs in other vertebral areas are more prominent in patients with ambigious lesions. It is seen that ambigious lesions turn into SPs in a small group of patients with follow-up data. The nature of these lesions needs to be evaluated in further imaging studies.

Table 1. The distribution of the lesions on lumbar spine

Location	Osteophyte	Osteophyte ≥ 2	Corner SP	Bridging SP	All SP	Erosion, Sclerosis, Squaring	Ambigious

AB1361 PAIN MANAGEMENT IN METASTATIC BONE DISEASE

B. A. Hiba[1], K. Dorra[1], R. Meriem[1], B. Chayma[1], K. Sonia[1], E. Hanen[1], K. Mahla[1], F. Raja[1], C. Elhem[1]. [1]*La Rabta Hospital, Pain Treatment Center, Tunis, Tunisia*

Background: Bone metastases are the most common cause of pain in patients with malignant disease. Bone metastasis (BM) pain management is one of the greatest challenges for oncologists, due not only to safety issues, but also to the significant impairment of patients' quality of life and performance status.
Objectives: To provide an overview of the epidemiology, clinicopathological features and treatment approaches of painful BM in patients followed-up at the pain treatment center (PTC) of Tunisia.
Methods: We performed a retrospective review of the medical records of all patients with BM, seen at the PTC of Tunisia in 2019. The information collected included patient demographics, clinicopathological features and treatment approaches of the BM.
Results: A total of 117 patients, with male to female ratio of 2.5 and a mean age of 61,2± 12.5 years [22-93], were included. Primary cancers were mainly lung cancer (40%), breast cancer (13,7%), prostate cancer (11,1%), malignant hemopathies (5%) and kidney cancer (3,5%). Mean cancer duration was 10.5 months [0-84]. Mean duration from the diagnosis of cancer to the diagnosis of BM was 4.2± 1.7 months [0-11].The most common BM sites were the spine (83.6%), the pelvis (28.5%) and the ribs (22.4%). BM was painful in 97% of cases. The mean number of consultations at the PTC was 5.5±2.8 [1-18].Malignant bone pain was nociceptive in 73.3% of cases, neuropathic in 9.5% and mixed (both nociceptive and neuropathic) in 33%. Mean visual analogue scale (VAS) pain was 8.7±1,5 [2-10]. Most of the patients (84.5%) were treated by opioid analgesics which was morphine in 98% of cases. The route of administration of morphine was the oral in 85.3% of cases with a median dose of 60mg/j [10-240]. Laxatives and antiemetic therapy, in prevention of side effects of morphine, were prescribed in respectivly 87% and 28% of cases. The transdermal fentanyl patch was prescribed for three hepatically impaired patients. Only 15.5% of patients had a good response to pain killers palier II (Tramadol) and did not necessitate to switch to morphin. Mean dose of Tramadol was 178±75.1 mg [75-300]. Pregabalin was indicated in 25% of cases with a mean dose of 227.5± 127.7mg [150-600].Tricyclic antidepressants were prescribed for 9.5% of the patients and the mean dose was 16 ±10 mg [10-40]. Corticoisteroids were used in almost two-third of cases with a mean daily dose of 1mg/kg/j [0,5-1.5]. However, in 14% of cases, non-steroidal anti-inflammatory drugs were prescribed instead of corticosteroids. Bisphosphonates were used in 15% of cases. Antalgic radiotherapy was indicated in one-third of cases. By a median follow-up of 3 months [0-24], mean VAS pain was 3.7±1.7 [1-9].
Conclusion: Currently, the treatment of painful BM remains palliative at best with systemic therapy as well as local treatments especially when BMs become symptomatic or complicated. Consequently, a multidisciplinary approach to BM is essential, to ensure a proper integration of local and systemic therapies

AB1362 LOCATION AND NUMBER OF SARCOIDOSIS GRANULOMA, A POSSIBLE DIAGNOSTIC ARGUMENT?

O. Dhrif[1], M. S. Hamdi[1], I. Kechaou[1], I. Boukhris[1], E. Cherif[1], S. Azzabi[1], L. Ben Hassine[1]. [1]*Charles nicolle's Hospital, Internal Medicine, Tunis, Tunisia*

Background: Sarcoidosis is a non-necrotizing granulomatous disease which diagnosis is often challenging and requires elimination of other causes of granulomatous lesions. Location and number of granulomatous lesions in patients are not yet established as arguments in diagnosing this disease.
Objectives: We therefor conducted a study aiming to compare locations and number of granulomas between patients with sarcoidosis and patients with other granulomatous diseases (OGD).
Methods: Cross sectional study in which were included patients in whom non-necrotizing granulomatous lesions have been identified via biopsy over a period of 11 years (2010 to 2021) then were stratified into two groups: sarcoidosis group and OGD group. Categorical variables were compared with the $\chi 2$ –test or Fisher's test. Comparisons of the differences of continuous variables were performed by the Mann–Whitney U test or Student's t-test. Pearson correlation ratio was used for linear correlation analysis.
Results: 30 patients were included in the sarcoidosis group and 32 in the OGD group. Aetiologies in the OGD group were: 10 tuberculosis cases, 5 lymphoma cases, 4 Primary biliary cholangitis cases, 1 Castleman's disease and 12 idiopathic granulomas.

Mean age was respectively in both groups 51+/-13 versus 57+/-17 years old (p=0.128), sex ratio (F/M) was 29/1 versus 27/5 (p=0.197). Associated signs were distributed in both groups as followed: 11(37%) versus 5(16%) general signs (p=0.085), 15(50%) versus 20(63%) lymphadenopathy (p=0.442), 4(13%) versus 6(19%) inflammatory arthralgias (p=0.733), 13(43%) versus 2(6%) cutaneous lesions (p=0.001), 4 versus no ocular manifestations (p=0.049), 20 (66%) versus 3(9%) pulmonary manifestations (p<0.001), 5 (17%) versus 10 (31%) abdominal manifestations (p=0.239). Cutaneous, salivary gland and ENT granulomas were significantly more frequent in patients with sarcoidosis with respectively 11(37%) versus 1 (3%) (12.3 risk ratio 95%CI 10.4 to 14.4)(p=0.001), 8 (27%) versus 0% (p=0.002), 8(27%) versus 2(6%) (4.5 risk ratio 95% CI 3.1 to 5.9) (p=0.025). Lymph node, hepatic and pulmonary granulomas prevalence was not significantly higher in sarcoidosis patients, 17 (57%) versus 24 (75%) (p=0.180), 2 (7%) versus 5 (16%)(p=0.427), 3(10%) versus 0%(p=0.308). Mean number of granulomas found in one patient was significantly higher in sarcoidosis patients with 1.7 (95% CI 1.5 to 2) versus 1.1 (95%CI 1 to 1.2) (p=0.001). There was also a significant correlation between the number of granulomas in one patient and the angiotensin converting enzyme titres (r=0.566, 95% CI 0.360 to 0.771); (p=004).
Conclusion: This study shows that sarcoidosis patients have more often granulomas in the skin, salivary gland and ENT regions, and that the number of granulomas is on average superior in sarcoidosis than in OGD, these findings could be considered when establishing future diagnostic algorithms, as taking into account these elements could ease this diagnostic challenge in clinical practice.

AB1363 IMAGE PATTERN ANALYSIS IN FLUORESCENCE OPTICAL IMAGING FOR DIFFERENTIAL DIAGNOSIS IN RHEUMATIC JOINT DISEASES

N. Stumper[1], J. Berger[2], G. Schmittat[1], A. Briel[3], D. Vogler[1], G. R. Burmester[1], P. Hoff[1], S. Ohrndorf[1]. [1]*Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*Xiralite GmbH, Xiralite GmbH, Berlin, Germany*; [3]*nanoPET Pharma GmbH, R&D, Berlin, Germany*

Background: As outlined in previous studies, different rheumatic joint diseases present specific characteristic patterns and features in fluorescence optical imaging (FOI) (1-4).
Objectives: We tested different features in FOI for their ability to differentiate various rheumatic joint diseases such as rheumatoid arthritis (RA), osteoarthritis (OA) and psoriatic arthritis (PsA) with the aim to identify clear FOI criteria for the diseases.
Methods: FOI images from patients with RA, OA, PsA and healthy volunteers were evaluated by two readers blinded for diagnosis and calibrated against each other, using the prima vista mode (PVM) and the 5-phase model. For the latter, the overall time course of FOI in each hand was divided into 5 phases with a computational algorithm. Phases 1 and 2 describe the inflow (start to 15% and 15%-90% on rising edge), phase 3 is the peak phase and phases 4 and 5 comprise the outflow (90%-36.8% and 36.8% to end on falling edge). Twenty-six different features were defined by an atlas, for example the streaky pattern feature (T) as a signal enhancement around the PIP area that appears streaky, whereby the stripes are orthogonal to the finger axis (Figure 1a). The cloudy pattern (W) is visible during the inflow on the back of the hand (Figure 1b). The enthesis feature (E) depicts a V shaped and filled pattern between nail and DIP (Figure 1c). The feature frequency in each patient and phase (PVM, 5-phase) was counted and statistically analysed.

Figure 1. Examples for FOI patterns and features: a) (T) Streaky pattern in PVM image (OA); b) (W) Cloudy pattern on the back of the hand in phase 1 (PsA); c) (E) Enthesis pattern in phase 3.

Results: In total, 128 patients (RA (age mean 54.2; SD 10.6; median 52.4), OA (58.0; 14.3; 60.1), and PsA (47.9; 12.7; 46.8)) and healthy volunteers (32 in each group) were included in the feature reading. In our analysis, OA can be differentiated from RA on the basis of the feature T. Feature T is found in phase 3 (χ^2: 4.61; diagnostic odds ratio (DOR): 7.49; sensitivity (TPR) 0.11; specificity (TNR): 0.98; positive predictive value (PPV): 0.87; negative predictive value (NPV): 0.52), phase 5 (χ^2: 18.5; DOR: 5.60; TPR 0.55; TNR: 0.82; PPV: 0.76; NPV: 0.64 and PVM (28.3; 12.1; 52%; 92% 87%; 65%). By means of the feature E, a distinction between RA and PsA is only limited possible (χ^2: 9.58; DOR: 3.65; TPR 0.40; TNR: 0.84; PPV: 0.71; NPV: 0.59). But PsA can well be distinguished from RA by the appearance of pattern W in phase 1 (χ^2: 7.68; DOR: 6.92; TPR 0.19; TNR: 0.97; PPV: 0.86; NPV: 0.54). Other significant features yield high specificity (70%-98%) while having low sensitivity (12%-52%).
Conclusion: This work demonstrates that FOI feature analysis has the potential for differential diagnosis with FOI, which could optimize the (early) diagnostic process of rheumatic joint diseases. A majority of features yield high specificity, but only low sensitivity. The combination of different features using artificial intelligence might lead to improved diagnostic accuracy.

AB1364 IMAGING DIAGNOSIS OF BRUCELLAR SPONDYLODISCITIS

S. Rekik[1], S. Boussaid[1], H. Tbini[1], S. Jemmali[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia*

Background: Spondylodiscitis is the most common location in the musculoskeletal involvement of brucellosis.
Objectives: The aim of this study is to describe magnetic resonance imaging (MRI) and computed tomography scan (CT) results in patients with brucellar spondylodiscitis.
Methods: A retrospective study over a period of 15 years, including 18 patients diagnosed with brucellar spondylodiscitis and having benefited from a CT scan and/or an MRI of the spine.
Results: Eighteen patients were included. In all cases spinal pain was reported, associated with radiculalgia in 8 patients. Low back pain was the most common symptom, present in 17 cases, associated with back pain in 3 cases including one case with neck pain. Isolated neck pain was noted in one patient. Neurologic examination was normal in all cases. Standard Radiographs showed disc narrowing in 14 cases, erosions in 9 cases and hazy changes of the vertebral end plate in 2 cases. A CT scan was performed in 11 cases. It showed disc narrowing in 6 cases, erosions in 3 cases and endplate destructions in 5 cases. Abscesses were found in 4 patients. Complementary MRI was performed in three of the patients who had already undergone CT. The MRI results were consistent with those of the CT scan, except for one patient in whom it revealed spondylodiscitis while the CT scan revealed degenerative lesions. Eleven patients underwent MRI in total. It showed unifocal and multifocal spondylodiscitis in 5 and 6 cases respectively, epiduritis in 6 cases, spinal cord compression in 2 cases and abscesses in 4 cases.
Conclusion: Our study showed that CT and spinal MRI allow early diagnosis of spondylodiscitis. They help to identify asymptomatic lesions and neurological complications.

AB1365 PROPOSAL FOR A STANDARDIZED ULTRASOUND SCANNING PROTOCOL OF THE NAIL PLATE.

D. Rotta[1], G. Adami[1], F. Bellinato[2], A. Fassio[1], L. Idolazzi[1], P. Gisondi[2], F. Tozzi[2], E. Filippucci[3], M. Rossini[1]. [1]*Rheumatology Unit, Medicine, University of Verona, VERONA, Italy*; [2]*Clinical Dermatology Unit, Medicine, Verona, Italy*; [3]*Clinica Reumatologica, Università Politecnica delle Marche, JESI, Italy*

Background: Ultrasonography of the nails with high frequency linear transducers can properly perform morphological images, achieving highly descriptive power but the lack of standardization may hesitate in lack of reproducibility and scarce usefulness.

Objectives: The aim of this study was to provide a detailed scan protocol of nail plate, including comparison of scan planes and probe positioning.
Methods: Transversal and longitudinal ultrasound scans were performed on each fingernail of both hands in healthy subjects. Nail plate thickness and Power Doppler of the nail bed were recorded. All the images were acquired using Canon Aplio i800 with a linear transducer of 22 MHz (i22LHB). Two different operators performed evaluation of thickness at distal, middle and proximal portion of nail in longitudinal view and at 0°, -45° and +45° for transverse view (Figure 1). ANOVA for repeated measures was used to determine differences between nail of the different digits.

Figure 1. Longitudinal and transverse view of the nail. In yellow the position and angles of the caliper used for acquiring the measures

Results: The study sample was composed of 27 healthy subjects between 25- and 40- year old with no rheumatological or dermatological nail issues. A total of 270 nails were scanned; none of them was excluded due to comorbidity, trauma or other conditions which can interfere in the evaluation. A decrease in nail thickness was observed from first to fifth digit, regardless the hand (dominant or not), that resulted significant for the ANOVA. No differences were found regarding the thickness in the different segments of nail plate and this occurred both for longitudinal and transverse scans.
Conclusion: We demonstrated the absence of a statistically significant difference between thickness at proximal, middle and distal portion of the nail in longitudinal view or at any different angle in transverse view, concluding the fastest and easiest way to measure the nail plate thickness is in the longitudinal view at the middle segment, avoiding potential issues in positioning the probe in the transverse view or in positioning the caliper at proximal or distal segment in longitudinal view. All the nails should be scanned per protocol, since the thickness is variable and the fifth may be the most interesting in order to consider its highest variance.

Background: Large-vessel vasculitis are characterized by the wall inflammation of the involved vessels, which can be detected by imaging tools **(1-3)**. Ultrasound (US) is one of the most commonly used tools for the diagnosis of giant cell arteritis (GCA), especially in patients with a cranial phenotype. Tocilizumab (TCZ) has shown efficacy in large-vessel vasculitis (LVV) including GCA **(4,5)**. However, the improvement objectified by imaging techniques such as US after TCZ therapy is poorly documented.
Objectives: To assess the effectiveness of TCZ improving the wall vessel inflammation by US.
Methods: Observational, multicenter study of 26 GCA patients treated with TCZ. GCA was diagnosed according to: **a)** ACR criteria, and/or **b)** biopsy of temporal artery, and/or **c)** presence of signs of vessel wall inflammation by US, defined by the presence of halo sign. In all the cases a baseline US and in the follow-up was mandatory. Patients were divided into two subgroups: **a)** with, and **b)** without signs of improvement (partial or total) in the follow-up US.
Results: We studied 26 patients (19 women/7 men; mean age, 76.3±9.7 years). Main clinical features of GCA with and without US improvement are shown in Table 1. We found no significant differences in any of the variables studied between the two groups.

Table 1. Main features of 27 GCA patients treated with tocilizumab followed by Ultrasound (US).

	With US improvement (n=21)	Without US improvement (n=5)	p
Baseline characteristics at TCZ onset			
General characteristics			
Age(years), mean±SD	77.3±8.9	72.2±12.9	0.270
Sex, female/male (% female)	17/4 (80,95)	2/3 (40)	0.101
Time from GCA diagnosis to TCZ onset (months), median [IQR]	6 [3-9]	3 [1-6]	0.452
Systemic manifestations, n (%)			
Fever, n (%)	1/21 (4.76)	1/5 (20)	0.354
Constitutional syndrome, n (%)	10/21 (47.62)	2/5 (40)	0.999
PmR, n (%)	11/21 (52.38)	1/5 (20)	0.330
Ischaemic manifestations, n (%)			
Visual involvement, n (%)	1/21 (4.76)	1/5 (20)	0.354
Headache, n (%)	15/21 (71.43)	5/5 (100)	0.298
Jaw claudication, n (%)	4/15 (26.67)	¼ (25)	0.999
Laboratory data			
ESR, mm 1st hour, median [IQR]	33 [22-49]	55 [54-80]	0.216
CRP, mg/dL, median [IQR]	1.5 [0.7-6.7]	3.8 [1-4.2]	0.948
Prednisone dose, mg/day, median [IQR]	13.7 [10-30]	30 [12.5-30]	0.505
Time from TCZ onset and follow-up US (months)	3.9±3.6	3.1±2.1	0.456

After TCZ onset, 21 of 26 patients (80.7%) showed US signs of improvement (12 complete, 9 partial). In 4 out of 5 patients in whom there was no improvement in US findings, clinical improvement was observed at first month after starting TCZ.
Conclusion: TCZ seems to be effective controlling GCA including vascular involvement detected by US. This improvement can be seen by follow-up US, especially when performed at least 3 months after TCZ onset.

Background: Positron emission tomography (PET) is one of the tools available for the diagnosis of extracranial large-vessel vasculitis **(1-5)**. Tocilizumab (TCZ) has shown efficacy in large-vessel vasculitis (LVV) including GCA. However, the improvement objectified by imaging techniques after TCZ therapy in extracranial GCA patients is controversial.

Objectives: To assess the effectiveness of TCZ improving the wall vessel inflammation by PET in GCA patients with large-vessel involvement.

Methods: Observational, multicenter study of 101 GCA patients treated with TCZ. GCA was diagnosed according to: **a)** ACR criteria, and/or **b)** biopsy of temporal artery, and/or **c)** presence of signs of vessel wall inflammation by PET, defined by the presence of vascular wall uptake of Fluorodeoxyglucose (FDG). Patients were divided into two subgroups: **a)** with, and **b)** without signs of improvement (partial or total) in the follow-up PET.

Results: We studied 101 patients (74 women/27 men; mean age 69.7±9.3 years). Main clinical features of GCA with and without PET improvement are shown in Table 1. The group of patients which experienced PET improvement was older and was receiving higher doses of corticosteroids at TCZ onset.

Table 1. Main features of 101 GCA patients treated with tocilizumab and with presence of signs of vessel wall inflammation by PET.

	With PET improvement (n=88)	Without PET improvement (n=13)	p
Baseline characteristics at TCZ onset			
General characteristics			
Age(years), mean±SD	70.6±9.1	63.8±9.2	**0.014**
Sex, female/male (% female)	67/21(76)	7/6 (54)	0.103
Time from GCA diagnosis to TCZ onset (months), median [IQR]	11 [4-24.2]	4 [2-6]	0.102
Systemic manifestations, n (%)			
Fever, n (%)	5 (6)	2 (15)	0.225
Constitutional syndrome, n (%)	36 (41)	4 (31)	0.466
PmR, n (%)	53 (60)	9 (10)	0.761
Ischaemic manifestations, n (%)			
Visual involvement, n (%)	2 (2)	1 (1)	0.342
Headache, n (%)	30 (34)	3 (23)	0.538
Jaw claudication, n (%)	8 (9)	0 (0)	0.592
Laboratory data			
ESR, mm 1st hour, median [IQR]	38.0 ± 26.2	13.54 ± 9.9	**0.001**
CRP, mg/dL, median [IQR]	1.5 [0.7-2.4]	1 [0.5-1.7]	0.179
Prednisone dose, mg/day, median [IQR]	40.3 ± 19.4	21.9 ± 12.7	**0.001**
Time from TCZ onset and follow-up PET (months)	13.1±8.0	10.1±5.3	0.446

Conclusion: TCZ seems to be effective controlling GCA including vascular involvement detected by PET. However, the improvement observed by PET is most often partial, and rarely complete.

AB1368 ULTRASONOGRAPHIC EVALUATION OF THE KNEE AND MUSCLE ARCHITECTURE IN OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS

S. C. Güven[1], Ş. Metin Tarhan[2], F. N. Göğüş[3]. *[1]Ankara City Hospital, Rheumatology, Ankara, Turkey*; *[2]Karabük Training and Research Hospiptal, Physical and Rehabilitation Medicine, Karabük, Turkey*; *[3]Gazi University Medical School, Physical and Rehabilitation Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Involvement of lower extremity joints in both rheumatoid arthritis (RA) and osteoarthritis (OA) is an important cause of declined functional status. Deterioration of skeletal muscle performance further contributes to disability. Quadriceps muscle plays an important role in most daily activities. Measuring thickness and pennation angle of quadriceps compartments can provide knowledge regarding quadriceps condition.

Objectives: Aim is to investigate structural and inflammatory changes in knee joint and architecture of quadriceps muscle in RA, knee OA patients and a group of healthy subjects.

Methods: Twenty RA patients and 20 knee OA patients with radiographic disease meeting Kellgren-Lawrence grade 2 and above were consecutively recruited, in absence of exclusion criteria. 20 healthy volunteers with similar demographics were recruited as control group. Knee symptoms and disability were evaluated by Lequesne Knee Index (LKI). Disease activity was evaluated by DAS28-CRP in RA patients. Quadriceps muscle was evaluated by ultrasonographic measurements of muscle thickness, subcutaneous fat tissue thickness and pennation angle of vastus muscles. Suprapatellar, lateral and medial compartments of knee joint were examined for effusion, synovial hypertrophy, power Doppler (PD) activity and degenerative changes.

Results: Demographics and clinical features of subjects and results of ultrasonographic evaluation are presented in Table 1. LKI scores were significantly higher in OA patients when compared to RA patients (p=0.004). Rate of degenerative changes was increased in RA and OA groups in comparison to controls (p=0.013). None of the subjects had PD activity. No differences were observed in thickness of rectus femoris, vastus muscles and subcutaneous fat between groups. Vastus medialis and intermedius pennation angles were reduced in OA and RA groups when compared to controls, but reached statistical significance only in vastus intermedius (3.56 ± 6.37 vs 4.89 ± 7.14 vs 7.29 ± 4.93, p=0.038).

Table 1. Demographics, clinical features and ultrasonographic findings of subjects

	OA (n=20)	RA (n=20)	Control (n=20)	*p*
Age, years¶	58.44 ± 6.68	54.67 ± 7.15	55.11 ± 5.89	0.178
Gender, female$^{\mu}$	17 (85)	15 (75)	16 (80)	0.732
BMI¶	30.05 ± 3.88	28.29 ± 4.78	28.27 ± 3.34	0.343
Duration of diagnosis, months¶	11.95 ± 17.15	14.80 ± 8.50		**0.023**
LKI¶	9.37 ± 2.65	6.95 ± 3.38		**0.004**
DAS28-CRP¶		2.59 ± 1.10		
Presence of effusion $^{\mu}$	9 (45)	9 (45)	4 (20)	0.166
Presence of SH $^{\mu}$	9 (45)	11 (55)	8 (40)	0.626
Presence of degeneration $^{\mu}$	16 (80)	13 (65)	7 (35)	**0.013**
Muscle thickness, mm¶				
VM	14.09 ± 4.17	15.38 ± 5.15	14.57 ± 3.41	0.243
VL	17.17 ± 3.53	16.96 ± 4.98	16.66 ± 3.18	0.985
VI	10.54 ± 2.65	10.49 ± 3.32	10.67 ± 1.83	0.926
RF	13.01 ± 3.92	13.74 ± 3.78	13.63 ± 3.49	0.879
SFT thickness, mm¶	12.59 ± 5.79	13.81 ± 7.10	12.53 ± 5.20	0.969
Pennation angle, degree ¶				
VM	5.50 ± 7.01	6.94 ± 8.29	9.05 ± 5.10	0.244
VL	13.61 ± 5.15	13.44 ± 3.40	13.29 ± 3.25	0.703
VI	3.56 ± 6.37	4.89 ± 7.14	7.29 ± 4.93	**0.038**

¶: mean ± SD, μ: number (%),LKI: Lequesne Knee Index, KL: Kellgren – Lawrence grade, SH: synovial hypertrophy, VM: vastus medialis, VL: vastus lateralis, VI: vastus intermedius, RF: rectus femoris, SFT: subcutaneous fat tissue

Conclusion: In our study ultrasound evaluation findings of knee joint and quadriceps muscle were similar between knee OA and RA patients.VM and VI pennation were reduced when compared to healthy subjects in both groups. These findings may indicate a similar degree of functional impairment in OA and RA due to knee joint involvement.

AB1369 DISCO-VERTEBRAL BIOPSY VERSUS INDIRECT DIAGNOSTIC TOOLS IN BRUCELLAR SPONDYLODISCITIS

S. Rekik[1], S. Boussaid[1], H. Tbini[1], S. Jemmali[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. *[1]Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia*

Background: The diagnosis of brucellar spondylodiscitis can be made by serological examinations or by isolating the germ on disco-vertebral biopsy (DVB).

Objectives: We aimed to study the interest of DVB and other less invasive diagnostic tools in brucellar spondylodiscitis.

Methods: A retrospective study over a period of 15 years, including 18 patients diagnosed with brucellar spondylodiscitis.

Results: Eighteen cases were collected (13 men and 5 woman).

Nine patients had a DVB. In all cases, microbiological study did not reveal the causative agent (Brucella). A case of superinfection with Staphylococus Xylosus was noted. Histopathological examination was performed in eight patients. It showed osteitis and chronic spondylodiscitis lesions in 4 cases, a non-specific inflammatory infiltrate in 3 cases, and a progressive infectious spondylitis in one case. Wright's serodiagnosis and the rose bengal test were positive in 7 out of 8 cases performed. As for the diagnosis by indirect immunofluorescence made in 6 cases, it was positive in 5 cases. For the other nine cases who did not undergo DVB, Wright's serodiagnosis and rose bengal test were positive in 9 and 6 patients respectively, indirect immunofluorescence made in 5 patients was positive in 4 cases.

Conclusion: Serological examinations in brucellar spondylodiscitis seem more profitable and less invasive than DVB. Other studies with a larger population seem to be necessary to compare the different methods and complete this preliminary study.

MICROVASCULAR CAPILLAROSCOPIC ABNORMALITIES AND AUTOANTIBODY OCCURRENCE IN SARCOIDOSIS PATIENTS.

F. Cattelan[1], E. Hysa[1], C. Pizzorni[1], M. Grosso[2], E. Barisione[2], S. Paolino[1], G. Pacini[1], G. Ferrari[1], A. Sulli[1], V. Smith[3], M. Cutolo[1].
[1]Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Italy - IRCCS San Martino Polyclinic, Genoa, Italy, Genova, Italy; *[2]Pneumology Unit, IRCCS San Martino Polyclinic, 16132 Genova, Italy, Genova, Italy*; *[3]Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Corneel Heymanslaan 10, 9000 Ghent, Belgium, Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium*

Background: Sarcoidosis (S) is a granulomatous disease with multi-organ involvement displaying a mixed immune-mediated pathophysiology. Raynaud's phenomenon (RP) has been occasionally reported in S patients [1] and serum positivity for autoantibodies has been detected in S patients but their significance is debated [2].
Objectives: We described nailfold videocapillaroscopy (NVC) findings and estimated the prevalence of serum anti-nuclear (ANA) and extractable nuclear antigen autoantibodies (ENA-Abs) in S patients, comparing them with age- and sex- matched healthy controls (HCs) and patients with primary Raynaud's phenomenon (PRP). Secondarily, we analysed potential correlations between NVC findings with the occurrence of autoantibodies, immunomodulatory treatment, laboratory parameters, variables of pulmonary function and whole-body imaging.
Methods: Twenty-seven (27) S patients, classified according to WASOG criteria[3], were assessed through NVC examination, laboratory parameters (including serum concentrations of angiotensin-converting enzyme [ACE], C-reactive protein [CRP], calcium, phosphorus, albumin, 25-hydroxyvitamin D, parathormone, ANA and ENA), pulmonary function tests (PFTs), chest-X ray and positron emission tomography/computerized tomography (PET/CT). Among NVC parameters, we analysed capillary dilations, giant capillaries, haemorrhages, nonspecific abnormalities, and capillary absolute number for mm [4]. Pulmonary involvement was classified by X-ray Scadding staging system (SSS) scoring S patients in 4 grades [5]. From PET data, the maximum standard uptake value (SUVmax) was quantified as a variable of tissue 18-fluorodeoxyglucose hyper-uptake: consequently, S patients were defined PET-positive when SUV value ≥ 2.5. NVC parameters and ANA/ENA dosage were recorded also in 30 PRPs and 30 HCs.
Results: We excluded, among the cohort of S patient, one participant having a systemic sclerosis in overlap with S. The remaining 26 S patients (mean age 56.5 ± 12.5 years, 53.8 % of females, disease duration 28.4 ± 55.1 months, 27% glucocorticoid-naïve) showed a significant higher rate of dilations and nonspecific abnormalities and a lower mean capillary absolute number than PRPs and HCs ($p < 0.01$ for all comparisons). (Figure 1) The prevalence of ANA positivity was significantly higher in S patients compared with PRPs and HCs ($p < 0.02$ for both). Among the whole cohort of patients only one S patient displayed a positive ENA-Ab (Ro52). In the analysis of S patients' subgroup, a significant negative correlation was detected between serum ACE levels with the presence of capillary dilations (rho = -0.45, p = 0.04), between CRP and mean capillary absolute number (rho = -0.49, p = 0.02) and a positive correlation was also detected between the mean capillary absolute number and the forced vital capacity percentage (FVC%) (rho = 0.40, p = 0.04).

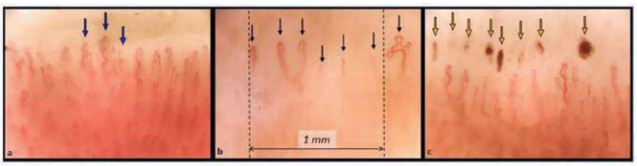

Figure 1 Examples of 3 nailfold videocapillaroscopy images recorded among 3 different sarcoidosis patients. (Magnification 200x).

a: blue arrows indicate the presence of "bushy" capillaries, sign of neoangiogenesis.
b: black arrows indicate the capillaries of the first row. The capillary number for linear mm is slightly reduced (6 capillaries/mm)
c: yellow arrows show the presence of hemosiderin deposits due to microhaemorrhages.

Conclusion: Our findings suggest a microvascular involvement in sarcoidosis whose investigation by NVC could be useful for the detection of an overlapping connective tissue disease and for the monitoring of the phenotypes of S patients displaying RP. The positivity for autoantibodies in S patients is in line with literature data suggesting, at least partially, autoimmune features of the disease or the production of autoantibodies reactive to tissue damage. The correlations between NVC findings with ACE levels and lung function variables generate hypotheses of a potential partial vascular impairment in sarcoidosis disease activity and lung involvement.

AB1371

USE OF ULTRASOUND TO DIAGNOSE INTERSTITIAL LUNG DISEASE IN RHEUMATIC DISEASES ON RUSSIAN COHORTS OF PATIENTS.

O. Ovsyannikova[1], O. Koneva[1], L. Garzanova[1], L. P. Ananyeva[1], A. Khelkovskaia-Sergeeva[1], R. Shayakhmetova[1], O. Desinova[1], M. Starovoytova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Systemic sclerosis, Moscow, Russian Federation*

Background: Interstitial lung disease (ILD) is one of the most relevant extra-articular manifestations of rheumatic diseases resulting in a substantial increase in morbidity and mortality. High-resolution computed tomography (HRCT), which is the current gold standard for diagnosis and evolutionary control, is problematic owing to ionizing radiation, cost, and accessibility. In the last decade, the use of lung ultrasound (LUS) in clinical medicine has increased. LUS is an accurate tool for the diagnosis of pneumonia, pneumothorax, acute pulmonary edema, and pleural effusion. LUS may also be useful in detection of ILD by the evaluation of B-lines, the sonographic hallmark of the interstitial syndrome.
Objectives: To compare semi-quantitative scores of B lines in patients with rheumatic disease with different intensity of lung fibrosis.
Methods: 50 pts with ILD of rheumatic disease such as: vasculitis n=11 (mean age 40.7± 9.1, fem 5); dermatomyositis (DM), anti-synthetase syndrome (ASS), polymyositis (PM) n=20, (mean age 48.7± 11.9, fem 13); rheumatoid arthritis (RA) n=9 (mean age 56.5± 6.3, fem 7); Sjogren's syndrome (SSj) n=9 (mean age 59.6± 12.3, fem 8). To determine the intensity of fibrosis of ILD we used a limited/extensive classification for disease extent, integrating HRCT observation. According this scheme pts were divided into 2 groups: group 1 included 33 pts had "limited" lung disease (lung lesions less than 20%) and the group 2 included 17 pts had "extensive" lung disease (lung lesions greater than 20%). LUS examination protocol that include the anterior, lateral, and/or posterior thorax have been suggested The B-lines score denoting the extension of ILD was calculated by summing the number of B-lines on a total of 58 scanning sites. In each patient ULC score was obtained by summing the number of comets detected as previously recommended. The data were collected in protocols for statistical testing. Other data collected including biological results (high-sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR)).
Results: the mean score of B-lines in each groups were: vasculitis (n=11) 21,4 ±12,6; (DM, PM, ASS) (n=20) 41,3±20.8; RA (n=9) 56.5±6.3; SSj (n=9) 59 ± 11.8. The mean score of B-lines in groups pts with different intensity of fibrosis are presented in Table 1.

Table 1.

Groups	mean score of B-lines	Anterior chest Mean score of B-lines	Posterior chest Mean score of B-lines
Limited (n=33)	22±14	6.6 ±7.1 5 [1;10]	15.4±13.4
Extensive (n=17)	61.3±27.4	24.2±12.5	36.4±22.4
P	<0.001	<0.001	<0.001

The correlations in Table 1 may confirm the connection of B-lines score and extensity of ILD association with rheumatic disease. The mean score of ULCs determined in all 50 pts didn't correlate with dates of ESR (R = 0,188, p>0.05) and hsCRP (R= -0,07, p>0.05).
Conclusion: In Russian cohorts presence of LUS score is associates with more severe ILD. Echographic examination of the lung allows evaluating the severity of lung fibrosis and can be used as an additional simple and available method to assess the ILD of rheumatic disease, but we couldn't find correlation with hsCRP and ESR.

SPECIFICITY AND SENSITIVITY OF LUNG ULTRASOUND (LUS) IN RHEUMATIC DISEASES ON RUSSIAN COHORTS OF PATIENTS

O. Ovsyannikova[1], O. Koneva[1], L. Garzanova[1], S. Glukhova[2], L. P. Ananyeva[1], A. Khelkovskaia-Sergeeva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Sclerosis, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Inflammatory Arthritis, Moscow, Russian Federation*

Background: Pulmonary disease is one of the most relevant with interstitial lung disease (ILD) being one of the most frequents forms of involvement with resultant worsening of morbidity and mortality in disorders such as systemic sclerosis (SSc), rheumatoid arthritis (RA), or inflammatory myopathies. High-resolution computed tomography (HRCT), which is the current gold standard for diagnosis and evolutionary control, is problematic owing to ionizing radiation, cost, and accessibility. In this context, lung ultrasound (LUS) is an attractive tool in a growing research and validation process.
Objectives: to assess specificity and sensitivity of LUS in rheumatic diseases on Russian cohorts of patients.
Methods: 110 pts with ILD of rheumatic disease such as: systemic sclerosis (n=60) (mean age 49.8±13.3, fem 57); vasculitis n=11 (mean age 40.7± 9.1, fem 5); dermatomyositis (DM), anti-synthetase syndrome (ASS), polymyositis (PM) n=20, (mean age 48.7± 11.9, fem 13); rheumatoid arthritis (RA) n=9 (mean age 56.5± 6.3, fem 7); Sjogren's syndrome (SSj) n=9 (mean age 59.6± 12.3, fem 8). Chest HRCT were evaluated. Control group (n=30) without rheumatic diseases and ILD (mean age 51.4± 15.4, fem 24); (chest X-ray (CXR) were evaluated). LUS examination protocol that include the anterior, lateral, and/or posterior thorax have been suggested. The B-lines score denoting the extension of ILD was calculated by summing the number of B-lines on a total of 58 scanning sites. In each patient ultrasound comets (ULC) score was obtained by summing the number of comets detected as previously recommended. The data were collected in protocols for statistical testing. The diagnostic accuracy LUS is expressed as sensitivity, specificity. ROC (receiver operating characteristic) curves and AUCs (areas under curve) were used of analyze the accuracy of B-lines in recognizing the presence of ILD on HRCT.
Results: the analysis included all the 110 patients enrolled in the study. ROC cure analysis the ULC score of anterior chest area was (AUC =0.876; 95% CI 0.82-0.96; p<0.0001); ROC cure analysis the ULC score of posterior chest area was (AUC =0.908; 95% CI 0.858-0.958; p<0.0001); ROC cure analysis for the total ULC score was (AUC =0.932; 95% CI 0.892-0.972; p<0.0001).
Accuracy of echographic signs (B-line) in the different chest areas in the detection of interstitial lung disease (Table 1).

Table 1.

	Total B-line Score (TBLS)	Sensitivity	Specificity
Anterior chest area	>5	61.8%	96%
	>10	48.2%	100%
Posterior chest area	>5	85.5%	83%
	>10	73.6%	90%
All chest areas	>5	89.1%	70%
	>10	81.8%	87%

Using the TBLS to identify a positive LUS examination, sensitivity and specificity were different depending on the area investigation. The best results were in the posterior area and all chest areas.
Conclusion: our research documented the high diagnostic accuracy of LUS in the detection of ILD. Our findings support the use of LUS a sensitive tool for ILD detection, especially considering that it's an inexpensive and nonionizing technique.

RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) AS AN ALTERNATIVE APPROACH TO BIOELECTRICAL IMPEDANCE ANALYSIS (BIA) FOR THE ASSESSMENT OF BODY COMPOSITION

P. Pisani[1], A. Natale[2], F. A. Lombardi[1], F. Conversano[1], E. Casciaro[1], M. Muratore[3], S. Casciaro[1]. [1]*National Research Council, Institute of Clinical Physiology, Lecce, Italy*; [2]*Echolight Spa, R&D Department, Lecce, Italy*; [3]*ASL, Rheumatology, Lecce, Italy*

Background: The evaluation of human body composition is crucial for body weight management, especially in pathological conditions. Patients whose body weight greatly exceeds or remain below the reference range, need regular monitoring in order to personalise the nutritional treatment plan. To this end, bioelectrical impedance analysis (BIA) is a widely accepted tool, along with ultrasound techniques. Among emerging ultrasound-based technologies, Radiofrequency Echographic Multi Spectrometry (REMS) is a powerful approach that can be effectively used for body composition analysis.
Objectives: The present study aims to assess the accuracy of REMS in comparison to BIA for body composition assessment.
Methods: The cohort included 141 males and females aged between 60 and 80 years. All subjects underwent body mass measurement by REMS and BIA and both body fat percentage (BFP) and basal metabolic rate (BMR) parameters were assessed.
Results: The estimation of BFP measured with BIA resulted in 40.4% (interquartile range [IQR]: 35.5% to 45.2%), which value did not differ from 41.1% (IQR: 36.5% to 47.1%) obtained with REMS (p=0.6). The BMR determined by BIA was 1329.0 kcal/day (IQR: 1270.5 to 1423.5 kcal/day), which was in a similar range as the value of 1323.5 kcal/day (IQR: 1266.0 to 1420.0 kcal/day) assessed by REMS (p=0.7).
Conclusion: The present study demonstrated the excellent ability of REMS to accurately determine the body composition, resulting as an alternative approach to conventional BIA.

AB1374

INTERSTITIAL LUNG DISEASE IN ASYMPTOMATIC PATIENTS AT THE ONSET OF INFLAMMATORY RHEUMATIC DISEASES

T. Hoffmann[1], P. Oelzner[1], F. Marcus[2], M. Förster[2], U. Teichgräber[3], G. Wolf[1], A. Pfeil[1]. [1]*Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine III, Jena, Germany*; [2]*Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine I, Jena, Germany*; [3]*Jena University Hospital – Friedrich Schiller University Jena, Institute of Diagnostic and Interventional Radiology, Jena, Germany*

Background: Interstitial lung disease (ILD) in inflammatory rheumatic diseases (IRD) is associated with increased mortality. Moreover, the lung is one of the most effected organs on IRD, but the clinical manifestations and severity can vary from subclinical abnormality to dyspnoea, respiratory failure, and death.
Objectives: The objective of the following study is to evaluate the frequency and type of ILD in asymptomatic patients at the onset of IRD.
Methods: The study represents a sub-analysis of a case-control study performed earlier, and includes 126 patients with a newly diagnosed IRD. The study cohort was divided in two groups (ILD group: n = 63 and control group: n = 63). The patients were evaluated for respiratory symptoms (cough, sputum, dyspnea) and sclerosiphonia. If possible, all patients received a lung function test and optional a chest x-ray. Patients with pathological findings in the screening tests (chest x-ray or reduced diffusing capacity for carbon monoxide (DLCO) < 80 %) maintained a high-resolution computer tomography (HR-CT) of the lung. The sub-analysis includes 20 patients with asymptomatic ILD at the onset of IRD.
Results: The asymptomatic ILD group consists out of 75 % female (n = 15) and 25 % male (n = 5) patients, with median age of 51.8 years (SD ± 17.1 years). In comparison, asymptomatic ILD patients are significant younger ($t(27.4) = 2.36$, $p = 0.026$), but the distribution of gender is similar. The mean values in different pulmonary function parameter are: FVC: 89.9% ± 19.3%; DLCO: 69.9% ± 21.2%; FEV1: 87.9% ± 21.4%; TLC: 91.0% ± 16.5% and TLCO: 82.1% ± 20.6% (FVC = Forced Vital Capacity, FEV1 = Forced Expiratory Volume in 1 second, TLC = Total Lung Capacity, TLCO = Transfer factor of the Lung for carbon monoxide). The observed CT patterns are pure ground glass opacities (GGO) (50%, n = 10), non-specific interstitial pneumonia (NSIP) (25%, n = 5), granuloma/proliferations (15%, n = 3), usual interstitial pneumonia (UIP) (5%, n = 1) and lymphocytic interstitial pneumonia (LIP) (5%, n = 1). The distribution of CT pattern was not significant to the symptomatic ILD group ($\chi^2(6) = 10.224$, $p = 0.116$).

Conclusion: The study highlighted that also clinical asymptomatic patients have ILD in IRD at the onset of the IRD. Frequently, a reduced DLCO is detectable in PFT as a sign of early lung involvement, so this represents a potential screening parameter. Moreover, asymptomatic patients are often younger than symptomatic patients. No significant difference was found in CT pattern, but further research is needed as the number of patients is quite small.

AB1375 PERFORMANCE OF ULTRASOUND EXAMINATION OF INSERTIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES.

G. Gainullina[1], E. Kirillova[1], A. Odincova[2], D. Abdulganieva[1]. *[1]Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation*; *[2]Republican Clinical Hospital of the Ministry of Health of the Republic of Tatarstan, Gastroenterology, Kazan, Russian Federation*

Background: Enthesitis is one of extraintestinal manifestation of inflammatory bowel diseases (IBD). US examination appears to be a useful imaging technique, specifically in identifying enthesis involvement in patients with inflammatory bowel diseases [1].
Objectives: The aim of the study was to perform the individual anatomical site analysis for the evaluation of enthesopathies in patients with inflammatory bowel diseases (IBD).
Methods: A total of 95 patients with IBD were prospectively enrolled, 55 with ulcerative colitis (UC) and 40 with Crohn's disease (CD). All patients underwent ultrasound in B-mode and PD-mode, to assess the presence of entesitis. Thirty four different anatomical sites (insertions of short head of the biceps brachii, coracoacromial ligament (2 sites), infrascapularis, supraspinatus, infraspinatus, triceps brachii, flexor carpi ulnaris, flexor carpi radialis, extensor carpi ulnaris, extensors carpi radialis (2), gluteus minimum, gluteus medium, spina iliaca anterior superior/inferior, ischiadicus tuberositas, medial collateral ligament of knee (2 sites), lateral collateral ligament of knee (2 sites), patellar ligament (2 sites), pes anserinus, biceps femoris, semimembranosus, quadriceps femoris, tibialis anterior, tibialis posterior, peroneus brevis, achille, plantar fascia, medial epicondyle, lateral epicondyle) were evaluated bilaterally with total count 6460. If typical ultrasound features, such as entheseal hypoechogenicity, entheseal thickening, presence of vascularization, were present, acute lesions was diagnosed. Bone erosions and enthesophytes were considered as chronic lesions. Fisher's exact test was used to calculate differences.
Results: The number of positive enthesitis sites was 293/6460 (4.5%), 177 positive sites in patients with UC versus 116 in patients CD (4,7% vs 4,2%). Most often involved sites were pes anserinus and proximal insertion of medial collateral ligament of knee (Figure 1). The number of positive vascularizated enthesitis sites was 62/6460 (1.0%), 40 in patients with UC versus 22 in patients with CD (1,0% vs 0,8%). Proximal insertion of medial collateral ligament of knee was involved more often then other sites. At least one positive enthesitis was detected in 72 (76%) patients, 42 (76%) patients with UC versus 30 (75%) patients with CD. Vascularizated enthesitis were detected in 35 (37%) patients, 21 (38%) patients with UC versus 14 (35%) patients with CD. There are not statistically significant differences between UC and CD. Signs of chronic lesion were often detected. The number of sites with erosions was 313/6460 (4.8%), 178 (4,8%) in patients with UC versus 135 (5,0%) in patients CD. Enthesophytes of insertion were detected in 91/6460 (1, 4%) sites, 41 (1,1%) in patients with UC versus 40 (1,5%) in patients CD. Most often erosion was detected in insertion of medial collateral ligament of knee (both sites) and enthesophyte was found in insertion of quadriceps femoris. There are not statistically significant differences between UC and CD.
Conclusion: Enthesis abnormalities are often features detected by ultrasound in patients with IBD. Most often involved site is medial collateral ligament of knee. There are not significant differences between UC and CD patients.

AB1376 RELATIONSHIP BETWEEN INTRANEURAL HYPERVASCULARIZATION OF THE MEDIAN NERVE IN POWER DOPPLER AND ELECTROMYOGRAPHIC SEVERITY STAGES IN THE DIAGNOSIS OF SEVERITY OF CARPAL TUNNEL SYNDROME (PRELIMINARY RESULTS)

H. Fouzia[1], T. Fatima Zahrae[1], K. Berrada[1], N. Takhrifa[1], I. Berrichi[1], F. E. Abourazzak[1]. *[1]CHU Tangier-Tetouan-El Hoceima, Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Tangier, Morocco, Department of Rheumatology, Tangier, Morocco*

Background: Carpal tunnel syndrome (CTS) is the most common tunnel syndrome in the upper limbs. Ultrasound has been increasingly used in recent years in the diagnosis of positive and severe CTS. Although the diagnosis of severity is essentially based on the ENMG, several studies have shown that ultrasound data can also constitute criteria for the severity of CTS.
Objectives: The objective of our study is to evaluate the relationship between intraneural hypervascularization of the median nerve in power Doppler and the severity of CTS measured by ENMG.
Methods: This is a descriptive cross-sectional study of patients with clinically retained CTS. We excluded from the study operated patients and patients who received cortisone infiltration in the previous six months. All patients underwent ultrasound examination (B mode and Doppler mode) and electromyography one week apart. The severity stages of CTS have been defined according to the classification of Stevens (1997). The study is still ongoing.
Results: To date we have included 14 patients with typical signs of CTS. 25 wrists were examined sonographically and by ENMG. The mean age of the patients was 54± 10 years. Bilateral SCC was present in 11 patients. Of the 25 affected wrists: 10, 7 and 8 were classified by the ENMG as mild, moderate and severe SCC respectively. On ultrasound, positive Doppler was found in 5 wrists (20% of wrists studied): Doppler was present in 10% of wrists with mild-stage SCC, 14.3% of wrists with moderate-stage SCC and in 37.5% of wrists with severe SCC. But this difference was not statistically significant (p=0.31) probably related to the small size of our current sample (study still ongoing).
Conclusion: The preliminary results of our study suggest that intraneural hypervascularization of the median nerve in power Doppler could provide additional information on the severity of carpal tunnel syndrome. Results to be confirmed by the final results.

AB1377 FULLY AUTOMATIC ASSESSMENT OF NAIL FOLD CAPILLAROSCOPY SOFTWARE – PILOT STUDY

O. Brzezińska[1], K. Rychlicki-Kicior[2], J. Makowska3. *[1]Medical University of Lodz, Department of Rheumatology, Łódź, Poland*; *[2]University of Economics and Human Sciences in Warsaw, Computer Science, Warsaw, Poland*; *[1]Medical University of Lodz, Department of Rheumatology, Łódź, Poland*

Background: The nail fold capillaroscopy is one of the basic techniques used in diagnosis and monitoring the course of connective tissue diseases, primarily a systemic sclerosis. However, the assessment of the capillary image is time-consuming and subjective, this makes it difficult for a detailed comparison of studies assessed by various physicians.
Objectives: The aim of this study was to validate an automated software for classification the nail fold capillaroscopy as normal or pathological and counting the numerous of vessels on a millimetre.
Methods: 100 correct and 100 pathological images were selected from the capillaroscopic image database. The original examination was performed with Dinolite MEDL4N Pro. The classic, manual evaluation of the capillaroscopy was performed twice. The imagines was classified as correct or pathological and mean number of capillaries per millimetre was calculated. The photos were then exported to the training program created for the study, the region of interest (ROI) and individual capillaries were marked. The

calculation of the number of vessels was made at a magnification of about 50x (ensuring the maximum quality of the image obtained during a classic examination). The neural network was trained using the fast.ai library (based on PyTorch). The ResNet-34 deep residual neural network was chosen, 10-fold cross-validation with validation and test set was performed, using Darknet-YoloV3 state of the art neural network in a GPU-optimized (P5000 GPU) environment. For calculation of 1mm capillaries, additional detection mechanism was designed, in order to automatically detect the scale of the image and transform it into proper pixel dimensions.

Results: The results obtained under neural network training have been referred to the results obtained as part of a manual photo assessment. For the image classification correct vs pathological test sensitivity 89.0% and specificity 86.9% was obtained. For validation (20% of images have been drawn as a validating group), 89.0% and 89.4% respectively were noticed. For the average number of capillaries in 1mm, an average of three regions have been estimated (the first region with 1mm from the left, the second with 1mm from the right and the third with 1mm in the middle). The estimated number of capillars in each region has been compared with ground truth data. The RMSE (Root Mean Squared Error) for the test set was 2.81 and the accuracy was 76.2%.

Conclusion: The use of fully automatic Nail Fold Capillaroscopy Software can be a fast and easy method of the correct and changed capillaroscopy pattern classification, the possibility of counting gives a repetitive result regardless of the physician evaluating the capillaroscopy pattern. In the further course of work on the software, it will be possible to distinguish megacapillary, branched vessels, avascularisation and other pathological features, which will allow full automatic image evaluation and easy follow-up of patients.

AB1378 RELATION BETWEEN SHARP SCORE AND RADIOLOGICAL PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE OBSERVATION

O. Alekseeva[1], D. Kudinsky[1], A. Smirnov[1], A. Volkov[1], E. Nasonov[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Diagnostic department, Moskva, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Chief Researcher, Moskva, Russian Federation*

Objectives: to analyse rheumatoid arthritis (RA)-patients depending on their individual peak radiographic progression.

Methods: 61 RA pts, mean age 50,0 [38,0; 59,0] yrs, mean disease duration 7 [4; 20] months were treated with MTX and biologics according to the Treat-To-Target concept. After first year of therapy management was following real clinical practice rules until the termination of the study (7 years FUP, median 7,7 [7,4;8,6]). The general characteristics of the group are presented in the Table 1. Hands and feet ultrasound (US) with grayscale (GS), power Doppler (PD), according to the criteria of OMERACT, were analyzed before initiation of treatment and in 3, 6, 9, and 12 months after. Radiographs were obtained at baseline, at 12 months, 4 years, and 7 years, radiographic changes were assessed using Sharp/van der Heijde modified scoring method. Structural damage progression was evaluated by change in the Sharp van der Heijde score (ΔSHS) between baseline and 1,4 and 7 year. We determined the individual peak radiographic progression (Δ SHS scores/time) in RA- patients.

Table 1. General characteristics

Characteristic	At baseline	After 1 year follow-up	After 4 years follow-up	After 7 years follow-up
Median age, years	50,0 [38,0; 59,0]			
Disease duration, months	7 [4; 20]			
GS	6 [4; 9]			
PD	2 [1; 6]			
DAS 28	5,6 [4,8; 6,5]	2,88 [2,02; 3,93]	3,76 [2,94; 5,09]	4,03 [3,42; 4,74]
ESR, mm/h	35,0 [13,0; 50,0]	12,0 [8,0; 28,0]	22,0 [14,0; 36,0]	22,0 [14,0; 36,0]
CRP, mg/l	10,6 [3,8; 32,3]	2,9 [1,1; 7,1]	3,0 [1,2; 8,8]	3,0 [1,2; 8,8]
Rheumatoid Factor, positive results	53 (87%)			
Anti-CPA, positive results	52 (85%)			
Erosion score	0 [0; 3]	1 [0; 4]	2 [0; 6]	3 [1; 11]
Joint-space narrowing score	57,0 [31,0; 88,0]	62,0 [31,0; 92,0]	93,0 [77,0; 106,0]	98,0 [77,0; 110,0]
Modified total Sharp score	70,0 [31,0; 88,0]	71,0 [31,0; 93,0]	97,0 [79,0; 112,0]	102,0 [78,0; 117,0]

Results: RA progression by 1 years FUP was identified in 10% (6 p) of pts, 4 years FUP was identified in 36% (22 p) of pts, by 7 years FUP was identified in 69% (42 p) of pts. All pts divided into groups based increase in erosions according to radiography (Rg +) and without it (Rg-). In the group Rg + GS at baseline was significantly higher than in Rg- group (6 [5; 10] and 5 [1; 8], respectively, p=0.04). We analyzed relation between SHS (erosion score and total Sharp score) 7 years FUP, individual peak radiographic progression and Δ erosion score and total Sharp score in the observation periods: 0-1 years, 1-4 years, 4-7 years and 0-7 years. The following correlations were identified of erosion score 7 years FUP with Δ erosion score in all observation periods (r=0,33 p=0,016, r=0,54 p=0,000, r=0,68 p=0,000, r=0,84 p=0,000, respectively) and with individual peak radiographic progression in the observation periods 1-4 years, 4-7 years, 0-7 years (r=0,54 p=0,000, r=0,49 p=0,000, r=0,84 p=0,000, respectively). The following correlations were identified of total Sharp score 7 years FUP with Δ total Sharp score in the observation periods 4-7 years, 0-7 years (r=0,43 p=0,000, r=0,34 p=0,007, respectively) and with individual peak radiographic progression in the observation periods 4-7 years, 0-7 years (r=0,43 p=0,000, r=0,34 p=0,007, respectively).

Conclusion: These data show that the radiological progression increases over time at different rates.

AB1379 PREDICTORS OF RADIOLOGICAL PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE OBSERVATION

O. Alekseeva[1], V. Rybakova[2], A. Smirnov[1], A. Volkov[1], E. Nasonov[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Diagnostic Department, Moskva, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology Rheumatic Diseases, Moskva, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, Chief Researcher, Moskva, Russian Federation*

Objectives: to identify the prognostic role of ultrasound signs (US) in radiologic progression in RA patients

Methods: 61 RA pts, mean age 50,0 [38,0; 59,0] yrs, mean disease duration 7 [4; 20] months were treated with MTX and biologics according to the Treat-To-Target concept. After first year of therapy management was following real clinical practice rules until the termination of the study (7 years FUP, median 7,7 [7,4;8,6]). Among them 40 patients with early RA, mean age 51,0 [43,0; 60,0], disease duration 5 [3; 6,5] months. The general characteristics of the group are presented in the Table 1. Hands and feet ultrasound (US) with grayscale (GS), power Doppler (PD), and destructive changes (erosion), according to the criteria of OMERACT, were analyzed before initiation of treatment and in 3, 6, 9, and 12 months after. Radiographs were obtained at baseline, at 12 months, 4 years, and 7 years, radiographic changes were assessed using Sharp/van der Heijde modified scoring method. Radiographic progression was documented based on Sharp/Van der Heijde modified score changes during the follow-up.

Table 1. General characteristics

Characteristic	At baseline	After 7 years follow up
Median age, years	50,0 [38,0; 59,0]	
Disease duration, months	7 [4; 20]	
GS	6 [4; 9]	
PD	2 [1; 6]	
DAS 28	5,6 [4,8; 6,5]	4,03 [3,42; 4,74]
ESR, mm/h	35,0 [13,0; 50,0]	22,0 [14,0; 36,0]
CRP, mg/l	10,6 [3,8; 32,3]	3,0 [1,2; 8,8]
Rheumatoid Factor, positive results	53 (87%)	
Anti-CPA, positive results	52 (85%)	
Mean erosion score	0 [0; 3]	3 [1; 11]
Mean joint-space narrowing score	57,0 [31,0; 88,0]	98,0 [77,0; 110,0]
Modified total Sharp score	70,0 [31,0; 88,0]	102,0 [78,0; 117,0]

Results: 52 ACPA+ (85%) and 9 ACPA– (15%) patients presented among the 61 patients with RA. RA progression by 4 years FUP was identified in 36% (22 p) of pts, by 7 years FUP was identified in 69% (42 p) of pts. During the 7 years FUP 42 of 61 patients had radiographic progression: the count of erosion increased from 0 [0; 3] to 3 [1; 11]. At the same time, on the background of therapy during the first year, a decrease in ultrasound signs of inflammation was determined according to the GS and PD: from 6 [4; 9] to 4 [2; 6] p = 0.000 and from 2 [1; 6] to 0 [0; 2] p = 0.000, respectively, and increase in the number of joints with erosions (from 1 [0; 2] to 2 [0; 3], p = 0.000).

All pts divided into groups based increase in erosions according to radiography (Rg +) and without it (Rg-). In the group Rg + GS at baseline was significantly higher than in Rg- group (6 [5; 10] and 5 [1; 8], respectively, p=0.04). CRP at 3 months and at 6 months was significantly higher in RG+ group than in RG- group (4,15 [1,2; 8,7] and 1,2 [0; 3,5], respectively, p=0.03 and 2,35 [0,8; 10,1] and 0,4 [0; 4,3], respectively, p=0.025).

Conclusion: Thus, we obtained the first data on the important prognostic role of ultrasound in assessing the progression of early RA in a prospective seven-year follow-up.

AB1380 ULTRASONOGRAPHIC CHANGES OF PLANTAR FASCIA IN PATIENTS WITH PLANTAR FASCIITIS DUE TO ACQUIRED FLAT FOOT

O. Turchin[1], A. Liabakh[1], O. Burianov[2], T. Omelchenko[2], L. Osadcha[1]. [1]*State Institute "The Institute of Traumatology and Orthopedics of Ukraine", The Clinic for Foot Pathologies and Complex Prosthetic Treatment, Kyiv, Ukraine*; [2]*Bogomolets National Medical University, traumatology&orthopaedics, Kyiv, Ukraine*

Background: Plantar fasciitis is a chronic degenerative process of the plantar fascia enthesis. It manifests by pain, predisposition to prolonged course and treatment resistance. In many cases, plantar fasciitis develops in patients with acquired flat feet. Taken into consideration above mentioned, the study of the plantar fascia changes in patients with acquired flat feet by sonography is relevant.

Objectives: To investigate the quantitative and qualitative sonographic changes of the plantar fascia in the case of plantar fasciitis in patients with acquired flat foot.

Methods: 190 patients with plantar fasciitis on the basis of acquired flat feet (133 females and 57 males). The average age of patients was 48 ± 0.97 years (18-81years). Unilateral pathology was noted in 117 patients and bilateral – in 73 patients. The average body mass index was 27.68±0.3. The average duration of pain syndrome was 101 ± 6.0 days (7-390 days). The pain syndrome lasted up from 1 to 6 months – in 152 patients, and more than 6 months – in 38 patients. The control group included 15 healthy volunteers (30 feet). Clinical radiological, sonographic, and statistical methods were used.

Results: The main sonographic features were significant reduction in echogenicity, erased or missing fibrous pattern, fuzzy contour of the aponeurosis; and modified contour of the calcaneus; small focal hyperechogenicity points in enthesis were detected. Loci of vascularization were detected using power Doppler sonography. The average thickness of plantar fascia in the study group was 6,14±1,5 mm (2,3-7,7 mm) and in control group – 3,5±0,1 mm (2,5-4,4 mm).

Conclusion: Sonographic signs of plantar fasciitis on the basis of acquired flat feet were changes in echogenicity and structure, changes in the contours of the cortical layer of enthesis and plantar fascia, the thickening of the enthesis of the plantar fascia of more than 4 mm.

AB1381 DETECTION OF QUANTITATIVE ULTRASOUND CHANGES AFTER CORTICOID INFILTRATION OF THE PREACHILLEAL BURSA IN PATIENTS WITH INFLAMMATORY OR MECHANICAL ENTHESOPATHIES

C. Guillén-Astete[1], M. Tortosa-Cabañas[1], Á. Andreu-Suárez[1]. [1]*Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: It has recently been demonstrated that computer analysis of static ultrasound images can detect exercise-induced stromal changes in the body's load-bearing tendons.

Objectives: The purpose of this study is to determine if the same analysis can detect enthesic changes in patients who have undergone corticosteroid infiltration in the preachilles bursa.

Methods: Serial images of patients who received corticosteroid injections (around 40mg of triamcinolone acetonide) in the preachilles bursa were selected. For the records to be considered it was necessary at least one baseline ultrasound study, one between the first and second month after the injection and one between the third and sixth month after the injection. All images were obtained with the same ultrasound equipment, by the same operator and with the same gain and frequency settings.

The images were analyzed using the ImageJ 1.53e program, which allowed the recording of the mean intensity of gray (MIG), dispersion of gray intensities (DIG) and mode of gray intensities (MoIG).

Results: Eighteen image collections from the same number of patients were selected. Eight corresponded to mechanical enthesopathies (without any diagnosis of spondyloarthritis) and ten were patients with a diagnosis of axial spondyloarthritis (5) or psoriatic arthritis (5). The ratios of MIG, DIG and MoIG of the injured enthesis with respect to its control were, respectively, 1.12 SD 0.14, 0.88 SD 0.42 and 2.04 SD 1.54 for the mechanical pathology group and 0.89 SD 0.05, 1 SD 0.04 and 0.96 SD 0.03 for the inflammatory pathology group. Statistically significant differences in the MIG ratio were detected between patients with inflammatory diseases and patients with mechanical injuries (t=4.69, P=.000). Among patients with inflammatory pathology, the change between baseline and 3-6 months after infiltration MIG was statistically significant (82.59 SD 37.68 vs 92.02 SD 38.67; t=-5.69, P=.000). The changes between DIG and MoIG were not significant (t=0.899, P=.392 and t=-1.542, P=.158, respectively). Among patients with mechanical pathology, there were no significant differences between final and baseline MIG, DIG, or MoIG (t=1.921, P=.096; t=-1.533, P=0.169; and t=1.761, P=0.122, respectively). Figure 1 summarizes the changes in the mean gray intensity index (iMIG) in patients with mechanical and inflammatory pathology. In patients with inflammatory diseases, the changes between the final and basal iMIG tend to normalize (approaching the unit). In the mechanical pathology group, the iMIG variation shows a less defined behavior.

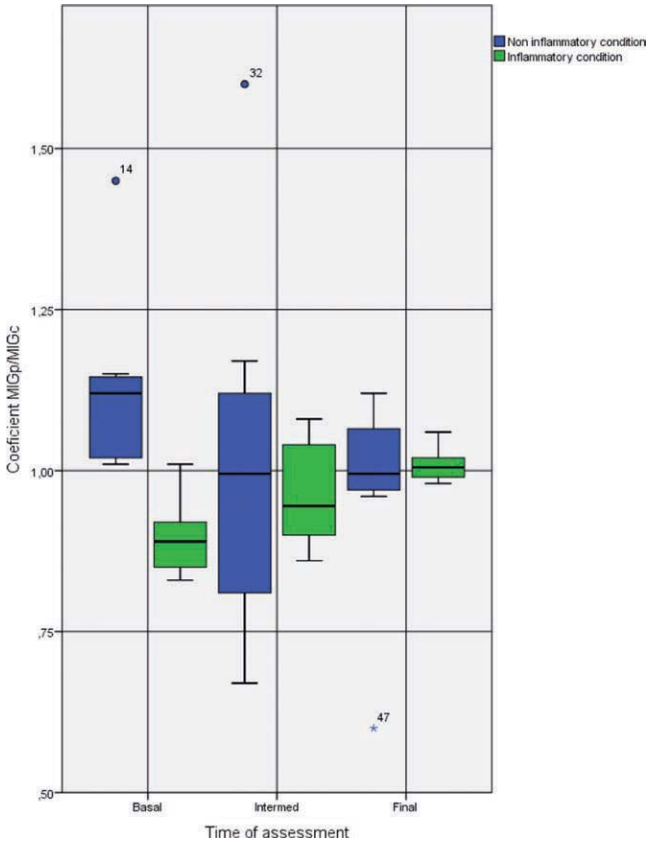

Figure 1. *Box and whisker plot showing the evolution over time of the pathological/healthy gray intensity mean coefficient. MIGp: Mean gray intensity in the pathological enthesis. MIGc: Mean gray intensity in the control enthesis of the same patient.*

Conclusion: The computer analysis of static images in gray scale can detect the changes observed in the Achilles enthesis of patients with inflammatory diseases such as spondyloarthritis. It is also demonstrated that in these patients the gray intensity change rate tends to be normalized (approaching the unit) after a steroid injection. Trend to normalization has not been evidenced in patients with mechanical pathology. Corticosteroids apparently do not act on the origin of the mechanical enthesopathies. Therefore, the study of the average, dispersion and fashion of gray intensities is erratic.

The capacity of MIG detecting evolutionary changes in inflammatory pathology shows a potential for the follow-up of patients with spondyloarthritis and enthesseal commitment.

AB1382 SCREENING OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS THROUGH AN ULTRASONOGRAPHY PROTOCOL

A. Brigante[1], J. Rebak[1], G. Rizzo[2], L. L. Holguín Arias[1], F. Rizzo[3], S. Quadrelli[2], D. Dubinsky[1]on behalf of Interstitial Pulmonary Diseases Service of the Sanatorio Güemes. [1]*Sanatorio Güemes, Rheumatology, Ciudad Autónoma de Buenos Aires, Argentina*; [2]*Sanatorio Güemes, Pneumology, Ciudad Autónoma de Buenos Aires, Argentina*; [3]*Sanatorio Güemes, Diagnostic Imaging Department, CABA, Argentina*

Background: Interstitial Lung Disease (ILD) is a frequent complication in patients with autoimmune diseases. Rheumatoid arthritis (RA) does not escape this statement. Different protocols have been proposed for the ultrasound evaluation of this affectation showing very good correlation with high-resolution computed tomography.

Objectives: To determine the sensitivity and specificity of an ultrasound evaluation protocol as a screening method for interstitial lung disease in rheumatoid arthritis.

Methods: Consecutive patients diagnosed with RA, with and without ILD, will be included. High-resolution chest CT (HRCT) will be performed in all patients. The lung evaluation protocol by ultrasonography (US); evaluates 50 intercostal spaces (ICS) and will be performed by a rheumatologist and imaging specialist trained in the procedure. The presence of B lines and pleural alterations in the EICs explored will be evaluated. A semiquantitative scale will be used to assess each EIC: 0 = normal, (<10 B lines); 1 = mild (11 to 20 B lines); 2 = moderate (21 to 50 B lines) and 3 = marked (> 50 B lines). CT scan was considered the "gold standard" for the diagnosis of ILD and they were evaluated by experienced pulmonologists who were blind to the patient.

Results: 79 patients were included. Female sex 77% with a mean age of 55 (SD 11.4). The comorbidities observed were: hypertension 27%, dyslipidemia 15%, diabetes mellitus 10%, hypothyroidism 30%, smokers 14%, former smokers 18% and osteoporosis in 14% of patients. The patients had a median duration of the disease in years of 7.5 [IQR 9.2]. Erosive disease was seen in 20 (20%) and rheumatoid nodules in 9.1% of patients. 91% of the patients were under treatment with corticosteroids. Rheumatoid factor was observed in 87% of the patients and Anti-CCP in 71% of the patients, of which 70% had high titers. DILD was observed by HRCT in 21 (27%) patients. The tomographic patterns observed were UIP 7 (33%), probable UIP 2 (10%), cellular NSIP 6 (29%), fibrosing NSIP 3 (14%). An indeterminate pattern was observed in 3 patients. The extent of pulmonary involvement was extensive in 48% of patients and limited in 52%. A sensitivity of 63% (CI95% 44-78) and a specificity of 92% (CI95% 81-97) were observed for the ultrasound evaluation protocol with a PPV of 81% (CI95% 61-92) and NPV of 83 % (95% CI 71-90) and an LR+ 8.1 (95% CI 4.6-14.3) and LR- 0.4 (95% CI 0.3-0.48). AUC: 0.81 (p<0.0001).

Conclusion: We observed a moderate sensitivity and specificity of the method to assess interstitial lung involvement in RA with an acceptable AUC for a screening method. These findings are similar to what was found in other cohorts. We observe a high NPV. This means that in patients with a negative study result, the possibility of ILD would be removed. Studies in larger cohorts and comparison with other factors associated with ILD are necessary to improve our understanding of the method and give it the place it deserves.

AB1383 QUANTIFICATION OF THE PD SIGNAL BY COMPUTER ANALYSIS OF STATIC IMAGES: INTRA-OBSERVER, INTRA-PATIENT AND SENSITIVITY TO CHANGE VALIDATION.

C. Guillén-Astete[1], Á. Andreu-Suárez[1], M. Tortosa-Cabañas[1]. [1]*University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: The computerized assessment of ultrasound images is an alternative to the dichotomous subjective assessment often used in the study of entheses. Previously, our group has demonstrated its usefulness in assessing greyscale images; however, the evaluation of enthesial hyperemia using this technique remains a pending task.

Objectives: -To determine the intra-observer and intra-patient variability of the hyperemia study using computer analysis of static images.

Methods: Patients with a diagnosis of known spondyloarthritis and ultrasound enthesitis of the Achilles tendon -according to EULAR criteria (detection of hyperemia by power Doppler (PD) signal within 2mm of the cortex)- were selected. Longitudinal medial, central and lateral image sections were obtained. Hyperemia was assessed by PD signal detection, and the images with the highest signal intensity were recorded, maintaining the same doppler gain and PRF settings for each subject. For image analysis, recordings were coded and randomized so that the analyst did not know to which patient a given section corresponded. Intra-patient validity was assessed by comparing the results of sections from the same patient with each other at two different times. Intra-observer validity was evaluated by subjecting the same image to two computer analyses at different times. Finally, validation of sensitivity to change was performed by successive measurements. The software used was ImageJ 1.53e (NIH, USA).

Results: Images of 12 patients with Achilles enthesitis were included: 6 patients with SpA-nRx, four patients with PsA, and two patients with SpA-Rx. On intra-patient evaluation, significant differences in PD signal intensity were detected between medial, lateral, and central sections. In all cases, the measurement obtained in the central section was the highest (Friedman 15.500 P=.000; medial-central -1.500, P=.001; lateral-central -1.250, P=.007). The coefficient of variation in the first and second determinations without considering the sign of the variation was: 4.2% SD 5.5%. In the intra-observer evaluation of the PD signal evaluations at the central cut-off, the mean coefficient of variation, without considering the sign, was: 9.1% SD 7.2%. In assessing sensitivity to change, patients with 6-month ultrasound studies were grouped into those who maintained treatment and those who eventually discontinued treatment due to therapeutic failure. In the seven patients who maintained treatment, the mean change in hyperemic areas was -94.3% SD 4.4%, while in the five patients who discontinued treatment, it was -65.4% SD 6.3% (p=.000).

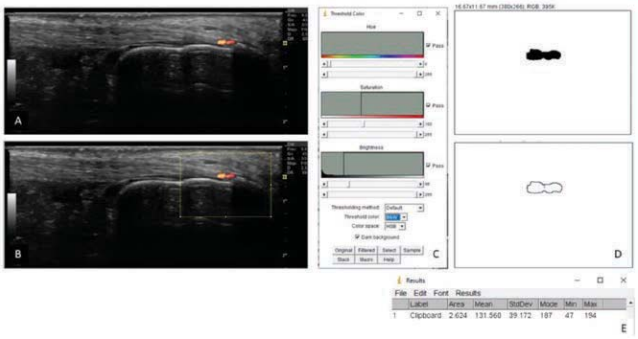

Figure 1. *Evaluation of the PD signal.*

Conclusion: Computer analysis of static Achilles tendon images conforms to the same ultrasound image acquisition recommendations. In addition, it demonstrates excellent intra-patient and inter-observer variability and sensitivity to change, at least when correlated with therapeutic success or failure from a clinical perspective.

AB1384 CLINICAL SIGNIFICANCE OF DENSE FINE SPECKLED PATTERN ANA

S. Sapkota[1], J. Molitor[2], M. Evans[3], B. Kofoed[4], A. Lord[4], L. Robinson[5], J. Crosson[6]. [1]*Colorado, Department of Medicine, Division of Rheumatology, Aurora, Colorado, United States of America*; [2]*University of Minnesota Medical Center, Department of Medicine, Division of Rheumatic and Autoimmune Diseases, Minneapolis, Minnesota, United States of America*; [3]*University of Minnesota, Clinical and Translational Science Institute, BDAC, Minneapolis, Minnesota, United States of America*; [4]*University of Minnesota Medical School, Medical School, Minneapolis, MN, United States of America*; [5]*Duke University School of Medicine, Department of Medicine, Durham, North Carolina, United States of America*; [6]*University of Minnesota Medical School, Department of Laboratory Medicine and Pathology, Minneapolis, MN, United States of America*

Background: The clinical significance of Dense Fine Speckled (DFS) pattern Anti-nuclear antibodies (ANA) by indirect immunofluorescence method (IIF) is unclear and has been inversely associated with rheumatic disease [1 2].

Objectives: Our purpose was to determine associations between DFS pattern ANA and the disease categories of inflammatory arthritis, ANA associated rheumatic diseases (AARD), fibromyalgia/chronic pain syndrome/chronic fatigue syndrome and atopic disorder.

Methods: This retrospective study used data from patients tested for ANA by IIF between August 2017 to August 2019 at the University of Minnesota Medical Center. Comparisons between the diagnostic categories listed in objectives were made for patients with negative ANA, positive ANA (any pattern) and DFS pattern. Individual disease diagnoses belonging to the above categories were also analyzed. The inflammatory arthritis category included seropositive rheumatoid arthritis (RA), seronegative RA, RA with unknown serology, ankylosing spondylitis, and psoriatic arthritis. The disease category of AARD included systemic lupus erythematosus (SLE), systemic sclerosis, mixed connective tissue disease, idiopathic inflammatory myopathies, Sjogren's syndrome (SS), and undifferentiated connective tissue disorder (UCTD). Atopic disorders included atopic dermatitis, allergic rhinitis, urticaria, and asthma. Frequency of Raynaud's phenomenon (RP) was also calculated.

Results: 13,845 patients with an ANA during the study period were identified. 9106 (65.8%) had negative ANA and 4739 (34.2%) had positive ANA by IIF (including all patterns). 640 (4.6%) had ANA positive DFS patterns. Relative risk (RR) was calculated for diagnostic categories and individual diseases. For patients with positive ANA and DFS pattern, the RR for diagnostic codes of inflammatory arthritis categories [1.35 (1.07- 1.71), p=0.02] was higher when compared to the frequency of codes in ANA negative. RR for AARD among patients with DFS pattern was also higher [1.78 (1.44- 2.2), p <0.001]. There was no significant difference in the frequency of diagnostic codes of chronic pain/fibromyalgia/chronic fatigue syndrome [1.02 (0.9- 1.2), p=0.84] atopic disorder [0.68 (0.4- 1.15), p=0.16] for DFS+ compared to the ANA group. The frequency of AARD diagnostic codes was lower for patients with DFS pattern [0.64 (0.52-0.79), p<0.001] compared to ANA positive patients with all other patterns, consistent with published data. There was no significant difference of frequency of diagnostic codes for the rest of the disease categories when comparison was made between ANA positive DFS pattern and ANA positive with other patterns.

Individual disease diagnostic codes of RA were higher among DFS+ patients when compared to ANA- patients. The frequency of diagnostic codes of SLE, SS, UCTD, fibromyalgia, Raynaud's phenomenon, and autoimmune thyroid disease was also higher among patients with DFS pattern compared to ANA- patients. The frequency of diagnostic codes of seropositive RA was lower among patients with DFS pattern compared to ANA+ with all other patterns. The frequency of diagnostic codes of SLE, SSc, UCTD, and chronic pain was also lower among DFS+ patients, compared to those with ANA of all other patterns, consistent with prior reports.

Conclusion: The frequency of diagnostic codes of RA, SS and Raynaud's was higher among DFS pattern ANA compared to ANA negative group but was not significantly different from ANA positive with other patterns. This suggests that the presence of a DFS pattern should not be used to indiscriminately exclude the presence of a rheumatic disease.

AB1385 CHARACTERISTICS OF MICROANGIOPATHY IN THE NAILFOLD AREA IN UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE

S. Lambova[1,2]. [1]*Medical University of Plovdiv, Department of Propaedeutics of Internal Diseases, Plovdiv, Bulgaria*; [2]*MHAT "Sveti Mina" Plovdiv, Department in Rheumatology, Plovdiv, Bulgaria*

Background: Undifferentiated connective tissue disease (UCTD) is characterized with presence of clinical signs and immunological findings suggestive of connective autoimmune disease, but the criteria for a definite rheumatic disease are not fulfilled. Duration of symptoms below 3 years defines UCTD as "early" pathological condition (1) that requires follow-up for assessment of possible disease progression. Raynaud's phenomenon could be found in approximately 50% of cases with UCTD and about half of patients with RP and UCTD exhibit "scleroderma-like" pattern.

Objectives: To assess the characteristics of capillaroscopic changes in early UCTD.

Methods: Inclusion criteria for the study were diagnosis UCTD made for the first time by rheumatologist in patients with RP. 14 patients were included in the study – 13 women, 1 men, mean age 37±14 years. Capillaroscopic examination was performed in all patients using USB microscope Dino-Lite. Follow-up was perfomed in 7 of the patients for a period between 1 and 2 years.

Results: At the time of the initial diagnosis "scleroderma-like" pattern, "early" phase (giant capillaries, presence of haemorrhages in some cases, preserved distribution, normal capillary density) was found in 8 patients. More advanced capillaroscopic changes with devascularization, derangement and neoangiogenesis were not observed. In 5 patients nonspecific capillaroscopic findings were present (dilated, tortuous capillaries, haemorrhages) and in 1 case – normal pattern. During 1-year follow-up in one patient the diagnosis was revised to systemic lupus erythematous due to newly appeared clinical, laboratory and immunological findings. The normal capillaroscopic pattern was changed to nonspecific findings in this case. In the rest 6 patients with available follow-up both clinical diagnosis and capillaroscopic findings remain unchanged.

Conclusion: In conclusion, the predominant finding in UCTD with capillaroscopic features of "scleroderma-like" microangiopathy is "early" pattern while more advanced microvascular pathology is not a characteristic finding. Stable capillaroscopic pattern during the follow-up correlates with stable clinical symptoms. Thus, capillaroscopy should be considered as a key technique for assessment of UCTD patients with manifestations of RP regarding vascular and overall disease progression.

AB1386 A SURVEY ON ACCEPTANCE OF COVID-19 VACCINATION AMONG PATIENTS WITH RHEUMATIC DISEASES -A SINGLE CENTER EXPERIENCE IN MALAYSIA

C. R. Ng[1], W. S. Wong[1]. [1]*Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia*

Background: According to Statista, 78.5% of the population in Malaysia have completed their vaccination as of 6th january 2022 [1].The acceptance of patients with rheumatic diseases on Covid-19 vaccination is crucial in the long term protection against Covid-19 infection. We conducted a survey to determine the acceptance of Covid-19 vaccination amongst patients with underlying rheumatic disease.

Objectives: To find out the reasons of vaccination refusal amongst rheumatology patients.

Methods: This was an interview survey. All rheumatology patients who were follow up in rheumatology clinic Hospital Sultan Ismail, Malaysia from 26th April 2021 to 25th July 2021 (total 3 months) were interviewed. Demographic and diagnosis of the patients were collected.

Results: A total of 952 patients were identified. 83.7% of them were female patients (797/952) and majority of them were Malay (46.4%). This was followed by Chinese (36.1%), Indian (16.3%) and others (1.2%). The mean age group was 48 (range from 13 -85). 97.6% of the respondents were categorized as having inactive disease during the interview sessions. 36.6% of the patients were diagnosed to have rheumatoid arthritis and 29.1% of them were having systemic lupus erythematosus. These were followed by psoriatic arthritis (10.9%), mixed connective tissue disease (5.5%), systemic sclerosis (2.9%), gout (2.6%), Sjogren syndrome (1.9%), ankylosing spondylitis (1.6%), myositis (1.5%), vasculitis (1.3%), osteoarthritis (1.2%), antiphospholipid syndrome (0.9%), non-specific arthralgia (0.8%), juvenile idiopathic arthritis (0.8%), seronegative spondyloarthropathy (0.8%), undifferentiated connective tissue disease (0.7%), adult onset still's disease 0.5%) and others (< 0.5% each for Ig G 4 related disease, soft tissue rheumatism and fibromyalgia). 87.3% of them were keen or have already received Covid-19 vaccination. 12.7% of them were not keen for the vaccination with various reasons. 48.8% of them were worrying about worsening clinical condition, 12.4% of them were not keen as they concerned about side effects (3 worry about fever, 1 worry about hepatitis, 1 for nausea, 1 for dizziness, 1 for breathlessness, and 7 for non-specific reasons). 10.7% of them were not keen due to pregnancy, 5.79% of them were not keen as worried about allergic reactions, 4.9% of them were worrying about sudden cardiac death, 4% were not keen as on chemotherapy treatment, 3 % of them doubted the efficacy of vaccination, 2.5% were not keen as they worried about heart disease, 2.5% worried about increase risks of infection and others (2 for old age, 2 for thrombotic event, 2 for drug interaction and 1 patient due to hemodialysis).

Conclusion: The overall acceptance rate of Covid-19 vaccination amongst patients with rheumatic diseases is very encouraging with the percentage of >85% despite of lacking knowledge about vaccine Covid-19. This result can assist our Ministry of Health to plan for future battle to improve vaccine uptake that hopefully can lead to herd immunity against COVID-19 infection. More counseling sessions are required to clear up the doubts of vaccination and increase the vaccination rate amongst rheumatic patients.

AB1387 THE EFFECTS OF PREGNANCY AND FERTILITY ON DRUG USAGE AND PREFERENCES IN RHEUMATOLOGICAL DISEASES: A SINGLE CENTER EXPERIENCE

B. Karataş[1], N. Çabuk Çelik[1], B. Karakaş[1], İ. Yalçın[1], G. Pire[1], H. Ş. Eren[1], M. Ş. Kuzu[2], M. Yıldırım[2], B. N. Özdamar[2], M. F. Aşkın[2], A. Sahin[1]. [1]*Sivas, Cumhuriyet University Internal Medicine-Rheumatology, Sivas, Turkey*; [2]*Sivas Cumhuriyet University Faculty of Medicine, Department of Internal Medicine, Sivas, Turkey*

Background: Rheumatological diseases usually affect women of reproductive age. Although the effects of these diseases on pregnancy vary; Joint and organ damage that may occur should be prevented, maternal and fetal effects of the treatment should be evaluated (1).

Objectives: The aim of this study to determine the effects of rheumatological diseases and drugs used on pregnancy and fertility.

Methods: Between January 2014 and January 2021, women between the ages of 18-45 who were diagnosed and treated at Cumhuriyet University Medical Faculty Rheumatology-Internal Medicine Department were retrospectively analyzed.

Results: The median age of the patients is 37 (min 19-max 45) years. 517 patients (51,7%) were pregnant after diagnosis, 39 patients (3,9%) had abortion after diagnosis, 957 patients (95,7%) had live birth, 69 patients (6,9%) had curettage, 43 patients (4,3%) could not have children. The median of pregnancies before diagnosis is 2 (min 1-max 11) the median of pregnancies after diagnosis is 1 (min 1-max 6) the median of abortions before diagnosis is 2 (min 1-max 7) the median of abortions after diagnosis is 1 (min. 1-max 4) the median of curettage is 1 (min 1-max 3) the median of live births is 2 (min 1-max 5). The distribution of patients according to drug use and drug used during pregnancy is shown in Figure 1. The distribution of the patients according to the diagnosis and the factors affecting pregnancies after diagnosis, abortions after diagnosis, curettage and live birth is shown in Table 1.

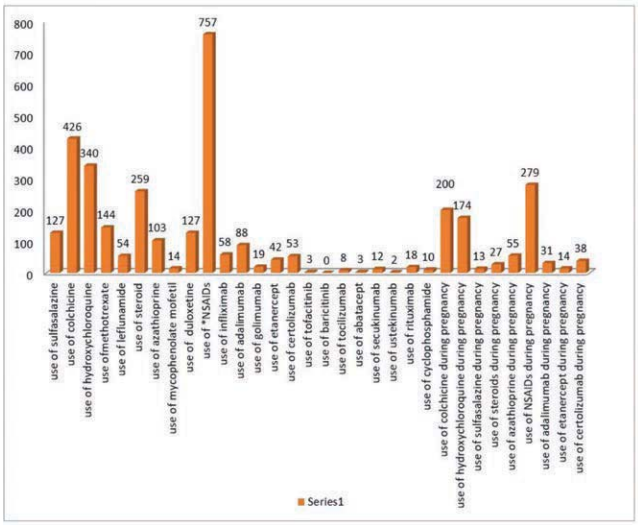

Figure 1. Distribution of patients according to drug use and drugs used during pregnancy

Conclusion: Women with rheumatic diseases should be in remission before pregnancy and should be followed closely throughout their pregnancy and treated with pregnancy-safe drugs. Preparations that can cause infertility in women during the reproductive period should not be used as much as possible. Patients should be informed in detail about the effects of their disease and the drugs used on pregnancy.

AB1388 CHARACTERISTICS ASSOCIATED WITH MYCHART ACTIVATION AND REASONS FOR NON-USE AMONG RHEUMATOLOGY CLINIC PATIENTS

C. Siegel[1], A. Bass[1,2], D. Jannat-Khah[1,2], O. Bruce[1], J. Olmscheid[1], N. Ghosh[1,2], S. E. Sattui[3], M. Schwartzman[1], D. Zisa[1], A. Lakhanpal[1], K. Yip[1], L. Yue[1], J. Aizer[1,2], J. Berman[1,2]. *[1]Hospital for Special Surgery, Medicine, New York, United States of America*; *[2]Weill Cornell Medicine, Medicine, New York, United States of America*; *[3]University of Pittsburgh, Medicine, Pittsburgh, United States of America*

Background: Electronic patient portals, such as MyChart by Epic, allow patients to view their medical records, request medication refills, and communicate with their health care providers. Factors associated with portal use include being younger, female, White, having private insurance, and having chronic illness.[1] The Hospital for Special Surgery (HSS) rheumatology clinic serves primarily patients with public insurance (Medicaid, which insures low-income adults, and Medicare, which insures adults >65 years old and those with eligible chronic illness/disability). These patients may be at increased risk for poor health outcomes due to clinical and socioeconomic factors and they are less likely to use MyChart than patients seen in HSS private practices. Increased MyChart use may benefit this high-risk group and improve health equity.

Objectives: This study aims to identify characteristics associated with MyChart activation and reasons for its underutilization among patients seen in the HSS rheumatology clinic.

Methods: We identified all patients aged ≥ 18 years seen in the HSS rheumatology clinic at least twice between January 15, 2019 and January 14, 2021, with at least one visit occurring between July 15, 2020 and January 14, 2021. MyChart status (active vs. inactive) and sociodemographic and clinical variables were extracted from the electronic health record (EHR). We used chi-square tests and t-tests to compare characteristics between patients with and without active MyChart; p-value <0.05 was considered significant (Table 1). In addition, 10 rheumatology fellows were prompted on 3 occasions over 6 weeks to informally survey their own clinic patients with inactive MyChart accounts by asking: "What is your primary reason for not using MyChart?"

Table 1. Baseline Characteristics of Hospital for Special Surgery Rheumatology Clinic Patients Stratified by MyChart Activation Status

	MyChart Active (N=726)	MyChart Inactive (N=501)	p-value
Age, yrs - Mean (SD)	50.3 (15.6)	60.0 (15.3)	*<0.01*
Female - N (%)	601 (82.8)	412 (82.2)	0.80
Race - N (%)			0.37
•White/Caucasian	275 (37.9)	184 (36.7)	
•Black/African American	185 (25.5)	135 (27.0)	
•Asian	58 (8.0)	25 (5.0)	
•Other	189 (26.0)	145 (28.9)	
•Unknown	18 (2.5)	11 (2.2)	
Ethnicity - N (%)			0.27
•Hispanic/Latino	294 (40.5)	226 (45.1)	
•Not Hispanic/Latino	422 (58.1)	268 (53.5)	
•Unknown	10 (1.4)	7 (1.4)	
Preferred language - N (%)			*<0.01*
•English	611 (84.2)	332 (66.3)	
•Spanish	72 (9.9)	134 (26.8)	
•Other	43 (5.9)	35 (7.0)	
Needs interpreter - N (%)	106 (14.6)	156 (31.1)	*<0.01*

Results: There were 1,227 patients included (93.2% with Medicaid and/or Medicare insurance). Compared to patients with inactive MyChart (42.9%), those with active MyChart (57.1%) were younger (50.3 ± 15.6 vs. 60.0 ± 15.3 years, p<0.01). The majority of patients in both groups was female. There was no significant difference in race or ethnicity between groups. Patients without active MyChart were less likely to identify English as their preferred language and more likely to require an interpreter for clinic visits (Table 1). The rheumatology fellows collectively asked 16 clinic patients with inactive MyChart their primary reason for non-use. The most commonly cited reason was difficulty using the technology (n=8; 50.0%); others included visual impairment (n=2; 12.5%), preference for using the telephone (n=2; 12.5%), concerns about security/spam (n=2; 12.5%), not having a smart phone/computer (n=1; 6.3%), and having a language barrier (n=1; 6.3%).

Conclusion: In the HSS rheumatology clinic, patients who did not have active MyChart were older and less likely to be English-speaking than those who did. The most common barrier to MyChart use reported by patients was difficulty with the technology. This pilot data suggests a need for interventions to facilitate patient-provider communication, specifically targeting older and non-English-speaking rheumatology clinic patients, with the goal of advancing patient engagement and health equity.

AB1389 COST-MINIMIZATION ANALYSIS IN RHEUMATOID ARTHRITIS IN SPAIN

J. M. Martínez-Sesmero[1], J. A. Schoenenberger-Arnaiz[2], C. Crespo-Diz[3], M. Cerezales[4]. *[1]Hospital Clínico San Carlos, Chief of Pharmacy Department, Madrid, Spain*; *[2]Institut Català de la Salut, Chief of Pharmacy Department. Regió Sanitària de Lleida, Lleida, Spain*; *[3]Servizo Galego de Saúde, Chief of Pharmacy Department. Área Sanitaria Pontevedra e O Salnés, Pontevedra, Spain*; *[4]Axentiva Solutions S.L., Health Economics, Oviedo, Spain*

Background: Rheumatoid Arthritis (RA) is a chronic condition causing fatigue, swelling and deformation of the joints. Together with its associated co-morbidities and high indirect costs represents a high humanistic and economic burden [1]. In Spain, RA has a prevalence around 1%[2], representing about 473.942 people. Since biological treatments were introduced, such as adalimumab (ADA), the clinical outcomes of RA's have improved[3]. Nevertheless, due to its high cost, biologics introduction was hurdled until biosimilars appeared[4]. At the moment, the available network meta-analyses[5,6] do not show a statistically significant difference in effectiveness between the different available treatment. Therefore, cost-minimization analysis can be a useful tool in this pathology.

Objectives: Our objective was to conduct a cost-minimization analysis for RA in Spain.

Methods: All the cost information for the therapeutic alternatives (certolizumab, etanercept, golimumab, infliximab, tocilizumab, tofacitinib, and upadacitinib)

was gathered from drug cost datasets[7], and a range of discounts were applied according to experts opinion obtained through a survey. Finally, non-pharmacological costs were obtained from literature review[8]. With all this information, a cost-minimization analysis between the suitable therapeutic alternatives was performed for a 1-year time horizone. Robustness of results was validated by a deterministic and probabilistic sensitivity analysis (PSA).

Results: ADA was the less expensive option with an annual cost of 4,529€ vs 4,650€ - 10,001€ for the alternative treatments. Infliximab had only a slightly higher cost than ADA (2,7% higher). Certolizumab, etanercept, and tofacitinib showed a higher cost profile, with an annual cost between 54% and 71% higher than ADA. Finally, golimumab, tocilizumab and upadacitinib had the highest cost, between 103% and 137% higher than ADA. Sensitivity analysis showed similar results. The deterministic sensitivity analysis showed ADA to be the best option with average and maximum discounts. In the PSA, only ADA and infliximab performed as the best alternative. ADA was the best option 63% of times.

Conclusion: According to our model, ADA was the most cost-effective biologic option for treating RA in Spain, and the sensitivity analysis validated the results.

AB1390 COMPLEMENTARY DIGITAL THERAPY SAFELY IMPROVES QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY ARTHRITIS

D. Fedkov[1], A. Berghofen[2], C. Weiss[3], C. Peine[4], F. Lang[4], J. Knitza[5,6,7], J. Leipe[8]. *[1]Bogomolets National Medical University, Department of Internal Medicine #3, Kyiv, Ukraine*; *[2]University Medical Centre Mannheim, Medical Faculty Mannheim, University of Heidelberg, Division of Rheumatology, Department of Medicine V, Mannheim, Germany*; *[3]Medical Faculty Mannheim, Heidelberg University, Theodor-Kutzer-Ufer, Department of Medical Statistics and Biomathematics, Mannheim, Germany*; *[4]Midaia GmbH, Product Development, Heidelberg, Germany*; *[5]Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Universitätsklinikum Erlangen, Erlangen, Germany*; *[6]Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Deutsches Zentrum für Immuntherapie (DZI), Erlangen, Germany*; *[7]Université Grenoble Alpes, AGEIS, Saint-Martin-d'Hères, France*; *[8]Medical Faculty Mannheim, Heidelberg University, Division of Rheumatology, Department of Medicine V, University Medical Centre, Mannheim, Germany*

Background: Self-management strategies play a central role in improving clinical outcomes in patients with inflammatory arthritis. EULAR recently highlighted the essential role of digital health to increase the self-management of patients. Evidence regarding these supporting digital tools, including mobile apps, is currently however very limited [1].

Objectives: To evaluate the efficacy and safety of a mobile app (Mida Rheuma App) in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA, including psoriatic arthritis [PsA]) in a prospective study.

Methods: Patients with RA, SpA/ PsA, stable on their antirheumatic therapy for ≥4 weeks, were eligible to use the Mida Rheuma App in addition to standard care treatment. The usage of the app targeted the optimization of non-medical treatment in a 4-step process: (1) collection of the information (HRQoL, disease activity, physical impairment, diet, mental health, physical activity, etc.) using standardized questionnaires via the conversational health coach Mida; (2) development of a patient profile that focuses on the patient's disease, well-being, and behavior; (3) creation of a personalized, evidence-based disease management program based on recommendations from medical guidelines, medical standards, and state-of-the-art clinical research; (4) implementation of personalized recommendations into the patient's daily life by providing short daily tasks that accelerate positive behavior change. Additionally, the health coach Mida supports the patient in coping with stress, sadness, depression, fatigue, and further disease-related symptoms. This is achieved by various cognitive behavioral techniques, meditation and relaxation methods.

Additionally, we assessed demographic parameters, treatment regimen, disease activity (e.g., SDAI, ASDAS), and other patient-reported outcomes (e.g., SF-36) at baseline and after 4 weeks. The study was approved by the Ethics Committee of the Medical Faculty of Mannheim, Heidelberg University.

Results: Of 20 patients screened after obtaining informed consent, 19 were enrolled in the study, and 17 patients (12 RA, SpA: 1 axSpA, 4 PsA) completed the study (2 drop-outs due to unwillingness to finish the study). 7 (41.2%) patients were male, and ages ranged from 19 to 63 (40.5±12.2) years). Patients were treated as follows: 7 NSAIDs (41.2%), 2 GC (>5 mg) (11.8%), 3 HCQ (17.6%), 10 MTX (58.8%), 1 LEF (5.9%), 1 SSZ (5.9%), 1 APR (5.9%), 3 JAKi (17.6%), 1 TNFi (5.9%), 2 IL-6i (11.8%), 1 IL-17i (5.9%). No significant change in antirheumatic treatment was observed during the study. At baseline, 29.4% of the RA and PsA patients were in remission, 25.2% had low, 29.4% had moderate, and none had high disease activity according to SDAI, one axSpA patient had low disease activity (ASDAS: 2.2). At the end of the study, slightly more RA and PsA patients were in remission and had low disease activity (58.8% and 23.5%, respectively) and less had moderate activity (11.8%); the axSpA patient had inactive disease (ASDAS: 1.8). Regarding patient-reported outcomes, statistically significant improvement was noted for the following parameters: SF-36 Total Score (relation of CI 90% and minimum clinically important difference of 2.5), increase of Physical Component Summary of SF-36 by 23.6% (p=0.024), 'role limitations due to physical health' by 76.9% (p=0.022), and 'general health' - by 17.1% (p=0.048); and evidence of potential clinical importance of their dynamics for Patient Health Questionnaire (PHQ)-9, 'emotional well-being' and RADAI-5. No negative changes were observed for assessed parameters. No adverse events were reported throughout the study.

Conclusion: This prospective study suggests that using an app-based personalized disease management program significantly quickly improves several measures of patient-reported outcomes and disease activity in patients with RA and PsA/SpA. These findings highlight the potential of complementary digital therapy in patients with inflammatory arthritis.

AB1391 19% PATIENTS WITH CHRONIC RHEUMATIC INFLAMMATORY DISEASES PRESENT AN UNFAVORABLE PREGNANCY OUTCOME: A DESCRIPTIVE ANALYSIS OF THE NATIONAL FRENCH SOCIAL SECURITY DATABASE

A. Moltó[1], A. Ajrouche[2], D. Tran[2], B. Roux[2], N. Costedoat-Chalumeau[3], E. Elefant[4], V. Tsatsaris[5], J. Fresson[6], B. Bader-Meunier[7], B. Fautrel[8], F. Tubach[2]. *[1]Cochin Hospital, Assistance Publique Hôpitaux de Paris, Rheumatology, Paris, France*; *[2]APHP, CEPHEPI, Paris, France*; *[3]Cochin Hospital, Assistance Publique Hôpitaux de Paris, Internal Medicine, Paris, France*; *[4]Hôpital Trousseau, CRAT, Paris, France*; *[5]Cochin Hospital, Assistance Publique Hôpitaux de Paris, Obstetrics, Paris, France*; *[6]CHU Nancy, Public Health, Paris,*

France; [7]*Hôpital Necker, Assistance Publique Hôpitaux de Paris, Pediatric Immuno-hematology, Paris, France*; [8]*Hôpital Pitié Salpêtrière, Assistance Publique Hôpitaux de Paris, Rheumatology, Paris, France*

Background: patients with chronic rheumatic inflammatory diseases (CRID, i.e. rheumatoid arthritis (RA) or spondyloarthritis (SpA)) have been reported to have poorer pregnancy outcomes than the general population.
Objectives: to describe the pregnancy outcomes of singleton in patients with CRID in France in the past decade.
Methods: this is an analysis of the French Health Insurance claims database (SNDS), which represents 87% of the French population) from 2008 to 2016. To be included in the analysis patients had to be identified as RA or SpA according to existing diagnostic algorithms, to have at least one pregnancy declaration in the database, and to have continuous health insurance from 1-year before pregnancy onset to 1-year after end of the pregnancy or until death (if death occured before the 1-year-period after the end of pregnancy) to be included. Only the first singleton pregnancy occurring during the study period was included in this analysis. Both maternal and pregnancy outcomes were considered. Outcomes were identified either by ICM-10 codes or hospital discharge summaries discharge between 2008-2016.
Results: Among the 35 737 identified adult females with a CRID diagnosis (40.7% with RA and 59.3% with SpA), 27 722 (78%) had a pregnancy during the study period. 11 274 (42%) had received at least one DMARD prior to the pregnancy and were included in the analysis. Among them, only 4025 (36%) were exposed to DMARDs during pregnancy. Mean (SD) age of females at the start of the pregnancy was 32 (5) years, and mean (SD) disease duration was 4 (4) years. Pregnancy ended before 13 WG in 21% and after 37 WG in 70% cases. Live-birth represented the most frequent pregnancy outcome (76.9%), and overall 34.7% patients presented at least one unfavorable outcome (see Table 1).

Table 1.

	Unfavourable outcome	N(%)
Pregnancy outcomes	**Miscarriage (<22WG)**	579 (5.3%)
	Abortion	91 (0.8%)
	Stillbirth	48 (0.4%)
	Preterm delivery (>= 22WG and <37 WG)	779 (7.1%)
	Low weight at birth (<3th percentile)	287 (2.6%)
	Perinatal mortality (22WG to 6 days of life)	2 (0%)
Maternal outcomes	**Severe maternal infection***	211 (1.9%)
Newborn outcomes	**Hospitalisation in neonatal intensive care > 48h in full-term newborns (after 37 WG)**	95 (0.8%)
	Neonatal mortality (27 first days of life)	2 (0%)
	Severe infection * during first year	603 (5.3%)

Conclusion: More than 75% pregnancies in patients with CRID resulted in a live-birth. Prevalence of miscarriage was surprisingly low, probably related to under-coding. Maternal and infant outcomes seemed comparable to general population. Whether medications had an impact on such outcomes is currently under evaluation.

AB1392 COVID-19 HAD AN ADVERSE IMPACT ON DENOSUMAB TREATMENT PROVISION - COMPARISON WITH PRE-PANDEMIC WAITING TIMES AT A UK-BASED RHEUMATOLOGY DEPARTMENT

S. Ling[1], L. Bromilow[1], S. Vasireddy[1]. [1]*Bolton NHS Foundation Trust, Department of Rheumatology, Bolton, United Kingdom*

Background: Denosumab treatment is licensed for prevention of osteoporotic fractures. It can cause hypocalcaemia, so bone profile blood tests must be checked prior to treatment. In our department, we have a Standard that patients have blood tests within 1 month before their denosumab injection, and that they receive the injection within 1 month from its due date. A customized MS Access database to record this information and generate a date for the next dose was established in 2015 after a quality improvement project (QIP)1. At the onset of the COVID-19 pandemic, UK national guidance recommended continued provision of denosumab as an essential service.
Objectives: 1. To re-audit delay from due date to actual injection date after establishment of our database.
2. To compare delay from due date to actual injection date before and after onset of COVID-19.
3. To compare the time between blood tests and actual injection date, before and after onset of COVID-19.
Methods: Data for 2 time-periods were extracted from the database: Time Period 1 (pre-COVID-19) 01-03-2019 – 29-02-2020; Time Period 2 (post-COVID-19 onset) 01-03-2020 – 28-02-2021. For each patient attendance, dates of blood test, due date and actual injection date were extracted. All patient details were anonymised, with a decryption key to identifiers held on a secure server at the host Trust. It was manually determined whether blood tests and injections were within 1 month of when they were due. Statistical analyses were carried out in Stata v.14.0. The Kolmogorov-Smirnov test was used to compare distributions between Time Periods 1 and 2.
Results: TIME PERIOD 1: 100 appointments were audited from 68 patients. 20% of blood tests were within 1 month of actual injection date. Median time between blood tests and actual injection was 45 days [IQR 35 – 59]. 52% of actual injections were given within 1 month from due date. (This compares favourably with our 2015 QIP, when 40% of actual injections were within 1 month from due date1). Median time between due date and actual injection was 29.5 days [IQR 13 – 50.5]. TIME PERIOD 2: 77 appointments were audited from 66 individual patients. 24.7% of blood tests were within 1 month of actual injection. Median time between blood tests and actual injection was 45 days [IQR 35 – 59]. 16.6% of actual injections were given within 1 month of due date. Median time between due date and actual injection was 82 days [IQR 40 – 141]. There were no significant differences in time between blood tests and actual injection between Time Periods 1 and 2. However, the time between due date and actual injection date was significantly longer in Time Period 2 ($p<0.005$).
Conclusion: The introduction of our customized database promoted an improvement in time between due date and actual injection date of denosumab. However, this improvement significantly declined after the onset of the COVID-19 pandemic. Resources may need to be increased and processes adapted to minimise the impact of future emergencies on denosumab provision.

AB1393 RHEUMABUDDY4.0 LEADING THE PATH TO A PATIENT-DRIVEN ELECTRONIC SUPPORT AND MONITORING TOOL

P. Studenic[1,2], T. Stamm[3], Y. Seidler[3], A. Dam[4], N. Weibrecht[5], G. Zauner[5], T. H. Jakobsen[4], R. L. Hansen[6], N. Popper[5,7], T. C. Wilhelmer[8,9], H. Radner[2], R. Ramos[3], J. [1]*Karolinska Institute, Department of Medicine (Solna), Division of Rheumatology, Stockholm, Sweden*; [2]*Medical University of Vienna, Department of Internal Medicine 3, Division of Rheumatology, Wien, Austria*; [3]*Medical University of Vienna, Section of Outcome Research; Center for Medical Statistics, Informatics and Intelligence Systems, Wien, Austria*; [4]*Daman, P/S, København, Denmark*; [5]*dwh GmbH, -, Wien, Austria*; [6]*Copenhagen University Hospital, Bispebjerg and Frederiksberg, The Parker Institute, København, Denmark*; [7]*Vienna University of Technology, Institute for Information Systems Engineering, Vienna, Austria*; [8]*EULAR - European Alliance of Associations for Rheumatology, Young PARE, Kilchberg, Switzerland*; [9]*Österreichische Rheumaliga, -, Maria Alm, Austria*; [10]*The Parker Institute´s Patient Association, -, Copenhagen, Denmark*

Background: The use of health apps has become more popular in recent years, but it is still a small and rather unregulated market. Few apps have been designed in collaboration with patients and these mostly address patient reported symptoms. Some clinical registries have already developed patient apps to complete patient-reported outcome measures (PROMs) on smartphones, which normally would have been collected during an outpatient visit and have shown interchangeability. The next step would be providing a patient app offering possibilities not only of individual disease tracking, but to provide automated peer support, health information and behavioural advice.
Objectives: We aimed to further develop and validate RheumaBuddy, a health app for patients with rheumatoid arthritis (RA), from a standard monitoring app to an intelligent health app tailored to the needs of the user that provides transparency to all important stakeholders in Rheumatology care.
Methods: This is an international interdisciplinary project between Austrian and Danish partners funded by the EUREKA program. Rheumatologists, health scientists, digital data experts and patients with RA joined forces in a 4 phase-program, running from 2020 to 2023. Phase 1 continues to develop the app in a co-creation approach in several iterations with patients. Phase 2 concerns developing an automated learning algorithm based on user data to identify patient strata and connect these with helpful non-pharmacological interventions. Phase 3 connects healthcare system data on diagnosis, medication prescription, healthcare facility usage with a large clinical RA database. By that we develop patient pathways that correlate high granularity data with system resources to retrieve results on socioeconomic impact. In phase 4 a randomised clinical trial will evaluate the effect of the developed RB4.0 on clinical disease activity and quality of life.

Results: Currently, RB is regularly being used by more than 3100 patients in 35 countries and 8 languages throughout Europe. The current RheumaBuddy version offers logging of symptoms using Likert scale questions, a joint mannequin to mark painful body parts and a peer-support forum. Additionally, the user can anytime display his/her entries over time in a graphical report and also share data with the healthcare provider. This version is extended with tracking of sleep, working hours and other behaviours. A consultation compass function helps the patient to reflect on goals and issues before the rheumatologist visit. Within this project, we already established a first version of a Recommender System (RS), which computes correlations between user entries (e.g. between a user's mood and pain), thus providing individual feedback. Through integration of information obtained from the app with claims data and clinical data from a RA registry, patterns can be identified and translated into different case models that concern the impact of common RA symptoms. By mapping these scenarios with evidence based behaviour and lifestyle advice, the "virtual coach" (advanced RS) will be developed and integrated into the RB4.0 system. During continuous data collection on app users, similarities in user behaviour can be identified, and similar entry patterns can be grouped. This will allow users to exchange and learn from each other regarding certain difficult situations (ex. "life-hack") etc. We are creating a comprehensive system in providing feedback to both clinical and psychosocial aspects of coping and disease management, as well as everyday practicalities for living with a chronic disease. Figure 1 displays these aspects, contributing the empowerment of patients.

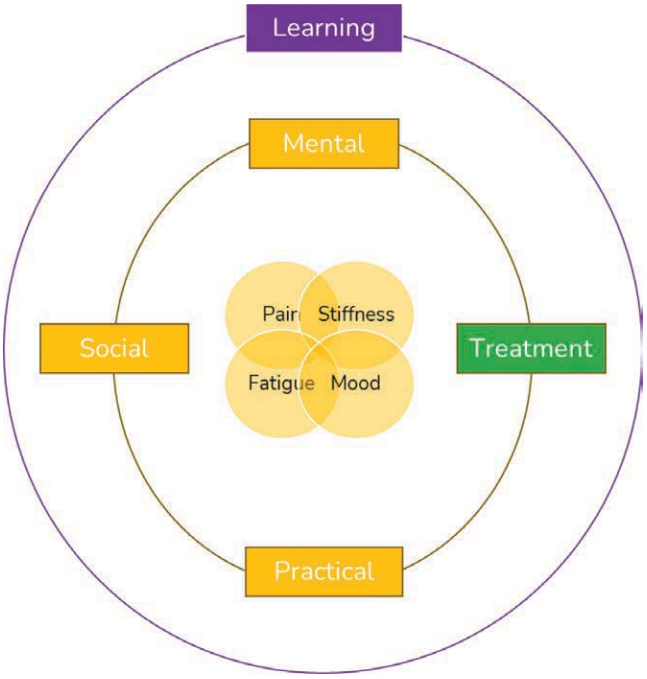

Figure 1. RB4.0 shall support people living with RA in dealing with disease impact

Conclusion: RheumaBuddy4.0 will provide RA patients the means to improve their quality of life on an individual level, better understand their needs and therapy which could support overcoming barriers of successful shared decision making to achieve better outcomes.

ON-FLARE RETREATMENT WITH RITUXIMAB IN RHEUMATOID ARTHRITIS: PATIENTS' AND RHEUMATOLOGISTS' PERCEPTIONS

D. Bertrand[1], A. Deprez[1], M. Doumen[1,2], D. De Cock[1,3], S. Pazmino[1], A. Marchal[4], M. Thelissen[4], J. Joly[2], B. Neerinckx[1,2], R. Westhovens[1,2], P. Verschueren[1,2]. [1]*Katholieke Universiteit Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium*; [2]*UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium*; [3]*Katholieke Universiteit Leuven, Clinical and Experimental Endocrinology, Leuven, Belgium*; [4]*ReumaNet vzw, ReumaNet, Zaventem, Belgium*

Background: Rituximab is an efficacious drug for the treatment of Rheumatoid Arthritis (RA). According to literature, administration of rituximab can be based on a fixed interval or on relapse of disease activity. In some countries, like Belgium, after the first rituximab cycle a flare is required for reimbursement of a subsequent cycle. A better understanding of the perceptions of patients and rheumatologists regarding this retreatment strategy would be informative in view of potential adjustments.
Objectives: The aim was to investigate patients' and rheumatologists' perceptions on the on-flare retreatment strategy of rituximab.
Methods: Patients with RA, who were currently or previously treated with rituximab, and rheumatologists were invited to participate in a qualitative study consisting of individual, in depth, face-to-face, semi-structured interviews. Participants were recruited based on purposive sampling to ensure diversity. Interviews were conducted via video or telephone call. Additional participants were interviewed until data saturation was achieved, meaning no new information emerged from the last 3 interviews. Interviews were audiotaped and transcribed verbatim, followed by analysis according to the Qualitative analysis guide of Leuven, which generated themes and subthemes. Patient experts were involved in this research.
Results: In total, 16 patients with RA and 13 rheumatologists were interviewed. Five overarching themes were generated from the interviews: flare definition, recognition, reaction, balance between benefits and barriers and suggestions (Figure 1). Patients and rheumatologists described how they perceive the on-flare retreatment strategy in daily practice, starting with the *FLARE DEFINITION* itself. Namely, what patients perceived as a flare and the impact of this flare. The second step was *RECOGNITION* of the flare. Both rheumatologists and patients indicated that patients are able to recognise a flare. However, the patient's ability to discriminate between inflammatory and other types of pain was perceived as a difficulty. Moreover, patients indicated that depending on the flare's intensity, they can cope with it themselves, delaying the need for a rituximab cycle. The next step after correctly recognising a flare, was the *REACTION*, from both the patient's and rheumatologist's side. It was stressed that patients must contact their treating rheumatologists in time. Furthermore, a swift response of the rheumatologists was perceived as important. After confirming eligibility, the shared decision to plan a new rituximab cycle can be made while keeping an eye on the organisation. Remarkably, it seemed that rheumatologists approached the retreatment strategy in different ways, meaning that not everyone adhered to the on-flare principle. Several perceived *BENEFITS* (e.g. lower safety risk, societal cost savings) and *BARRIERS* (e.g. disease activity fluctuations, slow working mechanism) were mentioned, making clear that the optimal retreatment strategy should be based on a *BALANCE* between both. Finally, some *SUGGESTIONS* (e.g. biomarkers for flare prediction, subcutaneous administration of rituximab) were brought up that could be helpful in applying the optimal retreatment strategy.

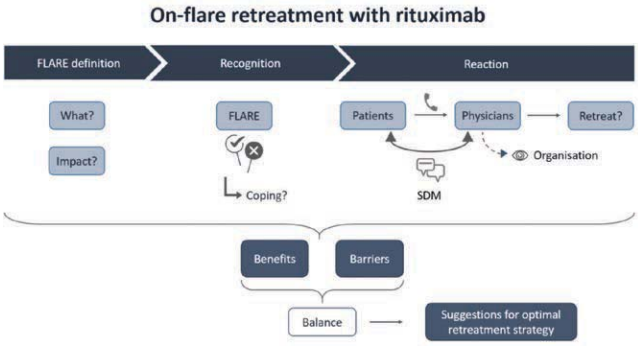

Figure 1. Conceptual framework of the perceptions of patients and rheumatologists regarding the on-flare retreatment strategy with rituximab. SDM = Shared decision making. (Icons: Iconfinder)

Conclusion: Patients play an important role in the recognition of flares and their reaction, in shared decision with the rheumatologist, contributes to the effectiveness of the rituximab on-flare retreatment strategy. Rheumatologists handle the on-flare retreatment strategy as pragmatically as possible, resulting in different approaches. Moreover, both benefits and barriers of on-flare retreatment were

perceived, making clear that a balance should be found to determine the optimal retreatment strategy.

AB1395 PATIENTS' AND RHEUMATOLOGISTS' PERCEPTIONS REGARDING TAPERING OF RITUXIMAB

D. Bertrand[1], A. Deprez[1], M. Doumen[1,2], D. De Cock[1,3], S. Pazmino[1], A. Marchal[4], M. Thelissen[4], J. Joly[2], B. Neerinckx[1,2], R. Westhovens[1,2], P. Verschueren[1,2]. *[1]Katholieke Universiteit Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium*; *[2]UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium*; *[3]Katholieke Universiteit Leuven, Clinical and Experimental Endocrinology, Leuven, Belgium*; *[4]ReumaNet vzw, ReumaNet, Zaventem, Belgium*

Background: Rituximab is an efficacious drug for the treatment of Rheumatoid Arthritis (RA). The commonly used dose consists of two infusions of 1000 mg with a 2-week interval, but evidence is growing that a lower dose could be as effective. Before implementing a tapering strategy, understanding the perceptions of patients and rheumatologists in this regard is important.
Objectives: The aim was to investigate patients' and rheumatologists' perceptions on rituximab tapering.
Methods: Patients with RA, who were currently or previously treated with rituximab, and rheumatologists were invited to participate in a qualitative study consisting of individual, in depth, face-to-face, semi-structured interviews. Participants were recruited based on purposive sampling to ensure diversity. Interviews were conducted via video or telephone call. Additional participants were interviewed until data saturation was achieved, meaning no new information emerged from the last 3 interviews. Interviews were audiotaped and transcribed verbatim, followed by analysis according to the Qualitative analysis guide of Leuven, which generated themes. Patient experts were involved in this research.
Results: In total, 16 patients with RA and 13 rheumatologists were interviewed. Four themes were found: In favour/reluctant of tapering, shared decision making, implementation and evidence gap (Figure 1). Patients and rheumatologists were *IN FAVOUR* of rituximab tapering, for reasons of safety and economic benefit. Patients and rheumatologists mentioned that a lower dose could allow shorter retreatment intervals, which might avoid flares. Furthermore, rheumatologists referred to available evidence of the effectiveness of a lower rituximab dose. Additionally, patients and rheumatologists indicated that the dose could be tailored based on the patient's clinical manifestations, e.g. usual cycle interval and disease activity measures. However, some patients and rheumatologists felt *RELUCTANT* towards rituximab tapering. Patients and rheumatologists were concerned about potential loss of effectiveness and quality of life, next to more practical concerns. Rheumatologists mentioned that they had insufficient experience with rituximab in general to feel comfortable with tapering. Moreover, when applying an on-flare retreatment strategy, patients present with an active disease at the time of retreatment and therefore the option of tapering is less appealing. The next theme was *SHARED DECISION MAKING*. Patients and rheumatologists mentioned that patients have trust in their physician and thus leave the tapering decision in the hands of the rheumatologists. However, rheumatologists added that this should be combined with explanation of the tapering rationale. Another theme was *IMPLEMENTATION*. When asking participants about 2 possible dose reduction regimens, a cycle consisting of 2 infusions with a lower dose or a cycle of only 1 infusion with a higher dose, advantages were raised for both regimens (e.g. safety reasons and time savings, respectively). On the other hand, the on-flare retreatment regimen itself was already perceived as a kind of tapering, as the interval is prolonged as much as possible between the cycles. *EVIDENCE GAP* was the last theme, meaning that patients and rheumatologists felt there was a need of more research regarding rituximab tapering. For instance, predictive tools for flares, as well as the possibility of subcutaneous administration of rituximab, were mentioned as unmet needs by rheumatologists.

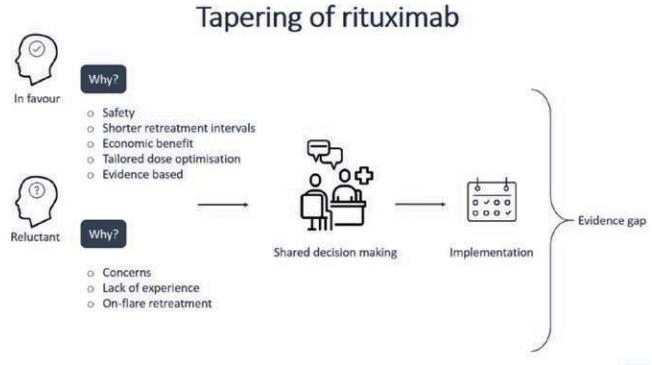

Figure 1. Conceptual framework of the patients' and rheumatologists' perceptions regarding tapering of rituximab. (Icons: Iconfinder)

Conclusion: It seems that rituximab tapering is not yet incorporated in daily practice as much as tapering of other antirheumatic drugs and this could potentially be related to a lack of experience with rituximab. However, with appropriate education and communication, rheumatologists and patients are willing to taper rituximab. Although, many questions remain, indicating an evidence gap and a need of more research.

AB1396 MULTICENTER QUALITATIVE STUDY ON THE EXPERIENCE OF USE OF BIOLOGIC AND TARGETED SYNTHETIC DISEASE-MODIFYING DRUGS IN PATIENTS WITH RHEUMATIC DISEASES. WHAT DO OUR PATIENTS THINK?

O. Rusinovich[1], M. Sanz[2], A. V. Esteban Vazquez[3], N. Molina Esteban[4], M. D. C. Uyaguari Morocho[2], M. Pavía Pascual[1], P. Navarro Palomo[1], M. Machattou[1], N. De la Torre Rubio[1], M. L. Andréu Sánchez[1]. *[1]Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain*; *[2]La Paz University Hospital, Rheumatology, Madrid, Spain*; *[3]Infanta Sofía University Hospital, Rheumatology, San Sebastián de los Reyes, Spain*; *[4]University Hospital October 12, Rheumatology, Madrid, Spain*

Background: The development of targeted biologic (bDMARDs) and targeted synthetic disease-modifying drugs (tsDMARDS) has made a substantial change in the control of our patients, and has allowed an increasing number of patients to achieve clinical remission.
Objectives: To gain understanding of patients' experiences of starting treatment with b/tsDMARDs, and explore their attitudes in order to improve the doctor-patient relationship, adherence to treatment, compliance, and knowledge about the experience of using b/tsDMARDs.
Methods: A qualitative study was carried out. A consecutive sample of 130 patients attended in the rheumatology units of four Madrid hospitals, from August 29th, 2021 to January 21st, 2022 completed a questionnaire that consisted of 31 questions, a subsequent qualitative analysis of discourse and content through focus groups with patients was carried out. Descriptive statistical analysis was performed. Chi-squared tests were applied to explore the dependency relationship between the different qualitative variables.
Results: One hundred and thirty questionnaires were collected (see general characteristics in the Table 1).

Table 1. Baseline demographics.

Sex, n (%)	96 female (73.85%), 34 male (26.15%)
Age, years, mean (SD)	51,62±12.31 years
Ethnicity/race, n(%)	74.6% White or Caucasian 22.3% Hispanic or Latino 2.3% Asiatic 0.8% Black or African American
Diagnosis, (%)	42.4% rheumatoid arthritis 25.3% axial spondyloarthritis 10% psoriatic arthritis 6.9% connective tissue diseases 15.4 % other
Time since diagnosis (years), mean (SD)	14,7 years (+/-11,43)
Time since initiation of treatment with b/tsDMARDs (years), mean (SD)	5,84 years (+/-4,28)

Most of the patients (68.46%) felt hope when they were informed that they were going to start treatment with b/tsDMARDs, 26.9% relief, 22.3% happiness and 27.7% fear and concern. 76% of the patients received information about why the treatment was modified, the advantages of b/tsDMARDs (60%), their mechanism of action (48.5%) and the precautions to be aware of (38.5 %). Fifty-two percent of the respondents searched for additional information on their own, with the most used sources being from internet search engines (34.2%), the corresponding drug insert (22.8%) and the page of the Spanish Society of Rheumatology (23.7%). 60% of the respondents were informed about the possible risks associated with the treatment, 49.4% reported being more concerned when they contracted an infection. Most of the patients were recommended to receive influenza (81.5%) and pneumococcal (69.2%) vaccination, of which 74.6% and 54.6% received those respectively. A statistically significant dependence was observed between the recommendation of the vaccine and vaccination, since most (91,5%) of those who received the recommendation were vaccinated ($p<0.001$). Most of the respondents kept their scheduled appointments (87.3%) and never forgot to take their medication (37.04%). 51% of the patients reported that with b/tsDMARDs they had experienced "considerable improvement", 38.5% indicated that "their life has changed", 10% reported little or no improvement. It was observed that men reported a maximum degree of improvement with a significantly higher frequency than women (77% vs 37% respectively), OR 5.79 ($p <0.009$, IC 95% 1.42, 23.67). To the question "In which

aspects have you noticed the greatest changes?" the respondents answered: reduction in outbreaks of the disease (67%), emotional improvement (38.6%) and regaining work activity (31.8%).

Conclusion: In our setting, education programs inform patients adequately, but it seems necessary to make a greater emphasis on therapeutic compliance, providing more safety information, and compliance to recommended vaccinations.

AB1397 WORK SMARTER NOT HARDER

K. Tempest[1], H. Reddy[1], S. Johns[1], K. Wright[1], S. Sultan[1]. [1]*Airedale General Hospital, Rhumatology, Steeton, United Kingdom*

Background: In 2014 we were a small team with only 1 WTE (Whole Time Equivalent) CNS (Clinical Nurse Specialist) and 2 WTE consultants for a population of 220,000. Most CNS clinic appointments were taken up for drug counselling. Waiting times were approx. 6 weeks for drug counselling. Consultants would often counsel for DMARDs. That year at a national meeting a virtual group MDT (multidisciplinary) was presented by the team at Manchester Royal infirmary (MRI). They used a good quality presentation for patients starting bDMARDs as a tool for drug counselling. After having to put on an extra clinic to counsel 5 patients, all for rituximab, frustratingly I asked why can't I get them all in the same room to save time? We needed to work smarter, not harder, utilise time & space to ensure best practice but also ensure gold standard, patient centered care continued. We modified the format used at MRI to a face to face group education and counselling of patients to improve waiting times and patient flow.

Objectives: Reduce the amount of clinic appointments used to counsel patients for sDMARDs (synthetic disease modifying anti-rheumatic drugs) and bDMARDs (biologic). Free up clinic appointments for follow up/ review and flares. Standardise information given out to ensure they are all given the same gold standard information and education.

Methods: We visited the team at MRI to view the format of their virtual clinic. It didn't meet the needs of our service so we modified and adapted the presentation.Set up a group education session to discuss the most common sDMARDs and bDMARDs used for Inflammatory Arthritis. I developed a power point presentation and booklet that can be used by CNS- ensuring the same information is given to every patient, both attending the group session and those not suitable for group session (ie Language barriers) who would be seen individually. We use a screening proforma to ensure safety of commencement for the individual prior to attending clinics which has a tick list for screening requirements. The session is undertaken in our education centre. Pre Covid the session could accommodate up to 10 patients per session per week, uptake on average 8-10 patients for sDMARDs and 5-6 for bDMARDs. We alternated biologic and sDMARD sessions, if demand required, we changed a session to accommodate. The room is booked for 1½ hours every week, the sDMARD presentation lasts approximately ½ an hour & bDMARD session 50 minutes, time is allowed for group & individual questions if required at the end. This contrasts with 25 minute appointment for sDMARD & 50 minute for bDMARD counselling 1:1. The booklet, along with information pack, is given at the group session to all patients. This includes all the information the patient requires (advice line information, blood forms). Prior to the group clinic admin team prepare the patient packs for the CNS to give to patients.

Results: We received 102 anonymous responses back from 136 patients asked. (75% response) Following these sessions we found less calls to the advice line regarding medication queries, able to add in further cDMARDs or switch to alternate due to S/Es over the telephone Feedback from patients.-120 comments received. Clear simple information about a number of possible drugs used to treat my condition not just the 1 I am prescribed. If my medication needs changing I already know about it. The lecture aspect of the types/contra-indications of meds was very useful & removed the 'fear' attached to these specialist drugs. The session with other patients present stopped me from feeling alone in this position. The booklet is brilliant as it includes everything that was in the session. Also it took away the 'fear' of the side effects.

Conclusion: 7 years on we feel that Group Counselling has been a huge success, we noticed how successful this was once we had to deal with the pandemic and cancel the group sessions. Patients feedback proves that they like the session and find them valuable. Whilst being beneficial and impoving work productivity and streamling the service.

AB1398 CORRELATES OF CANCELLED HEALTHCARE APPOINTMENTS IN PATIENTS WITH SYSTEMIC SCLEROSIS DURING THE COVID-19 PANDEMIC

N. Dorr[1], P. Fennell[2], L. Shapiro[3]. [1]*The College of Saint Rose, Psychology, Albany, United States of America*; [2]*Albany Health Management Associates, Inc., Psychology/Social Work, Albany, United States of America*; [3]*Albany Medical College, Rheumatology, Albany, United States of America*

Background: Rheumatologists have noted challenges in treating patients with systemic sclerosis (SSc) during the COVID-19 pandemic, such as patients on immunosuppressants and those with preexisting pulmonary issues.[1] Also of potential concern was patients delaying treatment due to fears of COVID.

Objectives: This study examined to what extent patients with SSc cancelled health-care appointments due to fears of COVID, how this correlated with their mental and physical functioning, and their levels of anxiety and depression.

Methods: Participants were 60 people with SSc who had not had COVID-19 or been vaccinated for COVID. Participants had a mean age of 58 years (*SD*=11.5) and were primarily female (92%) and white (87%).

Participants completed an online survey after learning about it from a scleroderma organization newsletter or at their visit with a rheumatologist specializing in scleroderma in New York State, USA. Data were collected August 2020 through March 2021. Participants completed measures assessing health-related appointments attendance, Patient Reported Outcome Measurement Information System (PROMIS) measures (anxiety, depression, fatigue, sleep disturbance, pain intensity, physical function), coping strategies to deal with the pandemic, and reported functioning relevant to SSc (hand, gastrointestinal, dyspnea, and Raynaud's disease).

Results: Due to COVID-19 concerns, 28 respondents (47%) cancelled one or more appointments with their primary care physician, specialist, physical or occupational therapist, pulmonologist, or dentist. Compared to those who did not cancel appointments due to COVID concerns, participants who cancelled reported higher anxiety, $t(58) = 2.46$, $p = .02$, higher sleep disturbance, $t(56) = 3.31$, $p = .002$, worse physical functioning, $t(56) = 2.00$, $p = .05$, more constipation, $t(55) = 2.05$, $p = .045$, and lower positive reframing as a coping strategy, $t(56) = 2.08$, $p = .04$.

Many participants reported moderate or severe anxiety (36%), depression (22%), fatigue (32%), sleep disturbance (28%), and physical dysfunction (40%). As shown in Table 1, anxiety scores were positively correlated with scores on measures of fatigue, sleep disturbance, physical dysfunction, diarrhea, and the coping strategies of substance use, self-distraction, emotional support, behavioral disengagement, and venting. Depression scores were positively correlated with scores on measures of fatigue, sleep disturbance, physical dysfunction, pain intensity, dyspnea, diarrhea, and behavioral disengagement as a coping strategy.

Table 1. Correlations Between Anxiety and Depression with Patient-Reported Outcomes and Coping with the Pandemic

Measure	Anxiety	Depression
Fatigue	.38**	.43**
Sleep disturbance	.35**	.34**
Physical dysfunction	.28*	.49**
Pain intensity	.16	.36**
Reflux	.25	.15
Distention/bloating	.28*	.24
Fecal soilage	-.001	.07
Diarrhea	.34**	.28*
Constipation	.21	-.03
Dyspnea	.18	.32*
Raynaud's disease activity	-.08	-.02
Hand functioning	.06	.25
Coping strategy		
Substance use	.29*	.21
Self-distraction	.32*	.18
Behavioral disengagement	.37**	.41**
Using emotional support	.43**	.06
Venting	.34**	.14

Note. *$p < .05$; **$p < .01$

Conclusion: Almost half of participants cancelled one or more health appointments due to COVID fears. This subgroup reported significantly higher anxiety, sleep disturbance, constipation, worse physical functioning, and less coping with the pandemic by looking for the positive. Anxiety and/or depression also played a role in 42% of SSc patients and were related to a variety of worse mental and physical health correlates. Future research should examine the extent to which changes in health-related care during the pandemic have implications for disease progression in patients with SSc.

AB1399 PEOPLE SUFFERING FROM RHEUMATIC AND MUSCULOSKELETAL DISEASES DESCRIBE THEIR OWN EXPERIENCES OF INTEGRATED CARE: FINDINGS FROM A CROSS-SECTIONAL STUDY AMONG ITALIAN PATIENTS

N. Spezia[1], S. Barello[1], C. Torri[1], A. Celano[2], G. Graffigna[1]. *[1]EngageMinds Hub - Consumer, Food, and Health Engagement Research Center, Psychology, Milan, Italy*; *[2]APMARR APS - National Association of People With Rhematic and Rare Diseases, Rheumatology, Lecce, Italy*

Background: Integrated care is an approach to health care based on multidisciplinary working and the continuity and coordination of different levels of care (1). In an integrated care setting, health services are designed to go beyond fragmentation and isolation and delivered in response to chronic patient health needs. Integrated care has been proved to enhance patients' quality of life (2), as well as reduce hospital admission rates and length of stay (3). Furthermore, integrated care favors patients' access to care and improves their satisfaction (4). To evaluate the application and benefits of integrated care, patient experiences should be measured (5). However, while the patient experiences of integrated care have been documented for various chronic diseases, little is known in the context of rheumatic and musculoskeletal diseases (RMDs).

Objectives: This study aims at providing an overview of the patient experience of integrated care of RMDs patients in Italy and defining the experience profiles and priorities of different patient subgroups.

Methods: A cross-sectional online self-administered survey formulated following a scoping review of the literature was administered to a purposive sample of Italian RMDs patients (n=433). Respondents were asked to evaluate their patient experience and the importance attributed to different aspects of integrated care. Explorative factor analysis (EFA) was performed to determine the dimensions of integrated care investigated by the survey. The differences in the responses provided by different subgroups of the sample were assessed using the non-parametric versions of ANOVA and ANCOVA statistical tests with Scheffe's adjustment for multiple comparisons.

Results: Two factors ("person-centered care" and "health service delivery") were extracted in the EFA. Respondents attributed high importance to both of them. However, an overall positive experience was reported only for the dimension of person-centered care. The delivery of integrated care services was evaluated poorly, especially for digital ones. Women described both dimensions of integrated care as more important compared to men ($H(1)=45.292$, $p<.001$ and $H(1)=6.998$, $p=.008$). However, their experience of integrated care services was significantly worse ($H(1)=20.201$, $p<.001$). Older participants reported poorer health service delivery compared to younger ones ($H(3)=73.203$, $p=.009$), especially for digital and outpatient services. Person-centered care was especially important for patients with comorbidities ($F(1,431)=4.944$, $p=.027$). However, this subgroup reported markedly worse experiences of integrated care services ($F=(1,431)=4.187$, $p=.041$).

Conclusion: Italian RMDs patients identified integrated care as something important to them. They reported receiving positive person-centered care but the delivery of integrated care services was evaluated poorly. Different patient subgroups described different experience profiles and priorities. This diversification can inform the design of tailored interventions to address the specific concerns and needs of each patient subgroup.

AB1400 ARE COMORBIDITIES IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES ASSOCIATED WITH TREATMENT NON-ADHERENCE TO BIOSIMILARS IN A NON-MEDICAL SWITCH SCENARIO?

I. Redeker[1,2], S. Moustakis[1,2], S. Tsiami[1,2], X. Baraliakos[1,2], I. Andreica[1,2], B. Buehring[1], J. Braun[1,2], U. Kiltz[1,2]. *[1]Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany*; *[2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*

Background: The availability of biosimilars has created a financial incentive to encourage non-medical switching if cheaper products are on the market. In patients with chronic inflammatory rheumatic diseases (CIRD), we have previously reported a relatively high retention rate after switching from originator etanercept to its biosimilar. However, this has been different in other studies and the reasons for non-adherence are poorly understood. Comorbidity has recently gained much attention in patients with CIRD and might be a reason for non-adherence.

Objectives: The aim of this study was to analyse the effectiveness and safety of systematic non-medical switching from originator adalimumab (ADA) to ADA ABP501 biosimilar (ABP) over 6 months in patients with CIRD and to investigate the influence of comorbidities on retention rates.

Methods: Patients with CIRD on originator ADA who switched to ABP subsequently from October 2018 onwards were identified from a large routine database and then followed for 6 months. The presence of comorbidities and disease characteristics as well as measures of disease activity, physical function and changes in treatment were documented at baseline (the time of switching from originator ADA to ABP), and at months 3 and 6. Longitudinal data including information on the clinical efficacy and safety of ABP, and the reasons for discontinuation were documented.

Results: A total of 111 CIRD patients on treatment with originator ADA were switched to the biosimilar ABP (Table 1). More than half of the patients (62%) had a Charlson comorbidity score of 0, though there were differences between disease subtypes. RA patients were comparatively older (mean age 65 years) and had the highest mean Charlson score (1.8). Treatment retention varied only slightly between patients with a Charlson score of 0 and those with ≥0 (Figure 1). In both groups, the majority of patients (90% vs 95%) continued therapy with ABP, while only a small proportion either switched back to originator ADA (6% vs 5%), switched to a different biologic (3% vs 0%), or dropped out (1% vs 0%). The main reason for back switch was the occurrence of adverse events, mostly subjective complaints, most frequently pain. Patients with a Charlson comorbidity score > 0 tended to have poorer scores in trajectories of scores for disease activity and physical function stratified by disease subtype.

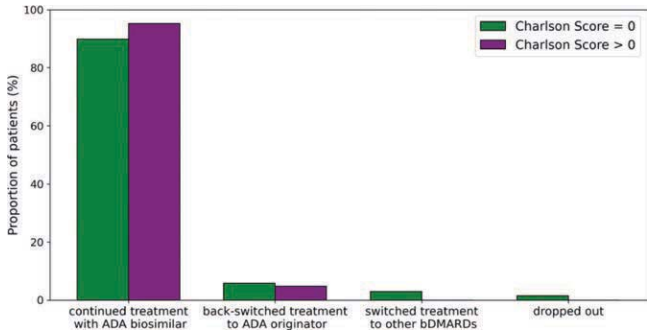

Figure 1. Treatment retention after 6 months stratified by the Charlson comorbidity score

Table 1. ***Patients and disease characteristics***

	RA	axSpA	PsA	Other
	N=23	N=68	N=15	N=5
Age (years), mean (SD)	65.1 (12.0)	47.3 (13.1)	51.1 (11.2)	41.8 (14.2)
Women	60.9% (14)	32.4% (22)	53.3% (8)	40.0% (2)
Disease duration (years), median (IQR)	4.0 (3.0-8.0)	5.0 (2.0-8.0)	4.0 (2.0-13.0)	7.0 (4.0-7.0)
Duration originator ADA therapy (month), mean (SD)	43.8 (28.6)	39.4 (26.9)	34.7 (29.0)	60.9 (27.7)
Charlson score, mean (SD)	1.8 (2.1)	0.6 (1.1)	0.7 (1.2)	0.2 (0.4)
Gastroenterological comorbidities	26.1% (6)	22.1% (15)	6.7% (1)	0
Hepatic comorbidities	17.4% (4)	2.9% (2)	13.3% (2)	0
Hematological conditions	8.7% (2)	2.9% (2)	13.3% (2)	0
Cardiovascular comorbidities	60.9% (14)	32.4% (22)	33.3% (5)	60.0% (3)
Neurological and psychological comorbidities	8.7% (2)	17.6% (12)	33.3% (5)	0
Metabolic comorbidities	21.7% (5)	7.4% (5)	26.7% (4)	40.0% (2)
Osteoporosis	43.5% (10)	11.9% (8)	6.7% (1)	20.0% (1)
Lung diseases	21.7% (5)	8.8% (6)	0	40.0% (2)
Skin diseases	26.1% (6)	26.5% (18)	80.0% (12)	20.0% (1)
Eye diseases	8.7% (2)	23.5% (16)	6.7% (1)	60.0% (3)
Kidney diseases	13.0% (3)	10.3% (7)	0	40.0% (2)

Conclusion: Comorbidity had no influence on the biosimilar retention rate after 6 months in this study but the majority of patients did not have Charlson scores > 0. However, disease activity and physical function tended to be worse among CIRD patients with comorbidity. Cardiovascular disease and osteoporosis were more often present in RA patients than in axSpA or PsA patients, while neurological and psychological comorbidities were more often observed in the latter.

AB1401

IMPACT OF THE COVID-19 PANDEMIC ON HEALTHCARE UTILIZATIONS OF RMD PATIENTS IN EUROPE. RESULTS FROM THE REUMAVID STUDY (PHASE 1 AND 2)

M. Garrido-Cumbrera[1,2], H. Marzo-Ortega[3,4], J. Correa-Fernández[1], L. Christen[5], V. Navarro-Compán[6]on behalf of the REUMAVID Working Group.
[1]*Health & Territory Research (HTR), Universidad de Sevilla, Seville, Spain*; [2]*Spanish Federation of Spondyloarthritis Patient Associations (CEADE), Patient Advocacy, Madrid, Spain*; [3]*NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, United Kingdom*; [4]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*; [5]*Novartis Pharma AG, Patient Engagement, Basel, Switzerland*; [6]*Hospital Universitario La Paz, IdiPaz, Madrid, Spain*

Background: The beginning of the COVID-19 pandemic led to a collapse of healthcare systems that was difficult to manage.
Objectives: The aim of this study was to assess the impact of the COVID-19 pandemic on RMD patients' healthcare utilization.
Methods: REUMAVID is an international cross-sectional study collecting data through an online survey on RMD in seven European countries led by the Health & Territory Research group of the University of Seville, together with a multidisciplinary team including patient representatives, rheumatologists, and health researchers. Data were collected in two phases, the first (P1) between April-July 2020 and the second (P2) between February-April 2021. Demographics, health behaviours, employment status, access to healthcare services, disease characteristics, WHO-5 Well-Being Index and Hospital Anxiety and Depression Scale (HADS) were collected in the survey. Healthcare utilization includes scheduled appointments and attendance at the rheumatologist, consultation of possible treatment effects if COVID-19 is contracted with the rheumatologist, primary health care and psychological care. Descriptive analysis and Mann-Whitney test was used to explore association with healthcare utilization in both phases of REUMAVID.
Results: There were a total of 2,002 participants across both phases with comparable demographic characteristics [mean age 52.6 (P1) vs. 55.0 years (P2); 80.2% female (P1) vs 83.7% (P2); 69.6% married (P1) vs 68.3% (P2), 48.6% university educated (P1) vs 47.8% (P2)]. Most prevalent RMD was axial spondyloarthritis in P1 (37.2%), and rheumatoid arthritis in P2 (53.1%). Only 39.2% could have a scheduled appointment with their rheumatologist during P1, compared to 72.5% of patients in P2 (p<0.001). In this sense, only 41.6% of participants in the P1 attended such an appointment while in P2 this figure was 61.5% (p<0.001). The majority of patients (83%) had their scheduled face-to-face appointment changed to an online or telephone phone in the P2, although this proportion was lower in the P1 (54.4%). The most frequent reason for canceling the face-to-face appointment was the alternative of making it by phone or online (54.4% in P1 vs. 83.0% in P2, p<0.001). Although, in P1, 38.1% of participants could contact with their rheumatologist by phone or online, this proportion was 64.3% in P2 (p<0.001). In P1, 64.0% of patients were able to consult with their rheumatologist about the possible effects of treatment in case of contracting COVID-19 (vs. 41.2% in P2; p<0.001). With respect to general practitioners, 57.6% of patients in P1 declared to had accessed primary care or general practitioner (vs. 77.5% in P2; p<0.001). Furthermore, in P2, a higher proportion of participants (63.2%) were able to continue their psychological or psychiatric therapy either online or by phone (vs. 48.3% in P1; p<0.001; Figure 1)
Conclusion: During the first year of COVID-19 pandemic, RMD patients had easier access to the healthcare system, specifically to their rheumatologist. This access was improved through phone and online care. In addition, access to primary care as well as psychological care improved during the second year of pandemic.

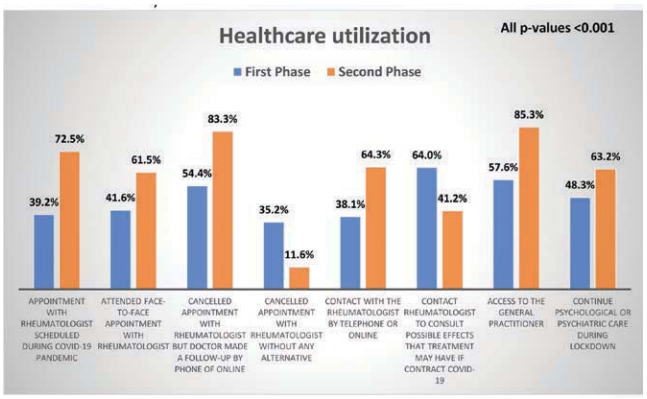

Figure 1. Bivariate analysis of healthcare utilization in P1 and P2 of REUMAVID

FACILITATORS AND BARRIERS OF VACCINE UPTAKE IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASE: A SCOPING REVIEW

S. Neusser[1], A. Neumann[1], C. Speckemeier[1], P. Zur Nieden[1], S. Schlierenkamp[1], A. Walendzik[1], U. Karbach[2], I. Andreica[3,4], K. Vaupel[3,4], X. Baraliakos[3,4], U. Kiltz[3,4]. [1]*EsFoMed Essener Forschungsinstitut für Medizinmanagement GmbH, Management, Essen, Germany*; [2]*Institute of Medical Sociology, Health Services Research and Rehabilitation Science (IMVR), University Hospital Cologne, Cologne, Germany*; [3]*Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; [4]*Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany*

Background: Patients with chronic inflammatory rheumatic diseases (CIRD) remain underrepresented in receiving vaccinations despite being disproportionately affected by infectious complications.
Objectives: To systematically review the literature regarding vaccination willingness and vaccination hesitancy in CIRD patients with focus on the perspective of patients and physicians.
Methods: A scoping review was conducted in PUBMED, EMBASE and the Cochrane Library through 2021. Study selection was performed by two independent reviewers, data were extracted using a standardized form and risk of bias was assessed using instruments from the McMaster University. Identified barriers and hurdles were synthesized by categorizing them into the WHO's Measuring Behavioural and Social Drivers of Vaccination (BeSD) conceptual model.
Results: The search yielded 1,644 hits, of which 30 were included (cross-sectional studies (n=27) based on interviews and 3 intervention studies). The majority of studies reported barriers to influenza and pneumococcal vaccination (n=11), or influenza vaccination only (n=9) from the patients perspective. Two studies assessed the attitudes towards COVID-19 vaccinations. Only one study assessed the view of rheumatologists. Patients mainly mentioned behavioral and social factors that negatively influence their willingness to be vaccinated while physicians see deficits in the organization and lack of time as a major barrier. Coverage of domains matched to the BeSD model suggests a lack of awareness of infection risk by both patients and physicians (Figure 1).

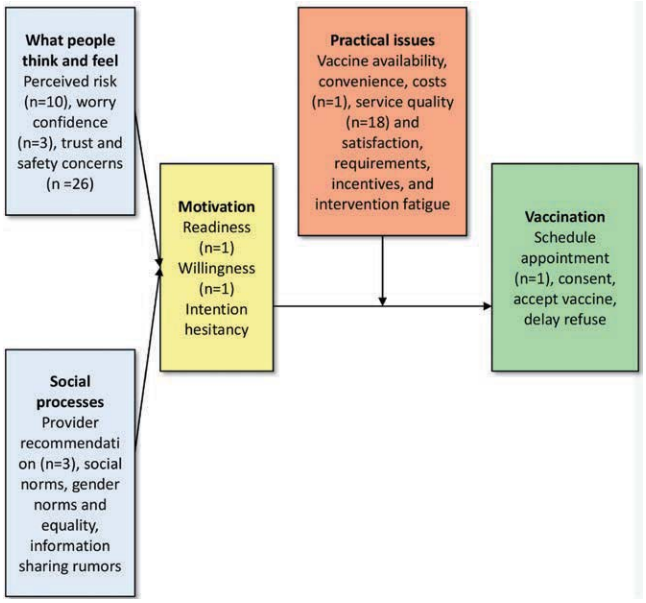

Figure 1. Coverage of domains matched to the WHO BeSD Model

Conclusion: The view of vaccination in CIRD patients diverges between patients and rheumatologists. Our results show that in-depth counseling on vaccines is important for patients, whereas physicians need support in implementing specific immunization recommendations. The themes identified provide a starting point for future interventions to improve vaccine rates in CIRD patients.

IMPACT OF THE SARS-COV 2 PANDEMIC AND RELATED EPIDEMIOLOGICAL RESTRICTIONS ON THE CARE OF PATIENTS WITH OSTEOPOROSIS – EXPERIENCES OF A HUNGARIAN CENTRE

Z. Kardos[1,2]. [1]*Borsod County Teaching Hospital, Rheumatology, Miskolc, Hungary*; [2]*University of Miskolc, Medical Faculty, Miskolc, Hungary*

Background: Treatment of patients with osteoporosis was inadequate even before the COVID-19 pandemic. Not only patients without fracture, but only a small proportion of patients with osteoporotic fracture have treated. In Hungary only 30% of patients with osteoporosis received adequate antiporotic treatment before the pandemic. Almost 90% of whom were women, less than 10% of men. The incidence of fractures is increasing dramatically worldwide. In 2010, the vertebral fracture rate was 3.5 million in Europe but it is expected to reach 4.5 million by 2025. In 1990, osteoporosis caused 1.26 million hip fractures and by 2025 this is estimated at 2.6 million worldwide. The care for patients with osteoporosis was further aggravated by the restrictions necessarily imposed due to the coronavirus.
Objectives: The aim of the study was to explore the extent and consequences of diagnostic and therapeutic failure in patients with osteoporosis.
Methods: I determined the number of osteoporosis examinations performed in our centre in 2019-2021 from the medical database. I surveyed how many patients were discontinued the antiporotic treatment during the pandemic according to the different drug groups in Hungary and also in our centre as well as the prevalence of wrist and hip fractures due to minor trauma in our county in the pre- and post-pandemic period.
Results: In our centre an average of 30 DEXA examinations were performed daily in the pre-pandemic period. From the end of October 2021 to the end of May 2021 there was not perform any ODM examinations. It means 3.980 missed exams and at least 1.000 missed osteoporosis diagnoses and therapy starts. More than 20% of patient were lost from the antiporotic care in Hungary. Drop-out was mainly seen in patients treated with bisphosphonates. There were 20730 bisphosphonate-treated patient in 2019, 19813 in 2020 and 17315 in 2021. Antiporotic treatment was discontinued in 30% of patients treated with bisphosphonate+vitamin-D (7849 in 2019, 6950 in 2020, 5484 in 2021) or bisphosphonate+calcium+vitamin-D fixed combination products (3256-2876-2289). In our centre, the prescribing of bisphosphonates has also decreased more than half. Patients treated with iv. bisphosphonates were interrupted or switched to oral formulations. Denosumab therapy was continuous: 581 injections were prescribed in the 12 months before and 579 during the pandemic. However, no new treatment started. In case of teriparatide, the initiated therapies were continued and even the number of prescriptions increased. As a consequence, an increase in the occurrence of fractures due to minor trauma is expected. Although epidemiological restrictions in this regard, the curfew has had some positive effects. According to international data, the number of wrist fractures has almost halved, while the data for hip fractures are controversial. The decrease of wrist fractures can also be verified in our county. The number of wrist fractures was 598 in April-May 2019, 393 in the same period in 2020, and 372 in 2021. After a significant reduction in hip fractures in 2020, there is already an upward trend in 2021 (470 in 2019, 358 in 2020, 393 in 2021). The real consequences of failure to treat osteoporosis are expected only after years.
Conclusion: Missed doctor-patient appointments were associated with missed diagnoses and interruptions of ongoing treatments. Fear of the virus, immobilisation due to home office and curfews, lack of exercise, sun exposure, caused depressive symptoms, increased alcohol consumption and caloric intake are all increase the risk of osteoporosis. Thus, traditional risk factors for osteoporosis expanded with the direct effects and the introduced restrictions because of the pandemic.

ELECTRONIC CONSULTATION: A USEFUL TOOL TO OPTIMIZE THE ON-SITE MEDICAL CONSULTATION IN RHEUMATOLOGY

D. V. Mendoza Mendoza[1], D. Ruiz-Montesinos[1], V. Moreira Navarrete[1], J. J. Pérez Venegas[1]. [1]*Hospital Virgen Macarena, Rheumatology, Seville, Spain*

Background: Electronic consultation (e-Consults) is a form of telemedicine. It permits communication between primary health care (PHC) and hospital care (HC). It is proving to be a helpful tool to reduce waiting times in consultations, to prioritize those pathologies that require an on-site consultation and also to avoid unnecessary travel for the patients (1).
Objectives: To evaluate the efficacy of e-Consults to avoid on-site consultations To evaluate the usefulness of e-Consults as a screening tool for on-site consultations To analyze the most frequent reasons for consultation To evaluate the evolution of e-Consults from the first to the second year of its implementation

Methods: Retrospective, observational study of all e-Consults carried out during 2021 in the hospital area *Virgen Macarena*, which includes 47 PHC centres. E-Consults were carried out by the tool "Plataforma de Teleconsultas del Servicio Andaluz de Salud" (teleconsultation platform of the Andalusian health service) as a clinical extension of the research project E-Hermes for the implementation of e-Consults. It collects information about the reason for the consultation, the suspected diagnosis of the rheumatologist, the response time of the TC and whether the consultation is completely resolved online (DISCHARGE), whether on-site consultation is required (CONSULTATION) or whether the patient needs further e-Consults in order to obtain more medical tests or to evaluate the treatment (FOLLOW-UP) The e-Consults of 2021 were compared to those of the previous year.
Results: Of the 733 e-Consults examined, 610 (83.2%) were fully resolved online and 123 (16.8%) required on-site consultation. Of those fully resolved online, 544 (89.2%) were resolved in the first consultation and 66 (11.8%) required more than one e-Consults. The most common reasons for consultation in this group of e-Consults were: suspected diagnoses of osteoporosis (19.1%), polyarthralgia (14.4%), questions about follow-up patients in Rheumatology (9.4%), joint swelling (7%), hand pain (6.8%) and questions about laboratory or imaging tests (3.9%). For 28% of patients, a rheumatic disease could be excluded, and for those patients who were diagnosed with a rheumatic disease, the most frequent diagnosis was: osteoarthritis 17.3%, osteoporosis 14.4%, fibromyalgia 8.3% and gout 3%. Of the patients that were recalled for an on-site evaluation, in 101 of the cases (90%) this decision was taken after the first e-Consults, while 11 patients (10%) were recalled after subsequent e-Consults. Among the patients recalled for an on-site visit, the most common reason was joint inflammation (23.4%), followed by polyarthralgia (22.1%), osteoporosis (18.2%) and hand pain (7.8%). The most frequent suspected diagnosis was inflammatory rheumatic disease (RA, PsA, SpA) in 49.4% of cases, followed by osteoporosis (24,4%) The average response time of the e-Consults was 82 hours (3 days and 10 hours) Compared to the e-Consults in 2020, it increased by 34%, 186 e-Consults more. The number of cases resolved without on-site consultation was 29% higher than in the previous year, while the e-Consults that required follow-up decreased by 7% and the number of patients that required further on-site consultation also decreased by 11%. The reasons for the consultation and suspected diagnosis were similar in both years.
Conclusion: E-Consults has proved efficacious, avoiding the necessity for on-site consultations in more than 80% of the patients. E-Consults helps to reduce on-site referrals to Rheumatology. E-Consults is effective in reducing waiting times before obtaining an evaluation from the rheumatologist and in prioritizing those patients who need on-site consultation. There are certain pathologies that are especially amenable to resolution without on-site consultation, like osteoarthritis, osteoporosis and fibromyalgia Over time, e-Consults is being integrated in the clinical practice of both the primary care physician and the rheumatologist and is becoming ever more efficient.

AB1405 THE USEFULNESS OF TELEMEDICINE IN RHEUMATOLOGY: POINTS OF VIEW OF PRACTITIONERS AND PATIENTS

M. Yasmine[1], D. Ben Nessib[1], H. Ferjani[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: The advent of COVID-19 has allowed a rapid expansion of telemedicine (TM) and its implementation in various specialties. Despite this extensive use of TM, its role in rheumatology is conflicting and much remains unknown about TM's acceptability and efficiency in rheumatology [1].
Objectives: Our study aimed to evaluate rheumatologists' and patients' willingness for TM and factors helping to adopt this alternative.
Methods: We conducted a cross-sectional study including patients attending our rheumatology department as well as rheumatologists. Patients were contacted by phone and rheumatologists were invited to answer a questionnaire via Google Form. We evaluated their points of view and suitability for TM by inquiring about their experience with tele-rheumatology, information technology supports, personal barriers to telemedicine, and reasons for adopting this alternative. Moreover, additional questions probed the clinician's perception of the appropriate clinical context for TM application as well as the corresponding legislation.
Results: Overall, 135 responses were collected including 60 rheumatologists and 75 patients. The distribution of diagnosis was as follows: rheumatoid arthritis (RA) (n=15), spondyloarthritis (SpA) (n=20), juvenile idiopathic arthritis (n=23), and osteoarthritis (n=17). Of the rheumatologists, 76.2 % were aged between 30 and 50 years old, 79.3% reported working at an academic center, and the majority were physician-level practitioners (71.2%), working for more than 5 years (61%). Afforded electronic devices were as follows: laptop (87.9%), smartphone (70.7%), afforded headset microphone (24.1%), camera (29.3%) for doctors. Forty-six percent of the rheumatologists estimate that they have a good internet connexion, 62.7% had an appropriate place for teleconsultation. Nearly, 40.7% of the rheumatologists were familiar with the concept of TM but only 39% reported experience with TM. Willingness to accept this model of care for rheumatologists and patients was found in 78% and 37.3% respectively. According to the doctors, the benefits of TM encompassed tele-training (61.7%), remote medical monitoring (61.7%) especially during the COVID-19 (70.2%), benefits for patients (74.5%), reduced inequalities in access to healthcare (46.8%), and improved quality of care (29.8%). The main barriers to TM were the lack of clear legislation (47.8%) and financial compensation (17.4%). Clinicians and patients identified common barriers to effective tele-rheumatology as the inability to perform a physical exam (91.3% vs 33.3%), the fear of trivializing the disease (34.8% vs 36%), and the lack of resources and infrastructures (43.5% vs 29.3%). The majority of the doctors (86.2%) expressed their willingness to attend training workshops. Reported areas to apply TM according to the doctors were mainly osteoarthritis (76.3%) and rheumatic diseases (64.4%), but also pediatric rheumatology (28.8%) and undiagnosed new patients (3.4%). Regarding legislation, most of practitioners estimated that it should be selective with specific authorizations (42.4%) or relaxed with the possibility of derogation (32.2%). Twenty-two percent of them reported that legislation should be strict with the possibility of sanctions, whereas a minority (3.4%) opted for a free practice without regulation at all. Factors associated with adherence to TM were age<40 years (p=0.036) for doctors and familiarity with the concept (p=0.006) and electronic devices afforded (p=0.000) for the patients.
Conclusion: Findings from this study showed the reluctance of the patients to adhere to TM compared to doctors. Concerns and risks may lessen for both sides, once remote consultations are applied. Nevertheless, patient education is required for the success of TM application.

AB1406 TELERHEUMATOLOGY FOR IMPROVING FIRST ACCESS TO THE OUTPATIENT CLINIC: A PILOT PROSPECTIVE MONOCENTRIC ITALIAN STUDY

E. Giacobbe[1], M. C. Gerardi[1], N. Ughi[1], A. Adinolfi[1], M. Alqoudah[2], L. Belloli[1], C. Casu[1], M. Di Cicco[1], D. A. Filippini[1], C. Gagliardi[1], M. Muscarà[1], E. Verduci[1], O. M. Epis[1] [1]*Ospedale Maggiore - Niguarda, Rheumatology Unit, Milan, Italy*; [2]*The Hashemite University, Internal Medicine, Zarqa, Jordan*

Background: The COVID-19 public health emergency has amplified both the potential value and the challenges with healthcare providers deploying telehealth solutions. Furthermore, outpatients may wait up to several months for their first

appointment with specialists including rheumatologists for diseases other than COVID-19. In Italy it is now possible to get access to telemedicine services within the national healthcare systems, yet only follow-up visits are allowed for reimbursement purposes. Instead, it is not clear the role of telemedicine as a tool for improving first access and patient acceptance of this innovation.

Objectives: To investigate the feasibility of a '*teletriagerheum*' service before the first visit and to identify potential benefits and disadvantages of it by comparing first face-to-face visit preceded by '*teletriagerheum*' service to regular first visit without it.

Methods: A pilot prospective monocentric study was conducted. Consecutive patients were contacted by phone 30 days before the scheduled rheumatological first visit by administrative staff to investigate their willingness to receive 20 days before the first visit a phone call ('*teletriagerheum*' service) by a physician of the Rheumatology Unit. The '*teletriagerheum'* service aimed at investigating the reason for the visit and at prescribing additional exams or specialistic consultations before the face-to-face first visit to facilitate the diagnosis process or anticipate the appointment in case of urgency. Socio-demographic characteristics, reason for referral, face-to-face visit duration, number of additional exams prescribed, number of definite diagnosis at first visit in the '*teletriagerheum*' group were compared to the ones receiving regular first visit without '*teletriagerheum*' service.

Results: In October 2021 a total of 102 patients were phone called by administrative staff: 18 (17.6%) did not answer for a maximum of three times, 9 (8.8%) responded but refused the 'teletriagerheum' service (6 cancelled the visit, 1 postponed, 2 for unknown reason) and 75 (73.5%) accepted the service, but 21 were not real first visits and 8 patients did not answer the call of physician. Among the remaining 46 (45.1%) pts (the 'teletriagerheum' group) the median call time was 11.5 minutes (IQR 5-15 min), blood exams were prescribed to 34 (74%) and instrumental exams to 8 (17.4%). Further consultation was prescribed only to 1 patient and the visit was not anticipated in any case. A preliminary diagnosis was possible in 36 (78.2%). In most of the cases (33, 76%) no difficulties were reported by the physician, in 7 (16.3%) there were difficulties in communication, in 1 (2.3%) difficulty to get the history from a patient suffering from a psychiatric disorder. Socio-demographic characteristics, Information and communication technologies skills, face-to-face visit duration were not statistically different between the '*teletriagerheum*' group (46 pts) and the group receiving regular first visit without '*teletriagerheum*' service (52 pts). In the '*teletriagerheum*' group, a lower number of blood exams (14% vs 46%, p<0.005) and a lower number of instrumental exams (25% vs 45%, p=0.04) were prescribed during the face-to-face first visit; a higher percentage of definitive diagnosis (79% vs 67%, whilst not statistically significant p=0.2) and a lower number of patients requiring a visit before 6 months (26% vs 54%, p<0.05) were observed compared to the group without teletriagerheum service.

Conclusion: These preliminary data showed that telemedicine for the first rheumatological visit was well-accepted by patients searching for rheumatology consultations and had the potential to be a tool for improving clinical diagnosis and rheumatological follow up in everyday clinical practice. A larger cohort will let us to further explore the potential benefits of telemedicine to improve accessibility to rheumatological services.

AB1407 TELERHEUMATOLOGY AND WORKING VISIT: INITIAL MONOCENTRIC EXPERIENCE ON USE OF TELEVISIT IN THE REGULAR FOLLOW-UP.

F. Cianci[1], A. Olga[1], M. Magnani[1], F. Pignataro[1], F. Massimo[2], M. Reta[1]. [1]*AUSL Bologna, Rheumatology and Internal Medicine, Bologna, Italy*; [2]*Catholic University, ALTEMS, Roma, Italy*

Background: The COVID-19 pandemic shifted most healthcare to remote delivery methods (telehealth technologies including clinical video televisit) to protect patients, clinicians, and hospital staff. Telerheumatology visits were found to be noninferior to in-person visits and are often more time and cost effective for patients.[1]

Objectives: Description of an initial integration of video televisit in regular follow-up.

Methods: In cooperation with the ALTEMS Operational Telemedicine Observatory, we built a procedural manual for televisit, whose phases were as much as possible similar to the usual visit scenario. Patients in remission or in mild disease activity at the time of enrolling visit were involved. Clinical characteristics, treatments and televisits' features were considered for all patients (Table 1). Patient overall satisfaction was evaluated (rating 1 to 5).

Table 1.

Patients (n.)	74
M/F	27/47
Age (y) median	46.2±13.5
RA n. (%)	19 (25.6)
PsA n. (%)	21 (28.3)
SpA (%)	13 (17.5)
CTD n. (%)	8 (10,4)
Vasculitis n. (%)	7 (9.4)
Other n. (%)	6 (8.1)
b or tsDMARDs n. (%)	20 (62.5)
Televisits n.	86
Mean duration (min.)	17±3.5
Satisfaction (1-5)	4.68
Device (PC/smartphone) %	62.5/37.5
Distance saved, mean (km)	77,5
Time travel saved, mean (min.)	66
CO2 saved (kg)	866.71
€ saved (per patient)	44,37
Working visit n. (%)	5 (15.6)

Results: 86 televisits were performed in 74 consecutive patients, with a mean age of 46.2 ± 13.5 years, diagnosed with the most common rheumatic diseases and on chronic immunosuppressive therapy (c-b-ts DMARDs mono or combination therapy). In 5 cases, in-person visit after televisit was required. the average duration of the televisit was 17 ± 3.5 minutes and the average overall satisfaction was 4.68 / 5. The average distance saved (round trip) was 77,5 km, equal to an avoided travel time of 66 minutes and with a total reduction in CO2 production of approximately 866 kg. 5 patients performed video visit from workplace, de facto inventing the "working visit."

Conclusion: Telemedicine is going to become an essential element of clinical practice in rheumatology,[2] especially for active, young, and working patients, helping to minimize the overall impact of the disease on QoL, as far as they are properly selected for clinical characteristics and informatic skills. The possibility to attend to televisit from the workplace will reduce the lost working-hours and the need of travel, thus acquiring undoubted social utility. In the near future, the use of televisit should be also extended to vulnerable patients lacking basic informatic resources, with the help of care-givers or dedicated territorial services.

AB1408 WELL-BEING AND MENTAL HEALTH OF RHEUMATOLOGY AND FAMILY MEDICINE RESIDENTS

M. Ketata[1], S. Miladi[1], A. Fazaa[1], H. Boussaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Department of Rheumatology, La Marsa, Tunisia*

Background: Burnouts and poor well-being among medical residents are becoming a global concern for health institutions. Its negative consequences are far-reaching, affecting patients, coworkers, family members, and healthcare organizations as well as the burned-out resident.

Objectives: The aim of the study was to measure the extent of burnout among rheumatology and family medicineresidents'and to elucidate wellness status as well as barriers to wellness.

Methods: An online questionnaire was issued to rheumatology and family medicine residents. We collected sociodemographic data (Age group, gender, marital status, children, smoking and alcohol status, Sport and other activities, Specialty, Weekly working Hours,Vacation) and mental health measurements. Participants were also requested to fill the 14-item Mental Health Continuum Short Form (MHC-SF) and the 5-item WHO-5 well-being form. Multivariable logistic regression analysis was used to explain the relationship between well-being and the work circumstances.

Results: A total of 64 residents with a 0,28 sex-ratio completed the online questionnaire. Sixty-nine percent (69%) of responders were in the [25-29] age group. Sixty three percent (63%) of responders were single and 14,1% had children. Most residents were not smokers (76,6%) nor alcohol users(68,8%). Eighty seven percent of responders were a family medicine resident. Thirty

four percent (34%) of responders practiced sports 2 to 4 times a year and 25% exercised 2 to 4 times a week. The average working hours per week was 30 hours [10-70] with an average of 3,38 weeks' vacation per year. Seventy eight percent (78%) of residents worked overnight shifts in hospitals with an average of 1,83 shift per month. Female sex (p=0,049), less physical activities (p=0,037) and long working hours (p=0,042) were associated with worst degree of quality of life (WHO5 Well-Being Index). Residents who practice art and had fewer overnight shifts showed a significantly flourishing mental health (p=0,032, p=0,014) according to the MHC-SF. Family medicine residents had more long working hours (p=0,039) and overnights shifts (p=0,047) than rheumatology residents.

Conclusion: Residents working more than 50 hours per week with more than 5 overnight shifts per month and those practicing fewer physical activities and art appear to be at high risk of developing languishing mental health according to the Who5 well-being index and the MHC-SF score. It is important to protect health care workers and to promote well-being to acquire a flourishing mental health.

AB1409 EVALUATING HOW EFFECTIVELY PATIENTS WITH A NEW INFLAMMATORY ARTHRITIS ARE BEING TRIAGED INTO THE APPROPRIATE CLINIC AT A TERTIARY CARE HOSPITAL IN THE UK: A RETROSPECTIVE AUDIT.

A. Vivekanantham[1,2], M. Ashraf[2], A. Soni[1,2]. [1]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [2]*Oxford University Hospitals, Nuffield Orthopaedic Centre, Oxford, United Kingdom*

Background: Inflammatory arthritis is associated with significant morbidity and costs to the NHS, social care, and wider economy. Early diagnosis and treatment are essential to reduce the impact of the disease. Therefore, it is important that referrals for a new inflammatory arthritis are appropriately triaged to be seen in the early inflammatory arthritis (EIA) clinic so that they can be seen and started on disease modifying anti-rheumatoid drugs (DMARDs) without delay. The British Society of Rheumatology guidance for inflammatory arthritis states that patients must be seen within three weeks of referral and started on DMARDs within six weeks.

Objectives: To evaluate how effectively people referred with a new EIA are currently being triaged. To evaluate whether we are meeting the national standards.

Methods: We performed a retrospective review of the medical notes of all new patients who were seen in the EIA clinic from 01/09/21-31/11/21. During this same time period, we will also reviewed all the patients who had been newly diagnosed and started on a DMARD in the other Rheumatology clinics (e.g., general rheumatology, vasculitis). We collected data on referral date, referral source (e.g., GP), date of clinic assessment, clinic type (e.g., EIA clinic or other Rheumatology clinic), diagnoses made, days' wait from referral to assessment and days' wait from referral to commencing DMARD. We then calculated the conversion rate (percentage of referrals triaged to the EIA clinic that have an EIA) and detection rate (percentage of new EIA patients that are seen in the EIA clinic (as opposed to in non-urgent clinics)). The standard for conversation rate (CR) was 50% and for detection rate (DR) was 95%.

Results: Of all the patients seen in the EIA clinic (n=73), 36 had a new diagnosis of an EIA, giving a CR of 49%. Of all the new diagnoses of EIA made during that time-period (n=53), 36 were appropriately triaged to be seen in the EIA clinic, giving a detection rate 68%. Those new referrals who had been appropriately seen in the EIA clinic had an average of 5 weeks wait from referral to assessment/ commencement of DMARD. In contrast, those new referrals who had been seen in other clinics had an average of 10 weeks from referral to assessment/ commencement of DMARD. A previous audit performed before the COVID-19 pandemic (01/11/19- 01/01/20) showed a CR of 25% (115 patients seen in EIA clinic, 29 new diagnoses) and a DR of 69% (29 new diagnoses, 20 seen in EIA clinic). **Conclusion:** Those patients with a new EIA who are appropriately seen in the EIA clinic do not meet the national guidance for being seen within three weeks of referral but do meet the guidance for starting a DMARD withing six weeks. However, those new EIA who are seen outside the EIA clinic do not meet either of these standards, with a delay of 10 weeks to be seen/ started on a DMARD. Given that only 68% of people with a new EIA are being correctly triaged to be seen in the EIA clinics, it highlights that there is a need for an improvement in the triage process (currently being done manually by Rheumatologists). Interestingly, when comparing our findings to the audit done pre-COVID-19 pandemic, the CR has improved whilst the DR has stayed steady. The next steps include exploring using additional data collected from patients electronically to improve the CR/ DR rates, as well as artificial intelligence informed modelling.

AB1410 IMPACT OF COVID-19 PANDEMIC ON HEALTHCARE RESOURCE USE AND CLINICAL OUTCOMES IN A COHORT OF PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES- AN INTERIM ANALYSIS FROM THE PER-MAS PROJECT.

F. Trentin[1], G. Fulvio[1], G. Andreozzi[2], C. Cigolini[1], M. Da Rio[2], V. Dell'Oste[3], E. Elefante[1], F. Fattorini[1], S. Fonzetti[3], V. Lorenzoni[2], M. Maffi[1], I. C. Navarro García[1], I. Palla[2], V. Pedrinelli[3], L. Scagnellato[1], D. Schilirò[1], A. Valevich[1], A. Gaglioti[1], C. Carmassi[3], C. Tani[1], L. Dell'osso[3], G. Turchetti[2], M. Mosca[1]on behalf of PER-MAS. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*; [2]*Institute of Management, Scuola Superiore Sant'Anna, Pisa, Italy*; [3]*Psychiatric Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

Background: Management of the health emergency caused by COVID-19 pandemic majorly disrupted the delivery of healthcare services to patients with chronic conditions like Systemic Autoimmune Diseases (SAD), both because resources were mainly channeled towards the care of infected patients, but also because patients tended to avoid seeking medical care for fear of becoming infected. PER-MAS is a 2-year project aimed at assessing the clinical, psychopathological, and socio-economic impact of COVID-19 in a cohort of patients with SAD.

Objectives: To assess the impact of COVID-19 pandemic on drug withdrawal, disease flares and hospitalizations for disease exacerbation in a cohort of patients with SAD through an interim analysis of data from the PER-MAS project.

Methods: A sample of 214 consecutive patients was recruited in a reference center for rare and complex autoimmune diseases from April 2021 to January 2022. Inclusion criteria were definite diagnosis of SAD (Connective Tissue Disease (CTD), Inflammatory Arthritis (IA) or Vasculitis), regular follow-up and at least 2 years of disease. Patients were asked to fill out an extensive self-administered questionnaire on disease activity and healthcare resource use during the pandemic (March 2020-moment of assessment). Pre-pandemic (March 2019-February 2020) and early pandemic (March 2020-February 2021) clinical data were recorded through retrospective chart review and patient interview.

Results: At enrolment, 119 patients were affected by CTDs (55.6%), 71 by IA (33.18%), 24 by vasculitis (11.21%), with mean age 50.44± 12.97, and mean disease duration 11.17 ± 8.94. 30.37% took steroids, 39.7% hydroxychloroquine, 61.68% DMARDs, and 9.3% vasoactive drugs. Overall, disease course was similar in pre-pandemic and early pandemic phase: in the first period, rheumatologic condition was stable in 57.35% of patients, persistently active in 27.3% and 35.61% had ≥ 1 episode of disease exacerbation (mean 0.665±1.15, range 0-6); in the second period, 60.56% of patients was stable, 24.88% persistently active, and 39.44% had ≥1 exacerbation (mean 0.49 ±0.77, range 0-4). Mean number of visits (2.56±2.57 and 2.61±2.79), hospitalizations (0.168±0.698 and 0.14±0.473, p=0.6), number of patients with outpatient visits=0 (7.47 vs 7%), and number of patients with ≥ 1 hospital admission (10.28 vs 11.6%) were also similar, while the number of patients with hospital admissions for disease exacerbation was significantly higher in the second period (6.1 vs 11.21%, p=0.001). 170 patients completed the survey: from March 2020 to enrolment, 18.2% suspended ≥*1* anti-rheumatic drug (6.25% of them for fear of contracting COVID-19 disease, 15.6% for difficulty in obtaining medications), 20% self-managed ≥ 1 disease exacerbation, and 40% had ≥ 1 telemedicine consult. From March to July 2020, 41.76% had their visit rescheduled (35.23% for hospital access restrictions, 5.3% for travel restrictions, 1.17% for fear). Conversely, only 14.7% of patients had their visit rescheduled (8.23% for hospital access restrictions, 4.7% for other reasons) from July 2020 to enrolment.

Conclusion: In the early pandemic phase, overall disease course was similar to the pre-pandemic phase, but we observed an increase in the number of patients with ≥ 1 hospitalization for disease. Moreover, despite our efforts, patients reported a non-negligible rate of drug discontinuation for non-medical indication and difficulty to get access to rheumatologic consultation, highlighting the need of alternative organizational models in case of future pandemics.

AB1411 JOINT RHEUMA-DERMA CLINIC: FOUR YEARS OF EXPERIENCE AT THE SAN MARCO HOSPITAL IN CATANIA

R. Foti[1], G. Giuffrida[2], A. Ramondetta[2], E. Visalli[1], G. Amato[1], Y. Dal Bosco[1], F. De Lucia[1], R. Foti[1], R. De Pasquale[2]. [1]*AOU Policlinico San Marco, Rheumatology Unit, Catania, Italy*; [2]*AOU Policlinico San Marco, Dermatology Unit, Catania, Italy*

Background: Psoriatic arthritis (PsA) affects up to one-third of patients with psoriasis. Many recent works in literature have underline that the percentage of undiagnosed PsA is still high. A direct collaboration between dermatologists and rheumatologists appears fundamental for a better management of these patients, to reduce the risk of joint damage, disability, and comorbidities.
Objectives: The aim of this study is to highlight the benefits of a Rheuma-Derma clinic and a shared approach, focused to an early diagnosis and prompt therapeutic strategy of PsA.
Methods: Patients with psoriasis complaining joint symptoms or rheumatologic patients with cutaneous involvement, were simultaneously assessed by a dermatologist and a rheumatologist. The collected data included demographics, clinical characteristics as joint patterns (axial/peripheral), clinimetric index evaluated (DAS28, HAQ, BASDAI, DAPSA, PASI, PGA) family history of psoriasis or PsA, BMI (Mass Body Index), psoriasis, comorbidities and Charlson Index, gastrointestinal and ophthalmic involvement, and previous and current treatments with conventional (csDMARDS) and/or biological therapy (bDMARDs).
Results: During the period from 2012 to 2016 the Rheumatology Department registered 255 of patients under biological treatment, against 374 of patients during the Rheuma-Derma Clinic (2017-2021), with an increase of 47% in number. CsDMARDs therapy counted 367 patients before the Rheuma-Derma Clinic and 539 after the shared outpatient activity, with a raise of the 46%. Globally the number of patients with the diagnosis of PsA moved from 622 to 913, reaching an increase of 47% of patients. The joint pattern have shown a peripheral involvement in 69.3% of cases in comparison to 11% of cases with axial involvement and a mixed for the rest of population, 19.8%. In the group analyzed 539 patients were treated with csDMARDs, 76.5% methotrexate, 30.7% salazopyrine and only 6.7% with cyclosporine. 374 patients under treatment with bDMARD: the majority of patients (86.1%) were treated with TNFα inhibitors, 25.4% Secukinumab, 20.1% Ustekinumab, 16% Apremilast, 4.8% Ixekizumab, 1.1% Tofacitinib. The Charlson Comorbidity Index (CCI) assesses comorbidity level by taking into account the number, the severity of pre-defined comorbid conditions and the age of patients. It provides a weighted score in a range from 0 to 8, which can be used to predict short term and long-term outcomes such as function, hospital length of stay and mortality rates. In our study the majority of patients (27%) had a score of 2 while fortunately only 0.5% of population had a score of 8. The most frequent comorbidities registred in our cohort were hypertension (24.6%) and dyslipidemia (28.3%). Psoriasis was diagnosed in 41% of patients: in 80% of them the skin disease preceded the articular symptoms while 20% of patients developed psoriasis after the arthritis onset. History of family psoriasis was positive in 26% of patients. The nails involvement was observed only in 8% of patients, followed by gastrointestinal disorders (3%) and uveitis (7%). The value of BMI (Body Mass Index), the majority of patients (56%) have shown a normal weight, followed by over-weight patients (31.7%); only 10% of patients presented an obesity grade I and 1.1% an obesity grade II-III. For all the clinimetric index evaluated (DAS28, HAQ, BASDAI, DAPSA, PASI, PGA), there was an improvement over the twelve months under the Reuma-Derma clinic
Conclusion: In conclusion, the diagnosis of an Early PsA is essential, as an early treatment and management can alter the natural course of PsA and prevent irreversible joint damage. Our experience proved the increased number of patients since the Rheuma-Derma Clinic have started, such as an increased number of patients under treatment, leading to a significant improvement in the quality of life of PsA and Pso patients.

AB1412 IMPORTANCE OF TELEMEDICINE IN THE SYSTEMIC SCLEROSIS DURING COVID-19 PANDEMIC

G. Cuomo[1], C. Di Vico[1], F. Masini[1], C. Iandoli[1], D. Perretta[1], R. Irace[1]. [1]*Università degli Studi della Campania, Precision of Medicine, Naples, Italy*

Background: Severe acute respiratory syndrome coronavirus 2 (SARSCoV-2), also called COVID-19 disease, was firstly reported in December 2019 in China and soon declared a pandemic by the World Health Organization (WHO) on March 11, 2020 (1). As a result, patients' visits to medical facilities are affected. Systemic sclerosis (SSc) is a chronic systemic autoimmune disease characterized by vascular damage, autoimmunity, and fibrosis. In these patients, a tight follow-up is crucial to verify the specific cases and clinical needs. In particular, the infection risk in SSc might also be related not only to disease activity but also to possible flares due to therapy discontinuation. Telemedicine has demonstrated as a valid alternative to improve the quality of rheumatic patients' care during COVID-19 pandemic, thus reducing hospitalizations only to urgent admissions (2)
Objectives: In december 2020 the Azienda Policlincio Vanvitelli approved telemedicine by IRPLUS platform as a particular measure in the face of the COVID-19 pandemic. In this study we examined the impact of the COVID-19 pandemic on visit status of SSc patients at our centre and the patient benefits of telemedicine
Methods: In this study, we retrospectively enrolled 480 SSc patients who visited in our centre between January and December 2021. Of the patients included in the study, 198 patients (18 males and 180 females) used telemedicine, while 282 patients (20 males and 262 females) did not use it
Results: During televisites, we assessed possible contacts with COVID-19 patients and/or potential risk of COVID-19, investigating about the occurrence of typical symptoms in the last 15 days. No significant differences in background data, such as the severity of the disease, type of treatment and frequency of complications were found between these two groups. In more detail, SSc is associated interstitial lung disease was complicated by 35.4% and 31.3% of patients in the telemedicine and non-telemedicine groups, respectively (p=0.9). Besides, 53.7% of patients in the telemedicine group and 49.9% of patients in the non-telemedicine group were treated with prednisone (p=0.344). 74.1% of patients in the telemedicine group were administered immunosuppressive drugs, compared to 78.5% of patients in the non-telemedicine group (p=1.000). The number of patients who discontinued treatment was significantly lower in the telemedicine group, with 14 patients (7%) compared to 30 patients (11.4%) in the non-telemedicine group (p=0.003). These patients who voluntarily discontinued treatment were finally resumed. However, the time required to resume treatment differed between the two groups. This means that the duration of treatment interruption was significantly shorter in the telemedicine group, with a mean (± standard deviation) of 1.85 (5.5) days compared to 7.5 (12.1) days in the non-telemedicine group (p=0.001). There was no difference in the amount of change in laboratory data between the groups receiving telemedicine and those not receiving telemedicine.
Conclusion: This study confirmed the data published by Norimatsu et al (3), as that telemedicine may help SSc patients to continue and/or resume treatment under the COVID-19 pandemic. SSc is associated to interstitial lung disease, cardiac involvement, vascular injury and prednisone and immunosuppressive agents have been used as treatment. Thus, disruptions in treatment can lead to worsening of symptoms and missed opportunities for early interventions for complications. Patients who use telemedicine may be more motivated to treat, and this retrospective study demonstered it. This study suggests that telemedicine can be useful in treating SSc and other diseases that require ongoing treatment in the COVID-19 infection.

AB1413 SURVEY ON THE PRESCRIPTION OF GENERAL CORTICOSTEROID THERAPY BY MOROCCAN RHEUMATOLOGISTS IN RHEUMATOID ARTHRITIS

N. Jaouad[1], I. El Binoune[1], B. Amine[1], S. Rostom[1], R. Bahiri[1]. [1]*El Ayachi Hospital, Ibn Sina University Hospital, Department of Rheumatology A, Salé, Morocco*

Background: The prescription of glucocorticoids at the diagnosis of rheumatoid arthritis (RA) is no longer systematically recommended because of the difficulty of withdrawal and the occurrence of adverse effects. The expert groups currently insist on a short duration of corticosteroids to obtain a low cumulative dose (1, 2). The real-life applicability of the current recommendations may be difficult to achieve (3).
Objectives: Moroccan rheumatologists were interviewed about their experiences on prescription of general corticosteroid therapy during the diagnosis of RA.
Methods: We conducted a descriptive cross-sectional study of practice conducted with the Moroccan rheumatologists belonging to public and private sectors according to a questionnaire established on a declarative and anonymous mode. The questionnaire was validated by a committee of experts before submitting them to rheumatologists and consisted of 24 single or multiple-choice questions. These questions were divided into 5 items: general data (3 questions), initiation of corticosteroid therapy at diagnosis (7 questions), withdrawal modalities and problems of withdrawal (8 questions), self-medication and patient information (6 questions). The elaboration of the questionnaire was done in "Google Forms" then the collected data were analyzed with the Microsoft office software Excel 2013.
Results: A total of 100 Moroccan rheumatologists responded to the questionnaire. In the initial treatment of RA, 14% of the rheumatologists reported starting corticosteroid therapy in all patients, 41% in two-thirds of their patients, 23% in one-third, 20% in half and 2% in none. The initial oral dose of prednisone or equivalent was 7.5 to 10 mg/day for 52% of rheumatologists and between 5 and 7.5 mg/day for 38%. Flare-up of activity and accompanying conventional treatment were the two first indications for initiation of corticosteroid therapy. 46% of rheumatologists considered weaning after 3 to 6 months of treatment, 26% between 6 months and one year, 23% in less than 3 months and 5% in more than one year. 35% achieve withdrawal in two thirds of their patients. The main problems encountered during withdrawal are self-medication and rebound of the disease. 96% of rheumatologists were in favour of introducing therapeutic education sessions using different tools adapted to the context of the patient and the disease.
Conclusion: The prescription of corticosteroids in RA must be based on the evaluation of the risk-benefit balance. A collaboration between rheumatologist and patient is necessary to prevent the risk of toxicity of corticosteroids and to achieve the goal of withdrawing them.

AB1414 THE COST OF PRENATAL CARE IN WOMEN WITH RHEUMATIC DISEASES.

M. E. Corral Trujillo[1], F. R. Arevalo Nieto[1], L. G. Espinosa Banuelos[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], A. Y. Lujano Negrete[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology Department, Monterrey, Mexico*

Background: In Mexico, over 60% of the population is uninsured and not able to afford private healthcare services. Women with autoimmune rheumatic diseases (ARDs) are a high-risk group during pregnancy. Morbidity associated with ARDs and pregnancy can include lower birth weight, increased preterm delivery, and more emergency cesarean sections than pregnant women without ARDs. Close monitoring and multidisciplinary care are necessary to prevent and timely treat complications, on the other hand these health interventions are not available to all women with ARDs because of the high prices that it represents.
Objectives: The aim of this study was to estimate the cost of prenatal care in women with ARDs without health insurance in Northeast Mexico.
Methods: To assess the costs of prenatal care of women with ARDs in the Northeast of Mexico from the perspective of a women without any health insurance, we estimated only the direct costs of the mandatory medical follow-up. Direct costs are all healthcare costs that are directly related to the consultations with a multidisciplinary team, serological and immune laboratory test, and ultrasounds per trimester. All costs and medical fees were obtained from a university hospital in Monterrey, Mexico. To assess the impact of prenatal care in real life, we compared the health expenditure per trimester reported by the pregnancy and rheumatic diseases clinic from the same institution. The data is presented in USD. We were not able to assess indirect costs related to health coverage (like transportation) and specific medical treatment (antirheumatic drugs or other interventions).
Results: The mean cost for medical consultations and ultrasounds per trimester was $184-277 USD. The average cost of immune test and general lab test ranges from $424-428 USD. The total cost per trimester was from $608 to 705 USD, and the direct cost per three trimesters was $1824-2115 USD.
The average family income per month was $614.23 USD and the average health expenditure (per month) was 105.71 USD; which represents 16.21% of the family income. The average family health expenditure per trimester was $317.13 USD.
Conclusion: The total cost for prenatal care per trimester was calculated in $608 to 705 USD. The cost of prenatal care per trimester is 193.69% higher than the average health expenditure per trimester for uninsured women with ARDs. More and new strategies are needed to solve and reduce inequalities in access to health.

Table 1. Average cost of prenatal care per trimester

Medical consultations and ultrasounds			
Medical Consultations	**Costs (USD)**	**Frecuency**	**COST PER TRIMESTER $184-277 USD**
Rheumatologist	$13	Monthly	
Genetics	$49	At least one	
Obtetrician	$14	Monthly	
US 1st Trimester	$54	Only one time	
US 2nd Trimester	$49	Only one time	
Psychologist	$39	If needed	
Nutritionist	$5	If needed	
Clinical test			
Clinical test	**Costs (USD)**	**Frecuency**	**COST PER TRIMESTER $188 USD**
Complete Blood Count	$9	One per trimester	
Blood Chemistry	$38	One per trimester	
Vitamin D (25-OH)	$59	One per trimester	
Thyroid profile test	$16	One per trimester	
PT, TTP	$36	One per trimester	
Protein C reactive	$20	One per trimester	
Erythrocyte sedimentation rate	$5	One per trimester	
Urine general test	$5	One per trimester	
Immune lab test (For patients with rheumatoid arthritis and spondylarthritis)			
Immune lab test	**Costs (USD)**	**Frecuency**	**COST PER TRIMESTER $240 USD**
Rheumatoid factor	$24	One per trimester	
Anti-CCP	$33	One per trimester	
Anti SS-A/RO	$19	One per trimester	
Anti-SS-B/LA	$19	One per trimester	
Anticardiolipins	$33	One per trimester	
Beta-2-glycoprotein	$66	One per trimester	
Lupus anticoagulant	$46	One per trimester	
Immune lab test (For patients with lupus, antiphospholipid syndrome, Sjogren's syndrome, vasculitis, and others) (Others: rheumatic skin and muscle diseases,)			
Immune lab test	**Costs (USD)**	**Frecuency**	**COST PER TRIMESTER $236 USD**
Anti-SS-A/RO	$21	One per trimester	
Anti-SS-B/LA	$21	One per trimester	
Anticardiolipins	$33	One per trimester	
Beta-2-glycoprotein	$66	One per trimester	
Lupus anticoagulant	$46	One per trimester	
Anti-DNA	$24	One per trimester	
Antinuclear antibodies	$25	One per trimester

AB1415

GENDER EQUITY IN RHEUMATOLOGY IN GERMANY, WHERE DO WE STAND? – PRELIMINARY RESULTS FROM A NATIONWIDE ONLINE SURVEY AMONG RHEUMATOLOGISTS IN GERMANY

J. Mucke[1,2], X. Baraliakos[2,3], E. Feist[2,4], B. Gundelach[2,5], I. Haase[1,2], B. Hoyer[2,6], M. Koehm[2,7], M. Krusche[2,8], C. Mentzel[2,5], P. Sewerin[1,2,3], A. Voormann[2,5], S. Ohrndorf[2,9]. [1]*University Clinic Duesseldorf, Policlinic for Rheumatology, Duesseldorf, Germany*; [2]*Commission for Gender Equity in Rheumatology, German Society for Rheumatology, Berlin, Germany*; [3]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Bochum, Germany*; [4]*HELIOS Clinic Vogelsang-Gommern, Department of Rheumatology and Immunology, Gommern, Germany*; [5], *German Society for Rheumatology, Berlin, Germany*; [6]*University Clinic Schleswig-Holstein, Rheumatology and Clinical Immunology, Campus Kiel, Kiel, Germany*; [7]*Frauhofer IME-TMP, Clinical Research, Frankfurt, Germany*; [8]*Universitätsklinikum Hamburg-Eppendorf, Center for Internal Medicine and Rheumatology, Hamburg, Germany*; [9]*Charité, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Despite the increasing number of female medical students and fellows, women are still underrepresented in higher career and academic positions in rheumatology [1].
Objectives: To assess gender distribution in rheumatology in Germany and to analyze potential hurdles of flexible work opportunities with the overall aim to improve gender equity in future German rheumatology.
Methods: A web-based anonymous survey using QuestionPro was distributed among rheumatologists in Germany via newsletters, social media and personal contacts (12/2021-01/2022). The survey was developed based on a narrative literature review [1] and discussions among the commission members. It was composed of 29 questions, with single or multiple answers and/or free text. Non-demographic questions could be answered with "I do not know".
Results: Among the total of 170 respondents who fully completed the survey, 72% were female, 28% were male and 1% was third gender. 73% were employed at a rheumatology clinic with 79% working at an academic institution and 20% at a non-academic clinic, 1% did not specify their institution. Of those working at a clinic, 48% were rheumatologists in training, 35% trained rheumatologists and 7% were head of rheumatology departments. Regarding the gender-ratio in different hierarchical levels, only 17% reported more male than female rheumatologists in training at their workplace, in 32% the gender ratio was balanced. On higher levels, respondents reported more male than female rheumatologist at staff level in 44% (29% balanced) and in leading positions in 74% (12% balanced). 53% of female respondents were responsible for >50% of family and housework, compared to 11% of the male respondents. Most men covered 50% (49% of male respondents) or less than 50% (32% of male respondents) of family work. There were coworkers in part time in the work environment of 86% of respondents, with only women working part time in 56% of cases, both women and men in part time in 29% and only men in part time in 1%. Most respondents stated that men and women working part time did not have the same opportunities as coworkers working full time. (Table 1)

Table 1. Opportunities for advancements of part time working employees compared to full time coworkers with similar qualification in percent of all respondents.

Employees working part time have similar opportunities for advancements as employees of the same gender working full time.

	Yes	No	I do not know
Women	23%	65%	12%
Men	21%	54%	25%

Many respondents perceived a preference of either gender despite equal performance regarding different aspects with men more often perceived as preferred in terms of opportunities for advancements and staffing of positions. (Figure 1)

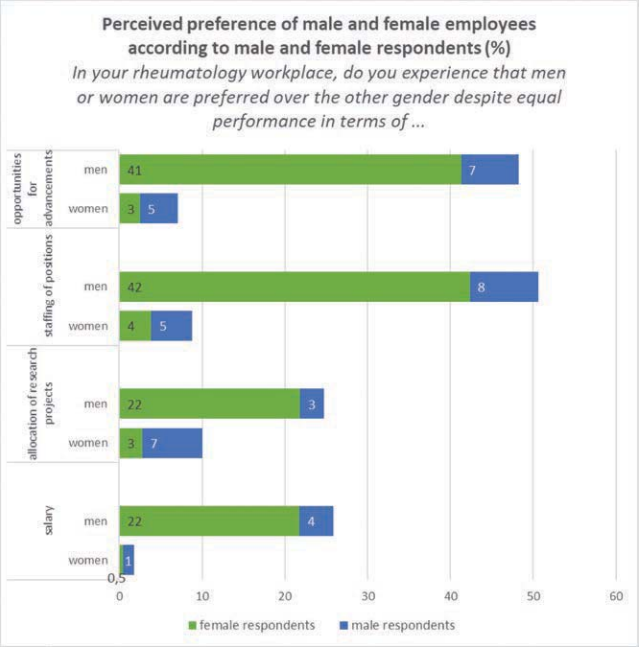

Figure 1. Perceived preference of employees in rheumatology with regards to opportunities for advancements, staffing of positions, allocation of research projects and salary according to gender by female and male survey-respondents. Perceived discrimination was not assessed.

66% of respondents agreed that activities to improve gender equity are necessary. The highest need was seen in the improvement of compatibility of care and work with adequate part time models, childcare options at work, and the higher acceptancy of part time working men and women by employers and persons in higher positions (freetext).
Conclusion: Gender misbalance is prevalent in rheumatology in Germany with lower numbers of women at higher hierarchical levels. Traditional role allocation is still common with a higher frequency of part time working females. Part time employment is perceived to decrease chances of advancement. The focus should be on promoting flexible job-sharing models, part time work among men and gender equity not only at work but also in private life ("care work"). Preference for one gender over the other is perceived differently between women and men.

AB1416

WHAT IS THE FULL ECONOMIC COST OF DELAYED DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS IN THE UK?

G. Xydopoulos[1], S. Howard Wilsher[1], F. Zanghelini[1], O. Afolabi[1], M. Mishra[1], R. Fordham[1]. [1]*University of East Anglia, Norwich School of Medicine, Norwich, United Kingdom*

Background: Axial Spondyloarthritis (AS) is an umbrella term for both inflammatory conditions known as Ankylosing Spondylitis and Non-radiographic Axial Spondyloarthritis. AS generally develops in younger people. Symptoms typically start in the late teenage years to early twenties (with the average age of onset being 24). Hence this condition has a life-long impact, which could increase if left untreated. Average delay to diagnosis is over eight years after the appearance of symptoms. There are currently 220,000 people in the UK living with this painful and progressive form of inflammatory arthritis. While people wait for a diagnosis, many withdraw from socialising and find it harder to establish careers, form relationships, and start families. In addition to healthcare costs, that include multiple visits to GPs, prescription of unnecessary medication and extensive use of over the counter painkillers, there are intangible costs that have large impacts on patients and society. For example, quality of life for the patient, their earning and saving for retirement capacity, social care costs.

Objectives: To determine the full economic cost, including medical productively loss and other out of pocket related costs of delayed diagnosis for AS in the UK.

Methods: We are building an economic Markov model to determine a total cost per patient per year of delay. The model will project disease progression forward in time-steps with feedback loops to allow movement in states back and forth. Transition states within each time-step will be constructed according to the various stage of the disease and they will be used primarily to demonstrate an assessment of the costs in the time taken to a confirmed diagnosis. The model will capture symptoms and impacts of AS leading up to that diagnosis and before initiation of treatment. Assuming the one-year maximum 'gold standard' time to diagnosis that NASS would like to see to, the sum of costs prior to this in each consecutive cycle will be estimated. The inputs will consist of the average delay to diagnosis per gender and age group, the health resources utilisation, the cost of managing the symptoms, cost related to productivity losses and any other parameters and costs reflecting real resources required to diagnose, confirm, treat, cope with, manage and accommodate AS symptoms. Data include anonymised diagnosed patient data with the pathways they followed pre-diagnosis shared under strict confidentiality data sharing agreement from the secondary health units participating in the project. Cost data gathered from national sources and research into AS, NHS unit costs reports, productivity related reports and interviews with people with AS and clinicians providing valuable insight into the condition. The model will be validated by experts in the field and sufferers of AS to ensure accurate representation of actual events.

Results: The results will be provided at the conference and this is work in progress. A preliminary analysis of anonymised data of the pathway of 513 people towards an AS diagnosis show that the delay on female patients is slightly longer (mean of 9.85 years) compared to male patients (mean of 9.39 years). In both genders the delay is higher if the patient present symptom after the age of 31 years increasing the mean of previous age groups by 5 to 9 yrs.

Table 1.

	Female			Male		
Age Group	**Obs.**	**Mean**	**95% CI**	**Obs.**	**Mean**	**95% CI**
0-15	1	1	-	2	1.00	0.00, 13.71
16-30	49	3.59	2.69, 4.49	144.00	4.01	3.45, 4.57
31-45	50	11.72	9.64, 13.80	161.00	9.61	8.58, 10.65
46-60	24	18.17	13.05, 23.28	60.00	15.90	13.30, 18.50
61+	3	17.33	0.00, 52.58	19.00	28.58	21.14, 36.02

Conclusion: The results will help the National Axial Spondyloarthritis Society (NASS) to build an economic case for earlier diagnosis. The interactive model will support decision making in the future by allowing assumptions to be changed e.g., changing prices over time; varying wage rates depending on staff and skill mix; and the anticipated scale of savings in actual practice.

AB1417 CORRELATION BETWEEN THE ATTITUDE OF PATIENTS SUFFERING FROM CHRONIC RHEUMATIC DISEASES TOWARDS REMOTE CONSULTATIONS BY RHEUMATOLOGIST AND THE HEALTH LOCUS OF CONTROL

D. Antinis[1], J. Sabaliauskienė[2]. [1]*Lithuanian University of Health Sciences, Rheumatolgy, Kaunas, Lithuania*; [2]*Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Rheumatolgy, Kaunas, Lithuania*

Background: During the COVID-19 pandemic telemedicine has become an important and safe means for patients suffering from chronic diseases to control their condition with the assistance of a physician [1]. In order to ensure that treatment of chronic rheumatic diseases is effective, it is important that patients develop a favorable attitude towards telerheumatology [2] as well as disease-related individual behavior, which significantly depends on the patients' health locus of control [3].

Objectives: To analyze the attitude of patients suffering from chronic rheumatic diseases towards peculiarities of remote consultations by a rheumatologist and their correlation with health locus of control.

Methods: To reveal the patients' attitude towards remote consultations by a rheumatologist, an original questionnaire has been prepared, which contains: reasons for choosing remote consultations, fears about such consultations and their advantages. Health locus of control was evaluated using a Multidimensional Health Locus of Control (MHLC) scale, which consists of three subscales: Internal, Chance, and Powerful Others. Demographical questions and questions related to health are also included in the questionnaire. 207 subjects participated in the study: 177 (85.5 %) women and 30 (14.5 %) men, (M_{age}=39.4, SD=11.76). The majority of subjects were diagnosed with spondyloarthritis (n=83), connective tissue diseases (n=53), rheumatoid arthritis (n=49), and osteoarthritis (n=20), 42 subjects were diagnosed with some other rheumatic diseases. 111 (53.6%) patients had the previous experience of remote consulting by a rheumatologist.

Results: It has been determined that the attitude of patients with rheumatic diseases is related to various demographic characteristics of patients, e.g., gender, etc., and the peculiarities of the disease, e.g., strength of the symptoms, etc. It has been found that patients without experience of remote consultations have more fears about such consultations (p=0.024). When comparing the average of statements revealing a positive attitude M=66.4% with the average of statements revealing a negative attitude M=27.3%, it becomes clear that the overall attitude of subjects toward remote consultations of a rheumatologist is favorable. To assess correlations between positive or negative attitude of patients with rheumatic diseases and health locus of control correlational analysis was performed. The results did not confirm the expected correlations between the positive attitude of patients with the internal locus of control. However, it has been obtained that negative attitude towards remote consultations by a rheumatologist positively correlates with two indicators of health locus of control – Chance (r=0.203, p≤0.0001) and Powerful Others (r=0.194, p=0.01), although the said correlation is not strong, but statistically significant.

Conclusion: The study has revealed the major fears and satisfaction sources related to remote consultations of Lithuanian patients with rheumatic diseases. In addition, it has shown that personal convictions of a patient that health depends on the circumstances and the influence of other people exacerbates the attitude towards remote consultations.

AB1418 A SYSTEMATIC REVIEW OF CURRENT RHEUMATOLOGY GUIDELINES FOR GERIATRIC PERSPECTIVES

B. Bitik[1], M. E. Tezcan[2], A. E. Yucel[1]. [1]*Başkent University Ankara Hospital, Rheumatology, Ankara, Turkey*; [2]*Kartal Dr. Lütfi Kırdar Şehir Hastanesi, Rheumatology, Istanbul, Turkey*

Background: Geriatric population (GP) includes people over 65 years of age. GP can also be divided into the 65-75 age group and >75 age group. In the last 50 years, the proportion of the elderly in the society has increased (1). Meanwhile, GP has higher frequency of rheumatological disorders. While managing the treatment of this special patient group, some physiological differences of the elderly should be considered. Elderly patients are at increased risk for adverse drug reactions as a result of age-related changes in pharmacokinetics and pharmacodynamics. Polypharmacy is contributing to increased risk of clinically significant drug interactions. In addition, alterations in cognitive functions may impair drug compliance. On the other hand, clinicians may hesitate to apply more effective treatment due to safety concerns. (2).Rheumatologists should be aware of the problems they may encounter when planning the treatment of this privileged group.

Objectives: We reviewed rheumatology guidelines to assess rheumatology organizations' perspective on GP.

Methods: Guidelines published by EULAR, ACR and the British Society for Rheumatology (BSR) for adult patients from 1970-2022 were reviewed by two

rheumatologists to assess the existence of specific recommendations for the treatment of adult patients over 65 years of age.
Results: In total, 58 guidelines were reviewed. None of the guidelines grouped patients by age. Seven (12%) guidelines had recommendations or statements about elderly patients (Table 1). As we observe, there are no satisfactory recommendations for the GP with rheumatological diseases. The most propable reason for this result is the lack of studies in the rheumatology literature to lead to guideline recommendations.

Table 1. Characteristics of guidelines reviewed

	Number of guidelines (n)	Guidelines with specific recommandation for GP
EULAR	38	1-2-3-4-5-6
ACR	11	6
BSR	9	7

[1]EULAR points to consider for the management of difficult-to-treatrheumatoidarthritis(recommendation 6)[2]. Points to consider for the development, evaluation and implementation of mobile health applications for self-management in patients with rheumaticdiseases (points to consider 8)[3]. 2019 update of EULAR recommendations for Vaccination in AdultPatientswithAutoimmuneInflammatoryRheumatics[4]. EULAR Recommendations for prevention and management of osteoporoticfractures(recommendation 6)[5]. EULAR Points to consider for monitoring (detection/prevention) comorbidities in inflammatoryrheumaticdiseases (point to consider 10)[6]. 2015 Recommendations for the management of polymyalgiarheumatica: a European League AgainstRheumatism/American College of Rheumatologycollaborativeinitiative (recommendation 9)[7]. BSR guidelines for the management of polymyalgiarheumatica (recommendation 6)

Conclusion: Current prominent rheumatology guidelines have insufficiently addressed the management of rheumatological diseases in GP. Additional studies ares needed to delineate specific guidelines for the management of geriatric patients with rheumatological diseases.

AB1419 PERFORMANCE OF AN EARLY TRIAGE SYSTEM FOR IDENTIFICATION OF PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

X. Baraliakos[1], I. Redeker[1], M. Zacharopoulou[1], S. Tsiami[1], J. Braun[1].
[1]*Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany*

Background: The preselection of patients with suspicion of an inflammatory rheumatic disease is not easy for general practitioners and orthopedists. In countries with a limited number of practicing rheumatologists waiting lists are often long, since a full rheumatologic examination often needs a long consultation time.
Objectives: To test the performance of an early triage strategy for early identification of patients with inflammatory rheumatic diseases.
Methods: Prior to the SARS-CoV 2 pandemic, physicians caring for patients contacting a tertiary rheumatologic cente were first contacted by a health-care professional (HPR) who offered an appointment the timing of which was based on the symptoms reported (Step 1). Patients were then seen by a rheumatologist who, within a 10-minute consultation (Step 2), shortly examined the patient to determine the urgency of a planned full work up. The main outcome of the study was the comparison between the initial assessment and the final expert diagnosis (Step 3).
Results: Within 9 months, physicians caring for 1.180 patients contacted the hospital, 972 of whom kept their appointment (82.4%). Most patients were transferred by GPs (73.1%) and orthopedists (22.1%). The mean time between Step 1 and Step 2 was 10.4 days, while 6.2% of patients were seen within 4 days, 24.4% within 7 days and 69.3% within 12 weeks. Only 36 patients (3.7%) of patients had an already established rheumatic disease. Complaints lasting between 0-4 weeks were reported by 69 (7.1%), of > 4-12 weeks by 100 (10.3%), and of > 12 weeks by 973 (82.6%) patients. Almost 90% of patients reported a pain intensity >4/10 (NRS) for < 2 weeks. An elevated CRP was found in 207 patients (24.5%). Prior treatment with glucocorticoids was reported in 163 (16.8%) and with NSAIDs in 730 (75.1% of) patients. The confirmed diagnosis at Step 3 was rheumatoid arthritis in 127 (13.1%), spondyloarthritis including psoriatic arthritis in 72 (7.4%), systemic diseases including connective tissue diseases in 112 (11.5%), vasculitides in 41 (4.2%), and crystal arthropathy in 38 (3.9%) patients, while 38 (3.9%) had an infection, a malignancy or a differential diagnosis such as Raynaud's phenomenon or sicca syndrome. Degenerative joint diseases (n=254; 26.1%) and non-inflammatory soft tissue syndromes such as fibromyalgia (n=369; 38%) accounted for more than half of the patients.
Conclusion: This study describes the performance of a standardized triage system hereby confirming the need for an early identification and preselection of patients with rheumatic musculoskeletal symptoms, including involvement of HPRs in the initial phase of contact. Based on the results, three patients with musculoskeletal complaints had to be examined in order to identify one patient with an inflammatory rheumatic disease.

AB1420 CLINICIAN-RELATED FACTORS MAY INFLUENCE REMOTE CONSULTATIONS IN RHEUMATOLOGY – ANALYSIS OF SENIOR VS TRAINEE CLINICIANS' OUTCOMES FROM A COVID-19 INITIATIVE

M. Hannides[1], S. Wig[1], S. Vasireddy[1]. [1]*Bolton NHS Foundation Trust, Rheumatology, Bolton, United Kingdom*

Background: Since COVID-19 pandemic started, there have been changes in clinical practice to limit transmission, such as switching from face-to-face to remote consultations. Our department switched to delivering remote consultations without suspending service. Patients were offered the preference of either video or telephone consultation. It is unclear what factors including clinician-related factors significantly influence remote consultations in Rheumatology.
Objectives: We aimed to study the influence of senior (substantively employed) vs trainee status of clinicians on remote consultations in our experience during the pandemic.
Methods: Between 15/10/2020 and 09/11/2020, 12 clinicians in our department completed data collection forms after each remote consultation, recording the technology used (video vs phone); technical problems encountered; discharge and subsequent appointment status; and technical aspects of the consultation itself using 11-point numerical rating scales (NRS) (Time Adequate; Relevant History; Physical Exam; Management Plan; and Communication Quality). Data were collated on an MS Access 2016 database, and transferred to SPSS version 25 for statistics.
Results: Nine senior clinicians (3 consultant rheumatologists, 3 Specialist Nurses, 1 Advanced Rheumatology Practitioner and 2 Senior Rheumatology Pharmacists) and 3 trainee clinicians (2 Specialty Trainee Registrars and 1 Foundation Year 2 doctor) completed forms. 285 forms were validated for analysis. The majority of consultations were completed by senior clinicians (266, 93.3% vs 19, 6.7%). Senior and trainee clinicians had a similar proportion of new patients compared to follow-up patients (18%, n=48 vs 15.8%, n=3; p=0.80); of female patients (68%, n=181 vs 63.2%, n=12; p=0.66); and video consultations (17.3%, n=43 vs 10.5%, n=2; p=0.45); and similar mean age of their patients (59.5 vs 56.7years; p=0.72) respectively. Senior clinicians accounted for all the technical issues reported (20%, n=48 vs 0%, n=0; p=0.03). Senior clinicians had lower mean scores compared to the trainee clinicians on NRS for Relevant History (8.68 vs 9.68; p<0.001), Physical Exam (1.49 vs 2.95; p=0.045), and Communication Quality (8.02 vs 9.37, p=0.002); and had no significant differences in scores for Time Adequate (8.46 vs 9.00; p=0.10) and Management Plan (7.17 vs 7.84; p=0.16). Senior and trainee clinicians and a similar proportion requests for subsequent face-to-face appointments (21.9%, n=51 vs 25%, n=4; p=0.77).
Conclusion: There were no significant differences between senior and trainee clinicians in distributions of patients and proportion of video consultations. While no technical issues were reported by the trainee clinicians, this may in part be a reflection of their smaller proportion of overall consultations. Although senior clinicians rated their consultations somewhat lower in some of the NRS, there was no significant difference in management plan scores and subsequent face-to-face appointment status compared to trainee clinicians. While the lower scores may partly reflect the technical issues reported by the senior clinicians, longer clinical experience and greater knowledge may also be an underlying factor for this. Further studies with larger numbers may clarify these issues.

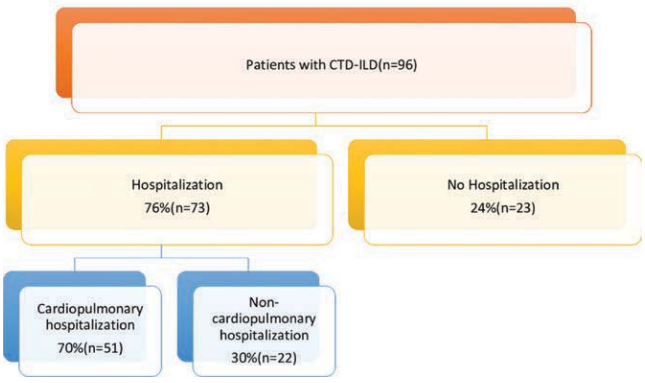
Epidemiology, risk factors for disease or disease progression

AB1421 IMPACT OF HOSPITALIZATION ON CLINICAL OUTCOMES IN PATIENTS WITH CONNECTIVE TISSUE DISEASE ASSOCIATED INTERSTITIAL LUNG DISEASE (CTD-ILD) - A SINGLE CENTER OBSERVATIONAL STUDY

N. Kaur[1,2], X. Xie[3], A. Korogodina[4], B. Ayesha[1], K. Cleven[5], A. Kumthekar[1]. [1]*Montefiore Medical Center Moses Campus Emergency Room, Rheumatology, Bronx, United States of America*; [2]*Touro University Medical Group, Rheumatology, Stockton, United States of America*; [3]*Albert Einstein College of Medicine, Epidemiology, Bronx, United States of America*; [4]*Montefiore Medical Center-Wakefield Campus, Internal Medicine, Bronx, United States of America*; [5]*Montefiore Medical Center, Pulmonary Medicine, Bronx, United States of America*

Background: Interstitial lung disease(ILD) is major cause of morbidity and mortality in patients with connective tissue disease (CTD). Hospitalization is being increasingly recognized as poor prognostic indicator in these patients.
Objectives: The objective of our study was to assess the impact of hospitalization on clinical outcomes in patients with CTD-ILD.
Methods: We conducted a retrospective chart review of patients with radiologically or biopsy proven ILD associated with rheumatologist diagnosed CTD who were seen at Montefiore Medical Center between January 2007 and December 2018. Patients with age>18 years who had either 2 CT scans of the chest and/or 2 sets of pulmonary function tests (PFT) atleast 6 months apart were included in the study. Clinical demographics, cause of hospitalization, length of stay, use of immunosuppression and mortality were identified. Patients were stratified into 2 cohorts; non-hospitalized and hospitalized patients. The latter cohort was further sub-stratified into patients with cardiopulmonary vs. non-cardiopulmonary hospitalization (Figure 1). Two-sample t-tests and Wilcoxon's rank sum tests were used for comparing the continuous variables. Chi-square tests and Fisher's exact tests were used for comparing the categorical variables as appropriate. Kaplan-Meier method was used for calculating the survival probabilities, and log-rank tests were used to compare differences between the groups.

Figure 1: Flow chart showing hospitalization pattern in CTD-ILD patients.



Results: During the study period, we identified 213 patients with CTD-ILD using ICD 9/10 code. Of the 213 patients, 96 met our inclusion criteria and 73 (76%) had at least 1 hospitalization (Figure 1). Both groups were similar in baseline clinical characteristics but we identified significantly higher transplant referrals in the hospitalized group(23.9%) vs. non-hospitalized group(0%) (Table 1). Overall rheumatoid arthritis (29.2%) was the most common CTD associated ILD followed by inflammatory myositis (21.9%) and scleroderma (14.6%). Median time from diagnosis of ILD to first hospitalization was 1.42 years. The patients hospitalized for cardiopulmonary cause were significantly older(57.2 ±13.1 years) than those admitted with non-cardiopulmonary cause(49.2±14.8 years)(Mean±SD). Older age (HR 1.95, p=0.02) and length of stay greater than 7 days for cardiopulmonary cause(HR 4.82,p=0.01) was associated with higher risk of mortality. Kaplan Meier curve analysis showed that hospitalization (p-value=0.02) was associated with statistically significant increased risk of death.
Conclusion: -Hospitalization in CTD-ILD patients especially length of stay more than 7 days due to cardiopulmonary causes was associated with statistically significant increased risk of death. Male gender and older age was associated with a worse prognosis in patients who were hospitalized.

Table 1. Baseline Characteristics of patients with CTD-ILD

Characteristic	Entire Cohort (n = 96)	Patients with CTD-ILD and hospitalization (n = 73)	Patients with CTD-ILD and no hospitalization (n = 23)	p-value
Age(mean ± SD)	54.15 ± 13.97	54.82 ± 13.77	52.00 ± 14.71	0.40

AB1422 PREVALENCE OF HYPERURICEMIA IN CHINESE ADULTS: DATA FROM A CROSS-SECTIONAL STUDY

J. Zeng[1], W. R. Lawrence[2]. [1]*Department of Ultrasound, Guangdong Second Provincial General Hospital, Guangzhou, Guangdong, China*; [2]*Department of Epidemiology and Biostatistics, School of Public Health, University at Albany, State University of New York, One University Place, Rensselaer, New York, United States of America*

Background: Previous studies have observed an increasing trend in the prevalence of hyperuricemia which is linked to the physiological prerequisite for gout in recent years. However, the prevalence of hyperuricemia varies across different populations and different areas.
Objectives: The aim of this study was to explore the prevalence of hyperuricemia and influencing factors in Chinese adults.
Methods: The analysis was a part of a cross-sectional study in Guangdong Second Provincial General Hospital in Guangzhou City, China between January 2009 and December 2019. A total of 205922 participants (21401 with hyperuricemia) were included in this study. Hyperuricemia was defined as serum uric acid ≥416.0 μmol/L (7.0 mg/dl) for men and ≥357.0 μmol/L(6.0 mg/dl) for women. We calculated the prevalence of hyperuricemia and used the multivariate-adjusted logistic regression model to identify the risk factors associated with hyperuricemia.
Results: The overall estimated prevalence of HUA was 10.4% in China. Our study showed the prevalence of hyperuricemia in male (10.7%) was higher than that in female (9.9%) (P<0.05). The prevalence of HUA in the age group(≥75) subjects (13.3%) was higher than others. Multivariate logistic regression analysis revealed that sex (OR=1.75), age (OR=1.68), blood urea nitrogen (BUN) (OR=1.051), creatinine (Cr) (OR=1.045), high-density lipoprotein cholesterol (HDL-C) (OR=1.225), low-density lipoprotein cholesterol (LDL-C) (OR=1.466), systolic blood pressure (SBP) (OR=1.012),triglycerides (TG) (OR=1.460) and Body Mass Index (BMI) (OR=1.080) could increase the risk of hyperuricemia, while diastolic blood pressure (DBP) (OR=0.998), fasting plasma glucose (FPG) (OR=0.902) and total cholesterol (TC) (OR=0.704) were associated with a lower risk of hyperuricemia in all adults.
Conclusion: The latest prevalence of hyperuricemia is high in Chinese adults and is associated with multiple factors, indicating that prevention and control strategies for hyperuricemia are needed urgently.

AB1423 CLINICAL AND LABORATORY FEATURES OF PATIENTS WITH IDIOPATHIC GRANULOMATOUS MASTITIS AT A TERTIARY MEDICAL CENTER

B. Abbi[1], X. Xie[2], S. Fineberg[3], A. Gupta[4], A. Kumthekar[1], B. Ayesha[1].
[1]Montefiore Medical Center, Department of Rheumatology, Bronx, United States of America; *[2]Albert Einstein College of Medicine, Department of Epidemiology & Population Health, Bronx, United States of America*; *[3]Montefiore Medical Center, Department of Pathology, Bronx, United States of America*; *[4]Montefiore Medical Center, Department of Surgical Oncology, Bronx, United States of America*

Background: Idiopathic granulomatous mastitis (IGM) is a benign, inflammatory disease of the breast. As per the literature review, etiopathogenesis of this disease is unclear. The gold standard of diagnosis is through breast biopsy and identification of non-caseating granulomas. **[1]** Until recently, there has been a lack of clinical, serological or histopathological criteria to guide physicians on management of IGM.
Objectives: The objective of our study is to identify distinguishing clinical and laboratory features amongst individuals with IGM based on serologic and histopathologic status. In this study, clinical and laboratory features were compared between patients with complete remission of IGM and those with relapse of IGM after three months of remission.
Methods: After institutional review board (IRB) approval, we queried pathology and clinical looking glass databases at Montefiore Medical Center between 1990-2021 to identify patients with the diagnosis of IGM. We identified 46 patients, and did a retrospective chart review to extract data. Clinical features were compared in patients with IGM who had complete resolution of disease and those who had relapse of disease using two-sample t-tests for continuous variables and chi-squared or Fisher's exact tests for categorical variables. In this study, we included females older than eighteen years of age. We excluded patients with breast cancer, lymphoproliferative disorders, solid organ malignancy, foreign body reaction in breast, plasma cell mastitis, and ductal ectasia.
Results: Of the 46 symptomatic patients with histopathological diagnosis of IGM, 27 female patients with sufficient clinical data were included in final analyses. All patients in our cohort had a mean age of 36 years (SD 9 years) and average body mass index of 31.5 kg/m^2 (SD 6.7 kg/m^2). Majority of patients were Hispanic, 11 patients (40.7%). Unilateral disease (96.3 %) was predominant in patients. Most patients had at least one previous full-term pregnancy prior to diagnosis, 25 patients (92.6%) and 8 patients were on hormonal oral contraceptives (29.6%).
Of the 27 patients, 18 patients (66.6%) had complete remission of disease. All of these patients were initially treated with antibiotic therapies until tissue cultures were reported negative. Six of these patients received steroid therapy after antibiotic therapy, while 5 patients were started on methotrexate therapy, starting with a dose of 15 milligrams (mg) orally once per week. Of the total cohort, 9 patients (33.3%) experienced relapse of the disease.
Conclusion: IGM is a relatively newer entity that is difficult to manage, due to lack of standard guidelines in literature. In this study, on comparing IGM patients with remission and relapse, there were no statistically significant differences in clinical and laboratory features. However, immunomodulating therapy with methotrexate can be considered in patients with relapsing IGM. Further studies are needed to evaluate patients with IGM and their disease evolution that can facilitate management to determine utility of methotrexate in improving relapse rates in these patients.

AB1424 INVESTIGATION OF THE TYPE AND FREQUENCY OF NEUROLOGICAL SIDE EFFECTS WITH BIOLOGICAL TREATMENT IN INFLAMMATORY RHEUMATIC DISEASES

S. Umut[1], T. Yuce Inel[2], I. S. Sengun[3], F. Onen[2], İ. Sari[2]. *[1]Dokuz Eylul University Faculty of Medicine, Internal Medicine, İzmir, Turkey*; *[2]Dokuz Eylul University Faculty of Medicine, Rheumatology, İzmir, Turkey*; *[3]Dokuz Eylul University Faculty of Medicine, Neurology, İzmir, Turkey*

Background: With the increasing use of biological treatment in inflammatory rheumatic diseases, some neurological side effects, especially central and peripheral nervous system demyelinating disorders, are seen.
Objectives: To evaluate whether there is an increase in the frequency of neurological disorders with biological treatment compared to the normal population, and the relationship between discontinuation of biological agents and neurological symptoms.
Methods: Adult patients using biological treatment followed in the Rheumatology outpatient clinic of Dokuz Eylul University between January 2011 and January 2020 were included. The relationship between biological agents and type, severity and duration of neurological symptoms, and the laboratory, imaging (cranial CT, MRI) and electrophysiological findings of the patients were retrospectively reviewed. Current treatments for rheumatologic disease and neurological findings, and disease activity were investigated.
Results: In our study, neurological side effects were observed in 16 (1.8%) of 877 patients using biological drugs. The mean age of the patients was 51.8±12.53 years, and the duration of rheumatologic disease was 10.69±4.86 years. Nine patients had peripheral neuropathy, two had CNS demyelinating disease, two had peripheral demyelinating disease, two had intracranial mass and one had

headache syndrome. The neurological disease developed a mean of 51.31±44.26 months after the first biological agents. The demographic and clinical characteristics of the patients and the neurological side effects that developed during the follow-up period are summarized in Table 1. Biological treatment was discontinued in 68.8% of patients. There was no significant correlation between biological agents' continuation status and progression of neurological findings.

Table 1. Demographic and clinical characteristics of patients who developed neurological symptoms with biological treatment

		n=16 (%)
Gender	Male	8 (50)
Age of diagnosis (years)¶		41,13±12,02
Disease duration (years)¶		10,7±4,86

	Foot drop	1 (6,3)
	Grade 2 astrocytoma	1 (6,3)
	Meningioma	1 (6,3)
	Cauda equina syndrome	1 (6,3)
	Cubital Tunnel Syndrome	1 (6,3)
	Multiple sclerosis (de nova)	1 (6,3)
	Multiple sclerosis attack	1 (6,3)
	Myasthenia gravis attack	1 (6,3)
	Radicular neuropathy	1(6,3)
	Sensorimotor polyneuropathy	1 (6,3)
	Sensory neuropathy	1 (6,3)
	Pseudotumor cerebri worsening	1(6,3)
	Facial paralysis	1 (6,3)
	CIDP progression	1(6,3)
	Guillain Barre Syndrome	1 (6,3)
Time to development of adverse events after last bDMARD¶		26,37±29,58
Time after neurological adverse event (months)¶		23,75±20,86
bDMARD continuation status after adverse events	bDMARD discontinuation	11 (68,8)
Neurological symptoms at last visit	Stable	6 (37,5)
	Improvement	9 (56,3)
	Progression	1(6,3)

¶ mean±SD. CIDP:Chronic inflammatory demyelinating polyneuropathy

Conclusion: In this study, the prevalence of neurological diseases such as brain tumors, multiple sclerosis, and myasthenia gravis increased in patients receiving biological treatment compared to the normal population. Therefore, patients using biological agents should also be questioned and examined in terms of neurological symptoms, and further examination should be applied if necessary. No significant relationship was found between discontinuation of biological drugs and improvement/progression of neurological symptoms, and more comprehensive studies are needed.

AB1425 MENTAL DISTRESS AND ITS CONTRIBUTING FACTORS AMONG ADOLESCENTS IN A RHEUMATOLOGY CENTER IN MALAYSIA

C. R. Ng[1], X. Y. Ng[2]. [1]*Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia*; [2]*Clinic Simpang Renggam, Department of Pharmacy, Kluang, Malaysia*

Background: According to World Health Organization 2021, approximately 1 in 7 from the age group of 10-19 years old encountered mental health conditions [1]. Multiple factors can affect their mental health including their underlying medical conditions and depression may influence both reporting symptoms and response to treatment. This study is to investigate the prevalence of depression among adolescents diagnosed with rheumatic diseases by using CES-D questionnaire and to determine its contributing factors.

Objectives: To screen for depression by using center for epidemiologic studies depression (CES-D) among adolescents diagnosed with rheumatic diseases and to determine its contributing factors.

Methods: This was a survey interview. All rheumatology patients from the age group of 12-21 who followed up in rheumatology clinic Hospital Sultan Ismail from March 2020 to December 2021 were identified and interviewed. Demographic data, clinical data and disease duration were identified and the results were analysed by using IBM SPSS Statistics version 20.

Results: A total of 71 patients were identified. 93% of them were female (66/71) and majority of them were Malay (60.6%). This was followed by Chinese (23.9%), Indian (7%) and others (8.5%). The mean age group was 16 (range from 12 to 21). 85.9% of them were diagnosed to have systemic lupus erythematosus. 5.6% of them were having juvenile idiopathic arthritis followed by 2.8 % for each juvenile dermatomyositis and psoriatic arthritis. The rest of them were having mixed connective tissues disease and rheumatoid arthritis with the percentage of 1.4% for both diseases. 57 .7% of the respondents were having inactive disease during the interview session. From our survey, it showed that 53.5 % of the respondents were considered depressed with the score of 16 points and above according to the cut off point determined by CES-D questionnaire. The statistics showed association in between disease activity with the score of depression by using Chi Square ($p<0.015$). However, there was no association between the races and the score of depression ($p = 0.1$, using Chi Square). There was also no association between duration of disease with the score of depression. ($p= 0.485$, by using independent t-test).

Conclusion: Our study showed the prevalence of depression amongst adolescents diagnosed with rheumatic diseases are more than 50% and there was an association between depression score and disease activity. Hence, it is recommended to routinely screen for depression among adolescent as it helps to improve their response and compliant to treatment. Treat to target approach must always be implemented by treating physician to keep disease in remission and indirectly helps to reduce emotional distress among patients.

AB1426 PREDICTORS OF RHEUMATIC TOXICITIES OF IMMUNE CHECKPOINT INHIBITORS AND CANCER OUTCOMES IN PATIENTS WITH ADVANCED MELANOMA

A. Bruce[1,2], A. Menzies[3,4,5], G. Long[3,4,5,6], B. Fernandes[7], F. Joshua[1,8]. [1]*Macquarie University, Faculty of Medicine, Health and Human Sciences, Sydney, Australia*; [2]*Gardens Medical Group, Rheumatology, Albury, Australia*; [3]*Royal North Shore and Mater Hospitals, Medical Oncology, Sydney, Australia*; [4]*The University of Sydney, Faculty of Medicine & Health, Sydney, Australia*; [5]*Melanoma Institute Australia, Sydney Medical Oncology, Wollstonecraft, Australia*; [6]*The University of Sydney, Charles Perkins Centre, Camperdown, Australia*; [7]*Royal Prince Alfred Hospital, Medicine, Sydney, Australia*; [8]*Integrated Specialist Medical Care, Rheumatology, Sydney, Australia*

Background: Immune checkpoint inhibitors (ICIs) including monoclonal antibodies to PD-1 and CTLA-4 have activity across various cancers. Dedicated cohort studies have examined the epidemiology and clinical course of rheumatic toxicities (1–3) and the effect of pre-existing autoimmune disease has been explored (4), with limited assessment of the effect of non-immune mediated rheumatic disease (3). A positive association between ICI-induced rheumatic disease and favourable cancer outcomes has been suggested (1,2), although derived from heterogenous cancer populations.

Objectives: To identify risk factors for the development of ICI-induced rheumatic disease and predictors of cancer outcomes in patients with advanced melanoma.

Methods: A single-centre observational study of patients with stage III or IV melanoma receiving all available ICI therapies, who completed a for-purpose questionnaire to capture rheumatic symptoms and risk factors upon recruitment and at 12-months. Symptom severity was assessed according to patient reported measures such as visual analogue scale (VAS) scores for pain. Clinical details were extracted from patients' medical records. Predictors of rheumatic toxicities and cancer outcomes were identified through regression analysis.

Results: Amongst 147 eligible patients, the prevalence of new or worsening rheumatic symptoms was 32.5% at recruitment and 21% at 12 months. The incidence of documented arthralgia, inflammatory arthritis and PMR-like syndrome was 39.5%, 5.4% and 3.4% respectively. Binary logistic regression identified pre-existing symptomatic rheumatic disease, including non-immune mediated rheumatic disease, as the primary risk factor for developing rheumatic toxicities (OR 3.161). Continuation of ICI therapy (OR 16.52), followed by rheumatic toxicities (OR = 4.368) were predictors of favourable tumour response.

Conclusion: Rheumatic toxicities of ICI therapy commonly affect patients with melanoma and are more likely to occur in patients with pre-existing autoimmune and non-immune mediated rheumatic disease. Continuation of ICI therapy improves cancer outcomes and can be facilitated by early detection of rheumatic symptoms using patient reported outcome measures.

AB1427

ASSOCIATION BETWEEN HYPERURICEMIA AND OSTEOPOROTIC IN CHINESE ADULTS, A CROSS-SECTIONAL STUDY

J. Zeng[1], J. Yang[2], W. R. Lawrence[3], C. Pan[4]. *[1]Department of Ultrasound, Guangdong Second Provincial General Hospital, Guangzhou, Guangdong, China*; *[2]School of Public Health, Guangzhou Medical University, Guangzhou, Guangdong, China*; *[3]Department of Epidemiology and Biostatistics, School of Public Health, University at Albany, State University of New York, One University Place, Rensselaer, New York, United States of America*; *[4]Department of Emergency, The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, Guangdong, China*

Background: Hyperuricemia may have a protective role in diseases characterized by high levels of oxidative stress, such as osteoporosis. Previous studies have shown that hyperuricemia is associated with osteoporotic. However, this association is controversial and even yielded conflicting results.

Objectives: This study investigated the relationship between hyperuricemia and osteoporotic among Chinese adults.

Methods: The data of cross-sectional study was collected at Guangdong Second Provincial General Hospital in Guangzhou City, China between January 2009 and December 2019. Physical examinations and laboratory measurement variables were obtained from the medical check-up system. The multivariate-adjusted logistic regression model was performed to assess the association between hyperuricemia and osteoporotic.

Results: A total of 18917 participants (11334 males and 7579 females) were included in this study, with an average age of 46.23 years (SD: 11.67) at baseline. It included 5881 cases of hyperuricemia and 1587 osteoporotic. After adjusted for the confounding factors in logistic regression analysis, we observed a negative significant association between hyperuricemia and risk of osteoporotic (odds ratio [OR],0.852, 95%CI 0.795–0.967; P <0.05). Further stratified analyses showed a negative significant association with the risk of osteoporotic in women (OR,0.787, 95%CI 0.698–0.853; P <0.05), man (OR,0.897, 95%CI 0.786–0.954; P <0.05) and old adults (OR, 0.808, 95%CI, 0.759-0.894; P <0.05). No significant differences in other groups.

Conclusion: Our study observed participants with hyperuricemia had significantly less osteoporosis. More high-quality research is needed to further support these findings.

AB1428 CONTRAINDICATIONS, BOXED WARNINGS AND SPECIAL WARNINGS OF BIOLOGICAL AND TARGETED SYNTHETIC DMARDS

L. Skaarup[1,2], T. W. Kragstrup[2,3]. [1]*Randers, Medical Department, Randers, Denmark*; [2]*Aarhus University, Biomedicine, Aarhus, Denmark*; [3]*Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark*

Background: The list of biological DMARDs (bDMARDS) and targeted synthetic DMARDs (tsDMARDs) approved to treat synovitis and extra-articular manifestations is long and constantly expanding. The choice of drug for the individual patient depends on multiple factors. 1) Among these, contraindications and warnings are pivotal to consider. 2), 3) However, a systematic collection of drug class specific warnings for the b/tsDMARDs based on regulatory drug approvals is lacking.
Objectives: Our aim was to make an overview of the different contraindications, boxed warnings and special warnings listed in the European Medicines Agency (EMA) summaries of product characteristics (SmPCs) and the U.S. Food and Drug Administration (FDA) Prescribing Information (PI) for b/tsDMARDs.
Methods: We included all b/tsDMARDs with an FDA and/or EMA approval for any of the diagnoses: rheumatoid arthritis (RA), psoriatic arthritis (PsA), spondylarthritis (SpA), juvenile idiopathic arthritis (JIA), uveitis, plaque psoriasis, inflammatory bowel diseases (IBD). The included drugs were tumor necrosis factor (TNF) inhibitors (inh), anti-CD20 (rituximab), inhibitors of interleukin (IL)-6 receptor (6R), IL-1, IL-17, IL-12/23, IL-23, CD80/86 (abatacept), janus kinase (JAK), the phosphodiesterase 4 (PDE4) (apremilast), and the $\alpha 4\beta 7$ antibody (vedolizumab) We used the most recent SmPCs and PIs for the reference products in case of existing biosimilar products and extracted the information listed in the categories; contraindications, boxed warnings, and special warnings.
Results: There was a big difference between the year of first approval of the drugs spanning from 1998 to 2017. All drug classes except apremilast had warnings about infection. A warning about herpes zoster was listed specifically for rituximab, inhibitors of IL-6R, IL-1, IL-12/23 and JAK, while warning about hepatitis was listed for TNF inhibitors, rituximab, IL-6R inh., IL-1 inh., abatacept and JAK inh. All drug classes except IL-17 inh., IL-12/23 inh. and apremilast had warnings about malignancy. A warning about demyelinating disease was listed for TNF inh., IL-6R inh., and abatacept. Heart failure was specific for TNF inh. and rituximab while risk of major adverse cardiac events and venous thromboembolism was listed only for JAK inh. A recommendation regarding monitoring lipids was listed for inhibitors of IL-6R and JAK, monitoring liver enzymes was listed for all drug classes except IL-17 inh., IL-12/23 inh., abatacept and apremilast. Development of IBD was listed for IL-17 inh. and risk of diverticulitis was listed for inhibitor of IL-6R and JAK. Cytopenia was listed for rituximab, inhibitors of TNF, IL-6R, IL-1 and JAK. Depression was listed for IL-17 inh. and apremilast.
Conclusion: We made a systematic description of contraindications, boxed warnings and special warnings for b/tsDMARDs with a focus on drugs approved for use in chronic inflammatory arthritis and related disease entities. There were some associations between time of first drug approval and number of listed concerns. This, we presume, is because some of the rare events will not be found before several years after marketing. Group effects and specific concerns for individual drugs were identified.
Based on the warnings, we made a figure with clinically relevant conditions to consider when choosing a drug.
This systematic data collection could prove to be a useful decision tool for clinical practice to ensure patient safety and improve personalized drug choices.

AB1429 PERSISTENT INFLAMMATION AND PULMONARY FUNCTION CHANGES PREDICT PROGRESSIVE FIBROSING INTERSTITIAL LUNG DISEASES DEVELOPMENT IN RHEUMATIC PATIENTS

T. J. Lee[1], Y. H. Chen[2], J. Y. Chien[2], S. C. Hsieh[1]. [1]*National Taiwan University Hospital, Division of Rheumatology, Immunology, and Allergy, Department of Internal Medicine, Taipei, Taiwan, Republic of China*; [2]*National Taiwan University Hospital, Division of Chest Medicine, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: The progressive fibrosing interstitial lung disease (PF-ILD) remains a challenge for clinical care. Studies reported that fibrosis-predominant pattern on high-resolution computed tomography (HRCT) and a worse baseline pulmonary function tests were associated with a progression to PF-ILD [1]. Whether the inflammatory marker changes predict PF-ILD development was unknown.
Objectives: To evaluate prognostic values of the early inflammatory markers and the pulmonary function tests of developing PF-ILD in patients with connective tissue disease-related interstitial lung disease (CTD-ILD) and interstitial pneumonia with autoimmune features (IPAF).
